Validate and revert changes if degree of accuracy is greater than tolerance	Select this check box to have Performance Advisor rerun the simulation and verify that, after the change, the model results are still within tolerance. If the result is outside tolerance, Performance Advisor reverts the changes.
Quick estimation of model build time	Select this check box to have Performance Advisor use the number of blocks of a referenced model to estimate model build time.

3 To run a single check, click **Run This Check** from the settings for the check. Performance Advisor displays the results in the right pane.

You can also select multiple checks from the left pane and click **Run Selected Checks** from the right pane. Select **Show report after run** to display the results of the checks after they run.

4 To limit the run time of Performance Advisor, specify a **Time Out** value in minutes. Use this option for models with long simulation times. The default setting for this option is 60 minutes.

Note The **Time Out** setting does not apply to a Quick Scan diagnosis.

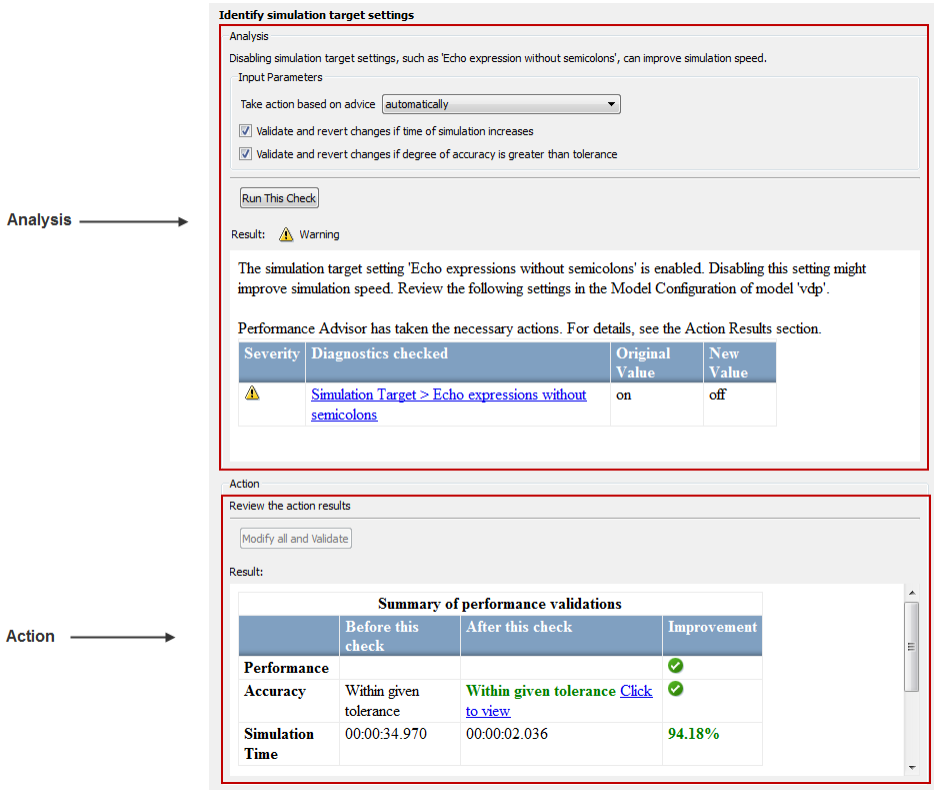
Performance Advisor also generates an HTML report of the current check results and actions in a file with a name in the form *model_name*\report_#.html

To view this report in a separate window, click the **Report** link in the right pane.

Note If you rename a system, you must restart Performance Advisor to check that system.

View and Respond to Results

After you run checks with Performance Advisor, the right pane shows the results:



To view the results of a check, in the left pane, select the check you ran. The right pane updates with the results of the check. This pane has two sections.

The **Analysis** section contains:

- Information about the check
- Option to run the simulation
- Settings to take action based on advice from Performance Advisor
- Result of the check (Passed, Failed or Warning)

The **Action** section contains:

- A setting to manually accept all recommendations for the check
- Summary of actions taken based on the recommendations for the check

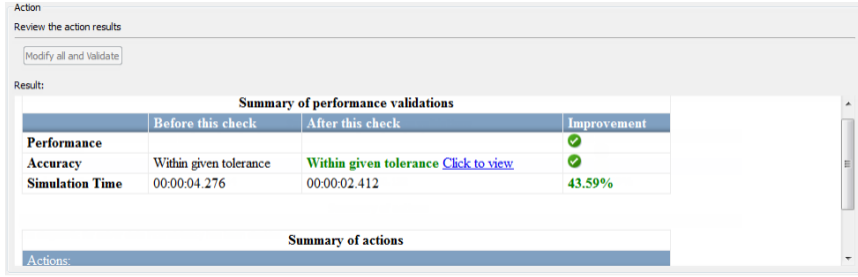
Respond to Results

Use the **Take action based on advice** parameter in the **Analysis** section to select how to respond to changes that Performance Advisor suggests.

Value	Response
`automatically`	• Performance Advisor makes the change for you. • You can evaluate the changes using the links in the summary table. • The **Modify All** button in the **Action** section is grayed out since Performance Advisor has already made all recommended changes for you.
`manually`	• Performance Advisor does not make the change for you. • The links in the summary table show recommendations. • Use the **Modify All** button in the **Action** section to implement all recommendations after reviewing them. Depending on how you set your validation input parameters before you ran the check, the button label can change to **Modify All and Validate**.

Review Actions

The **Action** section contains a summary of the actions that Performance Advisor took based on the **Input Parameters** setting. If the tool also performed validation actions, this section lists the results in a summary table. If performance has not improved, Performance Advisor reports that it reinstated the model to the settings it had before the check ran.



Severity	Description
	The actions succeeded. The table lists the percentage of improvement.
	The actions failed. For example, if Performance Advisor cannot make a recommended change, it flags it as failed. It also flags a check as failed if performance did not improve and reinstates the model to the settings it had before the check ran.

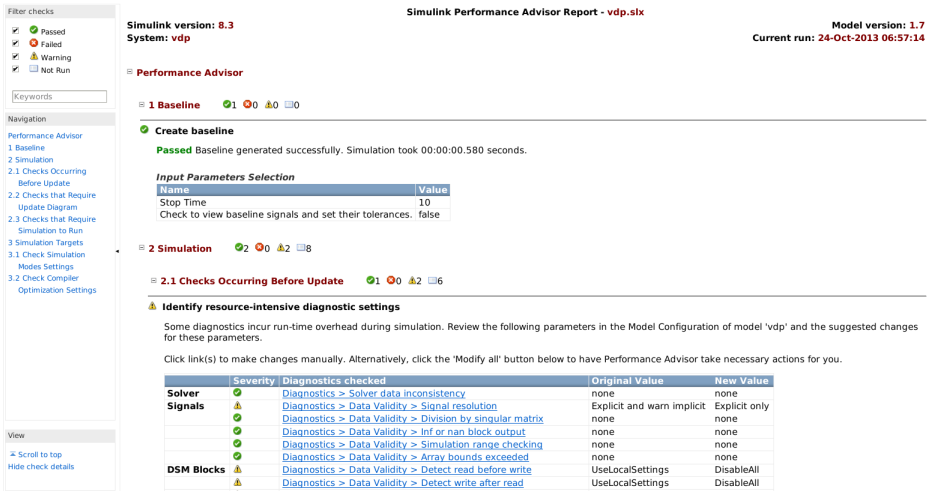
Caution Performance Advisor does not automatically save your model after it makes changes. When you are satisfied with the changes to the model from Performance Advisor, save the model.

View and Save Performance Advisor Reports

When Performance Advisor runs checks, it generates HTML reports of the results. To view a report, select a folder in the left pane and click the link in the **Report** box in the right pane.

As you run checks, Performance Advisor updates the reports with the latest information for each check in the folder. Time stamps indicate when checks ran.

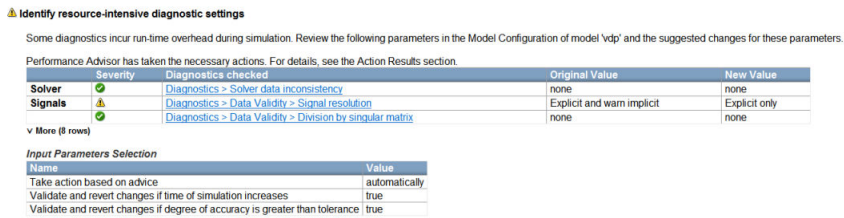
In the pane for global settings, when you select **Show report after run**, Performance Advisor displays a consolidated set of check results in the report.



You can perform these actions using the Performance Advisor report:

- Use the check boxes under **Filter checks** to view only the checks with the status that you are interested in viewing. For example, to see only the checks that failed or gave warnings, clear the **Passed** and **Not Run** check boxes.
- Perform a keyword search using the search box under **Filter checks**.
- Use the tree of checks under **Navigation** to jump to the category of checks or a specific check result that interests you.
- Expand and collapse content in the right pane of the report to view or hide check results.

Some checks have input parameters that you specify in the right pane of Performance Advisor. For example, **Identify resource intensive diagnostic settings** has several input parameters. When you run checks that have input parameters, Performance Advisor displays the values of the input parameters in the report.



Save Performance Advisor Reports

You can archive a Performance Advisor report by saving it to a new location. Performance Advisor does not update the saved version of a report when you run checks again. Archived reports serve as good points of comparison when you run checks again.

1. In the left pane of the Performance Advisor window, select the folder of checks for the report you want to save.
2. In the **Report** box, click **Save As**.
3. In the **Save As** dialog box, navigate to where you want to save the report, and click **Save**. Performance Advisor saves the report to the new location.

Perform a Quick Scan Diagnosis

Quick Scan is a fast method to diagnose settings in a model and deliver an approximate analysis of performance. A model can compile and simulate several times during a normal run in Performance Advisor. Quick Scan enables you to review performance issues without compiling or changing the model or validating any fixes. In models with long compile times, use Quick Scan to get a rapid analysis of possible improvements.

When you perform a Quick Scan diagnosis, Performance Advisor

- Does not perform a baseline measurement.
- Does not automatically apply advice to the model.
- Does not validate any changes you make to the model.
- Does not time out if the Quick Scan diagnosis takes longer than the **Time Out** duration you specify.

Run Quick Scan on a Model

1 Select checks to run.

> **Tip** If you are unsure of which checks apply, you can select and run all checks. After you see the results, clear the checks you are not interested in.

   - In the left pane of Performance Advisor, expand a folder, such as **Simulation** or **Simulation Targets**, to display checks related to specific tasks.
   - In the folder, select the checks you want to run using the check boxes.

2 Select the **Show report after run** checkbox to display the results of the checks after they run.

3 Click **Quick Scan** on the right pane.

Checks in Quick Scan Mode

- "Identify resource-intensive diagnostic settings"
- "Check optimization settings"
- "Identify inefficient lookup table blocks"

- “Check MATLAB System block simulation mode”
- “Identify Interpreted MATLAB Function blocks”
- “Identify simulation target settings”
- “Check model reference rebuild setting”

Improve vdp Model Performance

In this section...

This example shows you how to run Performance Advisor on the `vdp` model, review advice, and make changes to improve performance.

Enable Data Logging for the Model

1. In the `vdp` model, select **Simulation > Model Configuration Parameters**.
2. In the Configuration Parameters dialog box, click **Data Import/Export** in the left pane.
3. Set up signal logging. The model must log at least one signal for Performance Advisor to work. For example, select the **States** or **Output** check box.
4. Click **Configure Signals to Log** .
5. To select signals to log, select a signal in `vdp`. Right click and select **Properties**.
6. In the Signal Properties dialog box, check the **Log signal data** option and click **OK**.
7. Click **OK** in the Configuration Parameters dialog box.
8. Run the model once to make sure that the simulation is successful.

Create Baseline

1. Open Performance Advisor. In the `vdp` model, select **Analysis > Performance Tools > Performance Advisor**.
2. In the right pane, under **Set Up**, select a global setting for **Take Action**. To automatically apply advice to the model, select `automatically for all checks`.
3. Select global settings to validate any improvements in simulation time and accuracy after applying advice. To select the default setting for validation, for **Validate**

simulation time and **Validate simulation accuracy**, select `use check parameters`.

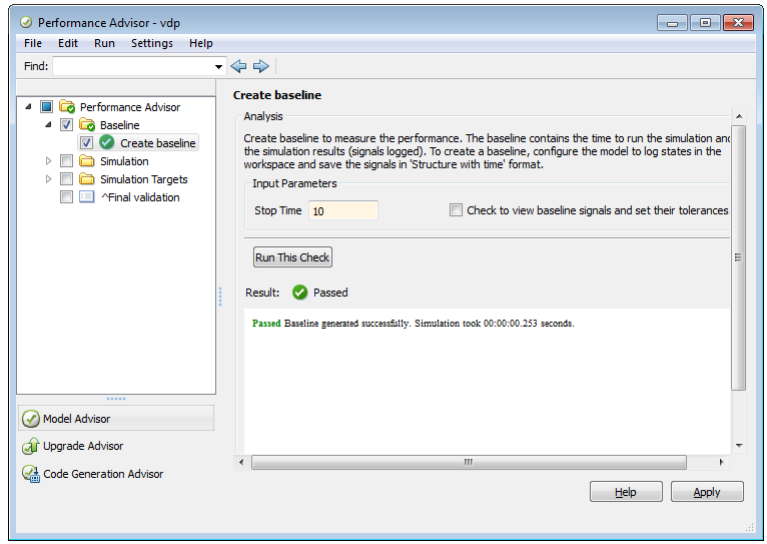
Note To validate any improvements automatically, change the global settings to `For all checks`. However, this can increase simulation time as validating all checks requires more simulation runs.

4 Select **Show report after run**. This opens an HTML report of check results.

5 In the left pane, select the **Create baseline** check. Clear the other checks.

6 In the **Create baseline** pane, set **Stop Time** to `10`. Click **Apply**.

7 Click **Run This Check**. The right pane updates to show that the baseline was created successfully.



Select Checks and Run

Note The global input parameters to take action and validate improvement apply to all the checks you select.

1 In the left pane, clear the baseline check. Select these checks:

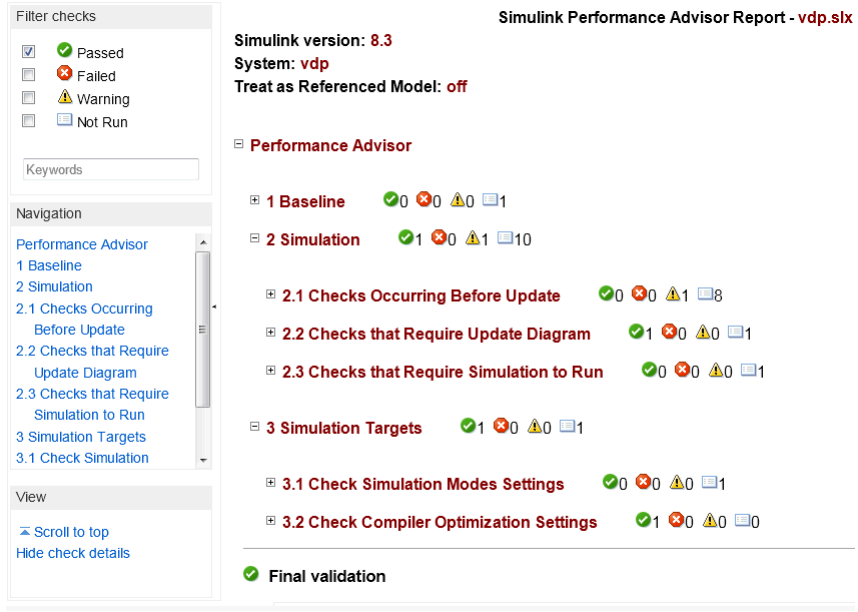
- In **Simulation > Checks Occurring Before Update**, select **Identify resource-intensive diagnostic settings**.
- In **Simulation > Checks that Require Update Diagram**, select **Check model reference parallel build**.
- In **Simulation Targets > Check Compiler Optimization Settings**, select **Select compiler optimizations on or off**.
- Select **Final validation**.

2. For every check that you have selected in the left pane, select options in the right pane to validate any improvements in simulation time and accuracy. Note that **Take Action based on advice** is set to `automatically`, a result of **Take Action** being set to `automatically for all checks`.
3. Select a value for **Time Out** if you want to limit the runtime duration of Performance Advisor.
4. Click **Run Selected Checks**.

Performance Advisor runs the checks you selected and opens an HTML report with check results.

Review Results

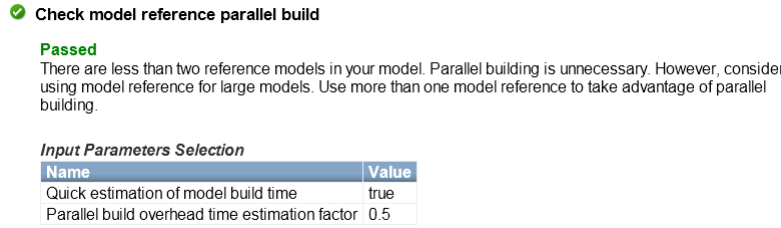
1. In the HTML report, filter the results to see only the checks that passed.



All of the selected checks passed successfully.

2 Navigate to the results for a particular check, for example**Check model reference parallel build**. Use the navigation tree in the left pane or scroll to the results for this check in the right pane.

3 Performance Advisor gives you information about this check, advice for performance improvement, as well as a list of related model configuration parameters.



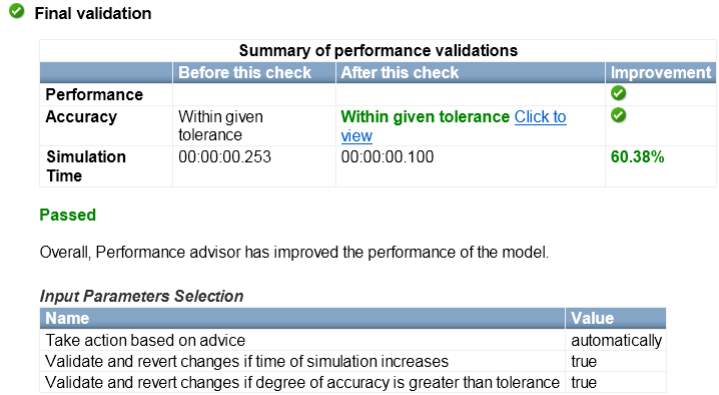
4 Filter the results to display warnings. See results for the **Identify resource-intensive diagnostic settings** check.

Performance Advisor identified diagnostic settings that incur runtime overhead during simulation. It modified values for some of these diagnostics. A table in the

report shows the diagnostics checked and whether Performance Advisor suggested a change to the value.

If the performance of the model improved, the HTML report gives you information about this improvement. If the performance has deteriorated, Performance Advisor discards all changes and reinstates the original settings in the model.

5 See details for the **Final Validation** check.



Final validation

Summary of performance validations

	Before this check	After this check	Improvement
Performance			✓
Accuracy	Within given tolerance	**Within given tolerance** Click to view	✓
Simulation Time	00:00:00.253	00:00:00.100	**60.38%**

Passed

Overall, Performance advisor has improved the performance of the model.

Input Parameters Selection

Name	Value
Take action based on advice	automatically
Validate and revert changes if time of simulation increases	true
Validate and revert changes if degree of accuracy is greater than tolerance	true

This check validates the overall performance improvement in the model. The check results show changes in simulation time and accuracy, depending on whether performance improved or degraded.

Apply Advice and Validate Manually

Generate advice for a check, apply it, and validate any improvements manually.

1 In the left pane, click **Performance Advisor**. Select these settings and click **Apply**:

- Set **Take Action** to `generate advice only`.
- Set **Validate simulation time** to `use check parameters`.
- Set **Validate simulation accuracy** to `use check parameters`.

2 For every check that you have selected in the left pane, select options in the right pane to validate any improvements in simulation time and accuracy. Note that **Take Action based on advice** is set to `manually`, a result of **Take Action** being set to `generate advice only`.

3 Select **Performance Advisor** in the left pane. Click **Run Selected Checks** in the Performance Advisor pane.

   If the performance of the model has improved, the **Final Validation** check results show the overall performance improvement.

4 In the results for **Identify resource-intensive diagnostic settings**, Performance Advisor suggests new values for the diagnostics it checked. Review these results to accept or reject the values it suggests.

   Alternatively, click **Modify all and Validate** to accept all changes and validate any improvement in performance.

Performance Advisor Window

When you open Performance Advisor, it displays two panes.

In the left pane, the performance checks you can run are stored in folders. Expand the folders to see the checks within and select checks to run. You can search for folders and checks using **Find** above the pane.

Use the right pane to:

- Understand the Performance Advisor workflow
- Set up the model to run checks
- Select actions to apply generated advice and validate check results
- Learn more about each check
- Specify input parameters
- Run checks
- View and save reports
- View Performance Advisor results

After you run a check, Performance Advisor displays the results in the right pane. The right pane changes depending on the check you have selected.

Selection	Right Pane Display
Folder	**Analysis** pane, containing: • **Run Selected Checks** button — Click to run the selected checks in the folder and its subfolders. • **Show report after run** check box — Select to display an HTML report of the check results in a separate window. **Report** pane, containing: • Link to HTML report of check results • **Save As** button — Click to export the HTML report to a specific location **Tips** and **Legend** panes, containing brief descriptions on using the checks.

Selection	Right Pane Display
Check	**Analysis** pane, containing: • Input Parameters section — Before running checks, specify how you want checks to run (for more information, see "Run Performance Advisor Checks" on page 31-6). • Result section — Display results after a check runs. **Action** pane, containing: • **Modify** button — After the check runs, Performance Advisor suggests actions to take to improve performance. Click here to accept the recommendations and modify the model. • Result section — Display results after performing recommended actions.

From Performance Advisor, you can also run:

- **Model Advisor** — Check a model or subsystem for conditions that result in inaccurate or inefficient simulation of the system. See "Run Model Checks".
- **Upgrade Advisor** — Upgrade and improve models with the current release. See "Consult the Upgrade Advisor" on page 6-2.
- **Code Generation Advisor** — Configure the model to meet code generation objectives. See "Application Objectives Using Code Generation Advisor" (Simulink Coder).

Solver Profiler

Examine Model Dynamics Using Solver Profiler

When model simulation slows down or stops responding, a close examination of the dynamics of the model can help you identify the factors affecting the simulation.

Understanding solver behavior enables you to interpret how the model simulates and what causes the solver to take small steps.

The Solver Profiler analyzes a model for patterns that affect its simulation. The Solver Profiler presents graphical and statistical information about the simulation, solver settings, events, and errors. You can use this data to identify locations in the model that caused simulation bottlenecks.

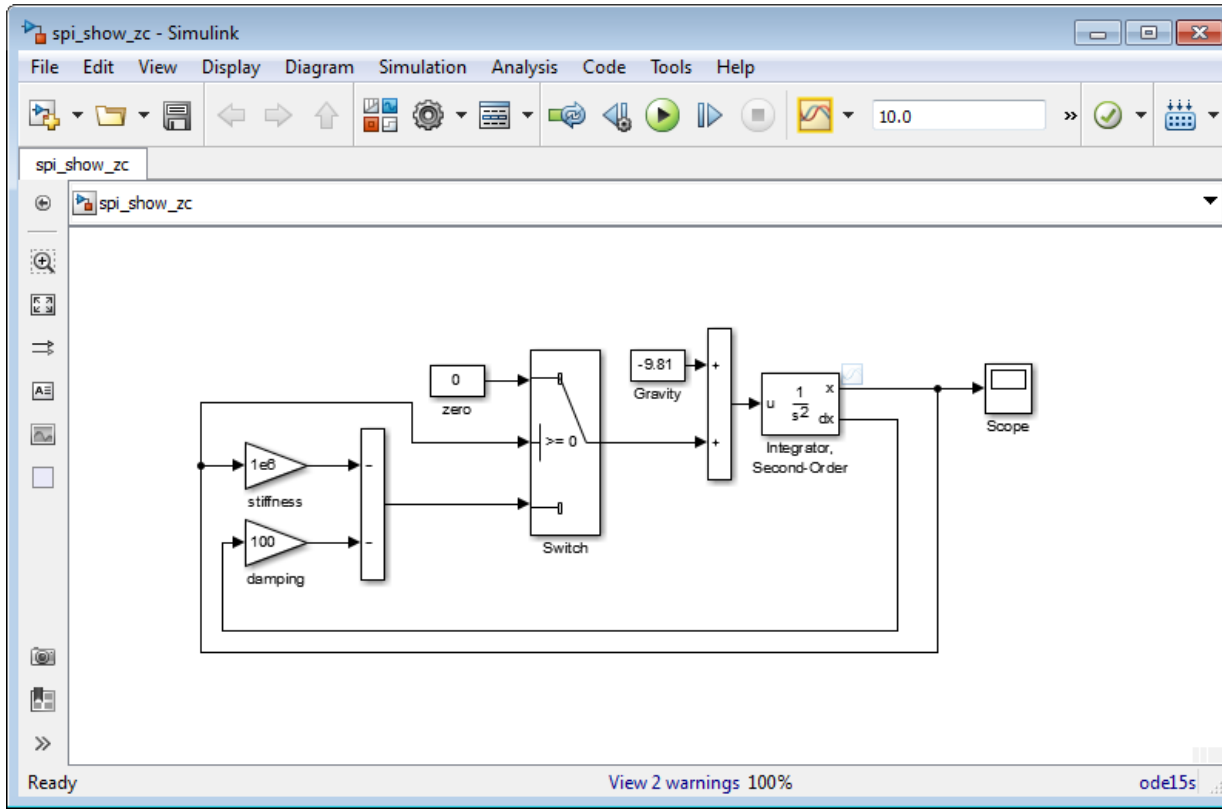
Note The Solver Profiler supports both fixed-step and variable-step solvers. However, it does not support models without continuous states.

In addition, in simulations that use variable-step solvers, the size of the step can be limited due to various reasons. The Solver Profiler logs and reports all the events when the solver tries to take too large steps:

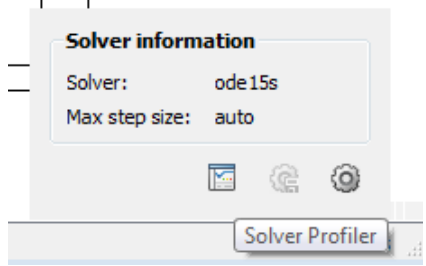
- Zero-crossing event
- Error control exception
- Newton iteration exception
- Differential algebraic equation (DAE) Newton iteration exception
- Infinite state exception

To examine model dynamics and identify causes that affect the simulation:

1 Open the model that is simulating slowly or unsuccessfully.



2 Open the Solver Profiler by clicking the hyperlink in the lower-right corner of the Simulink Editor.

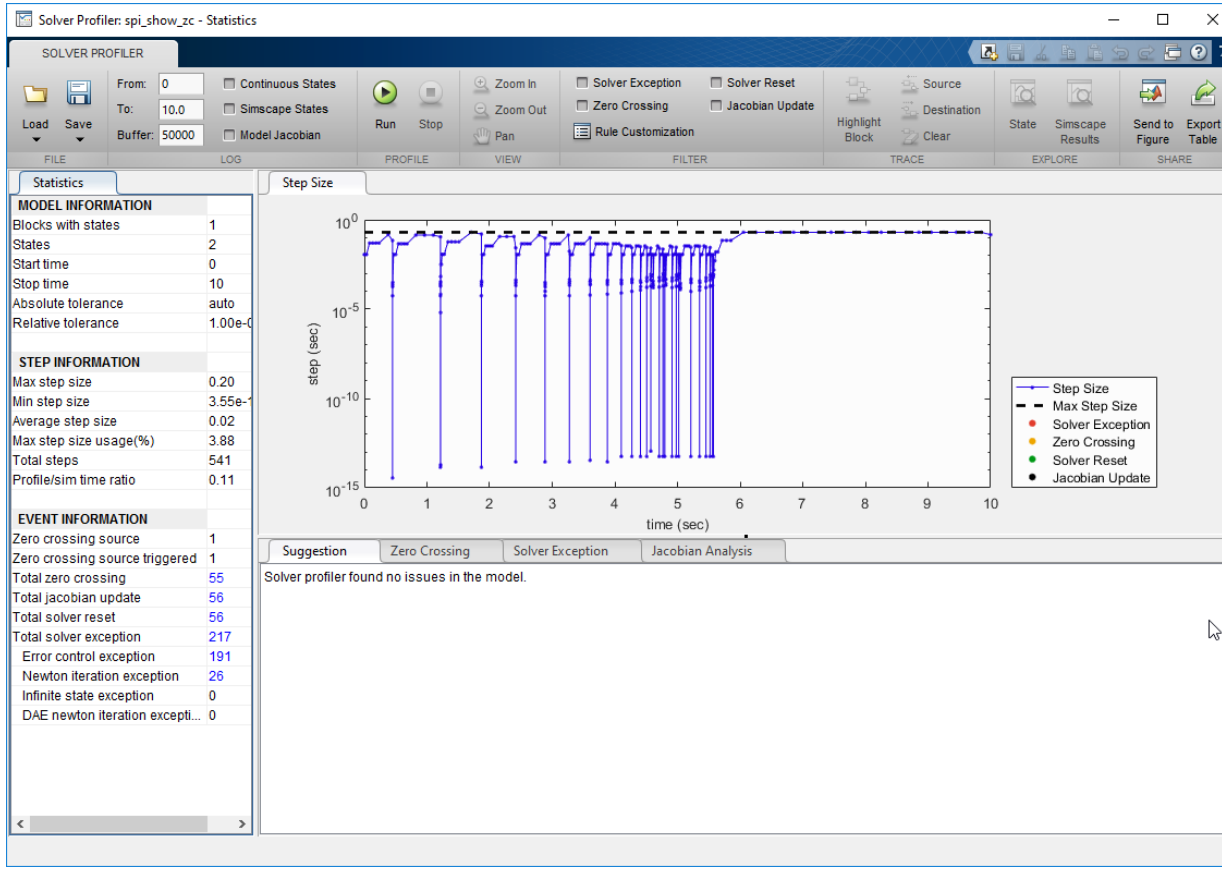


3 To log model states that have solver errors or exception events, select the **Continuous States** or **Simscape States** option before a run. Disable these options

only if you are running out of memory. After the run, access the States Explorer or Simscape Explorer to examine those states.

4 Click **Run**. The profiler simulates the model and starts capturing solver performance data.

When the simulation ends, the profiler displays the statistics and exceptions it captured over the duration of the simulation.



Tip You can pause or stop the simulation at any time to view the information captured until that point.

5 Use the profiler plot to highlight the parts of the model that caused generate the most events.

6 Click **Save** to capture your profiling session, or exit without saving.

Understand Profiling Results

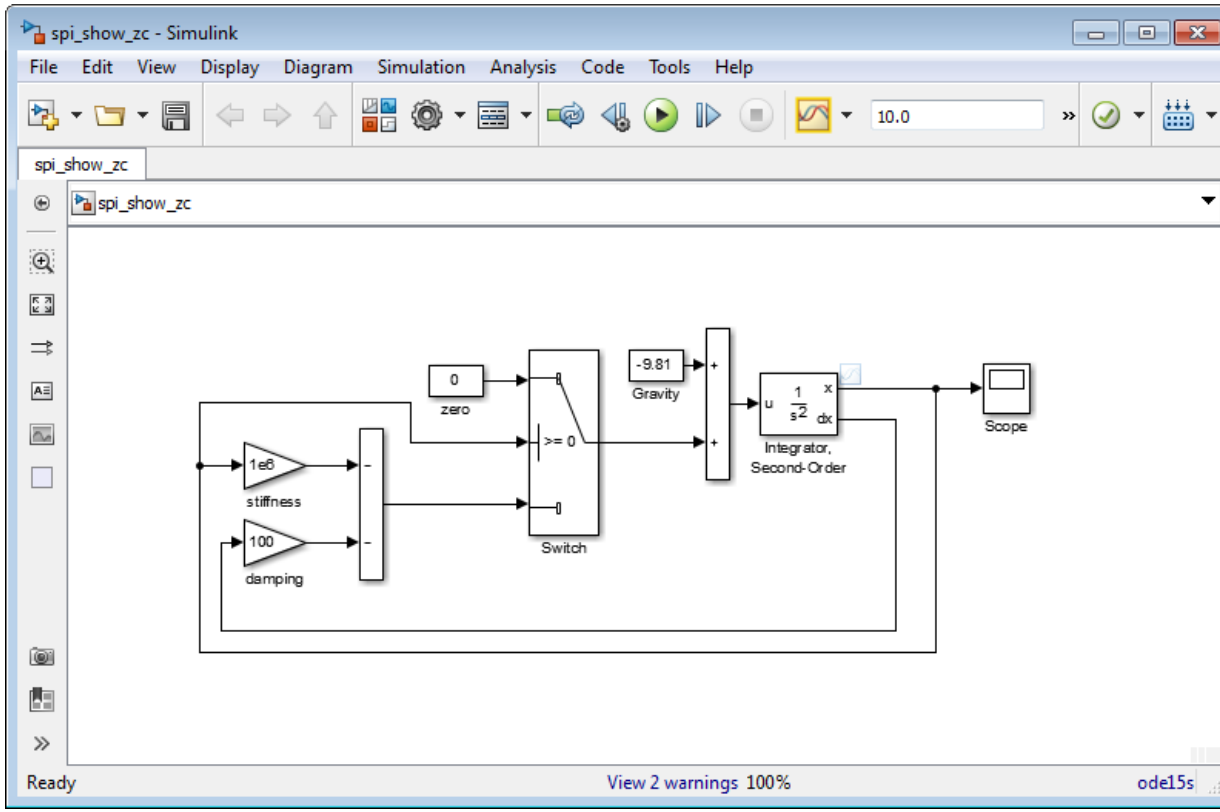
In this section...

If you have a large model, it can be challenging to identify which parts of your model cause the solver to take small steps. The Solver Profiler logs and reports events when the solver attempts to take large steps. This report of events helps you identify which parts of your model to focus on to improve solver performance.

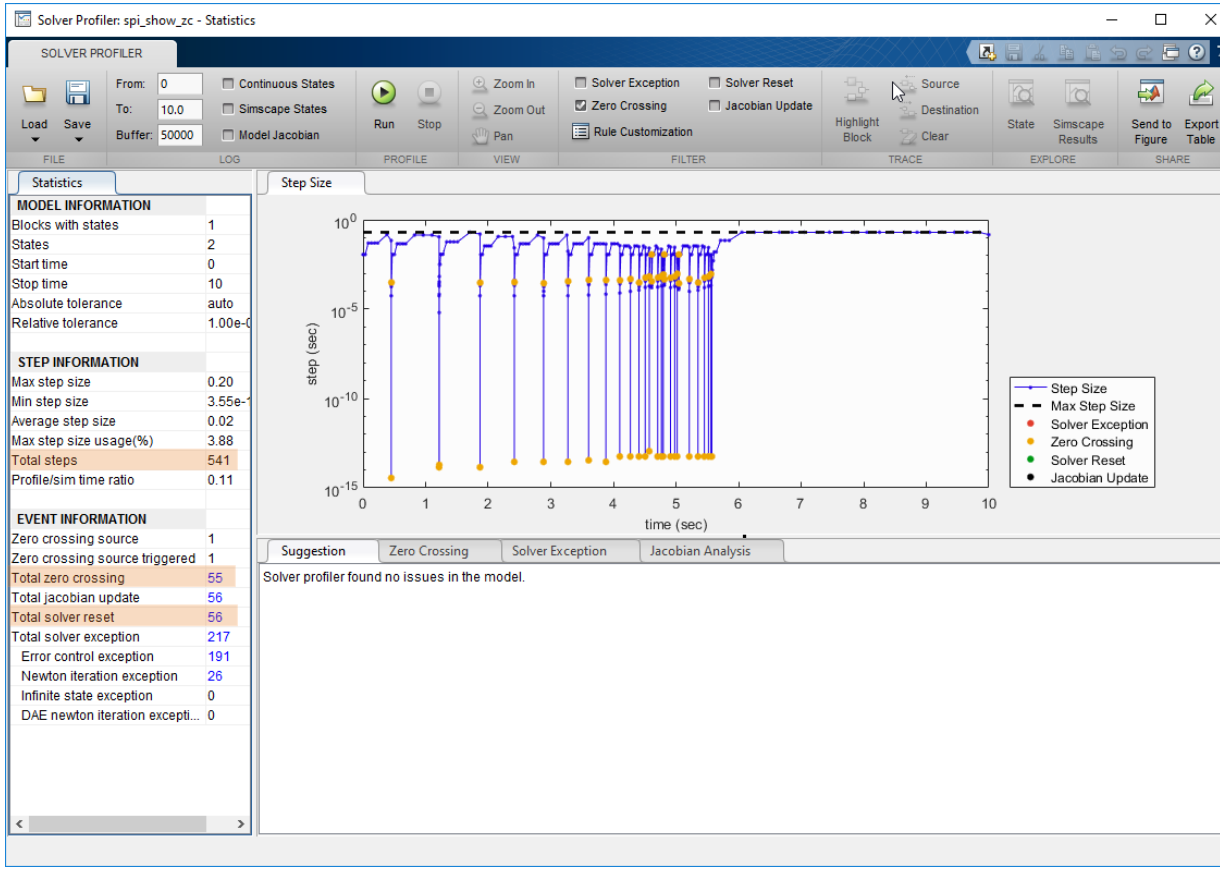
This topic presents simple examples that illustrate various events that the profiler reports.

Zero-Crossing Events

This example simulates a ball bouncing on a hard surface.

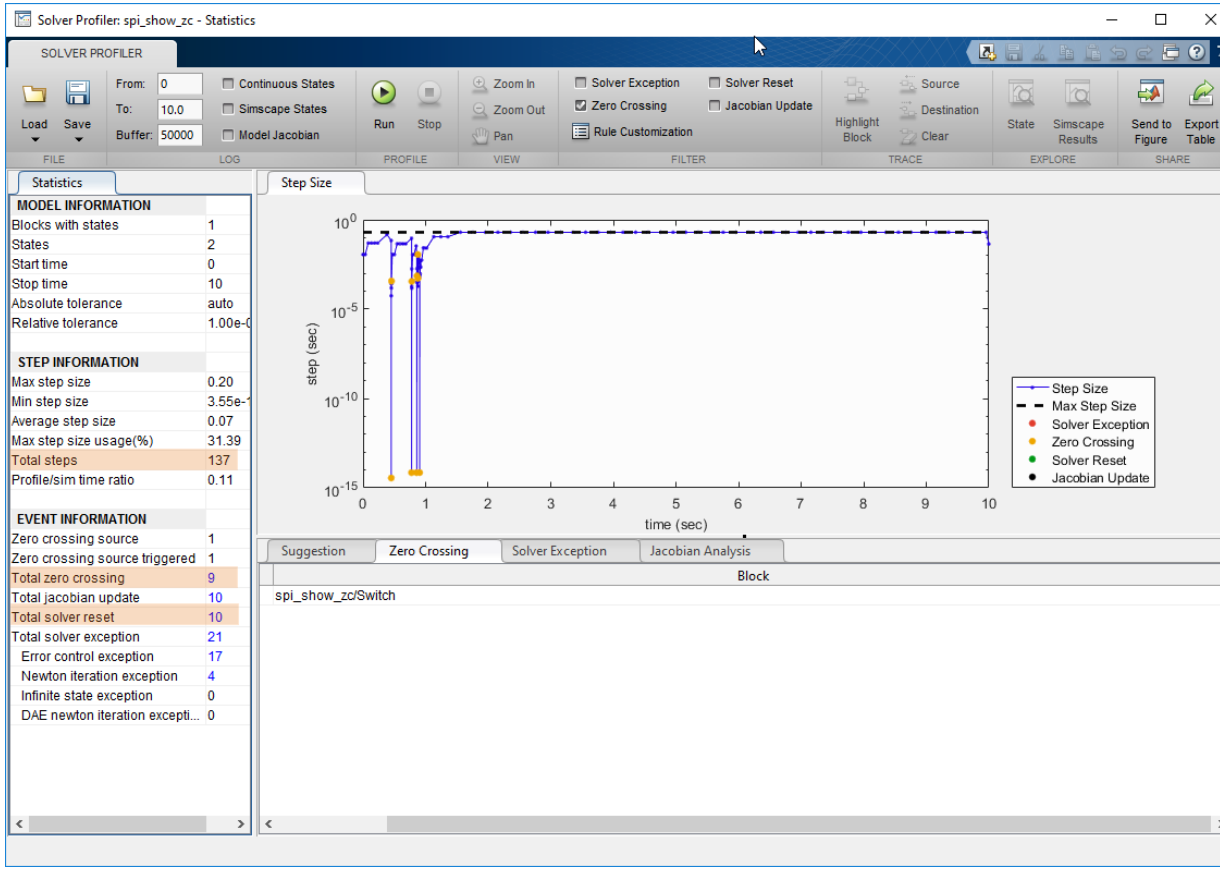


When you run the Solver Profiler on this model, the model simulates in `541` steps and that it triggers `55` zero-crossing events. To highlight the zero-crossing events on the step size plot, click the **Zero Crossing** tab and select the block that is causing the event.



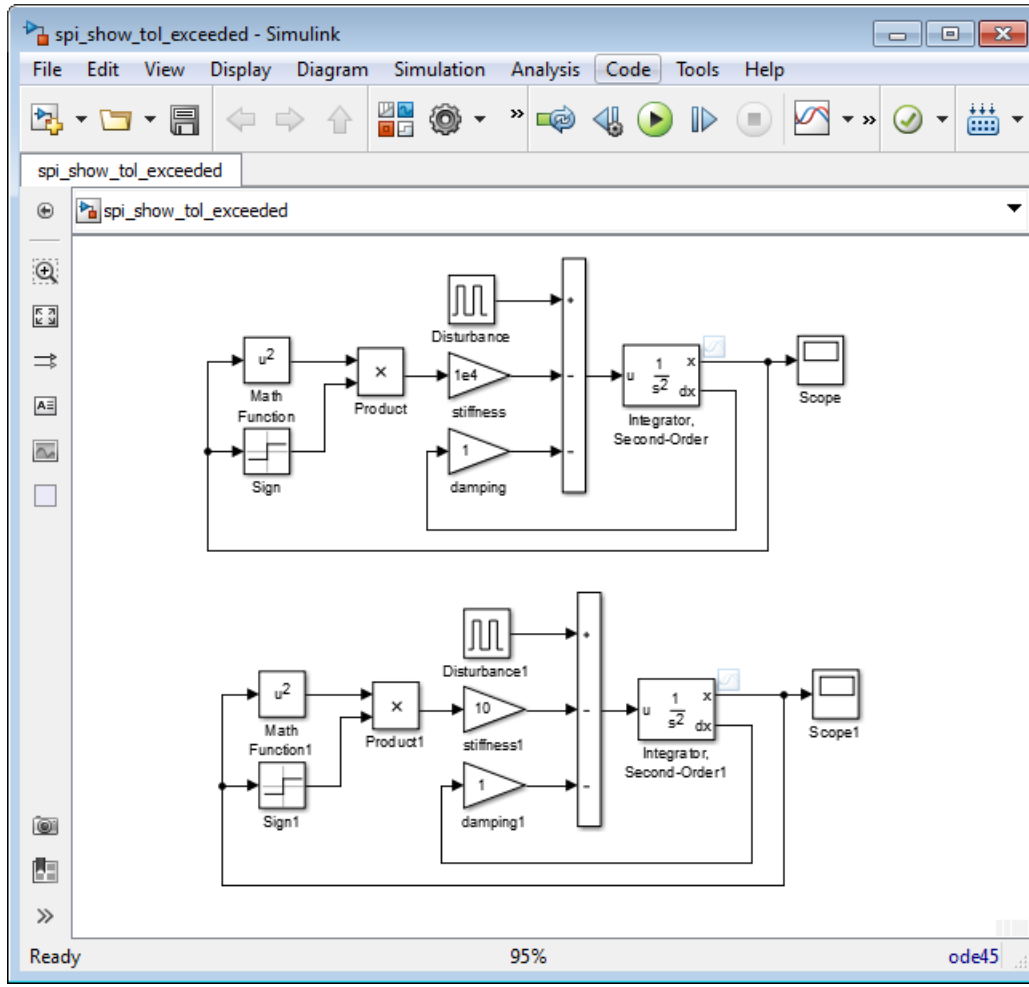
The result indicates that when the ball drops on the hard surface, it bounces 55 times before coming to a stop. The solver resets after each bounce, increasing the computational load. Having many resets improves accuracy at the cost of computation load. Therefore, it is important to be cognizant of this trade-off when modeling.

If this modeling construct belonged to a larger model, the Solver Profiler would help you locate it. You could then modify the model to improve solver performance. For example, you can decide to reduce the accuracy of the contact dynamic by increasing the damping factor, which would reduce the number of bounce events. Increasing the damping from 100 to 500 makes the ball bounce only `9` times, allowing the simulation to complete in only `137` steps.

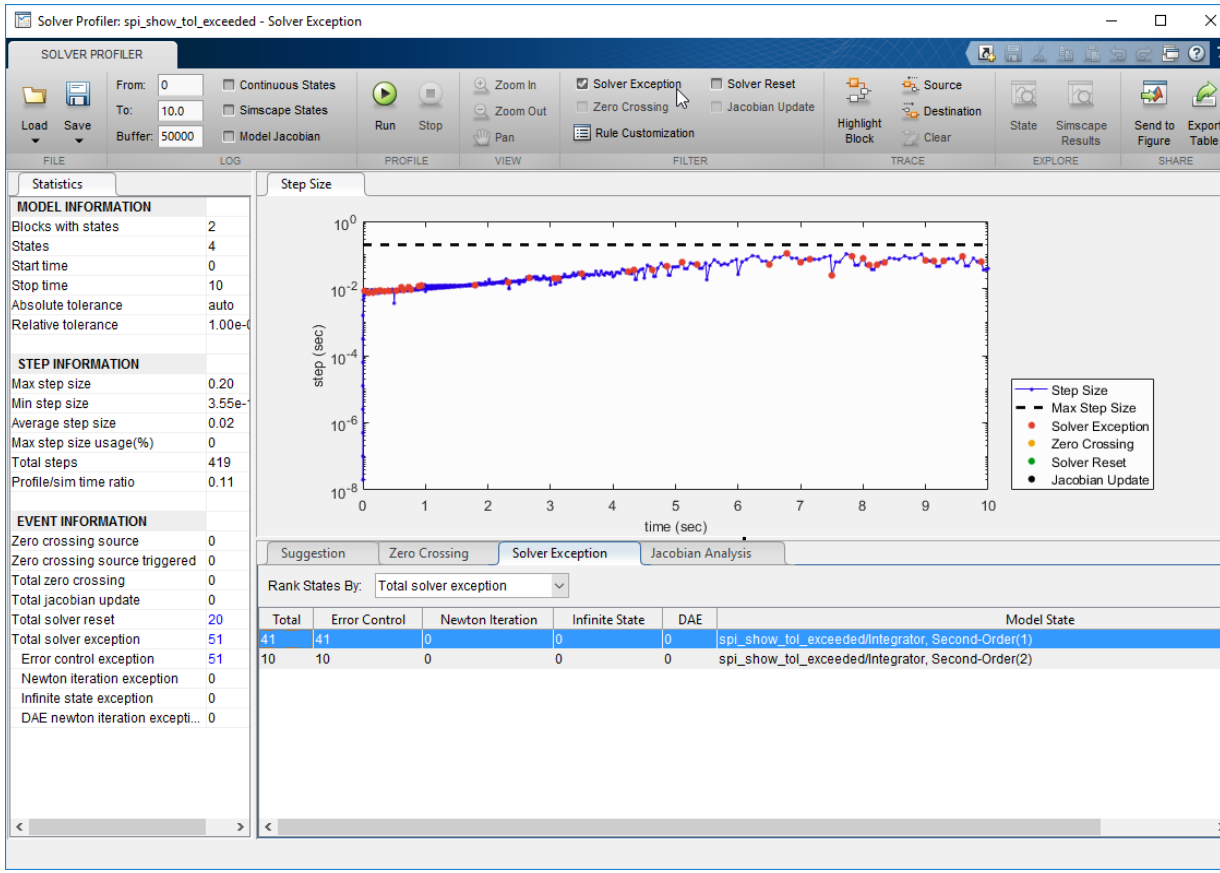


Tolerance-Exceeding Events

This example simulates two identical nonlinear spring-damping systems. The two systems have different spring stiffnesses.



When you run the Solver Profiler on this model, you can see the tolerance exceeding events in the **Solver Exception** tab.



The result indicates that the stiffer spring causes the solver tolerance to exceed the limit. Typically, model states that change the fastest tend to be closest to the solver tolerance limit.

The solver attempts to take the largest possible steps while optimally trading off between speed and accuracy. Occasionally, this trade-off causes the solver to take steps that exceed the tolerance limit and forces it to reduce the step size. Exceeding the tolerance limit is not a poor modeling practice in itself. This profiler statistic is not meant to help you reduce tolerance exceeding events to zero.

This statistic can help you identify parts of your model that are close to exceeding the tolerance limit. You can identify model components that change the fastest or are the

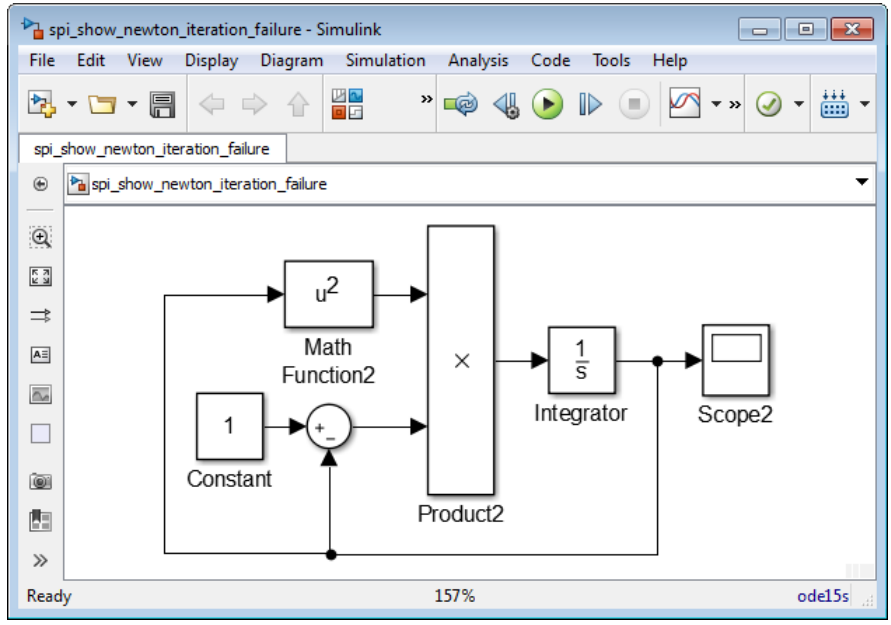
stiffest. You can decide to retain this model dynamic in the simulation or simplify it to speed up simulation.

The tolerance-exceeding statistic can also help you identify modeling errors. If you do not expect the highlighted states to change as fast, you can examine your model for errors. In this example, the modeling error could be the stiffness of the stiffer spring is specified as `N/m` instead the `N/mm`. This error makes the spring 1000 times stiffer than expected.

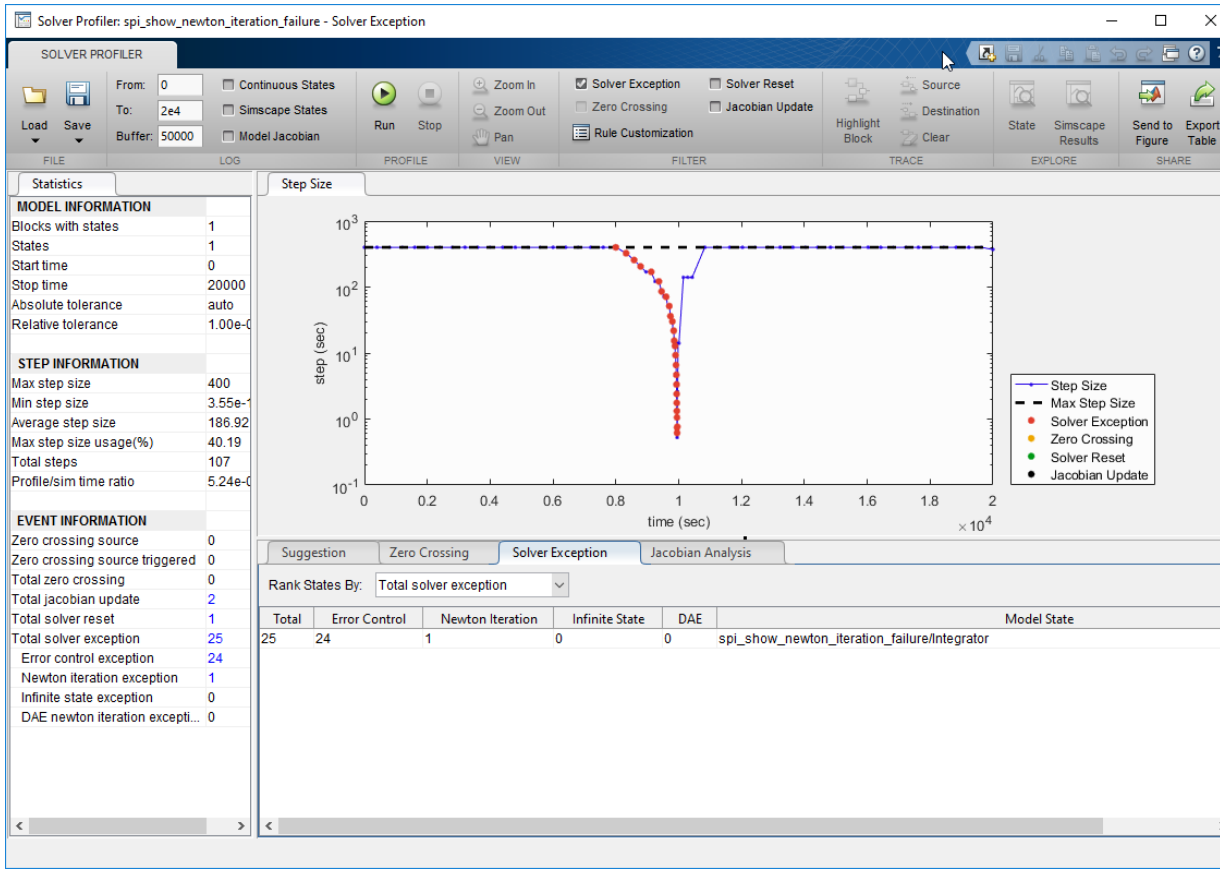
Newton Iteration Failures

Newton iteration failures are specific to implicit solvers like `ode15s` and `ode23t`, and they result from Newton iterations not converging after a few trials. Similar to tolerance-exceeding events, these failures tend to occur when a system changes quickly.

This example simulates how the radius of a ball of flame changes when you strike a match. The ball of flame grows rapidly until it reaches a critical size, when the amount of oxygen consumed balances the growth in ball surface.



When you run the Solver Profiler on this model, you can see the Newton iteration failures in the **Solver Exception** tab.



The result indicates that when the combustion begins, the solver tolerance is exceeded multiple times. When equilibrium is attained, the system appears different, and a Newton iteration failure occurs. The Jacobian of the system is recomputed, and the solver continues to move forward.

Newton failures are not indicative of poor modeling practices. This profiler statistic is not meant to help you reduce these failures to zero. In this example, you can reduce the solver tolerance to prevent this failure. But the solver then takes small steps unnecessarily, which is counterproductive. Therefore, in this example, this failure is acceptable.

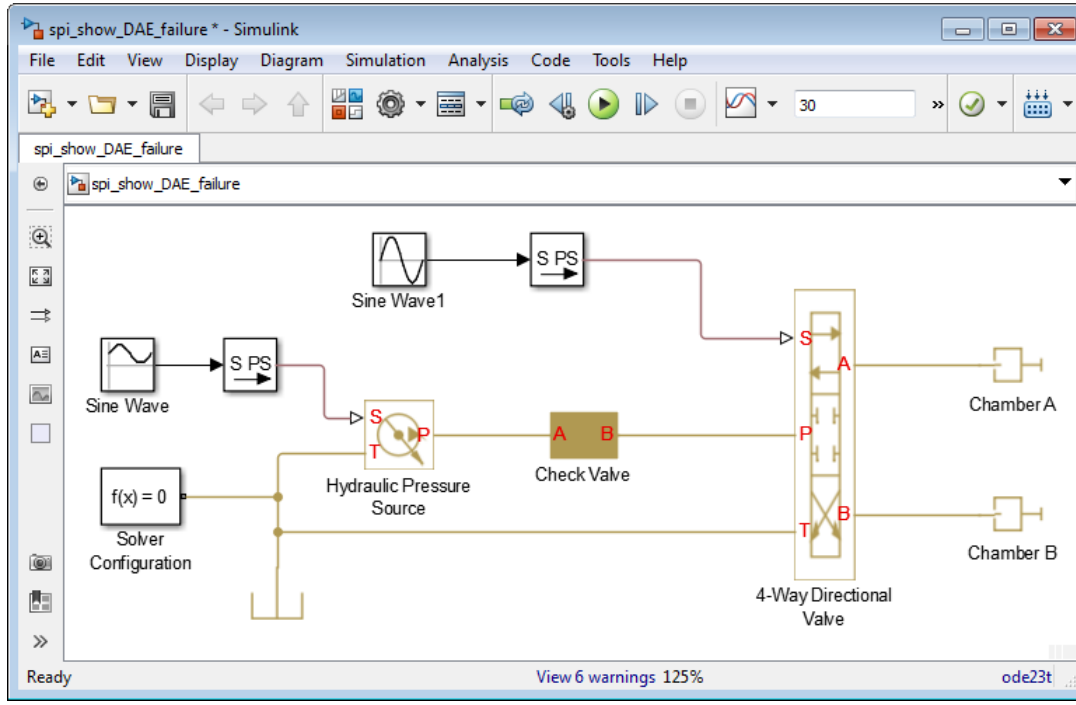
This type of failure becomes problematic when it occurs in large numbers over a short period, especially in Simscape models. Dense failures indicate that your model is not robust numerically. One way to improve numerical robustness is to tighten the solver tolerance. Another way is to modify the model to avoid rapid changes.

Differential Algebraic Equation Failures

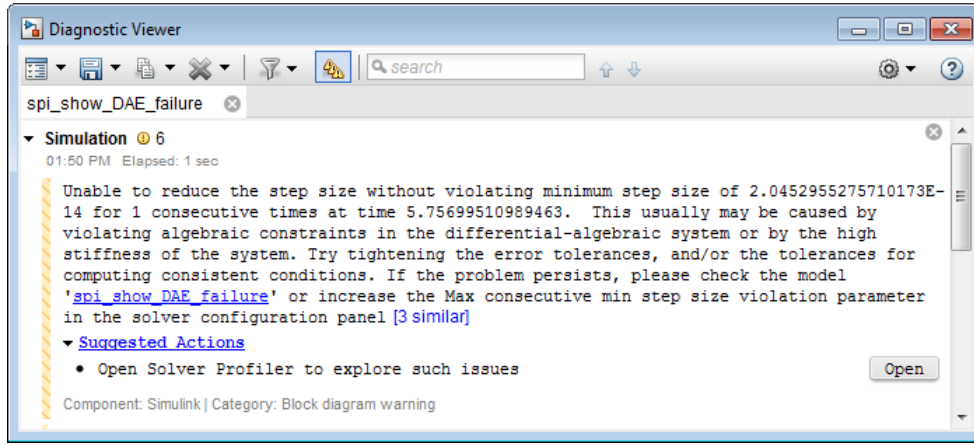
Most Simscape models are implemented using differential algebraic equations (DAEs), in contrast to Simulink models, which use ordinary differential equations.

The use of DAEs adds complexity to Simscape models. Solvers like `ode15s` and `ode23t` can handle many types of DAEs. However, when the algebraic constraints between Simscape components are complex and changing fast, the Newton iteration process fails to resolve to those constraints.

This example simulates a pressure source that can be directed toward one of two hydraulic chambers.

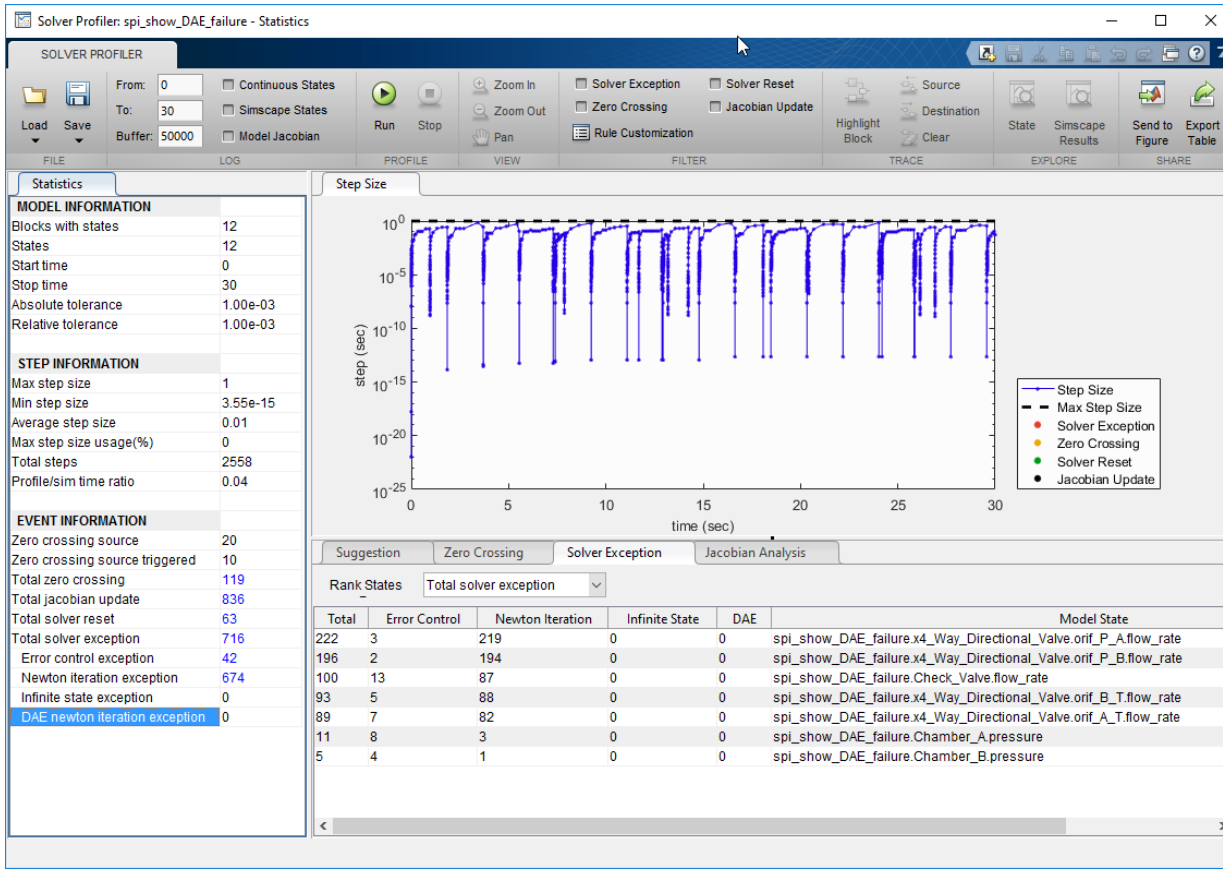


When you simulate this model, Simulink displays several warnings.



Typically, small models can handle such warnings and simulate to completion. However, this warning indicates that the model is not robust numerically. Minor changes to the model, or integration into a larger model, can result in errors.

When you run the Solver Profiler on this model, you can see the DAE failures in the **Solver Exception** tab.



In this case, the exception results from large solver tolerance. Tightening the solver tolerance forces the solver to take smaller steps and better capture the changes in algebraic constraints.

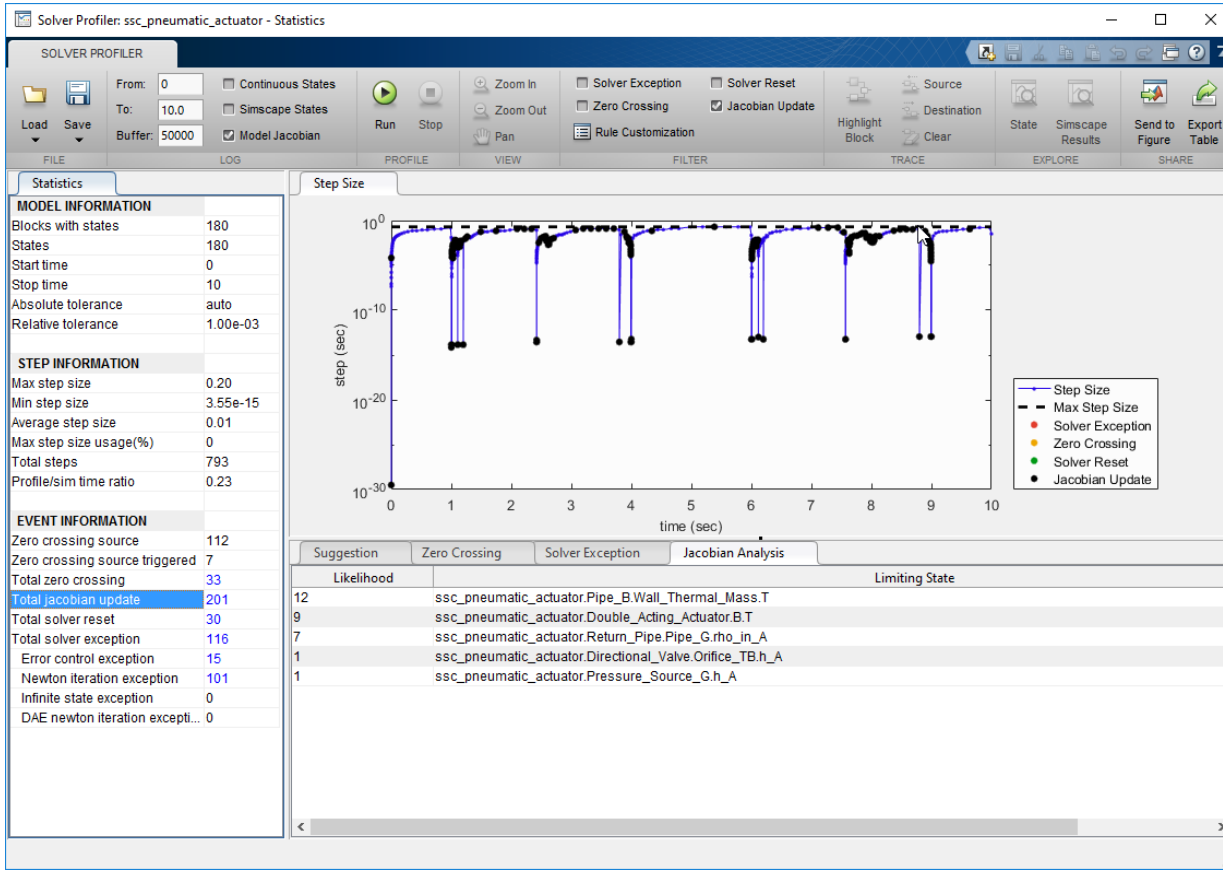
Alternatively, this exception can be avoided by removing the algebraic constraint. In this example, the **Check Valve** and the **4-Way Directional Valve** are directly connected. When their pressure–flow relationship changes rapidly, the solver is unable to capture the changes. Inserting a **Hydraulic Chamber** between those two components makes them compliant. To learn more about dry nodes, see Simscape documentation.

Jacobian Logging and Analysis

The Solver Profiler supports Jacobian logging and analysis for `ode15s` and `ode23t` solvers only.

You can select the **Model Jacobian** checkbox in the Solver Profiler to log updates to the Jacobian matrix for the model. When you run the Solver Profiler on a model, you can see the logs in the **Jacobian Analysis** tab.

The **Jacobian Analysis** tab indicates the states in the model that are likely slowing down the solver.



To investigate the cause of each limiting state, select a row in the **Jacobian Analysis** tab and click **Highlight Block**.

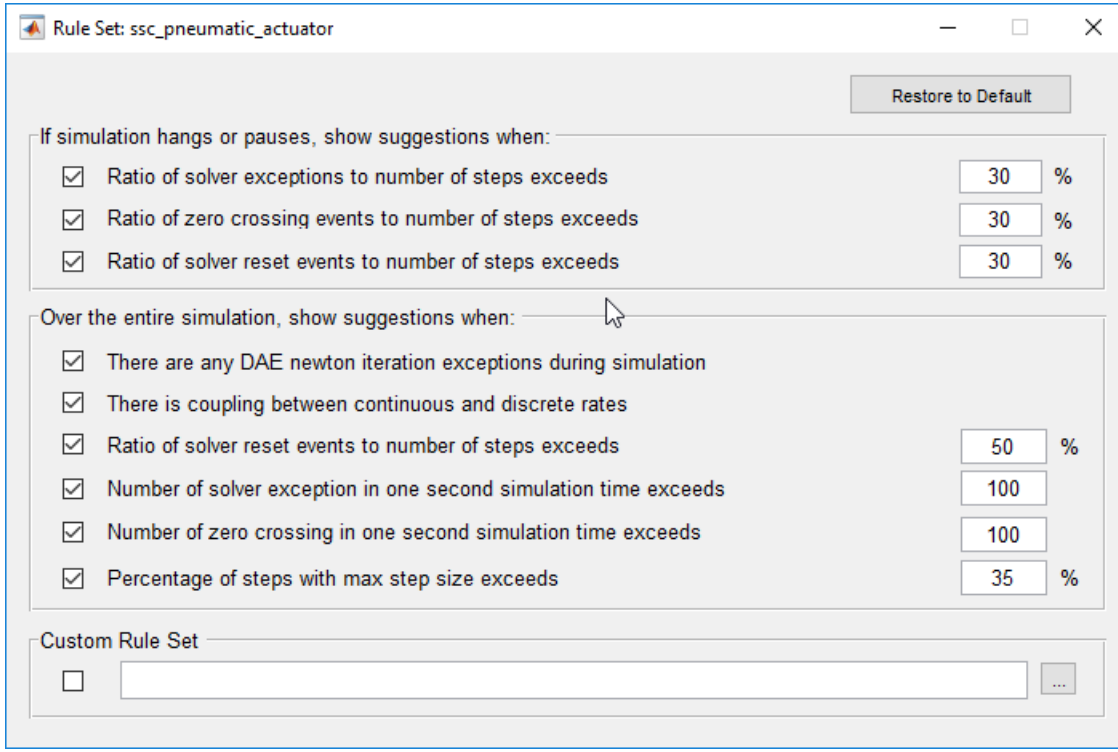
Modify Solver Profiler Rules

You can customize the suggestions that appear in the Solver Profiler in these ways:

- Change the thresholds of the Solver Profiler rules that detect failure patterns.
- Select which rules to apply during a profiling run.
- Author your own rule set as a MATLAB script.

Change Thresholds of Profiler Rules

Click **Rule Customization** in the Solver Profiler to access the rule set. You can change the thresholds for most of these rules and also select which rules you want to apply selectively during a simulation run.



Develop Profiler Rule Set

You can override the settings on the **Rule Set** dialog box by specifying a custom rule set.

Create a rule set as a MATLAB script and specify the path to the script in the **Custom Rule Set** section of the **Rule Set** dialog box.

A simple rule set example looks as follows:

```
function diagnosticsString = customRule(profilerData)
        if isempty(profilerData.zcEvents)
            diagnosticsString{1} = 'No zero-crossing event detected.';
        else
            diagnosticsString{1} = 'Zero-crossing events detected.';
        end
end
```

The input to the function is an array of structures called `profilerData`. This array of structures organizes all the information that the Solver Profiler collects during a profiling run. It contains the following substructures.

Substructure	Fields
`stateInfo`: Stores information on block states	• `name`: Block name • `value`: State values • `blockIdx`: Block ID
`blockInfo`: Cross-reference of blocks and state IDs	• `name`: Block name • `stateIdx`: State ID
`zcSrcInfo`: Stores information on blocks causing zero-crossing events	• `name`: Block name • `blockIdx`: Block ID
`zcEvents`: Cross-reference of the time stamps of zero-crossing events and the corresponding state IDs	• `t`: Event timestamp • `srcIdx`: Block ID
`exceptionEvents`: Cross-reference of exception event timestamps, the ID of the corresponding state that caused the event, and the cause.	• `t`: Event timestamp • `stateIdx`: State ID • `cause`: Cause of exception

Substructure	Fields
`resetTime`: Stores timestamps of solver resets.	None
`tout`: Stores simulation times.	None

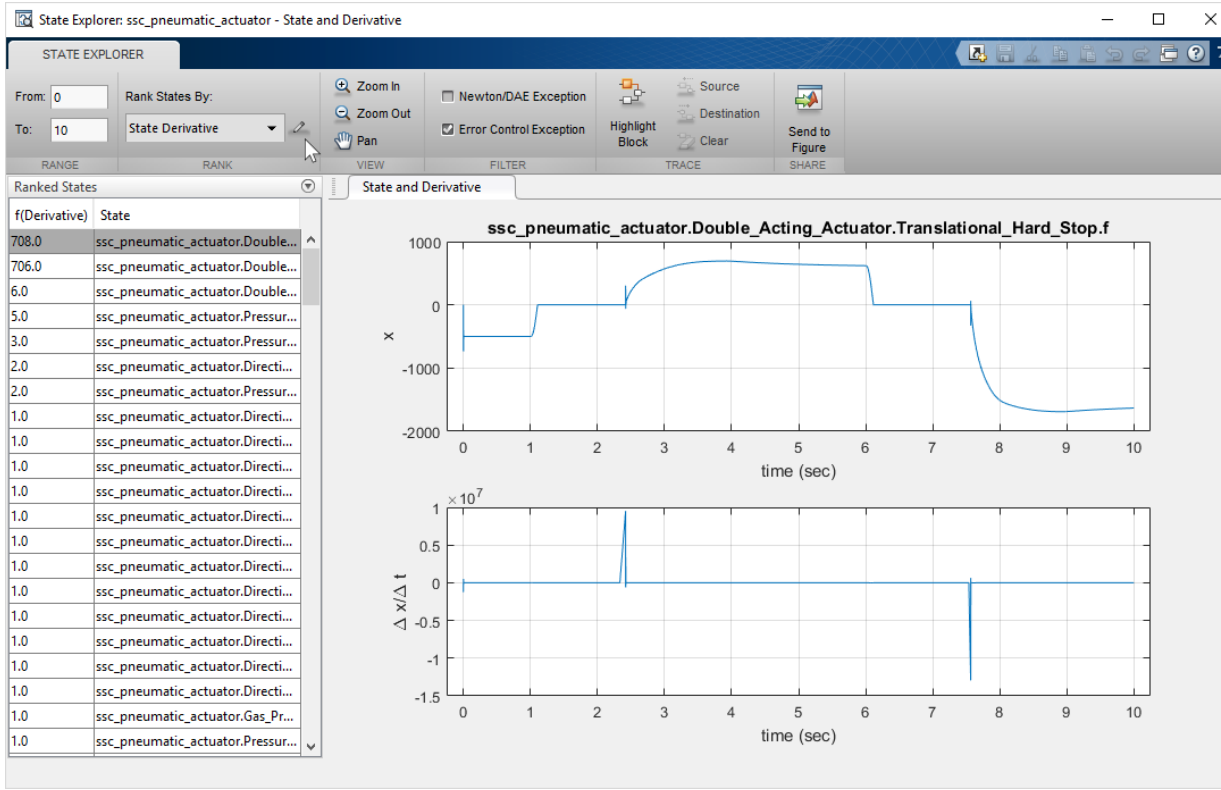
Customize State Ranking

If you log continuous states in the Solver Profiler, you can open the State Explorer to investigate each continuous state. The State Explorer ranks continuous states by the following metrics:

- State Derivative
- Newton/DAE Exception
- State Value
- Error Control Exception
- State Name
- State Chatter

In addition to these ranking metrics, you can write and upload your own algorithm to determine how continuous states are ranked in the State Explorer.

1 Click the edit button next to the **Rank States By** dropdown.



2 In the Custom Algorithm dialog box that appears, click **Add** and upload a MATLAB script that contains your ranking algorithm.

A simple algorithm that ranks states by value looks as follows:

Note The structures referenced in this example organize information that the Solver Profiler collects during a profiling run. For more information on the structures, see "Develop Profiler Rule Set" on page 32-20.

```
function [index,score] = customRank(sd,tl,tr)

% Allocate storage for index and score list
nStates = length(sd.stateInfo);
index = 1:nStates;
```

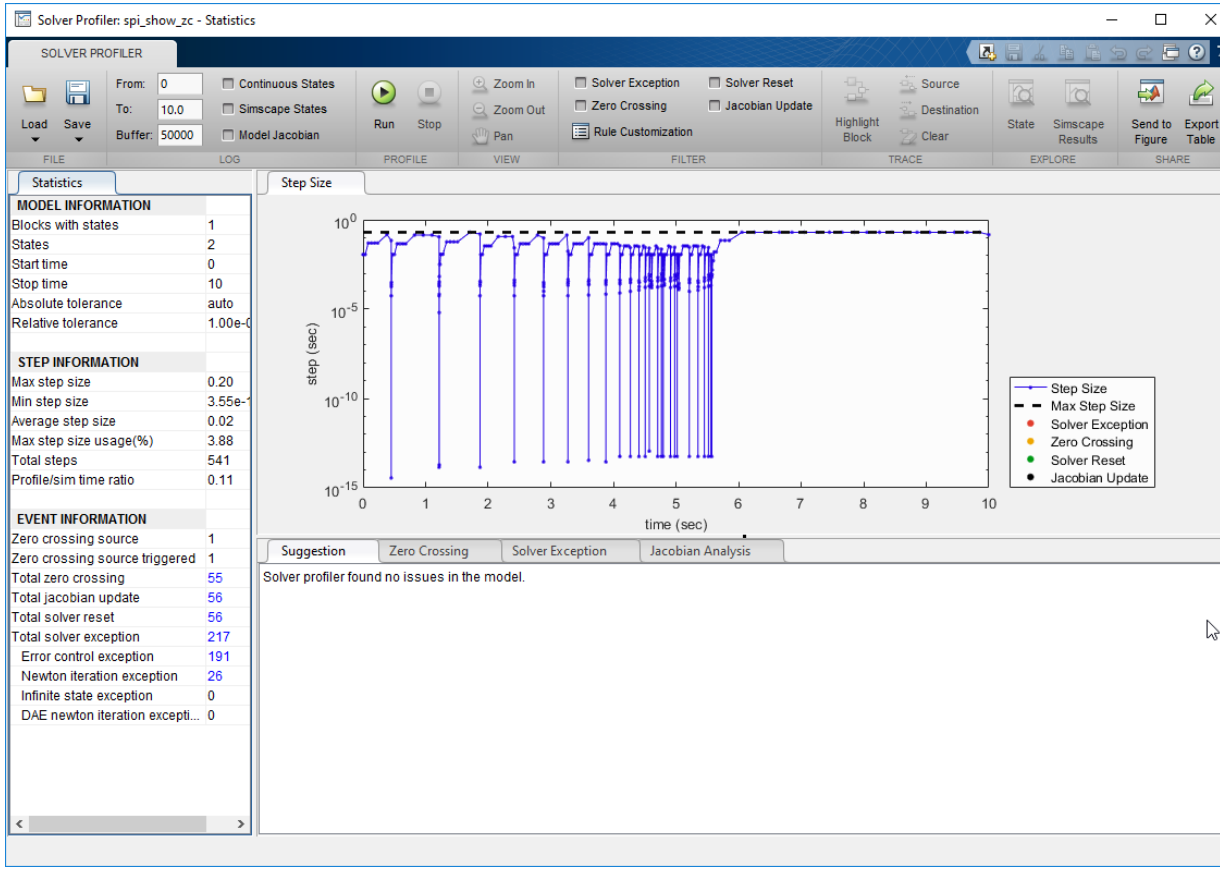
```
score = zeros(nStates,1);

% Loop through each state to calculate score
for i = 1:nStates
    x = sd.stateInfo(i).value;
    % apply time range constraints
    x = x(sd.tout>=tl & sd.tout<=tr);
    if max(x) > 1
        score(i) = 1;
    else
        score(i) = 0;
    end
end

% Rank the states
[score, order] = sort(score, 'descend');
index = index(order);

end
```

Solver Profiler Interface



The Solver Profiler enables you to:

- Start a profiling session, save a session, or open a saved session.
- Customize and filter the results displayed.
- Interact with the model and trace and highlight the states that contain exceptions.
- Open Simscape Explorer or States Explorer to analyze simulation data further.
- Customize profiler suggestions using your own rules.

Statistics Pane

The statistics pane displays information on model parameters, including:

- **Average step size** — A measure of how fast the solver advances. It is calculated as the total simulation time divided by the number of steps the solver used. It is bounded by the model configuration parameters **Max step size** and **Min step size**.
- **Max step size usage** — The percentage of maximum step sizes used by the solver among all step sizes.
- **Zero crossing** — A solver-specific event that affects model dynamics. During simulation, the solver detects zero crossing. Zero crossing detection incurs computation cost. For more information, see “Zero-Crossing Detection” on page 3-24.
- **Solver reset** — An event that causes the solver to reset its parameters. Solver reset detection incurs computation cost.
- **Solver exception** — An event that renders the solver unable to solve model states to meet accuracy specifications. To solve model states accurately, the solver has to run a few adjusted trials, which incur computation cost.
- **Error control exception** — An event where a solution obtained by the solver has an error that is greater than the tolerance specification.
- **Newton iteration exception** — An event specific to implicit solvers. Newton iterations do not converge after a few trials.
- **Infinite state exception** — An event where one or more states solved by the solver are infinite.
- **DAE newton iteration exception** — An event specific to implicit solvers for Simscape models. The Newton iteration does not converge even though the solver violates the minimum step size constraint.

Suggestions and Exceptions Pane

The suggestions and exceptions pane displays information on exceptions, including:

- **Solver exception** — An event that renders the solver unable to solve model states to meet accuracy specifications. To solve model states accurately, the solver has to run a few adjusted trials, which incur computation cost.
- **Error control exception** — An event where a solution obtained by the solver has an error that is greater than the tolerance specification.

- **Newton iteration exception** — An event specific to implicit solvers. Newton iterations do not converge after a few trials.
- **Infinite state exception** — An event where one or more states solved by the solver are infinite.
- **DAE newton iteration exception** — An event specific to implicit solvers for Simscape models. The Newton iteration does not converge even though the solver violates the minimum step size constraint.

Simulink Debugger

Introduction to the Debugger

With the debugger, you run your simulation method by method. You can stop after each method to examine the execution results. In this way, you can pinpoint problems in your model to specific blocks, parameters, or interconnections.

Note Methods are functions that the Simulink software uses to solve a model at each time step during the simulation. Blocks are made up of multiple methods. "Block execution" in this documentation is shorthand for "block methods execution." Block diagram execution is a multi-step operation that requires execution of the different block methods in all the blocks in a diagram at various points during the process of solving a model at each time step during simulation, as specified by the simulation loop.

The debugger has both a graphical and a command-line user interface. The graphical interface allows you to access the most commonly used features of the debugger. The command-line interface gives you access to all of the capabilities in the debugger. If you can use either to perform a task, the documentation shows you first how to use the graphical interface, "Debugger Graphical User Interface" on page 33-3, and then the command-line interface, "Debugger Command-Line Interface" on page 33-10.

All functions such as `atrace` and `ashow` can only be used within the debugger.

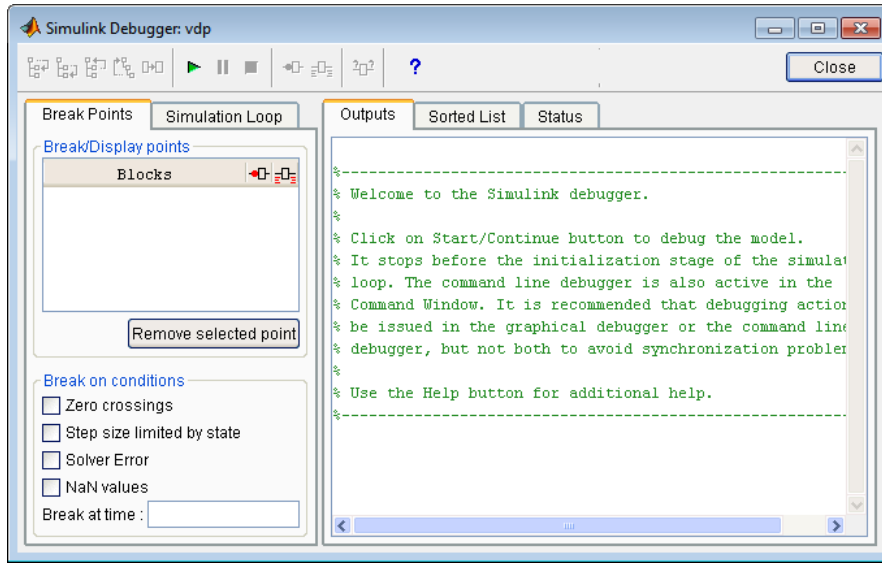
Debugger Graphical User Interface

In this section...

Displaying the Graphical Interface

Select **Debug Model** from a model window **Simulation** > **Debug** menu to display the debugger graphical interface.



Note The debugger graphical user interface does not display state or solver information. The command line interface does provide this information. See “Display System States” on page 33-31 and “Display Solver Information” on page 33-32.

Toolbar

The debugger toolbar appears at the top of the debugger window.

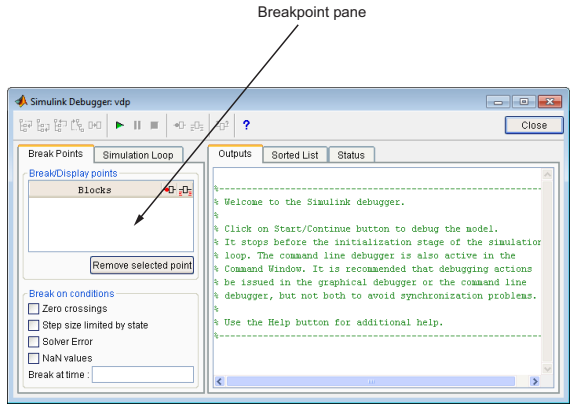
From left to right, the toolbar contains the following command buttons:

Button	Purpose
	Step into the next method (see “Stepping Commands” on page 33-20 for more information on this command, and the following stepping commands).
	Step over the next method.
	Step out of the current method.
	Step to the first method at the start of next time step.
	Step to the next block method.
	Start or continue the simulation.
	Pause the simulation.
	Stop the simulation.
	Break before the selected block.
	Display inputs and outputs of the selected block when executed (same as `trace gcb`).

Button	Purpose
	Display the current inputs and outputs of selected block (same as `probe gcb`).
	Display help for the debugger.
	Close the debugger.

Breakpoints Pane

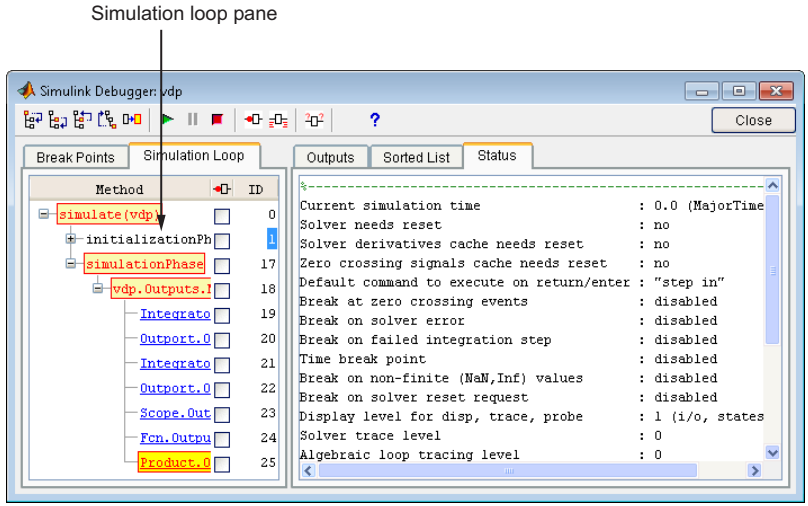
To display the **Breakpoints** pane, select the **Break Points** tab on the debugger window.



The **Breakpoints** pane allows you to specify block methods or conditions at which to stop a simulation. See “Set Breakpoints” on page 33-23 for more information.

Simulation Loop Pane

To display the **Simulation Loop** pane, select the **Simulation Loop** tab on the debugger window.



The **Simulation Loop** pane contains three columns:

- Method
- Breakpoints
- ID

Method Column

The **Method** column lists the methods that have been called thus far in the simulation as a method tree with expandable/collapsible nodes. Each node of the tree represents a method that calls other methods. Expanding a node shows the methods that the block method calls. Clicking a block method name highlights the corresponding block in the model diagram.

Whenever the simulation stops, the debugger highlights the name of the method where the simulation has stopped as well as the methods that invoked it. The highlighted method names indicate the current state of the method call stack.

Breakpoints Column

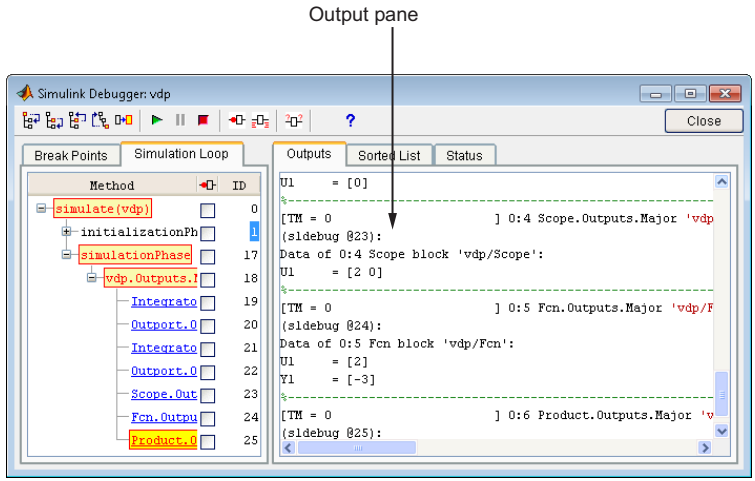
The breakpoints column consists of check boxes. Selecting a check box sets a breakpoint at the method whose name appears to the left of the check box. See “Setting Breakpoints from the Simulation Loop Pane” on page 33-25 for more information.

ID Column

The ID column lists the IDs of the methods listed in the **Methods** column. See “Method ID” on page 33-10 for more information.

Outputs Pane

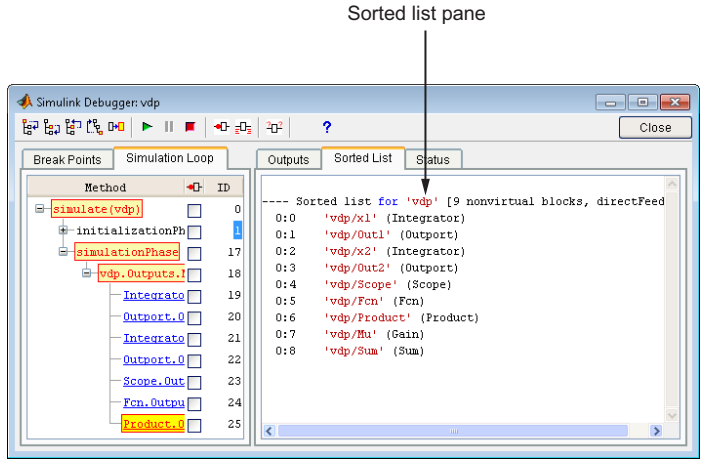
To display the **Outputs** pane, select the **Outputs** tab on the debugger window.



The Outputs pane displays the same debugger output that would appear in the MATLAB command window if the debugger were running in command-line mode. The output includes the debugger command prompt and the inputs, outputs, and states of the block at whose method the simulation is currently paused (see “Block Data Output” on page 33-19). The command prompt displays current simulation time and the name and index of the method in which the debugger is currently stopped (see “Block ID” on page 33-10).

Sorted List Pane

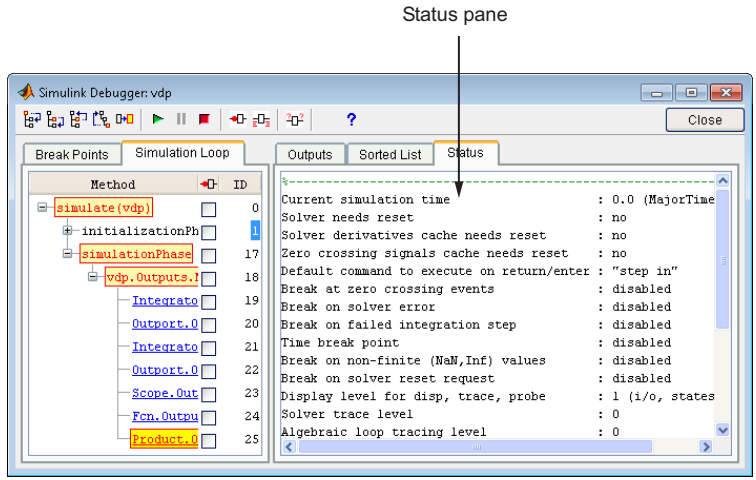
To display the **Sorted List** pane, select the **Sorted List** tab on the debugger window.



The **Sorted List** pane displays the sorted lists for the model being debugged. See “Display Model’s Sorted Lists” on page 33-34 for more information.

Status Pane

To display the **Status** pane, select the **Status** tab on the debugger window.



The **Status** pane displays the values of various debugger options and other status information.

Debugger Command-Line Interface

In this section...

Controlling the Debugger

In command-line mode, you control the debugger by entering commands at the debugger command line in the MATLAB Command Window. To enter commands at the debugger command line, you must start the debugger programmatically and not through the GUI. Use `sldebug` for this purpose. The debugger accepts abbreviations for debugger commands. For more information on debugger commands, see “Simulink Debugger”.

Note You can repeat some commands by entering an empty command (i.e., by pressing the **Enter** key) at the command line.

Method ID

Some of the Simulink software commands and messages use method IDs to refer to methods. A method ID is an integer assigned to a method the first time the method is invoked. The debugger assigns method indexes sequentially, starting with 0.

Block ID

Some of the debugger commands and messages use block IDs to refer to blocks. Block IDs are assigned to blocks while generating the model's sorted lists during the compilation phase of the simulation. A block ID has the form `sysIdx:blkIdx`, where `sysIdx` is an integer identifying the system that contains the block (either the root system or a nonvirtual subsystem) and `blkIdx` is the position of the block in the system's sorted list. For example, the block ID`0:1` refers to the first block in the model's root system. The `slist` command shows the block ID for each debugged block in the model.

Accessing the MATLAB Workspace

You can enter any MATLAB expression at the `sldebug` prompt. For example, suppose you are at a breakpoint and you are logging time and output of your model as `tout` and `yout`. The following command creates a plot.

```
(sldebug ...) plot(tout, yout)
```

You cannot display the value of a workspace variable whose name is partially or entirely the same as that of a debugger command by entering it at the debugger command prompt. You can, however, use the `eval` command to work around this problem. For example, use `eval('s')` to determine the value of `s` rather than `step` the simulation.

Debugger Online Help

You can get online help on using the debugger by clicking the **Help** button on the debugger toolbar. Clicking the **Help** button displays help for the debugger in the MATLAB product Help browser.

In command-line mode, you can get a brief description of the debugger commands by typing `help` at the debug prompt.

Start the Simulink Debugger

You can start the debugger from either a Simulink model window or from the MATLAB Command Window.

In this section...

Starting from a Model Window

1 In a model window, select **Simulation** > **Debug** > **Debug Model**.

The debugger graphical user interface opens. See “Debugger Graphical User Interface” on page 33-3.

2 Continue selecting toolbar buttons.

Note When running the debugger in graphical user interface (GUI) mode, you must explicitly start the simulation. For more information, see “Start a Simulation” on page 33-15.

Note When starting the debugger from the GUI, you cannot enter debugger commands in the MATLAB command window. For this, you must start the debugger from the command window using the `sim` or `sldebug` commands.

Starting from the Command Window

1 In the MATLAB Command Window, enter either

- the `sim` command. For example, enter

```
sim('vdp', 'StopTime', '10', 'debug', 'on')
```

- or the `sldebug` command. For example, enter

```
sldebug 'vdp'
```

In both cases, the example model `vdp` loads into memory, starts the simulation, and stops the simulation at the first block in the model execution list.

2 The debugger opens and a debugger command prompt appears within the MATLAB command window. Continue entering debugger commands at this debugger prompt.

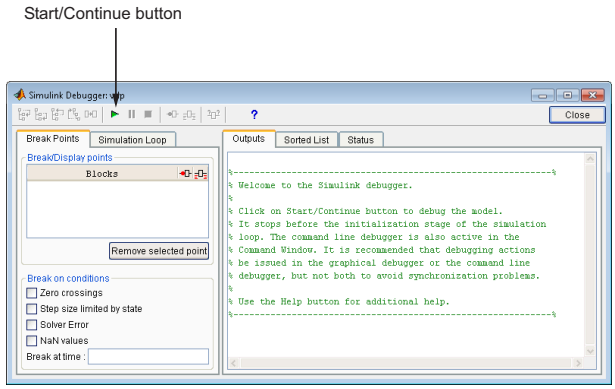
Start a Simulation

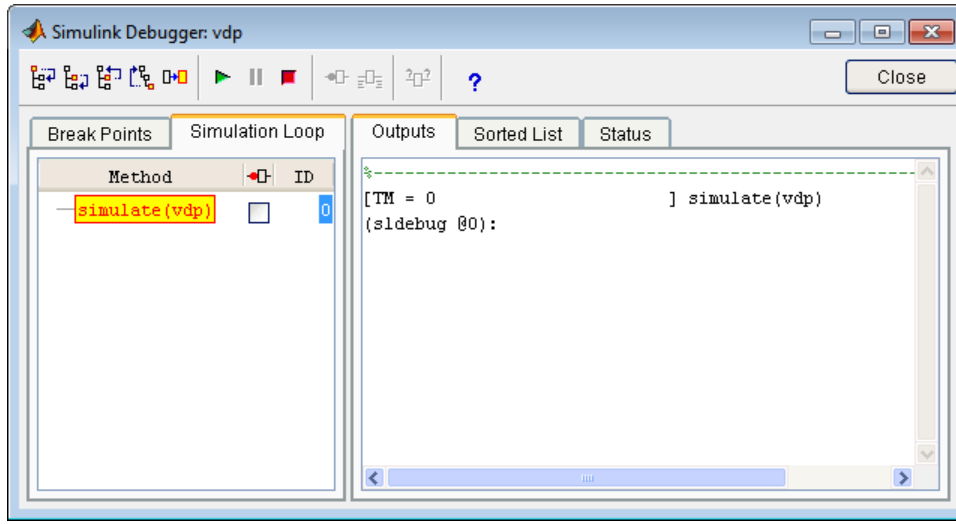
To start the simulation, click the **Start/Continue** button on the debugger toolbar.



The simulation starts and stops at the first simulation method that is to be executed. It displays the name of the method in its **Simulation Loop** pane. At this point, you can

- Set breakpoints.
- Run the simulation step by step.
- Continue the simulation to the next breakpoint or end.
- Examine data.
- Perform other debugging tasks.

The debugger displays the name of the method in the Simulation Loop pane, as shown in the following figure:



The following sections explain how to use the debugger controls to perform these debugging tasks.

Note When you start the debugger in GUI mode, the debugger command-line interface is also active in the MATLAB Command Window. However, to prevent synchronization errors between the graphical and command-line interfaces, you should avoid using the command-line interface.

Run a Simulation Step by Step

In this section...

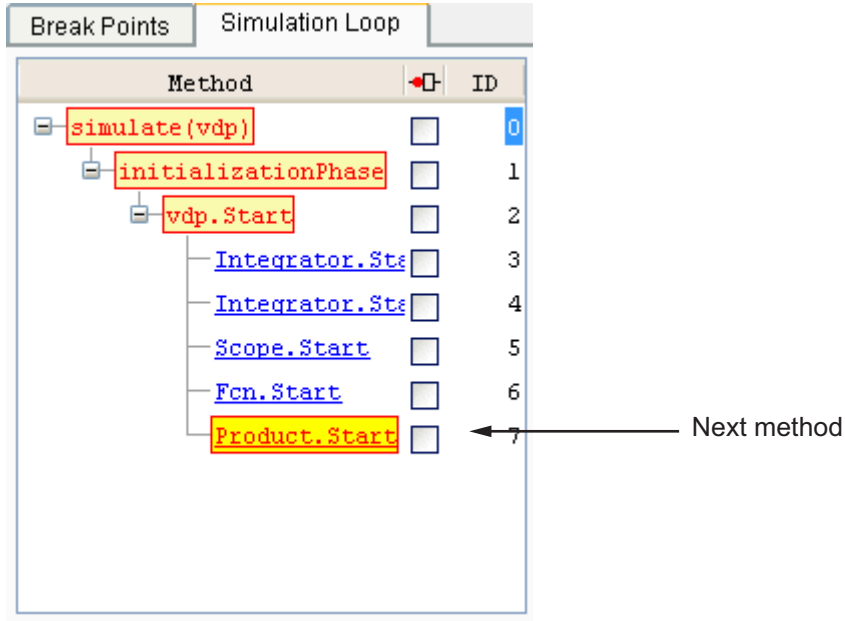
Introduction

The debugger provides various commands that let you advance a simulation from the method where it is currently suspended (the next method) by various increments (see “Stepping Commands” on page 33-20). For example, you can advance the simulation

- Into or over the next method
- Out of the current method
- To the top of the simulation loop.

After each advance, the debugger displays information that enables you to determine the point to which the simulation has advanced and the results of advancing the simulation to that point.

For example, in GUI mode, after each step command, the debugger highlights the current method call stack in the **Simulation Loop** pane. The call stack comprises the next method and the methods that invoked the next method either directly or indirectly. The debugger highlights the call stack by highlighting the names of the methods that make up the call stack in the **Simulation Loop** pane.



In command-line mode, you can use the `where` command to display the method call stack.

Block Data Output

After executing a block method, the debugger prints any or all of the following block data in the debugger **Output** panel (in GUI mode) or, if in command line mode, the MATLAB Command Window:

- `Un = v`

  where `v` is the current value of the block's `n`th input.

- `Yn = v`

  where `v` is the current value of the block's `n`th output.

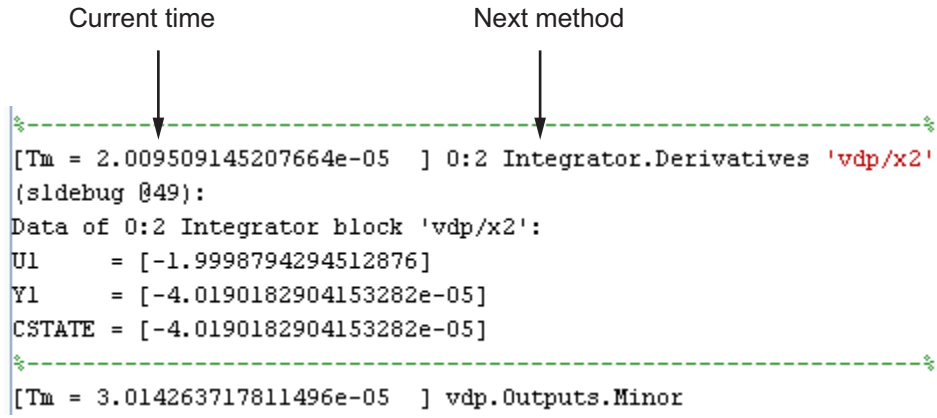
- `CSTATE = v`

  where `v` is the value of the block's continuous state vector.

- `DSTATE = v`

  where `v` is the value of the block's discrete state vector.

The debugger also displays the current time, the ID and name of the next method to be executed, and the name of the block to which the method applies in the MATLAB Command Window. The following example illustrates typical debugger outputs after a step command.



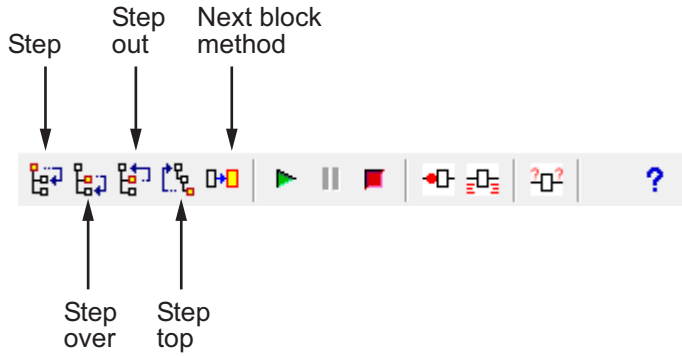
Stepping Commands

Command-line mode provides the following commands for advancing a simulation incrementally:

This command...	Advances the simulation...
`step [in into]`	Into the next method, stopping at the first method in the next method or, if the next method does not contain any methods, at the end of the next method
`step over`	To the method that follows the next method, executing all methods invoked directly or indirectly by the next method
`step out`	To the end of the current method, executing any remaining methods invoked by the current method
`step top`	To the first method of the next time step (i.e., the top of the simulation loop)

This command...	Advances the simulation...
`step blockmth`	To the next block method to be executed, executing all intervening model- and system-level methods
`next`	Same as `step over`

Buttons in the debugger toolbar allow you to access these commands in GUI mode.



Clicking a button has the same effect as entering the corresponding command at the debugger command line.

Continuing a Simulation

In GUI mode, the **Stop** button turns red when the debugger suspends the simulation for any reason. To continue the simulation, click the **Start/Continue** button. In command-line mode, enter `continue` to continue the simulation. By default, the debugger runs the simulation to the next breakpoint (see "Set Breakpoints" on page 33-23) or to the end of the simulation, whichever comes first.

Running a Simulation Nonstop

The `run` command lets you run a simulation to the end of the simulation, skipping any intervening breakpoints. At the end of the simulation, the debugger returns you to the command line. To continue debugging a model, you must restart the debugger.

Note The GUI mode does not provide a graphical version of the `run` command. To run the simulation to the end, you must first clear all breakpoints and then click the **Start/Continue** button.

Set Breakpoints

In this section...

About Breakpoints

The debugger allows you to define stopping points called breakpoints in a simulation. You can then run a simulation from breakpoint to breakpoint, using the debugger `continue` command. The debugger lets you define two types of breakpoints: unconditional and conditional. An unconditional breakpoint occurs whenever a simulation reaches a method that you specified previously. A conditional breakpoint occurs when a condition that you specified in advance arises in the simulation.

Breakpoints are useful when you know that a problem occurs at a certain point in your program or when a certain condition occurs. By defining an appropriate breakpoint and running the simulation via the `continue` command, you can skip immediately to the point in the simulation where the problem occurs.

Note When you stop a simulation at a breakpoint of a MATLAB S-function in the debugger, to exit MATLAB, you must first quit the debugger.

Setting Unconditional Breakpoints

You can set unconditional breakpoints from the:

- Debugger toolbar
- **Simulation Loop** pane
- MATLAB product Command Window (command-line mode only)

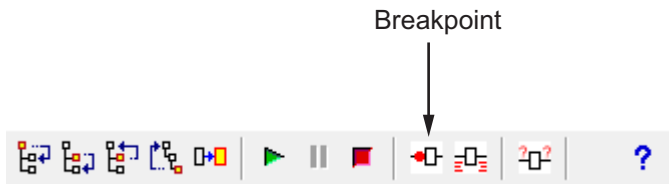
Setting Breakpoints from the Debugger Toolbar

To enable the **Breakpoint** button,

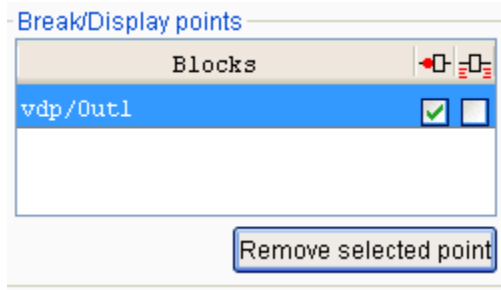
1 Simulate the model.

2 Click the **Step over current method** button until `simulationPhase` is highlighted.

3 Click the **Step into current method** button.



The debugger displays the name of the selected block in the **Break/Display points** panel of the **Breakpoints** pane.



Note Clicking the **Breakpoint** button on the toolbar sets breakpoints on the invocations of a block's methods in major time steps.

You can temporarily disable the breakpoints on a block by deselecting the check box in the breakpoints column of the panel. To clear the breakpoints on a block and remove its entry from the panel,

1 Select the entry.

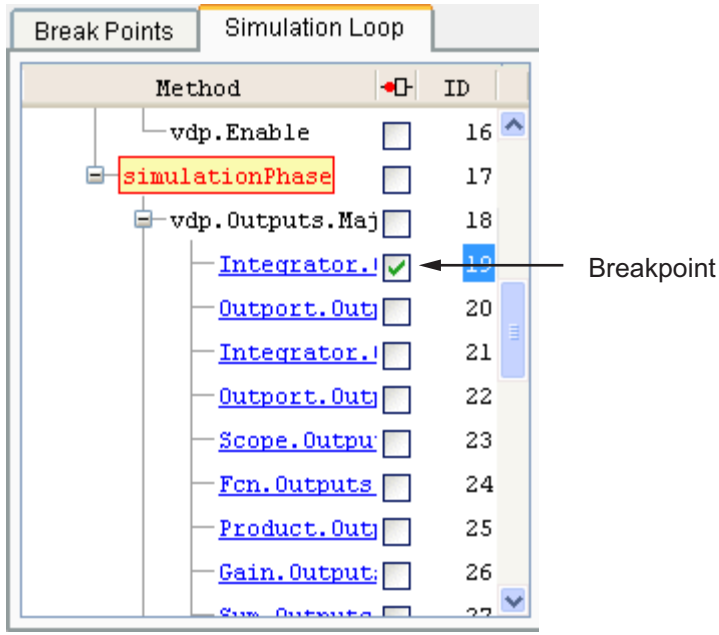
2 Click the **Remove selected point** button on the panel.

Note You cannot set a breakpoint on a virtual block. A virtual block is purely graphical: it indicates a grouping or relationship among a model's computational blocks. The debugger warns you if you try to set a breakpoint on a virtual block. You can get a listing

of a model's nonvirtual blocks, using the `slist` command (see “Displaying a Model's Nonvirtual Blocks” on page 33-35).

Setting Breakpoints from the Simulation Loop Pane

To set a breakpoint at a particular invocation of a method displayed in the Simulation Loop pane, select the check box next to the method's name in the breakpoint column of the pane.



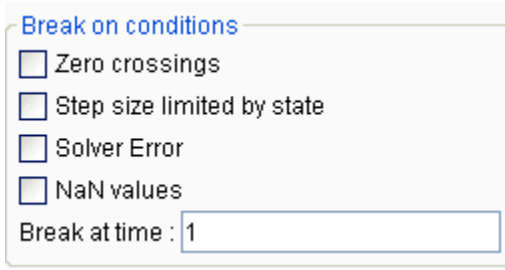
To clear the breakpoint, deselect the check box.

Setting Breakpoints from the Command Window

In command-line mode, use the `break` and `bafter` commands to set breakpoints before or after a specified method, respectively. Use the `clear` command to clear breakpoints.

Setting Conditional Breakpoints

You can use either the **Break on conditions** controls group on the debugger **Breakpoints** pane



or the following commands (in command-line mode) to set conditional breakpoints.

This command...	Causes the Simulation to Stop...
`tbreak [t]`	At a simulation time step
`ebreak`	At a recoverable error in the model
`nanbreak`	At the occurrence of an underflow or overflow (`NaN`) or infinite (`Inf`) value
`xbreak`	When the simulation reaches the state that determines the simulation step size
`zcbreak`	When a zero crossing occurs between simulation time steps

Setting Breakpoints at Time Steps

To set a breakpoint at a time step, enter a time in the debugger **Break at time** field (GUI mode) or enter the time using the `tbreak` command. This causes the debugger to stop the simulation at the `Outputs.Major` method of the model at the first time step that follows the specified time. For example, starting `vdp` in debug mode and entering the commands

```
tbreak 2
continue
```

causes the debugger to halt the simulation at the `vdp.Outputs.Major` method of time step `2.078` as indicated by the output of the `continue` command.

```
%--------------------------------------------------------------------%
[Tm = 2.034340153847549      ] vdp.Outputs.Minor
(sldebug @37):
```

Breaking on Nonfinite Values

Selecting the debugger **NaN values** option or entering the `nanbreak` command causes the simulation to stop when a computed value is infinite or outside the range of values that is supported by the machine running the simulation. This option is useful for pinpointing computational errors in a model.

Breaking on Step-Size Limiting Steps

Selecting the **Step size limited by state** option or entering the `xbreak` command causes the debugger to stop the simulation when the model uses a variable-step solver and the solver encounters a state that limits the size of the steps that it can take. This command is useful in debugging models that appear to require an excessive number of simulation time steps to solve.

Breaking at Zero Crossings

Selecting the **Zero crossings** option or entering the `zcbreak` command causes the simulation to halt when a nonsampled zero crossing is detected in a model that includes blocks where zero crossings can arise. After halting, the ID, type, and name of the block in which the zero crossing was detected is displayed. The block ID (`s:b:p`) consists of a system index `s`, block index `b`, and port index `p` separated by colons (see "Block ID" on page 33-10).

For example, setting a zero-crossing break at the start of execution of the `zeroxing` example model,

```
>> sldebug zeroxing
%--------------------------------------------------------------------
%
[TM = 0                       ] zeroxing.Simulate
(sldebug @0): >> zcbreak
Break at zero crossing events              : enabled
```

and continuing the simulation

```
(sldebug @0): >> continue
```

results in a zero-crossing break at

```
Interrupting model execution before running mdlOutputs at the left post of
(major time step just before) zero crossing event detected at the following location:
  6[-0]  0:5:2  Saturate  'zeroxing/Saturation'
%--------------------------------------------------------------------%
```

```
[TzL= 0.3435011087932808     ] zeroxing.Outputs.Major
(sldebug @16): >>
```

If a model does not include blocks capable of producing nonsampled zero crossings, the command prints a message advising you of this fact.

Breaking on Solver Errors

Selecting the debugger **Solver Errors** option or entering the `ebreak` command causes the simulation to stop if the solver detects a recoverable error in the model. If you do not set or disable this breakpoint, the solver recovers from the error and proceeds with the simulation without notifying you.

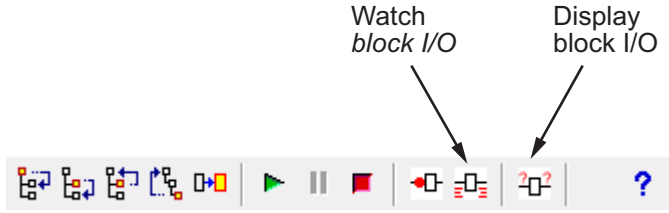
Display Information About the Simulation

In this section...

Display Block I/O

The debugger allows you to display block I/O by clicking the appropriate buttons on the debugger toolbar



or by entering the appropriate debugger command.

This command...	Displays a Blocks I/O...
`probe`	Immediately
`disp`	At every breakpoint any time execution stops
`trace`	Whenever the block executes

Note The two debugger toolbar buttons, Watch Block I/O () and Display Block I/O () correspond, respectively, to `trace gcb` and `probe gcb`. The `probe` and `disp` commands do not have a one-to-one correspondence with the debugger toolbar buttons.

Displaying I/O of a Selected Block

To display the I/O of a block, select the block and click  in GUI mode or enter the `probe` command in command-line mode. In the following table, the `probe gcb` command has a corresponding toolbar button. The other commands do not.

Command	Description
`probe`	Enter or exit `probe` mode. Typing any command causes the debugger to exit `probe` mode.
`probe gcb`	Display I/O of selected block. Same as  .
`probe s:b`	Print the I/O of the block specified by system number `s` and block number `b`.

The debugger prints the current inputs, outputs, and states of the selected block in the debugger **Outputs** pane (GUI mode) or the Command Window of the MATLAB product.

The `probe` command is useful when you need to examine the I/O of a block whose I/O is not otherwise displayed. For example, suppose you are using the `step` command to run a model method by method. Each time you step the simulation, the debugger displays the inputs and outputs of the current block. The `probe` command lets you examine the I/O of other blocks as well.

Displaying Block I/O Automatically at Breakpoints

The `disp` command causes the debugger to display a specified block's inputs and outputs whenever it halts the simulation. You can specify a block by entering its block index and entering `gcb` as the `disp` command argument. You can remove any block from the debugger list of display points, using the `undisp` command. For example, to remove `block 0:0`, enter `undisp 0:0`.

Note Automatic display of block I/O at breakpoints is not available in the debugger GUI mode.

The `disp` command is useful when you need to monitor the I/O of a specific block or set of blocks as you step through a simulation. Using the `disp` command, you can specify the blocks you want to monitor and the debugger will then redisplay the I/O of those blocks on every step. Note that the debugger always displays the I/O of the current block when

you step through a model block by block, using the `step` command. You do not need to use the `disp` command if you are interested in watching only the I/O of the current block.

Watching Block I/O

To watch a block, select the block and click  in the debugger toolbar or enter the `trace` command. In GUI mode, if a breakpoint exists on the block, you can set a watch on it as well by selecting the check box for the block in the watch column  of the **Break/Display points** pane. In command-line mode, you can also specify the block by specifying its block index in the `trace` command. You can remove a block from the debugger list of trace points using the `untrace` command.

The debugger displays a watched block's I/O whenever the block executes. Watching a block allows you obtain a complete record of the block's I/O without having to stop the simulation.

Display Algebraic Loop Information

The `atrace` command causes the debugger to display information about a model's algebraic loops (see “Algebraic Loops” on page 3-37) each time they are solved. The command takes a single argument that specifies the amount of information to display.

This command...	Displays for each algebraic loop...
`atrace 0`	No information
`atrace 1`	The loop variable solution, the number of iterations required to solve the loop, and the estimated solution error
`atrace 2`	Same as level 1
`atrace 3`	Level 2 plus the Jacobian matrix used to solve the loop
`atrace 4`	Level 3 plus intermediate solutions of the loop variable

Display System States

The `states` debug command lists the current values of the system states in the MATLAB Command Window. For example, the following sequence of commands shows the states of the bouncing ball example (`sldemo_bounce`) after its first, second, and third time steps. However, before entering the debugger, open the Configuration

Parameters dialog box and clear the **Block reduction** and **Signal storage reuse** check boxes.

```
 sldebug sldemo_bounce
%------------------------------------------------------------------%
[TM = 0                       ] simulate(sldemo_bounce)
(sldebug @0): >> step top
%------------------------------------------------------------------%
[TM = 0                       ] sldemo_bounce.Outputs.Major
(sldebug @16): >> next
%------------------------------------------------------------------%
[TM = 0                       ] sldemo_bounce.Update
(sldebug @23): >> states

Continuous States:
Idx  Value                     (system:block:element  Name   'BlockName')
  0  10                        (0:4:0  CSTATE  'sldemo_bounce/Second-Order  Integrator')
  1. 15                        (0:4:1)

(sldebug @23): >> next
%------------------------------------------------------------------%
[Tm = 0                       ] solverPhase
(sldebug @26): >> states

Continuous States:
Idx  Value                     (system:block:element  Name   'BlockName')
  0  10                        (0:4:0  CSTATE  'sldemo_bounce/Second-Order  Integrator')
  1. 15                        (0:4:1)

(sldebug @26): >> next
%------------------------------------------------------------------%
[TM = 0.01                    ] sldemo_bounce.Outputs.Major
(sldebug @16): >> states

Continuous States:
Idx  Value                     (system:block:element  Name   'BlockName')
  0  10.1495095                (0:4:0  CSTATE  'sldemo_bounce/Second-Order  Integrator')
  1. 14.9019                   (0:4:1)
```

Display Solver Information

The `strace` command allows you to pinpoint problems in solving a models differential equations that can slow down simulation performance. Executing this command causes the debugger to display solver-related information at the command line of the MATLAB product when you run or step through a simulation. The information includes the sizes of the steps taken by the solver, the estimated integration error resulting from the step size, whether a step size succeeded (i.e., met the accuracy requirements that the model specifies), the times at which solver resets occur, etc. If you are concerned about the time required to simulate your model, this information can help you to decide whether the

solver you have chosen is the culprit and hence whether choosing another solver might shorten the time required to solve the model.

Display Information About the Model

In this section...

Display Model’s Sorted Lists

In GUI mode, the debugger **Sorted List** pane displays lists of blocks for a models root system and each nonvirtual subsystem. Each list lists the blocks that the subsystems contains sorted according to their computational dependencies, alphabetical order, and other block sorting rules. In command-line mode, you can use the `slist` command to display a model's sorted lists.

```
---- Sorted list for 'vdp' [9 nonvirtual blocks, directFeed=0]
  0:0    'vdp/x1' (Integrator)
  0:1    'vdp/Out1' (Outport)
  0:2    'vdp/x2' (Integrator)
  0:3    'vdp/Out2' (Outport)
  0:4    'vdp/Scope' (Scope)
  0:5    'vdp/Fcn' (Fcn)
  0:6    'vdp/Product' (Product)
  0:7    'vdp/Mu' (Gain)
  0:8    'vdp/Sum' (Sum)
```

These displays include the block index for each command. You can use them to determine the block IDs of the models blocks. Some debugger commands accept block IDs as arguments.

Identifying Blocks in Algebraic Loops

If a block belongs to an algebraic list, the `slist` command displays an algebraic loop identifier in the entry for the block in the sorted list. The identifier has the form

```
algId=s#n
```

where `s` is the index of the subsystem containing the algebraic loop and `n` is the index of the algebraic loop in the subsystem. For example, the following entry for an Integrator block indicates that it participates in the first algebraic loop at the root level of the model.

```
0:1 'test/ss/I1' (Integrator, tid=0) [algId=0#1, discontinuity]
```

When the debugger is running, you can use the `ashow` command at the debugger command-line interface to highlight the blocks and lines that make up an algebraic loop. See "Displaying Algebraic Loops" on page 33-36 for more information.

Display a Block

To determine the block in a models diagram that corresponds to a particular index, enter `bshow s:b` at the command prompt, where `s:b` is the block index. The `bshow` command opens the system containing the block (if necessary) and selects the block in the systems window.

Displaying a Model's Nonvirtual Systems

The `systems` command displays a list of the nonvirtual systems in the model that you are debugging. For example, the `sldemo_clutch` model contains the following systems:

```
open_system('sldemo_clutch')
set_param(gcs, 'OptimizeBlockIOStorage','off')
sldebug sldemo_clutch
(sldebug @0): %--------------------------------------------------------------%
[TM = 0                      ] simulate(sldemo_clutch)
(sldebug @0): >> systems
 0   'sldemo_clutch'
 1   'sldemo_clutch/Locked'
 2   'sldemo_clutch/Unlocked'
```

Note The `systems` command does not list subsystems that are purely graphical. That is, subsystems that the model diagram represents as Subsystem blocks but that are solved as part of a parent system. are not listed. In Simulink models, the root system and triggered or enabled subsystems are true systems. All other subsystems are virtual (that is, graphical) and do not appear in the listing from the `systems` command.

Displaying a Model's Nonvirtual Blocks

The `slist` command displays a list of the nonvirtual blocks in a model. The listing groups the blocks by system. For example, the following sequence of commands produces a list of the nonvirtual blocks in the Van der Pol (`vdp`) example model.

```
sldebug vdp
%--------------------------------------------------------------%
```

```
[TM = 0                        ] simulate(vdp)
sldebug @0): >> slist

---- Sorted list for 'vdp' [9 nonvirtual blocks, directFeed=0]
  0:0    'vdp/x1' (Integrator)
  0:1    'vdp/Out1' (Outport)
  0:2    'vdp/x2' (Integrator)
  0:3    'vdp/Out2' (Outport)
  0:4    'vdp/Scope' (Scope)
  0:5    'vdp/Fcn' (Fcn)
  0:6    'vdp/Product' (Product)
  0:7    'vdp/Mu' (Gain)
  0:8    'vdp/Sum' (Sum)
```

Note The `slist` command does not list blocks that are purely graphical. That is, blocks that indicate relationships between or groupings among computational blocks.

Displaying Blocks with Potential Zero Crossings

The `zclist` command displays a list of blocks in which nonsampled zero crossings can occur during a simulation. For example, `zclist` displays the following list for the clutch sample model:

```
(sldebug @0): >> zclist
  0  0:4:0    F  HitCross  'sldemo_clutch/Friction Mode Logic/Lockup
Detection/Velocities Match'
  1  0:4:1    F
  2  0:10:0    F  Abs  'sldemo_clutch/Friction Mode Logic/Lockup
Detection/Required Friction for Lockup/Abs'
  3  0:12:0    F  RelationalOperator  'sldemo_clutch/Friction Mode
Logic/Lockup Detection/Required Friction for Lockup/Relational Operator'
  4  0:19:0    F  Abs  'sldemo_clutch/Friction Mode Logic/Break Apart
Detection/Abs'
  5  0:20:0    F  RelationalOperator  'sldemo_clutch/Friction Mode
Logic/Break Apart Detection/Relational Operator'
  6  2:3:0    F  Signum  'sldemo_clutch/Unlocked/slip direction'
```

Displaying Algebraic Loops

The `ashow` command highlights a specified algebraic loop or the algebraic loop that contains a specified block. To highlight a specified algebraic loop, enter `ashow s#n`, where `s` is the index of the system (see “Identifying Blocks in Algebraic Loops” on page 33-34) that contains the loop and `n` is the index of the loop in the system. To display the loop that contains the currently selected block, enter `ashow gcb`. To show a loop that

contains a specified block, enter `ashow s:b`, where `s:b` is the block's index. To clear algebraic-loop highlighting from the model diagram, enter `ashow clear`.

Displaying Debugger Status

In GUI mode, the debugger displays the settings of various debug options, such as conditional breakpoints, in its **Status** panel. In command-line mode, the `status` command displays debugger settings. For example, the following sequence of commands displays the initial debug settings for the `vdp` model:

```
sim('vdp', 'StopTime', '10', 'debug', 'on')
%------------------------------------------------------------------%
[TM = 0                      ] simulate(vdp)
(sldebug @0): >> status
%------------------------------------------------------------------%
Current simulation time                    : 0.0 (MajorTimeStep)
Solver needs reset                         : no
Solver derivatives cache needs reset       : no
Zero crossing signals cache needs reset    : no
Default command to execute on return/enter : ""
Break at zero crossing events              : disabled
Break on solver error                      : disabled
Break on failed integration step           : disabled

Accelerating Models

What Is Acceleration?

Acceleration is a mode of operation in the Simulink product that you can use to speed up the execution of your model. The Simulink software includes two modes of acceleration: accelerator mode and the rapid accelerator mode. Both modes replace the normal interpreted code with compiled target code. Using compiled code speeds up simulation of many models, especially those where run time is long compared to the time associated with compilation and checking to see if the target is up to date.

The accelerator mode works with any model, but performance decreases if a model contains blocks that do not support acceleration. The accelerator mode supports the Simulink debugger and profiler. These tools help with debugging and determining relative performance of various parts of your model. For more information, see "Run Accelerator Mode with the Simulink Debugger" on page 34-33 and "How Profiler Captures Performance Data" on page 30-5.

The rapid accelerator mode works with only those models containing blocks that support code generation of a standalone executable. For this reason, rapid accelerator mode does not support the debugger or profiler. However, this mode generally results in faster execution than the accelerator mode. When used with dual-core processors, the rapid accelerator mode runs Simulink and the MATLAB technical computing environment from one core while the rapid accelerator target runs as a separate process on a second core.

For more information about the performance characteristics of the Accelerator and rapid accelerator modes, and how to measure the difference in performance, see "Comparing Performance" on page 34-35.

To optimize your model and achieve faster simulation automatically using Performance Advisor, see "Automated Performance Optimization".

To employ modeling techniques that help achieve faster simulation, see "Manual Performance Optimization".

How Acceleration Modes Work

In this section...

Overview

The Accelerator and rapid accelerator modes use portions of the Simulink Coder product to create an executable.

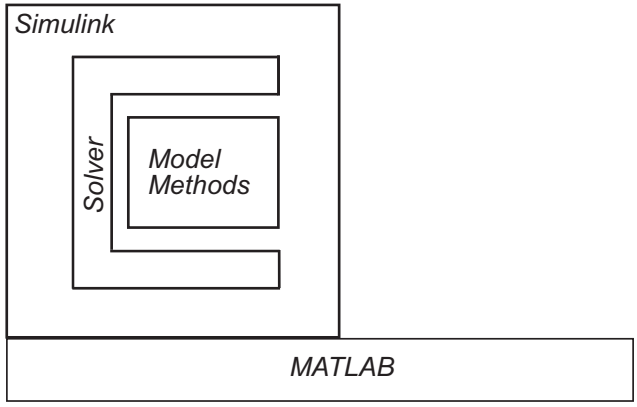
The Accelerator and rapid accelerator modes replace the interpreted code normally used in Simulink simulations, shortening model run time.

Although the acceleration modes use some Simulink Coder code generation technology, you do not need the Simulink Coder software installed to accelerate your model.

Note The code generated by the accelerator and rapid accelerator modes is suitable only for speeding the simulation of your model. Use Simulink Coder to generate code for other purposes.

Normal Mode

In normal mode, the MATLAB technical computing environment is the foundation on which the Simulink software is built. Simulink controls the solver and model methods used during simulation. Model methods on page 3-16 include such things as computation of model outputs. Normal mode runs in one process.



One Process

Accelerator Mode

By default, the accelerator mode uses Just-in-Time (JIT) acceleration to generate an execution engine in memory instead of generating C code or MEX files. You can also have your model fall back to the classic accelerator mode, in which Simulink generates and links code into a C-MEX S-function.

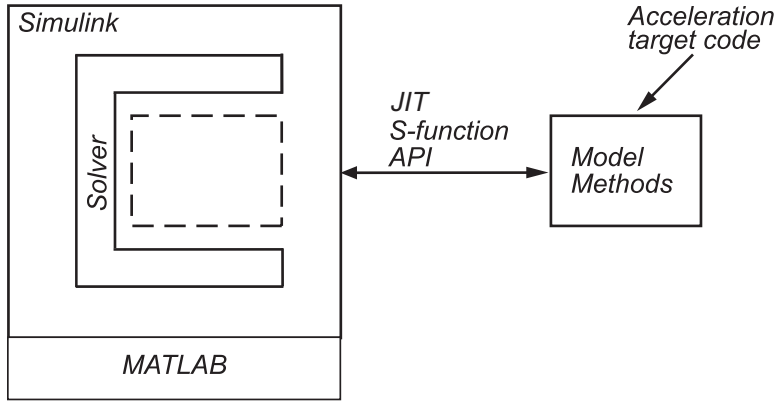
In the accelerator mode, the model methods are separate from the Simulink software and are part of the *acceleration target code*, which is used in later simulations.

Simulink checks that the acceleration target code is up to date before reusing it. For more information, see “Code Regeneration in Accelerated Models” on page 34-9 .

There are two modes of operation in accelerator mode.

Just-In-Time Accelerator Mode

In this default mode, Simulink generates an execution engine in memory for the top-level model only and not for referenced models. As a result, a C compiler is not required during simulation.



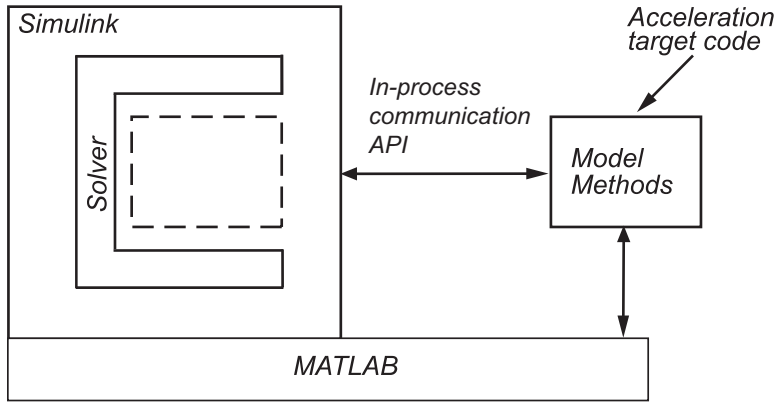
Because the acceleration target code is in memory, it is available for reuse as long as the model is open. Simulink also serializes the acceleration target code so that the model does not need rebuilding when it is opened.

Classic Accelerator Mode

If you want to simulate your model using the classic, C-code generating, accelerator mode, run the following command:

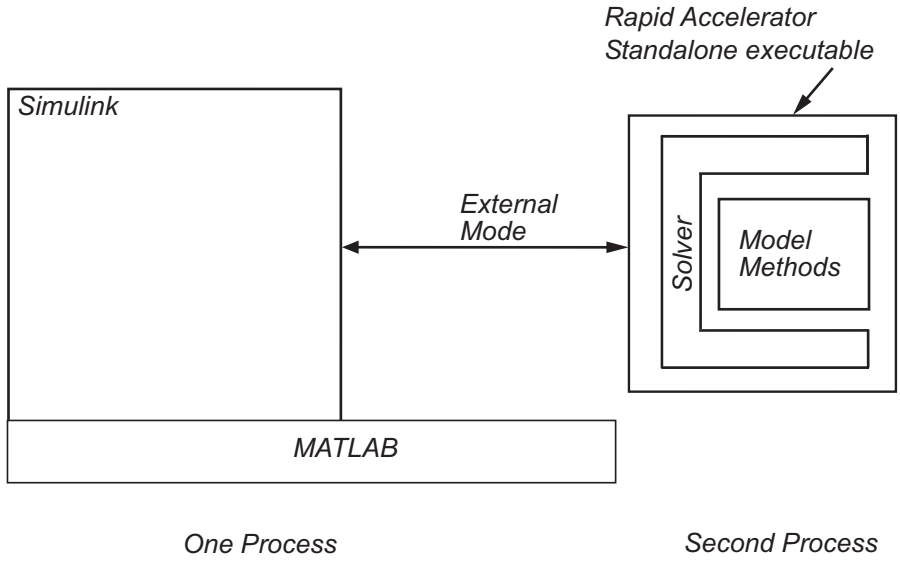
```
set_param(0, 'GlobalUseClassicAccelMode', 'on');
```

In this mode, Simulink generates and links code into a shared library, which communicates with the Simulink software. The target code executes in the same process as MATLAB and Simulink.



Rapid Accelerator Mode

The rapid accelerator mode creates a *Rapid Accelerator standalone executable* from your model. This executable includes the solver and model methods, but it resides outside of MATLAB and Simulink. It uses external mode (see “External Mode Communication” (Simulink Coder)) to communicate with Simulink.



MATLAB and Simulink run in one process, and if a second processing core is available, the standalone executable runs there.

Code Regeneration in Accelerated Models

In this section...

Changing the structure of your model causes the Rapid Accelerator mode to regenerate the standalone executable, and for the Accelerator mode to regenerate the target code and update (overwrite) the existing MEX-file. Changing the value of a tunable parameter does not trigger a rebuild.

Determine If the Simulation Will Rebuild

The Accelerator and Rapid Accelerator modes use a checksum to determine if the model has changed, indicating that the code should be regenerated. The checksum is an array of four integers computed using an MD5 checksum algorithm based on attributes of the model and the blocks it contains.

1. Use the `Simulink.BlockDiagram.getChecksum` command to obtain the checksum for your model. For example:

   ```
   cs1 = Simulink.BlockDiagram.getChecksum('myModel');
   ```

2. Obtain a second checksum after you have altered your model. The code regenerates if the new checksum does not match the previous checksum.
3. Use the information in the checksum to determine why the simulation target rebuilt.

For a detailed explanation of this procedure, see the example model `slAccelDemoWhyRebuild`.

Parameter Tuning in Rapid Accelerator Mode

In model rebuilds, Rapid Accelerator Mode handles block diagram and runtime parameters differently from other parameters.

Tuning Block Diagram Parameters

You can change some block diagram parameters during simulation without causing a rebuild. Tune these parameters using the `set_param` command or using the **Model Configuration Parameters** dialog box. These block diagram parameters include:

Solver Parameters		
AbsTol	MaxNumMinSteps	RelTol
ConsecutiveZCsStepRelTol	MaxOrder	StartTime
ExtrapolationOrder	MaxStep	StopTime
InitialStep	MinStep	ZCDetectionTol
MaxConsecutiveMinStep	OutputTimes	
MaxConsecutiveZCs	Refine	
Loading and Logging Parameters		
ConsistencyChecking	MinStepSizeMsg	SaveTime
Decimation	OutputOption	StateSaveName
FinalStateName	OutputSaveName	TimeSaveName
LimitDataPoints	SaveFinalState	
LoadExternalInput	SaveFormat	
MaxConsecutiveZCsMsg	SaveOutput	
MaxDataPoints	SaveState	

Tuning Runtime Parameters

To tune runtime parameters for maximum acceleration in Rapid Accelerator mode, follow this procedure which yields better results than using `set_param` for the same purpose:

1. Collect the runtime parameters in a runtime parameter structure while building a rapid accelerator target executable using the `Simulink.BlockDiagram.buildRapidAcceleratorTarget` function.
2. To change the parameters, use the `Simulink.BlockDiagram.modifyTunableParameters` function.
3. To specify the modified parameters to the `sim` command, use the `RapidAcceleratorParameterSets` and `RapidAcceleratorUpToDateCheck` parameters.

All other parameter changes can necessitate a rebuild of the model.

Parameter Changes	Passed Directly to `sim` command	Passed Graphically via Block Diagram or via `set_param` command
Runtime	Does not require rebuild	Can require rebuild
Block diagram (logging parameters)	Does not require rebuild	Does not require rebuild

For information about parameter tunability limitations with accelerated simulation modes, see “Tunability Considerations and Limitations for Other Modeling Goals” on page 36-45.

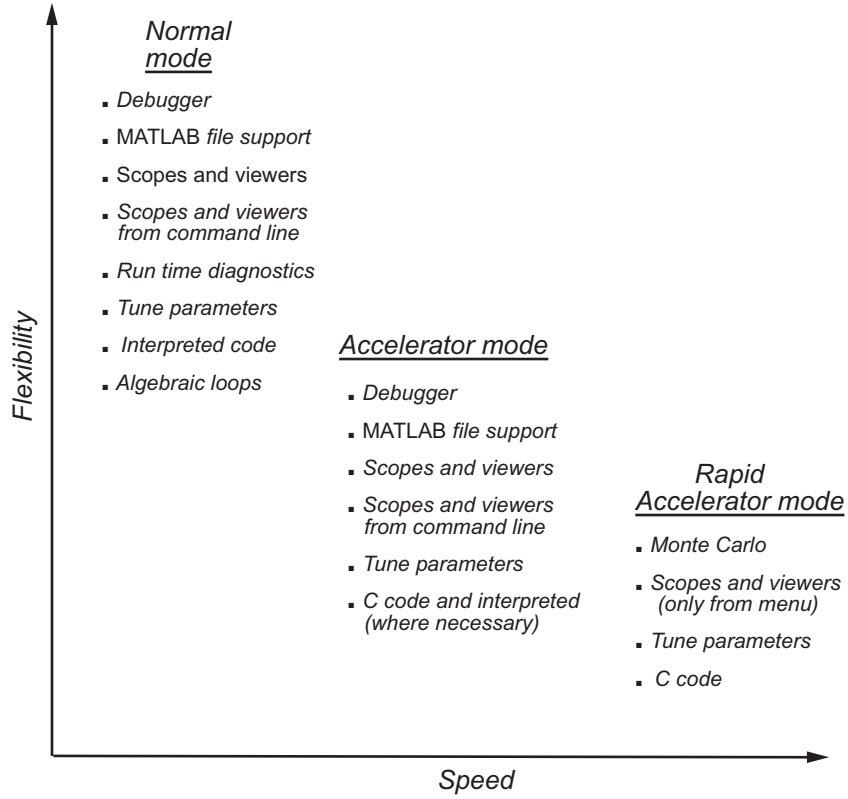
Choosing a Simulation Mode

In this section...

Simulation Mode Tradeoffs

In general, you must trade off simulation speed against flexibility when choosing either Accelerator mode or Rapid Accelerator mode instead of Normal mode.



Normal mode offers the greatest flexibility for making model adjustments and displaying results, but it runs the slowest.

Accelerator mode lies between Normal and Rapid Accelerator modes in performance and in interaction with your model. If your model has 3-D signals, use Normal or Accelerator mode. Accelerator mode does not support runtime diagnostics.

Rapid Accelerator mode runs the fastest, but this mode does not support the debugger or profiler, and works only with those models for which C code is available for all of the blocks in the model. In addition, Rapid Accelerator mode does not support 3-D parameters and sinks.

Note An exception to this rule occurs when you run multiple simulations, each of which executes in less than one second in Normal mode. For example:

```
for i=1:100
sim(model); % executes in less than one second in Normal mode
end
```

For this set of conditions, you will typically obtain the best performance by simulating the model in Normal mode.

Tip To gain additional flexibility, consider using model referencing to componentize your model. If the top-level model uses Normal mode, then you can simulate a referenced model in a different simulation mode than you use for other portions of a model. During the model development process, you can choose different simulation modes for different portions of a model. For details, see “Simulate Model Reference Hierarchies” on page 8-35.

Comparing Modes

The following table compares the characteristics of Normal mode, Accelerator mode, and Rapid Accelerator mode.

If you want to...	Then use this mode...		
	Normal	Accelerator	Rapid Accelerator
Performance			

If you want to...	Then use this mode...		
	Normal	Accelerator	Rapid Accelerator
Run your model in a separate address space			✓

Design Your Model for Effective Acceleration

In this section...

Select Blocks for Accelerator Mode

The Accelerator simulation mode runs the following blocks as if you were running Normal mode because these blocks do not generate code for the accelerator build. Consequently, if your model contains a high percentage of these blocks, the Accelerator mode may not increase performance significantly. All of these Simulink blocks use interpreted code.

- Display
- From File
- From Workspace
- Inport (root level only)
- Interpreted MATLAB Function
- Outport (root level only)
- Scope
- To File
- To Workspace
- XY Graph

Note In some instances, Normal mode output might not precisely match the output from Accelerator mode because of slight differences in the numerical precision between the interpreted and compiled versions of a model.

The following blocks can cause poor simulation runtime performance when run in the default JIT Accelerator mode.

- Transport Delay
- Variable Transport Delay

Select Blocks for Rapid Accelerator Mode

Blocks that do not support code generation (such as SimEvents) or blocks that generate code only for a specific target cannot be simulated in Rapid Accelerator mode.

Additionally, Rapid Accelerator mode does not work if your model contains any of the following blocks:

- Interpreted MATLAB Function
- Device driver S-functions, such as blocks from the Simulink Real-Time product, or those targeting Freescale™ MPC555

Note In some instances, Normal mode output might not precisely match the output from Rapid Accelerator mode because of slight differences in the numerical precision between the interpreted and compiled versions of a model.

Control S-Function Execution

Note In the default JIT Accelerator mode, inlining of user-written TLC S-Functions is not supported. If you run a model containing TLC S-Functions in the JIT Accelerator mode, there is a possibility of the execution speed reducing. The code generation speed, however, will be high due to JIT acceleration.

Inlining S-functions using the Target Language Compiler increases performance with the classic Accelerator mode by eliminating unnecessary calls to the Simulink API. By default, however, the classic Accelerator mode ignores an inlining TLC file for an S-function, even though the file exists. The Rapid Accelerator mode always uses the TLC file if one is available.

A device driver S-Function block written to access specific hardware registers on an I/O board is one example of why this behavior was chosen as the default. Because the

Simulink software runs on the host system rather than the target, it cannot access the targets I/O registers and so would fail when attempting to do so.

To direct the classic Accelerator mode to use the TLC file instead of the S-function MEX-file, specify `SS_OPTION_USE_TLC_WITH_ACCELERATOR` in the `mdlInitializeSizes` function of the S-function, as in this example:

```
static void mdlInitializeSizes(SimStruct *S)
{
/* Code deleted */
ssSetOptions(S, SS_OPTION_USE_TLC_WITH_ACCELERATOR);
}
```

The Rapid Accelerator mode will make use of the MEX file if the S-Function's C file is not present in the same folder.

Note to use the .c or .cpp code for your S-Function, ensure that they are in the same folder as the S-Function MEX-file, otherwise, you can include additional files to an S-function or bypass the path limitation by using the rtwmakecfg.m file. For more information, see Use rtwmakecfg.m API to Customize Generated Makefiles (Simulink Coder).

Accelerator and Rapid Accelerator Mode Data Type Considerations

- Accelerator mode supports fixed-point signals and vectors up to 128 bits.
- Rapid Accelerator mode supports fixed-point parameters up to 128 bits.
- Rapid Accelerator mode supports fixed-point root inputs up to 32 bits
- Rapid Accelerator mode supports root inputs of Enumerated data type
- Rapid Accelerator mode does not support fixed-point data for the From Workspace block.
- Rapid Accelerator mode ignores the selection of the **Log fixed-point data as a fi object** (FixptAsFi) check box for the To Workspace block.
- Rapid Accelerator mode supports bus objects as parameters.
- The Accelerator mode and Rapid Accelerator mode store integers as compactly as possible.
- Fixed-Point Designer does not collect min, max, or overflow data in the Accelerator or Rapid Accelerator modes.

- Accelerator mode does not support runtime diagnostics.

Behavior of Scopes and Viewers with Rapid Accelerator Mode

Running the simulation from the command line or the menu determines the behavior of scopes and viewers in Rapid Accelerator mode.

Scope or Viewer Type	Simulation Run from Menu	Simulation Run from Command Line
Simulink Scope blocks	Same support as Normal mode	• Logging is supported • Scope window is not updated
Simulink signal viewer scopes	Graphics are updated, but logging is not supported	Not supported
Other signal viewer scopes	Support limited to that available in External mode	Not supported
Signal logging	Supported, with limitations listed in "Signal Logging in Rapid Accelerator Mode" on page 61-72	Supported, with limitations listed in "Signal Logging in Rapid Accelerator Mode" on page 61-72.
Multirate signal viewers	Not supported	Not supported
Stateflow Chart blocks	Same support for chart animation as Normal mode	Not supported

Rapid Accelerator mode does not support multirate signal viewers such as the DSP System Toolbox spectrum scope or the Communications System Toolbox™ scatterplot, signal trajectory, or eye diagram scopes.

Note Although scopes and viewers do not update when you run Rapid Accelerator mode from the command line, they do update when you run the model from the menu. "Run Acceleration Mode from the User Interface" on page 34-25 shows how to run Rapid Accelerator mode from the menu. "Interact with the Acceleration Modes Programmatically" on page 34-29 shows how to run the simulation from the command line.

Factors Inhibiting Acceleration

- You cannot use the Accelerator or Rapid Accelerator mode if your model:
  - Passes array parameters to MATLAB S-functions that are not numeric, logical, or character arrays, are sparse arrays, or that have more than two dimensions.
  - Uses Fcn blocks containing trigonometric functions having complex inputs.
- In some cases, changes associated with external or custom code do not cause Accelerator or Rapid Accelerator simulation results to change. These include:
  - TLC code
  - S-function source code, including rtwmakecfg.m files
  - Integrated custom code
  - S-Function Builder

  In such cases, consider force regeneration of code for a top model. Alternatively, you can force regeneration of top model code by deleting code generation folders, such as slprj or the generated model code folder.

Note With JIT acceleration, the acceleration target code is in memory. It is therefore available for reuse as long as the model is open, even if you delete the `slprj` folder.

Rapid Accelerator Mode Limitations

- Rapid Accelerator mode does not support:
  - Algebraic loops.
  - Targets written in C++.
  - Interpreted MATLAB Function blocks.
  - Noninlined MATLAB language or Fortran S-functions. You must write S-functions in C or inline them using the Target Language Compiler (TLC) or you can also use the MEX file. For more information, see “Write Fully Inlined S-Functions” (Simulink Coder).
  - 3-D signals.
  - Debugger or Profiler.
  - Run time objects for Simulink.RunTimeBlock and Simulink.BlockCompOutputPortData blocks.

- Model parameters must be one of these data types:
  - `boolean`
  - `uint8` or `int8`
  - `uint16` or `int16`
  - `uint32` or `int32`
  - `single` or `double`
  - Fixed-point
  - Enumerated
- You cannot pause a simulation in Rapid Accelerator mode.
- If a Rapid Accelerator build includes referenced models (by using Model blocks), set up these models to use fixed-step solvers to generate code for them. The top model, however, can use a variable-step solver as long as the blocks in the referenced models are discrete.
- In certain cases, changing block parameters can result in structural changes to your model that change the model checksum. An example of such a change is changing the number of delays in a DSP simulation. In these cases, you must regenerate the code for the model. See "Code Regeneration in Accelerated Models" on page 34-9 for more information.
- For root inports, Rapid Accelerator mode supports only base as the `Srcworkspace`.
- For root inports, when you specify the minimum and maximum values that the block should output, Rapid Accelerator mode does not recognize these limits during simulation.
- In Rapid Accelerator mode, To File or To Workspace blocks inside function-call subsystems do not generate any logging files if the function-call port is connected to Ground or unconnected.

Reserved Keywords

Certain words are reserved for use by the Simulink Coder code language and by Accelerator mode and Rapid Accelerator mode. These keywords must not appear as function or variable names on a subsystem, or as exported global signal names. Using the reserved keywords results in the Simulink software reporting an error, and the model cannot be compiled or run.

The keywords reserved for the Simulink Coder product are listed in “Construction of Generated Identifiers” (Simulink Coder). Additional keywords that apply only to the Accelerator and Rapid accelerator modes are:

muDoubleScalarAbs	muDoubleScalarCos	muDoubleScalarMod
muDoubleScalarAcos	muDoubleScalarCosh	muDoubleScalarPower
muDoubleScalarAcosh	muDoubleScalarExp	muDoubleScalarRound
muDoubleScalarAsin	muDoubleScalarFloor	muDoubleScalarSign
muDoubleScalarAsinh	muDoubleScalarHypot	muDoubleScalarSin
muDoubleScalarAtan,	muDoubleScalarLog	muDoubleScalarSinh
muDoubleScalarAtan2	muDoubleScalarLog10	muDoubleScalarSqrt
muDoubleScalarAtanh	muDoubleScalarMax	muDoubleScalarTan
muDoubleScalarCeil	muDoubleScalarMin	muDoubleScalarTanh

Perform Acceleration

In this section...

Customize the Build Process

Compiler optimizations are off by default. This results in faster build times, but slower simulation times. You can optimize the build process toward a faster simulation.

1. From the **Simulation** menu, select **Model Configuration Parameters**.
2. In the Configuration Parameters dialog box, from the **Compiler optimization level** drop-down list, select `Optimizations on (faster runs)`.

   Code generation takes longer with this option, but the model simulation runs faster.
3. Select **Verbose accelerator builds** to display progress information using code generation, and to see the compiler options in use.

Changing the Location of Generated Code

By default, the Accelerator mode places the generated code in a subfolder of the working folder called `slprj/accel/`*modelname* (for example, `slprj/accel/f14`). To change the name of the folder into which the Accelerator Mode writes generated code:

1. In the Simulink editor window, select **File > Simulink Preferences**.

   The Simulink Preferences window appears.
2. In the Simulink Preferences window, navigate to the **Simulation cache folder** parameter.
3. Enter the absolute or relative path to your subfolder and click **Apply**.

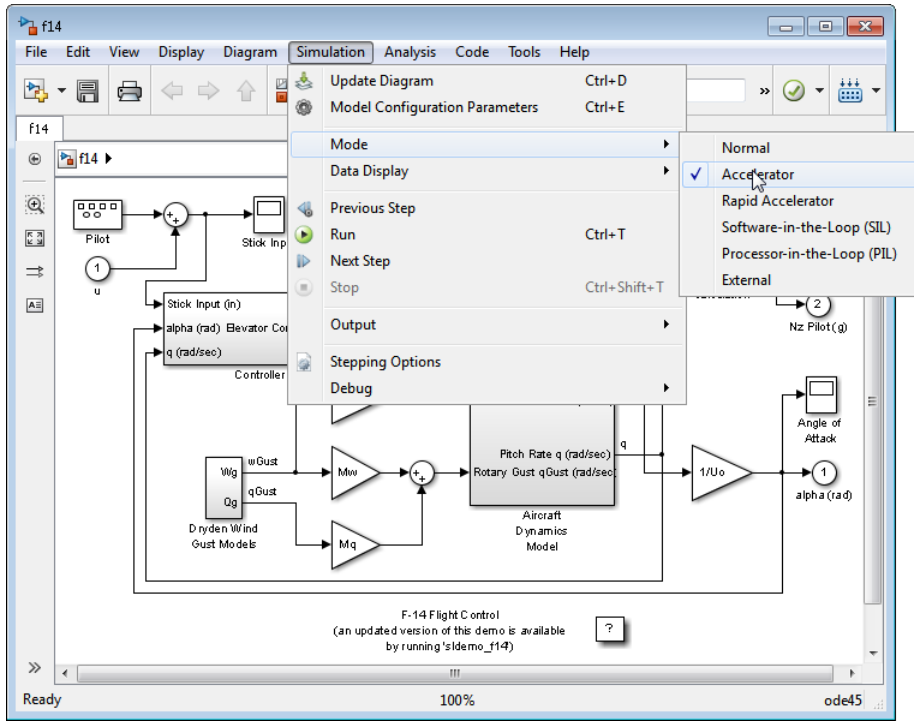
Run Acceleration Mode from the User Interface

To accelerate a model, first open it, and then from the **Simulation > Mode** menu, select either **Accelerator** or **Rapid Accelerator**. Then start the simulation.

The following example shows how to accelerate the already opened `f14` model using the Accelerator mode:

1 From the **Simulation** > **Mode** menu, select **Accelerator**.

Alternatively, you can select `Accelerator` from the Simulink Editor toolbar.



2 From the **Simulation** menu, select **Run**.

The Accelerator and Rapid Accelerator modes first check to see if code was previously compiled for your model. If code was created previously, the Accelerator or Rapid Accelerator mode runs the model. If code was not previously built, they first generate and compile the C code, and then run the model.

For an explanation of why these modes rebuild your model, see “Code Regeneration in Accelerated Models” on page 34-9.

The Accelerator mode places the generated code in a subfolder of the working folder called `slprj/accel/`*modelname* (for example, `slprj/accel/f14`). If you want to change this path, see "Changing the Location of Generated Code" on page 34-25.

The Rapid Accelerator mode places the generated code in a subfolder of the working folder called `slprj/raccel/`*modelname* (for example, `slprj/raccel/f14`).

Note The warnings that blocks generate during simulation (such as divide-by-zero and integer overflow) are not displayed when your model runs in Accelerator or Rapid Accelerator mode.

Making Run-Time Changes

A feature of the Accelerator and Rapid Accelerator modes is that simple adjustments (such as changing the value of a Gain or Constant block) can be made to the model while the simulation is still running. More complex changes (for example, changing from a `sin` to `tan` function) are not allowed during run time.

The Simulink software issues a warning if you attempt to make a change that is not permitted. The absence of a warning indicates that the change was accepted. The warning does not stop the current simulation, and the simulation continues with the previous values. If you wish to alter the model in ways that are not permitted during run time, you must first stop the simulation, make the change, and then restart the simulation.

In general, simple model changes are more likely to result in code regeneration when in Rapid Accelerator mode than when in Accelerator mode.

Interact with the Acceleration Modes Programmatically

In this section...

Why Interact Programmatically?

You can build an accelerated model, select the simulation mode, and run the simulation from the command prompt or from MATLAB script. With this flexibility, you can create Accelerator mode MEX-files in batch mode, allowing you to build the C code and executable before running the simulations. When you use the Accelerator mode interactively at a later time, it will not be necessary to generate or compile MEX-files at the start of the accelerated simulations.

Build JIT Accelerated Execution Engine

With the `accelbuild` command, you can build a JIT accelerated execution engine without actually simulating the model. For example, to build an Accelerator mode simulation of `myModel`:

```
accelbuild myModel
```

Control Simulation

You can control the simulation mode from the command line prompt by using the `set_param` command:

```
set_param('modelname','SimulationMode','mode')
```

The simulation mode can be `normal`, `accelerator`, `rapid`, or `external`.

For example, to simulate your model with the Accelerator mode, you would use:

```
set_param('myModel','SimulationMode','accelerator')
```

However, a preferable method is to specify the simulation mode within the `sim` command:

```
simOut = sim('myModel', 'SimulationMode', 'accelerator');
```

You can use `bdroot` to set parameters for the currently active model (that is, the active model window) rather than *`modelname`* if you do not wish to explicitly specify the model name.

For example, to simulate the currently opened system in the Rapid Accelerator mode, you would use:

```
simOut = sim(bdroot,'SimulationMode','rapid');
```

Simulate Your Model

You can use `set_param` to configure the model parameters (such as the simulation mode and the stop time), and use the `sim` command to start the simulation:

```
sim('modelname', 'ReturnWorkspaceOutputs', 'on');
```

However, the preferred method is to configure model parameters directly using the `sim` command, as shown in the previous section.

You can substitute `gcs` for *`modelname`* if you do not want to explicitly specify the model name.

Unless target code has already been generated, the `sim` command first builds the executable and then runs the simulation. However, if the target code has already been generated and no significant changes have been made to the model (see “Code Regeneration in Accelerated Models” on page 34-9 for a description), the `sim` command executes the generated code without regenerating the code. This process lets you run your model after making simple changes without having to wait for the model to rebuild.

Simulation Example

The following sequence shows how to programmatically simulate `myModel` in Rapid Accelerator mode for 10,000 seconds.

First open `myModel`, and then type the following in the Command Window:

```
simOut = sim('myModel', 'SimulationMode', 'rapid'...
'StopTime', '10000');
```

Use the `sim` command again to resimulate after making a change to your model. If the change is minor (adjusting the gain of a gain block, for instance), the simulation runs without regenerating code.

Customize the Acceleration Build Process

You can programmatically control the Accelerator mode and Rapid Accelerator mode build process and the amount of information displayed during the build process. See "Customize the Build Process" on page 34-25 for details on why doing so might be advantageous.

Controlling the Build Process

Use `SimCompilerOptimization` to set the degree of optimization used by the compiler when generating code for acceleration. The permitted values are `on` or `off`. The default is `off`.

Enter the following at the command prompt to turn on compiler optimization:

```
set_param('myModel', 'SimCompilerOptimization', 'on')
```

When `SimCompilerOptimization` is set to `on` in JIT accelerated mode, the simulation time for some models improves, while the build time can become slower.

Controlling Verbosity During Code Generation

Use the `AccelVerboseBuild` parameter to display progress information during code generation. The permitted values are `on` or `off`. The default is `off`.

Enter the following at the command prompt to turn on verbose build:

```
set_param('myModel', 'AccelVerboseBuild', 'on')
```

Run Accelerator Mode with the Simulink Debugger

In this section...

Advantages of Using Accelerator Mode with the Debugger

The Accelerator mode can shorten the length of your debugging sessions if you have large and complex models. For example, you can use the Accelerator mode to simulate a large model and quickly reach a distant break point.

For more information, see "Accelerator Mode" on page 34-5.

Note You cannot use the Rapid Accelerator mode with the debugger.

How to Run the Debugger

To run your model in the Accelerator mode with the debugger:

1. From the **Simulation** > **Mode** menu, select **Accelerator**.
2. At the command prompt, enter:

   ```
   sldebug modelname
   ```

3. At the debugger prompt, set a time break:

   ```
   tbreak 10000
   continue
   ```

4. Once you reach the breakpoint, use the debugger command `emode` (execution mode) to toggle between Accelerator and Normal mode.

When to Switch Back to Normal Mode

You must switch to Normal mode to step through the simulation by blocks, and when you want to use the following debug commands:

- `trace`
- `break`
- `zcbreak`
- `nanbreak`

Comparing Performance

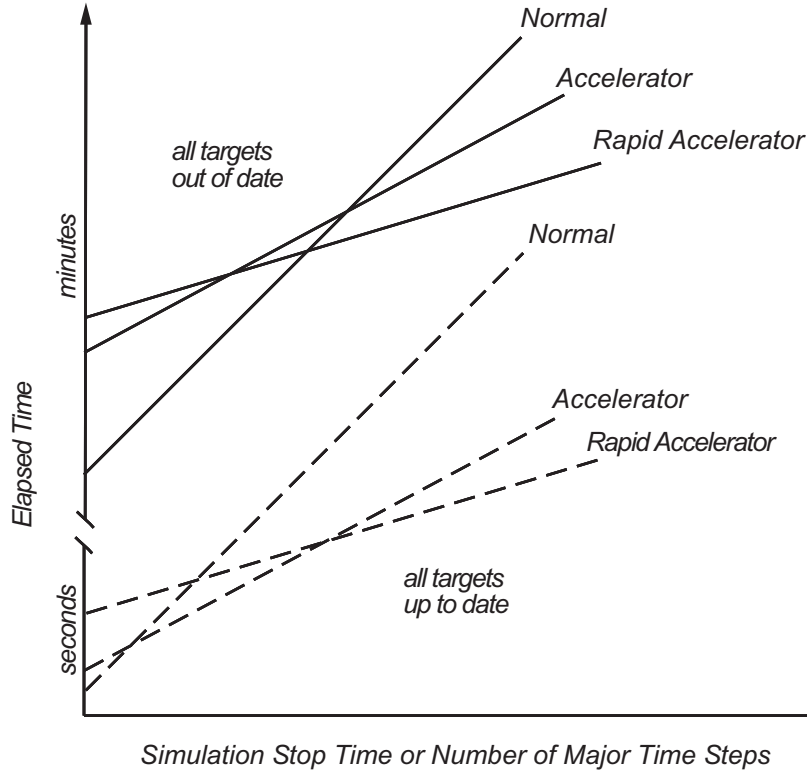
In this section...

Performance of the Simulation Modes

The Accelerator and Rapid Accelerator modes give the best speed improvement compared to Normal mode when simulation execution time exceeds the time required for code generation. For this reason, the Accelerator and Rapid Accelerator modes generally perform better than Normal mode when simulation execution times are several minutes or more. However, models with a significant number of Stateflow or MATLAB Function blocks might show only a small speed improvement over Normal mode because in Normal mode these blocks also simulate through code generation.

Including tunable parameters in your model can also increase the simulation time.

The figure shows in general terms the performance of a hypothetical model simulated in Normal, Accelerator, and Rapid Accelerator modes.



Performance When the Target Must Be Rebuilt

The solid lines in the figure show performance when the target code must be rebuilt ("all targets out of date"). For this hypothetical model, the time scale is on the order of minutes, but it could be longer for more complex models.

As generalized in the figure, the time required to compile the model in Normal mode is less than the time required to build either the Accelerator target or Rapid Accelerator executable. It is evident from the figure that for small simulation stop times Normal mode results in quicker overall simulation times than either Accelerator mode or Rapid Accelerator mode.

The crossover point where Accelerator mode or Rapid Accelerator mode result in faster execution times depends on the complexity and content of your model. For instance, those models running in Accelerator mode containing large numbers of blocks using

interpreted code (see “Select Blocks for Accelerator Mode” on page 34-18) might not run much faster than they would in Normal mode unless the simulation stop time is very large. Similarly, models with a large number of Stateflow Chart blocks or MATLAB Function blocks might not show much speed improvement over Normal mode unless the simulation stop times are long.

For illustration purposes, the graphic represents a model with a large number of Stateflow Chart blocks or MATLAB Function blocks. The curve labeled “Normal” would have much smaller initial elapsed time than shown if the model did not contain these blocks.

Performance When the Targets Are Up to Date

As shown by the broken lines in the figure (“all targets up to date”) the time for the Simulink software to determine if the Accelerator target or the Rapid Accelerator executable are up to date is significantly less than the time required to generate code (“all targets out of date”). You can take advantage of this characteristic when you wish to test various design tradeoffs.

For instance, you can generate the Accelerator mode target code once and use it to simulate your model with a series of gain settings. This is an especially efficient way to use the Accelerator or Rapid Accelerator modes because this type of change does not result in the target code being regenerated. This means the target code is generated the first time the model runs, but on subsequent runs the Simulink code spends only the time necessary to verify that the target is up to date. This process is much faster than generating code, so subsequent runs can be significantly faster than the initial run.

Because checking the targets is quicker than code generation, the crossover point is smaller when the target is up to date than when code must be generated. This means subsequent runs of your model might simulate faster in Accelerator or Rapid Accelerator mode when compared to Normal mode, even for short stop times.

Measure Performance

You can use the `tic`, `toc`, and `sim` commands to compare Accelerator mode or Rapid Accelerator mode execution times to Normal mode.

1. Open your model.
2. From the **Simulation** > **Mode** menu, select **Normal**.
3. Use the `tic`, `toc`, and `sim` commands at the command line prompt to measure how long the model takes to simulate in Normal mode:

```
tic,[t,x,y]=sim('myModel',10000);toc
```

`tic` and `toc` work together to record and return the elapsed time and display a message such as the following:

```
Elapsed time is 17.789364 seconds.
```

4. Select either **Accelerator** or **Rapid Accelerator** from the **Simulation > Mode** menu, and build an executable for the model by clicking the **Run** button. The acceleration modes use this executable in subsequent simulations as long as the model remains structurally unchanged. “Code Regeneration in Accelerated Models” on page 34-9 discusses the things that cause your model to rebuild.
5. Rerun the compiled model at the command prompt:

```
tic,[t,x,y]=sim('myModel',10000);toc
```

6. The elapsed time displayed shows the run time for the accelerated model. For example:

```
Elapsed time is 12.419914 seconds.
```

The difference in elapsed times (5.369450 seconds in this example) shows the improvement obtained by accelerating your model.

How to Improve Performance in Acceleration Modes

In this section...

Techniques

To get the best performance when accelerating your models:

- Verify that the Configuration Parameters dialog box settings are as follows:

Set...	To...
Solver data inconsistency	`none`
Array bounds exceeded	`none`
Signal storage reuse	selected

- Disable Stateflow debugging and animation.
- When logging large amounts of data (for instance, when using the Workspace I/O, To Workspace, To File, or Scope blocks), use decimation or limit the output to display only the last part of the simulation.
- Customize the code generation process to improve simulation speed. For details, see “Customize the Build Process” on page 34-25.

C Compilers

On computers running the Microsoft Windows operating system, the Accelerator and Rapid Accelerator modes use the default 64-bit C compiler supplied by MathWorks to compile your model. If you have a C compiler installed on your PC, you can configure the `mex` command to use it instead. You might choose to do this if your C compiler produces highly optimized code since this would further improve acceleration.

Note For an up-to-date list of 32- and 64-bit C compilers that are compatible with MATLAB software for all supported computing platforms, see:

`http://www.mathworks.com/support/compilers/current_release/`

Managing Blocks

Working with Blocks

Nonvirtual and Virtual Blocks

When creating models, you need to be aware that Simulink blocks fall into two basic categories: nonvirtual blocks and virtual blocks. Nonvirtual blocks play an active role in the simulation of a system. If you add or remove a nonvirtual block, you change the model's behavior. Virtual blocks, by contrast, play no active role in the simulation; they help organize a model graphically. Some Simulink blocks are virtual in some circumstances and nonvirtual in others. Such blocks are called conditionally virtual blocks. The table lists Simulink virtual and conditionally virtual blocks.

Block Name	Condition Under Which Block Is Virtual
Bus Assignment	Virtual if input bus is virtual.
Bus Creator	Virtual if output bus is virtual.
Bus Selector	Virtual if input bus is virtual.
Demux	Always virtual.
Enable	Virtual unless connected directly to an Outport block.
From	Always virtual.
Goto	Always virtual.
Goto Tag Visibility	Always virtual.
Ground	Always virtual.
Inport	Virtual *unless* the block resides in a conditionally executed or atomic subsystem *and* has a direct connection to an Outport block.
Mux	Always virtual.
Outport	Virtual when the block resides within any subsystem block (conditional or not), and does *not* reside in the root (top-level) Simulink window.
Selector	Virtual only when **Number of input dimensions** specifies `1` and **Index Option** specifies `Select all`, `Index vector (dialog)`, or `Starting index (dialog)`.
Signal Specification	Always virtual.

Block Name	Condition Under Which Block Is Virtual
Subsystem	Virtual unless the block is conditionally executed or the **Treat as atomic unit** check box is selected. You can check if a block is virtual with the `IsSubsystemVirtual` block property. See "Block-Specific Parameters".
Terminator	Always virtual.
Trigger	Virtual when the output port is *not* present.

- "Block Libraries"

Specify Block Properties

For each block in a model, you can set general block properties, such as:

- A description of the block
- The block execution order
- A block annotation
- Block callback functions

To set block properties, use the Property Inspector. You can set properties in the **Properties** and **Info** tabs of the Property Inspector when the block is selected. Alternatively, you can use the Block Properties dialog box. For more information on setting properties, see “Setting Properties and Parameters” on page 1-50.

Set Block Annotation Properties

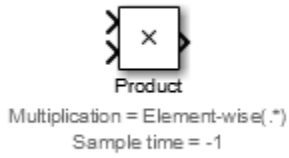
In the Property Inspector, use the **Block Annotation** section to display the values of selected block parameters in an annotation. The annotation appears below the block icon.

Enter the text of the annotation in the text box. You can use a block property token in the annotation. The value for the property replaces the token in the annotation in the model. To display a list of tokens that you can use in an annotation, type `%` in the text box. The parameters that are valid for the selected block appear. See “Common Block Properties” and “Block-Specific Parameters”.

Suppose that you specify the following annotation text and tokens for a Product block:

```
Multiplication = %<Multiplication>
Sample time = %<SampleTime>
```

In the Simulink Editor, the block displays this annotation:



You can also create block annotations programmatically. See “Create Block Annotations Programmatically” on page 35-6.

Specify Block Callbacks

Use the **Callbacks** section to specify block callbacks. Callbacks are MATLAB commands that execute when a specific model action occurs, such as when you select or delete a block. For more information on callbacks, see “Callbacks for Customized Model Behavior” on page 4-44.

1. Select the block whose callback you want to set.
2. In **Properties** tab of the Property Inspector, in the **Callbacks** section, select the function that you want to assign the callback to. For example, select `OpenFcn` to specify a behavior for double-clicking a block.
3. In the text box, enter the command that you want to execute when that block function occurs.

   After you assign a callback to a function, the function displays an asterisk next to it in the list. The asterisks helps you to see the functions that have callbacks assigned to them.

Note After you add an `OpenFcn` callback to a block, double-clicking the block does not open the block dialog box. Also, the block parameters do not appear in the Property Inspector when the block is selected. To set the block parameters, select **Block Parameters** from the block context menu.

Set a Block Callback Programmatically

This example shows how to use the `OpenFcn` callback to execute MATLAB scripts when you double-click a block. For example, in a MATLAB script you can define variables or open a plot of simulated data.

To create a callback programmatically, select the block to which you want to add this property. Then, at the MATLAB command prompt, enter a command in this form:

```
set_param(gcb,'OpenFcn','myfunction')
```

In this example, `myfunction` represents a valid MATLAB command or a MATLAB script on your MATLAB search path.

Specify Block Execution Priority and Tag

In the **Advanced Properties** section of the block properties, you can specify the block priority and identify the block by assigning a value to the **Tag** property.

- **Priority** — Specify the execution priority of the block relative to other blocks in the model. For more information, see “Assign Block Priorities” on page 35-42.
- **Tag** — Specify an identifier for the block. Specify text to assign to the block Tag parameter. Setting this property is useful for finding the block in the model by searching or programmatically using `find_system`. See “Find Model Elements in Simulink Models” on page 12-47.

Use Block Description to Identify a Block

The **Info** tab displays information about the block type. The block author provides this description.

You can also enter a description in the **Description** box to provide information about the block instance.

- If you add a description, you can set up your model display so that the description appears in a tool tip when you hover over the block. Use **Display > Blocks > Tool Tip Options > Description** to enable this tool tip.
- The **Description** property can help you to find a block by searching. See “Find Model Elements in Simulink Models” on page 12-47.

Create Block Annotations Programmatically

You can use a block `AttributesFormatString` parameter to display specified block parameter values below the block. “Common Block Properties” and “Block-Specific Parameters” describe the parameters that a block can have. Use the Simulink `set_param` function to set this parameter to the attributes format that you want.

The attributes format can be any text that has embedded parameter names. An embedded parameter name is a parameter name preceded by `%<` and followed by `>`, for example, `%<priority>`. Simulink displays the attributes format text below the block icon, replacing each parameter name with the corresponding value. You can use line-feed characters (`\n`) to display each parameter on a separate line. For example, select a Gain block and enter this command at the MATLAB command prompt:

```
set_param(gcb,'AttributesFormatString','pri=%<priority>\ngain=%<Gain>')
```

The Gain block displays this block annotation:

If a parameter value is not text or an integer, `N/S` (for not supported) appears in place of the value. If the parameter name is not valid, Simulink displays `???` in place of the value.

Adjust Visual Presentation to Improve Model Readability

As you build a model, you can adjust block positions, change block and background color, adjust fonts, and add elements that help to improve model readability. These changes can help to organize the model visually and help others understand the model when you share it.

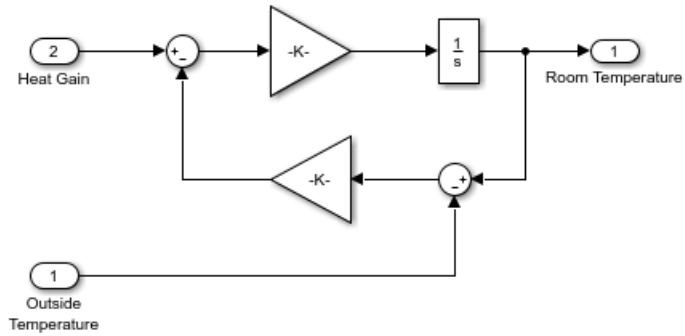
You can make these types of changes to improve model readability:

- Flip or rotate blocks. These adjustments help blocks to fit in the model and connect with other blocks. See “Flip or Rotate a Block” on page 35-8.
- Reposition or hide block names. See “Manage Block Names” on page 35-10.
- Add colors to blocks and to the background. See “Specify Model Colors” on page 35-11.
- Adjust aesthetics by changing fonts and deepening the intensity of drop shadows. See “Specify Fonts in Models” on page 35-12 and “Increase Drop Shadow Depth” on page 35-13.
- Surround groups of blocks with a box to show that the blocks are related. See “Box and Label Areas of a Model” on page 35-14.
- Copy formatting from a block, line, or area to another model element. See “Copy Formatting Between Model Elements” on page 35-15.
- Document a model using text, image, and math annotations. See “Describe Models Using Annotations” on page 4-3.
- Annotate a block. See “Set Block Annotation Properties” on page 35-4.
- Change the block icon, for example, display a graphic on the block. Use a mask to achieve this effect. A mask also enables you to design a custom interface for a block. To learn about masks, see “Masking Fundamentals” on page 38-2.

Flip or Rotate a Block

You can change the orientation of a block by rotating it in 90-degree increments or by flipping it 180 degrees about its horizontal or vertical axis. Rotate or flip a block so that it fits better in the model, for example, in feedback loops. You might also need to rotate a block so that inports align with outports.

The figure shows a Gain block flipped to simplify a feedback loop diagram.



- To rotate or flip a block, select the block and select a command from the **Diagram** > **Rotate & Flip** menu. You can rotate clockwise (**Ctrl+R**) or counterclockwise.

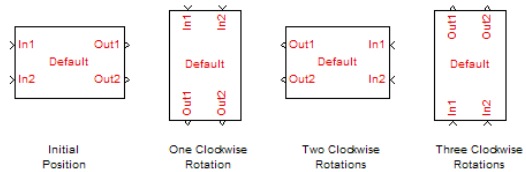
  The **Flip Block** command flips the block based on the orientation of its ports. For example, if the ports are on the sides, the block flips horizontally (about its vertical axis).

- Blocks rotate automatically when you place them on a signal line that has an orientation other than left to right. For example, if the signal goes from bottom to top and you place a block on it, the block rotates with its ports up.

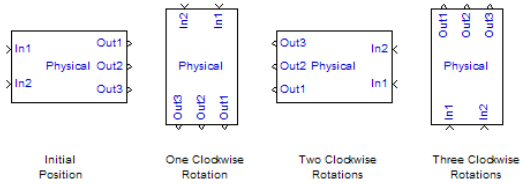
Port Location After Rotating or Flipping

Rotating moves block ports from the sides to top and bottom or the reverse, depending on the placement of the ports. The resulting positions of the block ports depend on the block port rotation type.

Rotating can reposition the ports on some blocks to maintain left-to-right or top-to-bottom port numbering order. A block whose ports are reordered after a rotation have the default port rotation type. This policy helps to maintain the left-right and top-down block diagram orientation convention used in control system modeling applications. Blocks by default use this rotation policy. The figure shows the effect of clockwise rotation on a block with the default port rotation policy.



A masked block can specify for ports to keep their order after rotation (see “Port rotation”). These blocks have a physical port rotation type. This policy helps when designing blocks to use in mechanical and hydraulic systems modeling and other applications where diagrams do not have a preferred orientation. The figure shows the effect of clockwise rotation on a block with a physical port rotation type.



Flipping a block moves the ports to the opposite side of the block, creating a mirror image, regardless of port rotation type.

Manage Block Names

You can manage block names by displaying or hiding them and by changing their location on the block.

Hide or Display Block Names

The Simulink Editor names blocks when you create them. The first occurrence of the block is the library block name, for example, Gain. The next occurrence is the block name with a number appended. Each new block increments the number, for example, Gain1, Gain2, and so on. These names are called automatic names. By default, the Editor hides these names.

You can choose whether to hide or display block names. You can:

- Display all the hidden automatic names. Select the **Display** menu, and clear the **Hide Automatic Names** check box.
- Temporarily display a hidden automatic block name by selecting the block.
- Name the block explicitly, for example, by its purpose in the model. The **Hide Automatic Names** setting does not affect blocks that you name explicitly. To name a block, select it, double-click the name, and type the new name.

In addition, you can explicitly hide or display any block name. Explicitly hidden or displayed blocks are not affected by the **Hide Automatic Names** setting. To explicitly

hide or display a block name, select the block, select **Diagram > Format > Show Block Name** and then select:

- **On** to always display the block name.
- **Off** to always hide the block name.
- **Auto** to return to the default state. If the block has an automatic name, **Hide Automatic Names** affects the block.

To display and hide block names programmatically, use `set_param` with the `'HideAutomaticNames'` option for models and the `'HideAutomaticName'` and `'ShowName'` options for blocks. For more information on these parameters, see "Model Parameters" and "Common Block Properties". The table shows how these parameters interact.

`'ShowName'` (block setting)	`'HideAutomaticName'` (block setting)	`'HideAutomaticNames'` (model setting)	Result
`'off'`	Any	Any	Name is hidden
`'on'`	`'on'`	`'on'`	Name is hidden
`'on'`	`'off'`	Any	Name is shown
`'on'`	`'on'`	`'off'`	Name is shown

Move Block Names

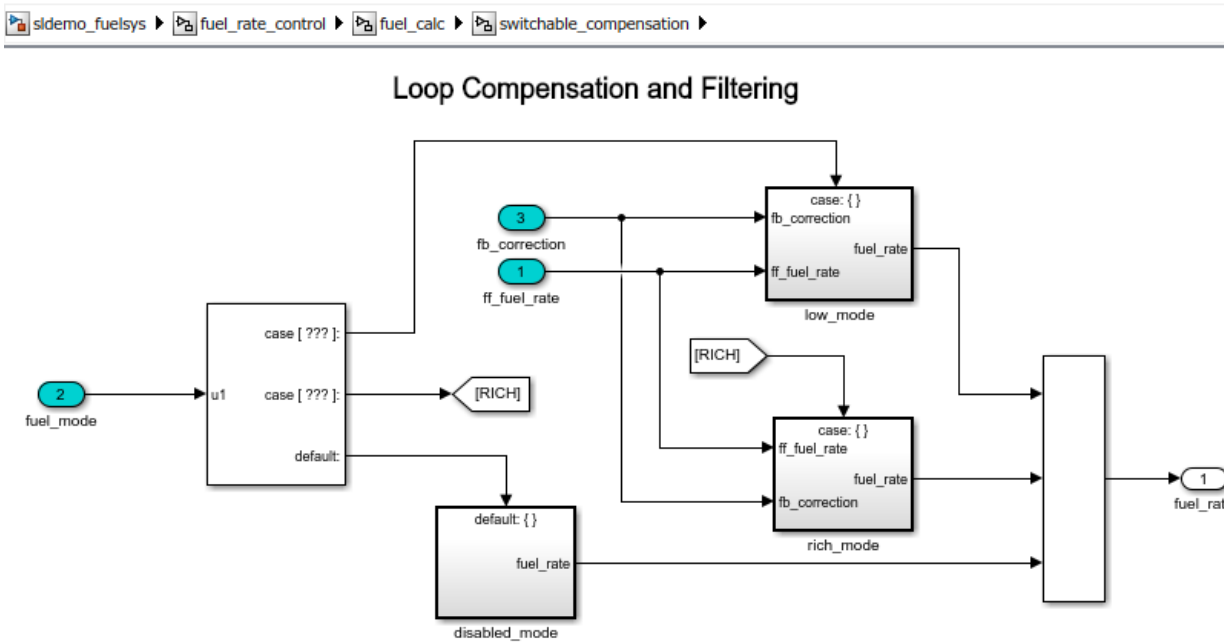
By default, block names appear below blocks whose ports are on the sides and to the left on blocks whose ports are on the top and bottom. To change the location of a block name, you can:

- Drag the block name to the opposite side of the block.
- Select the block and then select **Diagram > Rotate & Flip > Flip Block Name**.

Specify Model Colors

You can specify the outline and interior colors of any block, and you can change the background color for any system in a model. You can also change text color and background color for annotations and fill color for areas.

This subsystem uses color to identify the inports.



- To change outline color on a block, text color in an annotation, or interior color for an area, select the element, and then select **Diagram > Format > Foreground Color**. Changing the foreground color of a block also changes the color of its output signals.
- To change interior color on a block or background color in an annotation, select the element, and then select **Diagram > Format > Background Color**.
- To change a background color in a system, open the system, and then select **Diagram > Format > Canvas Color**.

You can select a color from the menu or select **Custom** to open the color picker and define your own color.

You can also use the Property Inspector to change color for an area or an annotation. To specify colors programmatically, see “Specify Colors Programmatically” on page 1-21

Specify Fonts in Models

Change font family, style, and size for any model element to make your model easier to read or to comply with company standards. You can modify the font for selected blocks,

signal labels, areas, and annotations. Changing a block's font changes the font for the name and for text that appears on the block.

You can also change the default font for the model. The default font affects any elements whose font you have not changed and any new elements you create. If you want to use the same default font in all new models, change the default model font in your default template. See "Use Customized Settings When Creating New Models" on page 1-8.

- To change the font of a block, signal label, area, or annotation, select the element, and then select **Diagram > Format > Font Style for Selection**. Use the dialog box to specify the font information.
- To change the default font for the model, with no selection, select **Diagram > Format > Font Style for Model**. Use the dialog box to specify the font information.

You can also use the Property Inspector to change font for an area or an annotation.

Select Font Dialog Box on Linux Machines

On Linux machines configured for English, the **Font style** list in the Select Font dialog box can appear out of order and in another language in some fonts. If the characters in your **Font style** list appear in another language, set the `LANG` environment variable to `en_US.utf-8` before you start MATLAB. For example, at a Linux terminal, enter:

```
setenv LANG en_US.utf-8
matlab
```

Increase Drop Shadow Depth

By default, blocks have a drop shadow. To make the block stand out more against the background, you can increase the depth of the drop shadow.

Select the blocks whose drop shadow depth you want to increase, and then select **Diagram > Format > Shadow**.

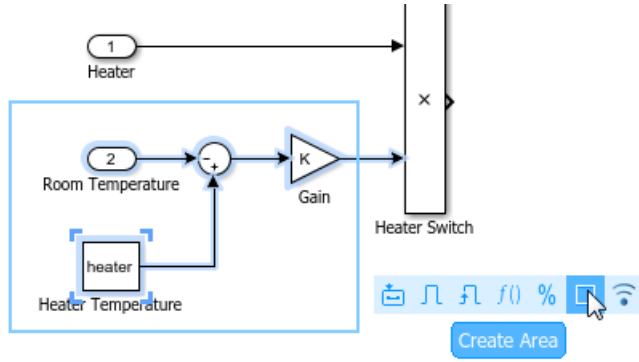
Tip To remove the default drop shadow for all blocks, select the Simulink Editor preference **Use classic diagram theme**.

Box and Label Areas of a Model

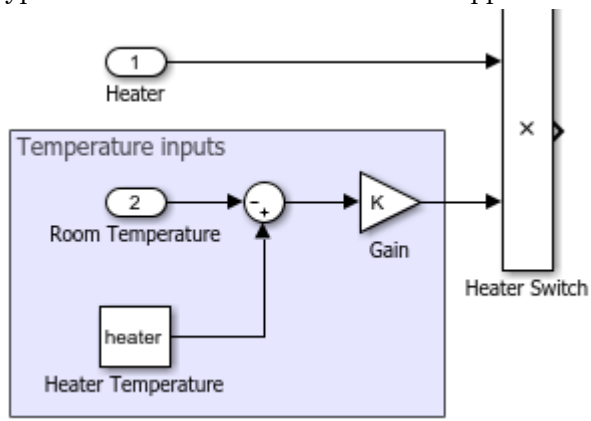
Add an area to your model to visually group related model elements in a box. An area can move with the blocks it surrounds. You can add text to an area to briefly describe or label the area.

1 Drag a box around the area of interest in the model.

2 From the action bar, select **Create Area**.



3 Type the name of the area. The name appears in the upper-left corner of the area.



To enter the name later, select the area, click the **?**, and start typing, or use the **Name** property in the Property Inspector.

4 Optionally, add a description of the area contents using the Property Inspector.

5 To move the area and its contents, drag the area near the border.

> **Tip** To move an area without moving its contents, hold **Alt** (**option** on a Mac) and drag.

Alternatively, you can drag an area box from the palette onto the canvas, resize the box, and move it to the desired location.

Convert Area to a Subsystem

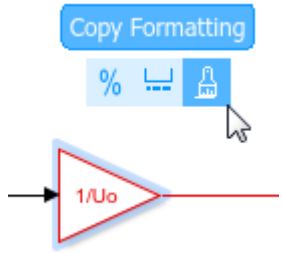
An area is similar to a subsystem in that it is a way to group related blocks. However, a subsystem creates a hierarchy, replacing multiple blocks in a model with a single block. You can initially group related blocks in an area and later decide to put those blocks in a subsystem by converting the area. The resulting subsystem has the same name, blocks, description, and requirements traceability information as the area.

To convert an area to a subsystem, right-click the area and select **Create Subsystem from Area**.

Copy Formatting Between Model Elements

If you have applied formatting to a block, signal line, or area in a model, you can copy the formatting and apply it to another model element. Examples of formatting include font changes, foreground and background color, and drop shadow effects.

1. Select the block, line, or area whose formatting you want to copy.
2. From the ellipsis menu, select **Copy Formatting**. The cursor becomes a paintbrush.



3. Using the paintbrush, click each element that you want to copy the formatting to.
4. To cancel the paintbrush cursor, click a blank spot on the canvas or press **Esc**.

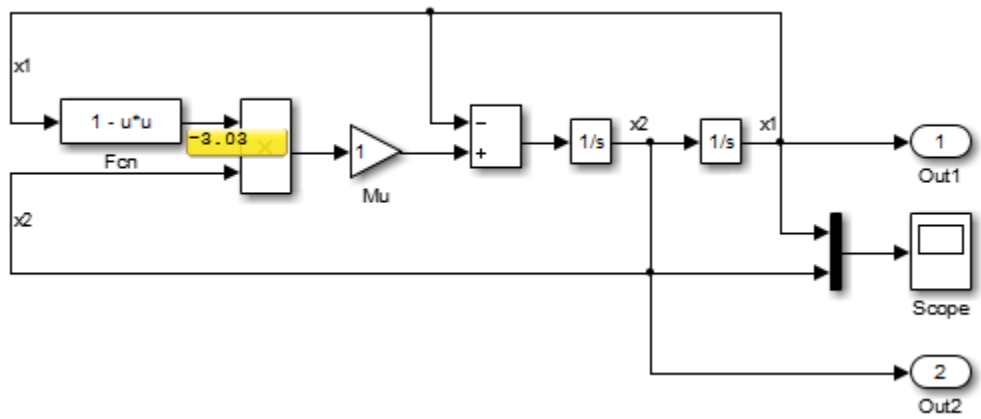
Display Port Values for Debugging

In this section...

Display Port Values for Easy Debugging

For many blocks whose signals carry data, Simulink can display signal values (block output) as port value labels (similar to tool tips) on the block diagram during and after a simulation. Port value labels display block output values when Simulink runs block output methods. This model shows a port value label for the port on the Fcn block, an output value of `-3.03`.

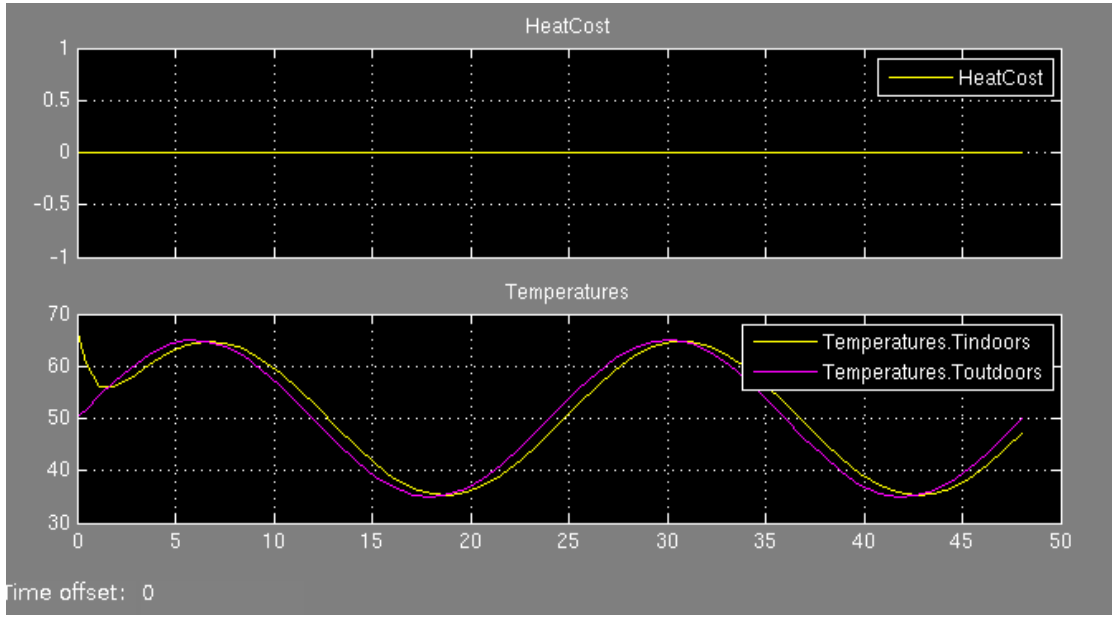


If the port value label appears empty, this means that no port value is currently available. For example, toggling a port value label on a continuous block when paused during simulation does not display any values in the label.

Port value labels are also empty when you have not yet simulated the model. This is because the block output methods do not run when the model does not simulate.

If you toggle or hover on a block that Simulink optimizes out of a simulation (such as a virtual subsystem block), while you simulate, the model displays the text `optimized`.

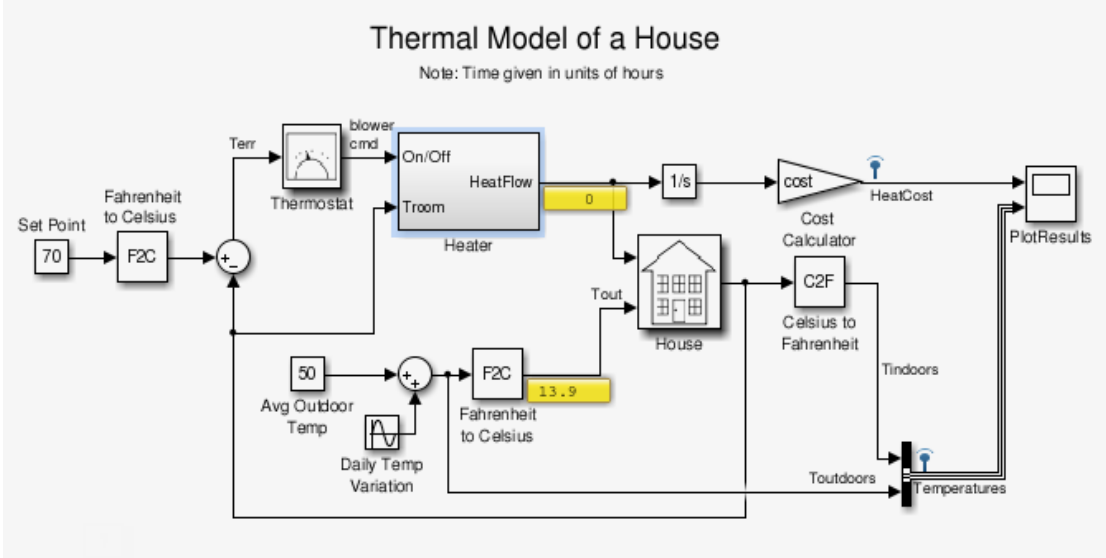
Displaying port value data tips can help during interactive debugging of a model. For example, the figure shows the output of a thermal model for a house.



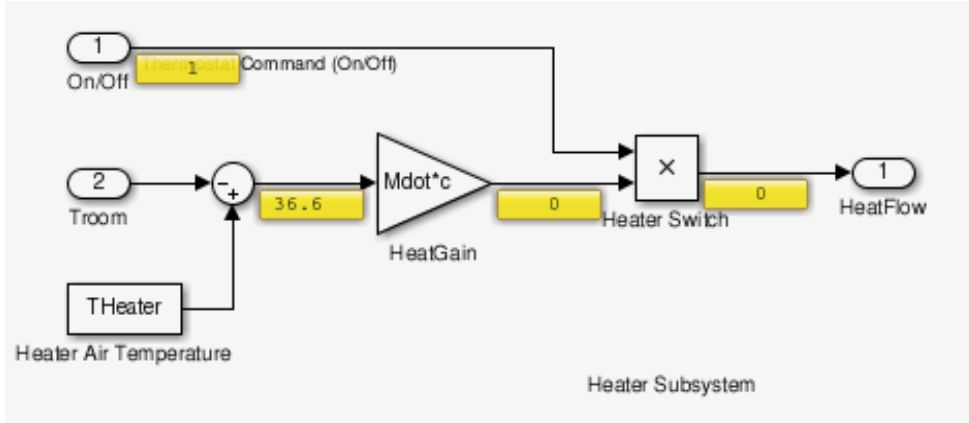
These results suggest a problem with the model because:

- The heating cost is `0` at all temperatures.
- The temperature inside the house matches ambient temperature almost exactly.

In such cases, debugging the blocks in the model interactively can help isolate the error. Port value labels provide information at the output of every block in the model. So in this example, if you step forward using Simulation Stepper, you can see that the output of the Heater subsystem is `0` at every time step.



To learn more, you can enable port value labels for blocks inside the Heater subsystem. Using Simulation Stepper, if you step forward again to display the values, you can see that there is an issue with the HeatGain block. The output is constant at `0`.



This technique helps you isolate the issue.

To simplify debugging, you can turn on and off port value labels during simulation. Besides providing useful information for debugging, port value displays can help you monitor a signal value during simulation. However, these labels are not saved with a model.

For nonnumeric data display, Simulink uses these values:

Message	Explanation
`action`	The signal executes action subsystems.
`fcn-call`	The signal is a function-call signal, e.g., Function Call Generator output.
`ground`	The signal is coming from a Ground block.
`not a data signal`	The signal does not contain valid data, e.g., the signal is from a block that is commented out.

In some cases:

- The port value display may not be able to acquire the value signal or
- The signal's value cannot be easily displayed

In such cases, Simulink uses these values.

Message	Explanation
...	The signal dimension exceeds the maximum number of elements Simulink can display. For more information, see "Display Port Values for a Model" on page 35-24.
(no message)	The simulation data available is insufficient. Step forward or press play to obtain more data.
`click to add signals`	You have enabled a port value label on a bus. However, you have not selected a signal to display. Click the label to select bus signals.
`inaccessible`	Simulink cannot obtain the port value. For an example, see "Signal Storage Reuse" on page 35-25.
`[m*n]`	This is a nonvector signal. Simulink cannot display the actual values of the matrix. It displays the matrix dimension instead.
`no data yet`	This message appears when: • The simulation data is not available. Start the simulation to see values. • If the model contains subsystems (for example, an enabled subsystem) and model references and they are not executed during a simulation.

Message	Explanation
`not used`	Simulink cannot obtain the signal value due to optimization.
`removed`	Simulink cannot obtain the signal value due to block reduction.
`optimized`	Simulink cannot obtain the signal value due to optimization. In Normal mode, this message appears for blocks with **Conditional input branch execution** enabled. For more information, see "Conditional Subsystems" on page 10-3.
`unavailable`	The simulation data available is insufficient. For example, see "Simulation Stepper" on page 35-26.

Note You can force a value label to display the signal value by designating the signal as a test point. Use the **Properties** dialog box to do this.

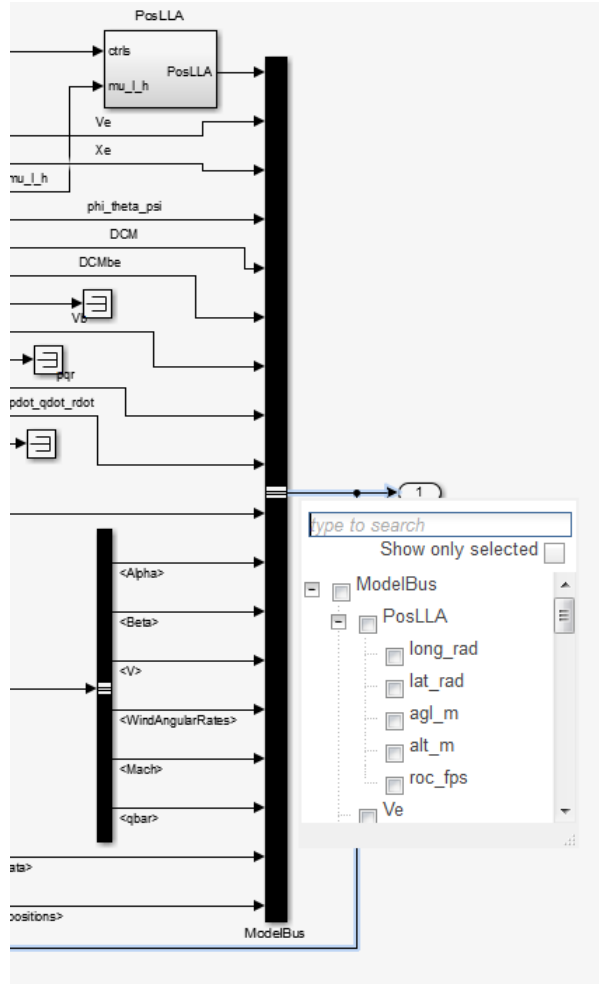
Display Value for a Specific Port

To display the value of a specific port or port values for a block before simulation, select one or more signals, right-click the selection, and select **Show Value Label of Selected Port**.

By default, Simulink displays the value of a signal when you click on it during simulation. You can control this behavior in **Display > Data Display in Simulation > Options > Display values > Enable by default during simulation**.

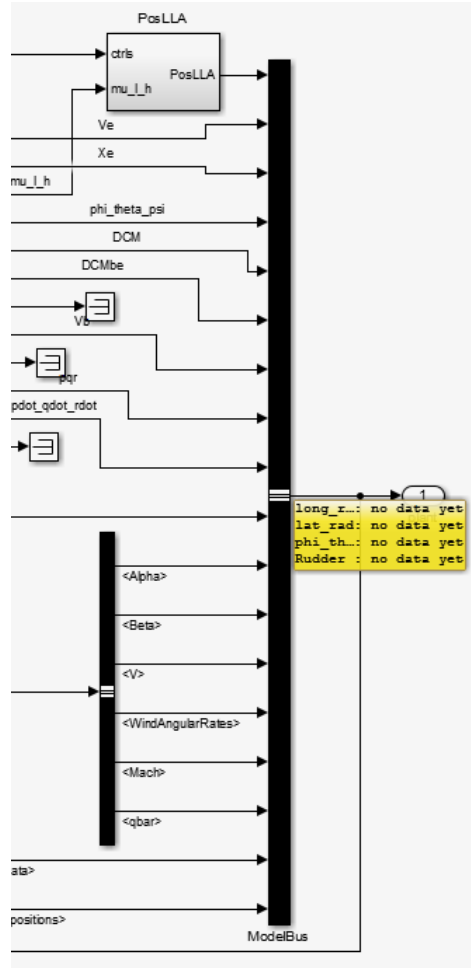
Note To remove all data tips, select **Display > Data Display in Simulation > Remove All Value Labels**.

For bus signals, the **Show Value Label of Selected Port** option opens a dialog box where you can select from all signals in the bus. For example, in this model, you can see the dialog box for all signals that are contained in ModelBus.

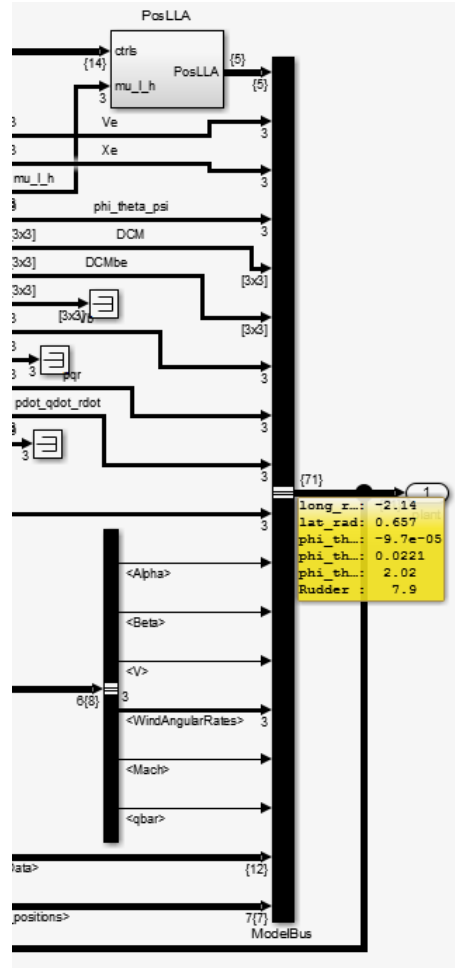


You can search for a signal by name or filter through the hierarchy. Select a parent signal to include all of the signals it contains. You can also filter the display to view only those signals you have selected.

Click anywhere outside the dialog box to close it. The port value label appears. The label has no data; it displays values when you simulate the model.



When you simulate the model, the port value label displays the names and values of the signals you chose. To change the signals to display, click on the port value label to reopen the dialog. You can also click on another signal to display its value.



Note Simulink does not save the values of a signal when you remove the port value label.

Display Port Values for a Model

Specify port value display formatting and the frequency of updates. The Value Label Display Options dialog box controls these settings on the entire model.

1. In the model whose port values you want to display, select **Display** > **Data Display in Simulation** > **Options**.
2. In the Value Label Display Options dialog box, specify your preferences for:
   - The display options, including font size, the refresh frequency, and the number of elements displayed for vector signals with signal widths greater than 1
   - The display mode
   - Floating-point or fixed-point format

Port Value Display Limitations

Performance

Enabling the hovering option for a model or setting at least one block to **Toggle Value Labels When Clicked** slows down simulation.

Accelerated Modes

Port values work in Normal and Accelerator modes only. They do not work in Rapid Accelerator and External modes. The table shows how accelerator modes affect the display of port values.

Accelerated Mode	Port Values
Accelerator	• Signals not optimized in Accelerator mode display port values as in Normal mode. Signals optimized in Accelerator mode display port values as `optimized`. For more information, see "Display Port Values for Easy Debugging" on page 35-17. • Model reference blocks simulated in Accelerator mode do not get their port value displays updated.
Rapid Accelerator	Incompatible. The limitation exists whether the model or its parent specifies accelerated simulation. For more information, see "Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File" (Simulink Coder).

Signal Storage Reuse

If the output port buffer of a block is shared with another block through the optimization of signal storage reuse, the port value displays as `inaccessible`. You can disable signal storage reuse using the **Signal storage reuse** check box. However, disabling signal storage reuse increases the memory used during simulation.

Signal Data Types

- Simulink displays the port value for ports connected to most kinds of signals, including signals with built-in data types (such as `double`, `int32`, or `Boolean`), `DYNAMICALLY_TYPED`, and several other data types.
- Simulink shows the floating format for only noncomplex signal value displays.
- Simulink displays the port value of fixed point data types based on the converted double value.
- Simulink does not display data for signals with some composite data types, such as bus signals.

Subsystems

- You cannot display port values for subsystems contained in a variant subsystem when there are no signal lines connecting to them. In such cases, during simulation, Simulink automatically determines block connectivity based on the active variant. However, you can display port values within the subsystems contained in the variant subsystem. You can also display values on signal lines outside of the variant subsystem.
- When you disable a conditionally executed subsystem, the port value display for a signal that goes into an Outport block displays the value of the Outport block, depending on the **Output when disabled** setting.
- Simulink does not display data for the ports of an enabled subsystem that is not enabled.

Simulation Stepper

If you do not enable port value display when stepping forward, the display will not be available when stepping back. When stepping back, if the port value is unavailable, the `unavailable` label is displayed.

Refine Factor

Port value displays do not honor refine factor values (**Configuration Parameters > Data Import/Export > Additional parameters > Refine factor**) because Simulink updates port value displays only during major time steps.

Signal Specification Block and Inport Block

When you display port values on Signal Specification and Inport blocks in a subsystem, the value that is driving the blocks displays instead of the block values.

Command-Line Simulations

For efficiency, Simulink does not support port value displays during a command-line simulation using the `sim` command.

Merge Block

Simulink does not display the output value of a merge block. To see this value, refer to the source block.

Command Line Interface

You cannot specify port value displays through the command line interface.

Non-Simulink signals

You cannot place port values on non-Simulink signals, such as Simscape or SimEvents signals. This limitation applies to conditional breakpoints as well.

Control and Display the Sorted Order

In this section...

What Is Sorted Order?

During the updating phase of simulation, Simulink determines the order in which to invoke the block methods during simulation. This block invocation ordering is the *sorted order*.

You cannot set this order, but you can assign priorities to nonvirtual blocks to indicate to Simulink their execution order relative to other blocks. Simulink tries to honor block priority settings, unless there is a conflict with data dependencies. To confirm the results of priorities that you have set, or to debug your model, display and review the sorted order of your nonvirtual blocks and subsystems.

Note For more information about block methods and execution, see:

- “Block Methods” on page 3-15
- “Conditional Subsystems” on page 10-3

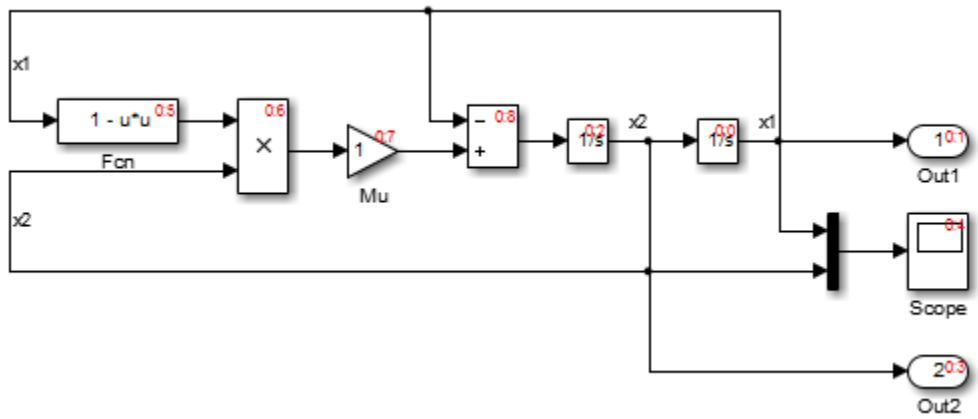
Display the Sorted Order

To display the sorted order of the `vdp` model:

1 Open the van der Pol equation model:

```
vdp
```

2 In the model window, select **Display** > **Blocks** > **Sorted Execution Order**.



Simulink displays a notation in the top-right corner of each nonvirtual block and each nonvirtual subsystem. These numbers indicate the order in which the blocks execute. The first block to execute has a sorted order of `0`.

For example, in the van der Pol equation model, the Integrator block with the sorted order `0:0` executes first. The Out1 block, with the sorted order `0:1`, executes second. Similarly, the remaining blocks execute in numeric order from `0:2` to `0:8`.

You can save the sorted order setting with your model. To display the sorted order when you reopen the model, select **Simulation** > **Update diagram**.

Sorted Order Notation

The sorted order notation varies depending on the type of block. The following table summarizes the different formats of sorted order notation. Each format is described in detail in the sections that follows the table.

Block Type	Sorted Order Notation	Description
"Nonvirtual Blocks" on page 35-33	*s*`:`*b*	• *s* is the system index of the model or subsystem the block resides in. For root-level models, *s* is always `0`.

Block Type	Sorted Order Notation	Description
	s:*b* {*x*, *y*}	• *b* specifies the block position within the sorted order for the designated execution context. • *x*,*y* are the system indices of the subsystems whose execution is controlled by this block.
"Nonvirtual Subsystems" on page 35-33 (not including function-call and action subsystems)	*s*:*b*	• *s* is the system index of the model or subsystem. • *b* specifies the block position within the sorted order for the designated execution context.
"Virtual Blocks and Subsystems" on page 35-35	Not applicable	Virtual blocks do not execute.
Action Subsystems	*s*:*b'*	• *s* is the system index of the model or subsystem the block resides in. For root-level models, *s* is always 0. • *b'* is the block index of the action block (but not of the action subsystem).
"Function-Call Subsystems" on page 35-36 and Function-Call models	One non-grounded initiator: *s*:b^{i}	• *s* is the system index of the model or subsystem the block resides in. For root-level models, *s* is always 0. • b^{i} is the block index of the root initiator in the subsystem's hierarchy.
	Two or more initiators: • *s*:b^{i1}, *s*:b^{i2}, ..., *s*:b^{in} where n is the number of non-grounded initiators.	• *s* is the system index of the model or subsystem the block resides in. For root-level models, *s* is always 0. • b^{i_n} is the block index of the n-th root initiator in the subsystem's hierarchy.

Block Type	Sorted Order Notation	Description
	Initiators are either Ground blocks or are unconnected: • *s*:G	• *s* is the system index of the model or subsystem the block resides in. For root-level models, *s* is always 0. • *G* indicates that all function-call initiators are grounded.
"Branched Function-Call Signals" on page 35-38	$s:b^i[B_k]$	• *s* is the system index of the model or subsystem the block resides in. For root-level models, *s* is always 0. • b^i is the block index of the root initiator in the subsystem's hierarchy. • B_k indicates that it is a branched function-call subsystem with branch index k.
Function-Call Feedback Latch Blocks	$s:b^i[B_m]$	• *s* is the system index of the model or subsystem the block resides in. For root-level models, *s* is always 0. • b^i is the block index of the root initiator in the subsystem's hierarchy. • B_m indicates that it is a branched subsystem with branch index m.
Blocks in a model with asynchronous function-call inputs	Function-call root-level Inport and Outport blocks: F_i	• *F* indicates that it is executed in a function-call context. • *i* is the function-call index.
	Root-level data Inport blocks: If they drive a function-call subsystem, it is the function-call index of the subsystem. If they are part of the model that is not driven by asynchronous function-call inputs, then no function-call index is displayed.	

Block Type	Sorted Order Notation	Description
	Root-level function-call blocks: F_i Root-level branched function-call blocks: $F_i[B_k]$	• F indicates that it is executed in a function-call context. • i is the function-call index.
Blocks inside Export Function Models (See "Execution Order for Function-Call Root-Level Inport Blocks" on page 10-83)	Function-call root-level Inport and Outport blocks: F_i	• F indicates that it is a function-call block. • i is the execution order for the function-call root-level Inport or Outport block in normal simulation mode.
	Root-level function-call subsystems: F_i Root-level branched function-call subsystems: $F_i[B_k]$	• F indicates that it is a function-call block. • i is the execution order for the function-call root-level Inport block in normal simulation mode. • B_k indicates a branched function-call subsystem with index k.
	Merge and Data Store Memory blocks: F_i, F_j, ...	• F indicates that it is a function-call block. • i is the block execution index.
	Root-level data Inport and Outport blocks: Same execution order as the function-call subsystems they are connected to.	
"Bus-Capable Blocks" on page 35-39	s:B	• s is the system index of the model or subsystem the block resides in. For root-level models, s is always 0. • B indicates a bus-capable block.

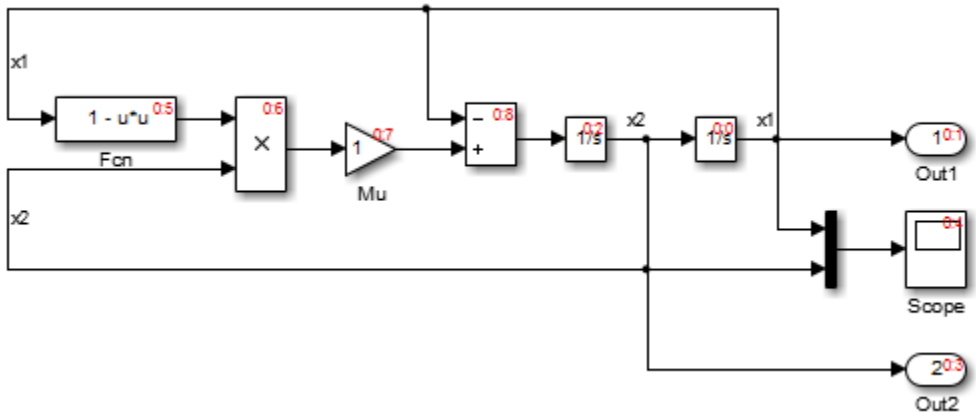
Nonvirtual Blocks

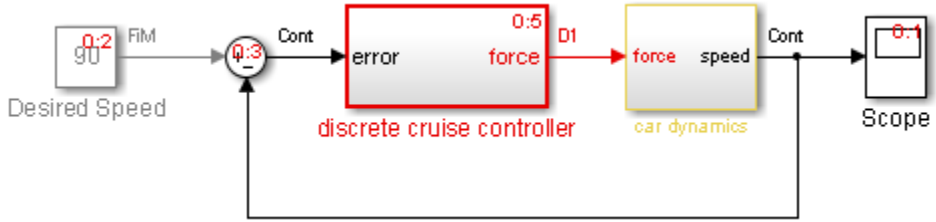
In the van der Pol equation model, all the nonvirtual blocks in the model have a sorted order. The system index for the top-level model is `0`, and the block execution order ranges from `0` to `8`.



Nonvirtual Subsystems

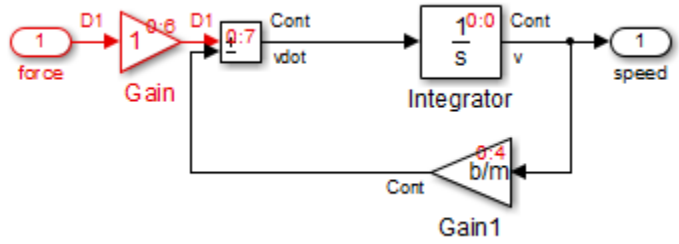
The following model contains an atomic, nonvirtual subsystem named Discrete Cruise Controller.

When you enable the sorted order display for the root-level system, Simulink displays the sorted order of the blocks.



The Scope block in this model has the lowest sorted order, but its input depends on the output of the Car Dynamics subsystem. The Car Dynamics subsystem is virtual, so it

does not have a sorted order and does not execute as an atomic unit. However, the blocks within the subsystem execute at the root level, so the Integrator block in the Car Dynamics subsystem executes first. The Integrator block sends its output to the Scope block in the root-level model, which executes second.

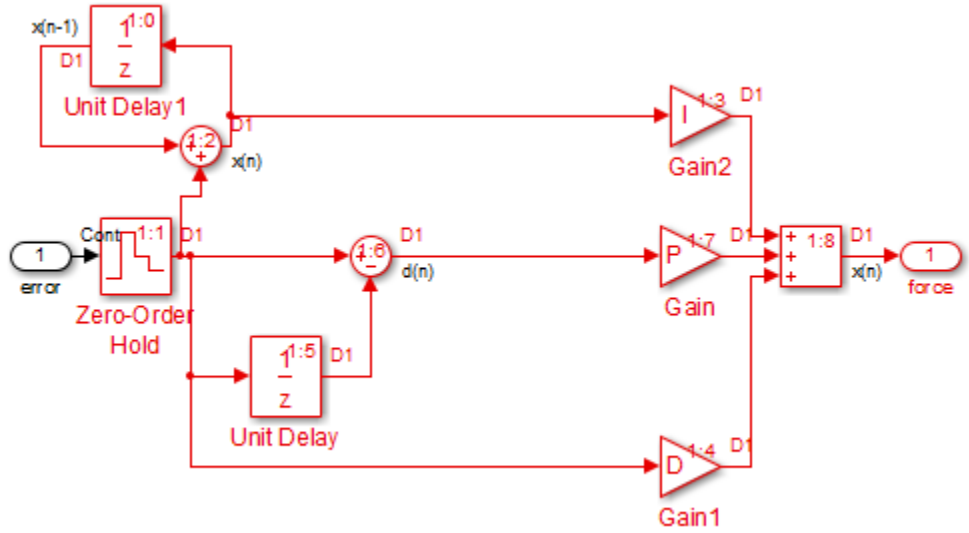


The Discrete Cruise Controller subsystem has a sorted order of `0:5`:

- `0` indicates that this atomic subsystem is part of the root level of the hierarchical system comprised of the primary system and the two subsystems.
- `5` indicates that the atomic subsystem is the sixth block that Simulink executes relative to the blocks within the root level.

The sorted order of each block inside the Discrete Cruise Controller subsystem has the form `1:`*b*, where:

- `1` is the system index for that subsystem.
- *b* is the block position in the execution order. In the Discrete Cruise Controller subsystem, the sorted order ranges from `0` to `8`.



Note Depending on your model configuration, Simulink can insert hidden, nonvirtual subsystems in your model. As a result, the visible blocks inside the hidden subsystem block can have a system index that is different from the current system index. For example, if you select **Conditional input branch execution**, Simulink creates hidden, nonvirtual subsystems, which can affect the sorted execution order.

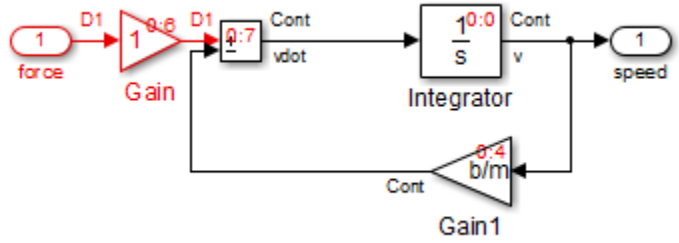
Virtual Blocks and Subsystems

Virtual blocks, such as the Mux block, exist only graphically and do not execute. Consequently, they are not part of the sorted order and do not display any sorted order notation.

Virtual subsystems do not execute as a unit, and like a virtual block, are not part of the sorted order. The blocks inside the virtual subsystem are part of the root-level system sorted order, and therefore share the system index.

In the model in "Nonvirtual Subsystems" on page 35-33, the virtual subsystem Car Dynamics does not have a sorted order. However, the blocks inside the subsystem have a sorted order in the execution context of the root-level model. The blocks have the same system index as the root-level model. The Integrator block inside the Car Dynamics

subsystem has a sorted order of `0:0`, indicating that the Integrator block is the first block executed in the context of the top-level model.

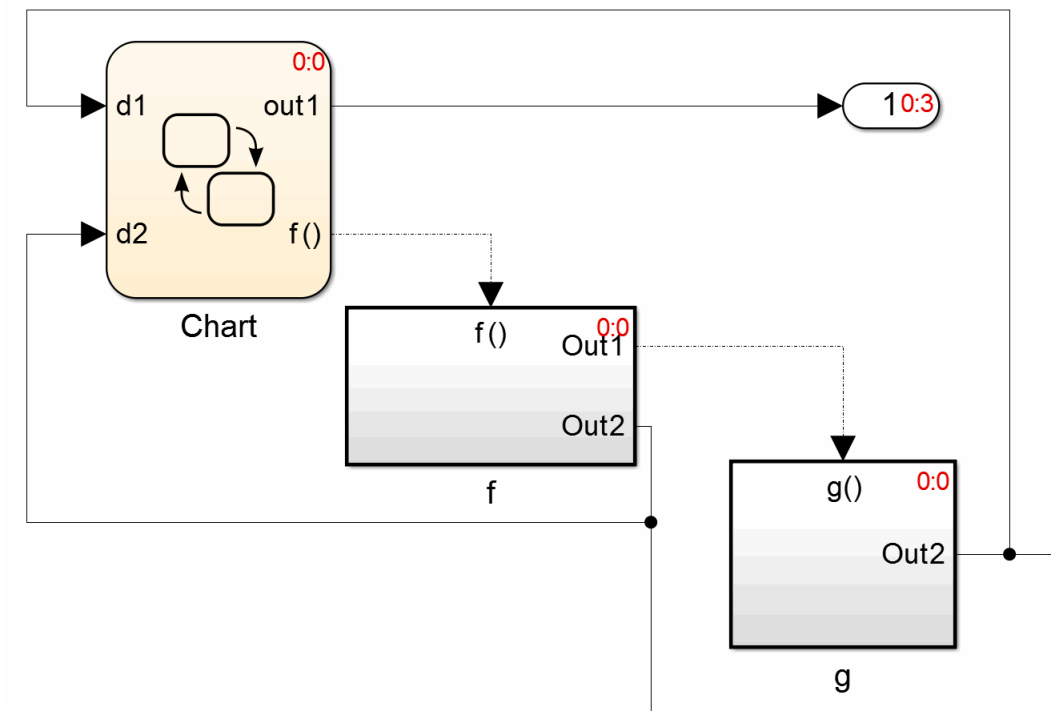


Function-Call Subsystems

Single Initiator

A function-call subsystem (or model) executes when the initiator invokes the function-call subsystem (or model) and, therefore, does not have a sorted order independent of its initiator. Specifically, for a subsystem that connects to one initiator, Simulink uses the notation s`:b`^{i}, where s is the index of the system that contains the initiator and `b`^{i} is the block index of the root initiator in the subsystems hierarchy.

For example, the sorted order for the subsystems f and g is `0:0`, since the sorted order of their root initiator, Chart, is `0:0`.

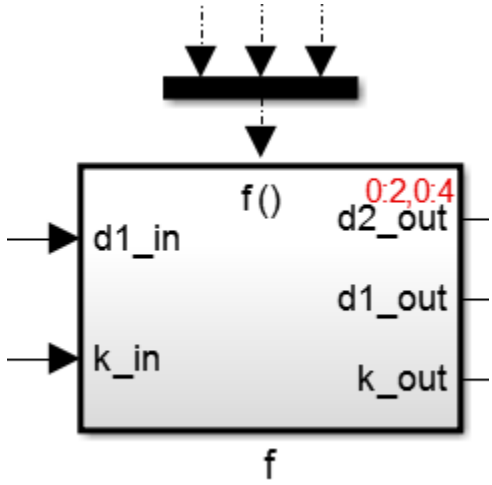


Multiple Initiators

For a function-call subsystem that connects to more than one initiator, the sorted order notation is s:b^{i1}, s:b^{i2}, ..., s:b^{in} where n is the number of non-grounded initiators, s is the system index of the model or subsystem the block resides in, and b^{i_n} is the block index of the n-th root initiator in the subsystem's hierarchy.

For example, open the `sl_subsys_fcncall6` model. The f subsystem has three initiators from the same level in the subsystem's hierarchy. Two are from the Stateflow chart, Chart1, and one from the Stateflow chart, Chart.

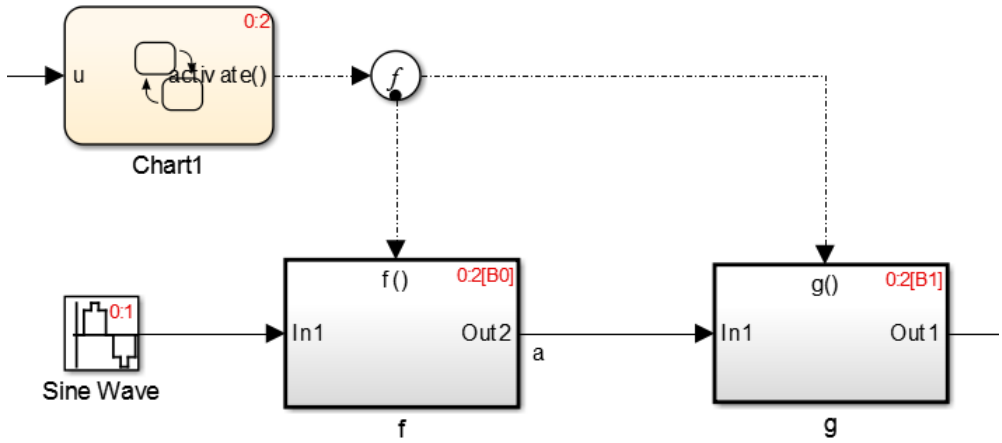
Because Chart1 has a sorted order `0:2` and Chart has a sorted order of `0:4`,the function-call subsystem f has a sorted order notation of `0:2,0:4`.



Branched Function-Call Signals

When a function-call signal is branched using a Function-Call Split block, Simulink displays the order in which subsystems (or models) that connect to the branches execute when the initiator invokes the function call. Simulink uses the notation $s{:}b^i[B_k]$ to indicate this order. s is the system index of the model or subsystem the block resides in, b^i is the block index of the root initiator in the subsystem's hierarchy, and B_k indicates that it is a branched function-call subsystem with branch index k.

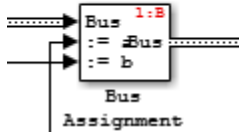
For example, open the `sl_subsys_fncall11` model and display the sorted order. The sorted order indicates that the subsystem f (`B0`) executes before the subsystem g (`B1`).



Bus-Capable Blocks

A bus-capable block does not execute as a unit and therefore does not have a unique sorted order. Such a block displays its sorted order as `s:B` where `B` stands for bus.

For example, open the `sldemo_bus_arrays` model and display the sorted order. Open the For Each Subsystem to see that the sorted order for the Bus Assignment block appears as `1:B`.



For more information, see “Bus-Capable Blocks” on page 65-48.

How Simulink Determines the Sorted Order

Direct-Feedthrough Ports Impact on Sorted Order

To ensure that the sorted order reflects data dependencies among blocks, Simulink categorizes block input ports according to the dependency of the block outputs on the

block input ports. An input port whose current value determines the current value of one of the block outputs is a *direct-feedthrough* port. Examples of blocks that have direct-feedthrough ports include:

- Gain
- Product
- Sum

Examples of blocks that have non-direct-feedthrough inputs:

- Integrator — Output is a function of its state.
- Constant — Does not have an input.
- Memory — Output depends on its input from the previous time step.

Rules for Sorting Blocks

To sort blocks, Simulink uses the following rules:

- If a block drives the direct-feedthrough port of another block, the block must appear in the sorted order ahead of the block that it drives.

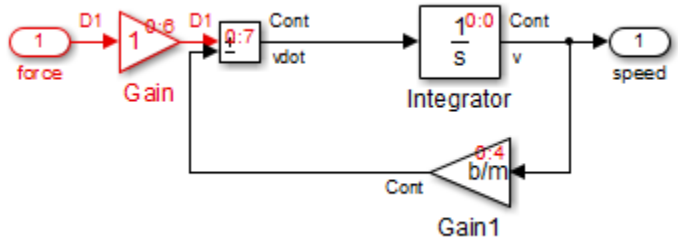
  This rule ensures that the direct-feedthrough inputs to blocks are valid when Simulink invokes block methods that require current inputs.
- Blocks that do not have direct-feedthrough inputs can appear anywhere in the sorted order as long as they precede any direct-feedthrough blocks that they drive.

  Placing all blocks that do not have direct-feedthrough ports at the beginning of the sorted order satisfies this rule. This arrangement allows Simulink to ignore these blocks during the sorting process.

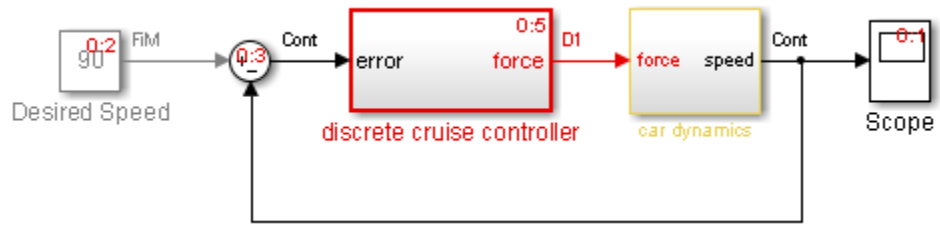
Applying these rules results in the sorted order. Blocks without direct-feedthrough ports appear at the beginning of the list in no particular order. These blocks are followed by blocks with direct-feedthrough ports arranged such that they can supply valid inputs to the blocks which they drive.

The following model, from “Nonvirtual Subsystems” on page 35-33, illustrates this result. The following blocks do not have direct-feedthrough and therefore appear at the beginning of the sorted order of the root-level system:

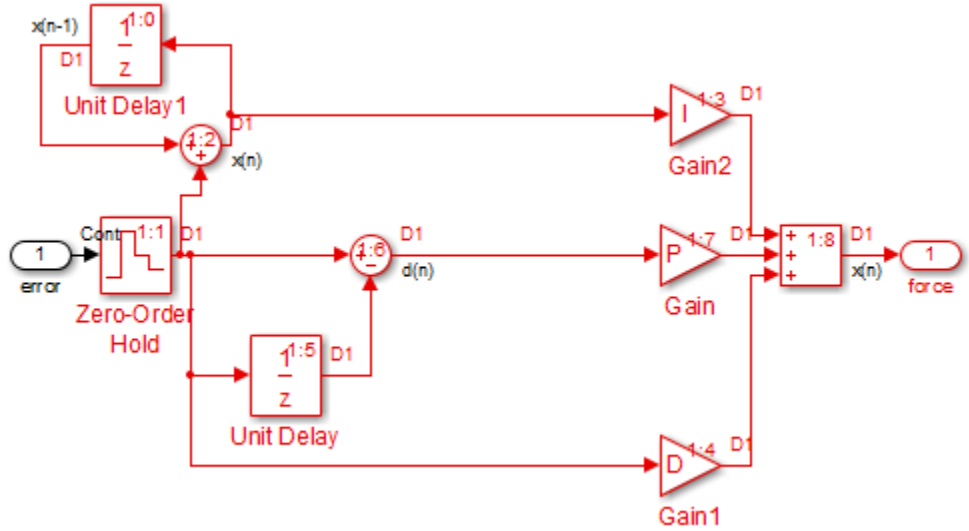
- Integrator block in the Car Dynamics virtual subsystem



- Speed block in the root-level model



Inside the Discrete Cruise Controller subsystem, all the Gain blocks, which have direct-feedthrough ports, run before the Sum block that they drive.



Assign Block Priorities

You can assign a priority to a nonvirtual block or to an entire subsystem. Higher priority blocks appear before lower priority blocks in the sorted order. The lower the number, the higher the priority. Set the block priority in the **General** tab of the Block Properties dialog.

Rules for Block Priorities

Simulink honors the block priorities that you specify unless they violate data dependencies. (“Block Priority Violations” on page 35-45 describes situations that cause block property violations.)

In assessing priority assignments, Simulink attempts to create a sorted order such that the priorities for the individual blocks within the root-level system or within a nonvirtual subsystem are honored relative to one another.

Three rules pertain to priorities:

- “Priorities Are Relative” on page 35-42
- “Priorities Are Hierarchical” on page 35-43
- “Lack of Priority May Not Result in Low Priority” on page 35-44

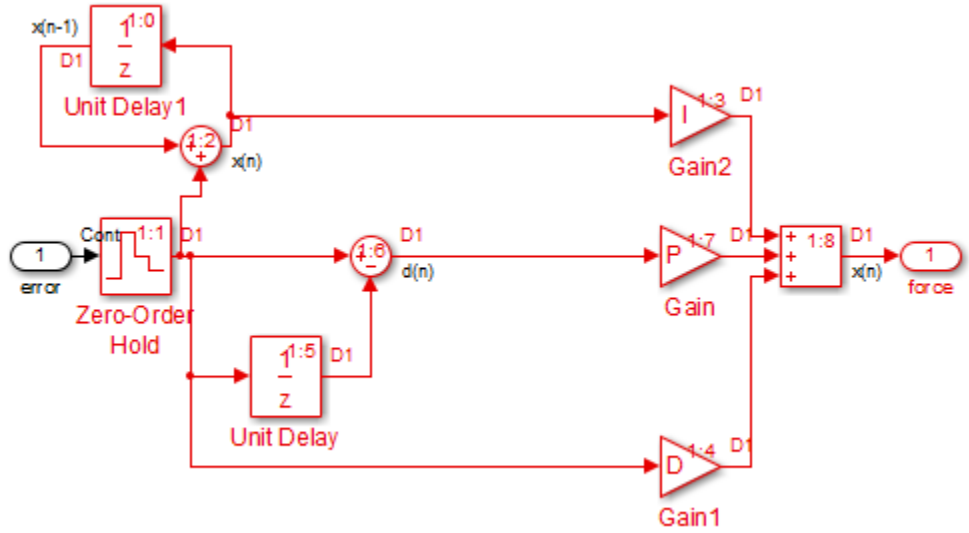
Priorities Are Relative

Priorities are relative; the priority of a block is relative to the priority of the blocks within the same system or subsystem.

For example, suppose you set the following priorities in the Discrete Cruise Controller subsystem in the model in “Nonvirtual Subsystems” on page 35-33.

Block	Priority
Gain	3
Gain1	2
Gain2	1

After updating the diagram, the sorted order for the Gain blocks is as follows.



The sorted order values of the Gain, Gain1, and Gain2 blocks reflect the respective priorities assigned: Gain2 has highest priority and executes before Gain1 and Gain; Gain1 has second priority and executes after Gain2; and Gain executes after Gain1. Simulink takes into account the assigned priorities relative to the other blocks in that subsystem.

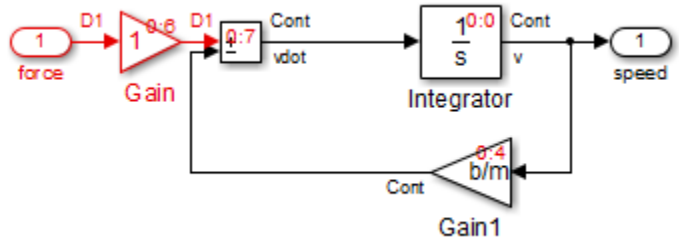
The Gain blocks are not the first, second, and third blocks to execute. Nor do they have consecutive sorted orders. The sorted order values do not necessarily correspond to the priority values. Simulink arranges the blocks so that their priorities are honored relative to each other.

Priorities Are Hierarchical

In the Car Dynamics virtual subsystem, suppose you set the priorities of the Gain blocks as follows.

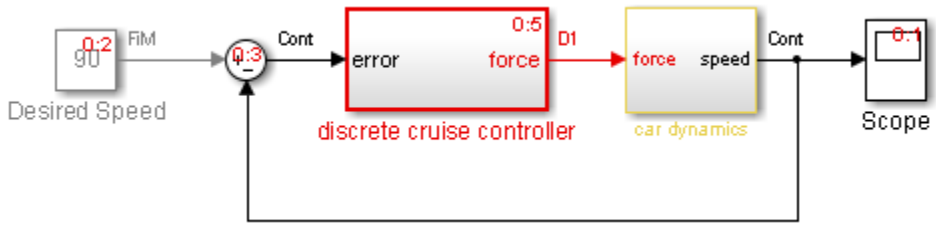
Block	Priority
Gain	2
Gain1	1

After updating the diagram, the sorted order for the Gain blocks is as illustrated. With these priorities, Gain1 always executes before Gain.



You can set a priority of `1` to one block in each of the two subsystems because of the hierarchical nature of the subsystems within a model. Simulink never compares the priorities of the blocks in one subsystem to the priorities of blocks in any other subsystem.

For example, consider this model again.



The blocks within the Car Dynamics virtual subsystem are part of the root-level system hierarchy and are part of the root-level sorted order. The Discrete Cruise Controller subsystem has an independent sorted order with the blocks arranged consecutively from `1:0` to `1:7`.

Lack of Priority May Not Result in Low Priority

A lack of priority does not necessarily result in a low priority (higher sorting order) for a given block. Blocks that do not have direct-feedthrough ports execute before blocks that have direct-feedthrough ports, regardless of their priority.

If a model has two atomic subsystems, A and B, you can assign priorities of `1` and `2` respectively to A and B. This priority causes all the blocks in A to execute before any of the blocks in B. The blocks within an atomic subsystem execute as a single unit, so the subsystem has its own system index and its own sorted order.

Block Priority Violations

Simulink software honors the block priorities that you specify unless they violate data dependencies. If Simulink is unable to honor a block priority, it displays a `Block Priority Violation` diagnostic message.

As an example:

1. Open the `sldemo_bounce` model.

   Notice that the output of the Memory block provides the input to the Coefficient of Restitution Gain block.
2. Set the priority of the Coefficient of Restitution block to `1`, and set the priority of the Memory block to `2`.

   Setting these priorities specifies that the Coefficient of Restitution block execute before the Memory block. However, the Coefficient of Restitution block depends on the output of the Memory block, so the priorities you just set violate the data dependencies.
3. In the model window, enable sorted order by selecting **Format > Block displays > Sorted Order**.
4. Select **Simulation > Update Diagram**.

   The block priority violation warning appears in the **Diagnostic Viewer**. To open the **Diagnostic Viewer** window, click **View > Diagnostic Viewer**. The warning includes the priority for the respective blocks:

   ```
   Warning: Unable to honor user-specified priorities.
   'sldemo_bounce/Memory' (pri=[2]) has to execute
   before 'sldemo_bounce/Coefficient of  Restitution'
    (pri=[1]) to satisfy data dependencies
   ```
5. Remove the priorities from the Coefficient of Restitution and Memory blocks and update the diagram again to see the correct sorted order.

Access Block Data During Simulation

In this section...

About Block Run-Time Objects

Simulink provides an application programming interface, called the block run-time interface, that enables programmatic access to block data, such as block inputs and outputs, parameters, states, and work vectors, while a simulation is running. You can use this interface to access block run-time data from the MATLAB command line, the Simulink Debugger, and from Level-2 MATLAB S-functions (see “Write Level-2 MATLAB S-Functions” in the online Simulink documentation).

Note You can use this interface even when the model is paused or is running or paused in the debugger.

The block run-time interface consists of a set of Simulink data object classes (see “Data Objects” on page 59-53) whose instances provide data about the blocks in a running model. In particular, the interface associates an instance of `Simulink.RunTimeBlock`, called the block's run-time object, with each nonvirtual block in the running model. A run-time object's methods and properties provide access to run-time data about the block's I/O ports, parameters, sample times, and states.

Access a Run-Time Object

Every nonvirtual block in a running model has a RuntimeObject parameter whose value, while the simulation is running, is a handle for the blocks' run-time object. This allows you to use `get_param` to obtain a block's run-time object. For example, the following statement

```
rto = get_param(gcb,'RuntimeObject');
```

returns the run-time object of the currently selected block. Run-time object data is read-only. You cannot use run-time objects to change a block's parameters, input, output, and state data.

Note Virtual blocks (see "Nonvirtual and Virtual Blocks" on page 35-2) do not have run-time objects. Blocks eliminated during model compilation as an optimization also do not have run-time objects (see "Block reduction"). A run-time object exists only while the model containing the block is running or paused. If the model is stopped, `get_param` returns an empty handle. When you stop a model, all existing handles for run-time objects become empty.

Listen for Method Execution Events

One application for the block run-time API is to collect diagnostic data at key points during simulation, such as the value of block states before or after blocks compute their outputs or derivatives. The block run-time API provides an event-listener mechanism that facilitates such applications. For more information, see the documentation for the `add_exec_event_listener` command. For an example of using method execution events, enter

```
sldemo_msfcn_lms
```

at the MATLAB command line. This Simulink model contains the S-function `adapt_lms.m`, which performs a system identification to determine the coefficients of an FIR filter. The S-function's `PostPropagationSetup` method initializes the block run-time object's DWork vector such that the second vector stores the filter coefficients calculated at each time step.

In the Simulink model, double-clicking on the annotation below the S-function block executes its `OpenFcn`. This function first opens a figure for plotting the FIR filter coefficients. It then executes the function `add_adapt_coef_plot.m` to add a `PostOutputs` method execution event to the S-function's block run-time object using the following lines of code.

```
% Add a callback for PostOutputs event
blk = 'sldemo_msfcn_lms/LMS Adaptive';

h   = add_exec_event_listener(blk, ...
         'PostOutputs', @plot_adapt_coefs);
```

The function `plot_adapt_coefs.m` is registered as an event listener that is executed after every call to the S-function's `Outputs` method. The function accesses the block run-time object's DWork vector and plots the filter coefficients calculated in the `Outputs` method. The calling syntax used in `plot_adapt_coefs.m` follows the standard needed for any listener. The first input argument is the S-function's block run-time object, and the second argument is a structure of event data, as shown below.

```
function plot_adapt_coefs(block, ei) %#ok<INUSD>
%
% Callback function for plotting the current adaptive filtering
% coefficients.

stemPlot  = get_param(block.BlockHandle,'UserData');

est = block.Dwork(2).Data;
set(stemPlot(2),'YData',est);
drawnow('expose');
```

Synchronizing Run-Time Objects and Simulink Execution

You can use run-time objects to obtain the value of a block output and display in the MATLAB Command Window by entering the following commands.

```
rto = get_param(gcb,'RuntimeObject')
rto.OutputPort(1).Data
```

However, the displayed data may not be the true block output if the run-time object is not synchronized with the Simulink execution. Simulink only ensures the run-time object and Simulink execution are synchronized when the run-time object is used either within a Level-2 MATLAB S-function or in an event listener callback. When called from the MATLAB Command Window, the run-time object can return incorrect output data if other blocks in the model are allowed to share memory.

To ensure the `Data` field contains the correct block output, open the Configuration Parameters dialog box, and then clear the **Signal storage reuse** check box (see “Signal storage reuse”).

Working with Block Parameters

Set Block Parameter Values

Blocks have numeric parameters that determine how they calculate output values. To control the calculations that blocks perform, you can specify parameter values. For example, a Gain block has a **Gain** parameter, and a Transfer Fcn block has multiple parameters that represent the transfer function coefficients.

You can use numbers, variables, and expressions to set block parameter values. Choose a technique based on your modeling goals. For example, you can:

- Share parameter values between blocks and models by creating variables.
- Control parameter characteristics such as data type and dimensions by creating parameter objects.
- Model an algorithm as code by using mathematical expressions.

Set block parameters using the Model Data Editor (**View > Model Data**) **Parameters** tab, the Property Inspector (**View > Property Inspector**), or the block dialog box. For more information, see "Setting Properties and Parameters" on page 1-50. To set block sample times, see "Specify Sample Time" on page 7-3.

Tip You can use the Model Explorer to make batch changes to many block parameter values at once. For more information, see "Search and Edit Using Model Explorer" on page 12-2.

Programmatically Access Parameter Values

To programmatically access block parameter values, use the `get_param` and `set_param` functions. You can use this technique to:

- Construct a model programmatically.
- Adjust parameter values during a simulation run when you simulate a model programmatically.

To sweep parameter values between simulation runs by using a script, use `Simulink.SimulationInput` objects instead of `get_param` and `set_param`. See "Optimize, Estimate, and Sweep Block Parameter Values" on page 36-48.

Suppose you create a model named `myModel` that contains a Constant block named My Constant. Next, you use the block dialog box to set the **Constant value** parameter to `15`.

To programmatically return the parameter value, use the function `get_param`. You specify the block path and the equivalent programmatic parameter name, `Value`.

```
paramValue = get_param('myModel/My Constant','Value')
```

```
paramValue =
```

```
15
```

To programmatically change the value, for example to `25`, use the function `set_param`. Use the character vector `'25'` as the input to the function.

```
set_param('myModel/My Constant','Value','25')
```

For a list of programmatic names of block parameters, see "Block-Specific Parameters".

For more information about programmatic simulation, see "Run Simulations Programmatically" on page 25-2.

To avoid using the `get_param` and `set_param` functions, use the name of a MATLAB variable or `Simulink.Parameter` object as the parameter value, and change the value of the variable or object at the command prompt. See "Share and Reuse Block Parameter Values by Creating Variables" on page 36-12.

Specify Parameter Values

Goal	Block Parameter Value	Description

Store the parameter value in the model file.	`2.3`
	
	`[1.2 2.3 4.5; 7.9 8.7 6.5]`
	
	`2 + 3i`
		Literal numeric value. Specify a scalar, vector, matrix, or multidimensional array. Use `i` to specify complex values.

Goal	Block Parameter Value	Description
• Access the parameter value without having to locate or identify the block in the model. • Change the parameter value without having to modify the model file. • Share the parameter value between blocks or between models. • Identify the parameter by a specific name when sweeping or tuning the value.	`myVar`	MATLAB variable that exists in a workspace. For more information, see "Share and Reuse Block Parameter Values by Creating Variables" on page 36-12.
• Avoid name clashes between workspace variables. • Organize parameter values using hierarchies and meaningful names. • Reduce the number of workspace variables that a model uses.	`myParam.a.SpeedVect`	Field of parameter structure. For more information, see "Organize Related Block Parameter Definitions in Structures" on page 36-22.
Use a portion of a matrix or array variable. For example, set the parameters of a n-D Lookup Table block.	`myMatrixParam(:,2)`	Index operation.

Goal	Block Parameter Value	Description
• Define parameter characteristics, such as data type, complexity, units, allowed value range, and dimensions, separately from the parameter value. • Define a system constant with custom documentation. • Create a tunable parameter in the generated code.	`myParam`	Parameter object. For more information, see "Use Parameter Objects" on page 36-6.

• Model a complicated algorithm or subroutine by using code instead of blocks.
• Reduce block population in a model.
• Use MATLAB operators and functions to perform calculations in a model.
• Write a custom MATLAB function that calculates parameter values.
	`5^3.2 - 1/3`
	
	`myParam * myOtherparam + sin(0.78*pi)`
	
	`myFun(15.23)`
		Expression or custom function.
		
		For more information, see "Use MATLAB Functions and Custom Functions" on page 36-6.

Specify a block parameter value by using a data type other than `double`.	`15.23`
	
	`single(15.23)`
	
	`myParam`
		Typed or untyped expression, numeric MATLAB variable, or parameter object.
		
		For more information about controlling parameter data types, see "Control Block Parameter Data Types" on page 36-55.

Use Parameter Objects

Parameter objects are `Simulink.Parameter` objects and objects of the subclasses that you create. The parameter object exists in a workspace such as the base workspace or a data dictionary.

You can use parameter objects to define system constants. For example, use a parameter object to represent the radius of the Earth. Use the properties of the object to specify the physical units and to document the purpose of the value.

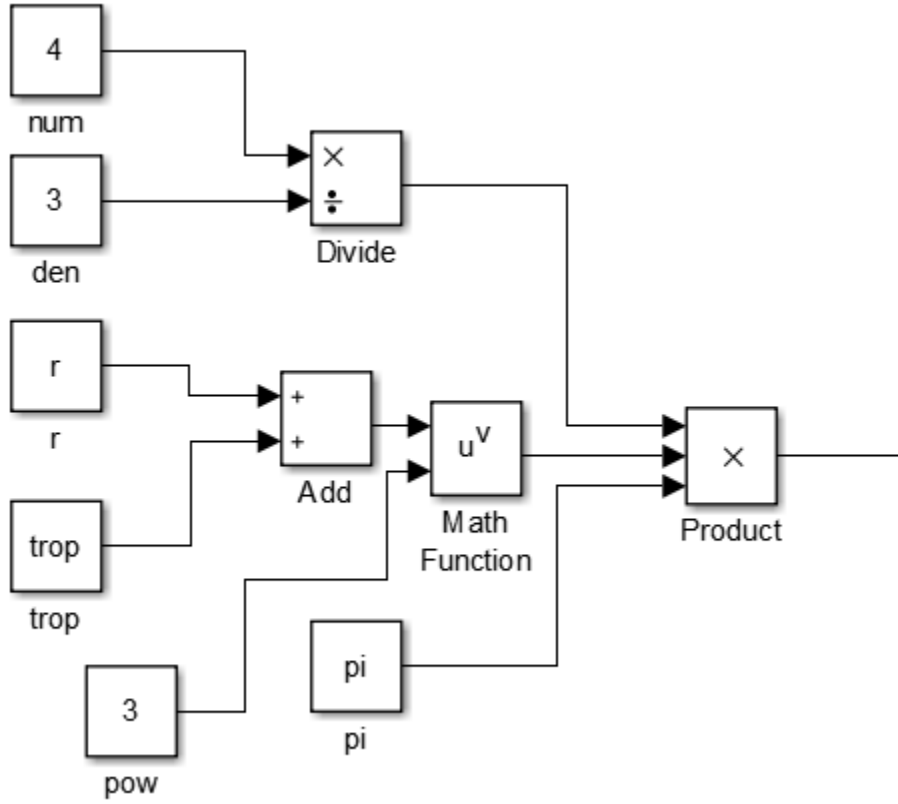
Create parameter objects to prepare your model for code generation. You can configure parameter objects to appear as tunable global variables in the generated code. You can also control the parameter data type through the object.

To create and use parameter objects in models, see “Data Objects” on page 59-53. For information about using variables to set block parameter values, see “Share and Reuse Block Parameter Values by Creating Variables” on page 36-12.

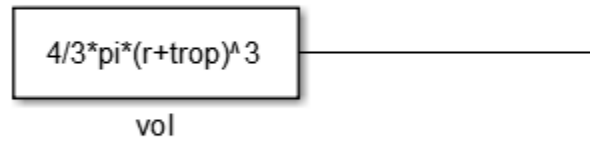
Use MATLAB Functions and Custom Functions

You can set a block parameter value to an expression that calls MATLAB functions and operators such as `sin` and `max`. You can also call your own custom functions that you write on the MATLAB path.

Suppose that a section of your block algorithm uses variables to calculate a single constant number used by the rest of the algorithm. You can perform the calculation by creating multiple blocks.



Instead, create a single Constant block that uses an expression written in MATLAB code. This technique reduces the size of the block algorithm and improves readability.



You can model a complicated portion of an algorithm by using an expression instead of many blocks. To operate on an existing signal, use a mathematical expression as the value of a parameter in an algorithmic block, such as the **Gain** parameter of a Gain block.

With expressions, you can also call your custom functions to set block parameter values. Suppose that you write a MATLAB function that calculates optimal P, I, and D parameters for a control algorithm by accepting a single input number.

paramFcn.m

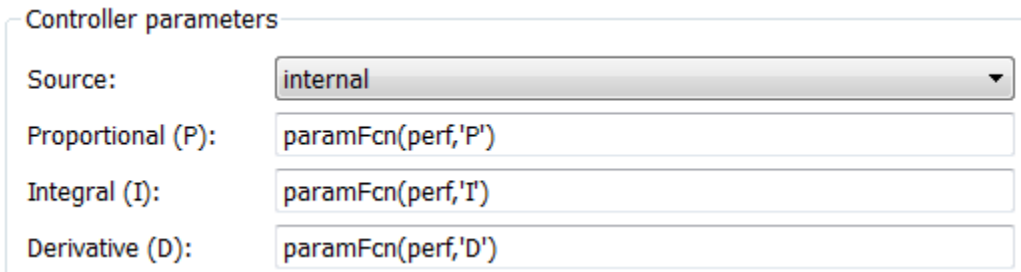
```
function paramValue = paramFcn(performance,parameter)
%PARAMVALUE = paramFcn(PERFORMANCE,PARAMETER) returns the P, I, or D
%value PARAMVALUE that you request using PARAMETER. Specify performance
%criteria using PERFORMANCE.

% Initialize output.
paramValue = [];

% Calculate parameter value.
switch parameter
    case 'P'
        paramValue = performance*3;
    case 'I'
        paramValue = sqrt(performance)/0.175;
    case 'D'
        paramValue = performance^0.25;

% Validation
```

You can parameterize a PID Controller block by using the function to set the parameter values.



To navigate to the documentation for a function, use the button ⋮ next to the parameter value. You can also navigate to the source code of a custom function.

Considerations for Other Modeling Goals

Choose a technique to set block parameter values based on your modeling goals.

Goal	Features or Products	Best Practice
Run multiple simulations quickly.	`Simulink.SimulationInput` objects and the `sim` function	Use variables or parameter objects to set block parameter values. This technique helps you to assign meaningful names to the parameters and to avoid having to identify or locate the blocks in the model. See "Optimize, Estimate, and Sweep Block Parameter Values" on page 36-48.
Sweep parameter values during testing.	Simulink Test™	Use variables or parameter objects to set block parameter values. Use iterations and parameter overrides to run multiple tests. See "Parameter Overrides" (Simulink Test) and "Run Combinations of Tests Using Iterations" (Simulink Test).
Estimate and optimize parameter values.	Simulink Design Optimization™	Use variables or parameter objects to set block parameter values. To estimate or optimize a parameter that uses a data type other than `double`, use a parameter object to separate the value from the data type. For parameter estimation, see "Parameter Estimation" (Simulink Design Optimization). For response optimization, see "Optimize Model Response" (Simulink Design Optimization).
Generate code from a model. Simulate an external program through SIL/PIL or External mode simulations.	Simulink Coder	Use parameter objects to set block parameter values. This technique helps you to declare and identify tunable parameters in the generated code and to control parameter data types. See "Block Parameter Representation in the Generated Code" (Simulink Coder). When you use expressions to set block parameter values, avoid using operators and functions that result in loss of tunability in the generated code. See "Tunable Expression Limitations" (Simulink Coder).

Share and Reuse Block Parameter Values by Creating Variables

To set a block parameter value, such as the **Gain** parameter of a Gain block, you can use numeric variables that you create and store in workspaces such as the base workspace, a model workspace, or a Simulink data dictionary. You can use the variable to set multiple parameter values in multiple blocks, including blocks in different models. To change the values of the block parameters, you change the value of the variable in the workspace.

Using a variable to set a block parameter value also enables you to:

- Change the parameter value without having to modify the model file (if you store the variable outside the model workspace).
- Identify the parameter by a specific, meaningful name when sweeping or tuning the value.

For basic information about setting block parameter values, see “Set Block Parameter Values” on page 36-2.

Reuse Parameter Values in Multiple Blocks and Models

You can create a numeric MATLAB variable in a workspace, such as the base workspace or a data dictionary, and use it to specify one or more block parameter values.

The example model `sldemo_fuelsys` represents the fueling system of a gasoline engine. A subsystem in the model, `feedforward_fuel_rate`, calculates the fuel demand of the engine by using the constant number `14.6`, which represents the ideal (stoichiometric) ratio of air to fuel that the engine consumes. Two blocks in the subsystem use the number to set the values of parameters. In this example, to share the number between the blocks, you create a variable named `myParam`.

1. Open the model.

   ```
   sldemo_fuelsys
   ```

2. In the model, select **View** > **Model Data**. In the Model Data Editor, inspect the **Parameters** tab.
3. In the model, navigate into the subsystem.

   ```
   open_system(...
       'sldemo_fuelsys/fuel_rate_control/fuel_calc/feedforward_fuel_rate')
   ```

4. In the Model Data Editor, in the **Filter contents** box, enter `14.6`.

   The data table contains two rows, which correspond to the **Constant value** parameters of two of the Constant blocks in the subsystem.
5. Use the **Value** column to replace the literal number `14.6` with `myParam`. Perform the replacement for both parameters.
6. In the **Filter contents** box, enter `myParam`.
7. While editing the value of one of the parameters, click the action button ⋮ and select **Create**.
8. In the **Create New Data** dialog box, set **Value** to `14.6` and click **Create**.

   The variable, `myParam`, appears in the base workspace.

Because the variable exists in the base workspace, you can use it in multiple models. However, when you end your MATLAB session, you lose the contents of the base workspace. Consider permanently storing the variable in a model workspace or data dictionary.

Define a System Constant

To define a system constant, such as a variable that represents the radius of the Earth, consider creating a `Simulink.Parameter` object instead of a numeric MATLAB variable. Parameter objects allow you to specify physical units and custom documentation as well as other characteristics.

To create and use parameter objects in models, see “Data Objects” on page 59-53.

Control Scope of Parameter Values

The scope of a variable is the set of models and blocks that can use the variable. For example, variables that you create in the base workspace have global scope because all blocks in all open models can use the variables. Variables that you store in a model workspace have limited scope because only the blocks in the host model can use the variables.

You cannot create two variables that have the same name in the same scope. Controlling the scope of a variable helps you to avoid name conflicts and establish clear ownership of the variable.

The table describes the different ways that you can control the scope of a reusable parameter value.

Scope	Technique
All open models	Create a variable in the base workspace.
One or more targeted models	Create a variable in a data dictionary. To reuse the variable in multiple models, create a referenced dictionary. See "What Is a Data Dictionary?" on page 63-2
One model, including all subsystems in the model	Create a variable in the model workspace. See "Model Workspaces" on page 59-124.
Multiple blocks inside a subsystem, including blocks in nested subsystems	Mask the subsystem and create a mask parameter instead of a workspace variable. To prevent blocks inside a subsystem from using workspace variables, in the subsystem block dialog box, set **Permit Hierarchical Resolution** to `None`. This technique allows you to use the same name to create both a variable in a workspace and a mask parameter in the subsystem mask. The blocks in the subsystem can use only the mask parameter. For information about subsystems, see Subsystem. For information about masking, see "Masking Fundamentals" on page 38-2.

To avoid name conflicts when you have a large model with many variables in the same scope, consider packaging the variables into a single structure. For more information, see "Organize Related Block Parameter Definitions in Structures" on page 36-22.

For basic information about how blocks use the variable names that you specify, see "Symbol Resolution" on page 59-136.

Permanently Store Workspace Variables

Variables that you create in the base workspace do not persist between MATLAB sessions. However, you can store the variables in a MAT-file or script file, and load the file whenever you open the model using a model callback. A model callback is a set of commands that Simulink executes when you interact with a model in a particular way, such as opening the model. You can use a callback to load variables when you open the model. Use this technique to store variables while you learn about Simulink and experiment with models.

1. In a model that contains a Gain block, set the value of the **Gain** parameter to `K`.
2. At the command prompt, create a variable `K` in the base workspace.

   ```
   K = 27;
   ```

3. In the Workspace browser, right-click the variable and select **Save As**.

   To save multiple variables in one file, select all of the target variables in the Workspace browser, and then right-click any of the selected variables.
4. In the dialog box, set **Save as type** to `MATLAB Script`. Set **File name** to `loadvar` and click **Save**.

   The script file `loadvar.m` appears in your current folder. You can open the file to view the command that creates the variable `K`.
5. In the model, select **File** > **Model Properties** > **Model Properties**.
6. In the **Callbacks** tab of the Model Properties dialog box, select `PreLoadFcn` as the callback that you want to define. In the **Model pre-load function** pane, enter `loadvar` and click **OK**.
7. Save the model.

The next time that you open the model, the `PreloadFcn` callback loads the variable `K` into the base workspace. You can also save the variable to a MAT-file, for example `loadvar.mat`, and set the model callback to `load loadvar`.

To learn about callbacks, see “Callbacks for Customized Model Behavior” on page 4-44 and “Callbacks for Customized Model Behavior” on page 4-44. To programmatically define a callback for loading variables, see “Programmatically Store Workspace Variables for a Model” on page 36-16.

When you save variables to a file, you must save the changes that you make to the variables during your MATLAB session. To permanently store variables for a model,

consider using a model workspace or a data dictionary instead of a MAT-file or script file. For more information about permanently storing variables, see “Determine Where to Store Variables and Objects for Simulink Models” on page 59-96.

Programmatically Store Workspace Variables for a Model

In the example above, you define a model callback that creates variables when you open a model. You can programmatically save the variable and set the model callback.

1. At the command prompt, create the variable `K` in the base workspace.

   ```
   K = 27;
   ```

2. Save the variable to a new script file named `loadvar.m`.

   ```
   matlab.io.saveVariablesToScript('loadvar.m','K')
   ```

3. Set the model callback to load the script file.

   ```
   set_param('mymodel','PreloadFcn','loadvar')
   ```

4. Save the model.

   ```
   save_system('myModel')
   ```

The function `matlab.io.saveVariablesToScript` saves variables to a script file. To save variables to a MAT-file, use the function `save`. To programmatically set model properties such as callbacks, use the function `set_param`.

Manage and Edit Workspace Variables

When you use variables to set block parameter values, you store the variables in a workspace or data dictionary. You can use the command prompt, the Model Explorer, and the Model Data Editor to create, move, copy, and edit variables. You can also determine where a variable is used in a model, list all of the variables that a model uses, and list all of the variables that a model does not use. For more information, see “Create, Edit, and Manage Workspace Variables” on page 59-105.

Package Shared Breakpoint and Table Data for Lookup Tables

To share breakpoint vectors or table data between multiple n-D Lookup Table, Prelookup, and Interpolation Using Prelookup blocks, consider storing the data in `Simulink.LookupTable` and `Simulink.Breakpoint` objects instead of MATLAB variables or `Simulink.Parameter` objects. This technique improves model readability

by clearly identifying the data as parts of a lookup table and explicitly associating breakpoint data with table data.

Store Standalone Lookup Table in Simulink.LookupTable Object

A standalone lookup table consists of a set of table data and one or more breakpoint vectors. You do not share the table data or any of the breakpoint vectors with other lookup tables.

When you share a standalone lookup table, you use all of the table and breakpoint data together in multiple n-D Lookup Table blocks. To store this data in a `Simulink.LookupTable` object:

1. Create the object in a workspace or data dictionary. For example, at the command prompt, enter:

   ```
   myLUTObj = Simulink.LookupTable;
   ```

2. Use the properties of the object to store the values of the table and breakpoint data.
3. Use the properties of the object to configure a unique name for the structure type in the generated code. In the property dialog box, under **Struct Type definition**, specify **Name**.
4. In the n-D Lookup Table blocks, set **Data specification** to `Lookup table object`.
5. To the right of **Data specification**, set **Name** to the name of the `Simulink.LookupTable` object.

For ways to create and configure `Simulink.LookupTable` objects, see `Simulink.LookupTable`

Store Shared Data in Simulink.LookupTable and Simulink.Breakpoint Objects

When you use Prelookup and Interpolation Using Prelookup blocks to more finely control the lookup algorithm, you can share breakpoint vectors and sets of table data. For example, you can share a breakpoint vector between two separate sets of table data. With this separation of the breakpoint data from the table data, you can share individual parts of a lookup table instead of sharing the entire lookup table.

To store breakpoint and table data:

1. Create a `Simulink.LookupTable` object for each unique set of table data. Create a `Simulink.Breakpoint` object for each unique breakpoint vector, including breakpoint vectors that you do not intend to share.

2. Use the properties of the objects to store the values of the table and breakpoint data.
3. Configure the `Simulink.LookupTable` objects to refer to the `Simulink.Breakpoint` objects for breakpoint data. In the `Simulink.LookupTable` objects, set **Specification** to `Reference`. Specify the names of the `Simulink.Breakpoint` objects.
4. In the Interpolation Using Prelookup blocks, set **Specification** to `Lookup table object`. Set **Name** to the name of a `Simulink.LookupTable` object.

   In the Prelookup blocks, set **Specification** to `Breakpoint object`. Set **Name** to the name of a `Simulink.Breakpoint` object.

The example model `fxpdemo_lookup_shared_param` contains two Prelookup and two Interpolation Using Prelookup blocks. Configure the blocks so that each combination of a Prelookup and an Interpolation Using Prelookup block represents a unique lookup table. Share the breakpoint vector between the two lookup tables. In this case, each lookup table has unique table data but shared breakpoint data.

1. Open the example model.
2. In the Prelookup block dialog box, set **Specification** to `Breakpoint object`. Set **Name** to `sharedBkpts`.
3. Click the button ⋮ next to the value of the **Name** parameter. Select **Create Variable**.
4. In the **Create New Data** dialog box, set **Value** to `Simulink.Breakpoint` and click **Create**.

   A `Simulink.Breakpoint` object appears in the base workspace.
5. In the property dialog box for `sharedBkpts`, specify **Value** as a vector such as `[1 2 3 4 5 6 7 8 9 10]`. Click **OK**.
6. In the Prelookup block dialog box, click **OK**.
7. In the Prelookup1 block dialog box, set **Specification** to `Breakpoint object`. Set **Name** to `sharedBkpts`.
8. In the Interpolation Using Prelookup block dialog box, set **Specification** to `Lookup table object`. Set **Name** to `dataForFirstTable`.
9. Click the button ⋮ next to the value of the **Name** parameter. Select **Create Variable**.

10 In the **Create New Data** dialog box, set **Value** to `Simulink.LookupTable` and click **Create**.

   A `Simulink.LookupTable` object appears in the base workspace.

11 In the property dialog box for `dataForFirstTable`, specify **Value** as a vector, such as `[10 9 8 7 6 5 4 3 2 1]`.

12 Set **Specification** to `Reference`.

13 In the table under **Specification**, set **Name** to `sharedBkpts` and click **OK**.

14 In the Interpolation Using Prelookup block dialog box, click **OK**.

15 Configure the Interpolation Using Prelookup1 block to use a `Simulink.LookupTable` object named `dataForSecondTable`. In the object property dialog box, specify **Value** as a vector, such as `[0 0.5 1 1.5 2 2.5 3 3.5 4 4.5]`. Configure the object to refer to `sharedBkpts` for the breakpoint data.

The model now represents two unique lookup tables:

- A combination of `sharedBkpts` and `dataForFirstTable`.
- A combination of `sharedBkpts` and `dataForSecondTable`.

These lookup tables share the same breakpoint data through `sharedBkpts`.

Parameter Interfaces for Reusable Components

You can use subsystems, referenced models, and custom library blocks as reusable components in other models. For guidelines to help you decide how to componentize a system, see “Componentization Guidelines” on page 15-29.

Typically, a reusable algorithm requires that numeric block parameters, such as the **Gain** parameter of a Gain block, either:

- Use the same value in all instances of the component.
- Use a different value in each instance of the component. Each value is instance specific.

By default, if you use a literal number or expression to set the value of a block parameter, the parameter uses the same value in all instances of the component. If you set multiple block parameter values by using a MATLAB variable, `Simulink.Parameter` object, or other parameter object in a workspace or data dictionary, these parameters also use the same value in all instances of the component.

Referenced Models

If you use model referencing to create a reusable component, to set parameter values that are specific to each instance, configure model arguments for the referenced model. When you instantiate the model by adding a Model block to a different model, you set the values of the arguments in the Model block. When you add another Model block to the same parent model or to a different model, you can set different values for the same arguments. Optionally, if you create more than two instances, you can set the same value for some of the instances and different values for the other instances.

If a model has many model arguments, consider packaging the arguments into a single structure. Instead of configuring many arguments, configure the structure as a single argument. Without changing the mathematical functionality of the component, this technique helps you to reduce the number of model argument values that you must set in each instance of the component.

For more information about model arguments, see “Parameterize Instances of a Reusable Referenced Model” on page 8-72.

Subsystems

If you use subsystems or custom libraries to create reusable components, to set parameter values that are specific to each instance, use masks, mask parameters, and parameter promotion. When you instantiate the component in a model, you set the values of the mask parameters in the Subsystem block. When you instantiate the component again in the same model or a different model, you can set different values for the same mask parameters. Optionally, if you create more than two instances, you can set the same value for some of the instances and different values for the other instances.

If the subsystem has many mask parameters, consider packaging the parameters into a single structure. Instead of configuring many mask parameters, configure the structure as a single parameter. Without changing the mathematical functionality of the component, this technique helps you to reduce the number of mask parameter values that you must set in each instance of the component.

For more information about subsystems, see Subsystem. For more information about custom block libraries, see “Create a Custom Block” on page 39-19. For more information about masks, see “Masking Fundamentals” on page 38-2. For more information about structures, see “Organize Related Block Parameter Definitions in Structures” on page 36-22.

Organize Related Block Parameter Definitions in Structures

When you use numeric MATLAB variables to set block parameter values in a model, large models can accumulate many variables, increasing the effort of maintenance and causing the variable names to grow in length.

Instead, you can organize these parameter values into structures. Each structure is a single variable and each field of the structure stores a numeric parameter value. You can assign meaningful names to the structures, substructures, and fields to indicate the purpose of each value.

Use structures to:

- Reduce the number of workspace variables that you must maintain.
- Avoid name conflicts between workspace variables.

  You cannot create two variables that have the same name in the same scope, such as in the base workspace. When you create structures, you must provide each field a name, but multiple structures can each contain a field that uses the same name. Therefore, you can use each structure and substructure as a namespace that prevents the field names from conflicting with each other and with other variable names in the same scope.
- Logically group sets of block parameter values. For example, use nested structures to clearly identify the parameter values that each subsystem or referenced model uses.

If you use mask parameters or model arguments to pass parameter values to the components of a system, you can use structures to reduce the number of individual mask parameters or model arguments that you must maintain. Instead of passing multiple variables, you can pass a single structure variable.

For basic information about creating and manipulating MATLAB structures, see Structures (MATLAB). For basic information about setting block parameter values in a model, see “Set Block Parameter Values” on page 36-2.

To use structures to initialize bus signals, see “Specify Initial Conditions for Bus Signals” on page 65-108.

Create and Use Parameter Structure

This example shows how to create and use a parameter structure in a model.

The example model `f14` uses multiple variables from the base workspace to set block parameter values. For example, when you open the model, it creates the variables `Zw`, `Mw`, and `Mq` in the base workspace. To organize these variables into a single structure variable:

1. At the command prompt, open the example model.

   ```
   f14
   ```

2. At the command prompt, create the parameter structure `myGains`. Set the field values by using the values of the target variables.

   ```
   myGains.Zw = Zw;
   myGains.Mw = Mw;
   myGains.Mq = Mq;
   ```

3. In the Model Explorer, on the **Model Hierarchy** pane, click **Base Workspace**. In the **Contents** pane, right-click the variable `Mq` and select **Find Where Used**.

4. In the **Select a system** dialog box, click the node **f14** and click **OK**. Click **OK** when asked about updating the diagram.

5. In the **Contents** pane, right-click the row corresponding to the block labeled Gain1 and select **Properties**. The Gain1 block dialog box opens.

6. Change the value of the **Gain** parameter from `Mq` to `myGains.Mq` and click **OK**.

7. In the **Contents** pane, right-click the row corresponding to the Transfer Fcn.1 block and select **Properties**.

8. Change the value of the **Denominator coefficients** parameter from `[1,-Mq]` to `[1,-myGains.Mq]` and click **OK**.

9. In the **Model Hierarchy** pane, click **Base Workspace**. Use **Find Where Used** to locate the blocks that use the variables `Mw` and `Zw`. In the block dialog boxes, replace the references to the variable names according to the table.

Variable Name	Replacement Name
`Mw`	`myGains.Mw`
`Zw`	`myGains.Zw`

10. Clear the old variables.

    ```
    clear Zw Mw Mq
    ```

Each of the modified block parameters now uses a field of the `myGains` structure. The numeric value of each structure field is equal to the value of the corresponding variable that you cleared.

You can use the functions `Simulink.BlockDiagram.createVarStruct` and `Simulink.BlockDiagram.applyVarStruct` to migrate a model to use a single parameter structure instead of multiple workspace variables. For an example, see "Migration to Structure Parameters".

Store Data Type Information in Field Values

To use a structure or array of structures to organize parameter values that use a data type other than `double`, you can explicitly specify the type when you create the structure. When you create the structure, use typed expressions such as `single(15.23)` to specify the field values.

```
myParams.Gain = single(15.23);
```

If you want to change the field value later, you must remember to explicitly specify the type again. If you do not specify the type, the field value uses the data type `double` instead:

```
myParams.Gain = 15.23;
% The field 'Gain' now uses the data type 'double' instead of 'single'.
```

To preserve the type specification, you can use subscripted assignment to assign a new value to the field:

```
% Assign value of type 'single'.
myParams.Gain = single(15.23);

% Assign new value while retaining type 'single'.
myParams.Gain(:) = 11.79;
```

To match a fixed-point data type, set the field value by using an `fi` object.

Control Field Data Types and Characteristics by Creating Parameter Object

A `Simulink.Parameter` object allows you to separate the value of a block parameter from its data type. If you use a parameter object to store a structure or array of

structures, you can create a `Simulink.Bus` object to use as the data type of the entire structure.

You can use the bus object and the parameter object to explicitly control:

- The data type of each field. When you use this technique, you do not have to remember to use typed expressions or subscripted assignment to set the field values.
- The complexity, dimensions, and units of each field.
- The minimum and maximum value of each field if the field represents a tunable parameter value.
- The shape of the entire structure. The shape of the structure is the number, names, and hierarchy of fields.
- The tunability of the structure in the code that you generate from the model.

1. Create a parameter structure `myParams`.

```
myParams = struct(...
    'SubsystemA',struct(...
        'Gain',15.23,...
        'Offset',89,...
        'Init',0.59),...
    'SubsystemB',struct(...
        'Coeffs',[5.32 7.99],...
        'Offset',57,...
        'Init1',1.76,...
        'Init2',2.76)...
);
```

2. Use the function `Simulink.Bus.createObject` to create `Simulink.Bus` objects that represent the structure and substructures.

```
Simulink.Bus.createObject(myParams)
```

   Because `myParams` contains two unique substructures, the function creates three `Simulink.Bus` objects: one named `slBus1` to represent the parent structure `myParams`, one named `SubsystemA` for the substructure `SubsystemA`, and one named `SubsystemB` for the substructure `SubsystemB`.

3. Rename the bus object `slBus1` as `myParamsType`.

```
myParamsType = slBus1;
clear slBus1
```

4. Store the structure `myParams` in a `Simulink.Parameter` object.

```
myParams = Simulink.Parameter(myParams);
```

The `Value` property of the parameter object contains the structure.

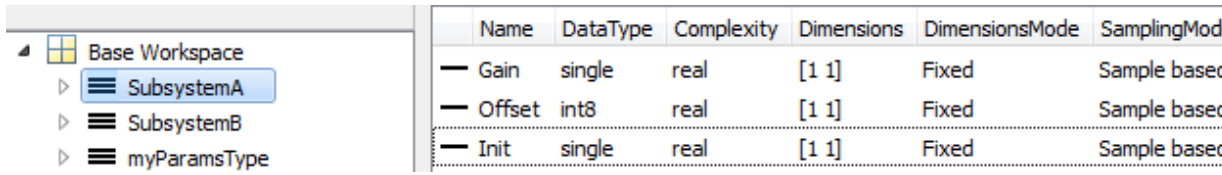
5 Set the data type of the parameter object to the bus object `myParamsType`.

```
myParams.DataType = 'Bus: myParamsType';
```

6 Open the Bus Editor to view the bus objects.

```
buseditor
```

7 In the **Model Hierarchy** pane, click the node SubsystemA. In the **Contents** pane, set the field data types according to the figure.



8 Optionally, set the field data types for the substructure `SubsystemB`.

The parameter object `myParams` stores the parameter structure. The data type of the parameter object is the bus object `myParamsType`. Prior to simulation and code generation, the parameter object casts the field values to the data types that you specified in the bus object.

To use one of the fields to set a block parameter value, specify an expression such as `myParams.SubsystemB.Init1`.

To access the field values at the command prompt, use the `Value` property of the parameter object. Because the bus object controls the field data types, you do not need to use a typed expression to set the field value.

```
myParams.Value.SubsystemA.Gain = 12.79;
```

The bus object strictly controls the field characteristics and the shape of the structure. For example, if you set the value of the two-element field `myParams.SubsystemB.Coeffs` to a three-element array, the model generates an error when you set a block parameter value. To change the dimensions of the field, modify the element `Coeffs` in the bus object `SubsystemB`.

To manipulate bus objects after you create them, see “Modify Bus Objects” on page 65-84 and “Save and Import Bus Objects” on page 65-90.

Match Field Data Type with Signal Data Type

Suppose that you use the field `myParams.SubsystemA.Gain` to set the value of the **Gain** parameter in a Gain block. If you want the data type of the field to match the data type of the output signal of the block, consider using a `Simulink.AliasType` or a `Simulink.NumericType` object to set the data type of the field and the signal. If you do not use a data type object, you must remember to change the data type of the field whenever you change the data type of the signal.

1. At the command prompt, create a `Simulink.AliasType` object that represents the data type `single`.

   ```
   myType = Simulink.AliasType;
   myType.BaseType = 'single';
   ```

2. In the Gain block dialog box, on the **Signal Attributes** tab, set **Output data type** to `myType`.
3. At the command prompt, open the Bus Editor.

   ```
   buseditor
   ```

4. In the **Model Hierarchy** pane, select the bus object `SubsystemA`. In the **Contents** pane, set the data type of the field `Gain` to `myType`.

Now, both the output signal of the Gain block and the structure field `myParams.SubsystemA.Gain` use the data type that you specify by using the `BaseType` property of `myType`.

For more information about data type objects, see `Simulink.AliasType` and `Simulink.NumericType`.

Manage Structure Variables

To create, modify, and inspect a variable whose value is a structure, you can use the Variable Editor. For more information, see “Modify Structure and Array Variables Interactively” on page 59-106.

Define Parameter Hierarchy by Creating Nested Structures

To further organize block parameter values, create a hierarchy of nested structures.

For example, suppose that you create subsystems named `SubsystemA` and `SubsystemB` in your model. You use variables such as `Offset_SubsystemA` and `Offset_SubsystemB` to set block parameter values in the subsystems.

```
Gain_SubsystemA = 15.23;
Offset_SubsystemA = 89;
Init_SubsystemA = 0.59;

Coeffs_SubsystemB = [5.32 7.99];
Offset_SubsystemB = 57;
Init1_SubsystemB = 1.76;
Init2_SubsystemB = 2.76;
```

Create a parameter structure that contains a substructure for each subsystem. Use the values of the existing variables to set the field values.

```
myParams = struct(...
    'SubsystemA',struct(...
        'Gain',Gain_SubsystemA,...
        'Offset',Offset_SubsystemA,...
        'Init',Init_SubsystemA),...
    'SubsystemB',struct(...
        'Coeffs',Coeffs_SubsystemB,...
        'Offset',Offset_SubsystemB,...
        'Init1',Init1_SubsystemB,...
        'Init2',Init2_SubsystemB)...
);
```

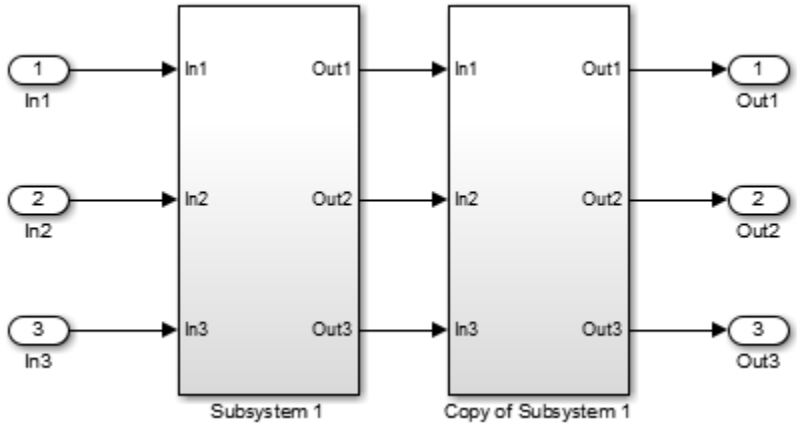
The single structure variable `myParams` contains all of the parameter information for the blocks in the subsystems. Because each substructure acts as a namespace, you can define the `Offset` field more than once.

To use the `Offset` field from the substructure `SubsystemB` as the value of a block parameter, specify the parameter value in the block dialog box as the expression `myParams.SubsystemB.Offset`.

Group Multiple Parameter Structures into an Array

To organize parameter structures that have similar characteristics, you can create a single variable whose value is an array of structures. This technique helps you to parameterize a model that contains multiple instances of an algorithm, such as a library subsystem or a referenced model that uses model arguments.

Suppose that you create two identical subsystems in a model.



Suppose that the blocks in each subsystem require three numeric values to set parameter values. Create an array of two structures to store the values.

```
myParams(1).Gain = 15.23;
myParams(1).Offset = 89;
myParams(1).Init = 0.59;

myParams(2).Gain = 11.93;
myParams(2).Offset = 57;
myParams(2).Init = 2.76;
```

Each structure in the array stores the three parameter values for one of the subsystems.

To set the value of a block parameter in one of the subsystems, specify an expression that references a field of one of the structures in the array. For example, use the expression `myParams(2).Init`.

Organize Parameter Values for Reusable Components and Iterative Algorithms

You can also partition an array of structures in a For Each Subsystem block. This technique helps you to organize workspace variables when a model executes an algorithm repeatedly, for example by iterating the algorithm over a vector signal. For an example, see “Repeat an Algorithm Using a For Each Subsystem” on page 65-139.

If you use model arguments to specify different parameter values across multiple instances of a referenced model, you can use arrays of structures to organize the model argument values. In the referenced model workspace, create a structure variable and configure the model to use the structure as a model argument. Use the fields of the structure to set block parameter values in the model. Then, create an array of structures in the base workspace or a data dictionary to which the parent model or models are linked. In the parent model or models, use each of the structures in the array as the value of the model argument in a Model block. Each structure in the array stores the parameter values for one instance of the referenced model.

The example model `sldemo_mdlref_datamngt` contains three instances (Model blocks) of the masked referenced model `sldemo_mdlref_counter_datamngt`. The base workspace variables `IC1`, `IC2`, `Param1`, and `Param2` are `Simulink.Parameter` objects whose values are structures. The parent model uses these variables to set the values of mask parameters on the Model blocks. Since `IC1` is structurally identical to `IC2`, and `Param1` to `Param2`, you can combine these four structures into two arrays of structures.

1 Open the example parent model.

```
sldemo_mdlref_datamngt
```

The model creates the four `Simulink.Parameter` objects in the base workspace.

2 Open the example referenced model.

```
sldemo_mdlref_counter_datamngt
```

The model workspace defines two model arguments, `CounterICs` and `CounterParams`, whose values are structures. The blocks in the model use the fields of these structures to set parameter values.

3 In the model `sldemo_mdlref_datamngt`, open the Model Data Editor (**View** > **Model Data**). In the Model Data Editor, inspect the **Parameters** tab.

4 In the model, click one of the Model blocks.

The Model Data Editor highlights rows that correspond to two mask parameters on the selected Model block. The block uses the mask parameters to set the values of the two model arguments defined by the referenced model, `sldemo_mdlref_counter_datamngt`. Each Model block uses a different combination of the four parameter objects from the base workspace to set the argument values.

5 In the Model Data Editor **Value** column, click one of the cells to begin editing the value of the corresponding mask parameter (for example, `IC1`). Next to the

parameter value, click the action button ⋮ and select **Open**. The property dialog box for the parameter object opens.

6 In the property dialog box, next to the **Value** box, click the action button and select **Open Variable Editor**.

The Variable Editor shows that the parameter object stores a structure. The structures in `Param2` and `IC2` have the same fields as the structures in `Param1` and `IC1` but different field values.

7 At the command prompt, combine the four parameter objects into two parameter objects whose values are arrays of structures.

```
% Create a new parameter object by copying Param1.
Param = Param1.copy;

% Use the structure in Param2 as the second structure in the new object.
Param.Value(2) = Param2.Value;
% The value of Param is now an array of two structures.

% Delete the old objects Param1 and Param2.
clear Param1 Param2

% Create a new parameter object by copying IC1.
% Use the structure in IC2 as the second structure in the new object.
IC = IC1.copy;
IC.Value(2) = IC2.Value;
clear IC1 IC2
```

8 In the parent model, in the Model Data Editor, use the **Value** column to replace the values of the mask parameters according to the table

Previous Value	New Value
`Param1`	`Param(1)`
`IC1`	`IC(1)`
`Param2`	`Param(2)`
`IC2`	`IC(2)`

Each Model block sets the value of the model argument `CounterICs` by using one of the structures in the array `IC`. Similarly, each block sets the value of `CounterParams` by using one of the structures in `Param`.

Enforce Uniformity in an Array of Structures

All of the structures in an array of structures must have the same hierarchy of fields. Each field in the hierarchy must have the same characteristics throughout the array. You can use a parameter object and a bus object to enforce this uniformity among the structures.

To use a parameter object to represent an array of parameter structures, set the value of the object to the array of structures:

```
% Create array of structures.
myParams(1).Gain = 15.23;
myParams(1).Offset = 89;
myParams(1).Init = 0.59;
myParams(2).Gain = 11.93;
myParams(2).Offset = 57;
myParams(2).Init = 2.76;

% Create bus object.
Simulink.Bus.createObject(myParams);
myParamsType = slBus1;
clear slBus1

% Create parameter object and set data type.
myParams = Simulink.Parameter(myParams);
myParams.DataType = 'Bus: myParamsType';
```

To use one of the fields to set a block parameter value, specify an expression such as `myParams(2).Offset`.

To access the field values at the command prompt, use the `Value` property of the parameter object.

```
myParams.Value(2).Offset = 129;
```

Create a Structure of Constant-Valued Signals

You can use a structure in a Constant block to create a single bus signal that transmits multiple numeric constants. For more information, see Constant. For information about bus signals, see “Buses” on page 65-3.

Considerations Before Migrating to Parameter Structures

- Before you migrate a model to use parameter structures, discover all of the blocks in the target model and in other models that use the variables that you intend to replace.

  For example, suppose two blocks in a model use the workspace variable `myVar`. If you create a structure `myParams` with a field `myVar`, and set the parameter value in only one of the blocks to `myParams.myVar`, the other block continues to use the variable `myVar`. If you delete `myVar`, the model generates an error because the remaining block requires the deleted variable.

  To discover all of the blocks that use a variable:

  1. Open all models that might use the variable. If the models are in a model reference hierarchy, you can open only the top model.
  2. Right-click the variable in the Model Explorer **Contents** pane and select **Find Where Used**. The Model Explorer displays all of the blocks that use the variable.

  You can discover variable usage only in models that are open. Before you migrate to parameter structures, open all models that might use the target variables. For more information about determining variable usage in a model, see "Finding Blocks That Use a Specific Variable" on page 59-114.

  Alternatively, you can refrain from deleting `myVar`. However, if you change the value of the `myParams.myVar` structure field, you must remember to change the value of `myVar` to match.

- You can combine multiple separate variables or parameter objects (such as `Simulink.Parameter`) into a structure that you store in a single variable or parameter object (to combine parameter objects, see "Combine Existing Parameter Objects Into a Structure" on page 36-33). However, the resulting variable or object acts as a single entity. As a result, you cannot apply different code generation settings, such as storage classes, to individual fields in the structure.

Combine Existing Parameter Objects Into a Structure

When you use parameter objects to set block parameter values (for example, so you can apply storage classes), to combine the objects into a single structure:

1. Create a MATLAB structure and store it in a variable. To set the field values, use the parameter values that each existing parameter object stores.
2. Convert the variable to a parameter object. Create and use a `Simulink.Bus` object as the data type of the parameter object (see "Control Field Data Types and Characteristics by Creating Parameter Object" on page 36-24).
3. Choose a storage class to apply to the resulting parameter object. You can choose only one storage class, which applies to the entire structure.
4. Transfer parameter metadata, such as the `Min` and `Max` properties of the existing parameter objects, to the corresponding properties of the `Simulink.BusElement` objects in the bus object.

For example, suppose you have three individual parameter objects.

```
coeff = Simulink.Parameter(17.5);
coeff.Min = 14.33;
coeff.DataType = 'single';
coeff.StorageClass = 'ExportedGlobal';

init = Simulink.Parameter(0.00938);
init.Min = -0.005;
init.Max = 0.103;
init.DataType = 'single';
init.StorageClass = 'SimulinkGlobal';

offset = Simulink.Parameter(199);
offset.DataType = 'uint8';
offset.StorageClass = 'ExportedGlobal';
```

1. Create a structure variable.

   ```
   myParams.coeff = coeff.Value;
   myParams.init = init.Value;
   myParams.offset = offset.Value;
   ```

2. Convert the variable to a parameter object.

   ```
   myParams = Simulink.Parameter(myParams);
   ```

3. Create a bus object and use it as the data type of the parameter object.

   ```
   Simulink.Bus.createObject(myParams.Value);
   paramsDT = copy(slBus1);

   myParams.DataType = 'Bus: paramsDT';
   ```

4 Transfer metadata from the old parameter objects to the bus elements in the bus object.

```
% coeff
paramsDT.Elements(1).Min = coeff.Min;
paramsDT.Elements(1).DataType = coeff.DataType;

% init
paramsDT.Elements(2).Min = init.Min;
paramsDT.Elements(2).Max = init.Max;
paramsDT.Elements(2).DataType = init.DataType;

% offset
paramsDT.Elements(3).DataType = offset.DataType;
```

To help you write a script that performs this transfer operation, you can use the `properties` function to find the properties that the bus elements and the old parameter objects have in common. To list the structure fields so that you can iterate over them, use the `fieldnames` function.

5 Apply a storage class to the parameter object.

```
myParams.StorageClass = 'ExportedGlobal';
```

Now, you can use the fields of `myParams`, instead of the old parameter objects, to set the block parameter values.

Parameter Structures in the Generated Code

You can configure parameter structures to appear in the generated code as structures and arrays of structures. For information about generating code with parameter structures, see “Organize Block Parameter Values into Structures in the Generated Code” (Simulink Coder).

Parameter Structure Limitations

- The value of a field that you use to set a block parameter must be numeric or of an enumerated type. The value of a field can be a real or complex scalar, vector, or multidimensional array.
- If the value of any of the fields of a structure is a multidimensional array, you cannot tune any of the field values during simulation.

- All of the structures in an array of structures must have the same hierarchy of fields. Each field in the hierarchy must have the same characteristics throughout the array:

  - Field name
  - Numeric data type, such as `single` or `int32`
  - Complexity
  - Dimensions

  Suppose that you define an array of two structures.

  ```
  paramStructArray = ...
  [struct('sensor1',int16(7),'sensor2',single(9.23)) ...
   struct('sensor1',int32(9),'sensor2',single(11.71))];
  ```

  You cannot use any of the fields in a block parameter because the field `sensor1` uses a different data type in each structure.

- Parameter structures do not support context-sensitive data typing in the generated code. If the parameter structure is tunable in the code, the fields of the structure use the numeric data types that you specify by using either typed expressions or a `Simulink.Bus` object. If you do not use typed expressions or a `Simulink.Bus` object, the fields of the structure use the `double` data type.

Package Shared Breakpoint and Table Data for Lookup Tables

When you share data between lookup table blocks, consider using `Simulink.LookupTable` and `Simulink.Breakpoint` objects instead of structures to store and group the data. This technique improves model readability by clearly identifying the data as parts of a lookup table and explicitly associating breakpoint data with table data. See “Package Shared Breakpoint and Table Data for Lookup Tables” on page 36-16.

Create Parameter Structure According to Structure Type from Existing C Code

You can create a parameter structure that conforms to a `struct` type definition that your existing C code defines. Use this technique to:

- Replace existing C code with a Simulink model.

- Integrate existing C code for simulation in Simulink (for example, by using the Legacy Code Tool). For an example, see “Integrate C Function Whose Arguments Are Pointers to Structures”.
- Generate C code (Simulink Coder) that you can compile with existing C code into a single application. For an example, see “Exchange Structured and Enumerated Data Between Generated and External Code” (Embedded Coder).

In MATLAB, store the parameter structure in a parameter object and use a bus object as the data type (see “Control Field Data Types and Characteristics by Creating Parameter Object” on page 36-24). To create the bus object according to your C-code `struct` type, use the `Simulink.importExternalCTypes` function.

Tune and Experiment with Block Parameter Values

As you construct a model you can experiment with block parameters, such as the coefficients of a Transfer Fcn block, to help you decide which blocks to use. You can simulate the model with different parameter values, and capture and observe the simulation output.

You can change the values of most numeric block parameters during a simulation. To observe the effects, you can visualize the simulation output in real time. This technique allows you to quickly test parameter values while you develop an algorithm. You can visually:

- Tune and optimize control parameters.
- Calibrate model parameters.
- Test control robustness under different conditions.

When you begin a simulation, Simulink first updates the model diagram. This operation can take time for larger models. To test parameter values without repeatedly updating the model diagram, you can tune the parameter values during a single simulation run.

Alternatively, to avoid updating the model diagram, use Fast Restart. For more information about Fast Restart, see “Get Started with Fast Restart” on page 70-6.

If you cannot visually analyze the simulation output in real time, or if you must run many simulations, consider using a programmatic approach to sweeping parameter values. You can capture the simulation output data and perform analysis later. For more information, see “Optimize, Estimate, and Sweep Block Parameter Values” on page 36-48.

For basic information about accessing and setting block parameter values, see “Set Block Parameter Values” on page 36-2.

Iteratively Adjust Block Parameter Value Between Simulation Runs

This example shows how to prototype a model by changing block parameter values between simulation runs. You can experiment with parameter values and observe simulation results to help you decide which blocks to use and how to build your model.

The example model `sldemo_fuelsys` represents the fueling system of a gasoline engine. A subsystem in the model, `feedforward_fuel_rate`, calculates the fuel demand of the

engine by using the constant number `14.6`, which represents the ideal (stoichiometric) ratio of air to fuel that the engine consumes. Two blocks in the subsystem use the number to set the values of parameters.

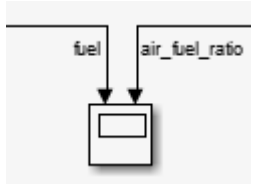
Suppose that you want to change the design value of the ideal air-to-fuel ratio from `14.6` to `17.5` to observe the effect on the fuel demand. To store the design value in the model, you can modify the value in the block dialog boxes. Alternatively, you can store the value in a variable with a meaningful name, which allows you to reuse the value in the two blocks.

To observe the change in simulation outputs by changing the value in the block dialog boxes:

1. Open the example model.

   ```
   sldemo_fuelsys
   ```

2. Set the model simulation time from `2000` to `50` for a faster simulation.
3. In the model, open the Scope block dialog box.



4. Simulate the model. Resize the window in the Scope dialog box to see all of the simulation results.

   The scope display shows that throughout the simulation, the `fuel` signal oscillates between approximately `0.9` and `1.6`. The `air_fuel_ratio` signal quickly climbs to `15` without overshoot.

5. In the model, open the Model Data Editor by selecting **View** > **Model Data**. In the Model Data Editor, inspect the **Parameters** tab.
6. In the model or at the command prompt, navigate to the target subsystem.

   ```
   open_system(...
       'sldemo_fuelsys/fuel_rate_control/fuel_calc/feedforward_fuel_rate')
   ```

7. In the Model Data Editor, use the **Value** column to change the **Constant value** (`Value`) parameter of the Constant block labeled `rich` from `1/(14.6*0.8)` to `1/(17.5*0.8)`.

8 Similarly, change the **Constant value** parameter of the block labeled `normal` from `1/14.6` to `1/17.5`.

9 Simulate the model.

The scope display shows that the signals now respond differently.

To replace the literal values in the block dialog boxes with a numeric variable:

1 Use the Model Data Editor to set the value of the `normal` Constant block to `1/mixture`.

2 Set the value of the `rich` block to `1/(mixture*0.8)`.

3 While editing the `rich` value, next to `1/(mixture*0.8)`, click the action button and select **Create**.

4 In the **Create New Data** dialog box, set **Value** to `17.5` and click **Create**.

The numeric variable `mixture` appears in the base workspace with value `17.5`. Between simulation runs, you can change the value of `mixture` in the base workspace instead of changing the parameter values in the block dialog boxes.

Tune Block Parameter Value During Simulation

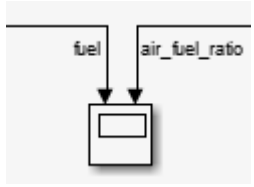
This example shows how to observe the effect of changing a block parameter value during a simulation. This technique allows you to avoid updating the model diagram between simulation runs and to interactively test and debug your model.

The example model `sldemo_fuelsys` contains a Constant block, `Throttle Command`, that represents the throttle command. To observe the effect of increasing the magnitude of the command during simulation:

1 Open the example model.

```
sldemo_fuelsys
```

2 In the model, open the Scope block dialog box.



3. Begin a simulation.

   The model is configured to simulate 2000 seconds. During the simulation, the values of the `fuel` and `air_fuel_ratio` signals appear on the scope graph in real time.
4. In the model, when the status bar indicates approximately `1000` (1000 seconds), click the Pause button to pause the simulation.
5. In the scope display, the **fuel** graph plots the simulation output prior to the pause time.
6. Open the block dialog box for the block labeled `Throttle Command`. Change the value of the **Output values** parameter from `[10 20 10]` to `[10 30 10]` and click **OK**.
7. Click the Step Forward button to advance the simulation step by step. Click the button about 15 times or until you see a change in the **fuel** graph in the scope display.

   The plot of the signal `fuel` indicates a sharp increase in fuel demand that corresponds to the increased throttle command.
8. In the model, resume the simulation by clicking the Continue button.

   The scope display shows the significant periodic increase in fuel demand, and the periodic reduction in the air-to-fuel ratio, throughout the rest of the simulation.

During the simulation, you must update the model diagram after you change the value of a workspace variable. For more information about updating the model diagram, see “Update Diagram and Run Simulation” on page 1-65.

Prepare for Parameter Tuning and Experimentation

- Consider using workspace variables to set block parameter values.

  To access the value of a block parameter, such as the **Constant value** parameter of a Constant block, you must navigate to the block in the model and open the block dialog box, search for the block by using the Model Explorer, or use the function `set_param` at the command prompt.

  Alternatively, if you set the block parameter value by creating a workspace variable, you can change the value of the variable by using the command prompt, the MATLAB Workspace browser, or the Model Explorer. You can also create a variable to set the same value for multiple block parameters. When you change the variable value, all of

the target block parameters use the new value. For more information about accessing and setting block parameter values, see “Set Block Parameter Values” on page 36-2.

- Learn how to visualize simulation output.

  To observe simulation output in real time while you tune block parameter values, you can use blocks in a model such as the Scope block. You can also capture simulation output at the end of a simulation run, and view the data in the Simulation Data Inspector. For more information, see “Decide How to Visualize Simulation Data” on page 29-2.

- Consider specifying value ranges for block parameters that you expect to tune during simulation.

  If you expect another person to use your model and tune the parameter, you can control the allowed tuning values by specifying a range. Also, it is a best practice to specify value ranges for all fixed-point block parameters that you expect to tune. To specify block parameter value ranges, see “Specify Minimum and Maximum Values for Block Parameters” on page 36-65.

- Learn how to control simulation duration and pace.

  A simulation run can execute so quickly that you cannot tune block parameter values. Also, if you want to change a parameter value at a specific simulation time, you must learn to control the simulation pace. You can configure the simulation to run for a specific duration or to run forever, and pause and advance the simulation when you want to. For more information about controlling simulation execution, see “Simulate a Model Interactively” on page 24-2. To programmatically control simulations, see “Control Simulations Programmatically” on page 25-8.

Interactively Tune Using Dashboard Blocks

You can tune block parameter values by adding blocks from the Dashboard library to your model. Dashboard blocks allow you to adjust the parameter values of other blocks, and to observe simulation output in real time, by interacting with knobs, switches, and readouts that mimic the appearance of industrial controls. You can interact with the Dashboard blocks without having to locate the target block parameters in the model. For more information, see “Tune and Visualize Your Model with Dashboard Blocks” on page 28-80.

Which Block Parameters Are Tunable During Simulation?

Nontunable block parameters are parameters whose values you cannot change during simulation. For example, you cannot tune the **Sample time** block parameter. If a parameter is nontunable, you cannot change its value during simulation by changing the value in the block dialog box or by changing the value of a workspace variable.

Nontunable block parameters include:

- Sample times.
- Parameters that control the appearance or structure of a block such as the number of inputs of a Sum block.
- Priority, which allows you to control block execution order.
- Parameters that control the block algorithm, such as the **Integrator method** parameter of a Discrete-Time Integrator block.

To determine whether a block parameter is tunable during simulation, use one of these techniques:

- Begin a simulation and open the block dialog box. If the value of the target block parameter is gray during simulation, you cannot tune the parameter.
- At the command prompt, determine whether the flags `read-write` and `read-only-if-compiled` describe the parameter.

  1. Select the block in the model.
  2. At the command prompt, use the function `get_param` to return information about the block dialog box parameters. The function returns a structure that has a field for each parameter in the block dialog box.

     ```
     paramInfo = get_param(gcb,'DialogParameters');
     ```

     Alternatively, rather than locating and selecting the block in the model, you can replace `gcb` with the block path, such as `'myModel/mySubsystem/myBlock'`.
  3. View the information about the target block parameter. For example, to view the information about the **Sample time** parameter of a block, view the value of the field `SampleTime`, which is also a structure.

     ```
     paramInfo.SampleTime

     ans =
     ```

```
          Prompt: 'Sample time:'
            Type: 'string'
            Enum: {}
      Attributes: {'read-write'  'read-only-if-compiled'  'dont-eval'}
```

4 Inspect the structure's `Attributes` field, whose value is a cell array of character vectors. If the flag `read-write` appears in the cell array, you can modify the parameter value. However, if the flag `read-only-if-compiled` also appears in the cell array, you cannot modify the parameter value during simulation.

If you use masks to create custom interfaces for blocks and subsystems, you can control the tunability of individual mask parameters. If you use model arguments to parameterize referenced models, you can tune the value of each model argument in each Model block.

Why Did the Simulation Output Stay the Same?

If the output of your simulation does not change after you change a parameter value, use these troubleshooting techniques:

- Locate the definition of a workspace variable.

  If you use a workspace variable to set block parameter values, determine where the variable definition resides. For example, if you define a variable `myVar` in a model workspace and use it to set a block parameter value in the model, you cannot change the parameter value by changing the value of a variable named `myVar` in the base workspace. You must access the variable definition in the model workspace.

  To locate the definition of a variable, while editing the value of a block parameter that uses the variable, click the nearby action button ⋮ and select **Explore**. A dialog box opens, such as the Model Explorer, which displays the definition of the variable in the appropriate workspace. For more information about how models use variables, see "Symbol Resolution" on page 59-136.

- Specify value ranges for fixed-point parameters that you want to tune during simulation.

  If the block parameter you want to tune uses a fixed-point data type with best-precision scaling, specify a minimum and maximum value for the parameter so that Simulink can calculate and apply an appropriate scaling. If you do not specify a value range, Simulink might apply a scaling that excludes the tuning values that you want

to use. To specify value ranges, see “Specify Minimum and Maximum Values for Block Parameters” on page 36-65.

- Update the model diagram during a simulation run. If you use a workspace variable to set the value of one or more block parameters, after you change the value of the variable during a simulation, you must update the model diagram.

  To learn how to update a model diagram, see “Update Diagram and Run Simulation” on page 1-65.

Tunability Considerations and Limitations for Other Modeling Goals

Referenced Models

When you use Model blocks, these parameter tunability limitations apply:

- If you set the simulation mode of a Model block to an accelerated mode or if you simulate the parent model in an accelerated mode, you cannot tune block parameters in the referenced model during simulation. However, if the referenced model uses variables in the base workspace or a data dictionary to set parameter values, you can tune the values of the variables.
- Suppose you use a MATLAB variable or `Simulink.Parameter` object in a model workspace to set the value of a block parameter in a model. If you use a Model block to refer to this model:

  - And you set the simulation mode of the Model block to an accelerated mode or simulate the parent model in an accelerated mode, you cannot change the value of the variable or object during the simulation.
  - When you simulate the parent model in an accelerated mode, changing the value of the variable or object between simulation runs causes Simulink to regenerate code.
  - And you use additional Model blocks to refer to the model multiple times in the parent model, you can choose a different simulation mode for each Model block. If at least one block uses normal simulation mode and any other block uses a different simulation mode, you cannot change the value of the variable or object during simulation. Also, when you simulate the parent model with fast restart on, you cannot change the value of the variable or object between fast-restart simulation runs.

  As a workaround, move the variable or object to the base workspace or a data dictionary.

Accelerator and SIL/PIL Simulations

These tunability limitations apply to accelerator, rapid accelerator, SIL, and PIL simulations:

- Suppose you use a MATLAB variable or `Simulink.Parameter` object in a model workspace to set the value of a block parameter in a model. If you use the `sim` function to simulate the model in rapid accelerator mode and set the `RapidAcceleratorUpToDateCheck` pair argument to `'off'`, you cannot use the `RapidAcceleratorParameterSets` pair argument to specify different values for the variable or object. The structure returned by `Simulink.BlockDiagram.buildRapidAcceleratorTarget` does not contain information about the variable or object.
- If a block parameter value references workspace variables, you cannot change the block parameter value during rapid accelerator simulation, such as by using the function `set_param`. Instead, you can tune the values of the referenced variables.

  Alternatively, use parameter sets to tune runtime parameters in between rapid accelerator simulations. For more information, see “Tuning Runtime Parameters” on page 34-10.

For more information about parameter tunability during accelerated simulations, see “Tuning Runtime Parameters” on page 34-10 and “sim in parfor with Rapid Accelerator Mode” on page 25-19. For more information about parameter tunability during SIL and PIL simulations, see “Tunable Parameters and SIL/PIL” (Embedded Coder).

Fast Restart

For more information about parameter tunability when you use fast restart, see “Factors Affecting Fast Restart” on page 70-16.

Code Generation and Simulation of External Programs

Parameters that are tunable during simulation can appear as nontunable inlined parameters in the generated code. If you simulate an external program by using SIL, PIL, or External mode simulation, parameter tunability during the simulation and between simulation runs can depend on your code generation settings.

To control parameter tunability in the generated code, you can adjust the code generation settings for a model by using the configuration parameter **Default parameter behavior**. You can also adjust settings for individual MATLAB variables,

`Simulink.Parameter` objects, and other parameter objects. For more information, see "Configure Data Accessibility for Rapid Prototyping" (Simulink Coder).

Stateflow Charts

To debug a Stateflow chart by changing data during simulation, see "Change Data Values During Simulation" (Stateflow).

Optimize, Estimate, and Sweep Block Parameter Values

When you sweep one or more parameters, you change their values between simulation runs, and compare and analyze the output signal data from each run. Use parameter sweeping to tune control parameters, estimate unknown model parameters, and test the robustness of a control algorithm by taking into consideration uncertainty in the real-world system.

You can sweep block parameter values or the values of workspace variables that you use to set the parameter values. Use the Model Data Editor (**View > Model Data**) **Parameters** tab, the Property Inspector (**View > Property Inspector**), the command prompt, or scripts to change parameter values between simulation runs.

If you want to repeatedly change the value of a block parameter, consider creating a variable in a workspace. You can use the Model Explorer or programmatic commands to change the value of the variable instead of locating or identifying the block in the model. Also, several features and products that facilitate parameter optimization, estimation, and sweeping require that you set block parameter values by creating workspace variables.

To learn how to manipulate parameter values during the iterative process of creating a model, see “Tune and Experiment with Block Parameter Values” on page 36-38.

For basic information about accessing and setting block parameter values as you design a model, see “Set Block Parameter Values” on page 36-2. For basic information about programmatically simulating a model, such as by using a script, see “Run Simulations Programmatically” on page 25-2.

Sweep Parameter Value and Inspect Simulation Results

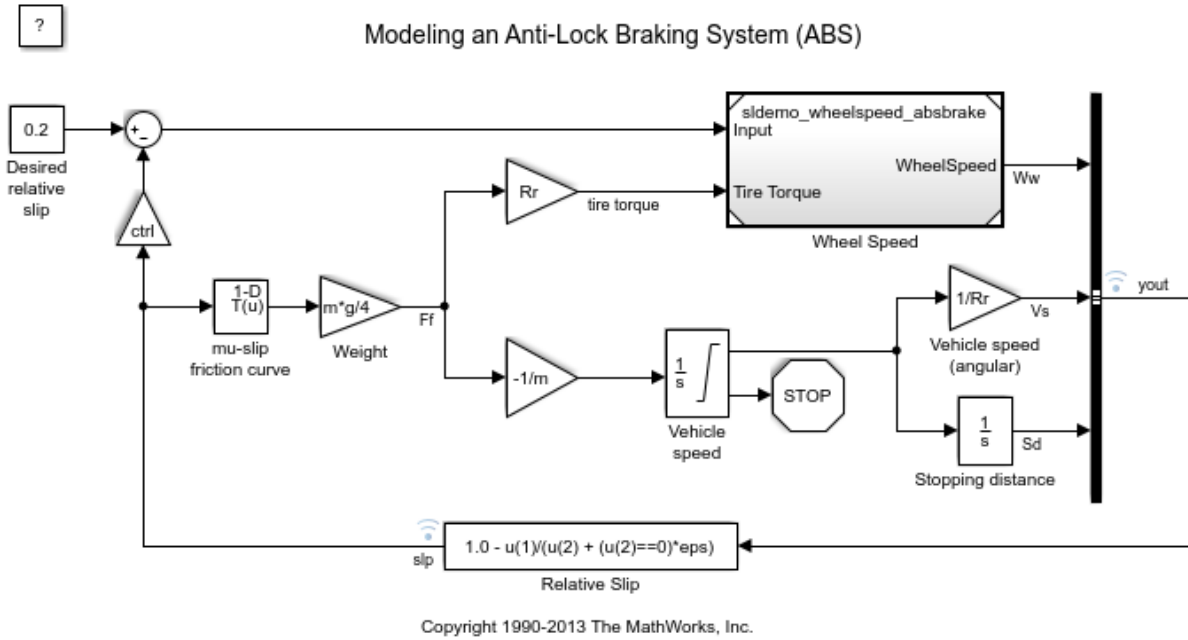
This example shows how to change a block parameter value between multiple programmatic simulation runs. Use this technique to determine an optimal parameter value by comparing the output signal data of each run.

The example model `sldemo_absbrake` uses a Constant block to specify a slip setpoint for an anti-lock braking system. Simulate the model with two different slip setpoint values, 0.24 and 0.25, and compare the output wheel speed of each simulation run.

To store the setpoint value, create a variable in the base workspace. This technique enables you to assign a meaningful name to the value.

Open the example model.

```
open_system('sldemo_absbrake');
```



In the model, select **View > Model Data**.

In the Model Data Editor, select the **Signals** tab.

Set the **Change view** drop-down list to `Instrumentation`. The **Log Data** column shows that the signals `yout` (which is a virtual bus) and `slp` are configured for logging. When you simulate the model, you can collect and later inspect the values of these signals by using the Simulation Data Inspector.

In the Model Data Editor, select the **Parameters** tab. Set **Change view** to `Design`.

In the model, select the Constant block labeled `Desired relative slip`. The Model Data Editor highlights the row that corresponds to the **Constant value** parameter of the block.

Use the **Value** column to set the parameter value to `relSlip`.

While editing the value, next to `relSlip`, click the action button (with three vertical dots) and select **Create**.

In the Create New Data dialog box, set **Value** to `0.2` and click **Create**. A variable, whose value is `0.2`, appears in the base workspace. The model now acquires the relative slip setpoint from this variable.

Alternatively, you can use these commands at the command prompt to create the variable and configure the block:

```
relSlip = 0.2;
set_param('sldemo_absbrake/Desired relative slip','Value','relSlip')
```

At the command prompt, create an array to store the two experimentation values for the relative slip setpoint, `0.24` and `0.25`.

```
relSlip_vals = [0.24 0.25];
```

Create a `Simulink.SimulationInput` object for each simulation that you want to run (in this case, two). Store the objects in a single array variable, `simIn`. Use the `setVariable` method of each object to identify each of the two experimentation values.

```
for i = 1:length(relSlip_vals)
    simIn(i) = Simulink.SimulationInput('sldemo_absbrake');
    simIn(i) = setVariable(simIn(i),'relSlip',relSlip_vals(i));
end
```

Use the `sim` function to simulate the model. Optionally, store the output in a variable named `simOutputs`.

```
simOutputs = sim(simIn);
```

```
[01-Sep-2017 20:28:44] Running simulations...
[01-Sep-2017 20:28:45] Completed 1 of 2 simulation runs
[01-Sep-2017 20:28:45] Completed 2 of 2 simulation runs
```

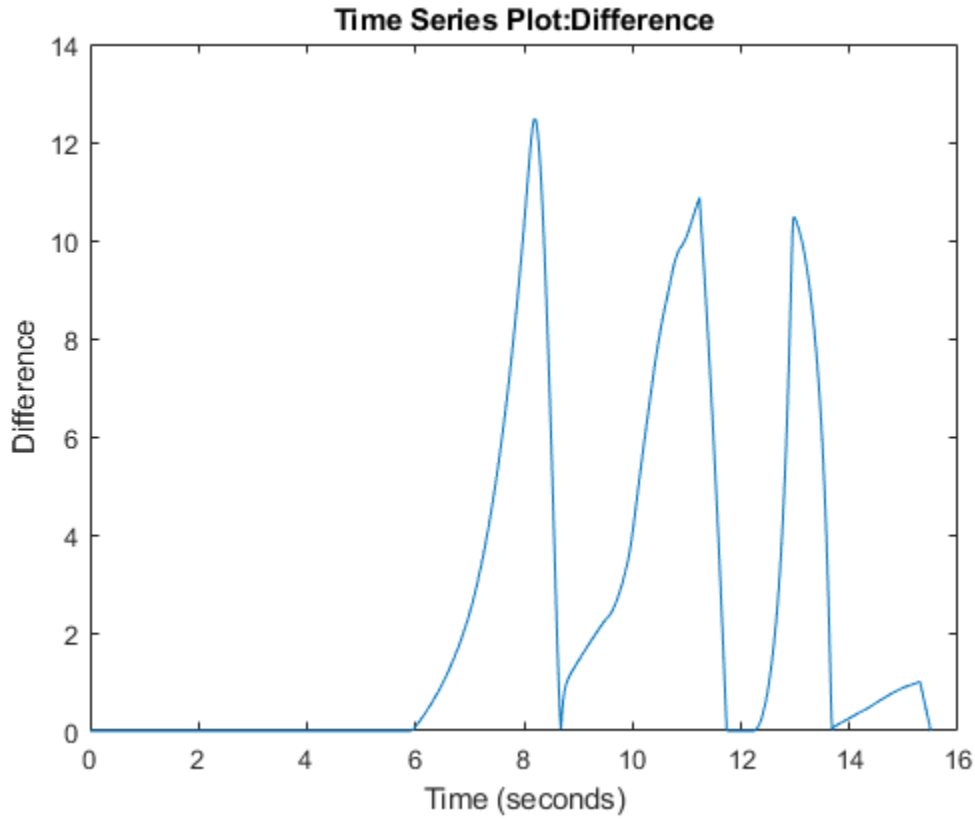
The model streams the logged signals, `yout` and `slp`, to the Simulation Data Inspector. You can view the signal data in the Simulation Data Inspector.

Compare the output data of the two latest simulation runs.

```
runIDs = Simulink.sdi.getAllRunIDs();
runResult = Simulink.sdi.compareRuns(runIDs(end-1), runIDs(end));
```

Plot the difference between the values of the `Ww` signal (which is an element of the virtual bus signal `yout`) by specifying the result index `1`.

```
signalResult = getResultByIndex(runResult,1);
plot(signalResult.Diff);
```



Store Sweep Values in Simulink.SimulationInput Objects

When you write a script to run many simulations, create an array of `Simulink.SimulationInput` objects (one object for each simulation that you want to run). Use the `setVariable` and `setBlockParameter` methods of each object to identify the parameter values to use for the corresponding simulation run. With this technique,

you avoid having to use the `set_param` function to modify block parameter values and assignment commands to modify workspace variable values between simulation runs.

For more information about using `Simulink.SimulationInput` objects to run multiple simulations, see `sim`.

Sweep Nonscalars, Structures, and Parameter Objects

If you use nonscalar variables, structure variables, or `Simulink.Parameter` objects to set block parameter values, use the `setVariable` method of each `Simulink.SimulationInput` object. Refer to the examples in the table.

Scenario	Example
MATLAB variable, `myArray`, whose value is an array. You want to set the third element in the array (assuming one-based indexing).	`setVariable(simIn,'myArray(3)',15.23)`
MATLAB variable, `myStruct`, that has a field named `field1`.	`setVariable(simIn,'myStruct.field1',15.23)`
Parameter object, `myParam`, whose `Value` property is a scalar.	`setVariable(simIn,'myParam.Value',15.23)`
Parameter object, `myArrayParam`, whose `Value` property is an array. You want to set the third element in the array.	`setVariable(simIn,'myArrayParam.Value(3)',15.23)`
Parameter object, `myStructParam`, whose `Value` property is a structure. The structure has a field named `field1`.	`setVariable(simIn,'myStructParam.Value.field1',15.23)`

Sweep Value of Variable in Model Workspace

If you use the model workspace to store variables, when you use the `setVariable` method of a `Simulink.SimulationInput` object to modify the variable value, use the `Workspace` pair argument to identify the containing model:

```
setVariable(simIn,'myVar',15.23,'Workspace','myModel')
```

Capture and Visualize Simulation Results

Each simulation run during a parameter sweep produces outputs, such as signal values from Outport blocks and from logged signals.

You can capture these outputs in variables and objects for later analysis. For more information, see “Export Simulation Data” on page 61-3.

To visualize simulation output data so you can compare the effect of each parameter value, see “Decide How to Visualize Simulation Data” on page 29-2.

Improve Simulation Speed

To perform many simulations that each use different parameter values, you can use accelerated simulation modes. For larger models, accelerated simulations take less time to execute than normal simulations. If you also have Parallel Computing Toolbox, you can use the multiple cores of your processor to simultaneously execute simulations. Use arguments of the `sim` and `parsim` functions.

To improve the simulation speed of your model by using accelerated simulations and other techniques, see “Performance”. For examples and more information, see “Run Multiple Simulations” on page 26-2.

Sweep Parameter Values to Test and Verify System

If you have Simulink Test, you can confirm that your model still meets requirements when you use different parameter values. Parameter overrides and test iterations enable you to set different parameter values for each test case. For more information, see “Parameter Overrides” (Simulink Test) and “Run Combinations of Tests Using Iterations” (Simulink Test).

Estimate and Calibrate Model Parameters

If you have Simulink Design Optimization, you can estimate model parameter values so that simulation outputs closely fit the data that you measure in the real world. Use this technique to estimate the real-world values of parameters in a plant model, which represents the dynamics of a real-world system, when you cannot directly measure the values. This estimation improves the accuracy of the plant model. For more information, see “Estimate Parameters from Measured Data” (Simulink Design Optimization).

Tune and Optimize PID and Controller Parameters

If you have Simulink Control Design, you can use PID Tuner to tune the parameters of a PID Controller block. For more information, see "PID Controller Tuning in Simulink" (Simulink Control Design).

If you have Simulink Design Optimization, you can optimize control parameter values so that simulation outputs meet response requirements that you specify. For more information, see "Design Optimization to Meet Step Response Requirements (GUI)" (Simulink Design Optimization).

Control Block Parameter Data Types

A block parameter, such as the **Gain** parameter of a Gain block, has a data type in the same way that a signal has a data type (see "Control Signal Data Types" on page 59-8). MATLAB variables, `Simulink.Parameter` objects, and other parameter objects that you use to set block parameter values also have data types. Control block parameter data types to:

- Accurately simulate the execution of your control algorithm on hardware.
- Generate efficient code.
- Integrate the generated code with your custom code.
- Avoid using data types that your target hardware does not support.

Reduce Maintenance Effort with Data Type Inheritance

By default, block parameters, numeric MATLAB variables that use the data type `double`, and `Simulink.Parameter` objects acquire a data type through inherited and context-sensitive data typing. For example, if the input and output signals of a Gain block use the data type `single`, the **Gain** parameter typically uses the same data type. If you use a `Simulink.Parameter` object to set the value of the block parameter, by default, the object uses the same data type as the parameter. You can take advantage of this inheritance to avoid explicitly specifying data types for parameters.

Some inheritance rules choose a parameter data type other than the data type that the corresponding signals use. For example, suppose that:

- The input and output signals of a Gain block use fixed-point data types with binary-point-only scaling.
- On the **Parameter Attributes** tab, **Parameter data type** is set to `Inherit: Inherit via internal rule` (the default).
- On the **Parameter Attributes** tab, you specify a minimum and maximum value for the parameter by using **Parameter minimum** and **Parameter maximum**.

The data type setting `Inherit: Inherit via internal rule` can cause the block to choose a different data type, with a different word length or scaling, than the data type that the signals use. The minimum and maximum values that you specified for the parameter influence the scaling that the block chooses.

When you select internal rules (`Inherit: Inherit via internal rule`) to enable Simulink to choose data types, before simulating or generating code, configure the characteristics of your target hardware. The internal rules can use these settings to choose data types that yield efficient generated code. To configure your hardware characteristics, see “Run on Target Hardware Pane”.

Context-Sensitive Data Typing

When you use a MATLAB variable or `Simulink.Parameter` object to set the value of a block parameter, you can configure the variable or parameter object to use context-sensitive data typing. When you simulate or generate code, the variable or parameter object uses the same data type as the block parameter. With this technique, you can match the data type of the variable or parameter object with the data type of the block parameter. To control the data type of the block parameter and the variable or object, you specify only the data type of the block parameter.

To use context-sensitive data typing, set the value of a MATLAB variable to a `double` value. For a `Simulink.Parameter` object, set the `Value` property by using a `double` value and set the `DataType` property to `auto` (the default).

Techniques to Explicitly Specify Parameter Data Types

Many blocks supported for discrete-time simulation and code generation (such as those in the built-in Discrete library) enable you to explicitly specify parameter data types. For example, in an **n-D Lookup Table** block dialog box, on the **Data Types** tab, you can specify a data type for the lookup table data by using the **Table data** parameter. In a Gain block dialog box, use the **Parameter Attributes** tab to set **Parameter data type**, which controls the data type of the **Gain** parameter.

Some blocks, such as those in the Continuous library, do not enable you to specify parameter data types. These block parameters use internal rules to choose a data type. To indirectly control the data type of such a parameter, apply the data type to a `Simulink.Parameter` object instead.

When you use a `Simulink.Parameter` object or other parameter object to set the value of a block parameter, you can use the `DataType` property of the object to specify a data type.

If you use model arguments, you can specify a data type:

- For the model argument that you store in the model workspace.
- With some blocks (such as those in the Discrete library), for the block parameter that uses the model argument.
- For the argument value that you specify in a Model block.

The default settings for these data types typically use inheritance and context-sensitive data typing. For example, the default value of the `DataType` property of a `Simulink.Parameter` object is `auto`, which causes the parameter object to acquire a data type from the block parameter or parameters that use the object.

To explicitly specify a data type, you can use the Data Type Assistant in block dialog boxes and property dialog boxes. For information about the Data Type Assistant, see "Specify Data Types Using Data Type Assistant" on page 59-39.

Calculate Best-Precision Fixed-Point Scaling for Tunable Block Parameters

When you apply fixed-point data types to a model, you can use the Data Type Assistant and the Fixed-Point Tool to calculate best-precision scaling for tunable block parameters. A block parameter, `Simulink.Parameter` object, or other parameter object is tunable if it appears in the generated code as a variable stored in memory.

The chosen scaling must accommodate the range of values that you expect to assign to the parameter. To enable the tools to calculate an appropriate scaling, specify the range information in the block or in a parameter object. Then, use one of these techniques to calculate the scaling:

- Use the Fixed-Point Tool to autoscale the entire model or subsystem. The tool can propose and apply fixed-point data types for data items including block parameters, `Simulink.Parameter` objects, signals, and states.
- Configure individual block parameters or parameter objects to calculate their own scaling.

  When you later change value ranges for parameters, this technique enables you or the model to recalculate the scaling without having to autoscale the entire model. However, if changing the value range of the parameter also changes the value range of an associated signal, you must manually calculate and apply a new scaling for the signal or use the Fixed-Point Tool to autoscale the model or subsystem.

For basic information about fixed-point data types, block parameters, and other tools and concepts, use the information in the table.

- "Calculate Best-Precision Scaling for Individual Parameters" on page 36-59

Autoscale Entire Model by Using the Fixed-Point Tool

You can use the Fixed-Point Tool to autoscale data items in your model, including tunable parameters and signals whose values depend on those parameters. If you use this technique:

- To configure parameters as tunable, use parameter objects (for example, `Simulink.Parameter`) instead of the Model Parameter Configuration dialog box. The Fixed-Point Tool can autoscale parameter objects, but cannot autoscale numeric variables that you select through the Model Parameter Configuration dialog box.

  If your model already uses the Model Parameter Configuration dialog box, use the `tunablevars2parameterobjects` function to create parameter objects instead.
- When you use `Simulink.Parameter` objects to set block parameter values, specify the value range information in the objects instead of the blocks. The Fixed-Point Tool uses the range information in each object to propose a data type for that object.
- To enable the tool to autoscale parameter values that you store as fields of a structure, use a `Simulink.Bus` object as the data type of the entire structure. Specify the range information for each field by using the `Min` and `Max` properties of the corresponding element in the bus object. The tool can then apply a data type to each element by using the `DataType` property.

To use a bus object as the data type of a parameter structure, see "Control Field Data Types and Characteristics by Creating Parameter Object" on page 36-24.

- Before you apply the data types that the Fixed-Point Tool proposes, clear the proposals for parameters and parameter objects whose data types you do not want the tool to change. For example, clear the proposals for these entities:

  - Parameter objects that you import into the generated code from your own handwritten code by applying a storage class such as `ImportedExtern`.
  - `Simulink.Parameter` model arguments in a model workspace.

    Alternatively, before autoscaling the model, consider replacing these parameter objects with numeric MATLAB variables to prevent the Fixed-Point Tool from autoscaling them.

    Allowing the tool to autoscale model arguments can increase the risk of unintentional data type mismatches between the model argument values (which you specify in Model blocks in a parent model), the model arguments in the model workspace, and the client block parameters in the model.
  - Parameter objects whose `DataType` property is set to `auto` (context-sensitive). Clear the proposals if you want the parameter objects to continue to use context-sensitive data typing.

For more information about using the Fixed-Point Tool to autoscale `Simulink.Parameter` objects, see "Autoscaling Data Objects Using the Fixed-Point Tool" (Fixed-Point Designer).

Calculate Best-Precision Scaling for Individual Parameters

You can configure a block parameter or `Simulink.Parameter` object to calculate its own best-precision scaling. First, specify value range information for the target parameter or parameter object. Then, use the Data Type Assistant or the function `fixdt` to apply a data type to the parameter or object. Use these techniques when you do not want to use the Fixed-Point Tool to autoscale the model.

Enable Block Parameter to Automatically Calculate Best-Precision Scaling

You can enable the parameters of some blocks (typically blocks in the Discrete library) to automatically calculate best-precision fixed-point scaling. Use this technique to store the range and data type information in the model instead of a parameter object. When you use this technique, if you later change the range information, the block parameter automatically recalculates best-precision scaling.

In the block dialog box, use the function `fixdt` to specify a fixed-point data type with unspecified scaling. For example, use best-precision scaling for lookup table data, and store the data in a 16-bit word:

1. On the **Data Types** tab of an n-D Lookup Table block, under the **Minimum** and **Maximum** columns, specify a value range for the elements of the table data.
2. Under the **Data Type** column, set the table data type to `fixdt(1,16)`.
3. If you use a tunable `Simulink.Parameter` object to set the value of the table data parameter, set the `DataType` property of the object to `auto`. In the generated code, the parameter object uses the same scaling as the block parameter.

When you simulate or generate code, the lookup table data uses a signed 16-bit fixed-point data type whose binary-point scaling depends on the range information that you specify. The calculated scaling allows the fixed-point type to represent values that lie within the range. If you later change the minimum or maximum values, the block recalculates the scaling when you simulate or generate code.

Calculate Scaling for Parameter Object

If you use a `Simulink.Parameter` object to set the values of multiple block parameters, and if the block parameters use different data types (including different fixed-point scaling), you cannot set the `DataType` property of the object to `auto` (the default). Instead, you can calculate best-precision fixed-point scaling for the parameter object by specifying range and data type information in the object. You can also use this technique to store range and data type information in a parameter object instead of a block dialog box. When you use this technique, if you later change the range information, you must recalculate the best-precision scaling by using the Data Type Assistant.

Suppose that you create a parameter object to represent the value `15.25`, and that the design range of the value is between `0.00` and `32.00`. To calculate best-precision scaling, use the Data Type Assistant.

1. At the command prompt, create a parameter object in the base workspace whose value is `15.25`.

   ```
   myParam = Simulink.Parameter(15.25);
   ```

2. In the MATLAB Workspace browser, double-click the object `myParam`. The property dialog box opens.
3. Specify range information in the object. For example, set **Minimum** to `0.00` and **Maximum** to `32.00`.

4. Set **Data type** to `fixdt(0,16,0)`.
5. Expand the Data Type Assistant and click **Calculate Best-Precision Scaling**.

   The data type changes from `fixdt(0,16,0)` to `fixdt(0,16,10)`.

The calculated scaling (a fraction length of 10 bits) enables the fixed-point data type to represent parameter values that lie within the range that you specified.

If you specify range and data type information in a parameter object, consider removing the range and data type information from the blocks that use the object. Some tools, such as the Fixed-Point Tool, ignore the range information that you specify in the block and use only the information in the parameter object. Removing the information from the block prevents confusion and user errors.

For example, on the **Parameter Attributes** tab of a Gain block dialog box, set **Parameter minimum** and **Parameter maximum** to `[]`. Set **Parameter data type** to an inherited data type such as `Inherit: Inherit from 'Gain'` so that the block parameter uses the same data type as the parameter object.

Detect Numerical Accuracy Issues Due to Quantization and Overflow

When the data type of a block parameter, MATLAB variable, or parameter object cannot represent the value that you specify, the data type quantizes the value, compromising numerical accuracy. For example, the 32-bit floating-point data type `single` (`float` in C code) cannot exactly represent the parameter value `1.73`. When the real-world value of a data item lies outside the range of values that the data type can represent, overflow can cause loss of information.

To detect these issues, use the diagnostic configuration parameters under **Configuration Parameters > Diagnostics > Data Validity > Parameters**. Set the values of these diagnostic configuration parameters to `warning` or `error`:

- **Detect downcast**
- **Detect precision loss**
- **Detect underflow**
- **Detect overflow**

Reuse Custom C Data Types for Parameter Data

In a model, you can create parameter data that conform to custom C data types, such as structures, that your existing C code defines. Use these data to:

- Replace existing C code with a Simulink model.
- Integrate C code for simulation in Simulink (for example, by using the Legacy Code Tool).
- Prepare to generate code (Simulink Coder) that you can integrate with existing code.

Use these techniques to match your custom data types:

- For a structure type, create a `Simulink.Bus` object. Use the object as the data type for a structure that you store in a `Simulink.Parameter` object. See "Organize Related Block Parameter Definitions in Structures" on page 36-22.
- For an enumeration, create an enumeration class and use it as the data type for block parameters. See "Use Enumerated Data in Simulink Models" on page 60-7.
- To match a `typedef` statement that represents an alias of a primitive, numeric data type, use a `Simulink.AliasType` object as the data type for block parameters. See `Simulink.AliasType`.

To create these classes and objects, you can use the function `Simulink.importExternalCTypes`.

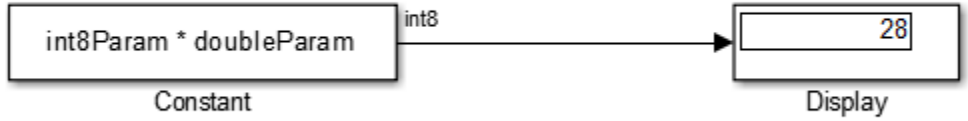
Data Types of Mathematical Expressions

If you specify a block parameter using a mathematical expression, the block determines the final parameter data type using a combination of MATLAB and Simulink data typing rules.

Suppose that you define two parameter objects `int8Param` and `doubleParam`, and use the objects to specify the **Constant value** parameter in a Constant block.

```
int8Param = Simulink.Parameter(3);
int8Param.DataType = 'int8';

doubleParam = Simulink.Parameter(9.36);
doubleParam.DataType = 'double';
```



The Constant block determines the data type of the **Constant value** parameter using these steps:

1 Each parameter object casts the specified numeric value to the specified data type.

Parameter object	Data type	Numeric value	Result
`int8Param`	`int8`	`3`	`int8(3)`
`doubleParam`	`double`	`9.36`	`double(9.36)`

2 The block evaluates the specified expression, `int8Param * doubleParam`, using MATLAB rules.

An expression that involves a `double` data type and a different type returns a result of the different type. Therefore, the result of the expression `int8(3) * double(9.36)` is `int8(28)`.

Block Parameter Data Types in the Generated Code

For more information about controlling parameter data types in the generated code, see "Parameter Data Types in the Generated Code" (Simulink Coder).

- “Specify Minimum and Maximum Values for Block Parameters” on page 36-65
- “Tune and Experiment with Block Parameter Values” on page 36-38
- “Data Validity Diagnostics Overview”

Specify Minimum and Maximum Values for Block Parameters

You can protect your model design by preventing block parameters from using values outside of a range. For example, if the value of a parameter that represents the angle of an aircraft aileron cannot feasibly exceed a known magnitude, you can specify a design maximum for the parameter in the model.

Fixed-Point Designer enables Simulink to use your range information to calculate best-precision fixed-point scaling for:

- Tunable parameters.
- Signals, by taking into consideration the range of values that you intend to assign to tunable parameters.

For basic information about block parameters, see "Set Block Parameter Values" on page 36-2.

Specify Block Parameter Value Ranges

To specify a value range for a block parameter, choose a technique based on your modeling goals.

- You can specify value ranges for some block parameters by using other parameters of the same block. For example, you can control the value range of the **Gain** parameter of a Gain block by using the **Parameter minimum** and **Parameter maximum** parameters in the **Parameter Attributes** tab in the block dialog box. For other blocks, such as n-D Lookup Table and PID Controller, use the **Data Types** tab.

  Use this technique to:

  - Store the range information in the model file.
  - Store the range information when you store fixed-point data type information in the block (for example, by setting the **Parameter data type** parameter of a Gain block to a fixed-point type, including best-precision scaling). This technique more clearly associates the range information with the data type information.
- To specify value ranges for the parameters of any block, consider using parameter objects (for example, `Simulink.Parameter`) to set the parameter values. You can specify the range information in the object, instead of the block, by using the `Min` and `Max` properties.

Use this technique to:

- Specify range information for blocks that cannot store minimum or maximum information, for example, many blocks in the Continuous library.
- Specify range information for a single value that you share between multiple block parameters (see "Share and Reuse Block Parameter Values by Creating Variables" on page 36-12). Instead of using a numeric MATLAB variable, use a parameter object so that you can specify the `Min` and `Max` properties.
- Store the range information when you store fixed-point data type information in a parameter object (by setting the `DataType` property to a fixed-point type instead of `auto`). This technique more clearly associates the range information with the data type information.

If you specify the range information in a parameter object, consider removing the range information from the block. For example, on the **Parameter Attributes** tab of a Gain block dialog box, set **Parameter minimum** and **Parameter maximum** to `[]`. Some tools, such as the Fixed-Point Tool, use the range information that you specify in the block only if you do not specify the range information in the parameter object. If you specify the range information in the parameter object, the tools ignore the range information that you specify in the block.

For basic information about creating and using data objects, see "Data Objects" on page 59-53.

Specify Valid Range Information

Specify a minimum or maximum as an expression that evaluates to a scalar, real number with `double` data type. For example, you can specify a minimum value for the **Gain** parameter in a Gain block by setting **Parameter minimum**:

- A literal number such as `98.884`. Implicitly, the data type is `double`.
- A numeric workspace variable (see "Share and Reuse Block Parameter Values by Creating Variables" on page 36-12) whose data type is `double`. Use this technique to share a minimum or maximum value between multiple data items.

  However, you cannot use variables to set the `Min` or `Max` properties of a parameter object.

To leave the minimum or maximum of a block parameter or parameter object unspecified, use an empty matrix `[]`, which is the default value.

Specify Range Information for Nonscalar Parameters

If the value of a block parameter is a vector or matrix, the range information that you specify applies to each element of the vector or matrix. If the value of any of the elements is outside the specified range, the model generates an error.

If the value of a block parameter is a structure or a field of a structure, specify range information for the structure fields by creating a `Simulink.Parameter` object whose data type is a `Simulink.Bus` object. Specify the range information by using the properties of the signal elements in the bus object. For more information, see "Control Field Data Types and Characteristics by Creating Parameter Object" on page 36-24.

Specify Range Information for Complex-Valued Parameters

If the value of a block parameter is complex (i), the range information that you specify applies separately to the real part and to the imaginary part of the complex number. If the value of either part of the number is outside the range, the model generates an error.

Restrict Allowed Values for Block Parameters

To protect your design by preventing block parameters from using values outside of a range, you can specify the minimum and maximum information by using other parameters of the same block. If you or your users set the value of the target parameter outside the range that you specify, the model generates an error.

Whether a block allows you to specify a value range for a parameter, consider using a parameter object (for example, `Simulink.Parameter`) to set the value of the target parameter. Use the properties of the object to specify the range information. This technique helps you to specify range information for a variable that you use to set multiple block parameter values.

Specify Range Information for Tunable Fixed-Point Parameters

When you use fixed-point data types in your model, you can enable Simulink to choose a best-precision scaling for block parameters and `Simulink.Parameter` objects. If you intend to tune such a parameter by changing its value during simulation or during execution of the generated code, the fixed-point scaling chosen by Simulink must accommodate the range of values that you expect to assign to the parameter.

Also, if you expect to change the value of a parameter, signal data types in the model must accommodate the corresponding expanded range of possible signal values. If you

use the Fixed-Point Tool to propose and apply fixed-point data types for a model, to allow the tool to accurately autoscale the signals, specify range information for tunable parameters.

To specify range information for tunable parameters, see “Calculate Best-Precision Fixed-Point Scaling for Tunable Block Parameters” on page 36-57. To learn how the Fixed-Point Tool autoscales signals by taking into account the value ranges of tunable parameters, see “Derive Ranges for Simulink.Parameter Objects” (Fixed-Point Designer).

Unexpected Errors or Warnings for Data with Greater Precision or Range than double

When a data item (signal or parameter) uses a data type other than `double`, before comparison, Simulink casts the data item and each design limit (minimum or maximum value that you specify) to the nondouble data type. This technique helps prevent the generation of unnecessary, misleading errors and warnings.

However, Simulink stores design limits as `double` before comparison. If the data type of the data item has higher precision than `double` (for example, a fixed-point data type with a 128-bit word length and a 126-bit fraction length) or greater range than `double`, and `double` cannot exactly represent the value of a design limit, Simulink can generate unexpected warnings and errors.

If the nondouble type has higher precision, consider rounding the design limit to the next number furthest from zero that `double` can represent. For example, suppose that a signal generates an error after you set the maximum value to `98.8847692348509014`. At the command prompt, calculate the next number furthest from zero that `double` can represent.

```
format long
98.8847692348509014 + eps(98.8847692348509014)

ans =

  98.884769234850921
```

Use the resulting number, `98.884769234850921`, to replace the maximum value.

Optimize Generated Code

If you have Embedded Coder, Simulink Coder can optimize the code that you generate from the model by taking into account the minimum and maximum values that you specify for signals and parameters. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

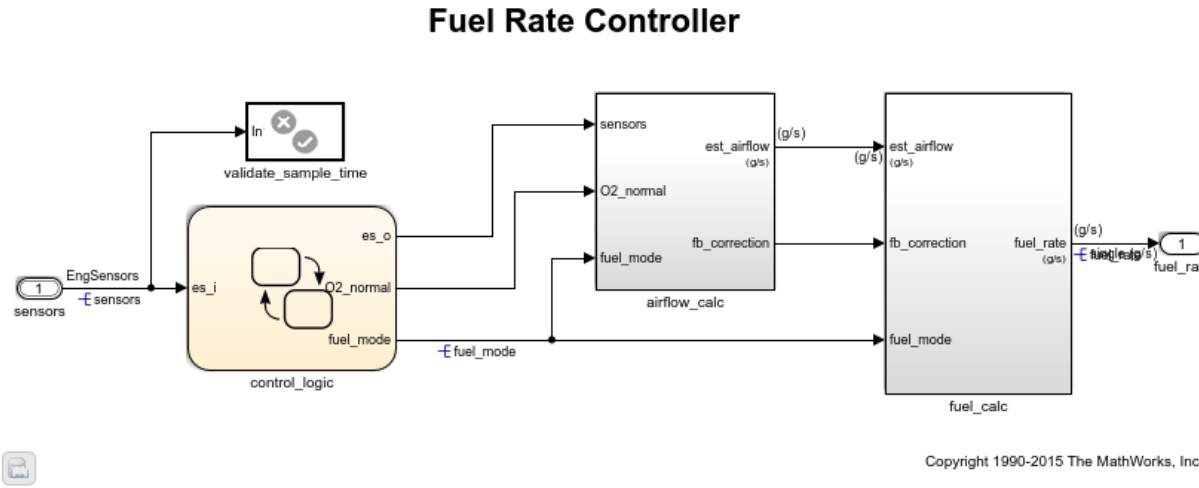
Switch Between Sets of Parameter Values During Simulation and Code Execution

To store multiple independent sets of values for the same block parameters, you can use an array of structures. To switch between the parameter sets, create a variable that acts as an index into the array, and change the value of the variable. You can change the value of the variable during simulation and, if the variable is tunable, during execution of the generated code.

Explore Example Model

Open this example model:

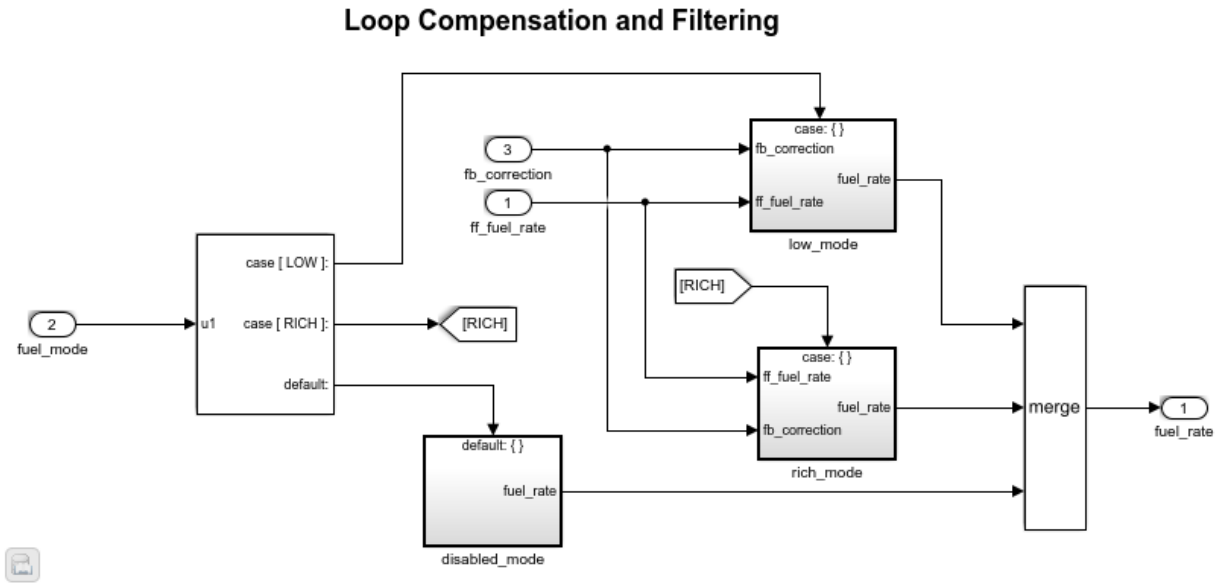
```
open_system('sldemo_fuelsys_dd_controller')
```



This model represents the fueling system of a gasoline engine. The output of the model is the rate of fuel flow to the engine.

Navigate to the `switchable_compensation` nested subsystem.

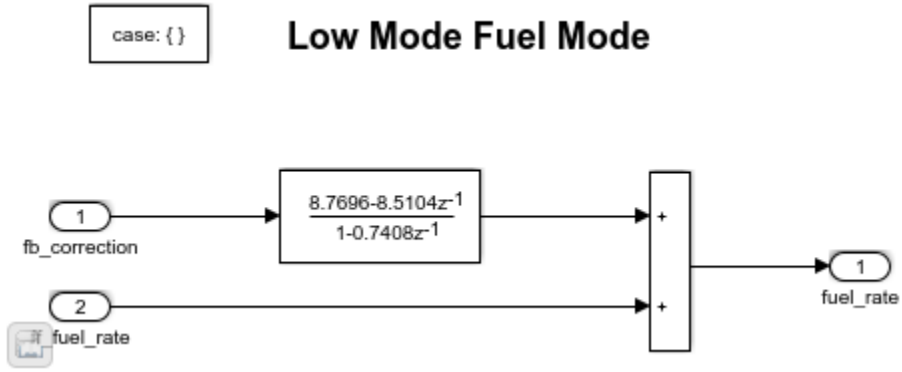
```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/',...
     'switchable_compensation'])
```



This subsystem corrects and filters noise out of the fuel rate signal. The subsystem uses different filter coefficients based on the fueling mode, which the control logic changes based on sensor failures in the engine. For example, the control algorithm activates the `low_mode` subsystem during normal operation. It activates the `rich_mode` subsystem in response to sensor failure.

Open the `low_mode` subsystem.

```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/',...
     'switchable_compensation/low_mode'])
```



The Discrete Filter block filters the fuel rate signal. In the block dialog box, the **Numerator** parameter sets the numerator coefficients of the filter.

The sibling subsystem `rich_mode` also contains a Discrete Filter block, which uses different coefficients.

Update the model diagram to display the signal data types. The input and output signals of the block use the single-precision, floating-point data type `single`.

In the lower-left corner of the model, click the data dictionary badge. The data dictionary for this model, `sldemo_fuelsys_dd_controller.sldd`, opens in the Model Explorer.

In the **Contents** pane, view the properties of the `Simulink.NumericType` objects, such as `s16En15`. All of these objects currently represent the single-precision, floating-point data type `single`. The model uses these objects to set signal data types, including the input and output signals of the Discrete Filter blocks.

Suppose that during simulation and execution of the generated code, you want each of these subsystems to switch between different numerator coefficients based on a variable whose value you control.

Store Parameter Values in Array of Structures

Store the existing set of numerator coefficients in a `Simulink.Parameter` object whose value is a structure. Each field of the structure stores the coefficients for one of the Discrete Filter blocks.

```
lowBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/'...
    'switchable_compensation/low_mode/Discrete Filter'];
```

```
richBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/'...
    'switchable_compensation/rich_mode/Discrete Filter'];
params.lowNumerator = eval(get_param(lowBlock,'Numerator'));
params.richNumerator = eval(get_param(richBlock,'Numerator'));
params = Simulink.Parameter(params);
```

Copy the value of `params` into a temporary variable. Modify the field values in this temporary structure, and assign the modified structure as the second element of `params`.

```
temp = params.Value;
temp.lowNumerator = params.Value.lowNumerator * 2;
temp.richNumerator = params.Value.richNumerator * 2;
params.Value(2) = temp;
clear temp
```

The value of `params` is an array of two structures. Each structure stores one set of filter coefficients.

Create Variable to Switch Between Parameter Sets

Create a `Simulink.Parameter` object named `Ctrl`.

```
Ctrl = Simulink.Parameter(2);
Ctrl.DataType = 'uint8';
```

In the `low_mode` subsystem, in the Discrete Filter block dialog box, set the **Numerator** parameter to the expression `params(Ctrl).lowNumerator`.

```
set_param(lowBlock,'Numerator','params(Ctrl).lowNumerator');
```

In the Discrete Filter block in the `rich_mode` subsystem, set the value of the **Numerator** parameter to `params(Ctrl).richNumerator`.

```
set_param(richBlock,'Numerator','params(Ctrl).richNumerator');
```

The expressions select one of the structures in `params` by using the variable `Ctrl`. The expressions then dereference one of the fields in the structure. The field value sets the values of the numerator coefficients.

To switch between the sets of coefficients, you change the value of `Ctrl` to the corresponding index in the array of structures.

Use Bus Object as Data Type of Array of Structures

Optionally, create a `Simulink.Bus` object to use as the data type of the array of structures. You can:

- Control the shape of the structures.
- For each field, control characteristics such as data type and physical units.
- Control the name of the `struct` type in the generated code.

Use the function `Simulink.Bus.createObject` to create the object and rename the object as `paramsType`.

```
Simulink.Bus.createObject(params.Value)
paramsType = slBus1;
clear slBus1
```

You can use the `Simulink.NumericType` objects from the data dictionary to control the data types of the structure fields. In the bus object, use the name of a data type object to set the `DataType` property of each element.

```
paramsType.Elements(1).DataType = 's16En15';
paramsType.Elements(2).DataType = 's16En7';
```

Use the bus object as the data type of the array of structures.

```
params.DataType = 'Bus: paramsType';
```

Use Enumerated Type for Switching Variable

Optionally, use an enumerated type as the data type of the switching variable. You can associate each of the parameter sets with a meaningful name and restrict the allowed values of the switching variable.

Create an enumerated type named `FilterCoeffs`. Create an enumeration member for each of the structures in `params`. Set the underlying integer value of each enumeration member to the corresponding index in `params`.

```
Simulink.defineIntEnumType('FilterCoeffs',{'Weak','Aggressive'},[1 2])
```

Use the enumerated type as the data type of the switching variable. Set the value of the variable to `Aggressive`, which corresponds to the index `2`.

```
Ctrl.Value = FilterCoeffs.Aggressive;
```

Add New Objects to Data Dictionary

Add the objects that you created to the data dictionary `sldemo_fuelsys_dd_controller.sldd`.

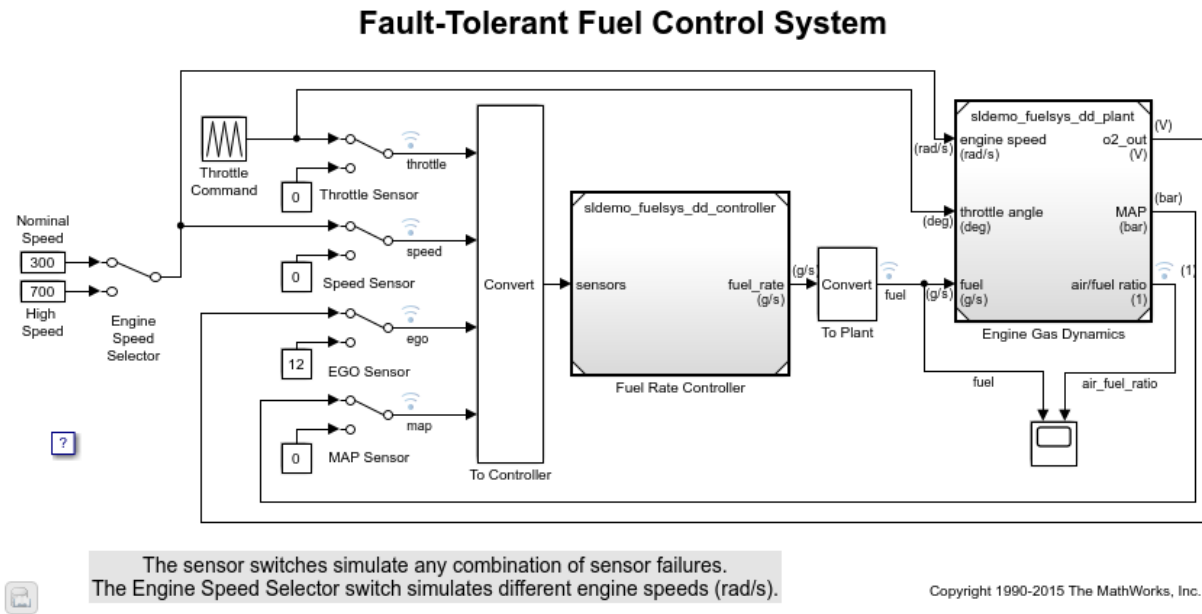
```
dictObj = Simulink.data.dictionary.open('sldemo_fuelsys_dd_controller.sldd');
sectObj = getSection(dictObj,'Design Data');
addEntry(sectObj,'Ctrl',Ctrl)
addEntry(sectObj,'params',params)
addEntry(sectObj,'paramsType',paramsType)
```

You can also store enumerated types in data dictionaries. However, you cannot import the enumerated type in this case because you cannot save changes to `sldemo_fuelsys_dd_controller.sldd`. For more information about storing enumerated types in data dictionaries, see “Enumerations in Data Dictionary” on page 63-14.

Switch Between Parameter Sets During Simulation

Open the example model `sldemo_fuelsys_dd`, which references the controller model `sldemo_fuelsys_dd_controller`.

```
open_system('sldemo_fuelsys_dd')
```



Set the simulation stop time to `Inf` so that you can interact with the model during simulation.

Begin a simulation run and open the Scope block dialog box. The scope shows that the fuel flow rate (the `fuel` signal) oscillates with significant amplitude during normal operation of the engine.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. Set the value of `Ctrl` to `FilterCoeffs.Weak`.

Update the `sldemo_fuelsys_dd` model diagram. The scope shows that the amplitude of the fuel rate oscillations decreases due to the less aggressive filter coefficients.

Stop the simulation.

Generate and Inspect Code

If you have Simulink Coder software, you can generate code that enables you to switch between the parameter sets during code execution.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. In the **Contents** pane, set **Column View** to `Storage Class`.

Use the **StorageClass** column to apply the storage class `ExportedGlobal` to `params` so that the array of structures appears as a tunable global variable in the generated code. Apply the same storage class to `Ctrl` so that you can change the value of the switching variable during code execution.

Alternatively, to configure the objects, use these commands:

```
tempEntryObj = getEntry(sectObj,'params');
params = getValue(tempEntryObj);
params.StorageClass = 'ExportedGlobal';
setValue(tempEntryObj,params);

tempEntryObj = getEntry(sectObj,'Ctrl');
Ctrl = getValue(tempEntryObj);
Ctrl.StorageClass = 'ExportedGlobal';
setValue(tempEntryObj,Ctrl);
```

Generate code from the controller model.

```
rtwbuild('sldemo_fuelsys_dd_controller')
```

```
### Starting build procedure for model: sldemo_fuelsys_dd_controller
### Successful completion of code generation for model: sldemo_fuelsys_dd_controller
```

In the code generation report, view the header file `sldemo_fuelsys_dd_controller_types.h`. The code defines the enumerated data type `FilterCoeffs`.

```
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw',...
    'sldemo_fuelsys_dd_controller_types.h');
rtwdemodbtype(file,'#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_',...
    '/* Forward declaration for rtModel */',1,0)
```

```
#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_
#define DEFINED_TYPEDEF_FOR_FilterCoeffs_

typedef enum {
  Weak = 1,                            /* Default value */
  Aggressive
```

```
} FilterCoeffs;

#endif
```

The code also defines the structure type `paramsType`, which corresponds to the `Simulink.Bus` object. The fields use the single-precision, floating-point data type from the model.

```
rtwdemodbtype(file,'#ifndef DEFINED_TYPEDEF_FOR_paramsType_',...
    '#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_',1,0)

#ifndef DEFINED_TYPEDEF_FOR_paramsType_
#define DEFINED_TYPEDEF_FOR_paramsType_

typedef struct {
  real32_T lowNumerator[2];
  real32_T richNumerator[2];
} paramsType;

#endif
```

View the source file `sldemo_fuelsys_dd_controller.c`. The code uses the enumerated type to define the switching variable `Ctrl`.

```
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw',...
    'sldemo_fuelsys_dd_controller.c');
rtwdemodbtype(file,'FilterCoeffs Ctrl = Aggressive;',...
    '/* Block signals (auto storage) */',1,0)

FilterCoeffs Ctrl = Aggressive;        /* Variable: Ctrl
                                        * Referenced by:
                                        *   '<S12>/Discrete Filter'
                                        *   '<S13>/Discrete Filter'
                                        */
```

The code also defines the array of structures `params`.

```
rtwdemodbtype(file,'/* Exported block parameters */',...
    '/* Variable: params',1,1)

/* Exported block parameters */
paramsType params[2] = { {
```

```
    { 8.7696F, -8.5104F },

    { 0.0F, 0.2592F }
  }, { { 17.5392F, -17.0208F },

    { 0.0F, 0.5184F }
  } } ;                                 /* Variable: params
```

The code algorithm in the model `step` function uses the switching variable to index into the array of structures.

To switch between the parameter sets stored in the array of structures, change the value of `Ctrl` during code execution.

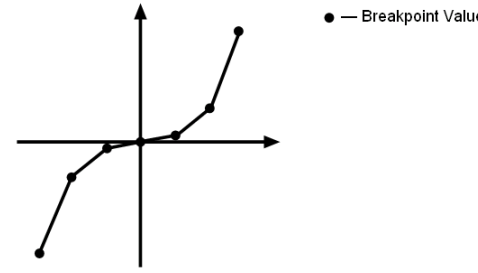
Working with Lookup Tables

About Lookup Table Blocks

A lookup table block uses an array of data to map input values to output values, approximating a mathematical function. Given input values, Simulink performs a "lookup" operation to retrieve the corresponding output values from the table. If the lookup table does not define the input values, the block estimates the output values based on nearby table values.

The following example illustrates a one-dimensional lookup table that approximates the function $y = x^3$. The lookup table defines its output (y) data discretely over the input (x) range `[-3, 3]`. The following table and graph illustrate the input/output relationship:

x	-3	-2	-1	0	1	2	3
y	-27	-8	-1	0	1	8	27

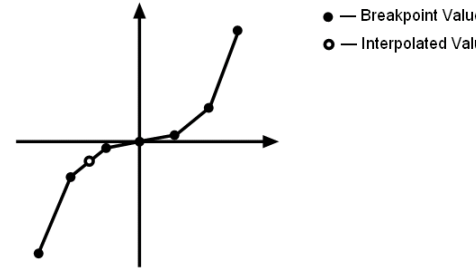


An input of -2 enables the table to look up and retrieve the corresponding output value (-8). Likewise, the lookup table outputs 27 in response to an input of 3.

When the lookup table block encounters an input that does not match any of the table's x values, it can interpolate or extrapolate the answer. For instance, the lookup table does not define an input value of -1.5; however, the block can linearly interpolate the nearest data points (-2, -8) and (-1, -1) to estimate and return a value of -4.5.

Linearly interpolated value

x	-3	-2	-1.5	-1	0	1	2	3
y	-27	-8	-4.5	-1	0	1	8	27

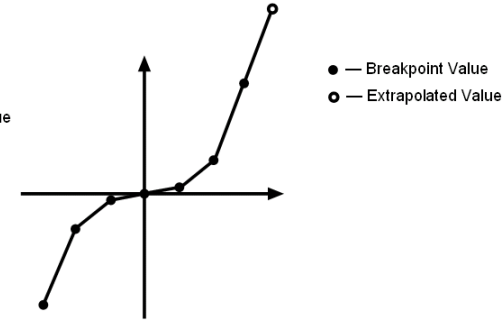


Similarly, although the lookup table does not include data for x values beyond the range of `[-3, 3]`, the block can extrapolate values using a pair of data points at either end of

the table. Given an input value of 4, the lookup table block linearly extrapolates the nearest data points (2, 8) and (3, 27) to estimate an output value of 46.

Linearly extrapolated value

x	-3	-2	-1	0	1	2	3	4
y	-27	-8	-1	0	1	8	27	46



Since table lookups and simple estimations can be faster than mathematical function evaluations, using lookup table blocks might result in speed gains when simulating a model. Consider using lookup tables in lieu of mathematical function evaluations when:

- An analytical expression is expensive to compute.
- No analytical expression exists, but the relationship has been determined empirically.

Simulink provides a broad assortment of lookup table blocks, each geared for a particular type of application. The sections that follow outline the different offerings, suggest how to choose the lookup table best suited to your application, and explain how to interact with the various lookup table blocks.

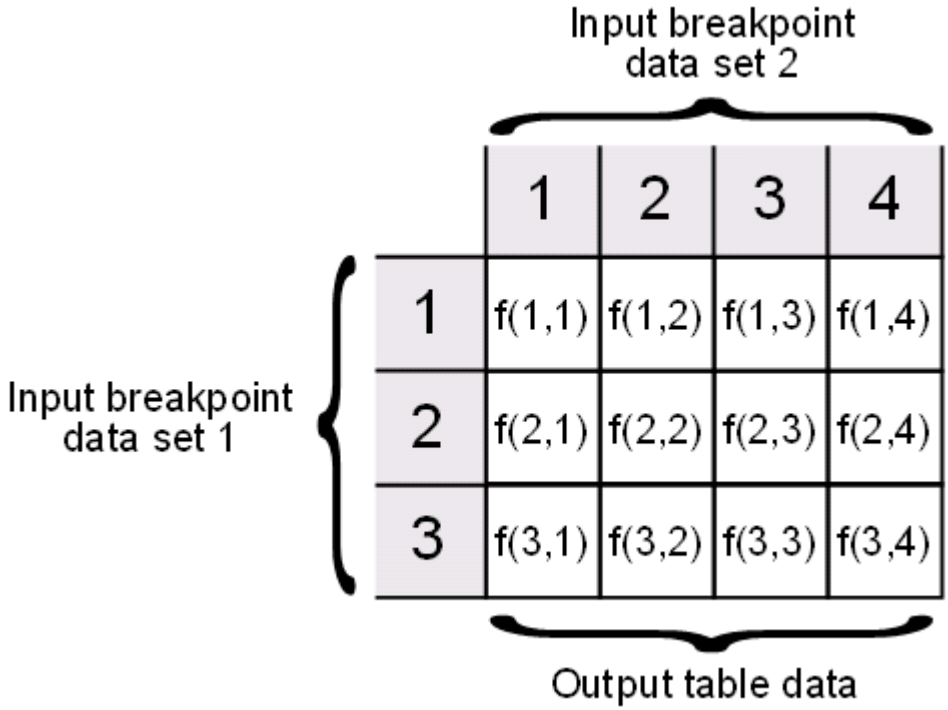
Anatomy of a Lookup Table

The following figure illustrates the anatomy of a two-dimensional lookup table. Vectors or breakpoint data sets and an array, referred to as table data, constitute the lookup table.



Each breakpoint data set is an index of input values for a particular dimension of the lookup table. The array of table data serves as a sampled representation of a function evaluated at the breakpoint values. Lookup table blocks use breakpoint data sets to relate a table's input values to the output values that it returns.

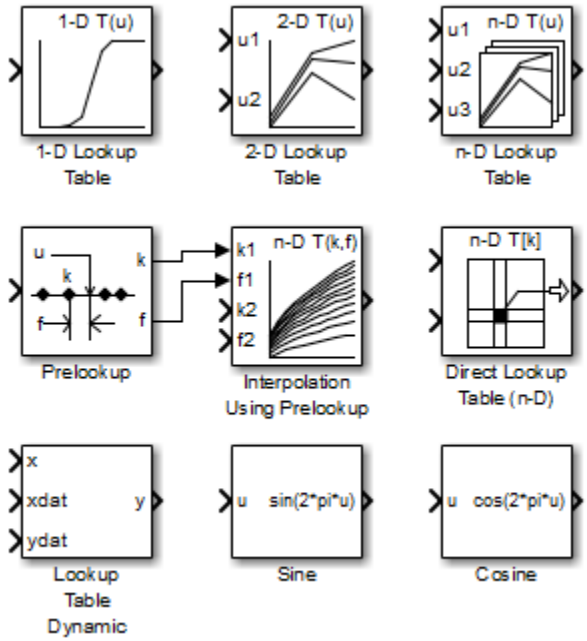
- “Edit Lookup Tables” on page 37-24

Lookup Tables Block Library

Several lookup table blocks appear in the Lookup Tables block library.



The following table summarizes the purpose of each block in the library.

Block Name	Description
1-D Lookup Table	Approximate a one-dimensional function.
2-D Lookup Table	Approximate a two-dimensional function.
n-D Lookup Table	Approximate an N-dimensional function.
Prelookup	Compute index and fraction for Interpolation Using Prelookup block.
Interpolation Using Prelookup	Use precalculated index and fraction values to accelerate approximation of N-dimensional function.
Direct Lookup Table (n-D)	Index into an N-dimensional table to retrieve the corresponding outputs.

Block Name	Description
Lookup Table Dynamic	Approximate a one-dimensional function using a dynamically specified table.
Sine	Use a fixed-point lookup table to approximate the sine wave function.
Cosine	Use a fixed-point lookup table to approximate the cosine wave function.

Guidelines for Choosing a Lookup Table

In this section...

Data Set Dimensionality

In some cases, the dimensions of your data set dictate which of the lookup table blocks is right for your application. If you are approximating a one-dimensional function, consider using either the 1-D Lookup Table or Lookup Table Dynamic block. If you are approximating a two-dimensional function, consider the 2-D Lookup Table block. Blocks such as the n-D Lookup Table and Direct Lookup Table (n-D) allow you to approximate a function of *N* variables.

Data Set Numeric and Data Types

The numeric and data types of your data set influence the decision of which lookup table block is most appropriate. Although all lookup table blocks support real numbers, the Direct Lookup Table (n-D), 1-D Lookup Table, 2-D Lookup Table, and n-D Lookup Table blocks also support complex table data. All lookup table blocks support integer and fixed-point data in addition to `double` and `single` data types.

Note For the Direct Lookup Table (n-D) block, fixed-point types are supported for the table data, output port, and optional table input port.

Data Accuracy and Smoothness

The desired accuracy and smoothness of the data returned by a lookup table determine which of the blocks you should use. Most blocks provide options to perform interpolation and extrapolation, improving the accuracy of values that fall between or outside of the

table data, respectively. For instance, the Lookup Table Dynamic block performs linear interpolation and extrapolation, while the n-D Lookup Table block performs either linear or cubic spline interpolation and extrapolation. In contrast, the Direct Lookup Table (n-D) block performs table lookups without any interpolation or extrapolation. You can achieve a mix of interpolation and extrapolation methods by using the Prelookup block with the Interpolation Using Prelookup block.

Dynamics of Table Inputs

The dynamics of the lookup table inputs impact which of the lookup table blocks is ideal for your application. The blocks use a variety of index search methods to relate the lookup table inputs to the table's breakpoint data sets. Most of the lookup table blocks offer a binary search algorithm, which performs well if the inputs change significantly from one time step to the next. The 1-D Lookup Table, 2-D Lookup Table, n-D Lookup Table, and Prelookup blocks offer a linear search algorithm. Using this algorithm with the option that resumes searching from the previous result performs well if the inputs change slowly. Some lookup table blocks also provide a search algorithm that works best for breakpoint data sets composed of evenly spaced breakpoints. You can achieve a mix of index search methods by using the Prelookup block with the Interpolation Using Prelookup block.

Efficiency of Performance

When the efficiency with which lookup tables operate is important, consider using the Prelookup block with the Interpolation Using Prelookup block. These blocks separate the table lookup process into two components — an index search that relates inputs to the table data, followed by an interpolation and extrapolation stage that computes outputs. These blocks enable you to perform a single index search and then reuse the results to look up data in multiple tables. Also, the Interpolation Using Prelookup block can perform sub-table selection, where the block interpolates a portion of the table data instead of the entire table. For example, if your 3-D table data constitutes a stack of 2-D tables to be interpolated, you can specify a selection port input to select one or more of the 2-D tables from the stack for interpolation. A full 3-D interpolation has 7 sub-interpolations but a 2-D interpolation requires only 3 sub-interpolations. As a result, significant speed improvements are possible when some dimensions of a table are used for data stacking and not intended for interpolation. These features make table lookup operations more efficient, reducing computational effort and simulation time.

Summary of Lookup Table Block Features

Use the following table to identify features that correspond to particular lookup table blocks, then select the block that best meets your requirements.

Feature	1-D Lookup Table	2-D Lookup Table	Lookup Table Dynamic	n-D Lookup Table	Direct Lookup Table (n-D)	Prelookup	Interp. Using Prelookup
Interpolation Methods							
Flat	•	•	•	•	•	•	•
Linear	•	•	•	•		•	•
Cubic spline	•	•		•			
Extrapolation Methods

Enter Breakpoints and Table Data

In this section...

Entering Data in a Block Parameter Dialog Box

This example shows how to populate a 1-D Lookup Table block using the parameter dialog box. The lookup table in this example approximates the function $y = x^3$ over the range `[-3, 3]`.

1. Copy a 1-D Lookup Table block from the Lookup Tables block library to a Simulink model.
2. In the 1-D Lookup Table block dialog box, enter the table dimensions and table data in the specified fields of the dialog box:

   - Set **Number of table dimensions** to `1`.
   - Set **Table data** to `[-27 -8 -1 0 1 8 27]`.

   Alternatively, to use an existing an existing lookup table (`Simulink.LookupTable`) object, select **Data specification** > **Lookup table object**.
3. Enter the breakpoint data set using either of two methods:

   - To specify evenly spaced data points, set **Breakpoint specification** to `Even spacing`. Set **First point** to `-3` and **Spacing** to `1`. The block calculates the number of evenly spaced breakpoints based on the table data.
   - To specify breakpoint data explicitly, set **Breakpoint specification** to `Explicit values` and set **Breakpoints 1** to `[-3:3]`.

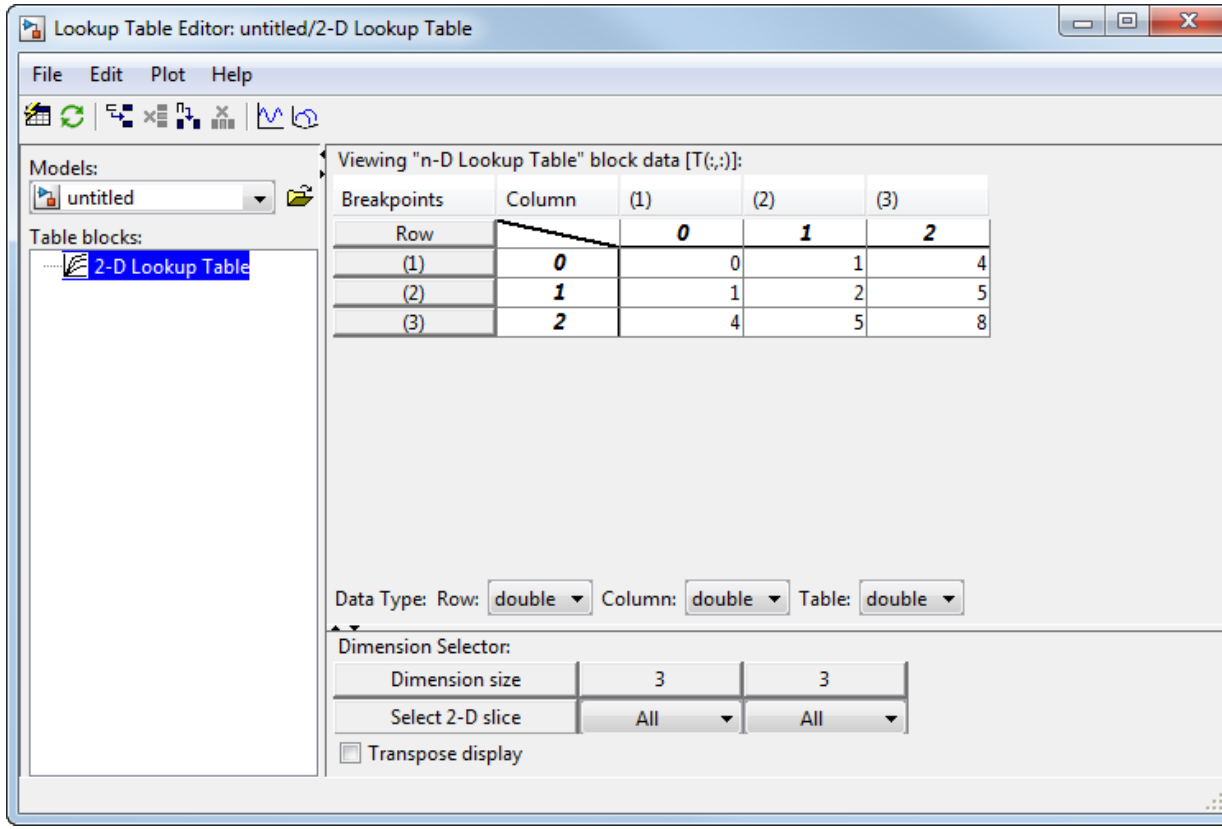
Entering Data in the Lookup Table Editor

Use the following procedure to populate a 2-D Lookup Table block using the Lookup Table Editor. In this example, the lookup table approximates the function $z = x^2 + y^2$ over the input ranges `x = [0, 2]` and `y = [0, 2]`.

1. Copy a 2-D Lookup Table block from the Lookup Tables block library to a Simulink model.
2. Open the Lookup Table Editor by selecting **Lookup Table Editor** from the Simulink **Edit** menu or by clicking **Edit table and breakpoints** on the dialog box of the 2-D Lookup Table block.
3. Under **Viewing "n-D Lookup Table" block data**, enter the breakpoint data sets and table data in the appropriate cells. To change data, click a cell, enter the new value, and press **Enter**.

   - In the cells associated with the **Row Breakpoints**, enter each of the values `[0 1 2]`.
   - In the cells associated with the **Column Breakpoints**, enter each of the values `[0 1 2]`.
   - In the table data cells, enter the values in the array `[0 1 4; 1 2 5; 4 5 8]`.

   The Lookup Table Editor looks like this:



4 In the Lookup Table Editor, select **File > Update Block Data** to update the data in the 2-D Lookup Table block.

5 Close the Lookup Table Editor.

Entering Data Using Inports of the Lookup Table Dynamic Block

Use the following procedure to populate a Lookup Table Dynamic block using that block's inports. In this example, the lookup table approximates the function $y = 3x^2$ over the range `[0, 10]`.

1 Copy a Lookup Table Dynamic block from the Lookup Tables block library to a Simulink model.

2 Copy the blocks needed to implement the equation $y = 3x^2$ to the Simulink model:

- One Constant block to define the input range, from the Sources library
- One Math Function block to square the input range, from the Math Operations library
- One Gain block to multiply the signal by 3, also from the Math Operations library

3 Assign the following parameter values to the Constant, Math Function, and Gain blocks using their dialog boxes:

Block	Parameter	Value
Constant	**Constant value**	`0:10`
Math Function	**Function**	`square`
Gain	**Gain**	`3`

4 Input the breakpoint data set to the Lookup Table Dynamic block by connecting the outport of the Constant block to the inport of the Lookup Table Dynamic block labeled **xdat**. This signal is the input breakpoint data set for x.

5 Input the table data to the Lookup Table Dynamic block by branching the output signal from the Constant block and connecting it to the Math Function block. Then connect the Math Function block to the Gain block. Finally, connect the Gain block to the inport of the Lookup Table Dynamic block labeled **ydat**. This signal is the table data for y.

Characteristics of Lookup Table Data

In this section...

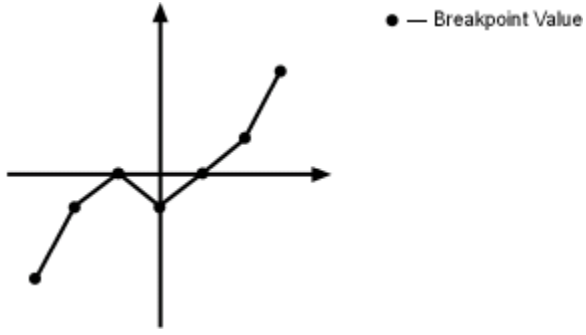
Sizes of Breakpoint Data Sets and Table Data

The following constraints apply to the sizes of breakpoint data sets and table data associated with lookup table blocks:

- The memory limitations of your system constrain the overall size of a lookup table.
- Lookup tables must use consistent dimensions so that the overall size of the table data reflects the size of each breakpoint data set.

To illustrate the second constraint, consider the following vectors of input and output values that create the relationship in the plot.

```
Vector of input values:   [-3 -2 -1  0 1 2 3]
Vector of output values:  [-3 -1  0 -1 0 1 3]
```



In this example, the input and output data are the same size (1-by-7), making the data consistently dimensioned for a 1-D lookup table.

The following input and output values define the 2-D lookup table that is graphically shown.

```
Row index input values:    [1 2 3]
Column index input values: [1 2 3 4]
Table data:                [11 12 13 14; 21 22 23 24; 31 32 33 34]
```

	1	2	3	4
1	11	12	13	14
2	21	22	23	24
3	31	32	33	34

In this example, the sizes of the vectors representing the row and column indices are 1-by-3 and 1-by-4, respectively. Consequently, the output table must be of size 3-by-4 for consistent dimensions.

Monotonicity of Breakpoint Data Sets

The first stage of a table lookup operation involves relating inputs to the breakpoint data sets. The search algorithm requires that input breakpoint sets be strictly monotonically increasing, that is, each successive element is greater than its preceding element. For example, the vector

```
A = [0  0.5  1  1.9  2.1  3]
```

is a valid breakpoint data set as each element is larger than its predecessors.

Note Although a breakpoint data set is strictly monotonic in `double` format, it might not be so after conversion to a fixed-point data type.

Formulation of Evenly Spaced Breakpoints

You can represent evenly spaced breakpoints in a data set by using one of these methods.

Formulation	Example	When to Use This Formulation
`[first_value:spacing:last_value]`	`[10:10:200]`	The lookup table does *not* use `double` or `single`.

Formulation	Example	When to Use This Formulation
`first_value + spacing * [0:(last_value-first_value)/spacing]`	`1 + (0.02 * [0:450])`	The lookup table uses `double` or `single`.

Because floating-point data types cannot precisely represent some numbers, the second formulation works better for `double` and `single`. For example, use `1 + (0.02 * [0:450])` instead of `[1:0.02:10]`. For a list of lookup table blocks that support evenly spaced breakpoints, see "Summary of Lookup Table Block Features" on page 37-10.

Among other advantages, evenly spaced breakpoints can make the generated code division-free and reduce memory usage. For more information, see:

- `fixpt_evenspace_cleanup` in the Simulink documentation
- "Effects of Spacing on Speed, Error, and Memory Usage" (Fixed-Point Designer) in the Fixed-Point Designer documentation
- "Identify questionable fixed-point operations" (Embedded Coder) in the Simulink Coder documentation

Tip Do not use the MATLAB `linspace` function to define evenly spaced breakpoints. Simulink uses a tighter tolerance to check whether a breakpoint set has even spacing. If you use `linspace` to define breakpoints for your lookup table, Simulink considers the breakpoints to be unevenly spaced.

Methods for Estimating Missing Points

In this section...

About Estimating Missing Points

The second stage of a table lookup operation involves generating outputs that correspond to the supplied inputs. If the inputs match the values of indices specified in breakpoint data sets, the block outputs the corresponding values. However, if the inputs fail to match index values in the breakpoint data sets, Simulink estimates the output. In the block parameter dialog box, you can specify how to compute the output in this situation. The available lookup methods are described in the following sections.

Interpolation Methods

When an input falls between breakpoint values, the block interpolates the output value using neighboring breakpoints. Most lookup table blocks have the following interpolation methods available:

- `Flat` — Disables interpolation and uses the rounding operation titled `Use Input Below`. For more information, see “Rounding Methods” on page 37-22.
- `Nearest` — Disables interpolation and returns the table value corresponding to the breakpoint closest to the input. If the input is equidistant from two adjacent breakpoints, the breakpoint with the higher index is chosen.
- `Linear` — Fits a line between the adjacent breakpoints, and returns the point on that line corresponding to the input.
- `Cubic spline` — Fits a cubic spline to the adjacent breakpoints, and returns the point on that spline corresponding to the input.

Note The Lookup Table Dynamic block does not let you select an interpolation method. The `Interpolation-Extrapolation` option in the **Lookup Method** field of the block parameter dialog box performs linear interpolation.

Each interpolation method includes a trade-off between computation time and the smoothness of the result. Although rounding is quickest, it is the least smooth. Linear interpolation is slower than rounding but generates smoother results, except at breakpoints where the slope changes. Cubic spline interpolation is the slowest method but produces the smoothest results.

Extrapolation Methods

When an input falls outside the range of a breakpoint data set, the block extrapolates the output value from a pair of values at the end of the breakpoint data set. Most lookup table blocks have the following extrapolation methods available:

- `Clip` — Disables extrapolation and returns the table data corresponding to the end of the breakpoint data set range. This does not provide protection against out-of-range values.
- `Linear` — If the interpolation method is `Linear`, this extrapolation method fits a line between the first or last pair of breakpoints, depending on whether the input is less than the first or greater than the last breakpoint. If the interpolation method is `Cubic spline`, this extrapolation method fits a linear surface using the slope of the interpolant at the first or last break point, depending on whether the input is less than the first or greater than the last breakpoint. The extrapolation method returns the point on the generated linear surface corresponding to the input.
- `Cubic spline` — Fits a cubic spline to the first or last pair of breakpoints, depending if the input is less than the first or greater than the last breakpoint, respectively. This method returns the point on that spline corresponding to the input.

Note The Lookup Table Dynamic block does not let you select an extrapolation method. The `Interpolation-Extrapolation` option in the **Lookup Method** field of the block parameter dialog box performs linear extrapolation.

In addition to these methods, some lookup table blocks, such as the n-D Lookup Table block, allow you to select an action to perform when encountering situations that require extrapolation. For instance, you can specify that Simulink generate either a warning or

an error when the lookup table inputs are outside the ranges of the breakpoint data sets. To specify such an action, select it from the **Diagnostic for out-of-range input** list on the block parameter dialog box.

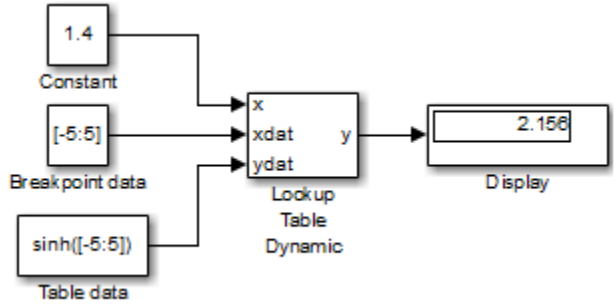
Rounding Methods

If an input falls between breakpoint values or outside the range of a breakpoint data set and you do not specify interpolation or extrapolation, the block rounds the value to an adjacent breakpoint and returns the corresponding output value. For example, the Lookup Table Dynamic block lets you select one of the following rounding methods:

- `Use Input Nearest` — Returns the output value corresponding to the nearest input value.
- `Use Input Below` — Returns the output value corresponding to the breakpoint value that is immediately less than the input value. If no breakpoint value exists below the input value, it returns the breakpoint value nearest the input value.
- `Use Input Above` — Returns the output value corresponding to the breakpoint value that is immediately greater than the input value. If no breakpoint value exists above the input value, it returns the breakpoint value nearest the input value.

Example Output for Lookup Methods

In the following model, the Lookup Table Dynamic block accepts a vector of breakpoint data given by `[-5:5]` and a vector of table data given by `sinh([-5:5])`.



The Lookup Table Dynamic block outputs the following values when using the specified lookup methods and inputs.

Lookup Method	Input	Output	Comment
`Interpolation-Extrapolation`	`1.4`	`2.156`	N/A
	`5.2`	`83.59`	N/A
`Interpolation-Use End Values`	`1.4`	`2.156`	N/A
	`5.2`	`74.2`	The block uses the value for `sinh(5.0)`.
`Use Input Above`	`1.4`	`3.627`	The block uses the value for `sinh(2.0)`.
	`5.2`	`74.2`	The block uses the value for `sinh(5.0)`.
`Use Input Below`	`1.4`	`1.175`	The block uses the value for `sinh(1.0)`.
	`-5.2`	`-74.2`	The block uses the value for `sinh(-5.0)`.
`Use Input Nearest`	`1.4`	`1.175`	The block uses the value for `sinh(1.0)`.

Edit Lookup Tables

In this section...

You can edit a lookup table using:

- Lookup Table block dialog box
- Lookup Table Editor

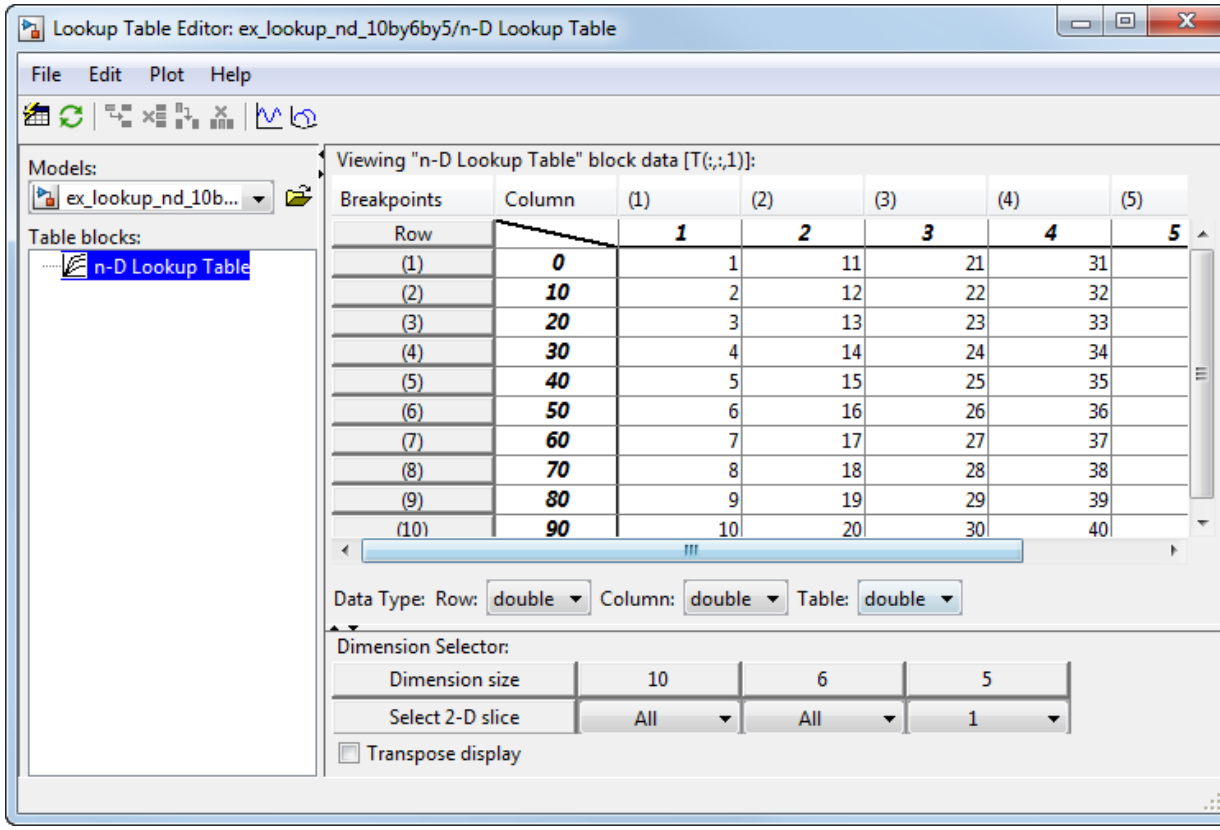
To edit the lookup table in a block:

1. Open the subsystem that contains the lookup table block.
2. Open the lookup table block’s dialog box.
3. In the Table and Breakpoints tab, edit the **Table data** and relevant **Breakpoints** parameters as needed.

With the Lookup Table Editor, you can skip these steps and edit the desired lookup table without navigating to the block that uses it. However, you cannot use the Lookup Table Editor to change the dimensions of a lookup table. You must use the block parameter dialog box for this purpose.

Edit N-Dimensional Lookup Tables

If the lookup table of the block currently selected in the Lookup Table Editor tree view has more than two dimensions, the table view displays a two-dimensional slice of the lookup table.



The **Dimension Selector** specifies which slice currently appears and lets you select another slice. The selector consists of a 2-by-`N` array of controls, where `N` is the number of dimensions in the lookup table. Each column corresponds to a dimension of the lookup table. The first column corresponds to the first dimension of the table, the second column to the second dimension of the table, and so on. The **Dimension size** row of the selector array displays the size of each dimension. The **Select 2-D slice** row specifies which dimensions of the table correspond to the row and column axes of the slice and the indices that select the slice from the remaining dimensions.

To select another slice of the table, specify the row and column axes of the slice in the first two columns of the **Select 2-D slice** row. Then select the indices of the slice from the pop-up index lists in the remaining columns.

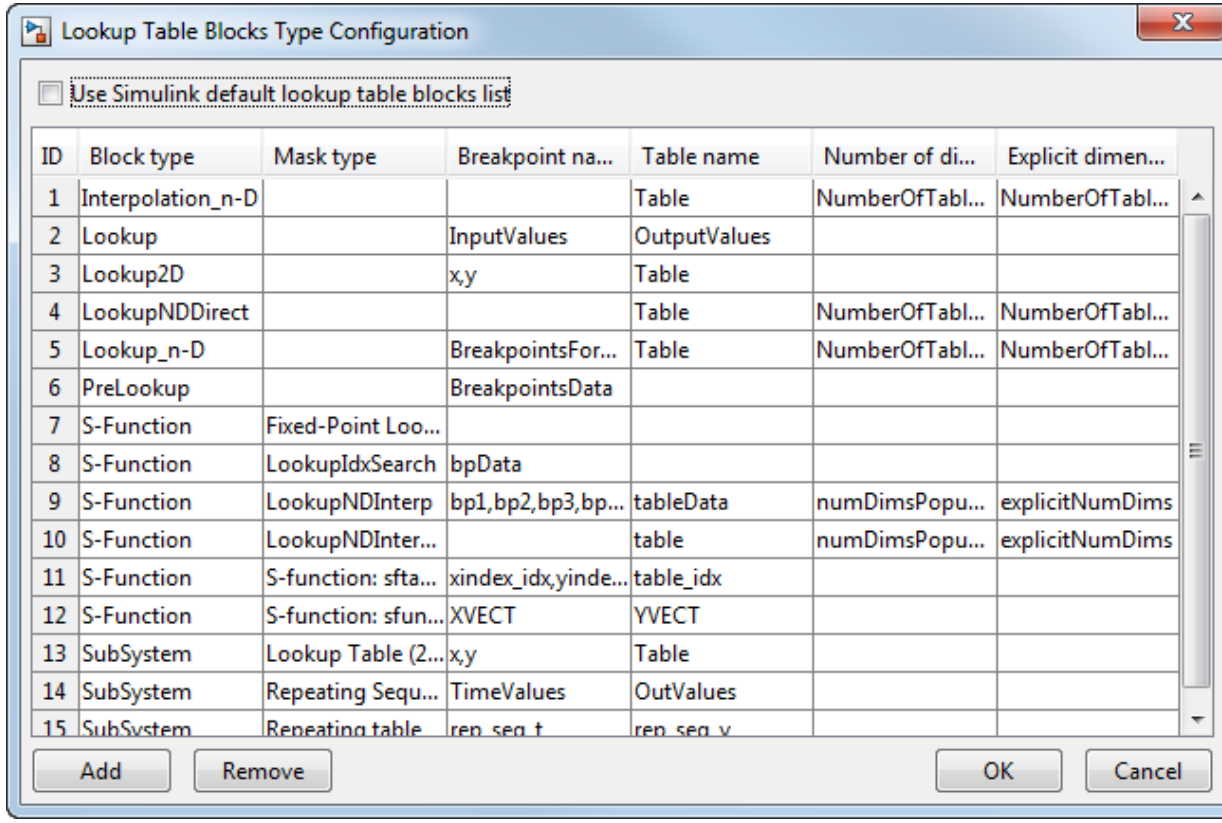
For example, the following selector displays slice (:,:,1) of a 3-D lookup table, as shown under Dimension Selector in the Lookup Table Editor.

To transpose the table display, select the **Transpose display** check box.

Edit Custom Lookup Table Blocks

You can use the Lookup Table Editor to edit custom lookup table blocks that you have created. To do this, you must first configure the Lookup Table Editor to recognize the custom lookup table blocks in your model.

1 Select **File** > **Configure**. The Lookup Table Blocks Type Configuration dialog box appears.



The dialog box displays a table of the lookup table block types that the Lookup Table Editor currently recognizes. This table includes the standard blocks. Each row of the table displays key attributes of a lookup table block type.

2 Click **Add** on the dialog box. A new row appears at the bottom of the block type table.

3 Enter information for the custom block in the new row under these headings.

Field Name	Description
Block type	Block type of the custom block. The block type is the value of the block's `BlockType` parameter.
Mask type	Mask type of the custom block. The mask type is the value of the block's `MaskType` parameter.
Breakpoint name	Names of the block parameters that store the breakpoints.
Table name	Name of the block parameter that stores the table data.
Number of dimensions	Leave empty.
Explicit dimensions	Leave empty.

4 Click **OK**.

To remove a custom lookup table block type from the list that the Lookup Table Editor recognizes, select the custom entry in the table of the Lookup Table Blocks Type Configuration dialog box and click **Remove**. To remove all custom lookup table block types, select the **Use Simulink default lookup table blocks list** check box at the top of the dialog box.

Import Lookup Table Data from MATLAB

In this section...

You can import table and breakpoint data from variables in the MATLAB workspace by referencing them in the **Table and Breakpoints** tab of the dialog box. The following examples show how to import and export standard format and non-standard format data from the MATLAB workspace.

Import Standard Format Lookup Table Data

Suppose you specify a 3-D lookup table in your n-D Lookup Table block.

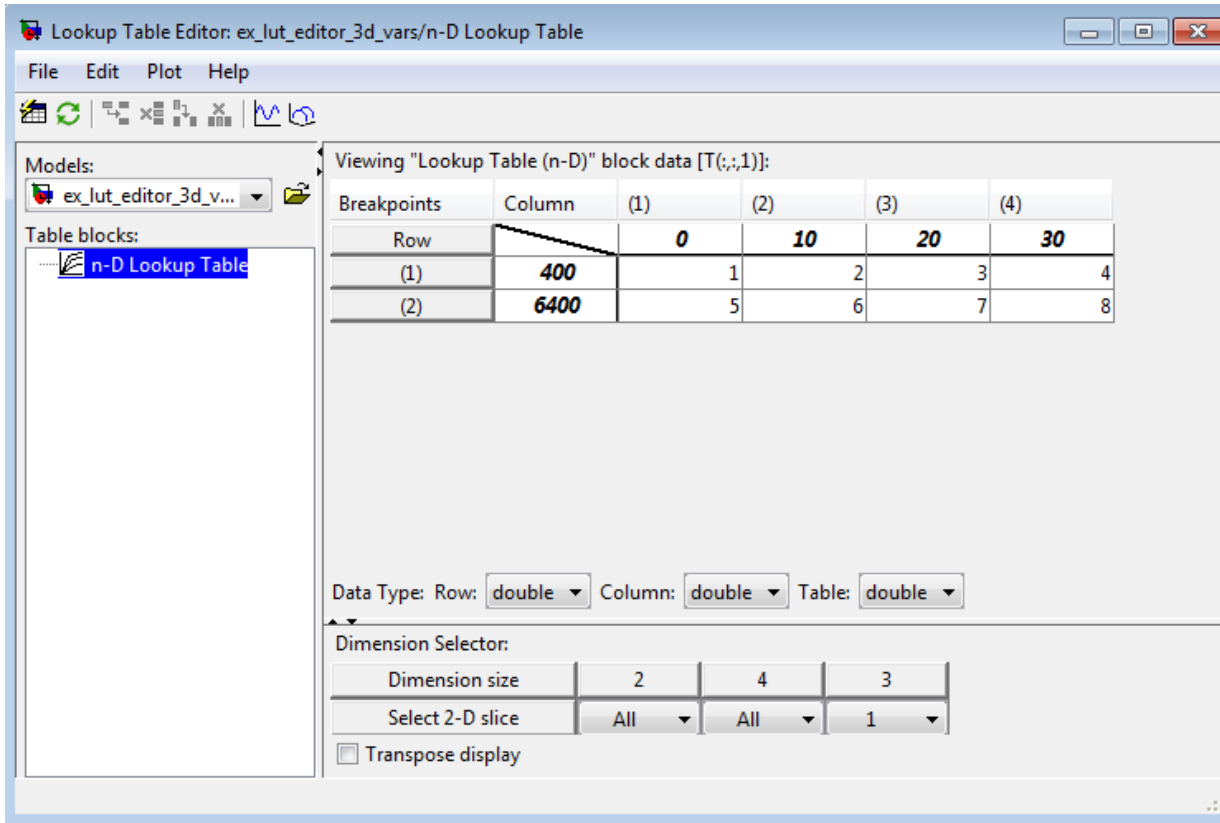
Create workspace variables to use as breakpoint and table data for the lookup table.

```
table3d_map = zeros(2,4,3);
table3d_map(:,:,1) = [     1     2     3     4;      5     6     7     8];
table3d_map(:,:,2) = [    11    12    13    14;     15    16    17    18];
table3d_map(:,:,3) = [   111   112   113   114;   115   116   117   118];
bp3d_z =[  0    10    20];
bp3d_x =[     0    10    20    30];
bp3d_y =[   400  6400];
```

Open the n-D Lookup Table block dialog box, and enter the following parameters in the Table and Breakpoints tab:

- Table data: table3d_map
- Breakpoints 1: bp3d_y
- Breakpoints 2: bp3d_x
- Breakpoints 3: bp3d_z

Click **Edit table and breakpoints** to open the Lookup Table Editor and show the data from the workspace variables.



Propagate Standard Format Lookup Table Data

When you make changes to your lookup table data, consider propagating the changes back to the MATLAB workspace variables the data was imported from using **File > Update Block Data**.

You can also use the Lookup Table Editor to edit the table data and breakpoint data set of `Simulink.LookupTable` and the breakpoint data set of `Simulink.Breakpoint` objects and propagate the changes back to the object.

Suppose you make a change to the lookup table variables imported from the MATLAB workspace variables in “Import Standard Format Lookup Table Data” on page 37-29. For example, change the value of the data in (1,1,1) from `1` to `33`. To propagate this change

back to `table3d_map` in the workspace, select **File** > **Update Block Data**. Click **Yes** to confirm that you want to overwrite `table3d_map`.

Import Nonstandard Format Lookup Table Data

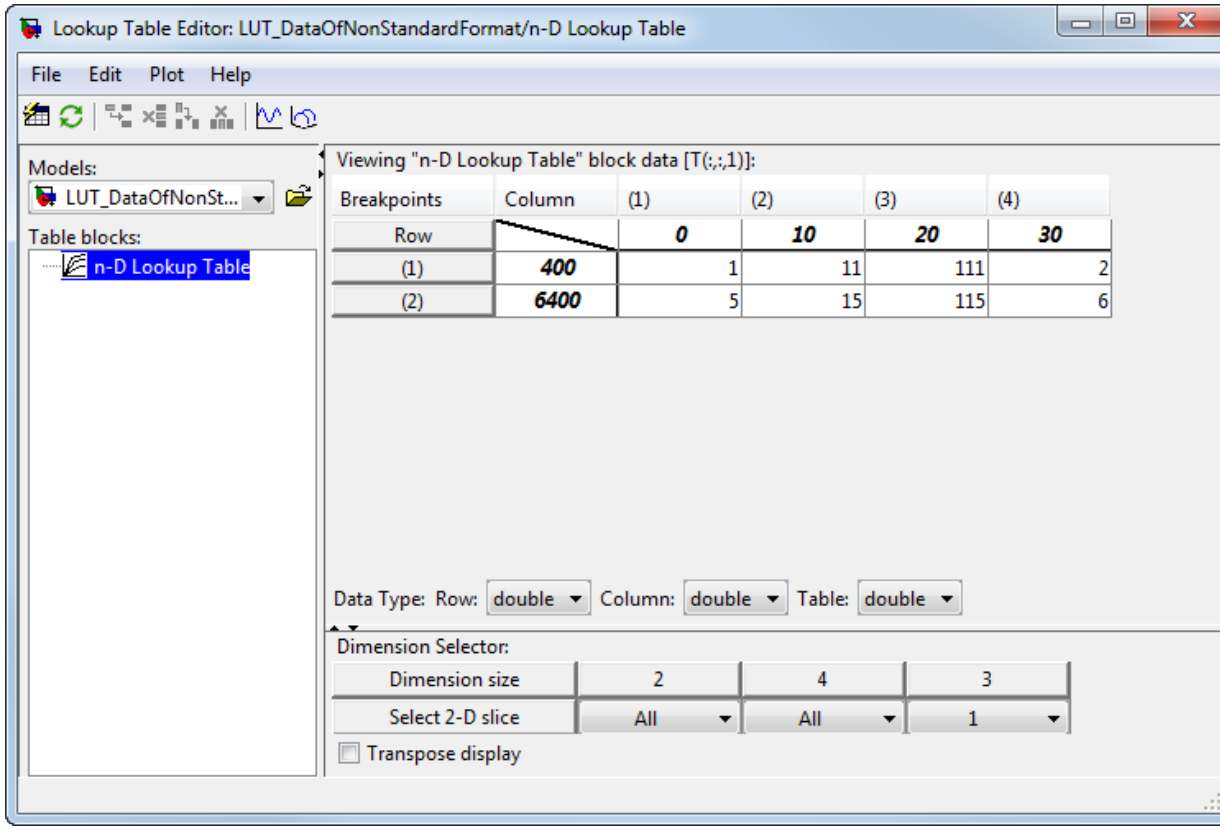
Suppose you specify a 3-D lookup table in your n-D Lookup Table block. Create workspace variables to use as breakpoint and table data for the lookup table. The variable for table data, `table3d_map_custom`, is a two-dimensional matrix.

```
table3d_map_custom = zeros(6,4);
table3d_map_custom = [     1     2     3     4;       5     6     7     8;
11      12     13      14;         15      16      17     18;
111   112    113    114;     115    116    117    118];
bp3d_z =[  0    10    20];
bp3d_x =[  0    10    20    30];
bp3d_y =[  400  6400];
```

Open the n-D Lookup Table block dialog box, and enter the following parameters in the Table and Breakpoints tab. Transform `table3d_map_custom` into a three-dimensional matrix for the table data input using the `reshape` command.

- Table data: `reshape(table3d_map_custom,[2,4,3])`
- Breakpoints 1: `bp3d_y`
- Breakpoints 2: `bp3d_x`
- Breakpoints 3: `bp3d_z`

Click **Edit table and breakpoints** to open the Lookup Table Editor and show the data from the workspace variables.



Change 1 to 33 in the Lookup Table Editor. The Lookup Table Editor records your changes by maintaining a copy of the table. To restore the variable values from the MATLAB workspace, select **File > Reload Block Data**. To update the MATLAB workspace variables with the edited data, select **File > Update Block Data** in the Lookup Table Editor. You cannot propagate the change to `table3d_map_custom`, the workspace variable that contains the nonstandard table data for the n-D Lookup Table block. To propagate the change, you must register a customization function that resides on the MATLAB search path. For details, see “Propagate Nonstandard Format Lookup Table Data” on page 37-33.

Propagate Nonstandard Format Lookup Table Data

This example shows how to propagate changes from the Lookup Table Editor to workspace variables of nonstandard format. Suppose your Simulink model from "Import Nonstandard Format Lookup Table Data" on page 37-31 has a three-dimensional lookup table that gets its table data from the two-dimensional workspace variable `table3d_map_custom`. Update the lookup table in the Lookup Table Editor and propagate these changes back to `table3d_map_custom` using a customization function.

1 Create a file named `sl_customization.m` with these contents.

```
function sl_customization(cm)
cm.LookupTableEditorCustomizer.getTableConvertToCustomInfoFcnHandle{end+1} = ...
@myGetTableConvertInfoFcn;
end
```

In this function:

- The argument `cm` is the handle to a customization manager object.
- The handle `@myGetTableConvertInfoFcn` is added to the list of function handles in the cell array for `cm.LookupTableEditorCustomizer.getTableConvertToCustomInfoFcnHandle`. You can use any alphanumeric name for the function whose handle you add to the cell array.

2 In the same file, define the `myGetTableConvertInfoFcn` function.

```
function blkInfo = myGetTableConvertInfoFcn(blk,tableStr)
        blkInfo.allowTableConvertLocal = true;
        blkInfo.tableWorkSpaceVarName = 'table3d_map_custom';
        blkInfo.tableConvertFcnHandle = @myConvertTableFcn;
end
```

The `myGetTableConvertInfoFcn` function returns the `blkInfo` object containing three fields.

- `allowTableConvertLocal` — Allows table data conversion for a block.
- `tableWorkSpaceVarName` — Specifies the name of the workspace variable that has a nonstandard table format.
- `tableConvertFcnHandle` — Specifies the handle for the conversion function.

When `allowTableConvertLocal` is set to `true`, the table data for that block is converted to the nonstandard format of the workspace variable whose name matches `tableWorkSpaceVarName`. The conversion function corresponds to the handle that

`tableConvertFcnHandle` specifies. You can use any alphanumeric name for the conversion function.

3 In the same file, define the `myConvertTableFcn` function. This function converts a three-dimensional lookup table of size *Rows* * *Columns* * *Height* to a two-dimensional variable of size *(Rows*Height)* * *Columns*.

```
% Converts 3-dimensional lookup table from Simulink format to
% nonstandard format used in workspace variable
function cMap = myConvertTableFcn(data)

% Determine the row and column number of the 3D table data
    mapDim = size(data);
    numCol = mapDim(2);
    numRow = mapDim(1)*mapDim(3);
    cMap = zeros(numRow, numCol);
   % Transform data back to a 2-dimensional matrix
    cMap = reshape(data,[numRow,numCol]);
end
```

4 Put `sl_customization.m` on the MATLAB search path. You can have multiple files named `sl_customization.m` on the search path. For more details, see "Behavior with Multiple Customization Functions" on page 37-35.

5 Refresh Simulink customizations at the MATLAB command prompt.

```
sl_refresh_customizations
```

6 Open the Lookup Table Editor for your lookup table block and select **File > Update Block Data**. Click **Yes** to overwrite the workspace variable `table3d_map_custom`.

7 Check the value of `table3d_map_custom` in the base workspace.

```
table3d_map_custom =

    33     2     3     4
     5     6     7     8
    11    12    13    14
    15    16    17    18
   111   112   113   114
   115   116   117   118
```

The change in the Lookup Table Editor has propagated to the workspace variable.

Note If you do not overwrite the workspace variable `table3d_map_custom`, you are prompted to replace it with numeric data. Click **Yes** to replace the expression in the **Table data** field with numeric data. Click **No** if you do not want your Lookup Table Editor changes for the table data to appear in the block dialog box.

Behavior with Multiple Customization Functions

At the start of a MATLAB session, Simulink loads each `sl_customization.m` customization file on the path and executes the `sl_customization` function. Executing each function establishes the customizations for that session.

When you select **File > Update Block Data** in the Lookup Table Editor, the editor checks the list of function handles in the cell array for `cm.LookupTableEditorCustomizer.getTableConvertToCustomInfoFcnHandle`. If the cell array contains one or more function handles, the `allowTableConvertLocal` property determines whether changes in the Lookup Table Editor can be propagated.

- If the value is set to `true`, then the table data is converted to the nonstandard format in the workspace variable.
- If the value is set to `false`, then table data is not converted to the nonstandard format in the workspace variable.
- If the value is set to `true` and another customization function specifies it to be `false`, the Lookup Table Editor reports an error.

- “Guidelines for Choosing a Lookup Table” on page 37-8
- “Import Lookup Table Data from Excel” on page 37-36

Import Lookup Table Data from Excel

This example shows how to use the MATLAB `xlsread` function in a Simulink model to import data into a lookup table.

1. Save the Excel file in a folder on the MATLAB path.
2. Open the model containing the lookup table block and select **File** > **Model Properties** > **Model Properties**.
3. In the Model Properties dialog box, in the **Callbacks** tab, click **PostLoadFcn** callback in the model callbacks list.
4. Enter the code to import the Excel Spreadsheet data in the text box. Use the MATLAB `xlsread` function, as shown in this example for a 2-D lookup table.

```
% Import the data from Excel for a lookup table
data = xlsread('MySpreadsheet','Sheet1');
% Row indices for lookup table
breakpoints1 = data(2:end,1)';
% Column indices for lookup table
breakpoints2 = data(1,2:end);
% Output values for lookup table
table_data = data(2:end,2:end);
```

5. Click **OK**.

After you save your changes, the next time you open the model, Simulink invokes the callback and imports the data.

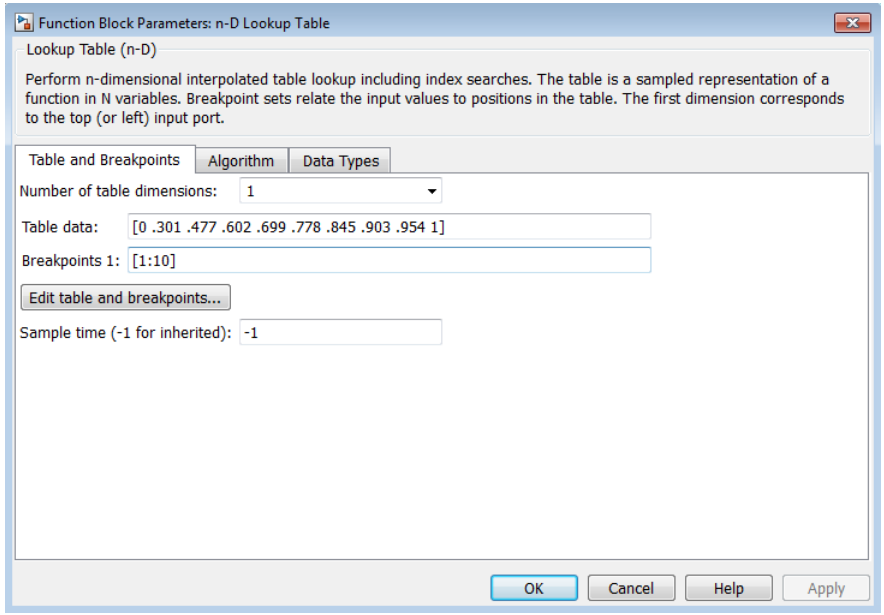
Create a Logarithm Lookup Table

Suppose you want to approximate the common logarithm (base 10) over the input range [1, 10] without performing an expensive computation. You can perform this approximation using a lookup table block as described in the following procedure.

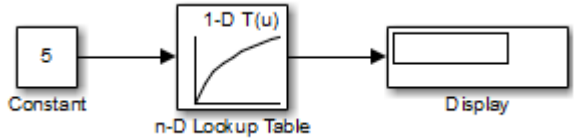
1. Copy the following blocks to a Simulink model:
   - One Constant block to input the signal, from the Sources library
   - One n-D Lookup Table block to approximate the common logarithm, from the Lookup Tables library
   - One Display block to display the output, from the Sinks library
2. Assign the table data and breakpoint data set to the n-D Lookup Table block:
   a. In the **Number of table dimensions** field, enter `1`.
   b. In the **Table data** field, enter `[0 .301 .477 .602 .699 .778 .845 . 903 .954 1]`.
   c. In the **Breakpoints 1** field, enter `[1:10]`.
   d. Click **Apply**.

   The dialog box looks something like this:



3 Double-click the Constant block to open the parameter dialog box, and change the **Constant value** parameter to `5`. Click **OK** to apply the changes and close the dialog box.

4 Connect the blocks as follows.



5 Start simulation.

The following behavior applies to the n-D Lookup Table block.

Value of the Constant Block	Action by the n-D Lookup Table Block	Example of Block Behavior	
		Input Value	Output Value
Equals a breakpoint	Returns the corresponding output value	5	0.699

Value of the Constant Block	Action by the n-D Lookup Table Block	Example of Block Behavior	
		Input Value	Output Value
Falls between breakpoints	Linearly interpolates the output value using neighboring breakpoints	7.5	0.874
Falls outside the range of the breakpoint data set	Linearly extrapolates the output value from a pair of values at the end of the breakpoint data set	10.5	1.023

For the n-D Lookup Table block, the default settings for **Interpolation method** and **Extrapolation method** are both `Linear`.

Prelookup and Interpolation Blocks

The following examples show the benefits of using Prelookup and Interpolation Using Prelookup blocks.

Action	Benefit	Example
Use an index search to relate inputs to table data, followed by an interpolation and extrapolation stage that computes outputs	Enables reuse of index search results to look up data in multiple tables, which reduces simulation time	To open the model, type `sldemo_bpcheck` at the command prompt.
Set breakpoint and table data types explicitly	Lowers memory required to store: • Breakpoint data that uses a smaller type than the input signal • Table data that uses a smaller type than the output signal	To open the model, type `sldemo_interp_memory` at the command prompt.
	Provides easier sharing of: • Breakpoint data among Prelookup blocks • Table data among Interpolation Using Prelookup blocks	To open the model, type `fxpdemo_lookup_shared_param` at the command prompt.
	Enables reuse of utility functions in the generated code	To open the model, type `fxpdemo_prelookup_utilfcn` at the command prompt.
Set the data type for intermediate results explicitly	Enables use of higher precision for internal computations than for table data or output data	To open the model, type `fxpdemo_interp_precision` at the command prompt.

Optimize Generated Code for Lookup Table Blocks

In this section...

Remove Code That Checks for Out-of-Range Inputs

By default, generated code for the following lookup table blocks include conditional statements that check for out-of-range breakpoint or index inputs:

- 1-D Lookup Table
- 2-D Lookup Table
- n-D Lookup Table
- Prelookup
- Interpolation Using Prelookup

To generate code that is more efficient, you can remove the conditional statements that protect against out-of-range input values.

Block	Check Box to Select
1-D Lookup Table	**Remove protection against out-of-range input in generated code**
2-D Lookup Table	
n-D Lookup Table	
Prelookup	
Interpolation Using Prelookup	**Remove protection against out-of-range index in generated code**

Selecting the check box on the block dialog box improves code efficiency because there are fewer statements to execute. However, if you are generating code for safety-critical applications, you should not remove the range-checking code.

To verify the usage of the check box, run the following Model Advisor checks and perform the recommended actions.

Model Advisor Check	When to Run the Check
By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code	For code efficiency
By Product >Simulink Check > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks	For safety-critical applications

For more information about the Model Advisor, see “Select and Run Model Advisor Checks” on page 5-2 in the Simulink documentation.

Optimize Breakpoint Spacing in Lookup Tables

When breakpoints in a lookup table are tunable, the spacing does not affect efficiency or memory usage of the generated code. When breakpoints are *not* tunable, the type of spacing can affect the following factors.

Factor	Even Power of 2 Spaced Data	Evenly Spaced Data	Unevenly Spaced Data
Execution speed	The execution speed is the fastest. The position search and interpolation are the same as for evenly-spaced data. However, to increase speed a bit more for fixed-point types, a bit shift replaces the position search, and a bit mask replaces the interpolation.	The execution speed is faster than that for unevenly-spaced data because the position search is faster and the interpolation uses a simple division.	The execution speed is the slowest of the different spacings because the position search is slower, and the interpolation requires more operations.

Factor	Even Power of 2 Spaced Data	Evenly Spaced Data	Unevenly Spaced Data
Error	The error can be larger than that for unevenly-spaced data because approximating a function with nonuniform curvature requires more points to achieve the same accuracy.	The error can be larger than that for unevenly-spaced data because approximating a function with nonuniform curvature requires more points to achieve the same accuracy.	The error can be smaller because approximating a function with nonuniform curvature requires fewer points to achieve the same accuracy.
ROM usage	Uses less command ROM, but more data ROM.	Uses less command ROM, but more data ROM.	Uses more command ROM, but less data ROM.
RAM usage	Not significant.	Not significant.	Not significant.

Follow these guidelines:

- For fixed-point data types, use breakpoints with even, power-of-2 spacing.
- For non-fixed-point data types, use breakpoints with even spacing.

To identify opportunities for improving code efficiency in lookup table blocks, run the following Model Advisor checks and perform the recommended actions:

- **By Product > Embedded Coder > Identify questionable fixed-point operations**
- **By Product > Embedded Coder > Identify blocks that generate expensive saturation and rounding code**

For more information about the Model Advisor, see "Select and Run Model Advisor Checks" on page 5-2 in the Simulink documentation.

Reduce Data Copies for Lookup Table Blocks

When you use workspace variables to store table and breakpoint data for Lookup Table blocks, and then configure these variables for tunability, you can avoid data copies by using the same data type for the block parameter and variable. Workspace variables include numeric MATLAB variables and `Simulink.Parameter` objects that you store in a workspace, such as the base workspace, or in a data dictionary. If the data type of the

variable is smaller than the data type of the block parameter, the generated code implicitly casts the data type of the variable to the data type of the block parameter. This implicit cast requires a data copy which can potentially significantly increase RAM consumption and slow down code execution speed for large vectors or matrices.

For more information, see “Parameter Data Types in the Generated Code” (Embedded Coder) and “Block Parameter Representation in the Generated Code” (Embedded Coder).

Update Lookup Table Blocks to New Versions

In this section...

Comparison of Blocks with Current Versions

In R2011a, the following lookup table blocks were replaced with newer versions in the Simulink library:

Block	Changes	Enhancements

Lookup Table	• Block renamed as 1-D Lookup Table
	• Icon changed
		• Default integer rounding mode changed from `Floor` to `Simplest`
		• Support for the following features:
		  • Specification of parameter data types different from input or output signal types
		  • Reduced memory use and faster code execution for nontunable breakpoints with even spacing
		  • Cubic-spline interpolation and extrapolation
		  • Table data with complex values
		  • Fixed-point data types with word lengths up to 128 bits
		  • Specification of data types for fraction and intermediate results
		  • Specification of index search method
		  • Specification of diagnostic for out-of-range inputs

Block	Changes	Enhancements

Lookup Table (2-D)	• Block renamed as 2-D Lookup Table
	• Icon changed
		• Default integer rounding mode changed from `Floor` to `Simplest`
		• Support for the following features:
		  • Specification of parameter data types different from input or output signal types
		  • Reduced memory use and faster code execution for nontunable breakpoints with even spacing
		  • Cubic-spline interpolation and extrapolation
		  • Table data with complex values
		  • Fixed-point data types with word lengths up to 128 bits
		  • Specification of data types for fraction and intermediate results
		  • Specification of index search method
		  • Specification of diagnostic for out-of-range inputs
		• Check box for **Require all inputs to have the same data type** now selected by default

Lookup Table (n-D)	• Block renamed as n-D Lookup Table • Icon changed	• Default integer rounding mode changed from `Floor` to `Simplest`

Compatibility of Models with Older Versions of Lookup Table Blocks

When you load existing models that contain the Lookup Table, Lookup Table (2-D), and Lookup Table (n-D) blocks, those versions of the blocks appear. The current versions of the lookup table blocks appear only when you drag the blocks from the Simulink Library Browser into new models.

If you use the `add_block` function to add the Lookup Table, Lookup Table (2-D), or Lookup Table (n-D) blocks to a model, those versions of the blocks appear. If you want to add the *current* versions of the blocks to your model, change the source block path for `add_block`:

Block	Old Block Path	New Block Path
Lookup Table	`simulink/Lookup Tables/Lookup Table`	`simulink/Lookup Tables/1-D Lookup Table`
Lookup Table (2-D)	`simulink/Lookup Tables/Lookup Table (2-D)`	`simulink/Lookup Tables/2-D Lookup Table`
Lookup Table (n-D)	`simulink/Lookup Tables/Lookup Table (n-D)`	`simulink/Lookup Tables/n-D Lookup Table`

How to Update Your Model

To update your model to use current versions of the lookup table blocks, follow these steps:

Step	Action	Reason
1	Run the Upgrade Advisor.	Identify blocks that do not have compatible settings with the 1-D Lookup Table and 2-D Lookup Table blocks.
2	For each block that does not have compatible settings: • Decide how to address each warning. • Adjust block parameters as needed.	Modify each Lookup Table or Lookup Table (2-D) block to ensure compatibility with the current versions.
3	Repeat steps 1 and 2 until you are satisfied with the results of the Upgrade Advisor check.	Ensure that block replacement works for the entire model.

After block replacement, the block names that appear in the model remain the same. However, the block icons match the ones for the 1-D Lookup Table and 2-D Lookup Table blocks. For more information about the Upgrade Advisor, see “Model Upgrades”.

What to Expect from the Model Advisor Check

The Model Advisor check groups all Lookup Table and Lookup Table (2-D) blocks into three categories:

- Blocks that have compatible settings with the 1-D Lookup Table and 2-D Lookup Table blocks

- Blocks that have incompatible settings with the 1-D Lookup Table and 2-D Lookup Table blocks
- Blocks that have repeated breakpoints

Blocks with Compatible Settings

When a block has compatible parameter settings, automatic block replacement can occur without backward incompatibilities.

Lookup Method in the Lookup Table or Lookup Table (2-D) Block	Parameter Settings After Automatic Block Replacement	
	Interpolation	Extrapolation
`Interpolation-Extrapolation`	`Linear`	`Linear`
`Interpolation-Use End Values`	`Linear`	`Clip`
`Use Input Below`	`Flat`	Not applicable

Depending on breakpoint spacing, one of two index search methods can apply.

Breakpoint Spacing in the Lookup Table or Lookup Table (2-D) Block	Index Search Method After Automatic Block Replacement
Not evenly spaced	`Binary search`
Evenly spaced and tunable	A prompt appears, asking you to select `Binary search` or `Evenly spaced points`.
Evenly spaced and not tunable	

Blocks with Incompatible Settings

When a block has incompatible parameter settings, the Model Advisor shows a warning and a recommended action, if applicable.

- If you perform the recommended action, you can avoid incompatibility during block replacement.
- If you use automatic block replacement without performing the recommended action, you might see numerical differences in your results.

Incompatibility Warning	Recommended Action	What Happens for Automatic Block Replacement
The **Lookup Method** is `Use Input Nearest` or `Use Input Above`. The replacement block does not support these lookup methods.	Change the lookup method to one of the following options: • `Interpolation - Extrapolation` • `Interpolation - Use End Values` • `Use Input Below`	The **Lookup Method** changes to `Interpolation - Use End Values`. In the replacement block, this setting corresponds to: • **Interpolation** set to `Linear` • **Extrapolation** set to `Clip` You also see a message that explains possible numerical differences.
The **Lookup Method** is `Interpolation - Extrapolation`, but the input and output are not the same floating-point type. The replacement block supports linear extrapolation only when all inputs and outputs are the same floating-point type.	Change the extrapolation method or the port data types of the block.	
The block uses small fixed-point word lengths, so that interpolation uses only one rounding operation. The replacement block uses two rounding operations for interpolation.	None	You see a message that explains possible numerical differences.

Blocks with Repeated Breakpoints

When a block has repeated breakpoints, the Model Advisor recommends that you change the breakpoint data and rerun the check. You cannot perform automatic block replacement for blocks with repeated breakpoints.

Lookup Table Glossary

The following table summarizes the terminology used to describe lookup tables in the Simulink user interface and documentation.

Term	Meaning
breakpoint	A single element of a breakpoint data set. A breakpoint represents a particular input value to which a corresponding output value in the table data is mapped.
breakpoint data set	A vector of input values that indexes a particular dimension of a lookup table. A lookup table uses breakpoint data sets to relate its input values to the output values that it returns.
extrapolation	A process for estimating values that lie beyond the range of known data points.
interpolation	A process for estimating values that lie between known data points.
lookup table	An array of data that maps input values to output values, thereby approximating a mathematical function. Given a set of input values, a “lookup” operation retrieves the corresponding output values from the table. If the lookup table does not explicitly define the input values, Simulink can estimate an output value using interpolation, extrapolation, or rounding.
monotonically increasing	The elements of a set are ordered such that each successive element is greater than or equal to its preceding element.
rounding	A process for approximating a value by altering its digits according to a known rule.
strictly monotonically increasing	The elements of a set are ordered such that each successive element is greater than its preceding element.

Term	Meaning
table data	An array that serves as a sampled representation of a function evaluated at a lookup table's breakpoint values. A lookup table uses breakpoint data sets to index the table data, ultimately returning an output value.

Working with Block Masks

Masking Fundamentals

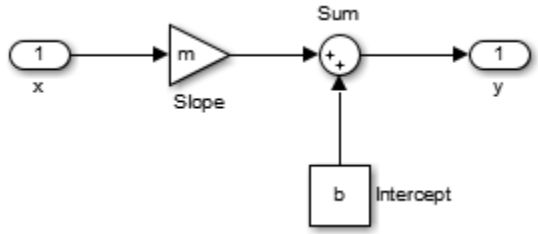
A mask is a custom interface for a block that hides the block content, making it appear as an atomic block with its own icon and parameter dialog box. It encapsulates the block logic, provides controlled access to the block data, and simplifies the graphical appearance of a model.

When you mask a block, a mask definition is created and saved along with the block. A mask changes only the block interface, and not the underlying block characteristics. You can provide access to one or more underlying block parameters by defining corresponding mask parameters on the mask.

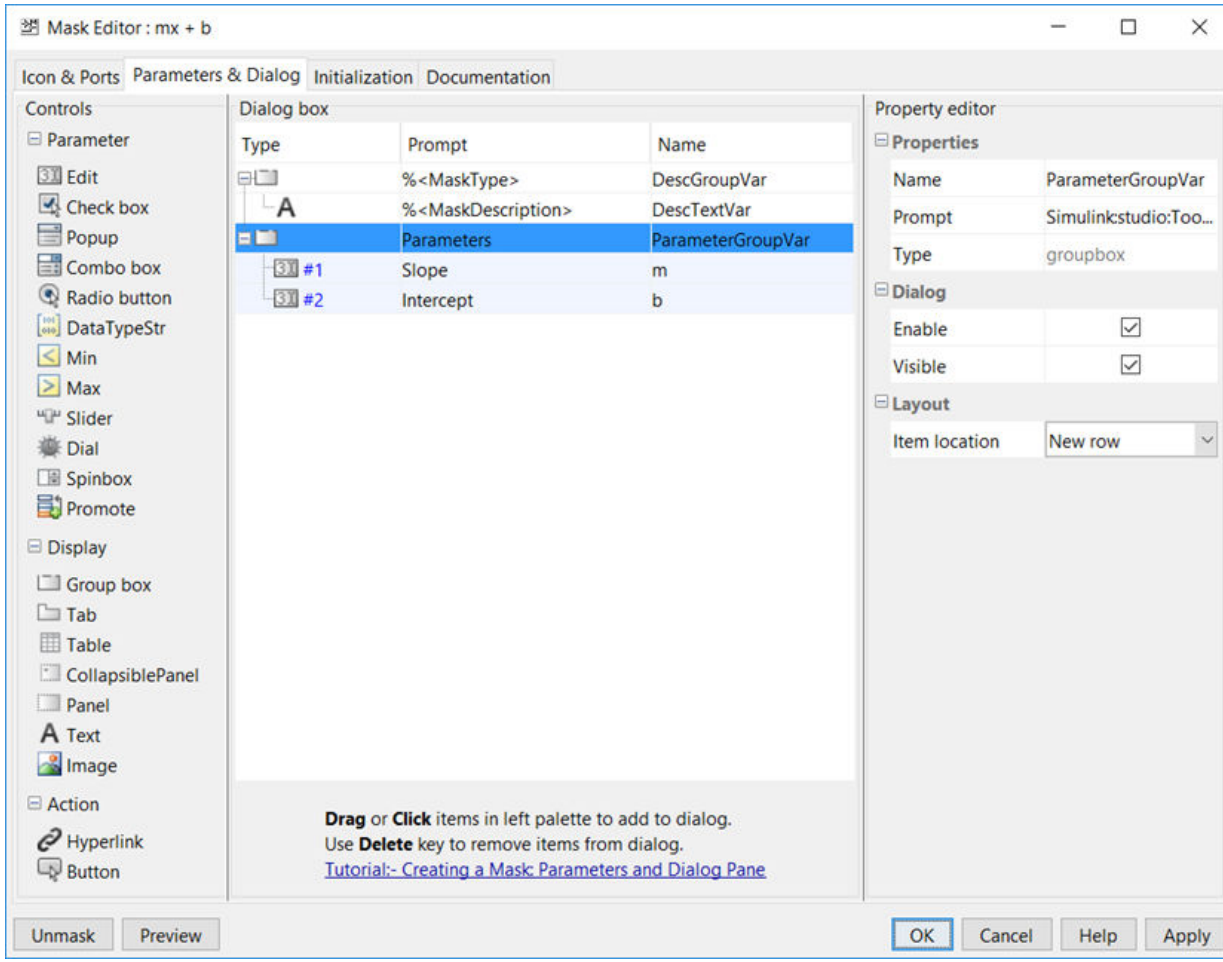
Mask a Simulink block to:

- Display a meaningful icon on a block
- Provide a customized dialog box for the block
- Provide a dialog box that enables you to access only select parameters of the underlying blocks
- Provide users customized description that is specific to the masked block
- Initialize parameters using MATLAB code

Consider the model masking_example that represents the equation of line `y = mx + b`.

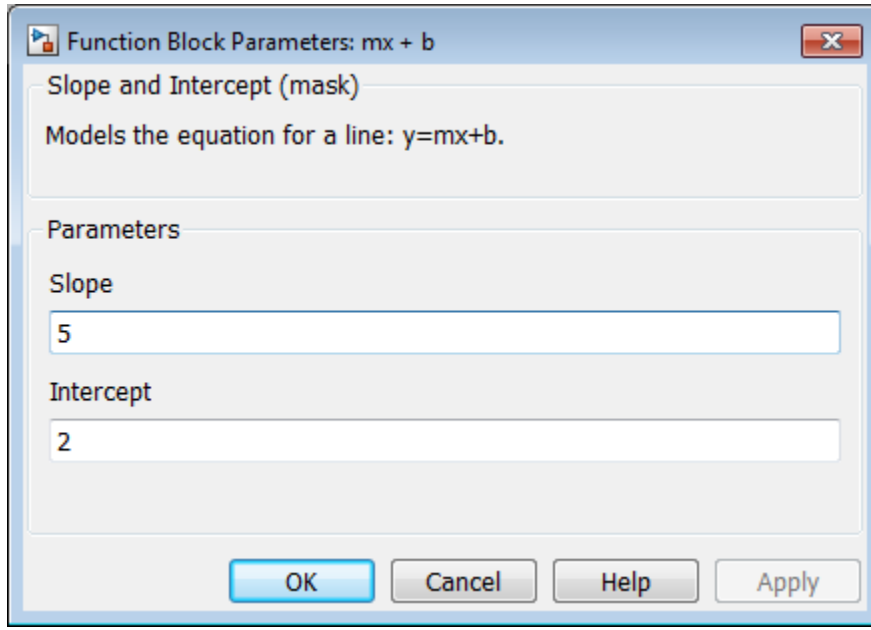


Each block has its own dialog box, making it complicated to specify the values for the line equation variables. To simplify the user interface, a mask is applied on the top-level subsystem block.



Here the variable `m` represents slope and the variable `b` represents the intercept for the line equation `y = mx + b`.

The mask dialog box displays the fields for **Slope** and **Intercept** that are internally mapped to variables `m` and `b`.



Masked blocks do not support content preview. To preview the contents of a subsystem, see “Preview Content of Hierarchical Items” on page 1-58.

Tip For masking examples, see Simulink Masking Examples. The examples are grouped by type. In an example model:

- To view the mask definition, double-click the View Mask block.
- To view the mask dialog box, double-click the block.

Masking Terminology

Term	Description
Mask icon	The masked block icon generated using drawing commands. Mask icon can be static or change dynamically with underlying block parameter values.

Term	Description
Mask parameters	The parameters that are defined in the Mask Editor and appear on the mask dialog box. Setting the value of a mask parameter on the mask dialog box sets the corresponding block parameter value.
Mask initialization code	MATLAB Code that initializes a masked block or reflects current parameter values. Add mask initialization code in the **Initialization** pane of the Mask Editor dialog box. For example, add initialization code to set a parameter value automatically.
Mask dialog callback code	MATLAB Code that runs in the base workspace when the value of a mask parameter changes. Use callback code to change the appearance of a mask dialog box dynamically and reflect current parameter values. For example, enable visible parameters on the dialog box.
Mask documentation	Description and usage information for a masked block defined in the Mask Editor.
Mask dialog box	A dialog box that contains fields for setting mask parameter values and provides mask description.
Mask workspace	Masks that define mask parameters or contain initialization code have a mask workspace. This workspace stores the evaluated values of the mask parameters and temporary values used by the mask.

More About

- “Block Masks”

- “Create a Simple Mask” on page 38-7
- “Mask Editor Overview”
- Set mask parameters
- Creating a Mask: Masking Fundamentals (3 min, 46 sec)

Create a Simple Mask

You can mask a block interactively by using the Mask Editor or mask it programmatically. This example describes how to mask a block by using the **Mask Editor**. To mask a block programmatically, see “Control Masks Programmatically” on page 38-37.

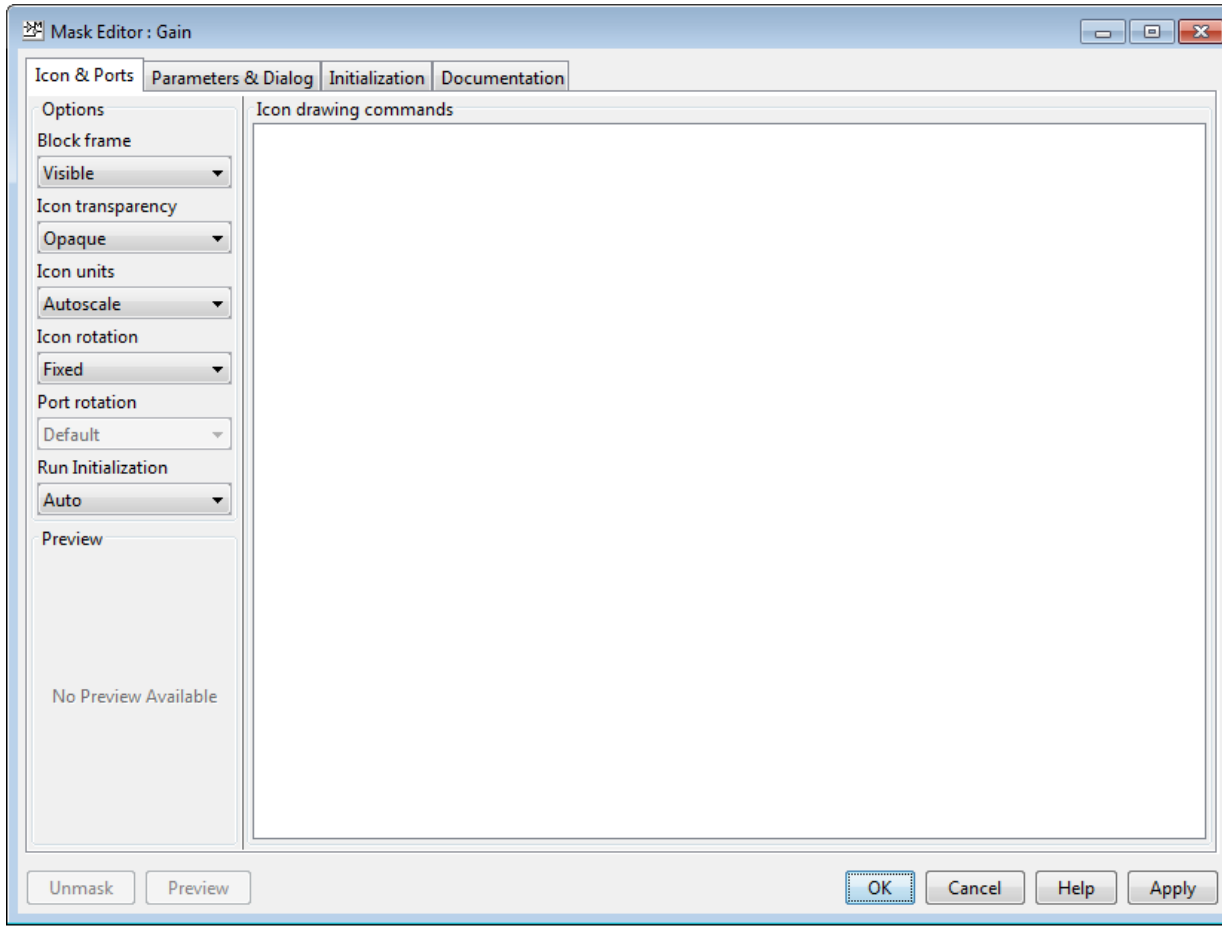
For masking examples, see Simulink Masking Examples.

Step 1: Open Mask Editor

1. Open the model in which you want to mask a block. For example, open `subsystem_example`.

   This model contains a Subsystem block that models the equation for a line: `y = mx + b`.

2. Right-click the Subsystem block and select **Mask > Create Mask**.



Step 2: Define the Mask

The **Mask Editor** contains four tabs that enable you to define the block mask and customize the dialog box for the mask.

For detailed information on each pane, see “Mask Editor Overview”.

Icon & Ports Tab

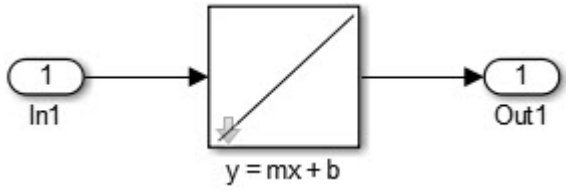
Use this tab to create an icon for the block mask. You can use the **Options** pane on the left to specify icon properties and icon visibility.

Add an image to the block mask.

1. In the **Block frame** drop-down box, select **Visible**.
2. In the **Icon transparency** drop-down box, select **Opaque**.
3. In the **Icon units** drop-down box, select **Autoscale**.
4. To restrict the icon rotation, select **Fixed** from the **Icon rotation** list.
5. In the **Icon drawing commands** text box, type,

   ```
   x = [0 0.5 1 1.5];y = [0 0.5 1 1.5];
   % An example to defines the variables x and y
   plot(y,x) % Command to plot the graph
   ```

   For more information on drawing command syntax, see “Icon drawing commands”.
6. To save the changes, click **Apply**. To preview the block mask icon without exiting the **Mask Editor**, click **Preview**



Note For detailed information, see “Icon & Ports Pane”.

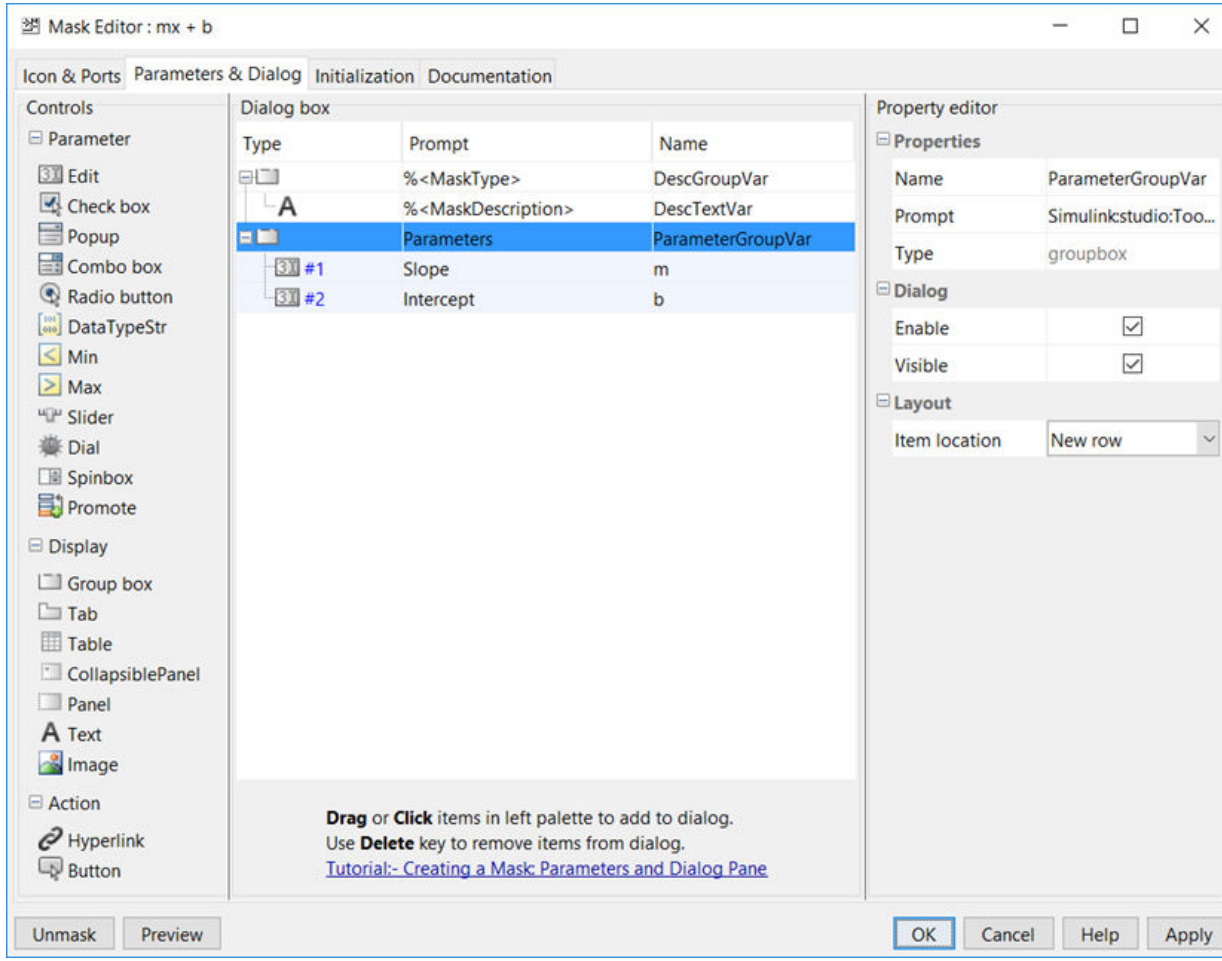
You can create static or dynamic block mask icons. For more information, see “Draw Mask Icon” on page 38-22 and slexMaskDisplayAndInitializationExample.

Parameters & Dialog Tab

Use this tab to add controls like parameters, displays, and action items to the mask dialog box.

To add **Edit** boxes to the block mask.

1. In the left pane, under **Parameter**, click **Edit** twice to add two new rows in the **Dialog box** pane.
2. Type `Slope` and `Intercept` in the **Prompt** and **Name** columns, respectively. The value that you enter in **Prompt** column appears on the mask dialog box. The value you enter in **Name** column is the mask parameter name. The mask parameter name must be a valid MATLAB name.
3. In the right pane, under **Property editor**, provide values in the **Properties**, **Dialog**, and **Layout** sections.
4. Click **Apply**.



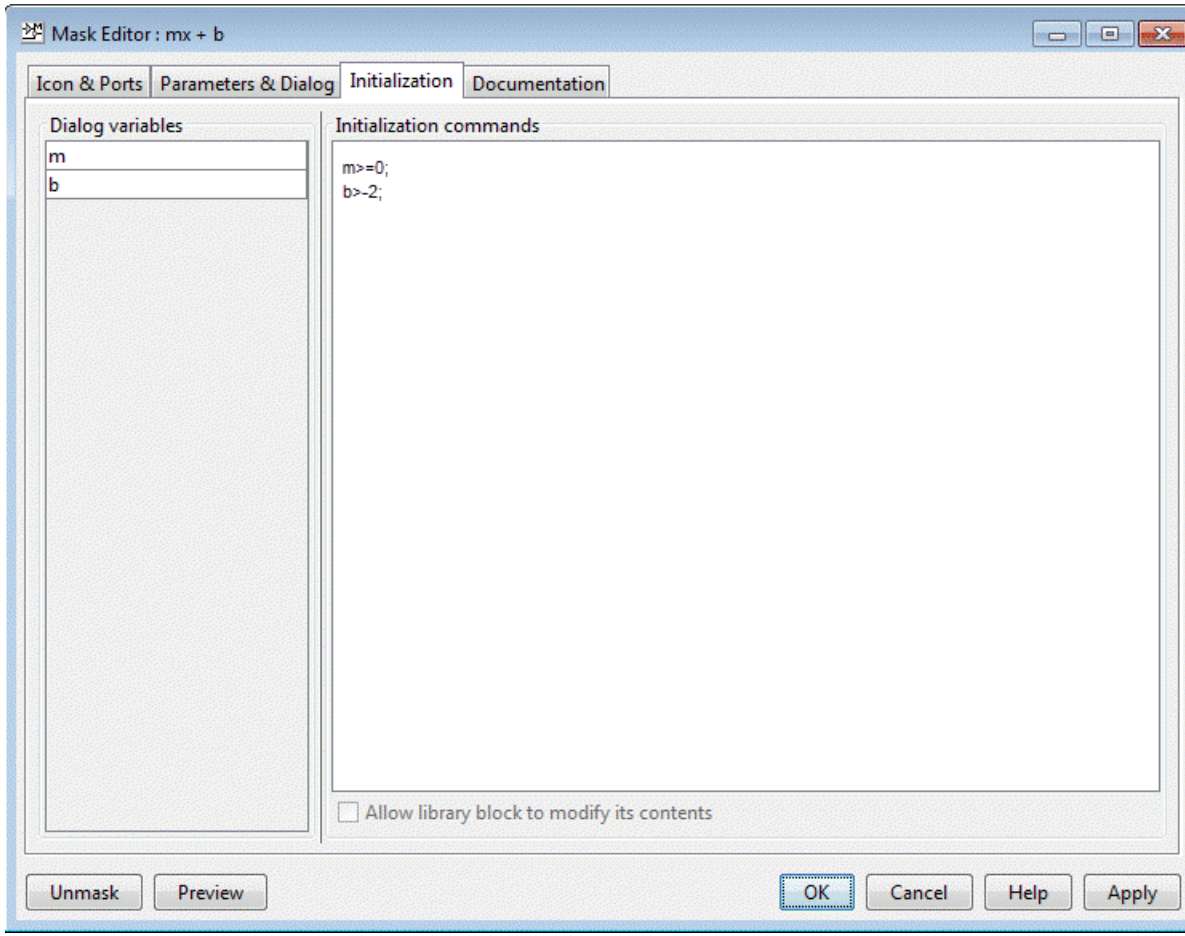
5 To preview the mask dialog box without exiting the Mask Editor, click **Preview**.

Note For detailed information, see “Parameters & Dialog Pane”.

Initialization Tab

Use this pane to specify MATLAB code to control the mask parameters. You can add conditions for the user specified values, provide a predefined value for a mask parameter, and so on.

Consider the equation `y = mx + b`. To allow positive value for `m`, you can add MATLAB code in the initialization pane to specify the acceptable range for `m` as greater than zero.



Note For detailed information, see “Initialization Pane”.

Documentation Tab

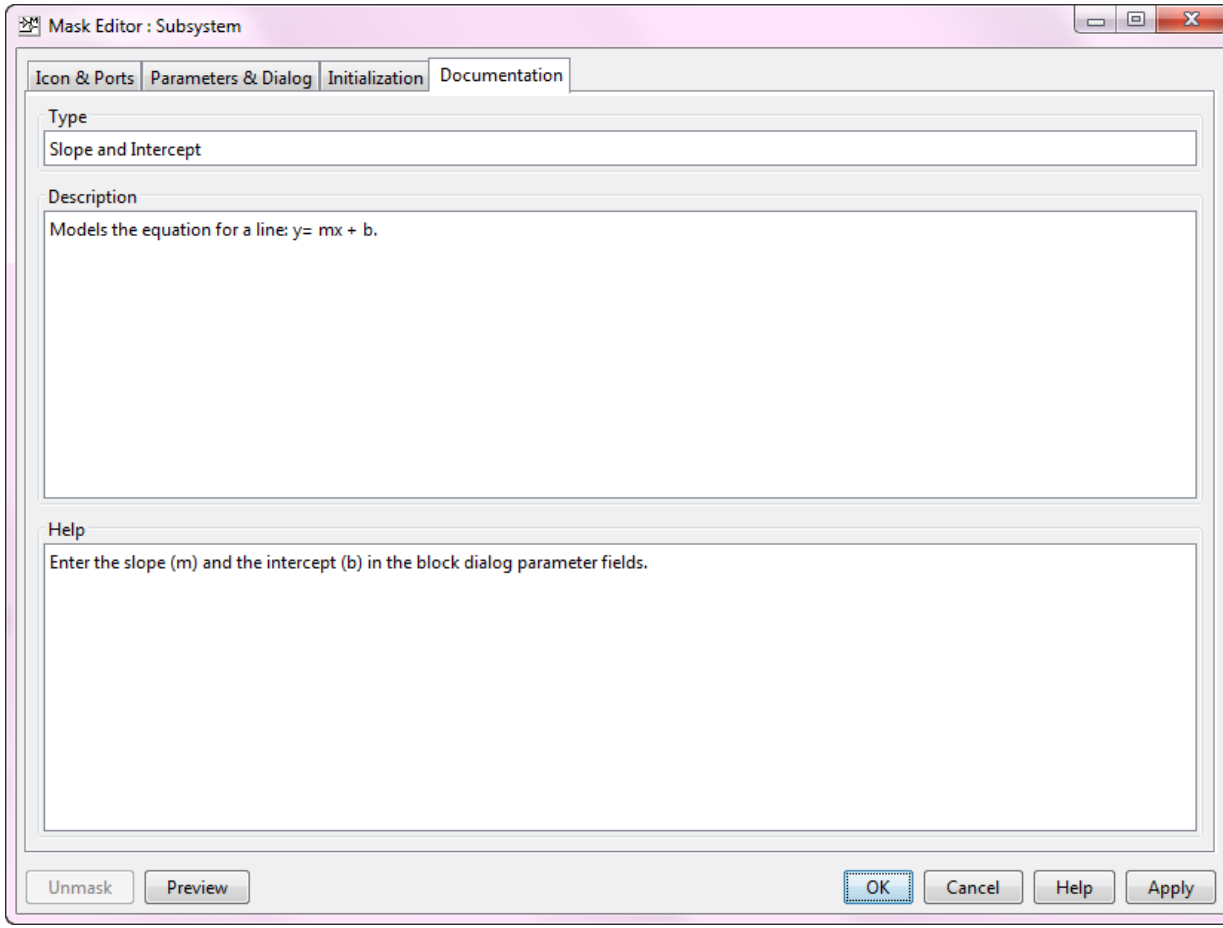
Use this tab to add a name, description, and additional information for the mask.

The **Documentation** tab contains these fields:

1. **Type**: You can add a name for the block mask in this box. The mask name appears on top of the mask dialog box. You cannot add new lines.
2. **Description**: You can add a description for the block mask in this box. By default, the description is displayed below the mask name, and it can contain new lines and spaces.
3. **Help**. You can add additional information for the block mask in this box. You click **Help** on the mask dialog box, this information is displayed. You can use plain text, HTML and graphics, URLs, and web or eval commands to add information in the **Help** field.

   After you have added information in the **Mask Editor**, click **Apply** or **OK**.

   The block is now masked.

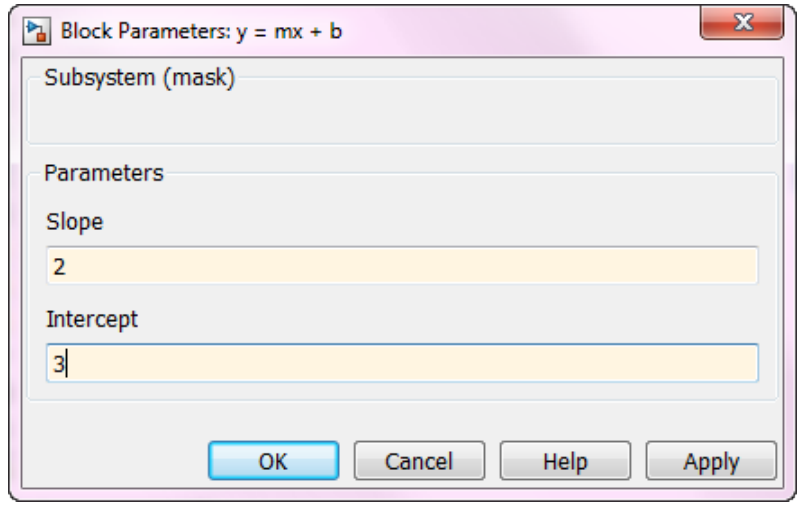


Note For detailed information, see “Documentation Pane”.

Step 3: Operate on Mask

1 You can preview the mask and choose to unmask the block or edit the block mask.

2 Double-click the masked block.



The mask dialog box appears.

3 Type values in the `Slope` and `Intercept` boxes of the mask dialog box. To view the output, simulate the model.

4 Click **OK**.

5 To edit the mask definition, right-click the block and select **Mask > Edit Mask**. For more information, see "Manage Existing Masks" on page 38-16.

6 Right-click the masked block and select **Mask > Look Under Mask** to view:

- The blocks inside the masked subsystem
- The built-in block dialog box of a masked block
- The base mask dialog box of a linked masked block

See Also

"Block Masks" | "Mask Editor Overview" | "Masking Fundamentals" on page 38-2 | Creating a Mask: Masking Fundamentals (3 min, 46 sec)

Manage Existing Masks

Change a Block Mask

You can change an existing mask by reopening the Mask Editor and using the same techniques that you used to create the mask:

1. Select the masked block.
2. Select **Mask** > **Edit Mask**.

The Mask Editor reopens, showing the existing mask definition. Change the mask as needed. After you change a mask, click **Apply** to preserve the changes.

View Mask Parameters

To display a mask dialog box, double-click the block. Alternatively, right-click the block and select **Mask** > **Mask Parameters** or click **Diagram** > **Mask** > **Mask Parameters**.

Tip Each block has a block parameter dialog box. To view the block parameters dialog box of a masked block, right-click the masked block and select **Block Parameters (BlockType)**.

Look Under Block Mask

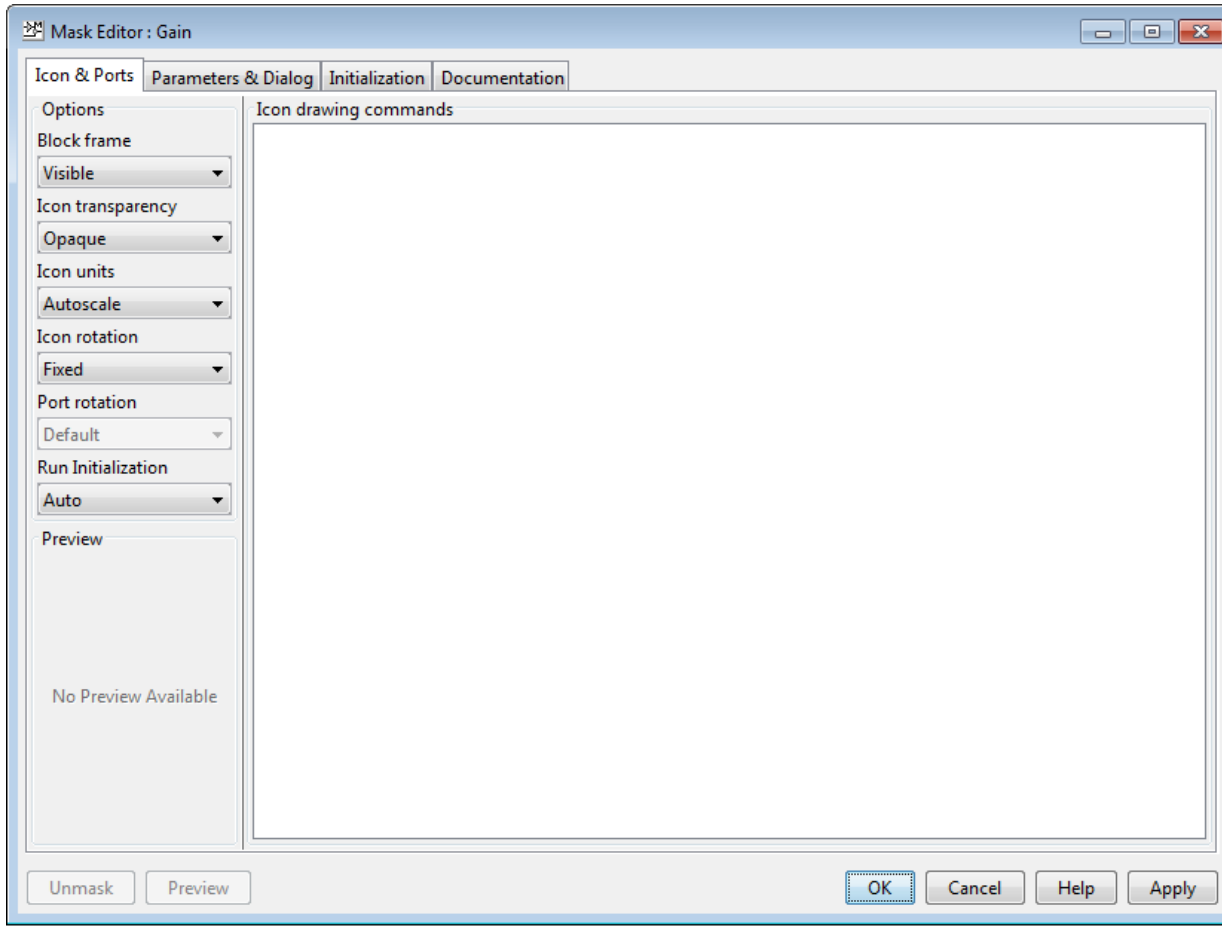
To see the block diagram under a masked Subsystem block, built-in block, or the model referenced by a masked model block, right-click the block and select **Mask** > **Look Under Mask**.

Remove Mask

To remove a mask from a block,

1. Right-click the block.
2. Select **Mask** > **Edit Mask**.

   The Mask Editor opens and displays the existing mask, for example:



3 Click **Unmask** in the lower left corner of the Mask Editor.

The Mask Editor removes the mask from the block.

"Create a Simple Mask" on page 38-7

Mask Callback Code

In this section...

Add Mask Code

You can use MATLAB code to initialize a mask and to draw mask icons. Since the location of code affects model performance, add your code to reflect the functionality you need.

Purpose	Add in Mask Editor	Programmatic Specification
Initialize the mask	**Initialization** pane	`MaskInitialization` parameter
Draw mask icon	**Icon & Ports** pane	`MaskDisplay` parameter
Callback code for mask parameters	**Parameters & Dialog** pane	`MaskCallbacks` parameter

Execute Drawing Command

Place MATLAB code for drawing mask icons in the **Icon Drawing Commands** section of the **Icon & Ports** pane. Simulink executes these commands sequentially to redraw the mask icon when:

- Block is rendered first on the Mask Editor canvas.
- Mask parameters and values that depend on drawing commands change.
- Block appearance is altered due to rotation or other changes.

Note Placing MATLAB code for drawing mask icons in the **Initialization** pane affects model performance. This behavior is because Simulink redraws the icon each time the masked block is evaluated in the model.

Execute Initialization Command

Initialization commands for all masked blocks in a model run when you:

- Update the diagram
- Start simulation
- Start code generation
- Apply mask changes
- Change any of the parameters that define the mask, such as `MaskDisplay` and `MaskInitialization`, using the Mask Editor or `set_param`.
- Rotate or flip the masked block, if the icon depends on initialization commands.
- Cause the icon to be drawn or redrawn, and the icon drawing depends on initialization code.
- Change the value of a mask parameter by using the block dialog box or `set_param`.
- Copy the masked block within the same model or between different models.

When you open a model, Simulink locates visible masked blocks that reside at the top level of the model or in an open subsystem.

Simulink only executes the initialization commands for these visible masked blocks if they meet either of the following conditions:

- The masked block has icon drawing commands.

  Note Simulink does not initialize masked blocks that do not have icon drawing commands, even if they have initialization commands during model load.

- The masked subsystem belongs to a library and has the **Allow library block to modify its contents** parameter enabled.

When you load a model into memory without displaying it graphically, no initialization commands initially run for any masked blocks. See “Load a Model” on page 1-13 and `load_system` for information about loading a model without displaying it.

Note The non-tunable parameters of a masked block are not evaluated if the model is already complied (initialized).

Execute Callback Code

Simulink executes the callback commands when:

- You open the mask dialog box. Callback commands execute sequentially, starting with the top mask dialog box.
- You modify a parameter value in the mask dialog box and then change the cursor location. For example, you press the **Tab** key or click into another field in the dialog box after changing the parameter value.

  Note When you modify the parameter value by using the `set_param` command, the callback commands do not execute.
- You modify the parameter value, either in the mask dialog box or using `set_param`, and then apply the change by clicking **Apply** or **OK**. Mask initialization commands execute after callback commands. For more information, see “Initialization Pane”.
- You hover over a masked block to see the tool tip for the block, when the tool tip contains parameter names and values.

  Note Callback commands do not execute if the mask dialog box is open when the block tool tip appears.
- You update a diagram (for example, by pressing **Ctrl+D** or by selecting **Simulation** > **Update diagram** in the Simulink Editor).
- If you close a mask dialog box without saving the changes, the Callback command for parameters is executed sequentially.

Note Buttons on mask dialog box are unavailable when the callback code associated with the button is being executed.

For related Simulink example models, see:

- Sequence mask callbacks
- Unsafe mask callbacks
- Unsafe nested mask callbacks

See Also

"Block Masks" | "Initialize Mask" on page 38-26

Draw Mask Icon

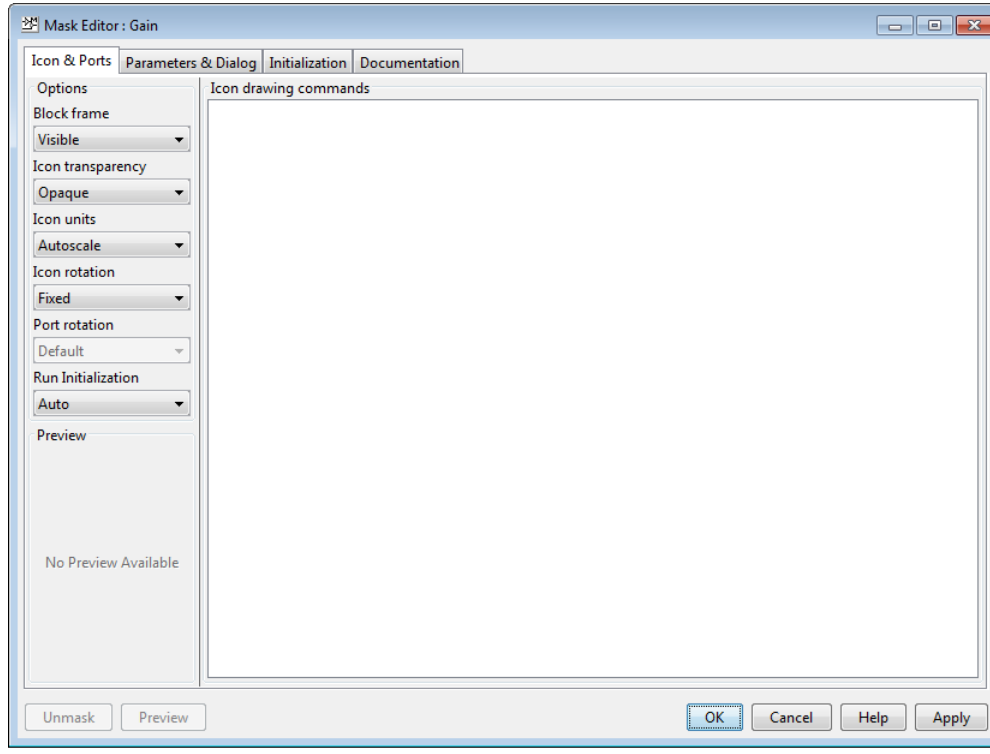
You can create icons that update when you change the mask parameters to reflect the purpose of the block. This example shows how to use drawing commands to create a mask icon.

In this section...

Draw Static Icon

A static mask icon remains unchanged, independent of the value of the mask parameters.

1 Right-click the masked block that requires the icon and select **Mask > Edit Mask**.



2 In the **Icons & Ports** tab, enter this command in the **Icon Drawing commands** pane:

```
% Use specified image as mask icon
image('engine.jpg')
```

The image file must be on the MATLAB path.

For more examples of drawing command syntax, see "Icon drawing commands".

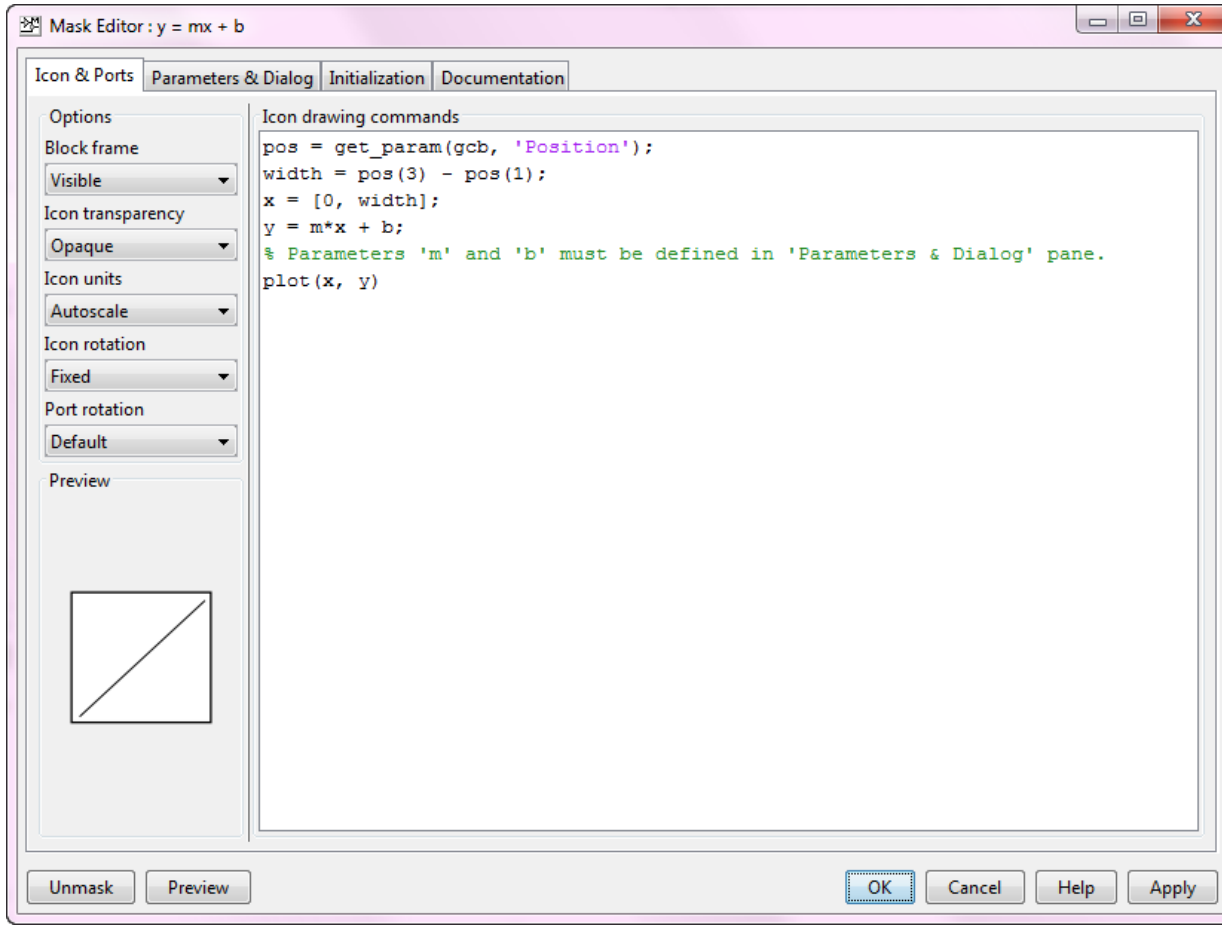
Images in formats `.cur`, `.hdf4`, `.ico`, `.pcx`, `.ras`, `.xwd`, `.svg` cannot be used as block mask images. However, you can use images in these formats if you wrap the file name in the `imread()` function and use the RGB triplet. Using the `imread()` function is not efficient. However, it is still supported for backward compatibility.

Draw Dynamic Icon

A dynamic icon changes with the values of the mask parameters. Use it to represent the purpose of the masked block.

1 Right-click the masked block that requires the icon and select **Mask > Edit Mask**.

The Mask Editor opens.



2 In the **Icons & Ports** tab, enter this command in the **Icon Drawing commands** pane:

```
pos = get_param(gcb, 'Position');
width = pos(3) - pos(1);
x = [0, width];
y = m*x + b;
% Parameters 'm' and 'b' must be defined in 'Parameters & Dialog' pane.
plot(x,y)
```

3 Under **Options**, set **Icon Units** to `Pixels`.

The drop-down lists under **Options** allow you to specify icon frame visibility, icon transparency, drawing context, icon rotation, and port rotation.

4 Click **Apply**. To view the icon generated, see model `masking_example`.

Note If Simulink cannot evaluate all commands in the **Icon Drawing commands** pane to generate an icon, three question marks (`? ? ?`) appear on the mask.

See `slexMaskDisplayAndInitializationExample` for more examples of icon drawing commands. This model shows how to draw:

- Static mask
- Dynamic shape mask
- Dynamic text mask
- Image mask

"Block Masks"

Initialize Mask

You can add MATLAB code in the Initialization pane of the Mask Editor to initialize a masked block. Simulink executes these initialization commands to initialize a masked subsystem at critical times, such as model loading and start of a simulation run. For more information, see “Execute Initialization Command” on page 38-19.

You can add mask initialization code for these cases:

- To specify the initial values of mask parameters. For example to specify an initial value of parameter `a`, type `a = 5` in the Initialization pane.
- To specify an acceptable range of inputs for mask parameter. For example, to specify the range between `0` and `10` as the acceptable values for parameter `a`, type `0 = a >= 10`.
- To specify the value of a child block. For example,

  ```
  set_param('Child block Name','Parameter name','Parameter Value')
  ```

- To create a self-modifiable mask. For more information, see Self-Modifying Mask.

The initialization code of a masked subsystem can refer only to the variables in its local workspace.

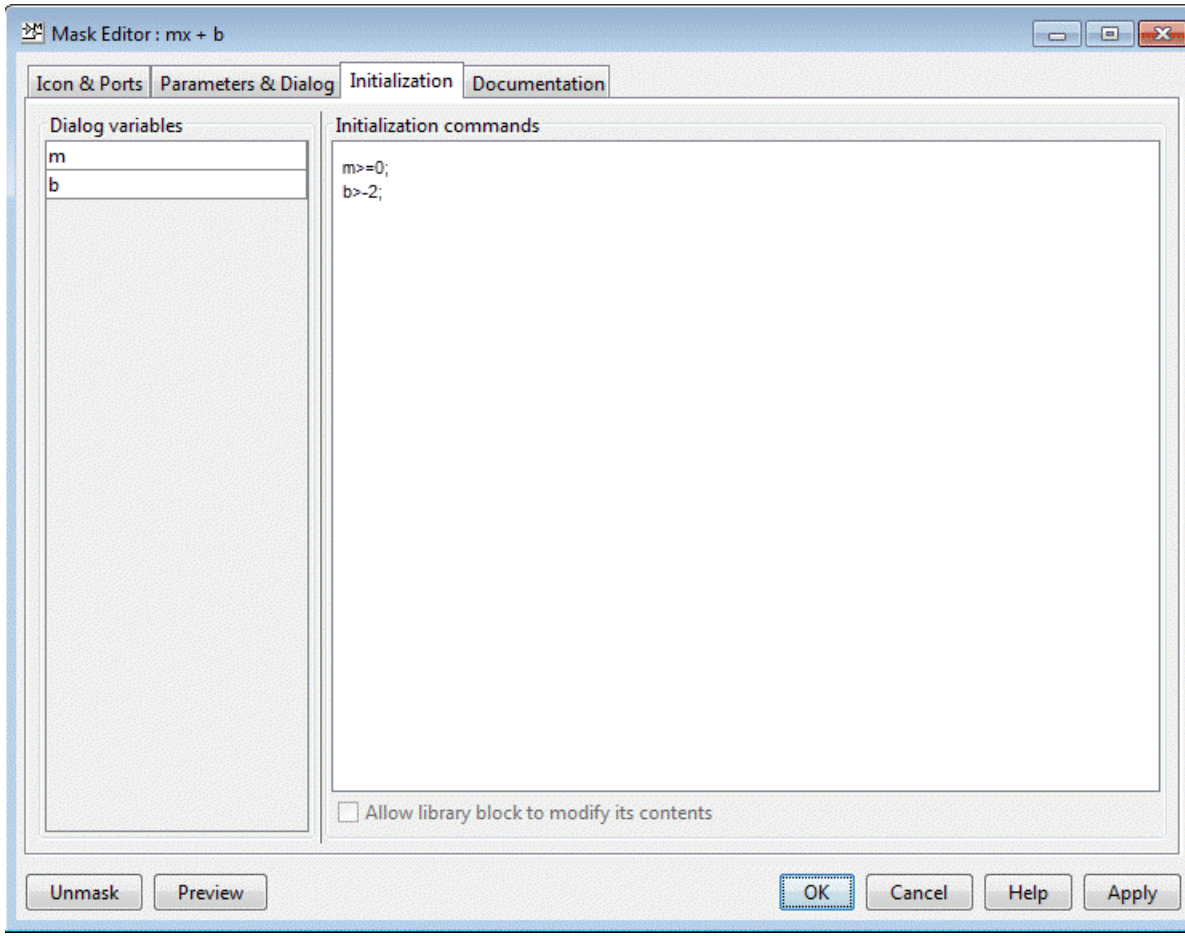
When you reference a block with, or copy a block into, a model, the mask dialog box displays the specified default values. You cannot use mask initialization code to change mask parameter default values in a library block or any other block.

Note Blocks that contain initialization code do not work as expected when using model reference.

Use the Mask Editor **Initialization** pane to add MATLAB commands that initialize a masked block.

The **Initialization** pane contains these sections:

- **Dialog variables**
- **Initialization commands**



Dialog Variables

The **Dialog variables** section displays the names of the variables associated with the mask parameters of the masked block that are defined in the **Parameters** pane.

You can copy the name of a parameter from this list and paste it into the **Initialization commands** section.

You can change the name of the mask parameter variable in the list by double-clicking and editing the name.

Initialization Commands

You can add the initialization commands in this section. The initialization code must be a valid MATLAB expression, consisting of MATLAB functions and scripts, operators, and variables defined in the mask workspace. Initialization commands cannot access base workspace variables.

To avoid echoing results to the MATLAB Command Window, terminate initialization commands with a semicolon.

To view related examples, see

- Define mask display and initialization
- Use MATLAB graphics in masking

Mask Initialization Best Practices

Mask initialization commands must observe the following rules:

- Do not use initialization code to create dynamic mask dialog boxes (Dialog boxes whose appearance or control settings change depending on changes made to other control settings). Instead, use the mask callbacks that are intended for this purpose. For more information, see “Dynamic Mask Dialog Box” on page 38-52.
- For nested masked subsystem, do not use `set_param` on a block located in the lower-level masked subsystem from the higher-level masked subsystem. The lower-level mask and the higher-level mask both could be initializing the same parameter of the block leading to unexpected behavior. For more information, see Unsafe Mask Callback Error.
- Do not use `set_param` commands on blocks that reside in another masked subsystem that you are initializing. Trying to set parameters of blocks in lower-level masked subsystems can trigger unresolved symbol errors if lower-level masked subsystems reference symbols defined by higher-level masked subsystems.

  Suppose, for example, a masked subsystem `A` contains a masked subsystem `B` which contains Gain block `C`, whose `Gain` parameter references a variable defined by `B`. Suppose also that subsystem `A` has initialization code that contains this command:

  ```
  set_param([gcb '/B/C'], 'SampleTime', '-1');
  ```

  Simulating or updating a model containing A causes an unresolved symbol error.

- You cannot use mask initialization code to create data objects. Data objects are objects of these classes:
  - `Simulink.Parameter` and subclasses
  - `Simulink.Signal` and subclasses
- Do not add initialization code to delete the same masked block.
- Use mask initialization code to control direct child blocks only.

Note Do not use mask initialization code to comment or uncomment a block.

Promote Parameter to Mask

In this section...

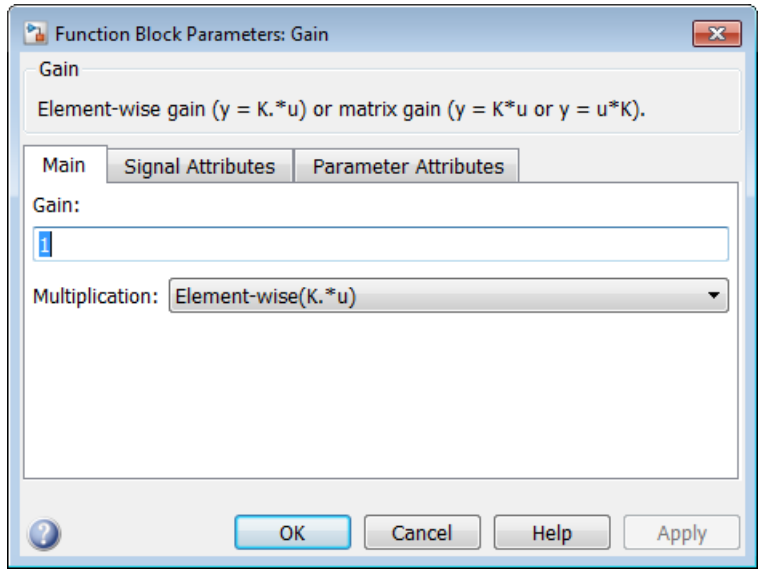
Blocks and subsystems can have multiple parameters associated with them. Block masks allow you to expose one or more of these parameters while hiding others from view. Promoting specific parameters to the mask block simplifies the interface and enables you to specify the parameters the user of the block can view and set.

You can use the **Promote** button on the Mask Editor to promote any underlying parameter of a block either to a block mask or to a subsystem mask. The promoted block parameter gets associated with a parameter in the mask, enabling you to edit the parameter value from the mask dialog box.

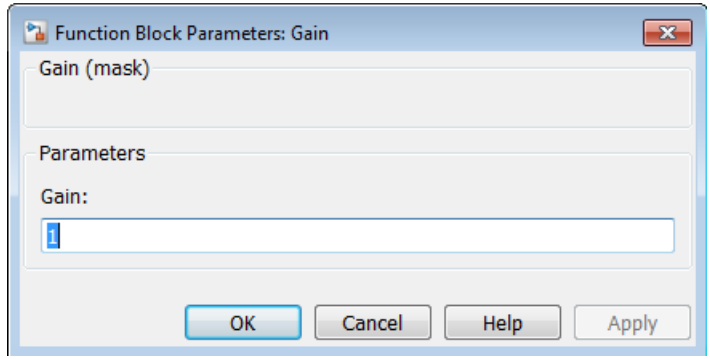
Promote parameters from the block dialog box to the mask:

- To customize the mask dialog box by moving the required parameters from the block dialog box to the mask dialog box.
- To reuse a library block at different instances of a model. For each instance of the library block, you can create individual mask dialog box by promoting parameters for each block.

Consider the block dialog box of the Gain block, which has parameters such as **Gain**, **Multiplication**.



To expose only the `Gain` parameter, mask the Gain block and promote the `Gain` parameter to the mask dialog box.



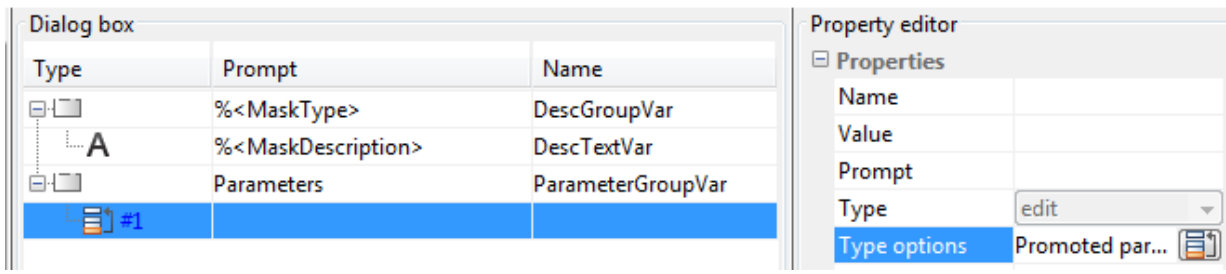
Similarly, you can mask a subsystem block and promote parameters to the mask from child blocks of the subsystem block. If the data type of subsystem child block parameters is same, you can associate a single mask parameter with multiple promoted parameters. For example, you can promote multiple **Gain** parameters in a subsystem to a single dialog box on your mask.

If the parameter is of data type `popup` or `DataType`, the options must also be the same for the parameters to be promoted together. The **Evaluate** attribute for all the parameters to be promoted must be similar.

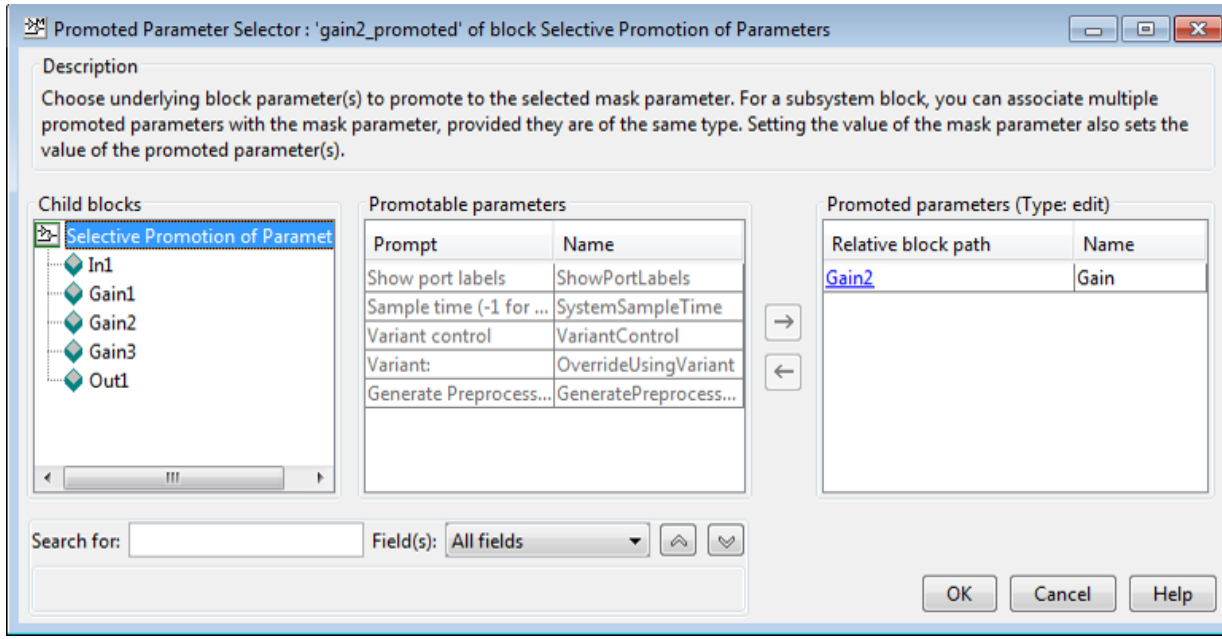
For a related example, see Promote mask parameters.

Promote Underlying Parameters to Block Mask

1. Right-click the block whose parameter you want to promote and select **Mask** > **Create Mask**.
2. In the **Mask Editor** dialog box, click the **Parameters & Dialog** tab.
3. In the **Controls** pane, click **Promote**.
4. In the **Property editor** pane, next to **Type options**, click  .



Use the **Promoted Parameter Selector** dialog box to select the parameters that you want to promote.



5 To add a parameter to the **Promoted parameters** list, select a parameter from the **Promotable parameters** table and click the **Add to promoted parameter list** button  .

To view the parameter properties such as **Type**, hover over the parameter name in the **Promotable parameter** pane.

Tip

- You can use the **Child blocks** list or the **Search** box to find underlying block parameters to promote.
- To prevent tuning of a property during simulation, you can disable the **Tunable** attribute while promoting a tunable parameter.

---

6 Click **OK**.

7 In the **Mask Editor** dialog box, edit the prompt names for the promoted parameters and click **OK**. You cannot edit the variable names.

8 Click **OK**. Look at the block mask. Only the parameters you promoted are available to set.

Note

- You can use **Promote all**  to promote all parameters. **Promote all** is available for all block masks except for subsystem masks.
- To remove a promoted parameter, select the parameter and press **Delete** key.
- You cannot view or promote parameters of a nested masked or linked child block.

Promote Underlying Parameters to Subsystem Mask

1 Right-click the subsystem and select **Mask** > **Create Mask**.

2 In the **Mask Editor** dialog box, click the **Parameters & Dialog** tab.

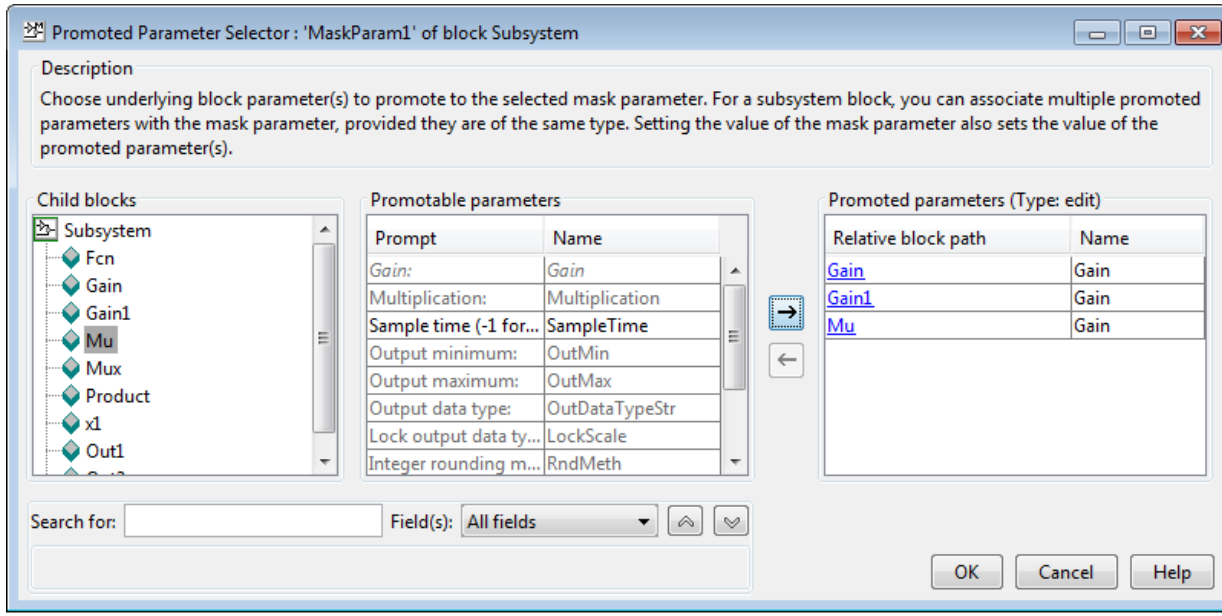
3 In the **Controls** pane, click **Promote**.

4 In the **Property editor** pane, next to **Type options**, click  .

5 In the **Promoted Parameter Selector** dialog box, select the parameters that you want to promote.

6 To add a parameter to the **Promoted parameters** list, select a parameter from the **Promotable parameters** table and click the **Add to promoted parameter list** button  .

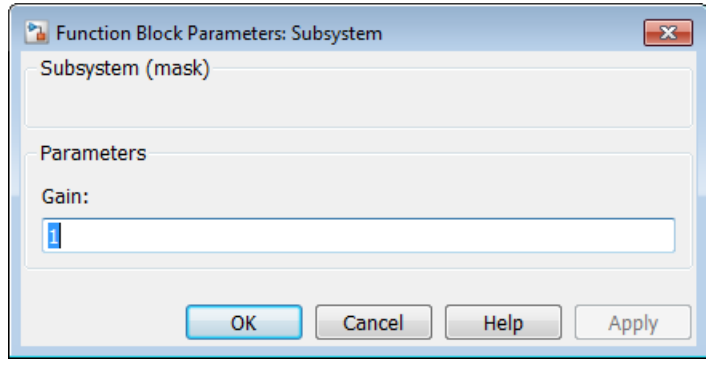
You can add parameters of the same data type from different child blocks to the **Promoted parameters** list. For example, the `Gain` parameter from a different child block can be added to the **Promoted parameters** list to promote to the single `Gain` parameter on the mask.



7 Click **OK**.

8 In the **Mask Editor** dialog box, edit the prompt names for the promoted parameters and click **OK**. You cannot edit the variable names.

9 Click **OK**. Look at the block mask. Only the parameters you promoted are available to set.



Unresolved Promoted Parameter

When a promoted parameter is disconnected from the underlying block parameter, the promoted parameter is unresolved. Unresolved promoted parameters can cause the model to be erroneous as the promoted parameter cannot find the corresponding block parameter. Promoted parameters can become unresolved for any of these reasons:

- The underlying block is deleted.
- The underlying block is replaced with another block of same name but does not have the specified parameter.
- The underlying block is moved within another mask.

Best Practices

- Set the value of a promoted parameter only in the mask dialog box and not in the underlying block dialog box or from the command line.
- Parameters once promoted cannot be promoted again to any other mask.
- Do not edit the **Evaluate** attribute of the promoted parameter. This property is inherited from the block parameter.
- If you are promoting a nontunable parameter, do not edit the **Tunable** attribute.
- Parameters of a masked or linked child block cannot be viewed or promoted.
- Callbacks associated with a block parameter are promoted to the block mask and not to the subsystem mask. User-defined callbacks are sequentially executed after the dynamic dialog callback execute.

Control Masks Programmatically

In this section...

Simulink defines a set of parameters that help in setting and editing masks. To set and edit a mask from the MATLAB command line, you can use `Simulink.Mask` and `Simulink.MaskParameter` class methods. You can also use the `get_param` and `set_param` functions to set and edit masks. However, since these functions use delimiters that do not support Unicode (Non-English) characters it is recommended that you use methods of the `Simulink.Mask` and `Simulink.MaskParameter` class methods to control masks.

Use Simulink.Mask and Simulink.MaskParameter

Use methods of `Simulink.Mask` and `Simulink.MaskParameter` classes to perform the following mask operations:

- Create, copy, and delete masks
- Create, edit, and delete mask parameters
- Determine the block that owns the mask
- Get workspace variables defined for a mask

1 In this example the `Simulink.Mask.create` method is used to create a block mask:

```
maskObj = Simulink.Mask.create(gcb);
```

```
maskObj =
     Simulink.Mask handle
     Package: Simulink
     Properties:
                    Type: ''
             Description: ''
                    Help: ''
          Initialization: ''
          SelfModifiable: 'off'
                 Display: ''
```

```
                IconFrame: 'on'
               IconOpaque: 'on'
    RunInitForIconRedraw: 'off'
               IconRotate: 'none'
               PortRotate: 'default'
                IconUnits: 'autoscale'
               Parameters: []
  Methods, Events, Superclasses
```

2 In this example the mask object is assigned to variable `maskObj` using the `Simulink.Mask.get` method:

```
maskObj = Simulink.Mask.get(gcb)
```

```
maskObj =
    Simulink.Mask handle
    Package: Simulink
    Properties:
                    Type: ''
             Description: ''
                    Help: ''
          Initialization: ''
          SelfModifiable: 'off'
                 Display: ''
                IconFrame: 'on'
               IconOpaque: 'on'
    RunInitForIconRedraw: 'off'
               IconRotate: 'none'
               PortRotate: 'default'
                IconUnits: 'autoscale'
               Parameters: [1x1 Simulink.MaskParameter]
     Methods, Events, Superclasses
```

For examples of other mask operations, like creating and editing mask parameters and copying and deleting masks see `Simulink.Mask` and `Simulink.MaskParameter` .

Use get_param and set_param

The `set_param` and `get_param` functions have parameters for setting and controlling the mask. You can use these functions to set the mask of any block in the model or library based on a value passed from the MATLAB command line:

```
set_param(gcb,'MaskStyleString','edit,edit',..
'MaskVariables','maskparameter1=@1;maskparameter2=&2;',..
```

```
'MaskPromptString','Mask Parameter 1:|Mask Parameter 2:',..
'MaskValues',{'1','2'});

get_param(gcb,'MaskStyleString');

set_param(gcb,'MaskStyles',{'edit','edit'},'MaskVariables',..
'maskparameter1=@1;maskparameter2=&2;','MaskPrompts',..
{'Mask Parameter 1:','Mask Parameter 2:'},..
'MaskValueString','1|2');

get_param(gcb,'MaskStyles');
```

where

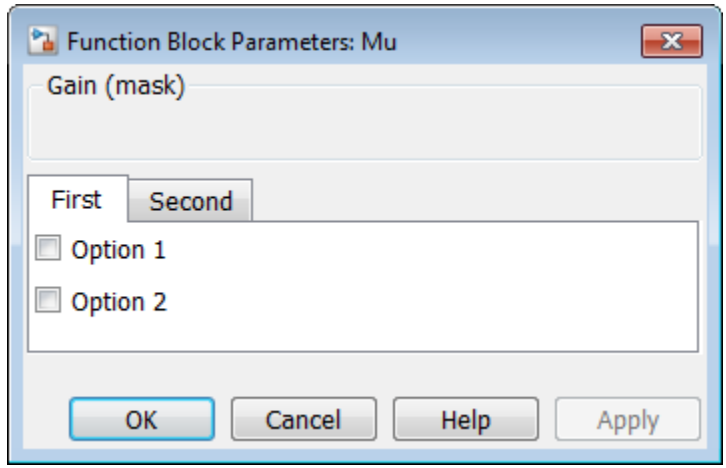
- `|` separates individual character vector values for the mask parameters.
- `@` indicates that the parameter field is evaluated.
- `&` indicates that the parameter field is not evaluated but assigned as a character vector.

Note When you use `get_param` to get the `Value` of a mask parameter, Simulink returns the value that was last applied using the mask dialog. Values that you have entered into the mask dialog but not applied are not reflected when you use the `get_param` command.

To control the mask properties programmatically for a release before R2014a, see Mask Parameters.

Programmatically Create Mask Parameters and Dialogs

This example shows how to create this simple mask dialog, add controls to the dialog, and change the properties of the controls.



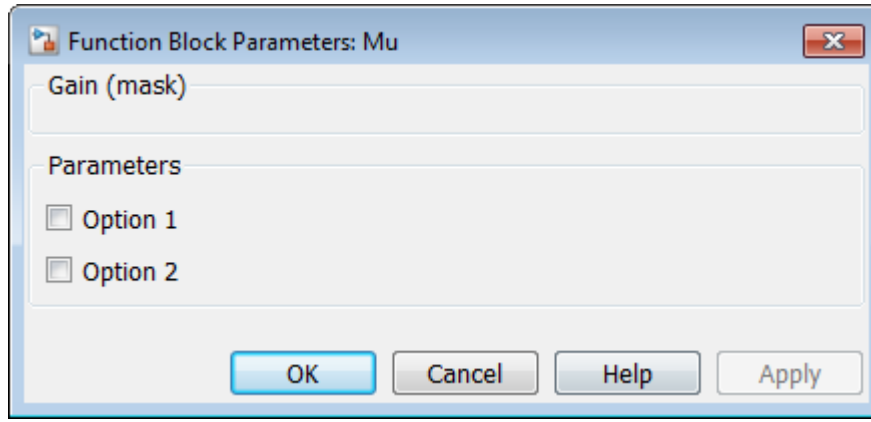
1 Create the mask for a block you selected in the model.

```
maskobj = Simulink.Mask.create(gcb);
```

2 Create parameters for the mask.

```
maskobj.addParameter('Type','checkbox','Prompt','Option 1',...
'Name','option1');
maskobj.addParameter('Type','checkbox','Prompt','Option 2',...
'Name','option2');
```

These commands create a mask dialog with the default layout. Simulink adds the two parameters to the **Parameters** group, which is internally named as `ParameterGroupVar` by default.



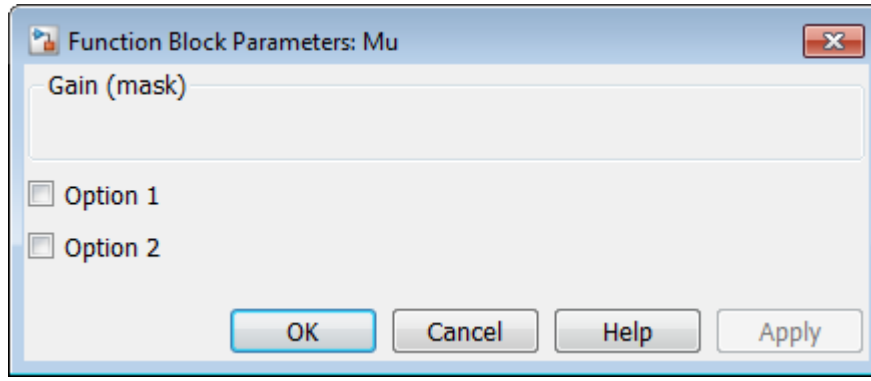
You can verify the group name programmatically.

```
dlg = maskobj.getDialogControls();
dlg(2)

ans =
        Group with properties:
                    Name: 'ParameterGroupVar'
                    Prompt: 'Simulink:studio:ToolBarParametersMenu'
                    Row: 'new'
                    Enabled: 'on'
                    Visible: 'on'
                DialogControls: [1x1 Simulink.dialog.parameter.CheckBox]
```

3 To customize the dialog and to use tabs instead of the default group, remove the **Parameters** group box.

```
maskobj.removeDialogControl('ParameterGroupVar');
```



Simulink preserves the child dialog controls– the two check boxes in this example– even when you delete the `ParametersGroupVar` group surrounding them. These controls are parameters, that cannot be deleted using dialog control methods.

You can delete parameters using methods such as `Simulink.Mask.removeAllParameters`, which belongs to the `Simulink.Mask` class.

4 Create a tab container and get its handle.

```
tabgroup = maskobj.addDialogControl('tabcontainer','tabgroup');
```

5 Create tabs within this tab container.

```
tab1 = tabgroup.addDialogControl('tab','tab1');
tab1.Prompt = 'First';
tab2 = tabgroup.addDialogControl('tab', 'tab2');
tab2.Prompt = 'Second';
tab3 = tabgroup.addDialogControl('tab','tab3');
tab3.Prompt = 'Third (invisible)';
```

Make the third tab invisible.

```
tab3.Visible = 'off'
```

```
tab3 =

  Tab with properties:

            Name: 'tab3'
          Prompt: 'Third (invisible)'
         Enabled: 'on'
```

```
            Visible: 'on'
      DialogControls: []
```

You can change the location and other properties of the parameters on the dialog by using the `Simulink.dialog.Control` commands. For more information on dialog controls and their properties, see `Simulink.dialog.Control`.

"Block Masks" | "Masking Fundamentals" on page 38-2 | "Initialize Mask" on page 38-26

Pass Values to Blocks Under the Mask

A masked block can pass values to the block parameters under the mask. The underlying blocks use the passed values during simulation to execute the block logic.

A masked block has variables associated with mask parameters. These variables are stored in the mask workspace for a model and can correspond to a block parameter under the mask. When such a block is evaluated, the block variables look for matching values in the mask workspace to get a value.

The mapping of variables from the mask workspace to the base workspace must be correct. A correct mapping ensures that the right block variable is assigned the value that is passed from the mask.

Use any of these options to pass values to blocks under the mask:

- Parameter promotion (recommended)
- Mask initialization
- Referencing block parameters using variable names (For the Edit Parameter only)

Parameter Promotion

When you promote a block parameter to its mask, the block parameter becomes accessible from the mask dialog box, allowing you to pass a value for the block parameter. Parameter promotion ensures correct mapping of parameter values and is a recommended way to pass values to the block from the mask dialog box. For more information on promoting a parameter, see “Promote Parameter to Mask” on page 38-30.

Mask Initialization

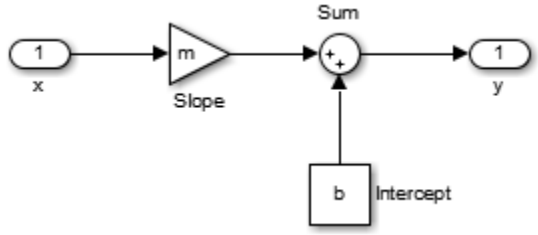
You can use MATLAB code in the Initialization pane of the Mask Editor to assign or pass values to the block parameters under the mask. You can assign a fixed value to a block parameter, specify an acceptable range for the input values, or specify a value for the child block. For more information, see “Initialize Mask” on page 38-26.

Referencing Block Parameters Using Variable Names

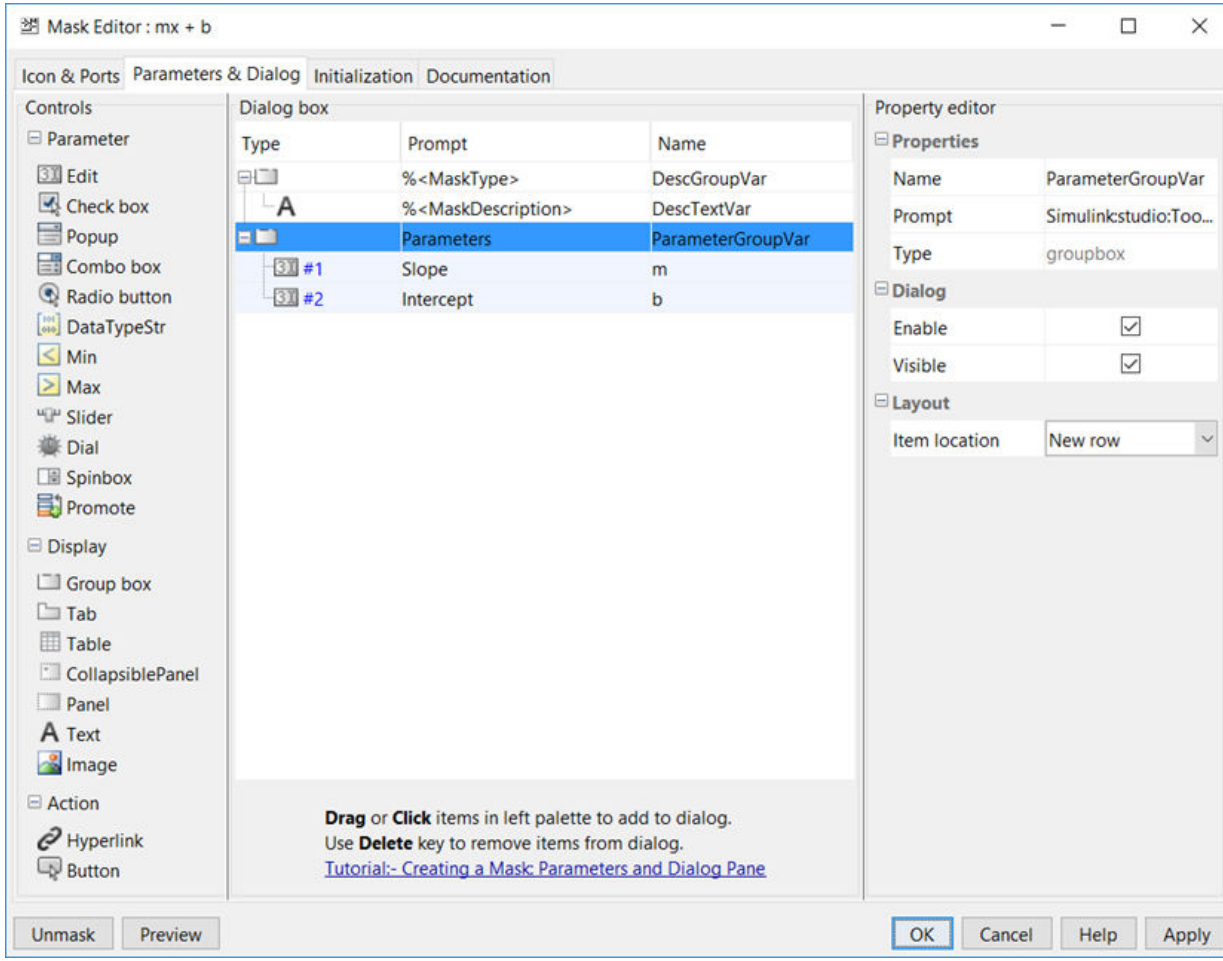
You can add an Edit parameter to the mask dialog box and pass values to the block parameters through it. The values that you provide for the Edit parameter in the mask

dialog box automatically becomes associated with the block parameter, by using the techniques described in “Symbol Resolution” on page 59-136.

Consider the model `masking_example`, which contains a masked Subsystem block and governs the equation `y = mx + b`. Here, `m` and `b` are variables controlling the slope and intercept of the equation and are associated with the Gain and the Constant block, respectively.



The variables `m` and `b` are assigned to the mask parameters **Slope** and **Intercept**, respectively, as parameter names in the Mask Editor.



When you type values for **Slope** and **Intercept** in the mask dialog box, these values are internally assigned to the variables `m` and `b`. When the model is simulated, the Gain block and the Constant block search for numeric values of `m` and `b` and apply them to resolve the equation `y = mx + b`.

See Also

“Block Masks” | “Masking Fundamentals” on page 38-2 | Creating a Mask: Masking Fundamentals (3 min, 46 sec)

Mask Linked Blocks

In this section...

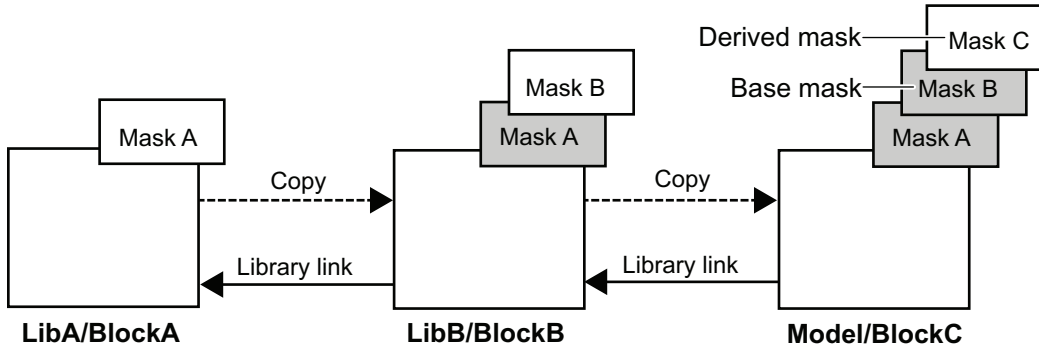
Simulink libraries can contain blocks that have masks. An example of this type of block is the Ramp block. These blocks become library links when copied to a model or another library. You can add a mask on this linked block. If this linked block is in a library and copied again, you can add another mask to this new linked block thus creating a stack of masks. Masking linked blocks allows you to add a custom interface to the link blocks similar to other Simulink blocks.

You can also apply a mask to a block, then include the block in a library. Masking a block that is later included in a library requires no special provisions. For more information, see “Create a Custom Library” on page 40-4.

The block mask that is present as part of the library is the base mask. A derived mask is the one created on top of the base mask.

For example, in the figure, Library A contains Block A, which has a Mask A. Block A is copied to Library B, and Mask B is added to it. When Block A is copied to Library B, a library link from Library B to Library A is created.

Block B is then copied to a model, and Mask C is added to it. This creates a library link from Block C to Library B. Block C now has Mask A, Mask B, and Mask C. Mask C is the derived mask and Mask B is the base mask.



For Block C:

- Mask parameter names are unique in the stack.
- You can set mask parameters for Mask B and Mask C.
- Mask B and Mask C inherit `MaskType` and `MaskSelfModifiable` parameters from Mask A.
- Mask initialization code for Mask C executes first, followed by Mask B and Mask A.
- Variables are resolved starting from the mask immediately above the current mask in the stack. If the current mask is the top mask, it follows the regular variable resolution rules.

Creating or changing a library block mask changes the block interface in all models that access the block using a library reference, but has no effect on instances of the block that exist as separate copies.

To view related example, see Use self-modifying library masks.

Guidelines for Mask Parameters

- You cannot use same names for the mask parameters. The exception is the `Promote` type mask parameter, for which the name is inherited and is the same as that of the parameter promoted to it.
- You cannot set mask parameters for masks below the base mask. Mask parameters for masks below the base mask are inherited from the library.

Mask Behavior for Masked, Linked Blocks

The following are some of the behaviors that are important to understand about masked, linked blocks.

- The `MaskType` and the `MaskSelfModifiable` parameters are inherited from the base mask.
- The mask display code for the derived mask executes first, followed by the display code for the masks below it until we come across a mask whose `MaskIconFrame` parameter is set to `opaque`.
- The mask initialization code for the derived mask executes first, followed by the initialization code for the masks below it.
- Variables are resolved starting from the mask immediately above the current mask in the stack. If the current mask is the top mask, the regular variable resolution rules apply.
- When you save a Simulink model or library containing a block with multiple masks, using **File > Export Model to > Previous Version**, the `Sourceblock` parameter is modified to point to the library block having the bottom-most mask.
- The following occurs when you disable, break, or reestablish links to libraries:
  - If you disable the link to the library block, the entire mask hierarchy is saved to the model file so that the block can act as a standalone block.
  - If you break the link to the library block, the block becomes a standalone block.
  - If you reestablish the link after disabling by doing a restore, all changes to the mask are discarded. If you mask subsystems, you must reestablish the link after disabling by doing a push. When you do a push, subsystem changes are pushed to the library block and top mask changes are pushed to the immediate library.

Mask a Linked Block

Step 1: Create Custom Library with Masked Linked Block

1. In the **Simulink Library Browser**, click the arrow next to  and select **New Library**.
2. Open the Ramp block in the Library editor window.
3. Right-click the Ramp block and select **Mask > Create Mask**.

   The **Mask Editor** opens.
4. In the **Icon drawing commands** section of the **Icons & Ports** pane, type:

   ```
   plot ([0:10],[0,1:10])
   ```
5. In the **Parameter & Dialog** pane, select  **Promote** to promote the `Slope` and `Initial Output` parameters.
6. Click **OK**.
7. Rename the block to Derived Ramp block.

Step 2: Add a Mask to the Masked, Link Block

1. In the **Simulink Library Browser**, click the arrow next to  and select **New Model**. The Model editor window opens.
2. Drag the Derived Ramp block from the Library editor to the Model editor.

   The Derived Ramp block in the model has multiple masks on it. You can set parameters of the derived mask.

Step 3: View Masks Below the Top Mask

- Right-click the Derived Ramp block in the model and select **Mask > View Base Mask**. This opens the **Mask Editor** displaying the base mask definition.

"Block Masks" | "Linked Blocks" on page 40-15

Dynamic Mask Dialog Box

In this section...

You can create dialogs for masked blocks whose appearance changes in response to user input. Features of masked dialog boxes that can change in this way include:

- Visibility of parameter controls — Changing a parameter can cause the control for another parameter to appear or disappear. The dialog expands or shrinks when a control appears or disappears, respectively.
- Enabled state of parameter controls — Changing a parameter can cause the control for another parameter to be enabled or disabled for input. A disabled control is grayed to indicate visually that it is disabled.
- Parameter values — Changing a mask dialog box parameter can cause related mask dialog box parameters to be set to appropriate values.

Creating a dynamic masked dialog box entails using the Mask Editor with the `set_param` command. Specifically, you use the Mask Editor to define parameters of the dialog box, both static and dynamic. For each dynamic parameter, you enter a callback function that defines how the dialog box responds to changes to that parameter (see “Execute Callback Code” on page 38-20). The callback function can in turn use the `set_param` command to set mask parameters that affect the appearance and settings of other controls on the dialog box (see “Create Dynamic Mask Dialog Box” on page 38-53). Finally, you save the model or library containing the masked subsystem to complete the creation of the dynamic masked dialog box.

To view related example, see Create dynamic mask dialog boxes.

Show Parameter

The selected parameter appears on the mask dialog box only if this option is checked (the default).

Enable Parameter

Clearing this option grays the prompt of the selected parameter and disables the edit control of the prompt.

Create Dynamic Mask Dialog Box

This example shows how to create a mask dialog blocks whose appearance changes in response to your input.

You can set two parameters using this mask dialog box. The first parameter is a popup menu through which you select one of three gain values: `2`, `5`, or `User-defined`. Depending on the value that you select in this popup menu, an edit field for specifying the gain appears or disappears.

1. Mask a subsystem by right-clicking the block and selecting **Mask > Create Mask**.
2. Select the **Parameters & Dialog** pane on the Mask Editor.
3. Drag and drop a **Popup** parameter and select it in the **Dialog box** pane.
   a. In the **Prompt** field, enter `Gain`.
   b. In the **Name** field, enter `gainpopup`.
   c. In the Property editor pane, clear **Evaluate** so that Simulink uses the literal values you specify for the popup.
   d. In the **Type options** field, click the **Edit** button to enter these three values in the Popup Options dialog box:

      ```
      2
      5
      User-defined
      ```
4. Enter this code in the **Dialog callback** field:

```
% Get the mask parameter values. This is a cell
%   array of character vectors.
maskStr = get_param(gcb,'gainpopup');

% The pop-up menu is the first mask parameter.
%   Check the value selected in the pop-up
if strcmp(maskStr(1),'U'),

    % Set the visibility of both parameters on when
```

```
        %   User-defined is selected in the pop-up.

        set_param(gcb,'MaskVisibilities',{'on';'on'}),

    else

        % Turn off the visibility of the Value field
        %   when User-defined is not selected.

        set_param(gcb,'MaskVisibilities',{'on';'off'}),

        % Set the character vector in the Values field equal to the
        % character vector selected in the Gain pop-up menu.

        %maskStr{2}=maskStr{1};
        set_param(gcb,'editvalue',maskStr);
    end
```

5 Drag and drop an **Edit** parameter and select it in the **Dialog box** pane.

   a In the **Prompt** field, enter `Value`.

   b In the **Name** field, enter `editvalue`.

   c In the Property editor pane, clear **Visible** so that Simulink turns off the visibility of this property by default.

6 Click **Apply**.

7 To open the mask dialog box, double-click the masked subsystem.

   If you select `2` or `5` as the **Gain**, Simulink hides the **Value**. If you select `User-defined` as the **Gain** the **Value** is visible.

Set Up Nested Masked Block Parameters

If lower-level masked subsystems reference symbols defined by higher-level masked subsystems and you try to set parameters of blocks in lower-level masked subsystems, unresolved symbol errors can occur. Therefore, avoid using `set_param` commands to set parameters of blocks residing in masked subsystems that reside in the masked subsystem being initialized. Trying if lower-level masked subsystems reference symbols defined by higher-level masked subsystems.

Suppose, for example, a masked subsystem A contains masked subsystem B, which contains Gain block C, whose Gain parameter references a variable defined by B. Suppose also that subsystem A's initialization code contains this command:

```
set_param([gcb '/B/C'], 'SampleTime', '-1');
```

Simulating or updating a model containing A causes an unresolved symbol error.

Dynamic Masked Subsystem

In this section...

Allow Library Block to Modify Its Contents

This check box is enabled only if the masked subsystem resides in a library. Checking this option allows the block initialization code to modify the contents of the masked subsystem (that is, it lets the code add or delete blocks and set the parameters of those blocks). Otherwise, an error is generated when a masked library block tries to modify its contents in any way. To set this option at the MATLAB prompt, select the self-modifying block and enter the following command.

```
set_param(gcb, 'MaskSelfModifiable', 'on');
```

Then save the block.

Create Self-Modifying Masks for Library Blocks

You can create masked library blocks that can modify their structural contents. These self-modifying masks allow you to:

- Modify the contents of a masked subsystem based on parameters in the mask dialog box or when the subsystem is initially dragged from the library into a new model.
- Vary the number of ports on a multiport S-Function block that resides in a library.

Creating Self-Modifying Masks Using the Mask Editor

To create a self-modifying mask using the Mask Editor:

1. Unlock the library (see “Lock and Unlock Libraries” on page 40-8).
2. Right-click the block in the library.
3. Select **Mask** > **Edit Mask**. The Mask Editor opens.
4. In the Mask Editor **Initialization** pane, select the **Allow library block to modify its contents** option.

5 Enter the code that modifies the masked subsystem in the mask **Initialization** pane.

   Do not enter code that structurally modifies the masked subsystem in a dialog parameter callback (see “Add Mask Code” on page 38-18). Doing so triggers an error when you edit the parameter.

6 Click **Apply** to apply the change or **OK** to apply the change and close the Mask Editor.

7 Lock the library.

Creating Self-Modifying Masks from the Command Line

To create a self-modifying mask from the command line:

1 Unlock the library using the following command:

```
set_param(gcs,'Lock','off')
```

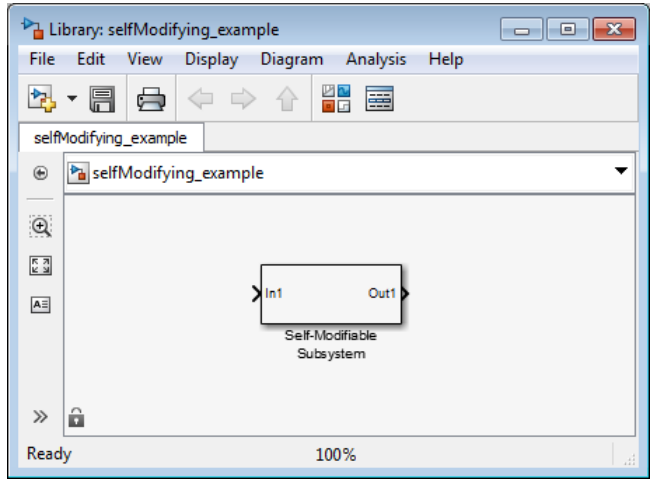
2 Specify that the block is self-modifying by using the following command:

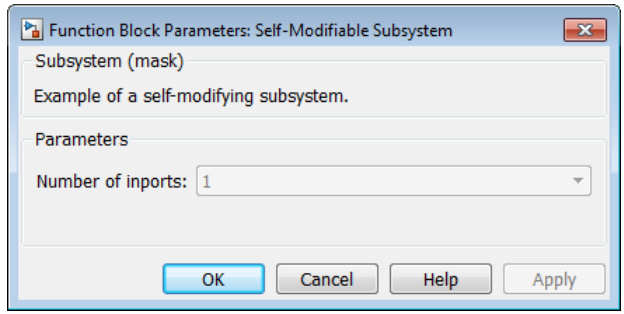
```
set_param(block_name,'MaskSelfModifiable','on')
```

   where `block_name` is the full path to the block in the library.

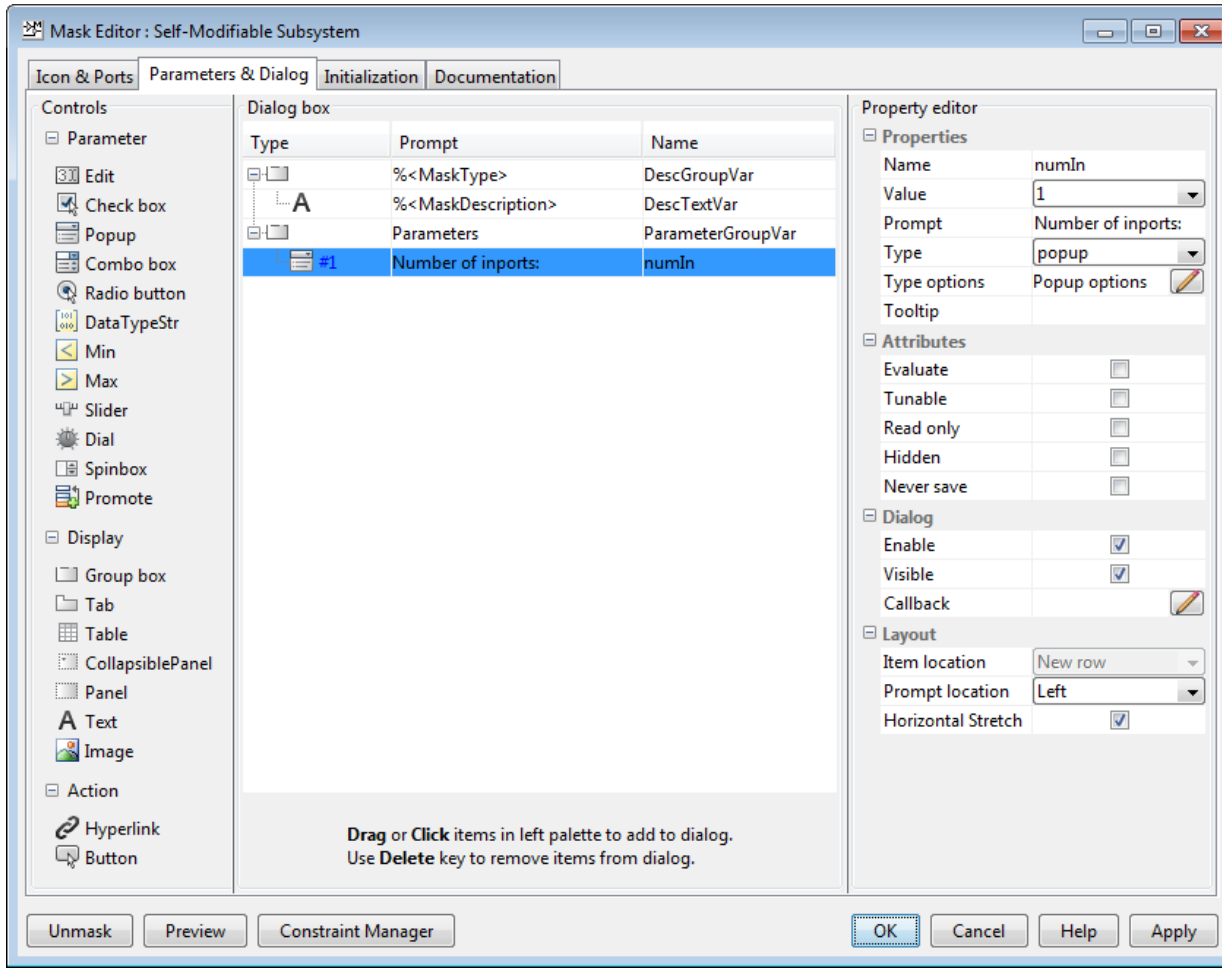
Create Self-Modifying Mask

The library `selfModifying_example` contains a masked subsystem that modifies its number of input ports based on a selection made in the subsystem mask dialog box.

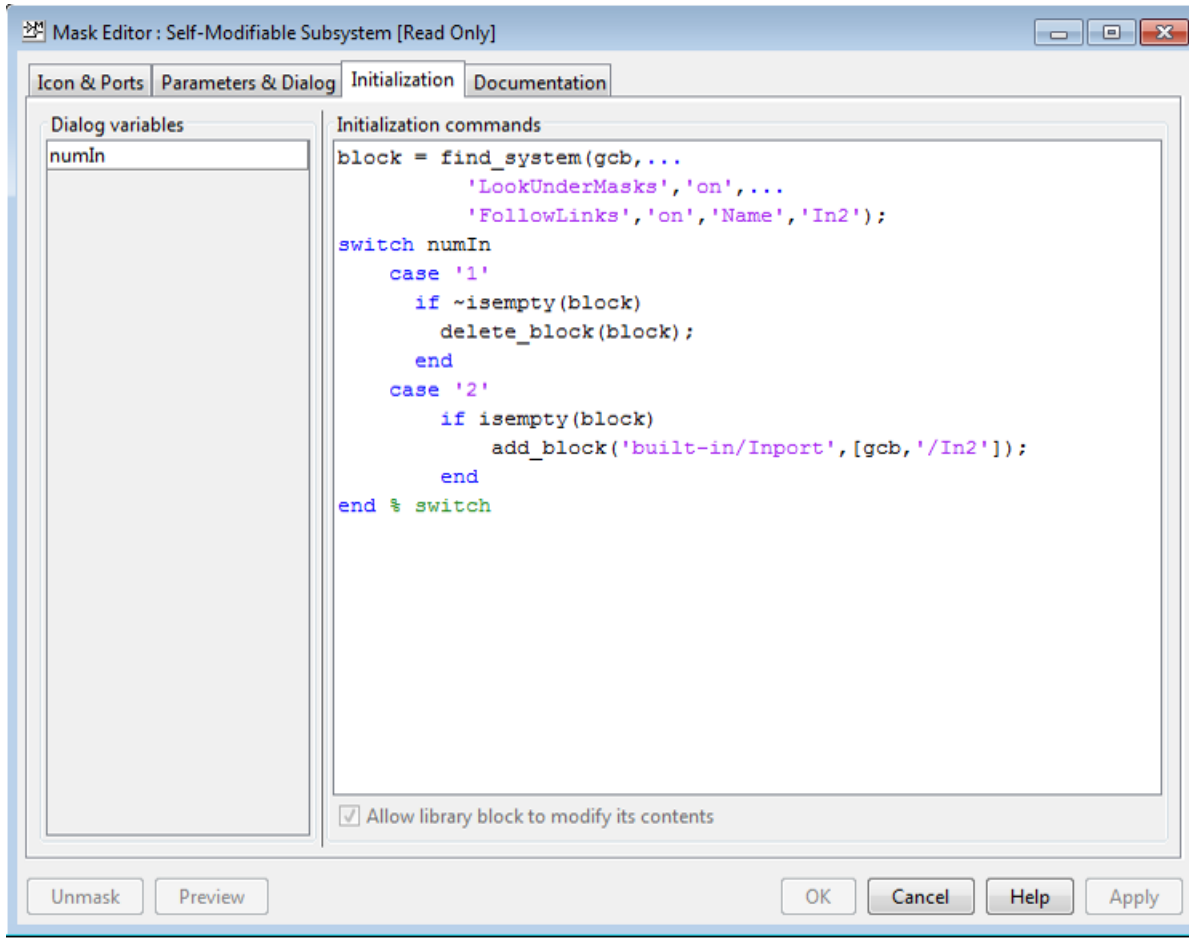




1. Click **Diagram > Unlock Library**.
2. Right-click the subsystem and select **Mask > Edit Mask**. The Mask Editor opens.
3. The Mask Editor **Parameters & Dialog** pane defines a parameter `numIn` that stores the value for the **Number of inports** option. This mask dialog box callback adds or removes Input ports inside the masked subsystem based on the selection made in the **Number of inports** list.



4 To allow the dialog box callback to function properly, the **Allow library block to modify its contents** option on the Mask Editor **Initialization** pane is selected. If this option is not selected, copy of the library block could not modify their structural contents. Also, changing the selection in the **Number of inports** list would produce an error.



Evaluate Blocks Under Self-Modifying Mask

This example shows how to force Simulink to evaluate blocks inside self-modifying masks.

Simulink evaluates elements of models containing masks in the following order:

1. Mask dialog box
2. Mask initialization code

3 Blocks or masked subsystems under the mask

Suppose a block named `myBlock` inside subsystem `mySubsys` masked by a self-modifying mask depends on mask parameter `myParam` to update itself.

`myParam` is exposed to the user through the **Mask Parameters** dialog box. `mySubsys` is updated through MATLAB code written in the **Mask Initialization** pane.

In this model, the sequence of updates is as follows:

1 You modify `myParam` through the mask dialog box.

2 The mask initialization code receives this change and modifies `mySubsys` under the mask.

3 `myBlock`, which lies under `mySubsys`, modifies itself based on the change to `myParam`.

In this sequence, Simulink does not evaluate `myBlock`, which lies under `mySubsys`, when the mask initialization code executes. Instead, Simulink only evaluates and updates the masked subsystem `mySubsys`. Meanwhile, `myBlock` remains unmodified.

You can force Simulink to evaluate such blocks earlier by using the `Simulink.Block.eval` method in the initialization code of the masked subsystem.

```
Simulink.Block.eval('mySubsys/myBlock');
```

Debug Masks That Use MATLAB Code

In this section...

Code Written in Mask Editor

Debug initialization commands and parameter callbacks entered directly into the Mask Editor by:

- Removing the terminating semicolon from a command to echo its results to the MATLAB Command Window.
- Placing a `keyboard` command in the code to stop execution and give control to the keyboard.

Tip To stop debugging the mask initialization callback code when an error is encountered, use the command `dbstop if caught error`.

Code Written Using MATLAB Editor/Debugger

Note You cannot debug icon drawing commands using the MATLAB Editor/Debugger. For information on icon drawing commands syntax, see “Icon drawing commands”.

Debug initialization commands and parameter callbacks written in files using the MATLAB Editor/Debugger in the same way that you would with any other MATLAB program file.

When debugging initialization commands, you can view the contents of the mask workspace. However, when debugging parameter callbacks, you can only access the base workspace of the block. If you need the value of a mask parameter, use `get_param`.

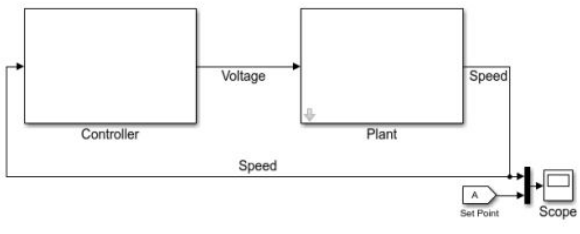
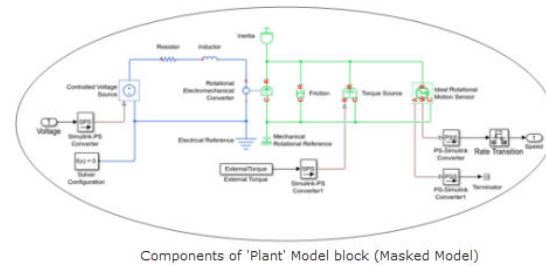
Introduction to Model Mask

A model consists of multiple blocks, with each block containing its own parameter and block dialog box. Simulink enables you to mask a model. By masking a model you encapsulate the model to have its own mask parameter dialog box. You can customize the mask parameter dialog box. When you mask a model, the model arguments become the model mask parameters. Referencing a masked model helps in having a better user interface for a model with ease of controlling the model parameters through the mask.

When you reference a masked model from a Model block, a mask is generated automatically on the Model block. The generated mask on the Model block is a copy of the model mask that it is referencing. You can reference a masked model from multiple Model block instances.

Consider a model that represents the DC motor equation. `Plant` in this model is a Model block that references a masked model, simplifying the user interface.





Components of 'Plant' Model block (Masked Model)

The `Plant` block contains same mask as that of the masked model and is uneditable. Mask can only be edited from the Mask Editor dialog box of the masked model.

Note You cannot use masked models as model variants.

See Also

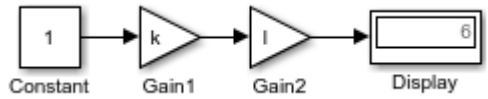
"Create and Reference a Masked Model" on page 38-65 | "Control Model Mask Programmatically" on page 38-72 | "Masking Fundamentals" on page 38-2

Create and Reference a Masked Model

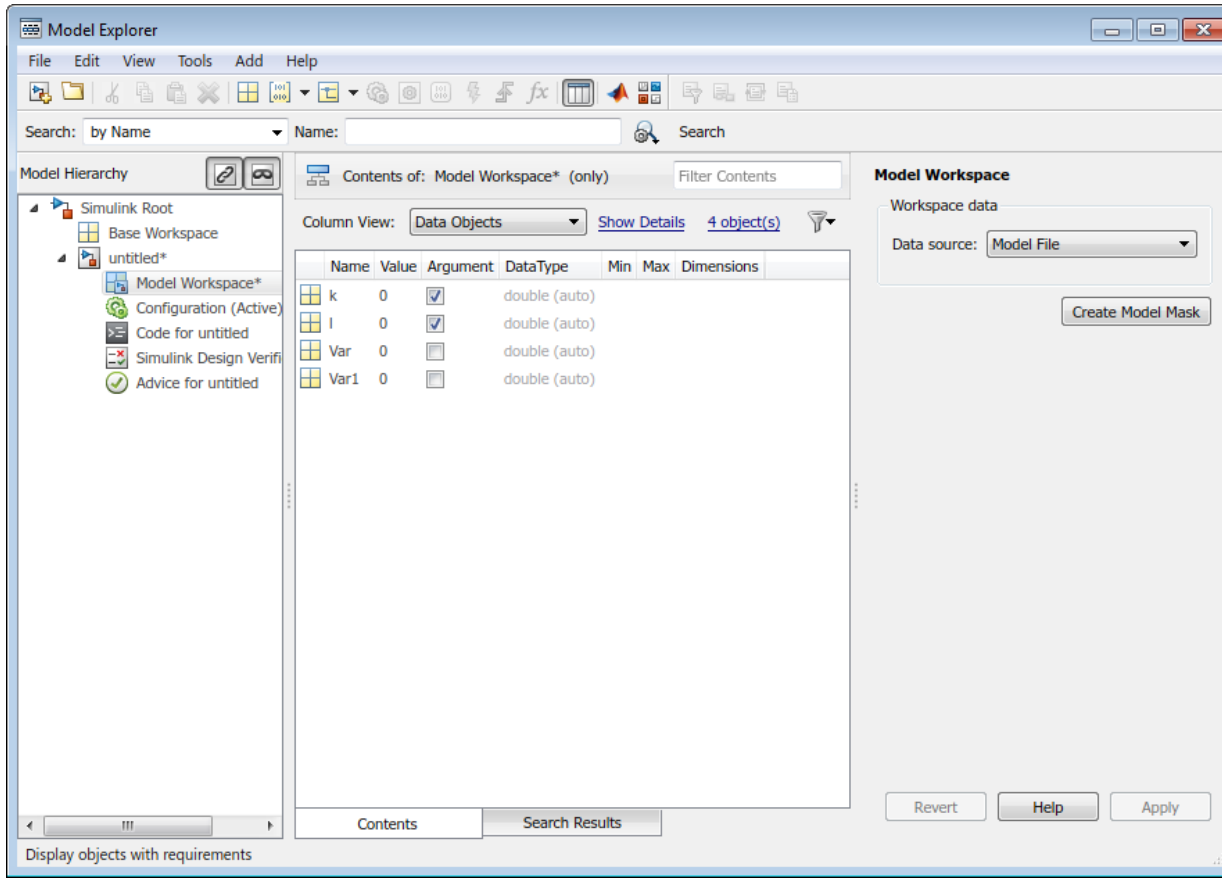
This example shows how to mask a model and reference the masked model from the Model block.

Step 1: Define Mask Arguments

1. Open the model in Simulink. For example, consider a simple model containing two Gain blocks, a Constant block, and a Display block.



2. Click **View** > **Model Explorer** > **Model Workspace**. The Model Explorer dialog box opens.
3. Click **Add** > **MATLAB Variable**. A variable of data type `double` is created in the Model Workspace.
4. Select the **Argument** check box corresponding to the MATLAB variables to make it a model argument, for example, `k` and `l`.



Step 2: Create Model Mask

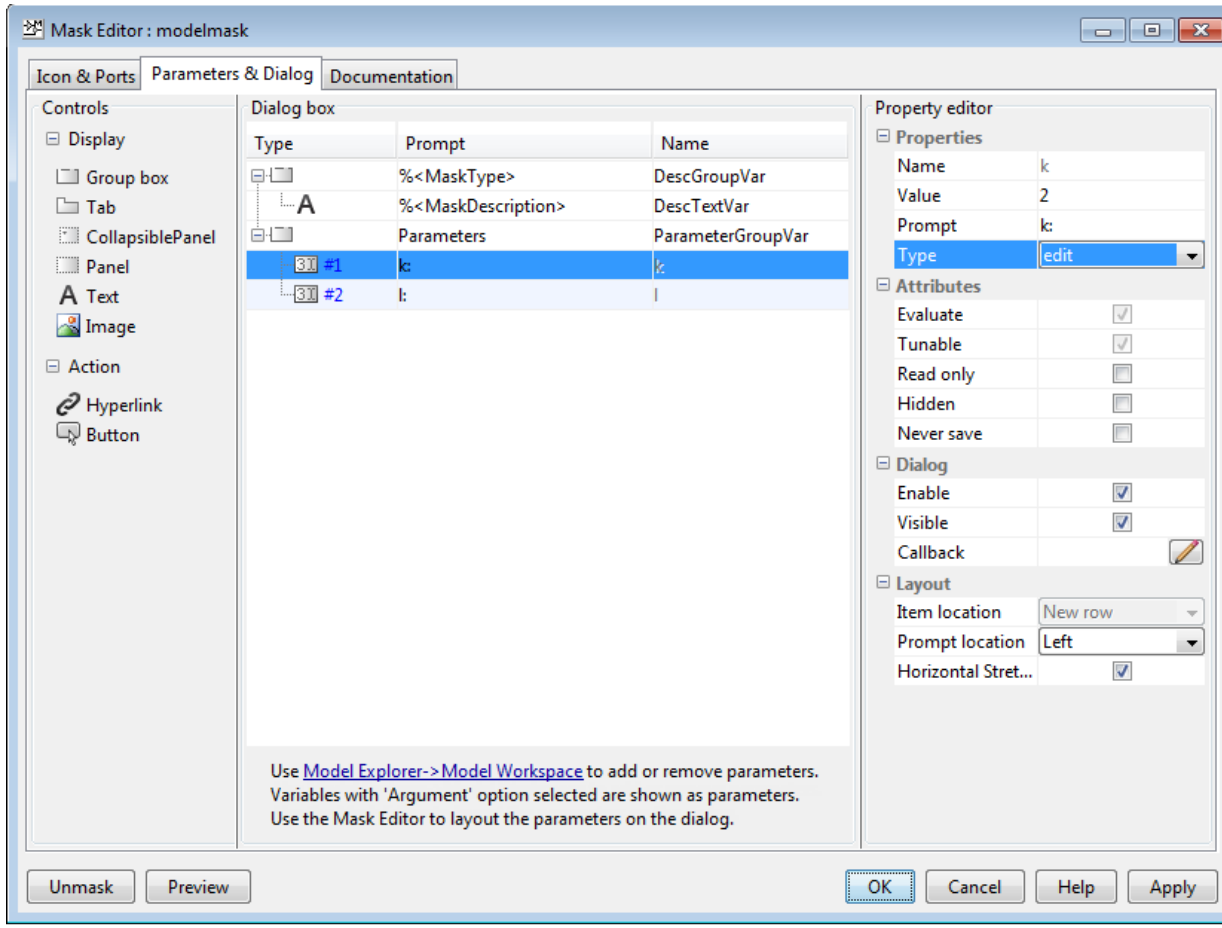
1 In the **Model Workspace** pane, click **Create Model Mask**.

Alternatively, in Simulink click **Diagram > Mask > Create Model Mask** or right-click the model, and in the context menu, click **Mask > Create Model Mask**.

The Mask Editor dialog box opens.

2 Click the **Parameters & Dialog** tab. The model arguments that you select in Model Explorer appear in the Mask Editor dialog box as mask parameters.

Tip Ensure that the model arguments you have selected in the Model Explorer dialog box are added as block parameters in the model. For example, the arguments `k` and `l` are passed to `Gain A` and `Gain B` blocks, respectively.



Note The Mask Editor dialog box for model mask does not contain the **Initialization** tab. Initialization code can alter the model and other model reference blocks, and thus affect the simulation results.

3 Select a mask parameter (`k` or `l`) on the **Dialog box** pane and edit its properties in the Property editor, as required. For example, you can change the prompt name, parameter type, value, or orientation.

By default, the **Edit** parameter type is assigned to a model mask parameter. You can change the parameter type by editing the **Type** property in the **Property editor** section.

Note

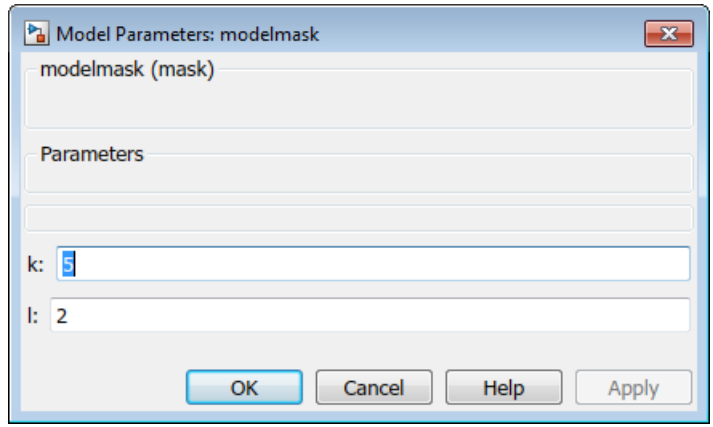
- Simulink supports only the **Edit**, **Slider**, **Dial**, and **Spinbox** parameter types for model mask.
- Model mask supports all types of display and action controls.

4 Click **OK**. The Simulink model is now masked and contains the model arguments as the mask parameter.

5 Save the model.

Step 3: View Model Mask Parameters

1 To view the mask parameter dialog box, click **Diagram** > **Mask** > **Model Mask Parameters**.



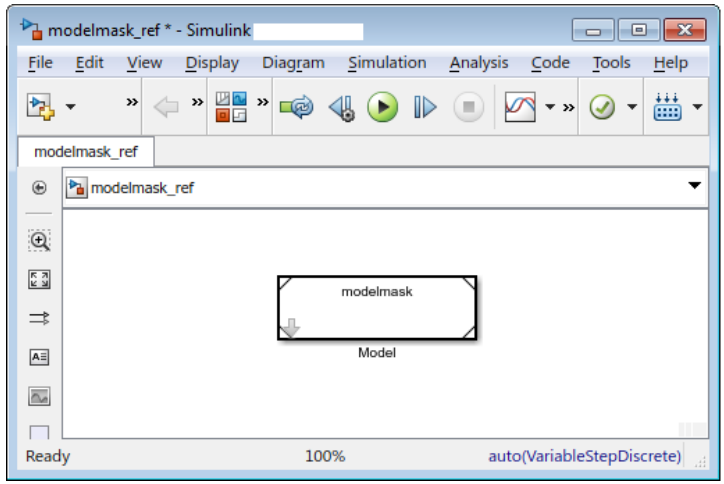
Tip To edit the model mask parameters, click **Diagram** > **Mask** > **Edit Model Mask**.

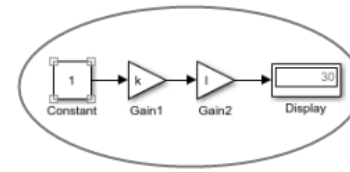
2 Save the masked model.

Step 4: Reference Masked Model

1 Open a blank model in Simulink and add the Model block from the library.

2 To reference the masked model from the Model block, specify the name of the masked model as the **Model name** in the **Block parameter** dialog box.

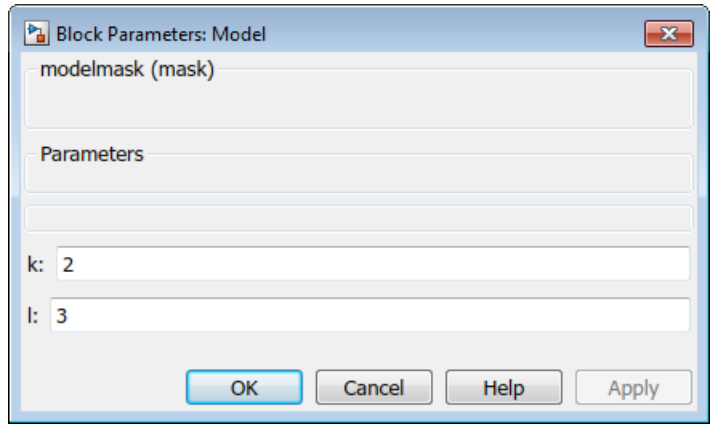




Masked model referenced by the Model block

3 To view the parameter dialog box of the referenced model, right-click the Model block, and in the context menu, click **Mask > Mask Parameters**. Alternatively, double-click the Model block.

4 Type `2` and `3` as the parameter values for `k` and `l` respectively.



5 Click **OK**.

6 Simulate the model and view the result on the display block.

7 To view the referenced model from the Model block, click **Mask > Look Under Mask**.

8 To view the mask, right-click the Model block and click **Mask > View Mask**. The **Mask Editor** dialog box opens. The Mask Editor dialog box displays the uneditable mask parameters of the referenced model.

"Introduction to Model Mask" on page 38-64 | "Control Model Mask Programmatically" on page 38-72 | "Masking Fundamentals" on page 38-2

Control Model Mask Programmatically

Simulink defines a set of parameters to configure and edit a model mask.

Note Adding, removing, and renaming parameters on a model mask using these methods is not supported:

- `addParameter`
- `removeParameter`
- `removeAllParameters`
- `MaskParameter.Name`

Simulink.Mask.create

Use the `Simulink.Mask.create` method to create mask on a model. The syntax to mask a model is,

- Using the model name:

```
Simulink.Mask.create(ModelName)
```

- Using the model handle

```
ModelHandle = get_param(gcs,'Handle') %To get the model handle
Simulink.Mask.create(ModelHandle) %To create mask using model handle
```

An example follows,

```
maskObj = Simulink.Mask.create('vdp');
```

```
                    Type: 'vdp'
             Description: 'The van der Pol Equation…'
                    Help: ''
          Initialization: ''
          SelfModifiable: 'off'
                 Display: ''
               IconFrame: 'on'
             IconOpaque: 'opaque'
    RunInitForIconRedraw: 'off'
              IconRotate: 'none'
```

```
              PortRotate: 'default'
               IconUnits: 'autoscale'
              Parameters: [0×0 Simulink.MaskParameter]
                BaseMask: [0×0 Simulink.Mask]
```

Simulink.Mask.get

Use the `Simulink.Mask.get` method to get the mask on a model as a mask object. The syntax to get the existing mask of a model is,

- Using the model name:

  ```
  Simulink.Mask.get(ModelName)
  ```

- Using the model handle

  ```
  ModelHandle = get_param(gcs,'Handle') %To get the model handle
  Simulink.Mask.get(ModelHandle) %To create mask using model handle
  ```

An example follows:

```
maskObj = Simulink.Mask.get('vdp');
```

```
                    Type: 'vdp'
             Description: 'The van der Pol Equation…'
                    Help: ''
          Initialization: ''
          SelfModifiable: 'off'
                 Display: ''
               IconFrame: 'on'
              IconOpaque: 'opaque'
    RunInitForIconRedraw: 'off'
              IconRotate: 'none'
              PortRotate: 'default'
               IconUnits: 'autoscale'
              Parameters: [0×0 Simulink.MaskParameter]
                BaseMask: [0×0 Simulink.Mask]
```

Note To get the model mask as a mask object in the mask callback, you can use `Simulink.Mask.get()` without passing a system name or system handle. Simulink does not require the system name (`gcb`) or the system handle (`gcs`) to query the mask object for the model mask.

Handling Large Number of Mask Parameters

The **Table** control in Mask Editor dialog box allows you to organize large number of mask parameters. The **Table** control can handle large (500+) number of mask parameters. You can include **Edit**, **Checkbox**, and **Popup** parameters within a **Table**.

You can also add large number of mask parameters in a **Table** programmatically. An example follows,

```
% Get mask object.
aMaskObj = Simulink.Mask.get(gcbh);

% Add Table controls to the mask.
aMaskObj.addDialogControl('Table', 'MyTable');

% Add parameters to table container.
for i = 1:length(Parameters) % To import values from an array called 'Parameters'
    aMaskObj.addParameter('Name', Parameters(i).Name, 'Type', Parameters(i).Type, 'Cont
end
```

Masking Example Models

The Simulink Masking example models help you to understand and configure mask parameters, properties, and features. The examples are grouped by type. In an example model:

- To view the mask definition, double-click the View Mask block.
- To view the mask dialog box, double-click the block.

"Block Masks" | "Mask Editor Overview" | "Masking Fundamentals" on page 38-2

Mask a Variant Subsystem

This example shows how to use a masked Variant Subsystem block in a Simulink model. Click the **Open Model** button located on the top right corner to view the related example model.

When you mask a Variant Subsystem block, you can specify the variant choice from the mask dialog box. The variant choice that you specify on the mask dialog box is applied on the underneath Variant Subsystem block.

To pass the variant choice from the mask to the Variant Subsystem block, you can either use the set_param command or the parameter promotion option.

Let's consider the cases described in the example model.

- Case 1: The mask parameter promotion option is used to promote the Variant Subsystem block parameter to the mask. The Variant Subsystem block is wrapped within a masked Subsystem block. Initialization code (`set_param`) is used in the Variant Subsystem block to define the variant choice which is further passed on to the mask on the Subsystem block using parameter promotion. This promoted parameter records the variant choice specified from the masked Subsystem block.
- Case 2: The Popup mask parameter is used to create the choice option on the top level masked Subsystem block. This masked Subsystem block contains a Variant Subsystem block. Initialization code (`set_param`) is used in the Variant Subsystem block to define the variant choice. The value that you specify as a variant choice from the mask dialog box (**Popup** parameter) is transferred to the underneath Variant Subsystem block to set it choices.
- Case 3: This case is like case 2 with an additional layer of Subsystem in the model. Here, the Variant Subsystem block is wrapped in a double layer of masked Subsystem block.

Creating Custom Blocks

Create Your Own Simulink Block

In this section...

Why Create Blocks

Create your own blocks to extend the built-in modeling functionality of Simulink. For example, create new blocks to:

- Integrate an existing code (legacy code) or algorithms into Simulink. Legacy code is your code that gives the functionality not available through existing Simulink library blocks. Simulink provides tools that let you integrate MATLAB, C/C++, and Fortran code. This method allows you to integrate System objects into Simulink.
- Create a new Simulink block customized for your needs. You may want to create a custom block if the built-in Simulink library does not have a block that provides a necessary functionality.
- Create a new custom functionality using a MATLAB function rather than using a Simulink block diagram.

To summarize, integrate existing code if you already have code that you would like to access in Simulink. If you do not have existing code, but have a particular functionality that Simulink does not satisfy, create your own block.

Types of Custom Blocks

MATLAB Function Blocks

A MATLAB Function block allows you to use the MATLAB language to define custom functionality. These blocks are a good starting point for creating a custom block if:

- You have an existing MATLAB function that models the custom functionality.

- You find it easier to model custom functionality using a MATLAB function than using a Simulink block diagram.
- The custom functionality does not include continuous or discrete dynamic states.

You can create a custom block from a MATLAB function using one of the following types of MATLAB function blocks.

- The Fcn block allows you to use a MATLAB expression to define a single-input, single-output (SISO) block.
- The Interpreted MATLAB Function block allows you to use a MATLAB function to define a SISO block.
- The MATLAB Function block allows you to define a custom block with multiple inputs and outputs that you can deploy to an embedded processor.

Each of these blocks has advantages in particular modeling applications. For example, you can generate code from models containing MATLAB Function blocks, whereas you cannot generate code for models containing an Fcn block.

MATLAB System Blocks

A MATLAB System block allows you to use System objects written with the MATLAB language to define custom functionality. These blocks are a good starting point for creating a custom block if:

- You have an existing System object that models the custom functionality.
- You find it easier to model custom functionality using the MATLAB language than using a Simulink block diagram.
- The custom functionality includes discrete dynamic states.

Subsystem Blocks

Subsystem blocks allow you to build a Simulink diagram to define custom functionality. These blocks serve as a good starting point for creating a custom block if:

- You have an existing Simulink diagram that models custom functionality.
- You find it easier to model custom functionality using a graphical representation rather than using handwritten code.
- The custom functionality is a function of continuous or discrete system states.
- You can model the custom functionality using existing Simulink blocks.

Once you have a Simulink subsystem that models the required behavior, you can convert it into a custom block by:

1. Masking the block to hide the block contents and provide a custom block dialog box.
2. Placing the block in a library to prohibit modifications and allow for easily updating copies of the block.

For more information, see “Libraries” and “Block Masks”.

S-Function Blocks

S-function blocks allow you to write MATLAB, C, or C++ code to define custom functionality. These blocks serve as a good starting point for creating a custom block if:

- You have existing MATLAB, C, or C++ code that models custom functionality.
- You use continuous or discrete dynamic states or other system behaviors that require access to the S-function API.
- You cannot model the custom functionality using existing Simulink blocks.

You can create a custom block from an S-function using one of the following types of S-function blocks.

- The Level-2 MATLAB S-Function block allows you to write your S-function using the MATLAB language. (See “Write Level-2 MATLAB S-Functions”). You can debug a MATLAB S-function during a simulation using the MATLAB debugger.
- The S-Function block allows you to write your S-function in C or C++, or to incorporate existing code into your model using a C MEX wrapper. (See “C/C++ S-Functions”.)
- The S-Function Builder block assists you in creating a C MEX S-function or a wrapper function to incorporate legacy C or C++ code. (See “C/C++ S-Functions”.)
- The Legacy Code Tool transforms existing C or C++ functions into C MEX S-functions. (See “Integrate C Functions Using Legacy Code Tool”.)

The S-function target in the Simulink Coder product automatically generates a C MEX S-function from a graphical subsystem. If you want to build your custom block in a Simulink subsystem, but implement the final version of the block in an S-function, you can use the S-function target to convert the subsystem to an S-function. See “Accelerate Simulation, Reuse Code, or Protect Intellectual Property by Using S-Function Target” (Simulink Coder) in the Simulink Coder User's Guide for details and limitations on using the S-function target.

Masked Blocks

You can customize any block by adding a mask to it. A mask is a custom interface to the block. You can customize a block using a mask in many ways, such as:

- Change the block appearance.
- Hide some or all of the parameters from the user of the block.
- Customize block parameters.

To learn more about masked blocks, see "Block Masks".

Comparing MATLAB S-Functions to MATLAB Functions for Code Generation

MATLAB S-functions and MATLAB functions for code generation have some fundamental differences.

- The Simulink Coder product can generate code for both MATLAB S-functions and MATLAB functions for code generation. However, MATLAB S-functions require a Target Language Compiler (TLC) file for code generation. MATLAB functions for code generation do not require a TLC file.
- MATLAB S-functions can use any MATLAB function whereas MATLAB functions for code generation are a subset of the MATLAB language. For a list of supported functions for code generation, see "Functions and Objects Supported for C/C++ Code Generation — Alphabetical List" on page 46-2.
- MATLAB S-functions can model discrete and continuous state dynamics whereas MATLAB functions for code generation cannot model state dynamics.

Using S-Function Blocks to Incorporate Legacy Code

Each S-function block allows you to incorporate legacy code into your model, as follows.

- A MATLAB S-function accesses legacy code through its TLC file. Therefore, the legacy code is available only in the generated code, not during simulation.
- A C MEX S-function directly calls legacy C or C++ code.
- The S-Function Builder generates a wrapper function that calls the legacy C or C++ code.

- The Legacy Code Tool generates a C MEX S-function to call the legacy C or C++ code, which is optimized for embedded systems. See “Integrate C Functions Using Legacy Code Tool” for more information.

See “Call Reusable External Algorithm Code for Simulation and Code Generation” (Simulink Coder) for more information.

See “S-Functions Incorporate Legacy C Code” in the Simulink Developing S-Functions for an example.

- “Expanding Custom Block Functionality” on page 39-18
- “Create a Custom Block” on page 39-19

Comparison of Custom Block Functionality

In this section...

When creating a custom block, consider:

- Does the block model continuous or discrete state behavior on page 39-10?
- Is the simulation performance on page 39-11 important?
- Do you need to generate code on page 39-13 for a model containing the custom block?

This table shows how each custom block type addresses the three concerns.

Modelling Considerations

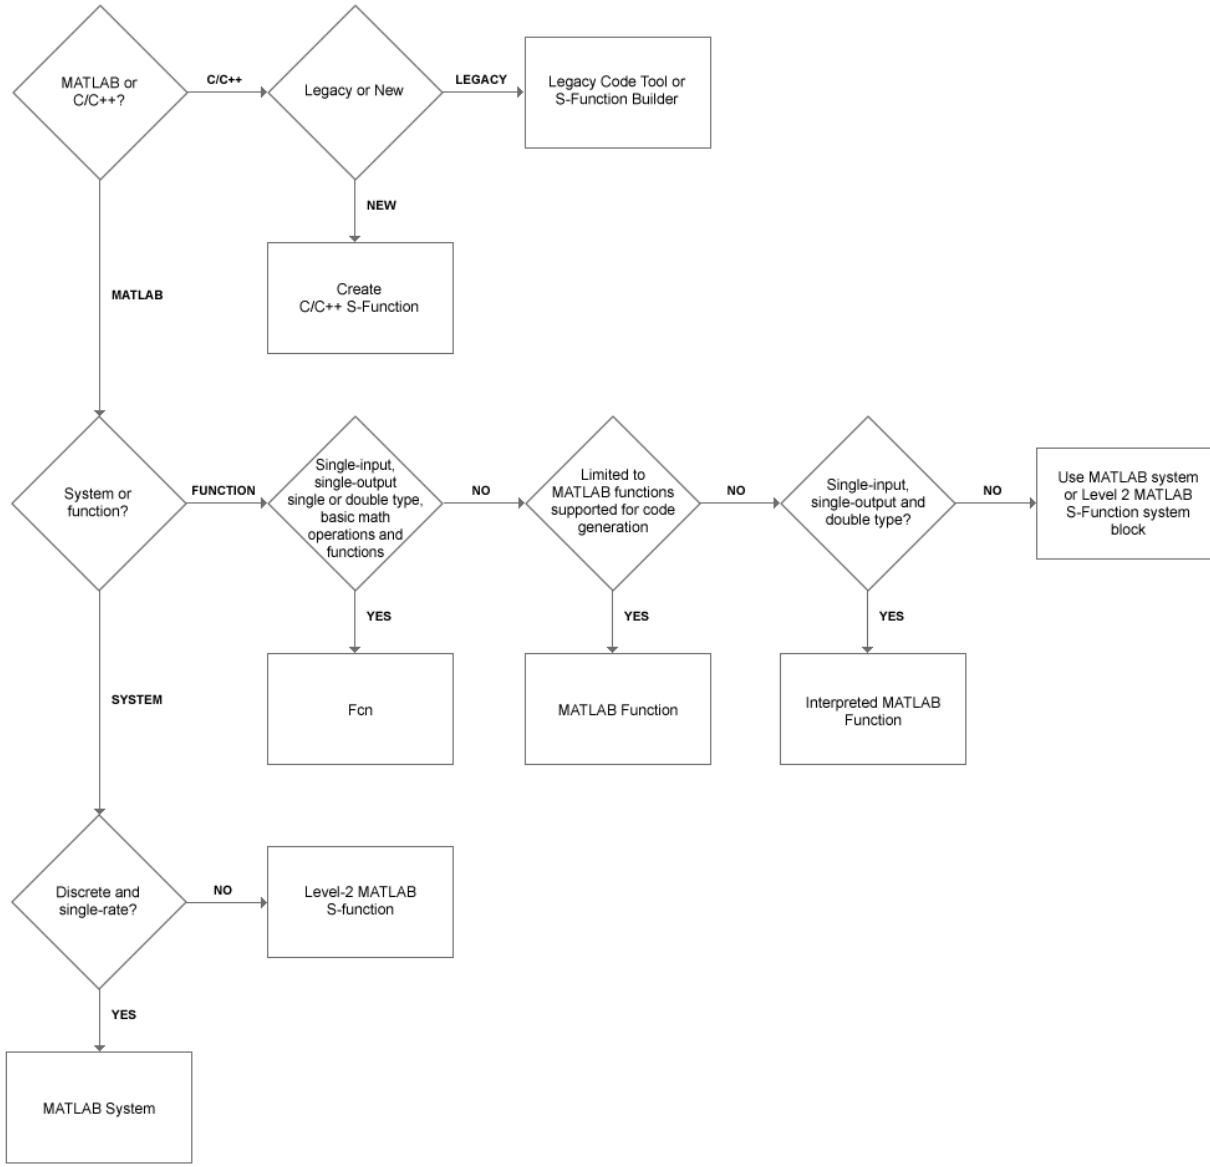
Custom Block Type	Model State Dynamics on page 39-10	Simulation Performance on page 39-11	Code Generation on page 39-13
Fcn	No	Very fast	Supported
Interpreted MATLAB Function	No	Less fast	Not supported
Level-2 MATLAB S-function	Yes	Less fast	Requires a TLC file
MATLAB Function	No	Fast	Supported with exceptions
MATLAB System	Yes	Fast	Supported with exceptions
S-Function	Yes	Fast	Requires a TLC file or non-inline S-Function support
S-Function Builder	Yes	Fast	Supported
Simulink Function	Yes	Fast	Supported
Subsystem	Yes	Fast	Supported

For detailed design of custom blocks, consider:

- Does the custom block need multiple input and output ports on page 39-14?
- What are the callback methods on page 39-16 to communicate with the Simulink engine and which custom blocks let you implement all or a subset of these callback methods?
- How important is the effect of the custom block on the speed of updating the Simulink diagram on page 39-15?

Block Type Flowchart

This diagram helps to decide which block to use. First, determine whether you need the block for a function or a system. A function defines the relationship between a set of inputs and outputs. A system defines the relationship between a set of states as well as a set of inputs and outputs, parameters, System object processing methods for initialization, output, update, termination, and so forth.



Note In the flowchart, Legacy stands for the existing code or models.

Model State Behavior

You need to model the state behavior for a block that requires some or all of its previous outputs to compute its current outputs. See “Modeling Dynamic Systems” on page 3-3 for more information.

Custom Block Type	Notes
Fcn, Interpreted MATLAB Function	Does not allow you to model state behavior.
MATLAB Function	Allows you to model a discrete state using `persistent` variables.
Level-2 MATLAB S-Function	Allows you to model both continuous and discrete state behavior using the `ContStates` or `Dwork` run-time object methods in combination with block callback methods. For a list of supported methods, see “Level-2 MATLAB S-Function Callback Methods” in “Write Level-2 MATLAB S-Functions”.
MATLAB System	Allows you to model discrete state behavior using `DiscreteState` properties of the System object, in combination with block callback methods. This block uses System object methods for callback methods: `mdlOutputs` (`stepImpl`, `outputImpl`), `mdlUpdate` (`updateImpl`), `mdlInitializeConditions` (`resetImpl`), `mdlStart` (`setupImpl`), `mdlTerminate` (`releaseImpl`). For more information see “What Are System Objects?” (MATLAB).
C MEX S-Function, S-Function Builder	Allows you to model both continuous and discrete state behavior in combination with block callback methods. For more information, see “Callback Methods for C MEX S-Functions”
Simulink Function	Communicates directly with the engine. You can model the state behavior using appropriate blocks from the continuous and discrete Simulink block libraries. When multiple calls to this function originate from different callers, the state values are also persistent between these calls. For more information, see “Call a Simulink Function Block from Multiple Sites” on page 10-131.

Custom Block Type	Notes
Subsystem	Communicates directly with the engine. You can model the state behavior using appropriate blocks from the continuous and discrete Simulink block libraries.

Simulation Performance

For most applications, all custom block types provide satisfactory simulation performance. Use the Simulink profiler to get the actual performance indication. See “How Profiler Captures Performance Data” on page 30-5 for more information.

The two categories of performance indication are the interface cost and the algorithm cost. The interface cost is the time it takes to move data from the Simulink engine into the block. The algorithm cost is the time it takes to perform the algorithm that the block implements.

Custom Block Type	Notes
Fcn	Has the highest simulation performance. The block is tightly integrated with the Simulink engine and optimized for simulation and code generation.
Interpreted MATLAB Function	Has a slower performance due to the interface, but has the same algorithm cost as a MATLAB function. When block data (such as inputs and outputs) is accessed or returned from an Interpreted MATLAB Function block, the Simulink engine packages this data into MATLAB arrays. This packaging takes additional time and causes a temporary increase in memory during communication. If you pass large amounts of data across this interface, such as frames or arrays, the performance can be substantially slow. Once the data has been converted, the MATLAB execution engine executes the algorithm. As a result, the algorithm cost is the same as for MATLAB function.

Custom Block Type	Notes
Level-2 MATLAB S-Function	Incurs the same algorithm costs as the Interpreted MATLAB Function block, but with a slightly higher interface cost. Since MATLAB S-Functions can handle multiple inputs and outputs, the packaging is more complicated than for the Interpreted MATLAB Function block. In addition, the Simulink engine calls the MATLAB execution engine for each block method you implement, whereas the Interpreted MATLAB Function block calls the MATLAB execution engine only for the `Outputs` method.
MATLAB Function	Performs simulation through code generation and incurs the same interface cost as other Simulink built-in blocks. The algorithm cost of this block is harder to analyze because of the block's implementation. On average, a function for this block and theMATLAB function run at about the same speed. If the MATLAB Function block has code that uses `coder.extrinsic` to call out to the MATLAB execution engine, it incurs all the costs that the MATLAB S-Function or Interpreted MATLAB Function block incur. Calling out to the MATLAB execution engine from a MATLAB Function block produces a warning to prevent you from doing so unintentionally. To reduce the algorithm cost, you can disable debugging for all MATLAB Function blocks.
MATLAB System	In the interpreted execution mode, performance is similar to that of the Level-2 MATLAB S-Function because the model simulates the block using the MATLAB execution engine. In the code generation mode, performance is similar to that of the MATLAB Function because the model simulates the block using the generated code. For more information, see the MATLAB Function entry in this table.
C MEX S-Function	Simulates via the compiled code and incurs the same interface cost as Simulink built-in blocks. The algorithm cost depends on the complexity of the S-Function.
S-Function Builder	This block only builds an S-Function from the specifications and C code you supply. You can also use this block as a wrapper for the generated S-Function in models. The algorithm cost of this block compared to C MEX S-Function is incurred only from the wrapper.

Custom Block Type	Notes
Simulink Function, Subsystem	If included in a library, introduces no interface or algorithm costs beyond what would normally be incurred if the block existed as a regular subsystem in the model. Performance is proportional to the complexity of the algorithm implemented in the subsystem. If the subsystem is contained in a library, some cost is incurred when Simulink loads any unloaded libraries the first time the diagram is updated or readied for simulation. If all referenced library blocks remain unchanged, Simulink does not subsequently reload the library. Compiling the model becomes faster than if the model did not use libraries.

Code Generation

You need code generation if your model is part of a bigger system. Not all custom block types support code generation with Simulink Coder.

Custom Block Type	Notes
Fcn	Supports code generation.
Interpreted MATLAB Function	Does not support code generation.
Level-2 MATLAB S-Function	Generates code only if you implement the algorithm using a Target Language Compiler (TLC) function. In accelerated and external mode simulations, you can choose to execute the S-Function in the interpretive mode by calling back to the MATLAB execution engine without implementing the algorithm in TLC. If the MATLAB S-Function is `SimViewingDevice`, the Simulink Coder product automatically omits the block during code generation.
MATLAB Function, MATLAB System	Supports code generation. However, if your block calls out to the MATLAB execution engine, it will build with the Simulink Coder product only if the calls to the MATLAB execution engine do not affect the block outputs. Under this condition, the Simulink Coder product omits these calls from the generated C code. This feature allows you to leave visualization code in place, even when generating embedded code.

Custom Block Type	Notes
C MEX S-Function, S-Function Builder	Both supports code generation. • For non-inlined S-Functions, the Simulink Coder product uses the C MEX function during code generation. • In the case of C MEX S-Functions, if you need to either inline the S-Function or create a wrapper for handwritten code, you must write a TLC file for the S-Function. • In the case of S-Function Builder, you can choose the Generate wrapper TLC option to automatically generate a TLC file. See “S-Functions and Code Generation” (Simulink Coder) for more information.
Simulink Function	Supports code generation.
Subsystem	Supports code generation as long as the blocks contained within the subsystem support code generation. For more information, see “Code Generation of Subsystems” (Embedded Coder)

Multiple Input and Output Ports

These types of custom blocks support multiple input and output ports.

Custom Block Type	Notes
Fcn, Interpreted MATLAB Function	Supports only a single input and a single output port.
MATLAB Function	Supports multiple input and output ports, including bus signals. See “How Structure Inputs and Outputs Interface with Bus Signals” on page 41-90 for more information.
MATLAB System	Supports multiple input and output ports, including bus signals. In addition, you can modify the number of input and output ports based on system object properties using the `getNumInputs` and `getNumOutputs` methods.

Custom Block Type	Notes
Level-2 MATLAB S-Function, C MEX S-Function, S-Function Builder	Supports multiple input and output ports. In addition, you can modify the number of input and output ports based on user-defined parameters. The C MEX S-Function and S-Function Builder support bus signals.
Simulink Function	Supports multiple input and output ports, including bus signals.
Subsystem	Supports multiple input and output ports, including bus signals. In addition, you can modify the number of input and output ports based on user-defined parameters. See “Self-Modifiable Linked Subsystems” on page 40-24 for more information.

Speed of Updating the Simulink Diagram

Simulink updates the diagram before every simulation and when requested by the user. Every block introduces some overhead into the diagram update process.

Custom Block Type	Notes
Fcn, Interpreted MATLAB Function	Low diagram update cost.
MATLAB Function	Simulation is performed through code generation, so this blocks can take a significant amount of time when first updated. However, because code generation is incremental, Simulink does not repeatedly update the block if the block and the signals connected to it have not changed.
MATLAB System	Faster than MATLAB Function because code is not generated to update the diagram. Since, code generation is incremental, Simulink does not repeatedly update the block if the block and the signals connected to it have not changed.

Custom Block Type	Notes
C MEX S-Function, Level-2 MATLAB S-Function	Incurs greater costs than other Simulink blocks only if it overrides methods executed when updating the diagram. If these methods become complex, they can contribute significantly to the time it takes to update the diagram. For a list of methods executed when updating the diagram, see the process view in "Simulink Engine Interaction with C S-Functions". When updating the diagram, Simulink invokes all relevant methods in the model initialization phase up to, but not including, `mdlStart`.
Simulink Function, Subsystem	The speed is proportional to the complexity of the algorithm implemented in the subsystem. If the subsystem is contained in a library, some cost is incurred when Simulink loads any unloaded libraries the first time the diagram is updated or readied for simulation. If all referenced library blocks remain unchanged, Simulink does not subsequently reload the library. Compiling the model becomes faster than if the model does not use libraries.

Callback Methods

Simulink blocks communicate with the Simulink engine through block callback methods, which fully specify the behavior of blocks (except the Simulink Function block). Each custom block type allows you to implement a different set of callback methods. To learn how blocks interact with Simulink engine, see "Simulink Engine Interaction with C S-Functions". This table uses "S-Function Callback Methods" names as equivalents.

Custom Block Type	Notes
Fcn, Interpreted MATLAB Function, MATLAB Function	All create a `mdlOutputs` method to calculate the value of outputs given the value of inputs. You cannot implement any other callback methods using one of these blocks and, therefore, cannot model state behavior.
Level-2 MATLAB S-Function	Allows implementation of a larger subset of callback methods, including methods you can use to model continuous and discrete states. For a list of supported methods, see "Level-2 MATLAB S-Function Callback Methods" in "Write Level-2 MATLAB S-Functions".

Custom Block Type	Notes
MATLAB System	Uses System object methods for callback methods: `mdlOutputs` (`stepImpl`, `outputImpl`), `mdlUpdate` (`updateImpl`), `mdlInitializeConditions` (`resetImpl`), `mdlStart` (`setupImpl`), `mdlTerminate` (`releaseImpl`). For more information, see "Simulink Engine Interaction with System Object Methods" on page 43-29
C MEX S-Function	Allows implementation of a complete set of callback methods.
S-Function Builder	Allows implementation of `mdlOutputs`, `mdlDerivatives` and `mdlUpdate`.
Simulink Function	Packaged as a standalone function. Any caller to this function becomes part of one of the callback methods based on the caller's location.
Subsystem	Communicates directly with the engine. You can model state behaviors using appropriate blocks from the continuous and discrete Simulink block libraries.

Expanding Custom Block Functionality

You can expand the functionality of any custom block using callbacks and MATLAB graphics.

Block callbacks perform user-defined actions at specific points in the simulation. For example, the callback can load data into the MATLAB workspace before the simulation or generate a graph of simulation data at the end of the simulation. You can assign block callbacks to any of the custom block types. For a list of available callbacks and more information on how to use them, see “Specify Block Callbacks” on page 4-52.

GUIDE, the MATLAB graphical user interface development environment, provides tools for easily creating custom user interfaces. See “App Building” (MATLAB) for more information on using GUIDE.

Create a Custom Block

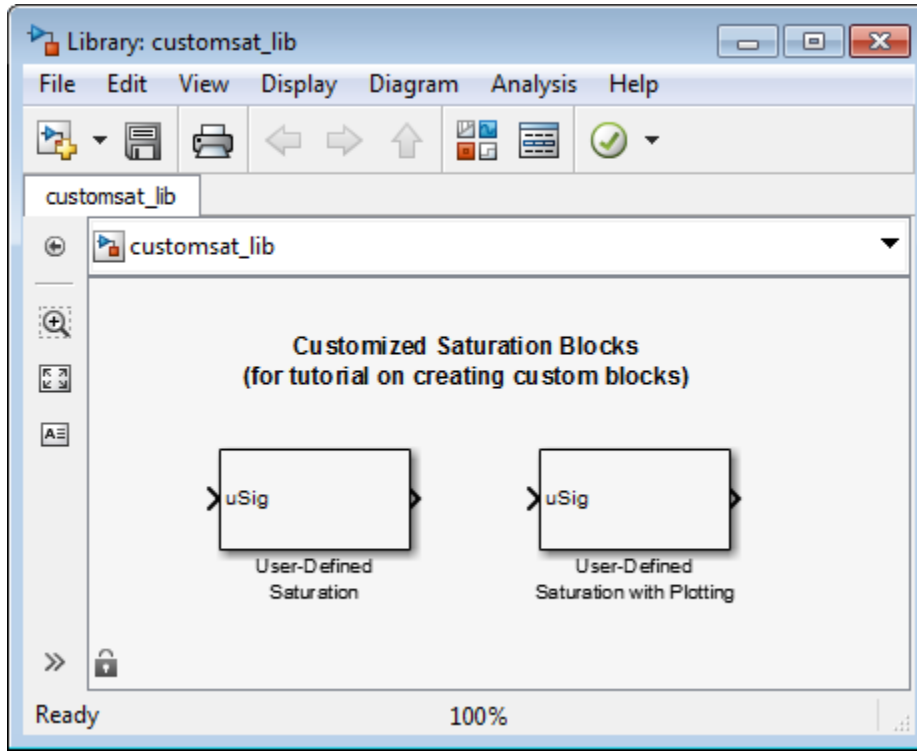
In this section...

How to Design a Custom Block

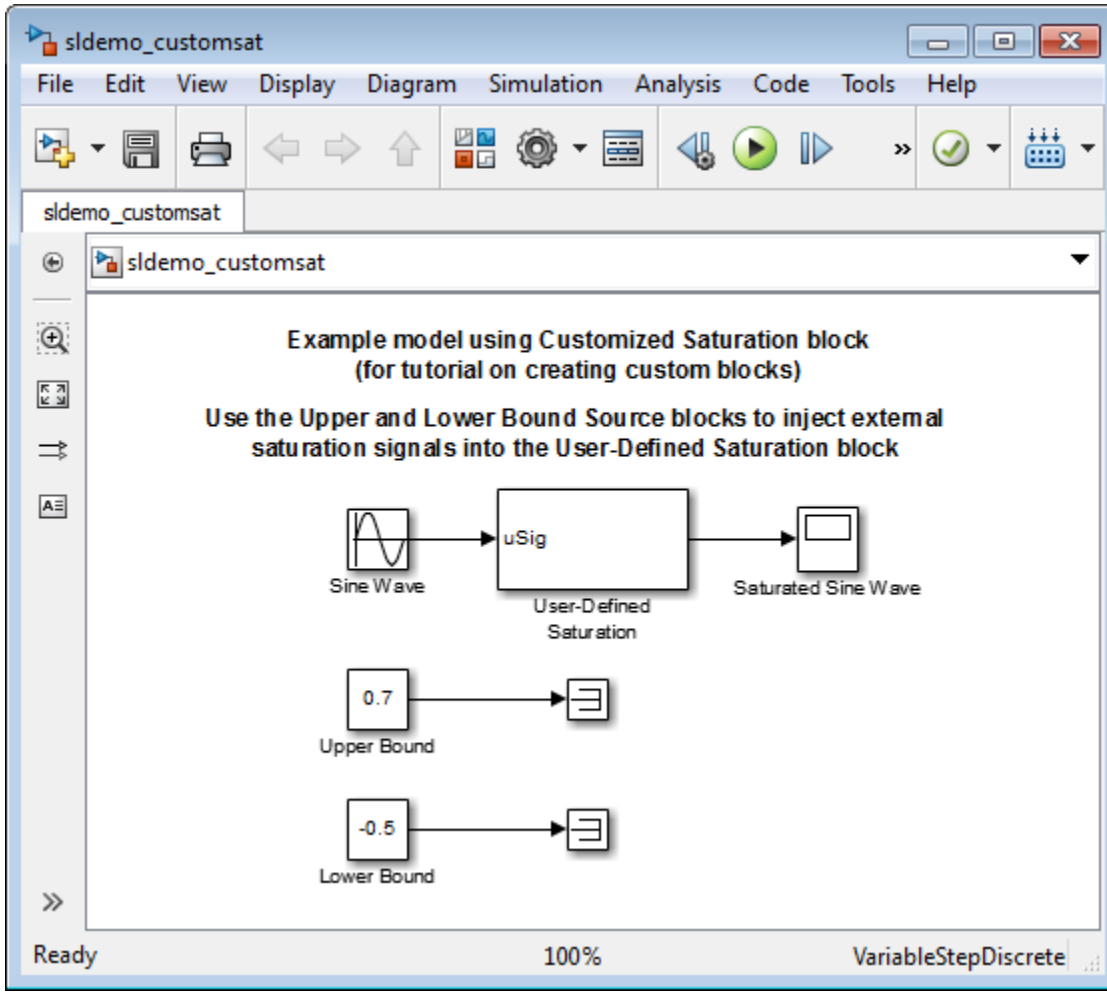
In general, use the following process to design a custom block:

1. “Defining Custom Block Behavior” on page 39-21
2. “Deciding on a Custom Block Type” on page 39-22
3. “Placing Custom Blocks in a Library” on page 39-26
4. “Adding a User Interface to a Custom Block” on page 39-29

Suppose you want to create a customized saturation block that limits the upper and lower bounds of a signal based on either a block parameter or the value of an input signal. In a second version of the block, you want the option to plot the saturation limits after the simulation is finished. The following tutorial steps you through designing these blocks. The library `ex_customsat_lib` contains the two versions of the customized saturation block.



The example model `sldemo_customsat` uses the basic version of the block.



Defining Custom Block Behavior

Begin by defining the features and limitations of your custom block. In this example, the block supports the following features:

- Turning on and off the upper or lower saturation limit.
- Setting the upper and/or lower limits via a block parameters.

- Setting the upper and/or lower limits using an input signal.

It also has the following restrictions:

- The input signal under saturation must be a scalar.
- The input signal and saturation limits must all have a data type of double.
- Code generation is not required.

Deciding on a Custom Block Type

Based on the custom block features, the implementation needs to support the following:

- Multiple input ports
- A relatively simple algorithm
- No continuous or discrete system states

Therefore, this tutorial implements the custom block using a Level-2 MATLAB S-function. MATLAB S-functions support multiple inputs and, because the algorithm is simple, do not have significant overhead when updating the diagram or simulating the model. See “Comparison of Custom Block Functionality” on page 39-7 for a description of the different functionality provided by MATLAB S-functions as compared to other types of custom blocks.

Parameterizing the MATLAB S-Function

Begin by defining the S-function parameters. This example requires four parameters:

- The first parameter indicates how the upper saturation limit is set. The limit can be off, set via a block parameter, or set via an input signal.
- The second parameter is the value of the upper saturation limit. This value is used only if the upper saturation limit is set via a block parameter. In the event this parameter is used, you should be able to change the parameter value during the simulation, i.e., the parameter is tunable.
- The third parameter indicates how the lower saturation limit is set. The limit can be off, set via a block parameter, or set via an input signal.
- The fourth parameter is the value of the lower saturation limit. This value is used only if the lower saturation limit is set via a block parameter. As with the upper saturation limit, this parameter is tunable when in use.

The first and third S-function parameters represent modes that must be translated into values the S-function can recognize. Therefore, define the following values for the upper and lower saturation limit modes:

- `1` indicates that the saturation limit is off.
- `2` indicates that the saturation limit is set via a block parameter.
- `3` indicates that the saturation limit is set via an input signal.

Writing the MATLAB S-Function

After you define the S-function parameters and functionality, write the S-function. The template `msfuntmpl.m` provides a starting point for writing a Level-2 MATLAB S-function. You can find a completed version of the custom saturation block in the file `custom_sat.m`. Save this file to your working folder before continuing with this tutorial.

This S-function modifies the S-function template as follows:

- The `setup` function initializes the number of input ports based on the values entered for the upper and lower saturation limit modes. If the limits are set via input signals, the method adds input ports to the block. The `setup` method then indicates there are four S-function parameters and sets the parameter tunability. Finally, the method registers the S-function methods used during simulation.

```
function setup(block)

% The Simulink engine passes an instance of the Simulink.MSFcnRunTimeBlock
% class to the setup method in the input argument "block". This is known as
% the S-function block's run-time object.

% Register original number of input ports based on the S-function
% parameter values

try % Wrap in a try/catch, in case no S-function parameters are entered
    lowMode    = block.DialogPrm(1).Data;
    upMode     = block.DialogPrm(3).Data;
    numInPorts = 1 + isequal(lowMode,3) + isequal(upMode,3);
catch
    numInPorts=1;
end % try/catch
block.NumInputPorts = numInPorts;
block.NumOutputPorts = 1;

% Setup port properties to be inherited or dynamic
block.SetPreCompInpPortInfoToDynamic;
block.SetPreCompOutPortInfoToDynamic;

% Override input port properties
```

```
block.InputPort(1).DatatypeID  = 0;  % double
block.InputPort(1).Complexity  = 'Real';

% Override output port properties
block.OutputPort(1).DatatypeID  = 0; % double
block.OutputPort(1).Complexity  = 'Real';

% Register parameters. In order:
% -- If the upper bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The upper limit value. Should be empty if the upper limit is off or
%    set via an input signal
% -- If the lower bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The lower limit value. Should be empty if the lower limit is off or
%    set via an input signal
block.NumDialogPrms     = 4;
block.DialogPrmsTunable = {'Nontunable','Tunable','Nontunable', ...
    'Tunable'};

% Register continuous sample times [0 offset]
block.SampleTimes = [0 0];

%% -----------------------------------------------------------------
%% Options
%% -----------------------------------------------------------------
% Specify if Accelerator should use TLC or call back into
% MATLAB script
block.SetAccelRunOnTLC(false);

%% -----------------------------------------------------------------
%% Register methods called during update diagram/compilation
%% -----------------------------------------------------------------

block.RegBlockMethod('CheckParameters',      @CheckPrms);
block.RegBlockMethod('ProcessParameters',    @ProcessPrms);
block.RegBlockMethod('PostPropagationSetup', @DoPostPropSetup);
block.RegBlockMethod('Outputs',              @Outputs);
block.RegBlockMethod('Terminate',            @Terminate);
%end setup function
```

- The `CheckParameters` method verifies the values entered into the Level-2 MATLAB S-Function block.

```
function CheckPrms(block)

lowMode = block.DialogPrm(1).Data;
lowVal  = block.DialogPrm(2).Data;
upMode  = block.DialogPrm(3).Data;
upVal   = block.DialogPrm(4).Data;

% The first and third dialog parameters must have values of 1-3
if ~any(upMode == [1 2 3]);
    error('The first dialog parameter must be a value of 1, 2, or 3');
end
```

```
if ~any(lowMode == [1 2 3]);
    error('The first dialog parameter must be a value of 1, 2, or 3');
end

% If the upper or lower bound is specified via a dialog, make sure there
% is a specified bound. Also, check that the value is of type double
if isequal(upMode,2),
    if isempty(upVal),
        error('Enter a value for the upper saturation limit.');
    end
    if ~strcmp(class(upVal), 'double')
        error('The upper saturation limit must be of type double.');
    end
end

if isequal(lowMode,2),
    if isempty(lowVal),
        error('Enter a value for the lower saturation limit.');
    end
    if ~strcmp(class(lowVal), 'double')
        error('The lower saturation limit must be of type double.');
    end
end

% If a lower and upper limit are specified, make sure the specified
% limits are compatible.
if isequal(upMode,2) && isequal(lowMode,2),
    if lowVal >= upVal,
        error('The lower bound must be less than the upper bound.');
    end
end

%end CheckPrms function
```

- The `ProcessParameters` and `PostPropagationSetup` methods handle the S-function parameter tuning.

```
function ProcessPrms(block)

%% Update run time parameters
block.AutoUpdateRuntimePrms;

%end ProcessPrms function

function DoPostPropSetup(block)

%% Register all tunable parameters as runtime parameters.
block.AutoRegRuntimePrms;

%end DoPostPropSetup function
```

- The `Outputs` method calculates the block's output based on the S-function parameter settings and any input signals.

```
function Outputs(block)

lowMode    = block.DialogPrm(1).Data;
upMode     = block.DialogPrm(3).Data;
sigVal     = block.InputPort(1).Data;
lowPortNum = 2; % Initialize potential input number for lower saturation limit

% Check upper saturation limit
if isequal(upMode,2), % Set via a block parameter
    upVal = block.RuntimePrm(2).Data;
elseif isequal(upMode,3), % Set via an input port
    upVal = block.InputPort(2).Data;
    lowPortNum = 3; % Move lower boundary down one port number
else
    upVal = inf;
end

% Check lower saturation limit
if isequal(lowMode,2), % Set via a block parameter
    lowVal = block.RuntimePrm(1).Data;
elseif isequal(lowMode,3), % Set via an input port
    lowVal = block.InputPort(lowPortNum).Data;
else
    lowVal = -inf;
end

% Assign new value to signal
if sigVal > upVal,
    sigVal = upVal;
elseif sigVal < lowVal,
    sigVal=lowVal;
end

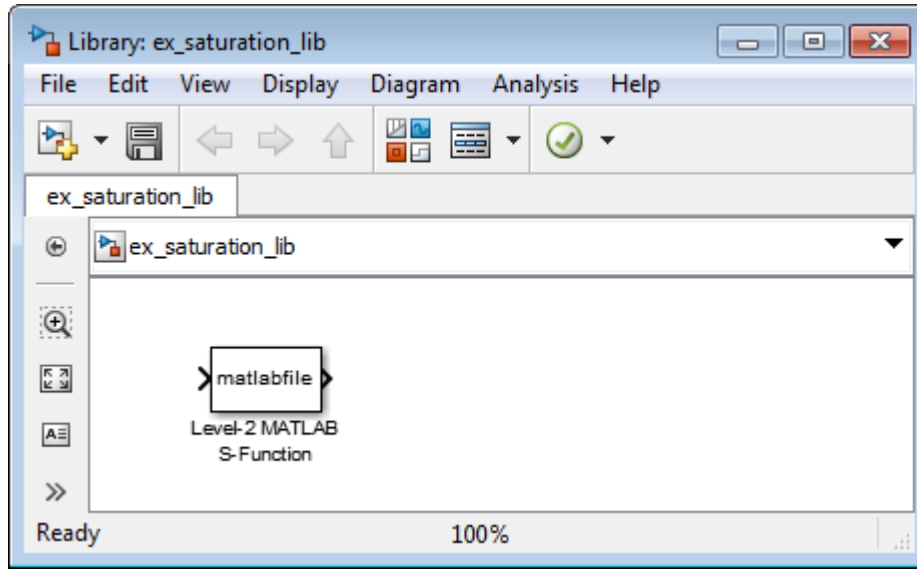
block.OutputPort(1).Data = sigVal;

%end Outputs function
```

Placing Custom Blocks in a Library

Libraries allow you to share your custom blocks with other users, easily update the functionality of copies of the custom block, and collect blocks for a particular project into a single location. This example places the custom saturation block into a library.

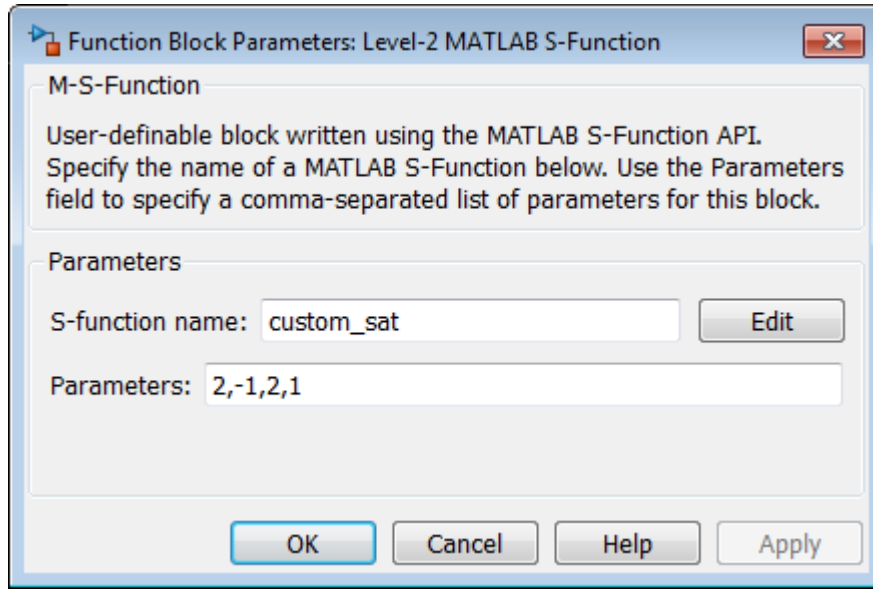
1. In the Simulink Library Browser, select **File > New > Library**.
2. From the User-Defined Functions library, drag a Level-2 MATLAB S-Function block into your new library.



3 Save your library with the filename `saturation_lib`.

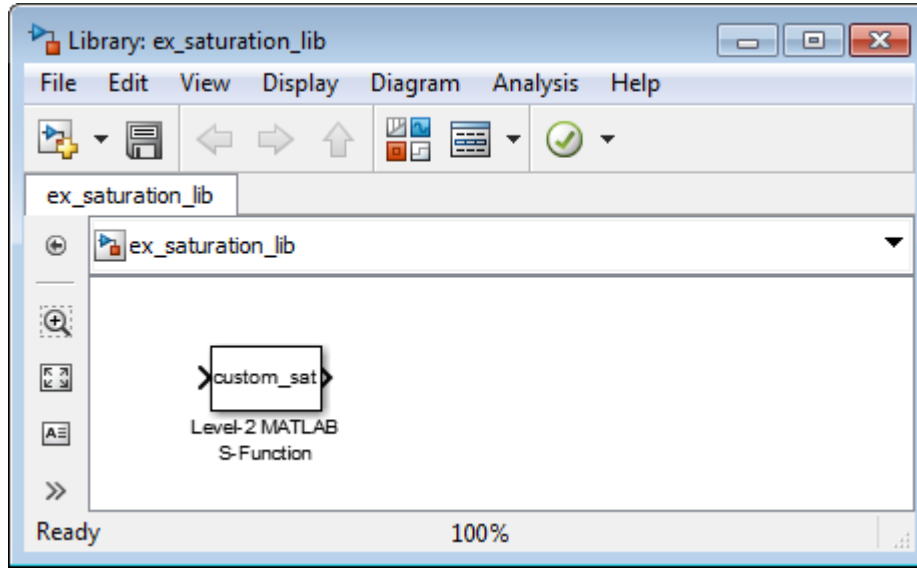
4 Double-click the block to open its Function Block Parameters dialog box.

5 In the **S-function name** field, enter the name of the S-function. For example, enter `custom_sat`. In the **Parameters** field enter `2,-1,2,1`.



6 Click **OK**.

You have created a custom saturation block that you can share with other users.



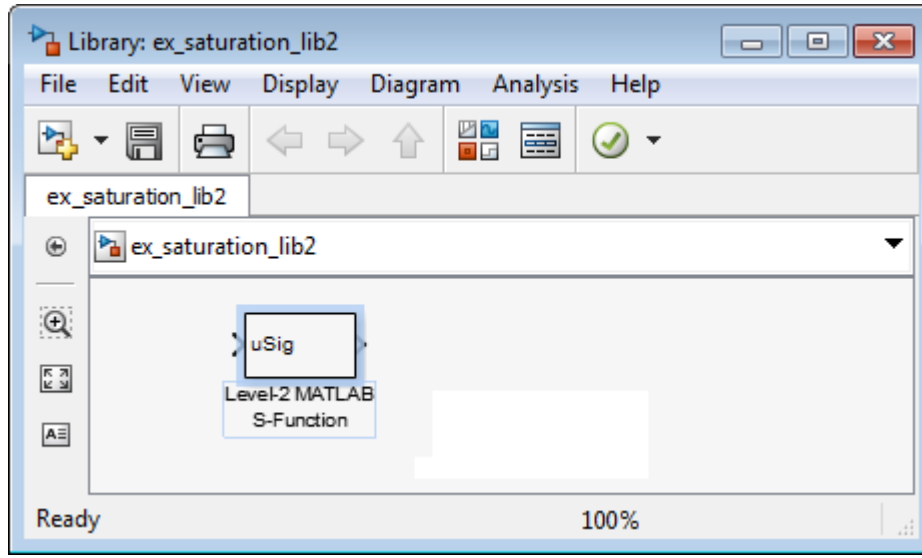
You can make the block easier to use by adding a customized user interface.

Adding a User Interface to a Custom Block

You can create a block dialog box for a custom block using the masking features of Simulink. Masking the block also allows you to add port labels to indicate which ports corresponds to the input signal and the saturation limits.

1. Open the library `saturation_lib` that contains the custom block you created,
2. Right-click the Level-2 MATLAB S-Function block and select **Mask > Create Mask**.
3. On the **Icon & Ports** pane in the **Icons drawing commands** box, enter `port_label('input',1,'uSig')`, and then click **Apply**.

   This command labels the default port as the input signal under saturation.



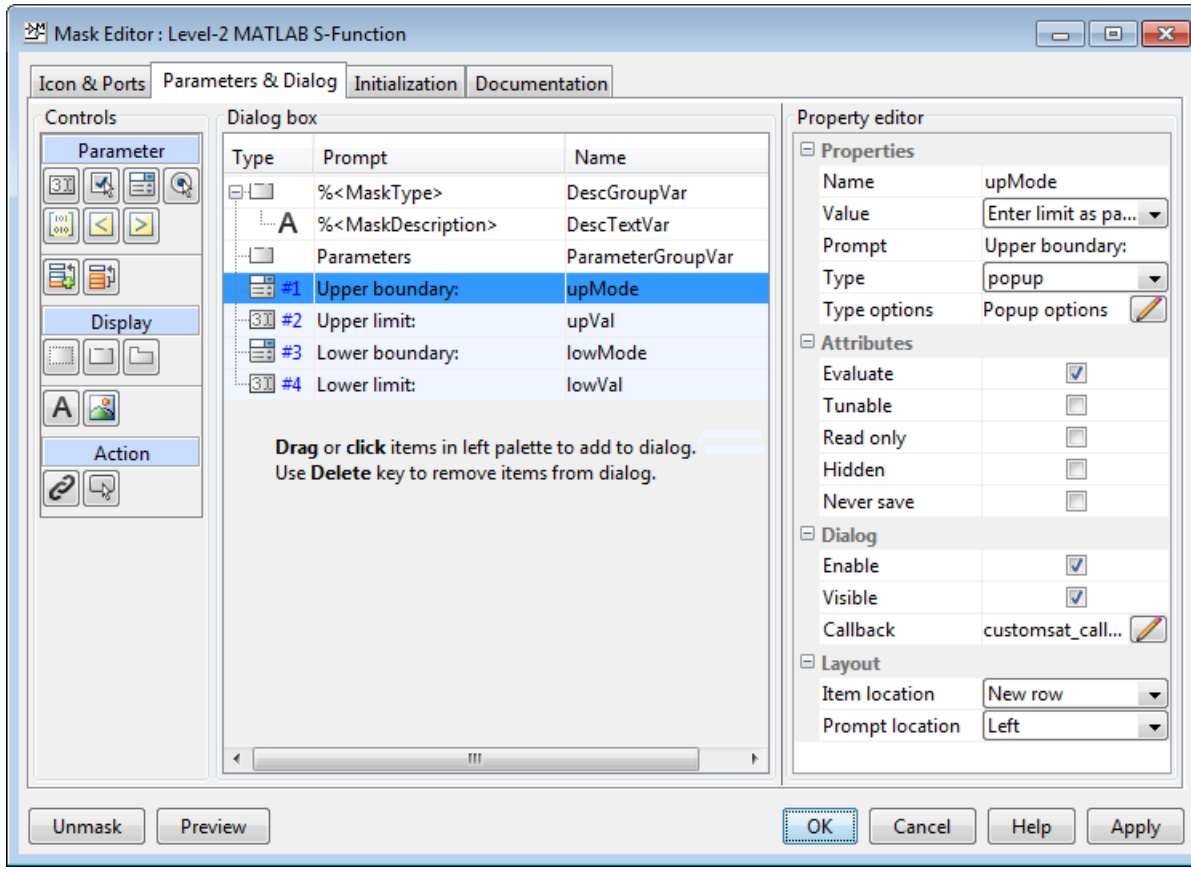
4. In the **Parameters & Dialog** pane, add four parameters corresponding to the four S-Function parameters. For each new parameter, drag a popup or edit control to the **Dialog box** section, as shown in the table. Drag each parameter into the Parameters group.

Type	Prompt	Name	Evaluate	Tunable	Popup options	Callback
popup	Upper boundary:	upMode	✓		No limit Enter limit as parameter Limit using input signal	customsat_callback('upperbound_callback', gcb)
edit	Upper limit:	upVal	✓	✓	N/A	customsat_callback('upperparam_callback', gcb)

Type	Prompt	Name	Evaluate	Tunable	Popup options	Callback
popup	Lower boundary:	lowMode	✓		No limit Enter limit as parameter Limit using input signal	customsat_callback('lowerbound_callback', gcb)
edit	Lower limit:	lowVal	✓	✓	N/A	customsat_callback('lowerparam_callback', gcb)

The MATLAB S-Function script `custom_sat_final.m` contains the mask parameter callbacks. Save `custom_sat_final.m` to your working folder to define the callbacks in this example. This MATLAB script has two input arguments. The first input argument is a character vector indicating which mask parameter invoked the callback. The second input argument is the handle to the associated Level-2 MATLAB S-Function block.

The figure shows the completed **Parameters & Dialog** pane in the Mask Editor.



5 In the **Initialization** pane, select the **Allow library block to modify its contents** check box. This setting allows the S-function to change the number of ports on the block.

6 In the **Documentation** pane:

- In the **Mask type** field, enter

  ```
  Customized Saturation
  ```

- In the **Mask description** field, enter

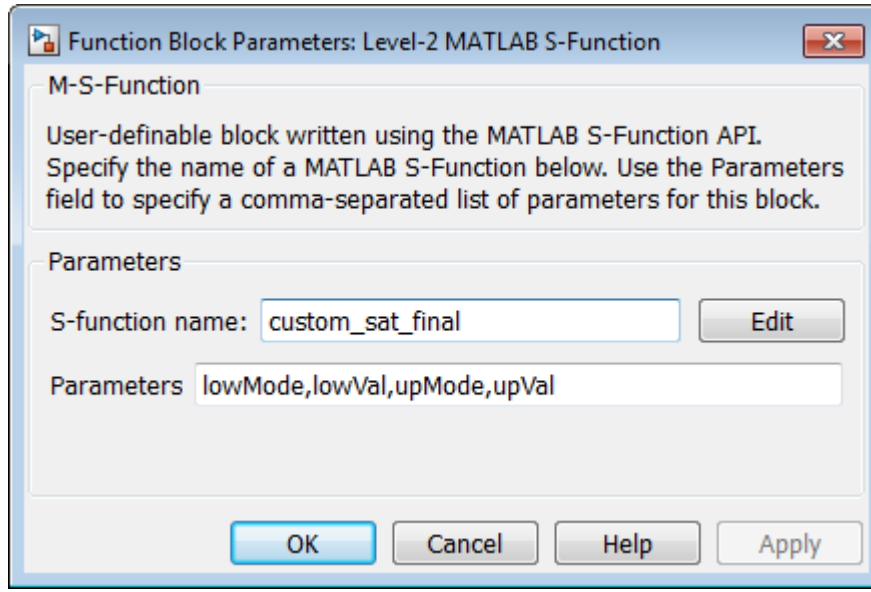
  ```
  Limit the input signal to an upper and lower saturation value
  set either through a block parameter or input signal.
  ```

7 Click **OK**.

8 To map the S-function parameters to the mask parameters, right-click the Level-2 MATLAB S-Function block and select **Mask > Look Under Mask**.

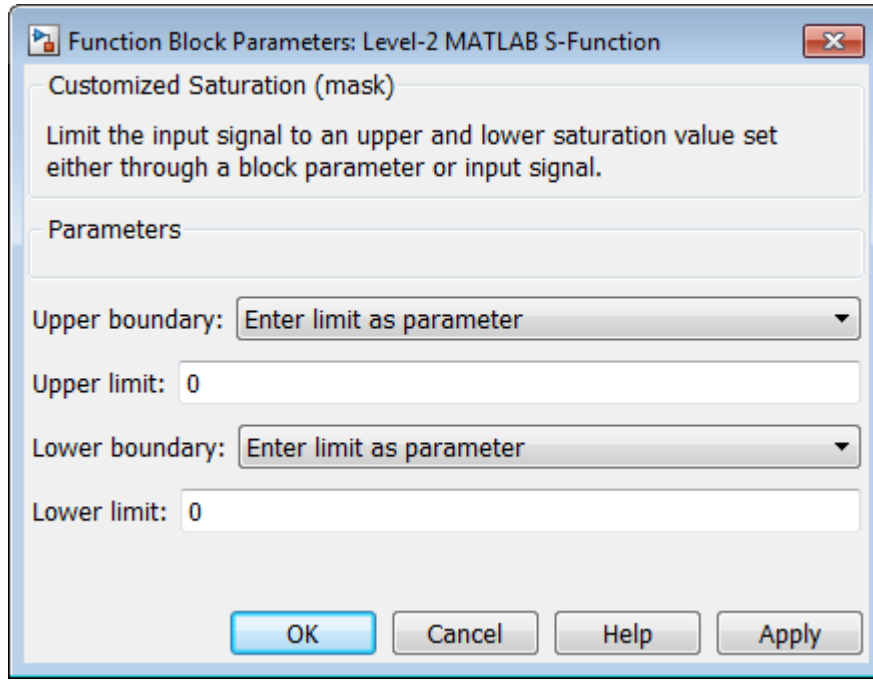
9 Change the **S-function name** field to `custom_sat_final` and the **Parameters** field to `lowMode,lowVal,upMode,upVal`.

The figure shows the Function Block Parameters dialog box after the changes.



10 Click **OK**. Save and close the library to exit the edit mode.

11 Reopen the library and double-click the customized saturation block to open the masked parameter dialog box.



To create a more complicated user interface, place a MATLAB graphics user interface on top of the masked block. The block `OpenFcn` invokes the MATLAB graphics user interface, which uses calls to `set_param` to modify the S-function block parameters based on settings in the user interface.

Writing the Mask Callback

The function `customsat_callback.m` contains the mask callback code for the custom saturation block mask parameter dialog box. This function invokes local functions corresponding to each mask parameter through a call to `feval`.

The following local function controls the visibility of the upper saturation limit's field based on the selection for the upper saturation limit's mode. The callback begins by obtaining values for all mask parameters using a call to `get_param` with the property name `MaskValues`. If the callback needed the value of only one mask parameter, it could call `get_param` with the specific mask parameter name, for example, `get_param(block,'upMode')`. Because this example needs two of the mask parameter values, it uses the `MaskValues` property to reduce the calls to `get_param`.

The callback then obtains the visibilities of the mask parameters using a call to `get_param` with the property name `MaskVisbilities`. This call returns a cell array of character vectors indicating the visibility of each mask parameter. The callback alters the values for the mask visibilities based on the selection for the upper saturation limit's mode and then updates the port label text.

The callback finally uses the `set_param` command to update the block's `MaskDisplay` property to label the block's input ports.

```
function customsat_callback(action,block)
% CUSTOMSAT_CALLBACK contains callbacks for custom saturation block

%   Copyright 2003-2007 The MathWorks, Inc.

%% Use function handle to call appropriate callback
feval(action,block)

%% Upper bound callback
function upperbound_callback(block)

vals = get_param(block,'MaskValues');
vis = get_param(block,'MaskVisibilities');
portStr = {'port_label(''input'',1,''uSig'')'};
switch vals{1}
    case 'No limit'
        set_param(block,'MaskVisibilities',[vis(1);{'off'};vis(3:4)]);
    case 'Enter limit as parameter'
        set_param(block,'MaskVisibilities',[vis(1);{'on'};vis(3:4)]);
    case 'Limit using input signal'
        set_param(block,'MaskVisibilities',[vis(1);{'off'};vis(3:4)]);
        portStr = [portStr;{'port_label(''input'',2,''up'')'}];
end
if strcmp(vals{3},'Limit using input signal'),
    portStr = [portStr;{['port_label(''input'',',num2str(length(portStr)+1), ...
        ',''low'')']}];
end
set_param(block,'MaskDisplay',char(portStr));
```

The final call to `set_param` invokes the `setup` function in the MATLAB S-function `custom_sat.m`. Therefore, the `setup` function can be modified to set the number of input ports based on the mask parameter values instead of on the S-function parameter values. This change to the `setup` function keeps the number of ports on the Level-2 MATLAB S-Function block consistent with the values shown in the mask parameter dialog box.

The modified MATLAB S-function `custom_sat_final.m` contains the following new `setup` function. If you are stepping through this tutorial, open the file and save it to your working folder.

```
%% Function: setup ===================================================
function setup(block)

% Register original number of ports based on settings in Mask Dialog
ud = getPortVisibility(block);
numInPorts = 1 + isequal(ud(1),3) + isequal(ud(2),3);

block.NumInputPorts = numInPorts;
block.NumOutputPorts = 1;

% Setup port properties to be inherited or dynamic
block.SetPreCompInpPortInfoToDynamic;
block.SetPreCompOutPortInfoToDynamic;

% Override input port properties
block.InputPort(1).DatatypeID  = 0;  % double
block.InputPort(1).Complexity  = 'Real';

% Override output port properties
block.OutputPort(1).DatatypeID  = 0; % double
block.OutputPort(1).Complexity  = 'Real';

% Register parameters. In order:
% -- If the upper bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The upper limit value. Should be empty if the upper limit is off or
%    set via an input signal
% -- If the lower bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The lower limit value. Should be empty if the lower limit is off or
%    set via an input signal
block.NumDialogPrms     = 4;
block.DialogPrmsTunable = {'Nontunable','Tunable','Nontunable','Tunable'};

% Register continuous sample times [0 offset]
block.SampleTimes = [0 0];

%% -----------------------------------------------------------------
%% Options
%% -----------------------------------------------------------------
% Specify if Accelerator should use TLC or call back into
% MATLAB script
block.SetAccelRunOnTLC(false);

%% -----------------------------------------------------------------
%% Register methods called during update diagram/compilation
%% -----------------------------------------------------------------

block.RegBlockMethod('CheckParameters',      @CheckPrms);
block.RegBlockMethod('ProcessParameters',    @ProcessPrms);
block.RegBlockMethod('PostPropagationSetup', @DoPostPropSetup);
block.RegBlockMethod('Outputs',              @Outputs);
block.RegBlockMethod('Terminate',            @Terminate);
%endfunction
```

The `getPortVisibility` local function in `custom_sat_final.m` uses the saturation limit modes to construct a flag that is passed back to the `setup` function. The `setup` function uses this flag to determine the necessary number of input ports.

```
%% Function: Get Port Visibilities =====================================
function ud = getPortVisibility(block)

ud = [0 0];

vals = get_param(block.BlockHandle,'MaskValues');
switch vals{1}
    case 'No limit'
        ud(2) = 1;
    case 'Enter limit as parameter'
        ud(2) = 2;
    case 'Limit using input signal'
        ud(2) = 3;
end

switch vals{3}
    case 'No limit'
        ud(1) = 1;
    case 'Enter limit as parameter'
        ud(1) = 2;
    case 'Limit using input signal'
        ud(1) = 3;
end
```

Adding Block Functionality Using Block Callbacks

The User-Defined Saturation with Plotting block in `customsat_lib` uses block callbacks to add functionality to the original custom saturation block. This block provides an option to plot the saturation limits when the simulation ends. The following steps show how to modify the original custom saturation block to create this new block.

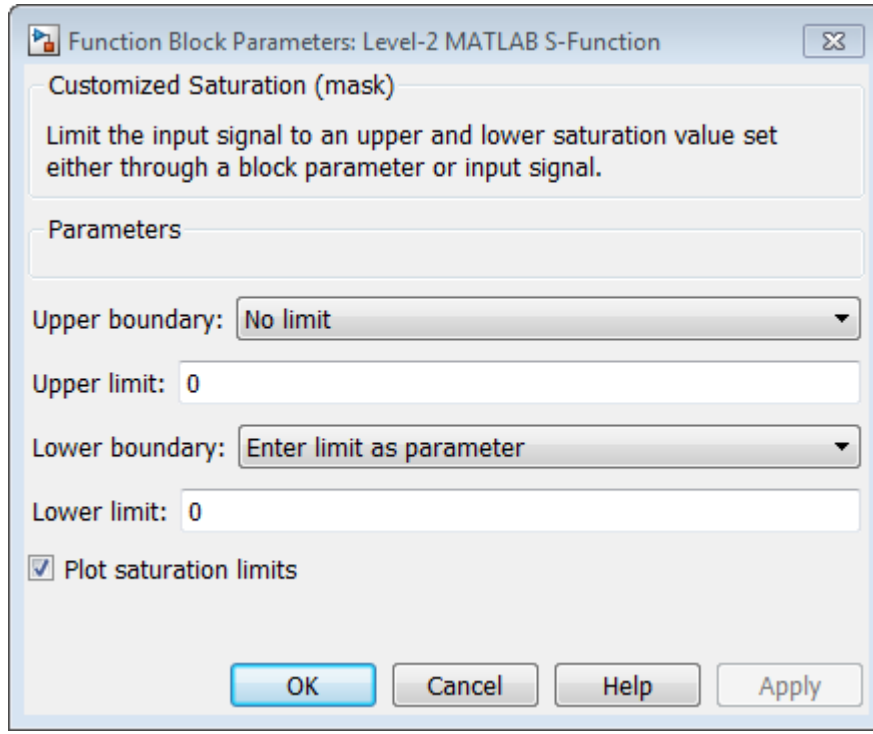
1. Add a check box to the mask parameter dialog box to toggle the plotting option on and off.

   a. Right-click the Level-2 MATLAB S-Function block in `saturation_lib` and select **Mask + Create Mask**.

   b. On the Mask Editor **Parameters** pane, add a fifth mask parameter with the following properties.

Prompt	Name	Type	Tunable	Type options	Callback
Plot saturation limits	`plotcheck`	`checkbox`	No	NA	`customsat_callback('plotsaturation',gcb)`

c Click **OK**.



2 Write a callback for the new check box. The callback initializes a structure to store the saturation limit values during simulation in the Level-2 MATLAB S-Function block `UserData`. The MATLAB script `customsat_plotcallback.m` contains this new callback, as well as modified versions of the previous callbacks to handle the new mask parameter. If you are following through this example, open `customsat_plotcallback.m` and copy its local functions over the previous local functions in `customsat_callback.m`.

```
%% Plotting checkbox callback
function plotsaturation(block)
```

```
% Reinitialize the block's userdata
vals = get_param(block,'MaskValues');
ud = struct('time',[],'upBound',[],'upVal',[],'lowBound',[],'lowVal',[]);

if strcmp(vals{1},'No limit'),
    ud.upBound = 'off';
else
    ud.upBound = 'on';
end

if strcmp(vals{3},'No limit'),
    ud.lowBound = 'off';
else
    ud.lowBound = 'on';
end

set_param(gcb,'UserData',ud);
```

3 Update the MATLAB S-function `Outputs` method to store the saturation limits, if applicable, as done in the new MATLAB S-function `custom_sat_plot.m`. If you are following through this example, copy the `Outputs` method in `custom_sat_plot.m` over the original `Outputs` method in `custom_sat_final.m`

```
%% Function: Outputs ===================================================
function Outputs(block)

lowMode    = block.DialogPrm(1).Data;
upMode     = block.DialogPrm(3).Data;
sigVal     = block.InputPort(1).Data;
vals = get_param(block.BlockHandle,'MaskValues');
plotFlag = vals{5};
lowPortNum = 2;

% Check upper saturation limit
if isequal(upMode,2)
    upVal = block.RuntimePrm(2).Data;
elseif isequal(upMode,3)
    upVal = block.InputPort(2).Data;
    lowPortNum = 3; % Move lower boundary down one port number
else
    upVal = inf;
end

% Check lower saturation limit
if isequal(lowMode,2),
    lowVal = block.RuntimePrm(1).Data;
elseif isequal(lowMode,3)
    lowVal = block.InputPort(lowPortNum).Data;
else
    lowVal = -inf;
end

% Use userdata to store limits, if plotFlag is on
```

```
if strcmp(plotFlag,'on');
    ud = get_param(block.BlockHandle,'UserData');
    ud.lowVal = [ud.lowVal;lowVal];
    ud.upVal = [ud.upVal;upVal];
    ud.time = [ud.time;block.CurrentTime];
    set_param(block.BlockHandle,'UserData',ud)
end

% Assign new value to signal
if sigVal > upVal,
    sigVal = upVal;
elseif sigVal < lowVal,
    sigVal=lowVal;
end

block.OutputPort(1).Data = sigVal;

%endfunction
```

4 Write the function `plotsat.m` to plot the saturation limits. This function takes the handle to the Level-2 MATLAB S-Function block and uses this handle to retrieve the block's `UserData`. If you are following through this tutorial, save `plotsat.m` to your working folder.

```
function plotSat(block)

% PLOTSAT contains the plotting routine for custom_sat_plot
%   This routine is called by the S-function block's StopFcn.

ud = get_param(block,'UserData');
fig=[];
if ~isempty(ud.time)
    if strcmp(ud.upBound,'on')
        fig = figure;
        plot(ud.time,ud.upVal,'r');
        hold on
    end
    if strcmp(ud.lowBound,'on')
        if isempty(fig),
            fig = figure;
        end
        plot(ud.time,ud.lowVal,'b');
    end
    if ~isempty(fig)
        title('Upper bound in red. Lower bound in blue.')
    end

    % Reinitialize userdata
    ud.upVal=[];
    ud.lowVal=[];
    ud.time = [];
    set_param(block,'UserData',ud);
end
```

5 Right-click the Level-2 MATLAB S-Function block and select **Properties**. The Block Properties dialog box opens. On the **Callbacks** pane, modify the `StopFcn` to call the plotting callback as shown in the following figure, then click **OK**.

Working with Block Libraries

Custom Libraries and Linked Blocks

Why Create Custom Libraries?

A *block library* is a collection of blocks that you can use to create instances of those blocks in a Simulink model. You can create instances of blocks from installed Simulink libraries, and you can create custom libraries to create and maintain instances of your own blocks in models.

You can access the installed libraries from the Simulink Library Browser. You cannot modify the installed libraries. Instead, if you want others to be able to create customized blocks, you can create your own library of your blocks and add it to the Library Browser. Otherwise, you can make your library accessible to the models that use it.

Creating your own libraries is a useful componentization technique for:

- Providing frequently used, and seldom changed, modeling utilities
- Reusing components in a model or in multiple models

To learn how using custom libraries compares to other Simulink componentization techniques, see “Manage Components Using Libraries” on page 22-12 and “Componentization Guidelines” on page 15-29.

How Block Instances Connect to Libraries

When you add masked blocks, subsystems, or charts from a custom library to a model, the block you add becomes a linked block. A linked block connects to the library block by way of a *library link*. The library block is the *prototype block*, and the linked block in the model is an *instance* of the library block.

The linked block looks and acts like the library block. However, if you change the library block, you need to update the link on the instances. Making changes to an instance can also require additional steps. To learn about how linked blocks work, see “Linked Blocks” on page 40-15.

- “Manage Components Using Libraries” on page 22-12

Create a Custom Library

In this section...

Create a Library

You can create your own library and, optionally, add it to the Simulink Library Browser. You save a library as a `.SLX` file as you do a model. However, you cannot simulate in a library, and a library becomes locked for editing each time you close it. You must unlock a library before you make changes to it. See “Lock and Unlock Libraries” on page 40-8.

1. From the Simulink start page, select **Blank Library** and click **Create Library**.
2. Add blocks from models or libraries to the new library. Make the changes you want to the blocks, such as changing block parameters, adding masks, or adding blocks to subsystems.

   Subsystem names in a library hierarchy must be unique. For example, do not create a hierarchy such as `Subsystem_Name1/Subsystem_Name2/Subsystem_Name1`.
3. Add annotations or images. Right-click the ones you want to appear in the library in the Library Browser and select **Show in Library Browser**.
4. If you plan to add the library to the Library Browser, you can order the blocks and annotations in your library model. By default, they appear alphabetically in the Library Browser, with subsystems first, then blocks, and then annotations. The user of your library can use the Library Browser context menu to choose between viewing them in alphabetical order or the order you specified. When the user selects this option, the order in which they appear in your library model determines the order they appear on the grid in the library in the Library Browser.
5. If you want the library to appear in the Library Browser, enable the model property `EnableLBRepository` before you save the library.

   ```
   set_param(gcs,'EnableLBRepository','on');
   ```

6 Save the library.

   Where you save the library depends on how you plan to use it. If you want to add it to the Library Browser, save it to a folder on the MATLAB path or add the location to the MATLAB path. Otherwise, save it to a location where the models that use the blocks can access it.

If you want the library to appear in the Library Browser, you must also create a function `slblocks` on your MATLAB path that adds the library to the browser. For an example that shows complete steps for adding a library to the browser, see "Add Libraries to the Library Browser" on page 40-10.

Note To update the Library Browser with your custom libraries, right-click anywhere in the Library Browser library list and select **Refresh Library Browser**. Refreshing the Library Browser also updates the quick insert list to include the blocks in custom libraries currently in effect. The quick insert list lets you add blocks to a model without leaving the canvas. Click the canvas and start typing to add blocks from the quick insert list.

Blocks for Custom Libraries

Your library can contain the blocks you need, configured for your purposes. Subsystems, masked blocks, and charts in your library become linked blocks as instances in the model and stay updated if you change them in your library. Knowing about custom blocks is also useful when you create a library. See "Create a Custom Block" on page 39-19.

You can create blocks in custom libraries with settings for specific purposes.

Create a Sublibrary

If your library contains many blocks, you can group the blocks into subsystems or separate sublibraries. To create a sublibrary, you create a library of the sublibrary blocks and reference the library from a Subsystem block in the parent library.

1 In the library you want to add a sublibrary to, add a Subsystem block.

2 Inside the Subsystem block, delete the default input and output ports.

3 If you want, create a mask for the subsystem that displays text or an image that conveys the sublibrary's purpose.

4 In the subsystem's block properties, set the `OpenFcn` callback to the name of the library you want to reference.

To learn more about masks, see "Create a Simple Mask" on page 38-7.

Prevent Library Block from Linking to Instance

You can configure a library block so the instances created from it are not linked blocks and are instead copies. Set the block's `CopyFcn` callback.

```
set_param(gcbh,'LinkStatus','none');
```

Include Block Description in Linked Block

To add a description that appears in the linked block, mask the library block and add the description in the **Documentation** pane of the mask. Descriptions added to the library block through the block's properties do not appear on the linked block.

Configure Subsystems with OpenFcn Callback for Library Browser

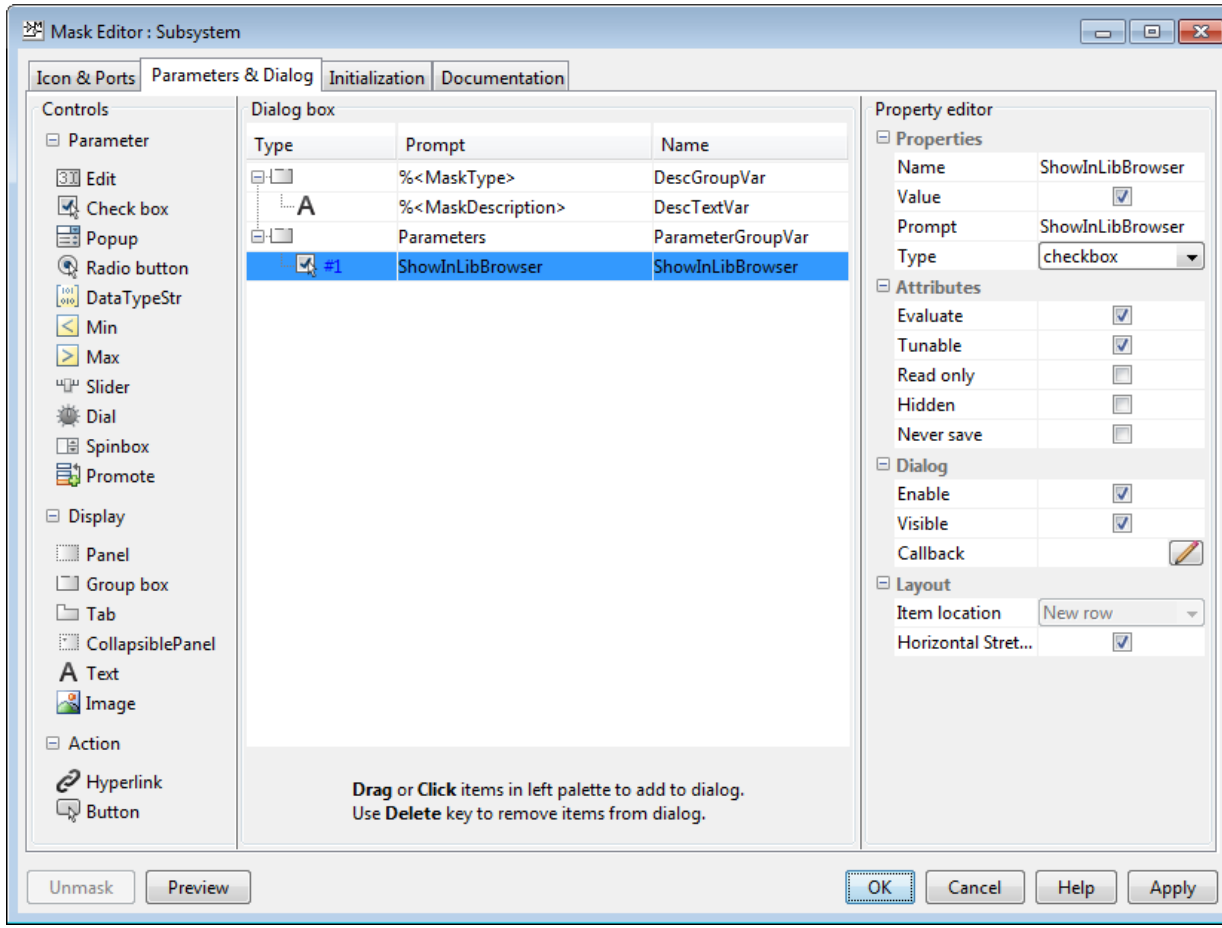
A common use of a Subsystem block in a custom library is to set the `OpenFcn` callback property to open a library, creating a library hierarchy. However, you can use the `OpenFcn` callback property of a Subsystem block for other purposes, for example to run MATLAB code or to open a link.

If your subsystem block in a library is empty and its `OpenFcn` callback contains code that performs an action other than point to a library or model, then you need to add a `'ShowInLibBrowser'` mask parameter to the subsystem to have it appear in the Library Browser.

1 Right-click the subsystem and select **Mask > Create Mask**. If the block already has a mask, select **Edit Mask** instead.

2 In the Mask Editor **Parameters & Dialog** tab, on the **Controls** pane, click **Check box**.

3 In the **Dialog box** pane, set the prompt and name for the new check box to `ShowInLibBrowser` and click **OK**.



Annotations in Custom Libraries

You can add annotations in your custom library and optionally have them appear in the Library Browser. For example, you can add an annotation that documents the library. You can also add annotations that the user of your library can add to their model from the Library Browser. Annotations can contain text and images or display an equation. Annotations can also perform an action when clicked. Learn more about annotations in “Describe Models Using Annotations” on page 4-3.

You can add callout lines from annotations to blocks in your library. However, the callouts do not appear in the Library Browser.

If you want the annotation to appear in the Library Browser, after you add it to your library, right-click it and select **Show in Library Browser**. If you want a description to appear in a tooltip when the user hovers over the annotation in the Library Browser, add the description to the annotation programmatically. At the MATLAB command prompt, enter:

```
set_param(annotationHandle,'Description','descriptionText)
```

To get the annotation handle, use `find_system`. This example gets all the annotations in the library `mylib`:

```
ann = find_system('mylib','FindAll','on','Type','annotation');
```

To get a specific annotation, turn on regular expression search and specify part of the annotation text with the `'Name'` argument:

```
ann = find_system('mylib2',FindAll','on','RegExp',...
'on','Type','annotation','Name','matchingText');
```

“Add Libraries to the Library Browser” on page 40-10 includes instructions for adding an annotation that appears in the Library Browser.

Lock and Unlock Libraries

When you close a library, it becomes locked for editing. When you next open it, unlock it if you want to make changes to it. Click the lock badge in the lower-left corner of the library to unlock it. Additionally, if you try to modify a locked library, a message prompts you to unlock it.

You can unlock a library programmatically. At the MATLAB command prompt, enter:

```
set_param('library_name','Lock','off');
```

To lock the library programmatically, enter:

```
set_param('library_name','Lock','on');
```

Prevent Disabling of Library Links

By default, a user of the blocks in your library can disable the link to library blocks. If you want to control editing of linked blocks and prevent the block user from disabling links, you can lock links to your library. Locking library links prevents the user from making any changes to the block instances.

- In your library, select **Diagram > Lock Links To Library**.

To understand how the block user interacts with blocks from locked libraries, see "Lock Links to Blocks in a Library" on page 40-29.

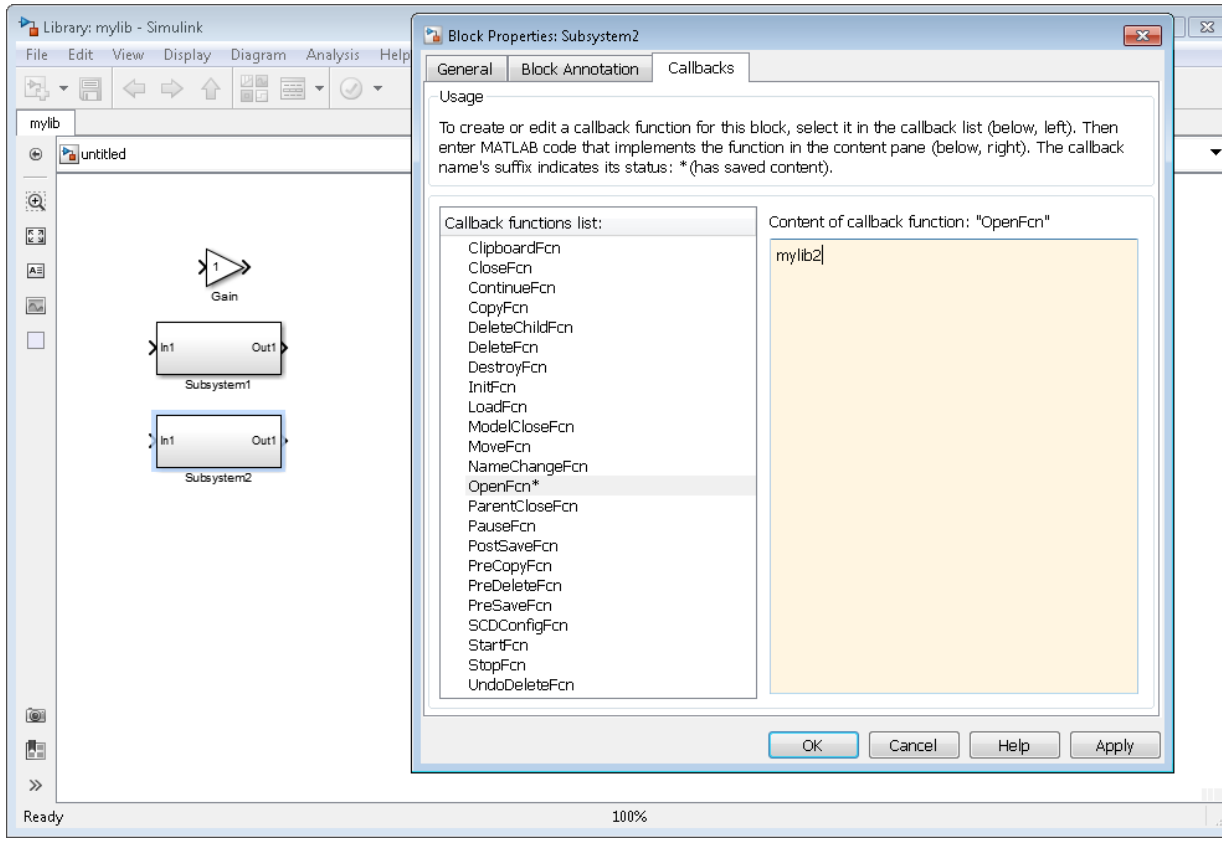
Add Libraries to the Library Browser

This example shows how to create a block library and add it to the Simulink Library Browser. You also add an annotation to the library that appears in the Library Browser.

You create a function `slblocks` to specify information about your library. You can save the function as a `.m` or `.mlx` file. You cannot save it as a P-code file.

1. From the Simulink start page, select **Blank Library** and click **Create Library**.
2. Add a Gain block and two Subsystem blocks to the library. Name the Subsystem blocks Subsystem1 and Subsystem2. In the Subsystem2 properties, set the `OpenFcn` callback to `mylib2`.



3. At the MATLAB command prompt, enter this command to enable the model property `EnableLBRepository`. Your library can appear in the browser only if this property is on when you save your library.

```
set_param(gcs,'EnableLBRepository','on');
```

4. Save the library in a folder on the MATLAB path. For this example, name the library `mylib`.

5. Create another library `mylib2` and add some blocks and an annotation that contains the text `My annotation`. Right-click the annotation and select **Show in Library Browser**.

6. Add a description for the annotation. The description appears in the Library Browser when you hover over the annotation. You can do this programmatically using `set_param`. Use `find_system` to get the annotation handle. Use part of your annotation text with the `'Name'` argument. The `'RegExp'` argument enables partial matches.

```
ann = find_system('mylib2','findall','on','RegExp',...
'on','Type','annotation','Name','annotation');
set_param(ann,'Description',...
'Use this annotation to label the model.');
```

7. Save `mylib2` to the same folder you saved `mylib` to.

   You can close both libraries if you want.

8. In MATLAB, right-click the folder you saved the library to and select **New File** > **Script**. Name the file `slblocks.m`.

9. Open `slblocks.m`. Add this function to it and save.

```
function blkStruct = slblocks
        % This function specifies that the library should appear
        % in the Library Browser
        % and be cached in the browser repository

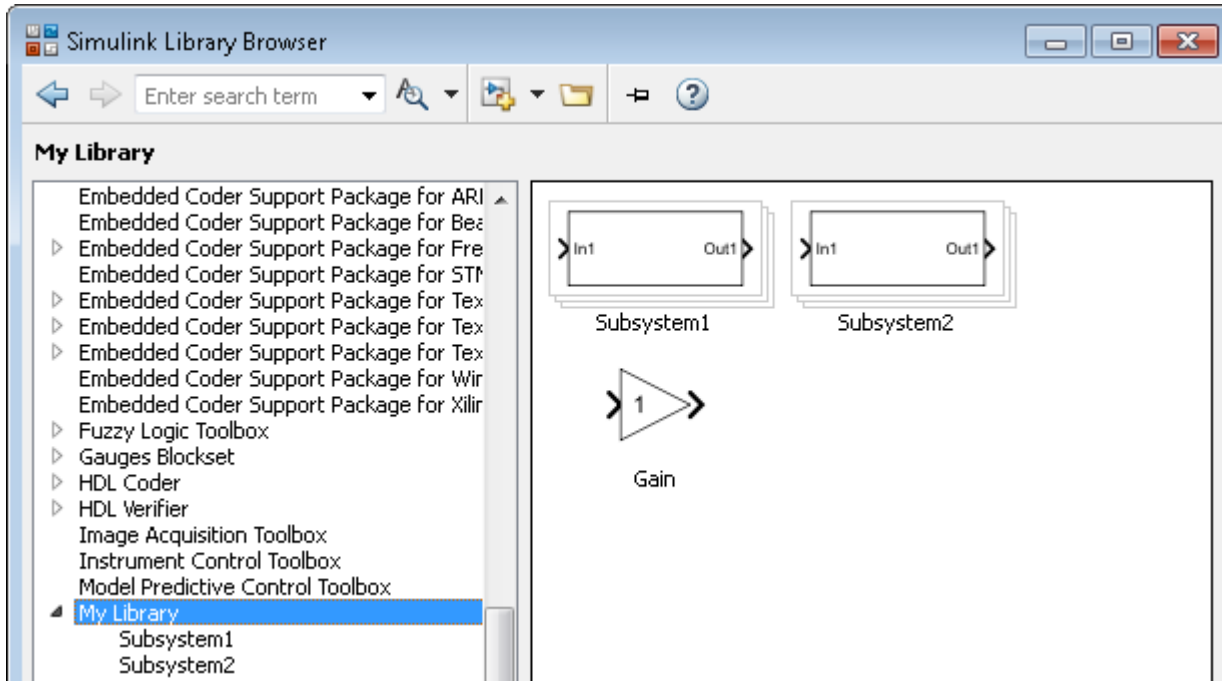
        Browser.Library = 'mylib';
        % 'mylib' is the name of the library

        Browser.Name = 'My Library';
        % 'My Library' is the library name that appears
             % in the Library Browser

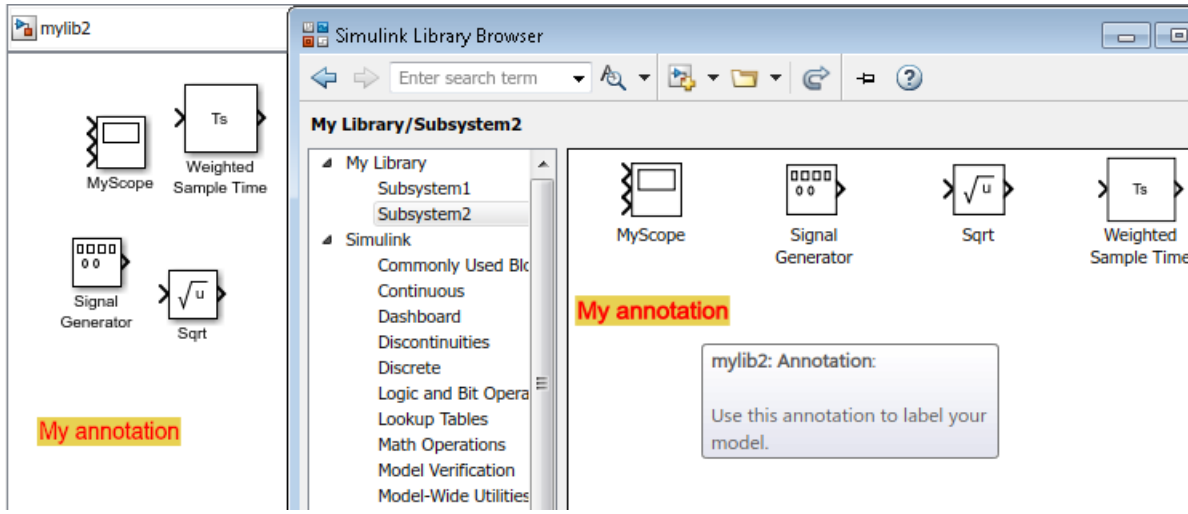
        blkStruct.Browser = Browser;
```

10 In the Library Browser, refresh to see the new library. Right-click the library list and select **Refresh Library Browser**.

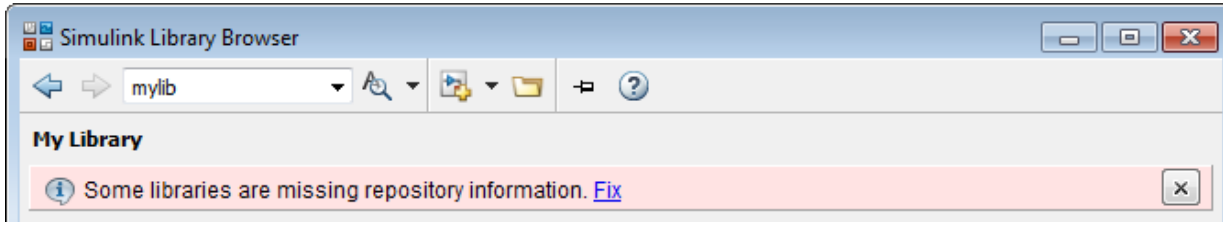
The figure shows the example library `mylib` with the Library Browser name **My Library**.



Because of the callback you created, clicking Subsystem2 displays the contents of the `mylib2` library. Hovering over the annotation in the Library Browser displays the description.



Note If you saved your library without setting `'EnableLBRepository'` to `'on'`, a message appears at the top of the Library Browser.



Click **Fix** and respond to the prompt as appropriate.

Specify Library Order in the Library List

You can specify the order of your library relative to the other libraries in the list by adding a `sl_customization.m` file to the MATLAB path and setting the sort priority of your library. For example, to see your library at the top of the list, you can set the sort priority to `-2`. By default, the sort priority of the Simulink library is `-1`. The other libraries have a sort priority of `0` by default, and these libraries appear below the Simulink library. Libraries with the same sort priority appear in alphabetical order.

This sample content of the `sl_customization.m` file places the new library at the top of the list of libraries.

```
function sl_customization(cm)
% Change the order of libraries in the Simulink Library Browser.
cm.LibraryBrowserCustomizer.applyOrder({'My Library',-2});
end
```

To make the customization take effect immediately, at the command prompt, enter:

```
sl_refresh_customizations
```

Linked Blocks

In this section...

When you add a masked library block or a Subsystem block from a Library to a Simulink model, a referenced instance of the library block is created. Such referenced instance of a library block is a called a linked block and contains link or path to the parent library block. The link or path allows the linked block to update when the library block is updated.

To locate the parent library block of a linked block, right-click the block and select **Library Link > Go To Library Link** (Ctrl + L). The **Go To Library Block** option is available only for the blocks that are linked and not for the Simulink built-in blocks. To prevent unintentional disabling of links to a library, use the locked links option on the library. For more information, see “Lock Links to Blocks in a Library” on page 40-29.

Note The tooltip for a linked block shows the name of the referenced masked library block.

When you edit a library block (either in Simulink Editor or at the command line), Simulink updates the changes in the corresponding linked blocks. The outdated links are updated when you:

- Simulate or update the model.
- Use the `find_system` command.
- **Diagram > Refresh Blocks (or press Ctrl+K)**
- Load the model or library (only visible links are updated).
- Use `get_param` to query the link status of the block (see “Control Linked Block Programmatically” on page 40-36).

Note You can use the `LinkStatus` parameter or the `StaticLinkStatus` parameter to query the link status.

- `LinkStatus`: First updates the linked block and then returns the link status.
- `StaticLinkStatus`: Returns the link status without updating the linked block.

Selective usage of `StaticLinkStatus` over `LinkStatus` can result in better Simulink performance. For more information on `StaticLinkStatus` and `LinkStatus`, see “Control Linked Block Programmatically” on page 40-36.

Rules for Linked Blocks

- You can change the values of a linked block parameter (including the existing mask).

Note The **Allow library block to modify its contents** check box in the **Initialization** pane of the library block must be selected.

- You cannot set callback parameters for a linked block.
- If the reference library block of a linked block is a subsystem, you can make nonstructural changes such as changing the parameter value of the linked subsystem. To make structural changes to a linked block, disable the link of the linked block from its library block (See “Disable or Break Links to Library Blocks” on page 40-27).

Linked Block Terminology

Terminology	Definition
Parent library block	Library block from which the linked blocks are referenced.
Linked block	Reference instance of a library block that contains links or path to its parent library block.
Locked links	Prevents unintentional modification of a linked block. For more information, see “Lock Links to Blocks in a Library” on page 40-29.

Terminology	Definition
Disabled links	Library links that are temporarily disconnected from their parent library block. For more information, see “Disable or Break Links to Library Blocks” on page 40-27.
Restore links	Restores the disabled link of a linked block to their parent library block. For more information, see “Restore Disabled or Parameterized Links” on page 40-31.
Break links	Permanently breaks link of a linked block from its parent library block. For more information, see “Disable or Break Links to Library Blocks” on page 40-27.
Self-Modifiable links	Linked block with the ability to have structural changes in a linked Subsystem block. For more information, see “Self-Modifiable Linked Subsystems” on page 40-24.
Parameterized links	Created when the parameter values of a linked block are modified through MATLAB command prompt. For more information, see “Parameterized Links and Self-Modifiable Linked Subsystems” on page 40-19.
Forwarding Tables	Maps old library block path to new library block path. For more information, see “Forwarding Tables” on page 40-39.
Transformation function	Corrects the mismatch of parameters in the `InstanceData` of the new and old library links thus ensuring that the library links continue to work. For more information, see “Transformation Functions” on page 40-43.

Parameterized Links and Self-Modifiable Linked Subsystems

You can use the MATLAB command prompt to change the value of a parameter in a linked block. Such parameter changes on the linked block result in parameterized links.

Similarly, you can also modify the structure of a linked Subsystem block without changing the parent library block. Such changes can be applied using the mask initialization code and as called self-modifiable linked subsystem.

Parameterized Links

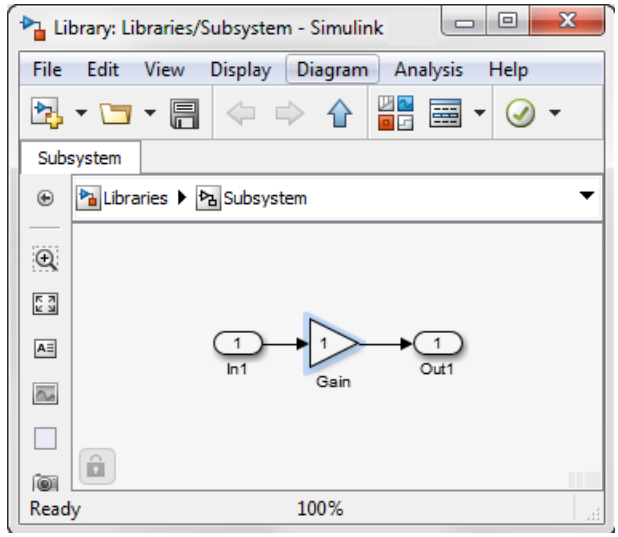
A parameterized link is created when you change the parameter values of the child blocks of a masked subsystem linked block.

A parameterized link allows you to have a different parameter value for the linked block and the parent library block. For such library blocks, the link to the parent block is still retained.

Note Changing the mask value of a parent library block does not create a parameterized link.

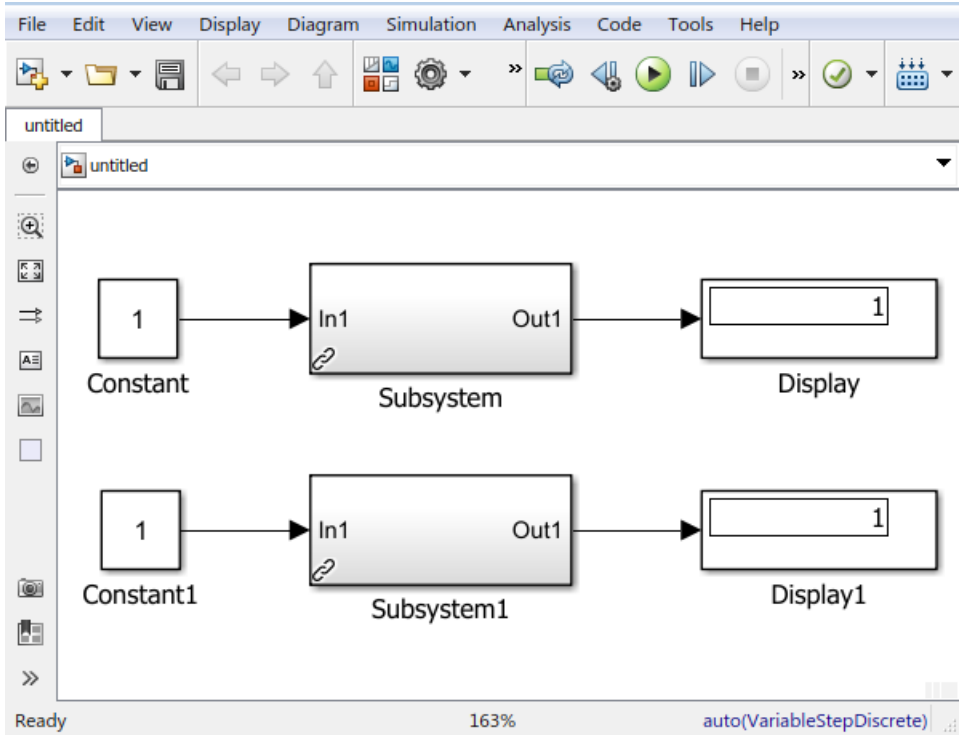
For example, you can use the `set_param` command to set a parameter value in the child blocks of a linked subsystem block. The `set_param` command overrides the parameter values of the child blocks of the subsystem linked block. Thus, differentiating the child block value from its parent library block and creating a parameterized link.

Consider a Subsystem library block (see “Subsystem Library Block” on page 40-20) that contains a Gain block within with its parameter value as `1`.



Subsystem Library Block

Use this Subsystem block as a linked block in a model.

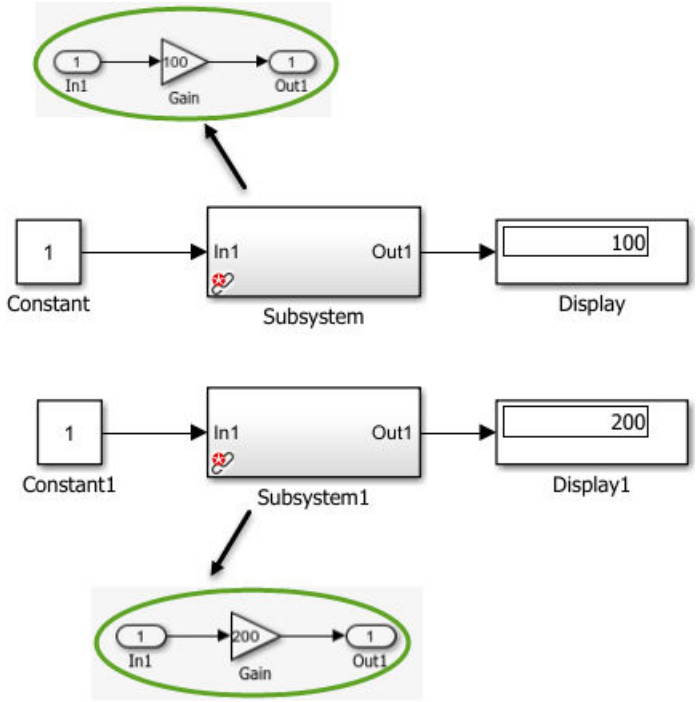


You can modify the parameter values of the child blocks of the linked block without changing the value of the parent library block. For example, you can change the parameter value of the Gain block within the `Subsystem` linked block.

To change the `Gain` parameter value of the Gain block within the `Subsystem` linked block to `100`, sequentially type these commands at MATLAB command prompt:

```
pathName = [ModelName,'/Gain_Subsystem1/Gain'];
set_param(pathName, 'Gain', '100')
```

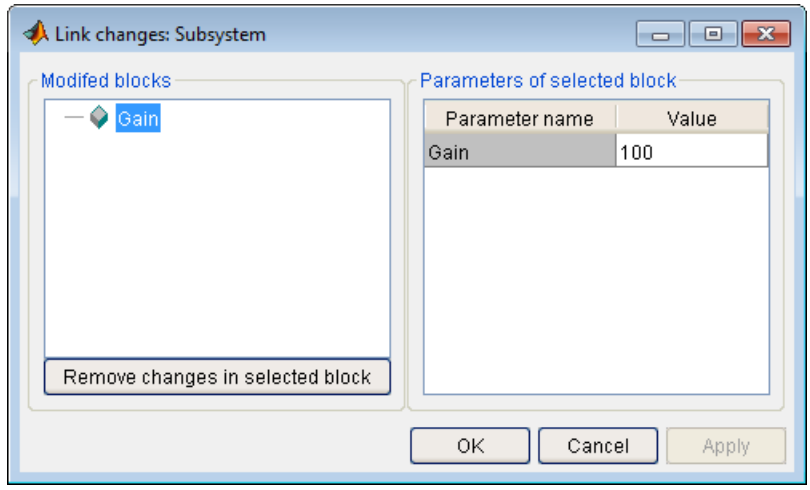
A parameterized link is now created, overriding the parameter value (see, “Parameterized Linked Block” on page 40-22). Similarly, change the `Gain` parameter value of the `Subsystem1` linked block.



Parameterized Linked Block

When you save a model containing a parameterized link, Simulink saves the changes to a local copy of the Subsystem with the path to the parent library. When you reopen the model, Simulink copies the library block into the loaded model and applies the saved changes.

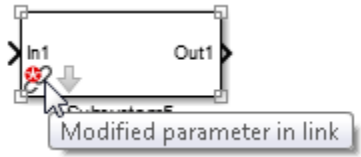
Note To view the parameterized changes on a block, right-click the block, and on the context menu, select **View Changes**. The **Link changes** dialog box opens displaying the list of modified blocks. You can also use this dialog box to remove parameterized changes from a block.



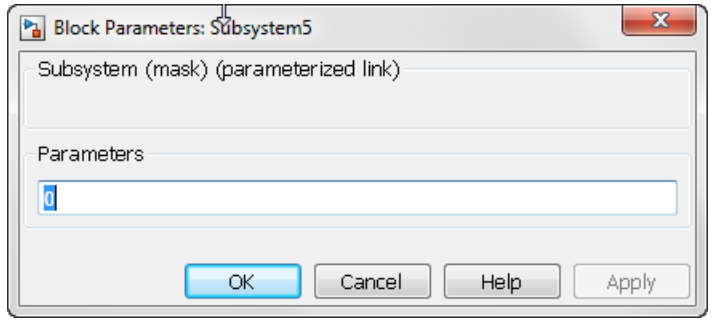
Identifying Parameterized Links

A parameterized link displays these identifications:

- The link badge of a parameterized link contains a black links with a red star icon, . For more information, “Display Library Links” on page 40-25.
- The tooltip of a parameterized linked block displays **Modified parameter in link**.



- Block dialog box of a linked Subsystem block contains **parametrized link**.



Self-Modifiable Linked Subsystems

Tip We recommend using variant blocks over self-modifiable linked subsystems.

A self-modifiable linked subsystem is a linked block with the ability to have structural changes in the subsystem without disabling the link. A self-modifiable linked subsystem is created when you use a library block containing a self-modifiable mask as a linked block. You can use the mask initialization code to change the structural contents.

For more information, see “Dynamic Masked Subsystem” on page 38-56 and Self-Modifiable Mask.

See Also

“Linked Blocks” on page 40-15 | “Disable or Break Links to Library Blocks” on page 40-27 | “Restore Disabled or Parameterized Links” on page 40-31

Display Library Links

Each linked block has a link badge associated with it. The badge makes it easier to identify the linked block in a model and also displays its link status.

To control the display of library link badges in a Simulink model, click **Display** > **Library Links** and use these options:

- **None** — displays no links.
- **Disabled** — displays only disabled links (the default for new models).
- **User Defined** — displays only links to user libraries.
- **All** — displays all links.

If activated, link badges are displayed at the bottom left corner of a linked block. You can right-click the link badge to access link menu options.

The color and icon of the link badge indicates the status of the link.

Link Badge	Status
Black links 	Active link
Gray separated links 	Inactive link
Black links with a red star icon 	Active and modified (parameterized link)

Link Badge	Status
White links, black background 	Locked link

Note If you have a variant subsystem block inside a linked block, modifying the parameters on the variant subsystem creates instance data on the topmost linked block. If the link badge is visible, the presence of instance data is indicated by the red star on the link badge.

"Linked Blocks" on page 40-15 | "Disable or Break Links to Library Blocks" on page 40-27 | "Restore Disabled or Parameterized Links" on page 40-31

Disable or Break Links to Library Blocks

Structural changes in a model include addition or deletion of blocks or adding ports while non-structural changes include changes in parameter value.

A linked block does not allow structural changes to it. You can disable the link of a linked block from its parent library block and perform required modifications. A disabled linked block behaves like a local instance of a block and allows you to make structural and nonstructural changes.

To disable a link, right-click the linked block and, on the context menu, click **Library Link > Disable Link**. Alternatively, select the linked block and click **Diagram > Library Link > Disable Link**

To prevent unintentional disabling of a linked block, you can lock its links to the library. To lock a link, on the library window, click **Diagram > Lock Links To Library**. You can later choose to unlock the locked link by selecting **Diagram > Unlock Links To Library** on the library window.

Note Simulink offers to disable the library links (unless the link is locked) when you try to make structural changes to a block that contains active library links.

Do not use `set_param` to make structural changes to an active link. The result of this type of change is undefined.

A disabled link of a linked block can be restored. For more information, see “Restore Disabled or Parameterized Links” on page 40-31.

Break Links

You can permanently break links to the parent library. Before you break a library link, the link must first be disabled. When you break a link, the linked block is converted to a standalone block.

To break a link, use any of these options:

- For disabled links, right-click the linked block and, in the context menu, select **Library Link > Break Link**.

- To copy and break links to multiple blocks simultaneously, select multiple blocks and then drag. The locked links are ignored and not broken.
- When you save the model, you can break links by supplying arguments to the `save_system` command. For more information, see `save_system`.

Note

- Some models can contain blocks from third-party libraries or optional Simulink block sets. Breaking the link for such models does not guarantee that you can run the model standalone. It is possible that a library block invokes functions supplied with the library and hence can run only if the library is installed on the system running the model.
- Breaking a link can cause a model to fail when you install a new version of the library on a system. For example, if a model block invokes a function that is supplied from a library. If you break the link for such a block, the function can no longer be invoked from the model, causing simulation to fail. To avoid such problems, avoid breaking links to libraries.

See Also

"Linked Blocks" on page 40-15 | "Restore Disabled or Parameterized Links" on page 40-31

Lock Links to Blocks in a Library

You can lock links to a library. Lockable library links prevent unintentional disabling of these links. Lockable libraries ensure robust usage of mature stable libraries.

To lock links to a library, in the library window, click **Diagram > Lock Links To Library**. The linked block links to its parent library is now locked. When you refresh the Model Explorer, you see a change in the link badge. The locked link badges have a black background.

Locked linked block links cannot be disabled from the parent library block. Such links can only be disabled from the command line by changing the `LinkStatus` to `inactive`. For more information, see “Control Linked Block Programmatically” on page 40-36.

The context menu of a locked linked block displays **Locked Library Link** and not **Library Link**. Also notice that the only enabled option on this menu is **Go To Library Block**.

If you open a locked linked block, the window title displays **Locked Link: *`blockname`***. The bottom left corner shows a lock icon and a link badge.

To unlock links from the library window, select **Diagram > Unlock Links To Library**.

Rules for Locked Links

- Locked links cannot be edited. If you try to make a structural change to a locked link (such as editing the diagram), you see a message that you cannot modify the link because it is either locked or inside another locked link.
- The mask and block parameter dialogs are disabled for blocks inside locked links. For a resolved linked block with a mask, its parameter dialog is always disabled.
- You cannot parameterize locked links in the Model Editor.
- When you copy a block, the library status determines the status of a link (locked or not). If you copy a block from a library with locked links, the link is locked. If you later unlock the library links, any existing linked blocks do not change to unlocked links until you refresh the links.
- If you use sublibraries, when you lock links to a library, lock links to the sublibraries.

See Also

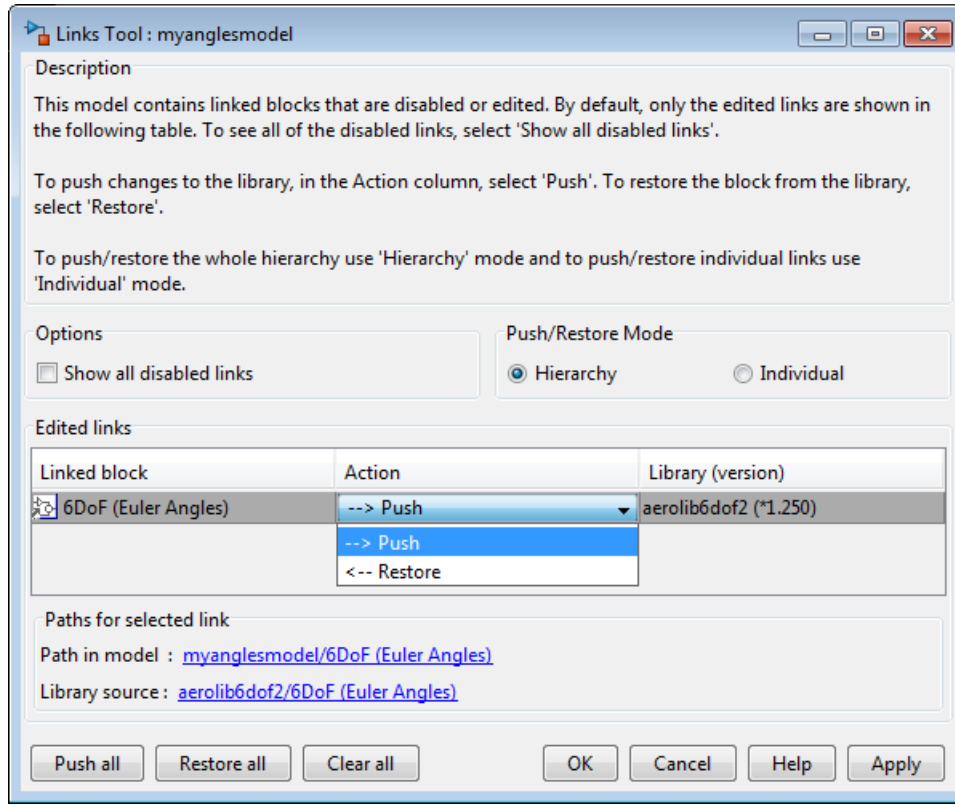
"Linked Blocks" on page 40-15 | "Restore Disabled or Parameterized Links" on page 40-31

Restore Disabled or Parameterized Links

You can restore disabled library links and resolve any differences between the linked block and its parent library block.

1 In the Model Editor window, right-click a disabled linked block, and on the context menu, select **Library Link > Resolve Link**.

The Links Tool window opens.



2 To view disabled links and the parameterized links, select **Show all disabled links** in the **Options** section.

3 To restore the links for an individual block or the whole hierarchy, select **Individual** or **Hierarchy** in the **Push/Restore Mode** section. For more information, see “Pushing or Restoring Link Hierarchies” on page 40-33.

4 The **Edited links** table has these columns:

- **Linked block** — Displays the list of linked blocks that have disabled or parameterized links. Select a block to restore its links.
- **Action** — Allows you to either push the linked block changes to the library or restore the linked block from the library.

Action Choice	Links Tool Action
`Push`	Replaces the version of the block in the library with the version in the model (linked block).
`Restore`	Replaces the version of the linked block in the model with the version in the library.
`Push Individual`	In the **Individual** mode, the disabled or edited block is pushed to the library, preserving the changes inside it without acting on the hierarchy. All other links are unaffected.
`Restore Individual`	In the **Individual** mode, the disabled or edited block is restored from the library, and all other links are unaffected.

To select the same action for all linked blocks, click **Push all**, **Restore all**, or **Clear all**.

- **Library** — Displays the library name and version number.

5 Click **OK** or **Apply** to complete the push or restore action. The version in the library and the linked block now match.

Note Changes that you push to the library are not saved until you actively save the library.

If a linked block name has a cautionary icon  , the model has other instances of this block linked from the same library block, and they have different changes. Choose one of the instances to push changes to the library block and restore links to the other blocks, or choose to restore all them with the library version.

Pushing or Restoring Link Hierarchies

Caution If you are using Push or Restore in the Hierarchy mode and you have a large hierarchy of edited and disabled links, ensure that you want to push or restore the whole hierarchy of links.

Pushing a hierarchy of disabled links affects the disabled links inside and outside the hierarchy for a given link. If you push changes from a disabled link in the middle of a hierarchy, the inside links are pushed and the outside links are restored if unchanged. This operation does not affect outer (parent) links with changes unless you also explicitly selected them for push. The Links Tool starts to push from the lowest inside links and then moves up in the hierarchy.

For examples:

1. Link A contains link B and both have changes.
   - Push A. The Links Tool pushes both A and B.
   - Push B. The Links Tool pushes B and not A.
2. Link A contains link B. A has no changes, and B has changes.
   - Push B. The Links Tool pushes B and restores A. When parent links are unmodified, they are restored.

If you have a hierarchy of parameterized links, the Links Tool can manipulate only the top level.

Tip To compare files and view structural changes, use **Analysis > Compare Simulink XML Files**.

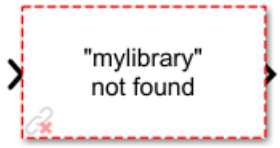
Fix Unresolved Library Links

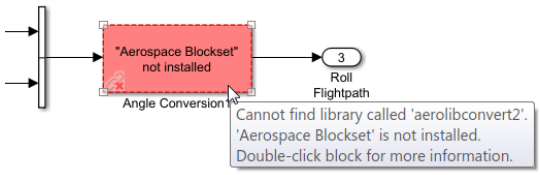
If Simulink is unable to find either the library block or the source library on your MATLAB path during linked block update, the link becomes unresolved. Simulink changes the appearance of these blocks.

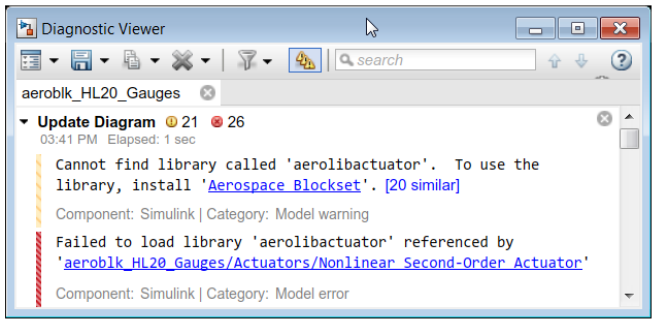


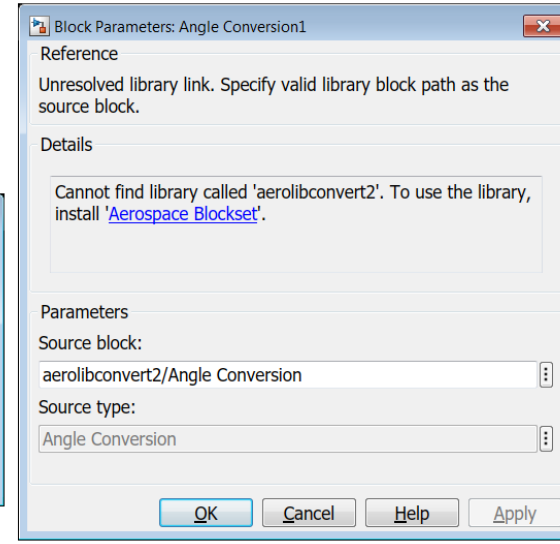
Simulink tries to help you find and install missing products that a model needs to run. If you open a model that contains built-in blocks or library links from missing products, you see labels and links to help you fix the problem.

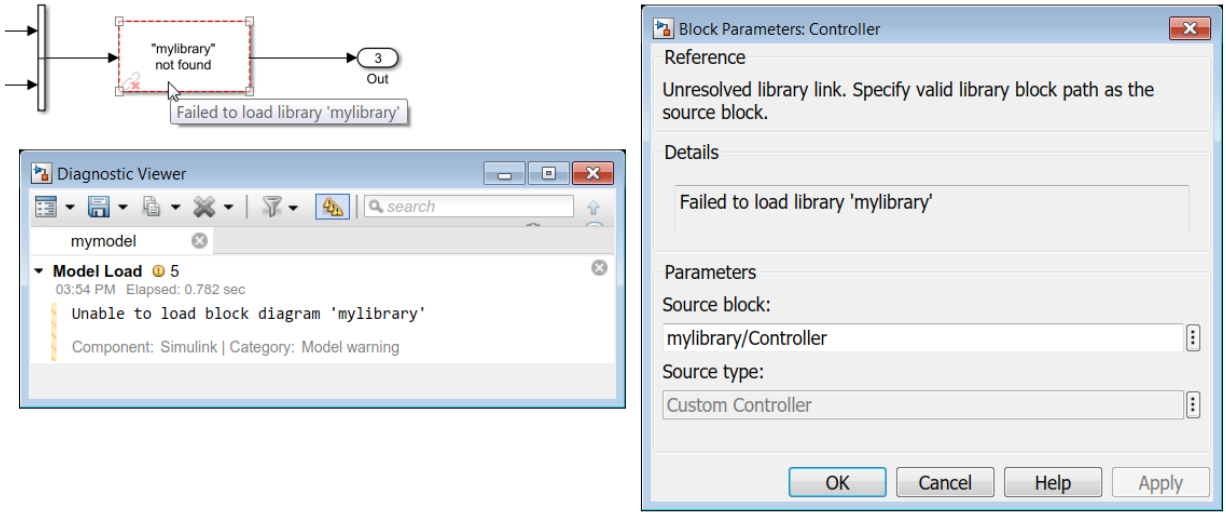
- Blocks are labeled with missing products (for example, **SimEvents not installed**)
- Tooltips include the name of the missing product
- Messages provide links to open Add-On Explorer and install the missing products

For unresolved library links, double-click the block to view details. Click the link to open Add-On Explorer and install the product.









To fix an unresolved link, you can:

- Double-click the unresolved block to open its dialog box (see the Unresolved Link block reference page). If a product is missing, click the link to open Add-On Explorer and install the product. Alternatively, correct the path name in the **Source block** field and click **OK**.
- Delete the unresolved block and copy the library block back into your model.
- Add the folder that contains the required library to the MATLAB path and select either **Simulation > Update Diagram** or **Diagram > Refresh Blocks**.

"Linked Blocks" on page 40-15 | "Display Library Links" on page 40-25 | Unresolved Link

Control Linked Block Programmatically

Linked Block Information

Use the `libinfo` command to get information about the linked blocks in the model. `libinfo` also provides information about the parent library blocks of a linked block.

An example is as follows:

```
 Block: 'tempModel/Subsystem1'%Linked block
            Library: 'temp'%Parent library block
    ReferenceBlock: 'temp/Subsystem1'
        LinkStatus: 'resolved' %Link status
```

The `ReferenceBlock` property gives the path of the library block to which a block links. You can change this path programmatically by using the `set_param` command. For example,

```
set_param('temp/Subsystem1', 'ReferenceBlock', 'temp/Subsystem2')
```

Here, `temp/Subsystem1` is the original library block path and `temp/Subsystem2` is the new library block path.

Lock Linked Blocks

Use the `LockLinksToLibrary` command to lock or unlock a linked block in a library from the command line. When you set the value of `LockLinksToLibrary` to `on`, the linked block links to the library are locked.

```
set_param('MyModelName', 'LockLinksToLibrary', 'on') %Lock links
```

```
set_param('MyModelName', 'LockLinksToLibrary', 'off') %Unlock links
```

Link Status

All blocks have a `LinkStatus` parameter and a `StaticLinkStatus` parameter that indicate whether the block is a linked block.

Use `get_param(gcb, 'StaticLinkStatus')` to query the link status without updating the linked blocks. You can use `StaticLinkStatus` to query the status of a linked block that either active or outdated.

Use `get_param` and `set_param` to query and set the `LinkStatus`, which can have these values.

Get LinkStatus Value	Description
`none`	Block is not a linked block.
`resolved`	Resolved link.
`unresolved`	Unresolved link.
`implicit`	Block resides in library block and is itself not a link to a library block. Suppose that A is a link to a subsystem in a library that contains the Gain block. If you open A and select the Gain block, `get_param(gcb, 'LinkStatus')` returns `implicit`.
`inactive`	Disabled link.
Set LinkStatus Value	**Description**
`none`	Breaks link. Use `none` to break a link, for example, `set_param(gcb, 'LinkStatus', 'none')`.
`breakWithoutHierarchy`	Breaks links in-place without breaking the nested parent hierarchy of link. For example, `set_param(gcb, 'LinkStatus', 'breakWithoutHierarchy')`.
`inactive`	Disables link. Use `inactive` to disable a link, for example, `set_param(gcb, 'LinkStatus', 'inactive')`.
`restore`	Restores an inactive or disabled link to a library block and discards any changes made to the local copy of the library block. For example, `set_param(gcb, 'LinkStatus', 'restore')` replaces the selected block with a link to a library block of the same type. It discards any changes in the local copy of the library block. `restore` is equivalent to `Restore Individual` in the Links Tool.
`propagate`	Pushes any changes made to the disabled link to the library block and re-establishes its link. `propagate` is equivalent to `Push Individual` in the Links Tool.
`restoreHierarchy`	Restores all disabled links in the hierarchy with their corresponding library blocks. `restoreHierarchy` is equivalent to `Restore` in hierarchy mode in the Links Tool.

Set LinkStatus Value	Description
`propagateHierarchy`	Pushes all links with changes in the hierarchy to their libraries. `propagateHierarchy` is equivalent to `Push` in the **Hierarchy** mode of the Links Tool. See “Restore Disabled or Parameterized Links” on page 40-31.

Note

- When you use `get_param` to query the link status of a block, the outdated block links also resolve.
- Using the `StaticLinkStatus` command to query the link status when `get_param` is being used in the callback code of a child block is efficient. `StaticLinkStatus` command does not resolve any outdated links.

If you call `get_param` on a block inside a library link, Simulink resolves the link wherever necessary. Executing `get_param` can involve loading part of the library and executing callbacks.

“Linked Blocks” on page 40-15 | “Display Library Links” on page 40-25

Forwarding Tables

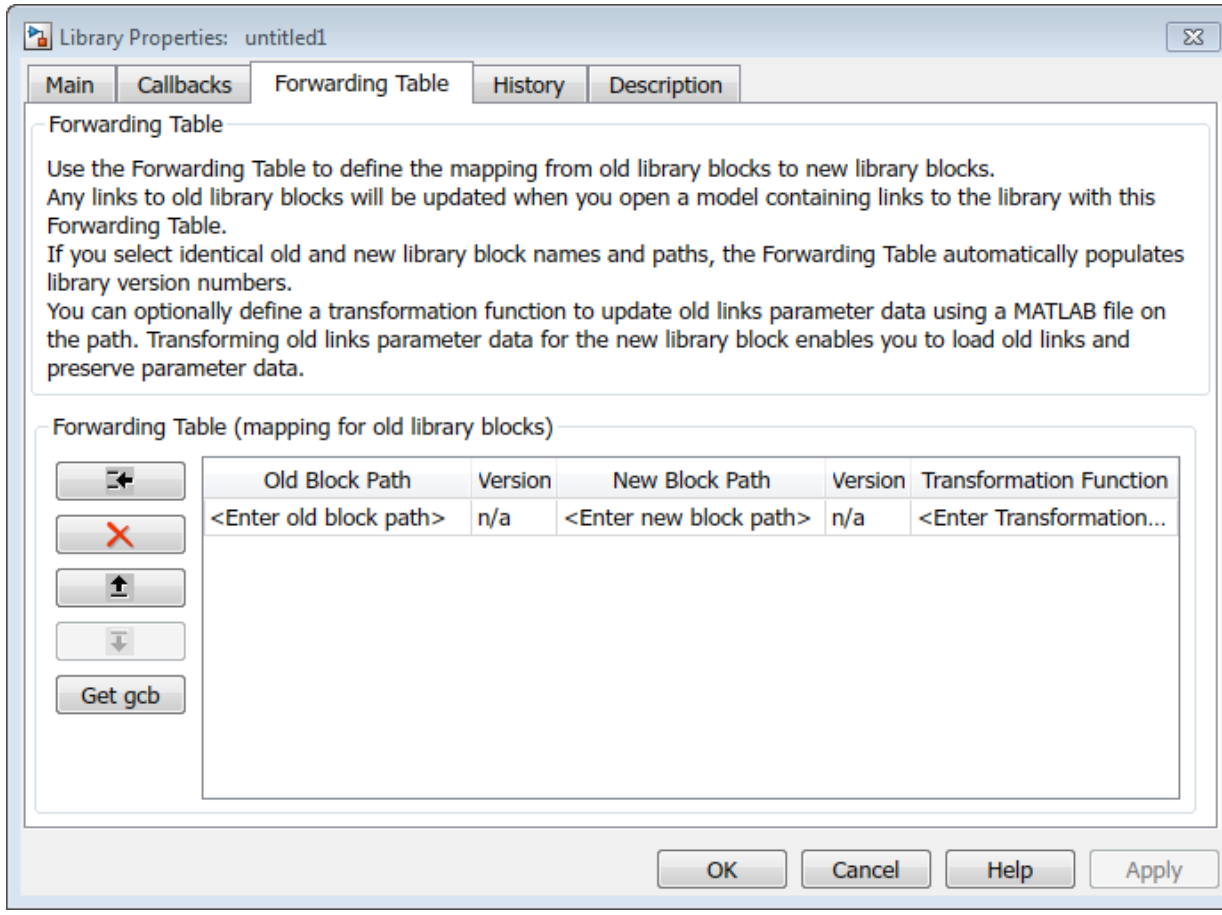
If you edit an existing library block, you would want to ensure that the changes do not break the model when the model is saved with an older version of the library block. The type of edits in the library block can include, library path change, library block name change, or addition, removal, or rename of parameters.

The Forwarding Table helps you to maintain compatibility of library blocks and thus ensures that the models continue to work. You can use the Forwarding table to create a map between the old and the new library blocks without any loss of data or functionality. After the mapping of old library blocks to new library blocks is specified in the forwarding table, links to the old library blocks update automatically during model load. For example, if you rename or move a block in a library, you can use a forwarding table to update the models that have link to the old library block.

Create Forwarding Table

Note Models that have broken or disabled links cannot be updated using the forwarding tables.

1. Open the library model.
2. Click **Diagram > Unlock Library**. The library is now unlocked for editing.
3. Click **File > Library Properties > Library Properties**. The **Library Properties** dialog box opens.
4. Click the **Forwarding Table** tab.
5. Click  (Add New Entry) button. A new row is added in the Forwarding Table.



6 Specify values in the **Old Block Path** and **New Block Path** columns. To get the path of a block, select the block in the model and click Get gcb.

7 In the **Version** column, you can choose to specify a version number for the library block.

If the old block name and the new block name are the same, the forwarding table populates the version number automatically. The initial value of the library version (`LibraryVersion`) is derived from the model version (`ModelVersion`) of the library at the time the library link is created. Any subsequent updated to the library block would update the library version to match the model version of the library.

Note

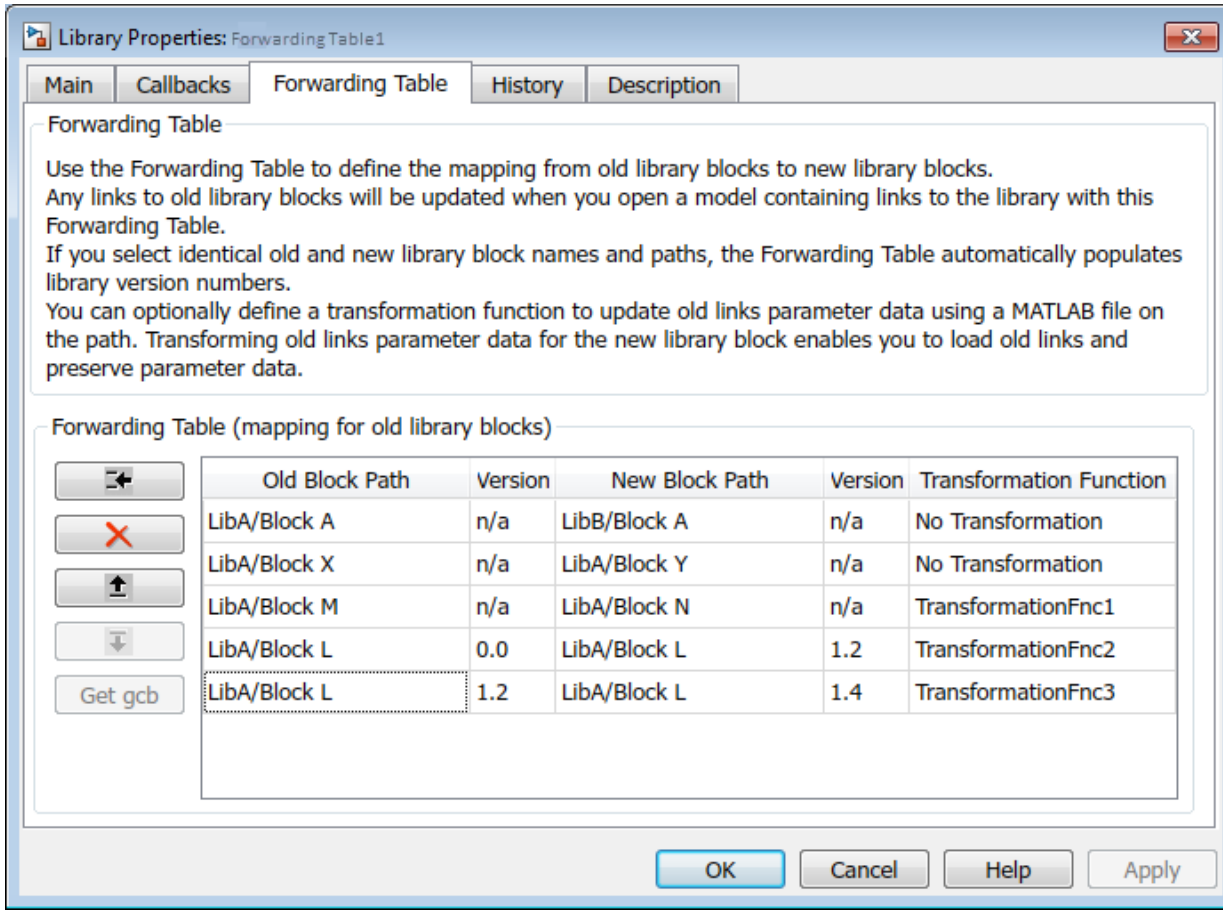
- Version number must be a numeric value.
- When the old and the new block paths are the same, the version number must be of the format `<major_version>.<minor_version>`. For example, while renaming a library block.
- The version number cannot have more than one dot notation. For example, a version number of `1.3` is acceptable whereas, version number `1.3.1` is not acceptable.
- When you use forwarding table to move a library block from one library to another, the version number format is not critical.

8 In the **Transformation Function** column, you can specify a MATLAB file that corrects the mismatch of parameter data between the old and the new link. Transforming old link parameter data for the new library block enables you to load old links and preserve parameter data. For more information, see "Transformation Functions" on page 40-43.

If no transformation function is specified, the Transformation Function column displays **No Transformation** when you save the library.

9 To apply the changes and close the dialog box, click **OK**. The mapping of old path to new path is created in the Forwarding Table. The links to the old library blocks are updated automatically when you open a model containing links to the library.

An example of user-defined forwarding table is as shown:



When you specify identical library block name and path for the older and the newer blocks, the Forwarding Table populates the version number automatically. For the first entry with identical names and path, the version number of the old block starts with 0, and the new version of the block is set as the model version of the library. You can view the model version of the library under the **History** tab of the Forwarding Table.

A transformation function must be specified when the instance-specific parameters (`InstanceData`) have changed in the old and the new library block.

In this example,

- Block path for `Block A` changes from `LibA` to `LibB`.
- Block name for `Block X` changes to `Block Y` while the library path remains the same.
- Block name for `Block M` changed to `Block N`. A transformation function is specified to take care of the instance-specific changes.
- Block version and instance-specific parameter changed for `Block L`.

Create Forwarding Table Programmatically

At the command line, you can create a simple forwarding table specifying the old locations and new locations of blocks that have moved within the library or to another library. You associate a forwarding table with a library by setting its `ForwardingTable` parameter to a cell array of two-element cell arrays, each of which specifies the old and new path of a block that has moved. For example, the syntax to create a forwarding table and assign it to a library named `Lib1` is,

```
set_param('Lib1', 'ForwardingTable', {{'Lib1/A', 'Lib2/A'}
{'Lib1/B', 'Lib1/C'}});
```

Here,

- `Lib1` is the library associated to the forwarding table.
- Block `A` is transferred from `Lib1` to `Lib2`.
- Block `B` is renamed to Block `C` in the same library.

Transformation Functions

A linked block instance is associated with instance-specific parameters called `InstanceData`. When you create versions of a library block, parameter sets can get added or removed from the `InstanceData`.

A transformation function corrects the mismatch of parameters in the `InstanceData` of the new and old library links thus ensuring that the library links continue to work.

You can define a transformation function using a MATLAB file on the path, then specify the function in the **Transformation Function** column of the **Forwarding Table**.

The new block path defined in the forwarding table overrides the values defined in the transformation function. If the new block path is a dynamic value that changes based on

certain conditions, then the new block path must be only defined using the transformation function.

The syntax for transformation function must be;

```
function outData = TransformationFcn(inData)
```

Here,

- `inData` is a structure with fields `ForwardingTableEntry` and `InstanceData`, and `ForwardingTableEntry` is also a structure.
- `outData` is a structure with fields `NewInstanceData` and `NewBlockPath`.

A general transformation function can have many local functions defined in it. The function calls the appropriate local functions based on old block names and versions. You can use this to combine multiple local functions into a single transformation function, to avoid having many transformation functions on the MATLAB path.

Consider the Compare to Const block in Simulink Library. Versions of this block are created without changing the name and the block path but parameters are added to the newer library block.

The table displays the parameter difference in two versions of the Compare to Const block. The instance data in each version has been highlighted.

Old Version	New Version

Block {
BlockType Reference
Name "Compare\nTo Constant"
Ports [1, 1]
Position [210, 60, 250, 100]
SourceBlock "fixpt_lib_4/Logic & Comparison/Compare\nTo Constant"
SourceType "Fixed-Point Compare To Constant"
relop "=="
const "3.0"
}
	Block {
	BlockType Reference
	Name "Compare\nTo Constant"
	SID "15"
	Ports [1, 1]
	Position [125, 50, 155, 80]
	ZOrder -5
	LibraryVersion "1.271"
	SourceBlock "simulink/Logic and Bit\nO
	SourceType "Compare To Constant"
	relop "<="
	const "3.0"
	OutDataTypeStr "boolean"
	ZeroCross on
	}

The New Version of the Compare to Const block has additional parameters (`OutDataTypeStr` and `ZeroCross`) associated with it. For such cases, the transformation function must ensure that the additional parameters in the `InstanceData` are set so that the old library links work.

An example of transformation function for the Compare to Const block to add the `OutDataTypestr` parameter with a value of `uint8` is as follows,

```
function [outData] = TransformationCompConstBlk(inData)
outData.NewBlockPath = ''; % No change in the library block path
outData.NewInstanceData = [];
instanceData = inData.InstanceData;
% Get the field type 'Name' from instanceData
[ParameterNames{1:length(instanceData)}] = instanceData.Name;

if (~ismember('OutDataTypeStr',ParameterNames))
    % OutDataTypeStr parameter is not present in old link. Add it and set value uint8
    instanceData(end+1).Name = 'OutDataTypeStr';
    instanceData(end).Value = 'uint8';
end

outData.NewInstanceData = instanceData;
```

Create Mask Parameter Aliases

If a mask parameter is renamed, you must ensure that the existing MATLAB scripts that use the old parameter names, continues to work. To ensure the compatibility, you can create alias (alternate names) for a mask parameter name. Alias allows you to change the name of a mask parameter in a library block without having to recreate links to the block in existing models.

Consider a masked block that contains an **Edit** parameter. The mask parameter name for this **Edit** parameter is `p1`.

```
MaskObj=
% MaskParameter with properties:

           Type: 'edit'
    TypeOptions: {0×1 cell}
           Name: 'p1'
         Prompt: 'p1'
          Value: '0'
       Evaluate: 'on'
        Tunable: 'on'
      NeverSave: 'off'
         Hidden: 'off'
        Enabled: 'on'
```

```
        Visible: 'on'
        ToolTip: 'on'
       Callback: ''
          Alias: ''
```

Notice that the **Edit** mask parameter does not have any alias name. To add an alias name for the mask parameter, you can set a value for the `Alias` mask parameter property.

```
MaskObj.Alias = 'pa'
```

You can either use the mask parameter name or the alias to do a function call on the mask parameter. For example, in this case you can either use `set_param(gcb, 'p1, '10)` (mask parameter name) `set_param(gcb, 'pa, '10)` (mask parameter alias) to set a value for the **Edit** mask parameter.

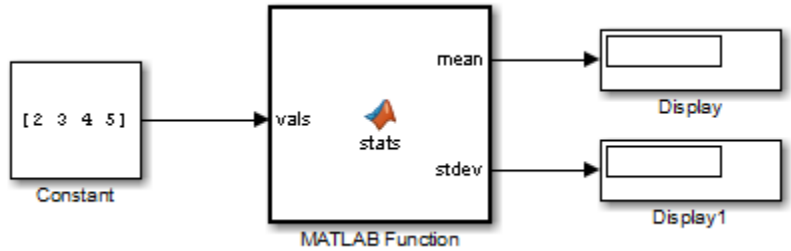
Using the MATLAB Function Block

- “Update Build Information from MATLAB code” on page 41-240

Integrate MATLAB Algorithm in Model

Here is an example of a Simulink model that contains a MATLAB Function block:



The MATLAB Function block contains the following algorithm:

```
function [mean,stdev] = stats(vals)

% calculates a statistical mean and a standard
% deviation for the values in vals.

len = length(vals);
mean = avg(vals,len);
stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
plot(vals,'-+');

function mean = avg(array,size)
mean = sum(array)/size;
```

You build this model in “Create Model That Uses MATLAB Function Block” on page 41-10.

Defining Local Variables for Code Generation

If you intend to generate code from the MATLAB algorithm in a MATLAB Function block, you must explicitly assign the class, size, and complexity of local variables before using them in operations or returning them as outputs (see “Data Definition for Code Generation” on page 49-2. In the example function `stats`, the local variable `len` is defined before being used to calculate mean and standard deviation:

```
len = length(vals);
```

Generally, once you assign properties to a variable, you cannot redefine its class, size, or complexity elsewhere in the function body, but there are exceptions (see “Reassignment of Variable Properties” on page 48-9).

More About

- “What Is a MATLAB Function Block?” on page 41-6

What Is a MATLAB Function Block?

The MATLAB Function block allows you to add MATLAB functions to Simulink models for deployment to desktop and embedded processors. This capability is useful for coding algorithms that are better stated in the textual language of MATLAB than in the graphical language of Simulink. From the MATLAB Function block, you can generate readable, efficient, and compact C/C++ code for deployment to desktop and embedded applications.

Calling Functions in MATLAB Function Blocks

MATLAB Function blocks can call any of the following types of functions:

- **Local functions**

  Local functions are defined in the body of the MATLAB Function block.

- **MATLAB toolbox functions that support code generation**

  From MATLAB Function blocks, you can call toolbox functions that support code generation. When you build your model with Simulink Coder, these functions generate C code that is optimized to meet the memory and performance requirements of desktop and embedded environments. For a list of supported functions, see "Functions and Objects Supported for C/C++ Code Generation — Alphabetical List" on page 46-2.

- **MATLAB functions that do not support code generation**

  From MATLAB Function blocks, you can also call *extrinsic* functions. These are functions on the MATLAB path that the compiler dispatches to MATLAB software for execution because the target language does not support them. These functions do not generate code; they execute only in the MATLAB workspace during simulation of the model. The Simulink Coder software attempts to compile all MATLAB functions unless you explicitly declare them to be extrinsic by using `coder.extrinsic`. See "Declaring MATLAB Functions as Extrinsic Functions" on page 56-10.

  The code generation software detects calls to many common visualization functions, such as `plot`, `disp`, and `figure`. For MEX code generation, it automatically calls out to MATLAB for these functions. For standalone code generation, it does not generate code for these visualization functions. This capability removes the requirement to declare these functions extrinsic using the `coder.extrinsic` function.

See “Resolution of Function Calls for Code Generation” on page 56-2.

- **Functions from Simulink Function blocks and Stateflow blocks**

  From MATLAB Function blocks, you can also call functions defined in a Simulink Function block. You can call Stateflow functions with **Export Chart Level Functions (Make Global)** and **Allow exported functions to be called by Simulink** checked in the chart Properties dialog box.

More About

- “Why Use MATLAB Function Blocks?” on page 41-8

Why Use MATLAB Function Blocks?

MATLAB Function blocks provide the following capabilities:

- **Allow you to build MATLAB functions into embeddable applications** — MATLAB Function blocks support a subset of MATLAB toolbox functions that generate efficient C/C++ code. For information see "Functions and Objects Supported for C/C++ Code Generation — Alphabetical List" on page 46-2.. With this support, you can use Simulink Coder to generate embeddable C code from MATLAB Function blocks that implement a variety of sophisticated mathematical applications. In this way, you can build executables that harness MATLAB functionality, but run outside the MATLAB environment.
- **Inherit properties from Simulink input and output signals** — By default, both the size and type of input and output signals to a MATLAB Function block are inherited from Simulink signals. You can also choose to specify the size and type of inputs and outputs explicitly in the Ports and Data Manager (see "Ports and Data Manager" on page 41-42) or in the Model Explorer (see "Search and Edit Using Model Explorer" on page 12-2).

More About

- "What Is a MATLAB Function Block?" on page 41-6

Use Nondirect Feedthrough in a MATLAB Function Block

By default, MATLAB Function blocks have direct feedthrough enabled. If you disable direct feedthrough, the Simulink semantics ensures that outputs rely only on current state. To use nondirect feedthrough, in the Ports and Data Manager, clear the **Allow direct feedthrough** check box. To open the Ports and Data Manager, in the MATLAB Function Block Editor, select **Edit Data** on the Editor tab. The Ports and Data Manager appears for the MATLAB Function block that is open and has focus. For more information, see "Ports and Data Manager" on page 41-42.

To use nondirect feedthrough, do not program outputs to rely on inputs or updated persistent variables. For example, do not use the following code in a nondirect feedthrough block:

```
counter = counter + 1;      % update state
output = counter;           % compute output based on updated state
```

Instead, use code such as:

```
output = counter;           % compute output based on current state
counter = counter + 1;      % update state
```

Also, nondirect feedthrough semantics require function inlining. Do not disable inlining.

Using nondirect feedthrough enables you to use MATLAB Function blocks in a feedback loop and prevent algebraic loops.

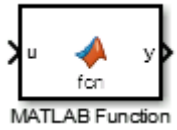
Create Model That Uses MATLAB Function Block

In this section...

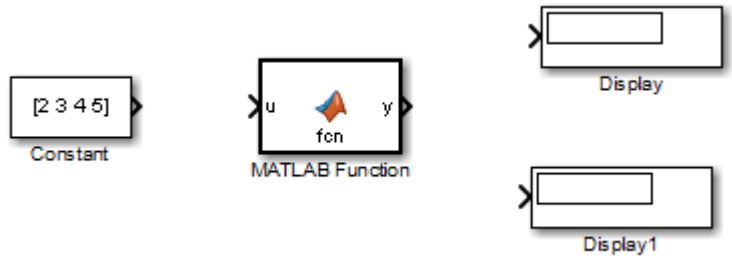
Adding a MATLAB Function Block to a Model

1 Create a new Simulink model and add a MATLAB Function block to the model from the User-Defined Functions library:



2 Add the following Source and Sink blocks to the model:

- From the Sources library, add a Constant block to the left of the MATLAB Function block and set its value to the vector `[2 3 4 5]`.
- From the Sinks library, add two Display blocks to the right of the MATLAB Function block.



3 In the Simulink Editor, select **File > Save As** and save the model as `call_stats_block1`.

Programming the MATLAB Function Block

The following exercise demonstrates programming the block to calculate the mean and standard deviation for a vector of values:

1. Open the `call_stats_block1` model that you saved at the end of "Adding a MATLAB Function Block to a Model" on page 41-10. Double-click the MATLAB Function block `fcn` to open it for editing.

   A default function signature appears.

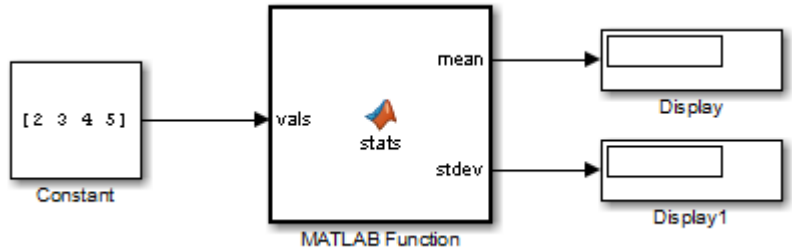
2. Edit the function header line:

   ```
   function [mean,stdev] = stats(vals)
   ```

   The function `stats` calculates a statistical mean and standard deviation for the values in the vector `vals`. The function header declares `vals` as an argument to the `stats` function, with `mean` and `stdev` as return values.

3. Save the model as `call_stats_block2`.

4. Complete the connections to the MATLAB Function block as shown.



5. In the MATLAB Function Block Editor, enter a line space after the function header and add the following code:

   ```
   % calculates a statistical mean and a standard
   % deviation for the values in vals.

   len = length(vals);
   mean = avg(vals,len);
   stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
   plot(vals,'-+');
   ```

```
function mean = avg(array,size)
mean = sum(array)/size;
```

More about `length`

The function `length` is an example of a toolbox function that supports code generation. When you simulate this model, C code is generated for this function in the simulation application.

More about `len`

The class, size, and complexity of local variable `len` matches the output of the toolbox function `length`, which returns a real scalar of type `double`.

By default, implicitly declared local variables like `len` are temporary. They come into existence only when the function is called and cease to exist when the function is exited. To make implicitly declared variables persist between function calls, see `persistent`.

More about `plot`

The function `plot` is not supported for code generation. The code generation software detects calls to many common visualization functions, such as `plot`, `disp`, and `figure`. For MEX code generation, it automatically calls out to MATLAB for these functions. For standalone code generation, it does not generate code for these visualization functions.

6 Save the model as `call_stats_block2`.

Building the Function and Checking for Errors

After programming a MATLAB Function block in a Simulink model, you can build the function and test for errors. This section describes the steps:

1 Set up your compiler on page 41-12.

2 Build the function on page 41-13.

3 Locate and fix errors on page 41-13.

Setting Up Your Compiler

Building your MATLAB Function block requires a supported compiler. MATLAB automatically selects one as the default compiler. If you have multiple MATLAB-

supported compilers installed on your system, you can change the default using the `mex -setup` command. See "Change Default Compiler" (MATLAB).

Supported Compilers for Simulation Builds

To view a list of compilers for building models containing MATLAB Function blocks for simulation:

1. Navigate to the Supported and Compatible Compilers Web page.
2. Select your platform.
3. In the table for Simulink and related products, find the compilers checked in the column titled Simulink for MATLAB Function blocks.

Supported Compilers for Code Generation

To generate code for models that contain MATLAB Function blocks, you can use any of the C compilers supported by Simulink software for code generation with Simulink Coder. For a list of these compilers:

1. Navigate to the Supported and Compatible Compilers Web page.
2. Select your platform.
3. In the table for Simulink and related products, find the compilers checked in the column titled Simulink Coder.

How to Generate Code for the MATLAB Function Block

1. Open the `call_stats_block2` model that you saved at the end of "Programming the MATLAB Function Block" on page 41-11.
2. Double-click its MATLAB Function block `stats` to open it for editing.
3. In the MATLAB Function Block Editor, select **Build Model > Build** to compile and build the example model.

   If no errors occur, the **Simulation Diagnostics** window displays a message indicating success. Otherwise, this window helps you locate errors, as described in "How to Locate and Fix Errors" on page 41-13.

How to Locate and Fix Errors

If errors occur during the build process, the **Simulation Diagnostics** window lists the errors with links to the offending code.

The following exercise shows how to locate and fix an error in a MATLAB Function block.

1 In the `stats` function, change the local function `avg` to a fictitious local function `aug` and then compile again to see the following messages in window:

   The **Simulation Diagnostics** window displays each detected error with a red button.

2 Click the first error line to display its diagnostic message in the bottom error window.

   The message also links to a report about compile-time type information for variables and expressions in your MATLAB functions. This information helps you diagnose error messages and understand type propagation rules. For more information about the report, see "MATLAB Function Reports" on page 41-58.

3 In the diagnostic message for the selected error, click the blue link after the function name to display the offending code.

   The offending line appears highlighted in the MATLAB Function Block Editor:

4 Correct the error by changing `aug` back to `avg` and recompile.

Defining Inputs and Outputs

In the `stats` function header for the MATLAB Function block you defined in "Programming the MATLAB Function Block" on page 41-11, the function argument `vals` is an input, and `mean` and `stdev` are outputs. By default, function inputs and outputs inherit their data type and size from the signals attached to their ports. In this topic, you examine input and output data for the MATLAB Function block to verify that it inherits the correct type and size.

1 Open the `call_stats_block2` model that you saved at the end of "Programming the MATLAB Function Block" on page 41-11. Double-click the MATLAB Function block `stats` to open it for editing.

2 In the MATLAB Function Block Editor, select **Edit Data**.

   The Ports and Data Manager opens to help you define arguments for MATLAB Function blocks.

   The left pane displays the argument `vals` and the return values `mean` and `stdev` that you have already created for the MATLAB Function block. Notice that `vals` is

assigned a **Scope** of `Input`, which is short for **Input from Simulink**. `mean` and `stdev` are assigned the **Scope** of `Output`, which is short for **Output to Simulink**.

3 In the left pane of the Ports and Data Manager, click anywhere in the row for `vals` to highlight it.

The right pane displays the **Data** properties dialog box for `vals`. By default, the class, size, units, and complexity of input and output arguments are inherited from the signals attached to each input or output port. Inheritance is specified by setting **Size** to `-1`**, Complexity** to `Inherited`, and **Type** to `Inherit: Same as Simulink`.

The actual inherited values for size and type are set during compilation of the model, and are reported in the **Compiled Type** and **Compiled Size** columns of the left pane.

You can specify the type of an input or output argument by selecting a type in the **Type** field of the **Data** properties dialog box, for example, `double`. You can also specify the size of an input or output argument by entering an expression in the **Size** field. For example, you can enter `[2 3]` in the **Size** field to specify `vals` as a 2-by-3 matrix. See "Type Function Arguments" on page 41-71 and "Size Function Arguments" on page 41-78 for more information on the expressions that you can enter for type and size.

Note The default first index for any arrays that you add to a MATLAB Function block function is `1`, just as it would be in MATLAB.

Add and Populate a MATLAB Function Block Programmatically

This example shows how to programmatically add a MATLAB Function block to a model and populate the block with MATLAB code. If you already have MATLAB code and do not want to add it to a MATLAB Function block manually, this workflow can be convenient.

1 Create the files for the example.

- Create and save a model `myModel`.
- Create this MATLAB function and save it in `myAdd.m`.

```
function c = myAdd(a, b)
c = a + b;
```

2 Write a MATLAB script that adds a MATLAB Function block to `myModel` and populates it with the contents of `myAdd.m`.

```
% Add a MATLAB Function block to a model and populate
% the block with MATLAB code.
%
% Copyright 2017 The Mathworks, Inc.

open_system('myModel.slx');
libraryBlockPath = 'simulink/User-Defined Functions/MATLAB Function';
newBlockPath = 'myModel/myBlockName';
add_block(libraryBlockPath, newBlockPath);
blockHandle = find(slroot, '-isa', 'Stateflow.EMChart', 'Path', newBlockPath);
blockHandle.Script = fileread('myAdd.m');
```

- This line of the script adds a MATLAB Function block to the model:

  ```
  add_block(libraryBlockPath, newBlockPath);
  ```

- In memory, open models and their parts are represented by a hierarchy of objects. The root object is `slroot`. This line of the script returns the object that represents the new MATLAB Function block:

  ```
  blockHandle = find(slroot, '-isa', 'Stateflow.EMChart', 'Path',
  newBlockPath);
  ```

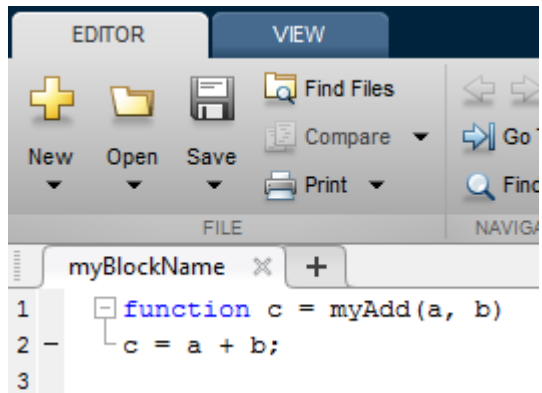
- The `Script` property of the object contains the contents of the block, represented as a character vector. This line of the script loads the contents of the file `myAdd.m` into the `Script` property:

```
blockHandle.Script = fileread('myAdd.m');
```

3 Run the script.

You see the new MATLAB Function block in `myModel`.

4 To see the code that you added to the block, double-click the block `myBlockName`.



5 Save and close the model.

6 Modify the script for your model.

- Replace `myModel` with the name of your model.
- Set `newBlockPath` to the path for the new block for your model.
- Replace `myAdd.m` with the name of the file that contains the MATLAB function that you want in the MATLAB Function block. Alternatively, you can specify the code directly in a character vector. For example:

```
blockHandle.Script = 'function c = fcn(a, b)';
```

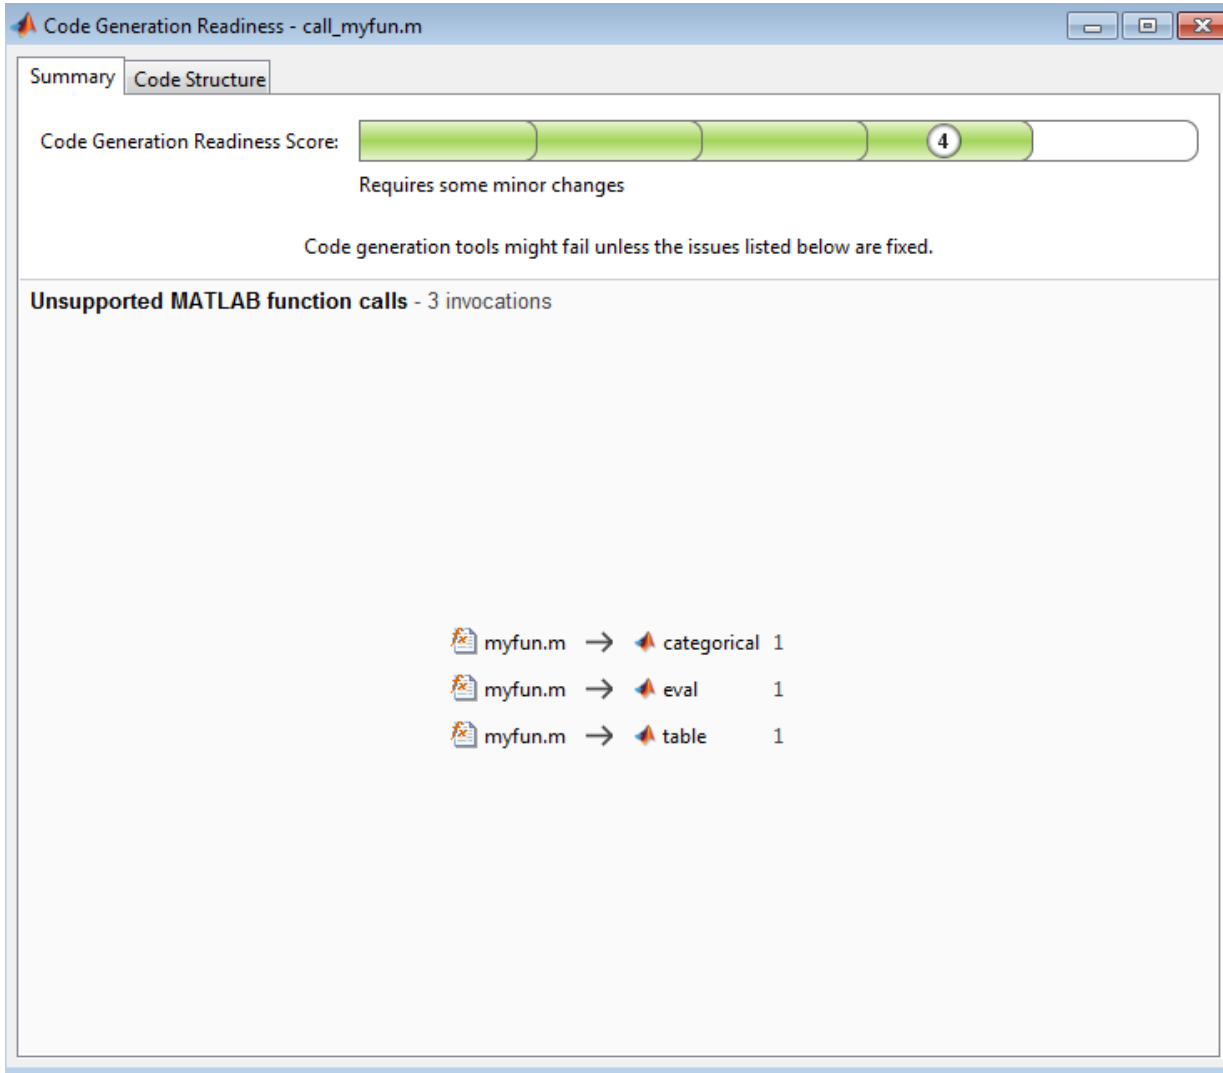
- “Create Model That Uses MATLAB Function Block” on page 41-10
- “Integrate MATLAB Algorithm in Model” on page 41-4

Code Generation Readiness Tool

The code generation readiness tool screens MATLAB code for features and functions that code generation does not support. The tool provides a report that lists the source files that contain unsupported features and functions. The report also indicates the amount of work required to make the MATLAB code suitable for code generation. It is possible that the tool does not detect all code generation issues. Under certain circumstances, it is possible that the tool can report false errors. Therefore, before you generate C code, verify that your code is suitable for code generation by generating a MEX function.

Summary Tab



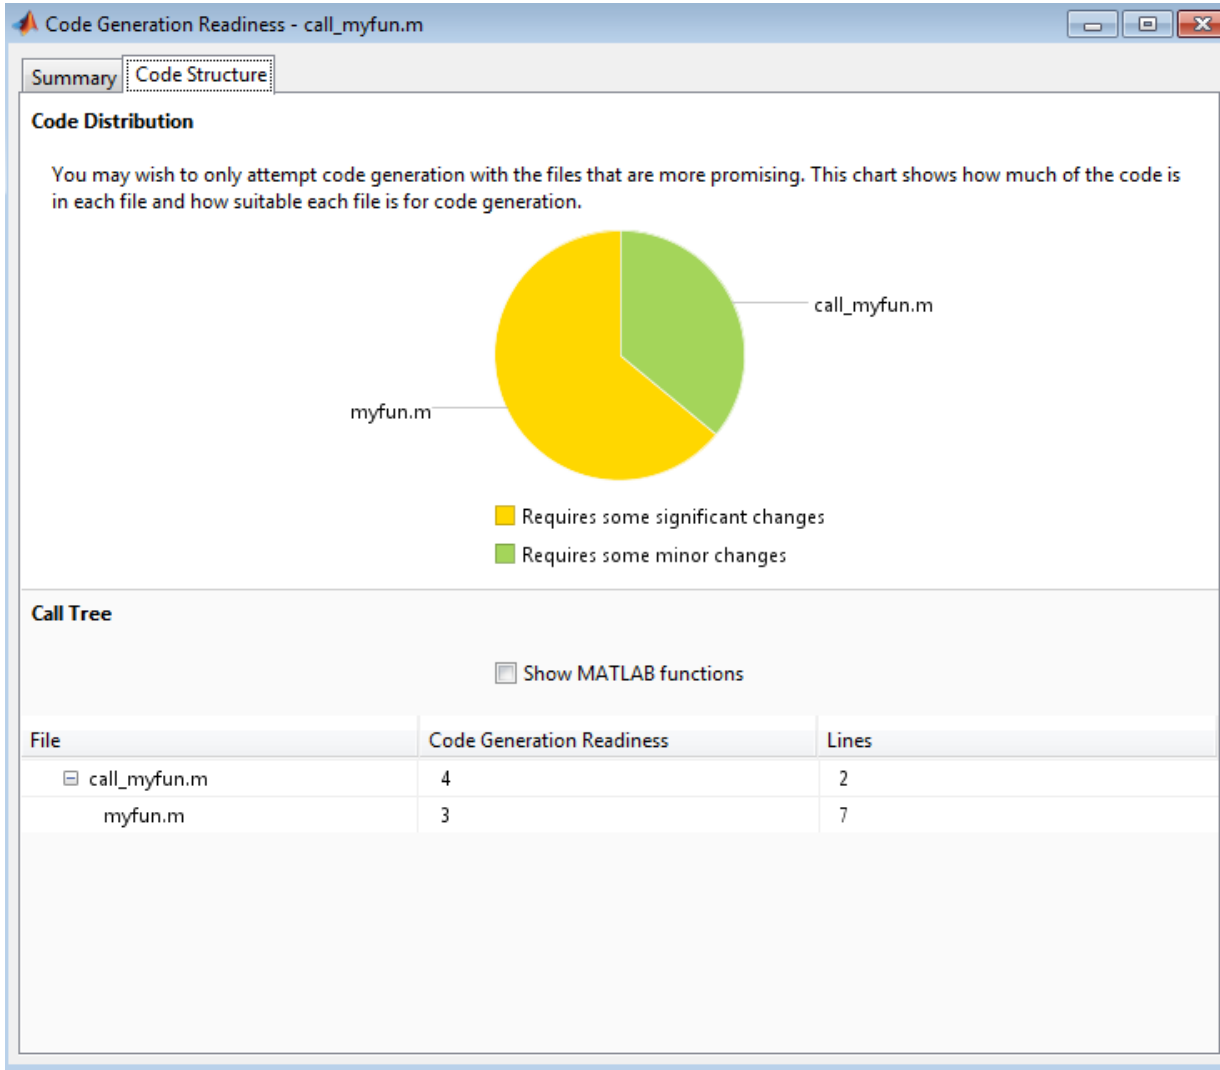
The **Summary** tab provides a **Code Generation Readiness Score**, which ranges from `1` to `5`. A score of `1` indicates that the tool detects issues that require extensive changes to the MATLAB code to make it suitable for code generation. A score of `5` indicates that the

tool does not detect code generation issues; the code is ready to use with minimal or no changes.

On this tab, the tool also displays information about:

- MATLAB syntax issues. These issues are reported in the MATLAB editor. To learn more about the issues and how to fix them, use the Code Analyzer.
- Unsupported MATLAB function calls.
- Unsupported MATLAB language features.
- Unsupported data types.

Code Structure Tab



If the code that you are checking calls other MATLAB functions, or you are checking multiple entry-point functions, the tool displays the **Code Structure Tab**.

This tab displays information about the relative size of each file and how suitable each file is for code generation.

Code Distribution

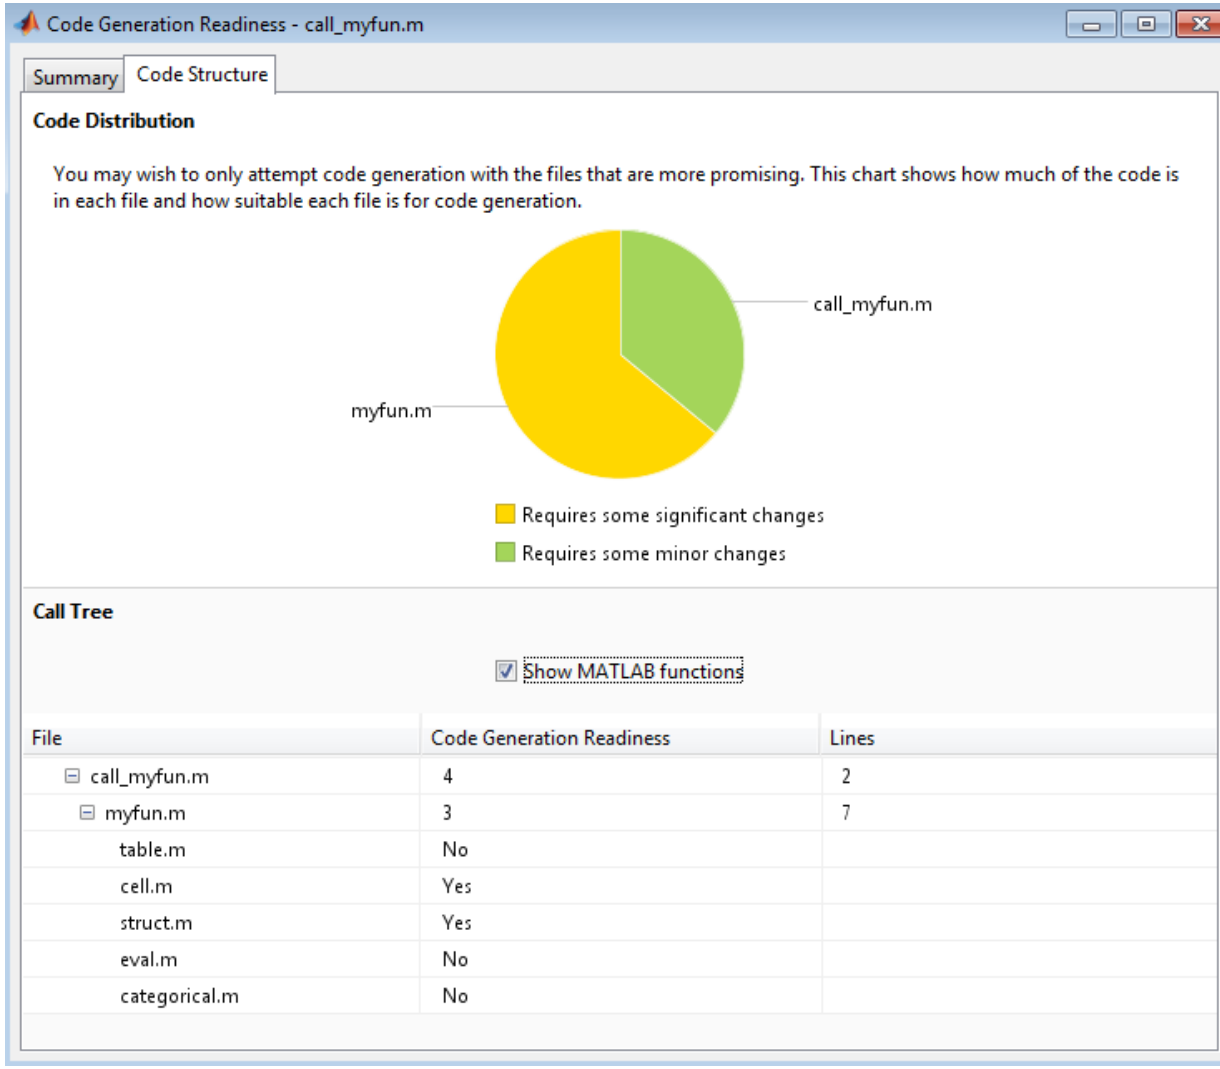
The **Code Distribution** pane displays a pie chart that shows the relative sizes of the files and how suitable each file is for code generation. During the planning phase of a project, you can use this information for estimation and scheduling. If the report indicates that multiple files are not suitable for code generation, consider fixing files that require minor changes before addressing files with significant issues.

Call Tree

The **Call Tree** pane displays information about the nesting of function calls. For each called function, the report provides a **Code Generation Readiness** score, which ranges from `1` to `5`. A score of `1` indicates that the tool detects issues that require extensive changes to the MATLAB code to make it suitable for code generation. A score of `5` indicates that the tool does not detect code generation issues. The code is ready to use with minimal or no changes. The report also lists the number of lines of code in each file.

Show MATLAB Functions

If you select **Show MATLAB Functions**, the report also lists the MATLAB functions that your function calls. For each of these MATLAB functions, if code generation supports the function, the report sets **Code Generation Readiness** to `Yes`.



Code Generation Readiness - call_myfun.m
Summary

Check Code Using the Code Generation Readiness Tool

In this section...

Run Code Generation Readiness Tool at the Command Line

1. Navigate to the folder that contains the file that you want to check for code generation readiness.
2. At the MATLAB command prompt, enter:

   ```
   coder.screener('filename')
   ```

   The **Code Generation Readiness** tool opens for the file named `filename`, provides a code generation readiness score, and lists issues that must be fixed prior to code generation.

Run the Code Generation Readiness Tool From the Current Folder Browser

1. In the current folder browser, right-click the file that you want to check for code generation readiness.
2. From the context menu, select `Check Code Generation Readiness`.

   The **Code Generation Readiness** tool opens for the selected file and provides a code generation readiness score and lists issues that must be fixed prior to code generation.

- “Code Generation Readiness Tool” on page 41-19

Debugging a MATLAB Function Block

In this section...

Debugging the Function in Simulation

In “Create Model That Uses MATLAB Function Block” on page 41-10, you created an example model with a MATLAB Function block that calculates the mean and standard deviation for a set of input values. The software enables debugging for a MATLAB Function when you set a breakpoint.

To debug the MATLAB Function in this model:

1. Open the `call_stats_block2` model and double-click the MATLAB Function block `stats` to open the editor.
2. In the MATLAB Function Block Editor, click the dash (–) in the left margin of the line:

   ```
   len = length(vals);
   ```

   A red dot appears in the line margin, indicating the breakpoint.

```
1    function [mean, stdev] = stats(vals)
2    %#codegen
3
4    % Calculates a statistical mean and a standard deviation
5    % for the values in vals
6
7 -  coder.extrinsic('plot');
8
9    len = length(vals);
10 - mean = avg(vals,len);
11 - stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
12 - plot(vals,'-+');
13
14   function mean = avg(array,size)
15 - mean = sum(array)/size;
```

3 Simulate the model.

Simulation pauses when execution reaches the breakpoint. This is indicated by a green arrow in the margin.

```
1    function [mean, stdev] = stats(vals)
2    %#codegen
3
4    % Calculates a statistical mean and a standard deviation
5    % for the values in vals
6
7 -  coder.extrinsic('plot');
8
9    len = length(vals);
10 - mean = avg(vals,len);
11 - stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
12 - plot(vals,'-+');
13
14   function mean = avg(array,size)
15 - mean = sum(array)/size;
```

4 In the toolbar, click **Step** to advance execution.

The execution arrow advances to the next line of `stats`, which calls the local function `avg`.

5 In the toolbar, click **Step In**.

Execution advances to enter the local function `avg`. Once you are in a local function, you can use the Step or Step In commands to advance execution. If the local function

calls another local function, use Step In to enter it. If you want to execute the remaining lines of the local function, use Step Out.

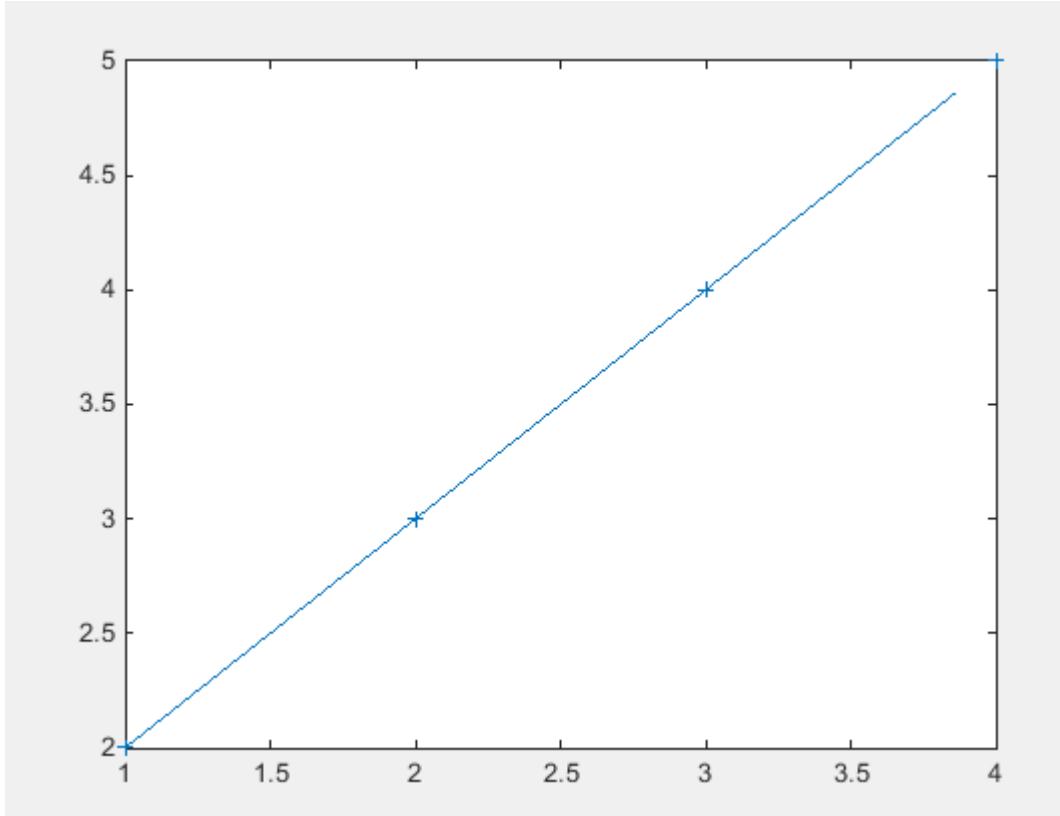
6 Click **Step** to execute the only line in the local function `avg`. When the local function `avg` finishes executing, a green arrow, pointing down, appears under the last line of the function.

7 Click **Step** to return to the function `stats`.

Execution advances to the line after the call to the local function `avg`.

8 Click **Step** twice to calculate the `stdev` and to execute the `plot` function.

The plot function executes in MATLAB:



In the MATLAB Function Block Editor, a green arrow points down under the last line of code, indicating the completion of the function `stats`.

9 Click **Continue** to continue execution of the model.

The computed values of `mean` and `stdev` appear in the Display blocks.

10 In the MATLAB Function Block Editor, click **Quit Debugging** to stop simulation.

Set Conditions on Breakpoints

To help you debug code, you can enter a MATLAB expression as a condition on a breakpoint inside a MATLAB Function block. Simulation then pauses on that breakpoint only when the condition is true. To set a conditional breakpoint, in the MATLAB Function block editor, right-click beside the line of code and select **Set Conditional Breakpoint**. Type the condition in the pop-up window. You can use any valid MATLAB expression as a condition. This condition expression can include numerical values and any data that is in scope at the breakpoint.

To add or modify a condition on an existing breakpoint, right-click the breakpoint and select **Set/Modify Condition**. You can also perform these actions from the **Breakpoints** menu.

Watching Function Variables During Simulation

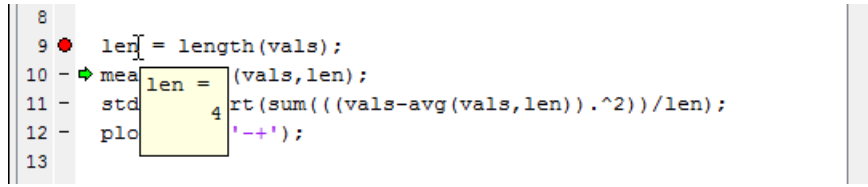
While you simulate a MATLAB Function block, you can use several tools to keep track of variable values in the function.

Watching with the Interactive Display

To display the value of a variable in the function of a MATLAB Function block during simulation:

1 In the MATLAB Function Block Editor, place the mouse cursor over the variable text and observe the pop-up display.

For example, to watch the variable `len` during simulation, place the mouse cursor over the text `len` in the code. The value of `len` appears adjacent to the cursor, as shown:



Watching with the Command Line Debugger

You can report the values for a function variable with the Command Line Debugger utility in the MATLAB window during simulation. When you reach a breakpoint, the Command Line Debugger prompt, `debug>>`, appears. At this prompt, you can see the value of a variable defined for the MATLAB Function block by entering its name:

```
debug>> stdev

    1.1180

debug>>
```

The Command Line Debugger also provides the following commands during simulation:

Command	Description
`ctrl-c`	Quit debugging and terminate simulation.
`dbcont`	Continue execution to next breakpoint.
`dbquit`	Quit debugging and terminate simulation.
`dbstep [in|out]`	Advance to next program step after a breakpoint is encountered. Step over or step into/out of a MATLAB local function.
`help`	Display help for command line debugging.
`print <var>`	Display the value of the variable `var` in the current scope. If `var` is a vector or matrix, you can also index into `var`. For example, `var(1,2)`.
`save`	Saves all variables in the current scope to the specified file. Follows the syntax of the MATLAB `save` command. To retrieve variables to the MATLAB base workspace, use `load` command after simulation has been ended.
`<var>`	Equivalent to "print <var>" if variable is in the current scope.
`who`	Display the variables in the current scope.
`whos`	Display the size and class (type) of all variables in the current scope.

You can issue any other MATLAB command at the `debug>>` prompt, but the results are executed in the workspace of the MATLAB Function block. To issue a command in the MATLAB base workspace at the `debug>>` prompt, use the `evalin` command with the first argument `'base'` followed by the second argument command, for example, `evalin('base','whos')`. To return to the MATLAB base workspace, use the `dbquit` command.

Watching with MATLAB

You can display the execution result of a MATLAB Function block line by omitting the terminating semicolon. If you do, execution results for the line are echoed to the MATLAB window during simulation.

Display Size Limits

The MATLAB Function Block Editor does not display the contents of matrices that have more than two dimensions or more than `200` elements. For matrices that exceed these limits, the MATLAB Function Block Editor displays the shape and base type only.

Checking for Data Range Violations

MATLAB Function blocks check inputs and outputs for data range violations when the input or output values enter or leave the blocks. To enable data range violation checking, set **Simulation range checking** in the **Diagnostics: Data Validity** pane of the Configuration Parameters dialog box to `error`.

Specifying a Range

To specify a range for input and output data, follow these steps:

1. In the Ports and Data Manager, select the input or output of interest.

   The data properties dialog box opens.
2. In the data properties dialog box, select the General tab and enter a limit range, as described in “Setting General Properties” on page 41-49.

Debugging Tools

Use the following tools during a MATLAB Function block debugging session:

Tool Button	Description	Shortcut Key
 **Build**	Access this tool from the **Editor** tab by selecting **Build Model** > **Build**. Check for errors and build a simulation application (if no errors are found) for the model containing this MATLAB Function block.	**Ctrl+B**

Tool Button	Description	Shortcut Key
 **Update Diagram**	Access this tool from the **Editor** tab by selecting **Build Model** > **Update Diagram**. Check for errors based on the latest changes you make to the MATLAB Function block.	**Ctrl+D**
 **Update Ports**	Access this tool from the **Editor** tab by selecting **Build Model** > **Update Ports**. Updates the ports of the MATLAB Function block with the latest changes made to the function argument and return values without closing the MATLAB Function Block Editor.	**Ctrl+Shift+A**
 **Run Model**	Start simulation of the model containing the MATLAB Function block. If execution is paused at a breakpoint, continues debugging.	**F5**
 **Stop Model**	Stop simulation of the model containing the MATLAB Function block. Alternatively, from the **Editor** tab, select **Quit Debugging** if execution is paused at a breakpoint.	**Shift+F5**
 **Set/Clear**	Access this tool by selecting **Breakpoints** > **Set/Clear**. Set a new breakpoint or clear an existing breakpoint for the selected line of code in the MATLAB Function block. The presence of the text cursor or highlighted text selects the line. A breakpoint indicator appears on the selected line. Alternatively, click the hyphen character (-) next to the line number. A breakpoint indicator appears in place of the hyphen. Click the breakpoint indicator to clear the breakpoint.	**F12**

Tool Button	Description	Shortcut Key
 **Enable/Disable**	Access this tool by selecting **Breakpoints** > **Enable/Disable**. Enable or disable an existing breakpoint for the selected line of code in the MATLAB Function block. If the breakpoint is disabled, an indicator  appears on the selected line.	**None**
 **Set Condition**	Access this tool by selecting **Breakpoints** > **Set Condition**. Set a condition on the breakpoint for the selected line of code in the MATLAB Function block. If the breakpoint has a condition associated with it, an indicator  appears on the selected line.	
 **Clear All**	Access this tool by selecting **Breakpoints** > **Clear All**. Clear all existing breakpoints in the MATLAB Function block code.	**None**
 **Step**	Step through the execution of the next line of code in the MATLAB Function block. This tool steps past function calls and does not enter called functions for line-by-line execution. You can use this tool only after execution has stopped at a breakpoint.	**F10**
 **Step In**	Step through the execution of the next line of code in the MATLAB Function block. If the line calls a local function, step into the first line of the local function. You can use this tool only after execution has stopped at a breakpoint.	**F11**
 **Step Out**	Step out of line-by-line execution of the current function or local function. If in a local function, the debugger continues to the line following the call to this local function. You can use this tool only after execution has stopped at a breakpoint.	**Shift+F11**

Tool Button	Description	Shortcut Key
 **Continue**	Continue debugging after a pause, such as stopping at a breakpoint. You can use this tool only after execution has stopped at a breakpoint.	**F5**
 **Quit Debugging**	Exit debug mode. You can use this tool only after execution has stopped at a breakpoint.	**Shift+F5**

Prevent Algebraic Loop Errors in MATLAB Function and Stateflow Blocks

You can use Stateflow charts, MATLAB Function blocks, and Stateflow Truth Tables in feedback loops in your model. You can also use these blocks with synchronous subsystems enabled by the State Control block. To prevent algebraic loop or synchronous semantic errors, apply these restrictions.

Simulink Block	Restrictions
Stateflow Chart	Use Moore charts to prevent an algebraic loop. In the Property Inspector, set the **State Machine Type** to `Moore`. Moore charts prevent algebraic loops by ensuring that outputs depend only on current state.
MATLAB Function block	Nondirect feedthrough semantics prevent algrebraic loop errors by ensuring that outputs depend only on current state. To enable these semantics, clear the **Allow direct feedthrough** property check box. If your block uses direct feedthrough, do not: • Call imported functions. • Define output function-call events. • Define or use persistent variables. When you apply these restrictions, you allow the Simulink solver to try to solve the algebraic loop.

Simulink Block	Restrictions
Truth Table	Do not: • Call imported functions. • Define local or output function-call events. • Define local or data store memory data. • Define or use persistent variables. • Use machine-parented data or events. When you apply these restrictions, you allow the Simulink solver to try to solve the algebraic loop.

- “Control States When Function-Call Inputs Reenable Charts” (Stateflow)

MATLAB Function Block Editor

In this section...

Customizing the MATLAB Function Block Editor

Use the toolbar icons to customize the appearance of the MATLAB Function Block Editor in the same manner as the MATLAB editor. See “Basic Settings” (MATLAB).

MATLAB Function Block Editor Tools

Use the following tools to work with the MATLAB Function block:

Tool Button	Description
 **Edit Data**	Opens the Ports and Data Manager dialog to add or modify arguments for the current MATLAB Function block. To learn more, see “Ports and Data Manager” on page 41-42).
 **View Report**	Opens the MATLAB Function report for the MATLAB Function block. For more information, see “MATLAB Function Reports” on page 41-58.
 **Simulation Target**	Opens the **Simulation Target** pane in the **Configuration Parameters** dialog to include custom code.
 **Go To Diagram**	Displays the MATLAB function in its native diagram without closing the editor.

See “Defining Inputs and Outputs” on page 41-14 for an example of defining an input argument for a MATLAB Function block.

Editing and Debugging MATLAB Function Block Code

Manual Indenting

To indent a block of code manually:

1. Highlight the text that you would like to indent.
2. Select one of the Indent tools on the Editor tab:

Tool	Description
	Applies smart indenting to selected text.
	Move selected text right one indent level.
	Move selected text left one indent level.

Opening a Selection

You can open a local function, function, file, or variable from within a file in the MATLAB Function Block Editor.

To open a selection:

1. Position the cursor in the name of the item you would like to open.
2. Right-click and select **Open <selection>** from the context menu.

The Editor chooses the appropriate tool to open the selection. For more information, refer to “Manage Files and Folders” (MATLAB).

Note If you open a MATLAB Function block input or output parameter, the Ports and Data Manager opens with the selected parameter highlighted. You can use the Ports and Data Manager to modify parameter attributes. For more information, refer to “Ports and Data Manager” on page 41-42.

Evaluating a Selection

You can use the **Evaluate a Selection** menu option to report the value for a MATLAB function variable or equation in the MATLAB window during simulation.

To evaluate a selection:

1. Highlight the variable or equation that you would like to evaluate.
2. Hold the mouse over the highlighted text and then right-click and select **Evaluate Selection** from the context menu. (Alternatively, select **Evaluate Selection** from the **Text** menu).

When you reach a breakpoint, the MATLAB command Window displays the value of the variable or equation at the Command Line Debugger prompt.

```
debug>> stdev

    1.1180

debug>>
```

Note You cannot evaluate a selection while MATLAB is busy, for example, running a MATLAB file.

Setting Data Scope

To set the data scope of a MATLAB Function block input parameter:

1. Highlight the input parameter that you would like to modify.
2. Hold the mouse over the highlighted text and then right-click and select **Data Scope for <selection>** from the context menu.
3. Select:
   - **Input** if your input data is provided by the Simulink model via an input port to the MATLAB Function block.
   - **Parameter** if your input is a variable of the same name in the MATLAB or model workspace or in the workspace of a masked subsystem containing this block.

For more information, refer to “Setting General Properties” on page 41-49.

- “Ports and Data Manager” on page 41-42

Ports and Data Manager

The Ports and Data Manager provides a convenient method for defining objects and modifying their properties in a MATLAB Function block.

The Ports and Data Manager provides the same data definition capabilities for individual MATLAB Function blocks as the Model Explorer provides across the model hierarchy (see “Search and Edit Using Model Explorer” on page 12-2).

Ports and Data Manager Dialog Box

The Ports and Data Manager dialog box allows you to add and define data arguments, input triggers, and function call outputs for MATLAB Function blocks. Using this dialog, you can also modify properties for the MATLAB Function block and the objects it contains.

The dialog box consists of two panes:

- The **Contents** (left) pane lists the objects that have been defined for the MATLAB Function block.
- The **Dialog** (right) pane displays fields for modifying the properties of the selected object.

Properties vary according to the scope and type of the object. Therefore, the Ports and Data Manager properties dialogs are dynamic, displaying only the property fields that are relevant for the object you add or modify.

When you first open the dialog box, it displays the properties of the MATLAB Function block.

Opening the Ports and Data Manager

To open the Ports and Data Manager from the MATLAB Function Block Editor, select **Edit Data** on the Editor tab. The Ports and Data Manager appears for the MATLAB Function block that is open and has focus.

Ports and Data Manager Tools

The following tools are specific to the Ports and Data Manager:

Tool Button	Description
 **Go to Block Editor**	Displays the MATLAB function in the MATLAB Function Block Editor.
 **Show Block Dialog**	Displays the default MATLAB function properties. To learn more, see “MATLAB Function Block Properties” on page 41-54. Use this button to return to the settings used by the block after viewing data associated with the block arguments.

Adding Function Call Outputs to a MATLAB Function Block

A function call output is an event on the output port of a MATLAB Function block that causes a Function-Call Subsystem block in the Simulink model to execute. Another block can invoke a function-call subsystem directly during a simulation. See "Using Function-Call Subsystems" on page 10-29.

Use the Ports and Data Manager to add and modify function call outputs to a MATLAB Function block that is open and has focus. To add a function call output and modify its properties, follow these steps:

1. In the Ports and Data Manager, select **Add** > **Function Call Output**.

   The Ports and Data Manager adds a default definition of the new function call output to the MATLAB Function block and displays the Function Call properties dialog.
2. Modify function call output properties.
3. Return to the MATLAB Function block properties at any time by selecting **Tools** > **Block Dialog**.

Considerations when Supplying Output to the Function-Call Subsystem

If a MATLAB Function block triggers a function-call subsystem, and supplies an output signal to the same function-call subsystem, the signal to the function-call subsystem can effectively be delayed by one time step compared to the function call. At the moment of the function call, the function-call subsystem sees the previous MATLAB Function block outport value even if the output data has been updated within the block MATLAB code.

The Function Call Properties Dialog

The Function Call properties dialog in the Ports and Data Manager allows you to edit the properties of function call outputs in MATLAB Function blocks.

To open the Function Call properties dialog, select a function call output in the Contents pane.

Setting Function Call Output Properties

You can set the following properties in the Function Call properties dialog:

Property	Description
Name	Name of the function call output, following the same naming conventions used in MATLAB.
Port	Index of the port associated with the function call output. Function call output ports are numbered sequentially after input and output ports.
Description	Description of the function call output.
Document link	Link to documentation for the function call output. You can enter a Web URL address or a MATLAB command that displays documentation in a suitable format, such as an HTML file or text in the MATLAB Command Window. When you click **Document link** displayed at the bottom of the **Function Call** properties dialog, the MATLAB Function block evaluates the link and displays the documentation.

See Also

Related Examples

- “What Is a MATLAB Function Block?” on page 41-6

Adding Input Triggers to a MATLAB Function Block

An input trigger is an event on the input port that causes the MATLAB Function block to execute. See “Triggered Subsystems” on page 10-20.

You can define the following types of triggers in MATLAB Function blocks:

- Rising
- Falling
- Either (rising or falling)
- Function call

For a description of each trigger type, see “Setting Input Trigger Properties” on page 41-46.

Use the Ports and Data Manager to add input triggers to a MATLAB Function block that is open and has focus. To add an input trigger and modify its properties, follow these steps:

1 In the Ports and Data Manager, select **Add** > **Input Trigger**.

  The Ports and Data Manager adds a default definition of the new input trigger to the MATLAB Function block and displays the Trigger properties dialog.

2 Modify trigger properties.

3 Return to the MATLAB Function block properties at any time by selecting **Tools** > **Block Dialog**.

The Trigger Properties Dialog

The Trigger properties dialog in the Ports and Data Manager allows you to set and modify the properties of input triggers in MATLAB Function blocks.

To open the Trigger properties dialog, select an input trigger in the Contents pane.

Setting Input Trigger Properties

You can set the following properties in the Trigger properties dialog:

Property	Description
Name	Name of the input trigger, following the same naming conventions used in MATLAB.
Port	Index of the port associated with the input trigger. The default value is `1`.
Trigger	Type of event that triggers execution of the MATLAB Function block. You can select one of the following types of triggers: • `Rising` (default) — Triggers execution of the MATLAB Function block when the control signal rises from a negative or zero value to a positive value (or zero if the initial value is negative). • `Falling`— Triggers execution of the MATLAB Function block when the control signal falls from a positive or zero value to a negative value (or zero if the initial value is positive). • `Either`— Triggers execution of the MATLAB Function block when the control signal is either rising or falling. • `Function call`— Triggers execution of the MATLAB Function block from a block that outputs function-call events, or from an S-function
Description	Description of the input trigger.
Document link	Link to documentation for the input trigger. You can enter a Web URL address or a MATLAB command that displays documentation in a suitable format, such as an HTML file or text in the MATLAB Command Window. When you click the blue text that reads **Document link** displayed at the bottom of the **Trigger** properties dialog, the MATLAB Function block evaluates the link and displays the documentation.

Adding Data to a MATLAB Function Block

You can define data arguments for MATLAB Function blocks using the following methods:

Method	For Defining	Reference
Define data directly in the MATLAB Function block code	Input and output data	See "Defining Inputs and Outputs" on page 41-14.
Use the Ports and Data Manager	Input, output, and parameter data in the MATLAB Function block that is open and has focus	See "Defining Data in the Ports and Data Manager" on page 41-49.
Use the Model Explorer	Input, output, and parameter data in MATLAB Function blocks at all levels of the model hierarchy	See "Search and Edit Using Model Explorer" on page 12-2

Defining Data in the Ports and Data Manager

To add a data argument, in the Ports and Data Manager, select **Add > Data** and modify the data properties.

Setting General Properties

You can set the following properties in the General tab:

Property	Description
Name	Name of the data argument, following the same naming conventions used in MATLAB.

Property	Description
Scope	Where data resides in memory, relative to its parent. Scope determines the range of functionality of the data argument. You can set scope to one of the following values: • `Parameter`— Specifies that the source for this data is a variable of the same name in the MATLAB or model workspace or in the workspace of a masked subsystem containing this block. If a variable of the same name exists in more than one of the workspaces visible to the block, the variable closest to the block in the workspace hierarchy is used (see "Model Workspaces" on page 59-124). • `Input`— Data provided by the model via an input port to the MATLAB Function block. • `Output`— Data provided by the MATLAB Function block via an output port to the model. • `Data Store Memory`— Data provided by a Data Store Memory block in the model. For more information, see "Defining Inputs and Outputs" on page 41-14 and "Add Parameter Arguments" on page 41-83.
Port	Index of the port associated with the data argument. This property applies only to input and output data.
Tunable	Indicates whether the parameter used as the source of this data item is tunable (see "Tunable Parameters" on page 3-8). This property applies only to parameter data. Clear this option if the parameter must be a constant expression, such as for MATLAB toolbox functions supported for code generation (see "Functions and Objects Supported for C/C++ Code Generation — Alphabetical List" on page 46-2).
Data must resolve to Simulink signal object	Specifies that the data argument must resolve to a Simulink signal object. This property applies only to output data. This property appears only if you set the model configuration parameter **Signal resolution** to a value other than `None`. See "Symbol Resolution" on page 59-136 for more information.
Size	Size of the data argument. Size can be a scalar value or a MATLAB vector of values. Size defaults to –1, which means that it is inherited, as described in "Inheriting Argument Sizes from Simulink" on page 41-78. This property does not apply to Data Store Memory data. For more details, see "Size Function Arguments" on page 41-78.

Property	Description
Variable Size	Indicates whether the size of this data item is variable. This property does not apply to Data Store Memory data.
Complexity	Indicates real or complex data arguments. You can set complexity to one of the following values: • `Off`— Data argument is a real number • `On`— Data argument is a complex number • `Inherited`— Data argument inherits complexity based on its scope. Input and output data inherit complexity from the Simulink signals connected to them; parameter data inherits complexity from the parameter to which it is bound.
Type	• Selecting a built-in type from the **Type** drop down list. • Entering an expression in the **Type** field that evaluates to a data type (see "About Data Types in Simulink" on page 59-3). • Using the Data Type Assistant to specify a data **Mode**, then specifying the data type based on that mode. **Note** To display the Data Type Assistant, click the Show data type assistant button:  For more information, see "Specifying Argument Types" on page 41-71.
Unit (e.g., m, m/s^2, N*m)	Specify physical units for input and output data. By default, the property is set to inherit the unit from the Simulink signal on the corresponding input or output port. See "Units in MATLAB Function Blocks" on page 41-81.

Property	Description
Limit range	Specify the range of acceptable values for input or output data. The MATLAB Function block uses this range to validate the input or output as it enters or leaves the block. You can enter an expression or parameter that evaluates to a numeric scalar value. • **Minimum** — The smallest value allowed for the data item during simulation. The default value is `-inf`. • **Maximum** — The largest value allowed for the data item during simulation. The default value is `inf`.

Setting Description Properties

You can set the following properties on the Description tab:

Property	Description
Save final value to base workspace	The MATLAB Function block assigns the value of the data argument to a variable of the same name in the MATLAB base workspace at the end of simulation.
Description	Description of the data argument.
Document link	Link to documentation for the data argument. You can enter a Web URL address or a MATLAB command that displays documentation in a suitable format, such as an HTML file or text in the MATLAB Command Window. When you click the blue text, **Document link**, displayed at the bottom of the **Data** properties dialog, the MATLAB Function block evaluates the link and displays the documentation.

MATLAB Function Block Properties

This section describes each property of a MATLAB Function block.

Name

Name of the MATLAB Function block.

Update method

Method for activating the MATLAB Function block. You can choose from the following update methods:

Update Method	Description
Inherited (default)	Input from the Simulink model activates the MATLAB Function block. If you define an input trigger, the MATLAB Function block executes in response to a Simulink signal or function-call event on the trigger port. If you do not define an input trigger, the MATLAB Function block implicitly inherits triggers from the model. These implicit events are the sample times (discrete or continuous) of the signals that provide inputs to the chart. If you define data inputs, the MATLAB Function block samples at the rate of the fastest data input. If you do not define data inputs, the MATLAB Function block samples as defined by its parent subsystem's execution behavior.
Discrete	The MATLAB Function block is sampled at the rate you specify as the block's **Sample Time** property. An implicit event is generated at regular time intervals corresponding to the specified rate. The sample time is in the same units as the Simulink simulation time. Note that other blocks in the model can have different sample times.
Continuous	The Simulink software wakes up (samples) the MATLAB Function block at each step in the simulation, as well as at intermediate time points that can be requested by the solver. This method is consistent with the continuous method.

Saturate on integer overflow

Option that determines how the MATLAB Function block handles overflow conditions during integer operations:

Setting	Action When Overflow Occurs
Enabled (default)	Saturates an integer by setting it to the maximum positive or negative value allowed by the word size. Matches MATLAB behavior.
Disabled	In simulation mode, generates a run-time error. For Simulink Coder code generation, the behavior depends on your C language compiler.

Note The **Saturate on integer overflow** option is relevant only for integer arithmetic. It has no effect on fixed-point or double-precision arithmetic.

When you enable **Saturate on integer overflow**, MATLAB adds additional checks during simulation to detect integer overflow or underflow. Therefore, it is more efficient to disable this option if you are sure that integer overflow and underflow will not occur in your MATLAB Function block code.

Note that the code generated by Simulink Coder does *not* check for integer overflow or underflow and, therefore, may produce unpredictable results when **Saturate on integer overflow** is disabled. In this situation, it is recommended that you simulate first to test for overflow and underflow before generating code.

Lock Editor

Option for locking the MATLAB Function Block Editor. When enabled, this option prevents users from making changes to the MATLAB Function block.

Treat these inherited Simulink signal types as fi objects

Setting that determines whether to treat inherited fixed-point and integer signals as Fixed-Point Designer `fi` objects (“Ways to Construct fi Objects” (Fixed-Point Designer)).

- When you select `Fixed-point`, the MATLAB Function block treats all fixed-point inputs as Fixed-Point Designer `fi` objects.

- When you select `Fixed-point & Integer`, the MATLAB Function block treats all fixed-point and integer inputs as Fixed-Point Designer `fi` objects.

MATLAB Function block fimath

Setting that defines `fimath` properties for the MATLAB Function block. The block associates the `fimath` properties you specify with the following objects:

- All fixed-point and integer input signals to the MATLAB Function block that you choose to treat as `fi` objects.
- All `fi` and `fimath` objects constructed in the MATLAB Function block.

You can select one of the following options for the **MATLAB Function block fimath**.

Setting	Description
Same as MATLAB	When you select this option, the block uses the same `fimath` properties as the current default fimath. The edit box appears dimmed and displays the current global fimath in read-only form.
Specify other	When you select this option, you can specify your own `fimath` object in the edit box. You can do so in one of two ways: • Constructing the `fimath` object inside the edit box. • Constructing the `fimath` object in the MATLAB or model workspace and then entering its variable name in the edit box. If you use this option and plan to share your model with others, make sure you define the variable in the model workspace. See “Sharing Models with Fixed-Point MATLAB Function Blocks” (Fixed-Point Designer). For more information on `fimath` objects, see “fimath Object Construction” (Fixed-Point Designer).

Description

Description of the MATLAB Function block.

Document link

Link to documentation for the MATLAB Function block. To document a MATLAB Function block, set the **Document link** property to a Web URL address or MATLAB

expression that displays documentation in a suitable format (for example, an HTML file or text in the MATLAB Command Window). The MATLAB Function block evaluates the expression when you click the blue **Document link** text.

MATLAB Function Reports

In this section...

About MATLAB Function Reports

When you build a Simulink model that contains MATLAB Function blocks, Simulink generates a report in HTML format for each MATLAB Function block in your model. You can use the report to debug your MATLAB functions and verify that they are suitable for code generation. The report provides links to your MATLAB functions and compile-time type information for the variables and expressions in these functions. If your model fails to build, this information simplifies finding sources of error messages and aids understanding of type propagation rules.

Note If you have a Stateflow license, there is one report for each Stateflow chart, regardless of the number of MATLAB functions it contains.

Note If you have identical MATLAB Function blocks in your model, for example, one in a library and one in the model, a single report is generated for the identical blocks.

Opening MATLAB Function Reports

Use one of the following methods:

- In the MATLAB Function Block Editor, select **View Report**.
- If compilation errors occur, in the **Diagnostic Viewer** window, select the`report` link.

Description of MATLAB Function Reports

When you build the MATLAB function, the code generation software generates an HTML report. The report provides the following information, as applicable:

- MATLAB code information, including a list of all functions and their compilation status
- Call stack information, providing information on the nesting of function calls
- Summary of compilation results, including type of target and number of warnings or errors
- List of error and warning messages
- List of variables in your MATLAB function

Viewing Your MATLAB Function Code

To view your MATLAB function code, click the **MATLAB code** tab. The report displays the MATLAB code for the function highlighted in the list on this tab.

The **MATLAB code** tab provides:

- A list of the MATLAB functions that have been compiled. The report displays icons next to each function name to indicate whether compilation was successful:
  -  Errors in function.
  -  Warnings in function.
  -  Successful compilation, no errors or warnings.
- A filter control that you can use to sort your functions by:

- Size
- Complexity
- Class

Viewing Local Functions

The report annotates the local function with the name of the parent function in the list of functions on the **MATLAB code** tab.

For example, if the MATLAB function `fcn1` contains the local function `subfcn` and `fcn2` contains the local function `subfcn2`, the report displays:

```
fcn1 > subfcn1
fcn2 > subfcn2
```

Viewing Specializations

If your MATLAB function calls the same function with different types of inputs, the report numbers each of these **specializations** in the list of functions on the **MATLAB code** tab.

For example, if the function `fcn` calls the function `subfcn` with different types of inputs:

```
function y = fcn(u)
% Specializations
y = y + subfcn(single(u));
y = y + subfcn(double(u));
```

The report numbers the specializations in the list of functions.

```
fcn > subfcn > 1
fcn > subfcn > 2
```

Viewing Call Stack Information

The report provides call stack information:

- On the **Call stack** tab.
- In the list of **Callers**.

  If a function is called from more than one function, this list provides details of each call site. Otherwise, the list is disabled.

Viewing Call Stack Information on the Call Stack Tab

To view call stack information, click the **Call stack** tab. The call stack lists the functions in the order that the top-level function calls them. It also lists the local functions that each function calls.

Viewing Function Call Sites in the Callers List

If a function is called from more than one function, this list provides details of each call site. To navigate between call sites, select a call site from the **Callers** list. If the function is not called more than once, this list is disabled.

Viewing the Compilation Summary Information

To view a summary of the compilation results, including type of target and number of errors or warnings, click the **Summary** tab.

Viewing Error and Warning Messages

The report provides information about errors and warnings. If errors occur during simulation of a Simulink model, simulation stops. If warnings occur, but no errors, simulation of the model continues.

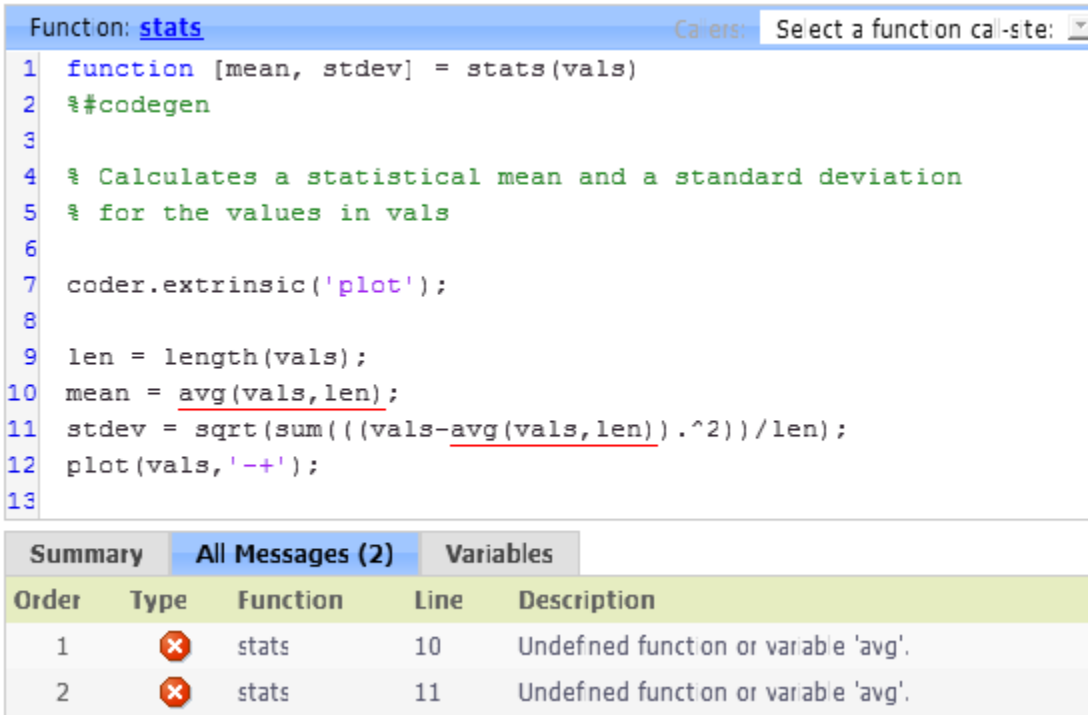
The report provides information about warnings and errors by listing all errors and warnings in chronological order in the **All Messages** tab.

Viewing Errors and Warnings in the All Messages Tab

If errors or warnings occurred during compilation, click the **All Messages** tab to view a complete list of these messages. The report lists the messages in the order that the compiler detects them. It is best practice to address the first message in the list, because often subsequent errors and warnings are related to the first message.

To locate the offending line of code for an error or warning in the list, click the message in the list. The report highlights errors in the list and MATLAB code in red and warnings in orange. Click the blue line number next to the offending line of code in the MATLAB code pane to go to the error in the source file.

Note You can fix errors only in the source file.



Viewing Error and Warning Information in Your MATLAB Code

If errors or warnings occurred during compilation, the report underlines them in your MATLAB code. The report underlines errors in red and warnings in orange. To learn more about a particular error or warning, place your pointer over the underlined text.

MATLAB Code Variables in a Report

The report provides compile-time type information for the variables and expressions in your MATLAB code, including name, type, size, complexity, and class. It also provides type information for fixed-point data types, including word length and fraction length. You can use this type information to find the sources of error messages and to understand type propagation rules.

You can view information about the variables in your MATLAB code:

- On the **Variables** tab, view the list.
- In your MATLAB code, place your cursor over the variable name.

  In the MATLAB code, an orange variable name indicates a compile-time constant argument to a specialized function. The information for a constant argument includes the value. This information helps you to see when code generation created function specializations for different constant argument values.

Variables on the Variables Tab

To view a list of the variables in your MATLAB function, click the **Variables** tab. The report displays a complete list of variables in the order that they appear in the function that you selected on the **MATLAB code** tab. Clicking a variable in the list highlights instances of that variable, and scrolls the MATLAB code pane so that you can view the first instance.

As applicable, the report provides the following information about each variable:

- Order
- Name
- Type
- Size
- Complexity
- Class
- DataTypeMode (DT mode) — for fixed-point data types only. For more information, see "Data Type and Scaling Properties" (Fixed-Point Designer).
- Signed — sign information for built-in data types, signedness information for fixed-point data types.
- Word length (WL) — for fixed-point data types only.
- Fraction length (FL) — for fixed-point data types only.

Note For more information on viewing fixed-point data types, see "Use Fixed-Point Code Generation Reports" (Fixed-Point Designer).

The report displays a column only if at least one variable in the code has information in that column. For example, if the code does not contain fixed-point data types, the report does not display the **DT mode**, **WL**, or **FL** columns.

Sorting Variables on the Variables Tab

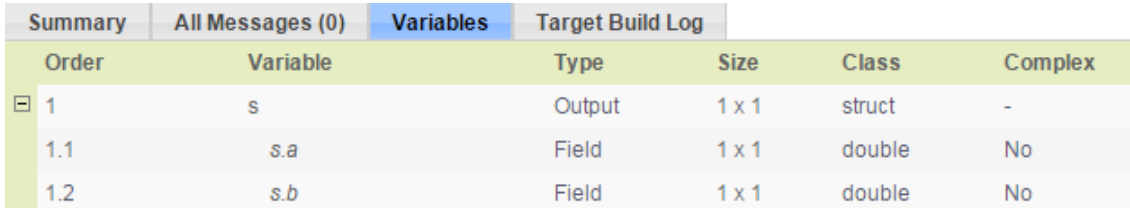
By default, the report lists the variables in the order that they appear in the selected function.

To sort the variables, click the column headings on the **Variables** tab. To sort the variables by multiple columns, hold down the **Shift** key when you click the column headings.

To restore the list to the original order, click the **Order** column heading.

Structures on the Variables Tab

To display structure field properties, expand the structure on the **Variables** tab.

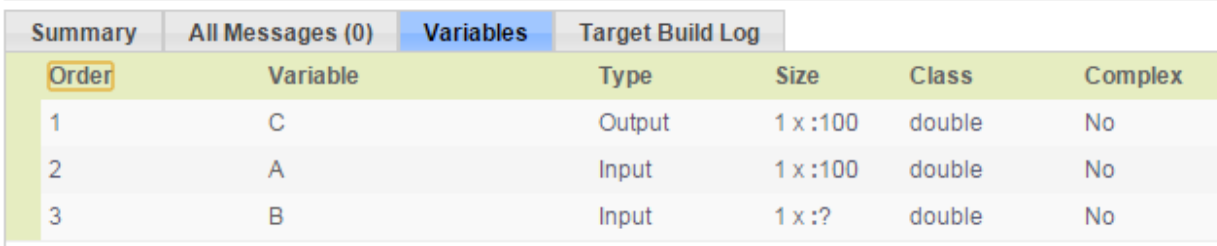


If you sort the variables by type, size, complexity, or class, it is possible that a structure and its fields do not appear sequentially in the list. To restore the list to the original order, click the **Order** column heading.

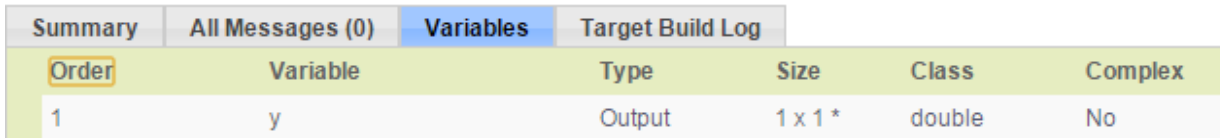
Variable-Size Arrays in the Variables Tab

For variable-size arrays, the **Size** field includes information about the computed maximum size of the array. The size of each array dimension that varies is prefixed with a colon `:`. The size of an unbounded dimension is `:?`.

In the following report, variables `A` and `B` are variable-size. The second dimension of `A` has a maximum size of 100. The size of the second dimension of `B` is `:?`.



If you declare a variable-size array, and then fix the dimensions of this array in the code, the report appends `*` to the size of the variable. In the generated C code, this variable appears as a variable-size array, but the sizes of its dimensions do not change during execution.

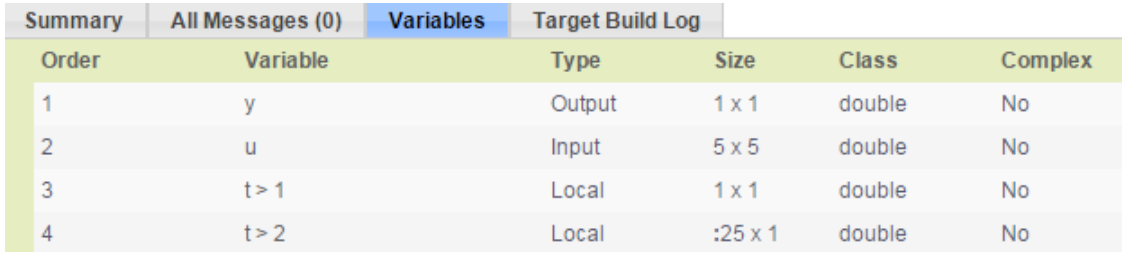


For information about how to use the size information for variable-size arrays, see "Code Generation for Variable-Size Arrays" on page 50-2.

Renamed Variables in the Variables Tab

If your MATLAB function reuses a variable with a different size, type, or complexity, the code generator attempts to create separate, uniquely named variables. For more information, see "Reuse the Same Variable with Different Properties" on page 48-10. The report numbers the renamed variables in the list on the **Variables** tab. When you place your cursor over a renamed variable, the report highlights only the instances of this variable that share data type, size, and complexity.

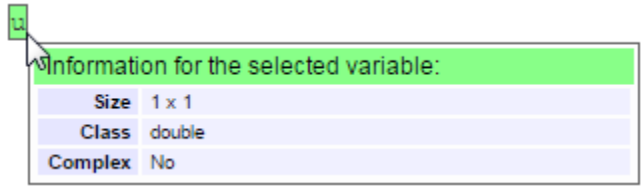
For example, suppose that your code uses the variable `t` to hold a scalar double, and reuses it outside the for-loop to hold a vector of doubles. In the list on the **Variables** tab, the report displays two variables, `t>1` and `t>2`,



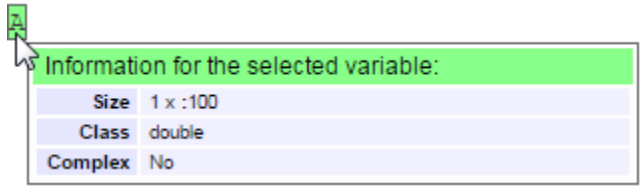
Viewing Information About Variables and Expressions in Your MATLAB Function Code

To view information about a particular variable or expression in your MATLAB function code, on the MATLAB code pane, place your cursor over the variable name or expression. The report highlights variables and expressions in different colors:

Green, when the variable has data type information at this location in the code



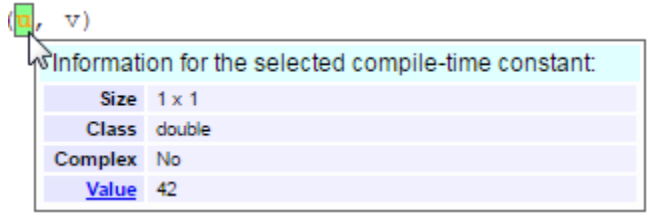
For variable-size arrays, the **Size** field includes information on the computed maximum size of the array. The size of each array dimension that varies is prefixed with a colon `:`.



Green with orange text, when a constant argument has data type and value information

When the variable is a compile-time constant argument to a specialized function:

- The variable name is orange.
- The information for the variable includes the value.



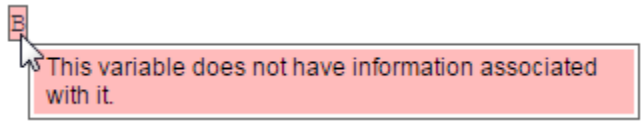
If you export the value as a variable to the base workspace, you can use the Workspace browser to view detailed information about the variable.

To export the value to the base workspace:

1. Click the **Value** link.
2. In the Export Constant Value dialog box, specify the **Variable name**.
3. Click **OK**.

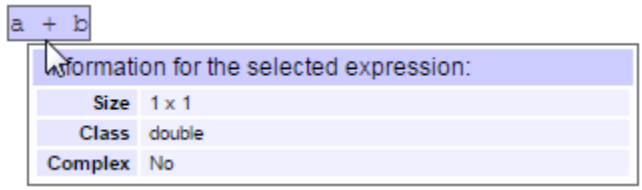
The variable and its value appear in the Workspace browser.

Pink, when the variable has no data type information

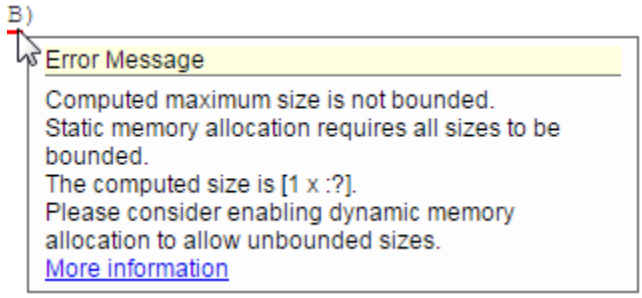


Purple, information about expressions

You can also view information about expressions in your MATLAB code. On the MATLAB code pane, place your cursor over an expression. The report highlights expressions in purple and provides more detailed information.



Red, when there is error information



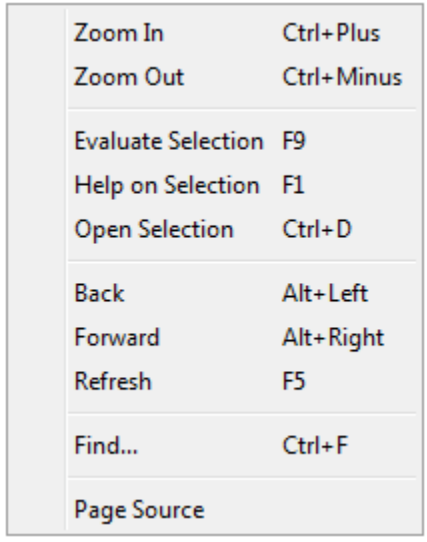
Keyboard Shortcuts for the MATLAB Function Report

You can use keyboard shortcuts settings to perform actions in the report.

This table lists actions that you can associate with a keyboard shortcut. The keyboard shortcuts are defined in your MATLAB preferences. See “Define Keyboard Shortcuts” (MATLAB).

Action	Default Keyboard Shortcut for a Windows Platform
Zoom in	**Ctrl+Plus**
Zoom out	**Ctrl+Minus**
Evaluate selected MATLAB code	**F9**
Open help for selected MATLAB code	**F1**
Open selected MATLAB code	**Ctrl+D**
Step backward through files that you opened in the code pane	**Alt+Left**
Step forward through files that you opened in the code pane	**Alt+Right**
Refresh	**F5**
Search	**Ctrl+F**

Alternatively, you can select these actions from a context menu. To open the context menu, right-click anywhere in the report.



This table lists keyboard shortcuts that help you navigate between panes and tabs in the code generation report. To advance through data in the selected pane, use the **Tab** key.

These keyboard shortcuts override the keyboard shortcut settings in your MATLAB preferences. See “Define Keyboard Shortcuts” (MATLAB).

To select	Use
MATLAB code tab	**Ctrl+M**
Call stack tab	**Ctrl+K**
Code Pane	**Ctrl+W**
Summary Tab	**Ctrl+S**
All Messages Tab	**Ctrl+A**
Variables Tab	**Ctrl+V**

Searching in the MATLAB Function Report

Use the keyboard shortcut associated with `Find` in your MATLAB preferences. The default keyboard shortcut for `Find` on a Windows platform is **Ctrl+F**.

Report Limitations

The report displays information about the variables and expressions in your MATLAB code with the following limitations:

varargin and varargout

The report does not support `varargin` and `varargout` arrays.

Loop Unrolling

The report does not display full information for unrolled loops. It displays data types of one arbitrary iteration.

Dead Code

The report does not display information about dead code.

Structures

The report does not provide complete information about structures.

- The report does not provide information about all structure fields in the `struct()` constructor.

- If a structure has a nonscalar field, and an expression accesses an element of this field, the report does not provide information for the field.

Column Headings on the Variables Tab

If you scroll through the list of variables, the report does not display the column headings on the **Variables** tab.

Multiline Matrices

On the **MATLAB code** pane, the report does not support selection of multiline matrices. It supports only selection of individual lines at a time. For example, if you place your cursor over the following matrix, you cannot select the entire matrix.

```
out1 = [1 2 3;
        4 5 6];
```

The report does support selection of single line matrices.

```
out1 = [1 2 3; 4 5 6];
```

- "MATLAB Function Block Properties" on page 41-54

Type Function Arguments

In this section...

About Function Arguments

You create function arguments for a MATLAB Function block by entering them in its function header in the MATLAB Function Block Editor. When you define arguments, the Simulink software creates corresponding ports on the MATLAB Function block that you can attach to signals. You can select a data type mode for each argument that you define for a MATLAB Function block. Each data type mode presents its own set of options for selecting a data type.

By default, the data type mode for MATLAB Function block function arguments is **Inherited**. This means that the function argument inherits its data type from the incoming or outgoing signal. To override the default type, you first choose a data type mode and then select a data type based on the mode.

Specifying Argument Types

To specify the type of a MATLAB Function block function argument:

1. From the MATLAB Function Block Editor, select **Edit Data** to open the Ports and Data Manager.
2. In the left pane, select the argument of interest.
3. In the **Data** properties dialog box (right pane), click the Show data type assistant button  to display the Data Type Assistant. Then, choose an option from the **Mode** drop-down menu.

The **Data** properties dialog box changes dynamically to display additional fields for specifying the data type associated with the mode.

4 Based on the mode you select, specify a desired data type:

Mode	What to Specify
`Inherit` (default)	You cannot specify a value. The data type is inherited from previously-defined data, based on the scope you selected for the MATLAB Function block function argument: • If scope is **Input**, data type is inherited from the input signal on the designated port. • If scope is **Output**, data type is inherited from the output signal on the designated port. • If scope is **Parameter**, data type is inherited from the associated parameter, which can be defined in the Simulink masked subsystem or the MATLAB workspace. See "Inheriting Argument Data Types" on page 41-73.
`Built in`	Select from the drop-down list of supported data types, as described in "Built-In Data Types for Arguments" on page 41-73.
`Fixed point`	Specify the fixed-point data properties as described in "Specifying Fixed-Point Designer Data Properties" on page 41-74.
`Expression`	Enter an expression that evaluates to a data type, as described in "Specifying Argument Types with Expressions" on page 41-74.
`Bus Object`	In the **Bus object** field, enter the name of a `Simulink.Bus` object to define the properties of a MATLAB structure. You must define the bus object in the base workspace. See "How Structure Inputs and Outputs Interface with Bus Signals" on page 41-90. **Note** You can click the **Edit** button to create or modify `Simulink.Bus` objects using the Simulink Bus Editor (see "Attach Bus Signals to MATLAB Function Blocks" on page 41-88.
`Enumerated`	In the Enumerated field, enter the name of a `Simulink.IntEnumType` object that you define in the base workspace. See "Code Generation for Enumerations" on page 41-121.

Inheriting Argument Data Types

MATLAB Function block function arguments can inherit their data types, including fixed point types, from the signals to which they are connected.

1. Select the argument of interest in the Ports and Data Manager
2. In the **Data** properties dialog, select `Inherit: Same as Simulink` from the **Type** drop-down menu.

See "Built-In Data Types for Arguments" on page 41-73 for a list of supported data types.

Note An argument can also inherit its complexity (whether its value is a real or complex number) from the signal that is connected to it. To inherit complexity, set the **Complexity** field on the **Data** properties dialog to **Inherited**.

After you build the model, the **Compiled Type** column of the Ports and Data Manager gives the actual type inherited from Simulink in the compiled simulation application.

The inherited type of output data is inferred from diagram actions that store values in the specified output. In the preceding example, the variables `mean` and `stdev` are computed from operations with double operands, which yield results of type `double`. If the expected type matches the inferred type, inheritance is successful. In all other cases, a mismatch occurs during build time.

Note Library MATLAB Function blocks can have inherited data types, sizes, and complexities like ordinary MATLAB Function blocks. However, all instances of the library block in a given model must have inputs with the same properties.

Built-In Data Types for Arguments

When you select **Built-in** for **Data type mode**, the **Data** properties dialog displays a **Data type** field that provides a drop-down list of supported data types. You can also choose a data type from the **Data Type** column in the Ports and Data Manager. The supported data types are:

Data Type	Description
`double`	64-bit double-precision floating point
`single`	32-bit single-precision floating point
`int32`	32-bit signed integer
`int16`	16-bit signed integer
`int8`	8-bit signed integer
`uint32`	32-bit unsigned integer
`uint16`	16-bit unsigned integer
`uint8`	8-bit unsigned integer
`boolean`	Boolean (1 = `true`; 0 = `false`)

Specifying Argument Types with Expressions

You can specify the types of MATLAB Function block function arguments as expressions in the Ports and Data Manager.

1. Select `<data type expression>` from the **Type** drop-down menu of the Data properties dialog.
2. In the **Type** field, replace "*`<data type expression>`*" with an expression that evaluates to a data type. The following expressions are allowed:
   - Alias type from the MATLAB workspace, as described in "Creating a Data Type Alias".
   - `fixdt` function to create a `Simulink.NumericType` object describing a fixed-point or floating-point data type
   - `type (Stateflow)` operator, to base the type on previously defined data

Specifying Fixed-Point Designer Data Properties

MATLAB Function blocks can represent signals and parameter values as fixed-point numbers. To simulate models that use fixed-point data in MATLAB Function blocks, you must install the Fixed-Point Designer product on your system.

You can set the following fixed-point properties:

Signedness. Select whether you want the fixed-point data to be `Signed` or `Unsigned`. Signed data can represent positive and negative quantities. Unsigned data represents positive values only. The default is `Signed`.

Word length. Specify the size (in bits) of the word that will hold the quantized integer. Large word sizes represent large quantities with greater precision than small word sizes. Word length can be any integer between 0 and 128 bits. The default is 16.

Scaling. Specify the method for scaling your fixed point data to avoid overflow conditions and minimize quantization errors. You can select the following scaling modes:

Scaling Mode	Description
`Binary point` (default)	If you select this mode, the Data Type Assistant displays the **Fraction Length** field, specifying the binary point location. Binary points can be positive or negative integers. A positive integer moves the binary point left of the rightmost bit by that amount. For example, an entry of 2 sets the binary point in front of the second bit from the right. A negative integer moves the binary point further right of the rightmost bit by that amount, as in this example:  The default is 0.
`Slope and bias`	If you select this mode, the Data Type Assistant displays fields for entering the **Slope** and **Bias**. • Slope can be any *positive* real number. The default is 1.0. • Bias can be any real number. The default value is 0.0. You can enter slope and bias as expressions that contain parameters defined in the MATLAB workspace.

Note You should use binary-point scaling whenever possible to simplify the implementation of fixed-point data in generated code. Operations with fixed-point data using binary-point scaling are performed with simple bit shifts and eliminate the expensive code implementations required for separate slope and bias values.

Data type override. Specify whether the data type override setting is `Inherit` (default) or `Off`.

Calculate Best-Precision Scaling. The Simulink software can automatically calculate "best-precision" values for both `Binary point` and `Slope and bias` scaling, based on the Limit range properties you specify.

To automatically calculate best precision scaling values:

1. Specify **Minimum**, **Maximum**, or both Limit range properties.
2. Click **Calculate Best-Precision Scaling**.

The Simulink software calculates the scaling values, then displays them in either the **Fraction Length**, or **Slope** and **Bias** fields.

Note The Limit range properties do not apply to `Constant` or `Parameter` scopes. Therefore, Simulink cannot calculate best-precision scaling for these scopes.

Fixed-point Details. You can view the following Fixed-point details:

Fixed-point Detail	Description
Representable maximum	The maximum number that can be represented by the chosen data type, sign, word length and fraction length (or data type, sign, slope and bias).
Maximum	The maximum value specified.
Minimum	The minimum value specified.
Representable minimum	The minimum number that can be represented by the chosen data type, sign, word length and fraction length (or data type, sign, slope and bias).

Fixed-point Detail	Description
Precision	The precision for the given word length and fraction length (or slope and bias).

Using Data Type Override with the MATLAB Function Block

If you set the Data Type Override mode to `Double` or `Single` in Simulink, the MATLAB Function block sets the type of all inherited input signals and parameters to `fi double` or `fi single` objects respectively (see "MATLAB Function Block with Data Type Override" (Fixed-Point Designer) for more information). You must check the data types of your inherited input signals and parameters and use the Ports and Data Manager (see "Ports and Data Manager" on page 41-42) to set explicit types for any inputs that should not be fixed-point. Some operations, such as `sin`, are not applicable to fixed-point objects.

Note If you do not set the correct input types explicitly, you may encounter compilation problems after setting Data Type Override.

How Do I Set Data Type Override?

To set Data Type Override, follow these steps:

1. From the Simulink **Analysis** menu, select **Fixed-Point Tool**.
2. Set the value of the **Data type override** parameter to `Double` or `Single`.

Size Function Arguments

In this section...

Specifying Argument Size

To examine or specify the size of an argument, follow these steps:

1. From the MATLAB Function Block Editor, select **Edit Data**.
2. Enter the size of the argument in the **Size** field of the Data properties dialog, located in the **General** pane.

Note The default value is `-1`, indicating that size is inherited, as described in “Inheriting Argument Sizes from Simulink” on page 41-78.

Inheriting Argument Sizes from Simulink

Size defaults to `-1`, which means that the data argument inherits its size from Simulink based on its scope:

For Scope	Inherits Size
`Input`	From the Simulink input signal connected to the argument.
`Output`	From the Simulink output signal connected to the argument.
`Parameter`	From the Simulink or MATLAB parameter to which it is bound. See “Add Parameter Arguments” on page 41-83.

After you compile the model, the **Compiled Size** column in the **Contents** pane displays the actual size used in the compiled simulation application.

The size of an output argument is the size of the value that is assigned to it. If the expected size in the Simulink model does not match, a mismatch error occurs during compilation of the model.

Note No arguments with inherited sizes are allowed for MATLAB Function blocks in a library.

Specifying Argument Sizes with Expressions

The size of a data argument can be a scalar value or a MATLAB vector of values.

To specify size as a scalar, set the **Size** field to 1 or leave it blank. To specify **Size** as a vector, enter an array of up to two dimensions in `[row column]` format where

- Number of dimensions equals the length of the vector.
- Size of each dimension corresponds to the value of each element of the vector.

For example, a value of `[2 4]` defines a 2-by-4 matrix. To define a row vector of size 5, set the **Size** field to `[1 5]`. To define a column vector of size 6, set the **Size** field to `[6 1]` or just `6`. You can enter a MATLAB expression for each `[row column]` element in the **Size** field. Each expression can use one or more of the following elements:

- Numeric constants
- Arithmetic operators, restricted to `+`, `-`, `*`, and `/`
- Parameters
- Calls to the MATLAB functions `min`, `max`, and `size`

The following examples are valid expressions for **Size**:

```
k+1
size(x)
min(size(y),k)
```

In these examples, `k`, `x`, and `y` are variables of scope `Parameter`.

Once you build the model, the **Compiled Size** column displays the actual size used in the compiled simulation application.

Units in MATLAB Function Blocks

In this section...

Units for Input and Output Data

MATLAB Function blocks support the specification of physical units as properties for data inputs and outputs. Specify units by using the **Unit (e.g., m, m/s^2, N*m)** parameter. When you start typing in the unit field, this parameter provides matching suggestions for units that Simulink supports. By default, the property is set to inherit the unit from the Simulink signal on the corresponding input or output port. If you select the **Data must resolve to Simulink signal object** property for output data, you cannot specify units. In this case, output data is assigned the same unit type as the Simulink signal connected to the output port.

To display the units on the Simulink lines in the model, select **Display > Signals and Ports > Port Units**.

Consistency Checking

MATLAB Function blocks check the consistency of the signal line unit from Simulink with the unit setting for the corresponding input or output data in the block. If the units do not match, Simulink displays a warning during model update.

Units for Stateflow Limitations

The unit property settings do not affect the execution of the MATLAB Function block. Simulink checks only consistency with the corresponding Simulink signal line connected to the input or output. It does not check consistency of assignments inside the MATLAB Function blocks. For example, Simulink does not warn against an assignment of an input with unit set to `ft` to an output with unit set to `m`. A MATLAB Function block does not perform unit conversions.

- "Unit Specification in Simulink Models" on page 9-2

Add Parameter Arguments

Parameter arguments for MATLAB Function blocks do not take their values from signals in the Simulink model. Instead, Simulink searches up the workspace hierarchy. Simulink first looks in a masked workspace if the MATLAB Function block or a parent subsystem is masked. If the value is not found, it next looks in the model workspace and then the MATLAB base workspace.

You can provide a custom interface for parameters by masking the MATLAB Function block. Creating a mask for a block allows you to define the access for each parameter.

1. In the MATLAB Function Block Editor, add an argument to the function header of the MATLAB Function block. The name of the argument must match the name of the masked parameter or MATLAB variable that you want to pass to the MATLAB Function block.

   The new argument appears as an input port on the MATLAB Function block in the model.
2. In the MATLAB Function Block Editor, click **Edit Data**.
3. Select the new argument.
4. Set **Scope** to `Parameter` and click **Apply**.

   The input port for the parameter argument no longer appears in the MATLAB Function block.

Note Parameter arguments appear as arguments in the function header of the MATLAB Function block to maintain MATLAB consistency. As a result, you can test functions in a MATLAB Function block by copying and pasting them to MATLAB.

Resolve Signal Objects for Output Data

In this section...

Implicit Signal Resolution

MATLAB Function blocks participate in signal resolution with Simulink signal objects. By default, output data from MATLAB Function blocks become associated with Simulink signal objects of the same name during a process called *implicit signal resolution*.

By default, implicit signal resolution generates a warning when you update the chart in the Simulink model. The following sections show you how to manage implicit signal resolution at various levels of the model hierarchy. See “Symbol Resolution” on page 59-136 and “Explicit and Implicit Symbol Resolution” on page 59-139 for more information.

Eliminating Warnings for Implicit Signal Resolution in the Model

To enable implicit signal resolution for all signals in a model, but eliminate the attendant warnings, follow these steps:

1 In the Simulink Editor, select **Simulation** > **Model Configuration Parameters**.

The Configuration Parameters dialog appears.

2 In the left pane of the Configuration Parameters dialog, under Diagnostics, select **Data Validity**.

Data Validity configuration parameters appear in the right pane.

3 In the Signal resolution field, select **Explicit and implicit**.

Disabling Implicit Signal Resolution for a MATLAB Function Block

To disable implicit signal resolution for a MATLAB Function block in your model, follow these steps:

1. Right-click the MATLAB Function block and select **Block Parameters (Subsystem)** in the context menu.

   The Block Parameters dialog opens.
2. In the Permit hierarchical resolution field, select **ExplicitOnly** or **None**, and click **OK**.

Forcing Explicit Signal Resolution for an Output Data Signal

To force signal resolution for an output signal in a MATLAB Function block, follow these steps:

1. In the Simulink model, right-click the signal line connected to the output that you want to resolve and select **Properties** from the context menu.
2. In the Signal Properties dialog, enter a name for the signal that corresponds to the signal object.
3. Select the **Signal name must resolve to Simulink signal object** check box and click **OK**.

Types of Structures in MATLAB Function Blocks

In MATLAB Function blocks, you can define structure data as inputs or outputs that interact with bus signals. MATLAB Function blocks also support arrays of buses. You can also define structures inside MATLAB functions that are not part of MATLAB Function blocks.

The following table summarizes how to create different types of structures in MATLAB Function blocks:

Scope	How to Create	Details
Input	Create structure data with scope of `Input`.	You can create structure data as inputs or outputs in the top-level MATLAB function for interfacing to other environments. See "Create Structures in MATLAB Function Blocks" on page 41-94.
Output	Create structure data with scope of `Output`.	
Local	Create a local variable implicitly in a MATLAB function.	See "Define Scalar Structures for Code Generation" on page 51-4.
Persistent	Declare a variable to be persistent in a MATLAB function.	See `persistent`.
Parameter	Create structure data with scope of `Parameter`.	See "Define and Use Structure Parameters" on page 41-101.

Structures in MATLAB Function blocks can contain fields of any type and size, including muxed signals, buses, and arrays of structures.

Attach Bus Signals to MATLAB Function Blocks

For an example of how to use structures in a MATLAB Function block, open the model emldemo_bus_struct.

In this model, a MATLAB Function block receives a bus signal using the structure `inbus` at input port 1 and outputs two bus signals from the structures `outbus` at output port 1 and `outbus1` at output port 2. The input signal comes from the Bus Creator block `MainBusCreator`, which bundles signals `ele1`, `ele2`, and `ele3`. The signal `ele3` is the output of another Bus Creator block `SubBusCreator`, which bundles the signals `a1` and `a2`. The structure `outbus` connects to a Bus Selector block `BusSelector1`; the structure `outbus1` connects to another Bus Selector block `BusSelector3`.

To explore the MATLAB function `fcn`, double-click the MATLAB Function block. Notice that the code implicitly defines a local structure variable `mystruct` using the `struct` function, and uses this local structure variable to initialize the value of the first output `outbus`. It initializes the second output `outbus1` to the value of field `ele3` of structure `inbus`.

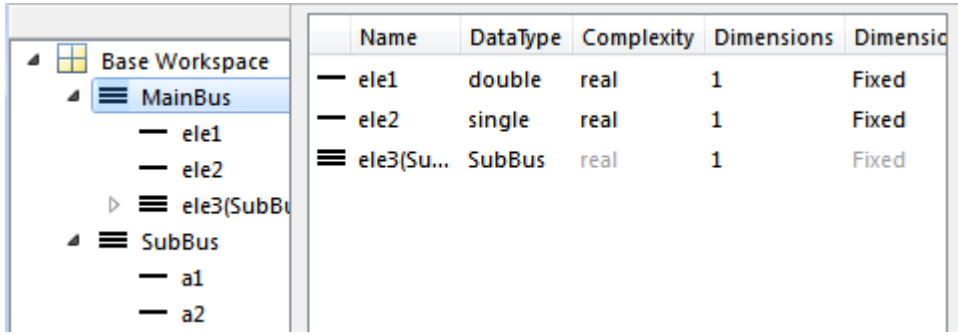
Structure Definitions in Example

Here are the definitions of the structures in the MATLAB Function block in the example, as they appear in the Ports and Data Manager:

	Name	Scope	Port	Resolve Signal	DataType	Size
	inbus	Input	1		Inherit: Same as Simulink	-1
	outbus	Output	1		Bus: MainBus	1
	outbus1	Output	2		Bus: SubBus	1

Bus Objects Define Structure Inputs and Outputs

Each structure input and output must be defined by a `Simulink.Bus` object in the base workspace (see “Create Structures in MATLAB Function Blocks” on page 41-94). This means that the structure shares the same properties as the bus object, including number, name, type, and sequence of fields. In this example, the following bus objects define the structure inputs and outputs:



The `Simulink.Bus` object `MainBus` defines structure input `inbus` and structure output `outbus`. The `Simulink.Bus` object `SubBus` defines structure output `outbus1`. Based on these definitions, `inbus` and `outbus` have the same properties as `MainBus` and, therefore, reference their fields by the same names as the fields in `MainBus`, using dot notation (see "Index Substructures and Fields" on page 41-92). Similarly, `outbus1` references its fields by the same names as the fields in `SubBus`. Here are the field references for each structure in this example:

Structure	First Field	Second Field	Third Field
`inbus`	`inbus.ele1`	`inbus.ele2`	`inbus.ele3`
`outbus`	`outbus.ele1`	`outbus.ele2`	`outbus.ele3`
`outbus1`	`outbus1.a1`	`outbus1.a2`	—

How Structure Inputs and Outputs Interface with Bus Signals

Buses in a Simulink model appear inside the MATLAB Function block as structures; structure outputs from the MATLAB Function block appear as buses in Simulink models. When you create structure inputs, the MATLAB Function block determines the type, size, and complexity of the structure from the input signal. When you create structure outputs, you must define their type, size, and complexity in the MATLAB function.

You connect structure inputs and outputs from MATLAB Function blocks to any bus signal, including:

- Blocks that output bus signals — such as Bus Creator blocks
- Blocks that accept bus signals as input — such as Bus Selector and Gain blocks
- S-Function blocks
- Other MATLAB Function blocks

You can use global bus type data in Data Store Memory blocks with MATLAB Function blocks. For more information on using buses and Data Store Memory, see “Data Stores with Buses and Arrays of Buses” on page 62-30.

Working with Virtual and Nonvirtual Buses

MATLAB Function blocks supports nonvirtual buses only (see “Virtual and Nonvirtual Buses” on page 65-4). For MATLAB Function block bus inputs, incoming virtual bus signals are converted to nonvirtual buses.

Rules for Defining Structures in MATLAB Function Blocks

Follow these rules when defining structures in MATLAB Function blocks:

- For each structure input or output in a MATLAB Function block, you must define a `Simulink.Bus` object in the base workspace to specify its type.
- MATLAB Function blocks support nonvirtual buses only.

Index Substructures and Fields

As in MATLAB, you index substructures and fields structures in MATLAB Function blocks by using dot notation. However, for code generation from MATLAB, you must reference field values individually (see “Structure Definition for Code Generation” on page 51-2).

For example, in the emldemo_bus_struct model described in “Attach Bus Signals to MATLAB Function Blocks” on page 41-88, the MATLAB function uses dot notation to index fields and substructures:

```
function [outbus, outbus1] = fcn(inbus)
%#codegen
substruct.a1 = inbus.ele3.a1;
substruct.a2 = int8([1 2;3 4]);

mystruct = struct('ele1',20.5,'ele2',single(100),
                  'ele3',substruct);

outbus = mystruct;
outbus.ele3.a2 = 2*(substruct.a2);

outbus1 = inbus.ele3;
```

The following table shows how the code generation software resolves symbols in dot notation for indexing elements of the structures in this example:

Dot Notation	Symbol Resolution
`substruct.a1`	Field `a1` of local structure `substruct`
`inbus.ele3.a1`	Value of field `a1` of field `ele3`, a substructure of structure input`inbus`
`inbus.ele3.a2(1,1)`	Value in row 1, column 1 of field `a2` of field `ele3`, a substructure of structure input `inbus`

Create Structures in MATLAB Function Blocks

Here is the workflow for creating a structure in a MATLAB Function block:

1. Decide on the type (or scope) of the structure (see "Types of Structures in MATLAB Function Blocks" on page 41-86).
2. Based on the scope, follow these guidelines for creating the structure:

For Structure Scope:	Follow These Steps:
Input	**a** Create a `Simulink.Bus` object in the base workspace to define the structure input. **b** Add data to the MATLAB Function block, as described in "Adding Data to a MATLAB Function Block" on page 41-49. The data should have the following properties • **Scope** = `Input` • **Type** = `Bus: <object name>` For `<object name>`, enter the name of the `Simulink.Bus` object that defines the structure input See "Rules for Defining Structures in MATLAB Function Blocks" on page 41-91.
Output	**a** Create a `Simulink.Bus` object in the base workspace to define the structure output. **b** Add data to the MATLAB Function block with the following properties: • **Scope** = `Output` • **Type** = `Bus: <object name>` For `<object name>`, enter the name of the `Simulink.Bus` object that defines the structure output **c** Define and initialize the output structure implicitly as a variable in the MATLAB function, as described in "Structure Definition for Code Generation" on page 51-2. **d** Make sure the number, type, and size of fields in the output structure variable definition match the properties of the `Simulink.Bus` object.

For Structure Scope:	Follow These Steps:
Local	Define the structure implicitly as a local variable in the MATLAB function, as described in "Structure Definition for Code Generation" on page 51-2. By default, local variables in MATLAB Function blocks are temporary.
Persistent	Define the structure implicitly as a persistent variable in the MATLAB function.
Parameter	**a** Create a structure variable in the base workspace. **b** Add data to the MATLAB Function block with the following properties: • **Name** = same name as the structure variable you created in step 1. • **Scope** = `Parameter` See "Define and Use Structure Parameters" on page 41-101.

Assign Values to Structures and Fields

You can assign values to any structure, substructure, or field in a MATLAB Function block. Here are the guidelines:

Operation	Conditions
Assign one structure to another structure	You must define each structure with the same number, type, and size of fields, either as `Simulink.Bus` objects in the base workspace or locally as implicit structure declarations (see "Create Structures in MATLAB Function Blocks" on page 41-94).
Assign one structure to a substructure of a different structure and vice versa	You must define the structure with the same number, type, and size of fields as the substructure, either as `Simulink.Bus` objects in the base workspace or locally as implicit structure declarations.
Assign an element of one structure to an element of another structure	The elements must have the same type and size.

For example, the following table presents valid and invalid structure assignments based on the specifications for the model described in "Attach Bus Signals to MATLAB Function Blocks" on page 41-88:

Assignment	Valid or Invalid?	Rationale
`outbus = mystruct;`	Valid	Both `outbus` and `mystruct` have the same number, type, and size of fields. The structure `outbus` is defined by the `Simulink.Bus` object `MainBus` and `mystruct` is defined locally to match the field properties of `MainBus`.
`outbus = inbus;`	Valid	Both `outbus` and `inbus` are defined by the same `Simulink.Bus` object, `MainBus`.
`outbus1 = inbus.ele3;`	Valid	Both `outbus1` and `inbus.ele3` have the same type and size because each is defined by the `Simulink.Bus` object `SubBus`.

Assignment	Valid or Invalid?	Rationale
`outbus1 = inbus;`	Invalid	The structure `outbus1` is defined by a different `Simulink.Bus` object than the structure `inbus`.

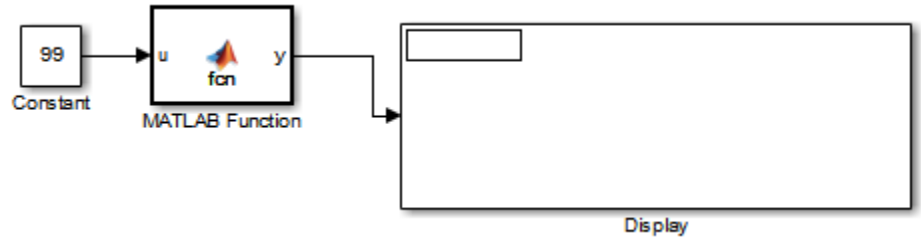
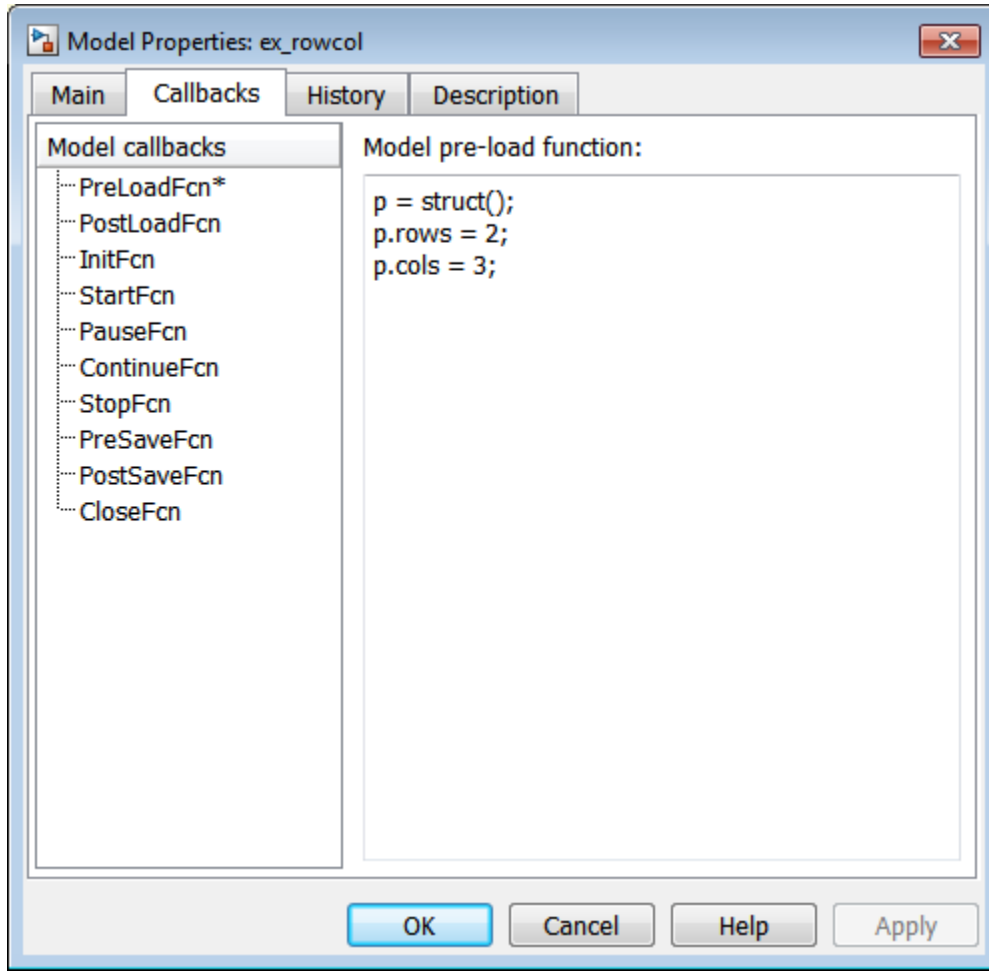
Initialize a Matrix Using a Nontunable Structure Parameter

The following simple example uses a nontunable structure parameter input to initialize a matrix output. The model looks like this:



This model defines a structure variable `p` in its pre-load callback function, as follows:



The structure `p` has two fields, `rows` and `cols`, which specify the dimensions of a matrix. The MATLAB Function block uses a constant input `u` to initialize the matrix output `y`. Here is the code:

```
function y = fcn(u, p)
y = zeros(p.rows,p.cols) + u;
```

Running the model initializes each element of the 2-by-3 matrix `y` to 99, the value of `u`:

Define and Use Structure Parameters

In this section...

Defining Structure Parameters

To define structure parameters in MATLAB Function blocks, follow these steps:

1 Define and initialize a structure variable

A common method is to create a structure in the base workspace.

2 In the Ports and Data Manager, add data in the MATLAB Function block with the following properties:

Property	What to Specify
Name	Enter same name as the structure variable you defined in the base workspace
Scope	Select `Parameter`
Tunable	Leave checked if you want to change (tune) the value of the parameter during simulation; otherwise, clear to make the parameter nontunable and preserve the initial value during simulation
Type	Select `Inherit: Same as Simulink`

3 Click **Apply**.

FIMATH Properties of Nontunable Structure Parameters

FIMATH properties for nontunable structure parameters containing fixed-point values are based on the initial values of the structure. They do *not* come from the FIMATH properties specified for fixed-point input signals to the parent MATLAB Function block. (These FIMATH properties appear in the properties dialog box for MATLAB Function blocks.)

Limitations of Structures and Buses in MATLAB Function Blocks

- Structures in MATLAB Function blocks support a subset of the operations available for MATLAB structures (see “Structures”).
- You cannot use structures that contain cell arrays or classes for Simulink signals, parameters, or data store memory.
- You cannot use variable-size data with arrays of buses (see “Array of Buses Requirements and Limitations” on page 65-123).

Declare Variable-Size Inputs and Outputs

By default, a MATLAB Function block input signal or output signal is not variable-size. To make the signal variable-size:

1. In the MATLAB Function Block Editor, select **Edit Data**.
2. Select the input or output signal.
3. Select the **Variable size** check box.
4. Enter the size according to this table.

For:	Specify
Input	To inherit the size from Simulink, enter `-1`. Otherwise, specify the explicit size and upper bound. For example, to specify a 2-by-4 matrix, enter `[2 4]`.
Output	Specify the explicit size and upper bound.

Use a Variable-Size Signal in a Filtering Algorithm

In this section...

About the Example

This example uses a variable-size vector to store the values of a white noise signal. The size of the vector can vary at run time because the signal values get pruned by functions that:

- Filter out signal values that are not unique within a specified tolerance of each other.
- Average every two signal values and output only the resulting means.

Simulink Model

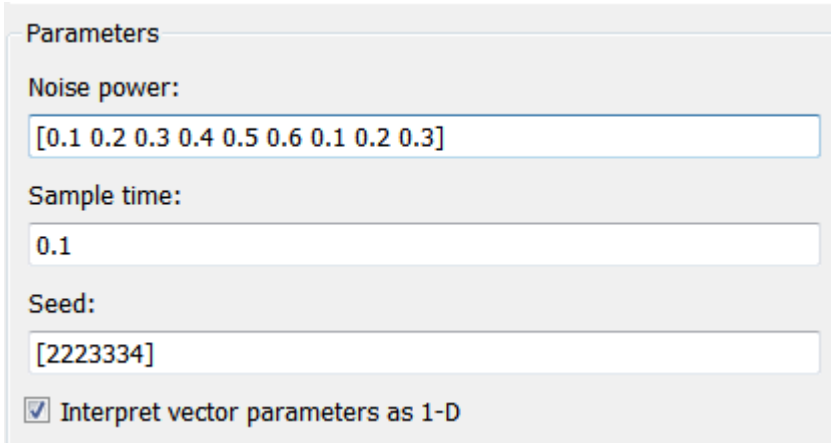
Open the example model by typing `emldemo_process_signal` at the MATLAB command prompt. The model contains the following blocks:

Simulink Block	Description
Band-Limited White Noise	Generates a set of normally distributed random values as the source of the white noise signal.
MATLAB Function `uniquify`	Filters out signal values that are not unique to within a specified tolerance of each other.
MATLAB Function `avg`	Outputs the average of a specified number of unique signal values.
Unique values	Scope that displays the unique signal values output from the `uniquify` function.

Simulink Block	Description
Average values	Scope that displays the average signal values output from the `avg` function.

Source Signal

The band-limited white noise signal has these properties:



The size of the noise power value defines the size of the array that holds the signal values. This array is a 1-by-9 vector of double values.

MATLAB Function Block: uniquify

This block filters out signal values that are not within a tolerance of 0.2 of each other. Here is the code:

```
function y = uniquify(u) %#codegen
y = emldemo_uniquetol(u,0.2);
```

The `uniquify` function calls an external MATLAB function `emldemo_uniquetol` to filter the signal values. `uniquify` passes the 1-by-9 vector of white noise signal values as the first argument and the tolerance value as the second argument. Here is the code for `emldemo_uniquetol`:

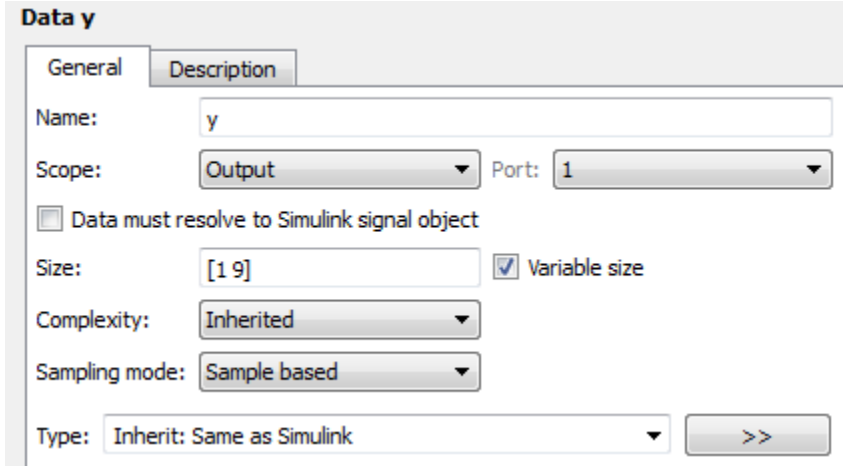
```
function B = emldemo_uniquetol(A,tol) %#codegen
```

```
A = sort(A);
coder.varsize('B',[1 100]);
B = A(1);
k = 1;
for i = 2:length(A)
    if abs(A(k) - A(i)) > tol
        B = [B A(i)];
        k = i;
    end
end
```

`emldemo_uniquetol` returns the filtered values of `A` in an output vector `B` so that `abs(B(i) - B(j)) > tol` for all `i` and `j`. Every time Simulink samples the Band-Limited White Noise block, it generates a different set of random values for `A`. As a result, `emldemo_uniquetol` may produce a different number of output signals in `B` each time it is called. To allow `B` to accommodate a variable number of elements, `emldemo_uniquetol` declares it as variable-size data with an explicit upper bound:

```
coder.varsize('B',[1 100]);
```

In this statement, `coder.varsize` declares `B` as a vector whose first dimension is fixed at 1 and whose second dimension can grow to a maximum size of 100. Accordingly, output `y` of the `uniquify` block must also be variable-size so that it can pass the values returned from `emldemo_uniquetol` to the **Unique values** scope. Here are the properties of `y`:



For variable-size outputs, you must specify an explicit size and upper bound, shown here as [1 9].

MATLAB Function Block: avg

This block averages signal values filtered by the `uniquify` block as follows:

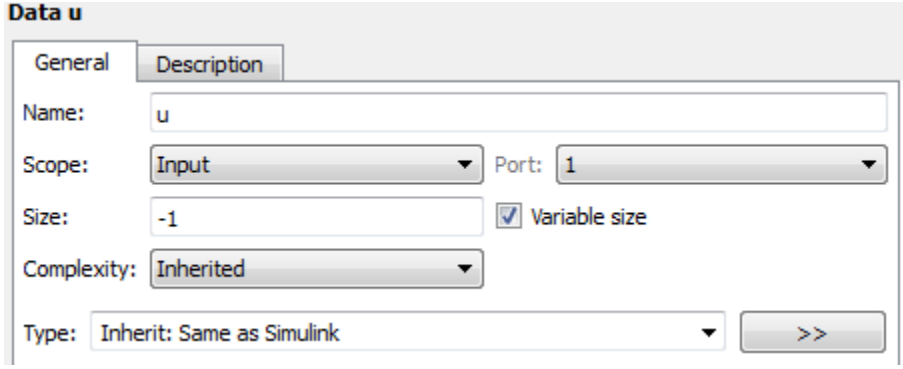
If number of signal values is	The MATLAB Function block
> 1 and divisible by 2	Averages every consecutive pair of values
> 1 but *not* divisible by 2	Drops the first (smallest) value and average the remaining consecutive pairs
= 1	Returns the value unchanged

The `avg` function outputs the results to the **Average values** scope. Here is the code:

```
function y = avg(u) %#codegen

if numel(u) == 1
    y = u;
else
    k = numel(u)/2;
    if k ~= floor(k)
        u = u(2:numel(u));
    end
    y = emldemo_navg(u,2);
end
```

Both input `u` and output `y` of `avg` are declared as variable-size vectors because the number of elements varies depending on how the `uniquify` function block filters the signal values. Input `u` inherits its size from the output of `uniquify`.



The `avg` function calls an external MATLAB function `emldemo_navg` to calculate the average of every two consecutive signal values. Here is the code for `emldemo_navg`:

```
function B = emldemo_navg(A,n) %#codegen

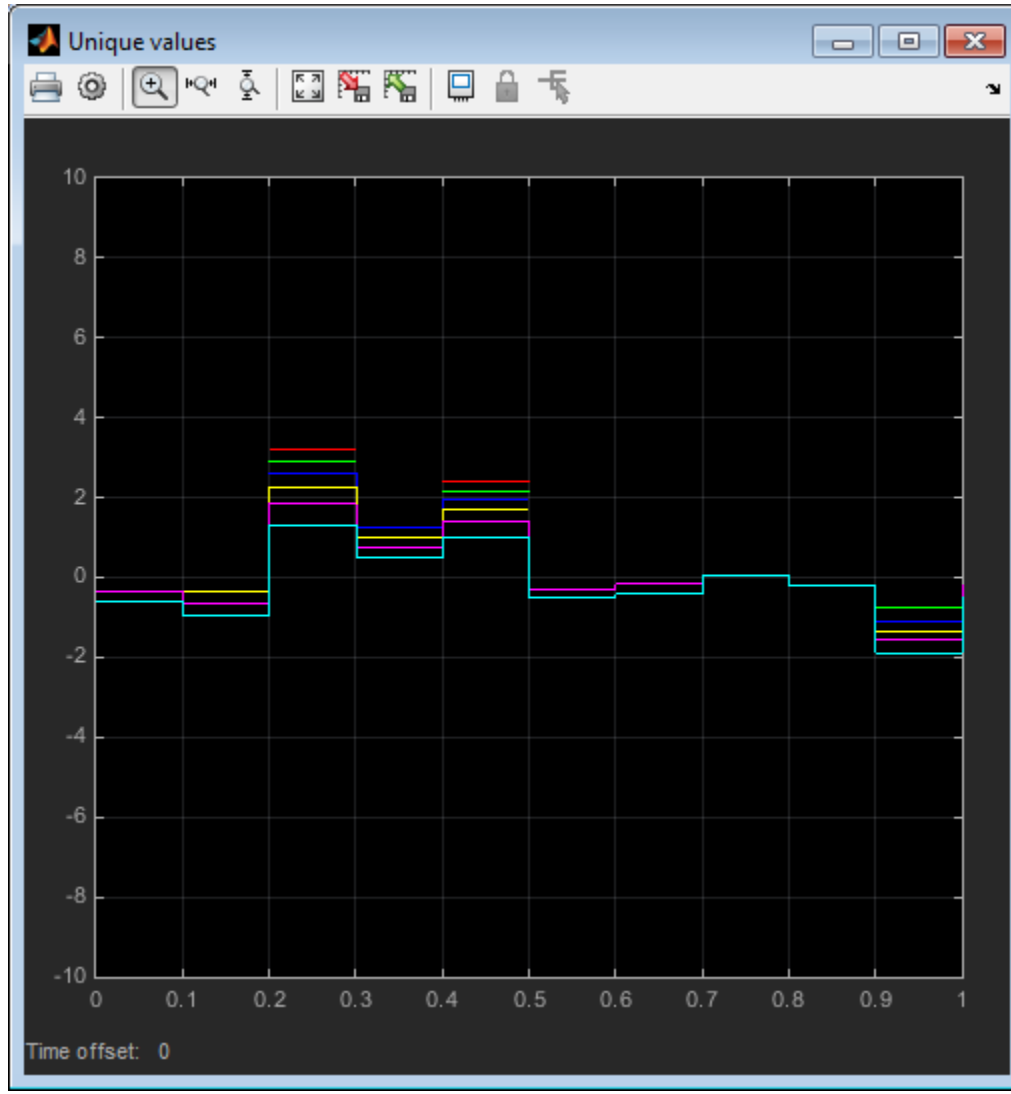
assert(n>=1 && n<=numel(A));

B = zeros(1,numel(A)/n);
k = 1;
for i = 1 : numel(A)/n
     B(i) = mean(A(k + (0:n-1)));
     k = k + n;
end
```

Variable-Size Results

Simulating the model produces the following results:

- The `uniquify` block outputs a variable number of signal values each time it executes:



- The `avg` block outputs a variable number of signal values each time it executes — approximately half the number of the unique values:

Control Memory Allocation for Variable-Size Arrays in a MATLAB Function Block

Dynamic memory allocation allocates memory on the heap as needed at run time, instead of allocating memory statically on the stack. You can use dynamic memory allocation for arrays inside a MATLAB Function block.

You cannot use dynamic memory allocation for:

- Input and output signals. Variable-size input and output signals must have an upper bound.
- Parameters or global variables. Parameters and global variables must be fixed-size.
- Fields of bus arrays. Bus arrays cannot have variable-size fields.
- Discrete state properties of System objects associated with a MATLAB System block.

Dynamic memory allocation is beneficial when:

- You do not know the upper bound of an array.
- You do not want to allocate memory on the stack for large arrays.

Dynamic memory allocation and the freeing of this memory can result in slower execution of the generated code. To control the use of dynamic memory allocation for variable-size arrays in a MATLAB Function block, you can:

- Provide upper bounds for variable-size arrays on page 41-114.
- Disable dynamic memory allocation for MATLAB Function blocks on page 41-115.
- Modify the dynamic memory allocation threshold on page 41-115.

Provide Upper Bounds for Variable-Size Arrays

For an unbounded variable-size array, the code generator allocates memory dynamically on the heap. For a bounded variable-size array, if the size, in bytes, is less than the dynamic memory allocation threshold, the code generator allocates memory statically on the stack. To avoid dynamic memory allocation, provide upper bounds for the array dimensions so that the size of the array, in bytes, is less than the dynamic memory allocation threshold. See “Specify Upper Bounds for Variable-Size Arrays” on page 50-5.

Disable Dynamic Memory Allocation for MATLAB Function Blocks

By default, dynamic memory allocation for MATLAB Function blocks is enabled for GRT-based targets and disabled for ERT-based targets. To change the setting, in the Configuration Parameters dialog box, clear or select **Dynamic memory allocation in MATLAB Function blocks**.

If you disable dynamic memory allocation, you must provide upper bounds for variable-size arrays.

Modify the Dynamic Memory Allocation Threshold

Instead of disabling dynamic memory allocation for all variable-size arrays, you can use the dynamic memory allocation threshold to specify when the code generator uses dynamic memory allocation.

Use the dynamic memory allocation threshold to:

- Disable dynamic memory allocation for smaller arrays. For smaller arrays, static memory allocation can speed up generated code. However, static memory allocation can lead to unused storage space. You can decide that the unused storage space is not a significant consideration for smaller arrays.
- Enable dynamic memory allocation for larger arrays. For larger arrays, when you use dynamic memory allocation, you can significantly reduce storage requirements.

The default value of the dynamic memory allocation threshold is 64 kilobytes. To change the threshold, in the Configuration Parameters dialog box, set the **Dynamic memory allocation threshold in MATLAB Function blocks** parameter.

To use dynamic memory allocation for all variable-size arrays, set the threshold to `0`.

- “Use Dynamic Memory Allocation for Variable-Size Arrays in a MATLAB Function Block” on page 41-117

Use Dynamic Memory Allocation for Variable-Size Arrays in a MATLAB Function Block

This example shows how to use dynamic memory allocation for variable-size arrays in a MATLAB Function block. Dynamic memory allocation allocates memory on the heap as needed at run time, instead of allocating memory statically on the stack. Dynamic memory allocation is beneficial when:

- You do not know the upper bound of an array.
- You do not want to allocate memory on the stack for large arrays.

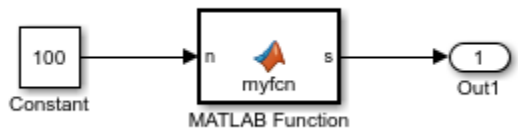
You can use dynamic memory allocation only for arrays that are local to the MATLAB Function block.

You cannot use dynamic memory allocation for:

- Input and output signals. Variable-size input and output signals must have an upper bound.
- Parameters or global variables. Parameters and global variables must be fixed-size.
- Fields of bus arrays. Bus arrays cannot have variable-size fields.
- Discrete state properties of System objects associated with a MATLAB System block.

Create Model

Create this Simulink model that has a MATLAB Function block with an unbounded variable-size array.



1. Create a Simulink model `mymodel`.
2. Add a MATLAB Function block to the model.
3. In the MATLAB Function block, add this code:

```
function s = myfcn(n)
Z = rand(1,n);
```

```
s = sum(Z);
end
```

4 Add a Constant block to the left of the MATLAB Function block.

5 Add an Outport block to the right of the MATLAB Function block.

6 Connect the blocks.

Configure Model for Dynamic Memory Allocation

Make sure that you configure the model to use dynamic memory allocation for variable-size arrays in MATLAB Function blocks. In the Configuration Parameters dialog box, in the **Simulation Target > Advanced parameters** category, make sure that:

- The **Dynamic memory allocation in MATLAB Function blocks** check box is selected.
- The **Dynamic memory allocation threshold in MATLAB Function blocks** parameter has the default value 65536.

Simulate Model Using Dynamic Memory Allocation

1 Simulate the model.

2 In the MATLAB Function Editor, to open the MATLAB Function report, click **View Report**.

The variables tab shows that `Z` is a 1-by-:? array. The colon (:) indicates that the second dimension is variable-size. The question mark (?) indicates that the second dimension is unbounded.

Simulation must use dynamic memory allocation for `Z` because the second dimension of `Z` does not have an upper bound.

Use Dynamic Memory Allocation for Bounded Arrays

When an array is unbounded, the code generator must use dynamic memory allocation. If an array is bounded, the code generator uses dynamic memory allocation only if the array size, in bytes, is greater than or equal to the dynamic memory allocation threshold. The default value for this threshold is 65536.

Dynamic memory has a run-time performance cost. By controlling its use, you can improve execution speed.

If you make `Z` a bounded variable-size array with a size that is greater than the threshold, the code generator uses dynamic memory allocation for `Z`. For example:

1. In `mymodel`, modify `myfcn` so that `Z` has an upper bound of 500.

   ```
   function s = myfcn(n)
   assert(n < 500);
   Z = rand(1,n);
   s = sum(Z);
   end
   ```

2. Simulate the model.

   In the MATLAB Function report, you see that `Z` is a 1-by-:500 array. It is variable-size with an upper bound of 500.

3. Lower the dynamic memory allocation to a value less than or equal to `4000`, which is the size, in bytes, of `Z`. In the Configuration Parameters dialog box, in the **Simulation Target > Advanced parameters** category, set the **Dynamic memory allocation threshold in MATLAB Function blocks** parameter to 4000.

4. Simulate the model.

   The code generator uses dynamic memory allocation because the size of `Z` is equal to the dynamic memory allocation threshold, 4000.

Generate C Code That Uses Dynamic Memory Allocation

If you have Simulink Coder, you can generate C code for this model. Then, you can see how the code generator represents dynamically allocated arrays.

1. Configure the model to use a fixed-step solver. In the Configuration Parameters dialog box, in the **Solver** pane, under **Solver options**:

   - For **Type**, select `Fixed-step`.
   - For **Solver**, select `discrete (no continuous states)`.

2. Configure the model to create and use a code generation report. In the Configuration Parameters dialog box, in the **Code Generation > Report** pane, select **Create code generation report** and **Open report automatically**.

3. Edit the code in the MATLAB Function block so that it looks like this code:

   ```
   function s = myfcn(n)
   Z = rand(1,n);
   ```

```
s = sum(Z);
end
```

`Z` is an unbounded variable-size array.

4 Make sure that the model is configured for dynamic memory allocation:

- The **Dynamic memory allocation in MATLAB Function blocks** check box is selected.
- The **Dynamic memory allocation threshold in MATLAB Function blocks** parameter has the default value 65536.

5 Build the model.

6 In the code generation report, open `mymodel.c`. You can tell that the code generator used dynamic memory allocation for `Z` because you see the `emxArray` type `emxArray_real_T_mymodel_T` and `emxArray` utility functions, such as `mymodel_emxInit_real_T`. The code generator uses an `emxArray` type for variables whose memory is dynamically allocated. The generated code uses the `emxArray` utility functions to manage the `emxArrays`.

If you have Embedded Coder, you can customize the identifiers for `emxArray` types and the utility functions. See "Identifier Format Control" (Embedded Coder).

Code Generation for Enumerations

Enumerations represent a fixed set of named values. Enumerations help make your MATLAB code and generated C/C++ code more readable. For example, the generated code can test equality with code such as `if (x == Red)` instead of using `strcmp`. To generate C/C++ code, you must have Simulink Coder.

When you use enumerations in a `MATLAB Function` block, adhere to these restrictions:

Define Enumerations for MATLAB Function Blocks

You can define enumerations for MATLAB Function blocks in two ways:

- To import an externally defined enumeration, use the `Simulink.defineIntEnumType` function. See "Import Enumerations Defined Externally to MATLAB" on page 60-12.
- In a class definition file, define an enumerated type. For example:

```
classdef PrimaryColors < Simulink.IntEnumType
    enumeration
        Red(1),
        Blue(2),
        Yellow(4)
    end
end
```

If you define an enumerated type in a class definition file, the class must derive from one of these base types: `Simulink.IntEnumType`, `int8`, `uint8`, `int16`, `uint16`, or `int32`. Then, you can exchange enumerated data between MATLAB Function blocks and other Simulink blocks in a model.

If you use Simulink Coder to generate C/C++ code, you can use the enumeration class base type to control the size of an enumerated type in generated C/C++ code. You can:

- Represent an enumerated type as a fixed-size integer that is portable to different targets.

- Reduce memory usage.
- Interface with legacy code.
- Match company standards.

The base type determines the representation of the enumerated type in generated C/C++ code.

If the base type is `Simulink.IntEnumType`, the code generator produces a C enumeration type. Consider the following MATLAB enumerated type definition:

```
classdef LEDcolor < Simulink.IntEnumType
    enumeration
        GREEN(1),
        RED(2)
    end
end
```

This enumerated type definition results in the following C code:

```
typedef enum {
  GREEN = 1,
  RED
} LEDcolor;
```

For built-in integer base types, the code generator produces a `typedef` statement for the enumerated type and `#define` statements for the enumerated values. Consider the following MATLAB enumerated type definition:

```
classdef LEDcolor < int16
    enumeration
        GREEN(1),
        RED(2)
    end
 end
```

This enumerated type definition results in the following C code:

```
typedef int16_T LEDcolor;

#define GREEN                          ((LEDcolor)1)
#define RED                            ((LEDcolor)2)
```

To customize the code generated for an enumerated type, see “Customize Simulink Enumeration” on page 60-9.

Allowed Operations on Enumerations

For code generation, you are restricted to the operations on enumerations listed in this table.

Operation	Example	Notes
assignment operator: =		—
relational operators: < > <= >= == ~=	`xon == xoff`	Code generation does not support using == or ~= to test equality between an enumeration member and a string array, a character array, or cell array of character arrays.
cast operation	`double(LEDcolor.RED)`	—

Operation	Example	Notes

conversion to character array or string	`y = char(LEDcolor.RED);`
	`y1 = cast(LEDcolor.RED,'char');`
	`y2 = string(LEDcolor.RED);`
		• You can convert only compile-time scalar valued enumerations. For example, this code runs in MATLAB, but produces an error in code generation:
		`y2 = string(repmat(LEDcolor.RED,1,2));`
		• The code generator preserves enumeration names when the conversion inputs are constants. For example, consider this enumerated type definition:
		`classdef AnEnum < int32`
		`  enumeration`
		`  zero(0),`
		`  two(2),`
		`  otherTwo(2)`
		`  end`
		`end`
		Generated code produces "`two`" for
		`y = string(AnEnum.two)`
		and "`otherTwo`" for
		`y = string(AnEnum.two)`

indexing operation	`m = [1 2]`
	`n = LEDcolor(m)`
	`p = n(LEDcolor.GREEN)`
		—

control flow statements: if, switch, while	`if state == sysMode.ON`
	`  led = LEDcolor.GREEN;`
	`else`
	`  led = LEDcolor.RED;`
	`end`
		—

MATLAB Toolbox Functions That Support Enumerations

For code generation, you can use enumerations with these MATLAB toolbox functions:

- `cast`
- `cat`
- `char`
- `circshift`
- `enumeration`
- `fliplr`
- `flipud`
- `histc`
- `intersect`
- `ipermute`
- `isequal`
- `isequaln`
- `isfinite`
- `isinf`
- `ismember`
- `isnan`
- `issorted`
- `length`
- `permute`
- `repmat`
- `reshape`
- `rot90`
- `setdiff`
- `setxor`
- `shiftdim`
- `sort`
- `sortrows`
- `squeeze`
- `string`
- `union`

- `unique`

- "Add Enumerated Inputs, Outputs, and Parameters to a MATLAB Function Block" on page 41-127
- "Use Enumerations to Control an LED Display" on page 41-129

Add Enumerated Inputs, Outputs, and Parameters to a MATLAB Function Block

When you add enumerated inputs, outputs, or parameters to a MATLAB Function block, follow these guidelines:

- For inputs, inherit the type from the enumerated type of the connected Simulink signal or specify the enumeration explicitly.
- For outputs, specify the enumerated type explicitly.
- For tunable parameters, specify the enumerated type explicitly. For nontunable parameters, derive properties from an enumerated parameter in a parent Simulink masked subsystem or enumerated variable defined in the MATLAB base workspace.

To add enumerated data to a MATLAB Function block:

1. In the MATLAB Function Block Editor, select **Edit Data**.
2. In the Ports and Data Manager, select **Add > Data**.
3. In the **Name** field, enter a name for the enumerated data.

   For parameters, the name must match the enumerated masked parameter or workspace variable name.
4. In the **Type** field, specify an enumerated type.

   - For an explicit enumerated type, set **Type** to `Enum:<class name>`. Replace `<class name>` with the name of an enumerated data type that you defined in a MATLAB file on the MATLAB path.

     The **Complexity** field is not visible because enumerated data types do not support complex values.
   - To inherit the enumerated type from a connected Simulink signal (for inputs only), set **Type** to `Inherit:Same as Simulink`.

Use Enumerations to Control an LED Display

In this section...

This example shows how to use enumerations in a MATLAB Function block. The example shows how MATLAB Function blocks exchange enumerated data with other Simulink blocks.

The `emldemo_led_switch` model uses enumerations to represent the modes of a device that controls the colors of an LED display. The MATLAB Function block receives an enumerated input signal that represents the mode. The enumerated output signal represents the color that the LED displays.

Simulink Model

To open the model, at the command prompt, enter:

```
emldemo_led_switch
```

The model contains the blocks listed in this table.

Simulink Block	Description
Step	Provides source of the on/off signal. Outputs an initial value of 0 (off) and at 10 seconds steps up to a value of 1 (on).
Data Type Conversion from `double` to `int32`	Converts the `Step` signal of type `double` to type `int32`.

Simulink Block	Description
Data Type Conversion from `int32` to enumerated type `switchmode`	Converts the value of type `int32` to the enumerated type `switchmode`. TheData Type Conversion block parameters have these settings: • Output minimum: `[]` • Output maximum: `[]` • Output data type: `Enum:switchmode`
MATLAB Function block `checkState`	Evaluates the enumerated input `state` to determine the value of the enumerated output `ledval`. `state` inherits its enumerated type `switchmode` from the Simulink step signal. `ledval` has the type `Enum:led`.
Display	Displays the value of `ledval`.

Enumeration Class Definitions

The `switchmode` enumeration represents the allowed modes for the input to the `checkstate` block.

```
classdef switchmode < Simulink.IntEnumType
  enumeration
    OFF(0)
    ON(1)
  end
end
```

The `led` enumeration represents the colors that the`checkstate` block can output.

```
classdef led < Simulink.IntEnumType
    enumeration
        GREEN(1),
        RED(8)
    end
end
```

Both enumeration classes inherit from the built-in type `Simulink.IntEnumType` and reside on the MATLAB path.

MATLAB Function Block Function

The function `checkState` uses enumerations to activate an LED display, based on the state of a device. It lights a green LED display to indicate the ON state. It lights a red LED display to indicate the OFF state.

```
function ledval = checkState(state)
%#codegen

if state == switchmode.ON
    ledval = led.GREEN;
else
    ledval = led.RED;
end
```

Simulation

When you simulate the model, the Display block displays the state of the LED display. If you simulate the model for less than 10 seconds, the state is off. The Display block displays `RED`. If you simulate the model for more than 10 seconds, the state is on. The Display block displays `GREEN`.

Share Data Globally

In this section...

When Do You Need to Use Global Data?

You might need to use global data with a MATLAB Function block if:

- You have multiple MATLAB functions that use global variables and you want to call these functions from MATLAB Function blocks.
- You have an existing model that uses a large amount of global data and you are adding a MATLAB Function block to this model, and you want to avoid cluttering your model with additional inputs and outputs.
- You want to scope the visibility of data to parts of the model.

Using Global Data with the MATLAB Function Block

In Simulink, you store global data using data store memory. You implement data store memory using either Data Store Memory blocks or `Simulink.Signal` objects. How you store global data depends on the number and scope of your global variables. For more information, see “Local and Global Data Stores” on page 62-3 and “Choosing How to Store Global Data” on page 41-133.

How MATLAB Globals Relate to Data Store Memory

In MATLAB functions in Simulink, global declarations are not mapped to the MATLAB global workspace. Instead, you register global data with the MATLAB Function block to map the data to data store memory. This difference allows global data in MATLAB

functions to inter-operate with the Simulink solver and to provide diagnostics if they are misused.

A global variable resolves hierarchically to the closest data store memory with the same name in the model. The same global variable occurring in two different MATLAB Function blocks might resolve to different data store memory depending on the hierarchy of your model. You can use this ability to scope the visibility of data to a subsystem.

How to Use Globals with the MATLAB Function Block

To use global data in your MATLAB Function block, or in any code that this block calls, you must:

1. Declare a global variable in your MATLAB Function block, or in any code that is called by the MATLAB Function block.
2. Register a Data Store Memory block or `Simulink.Signal` object that has the same name as the global variable with the MATLAB Function block.

For more information, see “Storing Data Using Data Store Memory Blocks” on page 41-134 and “Storing Data Using Simulink.Signal Objects” on page 41-136.

Choosing How to Store Global Data

The following table summarizes whether to use Data Store Memory blocks or `Simulink.Signal` objects.

If you want to:	Use:	For more information:
Use a small number of global variables in a single model that does not use model reference.	Data Store Memory blocks. **Note** Using Data Store Memory blocks scopes the data to the model.	“Storing Data Using Data Store Memory Blocks” on page 41-134

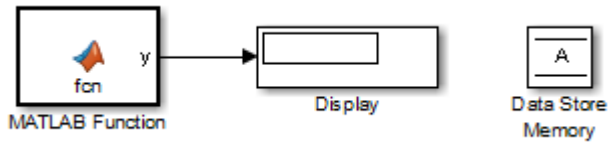
If you want to:	Use:	For more information:
Use a large number of global variables in a single model that does not use model reference.	`Simulink.Signal` objects defined in the model workspace. `Simulink.Signal` objects offer these advantages: • You do not have to add numerous Data Store Memory blocks to your model. • You can load the `Simulink.Signal` objects in from a MAT-file.	"Storing Data Using Simulink.Signal Objects" on page 41-136
Share data between multiple models (including referenced models).	`Simulink.Signal` objects defined in the base workspace **Note** If you use Data Store Memory blocks as well as `Simulink.Signal`, note that using Data Store Memory blocks scopes the data to the model.	"Storing Data Using Simulink.Signal Objects" on page 41-136

Storing Data Using Data Store Memory Blocks

This model demonstrates how a MATLAB Function block uses the global data stored in a Data Store Memory block `A`.

1 Open the `dsm_demo` model. At the MATLAB command line, enter:

```
run(docpath(fullfile(docroot, 'toolbox', 'simulink', 'examples', 'dsm_demo.mdl')))
```



2 Double-click the MATLAB Function block to open the MATLAB Function Block Editor.

The MATLAB Function block code declares a global variable `A`. The block modifies the value of `A` during each execution.

```
function y = fcn
%#codegen
global A;
A = A+1;
y = A;
```

3 Make sure the global variable is registered to the MATLAB Function block.

- **a** In the MATLAB Function Block Editor, select **Edit Data** to open the Ports and Data Manager dialog box.
- **b** In the Ports and Data Manager, select the data **A** in the left pane. This data uses the same name as the global variable.
- **c** The **Scope** of the data is set to `Data Store Memory`.

See also "Ports and Data Manager" on page 41-42.

4 Double-click the Data Store Memory block `A`. In the Block Parameters dialog box, you see that the **Data store name** `A` matches the global variable name. The block has an initial value of `25`.

When you add a Data Store Memory to your model:

- **a** Set the **Data store name** to match the name of the global variable in your MATLAB Function block code.
- **b** Set **Data type** to an explicit data type. The data type cannot be `auto`.
- **c** Set the **Signal type** and specify an **Initial value**.

5 Simulate the model.

The MATLAB Function block reads the initial value of global data stored in `A` and updates the value of `A` each time it executes.

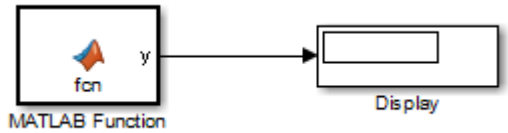
Storing Data Using Simulink.Signal Objects

This model demonstrates how a MATLAB Function block uses the global data stored in a `Simulink.Signal` object `A`.

1 Open the simulink_signal_local model.

Open the `simulink_signal_local` model. At the MATLAB command line, enter:

```
run(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
                          'examples', 'simulink_signal_local.mdl')))
```



The model uses a `Simulink.Signal` object in the model workspace.

Note To use the global data with multiple models, create a `Simulink.Signal` object in the base workspace .

2 Make sure that the `Simulink.Signal` object is added to the Model Explorer.

a From the model menu, select **View > Model Explorer**.

b In the left pane of the Model Explorer, select the model workspace for the `simulink_signal_local` model.

The **Contents** pane displays the data in the model workspace.

c Click the `Simulink.Signal` object `A`.

In the right pane, make sure that the Model Explorer displays these attributes for `A`.

Attribute	Value
Data type	`double`
Complexity	`real`
Dimensions	`1`
Initial value	`5`

See also "Search and Edit Using Model Explorer" on page 12-2.

3 Double-click the MATLAB Function block to open its editor.

The MATLAB Function block modifies the value of global data `A` each time it executes.

```
function y = fcn
%#codegen
global A;
A = A+1;
y = A;
```

4 Make sure the `Simulink.Signal` object is registered to the MATLAB Function block.

a In the MATLAB Function Block Editor, select **Edit Data** to open the Ports and Data Manager dialog box.

b In the Ports and Data Manager, select the data **A** in the left pane. This data uses the same name as the global variable.

c Set the **Scope** of the data to `Data Store Memory`.

See also "Ports and Data Manager" on page 41-42.

5 Simulate the model.

The MATLAB Function block reads the initial value of global data stored in `A` and updates the value of `A` each time it executes.

Using Data Store Diagnostics to Detect Memory Access Issues

You can configure your model to provide run-time and compile-time diagnostics for avoiding problems with data stores. Diagnostics are available in the Configuration Parameters dialog box and the parameters dialog box for the Data Store Memory block. These diagnostics are available for Data Store Memory blocks only, not for

`Simulink.Signal` objects. For more information on using data store diagnostics, see "Data Store Diagnostics" on page 62-3.

Note If you pass data store memory arrays to functions, optimizations such as `A=foo(A)` might result in the code generation software marking the entire contents of the array as read or written even though only some elements were accessed.

Limitations of Using Shared Data in MATLAB Function Blocks

There is no Data Store Memory support for:

- MATLAB structures
- Variable-sized data

Create Custom Block Libraries

In this section...

When to Use MATLAB Function Block Libraries

In Simulink, you can create your own block libraries as a way to reuse the functionality of blocks or subsystems in one or more models. If you want to reuse a set of MATLAB algorithms in Simulink models, you can encapsulate your MATLAB code in a MATLAB Function block library.

As with other Simulink block libraries, you can specialize each instance of MATLAB Function library blocks in your model to use different data types, sample times, and other properties. Library instances that inherit the same properties can reuse generated code

How to Create Custom MATLAB Function Block Libraries

Here is a basic workflow for creating custom block libraries with MATLAB Function blocks. To work through these steps with an example, see “Example: Creating a Custom Signal Processing Filter Block Library” on page 41-140.

1 Add polymorphic MATLAB code to MATLAB Function blocks in a Simulink model.

  Polymorphic code is code that can process data with different properties, such as type, size, and complexity.

2 Configure the blocks to inherit the properties you want to specialize.

  For a list of properties you can specialize, see “Properties You Can Specialize Across Instances of Library Blocks” on page 41-156.

3 Optionally, customize your library code using masking.

4 Add instances of MATLAB Function library blocks to a Simulink model.

Note If your MATLAB Function block library is masked, you cannot modify contents of the block with mask initialization code. The **Allow library block to modify its contents** option in the Mask dialog box is not supported for MATLAB Function block libraries.

Example: Creating a Custom Signal Processing Filter Block Library

What You Will Learn

This simple example takes you through the workflow described in "How to Create Custom MATLAB Function Block Libraries" on page 41-139 to show you how to:

- Create a library of signal processing filter algorithms using MATLAB Function blocks
- Customize one of the library blocks using mask parameters
- Convert one of the filter algorithms to source-protected P-code that you can call from a MATLAB Function library block

About the Filter Algorithms

The MATLAB filter algorithms are:

my_fft

Performs a discrete Fourier transform on an input signal. The input can be a vector, matrix, or multidimensional array whose length is a power of 2.

my_conv

Convolves two input vector signals. Outputs a subsection of the convolution with a size specified by a mask parameter, `Shape`.

my_sobel

Convolves a 2D input matrix with a Sobel edge detection filter.

Step 1: Add the Filter Algorithms to MATLAB Function Library Blocks

1. In Simulink, create a library model by selecting **File > New > Library**
2. Drag three MATLAB Function blocks into the model from the User-Defined Functions section of the Simulink Library Browser and name them:
   - `my_fft_filter`
   - `my_conv_filter`
   - `my_sobel_filter`
3. Save the library model as `my_filter_lib`.
4. Open the MATLAB Function block named `my_fft_filter`, replace the template code with the following code, and save the block:

   ```
   function y = my_fft(x)

   y = fft(x);
   ```
5. Replace the template code in `my_conv_filter` block with the following code and save the block:

   ```
   function c = my_conv(a, b)

   c = conv(a, b);
   ```
6. Replace the template code in `my_sobel_filter` block with the following code and save the block:

   ```
   function y = my_sobel(u)

   %% "my_sobel_filter" is a MATLAB function
   %%  on the  MATLAB path.
   y = my_sobel_filter(u);
   ```

   The `my_sobel` function acts as a wrapper that calls a MATLAB function, `my_sobel_filter`, on the code generation path. `my_sobel_filter` implements

the algorithm that convolves a 2D input matrix with a Sobel edge detection filter. By calling the function rather than inlining the code directly in the MATLAB Function block, you can reuse the algorithm both as MATLAB code and in a Simulink model. You will create `my_sobel_filter` next.

7 In the same folder where you created `my_filter_lib`, create a new MATLAB function `my_sobel_filter` with the following code:

```
function y = my_sobel_filter(u)

% Sobel edge detection filter
h = [1     2     1;...
     0     0     0;...
    -1    -2    -1];

y = abs(conv2(u, h));
```

Save the file as `my_sobel_filter.m`.

Step 2: Configure Blocks to Inherit Properties You Want to Specialize

In this example, the data in the signal processing filter algorithms must inherit size, type, and complexity from the Simulink model. By default, data in MATLAB Function blocks inherit these properties. To explicitly configure data to inherit properties:

1 Open a MATLAB Function block and select **Edit Data**.

2 In the left pane of the Ports and Data Manager, select the data of interest.

3 In the right pane, configure the data to inherit properties from Simulink:

To Inherit	What to Specify
Size	Enter `-1` in Size field
Complexity	Select **Inherited** from the Complexity menu
Type	Select **Inherit: Same as Simulink** from the Type menu

For example, if you open the MATLAB Function block my_fft_filter and look at the properties of input `x` in the Ports and Data Manager, you see that size, type, and complexity are inherited by default.

Note If your design has specific requirements or constraints, you can enter values for any of these properties, rather than inherit them from Simulink. For example, if your algorithm is not supposed to work with complex inputs, set **Complexity** to **Off**.

Step 3: Customize Your Library Using Masking

In this exercise you will modify the convolution filter `my_conv` to use a custom parameter `shape` that specifies what subsection of the convolution to output. To customize this algorithm for your library, place the `my_conv_filter` block under a masked subsystem and define `shape` as a mask parameter.

1 Convert the block to a masked subsystem:

   a Right-click the my_conv_filter block and select **Subsystem & Model Reference > Create Subsystem from Selection**.

   The my_conv_filter block changes to a subsystem block.

   b Change the name of the subsystem to my_conv_filter.

   c Right-click the my_conv_filter subsystem and select **Mask > Create Mask** from the context menu.

   The Mask Editor appears with the **Icon & Ports** tab open.

   d Enter in the **Icon drawing commands** text box:

```
disp('my_conv');
port_label('output', 1, 'c');
port_label('input', 1, 'a');
port_label('input', 2, 'b');
```

   e Select the **Parameters & Dialog** tab.

   f Highlight the **Parameters** line item in the Dialog box pane.

   g Add a popup-type parameter by clicking **Popup** under the **Parameter** list in the **Controls** pane.

   A new parameter will appear in the Dialog box pane.

   h In the **Property editor** pane, set the **Properties**:

Property	Value
Name	`shape`

Property	Value
Value	`full`
Prompt	`shape`
Type	`popup`

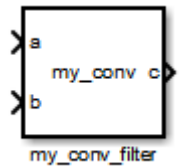
Type options	Open the Type Options Editor and enter:
	
	`full`
	`same`
	`valid`

i Set the **Attributes**, **Dialog**, and **Layout** properties in the **Property editor** pane:

Attributes, Dialog, and Layout Items	Value
Attributes	• Evaluate: Checked • Tunable: Cleared • Read only: Cleared • Hidden: Cleared • Never save: Cleared
Dialog	• Enable: Checked • Visible: Checked • Callback: no entry
Layout	• Item location: Grayed out • Prompt location: Left

j Click **OK**.

Your subsystem should now look like this:



2 Set subsystem properties for code reuse:

a Right-click the my_conv_filter subsystem and select **Block Parameters (Subsystem)** from the context menu.

b In the subsystem parameters dialog box, select the **Treat as atomic unit** check box.

The dialog box expands to display new fields.

c To generate a reusable function, select the Code Generation tab and in the **Function packaging** field, select `Reusable function` from the drop-down menu.

Note This is an optional step, required for this example. If you leave the default setting of **Auto**, the code generation software uses an internal rule to determine whether to inline the function or not.

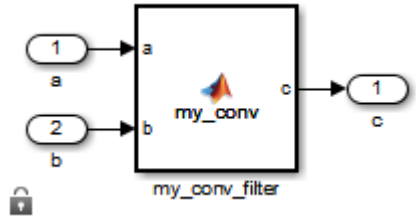
---

d Click **OK**.

3 Define the `shape` parameter in the MATLAB Function `my_conv`:

a Right-click the my_conv_filter subsystem and select **Mask > Look Under Mask** from the context menu.

The block diagram under the masked subsystem opens, containing the my_conv_filter block:



b Change the names of the port blocks to match the data names as follows:

Change:	To:
`In1`	`a`
`In2`	`b`
`Out1`	`c`

c Double-click the my_conv_filter block to open the MATLAB Function Block Editor.

d In the MATLAB Function Block Editor, select **Edit Data**.

e In the Ports and Data Manager, select **Add** > **Data**.

A new data element appears selected, along with its properties dialog.

f Enter the following properties:

Property	What To Specify
Name	Enter `shape`.
Scope	Select **Parameter**.
Tunable	Clear the box.

g Leave **Size**, **Complexity**, and **Type** as inherited (the defaults), as described in "Step 2: Configure Blocks to Inherit Properties You Want to Specialize" on page 41-142.

h Click **Apply**, close the Ports and Data Manager, and return to the MATLAB Function Block Editor.

4 Use the `shape` parameter to determine the size of the convolution to output:

a In the MATLAB Function Block Editor, modify the `my_conv` function to call `conv` with the right shape:

```
function c = my_conv(a, b, shape)
if shape == 1
    c = conv(a, b, 'full');
elseif shape == 2
    c = conv(a, b, 'same');
else
    c = conv(a, b, 'valid');
end
```

b Save your changes and close the MATLAB Function Block Editor.

Step 4: Add Instances of MATLAB Library Blocks to a Simulink Model

In this exercise, you will add specialized instances of the my_conv_filter library block to a simple test model.

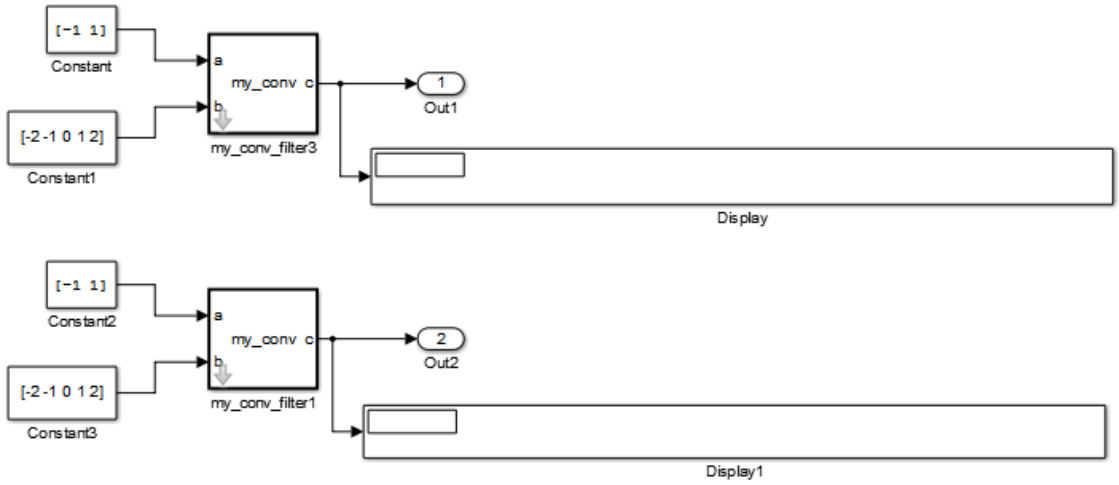
1 Open a new Simulink model.

For purposes of this exercise, set the following configuration parameters for simulation:

Pane	Section	What to Specify
Solver	**Solver options**	• Select **Fixed-Step** for **Type** • Select **discrete (no continuous states)** for **Solver** • Enter **1** for **Fixed-step size**
Data Import/Export	**Save options**	**Structure** for **Format**

2 Drag two instances of the my_conv_filter block from the `my_filter_lib` library into the model.

3 Add Constant, Outport, and Display blocks. Your model should look something like this:



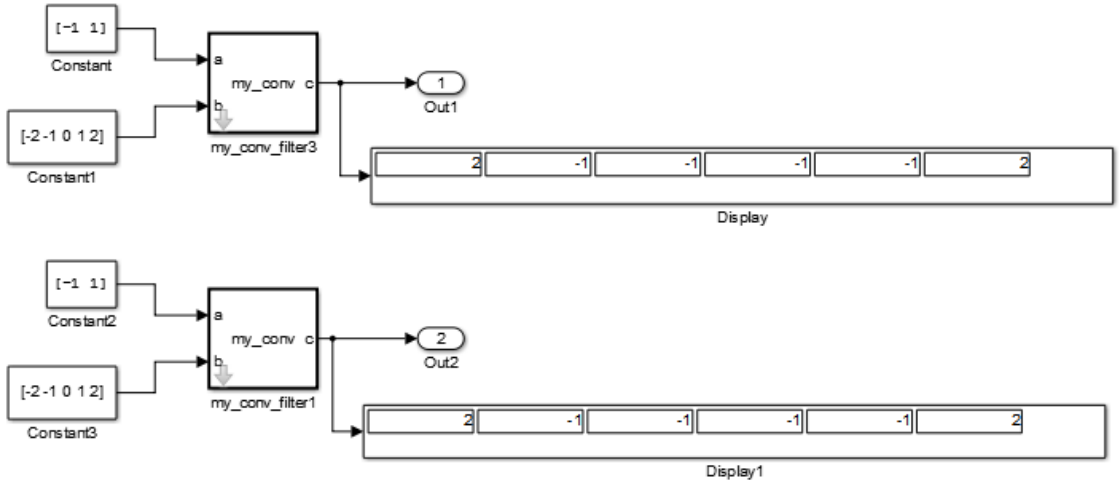
Both library instances share the same size, type, and complexity for inputs `a` and `b` respectively.

4 Double-click each library instance.

The `shape` parameter defaults to **full** for both instances.

5 Simulate the model.

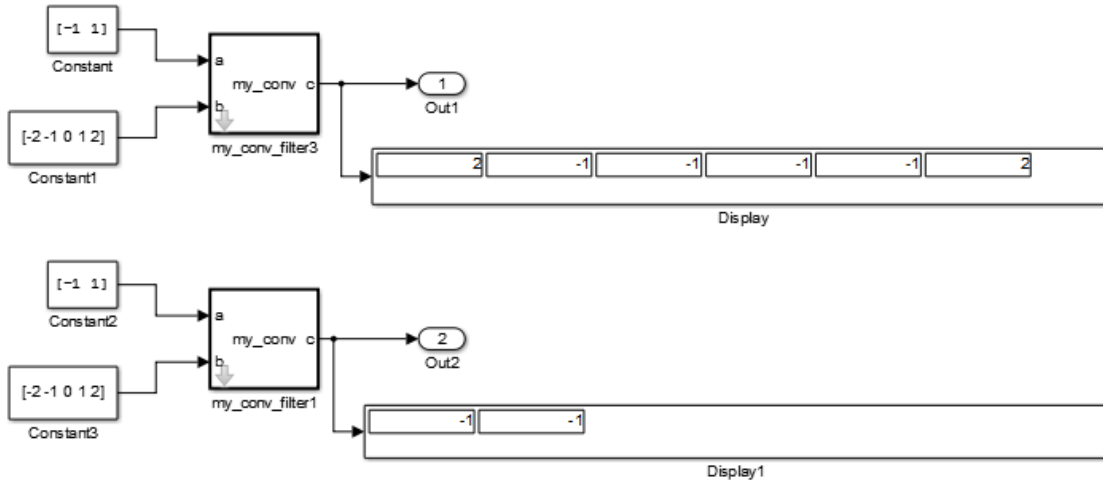
Each library instance outputs the same result, the full 2D convolution:



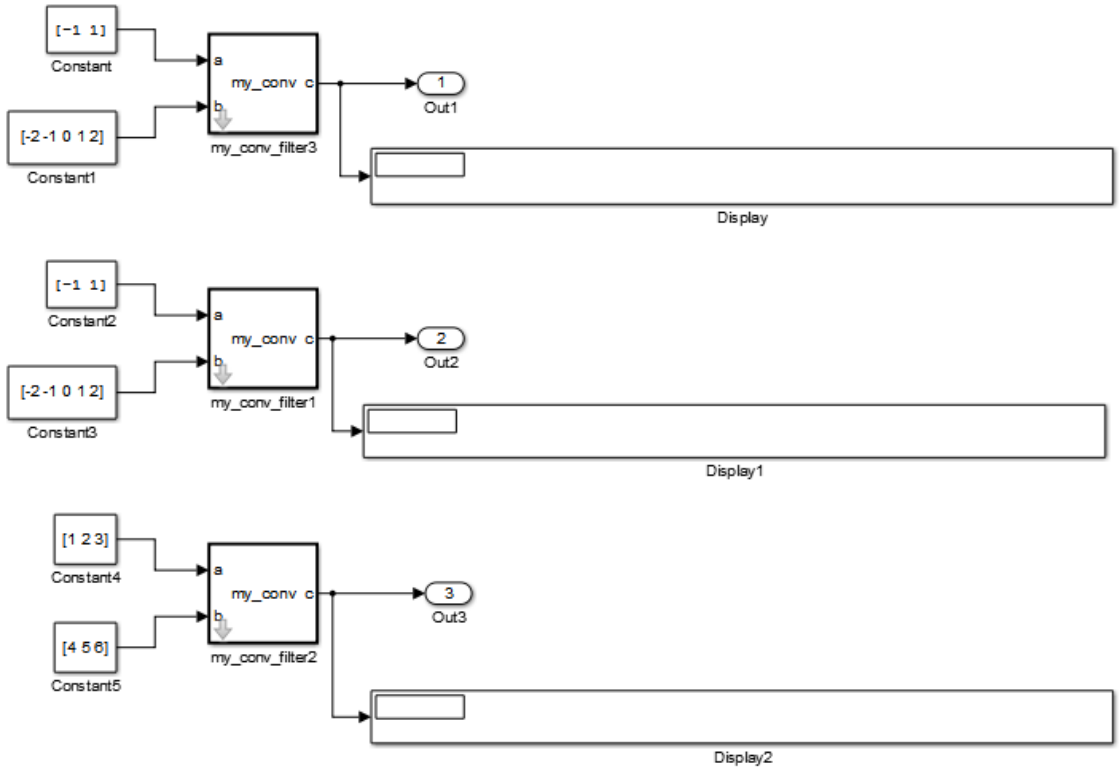
6 Specialize the second instance, my_conv_filter1 by setting the value of its `shape` parameter to **same**.

7 Now simulate the model again.

This time, the outputs have different sizes: my_conv_filter3 outputs the full 2D convolution, while my_conv_filter1 displays the central part of the convolution as a 1-by-2 vector, the same size as `a`:

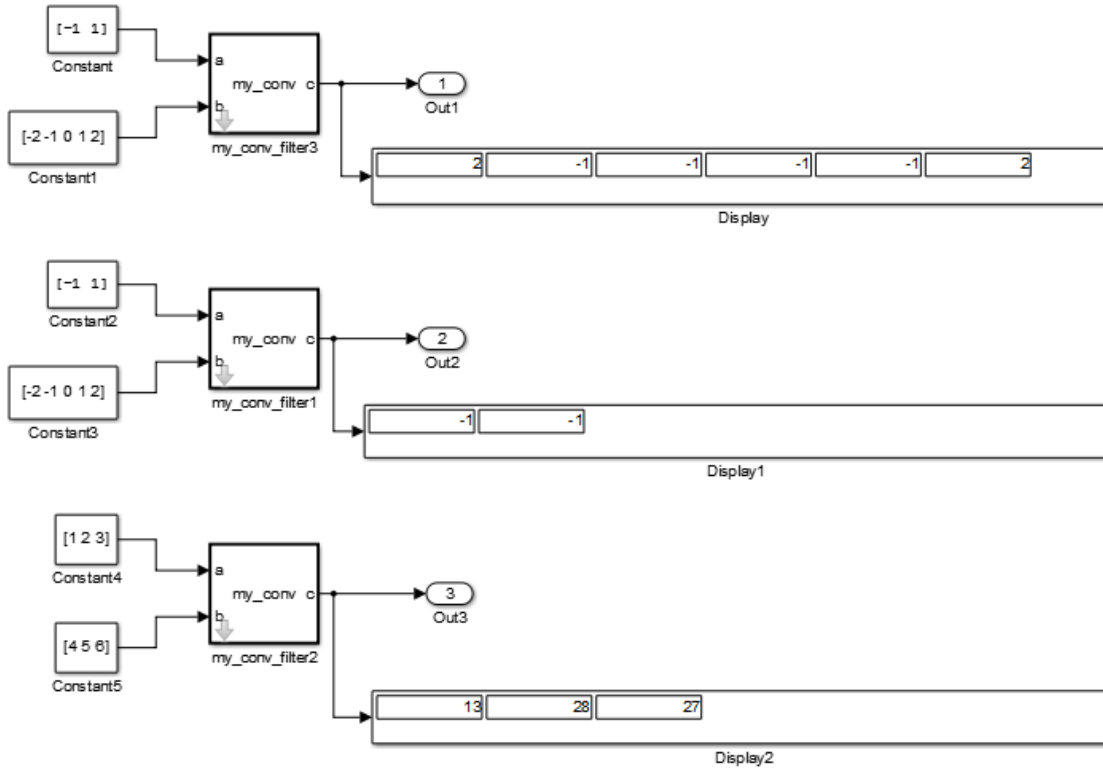


8 Now, add a third instance by copying my_conv_filter1. Specialize the new instance, my_conv_filter2, so that it does not inherit the same size inputs as the first two instances:



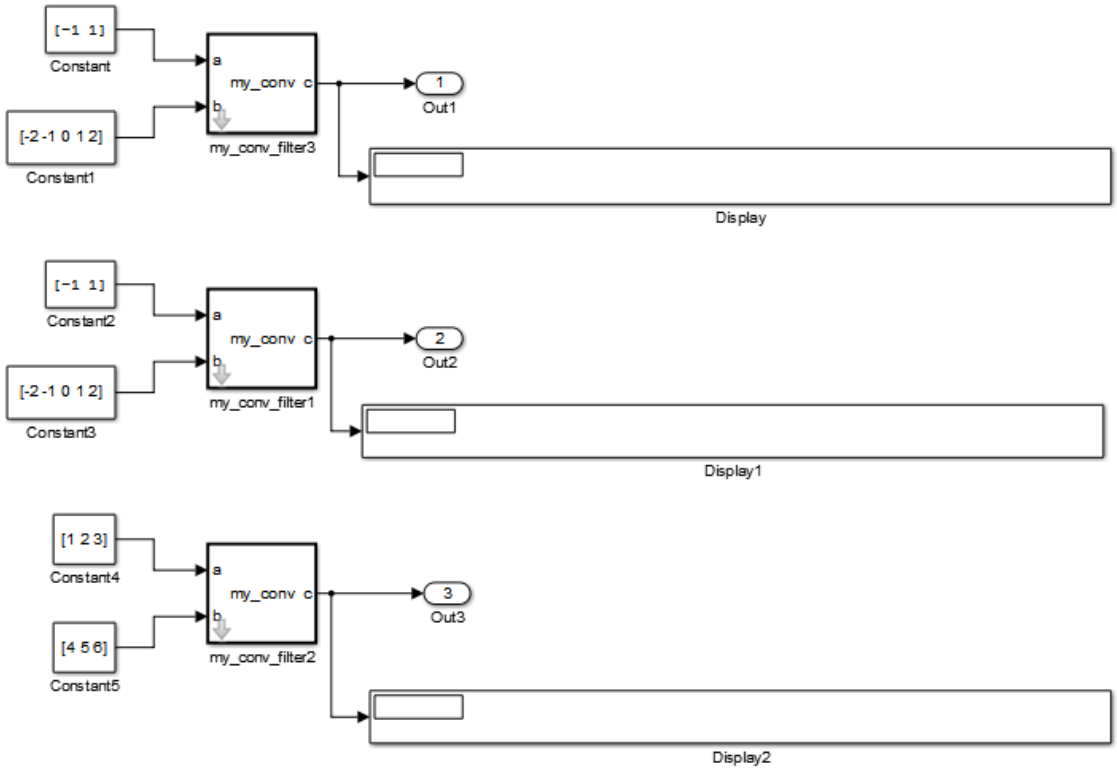
9 Simulate the model again.

This time, my_conv_filter1 and my_conv_filter2 each display the central part of the convolution, but the output sizes are different because each matches a different sized input `a`.



Code Reuse with Library Blocks

When instances of MATLAB Function library blocks inherit the same properties, they can reuse generated code, as illustrated by an example based on “Step 4: Add Instances of MATLAB Library Blocks to a Simulink Model” on page 41-146:



In this model, the library instances my_conv_filter and my_conv_filter1 inherit the same size, type, and complexity for each respective input. For each instance, input `a` is a 1-by-2 vector and input `b` is a 1-by-5 vector. By comparison, the inputs of my_conv_filter2 inherit different respective sizes; both are 1-by-3 vectors.

In addition, each library instance has a mask parameter called shape that determines what subsection of the convolution to output. Assume that the value of shape is the same for each instance.

To generate code for this example, follow these steps:

1 Enable code reuse for the library block:

a In the library, right-click the MATLAB Function block my_conv_filter and select **Block Parameters (Subsystem)** from the context menu.

b In the Function Block Parameters dialog box, set these parameters:

- Select the **Treat as atomic unit** check box.
- In the **Function packaging** field, select `Reusable function` from the drop-down menu.

2 Configure the model for code generation.

For purposes of this exercise, set the following configuration parameters:

Pane	Section	What to Specify
Code Generation	**Target selection**	Enter **ert.tlc** for `System target file`
Code Generation > **Report**		Select **Create code generation report** check box.

3 Build the model.

If you build this model, the generated C code reuses logic for the `my_conv_filter` and `my_conv_filter1` library instances because they inherit the same input properties:

```
/*
 * Output and update for atomic system:
 *    '<Root>/my_conv_filter'
 *    '<Root>/my_conv_filter1'
 */
void sp_algorithm_tes_my_conv_filter(const real32_T rtu_a[2], const real32_T
  rtu_b[5], rtB_my_conv_filter_sp_algorithm *localB)
{
  int32_T jA;
  int32_T jA_0;
  real32_T s;
  int32_T jC;

  /* MATLAB Function Block: '<S1>/my_conv_filter' */
  /* MATLAB Function 'my_conv_filter/my_conv_filter': '<S4>:1' */
  /* '<S4>:1:4' */
  for (jC = 0; jC < 6; jC++) {
    if (5 < jC + 2) {
      jA = jC - 4;
    } else {
      jA = 0;
    }

    if (2 < jC + 1) {
      jA_0 = 2;
    } else {
      jA_0 = jC + 1;
    }

    s = 0.0F;
    while (jA + 1 <= jA_0) {
      s += rtu_b[jC - jA] * rtu_a[jA];
      jA++;
    }

    localB->c[jC] = s;
  }

  /* end of MATLAB Function Block: '<S1>/my_conv_filter' */
}
```

However, a separate function is generated for my_conv_filter2:

```
/* Output and update for atomic system: '<Root>/my_conv_filter2' */
void sp_algorithm_te_my_conv_filter2(const real_T rtu_a[3], const real_T rtu_b[3],
  rtB_my_conv_filter_sp_algorit_h *localB)
{
  int32_T jA;
  int32_T jA_0;
  real_T s;
  int32_T jC;

  /* MATLAB Function Block: '<S3>/my_conv_filter' */
  /* MATLAB Function 'my_conv_filter/my_conv_filter': '<S6>:1' */
  /* '<S6>:1:4' */
  for (jC = 0; jC < 5; jC++) {
    if (3 < jC + 2) {
      jA = jC - 2;
    } else {
      jA = 0;
    }

    if (3 < jC + 1) {
      jA_0 = 3;
    } else {
      jA_0 = jC + 1;
    }

    s = 0.0;
    while (jA + 1 <= jA_0) {
      s += rtu_b[jC - jA] * rtu_a[jA];
      jA++;
    }

    localB->c[jC] = s;
  }

  /* end of MATLAB Function Block: '<S3>/my_conv_filter' */
}
```

Note Generating C code for this model requires a Simulink Coder or Embedded Coder license.

Debugging MATLAB Function Library Blocks

You debug MATLAB Function library blocks the same way you debug any MATLAB Function block. However, when you add a breakpoint in a library block, the breakpoint is shared by all instances. As you continue execution, the debugger stops at the breakpoint in each instance.

Properties You Can Specialize Across Instances of Library Blocks

You can specialize instances of MATLAB Function library blocks by allowing them to inherit any of the following properties from Simulink:

Property	Inherits by Default?	How to Specify Inheritance
Type	Yes	Set data type property to **Inherit: Same as Simulink**.
Size	Yes	Set data size property to **-1**.
Complexity	Yes	Set data complexity property to **Inherited**.
Limit range	No	Specify minimum and maximum values as Simulink parameters. For example, if minimum value = `aParam` and maximum value = `aParam` + 3, different instances of a MATLAB Function library block can resolve to different `aParam` parameters defined in their parent mask subsystems.
Sampling mode (input)	Yes	MATLAB Function block input ports always inherit sampling mode
Data type override mode for fixed-point data	Yes	Set data type override property to **Inherit**.
Sample time (block)	Yes	Set block sample time property to **-1**.

Use Traceability in MATLAB Function Blocks

In this section...

Extent of Traceability in MATLAB Function Blocks

Like other Simulink blocks, MATLAB Function blocks support bidirectional traceability, but extend navigation to lines of source code. That is, you can navigate between a line of generated code and its corresponding line of source code. In other Simulink blocks, you can navigate between a line of generated code and its corresponding object.

In addition, you can select to include the source code as comments in the generated code. When you select **MATLAB source code as comments** parameter, the MATLAB source code appears immediately after the associated traceability tag. For more information, see “How to Include MATLAB Code as Comments in the Generated Code” on page 41-161.

For information about how traceability works in Simulink blocks, see “What Is Code Tracing?” (Embedded Coder).

Traceability Requirements

To enable traceability comments in your code, you must have a license for Embedded Coder software. These comments appear only in code that you generate for an Embedded Real-Time (`ERT`) target.

Note Traceability is not supported for MATLAB files that you call from a MATLAB Function block.

Tutorial: Using Traceability in a MATLAB Function Block

This example shows how to trace between source code and generated code in a MATLAB Function block in the `eml_fire` model. Follow these steps:

1. Type `eml_fire` at the MATLAB prompt.
2. In the Simulink model window, select **Simulation** > **Model Configuration Parameters**.
3. In the **Code Generation** pane, go to the **Target selection** section and enter `ert.tlc` for the system target file. Then click **Apply**.Traceability comments appear hyperlinked in generated code only for embedded real-time (`ert`) targets.
4. In the **Code Generation > Report** pane, select the **Create code generation report** (Simulink Coder) parameter, if not already selected.

   This action automatically selects the "Open report automatically" (Simulink Coder), "Code-to-model" (Simulink Coder), and "Model-to-code" (Simulink Coder) parameters.
5. Verify that **Code-to-model** and **Model-to-code** parameters are enabled.
6. In the **Code Generation > Comments** pane, select the "MATLAB source code as comments" (Simulink Coder) and "Stateflow object comments" (Simulink Coder) parameters. These parameters control different parts of the traceability comment. See "Location of Comments in Generated Code" on page 41-162 for more information.
7. Go to the **Code Generation > Interface** pane. In the **Software environment** section, select the **continuous time** parameter. Then click **Apply**. Because this example model contains a block with a continuous sample time, you must perform this step before generating code.
8. In the model window, press **Ctrl+B**.

   This action generates source code and header files for the `eml_fire` model that contains the `flame` block. After the code generation process is complete, the code generation report appears automatically.
9. Click the `eml_fire.c` hyperlink in the report.
10. Scroll down through the code to see the traceability comments, which appear as links inside `/*...*/` brackets, as in this example.

```
/* '<S2>:1:19' for x = 1 : WIDTH */
for (x = 0; x < 256; x++) {
  /* '<S2>:1:21' yb = y+2; */
  yb = iU;

  /* '<S2>:1:22' xb1 = x-1; */
  xb1 = x;
```

11 Click the `<S2>:1:19` hyperlink in this traceability comment:

```
/* '<S2>:1:19' */
```

Line 19 of the function in the source code appears highlighted in the MATLAB Function Block Editor.

12 You can trace a line in a MATLAB function to lines of generated code. For example, right-click on line 21 of your function and select **Code Generation > Navigate to Code** from the context menu.

The code location for line 21 appears highlighted in `eml_fire.c`.

13 You can trace a line of generated code to a line of source code in a MATLAB function using the line number hyperlinks in the generated code.

Include MATLAB Code as Comments in Generated Code

If you have a Simulink Coder license, you can include MATLAB source code as comments in the code generated for a MATLAB Function block. Including this information in the generated code enables you to:

- Correlate the generated code with your source code.
- Understand how the generated code implements your algorithm.
- Evaluate the quality of the generated code.

When you select **MATLAB source code as comments** parameter, the generated code includes:

- The source code as a comment immediately after the traceability tag. When you enable traceability and generate code for ERT targets (requires an Embedded Coder license), the traceability tags are hyperlinks to the source code. For more information on traceability for the MATLAB Function block, see "Use Traceability in MATLAB Function Blocks" on page 41-158.

  For examples and information on the location of the comments in the generated code, see "Location of Comments in Generated Code" on page 41-162.
- The function help text in the function body in the generated code. The function help text is the first comment after the MATLAB function signature. It provides information about the capabilities of the function and how to use it.

Note With an Embedded Coder license, you can also include the function help text in the function banner of the generated code. For more information, see "Including MATLAB user comments in Generated Code" on page 41-164.

How to Include MATLAB Code as Comments in the Generated Code

To include MATLAB source code as comments in the code generated for a MATLAB Function block:

1. In the model, select **Simulation > Model Configuration Parameters**.
2. In the **Code Generation > Comments** pane, select **MATLAB source code as comments** and click **Apply**.

Location of Comments in Generated Code

The automatically generated comments containing the source code appear after the traceability tag in the generated code as follows.

```
/* '<S2>:1:18' for y = 1 : 2 : (HEIGHT-4) */
```

Selecting the **Stateflow object comments** parameter generates the traceability comment `'<S2>:1:18'`. Selecting the **MATLAB source code as comments** parameter generates the `for y = 1 : 2 : (HEIGHT-4)` comment.

Straight-Line Source Code

The comment containing the source code precedes the generated code that implements the source code statement. This comment appears after any comments that you add that precede the generated code. The comments are separated from the generated code because the statements are assigned to function outputs.

MATLAB Code

```
function [x y] = straightline(r,theta)
%#codegen
% Convert polar to Cartesian
x = r * cos(theta);
y = r * sin(theta);
```

Commented C Code

```
/* MATLAB Function 'straightline': '<S1>:1' */
        /*  Convert polar to Cartesian */
        /* '<S1>:1:4' x = r * cos(theta); */
        /* '<S1>:1:5' y = r * sin(theta); */
        straightline0_Y.x = straightline0_U.r * cos(straightline0_U.theta);

        /* Outport: '<Root>/y' incorporates:
         *  Inport: '<Root>/r'
         *  Inport: '<Root>/theta'
         *  MATLAB Function Block: '<Root>/straightline'
         */
        straightline0_Y.y = straightline0_U.r * sin(straightline0_U.theta);
```

If Statements

The comment for the `if` statement immediately precedes the code that implements the statement. This comment appears after any comments that you add that precede the

generated code. The comments for the `elseif` and `else` clauses appear immediately after the code that implements the clause, and before the code generated for statements in the clause.

MATLAB Code

```
function y = ifstmt(u,v)
%#codegen
if u > v
    y = v + 10;
elseif u == v
    y = u * 2;
else
    y = v - 10;
end
```

Commented C Code

```
/* MATLAB Function 'MLFcn': '<S1>:1' */
        /* '<S1>:1:3' if u > v */
        if (MLFcn_U.u > MLFcn_U.v) {
          /* Outport: '<Root>/y' */
          /* '<S1>:1:4' y = v + 10; */
          MLFcn_Y.y = MLFcn_U.v + 10.0;
        } else if (MLFcn_U.u == MLFcn_U.v) {
          /* Outport: '<Root>/y' */
          /* '<S1>:1:5' elseif u == v */
          /* '<S1>:1:6' y = u * 2; */
          MLFcn_Y.y = MLFcn_U.u * 2.0;
        } else {
          /* Outport: '<Root>/y' */
          /* '<S1>:1:7' else */
          /* '<S1>:1:8' y = v - 10; */
          MLFcn_Y.y = MLFcn_U.v - 10.0;
```

For Statements

The comment for the `for` statement header immediately precedes the generated code that implements the header. This comment appears after any comments that you add that precede the generated code.

MATLAB Code

```
function y = forstmt(u)
%#codegen
```

```
y = 0;
for i=1:u
    y = y + 1;
end
```

Commented C Code

```
/* MATLAB Function 'MLFcn': '<S1>:1' */
        /* '<S1>:1:3' y = 0; */
        rtb_y = 0.0;

        /* '<S1>:1:5' for i=1:u */
        for (i = 1.0; i <= MLFcn_U.u; i++) {
          /* '<S1>:1:6' y = y + 1; */
          rtb_y++;
```

While Statements

The comment for the `while` statement header immediately precedes the generated code that implements the statement header. This comment appears after any comments that you add that precede the generated code.

Switch Statements

The comment for the `switch` statement header immediately precedes the generated code that implements the statement header. This comment appears after any comments that you add that precede the generated code. The comments for the `case` and `otherwise` clauses appear immediately after the generated code that implements the clause, and before the code generated for statements in the clause.

Including MATLAB user comments in Generated Code

MATLAB user comments include the function help text and other comments. The function help text is the first comment after the MATLAB function signature. It provides information about the capabilities of the function and how to use it. You can include the MATLAB user comments in the code generated for a MATLAB Function block.

1. In the model, select **Simulation > Model Configuration Parameters**.
2. In the **Code Generation > Comments** pane, select “MATLAB user comments” (Simulink Coder) and click **Apply**.

Limitations of MATLAB Source Code as Comments

The MATLAB Function block has the following limitations for including MATLAB source code as comments.

- You cannot include MATLAB source code as comments for:
  - MathWorks toolbox functions
  - P-code
  - Simulation targets
  - Stateflow Truth Table blocks
- The appearance or location of comments can vary depending on the following conditions:
  - Comments might still appear in the generated code even if the implementation code is eliminated, for example, due to constant folding.
  - Comments might be eliminated from the generated code if a complete function or code block is eliminated.
  - For certain optimizations, the comments might be separated from the generated code.
  - The generated code always includes legally required comments from the MATLAB source code, even if you do not choose to include source code comments in the generated code.

Integrate C Code Using the MATLAB Function Block

In this section...

Call C Code from a Simulink model

You can call external C code from a Simulink model using a MATLAB Function block and the `coder.ceval` command. Follow these high-level steps:

1. Start with existing C code consisting of the source (`.c`) and header (`.h`) files.
2. In the MATLAB Function block, enter the MATLAB code that calls the C code. Use the command `coder.ceval`.
3. Specify the C source and header files for simulation in the **Simulation Target** pane of the Configuration Parameters dialog box.

   Include the header file using double quotations, such as `#include "program.h"`.
4. If you need to access C source and header files outside your working folder, list the path in the **Simulation Target** pane of the Configuration Parameters dialog box, in the **Include Directories** text box.
5. Test your Simulink model and ensure it functions correctly.
6. To use the same source and header files for code generation, click **Use the same custom code settings as Simulation Target** in the **Code Generation > Custom Code** pane.

   You can also specify different source and header files.

If you have a Simulink Coder license, you can generate code for targets using this method.

Example 41.1. Call the doubleIt Program Using a MATLAB Function Block

This example shows how to call the simple C program `doubleIt` from a MATLAB Function block.

1. Create the source file `doubleIt.c` in your current working folder.

```
/* doubleIt, a simple program that returns double the input */

#include "doubleIt.h"

double doubleIt(double u)
{
     return(u*2.0);
}
```

2 Create the header file `doubleIt.h` in your current working folder.

```
double doubleIt(double u);
```

3 Create a new Simulink model.

4 Add a MATLAB Function block to the model and double-click the block to open the editor.

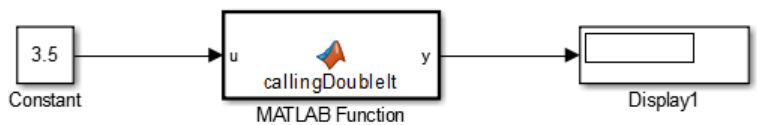
5 Enter code that calls the `doubleIt` program:

```
function y = callingDoubleIt(u)

y = 0.0;
y = coder.ceval('doubleIt',u);
```

6 Connect a Constant block having a value of `3.5` to the input port of the MATLAB Function block.

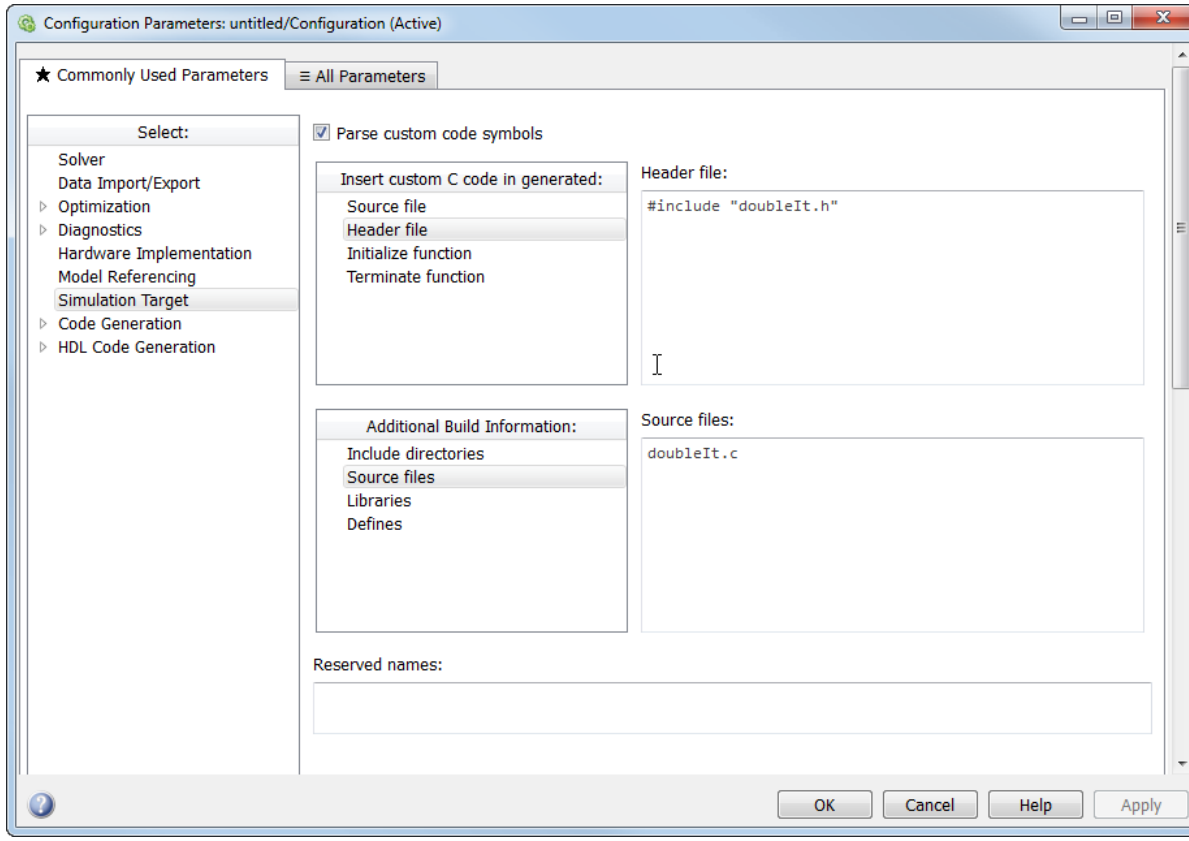
7 Connect a Display block to the output port.



8 In the Configuration Parameters dialog box, open the **Simulation Target** pane.

9 In the **Insert custom C code in generated** section, select **Header file** from the list, and enter `#include "doubleIt.h"` in the **Header file** text box.

10 In the **Include list of additional** section, select **Source files** from the list, enter `doubleIt.c` in the **Source files** text box, and click **OK**.



11 Simulate the model.

The value 7 appears in the Display block.

Control Imported Bus and Enumeration Type Definitions

This procedure applies to simulation only.

Simulink generates code for MATLAB Function blocks and Stateflow to simulate the model. When you call external C code using MATLAB Function blocks or Stateflow, you can control the type definitions for imported buses and enumerations in model simulation.

Simulink can generate type definitions, or you can supply a header file containing the type definitions. You control this behavior using the **Generate typedefs for imported bus and enumeration types** check box in the Configuration Parameters dialog box.

To include a custom header file defining the enumeration and bus types:

1. Clear the **Generate typedefs for imported bus and enumeration types** check box.
2. List the header file in the **Simulation Target** pane, in the **Header file** text box.

To configure Simulink to automatically generate type definitions:

1. Select the **Generate typedefs for imported bus and enumeration types** check box.
2. Do not list a header file that corresponds to the buses or enumerations.

Enhance Code Readability for MATLAB Function Blocks

In this section...

Requirements for Using Readability Optimizations

To use readability optimizations in your code, you must have an Embedded Coder license. These optimizations appear only in code that you generate for an embedded real-time (`ert`) target.

Note These optimizations do not apply to MATLAB files that you call from the MATLAB Function block.

For more information, see “Configure a System Target File” (Embedded Coder) and “Control Code Style” (Embedded Coder) in the Embedded Coder documentation.

Converting If-Elseif-Else Code to Switch-Case Statements

When you generate code for embedded real-time targets, you can choose to convert `if-elseif-else` decision logic to `switch-case` statements. This conversion can enhance readability of the code.

For example, when a MATLAB Function block contains a long list of conditions, the `switch-case` structure:

- Reduces the use of parentheses and braces
- Minimizes repetition in the generated code

How to Convert If-Elseif-Else Code to Switch-Case Statements

The following procedure describes how to convert generated code for the MATLAB Function block from `if-elseif-else` to `switch-case` statements.

Step	Task	Reference
1	Verify that your block follows the rules for conversion.	"Verifying the Contents of the Block" on page 41-174
2	Enable the conversion.	"Enabling the Conversion" on page 41-175
3	Generate code for your model.	"Generating Code for Your Model" on page 41-176

Rules for Conversion

For the conversion to occur, the following rules must hold. LHS and RHS refer to the left-hand side and right-hand side of a condition, respectively.

Construct	Rules to Follow
MATLAB Function block	Must have two or more *unique* conditions, in addition to a default. For more information, see "How the Conversion Handles Duplicate Conditions" on page 41-172.
Each condition	Must test equality only.
	Must use the same variable or expression for the LHS. **Note** You can reverse the LHS and RHS.
Each LHS	Must be a single variable or expression, not a compound statement.
	Cannot be a constant.
	Must have an integer or enumerated data type.
	Cannot have any side effects on simulation. For example, the LHS can read from but not write to global variables.
Each RHS	Must be a constant.
	Must have an integer or enumerated data type.

How the Conversion Handles Duplicate Conditions

If a MATLAB Function block has duplicate conditions, the conversion preserves only the first condition. The generated code discards all other instances of duplicate conditions.

After removal of duplicates, two or more unique conditions must exist. Otherwise, no conversion occurs and the generated code contains all instances of duplicate conditions.

The following examples show how the conversion handles duplicate conditions.

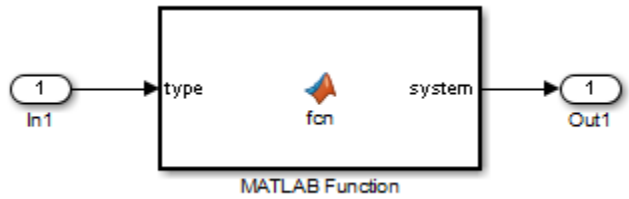
Example of Generated Code	Code After Conversion

`if (x == 1) {`
`  block1`
`} else if (x == 2) {`
`  block2`
`} else if (x == 1) {  // duplicate`
`  block3`
`} else if (x == 3) {`
`  block4`
`} else if (x == 1) {  // duplicate`
`  block5`
`} else {`
`  block6`
`}`
	`switch (x) {`
	`  case 1:`
	`  block1; break;`
	`  case 2:`
	`  block2; break;`
	`  case 3:`
	`  block4; break;`
	`  default:`
	`  block6; break;`
	`}`

`if (x == 1) {`
`  block1`
`} else if (x == 1) {  // duplicate`
`  block2`
`} else {`
`  block3`
`}`
	No change, because only one unique condition exists

Example of Converting Code for If-Elseif-Else Decision Logic to Switch-Case Statements

Suppose that you have the following model with a MATLAB Function block. Assume that the output data type is `double` and the input data type is `Controller`, an enumerated type that you define. (For more information, see “Code Generation for Enumerations” on page 41-121.)



The block contains the following code:

```
function system = fcn(type)
%#codegen

if (type == Controller.P)
    system = 0;
elseif (type == Controller.I)
    system = 1;
elseif (type == Controller.PD)
    system = 2;
elseif (type == Controller.PI)
    system = 3;
elseif (type == Controller.PID)
    system = 4;
else
    system = 10;
end
```

The enumerated type definition in `Controller.m` is:

```
classdef Controller < Simulink.IntEnumType
  enumeration
    P(0)
    I(1)
    PD(2)
    PI(3)
    PID(4)
    UNKNOWN(10)
  end
end
```

If you generate code for an embedded real-time target using default settings, you see something like this:

```
if (if_to_switch_eml_blocks_U.In1 == P) {
  /* '<S1>:1:4' */
  /* '<S1>:1:5' */
  if_to_switch_eml_blocks_Y.Out1 = 0.0;
} else if (if_to_switch_eml_blocks_U.In1 == I) {
  /* '<S1>:1:6' */
  /* '<S1>:1:7' */
  if_to_switch_eml_blocks_Y.Out1 = 1.0;
} else if (if_to_switch_eml_blocks_U.In1 == PD) {
  /* '<S1>:1:8' */
  /* '<S1>:1:9' */
  if_to_switch_eml_blocks_Y.Out1 = 2.0;
} else if (if_to_switch_eml_blocks_U.In1 == PI) {
  /* '<S1>:1:10' */
  /* '<S1>:1:11' */
  if_to_switch_eml_blocks_Y.Out1 = 3.0;
} else if (if_to_switch_eml_blocks_U.In1 == PID) {
  /* '<S1>:1:12' */
  /* '<S1>:1:13' */
  if_to_switch_eml_blocks_Y.Out1 = 4.0;
} else {
  /* '<S1>:1:15' */
  if_to_switch_eml_blocks_Y.Out1 = 10.0;
}
```

The LHS variable `if_to_switch_eml_blocks_U.In1` appears multiple times in the generated code.

Note By default, variables that appear in the block do not retain their names in the generated code. Modified identifiers guarantee that no naming conflicts occur.

Traceability comments appear between each set of `/*` and `*/` markers. To learn more about traceability, see “Use Traceability in MATLAB Function Blocks” on page 41-158.

Verifying the Contents of the Block

Check that the block follows all the rules in “Rules for Conversion” on page 41-171.

Construct	How the Construct Follows the Rules
MATLAB Function block	Five unique conditions exist, in addition to the default: • `(type == Controller.P)` • `(type == Controller.I)` • `(type == Controller.PD)` • `(type == Controller.PI)` • `(type == Controller.PID)`
Each condition	Each condition: • Tests equality • Uses the same input for the LHS
Each LHS	Each LHS: • Contains a single variable • Is the input to the block and therefore not a constant • Is of enumerated type `Controller`, which you define in `Controller.m` on the MATLAB path • Has no side effects on simulation
Each RHS	Each RHS: • Is an enumerated value and therefore a constant • Is of enumerated type `Controller`

Enabling the Conversion

1. Open the Configuration Parameters dialog box.
2. In the **Code Generation** pane, select `ert.tlc` for the **System target file**.

   This step specifies an embedded real-time target for your model.
3. In the **Code Generation > Code Style** pane, select the **Convert if-elseif-else patterns to switch-case statements** check box.

Tip This conversion works on a per-model basis. If you select this check box, the conversion applies to:

- All MATLAB Function blocks in a model
- MATLAB functions in all Stateflow charts of that model
- Flow charts in all Stateflow charts of that model

For more information, see "Enhance Readability of Code for Flow Charts" (Embedded Coder) in the Embedded Coder documentation.

Generating Code for Your Model

In the model window, press **Ctrl+B**.

The code for the MATLAB Function block uses `switch-case` statements instead of `if-elseif-else` code:

```
switch (if_to_switch_eml_blocks_U.In1) {
 case P:
  /* '<S1>:1:4' */
  /* '<S1>:1:5' */
  if_to_switch_eml_blocks_Y.Out1 = 0.0;
  break;

 case I:
  /* '<S1>:1:6' */
  /* '<S1>:1:7' */
  if_to_switch_eml_blocks_Y.Out1 = 1.0;
  break;

 case PD:
  /* '<S1>:1:8' */
  /* '<S1>:1:9' */
  if_to_switch_eml_blocks_Y.Out1 = 2.0;
  break;

 case PI:
  /* '<S1>:1:10' */
  /* '<S1>:1:11' */
  if_to_switch_eml_blocks_Y.Out1 = 3.0;
  break;

 case PID:
  /* '<S1>:1:12' */
  /* '<S1>:1:13' */
  if_to_switch_eml_blocks_Y.Out1 = 4.0;
```

```
  break;

 default:
  /* '<S1>:1:15' */
  if_to_switch_eml_blocks_Y.Out1 = 10.0;
  break;
}
```

The `switch-case` statements provide the following benefits to enhance readability:

- The code reduces the use of parentheses and braces.
- The LHS variable `if_to_switch_eml_blocks_U.In1` appears only once, minimizing repetition in the code.

Control Run-Time Checks

In this section...

Types of Run-Time Checks

In simulation, the code generated for your MATLAB Function block includes the following run-time checks:

- Memory integrity checks

  These checks detect violations of memory integrity in code generated for MATLAB Function blocks and stop execution with a diagnostic message.

  Caution For safety, these checks are enabled by default. Without memory integrity checks, violations result in unpredictable behavior.

- Responsiveness checks in code generated for MATLAB Function blocks

  These checks enable periodic checks for Ctrl+C breaks in the generated code. Enabling responsiveness checks also enables graphics refreshing.

  Caution For safety, these checks are enabled by default. Without these checks, the only way to end a long-running execution might be to terminate MATLAB.

When to Disable Run-Time Checks

Generally, generating code with run-time checks enabled results in more lines of generated code and slower simulation than generating code with the checks disabled. Disabling run-time checks usually results in streamlined generated code and faster simulation, with these caveats:

Consider disabling:	Only if:
Memory integrity checks	You are sure that your code is safe and that all array bounds and dimension checking is unnecessary.
Responsiveness checks	You are sure that you will not need to stop execution of your application using Ctrl+C.

How to Disable Run-Time Checks

MATLAB Function blocks enable run-time checks by default, but you can disable them explicitly for all MATLAB Function blocks in your Simulink model. Follow these steps:

1. Open your MATLAB Function block.
2. In the MATLAB Function Block Editor, select **Simulation Target**.
3. In the Configuration Parameters dialog box, clear the **Ensure memory integrity** or **Ensure responsiveness** check boxes, as applicable, and click **Apply**.

Track Object Using MATLAB Code

In this section...

Learning Objectives

In this tutorial, you will learn how to:

- Use the MATLAB Function block to add MATLAB functions to Simulink models for modeling, simulation, and deployment to embedded processors.

  This capability is useful for coding algorithms that are better stated in the textual language of MATLAB than in the graphical language of Simulink.
- Use `coder.extrinsic` to call MATLAB code from a MATLAB Function block.

  This capability allows you to do rapid prototyping. You can call existing MATLAB code from Simulink without having to make this code suitable for code generation.
- Check that existing MATLAB code is suitable for code generation before generating code.

  You must prepare your code before generating code.
- Specify variable-size inputs when generating code.

Tutorial Prerequisites

- “What You Need to Know” on page 41-181
- “Required Products” on page 41-181

What You Need to Know

To complete this tutorial, you should have basic familiarity with MATLAB software. You should also understand how to create and simulate a basic Simulink model.

Required Products

To complete this tutorial, you must install the following products:

- MATLAB
- MATLAB Coder
- Simulink
- Simulink Coder
- C compiler

For a list of supported compilers, see `http://www.mathworks.com/support/compilers/current_release/`.

You must set up the C compiler before generating C code. See "Setting Up Your C Compiler" on page 41-186.

For instructions on installing MathWorks products, see the MATLAB installation documentation for your platform. If you have installed MATLAB and want to check which other MathWorks products are installed, enter `ver` in the MATLAB Command Window.

Example: The Kalman Filter

Description

This section describes the example used by the tutorial. You do not have to be familiar with the algorithm to complete the tutorial.

The example for this tutorial uses a Kalman filter to estimate the position of an object moving in a two-dimensional space from a series of noisy inputs based on past positions.

The position vector has two components, `x` and `y`, indicating its horizontal and vertical coordinates.

Kalman filters have a wide range of applications, including control, signal and image processing; radar and sonar; and financial modeling. They are recursive filters that estimate the state of a linear dynamic system from a series of incomplete or noisy measurements. The Kalman filter algorithm relies on the state-space representation of filters and uses a set of variables stored in the state vector to characterize completely the behavior of the system. It updates the state vector linearly and recursively using a state transition matrix and a process noise estimate.

Algorithm

This section describes the algorithm of the Kalman filter and is implemented in the MATLAB version of the filter supplied with this tutorial.

The algorithm predicts the position of a moving object based on its past positions using a Kalman filter estimator. It estimates the present position by updating the Kalman state vector, which includes the position (*x* and *y*), velocity (*Vx* and *Vy*), and acceleration (*Ax* and *Ay*) of the moving object. The Kalman state vector, `x_est`, is a persistent variable.

```
% Initial conditions
persistent x_est p_est
if isempty(x_est)
    x_est = zeros(6, 1);
    p_est = zeros(6, 6);
end
```

`x_est` is initialized to an empty `6x1` column vector and updated each time the filter is used.

The Kalman filter uses the laws of motion to estimate the new state:

$$X = X_0 + Vx.dt$$

$$Y = Y_0 + Vy.dt$$

$$Vx = Vx_0 + Ax.dt$$

$$Vy = Vy_0 + Ay.dt$$

These laws of motion are captured in the state transition matrix `A`, which is a matrix that contains the coefficient values of `x`, `y`, V_x, V_y, A_x, and A_y.

```
% Initialize state transition matrix
dt=1;
```

```
A=[ 1 0 dt 0 0 0;...
    0 1 0 dt 0 0;...
    0 0 1 0 dt 0;...
    0 0 0 1 0 dt;...
    0 0 0 0 1 0 ;...
    0 0 0 0 0 1 ];
```

Filtering Process

The filtering process has two phases:

- Predicted state and covariance

  The Kalman filter uses the previously estimated state, `x_est`, to predict the current state, `x_prd`. The predicted state and covariance are calculated in:

  ```
  % Predicted state and covariance
  x_prd = A * x_est;
  p_prd = A * p_est * A' + Q;
  ```

- Estimation

  The filter also uses the current measurement, `z`, and the predicted state, `x_prd`, to estimate a more accurate approximation of the current state. The estimated state and covariance are calculated in:

  ```
  % Measurement matrix
  H = [ 1 0 0 0 0 0; 0 1 0 0 0 0 ];
  Q = eye(6);
  R = 1000 * eye(2);

  % Estimation
  S = H * p_prd' * H' + R;
  B = H * p_prd';
  klm_gain = (S \ B)';

  % Estimated state and covariance
  x_est = x_prd + klm_gain * (z - H * x_prd);
  p_est = p_prd - klm_gain * H * p_prd;

  % Compute the estimated measurements
  y = H * x_est;
  ```

Files for the Tutorial

About the Tutorial Files

The tutorial uses the following files:

- Simulink model files for each step of the tutorial.
- Example MATLAB code files for each step of the tutorial.

  Throughout this tutorial, you work with Simulink models that call MATLAB files containing a Kalman filter algorithm.
- A MAT-file that contains example input data.
- A MATLAB file for plotting.

Location of Files

The tutorial files are available in the following folder: `docroot\toolbox\simulink\examples\kalman`. To run the tutorial, you must copy these files to a local folder. For instructions, see "Copying Files Locally" on page 41-186.

Names and Descriptions of Files

Type	Name	Description
MATLAB function files	`ex_kalman01`	Baseline MATLAB implementation of a scalar Kalman filter.
	`ex_kalman02`	Version of the original algorithm suitable for code generation.

Type	Name	Description
	`ex_kalman03`	Version of Kalman filter suitable for code generation and for use with frame-based and packet-based inputs.
	`ex_kalman04`	Disabled inlining for code generation.
Simulink model files	`ex_kalman00`	Simulink model without a MATLAB Function block.
	`ex_kalman11`	Complete Simulink model with a MATLAB Function block for scalar Kalman filter.
	`ex_kalman22`	Simulink model with a MATLAB Function block for a Kalman filter that accepts fixed-size (frame-based) inputs.
	`ex_kalman33`	Simulink model with a MATLAB Function block for a Kalman filter that accepts variable-size (packet-based) inputs.
	`ex_kalman44`	Simulink model to call `ex_kalman04.m`, which has inlining disabled.
MATLAB data file	`position`	Contains the input data used by the algorithm.
Plot files	`plot_trajectory`	Plots the trajectory of the object and the Kalman filter estimated position.

Tutorial Steps

Copying Files Locally

Copy the tutorial files to a local working folder:

1. Create a local *solutions* folder, for example, `c:\simulink\kalman\solutions`.
2. Change to the `docroot\toolbox\simulink\examples` folder. At the MATLAB command line, enter:

   ```
   cd(fullfile(docroot, 'toolbox', 'simulink', 'examples'))
   ```

3. Copy the contents of the `kalman` subfolder to your local *solutions* folder, specifying the full path name of the *solutions* folder:

   ```
   copyfile('kalman', 'solutions')
   ```

   For example:

   ```
   copyfile('kalman', 'c:\simulink\kalman\solutions')
   ```

   Your *solutions* folder now contains a complete set of solutions for the tutorial. If you do not want to perform the steps for each task in the tutorial, you can view the solutions to see how the code should look.
4. Create a local *work* folder, for example, `c:\simulink\kalman\work`.
5. Copy the following files from your *solutions* folder to your *work* folder.

   - `ex_kalman01`
   - `ex_kalman00`
   - `position`
   - `plot_trajectory`

   Your *work* folder now contains all the files that you need to get started with the tutorial.

Setting Up Your C Compiler

Building your MATLAB Function block requires a supported compiler. MATLAB automatically selects one as the default compiler. If you have multiple MATLAB-supported compilers installed on your system, you can change the default using the `mex -setup` command. See “Change Default Compiler” (MATLAB).

About the ex_kalman00 Model

First, examine the `ex_kalman00` model supplied with the tutorial to understand the problem that you are trying to solve using the Kalman filter.

1. Open the `ex_kalman00` model in Simulink:

   a. Set your MATLAB current folder to the folder that contains your working files for this tutorial. At the MATLAB command line, enter:

      ```
      cd work
      ```

      where *`work`* is the full path name of the folder containing your files.

   b. At the MATLAB command line, enter:

      ```
      ex_kalman00
      ```

      This model is an incomplete model to demonstrate how to integrate MATLAB code with Simulink. The complete model is `ex_kalman11`, which is also supplied with this tutorial.

InitFcn Model Callback Function

The model uses this callback function to:

- Load position data from a MAT-file.
- Set up data used by the Index generator block, which provides the second input to the Selector block.

To view this callback:

1. Select **File > Model Properties > Model Properties**.
2. Select the **Callbacks** tab.
3. Select `InitFcn` in the **Model callbacks** pane.

   The callback appears.

   ```
   load position.mat;
   [R,C]=size(position);
   idx=(1:C)';
   t=idx-1;
   ```

Source Blocks

The model uses two Source blocks to provide position data and a scalar index to a Selector block.

Selector Block

The model uses a Selector block that selects elements of its input signal and generates an output signal based on its index input and its **Index Option** settings. By changing the configuration of this block, you can generate different size signals.

To view the Selector block settings, double-click the Selector block to view the function block parameters.

In this model, the **Index Option** for the first port is `Select all` and for the second port is `Index vector (port)`. Because the input is a `2 x 310` position matrix, and the index data increments from `1` to `310`, the Selector block simply outputs one `2x1` output at each sample time.

MATLAB Function Block

The model uses a MATLAB Function block to plot the trajectory of the object and the Kalman filter estimated position. This function:

- First declares the `figure`, `hold`, and `plot_trajectory` functions as extrinsic because these MATLAB visualization functions are not supported for code generation. When you call an unsupported MATLAB function, you must declare it to be extrinsic so MATLAB can execute it, but does not try to generate code for it.
- Creates a figure window and holds it for the duration of the simulation. Otherwise a new figure window appears for each sample time.
- Calls the `plot_trajectory` function, which plots the trajectory of the object and the Kalman filter estimated position.

Simulation Stop Time

The simulation stop time is `309`, because the input to the filter is a vector containing `310` elements and Simulink uses zero-based indexing.

Adding a MATLAB Function Block to Your Model

To modify the model and code yourself, work through the exercises in this section. Otherwise, open the supplied model `ex_kalman11` in your *`solutions`* subfolder to see the modified model.

For the purposes of this tutorial, you add the MATLAB Function block to the `ex_kalman00.mdl` model supplied with the tutorial. You would have to develop your own test bench starting with an empty Simulink model.

Adding the MATLAB Function Block

To add a MATLAB Function block to the `ex_kalman00` model:

1. Open `ex_kalman00` in Simulink.

   ```
   ex_kalman00
   ```

2. Add a MATLAB Function block to the model:

   a. At the MATLAB command line, type `slLibraryBrowser` to open the Simulink Library Browser.

   b. From the list of Simulink libraries, select the `User-Defined Functions` library.

   c. Click the MATLAB Function block and drag it into the `ex_kalman00` model. Place the block just above the red text annotation that reads `Place MATLAB Function Block here.`

   d. Delete the red text annotations from the model.

   e. Save the model in the current folder as `ex_kalman11`.

Calling Your MATLAB Code from the MATLAB Function Block

To call your MATLAB code from the MATLAB Function block:

1. Double-click the MATLAB Function block to open the MATLAB Function Block Editor.
2. Delete the default code displayed in the editor.
3. Copy the following code to the MATLAB Function block.

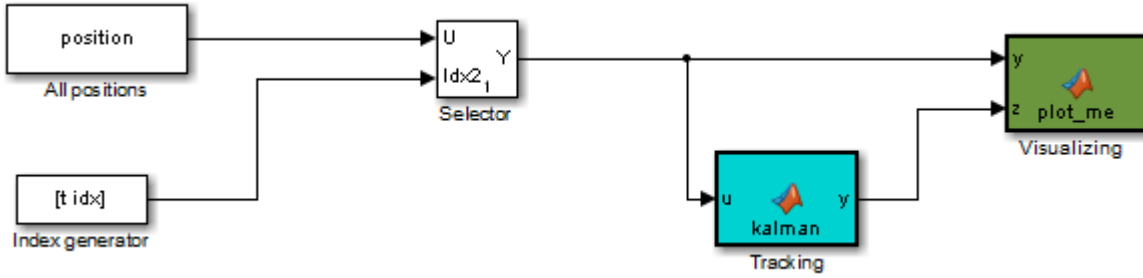
   ```
   function y = kalman(u)
   %#codegen

   y = ex_kalman01(u);
   ```

4. Save the model.

Connecting the MATLAB Function Block Input and Output

1 Connect the MATLAB Function block input and output so that your model looks like this.



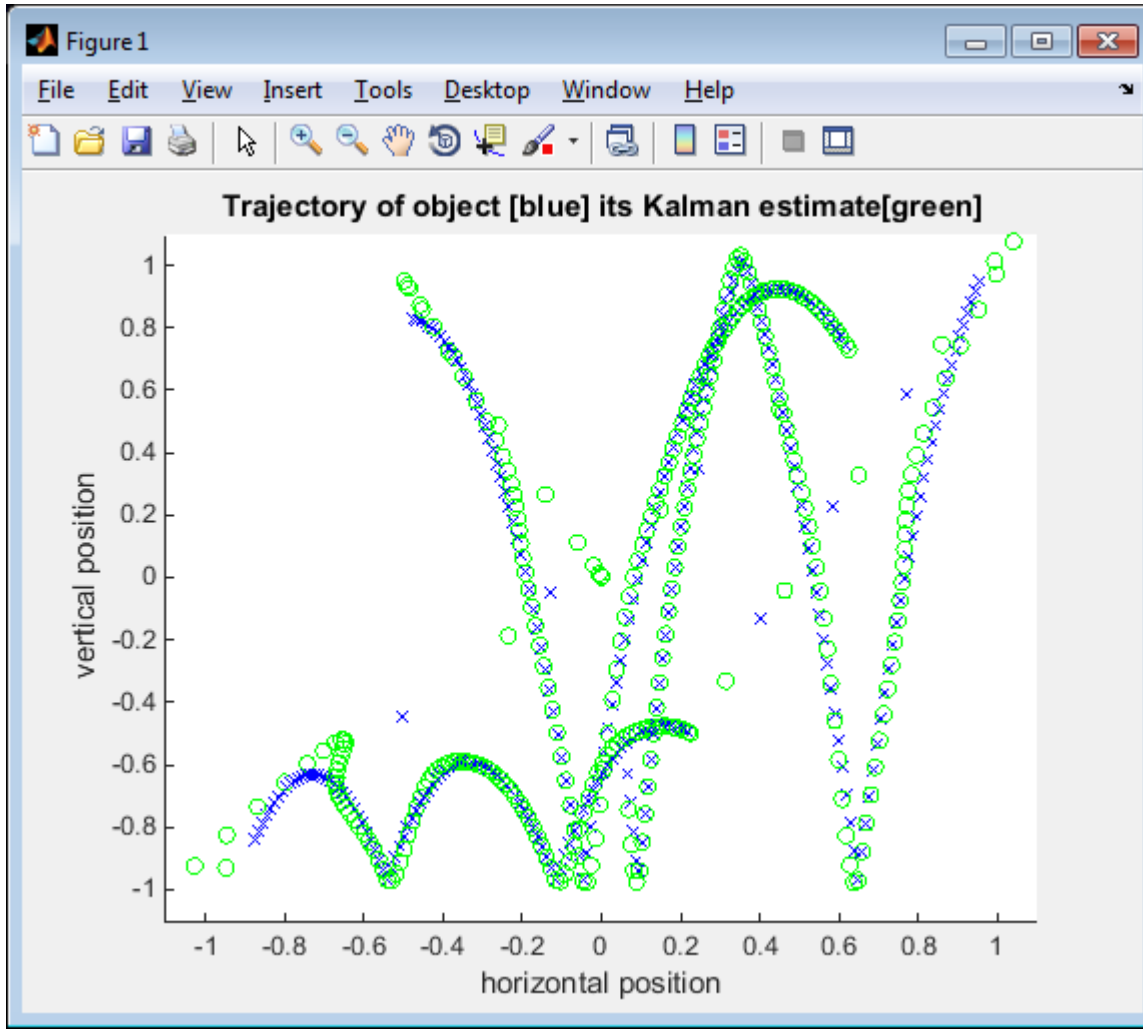
2 Save the model.

Simulating the ex_kalman11 Model

To simulate the model:

1 In the Simulink model window, select **Simulation** > **Run**.

As Simulink runs the model, it plots the trajectory of the object in blue and the Kalman filter estimated position in green. Initially, you see that it takes a short time for the estimated position to converge with the actual position of the object. Then three sudden shifts in position occur—each time the Kalman filter readjusts and tracks the object after a few iterations.



2 The simulation stops.

You have proved that your MATLAB algorithm works in Simulink. You are now ready to modify the filter to accept a fixed-size input, as described in “Modifying the Filter to Accept a Fixed-Size Input” on page 41-192.

Modifying the Filter to Accept a Fixed-Size Input

The filter you have worked on so far in this tutorial uses a simple batch process that accepts one input at a time, so you must call the function repeatedly for each input. In this part of the tutorial, you learn how to modify the algorithm to accept a fixed-sized input, which makes the algorithm suitable for frame-based processing. You then modify the model to provide the input as fixed-size frames of data and call the filter passing in the data one frame at a time.

Modifying Your MATLAB Code

To modify the code yourself, work through the exercises in this section. Otherwise, open the supplied file `ex_kalman03.m` in your *`solutions`* subfolder to see the modified algorithm.

You can now modify the algorithm to process a vector containing more than one input. You need to find the length of the vector and call the filter code for each element in the vector in turn. You do this by calling the filter algorithm in a `for` loop.

1. Open `ex_kalman02.m` in the MATLAB Editor. At the MATLAB command line, enter:

   ```
   edit ex_kalman02.m
   ```

2. Add a `for` loop around the filter code.

   a. Before the comment:

   ```
   % Predicted state and covariance
   ```

   insert:

   ```
   for i=1:size(z,2)
   ```

   b. After:

   ```
   % Compute the estimated measurements
   y = H * x_est;
   ```

   insert:

   ```
   end
   ```

   c. Select the code between the `for` statement and the end statement, right-click to open the context menu and select **Smart Indent** to indent the code.

Your filter code should now look like this:

```
for i=1:size(z,2)
     % Predicted state and covariance
     x_prd = A * x_est;
     p_prd = A * p_est * A' + Q;

     % Estimation
     S = H * p_prd' * H' + R;
     B = H * p_prd';
     klm_gain = (S \ B)';

     % Estimated state and covariance
     x_est = x_prd + klm_gain * (z - H * x_prd);
     p_est = p_prd - klm_gain * H * p_prd;

     % Compute the estimated measurements
     y = H * x_est;
end
```

3 Modify the line that calculates the estimated state and covariance to use the i^{th} element of input `z`.

Change:

```
x_est = x_prd + klm_gain * (z - H * x_prd);
```

to:

```
x_est = x_prd + klm_gain * (z(1:2,i) - H * x_prd);
```

4 Modify the line that computes the estimated measurements to append the result to the i^{th} element of the output `y`.

Change:

```
y = H * x_est;
```

to:

```
y(:,i) = H * x_est;
```

The code analyzer message indicator in the top right turns orange to indicate that the code analyzer has detected warnings. The code analyzer underlines the offending code in orange and places a orange marker to the right.

5 Move your pointer over the orange marker to view the error information.

The code analyzer detects that `y` must be fully defined before sub-scripting it and that you cannot grow variables through indexing in generated code.

6 To address this warning, preallocate memory for the output `y`, which is the same size as the input `z`. Add this code before the `for` loop.

```
% Pre-allocate output signal:
y=zeros(size(z));
```

The orange marker disappears and the code analyzer message indicator in the top right edge of the code turns green, which indicates that you have fixed all the errors and warnings detected by the code analyzer.

Why Preallocate the Outputs?

You must preallocate outputs here because the code generation does not support increasing the size of an array over time. Repeatedly expanding the size of an array over time can adversely affect the performance of your program. See "Preallocating Memory" (MATLAB).

7 Change the function name to `ex_kalman03` and save the file as `ex_kalman03.m` in the current folder.

You are ready to begin the next task in the tutorial, "Modifying Your Model to Call the Updated Algorithm" on page 41-194.

Modifying Your Model to Call the Updated Algorithm

To modify the model yourself, work through the exercises in this section. Otherwise, open the supplied model `ex_kalman22.mdl` in your *`solutions`* subfolder to see the modified model.

Next, update your model to provide the input as fixed-size frames of data and call `ex_kalman03` passing in the data one frame at a time.

1 Open `ex_kalman11` model in Simulink.

```
ex_kalman11
```

2 Double-click the MATLAB Function block to open the MATLAB Function Block Editor.

3 Replace the code that calls `ex_kalman02` with a call to `ex_kalman03`.

```
function y = kalman(u)
%#codegen

y = ex_kalman03(u);
```

4 Close the editor.

5 Modify the `InitFcn` callback:

   a Select **File > Model Properties > Model Properties**.

   The Model Properties dialog box opens.

   b In this dialog box, select the **Callbacks** tab.

   c Select `InitFcn` in the **Model callbacks** pane.

   d Replace the existing callback with:

```
load position.mat;
[R,C]=size(position);
FRAME_SIZE=5;
idx=(1:FRAME_SIZE:C)';
LEN=length(idx);
t=(1:LEN)'-1;
```

   This callback sets the frame size to `5`, and the index to increment by `5`.

   e Click **Apply** and close the Model Properties dialog box.

6 Update the Selector block to use the correct indices.

   a Double-click the Selector block to view the function block parameters.

   The Function Block Parameters dialog box opens.

   b Set the second **Index Option** to `Starting index (port)`.

   c Set the **Output Size** for the second input to `FRAME_SIZE`, click **Apply** and close the dialog box.

Now, the **Index Option** for the first port is `Select all` and for the second port is `Starting index (port)`. Because the index increments by `5` each sample time, and the output size is `5`, the Selector block outputs a `2x5` output at each sample time.

7 Change the model simulation stop time to `61`. Now the frame size is `5`, so the simulation completes in a fifth of the sample times.

a In the Simulink model window, select **Simulation > Model Configuration Parameters**.

b In the left pane of the Configuration Parameters dialog box, select **Solver**.

c In the right pane, set **Stop time** to `61`.

d Click **Apply** and close the dialog box.

8 Save the model as `ex_kalman22.mdl`.

Testing Your Modified Algorithm

To simulate the model:

1 In the Simulink model window, select **Simulation > Run**.

As Simulink runs the model, it plots the trajectory of the object in blue and the Kalman filter estimated position in green as before when you used the batch filter.

2 The simulation stops.

You have proved that your algorithm accepts a fixed-size signal. You are now ready for the next task, "Using the Filter to Accept a Variable-Size Input" on page 41-196.

Using the Filter to Accept a Variable-Size Input

In this part of the tutorial, you learn how to specify variable-size data in your Simulink model. Then you test your Kalman filter algorithm with variable-size inputs and see that the algorithm is suitable for processing packets of data of varying size. For more information on using variable-size data in Simulink, see "Variable-Size Signal Basics" on page 66-2.

Updating the Model to Use Variable-Size Inputs

To modify the model yourself, work through the exercises in this section. Otherwise, open the supplied model `ex_kalman33.mdl` in your *`solutions`* subfolder to see the modified model.

1 Open `ex_kalman22.mdl` in Simulink.

```
ex_kalman22
```

2 Modify the `InitFcn` callback:

a Select **File > Model Properties > Model Properties**.

The Model Properties dialog box opens.

b Select the **Callbacks** tab.

c Select `InitFcn` in the **Model callbacks** pane.

d Replace the existing callback with:

```
load position.mat;
idx=[ 1 1 ;2 3 ;4 6 ;7 10 ;11 15 ;16 30 ;
     31 70 ;71 100 ;101 200 ;201 250 ;251 310];
LEN=length(idx);
t=(0:1:LEN-1)';
```

This callback sets up indexing to generate eleven different size inputs. It specifies the start and end indices for each sample time. The first sample time uses only the first element, the second sample time uses the second and third elements, and so on. The largest sample, `101` to `200`, contains 100 elements.

e Click **Apply** and close the **Model Properties** dialog box.

3 Update the Selector block to use the correct indices.

a Double-click the Selector block to view the function block parameters.

The Function Block Parameters dialog box opens.

b Set the second **Index Option** to `Starting and ending indices (port)`, then click **Apply** and close the dialog box.

This setting means that the input to the index port specifies the start and end indices for the input at each sample time. Because the index input specifies different starting and ending indices at each sample time, the Selector block outputs a variable-size signal as the simulation progresses.

4 Use the Ports and Data Manager to set the MATLAB Function input `x` and output `y` as variable-size data.

a Double-click the MATLAB Function block to open the MATLAB Function Block Editor.

b From the editor menu, select **Edit Data**.

c In the Ports and Data Manager left pane, select the input `u`.

The Ports and Data Manager displays information about `u` in the right pane.

d On the **General** tab, select the **Variable size** check box and click **Apply**.

e In the left pane, select the output `y`.

f On the **General** tab:

i Set the **Size** of `y` to `[2 100]` to specify a 2-D matrix where the upper bounds are `2` for the first dimension and `100` for the second, which is the maximum size input specified in the `InitFcn` callback.

ii Select the **Variable size** check box.

iii Click **Apply**.

g Close the Ports and Data Manager.

5 Now do the same for the other MATLAB Function block. Use the Ports and Data Manager to set the Visualizing block inputs `y` and `z` as variable-size data.

a Double-click the Visualizing block to open the MATLAB Function Block Editor.

b From the editor menu, select **Edit Data**.

c In the Ports and Data Manager left pane, select the input `y`.

d On the **General** tab, select the **Variable size** check box and click **Apply**.

e In the left pane, select the input `z`.

f On the **General** tab, select the **Variable size** check box and click **Apply**.

g Close the Ports and Data Manager.

6 Change the model simulation stop time to `10`. This time, the filter processes one of the eleven different size inputs each sample time.

7 Save the model as `ex_kalman33.mdl`.

Testing Your Modified Model

To simulate the model:

1 In the Simulink model window, select **Simulation** > **Run**.

As Simulink runs the model, it plots the trajectory of the object in blue and the Kalman filter estimated position in green as before.

Note that the signal lines between the Selector block and the Tracking and Visualization blocks change to show that these signals are variable-size.

2 The simulation stops.

You have successfully created an algorithm that accepts variable-size inputs. Next, you learn how to debug your MATLAB Function block, as described in "Debugging the MATLAB Function Block" on page 41-199.

Debugging the MATLAB Function Block

You can debug your MATLAB Function block just like you can debug a function in MATLAB.

1. Double-click the MATLAB Function block that calls the Kalman filter to open the MATLAB Function Block Editor.
2. In the editor, click the dash (-) character in the left margin of the line:

   ```
   y = kalman03(u);
   ```

   A small red ball appears in the margin of this line, indicating that you have set a breakpoint.
3. In the Simulink model window, select **Simulation > Run**.

   The simulation pauses when execution reaches the breakpoint and a small green arrow appears in the left margin.
4. Place the pointer over the variable `u`.

   The value of `u` appears adjacent to the pointer.
5. From the MATLAB Function Block Editor menu, select **Step In**.

   The `kalman03.m` file opens in the editor and you can now step through this code using **Step**, **Step In**, and **Step Out**.
6. Select **Step Out**.

   The `kalman03.m` file closes and the MATLAB Function block code reappears in the editor.
7. Place the pointer over the output variable `y`.

   You can now see the value of `y`.
8. Click the red ball to remove the breakpoint.
9. From the MATLAB Function Block Editor menu, select **Quit Debugging**.
10. Close the editor.

11 Close the figure window.

Now you are ready for the next task, “Generating C Code” on page 41-200.

Generating C Code

You have proved that your algorithm works in Simulink. Next you generate code for your model.

Note Before generating code, you must check that your MATLAB code is suitable for code generation. If you call your MATLAB code as an extrinsic function, you must remove extrinsic calls before generating code.

---

1 Rename the MATLAB Function block to `Tracking`. To rename the block, double-click the annotation `MATLAB Function` below the MATLAB Function block and replace the text with `Tracking`.

When you generate code for the MATLAB Function block, Simulink Coder uses the name of the block in the generated code. It is good practice to use a meaningful name.

2 Before generating code, ensure that Simulink Coder creates a code generation report. This HTML report provides easy access to the list of generated files with a summary of the configuration settings used to generate the code.

a In the Simulink model window, select **Simulation > Model Configuration Parameters**.

The Configuration Parameters dialog box opens.

b In the left pane of the Configuration Parameters dialog box, select **Report** under **Code Generation**.

c In the right pane, select **Create code generation report**.

The **Open report automatically** option is also selected.

d Click **Apply** and close the Configuration Parameters dialog box.

e Save your model.

3 To generate code for the Tracking block:

a In your model, select the Tracking block.

b In the Simulink model window, select **Code** > **C/C++ Code** > **Build Selected Subsystem**.

4 The Simulink software generates an error informing you that it cannot log variable-size signals as arrays. You need to change the format of data saved to the MATLAB workspace. To change this format:

- In the Simulink model window, select **Simulation** > **Model Configuration Parameters**.

  The Configuration Parameters dialog box opens.
- In the left pane of the Configuration Parameters dialog box, select **Data Import/Export** and set the **Format** to `Structure with time`.

  The logged data is now a structure that has two fields: a time field and a signals field, enabling Simulink to log variable-size signals.
- Click **Apply** and close the Configuration Parameters dialog box.
- Save your model.

5 Repeat step `3` to generate code for the Tracking block.

The Simulink Coder software generates C code for the block and launches the code generation report.

For more information on using the code generation report, see "Reports for Code Generation" (Simulink Coder).

6 In the left pane of the code generation report, click the `Tracking.c` link to view the generated C code. Note that in the code generated for the MATLAB Function block, `Tracking`, there is no code for the `ex_kalman03` function because inlining is enabled by default.

7 Modify your filter algorithm to disable inlining:

a In `ex_kalman03.m`, after the function declaration, add:

```
coder.inline('never');
```

b Change the function name to `ex_kalman04` and save the file as `ex_kalman04.m` in the current folder.

c In your `ex_kalman33` model, double-click the Tracking block.

The MATLAB Function Block Editor opens.

d Modify the call to the filter algorithm to call `ex_kalman04`.

```
function y = kalman(u)
%#codegen

y = ex_kalman04(u);
```

e Save the model as `ex_kalman44.mdl`.

8 Generate code for the updated model.

a Select the Tracking block.

b In the model window, select **Code > C/C++Code > Build Selected Subsystem**.

The **Build code for Subsystem** dialog box appears.

c Click the **Build** button.

The Simulink Coder software generates C code for the block and launches the code generation report.

d In the left pane of the code generation report, click the `Tracking.c` link to view the generated C code.

This time the `ex_kalman04` function has code because you disabled inlining.

```
/* Forward declaration for local functions */
static void Tracking_ex_kalman04(const real_T z_data[620], const int32_T
  z_sizes[2], real_T y_data[620], int32_T y_sizes[2]);

/* Function for MATLAB Function Block: '<Root>/Tracking' */
static void Tracking_ex_kalman04(const real_T z_data[620], const int32_T   48
     z_sizes[2], real_T y_data[620], int32_T y_sizes[2])
```

Best Practices Used in This Tutorial

Best Practice — Saving Incremental Code Updates

Save your code before making modifications. This practice provides a fallback in case of error and a baseline for testing and validation. Use a consistent file naming convention. For example, add a two-digit suffix to the file name for each file in a sequence.

Key Points to Remember

- Back up your MATLAB code before you modify it.
- Decide on a naming convention for your files and save interim versions frequently. For example, this tutorial uses a two-digit suffix to differentiate the various versions of the filter algorithm.
- For simulation purposes, before generating code, call your MATLAB code using `coder.extrinsic` to check that your algorithm is suitable for use in Simulink. This practice provides these benefits:
  - You do not have to make the MATLAB code suitable for code generation.
  - You can debug your MATLAB code in MATLAB while calling it from Simulink.
- Create a Simulink Coder code generation report. This HTML report provides easy access to the list of generated files with a summary of the configuration settings used to generate the code.

Filter Audio Signal Using MATLAB Code

In this section...

Learning Objectives

In this tutorial, you will learn how to:

- Use the MATLAB Function block to add MATLAB functions to Simulink models for modeling, simulation, and deployment to embedded processors.

  This capability is useful for coding algorithms that are better stated in the textual language of MATLAB than in the graphical language of Simulink.
- Use `coder.extrinsic` to call MATLAB code from a MATLAB Function block.

  This capability allows you to call existing MATLAB code from Simulink without first having to make this code suitable for code generation, allowing for rapid prototyping.
- Check that existing MATLAB code is suitable for code generation.
- Convert a MATLAB algorithm from batch processing to streaming.
- Use persistent variables in code that is suitable for code generation.

  You need to make the filter weights persistent so that the filter algorithm does not reset their values each time it runs.

Tutorial Prerequisites

- “What You Need to Know” on page 41-205
- “Required Products” on page 41-205

What You Need to Know

To work through this tutorial, you should have basic familiarity with MATLAB software. You should also understand how to create a basic Simulink model and how to simulate that model. For more information, see “Create Simple Model”.

Required Products

To complete this tutorial, you must install the following products:

- MATLAB
- MATLAB Coder
- Simulink
- Simulink Coder
- DSP System Toolbox
- C compiler

  For a list of supported compilers, see http://www.mathworks.com/support/compilers/current_release/.

For instructions on installing MathWorks products, refer to the installation documentation. If you have installed MATLAB and want to check which other MathWorks products are installed, enter `ver` in the MATLAB Command Window. For instructions on installing and setting up a C compiler, see “Setting Up the C or C++ Compiler” (MATLAB Coder).

Example: The LMS Filter

Description

A least mean squares (LMS) filter is an adaptive filter that adjusts its transfer function according to an optimizing algorithm. You provide the filter with an example of the desired signal together with the input signal. The filter then calculates the filter weights,

or coefficients, that produce the least mean squares of the error between the output signal and the desired signal.

This example uses an LMS filter to remove the noise in a music recording. There are two inputs. The first input is the distorted signal: the music recording plus the filtered noise. The second input is the desired signal: the unfiltered noise. The filter works to eliminate the difference between the output signal and the desired signal and outputs the difference, which, in this case, is the clean music recording. When you start the simulation, you hear both the noise and the music. Over time, the adaptive filter removes the noise so you hear only the music.

Algorithm

This example uses the least mean squares (LMS) algorithm to remove noise from an input signal. The LMS algorithm computes the filtered output, filter error, and filter weights given the distorted and desired signals.

At the start of the tutorial, the LMS algorithm uses a batch process to filter the audio input. This algorithm is suitable for MATLAB, where you are likely to load in the entire signal and process it all at once. However, a batch process is not suitable for processing a signal in real time. As you work through the tutorial, you refine the design of the filter to convert the algorithm from batch-based to stream-based processing.

The baseline function signature for the algorithm is:

```
function [ signal_out, err, weights ] = ...
    lms_01(signal_in, desired)
```

The filtering is performed in the following loop:

```
for n = 1:SignalLength
  % Compute the output sample using convolution:
  signal_out(n,ch) = weights' * signal_in(n:n+FilterLength-1,ch);
  % Update the filter coefficients:
  err(n,ch) = desired(n,ch) - signal_out(n,ch) ;
  weights = weights + mu*err(n,ch)*signal_in(n:n+FilterLength-1,ch);
end
```

where `SignalLength` is the length of the input signal, `FilterLength` is the filter length, and `mu` is the adaptation step size.

What Is the Adaptation Step Size?

LMS algorithms have a step size that determines the amount of correction to apply as the filter adapts from one iteration to the next. Choosing the appropriate step size requires experience in adaptive filter design. A step size that is too small increases the time for the filter to converge. Filter convergence is the process where the error signal (the difference between the output signal and the desired signal) approaches an equilibrium state over time. A step size that is too large might cause the adapting filter to overshoot the equilibrium and become unstable. Generally, smaller step sizes improve the stability of the filter at the expense of the time it takes to adapt.

Filtering Process

The filtering process has three phases:

- Convolution

  The convolution for the filter is performed in:

  ```
  signal_out(n,ch) = weights' * signal_in(n:n+FilterLength-1,ch);
  ```

  #### What Is Convolution?

  Convolution is the mathematical foundation of filtering. In signal processing, convolving two vectors or matrices is equivalent to filtering one of the inputs by the other. In this implementation of the LMS filter, the convolution operation is the vector dot product between the filter weights and a subset of the distorted input signal.

- Calculation of error

  The error is the difference between the desired signal and the output signal:

  ```
  err(n,ch) = desired(n,ch) - signal_out(n,ch);
  ```

- Adaptation

  The new value of the filter weights is the old value of the filter weights plus a correction factor that is based on the error signal, the distorted signal, and the adaptation step size:

  ```
  weights = weights + mu*err(n,ch)*signal_in(n:n+FilterLength-1,ch);
  ```

Files for the Tutorial

About the Tutorial Files

The tutorial uses the following files:

- Simulink model files for each step of the tutorial.
- MATLAB code files for each step of the example.

  Throughout this tutorial, you work with Simulink models that call MATLAB files that contain a simple least mean squares (LMS) filter algorithm.

Location of Files

The tutorial files are available in the following folder: `docroot\toolbox\simulink\examples\lms`. To run the tutorial, you must copy these files to a local folder. For instructions, see "Copying Files Locally" on page 41-210.

Names and Descriptions of Files

Type	Name	Description
MATLAB files	`lms_01`	Baseline MATLAB implementation of batch filter. Not suitable for code generation.
	`lms_02`	Filter modified from batch to streaming.
	`lms_03`	Frame-based streaming filter with Reset and Adapt controls.
	`lms_04`	Frame-based streaming filter with Reset and Adapt controls. Suitable for code generation.

Type	Name	Description
	`lms_05`	Disabled inlining for code generation.
	`lms_06`	Demonstrates use of `coder.nullcopy`.
Simulink model files	`acoustic_environment`	Simulink model that provides an overview of the acoustic environment.
	`noise_cancel_00`	Simulink model without a MATLAB Function block.
	`noise_cancel_01`	Complete `noise_cancel_00` model including a MATLAB Function block.
	`noise_cancel_02`	Simulink model for use with `lms_02.m`.
	`noise_cancel_03`	Simulink model for use with `lms_03.m`.
	`noise_cancel_04`	Simulink model for use with `lms_04.m`.
	`noise_cancel_05`	Simulink model for use with `lms_05.m`.
	`noise_cancel_06`	Simulink model for use with `lms_06.m`.
	`design_templates`	Simulink model containing Adapt and Reset controls.

Tutorial Steps

Copying Files Locally

Copy the tutorial files to a local folder:

1. Create a local *solutions* folder, for example, `c:\test\lms\solutions`.
2. Change to the `docroot\toolbox\simulink\examples` folder. At the MATLAB command line, enter:

   ```
   cd(fullfile(docroot, 'toolbox', 'simulink', 'examples'))
   ```

3. Copy the contents of the `lms` subfolder to your *solutions* folder, specifying the full path name of the *solutions* folder:

   ```
   copyfile('lms', 'solutions')
   ```

   Your *solutions* folder now contains a complete set of solutions for the tutorial. If you do not want to perform the steps for each task, you can view the supplied solution to see how the code should look.
4. Create a local *work* folder, for example, `c:\test\lms\work`.
5. Copy the following files from your *solutions* folder to your *work* folder.

   - `lms_01`
   - `lms_02`
   - `noise_cancel_00`
   - `acoustic_environment`
   - `design_templates`

   Your *work* folder now contains all the files that you need to get started.

   You are now ready to set up your C compiler.

Setting Up Your C Compiler

Building your MATLAB Function block requires a supported compiler. MATLAB automatically selects one as the default compiler. If you have multiple MATLAB-supported compilers installed on your system, you can change the default using the `mex -setup` command. See “Change Default Compiler” (MATLAB) and the list of .

Running the acoustic_environment Model

Run the `acoustic_environment` model supplied with the tutorial to understand the problem that you are trying to solve using the LMS filter. This model adds band-limited white noise to an audio signal and outputs the resulting signal to a speaker.

To simulate the model:

1. Open the `acoustic_environment` model in Simulink:
   a. Set your MATLAB current folder to the folder that contains your working files for this tutorial. At the MATLAB command line, enter:

      ```
      cd work
      ```

      where *`work`* is the full path name of the folder containing your files. See "Find Files and Folders" (MATLAB) for more information.
   b. At the MATLAB command line, enter:

      ```
      acoustic_environment
      ```
2. Ensure that your speakers are on.
3. To simulate the model, from the Simulink model window, select **Simulation** > **Run**.

   As Simulink runs the model, you hear the audio signal distorted by noise.
4. While the simulation is running, double-click the Manual Switch to select the audio source.

   Now you hear the desired audio input without any noise.

The goal of this tutorial is to use a MATLAB LMS filter algorithm to remove the noise from the noisy audio signal. You do this by adding a MATLAB Function block to the model and calling the MATLAB code from this block.

Adding a MATLAB Function Block to Your Model

To modify the model and code yourself, work through the exercises in this section. Otherwise, open the supplied model `noise_cancel_01` in your *`solutions`* subfolder to see the modified model.

For the purposes of this tutorial, you add the MATLAB Function block to the `noise_cancel_00` model supplied with the tutorial. In practice, you would have to develop your own test bench starting with an empty Simulink model.

To add a MATLAB Function block to the `noise_cancel_00` model:

1. Open `noise_cancel_00` in Simulink.

   ```
   noise_cancel_00
   ```

2. Add a MATLAB Function block to the model:
   a. At the MATLAB command line, type `slLibraryBrowser` to open the Simulink Library Browser.
   b. From the list of Simulink libraries, select the `User-Defined Functions` library.
   c. Click the MATLAB Function block and drag it into the `noise_cancel_00` model. Place the block just above the red text annotation `Place MATLAB Function Block here`.
   d. Delete the red text annotations from the model.
   e. Save the model in the current folder as `noise_cancel_01`.

Calling Your MATLAB Code As an Extrinsic Function for Rapid Prototyping

In this part of the tutorial, you use the `coder.extrinsic` function to call your MATLAB code from the MATLAB Function block for rapid prototyping.

Why Call MATLAB Code As an Extrinsic Function?

Calling MATLAB code as an extrinsic function provides these benefits:

- For rapid prototyping, you do not have to make the MATLAB code suitable for code generation.
- Using `coder.extrinsic` enables you to debug your MATLAB code in MATLAB. You can add one or more breakpoints in the `lms_01.m` file, and then start the simulation in Simulink. When the MATLAB execution engine encounters a breakpoint, it temporarily halts execution so that you can inspect the MATLAB workspace and view the current values of all variables in memory. For more information about debugging MATLAB code, see “Debug a MATLAB Program” (MATLAB).

How to Call MATLAB Code As an Extrinsic Function

To call your MATLAB code from the MATLAB Function block:

1. Double-click the MATLAB Function block to open the MATLAB Function Block Editor.

2. Delete the default code displayed in the MATLAB Function Block Editor.
3. Copy the following code to the MATLAB Function block.

```
function [ Signal_Out, Weights ] = LMS(Noise_In, Signal_In) %#codegen
    % Extrinsic:
    coder.extrinsic('lms_01');

    % Compute LMS:
    [ ~, Signal_Out, Weights ] = lms_01(Noise_In, Signal_In);
end
```

Why Use the Tilde (~) Operator?

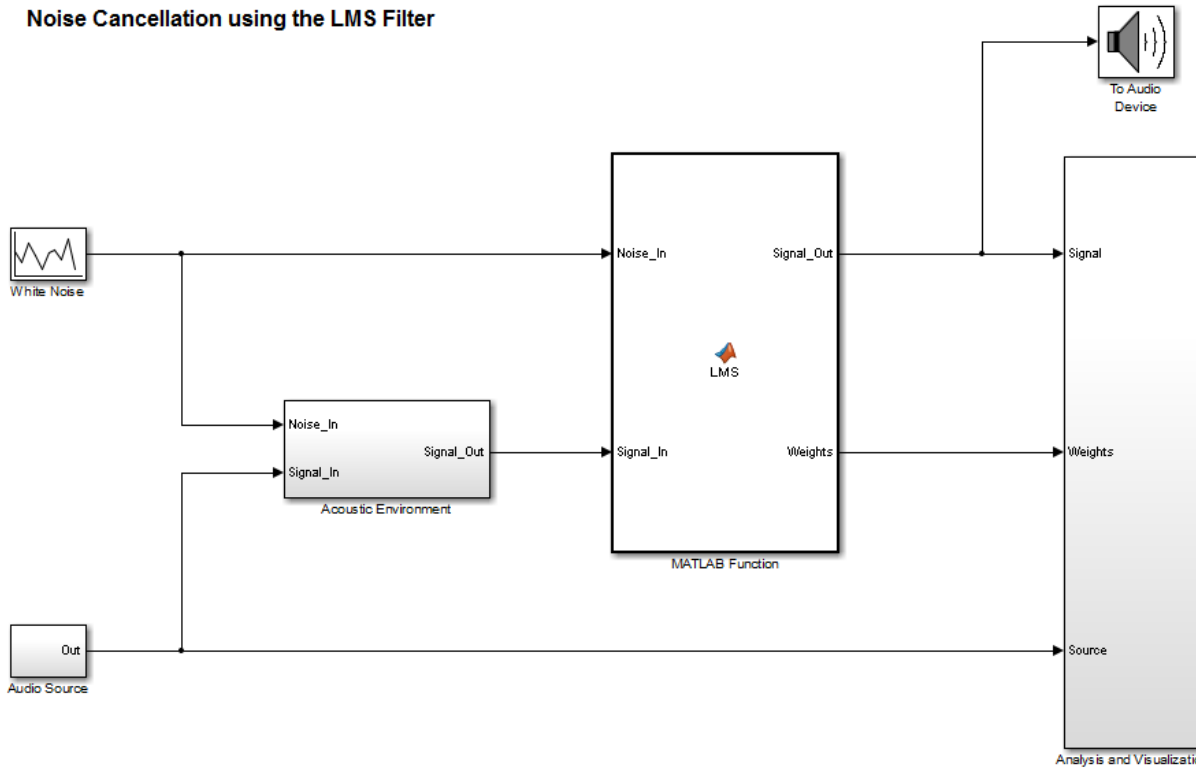
Because the `LMS` function does not use the first output from `lms_01`, replace this output with the MATLAB ~ operator. MATLAB ignores inputs and outputs specified by ~. This syntax helps avoid confusion in your program code and unnecessary clutter in your workspace, and allows you to reuse existing algorithms without modification.

4. Save the model.

   The `lms_01` function inputs `Noise_In` and `Signal_In` now appear as input ports to the block and the function outputs `Signal_Out` and `Weights` appear as output ports.

Connecting the MATLAB Function Block Inputs and Outputs

1. Connect the MATLAB Function block inputs and outputs so that your model looks like this.



See “Block and Signal Line Shortcuts and Actions” on page 1-92 for more information.

2 In the MATLAB Function block code, preallocate the outputs by adding the following code after the extrinsic call:

```
% Outputs:
Signal_Out = zeros(size(Signal_In));
Weights = zeros(32,1);
```

The size of `Weights` is set to match the Numerator coefficients of the Digital Filter in the Acoustic Environment subsystem.

Why Preallocate the Outputs?

For code generation, you must assign variables explicitly to have a specific class, size, and complexity before using them in operations or returning them as outputs in MATLAB functions. For more information, see “Differences Between Generated Code and MATLAB Code” on page 45-8.

3 Save the model.

You are now ready to check your model for errors.

Simulating the noise_cancel_01 Model

To simulate the model:

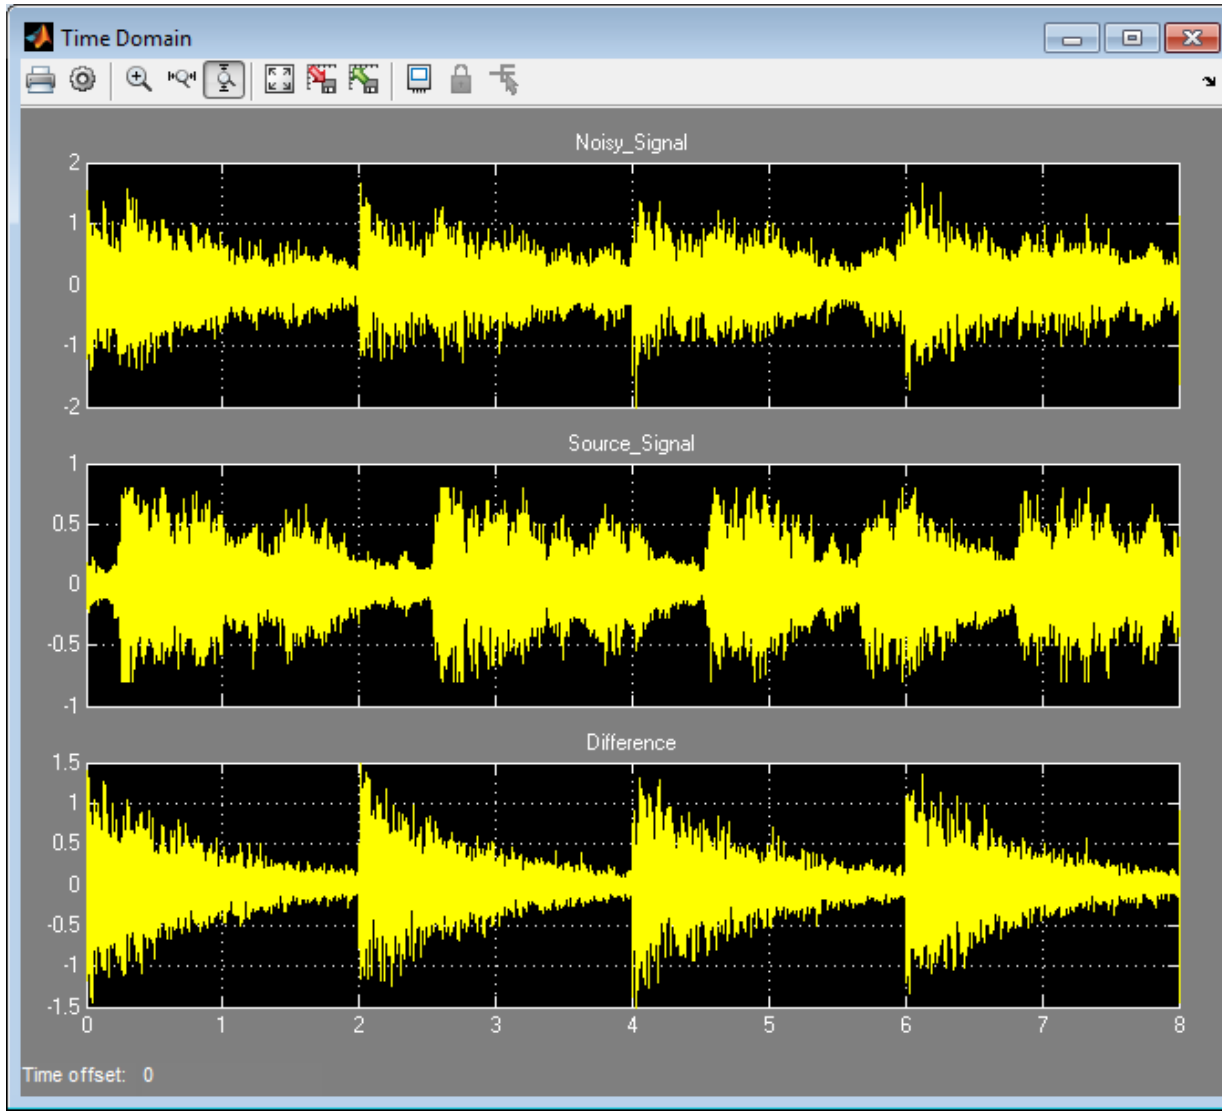
1 Ensure that you can see the **Time Domain** plots.

To view the plots, in the `noise_cancel_01` model, open the Analysis and Visualization block and then open the Time Domain block.

2 In the Simulink model window, select **Simulation > Run** .

As Simulink runs the model, you see and hear outputs. Initially, you hear the audio signal distorted by noise. Then the filter attenuates the noise gradually, until you hear only the music playing with very little noise remaining. After two seconds, you hear the distorted noisy signal again and the filter attenuates the noise again. This cycle repeats continuously.

MATLAB displays the following plot showing this cycle.



3 Stop the simulation.

Why Does the Filter Reset Every 2 Seconds?

The filter resets every 2 seconds because the model uses `16384` samples per frame and a sampling rate of `8192`, so the `16384` samples represent 2 seconds of audio.

To see the model configuration:

1. Double-click the White Noise subsystem and note that it uses a **Sample time** of `1/Fs` and **Samples per frame** of `FrameSize`. The `music` in the Audio Source subsystem also uses these values.
2. `FrameSize` is set in the model `InitFcn` callback. To view this callback:
   a. Right-click inside the model window and select **Model Properties** from the context menu.
   b. Select the **Callbacks** tab.
   c. Select `InitFcn` in the **Model callbacks** pane.

   Note that `FrameSize = 16*1024`, which is `16384`.
3. `Fs` is set in the model `PostLoadFcn` callback. To view this callback, select `PostLoadFcn` in the **Model callbacks** pane:

   The following MATLAB commands set up `Fs`:

```
data = load('handel.mat');
music = data.y;
Fs = data.Fs;
```

Modifying the Filter to Use Streaming

What Is Streaming?

A streaming filter is called repeatedly to process fixed-size chunks of input data, or *frames*, until it has processed the entire input signal. The frame size can be as small as a

single sample, in which case the filter would be operating in a sample-based mode, or up to a few thousand samples, for frame-based processing.

Why Use Streaming?

The design of the filter algorithm in `lms_01` has the following disadvantages:

- The algorithm does not use memory efficiently.

  Preallocating a fixed amount of memory for each input signal for the lifetime of the program means more memory is allocated than is in use.
- You must know the size of the input signal at the time you call the function.

  If the input signal is arriving in real time or as a stream of samples, you would have to wait to accumulate the entire signal before you could pass it, as a batch, to the filter.
- The signal size is limited to a maximum size.

In an embedded application, the filter is likely to be processing a continuous input stream. As a result, the input signal can be substantially longer than the maximum length that a filter working in batch mode could possibly handle. To make the filter work for any signal length, it must run in real time. One solution is to convert the filter from batch-based processing to stream-based processing.

Viewing the Modified MATLAB Code

The conversion to streaming involves:

- Introducing a first-in, first-out (FIFO) queue

  The FIFO queue acts as a temporary storage buffer, which holds a small number of samples from the input data stream. The number of samples held by the FIFO queue must be exactly the same as the number of samples in the filter's impulse response, so that the function can perform the convolution operation between the filter coefficients and the input signal.
- Making the FIFO queue and the filter weights persistent

  The filter is called repeatedly until it has processed the entire input signal. Therefore, the FIFO queue and filter weights need to persist so that the adaptation process does not have to start over again after each subsequent call to the function.

Open the supplied file `lms_02.m` in your *`work`* subfolder to see the modified algorithm.

Summary of Changes to the Filter Algorithm

Note the following important changes to the filter algorithm:

- The filter weights and the FIFO queue are declared as persistent:

```
persistent weights;
persistent fifo;
```

- The FIFO queue is initialized:

```
fifo = zeros(FilterLength,ChannelCount);
```

- The FIFO queue is used in the filter update loop:

```
% For each channel:
for ch = 1:ChannelCount

   % For each sample time:
   for n = 1:FrameSize

     % Update the FIFO shift register:
     fifo(1:FilterLength-1,ch) = fifo(2:FilterLength,ch);
     fifo(FilterLength,ch) = signal_in(n,ch);

     % Compute the output sample using convolution:
     signal_out(n,ch) = weights' * fifo(:,ch);

     % Update the filter coefficients:
     err(n,ch) = desired(n,ch) - signal_out(n,ch) ;
     weights = weights + mu*err(n,ch)*fifo(:,ch);

   end
end
```

- You cannot output a persistent variable. Therefore, a new variable, `weights_out`, is used to output the filter weights:

```
function [ signal_out, err, weights_out ] = ...
  lms_02(distorted, desired)

weights_out = weights;
```

Modifying Your Model to Call the Updated Algorithm

To modify the model yourself, work through the exercises in this section. Otherwise, open the supplied model `noise_cancel_02` in your *`solutions`* subfolder to see the modified model.

1. In the `noise_cancel_01` model, double-click the MATLAB Function block to open the MATLAB Function Block Editor.
2. Modify the MATLAB Function block code to call `lms_02`.
   a. Modify the extrinsic call.

   ```
   % Extrinsic:
   coder.extrinsic('lms_02');
   ```

   b. Modify the call to the filter algorithm.

   ```
   % Compute LMS:
   [ ~, Signal_Out, Weights ] = lms_02(Noise_In, Signal_In);
   ```

   #### Modified MATLAB Function Block Code

   Your MATLAB Function block code should now look like this:

   ```
   function [ Signal_Out, Weights ] = LMS(Noise_In, Signal_In)
     % Extrinsic:
     coder.extrinsic('lms_02');
     % Outputs:
     Signal_Out = zeros(size(Signal_In));
     Weights = zeros(32,1);
     % Compute LMS:
     [ ~, Signal_Out, Weights ] = lms_02(Noise_In, Signal_In);
   end
   ```

3. Change the frame size from `16384` to `64`, which represents a more realistic value.
   a. Right-click inside the model window and select **Model Properties** from the context menu.
   b. Select the **Callbacks** tab.
   c. In the **Model callbacks** list, select `InitFcn`.
   d. Change the value of `FrameSize` to `64`.
   e. Click **Apply** and close the dialog box.

4 Save your model as `noise_cancel_02`.

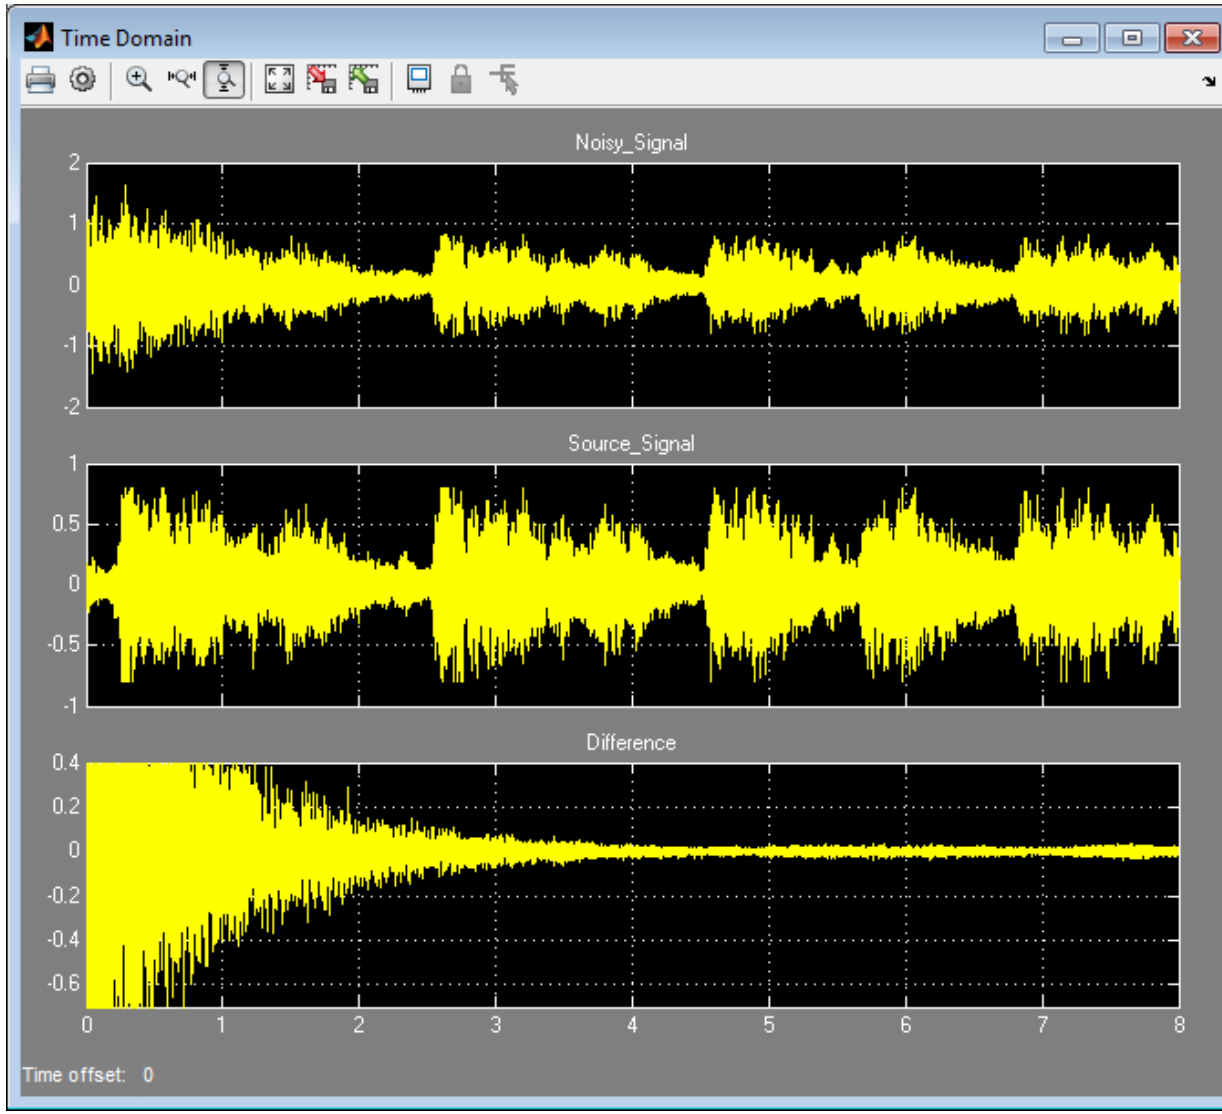
Simulating the Streaming Algorithm

To simulate the model:

1 Ensure that you can see the **Time Domain** plots.

2 Start the simulation.

As Simulink runs the model, you see and hear outputs. Initially, you hear the audio signal distorted by noise. Then, during the first few seconds, the filter attenuates the noise gradually, until you hear only the music playing with very little noise remaining. MATLAB displays the following plot showing filter convergence after only a few seconds.



3 Stop the simulation.

The filter algorithm is now suitable for Simulink. You are ready to elaborate your model to use `Adapt` and `Reset` controls.

Adding Adapt and Reset Controls

Why Add Adapt and Reset Controls?

In this part of the tutorial, you add Adapt and Reset controls to your filter. Using these controls, you can turn the filtering on and off. When `Adapt` is enabled, the filter continuously updates the filter weights. When `Adapt` is disabled, the filter weights remain at their current values. If `Reset` is set, the filter resets the filter weights.

Modifying Your MATLAB Code

To modify the code yourself, work through the exercises in this section. Otherwise, open the supplied file `lms_03.m` in your *`solutions`* subfolder to see the modified algorithm.

To modify your filter code:

1. Open `lms_02.m`.
2. In the `Set up` section, replace

   ```
   if ( isempty(weights) )
   ```

   with

   ```
   if ( reset || isempty(weights) )
   ```
3. In the filter loop, update the filter coefficients only if `Adapt` is `ON`.

   ```
   if adapt
     weights = weights + mu*err(n,ch)*fifo(:,ch);
   end
   ```
4. Change the function signature to use the `Adapt` and `Reset` inputs and change the function name to `lms_03`.

   ```
   function [ signal_out, err, weights_out ] = ...
     lms_03(signal_in, desired, reset, adapt)
   ```
5. Save the file in the current folder as `lms_03.m`:

Summary of Changes to the Filter Algorithm

Note the following important changes to the filter algorithm:

- The new input parameter `reset` is used to determine if it is necessary to reset the filter coefficients:

```
if ( reset || isempty(weights) )
  % Filter coefficients:
  weights = zeros(L,1);
  % FIFO Shift Register:
  fifo = zeros(L,1);
end
```

- The new parameter `adapt` is used to control whether the filter coefficients are updated or not.

```
if adapt
  weights = weights + mu*err(n)*fifo;
end
```

Modifying Your Model to Use Reset and Adapt Controls

To modify the model yourself, work through the exercises in this section. Otherwise, open the supplied model `noise_cancel_03` in your *`solutions`* subfolder to see the modified model.

1. Open the `noise_cancel_02` model.
2. Double-click the MATLAB Function block to open the MATLAB Function Block Editor.
3. Modify the MATLAB Function block code:
   a. Update the function declaration.

```
function [ Signal_Out, Weights ] = ...
   LMS(Adapt, Reset, Noise_In, Signal_In )
```

   b. Update the extrinsic call.

```
coder.extrinsic('lms_03');
```

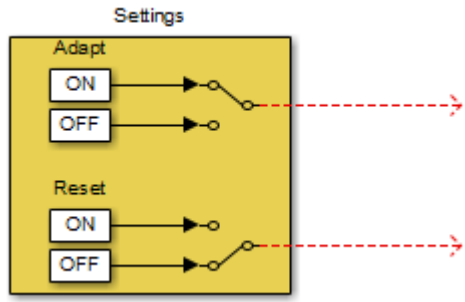
   c. Update the call to the LMS algorithm.

```
% Compute LMS:
[ ~, Signal_Out, Weights ] = ...
   lms_03(Noise_In, Signal_In, Reset, Adapt);
```

d Close the MATLAB Function Block Editor.

The `lms_03` function inputs `Reset` and `Adapt` now appear as input ports to the MATLAB Function block.

4 Open the `design_templates` model.



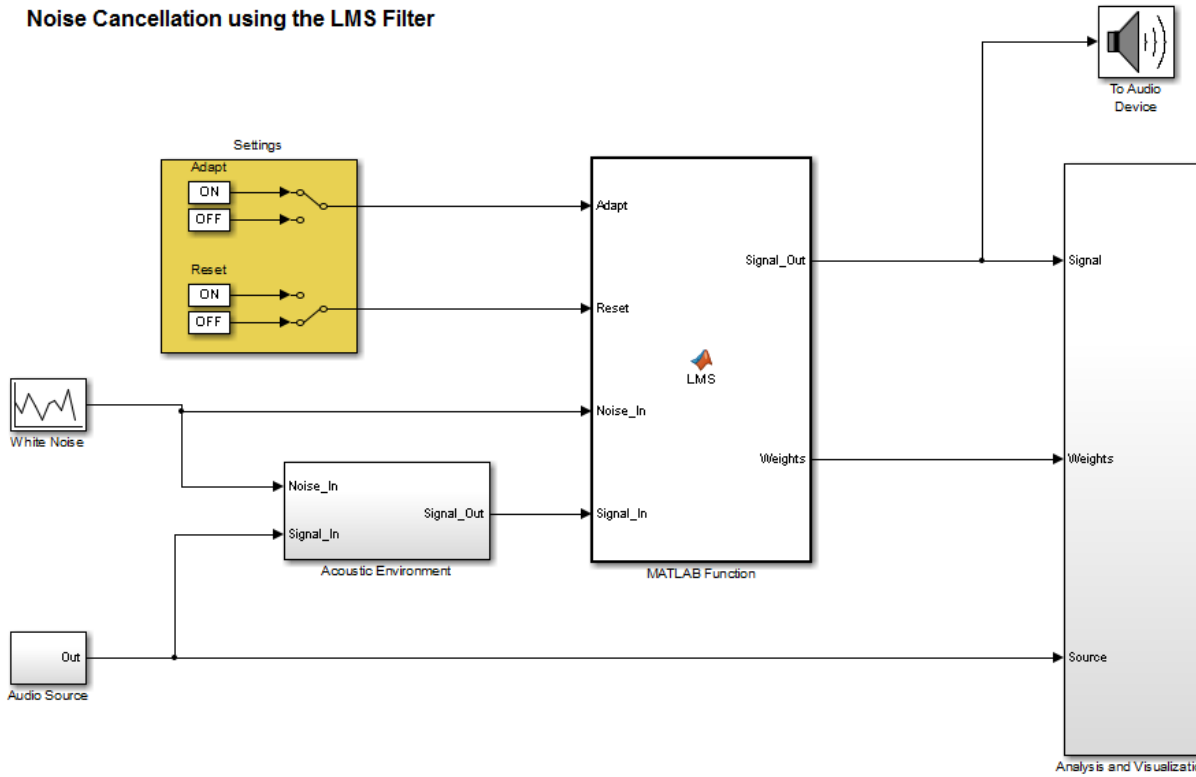
5 Copy the Settings block from this model to your `noise_cancel_02` model:

a From the `design_templates` model menu, select **Edit** > **Select All**.

b Select **Edit** > **Copy**.

c From the `noise_cancel_02` model menu, select **Edit** > **Paste**.

6 Connect the Adapt and Reset outputs of the Settings subsystem to the corresponding inputs on the MATLAB Function block. Your model should now appear as follows.



7 Save the model as `noise_cancel_03`.

Simulating the Model with Adapt and Reset Controls

To simulate the model and see the effect of the Adapt and Reset controls:

1 In the `noise_cancel_03` model, view the Convergence scope:

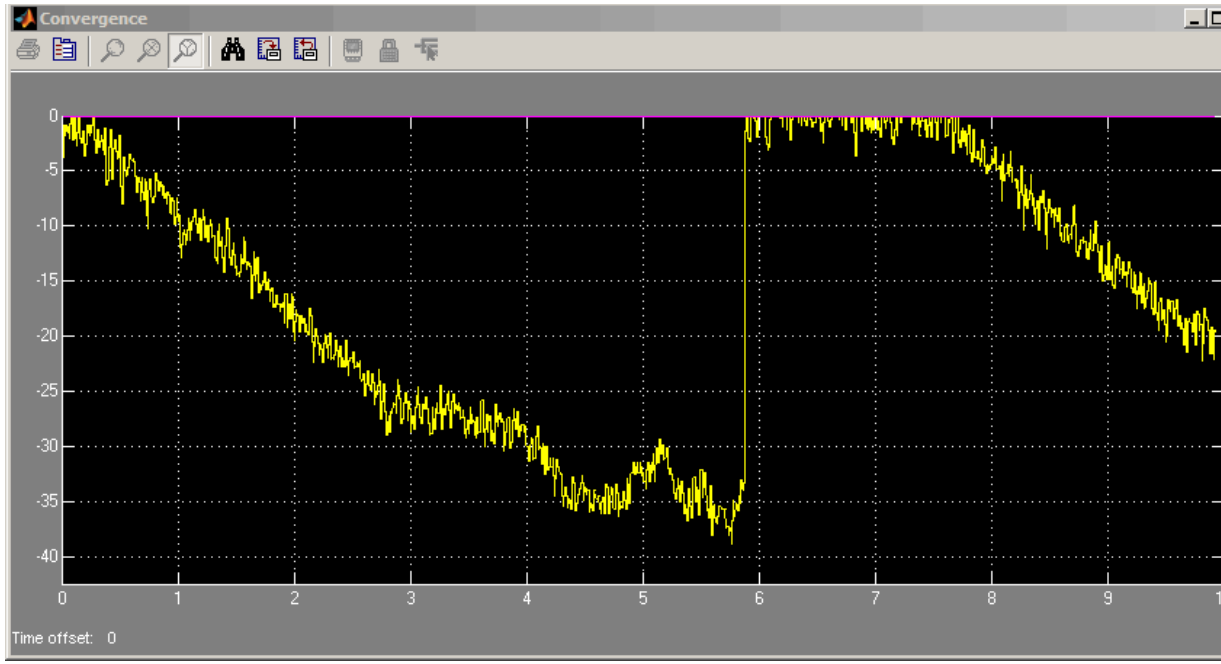
   a Double-click the Analysis and Visualization subsystem.

   b Double-click the Convergence scope.

2 In the Simulink model window, select **Simulation > Run**.

   Simulink runs the model as before. While the model is running, toggle the Adapt and Reset controls and view the Convergence scope to see their effect on the filter.

The filter converges when `Adapt` is `ON` and `Reset` is `OFF`, then resets when you toggle`Reset`. The results might look something like this:



3 Stop the simulation.

Generating Code

You have proved that your algorithm works in Simulink. Next you generate code for your model. Before generating code, you must ensure that your MATLAB code is suitable for code generation. For code generation, you must remove the extrinsic call to your code.

Making Your Code Suitable for Code Generation

To modify the model and code yourself, work through the exercises in this section. Otherwise, open the supplied model `noise_cancel_04` and file `lms_04.m` in your *`solutions`* subfolder to see the modifications.

1 Rename the MATLAB Function block to `LMS_Filter`. Select the annotation `MATLAB Function` below the MATLAB Function block and replace the text with `LMS_Filter`.

When you generate code for the MATLAB Function block, Simulink Coder uses the name of the block in the generated code. It is good practice to use a meaningful name.

2 In your `noise_cancel_03` model, double-click the MATLAB Function block.

The MATLAB Function Block Editor opens.

3 Delete the extrinsic declaration.

```
% Extrinsic:
coder.extrinsic('lms_03');
```

4 Delete the preallocation of outputs.

```
% Outputs:
Signal_Out = zeros(size(Signal_In));
Weights = zeros(32,1);
```

5 Modify the call to the filter algorithm.

```
% Compute LMS:
[ ~, Signal_Out, Weights ] = ...
   lms_04(Noise_In, Signal_In, Reset, Adapt);
```

6 Save the model as `noise_cancel_04`.

7 Open `lms_03.m`

a Modify the function name to `lms_04`.

b Turn on error checking specific to code generation by adding the `%#codegen` compilation directive after the function declaration.

```
function [ signal_out, err, weights_out ] = ...
    lms_04(signal_in, desired, reset, adapt) %#codegen
```

The code analyzer message indicator in the top right turns red to indicate that the code analyzer has detected code generation issues. The code analyzer underlines the offending code in red and places a red marker to the right of it.

8 Move your pointer over the first red marker to view the error information.

The code analyzer detects that code generation requires `signal_out` to be fully defined before subscripting it and does not support growth of variable size data through indexing.

9 Move your pointer over the second red marker and note that the code analyzer detects the same errors for `err`.

10 To address these errors, preallocate the outputs `signal_out` and `err`. Add this code after the filter setup.

```
% Output Arguments:

% Pre-allocate output and error signals:
signal_out = zeros(FrameSize,ChannelCount);
err = zeros(FrameSize,ChannelCount);
```

Why Preallocate the Outputs?

You must preallocate outputs here because code generation does not support increasing the size of an array over time. Repeatedly expanding the size of an array over time can adversely affect the performance of your program. See "Preallocating Memory" (MATLAB).

The red error markers for the two lines of code disappear. The code analyzer message indicator in the top right edge of the code turns green, which indicates that you have fixed all the errors and warnings detected by the code analyzer.

11 Save the file as `lms_04.m`.

Generating Code for noise_cancel_04

1 Before generating code, ensure that Simulink Coder creates a code generation report. This HTML report provides easy access to the list of generated files with a summary of the configuration settings used to generate the code.

   a In the Simulink model window, select **Simulation > Model Configuration Parameters**.

   b In the left pane of the Configuration Parameters dialog box, select **Code Generation > Report**.

   c In the right pane, select **Create code generation report**.

   The **Launch report automatically** option is also selected.

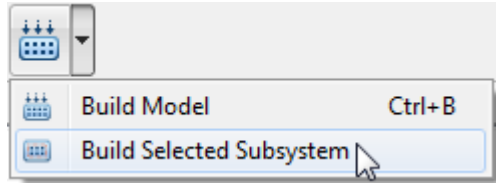
   d Click **Apply** and close the Configuration Parameters dialog box.

   e Save your model.

2 To generate code for the LMS Filter subsystem:

   a In your model, select the LMS Filter subsystem.

   b From the Build Model tool menu, select **Build Selected Subsystem**.



The **Build code for subsystem** dialog box appears. Click the **Build** button.

The Simulink Coder software generates C code for the subsystem and launches the code generation report.

For more information on using the code generation report, see "Generate a Code Generation Report" (Simulink Coder) in the Simulink Coder documentation.

c In the left pane of the code generation report, click the `LMS_Filter.c` link to view the generated C code. Note that the `lms_04` function has no code because inlining is enabled by default.

3 Modify your filter algorithm to disable inlining:

a In `lms_04.m`, after the function declaration, add:

```
coder.inline('never')
```

b Change the function name to `lms_05` and save the file as `lms_05.m` in the current folder.

c In your `noise_cancel_04` model, double-click the MATLAB Function block.

The MATLAB Function Block Editor opens.

d Modify the call to the filter algorithm to call `lms_05`.

```
% Compute LMS:
[ ~, Signal_Out, Weights ] = ...
   lms_05(Noise_In, Signal_In, Reset, Adapt);
```

e Save the model as `noise_cancel_05`.

4 Generate code for the updated model.

a In the model, select the LMS Filter subsystem.

b From the Build Model tool menu, select **Build Selected Subsystem**.

The **Build code for subsystem** dialog box appears.

c Click the **Build** button.

The Simulink Coder software generates C code for the subsystem and launches the code generation report.

d In the left pane of the code generation report, click the `LMS_Filter.c` link to view the generated C code.

This time the `lms_05` function has code because you disabled inlining.

```
/* Forward declaration for local functions */
   static void LMS_Filter_lms_05 ...
       (const real_T signal_in[64],const real_T ...
       desired[64], real_T reset, real_T adapt, ...
             real_T signal_out[64], ...
      real_T err[64], real_T weights_out[32]);

/* Function for MATLAB Function Block: 'root/LMS_Filter' */
   static void LMS_Filter_lms_05 ...
      (const real_T signal_in[64], const real_T ...
         desired[64], real_T reset, real_T adapt, ...
             real_T signal_out[64], ...
    real_T err[64], real_T weights_out[32])
```

Optimizing the LMS Filter Algorithm

This part of the tutorial demonstrates when and how to preallocate memory for a variable without incurring the overhead of initializing memory in the generated code.

In `lms_05.m`, the MATLAB code not only declares `signal_out` and `err` to be a `FrameSize`-by-`ChannelCount` vector of real doubles, but also initializes each element of `signal_out` and `err` to zero. These signals are initialized to zero in the generated C code.

MATLAB Code	Generated C Code

`% Pre-allocate output and error signals:`
`signal_out =`
`zeros(FrameSize,ChannelCount);`
`err = zeros(FrameSize,ChannelCount);`
	`/* Pre-allocate output and error signals: */`
	`79 for (i = 0; i < 64; i++) {`
	`80 signal_out[i] = 0.0;`
	`81 err[i] = 0.0;`
	`82 }`

This forced initialization is unnecessary because both `signal_out` and `err` are explicitly initialized in the MATLAB code before they are read.

Note You should not use `coder.nullcopy` when declaring the variables `weights` and `fifo` because these variables need to be initialized in the generated code. Neither variable is explicitly initialized in the MATLAB code before they are read.

Use `coder.nullcopy` in the declaration of `signal_out` and `err` to eliminate the unnecessary initialization of memory in the generated code:

1. In `lms_05.m`, preallocate `signal_out` and `err` using `coder.nullcopy`:

   ```
   % Pre-allocate output and error signals:
   signal_out = coder.nullcopy(zeros(FrameSize, ChannelCount));
   err = coder.nullcopy(zeros(FrameSize, ChannelCount));
   ```

   Caution After declaring a variable with `coder.nullcopy`, you must explicitly initialize the variable in your MATLAB code before reading it. Otherwise, you might get unpredictable results.

2. Change the function name to `lms_06` and save the file as `lms_06.m` in the current folder.
3. In your `noise_cancel_05` model, double-click the MATLAB Function block.

   The MATLAB Function Block Editor opens.
4. Modify the call to the filter algorithm.

   ```
   % Compute LMS:
   [ ~, Signal_Out, Weights ] = ...
      lms_06(Noise_In, Signal_In, Reset, Adapt);
   ```
5. Save the model as `noise_cancel_06`.

Generate code for the updated model.

1. Select the LMS Filter subsystem.
2. From the Build Model tool menu, select **Build Selected Subsystem**.

   The **Build code for subsystem** dialog box appears. Click the **Build** button.

   The Simulink Coder software and generates C code for the subsystem and launches the code generation report.
3. In the left pane of the code generation report, click the `LMS_Filter.c` link to view the generated C code.

In the generated C code, this time there is no initialization to zero of `signal_out` and `err`.

Encapsulating the Interface to External Code

Use the `coder.ExternalDependency` class to encapsulate the interface between external code and MATLAB code intended for code generation. With the encapsulation, you can separate the details of the interface from your MATLAB code. The methods of `coder.ExternalDependency`:

- specify the location of external files
- update build information
- define the programming interface for external functions

In your MATLAB code, you can call the external code without providing build information.

The workflow is:

1. Write a class definition file for a class that derives from `coder.ExternalDependency`.
2. Store the class definition file in a folder on the MATLAB path.
3. In your MATLAB code, use a method of the class to call an external function.
4. Generate code from your MATLAB code.

See Also

`coder.ExternalDependency`

Related Examples

- “Encapsulate Interface to an External C Library” on page 41-235

More About

- “Best Practices for Using coder.ExternalDependency” on page 41-238

Encapsulate Interface to an External C Library

Use `coder.ExternalDependency` to encapsulate the interface to an external C dynamic linked library .

Write a function `adder` that returns the sum of its inputs.

```
function c = adder(a,b)
    %#codegen
    c = a + b;
end
```

Generate a library that contains `adder`.

```
codegen('adder','-args', {-2,5}, '-config:dll', '-report');
```

Write the class definition file `AdderAPI.m` to encapsulate the library interface.

```
%=================================================================
% This class abstracts the API to an external Adder library.
% It implements static methods for updating the build information
% at compile time and build time.
%=================================================================

classdef AdderAPI < coder.ExternalDependency
    %#codegen

    methods (Static)

        function bName = getDescriptiveName(~)
            bName = 'AdderAPI';
        end

        function tf = isSupportedContext(ctx)
            if  ctx.isMatlabHostTarget()
                tf = true;
            else
                error('adder library not available for this target');
            end
        end

        function updateBuildInfo(buildInfo, ctx)
            [~, linkLibExt, execLibExt, ~] = ctx.getStdLibInfo();
```

```
    % Header files
    hdrFilePath = fullfile(pwd, 'codegen', 'dll', 'adder');
    buildInfo.addIncludePaths(hdrFilePath);

    % Link files
    linkFiles = strcat('adder', linkLibExt);
    linkPath = hdrFilePath;
    linkPriority = '';
    linkPrecompiled = true;
    linkLinkOnly = true;
    group = '';
    buildInfo.addLinkObjects(linkFiles, linkPath, ...
        linkPriority, linkPrecompiled, linkLinkOnly, group);

    % Non-build files
    nbFiles = 'adder';
    nbFiles = strcat(nbFiles, execLibExt);
    buildInfo.addNonBuildFiles(nbFiles,'','');
end

%API for library function 'adder'
function c = adder(a, b)
    if coder.target('MATLAB')
        % running in MATLAB, use built-in addition
        c = a + b;
    else
        % running in generated code, call library function
        coder.cinclude('adder.h');

        % Because MATLAB Coder generated adder, use the
        % housekeeping functions before and after calling
        % adder with coder.ceval.
        % Call initialize function before calling adder for the
        % first time.

        coder.ceval('adder_initialize');
        c = 0;
        c = coder.ceval('adder', a, b);

        % Call the terminate function after
        % calling adder for the last time.

        coder.ceval('adder_terminate');
```

```
            end
        end
    end
end
```

Write a function `adder_main` that calls the external library function `adder`.

```
function y = adder_main(x1, x2)
%#codegen
    y = AdderAPI.adder(x1, x2);
end
```

Generate a MEX function for `adder_main`. The MEX Function exercises the `coder.ExternalDependency` methods.

```
codegen('adder_main', '-args', {7,9}, '-report')
```

Copy the library to the current folder using the file extension for your platform.

For Windows, use:

```
copyfile(fullfile(pwd, 'codegen', 'dll', 'adder', 'adder.dll'));
```

For Linux, use:

```
copyfile(fullfile(pwd, 'codegen', 'dll', 'adder', 'adder.so'));
```

For Mac, use:

```
copyfile(fullfile(pwd, 'codegen', 'dll', 'adder', 'adder.dylib'));
```

Run the MEX function and verify the result.

```
adder_main_mex(2,3)
```

`coder.BuildConfig` | `coder.ExternalDependency` | `error`

More About

- “Encapsulating the Interface to External Code” on page 41-234

Best Practices for Using coder.ExternalDependency

In this section...

Terminate Code Generation for Unsupported External Dependency

The `isSupportedContext` method returns true if the external code interface is supported in the build context. If the external code interface is not supported, do not return false. Instead, use `error` to terminate code generation with an error message. For example:

```
function tf = isSupportedContext(ctx)
    if  ctx.isMatlabHostTarget()
        tf = true;
    else
        error('MyLibrary is not available for this target');
    end
end
```

Parameterize Methods for MATLAB and Generated Code

Parameterize methods that call external functions so that the methods run in MATLAB. For example:

```
...
if coder.target('MATLAB')
    % running in MATLAB, use built-in addition
    c = a + b;
else
    % running in generated code, call library function
    coder.ceval('adder_initialize');
end
...
```

Parameterize updateBuildInfo for Multiple Platforms

Parameterize the `updateBuildInfo` method to support multiple platforms. For example, use `coder.BuildConfig.getStdLibInfo` to get the platform-specific library file extensions.

```
...
    [~, linkLibExt, execLibExt, ~] = ctx.getStdLibInfo()
% Link files
linkFiles =  strcat('adder', linkLibExt);
buildInfo.addLinkObjects(linkFiles, linkPath, linkPriority, ...
    linkPrecompiled, linkLinkOnly, group);
...
```

Update Build Information from MATLAB code

You can control aspects of the build process that occur after code generation but before compilation. For example, you can specify compiler or linker options.

To customize the build from your MATLAB code:

1. In your MATLAB code, call `coder.updateBuildInfo` to update the build information object. You specify a build information object method and the input arguments for the method.
2. Generate code from your MATLAB code.

See Also

`coder.updateBuildInfo`

Define New System Objects

Customize System Block Appearance

In this section...

Specify Input and Output Names

Specify the names of the input and output ports of a System object–based block implemented using a MATLAB System block.

Use `getInputNamesImpl` and `getOutputNamesImpl` to specify the names of the input port as “source data” and the output port as “count.”

If you do not specify the `getInputNamesImpl` and `getOutputNamesImpl` methods, the object uses the `stepImpl` method input and output variable names for the input and output port names, respectively. If the `stepImpl` method uses *varargin* and *varargout* instead of variable names, the port names default to empty character vectors.

```
methods (Access = protected)
   function inputName = getInputNamesImpl(~)
          inputName = 'source data';
   end

   function outputName = getOutputNamesImpl(~)
          outputName = 'count';
   end
end
```

Complete Class Definition with Named Inputs and Outputs

```
classdef MyCounter < matlab.System

   % MyCounter Count values above a threshold

    properties
       Threshold = 1
    end
    properties (DiscreteState)
```

```
        Count
    end

    methods
        function obj = MyCounter(varargin)
            setProperties (obj,nargin,varargin{:});
        end
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.Count = 0;
        end
        function resetImpl(obj)
            obj.Count = 0;
        end
        function y = stepImpl(obj,u)
            if (u > obj.Threshold)
                obj.Count = obj.Count + 1;
            end
            y = obj.Count;
        end
        function inputName = getInputNamesImpl(~)
            inputName = 'source data';
        end
        function outputName = getOutputNamesImpl(~)
            outputName = 'count';
        end
    end
end
```

Add Text to Block Icon

Add text to the block icon of a System object–based block implemented using a MATLAB System block.

1. Subclass from custom icon class.

   ```
   classdef MyCounter < matlab.System & matlab.system.mixin.CustomIcon
   ```

2. Use `getIconImpl` to specify the block icon as `New Counter` with a line break between the two words.

   ```
   methods (Access = protected)
       function icon = getIconImpl(~)
   ```

```
        icon = {'New','Counter'};
    end
end
```

Complete Class Definition File with Defined Icon

```
classdef MyCounter < matlab.System & ...
   matlab.system.mixin.CustomIcon

   % MyCounter Count values above a threshold

    properties
       Threshold = 1
    end
    properties (DiscreteState)
       Count
    end

    methods
       function obj = MyCounter(varargin)
          setProperties(obj,nargin,varargin{:});
       end
    end

    methods (Access = protected)
       function setupImpl(obj)
          obj.Count = 0;
       end
       function resetImpl(obj)
          obj.Count = 0;
       end
       function y = stepImpl(obj,u)
          if (u > obj.Threshold)
             obj.Count = obj.Count + 1;
          end
          y = obj.Count;
       end
       function icon = getIconImpl(~)
          icon = {'New','Counter'};
       end
    end
end
```

Add Image to Block Icon

Define an image on the block icon of a System object–based block implemented using a MATLAB System block.

1 Subclass from custom icon class.

```
classdef MyCounter < matlab.System & matlab.system.mixin.CustomIcon
```

2 Use `getIconImpl` method to call the `matlab.system.display.Icon` class and specify the image.

```
methods (Access = protected)
    function icon = getIconImpl(~)
        icon = matlab.system.display.Icon('counter.png');
    end
end
```

Complete Class Definition File with Icon Image

```
classdef MyCounter < matlab.System & ...
   matlab.system.mixin.CustomIcon

   % MyCounter Count values above a threshold

    properties
       Threshold = 1
    end
    properties (DiscreteState)
       Count
    end

    methods
       function obj = MyCounter(varargin)
          setProperties(obj,nargin,varargin{:});
       end
    end

    methods (Access = protected)
       function setupImpl(obj)
          obj.Count = 0;
       end
       function resetImpl(obj)
          obj.Count = 0;
       end
```

```
            function y = stepImpl(obj,u)
               if (u > obj.Threshold)
                  obj.Count = obj.Count + 1;
               end
               y = obj.Count;
            end
            function icon = getIconImpl(~)
               icon = matlab.system.display.Icon('counter.png');
            end
         end
      end
```

Customize System Block Dialog Box

In this section...

Add Header to MATLAB System Block

Add a header panel to a System object–based block implemented using a MATLAB System block.

Define Header Title and Text

Use `getHeaderImpl` to specify a panel title and text for the `MyCounter` System object.

If you do not specify the `getHeaderImpl`, the block does not display any title or text for the panel.

You always set the `getHeaderImpl` method access to `protected` because it is an internal method that end users do not directly call or run.

```
methods (Static, Access = protected)
   function header = getHeaderImpl
      header = matlab.system.display.Header('MyCounter',...
        'Title','My Enhanced Counter');
   end
end
```

Complete Class Definition File with Defined Header

```
 classdef MyCounter < matlab.System

   % MyCounter Count values

    properties
       Threshold = 1
    end
```

```
    properties (DiscreteState)
       Count
    end

    methods (Static, Access = protected)
      function header = getHeaderImpl
         header = matlab.system.display.Header('MyCounter',...
           'Title','My Enhanced Counter',...
           'Text', 'This counter is an enhanced version.');
      end
    end

    methods (Access = protected)
       function setupImpl(obj,u)
          obj.Count = 0;
       end
       function y = stepImpl(obj,u)
          if (u > obj.Threshold)
             obj.Count = obj.Count + 1;
          end
          y = obj.Count;
       end
       function resetImpl(obj)
          obj.Count = 0;
       end
    end
end
```

Add Data Types Tab to MATLAB System Block

Add a **Data Types** tab to the MATLAB System block dialog box. This tab includes fixed-point data type settings.

Display Data Types Tab

Use `matlab.system.showFiSettingsImpl` to display the **Data Types** tab in the MATLAB System block dialog.

```
methods (Static, Access = protected)
   function showTab = showFiSettingsImpl
      showTab = true;
   end
end
```

Complete Class Definition File with Data Types Tab

Use `showFiSettingsImpl` to display the **Data Types** tab for a System object that adds an offset to a fixed-point input.

```
classdef FiTabAddOffset < matlab.System
% FiTabAddOffset Add an offset to input

   properties
      Offset = 1;
   end

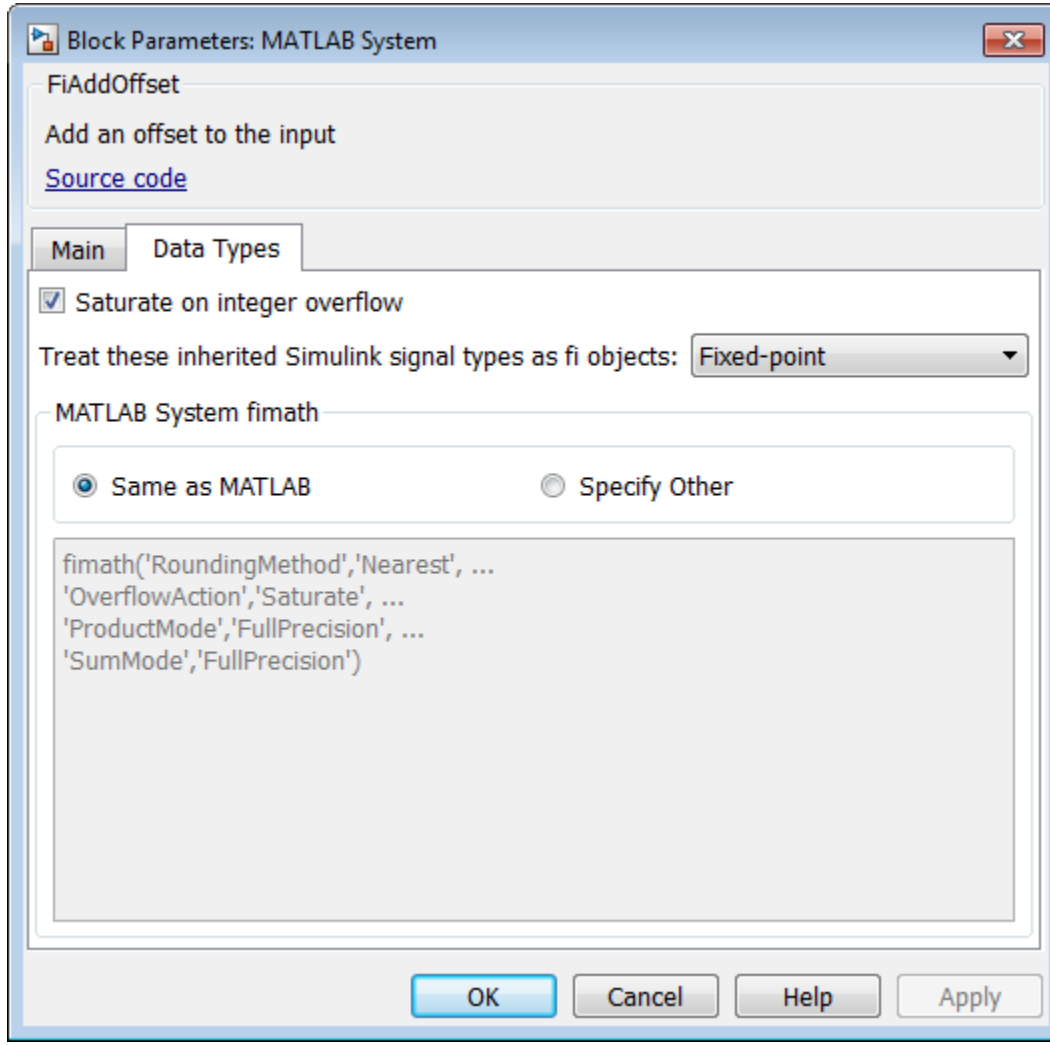
   methods
      function obj = FiTabAddOffset(varargin)
         setProperties(obj,nargin,varargin{:});
      end
   end

   methods (Access = protected)
      function y = stepImpl(~,u)
         y = u + obj.Offset;
      end
   end

   methods(Static, Access=protected)
      function header = getHeaderImpl
         header = matlab.system.display.Header('Title',...
              'Add Offset','Text','Add an offset to the input');
      end

      function isVisible = showFiSettingsImpl
         isVisible = true;
      end
   end
end
```

Dialog Box with the Data Types Tab



Add Property Groups to System Object and MATLAB System Block

Define property sections and section groups for System object display. The sections and section groups display as panels and tabs, respectively, in the MATLAB System block dialog.

Define Section of Properties

Use `matlab.system.display.Section` and `getPropertyGroupsImpl` to define two property group sections by specifying their titles and property lists.

If you do not specify a property in `getPropertyGroupsImpl`, the block does not display that property.

```
methods (Static, Access = protected)
   function groups = getPropertyGroupsImpl
      valueGroup = matlab.system.display.Section(...
           'Title','Value parameters',...
           'PropertyList',{'StartValue','EndValue'});

      thresholdGroup = matlab.system.display.Section(...
           'Title','Threshold parameters',...
           'PropertyList',{'Threshold','UseThreshold'});
      groups = [valueGroup,thresholdGroup];
   end
end
```

Define Group of Sections

Use `matlab.system.display.SectionGroup`, `matlab.system.display.Section`, and `getPropertyGroupsImpl` to define two tabs, each containing specific properties.

```
methods (Static, Access = protected)
   function groups = getPropertyGroupsImpl
      upperGroup = matlab.system.display.Section(...
           'Title', 'Upper threshold', ...
           'PropertyList',{'UpperThreshold'});
      lowerGroup = matlab.system.display.Section(...
           'Title','Lower threshold', ...
           'PropertyList',{'UseLowerThreshold','LowerThreshold'});

      thresholdGroup = matlab.system.display.SectionGroup(...
           'Title', 'Parameters', ...
           'Sections',  [upperGroup,lowerGroup]);

      valuesGroup = matlab.system.display.SectionGroup(...
           'Title', 'Initial conditions', ...
           'PropertyList',  {'StartValue'});

      groups = [thresholdGroup, valuesGroup];
```

```
    end
end
```

Complete Class Definition File with Property Group and Separate Tab

```
classdef EnhancedCounter < matlab.System
    % EnhancedCounter  Count values considering thresholds

    properties
        UpperThreshold = 1;
        LowerThreshold = 0;
    end

    properties (Nontunable)
        StartValue = 0;
    end

    properties(Logical,Nontunable)
        % Count values less than lower threshold
        UseLowerThreshold = true;
    end

    properties (DiscreteState)
        Count;
    end

    methods (Static, Access = protected)
        function groups = getPropertyGroupsImpl
            upperGroup = matlab.system.display.Section(...
                'Title', 'Upper threshold', ...
                'PropertyList',{'UpperThreshold'});
            lowerGroup = matlab.system.display.Section(...
                'Title','Lower threshold', ...
                'PropertyList',{'UseLowerThreshold','LowerThreshold'});

            thresholdGroup = matlab.system.display.SectionGroup(...
                'Title', 'Parameters', ...
                'Sections',  [upperGroup,lowerGroup]);

            valuesGroup = matlab.system.display.SectionGroup(...
                'Title', 'Initial conditions', ...
                'PropertyList',  {'StartValue'});

            groups = [thresholdGroup, valuesGroup];
        end
```

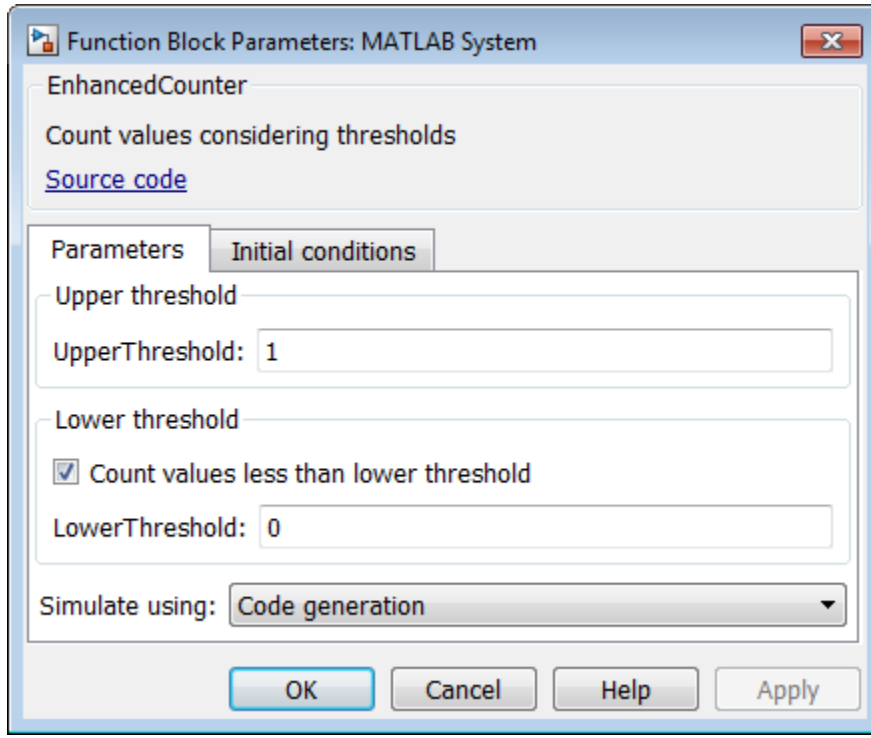
```
    end

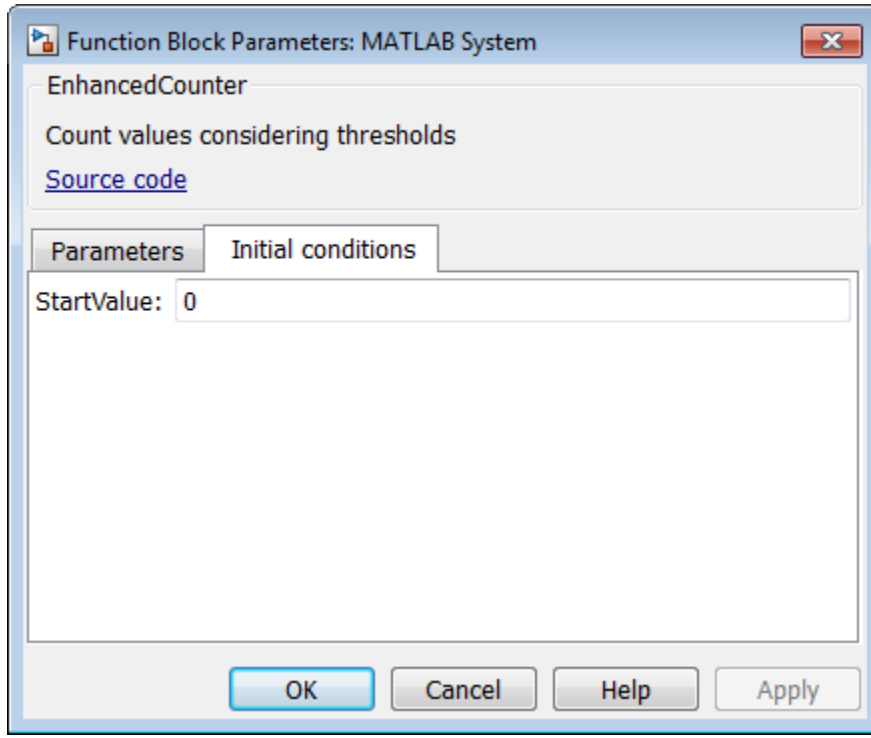
    methods (Access = protected)
        function setupImpl(obj)
            obj.Count = obj.StartValue;
        end

        function y = stepImpl(obj,u)
            if obj.UseLowerThreshold
                if (u > obj.UpperThreshold) || ...
                       (u <  obj.LowerThreshold)
                    obj.Count = obj.Count + 1;
                end
            else
                if (u > obj.UpperThreshold)
                    obj.Count = obj.Count + 1;
                end
            end
            y = obj.Count;
        end
        function resetImpl(obj)
            obj.Count = obj.StartValue;
        end

        function flag = isInactivePropertyImpl(obj, prop)
            flag = false;
            switch prop
                case 'LowerThreshold'
                    flag = ~obj.UseLowerThreshold;
            end
        end
    end
end
```

Customized Dialog Box





Control Simulation Type in MATLAB System Block

Specify a simulation type and whether the **Simulate using** parameter appears on the Simulink MATLAB System block dialog box. The simulation options are `'Code generation'` and `'Interpreted mode'`.

If you do not include the `getSimulateUsingImpl` method in your class definition file, the System object allows both simulation modes and defaults to `'Code generation'`. If you do not include the `showSimulateUsingImpl` method, the **Simulate using** parameter appears on the block dialog box.

You must set the `getSimulateUsingImpl` and `showSimulateUsingImpl` methods to `static` and the access for these methods to `protected`.

Use `getSimulateUsingImpl` to specify that only interpreted execution is allowed for the System object.

```
methods(Static,Access = protected)
   function simMode = getSimulateUsingImpl
       simMode = 'Interpreted execution';
    end
end
```

View the method in the complete class definition file.

```
classdef PlotRamp < matlab.System
  % Display a button to launch a plot figure.

  properties (Nontunable)
    RampLimit = 10;
  end

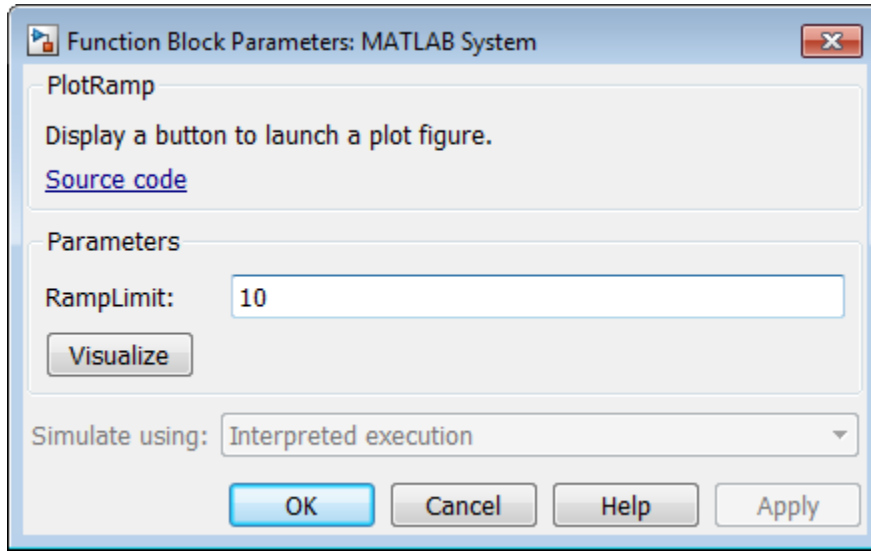
  methods(Static, Access=protected)
    function group = getPropertyGroupsImpl
      group = matlab.system.display.Section(mfilename('class'));
      group.Actions = matlab.system.display.Action(@(~,obj)...
            visualize(obj),'Label','Visualize');
    end

    function simMode = getSimulateUsingImpl
      simMode = 'Interpreted execution';
    end
  end

  methods
    function obj = ActionDemo(varargin)
      setProperties(obj,nargin,varargin{:});
    end

    function visualize(obj)
      figure;
      d = 1:obj.RampLimit;
      plot(d);
    end
   methods(Static,Access = protected)
   end
  end
end
```

Dialog Box with Simulation Type Parameter



Add Button to MATLAB System Block

Add a button to the MATLAB System block dialog box. This button opens a figure that plots a ramp function.

Define Action for Dialog Button

Use `matlab.system.display.Action` to define the MATLAB function or code associated with a button in the MATLAB System block dialog. The example also shows how to set button options and use an `actionData` object input to store a figure handle. This part of the code example uses the same figure when the button is clicked multiple times, rather than opening a new figure for each button click.

```
methods(Static,Access = protected)
  function group = getPropertyGroupsImpl
    group = matlab.system.display.Section(mfilename('class'));
    group.Actions = matlab.system.display.Action(@(actionData,obj)...
       visualize(obj,actionData),'Label','Visualize');
  end
end
```

```
methods
  function obj = ActionDemo(varargin)
    setProperties(obj,nargin,varargin{:});
  end

  function visualize(obj,actionData)
    f = actionData.UserData;
    if isempty(f) || ~ishandle(f)
      f = figure;
      actionData.UserData = f;
    else
      figure(f); % Make figure current
    end

    d = 1:obj.RampLimit;
    plot(d);
  end
end
```

Complete Class Definition File for Dialog Button

Define a property group and a second tab in the class definition file.

```
classdef PlotRamp < matlab.System
  % Display a button to launch a plot figure.

  properties (Nontunable)
    RampLimit = 10;
  end

  methods(Static,Access = protected)
    function group = getPropertyGroupsImpl
      group = matlab.system.display.Section(mfilename('class'));
      group.Actions = matlab.system.display.Action(@(actionData,obj)...
        visualize(obj,actionData),'Label','Visualize');
    end
  end

  methods
    function obj = ActionDemo(varargin)
      setProperties(obj,nargin,varargin{:});
    end

    function visualize(obj,actionData)
      f = actionData.UserData;
```

```
      if isempty(f) || ~ishandle(f)
        f = figure;
        actionData.UserData = f;
      else
        figure(f); % Make figure current
      end

      d = 1:obj.RampLimit;
      plot(d);
    end
  end
end
```

More About

- “System Object Input Arguments and ~ in Code Examples” (MATLAB)

Specify Output

In this section...

Sometimes, Simulink cannot infer the output characteristics of your System object during model compilation. To give Simulink more information about the System object output, use these methods.

Set Output Size

Specify the size of a System object output using the `getOutputSizeImpl` method. Use this method when Simulink cannot infer the output size from the inputs during model compilation.

For variable-size inputs, the propagated input size from `propagatedInputSizeImpl` differs depending on the environment.

- MATLAB — When you first run an object, it uses the actual sizes of the inputs.
- Simulink — The maximum of all the input sizes is set before the model runs and does not change during the run.

Subclass from both the `matlab.System` base class and the `Propagates` mixin class.

```
classdef CounterReset < matlab.System & ...
    matlab.system.mixin.Propagates
```

Use the `getOutputSizeImpl` method to specify the output size.

```
methods (Access = protected)
   function sizeout = getOutputSizeImpl(~)
      sizeout = [1 1];
   end
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System & matlab.system.mixin.Propagates
   % CounterReset Count values above a threshold

   properties
      Threshold = 1
   end

   properties (DiscreteState)
      Count
   end

   methods (Access = protected)
      function setupImpl(obj)
         obj.Count = 0;
      end

      function y = stepImpl(obj,u1,u2)
         % Add to count if u1 is above threshold
         % Reset if u2 is true
         if (u2)
           obj.Count = 0;
         elseif (any(u1 > obj.Threshold))
           obj.Count = obj.Count + 1;
         end
         y = obj.Count;
      end

      function resetImpl(obj)
         obj.Count = 0;
      end

      function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
         if strcmp(name,'Count')
            sz = [1 1];
            dt = 'double';
            cp = false;
         else
            error(['Error: Incorrect State Name: ', name.']);
         end
      end
      function dataout = getOutputDataTypeImpl(~)
         dataout = 'double';
```

```
      end
      function sizeout = getOutputSizeImpl(~)
         sizeout = [1 1];
      end
      function cplxout = isOutputComplexImpl(~)
         cplxout = false;
      end
      function fixedout = isOutputFixedSizeImpl(~)
         fixedout = true;
      end
      function inLocked = isInputSizeLockedImpl(~,idx)
         if idx == 1
           inLocked = false;
         else
           inLocked = true;
         end
      end
   end
end
```

Specify Whether Output Is Fixed-Size or Variable-Size

Specify System object output is fixed-sized or variable-size.

Specify the System object output is fixed-size. Fixed-size output is always the same size, while variable-size output can be different size vectors. `isOutputSizeLockedImpl` accepts the port index and returns `true` if the input size is locked (variable sized vectors are disallowed) and `false` if the input size is not locked (variable sized vectors are allowed). Use the `isOutputFixedSizeImpl` method when Simulink cannot infer the output type from the inputs during model compilation.

Subclass from both the `matlab.System` base class and the `matlab.system.mixin.Propagates` mixin class.

```
 classdef CounterReset < matlab.System & ...
     matlab.system.mixin.Propagates
```

Use the `isOutputFixedSizeImpl` method to specify that the output is fixed size.

```
methods (Access = protected)
   function fixedout = isOutputFixedSizeImpl(~)
      fixedout = true;
```

```
    end
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System & matlab.system.mixin.Propagates
    % CounterReset Count values above a threshold

    properties
        Threshold = 1
    end

    properties (DiscreteState)
        Count
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.Count = 0;
        end

        function resetImpl(obj)
            obj.Count = 0;
        end

        function y = stepImpl(obj,u1,u2)
            % Add to count if u1 is above threshold
            % Reset if u2 is true
            if (u2)
                obj.Count = 0;
            elseif (u1 > obj.Threshold)
                obj.Count = obj.Count + 1;
            end
            y = obj.Count;
        end

        function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
            if strcmp(name,'Count')
                sz = [1 1];
                dt = 'double';
                cp = false;
            else
                error(['Error: Incorrect State Name: ', name.']);
            end
        end
```

```
      function dataout = getOutputDataTypeImpl(~)
         dataout = 'double';
      end
      function sizeout = getOutputSizeImpl(~)
         sizeout = [1 1];
      end
      function cplxout = isOutputComplexImpl(~)
         cplxout = false;
      end
      function fixedout = isOutputFixedSizeImpl(~)
         fixedout = true;
      end
   end
end
```

For a System object with variable-size output, you do not need to add any method to the class definition file because variable-size output is the default.

Set Output Data Type

Specify the data type of a System object output using the `getOutputDataTypeImpl` method. A second example shows how to specify a gain object with bus output. Use this method when Simulink cannot infer the data type from the inputs during model compilation or when you want different input and output data types. If you want bus output, also use the `getOutputDataTypeImpl` method. To use bus output, you must define the bus data type in the base workspace and you must include the `getOutputDataTypeImpl` method in your class definition file.

For both examples, subclass from both the `matlab.System` base class and the `matlab.system.mixin.Propagates` mixin class.

```
  classdef DataTypeChange < matlab.System & ...
    matlab.system.mixin.Propagates
```

Specify, in your class definition file, how to control the output data type from a MATLAB System block. Use the `getOutputDataTypeImpl` method to change the output data type from double to single, or propagate the input as a double. It also shows how to cast the data type to change the output data type in the `stepImpl` method, if necessary.

```
methods (Access = protected)
   function out = getOutputDataTypeImpl(obj)
      if obj.Quantize == true
```

```
            out = 'single';
        else
            out = propagatedInputDataType(obj,1);
        end
    end
end

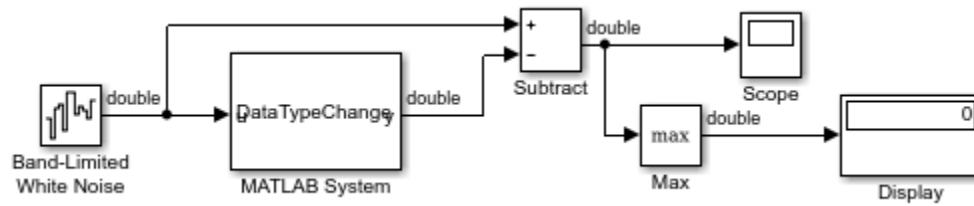
classdef DataTypeChange < matlab.System & ...
  matlab.system.mixin.Propagates

    properties(Nontunable)
        Quantize = false;
    end

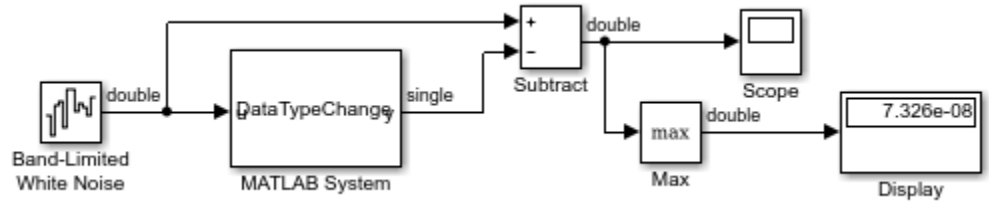
    methods(Access = protected)
        function y = stepImpl(obj,u)
            if obj.Quantize == true
                % Cast for output data type to differ from input.
                y = single(u);
            else
                % Propagate output data type.
                y = u;
            end
        end

        function out = getOutputDataTypeImpl(obj)
            if obj.Quantize == true
                out = 'single';
            else
                out = propagatedInputDataType(obj,1);
            end
        end
    end
end
```

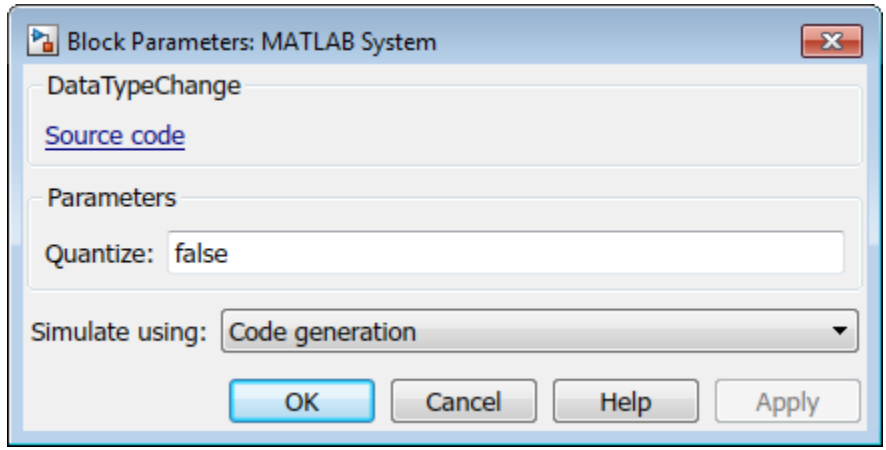
This model shows propagated double data type.



This model shows the result of changing the data type from double to single. The Display block shows the effect of quantizing the data.



The block mask for the MATLAB System block includes an edit field to switch between using propagation (**Quantize** = `false`) and switching from double to single (**Quantize** = `true`).



Use the `getOutputDataTypeImpl` method to specify the output data type as a bus. Specify the bus name in a property.

```
properties(Nontunable)
   OutputBusName = 'bus_name';
end

methods (Access = protected)
   function out = getOutputDataTypeImpl(obj)
      out = obj.OutputBusName;
   end
end
```

View the method in the complete class definition file. This class definition file also includes code to implement a custom icon for this object in the MATLAB System block

```
classdef busGain < matlab.System & matlab.system.mixin.Propagates
% busGain Apply a gain of two to bus input.

   properties
      GainK = 2;
   end

   properties(Nontunable)
      OutputBusName = 'bus_name';
   end

   methods (Access=protected)
      function out = stepImpl(obj,in)
         out.a = obj.GainK * in.a;
         out.b = obj.GainK * in.b;
      end

      function out = getOutputSizeImpl(obj)
         out = propagatedInputSize(obj, 1);
      end

      function out = isOutputComplexImpl(obj)
         out = propagatedInputComplexity(obj, 1);
      end

      function out = getOutputDataTypeImpl(obj)
         out = obj.OutputBusName;
      end

      function out = isOutputFixedSizeImpl(obj)
         out = propagatedInputFixedSize(obj,1);
      end
   end
end
```

Set Output Complexity

Specify whether a System object output is complex or real using the `isOutputComplexImpl` method. Use this method when Simulink cannot infer the output complexity from the inputs during model compilation.

Subclass from both the `matlab.System` base class and the `Propagates` mixin class.

```
classdef CounterReset < matlab.System & ...
    matlab.system.mixin.Propagates
```

Use the `isOutputComplexImpl` method to specify that the output is real.

```
methods (Access = protected)
   function cplxout = isOutputComplexImpl(~)
      cplxout = false;
   end
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System & matlab.system.mixin.Propagates
   % CounterReset Count values above a threshold

   properties
      Threshold = 1
   end

   properties (DiscreteState)
      Count
   end

   methods (Access = protected)
      function setupImpl(obj)
         obj.Count = 0;
      end

      function resetImpl(obj)
         obj.Count = 0;
      end

      function y = stepImpl(obj,u1,u2)
         % Add to count if u1 is above threshold
         % Reset if u2 is true
         if (u2)
            obj.Count = 0;
         elseif (u1 > obj.Threshold)
            obj.Count = obj.Count + 1;
         end
         y = obj.Count;
      end
```

```
        function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
           if strcmp(name,'Count')
              sz = [1 1];
              dt = 'double';
              cp = false;
           else
              error(['Error: Incorrect State Name: ', name.']);
           end
        end
        function dataout = getOutputDataTypeImpl(~)
           dataout = 'double';
        end
        function sizeout = getOutputSizeImpl(~)
           sizeout = [1 1];
        end
        function cplxout = isOutputComplexImpl(~)
           cplxout = false;
        end
        function fixedout = isOutputFixedSizeImpl(~)
           fixedout = true;
        end
    end
end
```

Specify Discrete State Output Specification

Specify the size, data type, and complexity of a discrete state property using the `getDiscreteStateSpecificationImpl` method. Use this method when your System object has a property with the `DiscreteState` attribute and Simulink cannot infer the output specifications during model compilation.

Subclass from both the `matlab.System` base class and from the `Propagates` mixin class.

```
classdef CounterReset < matlab.System & ...
    matlab.system.mixin.Propagates
```

Use the `getDiscreteStateSpecificationImpl` method to specify the size and data type. Also specify the complexity of a discrete state property, which is used in the counter reset example.

```
methods (Access = protected)
   function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
```

```
        sz = [1 1];
        dt = 'double';
        cp = false;
    end
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System & matlab.system.mixin.Propagates
    % CounterReset Count values above a threshold

    properties
        Threshold = 1
    end

    properties (DiscreteState)
        Count
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.Count = 0;
        end

        function resetImpl(obj)
            obj.Count = 0;
        end

        function y = stepImpl(obj,u1,u2)
            % Add to count if u1 is above threshold
            % Reset if u2 is true
            if (u2)
                obj.Count = 0;
            elseif (u1 > obj.Threshold)
                obj.Count = obj.Count + 1;
            end
            y = obj.Count;
        end

        function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
            sz = [1 1];
            dt = 'double';
            cp = false;
        end
        function dataout = getOutputDataTypeImpl(~)
```

```
            dataout = 'double';
        end
        function sizeout = getOutputSizeImpl(~)
            sizeout = [1 1];
        end
        function cplxout = isOutputComplexImpl(~)
            cplxout = false;
        end
        function fixedout = isOutputFixedSizeImpl(~)
            fixedout = true;
        end
    end
end
```

Set Model Reference Discrete Sample Time Inheritance

Disallow model reference discrete sample time inheritance for a System object. The System object defined in this example has one input, so by default, it allows sample time inheritance. To override the default and disallow inheritance, the class definition file for this example includes the `allowModelReferenceDiscreteSampleTimeInheritanceImpl` method, with its output set to `false`.

```
methods (Access = protected)
   function flag = ...
       allowModelReferenceDiscreteSampleTimeInheritanceImpl(obj)
     flag = false;
   end
end
```

View the method in the complete class definition file.

```
classdef MyCounter < matlab.System

   % MyCounter Count values

    properties
       Threshold = 1;
    end

    properties (DiscreteState)
       Count
    end

    methods (Static, Access = protected)
      function header = getHeaderImpl
         header = matlab.system.display.Header('MyCounter',...
           'Title','My Enhanced Counter',...
           'Text', 'This counter is an enhanced version.');
      end
    end

    methods (Access = protected)
       function flag = ...
            allowModelReferenceDiscreteSampleTimeInheritanceImpl(obj)
          flag = false
       end
```

```
        function setupImpl(obj,u)
           obj.Count = 0;
        end
        function y = stepImpl(obj,u)
           if (u > obj.Threshold)
              obj.Count = obj.Count + 1;
           end
           y = obj.Count;
        end
        function resetImpl(obj)
           obj.Count = 0;
        end
    end
end
```

Use Update and Output for Nondirect Feedthrough

Implement nondirect feedthrough for a System object by using the `updateImpl`, `outputImpl`, and `isInputDirectFeedthroughImpl` methods. In nondirect feedthrough, the object's outputs depend only on the internal states and properties of the object, rather than the input at that instant in time. You use these methods to separate the output calculation from the state updates of a System object. Implementing these two methods overrides the `stepImpl` method. These methods enable you to use the object in a feedback loop and prevent algebraic loops.

Subclass from the Nondirect Mixin Class

To use the `updateImpl`, `outputImpl`, and `isInputDirectFeedthroughImpl` methods, you must subclass from both the `matlab.System` base class and the `Nondirect` mixin class.

```
classdef IntegerDelaySysObj < matlab.System & ...
  matlab.system.mixin.Nondirect
```

Implement Updates to the Object

Implement an `updateImpl` method to update the object with previous inputs.

```
methods (Access = protected)
   function updateImpl(obj,u)
      obj.PreviousInput = [u obj.PreviousInput(1:end-1)];
   end
end
```

Implement Outputs from Object

Implement an `outputImpl` method to output the previous, not the current input.

```
methods (Access = protected)
   function [y] = outputImpl(obj,~)
      y = obj.PreviousInput(end);
   end
end
```

Implement Whether Input Is Direct Feedthrough

Implement an `isInputDirectFeedthroughImpl` method to indicate that the input is nondirect feedthrough.

```
methods (Access = protected)
   function flag = isInputDirectFeedthroughImpl(~,~)
      flag = false;
   end
end
```

Complete Class Definition File with Update and Output

```
classdef intDelaySysObj < matlab.System &...
     matlab.system.mixin.Nondirect
   % intDelaySysObj Delay input by specified number of samples.

   properties
      InitialOutput = 0;
   end
   properties (Nontunable)
      NumDelays = 1;
   end
   properties (DiscreteState)
      PreviousInput;
   end

   methods (Access = protected)
      function validatePropertiesImpl(obj)
         if ((numel(obj.NumDelays)>1) || (obj.NumDelays <= 0))
            error('Number of delays must be > 0 scalar value.');
         end
         if (numel(obj.InitialOutput)>1)
            error('Initial Output must be scalar value.');
         end
      end

      function setupImpl(obj)
         obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
      end

      function resetImpl(obj)
         obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
      end

      function [y] = outputImpl(obj,~)
         y = obj.PreviousInput(end);
      end
      function updateImpl(obj, u)
         obj.PreviousInput = [u obj.PreviousInput(1:end-1)];
```

```
      end
      function flag = isInputDirectFeedthroughImpl(~,~)
         flag = false;
      end
   end
end
```

Enable For Each Subsystem Support

Enable For Each subsystem support by using a System object in a Simulink For Each subsystem. Include the `supportsMultipleInstanceImpl` method in your class definition file. This method applies only when the System object is used in Simulink via the MATLAB System block.

Use the `supportsMultipleInstanceImpl` method and have it return `true` to indicate that the System object supports multiple calls in a Simulink For Each subsystem.

```
methods (Access = protected)
   function flag = supportsMultipleInstanceImpl(obj)
       flag = true;
   end
end
```

View the method in the complete class definition file.

```
classdef RandSeed < matlab.System
% RANDSEED Random noise with seed for use in For Each subsystem

    properties (DiscreteState)
       count;
    end

    properties (Nontunable)
       seed = 20;
    end

    properties (Nontunable,Logical)
       useSeed = false;
    end

   methods (Access = protected)
       function y = stepImpl(obj,u1)
         % Initial use after reset/setup
         % and use the seed
         if (obj.useSeed && ~obj.count)
             rng(obj.seed);
         end
         obj.count = obj.count + 1;
         [m,n] = size(u1);
         % Uses default rng seed
         y = rand(m,n) + u1;
```

```
        end

        function setupImpl(obj)
            obj.count = 0;
        end
        function resetImpl(obj)
            obj.count = 0;
        end

        function flag = supportsMultipleInstanceImpl(obj)
          flag = obj.useSeed;
        end
    end
end
```

Define System Object for Use in Simulink

In this section...

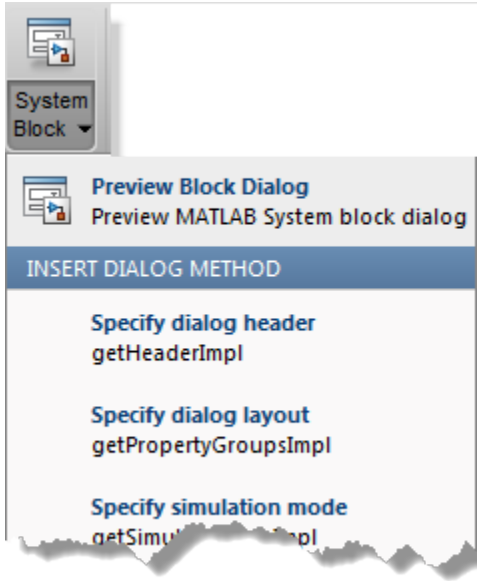
Develop System Object for Use in System Block

You can develop a System object for use in a System block and interactively preview the block dialog box. This feature requires Simulink.

With the **System Block** editing options, the MATLAB Editor inserts predefined code into the System object. This coding technique helps you create and modify your System object faster and increases accuracy by reducing typing errors.

Using these options, you can also:

- View and interact with the block dialog design as you define the System object.
- Add dialog customization methods. If the block dialog box is open when you make changes, the block dialog design preview updates the display on saving the file.
- Add icon methods. However, these elements display only on the MATLAB System Block in Simulink, not in the **Preview Dialog Box**.

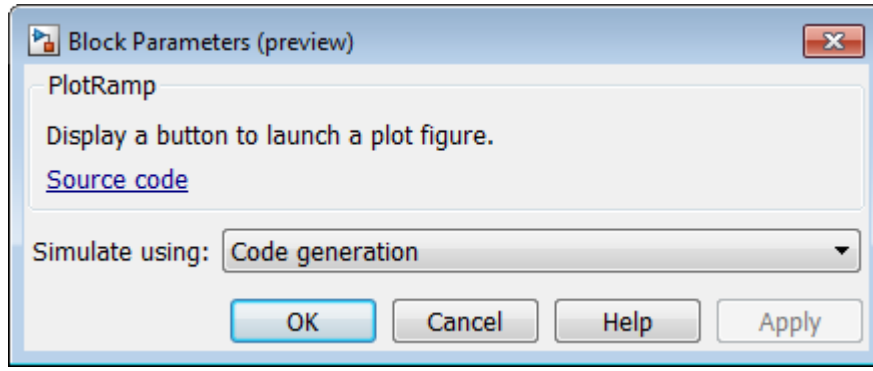


Define Block Dialog Box for Plot Ramp

1. Create a System object and name it `PlotRamp`. This name becomes the block dialog box title. Save the System object.
2. Add a comment that contains the block description.

   ```
   % Display a button to launch a plot figure.
   ```

   This comment becomes the block parameters dialog box description, under the block title.
3. Select **System Block > Preview Block Dialog**. The block dialog box displays as you develop the System object.



4 Add a ramp limit by selecting **Insert Property > Numeric**. Then change the property name and set the value to `10`.

```
properties (Nontunable)
  RampLimit = 10;
end
```

5 Using the **System Block** menu, insert the `getPropertyGrouplsImpl` method.

```
methods(Access = protected, Static)
    function group = getPropertyGroupsImpl
        % Define property section(s) for System block dialog
        group = matlab.system.display.Section(mfilename('class'));
    end
end
```

6 Create the group for the **Visualize** action.

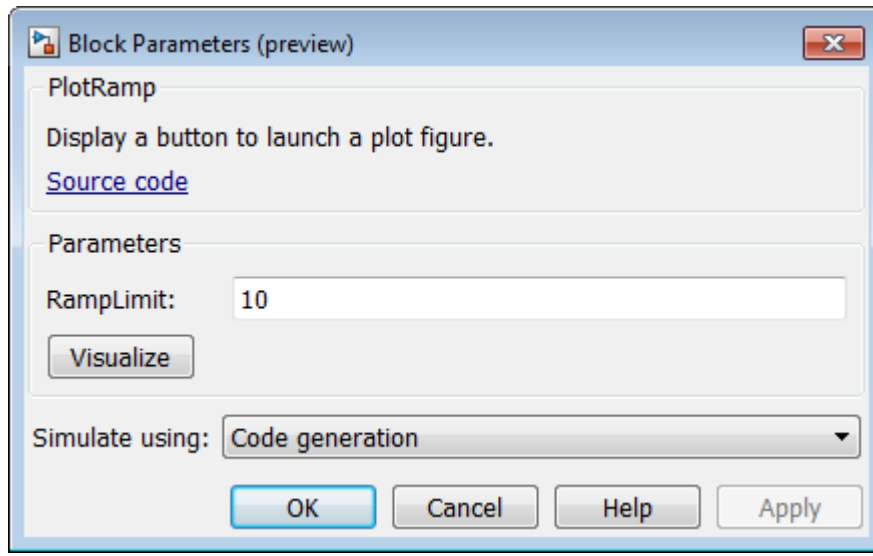
```
methods(Access = protected, Static)
    function group = getPropertyGroupsImpl
        % Define property section(s) for System block dialog
        group = matlab.system.display.Section(mfilename('class'));
        group.Actions = matlab.system.display.Action(@(~,obj)...
          visualize(obj),'Label','Visualize');
    end
end
```

7 Add a function that adds code to display the **Visualize** button on the dialog box.

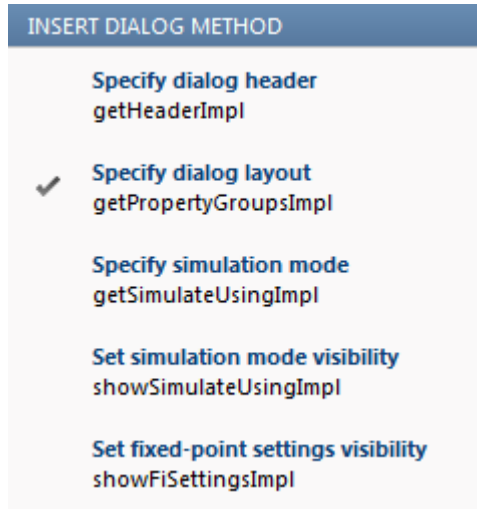
```
methods
  function visualize(obj)
    figure;
    d = 1:obj.RampLimit;
```

```
        plot(d);
    end
end
```

8 As you add elements to the System block definition, save your file. Observe the effects of your code additions to the System block definition.



The **System Block** menu also displays checks next to the methods you have implemented, which can help you track your development.



The class definition file now has all the code necessary for the `PlotRamp` System object.

```
classdef PlotRamp < matlab.System
  % Display a button to launch a plot figure.

  properties (Nontunable)
    RampLimit = 10;
  end

  methods(Static, Access=protected)
    function group = getPropertyGroupsImpl
      group = matlab.system.display.Section(mfilename('class'));
      group.Actions = matlab.system.display.Action(@(~,obj)...
            visualize(obj),'Label','Visualize');
    end
  end

  methods
    function visualize(obj)
      figure;
      d = 1:obj.RampLimit;
      plot(d);
    end
  end
end
```

After you complete your System block definition, save it, and then load it into a MATLAB System block in Simulink.

Use Enumerations in System Objects

Enumerated data is data that is restricted to a finite set of values. To use enumerated data in a System object in MATLAB or Simulink, you refer to them in your System object class definition and define your enumerated class in a separate class definition file.

For a System object that will be used in MATLAB only, see “Enumerations” (MATLAB).

For a System object that will be used in a MATLAB System block in Simulink, see “Enumerated Data”

Enumerations can derive from any integer type smaller than or equal to an `int32`. For example,

```
classdef Bearing < uint16
   enumeration
      North (0)
      East  (90)
      South (180)
      West  (270)
   end
end
```

Enumerations can also derive from `Simulink.IntEnumType`. You use this type of enumeration to add attributes, such as custom headers, to the input or output of the MATLAB System block. See “Use Enumerated Data in Simulink Models” on page 60-7.

Use Global Variables in System Objects

Global variables are variables that you can access in other MATLAB functions or Simulink blocks.

System Object Global Variables in MATLAB

For System objects that are used only in MATLAB, you define global variables in System object class definition files in the same way that you define global variables in other MATLAB code (see "Global Variables" (MATLAB)).

System Object Global Variables in Simulink

For System objects that are used in the MATLAB System block in Simulink, you also define global variables as you do in MATLAB. However, to use global variables in Simulink, you need to declare global variables in the `stepImpl`, `updateImpl`, or `outputImpl` method if you have declared them in methods called by `stepImpl`, `updateImpl`, or `outputImpl`, respectively.

You set up and use global variables for the MATLAB System block in the same way as you do for the MATLAB Function block (see "Data Stores" and "Share Data Globally" on page 41-132). Like the MATLAB Function block, you must also use variable name matching with a Data Store Memory block to use global variables in Simulink.

For example, this class definition file defines a System object that increments the first row of a matrix by 1 at each time step. If the file is P-coded, you must include `getGlobalNamesImpl`.

```
classdef GlobalSysObjMatrix < matlab.System
   methods (Access = protected)
      function y = stepImpl(obj)
         global B;
         B(1,:) = B(1,:)+1;
         y = B;
      end

      % Include getGlobalNamesImpl only if the class file is P-coded.
      function globalNames = getGlobalNamesImpl(~)
         globalNames = {'B'};
      end
```

```
    end
end
```

This model includes the `GlobalSysObjMatrix` object in a MATLAB System block and the associated Data Store Memory block.

Use System Objects in Simulink

In this section...

System Objects in the MATLAB Function Block

You can include System object code in Simulink models with the MATLAB Function block. Your function can include one or more System objects. Portions of your system may be easier to implement in the MATLAB environment than directly in Simulink. Many System objects have Simulink block counterparts with equivalent functionality. Before writing MATLAB code to include in a Simulink model, check for existing blocks that perform the desired operation.

System Objects in the MATLAB System Block

You can include individual System objects that you create with a class definition file into Simulink with the MATLAB System block. This provides one way to add your own algorithm blocks into your Simulink models. For information, see “System Object Integration”.

System Design in Simulink Using System Objects

In this section...

System Design and Simulation in Simulink

You can use System objects in your model to simulate in Simulink.

1. Create a System object to be used in your model. See “Define New System Objects for Use in Simulink” on page 42-52 for information.
2. Test your new System object in MATLAB. See “Test New System Objects in MATLAB” on page 42-58
3. Add the System object to your model by using the MATLAB System block. See “Add System Objects to Your Simulink Model” on page 42-58 for information.
4. Add other Simulink blocks as needed and connect the blocks to construct your system.
5. Run the system

Define New System Objects for Use in Simulink

- “Define System Object with Block Customizations” on page 42-52
- “Define System Object with Nondirect Feedthrough” on page 42-56

A System object is a component you can use to create your system in MATLAB. You can write the code in MATLAB and use that code to create a block in Simulink. To define your own System object, you write a class definition file, which is a text-based MATLAB file that contains the code defining your object. See “System Object Integration”.

Define System Object with Block Customizations

Create a System object for use in Simulink. The example performs system identification using a least mean squares (LMS) adaptive filter.

Create a class definition text file to define your System object. The code in this example creates a least mean squares (LMS) filter and includes customizations to the block icon and dialog appearance. It is similar to the System Identification Using MATLAB System Blocks Simulink example.

Note Instead of manually creating your class definition file, you can use the **New > System Object > Simulink Extension** menu option to open a template. This template includes customizations of the System object for use in the Simulink MATLAB System block. You edit the template file, using it as guideline, to create your own System object.

On the first line of the class definition file, specify the name of your System object and subclass from both `matlab.System` and `matlab.system.mixin.CustomIcon`. The `matlab.System` base class enables you to use all the basic System object methods and specify the block input and output names, title, and property groups. The `CustomIcon` mixin class enables the method that lets you specify the block icon.

Add the appropriate basic System object methods to set up, reset, set the number of inputs and outputs, and run your algorithm. See the reference pages for each method and the full class definition file below for the implementation of each of these methods.

- Use the `setupImpl` method to perform one-time calculations and initialize variables.
- Use the `stepImpl` method to implement the block's algorithm.
- Use the `resetImpl` method to reset the state properties or `DiscreteState` properties.
- Use the `getNumInputsImpl` and `getNumOutputsImpl` methods to specify the number of inputs and outputs, respectively.

Add the appropriate `CustomIcon` methods to define the appearance of the MATLAB System block in Simulink. See the reference pages for each method and the full class definition file below for the implementation of each of these methods.

- Use the `getHeaderImpl` method to specify the title and description to display on the block dialog.
- Use the `getPropertyGroupsImpl` method to specify groups of properties to display on the block dialog.
- Use the `getIconImpl` method to specify the text to display on the block icon.

- Use the `getInputNamesImpl` and `getOutputNamesImpl` methods to specify the labels to display for the block input and output ports.

The full class definition file for the least mean squares filter is:

```
classdef lmsSysObj < matlab.System &...
      matlab.system.mixin.CustomIcon
   % lmsSysObj Least mean squares (LMS) adaptive filtering.
   % #codegen

   properties
      % Mu Step size
      Mu = 0.005;
   end

   properties (Nontunable)
      % Weights  Filter weights
      Weights = 0;
      % N  Number of filter weights
      N = 32;
   end

   properties (DiscreteState)
      X;
      H;
   end

   methods (Access = protected)
      function setupImpl(obj)
         obj.X = zeros(obj.N,1);
         obj.H = zeros(obj.N,1);
      end

      function [y, e_norm] = stepImpl(obj,d,u)
         tmp = obj.X(1:obj.N-1);
         obj.X(2:obj.N,1) = tmp;
         obj.X(1,1) = u;
         y = obj.X'*obj.H;
         e = d-y;
         obj.H = obj.H + obj.Mu*e*obj.X;
         e_norm = norm(obj.Weights'-obj.H);
      end

      function resetImpl(obj)
```

```
        obj.X = zeros(obj.N,1);
        obj.H = zeros(obj.N,1);
    end

end

% Block icon and dialog customizations
methods (Static, Access = protected)
    function header = getHeaderImpl
        header = matlab.system.display.Header(...
            'lmsSysObj', ...
            'Title', 'LMS Adaptive Filter');
    end

    function groups = getPropertyGroupsImpl
        upperGroup = matlab.system.display.SectionGroup(...
            'Title','General',...
            'PropertyList',{'Mu'});

        lowerGroup = matlab.system.display.SectionGroup(...
            'Title','Coefficients', ...
            'PropertyList',{'Weights','N'});

        groups = [upperGroup,lowerGroup];
    end
end

methods (Access = protected)
    function icon = getIconImpl(~)
        icon = sprintf('LMS Adaptive\nFilter');
    end
    function [in1name, in2name] = getInputNamesImpl(~)
        in1name = 'Desired';
        in2name = 'Actual';
    end
    function [out1name, out2name] = getOutputNamesImpl(~)
        out1name = 'Output';
        out2name = 'EstError';
    end
```

```
    end
end
```

Define System Object with Nondirect Feedthrough

Create a System object for use in Simulink. The example performs system identification using a least mean squares (LMS) adaptive filter and uses feedback loops.

Create a class definition text file to define your System object. The code in this example creates an integer delay and includes feedback loops, and customizations to the block icon. For information on feedback loops, see “Use System Objects in Feedback Loops” on page 43-16. This example implements a System object that you can use for nondirect feedthrough. It is similar to the System Identification Using MATLAB System Blocks Simulink example.

On the first line of the class definition file, subclass from `matlab.System` and `matlab.system.mixin.CustomIcon`. The `matlab.System` base class enables you to use all the basic System object methods and specify the block input and output names, title, and property groups. The `CustomIcon` mixin class enables the method that lets you specify the block icon. The `Nondirect` mixin enables the methods that let you specify how the block is updated and what it outputs.

Add the appropriate basic System object methods to set up and reset the object and set and validate the properties. Since this object supports nondirect feedthrough, you do not implement the `stepImpl` method. You implement the `updateImpl` and `outputImpl` methods instead. See the reference pages for each method and the full class definition file below for the implementation of each of these methods.

- Use the `setupImpl` method to initialize some of the object’s properties.
- Use the `resetImpl` method to reset the property states.
- Use the `validatePropertiesImpl` method to check that the property values are valid.

Add the following `Nondirect` mixin class methods instead of the `stepImpl` method to specify how the block updates its state and its output. See the reference pages and the full class definition file below for the implementation of each of these methods.

- Use the `outputImpl` method to implement code to calculate the block output.
- Use the `updateImpl` method to implement code to update the block’s internal states.

- Use the `isInputDirectFeedthroughImpl` method to specify that the block is not direct feedthrough. Its inputs do not directly affect its outputs.

Add the `getIconImpl` method to define the block icon when it is used in Simulink via the MATLAB System block. See the reference page and the full class definition file below for the implementation of this method.

The full class definition file for the delay is:

```
classdef intDelaySysObj < matlab.System &...
     matlab.system.mixin.Nondirect &...
     matlab.system.mixin.CustomIcon
   % intDelaySysObj Delay input by specified number of samples.
   % #codegen

   properties
      % InitialOutput Initial output
      InitialOutput = 0;
   end

   properties (Nontunable)
      % NumDelays Number of delays
      NumDelays = 1;
   end

   properties (DiscreteState)
      PreviousInput;
   end

   methods (Access = protected)
      function setupImpl(obj, ~)
         obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
      end

      function [y] = outputImpl(obj, ~)
         % Output does not directly depend on input
         y = obj.PreviousInput(end);
      end

      function updateImpl(obj, u)
         obj.PreviousInput = [u obj.PreviousInput(1:end-1)];
      end

      function flag = isInputDirectFeedthroughImpl(~,~)
```

```
            flag = false;
        end

        function validatePropertiesImpl(obj)
            if ((numel(obj.NumDelays)>1) || (obj.NumDelays <= 0))
                error('Number of delays must be positive non-zero ...
                  scalar value.');
            end
            if (numel(obj.InitialOutput)>1)
                error('Initial output must be scalar value.');
            end
        end

        function resetImpl(obj)
            obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
        end

        function icon = getIconImpl(~)
            icon = sprintf('Integer\nDelay');
        end
    end
end
```

Test New System Objects in MATLAB

1. Create an instance of your new System object. For example, create an instance of the `lmsSysObj`.

   ```
   s = lmsSysObj;
   ```

2. Run the object multiple times with different inputs. This tests for syntax errors and other possible issues before you add it to Simulink. For example,

   ```
   desired = 0;
   actual = 0.2;
   s(desired,actual);
   ```

Add System Objects to Your Simulink Model

1. Add your System objects to your Simulink model by using the MATLAB System block as described in “Mapping System Objects to Block Dialog Box” on page 43-21.
2. Add other Simulink blocks, connect them, and configure any needed parameters to complete your model as described in the Simulink documentation. See the System Identification for an FIR System Using MATLAB System Blocks Simulink example.

3 Run your model in the same way you run any Simulink model.

Specify Sample Time for MATLAB System Block System Objects

This example shows how to control the sample time of the MATLAB System block using the System object class definition.

Inside the class definition, use the `matlab.system.mixin.SampleTime` methods to configure the sample time and modify System object behavior based on the current simulation time.

Specify Sample Time

To specify the sample time, implement the `getSampleTimeImpl` method. In this example, a property `SampleTimeTypeProp` is created to assign the sample time based on different property values. The `getSampleTimeImpl` method creates a sample time specification based on the `SampleTimeTypeProp` property. The `getSampleTimeImpl` method returns a sample time specification object `sts` to set the sample time specifications.

```
methods(Access = protected)
  function sts = getSampleTimeImpl(obj)
    switch obj.SampleTimeTypeProp
      case 'Inherited sample time'
         sts = createSampleTime(obj,'Type','Inherited');
      case 'Fixed In Minor Step sample time'
         sts = createSampleTime(obj,'Type','Fixed In Minor Step');
      case 'Discrete Periodic sample time'
         sts = createSampleTime(obj,'Type','Discrete Periodic',...
          'SampleTime',obj.SampleTime, ...
          'OffsetTime',obj.OffsetTime);
      end
  end
end
```

Query Simulation Time and Sample Time

Use the `getSampleTime` and `getCurrentTime` methods to query the MATLAB System block for the current sample time and simulation time, respectively. `getSampleTime` returns a sample time specification object with properties describing the sample time settings.

```
function [y,ct,st] = stepImpl(obj,u)
    y = obj.Count + u;
    obj.Count = y;
    ct = getCurrentTime(obj);
    sts = getSampleTime(obj);
```

```
        st = sts.SampleTime;
    end
```

Full Class Definition

```
classdef CountTime < matlab.System & matlab.system.mixin.SampleTime
    % Counts Hits and Time

    properties(Nontunable)
        SampleTimeTypeProp = 'Discrete Periodic sample time'; % Sample Time Type
        SampleTime = 1.4; % Sample Time
        OffsetTime = 0.2; % Offset Time
    end

    properties(DiscreteState)
        Count
    end

    properties(Constant, Hidden)
        SampleTimeTypePropSet = matlab.system.StringSet(...
           {'Inherited sample time',...
            'Fixed In Minor Step sample time', ...
            'Discrete Periodic sample time'});
    end
    methods(Access = protected)
        function sts = getSampleTimeImpl(obj)
            switch obj.SampleTimeTypeProp
                case 'Inherited sample time'
                    sts = createSampleTime(obj,'Type','Inherited');
                case 'Fixed In Minor Step sample time'
                    sts = createSampleTime(obj,'Type','Fixed In Minor Step');
                case 'Discrete Periodic sample time'
                    sts = createSampleTime(obj,'Type','Discrete Periodic',...
                      'SampleTime',obj.SampleTime, ...
                      'OffsetTime',obj.OffsetTime);
            end
        end

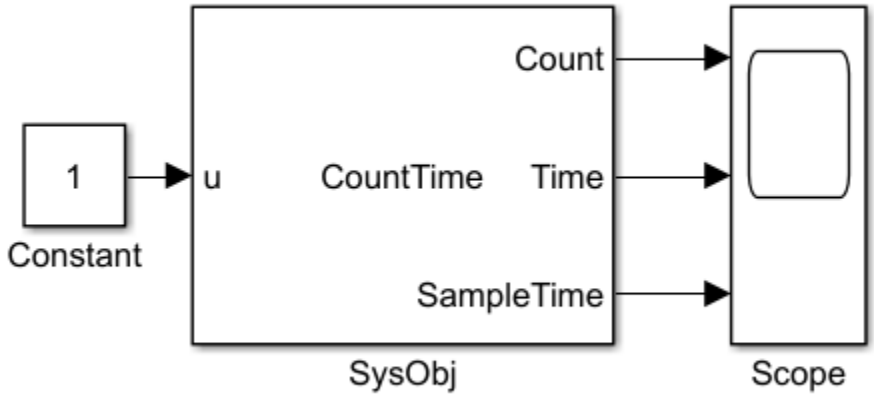
        function [Count, Time, SampleTime] = stepImpl(obj,u)
           Count = obj.Count + u;
            obj.Count = Count;
            Time = getCurrentTime(obj);
            sts = getSampleTime(obj);
            SampleTime = sts.SampleTime;
        end

        function setupImpl(obj)
            obj.Count = 0;
        end

        function flag = isInactivePropertyImpl(obj,prop)
            flag = false;
            switch obj.SampleTimeTypeProp
                case {'Inherited sample time', 'Fixed In Minor Step sample time'}
                    if any(strcmp(prop,{'SampleTime','OffsetTime','TickTime'}))
                        flag = true;
                    end
                case 'discrete periodic'
                    if any(strcmp(prop,{'TickTime'}))
                        flag = true;
```

```
                end
            end
        end
    end
end
```

Include this System object in a MATLAB System block. For example:



You can see the effect of the sample time specification in the Scope.

System Objects in Simulink

MATLAB System Block

In this section...

Why Use the MATLAB System Block?

System objects let you implement algorithms using the MATLAB language. The MATLAB System block enables you to use System objects in Simulink.

The MATLAB System block lets you:

- Share the same System object in MATLAB and Simulink
- Dedicate integration of System objects with Simulink
- Unit test your algorithm in MATLAB before using it in Simulink
- Customize dialog box customization
- Simulate efficiently with better initialization
- Handle states
- Customize block icons with port labels
- Access two simulation modes

Choosing the Right Block Type

There are several mechanisms for including MATLAB algorithms in Simulink, such as:

- MATLAB System block
- MATLAB Function block

- Interpreted MATLAB Function block
- Level-2 MATLAB S-Function block
- Fcn block

For help on choosing the right block, see “Comparison of Custom Block Functionality” on page 39-7.

System Objects

Before you use a MATLAB System block, you must have a System object to associate with the block. A System object is a specialized kind of MATLAB class. System objects are designed specifically for implementing and simulating dynamic systems with inputs that change over time.

For more information on creating System objects, see “Customize System Objects for Simulink”.

Note To use your System object in the Simulink environment, it must have a constructor that you can call with no arguments. By default, the System object constructor has this capability and you do not need to define your own constructor. However, if you create your own System object constructor, you must be able to call it with no arguments.

System objects exist in other MATLAB products. MATLAB System block supports only the System objects written in the MATLAB language. In addition, if a System object has a corresponding Simulink block, you cannot implement a MATLAB System block for it.

Interpreted Execution or Code Generation

You can use MATLAB System blocks in Simulink models for simulation via interpreted execution or code generation.

- With interpreted execution, the model simulates the block using the MATLAB execution engine.
- With code generation, the model simulates the block using code generation (requires the use the subset of MATLAB code supported for code generation). For a list of supported functions, see “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” on page 46-2.

Default Input Signal Attributes

If a MATLAB System block has one or more inputs that are unconnected to another block's output port or connected to a port that has underspecified attributes, the default input signal attributes for the unspecified attributes are:

Data Attribute	Default
Data Type	double
Size	[1 1] scalar
Complexity	real

MATLAB System Block Limitations

These capabilities are currently not supported.

Category	Limitation Description	Workaround
System Objects	Tunable logical and character vector properties of the System object are nontunable parameters in the MATLAB System block.	—
Data Types	• The MATLAB System block does not support virtual buses as input or output. • System objects cannot use fixed-point signals with nonbinary point scaling or nonzero bias. • System objects cannot use user-defined opaque data types.	—
Sample Time	Cannot use MATLAB System blocks to model continuous time or multirate systems.	—
Linearizations	Cannot use Jacobian based linearization.	—

Category	Limitation Description	Workaround
Global Variables	Global variables defined in the model Configuration Parameters **Simulation Target > Custom Code** pane and referenced by the System object are not shared with Stateflow and the MATLAB Function block.	—
Debugging	MATLAB debugging for code-generation-based simulation.	Set the MATLAB System block **Simulate using** parameter to `Interpreted execution`, and then debug. When you are done, set **Simulate using** back to `Code generation`.
Fixed-Point Tool	The Fixed-Point Tool does not return design min/max, min/max logging, and autoscaling information for MATLAB System blocks.	—
Model coverage analysis (Simulink Coverage software)	Simulink Coverage cannot perform model analysis for MATLAB System block with **Simulate using** parameter set to `Interpreted execution`.	—
Check model compatibility (Simulink Design Verifier software)	Simulink Design Verifier cannot perform compatibility checks for a model or subsystem that contains a MATLAB System block.	—

MATLAB System and System Objects Examples

For examples of MATLAB System and System objects, see:

Example	Description
System Identification for an FIR System Using MATLAB System Blocks	This example shows how to use the MATLAB System block to implement Simulink blocks using a System object. It highlights two MATLAB System blocks. Access the MATLAB source code for each System object by clicking the `Source code` link from the block dialog box.
Variable-Size Input and Output Signals Using MATLAB System Blocks	This example shows how to use the MATLAB System block to implement Simulink blocks with variable-size input and output signals. Due to the use of variable-size signals, the example uses propagation methods.
Illustration of Law of Large Numbers Using MATLAB System Blocks	This example shows how to use MATLAB System blocks to illustrate the law of large numbers. Due to the use of MATLAB functions not supported for code generation, the example uses propagation methods and interpreted execution.
Using Buses with MATLAB System Blocks	This example shows how to use MATLAB System blocks with nonvirtual buses at input or output. Due to the use Simulink buses, the example uses propagation methods. The example defines the bus types in the MATLAB base workspace using model callbacks.

Implement a MATLAB System Block

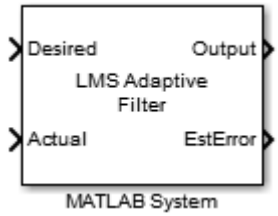
Implement a block and assign a System object to it. You can then explore the block to see the effect.

1 Create a new model and add the MATLAB System block from the User-Defined Functions library.

2 In the block dialog box, from the **New** list, select `Basic`, `Advanced`, or `Simulink Extension` if you want to create a new System object from a template. Modify the template according to your needs and save the System object.

3 Enter the full path name for the System object in the **System object name**. Click the list arrow. If valid System objects exist in the current folder, the names appear in the list.

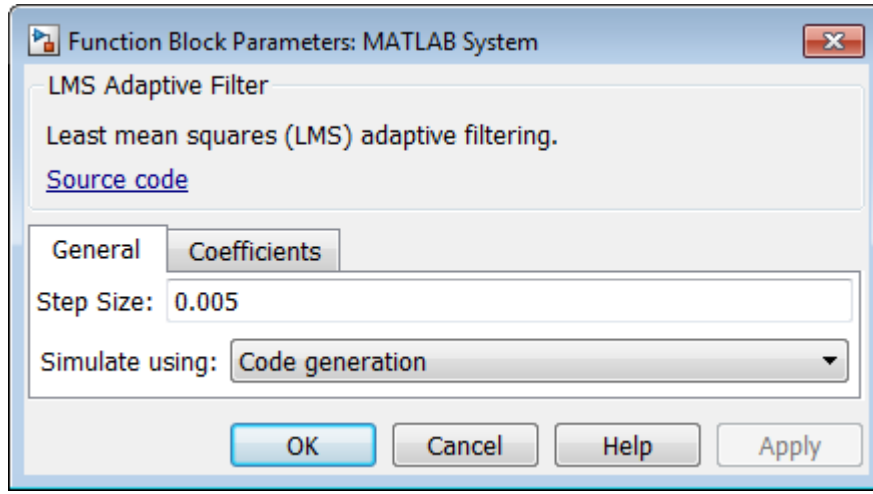
The MATLAB System block icon and port labels update to those of the corresponding System object. For example, suppose you selected a System object named lmsSysObj in your current folder. The block updates as shown in the figure:



Note After you associate the block with a System object class name, you cannot assign a new System object using the same MATLAB System block dialog box. Instead, right-click the MATLAB System block, select **Block Parameters (MATLABSystem)** and enter a new class name in **System object name**.

Understanding the MATLAB System Block

1 Double-click the block. The MATLAB System dialog box reflects the System object parameters. The dialog box usually includes a **Source code** link that leads to the System object class file. For example:



The **Source code** link appears if the System object uses MATLAB language. It does not appear if you have:

- Converted the System object to P-code
- Overridden the default behavior using the `getHeaderImpl` method

2 Click **Source code** and observe that the public and active properties in the System object appear in the MATLAB System block dialog box as block parameters.

3 Select how you want the model to simulate the block using the **Simulate using** parameter. (This parameter appears at the bottom of each MATLAB System block if there is only one tab, or the bottom of the first of multiple tabs.)

Change Blocks Implemented with System Objects

To implement a block with another System object, right-click the MATLAB System block and select Block Parameters (MATLABSystem). Then, use the block dialog box to identify a new class name in **System object name**. For more information, see "Implement a MATLAB System Block" on page 43-8.

Specify Single Sample Time for MATLAB System Block

To specify single sample time for MATLAB System block, you can use `matlab.system.mixin.SampleTime` methods.

To specify sample time, implement the `matlab.system.mixin.SampleTime.getSampleTimeImpl` method. To query the MATLAB System block for current sample time and simulation time, use the `matlab.system.mixin.SampleTime.getSampleTime` and `matlab.system.mixin.SampleTime.getCurrentTime` methods. For more information, see “Specify Sample Time for MATLAB System Block System Objects” on page 42-60.

Change Block Icon and Port Labels

To change the icon appearance of your block, you must use the `matlab.system.mixin.CustomIcon` class. You can define port labels using System object methods.

1. Add the `matlab.system.mixin.CustomIcon` class name to the System object, after the `matlab.System` class. For example:

   ```
   classdef lmsSysObj < matlab.System & matlab.system.mixin.CustomIcon
   ```

   This code subclasses from the `matlab.system.mixin.CustomIcon` class in addition to the `matlab.System` base class.

2. To define the icon, implement the `getIconImpl` method.

3. To define the port labels, implement the following optional methods to change the input and output port labels. You do not need the `matlab.system.mixin.CustomIcon` class to use these methods.

   ```
   getInputNamesImpl
   getOutputNamesImpl
   ```

If you do not implement these methods, the System object uses the input and output port names from the `stepImpl` method. If you are using the `matlab.system.mixin.Nondirect` class and do not implement these methods, the System object uses the input names from `updateImpl` and the output port names from `OutputImpl`.

Modify MATLAB System Block Dialog

To change the MATLAB System block dialog, implement the methods for the following classes:

Description	matlab.system.display Methods
Define header text for property group.	`matlab.system.display.Header`
Group properties together.	`matlab.system.display.Section`
Group properties into a separate tab.	`matlab.system.display.SectionGroup`

Change the MATLAB System Block Icon to an Image

You can change the image of MATLAB System block in MATLAB Editor. For a list of accepted image files, see `image`. To use an existing image file for the MATLAB System block:

1. Double-click your MATLAB System block.
2. In the block dialog box, click the **Source code**. The MATLAB Editor that contains the System object code opens.
3. In the MATLAB Editor, from the **System Block** drop-down list, select **Add Image Icon**.
4. In the **Add image icon** dialog window, click **Browse** to select an image of your choice.
5. Click **OK** to insert the corresponding code for the `getIconImpl` method in your System object.

For more information, see “Customize System Block Appearance” on page 42-2.

Nonvirtual Buses and MATLAB System Block

The MATLAB System block supports nonvirtual buses as input and output signals. The corresponding System object input or output must be a MATLAB structure whose fields match those defined by the nonvirtual bus. If the System object output is a MATLAB structure, it must define propagator methods. In addition, the `getOutputDataTypeImpl` method must return the name of the corresponding bus object. This bus object must exist in the base workspace or a data dictionary linked to the model.

Note If the output is the same bus type as the input, do not use the `propagatedInputDataType` method to obtain the name of the bus object. Instead, you must return the name of the bus object directly.

Use System Objects in Feedback Loops

If your algorithm needs to process nondirect feedthrough data through the System object, use the `matlab.system.mixin.Nondirect` class. This class uses the `output` and `update` methods to process nondirect feedthrough data through a System object.

Most System objects use direct feedthrough, where the object's input is needed to generate the output. For these direct feedthrough objects, the `step` method calculates the output and updates the state values. For nondirect feedthrough, however, the object's output depends on internal states and not directly on the inputs. The inputs, or a subset of the inputs, are used to update the object states. For these objects, calculating the output is separated from updating the state values. This enables you to use an object as a feedback element in a feedback loop.

A delay object is an example of a nondirect feedthrough object.

1. Add the `matlab.system.mixin.Nondirect` class to the top of the parent class file for the System object, after the `matlab.System` class. For example:

   ```
   IntegerDelaySysObj < matlab.System & matlab.system.mixin.Nondirect
   ```

   This step subclasses from the `matlab.system.mixin.Nondirect` class in addition to the `matlab.System` base class.

2. Implement the following methods:

   ```
   outputImpl
   updateImpl
   ```

   When implementing the `outputImpl` method, do not access the System object inputs for which the direct feedthrough flag is false.

3. If the System object supports code generation and does not inherit from `matlab.system.mixin.Propagates`, Simulink can automatically infer the direct feedthrough settings from the System object MATLAB code. However, if the System object does not support code generation, the default `isInputDirectFeedthroughImpl` method returns false (no direct feedthrough). In this case, override this method if you want nondefault behavior.

The processing of the nondirect feedthrough changes the way that the software calls the System object methods within the context of the Simulink engine.

Simulation Modes

Interpreted Execution vs. Code Generation

You can use MATLAB System block in Simulink models for simulation via interpreted execution or code generation. Implementing a MATLAB System block with a valid System object class name enables the **Simulate using** parameter. This parameter appears at the bottom of each MATLAB System block if there is only one tab, or the bottom of the first of multiple tabs. Use the **Simulate using** parameter to control how the block simulates. The table describes how to choose the right value for your purpose.

- With interpreted execution, the model simulates the block using the MATLAB execution engine.

  Note With interpreted execution, if you set the **Optimization > Use division for fixed-point net slope computation** parameter to `On` or `Use division for reciprocals of integers only` in the Configuration Parameters dialog box, you might get unoptimized numeric results. This is because MATLAB code does not support this parameter.

- With code generation, the model simulates the block using code generation, using the subset of MATLAB code supported for code generation.

Action	Select	Pros	Cons
Upon first model run, simulate and generate code for MATLAB System using only the subset of MATLAB functions supported for code generation. Choosing this option causes the simulation to run the generated code.	`Code generation` (default)	Potentially better performance.	System object is limited to the subset of MATLAB functions supported for code generation. Simulation may start more slowly.

Action	Select	Pros	Cons
Simulate model using all supported MATLAB functions. Choosing this option can slow simulation performance.	`Interpreted execution`	System object can contain any supported MATLAB function. Faster startup time.	Potentially slower performance. If the MATLAB functions in the System object do not support code generation, the System object must contain propagation methods.

To take advantage of faster performance, consider using propagation methods in your System object. For more information, see “Add and Implement Propagation Methods” on page 43-32.

Simulation Using Code Generation

While simulating and generating code for one or more simulation targets (in this case, System object blocks), the model displays status messages in the bottom left of the Simulink Editor window. A model can have multiple copies of the same block, where blocks are considered the same if they

- Use the same System object.
- Have inputs and tunable parameters that have identical signals, data types, and complexities.
- Have nontunable parameters that have the same value.

When the model has multiple copies of the same block, the software does not regenerate the code for each block. It reuses the code from the first time that code was generated for one of these blocks. The status messages reflect this and do not show status messages for each of these blocks.

When the code generation process is complete, Simulink creates a MEX-file for the generated code.

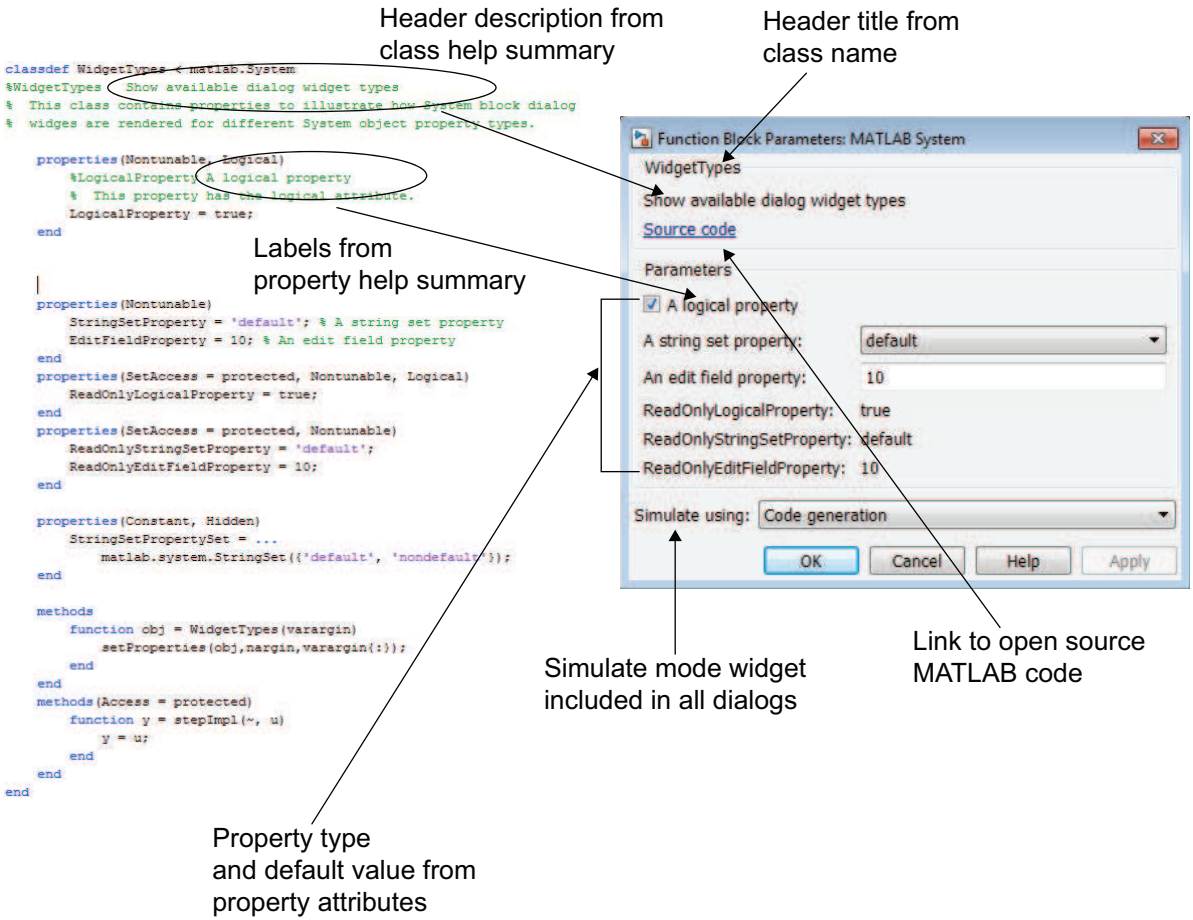
Mapping System Objects to Block Dialog Box

The System object source code controls the appearance of the block dialog box. This section describes System object to block dialog box mapping using the System Identification for an FIR System Using MATLAB System Blocks example. This example uses two System objects, one that uses default System object to block dialog box mapping, and one that uses a custom mapping.

In this section...

System Object to Block Dialog Box Default Mapping

The following figure shows how the source code corresponds to the dialog box elements if you do not customize the dialog using the `getHeaderImpl` or `getPropertyGroupsImpl` methods. (The link to open the source code and the **Simulate using** parameter appear on all MATLAB System block dialog boxes.)



```
classdef WidgetTypes < matlab.System
%WidgetTypes  Show available dialog widget types
%  This class contains properties to illustrate how System block dialog
%  widges are rendered for different System object property types.

    properties(Nontunable, Logical)
        %LogicalProperty: A logical property
        %  This property has the logical attribute.
        LogicalProperty = true;
    end

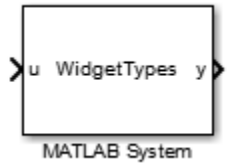
    properties(Nontunable)
        StringSetProperty = 'default'; % A string set property
        EditFieldProperty = 10; % An edit field property
    end
    properties(SetAccess = protected, Nontunable, Logical)
        ReadOnlyLogicalProperty = true;
    end
    properties(SetAccess = protected, Nontunable)
        ReadOnlyStringSetProperty = 'default';
        ReadOnlyEditFieldProperty = 10;
    end

    properties(Constant, Hidden)
        StringSetPropertySet = ...
            matlab.system.StringSet({'default', 'nondefault'});
    end

    methods
        function obj = WidgetTypes(varargin)
            setProperties(obj,nargin,varargin{:});
        end
    end
    methods(Access = protected)
        function y = stepImpl(~, u)
            y = u;
        end
    end
end
```

The Delay block from the System Identification for an FIR System Using MATLAB System Blocks is an example of a block that uses a System object that draws the dialog box using the default mapping. This block has one input and one output.

This block uses a System object that has direct feedthrough set to false (nondirect feedthrough). This setting means that the System object does not directly use the input to compute the output, enabling the model to use this block safely in a feedback system without introducing an algebraic loop. For more information on nondirect feedthrough, see “Use System Objects in Feedback Loops” on page 43-16.

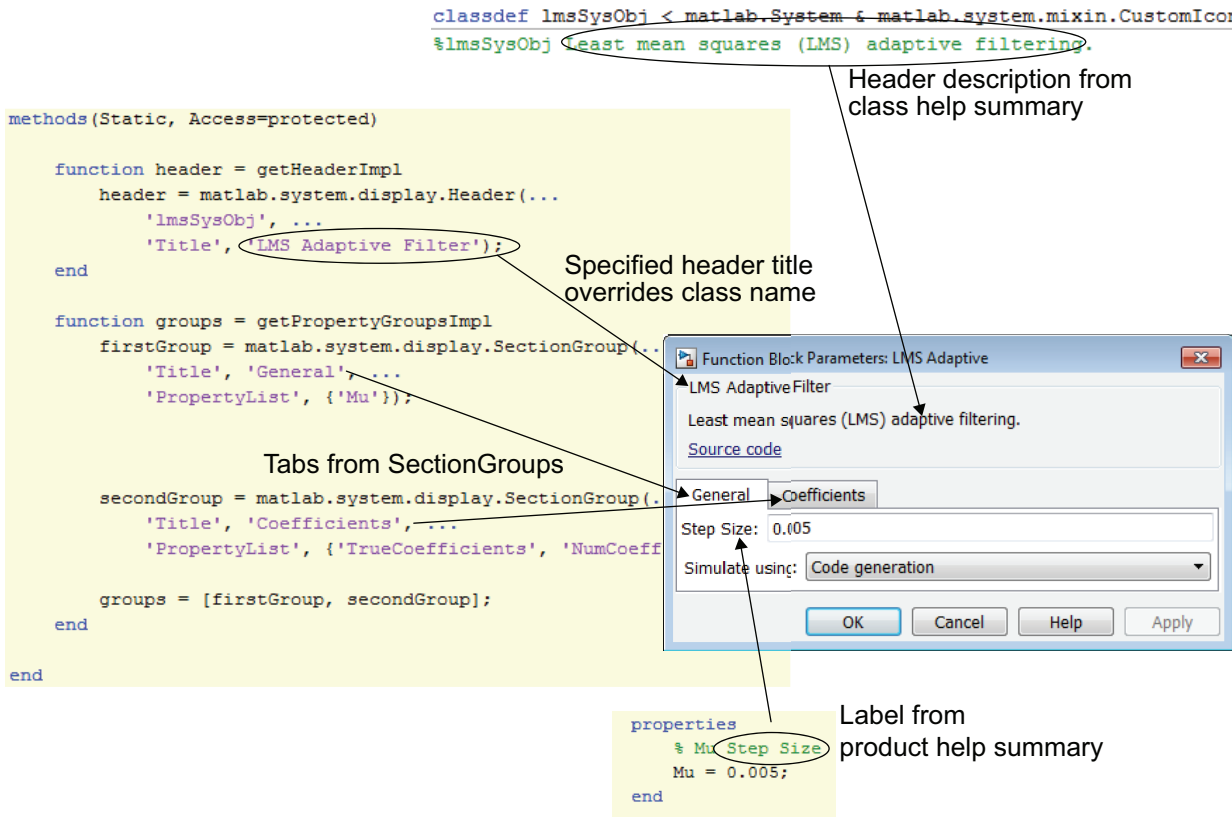


For an example of a custom block dialog box, see “System Object to Block Dialog Box Custom Mapping” on page 43-23.

System Object to Block Dialog Box Custom Mapping

The LMS Adaptive block is an example of a block with a custom header and property groups. The System object code uses the `getHeaderImpl` and `getPropertyGroupsImpl` methods from `matlab.System` to customize these block dialog elements.

The LMS Adaptive Filter block estimates the coefficients of an unknown system (formed by the Unknown System and Delay blocks). Its inputs are the desired signal and the actual signal. Its outputs are the estimated signal and the vector norm of the error in the estimated coefficients. It uses the lmsSysObj System object.



The source code for this System object also defines two input and output ports for the block.

```
function num = getNumInputsImpl(~)
    num = 2;
end

function num = getNumOutputsImpl(~)
    num = 2;
end

function icon = getIconImpl(~)
    icon = sprintf('LMS Adaptive\nFilter');
end

  function [name1, name2] = getInputNamesImpl(~)
      name1 = 'Desired';
      name2 = 'Actual';
  end

  function [name1, name2] = getOutputNamesImpl(~)
      name1 = 'Output';
      name2 = 'EstError';
  end
```

Considerations for Using System Objects in Simulink

In this section...

System Objects in Simulink

There are differences in how you can use System objects in a MATLAB System block in Simulink versus using the same object in MATLAB. You see these differences when working with variable-size signals and tunable parameters and when using System objects as properties.

Variable-Size Signals

To use variable-size signals in a System object, you must implement `matlab.system.mixin.Propagates` methods. In particular, use the isOutputFixedSizeImpl method to specify if an output is variable-size or fixed-size. This is true for interpreted execution and code generation simulation methods.

Tunable Parameters

Simulink registers public tunable properties of a System object as tunable parameters of the corresponding MATLAB System block. If a System object property is tunable, it is also tunable in the MATLAB System block. At runtime, you can change the parameter using one of the following approaches. The change applies at the top of the simulation loop.

- At the MATLAB command line, use the `set_param` to change the parameter value.
- In the Simulink editor, edit the MATLAB System block dialog box to change the parameter value, and then update the block diagram.

You cannot change public tunable properties from System object internal methods such as `stepImpl`.

During simulation, setting an invalid value on a tunable parameter causes an error message and stops simulation.

System Objects as Properties

The MATLAB System block allows a System object to have other System objects as public or private properties. However:

- System objects and other MATLAB objects stored as public properties are read only. As a result, you cannot set the value of the parameter, you can only get the value of a parameter.
- System objects stored as property values appear dimmed in the MATLAB System block dialog box.

Default Property Values

MATLAB does not require that objects assign default values to properties. However, in Simulink, if your System object has properties with no assigned default values, the associated dialog box parameter requires that the value data type be a built-in Simulink data type.

System Objects in For Each Subsystems

To use the MATLAB System block within a For Each Subsystem block, implement the `matlab.system` `supportsMultipleInstanceImpl` method. This method should return `true`. The MATLAB System block clones the System object for each For Each Subsystem iteration.

Input Validation

In Simulink, use the `validateInputsImpl` method to validate only attributes (size, data type, and complexity) of the input. Do not use this method to validate the value of the input.

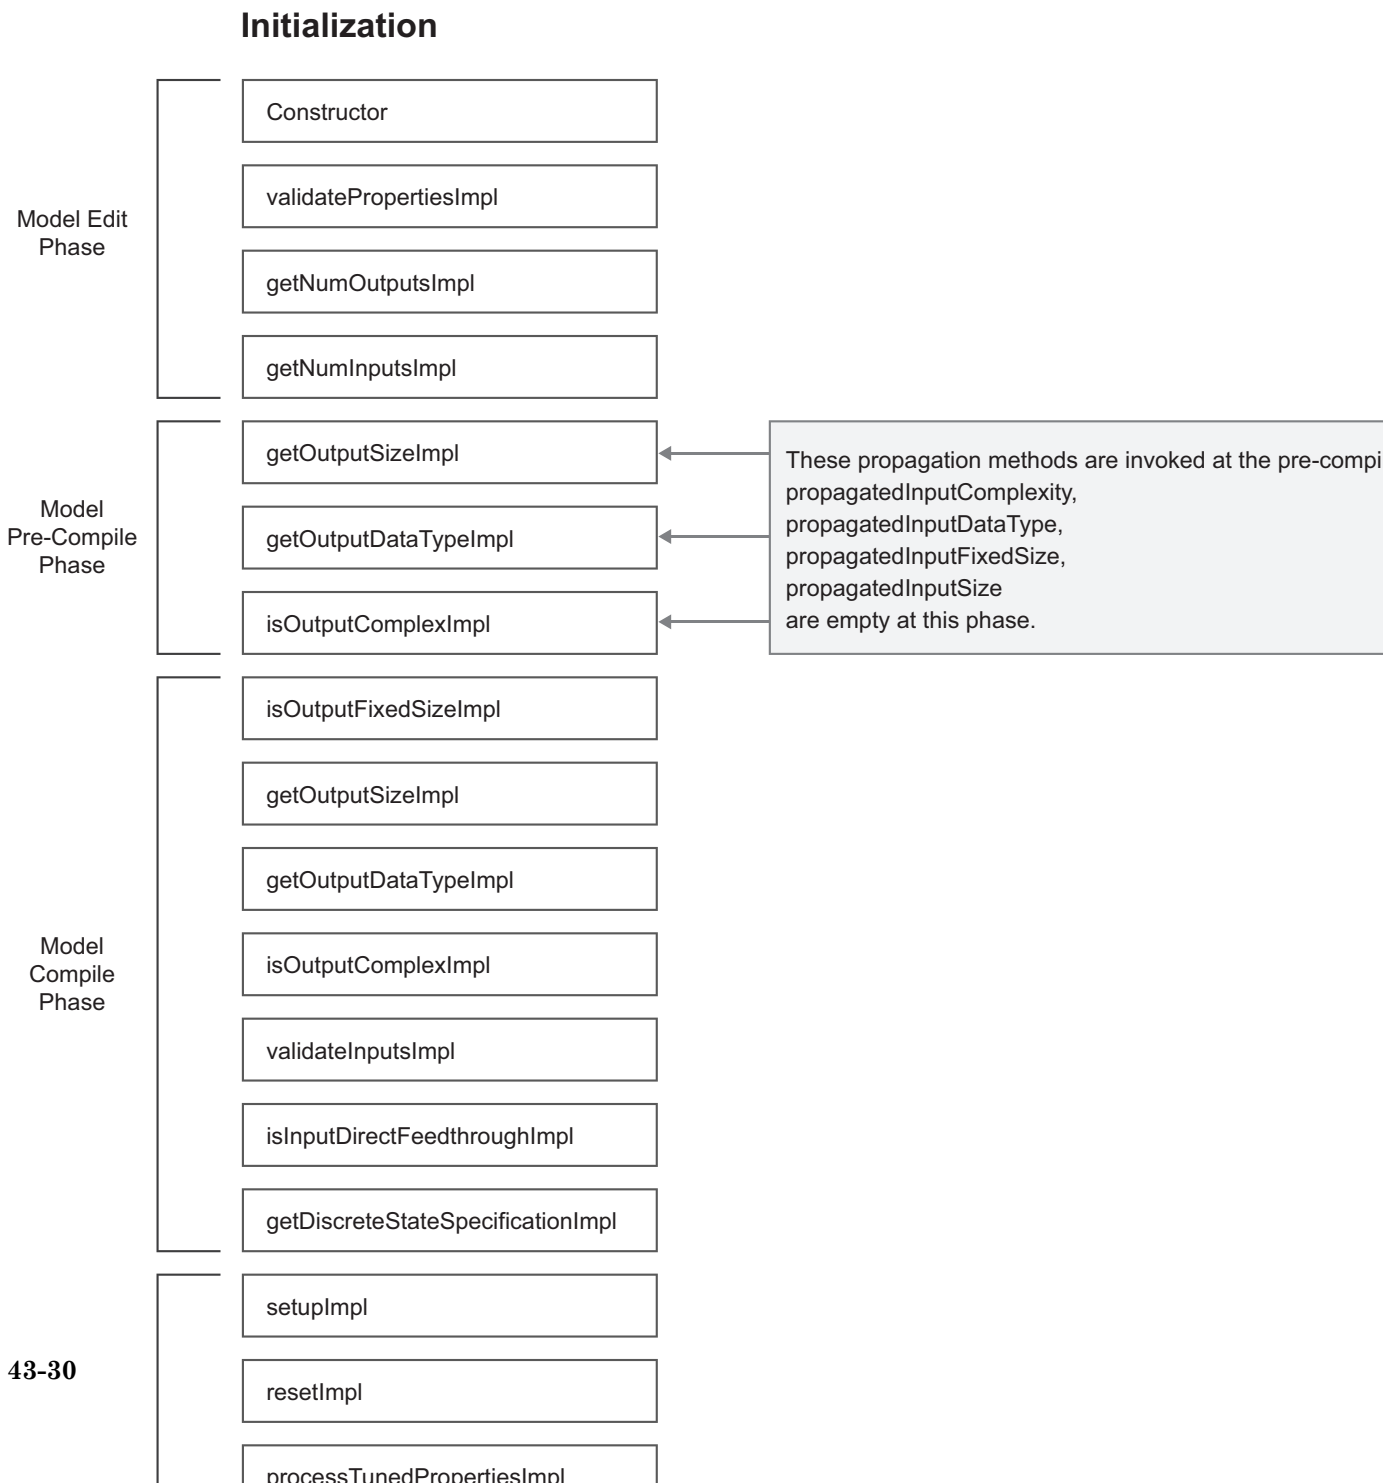
Simulink Engine Interaction with System Object Methods

Simulink Engine Phases Mapped to System Object Methods

This diagram shows a process view of the order in which the MATLAB System block invokes System object methods within the context of the Simulink engine.



Initialization
Model Edit Phase
Constructor
validatePropertiesImpl
getNumOutputsImpl
getNumInputsImpl
Model Pre-Compile Phase
getOutputSizeImpl
getOutputDataTypeImpl
isOutputComplexImpl
These propagation methods are invoked at the pre-compi
propagatedInputComplexity,
propagatedInputDataType,
propagatedInputFixedSize,
propagatedInputSize
are empty at this phase.
Model Compile Phase
isOutputFixedSizeImpl
getOutputSizeImpl
getOutputDataTypeImpl
isOutputComplexImpl
validateInputsImpl
isInputDirectFeedthroughImpl
getDiscreteStateSpecificationImpl
setupImpl
resetImpl
processTunedPropertiesImpl

Note the following:

- Simulink calls the `stepImpl`, `outputImpl`, and `updateImpl` methods multiple times during simulation at each time step. Simulink typically calls other methods once per simulation.
- The Simulink engine calls the `isOutputFixedSizeImpl`, `getDiscreteStateSpecificationImpl`, `isOutputComplexImpl`, `getOutputDataTypeImpl`, `getOutputSizeImpl` when using `matlab.system.mixin.Propagates`.
- Simulink calls `saveObjectImpl` and `loadObjectImpl` for saving and restoring SimState, the Simulation Stepper, and Fast Restart.
- Default implementations save and restore all properties with public access, including `DiscreteState`.

Add and Implement Propagation Methods

In this section...

When to Use Propagation Methods

Propagation methods define output specifications. Use them when the output specifications cannot be inferred directly from the inputs during Simulink model compilation.

Consider using propagation methods in your System object when:

- The System object requires access to all MATLAB functions that do not support code generation, which means that you cannot generate code for simulation. You must use propagation methods in this case. Use these methods to specify information for the outputs.
- You want to use variable-size signals.
- You do not care whether code is generated, but you want to improve startup performance. Use propagation methods to specify information for the inputs and outputs, enabling quicker startup time.

At startup, the Simulink software tries to evaluate the input and output ports of the model blocks for signal attribute propagation. In the case of MATLAB System blocks, if the software cannot perform this evaluation, it displays a message prompting you to add propagation methods to the System object.

Add Propagation Methods to System Objects

Propagation methods are in the class `matlab.system.mixin.Propagates`. To add these methods to the System object, add the `matlab.system.mixin.Propagates` class to the top of the parent class file for the System object, after the `matlab.System` class. For example:

```
classdef Counter < matlab.System & matlab.system.mixin.Propagates
```

Implement Propagation Methods

Simulink evaluates the uses of the propagation methods to evaluate the input and output ports of the MATLAB System block for startup.

Each method has a default implementation, listed in the **Default Implementation Should Suffice if** column. If your System object does not use the default implementation, you must implement a version of the propagation method for your System object.

Description	Propagation Method	Default Implementation Should Suffice if	Example
Gets dimensions of output ports. The associated method is `getOutputSize`.	`getOutputSizeImpl`	• Only one input • Only one output • An input size that is the same as the output size	• FindIfFixedInput or FindIfVarSizeInput block in MATLAB System Block with Variable-Size Input and Output Signals • Analysis block in Illustration of Law of Large Numbers
Gets data types of output ports. The associated method is `getOutputDataType`.	`getOutputDataTypeImpl`	• Only one input • Only one output • Output data type always the same as the input data type	• FindIfFixedInput or FindIfVarSizeInput block in MATLAB System Block with Variable-Size Input and Output Signals • Analysis block in Illustration of Law of Large Numbers

Description	Propagation Method	Default Implementation Should Suffice if	Example
Indicates whether output ports are complex or not. The associated method is `isOutput-Complex`.	`isOutputComplexImpl`	• Only one input • Only one output • Output complexity always the same as th input complexity	• FindIfFixedInput or FindIfVarSizeInput block in MATLAB System Block with Variable-Size Input and Output Signals • Analysis block in Illustration of Law of Large Numbers
Whether output ports are fixed size. The associated method is `isOutputFixed-Size`.	`isOutputFixedSizeImp l`	• Only one input • Only one output • Output and input are fixed-size	• FindIfFixedInput or FindIfVarSizeInput block in MATLAB System Block with Variable-Size Input and Output Signals • Analysis block in Illustration of Law of Large Numbers
Gets the size, data type, and complexity of a discrete state property. The associated method is `getDiscrete-State-Specification`.	`getDiscreteState-SpecificationImpl`	No `DiscreteState` properties	N/A

Share Data with Other Blocks

In this section...

Share data between MATLAB System and other blocks using the `global` keyword and the Data Store Memory block or `Simulink.Signal` object. You might need to use global data with a MATLAB System block if:

- You have an existing model that uses a large amount of global data, you are adding a MATLAB System block to this model, and you want to avoid cluttering your model with additional inputs and outputs.
- You want to scope the visibility of data to parts of the model.

Data Sharing with the MATLAB System Block

In Simulink, you store global data using data store memory. You implement data store memory using either Data Store Memory blocks or `Simulink.Signal` objects. How you store global data depends on the number and scope of your global variables.

Scoping Rules for Shared Data in MATLAB System Blocks

The MATLAB System block uses these scoping rules:

- If you use the same name for both Data Store Memory block and `Simulink.Signal` object, Data Store Memory block scopes the data to the model.
- A global variable resolves hierarchically to the closest Data Store Memory block with the same name in the model. The same global variable appearing in two different MATLAB System blocks might resolve to different Data Store Memory blocks depending on the hierarchy of the model. You can use this ability to scope the visibility of data to a subsystem.

Using Shared Data in MATLAB System Blocks

MATLAB System blocks support data store memory for:

- MATLAB structures (buses)
- Enumerated data types

How to Use Data Sharing with the MATLAB System Block

To use shared data in your MATLAB System block:

1. Declare a global variable in the System object that you associate with the MATLAB System block.

   You can use the `global` keyword in these methods of the System object:

   - `stepImpl`
   - `outputImpl`
   - `updateImpl`

2. Add a Data Store Memory block or `Simulink.Signal` object that has the same name as the global variable in the System object.

To share data between referenced models using the `Simulink.Signal` object, define the `Simulink.Signal` object in the base workspace and use the same global variable name as in the MATLAB System block.

Choose How to Store Shared Data

You can use Data Store Memory blocks or `Simulink.Signal` objects to store shared data.

Type of Data	Global Data Storage Method	Related Links
A small number of global variables in a single model that does not use model reference.	Data Store Memory blocks. **Note** Using Data Store Memory blocks scopes the data to the model.	"How to Use Data Store Memory Blocks for the MATLAB System Block" on page 43-38

Type of Data	Global Data Storage Method	Related Links
A large number of global variables in a single model that does not use model reference.	`Simulink.Signal` objects defined in the model workspace. `Simulink.Signal` objects offer these advantages: • You do not have to add numerous Data Store Memory blocks to your model. • You can load the `Simulink.Signal` objects in from a MAT-file.	"How to Set Up Simulink.Signal Objects" on page 43-40
Data shared between multiple models (including referenced models).	`Simulink.Signal` objects defined in the base workspace **Note** If you use Data Store Memory blocks as well as `Simulink.Signal`, note that using Data Store Memory blocks scopes the data to the model.	"How to Set Up Simulink.Signal Objects" on page 43-40

How to Use Data Store Memory Blocks for the MATLAB System Block

1 Declare a global keyword in the System object methods that support globals. For example:

```
global A;
```

2 Add a MATLAB System block to your model.

3 Double-click the MATLAB System block and associate the System object.

4 Add a Data Store Memory block to your model and set:

   a **Data store name** to match the name of the global variable in your MATLAB System block code.

b **Data type** to an explicit data type.

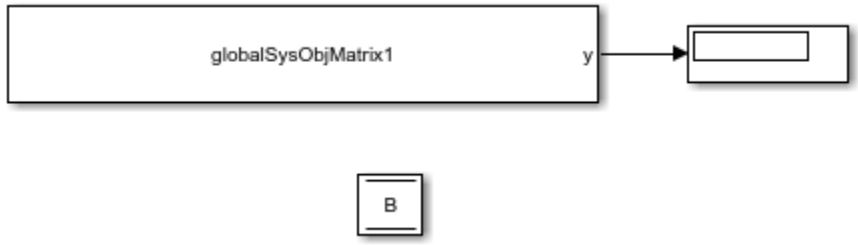
The data type cannot be `auto`.

c **Signal type**.

d **Initial value**.

The initial value of the Data Store Memory block cannot be unspecified.

Use Data Store Memory with the MATLAB System Block



This model demonstrates how a MATLAB System block uses the global data stored in Data Store Memory block `B`. The MATLAB System block is associated with the `globalSysObjMatrix1` System object. To see the completed model, open the `ex_globalsys_objmatrix1` model.

1 Drag these blocks into a new model:

- MATLAB System
- Data Store Memory
- Display

2 Create a System object to associate with the MATLAB System block. To start, from the MATLAB System block, create a Basic System object template file.

3 In MATLAB Editor, create a System object with code like the following. Save the System object as `globalSysObjMatrix1.m`. The System object modifies `B` each time it executes.

```
classdef globalSysObjMatrix1 < matlab.System
    % Global/DSM support scalar example

    methods(Access = protected)
        function setupImpl(obj)
```

```
            % Perform one-time calculations, such as computing constants
        end

        function y = stepImpl(obj)
            global B;
            B(:,1)= B(:,1)+100;
            y = B;
        end
    end
end
```

4 Double-click the MATLAB System block and associate the `globalSysObjMatrix1` System object with the block.

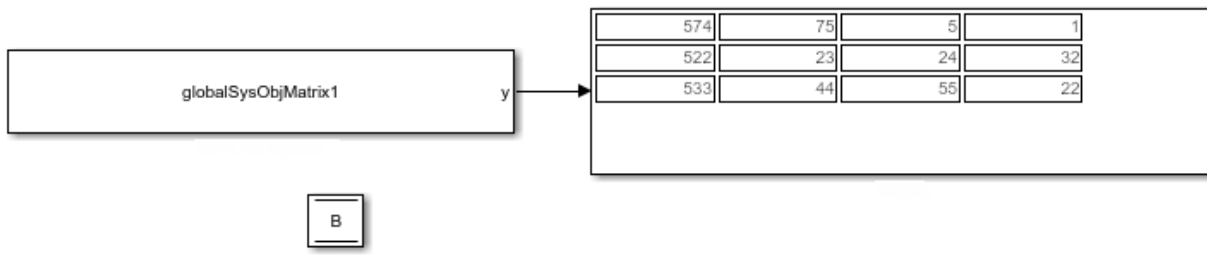
5 In the model, double-click the Data Store Memory block `B`.

6 In the Signal Attributes tab, enter an initial value, for example:

```
[74 75 5 1;22 23 24 32;33 44 55 22]
```

7 Simulate the model.

The MATLAB System block reads the initial value of global data stored in `B` and updates the value of `B` each time it executes. This model executes for five time steps.



8 Save and close your model.

How to Set Up Simulink.Signal Objects

Create a `Simulink.Signal` object in the model workspace.

Tip Create a `Simulink.Signal` object in the base workspace to use the global data with multiple models.

1 In the Model Explorer, navigate to ***model_name*** > **Model Workspace** in the **Model Hierarchy** pane.

   Select **Add** > **Simulink Signal**.

2 Ensure that these settings apply to the `Simulink.Signal` object:

   a Set **Data type** to an explicit data type.

      The data type cannot be `auto`.

   b Set **Dimensions** to be fully specified.

      The signal dimensions cannot be `-1` or inherited.

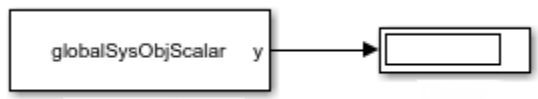
   c Set the **Complexity**.

   d Specify an **Initial value**.

      The initial value of the signal cannot be unspecified.

   e Set **Name** to the name of the global variable.

Use a Simulink.Signal Object with a MATLAB System Block



This simple model demonstrates how a MATLAB System block uses a `Simulink.Signal` with signal B. The MATLAB System block is associated with the `globalSysObjScalar` System object. To see the completed model, open the `ex_globalsys_simulink_signal_share` model.

1 Drag these blocks into a new model:

   - MATLAB System
   - Display

2 Create a System object to associate with the MATLAB System block. To start, from the MATLAB System block, create a Basic System object template file.

3 In MATLAB Editor, create a System object. Save the System object as `globalSysObjScalar.m`. The System object modifies `B` each time it executes.

```
classdef globalSysObjScalar < matlab.System
    % Global/DSM support scalar example
```

```
    methods(Access = protected)
        function setupImpl(obj)
            % Perform one-time calculations, such as computing constants
        end

        function y = stepImpl(obj)
            global B;
            B= B+100;
            y = B;
        end
    end
end
```

4 Double-click the MATLAB System block and associate the `globalSysObjScalar` System object with the block.

5 From the model menu, select **View** > **Model Explorer**.

6 In the left pane of the Model Explorer, select the model workspace for this model.

The **Contents** pane displays the data in the model workspace.

7 In the Model Explorer, in the **Model Hierarchy** pane, navigate to ***model_name*** > **Model Workspace**. In the **Contents** pane, set **Name** to `B`.

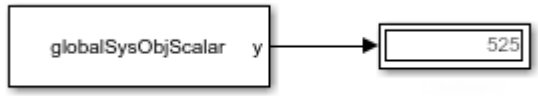
8 Navigate back to ***model_name*** > **Model Workspace**.

- Select **Add** > **Simulink Signal**.
- Make these settings for the `Simulink.Signal` object:

Attribute	Value
Data type	`double`
Complexity	`real`
Dimensions	`1`
Initial value	`25`

9 Simulate the model.

The MATLAB System block reads the initial value of global data stored in `B` and updates the value of `B` each time it executes. The model runs for five time steps.



10 Save and close your model.

Using Data Store Diagnostics to Detect Memory Access Issues

You can configure your model to provide run-time and compile-time diagnostics to avoid problems with data stores. Diagnostics are available in the Configuration Parameters dialog box and the Parameters dialog box for the Data Store Memory block. These diagnostics are available for Data Store Memory blocks only, not for `Simulink.Signal` objects. For more information on using data store diagnostics, see "Data Store Diagnostics" on page 62-3.

Limitations of Using Shared Data in MATLAB System Blocks

The MATLAB System block does not support data store memory for variable-sized data

Use Shared Data with P-Coded System Objects

If the System object is P-code, you must implement the `getGlobalNamesImpl` method to provide the global variable names you use in the System object. For example:

```
classdef GlobalSysObjMatrix < matlab.System
    % Matrix DSM support: Increment first row by 1 at each time step
    methods (Access = protected)
        function y = stepImpl(obj)
            global B;
            B(1,:) = B(1,:)+1;
            y = B;
        end

                function globalNames = getGlobalNamesImpl(~)
            globalNames = {'B'};
                end
    end
end
```

Troubleshoot System Objects in Simulink

In this section...

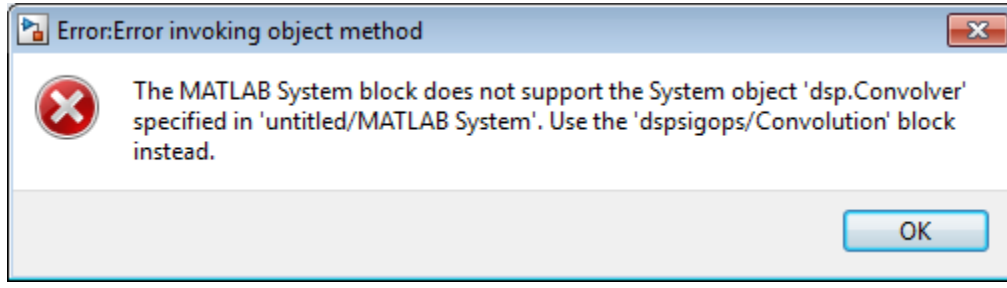
Class Not Found

The MATLAB System block **System object name** parameter requires that you enter the full path to the System object class. In addition:

- Check that the System object class is on your MATLAB path.
- Check capitalization to make sure it matches.
- Check that the class name is a supported System object.
- Do not include the file extension.

Error Invoking Object Method

The MATLAB System block supports only System objects written in the MATLAB language. If the software can identify an alternative block, it suggests that block in the error message, for example:



This message indicates that there is an existing dedicated and optimized block that you should use.

Performance

For fastest performance, set the block **Simulate using** parameter to `Code generation`. This setting allows the MATLAB System block to run as fast as it can. The parameter is set to this value by default.

This setting causes a slower startup time, as the software generates C code and creates a MEX-file from it. However, after code generation, later simulations have better performance. When the block uses generated code to simulate, performance is typically better than simulation without generated code.

In some cases, the implementation of your System object does not allow you to generate code, which requires you to set **Simulate using** to `Interpreted execution`. For example, your System object can require MATLAB functions beyond the subset supported for code generation. In this case, use propagation methods to specify the block input and output port information. The MATLAB System block then propagates this signal attribution information.

Import FMUs into Simulink

Import FMUs

In this section...

Use the FMU block to import Functional Mockup Units (FMUs) into Simulink.

The FMU block automatically selects the FMU mode based on the existing FMU you want to import:

- `Co-Simulation` — Integrate FMUs that implement an FMI Co-Simulation interface. These FMUs may contain local solvers be used for tool coupling.
- `Model Exchange` — Integrate FMUs that implement an FMI Model Exchange interface. These FMUs do not contain local solvers. Instead, these FMUs inherit solvers from Simulink.

This block supports FMI versions 1.0 and 2.0. For FMI version 2.0, if your FMU contains both Co-Simulation and Model Exchange elements, the block detects this and prompts you to select the mode you want the block to operate in.

You can use your FMU block as you do other Simulink blocks. These blocks support Normal and Accelerator modes.

This topic assumes that you provide a `.fmu` file.

FMU XML File Directives

The default parameter values derive from the corresponding parameter `start` value defined in the FMU `ModelDescription.xml` file. A block dialog parameter value overwrites the initial value of the corresponding parameter defined in the FMU binary implementation.

Simulink interprets these FMU tags accordingly.

FMU Tag	Simulink
`ScalarVariable` has attributes set as follows: • `causality="none"` or `causality="internal"` • `variability="parameter"` • `start` value is defined	Interprets `ScalarVariable` element as block parameter
`Real`	Interprets block parameter as edit field
`Integer`	Interprets block parameter as edit field
`Boolean`	Interprets block parameter as check box
`Enumeration`	Interprets block parameter as drop-down list
`String`	Interprets as UTF-8 encoded string

The FMU block supports the following encoding formats for the model description XML file:

- ISO-8859–1
- UTF-8
- UTF-16

Additional Support and Limitations

Capability	FMI Version 2.0 Support	FMI Version 1.0 Support
Save SimState to base workspace	✓	
Fast restart	✓	
Simulation Stepper	✓	
Solver Jacobian	✓	
Linearize models	✓	

Capability	FMI Version 2.0 Support	FMI Version 1.0 Support
Declare parameter as tunable and tune it during simulation	✓	
For Each subsystem blocks	✓	
Parameters of type string	✓	✓
Rapid Accelerator, software-in-the-loop (SIL), processor-in-the-loop (PIL) modes		
Code generation		
Model coverage		
Simulink Design Verifier		
Model reference in Accelerator mode		

FMU Import Examples

For examples of importing FMUs into and System objects, see **Integrating FMUs for Simulation** in Simulink Examples:

Example	Description
Importing a Co-Simulation FMU into Simulink	This model shows how to use the FMU block to load an FMU file that supports Co-Simulation mode.
Importing a Model Exchange FMU into Simulink	This model shows how to use the FMU block to load an FMU file that supports Model Exchange mode.
Using Bus Signals and Structure Parameters in the FMU Import Block	This model shows how to use bus signals and structure parameters in an FMU block that supports Model Exchange mode.

Implement an FMU Block

In this section...

Implement a block and assign a functional mockup unit (FMU) to it. You can then explore the block to see the FMU. This example uses the FMU block with the vehicle FMU.

1. Create a model and add the FMU block.
2. In the block dialog box, enter the path name for an FMU file in the **FMU name** parameter and click **OK** or **Apply**. The file extension `.fmu` is optional.

   The first time you click **OK** or **Apply**, the block identifies which FMU mode to set your FMU to, co-simulation or model exchange.

   The block also creates a `slprj/_fmu/`*`fmu_name`* folder and unpacks the contents of the FMU file into this folder, which can optionally contain:

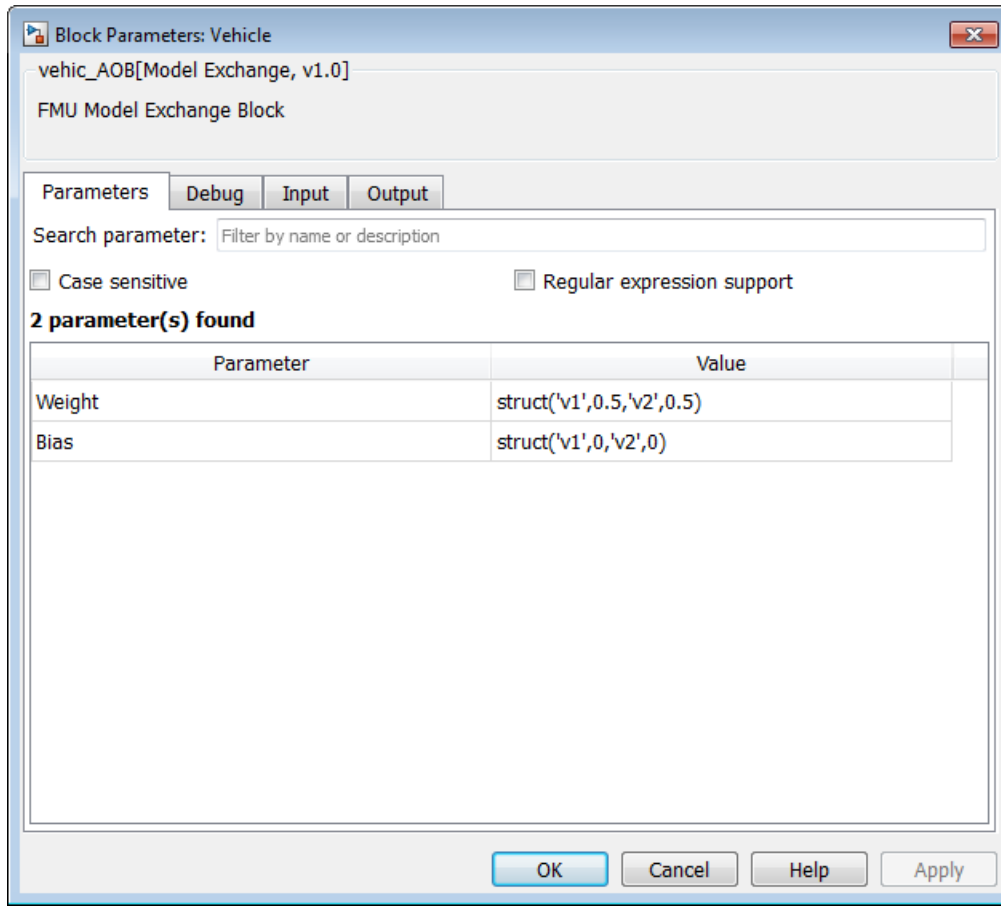
   - `binaries` — FMU binary files
   - `documentation` — FMU documentation HTML files
   - `resources` — FMU source files
   - `sources` — FMU source files
   - Other supporting files, such as block mask and description files

The FMU block icon and port labels update to the labels of the corresponding FMU. Suppose that you entered an FMU named `vehicleAOB` from your current folder. After you associate the block with an FMU, if you want to change the FMU, right-click the FMU block, and select **Block Parameters**, and enter a new FMU name in **FMU name**.

Understanding the FMU Block

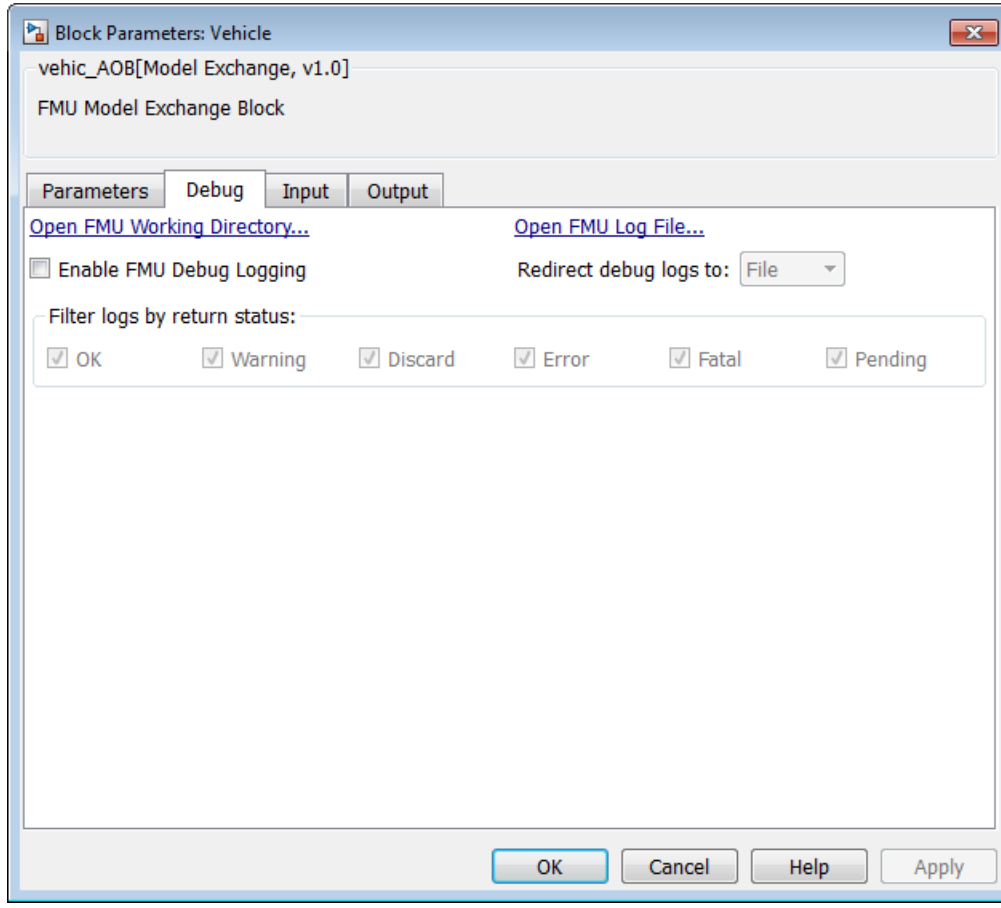
Double-click the block. The FMU block dialog box reflects the FMU parameters defined in the `vehicleAOB` file.

Parameters Tab



Lists the FMU block dialog parameters.

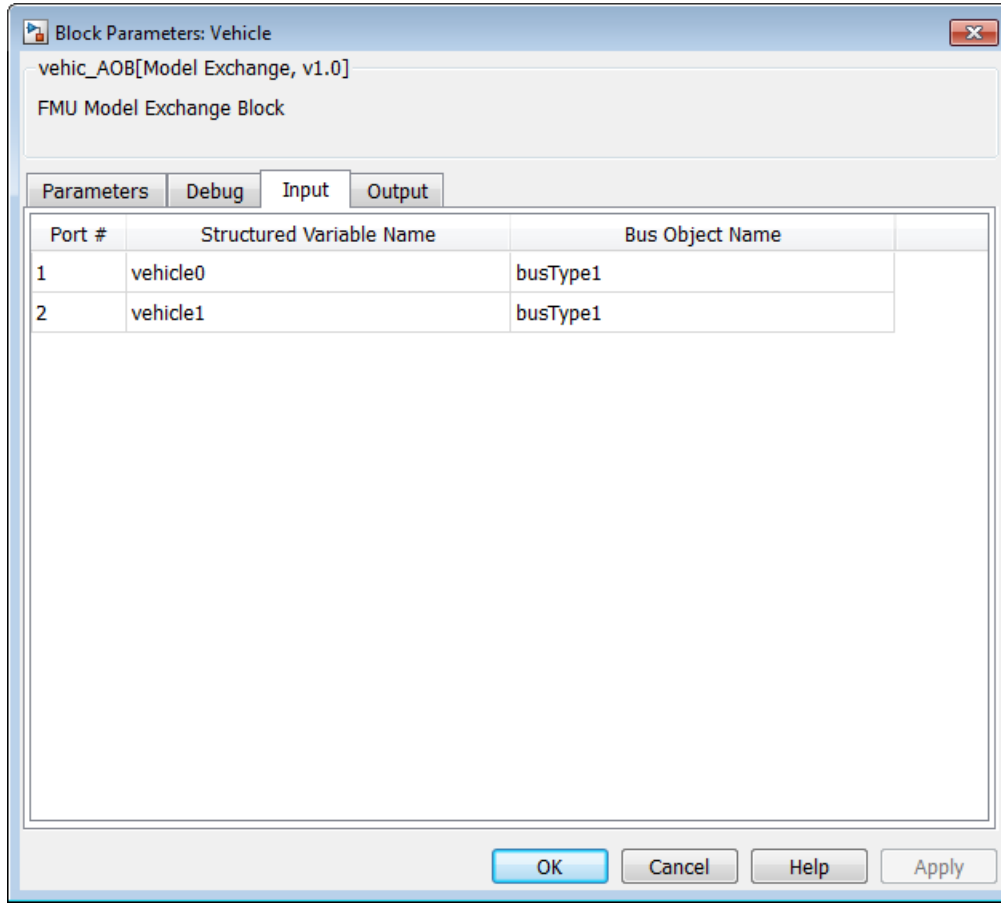
Debug Tab



Enables logging and associated customizations.

- Select the **Enable FMU Debug Logging** to enable logging.
- In **Redirect debug logs to**, select the destination for the logs.
  - `File`, saved to `slprj\_fmu\_logs_`*`modelname`*`\`*`modelname_blockname`*`.txt`
  - `Display`, displayed in the MATLAB Command Window.
- In the **Filter logs by return status**, select the check box for the return status you want.

Input Tab



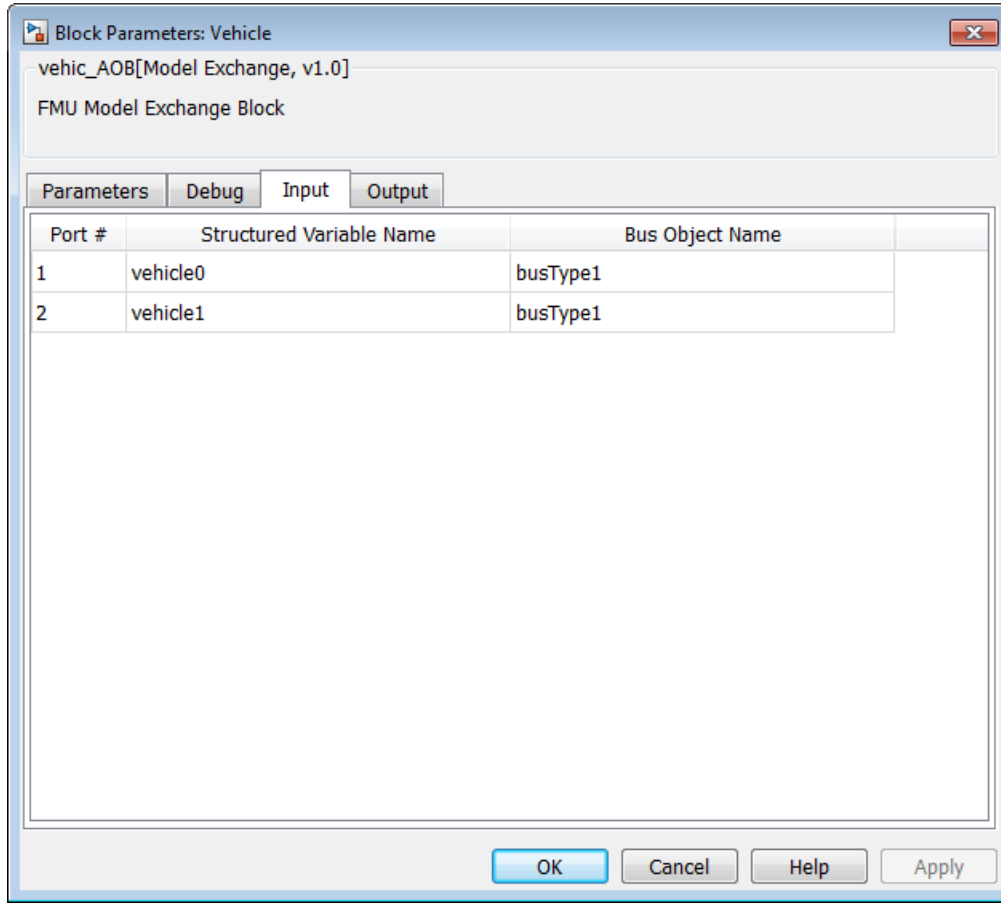
Lists the input bus objects that the block defines.

In the **Bus Object Name** parameter, you can change the bus object names to match the bus objects defined in the workspace.

To create a bus object in the workspace:

```
fmudialog.createBusType(gcb)
```

Output Tab



Lists the input bus objects that the block defines.

In the **Bus Object Name** parameter, you can change the bus object names to match the bus objects defined in the workspace.

To create a bus object in the workspace:

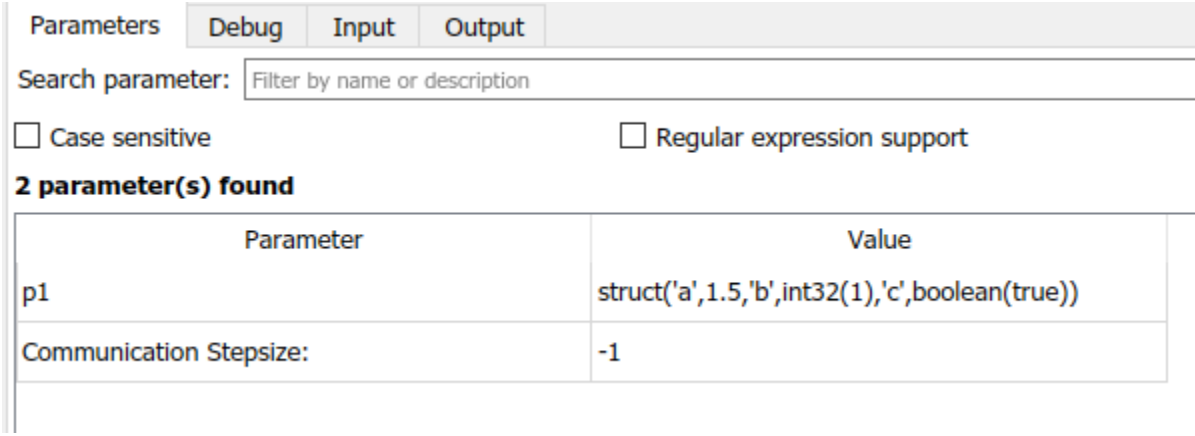
```
fmudialog.createBusType(gcb)
```

Changing Block Input, Output, and Parameter Structures

You can change the layout of FMU block input ports, output ports, and parameters with these parameters:

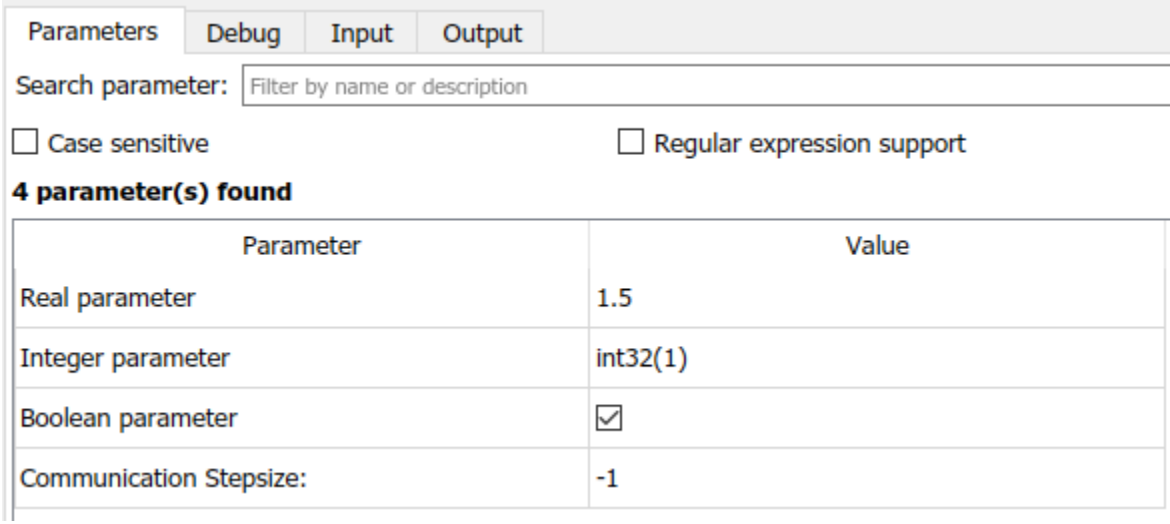
Parameter	Action	Settings
`FMUInputMapping`	Change hierarchy of input ports.	`'Flat'` — Separates input into individual signals. `'Structured'` — Combines input into a structure of signals (bus).
`FMUOutputMapping`	Change hierarchy of output ports.	`'Flat'` — Separates output into individual signals. `'Structured'` — Combines output into a structure of signals (bus).
`FMUParamMapping`	Change hierarchy of parameters.	`'Flat'` — Separates parameters into individual parameters, listed by the parameter name and value. `'Structured'` — Combines parameters into a structure of parameter values (`struct`).

Use the `get_param` and `set_param` functions to set these values. For example, assume a block parameter tab that looks like this:



The parameters are contained in a `struct`. To list the parameters individually, set the `FMUParamMapping` property to `'Flat'`:

```
set_param(gcb,'FMUParamMapping', 'Flat')
```



Troubleshooting FMUs

If there are problems with using the FMU:

- Check the compliance of the FMU with the FMI standard. Use the FMU compliance checker.
- Select the **Enable FMU Debug Logging** check box on the FMU block Debug tab.
- Contact the FMU supplier.

Simulink Community and Connection Partner Program

Simulink supports the integration of multiple third party functionalities, including apps, models, and toolboxes, from the Simulink community and commercial software tools.

For the integration of third-party functionality, this program includes:

- Simulink community — Provides direct access to all available Simulink apps, models, and toolboxes (Simulink community) using MATLAB® Add-Ons. (To open the Add-On Explorer, go to the MATLAB Command Window toolbar and click Add-Ons > get Add-Ons.)
- Third-Party Products — The MathWorks Connections Program includes commercially offered products and services that complement MATLAB and Simulink.

Design Considerations for C/C++ Code Generation

When to Generate Code from MATLAB Algorithms

Generating code from MATLAB algorithms for desktop and embedded systems allows you to perform your software design, implementation, and testing completely within the MATLAB workspace. You can:

- Verify that your algorithms are suitable for code generation
- Generate efficient, readable, and compact C/C++ code automatically, which eliminates the need to manually translate your MATLAB algorithms and minimizes the risk of introducing errors in the code.
- Modify your design in MATLAB code to take into account the specific requirements of desktop and embedded applications, such as data type management, memory use, and speed.
- Test the generated code and easily verify that your modified algorithms are functionally equivalent to your original MATLAB algorithms.
- Generate MEX functions to:
  - Accelerate MATLAB algorithms in certain applications.
  - Speed up fixed-point MATLAB code.
- Generate hardware description language (HDL) from MATLAB code.

When Not to Generate Code from MATLAB Algorithms

Do not generate code from MATLAB algorithms for the following applications. Use the recommended MathWorks product instead.

To:	Use:
Deploy an application that uses handle graphics	MATLAB Compiler™
Use Java	MATLAB Compiler SDK™
Use toolbox functions that do not support code generation	Toolbox functions that you rewrite for desktop and embedded applications
Deploy MATLAB based GUI applications on a supported MATLAB host	MATLAB Compiler
Deploy web-based or Windows applications	MATLAB Compiler SDK
Interface C code with MATLAB	MATLAB `mex` function

Which Code Generation Feature to Use

Prerequisites for C/C++ Code Generation from MATLAB

To generate C/C++ or MEX code from MATLAB algorithms, you must install the following software:

- MATLAB Coder product
- C/C++ compiler

MATLAB Code Design Considerations for Code Generation

When writing MATLAB code that you want to convert into efficient, standalone C/C++ code, you must consider the following:

- Data types

  C and C++ use static typing. To determine the types of your variables before use, MATLAB Coder requires a complete assignment to each variable.

- Array sizing

  Variable-size arrays and matrices are supported for code generation. You can define inputs, outputs, and local variables in MATLAB functions to represent data that varies in size at run time.

- Memory

  You can choose whether the generated code uses static or dynamic memory allocation.

  With dynamic memory allocation, you potentially use less memory at the expense of time to manage the memory. With static memory, you get better speed, but with higher memory usage. Most MATLAB code takes advantage of the dynamic sizing features in MATLAB, therefore dynamic memory allocation typically enables you to generate code from existing MATLAB code without modifying it much. Dynamic memory allocation also allows some programs to compile even when upper bounds cannot be found.

  Static allocation reduces the memory footprint of the generated code, and therefore is suitable for applications where there is a limited amount of available memory, such as embedded applications.

- Speed

  Because embedded applications must run in real time, the code must be fast enough to meet the required clock rate.

  To improve the speed of the generated code:

  - Choose a suitable C/C++ compiler. Do not use the default compiler that MathWorks supplies with MATLAB for Windows 64-bit platforms.
  - Consider disabling run-time checks.

By default, for safety, the code generated for your MATLAB code contains memory integrity checks and responsiveness checks. Generally, these checks result in more generated code and slower simulation. Disabling run-time checks usually results in streamlined generated code and faster simulation. Disable these checks only if you have verified that array bounds and dimension checking is unnecessary.

Differences Between Generated Code and MATLAB Code

To convert MATLAB code to efficient C/C++ code, the code generator introduces optimizations that intentionally cause the generated code to behave differently, and sometimes produce different results, than the original source code.

Here are some of the differences:

Character Size

MATLAB supports 16-bit characters, but the generated code represents characters in 8 bits, the standard size for most embedded languages like C. See "Encoding of Characters in Code Generation" on page 49-8.

Order of Evaluation in Expressions

Generated code does not enforce order of evaluation in expressions. For most expressions, order of evaluation is not significant. However, for expressions with side effects, the

generated code may produce the side effects in different order from the original MATLAB code. Expressions that produce side effects include those that:

- Modify persistent or global variables
- Display data to the screen
- Write data to files
- Modify the properties of handle class objects

In addition, the generated code does not enforce order of evaluation of logical operators that do not short circuit.

For more predictable results, it is good coding practice to split expressions that depend on the order of evaluation into multiple statements.

- Rewrite

  ```
  A = f1() + f2();
  ```

  as

  ```
  A = f1();
  A = A + f2();
  ```

  so that the generated code calls `f1` before `f2`.

- Assign the outputs of a multi-output function call to variables that do not depend on one another. For example, rewrite

  ```
  [y, y.f, y.g] = foo;
  ```

  as

  ```
  [y, a, b] = foo;
  y.f = a;
  y.g = b;
  ```

- When you access the contents of multiple cells of a cell array, assign the results to variables that do not depend on one another. For example, rewrite

  ```
  [y, y.f, y.g] = z{:};
  ```

  as

```
[y, a, b] = z{:};
y.f = a;
y.g = b;
```

Termination Behavior

Generated code does not match the termination behavior of MATLAB source code. For example, if infinite loops do not have side effects, optimizations remove them from generated code. As a result, the generated code can possibly terminate even though the corresponding MATLAB code does not.

Size of Variable-Size N-D Arrays

For variable-size N-D arrays, the `size` function might return a different result in generated code than in MATLAB source code. The `size` function sometimes returns trailing ones (singleton dimensions) in generated code, but always drops trailing ones in MATLAB. For example, for an N-D array `X` with dimensions `[4 2 1 1]`, `size(X)` might return `[4 2 1 1]` in generated code, but always returns `[4 2]` in MATLAB. See "Incompatibility with MATLAB in Determining Size of Variable-Size N-D Arrays" on page 50-19.

Size of Empty Arrays

The size of an empty array in generated code might be different from its size in MATLAB source code. See "Incompatibility with MATLAB in Determining Size of Empty Arrays" on page 50-20.

Size of Empty Array That Results from Deleting Elements of an Array

Deleting all elements of an array results in an empty array. The size of this empty array in generated code might differ from its size in MATLAB source code.

Case	Example Code	Size of Empty Array in MATLAB	Size of Empty Array in Generated Code

Delete all elements of an m-by-n array by using the `colon` operator (`:`).	`coder.varsize('X',[4,4],[1,1]);`
	`X = zeros(2);`
	`X(:) = [];`
		`0-by-0`	`1-by-0`

Delete all elements of a row vector by using the `colon` operator (`:`).	`coder.varsize('X',[1,4],[0,1]);`
	`X = zeros(1,4);`
	`X(:) = [];`
		`0-by-0`	`1-by-0`

Delete all elements of a column vector by using the `colon` operator (`:`).	`coder.varsize('X',[4,1],[1,0]);`
	`X = zeros(4,1);`
	`X(:) = [];`
		`0-by-0`	`0-by-1`

Delete all elements of a column vector by deleting one element at a time.	`coder.varsize('X',[4,1],[1,0]);`
	`X = zeros(4,1);`
	`for i = 1:4`
	`  X(1)= [];`
	`end`
		`1-by-0`	`0-by-1`

Floating-Point Numerical Results

The generated code might not produce the same floating-point numerical results as MATLAB in these:

When computer hardware uses extended precision registers

Results vary depending on how the C/C++ compiler allocates extended precision floating-point registers. Computation results might not match MATLAB calculations because of different compiler optimization settings or different code surrounding the floating-point calculations.

For certain advanced library functions

The generated code might use different algorithms to implement certain advanced library functions, such as `fft`, `svd`, `eig`, `mldivide`, and `mrdivide`.

For example, the generated code uses a simpler algorithm to implement `svd` to accommodate a smaller footprint. Results might also vary according to matrix properties.

For example, MATLAB might detect symmetric or Hermitian matrices at run time and switch to specialized algorithms that perform computations faster than implementations in the generated code.

For implementation of BLAS library functions

For implementations of BLAS library functions, generated C/C++ code uses reference implementations of BLAS functions. These reference implementations might produce different results from platform-specific BLAS implementations in MATLAB.

NaN and Infinity Patterns

The generated code might not produce exactly the same pattern of `NaN` and `Inf` values as MATLAB code when these values are mathematically meaningless. For example, if MATLAB output contains a `NaN`, output from the generated code should also contain a `NaN`, but not necessarily in the same place.

Negative Zero

In a floating-point type, the value `0` has either a positive sign or a negative sign. Arithmetically, `0` is equal to `-0`. Division by `0` produces `Inf`, but division by `-0` produces `-Inf`.

If the code generator detects that a floating-point variable takes only integer values of a suitable range, then the code generator can use an integer type for the variable in the generated code. If the code generator uses an integer type for the variable, then the variable stores `-0` as `+0` because an integer type does not store a sign for the value `0`. If the generated code casts the variable back to a floating-point type, the sign of `0` is positive. Division by `0` produces `Inf`, not `-Inf`.

Code Generation Target

The `coder.target` function returns different values in MATLAB than in the generated code. The intent is to help you determine whether your function is executing in MATLAB or has been compiled for a simulation or code generation target. See `coder.target`.

MATLAB Class Property Initialization

Before code generation, at class loading time, MATLAB computes class default values. The code generator uses the values that MATLAB computes. It does not recompute

default values. If the property definition uses a function call to compute the initial value, the code generator does not execute this function. If the function has side effects such as modifying a global variable or a persistent variable, then it is possible that the generated code can produce different results that MATLAB produces. For more information, see "Defining Class Properties for Code Generation" on page 53-4.

MATLAB Class Property Access Methods That Modify Property Values

When an object with property access methods is an input to or an output from an extrinsic function, simulation results can differ from MATLAB results if:

- A get method reads a property value and modifies the value before returning it.
- A set method modifies an input value before assigning it to the property.
- A get method or a set method has side effects such as modifying a global variable or writing to a file.

If property access methods modify property values or have side effects, results can differ due to inconsistencies in the use of property access methods when MATLAB and the simulation software pass objects to each other. If you return an object from an extrinsic function, MATLAB passes the object to the simulation software. The simulation software creates its own version of the object. To provide property values to the object creation process, MATLAB calls get methods. The object creation process assigns these property values from MATLAB directly to the new object without calling set methods.

When you pass an object to an extrinsic function for execution in MATLAB, the simulation software passes the object to MATLAB. MATLAB creates its own version of the object. To provide property values to MATLAB, instead of using get methods, the simulation software directly reads the property values. To assign property values in the MATLAB version of the object, the creation process uses set methods.

To avoid differences in results between MATLAB and simulation, for objects that are inputs to or outputs from extrinsic functions, do not use property access methods that modify property values or have other side effects.

For more information, see "Defining Class Properties for Code Generation" on page 53-4.

MATLAB Language Features Supported for C/C++ Code Generation

MATLAB Features That Code Generation Supports

Code generation from MATLAB code supports the following language features:

- n-dimensional arrays (see "Array Size Restrictions for Code Generation" on page 49-9)
- matrix operations, including deletion of rows and columns
- variable-sized data (see "Code Generation for Variable-Size Arrays" on page 50-2)
- subscripting (see "Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation" on page 50-23)
- complex numbers (see "Code Generation for Complex Data" on page 49-4)
- numeric classes (see "Supported Variable Types" on page 48-16)
- double-precision, single-precision, and integer math
- fixed-point arithmetic
- program control statements `if`, `switch`, `for`, `while`, and `break`
- arithmetic, relational, and logical operators
- local functions
- persistent variables
- global variables
- structures (see "Structure Definition for Code Generation" on page 51-2)
- cell arrays (see "Cell Arrays")
- characters (see "Encoding of Characters in Code Generation" on page 49-8)
- string scalars (see "Code Generation for Strings" on page 49-12)
- function handles (see "Function Handle Limitations for Code Generation" on page 54-2)
- anonymous functions (see "Code Generation for Anonymous Functions" on page 55-3)
- recursive functions (see "Code Generation for Recursive Functions" on page 56-18)
- nested functions (see "Code Generation for Nested Functions" on page 55-4)

- variable length input and output argument lists (see "Code Generation for Variable Length Argument Lists" on page 55-2)
- subset of MATLAB toolbox functions (see "Functions and Objects Supported for C/C++ Code Generation — Alphabetical List" on page 46-2)
- subset of functions and System objects in several toolboxes (see "Functions and Objects Supported for C/C++ Code Generation — Category List" on page 46-72)
- MATLAB classes (see "MATLAB Classes Definition for Code Generation" on page 53-2)
- function calls (see "Resolution of Function Calls for Code Generation" on page 56-2)

MATLAB Language Features That Code Generation Does Not Support

Code generation from MATLAB does not support the following frequently used MATLAB features:

- implicit expansion

  Code generation does not support implicit expansion of arrays with compatible sizes during execution of element-wise operations or functions. If your MATLAB code relies on implicit expansion, code generation results in a size-mismatch error. For fixed-size arrays, the error occurs at compile time. For variable-size arrays, the error occurs at run time. For more information about implicit expansion, see "Compatible Array Sizes for Basic Operations" (MATLAB).
- categorical arrays
- date and time arrays
- Java
- Map containers
- sparse matrices
- tables
- time series objects
- `try`/`catch` statements

This list is not exhaustive. To see if a feature is supported for code generation, see "MATLAB Features That Code Generation Supports" on page 45-15.

Functions, Classes, and System Objects Supported for Code Generation

Functions and Objects Supported for C/C++ Code Generation — Alphabetical List

You can generate efficient C/C++ code for a subset of MATLAB built-in functions and toolbox functions, classes, and System objects that you call from MATLAB code. These function, classes, and System objects appear in alphabetical order in the following table.

To find supported functions, classes, and System objects by MATLAB category or toolbox, see “Functions and Objects Supported for C/C++ Code Generation — Category List” on page 46-72.

Note For more information on code generation for fixed-point algorithms, refer to “Code Acceleration and Code Generation from MATLAB” (Fixed-Point Designer).

In the following table, an asterisk (*) indicates that the reference page has usage notes and limitations for C/C++ code generation.

Functions and Objects Supported for C/C++ Code Generation — Category List

You can generate efficient C/C++ code for a subset of MATLAB built-in functions and toolbox functions, classes, and System objects that you call from MATLAB code. These functions, classes, and System objects are listed by MATLAB category or toolbox category in the following tables.

For an alphabetical list of supported functions, classes, and System objects, see "Functions and Objects Supported for C/C++ Code Generation — Alphabetical List" on page 46-2.

Note For more information on code generation for fixed-point algorithms, refer to "Code Acceleration and Code Generation from MATLAB" (Fixed-Point Designer).

Fixed-Point Designer

The following general limitations apply to the use of Fixed-Point Designer functions in generated code, with `fiaccel`:

- `fipref` and `quantizer` objects are not supported.
- Word lengths greater than 128 bits are not supported.
- You cannot change the `fimath` or `numerictype` of a given `fi` variable after that variable has been created.
- The `boolean` value of the `DataTypeMode` and `DataType` properties are not supported.
- For all `SumMode` property settings other than `FullPrecision`, the `CastBeforeSum` property must be set to `true`.
- You can use parallel for (`parfor`) loops in code compiled with `fiaccel`, but those loops are treated like regular `for` loops.
- When you compile code containing `fi` objects with nontrivial slope and bias scaling, you may see different results in generated code than you achieve by running the same code in MATLAB.
- The general limitations of C/C++ code generated from MATLAB apply. For more information, see "MATLAB Language Features Supported for C/C++ Code Generation" (MATLAB Coder).

Image Acquisition Toolbox

If you install Image Acquisition Toolbox software, you can generate C and C++ code for the VideoDevice System object. See `imaq.VideoDevice` and "Code Generation with VideoDevice System Object" (Image Acquisition Toolbox).

Image Processing in MATLAB

Function	Remarks and Limitations
im2double	—
rgb2gray	—

Image Processing Toolbox

The following table lists the Image Processing Toolbox functions that have been enabled for code generation. You must have the MATLAB Coder software installed to generate C code from MATLAB for these functions.

Image Processing Toolbox provides three types of code generation support:

- Functions that generate C code.
- Functions that generate C code that depends on a platform-specific shared library (`.dll`, `.so`, or `.dylib`). Use of a shared library preserves performance optimizations

in these functions, but this limits the target platforms for which you can generate code. For more information, see "Code Generation for Image Processing" (Image Processing Toolbox).

- Functions that generate C code or C code that depends on a shared library, depending on which target platform you specify in MATLAB Coder. If you specify the generic `MATLAB Host Computer` target platform, these functions generate C code that depends on a shared library. If you specify any other target platform, these functions generate C code.

In generated code, each supported toolbox function has the same name, arguments, and functionality as its Image Processing Toolbox counterpart. However, some functions have limitations. The following table includes information about code generation limitations that might exist for each function. In the following table, all the functions generate C code. The table identifies those functions that generate C code that depends on a shared library, and those functions that can do both, depending on which target platform you choose.

An asterisk (*) indicates that the reference page has usage notes and limitations for C/C++ code generation.

Model Predictive Control Toolbox

C and C++ code generation for the following function requires the Model Predictive Control Toolbox.

An asterisk (*) indicates that the reference page has usage notes and limitations for C/C++ code generation.

`mpcqpsolver*`

Neural Network Toolbox

You can use `genFunction` in the Neural Network Toolbox™ to generate a standalone MATLAB function for a trained neural network. You can generate C/C++ code from this standalone MATLAB function. To generate Simulink blocks, use the `genSim` function. See “Deploy Trained Neural Network Functions” (Neural Network Toolbox).

Signal Processing Toolbox

C and C++ code generation for the following functions requires the Signal Processing Toolbox software. These functions do not support variable-size inputs, you must define the size and type of the function inputs. For more information, see "Specifying Inputs in Code Generation from MATLAB" (Signal Processing Toolbox).

Note Many Signal Processing Toolbox functions require constant inputs in generated code. To specify a constant input for `codegen`, use `coder.Constant`.

System Objects Supported for Code Generation

Code Generation for System Objects

You can generate C and C++ code for a subset of System objects provided by the following toolboxes.

Toolbox Name	See
Communications System Toolbox	"System Objects in MATLAB Code Generation" (MATLAB Coder)
Computer Vision System Toolbox	"System Objects in MATLAB Code Generation" (MATLAB Coder)
DSP System Toolbox	"System Objects in MATLAB Code Generation" (MATLAB Coder)
Image Acquisition Toolbox	• `imaq.VideoDevice` • "Code Generation with VideoDevice System Object" (Image Acquisition Toolbox)
Phased Array System Toolbox	"Code Generation" (Phased Array System Toolbox)
System Identification Toolbox	"Generate Code for Online Parameter Estimation in MATLAB" (System Identification Toolbox)
WLAN System Toolbox	"System Objects in MATLAB Code Generation" (MATLAB Coder)

To use these System objects, you need to install the requisite toolbox. For a list of System objects supported for C and C++ code generation, see "Functions and Objects Supported for C/C++ Code Generation — Alphabetical List" on page 46-2 and "Functions and Objects Supported for C/C++ Code Generation — Category List" on page 46-72.

System objects are MATLAB object-oriented implementations of algorithms. They extend MATLAB by enabling you to model dynamic systems represented by time-varying algorithms. System objects are well integrated into the MATLAB language, regardless of whether you are writing simple functions, working interactively in the command window, or creating large applications.

In contrast to MATLAB functions, System objects automatically manage state information, data indexing, and buffering, which is particularly useful for iterative computations or stream data processing. This enables efficient processing of long data

sets. For general information about MATLAB objects, see “Object-Oriented Programming” (MATLAB).

Defining MATLAB Variables for C/C++ Code Generation

Variables Definition for Code Generation

In the MATLAB language, variables can change their properties dynamically at run time so you can use the same variable to hold a value of any class, size, or complexity. For example, the following code works in MATLAB:

```
function x = foo(c) %#codegen
if(c>0)
  x = 0;
else
  x = [1 2 3];
end
disp(x);
end
```

However, statically-typed languages like C must be able to determine variable properties at compile time. Therefore, for C/C++ code generation, you must explicitly define the class, size, and complexity of variables in MATLAB source code before using them. For example, rewrite the above source code with a definition for *x*:

```
function x = foo(c) %#codegen
x = zeros(1,3);
if(c>0)
  x = 0;
else
  x = [1 2 3];
end
disp(x);
end
```

For more information, see “Best Practices for Defining Variables for C/C++ Code Generation” on page 48-3.

Best Practices for Defining Variables for C/C++ Code Generation

In this section...

Define Variables By Assignment Before Using Them

For C/C++ code generation, you should explicitly and unambiguously define the class, size, and complexity of variables before using them in operations or returning them as outputs. Define variables by assignment, but note that the assignment copies not only the value, but also the size, class, and complexity represented by that value to the new variable. For example:

Assignment:	Defines:
`a = 14.7;`	`a` as a real double scalar.
`b = a;`	`b` with properties of `a` (real double scalar).
`c = zeros(5,2);`	`c` as a real 5-by-2 array of doubles.
`d = [1 2 3 4 5; 6 7 8 9 0];`	`d` as a real 5-by-2 array of doubles.
`y = int16(3);`	`y` as a real 16-bit integer scalar.

Define properties this way so that the variable is defined on the required execution paths during C/C++ code generation.

The data that you assign to a variable can be a scalar, matrix, or structure. If your variable is a structure, define the properties of each field explicitly.

Initializing the new variable to the value of the assigned data sometimes results in redundant copies in the generated code. To avoid redundant copies, you can define variables without initializing their values by using the `coder.nullcopy` construct as described in “Eliminate Redundant Copies of Variables in Generated Code” on page 48-7.

When you define variables, they are local by default; they do not persist between function calls. To make variables persistent, see `persistent`.

Example 48.1. Defining a Variable for Multiple Execution Paths

Consider the following MATLAB code:

```
...
if c > 0
  x = 11;
end
% Later in your code ...
if c > 0
  use(x);
end
...
```

Here, *x* is assigned only if `c > 0` and used only when `c > 0`. This code works in MATLAB, but generates a compilation error during code generation because it detects that *x* is undefined on some execution paths (when `c <= 0`),.

To make this code suitable for code generation, define *x* before using it:

```
x = 0;
...
if c > 0
  x = 11;
end
% Later in your code ...
if c > 0
  use(x);
end
...
```

Example 48.2. Defining Fields in a Structure

Consider the following MATLAB code:

```
...
if c > 0
  s.a = 11;
  disp(s);
else
  s.a = 12;
  s.b = 12;
end
% Try to use s
```

```
use(s);
...
```

Here, the first part of the `if` statement uses only the field *a*, and the `else` clause uses fields *a* and *b*. This code works in MATLAB, but generates a compilation error during C/C++ code generation because it detects a structure type mismatch. To prevent this error, do not add fields to a structure after you perform certain operations on the structure. For more information, see “Structure Definition for Code Generation” on page 51-2.

To make this code suitable for C/C++ code generation, define all fields of *s* before using it.

```
...
% Define all fields in structure s
s = struct('a',0, 'b', 0);
if c > 0
  s.a = 11;
  disp(s);
else
  s.a = 12;
  s.b = 12;
end
% Use s
use(s);
...
```

Use Caution When Reassigning Variables

In general, you should adhere to the "one variable/one type" rule for C/C++ code generation; that is, each variable must have a specific class, size and complexity. Generally, if you reassign variable properties after the initial assignment, you get a compilation error during code generation, but there are exceptions, as described in “Reassignment of Variable Properties” on page 48-9.

Use Type Cast Operators in Variable Definitions

By default, constants are of type `double`. To define variables of other types, you can use type cast operators in variable definitions. For example, the following code defines variable `y` as an integer:

```
...
x = 15; % x is of type double by default.
```

```
y = uint8(x); % y has the value of x, but cast to uint8.
...
```

Define Matrices Before Assigning Indexed Variables

When generating C/C++ code from MATLAB, you cannot grow a variable by writing into an element beyond its current size. Such indexing operations produce run-time errors. You must define the matrix first before assigning values to its elements.

For example, the following initial assignment is not allowed for code generation:

```
g(3,2) = 14.6; % Not allowed for creating g
               % OK for assigning value once created
```

For more information about indexing matrices, see “Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation” on page 50-23.

Eliminate Redundant Copies of Variables in Generated Code

In this section...

When Redundant Copies Occur

During C/C++ code generation, the code generator checks for statements that attempt to access uninitialized memory. If it detects execution paths where a variable is used but is potentially not defined, it generates a compile-time error. To prevent these errors, define variables by assignment before using them in operations or returning them as function outputs.

Note, however, that variable assignments not only copy the properties of the assigned data to the new variable, but also initialize the new variable to the assigned value. This forced initialization sometimes results in redundant copies in C/C++ code. To eliminate redundant copies, define uninitialized variables by using the `coder.nullcopy` function, as described in "How to Eliminate Redundant Copies by Defining Uninitialized Variables" on page 48-7.

How to Eliminate Redundant Copies by Defining Uninitialized Variables

1. Define the variable with `coder.nullcopy`.
2. Initialize the variable before reading it.

   When the uninitialized variable is an array, you must initialize all of its elements before passing the array as an input to a function or operator — even if the function or operator does not read from the uninitialized portion of the array.

   ### What happens if you access uninitialized data?

   Uninitialized memory contains arbitrary values. Therefore, accessing uninitialized data may lead to segmentation violations or nondeterministic program behavior (different runs of the same program may yield inconsistent results).

Defining Uninitialized Variables

In the following code, the assignment statement `X = zeros(1,N)` not only defines *X* to be a 1-by-5 vector of real doubles, but also initializes each element of *X* to zero.

```
function X = fcn %#codegen

N = 5;
X = zeros(1,N);
for i = 1:N
   if mod(i,2) == 0
      X(i) = i;
   else
      X(i) = 0;
   end
end
```

This forced initialization creates an extra copy in the generated code. To eliminate this overhead, use `coder.nullcopy` in the definition of *X*:

```
function X = fcn2 %#codegen

N = 5;
X = coder.nullcopy(zeros(1,N));
for i = 1:N
   if mod(i,2) == 0
      X(i) = i;
   else
      X(i) = 0;
   end
end
```

Reassignment of Variable Properties

For C/C++ code generation, there are certain variables that you can reassign after the initial assignment with a value of different class, size, or complexity:

Dynamically sized variables

A variable can hold values that have the same class and complexity but different sizes. If the size of the initial assignment is not constant, the variable is dynamically sized in generated code. For more information, see “Variable-Size Data”.

Variables reused in the code for different purposes

You can reassign the type (class, size, and complexity) of a variable after the initial assignment if each occurrence of the variable can have only one type. In this case, the variable is renamed in the generated code to create multiple independent variables. For more information, see “Reuse the Same Variable with Different Properties” on page 48-10.

Reuse the Same Variable with Different Properties

In this section...

When You Can Reuse the Same Variable with Different Properties

You can reuse (reassign) an input, output, or local variable with different class, size, or complexity if the code generator can unambiguously determine the properties of each occurrence of this variable during C/C++ code generation. If so, MATLAB creates separate uniquely named local variables in the generated code. You can view these renamed variables in the code generation report (see "MATLAB Code Variables in a Report" on page 41-62).

A common example of variable reuse is in `if-elseif-else` or `switch-case` statements. For example, the following function `example1` first uses the variable *t* in an `if` statement, where it holds a scalar double, then reuses *t* outside the `if` statement to hold a vector of doubles.

```
function y = example1(u) %#codegen
if all(all(u>0))
    % First, t is used to hold a scalar double value
    t = mean(mean(u)) / numel(u);
    u = u - t;
end
% t is reused to hold a vector of doubles
t = find(u > 0);
y = sum(u(t(2:end-1)));
```

When You Cannot Reuse Variables

You cannot reuse (reassign) variables if it is not possible to determine the class, size, and complexity of an occurrence of a variable unambiguously during code generation. In this case, variables cannot be renamed and a compilation error occurs.

For example, the following `example2` function assigns a fixed-point value to *x* in the `if` statement and reuses *x* to store a matrix of doubles in the `else` clause. It then uses *x*

after the `if-else` statement. This function generates a compilation error because after the `if-else` statement, variable *x* can have different properties depending on which `if-else` clause executes.

```
function y = example2(use_fixpoint, data) %#codegen
  if use_fixpoint
            % x is fixed-point
      x = fi(data, 1, 12, 3);
  else
             % x is a matrix of doubles
      x = data;
  end
  % When x is reused here, it is not possible to determine its
  % class, size, and complexity
  t = sum(sum(x));
  y = t > 0;
end
```

Example 48.3. Variable Reuse in an if Statement

To see how MATLAB renames a reused variable *t*:

1 Create a MATLAB file `example1.m` containing the following code.

```
function y = example1(u) %#codegen
if all(all(u>0))
    % First, t is used to hold a scalar double value
    t = mean(mean(u)) / numel(u);
    u = u - t;
end
% t is reused to hold a vector of doubles
t = find(u > 0);
y = sum(u(t(2:end-1)));
end
```

2 Compile `example1`.

For example, to generate a MEX function, enter:

```
codegen -o example1x -report example1.m -args {ones(5,5)}
```

Note `codegen` requires a MATLAB Coder license.

When the compilation is complete, `codegen` generates a MEX function, `example1x` in the current folder, and provides a link to the code generation report.

3 Open the code generation report.

4 In the MATLAB code pane of the code generation report, place your pointer over the variable *t* inside the `if` statement.

The code generation report highlights both instances of *t* in the `if` statement because they share the same class, size, and complexity. It displays the data type information for *t* at this point in the code. Here, *t* is a scalar double.

```
% First time t is used to hold a scalar double value.
t = mean(mean(u)) / numel(u);
u = u - t;
```

Information for the selected variable:	
Size	1 x 1
Complex	No
Class	double

5 In the MATLAB code pane of the report, place your pointer over the variable *t* outside the for-loop.

This time, the report highlights both instances of *t* outside the `if` statement. The report indicates that *t* might hold up to `25` doubles. The size of *t* is `:25`, that is, a column vector containing a maximum of `25` doubles.

```
t = find(u);
y = sum(u(t(2:end-1)));
```

Information for the selected variable:	
Size	:25
Complex	No
Class	double

6 Click the **Variables** tab to view the list of variables used in `example1`.

The report displays a list of the variables in `example1`. There are two uniquely named local variables *t>1* and *t>2*.

7 In the list of variables, place your pointer over *t>1*.

The code generation report highlights both instances of *t* in the `if` statement.

8 In the list of variables, place your pointer over *t>2*

The code generation report highlights both instances of *t* outside the `if` statement.

Limitations of Variable Reuse

The following variables cannot be renamed in generated code:

- Persistent variables.
- Global variables.
- Variables passed to C code using `coder.ref`, `coder.rref`, `coder.wref`.
- Variables whose size is set using `coder.varsize`.
- Variables whose names are controlled using `coder.cstructname`.
- The index variable of a `for`-loop when it is used inside the loop body.
- The block outputs of a MATLAB Function block in a Simulink model.
- Chart-owned variables of a MATLAB function in a Stateflow chart.

Avoid Overflows in for-Loops

When memory integrity checks are enabled, if the code generator detects that a loop variable might overflow on the last iteration of the `for`-loop, it reports an error.

To avoid this error, use the workarounds provided in the following table.

Loop conditions causing the error	Workaround

• The loop counter increments by 1
• The end value equals the maximum value of the integer type
• The loop is not covering the full range of the integer type
	Rewrite the loop so that the end value is not equal to the maximum value of the integer type. For example, replace:
	`N=intmax('int16')`
	`for k=N-10:N`
	with:
	`for k=1:10`

• The loop counter decrements by 1
• The end value equals the minimum value of the integer type
• The loop is not covering the full range of the integer type
	Rewrite the loop so that the end value is not equal to the minimum value of the integer type. For example, replace:
	`N=intmin('int32')`
	`for k=N+10:-1:N`
	with:
	`for k=10:-1:1`

Loop conditions causing the error	Workaround

• The loop counter increments or decrements by 1
• The start value equals the minimum or maximum value of the integer type
• The end value equals the maximum or minimum value of the integer type
 	
The loop covers the full range of the integer type.
	Rewrite the loop casting the type of the loop counter start, step, and end values to a bigger integer or to double For example, rewrite:
	
	`M= intmin('int16');`
	`N= intmax('int16');`
	`for k=M:N`
	`    % Loop body`
	`end`
	
	to
	
	`M= intmin('int16');`
	`N= intmax('int16');`
	`for k=int32(M):int32(N)`
	`    % Loop body`
	`end`

• The loop counter increments or decrements by a value not equal to 1 • On last loop iteration, the loop variable value is not equal to the end value **Note** The software error checking is conservative. It may incorrectly report a loop as being potentially infinite.	Rewrite the loop so that the loop variable on the last loop iteration is equal to the end value.

Supported Variable Types

You can use the following data types for C/C++ code generation from MATLAB:

Type	Description
`char`	Character array
`complex`	Complex data. Cast function takes real and imaginary components
`double`	Double-precision floating point
`int8`, `int16`, `int32`, `int64`	Signed integer
`logical`	Boolean `true` or `false`
`single`	Single-precision floating point
`struct`	Structure
`uint8`, `uint16`, `uint32`, `uint64`	Unsigned integer
Fixed-point	See “Fixed-Point Data Types” (Fixed-Point Designer).

Defining Data for Code Generation

Data Definition for Code Generation

To generate efficient standalone code, you must define the following types and classes of data differently than you normally would when running your code in MATLAB.

Data	What Is Different	More Information
Arrays	Maximum number of elements is restricted	"Array Size Restrictions for Code Generation" on page 49-9
Complex numbers	• Complexity of variables must be set at time of assignment and before first use • Expressions containing a complex number or variable evaluate to a complex result, even if the result is zero **Note** Because MATLAB does not support complex integer arithmetic, you cannot generate code for functions that use complex integer arithmetic	"Code Generation for Complex Data" on page 49-4
Characters	Restricted to 8 bits of precision	"Encoding of Characters in Code Generation" on page 49-8
Enumerated data	• Supports integer-based enumerated types only • Restricted use in `switch` statements and `for`-loops	"Enumerations"

Data	What Is Different	More Information
Function handles	• Using the same bound variable to reference different function handles can cause a compile-time error. • Cannot pass function handles to or from primary or extrinsic functions • Cannot view function handles from the debugger	“Function Handles”

Code Generation for Complex Data

In this section...

Restrictions When Defining Complex Variables

For code generation, you must set the complexity of variables at the time of assignment. Assign a complex constant to the variable or use the `complex` function. For example:

```
x = 5 + 6i; % x is a complex number by assignment.
y = complex(5,6); % y is the complex number 5 + 6i.
```

After assignment, you cannot change the complexity of a variable. Code generation for the following function fails because `x(k) = 3 + 4i` changes the complexity of `x`.

```
function x = test1( )
x = zeros(3,3); % x is real
for k = 1:numel(x)
    x(k) = 3 + 4i;
end
end
```

To resolve this issue, assign a complex constant to `x`.

```
function x = test1( )
x = zeros(3,3)+ 0i; %x is complex
for k = 1:numel(x)
    x(k) = 3 + 4i;
end
end
```

Code Generation for Complex Data with Zero-Valued Imaginary Parts

For code generation, complex data that has all zero-valued imaginary parts remains complex. This data does not become real. This behavior has the following implications:

- In some cases, results from functions that sort complex data by absolute value can differ from the MATLAB results. See "Functions That Sort Complex Values by Absolute Value" on page 49-5.
- For functions that require that complex inputs are sorted by absolute value, complex inputs with zero-valued imaginary parts must be sorted by absolute value. These functions include `ismember`, `union`, `intersect`, `setdiff`, and `setxor`.

Functions That Sort Complex Values by Absolute Value

Functions that sort complex values by absolute value include `sort`, `issorted`, `sortrows`, `median`, `min`, and `max`. These functions sort complex numbers by absolute value even when the imaginary parts are zero. In general, sorting the absolute values produces a different result than sorting the real parts. Therefore, when inputs to these functions are complex with zero-valued imaginary parts in generated code, but real in MATLAB, the generated code can produce different results than MATLAB. In the following examples, the input to `sort` is real in MATLAB, but complex with zero-valued imaginary parts in the generated code:

- **You Pass Real Inputs to a Function Generated for Complex Inputs**

  1. Write this function:

     ```
     function myout = mysort(A)
     myout = sort(A);
     end
     ```

  2. Call `mysort` in MATLAB.

     ```
     A = -2:2;
     mysort(A)

     ans =

         -2    -1     0     1     2
     ```

  3. Generate a MEX function for complex inputs.

     ```
     A = -2:2;
     codegen mysort -args {complex(A)} -report
     ```

  4. Call the MEX Function with real inputs.

     ```
     mysort_mex(A)
     ```

```
ans =

     0     1    -1     2    -2
```

You generated the MEX function for complex inputs, therefore, it treats the real inputs as complex numbers with zero-valued imaginary parts. It sorts the numbers by the absolute values of the complex numbers. Because the imaginary parts are zero, the MEX function returns the results to the MATLAB workspace as real numbers.

- **Input to `sort` Is Output from a Function That Returns Complex in Generated Code**

  1. Write this function:

     ```
     function y = myfun(A)
     x = eig(A);
     y = sort(x,'descend');
     ```

     The output from `eig` is the input to `sort`. In generated code, `eig` returns a complex result. Therefore, in the generated code, `x` is complex.

  2. Call `myfun` in MATLAB.

     ```
     A = [2 3 5;0 5 5;6 7 4];
     myfun(A)
     ```

     ```
     ans =

        12.5777
         2.0000
        -3.5777
     ```

     The result of `eig` is real. Therefore, the inputs to `sort` are real.

  3. Generate a MEX function for complex inputs.

     ```
     codegen myfun -args {complex(A)}
     ```

  4. Call the MEX function.

     ```
     myfun_mex(A)
     ```

     ```
     ans =

        12.5777
        -3.5777
         2.0000
     ```

In the MEX function, `eig` returns a complex result. Therefore, the inputs to `sort` are complex. The MEX function sorts the inputs in descending order of the absolute values.

Results of Expressions That Have Complex Operands

In general, expressions that contain one or more complex operands produce a complex result in generated code, even if the value of the result is zero. Consider the following line of code:

```
z = x + y;
```

Suppose that at run time, `x` has the value `2 + 3i` and `y` has the value `2 - 3i`. In MATLAB, this code produces the real result `z = 4`. During code generation, the types for `x` and `y` are known, but their values are not known. Because either or both operands in this expression are complex, `z` is defined as a complex variable requiring storage for a real and an imaginary part. `z` equals the complex result `4 + 0i` in generated code, not `4`, as in MATLAB code.

Exceptions to this behavior are:

- Functions that take complex arguments but produce real results return real values.

  ```
  y = real(x); % y is the real part of the complex number x.
  y = imag(x); % y is the real-valued imaginary part of x.
  y = isreal(x); % y is false (0) for a complex number x.
  ```

- Functions that take real arguments but produce complex results return complex values.

  ```
  z = complex(x,y); % z is a complex number for a real x and y.
  ```

Encoding of Characters in Code Generation

MATLAB represents characters in 16-bit Unicode. The code generator represents characters in an 8-bit codeset that the locale setting determines. Differences in character encoding between MATLAB and code generation have these consequences:

- Code generation of characters with numeric values greater than 255 produces an error.
- For some characters in the range 128–255, it might not be possible to represent the character in the codeset of the locale setting or to convert the character to an equivalent 16-bit Unicode character. Passing characters in this range between MATLAB and generated code can result in errors or different answers.
- For code generation, some toolbox functions accept only 7-bit ASCII characters.
- Casting a character that is not in the 7-bit ASCII codeset to a numeric type, such as double, can produce a different result in the generated code than in MATLAB. As a best practice, for code generation, avoid performing arithmetic with characters.

Array Size Restrictions for Code Generation

For code generation, the maximum number of elements of an array is constrained by the code generator and the target hardware.

For fixed-size arrays and variable-size arrays that use static memory allocation, the maximum number of elements is the smaller of:

- `intmax('int32')`.
- The largest integer that fits in the C `int` data type on the target hardware.

For variable-size arrays that use dynamic memory allocation, the maximum number of elements is the smaller of:

- `intmax('int32')`.
- The largest power of 2 that fits in the C `int` data type on the target hardware.

These restrictions apply even on a 64-bit platform.

For a fixed-size array, if the number of elements exceeds the maximum, the code generator reports an error at compile time. For a variable-size array, if the number of elements exceeds the maximum during simulation, the software reports an error. Generated standalone code cannot report array size violations.

Code Generation for Constants in Structures and Arrays

The code generator does not recognize constant structure fields or array elements in the following cases:

Fields or elements are assigned inside control constructs

In the following code, the code generator recognizes that the structure fields `s.a` and `s.b` are constants.

```
function y = mystruct()
s.a = 3;
s.b = 5;
y = zeros(s.a,s.b);
```

If any structure field is assigned inside a control construct, the code generator does not recognize the constant fields. This limitation also applies to arrays with constant elements. Consider the following code:

```
function y = mystruct(x)
s.a = 3;
if x > 1
    s.b = 4;
else
    s.b = 5;
end
y = zeros(s.a,s.b);
```

The code generator does not recognize that `s.a` and `s.b` are constant. If variable-sizing is enabled, `y` is treated as a variable-size array. If variable-sizing is disabled, the code generator reports an error.

Constants are assigned to array elements using non-scalar indexing

In the following code, the code generator recognizes that `a(1)` is constant.

```
function y = myarray()
a = zeros(1,3);
a(1) = 20;
y = coder.const(a(1));
```

In the following code, because `a(1)` is assigned using non-scalar indexing, the code generator does not recognize that `a(1)` is constant.

```
function y = myarray()
a = zeros(1,3);
a(1:2) = 20;
y = coder.const(a(1));
```

A function returns a structure or array that has constant and nonconstant elements

For an output structure that has both constant and nonconstant fields, the code generator does not recognize the constant fields. This limitation also applies to arrays that have constant and nonconstant elements. Consider the following code:

```
function y = mystruct_out(x)
s = create_structure(x);
y = coder.const(s.a);

function s = create_structure(x)
s.a = 10;
s.b = x;
```

Because `create_structure` returns a structure `s` that has one constant field and one nonconstant field, the code generator does not recognize that `s.a` is constant. The `coder.const` call fails because `s.a` is not constant.

Code Generation for Strings

Code generation supports 1-by-1 MATLAB string arrays. Code generation does not support string arrays that have more than one element.

A 1-by-1 string array, called a string scalar, contains one piece of text, represented as a 1-by-n character vector. An example of a string scalar is `"Hello, world"`. For more information about strings, see “Represent Text with Character and String Arrays” (MATLAB).

For string scalars, code generation does not support:

- Global variables
- Indexing with curly braces `{}`
- Missing values
- Their use as Simulink signals, parameters, or data store memory

For code generation, limitations that apply to classes apply to strings. See “MATLAB Classes Definition for Code Generation” on page 53-2.

Code Generation for Variable-Size Data

Code Generation for Variable-Size Arrays

For code generation, an array dimension is fixed-size or variable-size. If the code generator can determine the size of the dimension and that the size of the dimension does not change, then the dimension is fixed-size. When all dimensions of an array are fixed-size, the array is a fixed-size array. In the following example, `Z` is a fixed-size array.

```
function Z = myfcn()
Z = zeros(1,4);
end
```

The size of the first dimension is 1 and the size of the second dimension is 4.

If the code generator cannot determine the size of a dimension or the code generator determines that the size changes, then the dimension is variable-size. When at least one of its dimensions is variable-size, an array is a variable-size array.

A variable-size dimension is either bounded or unbounded. A bounded dimension has a fixed upper size. An unbounded dimension does not have a fixed upper size.

In the following example, the second dimension of `Z` is bounded, variable-size. It has an upper bound of 16.

```
function s = myfcn(n)
if (n > 0)
    Z = zeros(1,4);
else
    Z = zeros(1,16);
end
s = length(Z);
```

In the following example, if the value of `n` is unknown at compile time, then the second dimension of `Z` is unbounded.

```
function s = myfcn(n)
Z = rand(1,n);
s = sum(Z);
end
```

You can define variable-size arrays by:

- Using constructors, such as `zeros`, with a nonconstant dimension

- Assigning multiple, constant sizes to the same variable before using it
- Declaring all instances of a variable to be variable-size by using `coder.varsize`

For more information, see "Define Variable-Size Data for Code Generation" on page 50-7.

You can control whether variable-size arrays are allowed for code generation. See "Enabling and Disabling Support for Variable-Size Arrays" on page 50-3.

Memory Allocation for Variable-Size Arrays

For fixed-size arrays and variable-size arrays whose size is less than a threshold, the code generator allocates memory statically on the stack. For unbounded, variable-size arrays and variable-size arrays whose size is greater than or equal to a threshold, the code generator allocates memory dynamically on the heap.

For a MATLAB Function block, you cannot use dynamic memory allocation for:

- Input and output signals. Variable-size input and output signals must have an upper bound.
- Parameters or global variables. Parameters and global variables must be fixed-size.
- Fields of bus arrays. Bus arrays cannot have variable-size fields.

You can control whether dynamic memory allocation is allowed or when it is used for code generation. See "Control Memory Allocation for Variable-Size Arrays in a MATLAB Function Block" on page 41-114.

The code generator represents dynamically allocated data as a structure type called `emxArray`. The code generator generates utility functions that create and interact with emxArrays. If you use Embedded Coder, you can customize the generated identifiers for the `emxArray` types and utility functions. See "Identifier Format Control" (Embedded Coder).

Enabling and Disabling Support for Variable-Size Arrays

By default, for MATLAB Function blocks, support for variable-size arrays is enabled. To disable this support:

1 In the MATLAB Function Block Editor, select **Edit Data**.

2 Clear the **Support variable-size arrays** check box.

Variable-Size Arrays in a MATLAB Function Report

You can tell whether an array is fixed-size or variable-size by looking at the **Size** column of the **Variables** tab in a MATLAB Function Report.

Variable	Type	Size
y	Output	1 x 1
n	Input	1 x 1
x	Local	1 x :?

A colon (:) indicates that a dimension is variable-size. A question mark (?) indicates that the size is unbounded. For example, a size of 2-by-:? indicates that the size of the first dimension is fixed-size 2 and the size of the second dimension is unbounded, variable-size. An asterisk (*) indicates that your code specifies that an array is variable-size, but the code generator determined that it does not change size.

Variable	Type	Size
y	Output	1 x 2
n	Input	1 x 1
Z	Local	1 x 4 *

- "Define Variable-Size Data for Code Generation" on page 50-7
- "Use Dynamic Memory Allocation for Variable-Size Arrays in a MATLAB Function Block" on page 41-117

Specify Upper Bounds for Variable-Size Arrays

Specify upper bounds for an array when:

- Dynamic memory allocation is disabled.

  If dynamic memory allocation is disabled, you must specify upper bounds for all arrays.
- You do not want the code generator to use dynamic memory allocation for the array.

  Specify upper bounds that result in an array size (in bytes) that is less than the dynamic memory allocation threshold.

Specify Upper Bounds for MATLAB Function Block Inputs and Outputs

See "Declare Variable-Size Inputs and Outputs" on page 41-105.

Specify Upper Bounds for Local Variables

When using static allocation, the code generator uses a sophisticated analysis to calculate the upper bounds of local data. However, when the analysis fails to detect an upper bound or calculates an upper bound that is not precise enough for your application, you must specify upper bounds explicitly for local variables.

Constrain the Value of Variables That Specify the Dimensions of Variable-Size Arrays

To constrain the value of variables that specify the dimensions of variable-size arrays, use the `assert` function with relational operators. For example:

```
function y = dim_need_bound(n) %#codegen
assert (n <= 5);
L= ones(n,n);
M = zeros(n,n);
M = [L; M];
y = M;
```

This `assert` statement constrains input `n` to a maximum size of 5. `L` is variable-size with upper bounds of 5 in each dimension. `M` is variable-size with an upper bound of 10 in the first dimension and 5 in the second dimension.

Specify the Upper Bounds for All Instances of a Local Variable

To specify the upper bounds for all instances of a local variable in a function, use the `coder.varsize` function. For example:

```
function Y = example_bounds1(u) %#codegen
Y = [1 2 3 4 5];
coder.varsize('Y',[1 10]);
if (u > 0)
    Y = [Y Y+u];
else
    Y = [Y Y*u];
end
```

The second argument of `coder.varsize` specifies the upper bound for each instance of the variable specified in the first argument. In this example, the argument `[1 10]` indicates that for every instance of `Y`:

- The first dimension is fixed at size 1.
- The second dimension can grow to an upper bound of 10.

- “Define Variable-Size Data for Code Generation” on page 50-7

Define Variable-Size Data for Code Generation

For code generation, before using variables in operations or returning them as outputs, you must assign them a specific class, size, and complexity . Generally, after the initial assignment, you cannot reassign variable properties. Therefore, after assigning a fixed size to a variable or structure field, attempts to grow the variable or structure field might cause a compilation error. In these cases, you must explicitly define the data as variable-size by using one of these methods.

Method	See
Assign the data from a variable-size matrix constructor such as: • `ones` • `zeros` • `repmat`	"Use a Matrix Constructor with Nonconstant Dimensions" on page 50-7
Assign multiple, constant sizes to the same variable before using (reading) the variable.	"Assign Multiple Sizes to the Same Variable" on page 50-8
Define all instances of a variable to be variable-size.	"Define Variable-Size Data Explicitly by Using coder.varsize" on page 50-8

Use a Matrix Constructor with Nonconstant Dimensions

You can define a variable-size matrix by using a constructor with nonconstant dimensions. For example:

```
function s = var_by_assign(u) %#codegen
y = ones(3,u);
s = numel(y);
```

If you are not using dynamic memory allocation, you must also add an `assert` statement to provide upper bounds for the dimensions. For example:

```
function s = var_by_assign(u) %#codegen
assert (u < 20);
y = ones(3,u);
s = numel(y);
```

Assign Multiple Sizes to the Same Variable

Before you use (read) a variable in your code, you can make it variable-size by assigning multiple, constant sizes to it. When the code generator uses static allocation on the stack, it infers the upper bounds from the largest size specified for each dimension. When you assign the same size to a given dimension across all assignments, the code generator assumes that the dimension is fixed at that size. The assignments can specify different shapes and sizes.

When the code generator uses dynamic memory allocation, it does not check for upper bounds. It assumes that the variable-size data is unbounded.

Inferring Upper Bounds from Multiple Definitions with Different Shapes

```
function s = var_by_multiassign(u) %#codegen
if (u > 0)
    y = ones(3,4,5);
else
    y = zeros(3,1);
end
s = numel(y);
```

When the code generator uses static allocation, it infers that `y` is a matrix with three dimensions:

- The first dimension is fixed at size 3
- The second dimension is variable-size with an upper bound of 4
- The third dimension is variable-size with an upper bound of 5

When the code generator uses dynamic allocation, it analyzes the dimensions of `y` differently:

- The first dimension is fixed at size 3.
- The second and third dimensions are unbounded.

Define Variable-Size Data Explicitly by Using coder.varsize

To explicitly define variable-size data, use the function `coder.varsize`. Optionally, you can also specify which dimensions vary along with their upper bounds. For example:

- Define `B` as a variable-size 2-dimensional array, where each dimension has an upper bound of 64.

  ```
  coder.varsize('B', [64 64]);
  ```

- Define `B` as a variable-size array:

  ```
  coder.varsize('B');
  ```

  When you supply only the first argument, `coder.varsize` assumes that all dimensions of `B` can vary and that the upper bound is `size(B)`.

If a MATLAB Function block input or output signal is variable-size, in the Ports and Data Manager, you must specify that the signal is variable-size. You must also provide the upper bounds. You do not have to use `coder.varsize` with the corresponding input or output variable inside the MATLAB Function block. However, if you specify upper bounds with `coder.varsize`, they must match the upper bounds in the Ports and Data Manager.

Specify Which Dimensions Vary

You can use the function `coder.varsize` to specify which dimensions vary. For example, the following statement defines `B` as an array whose first dimension is fixed at 2, but whose second dimension can grow to a size of 16:

```
coder.varsize('B',[2, 16],[0 1])
```

.

The third argument specifies which dimensions vary. This argument must be a logical vector or a double vector containing only zeros and ones. Dimensions that correspond to zeros or `false` have fixed size. Dimensions that correspond to ones or `true` vary in size. `coder.varsize` usually treats dimensions of size 1 as fixed. See “Define Variable-Size Matrices with Singleton Dimensions” on page 50-10.

For an input or output signal, if you specify the upper bounds with `coder.varsize` inside the MATLAB Function block, they must match the upper bounds in the Ports and Data Manager.

Allow a Variable to Grow After Defining Fixed Dimensions

Function `var_by_if` defines matrix `Y` with fixed 2-by-2 dimensions before the first use (where the statement `Y = Y + u` reads from `Y`). However, `coder.varsize` defines `Y` as

a variable-size matrix, allowing it to change size based on decision logic in the `else` clause:

```
function Y = var_by_if(u) %#codegen
if (u > 0)
    Y = zeros(2,2);
    coder.varsize('Y');
    if (u < 10)
        Y = Y + u;
    end
else
    Y = zeros(5,5);
end
```

Without `coder.varsize`, the code generator infers `Y` to be a fixed-size, 2-by-2 matrix. It generates a size mismatch error.

Define Variable-Size Matrices with Singleton Dimensions

A singleton dimension is a dimension for which `size(A,dim)` = 1. Singleton dimensions are fixed in size when:

- You specify a dimension with an upper bound of 1 in `coder.varsize` expressions.

  For example, in this function, `Y` behaves like a vector with one variable-size dimension:

  ```
  function Y = dim_singleton(u) %#codegen
  Y = [1 2];
  coder.varsize('Y', [1 10]);
  if (u > 0)
      Y = [Y 3];
  else
      Y = [Y u];
  end
  ```

- You initialize variable-size data with singleton dimensions by using matrix constructor expressions or matrix functions.

  For example, in this function, `X` and `Y` behave like vectors where only their second dimensions are variable-size.

  ```
  function [X,Y] = dim_singleton_vects(u) %#codegen
  Y = ones(1,3);
  ```

```
X = [1 4];
coder.varsize('Y','X');
if (u > 0)
    Y = [Y u];
else
    X = [X u];
end
```

You can override this behavior by using `coder.varsize` to specify explicitly that singleton dimensions vary. For example:

```
function Y = dim_singleton_vary(u) %#codegen
Y = [1 2];
coder.varsize('Y', [1 10], [1 1]);
if (u > 0)
    Y = [Y Y+u];
else
    Y = [Y Y*u];
end
```

In this example, the third argument of `coder.varsize` is a vector of ones, indicating that each dimension of `Y` varies in size.

Define Variable-Size Structure Fields

To define structure fields as variable-size arrays, use a colon (`:`) as the index expression. The colon (`:`) indicates that all elements of the array are variable-size. For example:

```
function y=struct_example() %#codegen

d = struct('values', zeros(1,0), 'color', 0);
data = repmat(d, [3 3]);
coder.varsize('data(:).values');

for i = 1:numel(data)
    data(i).color = rand-0.5;
    data(i).values = 1:i;
end

y = 0;
for i = 1:numel(data)
    if data(i).color > 0
        y = y + sum(data(i).values);
    end
end
```

The expression `coder.varsize('data(:).values')` defines the field `values` inside each element of matrix `data` to be variable-size.

Here are other examples:

- `coder.varsize('data.A(:).B')`

  In this example, `data` is a scalar variable that contains matrix `A`. Each element of matrix `A` contains a variable-size field `B`.

- `coder.varsize('data(:).A(:).B')`

  This expression defines field `B` inside each element of matrix `A` inside each element of matrix `data` to be variable-size.

Diagnose and Fix Variable-Size Data Errors

In this section...

Diagnosing and Fixing Size Mismatch Errors

Check your code for these issues:

Assigning Variable-Size Matrices to Fixed-Size Matrices

You cannot assign variable-size matrices to fixed-size matrices in generated code. Consider this example:

```
function Y = example_mismatch1(n) %#codegen
assert(n < 10);
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
    A = B;
end
Y = A;
```

Compiling this function produces this error:

```
??? Dimension 1 is fixed on the left-hand side
but varies on the right ...
```

There are several ways to fix this error:

- Allow matrix `A` to grow by adding the `coder.varsize` construct:

  ```
  function Y = example_mismatch1_fix1(n) %#codegen
  coder.varsize('A');
  assert(n < 10);
  B = ones(n,n);
  A = magic(3);
  A(1) = mean(A(:));
  if (n == 3)
      A = B;
  ```

```
end
Y = A;
```

- Explicitly restrict the size of matrix `B` to 3-by-3 by modifying the `assert` statement:

```
function Y = example_mismatch1_fix2(n) %#codegen
coder.varsize('A');
assert(n == 3)
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
    A = B;
end
Y = A;
```

- Use explicit indexing to make `B` the same size as `A`:

```
function Y = example_mismatch1_fix3(n) %#codegen
assert(n < 10);
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
    A = B(1:3, 1:3);
end
Y = A;
```

Empty Matrix Reshaped to Match Variable-Size Specification

If you assign an empty matrix `[]` to variable-size data, MATLAB might silently reshape the data in generated code to match a `coder.varsize` specification. For example:

```
function Y = test(u) %#codegen
Y = [];
coder.varsize('Y', [1 10]);
if u < 0
    Y = [Y u];
end
```

In this example, `coder.varsize` defines `Y` as a column vector of up to 10 elements, so its first dimension is fixed at size 1. The statement `Y = []` designates the first dimension of `Y` as 0, creating a mismatch. The right hand side of the assignment is an empty matrix and the left hand side is a variable-size vector. In this case, MATLAB reshapes the empty matrix `Y = []` in generated code to `Y = zeros(1,0)` so it matches the `coder.varsize` specification.

Performing Binary Operations on Fixed and Variable-Size Operands

You cannot perform binary operations on operands of different sizes. Operands have different sizes if one has fixed dimensions and the other has variable dimensions. For example:

```
function z = mismatch_operands(n) %#codegen
assert(n >= 3 && n < 10);
x = ones(n,n);
y = magic(3);
z = x + y;
```

When you compile this function, you get an error because `y` has fixed dimensions (3 x 3), but `x` has variable dimensions. Fix this problem by using explicit indexing to make `x` the same size as `y`:

```
function z = mismatch_operands_fix(n) %#codegen
assert(n >= 3 && n < 10);
x = ones(n,n);
y = magic(3);
z = x(1:3,1:3) + y;
```

Diagnosing and Fixing Errors in Detecting Upper Bounds

Check your code for these issues:

Using Nonconstant Dimensions in a Matrix Constructor

You can define variable-size data by assigning a variable to a matrix with nonconstant dimensions. For example:

```
function y = dims_vary(u) %#codegen
if (u > 0)
    y = ones(3,u);
else
    y = zeros(3,1);
end
```

However, compiling this function generates an error because you did not specify an upper bound for `u`.

To fix the problem, add an `assert` statement before the first use of `u`:

```
function y = dims_vary_fix(u) %#codegen
assert (u < 20);
if (u > 0)
    y = ones(3,u);
else
    y = zeros(3,1);
end
```

Incompatibilities with MATLAB in Variable-Size Support for Code Generation

In this section...

Incompatibility with MATLAB for Scalar Expansion

Scalar expansion is a method of converting scalar data to match the dimensions of vector or matrix data. If one operand is a scalar and the other is not, scalar expansion applies the scalar to every element of the other operand.

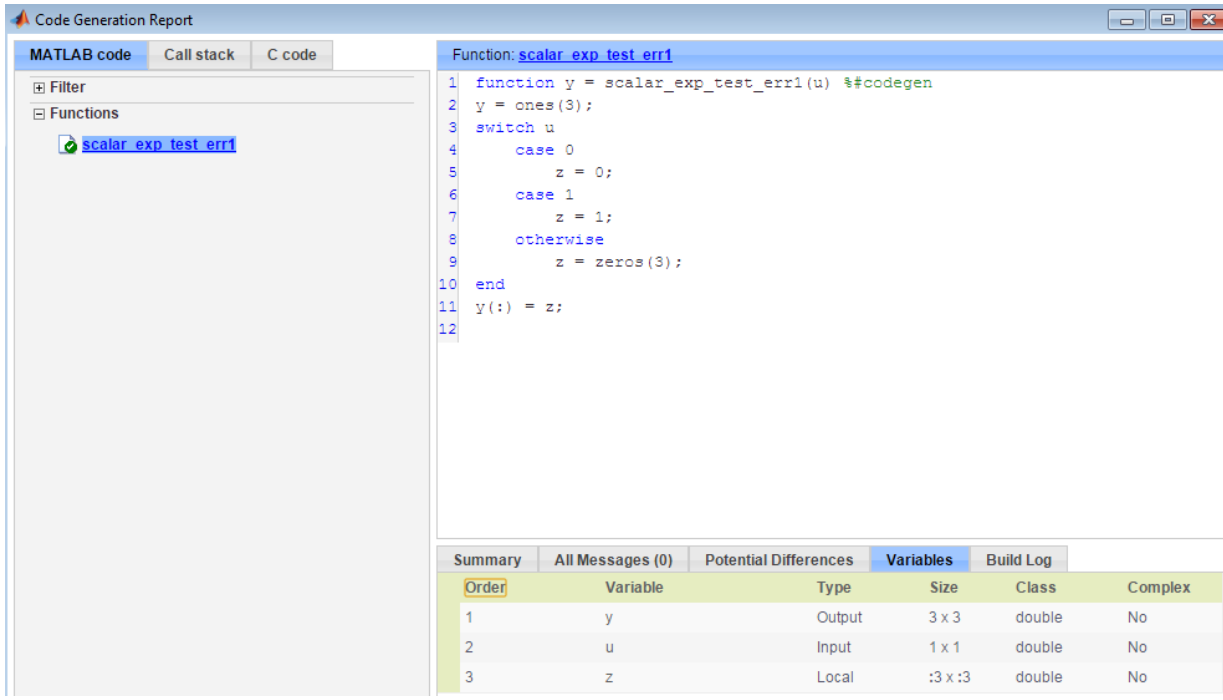
During code generation, scalar expansion rules apply except when operating on two variable-size expressions. In this case, both operands must be the same size. The generated code does not perform scalar expansion even if one of the variable-size expressions turns out to be scalar at run time. Therefore, when run-time error checks are enabled, a run-time error can occur.

Consider this function:

```
function y = scalar_exp_test_err1(u) %#codegen
y = ones(3);
switch u
    case 0
```

```
        z = 0;
    case 1
        z = 1;
    otherwise
        z = zeros(3);
end
y(:) = z;
```

When you generate code for this function, the code generator determines that `z` is variable size with an upper bound of `3`.



If you run the MEX function with `u` equal to 0 or 1, the generated code does not perform scalar expansion, even though `z` is scalar at run time. Therefore, when run-time error checks are enabled, a run-time error can occur.

```
scalar_exp_test_err1_mex(0)
Sizes mismatch: 9 ~= 1.

Error in scalar_exp_test_err1 (line 11)
y(:) = z;
```

To avoid this issue, use indexing to force `z` to be a scalar value.

```
function y = scalar_exp_test_err1(u) %#codegen
y = ones(3);
switch u
    case 0
        z = 0;
    case 1
        z = 1;
    otherwise
        z = zeros(3);
end
y(:) = z(1);
```

Incompatibility with MATLAB in Determining Size of Variable-Size N-D Arrays

For variable-size N-D arrays, the `size` function can return a different result in generated code than in MATLAB. In generated code, `size(A)` returns a fixed-length output because it does not drop trailing singleton dimensions of variable-size N-D arrays. By contrast, `size(A)` in MATLAB returns a variable-length output because it drops trailing singleton dimensions.

For example, if the shape of array `A` is `:?x:?x:?` and `size(A,3)==1`, `size(A)` returns:

- Three-element vector in generated code
- Two-element vector in MATLAB code

Workarounds

If your application requires generated code to return the same size of variable-size N-D arrays as MATLAB code, consider one of these workarounds:

- Use the two-argument form of `size`.

  For example, `size(A,n)` returns the same answer in generated code and MATLAB code.
- Rewrite `size(A)`:

  ```
  B = size(A);
  X = B(1:ndims(A));
  ```

This version returns `X` with a variable-length output. However, you cannot pass a variable-size `X` to matrix constructors such as `zeros` that require a fixed-size argument.

Incompatibility with MATLAB in Determining Size of Empty Arrays

The size of an empty array in generated code might be different from its size in MATLAB source code. The size might be `1x0` or `0x1` in generated code, but `0x0` in MATLAB. Therefore, you should not write code that relies on the specific size of empty matrices.

For example, consider the following code:

```
function y = foo(n) %#codegen
x = [];
i = 0;
while (i < 10)
    x = [5 x];
    i = i + 1;
end
if n > 0
    x = [];
end
y = size(x);
end
```

Concatenation requires its operands to match on the size of the dimension that is not being concatenated. In the preceding concatenation, the scalar value has size `1x1` and `x` has size `0x0`. To support this use case, the code generator determines the size for `x` as `[1 x :?]`. Because there is another assignment `x = []` after the concatenation, the size of `x` in the generated code is `1x0` instead of `0x0`.

For incompatibilities with MATLAB in determining the size of an empty array that results from deleting elements of an array, see “Size of Empty Array That Results from Deleting Elements of an Array” on page 45-10.

Workaround

If your application checks whether a matrix is empty, use one of these workarounds:

- Rewrite your code to use the `isempty` function instead of the `size` function.
- Instead of using `x=[]` to create empty arrays, create empty arrays of a specific size using `zeros`. For example:

```
function y = test_empty(n) %#codegen
x = zeros(1,0);
i=0;
while (i < 10)
    x = [5 x];
    i = i + 1;
end
if n > 0
    x = zeros(1,0);
end
y=size(x);
end
```

Incompatibility with MATLAB in Determining Class of Empty Arrays

The class of an empty array in generated code can be different from its class in MATLAB source code. Therefore, do not write code that relies on the class of empty matrices.

For example, consider the following code:

```
function y = fun(n)
x = [];
if n > 1
    x = ['a' x];
end
y=class(x);
end
```

`fun(0)` returns `double` in MATLAB, but `char` in the generated code. When the statement `n > 1` is false, MATLAB does not execute `x = ['a' x]`. The class of `x` is `double`, the class of the empty array. However, the code generator considers all execution paths. It determines that based on the statement `x = ['a' x]`, the class of `x` is `char`.

Workaround

Instead of using `x=[]` to create an empty array, create an empty array of a specific class. For example, use `blanks(0)` to create an empty array of characters.

```
function y = fun(n)
x = blanks(0);
if n > 1
    x = ['a' x];
```

```
end
y=class(x);
end
```

Incompatibility with MATLAB in Matrix-Matrix Indexing

In matrix-matrix indexing, you use one matrix to index into another matrix. In MATLAB, the general rule for matrix-matrix indexing is that the size and orientation of the result match the size and orientation of the index matrix. For example, if `A` and `B` are matrices, `size(A(B))` equals `size(B)`. When `A` and `B` are vectors, MATLAB applies a special rule. The special vector-vector indexing rule is that the orientation of the result is the orientation of the data matrix. For example, i`A` is 1-by-5 and `B` is 3-by-1, then `A(B)` is 1-by-3.

The code generator applies the same matrix-matrix indexing rules as MATLAB. If `A` and `B` are variable-size matrices, to apply the matrix-matrix indexing rules, the code generator assumes that the `size(A(B))` equals `size(B)`. If, at run time, `A` and `B` become vectors and have different orientations, then the assumption is incorrect. Therefore, when run-time error checks are enabled, an error can occur.

To avoid this issue, force your data to be a vector by using the colon operator for indexing. For example, suppose that your code intentionally toggles between vectors and regular matrices at run time. You can do an explicit check for vector-vector indexing.

```
...
if isvector(A) && isvector(B)
    C = A(:);
    D = C(B(:));
else
    D = A(B);
end
...
```

The indexing in the first branch specifies that `C` and `B(:)` are compile-time vectors. Therefore, the code generator applies the indexing rule for indexing one vector with another vector. The orientation of the result is the orientation of the data vector, `C`.

Incompatibility with MATLAB in Vector-Vector Indexing

In MATLAB, the special rule for vector-vector indexing is that the orientation of the result is the orientation of the data vector. For example, if `A` is 1-by-5 and `B` is 3-by-1,

then `A(B)` is 1-by-3. If, however, the data vector `A` is a scalar, then the orientation of `A(B)` is the orientation of the index vector `B`.

The code generator applies the same vector-vector indexing rules as MATLAB. If `A` and `B` are variable-size vectors, to apply the indexing rules, the code generator assumes that the orientation of `B` matches the orientation of `A`. At run time, if `A` is scalar and the orientation of `A` and `B` do not match, then the assumption is incorrect. Therefore, when run-time error checks are enabled, a run-time error can occur.

To avoid this issue, make the orientations of the vectors match. Alternatively, index single elements by specifying the row and column. For example, `A(row, column)`.

Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation

The following limitation applies to matrix indexing operations for code generation:

- Initialization of the following style:

  ```
  for i = 1:10
      M(i) = 5;
  end
  ```

  In this case, the size of `M` changes as the loop is executed. Code generation does not support increasing the size of an array over time.

  For code generation, preallocate `M`.

  ```
  M = zeros(1,10);
  for i = 1:10
      M(i) = 5;
  end
  ```

The following limitation applies to matrix indexing operations for code generation when dynamic memory allocation is disabled:

- `M(i:j)` where `i` and `j` change in a loop

  During code generation, memory is not dynamically allocated for the size of the expressions that change as the program executes. To implement this behavior, use `for`-loops as shown:

```
...
M = ones(10,10);
for i=1:10
    for j = i:10
        M(i,j) = 2*M(i,j);
    end
end
...
```

Note The matrix `M` must be defined before entering the loop.

Incompatibility with MATLAB in Concatenating Variable-Size Matrices

For code generation, when you concatenate variable-size arrays, the dimensions that are not being concatenated must match exactly.

Differences When Curly-Brace Indexing of Variable-Size Cell Array Inside Concatenation Returns No Elements

Suppose that:

- `c` is a variable-size cell array.
- You access the contents of `c` by using curly braces. For example, `c{2:4}`.
- You include the results in concatenation. For example, `[a c{2:4} b]`.
- `c{I}` returns no elements. Either `c` is empty or the indexing inside the curly braces produces an empty result.

For these conditions, MATLAB omits `c{I}` from the concatenation. For example, `[a c{I} b]` becomes `[a b]`. The code generator treats `c{I}` as the empty array `[c{I}]`. The concatenation becomes `[...[c{i}]...]`. This concatenation then omits the array `[c{I}]`. So that the properties of `[c{I}]` are compatible with the concatenation `[...[c{i}]...]`, the code generator assigns the class, size, and complexity of `[c{I}]` according to these rules:

- The class and complexity are the same as the base type of the cell array.
- The size of the second dimension is always 0.
- For the rest of the dimensions, the size of `Ni` depends on whether the corresponding dimension in the base type is fixed or variable size.

- If the corresponding dimension in the base type is variable size, the dimension has size 0 in the result.
- If the corresponding dimension in the base type is fixed size, the dimension has that size in the result.

Suppose that `c` has a base type with class `int8` and size `:10x7x8x:?`. In the generated code, the class of `[c{I}]` is `int8`. The size of `[c{I}]` is `0x0x8x0`. The second dimension is 0. The first and last dimensions are 0 because those dimensions are variable size in the base type. The third dimension is 8 because the size of the third dimension of the base type is a fixed size 8.

Inside concatenation, if curly-brace indexing of a variable-size cell array returns no elements, the generated code can have the following differences from MATLAB:

- The class of `[...c{i}...]` in the generated code can differ from the class in MATLAB.

  When `c{I}` returns no elements, MATLAB removes `c{I}` from the concatenation. Therefore, `c{I}` does not affect the class of the result. MATLAB determines the class of the result based on the classes of the remaining arrays, according to a precedence of classes. See "Valid Combinations of Unlike Classes" (MATLAB). In the generated code, the class of `[c{I}]` affects the class of the result of the overall concatenation `[...[c{I}]...]` because the code generator treats `c{I}` as `[c{I}]`. The previously described rules determine the class of `[c{I}]`.
- In the generated code, the size of `[c{I}]` can differ from the size in MATLAB.

  In MATLAB, the concatenation `[c{I}]` is a 0x0 double. In the generated code, the previously described rules determine the size of `[c{I}]`.

Variable-Sizing Restrictions for Code Generation of Toolbox Functions

In this section...

Common Restrictions

The following common restrictions apply to multiple toolbox functions, but only for code generation. To determine which of these restrictions apply to specific library functions, see the table in “Toolbox Functions with Restrictions for Variable-Size Data” on page 50-27.

Variable-length vector restriction

Inputs to the library function must be variable-length vectors or fixed-size vectors. A variable-length vector is a variable-size array that has the shape `1x:n` or `:nx1` (one dimension is variable sized and the other is fixed at size 1). Other shapes are not permitted, even if they are vectors at run time.

Automatic dimension restriction

This restriction applies to functions that take the working dimension (the dimension along which to operate) as input. In MATLAB and in code generation, if you do not supply the working dimension, the function selects it. In MATLAB, the function selects the first dimension whose size does not equal 1. For code generation, the function selects the first dimension that has a variable size or that has a fixed size that does not equal 1. If the working dimension has a variable size and it becomes 1 at run time, then the working dimension is different from the working dimension in MATLAB. Therefore, when run-time error checks are enabled, an error can occur.

For example, suppose that `X` is a variable-size matrix with dimensions `1x:3x:5`. In the generated code, `sum(X)` behaves like `sum(X,2)`. In MATLAB, `sum(X)` behaves like `sum(X,2)` unless `size(X,2)` is 1. In MATLAB, when `size(X,2)` is 1, `sum(X)` behaves like `sum(X,3)`.

To avoid this issue, specify the intended working dimension explicitly as a constant value. For example, `sum(X,2)`.

Array-to-vector restriction

The function issues an error when a variable-size array that is not a variable-length vector assumes the shape of a vector at run time. To avoid the issue, specify the input explicitly as a variable-length vector instead of a variable-size array.

Array-to-scalar restriction

The function issues an error if a variable-size array assumes a scalar value at run time. To avoid this issue, specify scalars as fixed size.

Toolbox Functions with Restrictions for Variable-Size Data

The following table list functions that have code generation restrictions for variable-size data. For additional restrictions for these functions, and restrictions for all functions and objects supported for code generation, see "Functions and Objects Supported for C/C++ Code Generation — Alphabetical List" (MATLAB Coder).

Function	Restrictions for Variable-Size Data
`all`	• See "Automatic dimension restriction" on page 50-26. • An error occurs if you pass the first argument a variable-size matrix that is 0-by-0 at run time.
`any`	• See "Automatic dimension restriction" on page 50-26. • An error occurs if you pass the first argument a variable-size matrix that is 0-by-0 at run time.
`cat`	• Dimension argument must be a constant. • An error occurs if variable-size inputs are empty at run time.
`conv`	• See "Variable-length vector restriction" on page 50-26. • Input vectors must have the same orientation, either both row vectors or both column vectors.
`cov`	• For `cov(X)`, see "Array-to-vector restriction" on page 50-27.
`cross`	• Variable-size array inputs that become vectors at run time must have the same orientation.

Function	Restrictions for Variable-Size Data
`deconv`	• For both arguments, see "Variable-length vector restriction" on page 50-26.
`detrend`	• For first argument for row vectors only, see "Array-to-vector restriction" on page 50-27 .
`diag`	• See "Array-to-vector restriction" on page 50-27 .
`diff`	• See "Automatic dimension restriction" on page 50-26. • Length of the working dimension must be greater than the difference order input when the input is variable sized. For example, if the input is a variable-size matrix that is 3-by-5 at run time, `diff(x,2,1)` works but `diff(x,5,1)` generates a run-time error.
`fft`	• See "Automatic dimension restriction" on page 50-26.
`filter`	• For first and second arguments, see "Variable-length vector restriction" on page 50-26. • See "Automatic dimension restriction" on page 50-26.
`hist`	• For second argument, see "Variable-length vector restriction" on page 50-26. • For second input argument, see "Array-to-scalar restriction" on page 50-27.
`histc`	• See "Automatic dimension restriction" on page 50-26.
`ifft`	• See "Automatic dimension restriction" on page 50-26.
`ind2sub`	• First input (the size vector input) must be fixed size.
`interp1`	• For the `xq` input, see "Array-to-vector restriction" on page 50-27. • If `v` becomes a row vector at run time, the array to vector restriction on page 50-27 applies. If `v` becomes a column vector at run time, this restriction does not apply.
`ipermute`	• Order input must be fixed size.
`issorted`	• For optional rows input, see "Variable-length vector restriction" on page 50-26.

Function	Restrictions for Variable-Size Data
`magic`	• Argument must be a constant. • Output can be fixed-size matrices only.
`max`	• See "Automatic dimension restriction" on page 50-26.
`mean`	• See "Automatic dimension restriction" on page 50-26. • An error occurs if you pass as the first argument a variable-size matrix that is 0-by-0 at run time.
`median`	• See "Automatic dimension restriction" on page 50-26. • An error occurs if you pass as the first argument a variable-size matrix that is 0-by-0 at run time.
`min`	• See "Automatic dimension restriction" on page 50-26.
`mode`	• See "Automatic dimension restriction" on page 50-26. • An error occurs if you pass as the first argument a variable-size matrix that is 0-by-0 at run time.
`mtimes`	Consider the multiplication `A*B`. If the code generator is aware that `A` is scalar and `B` is a matrix, the code generator produces code for scalar-matrix multiplication. However, if the code generator is aware that `A` and `B` are variable-size matrices, it produces code for a general matrix multiplication. At run time, if `A` turns out to be scalar, the generated code does not change its behavior. Therefore, when run-time error checks are enabled, a size mismatch error can occur.
`nchoosek`	• The second input, `k`, must be a fixed-size scalar. • The second input, `k`, must be a constant for static allocation.. • You cannot create a variable-size array by passing in a variable, `k`, .
`permute`	• Order input must be fixed-size.
`planerot`	• Input must be a fixed-size, two-element column vector. It cannot be a variable-size array that takes on the size 2-by-1 at run time.
`poly`	• See "Variable-length vector restriction" on page 50-26.

Function	Restrictions for Variable-Size Data
`polyfit`	• For first and second arguments, see "Variable-length vector restriction" on page 50-26.
`prod`	• See "Automatic dimension restriction" on page 50-26. • An error occurs if you pass as the first argument a variable-size matrix that is 0-by-0 at run time.
`rand`	• For an upper-bounded variable `N`, `rand(1,N)` produces a variable-length vector of `1x:M` where `M` is the upper bound on `N`. • For an upper-bounded variable `N`, `rand([1 N])` may produce a variable-length vector of `:1x:M` where `M` is the upper bound on `N`.
`randi`	• For an upper-bounded variable `N`, `randi(imax,1,N)` produces a variable-length vector of `1x:M` where `M` is the upper bound on `N`. • For an upper-bounded variable `N`, `randi(imax,[1 N])` may produce a variable-length vector of `:1x:M` where `M` is the upper bound on `N`.
`randn`	• For an upper-bounded variable `N`, `randn(1,N)` produces a variable-length vector of `1x:M` where `M` is the upper bound on `N`. • For an upper-bounded variable `N`, `randn([1 N])` may produce a variable-length vector of `:1x:M` where `M` is the upper bound on `N`.
`reshape`	• If the input is a variable-size array and the output array has at least one fixed-length dimension, do not specify the output dimension sizes in a size vector `sz`. Instead, specify the output dimension sizes as scalar values, `sz1,...,szN`. Specify fixed-size dimensions as constants. • When the input is a variable-size empty array, the maximum dimension size of the output array (also empty) cannot be larger than that of the input.
`roots`	• See "Variable-length vector restriction" on page 50-26.

Function	Restrictions for Variable-Size Data
`shiftdim`	• If you do not supply the second argument, the number of shifts is determined at compilation time by the upper bounds of the dimension sizes. Therefore, at run time the number of shifts is constant. • An error occurs if the dimension that is shifted to the first dimension has length 1 at run time. To avoid the error, supply the number of shifts as the second input argument (must be a constant). • First input argument must have the same number of dimensions when you supply a positive number of shifts.
`std`	• See "Automatic dimension restriction" on page 50-26. • An error occurs if you pass a variable-size matrix with 0-by-0 dimensions at run time.
`sub2ind`	• First input (the size vector input) must be fixed size.
`sum`	• See "Automatic dimension restriction" on page 50-26. • An error occurs if you pass as the first argument a variable-size matrix that is 0-by-0 at run time.
`trapz`	• See "Automatic dimension restriction" on page 50-26. • An error occurs if you pass as the first argument a variable-size matrix that is 0-by-0 at run time.
`typecast`	• See "Variable-length vector restriction" on page 50-26 on first argument.
`var`	• See "Automatic dimension restriction" on page 50-26. • An error occurs if you pass a variable-size matrix with 0-by-0 dimensions at run time.

Code Generation for MATLAB Structures

Structure Definition for Code Generation

To generate efficient standalone code for structures, you must define and use structures differently than you normally would when running your code in the MATLAB environment:

What's Different	More Information
Use a restricted set of operations.	"Structure Operations Allowed for Code Generation" on page 51-3
Observe restrictions on properties and values of scalar structures.	"Define Scalar Structures for Code Generation" on page 51-4
Make structures uniform in arrays.	"Define Arrays of Structures for Code Generation" on page 51-6
Reference structure fields individually during indexing.	"Index Substructures and Fields" on page 41-92
Avoid type mismatch when assigning values to structures and fields.	"Assign Values to Structures and Fields" on page 41-96

Structure Operations Allowed for Code Generation

To generate efficient standalone code for MATLAB structures, you are restricted to the following operations:

- Index structure fields using dot notation
- Define primary function inputs as structures
- Pass structures to local functions

Define Scalar Structures for Code Generation

In this section...

Restrictions When Defining Scalar Structures by Assignment

When you define a scalar structure by assigning a variable to a preexisting structure, you do not need to define the variable before the assignment. However, if you already defined that variable, it must have the same class, size, and complexity as the structure you assign to it. In the following example, `p` is defined as a structure that has the same properties as the predefined structure `S`:

```
...
S = struct('a',  0, 'b',  1, 'c',  2);
p = S;
...
```

Adding Fields in Consistent Order on Each Control Flow Path

When you create a structure, you must add fields in the same order on each control flow path. For example, the following code generates a compiler error because it adds the fields of structure `x` in a different order in each `if` statement clause:

```
function y = fcn(u) %#codegen
if u > 0
   x.a = 10;
   x.b = 20;
else
   x.b = 30;  % Generates an error (on variable x)
   x.a = 40;
end
y = x.a + x.b;
```

In this example, the assignment to `x.a` comes before `x.b` in the first `if` statement clause, but the assignments appear in reverse order in the `else` clause. Here is the corrected code:

```
function y = fcn(u) %#codegen
if u > 0
   x.a = 10;
   x.b = 20;
else
   x.a = 40;
   x.b = 30;
end
y = x.a + x.b;
```

Restriction on Adding New Fields After First Use

You cannot add fields to a structure after you perform the following operations on the structure:

- Reading from the structure
- Indexing into the structure array
- Passing the structure to a function

For example, consider this code:

```
...
x.c = 10; % Defines structure and creates field c
y = x; % Reads from structure
x.d = 20; % Generates an error
...
```

In this example, the attempt to add a new field `d` after reading from structure `x` generates an error.

This restriction extends across the structure hierarchy. For example, you cannot add a field to a structure after operating on one of its fields or nested structures, as in this example:

```
function y = fcn(u) %#codegen

x.c = 10;
y = x.c;
x.d = 20; % Generates an error
```

In this example, the attempt to add a new field `d` to structure `x` after reading from the structure's field `c` generates an error.

Define Arrays of Structures for Code Generation

In this section...

Ensuring Consistency of Fields

For code generation, when you create an array of MATLAB structures, corresponding fields in the array elements must have the same size, type, and complexity.

Once you have created the array of structures, you can make the structure fields variable-size using `coder.varsize`. For more information, see “Declare a Variable-Size Structure Field.” (MATLAB Coder).

Using repmat to Define an Array of Structures with Consistent Field Properties

You can create an array of structures from a scalar structure by using the MATLAB `repmat` function, which replicates and tiles an existing scalar structure:

1. Create a scalar structure, as described in “Define Scalar Structures for Code Generation” on page 51-4.
2. Call `repmat`, passing the scalar structure and the dimensions of the array.
3. Assign values to each structure using standard array indexing and structure dot notation.

For example, the following code creates `X`, a 1-by-3 array of scalar structures. Each element of the array is defined by the structure `s`, which has two fields, `a` and `b`:

```
...
s.a = 0;
s.b = 0;
X = repmat(s,1,3);
```

```
X(1).a = 1;
X(2).a = 2;
X(3).a = 3;
X(1).b = 4;
X(2).b = 5;
X(3).b = 6;
...
```

Defining an Array of Structures by Using struct

To create an array of structures using the `struct` function, specify the field value arguments as cell arrays. Each cell array element is the value of the field in the corresponding structure array element. For code generation, corresponding fields in the structures must have the same type. Therefore, the elements in a cell array of field values must have the same type.

For example, the following code creates a 1-by-3 structure array. For each structure in the array of structures, `a` has type `double` and `b` has type `char`.

```
s = struct('a', {1 2 3}, 'b', {'a' 'b' 'c'});
```

Defining an Array of Structures Using Concatenation

To create a small array of structures, you can use the concatenation operator, square brackets (`[ ]`), to join one or more structures into an array (see "Concatenating Matrices" (MATLAB)). For code generation, the structures that you concatenate must have the same size, class, and complexity.

For example, the following code uses concatenation and a local function to create the elements of a 1-by-3 structure array:

```
...
W = [ sab(1,2) sab(2,3) sab(4,5) ];

function s = sab(a,b)
  s.a = a;
  s.b = b;
...
```

Index Substructures and Fields

Use these guidelines when indexing substructures and fields for code generation:

Reference substructure field values individually using dot notation

For example, the following MATLAB code uses dot notation to index fields and substructures:

```
...
substruct1.a1 = 15.2;
substruct1.a2 = int8([1 2;3 4]);

mystruct = struct('ele1',20.5,'ele2',single(100),
                  'ele3',substruct1);

substruct2 = mystruct;
substruct2.ele3.a2 = 2*(substruct1.a2);
...
```

The generated code indexes elements of the structures in this example by resolving symbols as follows:

Dot Notation	Symbol Resolution
`substruct1.a1`	Field `a1` of local structure `substruct1`
`substruct2.ele3.a1`	Value of field `a1` of field `ele3`, a substructure of local structure `substruct2`
`substruct2.ele3.a2(1,1)`	Value in row 1, column 1 of field `a2` of field `ele3`, a substructure of local structure `substruct2`

Reference field values individually in structure arrays

To reference the value of a field in a structure array, you must index into the array to the structure of interest and then reference that structure's field individually using dot notation, as in this example:

```
...
y = X(1).a % Extracts the value of field a
           % of the first structure in array X
...
```

To reference all the values of a particular field for each structure in an array, use this notation in a `for` loop, as in this example:

```
...
s.a = 0;
s.b = 0;
X = repmat(s,1,5);
for i = 1:5
    X(i).a = i;
    X(i).b = i+1;
end
```

This example uses the `repmat` function to define an array of structures, each with two fields `a` and `b` as defined by `s`. See “Define Arrays of Structures for Code Generation” on page 51-6 for more information.

Do not reference fields dynamically

You cannot reference fields in a structure by using dynamic names, which express the field as a variable expression that MATLAB evaluates at run time (see “Generate Field Names from Variables” (MATLAB)).

Assign Values to Structures and Fields

When assigning values to a structure, substructure, or field for code generation, use these guidelines:

Field properties must be consistent across structure-to-structure assignments

If:	Then:
Assigning one structure to another structure.	Define each structure with the same number, type, and size of fields.
Assigning one structure to a substructure of a different structure and vice versa.	Define the structure with the same number, type, and size of fields as the substructure.
Assigning an element of one structure to an element of another structure.	The elements must have the same type and size.

For structures with constant fields, do not assign field values inside control flow constructs

In the following code, the code generator recognizes that the structure fields `s.a` and `s.b` are constants.

```
function y = mystruct()
s.a = 3;
s.b = 5;
y = zeros(s.a,s.b);
```

If a field of a structure is assigned inside a control flow construct, the code generator does not recognize that `s.a` and `s.b` are constant. Consider the following code:

```
function y = mystruct(x)
s.a = 3;
if x > 1
    s.b = 4;
else
    s.b = 5;
end
y = zeros(s.a,s.b);
```

If variable-sizing is enabled, `y` is treated as a variable-size array. If variable-sizing is disabled, `y`, the code generator reports an error.

Do not assign mxArrays to structures

You cannot assign `mxArrays` to structure elements; convert `mxArrays` to known types before code generation (see "Working with mxArrays" on page 56-15).

Do not assign cell arrays or classes to global variables that are structures

Global variables that are structures cannot contain cell arrays or classes.

Pass Large Structures as Input Parameters

If you generate a MEX function for a MATLAB function that takes a large structure as an input parameter, for example, a structure containing fields that are matrices, the MEX function might fail to load. This load failure occurs because, when you generate a MEX function from a MATLAB function that has input parameters, the code generator allocates memory for these input parameters on the stack. To avoid this issue, pass the structure by reference to the MATLAB function. For example, if the original function signature is:

```
y = foo(a, S)
```

where `S` is the structure input, rewrite the function to:

```
[y, S] = foo(a, S)
```

Code Generation for Cell Arrays

Code Generation for Cell Arrays

When you generate code from MATLAB code that contains cell arrays, the code generator classifies the cell arrays as homogeneous or heterogeneous. This classification determines how a cell array is represented in the generated code. It also determines how you can use the cell array in MATLAB code from which you generate code.

When you use cell arrays in MATLAB code that is intended for code generation, you must adhere to certain restrictions. See “Cell Array Limitations for Code Generation” on page 52-8.

Homogeneous vs. Heterogeneous Cell Arrays

A homogeneous cell array has these characteristics:

- The cell array is represented as an array in the generated code.
- All elements have the same properties. The type associated with the cell array specifies the properties of all elements rather than the properties of individual elements.
- The cell array can be variable-size.
- You can index into the cell array with an index whose value is determined at run time.

A heterogeneous cell array has these characteristics:

- The cell array is represented as a structure in the generated code. Each element is represented as a field of the structure.
- The elements can have different properties. The type associated with the cell array specifies the properties of each element individually.
- The cell array cannot be variable-size.
- You must index into the cell array with a constant index or with `for`-loops that have constant bounds.

The code generator uses heuristics to determine the classification of a cell array as homogeneous or heterogeneous. It considers the properties (class, size, complexity) of the elements and other factors, such as how you use the cell array in your program. Depending on how you use a cell array, the code generator can classify a cell array as homogeneous in one case and heterogeneous in another case. For example, consider the

cell array `{1 [2 3]}`. The code generator can classify this cell array as a heterogeneous 1-by-2 cell array. The first element is double scalar. The second element is a 1-by-2 array of doubles. However, if you index into this cell array with an index whose value is determined at run time, the code generator classifies it as a homogeneous cell array. The elements are variable-size arrays of doubles with an upper bound of 2.

Controlling Whether a Cell Array Is Homogeneous or Heterogeneous

For cell arrays with certain characteristics, you cannot control the classification as homogeneous or heterogeneous:

- If the elements have different classes, the cell array must be heterogeneous.
- If the cell array is variable-size, it must be homogeneous.
- If you index into the cell array with an index whose value is determined at run time, the cell array must be homogeneous.

For other cell arrays, you can control the classification as homogeneous or heterogeneous.

- If the cell array is fixed-size, you can force an otherwise homogeneous cell array to be heterogeneous by using `coder.cstructname`. For example:

  ```
  ...
  c = {1 2 3};
  coder.cstructname(c, 'myname');
  ...
  ```

- If the cell array elements have the same class, you can force a cell array to be homogeneous by using `coder.varsize`. See “Control Whether a Cell Array Is Variable-Size” on page 52-5.

Cell Arrays in Reports

To see whether a cell array is homogeneous or heterogeneous, view the variable in the MATLAB Function report.

For a homogeneous cell array, the report has one entry that specifies the properties of all elements. The notation `{:}` indicates that all elements of the cell array have the same properties.

Summary | All Messages (0) | Variables

Order	Variable	Type	Size	Class	Complex
1	z	Output	1 x 1	double	No
2	c	Local	1 x 2	cell	-
2.1	*c{:}*	Element	1 x 1	double	No

For a heterogeneous cell array, the report has an entry for each element. For example, for a heterogeneous cell array `c` with two elements, the entry for `c{1}` shows the properties for the first element. The entry for `c{2}` shows the properties for the second element.

Summary | All Messages (0) | Variables

Order	Variable	Type	Size	Class	Complex
1	z	Output	1 x 1	double	No
2	c	Local	1 x 2	cell	-
2.1	*c{1}*	Element	1 x 1	double	No
2.2	*c{2}*	Element	1 x 1	char	-

- “Control Whether a Cell Array Is Variable-Size” on page 52-5
- “Cell Array Limitations for Code Generation” on page 52-8
- “MATLAB Function Reports” on page 41-58

Control Whether a Cell Array Is Variable-Size

The code generator classifies a variable-size cell array as homogeneous. The cell array elements must have the same class. In the generated code, the cell array is represented as an array.

To make a cell array variable-size:

- Create the cell array by using the `cell` function. For example:

```
function z = mycell(n, j)
%#codegen
assert (n < 100);
x = cell(1,n);
for i = 1:n
    x{i} = i;
end
z = x{j};
end
```

  For code generation, when you create a variable-size cell array by using `cell`, you must adhere to certain restrictions. See "Definition of Variable-Size Cell Array by Using cell" on page 52-9.

- Grow the cell array. For example:

```
function z = mycell(n)
%#codegen
c = {1 2 3};
if n > 3
    c = {1 2 3 4};
end
z = c{n};
end
```

- Force the cell array to be variable-size by using `coder.varsize`. Consider this code:

```
function y =  mycellfun()
%#codegen
c = {1 2 3};
coder.varsize('c', [1 10]);
y = c{1};
end
```

Without `coder.varsize`, `c` is fixed-size with dimensions 1-by-3. With `coder.varsize`, `c` is variable-size with an upper bound of 10.

Sometimes, using `coder.varsize` changes the classification of a cell array from heterogeneous to homogeneous. Consider this code:

```
function y =  mycell()
%#codegen
c = {1 [2 3]};
y = c{2};
end
```

The code generator classifies `c` as heterogeneous because the elements have different sizes. `c` is fixed-size with dimensions 1-by-2. If you use `coder.varsize` with `c`, it becomes homogeneous. For example:

```
function y =  mycell()
%#codegen
c = {1 [2 3]};
coder.varsize('c', [1 10], [0 1]);
y = c{2};
end
```

`c` becomes a variable-size homogeneous cell array with dimensions 1-by-:10.

To force `c` to be homogeneous, but not variable-size, specify that none of the dimensions vary. For example:

```
function y =  mycell()
%#codegen
c = {1 [2 3]};
coder.varsize('c', [1 2], [0 0]);
y = c{2};
end
```

`coder.varsize`

More About

- “Code Generation for Cell Arrays” on page 52-2

- “Cell Array Limitations for Code Generation” on page 52-8
- “Code Generation for Variable-Size Arrays” on page 50-2

Cell Array Limitations for Code Generation

When you use cell arrays in MATLAB code that is intended for code generation, you must adhere to these restrictions:

Cell Array Element Assignment

You must assign a cell array element on all execution paths before you use it. For example:

```
function z = foo(n)
%#codegen
c = cell(1,3);
if n < 1
    c{2} = 1;

else
    c{2} = n;
end
z = c{2};
end
```

The code generator considers passing a cell array to a function or returning it from a function as a use of all elements of the cell array. Therefore, before you pass a cell array to a function or return it from a function, you must assign all of its elements. For example, the following code is not allowed because it does not assign a value to `c{2}` and `c` is a function output.

```
function c = foo()
%#codegen
```

```
c = cell(1,3);
c{1} = 1;
c{3} = 3;
end
```

The assignment of values to elements must be consistent on all execution paths. The following code is not allowed because `y{2}` is double on one execution path and char on the other execution path.

```
function y = foo(n)
y = cell(1,3)
if n > 1;
    y{1} = 1
    y{2} = 2;
    y{3} = 3;
else
    y{1} = 10;
    y{2} = 'a';
    y{3} = 30;
end
```

Definition of Variable-Size Cell Array by Using cell

For code generation, before you use a cell array element, you must assign a value to it. When you use `cell` to create a variable-size cell array, for example, `cell(1,n)`, MATLAB assigns an empty matrix to each element. However, for code generation, the elements are unassigned. For code generation, after you use `cell` to create a variable-size cell array, you must assign all elements of the cell array before any use of the cell array. For example:

```
function z = mycell(n, j)
%#codegen
assert(n < 100);
x = cell(1,n);
for i = 1:n
    x{i} = i;
end
z = x{j};
end
```

The code generator analyzes your code to determine whether all elements are assigned before the first use of the cell array. If the code generator detects that some elements are not assigned, code generation fails with a message like this message:

```
Unable to determine that every element of 'y' is assigned
before this line.
```

Sometimes, even though your code assigns all elements of the cell array, the code generator reports this message because the analysis does not detect that all elements are assigned. See “Unable to Determine That Every Element of Cell Array Is Assigned” on page 58-11.

To avoid this error, follow these guidelines:

- When you use `cell` to define a variable-size cell array, write code that follows this pattern:

  ```
  function z = mycell(n, j)
  %#codegen
  assert(n < 100);
  x = cell(1,n);
  for i = 1:n
      x{i} = i;
  end
  z = x{j};
  end
  ```

  Here is the pattern for a multidimensional cell array:

  ```
  function z = mycell(m,n,p)
  %#codegen
  assert(m < 100);
  assert(n < 100);
  assert(p < 100);
  x = cell(m,n,p);
  for i = 1:m
      for j =1:n
          for k = 1:p
              x{i,j,k} = i+j+k;
          end
      end
  end
  z = x{m,n,p};
  end
  ```

- Increment or decrement the loop counter by `1`.
- Define the cell array within one loop or one set of nested loops. For example, this code is not allowed:

```
function z = mycell(n, j)
assert(n < 50);
assert(j < 50);
x = cell(1,n);
for i = 1:5
    x{i} = 5;
end
for i = 6:n
    x{i} = 5;
end
z = x{j};
end
```

- Use the same variables for the cell dimensions and loop initial and end values. For example, code generation fails for the following code because the cell creation uses `n` and the loop end value uses `m`:

  ```
  function z = mycell(n, j)
  assert(n < 50);
  assert(j < 50);
  x = cell(1,n);
  m = n;
  for i = 1:m
      x{i} = 2;
  end
  z = x{j};
  end
  ```

  Rewrite the code to use `n` for the cell creation and the loop end value:

  ```
  function z = mycell(n, j)
  assert(n < 50);
  assert(j < 50);
  x = cell(1,n);
  for i = 1:n
      x{i} = 2;
  end
  z = x{j};
  end
  ```

- Create the cell array with this pattern:

  ```
  x = cell(1,n)
  ```

  Do not assign the cell array to a field of a structure or a property of an object. For example, this code is not allowed:

```
myobj.prop = cell(1,n)
for i = 1:n
...
end
```

Do not use the `cell` function inside the cell array constructor `{}`. For example, this code is not allowed:

```
x = {cell(1,n)};
```

- The cell array creation and the loop that assigns values to the cell array elements must be together in a unique execution path. For example, the following code is not allowed.

```
function z = mycell(n)
assert(n < 100);
if n > 3
    c = cell(1,n);
else
    c = cell(n,1);
end
for i = 1:n
    c{i} = i;
end
z = c{n};
end
```

To fix this code, move the assignment loop inside the code block that creates the cell array.

```
function z = cellerr(n)
assert(n < 100);
if n > 3
    c = cell( 1,n);
    for i = 1:n
        c{i} = i;
    end
else
    c = cell(n,1);
    for i = 1:n
        c{i} = i;
    end
end
z = c{n};
end
```

Cell Array Indexing

- You cannot index cell arrays by using smooth parentheses `()`. Consider indexing cell arrays by using curly braces `{}` to access the contents of the cell.
- You must index into heterogeneous cell arrays by using constant indices or by using `for`-loops with constant bounds.

  For example, the following code is not allowed.

  ```
  x = {1, 'mytext'};
  disp(x{randi});
  ```

  You can index into a heterogeneous cell array in a `for`-loop with constant bounds because the code generator unrolls the loop. Unrolling creates a separate copy of the loop body for each loop iteration, which makes the index in each loop iteration constant. However, if the `for`-loop has a large body or it has many iterations, the unrolling can increase compile time and generate inefficient code.

  If `A` and `B` are constant, the following code shows indexing into a heterogeneous cell array in a `for`-loop with constant bounds.

  ```
  x = {1, 'mytext'};
  for i = A:B
       disp(x{i});
  end
  ```

Growing a Cell Array by Using {end + 1}

To grow a cell array `X`, you can use `X{end + 1}`. For example:

```
...
X = {1 2};
X{end + 1} = 'a';
...
```

When you use `{end + 1}` to grow a cell array, follow these restrictions:

- In a MATLAB Function block, do not use `{end + 1}` in a `for`-loop.
- Use only `{end + 1}`. Do not use `{end + 2}`, `{end + 3}`, and so on.
- Use `{end + 1}` with vectors only. For example, the following code is not allowed because `X` is a matrix, not a vector:

```
...
X = {1 2; 3 4};
X{end + 1} = 5;

...
```

- Use `{end + 1}` only with a variable. In the following code, `{end + 1}` does not cause `{1 2 3}` to grow. In this case, the code generator treats `{end + 1}` as an out-of-bounds index into `X{2}`.

```
...
X = {'a' { 1 2 3 }};
X{2}{end + 1} = 4;
...
```

- When `{end + 1}` grows a cell array in a loop, the cell array must be variable-size. Therefore, the cell array must be homogeneous on page 52-2.

  This code is allowed because `X` is homogeneous.

```
...
X = {1  2};
for i=1:n
    X{end + 1} = 3;
end
...
```

  This code is not allowed because `X` is heterogeneous.

```
...
X = {1 'a' 2 'b'};
for i=1:n
    X{end + 1} = 3;
end
...
```

Variable-Size Cell Arrays

- Heterogeneous cell arrays cannot be variable-size.
- If you use `coder.varsize` to make a variable-size cell array, define the cell array with curly braces. For example:

```
...
c = {1 [2 3]};
```

```
coder.varsize('c')
...
```

Do not use the `cell` function. For example, this code is not allowed:

```
...
c = cell(1,3);
coder.varsize('c')
...
```

Cell Array Contents

Cell arrays cannot contain `mxarrays`. In a cell array, you cannot store a value that an extrinsic function returns.

Passing Cell Arrays to External C/C++ Functions

You cannot pass a cell array to `coder.ceval`. If a variable is an input argument to `coder.ceval`, define the variable as an array or structure instead of as a cell array.

Use in MATLAB Function Block

You cannot use cell arrays for Simulink signals, parameters, or data store memory.

Code Generation for MATLAB Classes

MATLAB Classes Definition for Code Generation

To generate efficient standalone code for MATLAB classes, you must use classes differently than when running your code in the MATLAB environment.

What's Different	More Information
Restricted set of language features.	"Language Limitations" on page 53-2
Restricted set of code generation features.	"Code Generation Features Not Compatible with Classes" on page 53-3
Definition of class properties.	"Defining Class Properties for Code Generation" on page 53-4
Use of handle classes.	"Generate Code for MATLAB Handle Classes and System Objects" on page 53-15 "Handle Object Limitations for Code Generation" on page 53-24
Calls to base class constructor.	"Calls to Base Class Constructor" on page 53-6
Global variables containing MATLAB objects are not supported for code generation.	N/A
Inheritance from built-in MATLAB classes is not supported.	"Inheritance from Built-In MATLAB Classes Not Supported" on page 53-8

Language Limitations

Although code generation support is provided for common features of classes such as properties and methods, there are a number of advanced features which are not supported, such as:

- Events
- Listeners
- Arrays of objects
- Recursive data structures
  - Linked lists

  - Trees
  - Graphs
- Overloadable operators `subsref`, `subsassign`, and `subsindex`

  In MATLAB, classes can define their own versions of the `subsref`, `subsassign`, and `subsindex` methods. Code generation does not support classes that have their own definitions of these methods.
- The `empty` method

  In MATLAB, classes have a built-in static method, `empty`, which creates an empty array of the class. Code generation does not support this method.
- The following MATLAB handle class methods:
  - `addlistener`
  - `delete`
  - `eq`
  - `findobj`
  - `findpro`
- The `AbortSet` property attribute

Code Generation Features Not Compatible with Classes

- You can generate code for entry-point MATLAB functions that use classes, but you cannot generate code directly for a MATLAB class.

  For example, if `ClassNameA` is a class definition, you cannot generate code by executing:

  ```
  codegen ClassNameA
  ```
- A handle class object cannot be an entry-point function input or output.
- A value class object can be an entry-point function input or output. However, if a value class object contains a handle class object, then the value class object cannot be an entry-point function input or output. A handle class object cannot be an entry-point function input or output.
- Code generation does not support global variables that are classes.
- You cannot use classes for Simulink signals, parameters, or data store memory.

- Code generation does not support assigning an object of a value class into a nontunable property. For example, `obj.prop=v;` is invalid when `prop` is a nontunable property and `v` is an object based on a value class.
- You cannot use `coder.extrinsic` to declare a class or method as extrinsic.
- You cannot pass a MATLAB class to `coder.ceval`. You can pass class properties to `coder.ceval`.
- If a property has a get method, a set method, or validators, or is a System object property with certain attributes, then you cannot pass the property by reference to an external function. See “Passing By Reference Not Supported for Some Properties” on page 53-23.
- If you use classes in code in the MATLAB Function block, you cannot use the debugger to view class information.
- The `coder.nullcopy` function does not support MATLAB classes as inputs.
- If an object has duplicate property names and the code generator tries to constant-fold the object, code generation can fail. The code generator constant-folds an object when it is used with `coder.const`, or when it is an input to or output from a constant-folded extrinsic function.

  Duplicate property names occur in an object of a subclass in these situations:

  - The subclass has a property with the same name as a property of the superclass.
  - The subclass derives from multiple superclasses that use the same name for a property.

  For information about when MATLAB allows duplicate property names, see “Subclassing Multiple Classes” (MATLAB).

Defining Class Properties for Code Generation

For code generation, you must define class properties differently than you do when running your code in the MATLAB environment:

- A property validation error ends a simulation with an error message. To test property validation, it is a best practice to run a simulation over the full range of input values. C/C++ code generated by Simulink Coderdoes not detect or report property validation errors.
- After defining a property, do not assign it an incompatible type. Do not use a property before attempting to grow it.

When you define class properties for code generation, consider the same factors that you take into account when defining variables. In the MATLAB language, variables can change their class, size, or complexity dynamically at run time so you can use the same variable to hold a value of varying class, size, or complexity. C and C++ use static typing. Before using variables, to determine their type, the code generator requires a complete assignment to each variable. Similarly, before using properties, you must explicitly define their class, size, and complexity.

- Initial values:
  - If the property does not have an explicit initial value, the code generator assumes that it is undefined at the beginning of the constructor. The code generator does not assign an empty matrix as the default.
  - If the property does not have an initial value and the code generator cannot determine that the property is assigned prior to first use, the software generates a compilation error.
  - For System objects, if a nontunable property is a structure, you must completely assign the structure. You cannot do partial assignment using subscripting.

    For example, for a nontunable property, you can use the following assignment:

    ```
    mySystemObject.nonTunableProperty=struct('fieldA','a','fieldB','b');
    ```

    You cannot use the following partial assignments:

    ```
    mySystemObject.nonTunableProperty.fieldA = 'a';
    mySystemObject.nonTunableProperty.fieldB = 'b';
    ```
  - `coder.varsize` is not supported for class properties.
  - If the initial value of a property is an object, then the property must be constant. To make a property constant, declare the `Constant` attribute in the property block. For example:

    ```
    classdef MyClass
        properties (Constant)
            p1 = MyClass2;
        end
    end
    ```
  - MATLAB computes class initial values at class loading time before code generation. If you use persistent variables in MATLAB class property initialization, the value of the persistent variable computed when the class loads belongs to MATLAB; it is not the value used at code generation time. If you use

`coder.target` in MATLAB class property initialization, `coder.target('MATLAB')` returns `true (1)`.

- If dynamic memory allocation is enabled, code generation supports variable-size properties for handle classes. Without dynamic memory allocation, you cannot generate code for handle classes that have variable-size properties.
- To avoid differences in results between MATLAB and simulation of a MATLAB Function block, for objects that are inputs to or outputs from extrinsic functions, do not use property access methods that modify property values or have other side effects. See "MATLAB Class Property Access Methods That Modify Property Values" on page 45-13.
- If a property is constant and its value is an object, you cannot change the value of a property of that object. For example, suppose that:
  - `obj` is an object of `myClass1`.
  - `myClass1` has a constant property `p1` that is an object of `myClass2`.
  - `myClass2` has a property `p2`.

  Code generation does not support the following code:

  ```
  obj.p1.p2 = 1;
  ```

Calls to Base Class Constructor

If a class constructor contains a call to the constructor of the base class, the call to the base class constructor must come before `for`, `if`, `return`, `switch` or `while` statements.

For example, if you define a class `B` based on class `A`:

```
classdef B < A
    methods
        function obj = B(varargin)
            if nargin == 0
                a = 1;
                b = 2;
            elseif nargin == 1
                a = varargin{1};
                b = 1;
            elseif nargin == 2
                a = varargin{1};
                b = varargin{2};
```

```
            end
            obj = obj@A(a,b);
        end

    end
end
```

Because the class definition for `B` uses an `if` statement before calling the base class constructor for `A`, you cannot generate code for function `callB`:

```
function [y1,y2] = callB
x = B;
y1 = x.p1;
y2 = x.p2;
end
```

However, you can generate code for `callB` if you define class `B` as:

```
classdef B < A
    methods
        function obj = NewB(varargin)
            [a,b] = getaandb(varargin{:});
            obj = obj@A(a,b);
        end

    end
end

function [a,b] = getaandb(varargin)
if nargin == 0
    a = 1;
    b = 2;
elseif nargin == 1
    a = varargin{1};
    b = 1;
elseif nargin == 2
    a = varargin{1};
    b = varargin{2};
end
end
```

Inheritance from Built-In MATLAB Classes Not Supported

You cannot generate code for classes that inherit from built-in MATLAB classes. For example, you cannot generate code for the following class:

```
classdef myclass < double
```

Classes That Support Code Generation

You can generate code for MATLAB value and handle classes and user-defined System objects. Your class can have multiple methods and properties and can inherit from multiple classes.

To generate code for:	Example:
Value classes	"Generate Code for MATLAB Value Classes" on page 53-10
Handle classes including user-defined System objects	"Generate Code for MATLAB Handle Classes and System Objects" on page 53-15

For more information, see:

- "Role of Classes in MATLAB" (MATLAB)
- "MATLAB Classes Definition for Code Generation" on page 53-2

Generate Code for MATLAB Value Classes

This example shows how to generate code for a MATLAB value class and then view the generated code in the code generation report.

1 In a writable folder, create a MATLAB value class, `Shape`. Save the code as `Shape.m`.

```
classdef Shape
% SHAPE Create a shape at coordinates
% centerX and centerY
    properties
        centerX;
        centerY;
    end
    properties (Dependent = true)
        area;
    end
    methods
        function out = get.area(obj)
            out =  obj.getarea();
        end
        function obj = Shape(centerX,centerY)
            obj.centerX = centerX;
            obj.centerY = centerY;
        end
    end
    methods(Abstract = true)
        getarea(obj);
    end
    methods(Static)
        function d = distanceBetweenShapes(shape1,shape2)
            xDist = abs(shape1.centerX - shape2.centerX);
            yDist = abs(shape1.centerY - shape2.centerY);
            d = sqrt(xDist^2 + yDist^2);
        end
    end
end
```

2 In the same folder, create a class, `Square`, that is a subclass of `Shape`. Save the code as `Square.m`.

```
classdef Square < Shape
% Create a Square at coordinates center X and center Y
```

```
% with sides of length of side
    properties
        side;
    end
    methods
        function obj = Square(side,centerX,centerY)
            obj@Shape(centerX,centerY);
            obj.side = side;
        end
        function Area = getarea(obj)
            Area = obj.side^2;
        end
    end
end
```

3 In the same folder, create a class, `Rhombus`, that is a subclass of `Shape`. Save the code as `Rhombus.m`.

```
classdef Rhombus < Shape
    properties
        diag1;
        diag2;
    end
    methods
        function obj = Rhombus(diag1,diag2,centerX,centerY)
            obj@Shape(centerX,centerY);
            obj.diag1 = diag1;
            obj.diag2 = diag2;
        end
        function Area = getarea(obj)
            Area = 0.5*obj.diag1*obj.diag2;
        end
    end
end
```

4 Write a function that uses this class.

```
function [TotalArea, Distance] =   use_shape
%#codegen
s = Square(2,1,2);
r = Rhombus(3,4,7,10);
TotalArea  = s.area + r.area;
Distance = Shape.distanceBetweenShapes(s,r);
```

5 Generate a static library for `use_shape` and generate a code generation report.

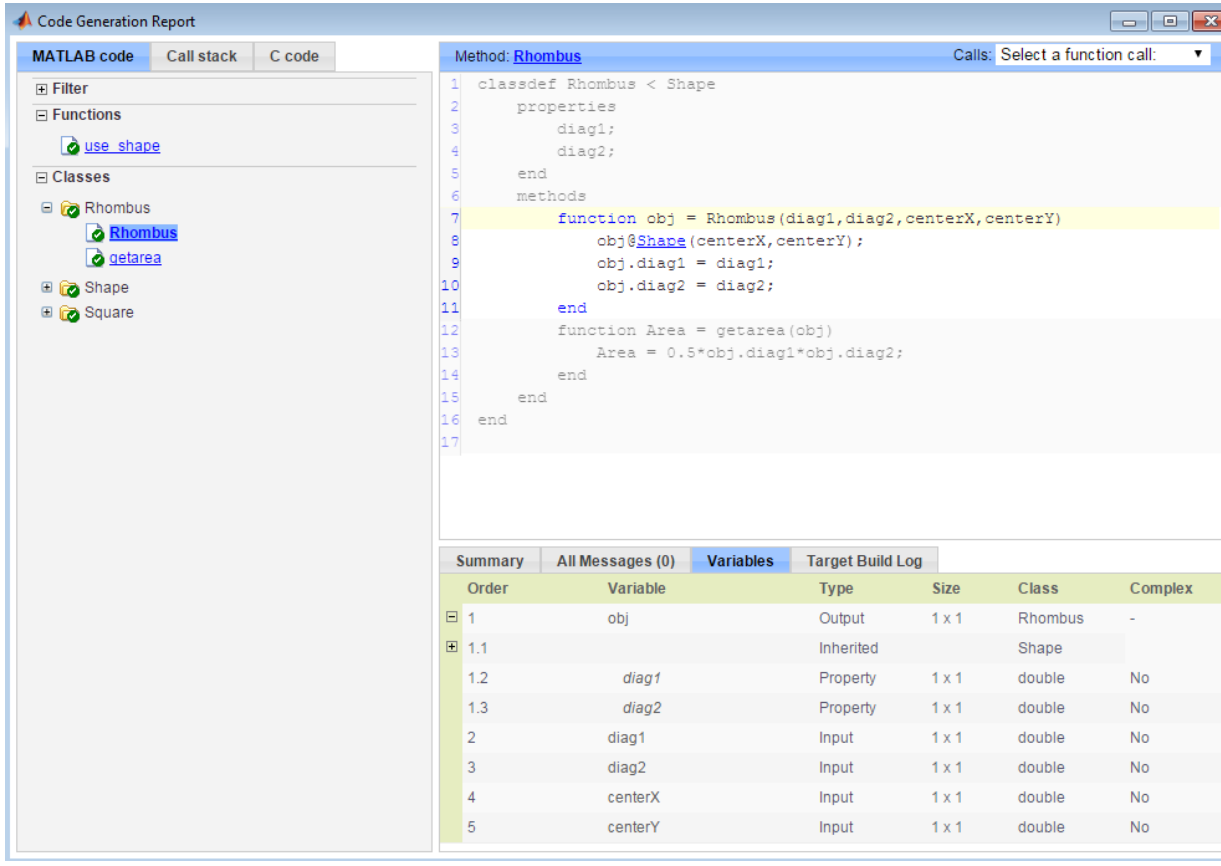
```
codegen -config:lib -report use_shape
```

`codegen` generates a C static library with the default name, `use_shape`, and supporting files in the default folder, `codegen/lib/use_shape`.

6 Click the **View report** link.

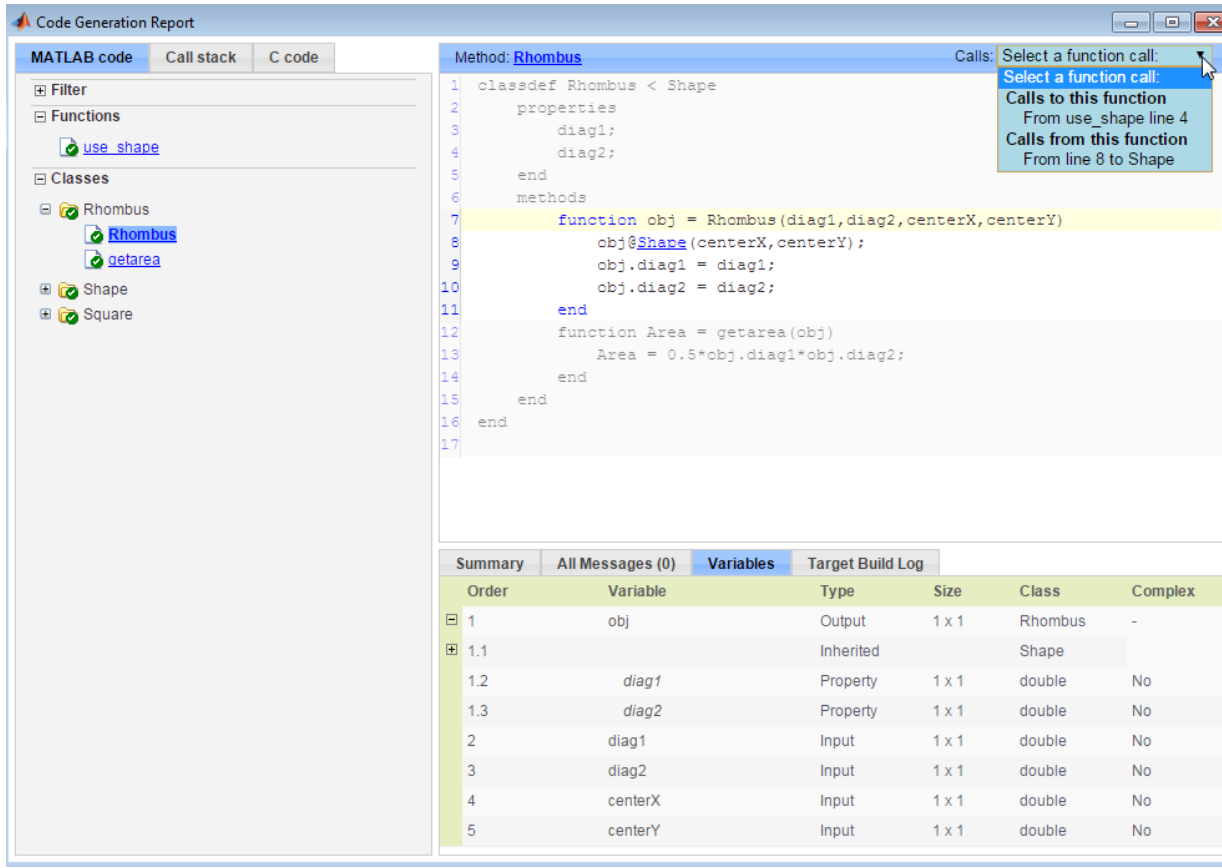
7 In the report, on the **MATLAB code** tab, click the link to the `Rhombus` class.

The report displays the class definition of the `Rhombus` class and highlights the class constructor. On the **Variables** tab, it provides details of the variables used in the class. If a variable is a MATLAB object, by default, the report displays the object without displaying its properties. To view the list of properties, expand the list. Within the list of properties, the list of inherited properties is collapsed. In the following report, the lists of properties and inherited properties are expanded.



8 At the top right side of the report, expand the **Calls** list.

The **Calls** list shows that there is a call to the `Rhombus` constructor from `use_shape` and that this constructor calls the `Shape` constructor.



9 The constructor for the `Rhombus` class calls the `Shape` method of the base `Shape` class: `obj@Shape`. In the report, click the `Shape` link in this call.

The link takes you to the `Shape` method in the `Shape` class definition.

Generate Code for MATLAB Handle Classes and System Objects

This example shows how to generate code for a user-defined System object and then view the generated code in the code generation report.

1. In a writable folder, create a System object, `AddOne`, which subclasses from `matlab.System`. Save the code as `AddOne.m`.

```
classdef AddOne < matlab.System
% ADDONE Compute an output value that increments the input by one

  methods (Access=protected)
    % stepImpl method is called by the step method
    function y = stepImpl(~,x)
      y = x+1;
    end
  end
end
```

2. Write a function that uses this System object.

```
function y = testAddOne(x)
%#codegen
  p = AddOne();
  y = p.step(x);
end
```

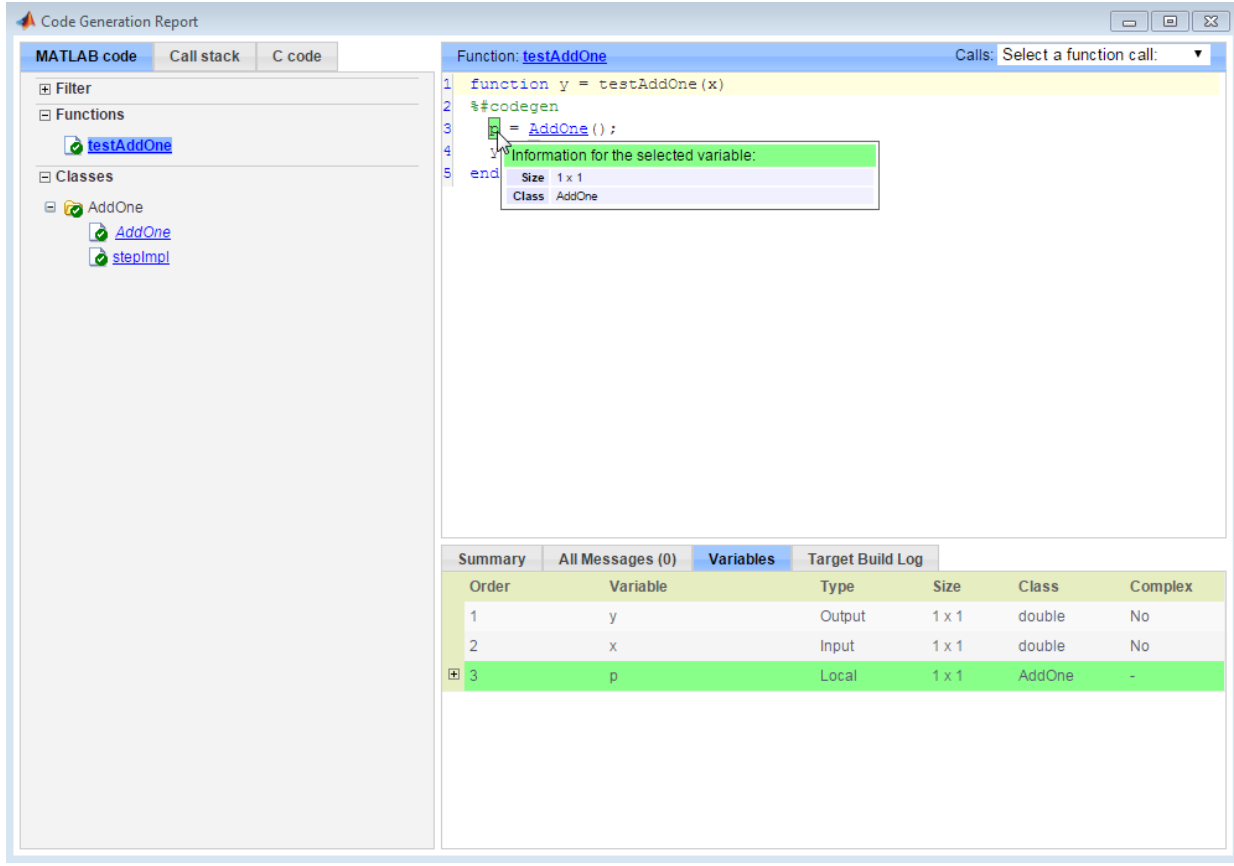
3. Generate a MEX function for this code.

```
codegen -report testAddOne -args {0}
```

   The `-report` option instructs `codegen` to generate a code generation report, even if no errors or warnings occur. The `-args` option specifies that the `testAddOne` function takes one scalar double input.

4. Click the **View report** link.

5. In the report, on the **MATLAB Code** tab **Functions** panel, click `testAddOne`, then click the **Variables** tab. You can view information about the variable `p` on this tab.



6 To view the class definition, on the **Classes** panel, click `AddOne`.

MATLAB Classes in Code Generation Reports

What Reports Tell You About Classes

Code generation reports:

- Provide a hierarchical tree of the classes used in your MATLAB code.
- Display a list of methods for each class in the MATLAB code tab.
- Display the objects used in your MATLAB code together with their properties on the **Variables** tab.
- Provide a filter so that you can sort methods by class, size, and complexity.
- List the set of calls from and to the selected method in the **Calls** list.

How Classes Appear in Code Generation Reports

In the MATLAB Code Tab

The report displays an alphabetical hierarchical list of the classes used in the your MATLAB code. For each class, you can:

- Expand the class information to view the class methods.
- View a class method by clicking its name. The report displays the methods in the context of the full class definition.
- Filter the methods by size, complexity, and class by using the **Filter functions and methods** option.

Default Constructors

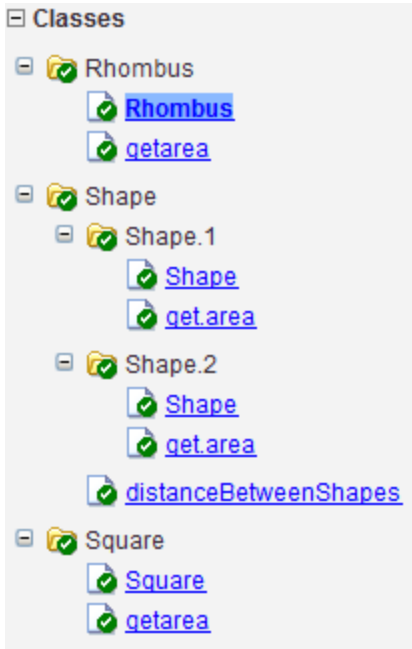
If a class has a default constructor, the report displays the constructor in italics.

Specializations

If the same class is specialized into multiple different classes, the report differentiates the specializations by grouping each one under a single node in the tree. The report associates the class definition functions and static methods with the primary node. It associates the instance-specific methods with the corresponding specialized node.

For example, consider a base class, `Shape` that has two specialized subclasses, `Rhombus` and `Square`. The `Shape` class has an abstract method, `getarea`, and a static method,

`distanceBetweenShapes`. The code generation report, displays a node for the specialized `Rhombus` and `Square` classes with their constructors and `getarea` method. It displays a node for the Shape class and its associated static method, `distanceBetweenShapes`, and two instances of the `Shape` class, `Shape1` and `Shape2`.



Packages

If you define classes as part of a package, the report displays the package in the list of classes. You can expand the package to view the classes that it contains. For more information about packages, see "Packages Create Namespaces" (MATLAB).

In the Variables Tab

The report displays the objects in the selected function or class. By default, for classes that have properties, the list of properties is collapsed. To expand the list, click the + symbol next to the object name. Within the list of properties, the list of inherited properties is collapsed. To expand the list of inherited properties, click the + symbol next to `Inherited`.

The report displays the properties using just the base property name, not the fully qualified name. For example, if your code uses variable `obj1` that is a MATLAB object

with property `prop1`, then the report displays the property as `prop1` not `obj1.prop1`. When you sort the **Variables** column, the sort order is based on the fully qualified property name.

In the Call Stack

The call stack lists the functions and methods in the order that the top-level function calls them. It also lists the local functions that each function calls.

Class Does Not Have Property

If a MATLAB class has a method, `mymethod`, that returns a handle class with a property, `myprop`, you cannot generate code for the following type of assignment:

```
obj.mymethod().myprop=...
```

For example, consider the following classes:

```
classdef MyClass < handle
  properties
    myprop
  end
  methods
    function this = MyClass
      this.myprop = MyClass2;
    end
    function y = mymethod(this)
      y = this.myprop;
    end
  end
end

classdef MyClass2 < handle
  properties
    aa
  end
end
```

You cannot generate code for function `foo`.

```
function foo

h = MyClass;

h.mymethod().aa = 12;
```

In this function, `h.mymethod()` returns a handle object of type `MyClass2`. In MATLAB, the assignment `h.mymethod().aa = 12;` changes the property of that object. Code generation does not support this assignment.

Solution

Rewrite the code to return the object and then assign a value to a property of the object.

```
function foo

h = MyClass;

b=h.mymethod();
b.aa=12;
```

Passing By Reference Not Supported for Some Properties

The code generator does not support passing a property by reference to an external function for these types of properties:

- A property with a get method or a set method.
- A property that uses validation functions.
- A System object property with an attribute, such as `Logical` or `PositiveInteger`, that constrains or modifies the property value.

Instead of passing a property by reference, save the property value in a temporary variable. Then, pass the temporary variable by reference to the external function. After the external function call, assign the temporary variable to the property. For example:

```
tmp = myObj.prop;
coder.ceval('myFcn', coder.ref(tmp));
myObj.prop = tmp;
```

The assignment after the `coder.ceval` call validates or modifies the property value according to the property access methods, validation functions, or attributes.

- “MATLAB Classes Definition for Code Generation” on page 53-2

Handle Object Limitations for Code Generation

The code generator statically determines the lifetime of a handle object. When you use handle objects, this static analysis has certain restrictions.

With static analysis the generated code can reuse memory rather than rely on a dynamic memory management scheme, such as reference counting or garbage collection. The code generator can avoid dynamic memory allocation and run-time automatic memory management. These generated code characteristics are important for some safety-critical and real-time applications.

For limitations, see:

- “A Variable Outside a Loop Cannot Refer to a Handle Object Created Inside a Loop” on page 53-24
- “A Handle Object That a Persistent Variable Refers To Must Be a Singleton Object” on page 53-25

The code generator analyzes whether all variables are defined prior to use. Undefined variables or data types cause an error during code generation. In certain circumstances, the code generator cannot determine if references to handle objects are defined. See “References to Handle Objects Can Appear Undefined” on page 53-26.

A Variable Outside a Loop Cannot Refer to a Handle Object Created Inside a Loop

Consider the handle class `mycls` and the function `usehandle1`. The code generator reports an error because `p`, which is outside the loop, has a property that refers to a `mycls` object created inside the loop.

```
classdef mycls < handle
   properties
       prop
   end
end

function usehandle1
p = mycls;
for i = 1:10
    p.prop = mycls;
end
```

A Handle Object That a Persistent Variable Refers To Must Be a Singleton Object

If a persistent variable refers to a handle object, the code generator allows only one instance of the object during the program's lifetime. The object must be a singleton object. To create a singleton handle object, enclose statements that create the object in the `if isempty()` guard for the persistent variable.

For example, consider the class `mycls` and the function `usehandle2`. The code generator reports an error for `usehandle2` because `p.prop` refers to the `mycls` object that the statement `inner = mycls` creates. This statement creates a `mycls` object for each invocation of `usehandle2`.

```
classdef mycls < handle
   properties
       prop
   end
end

function usehandle2(x)
assert(isa(x, 'double'));
persistent p;
inner = mycls;
inner.prop = x;
if isempty(p)
    p = mycls;
    p.prop = inner;
end
```

If you move the statements `inner = mycls` and `inner.prop = x` inside the `if isempty()` guard, code generation succeeds. The statement `inner = mycls` executes only once during the program's lifetime.

```
function usehandle2(x)
assert(isa(x, 'double'));
persistent p;
if isempty(p)
    inner = mycls;
    inner.prop = x;
    p = mycls;
    p.prop = inner;
end
```

Consider the function `usehandle3`. The code generator reports an error for `usehandle3` because the persistent variable `p` refers to the `mycls` object that the statement `myobj = mycls` creates. This statement creates a `mycls` object for each invocation of `usehandle3`.

```
function usehandle3(x)
assert(isa(x, 'double'));
myobj = mycls;
myobj.prop = x;
doinit(myobj);
disp(myobj.prop);
function doinit(obj)
persistent p;
if isempty(p)
    p = obj;
end
```

If you make `myobj` persistent and enclose the statement `myobj = mycls` inside an `if isempty()` guard, code generation succeeds. The statement `myobj = mycls` executes only once during the program's lifetime.

```
function usehandle3(x)
assert(isa(x, 'double'));
persistent myobj;
if isempty(myobj)
  myobj = mycls;
end

doinit(myobj);

function doinit(obj)
persistent p;
if isempty(p)
    p = obj;
end
```

References to Handle Objects Can Appear Undefined

Consider the function `refHandle` that copies a handle object property to another object. The function uses a simple handle class and value class. In MATLAB, the function runs without error.

```
function [out1, out2, out3] = refHandle()
  x = myHandleClass;
  y = x;
  v = myValueClass();
  v.prop = x;
  x.prop = 42;
  out1 = x.prop;
  out2 = y.prop;
  out3 = v.prop.prop;
end

classdef myHandleClass < handle
    properties
        prop
    end
end

classdef myValueClass
    properties
        prop
    end
end
```

During code generation, an error occurs:

```
Property 'v.prop.prop' is undefined on some execution paths.
```

Three variables reference the same memory location: `x`, `y`, and `v.prop`. The code generator determines that `x.prop` and `y.prop` share the same value. The code generator cannot determine that the handle object property `v.prop.prop` shares its definition with `x.prop` and `y.prop`. To avoid the error, define `v.prop.prop` directly.

System Objects in MATLAB Code Generation

In this section...

You can generate C/C++ code in MATLAB from your system that contains System objects by using MATLAB Coder. You can generate efficient and compact code for deployment in desktop and embedded systems and accelerate fixed-point algorithms.

Usage Rules and Limitations for System Objects for Generating Code

The following usage rules and limitations apply to using System objects in code generated from MATLAB.

Object Construction and Initialization

- If objects are stored in persistent variables, initialize System objects once by embedding the object handles in an `if` statement with a call to `isempty()`.
- Set arguments to System object constructors as compile-time constants.
- You cannot initialize System objects properties with other MATLAB class objects as default values in code generation. You must initialize these properties in the constructor.

Inputs and Outputs

- System objects accept a maximum of 1024 inputs. A maximum of eight dimensions per input is supported.
- The data type of the inputs should not change.
- If you want the size of inputs to change, verify that support for variable-size is enabled. Code generation support for variable-size data also requires that variable-size support is enabled. By default in MATLAB, support for variable-size data is enabled.

- System objects predefined in the software do not support variable-size if their data exceeds the `DynamicMemoryAllocationThreshold` value.
- Do not set System objects to become outputs from the MATLAB Function block.
- Do not use the Save and Restore Simulation State as SimState option for any System object in a MATLAB Function block.
- Do not pass a System object as an example input argument to a function being compiled with `codegen`.
- Do not pass a System object to functions declared as extrinsic (functions called in interpreted mode) using the `coder.extrinsic` function. System objects returned from extrinsic functions and scope System objects that automatically become extrinsic can be used as inputs to another extrinsic function. But, these functions do not generate code.

Properties

- In MATLAB System blocks, you cannot use variable-size for discrete state properties of System objects. Private properties can be variable-size.
- Objects cannot be used as default values for properties.
- You can only assign values to nontunable properties once, including the assignment in the constructor.
- Nontunable property values must be constant.
- If a tunable property has dependent data type properties, you can set tunable properties only at construction time or after the object is locked.
- For `getNumInputsImpl` and `getNumOutputsImpl` methods, if you set the return argument from an object property, that object property must have the `Nontunable` attribute.

Global Variables

- Global variables are allowed in a System object, unless you are using that System object in Simulink via the MATLAB System block. To avoid syncing global variables between a MEX file and the workspace, use a coder configuration object. For example:

  ```
  f = coder.MEXConfig;
  f.GlobalSyncMethod = 'NoSync'
  ```

  Then, include `'-config f'` in your `codegen` command.

Methods

- Code generation support is available only for these System object methods:
  - `get`
  - `getNumInputs`
  - `getNumOutputs`
  - `isDone` (for sources only)
  - `isLocked`
  - `release`
  - `reset`
  - `set` (for tunable properties)
  - `step`
- For System objects that you define, code generation support is available only for these methods:
  - `getDiscreteStateImpl`
  - `getNumInputsImpl`
  - `getNumOutputsImpl`
  - `infoImpl`
  - `isDoneImpl`
  - `isInputDirectFeedthroughImpl`
  - `outputImpl`
  - `processTunedPropertiesImpl`
  - `releaseImpl` — Code is not generated automatically for this method. To release an object, you must explicitly call the `release` method in your code.
  - `resetImpl`
  - `setupImpl`
  - `stepImpl`
  - `updateImpl`
  - `validateInputsImpl`
  - `validatePropertiesImpl`

System Objects in codegen

You can include System objects in MATLAB code in the same way you include any other elements. You can then compile a MEX file from your MATLAB code by using the `codegen` command, which is available if you have a MATLAB Coder license. This compilation process, which involves a number of optimizations, is useful for accelerating simulations. See "Getting Started with MATLAB Coder" (MATLAB Coder) and "MATLAB Classes" (MATLAB Coder) for more information.

Note Most, but not all, System objects support code generation. Refer to the particular object's reference page for information.

System Objects in the MATLAB Function Block

Using the MATLAB Function block, you can include any System object and any MATLAB language function in a Simulink model. This model can then generate embeddable code. System objects provide higher-level algorithms for code generation than do most associated blocks. For more information, see "What Is a MATLAB Function Block?" on page 41-6.

System Objects in the MATLAB System Block

Using the MATLAB System block, you can include in a Simulink model individual System objects that you create with a class definition file. The model can then generate embeddable code. For more information, see "MATLAB System Block" on page 43-2.

System Objects and MATLAB Compiler Software

MATLAB Compiler software supports System objects for use inside MATLAB functions. The compiler product does not support System objects for use in MATLAB scripts.

Code Generation for Function Handles

Function Handle Limitations for Code Generation

When you use function handles in MATLAB code intended for code generation, adhere to the following restrictions:

Do not use the same bound variable to reference different function handles

In some cases, using the same bound variable to reference different function handles causes a compile-time error. For example, this code does not compile:

```
function y = foo(p)
x = @plus;
if p
  x = @minus;
end
y = x(1, 2);
```

Do not pass function handles to or from `coder.ceval`

You cannot pass function handles as inputs to or outputs from `coder.ceval`. For example, suppose that `f` and `str.f` are function handles:

```
f = @sin;
str.x = pi;
str.f = f;
```

The following statements result in compilation errors:

```
coder.ceval('foo', @sin);
coder.ceval('foo', f);
coder.ceval('foo', str);
```

Do not associate a function handle with an extrinsic function

You cannot create a function handle that references an extrinsic MATLAB function.

Do not pass function handles to or from extrinsic functions

You cannot pass function handles to or from `feval` and other extrinsic MATLAB functions.

Do not pass function handles to or from entry-point functions

You cannot pass function handles as inputs to or outputs from entry-point functions. For example, consider this function:

```
function x = plotFcn(fhandle, data)

assert(isa(fhandle,'function_handle') && isa(data,'double'));

plot(data, fhandle(data));
x = fhandle(data);
```

In this example, the function `plotFcn` receives a function handle and its data as inputs. `plotFcn` attempts to call the function referenced by the `fhandle` with the input `data` and plot the results. However, this code generates a compilation error. The error indicates that the function `isa` does not recognize `'function_handle'` as a class name when called inside a MATLAB function to specify properties of inputs.

Do not try to view function handles from the debugger

You cannot display or watch function handles from the debugger. The function handles appear as empty matrices.

Do not use function handles for Simulink signals, parameters, or data store memory

You can use function handles in a MATLAB Function block. You cannot use function handles for Simulink signals, parameters, or data store memory.

Defining Functions for Code Generation

Code Generation for Variable Length Argument Lists

When you use `varargin` and `varargout` for code generation, there are these restrictions:

- You cannot use `varargin` or `varargout` in the function definition for a top-level function in a MATLAB Function block or in a Stateflow chart that uses MATLAB as the action language.
- You cannot write to `varargin`. If you want to write to input arguments, copy the values into a local variable.
- To index into `varargin` and `varargout`, use curly braces `{}`, not parentheses `()`.
- The code generator must be able to determine the value of the index into `varargin` or `varargout`.

See Also

More About

- “Nonconstant Index into varargin or varargout in a for-Loop” on page 58-16

Code Generation for Anonymous Functions

You can use anonymous functions in MATLAB code intended for code generation. For example, you can generate code for the following MATLAB code that defines an anonymous function that finds the square of a number.

```
sqr = @(x) x.^2;
a = sqr(5);
```

Anonymous functions are useful for creating a function handle to pass to a MATLAB function that evaluates an expression over a range of values. For example, this MATLAB code uses an anonymous function to create the input to the `fzero` function:

```
b = 2;
c = 3.5;
x = fzero(@(x) x^3 + b*x + c,0);
```

Anonymous Function Limitations for Code Generation

Anonymous functions have the code generation limitations of value classes and cell arrays.

You can use anonymous functions in a MATLAB Function block. You cannot use anonymous functions for Simulink signals, parameters, or data store memory.

- "Parameterizing Functions" (MATLAB)

Code Generation for Nested Functions

You can generate code for MATLAB functions that contain nested functions. For example, you can generate code for the function `parent_fun`, which contains the nested function `child_fun`.

```
function parent_fun
x = 5;
child_fun

    function child_fun
        x = x + 1;
    end

end
```

Nested Function Limitations for Code Generation

When you generate code for nested functions, you must adhere to the code generation restrictions for value classes, cell arrays, and handle classes. You must also adhere to these restrictions:

- If the parent function declares a persistent variable, it must assign the persistent variable before it calls a nested function that uses the persistent variable.
- A nested recursive function cannot refer to a variable that the parent function uses.
- If a nested function refers to a structure variable, you must define the structure by using `struct`.
- If a nested function uses a variable defined by the parent function, you cannot use `coder.varsize` with the variable in either the parent or the nested function.

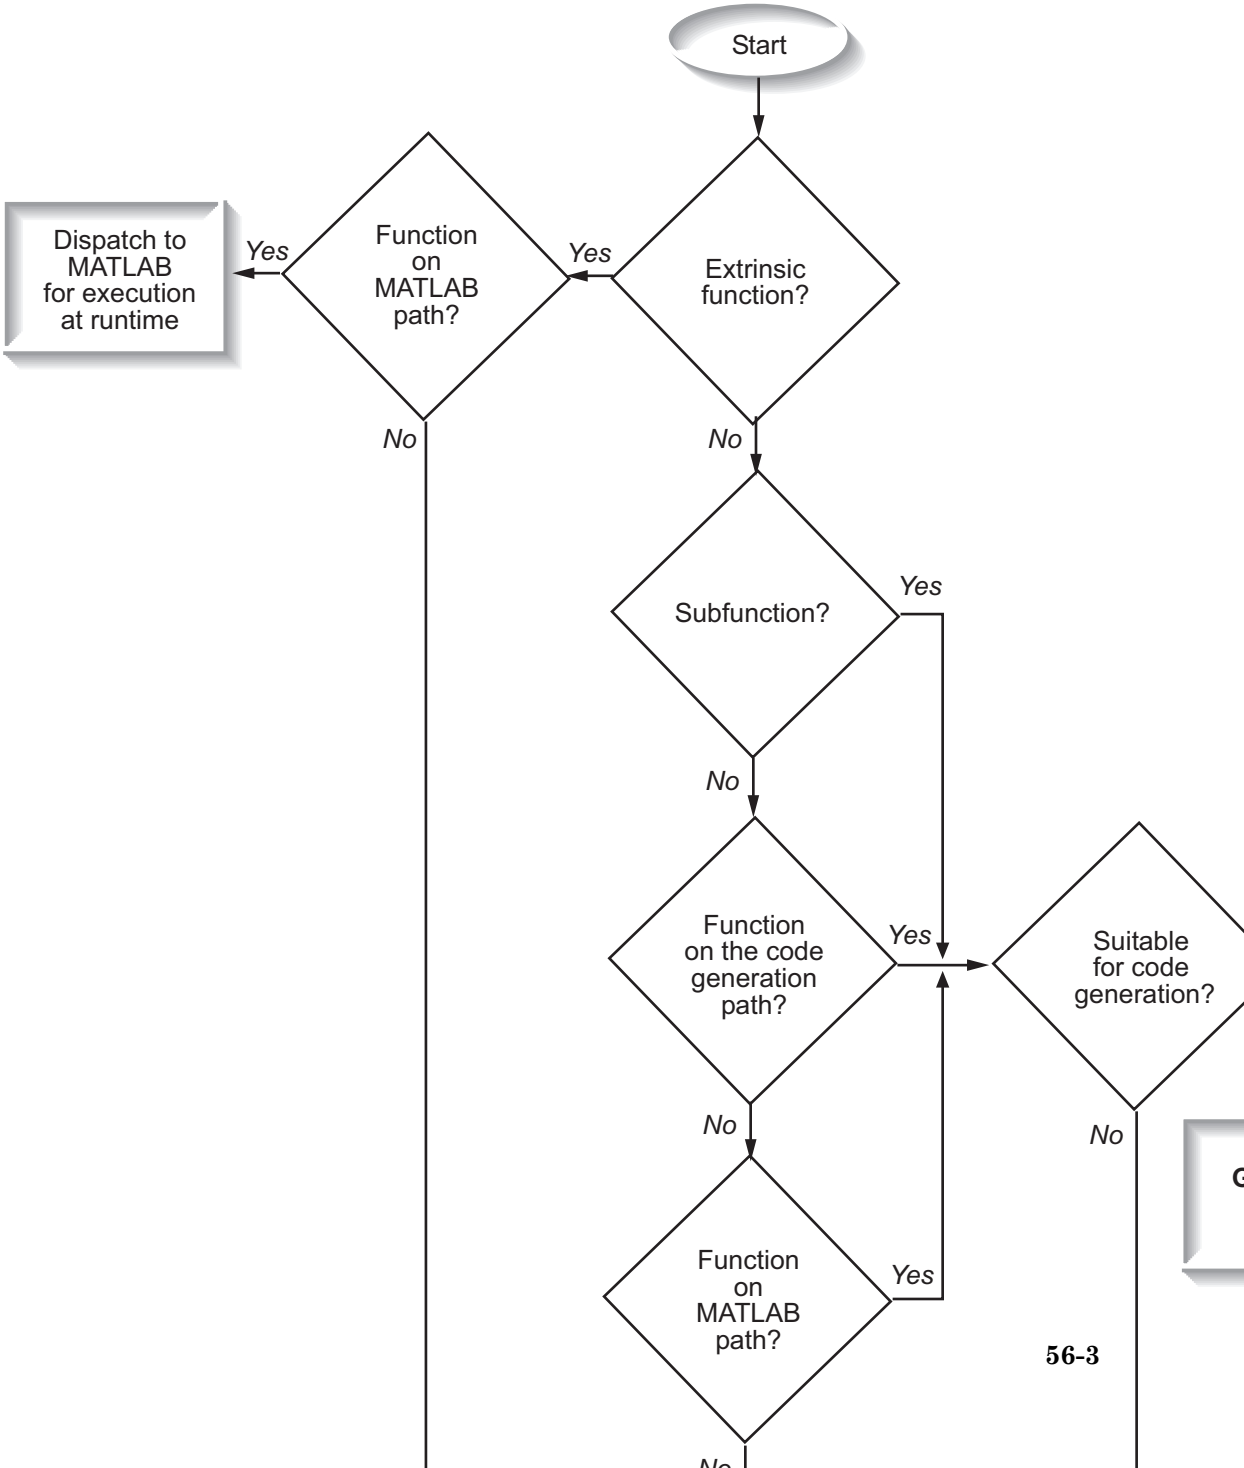
Calling Functions for Code Generation

Resolution of Function Calls for Code Generation

From a MATLAB function, you can call local functions, supported toolbox functions, and other MATLAB functions. MATLAB resolves function names for code generation as follows:



Start
Extrinsic function?
Yes
Function on MATLAB path?
Yes
Dispatch to MATLAB for execution at runtime
No
No
Subfunction?
Yes
No
Function on the code generation path?
Yes
Suitable for code generation?
No
No
Function on MATLAB path?
Yes
No

Key Points About Resolving Function Calls

The diagram illustrates key points about how MATLAB resolves function calls for code generation:

- Searches two paths, the code generation path and the MATLAB path

  See "Compile Path Search Order" on page 56-4.
- Attempts to compile functions unless the code generator determines that it should not compile them or you explicitly declare them to be extrinsic.

  If a MATLAB function is not supported for code generation, you can declare it to be extrinsic by using the construct `coder.extrinsic`, as described in "Declaring MATLAB Functions as Extrinsic Functions" on page 56-10. During simulation, the code generator produces code for the call to an extrinsic function, but does not generate the internal code for the function. Therefore, simulation can run only on platforms where MATLAB software is installed. During standalone code generation, the code generator attempts to determine whether the extrinsic function affects the output of the function in which it is called — for example by returning `mxArrays` to an output variable. Provided that the output does not change, code generation proceeds, but the extrinsic function is excluded from the generated code. Otherwise, compilation errors occur.

  The code generator detects calls to many common visualization functions, such as `plot`, `disp`, and `figure`. The software treats these functions like extrinsic functions but you do not have to declare them extrinsic using the `coder.extrinsic` function.
- Resolves file type based on precedence rules described in "Resolution of File Types on Code Generation Path" on page 56-6

Compile Path Search Order

During code generation, function calls are resolved on two paths:

1. Code generation path

   MATLAB searches this path first during code generation. The code generation path contains the toolbox functions supported for code generation.
2. MATLAB path

   If the function is not on the code generation path, MATLAB searches this path.

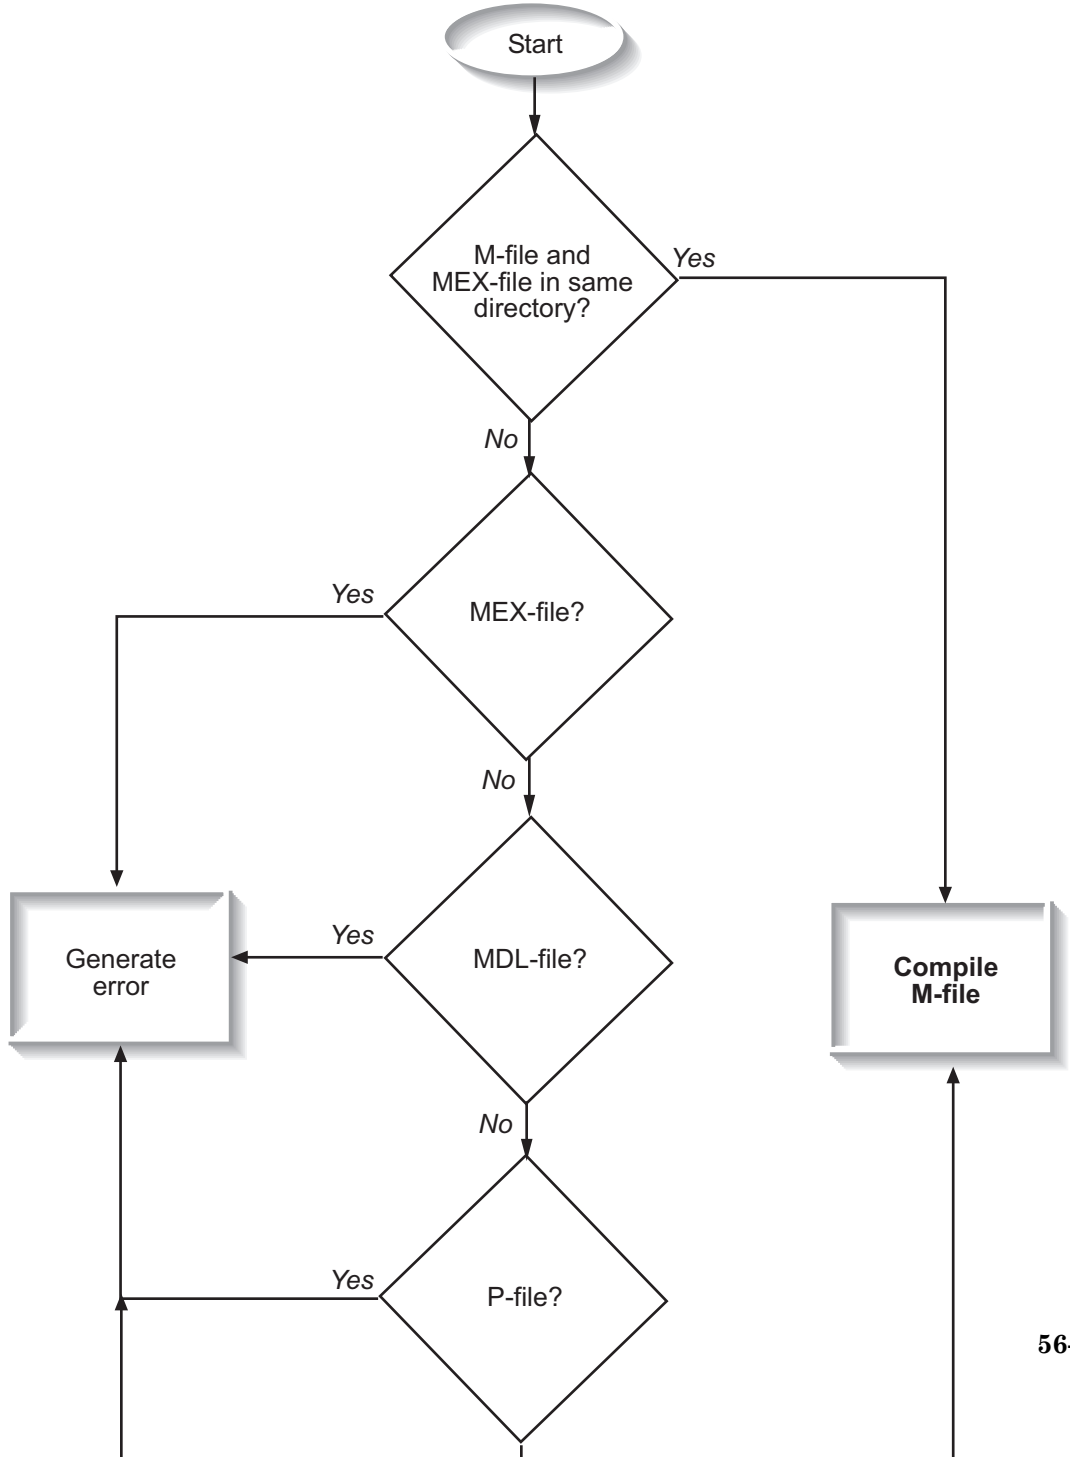
MATLAB applies the same dispatcher rules when searching each path (see “Function Precedence Order” (MATLAB)).

When to Use the Code Generation Path

Use the code generation path to override a MATLAB function with a customized version. A file on the code generation path shadows a file of the same name on the MATLAB path.

Resolution of File Types on Code Generation Path

MATLAB uses the following precedence rules for code generation:



Start
M-file and MEX-file in same directory?
Yes
No
MEX-file?
Yes
No
MDL-file?
Yes
No
P-file?
Yes
Generate error
Compile M-file

Compilation Directive %#codegen

Add the `%#codegen` directive (or pragma) to your function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation.

```
function y = my_fcn(x) %#codegen

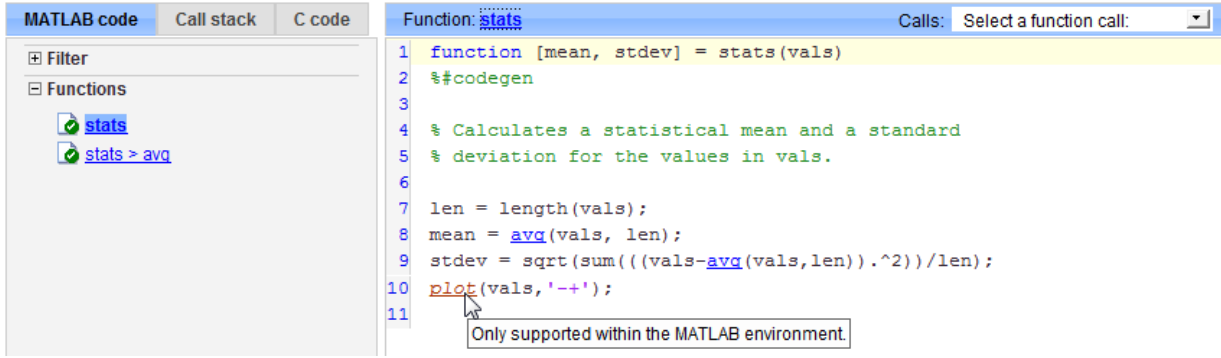
....
```

Note The `%#codegen` directive is not necessary for MATLAB Function blocks. Code inside a MATLAB Function block is always intended for code generation. The `%#codegen` directive, or the absence of it, does not change the error checking behavior.

Extrinsic Functions

The code generator attempts to generate code for functions, even if they are not supported for C code generation. The software detects calls to many common visualization functions, such as `plot`, `disp`, and `figure`. The software treats these functions like extrinsic functions but you do not have to declare them extrinsic using `coder.extrinsic`. During simulation, the code generator produces code for these functions, but does not generate their internal code. During standalone code generation, the code generator attempts to determine whether the visualization function affects the output of the function in which it is called. Provided that the output does not change, the code generator proceeds with code generation, but excludes the visualization function from the generated code. Otherwise, compilation errors occur.

For example, you might want to call `plot` to visualize your results in the MATLAB environment. If you generate a MEX function from a function that calls `plot` and then run the generated MEX function, the code generator dispatches calls to the `plot` function to MATLAB. If you generate a library or executable, the generated code does not contain calls to the `plot` function. The code generation report highlights calls from your MATLAB code to extrinsic functions so that it is easy to determine which functions are supported only in the MATLAB environment.



For unsupported functions other than common visualization functions, you must declare the functions to be extrinsic (see “Resolution of Function Calls for Code Generation” on page 56-2). Extrinsic functions are not compiled, but instead executed in MATLAB during simulation (see “Resolution of Extrinsic Functions During Simulation” on page 56-14).

There are two ways to declare a function to be extrinsic:

- Use the `coder.extrinsic` construct in main functions or local functions (see "Declaring MATLAB Functions as Extrinsic Functions" on page 56-10).
- Call the function indirectly using `feval` (see "Calling MATLAB Functions Using feval" on page 56-14).

Declaring MATLAB Functions as Extrinsic Functions

To declare a MATLAB function to be extrinsic, add the `coder.extrinsic` construct at the top of the main function or a local function:

```
coder.extrinsic('function_name_1', ... , 'function_name_n');
```

Declaring Extrinsic Functions

The following code declares the MATLAB `patch` function extrinsic in the local function `create_plot`. You do not have to declare `axis` as extrinsic because `axis` is one of the common visualization functions that the code generator automatically treats as extrinsic.

```
function c = pythagoras(a,b,color) %#codegen
% Calculates the hypotenuse of a right triangle
%  and displays the triangle.

c = sqrt(a^2 + b^2);
create_plot(a, b, color);

function create_plot(a, b, color)
%Declare patch as extrinsic

coder.extrinsic('patch');

x = [0;a;a];
y = [0;0;b];
patch(x, y, color);
axis('equal');
```

The code generator does not produce code for `patch` and `axis`, but instead dispatches them to MATLAB for execution.

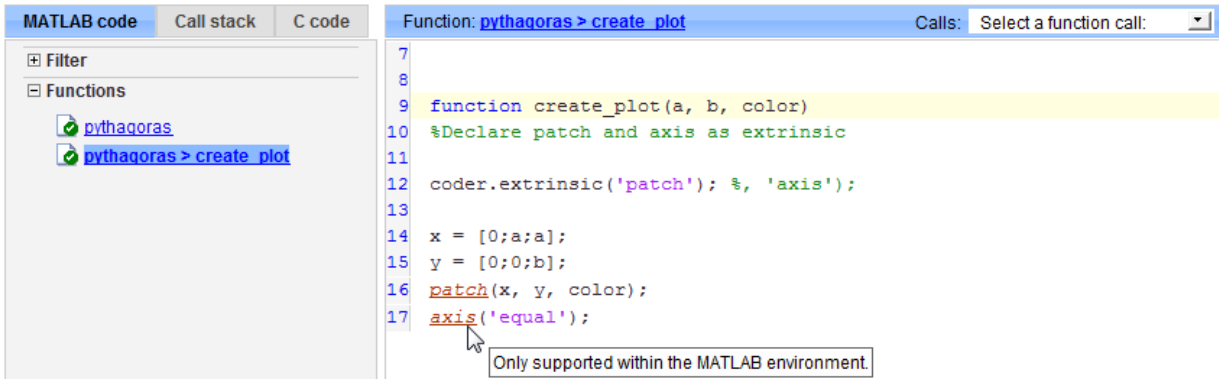
To test the function, follow these steps:

1 Convert `pythagoras` to a MEX function by executing this command at the MATLAB prompt:

```
codegen -report pythagoras -args {1, 1, [.3 .3 .3]}
```

2 Click the link to the code generation report and then, in the report, view the MATLAB code for `create_plot`.

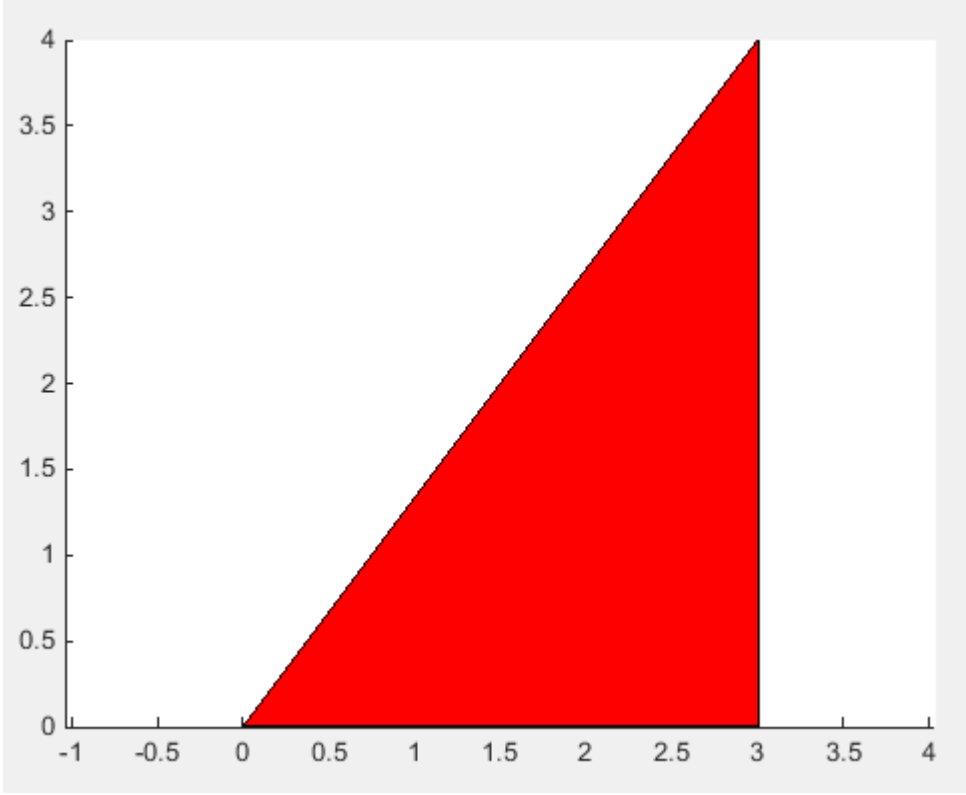
The report highlights the `patch` and `axis` functions to indicate that they are supported only within the MATLAB environment.



3 Run the MEX function by executing this command:

```
pythagoras_mex(3, 4, [1.0 0.0 0.0]);
```

MATLAB displays a plot of the right triangle as a red patch object:



When to Use the coder.extrinsic Construct

Use the `coder.extrinsic` construct to:

- Call MATLAB functions that do not produce output during simulation, without generating unnecessary code (see "Resolution of Extrinsic Functions During Simulation" on page 56-14).
- Make your code self-documenting and easier to debug. You can scan the source code for `coder.extrinsic` statements to isolate calls to MATLAB functions, which can potentially create and propagate `mxArrays` (see "Working with mxArrays" on page 56-15).
- Save typing. With one `coder.extrinsic` statement, each subsequent function call is extrinsic, as long as the call and the statement are in the same scope (see "Scope of Extrinsic Function Declarations" on page 56-13).

- Declare the MATLAB function(s) extrinsic throughout the calling function scope (see "Scope of Extrinsic Function Declarations" on page 56-13). To narrow the scope, use `feval` (see "Calling MATLAB Functions Using feval" on page 56-14).

Rules for Extrinsic Function Declarations

Observe the following rules when declaring functions extrinsic for code generation:

- Declare the function extrinsic before you call it.
- Do not use the extrinsic declaration in conditional statements.

Scope of Extrinsic Function Declarations

The `coder.extrinsic` construct has function scope. For example, consider the following code:

```
function y = foo %#codegen
coder.extrinsic('rat','min');
[N D] = rat(pi);
y = 0;
y = min(N, D);
```

In this example, `rat` and `min` as treated as extrinsic every time they are called in the main function `foo`. There are two ways to narrow the scope of an extrinsic declaration inside the main function:

- Declare the MATLAB function extrinsic in a local function, as in this example:

  ```
  function y = foo %#codegen
  coder.extrinsic('rat');
  [N D] = rat(pi);
  y = 0;
  y = mymin(N, D);

  function y = mymin(a,b)
  coder.extrinsic('min');
  y = min(a,b);
  ```

  Here, the function `rat` is extrinsic every time it is called inside the main function `foo`, but the function `min` is extrinsic only when called inside the local function `mymin`.
- Call the MATLAB function using `feval`, as described in "Calling MATLAB Functions Using feval" on page 56-14.

Calling MATLAB Functions Using feval

The function `feval` is automatically interpreted as an extrinsic function during code generation. Therefore, you can use `feval` to conveniently call functions that you want to execute in the MATLAB environment, rather than compiled to generated code.

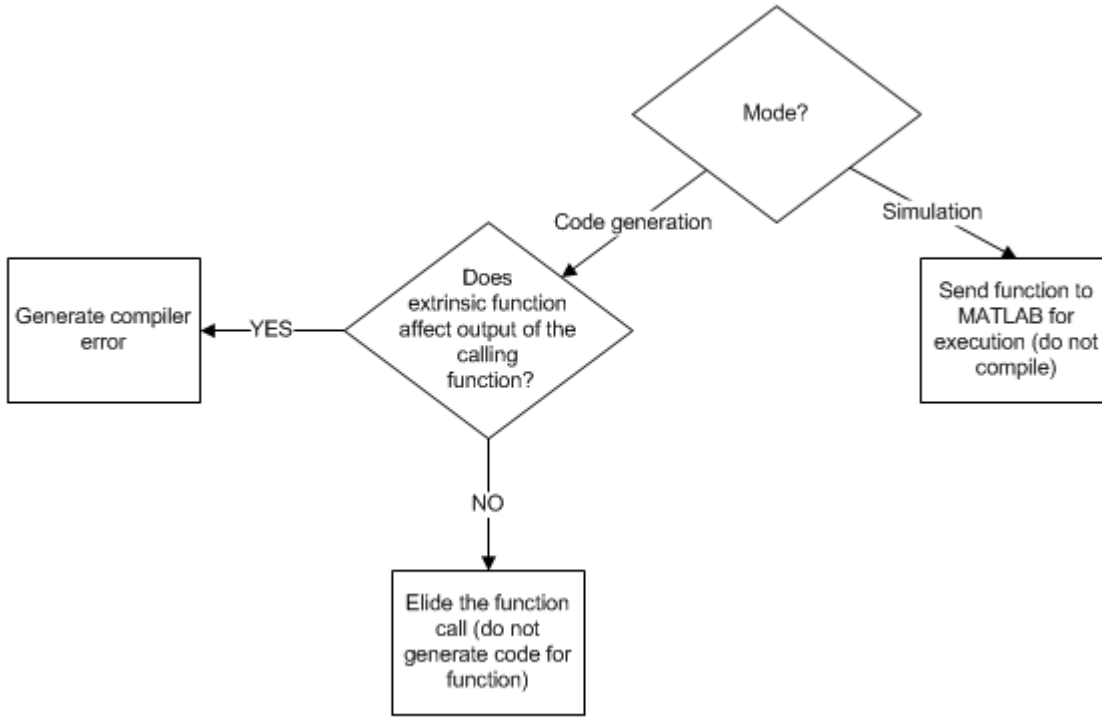
Consider the following example:

```
function y = foo
coder.extrinsic('rat');
[N D] = rat(pi);
y = 0;
y = feval('min', N, D);
```

Because `feval` is extrinsic, the statement `feval('min', N, D)` is evaluated by MATLAB — not compiled — which has the same result as declaring the function `min` extrinsic for just this one call. By contrast, the function `rat` is extrinsic throughout the function `foo`.

Resolution of Extrinsic Functions During Simulation

The code generator resolves calls to extrinsic functions — functions that do not support code generation — as follows:



During simulation, the code generator produces code for the call to an extrinsic function, but does not generate the internal code for the function. Therefore, you can run the simulation only on platforms where you install MATLAB software.

During code generation, the code generator attempts to determine whether the extrinsic function affects the output of the function in which it is called — for example by returning `mxArrays` to an output variable (see "Working with mxArrays" on page 56-15). Provided that the output does not change, code generation proceeds, but the extrinsic function is excluded from the generated code. Otherwise, the code generator issues a compiler error.

Working with mxArrays

The output of an extrinsic function is an `mxArray` — also called a MATLAB array. The only valid operations for `mxArrays` are:

- Storing `mxArrays` in variables
- Passing `mxArrays` to functions and returning them from functions
- Converting `mxArrays` to known types at run time

To use `mxArrays` returned by extrinsic functions in other operations, you must first convert them to known types, as described in "Converting mxArrays to Known Types" on page 56-16.

Converting mxArrays to Known Types

To convert an `mxArray` to a known type, assign the `mxArray` to a variable whose type is defined. At run time, the `mxArray` is converted to the type of the variable assigned to it. However, if the data in the `mxArray` is not consistent with the type of the variable, you get a run-time error.

For example, consider this code:

```
function y = foo %#codegen
coder.extrinsic('rat');
[N D] = rat(pi);
y = min(N, D);
```

Here, the top-level function `foo` calls the extrinsic MATLAB function `rat`, which returns two `mxArrays` representing the numerator `N` and denominator `D` of the rational fraction approximation of `pi`. Although you can pass these `mxArrays` to another MATLAB function — in this case, `min` — you cannot assign the `mxArray` returned by `min` to the output `y`.

If you run this function `foo` in a MATLAB Function block in a Simulink model, the code generates the following error during simulation:

```
Function output 'y' cannot be of MATLAB type.
```

To fix this problem, define `y` to be the type and size of the value that you expect `min` to return — in this case, a scalar double — as follows:

```
function y = foo %#codegen
coder.extrinsic('rat');
[N D] = rat(pi);
y = 0; % Define y as a scalar of type double
y = min(N,D);
```

Restrictions on Extrinsic Functions for Code Generation

The full MATLAB run-time environment is not supported during code generation. Therefore, the following restrictions apply when calling MATLAB functions extrinsically:

- MATLAB functions that inspect the caller, or read or write to the caller workspace do not work during code generation. Such functions include:
  - `dbstack`
  - `evalin`
  - `assignin`
  - `save`
- The MATLAB debugger cannot inspect variables defined in extrinsic functions.
- Functions in generated code can produce unpredictable results if your extrinsic function performs the following actions at run time:
  - Change folders
  - Change the MATLAB path
  - Delete or add MATLAB files
  - Change warning states
  - Change MATLAB preferences
  - Change Simulink parameters

Limit on Function Arguments

You can call functions with up to 64 inputs and 64 outputs.

Code Generation for Recursive Functions

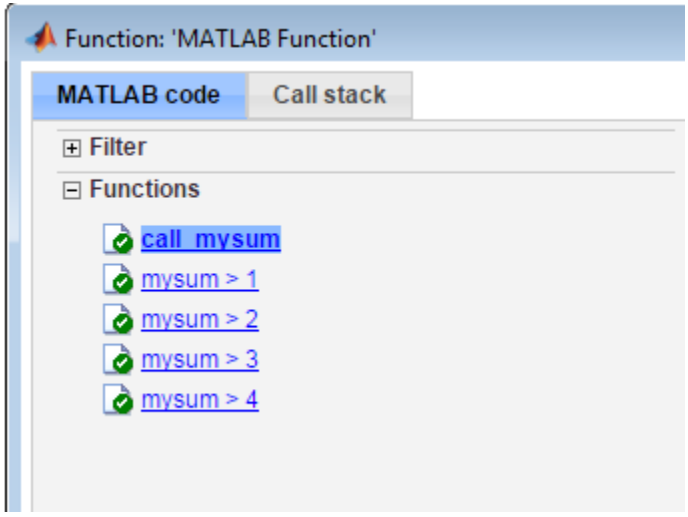
To generate code for recursive MATLAB functions, the code generator uses compile-time recursion on page 56-18 or run-time recursion on page 56-19. You can influence whether the code generator uses compile-time or run-time recursion by modifying your MATLAB code. See “Force Code Generator to Use Run-Time Recursion” on page 56-21.

You can disallow recursion on page 56-19 or disable run-time recursion on page 56-19 by modifying configuration parameters.

When you use recursive functions in MATLAB code that is intended for code generation, you must adhere to certain restrictions. See “Recursive Function Limitations for Code Generation” on page 56-20.

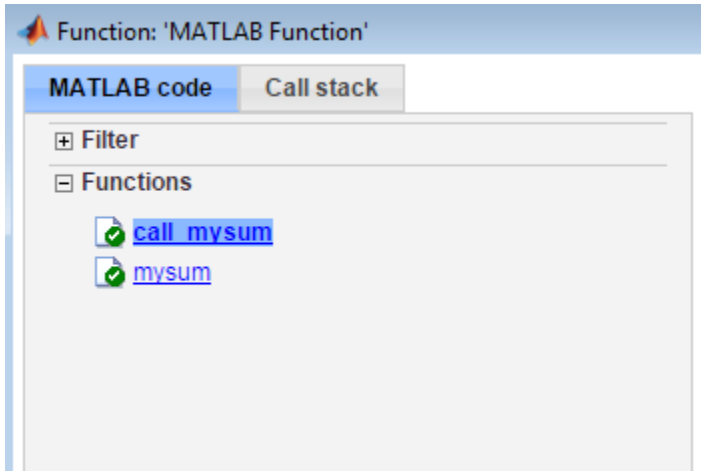
Compile-Time Recursion

With compile-time recursion, the code generator creates multiple versions of a recursive function in the generated code. The inputs to each version have values or sizes that are customized for that version. These versions are known as function specializations. You can tell that the code generator used compile-time recursion by looking at the MATLAB Function report or the generated C code. Here is an example of compile-time recursion in the report.



Run-Time Recursion

With run-time recursion, the code generator produces a recursive function in the generated code. You can tell that the code generator used run-time recursion by looking at the MATLAB Function report or the generated C code. Here is an example of run-time recursion in the report.



Disallow Recursion

In the model configuration parameters, set **Compile-time recursion limit for MATLAB functions** to 0.

Disable Run-Time Recursion

Some coding standards, such as MISRA®, do not allow recursion. To increase the likelihood of generating code that is compliant with MISRA C® , disable run-time recursion.

In the model configuration parameters, clear the **Enable run-time recursion for MATLAB functions** check box.

If your code requires run-time recursion and run-time recursion is disabled, you must rewrite your code so that it uses compile-time recursion or does not use recursion.

Recursive Function Limitations for Code Generation

When you use recursion in MATLAB code that is intended for code generation, follow these restrictions:

- The top-level function in a MATLAB Function block cannot be a recursive function, but it can call a recursive function.
- Assign all outputs of a run-time recursive function before the first recursive call in the function.
- Assign all elements of cell array outputs of a run-time recursive function.
- Inputs and outputs of run-time recursive functions cannot be classes.
- The **Maximum stack size** parameter is ignored for run-time recursion.

Force Code Generator to Use Run-Time Recursion

When your MATLAB code includes recursive function calls, the code generator uses compile-time or run-time recursion. With compile-time recursion on page 56-18, the code generator creates multiple versions of the recursive function in the generated code. These versions are known as function specializations. With run-time recursion on page 56-19, the code generator produces a recursive function. If compile-time recursion results in too many function specializations or if you prefer run-time recursion, you can try to force the code generator to use run-time recursion. Try one of these approaches:

- "Treat the Input to the Recursive Function as a Nonconstant" on page 56-21
- "Make the Input to the Recursive Function Variable-Size" on page 56-22
- "Assign Output Variable Before the Recursive Call" on page 56-23

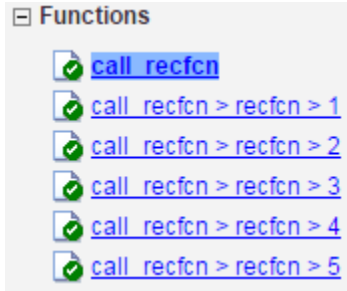
Treat the Input to the Recursive Function as a Nonconstant

Consider this function:

```
function y = call_recfcn(n)
A = ones(1,n);
x = 5;
y = recfcn(A,x);
end

function y = recfcn(A,x)
if size(A,2) == 1 || x == 1
    y = A(1);
else
    y = A(1)+recfcn(A(2:end),x-1);
end
end
```

`call_recfcn` calls `recfcn` with the value 5 for the second argument. `recfcn` calls itself recursively until `x` is 1. For each `recfcn` call, the input argument `x` has a different value. The code generator produces five specializations of `recfcn`, one for each call. You can see the specializations in the MATLAB Function report.



To force run-time recursion, in `call_recfcn`, in the call to `recfcn`, instruct the code generator to treat the value of the input argument `x` as a nonconstant value by using `coder.ignoreConst`.

```
function y = call_recfcn(n)
A = ones(1,n);
x = coder.ignoreConst(5);
y = recfcn(A,x);
end

function y = recfcn(A,x)
if size(A,2) == 1 || x == 1
    y = A(1);
else
    y = A(1)+recfcn(A(2:end),x-1);
end
end
```

In the MATLAB Function report, you see only one specialization.

Make the Input to the Recursive Function Variable-Size

Consider this code:

```
function z = call_mysum(A)
%#codegen
z = mysum(A);
```

```
end

function y = mysum(A)
coder.inline('never');
if size(A,2) == 1
    y = A(1);
else
    y = A(1)+ mysum(A(2:end));
end
end
```

If the input to `mysum` is fixed-size, the code generator uses compile-time recursion. To force the code generator to use run-time conversion, make the input to `mysum` variable-size by using `coder.varsize`.

```
function z = call_mysum(A)
%#codegen
B = A;
coder.varsize('B');
z = mysum(B);
end

function y = mysum(A)
coder.inline('never');
if size(A,2) == 1
    y = A(1);
else
    y = A(1)+ mysum(A(2:end));
end
end
```

Assign Output Variable Before the Recursive Call

The code generator uses compile-time recursion for this code:

```
function y = callrecursive(n)
x = 10;
y = myrecursive(x,n);
end

function y = myrecursive(x,n)
coder.inline('never')
if x > 1
    y = n + myrecursive(x-1,n-1);
```

```
else
    y = n;
end
end
```

To force the code generator to use run-time recursion, modify `myrecursive` so that the output `y` is assigned before the recursive call. Place the assignment `y = n` in the `if` block and the recursive call in the `else` block.

```
function y = callrecursive(n)
x = 10;
y = myrecursive(x,n);
end

function y = myrecursive(x,n)
coder.inline('never')
if x == 1
    y = n;
else
    y = n + myrecursive(x-1,n-1);
end
end
```

Generate Efficient and Reusable Code

Modularize MATLAB Code

For large MATLAB code, streamline code generation by modularizing the code:

1. Break up your MATLAB code into smaller, self-contained sections.
2. Save each section in a MATLAB function.
3. Generate C/C++ code for each function.
4. Call the generated C/C++ functions in sequence from a wrapper MATLAB function using `coder.ceval`.
5. Generate C/C++ code for the wrapper function.

Besides streamlining code generation for the original MATLAB code, this approach also supplies you with C/C++ code for the individual sections. You can reuse the code for the individual sections later by integrating them with other generated C/C++ code using `coder.ceval`.

Eliminate Redundant Copies of Function Inputs

You can reduce the number of copies in your generated code by writing functions that use the same variable as both an input and an output. For example:

```
function A = foo( A, B ) %#codegen
A = A * B;
end
```

This coding practice uses a reference parameter optimization. When a variable acts as both input and output, the generated code passes the variable by reference instead of redundantly copying the input to a temporary variable. In the preceding example, input `A` is passed by reference in the generated code because it also acts as an output for function `foo`:

```
...
/* Function Definitions */
void foo(double *A, double B)
{
    *A *= B;
}
...
```

The reference parameter optimization reduces memory usage and execution time, especially when the variable passed by reference is a large data structure. To achieve these benefits at the call site, call the function with the same variable as both input and output.

By contrast, suppose that you rewrite function `foo` without the optimization:

```
function y = foo2( A, B ) %#codegen
y = A * B;
end
```

The generated code passes the inputs by value and returns the value of the output:

```
...
/* Function Definitions */
double foo2(double A, double B)
{
   return A * B;
}
...
```

In some cases, the output of the function cannot be a modified version of its inputs. If you do not use the inputs later in the function, you can modify your code to operate on the inputs instead of on a copy of the inputs. One method is to create additional return values for the function. For example, consider the code:

```
function y1=foo(u1) %#codegen
  x1=u1+1;
  y1=bar(x1);
end

function y2=bar(u2)
  % Since foo does not use x1 later in the function,
  % it would be optimal to do this operation in place
  x2=u2.*2;
  % The change in dimensions in the following code
  % means that it cannot be done in place
  y2=[x2,x2];
end
```

You can modify this code to eliminate redundant copies.

```
function y1=foo(u1) %#codegen
  u1=u1+1;
  [y1, u1]=bar(u1);
end

function [y2, u2]=bar(u2)
    u2=u2.*2;
  % The change in dimensions in the following code
  % still means that it cannot be done in place
  y2=[u2,u2];
end
```

The reference parameter optimization does not apply to constant inputs. If the same variable is an input and an output, and the input is constant, the code generator treats the output as a separate variable. For example, consider the function `foo`:

```
function A = foo( A, B ) %#codegen
A = A * B;
end
```

Generate code in which `A` has a constant value `2`.

```
codegen -config:lib foo -args {coder.Constant(2) 3} -report
```

The generated code defines the constant `A` and returns the value of the output.

```
...
#define A                              (2.0)
...
double foo(double B)
{
  return A * B;
}
...
```

Inline Code

Inlining is a technique that replaces a function call with the contents (body) of that function. Inlining eliminates the overhead of a function call, but can produce larger C/C++ code. Inlining can create opportunities for further optimization of the generated C/C++ code. The code generator uses internal heuristics to determine whether to inline functions in the generated code. You can use the `coder.inline` directive to fine-tune these heuristics for individual functions. For more information, see `coder.inline`.

See Also

Control Inlining

Restrict inlining when:

- Generated code size limits are exceeded due to excessive inlining of functions. For example, suppose that you include the statement, `coder.inline('always')`, inside a certain function. You then call that function at many different sites in your code. The generated code size increases because the function is inlined every time it is called. However, the call sites must be different. For instance, inlining does not lead to large code size if the function to be inlined is called several times inside a loop.
- You have limited RAM or stack space.

You can control inlining or disable inlining altogether. To disable inlining at the command line, use the `-O disable:inline` option of the `codegen` command. This option disables inlining for all functions.

In this section...

Control Size of Functions Inlined

You can use the MATLAB Coder app or the command-line interface to control the maximum size of functions that can be inlined. The function size is measured in terms of an abstract number of instructions, not actual MATLAB instructions or instructions in the target processor. Experiment with this parameter to obtain the inlining behavior that you want.

- Using the app, in the project settings dialog box, on the **All Settings** tab, set the value of the field, **Inline threshold**, to the maximum size that you want.
- At the command line, create a `codegen` configuration object. Set the value of the property, `InlineThreshold`, to the maximum size that you want.

  ```
  cfg = coder.config('lib');
  cfg.InlineThreshold = 100;
  ```

  Generate code by using this configuration object.

Control Size of Functions After Inlining

You can use the MATLAB Coder app or the command-line interface to control the maximum size of functions after inlining. The function size is measured in terms of an abstract number of instructions, not actual MATLAB instructions or instructions in the target processor. Experiment with this parameter to obtain the inlining behavior that you want.

- Using the app, in the project settings dialog box, on the **All Settings** tab, set the value of the field **Inline threshold max** to the maximum size that you want.
- At the command line, create a `codegen` configuration object. Set the value of the property, `InlineThresholdMax`, to the maximum size that you want.

  ```
  cfg = coder.config('lib');
  cfg.InlineThresholdMax = 100;
  ```

  Generate code by using this configuration object.

Control Stack Size Limit on Inlined Functions

Specifying a limit on the stack space constrains the amount of inlining allowed. For out-of-line functions, stack space for variables local to the function is released when the function returns. However, for inlined functions, stack space remains occupied by the local variables even after the function is executed. The value of the property `InlineStackLimit` is measured in bytes. Based on information from the target hardware settings, the software estimates the number of stack variables that a certain value of `InlineStackLimit` can accommodate. This estimate excludes possible C compiler optimizations such as putting variables in registers.

You can use the MATLAB Coder app or the command-line interface to control the stack size limit on inlined functions.

- Using the app, in the project settings dialog box, on the **All Settings** tab, set the value of the field **Inline stack limit** to the maximum size that you want.
- At the command line, create a `codegen` configuration object. Set the value of the property, `InlineThresholdMax`, to the maximum size that you want.

  ```
  cfg = coder.config('lib');
  cfg.InlineStackLimit = 2000;
  ```

  Generate code by using this configuration object.

Fold Function Calls into Constants

This example shows how to specify constants in generated code using `coder.const`. The code generator folds an expression or a function call in a `coder.const` statement into a constant in generated code. Because the generated code does not have to evaluate the expression or call the function every time, this optimization reduces the execution time of the generated code.

Write a function `AddShift` that takes an input `Shift` and adds it to the elements of a vector. The vector consists of the square of the first 10 natural numbers. `AddShift` generates this vector.

```
function y = AddShift(Shift) %#codegen
y = (1:10).^2+Shift;
```

Generate code for `AddShift` using the `codegen` command. Open the Code Generation Report.

```
codegen -config:lib -launchreport AddShift -args 0
```

The code generator produces code for creating the vector. It adds `Shift` to each element of the vector during vector creation. The definition of `AddShift` in generated code looks as follows:

```
void AddShift(double Shift, double y[10])
{
  int k;
  for (k = 0; k < 10; k++) {
    y[k] = (double)((1 + k) * (1 + k)) + Shift;
  }
}
```

Replace the statement

```
y = (1:10).^2+Shift;
```

with

```
y = coder.const((1:10).^2)+Shift;
```

Generate code for `AddShift` using the `codegen` command. Open the Code Generation Report.

```
codegen -config:lib -launchreport AddShift -args 0
```

The code generator creates the vector containing the squares of the first 10 natural numbers. In the generated code, it adds `Shift` to each element of this vector. The definition of `AddShift` in generated code looks as follows:

```
void AddShift(double Shift, double y[10])
{
  int i0;
  static const signed char iv0[10] = { 1, 4, 9, 16, 25, 36,
                                       49, 64, 81, 100 };

  for (i0 = 0; i0 < 10; i0++) {
    y[i0] = (double)iv0[i0] + Shift;
  }
}
```

Control Stack Space Usage

This example shows how to set the maximum stack space that the generated code uses. Set the maximum stack usage when:

- You have limited stack space, for instance, in embedded targets.
- Your C compiler reports a run-time stack overflow.

The value of the property, `StackUsageMax`, is measured in bytes. Based on information from the target hardware settings, the software estimates the number of stack variables that a certain value of `StackUsageMax` can accommodate. This estimate excludes possible C compiler optimizations such as putting variables in registers.

Control Stack Space Usage Using the MATLAB Coder App

1. To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow  .
2. Set **Build type** to `Source Code`, `Static Library`, `Dynamic Library`, or `Executable` (depending on your requirements).
3. Click **More Settings**.
4. On the **Memory** tab, set **Stack usage max** to the value that you want.

Control Stack Space Usage at the Command Line

1. Create a configuration object for code generation.

   Use `coder.config` with arguments `'lib'`,`'dll'`, or `'exe'` (depending on your requirements). For example:

   ```
   cfg = coder.config('lib');
   ```

2. Set the property, `StackUsageMax`, to the value that you want.

```
cfg.StackUsageMax=400000;
```

- “Stack Allocation and Performance” (MATLAB Coder)

Stack Allocation and Performance

By default, local variables are allocated on the stack. Large variables that do not fit on the stack are statically allocated in memory.

Stack allocation typically uses memory more efficiently than static allocation. However, stack space is sometimes limited, typically in embedded processors. MATLAB Coder allows you to manually set a limit on the stack space usage to make your generated code suitable for your target hardware. You can choose this limit based on the target hardware configurations. For more information, see “Control Stack Space Usage” (MATLAB Coder).

For limited stack space, you can choose to allocate large variables on the heap instead of using static allocation. Heap allocation is slower but more memory-efficient than static allocation. To allocate large variables on the heap, do one of the following:

Allocate Heap Space from Command Line

1. Create a configuration object. Set the property, `MultiInstanceCode`, to `true`.

   ```
   cfg = coder.config('exe');
   cfg.MultiInstanceCode = true;
   ```

2. Generate code using this configuration object.

Allocate Heap Space Using the MATLAB Coder App

1. Using the MATLAB Coder app, in the project settings dialog box, on the **Memory** tab, select the **Generate re-entrant code** check box.

- Generate code.

Dynamic Memory Allocation and Performance

To achieve faster execution of generated code, minimize dynamic (or run-time) memory allocation of arrays.

MATLAB Coder does not provide a size for unbounded arrays in generated code. Instead, such arrays are referenced indirectly through pointers. For such arrays, memory cannot be allocated during compilation of generated code. Based on storage requirements for the arrays, memory is allocated and freed at run time as required. This run-time allocation and freeing of memory leads to slower execution of the generated code.

When Dynamic Memory Allocation Occurs

Dynamic memory allocation occurs when the code generator cannot find upper bounds for variable-size arrays. The software cannot find upper bounds when you specify the size of an array using a variable that is not a compile-time constant. An example of such a variable is an input variable (or a variable computed from an input variable).

Instances in the MATLAB code that can lead to dynamic memory allocation are:

- Array initialization: You specify array size using a variable whose value is known only at run time.
- After initialization of an array:
  - You declare the array as variable-size using `coder.varsize` without explicit upper bounds. After this declaration, you expand the array by concatenation inside a loop. The number of loop runs is known only at run time.
  - You use a `reshape` function on the array. At least one of the size arguments to the `reshape` function is known only at run time.

If you know the maximum size of the array, you can avoid dynamic memory allocation. You can then provide an upper bound for the array and prevent dynamic memory allocation in generated code. For more information, see “Minimize Dynamic Memory Allocation” on page 57-16.

Minimize Dynamic Memory Allocation

When possible, minimize dynamic memory allocation because it leads to slower execution of generated code. Dynamic memory allocation occurs when the code generator cannot find upper bounds for variable-size arrays.

If you know the maximum size of a variable-size array, you can avoid dynamic memory allocation. Follow these steps:

1. "Provide Maximum Size for Variable-Size Arrays" on page 57-17.
2. Depending on your requirements, do one of the following:
   - "Disable Dynamic Memory Allocation During Code Generation" on page 57-22.
   - "Set Dynamic Memory Allocation Threshold" (MATLAB Coder)

Caution If a variable-size array in the MATLAB code does not have a maximum size, disabling dynamic memory allocation leads to a code generation error. Before disabling dynamic memory allocation, you must provide a maximum size for variable-size arrays in your MATLAB code.

More About

- "Dynamic Memory Allocation and Performance" (MATLAB Coder)

Provide Maximum Size for Variable-Size Arrays

To constrain array size for variable-size arrays, do one of the following:

- **Constrain Array Size Using assert Statements**

  If the variable specifying array size is not a compile-time constant, use an `assert` statement with relational operators to constrain the variable. Doing so helps the code generator to determine a maximum size for the array.

  The following examples constrain array size using `assert` statements:

  - **When Array Size Is Specified by Input Variables**

    Define a function `array_init` which initializes an array `y` with input variable `N`:

    ```
    function y = array_init (N)
      assert(N <= 25); % Generates exception if N > 25
      y = zeros(1,N);
    ```

    The `assert` statement constrains input `N` to a maximum size of 25. In the absence of the `assert` statement, `y` is assigned a pointer to an array in the generated code, thus allowing dynamic memory allocation.

  - **When Array Size Is Obtained from Computation Using Input Variables**

    Define a function, `array_init_from_prod`, which takes two input variables, `M` and `N`, and uses their product to specify the maximum size of an array, `y`.

    ```
    function y = array_init_from_prod (M,N)
       size=M*N;
       assert(size <= 25); % Generates exception if size > 25
       y=zeros(1,size);
    ```

    The `assert` statement constrains the product of `M` and `N` to a maximum of 25.

    Alternatively, if you restrict `M` and `N` individually, it leads to dynamic memory allocation:

    ```
    function y = array_init_from_prod (M,N)
       assert(M <= 5);
       assert(N <= 5);
       size=M*N;
       y=zeros(1,size);
    ```

This code causes dynamic memory allocation because `M` and `N` can both have unbounded negative values. Therefore, their product can be unbounded and positive even though, individually, their positive values are bounded.

Tip Place the assert statement on a variable immediately before it is used to specify array size.

Tip You can use `assert` statements to restrict array sizes in most cases. When expanding an array inside a loop, this strategy does not work if the number of loop runs is known only at run time.

- **Restrict Concatenations in a Loop Using coder.varsize with Upper Bounds**

You can expand arrays beyond their initial size by concatenation. When you concatenate additional elements inside a loop, there are two syntax rules for expanding arrays.

1 **Array size during initialization is not a compile-time constant**

If the size of an array during initialization is not a compile-time constant, you can expand it by concatenating additional elements:

```
function out=ExpandArray(in) % Expand an array by five elements
  out = zeros(1,in);
  for i=1:5
     out = [out 0];
  end
```

2 **Array size during initialization is a compile-time constant**

Before concatenating elements, you have to declare the array as variable-size using `coder.varsize`:

```
function out=ExpandArray() % Expand an array by five elements
  out = zeros(1,5);
  coder.varsize('out');
  for i=1:5
     out = [out 0];
  end
```

Either case leads to dynamic memory allocation. To prevent dynamic memory allocation in such cases, use `coder.varsize` with explicit upper bounds. This example shows how to use `coder.varsize` with explicit upper bounds:

Example 57.1. Restrict Concatenations Using coder.varsize with Upper Bounds

1 Define a function, `RunningAverage`, that calculates the running average of an `N`-element subset of an array:

```
function avg=RunningAverage(N)

% Array whose elements are to be averaged
NumArray=[1 6 8 2 5 3];

% Initialize average:
% These will also be the first two elements of the function output
avg=[0 0];

% Place a bound on the argument
coder.varsize('avg',[1 8]);

% Loop to calculate running average
for i=1:N
  s=0;
  s=s+sum(NumArray(1:i));
  avg=[avg s/i];
  % Increase the size of avg as required by concatenation
end
```

The output, `avg`, is an array that you can expand as required to accommodate the running averages. As a new running average is calculated, it is added to the array `avg` through concatenation, thereby expanding the array.

Because the maximum number of running averages is equal to the number of elements in `NumArray`, you can supply an explicit upper bound for `avg` in the `coder.varsize` statement. In this example, the upper bound is 8 (the two initial elements plus the six elements of `NumArray`).

2 Generate code for `RunningAverage` with input argument of type `double`:

```
codegen -config:lib -report RunningAverage -args 2
```

In the generated code, `avg` is assigned an array of size 8 (static memory allocation). The function definition for `RunningAverage` appears as follows (using built-in C types):

```
void RunningAverage (double N, double avg_data[8], int avg_size[2])
```

3 By contrast, if you remove the explicit upper bound, the generated code dynamically allocates `avg`.

Replace the statement

```
coder.varsize('avg',[1 8]);
```

with:

```
coder.varsize('avg');
```

4 Generate code for `RunningAverage` with input argument of type `double`:

```
codegen -config:lib -report RunningAverage -args 2
```

In the generated code, `avg` is assigned a pointer to an array, thereby allowing dynamic memory allocation. The function definition for `RunningAverage` appears as follows (using built-in C types):

```
void Test(double N, emxArray_real_T *avg)
```

Note Dynamic memory allocation also occurs if you precede `coder.varsize('avg')` with the following assert statement:

```
assert(N < 6);
```

The `assert` statement does not restrict the number of concatenations within the loop.

- **Constrain Array Size When Rearranging a Matrix**

The statement `out = reshape(in,m,n,...)` takes an array, `in`, as an argument and returns array, `out`, having the same elements as `in`, but reshaped as an `m`-by-`n`-by-`...` matrix. If one of the size variables `m,n,...` is not a compile-time constant, then dynamic memory allocation of `out` takes place.

To avoid dynamic memory allocation, use an `assert` statement before the `reshape` statement to restrict the size variables `m,n,...` to `numel(in)`. This example shows how to use an `assert` statement before a `reshape` statement:

Example 57.2. Rearrange a Matrix into Given Number of Rows

1 Define a function, `ReshapeMatrix`, which takes an input variable, `N`, and reshapes a matrix, `mat`, to have `N` rows:

```
  function [out1,out2] = ReshapeMatrix(N)

  mat = [1 2 3 4 5; 4 5 6 7 8]
% Since mat has 10 elements, N must be a factor of 10
% to pass as argument to reshape

  out1 = reshape(mat,N,[]);
% N is not restricted

  assert(N < numel(mat));
% N is restricted to number of elements in mat
  out2 = reshape(mat,N,[]);
```

2 Generate code for `ReshapeArray` using the `codegen` command (the input argument does not have to be a factor of 10):

```
codegen -config:lib -report ReshapeArray -args 3
```

While `out1` is dynamically allocated, `out2` is assigned an array with size 100 (=10 X 10) in the generated code.

Tip If your system has limited memory, do not use the `assert` statement in this way. For an `n`-element matrix, the `assert` statement creates an `n`-by-`n` matrix, which might be large.

Disable Dynamic Memory Allocation During Code Generation

To disable dynamic memory allocation using the MATLAB Coder app:

1. To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow  .
2. Click **More Settings**.
3. On the **Memory** tab, under **Variable Sizing Support**, set **Dynamic memory allocation** to `Never`.

To disable dynamic memory allocation at the command line:

1. In the MATLAB workspace, define the configuration object:

   ```
   cfg=coder.config('lib');
   ```

2. Set the `DynamicMemoryAllocation` property of the configuration object to `Off`:

   ```
   cfg.DynamicMemoryAllocation = 'Off';
   ```

If a variable-size array in the MATLAB code does not have a maximum upper bound, disabling dynamic memory allocation leads to a code generation error. Therefore, you can identify variable-size arrays in your MATLAB code that do not have a maximum upper bound. These arrays are the arrays that are dynamically allocated in the generated code.

Set Dynamic Memory Allocation Threshold

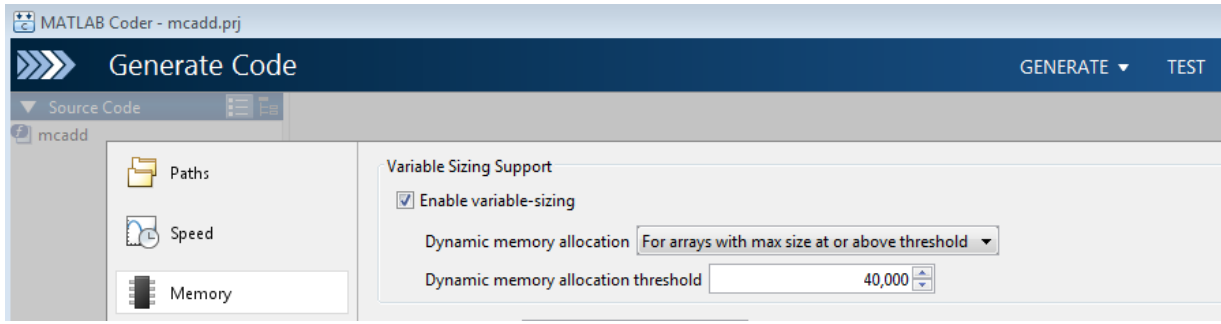
This example shows how to specify a dynamic memory allocation threshold for variable-size arrays. Dynamic memory allocation optimizes storage requirements for variable-size arrays, but causes slower execution of generated code. Instead of disabling dynamic memory allocation for all variable-size arrays, you can disable dynamic memory allocation for arrays less than a certain size.

Specify this threshold when you want to:

- Disable dynamic memory allocation for smaller arrays. For smaller arrays, static memory allocation can speed up generated code. Static memory allocation can lead to unused storage space. However, you can decide that the unused storage space is not a significant consideration for smaller arrays.
- Enable dynamic memory allocation for larger arrays. For larger arrays, when you use dynamic memory allocation, you can significantly reduce storage requirements.

Set Dynamic Memory Allocation Threshold Using the MATLAB Coder App

1. To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow  .
2. Click **More Settings**.
3. On the **Memory** tab, select the **Enable variable-sizing** check box.
4. Set **Dynamic memory allocation** to `For arrays with max size at or above threshold`.
5. Set **Dynamic memory allocation threshold** to the value that you want.



The **Dynamic memory allocation threshold** value is measured in bytes. Based on information from the target hardware settings, the software estimates the size of the array that a certain value of `DynamicMemoryAllocationThreshold` can accommodate. This estimate excludes possible C compiler optimizations such as putting variables in registers.

Set Dynamic Memory Allocation Threshold at the Command Line

1. Create a configuration object for code generation. Use `coder.config` with arguments `'lib'`,`'dll'`, or `'exe'` (depending on your requirements). For example:

   ```
   cfg = coder.config('lib');
   ```

2. Set `DynamicMemoryAllocation` to `'Threshold'`.

   ```
   cfg.DynamicMemoryAllocation='Threshold';
   ```

3. Set the property, `DynamicMemoryAllocationThreshold`, to the value that you want.

   ```
   cfg.DynamicMemoryAllocationThreshold = 40000;
   ```

   The value stored in `DynamicMemoryAllocationThreshold` is measured in bytes. Based on information from the target hardware settings, the software estimates the size of the array that a certain value of `DynamicMemoryAllocationThreshold` can accommodate. This estimate excludes possible C compiler optimizations such as putting variables in registers.

Excluding Unused Paths from Generated Code

In certain situations, you do not need some branches of an: `if, elseif, else` statement, or a `switch, case, otherwise` statement in your generated code. For instance:

- You have a MATLAB function that performs multiple tasks determined by a control-flow variable. You might not need some of the tasks in the code generated from this function.
- You have an `if/elseif/if` statement in a MATLAB function performing different tasks based on the nature (type/value) of the input. In some cases, you know the nature of the input beforehand. If so, you do not need some branches of the `if` statement.

You can prevent code generation for the unused branches of an `if/elseif/else` statement or a `switch/case/otherwise` statement. Declare the control-flow variable as a constant. The code generator produces code only for the branch that the control-flow variable chooses.

See Also

Related Examples

- “Prevent Code Generation for Unused Execution Paths” (MATLAB Coder)

Prevent Code Generation for Unused Execution Paths

In this section...

If a variable controls the flow of an: `if, elseif, else` statement, or a `switch, case, otherwise` statement, declare it as constant so that code generation takes place for one branch of the statement only.

Depending on the nature of the control-flow variable, you can declare it as constant in two ways:

- If the variable is local to the MATLAB function, assign it to a constant value in the MATLAB code. For an example, see “Prevent Code Generation When Local Variable Controls Flow” on page 57-26.
- If the variable is an input to the MATLAB function, you can declare it as constant using `coder.Constant`. For an example, see “Prevent Code Generation When Input Variable Controls Flow” on page 57-27.

Prevent Code Generation When Local Variable Controls Flow

1 Define a function `SquareOrCube` which takes an input variable, `in`, and squares or cubes its elements based on whether the choice variable, `ch`, is set to `s` or `c`:

```
function out = SquareOrCube(ch,in) %#codegen
 if ch=='s'
     out = in.^2;
 elseif ch=='c'
     out = in.^3;
 else
     out = 0;
 end
```

2 Generate code for `SquareOrCube` using the `codegen` command:

```
codegen -config:lib SquareOrCube -args {'s',zeros(2,2)}
```

The generated C code squares or cubes the elements of a 2-by-2 matrix based on the input for `ch`.

3 Add the following line to the definition of `SquareOrCube`:

```
ch = 's';
```

The generated C code squares the elements of a 2-by-2 matrix. The choice variable, `ch`, and the other branches of the `if/elseif/if` statement do not appear in the generated code.

Prevent Code Generation When Input Variable Controls Flow

1 Define a function `MathFunc`, which performs different mathematical operations on an input, `in`, depending on the value of the input, `flag`:

```
function out = MathFunc(flag,in) %#codegen
  %# codegen
   switch flag
     case 1
        out=sin(in);
     case 2
        out=cos(in);
     otherwise
        out=sqrt(in);
   end
```

2 Generate code for `MathFunc` using the `codegen` command:

```
codegen -config:lib MathFunc -args {1,zeros(2,2)}
```

The generated C code performs different math operations on the elements of a 2-by-2 matrix based on the input for `flag`.

3 Generate code for `MathFunc`, declaring the argument, `flag`, as a constant using `coder.Constant`:

```
codegen -config:lib MathFunc -args {coder.Constant(1),zeros(2,2)}
```

The generated C code finds the sine of the elements of a 2-by-2 matrix. The variable, `flag`, and the `switch/case/otherwise` statement do not appear in the generated code.

Generate Code with Parallel for-Loops (parfor)

This example shows how to generate C code for a MATLAB algorithm that contains a `parfor`-loop.

1. Write a MATLAB function that contains a `parfor`-loop. For example:

   ```
   function a = test_parfor %#codegen
   a=ones(10,256);
   r=rand(10,256);
   parfor i=1:10
     a(i,:)=real(fft(r(i,:)));
   end
   ```

2. Generate C code for `test_parfor`. At the MATLAB command line, enter:

   ```
   codegen -config:lib test_parfor
   ```

   Because you did not specify the maximum number of threads to use, the generated C code executes the loop iterations in parallel on the available number of cores.

3. To specify a maximum number of threads, rewrite the function `test_parfor` as follows:

   ```
   function a = test_parfor(u) %#codegen
   a=ones(10,256);
   r=rand(10,256);
   parfor (i=1:10,u)
     a(i,:)=real(fft(r(i,:)));
   end
   ```

4. Generate C code for `test_parfor`. Use `-args 0` to specify that the input, `u`, is a scalar double. At the MATLAB command line, enter:

   ```
   codegen -config:lib test_parfor -args 0
   ```

   In the generated code, the iterations of the `parfor`-loop run on at most the number of cores specified by the input, `u`. If less than `u` cores are available, the iterations run on the cores available at the time of the call.

Minimize Redundant Operations in Loops

This example shows how to minimize redundant operations in loops. When a loop operation does not depend on the loop index, performing it inside a loop is redundant. This redundancy often goes unnoticed when you are performing multiple operations in a single MATLAB statement inside a loop. For example, in the following code, the inverse of the matrix `B` is being calculated 100 times inside the loop although it does not depend on the loop index:

```
for i=1:100
     C=C + inv(B)*A^i*B;
  end
```

Performing such redundant loop operations can lead to unnecessary processing. To avoid unnecessary processing, move operations outside loops as long as they do not depend on the loop index.

1. Define a function, `SeriesFunc(A,B,n)`, that calculates the sum of `n` terms in the following power series expansion:

   $$C = 1 + B^{-1}AB + B^{-1}A^2B + \ldots$$

   ```
   function C=SeriesFunc(A,B,n)

   % Initialize C with a matrix having same dimensions as A
   C=zeros(size(A));

   % Perform the series sum
   for i=1:n
      C=C+inv(B)*A^i*B;
   end
   ```

2. Generate code for `SeriesFunc` with 4-by-4 matrices passed as input arguments for `A` and `B`:

   ```
   X = coder.typeof(zeros(4));
   codegen -config:lib -launchreport SeriesFunc -args {X,X,10}
   ```

   In the generated code, the inversion of `B` is performed `n` times inside the loop. It is more economical to perform the inversion operation once outside the loop because it does not depend on the loop index.

3. Modify `SeriesFunc` as follows:

```
  function C=SeriesFunc(A,B,n)

% Initialize C with a matrix having same dimensions as A
  C=zeros(size(A));

% Perform the inversion outside the loop
  inv_B=inv(B);

% Perform the series sum
  for i=1:n
     C=C+inv_B*A^i*B;
  end
```

This procedure performs the inversion of `B` only once, leading to faster execution of the generated code.

Unroll for-Loops

When the code generator unrolls a `for`-loop, instead of producing a `for`-loop in the generated code, it produces a copy of the loop body for each iteration. For small, tight loops, unrolling can improve performance. However, for large loops, unrolling can significantly increase code generation time and generate inefficient code.

The code generator uses heuristics to determine when to unroll a `for`-loop. To force loop unrolling, use `coder.unroll`. For example:

```
function z = call_myloop()
%#codegen
z = myloop(5);
end

function b = myloop(n)
b = zeros(1,n);
coder.unroll();
for i = 1:n
    b(i)=i+n;
end
end
```

Here is the generated code for the for-loop:

```
  z[0] = 6.0;
  z[1] = 7.0;
  z[2] = 8.0;
  z[3] = 9.0;
  z[4] = 10.0;
```

To control when a `for`-loop is unrolled, use the `coder.unroll flag` argument. For example, unroll the loop only when the number of iterations is less than 10.

```
function z = call_myloop()
%#codegen
z = myloop(5);
end

function b = myloop(n)
unroll_flag = n < 10;
b = zeros(1,n);
coder.unroll(unroll_flag);
```

```
for i = 1:n
    b(i)=i+n;
end
end
```

To unroll a `for`-loop, the code generator must be able to determine the bounds of the `for`-loop. For example, code generation fails for the following code because the value of `n` is not known at code generation time.

```
function b = myloop(n)
b = zeros(1,n);
coder.unroll();
for i = 1:n
    b(i)=i+n;
end
end
```

Disable Support for Integer Overflow or Non-Finites

The code generator produces supporting code for the following situations:

- The result of an integer operation falls outside the range that a data type can represent. This situation is known as integer overflow.
- An operation generates non-finite values (`inf` and `NaN`). The supporting code is contained in the files `rt_nonfinite.c`, `rtGetInf.c`, and `rtGetNaN.c` (with corresponding header files).

If you know that these situations do not occur, you can suppress generation of the supporting code. You therefore reduce the size of the generated code and increase its speed. However, if one of these situations occurs, it is possible that the generated code does not match the behavior of the original MATLAB code.

Disable Support for Integer Overflow

You can use the MATLAB Coder app or the command-line interface to disable support for integer overflow. When you disable this support, the overflow behavior of your generated code depends on your target C compiler. Most C compilers wrap on overflow.

- Using the app:

  1. To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow  .
  2. Click **More Settings**.
  3. On the **Speed** tab, clear `Saturate on integer overflow`.

- At the command line:

  1. Create a configuration object for code generation. Use `coder.config` with arguments `'lib'`, `'dll'`, or `'exe'` (depending on your requirements). For example:

     ```
     cfg = coder.config('lib');
     ```

  2. Set the `SaturateOnIntegerOverflow` property to `false`.

     ```
     cfg.SaturateOnIntegerOverflow = false;
     ```

Disable Support for Non-Finite Numbers

You can use the MATLAB Coder app or the command-line interface to disable support for non-finite numbers(`inf` and `NaN`).

- Using the app:

  1. To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow  .
  2. Set **Build type** to `Source Code`, `Static Library`, `Dynamic Library`, or `Executable` (depending on your requirements).
  3. Click **More Settings**.
  4. On the **Speed** tab, clear the **Support non-finite numbers** check box.

- At the command line:

  1. Create a configuration object for code generation. Use `coder.config` with arguments `'lib'`, `'dll'`, or `'exe'` (depending on your requirements). For example:

     ```
     cfg = coder.config('lib');
     ```

  2. Set the `SupportNonFinite` property to `false`.

     ```
     cfg.SupportNonFinite = false;
     ```

Integrate External/Custom Code

This example shows how to integrate external or custom code to enhance performance of generated code. Although MATLAB Coder generates optimized code for most applications, you might have custom code optimized for your specific requirements. For example:

- You have custom libraries optimized for your target environment.
- You have custom libraries for functions not supported by MATLAB Coder.
- You have custom libraries that meet standards set by your company.

In such cases, you can integrate your custom code with the code generated by MATLAB Coder.

This example illustrates how to integrate the function `cublasSgemm` from the NVIDIA® CUDA® Basic Linear Algebra Subroutines (CUBLAS) library in generated code. This function performs matrix multiplication on a Graphics Processing Unit (GPU).

1 Define a class `ExternalLib_API` that derives from the class `coder.ExternalDependency`. `ExternalLib_API` defines an interface to the `CUBLAS` library through the following methods:

   - `getDescriptiveName`: Returns a descriptive name for `ExternalLib_API` to be used for error messages.
   - `isSupportedContext`: Determines if the build context supports the `CUBLAS` library.
   - `updateBuildInfo`: Adds header file paths and link files to the build information.
   - `GPU_MatrixMultiply`: Defines the interface to the `CUBLAS` library function `cublasSgemm`.

   ExternalLib_API.m

```
classdef ExternalLib_API < coder.ExternalDependency
    %#codegen

    methods (Static)

        function bName = getDescriptiveName(~)
            bName = 'ExternalLib_API';
```

```
end

function tf = isSupportedContext(ctx)
    if  ctx.isMatlabHostTarget()
        tf = true;
    else
        error('CUBLAS library not available for this target');
    end
end

function updateBuildInfo(buildInfo, ctx)
    [~, linkLibExt, ~, ~] = ctx.getStdLibInfo();

    % Include header file path
    % Include header files later using coder.cinclude
    hdrFilePath = 'C:\My_Includes';
    buildInfo.addIncludePaths(hdrFilePath);

    % Include link files
    linkFiles = strcat('libcublas', linkLibExt);
    linkPath = 'C:\My_Libs';
    linkPriority = '';
    linkPrecompiled = true;
    linkLinkOnly = true;
    group = '';
    buildInfo.addLinkObjects(linkFiles, linkPath, ...
        linkPriority, linkPrecompiled, linkLinkOnly, group);

    linkFiles = strcat('libcudart', linkLibExt);
    buildInfo.addLinkObjects(linkFiles, linkPath, ...
        linkPriority, linkPrecompiled, linkLinkOnly, group);

end

%API for library function 'cuda_MatrixMultiply'
function C = GPU_MatrixMultiply(A, B)
    assert(isa(A,'single'), 'A must be single.');
    assert(isa(B,'single'), 'B must be single.');

    if(coder.target('MATLAB'))
        C=A*B;
    else

        % Include header files
```

```
%     for external functions and typedefs
% Header path included earlier using updateBuildInfo
coder.cinclude('"cuda_runtime.h"');
coder.cinclude('"cublas_v2.h"');

% Compute dimensions of input matrices
m = int32(size(A, 1));
k = int32(size(A, 2));
n = int32(size(B, 2));

% Declare pointers to matrices on destination GPU
d_A = coder.opaque('float*');
d_B = coder.opaque('float*');
d_C = coder.opaque('float*');

% Compute memory to be allocated for matrices
% Single = 4 bytes
size_A = m*k*4;
size_B = k*n*4;
size_C = m*n*4;

% Define error variables
error = coder.opaque('cudaError_t');
cudaSuccessV = coder.opaque('cudaError_t', ...
    'cudaSuccess');

% Assign memory on destination GPU
error = coder.ceval('cudaMalloc', ...
    coder.wref(d_A), size_A);
assert(error == cudaSuccessV, ...
    'cudaMalloc(A) failed');
error = coder.ceval('cudaMalloc', ...
    coder.wref(d_B), size_B);
assert(error == cudaSuccessV, ...
    'cudaMalloc(B) failed');
error = coder.ceval('cudaMalloc', ...
    coder.wref(d_C), size_C);
assert(error == cudaSuccessV, ...
    'cudaMalloc(C) failed');

% Define direction of copying
hostToDevice = coder.opaque('cudaMemcpyKind', ...
    'cudaMemcpyHostToDevice');
```

```
% Copy matrices to destination GPU
error = coder.ceval('cudaMemcpy',  ...
    d_A, coder.rref(A), size_A, hostToDevice);
assert(error == cudaSuccessV, 'cudaMemcpy(A) failed');

error = coder.ceval('cudaMemcpy',  ...
    d_B, coder.rref(B), size_B, hostToDevice);
assert(error == cudaSuccessV, 'cudaMemcpy(B) failed');

% Define type and size for result
C = zeros(m, n, 'single');

error = coder.ceval('cudaMemcpy', ...
    d_C, coder.rref(C), size_C, hostToDevice);
assert(error == cudaSuccessV, 'cudaMemcpy(C) failed');

% Define handle variables for external library
handle = coder.opaque('cublasHandle_t');
blasSuccess = coder.opaque('cublasStatus_t', ...
    'CUBLAS_STATUS_SUCCESS');

% Initialize external library
ret = coder.opaque('cublasStatus_t');
ret = coder.ceval('cublasCreate', coder.wref(handle));
assert(ret == blasSuccess, 'cublasCreate failed');

TRANSA = coder.opaque('cublasOperation_t', ...
    'CUBLAS_OP_N');
alpha = single(1);
beta = single(0);

% Multiply matrices on GPU
ret = coder.ceval('cublasSgemm', handle, ...
    TRANSA,TRANSA,m,n,k, ...
    coder.rref(alpha),d_A,m, ...
    d_B,k, ...
    coder.rref(beta),d_C,k);

assert(ret == blasSuccess, 'cublasSgemm failed');

% Copy result back to local host
deviceToHost = coder.opaque('cudaMemcpyKind', ...
    'cudaMemcpyDeviceToHost');
```

```
                error = coder.ceval('cudaMemcpy', coder.wref(C), ...
                    d_C, size_C, deviceToHost);
                assert(error == cudaSuccessV, 'cudaMemcpy(C) failed');

            end
        end
    end
end
```

2 To perform the matrix multiplication using the interface defined in method `GPU_MatrixMultiply` and the build information in `ExternalLib_API`, include the following line in your MATLAB code:

```
C= ExternalLib_API.GPU_MatrixMultiply(A,B);
```

For instance, you can define a MATLAB function `Matrix_Multiply` that solely performs this matrix multiplication.

```
function C = Matrix_Multiply(A, B) %#codegen
 C= ExternalLib_API.GPU_MatrixMultiply(A,B);
```

3 Define a `MEX` configuration object using `coder.config`. For using the `CUBLAS` libraries, set the target language for code generation to `C++`.

```
cfg=coder.config('mex');
cfg.TargetLang='C++';
```

4 Generate code for `Matrix_Multiply` using `cfg` as the configuration object and two `2 X 2` matrices of type `single` as arguments. Since `cublasSgemm` supports matrix multiplication for data type `float`, the corresponding MATLAB matrices must have type `single`.

```
codegen -config cfg Matrix_Multiply ...
            -args {ones(2,'single'),ones(2,'single')}
```

5 Test the generated `MEX` function `Matrix_Multiply_mex` using two `2 X 2` identity matrices of type `single`.

```
Matrix_Multiply_mex(eye(2,'single'),eye(2,'single'))
```

The output is also a `2 X 2` identity matrix.

Generate Reusable Code

With MATLAB, you can generate reusable code in the following ways:

- Write reusable functions using standard MATLAB function file names which you can call from different locations, for example, in a Simulink model or MATLAB function library.
- Compile external functions on the MATLAB path and integrate them into generated C code for embedded targets.

See “Resolution of Function Calls for Code Generation” (MATLAB Coder).

Common applications include:

- Overriding generated library function with a custom implementation.
- Implementing a reusable library on top of standard library functions that can be used with Simulink.
- Swapping between different implementations of the same function.

LAPACK Calls for Linear Algebra in a MATLAB Function Block

To improve the simulation speed of MATLAB Function block algorithms that call certain linear algebra functions, Simulink can call LAPACK functions. LAPACK is a software library for numerical linear algebra. If the input arrays for the linear algebra functions meet certain criteria, the simulation calls LAPACK functions in the LAPACK library that is included with MATLAB. MATLAB uses LAPACK in some linear algebra functions such as `eig` and `svd`.

If you use Simulink Coder to generate code for these algorithms, you can specify that the code generator produce LAPACK function calls. The code generator uses the LAPACKE C interface to LAPACK. If you specify that you want to generate LAPACK calls, and the input arrays for the linear algebra functions meet the criteria, the code generator produces LAPACK calls. The build process links to the LAPACK library that you specify. See "Speed Up Linear Algebra in Code Generated from a MATLAB Function Block" (Simulink Coder).

Troubleshooting MATLAB Code in MATLAB Function Blocks

Compile-Time Recursion Limit Reached

Issue

You see a message such as:

```
Compile-time recursion limit reached. Size or type of
input #1 of function 'foo' may change at every call.
```

```
Compile-time recursion limit reached. Size of input #1
of function 'foo' may change at every call.
```

```
Compile-time recursion limit reached. Value of input #1
of function 'foo' may change at every call.
```

Cause

With compile-time recursion, the code generator produces multiple versions of the recursive function instead of producing a recursive function in the generated code. These versions are known as function specializations. The code generator is unable to use compile-time recursion for a recursive function in your MATLAB code because the number of function specializations exceeds the limit.

Solutions

To address the issue, try one of these solutions:

- “Force Run-Time Recursion” on page 58-2
- “Increase the Compile-Time Recursion Limit” on page 58-5

Force Run-Time Recursion

- For this message:

  ```
  Compile-time recursion limit reached. Value of input #1
  of function 'foo' may change at every call.
  ```

  Use this solution:

  “Force Run-Time Recursion by Treating the Input Value as Nonconstant” on page 58-3.

- For this message:

  ```
  Compile-time recursion limit reached. Size of input #1
  of function 'foo' may change at every call.
  ```

  Use this solution:

  "Force Run-Time Recursion by Making the Input Variable-Size" on page 58-4.

- For this message:

  ```
  Compile-time recursion limit reached. Size or type of
  input #1 of function 'foo' may change at every call.
  ```

  In the MATLAB Function report, look at the function specializations. If you can see that the size of an argument is changing for each function specialization, then try this solution:

  "Force Run-Time Recursion by Making the Input Variable-Size" on page 58-4.

Force Run-Time Recursion by Treating the Input Value as Nonconstant

Consider this function:

```
function y = call_recfcn(n)
A = ones(1,n);
x = 100;
y = recfcn(A,x);
end

function y = recfcn(A,x)
if size(A,2) == 1 || x == 1
    y = A(1);
else
    y = A(1)+recfcn(A(2:end),x-1);
end
end
```

The second input to `recfcn` has the constant value 100. The code generator determines that the number of recursive calls is finite and tries to produce 100 copies of `recfcn`. This number of specializations exceeds the compile-time recursion limit. To force run-time recursion, instruct the code generator to treat the second input as a nonconstant value by using `coder.ignoreConst`.

```
function y = call_recfcn(n)
A = ones(1,n);
x = coder.ignoreConst(100);
y = recfcn(A,x);
end

function y = recfcn(A,x)
if size(A,2) == 1 || x == 1
    y = A(1);
else
    y = A(1)+recfcn(A(2:end),x-1);
end
end
```

If the code generator cannot determine that the number of recursive calls is finite, it produces a run-time recursive function.

Force Run-Time Recursion by Making the Input Variable-Size

Consider this function:

```
function z = call_mysum(A)
%#codegen
z = mysum(A);
end

function y = mysum(A)
coder.inline('never');
if size(A,2) == 1
    y = A(1);
else
    y = A(1)+ mysum(A(2:end));
end
end
```

If the input to `mysum` is fixed-size, the code generator uses compile-time recursion. If `A` is large enough, the number of function specializations exceeds the compile-time limit. To cause the code generator to use run-time conversion, make the input to `mysum` variable-size by using `coder.varsize`.

```
function z = call_mysum(A)
%#codegen
B = A;
coder.varsize('B');
```

```
z = mysum(B);
end

function y = mysum(A)
coder.inline('never');
if size(A,2) == 1
    y = A(1);
else
    y = A(1)+ mysum(A(2:end));
end
end
```

Increase the Compile-Time Recursion Limit

The default compile-time recursion limit of 50 is large enough for most recursive functions that require compile-time recursion. Usually, increasing the limit does not fix the issue. However, if you can determine the number of recursive calls and you want compile-time recursion, increase the limit. For example, consider this function:

```
function z = call_mysum()
%#codegen
B = 1:125;
z = mysum(B);
end

function y = mysum(A)
coder.inline('never');
if size(A,2) == 1
    y = A(1);
else
    y = A(1)+ mysum(A(2:end));
end
end
```

You can determine that the code generator produces 125 copies of the `mysum` function. In this case, if you want compile-time recursion, increase the compile-time recursion limit to 125.

To increase the limit, increase the value of the **Compile-time recursion limit for MATLAB functions** configuration parameter.

Output Variable Must Be Assigned Before Run-Time Recursive Call

Issue

You see one of these messages:

```
All outputs must be assigned before any run-time
recursive call. Output 'y' is not assigned here.

Simulink does not have enough information to determine output
sizes for this block
```

.

Cause

Run-time recursion produces a recursive function in the generated code. The code generator is unable to use run-time recursion for a recursive function in your MATLAB code because an output is not assigned before the first recursive call.

Solution

Rewrite the code so that it assigns the output before the recursive call.

Direct Recursion Example

In the following code, the statement `y = A(1)` assigns a value to the output `y`. This statement occurs after the recursive call `y = A(1)+ mysum(A(2:end))`.

```
function z = call_mysum(A)
B = A;
coder.varsize('B');
z = mysum(B);
end

function y = mysum(A)
coder.inline('never');
if size(A,2) > 1
    y = A(1)+ mysum(A(2:end));
```

```
else
    y = A(1);
end
end
```

Rewrite the code so that assignment `y = A(1)` occurs in the `if` block and the recursive call occurs in the `else` block.

```
function z = call_mysum(A)
B = A;
coder.varsize('B');
z = mysum(B);
end

function y = mysum(A)
coder.inline('never');

if size(A,2) == 1
    y = A(1);
else
    y = A(1)+ mysum(A(2:end));
end
end
```

Alternatively, before the `if` block, add an assignment, for example, `y = 0`.

```
function z = call_mysum(A)
B = A;
coder.varsize('B');
z = mysum(B);
end

function y = mysum(A)
coder.inline('never');
y = 0;
if size(A,2) > 1
    y = A(1)+ mysum(A(2:end));

else
    y = A(1);
end
end
```

Indirect Recursion Example

In the following code, `rec1` calls `rec2` before the assignment `y = 0`.

```
function z = callrec(n)
z = rec1(n);
end

function y = rec1(x)
%#codegen

if x >= 0
    y = rec2(x-1)+1;
else
    y = 0;
end
end

function y = rec2(x)
y = rec1(x-1)+2;
end
```

Rewrite this code so that in `rec1`, the assignment `y = 0` occurs in the `if` block and the recursive call occurs in the `else` block.

```
function z = callrec(n)
z = rec1(n);
end

function y = rec1(x)
%#codegen

if x < 0
    y = 0;
else
    y = rec2(x-1)+1;
end
end

function y = rec2(x)
y = rec1(x-1)+2;
end
```

Unable to Determine That Every Element of Cell Array Is Assigned

Issue

You see one of these messages:

```
Unable to determine that every element of 'y' is
assigned before this line.

Unable to determine that every element of 'y' is
assigned before exiting the function.

Unable to determine that every element of 'y' is
assigned before exiting the recursively called function.
```

Cause

For code generation, before you use a cell array element, you must assign a value to it. When you use `cell` to create a variable-size cell array, for example, `cell(1,n)`, MATLAB assigns an empty matrix to each element. However, for code generation, the elements are unassigned. For code generation, after you use `cell` to create a variable-size cell array, you must assign all elements of the cell array before any use of the cell array.

The code generator analyzes your code to determine whether all elements are assigned before the first use of the cell array. The code generator detects that all elements are assigned when the code follows this pattern:

```
function z = mycell(n, j)
%#codegen
assert(n < 100);
x = cell(1,n);
for i = 1:n
    x{i} = i;
end
z = x{j};
end
```

Here is the pattern for a multidimensional cell array:

```
function z = mycell(m,n,p)
%#codegen
assert(m < 100);
assert(n < 100);
assert(p < 100);
x = cell(m,n,p);
for i = 1:m
    for j =1:n
        for k = 1:p
            x{i,j,k} = i+j+k;
        end
    end
end
z = x{m,n,p};
end
```

If the code generator detects that some elements are not assigned, code generation fails. Sometimes, even though your code assigns all elements of the cell array, code generation fails because the analysis does not detect that all elements are assigned.

Here are examples where the code generator is unable to detect that elements are assigned:

- Elements are assigned in different loops

  ```
  ...
  x = cell(1,n)
  for i = 1:5
      x{i} = 5;
  end
  for i = 6:n
      x{i} = 7;
  end
  ...
  ```

- The variable that defines the loop end value is not the same as the variable that defines the cell dimension.

  ```
  ...
  x = cell(1,n);
  m = n;
  for i = 1:m
      x{i} = 2;
  end
  ...
  ```

For more information, see “Definition of Variable-Size Cell Array by Using cell” on page 52-9.

Solution

Try one of these solutions:

- “Use recognized pattern for assigning elements” on page 58-13
- “Use repmat” on page 58-13
- “Use coder.nullcopy” on page 58-14

Use recognized pattern for assigning elements

If possible, rewrite your code to follow this pattern:

```
...
x = cell(1,n);
for i = 1:n
    x{i} = i;
end
z = x{j};
...
```

Use repmat

Sometimes, you can use `repmat` to define the variable-size cell array.

Consider this code that defines a variable-size cell array. It assigns the value 1 to odd elements and the value 2 to even elements.

```
function z = mycell2(n, j)
%#codegen
assert(n < 100);
c =cell(1,n);
for i = 1:2:n-1
    c{i} = 1;
end
for i = 2:2:n
    c{i} = 2;
end
z = c{j};
```

Code generation does not allow this code because:

- More than one loop assigns the elements.
- The loop counter does not increment by 1.

Rewrite the code to first use `cell` to create a 1-by-2 cell array whose first element is 1 and whose second element is 2. Then, use `repmat` to create a variable-size cell array whose element values alternate between 1 and 2.

```
function z = mycell2(n, j)
%#codegen
assert(n < 100);
c = cell(1,2);
c{1} = 1;
c{2} = 2;
c1= repmat(c,1,n);
z = c1{j};
end
```

Use coder.nullcopy

As a last resort, you can use `coder.nullcopy` to indicate that the code generator can allocate the memory for your cell array without initializing the memory. For example:

```
function z = mycell3(n, j)
%#codegen
assert(n < 100);
c =cell(1,n);
c1 = coder.nullcopy(c);
for i = 1:4
    c1{i} = 1;
end
for i = 5:n
    c1{i} = 2;
end
z = c1{j};
end
```

Use `coder.nullcopy` with caution. If you access uninitialized memory, results are unpredictable.

- “Cell Array Limitations for Code Generation” on page 52-8

Nonconstant Index into varargin or varargout in a for-Loop

Issue

Your MATLAB code contains a `for`-loop that indexes into `varargin` or `varargout`. When you generate code, you see this error message:

```
Non-constant expression or empty matrix. This expression
must be constant because its value determines the size
or class of some expression.
```

Cause

At code generation time, the code generator must be able to determine the value of an index into `varargin` or `varagout`. When `varargin` or `varagout` are indexed in a `for`-loop, the code generator determines the index value for each loop iteration by unrolling the loop. Loop unrolling makes a copy of the loop body for each loop iteration. In each iteration, the code generator determines the value of the index from the loop counter.

The code generator is unable to determine the value of an index into `varargin` or `varagout` when:

- The number of copies of the loop body exceeds the limit for loop unrolling.
- Heuristics fail to identify that loop unrolling is warranted for a particular `for`-loop. For example, consider the following function:

  ```
  function [x,y,z] = fcn(a,b,c)
  %#codegen

  [x,y,z] = subfcn(a,b,c);

  function varargout = subfcn(varargin)
  j = 0;
  for i = 1:nargin
      j = j+1;
      varargout{j} = varargin{j};
  end
  ```

  The heuristics do not detect the relationship between the index `j` and the loop counter `i`. Therefore, the code generator does not unroll the `for`-loop.

Solution

Use one of these solutions:

- “Force Loop Unrolling” on page 58-17
- “Rewrite the Code” on page 58-17

Force Loop Unrolling

Force loop unrolling by using `coder.unroll`. For example:

```
function [x,y,z] = fcn(a,b,c)
%#codegen
[x,y,z] = subfcn(a,b,c);

function varargout = subfcn(varargin)
j = 0;

coder.unroll();
for i = 1:nargin
    j = j + 1;
    varargout{j} = varargin{j};
end
```

Rewrite the Code

Rewrite the code so that the code generator can detect the relationship between the index and the loop counter. For example:

```
function [x,y,z] = fcn(a,b,c)
%#codegen
[x,y,z] = subfcn(a,b,c);

function varargout = subfcn(varargin)
for i = 1:nargin
    varargout{i} = varargin{i};
end
```

Unknown Output Type for coder.ceval

Issue

You see this error message:

```
Output of 'coder.ceval' has unknown type. The enclosing
expression cannot be evaluated.
Specify the output type by assigning the output of
'coder.ceval' to a variable with a known type.
```

Cause

This error message occurs when the code generator cannot determine the output type of a `coder.ceval` call.

Solution

Initialize a temporary variable with the expected output type. Assign the output of `coder.ceval` to this variable.

Example

Assume that you have a C function called `cFunctionThatReturnsDouble`. You want to generate C library code for a function `foo`. The code generator returns the error message because it cannot determine the return type of `coder.ceval`.

```
function foo
%#codegen
callFunction(coder.ceval('cFunctionThatReturnsDouble'));
end

function callFunction(~)
end
```

To fix the error, define the type of the C function output by using a temporary variable.

```
function foo
%#codegen
temp = 0;
temp = coder.ceval('cFunctionThatReturnsDouble');
```

```
callFunction(temp);
end

function callFunction(~)
end
```

You can also use `coder.opaque` to initialize the temporary variable.

Example Using Classes

Assume that you have a class with a custom `set` method. This class uses the `set` method to ensure that the object property value falls within a certain range.

```
classdef classWithSetter
   properties
      expectedResult = []
   end
   properties(Constant)
      scalingFactor = 0.001
   end
   methods
      function obj = set.expectedResult(obj,erIn)
         if erIn >= 0 && erIn <= 100
            erIn = erIn.*obj.scalingFactor;
            obj.expectedResult = erIn;
         else
            obj.expectedResult = NaN;
         end
      end
   end
end
```

When generating C library code for the function `foo`, the code generator produces the error message. The input type into the `set` method cannot be determined.

```
function foo
%#codegen
obj = classWithSetter;
obj.expectedResult = coder.ceval('cFunctionThatReturnsDouble');
end
```

To fix the error, initialize a temporary variable with a known type. For this example, use a type of scalar double.

```
function foo
%#codegen
obj = classWithSetter;
temp = 0;
temp = coder.ceval('cFunctionThatReturnsDouble');
obj.expectedResult = temp;
end
```

Managing Data

Working with Data

About Data Types in Simulink

In this section...

About Data Types

The term *data type* refers to the way in which a computer represents numbers in memory. A data type determines the amount of storage allocated to a number, the method used to encode the number's value as a pattern of binary digits, and the operations available for manipulating the type. Most computers provide a choice of data types for representing numbers, each with specific advantages in the areas of precision, dynamic range, performance, and memory usage. To optimize performance, you can specify the data types of variables used in the MATLAB technical computing environment. Simulink builds on this capability by allowing you to specify the data types of Simulink signals and block parameters.

The ability to specify the data types of a model's signals and block parameters is particularly useful in real-time control applications. For example, it allows a Simulink model to specify the optimal data types to use to represent signals and block parameters in code generated from a model by automatic code-generation tools, such as the Simulink Coder product. By choosing the most appropriate data types for your model's signals and parameters, you can dramatically increase performance and decrease the size of the code generated from the model.

Simulink performs extensive checking before and during a simulation to ensure that your model is *typesafe*, that is, that code generated from the model will not overflow or underflow and thus produce incorrect results. Simulink models that use the default data type (`double`) are inherently typesafe. Thus, if you never plan to generate code from your model or use a nondefault data type in your models, you can skip the remainder of this section.

On the other hand, if you plan to generate code from your models and use nondefault data types, read the remainder of this section carefully, especially the section on data type rules (see “Data Typing Guidelines” on page 59-4). In that way, you can avoid introducing data type errors that prevent your model from running to completion or simulating at all.

Data Typing Guidelines

Observing the following rules can help you to create models that are typesafe and, therefore, execute without error:

- Signal data types generally do not affect parameter data types, and vice versa.

  A significant exception to this rule is the Constant block, whose output data type is determined by the data type of its parameter.
- If the output of a block is a function of an input and a parameter, and the input and parameter differ in type, Simulink converts the parameter to the input type before computing the output.
- In general, a block outputs the data type that appears at its inputs.

  Significant exceptions include Constant blocks and Data Type Conversion blocks, whose output data types are determined by block parameters.
- Virtual blocks accept signals of any type on their inputs.

  Examples of virtual blocks include Mux and Demux blocks and unconditionally executed subsystems.
- The elements of a signal array connected to a port of a nonvirtual block must be of the same data type.
- The signals connected to the input data ports of a nonvirtual block cannot differ in type.
- Control ports (for example, Enable and Trigger ports) accept any data type.
- Solver blocks accept only `double` signals.
- Connecting a non-`double` signal to a block disables zero-crossing detection for that block.

Data Type Propagation

Whenever you start a simulation, enable display of port data types, or refresh the port data type display, Simulink performs a processing step called data type propagation. This step involves determining the types of signals whose type is not otherwise specified and checking the types of signals and input ports to ensure that they do not conflict. If type conflicts arise, an error dialog is displayed that specifies the signal and port whose data types conflict. The signal path that creates the type conflict is also highlighted.

Note You can insert typecasting (data type conversion) blocks in your model to resolve type conflicts. For more information, see Data Type Conversion.

- “Specify Fixed-Point Data Types” on page 59-37
- “Data Types Supported by Simulink” on page 59-6

Data Types Supported by Simulink

Simulink supports all built-in numeric MATLAB data types except `int64` and `uint64`. The term *built-in data type* refers to data types defined by MATLAB itself as opposed to data types defined by MATLAB users. Unless otherwise specified, the term data type in the Simulink documentation refers to built-in data types.

The following table lists the built-in MATLAB data types supported by Simulink.

Name	Description
`double`	Double-precision floating point
`single`	Single-precision floating point
`int8`	Signed 8-bit integer
`uint8`	Unsigned 8-bit integer
`int16`	Signed 16-bit integer
`uint16`	Unsigned 16-bit integer
`int32`	Signed 32-bit integer
`uint32`	Unsigned 32-bit integer

Besides these built-in types, Simulink defines a `boolean` (`true` or `false`) type. The values `1` and `0` represent `true` and `false` respectively. For this data type, Simulink represents real, nonzero numeric values (including `Inf`) as `true` (`1`).

Block Support for Data and Signal Types

All Simulink blocks accept signals of type `double` by default. Some blocks prefer `boolean` input and others support multiple data types on their inputs. For more information on the data types supported by a specific block for parameter and input and output values, in the Simulink documentation see the Data Type Support section of the reference page for that block. If the documentation for a block does not specify a data type, the block inputs or outputs only data of type `double`.

Several blocks support bus objects (`Simulink.Bus`) as data types. See “Data Types for Bus Signals” on page 59-52.

Many Simulink blocks also support fixed-point data types. For more information about fixed-point data, see “Specify Fixed-Point Data Types” on page 59-37. For more

information on the data types supported by a specific block for parameter and input and output values, in the Simulink documentation see the Data Type Support section of the reference page for that block. If the documentation for a block does not specify a data type, the block inputs or outputs only data of type `double`.

To view a table that summarizes the data types supported by the blocks in the Simulink block libraries, execute the following command at the MATLAB command line:

```
showblockdatatypetable
```

- “Specify Data Types Using Data Type Assistant” on page 59-39
- “About Data Types in Simulink” on page 59-3

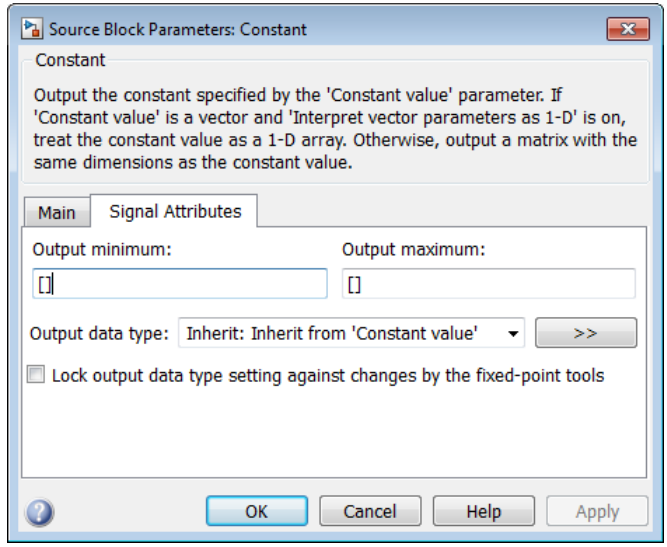
Control Signal Data Types

To control the data type of a signal in a Simulink model, you specify a data type for the corresponding block output.

You can also introduce a new signal of a specific data type into a model in any of the following ways:

- Load signal data of the desired type from the MATLAB workspace into your model via a root-level Inport block or a From Workspace block.
- Create a Constant block in your model and set its parameter to the desired type.
- Use a Data Type Conversion block to convert a signal to the desired data type.

Simulink blocks determine the data type of their outputs by default. Many blocks allow you to override the default type and explicitly specify an output data type, using a block parameter that is typically named **Output data type**. For example, the **Output data type** parameter appears on the **Signal Attributes** pane of the Constant block dialog box.



See the following topics for more information:

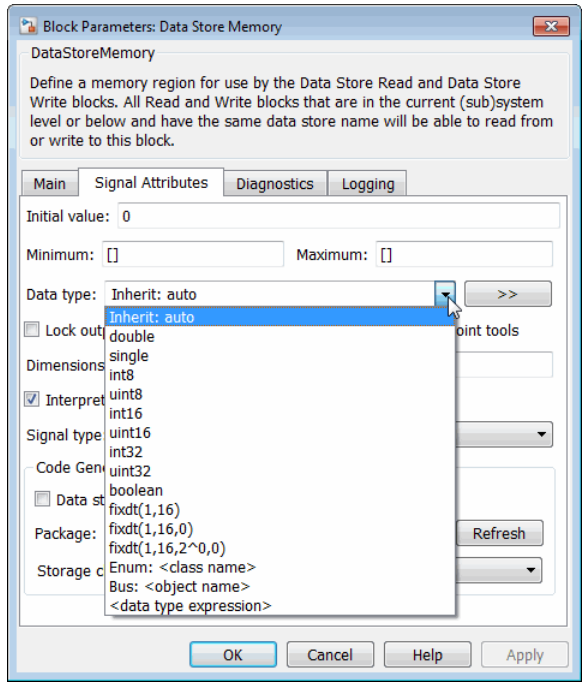
For Information About...	See...
Valid data type values that you can specify	"Entering Valid Data Type Values" on page 59-9
An assistant that helps you specify valid data type values	"Specify Data Types Using Data Type Assistant" on page 59-39
Specifying valid data type values for multiple blocks simultaneously	"Use the Model Data Editor for Batch Editing" on page 59-12

Entering Valid Data Type Values

In general, you can specify the output data type as any of the following:

- A rule that inherits a data type (see "Data Type Inheritance Rules" on page 59-10)
- The name of a built-in data type (see "Built-In Data Types" on page 59-11)
- An expression that evaluates to a data type (see "Data Type Expressions" on page 59-12)

Valid data type values vary among blocks. You can use the pull-down menu associated with a block data type parameter to view the data types that a particular block supports. For example, the **Data type** pull-down menu on the Data Store Memory block dialog box lists the data types that it supports, as shown here.



For more information about the data types that a specific block supports, see the documentation for the block in the Simulink documentation.

Data Type Inheritance Rules

Blocks can inherit data types from a variety of sources, including signals to which they are connected and particular block parameters. You can specify the value of a data type parameter as a rule that determines how the output signal inherits its data type. To view the inheritance rules that a block supports, use the data type pull-down menu on the block dialog box. The following table lists typical rules that you can select.

Inheritance Rule	Description
`Inherit: Inherit via back propagation`	Simulink automatically determines the output data type of the block during data type propagation (see “Data Type Propagation” on page 59-4). In this case, the block uses the data type of a downstream block or signal object.

Inheritance Rule	Description
`Inherit: Same as input`	The block uses the data type of its sole input signal for its output signal.
`Inherit: Same as first input`	The block uses the data type of its first input signal for its output signal.
`Inherit: Same as second input`	The block uses the data type of its second input signal for its output signal.
`Inherit: Inherit via internal rule`	The block uses an internal rule to determine its output data type. The internal rule chooses a data type that optimizes numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. It is not always possible for the software to optimize efficiency and numerical accuracy at the same time.

When you apply inherited data types to a signal, Simulink determines the specific data type of the signal only after you update the block diagram.

- To display this specific data type on the block diagram, see “Port Data Types” on page 64-66.
- To inspect this specific data type for multiple signals in a searchable, sortable table, use the Model Data Editor (**View > Model Data**). The right side of the **Data Type** column shows the specific data type for each signal. For more information about the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 59-141.

Built-In Data Types

You can specify the value of a data type parameter as the name of a built-in data type, for example, `single` or `boolean`. To view the built-in data types that a block supports, use the data type pull-down menu on the block dialog box. See “Data Types Supported by Simulink” on page 59-6 for a list of all built-in data types that are supported.

Data Type Expressions

You can specify the value of a data type parameter as an expression that evaluates to a numeric data type object. Simply enter the expression in the data type field on the block dialog box. In general, enter one of the following expressions:

- **`fixdt` Command**

  Specify the value of a data type parameter as a command that invokes the `fixdt` function. This function allows you to create a `Simulink.NumericType` object that describes a fixed-point or floating-point data type. See the documentation for the `fixdt` function for more information.

- **Data Type Object Name**

  Specify the value of a data type parameter as the name of a data object that represents a data type. Simulink data objects that you instantiate from classes, such as `Simulink.NumericType` and `Simulink.AliasType`, simplify the task of making model-wide changes to output data types and allow you to use custom aliases for data types. See "Data Objects" on page 59-53 for more information about Simulink data objects.

Use the Model Data Editor for Batch Editing

Using the Model Data Editor (see "Configure Data Properties by Using the Model Data Editor" on page 59-141), you can assign the same data type to multiple signals simultaneously. You can use this technique to design the interface of your model by configuring data types and other attributes of multiple Inport and Outport blocks at once (see "Configure Data Interface for Component" on page 22-16). You can also finely control the data types of arbitrary signals in your block algorithm.

For example, the `slexAircraftExample` model that comes with the Simulink product contains numerous Gain blocks. Suppose you want to specify the output data type of the three Gain blocks at the root level of the model as `single`. You can achieve this task as follows:

1. In the Model Data Editor (**View > Model Data**), inspect the **Signals** tab.
2. Next to the **Filter contents** box, toggle the **Filter using selection** button.
3. At the top level of the model, select the signal lines that represent the outputs of the three Gain blocks (labeled `Zw`, `Mw`, and `Mq`). The Model Data Editor shows three rows that correspond to the three signals.

4 In the Model Data Editor, select all three signals (rows). For example, you can press **Ctrl+A** or hold **Shift** while clicking the top and bottom rows in the **Source** column.

5 For any of the three signals, click the cell in the **Data Type** column. From the drop-down list, select `single`. The Model Data Editor applies this selection to all of the selected rows.

To convert a model to a strict single precision design, see "Validate a Floating-Point Embedded Model" on page 59-17.

Share a Data Type Between Separate Algorithms, Data Paths, Models, and Bus Elements

In some cases, you cannot rely on data type inheritance (see "Data Type Inheritance Rules" on page 59-10) to establish equivalence between the data types of different data items (such as signal lines in parallel data paths or bus elements in a `Simulink.Bus` object). Instead, you can create a `Simulink.NumericType` or `Simulink.AliasType` object in a workspace or data dictionary.

Create a `Simulink.NumericType` object if you do not want to rename the shared data type by creating an alias. Set the `IsAlias` property to `false` (the default).

This example shows how to use a `Simulink.NumericType` object to share an output data type between two lookup table blocks in the same model.

1 Open the example model `sldemo_fuelsys`.

```
sldemo_fuelsys
```

The model creates `Simulink.NumericType` objects in the base workspace. One of the objects is named `s16En15`.

2 At the command prompt, inspect the properties of `s16En15`.

```
s16En15
```

```
s16En15 =

  NumericType with properties:

    DataTypeMode: 'Single'
         IsAlias: 0
```

```
      DataScope: 'Auto'
     HeaderFile: ''
    Description: ''
```

This object represents the built-in Simulink data type `single`.

3. In the model, navigate into the `fuel_rate_control/airflow_calc` subsystem.
4. Select **View > Model Data**. In the Model Data Editor, inspect the **Signals** tab.
5. In the model, click the output signal of the Pumping Constant block. The Model Data Editor **Data Type** column shows that the signal data type is set to `s16En15`.
6. Click the output signal of the Ramp Rate Ki block. The output data type of this block is also set to `s16En15`.
7. Update the block diagram and, if necessary, expand the width of the **Data Type** column. The right side of the column shows that the two lookup table blocks use the data type `single`.
8. At the command prompt, configure `s16En15` to represent the data type `double`.

   ```
   s16En15.DataTypeMode = 'Double';
   ```

9. Update the block diagram.

   The output signals of the two lookup table blocks now use the data type `double`. Due to data type inheritance, other signals, such as `e0` and `e1`, acquire the same data type.

Alternatively, to establish data type equivalence between algorithms or data paths in the same model, you can use blocks such as Data Type Propagation and Data Type Conversion Inherited. When you use these blocks, you do not need to create and permanently store a data type object. However, you cannot use the blocks to share a data type between signals in different models unless the models are in the same model reference hierarchy.

Reuse Custom C Data Types for Signal Data

In a model, you can create signals that conform to custom C data types, such as structures, that your existing C code defines. Use these signals to:

- Replace existing C code with a Simulink model.
- Integrate C code for simulation in Simulink (for example, by using the Legacy Code Tool).

- Prepare to generate code (Simulink Coder) that you can integrate with existing code.

Use these techniques to match your custom data types:

- For a structure type, create a `Simulink.Bus` object. Use the object as the data type for bus signals. See "Data Types for Bus Signals" on page 59-52.
- For an enumeration, create an enumeration class and use it as the data type for signals. See "Use Enumerated Data in Simulink Models" on page 60-7.
- To match a `typedef` statement that represents an alias of a primitive, numeric data type, use a `Simulink.AliasType` object as the data type for signals. See `Simulink.AliasType`.

To create these classes and objects, you can use the function `Simulink.importExternalCTypes`.

Determine Data Type of Signal That Uses Inherited Setting

When a signal uses an inherited data type setting such as `Inherit: Inherit via internal rule` (the default setting for most blocks), to determine the meaningful data type that the signal uses for simulation, update the block diagram and then use one or both of these techniques:

- In the Simulink Editor, select **Display > Signals & Ports > Port Data Types**. The data types appear on the block diagram next to each signal. For more information, see "Port Data Types" on page 64-66.
- Inspect the right side of the **Data Type** column in the Model Data Editor (**View > Model Data**). For more information about the Model Data Editor, see "Configure Data Properties by Using the Model Data Editor" on page 59-141.

Using these techniques to inspect data types helps you to:

- Design the data type strategy for a model on a high level.
- Debug numerical issues due to quantization and overflows.
- Make a model more easily understood when sharing it.

For more information, see "Port Data Types" on page 64-66.

Data Types Remain double Despite Changing Settings

If many of the data items (signals, parameters, and states) in your model continue to use the data type `double` after you configure block parameters such as **Output data type**, confirm that the model is not configured to override data types. See “Control Data Type Override” on page 59-35.

Validate a Floating-Point Embedded Model

You can use data type override mode to temporarily switch the data types in your model. This capability allows you to maintain one model but simulate your model using multiple data types, and validate the numerical behavior for each type. For example, if you implement an algorithm using double-precision data types and want to check whether the algorithm is also suitable for single-precision use, you can apply a data type override to floating-point data types to replace all doubles with singles without permanently affecting any other data types in your model.

Apply a Data Type Override to Floating-Point Data Types

To apply data type override, you must specify the data type that you want to apply and the data type that you want to replace.

You can set data type override using the following method. This example changes all floating-point data types to single.

For example:

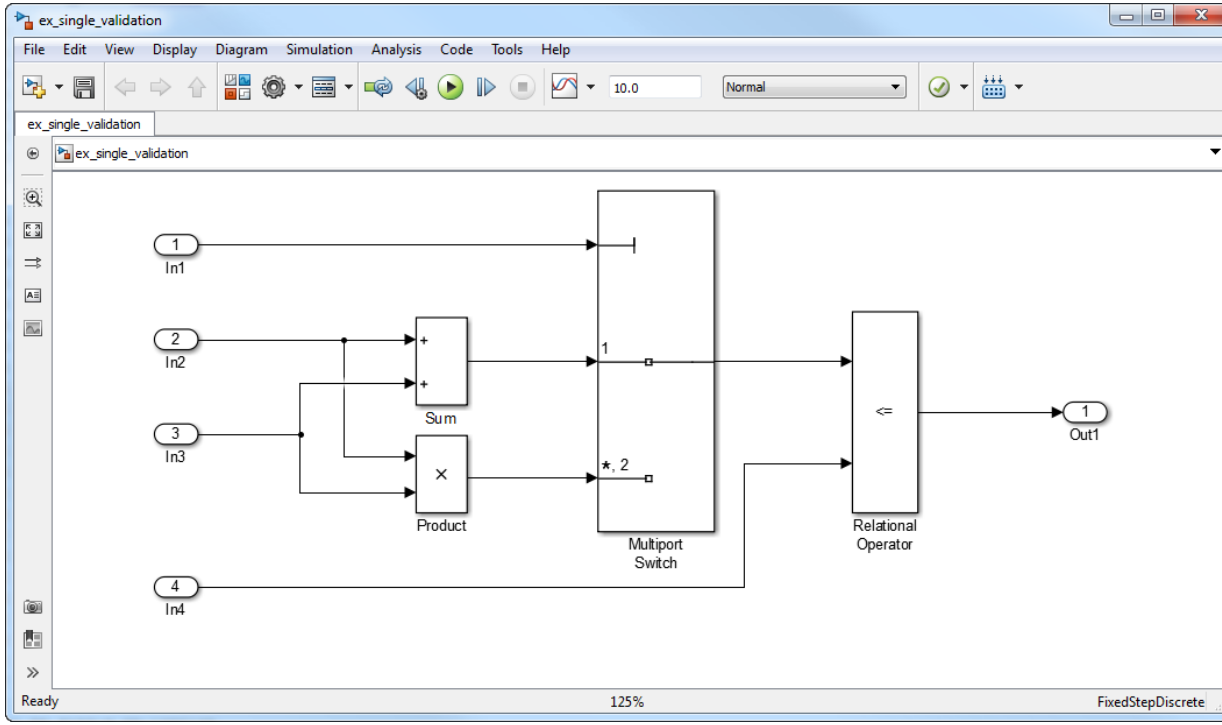
```
set_param(gcs, 'DataTypeOverride', 'Single',...
 'DataTypeOverrideAppliesTo','Floating-point');
```

For more information on data type override settings, see “Control Data Type Override” on page 59-35.

Validate a Single-Precision Model

This example uses the `ex_single_validation` model to show how you can use data type override. It proves that an algorithm, which implements double-precision data types, is also suitable for single-precision embedded use.

About the Model



- The inputs `In2` and `In3` are double-precision inputs to the Sum and Product blocks.
- The outputs of the Sum and Product blocks are data inputs to the Multiport Switch block.
- The input `In1` is the control input to the Multiport Switch block. The value of this control input determines which of its other inputs, the sum of `In2` and `In3` or the product of `In2` and `In3`, passes to the output port. Because `In1` is a control input, its data type is `int8`.
- The Relational Operator block compares the output of the Multiport Switch block to `In4`, and outputs a Boolean signal.

Run the Example

Open the Model

1 Open the `ex_single_validation` model. At the MATLAB command line, enter:

```
addpath(fullfile(docroot,'toolbox','simulink','examples'))
ex_single_validation
```

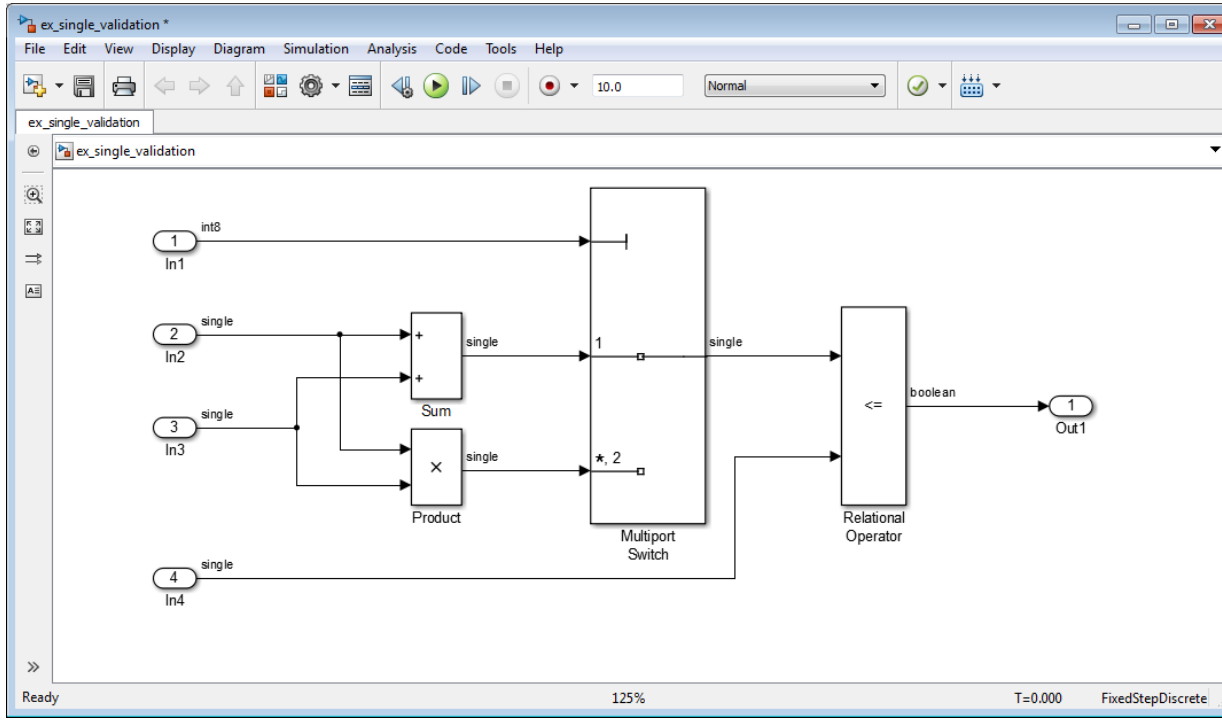
Override Floating-Point Data Types With Singles

1 At the command line, override the floating-point data types in the model with singles

```
set_param(gcs, 'DataTypeOverride', 'Single',...
 'DataTypeOverrideAppliesTo','Floating-point');
```

2 In the model menu, select **Simulation > Update Diagram**.

The data type override replaces all the floating-point (`double`) data types in the model with `single` data types, but does not affect the integer or Boolean data types.



Run Model Advisor Check

1 From the model menu, select **Analysis > Model Advisor > Model Advisor**.

2 In the System Selector dialog box, click **OK**.

The Model Advisor opens.

3 In the Model Advisor, expand the **By Task** node and, under **Modeling Single-Precision Systems**, select the **Identify questionable operations for strict single-precision design** check.

4 In the right pane, click **Run This Check**.

The check passes indicating that this algorithm is suitable for single-precision use. To ensure that no double-precision data types remain in the generated code, use the Single-Precision Converter before generating code for single-precision embedded use. For more information, see "Getting Started with Single Precision Converter" (Fixed-Point Designer).

Blocks That Support Single Precision

To identify Simulink blocks that support single precision, at the command prompt, enter `showblockdatatypetable`. In a model, to find blocks that do not support single precision, use the Model Advisor check "Identify questionable operations for strict single-precision design".

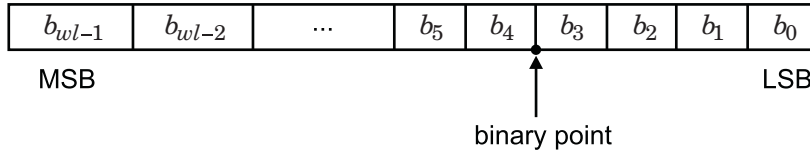
Fixed-Point Numbers

In this section...

In digital hardware, numbers are stored in binary words. A binary word is a fixed-length sequence of binary digits (1's and 0's). The way in which hardware components or software functions interpret this sequence of 1's and 0's is described by a data type. There are several distinct differences between fixed-point data types and the built-in integer types in MATLAB®. The most notable difference, is that the built-in integer data types can only represent whole numbers, while the fixed-point data types also contain information on the position of the binary point, or the scaling of the number.

Binary numbers are represented as either fixed-point or floating-point data types. A fixed-point data type is characterized by the word size in bits, the binary point, and whether it is signed or unsigned. The position of the binary point is the means by which fixed-point values are scaled and interpreted. With Fixed-Point Designer, fixed-point data types can be integers, fractionals, or generalized fixed-point numbers. The main difference between these data types is their default binary point. For example, a binary representation of a generalized fixed-point number (either signed or unsigned) is shown below:



where

- b_i is the i^{th} binary digit.
- wl is the word length in bits.
- b_{wl-1} is the location of the most significant, or highest, bit (MSB).
- b_0 is the location of the least significant, or lowest, bit (LSB).
- The binary point is shown four places to the left of the LSB. In this example, therefore, the number is said to have four fractional bits, or a fraction length of four.

Binary Point Interpretation

The binary point is the means by which fixed-point numbers are scaled. It is usually the software that determines the binary point. When performing basic math functions such as addition or subtraction, the hardware uses the same logic circuits regardless of the value of the scale factor. In essence, the logic circuits have no knowledge of a scale factor. They are performing signed or unsigned fixed-point binary algebra as if the binary point is to the right of b_0.

Fixed-Point Designer supports the general binary point scaling $V=Q*2\text{^}E$. `V` is the real-world value, `Q` is the stored integer value, and `E` is equal to `-FractionLength`. In other words, `RealWorldValue = StoredInteger * 2 ^ -FractionLength`.

`FractionLength` defines the scaling of the stored integer value. The word length limits the values that the stored integer can take, but it does not limit the values `FractionLength` can take. The software does not restrict the value of exponent `E` based on the word length of the stored integer `Q`. Because `E` is equal to `-FractionLength`, restricting the binary point to being contiguous with the fraction is unnecessary; the fraction length can be negative or greater than the word length.

For example, a word consisting of three unsigned bits is usually represented in scientific notation in one of the following ways.

$$bbb. = bbb. \times 2^{0}$$

$$bb.b = bbb. \times 2^{-1}$$

$$b.bb = bbb. \times 2^{-2}$$

$$.bbb = bbb. \times 2^{-3}$$

If the exponent were greater than 0 or less than -3, then the representation would involve lots of zeros.

$$bbb00000. = bbb. \times 2^{5}$$

$$bbb00. = bbb. \times 2^{2}$$

$$.00bbb = bbb. \times 2^{-5}$$

$$.00000bbb = bbb. \times 2^{-8}$$

These extra zeros never change to ones, however, so they don't show up in the hardware. Furthermore, unlike floating-point exponents, a fixed-point exponent never shows up in the hardware, so fixed-point exponents are not limited by a finite number of bits.

Consider a signed value with a word length of 8, a fraction length of 10, and a stored integer value of 5 (binary value `00000101`). The real-word value is calculated using the formula
`RealWorldValue = StoredInteger * 2 ^ -FractionLength`. In this case, `RealWorldValue = 5 * 2 ^ -10 = 0.0048828125`. Because the fraction length is 2 bits longer than the word length, the binary value of the stored integer is `x.xx00000101` , where `x` is a placeholder for implicit zeros. `0.0000000101` (binary) is equivalent to `0.0048828125` (decimal). For an example using a `fi` object, see "Create a fi Object With Fraction Length Greater Than Word Length" (Fixed-Point Designer).

Signed Fixed-Point Numbers

Computer hardware typically represents the negation of a binary fixed-point number in three different ways: sign/magnitude, one's complement, and two's complement. Two's complement is the preferred representation of signed fixed-point numbers and is the only representation used by Fixed-Point Designer.

Negation using two's complement consists of a bit inversion (translation into one's complement) followed by the addition of a one. For example, the two's complement of 000101 is 111011.

Whether a fixed-point value is signed or unsigned is usually not encoded explicitly within the binary word; that is, there is no sign bit. Instead, the sign information is implicitly defined within the computer architecture.

- "Scaling, Precision, and Range" on page 59-26

Benefits of Using Fixed-Point Hardware

Digital hardware is becoming the primary means by which control systems and signal processing filters are implemented. Digital hardware can be classified as either off-the-shelf hardware (for example, microcontrollers, microprocessors, general-purpose processors, and digital signal processors) or custom hardware. Within these two types of hardware, there are many architecture designs. These designs range from systems with a single instruction, single data stream processing unit to systems with multiple instruction, multiple data stream processing units.

Within digital hardware, numbers are represented as either fixed-point or floating-point data types. For both of these data types, word sizes are fixed at a set number of bits. However, the dynamic range of fixed-point values is much less than floating-point values with equivalent word sizes. Therefore, in order to avoid overflow or unreasonable quantization errors, fixed-point values must be scaled. Since floating-point processors can greatly simplify the real-time implementation of a control law or digital filter, and floating-point numbers can effectively approximate real-world numbers, then why use a microcontroller or processor with fixed-point hardware support?

- Size and Power Consumption — The logic circuits of fixed-point hardware are much less complicated than those of floating-point hardware. This means that the fixed-point chip size is smaller with less power consumption when compared with floating-point hardware. For example, consider a portable telephone where one of the product design goals is to make it as portable (small and light) as possible. If one of today's high-end floating-point, general-purpose processors is used, a large heat sink and battery would also be needed, resulting in a costly, large, and heavy portable phone.
- Memory Usage and Speed — In general fixed-point calculations require less memory and less processor time to perform.
- Cost — Fixed-point hardware is more cost effective where price/cost is an important consideration. When digital hardware is used in a product, especially mass-produced products, fixed-point hardware costs much less than floating-point hardware and can result in significant savings.

After making the decision to use fixed-point hardware, the next step is to choose a method for implementing the dynamic system (for example, control system or digital filter). Floating-point software emulation libraries are generally ruled out because of timing or memory size constraints. Therefore, you are left with fixed-point math where binary integer values are scaled.

- “Fixed-Point Numbers” on page 59-21

Scaling, Precision, and Range

In this section...

The dynamic range of fixed-point values is less than floating-point values with equivalent word sizes. To avoid overflow and minimize quantization errors, fixed-point numbers must be scaled.

Scaling

With Fixed-Point Designer, you can select a fixed-point data type whose scaling is defined by its binary point, or you can select an arbitrary linear scaling that suits your needs.

Slope and Bias Scaling

You can represent a fixed-point number by a general slope and bias encoding scheme. The real world value of a slope bias scaled number can be represented by:

$$\text{real-world value} = (\text{slope} \times \text{integer}) + \text{bias}$$

$$\text{slope} = \text{slope adjustment factor} \times 2^{\text{fixed exponent}}$$

The slope and bias together represent the scaling of the fixed-point number. In a number with zero bias, only the slope affects the scaling. A fixed-point number that is only scaled by binary point position is equivalent to a number in slope bias representation that has a bias equal to zero and a slope adjustment factor equal to one. This is referred to as binary point-only scaling or power-of-two scaling.

Binary-Point-Only Scaling

Binary-point-only or power-of-two scaling involves moving the binary point within the fixed-point word. The advantage of this scaling mode is to minimize the number of processor arithmetic operations. The real world value of a binary-point only scaled number can be represented by:

$$\text{real world value} = 2^{-\text{fraction length}} \times \text{integer}$$

Precision

The precision of a fixed-point number is the difference between successive values representable by its data type and scaling, which is equal to the value of its least significant bit. The value of the least significant bit, and therefore the precision of the number, is determined by the number of fractional bits. A fixed-point value can be represented to within half of the precision of its data type and scaling.

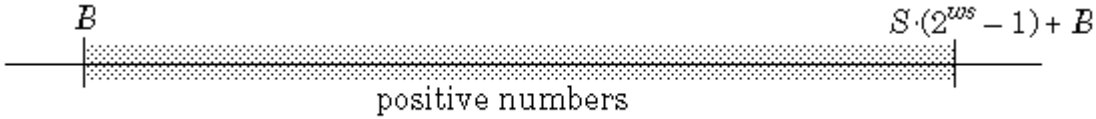
For example, a fixed-point representation with four bits to the right of the binary point has a precision of 2^{-4} or 0.0625, which is the value of its least significant bit. Any number within the range of this data type and scaling can be represented to within $(2^{-4})/2$ or 0.03125, which is half the precision.

Rounding Methods

When you represent numbers with finite precision, not every number in the available range can be represented exactly. If a number cannot be represented exactly by the specified data type and scaling, a rounding method is used to cast the value to a representable number. Although precision is always lost in the rounding operation, the cost of the operation and the amount of bias that is introduced depends on the rounding method itself. For more information on the rounding methods available with Fixed-Point Designer, see "Rounding Methods" (Fixed-Point Designer)

Range

Range is the span of numbers that a fixed-point data type and scaling can represent. The range of representable numbers for an unsigned two's complement fixed-point number of word length *ws*, scaling *S*, and bias *B* is illustrated below:



The following figure illustrates the range of representable numbers for a two's complement signed fixed-point number:

For both signed and unsigned fixed-point numbers of any data type, the number of different bit patterns is 2^{wl}.

For example, in two's complement, negative numbers must be represented as well as zero, so the maximum value is 2^{wl-1}-1. Because there is only one representation for zero, there are an unequal number of positive and negative numbers. This means there is a representation for —2^{wl-1}, but not for 2^{wl-1}.

Fixed-Point Data in MATLAB and Simulink

In this section...

Fixed-Point Data in Simulink

You can use the `fixdt` function in Simulink to specify a fixed-point data type. The `fixdt` function creates a `Simulink.NumericType` object.

Fixed-Point Data Type and Scaling Notation

Simulink data type names must be valid MATLAB identifiers with less than 128 characters. The data type name provides information about container type, number encoding, and scaling.

The following table provides a key for various symbols that appear in Simulink products to indicate the data type and scaling of a fixed-point value.

Symbol	Description	Example
Container Type		
`ufix`	Unsigned fixed-point data type	`ufix8` is an 8-bit unsigned fixed-point data type
`sfix`	Signed fixed-point data type	`sfix128` is a 128-bit signed fixed-point data type
`fltu`	Scaled double override of an unsigned fixed-point data type (`ufix`)	`fltu32` is a scaled doubles override of `ufix32`
`flts`	Scaled double override of a signed fixed-point data type (`sfix`)	`flts64` is a scaled doubles override of `sfix64`
Number Encoding		
`e`	10^	`125e8` equals `125*(10^(8))`

Symbol	Description	Example
`n`	Negative	`n31` equals `-31`

`p`	Decimal point	`1p5` equals `1.5`
		
		`p2` equals `0.2`

Scaling Encoding		
`S`	Slope	`ufix16_S5_B7` is a 16-bit unsigned fixed-point data type with `Slope` of `5` and `Bias` of `7`
`B`	Bias	`ufix16_S5_B7` is a 16-bit unsigned fixed-point data type with `Slope` of `5` and `Bias` of `7`
`E`	Fixed exponent (2^) A negative fixed exponent describes the fraction length	`sfix32_En31` is a 32-bit signed fixed-point data type with a fraction length of `31`
`F`	Slope adjustment factor	`ufix16_F1p5_En50` is a 16-bit unsigned fixed-point data type with a `SlopeAdjustmentFactor` of `1.5` and a `FixedExponent` of `-50`
C,c,D, or d	Compressed encoding for Bias **Note** If you pass this character vector to the `slDataTypeAndScale` function, it returns a valid `fixdt` data type.	No example available. For backwards compatibility only. To identify and replace calls to `slDataTypeAndScale`, use the "Check for calls to slDataTypeAndScale" Model Advisor check.

Symbol	Description	Example
T or t	Compressed encoding for Slope **Note** If you pass this character vector to the `slDataTypeAndScale`, it returns a valid `fixdt` data type.	No example available. For backwards compatibility only. To identify and replace calls to `slDataTypeAndScale`, use the "Check for calls to slDataTypeAndScale" Model Advisor check.

Fixed-Point Data in MATLAB

To assign a fixed-point data type to a number or variable in MATLAB, use the `fi` constructor. The resulting fixed-point value is called a `fi` object. For example, the following creates `fi` objects *a* and *b* with attributes shown in the display, all of which we can specify when the variables are constructed. Note that when the `FractionLength` property is not specified, it is set automatically to "best precision" for the given word length, keeping the most-significant bits of the value. When the `WordLength` property is not specified it defaults to 16 bits.

```
a = fi(pi)

a =

              3.1416015625

          DataTypeMode: Fixed-point: binary point scaling
            Signedness: Signed
            WordLength: 16
        FractionLength: 13

b = fi(0.1)

b =

         0.0999984741210938

          DataTypeMode: Fixed-point: binary point scaling
            Signedness: Signed
            WordLength: 16
        FractionLength: 18
```

Read Fixed-Point Data from the Workspace

Use the From Workspace block to read fixed-point data from the MATLAB workspace into a Simulink model. To do this, the data must be in structure format with a `fi` object in the `values` field. In array format, the From Workspace block only accepts real, double-precision data.

Write Fixed-Point Data to the Workspace

You can write fixed-point output from a model to the MATLAB workspace via the To Workspace block in either array or structure format. Fixed-point data written by a To Workspace block to the workspace in structure format can be read back into a Simulink model in structure format by a From Workspace block.

Scaled Doubles

Scaled doubles are a hybrid between floating-point and fixed-point numbers. Fixed-Point Designer stores them as doubles with the scaling, sign, and word length information retained. For example, the storage container for a fixed-point data type `sfix16_En14` is `int16`. The storage container of the equivalent scaled doubles data type, `flts16_En14` is floating-point `double`. Fixed-Point Designer applies the scaling information to the stored floating-point double to obtain the real-world value. Storing the value in a double almost always eliminates overflow and precision issues.

Functions

`Simulink.NumericType` | `fi` | `fimath` | `fixdt`

Share Fixed-Point Models

You can edit a model containing fixed-point blocks without having Fixed-Point Designer. However, you must have Fixed-Point Designer to:

- Update a Simulink diagram (**Ctrl+D**) containing fixed-point data types
- Run a model containing fixed-point data types
- Generate code from a model containing fixed-point data types
- Log the minimum and maximum values produced by a simulation
- Automatically scale the output of a model

If you do not have Fixed-Point Designer, you can work with a model containing Simulink blocks with fixed-point settings as follows:

1
```
set_param(gcs, 'DataTypeOverride', 'Double',...
 'DataTypeOverrideAppliesTo','AllNumericTypes',...
 'MinMaxOverflowLogging','ForceOff')
```

2 If you use `fi` objects or embedded numeric data types in your model, set the `fipref` `DataTypeOverride` property to `TrueDoubles` or `TrueSingles` (to be consistent with the model-wide data type override setting) and the `DataTypeOverrideAppliesTo` property to `All numeric types`.

   For example, at the MATLAB command line, enter:

```
p = fipref('DataTypeOverride', 'TrueDoubles', ...
       'DataTypeOverrideAppliesTo', 'AllNumericTypes');
```

Note If you use `fi` objects or embedded numeric data types in your model or workspace, you might introduce fixed-point data types into your model. You can set `fipref` to prevent the checkout of a Fixed-Point Designer license.

- “Fixed-Point Data in MATLAB and Simulink” on page 59-29

Control Fixed-Point Instrumentation and Data Type Override

In this section...

The conversion of a model from floating point to fixed point requires configuring fixed-point instrumentation and data type overrides. However, leaving these settings on after the conversion can lead to unexpected results. If you do not have Fixed-Point Designer, you can work with a model containing Simulink blocks with fixed-point settings by turning off fixed-point instrumentation and setting data type override to scaled doubles.

Control Instrumentation Settings

The fixed-point instrumentation mode controls which objects log minimum, maximum, and overflow data during simulation. Instrumentation is required to collect simulation ranges using the Fixed-Point Tool. These ranges are used to propose data types for the model. When you are not actively converting your model to fixed point, disable the fixed-point instrumentation to restore the maximum simulation speed to your model.

To enable instrumentation outside of the Fixed-Point Tool, at the command line set the `MinMaxOverflowLogging` parameter to `MinMaxAndOverflow` or `OverflowOnly`.

```
set_param('MyModel', 'MinMaxOverflowLogging', 'MinMaxOverflow')
```

Instrumentation requires a Fixed-Point Designer license. To disable instrumentation on a model, set the parameter to `ForceOff` or `UseLocalSettings`.

```
set_param('MyModel', 'MinMaxOverflowLogging', 'UseLocalSettings')
```

Control Data Type Override

Use data type override to simulate your model using double, single, or scaled double data types. If you do not have Fixed-Point Designer software, you can still configure data type override settings to simulate a model that specifies fixed-point data types. Using this setting, the software temporarily overrides data types with floating-point data types during simulation.

```
set_param('MyModel', 'DataTypeOverride', 'Double')
```

To observe the true behavior of your model, set the data type override parameter to `UseLocalSettings` or `Off`.

```
set_param('MyModel', 'DataTypeOverride', 'Off')
```

- “Share Fixed-Point Models” on page 59-33

Specify Fixed-Point Data Types

Simulink allows you to create models that use fixed-point numbers to represent signals and parameter values. Use of fixed-point data can reduce the memory requirements and increase the speed of code generated from a model.

To execute a model that uses fixed-point numbers, you must have the Fixed-Point Designer product installed on your system. Specifically, you must have the product to:

- Update a Simulink diagram (**Ctrl+D**) containing fixed-point data types
- Run a model containing fixed-point data types
- Generate code from a model containing fixed-point data types
- Log the minimum and maximum values produced by a simulation
- Automatically scale the output of a model using the autoscaling tool

If the Fixed-Point Designer product is not installed on your system, you can execute a fixed-point model as a floating-point model by enabling automatic conversion of fixed-point data to floating-point data during simulation. See "Overriding Fixed-Point Specifications" on page 59-37 for details.

If you do not have the Fixed-Point Designer product installed and do not enable automatic conversion of fixed-point to floating-point data, an error occurs if you try to execute a fixed-point model.

Note You do not need the Fixed-Point Designer product to edit a model containing fixed-point blocks, or to use the Data Type Assistant to specify fixed-point data types, as described in "Specifying a Fixed-Point Data Type" on page 59-42.

Fixed-point data types that resolve to a base integer type do not require a Fixed-Point Designer license. For example, a block or signal that specifies a data type of `fixdt(1,8,0)`, which is equivalent to the `int8` built-in type will not check out a Fixed-Point Designer license.

Overriding Fixed-Point Specifications

Most of the functionality in the Fixed-Point Tool is for use with Fixed-Point Designer. However, even if you do not have Fixed-Point Designer, you can configure data type override settings to simulate a model that specifies fixed-point data types. In this mode,

Simulink temporarily overrides fixed-point data types with floating-point data types when simulating the model.

Note If you use fi objects or embedded numeric data types in your model or workspace, you might introduce fixed-point data types into your model. You can set fipref to prevent the checkout of a Fixed-Point Designer license.

To simulate a model without using Fixed-Point Designer, enter the following at the command line.

```
set_param(gcs, 'DataTypeOverride', 'Double', ...
'DataTypeOverrideAppliesTo', 'AllNumericTypes')
```

If you use `fi` objects or embedded numeric data types in your model, set the `fipref` `DataTypeOverride` property to `TrueDoubles` or `TrueSingles` (to be consistent with the model-wide data type override setting) and the `DataTypeOverrideAppliesTo` property to `All numeric types`.

For example, at the MATLAB command line, enter:

```
p = fipref('DataTypeOverride', 'TrueDoubles', ...
       'DataTypeOverrideAppliesTo', 'AllNumericTypes');
```

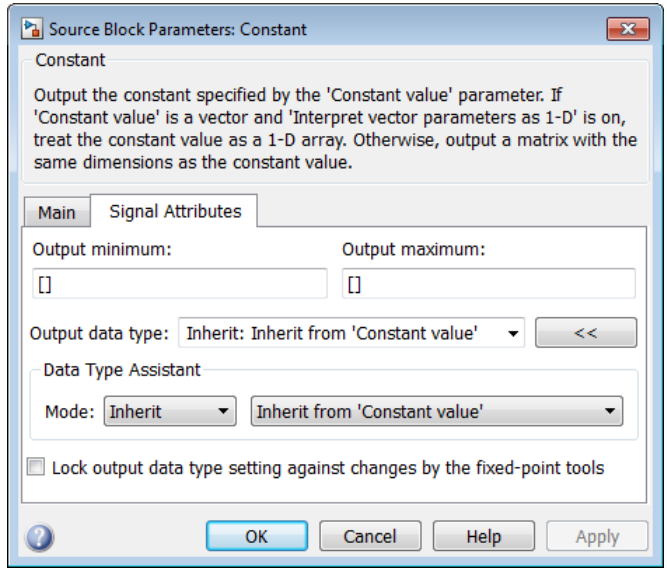
- “Data Types Supported by Simulink” on page 59-6

Specify Data Types Using Data Type Assistant

The **Data Type Assistant** is an interactive graphical tool that simplifies the task of specifying data types for blocks and data objects. The assistant appears on block and object dialog boxes, adjacent to parameters that provide data type control, such as the **Output data type** parameter. For example, it appears on the **Signal Attributes** pane of the Constant block dialog box shown here.



You can selectively show or hide the **Data Type Assistant** by clicking the applicable button:

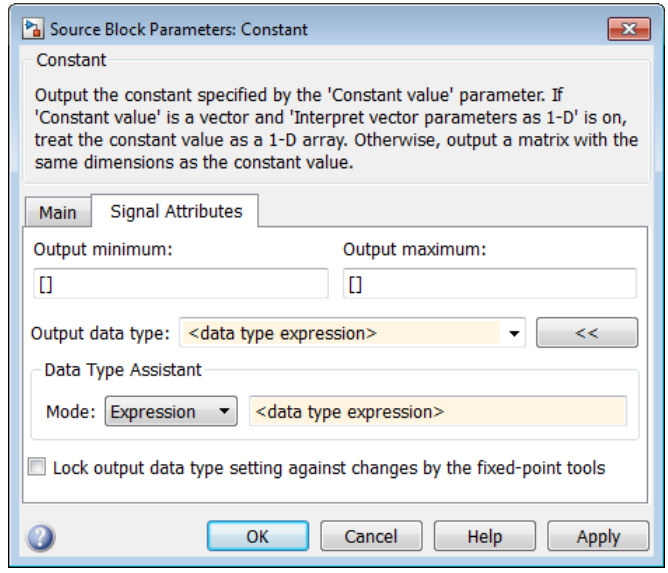
- Click the **Show data type assistant** button  to display the assistant.
- Click the **Hide data type assistant** button  to hide a visible assistant.

Use the **Data Type Assistant** to specify a data type as follows:

1 In the **Mode** field, select the category of data type that you want to specify. In general, the options include the following:

Mode	Description
`Inherit`	Inheritance rules for data types
`Built in`	Built-in data types
`Fixed point`	Fixed-point data types
`Enumerated`	Enumerated data types
`Bus object`	Bus object data types
`Expression`	Expressions that evaluate to data types

The assistant changes dynamically to display different options that correspond to the selected mode. For example, setting **Mode** to `Expression` causes the Constant block dialog box to appear as follows.

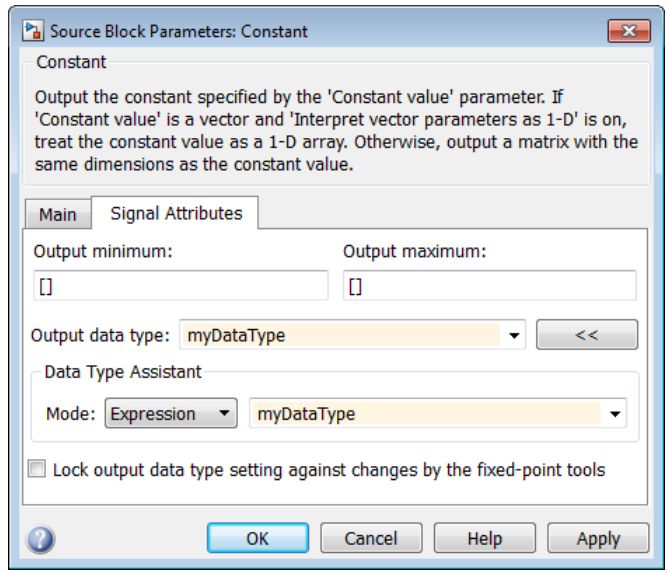


2 In the field that is to the right of the **Mode** field, select or enter a data type.

For example, suppose that you designate the variable `myDataType` as an alias for a `single` data type. You create an instance of the `Simulink.AliasType` class and set its `BaseType` property by entering the following commands:

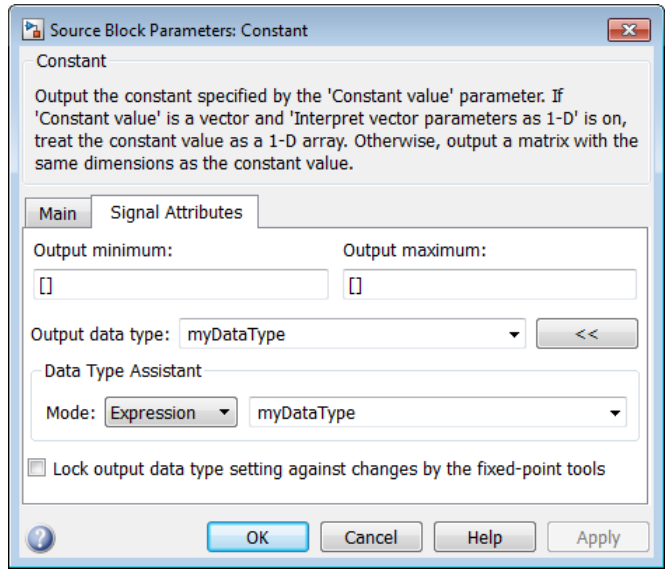
```
myDataType = Simulink.AliasType
myDataType.BaseType = 'single'
```

You can use this data type object to specify the output data type of a Constant block. Enter the data type alias name, `myDataType`, as the value of the expression in the assistant.



3 Click the **OK** or **Apply** button to apply your changes.

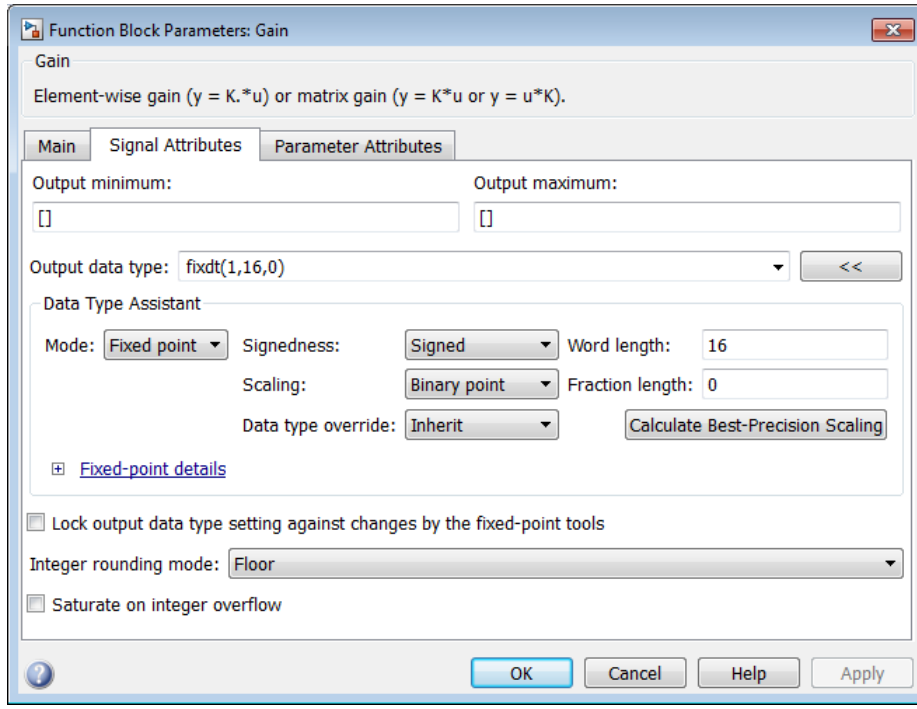
The assistant uses the data type that you specified to populate the associated data type parameter in the block or object dialog box. In the following example, the **Output data type** parameter of the Constant block specifies the same expression that you entered using the assistant.



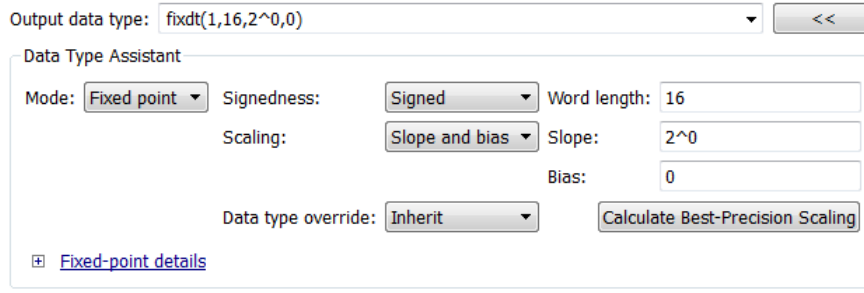
For more information about the data types that you can specify using the **Data Type Assistant**, see “Entering Valid Data Type Values” on page 59-9. For details about specifying fixed-point data types, see “Specify Fixed-Point Data Types with the Data Type Assistant” (Fixed-Point Designer).

Specifying a Fixed-Point Data Type

When the Data Type Assistant **Mode** is `Fixed point`, the Data Type Assistant displays fields for specifying information about your fixed-point data type. For a detailed discussion about fixed-point data, see “Fixed-Point Basics in MATLAB” (Fixed-Point Designer). For example, the next figure shows the Block Parameters dialog box for a Gain block, with the **Signal Attributes** tab selected and a fixed-point data type specified.



If the **Scaling** is `Slope and bias` rather than `Binary point`, the Data Type Assistant displays a **Slope** field and a **Bias** field rather than a **Fraction length** field:



You can use the Data Type Assistant to set these fixed-point properties:

Signedness

Specify whether you want the fixed-point data to be `Signed` or `Unsigned`. Signed data can represent positive and negative values, but unsigned data represents positive values only. The default setting is `Signed`.

Word length

Specify the bit size of the word that will hold the quantized integer. Large word sizes represent large values with greater precision than small word sizes. Word length can be any integer between 0 and 32. The default bit size is 16.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors. The default method is `Binary point` scaling. You can select one of two scaling modes:

Scaling Mode	Description
`Binary point`	If you select this mode, the Data Type Assistant displays the **Fraction Length** field, which specifies the binary point location. Binary points can be positive or negative integers. A positive integer moves the binary point left of the rightmost bit by that amount. For example, an entry of 2 sets the binary point in front of the second bit from the right. A negative integer moves the binary point further right of the rightmost bit by that amount, as in this example:  The default binary point is 0.

Scaling Mode	Description
`Slope and bias`	If you select this mode, the Data Type Assistant displays fields for entering the **Slope** and **Bias**. Slope can be any positive real number, and the default slope is 1.0. Bias can be any real number, and the default bias is 0.0. You can enter slope and bias as expressions that contain parameters you define in the MATLAB workspace.

Note Use binary-point scaling whenever possible to simplify the implementation of fixed-point data in generated code. Operations with fixed-point data using binary-point scaling are performed with simple bit shifts and eliminate expensive code implementations, which are required for separate slope and bias values.

For more information about fixed-point scaling, see "Scaling" (Fixed-Point Designer).

Data type override

When the **Mode** is `Built in` or `Fixed point`, you can use the **Data type override** option to specify whether you want this data type to inherit or ignore the data type override setting specified for its context, that is, for the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal. The default behavior is `Inherit`.

Data Type Override Mode	Description
`Inherit` (default)	Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.
`Off`	Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

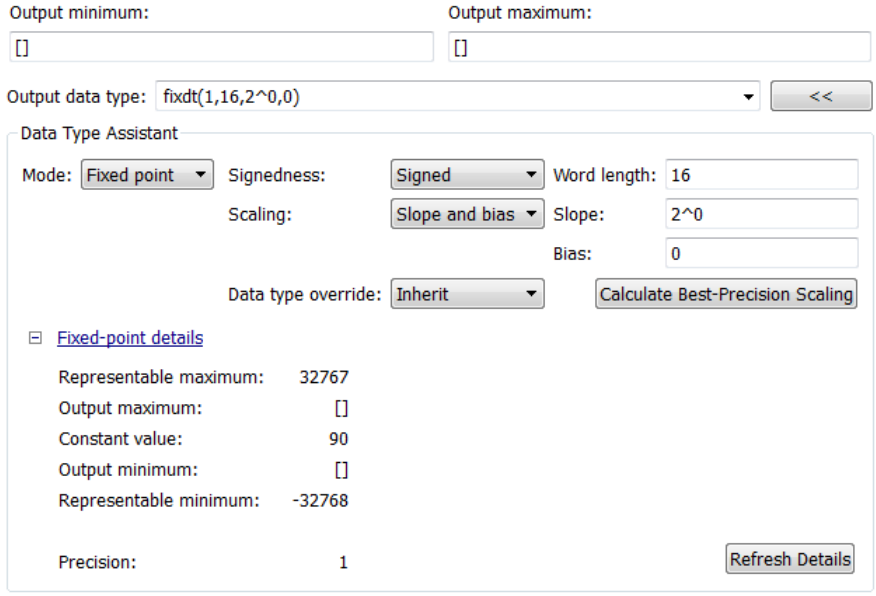
The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

Calculate Best-Precision Scaling

Click this button to calculate best-precision values for both `Binary point` and `Slope and bias` scaling, based on the specified minimum and maximum values. Simulink displays the scaling values in the **Fraction Length** field or the **Slope** and **Bias** fields. For more information, see "Constant Scaling for Best Precision" (Fixed-Point Designer).

Showing Fixed-Point Details

When you specify a fixed-point data type, you can use the **Fixed-point details** subpane to see information about the fixed-point data type that is currently displayed in the Data Type Assistant. To see the subpane, click the expander next to **Fixed-point details** in the Data Type Assistant. The **Fixed-point details** subpane appears at the bottom of the Data Type Assistant:



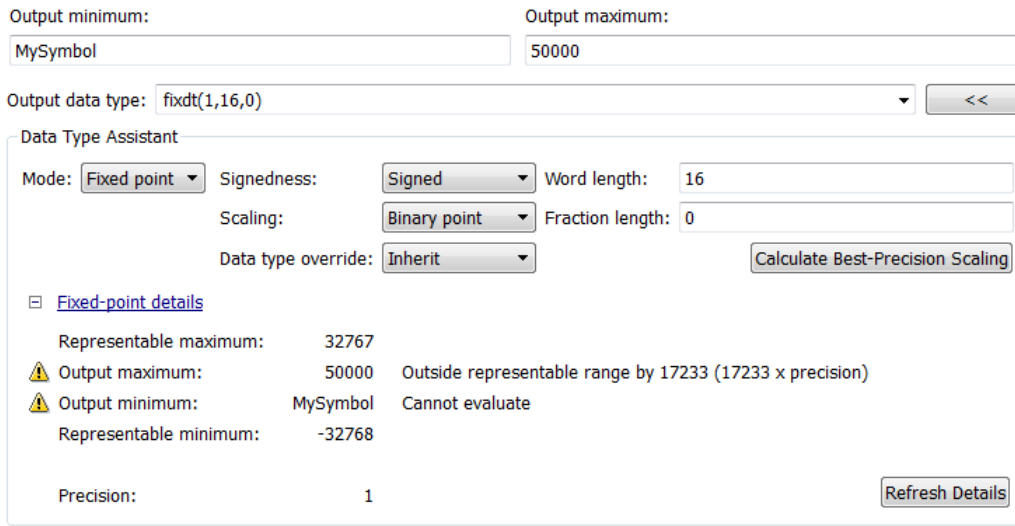
The rows labeled `Output minimum` and `Output maximum` show the same values that appear in the corresponding **Output minimum** and **Output maximum** fields above the Data Type Assistant. The names of these fields may differ from those shown. For example, a fixed-point block parameter would show **Parameter minimum** and **Parameter maximum**, and the corresponding **Fixed-point details** rows would be labeled accordingly. See "Signal Ranges" on page 64-45 and "Specify Minimum and Maximum Values for Block Parameters" on page 36-65 for more information.

The rows labeled `Representable minimum`, `Representable maximum`, and `Precision` always appear. These rows show the minimum value, maximum value, and precision that can be represented by the fixed-point data type currently displayed in the Data Type Assistant. For information about these three quantities, see "Fixed-Point Basics in MATLAB" (Fixed-Point Designer).

The values displayed by the **Fixed-point details** subpane *do not* automatically update if you click **Calculate Best-Precision Scaling**, or change the range limits, the values that define the fixed-point data type, or anything elsewhere in the model. To update the values shown in the **Fixed-point details** subpane, click **Refresh Details**. The Data Type Assistant then updates or recalculates all values and displays the results.

Clicking **Refresh Details** does not change anything in the model, it only changes the display. Click **OK** or **Apply** to put the displayed values into effect. If the value of a field cannot be known without first compiling the model, the **Fixed-point details** subpane shows the value as `Unknown`.

If any errors occur when you click **Refresh Details**, the **Fixed-point details** subpane shows an error flag on the left of the applicable row, and a description of the error on the right. For example, the next figure shows two errors:



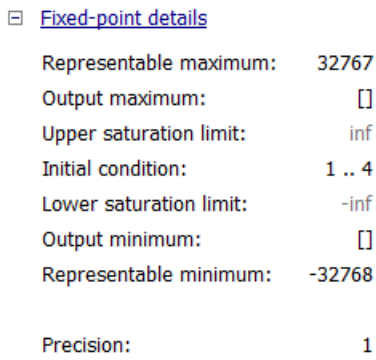
The row labeled `Output minimum` shows the error `Cannot evaluate` because evaluating the expression `MySymbol`, specified in the **Output minimum** field, did not return an appropriate numeric value. When an expression does not evaluate successfully,

the **Fixed-point details** subpane displays the unevaluated expression (truncating to 10 characters if necessary to save space) in place of the unavailable value.

To correct the error in this case, you would need to define `MySymbol` in an accessible workspace to provide an appropriate numeric value. After you clicked **Refresh Details**, the value of `MySymbol` would appear in place of its unevaluated text, and the error indicator and error description would disappear.

To correct the error shown for `Output maximum`, you would need to decrease **Output maximum**, increase **Word length**, or decrease **Fraction length** (or some combination of these changes) sufficiently to allow the fixed-point data type to represent the maximum value that it could have.

Other values relevant to a particular block can also appear in the **Fixed-point details** subpane. For example, on a Discrete-Time Integrator block **Signal Attributes** tab, the subpane can look like this:



The values displayed for **Upper saturation limit** and **Lower saturation limit** are greyed out. This appearance indicates that the corresponding parameters are not currently used by the block. The greyed-out values can be ignored.

To conserve space, **Initial condition** displays the smallest value and the largest value in the vector or matrix, using ellipsis to represent the other values. The underlying definition of the vector or matrix is unaffected.

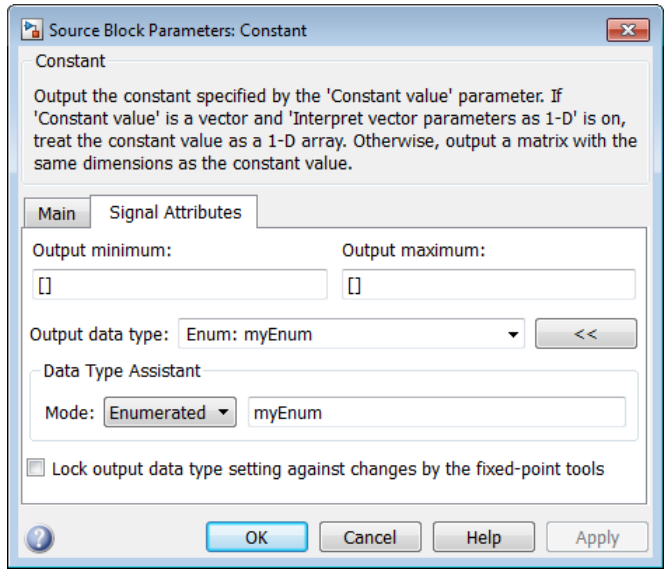
Lock output data type setting against changes by the fixed-point tools

Select this check box to prevent replacement of the current data type with a type that the Fixed-Point Tool or Fixed-Point Advisor chooses. For instructions on autoscaling fixed-point data, see “Scaling” (Fixed-Point Designer).

Specify an Enumerated Data Type

You can specify an enumerated data type by selecting the `Enum: <class name>` option and specify an enumerated object.

In the **Data Type Assistant**, you can use the **Mode** parameter to specify a bus as a data object for a block. Select the `Enumerated` option and specify an enumerated object.

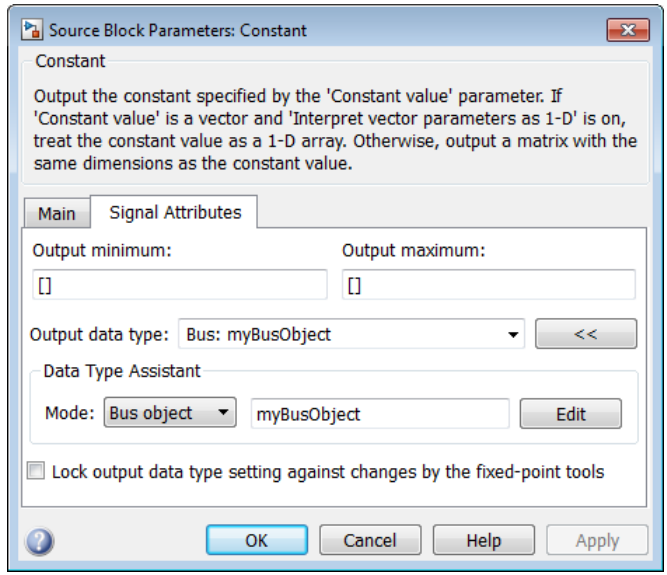


For details about enumerated data types, see “Data Types”.

Specify a Bus Object Data Type

The blocks listed in the section called “Data Types for Bus Signals” on page 59-52 support your specifying a bus object as a data type. For those blocks, in the **Data type** parameter, select the `Bus: <object name>` option and specify a bus object. You cannot use the `Expression` option to specify a bus object as a data type for a block.

In the **Data Type Assistant**, you can use the **Mode** parameter to specify a bus as a data object for a block. Select the `Bus` option and specify a bus object.



You can specify a bus object as the data type for data objects such as `Simulink.Signal`, `Simulink.Parameter`, and `Simulink.BusElement`. In the Model Explorer, in Properties dialog box for a data object, in the **Data type** parameter, select the `Bus: <object name>` option and specify a bus object. You can also use the `Expression` option to specify a bus object.

For more information on specifying a bus object data type, see “When to Use Bus Objects” on page 65-64.

Data Types for Bus Signals

A bus object (`Simulink.Bus`) specifies the architectural properties of a bus, as distinct from the values of the signals it contains. For example, a bus object can specify the number of elements in a bus, the order of those elements, whether and how elements are nested, and the data types of constituent signals; but not the signal values.

You can specify a bus object as a data type for the following blocks:

- Bus Creator
- Constant
- Data Store Memory
- Inport
- Outport
- Signal Specification

You can specify a bus object as a data type for the following classes:

- `Simulink.BusElement`
- `Simulink.Parameter`
- `Simulink.Signal`

See “Specify a Bus Object Data Type” on page 59-49 for information about how to specify a bus object as a data type for blocks and classes.

Data Objects

In this section...

You can create data objects to specify values, value ranges, data types, tunability, and other characteristics of signals, states, and block parameters. You use the object names in Simulink dialog boxes to specify signal, state, and parameter characteristics. The objects exist in a workspace such as the base workspace, a model workspace, or a Simulink data dictionary. Data objects allow you to make model-wide changes to signal, state, and parameter characteristics by changing only the values of workspace objects.

You create data objects as instances of data classes. Memory structures called data class packages contain the data class definitions. The built-in package `Simulink` defines two data classes, `Simulink.Signal` and `Simulink.Parameter`, that you can use to create data objects. To store lookup table data for sharing between lookup table blocks (such as n-D Lookup Table), you can use the `Simulink.LookupTable` and `Simulink.Breakpoint` classes.

To decide whether to use data objects to configure signals, including Inport and Outport blocks, see “Store Design Attributes of Signals and States” on page 64-6.

You can customize data object properties and methods by defining subclasses of the built-in data classes. For more information about creating a data class package, see “Define Data Classes” on page 59-90.

Data Class Naming Conventions

Simulink uses dot notation to name data classes:

package.class

- *package* is the name of the package that contains the class definition.
- *class* is the name of the class.

This notation allows you to create and reference identically named classes that belong to different packages. In this notation, the name of the package qualifies the name of the class.

Class and package names are case sensitive. For example, you cannot use `MYPACKAGE.MYCLASS` and `mypackage.myclass` interchangeably to refer to the same class.

Use Data Objects in Simulink Models

To specify simulation and code generation options for signals, block parameters, and states by modifying variables in a workspace or data dictionary, use data objects. Associate the objects with signals, parameters, and states in a model diagram.

Use Parameter Objects

You can use parameter objects, instead of numeric MATLAB variables, to specify values for block parameters. For example, to create and use a `Simulink.Parameter` object named `myParam` to specify the **Gain** parameter of a Gain block:

1. In the model, select **View** > **Property Inspector**.
2. In the model, click the target Gain block. The Property Inspector shows the properties and parameters of the block.
3. Set the value of the **Gain** parameter to `myParam`.
4. Next to the parameter value, click the action button ⋮ and select **Create**.
5. In the **Create New Data** dialog box, set **Value** to `Simulink.Parameter(15.23)` and click **Create**.

The `Simulink.Parameter` object, `myParam`, appears in the base workspace. The property dialog box shows that the object stores the parameter value `15.23` in the **Value** property.

6 Use the property dialog box to specify other characteristics for the block parameter by adjusting the object properties. For example, to specify the minimum and maximum values the parameter can take, use the **Minimum** and **Maximum** properties.

During simulation, the **Gain** parameter now uses the value `15.23`.

To share lookup table data by using `Simulink.LookupTable` and `Simulink.Breakpoint` objects, see "Package Shared Breakpoint and Table Data for Lookup Tables" on page 36-36.

Use Signal Objects

You can associate a signal line or block state, such as the state of a Unit Delay block, with a signal object.

For Signals

To use a signal object to control the characteristics of a signal in a model, create the object in a workspace by using the same name as the signal.

1 In the model, select **View** > **Model Data**.

2 In the Model Data Editor, select the **Signals** tab.

3 In the model, select the target signal. The Model Data Editor highlights the row that corresponds to the signal.

4 In the Model Data Editor, in the **Name** column, give the signal a name such as `mySig`.

5 Click the button ⋮ next to the signal name. Select **Create and Resolve**.

6 In the Create New Data dialog box, set **Value** to `Simulink.Signal`. Use the **Location** drop-down list to select a workspace to store the object (the default value is `Base Workspace`). Click **Create**.

The `Simulink.Signal` object `mySig` appears in the target workspace. Simulink selects the signal property **Signal name must resolve to Simulink signal object**, which forces the signal in the model to use the properties that the signal object

stores. To learn how to control the way that signal names resolve to signal objects, see “Symbol Resolution” on page 59-136.

The property dialog box of the new object opens.

7 Use the property dialog box to specify the signal characteristics. Click **OK**.

To configure the signal programmatically:

```
% Create the signal object.
mySig = Simulink.Signal;
mySig.DataType = 'boolean';

% Get a handle to the block port that creates the
% target signal.
portHandles = get_param('myModel/myBlock','portHandles');
outportHandle = portHandles.Outport;

% Specify the programmatic port parameter 'Name'.
set_param(outportHandle,'Name','mySig')

% Set the port parameter 'MustResolveToSignalObject'.
set_param(outportHandle,'MustResolveToSignalObject','on')
```

To configure a root-level Outport block programmatically, you must use a slightly different technique:

```
% Create the signal object.
mySig = Simulink.Signal;
mySig.DataType = 'boolean';

% Specify the programmatic block parameter 'SignalName'.
set_param('myModel/myOutport','SignalName','mySig')

% Set the block parameter 'MustResolveToSignalObject'.
set_param('myModel/myOutport','MustResolveToSignalObject','on')
```

For States

You can use a signal object to control the characteristics of a block state, such as that of the Discrete-Time Integrator block.

1 In the model, select **View > Model Data**.

2 In the Model Data Editor, select the **States** tab.

3. In the model, select the block that harbors the target state. The Model Data Editor highlights the row that corresponds to the state.
4. In the Model Data Editor, in the **Name** column, give the state a name such as `myState`.
5. Click the button ⋮ next to the state name. Select **Create and Resolve**.
6. In the Create New Data dialog box, set **Value** to `Simulink.Signal`. Use the **Location** drop-down list to select a workspace to store the object (the default value is `Base Workspace`). Click **Create**.

   The `Simulink.Signal` object `myState` appears in the target workspace. Simulink selects the block parameter **State name must resolve to Simulink signal object**, which forces the state in the model to use the properties that the signal object stores. To learn how to control the way that state names resolve to signal objects, see "Symbol Resolution" on page 59-136.

   The property dialog box of the new object opens.
7. Use the property dialog box to specify the state characteristics. Click **OK**.

To configure the state programmatically:

```
% Create the signal object.
myState = Simulink.Signal;
myState.DataType = 'int16';

% Set the state name in the block.
set_param('myModel/myBlock','StateName','myState')

% Set the port parameter 'StateMustResolveToSignalObject'.
set_param('myModel/myBlock','StateMustResolveToSignalObject','on')
```

Data Object Properties

To control parameter and signal characteristics using data objects, you specify values for the data object properties. For example, parameter and signal data objects have a `DataType` property that determines the data type of the target block parameter or signal. Data class definitions determine the names, value types, default values, and valid value ranges of data object properties.

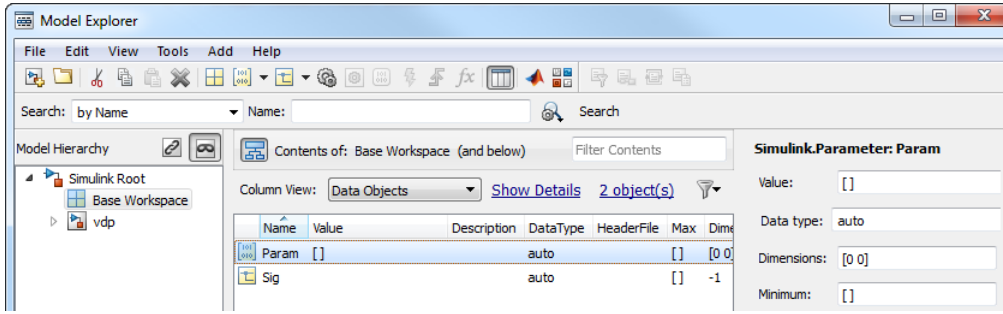
You can use either the Model Explorer or MATLAB commands to change a data object's properties.

For a list of signal object properties, see `Simulink.Signal`. For a list of parameter object properties, see `Simulink.Parameter`.

Use the Model Explorer to Change an Object's Properties

To use the Model Explorer to change an object's properties, select the workspace that contains the object in the Model Explorer's **Model Hierarchy** pane. Then select the object in the Model Explorer's **Contents** pane.

The Model Explorer displays the object's property dialog box in its **Dialog** pane (if the pane is visible).



You can configure the Model Explorer to display some or all of the properties of an object in the **Contents** pane (see "Model Explorer: Contents Pane" on page 12-18). To edit a property, click its value in the **Contents** or **Dialog** pane. The value is replaced by a control that allows you to change the value.

Use MATLAB Commands to Change an Object's Properties

You can also use MATLAB commands to get and set data object properties. Use the following dot notation in MATLAB commands and programs to get and set a data object's properties:

```
value = obj.property;
obj.property = value;
```

where *`obj`* is a variable that references either the object if it is an instance of a value class or a handle to the object if the object is an instance of a handle class (see "Handle Versus Value Classes" on page 59-69), `PROPERTY` is the property's name, and `VALUE` is the property's value. For example, the following MATLAB code creates a data type alias object (i.e., an instance of `Simulink.AliasType`) and sets its base type to `uint8`:

```
gain = Simulink.AliasType;
gain.BaseType = 'uint8';
```

You can use dot notation recursively to get and set the properties of objects that are values of other object's properties, e.g.,

```
gain.CoderInfo.StorageClass = 'ExportedGlobal';
```

Create Data Objects from Built-In Data Class Package Simulink

The built-in package `Simulink` defines two data object classes `Simulink.Parameter` and `Simulink.Signal`. You can create these data objects using the user interface or programmatically.

Create Data Objects

1. In the Model Explorer **Model Hierarchy** pane, select a workspace to contain the data objects. For example, click `Base Workspace`.
2. On the toolbar, click the arrow next to Add Parameter  or Add Signal  . From the drop-down list, select **Simulink Parameter** or **Simulink Signal**.

   A parameter or signal object appears in the base workspace. The default name for new parameter objects is `Param`. The default name for new signal objects is `Sig`.
3. To create more objects, click Add Parameter or Add Signal.

To create `Simulink.LookupTable` and `Simulink.Breakpoint` objects, on the Model Explorer toolbar, use the  button.

Programmatically Create Data Objects

```
% Create a Simulink.Parameter object named myParam whose value is 15.23.
myParam = Simulink.Parameter(15.23);

% Create a Simulink.Signal object named mySig.
mySig = Simulink.Signal;
```

Convert Numeric Variable into Parameter Object

You can convert a numeric variable into a `Simulink.Parameter` object as follows.

```
/* Define numeric variable in base workspace
myVar = 5;
/* Create data object and assign variable value
myObject = Simulink.Parameter(myVar);
```

Create Data Objects from Another Data Class Package

You can create your own package to define custom data object classes that subclass `Simulink.Parameter` and `Simulink.Signal`. You can use this technique to add your own properties and methods to data objects. If you have an Embedded Coder license, you can define custom storage classes and memory sections in the package. For more information about creating a data class package, see "Define Data Classes" on page 59-90.

Create Data Objects from Another Package

Suppose that you define a data class package called `myPackage`. Before you can create data objects from the package, you must include the package folder on your MATLAB path.

1. In the Model Explorer **Model Hierarchy** pane, select a workspace to contain the data objects. For example, click `Base Workspace`.
2. Click the arrow next to Add Parameter  or Add Signal  and select **Customize class lists**.
3. In the dialog box, select the check box next to the class that you want. For example, select the check boxes next to `myPackage.Parameter` and `myPackage.Signal`. Click **OK**.
4. Click the arrow next to Add Parameter or Add Signal. Select the class for the data object that you want to create. For example, select **myPackage Parameter** or **myPackage Signal**.

   A parameter or signal object appears in the base workspace. The default name for new parameter objects is `Param`. The default name for new signal objects is `Sig`.
5. To create more data objects from the package `myPackage`, click Add Parameter or Add Signal again.

Programmatically Create Data Objects from Another Package

Suppose that you define a data class package called `myPackage`. Before you can create data objects from the package, you must include the package folder on your MATLAB path.

```
% Create a myPackage.Parameter object named
% myParam whose value is 15.23.
myParam = myPackage.Parameter(15.23);

% Create a myPackage.Signal object named mySig.
mySig = myPackage.Signal;
```

Create Data Objects Directly from Dialog Boxes

When you open a Signal Properties dialog box, a block dialog box, or the Property Inspector (**View** > **Property Inspector**), you can efficiently create a signal or parameter data object in a workspace or data dictionary.

Create Parameter Object from Block Dialog Box

1. In a numeric block parameter in the dialog box, specify the name that you want for the data object. For example, specify the name `myParam`.
2. Click the button ⋮ next to the value of the block parameter. Select **Create**.
3. In the **Create New Data** dialog box, specify **Value** as `Simulink.Parameter`.

   Alternatively, you can specify the name of a data class that you created, such as `myPackage.Parameter`. You can also use the drop-down list to select from a list of available data object classes.
4. Specify **Location** as `Base Workspace` and click **Create**.

   You can use the **Location** option to select a workspace to contain the new data object. If a model is linked to a data dictionary, you can choose to create a data object in the dictionary.
5. In the dialog box that opens, configure the data object properties. Specify a numeric value for the parameter in the **Value** box. Click **OK**.

   The parameter object `myParam` appears in the base workspace.
6. In the block parameter dialog box, click **OK**.

Create Signal Object from Signal Properties Dialog Box

1. In the **Signal name** box, specify a signal name such as `mySig`. Click **Apply**.
2. Click the button ⋮ next to the value of **Signal name**. Select **Create and Resolve**.
3. In the **Create New Data** dialog box, specify **Value** as `Simulink.Signal`.

   Alternatively, you can specify the name of a data class that you created, such as `myPackage.Signal`. Also, from the drop-down list, you can select a data object class that exists on the MATLAB path.
4. Specify **Location** as `Base Workspace` and click **Create**.

   You can use the **Location** option to select a workspace to contain the new data object. If a model is linked to a data dictionary, you can choose to create a data object in the dictionary.
5. In the dialog box that opens, configure the data object properties and click **OK**.

   The signal object `mySig` appears in the base workspace. In the Signal Properties dialog box, the **Signal name must resolve to Simulink signal object** property is selected.

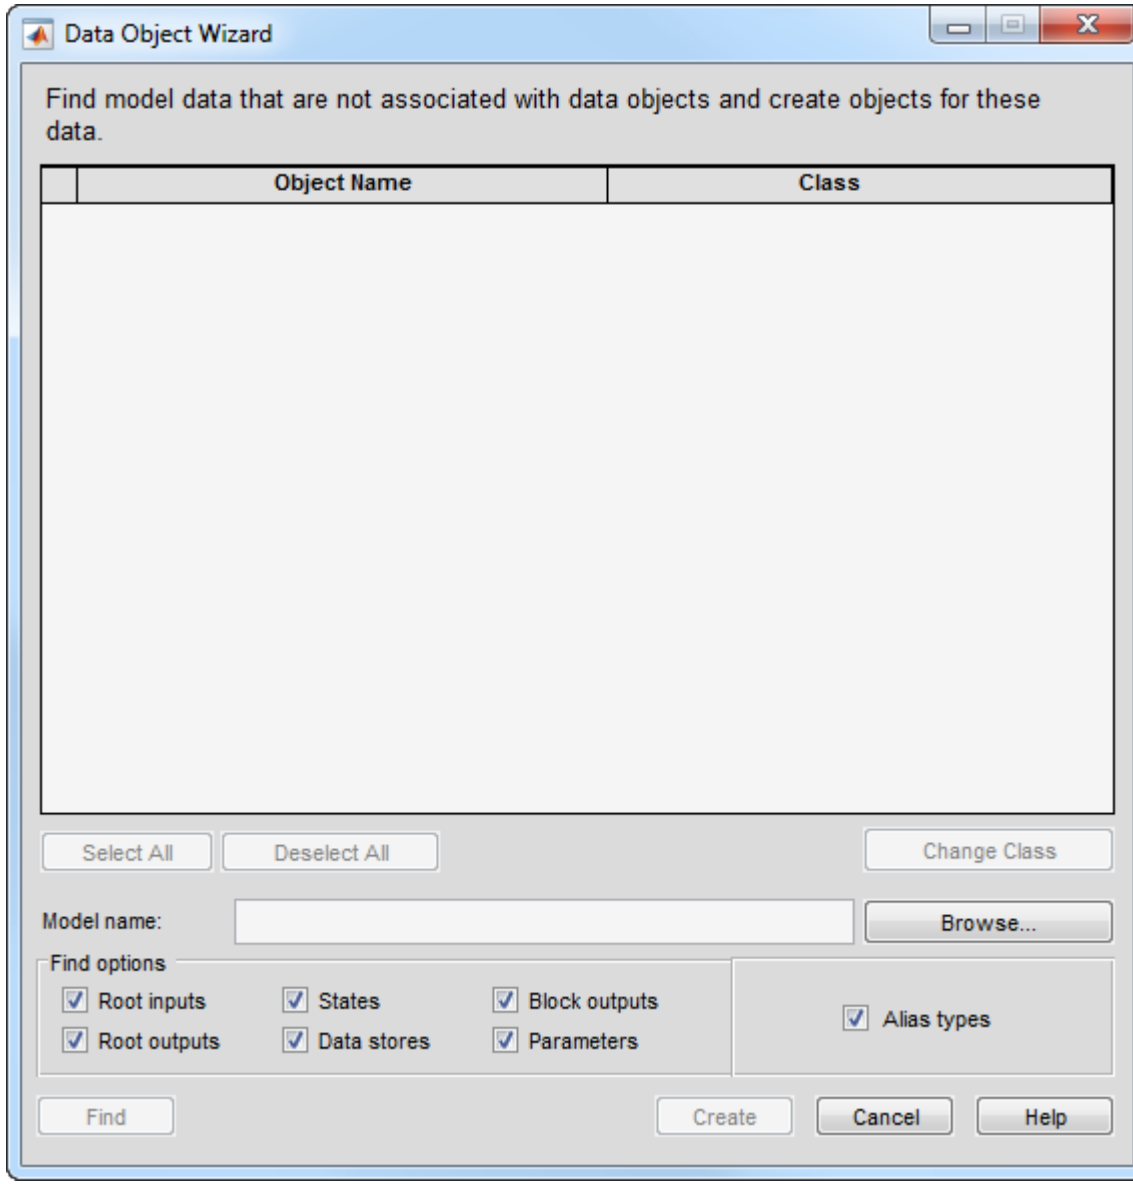
Create Data Objects for a Model Using Data Object Wizard

To create data objects that represent signals, parameters, and states in a model, you can use the Data Object Wizard. The wizard finds data in the model that do not have corresponding data objects.

Based on specifications in the model, the wizard creates the objects and assigns these characteristics:

- Signal, parameter, or state name.
- Numeric value for parameter objects.
- Data type. For signal objects, includes alias types such as `Sumlink.AliasType` and `Simulink.NumericType`.

1. In the Simulink Editor, select **Code** > **Data Objects** > **Data Object Wizard**.



2 In the **Model name** box, enter the name of the model that you want to search.

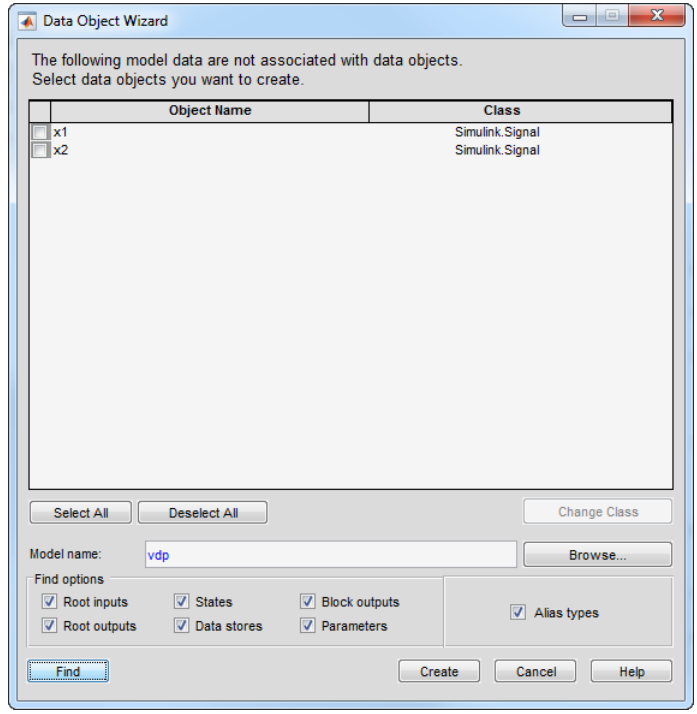
By default, the box contains the name of the model from which you opened the wizard.

3 Under **Find options**, select the check boxes next to the data object types that you want to create. The table describes the options.

Option	Description
Root inputs	Named signals from root-level Inport blocks.
Root outputs	Named signals from root-level Outport blocks.
States	States associated with these discrete blocks: Discrete Filter Discrete State-Space Discrete-Time Integrator Discrete Transfer Fcn Discrete Zero-Pole Memory PID Controller PID Controller (2DOF) Unit Delay
Data stores	Data stores. For more information about data stores, see “Local and Global Data Stores” on page 62-3 .
Block outputs	Named signals whose sources are non-root-level blocks.
Parameters	• Numeric parameters, for example the parameters in these blocks: Constant Gain Relay • Stateflow data with **Scope** set to `Parameter`. For more information, see “Share Simulink Parameters with Charts” (Stateflow) in the Stateflow documentation.
Alias types	Data type replacement names that you specify in **Configuration Parameters > Code Generation > Data Type Replacement**. If you have an Embedded Coder license, the Data Object Wizard creates `Simulink.AliasType` objects for these data type replacement names. For more information about data type replacement, see “Model Configuration Parameters: Code Generation Data Type Replacement” (Embedded Coder)

4 Click **Find**.

The data object table displays the proposed objects.



5 (Optional) To create objects from a data class other than the default classes, select the check box next to the objects whose class you want to change. To select all of the objects, click **Select All**. Click **Change Class**. In the dialog box that opens, select classes by using the drop-down lists next to **Parameter** and **Signal**.

If the classes that you want do not appear in the drop-down list, select `Customize class lists`. In the dialog box that opens, select the check box next to the classes that you want, and click **OK**.

To change the default parameter and signal classes that the wizard uses to propose objects:

- On the Model Explorer **Model Hierarchy** pane, select a workspace. For example, select **Base Workspace**.

- On the toolbar, click the arrow next to Add Parameter  or Add Signal  .
- From the drop-down list, select the class that you want the wizard to use. For example, select **myPackage Parameter** or **myPackage Signal**.

  A parameter or signal object appears in the selected workspace. The default name for new parameter objects is `Param`. The default name for new signal objects is `Sig`.

  The next time that you use the Data Object Wizard, the wizard proposes objects using the parameter or signal class that you selected in Model Explorer.

6 Select the check box next to the proposed objects that you want to create. To select all of the proposed objects, click **Select All**.

7 Click **Create**.

The data objects appear in the base workspace. If the target model is linked to a data dictionary, the objects appear in the dictionary.

The wizard changes settings in your model depending on the configuration parameter **Configuration Parameters > Diagnostics > Data Validity > Signal resolution**.

- If you set the parameter to `Explicit only`, the wizard forces the corresponding signals and states in your model to resolve to the new signal objects. The wizard selects the option **Signal name must resolve to Simulink signal object** in each Signal Properties dialog box and **State name must resolve to Simulink signal object** in each block dialog box.
- If you set the parameter to `Explicit and implicit` or `Explicit and warn implicit`, the wizard does not change the setting of **Signal name must resolve to Simulink signal object** or **State name must resolve to Simulink signal object** for any signals or states.

Consider turning off implicit signal object resolution for your model by using the function `disableimplicitsignalresolution`. For more information, see “Explicit and Implicit Symbol Resolution” on page 59-139.

Data Object Wizard Troubleshooting

The Data Object Wizard does not propose creation of data objects for these entities in a model:

- Multiple separate signals that have the same name.
- A signal with the same name as a variable used in a block parameter.
- A signal that lacks a single contiguous source block.
- A signal whose source block is commented out or commented through.
- Data items that are rendered inactive by Variant Source and Variant Sink blocks. The wizard proposes objects only for data items that are associated with active blocks.
- Signals and states when you set the model configuration parameter **Signal resolution** to `None`.

Create Data Objects from External Data Source Programmatically

This example shows how to create data objects based on an external data source (such as a Microsoft Excel file) by using a script.

1. Create a new MATLAB script file.
2. Place information in the file that describes the data in the external file that you want to convert to data objects. For example, the following information creates two `Simulink` data objects with the indicated properties. The first is for a parameter and the second is for a signal:

```
% Parameters
ParCon = Simulink.Parameter;
ParCon.CoderInfo.StorageClass = 'Custom'
ParCon.CoderInfo.CustomStorageClass ='Const';
ParCon.Value = 3;
% Signals
SigGlb = Simulink.Signal;
SigGlb.DataType = 'int8';
```

3. Run the script file. The data objects appear in the MATLAB workspace.

If you want to import the target data from the external source, you can write MATLAB functions and scripts that read the information, convert the information to data objects, and load the objects into the base workspace.

You can use these functions to interact with files that are external to MATLAB:

- `xmlread`
- `xmlwrite`

- `xlsread`
- `xlswrite`
- `csvread`
- `csvwrite`
- `dlmread`
- `dlmwrite`

Data Object Methods

Data classes define functions, called methods, for creating and manipulating the objects that they define. A class may define any of the following kinds of methods.

Dynamic Methods

A dynamic method is a method whose identity depends on its name and the class of an object specified implicitly or explicitly as its first argument. You can use either function or dot notation to specify this object, which must be an instance of the class that defines the method or an instance of a subclass of the class that defines the method. For example, suppose class `A` defines a method called `setName` that assigns a name to an instance of `A`. Further, suppose the MATLAB workspace contains an instance of A assigned to the variable `obj`. Then, you can use either of the following statements to assign the name `'foo'` to `obj`:

```
obj.setName('foo');
setName(obj, 'foo');
```

A class may define a set of methods having the same name as a method defined by one of its super classes. In this case, the method defined by the subclass overrides the behavior of the method defined by the parent class. Simulink determines which method to invoke at runtime from the class of the object that you specify as its first or implicit argument. Hence, the term dynamic method.

Note Most Simulink data object methods are dynamic methods. Unless the documentation for a method specifies otherwise, you can assume that a method is a dynamic method.

Static Methods

A static method is a method whose identity depends only on its name and hence cannot change at runtime. To invoke a static method, use its fully qualified name, which includes the name of the class that defines it followed by the name of the method itself. For example, `Simulink.ModelAdvisor` class defines a static method named `getModelAdvisor`. The fully qualified name of this static method is `Simulink.ModelAdvisor.getModelAdvisor`. The following example illustrates invocation of a static method.

```
ma = Simulink.ModelAdvisor.getModelAdvisor('vdp');
```

Constructors

Every data class defines a method for creating instances of that class. The name of the method is the same as the name of the class. For example, the name of the `Simulink.Parameter` class's constructor is `Simulink.Parameter`. The constructors defined by Simulink data classes take no arguments.

The value returned by a constructor depends on whether its class is a handle class or a value class. The constructor for a handle class returns a handle to the instance that it creates if the class of the instance is a handle class; otherwise, it returns the instance itself (see “Handle Versus Value Classes” on page 59-69).

Handle Versus Value Classes

Simulink classes, including data object classes, fall into two categories: value classes and handle classes.

About Value Classes

The constructor for a *value* class (see “Constructors” on page 59-69) returns an instance of the class and the instance is permanently associated with the MATLAB variable to which it is initially assigned. Reassigning or passing the variable to a function causes MATLAB to create and assign or pass a copy of the original object.

For example, `Simulink.NumericType` is a value class. Executing the following statements

```
x = Simulink.NumericType;
y = x;
```

creates two instances of class `Simulink.NumericType` in the workspace, one assigned to the variable `x` and the other to `y`.

About Handle Classes

The constructor for a *handle* class returns a handle object. The handle can be assigned to multiple variables or passed to functions without causing a copy of the original object to be created. For example, `Simulink.Parameter` class is a handle class. Executing

```
x = Simulink.Parameter;
y = x;
```

creates only one instance of `Simulink.Parameter` class in the MATLAB workspace. Variables x and y both refer to the instance via its handle.

A program can modify an instance of a handle class by modifying any variable that references it, e.g., continuing the previous example,

```
x.Description = 'input gain';
y.Description

ans =
input gain
```

Most Simulink data object classes are value classes. Exceptions include `Simulink.Signal` and `Simulink.Parameter` class.

You can determine whether a variable is assigned to an instance of a class or to a handle to that class by displaying the variable at the MATLAB command line. MATLAB appends the text `(handle)` to the name of the object class in the value display, e.g.,

```
>> gain = Simulink.Parameter

gain =

Simulink.Parameter (handle)
          Value: []
       CoderInfo: [1x1 Simulink.CoderInfo]
    Description: ''
       DataType: 'auto'
            Min: []
            Max: []
           Unit: ''
```

```
    Complexity: 'real'
    Dimensions: [0 0]
```

Copy Handle Classes

Use the copy method of a handle class to create copies of instances of that class. For example, `Simulink.ConfigSet` is a handle class that represents model configuration sets. The following code creates a copy of the current model's active configuration set and attaches it to the model as an alternate configuration geared to model development.

```
activeConfig = getActiveConfigSet(gcs);
develConfig = copy(activeConfig);
develConfig.Name = 'develConfig';
attachConfigSet(gcs, develConfig);
```

Compare Data Objects

Simulink data objects provide a method, named `isequal`, that determines whether object property values are equal. This method compares the property values of one object with those belonging to another object and returns true (`1`) if all of the values are the same or false (`0`) otherwise. For example, the following code instantiates two signal objects (A and B) and specifies values for particular properties.

```
A = Simulink.Signal;
B = Simulink.Signal;
A.DataType = 'int8';
B.DataType = 'int8';
A.InitialValue = '1.5';
B.InitialValue = '1.5';
```

Afterward, use the `isequal` method to verify that the object properties of A and B are equal.

```
result = isequal(A,B)

result =

     1
```

Create Persistent Data Objects

To preserve data objects so that they persist when you close MATLAB, you can:

- Store the objects in a data dictionary or model workspace. To decide where to permanently store model data, see “Determine Where to Store Variables and Objects for Simulink Models” on page 59-96.
- Use the `save` command to save data objects in a MAT-file and the `load` command to restore them to the MATLAB base workspace in the same or a later session. Configure the model to load the objects from the MAT-file or a script file when the model loads.

To load data objects from a file when you load a model, write a script that creates the objects and configures their properties. Alternatively, save the objects in a MAT-file. Then use either the script or a load command as the `PreLoadFcn` callback routine for the model that uses the objects. Suppose that you save the data objects in a file named `data_objects.mat`, and the model to which they apply is open and active. At the command prompt, entering:

```
set_param(gcs, 'PreLoadFcn', 'load data_objects');
```

sets `load data_objects` as the model's preload function. Whenever you open the model, the data objects appear in the base workspace.

Definitions of the classes of saved objects must exist on the MATLAB path for them to be restored. If the class of a saved object acquires new properties after the object is saved, Simulink adds the new properties to the restored version of the object. If the class loses properties after the object is saved, only the properties that remain are restored.

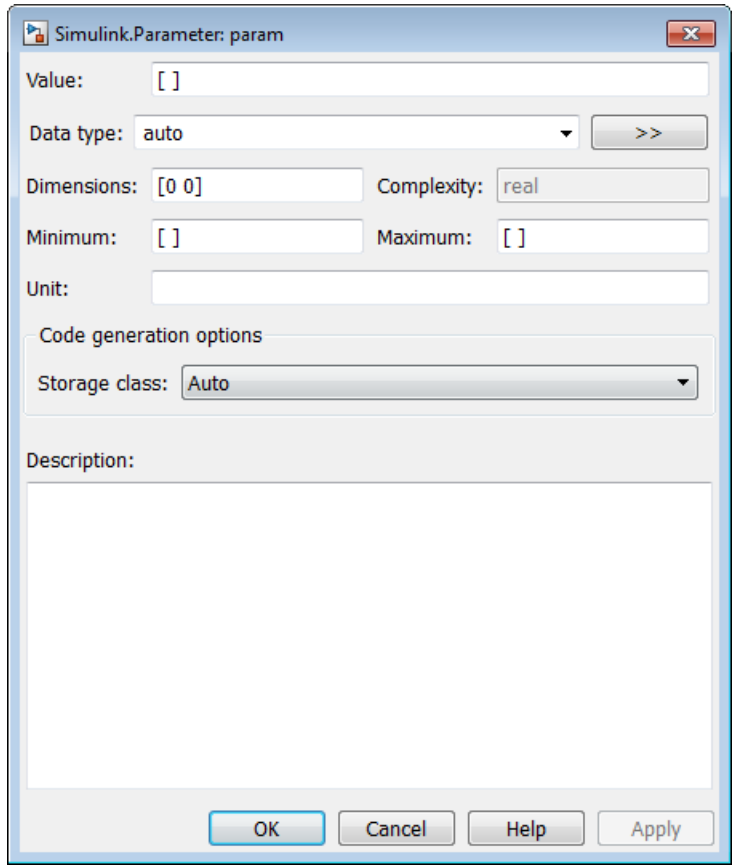
Simulink.Parameter Property Dialog Box

Create a `Simulink.Parameter` object to set the value of one or more block parameters in a model, such as the **Gain** parameter of a Gain block. For examples and programmatic information, see `Simulink.Parameter`.



Value

Ideal real-world value that the object stores. Block parameters that refer to the object use the value that you specify.

You can use MATLAB expressions to specify the value.

Example Expression	Description
`15.23`	Specifies a scalar value
`[3 4; 9 8]`	Specifies a matrix
`3+2i`	Specifies a complex value
`struct('A',20,'B',5)`	Specifies a structure with two fields, `A` and `B`, with double-precision values `20` and `5`. Organize block parameters into structures (see "Organize Related Block Parameter Definitions in Structures" on page 36-22) or initialize the signal elements in a bus (see "Specify Initial Conditions for Bus Signals" on page 65-108).

To use a `Simulink.Parameter` object to store a value of a particular numeric data type, specify the ideal value with the **Value** property, and control the type with the **Data type** property.

If you set the **Value** property by using a typed expression such as `single(32.5)`, the **Data type** property changes to reflect the new type. A best practice is using an expression that is not typed. You can avoid accumulating numerical error through repeated quantizations or data type saturation, especially for fixed-point data types.

When you specify an array with three or more dimensions, the **Value** property displays the array as an expression that contains a call to the `reshape` function. To edit the values in the array, modify the first argument of the `reshape` call, which contains all of the array values in a serialized vector. When you add or remove elements along a dimension, you must also correct the argument that represents the length of the modified dimension.

To more easily edit a large vector, 2-D matrix, or structure that you store in a `Simulink.Parameter` object, consider using the Variable Editor. See "Manage and Edit Workspace Variables" on page 36-16.

Data type

Data type of the parameter value that you specify in the **Value** property. When you simulate the model or generate code, Simulink casts the value to the specified data type.

If you select `auto`, the default setting, the parameter object uses the same data type as the block parameters that use the object. See "Reduce Maintenance Effort with Data Type Inheritance" on page 36-55.

When you set the **Value** property by using something other than a `double` number, the object typically sets the **Data type** property based on the value of the **Value** property. For example, when you set the **Value** property to `int8(5)`, the object sets the value of the **Data type** property to `int8`.

You can select a data type from the drop-down list or specify the name of a data type with text.

To explicitly specify a built-in data type (see "Data Types Supported by Simulink" on page 59-6), use one of these options:

- `double`
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`
- `boolean`

To specify a fixed-point data type, use the `fixdt` function. For example, specify `fixdt(1,16,5)`.

If you use a `Simulink.AliasType` or `Simulink.NumericType` object to create and share custom data types in your model, specify the name of the object.

To specify an enumerated data type, use the name of the type preceded by `Enum:`. For example, specify `Enum: myEnumType`.

When you store a structure or array of structures in the **Value** property of the object, the object sets the **Data type** property to `struct`. To specify a `Simulink.Bus` object as the data type, use the name of the bus object preceded by `Bus:`. For example, specify `Bus: myBusObject`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Data type** parameter. For more information, see "Specify Data Types Using Data Type Assistant" on page 59-39.

Dimensions

Dimensions of the parameter value.

When you set the **Value** property of the object, the object sets the value of the **Dimensions** property to a `double` row vector. The vector is the same vector that the `size` function returns.

To use symbolic dimensions, see "Implement Dimension Variants for Array Sizes in Generated Code" (Embedded Coder).

Complexity

Numeric complexity of the parameter value. Simulink determines the complexity from the parameter value that you specify in the **Value** property. This property is read only.

Minimum

Minimum value that the parameter can have. The default value is `[]` (empty), which means the parameter value does not have a minimum. Specify a real `double` scalar.

If you store a complex number in the **Value** property, the **Minimum** property applies separately to the real and imaginary parts.

If you store a structure in the **Value** property, the object ignores the **Minimum** property. Instead, use a `Simulink.Bus` object as the data type of the parameter object, and specify a minimum value for each field by using the elements of the bus object. See "Control Field Data Types and Characteristics by Creating Parameter Object" on page 36-24.

If the parameter value is less than the minimum value or if the minimum value is outside the range of the object data type, Simulink generates a warning. When updating the diagram or starting a simulation, Simulink generates an error.

For more information about how Simulink uses this property, see "Specify Minimum and Maximum Values for Block Parameters" on page 36-65.

Maximum

Maximum value that the parameter can have. The default value is `[]` (empty), which means the parameter value does not have a maximum. Specify a real `double` scalar.

If you store a complex number in the **Value** property, the **Maximum** property applies separately to the real and imaginary parts.

If you store a structure in the **Value** property, the object ignores the **Maximum** property. Instead, use a `Simulink.Bus` object as the data type of the parameter object, and specify a maximum value for each field by using the elements of the bus object. See "Control Field Data Types and Characteristics by Creating Parameter Object" on page 36-24.

If the parameter value is greater than the maximum value or if the maximum value is outside the range of the object data type, Simulink generates a warning. When updating the diagram or starting a simulation, Simulink generates an error.

For more information about how Simulink uses this property, see "Specify Minimum and Maximum Values for Block Parameters" on page 36-65.

Unit

Physical unit in which this value is expressed (for example, inches). To specify a unit, begin typing in the text box. As you type, the parameter displays potential unit string matches. For more information, see "Unit Specification in Simulink Models" on page 9-2.

Storage class

Storage class of this parameter object. Simulink code generation toolboxes use this property to allocate memory for this parameter object in the generated code.

For more information, see "Override Default Parameter Behavior by Creating Global Variables in the Generated Code" (Simulink Coder) and "Simulink Package Custom Storage Classes" (Embedded Coder).

Alias

Alternative name for this parameter in the generated code.

Alignment

Data alignment boundary for code generation, specified in number of bytes. The starting memory address for the data allocated for the parameter is a multiple of the **Alignment** setting. The default value is `-1`, which specifies that the code generator determine an optimal alignment based on usage. Otherwise, specify a positive integer that is a power of 2, not exceeding 128. For more information, see "Data Alignment for Code Replacement" (Embedded Coder).

Description

Custom description of this parameter object. Use this property to document the significance that the parameter object has in your algorithm.

If you have Embedded Coder, you can configure this description to appear in the generated code as a comment. See “Simulink data object descriptions” (Simulink Coder).

`Simulink.Parameter`

Use Simulink.Signal Objects to Specify and Control Signal Attributes

A `Simulink.Signal` object enables you to assign or validate the attributes of a signal or discrete state, such as its data type, numeric type, dimensions, and so on. For programmatic and reference information, see `Simulink.Signal`.

Using Signal Objects to Assign or Validate Signal Attributes

This section describes how you can use signal objects to assign or validate signal attributes. The same techniques work with discrete states also. To use a signal object to assign or validate signal attribute values:

1. Create a `Simulink.Signal` object that has the same name as the signal to which you want to assign attributes or whose attributes you want to validate.
   a. Open the Model Explorer.
   b. In the Model Hierarchy pane, select either the Base workspace or Model workspace node, depending on the context you want for the signal object. If you create the signal object in a model workspace, you must set the **Storage class** parameter to `Auto`.
   c. Select **Add** > **Simulink Signal**.
2. Set the properties of the object that correspond to the attributes left unspecified by the signal source, or that correspond to the attributes you want to validate. See "Property Dialog Box" on page 59-84 for details.
3. Enable explicit or implicit signal resolution:
   - **Explicit resolution:** In the Signal Properties dialog box for the signal, enable **Signal name must resolve to Simulink signal object**. This is the preferred technique. See "Explicit and Implicit Symbol Resolution" on page 59-139 for more information.

     When you use this technique, set **Configuration Parameters > Diagnostics > Data Validity > Signal resolution** to a value other than `None`. To use only explicit resolution (a best practice), set the parameter to `Explicit only`.
   - **Implicit resolution:** Set the **Configuration Parameters > Diagnostics > Data Validity > Signal resolution** option for the model to `Explicit and`

`implicit` or `Explicit and warn implicit`. Explicit resolution is the preferred technique.

4. Assign the signal object to a workspace variable.
5. Associate the signal object with the source signal.
   - Give the signal the same name as the workspace variable that references the signal object.
   - You can use a variety of techniques to associate a signal object with a signal. For examples, see "Use Signal Objects to Initialize Signals and Discrete States" on page 64-55, "Using Signal Objects to Tune Initial Values" on page 64-56, and "Control Data Representation by Applying Custom Storage Classes" (Embedded Coder).

Validation

The result when a signal does not match a signal object can depend on several factors. Simulink software can validate a signal property when you update the diagram, while you run a simulation, or both. When and how validation occurs can depend on internal rules that are subject to change, and sometimes on configuration parameter settings.

Not all signal validation compares signal source attributes with signal object properties. For example, if you specify **Minimum** and **Maximum** signal values using a signal object, the signal source must specify the same values as the signal object (or inherit the values from the object) but such validation relates only to agreement between the source and the object, not to enforcement of the minimum and maximum values during simulation.

If the value of **Configuration Parameters > Diagnostics > Data Validity > Simulation range checking** is `none` (the default), Simulink does not enforce any minimum and maximum signal values during simulation, even though a signal object provided or validated them. To enforce minimum and maximum signal values during simulation, set **Simulation range checking** to `warning` or `error`. See "Signal Ranges" on page 64-45 and "Model Configuration Parameters: Data Validity Diagnostics" for more information.

Multiple Signal Objects

You can associate a given *signal object* with more than one signal if the storage class of the signal object is `Auto` or `Reusable`. If the storage class is `Auto` and you clear

optimizations such as **Signal storage reuse** so that the generated code allocates memory for all of the associated signals, the signals each appear as a uniquely named field of the global structure that contains signal and state data. If the storage class of the object is other than `Auto` or `Reusable`, you can associate the signal object with no more than one signal.

You can associate a given *signal* with no more than one signal object. The signal can refer to the signal object more than once, but every reference must resolve to exactly the same signal object. Referencing two different signal objects that have exactly the same properties causes a compile-time error.

A compile-time error occurs if a model associates more than one signal object with any signal. To prevent the error, decide which object you want the signal to use, then delete or reconfigure all references to any other signal objects, so that all remaining references resolve to the chosen signal object. See "Highlight Signal Sources and Destinations" on page 64-39 for a description of techniques that you can use to trace the full extent of a signal.

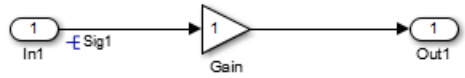
Signal Specification Block: An Alternative to Simulink.Signal

You can use a Signal Specification block rather than a `Simulink.Signal` object to assign properties left unspecified by a signal source. Each technique has advantages and disadvantages:

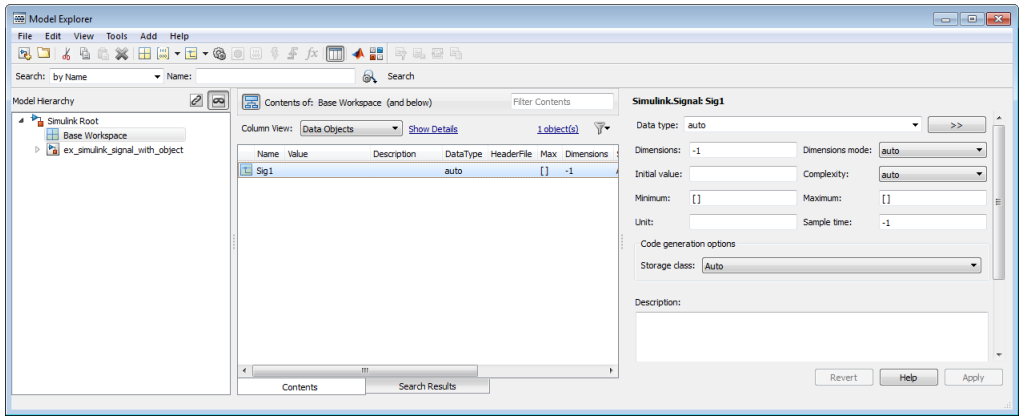
- Using a signal object simplifies the model and allows you to change signal property values without editing the model, but does not show signal property values directly in the block diagram.
- Using a Signal Specification block displays signal property values directly in the block diagram, but complicates the model and requires editing it to change signal property values.
- You can use a Signal Specification block with virtual and nonvirtual buses; you can use only nonvirtual buses with a `Simulink.Signal` object.

The following two models illustrate the respective advantages of the two ways of assigning attributes to a signal.

In the first example, the signal object named `Sig1` specifies the sample time and data type of the signal emitted by input port `In1`.



To determine the properties of the `Sig1` signal, you can view the signal object in the Model Explorer. In this model, the sample time is `-1` and the data type is `auto`.



Using a signal object to specify the sample time and data type properties of signal `Sig1` allows you to change the sample time or data type without having to edit the model. For example, you could use the Model Explorer, the MATLAB command line, or a MATLAB program to change these properties.

The second example uses a Signal Specification block specifies the sample time and data type of the signal emitted by input port `In2`. The Signal Specification block displays the data type and signal sample time properties right in the diagram, which in this case are `uint8` and `4`, respectively.

Bus Support

Using Bus Objects as the Data Type

`Simulink.Signal` supports nonvirtual buses as the output data type.

If you set the **Data type** of the signal object to be a bus object, then you cannot associate the signal object with a non-bus signal.

Using Structures for the Initial Value

If you use a bus object as the data type, set **Initial value** to `0` or a MATLAB structure that matches the bus object.

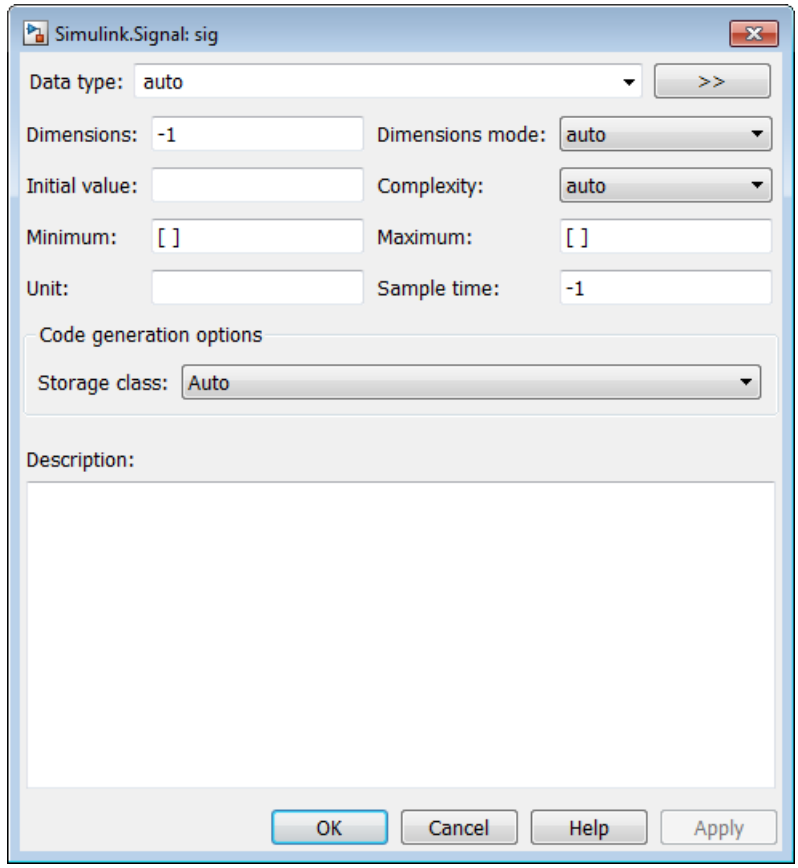
The structure you specify must contain a value for every element of the bus represented by the bus object.

You can use the `Simulink.Bus.createMATLABStruct` to create a full structure that corresponds to a bus.

You can use `Simulink.Bus.createObject` to create a bus object from a MATLAB structure.

Property Dialog Box

For examples and programmatic information about `Simulink.Signal`, see `Simulink.Signal`.



Data type

Data type of the signal. The default entry, `auto`, specifies that Simulink should determine the data type. Use the adjacent pulldown list to specify built-in data types (for example, `uint8`). To specify a custom data type, enter a MATLAB expression that specifies the type, (for example, a base workspace variable that references a `Simulink.NumericType` object).

To specify a bus object as the data type for the signal object, use the `Bus: <object_name>` option. See "Bus Support" on page 59-84 for details about what you need to do if you specify a bus object as the data type.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Data type** parameter. (See "Specify Data Types Using Data Type Assistant" on page 59-39 in *Simulink User's Guide*.)

Complexity

Numeric type of the signal. Valid values are `auto` (determined by Simulink), `real`, or `complex`.

Dimensions

Dimensions of this signal. Valid values are `-1` (the default) specifying any dimensions, `N` specifying a vector signal of size `N`, or `[M N]` specifying an `MxN` matrix signal.

Dimensions mode

Dimensions mode of this signal. From the drop-down list, select

- Auto — Allows variable-size and fixed-size signals.
- Fixed — Allows only fixed-size signals. Does not allow variable-size signals.
- Variable — Allows only variable-size signals.

Sample time

Rate at which the value of this signal should be computed. See "Specify Sample Time" on page 7-3 for details.

Minimum

Minimum value that the signal should have. The default value is `[]` (unspecified). Specify a finite, real, double, scalar value.

Note If you specify a bus object as the data type for a signal, do not set the minimum value for bus data on the signal property dialog box. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see `Simulink.BusElement`.

Simulink uses this value in the following ways:

- When updating the diagram or starting a simulation, Simulink generates an error if the signal's initial value is less than the minimum value or if the minimum value is outside the range for the data type of the signal.

- When you enable the **Simulation range checking** diagnostic, Simulink alerts you during simulation if the signal value is less than the minimum value (see "Simulation range checking").

Maximum

Maximum value that the signal should have. The default value is `[]` (unspecified). Specify a finite, real, double, scalar value.

Note If you specify a bus object as the data type for a signal, do not set the maximum value for bus data on the signal property dialog box. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see `Simulink.BusElement`.

Simulink uses this value in the following ways:

- When updating the diagram or starting a simulation, Simulink generates an error if the initial value of the signal is greater than the maximum value or if the maximum value is outside the range of the data type of the signal.
- When you enable the **Simulation range checking** diagnostic, Simulink alerts you during simulation if the signal value is greater than the maximum value (see "Simulation range checking").

Initial value

Signal or state value before a simulation takes its first time step. You can specify any MATLAB expression, including the name of a workspace variable, that evaluates to a numeric scalar value or array.

You can use the MATLAB command prompt to provide an initial value for a signal. Even if you use a number, specify the initial value as a character vector.

```
mySigObject.InitialValue='5.3';

mySigObject.InitialValue = 'myNumericVariable';
```

To specify an initial value for a signal that uses a numeric data type other than `double`, cast the initial value to the signal data type. For example, you can specify `single(73.3)` to use `73.3` as the initial value for a signal of data type `single`.

If you use a bus object as the data type for the signal object, set **Initial value** to a character vector containing either `0` or a MATLAB structure that matches the bus object. See "Bus Support" on page 59-84 for details.

If the initial value evaluates to a MATLAB structure, then in the **Configuration Parameters** dialog box, set "Underspecified initialization detection" to `simplified`.

If necessary, Simulink converts the initial value to ensure type, complexity, and dimension consistency with the corresponding block parameter value. If you specify an invalid value or expression, an error message appears when you update the model. Also, Simulink performs range checking of the initial value. The software alerts you when the initial value of the signal lies outside a range that corresponds to its specified minimum and maximum values and data type.

Classic initialization mode: In this mode, initial value settings for signal objects that represent the following signals and states override the corresponding block parameter initial values if undefined (specified as `[]`):

- Output signals of conditionally executed subsystems and Merge blocks
- Block states

Simplified initialization mode: In this mode, initial values of signal objects associated with the following blocks are ignored. The initial values of the corresponding blocks are used instead.

- Outport blocks of conditionally executed subsystems
- Merge blocks

Unit

Physical unit in which the value of this signal is expressed, (for example, inches). To specify a unit, begin typing in the text box. As you type, the parameter displays potential matching units. For more information, see "Unit Specification in Simulink Models" on page 9-2.

Storage class

Storage class of this signal. For more information, see "Storage Classes for Signals and States" (Simulink Coder) and "Simulink Package Custom Storage Classes" (Embedded Coder).

If you create the signal object in a model workspace, you must set the object storage class to `Auto`.

Alias

Alternate name for this signal. Simulink ignores this setting. This property is used for code generation.

Alignment

Data alignment boundary, specified in number of bytes. The starting memory address for the data allocated for the signal will be a multiple of the **Alignment** setting. The default value is `-1`, which specifies that the code generator should determine an optimal alignment based on usage. Otherwise, specify a positive integer that is a power of 2, not exceeding 128. This field is intended for use by Simulink Coder software. See "Data Alignment for Code Replacement" (Embedded Coder). Simulink software ignores this setting.

Description

Description of this signal. This field is intended for use in documenting this signal. This property is used by the Simulink Report Generator and for code generation.

If you have an Embedded Coder license, you can add the signal description as a comment for the variable declaration in generated code.

- Specify a storage class for the signal object other than `Auto`.
- On the **Code Generation > Comments** pane of the Model Configuration Parameters dialog box, select the model configuration parameter **Simulink data object descriptions**. For more information, see "Simulink data object descriptions" (Simulink Coder).

`Simulink.Signal`

Define Data Classes

This example shows how to subclass Simulink data classes.

Use MATLAB class syntax to create a data class in a package. Optionally, assign properties to the data class and define custom storage classes.

Use an example to define data classes

1. View the `+SimulinkDemos` data class package in the folder *`matlabroot`*`/toolbox/simulink/simdemos/dataclasses` (open).

   This package contains predefined data classes.
2. Copy the folder to the location where you want to define your data classes.
3. Rename the folder `+mypkg` and add its parent folder to the MATLAB path.
4. Modify the data class definitions.

Manually define data class

1. Create a package folder `+mypkg` and add its parent folder to the MATLAB path.
2. Create class folders `@Parameter` and `@Signal` inside `+mypkg`.

   Note Simulink requires data classes to be defined inside `+Package/@Class` folders.
3. In the `@Parameter` folder, create a MATLAB file `Parameter.m` and open it for editing.
4. Define a data class that is a subclass of `Simulink.Parameter` using MATLAB class syntax.

   ```
   classdef Parameter < Simulink.Parameter

   end % classdef
   ```

To use a custom class name other than `Parameter` or `Signal`, name the class folders using the custom name. For example, to define a class `mypkg.myParameter`:

- Define the data class as a subclass of `Simulink.Parameter` or `Simulink.Signal`.

```
classdef myParameter < Simulink.Parameter

end % classdef
```

- In the class definition, name the constructor method as `myParameter` or `mySignal`.
- Name the class folder, which contains the class definition, as `@myParameter` or `@mySignal`.

Optional: Add properties to data class

The `properties` and `end` keywords enclose a property definition block.

```
classdef Parameter < Simulink.Parameter
    properties % Unconstrained property type
        Prop1 = [];
    end

    properties(PropertyType = 'logical scalar')
        Prop2 = false;
    end

    properties(PropertyType = 'char')
        Prop3 = '';
    end

    properties(PropertyType = 'char',...
      AllowedValues = {'red'; 'green'; 'blue'})
        Prop4 = 'red';
    end
end % classdef
```

If you add properties to a subclass of `Simulink.Parameter`, `Simulink.Signal`, or `Simulink.CustomStorageClassAttributes`, you can specify the following property types.

Property Type	Syntax
Double number	`properties(PropertyType = 'double scalar')`
int32 number	`properties(PropertyType = 'int32 scalar')`
Logical number	`properties(PropertyType = 'logical scalar')`

Property Type	Syntax
Character vector (char)	`properties(PropertyType = 'char')`
Character vector with limited set of allowed values	`properties(PropertyType = 'char', AllowedValues = {'a', 'b', 'c'})`

If you use MATLAB property validation (see "Validate Property Values" (MATLAB)) instead of `PropertyType` and `AllowedValues`, the property validation does not affect the appearance in the property dialog box of the class. For example, a Boolean (`boolean`) property does not appear in the property dialog box as a check box. It is a best practice to use `PropertyType` and `AllowedValues` instead of MATLAB property validation.

Optional: Add initialization code to data class

You can add a constructor within your data class to perform initialization activities when the class is instantiated.

In this example, the constructor initializes the value of object `obj` based on an optional input argument.

```
classdef Parameter < Simulink.Parameter
    methods
        function obj = Parameter(optionalValue)
            if (nargin == 1)
                obj.Value = optionalValue;
            end
        end
    end % methods
end % classdef
```

Optional: Define custom storage classes

Use the `setupCoderInfo` method to configure the `CoderInfo` object of your class. Then, create a call to the `useLocalCustomStorageClasses` method and open the Custom Storage Class Designer.

1 In the constructor within your data class, call the `useLocalCustomStorageClasses` method.

```
classdef Parameter < Simulink.Parameter
    methods
        function setupCoderInfo(obj)
            useLocalCustomStorageClasses(obj, 'mypkg');
```

```
            obj.CoderInfo.StorageClass = 'Custom';
        end
    end % methods
end % classdef
```

2 Open the Custom Storage Class Designer for your package.

```
cscdesigner('mypkg')
```

3 Define custom storage classes.

Optional: Define custom attributes for custom storage classes

1 Create a MATLAB file `myCustomAttribs.m` and open it for editing. Save this file in the `+mypkg/@myCustomAttribs`folder, where `+mypkg` is the folder containing the `@Parameter` and `@Signal` folders.

2 Define a subclass of `Simulink.CustomStorageClassAttributes` using MATLAB class syntax. For example, consider a custom storage class that defines data using the original identifier but also provides an alternate name for the data in generated code.

```
classdef myCustomAttribs < Simulink.CustomStorageClassAttributes
    properties(PropertyType = 'char')
        AlternateName = '';
    end
end % classdef
```

3 Override the default implementation of the `isAddressable` method to determine whether the custom storage class is writable.

```
classdef myCustomAttribs < Simulink.CustomStorageClassAttributes
        properties(PropertyType = 'logical scalar')
            IsAlternateNameInstanceSpecific = true;
        end

        methods
            function retVal = isAddressable(hObj, hCSCDefn, hData)
                retVal = false;
            end
        end % methods
end % classdef
```

4 Override the default implementation of the `getInstanceSpecificProps` method.

For examples, see `CSCTypeAttributes_FlatStructure.m` in the folder *`matlabroot`*`\toolbox\simulink\simulink\dataclasses\+Simulink\@CSCTypeAttributes_FlatStructure` (open) and `CSCTypeAttributes_Unstructed.m` in the folder *`matlabroot`*`\toolbox\simulink\simulink\dataclasses\+mpt\@CSCTypeAttributes_Unstructed` (open).

Note This is an optional step. By default, all custom attributes are instance-specific and are modifiable for each data object. However, you can limit which properties are allowed to be instance-specific.

---

5 Override the default implementation of the `getIdentifiersForInstance` method to define identifiers for objects of the data class.

Note In its default implementation, this method queries the name or identifier of the data object and uses that identifier in generated code. By overriding this method, you can control the identifier of your data objects in generated code.

```
classdef myCustomAttribs < Simulink.CustomStorageClassAttributes
    properties(PropertyType = 'char')
        GetFunction = '';
        SetFunction = '';
    end

    methods
        function retVal = getIdentifiersForInstance(hCSCAttrib,...
 hCSCDefn, hData, identifier)
            retVal = struct('GetFunction',...
 hData.CoderInfo.CustomAttributes.GetFunction, ...
            'SetFunction', hData.CoderInfo.CustomAttributes.SetFunction);
        end%
    end % methods
end % classdef
```

6 If you are using grouped custom storage classes, override the default implementation of the `getIdentifiersForGroup` method to specify the identifier for the group in generated code.

For an example, see `CSCTypeAttributes_FlatStructure.m` in the folder *`matlabroot`*`\toolbox\simulink\simulink\dataclasses\+Simulink\@CSCTypeAttributes_FlatStructure` (open).

Determine Where to Store Variables and Objects for Simulink Models

Model data are objects and variables that you create in workspaces such as the base workspace or a data dictionary. Model data include:

- Numeric values for block parameters, such as `Simulink.Parameter` objects and MATLAB variables
- Signals, such as `Simulink.Signal` objects
- Data types
- Model configuration sets
- Simulation input and output data

You can store, partition, and share model data in a location that is appropriate for your design. The storage locations that you choose can depend on:

- Your modeling goals.
- The model architecture (referenced models, subsystems, and other partitioning strategies) and component structure.
- The types of data that you use.

Types of Data

- Simulation data is the set of input data that you use to drive a simulation and the set of output data that a simulation generates. For example, you can use variables to store input data that a simulation acquires through Inport blocks. A simulation can export output data through, for example, Outport blocks, To Workspace blocks, and logged signals.

  You can store simulation data for your current MATLAB session in the base workspace. To permanently store this simulation data, save it in a MAT-file or script file. For more information about loading, generating, and storing simulation data, see “Comparison of Signal Loading Techniques” on page 61-128 and “Export Simulation Data” on page 61-3.
- Design data is the set of variables that you use to specify block parameters and signal characteristics in a model. For example, design data includes numeric MATLAB variables, parameter and signal data objects, data type objects, and bus objects.

You can store design data in the base workspace, model workspaces, or the Design Data section of a data dictionary. To permanently store local design data with a model, use model workspaces. To share design data between models, use data dictionaries or the base workspace. Data dictionaries permanently store the data, and you can control the data scope to establish ownership, partition the data to ease readability and maintenance, and track changes. If you use the base workspace, to permanently store the data, you must save it in a MAT-file or script file.

- Configuration sets are sets of model configuration parameters. By default, configuration sets reside in the model file, so you do not need to store the sets separately from the model. However, you cannot share these sets with other models.

  To share configuration sets between models, you must create `Simulink.ConfigSet` objects. Each object represents a standalone configuration set. You can store these objects in the base workspace or in the Configurations section of a data dictionary. If you use data dictionaries, you can define the scope of each configuration set, compare different configuration sets, and track changes. A data dictionary inherently partitions configuration sets from other kinds of data.

Store Data for Your Design

The table shows the techniques you can use to store, partition, and manage design data and configuration sets.

Modeling Scenario	Scenario Description	Storage Locations and Techniques
Rapid prototyping and model experimentation	You want to create temporary data, such as variables to specify numeric block parameters, while you learn to use Simulink. You want to experiment with modeling techniques. You do not need to permanently store the data that you create.	Store data in the base workspace so you can quickly create and change the data.
Standalone model	You have a single model that does not depend on other systems for data. The model stands alone because it is not a piece of a larger system.	Store data in the model workspace to improve model portability. Use a data dictionary to store data that you cannot store in the model workspace. Alternatively, store all of the model data in a data dictionary. If you use a dictionary, you can partition the data by using referenced dictionaries.

Modeling Scenario	Scenario Description	Storage Locations and Techniques
Standalone hierarchy of referenced models	You have a hierarchy of referenced models that does not depend on other systems for data. The hierarchy stands alone because it is not a piece of a larger system.	Store local model data in each model workspace. Store data that the models share, such as bus objects and configuration sets, in a data dictionary. Link all of the models in the hierarchy to the dictionary. For examples, see "Migrate Model Reference Hierarchy to Use Dictionary" on page 63-8 and Using a Data Dictionary to Manage the Data for a Fuel Control System.
System of components	One or more teams maintain the components of a system of models. A component is a single model or a hierarchy of referenced models that represents a piece of a larger system.	Store local model data in model workspaces. Store data that the models in a component share, such as bus objects and configuration sets, in a data dictionary. Link all of the models in the component to the dictionary. Use additional referenced dictionaries to store data that the components share. For an example, see "Partition Data for Model Reference Hierarchy Using Data Dictionaries" on page 63-37.

Storage Locations

Choose any of these locations to store data:

- The MATLAB base workspace. Use the base workspace to store variables while you experiment with temporary models.

- A model workspace. Use a model workspace to permanently store data that is local to a model.
- A data dictionary. Use data dictionaries to permanently store global data, share data between models, and track changes made to data.

The chart shows the capabilities and advantages of each storage location.

Capability	Base Workspace	Model Workspace	Data Dictionary
Data-model linkage	implicit	implicit	✓
Unified interface for defining data	✓	✓	✓
Model-data dependency	✓	✓	✓
Data entry comparison	✓	✓	✓
Data entry persistence		✓	✓
Options to remedy a missing variable	✓	✓	Additional options
Shared data	✓		✓
Data grouping			✓
Change tracking for data entries			✓
Change tracking for configuration sets			✓
Data entry merging and reconciliation			✓
Storage and partitioning of auxiliary data			✓
Requirements linking			✓

For information about the way that models interact with workspaces and workspace variables, see “Symbol Resolution” on page 59-136.

Temporary Data: Base Workspace

Use the base workspace to temporarily store data:

- While you learn to use Simulink
- When you need to quickly create variables while experimenting with modeling techniques

- When you do not need to store the data permanently

To create variables in the base workspace, you can use the MATLAB command prompt or the Model Explorer. All open models can use the data that you create in the base workspace.

If you use variables to specify numeric block parameters in the model, you can programmatically change the parameter values during simulation by using commands at the command prompt. To programmatically change the values of parameters that you store in the model workspace or data dictionaries, you must use the function interfaces for those storage locations.

To permanently store base workspace data before you end a MATLAB session, you can save the data in a MAT-file or a script file. During a later session, you can load the data from the file. However, if you make changes to the data in the base workspace, you must save the data to the file again. Consider instead using a model workspace or data dictionary to permanently store data.

Local Data: Model Workspace

Use a model workspace to store data that you use only in the associated model. This data can include:

- Constant parameters, for example, numeric variables that you use to specify block parameter values.
- Data objects, such as `Simulink.Signal` and `Simulink.Parameter` objects, that you use to control signal and parameter characteristics. However, signal objects in a model workspace can use only the `Auto` storage class. If you store an `AUTOSAR.Parameter` object in a model workspace, the code generator ignores the storage class that you specify for the object.
- `Simulink.NumericType` objects that you use to specify data types. However, you cannot use the object as a data type alias. You must set the `IsAlias` property to `false`.
- Model arguments.

You can improve model portability and establish data ownership by storing the data in the model workspace. In this case, the model file permanently stores the data.

In a model reference hierarchy, each model workspace acts as a unique namespace. Therefore, you can use the same variable name in multiple model workspaces. You can then assign a unique variable value for each model.

You can use the Model Explorer to manipulate model workspace data. Alternatively, you can use the command prompt or scripts in conjunction with the model workspace programmatic interface.

For more information about using model workspaces to store local data, see “Model Workspaces” on page 59-124.

Global and Shared Data: Data Dictionary

A data dictionary is a standalone file that permanently stores data. Use data dictionaries instead of the base workspace to partition data, track changes, control access, and share data. If you link a model to a data dictionary, the model does not use variables in the base workspace anymore.

As you can with model workspaces, you can use data dictionaries to directly associate data with a model. You can use this association to scope the data and to establish ownership.

When you use dictionaries, you can partition the data by storing it in additional referenced dictionaries. However, each entry in a dictionary must use a unique name. You must manage each dictionary as a separate file.

Use a data dictionary to store data that multiple models or system components share. This data can include:

- Numeric variables that multiple models use to specify block parameter values.
- `Simulink.AliasType` and `Simulink.NumericType` objects that you use to specify data types in multiple models at once.
- Data objects, including signal objects (such as `Simulink.Signal`) that use a storage class other than `Auto`. If you have a Simulink Coder license, these objects can represent signals and tunable parameters that appear as global variables in the generated code.
- `Simulink.Bus` objects that you use to define signal interfaces between referenced models.
- `Simulink.ConfigSet` objects that you use to maintain configuration parameter uniformity across multiple models.
- Enumerated type definitions, which you store using `Simulink.data.dictionary.EnumTypeDefinition` objects.

You can use the Model Explorer to manipulate dictionary data. Alternatively, you can use the command prompt or scripts in conjunction with the data dictionary programmatic interface.

For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 63-2.

Considerations for Code Generation

If you intend to generate C code from a model (Simulink Coder), take these considerations into account.

- If you apply a storage class other than `Auto` to a signal object (such as `Simulink.Signal`) to control the appearance of a signal or block state in the generated code, you cannot store the object in a model workspace. Store the object in the base workspace or a data dictionary. For more information about storage classes for signals and states, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder).
- If you apply a storage class other than `Auto` to a parameter object (such as `Simulink.Parameter`), you can store the object in the base workspace, a model workspace, or a data dictionary. However, if you store the object in a model workspace, the code generator assumes that the containing model owns the parameter. For more information, see “Impact of Storage Location for Parameter Objects” (Simulink Coder).

Create, Edit, and Manage Workspace Variables

To share information such as parameter values and signal data types between separate blocks and models, you use workspace variables. For example, you can create a numeric MATLAB variable in the base workspace and use the variable to set the value of the **Gain** parameter in multiple Gain blocks simultaneously (see "Share and Reuse Block Parameter Values by Creating Variables" on page 36-12). You can create a `Simulink.Bus` object to explicitly define the structure of a bus signal.

You can store workspace variables in the base workspace, model workspaces, or data dictionaries. To decide where to store variables, see "Determine Where to Store Variables and Objects for Simulink Models" on page 59-96.

Tools for Managing Variables

Use one or more of these techniques to create, modify, store, and migrate workspace variables:

- To share block parameter values and create `Simulink.Parameter` and `Simulink.Signal` objects (for example, in preparation for code generation), you can use the Model Data Editor. You can interact with all of the block parameters, signal lines, and block states in a model at once. You can also inspect tunable block parameters in a list that you can search, sort, and filter.

  - To create a variable, in the data table, begin editing the cell that corresponds to a block parameter value (in the **Value** column) or a signal or state name (in the **Name** column). Enter the name of the variable you want to create and click the action button ⋮ in the right side of the cell.
  - To modify variables by using the columns in the data table, click the **Show/ refresh additional information** button. Then, the data table contains rows that correspond to the variables and objects that the model uses.
  - To interact with one variable at a time (for example, to inspect all of the variable properties at once), open the Property Inspector (**View > Property Inspector**) and select the relevant row in the data table. The Property Inspector shows the properties of the selected variable.

  For more information about the Model Data Editor, see "Configure Data Properties by Using the Model Data Editor" on page 59-141.

- To interact with a small number of parameters, signals, or states at a time, use individual block parameter dialog boxes or the Property Inspector to create variables for sharing block parameter values and create and configure parameter and signal objects for code generation.

  In the dialog box or the Property Inspector, click the action button ⋮ next to the value of a block parameter, signal name, or state name.
- To create and edit any type or class of variable or object, move variables between workspaces, and inspect all of the variables in a workspace at once, use the Model Explorer. You can also rename variables and precisely analyze the way that an entire model or an individual block uses variables. See "Search and Edit Using Model Explorer" on page 12-2 and "Edit and Manage Workspace Variables by Using Model Explorer" on page 59-111.

Edit Variable Value or Property From Block Parameter

This example shows how to change the value of a **Gain** parameter (Gain block) whose value is set by a numeric variable. Modify the variable, not the block parameter.

1. Open the model `f14`. The model loads variables into the base workspace.
2. In the model, open the Property Inspector. Select **View** > **Property Inspector**.
3. In the model, select the Gain block that uses the variable `Mw`.
4. In the Property Inspector, click the button ⋮ next to the value of the **Gain** parameter. Select **Open**.
5. In the **Data properties** dialog box, type a new value for the variable in the **Value** box and click **OK**.

Modify Structure and Array Variables Interactively

To inspect and modify a variable whose value is a structure or array, you can launch the Variable Editor by clicking the nearby button ⋮. Choose one of these techniques:

- In the Model Explorer, select the variable in the **Contents** pane. In the Dialog pane (the right pane), the button appears.
- In the Model Data Editor (**View** > **Model Data**), on the **Parameters** tab, click the **Show/refresh additional information** button. In the data table, find the row that

corresponds to the variable and, in the **Value** column, begin editing the value of the variable. The button appears in the right side of the cell.

- In a block dialog box or the Property Inspector, the button appears next to the value of a block parameter that uses the variable. Click the button and use the menu options to open the property dialog box for the variable. Then, in the property dialog box, click the button again to launch the Variable Editor. You can use this technique only for parameter objects such as `Simulink.Parameter`.

Ramifications of Modifying or Deleting a Variable

When you modify or delete a variable, the change can impact multiple blocks and models that use the variable. To assess the impact by determining where the variable is used, use the Model Explorer (see "Analyze Variable Usage in a Model" on page 59-107). However, you can analyze variable usage only for models that are open at the time of the analysis. Before you perform the analysis, open any models that you suspect use the variable.

Models and blocks use variables through name resolution (see "Symbol Resolution" on page 59-136). When you change the name of a variable without making corresponding changes to dependent blocks and models, the blocks and models generate errors. Instead, to rename a variable in the context of one or more models, see "Rename a Variable Throughout a Model" on page 59-108.

When a block or model cannot access a variable that it needs, it generates an error in the Diagnostic Viewer. In some cases, you can use buttons in the Diagnostic Viewer to fix the error (for example, by restoring a deleted variable). To increase the likelihood that you can use the Diagnostic Viewer to recover from the absence of a variable, store variables in a data dictionary instead of the base workspace. With a data dictionary, you gain additional options for recovery. For information about data dictionaries, see "What Is a Data Dictionary?" on page 63-2.

Analyze Variable Usage in a Model

To analyze the ways in which a model uses variables, use the Model Explorer. You can:

- Determine where a variable is used in a model.
- Determine whether a model uses a variable.
- Determine which variables in a workspace are not used by a model.

For more information, see “Edit and Manage Workspace Variables by Using Model Explorer” on page 59-111.

Rename a Variable Throughout a Model

This example shows how to rename a variable by navigating to the Model Explorer from a block parameter in the Model Data Editor. To rename a variable, you must use the Model Explorer.

1. Open the model `f14`. The model loads variables into the base workspace.
2. In the model, select **View** > **Model Data**. In the Model Data Editor, inspect the **Parameters** tab.
3. In the model, click the Gain block labeled `Mw`.

   In the Model Data Editor, the **Value** column shows that the block uses the variable `Mw`. Suppose you want to rename this variable.
4. In the Model Data Editor, click the **Show/refresh additional information** button.

   Now, the data table contains rows that correspond to workspace variables that the model uses.
5. Activate the **Change scope** button.

   Now, the data table shows information about data items in subsystems.
6. In the **Filter contents** box, enter `Mw`.

   The data table shows rows that correspond to the variable and to blocks that use the variable.
7. In the leftmost column, for the row that represents `Mw`, double-click the icon.

   The Model Explorer opens with `Mw` selected in the **Contents** pane (the middle pane).
8. In Model Explorer, right-click the variable `Mw` and select **Rename All**.
9. In the **Select a system** dialog box, click the name of the model `f14` to select it as the context for renaming the variable `Mw`.
10. Clear the **Search in referenced models** check box, since `f14` does not reference any models, and click **OK**.

With **Search in referenced models** selected, you can rename the target variable everywhere it is used in a model reference hierarchy. However, renaming the target variable in an entire hierarchy can take more time.

The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.

11 In the **Rename All** dialog box, type the new name for the variable in the **New name** box and click **OK**.

12 In the Model Data Editor, click **Show/refresh additional information** again. Because the renaming operation changed the name of the variable and the values of some block parameters, for more accurate information in the Model Data Editor, you must click **Show/refresh additional information**.

Interact With Variables Programmatically

At the command prompt, you can create and modify variables in the base workspace by entering commands such as `myVar = 15;`. To programmatically create, modify, and store variables in a different workspace, such as a model workspace, use the programmatic interface for the target workspace. The table shows the interfaces and techniques that you can use to programmatically manage variables.

Target Workspace	Technique or Interface
Base workspace	Enter commands at the command prompt.
Model workspace	See `Simulink.ModelWorkspace`.
Data dictionary	See "Store Data in Dictionary Programmatically" on page 63-53.

To programmatically list the variables that a model uses or does not use, see `Simulink.findVars`.

To programmatically access variables for the purpose of sweeping block parameter values, consider using `Simulink.SimulationInput` objects instead of modifying the variables through the programmatic workspace interfaces. See "Optimize, Estimate, and Sweep Block Parameter Values" on page 36-48.

Edit and Manage Workspace Variables by Using Model Explorer

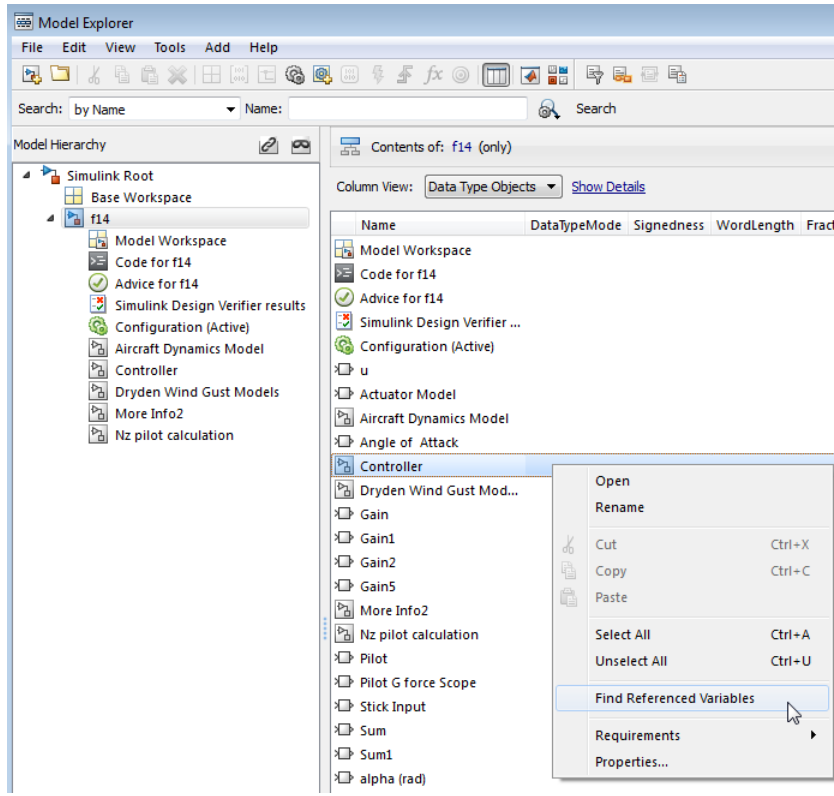
In this section...

To learn all of the techniques you can use to create, edit, and manage workspace variables, see “Create, Edit, and Manage Workspace Variables” on page 59-105.

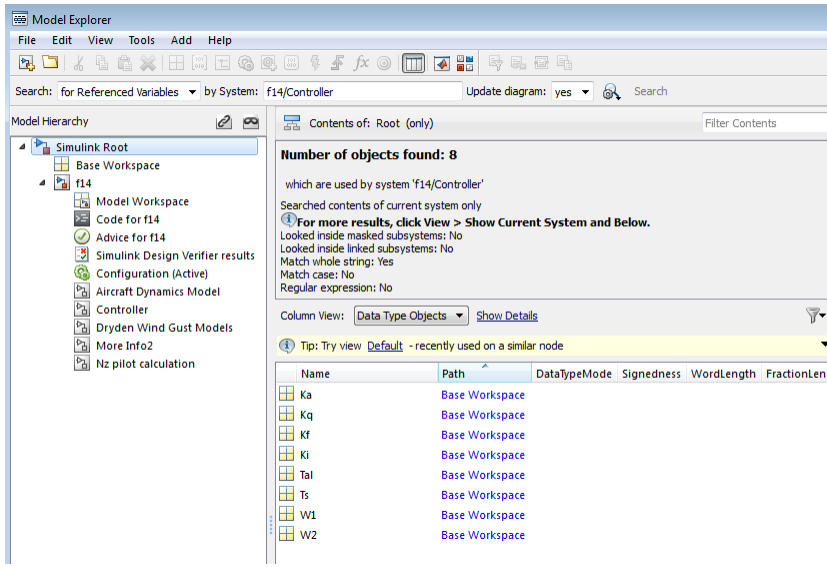
Finding Variables That Are Used by a Model or Block

In the Model Explorer, you can get a list of variables that a model or block uses. The following approach is one way to get that list of variables:

1. In the **Contents** pane, right-click the block for which you want to find the variables that it uses.
2. Select the **Find Referenced Variables** menu item.



Model Explorer returns results similar to these:



For performance, Model Explorer uses cached information from the last compiled version of the model. If you want to recompile the model, either do so manually or, in the Model Explorer, set the **Update diagram** field to `yes` and repeat the search.

You can also use the following approaches to find variables that a model or block uses:

- In the Model Explorer, in the **Model Hierarchy** pane, right-click a block or model node and select the **Find Referenced Variables** menu item.
- In the Model Explorer, in the search bar, use the `for Referenced Variables` search type option.
- In the Simulink Editor, right-click a block, subsystem, or in the canvas and select the **Find Referenced Variables** menu item. Clicking the canvas returns results for the whole model.

The `Simulink.findVars` function provides additional options for returning information about workspace variables that is not available from the Model Explorer or Simulink Editor.

For information about limitations when finding referenced variables, see the `Simulink.findVars` documentation.

Using the Set of Returned Variables

For a variable in the set of returned variables, you can find the blocks that use that variable (for details, see “Finding Blocks That Use a Specific Variable” on page 59-114). Also, you can export variables from the returned set of variables. For details, see “Export Workspace Variables” on page 59-120.

Finding Blocks That Use a Specific Variable

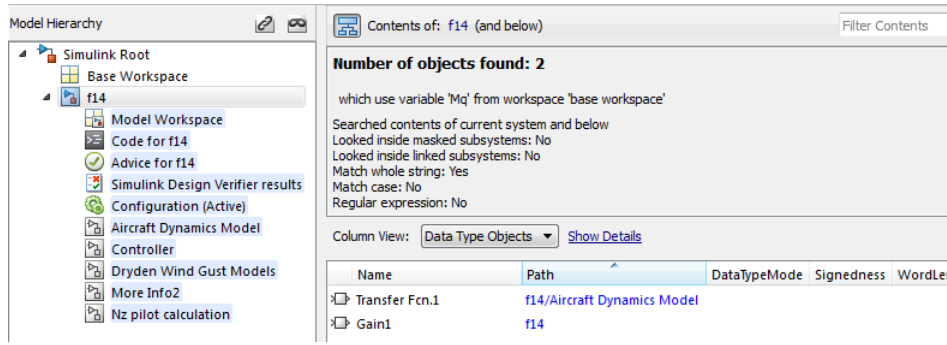
This example shows how to use Model Explorer to get a list of blocks that use a specific workspace variable.

1. Open the model `f14`.
2. Open Model Explorer.
3. In the **Model Hierarchy** pane, select the `Base Workspace` node.
4. In the **Contents** pane, right-click the variable `Mq` and select **Find Where Used**.
5. In the **Select a system** dialog box, select `f14`.
6. Clear the **Search in referenced models** check box, since `f14` does not reference any models, and click **OK**.

   With **Search in referenced models** selected, you can find the target variable everywhere it is used in a model reference hierarchy. However, finding the target variable in an entire hierarchy can take more time.

   The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.
7. Click **OK** in response to the message to update the model diagram.

   Because you just opened the model, you must update the model diagram at least once before finding a variable. You could have selected **Update diagram to include recent changes** in the **Select a system** dialog box to force an initial diagram update, though you typically use that option when you make changes to the model while performing multiple searches with **Find Where Used**.
8. Model Explorer displays the search results:



The property columns whose values include `Mq` represent the block parameters that use the `Mq` variable. If those property columns are not already in the view, then the Model Explorer adds them to the end of the search results display.

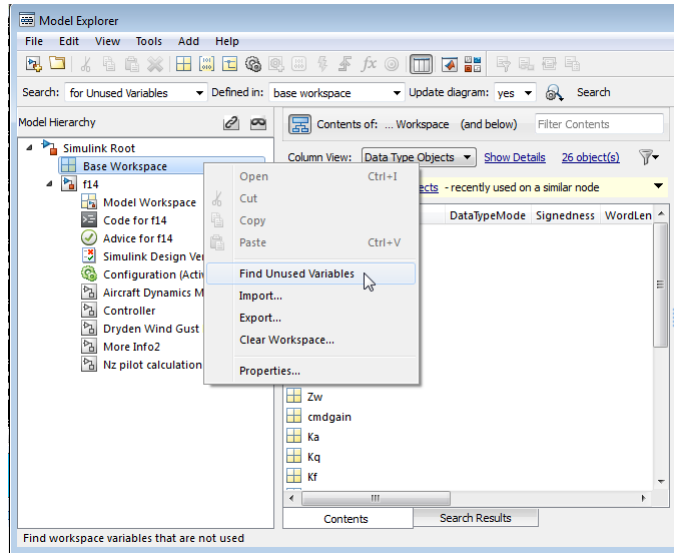
You can also find blocks that use a specific variable by using one of these approaches:

- In the search bar, select the `for Variable Usage` search type option.
- In the **Search Results** pane, right-click a variable and select the **Find Where Used** menu item.

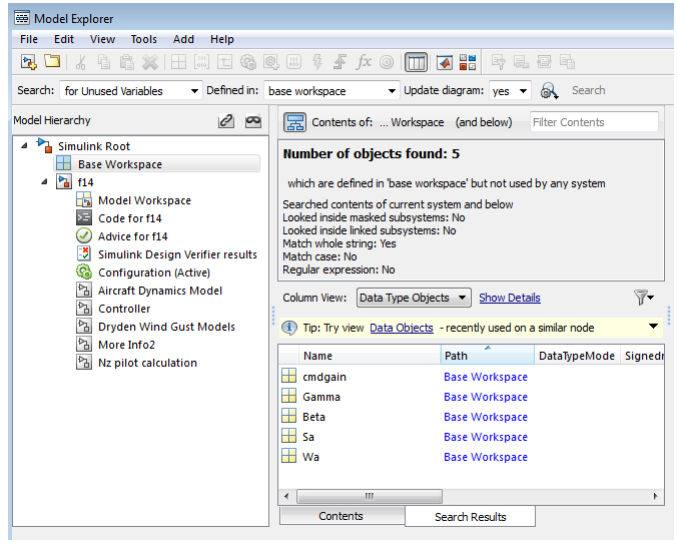
Finding Unused Workspace Variables

You can use the Model Explorer to get a list of variables that are defined in a workspace but not used by a model or block. One way to get that list of variables is to right-click a workspace name in the **Model Hierarchy** pane and select the **Find Unused Variables** menu item. For example:

1. Open the `f14` model.
2. Open the Model Explorer.
3. In the search toolbar, set the **Update diagram** field to `yes`.
4. In the **Model Hierarchy** pane, right-click the `Base Workspace` node and select the **Find Unused Variables** menu item.



5 The Model Explorer displays output similar to this:



The `Simulink.findVars` function provides additional options for returning information about unused workspace variables that is not available from the Model Explorer or Simulink Editor.

Editing Workspace Variables

In the Model Explorer, you can use the Variable Editor to edit variables from the MATLAB base workspace or model workspace. The Variable Editor is available for editing large arrays and structures.

To open the Variable Editor:

1. In the **Contents** pane, select the variable.
2. In the Dialog pane (the right pane), click the button ⋮ near the value of the variable.
3. In the menu, select **Open Variable Editor**.

Alternatively, to open the Variable Editor from the **Contents** pane instead of the Dialog pane, begin editing the value of the variable by clicking the appropriate cell. The button appears in the cell.

Representation of Arrays with Three or More Dimensions

When the value of a variable or `Simulink.Parameter` object is an array with three or more dimensions, the **Value** column displays the array as an expression that contains a call to the `reshape` function.

To edit the values in the array, modify the first argument of the `reshape` call, which contains all of the array values in a serialized vector. When you add or remove elements along a dimension, you must also correct the argument that represents the length of the modified dimension.

Rename Variables

This example shows how to use Model Explorer to rename a variable everywhere it is used by blocks in Simulink models.

1. Open the model `sldemo_absbrake`. The model loads data to the MATLAB base workspace.
2. Open Model Explorer.
3. In the **Model Hierarchy** pane, select the base workspace.
4. In the **Contents** pane, right-click the base workspace variable `m` and select **Rename All**.

5 In the **Select a system** dialog box, click the name of the model `sldemo_absbrake` to select it as the context for renaming the variable `m`.

6 Clear the **Search in referenced models** check box and click **OK**. The model `sldemo_absbrake` references the model `sldemo_wheelspeed_absbrake`, but only `sldemo_absbrake` uses the variable `m`.

   With **Search in referenced models** selected, you can rename the target variable everywhere it is used in a model reference hierarchy. However, renaming the target variable in an entire hierarchy can take more time.

   The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.

7 Click **OK** in response to the message to update the model diagram.

   Since you just opened the model, you must update the model diagram at least once before renaming a variable. You could have selected **Update diagram to include recent changes** in the **Select a system** dialog box to force an initial diagram update, though you typically use that option when you make changes to the model while performing multiple variable renaming operations.

8 In the **Rename All** dialog box, type a new name for the variable in the **New name** box and click **OK**.

   You can use the hyperlinks in the **Corresponding blocks** section of the **Rename All** dialog box to view the target blocks.

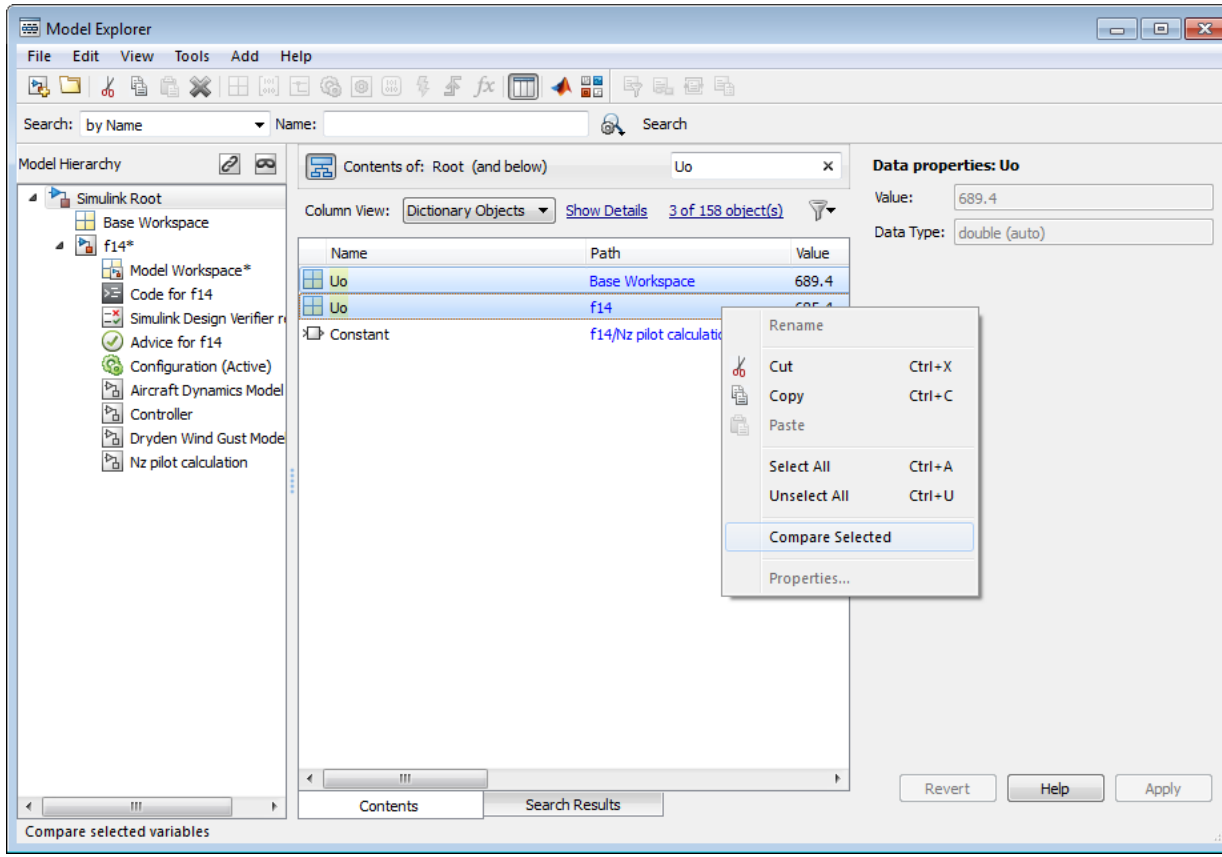
Note You can rename only variables that the function `Simulink.findVars` supports.

For help with renaming files, use a project. See “Automatic Updates When Renaming, Deleting, or Removing Files” on page 17-13.

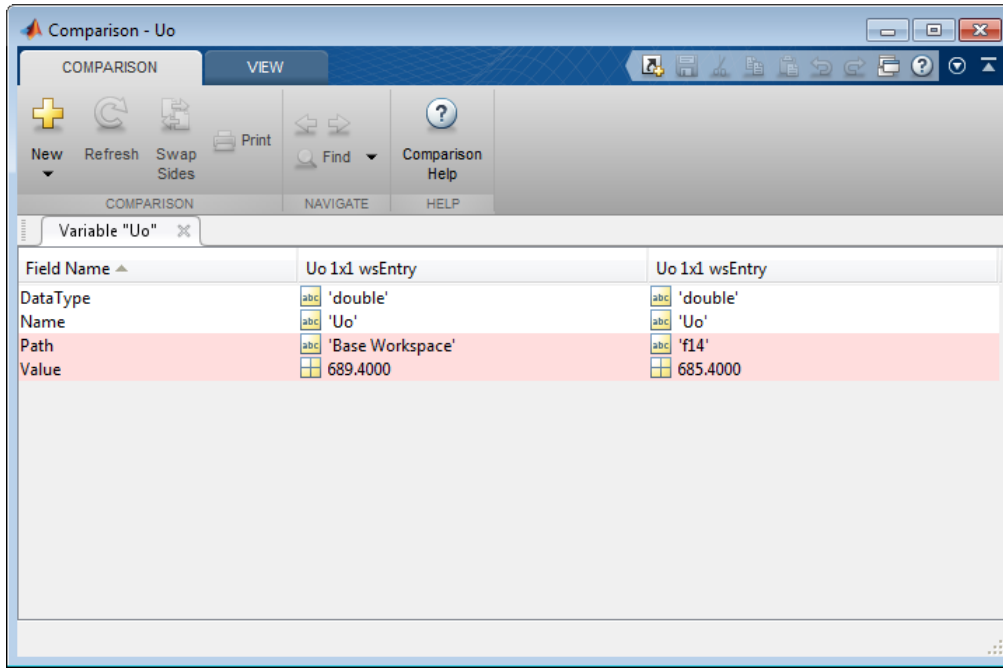
Compare Duplicate Workspace Variables

You can compare duplicate variables that are stored in the same workspace or in different workspaces. For example, you can compare a variable stored in the base workspace with its duplicate, which is stored in the model workspace.

1. Open a model and the Model Explorer.
2. In the search toolbar, search for the variable that is duplicated. Select the rows with the duplicate entries. Then, right-click and select **Compare Selected**.



3. Review the differences in the **Comparison Viewer**.



Export Workspace Variables

You can export (save) a set of variables listed in the Model Explorer, exporting either individual variables or all the variables in the base or model workspace.

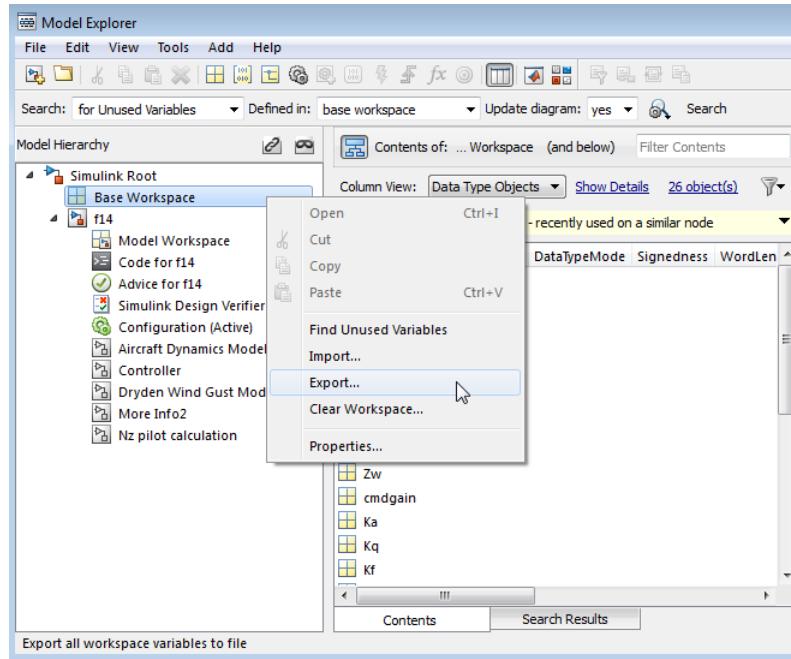
One possible workflow is to export the set of variables returned with the **Find Referenced Variables** option or the `Simulink.findVars` function. For details, see “Finding Variables That Are Used by a Model or Block” on page 59-111.

Note All the variables that you export must be from the same workspace.

To export all the variables in a workspace in the Model Explorer to a MATLAB code file or MAT-file:

1 Select the variables that you want to export.

a To select all the variables in a workspace, right-click the workspace node (for example, `Base Workspace`) and select the **Export** menu item. For example:



b To select individual variables, in the **Contents** pane, select the variables that you want to export. Right-click one of the highlighted variables and select the **Export Selected** menu item.

If the **Contents** pane has data grouped by a property, selecting the top line in a group does not select all the variables in that group. For details about grouped data, see “Group by a Property” on page 12-24.

2 Specify whether to save the variables in a MATLAB code file or a MAT-file.

The MATLAB code file format is easier to read, is editable, and supports version control. The MAT-file format is binary, which has performance advantages.

If you specify a MATLAB code file format, the Model Explorer may create an associated MAT-file, reflecting the name of the MATLAB code file, but with an extension of `.mat` instead of `.m`.

3 Specify a name and location for the file.

4 If the file already exists, Model Explorer displays a dialog box asking you to choose one of these options:

- **Overwrite entire file**
  - Replaces all variables in the target file with the selected variables, which are stored in alphabetical order.
- **Update variables that exist in file and append new variables to file**
  - Updates existing variables in place and appends new variables.
- **Only update variables that exist in file**
  - Updates existing variables, but does not add any new variables, which eliminates potentially extraneous variables.

To permanently store workspace variables for a model, instead of using the base workspace, create a data dictionary. See "What Is a Data Dictionary?" on page 63-2.

Importing Workspace Variables

You can import (load) a set of variables from a file into the base workspace or into a model workspace using the Model Explorer. When you import variables into a workspace, the Model Explorer overwrites existing variables and adds any new variables.

To import variables into a workspace:

1 In the **Model Hierarchy** pane, right-click the workspace into which you want to import variables.

2 Select the **Import** menu item.

3 In the Import from File dialog box, select a MATLAB code file or MAT-file for the variables that you want to import.

Note If you import a MATLAB code file, then Simulink also imports the associated MAT-file.

Model Workspaces

In this section...

Model Workspace Differences from MATLAB Workspace

Each model is provided with its own workspace for storing variable values.

The model workspace is similar to the base MATLAB workspace except that:

- Variables in a model workspace are visible only in the scope of the model.

  If both the MATLAB workspace and a model workspace define a variable of the same name, and the variable does not appear in any intervening masked subsystem or model workspaces, the Simulink software uses the value of the variable in the model workspace. A model's workspace effectively provides it with its own name space, allowing you to create variables for the model without risk of conflict with other models.
- When the model is loaded, the workspace is initialized from a data source.

  The data source can be a Model file, a MAT-file, a MATLAB file, or MATLAB code stored in the model file. For more information, see “Data source” on page 59-128.
- You can interactively reload and save MAT-file, MATLAB file, and MATLAB code data sources.
- To store a signal object in a model workspace, set the storage class of the object to `Auto`. Signal objects include `Simulink.Signal` and subclasses that you create.

  If you specify a storage class other than `Auto`, you must store signal objects in the base workspace or a data dictionary to ensure the objects are unique within the global Simulink context and accessible to all models.
- When you store MATLAB variables and parameter objects (such as `Simulink.Parameter`) in a model workspace, some tunability limitations apply. See “Tunability Considerations and Limitations for Other Modeling Goals” on page 36-45. In addition, if you store an `AUTOSAR.Parameter` object in a model workspace, the code generator ignores the storage class that you specify for the object.

Note When resolving references to variables used in a referenced model, the variables of the referenced model are resolved as if the parent model did not exist. For example, suppose a referenced model references a variable that is defined in both the parent model's workspace and in the MATLAB workspace but not in the referenced model's workspace. In this case, the MATLAB workspace is used.

Troubleshooting Memory Issues

When you use a workspace variable as a block parameter, Simulink creates a copy of the variable during the compilation phase of the simulation and stores the variable in memory. This can cause your system to run out of memory during simulation, or in the process of generating code. Your system might run out of memory if you have:

- Large models with many parameters
- Models with parameters that have a large number of elements

This issue does not affect the amount of memory that is used to represent parameters in generated code.

Manipulate Model Workspace Programmatically

An object of the `Simulink.ModelWorkspace` class describes a model workspace. Simulink creates an instance of this class for each model that you open during a Simulink session. The methods associated with this class can be used to accomplish a variety of tasks related to the model workspace, including:

- Listing the variables in the model workspace
- Assigning values to variables
- Evaluating expressions
- Clearing the model workspace
- Reloading the model workspace from the data source
- Saving the model workspace to a specified MAT-file or MATLAB file
- Saving the workspace to the MAT-file or MATLAB file that the workspace designates as its data source

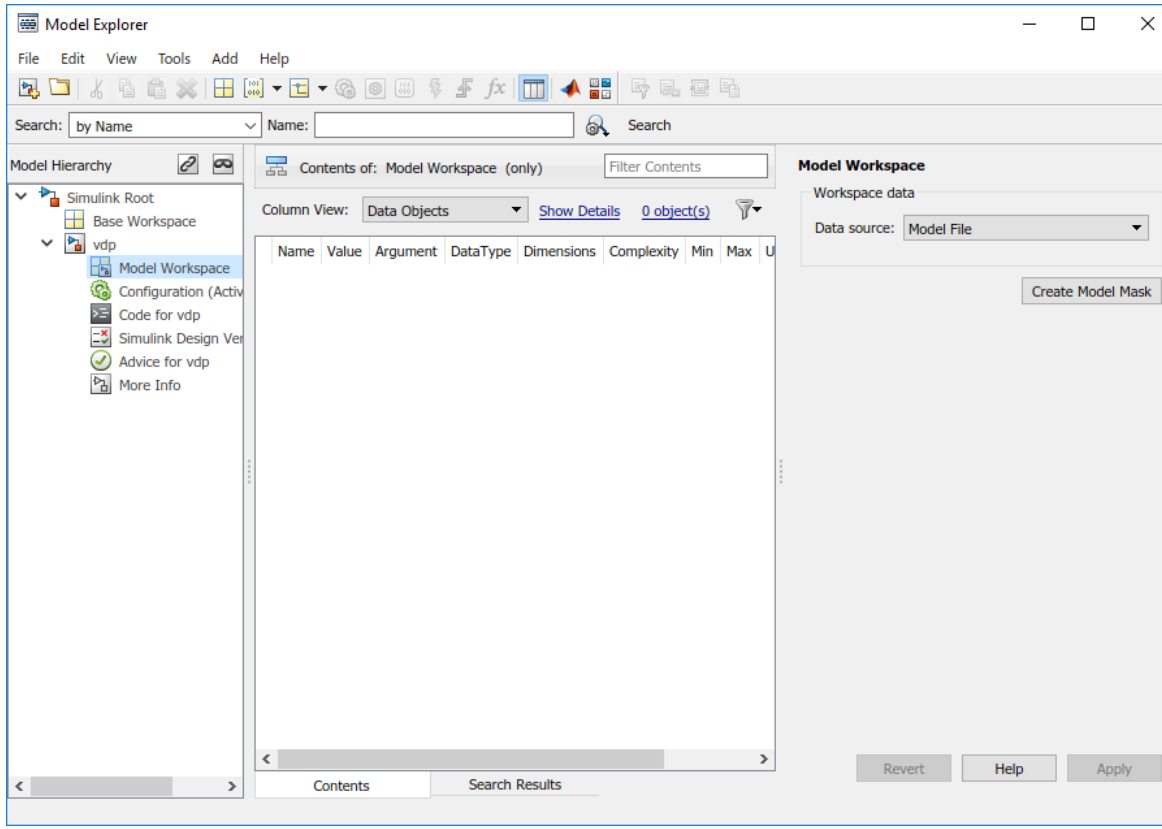
Specify Source for Data in Model Workspace

When you use a model workspace to contain the variables that a model uses, you can choose to store the variables in one of these sources:

- The model file, which can store static variable definitions.
- A separate MAT-file or MATLAB file. You can reload the variables from the external file into the model workspace at any time.
- Your own custom MATLAB code that creates variables. You can save the code as part of the model file, and reload the code at any time.

To specify a data source for a model workspace, in the Model Explorer, use the Model Workspace dialog box. To display the dialog box for a model workspace:

1. Open the Model Explorer by selecting **View** > **Model Explorer**.
2. In the **Model Hierarchy** pane, right-click the model workspace.



3 Select the **Properties** menu item, which opens the Model Workspace dialog box.

To use MATLAB commands to change data in a model workspace, see “Use MATLAB Commands to Change Workspace Data” on page 59-134.

Data source

The **Data source** field in the Model Workspace dialog box includes the following data source options for a workspace:

- `Model File`

  Specifies that the data source is the model itself.

- `MAT-File`

  Specifies that the data source is a MAT file. Selecting this option causes additional controls to appear (see "MAT-File and MATLAB File Source Controls" on page 59-129).

- `MATLAB File`

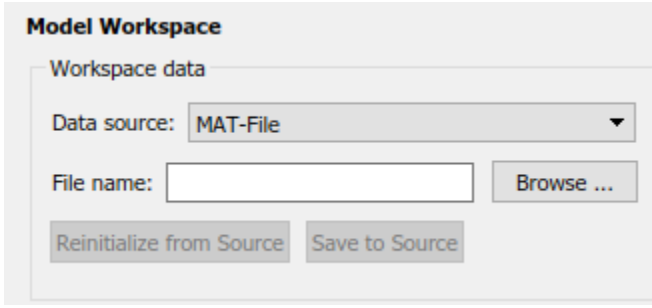
  Specifies that the data source is a MATLAB file. Selecting this option causes additional controls to appear (see "MAT-File and MATLAB File Source Controls" on page 59-129).

- `MATLAB Code`

  Specifies that the data source is MATLAB code stored in the model file. Selecting this option causes additional controls to appear (see "MATLAB Code Source Controls" on page 59-130).

MAT-File and MATLAB File Source Controls

Selecting `MAT-File` or `MATLAB File` as the **Data source** for a workspace causes the Model Workspace dialog box to display additional controls.



File name

Specifies the file name or path name of the MAT-file or MATLAB file that is the data source for the selected workspace. If you specify a file name, the name must reside on the MATLAB path.

Reinitialize From Source

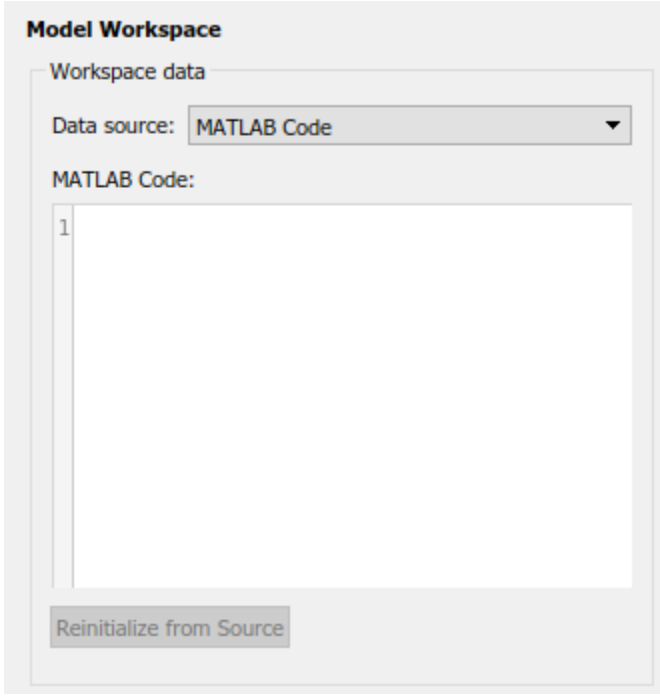
Clears the workspace and reloads the data from the MAT-file or MATLAB file specified by the **File name** field.

Save To Source

Saves the workspace in the MAT-file or MATLAB file specified by the **File name** field.

MATLAB Code Source Controls

Selecting `MATLAB Code` as the **Data source** for a workspace causes the Model Workspace dialog box to display additional controls.



MATLAB Code

Specifies MATLAB code that initializes the selected workspace. To change the initialization code, edit this field, then select the **Reinitialize from source** button on the dialog box to clear the workspace and execute the modified code.

Reinitialize from Source

Clears the workspace and executes the contents of the **MATLAB Code** field.

Create Model Mask

Mask the model, which enables you to control how users of the model interact with model arguments. For more information, see “Introduction to Model Mask” on page 38-64.

- “Change Model Workspace Data” on page 59-132

Change Model Workspace Data

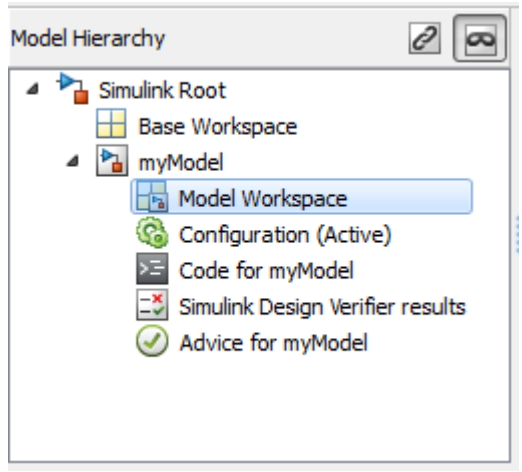
When you use a model workspace to contain the variables that a model uses, you choose a source to store the variables, such as the model file or an external MAT-file. To modify the variables at the source, you use a different procedure depending on the type of source that you selected.

Change Workspace Data Whose Source Is the Model File

If the data source of a model workspace is the model file, you can use Model Explorer or MATLAB commands to modify the stored variables (see “Use MATLAB Commands to Change Workspace Data” on page 59-134).

For example, to create a variable in a model workspace:

1. Open the Model Explorer by selecting **View** > **Model Explorer** or by pressing **Ctrl +H**.
2. In the Model Explorer **Model Hierarchy** pane, expand the node for your model, and select the model workspace.



3. Select **Add** > **MATLAB Variable**.

   You can similarly use the **Add** menu or toolbar to add a `Simulink.Parameter` object to a model workspace.

To change the value of a model workspace variable:

1. Open the Model Explorer by selecting **View** > **Model Explorer**.
2. In the Model Explorer **Model Hierarchy** pane, select the model workspace.
3. In the **Contents** pane, select the variable.
4. In the **Contents** pane or in **Dialog** pane, edit the value displayed.

To delete a model workspace variable:

1. Open the Model Explorer by selecting **View** > **Model Explorer**.
2. In the Model Explorer **Model Hierarchy** pane, select the model workspace.
3. In **Contents** pane, select the variable.
4. Select **Edit** > **Delete**.

Change Workspace Data Whose Source Is a MAT-File or MATLAB File

You can use Model Explorer or MATLAB commands to modify workspace data whose source is a MAT-file or MATLAB file.

To make the changes permanent, in the Model Workspace dialog box, use the **Save To Source** button to save the changes to the MAT-file or MATLAB file.

1. Open the Model Explorer by selecting **View** > **Model Explorer**.
2. In the Model Explorer **Model Hierarchy** pane, right-click the workspace.
3. Select the **Properties** menu item.
4. In the Model Workspace dialog box, use the **Save To Source** button to save the changes to the MAT-file or MATLAB file.

To discard changes to the workspace, in the Model Workspace dialog box, use the **Reinitialize From Source** button.

Changing Workspace Data Whose Source Is MATLAB Code

The safest way to change data whose source is MATLAB code is to edit and reload the source. Edit the MATLAB code and then in the Model Workspace dialog box, use **Reinitialize From Source** button to clear the workspace and re-execute the code.

To save and reload alternative versions of the workspace that result from editing the MATLAB code source or the workspace variables themselves, see “Export Workspace Variables” on page 59-120 and “Importing Workspace Variables” on page 59-122.

Use MATLAB Commands to Change Workspace Data

To use MATLAB commands to change data in a model workspace, first get the workspace for the currently selected model:

```
hws = get_param(bdroot, 'modelworkspace');
```

This command returns a handle to a `Simulink.ModelWorkspace` object whose properties specify the source of the data used to initialize the model workspace. Edit the properties to change the data source.

Use the workspace methods to:

- List, set, and clear variables
- Evaluate expressions in the workspace
- Save and reload the workspace

For example, the following MATLAB code creates variables specifying model parameters in the model workspace, saves the parameters, modifies one of them, and then reloads the workspace to restore it to its previous state.

```
hws = get_param(bdroot, 'modelworkspace');
hws.DataSource = 'MAT-File';
hws.FileName = 'params';
hws.assignin('pitch', -10);
hws.assignin('roll', 30);
hws.assignin('yaw', -2);
hws.saveToSource;
hws.assignin('roll', 35);
hws.reload;
```

To programmatically access variables for the purpose of sweeping block parameter values, consider using `Simulink.SimulationInput` objects instead of modifying the variables through the programmatic interface of the model workspace. See “Optimize, Estimate, and Sweep Block Parameter Values” on page 36-48.

Create Model Mask

Mask the model, which enables you to control how users of the model interact with model arguments. For more information, see “Introduction to Model Mask” on page 38-64.

Symbol Resolution

In this section...

Symbols

When you create a Simulink model, you can use symbols to provide values and definitions for many types of entities in the model. Model entities that you can define with symbols include block parameters, configuration set parameters, data types, signals, signal properties, and bus architecture.

A symbol that provides a value or definition must be a legal MATLAB identifier. Such an identifier starts with an alphabetic character, followed by alphanumeric or underscore characters up to the length given by the function `namelengthmax`. You can use the function `isvarname` to determine whether a symbol is a legal MATLAB identifier.

A symbol provides a value or definition in a Simulink model by corresponding to some item that:

- Exists in an accessible workspace
- Has a name that matches the symbol
- Provides the required information

Symbol Resolution Process

The process of finding an item that corresponds to a symbol is called *symbol resolution* or *resolving the symbol*. The matching item can provide the needed information directly, or it can itself be a symbol. A symbol must resolve to some other item that provides the information.

When the Simulink software compiles a model, it tries to resolve every symbol in the model, except symbols in MATLAB code that runs in a callback or as part of mask initialization. Depending on the particular case, the item to which a symbol resolves can be a variable, object, or function.

Simulink attempts to resolve a symbol by searching through the accessible workspaces in hierarchical order for a MATLAB variable or Simulink object whose name is the same as the symbol.

The search path is identical for every symbol. The search begins with the block that uses the symbol, or is the source of a signal that is named by the symbol, and proceeds upward. Except when simulation occurs via the `sim` command, the search order is:

1. Any mask workspaces, in order from the block upwards (see "Masking Fundamentals" on page 38-2).
2. The model workspace of the model that contains the block (see "Model Workspaces" on page 59-124).
3. The MATLAB base workspace (see "Create and Edit Variables" (MATLAB)). If the model is linked to a data dictionary, Simulink searches in the dictionary instead of the base workspace. For more information about data dictionaries, see "What Is a Data Dictionary?" on page 63-2.

If Simulink finds a matching item in the course of this search, the search terminates successfully at that point, and the symbol resolves to the matching item. The result is the same as if the value of that item had appeared literally instead of the symbol that resolved to the item. An object defined at a lower level shadows any object defined at a higher level.

If no matching item exists on the search path, Simulink attempts to evaluate the symbol as a function. If the function is defined and returns an appropriate value, the symbol resolves to whatever the function returned. Otherwise, the symbol remains unresolved, and an error occurs. Evaluation as a function occurs as the final step whenever a hierarchical search terminates without having found a matching workspace variable.

If the model that contains the symbol is a referenced model, and the search reaches the model workspace but does not succeed there, the search jumps directly to the base workspace or data dictionary *without* trying to resolve the symbol in the workspace of any parent model. Thus a given symbol resolves to the same item, irrespective of whether the model that contains the symbol is a referenced model. For information about model referencing, see "Model Referencing".

Numeric Values with Symbols

You can specify any block parameter that requires a numeric value by providing a literal value, a symbol, or an expression, which can contain symbols and literal values. Each symbol is resolved separately, as if none of the others existed. Different symbols in an expression can thus resolve to items on different workspaces, and to different types of item.

When a single symbol appears and resolves successfully, its value provides the value of the parameter. When an expression appears, and all symbols resolve successfully, the value of the expression provides the value of the parameter. If any symbol cannot be resolved, or resolves to a value of inappropriate type, an error occurs.

For example, suppose that the **Gain** parameter of a Gain block is given as `cos(a*(b +2))`. The symbol `cos` will resolve to the MATLAB cosine function, and `a` and `b` must resolve to numeric values, which can be obtained from the same or different types of items in the same or different workspaces. If the symbols resolve to numeric values, the value returned by the cosine function becomes the value of the **Gain** parameter.

Other Values with Symbols

Most symbols and expressions that use them provide numeric values, but the same techniques that provide numeric values can provide any type of value that is appropriate for its context.

Another common use of symbols is to name objects that provide definitions of some kind. For example, a signal name can resolve to a signal object (`Simulink.Signal`) that defines the properties of the signal, and a Bus Creator block **Data type** parameter can name a bus object (`Simulink.Bus`) that defines the properties of the bus. You can use symbols for many purposes, including:

- Define data types
- Specify input data sources
- Specify logged data destinations

For hierarchical symbol resolution, all of these different uses of symbols, whether singly or in expressions, are the same. Each symbol is resolved, if possible, independently of any others, and the result becomes available where the symbol appeared. The only difference between one symbol and another is the specific item to which the symbol resolves and the

use made of that item. The only requirement is that every symbol must resolve to something that can legally appear at the location of the symbol.

Limit Signal Resolution

Hierarchical symbol resolution traverses the complete search path by default. You can truncate the search path by using the **Permit Hierarchical Resolution** option of any subsystem. This option controls what happens if the search reaches that subsystem without resolving to a workspace variable. The **Permit Hierarchical Resolution** values are:

- `All`

  Continue searching up the workspace hierarchy trying to resolve the symbol. This is the default value.

- `None`

  Do not continue searching up the hierarchy.

- `ExplicitOnly`

  Continue searching up the hierarchy only if the symbol specifies a block parameter value, data store memory (where no block exists), or a signal or state that explicitly requires resolution. Do not continue searching for an implicit resolution. See “Explicit and Implicit Symbol Resolution” on page 59-139 for more information.

If the search does not find a match in the workspace, and terminates because the value is `ExplicitOnly` or `None`, Simulink evaluates the symbol as a function. The search succeeds or fails depending on the result of the evaluation, as previously described.

Explicit and Implicit Symbol Resolution

Models and some types of model entities have associated parameters that can affect symbol resolution. For example, suppose that a model includes a signal named Amplitude, and that a `Simulink.Signal` object named Amplitude exists in an accessible workspace. If the Amplitude signal's **Signal name must resolve to Simulink signal object** option is checked, the signal will resolve to the object. See “Signal Properties Controls” for more information.

If the option is not checked, the signal may or may not resolve to the object, depending on the value of **Configuration Parameters > Data Validity > Signal resolution**. This

parameter can suppress resolution to the object even though the object exists, or it can specify that resolution occurs on the basis of the name match alone. For more information, see "Model Configuration Parameters: Data Validity Diagnostics" > "Signal resolution".

Resolution that occurs because an option such as **Signal name must resolve to Simulink signal object** requires it is called *explicit symbol resolution*. Resolution that occurs on the basis of name match alone, without an explicit specification, is called *implicit symbol resolution*.

Tip Implicit symbol resolution can be useful for fast prototyping. However, when you are done prototyping, consider using explicit symbol resolution, because implicit resolution slows performance, complicates model validation, and can have nondeterministic effects.

Configure Data Properties by Using the Model Data Editor

Models contain data items such as signals, block parameters (for example, the **Gain** parameter of a Gain block), and data stores. The Model Data Editor enables you to inspect and edit data items in a list that you can sort, group, and filter. You can then configure properties and parameters, such as data types and dimensions, without having to locate the items in the block diagram.

While creating and debugging a model, you can configure multiple data items at once by selecting the corresponding signals and blocks in the block diagram. Work with the selected items in the Model Data Editor instead of opening individual dialog boxes. Use this technique to more quickly view and compare properties of multiple signals that are close to each other in the diagram, for example, in a subsystem.

Use the Model Data Editor to configure:

- Instrumentation for signals and data stores, which means you want to view and collect the simulation values. For example, you can log signals to compare data in the Simulation Data Inspector.
- Design attributes such as data type, minimum and maximum value, and physical units. For example, you use these attributes to:
  - Specify the values of numeric block parameters.
  - Control the interaction (interface) between components through Inport and Outport blocks and data stores (see “Configure Data Interface for Component” on page 22-16).
  - Specify the dimensions of nonscalar signals in a model.
- Storage classes, which control the representation of the data in the code (for example, C) that you generate from the model.

To open the Model Data Editor in a model, select **View** > **Model Data**.

Note The Model Data Editor does not show information about data items in referenced models (which you reference with Model blocks). To work with data items in a referenced model, open the Model Data Editor in that model.

Configure Distant Data Items

The example model `sldemo_fuelsys_dd` represents the fueling system of a vehicle engine. The referenced model `sldemo_fuelsys_dd_controller` controls the rate of fuel flow to the engine. In this example, use the Model Data Editor to log signals in different subsystems and referenced models so you can inspect their data using the Simulation Data Inspector.

Explore Example Models

1. Open `sldemo_fuelsys_dd` and the referenced model `sldemo_fuelsys_dd_controller`.
2. Navigate to the `airflow_calc` subsystem.

   The Pumping Constant block contains a lookup table that describes the performance of a fuel pump. You can stream the output of this block to the Simulation Data Inspector.
3. Navigate to the root of the model and into the `fuel_calc` subsystem.
4. Navigate into the `feedforward_fuel_rate` subsystem.

   The Outport block named `ff_fuel_rate` passes feedforward information to the fuel rate control algorithm.
5. Navigate back to the `fuel_calc` subsystem and into the `switchable_compensation` subsystem.

   The Inport block named `ff_fuel_rate` carries the feedforward information. You can stream the output of this Inport block.

Log Signals for Data Inspection

1. Navigate to the root of the `sldemo_fuelsys_dd_controller` model.
2. In the Model Data Editor, inspect the **Signals** tab.
3. Set the **Change view** drop-down to `Instrumentation`.
4. Activate the **Change scope** button  to display the contents of the subsystems.

   The Model Data Editor identifies all the signals in the model. The **Path** column appears.

5 In the **Filter Contents** box, type `ff_fuel_rate`.

The Model Data Editor updates the list of signals to include only those named `ff_fuel_rate`. You can click the link in the **Path** column to view where the signal resides within the model.

6 Select the **Log Data** check box for the signal whose path is `sldemo_fuelsys_dd_controller/fuel_calc/switchable_compensation`.

This instructs Simulink to send the data for the logged signals to the Simulation Data Inspector.

7 Filter the signals again using the text `Pumping Constant`.

The table contains one row that corresponds to the output of the Pumping Constant block.

8 Select the **Log Data** check box for the `Pumping Constant` signal.

9 Simulate the system model, `sldemo_fuelsys_dd`. During the simulation, double-click a Manual Switch block, such as `Engine Speed Selector`, to disturb the fuel control system.

10 When the simulation finishes, the **Simulation Data Inspector** button  is highlighted. This indicates that there is data to inspect and compare. Click the **Simulation Data Inspector** button.

11 In the left pane, expand the **Run** node that corresponds to the simulation run and select the check boxes for the signals whose data you want to inspect and compare.

The Simulation Data Inspector presents the values for the selected signals on the same graph.

Select Multiple Data Items from Block Diagram

In the example model `sldemo_househeat`, use the Model Data Editor to log the signals in the `Heater` subsystem for inspection using the Simulation Data Inspector.

1 In the example model `sldemo_househeat`, open the `Heater` subsystem.

2 Open the Model Data Editor and select the **Signals** tab.

The Model Data Editor identifies all the signals in the subsystem.

3 In the Model Data Editor, set the **Change view** drop-down list to `Instrumentation`.

4 Using the Simulink Editor, select all the signals in the subsystem. Optionally, do not select the output of the Constant block because the signal value does not change during the simulation.

   In response, the Model Data Editor highlights the rows that correspond to the signals you selected.

5 In the Model Data Editor, for any of the signals, click the check box in the **Log Data** column.

   The Model Data Editor selects the check box for all of the selected signals.

6 Simulate the model.

7 Open the Simulation Data Inspector and, in the leftmost pane, expand the **Run** node that corresponds to the simulation run. Select the check boxes for the signals whose values you want to inspect and compare.

Interact with a Model That Uses Workspace Variables

When you use workspace variables (such as numeric MATLAB variables and `Simulink.AliasType` objects) to share settings between data items, you can interact with those variables through the Model Data Editor. You do not need to work outside the Editor to configure the data items. In the Editor, click the **Show/refresh additional information** button  , which finds variables that the model uses by updating the block diagram.

This example shows how to work with objects that a model uses to set block parameter values. You modify the value of a `Simulink.Parameter` object that the model `sldemo_fuelsys_dd_controller` uses.

1 Open the model.

```
sldemo_fuelsys_dd_controller
```

2 Open the Model Data Editor **Parameters** tab.

3 In the Model Data Editor, click the **Show/refresh additional information** button.

   The data table now contains rows that correspond to variables and objects that the model uses.

4. In the model, navigate into the `airflow_calc` subsystem.
5. In the Model Data Editor, next to the **Filter contents** box, select the **Filter using selection** button.

   With this button selected, when you select a block or signal in the block diagram, the data table shows only the data items and workspace variables that are relevant to that block or signal.
6. In the model, click the lookup table block labeled `Pumping Constant`.

   The Model Data Editor shows that the block uses three workspace variables. The block acquires some breakpoint values from the `Simulink.Parameter` object `SpeedVect`.

Now, you can use the columns in the Model Data Editor to configure the properties of `SpeedVect`.

You can further interact with a variable to:

- Configure other properties that the columns do not represent:

  1. In the model, open the Property Inspector (**View** > **Property Inspector**).
  2. In the Model Data Editor, select the row that corresponds to the target variable or object. If the Property Inspector does not respond, select a different row and then select the target row again.
  3. Use the Property Inspector to configure the target properties.
- Move the variable between workspaces and data dictionaries and configure the variable alongside other variables. Use the Model Explorer. To open the Model Explorer, in the Model Data Editor data table, double-click the icon in the leftmost column. For more information about using the Model Explorer, see “Edit and Manage Workspace Variables by Using Model Explorer” on page 59-111.

Find and Organize Data by Filtering, Sorting, and Grouping

In the example model `sldemo_fuelsys_dd_controller`, workspace variables and parameter objects set the values of block parameters. The variables and objects reside in a data dictionary. Use the Model Data Editor to display these dictionary entries together in a group.

1. In the example model, open the Model Data Editor and select the **Parameters** tab.
2. Activate the **Change scope** button to display the contents of the subsystems.
3. Click the **Show/refresh additional information** button to display rows that correspond to the dictionary entries.
4. Right-click the **Source** column header and select **Group by This Column**.

   The Model Data Editor groups the list by block or workspace (including a group for the dictionary entries).
5. Find the group labeled **Source: Dictionary**. Now, you can use the Model Data Editor to inspect and modify the attributes of the variables and objects in the dictionary.

You can filter the data table through a text search. Use the **Filter contents** box.

Alternatively, you can filter based on the blocks or signals that you select in the model. Next to the **Filter contents** box, select the **Filter using selection** button. Then, as you click blocks and signals in the model, the Model Data Editor shows you only the rows that are relevant to that block or signal. If you lasso multiple blocks or signals, the Model Data Editor shows only the rows that are relevant to those model elements.

Inspect Individual Data Item

To focus on an individual data item, use one of these techniques:

- In the Model Data Editor, next to the **Filter contents** box, select the **Filter using selection** button. Then, in the model, click the block or signal that corresponds to the data item.

  Use this technique to configure the item by using the columns in the data table.
- In the model, open the Property Inspector (**View > Property Inspector**). Then, in the data table, click the target row. The Property Inspector shows the properties of the data item. If the Property Inspector does not respond when you click the target row, click a different row and then click the target row again.

  Use this technique to inspect all of the properties that the Model Data Editor can access at once (in other words, the union of the columns available in the `Design`, `Instrumentation`, and `Code` views).

- In the model, open the Property Inspector. Then, in the data table, for the target row, double-click the cell in the leftmost column (the icon). In the model, select the highlighted block or signal.

  Use this technique to inspect all properties, including those that the Model Data Editor cannot access.

Navigate from Model Data Editor to Block Diagram

To navigate from a data item in the Model Data Editor to the block in the diagram that owns the data item, double-click the icon in the left-most column. The Simulink Editor then focuses on the relevant block. Use this technique to navigate to blocks when you select **Change scope** to view the contents of subsystems below the current system.

Columns in the Data Table

Use this table to find more information about the purpose of the columns in the Model Data Editor.

Column Name	Purpose and More Information
Source	Shows the name of the block that defines the data item. For signals, also shows the number of the block port that generates the signal. For workspace variables, shows the name of the workspace or data dictionary that contains the variable.
Signal Name or **Name**	Sets the name of the signal, state, or data store. For information about naming signals, see “Signal Names and Labels” on page 64-4. For parameters, displays the programmatic name of each parameter. For workspace variables, sets the name of the variable.

Column Name	Purpose and More Information
Data Type	"Control Signal Data Types" on page 59-8
Min and **Max**	"Signal Ranges" on page 64-45
Dimensions	"Signal Dimensions" on page 64-31
Complexity	Sets the numeric complexity of the data item.
Sample Time	"What Is Sample Time?" on page 7-2
Unit	"Unit Specification in Simulink Models" on page 9-2
Test Point	"Test Points" on page 64-62
Log Data	"Iterate Model Design with the Simulation Data Inspector" on page 28-9
Resolve	Corresponds to the **Signal name must resolve to Simulink signal object** check box in the Signal Properties dialog box and similar check boxes in block dialog boxes for states and data stores. See "Use Signal Objects" on page 59-55.
Storage Class	"Control Signals and States in Code by Applying Storage Classes" (Simulink Coder) To use a custom storage class from a package that you create, see "Configure Data Interface by Using Model Data Editor" (Embedded Coder).
Header File **Definition File** **Get Function** **Set Function** **Struct Name**	Sets custom attributes for custom storage classes, which you select with **Storage Class**. See "Control Data Representation by Applying Custom Storage Classes" (Embedded Coder).

Column Name	Purpose and More Information
Shared	Corresponds to the **Share across model instances** parameter of the Data Store Memory block. See Data Store Memory.
Initial Value	Sets the initial value of the state or data store. See "Initializing Signal Values" on page 64-17.
Value	"Set Block Parameter Values" on page 36-2
Argument	Configures a variable in a model workspace as a model argument. See "Parameterize Instances of a Reusable Referenced Model" on page 8-72.
Path	Shows the location of the block in the model and provides a link to the block in the Simulink Editor. Visible when you click the **Change Scope** button.

Two Entries Per Cell in the Data Table

When a cell contains two entries (for instance, in the **Data Type** column), the entry on the right side of the cell indicates compiled information. The compiled information shows you the value that the data item uses for simulation.

For example, the default data type setting for most signals in a model is `Inherit: Inherit via internal rule`. With this setting, after you update the block diagram, Simulink chooses a specific data type, such as `single`, for the signal to use for simulation. In the Model Data Editor, the cell in the **Data Type** column shows `Inherit: Inherit via internal rule` on the left side and `single` on the right side.

Model Data Editor Limitations

- You cannot specify these attributes by using the Model Data Editor:
  - Any settings for block parameters other than the parameter value. However, you can click the **Show/refresh additional information** button and use the data table to configure MATLAB variables and `Simulink.Parameter` objects that you use to set block parameter values.

  - Any settings for nontunable mask parameters. Some built-in blocks are masked and have nontunable mask parameters.
  - Any settings for parameters of Simscape blocks.
  - Any settings for data items in referenced models. Instead, open the Model Data Editor in the referenced models.
  - Design attributes for `Simulink.LookupTable` and `Simulink.Breakpoint` objects. However, you can open the Property Inspector, click the row that corresponds to the object, and use the Property Inspector to configure the object properties.

    Alternatively, in the Model Data Editor, in the leftmost column, double-click the icon to open the Model Explorer, which you can use the configure the object properties.
- The Model Data Editor does not show Stateflow data. However, the Model Data Editor shows the data for Simulink Functions that you define inside Stateflow charts.

  To manage Stateflow data, events, and messages in a chart, see "Manage Stateflow Data, Events, and Messages in the Symbols Window" (Stateflow).
- When using the Model Data Editor, if you specify a storage class for a signal and do not provide a signal name, the software generates a signal name. The generated name is derived from the block that generates the signal. If a block has non-ASCII values as part of its name or any invalid C variable name, only the ASCII values in the block names generate a name for the signal. If the two ASCII block names are not unique, this issue leads to a conflict in signal names during code generation.

Upgrade Level-1 Data Classes

Simulink no longer supports level-1 data classes. You must upgrade data classes that you created using the level-1 data class infrastructure, which was removed in a previous release.

Run the following utility function while specifying the destination folder for the upgraded classes.

Note Property types defined in level-1 data classes that are not subclasses of `Simulink.Parameter`, `Simulink.Signal`, or `Simulink.CustomStorageClassAttributes` are not preserved during an upgrade. Only subclasses of these three classes will preserve attributes `PropertyType` and `AllowedValues`.

---

1. This command upgrades all your level-1 data class packages. You cannot upgrade selected data packages.

   ```
   Simulink.data.upgradeClasses('C:\MyDataClasses')
   ```

   Here, `C:\MyDataClasses` is the destination folder for your level-2 data classes.

   Note Do not place your upgraded level-2 classes and their equivalent level-1 classes in the same folder.

   `Simulink.data.upgradeClasses` uses the `packagedefn.mat` file in your level-1 class packages for the upgrade and creates level-2 classes in the specified destination folder. Then, `Simulink.data.upgradeClasses` adds the folder to top of the MATLAB path and saves the path.

   Note If `Simulink.data.upgradeClasses` cannot save the MATLAB path because of restricted access, a warning appears. In this case, manually add the folder to the top of the MATLAB path and save the path using `savepath`.

   ---

2. You can change the location of the level-2 package folders after they have been generated. However, you will need to update your MATLAB path so that MATLAB can find these package folders.

3 Resave MAT-files and models that contain level-1 data objects.

4 Retain your level-1 classes on the MATLAB path until you have resaved all of your models and MAT-files that contain level-1 data objects. Any models or MAT-files that contain level-1 data objects will continue to load successfully while your level-1 data classes are on the MATLAB path.

Note You cannot use both level-1 and level-2 data classes at the same time. Level-2 classes need to be above the level-1 classes on the MATLAB path so that they are found by MATLAB.

Associating User Data with Blocks

You can use the `set_param` command to associate your own data with a block. For example, the following command associates the value of the variable `mydata` with the currently selected block.

```
set_param(gcb, 'UserData', mydata)
```

The value of `mydata` can be any MATLAB data type, including arrays, structures, objects, and Simulink data objects.

Use `get_param` to retrieve the user data associated with a block.

```
get_param(gcb, 'UserData')
```

The following command saves the user data associated with a block in the model file of the model containing the block.

```
set_param(gcb, 'UserDataPersistent', 'on');
```

Note If persistent UserData for a block contains any Simulink data objects, the directories containing the definitions for the classes of those objects must be on the MATLAB path when you open the model containing the block.

Support Limitations for Simulink Software Features

Simulink Design Verifier does not support the following Simulink software features. Avoid using these unsupported features.

Not Supported	Description
Variable-step solvers	The software supports only fixed-step solvers. For more information, see “Choose a Fixed-Step Solver” on page 24-15.
Callback functions	The software does not execute model callback functions during the analysis. The results that the analysis generates, such as the harness model, may behave inconsistently with the expected behavior. • If a model or any referenced model calls a callback function that changes any block parameters, model parameters, or workspace variables, the analysis does not reflect those changes. • Changing the storage class of base workspace variables on model callback functions or mask initializations is not supported. • Callback functions called prior to analysis, such as the `PreLoadFcn` or `PostLoadFcn` model callbacks, are fully supported.
Model callback functions	The software only supports model callback functions if the `InitFcn` callback of the model is empty.
Algebraic loops	The software does not support models that contain algebraic loops. For more information, see “Algebraic Loops” on page 3-37.
Masked subsystem initialization functions	The software does not support models whose masked subsystem initialization modifies any attribute of any workspace parameter.
Complex signals	The software supports only real signals. For more information, see “Complex Signals” on page 64-16.

Not Supported	Description
Variable-size signals	The software does not support variable-size signals. A variable-size signal is a signal whose size (number of elements in a dimension), in addition to its values, can change during model execution. For more information, see “Variable-Size Signal Basics” on page 66-2.
Multiword fixed-point data types	The software does not support multiword fixed-point data types larger than 128 bits.
Nonzero start times	Although Simulink allows you to specify a nonzero simulation start time, the analysis generates signal data that begins only at zero. If your model specifies a nonzero start time: • If you do not select the **Reference input model in generated harness** parameter (the default), the harness model is a subsystem. The analysis sets the start time of the harness model to 1 and continues the analysis. • If you select the **Reference input model in generated harness** parameter, a Model block references the harness model. The software cannot change the start time of the harness model, so the analysis stops and you see a recommendation to set the **Start time** parameter to 0.

Not Supported	Description
Nonfinite data	The software does not support nonfinite data (for example, `NaN` and `Inf`) and related operations. In the Relational Operator block, the software assigns the output as follows: • If the **Relational operator** parameter is `isFinite`, the output is always 1. • If the **Relational operator** parameter is `isNan` or `isInf`, the output is always 0. In the MATLAB Function block, the software assigns the return value as follows: • For the `isFinite` function, the output is always 1. • For the `isNan` and `isInf` functions, the output is always 0.
Concurrent execution	The software does not support models that are configured for concurrent execution.
Signals with nonzero sample time offset	The software does not support models with signals that have nonzero sample time offsets.
Models with no output ports	The software only supports models that have one or more output ports.
Large floating-point constants outside the range `[-realmax/2, realmax/2]`	The use of large floating-point constants can cause out of memory errors or substantial loss of precision. Avoid using such constants if possible.
Symbolic Dimensions	The software does not support symbolic dimensions for test generation, property proving, or design error detection.

- “Support Limitations for Stateflow Software Features” on page 59-170

Supported and Unsupported Simulink Blocks

The software provides various levels of support for Simulink blocks:

- Fully supported
- Partially supported
- Not supported

If your model contains unsupported blocks, you can enable automatic stubbing. Automatic stubbing considers the interface of the unsupported blocks, but not their behavior. If any of the unsupported blocks affect the simulation outcome, however, the analysis may achieve only partial results. For details about automatic stubbing, see "Handle Incompatibilities with Automatic Stubbing" (Simulink Design Verifier).

To achieve 100% coverage, avoid using unsupported blocks in models that you analyze. Similarly, for partially supported blocks, specify only the block parameters that the software recognizes.

The following tables summarize the analysis support for Simulink blocks. Each table lists the blocks in a Simulink library and describes support information for that particular block.

Additional Math and Discrete Library

The software supports all blocks in the Additional Math and Discrete library.

Commonly Used Blocks Library

The Commonly Used Blocks library includes blocks from other libraries. Those blocks are listed under their respective libraries.

Continuous Library

Block	Support Notes
Derivative	Not supported
Integrator	Not supported and not stubbable
Integrator Limited	Not supported and not stubbable
PID Controller	Not supported
PID Controller (2 DOF)	Not supported

Block	Support Notes
Second Order Integrator	Not supported and not stubbable
Second Order Integrator Limited	Not supported and not stubbable
State-Space	Not supported and not stubbable
Transfer Fcn	Not supported and not stubbable
Transport Delay	Not supported
Variable Time Delay	Not supported
Variable Transport Delay	Not supported
Zero-Pole	Not supported and not stubbable

Discontinuities Library

The software supports all blocks in the Discontinuities library.

Discrete Library

Block	Support Notes
Delay	Supported
Difference	Supported
Discrete Derivative	Supported
Discrete Filter	Supported
Discrete FIR Filter	Supported
Discrete PID Controller	Supported
Discrete PID Controller (2 DOF)	Supported
Discrete State-Space	Not supported
Discrete Transfer Fcn	Supported
Discrete Zero-Pole	Not supported
Discrete-Time Integrator	Supported
First-Order Hold	Supported
Memory	Supported
Tapped Delay	Supported
Transfer Fcn First Order	Supported

Block	Support Notes
Transfer Fcn Lead or Lag	Supported
Transfer Fcn Real Zero	Supported
Unit Delay	Supported
Zero-Order Hold	Supported

Logic and Bit Operations Library

The software supports all blocks in the Logic and Bit Operations library.

Lookup Tables Library

Block	Support Notes
Cosine	Supported
Direct Lookup Table (n-D)	Supported
Interpolation Using Prelookup	Not supported when: • The **Interpolation method** parameter is `Linear` and the **Number of table dimensions** parameter is greater than `4`. or • The **Interpolation method** parameter is `Linear` and the **Number of sub-table selection dimensions** parameter is not `0`.
1-D Lookup Table	Not supported when the **Interpolation method** or the **Extrapolation method** parameter is `Cubic Spline`.
2-D Lookup Table	Not supported when the **Interpolation method** or the **Extrapolation method** parameter is `Cubic Spline`.

Block	Support Notes
n-D Lookup Table	Not supported when: • The **Interpolation method** or the **Extrapolation method** parameter is `Cubic Spline`. or • The **Interpolation method** parameter is `Linear` and the **Number of table dimensions** parameter is greater than `5`.
Lookup Table Dynamic	Supported
Prelookup	Supported
Sine	Supported

Math Operations Library

Block	Support Notes
Abs	Supported
Add	Supported
Algebraic Constraint	Supported
Assignment	Supported
Bias	Supported
Complex to Magnitude-Angle	Not supported
Complex to Real-Imag	Supported
Divide	Supported
Dot Product	Supported
Find Nonzero Elements	Not supported
Gain	Supported
Magnitude-Angle to Complex	Supported

<table>
<tr><th>Block</th><th>Support Notes</th></tr>
<tr><td>Math Function</td><td>All signal types support the following Function parameter settings.
<table><tr><td>conj</td><td>hermitian</td><td>magnitude^2</td><td>mod</td></tr><tr><td>rem</td><td>reciprocal</td><td>square</td><td>transpose</td></tr></table>
The software does not support the following Function parameter settings.
<table><tr><td>10^u</td><td>exp</td><td>hypot</td></tr><tr><td>log</td><td>log10</td><td>pow</td></tr></table></td></tr>
<tr><td>Matrix Concatenate</td><td>Supported</td></tr>
<tr><td>MinMax</td><td>Supported</td></tr>
<tr><td>MinMax Running Resettable</td><td>Supported</td></tr>

<tr><td>Polynomial</td><td>Supported</td></tr>
<tr><td>Product</td><td>Supported</td></tr>
<tr><td>Product of Elements</td><td>Supported</td></tr>
<tr><td>Real-Imag to Complex</td><td>Supported</td></tr>
<tr><td>Reciprocal Sqrt</td><td>Not supported</td></tr>
<tr><td>Reshape</td><td>Supported</td></tr>
<tr><td>Rounding Function</td><td>Supported</td></tr>
<tr><td>Sign</td><td>Supported</td></tr>
<tr><td>Signed Sqrt</td><td>Not supported</td></tr>
<tr><td>Sine Wave Function</td><td>Not supported</td></tr>
<tr><td>Slider Gain</td><td>Supported</td></tr>
<tr><td>Sqrt</td><td>Supported</td></tr>
<tr><td>Squeeze</td><td>Supported</td></tr>
<tr><td>Subtract</td><td>Supported</td></tr>
</table>

Block	Support Notes
Sum	Supported
Sum of Elements	Supported
Trigonometric Function	Supported if **Function** is `sin`, `cos`, or `sincos`, and **Approximation method** is `CORDIC`.
Unary Minus	Supported
Vector Concatenate	Supported
Weighted Sample Time Math	Supported

Model Verification Library

The software supports all blocks in the Model Verification library.

Model-Wide Utilities Library

Block	Support Notes
Block Support Table	Supported
DocBlock	Supported
Model Info	Supported
Timed-Based Linearization	Not supported
Trigger-Based Linearization	Not supported

Ports & Subsystems Library

Block	Support Notes
Atomic Subsystem	Supported
Code Reuse Subsystem	Supported
Configurable Subsystem	Supported
Enable	Supported

Block	Support Notes
Enabled Subsystem	Design range checks do not consider specified minimum and maximum values for blocks connected to the outport of the subsystem. For more information on design range checks, see “Check for Specified Intermediate Minimum and Maximum Signal Values” (Simulink Design Verifier). Simulink Design Verifier treats Enabled Subsystems as short-circuited during test generation.
Enabled and Triggered Subsystem	Not supported when the trigger control signal specifies a fixed-point data type. Design range checks do not consider specified minimum and maximum values for blocks connected to the outport of the subsystem. For more information on design range checks, see “Check for Specified Intermediate Minimum and Maximum Signal Values” (Simulink Design Verifier). Simulink Design Verifier treats Enabled and Triggered Subsystems as short-circuited during test generation.
For Each	Supported with the following limitations: • When For Each Subsystem contains one or more Simulink Design Verifier Test Condition, Test Objective, Proof Assumption, or Proof Objective blocks, not supported. • When the mask parameters of the For Each Subsystem are partitioned, not supported.
For Each Subsystem	Supported with the following limitations: • When For Each Subsystem contains one or more Simulink Design Verifier Test Condition, Test Objective, Proof Assumption, or Proof Objective blocks, not supported. • When the mask parameters of the For Each Subsystem are partitioned, not supported.
For Iterator Subsystem	Supported

Block	Support Notes
Function-Call Feedback Latch	Supported
Function-Call Generator	Supported
Function-Call Split	Supported
Function-Call Subsystem	Design range checks do not consider specified minimum and maximum values for blocks connected to the outport of the subsystem. For more information on design range checks, see "Check for Specified Intermediate Minimum and Maximum Signal Values" (Simulink Design Verifier). Not supported when the Function-Call Subsystem is invoked using function-call triggers passed via root-level Inport blocks. For more information see, "Export-Function Models" on page 10-76.
If	Parameter configurations are not supported. The analysis ignores parameter configurations that you specify for an If block.
If Action Subsystem	Supported
In Bus Element	Supported
Inport	Supported
Model	Supported except for the limitations described in "Support Limitations for Model Blocks" (Simulink Design Verifier).
Model Variants	Supported except for the limitations described in "Support Limitations for Model Blocks" (Simulink Design Verifier).
Out Bus Element	Supported
Outport	Supported
Resettable Subsystem	Supported
Subsystem	Supported
Switch Case	Supported
Switch Case Action Subsystem	Supported
Trigger	Supported

Block	Support Notes
Triggered Subsystem	Not supported when the trigger control signal specifies a fixed-point data type. Design range checks do not consider specified minimum and maximum values for blocks connected to the outport of the subsystem. For more information on design range checks, see “Check for Specified Intermediate Minimum and Maximum Signal Values” (Simulink Design Verifier). Simulink Design Verifier treats Enabled Subsystems as short-circuited during test generation.
Variant Subsystem	Not supported when the **Generate preprocessor conditionals** parameter is enabled. Only the active variant is analyzed.
While Iterator Subsystem	Supported

Signal Attributes Library

The software supports all blocks in the Signal Attributes library.

Signal Routing Library

Block	Support Notes
Bus Assignment	Supported
Bus Creator	Supported
Bus Selector	Supported
Data Store Memory	Supported
Data Store Read	Supported
Data Store Write	Supported
Demux	Supported
Environment Controller	Supported
From	Supported
Goto	Supported
Goto Tag Visibility	Supported

Block	Support Notes
Index Vector	Supported
Manual Switch	The Manual Switch block is compatible with the software, but the analysis ignores this block in a model. The analysis does not flag the coverage objectives for this block as satisfiable or unsatisfiable. Model coverage data is collected for the Manual Switch block.
Merge	Supported
Multiport Switch	Supported
Mux	Supported
Selector	Supported
Switch	Supported
Vector Concatenate	Supported

Sinks Library

Block	Support Notes
Display	Supported
Floating Scope	Supported
Outport (Out1)	Supported
Scope	Supported
Stop Simulation	Not supported and not stubbable
Terminator	Supported
To File	Supported
To Workspace	Supported
XY Graph	Supported

Sources Library

Block	Support Notes
Band-Limited White Noise	Not supported
Chirp Signal	Not supported

Block	Support Notes
Clock	Supported
Constant	Supported unless **Constant value** is `inf`.
Counter Free-Running	Supported
Counter Limited	Supported
Digital Clock	Supported
Enumerated Constant	Supported
From File	Not supported. When MAT-file data is stored in MATLAB `timeseries` format, not stubbable.
From Workspace	Not supported
Ground	Supported
Inport (In1)	Supported
Pulse Generator	Supported
Ramp	Supported
Random Number	Not supported and not stubbable
Repeating Sequence	Not supported
Repeating Sequence Interpolated	Not supported
Repeating Sequence Stair	Supported
Signal Builder	Not supported
Signal Generator	Not supported
Sine Wave	Not supported
Step	Supported
Uniform Random Number	Not supported and not stubbable

User-Defined Functions Library

Block	Support Notes
Fcn	Supports all operators except `^`, and supports only the mathematical functions `abs`, `ceil`, `fabs`, `floor`, `rem`, and `sgn`. Parameter configurations are not supported. The analysis ignores parameter configurations that you specify for these blocks.
Interpreted MATLAB Function	Not supported
Level-2 MATLAB S-Function	For limitations, see “Support Limitations for S-Functions” (Simulink Design Verifier).
MATLAB Function	For limitations, see “Support Limitations for MATLAB for Code Generation” (Simulink Design Verifier).
Simulink Function	For limitations, see “Support Limitations for S-Functions” (Simulink Design Verifier).
S-Function Builder	For limitations, see “Support Limitations for S-Functions” (Simulink Design Verifier).
Simulink Function	Simulink Function blocks with output arguments that are of bus data-type are not supported. Calls to Simulink Functions across model boundaries are not supported.

More About

- “Support Limitations for Simulink Software Features” on page 59-154
- “Support Limitations for Stateflow Software Features” on page 59-170

Support Limitations for Stateflow Software Features

Simulink Design Verifier does not support the following Stateflow software features. Avoid using these unsupported features in models that you analyze.

In this section...

ml Namespace Operator, ml Function, ml Expressions

The software does not support calls to MATLAB functions or access to MATLAB workspace variables, which the Stateflow software allows. (See “Access Built-In MATLAB Functions and Workspace Data” (Stateflow) in the Stateflow documentation.)

C Math Functions

The software supports calls to the following C math functions:

- `abs`
- `ceil`
- `fabs`
- `floor`
- `fmod`
- `labs`
- `ldexp`

- `pow` (only for integer exponents)

The software does not support calls to other C math functions, which the Stateflow software allows. If automatic stubbing is enabled, which it is by default, the software eliminates these unsupported functions during the analysis.

For information about C math functions in Stateflow, see "Call C Functions in C Charts" (Stateflow) in the Stateflow documentation.

Note For details about automatic stubbing, see "Handle Incompatibilities with Automatic Stubbing" (Simulink Design Verifier).

Atomic Subcharts That Call Exported Graphical Functions Outside a Subchart

The software does not support atomic subcharts that call exported graphical functions, which the Stateflow software allows.

Note For information about exported functions, see "Export Stateflow Functions for Reuse" (Stateflow) in the Stateflow documentation.

Atomic Subchart Input and Output Mapping

If an input or output in an atomic subchart maps to chart-level data of a different scope, the software does not support the chart that contains that atomic subchart.

For an atomic subchart input, this incompatibility applies when the input maps to chart-level data of output, local, or parameter scope. For an atomic subchart output, this incompatibility applies when the output maps to chart-level data of local scope.

Recursion and Cyclic Behavior

The software does not support recursive functions, which occur when a function calls itself directly or indirectly through another function call. Stateflow software allows you to implement recursion using graphical functions.

In addition, the software does not support recursion that the Stateflow software allows you to implement using a combination of event broadcasts and function calls.

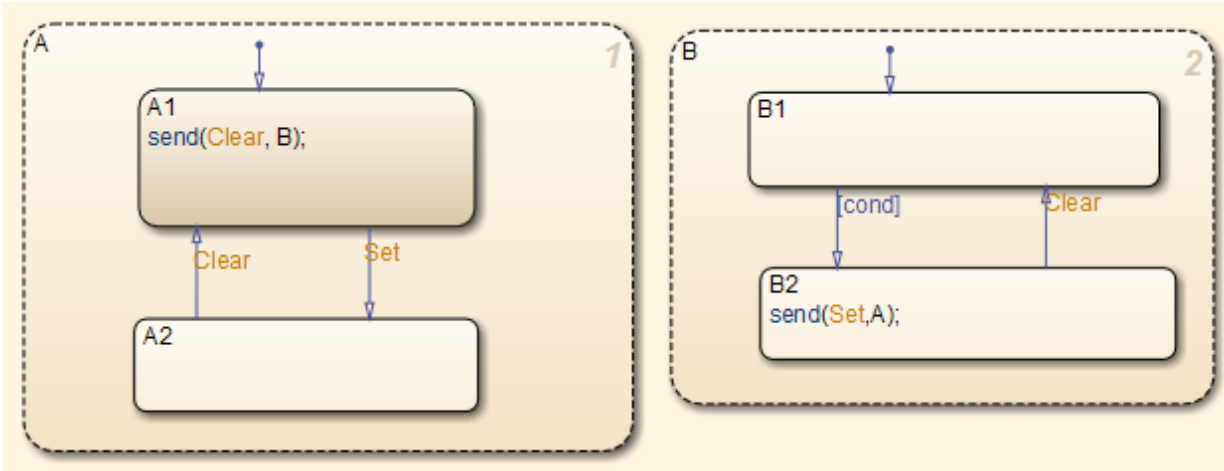
Note For information about avoiding recursion in Stateflow charts, see "Guidelines for Avoiding Unwanted Recursion in a Chart" (Stateflow) in the Stateflow documentation.

Stateflow software also allows you to create *cyclic behavior*, where a sequence of steps is repeated indefinitely. If your model has a chart with cyclic behavior, the software cannot analyze it.

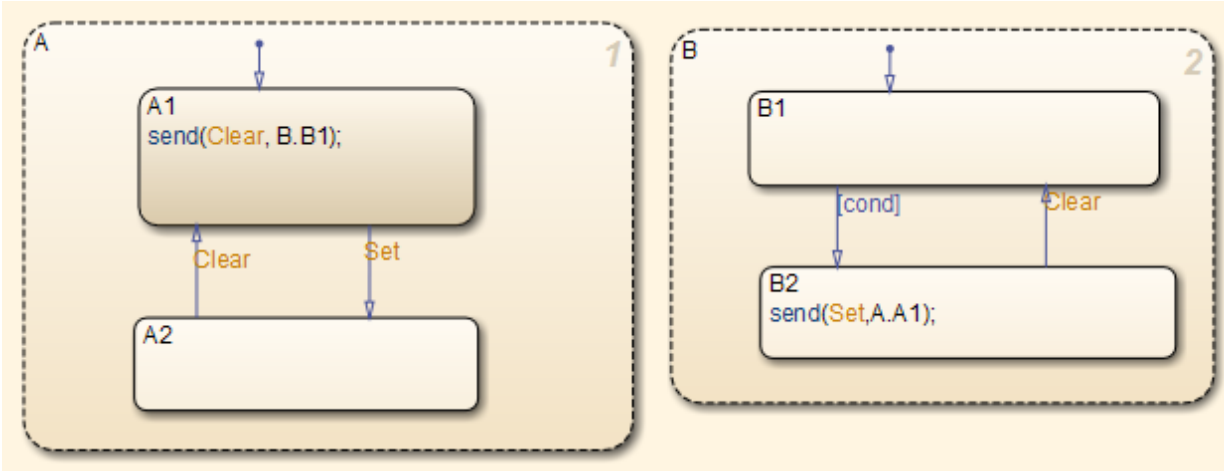
Note For information about cyclic behavior in Stateflow charts, see "Cyclic Behavior in a Chart" (Stateflow) in the Stateflow documentation.

However, you can modify a chart with cyclic behavior so that it is compatible, as in the following example.

The following chart creates cyclic behavior. State A calls state A1, which broadcasts a `Clear` event to state B, which calls state B2, which broadcasts a `Set` event back to state A, causing the cyclic behavior.



If you change the `send` function calls to use directed event broadcasts so that the Set and Clear events are broadcast directly to the states B1 and A1, respectively, the cyclic behavior disappears and the software can analyze the model.



Note For information about the benefits of directed event broadcasts, see "Broadcast Events to Synchronize States" (Stateflow) in the Stateflow documentation.

Custom C or C++ Code

The software does not support custom C or C++ code, which the Stateflow software allows.

Machine-Parented Data

The software does not support machine-parented data (i.e., defined at the level of the Stateflow machine), which the Stateflow software allows.

For more information, see "Best Practices for Using Data in Charts" (Stateflow) in the Stateflow documentation.

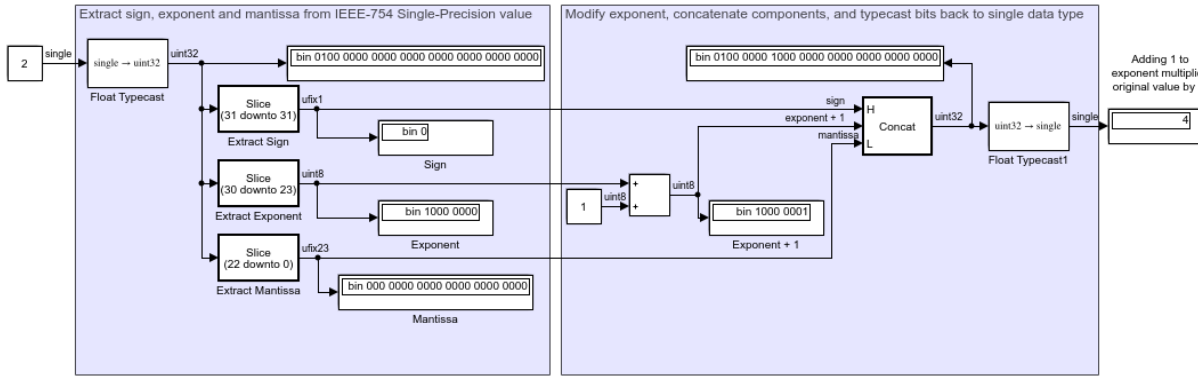
Textual Functions with Literal String Arguments

The software does not support literal string arguments to textual functions in a Stateflow chart.

Using the Float Typecast Block

This example shows how you can use the Float Typecast block to extract the sign, exponent, and mantissa bits from a floating-point input, and then convert the bits back to a floating-point output after performing any computations.

Open this model. The model multiplies the floating-point input by two to produce the floating-point output. To multiply the input, the algorithm increments the exponent by one.



Enumerations and Modeling

Simulink Enumerations

Enumerated data is data that is restricted to a finite set of values. An *enumerated data type* is a MATLAB class that defines a set of *enumerated values*. Each enumerated value consists of an *enumerated name* and an *underlying integer* which the software uses internally and in generated code.

Before you begin to use enumerations in a modeling context, you should understand information provided in "Enumerations" (MATLAB).

To define an enumeration for use in Simulink models, choose one of these techniques:

- Use the function `Simulink.defineIntEnumType`. The enumeration exists for the duration of your MATLAB session.
- Create a permanent enumeration class by subclassing one of these built-in classes:
  - Many of the built-in integer data types such as `int8` and `uint16`
  - `Simulink.IntEnumType`
- Use the function `Simulink.importExternalCTypes` to create a Simulink representation of an enumerated data type (`enum`) that your external C code defines.

  Use this technique to help you:

  - Replace existing C code with a Simulink model.
  - Integrate existing C code for simulation in Simulink (for example, by using the Legacy Code Tool).
  - Generate C code (Simulink Coder) that you can compile with existing C code into a single application.

For more information, see "Define Simulink Enumerations" on page 60-7.

The following examples show how to use enumerations in Simulink and Stateflow.

Example	Shows How To Use...
Data Typing in Simulink	Data types in Simulink, including enumerated data types
Modeling a CD Player/Radio Using Enumerated Data Types	Enumerated data types in a Simulink model that contains a Stateflow chart

For information on using enumerations in Stateflow, see "Enumerated Data" (Stateflow).

Simulink Constructs that Support Enumerations

Overview

In general, all Simulink tools and constructs support enumerated types for which the support makes sense given the purpose of enumerated types: to represent program states and to control program logic. The Simulink Editor, Simulink Debugger, Port Value Displays, referenced models, subsystems, masks, buses, data logging, and most other Simulink capabilities support enumerated types without imposing any special requirements.

Enumerated types are not intended for mathematical computation, so no block that computes a numeric output (as distinct from passing a numeric input through to the output) supports enumerated types. Thus an enumerated type is not considered to be a numeric type, even though an enumerated value has an underlying integer. See "Enumerated Values in Computation" on page 60-22 for more information.

Most capabilities that do not support enumerated types obviously could not support them. Therefore, the Simulink documentation usually mentions enumerated type nonsupport only where necessary to prevent a misconception or describe an exception. See "Simulink Enumeration Limitations" on page 60-5 for information about certain constructs that could support enumerated types but do not.

Block Support

The following Simulink blocks support enumerated types:

- Constant (but Enumerated Constant is preferable)
- Data Type Conversion
- Data Type Conversion Inherited
- Data Type Duplicate
- Display

- MATLAB Function
- Enumerated Constant
- Floating Scope
- From File
- From Workspace
- Inport
- Interval Test
- Interval Test Dynamic
- Multiport Switch
- Outport
- Probe (input only)
- Relational Operator
- Relay (output only)
- Repeating Sequence Stair
- Scope
- Signal Specification
- Switch
- Switch Case
- To File
- To Workspace

All members of the following categories of Simulink blocks support enumerated types:

- Bus-capable blocks (see “Bus-Capable Blocks” on page 65-48)
- Pass-through blocks:
  - With state, like the Data Store Memory and Unit Delay blocks.
  - Without state, like the Mux block.

Many Simulink blocks in addition to those named above support enumerated types, but they either belong to one of the categories listed above, or are rarely used with enumerated types. The Data Type Support section of each block reference page describes all data types that the block supports.

Class Support

The following Simulink classes support enumerated types:

- `Simulink.Signal`
- `Simulink.Parameter`
- `Simulink.AliasType`
- `Simulink.BusElement`

Logging Enumerated Data

Root-level outports, To Workspace blocks, and Scope blocks can all export enumerated values. Signal and State logging work with enumerated data in the same way as with any other data. All logging formats are supported. The From File block does not support enumerated data. Use the From Workspace block instead, combined with some technique for transferring data between a file and a workspace. See “Save Runtime Data from Simulation” for more information.

Importing Enumerated Data

Root-level inports and From Workspace blocks can output enumerated signals during simulation. Data must be provided in a `Structure`, `Structure with Time`, or `TimeSeries` object. No interpolation occurs for enumerated values between the specified simulation times. From File blocks produce only data of type `double`, so they do not support enumerated types. See “Load Signal Data for Simulation” for more information.

Simulink Enumeration Limitations

Enumerations and Scopes

When a Scope block displays an enumerated signal, the vertical axis displays the names of the enumerated values only if the scope was open during simulation. If you open the Scope block for the first time before any simulation has occurred, or between simulations, the block displays only numeric values. When simulation begins, enumerated names replace the numeric values, and thereafter appear whenever the Scope block is opened.

When a Floating Scope block displays multiple signals, the names of enumerated values appear on the Y axis only if all signals are of the same enumerated type. If the Floating Scope block displays more than one type of enumerated signal, or any numeric signal, no names appear, and any enumerated values are represented by their underlying integers.

Enumerated Types for Switch Blocks

The control input of a Switch block can be of any data type supported by Simulink. However, the `u2 ~=0` mode is not supported for enumerations. If the control input has an enumeration, choose one of the following methods to specify the criteria for passing the first input:

- Select `u2 >= Threshold` or `u2 > Threshold` and specify a threshold value of the same enumerated type as the control input.
- Use a Relational Operator block to do the comparison and then feed the Boolean result of this comparison into the control port of the Switch block.

Nonsupport of Enumerations

The following limitations exist when using enumerated data types with Simulink:

- Packages cannot contain enumeration class definitions.
- The If Action block might support enumerations, but currently does not do so.
- Generated code does not support logging enumerated data.
- Custom Stateflow targets do not support enumerated types.

Use Enumerated Data in Simulink Models

In this section...

Enumerated data is data that is restricted to a finite set of values. An *enumerated data type* is a MATLAB class that defines a set of *enumerated values*. Each enumerated value consists of an *enumerated name* and an *underlying integer* which the software uses internally and in generated code.

For basic conceptual information about enumerations in Simulink, see "Simulink Enumerations" on page 60-2.

For information about generating code with enumerations, see "Use Enumerated Data in Generated Code" (Simulink Coder).

Define Simulink Enumerations

To define an enumerated data type that you can use in Simulink models, use one of these methods:

- Define an enumeration class using a `classdef` block in a MATLAB file.
- Use the function `Simulink.defineIntEnumType`. You do not need a script file to define the type. For more information, see the function reference page.
- Use the function `Simulink.importExternalCTypes` to create a Simulink representation of an enumerated data type (`enum`) that your external C code defines.

Workflow to Define a Simulink Enumeration Class

1 Create a class definition on page 60-8.

2 Optionally, customize the enumeration on page 60-9.

3 Optionally, save the enumeration in a MATLAB file on page 60-11.

4 Optionally, permanently store the enumeration definition in a Simulink data dictionary. See "Permanently Store Enumerated Type Definition" on page 60-14.

Create Simulink Enumeration Class

To create a Simulink enumeration class, in the class definition:

- Define the class as a subclass of `Simulink.IntEnumType`. You can also base an enumerated type on one of these built-in integer data types: `int8`, `uint8`, `int16`, `uint16`, and `int32`.
- Add an `enumeration` block that specifies enumeration values with underlying integer values.

Consider the following example:

```
classdef BasicColors < Simulink.IntEnumType
  enumeration
    Red(0)
    Yellow(1)
    Blue(2)
  end
end
```

The first line defines an integer-based enumeration that is derived from built-in class `Simulink.IntEnumType`. The enumeration is integer-based because `IntEnumType` is derived from `int32`.

The `enumeration` section specifies three enumerated values.

Enumerated Value	Enumerated Name	Underlying Integer
`Red(0)`	`Red`	`0`
`Yellow(1)`	`Yellow`	`1`
`Blue(2)`	`Blue`	`2`

When defining an enumeration class for use in the Simulink environment, consider the following:

- The name of the enumeration class must be unique among data type names and base workspace variable names, and is case-sensitive.

- Underlying integer values in the `enumeration` section need not be unique within the class and across types.
- Often, the underlying integers of a set of enumerated values are consecutive and monotonically increasing, but they need not be either consecutive or ordered.
- For simulation, an underlying integer can be any `int32` value. Use the MATLAB functions `intmin` and `intmax` to get the limits.
- For code generation, every underlying integer value must be representable as an integer on the target hardware, which may impose different limits. See "Configure a System Target File" (Simulink Coder) and "Hardware Implementation Pane" for more information.

For more information on superclasses, see "Convert to Superclass Value" (MATLAB). For information on how enumeration classes are handled when there is more than one name for an underlying value, see "How to Alias Enumeration Names" (MATLAB).

Customize Simulink Enumeration

About Simulink Enumeration Customizations

You can customize a Simulink enumeration by implementing specific static methods in the class definition. If you define these methods using the appropriate syntax, you can change the behavior of the class during simulation and in generated code.

The table shows the methods you can implement to customize an enumeration.

Static Method	Purpose	Default Value Without Implementing Method	Custom Return Value	Usage Context
`getDefaultValue`	Specifies the default enumeration member for the class.	First member specified in the enumeration definition	A character vector containing the name of an enumeration member in the class (see "Instantiate Enumerations" on page 60-19)	Simulation and code generation
`getDescription`	Specifies a description of the enumeration class.	`''`	A character vector containing the description of the type	Code generation

Static Method	Purpose	Default Value Without Implementing Method	Custom Return Value	Usage Context
`getHeaderFile`	Specifies the name of a header file. The method `getDataScope` determines the significance of the file.	`''`	A character vector containing the name of the header file that defines the enumerated type	Code generation
`getDataScope`	Specifies whether generated code exports or imports the definition of the enumerated data type. Use the method `getHeaderFile` to specify the generated or included header file that defines the type.	`'Auto'`	One of: `'Auto'`, `'Exported'`, or `'Imported'`	Code generation
`addClassNameToEnumNames`	Specifies whether to prefix the class name in generated code.	`false`	`true` or `false`	Code generation

For more examples of these methods as they apply to code generation, see “Customize Enumerated Data Type” (Simulink Coder).

Specify a Default Enumerated Value

Simulink and related generated code use an enumeration's default value for ground-value initialization of enumerated data when you provide no other initial value. For example, an enumerated signal inside a conditionally executed subsystem that has not yet executed has the enumeration's default value. Generated code uses an enumeration's default value if a safe cast fails, as described in “Type Casting for Enumerations” (Simulink Coder).

Unless you specify otherwise, the default value for an enumeration is the first value in the enumeration class definition. To specify a different default value, add your own `getDefaultValue` method to the `methods` section. The following code shows a shell for the `getDefaultValue` method:

```
function retVal = getDefaultValue()
  % GETDEFAULTVALUE Specifies the default enumeration member.
  % Return a valid member of this enumeration class to specify the default.
  % If you do not define this method, Simulink uses the first member.
  retVal = ThisClass.EnumName;
end
```

To customize this method, provide a value for *`ThisClass.EnumName`* that specifies the desired default.

- *`ThisClass`* must be the name of the class within which the method exists.
- *`EnumName`* must be the name of an enumerated value defined in that class.

For example:

```
classdef BasicColors < Simulink.IntEnumType
  enumeration
    Red(0)
    Yellow(1)
    Blue(2)
  end
  methods (Static)
    function retVal = getDefaultValue()
      retVal = BasicColors.Blue;
    end
  end
end
```

This example defines the default as `BasicColors.Blue`. If this method does not appear, the default value would be `BasicColors.Red`, because that is the first value listed in the enumerated class definition.

The seemingly redundant specification of *`ThisClass`* inside the definition of that same class is necessary because `getDefaultValue` returns an instance of the default enumerated value, not just the name of the value. The method, therefore, needs a complete specification of what to instantiate. See “Instantiate Enumerations” on page 60-19 for more information.

Save Enumeration in a MATLAB File

You can define an enumeration within a MATLAB file.

- The name of the definition file must match the name of the enumeration exactly, including case. For example, the definition of enumeration `BasicColors` must reside in a file named `BasicColors.m`. Otherwise, MATLAB will not find the definition.

- You must define each class definition in a separate file.
- Save each definition file on the MATLAB search path. MATLAB searches the path to find a definition when necessary.

  To add a file or folder to the MATLAB search path, type `addpath` *`pathname`* at the MATLAB command prompt. For more information, see "What Is the MATLAB Search Path?" (MATLAB), `addpath`, and `savepath`.
- You do not need to execute an enumeration class definition to use the enumeration. The only requirement, as indicated in the preceding bullet, is that the definition file be on the MATLAB search path.

Change and Reload Enumeration Classes

You can change the definition of an enumeration by editing and saving the file that contains the definition. You do not need to inform MATLAB that a class definition has changed. MATLAB automatically reads the modified definition when you save the file. However, the class definition changes do not take full effect if any class instances (enumerated values) exist that reflect the previous class definition. Such instances might exist in the base workspace or might be cached.

The following table explains options for removing instances of an enumeration from the base workspace and cache.

If In Base Workspace...	If In Cache...
Do one of the following: • Locate and delete specific obsolete instances. • Delete everything from the workspace by using the `clear` command.	• Delete obsolete instances by closing all models that you updated or simulated while the previous class definition was in effect. • Clear functions and close models that are caching instances of the class.

For more information about applying enumeration changes, see "Automatic Updates for Modified Classes" (MATLAB).

Import Enumerations Defined Externally to MATLAB

If you have enumerations defined externally to MATLAB that you want to import for use within the Simulink environment, you can do so programmatically with calls to one of these functions:

- `Simulink.defineIntEnumType` — Defines an enumeration that you can use in MATLAB as if it is defined by a class definition file. In addition to specifying the enumeration class name and values, each function call can specify:

  - Character vector that describes the enumeration class.
  - Which of the enumeration values is the default.

  For code generation, you can specify:

  - Header file in which the enumeration is defined for generated code.
  - Whether the code generator applies the class name as a prefix to enumeration members — for example, `BasicColors_Red` or `Red`.

  As an example, consider the following class definition:

```
classdef BasicColors < Simulink.IntEnumType
    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
    end
    methods (Static = true)
        function retVal = getDescription()
            retVal = 'Basic colors...';
        end
        function retVal = getDefaultValue()
            retVal = BasicColors.Blue;
        end
        function retVal = getHeaderFile()
            retVal = 'mybasiccolors.h';
        end
        function retVal = addClassNameToEnumNames()
            retVal = true;
        end
    end
end
```

  The following function call defines the same class for use in MATLAB:

```
Simulink.defineIntEnumType('BasicColors', ...
     {'Red', 'Yellow', 'Blue'}, [0;1;2],...
     'Description', 'Basic colors', ...
     'DefaultValue', 'Blue', ...
```

```
        'HeaderFile', 'mybasiccolors.h', ...
        'DataScope', 'Imported', ...
        'AddClassNameToEnumNames', true);
```

- `Simulink.importExternalCTypes` — Creates Simulink representations of enumerated data types (`enum`) that your existing C code defines.

Permanently Store Enumerated Type Definition

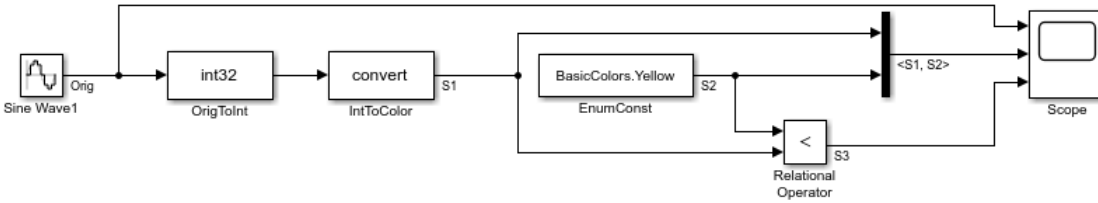
Whether you define an enumeration by using a class file or by using the function `Simulink.defineIntEnumType`, you can permanently store the enumeration definition in a Simulink data dictionary. Models that are linked to the dictionary can use the enumeration. For more information, see “Enumerations in Data Dictionary” on page 63-14.

Simulate with Enumerations

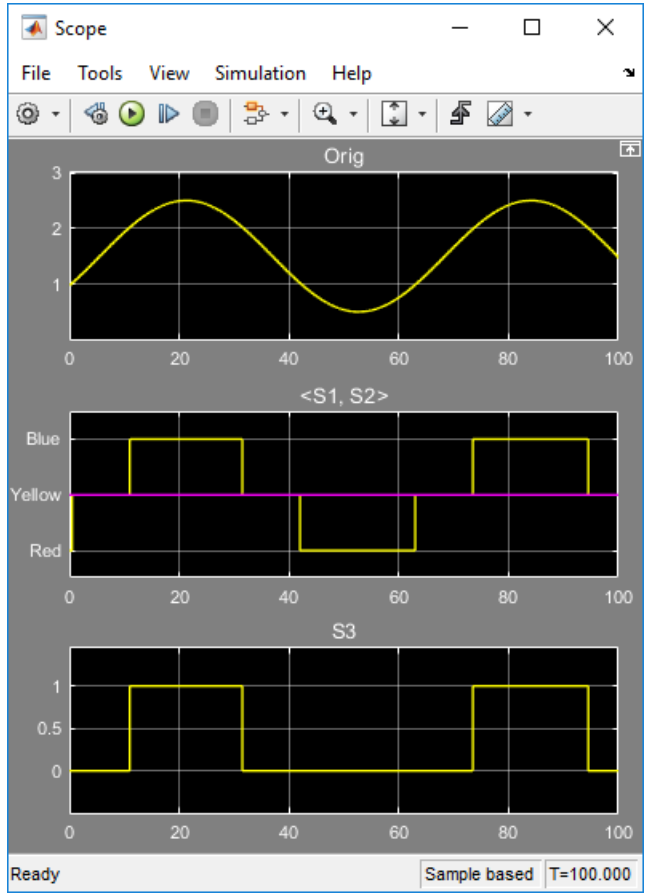
Consider the following enumeration class definition — `BasicColors` with enumerated values `Red`, `Yellow`, and `Blue`, with `Blue` as the default value:

```
classdef BasicColors < Simulink.IntEnumType
  enumeration
    Red(0)
    Yellow(1)
    Blue(2)
  end
  methods (Static)
    function retVal = getDefaultValue()
      retVal = BasicColors.Blue;
    end
  end
end
```

Once this class definition is known to MATLAB, you can use the enumeration in Simulink and Stateflow models. Information specific to enumerations in Stateflow appears in “Enumerated Data” (Stateflow). The following Simulink model uses the enumeration defined above:



The output of the model looks like this:



The Data Type Conversion block **OrigToInt** specifies an **Output data type** of `int32` and **Integer rounding mode:** `Floor`, so the block converts the Sine Wave block output, which appears in the top graph of the Scope display, to a cycle of integers: `1`, `2`, `1`, `0`, `1`, `2`, `1`. The Data Type Conversion block **IntToColor** uses these values to select colors from the enumerated type `BasicColors` by referencing their underlying integers.

The result is a cycle of colors: `Yellow`, `Blue`, `Yellow`, `Red`, `Yellow`, `Blue`, `Yellow`, as shown in the middle graph. The Enumerated Constant block **EnumConst** outputs `Yellow`, which appears in the second graph as a straight line. The Relational Operator block compares the constant `Yellow` to each value in the cycle of colors. It outputs `1` (`true`) when `Yellow` is less than the current color, and `0` (`false`) otherwise, as shown in the third graph.

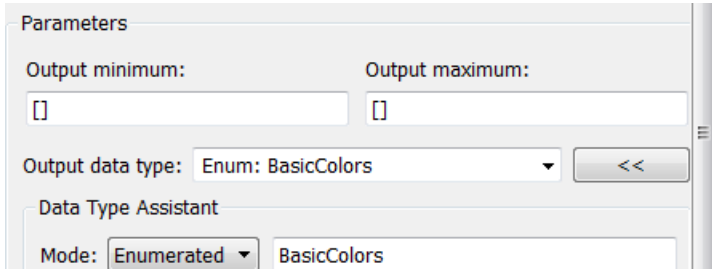
The sort order used by the comparison is the numeric order of the underlying integers of the compared values, *not* the lexical order in which the enumerated values appear in the enumerated class definition. In this example the two orders are the same, but they need not be. See "Specify Enumerations as Data Types" on page 60-16 and "Enumerated Values in Computation" on page 60-22 for more information.

Specify Enumerations as Data Types

Once you define an enumeration, you can use it much like any other data type. Because an enumeration is a class rather than an instance, you must use the prefix ? or `Enum:` when specifying the enumeration as a data type. You must use the prefix `?` in the MATLAB Command Window. However, you can use either prefix in a Simulink model. `Enum:` has the same effect as the `?` prefix, but `Enum:` is preferred because it is more self-explanatory in the context of a graphical user interface.

Depending on the context, type `Enum:` followed by the name of an enumeration, or select `Enum: <class name>` from a menu (for example, for the **Output data type** block parameter) , and replace `<class name>`.

To use the Data Type Assistant, set the **Mode** to `Enumerated`, then enter the name of the enumeration. For example, in the previous model, the Data Type Conversion block **IntToColor**, which outputs a signal of type `BasicColors`, has the following output signal specification:



You cannot set a minimum or maximum value for a signal defined as an enumeration, because the concepts of minimum and maximum are not relevant to the purpose of enumerations. If you change the minimum or maximum for a signal of an enumeration from the default value of `[]`, an error occurs when you update the model. See "Enumerated Values in Computation" on page 60-22 for more information.

Get Information About Enumerated Data Types

The functions `enumeration` and `Simulink.data.getEnumTypeInfo` return information about enumerated data types.

Get Information About Enumeration Members

Use the function `enumeration` to:

- Return an array that contains all enumeration values for an enumeration class in the MATLAB Command Window
- Get the enumeration values programmatically
- Provide the values to a Simulink block parameter that accepts an array or vector of enumerated values, such as the **Case conditions** parameter of the Switch Case block

Get Information About Enumerated Class

Use the function `Simulink.data.getEnumTypeInfo` to return information about an enumeration class, such as:

- The default enumeration member
- The name of the header file that defines the type in generated code
- The data type used in generated code to store the integer values underlying the enumeration members

Enumeration Value Display

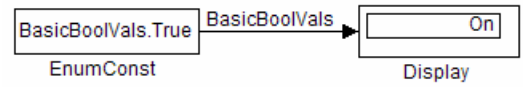
Wherever possible, Simulink displays enumeration values by name, not by the underlying integer value. However, the underlying integers can affect value display in Scope and Floating Scope blocks.

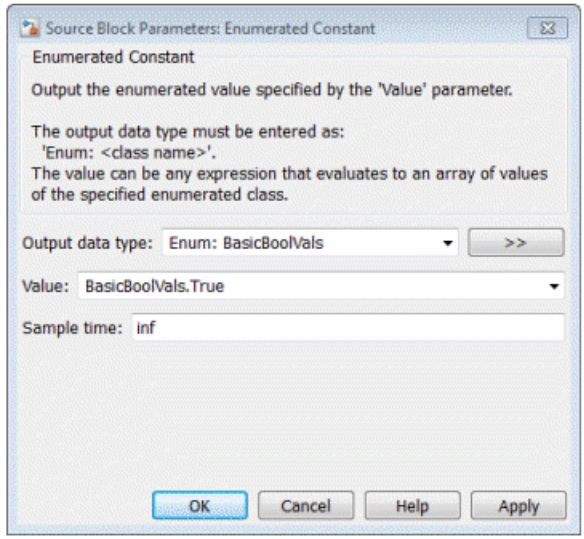
Block...	Affect on Value Display...
Scope	When displaying an enumerated signal, the names of the enumerated values appear as labels on the Y axis. The names appear in the order given by their underlying integers, with the lowest value at the bottom.
Floating Scope	When displaying signals that are of the same enumeration, names appear on the Y axis as they would for a Scope block. If the Floating Scope block displays mixed data types, no names appear, and any enumerated values are represented by their underlying integers.

Enumerated Values with Non-Unique Integers

More than one value in an enumeration can have the same underlying integer value, as described in “Specify Enumerations as Data Types” on page 60-16. When this occurs, the value on an axis of Scope block output or in Display block output always is the first value listed in the enumerated class definition that has the shared underlying integer. For example:

```
classdef BasicBoolVals < Simulink.IntEnumType
  enumeration
    On(1)
    Off(0)
    True(1)
    False(0)
  end
end
```





Although the Enumerated Constant block outputs `True`, both `On` and `True` have the same underlying integer, and `On` is defined first in the class definition `enumeration` section. Therefore, the Display block shows `On`. Similarly, a Scope axis would show only `On`, never `True`, no matter which of the two values is input to the Scope block.

Instantiate Enumerations

Before you can use an enumeration, you must instantiate it. You can instantiate an enumeration in MATLAB, in a Simulink model, or in a Stateflow chart. The syntax is the same in all contexts.

Instantiating Enumerations in MATLAB

To instantiate an enumeration in MATLAB, enter *`ClassName.EnumName`* in the MATLAB Command Window. The instance is created in the base workspace. For example, if `BasicColors` is defined as in “Create Simulink Enumeration Class” on page 60-8, you can type:

```
bcy = BasicColors.Yellow

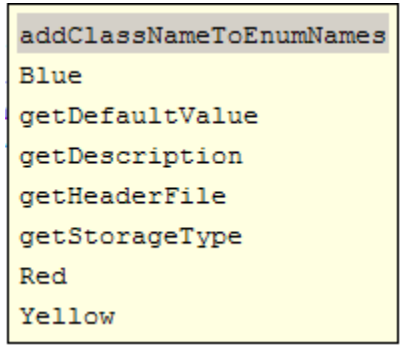
bcy =

    Yellow
```

Tab completion works for enumerations. For example, if you enter:

```
bcy = BasicColors.<tab>
```

MATLAB displays the elements and methods of `BasicColors` in alphabetical order:



Double-click an element or method to insert it at the position where you pressed `<tab>`. See “Automatic Code Suggestions and Completions” (MATLAB) for more information.

Casting Enumerations in MATLAB

In MATLAB, you can cast directly from an integer to an enumerated value:

```
bcb = BasicColors(2)

bcb =

    Blue
```

You can also cast from an enumerated value to its underlying integer:

```
>> bci = int32(bcb)

bci =

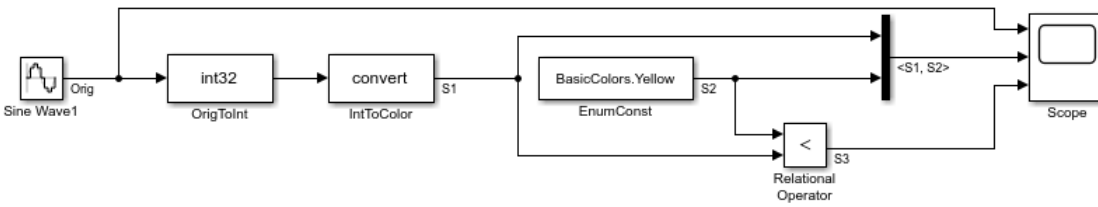
    2
```

In either case, MATLAB returns the result of the cast in a 1x1 array of the relevant data type.

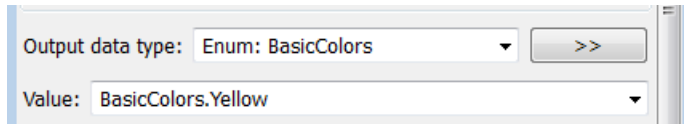
Although casting is possible, use of enumeration values is not robust in cases where enumeration values and the integer equivalents defined for an enumeration class might change.

Instantiating Enumerations in Simulink (or Stateflow)

To instantiate an enumeration in a Simulink model, you can enter *`ClassName.EnumName`* as a value in a dialog box. For example, consider the following model:



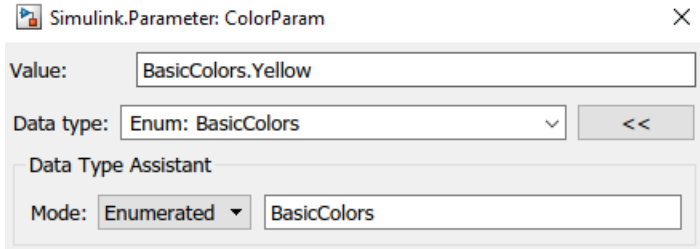
The Enumerated Constant block **EnumConst**, which outputs the enumerated value `Yellow`, defines that value as follows:



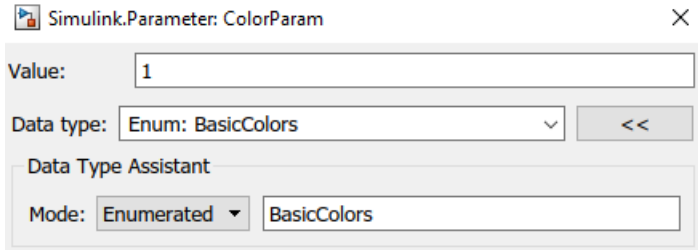
You can enter any valid MATLAB expression that evaluates to an enumerated value, including arrays and workspace variables. For example, you could enter `BasicColors(1)`, or if you had previously executed `bcy = BasicColors.Yellow` in the MATLAB Command Window, you could enter `bcy`. As another example, you could enter an array, such as `[BasicColors.Red, BasicColors.Yellow, BasicColors.Blue]`.

You can use a Constant block to output enumerated values. However, that block displays parameters that do not apply to enumerated types, such as **Output Minimum** and **Output Maximum**.

If you create a `Simulink.Parameter` object as an enumeration, you must specify the **Value** parameter as an enumeration member and the **Data type** with the `Enum:` or `?` prefix, as explained in "Specify Enumerations as Data Types" on page 60-16.



You *cannot* specify the integer value of an enumeration member for the **Value** parameter. See "Enumerated Values in Computation" on page 60-22 for more information. Thus, the following fails even though the integer value for `BasicColors.Yellow` is `1`.



The same syntax and considerations apply in Stateflow. See "Enumerated Data" (Stateflow) for more information.

Enumerated Values in Computation

By design, Simulink prevents enumerated values from being used as numeric values in mathematical computation, even though an enumerated class is a subclass of the MATLAB `int32` class. Thus, an enumerated type does not function as a numeric type despite the existence of its underlying integers. For example, you cannot input an enumerated signal directly to a Gain block.

You can use a Data Type Conversion block to convert in either direction between an integer type and an enumerated type, or between two enumerated types. That is, you can use a Data Type Conversion block to convert an enumerated signal to an integer signal (consisting of the underlying integers of the enumerated signal values) and input the resulting integer signal to a Gain block. See "Casting Enumerated Signals" on page 60-23 for more information.

Enumerated types in Simulink are intended to represent program states and control program logic in blocks like the Relational Operator block and the Switch block. When a Simulink block compares enumerated values, the values compared must be of the same enumerated type. The block compares enumerated values based on their underlying integers, not their order in the enumerated class definition.

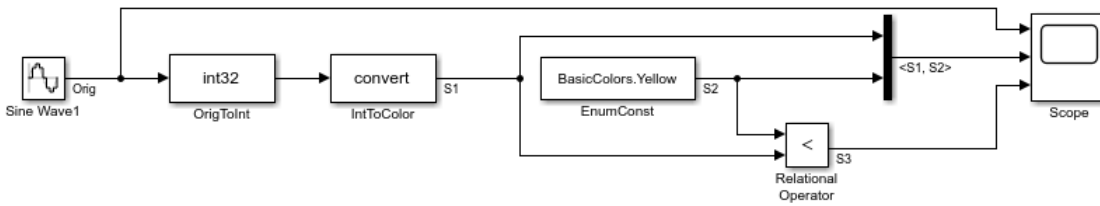
When a block like the Switch block or Multiport Switch block selects among multiple data signals, and any data signal is of an enumerated type, all the data signals must be of that same enumerated type. When a block inputs both control and data signals, as Switch and Multiport Switch do, the control signal type need not match the data signal type.

Casting Enumerated Signals

You can use a Data Type Conversion block to cast an enumerated signal to a signal of any numeric type, provided that the underlying integers of all enumerated values input to the block are within the range of the numeric type. Otherwise, an error occurs during simulation.

Similarly, you can use a Data Type Conversion block to cast a signal of any integer type to an enumerated signal, provided that every value input to the Data Type Conversion block is the underlying integer of some value in the enumerated type. Otherwise, an error occurs during simulation.

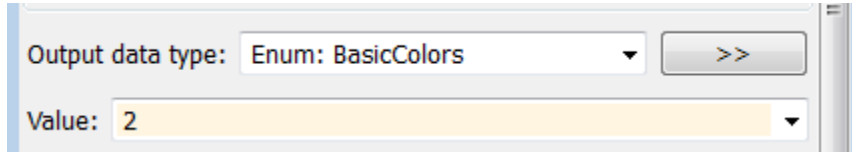
You cannot use a Data Type Conversion block to cast a numeric signal of any non-integer data type to an enumerated type. For example, the model used in "Simulate with Enumerations" on page 60-14 needed two Data Conversion blocks to convert a sine wave to enumerated values.



The first block casts `double` to `int32`, and the second block casts `int32` to `BasicColors`. You cannot cast a complex signal to an enumerated type regardless of the data types of its real and imaginary parts.

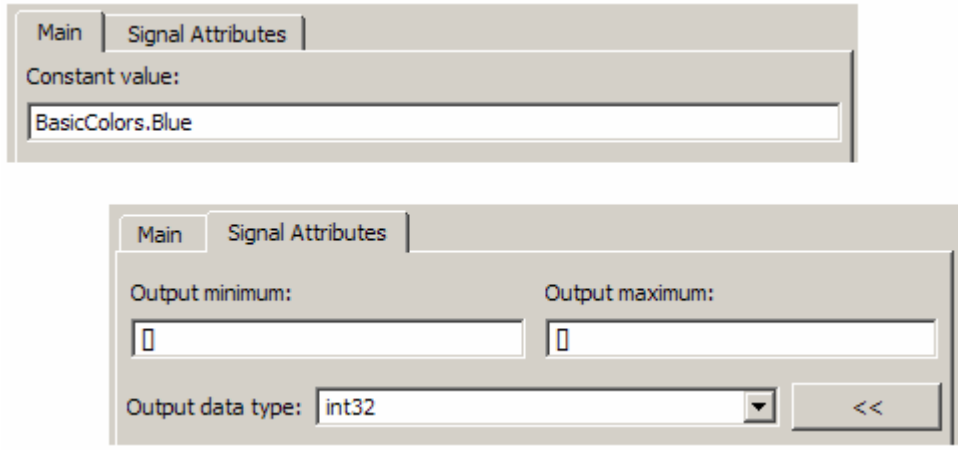
Casting Enumerated Block Parameters

You cannot cast a block parameter of any numeric data type to an enumerated data type. For example, suppose that an Enumerated Constant block specifies a **Value** of `2` and an **Output data type** of `Enum: BasicColors`:



An error occurs because the specifications implicitly cast a `double` value to an enumerated type. The error occurs even though the numeric value corresponds arithmetically to one of the enumerated values in the enumerated type.

You cannot cast a block parameter of an enumeration to any other data type. For example, suppose that a Constant block specifies a **Constant value** of `BasicColors.Blue` and an **Output data type** of `int32`.



An error occurs because the specifications implicitly cast an enumerated value to a numeric type. The error occurs even though the enumerated value's underlying integer is a valid `int32`.

Importing and Exporting Simulation Data

Export Simulation Data

In this section...

Exporting (logging) simulation data provides a baseline for analyzing and debugging a model. Use standard or custom MATLAB functions to generate simulated system input signals and to graph, analyze, or otherwise postprocess the system outputs.

Simulation Data

Simulation data can include any combination of signal, time, output, state, and data store logging data.

Exporting simulation data involves saving signal values to the MATLAB workspace or to a MAT-file during simulation for later retrieval and postprocessing. Exporting data is also known as “data logging” or “saving simulation data.”

You can have data logged in different formats:

- Array
- Structure
- Structure with time
- MATLAB timeseries
- `ModelDataLogs`

Note The `ModelDataLogs` class is supported for backward compatibility. Starting in R2016a, you cannot log data in the `ModelDataLogs` format. Signal logging uses the `Dataset` format. In R2016a or later, when you open a model from an earlier release that had used `ModelDataLogs` format, the model simulated in use `Dataset` format.

Consider converting this data to the `Dataset` format, which can simplify the post-processing of data. For more information, see “Dataset Conversion for Logged Data” on page 61-22.

You can also import the exported data to use as input for simulating a model.

Approaches for Exporting Signal Data

Exporting simulation data often involves exporting signal data. You can use various approaches for exporting signal data.

Export Approach	Usage	Documentation
Connect a Scope block or viewer to a signal.	If you use a Scope block for viewing results during simulation, consider also using the Scope block to export data. Save output at a sample rate other than the base sample rate. Scopes store data and can be memory intensive.	Scope
Connect a signal to a To File block.	Consider using a To File block for exporting large amounts of data. Save output at a sample rate other than the base sample rate. Use the MAT-file only after the simulation has completed.	To File
Connect a signal to a To Workspace block.	Document in the diagram the workspace variables used to store signal data. Save output at a sample rate other than the base sample rate.	To Workspace

Export Approach	Usage	Documentation
Connect a signal to a root-level Outport block.	Consider using this approach for logging data in a top-level model, if the model already includes an Outport block.	Outport
Set the signal logging properties for a signal.	Use signal logging to avoid adding blocks. Log signals based on individual signal rates. Data is available only when simulation is paused or completed. Use signal logging to log array of buses signals.	"Export Signal Data Using Signal Logging" on page 61-71
Configure Simulink to export time, state, and output data.	To capture complete information about the simulation as a whole, consider exporting this data. Outputs and states are logged at the base sample rate of the model.	"Data Format for Logged Simulation Data" on page 61-16 "Limit Amount of Exported Data" on page 61-42 "Samples to Export for Variable-Step Solvers" on page 61-67
Log a data store.	Log a data store to share data throughout a model hierarchy, capturing the order of all data store writes.	"Log Data Stores" on page 62-39

Export Approach	Usage	Documentation
Use the `sim` command to log simulation data programmatically.	Use `sim` to export to one data object the time, states, and signal simulation data. Select the **Return as single object** parameter when simulating the model using the `sim` command inside a function or a `parfor` loop.	`sim`

Enable Simulation Data Export

To export the states and root-level output ports of a model to the MATLAB base workspace during simulation of the model, use one of these interfaces:

- **Configuration Parameters > Data Import/Export** pane (for details, see "Model Configuration Parameters: Data Import/Export")
- `sim` command

In both approaches, specify:

- The kinds of simulation data that you want to export:
  - Signal logging
  - Time
  - Output
  - State or final state
  - Data store

  Each kind of simulation data export has an associated default variable. You can specify your own variables for the exported data.
- The characteristics of the logged data, including:
  - "Data Format for Logged Simulation Data" on page 61-16
  - "Limit Data Logged" on page 61-79
  - "Samples to Export for Variable-Step Solvers" on page 61-67

View Logged Data Using Simulation Data Inspector

To inspect exported simulation data interactively, consider using the Simulation Data Inspector on page 28-2.

The Simulation Data Inspector has some limitations on the kinds of logged data that it displays. See "Populate the Simulation Data Inspector with Your Data" on page 28-4.

Memory Performance

Optimization for Logged Data

When exporting simulation data in a simulation mode other than rapid accelerator, Simulink optimizes memory usage in the following situations.

- When time steps happen at regular intervals, Simulink uses compressed time representation. Simulink stores the value for the first timestamp, the length of the interval (time step), and the total number of timestamps.
- When multiple signals use identical sequences of timestamps, the signals share a single stored timestamp sequence. Sharing a single stored timestamp can reduce memory use for logged data by as much as a factor of two. An example when this memory performance can be a critical performance factor is when logging bus signals that have thousands of bus elements.

Logging to Persistent Storage

You can encounter memory issues when you log many signals in a long simulation that has many time steps. Logging to persistent storage can address this kind of memory issue.

To log to persistent storage, in the **Configuration Parameters > Data Import/Export** pane, select **Log Dataset data to file** option. Specify the kinds of logging (for example, signal logging and states logging).

- For logging output and states data, set the **Format** parameter to `Dataset`.
- If you select the **Final states** parameter, clear the **Save complete SimState in final state** parameter.

Using a `Simulink.SimlationData.DatasetRef` object to access signal logging and states logging data loads data into the model workspace incrementally. Accessing data for other kinds of logging loads all the data at once.

For details, see “Log Data to Persistent Storage” on page 61-48.

Provide Signal Data for Simulation

In this section...

A Simulink model performs algorithms on input signal data and produces output signals. The model defines what input data to use at the start of simulation and what output to capture at the end of simulation. As you create and simulate your model, you:

1. “Identify Model Signal Data Requirements” on page 61-9
2. “Load Input Signal Data” on page 61-13
3. “Log Output Signal Data” on page 61-14

As you create, debug, and test a model, you can use different sets of input signal data for simulation. You can use logged simulation data as input to another simulation.

Identify Model Signal Data Requirements

To use system-generated signal data, use source blocks such as a Sine Wave block. Source blocks do not require the use of a variable or external data source. If you cannot configure source blocks to meet your modeling requirements, then supply the signal data.

As you determine your signal data requirements, identify the:

- Blocks (including subsystems and Model blocks) that you need to provide data for — Design interfaces for blocks and for model components, including data types of signals.
- Range characteristics of signals, such as sample time, dimensions, and data type.
- Storage location for data for each input signal — Determine where to store signal data: in workspace variables, a MAT-file, or an external data file such as an Microsoft Excel spreadsheet.

Create a list of equation variables and constant coefficients, and then determine the coefficient values from published sources or by performing experiments on the system.

For an example of identifying model signal data requirements, see "Model a Dynamic System"`Model a Dynamic System`. For information about storage locations for signal data, see "Signal Data Storage for Loading" on page 61-10.

Signal Data Storage for Loading

Store signal data for loading into a model in these locations:

- MATLAB (base) workspace, or function workspace
- Model workspace
- Function workspace
- Masking workspace
- Blocks
- MAT-files
- Spreadsheets

The MATLAB (base) workspace is the most common workspace to use for loading signal data.

MATLAB Workspace for Signal Data

Consider using the MATLAB (base) workspace when you want to:

- Use a small amount of signal data for iterative simulations.
- Use signal data logged during one simulation as input for another simulation.
- Have multiple models use the same signal data.

Create Signal Data in the MATLAB Workspace

- At the MATLAB command line or editor, create the signal data.
- Use the `xlsread` function to read data from an Excel spreadsheet into the MATLAB workspace.

- Use the `csvread` function to read data from a CSV spreadsheet into the MATLAB workspace.
- Use a model callback to load signal data.
- Use one of these Simulink logging techniques:
  - Signal logging
  - To Workspace block
  - Scope block
  - The **Configuration Parameters > Data Import/Export** pane, the **Output**, **States**, or **Final states** parameters.
  - Data store
  - The `sim` command configured to log simulation data

Load Signal Data from the MATLAB Workspace

To load signal data from a workspace, use one of these techniques:

- Add a From Workspace block.
- Use a root-level input port.
  - Specify workspace variables in the **Configuration Parameters > Data Import/Export > Input** parameter.
  - Use the Root Inport Mapper tool to specify the data for the **Input** parameter.

Source and Signal Builder Blocks for Signal Data

Source blocks, such as the Sine Wave block, generate signals that you can use as inputs to other blocks. Source blocks do not store signal data. Source blocks can be useful for initial prototyping of a model when the generated signal data serves your modeling requirements.

To define signal groups to use as inputs to a model, you can use the Signal Builder block. The Signal Builder block stores the signal group definitions.

Consider using a source block to:

- Avoid having to create the data manually.
- Reduce memory consumption — source blocks do not store signal data.

- Graphically represent in the model the kind of signal data.

Consider using a Signal Builder block to:

- Create and import signal groups for use in testing.

  You can use signal groups with Simulink and with these products:

  - Simulink Test
  - Simulink Coverage
- Switch between signal groups quickly.

MAT-Files for Signal Data

Consider storing signal data in a MAT-file to:

- Load a large amount of signal data efficiently.
- Reuse the same signal data in different models.
- Reduce memory requirements for the model.
- Use different sets of signal data with the same model, with minimal model updates.

Store Signal Data in a MAT-File

To create a MAT-file to store signal data to import, you can use:

- A To File block
- The Root Inport Mapper tool. Export to a MAT-file the signal data that you work on with the tool.
- MATLAB to create signal data that you store in a MAT-file
- `Simulink.saveVars` function to save to a MAT-file the simulation signal data that Simulink stores as workspace variables

Load Signal Data from a MAT-File

To load signal data from a MAT-file into a model, you can use a From File block.

Spreadsheets for Signal Data

Consider using an Excel or CSV spreadsheet to:

- Use an existing spreadsheet that already has the necessary signal data or that you can update easily to contain the signal data.
- Load a large amount of signal data efficiently.
- Reduce memory requirements for the model.
- Use different sets of signal data with the same model, with minimal model updates.
- Share the signal data with other people who do not have Simulink installed.

Store Signal Data in a Spreadsheet

Use one of these approaches:

- Create the signal data directly in the spreadsheet. For spreadsheet requirements, see "Storage Formats" on page 61-248.
- Export MATLAB signal data to an Excel or CSV spreadsheet using the `xlswrite` or `csvwrite` function.

Load Signal Data from a Spreadsheet

Use one of these blocks:

- From Spreadsheet block
- Signal Builder block

The From Spreadsheet and Signal Builder blocks load Microsoft Excel on all platforms. These blocks load CSV spreadsheets only on Microsoft Windows platforms.

The From Spreadsheet block incrementally loads the data directly from the spreadsheet, to minimize memory consumption. The Signal Builder block imports all the spreadsheet data into MATLAB memory at one time and saves the data in the block.

Load Input Signal Data

You can use various sources for input signal data for simulating a model. You can:

- Use existing data from a file, such as a spreadsheet.
- Write a MATLAB script to define variables for the signal data. For example, you can create `Dataset` format data that you can use with all the signal loading techniques.
- Use data logged from a previous simulation.

You can use several different approaches to load data into a model, including:

- Root-level input ports — Import signal data from a workspace, using the **Input** configuration parameter to import it to a root-level input port of a Inport, Enable, or Trigger block. You can specify the input data directly in the **Input** parameter. To import multiple signals to root-level input ports, consider using the Root Inport Mapping tool on page 61-137. That tool updates the **Input** parameter based on the signal data that you import and map to root-level input ports.
- Source blocks — Add a source block, such Sine Wave block, to generate signals to input to another block.
- From File block — Read data from a MAT-file, outputting the data as a signal.
- From Spreadsheet block — Read data from Microsoft Excel spreadsheets or CSV spreadsheets, outputting the data as one or more signals.
- Signal Builder block — Create interchangeable groups of piecewise linear signal sources to use in a model.

To determine the approach to meet the input signal data requirements of your model, see "Comparison of Signal Loading Techniques" on page 61-128.

Log Output Signal Data

You can save signal values to the MATLAB workspace or to a MAT-file during simulation for later retrieval and postprocessing. Saving simulation data is also known as logging or exporting simulation data.

To determine which approach to use for logging signal data, see "Export Simulation Data" on page 61-3.

Saving simulation data in `Dataset` format simplifies postprocessing by providing a common format for the results of various logging techniques. Using `Dataset` format stores the data as MATLAB `timeseries`objects, which you can process with MATLAB. Simulink provides tools for converting data logged in other formats to `Dataset` format.

For more information about logging output signal data, see "Save Runtime Data from Simulation".

Data Format for Logged Simulation Data

In this section...

Data Format for Block-Based Logged Data

You can use the Scope, To File, or To Workspace blocks to export simulation data. Each of these blocks has a data format parameter.

Data Format for Model-Based Logged Data

The data format for model-based exporting of simulation data specifies how Simulink stores the exported data.

Simulink uses different data formats, depending on the kind of data that you export. For details, see:

- “Signal Logging Format” on page 61-16
- “Logged Data Store Format” on page 61-17
- “Time, State, and Output Data Format” on page 61-17

Signal Logging Format

For data that you log in `Dataset` format (as `Simulink.SimulationData.Dataset` objects), you can specify whether you want the data for individual signals in the dataset to use MATLAB `timeseries` or `timetable` elements. To control how `Dataset` elements are saved, set the **Dataset signal format** configuration parameter. The default is `timeseries`. For details, see “Dataset signal format”.

The **Dataset signal format** parameter applies to signal logging data, as well as output and states logging data when you set the **Format** configuration parameter to `Dataset`.

Logged Data Store Format

When you log data store data, Simulink uses a `Simulink.SimulationData.Dataset` object.

For details, see "Accessing Data Store Logging Data" on page 62-42.

Time, State, and Output Data Format

For exported time, states, and output data, use one of the following formats:

- "Dataset" on page 61-17 (default)
- "Array" on page 61-18
- "Structure with Time" on page 61-18
- "Structure" on page 61-21

If you select the **Configuration Parameters > Data Import/Export > Output** check box, Simulink logs fixed-point data as double. To log fixed-point data, consider using one of these approaches:

- Signal logging — For details, see "Export Signal Data Using Signal Logging" on page 61-71.

  1. In the Simulink Editor, select one or more signals.
  2. Click the **Simulation Data Inspector** button arrow and click **Log Selected Signals to Workspace**.
- To File block
- To Workspace block — In the To Workspace Block Parameters dialog box, enable the **Log fixed-point data as a fi object** parameter.

For information about the format for logged final state data, see "State Information" on page 61-258.

Dataset

`Dataset` format:

- Uses MATLAB `timeseries` objects to store logged data. MATLAB `timeseries` objects allow you to work with logged data in MATLAB without a Simulink license.

- Supports logging multiple data values for a given time step, which can be important for Iterator subsystem and Stateflow signal logging.
- Supports inclusion of units information in logged data for output data
- Does not support logging nonvirtual bus data for code generation or in rapid accelerator mode.

Array

If you select this `Array` option, Simulink saves the states and outputs of a model in a state and output array, respectively.

The state matrix has the name specified in the **Configuration Parameters > Data Import/Export** pane (for example, `xout`). Each row of the state matrix corresponds to a time sample of the states of a model. Each column corresponds to an element of a state. For example, suppose that your model has two continuous states, each of which is a two-element vector. Then the first two elements of each row of the state matrix contain a time sample of the first state vector. The last two elements of each row contain a time sample of the second state vector.

The model output matrix has the name specified in the **Configuration Parameters > Data Import/Export** pane (for example, `yout`). Each column corresponds to a model output port, and each row to the outputs at a specific time.

Note Use array format to save your model outputs and states only if the logged data meets *all* these conditions:

- Data is all scalars or all vectors (or all matrices for states)
- Data is all real or all complex
- Data all has the same data type

If your model outputs and states do not meet these conditions, use the `Structure` or `Structure with time` output formats (see "Structure with Time" on page 61-18).

Structure with Time

If you select this format, Simulink saves the model states and outputs in structures that have their names specified in the **Configuration Parameters > Data Import/Export** pane. By default, the structures are `xout` for states and `yout` for output.

The structure used to save outputs has two top-level fields:

- `time`

  Contains a vector of the simulation times.
- `signals`

  Contains an array of substructures, each of which corresponds to a model output port.

Each substructure has four fields:

- `values`

  Contains the outputs for the corresponding output port.

  - If outputs are scalars or vectors — `values` field is a matrix each of whose rows represent an output at the time specified by the corresponding time vector element.
  - If the outputs are matrix (2-D) values — `values` field is a 3-D array of dimensions M-by-N-by-T. M-by-N is the dimensions of the output signal and T is the number of output samples.
  - If T = 1 — MATLAB drops the last dimension. Therefore, the `values` field is an M-by-N matrix.
- `dimensions`

  Specifies the dimensions of the output signal.
- `label`

  Specifies the label of the signal connected to the output port, S-Function block, or the type of state (continuous or discrete). The label is `DSTATE` or `CSTATE`, except for S-Function block state labels. For S-Function block state labels for discrete states, the label is the name of the state (instead of `DSTATE`).
- `blockName`

  Specifies the name of the corresponding output port or block with states.
- `inReferencedModel`

  If the `signals` field records the final state of a block that resides in the reference model, contains a value of `1`. Otherwise, the value is false (`0`).

The following example shows the structure-with-time format for a nonreferenced model.

```
xout.signals(1)

ans =

               values: [296206x1 double]
           dimensions: 1
                label: 'CSTATE'
            blockName: 'vdp/x1'
    inReferencedModel: 0
```

The structure used to save states has a similar organization. The states structure has two top-level fields:

- `time`

  The `time` field contains a vector of the simulation times.

- `signals`

  The field contains an array of substructures, each of which corresponds to one of the states of the model.

Each `signals` structure has four fields: `values`, `dimensions`, `label`, and `blockName`. The `values` field contains time samples of a state of the block specified by the `blockName` field. The `label` field for built-in blocks indicates the type of state: either `CSTATE` (continuous state) or `DSTATE` (discrete state). For S-Function blocks, the label contains whatever name is assigned to the state by the S-Function block.

The time samples of a state are stored in the `values` field as a matrix of values. Each row corresponds to a time sample. Each element of a row corresponds to an element of the state. If the state is a matrix, the matrix is stored in the `values` array in column-major order. For example, suppose that the model includes a 2-by-2 matrix state and that 51 samples of the state are logged during a simulation run.

The `values` field for this state would contain a 51-by-4 matrix. Each row corresponds to a time sample of the state, and the first two elements of each row correspond to the first column of the sample. The last two elements correspond to the second column of the sample.

Note Simulink can read back simulation data saved to the MATLAB workspace in the `Structure with time` output format. See "Examples of Specifying Signal and Time Data" on page 61-164 for more information.

Structure

This format is the same as for `Structure with time` output format, except that Simulink does not store simulation times in the `time` field of the saved structure.

Dataset Conversion for Logged Data

In this section...

Why Convert to Dataset Format?

You can use the `Simulink.SimulationData.Dataset` constructor to convert a MATLAB workspace variable that contains data that was logged in one of these formats to `Dataset` format:

- Array
- Structure
- Structure with time
- MATLAB timeseries
- `ModelDataLogs`

Converting data from other Simulink logging formats to `Dataset` format simplifies writing scripts to post-process data logged. For example, a model with multiple To Workspace blocks can use different data formats. Converting the logged data to `Dataset` format avoids the need to write special code to handle different formats.

Different simulation modes have different levels of support for data logging formats. Switching between normal and accelerator modes can require changes to the logging formats used.

The conversion to `Dataset` format also makes it easier to take advantage of features that require `Dataset` format. You can easily convert data logged in earlier releases that used a format other than `Dataset` to work well with `Dataset` data in a more recent release.

The `Dataset` format:

- Uses MATLAB `timeseries` objects to store logged data, which allows you to work with logging data in MATLAB without a Simulink license. For example, to

manipulate the logged data, you can use MATLAB time-series methods such as `filter`, `detrend`, and `resample`.

- Supports logging multiple data values for a given time step, which is important for Iterator subsystem and Stateflow signal logging.

By default, the resulting `Dataset` object uses the variable name as its name. You can use a name-value pair to specify a `Dataset` name.

You can use the `Simulink.SimulationData.Dataset.concat` method to combine `Dataset` objects into one concatenated `Dataset` object.

Results of Conversion

`Dataset` objects hold data as elements. To display the elements of a `Dataset` variable, enter the variable name at the MATLAB command prompt. The elements of `Dataset` objects are different types, depending on the data they store. For example, signal logging stores data as `Simulink.SimulationData.Signal` elements and state logging in `Dataset` format stores data as `Simulink.SimulationData.State` elements. Each element holds data as a MATLAB time-series object. At conversion, the elements and time-series field populate as much as possible from the converted object.

Format	Conversion Result Notes
MATLAB time series	If you log nonbus data, during conversion, the software first adds the data as a `Simulink.SimulationData.Signal` object. It then adds that object as an element of the newly created `Dataset`. If you log bus data in time-series format, one time series corresponds to each element of a bus. Converting arranges the logged data as a structure with time-series objects as leaf nodes. This structure hierarchy matches the bus hierarchy. Conversion of this type of structure of time-series objects adds the whole structure to a `Simulink.SimulationData.Signal` object. It then adds that object as an element of the data set. Time-series objects hold relevant information such as block path and timestamps. The conversion tries to preserve this information.
Structure and structure with time	Structure and structure with time formats do not always contain as much information as if you log in `Dataset` format. However, before converting structure and structure with time formats, the data structure must have `time` and `signals` fields. Conversion populates a `Simulink.SimulationData.Signal` object with the structure and adds it as an element of the data set. If other information is available, converting also adds it to the element or time-series values. For example, if the structure has a field called `blockName`, converting adds it to the block path. Otherwise, the block path is empty. When scope data is logged in structure format, the logged structure has a `PlotStyle` field. The software uses this field to set the interpolation in the `Dataset` object.

Format	Conversion Result Notes
Array	Arrays contain little information. For example, there is no block path information. Conversion adds the array to a `Simulink.SimulationData.Signal` object and adds it as an element of the `Dataset` object. The conversion leaves unavailable information such as block path and timestamp fields as either empty or with default values.
`ModelDataLogs`	Converts data from `ModelDataLogs` format to `Dataset` format. **Note** The `ModelDataLogs` format is no longer used for signal logging.

Dataset Conversion Limitations

- Converting logged data to `Dataset` format results in a `Dataset` object that contains all the information that the original logged data included. However, if there is no corresponding information for the other `Dataset` properties, the conversion uses default values for that information.
- To log variable-size signals, use the To Workspace block. If you convert data logged with To Workspace to be `Dataset` format, you lose the information about the variable-size signals.
- When you log a bus signal in array, structure, or structure with time formats, the logged data is organized with:

  - The first column containing the data for the first signal in the bus
  - The second column containing data for the second bus signal, and so on

  When you convert that data to `Dataset`, the `Dataset` preserves that organization. But if you log the bus signal in `Dataset` format without conversion, the conversion captures the bus data as a structure of time-series objects.
- If the logged data does not include a time vector, when you convert that data to `Dataset`, the conversion inserts a time vector. There is one time step for each data value. However, the simulation time steps and the `Dataset` time steps can vary.

- `Dataset` format ignores the specification of frame signals. Conversion of structure or structure with time data to `Dataset` reshapes the data for logged frame signals.

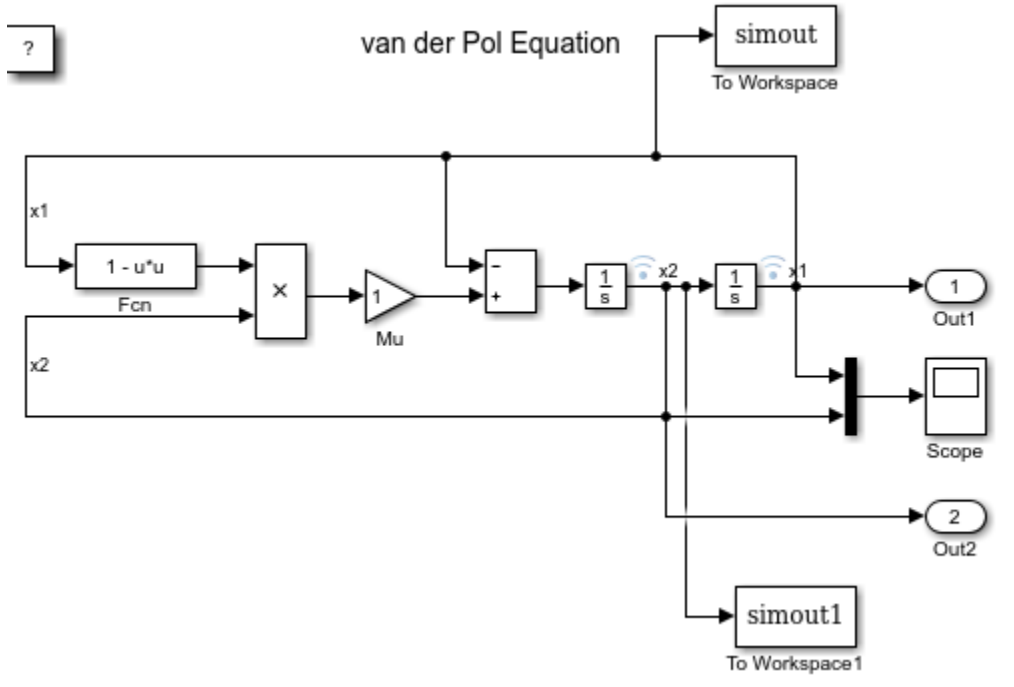
Convert Logged Data to Dataset Format

In this section...

Convert Workspace Data to Dataset

This example shows how to convert MATLAB time-series data to `Dataset` format. `myvdp_timeseries` is the `vdp` model with two To Workspace blocks configured for simout and simout1 logging data in MATLAB time-series format. Consider using a procedure like this one if you have models that use To Workspace blocks to log data to MATLAB time-series format.



Use the `Simulink.SimulationData.Dataset` constructor to convert the MATLAB time-series data to `Dataset` format and then concatenate the two data sets.

1. Starting with the `vdp` model, add two To Workspace blocks to the model as shown.
2. Set the **Save format** parameter of both blocks. Set `Timeseries`.
3. Save the model as `myvdp_timeseries`.
4. Simulate the model.

   The simulation logs data using the To Workspace blocks.
5. Access the signal logging format, `logsout`.

```
logsout
```

```
logsout =

  Simulink.SimulationData.Dataset
  Package: Simulink.SimulationData

  Characteristics:
              Name: 'logsout'
    Total Elements: 2

  Elements:
    1: 'x1'
    2: 'x2'

  -Use get or getElement to access elements by index or name.
  -Use addElement or setElement to add or modify elements.

  Methods, Superclasses
```

6. Convert the MATLAB time-series data from both To Workspace blocks to `Dataset`.

```
ds = Simulink.SimulationData.Dataset(simout);
ds1 = Simulink.SimulationData.Dataset(simout1);
```

   ds is the variable name of the first To Workspace block data. *ds1* is the variable name of the second To Workspace block data.
7. Concatenate both datasets into *dsfinal*. Observe that the format of *dsfinal* matches that of `logsout`.

```
dsfinal = ds.concat(ds1)
```

```
dsfinal =

  Simulink.SimulationData.Dataset
  Package: Simulink.SimulationData

  Characteristics:
              Name: 'simout'
    Total Elements: 2

  Elements:
    1: 'x1'
    2: 'x2'

  -Use get or getElement to access elements by index or name.
  -Use addElement or setElement to add or modify elements.

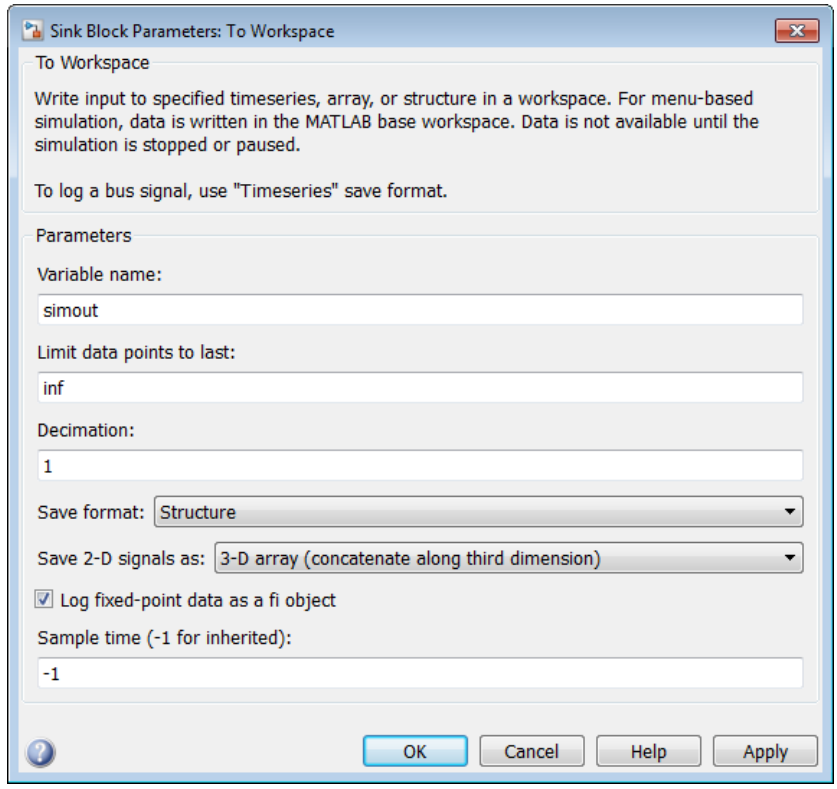
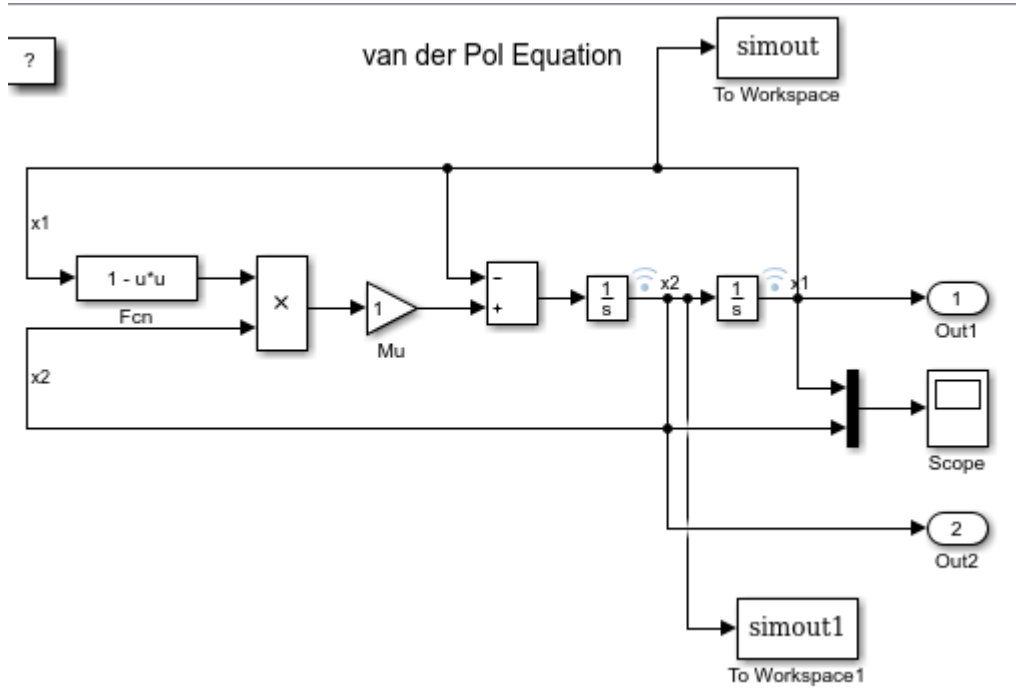
Convert Structure Without Time to Dataset

This example shows how to convert structure without time data to `Dataset` format. `myvdp_structure` is the `vdp` model with two To Workspace blocks configured for simout and simout1 logging data in structure format, as shown.



If you have models that use To Workspace blocks to log data to structure format, consider using a procedure like this one to convert them to `Dataset` format.

1 Starting with the `vdp` model, add two To Workspace blocks to the model as shown.



2 In the **Save format** parameter of both blocks, select `Structure`.

3 Enable signal logging for the two signals going to the two To Workspace blocks to log in `Ds` format.

4 Save the model as `myvdp_structure`.

5 Simulate the model.

The simulation logs data using the To Workspace blocks.

6 Convert the structure data from both To Workspace blocks to `Dataset`.

```
ds = Simulink.SimulationData.Dataset(simout);
ds1 = Simulink.SimulationData.Dataset(simout1);
```

simout is the variable name of the first To Workspace block data. *simout1* is the variable name of the second To Workspace block data.

With the conversion of structure without time or an array, time starts at t=0 and increments by 1.

7 Get the values of the first element in *ds*.

```
ds.get(1).Values.Time

ans =

     0
     1
     2
     3
     .
     .
     .
    61
    62
    63
```

8 Get the time values of the first element from signal logging.

```
logsout.get(1).Values.Time

ans =

         0
    0.0001
    0.0006
    0.0031
    .
    .
    .
   19.2802
   19.6802
   20.0000
```

9 Observe the discrepancy in timestamps between

- Data logged in structure without time that you convert to `Dataset` format
- Data logged in `Dataset` format

Programmatically Access Logged Dataset Format Data

When you use the default `Dataset` signal logging format, Simulink saves the logging data in a `Simulink.SimulationData.Dataset` object. For information about extracting signal data from that object, see the `Simulink.SimulationData.Dataset` reference page.

The `Simulink.SimulationData.Dataset` object contains a `Simulink.SimulationData.Signal` object for each logged signal.

For bus signals, the `Simulink.SimulationData.Signal` object contains a structure of MATLAB `timeseries` objects.

The `Simulink.SimulationData.Dataset` class provides two methods for accessing the signal logging data and its associated information.

Name	Description
`Simulink.SimulationData.DataSet.get` You can also use the `getElement` method, which shares syntax and behavior as the `get` method.	Get element or collection of elements from the dataset, based on index, name, or block path.
`Simulink.SimulationData.DataSet.numElements`	Get number of elements in the dataset.

For example of accessing signal logging data that uses the `Dataset` format, see `Simulink.SimulationData.Dataset`.

Access Array of Buses Signal Logging Data

Signal logging data for an array of buses uses `Dataset` signal logging format.

The general approach to access data for a specific signal in an array of buses is:

1. Use a `Simulink.SimulationData.Dataset.get` (or `getElement`) method to access a specific signal in the logged data (by default, the `logsout` variable).
2. To get the values, index within the array of buses.
3. Index again to get data for a specific bus.

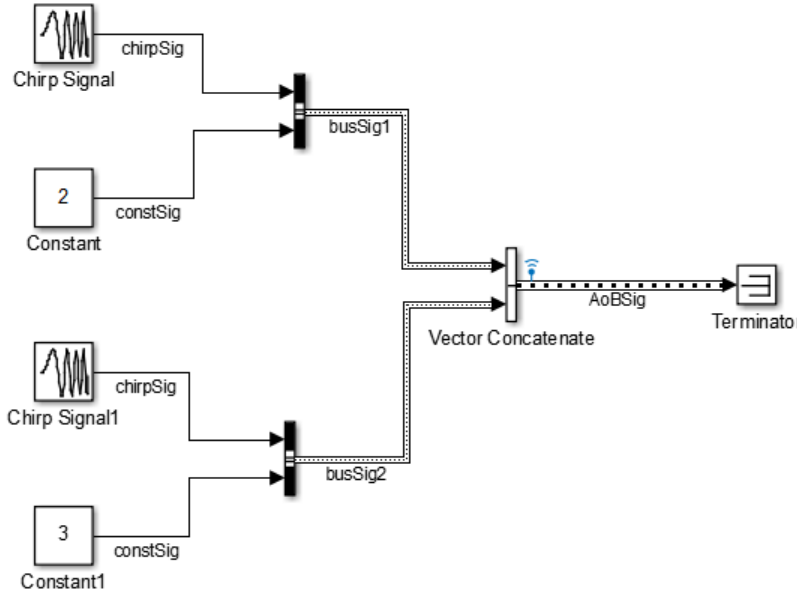
For example, to obtain the signal logging data for the Constant6 block in the `ex_log_nested_aob` model, for the `topBus` signal that feeds the Terminator block:

```
logsout.getElement('topBus').Values.a(2,2).firstConst.data
```

Here are additional examples of accessing array of buses signal logging data. For another example that shows how to log array of buses data, see `sldemo_mdlref_bus`.

Simple Array of Buses

The `ex_log_simple_aob` model includes an array of buses signal `AoBSig` that combines two bus signals (`busSig1` and `busSig2`).



To access the signal logging data for the array of buses signal, navigate through the structure hierarchy and use an index to access a specific node. This example shows navigation to the `chirpSig` signal value in `busSig2`.

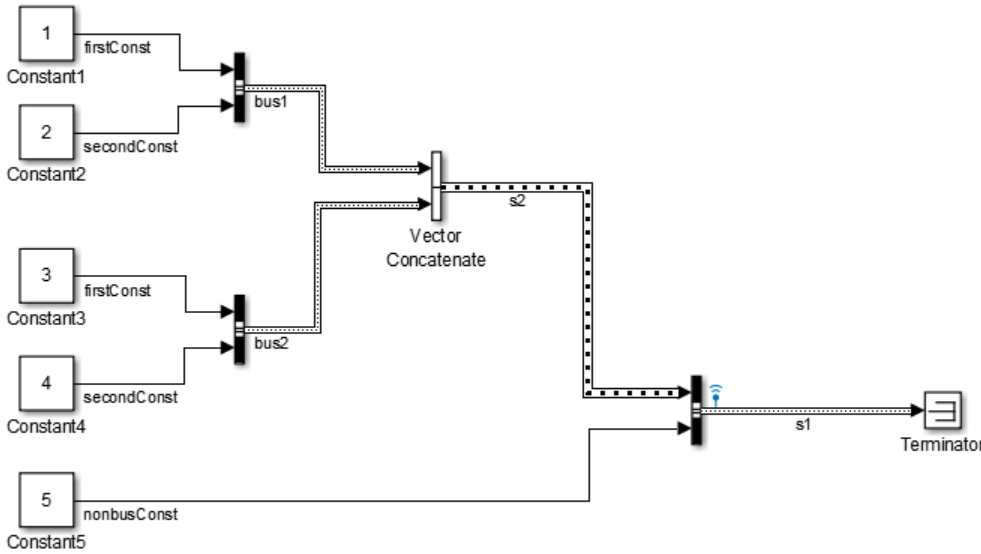
```
logsout.getElement('AoBSig').Values(2).chirpSig.Data

ans=

    0
  0.9585
```

Array of Buses in a Bus

The `ex_log_aob_in_bus` model has an array of buses (`s2`) that feeds into bus `s1`.



This example shows navigation to the `Constant3` block, which is a signal in `bus2`.

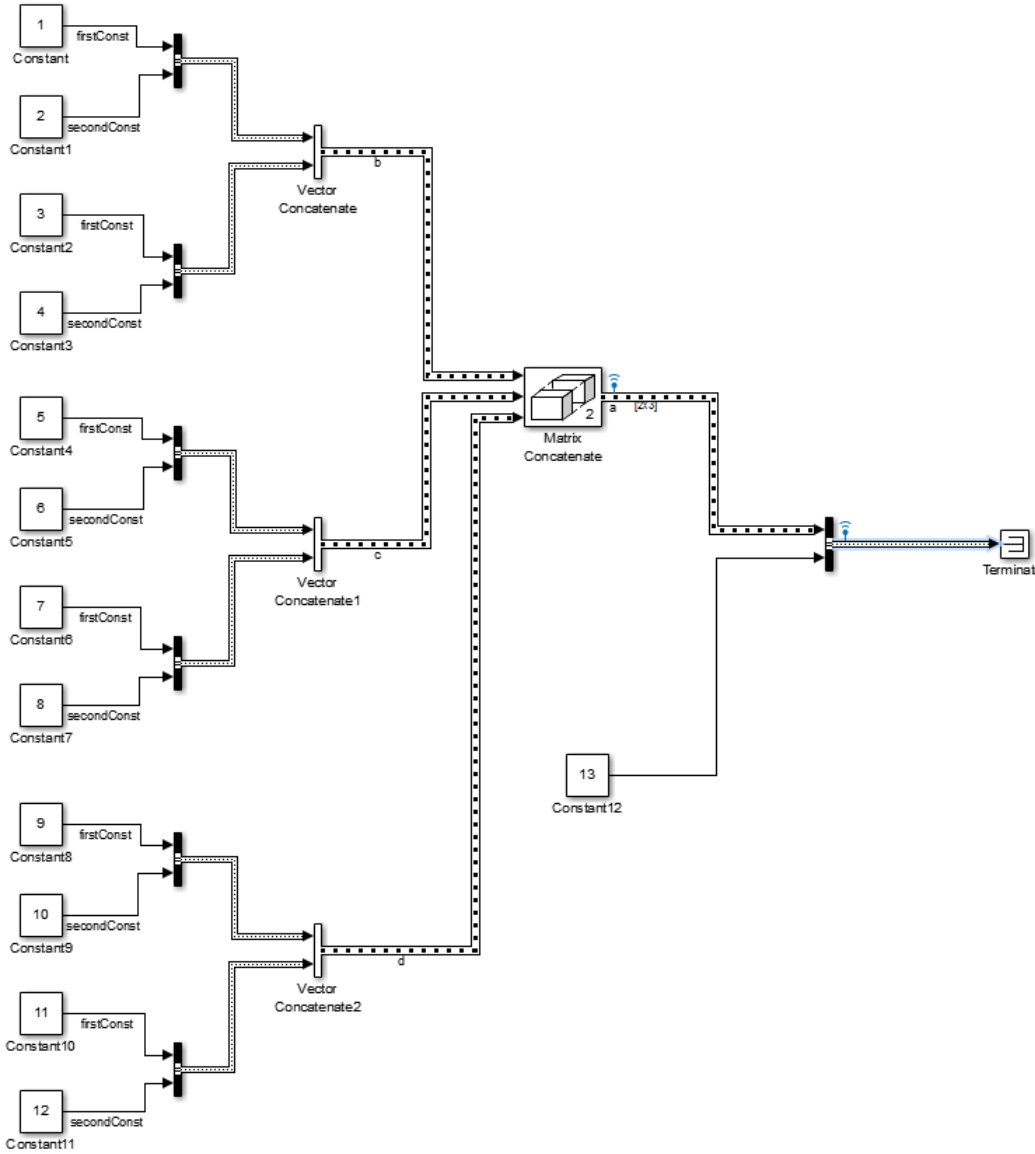
```
logsout.getElement('s1').Values.s2(2).firstConst.Data
```

```
ans=

   3
   3
   3
   3
   3
   3
```

Nested Arrays of Buses

The `ex_log_nested_aob` model has an array of buses (`a`) that is made up of three arrays of buses: `b`, `c`, and `d`. The Matrix Concatenate block combines the nested arrays of buses into array of buses `a`.



This example shows navigation to the `Constant6` block.

```
logsout.getElement('topBus').Values.a(2,2).firstConst.Data

ans=

  7
  7
  7
  7
  7
  7
  7
  7
  7
  7
  7
```

Accessing Data for Signals with a Duplicate Name

For a model with multiple signals that have the same signal name, signal logging data includes a `Simulink.SimulationData.Signal` object for each signal that has a duplicate name.

To access a specific signal that has a duplicate name, use *one* of these approaches:

- To find the data for the specific signal, visually inspect the displayed output of `Simulink.SimulationData.Signal` objects.
- Use the `Simulink.SimulationData.Dataset.getElement` method, specifying the blockpath for the source block of the signal.
- To iterate through the signals with a duplicate signal name, create a script using the `Simulink.SimulationData.Dataset.getElement` method with an index argument.
- Use the Signal Properties dialog box to specify a different name. Consider using this approach when the signals with a duplicate name do not appear in multiple instances of a referenced model in normal mode.

  1. In the model, right-click the signal.
  2. In the context menu, select **Properties**.
  3. In the Signal Properties dialog box, set **Logging name** to `Custom` and specify a different name than the signal name.

4 Simulate the model and use the `Simulink.SimulationData.Dataset.getElement` method with a name argument.

Tip Alternatively, you can use the Signal Logging Selector to access a specific signal. For details, see "Override Signal Logging Settings with Signal Logging Selector" on page 61-97.

Handling Newline Characters in Signal Logging Data

To handle newline characters in logging names in signal logging data that uses `Dataset` format, use a `sprintf` command within a `getElement` call. For example:

```
topOut.getElement(sprintf('INCREMENT\nBUS'))
```

Log Signal Data That Uses Units

To have logged data include the units specified for signals, use the `Dataset` or `Timeseries` logging format, which stores logging information in MATLAB `timeseries` objects.

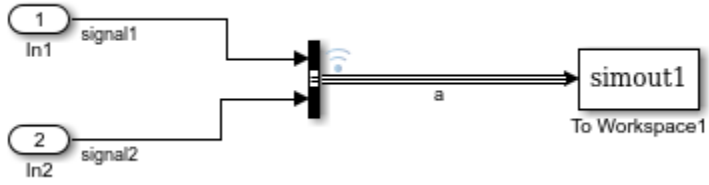
Signal logging uses `Dataset` format. Output logging (**Configuration Parameters** > **Data Import/Export** > **Output**) uses `Dataset` as the default format. The default save format for the To File and To Workspace blocks is `Timeseries`.

If you use `Dataset` or `Timeseries` format for signal logging or for To File block or To Workspace block logging, the logged data includes units information.

To capture units information for output logging:

1. Set the **Format** configuration parameter to `Dataset`.
2. In the Block Parameters dialog box for Outport blocks for which you want to capture units information, set the **Unit** parameter to match the units of the input signal.

For example, in this model the `In1` block has its **Unit** parameter set to `newton` and `In2` block uses `m` (meters). Open the model. After you simulate the model, you can see the units for the logged data.



- You can view the units in the signal logging data for `signal1` of the bus signal `b`.

```
logsout.get('a').Values.signal1.DataInfo

tsdata.datametadata
  Package: tsdata

  Common Properties:
              Units: newton (Simulink.SimulationData.Unit)
      Interpolation: linear (tsdata.interpolation)
```

- You can view the units in the data logged in the To Workspace block.

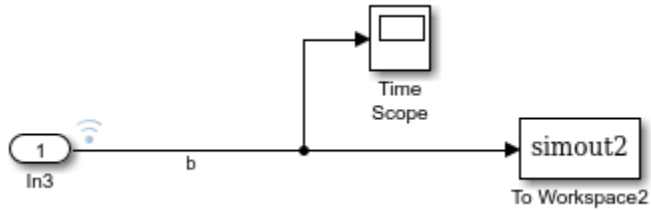
```
simout1.signal2.DataInfo.Units

ans =

  Units with properties:

    Name: 'm'
```

This example model shows how to view the data logged in a Time Scope block. Open the model.



To use the Time Scope block to log data, in the scope select **Configuration Properties > Logging > Log data to workspace** and specify a variable (`ScopeData` in this example). The `In3` block uses `m` (meters). Simulate the model and then at the MATLAB command line, enter:

```
ScopeData.get(1).Values.DataInfo.Units

ans =

  Units with properties:

    Name: 'm'
```

Limit Amount of Exported Data

In this section...

You can use several options to reduce the amount of data logged during a simulation. Limiting the amount of exported simulation data reduces memory usage and speeds up simulation. However, if you limit the amount of simulation data, the logged data can skip some time steps that are critical for testing and analyzing the model.

You can use multiple techniques for the same simulation.

Technique	Description
Specify a decimation factor	Skip samples when exporting data.
Limit data points	Limit the number of samples saved to be only the most recent samples
Specify an interval for logging	Specify ranges of time steps for logging

Alternatively, for logging large amounts of data that can cause memory issues, consider logging to persistent storage. This approach preserves all the logging data, minimizing MATLAB workspace memory usage. For details, see “Log Data to Persistent Storage” on page 61-48.

Decimation

To skip samples when exporting data, apply a decimation factor. For example, a decimation factor of 2 saves every other sample. By default, decimation is set to 1, which does not skip any samples.

The approach you use to specify a decimation factor depends on the kind of logging data.

Data	How to Specify
Signal logging	Right-click the signal. In the Signal Properties dialog box, select the **Decimation** parameter.

Data	How to Specify
Data store logging	From the Block Parameters dialog box for that block, open the **Logging** tab. Apply a decimation factor using the **Decimation** parameter.
State and output	Enter a value in the field to the right of the **Decimation** label.

Limit Data Points

To limit the number of samples saved to be only the most recent samples, set the **Limit Data Points** parameter.

The approach you use depends on the kind of logging data.

Data	How to Specify
Signal logging	Right-click the signal. In the Signal Properties dialog box, select the **Limit Data Points to Last** parameter.
Data store logging	From the Block Parameters dialog box for that block, open the **Logging** tab. Select the **Limit Data Points to Last** parameter.
Time, state, and output logging	Select the **Limit data points** configuration parameter and for the **Maximum number of data points** configuration parameter, specify the limit.

Logging Intervals

To specify an interval for logging, use the **Configuration Parameters** > **Data Import/Export** > **Logging intervals** parameter. Limiting logging to a specified interval allows you to examine specific logged data without changing the model or adding complexity to a model.

The logging intervals apply to data logged for:

- Time

- States
- Output
- Signal logging
- The To Workspace block
- The To File block

The logging intervals do not apply to final state logged data, scopes, or streaming data to the Simulation Data Inspector.

The intervals specified with **Logging intervals** establish the set of times to which the **Decimation** and **Limit data points to last** parameters apply. For example, suppose that you set the logging interval `[2,4;7,9]` with a fixed-step solver with a fixed-step size of 1. The logged times are 2, 3, 4, 7, 8, and 9.

Work with Big Data for Simulations

Simulation of models with many time steps and signals can involve big data that is too large to fit into the RAM of your computer. Such situations include:

- Logging simulation data (signal logging, outport logging, and state logging)
- Loading input signal data for simulating a model
- Running multiple or parallel simulations

To work with big data for simulations, store the data to persistent storage in a MAT-file. Using big data techniques for simulations requires additional steps beyond what you do when the data is small enough to fit in workspace memory. As you develop a model, consider logging and loading simulation data without using persistent storage unless you discover that your model has big data requirements that overload memory.

Big Data Workflow

This example is a high-level workflow for handling big data that one simulation produces and that another simulation uses as input. For more detailed information about the major workflow tasks, see:

- “Log Data to Persistent Storage” on page 61-48
- “Load Big Data for Simulations” on page 61-54
- “Analyze Big Data from a Simulation” on page 61-63

Tip This example uses a `SimulationDatastore` object for streaming data into a model. Alternatively, you can stream a `DatasetRef` object directly into a model.

1. Configure two models to log several signals.
2. Simulate the models, logging the data to persistent storage for each model.

   ```
   sim(mdl1,'LoggingToFile','on','LoggingFileName','data1.mat');
   sim(mdl2,'LoggingToFile','on','LoggingFileName','data2.mat');
   ```

   Logging that involves big data requires saving the data to persistent storage as a v7.3 MAT-file. Only the data logged in `Dataset` format is saved to the file. Data logged in other formats, such as `Structure with time`, is saved in memory, in the base workspace.

The data that you log to persistent storage is streamed during the simulation in small chunks, to minimize memory requirements. The data is stored in a file that contains `Dataset` objects for each set of logged data (for example, `logsout` and `xout`).

3. Create `DatasetRef` objects (`dsr1` and `dsr2`) for specific sets of logged signals. Then create `SimulationDatastore` objects (`dst1` and `dst2`) for values of elements of the `DatasetRef` objects. This example code creates a `SimulationDatastore` for the 12th element of `logsout` for the first simulation. For the second simulation, the example code creates a signal with values being a `SimulationDatastore` object for the seventh element of `logsout`. You can use curly braces for indexing.

```
dsr1 = Simulink.SimulationData.DatasetRef('data1.mat','logsout');
dsr2 = Simulink.SimulationData.DatasetRef('data2.mat','logsout');
dst1 = dsr1{12};
dst2 = dsr2{7};
```

4. Use `SimulationDatastore` objects as an external input for another simulation. To load the `SimulationDatastore` data, include it in a `Dataset` object. The datastore input is incrementally loaded from the MAT-file. The third input is a `timeseries` object, which is loaded into memory as a whole, not incrementally.

```
input = Simulink.SimulationData.Dataset;
input{1} = dst1;
input{2} = dst2;
ts = timeseries(rand(5,1),1,'Name','RandomSignals');
input{3} = ts;
sim(mdl3,'ExternalInput','input');
```

5. Use MATLAB big data analysis to work with the `SimulationDatastore` objects. Create a `timetable` object by reading the values of a `SimulationDatastore` object. The `read` function reads a portion of the data. The `readall` function reads all the data.

```
tt = dst1.Values.read;
```

6. Set the MATLAB session as the global execution environment (`mapreducer`) for working with the tall `timetable`. Create a tall `timetable` from a `SimulationDatastore` object and read a `timetable` object with in-memory data.

```
mapreducer(0);
ttt = tall(dst1.Values);
```

Log Data to Persistent Storage

In this section...

When to Log to Persistent Storage

Logging many signals in a long simulation that has many time steps can produce big data that can overload computer memory. Using persistent storage can help to address big data memory issues. Also, persistent storage is useful for logging when you run simulations in parallel or for running multiple simulations.

You can store logged simulation data to persistent storage in a MAT-file. Using persistent storage minimizes the amount of logged data stored in memory during simulation. You control logging to persistent storage at the model level. You can enable and disable the feature by changing one model configuration parameter (**Log Dataset data to file**) without changing the model layout.

If you use `Dataset` format for logging, you can log each of these kinds of data to persistent storage:

- Signal logging — Uses `Dataset` format only.
- States — Defaults to `Dataset` format. You can use other formats.
- Final states — Requires that you clear the **Save complete SimState in final state** parameter
- Output — Defaults to `Dataset` format.
- Data stores — Uses `Dataset` format only.

By default, logging to persistent storage is disabled, so that logged data is stored in the MATLAB workspace. For most models, logging to the workspace is simpler because it avoids loading and saving logging files. Compared to accessing data logged to memory, accessing data logged to persistent storage requires some additional steps. For short

simulations, logging to the MATLAB workspace can be faster and possibly use less memory than logging to persistent storage.

Limitations for Logging to Persistent Storage

- Only data logged in `Dataset` format is stored in the MAT-file. Data logged in other formats is stored in the MATLAB workspace.
- To use persistent storage for logging final states data, you cannot enable the **Configuration Parameters > Data Import/Export > Save complete SimState in final state**.
- The Simulation Stepper and fast restart do not support logging to persistent storage.
- During simulation, you cannot load data from the persistent storage file directly into the model. Create objects that reference the data in the file and then load the referencing object.

Alternative Approaches for Reducing Logging Memory Usage

If simulating a model that uses logging cause not cause memory issues, consider using alternatives instead of logging to persistent storage.

- Limit the amount of simulation data stored in the workspace.

  You can limit the amount of simulation data stored in the workspace by using one or more of these techniques. For details, see “Limit Amount of Exported Data” on page 61-42.

Technique	Description
Specify a decimation factor.	Skip samples when exporting data.
Limit data points.	Limit the number of samples saved to be only the most recent samples.
Specify intervals for logging.	Specify ranges of time steps for logging.

  However, if you limit the amount of simulation data, the logged data can skip some time steps that are critical for testing and analyzing the model.

- Use a To File block for each signal that you want to log.

  Connecting a To File block to signals that you want to log stores the logged data in a MAT-file, rather than in the MATLAB workspace. However, this approach:

  - Is a per-signal approach that can clutter a model with multiple To File blocks attached to individual signals.

- Creates a separate MAT-file for each To File block, compared to the one MAT-file used by logging to persistent storage.

Log to Persistent Storage

1. Specify the kinds of logging to perform (for example, signal logging and output logging) and the variable names for the logging data.
2. In the model diagram, mark selected signals for signal logging.
3. Use `Dataset` format for logging the data. Data that is logged in any other format is stored in the workspace.
   - Signal logging and data store logging use `Dataset` format only. The default format for output, states, and final states logging is `Dataset`.
   - For final states logging, clear the **Save complete SimState in final state** configuration parameter.
4. Enable logging to persistent storage and specify an output MAT-file name.
   - Select the **Log Dataset data to file** configuration parameter.
   - Specify the MAT-file to use. Do not use a file name from one locale in a different locale.
5. To save the logged `Dataset` data using `timeseries` or `timetable` elements, set the **Dataset signal format** configuration parameter. The default format is `timeseries`. The `timetable` format is helpful for MATLAB combining logged data from multiple simulations. For details about the `timetable` format, see “Dataset signal format”.
6. Simulate the model.

Enable Logging to Persistent Storage Programmatically

You can programmatically log to persistent storage. To enable logging to persistent storage, use the `LoggingToFile` and `LoggingFileName` name-value pairs with either the `sim` command or `set_param` command.

To enable the logging approaches that you want to use, set these parameters to `'on'`, as applicable:

- `SignalLogging`

- `SaveState`
- `SaveFinalState`
- `SaveOutput`
- `DSMLogging`

To log output, states, and final states data to persistent storage, set the `SaveFormat` parameter to `'Dataset'`.

To log final states data to persistent storage, set the `SaveCompleteFinalSimState` to `'off'`.

How Simulation Data Is Stored

Logging to persistent storage saves logged simulation data in the specified MAT-file. The data is stored as a `Simulink.SimulationData.Dataset` objects for each type of logging that uses `Dataset` format. The `Dataset` elements are stored as either `timeseries` or `timetable` objects, depending on how you set the **Dataset signal format** parameter. For details about the `timetable` format, see "Dataset signal format".

The `Dataset` object name in the file is the name of the variable that you used for logging. For example, if you use the default signal logging variable `logsout`, the `Dataset` object in the MAT-file is `logsout`.

Save Logged Data from Successive Simulations

The approach you use for saving data logged from successive simulations depends on whether you are performing parallel simulations.

Without Using Parallel Simulations

Each time you simulate a model without using parallel simulation, Simulink overwrites the contents of the MAT-file unless you change the name of the file between simulations. When you use a `Simulink.SimulationData.DatasetRef` object that references data in the MAT-file to retrieve data in the file, it retrieves the most recent version of the data. To preserve data from an earlier simulation, use one of these approaches:

- Between simulations, use the **Configuration Parameters > Data Import/Export** pane to specify a different name for MAT-file for logging.

- Between simulations, save a copy of the MAT-file. Use a different file name than the name that you specify as the MAT-file for persistent storage, or move the MAT-file.
- Programmatically specify a new file name for each simulation run.

If you change the file name used for logging to persistent storage, then to access the logged data, use one of these approaches:

- Create a `Simulink.SimulationData.DatasetRef` object.
- To match the new file name, change the `Location` property of the `DatasetRef` objects.

For details about using `DatasetRef` objects to access logged data, see "Load Big Data for Simulations" on page 61-54.

With Parallel Simulations

For parallel simulations, for which you specify an array of input objects, if you log to file, Simulink:

- Creates a MAT-file for each simulation
- Creates `Simulink.SimulationData.DatasetRef` objects to access output data in the MAT-file and includes those objects in the `SimulationOutput` object data
- Enables the `CaptureErrors` argument for simulation

For more information about parallel simulations, see "Run Multiple Simulations" on page 26-2.

Load Big Data for Simulations

In this section...

Simulation of models with many time steps and signals can involve big data that is too large to fit into the RAM of your computer. Such situations include:

- Logging simulation data (signal logging, outport logging, and state logging)
- Loading input signal data for simulating a model
- Running parallel simulations

To work with simulation big data, store the data to persistent storage in a MAT-file (see “Log Data to Persistent Storage” on page 61-48). Using big data techniques for simulations requires additional steps not needed for signal data that workspace memory and blocks such as From File and From Spreadsheet can handle. As you develop a model, consider logging and loading simulation data without using persistent storage unless you discover that your model has big data requirements that overload memory.

You can use the data logged to persistent storage from one simulation as input for another simulation. You can use a `matlab.io.datastore.SimulationDatastore` object in a `Simulink.SimulationData.Dataset` object to stream data into a root Inport block. Create the `SimulationDatastore` object for a leaf signal in a `Simulink.SimulationData.DatasetRef` object, by using an index into the `DatasetRef` object.

`SimulationDatastore` input data streams in small chunks (by default, 100 samples at a time). The data is loaded as needed by the simulation. The entire data for a signal is never fully loaded into memory.

Prepare Dataset Data for Loading

The first step is to create a `Simulink.SimulationData.Dataset` object with signal data to load into root-level input ports. You can use the data logged to persistent storage in one simulation as input for another simulation. Alternatively, you can create a `Dataset` object in MATLAB (see “Create a Dataset Object for Root-Level Inports” on page 61-55.

Then create `Simulink.SimulationData.DatasetRef` objects for loading data for individual signals.

To load the data:

- You can use the `load` command to load a `Dataset` object from a persistent storage MAT-file into a model. The entire dataset is loaded into memory, so it is not a good approach to use for big data.
- To avoid overflowing memory when loading big data, you can use one of these approaches to stream `Dataset` data into a model for simulation:
- • "Create DatasetRef Objects for Streaming" on page 61-58

  Streaming a `DatasetRef` object directly into a model is the simpler approach.

  • "Create SimulationDatastores for Streaming" on page 61-60

  Streaming a `matlab.io.datastore.SimulationDatastore` object that is contained in a `Dataset` object gives you more control over the streaming. Also, you can use a `SimulationDatastore` object to create a MATLAB tall timetable object and directly use MATLAB tools for working with big data.

Create a Dataset Object for Root-Level Inports

To load big data into the root-level Inport blocks in a model, create a `Dataset` object that has the same number of elements as there are Inport blocks. The order of the elements must correspond to the order of the Inport blocks in the model. You can use an empty array (`[]`) to use ground values for an Inport block. You can either use data logged to persistent storage from another simulation (stored in a MAT-file) or create a Dataset object manually.

For creating a `Dataset` object manually, you can use the `createInputDataset` function to create a `Dataset` object that contains elements that correspond to the Inport blocks in a model. Signals in the generated dataset have the properties of the root inports and the corresponding ground values at model start and stop times.

Simulink uses ground values for any Inport blocks for which you do not specify data in the corresponding `Dataset` element.

For individual non-bus signal data, you can specify these types of data for `Dataset` elements:

- `timeseries`
- `timetable`
- `matlab.io.datastore.SimulationDatastore`
- `double` vectors or structure of `double` data
- `timeseries`
- a `Simulink.SimulationData.Signal`, `Simulink.SimulationData.State`, or `Simulink.SimulationData.DataStoreMemory` object

For bus signals, use a structure with a data element for each leaf signal, using one of these formats:

- A MATLAB `timeseries` object
- A MATLAB `timetable` object
- A `matlab.io.datastore.SimulationDatastore` object
- An empty matrix
- An array that meets one of these requirements:
  - An array with time in the first column and the remaining columns each corresponding to an input port. See “Create Data Arrays for Root-Level Inputs” on page 61-165.
  - An `nx1` array for a root inport that drives a function-call subsystem.
- Another structure, with data elements for each signal that are consistent with these requirements for a structure for bus data

This example shows how to create a `Dataset` object to contain a mixture of `timeseries` and `SimulationDatastore` data types. For this example, suppose that you have two datasets:

- `ds3` — Stored in `dataFileName.mat`
- `in_mem_ds` — Saved in memory as `dataFileName2`

1. Create a `DatasetRef` for `ds3` and load `in_mem_ds` into memory.

```
dsr = Simulink.SimulationData.DatasetRef(dataFileName,'ds3');
in_mem_ds = load(dataFileName2);
```

2. Aggregate the elements for the next simulation. Use one in-memory signal, one signal whose values are a `SimulationDatastore` that references data in the MAT-

file, and one raw `SimulationDatastore` without the `Simulink.SimulationData.Signal` object wrapper.

```
el1 = in_mem_ds.get(1);
el2 = dsr{2};
el2 = dsr{3}.Values;
whos el1 el2 el3
```

```
Name    Size     Bytes   Class

el1     1x1      664     Simulink.SimulationData.Signal
el2     1x1      222     Simulink.SimulationData.Signal
el3     1x1        8     matlab.io.datastore.SimulationDatastore
```

3 Create a `Dataset` object and populate it with elements for the signals of interest.

```
input_ds = Simulink.SimulationData.Dataset;
input_ds = input_ds.add(el1,'in memory values');
input_ds = input_ds.add(el2,'datastore values');
input_ds = input_ds.add(el3,'raw datastore')
```

```
input_ds =

  Simulink.SimulationData.Dataset
  Package: Simulink.SimulationData

  Characteristics:
              Name: ''
    Total Elements: 3

  Elements:
    1 : 'in memory values'
    2 : 'datastore values'
    3 : 'raw datastore'
```

4 Simulate the model with the `input_ds` dataset as the external input.

```
out = sim('mdl''LoadExternalInput','on','ExternalInput','input_ds');
```

The simulation streams in values specified by the datastores.

Get List of Dataset Variables

To create a reference to persistent storage `Dataset` objects in the MAT-file that stores the logged data, you use the name of a `Dataset` variable in the file. You can use the

`Simulink.SimulationData.DatasetRef.getDatasetVariableNames` function to get a list of the `Dataset` variables in a MAT-file.

Tip Using the `Simulink.SimulationData.DatasetRef.getDatasetVariableNames` function to get the names of `Dataset` variables in the MAT-file processes faster than using the `who` or `whos` functions.

Create DatasetRef Objects for Streaming

For big data, use `Simulink.SimulationData.DatasetRef` objects to access a specific type of logged data in a dataset. You can access elements of the `DatasetRef` object to access data for a specific signal.

When you access signal logging, output, or states logging data from a MAT-file created by logging to persistent storage, Simulink reads the data to the MATLAB workspace incrementally (signal by signal).

When you use a `DatasetRef` object that references data in a MAT-file to retrieve data in the file, it retrieves the most recent version of the data.

This example shows how to construct and use `DatasetRef` objects to access data for a model that logs to persistent storage. This simple example shows the basic steps for logging to persistent storage. This example does not represent a real-world situation for logging to persistent storage because it shows a short simulation with small memory requirements. However, you can use the same workflow for big data.

1. Open the `vdp` model.
2. In the **Configuration Parameters** > **Data Import/Export** pane, select these parameters:

   - **States**
   - **Log Dataset data to file**.

   Set the **Format** parameter to `Dataset`.

   Leave the other parameter settings as they are and click **Apply**.
3. In the model, click a signal and in action bar, select **Enable Data Logging**.

4 Simulate the model.

5 Get a list of `Dataset` variable names in the `out.mat` file. In this example, the variables are for data from states logging (`xout`) and signal logging (`logsout`).

```
varNames = Simulink.SimulationData.DatasetRef.getDatasetVariableNames('out.mat')
```

```
varNames =

    'xout'    'logsout'
```

6 Create a reference to the logged states data (`xout`) that is stored in `out.mat`.

```
statesLogRef = Simulink.SimulationData.DatasetRef('out.mat','xout')
```

```
statesLogRef =

  Simulink.SimulationData.DatasetRef
  Characteristics:
          Location: out.mat (/myDir/out.mat)
        Identifier: xout

  Resolved Dataset: 'xout' with 2 elements

       Name  BlockPath
       ____  _________
    1  ''    vdp/x1
    2  ''    vdp/x2
```

7 Create a reference to the signal logging data that is stored in `out.mat`. The variable for the signal logging data is `logsout`.

```
sigLogRef = Simulink.SimulationData.DatasetRef('out.mat','logsout')
```

```
sigLogRef =

  Simulink.SimulationData.DatasetRef
  Characteristics:
          Location: out.mat (/myFile/out.mat)
        Identifier: logsout

  Resolved Dataset: 'logsout' with 1 element

       Name  BlockPath
       ____  _________
    1  x1    vdp/x1
```

8 Use the `DatasetRef` to access the first element of the signal logging `Dataset`.

```
sigLogRef{1}
```

```
ans =

  Simulink.SimulationData.Signal
  Package: Simulink.SimulationData
```

```
    Properties:
                Name: 'x1'
      PropagatedName: ''
           BlockPath: [1x1 Simulink.SimulationData.BlockPath]
            PortType: 'outport'
           PortIndex: 1
              Values: [1×1 matlab.io.datastore.SimulationDatastore]
```

Create SimulationDatastores for Streaming

You can create `matlab.io.datastore.SimulationDatastore` for a signal logged to persistent storage. You can use a `SimulationDatastore` object as an element of a `Dataset` object that you load into a model. However, you cannot load a `Datastore` object directly into a model. Also, you can use a `SimulationDatastore` object to create a MATLAB tall timetable object. When you use a `SimulationDatastore` object to access data from a MAT-file created by logging to persistent storage, Simulink reads the data for a signal to the MATLAB workspace incrementally (sample by sample).

Suppose that you use the `out.mat` file created in the example in "Create a Dataset Object for Root-Level Inports" on page 61-55. You can create a `SimulationDatastore` object for the first signal in a `logsout` dataset. You can use the `readsize` function with a `SimulationDatastore` object to reset the size of chunks for streaming.

```
sigLogRef = Simulink.SimulationData.DatasetRef('out.mat','logsout');
loggedSig1 = sigLogRef{1};
loggedSig1.Values

ans =

        SimulationDatastore with properties:

         ReadSize: 100
          FileName: 'out.mat'
```

Alternatively, you can use the `Simulink.SimulationData.DatasetRef.getAsDatastore` function to create a `SimulationDatastore` from a `DatasetRef` object. For example:

```
sigLogRef = Simulink.SimulationData.DatasetRef('out.mat','logsout');
loggedSig1 = sigLogRef.getAsDatastore(1);
```

If you use index syntax or the `Simulink.SimulationData.DatasetRef.getAsDatastore` method to access a `DatasetRef` object element, the returned value is a `timeseries` object. For example:

```
sigLogRef = Simulink.SimulationData.DatasetRef('out.mat','logsout');
loggedSig1 = sigLogRef.getAsDatastore(1);
loggedSig1.Values
```

Note A `SimulationDatastore` streams data from memory, not from the MAT-file, when the `Dataset` object that the `SimulationDatastore` object was built from meets either of these conditions:

- The `Dataset` object was saved to a MAT-file before R2017a.
- The MAT-file used is not a v7.3 MAT-file.

Stream Data into a Model

To minimize the amount of memory used, you can stream data from a `Simulink.SimulationData.DatasetRef` object or from a `matlab.io.datastore.SimulationDatastore` object that is contained in a `Dataset` object as simulation input for root-level Inport blocks. To do so, in the **Input** configuration parameter, specify the `DatasetRef` or `Dataset` object that contains the `SimulationDatastore` object (or objects).

Load Logged Data Store Memory Data

When you load data store logging data that was logged to persistent storage, the behavior depends on the simulation mode used during loading.

- When you load the data store logging data in normal mode, Simulink streams the data store data into the model.
- In other simulation modes, all the logged data store data is loaded into memory as a whole.

Analyze Big Data from a Simulation

In this section...

To access data logged to persistent storage (a MAT-file) for analysis in MATLAB, use references to the data in the MAT-file. You can work directly with data logged in a format other than `Dataset` format, because that data is stored in the MATLAB workspace.

Create DatasetRef Objects to Access Logged Datasets

When you log to a MAT-file, Simulink stores in the specified MAT-file a `Simulink.SimulationData.Simulink.Dataset` object whose elements are `Dataset` objects. There is one `Dataset` object for each set of logged simulation data (for example, `Dataset` objects for `logsout` and `xout`, for signal logging and state logging).

To access simulation `Dataset` format data for a set of logged simulation data, create `Simulink.SimulationData.DatasetRef` objects. You can access individual elements of the dataset using `DatasetRef` objects. For details, see:

- “Get List of Dataset Variables” on page 61-57
- “Prepare Dataset Data for Loading” on page 61-54

Use SimulationDatastore Objects to Access Signal Data

To access leaf signals in a logged `Dataset`, create a `matlab.io.datastore.SimulationDatastore` object for the signal, based on the `DatasetRef` object for the `Dataset` that contains the signal. For details, see

“Create SimulationDatastores for Streaming” on page 61-60.

You can operate on data referenced by a `SimulationDatastore` object. For example, you can get the data in a chunk to be read into memory from the MAT-file. For an example, see `matlab.io.datastore.SimulationDatastore`.

Create Timetables for MATLAB Analysis

When you read a `SimulationDatastore` object, using the `read` or `readall` method the output is in MATLAB `timetable` format. For details about the timetable format, see "Dataset signal format".

You can use a `SimulationDatastore` object to create a `timetable` for the signal values and read a `timetable` object with in-memory data. For example, for `SimulationDatastore` object `dst1`:

```
tt = dst1.Values.read;
ttt = tall(dst1.Values);
```

Create Tall Timetables

You can create a tall `timetable`:

```
mapreducer(0);
ttt = tall(dst1.Values);
```

Note You cannot load a tall `timetable` as simulation input, and you cannot use a tall `timetable` as a `Dataset`element.

Access Persistent Storage Metadata

If you use persistent storage for several simulations, you can have multiple MAT-files. When you run multiple simulations using batch processing, you get multiple MAT-files if you specify a different persistent storage MAT-file for each simulation. For parallel simulations, Simulink produces a separate MAT-file for each simulation run. To help you identify and understand the context of the simulation data included in a MAT-file, Simulink stores metadata about logging to persistent storage.

A `Simulink.SimulationMetadata` object includes in its `ModelInfo` structure a `LoggingInfo` structure with two fields:

- `LoggingToFile` — Indicates whether logging to persistent storage is enabled (`'on'` or `'off'`)
- `LoggingFileName` — Specifies the resolved file name for the persistent storage MAT-file (if `LoggingToFile` is `'on'`).

The MAT-file used for persistent storage contains a `SimulationMetadata` variable that stores the same simulation metadata as the `Simulink.SimulationMetadata` object. The `SimulationMetadata` is a system-generated name, not a variable name that you specify.

To access the persistent logging storage metadata, use one of these alternatives:

- View simulation metadata by using the `SimulationOutput` object `SimulationMetadata` property.
- Use tab completion to access `SimulationMetadata` object properties such as `ModelInfo` and to access field names.
- Display simulation metadata in the Variable Editor. Click the `SimulationOutput` object and use one of these approaches:
  - Select the **Explore Simulation Metadata** check box (which displays the data in a tree structure).
  - Double-click the **SimulationMetadata** row.

Access Error Information

You can view error message and information about the stack and causes for simulation data by using the `SimulationOutput` object `ErrorMessage` property. For parallel simulations, if you are logging to file, Simulink enables the `CaptureErrors` argument for simulation.

Samples to Export for Variable-Step Solvers

In this section...

Output Options

Use the **Output options** list under **Configuration Parameters > Data Import/ Export > Additional parameters** to control how much output the simulation generates when your model uses a variable-step solver.

- `Refine factor` (default)
- `Produce additional output`
- `Produce specified output only`

Refine Output

The `Refine output` option provides additional output points when the simulation output does not include as many points as you would like. This parameter provides an integer number of output points between time steps. For example, a refine factor of 2 provides output midway between the time steps and at the steps. The default refine factor is 1.

Suppose that a sample simulation generates output at these times:

```
0, 2.5, 5, 8.5, 10
```

Choosing `Refine output` and specifying a refine factor of 2 generates output at these times:

```
0, 1.25, 2.5, 3.75, 5, 6.75, 8.5, 9.25, 10
```

To get smoother output more efficiently, change the refine factor instead of reducing the step size. When you change the refine factor, the solver generates additional points by evaluating a continuous extension formula at sample points. This option changes the

simulation step size so that time steps coincide with the times that you specify for additional output.

The refine factor applies to variable-step solvers and is most useful when you are using `ode45`. The `ode45` solver can take large steps. However, when you graph simulation output, the output from this solver sometimes is not sufficiently smooth. In such cases, run the simulation again with a larger refine factor. A value of such as 4 for `ode45` can provide much smoother results.

Note This option helps the solver locate zero crossings, although it does not ensure that Simulink detects all zero crossings (see "Zero-Crossing Detection" on page 3-24).

Produce Additional Output

Use the `Produce additional output` option to specify directly those additional times at which the solver generates output. When you select this option, the **Data Import/ Export** pane displays an **Output times** configuration parameter. In this parameter, enter a MATLAB expression that evaluates to an additional time or a vector of additional times. The solver produces hit times at the output times that you specify, in addition to the times it requires for accurate simulation.

Suppose that a sample simulation generates output at these times:

```
0, 2.5, 5, 8.5, 10
```

Choosing the `Produce additional output` option and specifying `[0:10]` generates output at these times:

```
0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10
```

and perhaps at additional times, depending on the step size chosen by the variable-step solver.

Tips

- This option helps the solver locate zero crossings, although it does not ensure that Simulink detects all zero crossings (see "Zero-Crossing Detection" on page 3-24).
- Set the **Output times** configuration parameter to a value other than the default empty matrix (`[]`).

- For triggered subsystems and function-call subsystems, the calling function must inherit the sampling rate.

Produce Specified Output Only

Simulink generates output at the start and stop times, in addition to the times that you specify.

Suppose that a sample simulation generates output at these times:

```
0, 2.5, 5, 8.5, 10
```

Choosing the `Produce specified output only` option and specifying `[1:9]` generates output at these times:

```
0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10
```

This option changes the simulation step size so that time steps coincide with the times that you specify for producing output. The solver can hit other time steps to accurately simulate the model. However, the output does not include these points. This option is useful when you are comparing different simulations to check that the simulations produce output at the same times.

Tips

- This option helps the solver locate zero crossings, although it does not ensure that Simulink detects all zero crossings (see "Zero-Crossing Detection" on page 3-24).
- Set the **Output times** configuration parameter to a value other than the default empty matrix (`[]`).
- In normal, accelerator, and rapid accelerator modes, Simulink generates output at the start and stop times, as well as at the times that you specify.
- When you simulate a model in normal mode, triggered subsystems and function-call subsystems use:
  - The times that you specify
  - All the time steps in between the values that you specify
  - The simulation start and stop times
- For triggered subsystems and function-call subsystems, the calling function must inherit the sampling rate.

Export Signal Data Using Signal Logging

In this section...

Signal Logging

To capture signal data from a simulation, usually you can use signal logging. Mark the signals that you want to log and enable signal logging for the model. For details, see “Configure a Signal for Logging” on page 61-75 and “Enable Signal Logging for a Model” on page 61-90.

For a summary of other approaches to capture signal data, see “Export Simulation Data” on page 61-3.

Signal Logging Workflow

To collect and use signal logging data, perform these tasks.

1. Mark individual signals for signal logging. See “Configure a Signal for Logging” on page 61-75.
2. Enable signal logging for a model. See “Enable Signal Logging for a Model” on page 61-90.
3. Simulate the model.
4. Access the signal logging data. See “View and Access Signal Logging Data” on page 61-109.

Log Subsets of Signals

One approach for testing parts of a model as you develop it is to mark a superset of signals for logging. Then overriding signal logging settings to select different subsets of signals for logging. You can use the Signal Logging Selector or a programmatic interface. See “Override Signal Logging Settings” on page 61-95.

Use this approach to log signals in models that use model referencing. See “Models with Model Referencing: Overriding Signal Logging Settings” on page 61-99.

Additional Signal Logging Options

With the basic signal logging workflow, you can specify additional options related to the data that signal logging collects and to how that data is displayed. You can:

- Specify a name for the signal logging data for a signal. See “Specify Signal-Level Logging Name” on page 61-77.
- Control how much data the simulation generates for a signal. See “Limit Data Logged” on page 61-79.
- Review the signal logging configuration for a model. See “View the Signal Logging Configuration” on page 61-83.
- Specify the samples for export for models with variable-step solvers. See “Samples to Export for Variable-Step Solvers” on page 61-67.
- Configure the model to display signal logging data in the Simulation Data Inspector. See “Simulation Data Inspector in Your Workflow” on page 28-2.

Signal Logging in Rapid Accelerator Mode

Signal logging in rapid accelerator mode does not log the following kinds of signals. When you update or simulate a model that contains these signals, Simulink displays a warning that those signals are not logged.

- Signals inside Stateflow charts
- Signals that use a custom data type

If you set the **Configuration Parameters > Solver > Periodic sample time constraint** parameter to `Ensure sample time independent`, you cannot use signal logging in rapid accelerator mode.

Signal Logging Limitations

- Rapid accelerator mode supports signal logging, with the requirements and limitations described in “Signal Logging in Rapid Accelerator Mode” on page 61-72.
- Top-model and Model block software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulation modes support signal logging. For a description of limitations, see “Top-

Model SIL/PIL Limitations" (Embedded Coder) and "Model Block SIL/PIL Limitations" (Embedded Coder).

- Array of buses signals support signal logging, with the requirements described in "Import Array of Buses Data" on page 61-175.
- You cannot log bus signals directly in For Each subsystems.
- You cannot log a signal inside a referenced model that is inside a For Each subsystem if either of these conditions exists:
  - The For Each subsystem is in a model simulating in rapid accelerator mode.
  - The For Each subsystem itself is in a model referenced by a Model block in accelerator mode.
- You cannot log signals that feed Function-Call subsystems or Action subsystems.
- You cannot log an input signal to a Merge block. You can log a Merge block output signal.
- For Integrator and Discrete-Time Integrator blocks that have the **Show state port** parameter enabled, you cannot log the state port signal.
- If you configure a bus signal or bus element for signal logging that is an input to a subsystem, you cannot automatically refactor the subsystem interface to use In Bus Element and Out Bus Element blocks. For details about that refactoring, see "Convert Models to Use Bus Element Ports" on page 65-34.
- You cannot log local data in Stateflow Truth Table blocks.

Configure a Signal for Logging

In this section...

Mark a Signal for Logging

Enable logging by marking a signal, using one of the following techniques:

- “Enable Logging Using Simulink Editor Menu Options” on page 61-75
- “Enable Logging Using Signal Properties” on page 61-76
- “Enable Logging Using the Model Data Editor” on page 61-76
- “Programmatic Interface” on page 61-77

The Simulink Editor menu options are generally the simplest way to mark signals for logging.

A signal for which you enable logging is a *logged signal*. By default, Simulink displays a logged signal indicator  for each logged signal.

Enable Logging Using Simulink Editor Menu Options

1. In the Simulink Editor, select one or more signals.
2. Click the **Simulation Data Inspector** button arrow  and select **Log Selected Signals**.

Alternatively, you can select one or more signals and check **Simulation** > **Output** > **Log Selected Signals**.

If you select multiple signals, the signal logging configuration that Simulink sets depends on whether any of the selected signals are marked for logging.

Signal Logging for Selected Signals	Result of Enabling the Log/Unlog Selected Signals Option
At least one of the selected signals does not have logging enabled.	Enables logging for all the selected signals
All selected signals have logging enabled.	Disables logging for all the selected signals

Enable Logging Using Signal Properties

1. In the Simulink Editor, right-click the signal.
2. From the context menu, select **Properties**.
3. In the Signal Properties dialog box, in the **Logging and accessibility** tab, select **Log signal data**.
4. Click **OK**.

Alternatively, you can select the **Log Selected Signals** from the context menu that appears when you right-click the selected signal.

Enable Logging Using the Model Data Editor

The Model Data Editor enables you to view a flat list of signals in your model. You can sort, group, and filter the list. Use this technique to enable logging for:

- Working with many signals at once, especially when the signals are not close to each other in the block diagram.
- Signals that are difficult to locate in a large model or hierarchy of subsystems.

To select signals to log using the Model Data Editor:

1. In the top menu of the model, select **View** > **Model Data**.
2. Click the **Signals** tab at the top of the Model Data Editor.
3. Ensure the `Instrumentation` option is selected on the **Change View** drop-down.
4. Check the boxes in the **Log Data** column for signals you would like to log.
5. Close the Model Data Editor when you have finished selecting signals to log.

See “Configure Data Properties by Using the Model Data Editor” on page 59-141 for more information about the Model Data Editor.

Programmatic Interface

To enable signal logging programmatically for selected blocks, use the outport `DataLogging` property. Set this property using the `set_param` command. For example:

1. At the MATLAB Command Window, open a model. Type

   ```
   vdp
   ```

2. Get the port handles of the signal that you want to log. For example, for the Mu block outport signal.

   ```
   ph = get_param('vdp/Mu','PortHandles')
   ```

3. Enable signal logging for the desired outport signal.

   ```
   set_param(ph.Outport(1),'DataLogging','on')
   ```

   The logged signal indicator appears.

Logging Referenced Model Signals

You can log any logged signal in a referenced model. Use the Signal Logging Selector to configure signal logging for a model reference hierarchy. For details, see “Models with Model Referencing: Overriding Signal Logging Settings” on page 61-99.

Specify Signal-Level Logging Name

You can specify a signal-level logging name to the object that Simulink uses to store logging data for a signal. Specifying a signal-level logging name can be useful for signals that are unnamed or that share a duplicate name with another signal in the model hierarchy. Specifying signal-level logging names, rather than using the names that Simulink generates, can make the logged data easier to analyze.

To specify a signal-level logging name, use *one* of the following approaches:

- “Signal-Level Logging Name in the Editor” on page 61-78
- “Signal-Level Logging Name in Model Explorer” on page 61-78
- “Signal-Specific Logging Name Specified Programmatically” on page 61-78

If you do not specify a custom signal-level logging name, Simulink uses the signal name. If the signal does not have a name, the action Simulink uses a blank name.

Note The signal-level logging name is distinct from the model-level signal logging name. The model-level signal logging name is the name for the object containing all the logged signal data for the whole model. The default model-level signal logging name is `logsout`. For details about the model-level signal logging name, see "Specify a Name for Signal Logging Data" on page 61-93.

Signal-Level Logging Name in the Editor

1. In the Simulink Editor, right-click the signal.
2. From the context menu, select **Signal Properties**.
3. Specify the logging name:
   a. In the Signal Properties dialog box, select the **Logging and accessibility** tab.
   b. From the **Logging name** list, select `Custom`.
   c. Enter the logging name in the adjacent text field.

Signal-Level Logging Name in Model Explorer

1. In the Model Explorer **Model Hierarchy** pane, select the node that contains the signal for which you want to specify a logging name.
2. If the **Contents** pane does not display the `LoggingName` property, add the `LoggingName` property to the current view. For details about column views, see "Customize Model Explorer Views" on page 12-38.
3. Enter a logging name for one or more signals using the `LoggingName` column.

Signal-Specific Logging Name Specified Programmatically

Enable signal logging programmatically for selected blocks with the outport `DataLogging` property. Set this property using the `set_param` command.

1. At the MATLAB Command Window, open a model. For example, type:

   ```
   vdp
   ```

2. Get the port handles of the signal that you want to log. For example, for the Mu block outport signal:

   ```
   ph = get_param('vdp/Mu','PortHandles');
   ```

3. Enable signal logging for the desired outport signal:

```
set_param(ph.Outport(1),'DataLogging','on');
```

The logged signal indicator appears.

4 Issue commands that use the `DataLoggingNameMode` and `DataLoggingName` parameters. For example:

```
set_param(ph.Outport(1),'DataLoggingNameMode','Custom');
set_param(ph.Outport(1),'DataLoggingName','x2_log');
```

Limit Data Logged

You can limit the amount of data logged for a signal by:

- Specifying a decimation factor
- Limiting the number of samples saved to be only the most recent samples

You can limit data logged for a signal by using the Signal Properties dialog box, the Model Explorer, the Signal Logging Selector, or programmatically. The following sections describe the first two approaches.

Use Signal Properties to Limit Logged Data

1 In the Simulink Editor, right-click the signal.

2 From the context menu, select **Signal Properties**.

3 In the Signal Properties dialog box, click the **Logging and accessibility** tab. Then select one or both of these options:

- **Limit data points to last**
- **Decimation**

Use Model Explorer to Limit Data Logged

1 In the Model Explorer **Model Hierarchy** pane, select the node that contains the signal for which you want to limit the amount of data logged.

2 If the **Contents** pane does not display the `DataLoggingDecimation` property or the `DataLoggingLimitDataPoints` property, add one or both of those properties to the current view. For details about column views, see “Customize Model Explorer Views” on page 12-38.

3 To specify a decimation factor, edit the `Decimation` and `DecimateData` properties. To limit the number of samples logged, edit the `LimitDataPoints` property.

Set Sample Time for a Logged Signal

To set the sample time for a logged signal, in the Signal Properties dialog box, use the **Sample Time** option. This option:

- Separates design and testing, because you do not need to insert a Rate Transition block to have a consistent sample time for logged signals
- Reduces the amount of logged data for a continuous time signal, for which setting decimation is not relevant
- Eliminates the need to postprocess logged signal data for signals with different sample times

Usage Notes

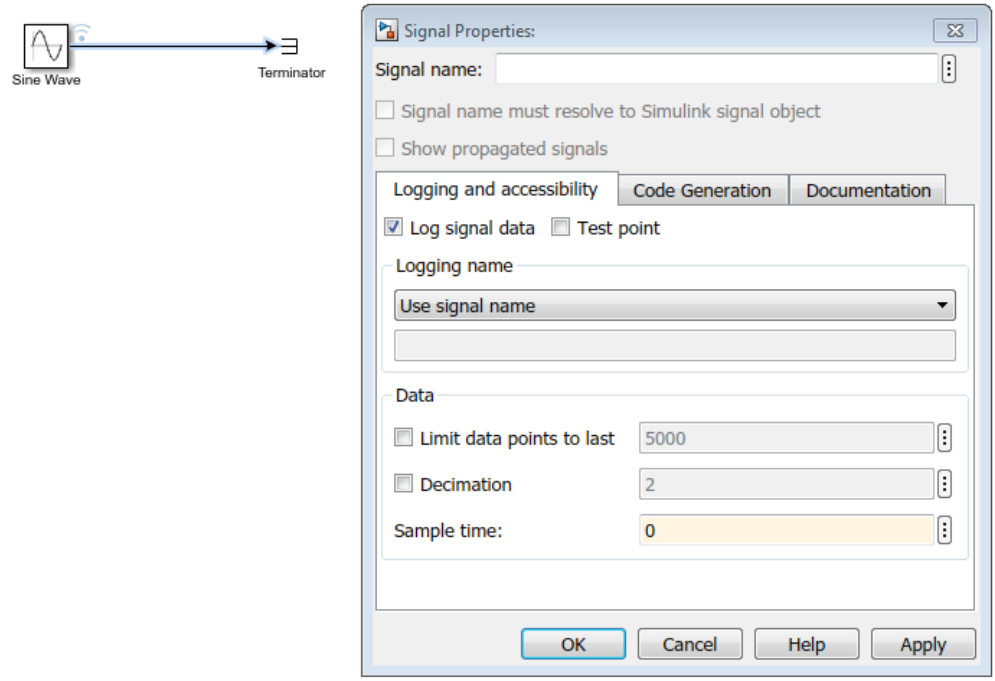
Do not specify a sample time for:

- Frame-based signals
- Conditional subsystems (for example, function-call or triggered subsystems) and conditional referenced models, which require an inherited sample time

If you simulate in SIL mode, signal logging ignores the sample times you specify for logged signals.

When you mark a signal for signal logging, Simulink inserts a hidden To Workspace block. When you specify a sample time for a logged signal, Simulink inserts a hidden Rate Transition block and a hidden To Workspace block.

Specifying a sample time for signal logging does not affect the simulation result. However, it is possible that the signal logging output for a logged signal varies depending on whether you specify a sample rate. For example, the interpolation method can differ depending on whether you specify a sample time for signal logging. Suppose that a model includes a continuous signal and the sample time is inherited (`-1`). The logged output for that signal shows that the interpolation method is `linear`.



```
logsout.get(1).Values.DataInfo
```

```
tsdata.datametadata
  Package: tsdata

  Common Properties:
              Units: ''
      Interpolation: linear (tsdata.interpolation)
```

If you change the sample time to be continuous (`0`), the logged output for that signal shows that the interpolation method is `zoh` (zero-order hold).

View the Signal Logging Configuration

In this section...

Approaches for Viewing the Signal Logging Configuration

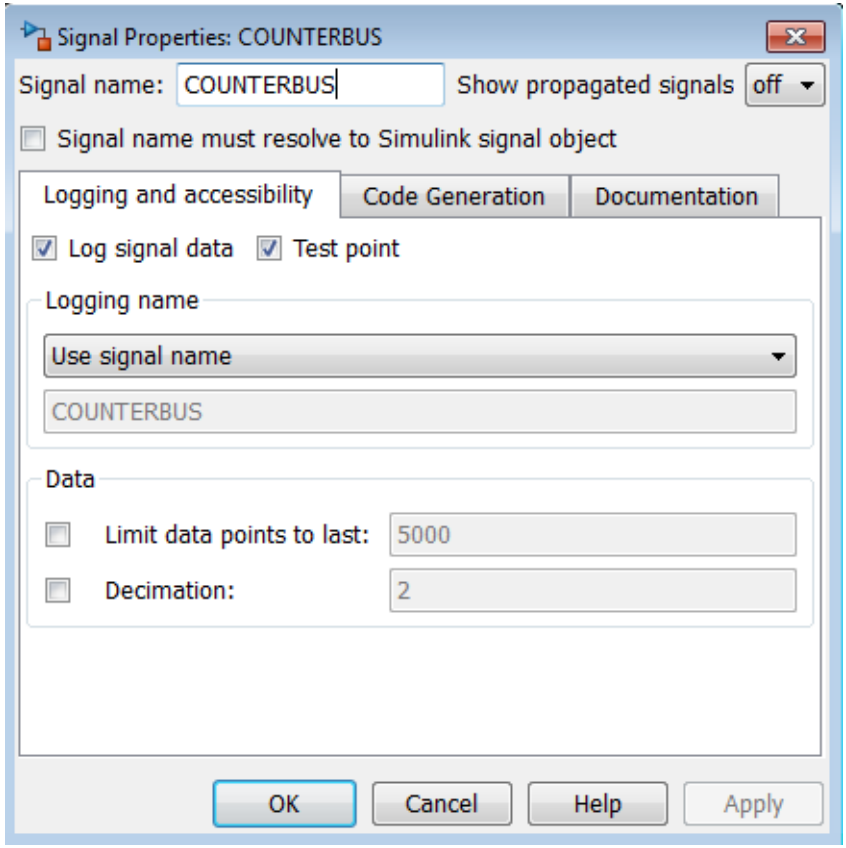
Signal Logging Configuration Viewing Approach	Usage	Documentation
In the Simulink Editor, view signal logging indicators.	Consider using this approach for models that have few signals marked for signal logging and have a shallow model hierarchy. This approach avoids leaving the Simulink Editor. Open the Signal Properties dialog box for each signal.	“Use Simulink Editor to View Signal Logging Configuration” on page 61-85

Signal Logging Configuration Viewing Approach	Usage	Documentation
Use the Signal Logging Selector.	Consider using this approach for models with deep hierarchies. View a model that has signal logging override settings for some signals. View the configuration as part of specifying a subset of signals for logging from all signals marked for signal logging. View signal logging configuration without displaying the signal logging indicators in the model. View signal logging configuration information such as decimation and output options in one window.	"View Logging Configuration with Signal Logging Selector" on page 61-86
Use the Model Explorer.	View signal logging configuration in the context of other model component properties. Adjust the column view to display signal logging properties, if necessary.	"Use Model Explorer to View Signal Logging Configuration" on page 61-88
Use MATLAB commands	Get the handles of the signals in the model and find the ones that have data logging enabled.	"Programmatically Find Signals Configured for Logging" on page 61-89

Use Simulink Editor to View Signal Logging Configuration

By default, Simulink Editor displays an indicator on each signal that is marked for signal logging. To view the signal logging setting for a signal:

1. Right-click the signal. From the context menu, select **Signal Properties**.
2. Select the **Logging and accessibility** tab.



For example, in the following model the output of the Sine Wave block is logged:

If you use the command-line interface to override logging for a signal, the Simulink Editor continues to display the signal logging indicator for that signal. When you simulate the model, Simulink displays a red signal logging indicator for all signals marked to be logged, reflecting any overrides. For details about configuring a signal for logging, see "Configure a Signal for Logging" on page 61-75.

A logged signal can also be a test point. See "Test Points" on page 64-62 for information about test points.

To hide the logging indicators, clear **Display > Signals & Ports > Testpoint & Logging Indicators**.

View Logging Configuration with Signal Logging Selector

1 Open the model for which you want to view the signal logging configuration.

2 Open the Signal Logging Selector, using one of the following approaches:

- In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.

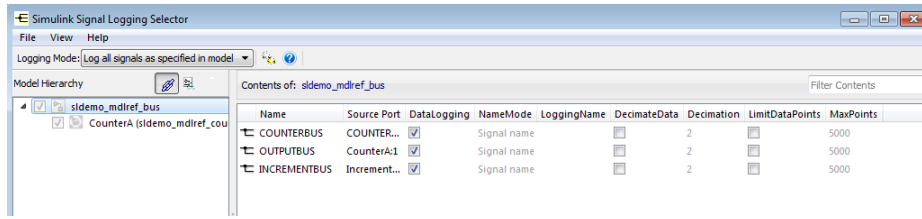
  If necessary, select **Signal logging** to enable the **Configure Signals to Log** button.

- For a model that includes a Model block, you can also use the following approach:

  a In the Simulink Editor, right-click a Model block.

  b In the context menu, select **Log Referenced Signals**.

3 In the **Model Hierarchy** pane, select the model node for which you want to view the signal logging configuration. For example:



To expand a node in the **Model Hierarchy** pane, right-click the arrow to the left of the node.

If no signals for a node are marked for signal logging, the **Contents** pane is empty.

For a model that references a model, the **Model Hierarchy** pane check box to the left of a model node indicates the override configuration of the node.

Check Box	Signal Logging Configuration
	For the top-level model node, logs all logged signals in the top model. For a Model block node, logs all logged signals in the model reference hierarchy for that block.
	For the top-level model node, disables logging for all logged signals in the top model. For a Model block node, disables logging for all signals in the model reference hierarchy for that block.
	For the top-level model node, logs all logged signals that have the `DataLogging` setting enabled. For a Model block node, logs all logged signals in the model reference hierarchy for that block that have the `DataLogging` setting enabled.

View Configuration of Subsystems and Linked Libraries

The following table describes default **Model Hierarchy** pane display of subsystems, masked subsystems, and linked library nodes.

Node	Display Default
Subsystem	Displays subsystems all that include logged signals
Masked subsystem	Does not display masked subsystems
Linked library	Displays all subsystems that include logged signals

You can control how the **Model Hierarchy** pane displays subsystems, masked subsystems, and linked libraries. Use icons at the top of the **Model Hierarchy** pane or use the **View** menu, using the same approach as you use in the Model Explorer. For details, see "Display Linked Library Subsystems and Masked Subsystems" on page 12-14 and "Manage Existing Masks" on page 38-16.

- To display all subsystems, including subsystems that do not include signals marked for logging, select the icon or **View > Show All Subsystems**. This subsystem setting also applies to masked subsystems, if you specify to display masked subsystems.
- To display masked subsystems with logged signals, use the icon or **View > Show Masked Subsystems**
- To display linked libraries, use the icon or **View > Show Library Links**

Filtering Signal Logging Selector Contents

To find a specific signal or property value for a signal, use the **Filter Contents** edit box. Use the same approach as you use in the Model Explorer; for details, see "Filtering Contents" on page 12-33.

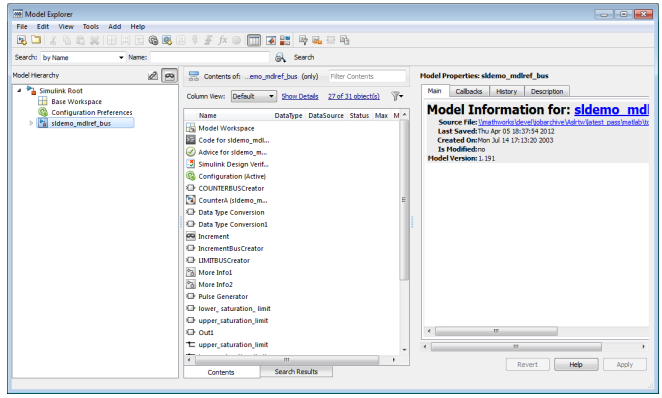
Highlighting a Block in a Model

To use the Model Hierarchy pane to highlight a block in model, right-click the block or signal and select **Highlight block in model**.

Use Model Explorer to View Signal Logging Configuration

1 To access the logging configuration information for referenced models, open the model for which you want to view the signal logging configuration. Select the top-level model in a model reference hierarchy.

2 In the **Contents** pane, set **Column View** to the `Signals` view.



For further information, see “Model Explorer: Model Hierarchy Pane” on page 12-10 and “Model Explorer: Contents Pane” on page 12-18.

Programmatically Find Signals Configured for Logging

Use MATLAB commands to get the handles of the signals in the model and find the ones that have data logging enabled. For example:

```
mdlsignals = find_system(gcs,'FindAll','on','LookUnderMasks','all',...
        'FollowLinks','on','type','line','SegmentType','trunk');
ph = get_param(mdlsignals,'SrcPortHandle')
for i=1: length(ph)
    get_param(ph{i},'datalogging')
end
```

Enable Signal Logging for a Model

In this section...

Enable and Disable Logging at the Model Level

To log a signal, mark it for logging. For details, see “Configure a Signal for Logging” on page 61-75.

Enable or disable logging globally for all signals that you mark for logging in a model. By default, signal logging is enabled. Simulink logs signals only if the **Configuration Parameters > Data Import/Export > Signal logging** parameter is checked. If the option is not checked, Simulink ignores the signal logging settings for individual signals.

When signals are marked for logging, the signal data is logged to the workspace and also sent directly to the Simulation Data Inspector, by default. You can disable logging signals to the workspace through the Configuration Parameters dialog box or programmatically.

- In the Configuration Parameters dialog box, clear the **Configuration Parameters > Data Import/Export > Signal logging** parameter check box.
- From the command line, use the `SignalLogging` parameter.

```
set_param(bdroot,'SignalLogging','off')
```

Data for signals marked for logging is always sent to the Simulation Data Inspector.

Selecting a Subset of Signals to Log

You can select a subset of signals to log for a model that has:

- Signal logging enabled
- Logged signals

For details, see “Override Signal Logging Settings” on page 61-95.

Specify Format for Dataset Signal Elements

Signal logging data is saved in `Dataset` format (as `Simulink.SimulationData.Dataset` objects). To specify whether you want the data for individual signals in the dataset to use MATLAB `timeseries` or `timetable` elements, set the **Dataset signal format** configuration parameter. The default is `timeseries`. For details, see "Dataset signal format".

Migrate Scripts That Use Legacy ModelDataLogs API

For scripts that simulate a model created in a release earlier than R2016a that uses `ModelDataLogs` format for logging, update the code to log in `Dataset` format.

If you have already logged signal data in the `ModelDataLogs` format, you can use the `Simulink.ModelDataLogs.convertToDataset` function to update the `ModelDataLogs` signal logging data to use `Dataset` format. For example, to update the `older_model_dataset` from `ModelDataLogs` format to `Dataset` format:

```
new_dataset = logsout.convertToDataset('older_model_data')
```

Converting a model from using `ModelDataLogs` format to using `Dataset` format can require that you modify your existing models and to code in callbacks, functions, scripts, or tests. The following table identifies possible issues to address after converting to `Dataset` format. The table provides solutions for each issue.

Possible Issue After Conversion to Dataset Format	Solution

Code in existing callbacks, functions, scripts, or tests that used the `ModelDataLogs` programmatic interface to access data can result in an error.	Check for code that uses `ModelDataLogs` format access methods. Update that code to use `Dataset` format access methods.
	
	For example, suppose that existing code includes the following line:
	
	`logsout.('Subsystem Name').X.data`
	
	Replace that code with a `Dataset` access method:
	
	`logsout.getElement('x').Values.data`

Possible Issue After Conversion to Dataset Format	Solution
Mux block signal names are lost.	The `Dataset` format treats Mux block signals as a vector. To identify signals by signal names, replace Mux blocks with Bus Creator blocks.
Signal Viewer cannot be used for signal logging.	Simulink does not log signal logging data in the Signal Viewer. Use the signal logging output variable to view the logged data.
The `unpack` method generates an error.	The `unpack` method, which is supported for `Simulink.ModelDataLogs` and `Simulink.SubsysDataLogs` objects, is *not* supported for `Simulink.SimulationData.Dataset` objects. For example, if the data in `mlog` has three fields: `x`, `y`, and `z`, then: For `ModelDataLogs` format data, the `mlog.unpack` method creates three variables in the base workspace. For `Dataset` format data, access methods by names. For example: `x = logsout.getElement('x').Values`

Possible Issue After Conversion to Dataset Format	Solution
The `ModelDataLogs` and `Dataset` formats have different naming rules for unnamed signals.	If necessary, add signal names. In `ModelDataLogs` format, for an unnamed signal coming from a block, Simulink assigns a name in this form: `SL_BlockName+<portIndex>` For example, `SL_Gain1`. In `Dataset` format, elements do not need a name, so Simulink leaves the signal name empty. For both `ModelDataLogs` and `Dataset` formats, Simulink assigns the same name to unnamed signals that come from Bus Selector blocks.
Test points in referenced models are not logged.	Consider enabling signal logging for test points in a referenced model.
Script uses `who` or `whos` functions.	Consider using `Simulink.SimulationData.Dataset.find` instead.

Specify a Name for Signal Logging Data

You use the model-level signal logging name to access the signal logging data for a model. The default name for the signal logging data is `logsout`. Specifying a model-level signal logging name can make it easier to identify the source of the logged data. For example, you could specify the signal logging name `car_logsout` to identify the data as being the signal logging data for the `car` model.

To specify a different model-level signal logging name, use either of these approaches:

- In the edit box next to the **Configuration Parameters > Data Import/Export > Signal logging** parameter, enter the signal logging name.
- Use the `SignalLoggingName` parameter, specifying a signal logging name. For example:

```
set_param(bdroot, 'SignalLoggingName', 'heater_model_signals')
```

Override Signal Logging Settings

In this section...

Benefits of Overriding Signal Logging Settings

As you develop a model, you may want to override the signal logging settings for a specific simulation run. You can override signal logging properties without changing the model in the Simulink Editor.

To reduce memory overhead and to facilitate the analysis of simulation logging results, override signal logging properties. By overriding signal logging settings, you can avoid recompiling a model.

Overriding signal logging properties is useful when you want to:

- Focus on only a few signals by disabling logging for most of the signals marked for logging. You can mark a superset of signals for logging, and then select different subsets of them for logging.
- Exclude a few signals from the signal logging output.
- Override specific signal logging properties, such as decimation, for a signal.
- Collect only what you need when running multiple test vectors.

Two Interfaces for Overriding Signal Logging Settings

Use either of two interfaces to override signal logging settings:

- "Override Signal Logging Settings with Signal Logging Selector" on page 61-97
- "Override Signal Logging Settings from MATLAB" on page 61-102

You can use a combination of the two interfaces. The Signal Logging Selector creates `Simulink.SimulationData.ModelLoggingInfo` objects when saving the override

settings. The command-line interface has properties whose names correspond to the Signal Logging Selector interface. For example, the `Simulink.SimulationData.ModelLoggingInfo` class has a `LoggingMode` property, which corresponds to the **Logging Mode** parameter in the Signal Logging Selector.

Scope of Signal Logging Setting Overrides

When you override signal logging settings, Simulink uses those override settings when you simulate the model.

Simulink saves in the model the signal logging override configuration that you specify. However, Simulink does not change the signal logging settings in the Signal Properties dialog box for each signal in the model.

In the Signal Logging Selector, if you override some signal logging settings, and then set the **Logging Mode** to `Log all signals as specified in model`, the logging settings defined in the model appear in the Signal Logging Selector. The override settings are greyed out, indicating that you cannot override these settings. To reactivate the override settings, set **Logging Mode** to `Override signals`. Using the Signal Logging Selector to override logging for a specific signal does not affect the signal logging indicator for that signal.

If you close and then reopen the model, the logging setting overrides that you made are in effect, if logging mode is set to override signals for that model. When the model displays the signal logging indicators, it displays the indicators for all logged signals, including logged signals that you have overridden.

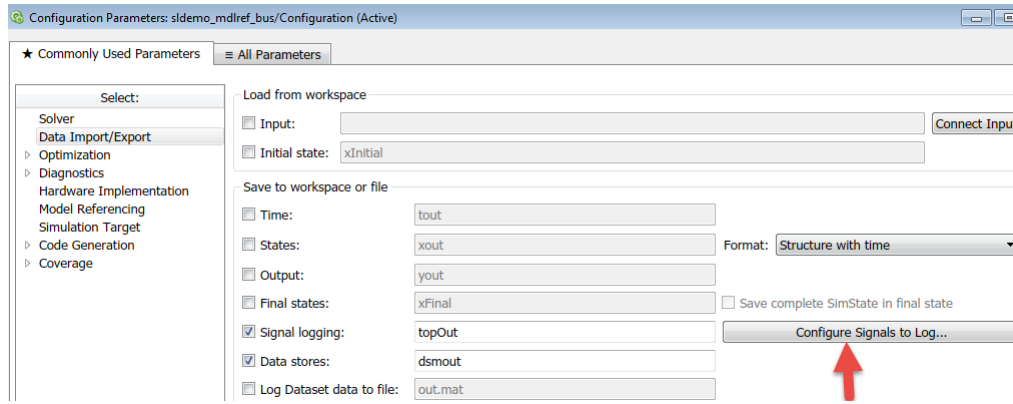
Note Simulink rebuilds a model in the following situation:

1. The model contains one or more signals marked for signal logging.
2. You simulate the model in rapid accelerator mode.
3. You use the Signal Logging Selector or MATLAB command line to modify the signal logging configuration.
4. You simulate the model in rapid accelerator mode again.

Override Signal Logging Settings with Signal Logging Selector

1 Open the Signal Logging Selector, using one of the following approaches:

- In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.

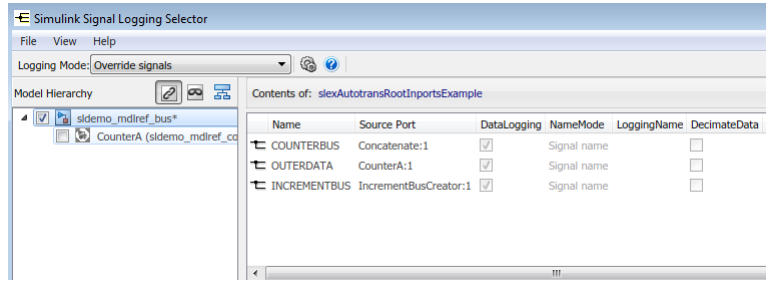


If necessary, select **Signal logging** to enable the **Configure Signals to Log** button.

- For a model that includes a Model block, you can also use the following approach:

  a In the Simulink Editor, right-click a Model block.

  b In the context menu, select **Log Referenced Signals**.



2 Set **Logging Mode** to `Override signals`.

Note The `Override signals` setting affects all levels of the model hierarchy. This setting can result in turning off logging for any signal throughout the hierarchy,

based on existing settings. To review settings, select the appropriate node in the **Model Hierarchy** pane.

3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration with Signal Logging Selector” on page 61-86.

4 Override signal logging settings. Use one of the following approaches, depending on whether your model uses model referencing:

- “Models Without Model Referencing: Overriding Signal Logging Settings” on page 61-98
- “Models with Model Referencing: Overriding Signal Logging Settings” on page 61-99

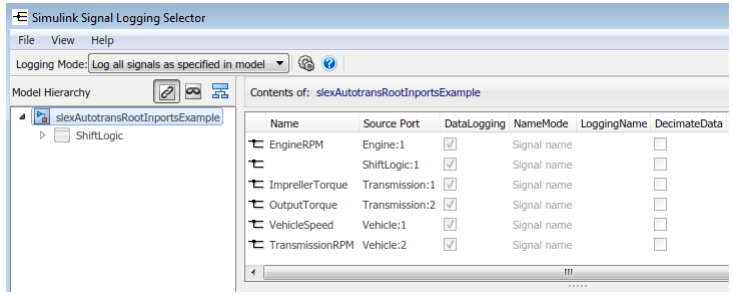
Tip To open the **Configuration Parameters > Data Import/Export** pane from the Signal Logging Selector, use the  button.

Models Without Model Referencing: Overriding Signal Logging Settings

If your model does not use model referencing (that is, the model does not include any Model blocks), override signal logging settings using the following procedure.

1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.

- If necessary, select **Signal logging** to enable the **Configure Signals to Log** button.



2. Set **Logging Mode** to `Override signals`.
3. View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See "View Logging Configuration with Signal Logging Selector" on page 61-86.
4. In the **Contents** pane table, select the signal whose logging settings you want to override.
5. Override logging settings:
   - To disable logging for a signal, clear the `DataLogging` check box for that signal.
   - To override other signal logging settings (for example, decimation), ensure that the `DataLogging` check box is selected. Then, edit values in the appropriate columns.

Models with Model Referencing: Overriding Signal Logging Settings

If your model uses model referencing (that is, the model includes at least one Model block), override signal logging settings using one or more of these procedures:

- "Enable Logging for All Logged Signals" on page 61-99
- "Disable Logging for All Signals in Node" on page 61-100
- "Override Signal Logging for a Subset of Signals" on page 61-101
- "Override Other Signal Logging Properties" on page 61-101

Enable Logging for All Logged Signals

By default, Simulink logs all the logged signals in a model, including the logged signals throughout model reference hierarchies.

If logging is disabled for any logged signals in the top-level model or in the top-level Model block in a model reference hierarchy, then in the **Model Hierarchy** pane, the check box to the left of that node is:

- Solid (), if logging is disabled for some of signals.
- Empty (), if logging is disabled for all the signals.

To enable logging of all logged signals for a node:

1. Open the Signal Logging Selector. In the **Configuration Parameters** > **Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.
2. Set **Logging Mode** to `Override signals`.
3. View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See "View Logging Configuration with Signal Logging Selector" on page 61-86.
4. In the **Model Hierarchy** pane, select the check box to the left of the node, so that the check box has a check mark ().

   - For the top-level model, logging is enabled for all logged signals in the top-level model, but not for logged signals in model reference hierarchies.
   - For a Model block at the top of a model referencing hierarchy, logging is enabled for the whole model reference hierarchy for the selected referenced model.

Disable Logging for All Signals in Node

If signal logging is enabled for any signals in a model node, then in the **Model Hierarchy** pane, the check box to the left of the node is:

- Solid (), if logging is enabled for some signals.
- Checked (), if logging is enabled for all signals.

To disable logging for all logged signals in a node of a model:

1. Open the Signal Logging Selector. In the **Configuration Parameters** > **Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.
2. Set **Logging Mode** to `Override signals`.
3. View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See "View Logging Configuration with Signal Logging Selector" on page 61-86.
4. In the **Model Hierarchy** pane, clear the check box to the left of the node, so that the check box is empty ().

   - For the top-level model, logging is disabled for all logged signals in the top-level model, but not for logged signals in model reference hierarchies.

- For a Model block at the top of a model referencing hierarchy, logging is disabled for the whole model reference hierarchy for the selected reference model.

Override Signal Logging for a Subset of Signals

To log some, but not all, logged signals in a model node:

1. Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.
2. Set **Logging Mode** to `Override signals`.
3. View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See "View Logging Configuration with Signal Logging Selector" on page 61-86.
4. In the **Model Hierarchy** pane, ensure that the check box for the top-level model or Model block is either solid (), if logging is disabled for some of the signals, or empty (), if logging is disabled for all the signals. Click the check box to cycle through different states.
5. In the **Contents** pane table, for the signals that you want to log, select the check box in the `DataLogging` column.

   To enable logging for multiple signals, hold the **Shift** or **Ctrl** key and select a range of signals or individual signals. Select the check box in the `DataLogging` column of one of the highlighted signals.

Note You cannot use the Signal Logging Selector to override a subset of signals for model reference variant systems, including:

- Model reference variants
- Model blocks that contain a Subsystem Variant or model reference variant

You can override programmatically a subset of signals in those configurations. For details, see "Override Signal Logging Settings from MATLAB" on page 61-102.

Override Other Signal Logging Properties

In addition to overriding the setting for the `DataLogging` property for a signal, you can override other signal logging properties, such as decimation.

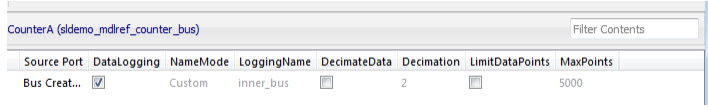
1. Open the Signal Logging Selector. In the **Configuration Parameters** > **Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.
2. Set **Logging Mode** to `Override signals`.
3. View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See "View Logging Configuration with Signal Logging Selector" on page 61-86.
4. In the **Model Hierarchy** pane, ensure that the check box for the top-level model or Model block is solid ( ) if logging is disabled for some signals, or empty ( ), if logging is disabled for all signals. Click the check box to cycle through different states.
5. In the **Contents** pane table, for the signals for which you want to override logging properties, enable logging by selecting the check box in the `DataLogging` column.

   To enable logging for multiple signals, hold the **Shift** or **Ctrl** key and select a range of signals or individual signals. Select the check box in the `DataLogging` column of one of the highlighted signals.
6. In the **Contents** pane table, modify the settings for properties, such as `DecimateData` and `Decimation`.

Override Signal Logging Settings from MATLAB

The MATLAB command-line interface for overriding signal logging settings includes:

- The `DataLoggingOverride` model parameter — Use to view or set signal logging override values for a model
- The following classes:
  - `Simulink.SimulationData.ModelLoggingInfo` — Specify signal logging override settings for a model. This class corresponds to the overall Signal Logging Selector interface.
  - `Simulink.SimulationData.SignalLoggingInfo` — Override settings for a specific signal. This class corresponds to a row in the logging property table in the Signal Logging Selector:



- `Simulink.SimulationData.LoggingInfo` — Overrides for signal logging settings such as decimation. This class corresponds to the editable columns in a row in the logging property table in the Signal Logging Selector.

To query a model for its signal logging override status, use the `DataLoggingOverride` parameter.

To configure signal logging from the command line, use methods and properties of the three classes listed above. To apply the configuration, use `set_param` with the `DataLoggingOverride` model parameter.

The following sections describe how to use the command-line interface to perform some common signal logging configuration tasks.

- "Create a Model Logging Information Object" on page 61-103
- "Specify Which Models to Log" on page 61-104
- "Log a Subset of Signals" on page 61-105
- "Override Other Signal Logging Properties" on page 61-107

Create a Model Logging Information Object

To use the command-line interface for overriding signal logging settings, first create a `Simulink.SimulationData.ModelLoggingInfo` object. For example, use the following commands to create the model logging override object for the `ex_bus_logging` model and automatically add each logged signal in the model to that object:

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_bus_logging')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_mdlref_counter_bus')));
mi = Simulink.SimulationData.ModelLoggingInfo.createFromModel(...
'ex_bus_logging')
```

```
mi =

  ModelLoggingInfo with properties:

                  Model: 'ex_bus_logging'
            LoggingMode: 'OverrideSignals'
   LogAsSpecifiedByModels: {}
                Signals: [1x4 Simulink.SimulationData.SignalLoggingInfo]
```

The `LoggingMode` property is set to `OverrideSignals`, which configures the model logging override object to log only the signals specified in the `Signals` property.

To apply the model override object settings, use:

```
set_param(ex_bus_logging, 'DataLoggingOverride', mi);
```

Simulink saves the settings when you save the model.

You can control the kinds of systems from which to include logged signals. By default, the `Simulink.SimulationData.ModelLoggingInfo` object includes logged signals from:

- Libraries
- Masked subsystems
- Referenced models
- Active variants

As an alternative, you can use the `Simulink.SimulationData.ModelLoggingInfo` constructor and specify a `Simulink.SimulationData.SignalLoggingInfo` object for each signal. To ensure that you specified valid signal logging settings for a model, use the `verifySignalAndModelPaths` method with the `Simulink.SimulationData.ModelLoggingInfo` object for the model.

Specify Which Models to Log

To specify whether to use the signal logging settings as specified in the model and all referenced models, or to override those settings, use the `LoggingMode` property of a `Simulink.SimulationData.ModelLoggingInfo` object.

You can control whether a top-level model and referenced models use override signal logging settings or use the signal logging settings specified by the model. See the `Simulink.SimulationData.ModelLoggingInfo` documentation.

This example shows how to log all signals as specified in the top model and all referenced models. The signal logging output is stored in `topOut`.

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_bus_logging')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_mdlref_counter_bus')));
mi = Simulink.SimulationData.ModelLoggingInfo...
     ('ex_bus_logging');
mi.LoggingMode = 'LogAllAsSpecifiedInModel'
```

```
mi =

  ModelLoggingInfo with properties:
```

```
                    Model: 'ex_bus_logging'
                LoggingMode: 'LogAllAsSpecifiedInModel'
    LogAsSpecifiedByModels: {}
                   Signals: []
```

To apply the model override object settings, use:

```
set_param(ex_bus_logging, 'DataLoggingOverride', mi);
```

The following example shows how to log only signals in the top model:

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_bus_logging')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_mdlref_counter_bus')));
mi = Simulink.SimulationData.ModelLoggingInfo...
     ('ex_bus_logging');
mi.LoggingMode = 'OverrideSignals';
mi = mi.setLogAsSpecifiedInModel('ex_bus_logging',true);
```

To apply the model override object settings, use:

```
set_param(ex_bus_logging,'DataLoggingOverride', mi);
```

Simulink saves the settings when you save the model.

Log a Subset of Signals

For a simple model with a limited number of logged signals, you could create an empty `Simulink.SimulationData.ModelDataLogInfo` object. Then create `Simulink.SimulationData.SignalLoggingInfo` objects for each of the signals that you want to log, and assign those objects to the model logging information object.

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_bus_logging')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_mdlref_counter_bus')));
mdl = 'ex_bus_logging';
blk = 'ex_bus_logging/IncrementBusCreator';
blkPort = 1;

load_system(mdl);

ov = Simulink.SimulationData.ModelLoggingInfo(mdl);
```

```
so = Simulink.SimulationData.SignalLoggingInfo(blk,blkPort);

ov.Signals(1) = so;

% apply this object so the model
set_param(mdl,'DataLoggingOverride',ov);

% Simulate
sim(mdl);

% observe that only the signal
topOut
```

To apply the model override object settings, use:

```
set_param(mdl, 'DataLoggingOverride', ov);
```

Simulink saves the settings when you save the model.

For a model that uses model referencing, or that is complex, to specify a subset of logged signals to log, consider using the `findSignal` method with a `Simulink.SimulationData.ModelLoggingInfo` object. For example, to log only one signal from the referenced model instance referenced by:

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_bus_logging')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
 'examples', 'ex_mdlref_counter_bus')));

mi = Simulink.SimulationData.ModelLoggingInfo.createFromModel(...
             'ex_bus_logging');
pos = mi.findSignal({'ex_bus_logging/CounterA' ...
                     'ex_mdlref_counter_bus/Bus Creator'}, 1)

pos =

     4

for idx=1:length(mi.Signals)
  mi.Signals(idx).LoggingInfo.DataLogging = (idx == pos);
end
```

To apply the model override object settings, use:

```
set_param(ex_bus_logging,'DataLoggingOverride', mi);
```

Simulink saves the settings when you save the model.

Note You can override programmatically a subset of signals for model reference variant systems, including:

- Model reference variants
- Model blocks that contain a Subsystem Variant or model reference variant

To log a subset of signals for these model reference variant systems, set the `SignalLoggingSaveFormat` parameter to `Dataset`.

Override Other Signal Logging Properties

In addition to overriding the setting for the `DataLogging` property for a signal, you can override other signal logging properties, such as decimation.

Use `Simulink.SimulationData.LoggingInfo` properties to override signal logging properties. The following example shows how to set the decimation override settings.

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
 'examples', 'ex_bus_logging')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_mdlref_counter_bus')));
mi = Simulink.SimulationData.ModelLoggingInfo.createFromModel...
    ('ex_bus_logging');
pos = mi.findSignal({'ex_bus_logging/CounterA' ...
                     'ex_mdlref_counter_bus/Bus Creator'}, 1);
mi.Signals(pos).LoggingInfo.DecimateData = true;
mi.Signals(pos).LoggingInfo.Decimation = 2;
```

To apply the model override object settings, use:

```
set_param(ex_bus_logging,'DataLoggingOverride', mi);
```

Simulink saves the settings when you save the model.

View and Access Signal Logging Data

In this section...

You can view the signal logging data during simulation, using the Simulation Data Inspector, or for paused or stopped simulations, using other visualization interfaces. See “Decide How to Visualize Simulation Data” on page 29-2.

Alternatively, you can access signal logging data programmatically, using MATLAB commands, as described in this topic.

Tip If you do not see logging data for a signal that you marked in the model for signal logging, check the logging configuration. Use the Signal Logging Selector to enable logging for a signal whose logging is overridden. For details, see “View the Signal Logging Configuration” on page 61-83 and “Override Signal Logging Settings” on page 61-95.

Signal Logging Object

Simulink saves signal logging data in a `Simulink.SimulationData.Dataset` object, which is a MATLAB workspace variable. The default name of the signal logging variable is `logsout`. You can change the variable name. For details, see “Specify a Name for Signal Logging Data” on page 61-93.

You can specify whether you want the data for individual signals in a dataset to use MATLAB `timeseries` or `timetable` elements. Set the **Dataset signal format** configuration parameter (for details, see “Dataset signal format”).

Releases earlier than R2016a also supported a `ModelDataLogs` format. For details, see “Migrate Scripts That Use Legacy ModelDataLogs API” on page 61-91.

Access Data Programmatically

You can use the `Simulink.SimulationData.Dataset` API to access signal logging data programmatically. To access `Dataset` object elements, use indexing with curly braces. For example, you can access the first element of the `topOut` signal logging `Dataset` object using index `1`. This example is based on the use of the default setting of `timeseries` for the dataset elements. For details about `timeseries` and `timetable` format data, see "Dataset signal format".

```
open_system(docpath(fullfile(docroot,'toolbox','simulink',...
'examples','ex_bus_logging')));
open_system(docpath(fullfile(docroot,'toolbox','simulink',...
'examples','ex_mdlref_counter_bus')));
sim('ex_bus_logging')
topOut
```

```
Simulink.SimulationData.Dataset 'topOut' with 4 elements

                      Name          BlockPath
                      ____________  ____________________________________
    1  [1x1 Signal]   COUNTERBUS    ex_bus_logging/COUNTERBUSCreator
    2  [1x1 Signal]   OUTPUTBUS     ex_bus_logging/CounterA
    3  [1x1 Signal]   INCREMENTBUS  ex_bus_logging/IncrementBusCreator
    4  [1x1 Signal]   inner_bus     ...erA|ex_mdlref_counter_bus/Bus Creator

  - Use braces { } to access, modify, or add elements using index.
```

```
element1 = topOut{1}
```

```
element1 =

  Simulink.SimulationData.Signal
  Package: Simulink.SimulationData

  Properties:
              Name: 'COUNTERBUS'
    PropagatedName: ''
         BlockPath: [1x1 Simulink.SimulationData.BlockPath]
          PortType: 'outport'
         PortIndex: 1
            Values: [1x1 struct]

  Methods, Superclasses
```

```
element1.Values
```

```
ans =

      data: [1x1 timeseries]
    limits: [1x1 struct]
```

To search for specific elements in a `Dataset` object, use the `find` method. To return the names of the `Dataset` object elements, use the `getNames` method.

Tip To call a function on each specified MATLAB `timeseries` object, you can use the `Simulink.SimulationData.forEachTimeseries` function. For example, you can use this function to make it easy to resample every element of a structure of `timeseries` objects obtained by logging a bus signal.

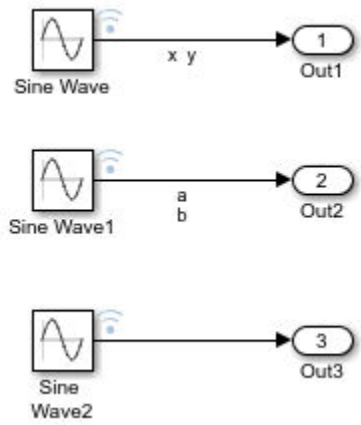
Handling Spaces and Newlines in Logged Names

Signal names in data logs can have spaces or newlines in their names when:

- The signal is named and the name includes a space or newline character.
- The signal is unnamed and originates in a block whose name includes a space or newline character.
- The signal exists in a subsystem or referenced model (or any parent block) whose name includes a space or newline character.

The following three examples show signals whose names contain:

- A space
- A signal whose name contains a newline
- An unnamed signal that originates in a block whose name contains a newline



The following example shows how to handle spaces or new lines in logged names when a model uses the default of `logsout` for the signal logging data.

```
logsout

Simulink.SimulationData.Dataset 'logsout' with 3 elements

                          Name  BlockPath
                          ____  _____________________
    1  [1x1 Signal]       ''    untitled/Sine  Wave2
    2  [1x1 Signal]       x y   untitled/Sine Wave
    3  [1x1 Signal]       x y   untitled/Sine Wave1

  - Use braces { } to access, modify, or add elements using index.
```

To access a signal with a space or newline, use the index. For example, to access the `x y` signal:

```
>> logsout.getElement{2}

ans =

  Simulink.SimulationData.Signal
  Package: Simulink.SimulationData

  Properties:
              Name: 'x  y'
```

```
    PropagatedName: ''
         BlockPath: [1x1 Simulink.SimulationData.BlockPath]
          PortType: 'outport'
         PortIndex: 1
            Values: [1x1 timeseries]
```

Access Logged Signal Data in ModelDataLogs Format

Before R2016a, you could log signals in `ModelDataLogs` format. Starting in R2016a, you cannot log data in the `ModelDataLogs` format. Signal logging uses the `Dataset` format.

However, you can use data that was logged in a previous release using `ModelDataLogs` format.

For more information, see `Simulink.ModelDataLogs`.

Log Signals in For Each Subsystems

In this section...

The approach you use to log data for a signal in a For Each subsystem depends on whether the signal is a:

- Nonbus signal — Log directly in a For Each subsystem
- A bus or array of buses signal — Use one of these approaches:
  - Use a Bus Selector block to select the signals you want to log and mark those signals for signal logging. This approach works well for many models.
  - Attach the signal to an Outport block and log the signal outside of the For Each subsystem. Use this approach when you want to log a whole bus signal, and that bus signal includes many bus element signals.

Note You cannot log bus signals directly in a For Each subsystem.

You cannot log a signal inside a referenced model that is inside a For Each subsystem if either of these conditions exists:

- The For Each subsystem is in a model simulating in rapid accelerator mode.
- The For Each subsystem itself is in a model referenced by a Model block in accelerator mode.

The data for each logged signal in a For Each subsystem is saved in a separate `Dataset` element as a `Simulink.SimulationData.Signal` object. The format of the logged signal data depends on how you set the **Dataset signal format** configuration parameter:

- If the setting is `timeseries`, then each signal object contains an array of MATLAB `timeseries` objects. The array keeps the data from different For Each iteration separate.
- If the setting is `timetable`, then each signal object contains a cell array of MATLAB `timetable` objects. The dimensions of this array match the number of For Each

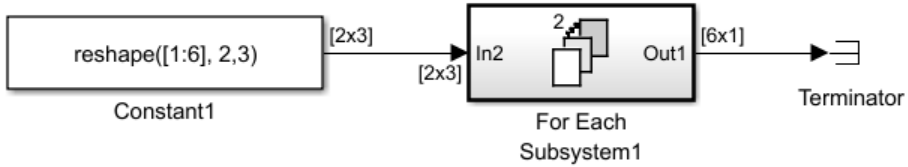
iterations. For example, if the For Each subsystem has three iterations, then the logged data has a `3x1` array of `timeseries` or `timetable` objects. For nested For Each subsystems, each layer of nesting adds another dimension to the logged data.

Log Signal in Nested For Each Subsystem

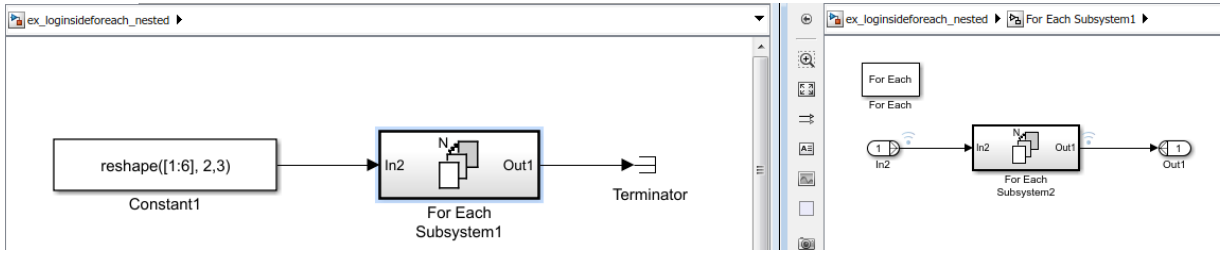
This example logs a signal in a nested For Each subsystem.

Open the `ex_loginsideforeach_nested` model.

```
open_system(docpath(fullfile(docroot,'toolbox','simulink',...
'examples','ex_loginsideforeach_nested.slx')))
```



In the Simulink Editor, open the `For Each Subsystem1` block, and inside that subsystem, open the `For Each Subsystem2` block.



Simulate the model and examine the signal logging data for the first iteration of the top subsystem and the third iteration of the bottom subsystem. The `2x3 timeseries` results from two iterations at the first For Each level and three iterations at the second (nested) level

```
sim('ex_loginsideforeach_nested');
logsout.get('nestedDelay')
```

```
ans =

  Simulink.SimulationData.Signal
  Package: Simulink.SimulationData

  Properties:
  struct with fields:

              Name: 'nestedDelay'
    PropagatedName: ''
         BlockPath: [1×1 Simulink.SimulationData.BlockPath]
          PortType: 'outport'
         PortIndex: 1
            Values: [2×3 timeseries]
```

Return the values of the `nestedDelay` object.

```
logsout.get('nestedDelay').Values(1,3)
```

```
timeseries

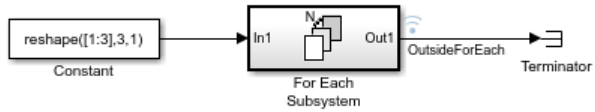
  Common Properties:
            Name: 'nestedDelay'
            Time: [5x1 double]
        TimeInfo: [1x1 tsdata.timemetadata]
            Data: [1x1x5 double]
        DataInfo: [1x1 tsdata.datametadata]
```

Log Bus Signals in For Each Subsystem

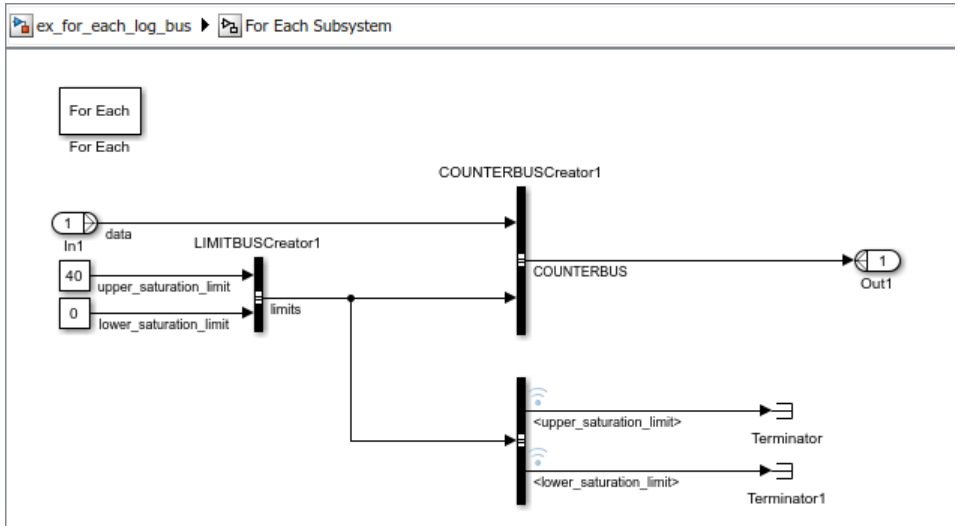
This example logs a two bus signal in a For Each subsystem. For one bus signal, you use a Bus Selector block and then log each selected signal. For the other bus signal, you use Outport blocks and log outside of the For Each subsystem.

Open the `ex_for_each_log_bus` model.

```
open_system(docpath(fullfile(docroot,'toolbox','simulink',...
'examples','ex_for_each_log_bus.slx')))
```



In the Simulink Editor, open the `For Each Subsystem` block.



To log the signals in the `limits` bus signal, the signal is branched to a Bus Selector block, and each of the bus element signals is marked for signal logging.

To log the whole `COUNTERBUS` signal, the bus signal is connected to an Outport block. The output signal from the For Each subsystem is marked for signal logging. To have the bus signal cross the subsystem boundary, the Bus Creator block that creates the `COUNTERBUS` signal has the **Output data type** parameter set to `Bus: COUNTERBUS` and **Output as nonvirtual bus** check box selected.

Simulate the model and examine the signal logging output. Focus on one of the bus element signals logged inside the For Each subsystem and on the bus signal logged outside of the For Each subsystem.

```
sim('ex_for_each_log_bus');
logsout
```

```
Simulink.SimulationData.Dataset 'logsout' with 3 elements

                        Name                       BlockPath
    1   [1x1 Signal]    OutsideForEach             ex_for_each_log_bus/For Each Subsystem
    2   [1x1 Signal]    <lower_saturation_limit>   ...g_bus/For Each Subsystem/Bus Selector
    3   [1x1 Signal]    <upper_saturation_limit>   ...g_bus/For Each Subsystem/Bus Selector

  - Use braces { } to access, modify, or add elements using index.
```

Return the values of the `lower_saturation_limit` object.

```
logsout{2}.Values
```

```
3×1 timeseries array with properties:

    Events
    Name
    UserData
    Data
    DataInfo
    Time
    TimeInfo
    Quality
    QualityInfo
    IsTimeFirst
    TreatNaNasMissing
    Length
```

Return the values of the `OutsideForEach` object.

```
logsout{1}.Values
```

```
 ans =

  3×1 struct array with fields:

    data
    limits
```

If the `Dataset` signal format is `timetable`, then the output is a cell array of `timetable` objects. For example:

```
out = sim('ex_for_each_log_bus','DatasetSignalFormat','timetable');
out.logsout{2}.Values
```

```
ans =
 3x1 cell array

  {11x1 timetable}
  {11x1 timetable}
```

```
{11x1 timetable}
```

Overview of Signal Loading Techniques

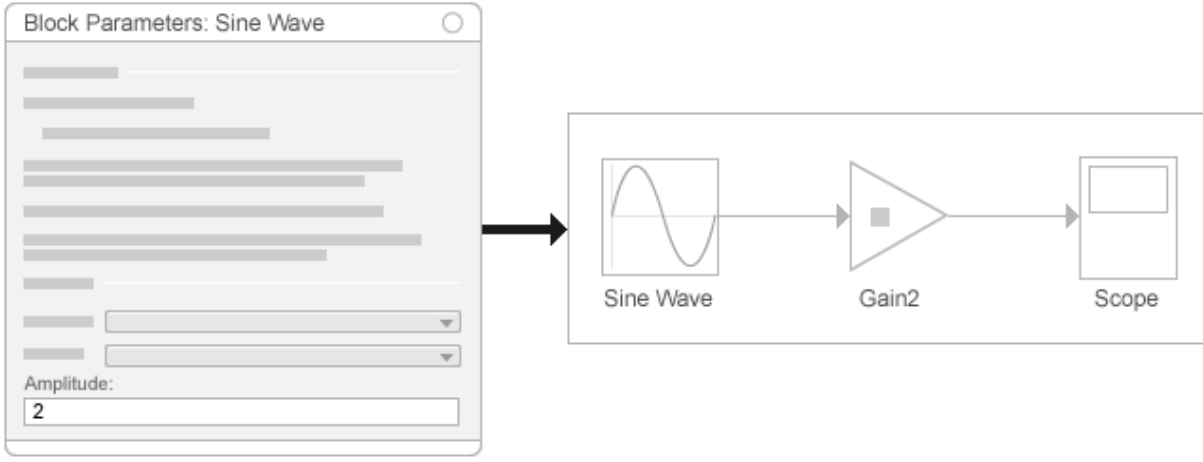
In this section...

Simulink provides several techniques for importing signal data into a model. Each of the signal data loading techniques uses blocks to represent signal data sources visually.

For additional details about which technique to use to meet specific modeling requirements, see “Comparison of Techniques” on page 61-129.

Source Blocks

You can add a source block, such as a Sine Wave block, to generate signals to input to another block. To specify how to generate the signal, use the Block Parameters dialog box. For example, in the Sine Wave Block Parameters dialog box, you can specify the `sim` function to use and time-based or sample-based data.



The output data types of source blocks vary. For example, a Sine Wave block outputs a vector of real doubles.

For an example of using a source block, see "Build and Edit a Model in the Simulink Editor" on page 1-23.

Recommended Uses

- Do initial prototyping in a model, when the generated signal data serves your modeling requirements
- Avoid creating the data manually.
- Reduce memory consumption. Source blocks do not store signal data.
- Make the kind of signal data visually clear in the model.

Limitations

Source blocks generate signals based on a predefined algorithm. To use actual data from an external source or to test a model without having to modify the model, use a different signal loading technique.

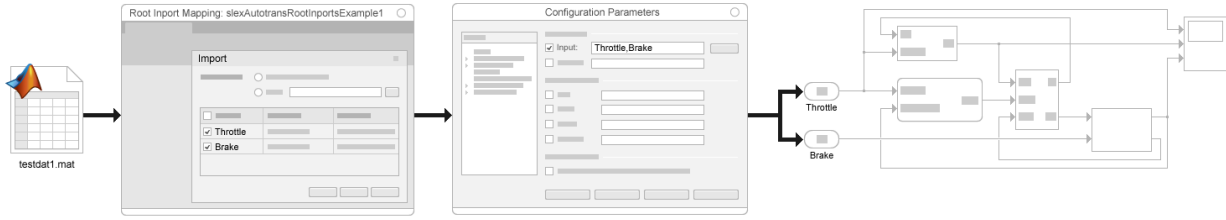
Root-Level Input Ports

You can import signal data from a workspace and apply it to a root-level input port using one of these blocks:

- Enable
- Inport
- Trigger block that has an edge-based (rising, falling, or either) trigger type

The root-level input ports load external inputs from the MATLAB (base), model, or mask workspace. These blocks import data from the workspace based on the value of the **Configuration Parameters > Data Import/Export > Input** parameter or a `sim` command argument. For an example, see "Load Data to Model a Continuous Plant" on page 61-146.

To import many signals to root-level input ports, consider using the Root Inport Mapper tool. This tool updates the **Input** configuration parameter based on the signal data that you import and map to root-level input ports. For an example, see "Map Data Using Root Inport Mapper Tool" on page 61-137.



Recommended Uses

Use root input ports to:

- Import many signals to many blocks
- Test your model as a referenced model in a wider context with signals from the workspace, without modifying your model

For importing signal data to meet most modeling requirements and to maintain model flexibility, root-level inport mapping is a convenient technique. Root-level inport mapping:

- Displays signal data for you to inspect without loading all the signal data into MATLAB memory
- Provides memory-efficient signal viewing

Requirements

To ensure that the Simulink variable solver executes at the times that you specify in the imported data, set the **Configuration Parameters** > **Data Import/Export** > **Additional parameters** > **Output options** parameter to `Produce additional output`.

Limitations

- You cannot use input ports to import buses in external modes. To import bus data in rapid accelerator mode, use `Dataset` format.
- The Root Inport Mapper tool supported map modes depend on the data type of a signal. For details, see “Choose a Base Workspace and MAT-File Format” on page 61-186.

From File Block

A From File block reads data from a MAT-file and outputs the data as a signal.

For an example, see “From File Block Loading Timeseries Data”.

Recommended Uses

Consider using a From File block for loading:

- Large amounts of data. For a Version 7.3 MAT-file, the From File block loads data incrementally from the MAT-file during simulation.

  Tip To convert a Version 7.0 file to Version 7.3 (for example, `my_data_file.mat` that contains the variable `var`), at the MATLAB command line, enter:

  ```
  load('my_data_file.mat')
  save('my_data_file.mat', 'var', '-v7.3')
  ```

- Data that was exported to a To File block. The From File block reads data written by a To File block without any you modifying the data or making other special provisions.
- Data stored in a MAT-file that is separate from the model file.

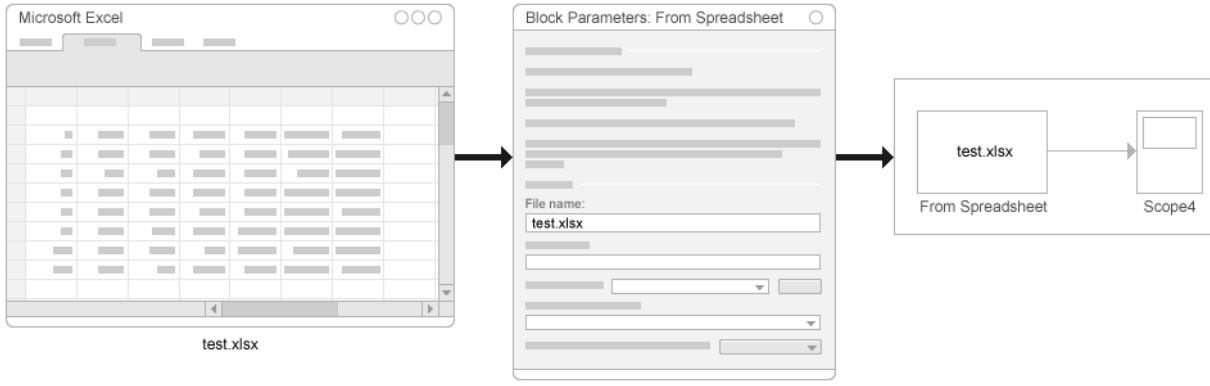
Limitations

- For *Version 7.0* or earlier MAT-file, the From File block reads only array-format data.

- Version 7.3 and Version 7.0 or earlier MAT-files handle multiple variables differently. See “MAT-File Variable” on page 61-250.
- The From File block supports reading nonvirtual bus signals in MATLAB `timeseries` format.
- For array data, the From File block reads only double signal data.
- Code generation that involves building ERT or GRT targets, or using SIL or PIL simulation modes, has some special considerations. See “Code Generation Requirements”.

From Spreadsheet Block

The From Spreadsheet block reads data from Microsoft Excel spreadsheets (all platforms) or CSV spreadsheets (Microsoft Windows platform with Microsoft Office only) and outputs the data as one or more signals.



Recommended Uses

Use the From Spreadsheet block for loading:

- Large Microsoft Excel or CSV spreadsheets. The From Spreadsheet block incrementally reads data from the spreadsheet during simulation, rather than loading the data into Simulink memory.
- Spreadsheets that you expect to modify. The From Spreadsheet block handles changes to worksheet values automatically, because it loads data directly from the spreadsheet.

Limitations

- You cannot import bus data.
- The From Spreadsheet file has requirements for the spreadsheet data. Organize Excel spreadsheet data using the format described in "Supported Microsoft Excel File Formats" on page 61-189.
- Linux and Mac platforms do not support using a From Spreadsheet block to import data from a CSV spreadsheet.

From Workspace Block

The From Workspace block reads signal data from a workspace and outputs the data as a signal. In the Block Parameters dialog box, in the **Data** parameter, enter a MATLAB expression that specifies the workspace data.

For an example of how to use a From Workspace block, see "Use From Workspace Block for Test Case" on page 61-152.

Recommended Uses

Use the From Workspace block for loading:

- A small set of signal data to perform local, temporary testing
- Data from the MATLAB (base), model, mask, or function workspace
- Variable-size signals
- Data that you saved using a To Workspace block in MATLAB `timeseries` format, without manual changes to the data

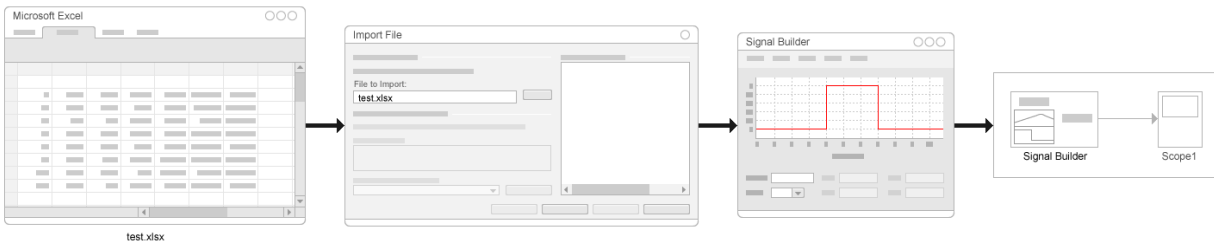
- Data saved in a previous simulation by a To Workspace block in either `Timeseries` or `Structure with Time` format for use in a later simulation

Limitations

- The data expressions that you specify must evaluate to one of these types of data:
  - A MATLAB `timeseries` object
  - A structure of MATLAB `timeseries` objects
  - An array or structure containing an array of simulation times and corresponding signal values

Signal Builder Block

Using a Signal Builder block, you can create interchangeable groups of piecewise linear signal sources to use in a model.



For examples of how to use a Signal Builder block, see:

- “Load Data for an Input Test Case” on page 61-151
- `sldemo_pid2dof`
- `sf_test_vectors`

Recommended Uses

Use the Signal Builder block to create and load signal groups to use in testing.

These products integrate the Signal Builder block into their workflows:

- Simulink Test
- Simulink Coverage

Limitations

- The Signal Builder block has requirements for the spreadsheet data. Organize Excel spreadsheet data using the format described in "Importing Signal Group Sets" on page 64-88.
- Data stores are not supported.
- The data type for signals must be `double`.

Comparison of Signal Loading Techniques

In this section...

Techniques

Simulink provides several techniques for importing signal data into a model. Each signal data loading technique uses a block to represent signal data sources visually. You can use a:

- Source on page 61-120 block, such as the Sine Wave block, to generate signal data as input to another block
- Root-level input port on page 61-121 (Inport, Enable, or Trigger block). Loading signal data to root-level input ports, either manually or by using the Root Inport Mapper tool. “Root-level input ports” refers to both approaches and “Root Inport Mapper tool” refers specifically to using that tool.
- From File on page 61-123 block
- From Spreadsheet on page 61-124 block
- From Workspace on page 61-125 block
- Signal Builder on page 61-126 block

Impact of Loading Techniques on Block Diagrams

To test reusable systems, it is helpful to separate signal data loading from the block diagram. Loading root-level input ports provides a good framework for testing complex systems on an ongoing basis. Using the Root Inport Mapper tool allows you to visualize the signal data that is loaded.

To perform temporary testing on standalone models, adding data loading blocks can be simpler and make the source of the signal data visible from within the block diagram.

To avoid adding data loading blocks to a model, load the signal data to root-level input ports. You can change the data to use by changing the **Configuration Parameters >**

Data Import/Export > Input parameter. You do not need to add or change blocks, or reset block parameters. You can use the Root Inport Mapper tool to update the **Input** parameter so that it reflects the mapping of signal data to the appropriate ports.

Test Harness Models

You can use a test harness model with different test cases to load:

- Different signal data to a port
- Signal data to different ports

The Signal Builder block is useful in test harness models to simplify loading data to multiple input ports.

Alternatively, you can use the Root Inport Mapper tool to create scenarios that you can use instead of creating separate test harness models. Creating separate test harness models can be simpler to create than setting up root inport mapping. However, you then need to manage the separate test harness models. For an example of using root inport mapping instead of a test harness, see "Converting Harness-Driven Models to Use Harness-Free External Inputs" on page 61-222

Comparison of Techniques

Each technique addresses many of these modeling considerations:

Purpose of Importing Signal Data

The model development phase you are in and your goals for loading signal data can influence the signal loading technique that you choose.

Modeling Goal	Supported Techniques
Perform local, temporary testing by importing a small set of signal data	All From File, From Spreadsheet, and From Workspace blocks work well for this goal. Root-level input ports for reusable systems.
Test a model that you want to use as a referenced model	Root-level input ports.
Verify a model by using multiple test cases	Root Inport Mapper tool, using exported signal data.
Represent a continuous plant	All Root-level input ports work well for this goal.
Test a discrete algorithm	All Root-level input ports work well for this goal.

Model Development Phase

Modeling Requirement	Suggested Signal Loading Technique
Initial prototyping	Signal values that source blocks generate meet your requirements, use Source blocks on page 61-120. From File, From Spreadsheet, and From Workspace blocks.
System testing, sharing, and code generation	Root-level input port on page 61-121. You can use the Root Inport Mapper tool to create and map signal data to load

For many models, loading signal data to a root inport block is an effective approach. The Root Inport Mapping tool on page 61-137 provides a convenient way to load data for several signals to root inports.

Signal Data

The amount, source, and kind of the signal data can influence the signal loading technique that you choose.

Signal Data	Supported Techniques
Large data set	From File and From Spreadsheet blocks work well for large data sets, because they incrementally load the data. You can log big simulation data to persistent storage and then incrementally load data from a file to root-level Inport blocks.
Data exported by using a To File block	From File block.
Data exported by using a To Workspace block	From Workspace block.
Excel or CSV spreadsheet	From Spreadsheet and Signal Builder blocks, which can import Microsoft Excel (all platforms) or CSV (Microsoft Windows platform with Microsoft Office only) spreadsheet data directly into Simulink.
Variable-size signals	From Workspace block.

Data Format or Type

Each of the signal loading techniques supports a wide range of data formats for signal data (such as array or `Dataset`). A few signal loading techniques have some limitations for specific formats.

Note Some of the Root Inport Mapper tool map modes do not support all the data types that you can use with the tool. For details, see "Choose a Base Workspace and MAT-File Format" on page 61-186.

Data Format or Type	Supported Techniques
Array	All. For array data in a Version 7.0 MAT-file, the From File block loads only double signal values. Use Version 7.3 MAT-files for other types of signal data.
Structure with time	All.
Structure without time	All.
MATLAB `timeseries`	All.
`Simulink.SimulationData.Dataset`	All.
Enumeration	All except that Signal Builder block can load, but not output enumerations.
Fixed-point	Signal Builder block can load, but not output fixed-point data. From File block has a word length limit of 32 or fewer bits.
Function-call	Root-level input ports (select the **Output function call** parameter).

Bus Support

You can use any of the signal loading techniques to load bus data. However, for some kinds of bus data, you need to use a specific technique.

Type of Bus or Bus Element	Supported Techniques
Virtual and nonvirtual buses	All techniques support both types of buses. The Root Inport Mapper tool does not support loading bus data in rapid accelerator mode.

Type of Bus or Bus Element	Supported Techniques
Partial bus specification	For the Signal Builder block, the outputs for loaded bus data are either scalar double signals or a flat virtual bus. From File uses ground values for unspecified bus elements.
Array of buses signals	Root-level input ports.

Time Points

The kind of time points in signal data impacts the signal loading technique that you choose.

Time Points for Signal Data	Supported Techniques
Single time point	All.
Continuous	All.
Discrete	All.
Repeated sequence without time	Structure data by using root-level input ports and From Workspace block.

Location for Data Storage

Whether you want to store the signal data with the model or separate from the model impacts the signal loading technique that you choose.

Location	Supported Techniques
In a block	Signal Builder block.
In the base or model workspace	From Workspace block. Root-level input ports or a Trigger, Enable, or Function-Call Subsystem block.
In a MAT-file separate from the model file	From File block. You can log big simulation data to persistent storage and then incrementally load data from a file to root-level Inport blocks.

Location	Supported Techniques
In an Excel or CSV spreadsheet	From Spreadsheet block. **Tip** For Excel and CSV spreadsheet requirements, see "Storage Formats" on page 61-248. Loading CSV data is supported only for Microsoft Windows platforms. You can use a Signal Builder block to import data from a spreadsheet. However, that block loads all the spreadsheet data into MATLAB memory and stores the data in the model. The From Spreadsheet incrementally loads the data directly from the spreadsheet.

Signal Data Inspection

The Root Inport Mapper tool, From File block, and Signal Builder block each provide an interface for plotting and inspecting the signal data to load.

Handling of Loaded Data

How Simulink processes the signal data as it loads it into a model impacts the signal logging technique that you choose.

Data Loading Handling	Supported Techniques
Incremental data loading	From File and From Spreadsheet blocks.
Interpolation	All.
Extrapolation	From File, From Spreadsheet, and blocks. For information about From Workspace extrapolation, see "Form output after final data value by".
Zero-crossing detection	All except root-level input ports.
Fast restart	All techniques.

Simulation Mode

All signal loading techniques support all simulation modes except for SIL or PIL. Some techniques have limitations for specific simulation modes.

Simulation Modes	Supported Techniques
Normal and accelerator	All.
Rapid accelerator	All, with these rapid accelerator exceptions: Root —level input ports support only array and structure data. From Workspace block does not support `timeseries` format.
ERT/GRT	All. From Workspace and From File blocks are not tunable.
SIL or PIL	From Workspace block.
External mode	All. Root-level input ports do not load bus data in external mode.

Map Data Using Root Inport Mapper Tool

In this section...

Use the Root Inport Mapper tool to import, visualize, and map signal and bus data to root-level inports.

Root-level inport mapping imports signal data meets most modeling requirements and maintains model flexibility.

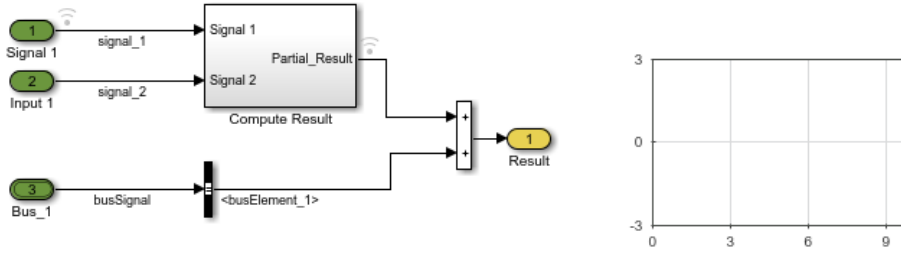
- Test your model with signals from the workspace and use your model as a referenced model in a larger context without any modification. Test signals in your model without disconnecting the inports and connecting sources to them.
- Use the Root Inport Mapper tool to update the **Input** parameter based on the signal data that you import and map to root-level inports.
- Visually inspect signal data without loading all the signal data into MATLAB memory.

To use the Root Inport Mapper tool:

1. Create signal data in the MATLAB workspace.
2. For a Simulink model, import the data from the workspace. You can visualize the data you import.
3. Map the data to root-level inports.
4. Simulate the model.
5. Save the Root Inport Mapper scenario.

The Model

This model has three root-level Inport blocks. Two of the Inport blocks output scalar signals and the other Inport block outputs bus data. Open the model.



This example shows how you can use the Root Inport Mapper tool to test the model with data. This approach can be useful for performing standalone testing of a model that another model references.

Create Signal Data

You can define the signal data as MATLAB `timeseries` objects.

1 Define the time values for the signal data.

```
sampleTime = 0.01;
endTime = 10;
numberOfSamples = endTime * 1/sampleTime +1;
timeVector = (0:numberOfSamples) * sampleTime;
```

2 Create the data for the two scalar signals. Naming the data variable to match the name of the corresponding signal makes it easier to map data to signals.

```
signal_1 = timeseries(sin(timeVector)*10,timeVector);
signal_2 = timeseries(rand(size(timeVector)),timeVector);
```

3 Create the signals for the bus.

```
busSignal.busElement_1 = timeseries(cos(timeVector)*2,timeVector);
busSignal.busElement_2 = timeseries(randn(size(timeVector)),timeVector);
```

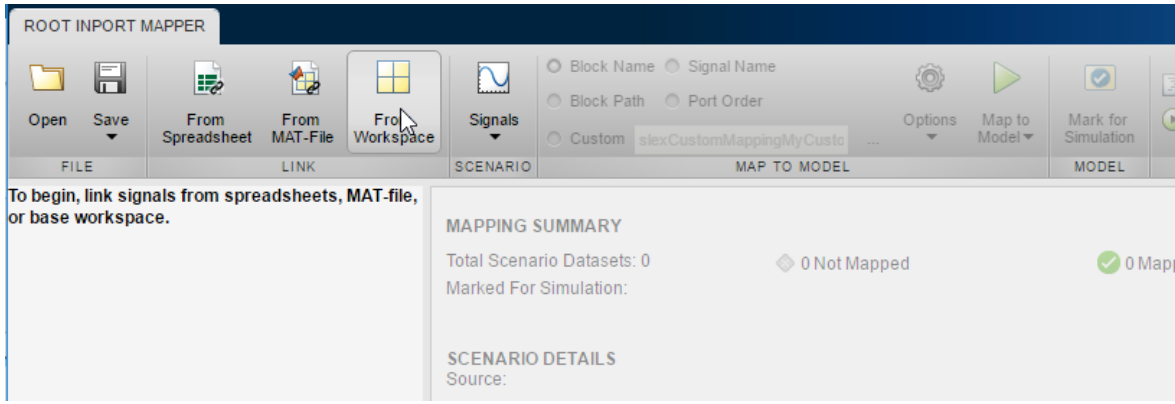
4 Create the bus object for the output data type of the `Bus_1` Inport block. You can create the bus object from the bus signal that you defined. Use a bus object for bus signals that cross model reference boundaries.

```
busInfo = Simulink.Bus.createObject(busSignal);
```

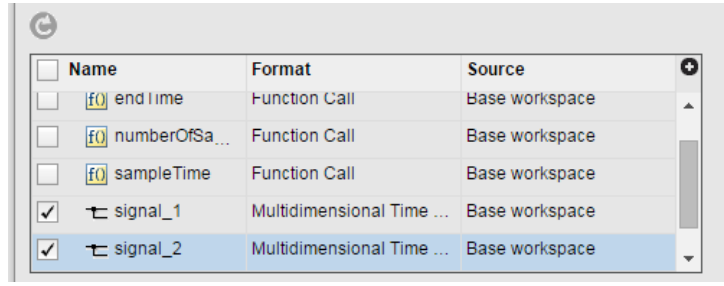
Import and Visualize Workspace Signal Data

Import the signal data that you created from the workspace into the Root Inport Mapper tool. Then you can use the tool to visualize the imported data.

1. Open the Root Inport Mapper tool. Open the Block Parameters dialog box for one of the Inport blocks in the model and click **Connect Input**.
2. In the Root Inport Mapper tool, select the **From Workspace** button.



3. In the Import dialog box, specify a MAT-file to save signals to. For this example, use the default.
4. To clear the data variables, click the **Name** check box. Then click the check boxes for the `busSignal`, `signal_1`, and `signal_2` signals.

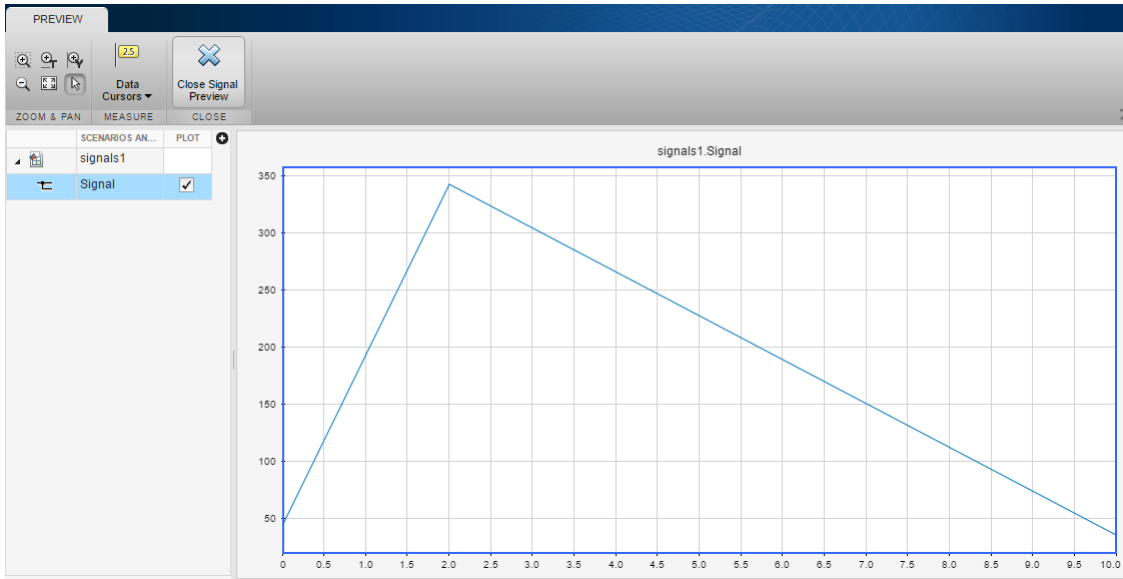


Although in this example you select all the signals, you can select a subset of signals.

5. Leave the **Convert signals into a scenario dataset and save to MAT-file** check box enabled and click **OK**.

6 You can visualize signals. In the Root Inport Mapper dialog box toolbar, click **Signals** > **Preview Signals**.

The **Preview** tab appears. You can select signals to plot. For example, to see a plot of `signal_1`, in the Navigation pane, expand the scenario data set (in this example, the top node, `untitled`) and then expand the `signal_1` entry. Select the check box for `signal_1(1,1,:)` to plot the data.



7 Close the **Preview** tab by clicking the **Close Signal Preview** button.

Map the Data to Inports

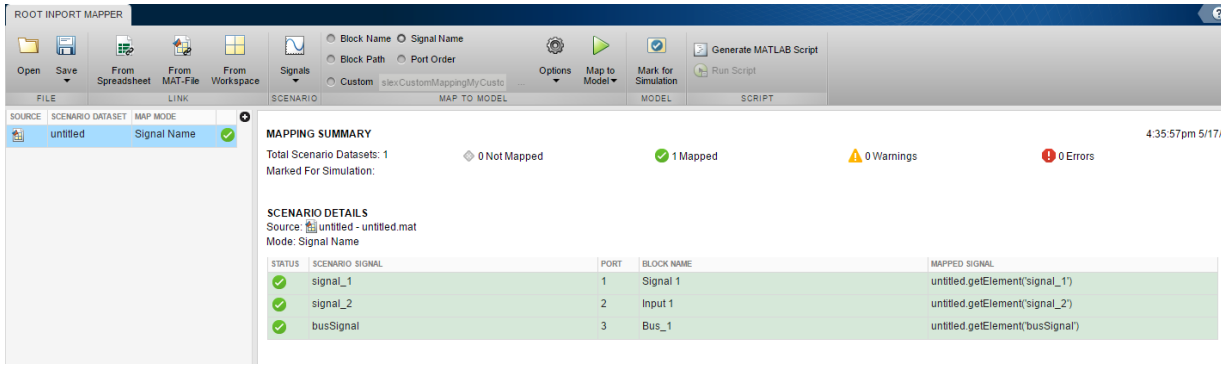
After you import the data, you map which data to use for specific Inport blocks.

1 Select the map mode, which specifies the criteria the mapping uses. In the toolbar, select the **Signal Name** option button.

The signals in this model have names, so mapping based on signal names makes it very clear which data is going to an Inport block.

2 You can specify options for the mapping. In the toolbar, select **Options**. Select **Update Model**, which updates the model after you do the mapping. Compiling the model verifies that signal dimensions and data types match between the data and the Inport blocks.

3 Map the data. In the Navigation pane, select the scenario data set. In the toolbar, click **Map to Model**. The dialog box shows the mapped data.



Save the Mapping and Data

If you want to reuse the mapping and data that you have set up, you can save it as a scenario. In the Root Inport Mapper tool, click **Save** > **Save As** and save the scenario as an `.mldatx` file.

Simulate the Model

1 In the Navigation pane, select the scenario data set.

2 In the toolbar, click **Mark for Simulation**.

The model is now set up to simulate using the workspace signal data that you mapped to root-level Inport blocks.

3 Simulate the model.

This model includes a Dashboard block that shows the data used during simulation for `signal_1`. The plot matches the plot you did when you visualized the data as part of the data import process.

Load Data Logged In Another Simulation

In this section...

A common source of signal data to load into a model is data that you log from a simulation. You can use the signal data captured from a simulation as roundtrip input to:

- Simulate the same model again from a known starting point.
- Test simulation results.
- Simulate another model starting with the captured signal values from a model. For example, you can log signal data when you simulate a model. Then load the signal data from that simulation as inputs to a second model that you want to reference from the first model.

You can capture the signal data from a simulation in a workspace or in a file. Use one of these techniques to capture signal data from a simulation:

- Signal logging
- To Workspace block
- To File block
- Scope block
- In the **Configuration Parameters** > **Data Import/Export** pane, the **Output**, **States**, or **Final states** parameters
- Data store
- The `sim` command configured to log simulation data

For an example of using simulation data for roundtrip signal data loading, see “Load Data to Model a Continuous Plant” on page 61-146.

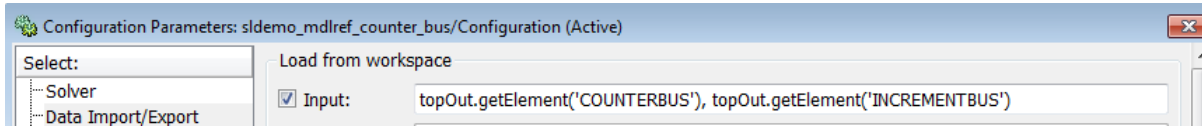
Load Logged Data

Here is a workflow for using signal logging data for standalone simulation of a referenced model. You can use a similar approach for other data logged in `Dataset` format.

1. Use the default signal logging output variable, `logsout`, or specify a variable using the **Configuration Parameters** > **Data Import/Export** > **Signal logging** edit box.
2. Simulate the parent model.

   The signal logging output is a `Simulink.SimulationData.Dataset` object.
3. Use the `Simulink.SimulationData.Dataset.getElement` method to access the logged data. The logging data for individual signals is stored in `Simulink.SimulationData.Signal` objects.
4. For the referenced model that you want to simulate standalone, use the `Simulink.SimulationData.Signal.getElement` method to specify signal elements for the **Configuration Parameters** > **Data Import/Export** > **Input** parameter.

   For example:



5. Simulate the referenced model.

For an example of loading signal logging data for a model that uses model referencing, see the open the `sldemo_mdlref_bus` model. After you open the model, double-click the blue block labeled **Interface Specification** and see the sections called:

- Logging Model Reference Signals
- Loading Data

Also, the “Load Data to Model a Continuous Plant” on page 61-146 example illustrates loading signal logging data.

To import signal logging data for array of buses signals, see “Import Array of Buses Data” on page 61-175.

Configure Logging to Meet Loading Requirements

Different logging techniques support different data formats. Most logging techniques support the `Dataset` format, which provides a consistent data format for logged signal

data. You can use the `Simulink.SimulationData.Dataset` constructor to convert other data formats to `Dataset` format.

To log only the data that you require, use the **Configuration Parameters > Data Import/Export > Logging intervals** parameter to specify start and stop time intervals.

Load Data to Model a Continuous Plant

A continuous plant model uses signal data that is smooth and uninterrupted in time. There is signal data for each time value. A continuous plant model uses a continuous solver (any solver other than an explicit discrete solver). The solver can be fixed-step or variable. The model includes blocks from the Continuous library in Simulink, such as an Integrator block.

To load data to represent a continuous plant, consider using either a root-level input port or a From Workspace block. Using a From Workspace block can be useful when loading data to a port buried deep within a model.

For the signal data:

- Specify a time vector and signal values extracted from a continuous plant. For example, extract from data that you acquire experimentally or from the results of a previous simulation.
- Use any of the data formats listed in "Specify Input Data" on page 61-155. Here are recommended formats for the following imported data sources:
  - Another simulation — `Dataset`
  - An equation — MATLAB time expression
  - Experimental data — MATLAB `timeseries`, structure with time, a structure without time, or a data array

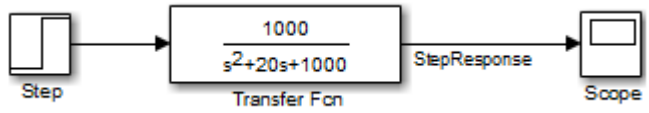
  For structure data, see "Specify Time Data" on page 61-162.

Use Simulation Data to Model a Continuous Plant

This example illustrates how to reuse signal logging data from the simulation of one model in the simulation of a second model. For more information, see "Load Data Logged In Another Simulation" on page 61-143.

When reusing data from a variable step size simulation for simulation in another model, the second simulation must read the data at the same time steps as the first simulation.

1 Open the `ex_data_import_continuous` model.



This model uses the `ode15s` solver and produces continuous signals.

2 To use the output of this model as input to the simulation of another model, log the signal that you want to reuse. In the Simulink Editor, select that signal, click the **Simulation Data Inspector** button arrow  and click **Log Selected Signals to Workspace**.

Note To enable signal logging, select the **Configuration Parameters > Data Import/Export > Signal logging** parameter. This model has **Signal logging** enabled.

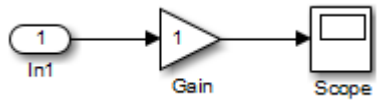
---

3 Simulate the model.

Simulating the model saves a variable-step signal to the workspace, using the `logsout` variable. The signal logging output is a `Simulink.SimulationData.Dataset` object.

Use the `Simulink.SimulationData.Dataset.getElement` method to access the logged data. The logged data for individual signals is stored in `Simulink.SimulationData.Signal` objects. For this model, there is one logged signal: `StepResponse`.

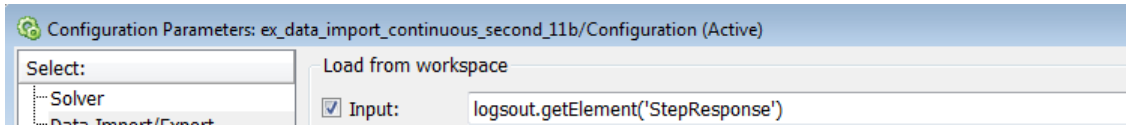
4 Open a second model, named `ex_data_import_continuous_second`.



You can configure this second model to simulate using the logged data from the first model. In this example, the second model uses a root-level Inport block to import the logged data. The Inport block has the **Interpolate data** option selected.

5 In the second model, select the **Configuration Parameters > Data Import/Export > Input** parameter.

Use the `Simulink.SimulationData.Signal.getElement` method to specify the `StepResponse` signal element:



6 Specify that for the second model, the Simulink solver runs at the time steps specified in the saved data (`u`). In the Data Import/Export pane, set the **Output options** parameter to `Produce additional output` and the **Output times** parameter to:

```
logsout.getElement('StepResponse').Values.Time
```

7 Simulate the second model.

Note Simulink does not feed minor time step data through root input ports. For details about minor time steps, see “Minor Time Steps” on page 3-22.

More About

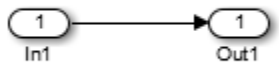
- “Overview of Signal Loading Techniques” on page 61-120

Load Data to Test a Discrete Algorithm

Discrete signals are signals that you define using evenly spaced time values. One signal value is read at each time step, using the sample time of the source block.

Use a structure that has an empty time vector, which results in the model using the sample time of the source block. Using this approach avoids possible mismatches between the vector and the Simulink time steps. The double-precision rounding used by computers and the values expected by Simulink can differ.

Suppose that you want to import signal data for this simple model.



1. In the Block Parameters dialog box for the Inport block:
   - Set the sample time.
   - Clear the **Interpolate data** parameter.
2. For the data that you want to import, specify a structure variable that does *not* include a time vector. For example, for the variable called `import_var`:

   ```
   import_var.time = [];
   import_var.signals.values = [0; 1; 5; 8; 10];
   import_var.signals.dimension = 1;
   ```

   The input for the first time step is read from the first element of an input port value array. The value is `0`. The value for the second time step is read from the second element of the value array (`1`), and so on.

   For details about how to specify the signal value and dimension data, see "Create Data Structures for Root-Level Inputs" on page 61-161.
3. Select the **Configuration Parameters > Data Import/Export > Input** parameter and specify `import_var` for the data to import.

If you are using a From Workspace block to import data, use a similar approach. In addition, set the **Form output after final data value by** parameter to a value other than `Extrapolation`.

Load Data for an Input Test Case

In this section...

For most input test cases, you try to minimize the number of time points. The signal data you load includes samples with ramps and discontinuities.

Guidelines for Importing a Test Case

Typically when importing a test case data, you want to minimize the number of time points. The test data focuses on discontinuities in the signal data.

- Create a signal that has ramps and steps. In other words, the signal has one or more discontinuities.
- Create the signal using the fewest points possible.
- Have the Simulink solver execute at the specified discontinuities.

To import this signal in Simulink, use a From Workspace, From File, or Signal Builder block, all of which support zero-crossing detection.

You can load data of these types:

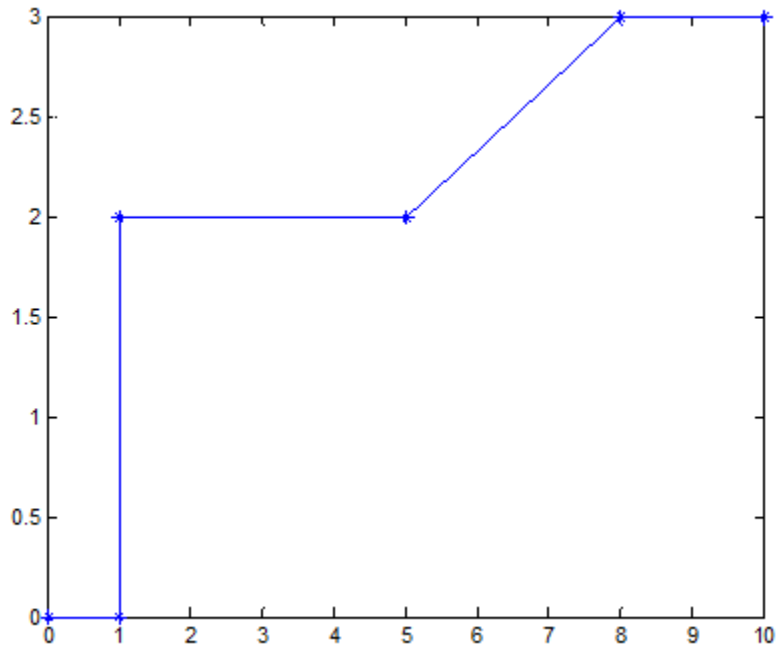
- A `Simulink.SimulationData.Dataset`
- Array
- `Simulink.SimulationData.Signal`
- Structure
- A structure array containing data for all input ports.
- Empty matrix — Use an empty matrix for ports for which you want to use ground values, without having to create data values.
- Time expression

Specify a time vector and signal values, but specify only the time steps at points where the shape of the output jumps. For details about specifying a time vector, see “Specify Time Data” on page 61-162.

Use any of the input data formats described in “Forms of Input Data” on page 61-157, except for MATLAB time expressions.

Example of Test Case Data

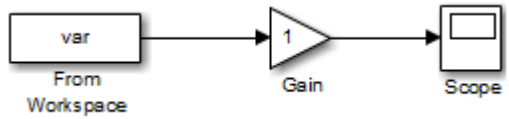
The following is an example of test case data:



The following two examples use this test case data.

Use From Workspace Block for Test Case

1 Open the model `ex_data_import_test_case_from_workspace`.



2 Enable zero-crossing detection. In the From Workspace block dialog box, select **Enable zero-crossing detection**. Zero-crossing detection allows you to capture discontinuities accurately.

3 Create a signal structure for the test case. At each discontinuity, enter a duplicate entry in the time vector, which generates a zero crossing and forces the variable-step solver to take a time step at this exact time. For details, see "Load Data Using the From Workspace Block" on page 61-251.

Define the `var` structure representing the test case:

```
var.time = [0 1 1 5 5 8 8 10];
var.signals.values = [0 0 2 2 2 3 3 3]';
var.signals.dimensions = 1;
```

4 To import the test case structure, in the From Workspace block dialog box, in the **Data** parameter, specify `var`.

5 Simulate the model. The Scope block reflects the test case data.

Use Signal Builder Block for Test Case

Instead of using a From Workspace block, you can use a Signal Builder block to either:

- Create a signal interactively
- Import a signal from a MAT-file

1 Open the `ex_data_import_signal_builder` model.

2 Create a structure and save it in a MAT-file:

```
var.time = [0 1 1 5 5 8 8 10];
var.signals.values = [0 0 2 2 2 3 3 3]';
var.signals.dimensions = 1;
```

```
var.signals.label = 'var';
save var.mat var
```

3. Open the Signal Builder dialog box by double-clicking the Signal Builder block.
4. Select **File** > **Import From File** menu item, and select the `var.mat` file.
5. In the **Select** parameter, select `Replace existing dataset`. In the **Data to Import** section, select the **Select All** check box. Confirm the selection and click **OK**.

   The Signal Builder block display reflects the test case data.

- “Overview of Signal Loading Techniques” on page 61-120

Load Data to Root-Level Input Ports

In this section...

You can load data from a workspace to a root-level inport modeled using one of these blocks:

- Inport block
- Enable block
- Trigger block that has an edge-based (rising, falling, or either) trigger type

These blocks import data from the workspace based on the value of the **Configuration Parameters > Data Import/Export > Input** parameter.

Tip To import many signals to root-level input ports, consider using the Root Inport Mapper tool. For more information, see “Map Root Inport Signal Data” on page 61-182.

You can also import data from a workspace using a From Workspace block. For details, see the From Workspace documentation and “Load Data for an Input Test Case” on page 61-151.

Specify Input Data

You can specify input data manually, using the **Input** configuration parameter. To load many signals to root-level input ports, consider using the Root Inport Mapping tool,

which automatically specifies in the **Input** parameter the data you map using the tool. For details, see "Map Data Using Root Inport Mapper Tool" on page 61-137.

1 Select the **Configuration Parameters** > **Data Import/Export** > **Input** parameter.

Note The use of the **Input** configuration parameter is independent of the setting of the **Format** configuration parameter for saving logged data.

2 Enter an external input specification in the adjacent edit box and click **Apply**. For a list of the forms of data you can specify, see "Forms of Input Data" on page 61-157.

In the **Input** box, specify the signal input using one of these approaches:

- Create data at run-time for each simulation time step using the input `u = UT(t)` for either a MATLAB function (expressed as a string) or MATLAB expression.
- Specify the data directly, using one of the input data forms described in "Forms of Input Data" on page 61-157.

Comma-Separated List

If you specify `Dataset` data, specify only one `Dataset` object for the **Input** parameter. Do not include it in a comma-separated list.

Each variable or expression must evaluate to an appropriate object that corresponds to a specific root-level input port in the model. Each variable or expression in the list must evaluate to the appropriate object that corresponds to one of the root-level input ports of the model. The first item corresponding to the first root-level input port, the second to the second root-level input port, and so on. The dimensions for each data sample must match the dimensions of the data specified in the input block parameter.

For an Enable or Trigger block, the signal driving the enable or trigger port must be the last item in the comma-separated list. If you have both an enable and a trigger port, then specify:

- The enable port as the next-to-last item in the list
- The trigger port as the last item

Use an empty matrix to specify ground values for a port. For example, to load data for input ports `in1` and `in3`, and to use ground values for port `in2`, enter the following in the **Input** parameter:

```
in1, [], in3
```

Forms of Input Data

The input data can take these forms:

- `Simulink.SimulationData.Dataset` object — Collection of logged data in MATLAB `timeseries` format. For details, see "Create Dataset Data for Root-Level Inputs" on page 61-158.
- MATLAB `timeseries` — See:
  - "Create MATLAB Timeseries Data for Root-Level Inputs" on page 61-159
  - "Load Bus Data to Root-Level Input Ports" on page 61-170
- `Simulink.SimulationData.DatasetRef` — See "Load Big Data for Simulations" on page 61-54
- MATLAB `timetable` — For details, see "Create MATLAB Timetable Data for Root-Level Inputs" on page 61-160.
- Array — See "Create Data Arrays for Root-Level Inputs" on page 61-165.
- `Simulink.SimulationData.Signal` — For details, see "Load Data Logged In Another Simulation" on page 61-143.
- Structure — To simplify the specification of external data to input, you can load data for a subset of root-level input port blocks. This approach avoids having to create data structures for the ports for which you want to use ground values. For information about ground values, see "Initialize Signals and Discrete States" on page 64-53. See "Create Data Structures for Root-Level Inputs" on page 61-161.
- Structure array containing data for all input ports.
- Empty matrix — Use an empty matrix for ports for which you want to use ground values, without having to create data values.
- Time expression — See "Create MATLAB Time Expressions for Root Inports" on page 61-168.

For information about importing bus data, see "Load Bus Data to Root-Level Input Ports" on page 61-170.

Time Values for the Input Parameter

Time values that you specify in the **Input** parameter do not control the times the solver uses. Solvers have their own logic for propagating time and might require input data at

an arbitrary time value. The **Interpolate** parameter setting for the root-level input block (for example, the root-level Inport block) specifies how to handle output at time steps for which no corresponding workspace data exists.

Data Loading

If you select the **Interpolate data** option for the corresponding Inport, Enable, or Trigger block, Simulink linearly interpolates or extrapolates input values as necessary.

Simulink resolves symbols used in the external input specification as described in "Symbol Resolution" on page 59-136. The `sim` command provides some data import capabilities that are available only for programmatic simulation.

If you use a `Simulink.SimulationData.Dataset` object that includes a `matlab.io.datastore.SimulationDatastore` object as an element, then the data stored in persistent storage is streamed in from a file. For more information, see "Load Big Data for Simulations" on page 61-54.

Create Dataset Data for Root-Level Inputs

You can use a Dataset object as a value for the **Configuration Parameters > Data Import/Export > Input** parameter. Specify only one `Dataset` object and do not include it in a comma-separated list. The number of elements in the data set must match the number of root-level input ports.

Dataset Elements

A `Dataset` object can include elements with different data types.

For individual non-bus signal data, you can specify these types of data for `Dataset` elements:

- `timeseries`
- `timetable`
- `matlab.io.datastore.SimulationDatastore`
- `double` vectors or structure of `double` data
- `timeseries`
- a `Simulink.SimulationData.Signal`, `Simulink.SimulationData.State`, or `Simulink.SimulationData.DataStoreMemory` object

For bus signals, use a structure with a data element for each leaf signal, using one of these formats:

- A MATLAB `timeseries` object
- A MATLAB `timetable` object
- A `matlab.io.datastore.SimulationDatastore` object
- An empty matrix
- An array that meets one of these requirements:
  - An array with time in the first column and the remaining columns each corresponding to an input port. See "Create Data Arrays for Root-Level Inputs" on page 61-165.
  - An `nx1` array for a root inport that drives a function-call subsystem.
- Another structure, with data elements for each signal that are consistent with these requirements for a structure for bus data

Create a Dataset Object for Inport Blocks

To generate a `Simulink.SimulationData.Dataset` object from the root-level Inport blocks in a model, you can use the `createInputDataset` function. Signals in the generated dataset have the properties of the Inport blocks and the corresponding ground values at model start and stop times. You can create `timeseries` and `timetable`objects for the time and values for signals for loading. The other signals use ground values.

You can load into a root-level input port data specified by a MATLAB `timeseries` object that resides in a workspace.

Note This documentation about importing MATLAB timeseries data includes examples of root Inport blocks. Unless specifically noted otherwise, the examples are applicable to root-level Enable, Trigger, and From Workspace blocks.

Create MATLAB Timeseries Data for Root-Level Inputs

Enum Data

If you specify an `Enum` in `timetable` data, then in the Inport block, clear the **Interpolate data** block parameter.

Create MATLAB Timetable Data for Root-Level Inputs

Note In general, you can load MATLAB`timetable` data the same way you load MATLAB timeseries data (see "Create MATLAB Timeseries Data for Root-Level Inputs" on page 61-159).

The time value column (the first dimension) cannot include `NAN` or `Inf` values. The time column cannot be sparse.

Time Dimension

When you create a MATLAB `timeseries` object to import data to Simulink, the time dimension (number of time samples) depends on the dimension and the type of signal data.

Signal Data Dimension or Type	Time Dimension Alignment	Example of timeseries Constructor

Scalar or a 1D vector	First	Constructor for a scalar signal. Time is aligned with the first dimension.
		`t = (0:10)';`
		`ts = timeseries(sin(t), t);`

2D (including row and column vectors) or greater	Last	Constructor for a matrix signal. Time is aligned with the last dimension.
		`t = 0;`
		`ts = timeseries([1 2; 3 4], t);`

2D row vector, and there is only one time step	Last	`'InterpretSingleRowDataAs3D', true`
		For example:
		`t = 0;`
		`ts = timeseries([1 2], t, 'Interpret`

Create Data Structures for Root-Level Inputs

Data Structures

You can load to a root-level input port data from the workspace in the form of a structure, whose name you specify in the **Configuration Parameters > Data Import/ Export > Input** parameter. For information about defining MATLAB structures, see "Create Structure Array" (MATLAB).

You can specify structures for the model as a whole or on a per-port basis. For information about specifying per-port structures for the **Input** parameter, see "Structures for All Ports or for Each Port" on page 61-161.

The structure always includes a signals substructure, which contains a values field and a dimensions field. Depending on the modeling task that you want to perform, the structure can also include a time field. The form of a structure that you use depends on the type of signals for which you are importing data:

- Discrete signals (the signal is defined at evenly spaced values of time) — Use a structure that has an empty time vector. Specify a `signals` field, which contains an array of substructures, each of which corresponds to a model input port.
- Continuous signals (the signal is defined for all values of time) — The approach that you use depends on whether the data represents a smooth curve (continuous) or a curve that has discontinuities (jumps) over its range (discrete). Specify a `signals` field, which contains an array of substructures, each of which corresponds to a model input port. You can specify a `time` field, which contains a time vector. See "Specify Time Data" on page 61-162.

For examples of importing data for discrete and continuous signals, see:

- "Load Data to Test a Discrete Algorithm" on page 61-149
- "Load Data to Model a Continuous Plant" on page 61-146
- "Load Data for an Input Test Case" on page 61-151

Structures for All Ports or for Each Port

You can specify one structure to provide input to all root-level input ports in a model, or you can specify a separate structure for each port.

The per-port structure format consists of a separate structure-with-time or structure-without-time for each port. The input data structure for each has only one `signals` field.

To specify this option, enter the names of the structures in the **Input** text field as a comma-separated list, `in1, in2,..., inN`. The value `in1` is the data for first input port in the model, `in2` for the second input port, and so on.

To specify one structure for all ports:

- The `values` field must contain an array of inputs for the corresponding input port. If you specify a time vector, each input must correspond to a time value specified in the `time` field.

  If the inputs for a port are scalar or vector values, the `values` field must be an `M-by-N` array. If you specify a time vector, `M` must be the number of time points specified by the `time` field and `N` is the length of each vector value.

  If the inputs for a port are matrices (2-D arrays), the `values` field must be an `M-by-N-by-T` array. `M` and `N` are the dimensions of each matrix input and `T` is the number of time points. For example, suppose that you want to input 51 time samples of a 4-by-5 matrix signal into one of the input ports in your model. Then, the corresponding `dimensions` field of the workspace structure must equal `[4 5]` and the `values` array must have the dimensions `4-by-5-by-51`.
- The `dimensions` field specifies the dimensions of the input. If each input is a scalar or vector (1-D array) value, the `dimensions` field must be a scalar value specifying the length of the vector (1 for a scalar). If each input is a matrix (2-D array), the `dimensions` field must be a two-element vector whose:
  - First element specifies the number of rows in the matrix
  - Second element specifies the number of columns

Note Set the **Port dimensions** parameter of the Inport or the Trigger block to be the same value as the `dimensions` field of the corresponding input structure. If the values differ, you get an error message when you try to simulate the model.

Specify Time Data

You can specify a time vector of doubles as part of the data structure to import. For example, specify a time vector when importing signal data to represent a continuous plant or to create a test case. To test a discrete algorithm, use a structure with an empty time vector. This table provides additional recommendations for specifying time values, based on the kind of signal data you want to load.

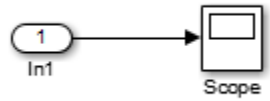
Signal Data	Time Data Recommendation
Inport or Trigger block with a discrete sample time	Do not specify a time vector. Simulink loads one signal value at each time step.

Evenly spaced discrete signals	Use an expression in this form:
	`timeVector = timeStep * [startTime:numSteps-1]'`
	The vector is transposed. Also, because the start time is a time step, you need specify the number of steps you want minus 1. For example, to specify 50 time values at 0.2 time steps:
	`T1 = 0.2 * [0:49]'`
	Note Do *not* use an expression in this form:
	`timeVector = [startTime:timeStep:endTime]'`
	For example, do not use:
	`T2 = [0:0.2:10]'`
	This time vector form is not equivalent to the form that multiplies by time steps (`T1`), because of double-precision rounding used by computers. Simulink expects exact values, with no double-precision rounding. Using the `T2` form can lead to mismatches between the provided time vector and the times steps taken by Simulink, resulting in unexpected simulation results.

Unevenly spaced values	Use any valid MATLAB array expression; for example, `[1:5 5:10]` or `(1 6 10 15)`. The From Workspace, From File, and Signal Builder blocks support zero-crossing detection. If the root-level input port is connected to one of those blocks, you can specify a zero-crossing time by using a duplicate time entry.

Examples of Specifying Signal and Time Data

In the first example, consider the following model that has a single input port:

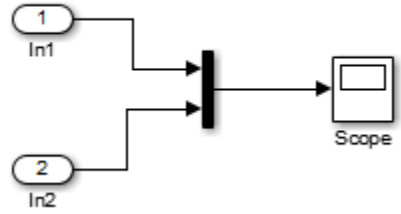


1. Create an input structure for loading 11 time samples of a two-element signal vector of type `int8` into the model:

```
N = 10
Ts = 0.1
a.time = Ts*[0:N]';
c1 = int8([0:1:10]');
c2 = int8([0:10:100]');
a.signals(1).values = [c1 c2];
a.signals(1).dimensions = 2;
```

2. In the **Configuration Parameters** > **Data Import/Export** > **Input** parameter edit box, specify the variable `a`.
3. In the Inport block dialog box, in the **Signal Attributes** tab, set **Port dimensions** to `2` and **Data type** to `int8`.

As another example, consider a model that has two inputs.



Suppose that you want to input a sine wave into the first port and a cosine wave into the second port. Define a structure, `a`, as follows, in the MATLAB workspace:

```
a.time = 0.1*[0:1]';
a.signals(1).values = sin(a.time);
```

```
a.signals(1).dimensions = 1;
a.signals(2).values = cos(a.time);
a.signals(2).dimensions = 1;
```

Enter the structure name (`a`) in the **Configuration Parameters** > **Data Import/Export** > **Input** parameter edit box.

Note In this model you do not need to specify the dimension and data type, because the default values are `1` and `double`.

Create Data Arrays for Root-Level Inputs

You can load to a root-level input port data from the workspace in the form of a data array, which you specify in the **Configuration Parameters** > **Data Import/Export** > **Input** parameter.

This import format consists of a real (noncomplex) matrix of data type `double`. The first column of the matrix must be a vector of times in ascending order. The remaining columns specify input values.

- Each column represents the input for a different Inport or Trigger block signal (in sequential order).
- Each row is the input value for the corresponding time point.

For a Trigger block, the signal that drives the trigger port must be the last data item.

The total number of columns of the input matrix must equal `n + 1`, where `n` is the total number of signals entering the model input ports.

Specify the Input Expression

The default input expression for a model is `[t,u]` and the default input format is `Array`. If you define `t` and `u` in the MATLAB workspace, simply select the **Configuration Parameters** > **Data Import/Export** > **Input** parameter to input data from the model workspace.

Suppose that you have a model with two Inport blocks:

- The `In1` block accepts two signals (the block has the **Port dimensions** parameter set to `2`).

- The `In2` block accepts one signal (the block uses the default value for the **Port dimensions** parameter).

You define `t` and `u` in the MATLAB workspace:

```
numSteps = 9;
timeStep = 0.1;
t = (timeStep*(0:numSteps))';
u = [sin(t),cos(t),4*cos(t)];
```

When the simulation runs, the signal data `sin(t)` and `cos(t)` are assigned to `In1` and the signal data `4*cos(t)` is assigned to `In2`. Signal data is input for 100 time points.

Note The array input format allows you to load only real (noncomplex) scalar or vector data of type `double`. Use the structure format to input complex data, matrix (2-D) data, and data types other than `double`.

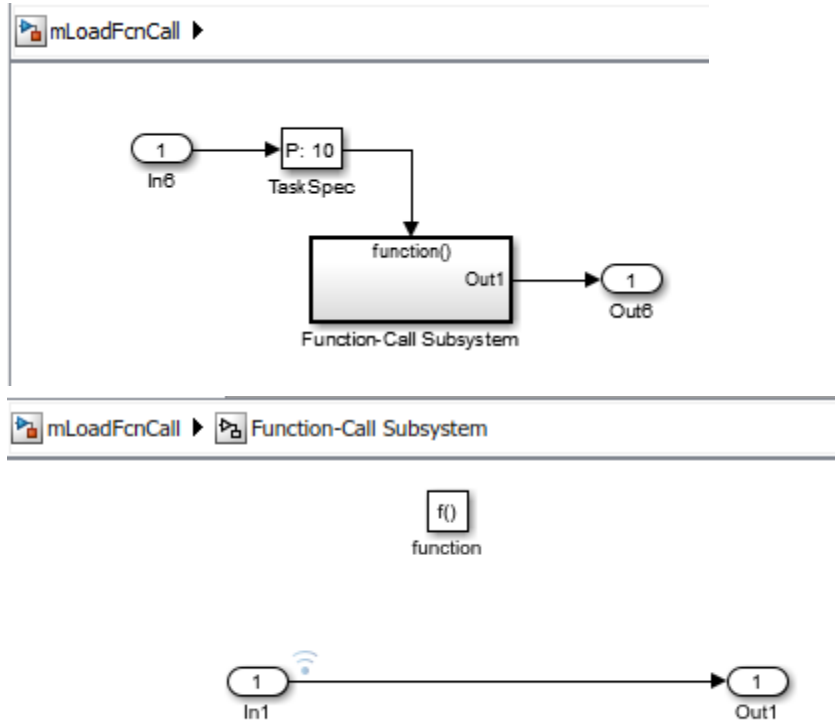
Arrays for Input Ports Driving Function-Call Subsystems

You can use an array to drive a Function-Call Subsystem through a root-level input port. You can use an array or an array that is an element of a `Dataset` object. The array must be an `nx1` array. For the root-level Inport block, select the **Output function call** parameter.

For example, this `Dataset` object has an array element `x`:

```
ds = Simulink.SimulationData.Dataset;
x = [1 3 7 8]';
ds = ds.addElement(x,'theElementName');
```

This model uses the `ds` data set in the **Configuration Parameters** > **Data Import/Export** > **Input** parameter.



When you simulate the model, the time values of the logged signal data in the Function-Call Subsystem show that the Function-Call Subsystem was triggered only for the times specified in an array stored in `ds`.

```
>> logsout{1}.Values.Time

ans =

     1
     3
     7
     8
```

Create MATLAB Time Expressions for Root Inports

Specify the Input Expression

You can use a MATLAB time expression to load data from a workspace into a root-level input port. To use a time expression, enter the expression as a string (enclosed in single quotes) in the **Input** field of the **Data Import/Export** pane. The time expression can be any MATLAB expression that evaluates to a row vector equal in length to the number of signals entering the input ports of the model. Suppose that a model has one vector Inport that accepts two signals. Also, suppose that `timefcn` is a user-defined function that returns a row vector two elements long. Here are valid input time expressions for such a model:

```
'[3*sin(t), cos(2*t)]'
```

```
'4*timefcn(w*t)+7'
```

The expression is evaluated at each step of the simulation, applying the resulting values to the input ports of the model. Simulink defines the variable `t` when it runs the simulation. Also, you can omit the time variable in expressions for functions of one variable. For example, the expression `sin` is interpreted as `sin(t)`.

Load Bus Data to Root-Level Input Ports

In this section...

You can import bus data to top-level input ports by manually specifying the data in the **Input** configuration parameter or by using the Root Inport Mapper tool. For information about importing bus data using the Root Inport Mapper tool, see “Import Bus Data” on page 61-193.

Imported Bus Data Requirements

You can import bus (virtual, nonvirtual, or array of buses) data to a top-level input port defined by a bus object (see `Simulink.Bus`). In the top-level Inport block, set **Data type** to `Bus` and specify the name of a bus object. To specify data values for bus signals, use a structure of:

- MATLAB `timeseries` objects
- MATLAB `timetable` objects
- A combination of `timeseries` and `timetable` objects

Bus elements for which you do not include a field in the structure use ground values. You can use an empty matrix to specify to use ground values.

The structure of `timeseries` or `timetable` (or both) objects must match the bus elements in terms of:

- Hierarchy
- Name of the structure field, which must match the bus element name. (The `name` property of the `timeseries` object does not need to match the bus element name.)
- Data type
- Dimensions

- Complexity

The order of the structure fields does not have to match the order of the bus elements.

You can include the structure as an element of a `Dataset` object. You can use a structure in a comma-separated list. You can specify an empty matrix in a comma-separated list. The empty matrix uses the ground values for the bus signal.

For example, to load data for input ports `in1` and `in3`, and to use ground values for port `in2`, enter the following in the **Input** parameter:

```
in1, [], in3
```

Note If you use a structure of MATLAB `timeseries` objects for a root Inport block in a model with multiple root Inport blocks, all root Inport blocks must use MATLAB `timeseries` or `timetable` objects. Convert any root Inport block data that uses `Simulink.TsArray` or `Simulink.Timeseries` objects to MATLAB `timeseries` objects.

Initialize Bus Signals

You can initialize bus signals, including using partial specification of initialization data. For details, see "Specify Initial Conditions for Bus Signals" on page 65-108.

For details about importing array of bus data to a root Inport block, see "Import Array of Buses Data" on page 61-175.

Limitations for Importing Bus Data to Top-Level Inputs

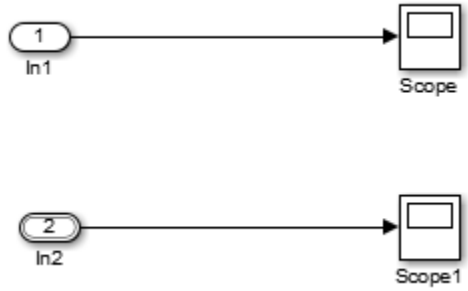
The signal data that you can use the Root Inport Mapper tool to import and map to a top-level Inport block can include bus data. You cannot use that tool to map bus signals to a top-level Enable or Trigger block.

You cannot use input ports to import buses in external modes. To import bus data in rapid accelerator mode, use `Dataset` format.

Import Bus Data to a Top-Level Inport

This model has two Inport blocks connected to Scope blocks. The data type of the `In1` block is inherited (nonbus data) and the data type of the `In2` block is defined by the bus

object `BusObject`. The model has a callback that loads `BusObject` and its sub-bus `BusObject1`.



The `BusObject` bus object has two elements:

- `c`
- `s1`, which is a subbus that has two elements:
  - `a`
  - `b`

1. Open the .
2. Create a MATLAB `timeseries` object for `In1`, for which you want to import nonbus data.

   For example:

   ```
   t1 = (1:10)';
   d1 = sin(t1);
   in1 = timeseries(d1,t1);
   ```

3. Create an input structure, which can consist of MATLAB `timeseries` objects or MATLAB `timetable` objects, or a combination of those types of objects. Create one `timeseries` or `timetable` object for each leaf bus element for which you do not want to use ground values. This example uses ground values for the `b` bus element, so it does not need a `timeseries` or `timetable` object for that element.

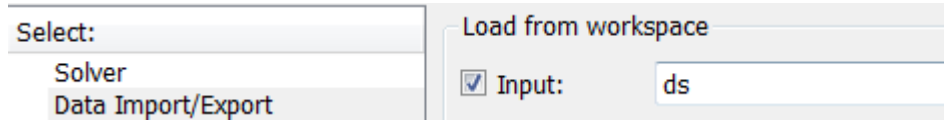
   ```
   t2 = (1:5)';
   d2 = cos(t2);
   in2.c = timeseries(d1,t1);
   in2.s1.a = timetable(seconds(t2),d2);
   ```

The MATLAB `timeseries` objects that you create must match the corresponding bus elements, as described in "Imported Bus Data Requirements" on page 61-170.

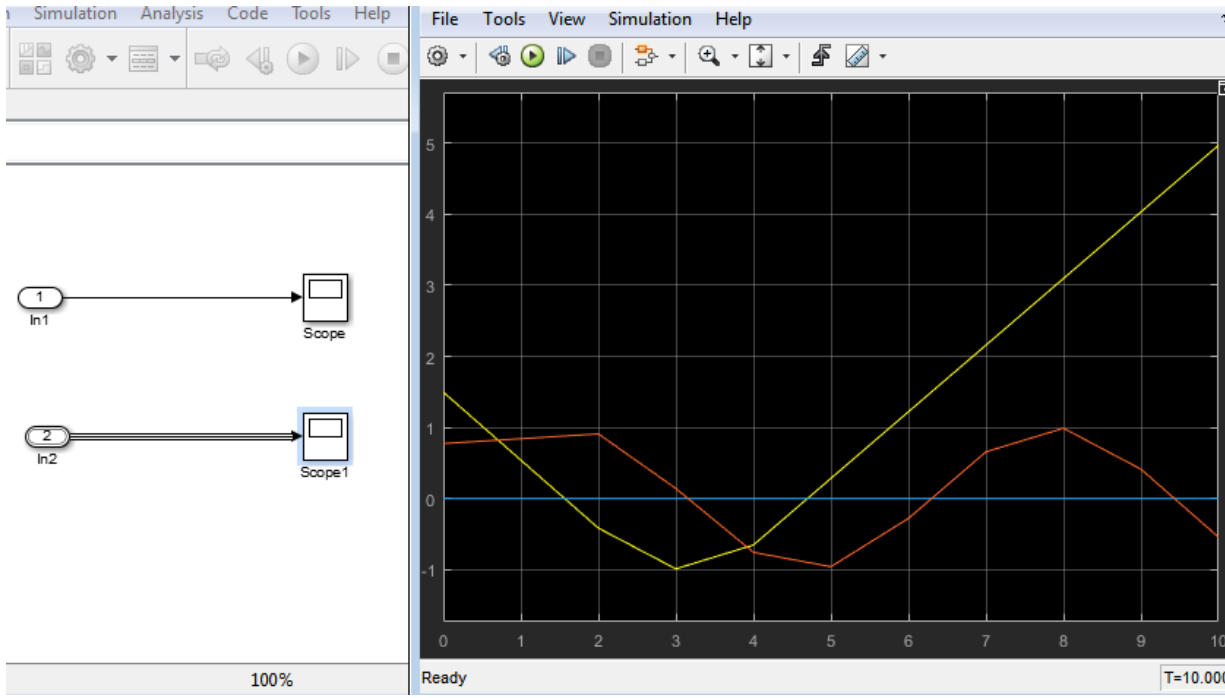
4 Create a `Dataset` object and add `in1` and `in2` to the data set.

```
ds = Simulink.SimulationData.Dataset;
ds = ds.addElement(in1,'in1_signal');
ds = ds.addElement(in2,'in2_signal');
```

5 In the **Configuration Parameters > Import/Export > Input** parameter edit box, enter the `Dataset` object `ds`.



6 Simulate the model. The Scope block connected to In2 shows the imported bus data.



Get Information About Bus Objects

To determine the number of MATLAB `timeseries` objects and data type, complexity, and dimensions needed for creating a structure of `timeseries` objects from a bus, use these methods:

- `Simulink.Bus.getNumLeafBusElements`
- `Simulink.Bus.getLeafBusElements`

For example, for the bus object `BusObject`:

```
num_el = BusObject.getNumLeafBusElements

num_el =

     3

el_list = BusObject.getLeafBusElements

el_list =

  3x1 BusElement array with properties:

    Min
    Max
    DimensionsMode
    SampleTime
    Description
    Units
    Name
    DataType
    Complexity
    Dimensions

el_list(1).Dimensions

ans =

     1
```

Create Structures of Timeseries Objects from Buses

If you have `timeseries` objects defined, you can use them to create a structure of `timeseries` objects based on a bus object. Use the

`Simulink.SimulationData.createStructOfTimeseries` function. For example, if you have defined `timeseries` objects `ts1`, `ts2`, and `ts3`, and you have a bus object `MyBusObject`, you can use this command to create a structure of `timeseries` objects:

```
input = Simulink.SimulationData.createStructOfTimeseries(...
'MyBusObject',{ts1,ts2,ts3});
```

The number of `timeseries` objects in the cell array must match the number of leaf elements in the bus object. The data type, dimensions, and complexity of each `timeseries` object must match those attributes of the corresponding bus object leaf node.

Import Array of Buses Data

To import (load) array of buses data using a root Inport block, use an array of structures of MATLAB `timeseries` objects.

Note You cannot use an Enable, Trigger, From Workspace, or From File block to import data for an array of buses.

Full Specification of Data

You can use logged data for an array of buses signal from a previous simulation as roundtrip input to a root-level Inport in a subsequent simulation run. The logged data is a full specification of data for the Inport block.

If you construct an array of structures of MATLAB `timeseries` objects to specify fully the data to import:

- Specify the structure fields in the same order as the signals in the bus signals.
- Do not include more fields in the structure than there are signals in the bus.

  For leaf fields, match exactly the data type, dimensions, and complexity of the corresponding signal in the bus.

Partial Specification of Data

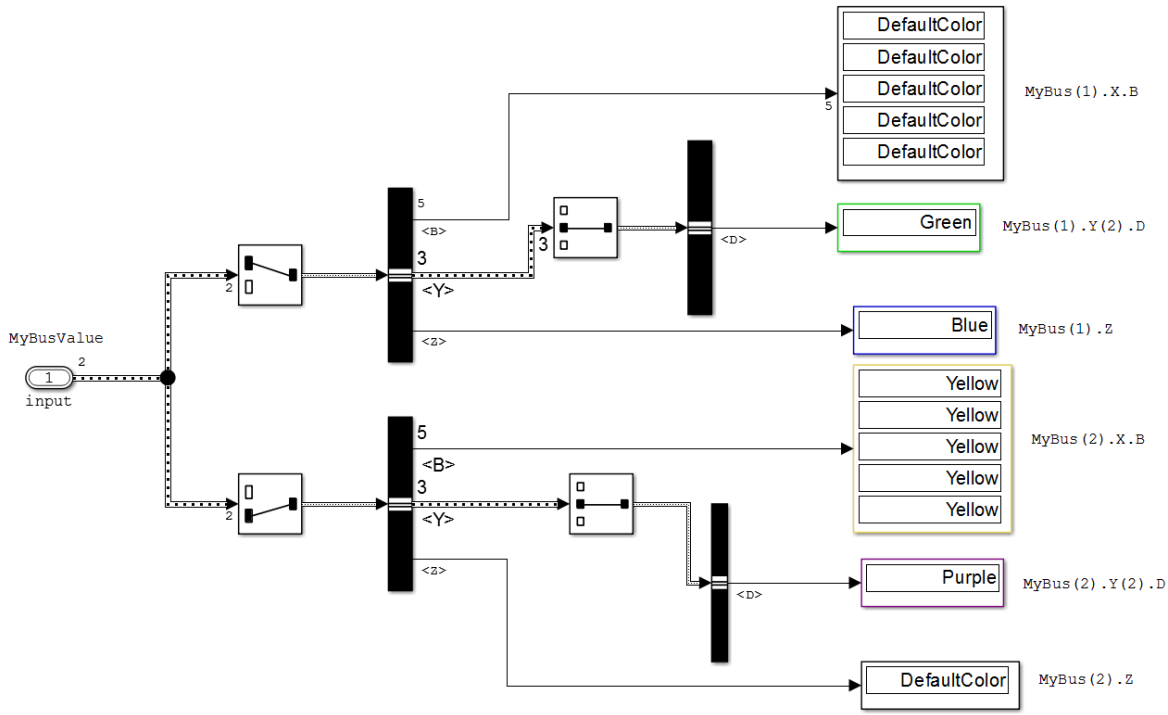
To specify partial data for array of buses, create a MATLAB array of structures with MATLAB `timeseries` objects at the leaf nodes.

The structure that you create to specify partial data must be consistent with these rules:

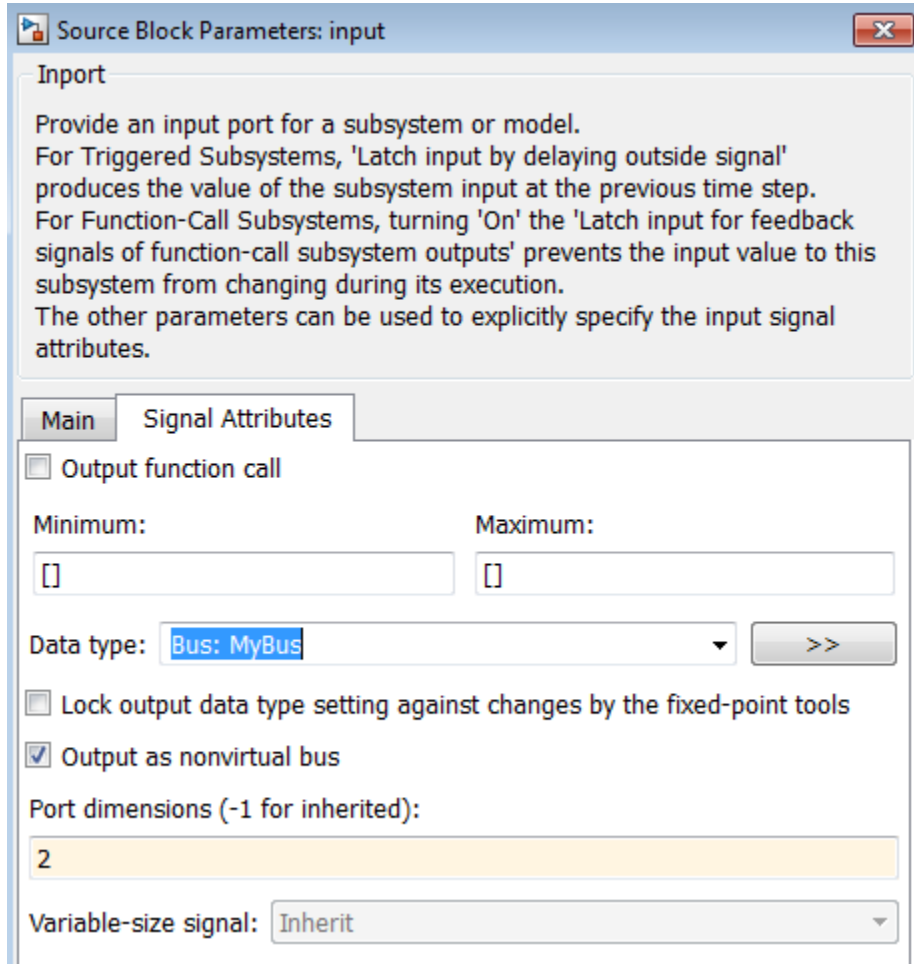
- You can omit fields, including leaf nodes and subbranches. You can also omit dimensions. If you do not specify a field, Simulink uses the ground value for that field.
- For subbus nodes, make the dimension of each field equal to, or smaller than, the dimension for the corresponding node of the array of buses.

This example shows how you can specify partial data to be imported using a root Inport block whose data type is defined as bus object `MyBus`. You can open the model (`ex_partial_loading_aob_model`) and the MATLAB code that defines the data to import (ex_partial_loading_aob_data.m).

When you simulate `ex_partial_loading_aob_model`, you see:

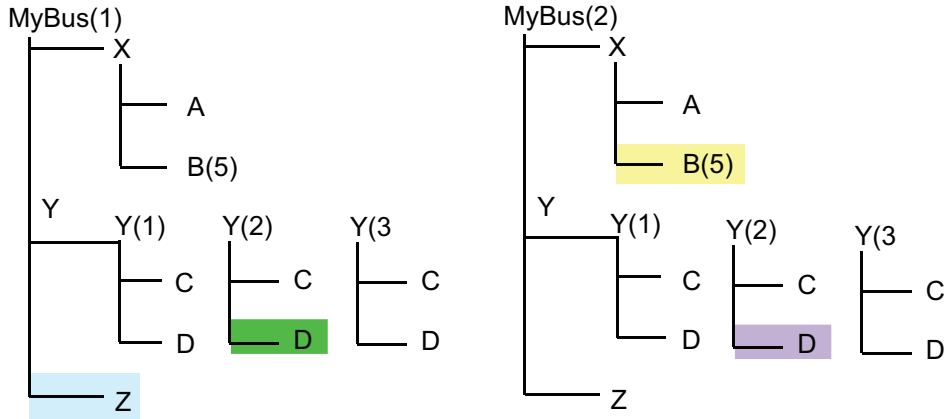


The `input` Inport block uses the `MyBus` bus object as its data type.



The `MyBus` array of buses includes `MyBus(1)` and `MyBus(2)`. The port dimension is set to 2 to reflect the two buses in the array of buses, and **Output as nonvirtual bus** is enabled.

Here are the elements of the array of buses, which includes `MyBus(1)` and `MyBus(2)`. The color highlighting shows the nodes of the array of buses for which data is being imported.



Here is MATLAB code that defines the data to import. The color that highlights the code matches the color of the corresponding node in the array of buses. To view the code used in this model, open the MATLAB code file ex_partial_loading_aob_data.m.

```
%% Create timeseries data for leaf signals
N = 10; Ts = 1;
Time = ((0:N)*Ts)';
[m, n] = size(Time);

ZData = repmat(ex_partial_loading_aob_basicColors.Blue,m,n);
BData = repmat(ex_partial_loading_aob_basicColors.Yellow,m,5);
D1Data = repmat(ex_partial_loading_aob_basicColors.Green,m,n);
D2Data = repmat(ex_partial_loading_aob_basicColors.Purple,m,n);

% Create individual timeseries objects to represent Z, B, D1 and D2
ZT = timeseries(ZData, Time, 'Name', 'Z');
BT = timeseries(BData, Time, 'Name', 'B');
D1T = timeseries(D1Data, Time, 'Name', 'D1');
D2T = timeseries(D2Data, Time, 'Name', 'D2');

%% Construct MyBusValue(1)

% Y(2).D
Y(2) = struct('D',D1T);

% Set X.B to empty to allow the second element to support specification for
% this field
X = struct('B',[]);

% MyBusValue(1)
MyBusValue(1) = struct('Z',ZT,'Y',Y,'X',X);
clear X Y;

%% Construct MyBusValue(2)

% Specify timeseries for MyBusValue(2).X.B
MyBusValue(2).X.B = BT;

% Specify timeseries for MyBusValue(2).Y(2).D
MyBusValue(2).Y(2).D = D2T;
```

In the code that defines the import data:

- The `timeseries` object `MyBusValue` specifies the data for the highlighted nodes.
- The `timeseries` object `BT` for `MyBus(2)`, because `BT` is a leaf node, it must match exactly the dimensions, data type, and complexity of the corresponding bus element.
- The structure specifies data for `Y(2)`. You can skip the first and last subbuses of `Y` (that is, `Y(1)` and `Y(3)`).

This example specifies data for `Y(2)`; you can skip the first and last subbuses of `Y` (that is, `Y(1)` and `Y(3)`).

After you define the `MyBusValue` variable for the import data, set the **Configuration Parameters > Data Import/Export > Input** parameter to `MyBusValue`.

Map Root Inport Signal Data

In this section...

To import, visualize, and map signal and bus data to root-level inports, use the Root Inport Mapper tool or the `getRootInportMap` function. At the top level of a model or referenced model, root-level inports are ports of one of these blocks:

- Inport block
- Enable block
- Trigger block

Root-level inport blocks import data from the MATLAB workspace based on the value of the **Configuration Parameters > Data Import/Export > Input** parameter.

Root-level inport mapping imports signal data in a way that meets most modeling requirements and maintains model flexibility. You can:

- Test your model with signals from the workspace and use your model as a referenced model in a larger context without any modification.
- Update the **Input** parameter based on the signal data that you import and map to root-level inports.
- Visually inspect signal data without loading all the signal data into MATLAB memory.

Tip To determine whether another data import technique meets your specific modeling requirements (such as the amount of data or the storage location) better, see “Comparison of Signal Loading Techniques” on page 61-128.

Open the Root Inport Mapper Tool

Use either of these approaches to open the Root Inport Mapper tool:

- In the **Configuration Parameters** > **Data Import/Export** pane, click **Connect Input**.
- In the block parameters dialog box for the Inport block, select **Connect Input**.

Command-Line Interface

You can use the `getRootInportMap` to create a custom object to map signals to root-level inports and `getSlRootInportMap` to create a custom mapping mode. For more information, see "Create and Use Custom Map Modes" on page 61-236.

Import and Mapping Workflow

1. Identify and possibly create signal data to import and map on page 61-185.
2. Import on page 61-191 and inspect signal data on page 61-195.
3. Map the imported signal data on page 61-182. For example, you can map the signal data by block path or signal name.
4. Simulate the model using the mapped data. After associating a scenario with the model, you can generate scripts for simulation with scenarios on page 61-235 to perform batch simulations.
5. Optionally, save the current Root Inport Mapper scenario on page 61-239 for future reference or to share with other people.

Tip To extend the Root Inport Mapper tool map modes, you can create a custom mapping file function to map data to root-level inports.

Choose a Map Mode

To specify how you want the Root Inport Mapper tool to map the signal data to a model, select from these map modes in the **MAP TO MODEL** section of the toolbar:

- Block name — Connect signal data to ports based the name of a root-inport block.
- Block path — Connect signal data to ports based the path of a root-inport block.
- Signal name — Connect signal data to ports based on the name of the signal on a port.
- Port order — Connect sequential port numbers to the imported data.

- Custom — Connect signal data to ports based on the definitions in a custom mapping file.

Each supported input format supports one or more mapping modes. To import MATLAB `timeseries` data, for example, you use any mapping mode. To import data array signal data, use the port order mapping mode.

More About

- “Create Signal Data for Root Inport Mapping” on page 61-185

Create Signal Data for Root Inport Mapping

In this section...

The first step for using the Root Inport Mapper tool is to know the source of signal data to import and map. You can use existing signal data (for example, in a Microsoft Excel spreadsheet), create data in a MAT-file, or use the Signal Editor interface to create signal data.

For a summary of the other steps involved in using the Root Inport Mapper tool, see “Import and Mapping Workflow” on page 61-183.

Identify Signal Data to Import and Map

You can import data from these sources.

- Base workspace — You can selectively import signal data from the base workspace. For more information about supported data formats, see “Choose a Base Workspace and MAT-File Format” on page 61-186.
- Data files — You can selectively import signals contained in MAT-files and Microsoft Excel files. Each time that you import the contents of the file, the contents overwrite data already loaded for the file in the Root Inport Mapper tool.

  For more information, see “Choose a Base Workspace and MAT-File Format” on page 61-186 and “Supported Microsoft Excel File Formats” on page 61-189.

Tip To import signal data from an Microsoft Excel spreadsheet, consider using the From Spreadsheet block. The From Spreadsheet block incrementally loads data from the spreadsheet during simulation. If you use a From Spreadsheet block, you do not need to do anything to handle changes to sheet values.

You can also use the Signal Editor interface to create and edit signal data. For more information, see “Create and Edit Signal Data” on page 61-198.

Choose a Naming Convention for Signal and Buses

When identifying signals to import, consider using a naming convention for signals and buses such that this grouping of data (signal group) is interchangeable. For example, you can have two MAT-files whose data has different values but the same variable names. Then you can switch the groups of input data into and out of a model quickly.

Choose a Base Workspace and MAT-File Format

The Root Inport Mapper tool supports these MATLAB data types or formats for imported signal data. For each data type, you can use one or more mapping modes.

Data Formats	Block Name	Block Path	Signal Name	Port Order	Custom
`Simulink.SimulationData.Dataset`	✓	✓	✓	✓	✓
MATLAB `timeseries`	✓		✓	✓	✓
MATLAB `timetable`	✓		✓	✓	✓
`Simulink.SimulationData.Signal`	✓	✓	✓	✓	✓
`Stateflow.SimulationData.State`	✓	✓	✓	✓	✓
Structure with time and structure without time				✓	
Data array				✓	
Array of buses	✓		✓	✓	✓
Asynchronous function-call signal on page 10-88	✓		✓	✓	✓

Note If your MAT-file or base workspace contains data in a format that the Root Inport Mapper tool does not support, the tool ignores that data.

Note Although the Root Inport Mapper tool accepts these formats, it can only link in a `Simulink.SimulationData.Dataset` object. To convert the data in your MAT-file to a `Simulink.SimulationData.Dataset` object, in the Root Inport Mapper From dialog box, select the **Convert signals into a scenario dataset and save to MAT-file** check box. Alternatively, use the `convertToSlDataset` function to convert your data.

Dataset Signal Data

If data sets have nonunique element names, use the **Port Order** map mode.

MATLAB Timeseries Signal Data

If you have MATLAB timeseries data with enumeration, and the enumeration class is not on your MATLAB path, the tool ignores that timeseries data.

Structure Signal Data

When converting structure signal data to datasets, the signals are named using the value contained in the label field of the signal field of the structure signal.

Array Signal Data

The Root Inport Mapper tool tries to map the data array to a single inport. In this case, you can choose any of the map modes.

Bus Signal Data for Root Inport Mapping

The signal data that you import and map to a root-level Inport block can include bus data. You cannot map bus signals to a root-level Enable or Trigger block.

1. In the MATLAB workspace, create or load a bus object on page 65-64 for the bus data that you want to import and map.
2. If you create a bus object in the base workspace, save the bus object definition to a MAT-file, such as `d_myBusObj.mat`.
3. Create a separate MAT-file that contains the bus data you want to import for the bus object. Use one of these approaches:

   - Use an existing MAT-file that already contains a MATLAB struct or `Simulink.SimulationData.Dataset` object.

- Create the bus in the base workspace and then save it to a MAT-file.

4 Set up the model to load the bus object.

- For root-level Inport blocks that you map signals to, set the **Data type** field to `Bus`. Specify the name of the variable for the bus object to be used for signal data mapping.
- Load into the model the MAT-file that includes the bus objects used for mapping. For example, use a `PreLoadFcn` callback function. For details, see "Alternative Workflows to Load Data" on page 61-229.

Create Signal Data in a MAT-File for Root Inport Mapping

You can create signal data in a MAT-file to use for root-inport mapping. For example, you can import three signals (`signal1`, `signal2`, and `signal3`), and save the signals in a MAT-file. The `Simulink.SimulationData.Signal` objects include signal names, block names, block paths, and port order index values.

You can use the `convertToSlDataset` function convert MAT-files to `Simulink.SimulationData.Dataset` objects.

1 In MATLAB, create three `Simulink.SimulationData.Signal` objects, specifying signal names, block paths, and port order index values.

```
signal1 = Simulink.SimulationData.Signal;
signal1.Name = 'signal1';
signal1.BlockPath = Simulink.SimulationData.BlockPath('Out1');
signal1.PortType = 'inport';
signal1.PortIndex = 1;

signal2 = Simulink.SimulationData.Signal;
signal2.Name = 'signal2';
signal2.BlockPath = Simulink.SimulationData.BlockPath('Out2');
signal2.PortType = 'inport';
signal2.PortIndex = 2;

signal3 = Simulink.SimulationData.Signal;
signal3.Name = 'signal3';
signal3.BlockPath = Simulink.SimulationData.BlockPath('Out3');
signal3.PortType = 'inport';
signal3.PortIndex = 3;
```

2. In the MATLAB workspace, select `signal1`, `signal2`, and `signal3`. Right-click and in the context menu, click **Save as**. Save the file as `mySigData.mat`.
3. Open the MAT-file.

```
open mySigData.mat

ans =

    signal1: [1x1 Simulink.SimulationData.Signal]
    signal2: [1x1 Simulink.SimulationData.Signal]
    signal3: [1x1 Simulink.SimulationData.Signal]
```

You can use the **Signal Name**, **Block Name**, **Block Path**, or **Port Order** map mode with this MAT-file. Based on your map mode, the Root Inport Mapper tool maps the signal data from the MAT-file to corresponding ports.

Supported Microsoft Excel File Formats

You can use the Root Inport Mapper tool to import signal data into Excel spreadsheets. You can also use the Root Inport Mapper tool to import signal data in CSV files on a Windows system with Microsoft Office installed.

- Use sheet names that follow MATLAB variable name rules. If you import from a sheet whose name does not follow these rules, the Root Inport Mapper tool uses a modified sheet name. This modified sheet name follows the MATLAB variable name rules. For example, if you have a sheet name `Group Name`, the Root Inport Mapper uses the modified name `GroupName`.
- For signal names, use the first row of a sheet. Either specify a signal name for every signal or do not specify any signal names. If you do not specify any signal names, the tool assigns signal names by using the format `Signal#`.
- For time values, use the first column of the remaining rows. The time values must increase for each row.
- Put signal values in the remaining columns.

This example of an Microsoft Excel spreadsheet that is set up for root-inport mapping.

- The sheet name is `sigData`, which is a valid MATLAB variable name.
- The first row contains the signal names `signal1`, `signal2`, and `signal3`.
- The first column has six time values.

- In each row with a time value, columns to the right of the first column contain signal data values for each signal.

	A	B	C	D	E
1		signal1	signal2	signal3	
2	0	2	4	6	
3	1	3	5	7	
4	2	2	4	6	
5	3	4	6	8	
6	4	5	7	9	
7	5	6	8	10

Import Signal Data for Root Inport Mapping

In this section...

Import Signal Data

Before you can import data, identify the signals that you want to import and set up the data to use with root-level inport mapping. See “Create Signal Data for Root Inport Mapping” on page 61-185. For a summary of the other steps involved in using the Root Inport Mapper tool, see “Import and Mapping Workflow” on page 61-183.

For data import purposes, the Root Inport Mapper From MAT-File and From Workspace dialog boxes provide a **Convert signals into a scenario dataset and save to MAT-file** check box, selected by default. To convert the data in your MAT-file to a `Simulink.SimulationData.Dataset` object, select this check box. Alternatively, use the `convertToSlDataset` function to convert your data.

Note The Root Inport Mapper tool uses the term link to refer to the act of importing Simulink data. The sources from which you can link your data are in the LINK section of the tool.

To import signal data for root-inport mapping:

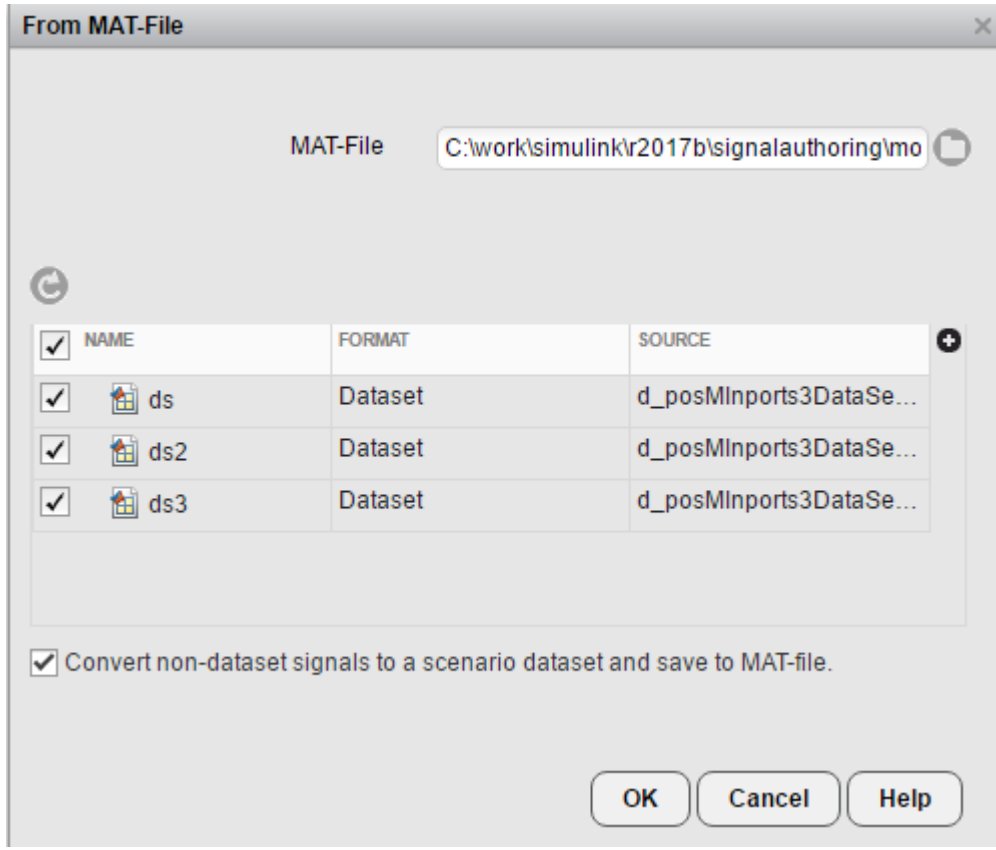
1. Open the Root Inport Mapper tool. In the **Configuration Parameters** > **Data Import/Export** pane, click **Connect Input**.
2. In the LINK section, select the data source.

   - To browse to the MAT-file or spreadsheet file that contains the signals you want to import, select **From Spreadsheet** or **From MAT-File**. To return to the LINK section, click **Open**. Then click **OK**.

Note To import bus data for root inport mapping, see “Import Bus Data” on page 61-193.

- To display a list of base workspace variables that you can import, select **From Workspace**. Select the variables that you want to import and click **OK**.

The From MAT-File dialog box displays the contents of the spreadsheet, file, or base workspace.



3 Select the data that you want to import, and then click **OK**.

The Root Inport Mapper tool displays the imported data.

Alternatively, you can create signal data to map using the **Signals > New MAT-File** option. For more information, see "Create and Edit Signal Data" on page 61-198.

Import Bus Data

Use bus objects for bus data that you want to import and map to root inports.

Store the bus objects in a MAT-file. Use a different MAT-file that contains the bus data that you want to import for the bus object. This file can be an existing MAT-file that already contains a MATLAB `struct`. You can also create the bus in the base workspace and save it to a MAT-file. For more information, "Bus Signal Data for Root Inport Mapping" on page 61-187.

To import the bus data, in the LINK section of the Root Inport Mapper toolstrip, click **From MAT-File**. Select the MAT-file that contains the bus data and click **OK**.

Import Signal Data from Other Sources

Use the Root Inport Mapper tool to import signals from other sources.

- To import signals from models that contain Signal Builder blocks, see "Import Data from Signal Builder" on page 61-193. For an example, see "Converting Harness-Driven Models to Use Harness-Free External Inputs" on page 61-222.
- You can import Excel spreadsheet data. The Root Inport Mapper tool imports a worksheet as a `Simulink.SimulationData.Dataset` object that contains timeseries elements.
- To import test vectors from Simulink Design Verifier, see "Import Test Vectors from Simulink Design Verifier Environment" on page 61-194.

Import Data from Signal Builder

You can import and map data exported from the Signal Builder block in a MAT-file or MATLAB workspace. Use one of these methods to export the data:

- Signal Builder block **File > Export Data > To MAT-file** option, then import the MAT-file.
- `signalbuilder get` function with data sets, then perform either of these steps:

- Import the data sets in the workspace to a MAT-file and import the MAT-file
- Save the data sets in the workspace to a MAT-file and import the MAT-file

For more information on exporting from a Signal Builder block, see “Exporting Signal Group Data” on page 64-119.

Import Test Vectors from Simulink Design Verifier Environment

You can import and map Simulink Design Verifier test vectors. This workflow requires a Simulink Design Verifier license.

Before importing, use the Simulink Design Verifier `sldvsimdata` function to convert a Simulink Design Verifier test structure to a `Simulink.SimulationData.Dataset` object. This file contains a test vector structure `sldvData`. Save the output to a MAT-file and then import that file into the Root Inport Mapper tool.

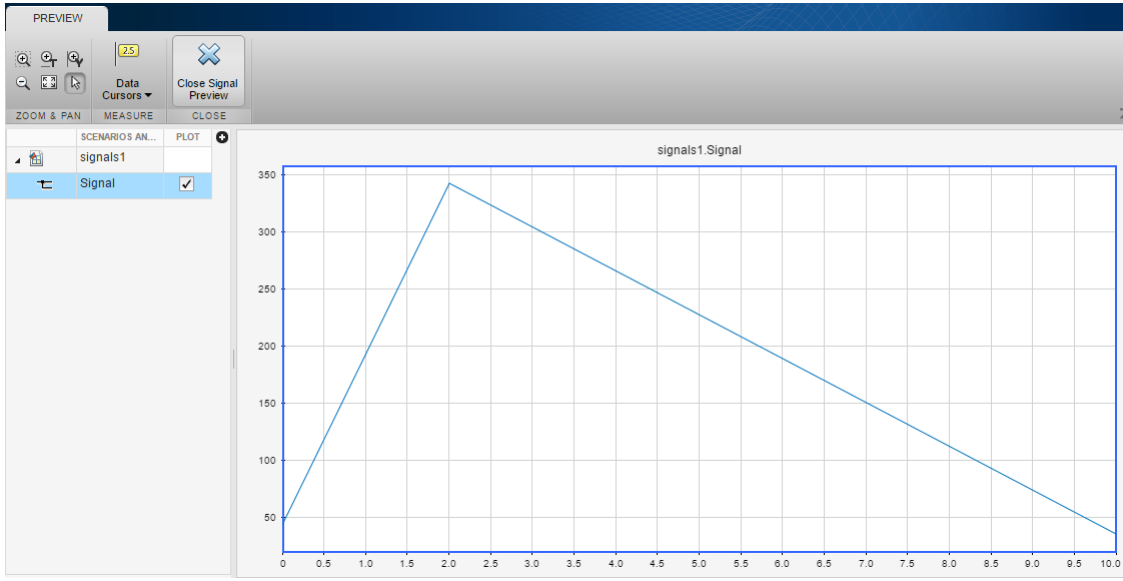
View and Inspect Signal Data

After you import signal or bus data, you can view and inspect signal data.

For a summary of the other steps involved in using the Root Inport Mapper tool, see "Import and Mapping Workflow" on page 61-183.

1 In the **SCENARIO** tab, click **Signals** > **Preview Signals**.

2 To plot the signal, in the **Plot** column, select the check box next to the signal. If the format is a bus, click the expander (▸) to see and select the elements of the bus.



3 Explore the plots using the **Measure** and **Zoom & Pan** sections on the toolbar.

- In the **Measure** section, use the **Data Cursors** button to display one or two cursors for the plot. These cursors display the T and Y values of a data point in the plot. To view a data point, click a point on the plot line.
- In the **Zoom & Pan** section, select how you want to zoom and pan the signal plots. Zooming is only for the selected axis.

Type of Zoom or Pan	Button to Click
Zoom in along the T and Y axes.	

Type of Zoom or Pan	Button to Click
Zoom in along the time axis. After selecting the icon, on the graph, drag the mouse to select an area to enlarge.	
Zoom in along the data value axis. After selecting the icon, on the graph, drag the mouse to select an area to enlarge.	
Zoom out from the graph.	
Fit the plot to the graph. After selecting the icon, click the graph to enlarge the plot to fill the graph.	
Pan the graph up, down, left, or right. Select the icon. On the graph, hold the left mouse button and move the mouse to the area of the graph that you want to view.	

If you view and inspect signal using the `Simulink.SimulationData.Dataset` or `Simulink.SimulationData.DatasetRef` `plot` method, the Signal Preview window contains an **Open Simulation Data Inspector** button. Click this button to plot the data using the Simulation Data Inspector.

Create and Edit Signal Data

In this section...

Use the Signal Editor user interface to create and edit input signals that you can organize for multiple simulations. You can then save the signal data to a MAT-file for simulation or to map to root-level ports. You can access the Signal Editor in the following ways:

- `signalEditor` function — Signal Editor starts from the command line.
- From the Root Inport Mapper on page 61-182 — To create a MAT-file for your new signal data, select **Signals > New MAT-File**. To link in an existing signal data file from an existing scenario and edit the signals in that file, use the **Signals > Edit MAT-File**.
- From the Signal Editor block

Signal Editor works only with MAT-files.

You can:

- Create and edit multiple signals in multiple data sets.
- Use existing scenarios to get existing data sets for which you can edit and signals.

While editing signal data:

- Use tabular editing to modify signal data.

- Modify signal properties such as name, interpolation, and unit properties.
- Drag and drop signals to change signal hierarchies for buses and data sets.

Alternatively, you can import data from external sources and edit them in Signal Editor. For more information, see “Link in Signal Data from Signal Builder Block and Simulink Design Verifier Environment” on page 61-199.

Differences Between the Signal Editor User Interfaces

Generally, the Signal Editor user interface is the same regardless of how you access it. Here are the differences in the Root Inport Mapper Signal Editor:

- FILE section **Save and Sync** and **SAVE** commands save and synchronize to the Root Inport Mapper.
- INSERT section **Scenario** command always has the option, **Scenario from Model**.

The `signalEditor` function Signal Editor user interface shows the option **Scenario from Model** in the INSERT section if you start the function with a model name.

Signal Editor Table Editing Limitations

These capabilities are currently not supported:

Limitation Description	Workaround
Multidimensional and fixed-point signal data is not editable	Edit the multidimensional and fixed-point signal data in the MATLAB base workspace, then import the data as a scenario to Signal Editor.
MATLAB expressions such as `sin` and `cos` are not supported.	Create function-generated signals in the MATLAB base workspace, then import the contents of the base workspace to the Signal Editor.

Link in Signal Data from Signal Builder Block and Simulink Design Verifier Environment

You can use **Signals** > **Edit MAT-File** to link in MAT-file data from these sources for editing.

- Signal Builder blocks, see “Link in Data from Signal Builder” on page 61-200

- Simulink Design Verifier, see “Link in Test Vectors from Simulink Design Verifier Environment” on page 61-200.

Link in Data from Signal Builder

You can link in and edit data exported from the Signal Builder block in a MAT-file or MATLAB. Use one of these methods to export the data:

- Signal Builder block **File > Export Data > To MAT-file** option, then link in the MAT-file.
- `signalbuilder get` function with data sets, then perform either of these steps:
  - Import the data sets in the workspace and save to a MAT-file
  - Save the data sets in the workspace to a MAT-file and import the MAT-file

For more information on exporting from a Signal Builder block, see “Exporting Signal Group Data” on page 64-119.

Link in Test Vectors from Simulink Design Verifier Environment

You can link in and edit Simulink Design Verifier test vectors. This workflow requires a Simulink Design Verifier license.

Before linking in, use the Simulink Design Verifier `sldvsimdata` function to convert a Simulink Design Verifier test structure to a `Simulink.SimulationData.Dataset` object. This file contains a test vector structure `sldvData`. Save the output to a MAT-file and then import that file into Signal Editor.

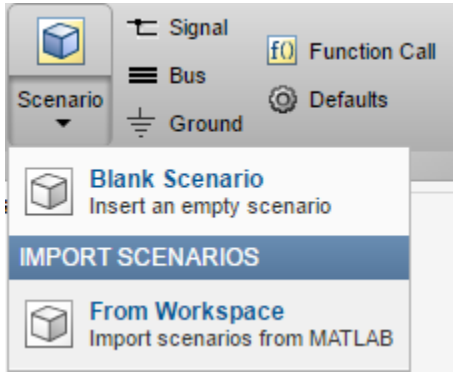
Create Signal Data

Create signal data either from existing model data (scenarios), start with an empty scenario, or immediately start creating signals.

After inserting the signal, view and plot the data by clicking the **PLOT** check box.

Use Scenarios

Signal Editor uses scenarios to group and organize sets of inputs to be saved to a MAT-file for a single simulation. To create signal data using existing data sets from existing scenarios, or create an empty scenario into which to add signals, use the Signal Editor **Scenario** menu.



Action	Option
To create a scenario from the root inports of a model	Select **Scenario** > **Scenario from Model**. (Available only when accessing Signal Editor from the Root Inport Mapper.) **Note** When using this option, the resulting scenario contains signals with the data types and dimensions of the inport ports. Alternatively, use the `signaleditor` function with a model argument.
To create an empty scenario and create signals from scratch	Select **Scenario** > **Blank Scenario**.
To import scenarios from MATLAB workspace	Select **Scenario** > **From Workspace**.

After you have your scenario:

- To begin inserting signals, use the other options in the INSERT section. For more information, see “Insert Signals” on page 61-202.
- To change the signal order in the hierarchy or change the name of a signal, see “Change Signal Names and Hierarchy Orders” on page 61-203.

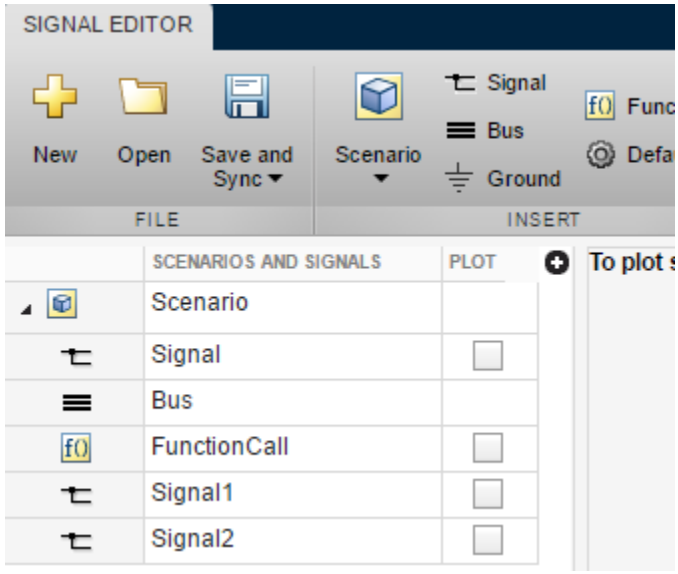
Insert Signals

To insert signals into scenarios or just to a list of signals, select the scenario, then click a signal type from the INSERT section.

- Signal
- Bus
- Ground
- Function Call

  If you need a function-call signal for a root inport with explicit periodic sample time, insert a ground signal instead. Simulink then executes the function-call automatically.

The new signals appear in the SCENARIOS AND SIGNALS section.



You can also insert multiple signals of the same type. For more information, see “Create Signals with the Same Properties” on page 61-209.

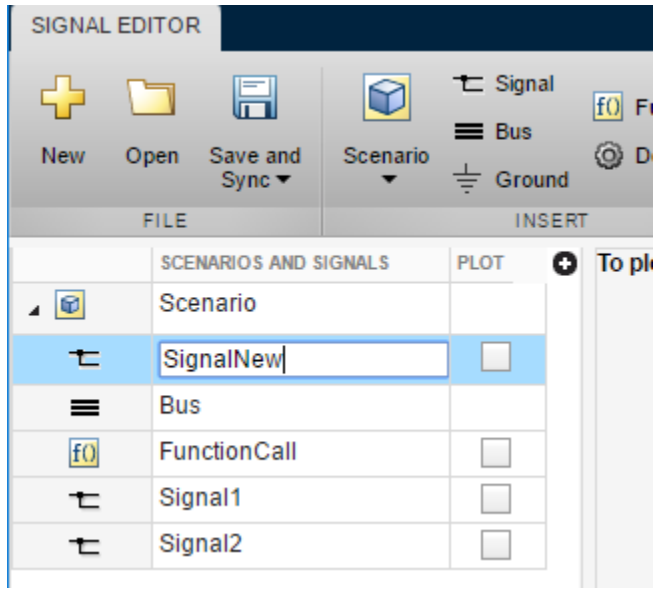
To change the signal order in the hierarchy or change the name of a signal, see “Change Signal Names and Hierarchy Orders” on page 61-203.

To edit the properties of a signal, see “Work with Signal Data” on page 61-206.

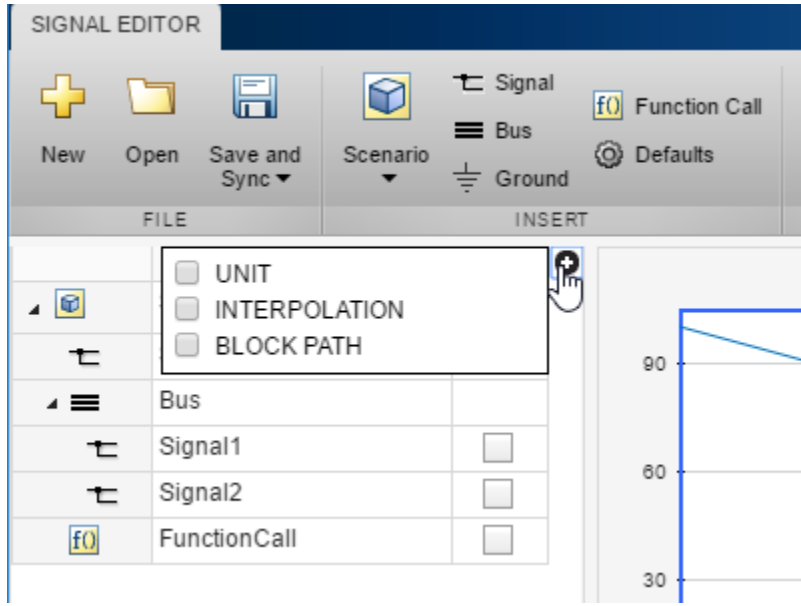
Change Signal Names and Hierarchy Orders

In the SCENARIOS AND SIGNALS section, you can change signal names and hierarchy order, create duplicates of signals, and delete signals. Simulink ignores leading and trailing spaces in signal names.

- To change a signal name, double-click the name and change it.

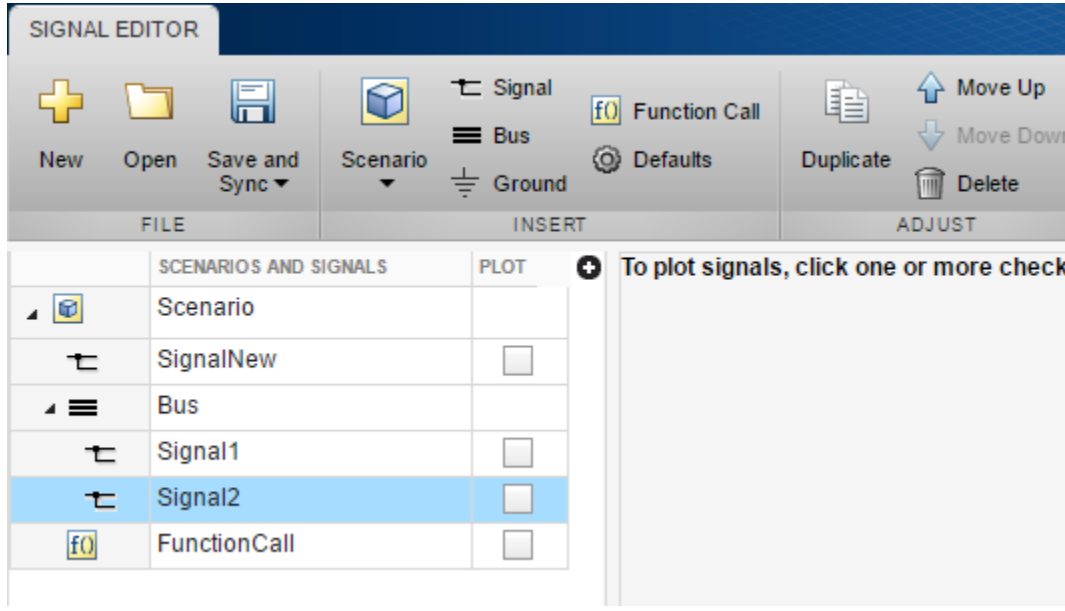


- To change the unit or interpolation of a signal, click the plus sign and click the **UNIT** or **INTERPOLATION** check boxes.



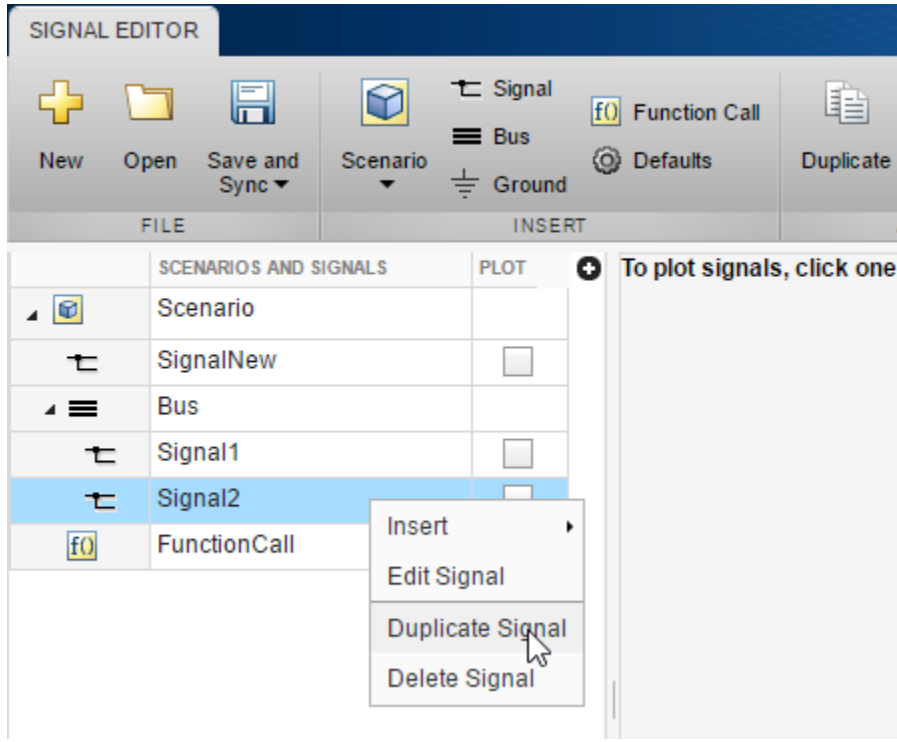
The pane updates with UNIT and INTERPOLATION columns.

  - In the UNIT column, enter an appropriate unit expression. For a suggested list of unit expressions, see allowed units.
  - In the INTERPOLATION column, from the dropdown list, select `linear` or `zero order hold`.
- To change the order of a signal in the hierarchy, drag and drop it. For example, you can drag and drop signals into a bus.



Alternatively, use the **Move Up** and **Move Down** buttons in the ADJUST section.

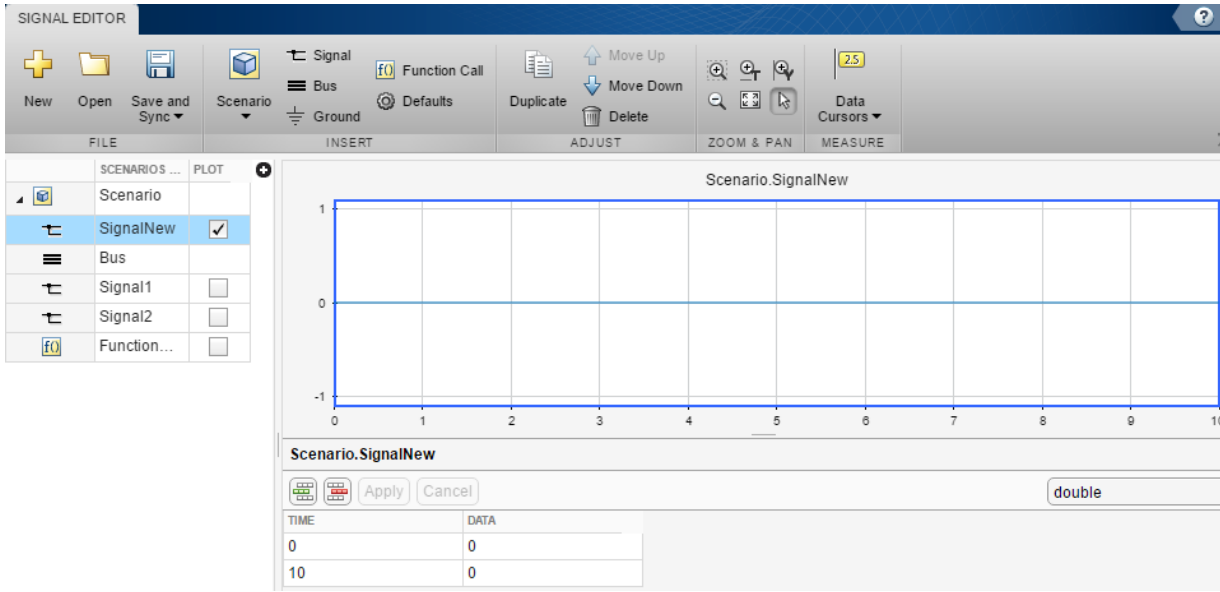
- To duplicate a signal, right-click it and select **Duplicate Signal**.



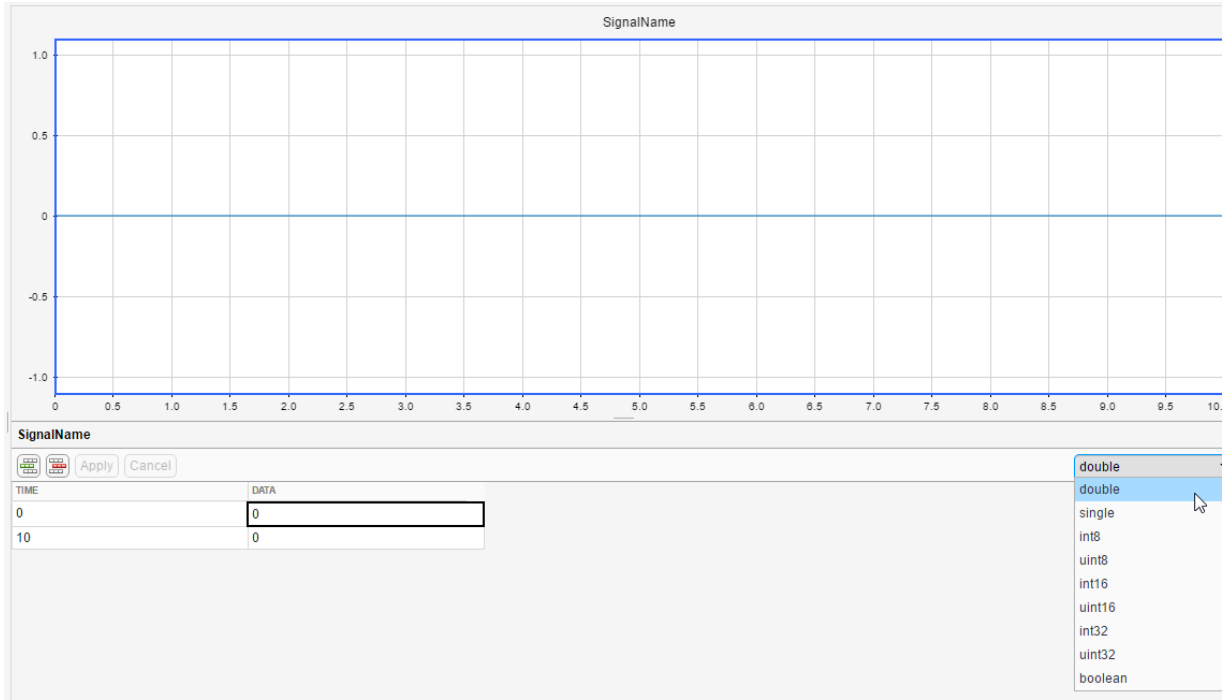
Alternatively, use the **Duplicate** button in the ADJUST section. You can also adjust the default properties of the signal you duplicate. For more information, see “Create Signals with the Same Properties” on page 61-209.

Work with Signal Data

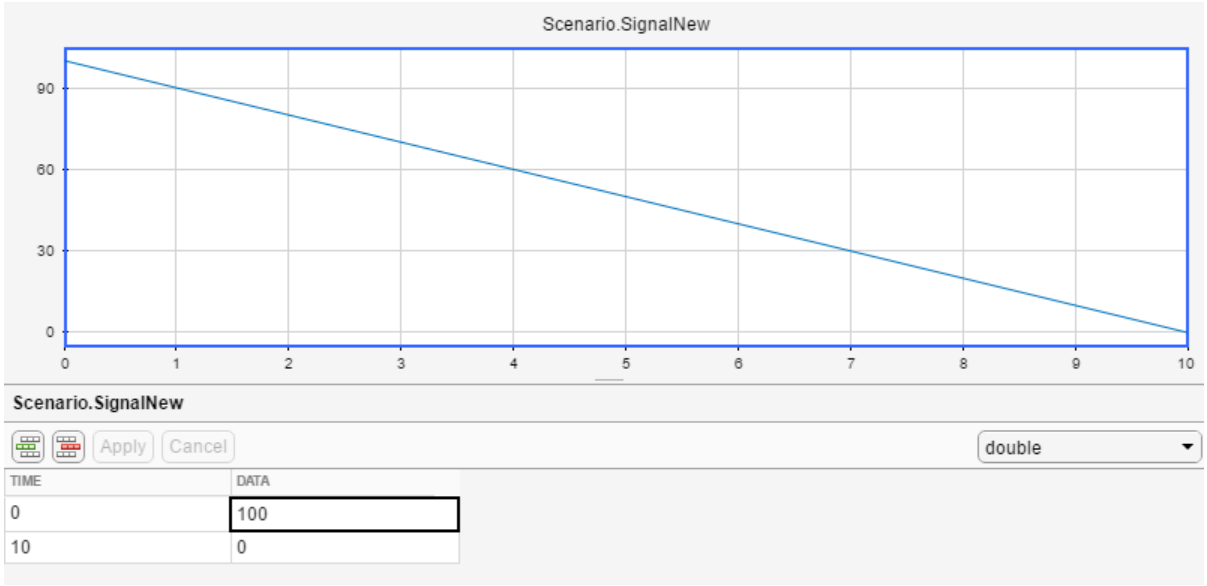
To edit signal data, select a signal and click the associated **Plot** check box. A plot of the signal displays. Under the signal plot is a tabular editor.



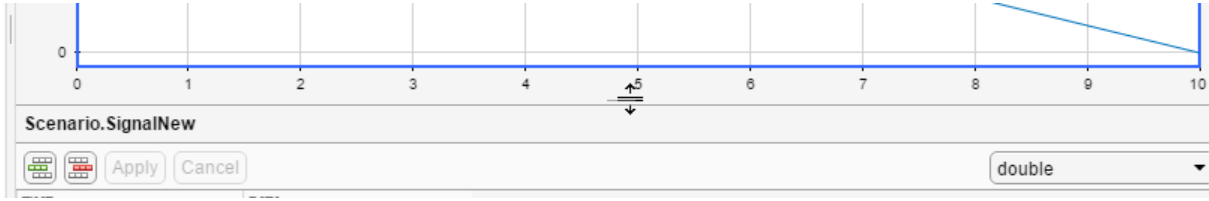
- To insert or delete a data row for a signal, use  or  , respectively.
- To change the data type for signal data, select the type from the pull-down.



- To change the time or data for each signal, edit the associated column of the data row, then click **Apply** to update the plot of the signal.

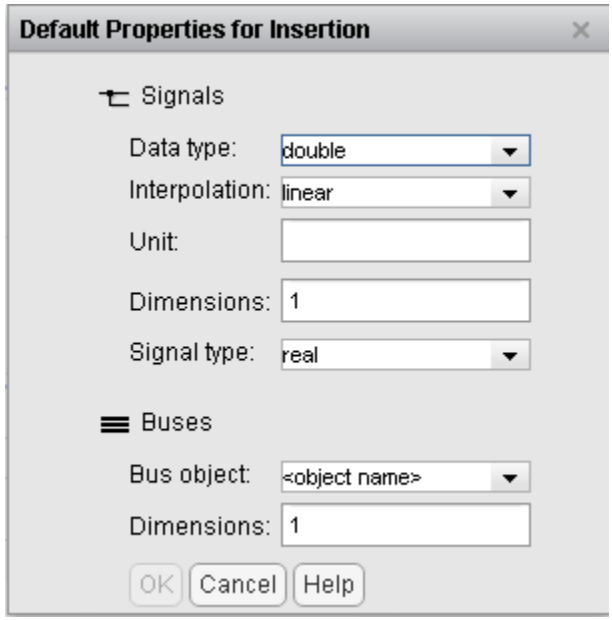


- To change the size of the plot or tabular area, move the separator up and down.



Create Signals with the Same Properties

To create signals of the same predefined type, use the **Duplicate** button in the ADJUST section. To change the predefined signal type, click the **Defaults** icon, . A **Default Properties for Insertion** dialog box displays.



- **Data type** — From the dropdown list, select the signal data type.
- **Enumeration** — When you select the `Enum` data type, this parameter displays. Enter the class name of your enumeration.

  If you define an enumeration class that contains the same integer value multiple times, for example:

```
classdef(Enumeration) hEnumColors_duplicateValues < Simulink.IntEnumType
  enumeration
    Red(118)
    Yellow(-14)
    Blue(90)
    Green(87)
    White(-14)
    Black(198)
    Brown(90)
    Pink(118)
    Purple(90)
  end
  methods (Static = true)
    function retVal = getDefaultValue()
      retVal = hEnumColors_duplicateValues.Blue;
    end
  end
end
```

The Signal Editor treats the first enumeration value (`Red (118)`) as the canonical value and equates all subsequent instances of the same underlying integer `118` to the enumerated name `Red`. In other words, `Pink` equals `Red`.

- **Interpolation** — From the dropdown list, select `linear` or `zero order hold`.
- **Unit** — Enter an appropriate unit expression. For a suggested list of unit expressions, see allowed units.
- **Dimensions** — Enter the number of dimensions for the signal.
- **Signal type** — From the dropdown list, select `real` or `complex`.
- **Bus object** — From the dropdown list, select the bus object for which to define the dimensions. If you leave the **Bus object** parameter at the default `<object name>`, Signal Editor adds empty buses.
- **Dimensions** — Enter the number of dimensions for the bus object.

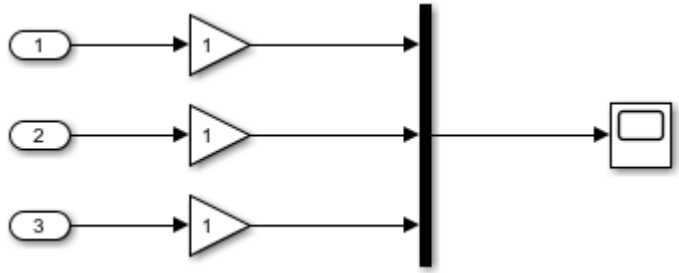
Add Signals to Scenarios

This example describes how to create a scenario to be linked to from the Root Inport Mapper tool. You can then start the Signal Editor to manipulate and add signals to this scenario.

1. In the MATLAB Command Window, create some data by typing:

   ```
   ts = timeseries([0;20],[0;10]);
   ```

2. In Simulink Editor, create a model that contains three Inport blocks, three Gain blocks, a Mux block, and a Scope block. Connect these blocks as shown:



3. Set the gain for the Gain blocks to `5`, `10`, and `15`, respectively.
4. Click one of the Inport blocks, then click the **Connect Input** button.

   The Root Inport Mapper tool displays.

5 In Root Inport Mapper LINK section, select **From Workspace**.

6 In the From Workspace window, enter a name to store the MAT-file, then click **OK**.

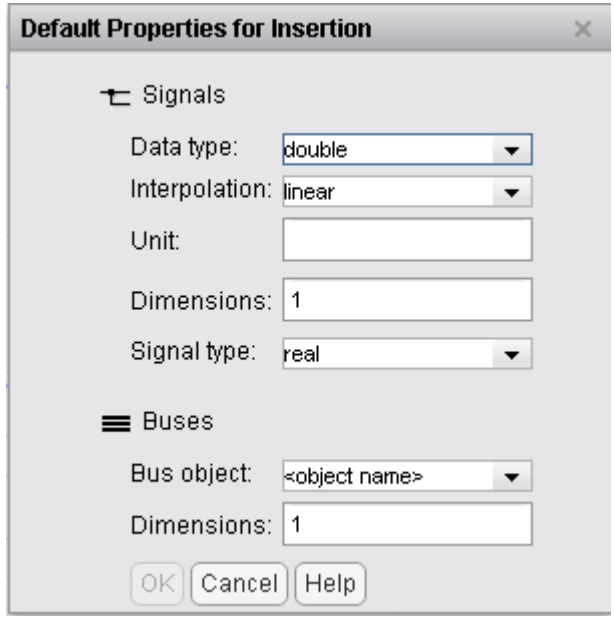
7 In the SCENARIO section of the Signal Editor, click **Signals > Edit MAT-File**.

8 In the Edit Signal File window, select the new MAT-file and click **OK**.

The Signal Editor displays.

9 Add a signal, *Signal*, to the scenario. Right-click the scenario and select **Insert > Signal**.

This action adds *Signal* with these default properties.

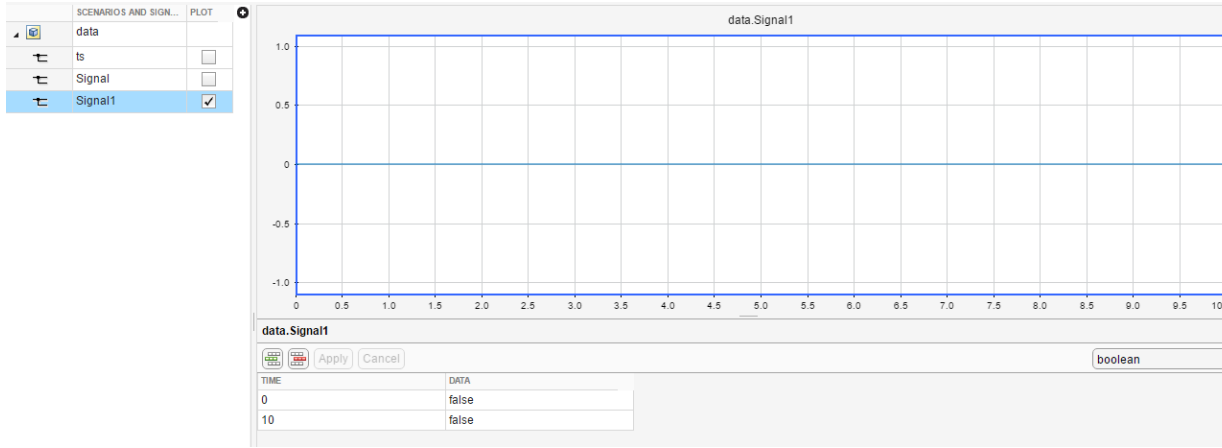


Alternatively, insert signals by clicking a signal type from the INSERT section.

10 Change the default properties of signals you want to add. In the INSERT section, select **Defaults**. In the Default Properties for Insertion dialog box, change the data type to boolean, then right-click the scenario and select **Insert > Signal**.

This action adds *Signal1* with the data type boolean.

11 To check that the data type is boolean, click the plot check box for *Signal1*.

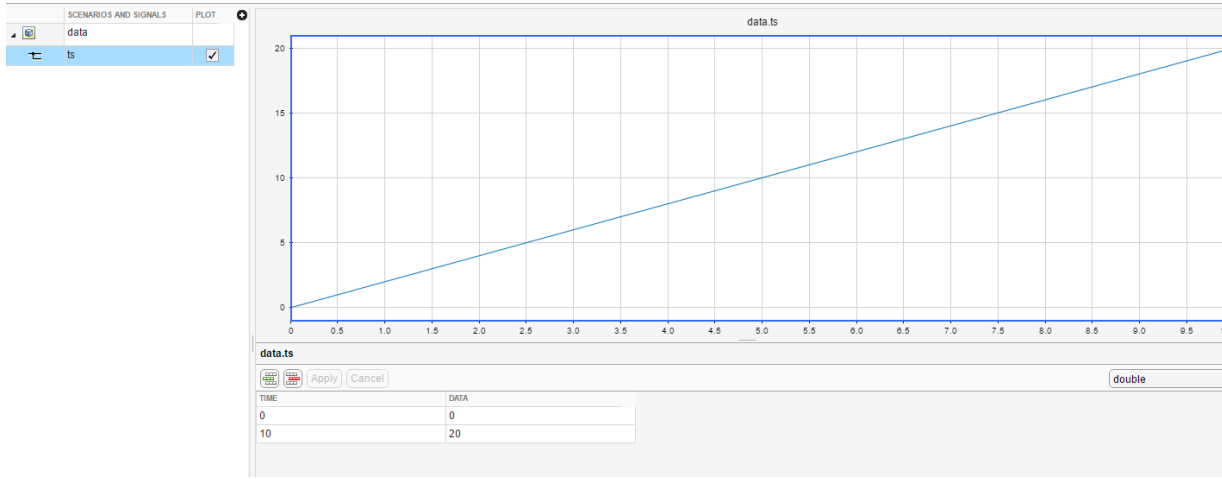


To add data for these signals, see “Work with Data in Signals” on page 61-213.

Work with Data in Signals

This example describes how to add and delete data to the signals in the linked scenario. To create a model and data to work with, see “Add Signals to Scenarios” on page 61-211.

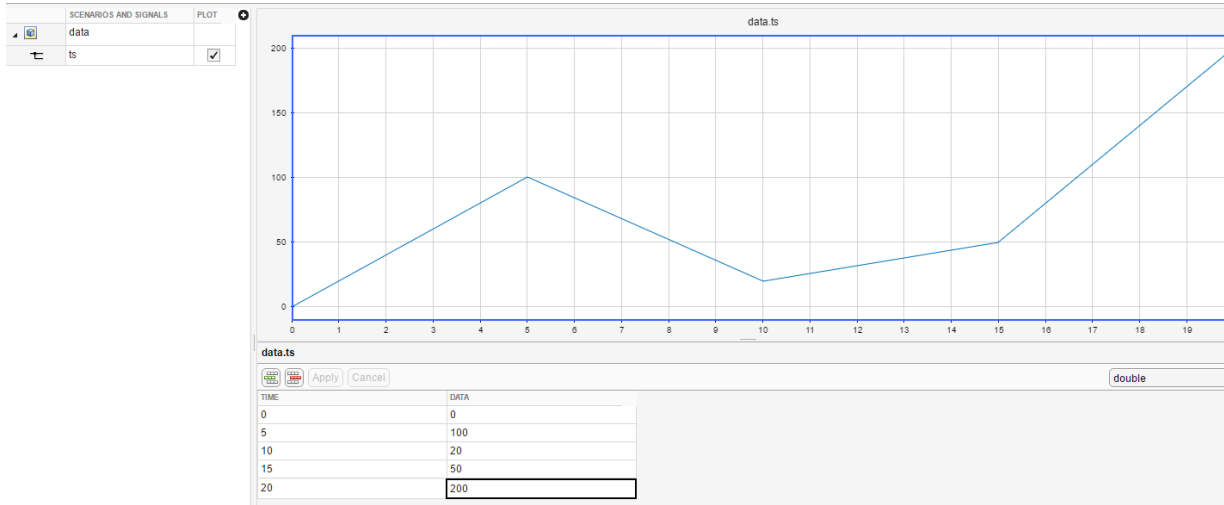
1 In the Signal Editor, in the SCENARIOS AND SIGNALS section, click the plot check box for the signal `ts`.



2 Add some data to the signal `ts`.

a Click the add row icon and some signals. To add a signal row between other signals, click the signal before and click the add row icon.

b When done, click **Apply**. Clicking **Apply** updates the plot.



3 Remove the time 20 line from the signal. Select `20` and click .

Save and Send Changes to the Root Inport Mapper Tool

When you are done adding and modifying signals and scenarios, use the **Save and Sync** button to save the changes to a MAT-file. The Signal Editor also sends the data to the Root Inport Mapper Tool:

- If the Root Inport Mapper tool has the scenario loaded, the Root Inport Mapper tool updates with the new data.
- If the Root Inport Mapper tool has the scenarios mapped and your changes affect the mapping, the Root Inport Mapper tool unmaps the scenario.

- “Map Root Inport Signal Data” on page 61-182

Map Signal Data to Root Inports

In this section...

After you import data, map signal data to root inports by selecting map modes and options and selecting data.

For a summary of the other steps involved in using the Root Inport Mapper tool, see “Import and Mapping Workflow” on page 61-183.

Select Map Mode

To map signal data to root-level ports, use one of these map modes in the MAP TO MODEL section of the Root Inport Mapper toolstrip.

Goal	Map Mode
Assign signals to ports according to the name of the root-inport block. If the name of a signal or bus element matches the name of a root-inport block, the data is mapped to the corresponding port.	**Block Name**
Assign signals to ports according to the block path of the root-inport block. If the block path of a signal matches the block path of a root-inport block, the data is mapped to the corresponding port.	**Block Path**

Goal	Map Mode
Assign signals to ports according to the name of the signal on the port. If the signal name of a data element matches the name of a signal at a port, the signal is mapped to the corresponding port.	**Signal Name**
Assign sequential port numbers to the imported data, starting at 1. Map signals to the corresponding inports. If there is more data than inports, the remaining data is mapped to enable and then trigger inports. If the data is not in the form of a dataset, it is processed in the order in which it appears in the data file.	**Port Order**
Assign signals to ports according to the definitions in a custom file. To create a custom mapping mode, see “Create and Use Custom Map Modes” on page 61-236.	**Custom**

Set Options for Mapping

If you want to set up mapping options, in the MAP TO MODEL section on the Root Inport Mapper toolstrip, click **Options**. To map the signals, see “Map Data” on page 61-219.

Goal	Option
Compile the model and review the data types of root-level inports and imported data.	**Update Model**. Compare the signal data and inport parameters to the root-level port and display the results. If you do not select this option, the tool maps the imported data to the root-level inport but does not compile the model. If your model uses configuration references to reference configuration sets, you cannot compile the model. To compile the model with the Root Inport Mapper tool, use the Model Explorer to activate a configuration set first. See "Understand Mapping Results" on page 61-220. If the data that is in the comparison window is inherited from the connected block, a warning appears.
Use strong data typing when mapping data from spreadsheets.	**Use Strong Data Typing with Spreadsheets**. Clear this check box to allow the Root Inport Mapper tool to automatically convert spreadsheet input signals to the data types of the corresponding root inports. The Root Inport Mapper tool can cast the spreadsheet data to only these data types: `double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`. If you select this check box or if the root inport is not one of these data types, you may receive a data type mismatch error.
Import bus data that is only partially defined.	**Allow partial**. Confirm that any partially specified bus data you import maps properly to root-level inports.

Select Data to Map

To specify a subset of scenarios to map, click the down arrow on the **Map to Model** button. You can choose different mapping modes for different scenarios.

Goal	Option
Map all the scenario datasets (default).	**Map All**
Map the datasets of the scenarios currently selected in the SCENARIO DATASET section.	**Map Selected**
Map the disconnected datasets.	**Map Unconnected**
Map datasets that previously failed a mapping.	**Map Failed**
Map datasets that previously caused warnings.	**Map Warned**

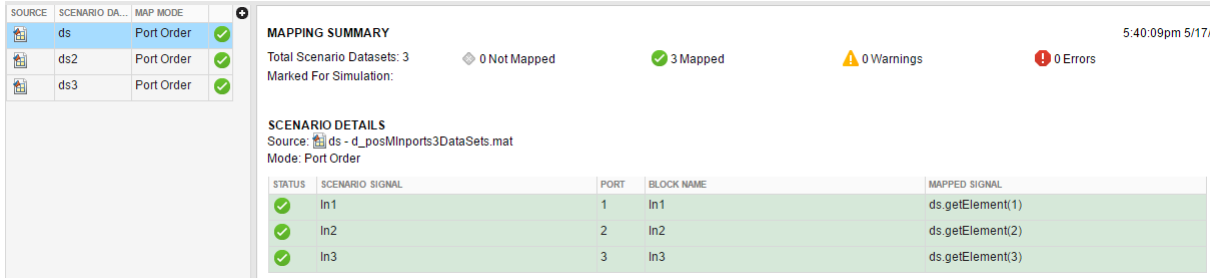
Map Data

After you import signals or buses, you can map data.

1 On the Root Inport Mapper toolbar, click **Map to Model**.

The results of a signal mapping appear in the **SCENARIO DATASET** tab.

2 In the FILE section, click a data set to see the mapping results



- The **MAPPING SUMMARY** section lists the input data and the status of the mapping.

  Note See “Understand Mapping Results” on page 61-220.

- The mapping definition for the input data is applied to the model.

After you save and close the model, when you load input data of the same signal group to the workspace, the model uses the mapping defined for that signal group.

For an example of mapping signal data to root-level inputs, see “Converting Harness-Driven Models to Use Harness-Free External Inputs” on page 61-222.

After you save the mapping definition for a model, you can automate data loading. For more information, see “Alternative Workflows to Load Data” on page 61-229.

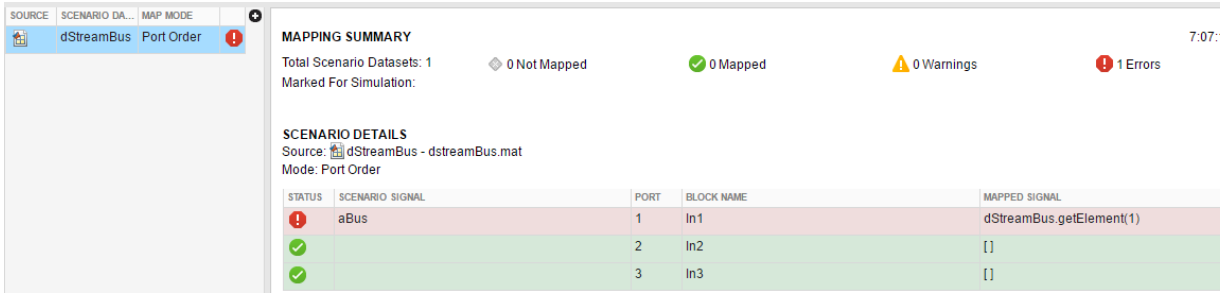
Understand Mapping Results

When you complete the import and map process, the **MAPPING SUMMARY** section displays the results in the status area. The results depend on whether you select the **Compile** option when you set up the mapping.

Status	Compile	Continue Without Compile
	The properties of the mapped data and the inport are appropriate for simulation.	The data type, dimension, and signal type properties of the data and inport are compatible.
	Not applicable	Comparison of data and root-level port data type, dimension, and signal type properties cannot determine whether there is a match. If you do not compile before mapping, the tool cannot evaluate whether all the data types match unless you explicitly specify the inport data types. Confirm that you set these block parameters correctly: Inport block parameter **Data type** is not set to `Inherit:auto`. Inport block parameter **Dimension** is not set to `-1`. Inport block parameter **Signal type** cannot be `auto`.
	The properties of the mapped data and the inport are not appropriate for simulation.	One or more of the data types, dimensions, or signal types of the signal data are not compatible with the root-level inport.

Root-level input ports that have not been mapped are displayed as empty ([]).

This figure shows mapping successes and failures.



In the Root Inport Mapper tool, clicking **Mark for Simulation** selects the **Input** check box in the **Data Import/Export** pane in the model Configuration Parameters dialog box. It also sets the value to the imported data variables. To apply the changes to the model configuration, in the **Data Import/Export** pane, click **OK**.

If your model uses configuration references to reference configuration sets, you cannot mark the model for simulation. To use this data to simulate the model with the Root Inport Mapper tool, use the Model Explorer to activate a configuration set first.

This graphic illustrates the application of the changes to the model configuration for the model in “Map Data” on page 61-219.

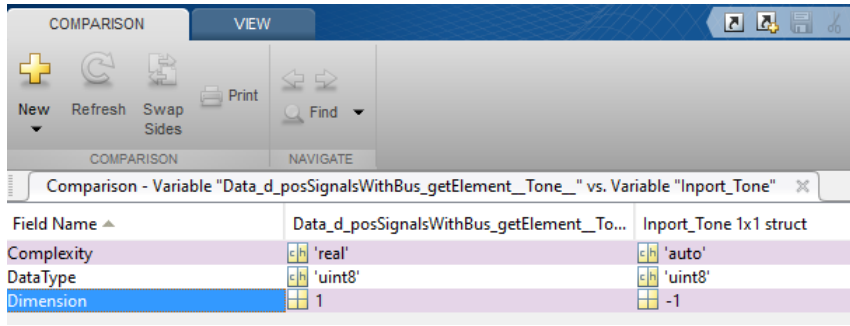
To inspect the imported data, you can:

- Connect the output to a scope, simulate the model, and observe the data.
- Log the signals and use the Simulation Data Inspector tool to observe the data.

To highlight the Inport block that is associated with the signal, select an item in the **MAPPING SUMMARY** section. The selected Inport block is outlined with blue.

Use the Comparison Tool to evaluate your next action. The Comparison Tool shows the properties for the root-level inport and the signals that you are trying to map to the inport. You can tell from this table whether there is a mismatch that prevents the mapping. For example, if there is a mismatch, you can update the imported signals or edit the root-level inport. When you are done, reimport the data to map it.

To investigate warnings and failures, in the **MAPPING SUMMARY** section, click the line item that you want to inspect. The Comparison Tool lists the selected variable, including the field name, input data, and root-level inport.



Note When the input is a bus, click the levels of the bus object to see the individual elements in the bus.

Sometimes the Comparison Tool shows a warning or error, but your investigation of the elements indicates that there is no problem with mapping the data. In these cases, if you did not select the **Compile** check box from the **Options** menu, select it and click **Map** again.

Tip Each time you click a nongreen status item, a new Comparison Tool instance appears. To dock all Comparison Tool instances in one window, click the **Dock** button .

For more information on the Comparison Tool, see “Comparing Files and Folders” (MATLAB).

Converting Harness-Driven Models to Use Harness-Free External Inputs

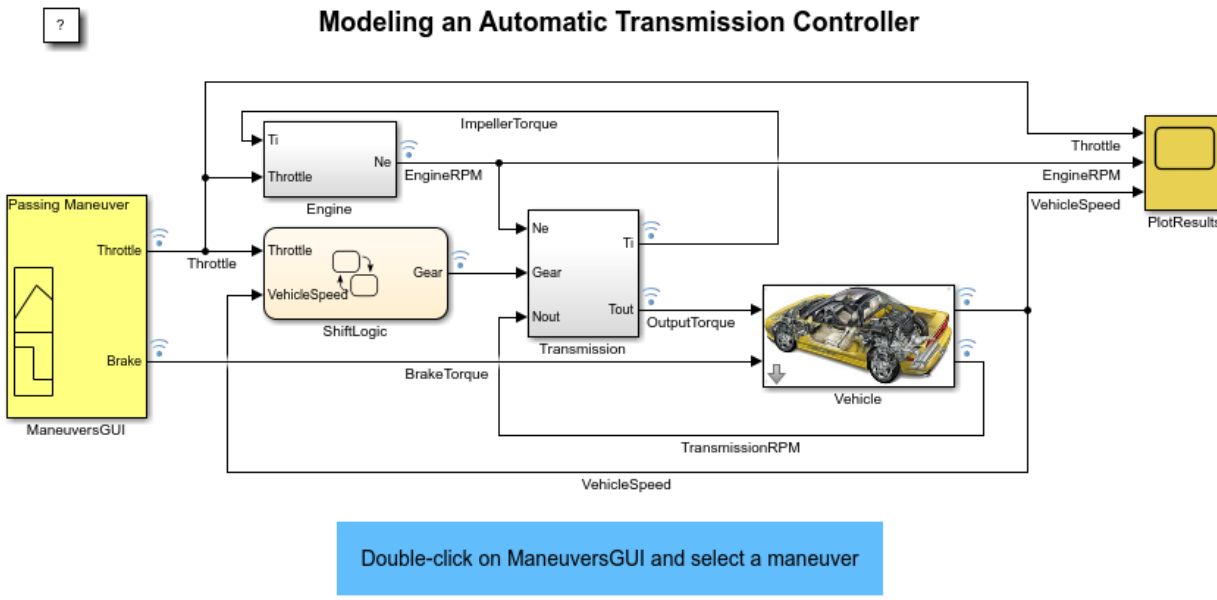
This example shows how to convert a harness model that uses a Signal Builder block as an input to a harness-free model with root inports. The example collects data from the harness model and stores it in MAT-files, for use by the harness-free model. After storing the data, the example removes the Signal Builder block from the harness model and adds root inports to create a harness-free model. Then, the data in the MAT-files is mapped to the root inports of the model.

Save Harness Data to MAT-Files

Before converting the model to be harness-free, capture the test cases in the harness.

For this example, you will modify the model sldemo_autotrans from the **Modeling an Automatic Transmission Controller** example.

Open the example model. In the MATLAB Command Window type `sldemo_autotrans`.



Exporting Signal Builder block groups

You can export data that defines Signal Builder block signal groups to a MAT-file from the Signal Builder window. To export Signal Builder signal data, formatted as Simulink.SimulationData.Dataset, to a MAT-file, open the Signal Builder window and select **File** > **Export Data** > **To MAT-file**. A dialog appears where you can enter a name for the MAT-file to contain the data and the number of the group you want to export. For this example, the file name is `slexAutotransRootInportPassingManeuver.mat` and the group number is 1 for the Passing Maneuver group.

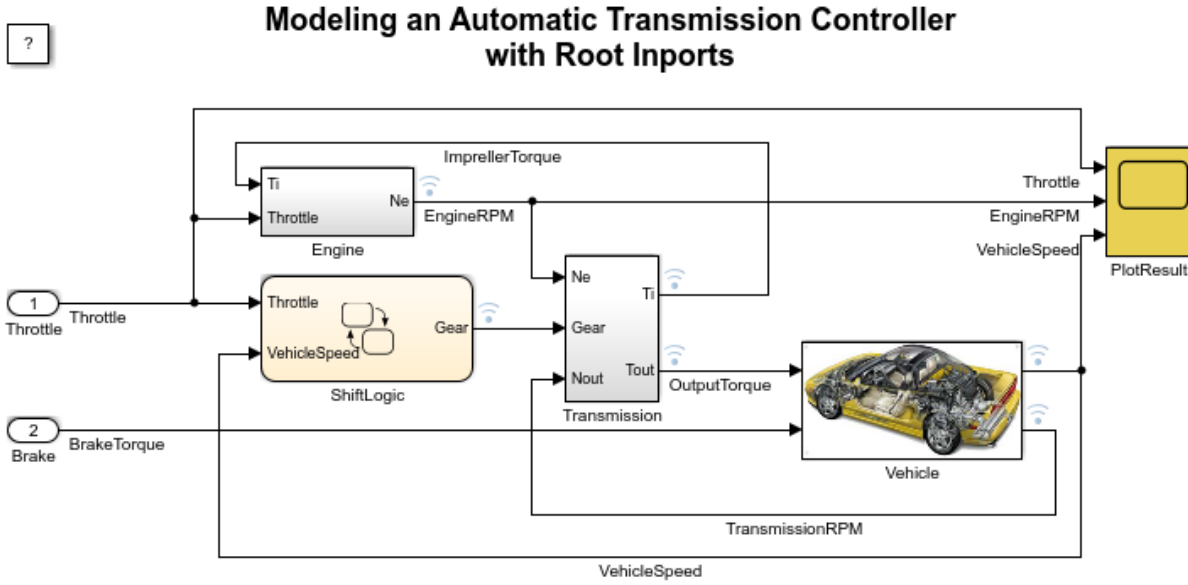
Remove the Signal Builder Block

Remove the Signal Builder block named ManeuversGUI and replace it with two inports.

1. Delete the Signal Builder block named ManeuversGUI.
2. Open the **Simulink Library Browser** and select **Commonly Used Blocks**.
3. Drag and drop two **input ports** from the **Library Browser** to the model.
4. Connect the input ports to the lines previously connected to the Signal Builder block.
5. Rename the inport ports. Name the input port connected to the Throttle line **Throttle**. Name the input port connected to the BrakeTorque line **Brake**.

Save the model as `slexAutotransRootInportsExample1.slx` or use the example `slexAutotransRootInportsExample.slx`.

The remaining steps of this example use the model `slexAutotransRootInportsExample.slx`. If you saved the model with a different name use your model name in the steps going forward.



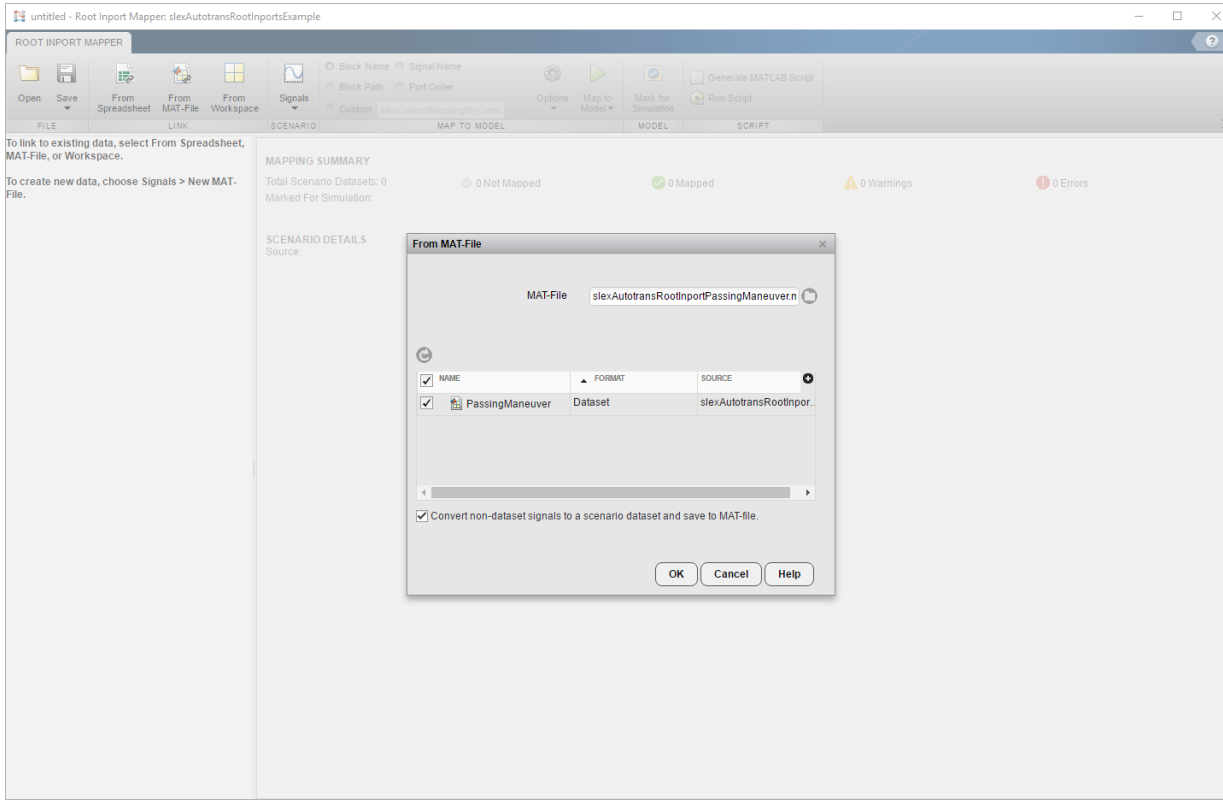
Set Up Harness-Free Inputs

Now that the model is harness-free, set up the inputs that you already saved (See "Save Harness Data to MAT-Files").

From the **Simulation->Model Configuration Parameters->Data Import/Export** pane, click the **Connect Input** button.

Map Signals to Root Inport

The Root Inport Mapper tool opens.



This example uses this tool to set up the model inputs from the MAT-file and map those inputs to an input port, based on a mapping algorithm. To select the MAT-file that contains the input data, click the **From MAT-File** button on the Root Inport Mapper toolbar. When the link dialog appears, click the Open Folder button. In the browser, select the MAT-file that you saved earlier.

Select a Mapping Mode

Once you select the MAT-file `slexAutotransRootInportPassingManeuver.mat` that contains the input data, determine the root input port to which to send input data. Simulink matches input data with input ports based on one of five criteria:

- **Port Order** - Maps in the order it appears in the file to the corresponding port number.

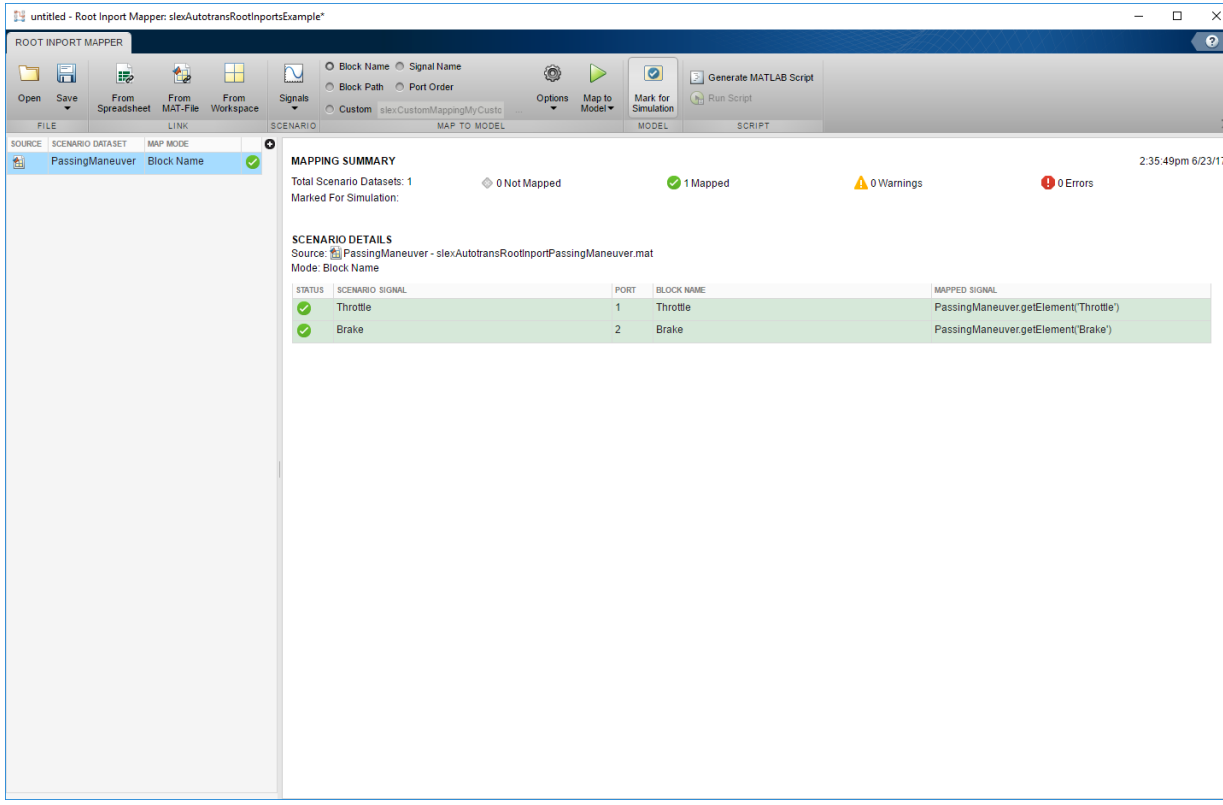
- **Block Name** - Maps by variable name to the corresponding root inport with the matching block name.
- **Signal Name** - Maps by variable name to the corresponding root inport with the matching signal name.
- **Block Path** - Maps by the BlockPath parameter to the corresponding root inport with the matching block path.
- **Custom** - Maps using a MATLAB function.

Earlier in this example, you saved input data to variables of the same name as the harness signals Throttle and Brake, and you added input ports with names matching the variables. Given the set of conditions for the input data and the model input ports, the best choice for a mapping criteria is **Block Name**. Using this criteria, Simulink tries try to match input data variable names to the names of the input ports. To select this option:

1. Click the **Block Name** radio button.
2. Click the **Options** button and select Compile from the dropdown. This will provide some verification on the mapping.
3. Click the **Map** button.

When compiling the data, Simulink evaluates inports against the following criteria to determine whether or not there is a compatibility issue. The status of this compatibility is reflected by the table colors green, orange, or red. Clicking a cell in the table which has orange or red color will open the Comparison Tool for further inspection.

- **Data Type** - Double, single, enum, ...
- **Complexity** - Real or complex
- **Dimensions** - Signal dimensions vs port dimensions

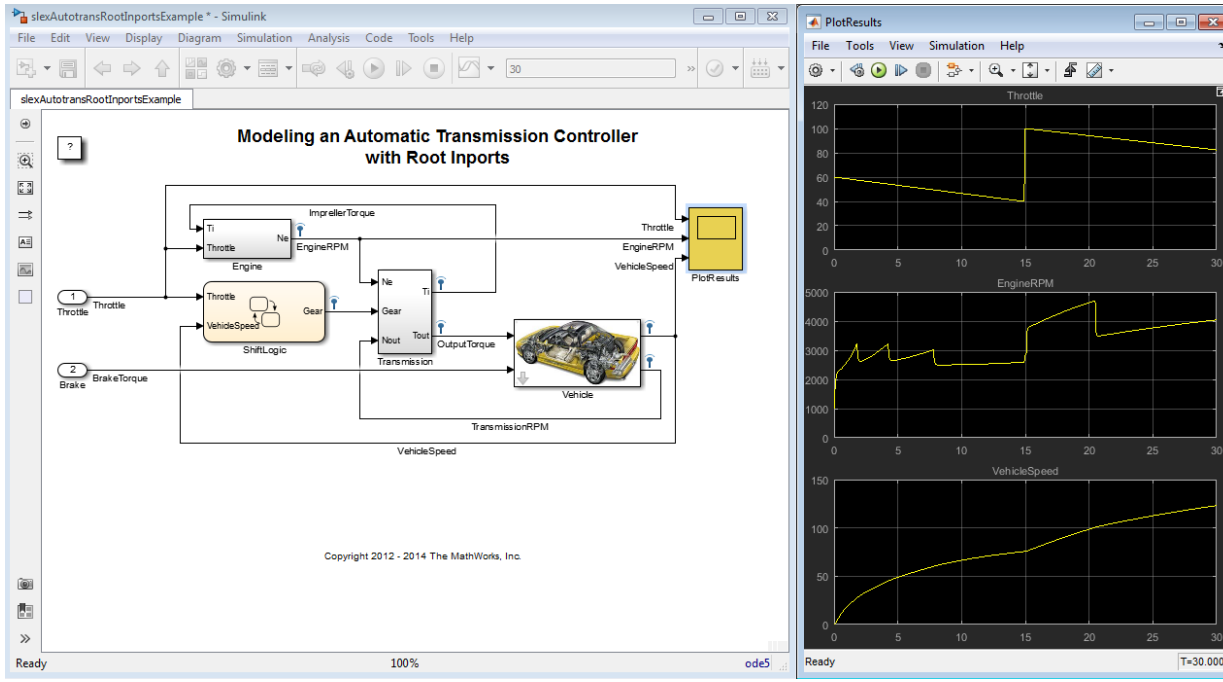


Finalize the Inputs to the Model

Review the results of the mapping compatibility. Click the Scenario Dataset 'PassingManeuver' in the scenario dataset list. To apply the results of the **Map** action and load the data that was mapped to the input ports from the MAT-file to the base workspace click the **Mark for Simulation** button. This action also sets the **Model Configuration Parameters->Data Import/Export->External Input** edit box with the proper comma-separated list of inputs.

Simulating the Model

With the changes applied you can now simulate the model and view the results. Click the **Play** button on the model. To view the results of the simulation, double-click the Scope Block **PlotResults**.



Alternative Workflows to Load Data

After you save the mapping definition to a model, you can automate data loading and simulation. Consider one of the following methods.

Command Line or Script

To load data and simulate the model from the MATLAB command line, use commands similar to:

```
load('signaldata.mat');
simout = sim('model_name');
```

To automate testing and load different signal groups, consider using a script.

The following example code creates timeseries data and simulates a model after loading each signal group. It:

- Creates signal groups with variable names *In1*, *In2*, and *In3*, and saves these variables to MAT-files.
- Simulates a model after loading each signal group.

Note The variable names must match the import data variables in the **Configuration Parameters > Data Import/Export > Input** parameter.

```
% Create signal groups
fileName = 'testCase';
for k =1 :3

    % Create the timeseries data
    var1 = timeseries(rand(10,1));
    var2 = timeseries(rand(10,1));
    var3 = timeseries(rand(10,1));

    %create a dataset
    ds = Simulink.SimulationData.Dataset();
    ds = ds.addElement( var1, 'var1');
    ds = ds.addElement( var2, 'var2');
    ds = ds.addElement( var3, 'var3');

    % Save the data
    save([fileName '_' num2str(k) '.mat' ],'ds');
end
clear all

% After mapping and saving the model loop over signal groups and simulate
% Set the filename to append testcase # to
fileName = 'testCase';
% Loop backwards to preallocate
for k=3:-1:1
   % Load the MAT-file.
   load([fileName '_' num2str(k) '.mat']);

   % Simulate the model
   simOut{k} = sim('model_name');
end
```

Use the PreLoadFcn Pane

When you are satisfied with the data and mapping, you can configure your model to load to the MATLAB workspace a MAT-file of the same signal group. Call the `load` function in a `PreLoadFcn` callback in the model properties node.

1. After saving the MAT-file, in the Simulink editor, select **File > Model Properties > Model Properties**.
2. In the Model Properties window, select the `PreLoadFcn` node.
3. Enter a load function that loads the signal data MAT-file. For example,

```
load d_signal_data.mat;
```

4 Click **OK** and save the model.

Preview Signal Data

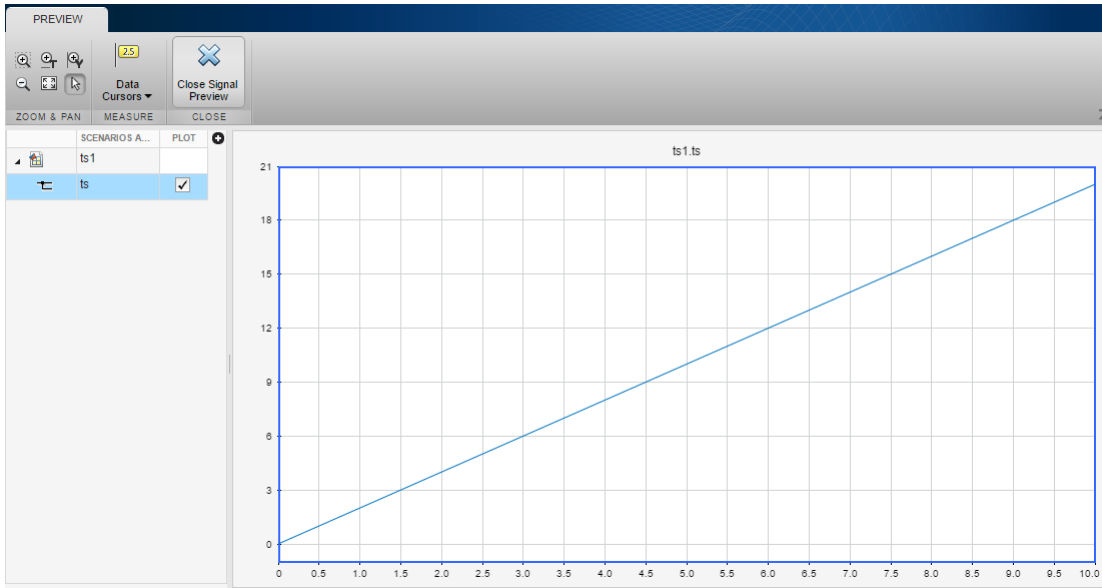
Preview input signal or bus data with the **Signal Preview** window. You can access this window from:

- From File block
- `Simulink.SimulationData.DatasetRef` and `Simulink.SimulationData.Dataset` `plot` methods

1 Preview input signal or bus data with the **Signal Preview** window.

- For From File block, browse to a MAT-file that contains the data you want to preview, then plot the data by clicking  .
- For `Simulink.SimulationData.Dataset` or `Simulink.SimulationData.DatasetRef` elements, use the `plot` method on the dataset.

  If you view and inspect signal using the `Simulink.SimulationData.Dataset` or `Simulink.SimulationData.DatasetRef` `plot` method, the Signal Preview window contains an **Open Simulation Data Inspector** button. Click this button to plot the data using the Simulation Data Inspector.



2 Explore the plots using the **Measure** and **Zoom & Pan** sections on the toolbar.

- In the **Measure** section, use the **Data Cursors** button to display one or two cursors for the plot. These cursors display the T and Y values of a data point in the plot. To view a data point, click a point on the plot line.
- In the **Zoom & Pan** section, select how you want to zoom and pan the signal plots. Zooming is only for the selected axis.

Type of Zoom or Pan	Button to Click
Zoom in along the T and Y axes.	
Zoom in along the time axis. After selecting the icon, on the graph, drag the mouse to select an area to enlarge.	
Zoom in along the data value axis. After selecting the icon, on the graph, drag the mouse to select an area to enlarge.	
Zoom out from the graph.	

Type of Zoom or Pan	Button to Click
Fit the plot to the graph. After selecting the icon, click the graph to enlarge the plot to fill the graph.	
Pan the graph up, down, left, or right. Select the icon. On the graph, hold the left mouse button and move the mouse to the area of the graph that you want to view.

Generate MATLAB Scripts for Simulation with Scenarios

After associating a scenario with the model, you can generate a MATLAB script to perform batch simulations. These scripts enable you to connect multiple sets of input signals to your Simulink model for interactive or batch simulation. You can run simulations multiple times and quickly generate data. This topic assumes that you have a scenario ready to run (see "Root Inport Mapping Scenarios" on page 61-239).

1. Associate your scenario with the model.
2. In the **SCRIPT** section, click **Generate MATLAB Script** and supply a script name when prompted.
3. To run the script, click **Run Script**.
4. To evaluate the results of the simulation, see the base workspace.

The resulting script uses the `Simulink.SimulationInput` object and `parsim` function.

- "Root Inport Mapping Scenarios" on page 61-239

Create and Use Custom Map Modes

You can create custom map modes to supplement the map modes that the Root Inport Mapper tool provides (see “Choose a Map Mode” on page 61-183).

For a summary of the other steps involved in using the Root Inport Mapper tool, see “Import and Mapping Workflow” on page 61-183.

Create Custom Mapping File Function

If you do not want to use the map modes in the Root Inport Mapper tool, create a custom mapping file function. For example, consider creating a custom mapping file function if:

- Your signal data contains a common prefix that is not in your model.
- You want to map a signal explicitly.

When the data contains a signal name that does not match one of the block names, a custom mapping function is useful for block name mapping.

For examples, see these files in the folder *matlabroot*`/help/toolbox/simulink/examples` (open).

File	Description
`BlockNameIgnorePrefixMap.m`	Custom mapping file function that ignores the prefix of a signal name when importing signals
`BlockNameIgnorePrefixData.mat`	MAT-file of signal data to be imported
`ex_BlockNameIgnorePrefixExample`	Model file into which you can import and map data

In addition, see the example Using Mapping Modes with Custom-Mapped External Inputs.

To create a custom mapping file function:

1 Create a MATLAB function with these input parameters:

   - Model name
   - Signal names specified as a cell array of character vectors

- Signals specified as a cell array of signal data

2. In the function, call the `getRootInportMap` function to create a variable that contains the mapping object (for an example, see `BlockNameIgnorePrefixMap.m`).
3. Save and close the MATLAB function file.
4. Add the path for the new function to the MATLAB path.

To use the custom mapping file function:

1. Open the model that you want to import data to (for example, `ex_BlockNameIgnorePrefixExample`).
2. Open the Configuration Parameters dialog box for the model and select the **Data Import/Export** pane.
3. In the **Load from workspace** section, click **Connect Input**.
4. Import your signal (for example, `BlockNameIgnorePrefixData.mat`).
5. In the **MAP TO MODEL** section of the toolstrip, click **Custom**.
6. In the **Custom** text box, select the MATLAB function file (for example, `BlockNameIgnorePrefixMap.m`) using the browser.

   By default, this text box contains `slexcustomMappingMyCustomMap`, which is the custom function for the Attaching Input Data to External Inputs via Custom Input Mappings example.

   Tip The Root Inport Mapper tool parses your custom code. Parsing reorders output alphabetically and verifies that data types are consistent.
7. Click **Options** and select the **Compile** check box.
8. Click **Map**.

   The model is compiled and the Root Inport Mapper tool gets updated.

   To understand the mapping results, see "Understand Mapping Results" on page 61-220.
9. Save and close the model.

After you save the mapping definition for a model, you can automate data loading. The next time that you load input data of the same signal group into the workspace, the model uses the mapping definition during simulation. For more information, see "Alternative Workflows to Load Data" on page 61-229.

Custom Mapping Modes Similar to Simulink Modes

If your custom mapping mode is similar to a Simulink mapping mode, use the `getSlRootInportMap` function in your custom mapping file function to perform the data mapping.

For an example of a custom mapping function that uses this function, see Using Mapping Modes with Custom-Mapped External Inputs.

Command-Line Interface for Input Variables

Use the `getInputString` function to supply a set of input variables to:

- The `sim` command
- A list of input variables that you can paste in the **Configuration Parameters** > **Data Import/Export** > **Input** parameter

Root Inport Mapping Scenarios

In this section...

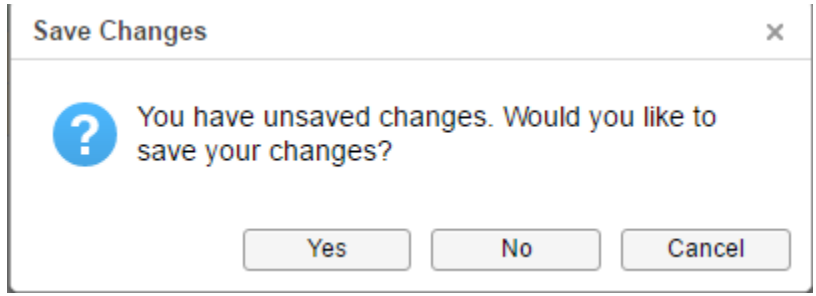
Use the Root Inport Mapper tool to create scenarios, save scenarios, and load previously saved scenarios. The Root Inport Mapper tool uses scenarios to save a snapshot of the current state of the imported and mapped signals in an MLDATX file. A scenario file contains information about the:

- Location of signal files (MAT-file or Microsoft Excel files)
- Location of the model
- Map mode
- Mapping options
- Mapped state

When sharing scenario files, include the scenario file and signal files (MAT-file or Microsoft Excel. Place the signal files in the last known location (where you used the Root Inport Mapper tool most recently) or the MATLAB path.

Open Scenarios

To open an existing scenario, click **Open**. If you are working in another scenario, the Root Inport Mapper tool displays a message.



To...	Click...
Open a new scenario. Remove the existing scenario without saving it.	**No**
Cancel opening a scenario.	**Cancel**
To save the existing scenario, click **Yes**. Then click the **Open** button again to open an existing scenario.	**Yes**

Save Scenarios

When the **Save** icon turns blue or when the model name in the title bar is has an asterisk (*), you can save a scenario.

1. On the Root Inport Mapper toolbar, select **Save** > **Save As**.
2. In the Save As dialog box, browse to a writable folder, specify a scenario file name, and then click **Save**.

   - To save the signals and the scenario file, click **Yes**.

     If a MAT-file is already associated with the scenario, the tool appends the base workspace variables to this file.

Save a scenario to an existing file (the file from which the scenario was last loaded):

1. On the Root Inport Mapper tool toolbar, click **Save**.
2. Browse to the `.mldatx` file in which to save the scenario, and then click **Save**.

   If you have not saved the signals from the scenario, the tool prompts you to save the signals to a MAT-file.

Goal	Action
Overwrite the existing `.mldatx` file.	**Yes**
Exit the dialog box. The tool does not save the scenario.	**No**

Open Existing Scenarios

You can open previously saved scenario files in one of the following ways:

- Double-click the previously saved scenario file (*.`mldatx`). The Root Inport Mapper tool opens and loads the model. Alternatively, right-click the file and select **Open**.
  - When loading scenario files, the tool looks for the associated model and MAT-file or Microsoft Excel file in the last known location, and then looks on the MATLAB path. If the tool cannot find the model or signal files in these two locations, an error occurs.
  - If the previously saved scenario has mapped signals, when you open the scenario, the tool applies the mapping. Also, the tool adds the signals to the base workspace so that you can simulate the model.
- Open the Root Inport Mapper tool for the model, click **Open**, and select the previously saved scenario file.

If the model is already open, the new scenario overwrites the existing scenario for the model. If there are unsaved changes in the open scenario, respond to the prompt.

Goal	Click
Save the existing scenario and associated data before loading the new scenario.	**Yes**
Open the new scenario without saving the existing scenario. This option also removes the data in the existing scenario.	**No**

Work with Multiple Scenarios

You can open and work with multiple scenario files simultaneously. Working with multiple scenario files lets you view, edit, group, and nest multiple scenario files. Use multiple scenario files to test more complex systems with interrelated components.

As you open each multiple scenario, the Root Inport Mapper tool adds its data set to the SCENARIO DATASET section. If the scenario contains only signals, convert the signals to the `Simulink.SimulationData.Dataset` format:

1. To convert the signals to a `Simulink.SimulationData.Dataset` format, use the `convertToSlDataset` function.
2. Link to the new data set. You do not need to reopen the scenario.

Load Signal Data That Uses Units

Signal data logged in a previous simulation using signal logging or the To File or To Workspace block can include units information for `Dataset` or `Timeseries` logging formats.

Logging root-level Outport data from a previous simulation contains units information if:

- These **Data Import/Export** configuration parameter settings:
  - **Output** is enabled.
  - **Format** is `Dataset`.
- For the Outport blocks that you log, in the Block Parameters dialog box, you set the **Unit** parameter.

Otherwise, to include units in signal data that you load, for the `Units` property of the MATLAB `timeseries` objects that you want to load, specify a `Simulink.SimulationData.Unit` object.

Loading Bus Signals That Have Units

When you input a bus signal to a root-level Inport or Outport block, or you use a From File or From Workspace block, the output data type of the block must be a bus object. When you load the data from these blocks, the units in loaded data must match the units specified for the bus elements in the bus object. If the units for the loaded data do not match the units for a bus element in the bus object, Simulink uses the units specified in the bus object.

Load Data Using the From File Block

In this section...

To load signal data into a model using a From File block:

1. Create a MAT-file with the signal data that you want to load. See “Create Data for a From File Block” on page 61-247.
2. Add a From File block to a model. Connect the From File block to the block that the From File provides input to.
3. Double-click the From File block and specify:
   - The path to the file that you want to load data from
   - The data format for the From File block output
   - How the data is loaded, including sample time, how data for missing data points is handled, and whether to use zero-crossing detection

Data Loading

For a Version 7.0 and earlier MAT-file, the From File block loads the complete, uncompressed data from the file into memory at the start of simulation. For a Version 7.3 MAT-file, the From File block incrementally loads data from the file during simulation.

For each simulation time hit for which the MAT-file contains no matching timestamp, Simulink uses interpolation or extrapolation to obtain the needed data. You specify the interpolation and extrapolation methods.

During simulation, the From File block cannot load data from a MAT-file that a To File block is exporting data to.

Sample Time

The From File block **Sample time** parameter specifies the sample time to load data from a MAT-file. The timestamps in the file must be monotonically nondecreasing. For details, see the From File block documentation.

Simulation Time Hits Without Corresponding Time Data

If a simulation time hit does not have a corresponding MAT-file timestamp, then the From File block output depends on:

- Whether the simulation time hit occurs before the first timestamp, within the range of timestamps, or after the last timestamp
- The interpolation or extrapolation methods that you select
- The data type of the MAT-file data

For details about interpolation and extrapolation options, see the documentation for these From File block parameters:

- **Data extrapolation before first data point**
- **Data interpolation within time range**
- **Data extrapolation after last data point**

Duplicate Timestamps

Sometimes the MAT-file includes duplicate timestamps (two or more data values that have the same timestamp). In such cases, the From File block action depends on when the simulation time hit occurs, relative to the duplicate timestamps in the MAT-file.

Suppose that the MAT-file contains the following data, with three data values having a timestamp value of `2`:

```
time stamps:    0 1 2 2 2 3 4
data values:    2 3 6 4 9 1 5
```

The following table describes the From File block output.

Simulation Time, Relative to Duplicate Timestamp Values in MAT-File	From File Block Action
Before the duplicate timestamps	Uses the first of the duplicate timestamp values as the basis for interpolation. (In this example, that timestamp value is `6`.)
At or after the duplicate timestamps	Uses the last of the duplicate timestamp values as the basis for interpolation. (In this example, that timestamp value is `9`.)

Detect Zero Crossings

Zero-crossing detection locates a discontinuity in timestamps, without resorting to excessively small time steps. By default, the From File block does not enable zero-crossing detection.

For the From File block, zero-crossing detection occurs only at timestamps in the file. Simulink examines only the timestamps, not the data values.

For bus signals, Simulink detects zero-crossings across all leaf bus elements.

For more information, see the From File block documentation of the **Enable zero-crossing detection** parameter.

Create Data for a From File Block

Data Saved by a To File Block

The From File block loads data that was written by a To File block without any modifications to the data or any other special provisions.

Supported MAT-File Versions

The supported MAT-file versions are:

- Version 7.0 or earlier
- Version 7.3

For a Version 7.0 and earlier MAT-file, the From File block loads the complete, uncompressed data from the file into memory when the simulation begins. For a Version 7.3 MAT-file, the From File block incrementally loads data from the file during simulation.

For more information about MAT-files, see "MAT-File Versions" (MATLAB).

Convert Version 7.0 and Earlier Version MAT-Files

If you have a Version 7.0 or earlier version MAT-file that you want to use with the From File block, consider converting the file to Version 7.3. Use a Version 7.3 MAT-file if you want the From File block to load data incrementally during simulation or you want to use MATLAB `timeseries` data. For example, to convert a Version 7.0 file named `my_data_file.mat` that contains the variable `var`, at the MATLAB command prompt, enter:

```
load('my_data_file.mat')
save('my_data_file.mat', 'var', '-v7.3')
```

Storage Formats

When the From File block loads data from a MAT-file, that data must be stored in array format or as a MATLAB `timeseries` object.

Array Data

You can use the array format only for vector, double, noncomplex signal data.

For a Version 7.0 MAT-file, the From File block loads array data, but not MATLAB `timeseries` data.

The array format for stored data is a matrix containing two or more rows. The matrix in the MAT-file must have the following form:

$$\begin{bmatrix} t_1 & t_2 & \dots & t_{final} \\ u1_1 & u1_2 & \dots & u1_{final} \\ \dots & & & \\ un_1 & un_2 & \dots & un_{final} \end{bmatrix}$$

The first element of each column contains a timestamp. The remainder of each column contains data for the corresponding output values. Each element must be a double. Elements cannot include a `NaN`, `Inf`, or `-Inf`.

MATLAB Timeseries Data

To use bus data with a From File block, use the MATLAB `timeseries` format.

MATLAB `timeseries` format data can have:

- Any dimensionality and complexity
- Any built-in data type, including `Boolean`
- A fixed-point data type with a word length of up to 32 bits
- An enumerated data type

For data stored using the array format, the width of the From File output depends on the number of rows in the matrix. For a matrix containing *m* rows, the block outputs a vector of length *m*–1.

The MATLAB `timeseries` format supports the following simulation and code generation modes:

- Normal
- Accelerator
- Rapid accelerator
- Model reference accelerator

See the From File block documentation for an example of creating a MAT-file with MATLAB `timeseries` data load with a From Workspace block.

Timestamps

The timestamps in the file must be monotonically nondecreasing.

Bus Data

The From File block supports loading nonvirtual bus signals.

The data must be in a MATLAB structure that matches the bus hierarchy. Each leaf of the structure must be a MATLAB `timeseries` object.

The structure can underspecify the bus signal, but must not overspecify the bus signal. The structure cannot have any elements that do not have corresponding signals in the bus.

The structure does not require a `timeseries` object for every element in the bus hierarchy. However, the structure must have a `timeseries` object for at least one of the signals in the bus. For signals that do not specify data, the From File block outputs the ground values.

MAT-File Variable

If a MAT-file contains only one variable, then the From File block uses that variable. If the MAT-file contains more than one variable:

- For Version 7.3 MAT-files, the From File block uses the variable that is first alphabetically.
- For Version 7.0 or earlier MAT-files, the From File block uses the first variable. However, for these versions, the ordering algorithm for variables is complicated. Use a MAT-file that contains only the variable with the data that you want the From File block to load.

- “Comparison of Signal Loading Techniques” on page 61-128

Load Data Using the From Workspace Block

In this section...

To load signal data with a From Workspace block:

1. Create a workspace variable with the signal data that you want to load.
2. Add a From Workspace block to a model. Connect the From Workspace block to the block that the From Workspace block provides input to.
3. Double-click the From Workspace block and configure:

   - The workspace data to load
   - The data format for the From Workspace block output
   - How the data is loaded, including sample time, how data for missing data points are handled, and whether to use zero-crossing detection

   Suppose that the workspace contains a column vector of times named `T` and a column vector of corresponding signal values named `U`. Entering the expression `[T U]` for **Data** parameter yields the required input array. If the required array or structure exists in the workspace, enter the name of the structure or matrix in the **Data** parameter.

An alternative to using a From Workspace block for loading workspace data is to load data to a root-level input port. For more information, see “Root-Level Input Ports” on page 61-121.

Specify the Workspace Data

Double-click the From Workspace block, and in the **Data** parameter, specify the workspace data to load. Specify a MATLAB expression (for example, the name of a variable in the MATLAB workspace) that evaluates to one of the following:

- A MATLAB `timeseries` object

  Real signals of type `double` can be in any format that the From Workspace block supports. For complex signals and real signals of a data type other than `double`, use any format except `Array`.
- A structure of MATLAB `timeseries` objects

  For bus data, use a structure of MATLAB `timeseries` objects. Match the bus hierarchy and specify a `timeseries` object for each leaf signal in the bus. Set up the data the same way as you do for loading bus signals to a root-level input port. For details, see “Load Bus Data to Root-Level Input Ports” on page 61-170.
- A structure, with or without time

  For details, see “Specify Structure Data for the From Workspace Block” on page 61-252.
- A two-dimensional matrix

  You can use a matrix to specify only one-dimensional signals. The first element of each matrix row is a timestamp. The rest of each row is a scalar or vector of signal values.

Specify Structure Data for the From Workspace Block

You can use a structure for one-dimensional or multidimensional signals, with or without time values. For the structure, use this format:

- A `signals.values` field, which contains a column vector of signal values.
- An optional `signals.dimensions` array, which contains the dimensions of the signal.
- An optional `time` vector of doubles, which is a column vector of timestamps.

  The `n`th `time` element is the timestamp of the `n`th `signals.values` element.

The form of a structure that you use depends on whether you are importing data for:

- Discrete signals (the signal is defined at evenly spaced values of time) — Use a structure that has an empty time vector.
- Continuous signals (the signal is defined for all values of time) — The approach that you use depends on whether the data represents a smooth curve or a curve that has discontinuities (jumps) over its range.

For examples, see:

- "Load Data to Test a Discrete Algorithm" on page 61-149
- "Use From Workspace Block for Test Case" on page 61-152

For both discrete and continuous signals, specify a `signals` field, which contains an array of substructures, each of which corresponds to a model input port.

Each `signals` substructure must contain two fields: `values` and `dimensions`.

- The `values` field must contain an array of inputs for the corresponding input port. If you specify a time vector, each input must correspond to a time value specified in the `time` field.

  If the inputs for a port are scalar or vector values, the `values` field must be an `M-by-N` array. If you specify a time vector, `M` must be the number of time points specified by the `time` field and `N` is the length of each vector value.

  If the inputs for a port are matrices (2-D arrays), the `values` field must be an `M-by-N-by-T` array. `M` and `N` are the dimensions of each matrix input and `T` is the number of time points. Suppose that you want to input 51 time samples of a 4-by-5 matrix signal into one of your model input ports. Then, the corresponding `dimensions` field of the workspace structure must equal `[4 5]` and the `values` array must have the dimensions `4-by-5-by-51`.
- The `dimensions` field specifies the dimensions of the input. If each input is a scalar or vector (1-D array) value, the `dimensions` field must be a scalar value that specifies the length of the vector (1 for a scalar). If each input is a matrix (2-D array), the `dimensions` field must be a two-element vector whose first element specifies the number of rows in the matrix and whose second element specifies the number of columns.

For continuous signals, you can specify a `time` field, which contains a time vector. How you specify the time values depends on the kind of signal data that you want.

For information about defining MATLAB structures, see "Create Structure Array" (MATLAB).

Signal Data	Time Data Recommendation

Evenly spaced discrete signals	Use an expression in this form:
	`timeVector = timeStep * [startTime:numSteps-1]'`
	The vector is transposed. Also, because the start time is a time step, you need specify the number of steps you want minus 1. For example, to specify 50 time values at 0.2 time steps:
	`T1 = 0.2 * [0:49]'`
	Note Do *not* use an expression in this form:
	`timeVector = [startTime:timeStep:endTime]'`
	For example, do not use:
	`T2 = [0:0.2:10]'`
	This time vector form is not equivalent to the form that multiplies by time steps (`T1`), because of double-precision rounding used by computers. Simulink expects exact values, with no double-precision rounding. Using the `T2` form can lead to unexpected simulation results.

Unevenly spaced values	Use any valid MATLAB array expression; for example, `[1:5 5:10]` or `(1 6 10 15)`. The From Workspace, From File, and Signal Builder blocks support zero-crossing detection. If the root-level input port is connected to one of those blocks, you can specify a zero-crossing time by using a duplicate time entry.

If you load a structure that does not specify a time vector:

1 Set **Sample time (-1 for inherited)** to a value other than `0` (continuous).

2. Clear **Interpolate data**.
3. Set **Form output after final data value by** to a value other than `Extrapolation`.

Use Data from a To File Block

You can use the From Workspace block to load data exported by a To Workspace block in a previous simulation for use in a later simulation. Save the To Workspace block data in either `Timeseries` or `Structure with Time` format. Loading data that was exported to a file by a To File block using MATLAB `timeseries` does not require that you change the data.

If you set the To File block **Save format** parameter to `Array`, transpose the exported array data. The data saved by the To File block contains columns with consecutive timestamps, followed by the corresponding data. The transposed data contains rows with consecutive timestamps, followed by the corresponding data. To provide the required format, use MATLAB `load` and `transpose` commands with the MAT-file. See "Reshaping a Matrix" (MATLAB). To avoid transposing the data again, resave the transposed data.

Load Dataset Data

To use workspace data that is in the `Simulink.SimulationData.Dataset` format, extract a MATLAB `timeseries` object from the data set. For example, if you use signal logging with the `Dataset` format and use the default output variable `logsout`, for a single logged signal enter:

```
logsout.get(1).values
```

Specifying Variable-Size Signals

You can use a To Workspace block (with the `Structure` or `Structure With Time` format) or a root Outport block to log variable-size signals. Then use the To Workspace variable with the From Workspace block.

Alternatively, create a MATLAB structure that contains variable-size signal data. For each `values` field in the structure, include a `valueDimensions` field that specifies the run-time dimensions for the signal. For details, see Simulink Models Using Variable-Size Signals on page 66-7.

Store Data for Model Linked to Data Dictionary

When you use a From Workspace block in a model that is linked to a data dictionary, you must choose the location to store the data that the block refers to. Set the value of the **Data** parameter based on the workspace or dictionary that contains the target data to load. For more information, see “Load Data Using the From Workspace Block” on page 61-251.

Sample Time

The From Workspace block **Sample time** parameter specifies the sample time to load data from a workspace. The timestamps in the workspace data must be monotonically nondecreasing. For details, see “Specify Sample Time” on page 7-3.

Interpolate Missing Data Values

To use linear Lagrangian interpolation to compute data values for time hits that occur between the time hits for which the workspace supplies the data, select **Interpolate data**.

For variable-size signals, clear **Interpolate data**.

Specify Output After Final Data

To determine the block output after the last time hit for which workspace data is available, combine the settings of these parameters:

- **Interpolate data**
- **Form output after final data value by**

In the From Workspace block documentation, see the **Form output after final data value by** parameter.

Detect Zero Crossings

By default, the From Workspace block does not enable zero-crossing detection. Zero-crossing detection locates discontinuities, without resorting to excessively small time steps.

The **Enable zero-crossing detection** parameter applies only if the sample time is continuous (`0`).

If you select the **Enable zero-crossing detection** parameter, and if an input array contains multiple entries for the same time hit, Simulink detects a zero crossing at that time hit.

For bus signals, Simulink detects zero crossings across all leaf bus elements.

State Information

In this section...

Simulation State Information

Some blocks maintain state information that they use during simulation. For example, the state information for a Unit Delay block is the output signal value from the previous simulation step. The block uses the state information for calculating the output signal value for the current simulation step.

Some examples of uses of saved state information include:

- Stopping a simulation for a model and using the saved state information as input when you restart the simulation.
- Simulating one model and using the saved state information as input for the simulation of another model that builds on the results of the first model.
- Examining changes in state information throughout a simulation.

Types of State Information

You can save these kinds of state information.

Type of State Information	Description	Configuration Parameters in Data Import/Export Pane
States for each simulation step	State information of blocks (referred to as partial state data) at each time step of a simulation	**States**
Final state	State information of blocks at the end of the simulation	**Final states**

Type of State Information	Description	Configuration Parameters in Data Import/Export Pane
Final state with `SimState`	Final state with a `SimState` object that captures additional internal information that Simulink uses during simulation	**Final States** and **Save complete SimState in final state**

`SimState` provides more complete final simulation state information than final states information by itself does. However, if the requirements and limitations of using `SimState` do not meet your modeling requirements, save final state information without `SimState`.

Comparison of SimState and Final State Logging

Characteristic	Final State	Final State with SimState
Simulation mode	Supports all simulation modes	Normal or Accelerator.
Model reference	"State Information for Referenced Models" on page 61-262	See "Model Referencing" on page 24-43.
Resumed simulation	Not supported	Supported.
Saved state data	Only logged states — the continuous and discrete states of blocks — which are a subset of the complete simulation state of the model User data, run-time parameters, or logs of the model not saved	Complete state information Does not save user data, run-time parameters, or logs of the model.

Characteristic	Final State	Final State with SimState
Block output	User data, run-time parameters, or logs of the model not saved	Simulink tries to save the output of a block as part of a `SimState` even if S-functions declare that no `SimState` states exist in the block. If the block output is of custom type, Simulink displays an error.
Readability	Use structure with time format for best readability	To examine a simplified view of the data, consider using looking at the `loggedStates` property of the `Simulink.SimState.ModelSimState` class.
Restoring state data	Can save and restore in different simulation modes. If logged state information is not sufficient, you can obtain different results in the two simulation modes.	Cannot save in normal mode and restore in Accelerator, or conversely save in accelerator mode and restore in normal mode.
Restoring multiple states	You can initialize only one out of multiple logged states in the model.	You restore all states in the model. You cannot load a subset of states.
Structural changes	You can make structural changes between simulation and restoring the simulation.	You cannot make structural changes to the model between when you save the `SimState` and when you restore the simulation using the `SimState`. For example, you cannot add or remove a block after saving the `SimState` without repeating the simulation and saving the new `SimState`.

Characteristic	Final State	Final State with SimState
Input to `model` function	To input to model function, use `Array` format with non-complex data of type `double`.	You cannot input the `SimState` to model function.
Code generation	Supported	Not supported

For both `SimState` and final state logging, Simulink saves state information at one of these points:

- At the final time step
- At the execution time at which the simulation paused or stopped

For additional information about `SimState`, see “Limitations of SimState” on page 24-42.

Format for State Information Saved Without SimState

If you do not use the `SimState` for saving state information, then use **Configuration Parameters > Data Import/Export > Format** to specify the data format for the saved state information.

You can set **Format** to:

- `Dataset` (default)
- `Array`
- `Structure`
- `Structure with time`

The `Array` option for the **Configuration Parameters > Data Import/Export > Format** option supports compatibility with models developed in earlier releases, when Simulink supported only the array format for saving state information.

The array format reflects the order of signals. The order of saved state information can change between simulations when you change any of the following:

- The model (even without changing the signal)
- The simulation mode

- The code generation mode

The `Structure` and `Structure with time` formats are easier to read and consistent across simulations. Also, these two formats are useful when using state information to initialize a model for simulation, allowing you to:

- Associate initial state values directly with the full path name to the states. This association eliminates errors that can occur if Simulink reorders the states, but the order of the initial state array does not change correspondingly.
- Assign a different data type to the initial value of each state.
- Initialize only a subset of the states.
- `Dataset` format:
  - Uses MATLAB `timeseries` objects to store logged data. MATLAB `timeseries` objects allow you to work with logged data in MATLAB without a Simulink license.
  - Supports logging multiple data values for a given time step, which can be important for Iterator subsystem and Stateflow signal logging
  - Does not support logging nonvirtual bus data for code generation or rapid accelerator mode.

State Information for Referenced Models

When Simulink saves states in the structure or structure-with-time format, it adds an `inReferencedModel` subfield to the `signals` field of the structure. The value of this additional subfield is true (`1`) if the `signals` field records the final state of a block that resides in the reference model. For example:

```
xout.signals(1)

ans =

               values: [101x1 double]
           dimensions: 1
                label: 'DSTATE'
            blockName: [1x66 char]
    inReferencedModel: 1
```

If the signals field records a referenced model state, its `blockName` subfield contains a compound path of a top model path and a reference model path. The top model path is

the path from the model root to the Model block that references the reference model. The reference model path is the path from the reference model root to the block whose state the `signals` field records. The compound path uses a `|` character to separate the top and reference model paths. For example:

```
>> xout.signals(1).blockName

ans =

sldemo_mdlref_basic/CounterA|sldemo_mdlref_counter/Previous Output
```

Save State Information

In this section...

Save State Information for Each Simulation Step

You can save state information for logged states for each simulation step during a simulation. That level of state information can be helpful for debugging.

1. Select the **Configuration Parameters** > **Data Import/Export** > **States** check box.
2. In the **States** edit box, you can specify a different variable for the state information, if you do not want to use the default `xout` variable.
3. Also in the **Data Import/Export** pane, set the **Format** parameter to `Dataset`, `Structure`, or `Structure with time`, unless you use array format for compatibility with a legacy model.

   `Dataset` format does not support:

   - Logging states information inside a function-call subsystem
   - Rapid accelerator simulation mode
   - Code generation
4. Click **Apply**.
5. Simulate the model.

Save Partial Final State Information

To save just the logged states (the continuous and discrete states of blocks):

1. Select the **Configuration Parameters** > **Data Import/Export** > **Final states** check box.
2. In the **Final states** edit box, you can specify a different variable for the state information, if you do not want to use the default `xFinal` variable.

3. Clear the **Save complete SimState in final state** parameter.
4. Set the **Format** parameter to `Dataset`, `Structure`, or `Structure with time`.
5. Click **Apply**.
6. Simulate the model.

Examine State Information Saved Without the SimState

If you enable the **Configuration Parameters** > **Data Import/Export** > **Final states** or **States** parameters, Simulink saves the state information in the format that you specify with the **Format** parameter. The default variable for **Final state** information is `xFinal`, and the variable for state information for States information is `xout`.

If a model has no states saved, then `xFinal` and `xout` are empty variables. To determine whether a model has states saved, use the `isempty(xout)` command.

Final State Information in Dataset Format

For example, suppose that you saved final state information in `Dataset` format, and use the default `xFinal` variable for the saved state information.

```
xFinal
```

```
xFinal =

Simulink.SimulationData.Dataset 'xFinal' with 2 elements

                          Name    BlockPath
                          ______  _________
    1  [1x1 State]        CSTATE  vdp/x1
    2  [1x1 State]        DSTATE  vdp/x2

  - Use braces { } to access, modify, or add elements using index.
```

Examine the first element of the state data set.

```
xFinal{1}
```

```
ans =

  Simulink.SimulationData.State
  Package: Simulink.SimulationData
```

```
  Properties:
         Name: 'CSTATE'
    BlockPath: [1x1 Simulink.SimulationData.BlockPath]
        Label: CSTATE
       Values: [1x1 timeseries]
```

Final State Information in Structure with Time Format

For example, suppose that you saved final state information in a structure with time format, and use the default `xFinal` variable for the saved state information.

To find the simulation time and number of states in the `vdp` model, enter the `xFinal` variable.

```
xFinal
```

```
xFinal =

       time: 20
    signals: [1x2 struct]
```

In this case, the simulation time is 20 and there are two states. To examine the first state, use this command.

```
xFinal.signals(1)
```

```
ans =

               values: 2.0108
           dimensions: 1
                label: 'CSTATE'
            blockName: 'vdp/x1'
            stateName: ''
    inReferencedModel: 0
```

The `values` and `blockName` fields of the first state structure show that the final value for the output signal of the x1 block is 2.018.

Note If you write a script to analyze state information, use a combination of `label` and `blockName` values to identify a specific state uniquely. Do not rely on the order of the states.

Save Final State Information with SimState

To save complete state information, save the `SimState` for a simulation.

1. Select the **Configuration Parameters** > **Data Import/Export** > **Final states** check box.
2. Also in the Data Import/Export pane, select the **Save complete SimState in final state** parameter.
3. In the edit box next to the **Save complete SimState in final state** parameter, enter a variable name for the `SimState` and click **Apply**.
4. Simulate the model.

For more information about using the `SimState`, see “Save and Restore Simulation State as SimState” on page 24-37.

Load State Information

In this section...

Import Initial States

To initialize a simulation, you can use:

- Final state information (with or without `SimState`) from a previous simulation
- State information that you create in MATLAB

Use **Configuration Parameters** > **Data Import/Export** parameters to import initial states.

1. Enable the **Initial state** parameter.
2. In the **Initial state** edit box, enter the name of the variable for the state information that you want to use for initialization.

The initial values that the variable specifies override the initial state values that the blocks in the model specify in initial condition parameters.

You can specify `Dataset`, structure, or structure with time data.

Initialize a State

You can initialize a specific state. This example creates an initial state structure for the `x2` state of the `vdp` model. The `x1` state is not initialized in the structure. Therefore, during simulation, Simulink uses the value in the Integrator block associated with the `x1` state.

1. Open the model.

   ```
   open_system('vdp');
   ```

2. Set the `SaveFormat` model argument to `'Structure'`.

```
set_param('vdp','SaveFormat','Structure');
```

3 Obtain an initial state structure.

```
states = Simulink.BlockDiagram.getInitialState('vdp');
```

4 Set the initial value of the signals structure element associated with `x2` to 2.

```
states.signals(2).values = 2;
```

5 Remove the signals structure element associated with `x1`.

```
states.signals(1) = [];
```

6 Use the `states` variable for the `vdp` model. Select the initial state configuration parameter.

```
set_param('vdp','LoadInitialState','on','InitialState','states');
```

7 Simulate the model and examine the initial values of `x2` and `x1`.

```
sim('vdp');
states
```

```
states =

  struct with fields:

      time: 0
    signals: [1×1 struct]
```

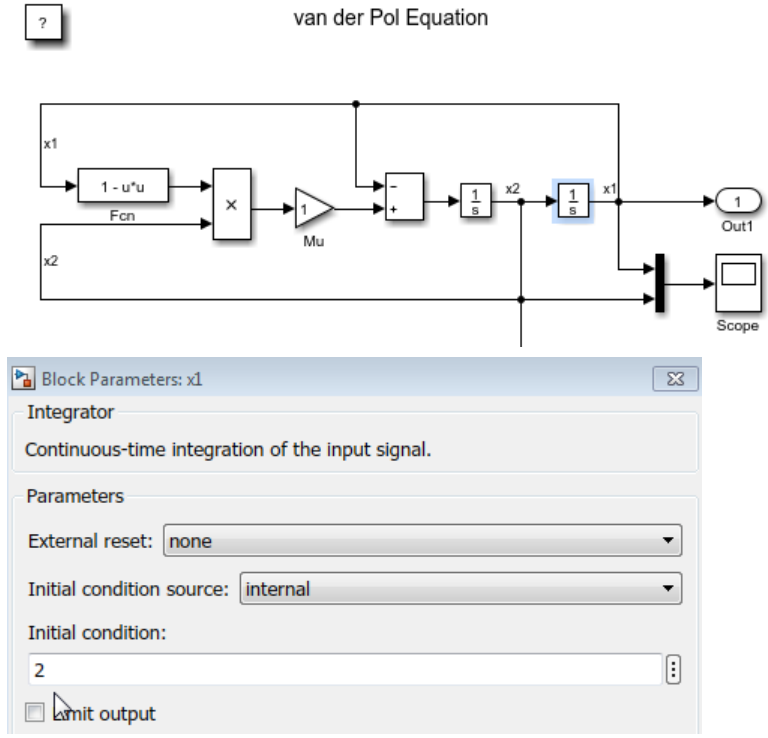
```
states.signals
```

```
ans =

  struct with fields:

              values: 2
          dimensions: 1
               label: 'CSTATE'
           blockName: 'vdp/x2'
           stateName: ''
    inReferencedModel: 0
          sampleTime: [0 0]
```

When you simulate the model, both states have the initial value of 2. The initial value of the `x2` state is assigned in the `states` structure, while the initial value of the `x1` state is assigned in its Integrator block.



Initialize States in Referenced Models

To initialize the states of a top model and the models that it references, use the structure or structure with time format or use `SimState`.

If the top model is in rapid accelerator mode, you cannot load discrete state data.

Working with Data Stores

Data Store Basics

A *data store* is a repository to which you can write data, and from which you can read data, without having to connect an input or output signal directly to the data store. Data stores are accessible across model levels, so subsystems and referenced models can use data stores to share data without using I/O ports.

In this section...

When to Use a Data Store

Data stores can be useful when multiple signals at different levels of a model need the same global values, and connecting all the signals explicitly would clutter the model unacceptably or take too long to be feasible. Data stores are analogous to global variables in programs, and have similar advantages and disadvantages, such as making verification more difficult.

To share data between the instances of a reusable algorithm (for example, a subsystem in a custom library or a reusable referenced model), you can use a data store. For more information about data sharing for a reusable referenced model, see "Specify Reusability of Referenced Models" on page 8-11.

Data Stores and Software Verification

Data stores can have significant effects on software verification, especially in the area of data coupling and control. Models and subsystems that use only inports and outports to pass data result in clean, well-specified, and easily verifiable interfaces in the generated code.

Data stores, like any type of global data, make verification more difficult. If your development process includes software verification, consider planning for the effect of data stores early in the design process.

For more information, see RTCA DO-331, "Model-Based Development and Verification Supplement to DO-178C and DO-278A," Section MB.6.3.3.b.

Goto and From Blocks as a Signal Routing Alternative

In some cases, you may be able to use a simpler technique, Goto blocks and From blocks, to obtain results similar to those provided by data stores. The principal disadvantage of data Goto/From links is that they generally are not accessible across nonvirtual subsystem boundaries, while an appropriately configured data store can be accessed anywhere. See the Goto and From block reference pages for more information about Goto/From links.

Local and Global Data Stores

You can define two types of data stores:

- A *local data store* is accessible from anywhere in the model hierarchy that is at or below the level at which you define the data store, except from referenced models. You can define a local data store graphically in a model or by creating a model workspace signal object (`Simulink.Signal`).
- A *global data store* is accessible from throughout the model hierarchy, including from referenced models. Define a global data stores only in the MATLAB base workspace, using a signal object. The only type of data store that a referenced model can access is a global data store.

In general, locate a data store at the lowest level in the model that allows access to the data store by all the parts of the model that need that access. Some examples of local and global data stores appear in “Data Store Examples” on page 62-13.

For information about using referenced models, see “Model Referencing”.

Data Store Diagnostics

About Data Store Diagnostics

Simulink provides various run-time and compile-time diagnostics that you can use to help avoid problems with data stores. Diagnostics are available in the Model

Configuration Parameters dialog box and the Data Store Memory block's parameters dialog box. The Simulink Model Advisor provides support by listing cases where data store errors are more likely because diagnostics are disabled.

Detecting Access Order Errors

- "Data Store Diagnostics and Models Referenced in Accelerator Mode" on page 62-5
- "Data Store Diagnostics and the MATLAB Function Block" on page 62-6

You can use data store run-time diagnostics to detect unintended sequences of data store reads and writes that occur during simulation. You can apply these diagnostics to all data stores, or allow each Data Store Memory block to set its own value. The diagnostics are:

- **Detect read before write:** Detect when a data store is read from before written.
- **Detect write after read:** Detect when a data store is written.
- **Detect write after write:** Detect when a data store is written.

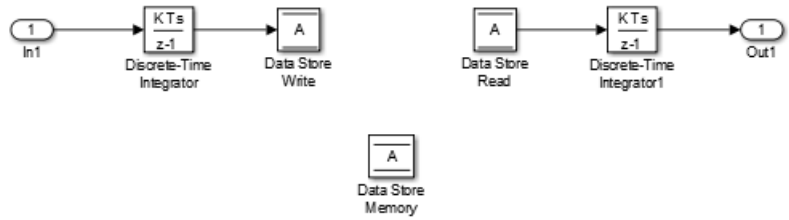
These diagnostics appear in the **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block** pane, where each can have one of the following values:

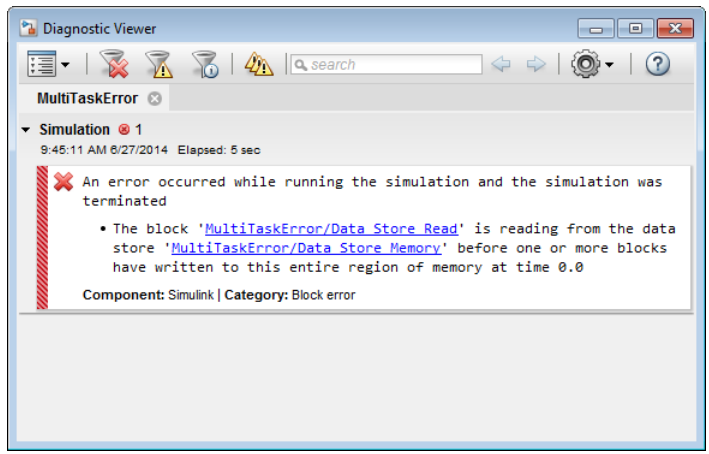
- `Disable all` — Disables this diagnostic for all data stores accessed by the model.
- `Enable all as warnings` — Displays the diagnostic as a warning in the MATLAB Command Window.
- `Enable all as errors` — Halts the simulation and displays the diagnostic in an error dialog box.
- `Use local settings` — Allow each Data Store Memory block to set its own value for this diagnostic (default).

The same diagnostics also appear in each Data Store Memory block parameters dialog box **Diagnostics** tab. You can set each diagnostic to `none`, `warning`, or `error`. The value specified by an individual block takes effect only if the corresponding configuration parameter is `Use local settings`. See "Model Configuration Parameters: Data Validity Diagnostics" and the Data Store Memory documentation for more information.

The most conservative technique is to set all data store diagnostics to `Enable all as errors` in **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block**. However, this setting is not best in all cases, because it can flag

intended behavior as erroneous. For example, the next figure shows a model that uses block priorities to force the Data Store Read block to execute before the Data Store Write block:





An error occurred during simulation because the data store `A` is read from the Data Store Read block before the Data Store Write block updates the store. If the associated delay is intended, you can suppress the error by setting the global parameter **Detect read before write** to `Use local settings`, then setting that parameter to `none` in the **Diagnostics** pane of the Data Store Memory block dialog box. If you use this technique, set the parameter to `error` in all other Data Store Memory blocks aside from those that are to be intentionally excluded from the diagnostic.

Data Store Diagnostics and Models Referenced in Accelerator Mode

For models referenced in Accelerator mode, Simulink ignores the following **Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block** parameters if you set them to a value other than `Disable all`.

- **Detect read before write** (`ReadBeforeWriteMsg`)
- **Detect write after read** (`WriteAfterReadMsg`)
- **Detect write after write** (`WriteAfterWriteMsg`)

You can use the Model Advisor to identify models referenced in Accelerator mode for which Simulink ignores the configuration parameters listed above.

1. In the Simulink Editor, select **Analysis** > **Model Advisor**.
2. Select **By Task**.
3. Run the **Check diagnostic settings ignored during accelerated model reference simulation** check.

Data Store Diagnostics and the MATLAB Function Block

Diagnostics might be more conservative for data store memory used by MATLAB Function blocks. For example, if you pass arrays of data store memory to MATLAB functions, optimizations such as `A=foo(A)` might result in MATLAB marking the entire contents of the array as read or written, even though only some elements were accessed.

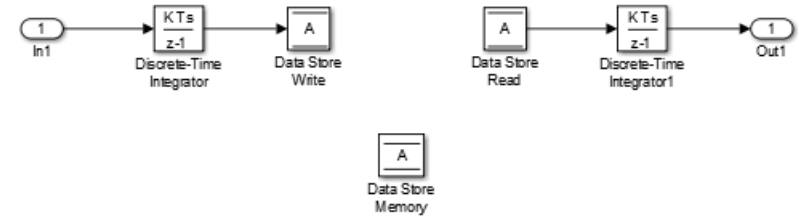
Detecting Multitasking Access Errors

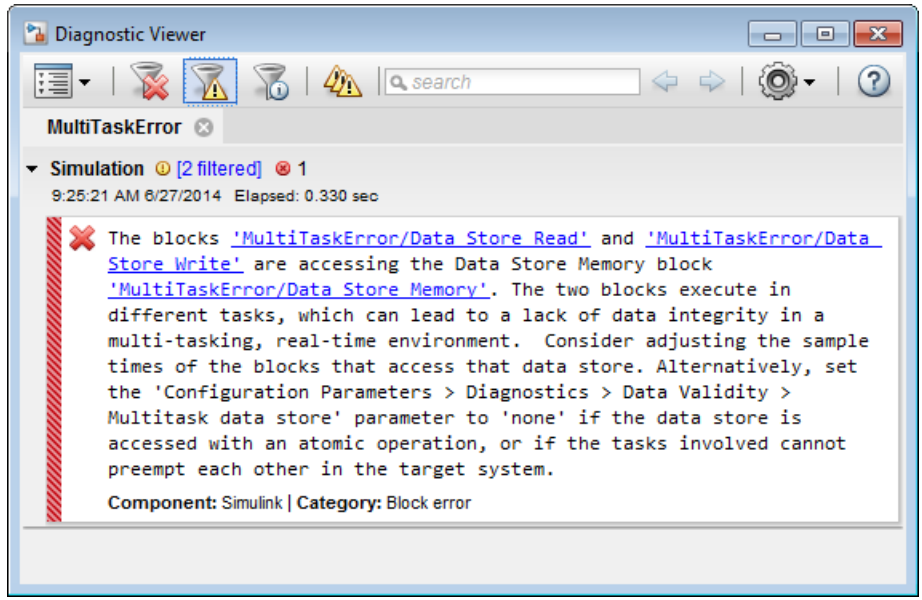
Data integrity may be compromised if a data store is read from in one task and written to in another task. For example, suppose that:

1. A task is writing to a data store.
2. A second task interrupts the first task.
3. The second task reads from that data store.

If the first task had only partly updated the data store when the second task interrupted, the resulting data in the data store is inconsistent. For example, if the value is a vector, some of its elements may have been written in the current time step, while the rest were written in the previous step. If the value is a multi-word, it may be left in an inconsistent state that is not even partly correct.

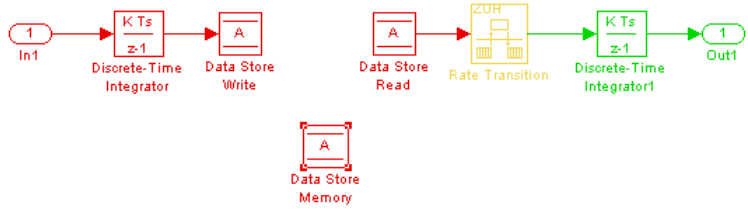
Unless you are certain that task preemption cannot cause data integrity problems, set the compile-time diagnostic **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block > Multitask data store** to `warning` (the default) or `error`. This diagnostic flags any case of a data store that is read from and written to in different tasks. The next figure illustrates a problem detected by setting **Multitask data store** to `error`:





Since the data store `A` is written to in the fast task and read from in the slow task, an error is reported, with suggested remedy. This diagnostic is applicable even in the case that a data store read or write is inside of a conditional subsystem. Simulink correctly identifies the task that the block is executing within, and uses that task for the purpose of evaluating the diagnostic.

The next figure shows one solution to the problem shown above: place a rate transition block after the data store read, which previously accessed the data store at the slower rate.



With this change, the data store write can continue to occur at the faster rate. This may be important if that data store must be read at that faster rate elsewhere in the model.

The **Multitask Data Store** diagnostic also applies to data store reads and writes in referenced models. If two different child models execute a data store's reads and writes in differing tasks, the error will be detected when Simulink compiles their common parent model.

Detecting Duplicate Name Errors

Data store errors can occur due to duplicate uses of a data store name within a model. For instance, data store shadowing occurs when two or more data store memories in different nested scopes have the same data store name. In this situation, the data store memory referenced by a data store read or write block at a low level may not be the intended store.

To prevent errors caused by duplicate data store names, set the compile-time diagnostic **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block > Duplicate data store names** to `warning` or `error`. By default, the value of the diagnostic is `none`, suppressing duplicate name detection. The next figure shows a problem detected by setting **Duplicate data store names** to `error`:

The data store read at the bottom level of a subsystem hierarchy refers to a data store named `A`, and two Data Store Memory blocks in the same model have that name, so an

error is reported. This diagnostic guards against assuming that the data store read refers to the Data Store Memory block in the top level of the model. The read actually refers to the Data Store Memory block at the intermediate level, which is closer in scope to the Data Store Read block.

Data Store Diagnostics in the Model Advisor

The Model Advisor provides several diagnostics that you can use with data stores. See these sections for information about Model Advisor diagnostics for data stores:

"Check Data Store Memory blocks for multitasking, strong typing, and shadowing issues"

"Check data store block sample times for modeling errors"

"Check if read/write diagnostics are enabled for data store blocks"

Specify Initial Value for Data Store

In general, to specify an initial value for a data store, you can use the same techniques that you use for other blocks. See "Initialize Signals and Discrete States" on page 64-53.

With most blocks, you can take advantage of scalar expansion to minimize the effort of specifying an initial value for a nonscalar signal. When you specify a scalar initial value, each element in the signal uses that scalar.

However, when you set the **Dimensions** parameter to `-1` in a Data Store Memory block (the default), you cannot use scalar expansion. Instead, you must specify an initial value that has the same dimensions as the stored signal. To take advantage of scalar expansion of the initial value, set the **Dimensions** parameter to a specific value such as `[1 2]` or `[1 myDim]` (for symbolic dimensions).

Model Global Data by Creating Data Stores

In this section...

A *data store* is a repository to which you can write data, and from which you can read data, without having to connect an input or output signal directly to the data store. Data stores are accessible across model levels, so subsystems and referenced models can use data stores to share data without using I/O ports. To decide whether to use data stores, see “Data Store Basics” on page 62-2.

Data Store Examples

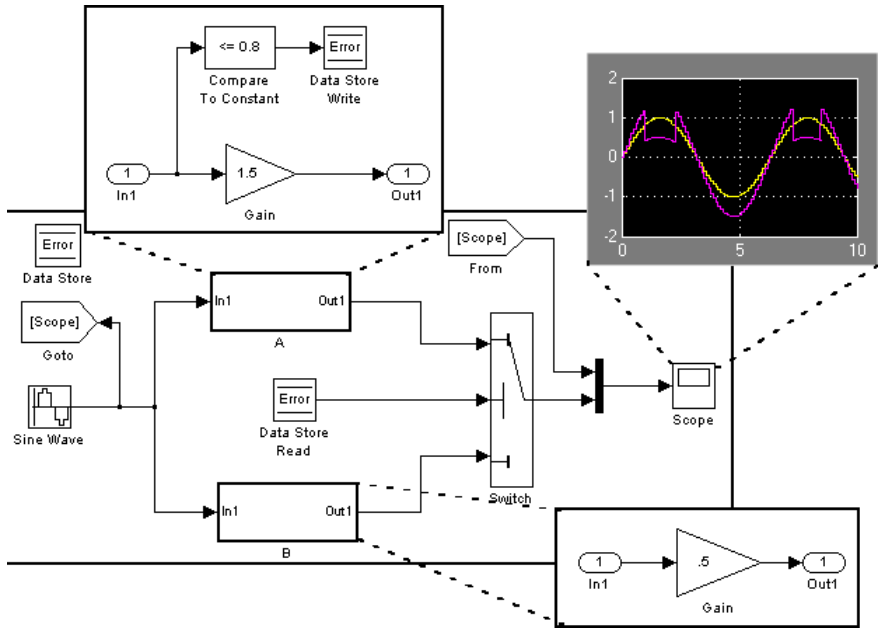
Overview

The following examples illustrate techniques for defining and accessing data stores. See “Order Data Store Access” on page 62-25 for techniques that control data store access over time, such as ensuring that a given data store is always written before it is read. See “Data Store Diagnostics” on page 62-3 for techniques you can use to help detect and correct potential data store errors without needing to run any simulations.

Note In addition to the following examples, see the sldemo_mdlref_dsm model, which shows how to use global data stores to share data among referenced models.

Local Data Store Example

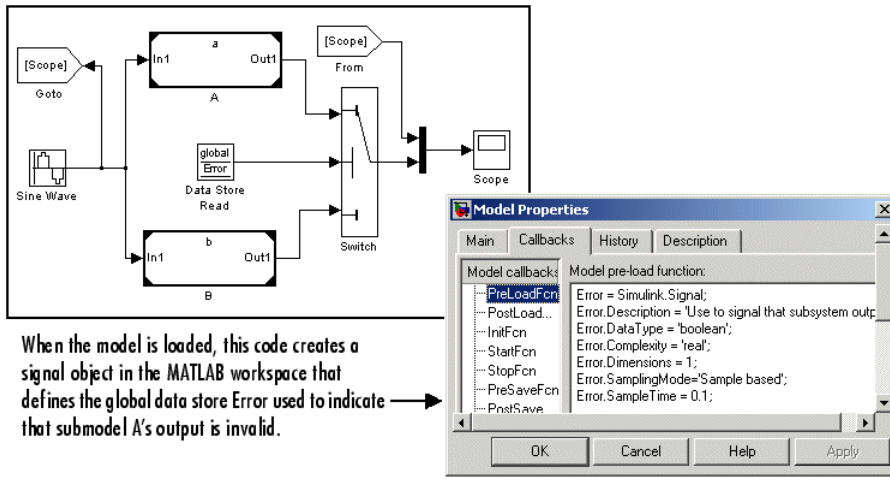
The following model illustrates creation and access of a local data store, which is visible only in a model or particular subsystem.



This model uses a data store to permit subsystem A to signal that its output is invalid. If subsystem A's output is invalid, the model uses the output of subsystem B.

Global Data Store Example

The following model replaces the subsystems of the previous example with functionally identical referenced models to illustrate use of a global data store to share data in a model reference hierarchy.



In this example, the top model uses a signal object in the MATLAB workspace to define the error data store. This is necessary because data stores are visible across model boundaries only if they are defined by signal objects in the MATLAB workspace.

Create and Apply Data Stores

Note To use buses and arrays of buses with data stores, perform *both* the following procedure and "Setting Up a Model to Use Data Stores with Buses and Arrays of Buses" on page 62-31.

The following is a general workflow for configuring data stores. You can perform the tasks in a different order, or separately from the rest, depending on how you use data stores.

1. Where applicable, plan your use of data stores to minimize their effect on software verification. For more information, see "Data Stores and Software Verification" on page 62-2.
2. Create data stores using the techniques described in "Data Stores with Data Store Memory Blocks" on page 62-17 or "Data Stores with Signal Objects" on page 62-20. For greater reliability, consider assigning rather than inheriting data store attributes, as described in "Specifying Data Store Memory Block Attributes" on page 62-17.

3. Add to the model Data Store Write and Data Store Read blocks to write to and read from the data stores, as described in "Access Data Stores with Simulink Blocks" on page 62-22.
4. Configure the model and the blocks that access each data store to avoid concurrency failures when reading and writing the data store, as described in "Order Data Store Access" on page 62-25.
5. Apply the techniques described in "Data Store Diagnostics" on page 62-3 as needed to prevent data store errors, or to diagnose them if they occur during simulation.
6. If you intend to generate code for your model, see "Data Stores in Generated Code" (Simulink Coder).

To create a data store, you create a Data Store Memory block or a `Simulink.Signal` object. The block or signal object represents the data store and specifies its properties. Every data store must have a unique name.

- A Data Store Memory block implements a local data store. See "Data Stores with Data Store Memory Blocks" on page 62-17.
- A `Simulink.Signal` object can act as a local or global data store. See "Data Stores with Signal Objects" on page 62-20.

Data stores implemented with Data Store Memory blocks:

- Support data store initialization
- Provide control of data store scope and options at specific levels in the model hierarchy
- Require a block to represent the data store
- Cannot be accessed within referenced models
- Cannot be in a subsystem that a For Each Subsystem block represents.

Data stores implemented with `Simulink.Signal` objects:

- Provide model-wide control of data store scope and options
- Do not require a block to represent the data store
- Can be accessed in referenced models, if the data store is global

Be careful not to equate local data stores with Data Store Memory blocks, and global data stores with `Simulink.Signal` objects. Either technique can define a local data store, and a signal object can define either a local or a global data store.

Data Stores with Data Store Memory Blocks

Creating the Data Store

To use a Data Store Memory block to define a data store, drag an instance of the block into the model at the topmost level from which you want the data store to be visible. The result is a local data store, which is not accessible within referenced models.

- To define a data store that is visible at every level within a given model, except within Model blocks, drag the Data Store Memory block into the root level of the model.
- To define a data store that is visible only within a particular subsystem and the subsystems that it contains, but not within Model blocks, drag the Data Store Memory block into the subsystem.

Once you have added the Data Store Memory block, use its parameters to define the data store's properties. The **Data store name** property specifies the name of the data store that the Data Store Write and Data Store Read blocks access. See Data Store Memory documentation for details.

You can specify data store properties beyond those definable with Data Store Memory block parameters by selecting the **Data store name must resolve to Simulink signal object** option and using a signal object as the data store name. See "Specifying Attributes Using a Signal Object" on page 62-18 for details.

Specifying Data Store Memory Block Attributes

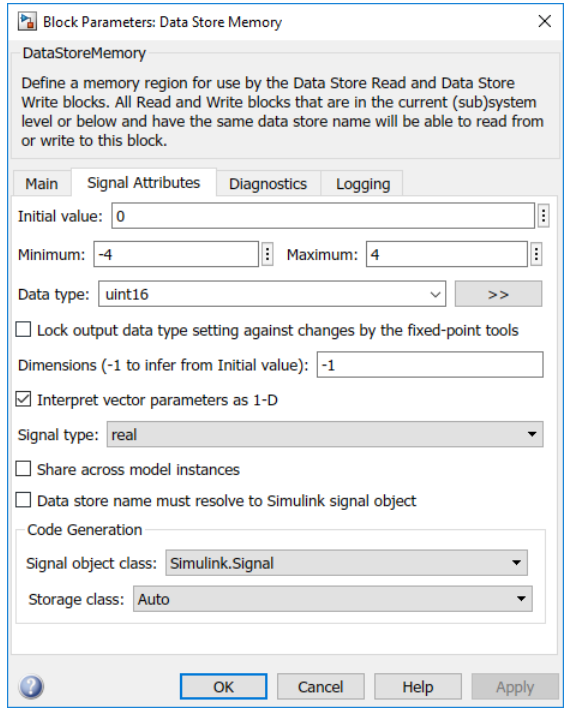
A Data Store Memory block can inherit three data attributes from its corresponding Data Store Read and Data Store Write blocks. The inheritable attributes are:

- Data type
- Complexity
- Sample time

However, allowing these attributes to be inherited can cause unexpected results that can be difficult to debug. To prevent such errors, use the Data Store Memory block dialog or a `Simulink.Signal` object to specify the attributes explicitly.

Specifying Attributes Using Block Parameters

You can use the Data Store Memory block dialog box or the Model Data Editor **Data Stores** tab (**View > Model Data**) to specify the data type and complexity of a data store. In the next figure, the block dialog box sets the **Data type** to `uint16` and the **Signal type** to `real`.

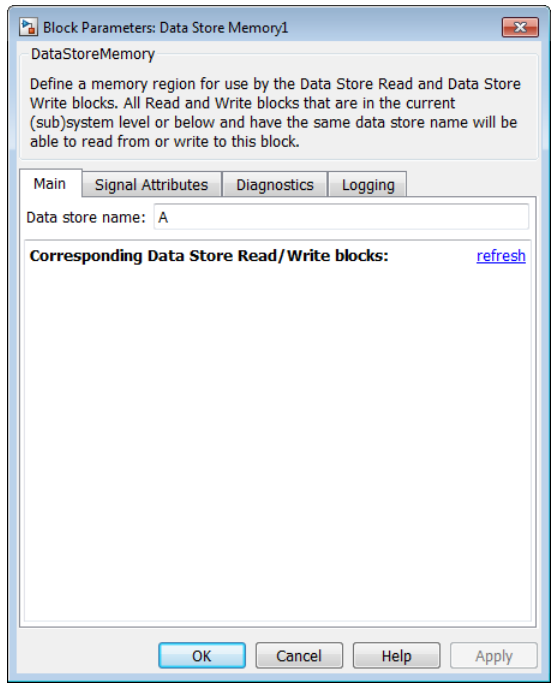


Specifying Attributes Using a Signal Object

You can use a `Simulink.Signal` object to specify data store attributes for a Data Store Memory block.

Tip To establish an implicit data store, as described in "Data Stores with Signal Objects" on page 62-20, use the same general approach as when you explicitly associate a signal object with a Data Store Memory block.

The next figure shows a Data Store Memory block that specifies resolution to a `Simulink.Signal` object, named `A`. To use a signal object for the data store, set **Data store name** to the name of the signal object. For compile-time checking, open the **Signal Attributes** tab and select the **Data store name must resolve to Simulink signal object** parameter.



Alternatively, on the Model Data Editor **Data Stores** tab (**View** > **Model Data**), while editing the data store name, click the nearby action button ⋮ and select **Create and Resolve**. In the Create New Data dialog box, set **Value** to `Simulink.Signal`.

The signal object specifies values for all three data attributes that the data store would otherwise inherit. In this example, which defines a local data store, the `Simulink.Signal` object `A` has the following inherited properties: `DataType`, `Complexity`, and `SampleTime`.

```
A =

Simulink.Signal (handle)
         CoderInfo: [1x1 Simulink.CoderInfo]
```

```
      Description: ''
         DataType: 'auto'
              Min: []
              Max: []
             Unit: ''
       Dimensions: 1
   DimensionsMode: 'auto'
       Complexity: 'auto'
       SampleTime: -1
     InitialValue: 0
```

For more information about specifying signal object attributes for local and global data stores, see “Signal Object Attributes for Data Stores” on page 62-21.

Use Model Data Editor to Configure Data Store Memory Blocks in a List

Use the **Data Stores** tab in the Model Data Editor to configure the parameters of a Data Store Memory block. Use this technique to configure the data store without locating it in the model and to configure the data store together with other interface elements such as Inport and Outport blocks. The Model Data Editor also shows you information for Data Store Read and Data Store Write blocks in the same list.

To open the Model Data Editor, select **View > Model Data**. For information about using the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 59-141.

Data Stores with Signal Objects

Creating the Data Store

To use a `Simulink.Signal` object to define a data store without using a Data Store Memory block, create the signal object in a workspace that is visible to every component that needs to access the data store. The name of the associated data store is the name of the signal object. You can use this name in Data Store Read and Data Store Write blocks, just as if it were the **Data store name** of a Data Store Memory block. Simulink creates an associated data store when you use the signal object for data storage.

Local and Global Data Stores

You can use a `Simulink.Signal` object to define either a local or a global data store.

- If you define the object in the MATLAB base workspace or a data dictionary, the result is a global data store, which is accessible in every model within Simulink, including all referenced models.
- If you create the object in a model workspace, the result is a local data store, which is accessible at every level in a model except any referenced models.

Signal Object Attributes for Data Stores

Those data store attributes that a signal object does not define have the same default values that they do in a Data Store Memory block. The property values of a signal object used as a data store have different requirements, depending on whether the data store is local or global.

Once you have created the object, set the properties of the signal object to the values that you want the corresponding data store properties to have. For example, the following commands define a data store named `Error` in the MATLAB base workspace:

```
Error = Simulink.Signal;
Error.Description = 'Use to signal that subsystem output is invalid';
Error.DataType = 'boolean';
Error.Complexity = 'real';
Error.Dimensions = 1;
Error.SampleTime = 0.1;
```

Attributes for Local Data Stores

For a local data store, for each parameter listed below, you can either set the value explicitly or you can have the data store inherit the value from the Data Store Write and Data Store Read blocks.

- `DataType`
- `Complexity`
- `SampleTime`

To define a local data store using a Data Store Memory block, you can use a signal object for the **Data store name** parameter. For compile-time checking, in the **Signal Attributes** tab, select the **Data store must resolve to Simulink signal object** parameter. The **Data store must resolve to Simulink signal object** parameter

causes Simulink to display an error and stop compilation if Simulink cannot find the signal object or if the signal object properties are inconsistent with the signal object properties.

Attributes for Global Data Stores

The following table describes the parameter requirements for global data stores.

Parameter	Global Data Store Value
`DataType`	Must be set explicitly
`Complexity`	Must be set explicitly
`Dimensions`	Can be set or inherited
`SampleTime`	Can be set or inherited

Modify Attributes of Data Store Defined by Signal Object

You can use the Model Data Editor (**View > Model Data**) to modify and inspect the attributes of data stores, Data Store Read, and Data Store Write blocks. On the **Data Stores** tab, to show the attributes of data stores that you define by using signal objects (such as `Simulink.Signal`), click the **Show/refresh additional information** button. Then, if a Data Store Read or Data Store Write block shown in the data table refers to a data store defined by a signal object, the table includes a row that corresponds to the object.

For more information about the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 59-141.

Access Data Stores with Simulink Blocks

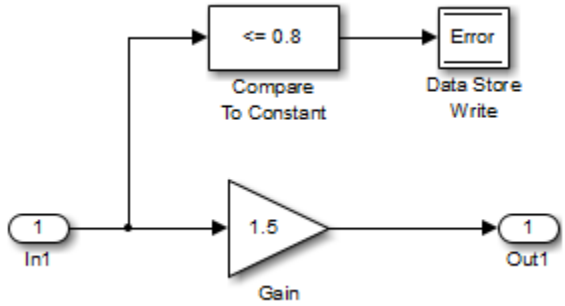
Writing to a Data Store

To set the value of a data store at each time step:

1 Create an instance of a Data Store Write block at the level of your model that computes the value.

2 Set the Data Store Write block **Data store name** parameter to the name of the data store to which you want it to write data.

3 Connect the output of the block that computes the value to the input of the Data Store Write block.



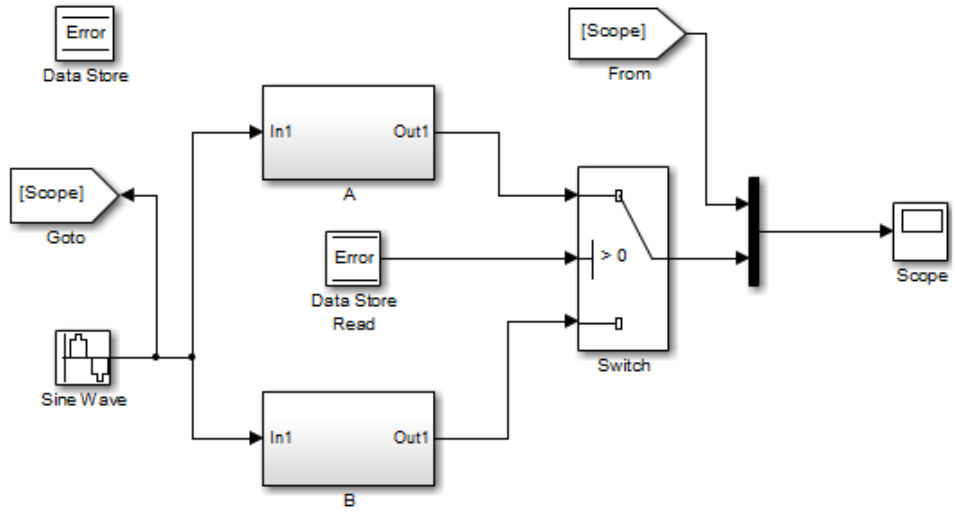
Reading from a Data Store

To get the value of a data store at each time step:

1 Create an instance of a Data Store Read block at the level of your model that needs the value.

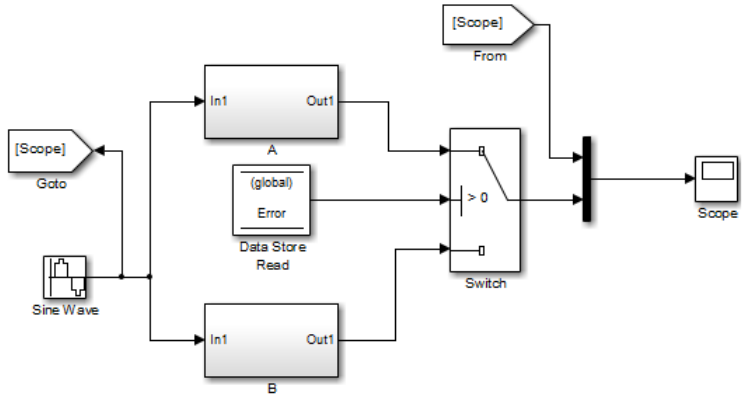
2 Set the Data Store Read block **Data store name** parameter to the name of the data store from which you want it to read.

3 Connect the output of the Data Store Read block to the input of the block that needs the data store value.



Accessing a Global Data Store

When connected to a global data store (one that is defined by a signal object in the MATLAB workspace), a Data Store Read or Data Store Write block displays the word `global` above the data store name.



Order Data Store Access

About Data Store Access Order

To obtain correct results from data stores, you must control the order of execution of the data store's reads and writes. If a data store's read occurs before its write, latency is introduced into the algorithm: the read obtains the value that was computed and stored in the previous time step, rather than the value computed and stored in the current time step.

Such latency may cause the system to behave other than as designed, and in some cases may destabilize the system. Even if these problems do not occur, an uncontrolled access order could change from one release of Simulink to the next.

This section describes several strategies for explicitly controlling the order of execution of a data store's reads and writes. See "Data Store Diagnostics" on page 62-3 for techniques you can use to detect and correct potential data store errors without running simulations.

Ordering Access Using Function Call Subsystems

You can use function call subsystems to control the execution order of model components that access data stores. The next figure shows this technique:

The subsystem `Before` contains the Data Store Write, and the Stateflow chart calls that subsystem before it calls the subsystem `After`, which contains the Data Store Read.

Ordering Access Using Block Priorities

You can embed data store reads and writes inside atomic subsystems or Model blocks whose priorities specify their relative execution order.

The Model block `beforeDSM` has a lower priority then `afterDSM`, so it is guaranteed to execute first. Since `beforeDSM` is atomic, all of its operations, including the Data Store Write, will execute prior to `afterDSM` and all of its operations, including the Data Store Read.

To assign priorities to blocks, see “Assign Block Priorities” on page 35-42.

Data Stores with Buses and Arrays of Buses

Benefits of using data stores with buses and arrays of buses include:

- Simplifying the model layout by associating multiple signals with a single data store
- Producing generated code that represents the data in the store data as structures that reflect the bus hierarchy
- Writing to and reading from data stores without creating data copies, which results in more efficient data access

You cannot use a bus or array of buses that contains:

- Variable-dimension signals

- Frame-based signals

Setting Up a Model to Use Data Stores with Buses and Arrays of Buses

This procedure applies to local and global data stores, and to data stores defined with a Data Store Memory block or a `Simulink.Signal` object. Before performing the procedure, you must understand how to use data stores in a model, as described in "Create and Apply Data Stores" on page 62-15.

To use buses and arrays of buses with data stores:

1. Use the Bus Editor to define a bus object whose properties match the bus data that you want to write to and read from a data store. For details, see "Create Bus Objects with the Bus Editor" on page 65-69.
2. Add a data store (using a Data Store Memory block or a `Simulink.Signal` object) for storing the bus data.
3. Specify the bus object as the data type of the data store. For details, see "Specify a Bus Object Data Type" on page 59-49.
4. In the **Model Configuration Parameters** > **Diagnostics** > **Connectivity** pane, set the **Mux blocks used to create bus** diagnostic to `error`.
5. If you use a MATLAB structure for the initial value of the data store, then set **Configuration Parameters** > **Diagnostics** > **Data Validity** > **Advanced parameters** > **Underspecified initialization detection** to `Simplified`. For details, see "Specify Initial Conditions for Bus Signals" on page 65-108 and "Underspecified initialization detection".
6. (Optional) Select individual bus elements to write to or read from a data store. For details, see "Accessing Specific Bus and Matrix Elements" on page 62-31.

Accessing Specific Bus and Matrix Elements

Selecting Specific Bus or Matrix Elements

By default, a model writes and reads all bus and matrix elements to and from a data store.

To select specific bus or matrix elements to write to or read from a data store, use the **Element Assignment** pane of the Data Store Write block and the **Element Selection** pane of the Data Store Read block . Selecting specific bus or matrix elements offers the following benefits:

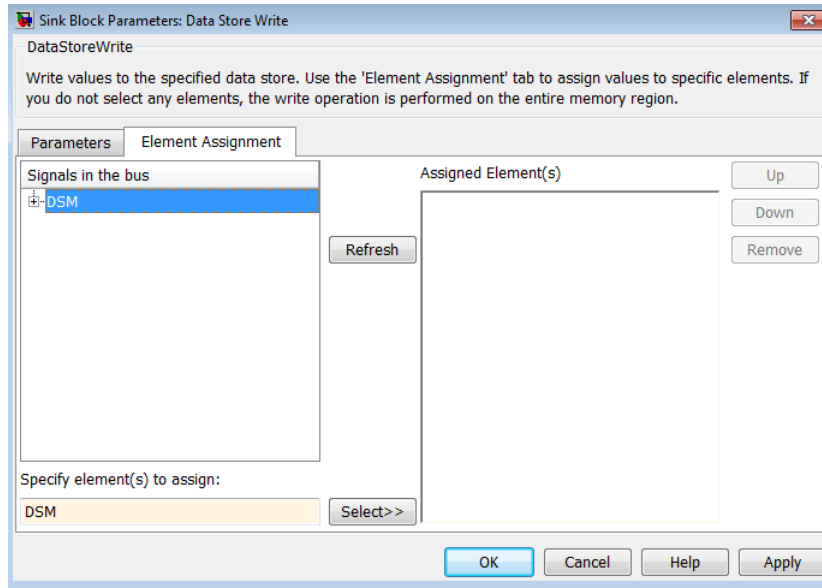
- Reducing the number of blocks in the model. For example, you can eliminate a Data Store Read and Bus Selector block pair or a Data Store Write and Bus Assignment block pair for each specific bus element that you want to access).
- Faster simulation of models with large buses and arrays of buses.

Writing Specific Elements to a Data Store

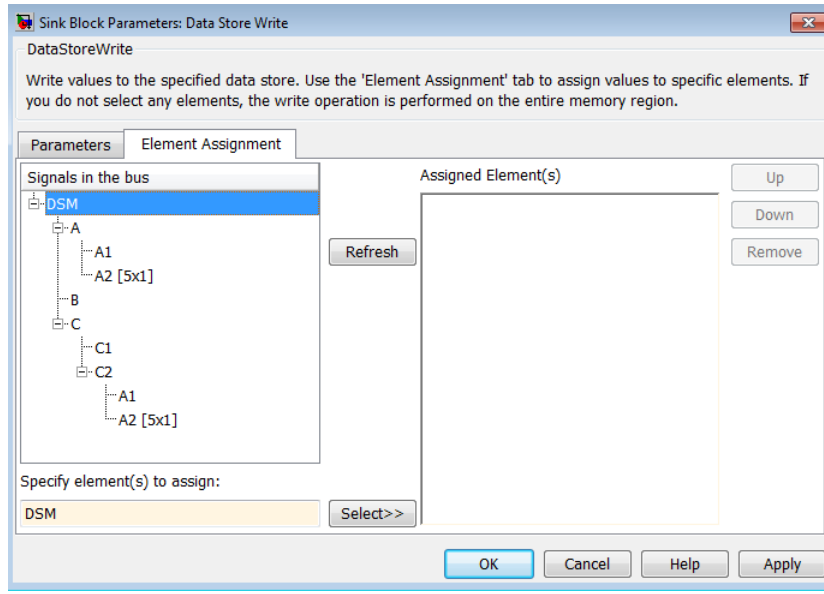
Note The following procedure describes how to use the Data Store Write block interface to write specific elements to a data store. You can also perform this task at the command line, using the `DataStoreElements` parameter to specify elements. For details, see "Specification using the command line" on page 62-36.

To assign specific bus or matrix elements to write to a data store:

1 Select the Data Store Write block and in the parameters dialog box, select the **Element Assignment** pane. For example, suppose you are using a bus with a data store named `DSM`:

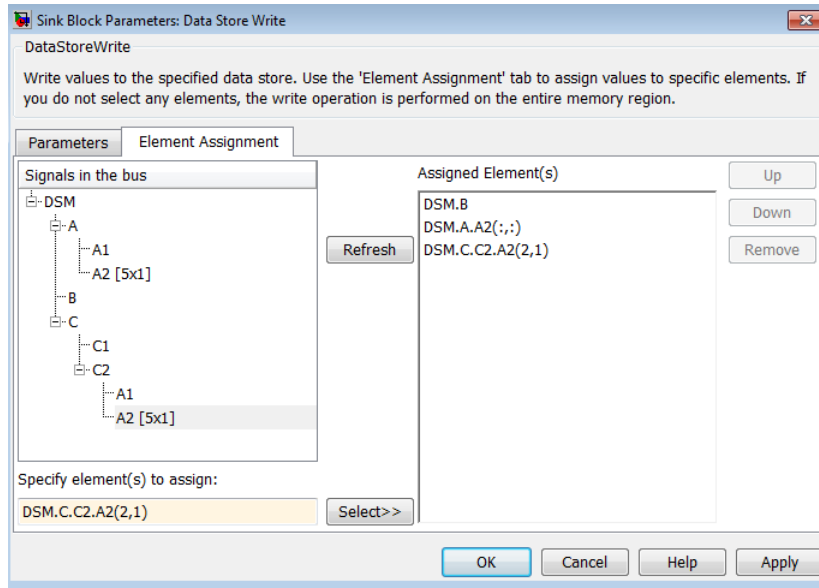


2 Expand all the elements in the **Signals in the bus** list.



3 Specify the elements that you want to write to the data store. For example:

- In the **Signals in the bus** list, click `B`. Then click **Select>>** to select the element `B`.
- To write all the elements of `A2` (in the `A` subbus), select `A2[5x1]`. Then click **Select>>**.
- To write the second element of `A2` in the `C2` subbus, select the `A2[5x1]` element. In the **Specify element(s) to assign** text box, edit the text to say `DSM.C.C2.A2(2,1)`.



For more examples, see “Specifying Elements to Assign or Select” on page 62-35.

4 (Optional) Reorder the assigned elements, which changes the order of the ports of the Data Store Write block.

- To reorder an assigned element, in the **Assigned element(s)** list, select the element that you want to move, and click **Up** or **Down**.
- To remove an assigned element, click **Remove**.

5 To apply the assigned elements, click **OK**.

The Data Store Write block has a port for each assigned element. The names of the selected elements that correspond to each port appear in the block icon. If you assign several signals, these additions may diminish the readability of the model. To improve readability, you can expand the size of the block or create multiple Data Store Write blocks.

Reading Specific Elements from a Data Store

Reading specific elements from a data store involves very similar steps as described in “Writing Specific Elements to a Data Store” on page 62-32. The Data Store Read block differs slightly from the Data Store Write block. A Data Store Read block has:

- An **Element Selection** pane instead of an **Element Assignment** pane
- A **Selected element(s)** list instead of an **Assigned element(s)** list

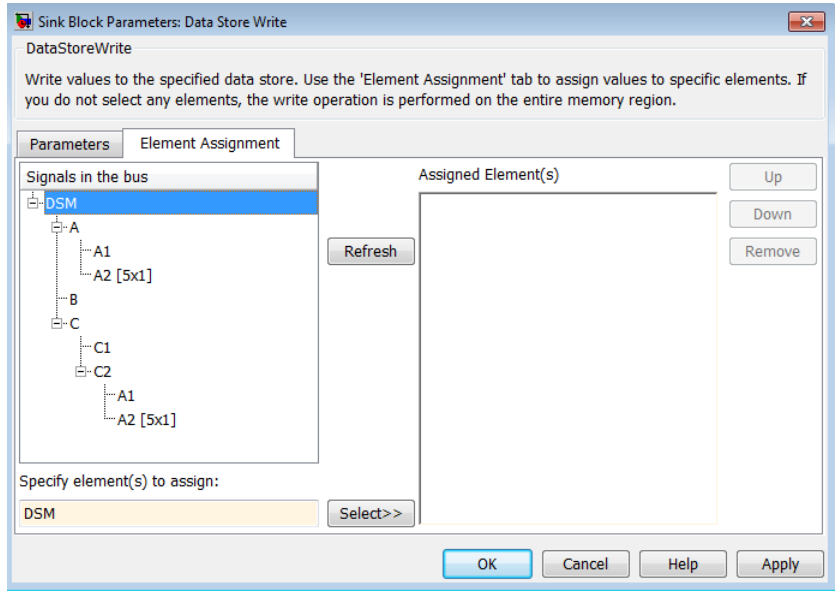
Specifying Elements to Assign or Select

Use MATLAB matrix element syntax to specify specific elements. For details about specifying matrices in MATLAB, see "Creating and Concatenating Matrices" (MATLAB).

Note To select matrix elements, you cannot use dynamic indexing with the **Element Assignment** and **Element Selection** panes of Data Store Read and Bus Assignment block pairs or Data Store Write and Bus Selector block pairs. You can, however, use a MATLAB Function block for dynamic indexing.

Valid element specifications

The following table shows examples of valid syntax for specifying elements to assign or select. These examples use the `A2` subbus of the `A` bus, as shown in the bus hierarchy used in "Writing Specific Elements to a Data Store" on page 62-32.



Valid Syntax	Description
`DSM.A.A2(:,:)`	Selects all elements in every dimension
`DSM.A.A2([1,3,5],1)`	Selects the first, third, and fifth elements
`DSM.A.A2(2:5,1)`	Selects the second through the fifth element

Invalid element specifications

The following table shows examples of invalid syntax for specifying elements to assign or select. These examples use the `A2` subbus of the `A` bus, as shown in the bus hierarchy used in "Writing Specific Elements to a Data Store" on page 62-32.

Invalid Syntax	Reason the Syntax Is Invalid
`DSM.A.A2(:)`	You must specify a colon for each dimension. For the bus hierarchy used in these examples, you must use two colons.
`DSM.A.A2(2:end,1)`	You cannot use the `end` operator.
`DSM.A.A2(idx,1)`	You cannot use variables to specify indices. Consider using a MATLAB Function block.
`DSM.A.A2(-1,1)`	The dimension –1 is not within the valid dimension bounds.

Specification using the command line

To set the elements to write to or read from, use the `DataStoreElements` parameter. Use a pound sign (#) to delimit multiple elements. For example, select the Data Store Write or Data Store Read block for which you want to specify elements and enter a command such as:

```
set_param(gcb, 'DataStoreElements', 'DSM.A#DSM.B#DSM.C(3,4)')
```

This specification results in the block now having three ports corresponding to the elements that you specified.

Rename Data Stores

- "Rename Data Store Defined by Block" on page 62-37
- "Rename Data Store Defined by Signal Object" on page 62-37

Rename Data Store Defined by Block

Rename a data store everywhere it is used by Data Store Read and Data Store Write blocks in a model.

1. In a Data Store Memory block dialog box, type a new name in the **Data store name** box, and click **Rename All**.
2. In the **Rename All** dialog box, confirm the new data store name in the **New name** field, and click **OK**

Note You cannot use **Rename All** to rename a data store if you create a `Simulink.Signal` object in a workspace to control the code generated for the data store. Instead, you must rename the corresponding `Simulink.Signal` object using Model Explorer. For an example, see "Rename Data Store Defined by Signal Object" on page 62-37.

Rename Data Store Defined by Signal Object

This example shows how to rename a data store defined by a `Simulink.Signal` object. You can use Model Explorer to rename the object everywhere it is used by Data Store Read and Data Store Write blocks in a model or in a model reference hierarchy.

1. Open the model `sldemo_mdlref_dsm`. The model creates a `Simulink.Signal` object `ErrorCond` in the MATLAB base workspace and uses the object as a global data store in a model reference hierarchy.
2. Open Model Explorer.
3. In the **Model Hierarchy** pane, select the base workspace.
4. In the **Contents** pane, right-click the data store `ErrorCond` and select **Rename All**.
5. In the **Select a system** dialog box, click the name of the model `sldemo_mdlref_dsm` to select it as the context for renaming the data store `ErrorCond`.
6. Select **Search in referenced models** since `ErrorCond` is a global data store that is used in a referenced model. Click **OK**.

   The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.

7 Click **OK** in response to the message to update the model diagram.

   Since you just opened the model, you must update the model diagram at least once before renaming a variable such as `ErrorCond`. You could have selected **Update diagram to include recent changes** in the **Select a system** dialog box to force an initial diagram update, though you typically use that option when you make changes to the model while performing multiple variable renaming operations.

8 In the **Rename All** dialog box, type the new name for the data store in the **New name** box and click **OK**.

Customized Data Store Access Functions in Generated Code

Embedded Coder provides a custom storage class that you can use to specify customized data store access functions in generated code. See "Control Data Representation by Applying Custom Storage Classes" (Embedded Coder) and "Access Data Through Functions with Custom Storage Class GetSet" (Embedded Coder).

Log Data Stores

In this section...

Logging Local and Global Data Store Values

You can log the values of a local or global data store data variable for all the steps in a simulation. Two common uses of data store logging are for:

- Model debugging – view the order of all data store writes
- Confirming a model modification – use the logged data to establish a baseline for comparing results for identifying the impact of a model modification

For an example of logging a global data store, see “Using Data Stores Across Multiple Models”.

Supported Data Types, Dimensions, and Complexity for Logging Data Stores

You can log data stores that use the following data types:

- All built-in data types
- Enumerated data types
- Fixed-point data types

You can log data stores that use any dimension level or complexity.

Data Store Logging Limitations

Limitations for using data store logging in a model are:

- To log data for a data store memory:
  - Simulate the top-level model in Normal mode.
  - For local data stores, the model containing the Data Store Memory block must be in Model Reference Normal mode.
  - Any block in a referenced model that writes to the data store memory must be executed in model reference Normal mode.
- In the Solver pane of the Configuration Parameters dialog box, if **Treat each discrete rate as a separate task** is selected, you cannot log Data Store Memory blocks that use asynchronous sample times or hybrid sample times (that is, sample times resulting from when different data sources for the data store have different sample times).

  For details about viewing information about sample times, see "View Sample Time Information" on page 7-9.
- You cannot log data stores that use custom data types.

Logging Data Stores Created with a Data Store Memory Block

To log a local data store that you create with a Data Store Memory block:

1. In the model, open the Model Data Editor. Select **View** > **Model Data**.
2. On the **Data Stores** tab, set the **Change view** drop-down list to `Instrumentation`.
3. In the data table, for the target data store, select the check box in the **Log Data** column.

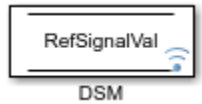
   If the target data store does not appear in the table, click the **Change scope** button to display data stores that are defined in subsystems below your current system.
4. Optionally, to configure additional logging characteristics such as the maximum number of data points to log, open the Property Inspector (**View** > **Property Inspector** in the model). Use the Property Inspector to open the block dialog box and inspect the **Logging** tab.

5 Enable data store logging with the **Model Configuration Parameters** > **Data Import/Export** > **Data stores** parameter.

6 Simulate the model.

Logging Icon for the Data Store Memory Block

When you enable logging for a model, and you configure a local data store for logging, the Data Store Memory block displays a blue icon. If you do not enable logging for the model, then the icon is gray.



Logging Data Stores Created with a Simulink.Signal Object

You can create local and global data stores using a `Simulink.Signal` object. See "Data Stores with Signal Objects" on page 62-20 for details.

To log a data store that you create with a `Simulink.Signal` object:

1 Create a `Simulink.Signal` object in a workspace that is visible to every component that needs to access the data store, as described in "Data Stores with Signal Objects" on page 62-20.

2 Use the name of the `Simulink.Signal` object in the **Data store name** block parameters of the Data Store Read and Data Store Write blocks that you want to write to and read from the data store.

3 From the MATLAB command line, set `DataLogging` (which is a property of the `LoggingInfo` property of `Simulink.Signal`) to `1`.

   For example, if you use a `Simulink.Signal` object called `DataStoreSignalObject` to create a data store, use the following command:

   ```
   DataStoreSignalObject.LoggingInfo.DataLogging = 1
   ```

4 Optionally, specify limits for the amount of data logged, using the following properties, which are properties of the `LoggingInfo` property of the `Simulink.Signal` object: `Decimation`, `LimitDataPoints`, and `MaxPoints`.

5 Enable data store logging with the **Model Configuration Parameters** > **Data Import/Export** > **Data stores** parameter.

6 Simulate the model.

Accessing Data Store Logging Data

The following Simulink classes represent data from data store logging and provide methods for accessing that data:

Class	Description
`Simulink.SimulationData.BlockPath`	Represents a fully specified Simulink block path; use for capturing the full model reference hierarchy
`Simulink.SimulationData.Dataset`	Stores logged data elements and provides searching capabilities; use to group `Simulink.SimulationData.Element` objects in a single object
`Simulink.SimulationData.DataStoreMemory`	Stores logging information from a data store during simulation

You can also convert data logged in formats other than Dataset. For more information, see “Dataset Conversion for Logged Data” on page 61-22.

Viewing Data Store Data

To view data store logging data from the command line, view the output data set in the base workspace. The default variable for the data store logging data set is `dsmout`.

The sldemo_mdlref_dsm model illustrates approaches for viewing data store logging data.

Accessing Elements in the Data Store Logging Data

To find an element in the data store logging data, based on the `Name` or `BlockType` property, use the `getElement` method of `Simulink.SimulationData.Dataset`. For example:

```
dsmout.getElement('RefSignalVal')

ans =
Simulink.SimulationData.DataStoreMemory
Package: Simulink.SimulationData
```

```
Properties:
                 Name: 'RefSignalVal'
            Blockpath: [1x1 Simulink.SimulationData.BlockPath]
                Scope: 'local'
  DSMWriterBlockPaths: [1x2 Simulinkl.SimulationData.BlockPath]
           DSMWriters: [101x1 uint32]
               Values: [101x1 timeseries]
```

To access an element by index, use the `Simulink.SimulationData.Dataset.getElement` method.

Simulink Data Dictionary

What Is a Data Dictionary?

A data dictionary is a persistent repository of data that are relevant to your model. You can also use the base workspace to store design data that are used by your model during simulation. However, a data dictionary provides more capabilities.

The dictionary stores design data, which define parameters and signals, and include data that define the behavior of the model. The dictionary does not store simulation data, which are inputs or outputs of model simulation that enter and exit Inport and Outport blocks.

In this section...

Dictionary Capabilities

Dictionary Capability	Benefit
Dictionary as data source	All entries in a dictionary are persistent. You do not need to reload data during development.
Explicit data-model linkage	You can define a data dictionary as the data source for a model. During model simulation and code generation, the model retrieves design data from the data dictionary.
Change tracking	When you modify an entry, its status is updated in the dictionary and stored as metadata that can be tracked. The dictionary also tracks who made the changes and when. You can also view or revert changes.
Entry comparison	Compare values of entries in two dictionaries.
Data grouping into reference dictionaries	Partition and organize data items into reference dictionaries.
Model-data dependency	Discover how entries are used in the model.

Dictionary Capability	Benefit
Additional options to remedy a missing variable	When a workspace variable that a model needs is not available, you have additional options for remediation. For example, if you renamed the variable in a dictionary, you can create a new variable by copying the old one.
Store and partition reference data	Store and partition data that are relevant to a model, such as equipment specifications, but not used by the model during simulation.
Unified interface for defining data	Use the Model Explorer to work with design data in a dictionary.
Incremental update in memory	Improved performance and scalability with minimal footprint on memory.
Requirements traceability linking	Navigate from a data dictionary entry to a location in a requirements document.

Sections of a Dictionary

A Simulink data dictionary is made up of three parts called sections.

1. **Design Data**: Contains the variables and data types that define parameters, signals, and design data that determine the behavior of the model. Design data created or imported in a dictionary are stored in this section.

   This section can store only certain classes and data types. See “Valid Design Data Classes” on page 63-11 for more information.

2. **Configurations**: Contains configuration sets, which are objects of the `Simulink.ConfigSet` class, that determine how the model is configured during simulation. These objects control attributes such as sample time and simulation start time.

   When you store configuration sets in a data dictionary, you use configuration references to access the configuration sets. Models that are linked to a dictionary resolve configuration references to configuration sets in the dictionary. For more information about configuration references, see “About Configuration References” on page 13-29.

This section can also store variant configuration objects, which belong to the `Simulink.VariantConfigurationData` class. These objects store information about variant configurations, active and default variant settings, and definitions of the control variable associated with each configuration.

Note If you load a configuration set from the data dictionary that contains a component that is not available on your system, the parameters in the missing component are reset to their default values.

3 **Other Data**: Contains information that is relevant to your model but not used by the model during simulation. Use this section to store reference information such as data that describe physical equipment and processes that are represented by your model.

This section can store almost any built-in or custom class or data type. See “Invalid Other Data Classes” on page 63-12 for more information.

Manage and Edit Entries in a Dictionary

To create, modify, and view the entries in a data dictionary, use the Model Explorer. For more information, see “Create, Edit, and Manage Workspace Variables” on page 59-105 and “View and Revert Changes to Dictionary Data” on page 63-27.

To manage entries in a dictionary programmatically, see “Store Data in Dictionary Programmatically” on page 63-53.

Dictionary Referencing

You can reference one or more dictionaries in a parent dictionary. The data in the referenced dictionaries are visible in the parent dictionary. Use this technique to meaningfully partition data, especially for model reference hierarchies. For more information, see “Partition Dictionary Data Using Referenced Dictionaries” on page 63-34 and “Partition Data for Model Reference Hierarchy Using Data Dictionaries” on page 63-37.

Import and Export File Formats

File Format	Import to Dictionary	Export from Dictionary
MAT-file	✓	✓

File Format	Import to Dictionary	Export from Dictionary
MATLAB script	✓	✓

Migrate Models to Use Simulink Data Dictionary

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 63-2.

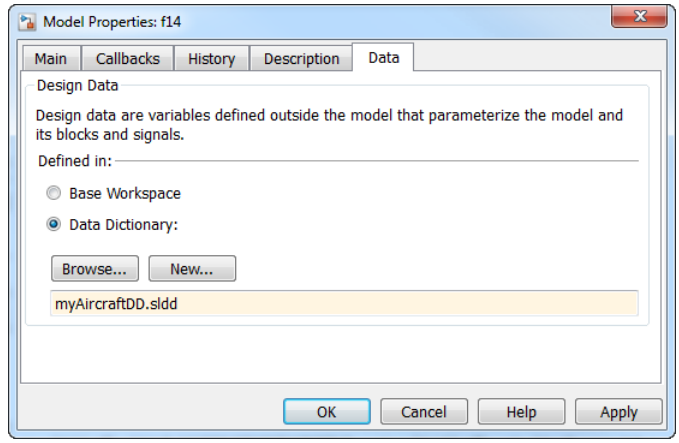
In this section...

Migrate Single Model to Use Dictionary

This example shows how to link a single standalone model to a single data dictionary.

Note Simulink does not import simulation data such as Timeseries objects into the data dictionary.

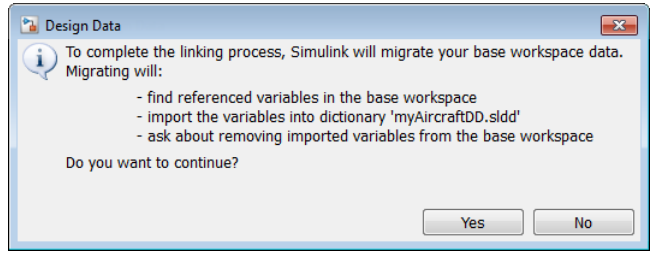
1. Open the `f14` model, which loads design data into the base workspace.
2. Save a copy of the model to your current folder. Open the copy.
3. In the Simulink Editor, click **File > Model Properties > Link to Data Dictionary**.
4. In the **Model Properties** dialog box, set **Defined in** to **Data Dictionary** and click **New** to create a data dictionary.



5 Name the data dictionary, save it, and click **Apply**.

6 Click **Add path**, if you see the message to add the dictionary location to the MATLAB path.

7 Click **Yes** in response to the message that explains how Simulink migrates design data stored in the base workspace.



8 Click **Yes** in response to the message about removing imported items from the base workspace.

9 Click **OK** in the **Model Properties** dialog box.

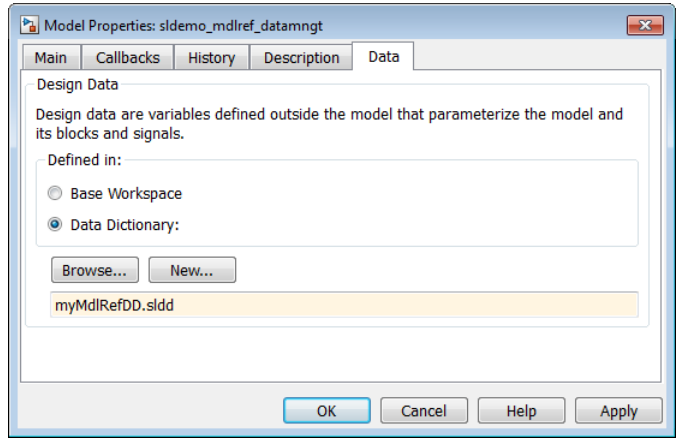
A notification appears in the Simulink Editor, reporting that your model is now linked to the data dictionary.

10 In the Simulink Editor, click the data dictionary badge  in the bottom left corner to open the dictionary.

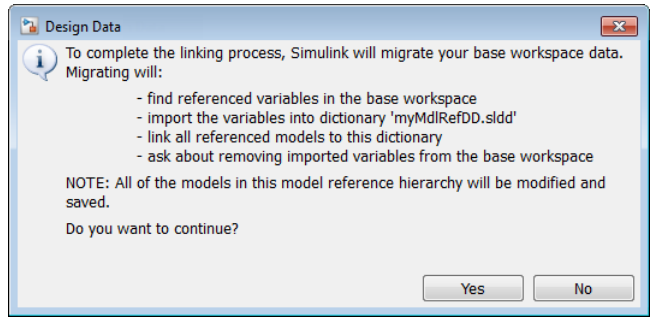
Migrate Model Reference Hierarchy to Use Dictionary

This example shows how to link a parent model and all its referenced models to a single data dictionary.

1. Open the example model `sldemo_mdlref_datamngt`, which references the model `sldemo_mdlref_counter_datamngt`.
2. Save copies of the models to your current folder.
3. Open the top model, `sldemo_mdlref_datamngt`.
4. In the Simulink Editor, click **File** > **Model Properties** > **Link to Data Dictionary**.
5. In the **Model Properties** dialog box, set **Defined in** to **Data Dictionary** and click **New** to create a data dictionary.



6. Name the data dictionary, save it, and click **Apply**.
7. Click **Yes** in response to the message that explains how Simulink migrates design data stored in the base workspace.



8 Click **Yes** in response to the message about removing the imported items from the base workspace.

9 Click **OK** in response to the message about migrating enumerated types.

Considerations before Migrating to Data Dictionary

Check for Data-Loading Callbacks

You can use model callbacks such as the `PreLoadFcn` callback to load design data from a file into the base workspace when a model is loaded. For example, the following callback loads design data from the MAT file `myData.mat`.

```
load myData
```

After you migrate to a data dictionary, these callbacks will continue to load design data into the base workspace. Since the model then derives design data from the dictionary, manually remove or comment out these data-loading callbacks.

You can use the Simulink Manifest Tools to find data-loading callbacks. See "Analyze Model Dependencies" on page 18-25.

Check Scripts

If you make explicit references to the base workspace by using the handle `base` in your scripts, consider changing these references. When you move any of your data to a data dictionary, the model no longer looks into the base workspace to find design data.

After you migrate design data to a data dictionary, explicit references to the base workspace cannot resolve and errors can occur.

Consider this example. Here, the script searches the base workspace for variable `sensor` and sets the parameter `enable` depending on the value of `sensor.noiseEnable`.

```
if evalin('base','sensor.noiseEnable')
    enable = 'Enabled';
else
    enable = 'Disabled';
end
```

When you migrate to a data dictionary, replace these explicit references to `base` as follows:

```
if Simulink.data.evalinGlobal(myExampleModel,...
'sensor.noiseEnable')
    enable = 'Enabled';
else
    enable = 'Disabled';
end
```

The `Simulink.data.evalinGlobal` function evaluates an expression in the global scope of the specified model. Here, the global scope can be in a data dictionary or the base workspace, if the model is not linked to a dictionary.

Check Tunable Parameters for Code Generation

- If your model is linked to a data dictionary, Simulink ignores storage class information specified in the Model Parameter Configuration dialog box.
- If you use the Simulink interface to migrate a model to use a data dictionary, Simulink also migrates the storage class information of the model. If your model contains storage class information for variables in the base workspace, Simulink converts these variables into `Simulink.Parameter` objects during migration. Then, Simulink sets the storage class of these `Simulink.Parameter` objects using the storage class information from the model.

- If you migrate this model back to the base workspace, Simulink does not restore the storage class information in the model. To preserve the storage class for these variables, use the parameter objects from the data dictionary. You can also manually reset the storage class information in the model.
- If you set the `DataDictionary` property of a model from the command line, convert tunable variables to `Simulink.Parameter` objects using the `tunablevars2parameterobjects` function.

Data Shared by Model References

When you use model referencing to break a large system of models into smaller components and subcomponents, you can create data dictionaries to segregate the design data. Design data is the set of workspace variables that the models use to specify block parameters and signal characteristics.

The models in a model reference hierarchy typically share data. Data ownership, the number of shared variables, and the complexity of your sharing strategy can influence the way that you use dictionaries. For more information, see “Determine Where to Store Variables and Objects for Simulink Models” on page 59-96.

Valid Design Data Classes

You can import, store, or create MATLAB variables that use Simulink supported data types, such as `boolean` and `int32`, and structures in the **Design Data** section of a Simulink data dictionary. You can also use objects of these classes and objects of most classes that subclass these classes:

- `Simulink.AliasType`
- `Simulink.Bus`
- `Simulink.NumericType`
- `Simulink.Parameter`
- `Simulink.LookupTable`
- `Simulink.Breakpoint`
- `Simulink.Signal`
- `Simulink.Variant`
- `Simulink.data.dictionary.EnumTypeDefinition`
- `embedded.fi`

- `embedded.fimath`
- `numlti`

In addition, you can import, store, or create configuration objects of the following classes in the **Configurations** section of a Simulink data dictionary.

- `Simulink.ConfigSet`
- `Simulink.VariantConfigurationData`

Invalid Other Data Classes

You can import, store, or create data objects of many built-in and custom classes or data types in the **Other Data** section of a Simulink data dictionary, except for the following:

- Arrays of objects created from built-in or custom classes
- Custom classes that have a property with any of these names:
  - `LastModified`
  - `LastModifiedBy`
  - `DataSource`
  - `Status`
  - `Variant`

Migration With From Workspace Blocks

If a model contains a From Workspace block that refers to a variable in the base workspace, you can migrate the model to a data dictionary. However, the migration process takes different actions depending on the nature of the variable that the block refers to:

- If the value of the variable is not a `timeseries` object, the migration process imports the variable to the Design Data section of the data dictionary. The block can still refer to the variable.
- If the value of the variable is a `timeseries` object (which a data dictionary cannot store), the migration process does not import the variable. Then, when you try to update the diagram or simulate the model, the From Workspace block cannot find the variable and issues an error. In such a case, you can configure the block to refer to the base workspace variable by using the `evalin` function. See “Use With Data Dictionary”.

Data Dictionary Limitations

- Simulink cannot automatically migrate variables used only by inactive variant models into a data dictionary.
- You cannot import certain kinds of design data such as `meta` class objects and `timeseries` objects into the Design Data section of a data dictionary.
- Simulink does not allow implicit signal resolution for a model linked to a data dictionary. To use a data dictionary, set the model configuration parameter **Signal resolution** to `Explicit only` or `None`.
- If a model reference hierarchy is already linked to a data dictionary, you can protect a referenced model that is part of the hierarchy. However, if you migrate a model reference hierarchy that includes a protected model, simulation will fail.

  In other words, migrate a model to use a data dictionary before protecting it.

Enumerations in Data Dictionary

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types including enumerated types. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 63-2.

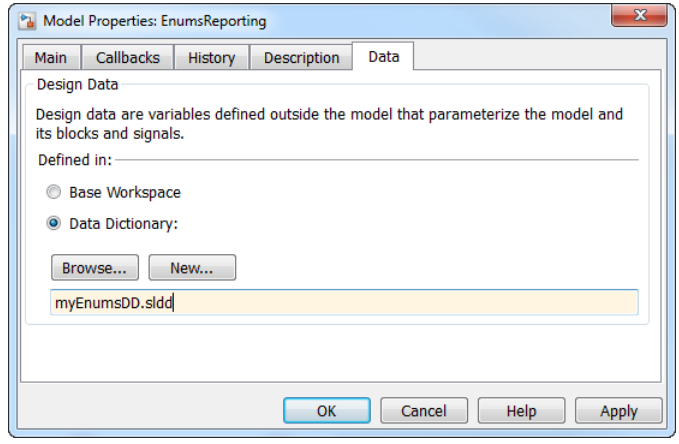
In this section...

Migrate Enumerated Types into Data Dictionary

This example shows how to migrate enumerated types that are used by a model into a data dictionary.

Import Design Data

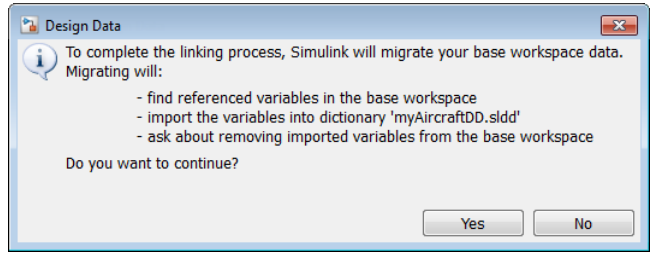
1. Open a model that uses enumerated types for design data or for blocks in the model.
2. In the Simulink Editor, click **File** > **Model Properties** > **Link to Data Dictionary**.
3. In the **Model Properties** dialog box, set **Defined in** to **Data Dictionary** and click **New** to create a data dictionary.



4. Name the data dictionary, save it, and click **Apply**.

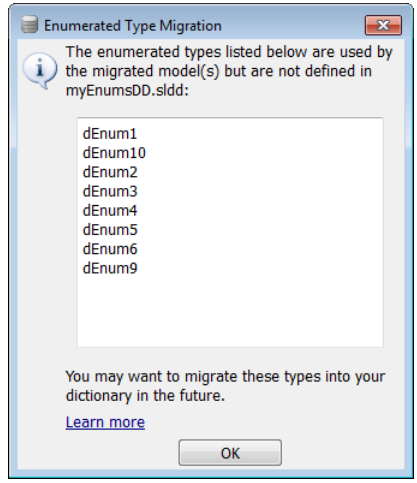
5 Click **Add path**, if you see the message to add the dictionary location to the MATLAB path.

6 Click **Yes** in response to the message that explains how Simulink migrates design data stored in the base workspace.



A message appears, reporting the number of items imported from the base workspace to the data dictionary.

7 Simulink reports the enumerated types that were not imported into the data dictionary.



8 Click **OK**.

A notification appears in the Simulink Editor, reporting that your model is now linked to the data dictionary.

Import Enumerated Types

Import the definitions of enumerated types only after you import all the design data that were creating using the types. When you import enumerated types to a data dictionary, Simulink disables MATLAB files or P-files that contain the type definitions, causing variables that remain in the MATLAB base workspace to lose their definitions.

1 At the MATLAB command prompt, get the names of enumerated types that are used in model blocks.

```
% Find all variables and enumerated types used in model blocks
usedTypesVars = Simulink.findVars('EnumsReporting','IncludeEnumTypes',true);
% Here, EnumsReporting is the name of the model and
% usedTypesVars is an array of Simulink.VariableUsage objects

% Find indices of enumerated types that are defined by MATLAB files or P-files
enumTypesFile = strcmp({usedTypesVars.SourceType},'MATLAB file');

% Find indices of enumerated types that are defined using the function
% Simulink.defineIntEnumType
enumTypesDynamic = strcmp({usedTypesVars.SourceType},'dynamic class');

% In one array, represent indices of both kinds of enumerated types
enumTypesIndex = enumTypesFile | enumTypesDynamic;

% Use logical indexing to return the names of used enumerated types
enumTypeNames = {usedTypesVars(enumTypesIndex).Name}'
```

```
enumTypeNames =

    'dEnum1'
    'dEnum10'
    'dEnum2'
    'dEnum3'
    'dEnum4'
    'dEnum5'
    'dEnum6'
    'dEnum9'
```

2 Open the data dictionary, and represent it with a `Simulink.data.Dictionary` object.

```
ddConnection = Simulink.data.dictionary.open('myEnumsDD.sldd')
```

```
ddConnection =
```

```
  Dictionary with properties:

         DataSources: {0x1 cell}
    HasUnsavedChanges: 0
       NumberOfEntries: 3
```

3 Use the `importEnumTypes` method to import the enumerated types that are used by blocks in the model. The method saves changes made to the target dictionary, so before you use the method, confirm that unsaved changes are acceptable.

```
[successfulMigrations, unsuccessfulMigrations] = ...
importEnumTypes(ddConnection,enumTypeNames)

successfulMigrations =

1x6 struct array with fields:

    className
    renamedFiles

unsuccessfulMigrations =

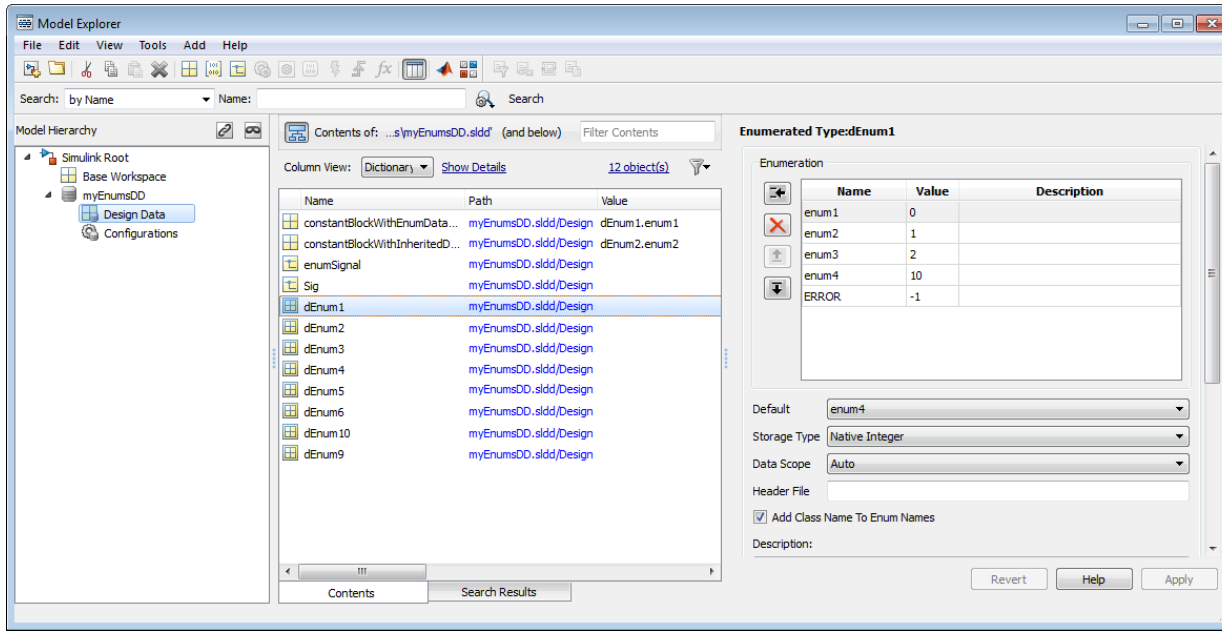
1x2 struct array with fields:

    className
    reasons
```

When enumerated types are imported, `importEnumTypes` renames the enumerated class definition file by appending `.save` to the file name. For example, if the original enumerated class definition is named `Enum1.m`, Simulink renamed the file as `Enum1.m.save`.

The structure `unsuccessfulMigrations` reports enumerated types that are not be migrated. In this example, two enumerated type instances are defined in the model workspace and can be imported after closing the model. Close the model to import these enumerated types.

4 Open the dictionary to view the migrated enumerated types.



Manipulate Enumerations in Data Dictionary

These examples show how to operate on existing enumerations in a data dictionary.

Rename Enumerated Type Definition

1. In the data dictionary, create a copy of the enumerated type, and rename the copy instead.
2. Find enumeration objects used by your model that are derived from the type with the old name.
3. Replace these objects with those derived from the renamed type.
4. Delete the type with the old name.

Rename Enumeration Members

Use one of the following approaches.

- Select the enumeration within the dictionary, and rename one or more enumeration members.
- If your model references enumeration members, change these references to match the renamed member.

Delete Enumeration Members

1. Find references in your model to an enumeration member you want to delete.
2. Replace these references with an alternate member.
3. Delete the original member from the enumeration.

Change Underlying Value of Enumeration Member

You can change the values of enumeration members when you represent these values as MATLAB variables or by using `Value` field of `Simulink.Parameter` objects.

1. Find references in your model to an enumeration member whose value you want to change.
2. Make a note of these references.
3. Change the value of the enumeration member.
4. Manually update references to the enumeration member in your model.

Import and Export Dictionary Data

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 63-2.

In this section...

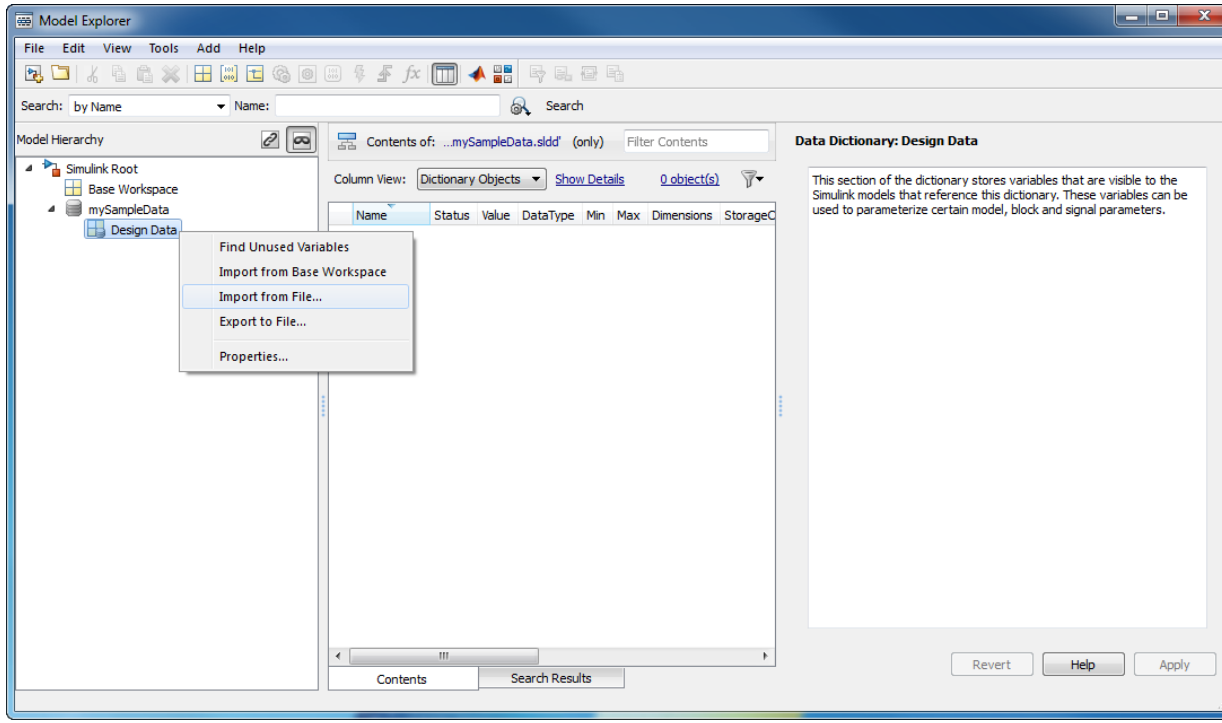
Import Data to Dictionary from File

You can import data from a MATLAB file or MAT-file to a data dictionary using the Model Explorer window. Import variables and data objects that are used by a model during simulation to the Design Data section of a dictionary. Import variables and objects that you want to store with a model, but that are not used by the model during simulation, to the Other Data section of a dictionary.

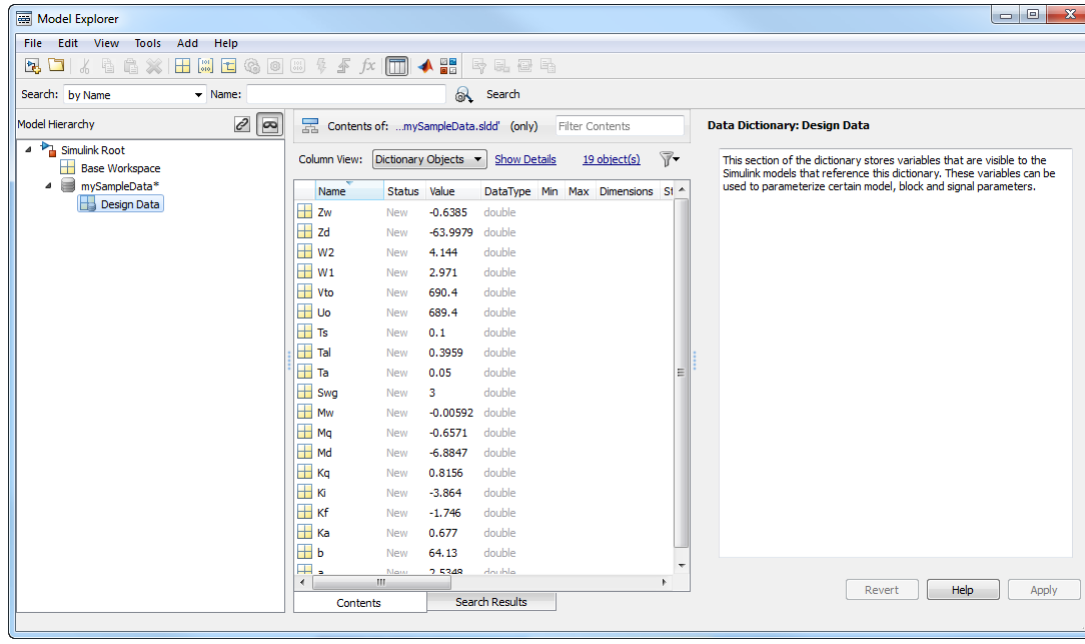
Import Design Data from File

This example shows how to import design data from a file into the Design Data section of a dictionary.

1. In the Simulink Editor, select **View** > **Model Explorer** to open the Model Explorer.
2. Click **File** > **Open**. Then browse to an existing dictionary.
3. In the **Model Hierarchy** pane, right-click the **Design Data** section of the dictionary and select **Import from File**. Then browse to and select the MAT-file or MATLAB file that contains the data to import.



Design data from the MAT-file populate the dictionary. Data appear with **DataSource** set to the name of the dictionary.

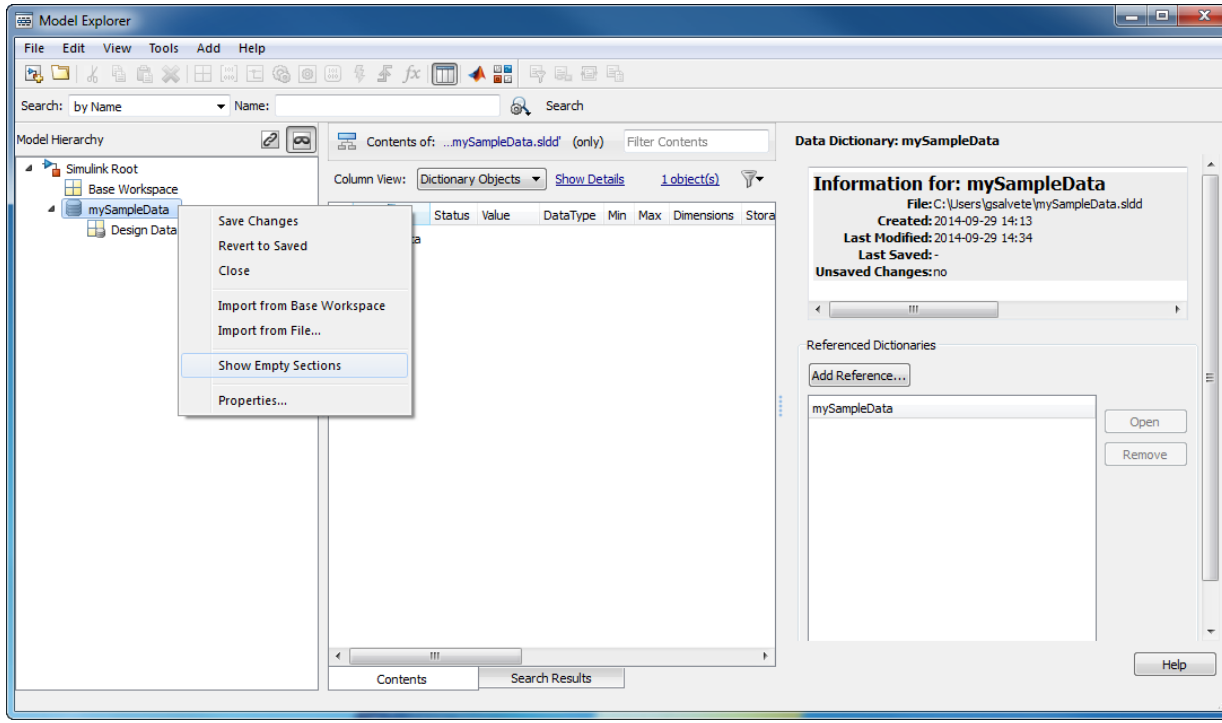


If you import from the same MAT-file again, Simulink only imports changed or new entries into the dictionary.

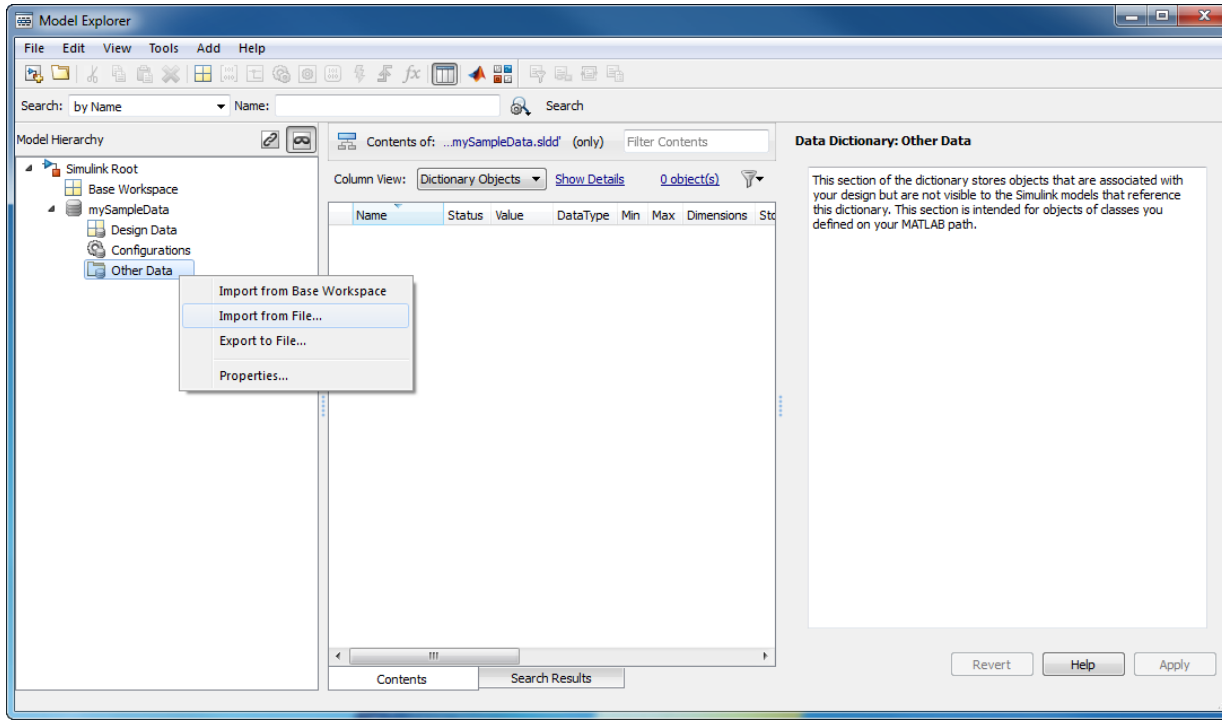
Import Other Data from File

This example shows how to import data from a file into the Other Data section of a data dictionary. Use this section to store reference information that is not used by Simulink during simulation, such as data that describe physical equipment and processes that are represented by your model.

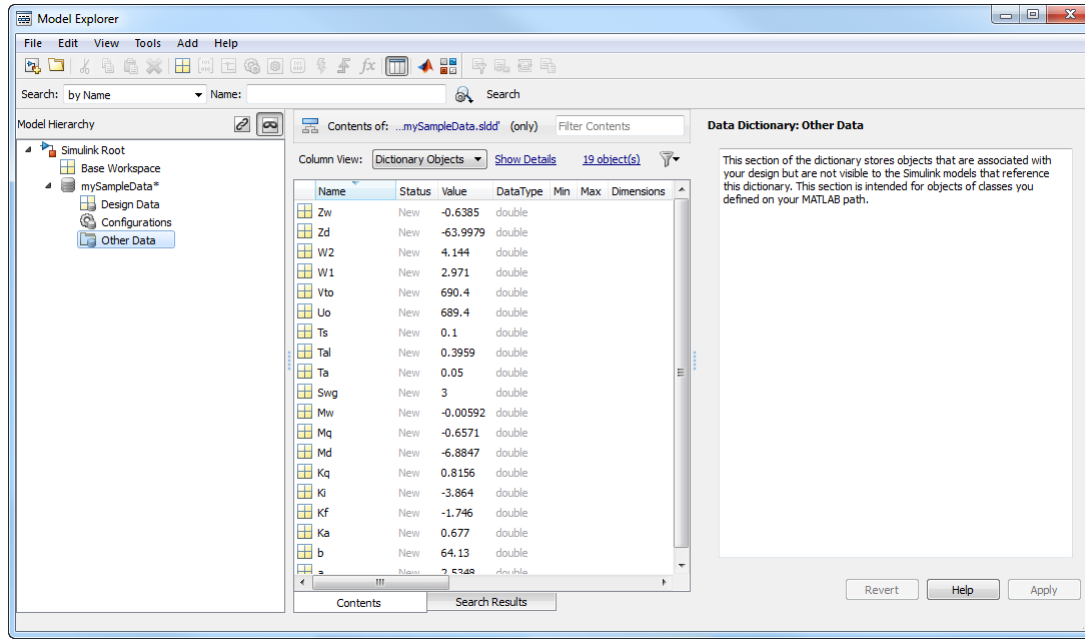
1. In the Simulink Editor, select **View > Model Explorer** to open the Model Explorer.
2. Click **File > Open**. Then browse to an existing dictionary.
3. In the **Model Hierarchy** pane, right-click the dictionary node and select **Show Empty Sections**. Model Explorer reveals the **Other Data** and **Configurations** sections of the dictionary, even if they are empty, in addition to the **Design Data** section.



4 In the **Model Hierarchy** pane, right-click the **Other Data** section of the dictionary and select **Import from File**. Then browse to and select the MAT-file or MATLAB file that contains the reference data to import.



Data from the MAT-file populate the Other Data section of the dictionary. Data appear with **DataSource** set to the name of the dictionary.

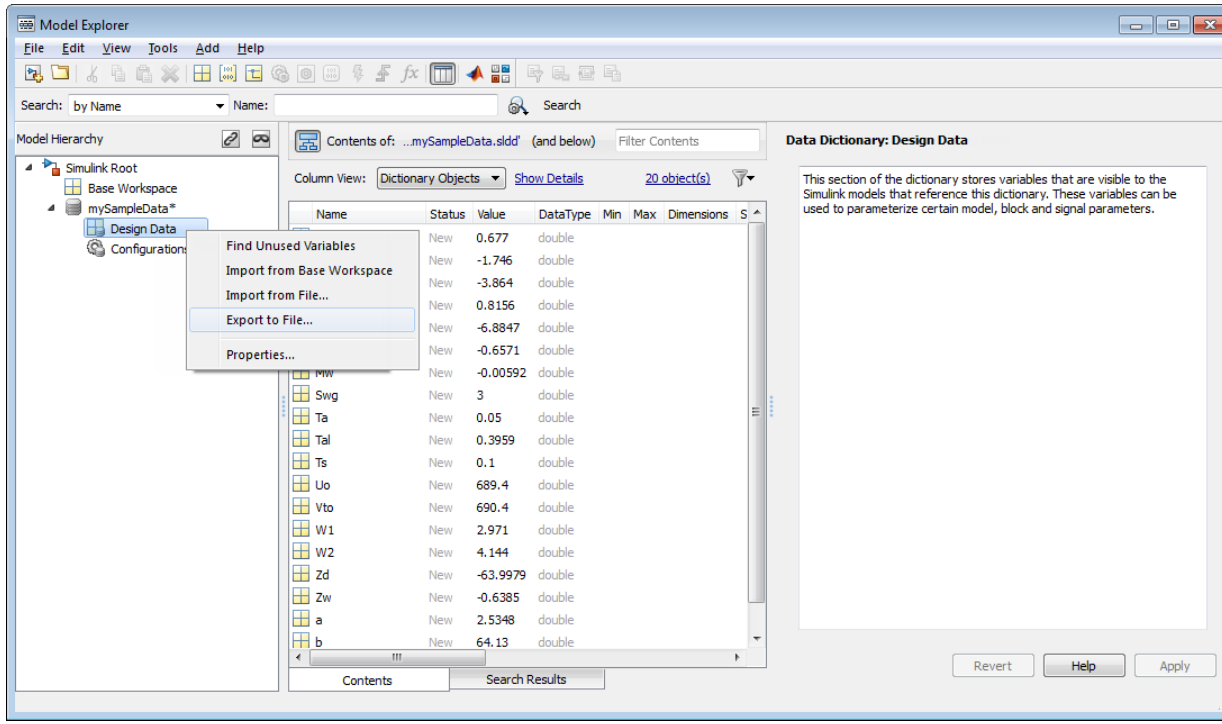


If you import from the same MAT-file again, Simulink only imports changed or new entries into the dictionary.

Export Design Data from Dictionary

This example shows how to export model design data from a data dictionary into a MAT-file or MATLAB script.

1. In the Simulink Editor, select **View** > **Model Explorer** to open the Model Explorer.
2. Open a data dictionary using **File** > **Open Data Dictionary**.
3. In the **Model Hierarchy** pane, expand the dictionary node and select **Design Data** > **Export to File**. Then save the design data to a MAT-file or MATLAB script.



The dictionary does not export enumerated data types (which are stored as `Simulink.data.dictionary.EnumTypeDefinition` objects). To transfer or copy an enumerated type from one dictionary to another, use the Model Explorer to cut or copy and paste the object.

- “View and Revert Changes to Dictionary Data” on page 63-27
- “Migrate Models to Use Simulink Data Dictionary” on page 63-6

View and Revert Changes to Dictionary Data

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 63-2.

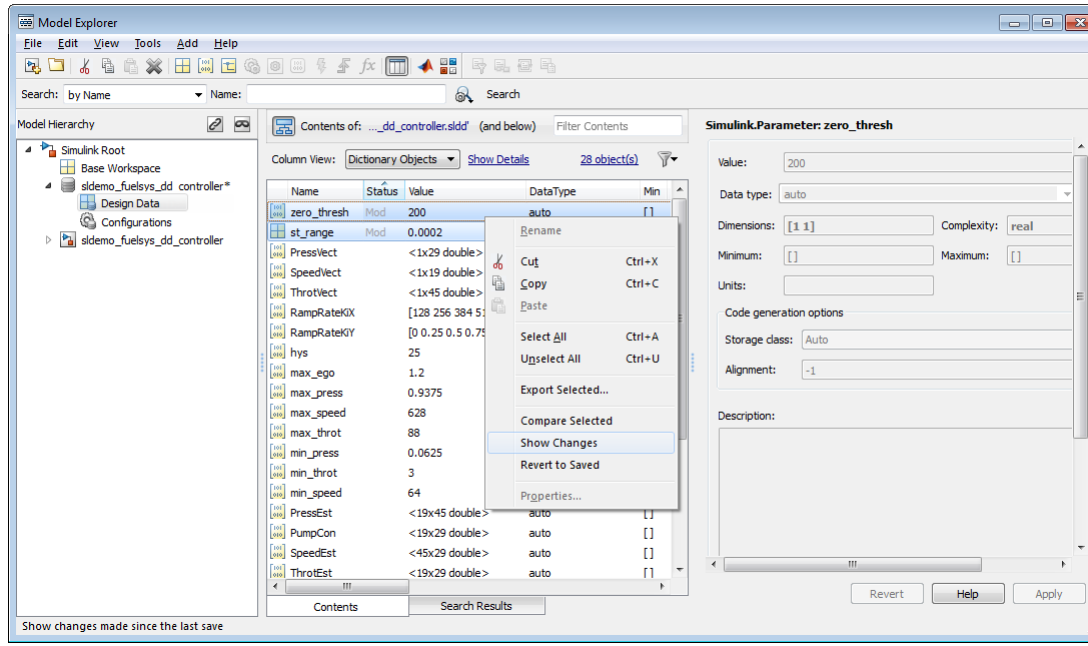
In this section...

View and Revert Changes to Dictionary Entries

This example shows how to view unsaved changes to dictionary entries, who made them, and when. You can view changes to entries in any section, including data stored in the Other Data section and configuration sets stored in the Configurations section.

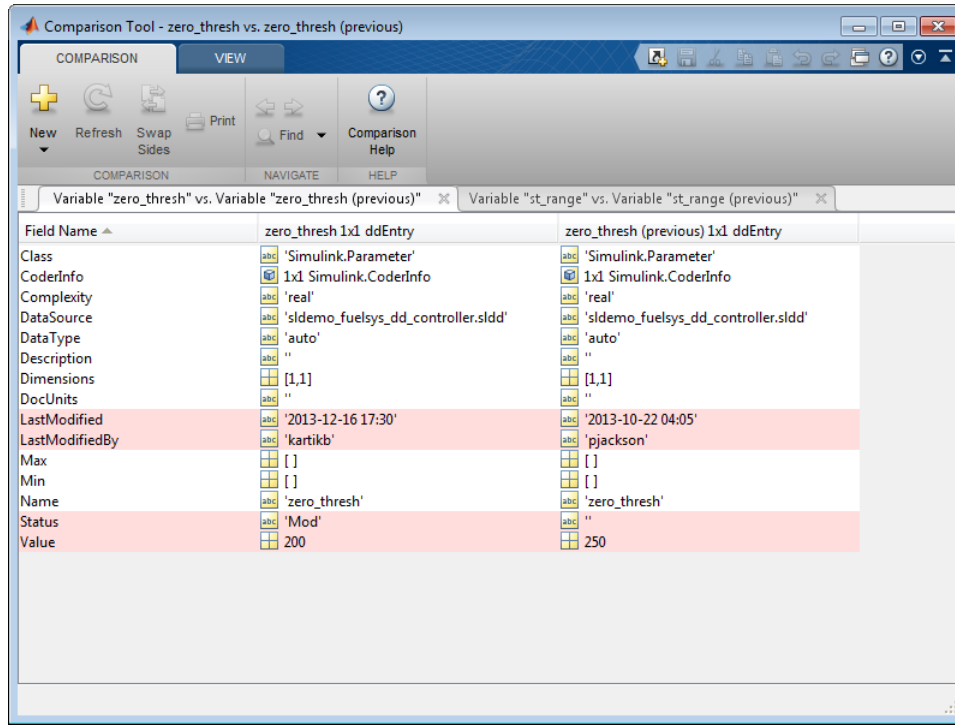
1. Open the `sldemo_fuelsys_dd_controller` model.
2. Open the data dictionary linked to this model by clicking the data dictionary badge  in the bottom left corner of each model.
3. In the **Contents** pane, change `st_range` to `0.0002` and `zero_thresh` to `200`.

   The **Status** column of these entries changes to `Mod`, indicating that they have been modified.
4. Click the heading of the **Status** column to sort the entries. Then, select the modified entries, which are indicated by the `Mod` status.

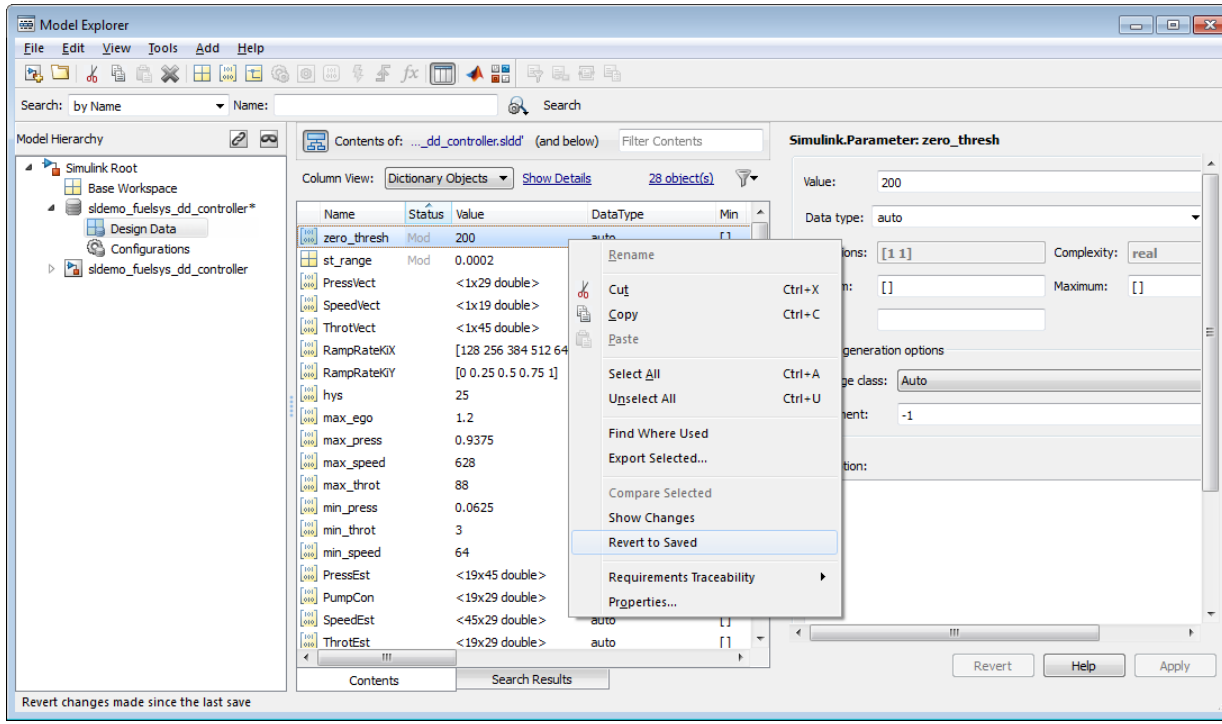


5 Right-click and select **Show Changes**.

The Comparison Tool appears, displaying changed entries in separate tabs. The tool highlights changed values.



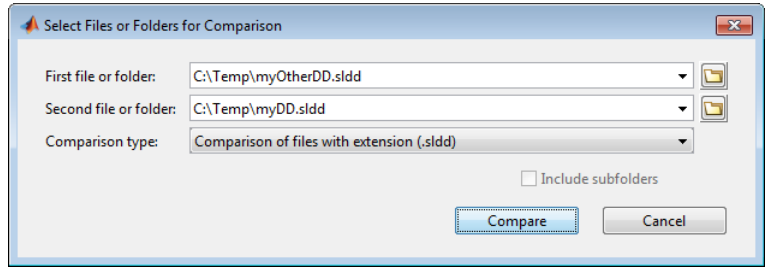
6 In the **Contents** pane of the Model Explorer, right-click `zero_thresh` and select **Revert to Saved**.



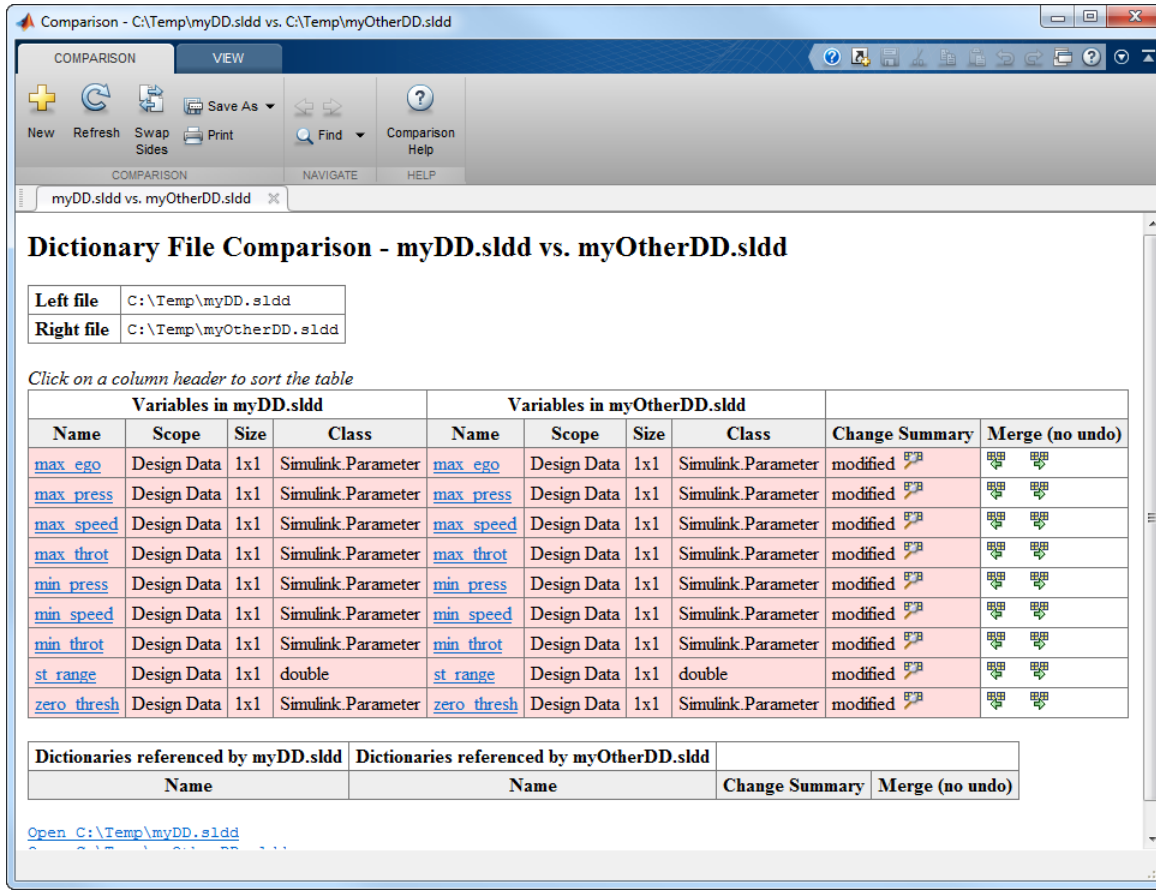
Simulink reverts `zero_thresh` to its value at the time of the last save action.

7 You can merge entries between dictionaries using the Comparison Tool. From the MATLAB desktop, on the **Home** tab, in the **File** section, click **Compare**.

8 Select the dictionaries to compare and merge.



9 In the comparison report, select the merge direction for each dictionary entry.



View and Revert Changes to Entire Dictionary

If you store model variables in a data dictionary, you can view and manage the changes that you make while you work. You can use the Comparison Tool to see the changes made to a dictionary, which compares the modified dictionary with the most recent saved version.

When you view the changes to a dictionary, you can choose to discard changes to individual entries or dictionary references, which reverts to the last saved state. You can use this technique to recover entries that you delete in your modified version or dictionary references that you remove.

If you view changes to a dictionary that references other dictionaries, the Comparison Tool also reports changes made to the entries in the referenced dictionaries.

1 View the example data dictionary `sldemo_fuelsys_dd` in Model Explorer.

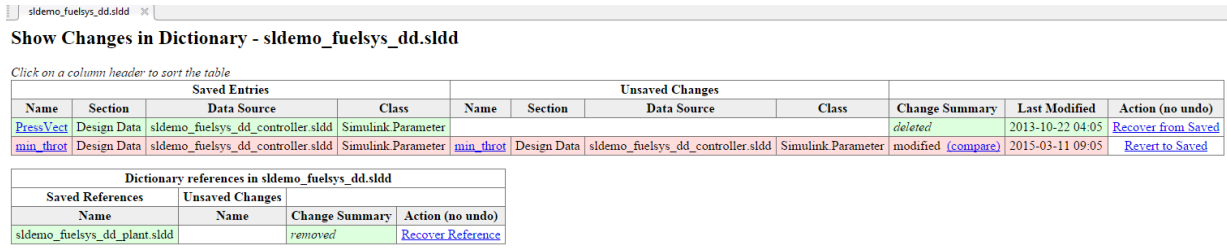
```
dictionary = Simulink.data.dictionary.open('sldemo_fuelsys_dd.sldd');
show(dictionary)
```

The dictionary contains entries that are defined in several referenced dictionaries, including `sldemo_fuelsys_dd_controller` and `sldemo_fuelsys_dd_plant`.

2 Run the script `ex_dictionary_changes`, which makes changes to `sldemo_fuelsys_dd`. Later, you can use the Comparison Tool to investigate the changes.

3 In the **Model Hierarchy** pane of Model Explorer, right-click the node `sldemo_fuelsys_dd` and select **Show Changes**.

The Comparison Tool displays the changes made to the dictionary.



sldemo_fuelsys_dd.sldd

Show Changes in Dictionary - sldemo_fuelsys_dd.sldd

Click on a column header to sort the table

Saved Entries				Unsaved Changes						
Name	Section	Data Source	Class	Name	Section	Data Source	Class	Change Summary	Last Modified	Action (no undo)
PressVect	Design Data	sldemo_fuelsys_dd_controller.sldd	Simulink.Parameter					*deleted*	2013-10-22 04:05	Recover from Saved
min_throt	Design Data	sldemo_fuelsys_dd_controller.sldd	Simulink.Parameter	min_throt	Design Data	sldemo_fuelsys_dd_controller.sldd	Simulink.Parameter	modified (compare)	2015-03-11 09:05	Revert to Saved

Dictionary references in sldemo_fuelsys_dd.sldd			
Saved References	Unsaved Changes		
Name	Name	Change Summary	Action (no undo)
sldemo_fuelsys_dd_plant.sldd		*removed*	Recover Reference

4 In the table at the top of the report, click **compare** in the Change Summary column of the row that corresponds to the entry `min_throt`.

A new tab shows the changes made to `min_throt`. The script changed the parameter data type from `auto` to `int8` and the parameter value from `3` to `4`.

5 Click the tab that shows the changes made to the dictionary. In the Action column of the row that corresponds to the entry `min_throt`, click **Revert to Saved**.

The entry reverts to the definition from the last saved version of the dictionary.

6 The remaining row in the report shows that the script deleted the entry `PressVect`, which was defined in the referenced dictionary `sldemo_fuelsys_dd_controller`. Click **Recover from Saved**, which recovers the entry in the referenced dictionary.

7 The table **Dictionary references in sldemo_fuelsys_dd.sldd** shows that the script removed the reference to the dictionary `sldemo_fuelsys_dd_plant`. In the Action column, click **Recover Reference**.

The report shows that there are no more unsaved changes to `sldemo_fuelsys_dd`.

Partition Dictionary Data Using Referenced Dictionaries

This example shows how to partition a data dictionary into reference dictionaries that can be shared in a team. A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types.

Open dictionary for partitioning

1. Open the Model Explorer. In the Simulink Editor, select **View** > **Model Explorer**.
2. Click **File** > **Open**.

   Browse and locate your dictionary.

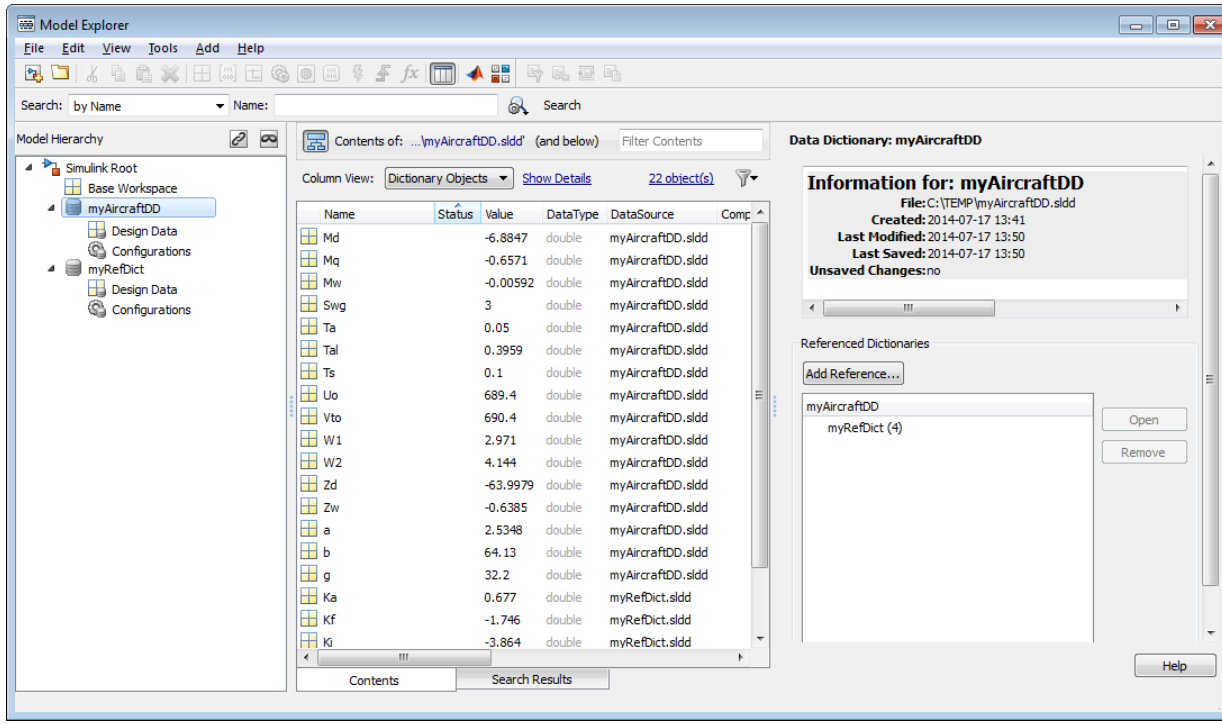
Create reference dictionary

Use a reference dictionary to store a subset of entries from the main dictionary.

1. Click **File** > **New** > **Data Dictionary**.

   Name the reference dictionary and save it.

   Both dictionaries appear as nodes in the **Model Hierarchy** pane.
2. In the **Model Hierarchy** pane, select the dictionary that serves as the parent.
3. In the dialog box pane, in the **Referenced Dictionaries** section, click **Add Reference**. Browse to the location of the reference dictionary and add it as a reference.



Move entries into reference dictionary

1. In the **Model Hierarchy** pane, select the **Design Data** node of the parent dictionary.
2. In the **Contents** pane, select the entries you want to move to the reference dictionary.
3. For one of the selected entries, set **DataSource** to the reference dictionary using the dropdown menu. You can also drag and drop entries between dictionaries.

   To make the **DataSource** column visible, click **Show Details** in the **Contents** pane. In the text box, enter `DataSource`, and add `DataSource` to the list of displayed columns.

Organize display of entries

1. Click the name of the **DataSource** column to sort the entries by the dictionaries that define them.

2 Right-click the name of the **DataSource** column and select **Group by This Column** to group the entries. The **Contents** pane creates a group for each dictionary that defines the entries.

Partition Data for Model Reference Hierarchy Using Data Dictionaries

When you use model referencing to break a large system of models into smaller components and subcomponents, you can create data dictionaries to segregate the design data. Design data is the set of workspace variables that the models use to specify block parameters and signal characteristics. For basic information about data dictionaries, see "What Is a Data Dictionary?" on page 63-2.

You can migrate all of the models in a model reference hierarchy to use one or more data dictionaries using either of these techniques:

- Migrate all of the models in the hierarchy at once to use a single dictionary. Then, create separate referenced dictionaries to organize the design data.
- Incrementally migrate by beginning with the models at the bottom of the hierarchy. Use this technique if you cannot migrate all of the models at once.

Create a Dictionary for Each Component

This example shows how to partition design data into dictionaries. When you finish, each component and subcomponent in the system has a dictionary, and dictionary references allow the components and subcomponents to share data.

Explore Example Model Hierarchy

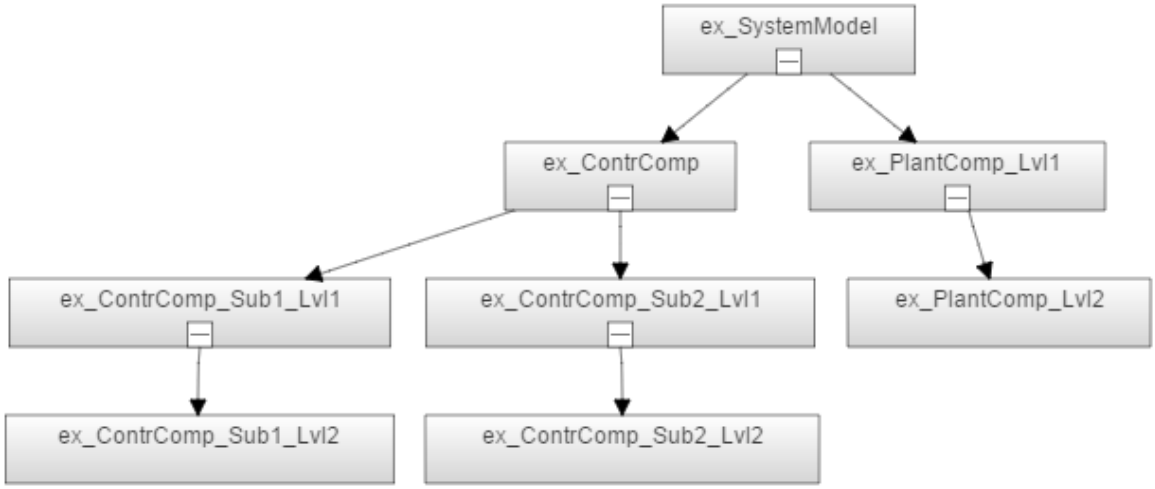
1. Navigate to the folder *matlabroot*`/help/toolbox/simulink/examples` (open).
2. Copy these files to a writable folder:
   - `ProjectData.mat`
   - `ex_SystemModel`
   - `ex_PlantComp_Lvl1`
   - `ex_PlantComp_Lvl2`
   - `ex_ContrComp`
   - `ex_ContrComp_Sub1_Lvl1`
   - `ex_ContrComp_Sub1_Lvl2`
   - `ex_ContrComp_Sub2_Lvl1`

- `ex_ContrComp_Sub2_Lvl2`

3 Load the MAT-file `ProjectData.mat` to create design data in the base workspace.

4 Open the example model `ex_SystemModel`. This model is at the top of a reference hierarchy that includes the other example models.

5 Select **Analysis > Model Dependencies > Model Dependency Viewer > Models Only**. The model reference hierarchy contains a system model, a plant component with two models, and a controller component. The controller component contains two subcomponents, each of which consist of two models.



6 In the model, update the diagram. Each bus signal in the model uses a `Simulink.Bus` object as a data type. The objects, `SensorBus` and `CtrlBus`, are in the base workspace.

The referenced models `ex_PlantComp_Lvl1` and `ex_ContrComp` use the bus objects for root-level inputs and outputs, which means the plant and controller components share the objects.

7 In the base workspace, double-click the `Simulink.NumericType` object named `FloatType`. Signals, parameters, and other data items in the controller component use this shared data type.

8 In the Model Explorer **Model Hierarchy** pane, expand the node ex_SystemModel.

The node Reference to SimConfigSet appears. `SimConfigSet` is a `Simulink.ConfigSet` object in the base workspace. To maintain configuration parameter uniformity for simulation, all of the models in the hierarchy refer to `SimConfigSet`.

9 Right-click the node Controller (ex_ContrComp) and select **Open**.

10 In the Model Explorer **Model Hierarchy** pane, expand the new node ex_ContrComp. Expand the node Model (ex_ContrComp_Sub1_Lvl1).

The node Reference to CodeGenConfigSet appears. `CodeGenConfigSet` is a `Simulink.ConfigSet` object in the base workspace. To maintain configuration parameter uniformity for code generation, the models in the controller component refer to `CodeGenConfigSet`. The models in the plant component do not use `CodeGenConfigSet`.

11 In the **Model Hierarchy** pane, select **Base Workspace**. In the **Contents** pane, right-click the variable `diff` and select **Find Where Used**. In the **Select a system** dialog box, select `ex_SystemModel` and click **OK**. If you see a message about updating the diagram, click **OK**.

In the **Contents** pane, the variable `diff` is used by Constant blocks in the models `ex_ContrComp_Sub1_Lvl1` and `ex_ContrComp_Sub1_Lvl2`, which make up the first controller subcomponent. Similarly, other models in the hierarchy share the base workspace variables `coeff`, `init`, `mu`, and `rho`.

The table shows the models that share each variable in the base workspace.

Variable Name	Models Using the Variable	Scope of Sharing
`CtrlBus`	Top-level models in the plant and controller components	Shared globally by entire system
`SensorBus`	Top-level models in the plant and controller components	Shared globally by entire system
`SimConfigSet`	All models in the hierarchy	Shared globally by entire system
`rho`	`ex_PlantComp_Lvl2` ,`ex_ContrComp_Sub1_Lvl2`, and `ex_ContrComp_Sub2_Lvl2`	Shared globally by entire system

Variable Name	Models Using the Variable	Scope of Sharing
`mu`	`ex_PlantComp_Lvl1` and `ex_PlantComp_Lvl2`	Shared by models in the plant component
`FloatType`	All models in the controller component	Shared by controller component and subcomponents
`CodeGenConfigSet`	All models in the controller component	Shared by controller component and subcomponents
`init`	`ex_ContrComp_Sub1_Lvl2` and `ex_ContrComp_Sub2_Lvl1`	Shared by controller subcomponents
`diff`	`ex_ContrComp_Sub1_Lvl1` and `ex_ContrComp_Sub1_Lvl2`	Shared by models in the first controller subcomponent
`coeff`	`ex_ContrComp_Sub2_Lvl1` and `ex_ContrComp_Sub2_Lvl2`	Shared by models in the second controller subcomponent

Suppose that three teams of developers maintain the plant component and the two controller subcomponents. You can use data dictionaries to store and scope the shared design data.

Create System Dictionary

1. In the model `ex_SystemModel`, select **File > Model Properties > Link to Data Dictionary**.
2. In the dialog box, under **Defined in**, select **Data Dictionary**. Click **New**.
3. Set the new dictionary name to `System` and click **Save**.
4. In the **Model Properties** dialog box, click **OK**.
5. Click **Yes** in response to the message about migrating workspace data.
6. Click **Yes** in response to the message about removing imported items from the base workspace.
7. Save the model.

You can simulate and generate code from the models in the hierarchy. All of the models in the hierarchy are linked to the dictionary. All of the variables in the base workspace now reside in the new dictionary `System.sldd`.

Create Dictionary for Plant Component

1. Open the model `ex_PlantComp_Lvl1`.
2. Select **File > Model Properties > Link to Data Dictionary**.
3. In the dialog box, under **Defined in**, click **New**.
4. Set the new dictionary name to `Plant` and click **Save**.
5. In the **Model Properties** dialog box, click **OK**.
6. In response to the message, click **Move Data**.
7. Click **Yes** in response to the message about migrating data.
8. Save the model.

The models in the plant component, `ex_PlantComp_Lvl1` and `ex_PlantComp_Lvl2`, are linked to the new dictionary `Plant.sldd`. The other models in the hierarchy remain linked to `System.sldd`. Because the model `ex_PlantComp_Lvl1` uses globally shared variables such as `CtrlBus` and `SensorBus`, the migration process moves these variables to `Plant.sldd`. However, `System.sldd` now references `Plant.sldd`, so all of the models in the hierarchy can continue to use the globally shared variables.

The variable that the plant models share, `mu`, also resides in `Plant.sldd`. Other variables that the controller models share, such as `init` and `diff`, remain in `System.sldd`.

The plant component can stand alone from the rest of the system because all of its data is in `Plant.sldd`. However, the controller component depends on the shared data that is also stored in `Plant.sldd`.

Create Dictionary for Controller Component

Open the model `ex_ContrComp`, which is the top model in the controller component. Link this model to a new dictionary named `Contr.sldd`. Then, save the model.

When you finish, the five models in the controller component are linked to `Contr.sldd`. Because the globally shared variables such as `CtrlBus` and `SensorBus` still reside in the dictionary `Plant.sldd`, the dictionary `Contr.sldd` references `Plant.sldd`. Due to

this reference, the models in the controller component can continue to use the globally shared variables.

The variables that the controller models share, such as `diff`, `init`, and `CodeGenConfigSet`, now reside in `Contr.sldd`.

Create Dictionary for First Controller Subcomponent

Open the model `ex_ContrComp_Sub1_Lvl1`. Link this model to a new dictionary named `ContrSub1.sldd`. Then, save the model.

When you finish, the models in the first controller subcomponent, `ex_ContrComp_Sub1_Lvl1` and `ex_ContrComp_Sub1_Lvl2`, are linked to `ContrSub1.sldd`. The models in the second subcomponent remain linked to the dictionary `Contr.sldd`.

Create Dictionary for Second Controller Subcomponent

Open the model `ex_ContrComp_Sub2_Lvl1`. Link this model to a new dictionary named `ContrSub2.sldd`. Then, save the model.

The controller dictionary `Contr.sldd` references the subcomponent dictionaries, `ContrSub1.sldd` and `ContrSub2.sldd`. Therefore, the controller dictionary and the top model in the controller component (`ex_ContrComp`) can use all of the data defined in these subcomponent dictionaries.

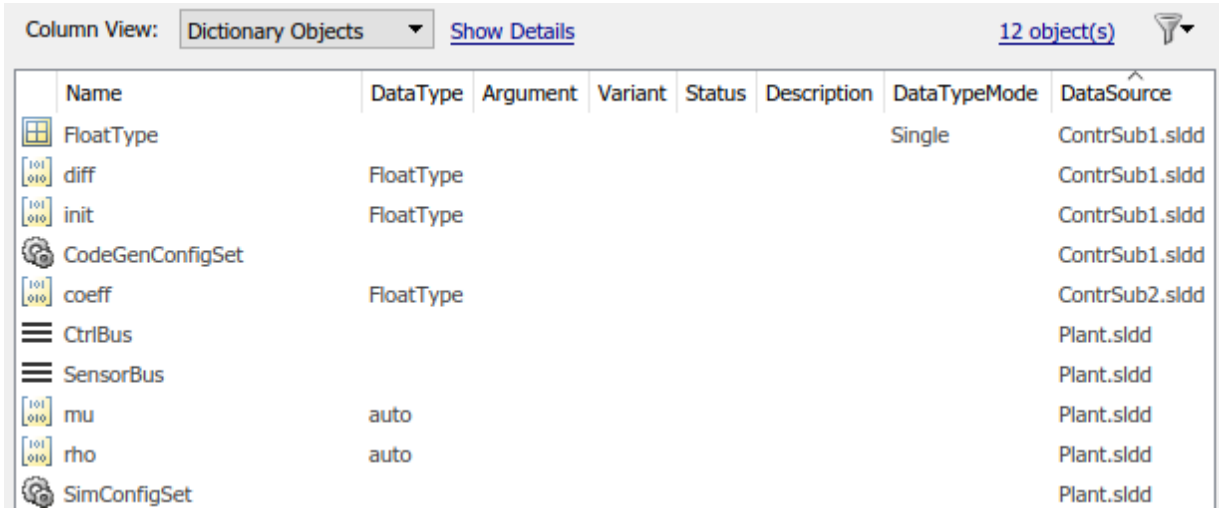
The first subcomponent dictionary, `ContrSub1.sldd`, defines data that the subcomponents share, such as `CodeGenConfigSet`. The second subcomponent dictionary, `ContrSub2.sldd`, references `ContrSub1.sldd` so that the models in the second subcomponent can use this shared data.

The subcomponent dictionaries `ContrSub1.sldd` and `ContrSub2.sldd` reference `Plant.sldd`. Therefore, all of the models in the hierarchy can continue to use globally shared variables such as `SensorBus` and `SimConfigSet`, which are stored in `Plant.sldd`.

Inspect Data Storage

In the Model Explorer **Model Hierarchy** pane, select the dictionary node System. In the **Contents** pane, to view the contents of `System.sldd`, click the **Show Current System**

and Below button  . The contents of the Design Data and Configurations sections appear.



The **DataSource** column shows the variables and objects that each dictionary stores.

All of the globally shared variables, such as `CtrlBus` and `SensorBus`, reside in `Plant.sldd`. The variable `init`, which both of the controller subcomponents share, resides in `ContrSub1.sldd`. Due to dictionary references created by the migration process, the components and subcomponents can still share these variables.

If the development teams assigned to the controller component must make changes to the globally shared variables, they must access the plant dictionary file. Similarly, if the team assigned to the second controller subcomponent must make changes to the variable `init`, they must access the first subcomponent dictionary file.

Optimize Data Sharing Using Reference Dictionaries

To share global variables such as `CtrlBus`, and `SensorBus` by clearly defining variable scope, you can create a reference dictionary. Add the new dictionary as a reference to all of the component and subcomponent dictionaries that require the shared data.

1 Close all of the models that you have open.

```
bdclose all
```

2. In Model Explorer, select **File** > **New** > **Data Dictionary**.
3. Set the new dictionary name to `GlobalShare` and click **Save**.
4. In the **Model Hierarchy** pane, select the node ContrSub2. In the Dialog pane, click **Add Reference**.
5. Double-click `GlobalShare.sldd`.
6. In the **Model Hierarchy** pane, right-click the node ContrSub2 and select **Save Changes**.
7. Add `GlobalShare.sldd` as a reference to the dictionaries `ContrSub1.sldd` and `Plant.sldd`. Save each dictionary after you add the reference.
8. In the **Model Hierarchy** pane, select the node System.
9. In the **Contents** pane, select the globally shared variables:
   - `CtrlBus`
   - `SensorBus`
   - `SimConfigSet`
   - `rho`
10. In the **DataSource** column, select `GlobalShare.sldd` for any of the selected variables.

    All of the variables move from `Plant.sldd` to `GlobalShare.sldd`.
11. Save changes to the dictionary `System.sldd`.

Now, if any of the three development teams need to make changes to the globally shared variables such as `SimConfigSet` and `CtrlBus`, they can access the dictionary `GlobalShare.sldd`. This dictionary contains only the variables that all of the models in the system share. Because the component and subcomponent dictionaries `Plant.sldd`, `ContrSub1.sldd`, and `ContrSub2.sldd` all reference the globally shared dictionary `GlobalShare.sldd`, all of the models in the hierarchy can use the data.

To further partition and scope the shared data, create another reference dictionary to contain the variables that the controller subcomponents share.

1. In Model Explorer, select **File** > **New** > **Data Dictionary**.
2. Set the new dictionary name to `ContrShare` and click **Save**.
3. In the **Model Hierarchy** pane, select the dictionary node ContrSub2. In the Dialog pane, select **Add Reference**.

4. In the dialog box, double-click `ContrShare.sldd`.
5. In the **Model Hierarchy** pane, right-click the node ContrSub2 and select **Save Changes**.
6. Add `ContrShare.sldd` as a reference to `ContrSub1.sldd` and save the dictionary `ContrSub1.sldd`.
7. Add `GlobalShare.sldd` as a reference to `ContrShare.sldd` and save the dictionary `ContrShare.sldd`.
8. In the **Model Hierarchy** pane, select the node System.
9. In the **Contents** pane, select these variables:
   - `CodeGenConfigSet`
   - `init`
   - `FloatType`
10. In the **DataSource** column, select `ContrShare.sldd` for any of the selected variables.

    All of the selected variables move from `ContrSub1.sldd` to `ContrShare.sldd`.
11. Save changes to the dictionary `System.sldd`.

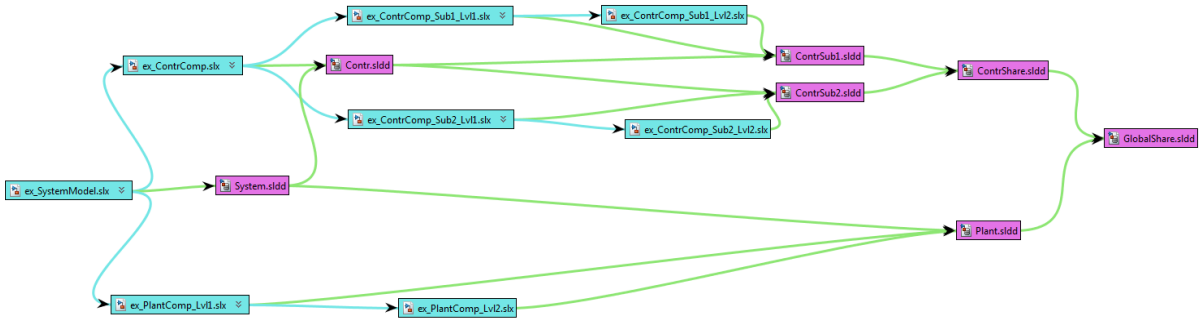
To further optimize the dictionary hierarchy, remove the unnecessary references that the migration process created. Also, remove the unnecessary references that you created from `ContrSub1.sldd` and `ContrSub2.sldd` to `GlobalShare.sldd`. Because `ContrShare.sldd` references `GlobalShare.sldd`, the controller subcomponent dictionaries can use the data in `GlobalShare.sldd` without directly referencing `GlobalShare.sldd`.

1. In the Model Explorer **Model Hierarchy** pane, select the dictionary node Contr. In the Dialog pane, in the **Referenced Dictionaries** list, select Plant and click **Remove**. Save the change to `Contr.sldd`.
2. Remove the references to `GlobalShare.sldd` and `Plant.sldd` from `ContrSub1.sldd`. Save the changes to `ContrSub1.sldd`.
3. Remove the references to `GlobalShare.sldd`, `Plant.sldd`, and `ContrSub1.sldd` from `ContrSub2.sldd`. Save the changes to `ContrSub2.sldd`.

Inspect Dictionary Hierarchy

To view the entire dictionary and model hierarchy, you can perform a dependency analysis in a Simulink project.

1. Open your saved model `ex_SystemModel`. Select **File** > **Simulink Project** > **Create Project from Model**.
2. Specify a name for the project in the **Project name** box. Click **Create**.
3. In the Simulink Project, click **Dependency Analysis**. Click **Analyze**.



The system model, `ex_SystemModel`, is linked to the dictionary `System.sldd`. The plant component, the controller component, and the controller subcomponents are each linked to a separate dictionary. These dictionaries form a reference hierarchy. To access the shared data, the component and subcomponent dictionaries reference the dictionaries `ContrShare.sldd` and `GlobalShare.sldd`.

To inspect the data in the dictionaries, use Model Explorer.

1. In your saved model `ex_SystemModel`, click the data dictionary badge  .
2. In the Model Explorer **Contents** pane, click the column name **DataSource** to sort the design data. The dictionaries in the hierarchy partition the variables based on the shared scope of each variable.

   You can also right-click the column name and select **Group by This Column** to group the entries by the dictionaries that define them.
3. In the **Model Hierarchy** pane, under the node System, click the node Configurations. In the **Contents** pane, the `Simulink.ConfigSet` object

`CodeGenConfigSet` is stored in the shared dictionary for the controller component. `SimConfigSet` is stored in the globally shared dictionary.

Strategies to Discover Shared Data

To learn how the models in a model reference hierarchy share data, use these techniques:

- In an open model, select **Edit > Find Referenced Variables**. The Model Explorer displays the variables that the model uses, as well as the variables that referenced models use. You can then right-click a variable and select **Find Where Used** to display all of the models that use the variable. For more information, see "Edit and Manage Workspace Variables by Using Model Explorer" on page 59-111.
- At the command prompt, use the function `Simulink.findVars` to determine the variables a model uses. You can then use the function `intersect` to determine the variables two models, components, or subcomponents share.

Migrate Model Hierarchy to Dictionaries Incrementally

If you cannot migrate all of the models in a model reference hierarchy to a single dictionary at once, you can migrate an individual model, component, or subcomponent at the bottom of the hierarchy. Over time, you can migrate the entire hierarchy.

If you want to simulate and generate code from the hierarchy after you migrate each component, the components that you migrate cannot share any design data with other models in the hierarchy. In the example "Create a Dictionary for Each Component" on page 63-37, the components and subcomponents of a model reference hierarchy share data in the base workspace, such as `Simulink.Bus` and `Simulink.Parameter` objects. Due to these dependencies, if you migrate the hierarchy incrementally from the bottom, you cannot simulate or generate code from the hierarchy until you migrate all of the models.

Similarly, if you use configuration set references to maintain configuration parameter uniformity throughout the hierarchy, the component that you choose to migrate cannot share a configuration set with other models in the hierarchy. To permit simulation and code generation after you migrate the component, you must eliminate the dependency that the component has on the shared configuration set.

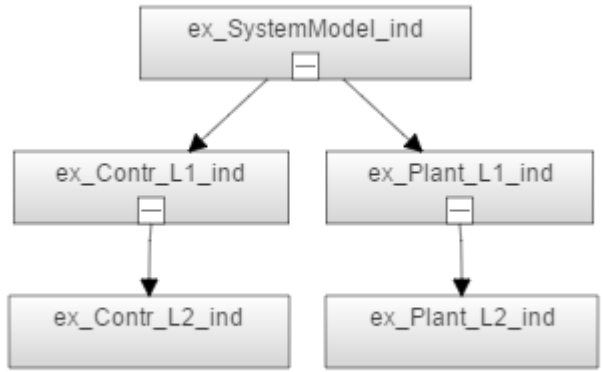
For example, when you migrate the component, copy the shared configuration set from the base workspace into the new dictionary. Then, rename the configuration set in the data dictionary, and set all of the models in the migrated component to use this renamed

configuration set. The models in the migrated component use the configuration set in the data dictionary, while the rest of the models in the hierarchy use the configuration set in the base workspace. As you migrate additional components, set the models in each component to use the configuration set in the data dictionary.

If you choose to migrate a model reference hierarchy incrementally by using this technique, you must begin with the models or components at the bottom of the hierarchy. In the example “Create a Dictionary for Each Component” on page 63-37, a controller model references two subcomponents, each of which contains two models. You cannot migrate the controller model before you migrate the models in the controller subcomponents.

Explore Example Model Hierarchy

1. Navigate to the folder *matlabroot*`/help/toolbox/simulink/examples` (open).
2. Copy these files to a writable folder:
   - `ProjectData_ind.mat`
   - `ex_SystemModel_ind`
   - `ex_Plant_L1_ind`
   - `ex_Plant_L2_ind`
   - `ex_Contr_L1_ind`
   - `ex_Contr_L2_ind`
3. Load the MAT-file `ProjectData_ind.mat` to create design data in the base workspace.
4. Open the example model `ex_SystemModel_ind`. This model is at the top of a reference hierarchy that includes the other example models.
5. Select **Analysis > Model Dependencies > Model Dependency Viewer > Models Only**. The model reference hierarchy contains a system model, a plant component with two models, and a controller component with two models.



6 In the Model Explorer **Model Hierarchy** pane, select **Base Workspace**. In the **Contents** pane, right-click the variable `diff` and select **Find Where Used**. In the **Select a system** dialog box, select `ex_SystemModel_ind` and click **OK**. If you see a message about updating the diagram, click **OK**.

   In the **Contents** pane, the variable `diff` is used by Constant blocks in the models `ex_Contr_L1_ind` and `ex_Contr_L2_ind`, which make up the controller component. Similarly, other models in the hierarchy share the base workspace variable `mu`.

The table shows the models that share each workspace variable.

Variable Name	Models Using the Variable	Scope of Sharing
`diff`	`ex_ContrComp_Lvl1` and `ex_ContrComp_Lvl2`	Shared by models in the controller component
`mu`	`ex_PlantComp_Lvl1` and `ex_PlantComp_Lvl2`	Shared by models in plant component

Suppose that two teams of developers maintain the plant component and the controller component. You can use data dictionaries to store and scope the design data. The teams can incrementally migrate the components to use data dictionaries.

Create Data Dictionary for Controller Component

Suppose that only the controller component team is ready to migrate their models to a data dictionary. You can independently migrate these two models.

1. Open the example model `ex_Contr_L1_ind`. This model is at the top of the controller component.
2. Select **File > Model Properties > Link to Data Dictionary**.
3. In the dialog box, under **Defined in**, select **Data Dictionary** and click **New**.
4. Set the new dictionary name to `Contr` and click **Save**.
5. In the **Model Properties** dialog box, click **OK**.
6. Click **Yes** in response to the message about migrating workspace data.
7. Click **Yes** in response to the message about removing imported items from the base workspace.
8. Save the model.

You can simulate and generate code from the model hierarchy. The models in the controller component use the data in the dictionary `Contr`, which contains the variable `diff`. The other models in the hierarchy continue to use the data in the base workspace.

Create Data Dictionary for Plant Component

Open the example model `ex_Plant_L1_ind`. Link this model to a new data dictionary `Plant.sldd`. After you link the model to the new dictionary, save the model.

The migration process moves the variable `mu` into the new dictionary.

Create Data Dictionary for System Model

Open the example model `ex_SystemModel_ind`. Link this model to a new data dictionary `System.sldd`. After you link the model to the new dictionary, save the model.

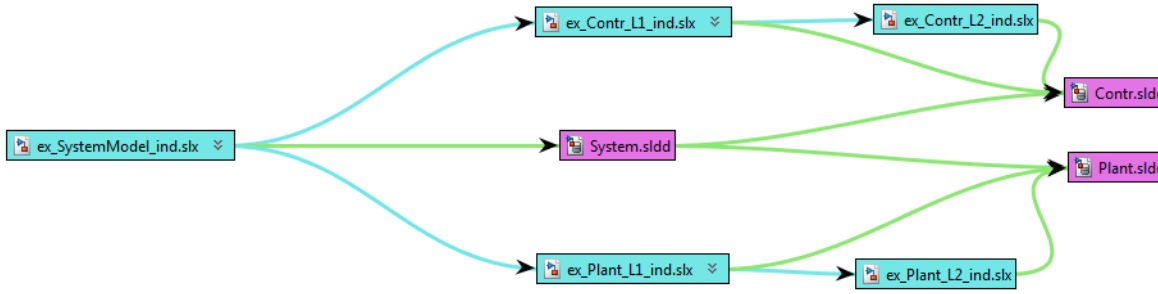
The migration process causes the new dictionary, `System.sldd`, to reference the other dictionaries that you created.

Inspect Dictionary Hierarchy

Each of the components has a data dictionary. To view the entire dictionary and model hierarchy, you can perform a dependency analysis in a Simulink project.

1. In your saved model `ex_SystemModel_ind`, select **File** > **Simulink Project** > **Create Project from Model**.
2. Specify a name for the project in the **Project name** box. Click **Create**.
3. In the Simulink Project, click **Dependency Analysis**. Click **Analyze**.

Each team's models are linked to the appropriate dictionaries. The system dictionary references the component dictionaries.



To inspect the data in the dictionaries, use the Model Explorer.

1. In your saved model `ex_SystemModel_ind`, click the data dictionary badge  .
2. In the Model Explorer **Contents** pane, the data source for each entry is the dictionary for the appropriate component.

Store Data in Dictionary Programmatically

In this section...

A data dictionary stores Simulink model data and offers more data management features than the MATLAB base workspace or the model workspace (see “What Is a Data Dictionary?” on page 63-2). To interact with the data in a dictionary programmatically:

1. Create a `Simulink.data.Dictionary` object that represents the target dictionary.
2. Create a `Simulink.data.dictionary.Section` object that represents the target section, for example the Design Data section. Use the object to interact with the entries stored in the section and to add entries.
3. Optionally, create `Simulink.data.dictionary.Entry` objects that each represent an entry in the target section. Use these objects to interact with individual entries in the target section.

To programmatically access variables for the purpose of sweeping block parameter values, consider using `Simulink.SimulationInput` objects instead of modifying the variables through the programmatic interface of the data dictionary. See “Optimize, Estimate, and Sweep Block Parameter Values” on page 36-48.

Add Entry to Design Data Section of Data Dictionary

1. Represent the Design Data section of the data dictionary `myDictionary_ex_API.sldd` with a `Simulink.data.dictionary.Section` object named `dDataSectObj`.

```
myDictionaryObj = Simulink.data.dictionary.open('myDictionary_ex_API.sldd');
dDataSectObj = getSection(myDictionaryObj,'Design Data');
```

2 Add an entry to the Design Data section of `myDictionary_ex_API.sldd` an entry `myNewEntry` with value `237`.

```
addEntry(dDataSectObj,'myNewEntry',237)
```

Increment Value of Data Dictionary Entry

1 Represent the data dictionary entry `fuelFlow` with a `Simulink.data.dictionary.Entry` object named `fuelFlowObj`. `fuelFlow` is defined in the data dictionary `myDictionary_ex_API.sldd`.

```
myDictionaryObj = Simulink.data.dictionary.open('myDictionary_ex_API.sldd');
dDataSectObj = getSection(myDictionaryObj,'Design Data');
fuelFlowObj = getEntry(dDataSectObj,'fuelFlow');
```

2 Store the value of the target entry in a temporary variable. Increment the value of the temporary variable by one.

```
temp = getValue(fuelFlowObj);
temp = temp+1;
```

3 Set the value of the target entry by using the temporary variable.

```
setValue(fuelFlowObj,temp)
```

Data Dictionary Management

Use `Simulink.data.Dictionary` objects to interact with entire data dictionaries.

Goal	Use
Represent existing data dictionary with `Simulink.data.Dictionary` object	`Simulink.data.dictionary.open`
Create and represent data dictionary with `Simulink.data.Dictionary` object	`Simulink.data.dictionary.create`
Interact with data dictionary	`Simulink.data.Dictionary` class

Goal	Use
Import variables to data dictionary from MATLAB base workspace	`Simulink.data.Dictionary.importFromBaseWorkspace` method
Add reference dictionary to a data dictionary	`Simulink.data.Dictionary.addDataSource` method
Remove reference dictionary from a data dictionary	`Simulink.data.Dictionary.removeDataSource` method
Save changes to data dictionary	`Simulink.data.Dictionary.saveChanges` method
Discard changes to data dictionary	`Simulink.data.Dictionary.discardChanges` method
View a list of entries stored in data dictionary	`Simulink.data.Dictionary.listEntry` method
Import enumerated type definitions to data dictionary	`Simulink.data.Dictionary.importEnumTypes` method
Return file name and path of data dictionary	`Simulink.data.Dictionary.filepath` method
Show data dictionary in Model Explorer window	`Simulink.data.Dictionary.show` method
Hide data dictionary from Model Explorer window	`Simulink.data.Dictionary.hide` method
Close connection between data dictionary and `Simulink.data.Dictionary` object	`Simulink.data.Dictionary.close` method
Identify data dictionaries that are open	`Simulink.data.dictionary.getOpenDictionaryPaths`
Close all connections to all open data dictionaries	`Simulink.data.dictionary.closeAll`

Dictionary Section Management

Data dictionaries store data as entries contained in sections, and by default all dictionaries have at least three sections named Design Data, Other Data, and

Configurations. Use `Simulink.data.dictionary.Section` objects to interact with data dictionary sections.

Goal	Use
Represent data dictionary section with `Section` object.	`Simulink.data.Dictionary.getSection` method
Interact with data dictionary section	`Simulink.data.dictionary.Section` class
Import variables to data dictionary section from MAT-file or MATLAB file	`Simulink.data.dictionary.Section.importFromFile` method
Export entries in data dictionary section to MAT-file or MATLAB file	`Simulink.data.dictionary.Section.exportToFile` method
Delete entry from data dictionary section	`Simulink.data.dictionary.Section.deleteEntry` method
Evaluate MATLAB expression in data dictionary section	`Simulink.data.dictionary.Section.evalin` method
Search for entries in data dictionary section	`Simulink.data.dictionary.Section.find` method
Determine whether entry exists in data dictionary section	`Simulink.data.dictionary.Section.exist` method

Dictionary Entry Manipulation

A variable that is stored in a data dictionary is called an entry of the dictionary. Entries have additional properties that store status information, such as the time and date the entry was last modified. Use `Simulink.data.dictionary.Entry` objects to manipulate data dictionary entries.

Goal	Use
Represent data dictionary entry with `Entry` object	`Simulink.data.dictionary.Section.getEntry` method
Add data dictionary entry to section and represent with `Entry` object	`Simulink.data.dictionary.Section.addEntry` method

Goal	Use
Manipulate data dictionary entry	`Simulink.data.dictionary.Entry` class
Assign new value to data dictionary entry	`Simulink.data.dictionary.Entry.setValue` method
Display changes made to data dictionary entry	`Simulink.data.dictionary.Entry.showChanges` method
Save changes made to data dictionary	`Simulink.data.Dictionary.saveChanges` method
Discard changes made to data dictionary entry	`Simulink.data.dictionary.Entry.discardChanges` method
Search in an array of data dictionary entries	`Simulink.data.dictionary.Entry.find` method
Return value of data dictionary entry	`Simulink.data.dictionary.Entry.getValue` method
Delete data dictionary entry	`Simulink.data.dictionary.Entry.deleteEntry` method
Store enumerated type definition in dictionary	`Simulink.data.dictionary.EnumTypeDefinition` class

Transition to Using Data Dictionary

These functions help you transition to data dictionaries by operating on Simulink model data either in the base workspace or in a data dictionary, as appropriate for the model.

Goal	Use
Change value of data dictionary entry or workspace variable in context of Simulink model	`Simulink.data.assigninGlobal`
Evaluate MATLAB expression in context of Simulink model	`Simulink.data.evalinGlobal`
Determine existence of data dictionary entry or workspace variable in context of Simulink model	`Simulink.data.existsInGlobal`

Programmatically Migrate Single Model to Use Dictionary

To change the data source of a Simulink model from the MATLAB base workspace to a new data dictionary, use this example code as a template.

```
% Define the model name and the data dictionary name
modelName = 'f14';
dictionaryName = 'myNewDictionary.sldd';

% Load the target model
load_system(modelName);

% Identify all model variables that are defined in the base workspace
varsToImport = Simulink.findVars(modelName,'SourceType','base workspace');
varNames = {varsToImport.Name};

% Create the data dictionary
dictionaryObj = Simulink.data.dictionary.create(dictionaryName);

% Import to the dictionary the model variables defined in the base
% workspace, and clear the variables from the base workspace
[importSuccess,importFailure] = importFromBaseWorkspace(dictionaryObj,...
    'varList',varNames,'clearWorkspaceVars',true);

% Link the dictionary to the model
set_param(modelName,'DataDictionary',dictionaryName);
```

Note This code does not migrate the definitions of enumerated data types that were used to define model variables. If you import model variables of enumerated data types to a data dictionary but do not migrate the enumerated type definitions, the dictionary is less portable and might not function properly if used by someone else. To migrate enumerated data type definitions to a data dictionary, see “Enumerations in Data Dictionary” on page 63-14.

Import Directly From External File to Dictionary

This example shows how to use a custom MATLAB function to import data directly from an external file to a data dictionary without creating or altering variables in the base workspace.

1 Create a two-dimensional lookup table in one sheet of a Microsoft Excel workbook. Use the upper-left corner of the sheet to provide names for the two breakpoints and for the table. Use column B and row 2 to store the two breakpoints, and use the rest of the sheet to store the table. For example, your lookup table might look like this:

	A	B	C	D	E	F	G	H
1		bkpt2Name						
2	bkpt1Name	tableName	0.1	0.2	0.3	0.4	0.5	
3		0.25	0.35	0.6	0.85	1.1	1.35	
4		0.5	0.45	0.7	0.95	1.2	1.45	
5		0.75	0.55	0.8	1.05	1.3	1.55	
6		1	0.65	0.9	1.15	1.4	1.65	
7		1.25	0.75	1	1.25	1.5	1.75	
8								

Save the workbook in your current folder as `my2DLUT.xlsx`.

2 Copy this custom function definition into a MATLAB file, and save the file in your current folder as `importLUTToDD.m`.

```
function importLUTToDD(workbookFile,dictionaryName)
    % IMPORTLUTTODD(workbookFile,dictionaryName) imports data for a
    % two-dimensional lookup table from a workbook directly into a data
    % dictionary. The two-dimensional lookup table in the workbook can be
    % any size but must follow a standard format.

    % Read in the entire first sheet of the workbook.
    [data,names,~] = xlsread(workbookFile,1,'');

    % Divide the raw imported data into the breakpoints, the table, and their
    % names.
    % Assume breakpoint 1 is in the first column and breakpoint 2 is in the
    % first row.
    % Assume cells A1, B1, and B2 define the breakpoint names and table name.
    bkpt1 = data(2:end,1);
    bkpt2 = data(1,2:end);
    table = data(2:end,2:end);
    bkpt1Name = names{2,1};
    bkpt2Name = names{1,2};
    tableName = names{2,2};

    % Prepare to import to the Design Data section of the target data
    % dictionary.
    myDictionaryObj = Simulink.data.dictionary.open(dictionaryName);
    dDataSectObj = getSection(myDictionaryObj,'Design Data');
```

```
% Create entries in the dictionary to store the imported breakpoints and
% table. Name the entries using the breakpoint and table names imported
% from the workbook.
addEntry(dDataSectObj,bkpt1Name,bkpt1);
addEntry(dDataSectObj,bkpt2Name,bkpt2);
addEntry(dDataSectObj,tableName,table);

% Save changes to the dictionary and close it.
saveChanges(myDictionaryObj)
close(myDictionaryObj)
```

3 At the MATLAB command prompt, create a data dictionary to store the lookup table data.

```
myDictionaryObj = Simulink.data.dictionary.create('myLUTDD.sldd');
```

4 Call the custom function to import your lookup table to the new data dictionary.

```
importLUTToDD('my2DLUT.xlsx','myLUTDD.sldd')
```

5 Open the data dictionary in Model Explorer.

```
show(myDictionaryObj)
```

Three new entries store the imported breakpoints and lookup table. These entries are ready to use in a 2-D Lookup Table block.

Programmatically Partition Data Dictionary

To partition a data dictionary into reference dictionaries, use this example code as a template. You can use reference dictionaries to make large data dictionaries more manageable and to contain standardized data that is useful for multiple models.

```
% Define the names of a parent data dictionary and two
% reference data dictionaries
parentDDName = 'myParentDictionary.sldd';
typesDDName = 'myTypesDictionary.sldd';
paramsDDName = 'myParamsDictionary.sldd';

% Create the parent data dictionary and a
% Simulink.data.Dictionary object to represent it
parentDD = Simulink.data.dictionary.create(parentDDName);

% Create a Simulink.data.dictionary.Section object to represent
% the Design Data section of the parent dictionary
```

```
designData_parentDD = getSection(parentDD,'Design Data');

% Import some data to the parent dictionary from the file partDD_Data_ex_API.m
importFromFile(designData_parentDD,'partDD_Data_ex_API.m');

% Create two reference dictionaries
Simulink.data.dictionary.create(typesDDName);
Simulink.data.dictionary.create(paramsDDName);

% Create a reference dictionary hierarchy by adding reference dictionaries
% to the parent dictionary
addDataSource(parentDD,typesDDName);
addDataSource(parentDD,paramsDDName);

% Migrate all Simulink.Parameter objects from the parent data dictionary to
% a reference dictionary
paramEntries = find(designData_parentDD,'-value','-class','Simulink.Parameter');
for i = 1:length(paramEntries)
    paramEntries(i).DataSource = 'myParamsDictionary.sldd';
end

% Migrate all Simulink.NumericType objects from the parent data dictionary
% to a reference dictionary
typeEntries = find(designData_parentDD,'-value','-class','Simulink.NumericType');
for i = 1:length(typeEntries)
    typeEntries(i).DataSource = 'myTypesDictionary.sldd';
end

% Save all changes to the parent data dictionary
saveChanges(parentDD)
```

Make Changes to Configuration Set Stored in Dictionary

You can store a configuration set (a `Simulink.ConfigSet` object) in the Configurations section of a dictionary. To change the setting of a configuration parameter in the set programmatically:

1. Create a `Simulink.data.dictionary.Entry` object that represents the configuration set (which is an entry in the dictionary). For example, suppose the name of the dictionary is `myData.sldd` and the name of the `Simulink.ConfigSet` object is `myConfigs`.

```
dictionaryObj = Simulink.data.dictionary.open('myData.sldd');
configsSectObj = getSection(dictionaryObj,'Configurations');
entryObj = getEntry(configsSectObj,'myConfigs');
```

2 Store a copy of the target `Simulink.ConfigSet` object in a temporary variable.

```
temp = getValue(entryObj);
```

3 In the temporary variable, modify the target configuration parameter (in this case, set **Stop time** to `20`).

```
set_param(temp,'StopTime','20');
```

4 Use the temporary variable to overwrite the configuration set in the dictionary.

```
setValue(entryObj,temp);
```

5 Save changes made to the dictionary.

```
saveChanges(dictionaryObj)
```

Managing Signals

Working with Signals

Signal Basics

In this section...

About Signals

A *signal* is a time-varying quantity that has values at all points in time. You can specify a wide range of signal attributes, including:

- Signal name
- Data type (for example, 8-bit, 16-bit, or 32-bit integer)
- Numeric type (real or complex)
- Dimensionality (one-dimensional, two-dimensional, or multidimensional array)

Many blocks can accept or output signals of any data or numeric type and dimensionality. Other blocks impose restrictions on the attributes of the signals that they can handle.

In Simulink, signals are the outputs of dynamic systems represented by blocks in a Simulink diagram and by the diagram itself. The lines in a block diagram represent mathematical relationships among the signals defined by the block diagram. For example, a line connecting the output of block A to the input of block B indicates that the signal output of B depends on the signal output of A.

Simulink block diagrams represent signals with lines that have an arrowhead. The source of the signal corresponds to the block that writes to the signal during evaluation of its block methods (equations). The destinations of the signal are blocks that read the signal during the evaluation of the block methods (equations).

Note Simulink signals are mathematical, not physical, entities. The lines in a block diagram represent mathematical, not physical, relationships among blocks. Simulink

signals do not travel along the lines that connect blocks in the same way that electrical signals travel along a wire. Block diagrams do not represent physical connections between blocks.

Creating Signals

Create a signal by adding a source block to your model. For example, you can create a signal that varies sinusoidally with time by adding an instance of the Sine block from the Simulink Sources library into your model. For information about blocks that create signals in a model, see “Sources” .

You can use the Signal & Scope Manager to create signals in your model without using blocks. For more information, see “Signal and Scope Manager” on page 27-85 .

Signal Line Styles

A Simulink model can include many different types of signals. For details, see “Signal Types” on page 64-9. Different line styles help you to differentiate the signal types.

As you construct a block diagram, all signal types appear as a thin, solid line. After you update the diagram or start simulation, the signals appear with the specified line styles. The only line style that you can customize is the nonscalar signal type. For information about this option, see “Wide Nonscalar Lines” on page 64-70.

Signal Type	Line Style
Scalar and nonscalar	Nonscalar (with the **Wide nonscalar lines** option enabled—see “Display Signal Attributes” on page 64-65)	
Control signal	Virtual bus	
Nonvirtual bus	
Array of buses	
Signal Type	Line Style
Variable-size	
Signal Properties

Specify Signal Properties

Use the Property Inspector, the Model Data Editor, or the Signal Properties dialog box to specify properties for:

- Signal names and labels
- Signal logging
- Simulink Coder to use to generate code
- Documentation of the signal

To access the signal properties in the Property Inspector, first display the Property Inspector. Select **View > Property Inspector**. When you select a signal, the properties appear in the Property Inspector. To use the Model Data Editor (**View > Model Data**), inspect the **Signals** tab and select a signal. To use the Signal Properties dialog box, right-click a signal and select **Properties**. For information about the benefits of each approach, see “Setting Properties and Parameters” on page 1-50.

Programmatically Specify Signal Properties

To specify signal properties programmatically, use a function such as `get_param` to get a handle to the block output port that creates the signal line. Then, use `set_param` to set the programmatic parameters of the port.

For an example, see “Name a Signal Programmatically” on page 1-17.

To learn how to map signal properties to programmatic port parameters, see “Signal Properties Dialog Box Overview”.

Signal Names and Labels

You can name a signal. By default, the signal name appears below a signal, displayed as a signal label. You can name a signal interactively in the model or by using the Property Inspector (**View > Property Inspector**), the Model Data Editor (**View > Property Inspector**) **Signals** tab, or the Signal Properties dialog box. You can also name the

signal at the command prompt (see “Name a Signal Programmatically” on page 1-17). For a summary of how to work with signal names and labels in the Simulink Editor, see “Signal Name and Label Actions” on page 1-93.

The syntactic requirements for a signal name depend on how you use the name. The most common cases are:

- The signal name can resolve to a `Simulink.Signal` object. (See `Simulink.Signal`.) The signal name must then be a legal MATLAB identifier. This identifier starts with an alphabetic character, followed by alphanumeric or underscore characters up to the length given by the function `namelengthmax`.
- The signal has a name so the signal can be identified and referenced by name in a data log. (See “Export Signal Data Using Signal Logging” on page 61-71.) Such a signal name can contain space and newline characters. These characters can improve readability but sometimes require special handling techniques, as described in “Handling Spaces and Newlines in Logged Names” on page 61-111
- The signal name exists only to clarify the diagram and has no computational significance. Such a signal name can contain anything and does not need special handling.
- The signal is an element of a bus object. Use a valid C language identifier for the signal name.
- Inputs to a Bus Creator block must have unique names. If there are duplicate names, the Bus Creator block appends `(signal#)` to all input signal names, where `#` is the input port index.

Making every signal name a legal MATLAB identifier handles a wide range of model configurations. Unexpected requirements can require changing signal names to follow a more restrictive syntax. You can use the function `isvarname` to determine whether a signal name is a legal MATLAB identifier.

Signal Display Options

Displaying signal attributes in the model diagram can make the model easier to read. For example, in the Simulink Editor, use the **Display > Signals & Ports** menu to include in the model layout information about signal attributes, such as:

- Port data types
- Design ranges
- Signal dimensions

- Signal resolution

For details, see “Display Signal Attributes” on page 64-65.

You can also highlight a signal and its source or destination blocks. For details, see “Highlight Signal Sources and Destinations” on page 64-39.

Store Design Attributes of Signals and States

You can use block parameters and signal properties to specify signal design attributes such as data type, minimum and maximum values, physical unit, and numeric complexity. To configure states, you can use block parameters. When you use these block parameters and signal properties, you store the specifications in the model file.

Alternatively, you can specify these attributes by using the properties of a `Simulink.Signal` object that you store in a workspace or data dictionary. See `Simulink.Signal` and “Data Objects” on page 59-53.

Choose which strategy to use based on your modeling goals.

- To improve model portability, readability, and ease of maintenance, store these specifications in the model file. Use the Property Inspector, the Model Data Editor, block dialog boxes, and signal properties dialog boxes to access the parameters and properties. You do not need to save and manage external `Simulink.Signal` objects. Consider setting the model configuration parameter **Signal resolution** to `None`, which disables the use of `Simulink.Signal` objects by the model.

  To configure design attributes and code generation settings for signals by using a list that you can sort, group, and filter, consider the Model Data Editor. With this tool, you store the specifications in the model file instead of using `Simulink.Signal` objects. See “Configure Data Properties by Using the Model Data Editor” on page 59-141.
- To separate these specifications from the model so that you can manage each independently, use `Simulink.Signal` objects. You can then configure the specifications in a flat list that you can sort, group, and filter with the Model Data Editor or the Model Explorer. To determine where to permanently store the objects, see “Determine Where to Store Variables and Objects for Simulink Models” on page 59-96.

Testing Signals

You can perform the following kinds of tests on signals:

- "Minimum and Maximum Values" on page 64-7
- "Connection Validation" on page 64-7

Minimum and Maximum Values

For many Simulink blocks, you can specify a range of valid values for the output signals. Simulink provides a diagnostic for detecting when blocks generate signals that exceed their specified ranges during simulation. For details, see "Signal Ranges" on page 64-45.

Connection Validation

Many Simulink blocks have limitations on the types of signals that they accept. Before simulating a model, Simulink checks all blocks to ensure that the blocks can accommodate the types of signals output by the ports to which the blocks connect and reports errors about incompatibilities.

To detect signal compatibility errors before running a simulation, update the diagram.

Signal Groups

The Signal Builder block displays interchangeable groups of signal sources. Use the Signal Builder to create or edit groups of signals and to switch the groups into and out of a model.

Signal groups can help with testing a model, especially when you use them with Simulink Assertion blocks and the Model Coverage Tool in the Simulink Verification and Validation product.

For details, see "Signal Groups" on page 64-72.

Signal Types

In this section...

Summary of Signal Types

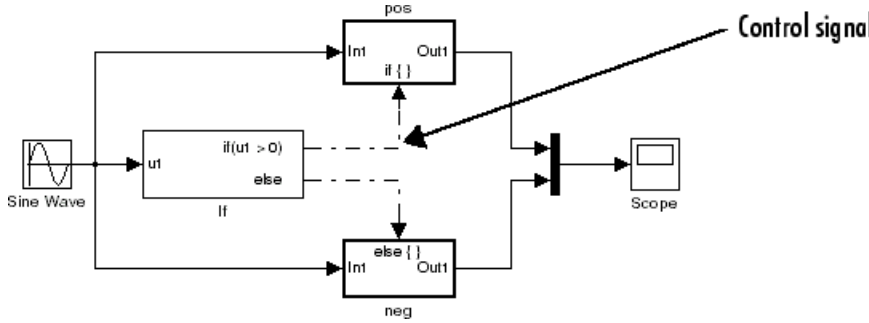
You can use many different kinds of signals in a model. The following table summarizes the signal types, and links to sections that describe each type in detail.

Signal Type	Description
Array of buses	An array whose elements are buses. See “Combine Buses into an Array of Buses” on page 65-118.
Bus (Composite)	A Simulink composite signal made up of other signals, optionally including other bus signals. See “Composite (Bus) Signals” on page 64-10.
Control	Signal used by one block to initiate execution of another block. For example, a signal that executes a function-call or action subsystem. For details, see “Control Signals” on page 64-9.
Nonvirtual	Signal that occupies its own storage. A nonvirtual bus reads inputs and writes outputs by accessing copies of the component signals.
Mux	A virtual vector created with a Mux block. See “Mux Signals” on page 64-12.
Variable-Size	Signal whose size (the number of elements in a dimension), in addition to its values, can change during a model simulation.
Virtual	Signal that represents another signal or set of signals. A virtual signal is used for graphical purposes and has no functional effect. See “Virtual Signals” on page 64-12.

Control Signals

A *control signal* is a signal used by one block to initiate execution of another block. For example, a signal that executes a function-call or action subsystem is a control signal.

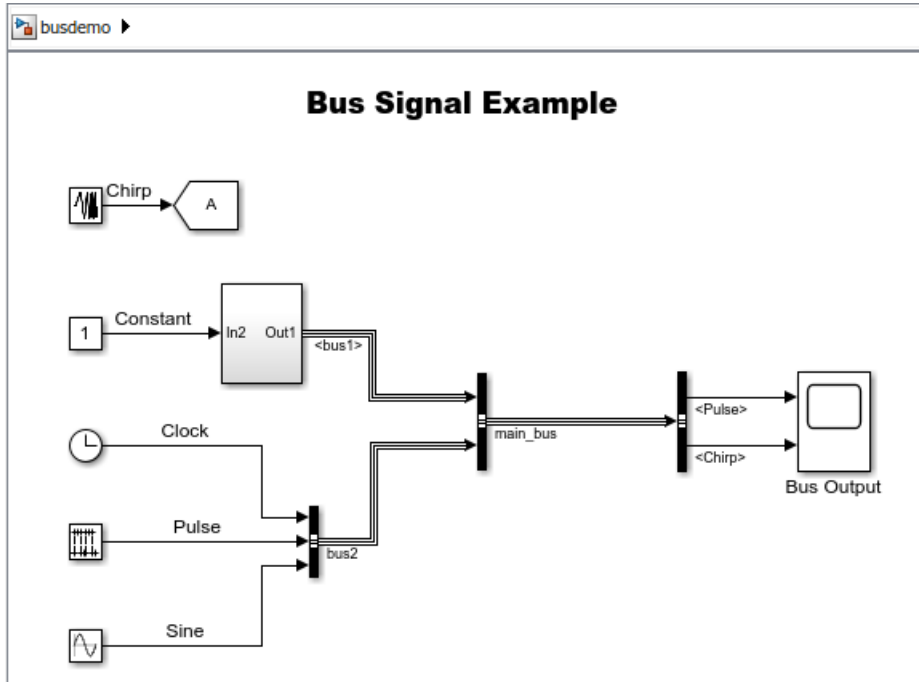
When you update or simulate a block diagram, Simulink uses a dash-dot pattern to redraw lines representing the control signals.



Composite (Bus) Signals

You can group multiple signals into a hierarchical composite signal, called a *bus*, route the bus from block to block, and extract constituent signals from the bus where needed. When you have many parallel signals, buses can simplify the appearance of a model and help to clarify generated code. A bus can be either virtual or nonvirtual.

For example, if you open and simulate the `busdemo` example model, the `bus1`, `bus2`, and `main_bus` signals are bus signals. These virtual bus signals use the triple line style.



For information about buses, see slexBusExample and “Buses” on page 65-3.

Virtual Signals

In this section...

About Virtual Signals

A *virtual signal* is a signal that graphically represents other signals or parts of other signals. Virtual signals are purely graphical entities; they have no mathematical or physical significance. Simulink ignores them when simulating a model, and they do not exist in generated code. Some blocks, such as the Mux block, always generate virtual signals. Others, such as Bus Creator, can generate either virtual or nonvirtual signals.

The nonvirtual components of a virtual signal are called *regions*. A virtual signal can contain the same region more than once. For example, if the same nonvirtual signal is connected to two input ports of a Mux block, the block outputs a virtual signal that has two regions. The regions behave as they would if they had originated in two different nonvirtual signals, even though the resulting behavior duplicates information.

Bus signals can also be virtual or nonvirtual. For details, see “Virtual and Nonvirtual Buses” on page 65-4.

Mux Signals

A Simulink mux is a virtual signal that graphically combines two or more scalar or vector signals into one signal line. A Simulink mux is not a hardware multiplexer, which combines multiple data streams into a single channel. A Simulink mux does not combine signals in any functional sense: it exists only virtually, and its only purpose is to simplify the visual appearance of a model. Using a mux has no effect on simulation or generated code.

You can use a mux anywhere that you could use an ordinary (contiguous) vector. For example, you can perform calculations on a mux. The computation affects each constituent value in the mux just as if the values existed in a contiguous vector, and the result is a contiguous vector, not a mux. Using a mux to perform computations on multiple vectors avoids the overhead of copying the separate values to contiguous storage.

The Simulink documentation refers, sometimes interchangeably, to “muxes”, “vectors”, and “wide signals”, and all three terms appear in Simulink dialog box labels and API names. This terminology can be confusing, because most vector signals are nonvirtual and hence are not muxes. To avoid confusion, reserve the term “mux” to refer specifically to a virtual vector.

A mux is a *virtual* vector signal. The constituent signals of a mux retain their separate existence in every way, except visually. You can also combine scalar and vector signals into a *nonvirtual* vector signal, by using a Vector Concatenate block. The signal output by a Vector Concatenate block is an ordinary contiguous vector, inheriting no special properties from the fact that it was created from separate signals.

To create a composite signal whose constituent signals retain their identities and can have different data types, use a Bus Creator or Out Bus Element block, rather than a Mux block. For details, see “Composite Signal Techniques” on page 65-3.

Using Muxes

The Signal Routing library provides two virtual blocks for implementing muxes:

Mux

Combine several input signals into a mux (virtual vector) signal

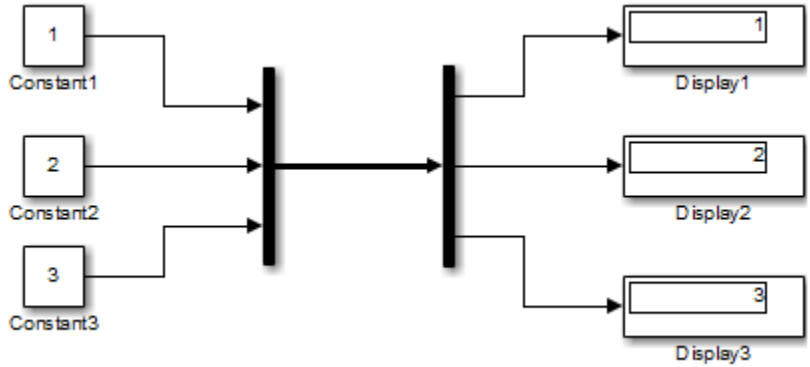
Demux

Extract and output the values in a mux (virtual vector) signal

To implement a mux signal:

1. Select a Mux and Demux block from the Signal Routing library.
2. Set the Mux block **Number of inputs** and the Demux block **Number of outputs** block parameters to the desired values.
3. Connect the Mux, Demux, and other blocks as needed to implement the desired signal.

The next figure shows three signals that are input to a Mux block, transmitted as a mux signal to a Demux block, and output as separate signals.



The Mux and Demux blocks are the left and right vertical bars, respectively. To reduce visual complexity, neither block displays a name. In this example, the line connecting the blocks, representing the mux signal, is wide because the model has been built with **Display > Signals & Ports > Wide Nonscalar Lines** option enabled. See "Display Signal Attributes" on page 64-65 for details.

Signals input to a Mux block can be any combination of scalars, vectors, and muxes. The signals in the output mux appear in the order in which they were input to the Mux block. You can use multiple Mux blocks to create a mux in several stages, but the result is flat, not hierarchical, just as if the constituent signals had been combined using a single mux block.

The values in all signals input to a Mux block must have the same data type.

If a Demux block attempts to output more values than exist in the input signal, an error occurs. A Demux block can output fewer values than exist in the input mux, and can group the values it outputs into different scalars and vectors than were input to the Mux block. However, the Demux block cannot rearrange the order of those values. For details, see Demux.

Note Do not use Mux and Demux blocks to create and access buses.

Signal Values

In this section...

Signal Data Types

Data type refers to the format used to represent signal values internally. By default, the data type of Simulink signals is double. You can create signals of other data types. Simulink signals support the same range of data types as MATLAB. See “About Data Types in Simulink” on page 59-3 for more information.

Signal Dimensions, Size, and Width

Simulink blocks can output one-dimensional, two-dimensional, or multidimensional signals. The Simulink user interface and documentation generally refer to 1-D signals as vectors and 2-D or multidimensional signals as matrices. A one-element array is frequently referred to as a scalar.

The size of a signal refers to the number of elements that a signal contains. The size of a matrix (2-D) signal is generally expressed as M-by-N, where M is the number of columns and N is the number of rows making up the signal. The size of a vector signal is referred to as the width of the signal.

For more information, see “Signal Dimensions” on page 64-31.

Complex Signals

The values of signals can be complex numbers or real numbers. A signal whose values are complex numbers is a complex signal. Create a complex-valued signal using one of the following approaches:

- Load complex-valued signal data from the MATLAB workspace into the model via a root-level Inport block.
- Create a Constant block in your model and set its value to a complex number.
- Create real signals corresponding to the real and imaginary parts of a complex signal, then combine the parts into a complex signal, using the Real-Imag to Complex conversion block.

Manipulate complex signals via blocks that accept them. If you are not sure whether a block accepts complex signals, see the documentation for the block.

Initializing Signal Values

If a signal does not have an explicit initial value, the initial value that Simulink uses depends on the data type of the signal.

Signal Data Type	Default Initial Value
Numeric (other than fixed-point)	Zero
Fixed-point	Real-world ground value
Boolean	False
Enumerated	Default value

You can specify the non-default initial values of signals for Simulink to use at the beginning of simulation.

- For any signal, you can define a signal object (`Simulink.Signal`), and use that signal object to specify an initial value for the signal.
- For some blocks, such as Outport, Data Store Memory, and Memory, you can use either a signal object or a block parameter, or both, to specify the initial value of a block state or output.

For details, see “Initialize Signals and Discrete States” on page 64-53.

Viewing Signal Values

You can use either blocks or the signal viewers (such as the Signal & Scope Manager) to display the values of signals during a simulation. For example, you can use either the Scope block or the Signal & Scope Manager to graph time-varying signals on an oscilloscope-like display during simulation. For general information about options for

viewing signal values, see “Scope Blocks and Scope Viewer Overview” on page 27-8. For detailed information about:

- Blocks that you can use to display signals in a model, see “Sinks”
- Signal viewers, see “Floating Scope and Scope Viewer Tasks” on page 27-77
- The Signal & Scope Manager, see “Signal and Scope Manager” on page 27-85
- Test points, which are signals that Simulink guarantees to be observable when using a Floating Scope block in a model, see “Test Points” on page 64-62.

Displaying Signal Values in Model Diagrams

To include graphical displays of signal values in a model diagram, use one of the following approaches:

- “Display Data Tips During Simulation” on page 64-18
- “Display Signal Value After Simulation” on page 64-18

Display Data Tips During Simulation

For many blocks, Simulink can display block output (port values) as data tips on the block diagram while a simulation is running.

1. In the Simulink Editor, select **Display > Data Display in Simulation**.
2. From the submenu, select either **Show Value Labels When Hovering** or **Show Value Labels When Clicked**.
3. To change display options, use the **Options** submenu.

For details, see “Display Port Values for Debugging” on page 35-17.

Display Signal Value After Simulation

To display, below a specific signal, the signal value after simulation:

1. Right-click the signal.
2. In the context menu, select **Show Value Label of Selected Port**.

Exporting Signal Data

You can save signal values to the MATLAB workspace during simulation, for later retrieval and postprocessing. For a summary of different approaches, see “Approaches for Exporting Signal Data” on page 61-4.

Signal Label Propagation

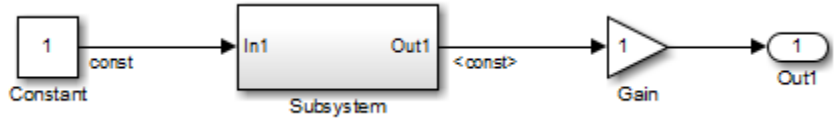
In this section...

Propagated Signal Labels

When you enable the display of signal label propagation for output signals of the blocks listed in “Blocks That Support Signal Label Propagation” on page 64-20:

- If there is a user-specified signal name that Simulink can propagate, the propagated signal label includes the name in angle brackets (for example, `<sig1>`).
- If there is no signal name to propagate, Simulink displays an empty set of angle brackets (<>) for the label.

For example, in the following model, the output signal from the Subsystem block is configured for signal label propagation. The propagated signal label (`<const>`) is based on the name of the upstream output signal of the Constant block (`const`).



For more information on how Simulink creates propagated signal labels, see “How Simulink Propagates Signal Labels” on page 64-22.

Blocks That Support Signal Label Propagation

You can use signal label propagation with output signals for several *connection* blocks, which route signals through the model without changing the data. Connection blocks perform no signal transformation.

Also, Model blocks support signal label propagation.

The connection blocks that support signal label propagation are:

- Enable
- From
- Function Call Split
- Goto
- Inport (subsystem only; not root inports)
- Signal Specification
- Subsystem (through subsystem Inport and Outport blocks)
- Trigger
- Two-Way Connection (a Simscape block)

The Bus Creator and Bus Selector blocks do *not* support signal label propagation. However, if you want to view the hierarchy for any bus signal, use the "Signal Hierarchy Viewer" on page 65-42.

The Signal Properties dialog box for a signal indicates whether that signal supports signal label propagation. The **Show propagated signals** parameter is available only for blocks that support signal label propagation. For details, see "Display Propagated Signal Labels" on page 64-21.

Display Propagated Signal Labels

To display a propagated signal label:

1. Right-click the signal for which you want to display a propagated signal label and select **Properties**.
2. In the Signal Properties dialog box, select **Show propagated signals**.

   The **Show propagated signals** parameter is available only for output signals from blocks that support signal label propagation.

To enable this signal property programmatically, create a handle to the signal line, and specify `signalPropagation` as `'on'`. For example, you can use this code to enable or disable the property for all of the signals in a model diagram.

```
% Create an array of handles to every signal line in the diagram
signalLines = find_system(gcs,'FindAll','on','type','line');

% Enable or disable the property for each signal line
for i = 1:length(signalLines)

      % set(signalLines(i),'signalPropagation','off');
      set(signalLines(i),'signalPropagation','on');
end
```

If a signal already has a label, then an *alternative* approach for displaying a propagated signal label is:

1. In the model diagram, click the signal label.
2. Remove the label text.
3. In the signal label text box, enter an angle bracket (<).
4. Click outside the signal label.

   Simulink displays the propagated signal label.

How Simulink Propagates Signal Labels

Understanding how Simulink propagates signal labels helps you to:

- Anticipate the scope of the signal label propagation, from source to final destination
- Configure your model to display signal labels for the signals that you want

For output signals from supported blocks, you can choose to have Simulink display propagated signal labels. For a list of supported blocks, see “Blocks That Support Signal Label Propagation” on page 64-20.

In general, Simulink performs signal label propagation consistently:

- For different modeling constructs (for example, non-bus and bus signals, virtual and nonvirtual buses, subsystem and model variants, model referencing, and libraries)
- In models with or without hidden blocks, which Simulink inserts in certain cases to enable simulation

- At model load, edit, update, and simulation times

For information about some special cases, see:

- "Processing for Referenced Models" on page 64-27
- "Processing for Variants and Configurable Subsystems" on page 64-29

General Signal Label Propagation Processing

In general, when you enable signal label propagation for an output signal of a block (for example, BlockA), Simulink performs the following processing to find the source signal name to propagate:

1. Checks the block whose output signal connects to BlockA, and if necessary, continues checking upstream blocks, working backward from the closest block to the farthest block.
2. Stops when it encounters a block that either:
   - Supports signal label propagation and has a signal name
   - Does not support signal label propagation
3. Obtains the signal name, if any, of the output signal for the block at which Simulink stops.
4. Uses that signal name for the propagated signal label of any output signals of downstream blocks for which you enable signal label propagation.

For example, in the following model, suppose that you enable signal label propagation for the output signal for the Subsystem block (that is, the signal connected to the `Out1` port).

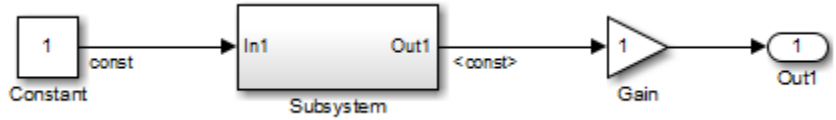
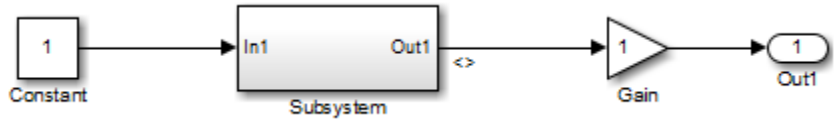
Simulink checks inside the subsystem, checks upstream from the From and GoTo blocks (which support signal label propagation and do not have a name), and then checks farther upstream, to the Constant block, which does not support signal label propagation.

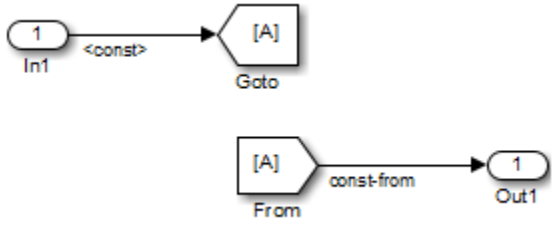
Simulink uses the signal name of the Constant block output signal, `const`. The propagated signal label for the Subsystem output signal is `<const>`.



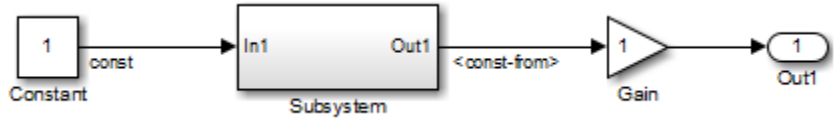
If the output signal from the Constant block did not have a signal name, then the propagated signal label would be an empty set of angle brackets (<>).



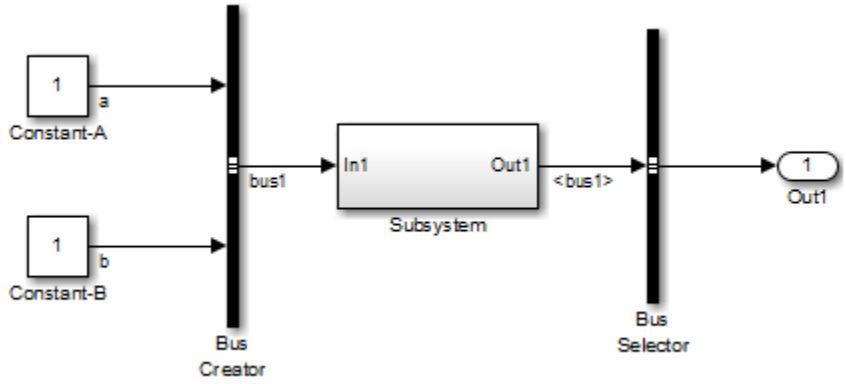
Suppose that in the Subsystem block you enable signal label propagation for the output signal from the In1 block, and you use the Signal Properties dialog box to specify the signal name `const-from` for the output signal of the From block, as shown below.



The propagated signal label for the Subsystem output signal changes to `<const-from>`, because that is the first named signal that Simulink encounters in its signal label propagation processing.



In the following model, the signal label propagation for the output signal of the Subsystem block uses the signal name `bus1`, which is the name of the output bus signal of the Bus Creator block. The propagated signal label does not include the names of the bus element signals (`a` and `b`).



Processing for Referenced Models

To enable signal label propagation for referenced models, in addition to the steps described in "Display Propagated Signal Labels" on page 64-21, use the default setting for the **Model Configuration Parameters > Model Referencing > Propagate all signal labels out of the model** parameter. In other words, make sure the parameter is enabled.

If you make a change inside a referenced model that affects signal label propagation, the propagated signal labels outside of the referenced model do not reflect those changes until after you update the diagram or simulate the model.

For example, the model `ex_signal_label_prop_model_ref` has a referenced model that includes an output signal from the In1 block that has a signal name of `input_1`.

If you enable signal label propagation for the signal from the Out1 port of the Model block, that signal does *not* reflect the name `input_1` until after you update the diagram or simulate the model.

Processing for Variants and Configurable Subsystems

Simulink updates the propagated signal label (if enabled) for the output signal of the Subsystem or Model block, when *both* of these conditions occur:

- The output signals for model reference variants have different signal names.
- You change the active variant model or variant subsystem.

For Subsystem blocks, the signal label updates at edit time. For Model blocks, the update occurs when you update diagram or simulate the model.

Signal Dimensions

In this section...

About Signal Dimensions

Simulink blocks can output one-dimensional, two-dimensional, or multidimensional signals. The Simulink user interface and documentation generally refer to 1-D signals as *vectors* and 2-D or multidimensional signals as *matrices*. A one-element array is frequently referred to as a *scalar*. A *row vector* is a 2-D array that has one row. A *column vector* is a 2-D array that has one column.

- A one-dimensional (1-D) signal consists of a series of one-dimensional arrays output at a frequency of one array (vector) per simulation time step.
- A two-dimensional (2-D) signal consists of a series of two-dimensional arrays output at a frequency of one 2-D array (matrix) per block sample time.
- A multidimensional signal consists of a series of multidimensional (two or more dimensions) arrays output at a frequency of one array per block sample time. You can specify multidimensional arrays with any valid MATLAB multidimensional expression, such as [4 3]. See "Multidimensional Arrays" (MATLAB) for information on multidimensional arrays.

Simulink blocks vary in the dimensionality of the signals they can accept or output. Some blocks can accept or output signals of any dimension. Some can accept or output only scalar or vector signals. To determine the signal dimensionality of a particular block, see the block documentation. See "Determine Output Signal Dimensions" on page 64-33 for information on what determines the dimensions of output signals for blocks that can output nonscalar signals.

Note Simulink does not support dynamic signal dimensions during a simulation. That is, the dimension of a signal must remain constant while a simulation is executing. However, you can change the size of a signal during a simulation. See "Variable-Size Signal Basics" on page 66-2.

Simulink Blocks that Support Multidimensional Signals

The Simulink Block Data Type Support table includes a column identifying the blocks with multi-dimension signal support.

1. In the Simulink editor, from the **Help** menu, click **Simulink > Block Data Types & Code Generation Support > All Tables**.

   A separate window with the Simulink Block Data Type Support table opens.
2. In the Block column, locate the name of a Simulink block. Columns to the right are data types or features. An a **X** in a column indicates support for that feature.

Simulink supports signals with up to 32 dimensions. Do not use signals with more than 32 dimensions.

Determine Output Signal Dimensions

In this section...

About Signal Dimensions

If a block can emit nonscalar signals, the dimensions of the signals that the block outputs depend on the block parameters, if the block is a source block; otherwise, the output dimensions depend on the dimensions of the block input and parameters.

To determine the dimensions that a signal ultimately uses for simulation, first update the block diagram (for example, by pressing **Ctrl+D**). Then, choose one of these techniques:

- Display the dimensions directly on the block diagram. Use this technique to trace signal dimensions along a path of blocks. In the model, select **Display > Signals and Ports > Signal Dimensions**).
- Inspect the dimensions in the Model Data Editor, which shows you information in a searchable, sortable table. In the table, the right side of each cell in the **Dimensions** column shows the true dimensions of the corresponding signal line in the model. For more information about the Model Data Editor, see "Configure Data Properties by Using the Model Data Editor" on page 59-141.

Determining the Output Dimensions of Source Blocks

A *source* block is a block that has no inputs. Examples of source blocks include the Constant block and the Sine Wave block. See "Sources" for a complete listing of Simulink source blocks. The output dimensions of a source block are the same as those of its output value parameters if the block's **Interpret vector parameters as 1-D** parameter is off (that is, not selected in the block parameter dialog box). If the **Interpret vector parameters as 1-D** parameter is on, the output dimensions equal the output value

parameter dimensions unless the parameter dimensions are N-by-1 or 1-by-N. In the latter case, the block outputs a vector signal of width N.

As an example of how a source block's output value parameter(s) and **Interpret vector parameters as 1-D** parameter determine the dimensionality of its output, consider the Constant block. This block outputs a constant signal equal to its **Constant value** parameter. The following table illustrates how the dimensionality of the **Constant value** parameter and the setting of the **Interpret vector parameters as 1-D** parameter determine the dimensionality of the block's output.

Constant Value	Interpret vector parameters as 1-D	Output
scalar	off	one-element array
scalar	on	one-element array
1-by-N matrix	off	1-by-N matrix
1-by-N matrix	on	N-element vector
N-by-1 matrix	off	N-by-1 matrix
N-by-1 matrix	on	N-element vector
M-by-N matrix	off	M-by-N matrix
M-by-N matrix	on	M-by-N matrix

Simulink source blocks allow you either to specify the dimensions of the signals that they output or specify values from which Simulink infers the dimensions. You can therefore use the source blocks to introduce signals of various dimensions into your model.

Determining the Output Dimensions of Nonsource Blocks

If a block has inputs, the dimensions of its outputs are, after scalar expansion, the same as those of its inputs. (All inputs must have the same dimensions, as discussed in “Signal and Parameter Dimension Rules” on page 64-34).

Signal and Parameter Dimension Rules

When creating a Simulink model, you must observe the following rules regarding signal and parameter dimensions.

Input Signal Dimension Rule

All nonscalar inputs to a block must have the same dimensions.

A block can have a mix of scalar and nonscalar inputs as long as all the nonscalar inputs have the same dimensions. Simulink expands the scalar inputs to have the same dimensions as the nonscalar inputs (see "Scalar Expansion of Inputs and Parameters" on page 64-36).

Block Parameter Dimension Rule

In general, block parameters must have the same dimensions as the dimensions of the inputs to the block. Simulink performs some processing that provides flexibility relating to that general rule.

- A block can have scalar parameters corresponding to nonscalar inputs. In this case, Simulink expands a scalar parameter to have the same dimensions as the corresponding input (see "Scalar Expansion of Inputs and Parameters" on page 64-36).
- If an input is a vector, the corresponding parameter can be either an N-by-1 or a 1-by-N matrix. In this case, Simulink applies the N matrix elements to the corresponding elements of the input vector. This exception allows use of MATLAB row or column vectors, which are actually 1-by-N or N-by-1 matrices, respectively, to specify parameters that apply to vector inputs.

Vector or Matrix Input Conversion Rules

Simulink converts vectors to row or column matrices and row or column matrices to vectors under the following circumstances:

- If a vector signal is connected to an input that requires a matrix, Simulink converts the vector to a one-row or one-column matrix.
- If a one-column or one-row matrix is connected to an input that requires a vector, Simulink converts the matrix to a vector.
- If the inputs to a block consist of a mixture of vectors and matrices and the matrix inputs all have one column or one row, Simulink converts the vectors to matrices having one column or one row, respectively.

Note You can configure Simulink to display a warning or error message if a vector or matrix conversion occurs during a simulation. See "Vector/matrix block input conversion" for more information.

Scalar Expansion of Inputs and Parameters

Scalar expansion is the conversion of a scalar value into a nonscalar array. Many Simulink blocks support scalar expansion of inputs and parameters. Block-specific descriptions indicate whether Simulink applies scalar expansion to a block's inputs and parameters.

Scalar expansion of inputs refers to the expansion of scalar inputs to match the dimensions of other nonscalar inputs or nonscalar parameters. When the input to a block is a mix of scalar and nonscalar signals, Simulink expands the scalar inputs into nonscalar signals having the same dimensions as the other nonscalar inputs. For example, a scalar of 4 is expanded to the vector [4 4 4] if the associated nonscalar has a dimension of 3.

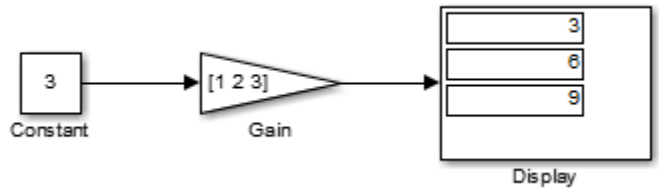
Scalar expansion of parameters refers to the expansion of scalar block parameters to match the dimensions of nonscalar inputs.

Input(s)	Associated Block Parameter	Scalar Expansion
Scalar	Nonscalar	Input expanded to match parameter dimensions. See "Scalar Input and Nonscalar Parameter" on page 64-37.
Nonscalar	Scalar	Scalar parameter expanded to match number of elements of input. See "Nonscalar Input and Scalar Parameter" on page 64-37.

Input(s)	Associated Block Parameter	Scalar Expansion
Combination of scalar and nonscalar	No corresponding parameter	Scalar inputs expanded to match dimensions of largest nonscalar input. See "Scalar and Nonscalar Inputs and No Associated Parameter" on page 64-38.

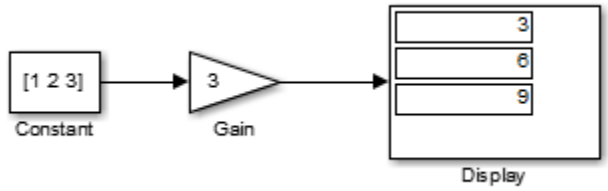
Scalar Input and Nonscalar Parameter

In this example, the Constant block input to the Gain block is scalar. The Gain block **Gain** parameter is a nonscalar. Simulink expands the scalar input to match the dimensions of a nonscalar **Gain** parameter, as reflected in the simulation results in the Display block.



Nonscalar Input and Scalar Parameter

In this example, the Constant block input to the Gain block is nonscalar. The Gain block **Gain** parameter is a scalar. Simulink expands the scalar parameter to match the dimensions of a nonscalar input from the Constant block, as reflected in the simulation results in the Display block.



Scalar and Nonscalar Inputs and No Associated Parameter

In this example, the Constant1 block input to the Sum block is nonscalar, and the Constant2 block input is scalar. The Sum block has no associated parameter. Simulink expands the scalar input from Constant2 to match to the dimensions of the nonscalar Constant1 block input. The input is expanded to the vector `[3 3 3]`.

Highlight Signal Sources and Destinations

In this section...

You can highlight a signal and its source or destination blocks, then remove the highlighting once it has served its purpose. Signal highlighting crosses subsystem and model reference boundaries, allowing you to trace a signal across multiple subsystem levels. If a signal is composite, all source or destination blocks are highlighted. See “Composite Signal Techniques” on page 65-3.

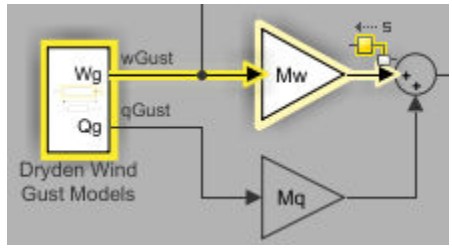
To continue the trace towards the source or destination of the signal, use the left and right arrow keys of your keyboard, respectively.

Highlight Signal Source

To begin a trace to the source blocks of a signal, select the **Highlight Signal to Source** option from the context menu for the signal. The

badge identifies the start of the trace. This option highlights:

- All branches of the signal anywhere in the model
- All virtual blocks through which the signal passes
- The nonvirtual blocks that write the value of the signal



To continue tracing towards the source of the signal, press the **Left** arrow key.

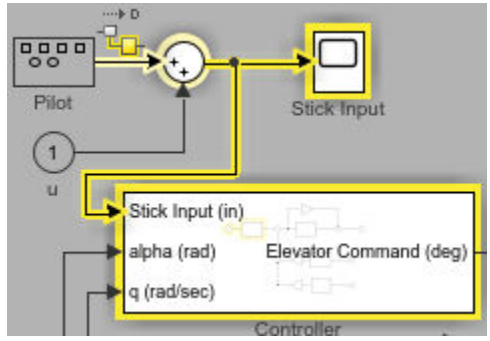
Highlight Signal Destination

To begin a trace to the destination blocks of a signal, select the **Highlight Signal to Destination** option from the context menu for the signal. Press the **Right** arrow key to move the trace towards the final destination. The

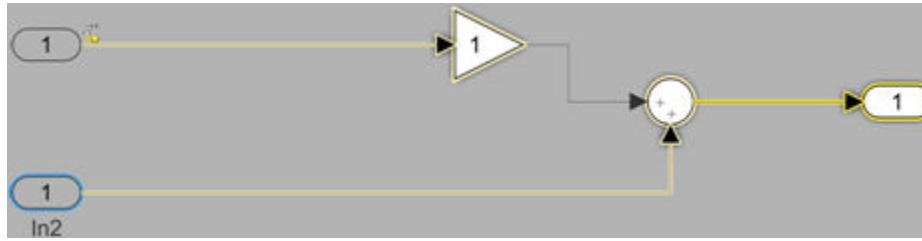
badge identifies the start of the trace. This option highlights:

- All branches of the signal anywhere in the model
- All virtual blocks through which the signal passes
- The nonvirtual blocks that read the value of the signal
- The signal and destination block for all blocks that are duplicates of the inport block for the line that you select

In this example, the selected trace shows a path of the signal from the Stick Input to the Elevator Command in the Controller subsystem of the `f14` model.

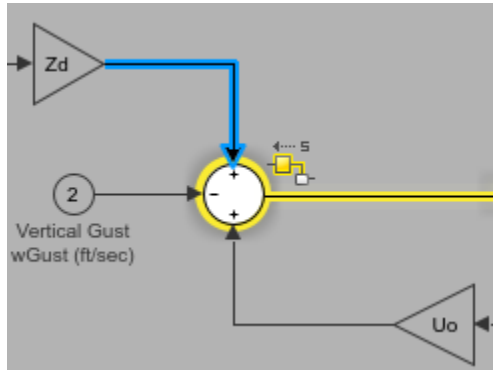


In the next example, selecting the signal from In2 and choosing the **Highlight Signal to Destination** option highlights the signal and destination block for In2 and In1, because In1 and In2 are duplicate inport blocks.



Choose the Path of a Trace

In some situations, a signal trace can take multiple viable paths in the next segment of the trace. This can be seen when a signal is combined or split through a Mux or Demux block, or if it is branched out as an input to another block. In such cases, the options are highlighted in blue and can be cycled using the **Up** and **Down** arrow keys on the keyboard. Once you have highlighted the block to which you would like to move, proceed as normal.

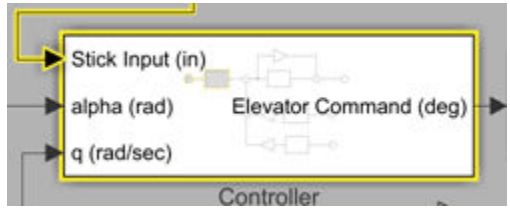


In the figure above, the trace to source has reached the Sum block where it can take one of three possible paths. The first option to Gain *Zd* is highlighted in blue.

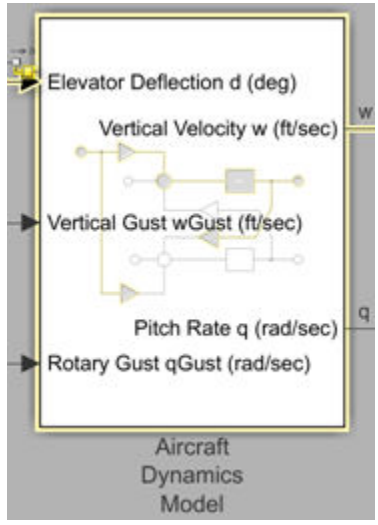
Subsystems

When the trace reaches a subsystem, it does not automatically trace in. Instead, the trace highlights the target subsystem and you are able to see a preview of the trace within the subsystem.

In this example, the selected signal trace to destination has reached the Controller subsystem of the `f14` model. You can see that the contents of the subsystem are visible and the next segment of the trace is highlighted within the preview.



When the trace comes out of a subsystem, the subsystem preview also displays the path of the trace inside it. The next example shows the path of a trace through the Aircraft Dynamics Model subsystem from the input `wGust` to vertical velocity `w` output.



Note You cannot jump over a subsytem or a referenced model in your trace. You need to trace the signal path through them.

Display Port Values Along a Trace

Once you have traced the path of a signal, press the **P** key to display the value(s) of a signal at the output port of each block.

Remove Highlighting

To remove all highlighting, select **Remove Highlighting** from the context menu of the model, or select **Display > Remove Highlighting**. You can also press **Ctrl+Shift+H** or click the  icon at the top right corner of the editor.

To back up a trace, press the arrow key opposite to the original intent of the trace. For example, if you would like to back up a trace to the destination of the signal, press the left arrow key. To back up a trace to the source of a signal, press the **right arrow** key.

Resolve Incomplete Highlighting to Library Blocks

If the path from a source block or to a destination block includes an unresolved reference to a library block, the highlighting options highlight the path from or to the library block, respectively. To display the complete path, press **Ctrl+D** to update the diagram. The diagram update resolves all library references and displays the complete path to a destination block or from a source block.

Limitations

The signal tracing tool has the following limitations in its usage:

- The signal trace does not preserve bus information when tracing into or out of a referenced model.
- Tracing past a Goto block changes the active level to that containing the matching From block. However, this does not guarantee that the matching From block is the active block if there are other valid blocks at the same level.
- Signal tracing is unsupported by certain blocks. Unsupported blocks are blocks where:
  - You cannot trace into them to highlight their contents. Examples of such blocks are Stateflow charts, Simscape subsystems, function blocks, and so on.
  - You cannot cross them and continue tracing (e.g. Simscape blocks).

- The styling of the signal does not update with modifications to the model when signal tracing is enabled.

Signal Ranges

In this section...

About Signal Ranges

Many Simulink blocks allow you to specify a range of valid values for their output signals. Simulink provides a diagnostic that you can enable to detect when blocks generate signals that exceed their specified ranges during simulation. See the sections that follow for more information.

Blocks That Allow Signal Range Specification

The following blocks allow you to specify ranges for their output signals:

- Abs
- Constant
- Data Store Memory
- Data Type Conversion
- Difference
- Discrete Derivative
- Discrete-Time Integrator
- Gain
- Inport
- Interpolation Using Prelookup
- 1-D Lookup Table

- 2-D Lookup Table
- n-D Lookup Table
- Math Function
- MinMax
- Multiport Switch
- Outport
- Product, Divide, Product of Elements
- Relay
- Repeating Sequence Interpolated
- Repeating Sequence Stair
- Saturation
- Saturation Dynamic
- Signal Specification
- Sum, Add, Subtract, Sum of Elements
- Switch

Specify Ranges for Signals

In general, use the **Output minimum** and **Output maximum** parameters of a block to specify a range of valid values for the block output signal. Exceptions include the Data Store Memory, Inport, Outport, and Signal Specification blocks, for which you use their **Minimum** and **Maximum** parameters to specify a signal range. See "Blocks That Allow Signal Range Specification" on page 64-45 for a list of applicable blocks.

To access these parameters, use the Property Inspector (**View > Property Inspector**), the Model Data Editor (**View > Model Data**), or the block dialog box. To use each technique efficiently, see "Setting Properties and Parameters" on page 1-50.

Specify a minimum or maximum as an expression that evaluates to a scalar, real number with `double` data type. For example, you can use:

- A literal number such as `98.884`. Implicitly, the data type is `double`.
- A numeric workspace variable (see "Share and Reuse Block Parameter Values by Creating Variables" on page 36-12) whose data type is `double`. Use this technique to share a minimum or maximum value between multiple data items.

However, you cannot use variables to set the `Min` or `Max` properties of a `Simulink.Signal` object.

The scalar value that you specify applies to each element of a composite signal (for example, when the signal is nonscalar or a bus). For information about scalar expansion, see "Scalar Expansion of Inputs and Parameters" on page 64-36.

To leave the minimum or maximum of a signal unspecified, use an empty matrix `[]`, which is the default value.

Specify Ranges for Modeling Constructs

If you use modeling constructs such as bus signals, data stores, and Stateflow charts, you can use different techniques to specify design range information. Use the information in the table.

Description of Target Signal	Technique and More Information
Numerically complex signal	When you specify an **Output minimum** or **Output maximum** for a signal that is numerically complex, the specified minimum and maximum values apply separately to the real part and to the imaginary part of the complex number. If the value of either part of the number is less than the minimum, or greater than the maximum, the complex number is outside the specified range. No range checking occurs against any combination of the real and imaginary parts, such as `(sqrt(a^2+b^2))`.
Signal elements in a bus	If you assemble the bus by using a Bus Creator block, you can specify range information on the upstream blocks that feed the Bus Creator. Regardless of the technique you use to assemble the bus, you can create a `Simulink.Bus` object and use it as the data type of the bus signal. In this case, consider specifying range information by using the `Min` and `Max` properties of the `Simulink.BusElement` objects that reside in the bus object. For more information, see "When to Use Bus Objects" on page 65-64.
Signal in a MATLAB Function block	Use the Ports and Data Manager to specify the **Minimum** and **Maximum** properties of the data. See "Setting General Properties" on page 41-49.

Description of Target Signal	Technique and More Information
Signal in a Stateflow chart	Set the **Minimum** and **Maximum** properties of the corresponding Stateflow data. See "Limit range properties" (Stateflow).
Signal that you associate with a signal object (such as `Simulink.Signal`)	Set the `Min` and `Max` properties of the signal object. See `Simulink.Signal`.
Data store (Data Store Memory block or `Simulink.Signal` object)	For a Data Store Memory block, set the **Minimum** and **Maximum** block parameters. For a signal object, set the `Min` and `Max` properties.

Check for Signal Range Errors

Simulink provides a diagnostic named **Simulation range checking**, which you can enable to detect when signals exceed their specified ranges during simulation. When enabled, Simulink compares the signal values that a block outputs with both the specified range (see "Specify Ranges for Signals" on page 64-46) and the block data type. That is, Simulink performs the following check:

```
DataTypeMin ≤ MinValue ≤ VALUE ≤ MaxValue ≤ DataTypeMax
```

where

- `DataTypeMin` is the minimum value representable by the block data type.
- `MinValue` is the minimum value the block should output, specified by, e.g., **Output minimum**.
- `VALUE` is the signal value that the block outputs.
- `MaxValue` is the maximum value the block should output, specified by, e.g., **Output maximum**.
- `DataTypeMax` is the maximum value representable by the block data type.

Note It is possible to overspecify how a block handles signals that exceed particular ranges. For example, you can specify values (other than the default values) for both signal range parameters and enable the **Saturate on integer overflow** parameter. In

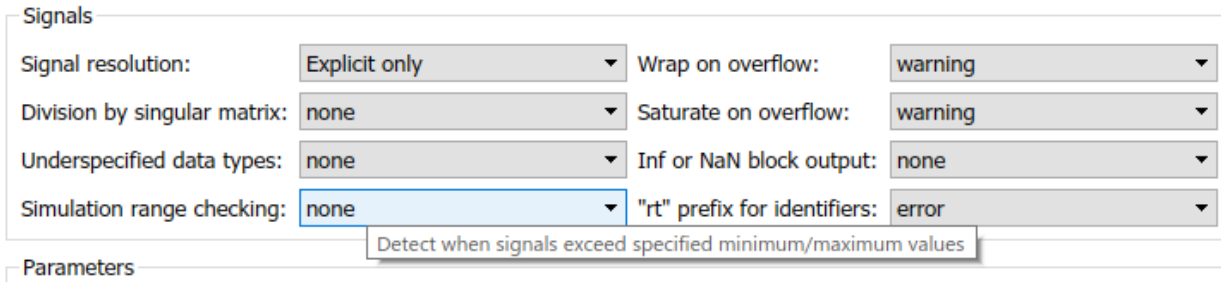
this case, Simulink displays a warning message that advises you to disable the **Saturate on integer overflow** parameter.

Enable Simulation Range Checking

To enable the **Simulation range checking** diagnostic:

1. In your model window, select **Simulation** > **Model Configuration Parameters**.

   Simulink displays the Configuration Parameters dialog box.
2. In the **Select** tree on the left side of the Configuration Parameters dialog box, click the **Diagnostics** > **Data Validity** category. On the right side under **Signals**, set the **Simulation range checking** diagnostic to `error` or `warning`.



3. Click **OK** to apply your changes and close the Configuration Parameters dialog box.

See “Simulation range checking” for more information.

Simulate Models with Simulation Range Checking

To check for signal range errors or warnings:

1. Enable the **Simulation range checking** diagnostic for your model (see “Enable Simulation Range Checking” on page 64-49).
2. In your model window, select **Simulation** > **Run** to simulate the model.

   Simulink simulates your model and performs signal range checking. If a signal exceeds its specified range when the **Simulation range checking** diagnostic specifies `error`, Simulink stops the simulation and generates an error (for example, in the Diagnostic Viewer).

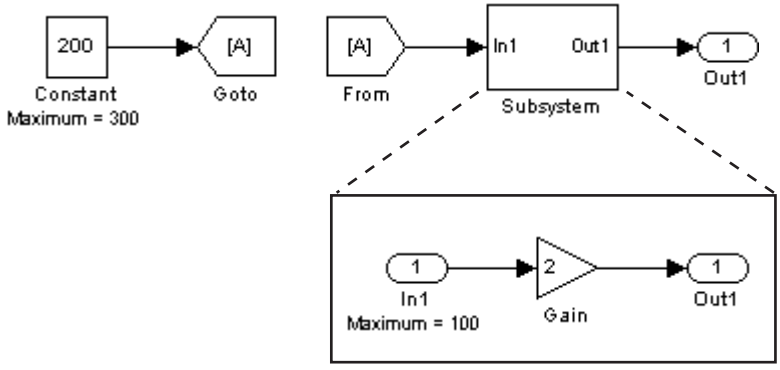
   Otherwise, if a signal exceeds its specified range when the **Simulation range checking** diagnostic specifies `warning`, Simulink generates a warning message in

the MATLAB Command Window. Each message identifies the block whose output signal exceeds its specified range, and the time step at which this violation occurs.

Signal Range Propagation for Virtual Blocks

Some virtual blocks (see "Nonvirtual and Virtual Blocks" on page 35-2) allow you to specify ranges for their output signals, for example, the Inport and Outport blocks. When the **Simulation range checking** diagnostic is enabled for a model that contains such blocks, the signal range of the virtual block propagates backward to the first instance of a nonvirtual block whose output signal it receives. If the nonvirtual block specifies different values for its own range, Simulink performs signal range checking with the tightest range possible. That is, Simulink checks the signal using the larger minimum value and the smaller maximum value.

For example, consider the following model:



In this model, the Constant block specifies its **Output maximum** parameter as 300, and that of the Inport block is set to 100. Suppose you enable the **Simulation range checking** diagnostic and simulate the model. The Inport block back propagates its maximum value to the nonvirtual block that precedes it, i.e., the Constant block. Simulink then uses the smaller of the two maximum values to check the signal that the Constant block outputs. Because the Constant block outputs a signal whose value (200) exceeds the tightest range, Simulink generates an error.

Unexpected Errors or Warnings for Data with Greater Precision or Range than double

When a data item (signal or parameter) uses a data type other than `double`, before comparison, Simulink casts the data item and each design limit (minimum or maximum

value that you specify) to the nondouble data type. This technique helps prevent the generation of unnecessary, misleading errors and warnings.

However, Simulink stores design limits as `double` before comparison. If the data type of the data item has higher precision than `double` (for example, a fixed-point data type with a 128-bit word length and a 126-bit fraction length) or greater range than `double`, and `double` cannot exactly represent the value of a design limit, Simulink can generate unexpected warnings and errors.

If the nondouble type has higher precision, consider rounding the design limit to the next number furthest from zero that `double` can represent. For example, suppose that a signal generates an error after you set the maximum value to `98.8847692348509014`. At the command prompt, calculate the next number furthest from zero that `double` can represent.

```
format long
98.8847692348509014 + eps(98.8847692348509014)

ans =

  98.884769234850921
```

Use the resulting number, `98.884769234850921`, to replace the maximum value.

Optimize Generated Code

If you have Embedded Coder, Simulink Coder can optimize the code that you generate from the model by taking into account the minimum and maximum values that you specify for signals and parameters. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Initialize Signals and Discrete States

In this section...

About Initialization

Note For information about initializing bus signals, see "Specify Initial Conditions for Bus Signals" on page 65-108.

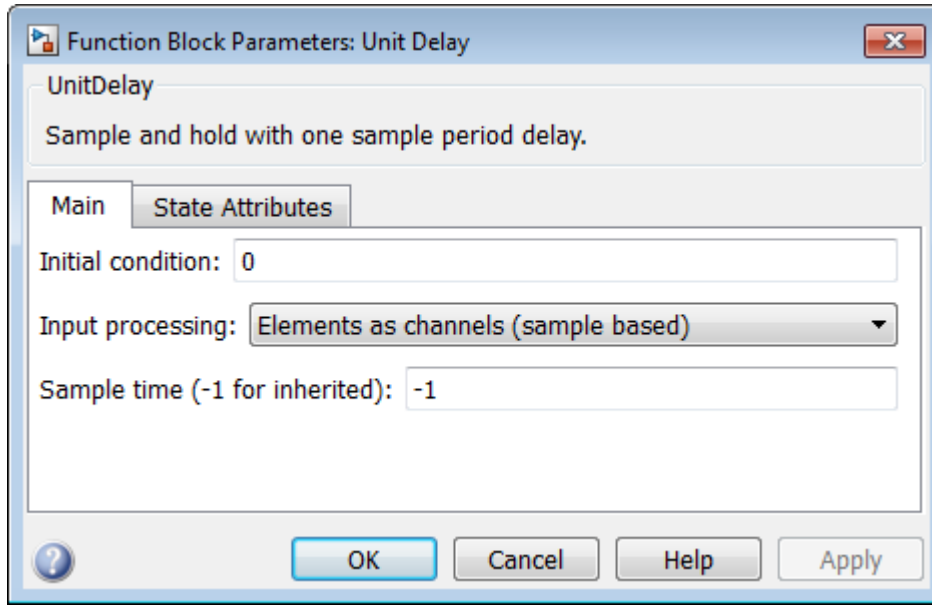
Simulink allows you to specify the initial values of signals and discrete states, i.e., the values of the signals and discrete states at the **Start time** of the simulation. You can use signal objects to specify the initial values of any signal or discrete state in a model. In addition, for some blocks, e.g., Outport, Data Store Memory, or Memory, you can use either a signal object or a block parameter or both to specify the initial value of a block state or output. In such cases, Simulink checks to ensure that the values specified by the signal object and the parameter are consistent.

When you specify a signal object for signal or discrete state initialization, or a variable as the value of a block parameter, Simulink resolves the name that you specify to an appropriate object or variable, as described in "Symbol Resolution" on page 59-136.

A given signal can be associated with at most one signal object under any circumstances. The signal can refer to the object more than once, but every reference must resolve to exactly the same object. A different signal object that has exactly the same properties will not meet the requirement for uniqueness. A compile-time error occurs if a model associates more than one signal object with any signal. For more information, see `Simulink.Signal` and the Merge block.

Using Block Parameters to Initialize Signals and Discrete States

For blocks that have an initial value or initial condition parameter, you can use that parameter to initialize a signal. For example, the following Block Parameters dialog box initializes the signal for a Unit Delay block with an initial condition of 0.



To access these block parameters, choose one of these techniques:

- Use the Model Data Editor (**View** > **Model Data**). Use this technique to configure multiple signals and states with a searchable, sortable table. To initialize a block state or data store, you can use the appropriate tab (**States** or **Data Stores**). To initialize a signal, state, or data store, you can use the **Parameters** tab and find the row that corresponds to the relevant block parameter.

  For more information about the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 59-141.
- Use the Property Inspector (**View** > **Model Data**). Use this technique to configure one signal or state at a time. Select the block that maintains the target state or generates the target signal and find the relevant block parameter.
- Use the block parameter dialog box. Use this technique to configure one signal or state at a time or to compare the configurations of a few signals or states side by side.

For more information about techniques to access block parameters (including the parameters that control signal and state initialization), see “Setting Properties and Parameters” on page 1-50.

Use Signal Objects to Initialize Signals and Discrete States

You can use signal objects that have a storage class other than `'auto'` or `'SimulinkGlobal'` to initialize:

- Discrete states with an initial condition parameter
- Signals in a model except bus signals and blocks that output constant value

To specify an initial value, use the Model Explorer or MATLAB commands to do the following:

1. Create the signal object.

   On the Model Explorer toolbar, select **Add** > **Simulink Signal**. The signal object appears in the base workspace with a default name. Rename the object as `S1`. Alternatively, use this command at the command prompt:

   ```
   S1 = Simulink.Signal;
   ```

   The name of the signal object must be the same as the name of the signal that the object is initializing. Although not required, consider setting the **Signal name must resolve to Simulink signal object** option in the Signal Properties dialog box. This setting makes signal objects in the MATLAB workspace consistent with signals that appear in your model.

   Consider using the Data Object Wizard to create signal objects. The Data Object Wizard searches a model for signals for which signal objects do not exist. You can then selectively create signal objects for multiple signals listed in the search results with a single operation. For more information about the Data Object Wizard, see “Create Data Objects for a Model Using Data Object Wizard” on page 59-62.

2. Set the signal object's storage class to a value other than `auto` or `SimulinkGlobal`. In the Model Explorer **Contents** pane, select the signal object. In the Dialog pane, set **Storage class** to `ExportedGlobal`. Alternatively, use this command at the command prompt:

   ```
   S1.CoderInfo.StorageClass = 'ExportedGlobal';
   ```

3 Set the initial value. You can specify a MATLAB expression, including the name of a workspace variable, that evaluates to a numeric scalar value or array.

   The Simulink engine converts the initial value so the type, complexity, and dimension are consistent with the corresponding block parameter value. If you specify an invalid value or expression, an error message appears when you update the model.

   In the Model Explorer Dialog pane, set **Initial value** to `0.5`. Alternatively, use this command at the command prompt:

   ```
   S1.InitialValue = '0.5'
   ```

   If you can also use a block parameter to set the initial value of the signal or state, you should set the parameter either to empty (`[]`) or to the same value as the initial value of the signal object. If you set the parameter value to empty, Simulink uses the value specified by the signal object to initialize the signal or state. If you set the parameter to any other value, Simulink compares the parameter value to the signal object value and displays an error if they differ.

Some initial value settings may depend on the initialization mode. For more information, see “Underspecified initialization detection”.

Classic initialization mode: In this mode, initial value settings for signal objects that represent the following signals and states override the corresponding block parameter initial values if undefined (specified as `[]`):

- Output signals of conditionally executed subsystems and Merge blocks
- Block states

Simplified initialization mode: In this mode, initial values of signal objects associated with the output of the following blocks are ignored. The initial values of the corresponding blocks are used instead.

- Output signals of conditionally executed subsystems
- Merge blocks

Using Signal Objects to Tune Initial Values

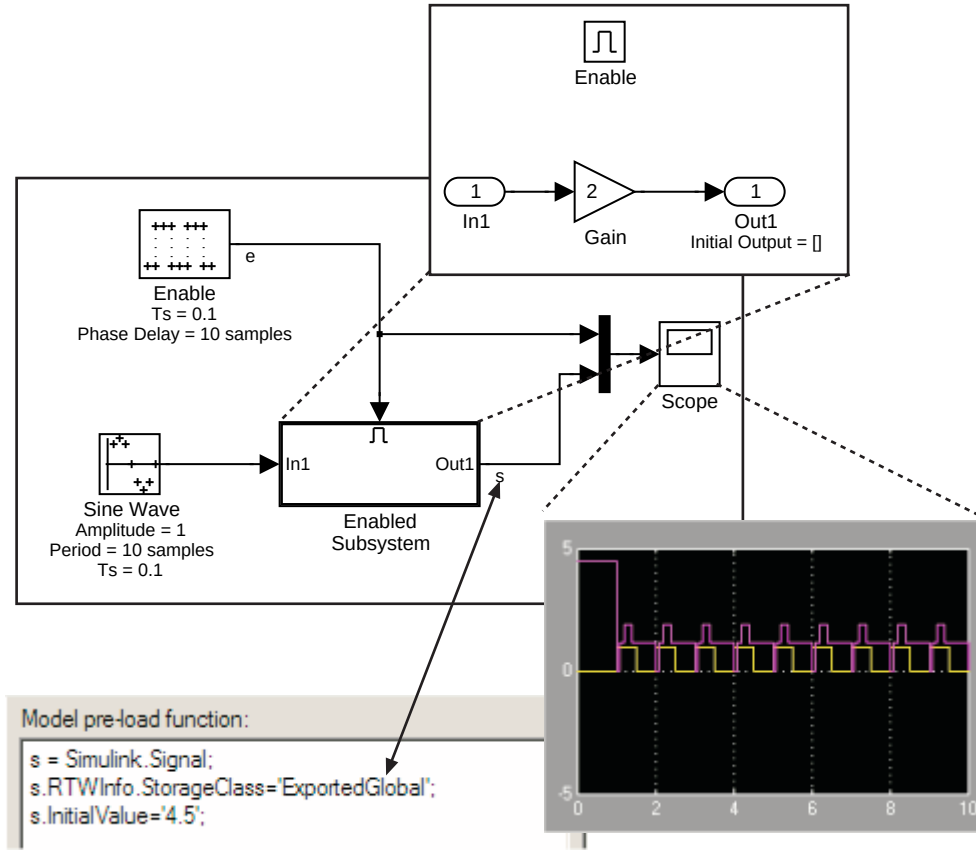
Simulink allows you to use signal objects as an alternative to parameter objects (see `Simulink.Parameter`) to tune the initial values of block outputs and states that can be

specified via a tunable parameter. To use a signal object to tune an initial value, create a signal object with the same name as the signal or state and set the signal object's initial value to an expression that includes a variable defined in the MATLAB workspace. You can then tune the initial value by changing the value of the corresponding workspace variable during the simulation.

For example, suppose you want to tune the initial value of a Memory block state named `M1`. To do this, you might create a signal object named `M1`, set its storage class to `'ExportedGlobal'`, set its initial value to `K` (`M1.InitialValue='K'`), where `K` is a workspace variable in the MATLAB workspace, and set the corresponding initial condition parameter of the Memory block to `[]` to avoid consistency errors. You could then change the initial value of the Memory block's state any time during the simulation by changing the value of `K` at the MATLAB command line and updating the block diagram (e.g., by typing **Ctrl+D**).

Example: Using a Signal Object to Initialize a Subsystem Output

The following example shows a signal object specifying the initial output of an enabled subsystem.

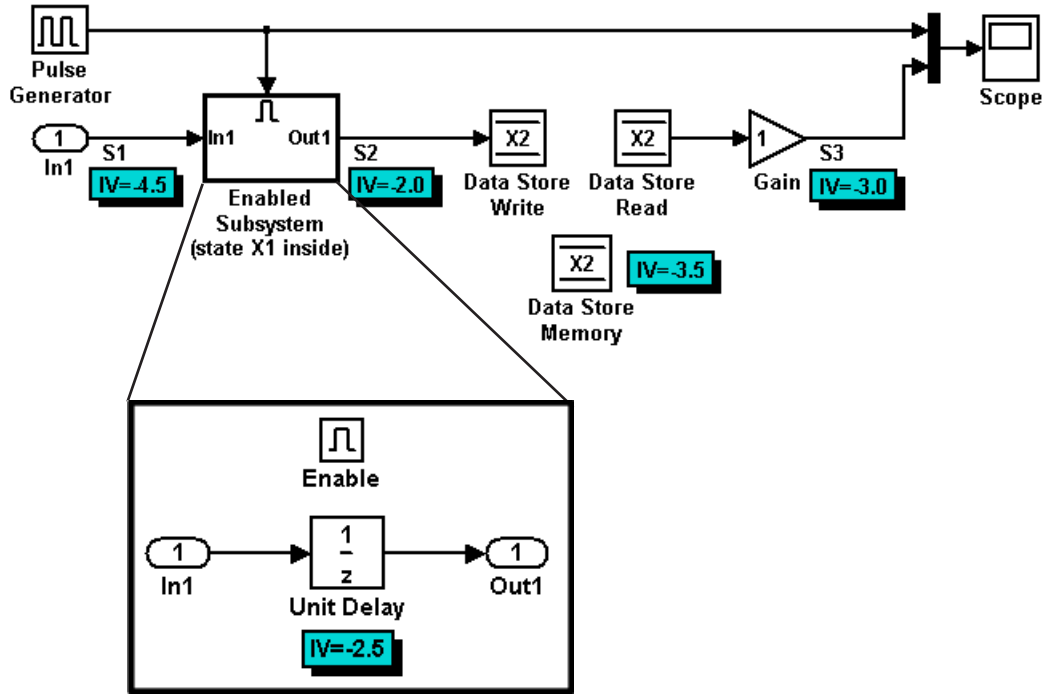


Signal `s` is initialized to 4.5. To avoid a consistency error, the initial value of the enabled subsystem's Outport block must be `[]` or 4.5.

If you need a signal object and its initial value setting to persist across Simulink sessions, see “Create Persistent Data Objects” on page 59-71.

Initialization Behavior Summary for Signal Objects

The following model and table show different types of signals and discrete states that you can initialize and the simulation behavior that results for each.



Signal or Discrete State	Description	Behavior
S1	Root inport	• Initialized to `S1.InitialValue`. • If you use the **Data Import/Export** pane of the Configuration Parameters dialog to specify values for the root inputs, the initial value is overwritten and may differ at each time step. Otherwise, the value remains constant.

Signal or Discrete State	Description	Behavior
X1	Unit Delay block — Block with a discrete state that has an initial condition	• Initialized to `X1.InitialValue`. • Simulink checks whether `X1.InitialValue` matches the initial condition specified for the block and displays an error if a mismatch occurs. • At first write, the output equals `X1.InitialValue` and the state equals `S1`. • At each time step after the first write, the output equals the state and the state is updated to equal `S1`. • If the block is inside an enabled subsystem, you can use the initial value as a reset value if the subsystem's Enable block parameter **States when enabling** is set to `reset`.
X2	Data Store Memory block	• Data type work (DWork) vector initialized to `X2.InitialValue`. For information on work vectors, see "DWork Vector Basics". • Simulink checks whether `X2.InitialValue` matches the initial condition specified for the block, and displays an error if a mismatch occurs. • Data Store Write blocks overwrite the value.
S2	Output of an enabled subsystem	• Initialized to `S2.InitialValue` or the value of the Outport block. If multiple initial values are specified for the same signal, all initial values must be the same. • The first write occurs when the subsystem is enabled. The block feeding the subsystem output sets the value. • The initial value is also used as a reset value if the subsystem's Enable block parameter **States when enabling** or Outport block parameter **Output when disabled** is set to `reset`.
S3	Persistent signals	• Initialized to `S3.InitialValue`. • The output value is reset by the block at each time step. • Affects code generation only. For simulation, setting the initial value for `S3` is irrelevant because the values are overwritten at the model's simulation start time.

Test Points

In this section...

What Is a Test Point?

A *test point* is a signal that Simulink guarantees to be observable when using a Floating Scope block in a model. Simulink allows you to designate any signal in a model as a test point.

Designating a signal as a test point exempts the signal from model optimizations, such as signal storage reuse (see “Signal storage reuse”) and block reduction (see “Implement logic signals as Boolean data (vs. double)”). These optimizations render signals inaccessible and hence unobservable during simulation.

Signals designated as test points will not have algebraic loops minimized, even if **Minimize algebraic loop occurrences** is selected (for more information about algebraic loops, see “Algebraic Loops” on page 3-37).

Test points are primarily intended for use when generating code from a model with Simulink Coder. For more information about test points in the context of code generation, see “Signals with Test Points” (Simulink Coder).

Marking a signal as a test point has no impact on signal logging that uses the `Dataset` logging format. For information about logging signals, see “Export Signal Data Using Signal Logging” on page 61-71.

Configure Signals as Test Points

Use one of the following ways to designate a signal as a test point:

- Open the signal's **Signal Properties** dialog and check **Test Point** in the **Logging and accessibility** section.
- Use the Model Data Editor for batch configuration and for signals that are difficult to locate in a large model or hierarchy of subsystems. On the **Signals** tab, set the

Change view drop-down list to `Instrumentation` and use the **Test Point** column. For information about the Model Data Editor, see "Configure Data Properties by Using the Model Data Editor" on page 59-141.

- To configure Stateflow data in a chart as test points, see "Monitor Test Points in Stateflow Charts" (Stateflow).

To configure a signal as a test point programmatically:

1. Get handles to the ports of the block.

   ```
   portHandles = get_param('myModel/myBlock','portHandles');
   ```

   `portHandles` is a structure. Each field stores a handle to a block port.

2. Extract a handle to the output port that creates the target signal line.

   ```
   outportHandle = portHandles.Outport;
   ```

3. Set the port parameter `TestPoint` to `'on'`.

   ```
   set_param(outportHandle,'TestPoint','on')
   ```

Displaying Test Point Indicators

By default, Simulink displays an indicator on each signal whose **Signal Properties > Test point** option is enabled. For example, in the following model signals `s2` and `s3` are test points:

Note Simulink does not display an indicator on a signal that is specified as a test point by a `Simulink.Signal` object, because such a specification is external to the graphical model.

A signal that is a test point can also be logged. See "Export Signal Data Using Signal Logging" on page 61-71 for information about signal logging. The appearance of the indicator changes to indicate signals for which logging is also enabled.

To turn display of test point indicators on or off, in the Simulink Editor, select or clear **Display > Signals & Ports > Testpoint & Logging Indicators**.

Display Signal Attributes

In this section...

A signal line in a model has attributes such as data type, dimensions, and numeric complexity. When you display these attributes on the block diagram, you can:

- Make the model easier to understand by others.
- Determine the value of the attribute that the signal ultimately uses for simulation (for example, when a signal uses an inherited data type).
- Plan your strategy to control these attributes along a data path (a series of connected blocks).

Additionally, to inspect and specify these attributes in a searchable, sortable table, you can use the Model Data Editor (see “Configure Data Properties by Using the Model Data Editor” on page 59-141).

Ports & Signals Menu

The **Display** > **Signals & Ports** submenu of the Simulink Editor offers the following options for displaying signal properties on the block diagram:

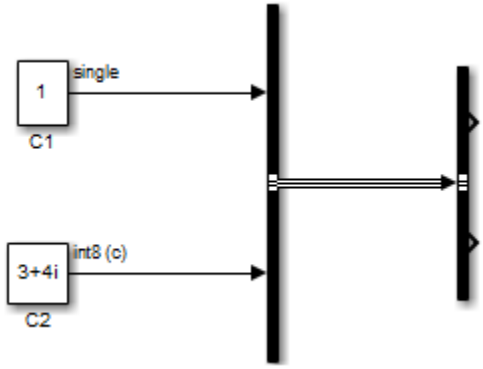
- Linearization Indicators
- Port Data Types (See “Port Data Types” on page 64-66)
- Design Ranges (See “Design Ranges” on page 64-68)
- Signal Dimensions (See “Signal Dimensions” on page 64-68)
- Storage Class
- Testpoint/Logging Indicators

- Signal Resolution Indicators (See “Signal to Object Resolution Indicator” on page 64-69)
- Viewer Indicators
- Wide Nonscalar Lines (See “Wide Nonscalar Lines” on page 64-70)

In addition, you can display sample time information. If you first select **Display > Sample Time**, a submenu provides the choices of **Colors**, **Annotations** and **All**. The **Colors** option allows the block diagram signal lines and blocks to be color-coded based on the sample time types and relative rates. The **Annotations** option provides black codes on the signal lines which indicate the type of sample time. **All** causes both the colors and the annotations to display. All of these options cause a Sample Time Legend to appear. The legend contains a description of the type of sample time and the sample time rate. If **Colors** is turned 'on', color codes also appear in the legend. The same is true if **Annotations** are turned 'on'.

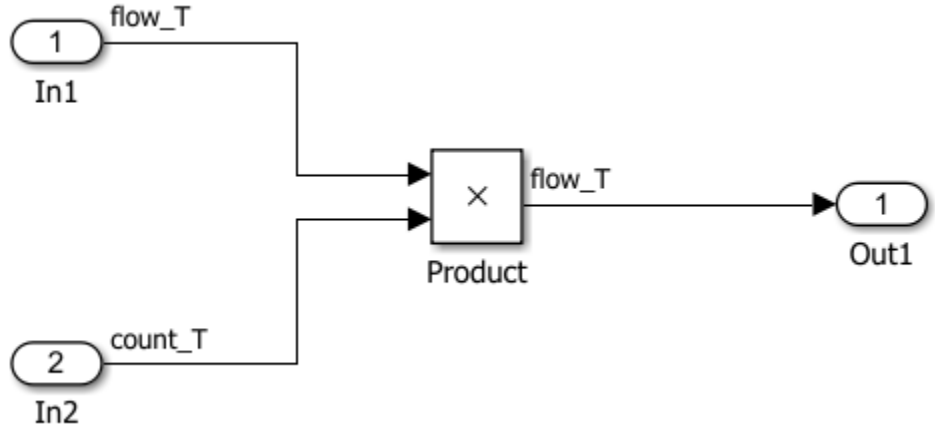
Port Data Types

Displays the data type that each signal uses for simulation and code generation. The data type appears next to the output port that emits the signal.



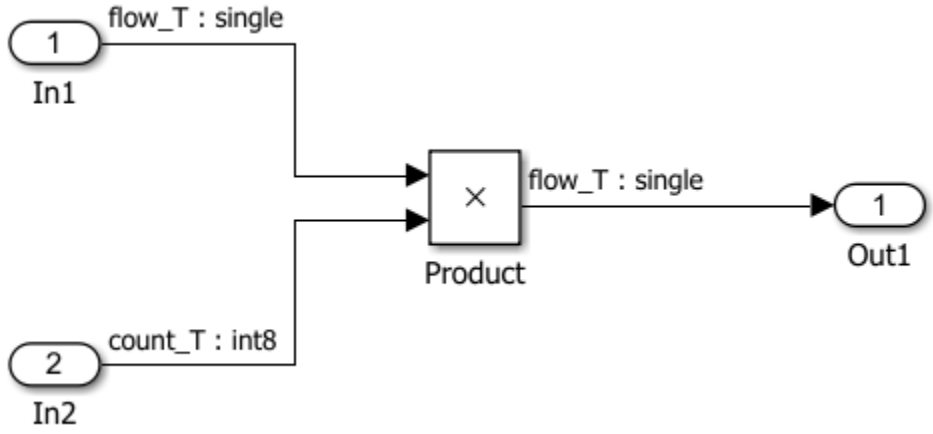
The notation `(c)` indicates that the signal is numerically complex (`i`).

If you use data type aliases (such as a `Simulink.AliasType` objects in the base workspace or a data dictionary) to set output data types in your model, by default, the diagram displays the aliases.



If you create a chain of aliases (for example, by using one `Simulink.AliasType` object as the base type of another `Simulink.AliasType` object), the diagram displays only the alias that you use to set the output data type of each signal. The diagram does not display the underlying aliases in the chain.

To display the lowest underlying base data type (such as `int8`, `single`, or `s16En14`) as well as the alias, in the model, select **Display > Signals and Ports > Port Data Type Display Format > Base and Alias Types**.



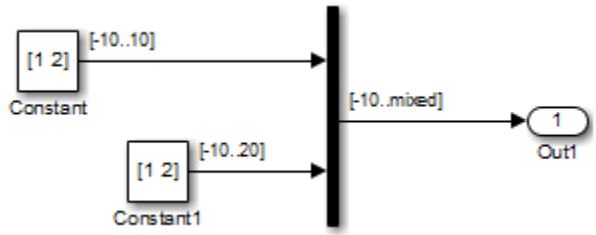
Alternatively, you can display the base type and not the alias by selecting **Base Type**.

When you use a fixed-point data type, the diagram displays the base type by using a standard notation that indicates the characteristics of the type (such as signedness and binary fraction length). To interpret this notation, see "Fixed-Point Data Type and Scaling Notation" (Fixed-Point Designer).

Enabling this option also enables the display of signal attributes at model load time and as you edit the model. For more information, see "Display Signal Attributes at Model Load Time" on page 12-75.

Design Ranges

Displays the compiled design range of a signal next to the output port that emits the signal. The ranges are computed during an update diagram.

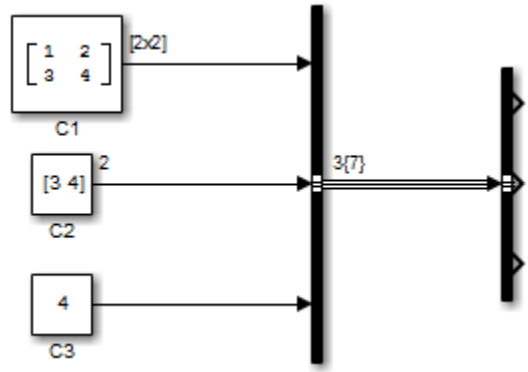


Ranges are displayed in the format `[min..max]`. In the above example, the design range at the output port of the Mux block is displayed as `[-10..mixed]`, because the two signals the Mux block combines have the same design minimum but different design maximums.

You can also use command-line parameters `CompiledPortDesignMin` and `CompiledPortDesignMax` to access the design minimum and maximum of port signals, respectively, at compile time. For more information, see "Common Block Properties".

Signal Dimensions

Display the dimensions of nonscalar signals next to the line that carries the signal.



The format of the display depends on whether the line represents a single signal or a bus. If the line represents a single vector signal, Simulink displays the width of the signal. If the line represents a single matrix signal, Simulink displays its dimensions as `[`N_1`x`N_2`]` where N_i is the size of the `i`th dimension of the signal. If the line represents a bus carrying signals of the same data type, Simulink displays `N{M}` where `N` is the number of signals carried by the bus and `M` is the total number of signal elements carried by the bus. If the bus carries signals of different data types, Simulink displays only the total number of signal elements `{M}`.

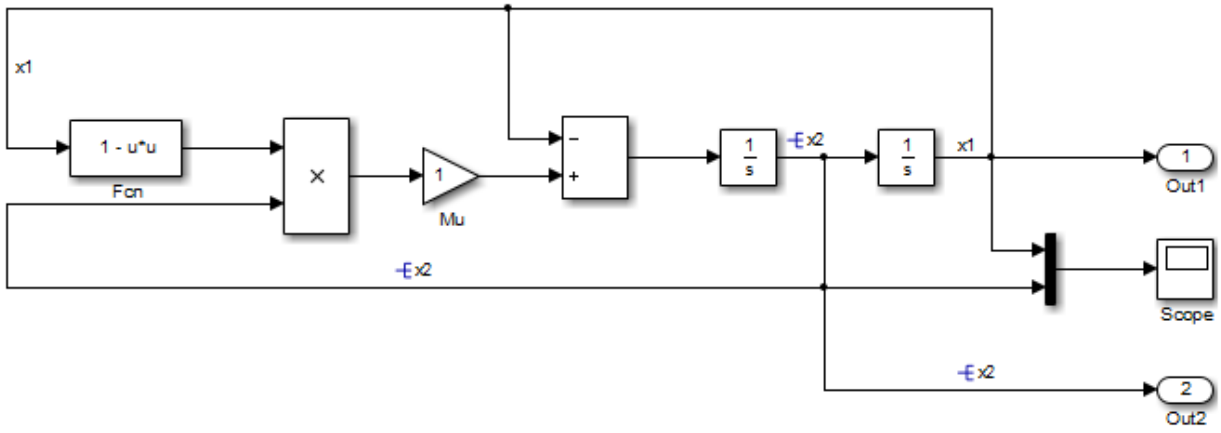
Enabling this option also enables the display of signal dimensions at model load time and as you edit the model. For more information, see “Display Signal Attributes at Model Load Time” on page 12-75.

Signal to Object Resolution Indicator

The Simulink Editor by default graphically indicates signals that must resolve to signal objects. For any labeled signal whose **Signal name must resolve to signal object** property is enabled, a signal resolution icon appears to the left of the signal name. The icon looks like this:

A signal resolution icon indicates only that a signal's **Signal name must resolve to signal object** property is enabled. The icon does not indicate whether the signal is actually resolved, and does not appear on a signal that is implicitly resolved without its **Signal name must resolve to signal object** property being enabled.

Where multiple labels exist, each label displays a signal resolution icon. No icon appears on an unlabeled branch. In the next figure, signal `x2` must resolve to a signal object, so a signal resolution icon appears to the left of the signal name in each label:

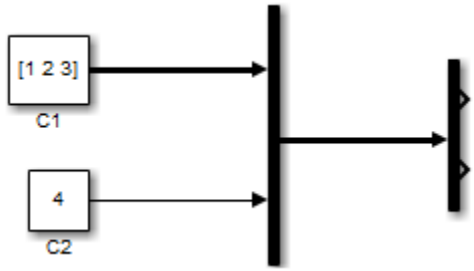


To suppress the display of signal resolution icons, in the model window deselect **Display > Signals & Ports > Signal to Object Resolution Indicator**, which is selected by default. To restore signal resolution icons, reselect **Signal to Object Resolution Indicator**. Individual signals cannot be set to show or hide signal resolution indicators independently of the setting for the whole model. For additional information, see:

- “Symbol Resolution” on page 59-136
- “Initialize Signals and Discrete States” on page 64-53
- `Simulink.Signal`

Wide Nonscalar Lines

Draws lines that carry vector or matrix signals wider than lines that carry scalar signals.



See “Mux Signals” on page 64-12 for more information about vector and matrix signals.

- “Signal Basics” on page 64-2

Signal Groups

In this section...

About Signal Groups

The Signal Builder block displays and allows you to create or edit interchangeable groups of signal sources and quickly switch the groups into and out of a model.

Signal groups can greatly facilitate testing a model, especially when you use them with conjunction with Simulink Assertion blocks and the Model Coverage Tool from the Simulink Coverage. For a description of the Model Coverage Tool, see “Model Coverage Collection Workflow” (Simulink Coverage).

Model Configuration Parameter **Solver** pane settings can affect the Signal Builder block output. See “Simulation Phases in Dynamic Systems” on page 3-17 and “Solvers” on page 3-21 for a description of how solvers affect simulation.

Using the Signal Builder Block with Fast Restart

After you turn on fast restart:

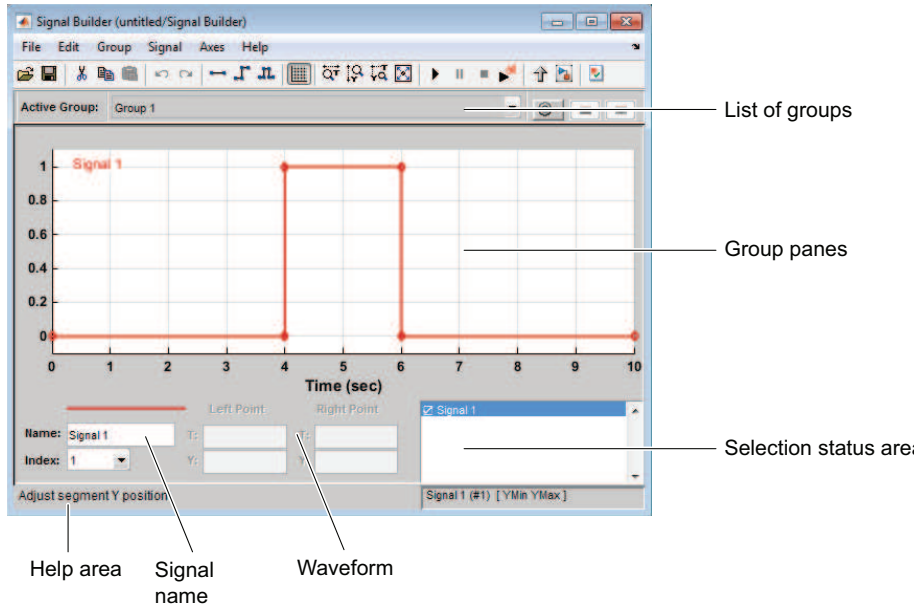
- In between runs, you can change data, rename signals and signal groups, and add new groups. You cannot:

  - Import signals or signal groups
  - Change signal output settings
- You can click the **Run all** button once. To reenable the **Run all** button, toggle the fast restart button on the Simulink Editor tool bar. However, **Run all** does not use fast restart.

Signal Builder Window

The Signal Builder block window allows you to define the shape of the signals (waveform) output by the block. You can specify any waveform that is piecewise linear.

To open the window, double-click the block. The Signal Builder window appears.



The Signal Builder window allows you to create and modify signal groups represented by a Signal Builder block. The Signal Builder window includes the following controls.

Note The Signal Builder block adds a port for each signal you create. The block **Position** parameter limits the number of ports the Signal Builder block can have, and therefore the number of signals you can create. For more information, see the **Position** parameter at “Common Block Properties”.

Group Pane

Displays the set of interchangeable signal source groups represented by the block. The pane for each group displays an editable representation of each waveform in the group. The name of the group appears at the top of the pane. Only one pane is visible at a time. To display a group that is not visible, from the list, select the group name. The block outputs the group of signals whose pane is currently visible. Each pane occupies a pane in the Signal Builder block dialog box. Up to sixteen signals can display at one time.

Signal Axes

The signals appear on separate axes that share a common time range (see "Signal Builder Time Range" on page 64-118). This presentation allows you to compare the relative timing of changes in each signal. The Signal Builder automatically scales the range of each axis to accommodate the signal that it displays. Use the Signal Builder **Axes** menu to change the time (T) and amplitude (Y) ranges of the selected axis.

Signal List

Displays the names and visibility (see "Editing Signals" on page 64-76) of the signals that belong to the currently selected signal group. Clicking an entry in the list selects the signal. Double-clicking a signal entry in the list hides or displays the waveform on the group pane.

Selection Status Area

Displays the name of the currently selected signal and the index of the currently selected waveform segment or point.

Waveform Coordinates

Displays the coordinates of the currently selected waveform segment or point. You can change the coordinates by editing the displayed values (see "Editing Waveforms" on page 64-113).

Name

Name of the currently selected signal. You can change the name of a signal by editing this field (see "Renaming a Signal" on page 64-83).

Index

Index of the currently selected signal. The index indicates the output port at which the signal appears. An index of 1 indicates the topmost output port, 2 indicates the second

port from the top, and so on. You can change the index of a signal by editing this field (see “Changing a Signal Index” on page 64-86).

Help Area

Displays context-sensitive tips on using Signal Builder window features.

Editing Signal Groups

The Signal Builder window allows you to create, rename, move, then delete signal groups from the set of groups represented by a Signal Builder block.

Creating and Deleting Signal Groups

To create a signal group:

1. In Signal Builder, copy an existing signal group.
2. Modify it to suit your needs.

To copy an existing signal group:

1. In Signal Builder, select the group from the list.
2. Select **Group** > **Copy**.

   A new group is created.

To delete a group, select the group from the list, and select **Group** > **Delete**.

Renaming Signal Groups

To rename a signal group:

1. In Signal Builder, select the group from the list,
2. Select **Group** > **Rename**.

   A dialog box appears.
3. Edit the existing name in the dialog box or enter a new name. Click **OK**.

Moving Signal Groups

To reposition a group in the stack of group panes:

1. In Signal Builder, select the pane.

2 To move the group lower in the stack, select **Group** > **Move Down**.

3 To move the pane higher in the stack, select **Group** > **Move Up**.

Editing Signals

Signal Builder allows you to create, cut and paste, hide, and delete signals from signal groups.

Creating Signals

To create a signal in the currently selected signal group:

1 In Signal Builder, from the Active Group list, select the group you want to add the signal to.

2 Select **Signal** > **New**.

The menu lists the waveforms you can add.

Waveform	Description	Inputs	Output
Constant	Constant waveform	None.	Step	Step waveform	None.	
Waveform	Description	Inputs	Output
Pulse	Pulse waveform	None.	Square	Square waveform	• **Frequency (Hz)** Waveform frequency, in hertz • **Amplitude** Waveform amplitude • **Y Offset** Waveform vertical offset • **% Duty cycle** Percent of the period the signal is positive (a value between 0 and 100)	Sawtooth	Sawtooth waveform	• **Frequency (Hz)** Waveform frequency, in hertz. • **Amplitude** Waveform amplitude • **Y Offset** Waveform vertical offset	
Waveform	Description	Inputs	Output
Sampled Sin	Sampled sinewave waveform	• **Frequency (Hz)** Waveform frequency, in hertz • **Amplitude** Waveform amplitude • **Y Offset** Waveform vertical offset • **Samples Per Period** Number of samples per waveform period	Sampled Gaussian Noise	Sampled Gaussian noise waveform based on a Gaussian distribution with input mean and standard deviation at input frequency	• **Frequency (Hz)** Waveform frequency, in hertz • **Mean** The mean value of the random variable output • **Standard Deviation** The standard deviation squared of the random variable output • **Seed (empty to use current state)** The initial seed value for the random number generator	
Waveform	Description	Inputs	Output
Pseudorandom Noise	Pseudorandom noise waveform based on a binomial distribution with upper and lower values at input frequency	• **Frequency (Hz)** Frequency with which waveform fluctuates between **Upper value** and **Lower value**, in hertz • **Upper value** Upper limit of signal • **Lower value** Lower limit of signal • **Seed** The initial seed value for the random number generator	Poisson Random Noise	Poisson random noise waveform that alternates between 0 and 1	• **Avg rate (1/sec)** Average rate of transition between 0 and 1 • **Seed (empty to use current state)** The initial seed value for the random number generator	
Waveform	Description	Inputs	Output
Custom	Custom piecewise linear waveform; custom values must fit within the display area	• **Time values** Vector of two or more time coordinates • **Y values** Vector of two or more signal amplitudes that correspond to the values in **Time values** The entries in either field can be any MATLAB expression that evaluates to a vector, including the results from the evaluation of a MATLAB workspace variable. The resulting vectors must be of equal length. **Note** Signal Builder displays a warning if you add a custom waveform with a large number of data points (100,000,000 or more).	

3 Select the waveform you want to add.

4 Specify the inputs (in prompt), and click **OK**.

If you select a standard waveform, Signal Builder adds a signal with that waveform to the group. If you select a custom waveform, you are prompted for **Time values** and **Y values**.

You can also use MATLAB workspace variables to create new signals.

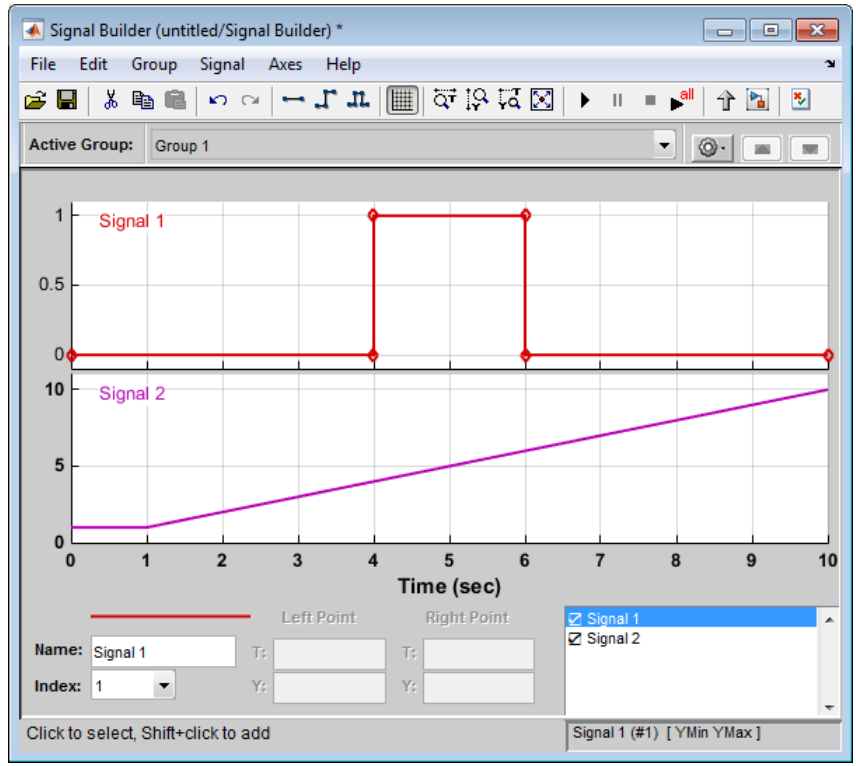
1 In the MATLAB Command Window, create data for two variables, *t* and *y*.

```
t = 1:10
y = 1:10
```

These vectors must be the same size.

2. Create a model and add a Signal Builder block.
3. Double-click the Signal Builder block.
4. Select **Signal** > **New** > **Custom**.
5. In the Custom Waveform window, enter *t* in the **Time values** field and *y* in the **Y values** field and then click **OK**.

The Signal Builder block window displays the new signal as Signal 2.



Defining Signal Output

To specify the type of output to use for sending test signals:

1 In Signal Builder, select **Signal** > **Output**.
2 From the list, select:

- **Ports**

  Default. Sends individual signals from the block. An output port named Signal *N* appears for each Signal *N*.

- **Bus**

  Sends single, virtual, nonhierarchical bus of signals from the block. An output port named Bus appears.

Tip

- You cannot use the **Bus** option to create a bus of nonvirtual signals.
- The **Bus** option enables you to change your model layout without having to reroute Signal Builder block signals. Use the Bus Selector block to select the signals from this bus.
- If you create a Signal Builder block using the Signal & Scope Manager or using the **Create & Connect Generator** option from a signal line context menu, you cannot define signal output. In these cases, the block sends individual signals.

Copying and Pasting Signals

To copy a signal from one group and paste it into another group as a new signal:

1 In Signal Builder, select the signal you want to copy.
2 Select **Edit** > **Copy**.
3 Select the group you want to paste the signal into.
4 Select **Edit** > **Paste**.

To copy a signal from one axis and paste it into another axis to replace its signal:

1 Select the signal you want to copy.
2 Select **Edit** > **Copy**.
3 Select the signal on the axis that you want to update.
4 Select **Edit** > **Paste**.

Deleting Signals

To delete a signal, in Signal Builder, select the signal and choose **Delete** or **Cut** from the **Edit** menu. Signal Builder deletes the signal from the current group. Because each signal group must contain the same number of signals, Signal Builder also deletes all signals sharing the same index in the other groups.

Renaming a Signal

To rename a signal:

1. In Signal Builder, select **Signal** > **Rename**.

   A dialog box appears with an edit field that displays the current name of the signal.
2. Edit or replace the current name with a new name.
3. Click **OK**.

You can also edit the signal name in the **Name** field in the lower-left corner of the Signal Builder window.

Replacing a Signal

To replace a signal:

1. In Signal Builder, select the signal, then select **Signal** > **Replace with** .

   A menu of waveforms appears. It includes a set of standard waveforms (**Constant**, **Step**, and so on) and a **Custom** waveform option.
2. Select one of the waveforms.

   If you select a standard waveform, the Signal Builder replaces a signal in the currently selected group with that waveform. For other waveforms, the Signal Builder displays a dialog to allow you to provide input for the requested waveform.

Waveform	Description	Inputs
Constant	Constant waveform.	None.
Step	Step waveform.	None.
Pulse	Pulse waveform.	None.

Waveform	Description	Inputs
Square	Square waveform.	• **Frequency (Hz)** Waveform frequency, in Hertz. • **Amplitude** Waveform amplitude. • **Y Offset** Waveform vertical offset. • **% Duty cycle** Percent of the period in which the signal is positive. Enter a value between 0 and 100.
Sawtooth	Sawtooth waveform.	• **Frequency (Hz)** Waveform frequency, in Hertz. • **Amplitude** Waveform amplitude • **Y Offset** Waveform vertical offset.
Sampled Sin	Sampled sinewave waveform.	• **Frequency (Hz)** Waveform frequency, in Hertz. • **Amplitude** Waveform amplitude • **Y Offset** Waveform vertical offset. • **Samples Per Period** Number of samples per waveform period.

Waveform	Description	Inputs
Sampled Gaussian Noise	Sampled Gaussian noise waveform based on a Gaussian distribution with input mean and standard deviation at input frequency.	• **Frequency (Hz)** Waveform frequency, in Hertz. • **Mean** The mean value of the random variable output. • **Standard Deviation** The standard deviation squared of the random variable output. • **Seed (empty to use current state)** The initial seed value for the random number generator.
Pseudorandom Noise	Pseudorandom noise waveform based on a binomial distribution with upper and lower values at input frequency.	• **Frequency (Hz)** Frequency with which waveform fluctuates between **Upper value** and **Lower value**, in Hertz. • **Upper value** Upper limit of signal. • **Lower value** Lower limit of signal. • **Seed** The initial seed value for the random number generator
Poisson Random Noise	Poisson random noise waveform that alternates between 0 and 1.	• **Avg rate (1/sec)** Average rate of transition between 0 and 1. • **Seed (empty to use current state)** The initial seed value for the random number generator

Waveform	Description	Inputs
Custom	Custom piecewise linear waveform. Custom values must fit within the display area.	• **Time values** Vector of two or more time coordinates. • **Y values** Vector of two or more signal amplitudes that correspond to the values in **Time values**. The entries in either field can be any MATLAB expression that evaluates to a vector. The resulting vectors must be of equal length. **Note** Signal Builder returns a warning if you add a custom waveform with a large number of data points (100,000,000 or more). You can then cancel the action.

You can also edit the signal name in the **Name** field in the lower-left corner of the Signal Builder window.

Changing a Signal Index

To change a signal index:

1. In Signal Builder, select the signal, then select **Signal** > **Change Index**.

   A dialog box appears with a drop-down list field containing the existing index of the signal.
2. From the drop-down list, another index and select **OK**. Or select an index from the **Index** list in the lower-left corner of the Signal Builder window.

Hiding Signals

By default, the Signal Builder window displays the group waveforms in the group pane. To hide a waveform:

1. In Signal Builder, select the waveform, then select **Signal** > **Hide**.
2. To redisplay a hidden waveform, select the **Group** pane, then select **Signal** > **Show**.

3 Select the signal from the list. Alternatively, you can hide and redisplay a hidden waveform by double-clicking its name in the Signal Builder signal list (see "Signal List" on page 64-74).

Creating Signal Group Sets

You can create signal groups in the Signal Builder block by:

- "Creating Signal Group Sets Manually" on page 64-87
- "Importing Signal Group Sets" on page 64-88
- "Importing Data with Custom Formats" on page 64-112

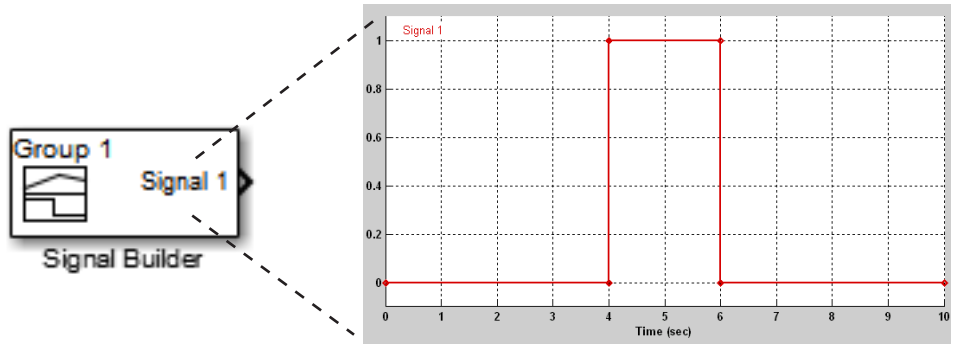
You can also use the `signalbuilder` function to populate the Signal Builder block.

Creating Signal Group Sets Manually

This topic describes how to create signal group sets manually. If you have signal data files, such as those from test cases, consider importing this data as described in "Importing Signal Group Sets" on page 64-88.

To create an interchangeable set of signal groups:

1 Drag an instance of the Signal Builder block from the Simulink Sources library and drop it into your model.



By default, the block represents a single signal group containing a single signal source that outputs a square wave pulse.

2 Use the block signal editor (see "Signal Builder Window" on page 64-73) to create additional signal groups, add signals to the signal groups, modify existing signals and signal groups, and select the signal group that the block outputs.

Note Each signal group must contain the same number of signals.

3 Connect the output of the block to your diagram.

The block displays an output port for each signal that the block can output.

You can create as many Signal Builder blocks as you like in a model, each representing a distinct set of interchangeable groups of signal sources. When a group has multiple signals, the signals might have different end times. However, Signal Builder block requires the end times of signals within a group to match. If a mismatch occurs, Signal Builder block matches the end times by holding the last value of the signal with the smaller end time.

See "Simulating with Signal Groups" on page 64-122 for information on using signal groups in a model.

Importing Signal Group Sets

The topics in this section describe how to import signal data into the Signal Builder block. You should already have a signal data file whose contents you want to import. For example, you might have signal data from previously run test cases. See "Importing Signal Groups from Existing Data Sets" on page 64-88 for a description of the data formats that the Signal Builder block accepts. The procedures in the following topics use the file `3Grp_3Sig.xls` in the folder *`matlabroot`*`\help\toolbox\simulink\ug\examples\signals` (open).

Signal Builder accepts signals only of type double.

If you import a `Simulink.SimulationData.Dataset` data set, the block imports it as its own group.

Importing Signal Groups from Existing Data Sets

You might have existing signal data sets that you want to enter into the Signal Builder block. The **File > Import from File** command on the Signal Builder window starts the Import File dialog box. This dialog box is modal, which means that focus cannot change to another MATLAB window while the dialog box is running. If you want to see changes in the Signal Builder window after you import data, do one of the following:

- Close the Import File dialog box.
- Set up the Import File dialog box and Signal Builder window side by side.

Note You cannot undo the results of importing a signal data file. In addition, you cannot undo the last action performed before opening the Import File dialog box. When you close the Import File dialog box, the **Undo last edit** and **Redo last edit** buttons on the Signal Builder window are grayed out. These buttons are grayed out regardless of whether you imported a data file.

The Import File dialog box accepts the following appropriately formatted file types:

- Microsoft Excel (`.xls`, `.xlsx`)
- Comma-separated value (CSV) text files (`.csv`)
- MAT-files (`.mat`)

Tip To import signal data from an Microsoft Excel spreadsheet, consider using the From Spreadsheet block. The From Spreadsheet block incrementally loads data from the spreadsheet during simulation. If you use a From Spreadsheet block, you do not need to do anything to handle changes to sheet values.

Note Signal Builder block uses the `xlsread` function. See the `xlsread` documentation for information on supported platforms.

You can import your data set file only if it is appropriately formatted.

For Microsoft Excel spreadsheets:

- The Signal Builder block interprets the first row as signal name. If you do not specify a signal name, the Signal Builder block assigns a default one with the format `Imported_Signal #`, where # increments with each additional unnamed signal.
- The Signal Builder block interprets the first column as time. In this column, the time values must increase.
- The Signal Builder block interprets the remaining columns as signals.
- If there are multiple sheets:
  - Each sheet must have the same number of signals (columns).
  - Each sheet must have the same set of signal names (if any).
  - Each column on each sheet must have the same number of rows.

- Signal Builder block interprets each worksheet as a signal group.

This example contains an acceptably formatted Microsoft Excel spreadsheet. It has three worksheets named Group1, Group2, and Group3, representing three signal groups.

	Time	DC In	Trigger	AC In
2	0	1	2	3
3	1	2	3	4
4	2	3	4	5
5	3	4	5	6
6	4	5	6	7
7	5	6	7	8
8	6	7	8	9
9	7	8	9	10
10	8	9	10	11
11	9	10	11	12
12	10	11	12	13
13	11	12	13	14
14	12	13	14	15
15	13	14	15	16
16	14	15	16	17
17	15	16	17	18

For CSV text files:

- Each file contains only numbers. Do not name signals in a CSV file.
- The Signal Builder block interprets the first column as time. In this column, the time values must increase.
- The Signal Builder block interprets the remaining columns as signals.
- Each column must have the same number of entries.
- The Signal Builder block interprets each file as one signal group.

- The Signal Builder block assigns a default signal name to each signal with the format `Imported_Signal #`, where `#` increments with each additional signal.

This example contains an acceptably formatted CSV file. The contents represent one signal group.

```
0,0,0,5,0
1,0,1,5,0
2,0,1,5,0
3,0,1,5,0
4,5,1,5,0
5,5,1,5,0
6,5,1,5,0
7,0,1,5,0
8,0,1,5,1
9,0,1,5,1
10,0,1,5,0
```

For MAT-files:

- The Signal Builder block supports data store logging that the `Simulink.SimulationData.Dataset` object represents and interprets this data as a single group.
- The Signal Builder block supports Simulink output saved as a structure with time.
- The Signal Builder block supports the Signal Builder data format. This format is a group of cell arrays that must be labeled:

  - `time`
  - `data`
  - `sigName`
  - `groupName`

  `sigName` and `groupName` are optional.
- For backwards compatibility, the Signal Builder block supports logged data from the `Simulink.ModelDataLogs` object and interprets this data as a single group. The `ModelDataLogs` format will be removed in a future release.
- Signal Builder block does not support:

  - Simulink output as only a structure

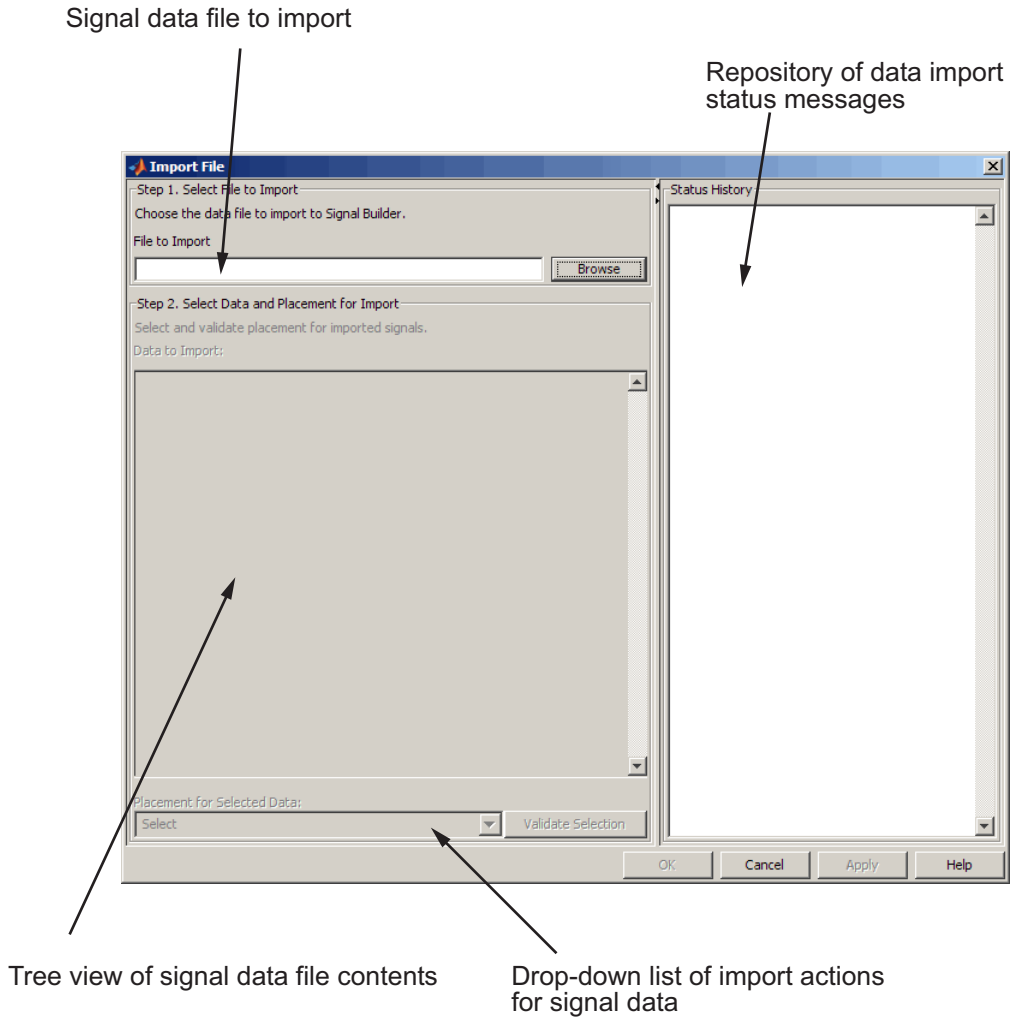
- Simulink output as only an array

Note Signal Builder returns a warning if you import a large number of data points (100,000,000 or more). You can then cancel the action.

This example contains an acceptably logged MATLAB workspace. Use the MATLAB workspace **Save** command to save the variables to a MAT-file. Import this file to the Signal Builder block.

Signal Builder Block Import File Dialog Box

The Signal Builder Import File dialog box allows you to import existing signal data files into the Signal Builder block.



Replacing All Signal Data with Selected Data

Simulink software creates a default Signal Builder block with one signal. To replace this signal and all other signal data that the block might display:

1. Create a model and drag a Signal Builder block into that model.
2. Double-click the block.

The Signal Builder window appears with its default Signal 1.

3 In Signal Builder, select **File** > **Import from File**.

The Import File dialog box appears.

4 In the **File to Import** field, enter a signal data file name or click **Browse**.

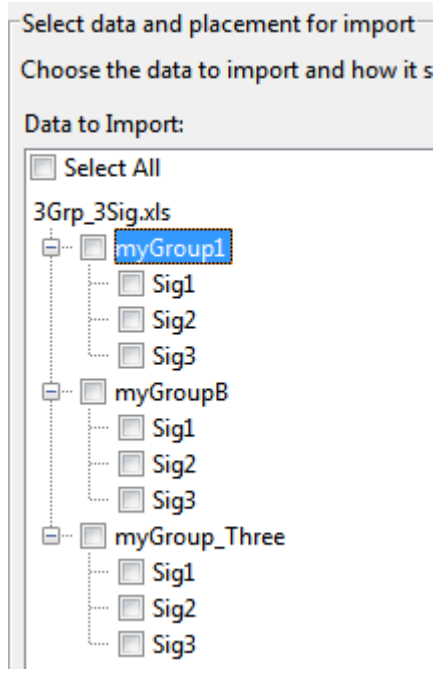
The file browser appears.

5 If you select the file browser, navigate to and select a signal data file. For example, select `3Grp_3Sig.xls`.

Note If you try to import an improperly formatted data file, an error message pops up. When you click to dismiss this window, the **Status History** pane displays a more detailed error message (if there is one). For example:

```
File 'signals.mat' format does not
comply with Signal Builder required format.
There is no 'time' parameter defined.
.....................
```

The **Data to Import** pane contains the signal data from the file. Click the expander to display all the signals.



6 Select the signals you want to import. To import all the signals, click **Select All**.

7 From the **Placement for Selected Data** list, select the action to take on the signal data. For example, select `Replace existing dataset`.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action. If the signal data selection is not appropriate, **Confirm Selection** remains grayed out. For example, **Confirm Selection** remains grayed out if the number of signals you select is not the same as the number of signals in the Signal Builder group that you want to replace.

8 Click the **Confirm Selection** button.

If the requested action is a valid one, the Status History pane displays messages to indicate the status. For example:

```
Current data in Signal Builder will be replaced
by new data.
Number of groups: 3
Group name(s):
  myGroup1
  myGroupB
  myGroup_Three

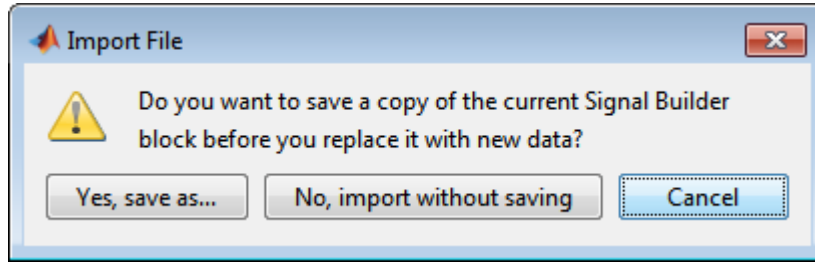
Number of signals per group: 3
Signal name(s):
  Sig1
  Sig2
  Sig3

(Names may have been renamed for uniqueness.)
.....................
```

The confirmation also enables the **OK** and **Apply** buttons.

9 If you are satisfied with the status message, click **Apply** to replace the existing signal data with the contents of this file.

When selecting `Replace existing dataset`, the software gives you the opportunity to save the existing contents of the Signal Builder block.

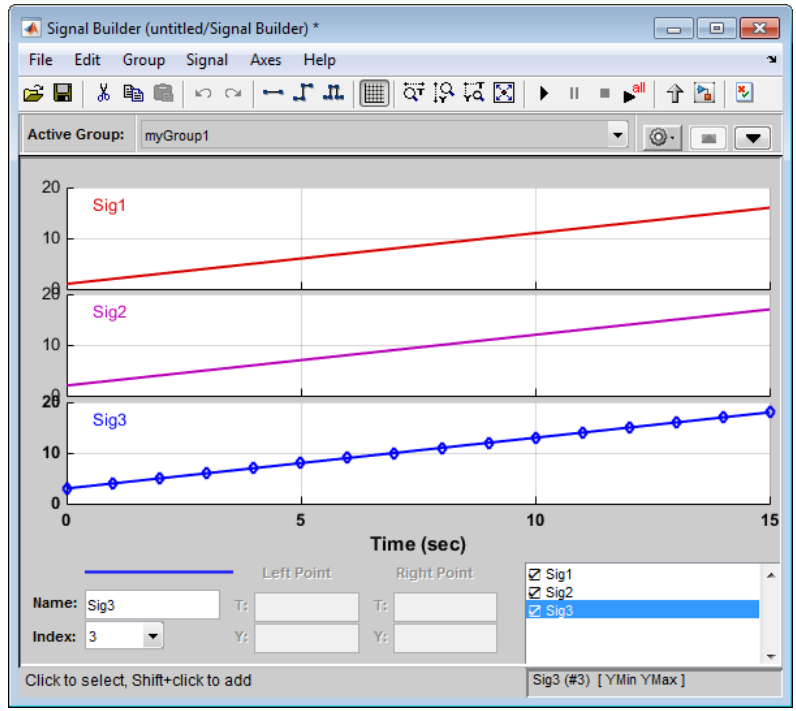


10 Click a button, as follows:

To...	Click...
Save the contents of the Signal Builder block before replacing it with the new signal data. **Note** This selection prompts you to save the Signal Builder block in a model name of your choice. The software saves only the Signal Builder block and no other model content.	**Yes, save as**
Replace the contents of the Signal Builder block without saving them first.	**No, import without saving**
Stop the replacement process.	**Cancel**

For this example, select **No, import without saving** to replace the contents of the Signal Builder block.

11 The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the Signal Builder block.



12 Click **OK**.

13 Inspect the updated Signal Builder window to confirm that your signal data is intact.

14 Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder1`.

Appending Selected Signals to All Existing Signal Groups

You can import signals from a signal data file and append selected signals to the end of all existing signal groups. If the signal names to be appended are not unique, the software renames them by incrementing each name by 1 or higher until it is a unique signal name. For example, if the block and data file contain signals named `thermostat`, the software renames the imported signal to `thermostat1` upon appending. If you add another signal named `thermostat`, the software names that latest version `thermostat2`.

This topic uses `signalbuilder1` from the procedure in “Replacing All Signal Data with Selected Data” on page 64-93.

1. In the MATLAB Command Window, type `signalbuilder1`.
2. Double-click the Signal Builder block.

   The Signal Builder window appears.
3. In the Signal Builder window, select **File > Import from File**.

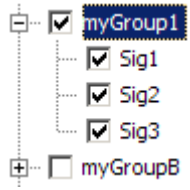
   The Import File dialog box appears.
4. In the **File to Import** field, enter a signal data file name or click **Browse**.

   The file browser is displayed.
5. If you select the file browser, navigate to and select a signal data file. For example, select `3Grp_3Sig.xls`.

Note If you try to import an improperly formatted signal data file, an error message pops up. When you click to dismiss this window, the **Status History** pane displays an error message. For example:

```
File 'signals.mat' format does not
comply with Signal Builder required format.
There is no 'time' parameter defined.
.....................
```

   The **Data to Import** pane contains the signal data from the file. Click the expander to display all the signals.
6. Select the signals you want to import. In this example, there are three groups, myGroup1, myGroupB, and myGroup_Three. Select all the signals in myGroup1.



7. From the **Placement for Selected Data** list, select the action to take on the signal data. For example, select `Append selected signals to all groups`.

   The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action. If the signal data selection is not appropriate, **Confirm Selection** remains grayed out. For example, **Confirm**

Selection remains grayed out if the number of signals you select is not the same as the number of signals in the Signal Builder group that you want to replace.

8 Click the **Confirm Selection** button.

If the requested action is a valid one, the Status History pane displays messages to indicate the state. For example:

```
3 signal(s) will be appended to each group.
Selected signal name(s):
Before:
  Sig1
  Sig2
  Sig3

After:
  Sig4
  Sig5
  Sig6

Signal name(s) in the block:
Before:
  Sig1
  Sig2
  Sig3

After:
  Sig1
  Sig2
  Sig3
  Sig4
  Sig5
  Sig6

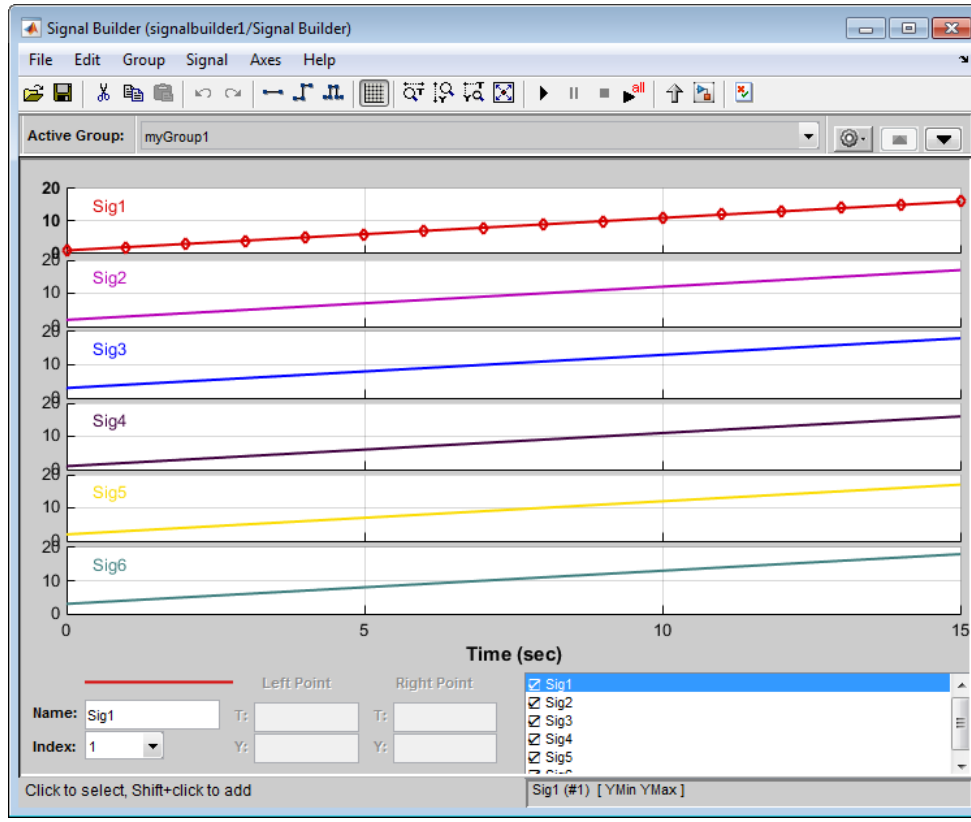
(Names may have been renamed for uniqueness.)
```

The confirmation also enables the **OK** and **Apply** buttons.

Observe the **Before** and **After** headings for the signals. These sections indicate the names of the block and imported data signals before and after the append action.

9 If you are satisfied with the status message, click **Apply** to append the selected signals to all the signal groups in the Signal Builder block.

10 The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the Signal Builder block.



11 Click **OK**.

12 Inspect the updated Signal Builder window to confirm that your signal data is intact. Notice that the software has renamed the signals Sig1, Sig2, and Sig3 from the signal data file to Sig4, Sig5, and Sig6 in the Signal Builder block.

13 Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder2`.

Appending Selected Signals to Sequential Existing Signal Groups

You can append signals, in the order in which they are selected, to the end of sequential signal groups. This statement means that you select the same number of signals as there are signal groups, and sequentially append each signal to a different group. The software renames each appended signal to the name of the last appended signal.

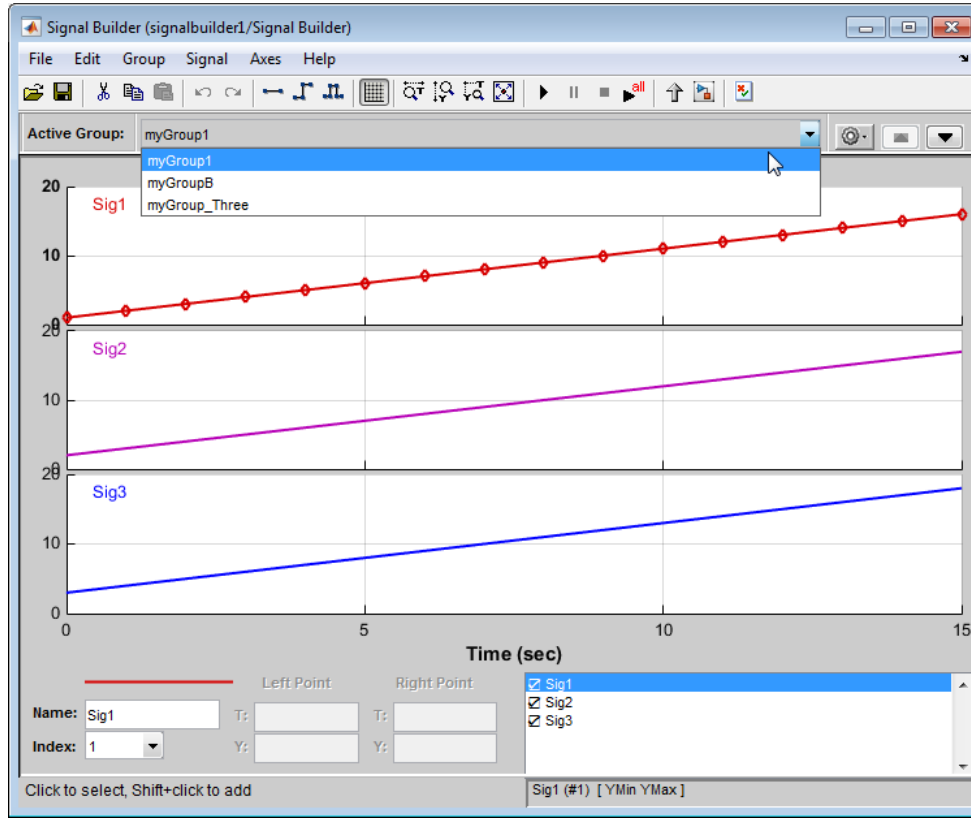
This topic uses `signalbuilder1` from the procedure in “Replacing All Signal Data with Selected Data” on page 64-93.

1 In the MATLAB Command Window, type `signalbuilder1`.

2 Double-click the Signal Builder block.

The Signal Builder window appears.

3 Note how many groups exist in the Signal Builder block. For example, this Signal Builder block has three groups, myGroup1, myGroupB, and myGroup_Three.



4 In the Signal Builder window, select **File > Import from File**.

The Import File dialog box appears.

5 In the **File to Import** field, enter a signal data file name or click **Browse**.

The file browser appears.

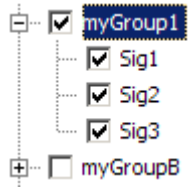
6 If you select the file browser, navigate to and select a signal data file. For example, select `3Grp_3Sig.xls`.

Note If you try to import an improperly formatted signal data file, an error message popup window. When you click to dismiss this window, the **Status History** pane displays an error message. For example:

```
File 'signals.mat' format does not
comply with Signal Builder required format.
There is no 'time' parameter defined.
.....................
```

The **Data to Import** pane contains the signal data from the file. Click the expander to display all the signals.

7 Select the signals you want to import. In this example, there are three groups, myGroup1, myGroupB, and myGroup_Three. Select all the signals in myGroup1.



8 From the **Placement for Selected Data** list, select the action to take on the signal data. For example, select `Append selected signals to different groups (in order)`.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action.

9 Click the **Confirm Selection** button.

If the requested action is a valid one, the Status History pane displays messages to indicate the state. For example:

```
 1 signal will be appended to each group.
Selected signal names:
Before:
  Sig1
  Sig2
  Sig3

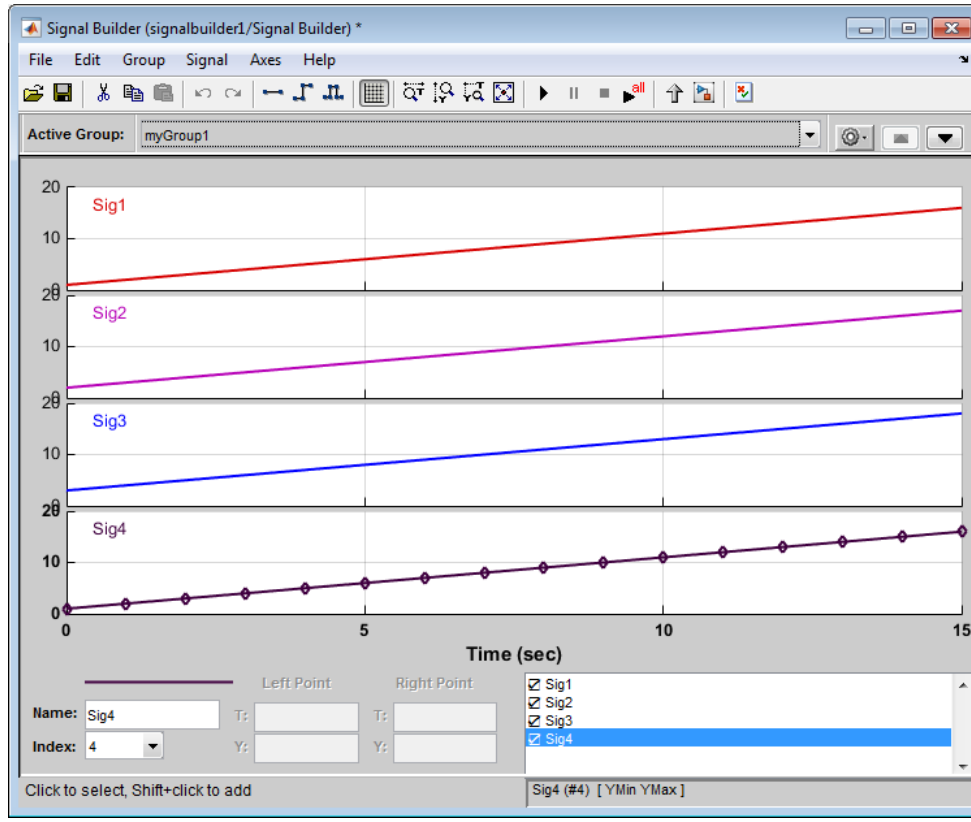
Selected unique signal name:
After:
  Sig4
```

The confirmation also enables the **OK** and **Apply** buttons.

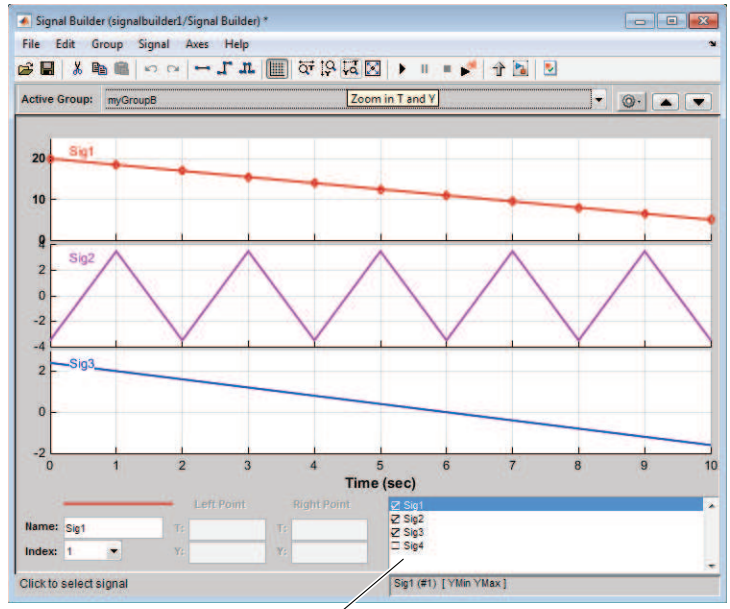
10 If you are satisfied with the status message, click **Apply** to append the signals.

The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the three groups of the Signal Builder block.

The topmost signal group, myGroup1, shows all signals by default, including the new Sig4.

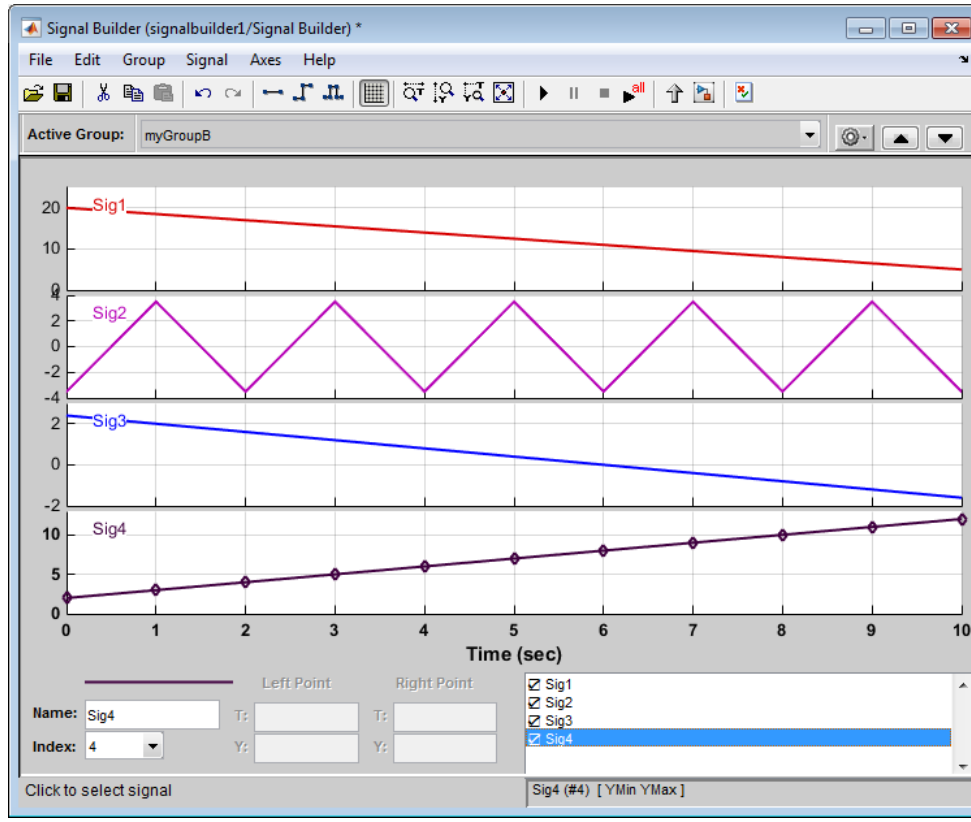


11 Click another group name, for example, myGroupB. Notice that Sig4 exists for the group, hidden by default.



Sig4 appears in signal list, but does not appear in group pane

12 To show Sig4 on this pane, double-click Sig4 in the Selection Status area of the pane. The graph is updated to reflect Sig4.



13 Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder3`.

Appending Signal Groups to Existing Groups

You can append one or more signal groups to the end of the list of existing signal groups. If the block already has a signal group with the same name as the one you are adding, the software increments the group name by 1 or higher until it is unique before adding it. For example, if the block and data file contain groups named `MyGroup1`, the software renames the imported group to `MyGroup2` upon appending. If you add another group named `MyGroup1`, the software names that latest version `MyGroup3`.

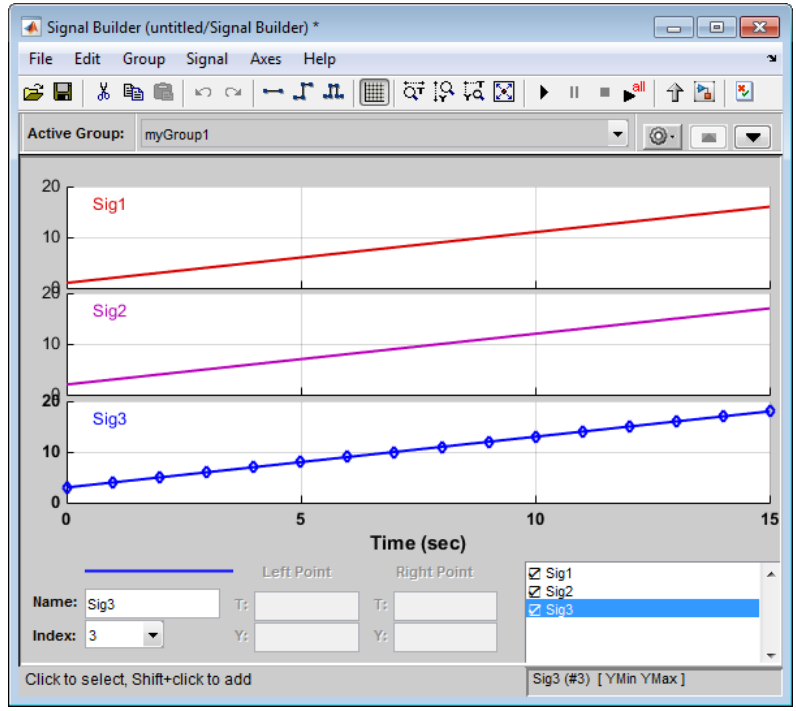
This topic uses `signalbuilder1` from the procedure in “Replacing All Signal Data with Selected Data” on page 64-93.

1 In the MATLAB Command Window, type `signalbuilder1`.

2 Double-click the Signal Builder block.

The Signal Builder window appears.

3 Note how many groups exist in the Signal Builder block, and how many signals exist in each group. The Signal Builder block requires that all groups have the same number of signals. For example, this Signal Builder block has three groups, myGroup1, myGroupB, and myGroup_Three. Three signals exist in each group.



4 Double-click the block.

The Import File dialog box appears.

5 In the **File to Import** text field, enter a signal data file name or click **Browse**.

The file browser appears.

6 If you select the file browser, navigate to and select a signal data file. For example, select `3Grp_3Sig.xls`.

The **Data to Import** pane contains the signal data from the file. Click the expander to display all the signals.

7 Evaluate the number of signals in the groups of this data file. If the number of signals in each group equals the number of signals in the groups that exist in the block, you can append one of these groups to the block.

8 Select the group you want to import. In this example, there are three groups, myGroup1, myGroupB, and myGroup_Three. Select myGroupB.

9 From the **Placement for Selected Data** list, select the action to take on the signal group. For example, select `Append groups`.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action.

10 Click the **Confirm Selection** button.

If the requested action is a valid one, the Status History pane displays messages to indicate the state. For example:

```
1 group(s) (each with 3 signal(s)),
will be appended to the existing block.
Selected group name(s):
Before:
  myGroupB

After:
  myGroupB1

Signal name(s) in selected group(s):
Before:
  Sig1
  Sig2
  Sig3

Signal name(s) in the block:
Before:
  Sig1
  Sig2
  Sig3

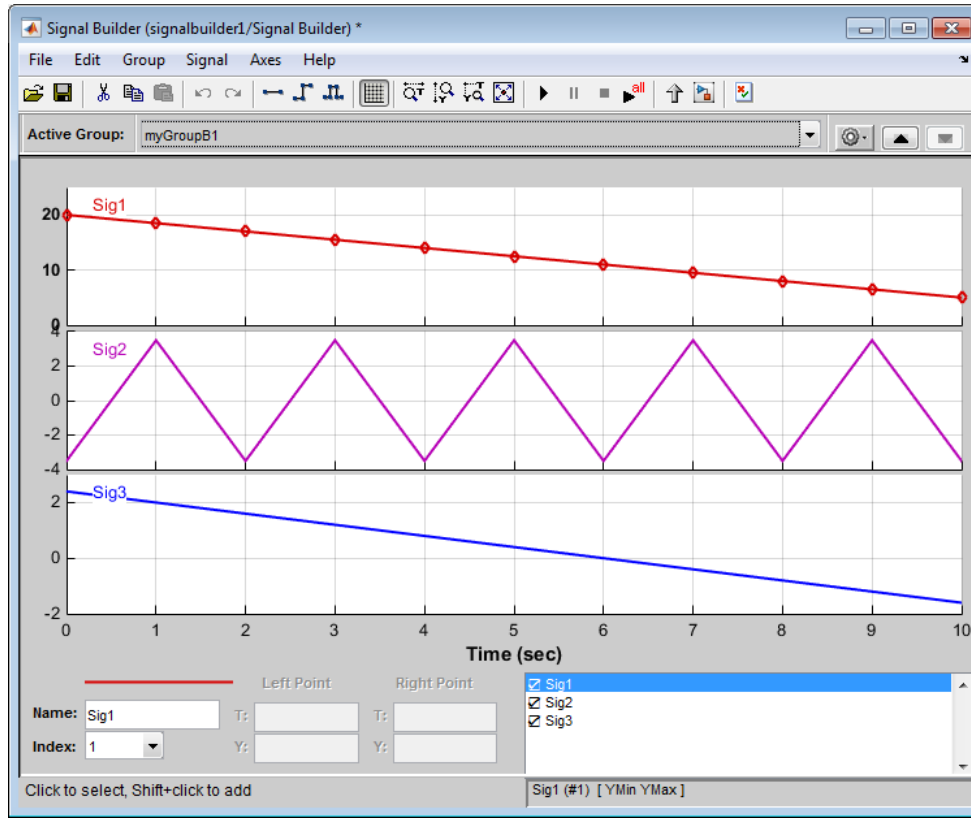
After:
  Sig1
  Sig2
  Sig3
```

The confirmation also enables the **OK** and **Apply** buttons.

11 If you are satisfied with the status message, click **Apply** to append the signals.

The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the groups of the Signal Builder block.

Notice the addition of the new signal group as the last pane. Because there is already a signal group named myGroupB, the software automatically increments the new signal group name by 1. Select myGroupB.



12 Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder4`.

Appending Signals with the Same Name to Existing Signal Groups

If you append a signal whose name is the same as a signal that exists in the Signal Builder block, the software increments the name of the appended signal by 1. The software repeats incrementing until the appended signal name is unique. For example:

1 Assume your Signal Builder block has a signal group, `myGroup1`, with the signals Sig1, Sig2, and Sig3.

2 Append a signal named Sig1 to `myGroup1`.

3 Observe that the software increments Sig1 to Sig4 before appending it to `myGroup1`.

Appending a Group of Signals with Different Signal Names

If you append a signal group whose signal names differ from those that exist in the Signal Builder block, the software changes the names of the existing signals to be the same as the appended signals. For example,

1. Assume your Signal Builder block has a signal group, `myGroup1`, with the signals Sig1, Sig2, and Sig3.
2. Append a signal group named `myGroup2` whose signal names are SigA, SigB, and SigC.
3. Observe that the software:
   - Appends `myGroup2`.
   - Renames the signals in `myGroup1` to be the same as those in `myGroup2`.

Importing Data with Custom Formats

This topic describes how to import signal data formatted in a custom format. You should already have a signal data from a file whose contents you want to import. See "Importing Signal Groups from Existing Data Sets" on page 64-88 for a description of the data formats that the Signal Builder block accepts. If your data is not formatted using one of these data formats, use the following workflow to import the custom formatted data. This workflow uses the following files, located in the folder *`matlabroot`*`\help\toolbox\simulink\ug\examples\signals` (open), as examples:

- `SigBldCustomFile.xls` — Signal data Microsoft Excel file using a format that Signal Builder block does not accept, for example:

Group1	Time	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
	Signal1	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
	Signal2	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
	Signal3	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
	Signal4	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
Group2	Signal1	1.6	2.6	3.6	4.6	5.6	6.6	7.6	8.6	9.6	10.6	11.6	12.6	13.6	14.6	15.6	16.6
	Signal2	1.8	2.8	3.8	4.8	5.8	6.8	7.8	8.8	9.8	10.8	11.8	12.8	13.8	14.8	15.8	16.8
	Signal3	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17
	Signal4	2.2	3.2	4.2	5.2	6.2	7.2	8.2	9.2	10.2	11.2	12.2	13.2	14.2	15.2	16.2	17.2

- `createSignalBuilderSupportedFormat.m` — Custom MATLAB function that uses `xlsread` to read Microsoft Excel spreadsheets. This example function reformats the custom data, in a format that the Signal Builder block supports, as follows:
  - *`grpNames`* — Cell array that contains group name character vectors with number of rows = 1, number of columns = number of groups.

- *sigNames* — Cell array that contains signal name character vectors with number of rows = 1, columns = number of signals.
- *time* — Cell array that contains time data with number of rows = number of signals, columns = number of groups.
- *data* — Cell array that contains signal data with number of rows = number of signals, columns = number of groups.

Signal Builder has the following requirements for this custom function:

- Number of signals in each group must be the same.
- Signal names in each group must be the same.
- Number of data points in each signal must be the same.
- Each element in the *time* and *data* cell array holds a matrix of real numbers. This matrix can be [1x*N*] or [*N*x1], where *N* is the number of data points in every signal.

1. Identify the format of your custom signal data, for example:

   ```
   SigBldCustomFile.xls
   ```

2. Create a custom MATLAB function that:

   a. Uses a MATLAB I/O function, such as `xlsread`, to read your custom formatted signal data. For example, `createSignalBuilderSupportedFormat.m`.

   b. Formats the custom formatted signal data to one that the Signal Builder block accepts, for example, a MAT-file.

3. Use your custom MATLAB function to write your custom formatted signal data to a file that Signal Builder block accepts. For example:

   ```
   createSignalBuilderSupportedFormat('SigBldCustomFile.xls', 'OutputData.mat')
   ```

4. Import the reformatted signal data file, `OutputData.mat`, into the Signal Builder block (see “Importing Signal Group Sets” on page 64-88).

Editing Waveforms

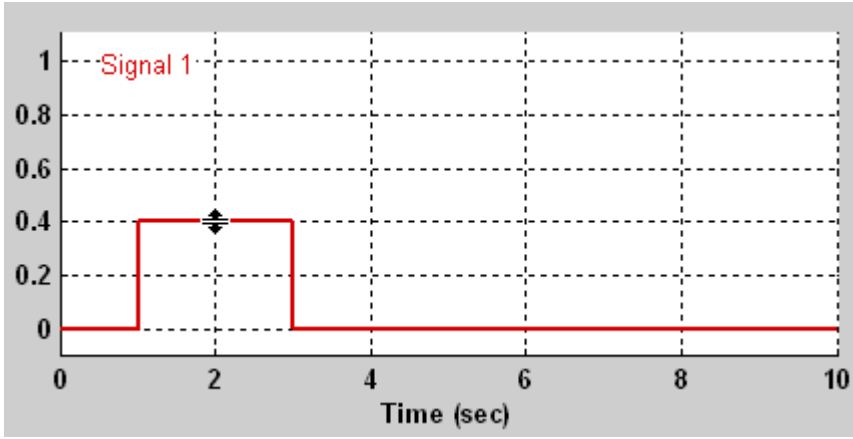
Signal Builder allows you to change the shape, color, and line style and thickness of the waveforms output by a group.

Reshaping a Waveform

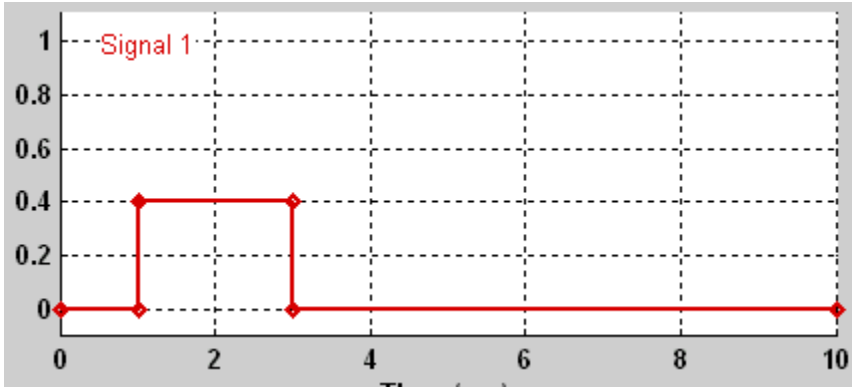
Signal Builder allows you to change the waveform by selecting and dragging its line segments and points with the mouse or arrow keys or by editing the coordinates of segments or points.

Selecting a Waveform

To select a waveform, left-click the mouse on any point on the waveform.



The Signal Builder displays the waveform points to indicate that the waveform is selected.



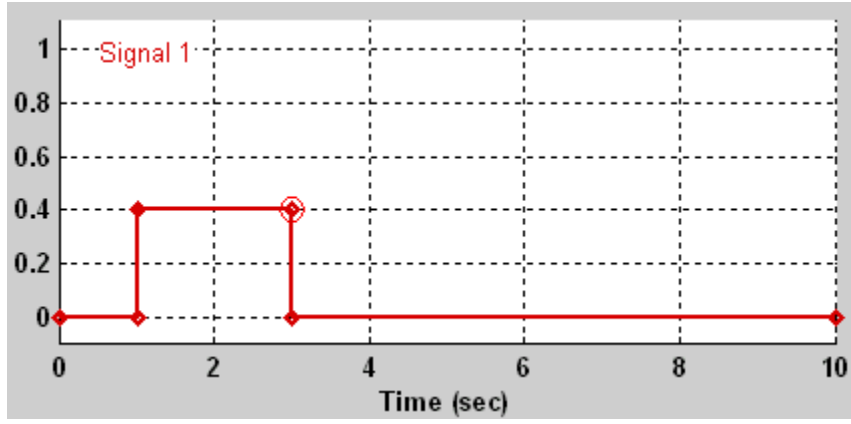
To deselect a waveform, left-click any point on the waveform axis that is not on the waveform itself or press the **Esc** key.

Working with Points

You can work with points in a waveform:

- To select a point of a waveform, first select the waveform. Then position the mouse cursor over the point. The cursor changes shape to indicate that it is over a point.

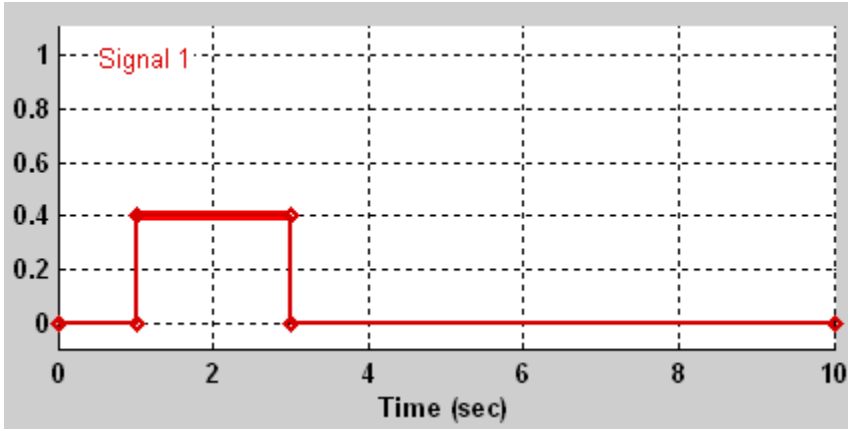
  Left-click the point with the mouse. The Signal Builder draws a circle around the point to indicate your selection.



- To insert a point, select the waveform and **Shift+**click the section for the point.
- To deselect the point, press the **Esc** key.
- To delete a point, select the point and press the **Backspace** or **Delete** keys.
- To edit a point with the `signalbuilder` function, use the `signalbuilder set` function to replace the waveform. You cannot programmatically remove a point.

Selecting Segments

To select a line segment, first select the waveform that contains it. Then left-click the segment. The Signal Builder thickens the segment to indicate that it is selected.



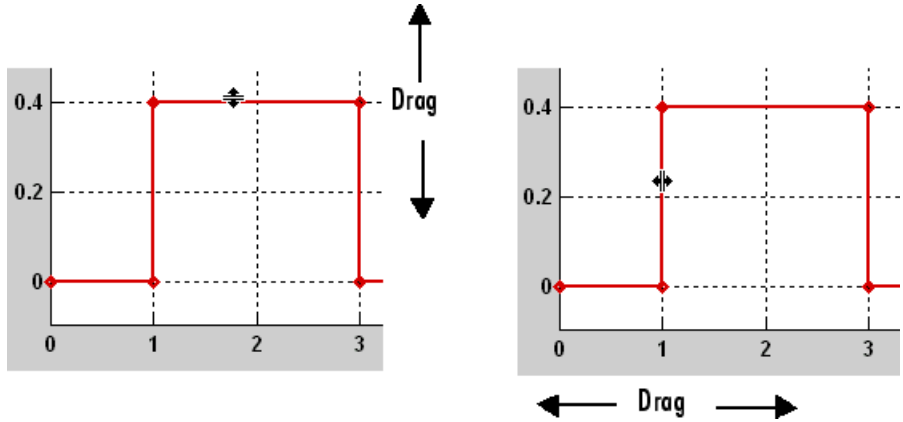
To deselect the segment, press the **Esc** key.

Moving Waveforms

To move a waveform, select it and use the arrow keys on your keyboard to move the waveform in the desired direction. Each key stroke moves the waveform to the next location on the snap grid (see “Snap Grid” on page 64-117) or by `0.1` inches if the snap grid is not enabled.

Dragging Segments

To drag a line segment to a new location, position the mouse cursor over the line segment. The mouse cursor changes shape to show the direction in which you can drag the segment.



Press the left mouse button and drag the segment in the direction indicated to the desired location. You can also use the arrow keys on your keyboard to move the selected line segment.

Dragging points

To drag a point along the signal amplitude (vertical) axis, move the mouse cursor over the point. The cursor changes shape to a circle to indicate that you can drag the point. Drag the point parallel to the *y*-axis to the desired location. To drag the point along the time (horizontal) axis, press the **Shift** key while dragging the point. You can also use the arrow keys on your keyboard to move the selected point.

Snap Grid

Each waveform axis contains an invisible snap grid that facilitates precise positioning of waveform points. The origin of the snap grid coincides with the origin of the waveform axis. When you drop a point or segment that you have been dragging, the Signal Builder moves the point or the segment points to the nearest point or points on the grid, respectively. The Signal Builder **Axes** menu allows you to specify the grid horizontal (time) axis and vertical (amplitude) axis spacing independently. The finer the spacing, the more freedom you have in placing points but the harder it is to position points precisely. By default, the grid spacing is 0, which means that you can place points anywhere on the grid; i.e., the grid is effectively off. Use the **Axes** menu to select the spacing that you prefer.

Inserting and Deleting points

To insert a point, first select the waveform. Then hold down the **Shift** key and left-click the waveform at the point where you want to insert the point. To delete a point, select the point and press the **Del** key.

Editing Point Coordinates

To change the coordinates of a point, first select the point. The Signal Builder displays the current coordinates of the point in the **Left Point** edit fields at the bottom of the Signal Builder window. To change the amplitude of the selected point, edit or replace the value in the **Y** field with the new value and press **Enter**. The Signal Builder moves the point to its new location. Similarly edit the value in the **T** field to change the time of the selected point.

Editing Segment Coordinates

To change the coordinates of a segment, first select the segment. The Signal Builder displays the current coordinates of the endpoints of the segment in the **Left Point** and **Right Point** edit fields at the bottom of the Signal Builder window. To change a coordinate, edit the value in its corresponding edit field and press **Enter**.

Changing the Color of a Waveform

To change the color of a waveform, select the waveform and then select **Color** from the Signal Builder **Signal** menu. The Signal Builder displays the MATLAB color chooser. Choose a new color for the waveform. Click **OK**.

Changing a Waveform Line Style and Thickness

The Signal Builder can display a waveform as a solid, dashed, or dotted line. It uses a solid line by default. To change the line style of a waveform, select the waveform, then select **Line Style** from the Signal Builder **Signal** menu. A menu of line styles pops up. Select a line style from the menu.

To change the line thickness of a waveform, select the waveform, then select **Line Width** from the **Signal** menu. A dialog box appears with the line current thickness. Edit the thickness value and click **OK**.

Signal Builder Time Range

The Signal Builder time range determines the span of time over which its output is explicitly defined. By default, the time range runs from 0 to 10 seconds. You can change

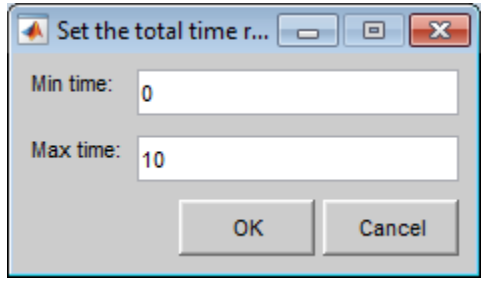
both the beginning and ending times of a block time range (see “Changing a Signal Builder Time Range” on page 64-119).

If the simulation starts before the start time of a block time range, the block extrapolates its initial output from its first two defined outputs. If the simulation runs beyond the block time range, the block by default outputs values extrapolated from the last defined signal values for the remainder of the simulation. The Signal Builder **Simulation Options** dialog box allows you to specify other final output options (see “Signal values after final time” on page 64-123 for more information).

Note When you click the **Start simulation** button on the Signal Builder block toolbar, the simulation uses the stop time of the model. The end of the time range specified in the waveform is not the stop time for the model.

Changing a Signal Builder Time Range

To change the time range, select **Change Time Range** from the Signal Builder **Axes** menu. A dialog box appears.

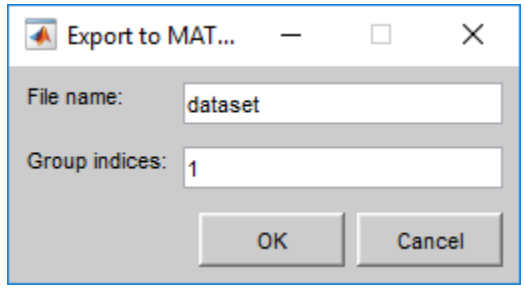


Edit the **Min time** and **Max time** fields as necessary to reflect the beginning and ending times of the new time range, respectively. Click **OK**.

Exporting Signal Group Data

You can export data that defines Signal Builder block signals groups to a MAT-file or the MATLAB Workspace.

To export Signal Builder signal data, formatted as `Simulink.SimulationData.Dataset`, to a MAT-file, select **File > Export Data > To MAT-file**. A dialog box appears.

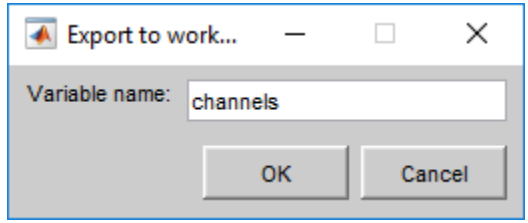


- **File name** — Enter a name for the MAT-file to contain the data.
- **Group indices** — Enter one or signal group numbers for which you want to export the data, specified as a scalar or vector. Numbers must correspond to an existing group in the block.

Alternatively, you can use the `signalbuilder get` function to return one or more data sets. For example:

```
[ds1 ds2]=signalbuilder(block,'get',[group1 group2])
```

To export signal data to the MATLAB workspace, select **File > Export Data > To Workspace**. A dialog box appears.



The Signal Builder exports the data by default to a workspace variable named `channels`. To export to a differently named variable, enter the variable name in the **Variable name** field. Click **OK**. The Signal Builder exports the data to the workspace as the value of the specified variable.

The exported data is an array of structures. The structure `xData` and `yData` fields contain the coordinate points defining signals in the currently selected signal group.

To access all the data in the signal groups of a Signal Builder block, use the `signalbuilder get` function:

```
[time, data]=signalbuilder(block,'get',signal,group)
```

For example:

```
% For time 0 to 5, create three signal groups.
block = signalbuilder([], 'create', [0 5], {[2 2] [4 4] [7 8];[0 2] [0 4] [7 10]});
% Get the signals for all three groups.
[time, data]=signalbuilder(block,'get',[1 2],[1:3])

time =

  2×3 cell array

    [1×2 double]    [1×2 double]    [1×2 double]
    [1×2 double]    [1×2 double]    [1×2 double]

data =

  2×3 cell array

    [1×2 double]    [1×2 double]    [1×2 double]
    [1×2 double]    [1×2 double]    [1×2 double]
```

Printing, Exporting, and Copying Waveforms

Signal Builder allows you to print, export, and copy the waveforms visible in the active signal group.

To print the waveforms to a printer, select **Print** from the block **File** menu.

You can also export the waveforms to other destinations by using the **Export** option from the block **File** menu. From this submenu, select one of the following destinations:

- **To File** — Converts the current view to a graphics file.

  Select the format of the graphics file from the **Save as type** drop-down list on the resulting **Export** dialog box.
- **To Figure** — Converts the current view to a MATLAB figure window.

To copy the waveforms to the system clipboard for pasting into other applications, select **Copy Figure To Clipboard** from the block **Edit** menu.

Simulating with Signal Groups

You can use standard simulation commands to run models containing Signal Builder blocks or you can use the **Run** or **Run all** button in the Signal Builder window (see "Running All Signal Groups" on page 64-122).

If you want to capture inputs and outputs that the **Run all** button generates, consider using the SystemTest™ software.

Activating a Signal Group

During a simulation, a Signal Builder block always outputs the active signal group. The active signal group is the group selected in the Signal Builder window for that block, if the dialog box is open. Otherwise, the active group is the group that was selected when the dialog box was last closed. To activate a group, open the group Signal Builder window and select the group.

Running Different Signal Groups in Succession

The Signal Builder toolbar includes the standard Simulink buttons for running a simulation. This facilitates running several different signal groups in succession. For example, you can open the dialog box, select a group, run a simulation, select another group, run a simulation, etc., all from the Signal Builder window.

Running All Signal Groups

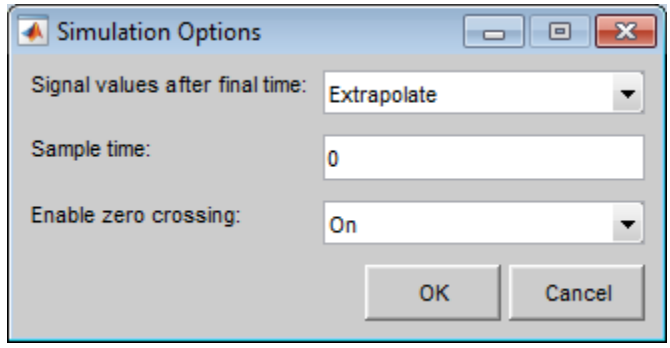
To run all the signal groups defined by a Signal Builder block, open the block dialog box and click the **Run all** button

from the Signal Builder toolbar. The **Run all** button runs a series of simulations, one for each signal group defined by the block. If you installed Simulink Coverage on your system and are using the Model Coverage Tool, the **Run all** button configures the tool to collect and save coverage data for each simulation in the MATLAB workspace and display a report of the combined coverage results at the end of the last simulation. This allows you to quickly determine how well a set of signal groups tests your model.

Note To stop a series of simulations started by the **Run all** command, enter **Ctrl+C** at the MATLAB command line.

Simulation Options Dialog Box

The **Simulation Options** dialog box allows you to specify simulation options pertaining to the Signal Builder. To display the dialog box, select **Simulation Options** from the **File** menu of the Signal Builder window. The dialog box appears.



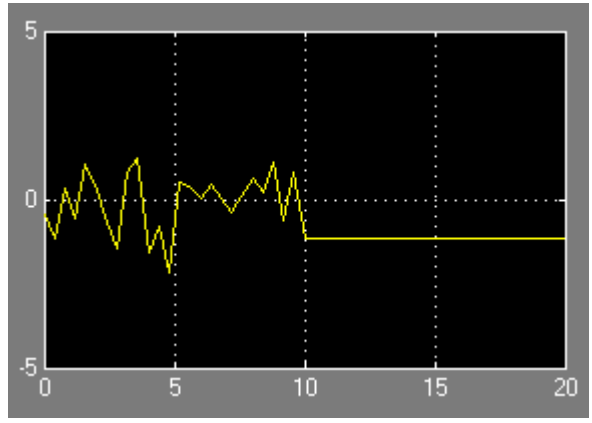
The dialog box allows you to specify the following options.

Signal values after final time

The setting of this control determines the output of the Signal Builder block if a simulation runs longer than the period defined by the block. The options are

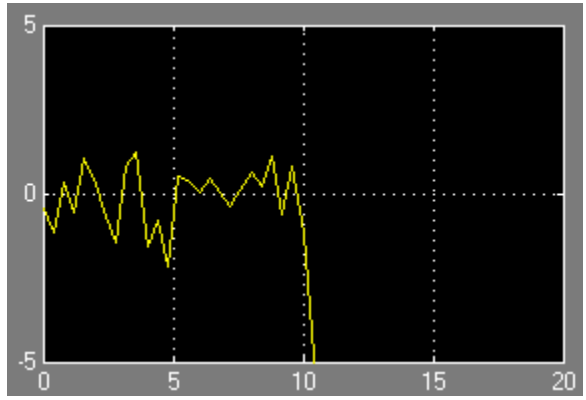
- `Hold final value`

  Selecting this option causes the Signal Builder block to output the last defined value of each signal in the currently active group for the remainder of the simulation.



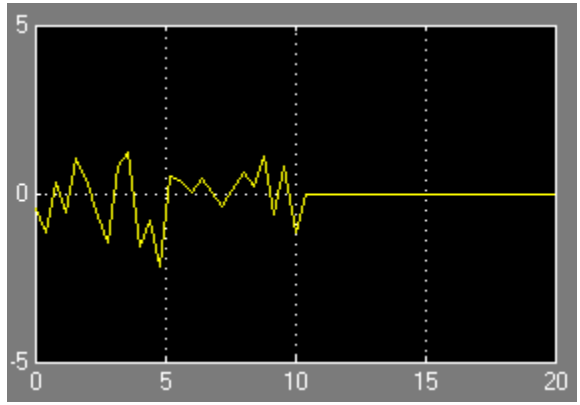
- `Extrapolate`

  Selecting this option causes the Signal Builder block to output values extrapolated from the last defined value of each signal in the currently active group for the remainder of the simulation.



- `Set to zero`

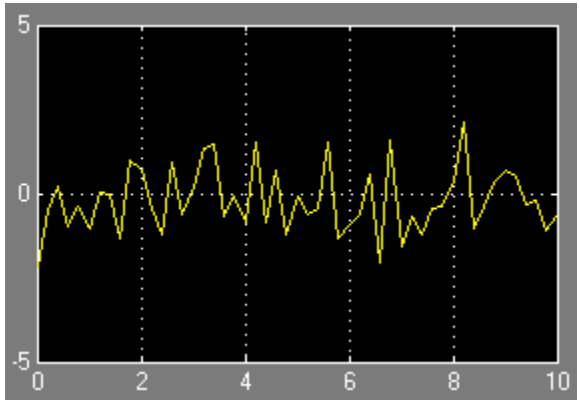
  Selecting this option causes the Signal Builder block to output zero for the remainder of the simulation.



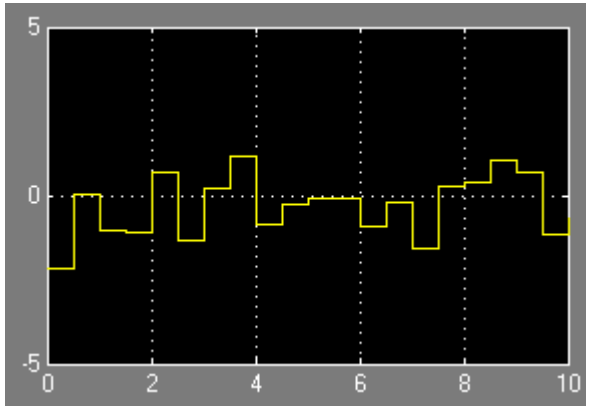
Sample time

Determines whether the Signal Builder block outputs a continuous (the default) or a discrete signal. If you want the block to output a continuous signal, enter 0 in this field.

For example, the following display shows the output of a Signal Builder block set to output a continuous Gaussian waveform over a period of 10 seconds.



If you want the block to output a discrete signal, enter the sample time of the signal in this field. The following example shows the output of a Signal Builder block set to emit a discrete Gaussian waveform having a `0.5` second sample time.



Enable zero crossing

Specifies whether the Signal Builder block detects zero-crossing events (enabled by default). This block sets the zero-crossing detection on the From Workspace block that you use to create the Signal Builder signal groups. For more information, see “Zero-Crossing Detection” on page 3-24.

Using Composite Signals

Composite Signal Techniques

In this section...

You can use composite signals to reduce visual complexity in a model. A composite signal is a signal that is composed of other signals. The individual element signals originate separately and join to form the composite signal. You can extract individual signals from the composite signal downstream and use the extracted signal as if it never was part of a composite signal.

Use one or more of these techniques to combine signals into a composite signal.

- “Buses” on page 65-3
- “Arrays of Buses” on page 65-7
- “Muxes” on page 65-8
- “Concatenated Contiguous Output Signals” on page 65-9

To select a composite signal technique that meets your modeling requirements, see “Select a Composite Signal Technique” on page 65-11.

Buses

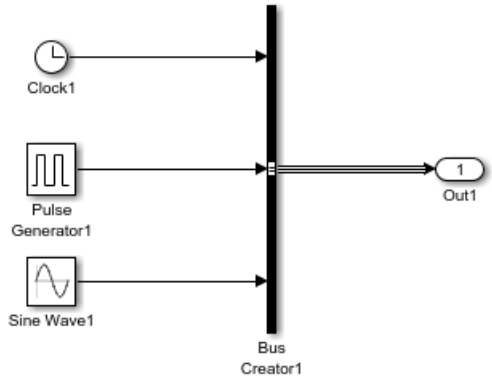
A *bus signal* (also called a *bus*) is analogous to a bundle of wires held together by tie wraps. Simulink implements a bus as a name-based hierarchical structure. A Simulink bus is not like a hardware bus, such as the bus in computer hardware architecture. A Simulink bus is more like a programmatic structure defined in a language such as MATLAB or C.

A bus is composed of signals that are called *elements*. The constituent signals retain their separate identities within the bus and can be of any type or types, including other buses nested to any level. The elements of a bus can be:

- Mixed data type signals (for example, double, integer, fixed-point)
- Mixed scalar and vector elements
- Mixed of real and complex signals
- Other buses
- Multidimensional signals

Not all blocks can accept buses. See “Bus-Capable Blocks” on page 65-48 for more information about which blocks can handle which types of buses. Also, see “Use Buses with Inport and Outport Blocks” on page 65-104.

For example, this model has a bus signal `bus1`, composed of the bus elements `Clock`, `Pulse`, and `Sine`.



For complete examples using buses, see slexBusExample and “Getting Started with Buses” on page 65-16.

Virtual and Nonvirtual Buses

A bus can be either *virtual* or *nonvirtual*. Virtual and nonvirtual buses provide the same visual simplification, but Simulink handles them differently.

Bus	Functional Effect	Signal Storage	Generated Code
Virtual	Exists only graphically; has no functional effect.	Each bus element signal occupies its own storage in memory, but the bus signal is not stored in memory. A block connected to a *virtual* bus reads inputs and writes outputs by accessing the memory allocated to the component signals. These signals are typically noncontiguous. Information about the size and data type of signals propagates from the signal sources.	Do not appear in generated code; only the constituent signals appear.
Nonvirtual	Can have functional effects.	Bus signal occupies its own storage in contiguous memory. A block connected to a *nonvirtual* bus reads inputs and writes outputs by accessing copies of the component signals. The copies are maintained in a contiguous area of memory allocated to the bus.	Appear as structures in generated code.

When you simulate or perform an update diagram operation for a model that contains buses, Simulink uses different line styles for virtual and nonvirtual bus signals.

Virtual Bus	Nonvirtual Bus	

Bus Objects

A bus can have an associated *bus object*, which provides bus properties that Simulink uses to validate the bus signal. Bus objects are optional for virtual buses, but required for nonvirtual buses.

A bus object specifies only the architectural properties of a bus, as distinct from the values of the signals it contains. For example, a bus object can specify the number of elements in a bus, the order of those elements, whether and how elements are nested, and the data types of constituent signals; but not the signal values. A bus object is analogous to a structure definition in C: it defines the members of the bus but does not create a bus. Another way of thinking of a bus object is that it is similar to a cable connector. The connector defines all the pins and their configuration and controls what types of wires can be connected to it. Similarly, a bus object defines the configuration and properties of the signals that the associated bus must have.

A bus object is an instance of class `Simulink.Bus` that can be in stored in a location such as the base workspace. The object defines the structure of the bus and the properties of its elements, such as nesting, data type, and size. You can create bus objects programmatically or by using the Simulink Bus Editor, which you can use to interactively create and manage bus objects. You can save bus objects as MATLAB code or as a MAT-file. For more information, see “When to Use Bus Objects” on page 65-64 and “Create Bus Objects with the Bus Editor” on page 65-69.

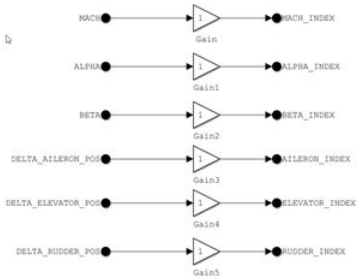
Generated Code for Buses

For simulation, virtual buses and nonvirtual buses are similar, except that all elements of a nonvirtual bus must have the same sample time. However, the type of bus can make a significant difference in the efficiency, size, and readability of generated code. For an example of this difference, see “Generate Code for Buses” on page 65-23.

If you intend to generate code for a model that uses buses, for information about the best techniques to use, see “Generate Efficient Code for Bus Signals” (Simulink Coder).

Bus Element Ports

The In Bus Element and Out Bus Element blocks provide a simplified and flexible way to use bus signals as inputs and outputs to subsystems. Here is model that uses bus element port blocks.



You can refactor a subsystem interface that uses Inport, Bus Selector, Bus Creator, and Outport blocks to use In Bus Element and Out Bus Element blocks. Conversion operations are supported only when the signal lines or blocks do not have any extra specification. You can use single-click operations to:

- Convert Inport and Bus Selector blocks in a subsystem to In Bus Element blocks.
- Convert Outport and Bus Creator blocks in a subsystem to Out Bus Element blocks.
- Transform input or output interfaces of subsystems to use bus element port blocks.

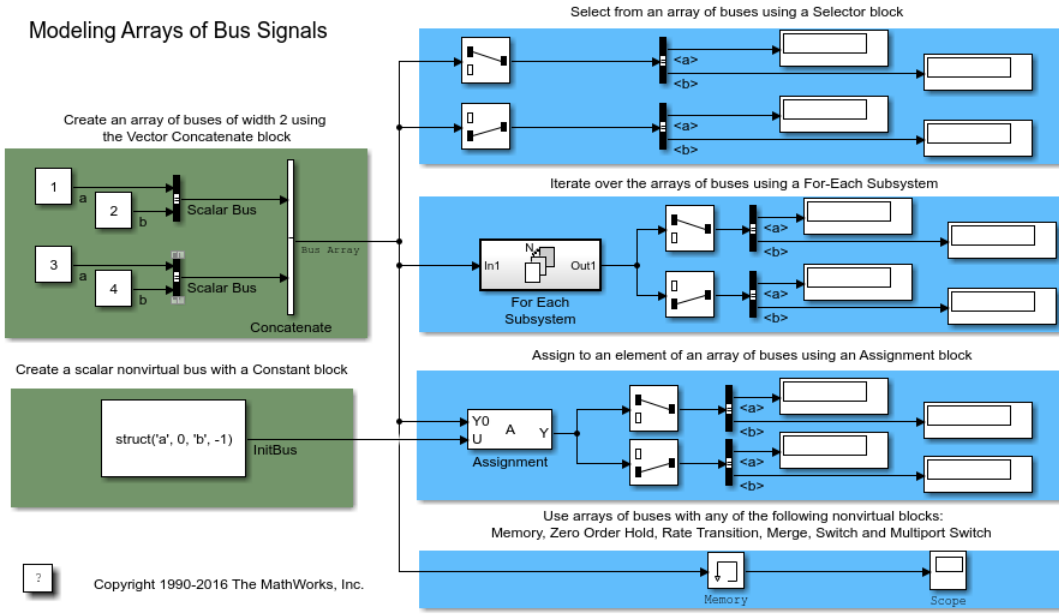
See slexBusExample and "Simplify Subsystem Bus Interfaces" on page 65-29.

Arrays of Buses

You can combine multiple nonvirtual buses with identical properties into an array of buses. An array of buses is an array whose elements are buses. Each bus object has the same signal name, hierarchy, and attributes for its bus elements. An array of buses is equivalent to an array of structures in MATLAB.

An example of using an array of buses is to model a multi-channel system. You can model all the channels using the same bus object, although each of the channels could have a different value.

For an example of a model that uses an array of buses, open the `sldemo_bus_arrays` model. In this example, the nonvirtual bus input signals connect to a Vector Concatenate or Matrix Concatenate block that creates an array of bus signals. Here is how the simulated model appears.



The model uses the array of buses with:

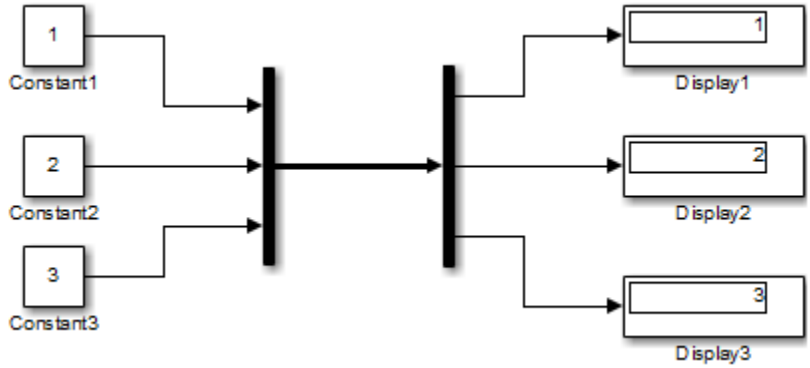
- An Assignment block, to assign values to a bus in the array
- A For Each Subsystem block, to perform iterative processing over each bus in the array
- A Memory block, to output the array of buses input from the previous time step

See “Combine Buses into an Array of Buses” on page 65-118.

Muxes

If all signals in a composite signal have the same type, generally you can use a mux, which is a special type of noncontiguous vector (virtual) vector. If a block or modeling configuration requires a bus, then do not use a mux.

This model has three signals that are input to a Mux block, transmitted as a mux signal to a Demux block, and output as separate signals.



The Mux and Demux blocks are the left and right vertical bars, respectively. To reduce visual complexity, neither block displays a name.

For more information, see “Mux Signals” on page 64-12.

Concatenated Contiguous Output Signals

You can concatenate input signals of same data type to create contiguous output signal. You can use a Vector Concatenate or Matrix Concatenate block to concatenate the signals at its inputs to create an output signal whose elements reside in contiguous locations in memory.

For example, this model sets the Matrix Concatenate block parameter **Concatenate dimension** to `2`. Inputs are 2-D matrices. The Matrix Concatenate block performs horizontal matrix concatenation and places the input matrices side by side to create the output matrix.

Select a Composite Signal Technique

In this section...

Choose the composite signal technique that meets your modeling requirements. For background information about each technique, see “Composite Signal Techniques” on page 65-3.

Virtual Bus Usage Guidelines

Use virtual buses to reduce signal clutter in a block diagram. In general, using a virtual bus is simpler and can be more efficient than using a nonvirtual bus. However, some modeling features require nonvirtual buses, such as bus data that crosses MATLAB Function block or Stateflow chart boundaries. For example, use a virtual bus for bus signals that:

- Have bus elements that have different sample rates
- Cross model reference boundaries, if the referenced model only uses a few of the bus elements.

Compared with nonvirtual buses, virtual buses reduce memory requirements. Virtual buses do not require a separate contiguous storage block. During simulation, virtual buses execute faster because they do not require copying data to and from that block. The generated code also executes faster for virtual buses than for nonvirtual buses.

Nonvirtual Bus Usage Guidelines

Use nonvirtual buses to:

- Display and log bus signals with a Scope block.

- Construct an array of buses.
- Have bus data cross MATLAB Function block or Stateflow chart boundaries.
- Interface with external code through an S-function.
- Package bus data as structures in the generated C code.

Generated code represents a nonvirtual bus as a structure. The structure can be helpful for tracing the correspondence between the model and the code. Generated code for nonvirtual buses can result in multiple copies of some bus signals. For an example of the difference in generated code for virtual and nonvirtual buses, see “Generate Code for Buses” on page 65-23. For additional guidelines for generating code for nonvirtual buses, see “Group Signals into Structures in the Generated Code Using Buses” (Simulink Coder).

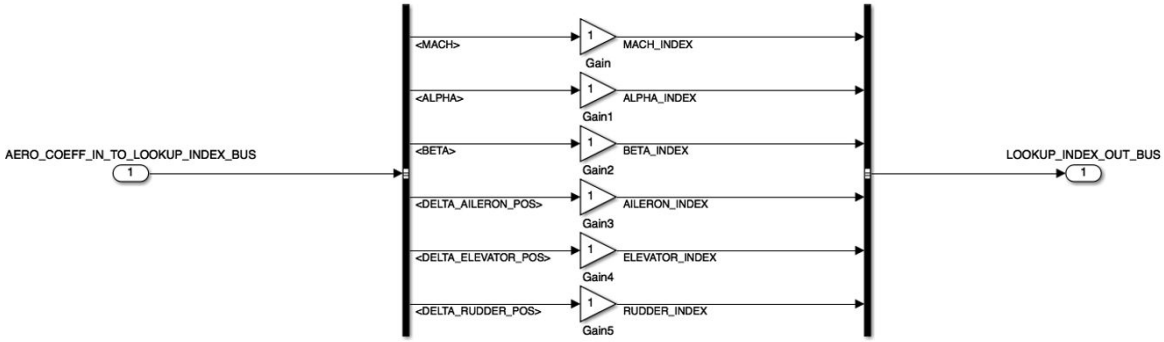
All signals in a nonvirtual bus input to a block must use the same sample time, even if the elements of the associated bus object specify inherited sample times. You can use a Rate Transition block to change the sample time of an individual signal, or of all signals in a bus.

Bus Element Port Usage Guidelines

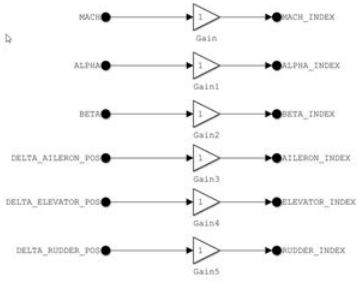
For models that include bus signals composed of many bus elements that feed subsystems, consider using the In Bus Element and Out Bus Element blocks. You can use these bus element port blocks instead of Inport with Bus Selector blocks for inputs, and Outport with Bus Creator blocks for outputs. These bus element port blocks:

- Reduce signal line complexity and clutter in a block diagram.
- Make it easier to change the interface incrementally.
- Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Selector and Goto block configuration.

For example, here is a model that uses Inport, Bus Selector, Bus Creator, and Outport blocks.



Here is an equivalent model that uses bus element port blocks.



Consider using bus element ports for models with bus signals that you anticipate changing frequently during the model development process.

Bus element port blocks have these restrictions:

- The Out Bus Element output bus is a virtual bus.
- Bus objects associated with signals used with bus element port blocks are ignored.
- You cannot specify the underlying Inport or Outport block specifications, such as word length.

You can refactor a subsystem interface that uses Inport, Bus Selector, Bus Creator, and Outport blocks to use In Bus Element and Out Bus Element blocks. Conversion operations are supported only when the signal lines or blocks do not have any extra specification. You can use single-click operations to:

- Convert Inport and Bus Selector blocks in a subsystem to In Bus Element blocks.

- Convert Outport and Bus Creator blocks in a subsystem to Out Bus Element blocks.
- Transform input or output interfaces of subsystems to use bus element port blocks.

For more information, see “Simplify Subsystem Bus Interfaces” on page 65-29.

Array of Buses Usage Guidelines

Combine multiple nonvirtual buses into an array. An array of buses is equivalent to an array of structures in MATLAB. An example of using an array of buses is to model a multi-channel system. You can model all the channels using the same bus object, although each of the channels can have a different value.

Each element in an array of buses must be nonvirtual and must have the same bus object. Each bus object has the same signal name, hierarchy, and attributes for its bus elements. Arrays of buses require the use of bus objects. For details, see“Combine Buses into an Array of Buses” on page 65-118.

Mux Usage Guidelines

To combine signals of same type into a vector, you can use a Mux block. A mux is a special kind of noncontiguous (virtual) vector. You can use a mux anywhere that you could use an ordinary (contiguous) vector. For example, you can perform calculations on a mux. The computation affects each constituent value in the mux, as if the values existed in a contiguous vector. Using a mux to perform computations on multiple vectors avoids the overhead of copying the separate values to contiguous storage. Also, you can use a Mux block to create a vector of function calls.

To combine a vector or matrix, you can use a Vector Concatenate or Matrix Concatenate block. These blocks are useful for creating an output signal that is contiguous.

If you want index-based access, use a Mux block. For name-based access, use a bus.

Concatenated Contiguous Output Signal Guidelines

You can combine a vector or matrix by using a Vector Concatenate or Matrix Concatenate block. These blocks are useful for creating an output signal that is contiguous. You can use this concatenation in mathematical operations. For examples of using these blocks, see the Vector Concatenate and Matrix Concatenate block documentation.

Getting Started with Buses

In this section...

You can combine signals into a bus signal and then access the bus as a whole or select specific signals from the bus. These examples show the fundamentals of creating and using buses in models and in generated code. For additional information, see “Buses” on page 65-3.

Example	Description
“Create and Use Virtual Buses” on page 65-17	Virtual buses provide the simplest approach for using buses to reduce signal clutter in a block diagram.
“Create and Use Nonvirtual Buses” on page 65-20	Nonvirtual buses support modeling components (such as S-functions or MATLAB Function blocks) that require explicitly specified interfaces.
“Generate Code for Buses” on page 65-23	Generated code for virtual and nonvirtual buses differs. Code generation for a nonvirtual buse produces a structure, which can be helpful for tracing the correspondence between a model and its generated code.
slexBusExample	Simple examples that introduce using bus-related blocks, including animations for smart editing of bus signals.

Tip For models that include bus signals composed of many bus elements that feed subsystems, consider using the In Bus Element and Out Bus Element blocks. You can use these bus element port blocks instead of Inport with Bus Selector blocks for inputs, and Outport with Bus Creator blocks for outputs. These bus element port blocks:

- Reduce signal line complexity and clutter in a block diagram.
- Make it easier to change the interface incrementally.

- Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Selector and Goto block configuration.

For more information, see “Simplify Subsystem Bus Interfaces” on page 65-29.

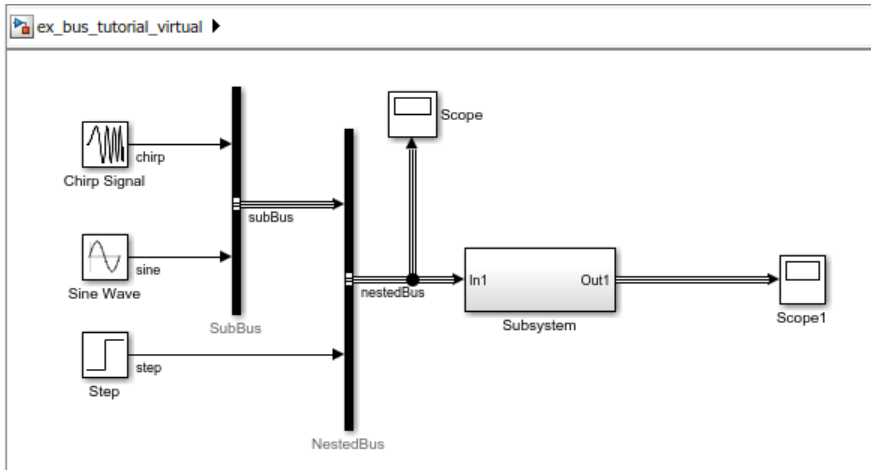
These examples are simple, to focus on the basic steps in creating and using buses. Buses are most useful when you have many signals that make sense to combine to reduce visual complexity. The examples also include steps to label blocks and signals, to clarify the relationship between signals and buses and between blocks. If you choose to build the example models step-by-step, you can skip those steps if you like.

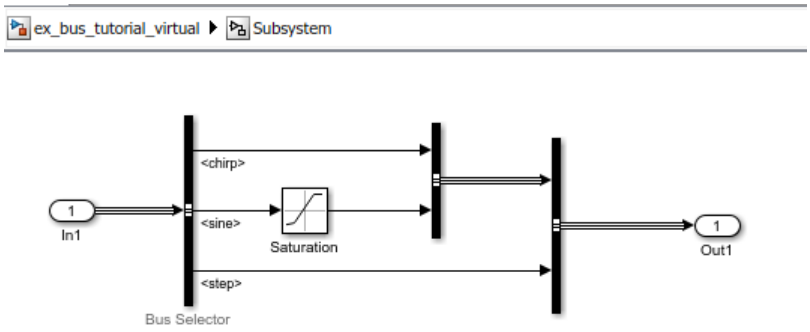
Create and Use Virtual Buses

This example shows how to combine signals into virtual buses. The model selects individual signals (bus elements) from a virtual bus and uses the bus elements as individual signals.

Tip To change bus element values without adding Bus Selector and Bus Creator blocks that select bus elements and reassemble them into a bus, you can use a Bus Assignment block. For details, see “Assign Signal Values to a Bus” on page 65-53.

To see the completed model, open the `ex_bus_tutorial_virtual` model. When you simulate the model, the bus signal lines indicate that the buses are virtual.





Perform these steps to gain experience creating and using virtual buses.

1. From the Simulink Start Page, select a blank model template.
2. In the Simulink Editor, add a Chirp Signal block and a Sine Wave block.
3. Create a bus for the signals from the two blocks. Drag to select the blocks and in the action bar that appears, click **Create Bus**.

   Simulink adds a Bus Creator block and connects the input signals to that block.
4. By default, the Bus Creator block name does not appear. To add a block name, select the block and from the action bar that appears, select **Show Block Name**. Then edit the name, changing it from `Bus Creator` to `SubBus`.

5 You do not have to label the signals in a bus. However, labeling makes it easier to see the relationship between bus element signals and bus signals. Label the output signal for the Chirp Signal block. Right-click the signal and select **Properties**. In the **Signal name** property, enter `chirp`. Similarly, set the Sine Wave signal name to `sine`.

Note Inputs to a Bus Creator block must have unique names. If there are duplicate names, the Bus Creator block appends `(signal#)` to all input signal names, where `#` is the input port index.

---

6 Add a Step block below the Sine Wave block.

7 To create a nested bus, add a Bus Creator block to the right of the current blocks. Connect the signal from the `SubBus` block and the signal from the Step block to the second Bus Creator block.

8 Label the output signal from the `SubBus` block `subBus` and the signal from the Step block `step`.

9 Show the block name for the Bus Creator block that creates the nested bus. Change the name to `NestedBus`.

10 Attach a Scope block to the `nestedBus` signal.

11 To the right of the `NestedBus` block, add a Subsystem block and connect the `NestedBus` output signal to the subsystem.

12 Connect the Subsystem block output port to a Scope block.

13 In the subsystem, disconnect the Inport and Outport blocks and insert a Bus Selector block to the right of the Inport block. Connect the Inport block to a Bus Selector block.

14 Show the Bus Selector block name. Change the name to `BusSelector`.

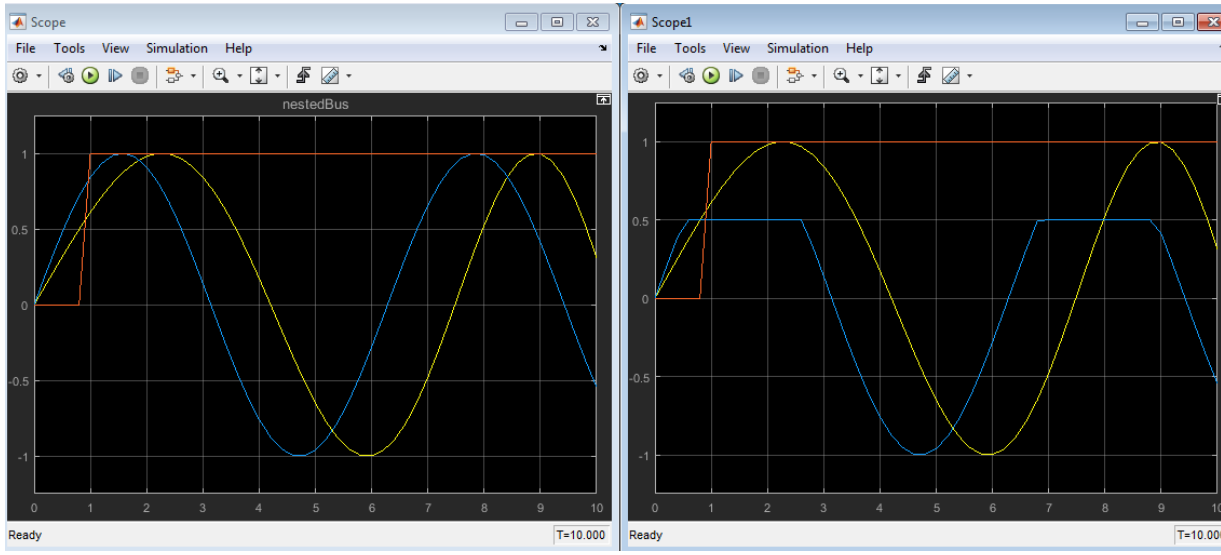
15 To the right of the Bus Selector block, add a Saturation block and set its **Lower limit** parameter to `-inf`.

16 Combine the `chirp` signal and the Saturation block output signal into a bus.

17 Combine the bus signal and the `step` signal into a nested bus.

18 Connect the nested bus to the Outport block.

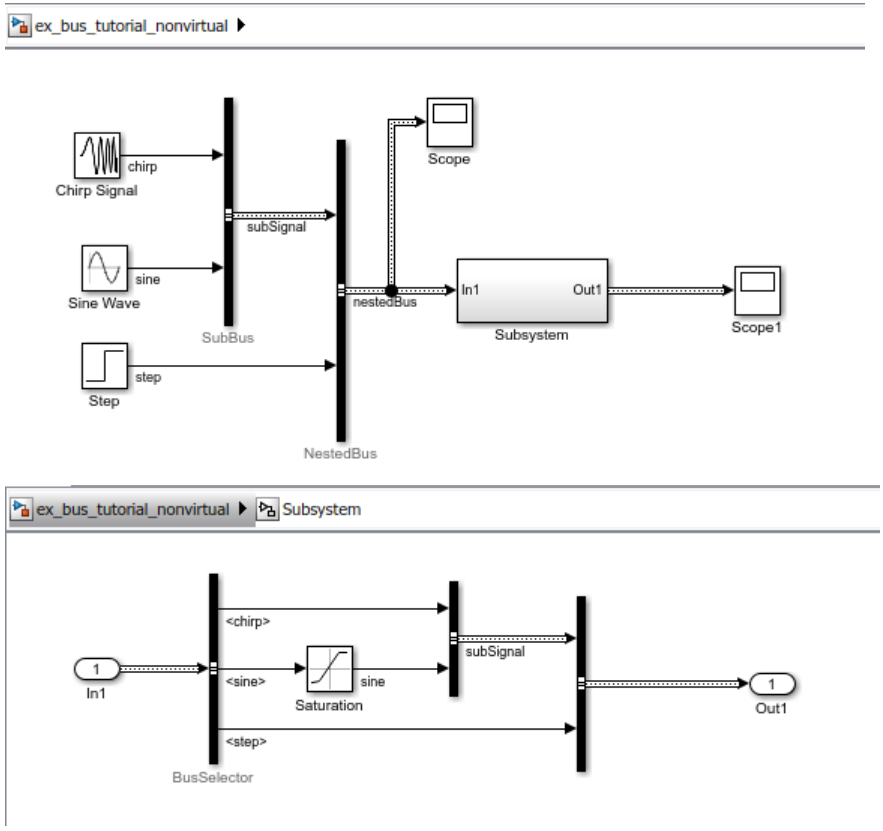
19 To see the simulation results, simulate the model and open the Scope blocks.



Create and Use Nonvirtual Buses

This example changes the virtual buses used in the `ex_bus_tutorial_virtual` model to nonvirtual buses. To see the completed model, open the `ex_bus_tutorial_nonvirtual` model. Nonvirtual buses are required for certain modeling situations. Generating code for a nonvirtual bus represents the bus as a structure. For more information about when to use nonvirtual buses, see “Nonvirtual Bus Usage Guidelines” on page 65-11.

When you simulate the model, the bus signal lines indicate that the virtual are converted to nonvirtual buses.



Perform these steps to gain experience creating and using nonvirtual buses.

1. Open the `ex_bus_tutorial_virtual` model.
2. Bus signals do not specify whether they are virtual or nonvirtual; they inherit that specification from the block in which they originate. Every block that creates or requires a nonvirtual bus must have an associated bus object.

   For the `SubBus` block, specify to produce nonvirtual bus output. In the Block Parameters dialog box, set **Output data type** to `Bus: subBus`. This setting uses the `subBus` bus object, which provides bus properties that Simulink uses to validate the bus signal.

   Also, select the **Output as nonvirtual bus** parameter.

Note When you use bus objects to create nonvirtual buses, the bus object must be in the base workspace before simulating the model. You need to define the bus object or use an already defined bus object. To simplify this example, when you open the model, a model callback loads the necessary bus objects into the base workspace. To see the callback, open **File > Model Properties > Model Properties** and open the **Callbacks** tab.

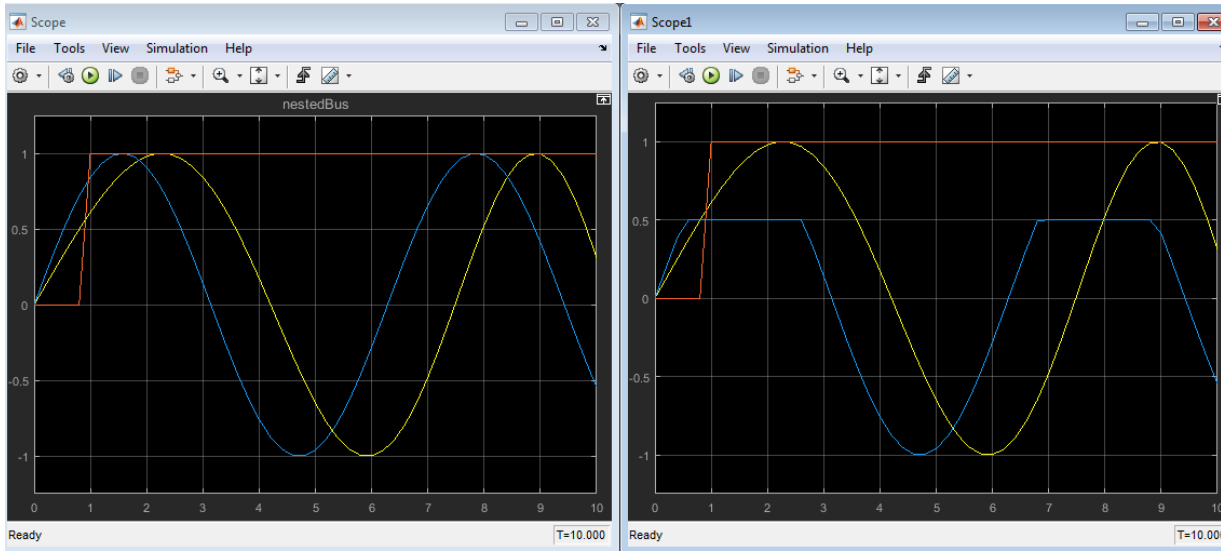
For information about creating bus objects, see "Create Bus Objects" on page 65-70.

3 In the `NestedBus` block, set **Output data type** to `Bus: topBus` and select the **Output as nonvirtual bus** parameter.

4 The `subBus` bus object expects the second input signal in the bus to be called `sine`. Although the Bus Selector block selected the `sine` signal from the bus, the default name of the output signal of the Saturation block is not `sine`. Use the **Signal Properties** dialog box to name the Saturation block output signal `sine`.

5 The `topBus` bus object expects the first input signal in the bus to be called `subSignal`. Use the **Signal Properties** dialog box to name the bus signal `subSignal`.

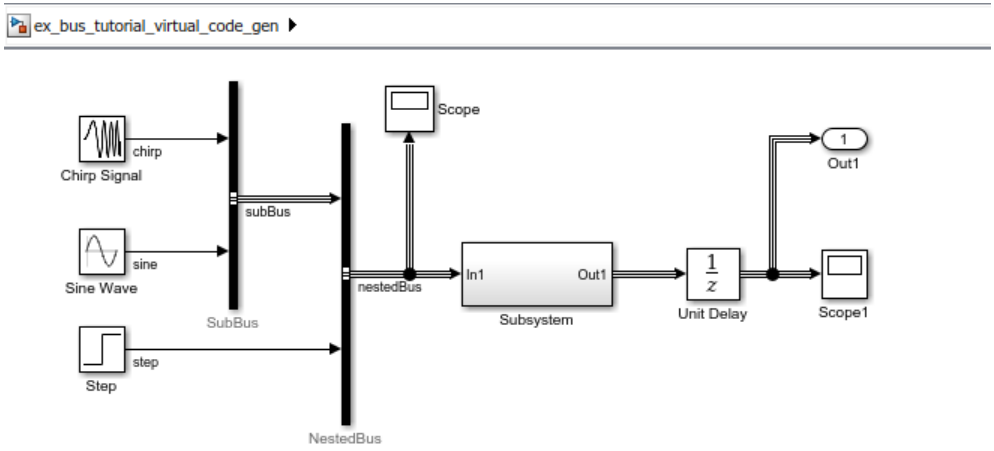
6 To see the simulation results, simulate the model and open the Scope blocks. The results are the same as when you simulate the `ex_bus_tutorial_virtual` model that you used as a base for this model.



Generate Code for Buses

The simulation results are the same for the model that uses virtual buses (`ex_bus_tutorial_virtual`) and for the model that uses nonvirtual buses (`ex_bus_tutorial_nonvirtual`). However, the generated code is different.

Adding a Unit Delay block and an Outport block after the Subsystem block in each of the models helps to highlight the differences in the generated code.



Generated Code for the Virtual Bus Model

Generate code from the `ex_bus_tutorial_virtual_code_gen` model.

The virtual buses do not affect the generated code. For example, in the generated file `ex_bus_tutorial_virtual_code_gen.c`, the algorithm in the model `step` function effectively implements three Unit Delay blocks (one for each meaningful signal, such as `chirp`, that passes through the block).

```
/* UnitDelay: '<Root>/Unit Delay' */
rtb_chirp = ex_bus_tutorial_virtual_code_DW.UnitDelay_1_DSTATE;

/* UnitDelay: '<Root>/Unit Delay' */
rtb_signal2 = ex_bus_tutorial_virtual_code_DW.UnitDelay_2_DSTATE;

/* UnitDelay: '<Root>/Unit Delay' */
rtb_step = ex_bus_tutorial_virtual_code_DW.UnitDelay_3_DSTATE;
```

Generated Code for the Nonvirtual Bus Model

For the nonvirtual bus model, the **Output data type** is set to `Bus: topBus` and Scope blocks are commented out, because Scope blocks are not needed for the generated code and do not support code generation.

Generate code from the `ex_bus_tutorial_nonvirtual_code_gen` model.

The nonvirtual buses appear in the generated code as structures. Each `Simulink.Bus` object appears as a structure type. The type definitions appear in `ex_bus_tutorial_nonvirtual_code_gen_types.h`.

```
typedef struct {
  real_T chirp;
  real_T sine;
} subBus;

typedef struct {
  subBus subSignal;
  real_T step;
} topBus;
```

The algorithm in the model `step` function can implement the Unit Delay block as a single line of code. The block state and output are structures of type `topBus`.

```
  /* UnitDelay: '<Root>/Unit Delay' */
  rtb_UnitDelay = ex_bus_tutorial_nonvirtual_c_DW.UnitDelay_DSTATE;
```

Bus Creation Using Bus Creator Blocks

Tip For models that include bus signals composed of many bus elements that feed subsystems, consider using the In Bus Element and Out Bus Element blocks. For details, see "Simplify Subsystem Bus Interfaces" on page 65-29.

Bus Signal Naming

The Bus Creator block assigns a name to each signal on the bus that it creates. You can then refer to signals by name when you search for their sources (see "Browse Signals in a Bus" on page 65-26) or select signals for connection to other blocks.

Specify one of the following signal naming options:

- Each signal on the bus inherits the name of the signal connected to the bus (the default).

  Inputs to a Bus Creator block must have unique names. If there are duplicate names, the Bus Creator block appends the port index number to all input signal names.

  The Bus Creator block generates names for bus signals whose corresponding inputs do not have names. The names are in the form `signaln`, where `n` is the number of the port the input signal connects to.
- Each input signal must have a specific name.
- If the bus output data type is a bus object, bus signal names use the corresponding bus object element names.

You can change the name of any signal by editing the name on the block diagram or in the Signal Properties dialog box. If you change the signal name while the Bus Creator Block Parameters dialog box is open,you can see the updated name in the dialog box by clicking **Refresh**.

Browse Signals in a Bus

The **Signals in the bus** list on a Bus Creator Block Parameters dialog box displays a list of the signals entering the block. You can view all signals entering the block, including the signals entering via buses. An arrow next to a signal indicates that the signal is itself a bus. To display the contents of that bus, click the arrow.

When you modify the **Number of inputs** parameter, click **Refresh** to update the list of signals. After editing the name of an input signal, update the list by licking **Refresh**.

To find the source of any signal entering the block, select the signal in the **Signals in the bus** list and click the **Find** button. Simulink opens the subsystem containing the signal source, if necessary, and highlights the icon of the source.

Rearrange Signals in a Bus

To rearrange the signals in the bus, use buttons such as **Up** or **Down**.

You can select multiple contiguous signals in the **Signals in the bus** list to reorder or remove. You cannot rearrange leaf signals within a bus. For example, you can move bus signal `Bus1` up or down in the list, but you cannot reorder any of the bus elements of `Bus1`.

After making your edits, click **Apply**.

Note If you change elements or the order of elements in the Bus Creator block and the incoming bus is a nonvirtual bus, Simulink reports inconsistency errors when you compile the model.

Bus Object as the Output Data Type

You can use a bus object as the bus output data type for a Bus Creator block. Using a bus object can provide strong data typing with an explicit signal interface. Model referencing requires using bus objects for bus signals that cross model reference boundaries. For more information, see “When to Use Bus Objects” on page 65-64.

To create a nonvirtual bus using a Bus Creator block, use these settings.

- For the **Output data type** parameter, use a bus object.
- Select **Output as nonvirtual bus**.

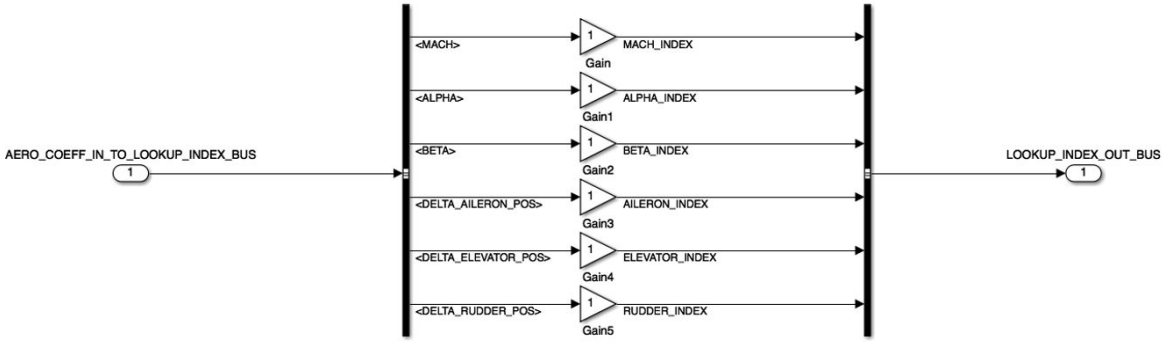
Simplify Subsystem Bus Interfaces

In this section...

The In Bus Element and Out Bus Element blocks provide a simplified and flexible way to use bus signals as inputs and outputs to subsystems. The In Bus Element block is equivalent to an Inport block combined with a Bus Selector block. The Out Bus Element block is equivalent to an Outport block combined with a Bus Creator block.

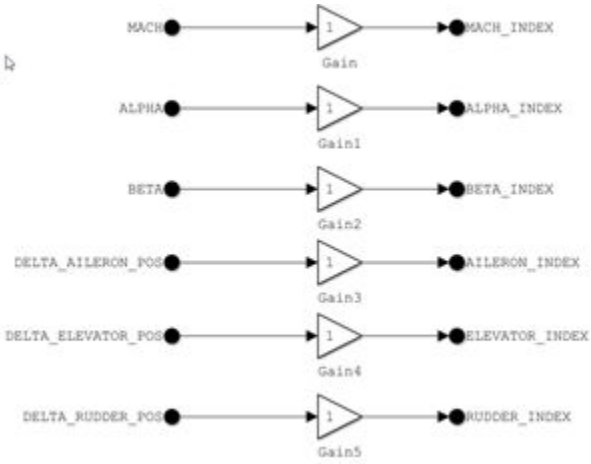
Using Bus Creator and Bus Selector Blocks

This model uses Inport, Bus Selector, Bus Creator, and Outport blocks.



Using Simplified Approach

Here is an equivalent model that simplifies the interface by using bus element port blocks.



To work with buses at subsystem interfaces, consider using In Bus Element and Out Bus Element blocks. This bus element port block combination:

- Reduces signal line complexity and clutter in a block diagram.
- Makes it easy to change the interface incrementally.
- Allows access to a bus element closer to the point of usage.
  - For input, avoid a configuration that contains duplicate Inport blocks and a Bus Selector, Goto, and From blocks.
  - For output, avoid a configuration that contains duplicate Goto, From, and Bus Creator blocks.

Tip To refactor a subsystem interface that uses Inport, Bus Selector, Bus Creator, and Outport blocks to use In Bus Element and Out Bus Element blocks, you can use Simulink Editor action bars. For details, see “Convert Models to Use Bus Element Ports” on page 65-34

.

Bus Element Ports

The simplified interface involves creating bus element ports. Use In Bus Element blocks to select elements from a bus signal that is fed to a subsystem. For nonbus signals

(including array of buses signals) that feed a subsystem, the In Bus Element block can pass (if no signals are selected) through the value of the input signal for use within the subsystem.

Use Out Bus Element blocks to combine subsystem signals into a virtual bus to output from the subsystem.

You can use bus element port blocks with virtual buses. For nonvirtual bus signals, array of buses signals, and nonbus signals, these limitations apply:

- For array of bus signals and nonbus signals, the bus element port blocks can only pass through the whole signal, rather than selecting individual elements of the signal.
- An Out Bus Element block outputs a virtual bus signal from the subsystem.

The In Bus Element block is of block type Inport. The Out Bus Element block is of block type Outport. The bus element port blocks support inherited workflows. You cannot use the Block Parameters dialog box of a bus element port block to specify bus element attributes, such as data type or dimensions.

In the same subsystem, you can use a combination of bus element port blocks with Inport and Outport blocks. However, to improve the readability of the model, define a bus interface for a subsystem by using bus element port blocks throughout the subsystem.

Note If you save a model containing bus element port blocks to a version of Simulink earlier than R2017a, Simulink converts the model to use a subsystem that contains Bus Selector and Bus Creator blocks, as appropriate.

Create Bus Element Ports

For a new subsystem, creating bus element ports involves adding In Bus Element blocks to select subsystem input signals and Out Bus Element blocks to create virtual bus output signals for the subsystem. For an example showing the workflow for adding bus element ports, see the In Bus Element documentation.

Note The In Bus Element block has two different names, depending on the Simulink library in which it appears. The functionality of both blocks is the same.

- In the Sources library and the Ports & Subsystems library — In Bus Element

- In the Signal Routing library — Bus Element In

The Out Bus Element block has two different names, depending on the Simulink library in which it appears. The functionality of both blocks is the same.

- In the Sinks library and the Ports & Subsystems library — Out Bus Element
- In the Signal Routing library — Bus Element Out

Add In Bus Element Blocks

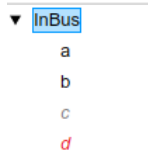
To add an In Bus Element block, you can:

- Drag the block from the Library Browser. This action adds a port or adds a new element if a port with the same name exists.
- Use quick insert. This action adds a port.
- Copy the block from an existing block. Either use copy and paste or right-click and drag the block. If you use the right-click approach, specify whether to use the same port as the original block for new block or to add a subsystem port.
- In the Block Parameters dialog box list of input signals, select a signal and click  .

Tip Before selecting a signal, make sure that a bus input signal is connected to a subsystem input port.

To select a signal from the input port, use one of these approaches. To select multiple signals from an input bus signal, create multiple In Bus Element blocks, one for each selected signal.

- Using the Block Parameters dialog box, select from the signals that are in the bus connected to this port. The signals listed in black are already selected and used in the subsystem, and signals in grey are available but are not used already. Signals in red are not available in the input bus signal. For example, signals a and b are already selected, signal c is available to select, and signal d is not available.



After you select the signals, click 

- In the Simulink Editor, edit the element part of the block icon text. If the port is already connected outside the subsystem, you can select from a list of available signals. For example, if you did a right-click copy of an In Bus Element port block and used the existing port, you can click on text to change the selected element.

If you delete the b (the element part of the block icon text), then you get a list of signals that you can select.

To pass through a whole signal, leave the element section of the block icon text empty.

You can specify the background color for bus element port blocks, using the Block Parameters dialog box **Set color** option. This action sets the color of blocks associated with selected elements, or to all blocks if you do not select elements. You can change the name of the port using the Block Parameters dialog box.

Add Out Bus Element Blocks

To output multiple signals from a subsystem as a bus signal, create multiple Out Bus Element blocks, one for each signal that you want to include in the bus. To add an Out Bus Element block, you can:

- Drag the block from the Library Browser. This action adds a port or adds a new element if a port with the same name exists.

- Use quick insert. This action adds a port.
- Copy the block from an existing block. Either copy and paste or right-click and drag the block. If you use the right-click approach, specify whether to use the same port as the original block for the new block or to add a subsystem port.
- In the Block Parameters dialog box, click  . To change the signal name, double-click the signal name in the tree view or in the block diagram and edit the icon text.

If an Out Bus Element block creates a signal `A`, then another Out Bus Element block for the same port cannot specify signal `A` (or a child of signal `A`) as an element.

To add a subbus, in the Block Parameters dialog box, click  . To remove blocks associated with selected elements, click  .

You can reorder bus elements by dragging and dropping a signal in the list of signals in the Block Parameters dialog box.

You can specify the background color for bus element port blocks, using the Block Parameters dialog box **Set color** option. This action sets the color of blocks associated with selected elements, or of all blocks if you do not select elements.

Convert Models to Use Bus Element Ports

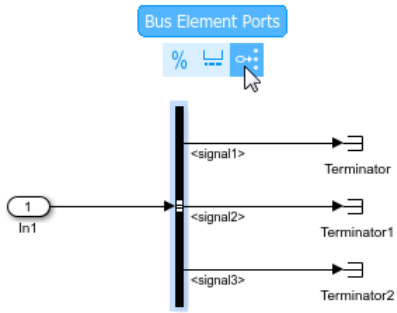
You can refactor a subsystem interface that uses Inport, Bus Selector, Bus Creator, and Outport blocks to use In Bus Element and Out Bus Element blocks. Conversion operations are supported only when the signal lines or blocks do not have any extra specification, including signal logging. You can:

- Convert Inport and Bus Selector blocks in a subsystem to In Bus Element blocks.
- Convert Outport and Bus Creator blocks in a subsystem to Out Bus Element blocks.
- Transform input or output interfaces of subsystems to use bus element port blocks.

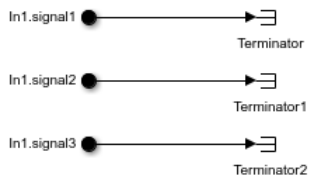
Convert Subsystem Bus Selector Blocks

You can convert a subsystem that uses Bus Selector blocks to use In Bus Element blocks instead.

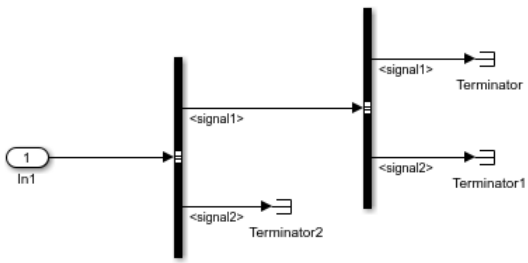
1. Click the Bus Selector block that is connected to the Inport block.
2. From the action bar, select **Bus Element Ports**.



The converted subsystem uses In Bus Element blocks.



You can do a similar conversion for multiple layers of Bus Selector blocks.



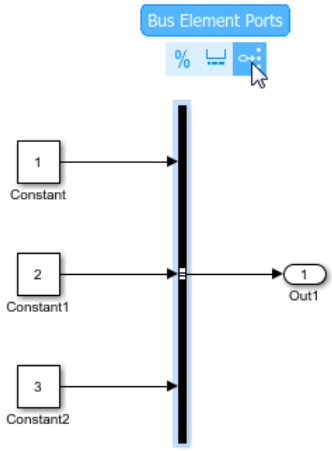
1. Perform the conversion on the Bus Selector block that is connected to the Inport block.
2. Convert the second Bus Selector block.

Note This action is not available if the Bus Creator block output signal has a branch.

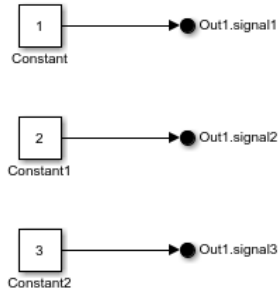
Convert Subsystem Bus Creator Blocks

You can convert a subsystem that uses Bus Creator blocks to use Out Bus Element blocks instead.

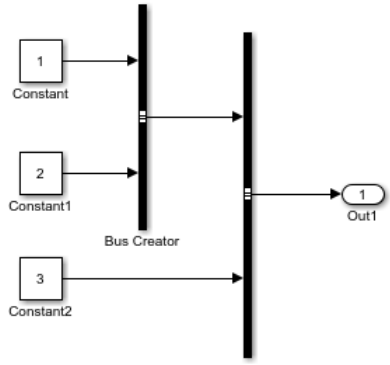
1. Click the Bus Creator block that is connected to the Outport block.
2. From the action bar, select **Bus Element Ports**.



The converted subsystem uses Out Bus Element blocks.



You can do a similar conversion for multiple layers of Bus Creator blocks.



1. Perform the conversion on the Bus Creator block that is connected to the Outport block.
2. Convert the second Bus Creator block.

Transform Subsystem Input and Output Interfaces

You can convert signals between subsystems to use In Bus Element and Out Bus Element blocks.

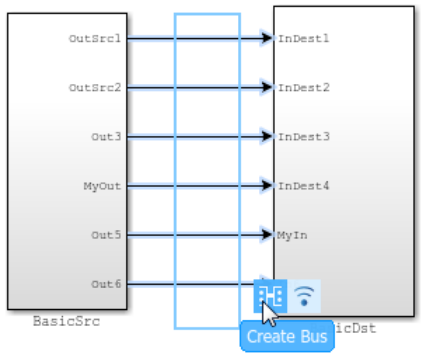
Note Conversion of existing subsystem inputs and outputs to use bus element ports creates virtual buses. If your model relies on the types of the original signals being nonvirtual buses, array of buses, or scalars, choose one of these options:

- Do not perform the conversion.
- Modify the model so that it works properly with the newly created virtual buses.

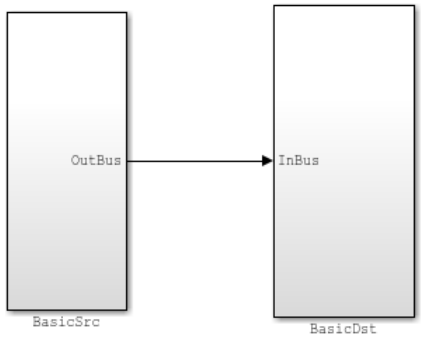
---

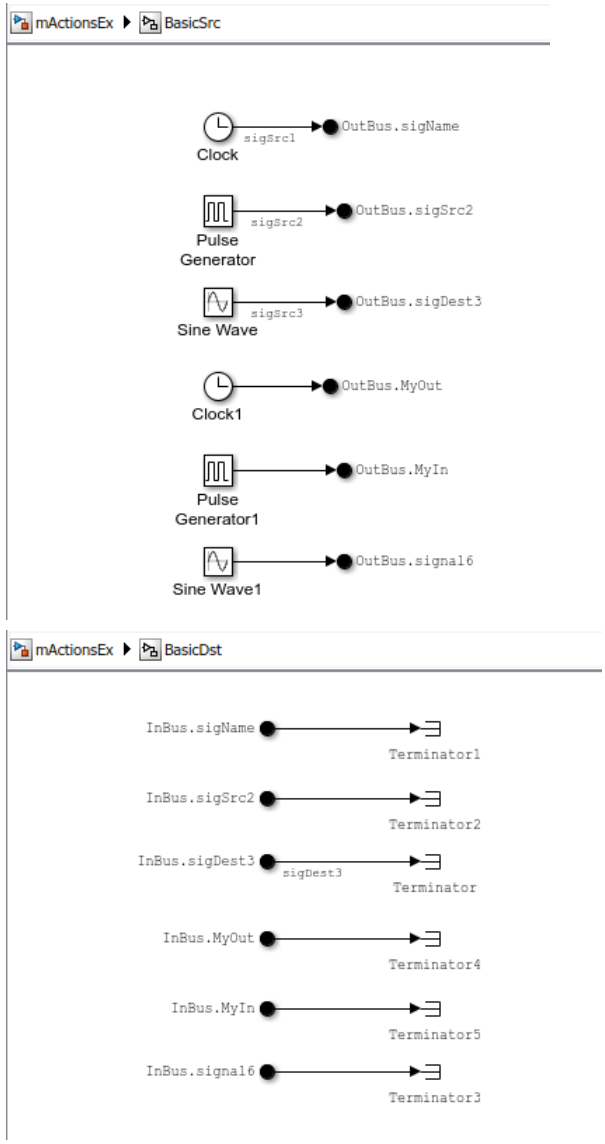
1. Perform a marquee selection of the signals that connect two subsystems.
2. From the action bar, select **Create Bus**.

   The conversion creates Out Bus Element blocks in the source subsystem and In Bus Element blocks in the destination subsystem.



In the converted model, there is one bus signal between the subsystems, and the `BasicSrc` and `BasicDst` subsystems use In Bus Element and Out Bus Element blocks, respectively.

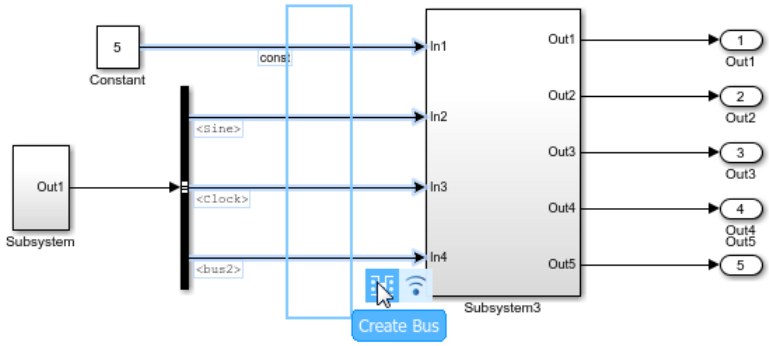




If the input of a subsystem is not directly connected to another subsystem, you can transform the input of the subsystem. If you transform the subsystem input, Simulink

inserts a Bus Creator block to maintain connectivity and the subsystem uses In Bus Element blocks.

1. Perform a marquee selection of the input signals of the subsystem.
2. From the action bar, select **Create Bus**.



The converted model uses Bus Creator blocks for subsystem inputs and Bus Selector blocks for subsystem outputs. The converted subsystem (`Subsystem3`) contains In Bus Element and Out Bus Element blocks.

Display Information About Buses

In this section...

Viewing information about bus signals can help you during model creation, debugging, and analysis. To view information about buses, you can use different approaches, depending on your modeling task:

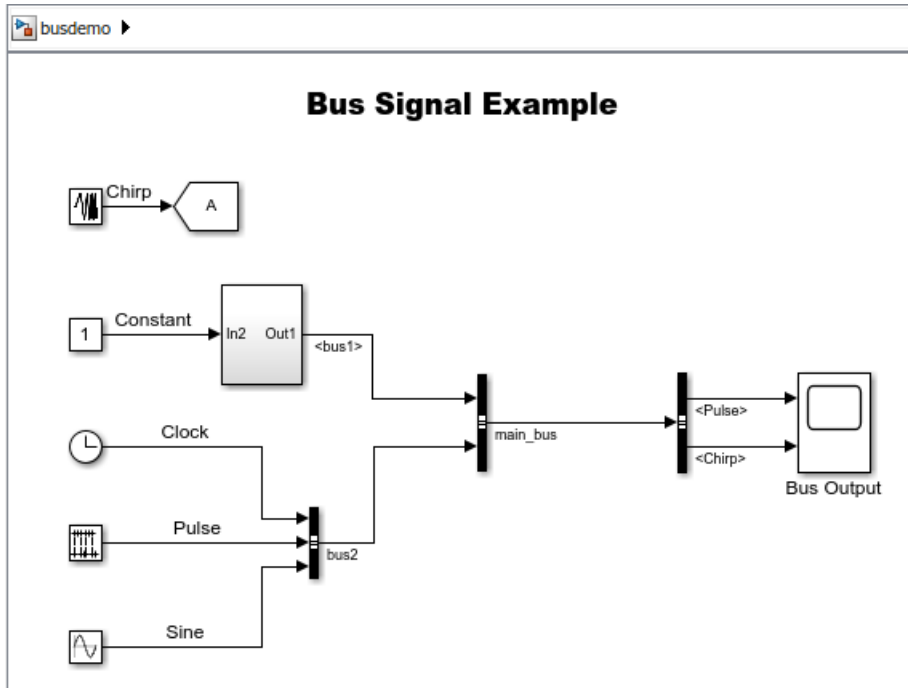
- To display bus signals in a bus hierarchy interactively, use the “Signal Hierarchy Viewer” on page 65-42.
- To display the value of a specific port or port values for a block before simulation, right click on the signal and select **Show Value Label of Selected Port**. For details, see “Port Value Display” on page 65-45.
- To display at the MATLAB command line the type and hierarchy of a bus signal use the `CompiledType` and `SignalHierarchy` parameters. For details, see “CompiledBusType and SignalHierarchy Parameters” on page 65-46.

Signal Hierarchy Viewer

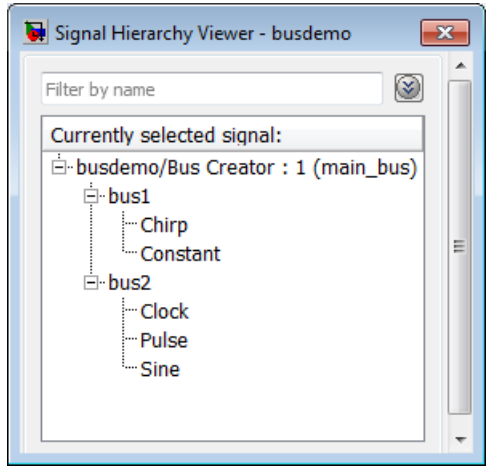
You can use the Signal Hierarchy Viewer to display information about a signal. To display the bus hierarchy:

1. Right-click a signal line.
2. Select the **Signal Hierarchy** option. The Signal Hierarchy Viewer dialog box appears.

For example, open the `busdemo` model.



Right-click the `main_bus` signal (output signal for the Bus Creator block), and select **Signal Hierarchy**.



Each Signal Hierarchy Viewer is associated with a specific model. If you edit a model while the associated Signal Hierarchy Viewer is open, the Signal Hierarchy Viewer reflects those updates.

You can also open the Signal Hierarchy Viewer in the Simulink Editor.

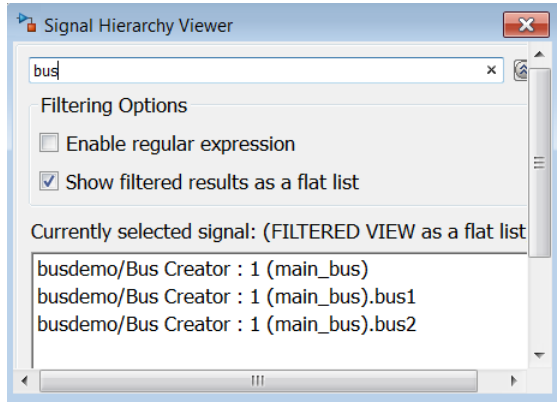
1 Select **Diagram > Signals & Ports > Signal Hierarchy**.

2 Select a signal.

Note To produce accurate results at edit time, the Signal Hierarchy Viewer requires that the model compiles successfully.

To filter the displayed signals, click the **Options** button on the right-hand side of the **Filter by name** edit box ().

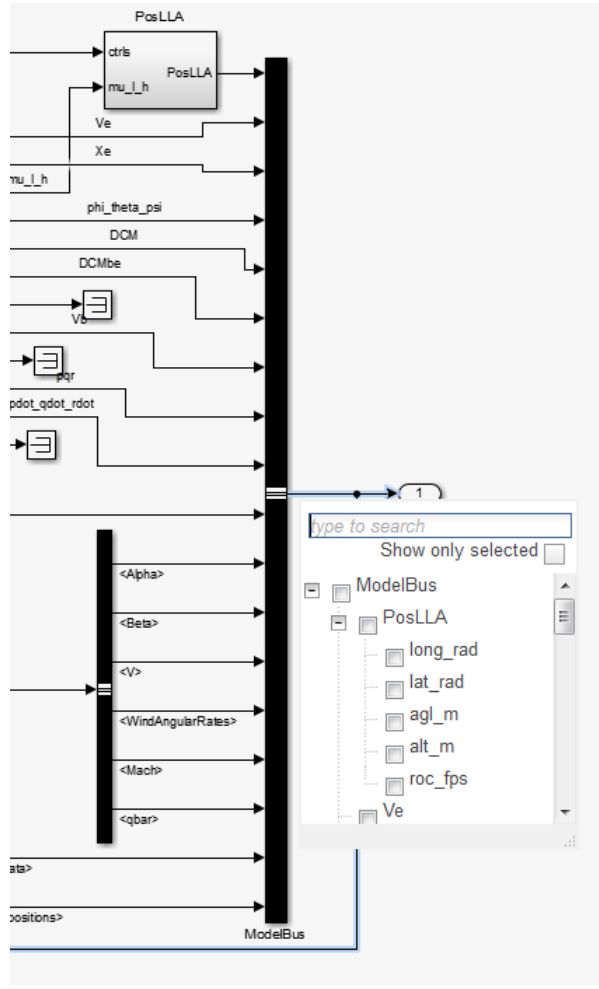
- To use MATLAB regular expressions for filtering signal names, select **Enable regular expression**. For example, to display all signals whose names end with a lowercase `r` (and their immediate parents), enter `r$` in the **Filter by name** edit box. For details, see "Regular Expressions" (MATLAB).
- To use a flat list format to display the list of filtered signals, based on the search text in the **Filter by name** edit box, select **Show filtered results as a flat list**. The flat list format uses dot notation to reflect the hierarchy of bus signals. This example shows a flat list format for a filtered set of nested bus signals.



Port Value Display

To display the value of a specific port or port values for a block before simulation, right click on the signal and select **Show Value Label of Selected Port**.

For bus signals, the **Show Value Label of Selected Port** option opens a dialog box where you can select from all signals in the bus. For example, in this model, you can see the dialog box for all signals that are contained in `ModelBus`.



For more information about port value display, see “Display Value for a Specific Port” on page 35-21.

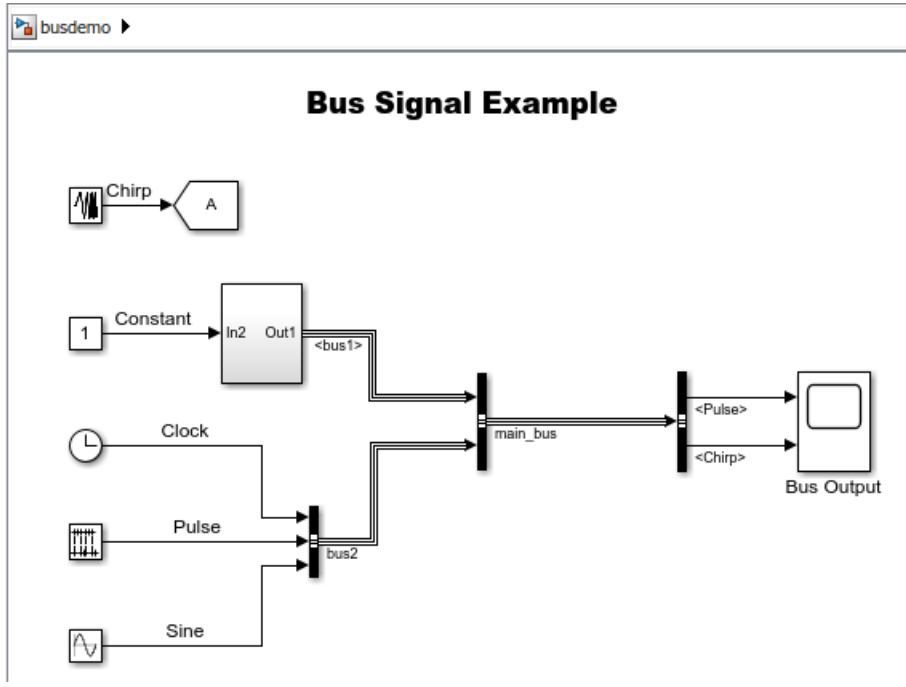
CompiledBusType and SignalHierarchy Parameters

To get information about the type and hierarchy of a bus signal in a compiled model, use these parameters with the `get_param` command:

- `CompiledBusType` — For a compiled model, returns information about whether the signal connected to a port is a bus and whether the signal is a virtual or nonvirtual bus.
- `SignalHierarchy` — If the signal is a bus, returns the name and hierarchy of the signals in the bus.

Before you use these commands, for `CompiledBusType`, update the diagram or simulate the model.

For example, open and simulate the `busdemo` model.



This code illustrates how you can use the `SignalHierarchy` and `CompiledBusType` parameters:

```
mdl = 'busdemo';
open_system(mdl)
% Obtain the handle a port
ph = get_param([mdl '/Bus Creator'], 'PortHandles');
% SignalHierarchy is available at edit time
sh = get_param(ph.Outport, 'SignalHierarchy')
% Compile the model
busdemo([],[],[],'compile');
bt = get_param(ph.Outport, 'CompiledBusType')
% Terminate the model
busdemo([],[],[],'term');
```

Bus-Capable Blocks

Bus-capable blocks can accept bus signals as input, produce bus signals as output, or both. Some bus-capable blocks work with nonvirtual buses, but not with virtual buses. Some bus-capable blocks have additional requirements for bus signals; see the block documentation for details.

Block	Input	Output
All virtual blocks	✓	✓
Assignment(nonvirtual buses)	✓	✓
Bus Assignment	✓	✓
Bus Creator	✓	✓
Bus Selector	✓	✓
Constant (nonvirtual buses)		✓
Data Store Memory (nonvirtual buses)	Has no input port, can store bus signals	
Data Store Read (nonvirtual buses)		✓
Data Store Write (nonvirtual buses)	✓	
Delay	✓ (special requirements)	✓ (special requirements)
From File (nonvirtual buses)		✓
From Workspace (nonvirtual buses)		✓
Interpolation Using Prelookup	✓	
Manual Switch	✓	✓
Memory	✓ (special requirements)	
Merge	✓ (special requirements))	

Block	Input	Output
Multiport Switch	✓ (special requirements)	
Prelookup		✓ (special requirements)
Rate Transition	✓ (special requirements)	
Signal Conversion	✓	✓ (special requirements)
Signal Specification	✓	✓
Switch	✓ (special requirements)	✓
To File (nonvirtual buses)	✓ (special requirements)	
To Workspace (nonvirtual buses)	✓	
Unit Delay	✓ (special requirements)	✓
Vector Concatenate(nonvirtual buses)	✓	✓
Zero-Order Hold	✓	✓

These modeling patterns support the use of buses. See the documentation for those features for any special considerations relating to the use of buses. Subsystems, models, and S-functions support the use of buses.

- Subsystems
- Model referencing
- S-Functions
- Stateflow charts
- MATLAB Function blocks
- MATLAB System blocks

Buses that contain signals of enumerated data types do not pass through a block that requires a nonzero scalar initial value (such as a Unit Delay block). Use a structure value to initialize signals with enumerated types.

Root level bus outputs are not logged when you select the **Output** configuration parameter. Use standard signal logging instead, as described in “Export Signal Data Using Signal Logging” on page 61-71.

Do not use signal logging for bus or array of buses signals directly from within a For Each subsystem. Either use a Bus Selector block to select the bus element signals to log or add an Outport block outside of the subsystem and then log that signal. For details, see “Log Signals in For Each Subsystems” on page 61-114.

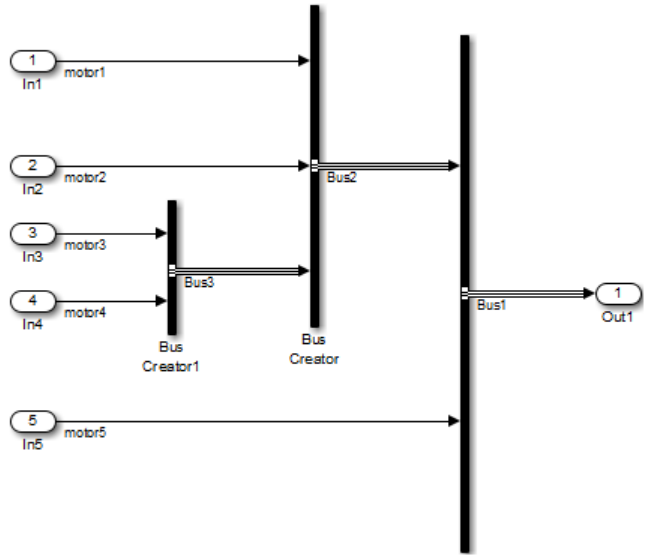
- “Select a Composite Signal Technique” on page 65-11
- “Getting Started with Buses” on page 65-16

Nest Buses

You can nest buses to any depth. To create a nested bus, use a Bus Creator block. If one of the inputs to the Bus Creator block is a bus, then the output is a nested bus. To select a signal within a nested bus, use a Bus Selector block.

For example, in the next model, the `Bus3` bus signal combines two signals, `motor3` and `motor4`. The `Bus2` signal combines the `Bus3` bus signal and the `motor1` and `motor2` signals. The `Bus1` signal combines the `Bus2` bus signal and the `motor5` signal.



All the signals retain their separate identities, as if no bus creation and selection occurred. You can use Bus Selector blocks to select individual signals from a nested bus.

The Simulink software automatically handles most of the complexities involved. For example, you can have Simulink repair broken selections in the Bus Selector and Bus Assignment block parameter dialog boxes due to upstream bus hierarchy changes. To enable these automatic repairs, in the **Configuration Parameters** dialog box, set the **Repair bus selections** diagnostic to `Warn and repair`. The repairs occur when you update a model. To save the repairs, save the model.

Circular Dependency in Bus Definitions

Nesting buses can produce a loop of Bus Creator, Bus Selector, and bus-capable blocks that inadvertently includes a bus as an element of itself. The resulting circular definition cannot be resolved and therefore causes an error.

The error message that appears specifies the location at which the Simulink software determined that the circular structure exists. The error is not really at any one location: the structure as a whole is in error. Nonetheless, the location cited in the error message can be useful for beginning to trace the definition cycle. However, the circular structure is not always obvious on visual inspection.

1. Begin by selecting a signal line associated with the location cited in the error message.
2. Right-click a signal and choose **Highlight Signal to Source** or **Highlight Signal to Destination**. See "Highlight Signal Sources and Destinations" on page 64-39 for more information.
3. Continue choosing signals and highlighting their sources and destinations until the cycle becomes clear.
4. Restructure the model to eliminate the circular bus definition.

Because the problem is a circular definition rather than a circular computation, the cycle cannot be broken by inserting additional blocks. You cannot fix the circular definition the way that you can break an algebraic loop by inserting a Unit Delay block. Restructure the model to eliminate the circular bus definition.

Assign Signal Values to a Bus

To assign the values of a signal to bus element, you can use a Bus Assignment block. Use a Bus Assignment block to change bus element values without adding Bus Selector and Bus Creator blocks that select bus elements and reassemble them into a bus.

Connect to the Bus Assignment block ports:

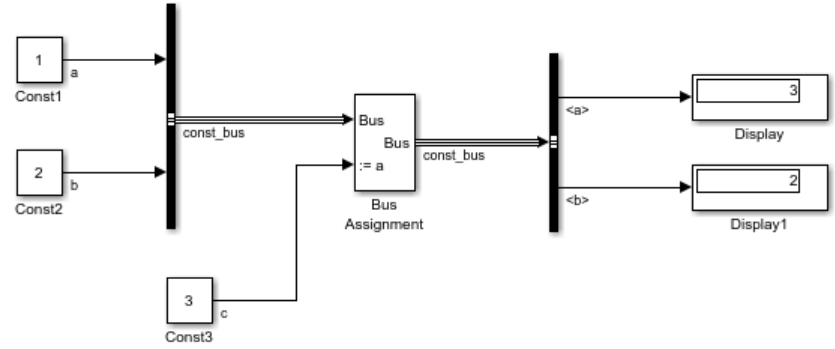
- The bus signal to which you want to assign the signal values
- The signals whose values you want to assign to specified bus elements

Connect the bus signal to the first input port of the Bus Assignment block, and one or more signals to be assigned to the other ports. The Block Parameters dialog box lists the signals available for assignment in the bus. The bus can be virtual or nonvirtual. Select the elements to which you want to assign signal values. If you specify more than one signal to assign values to, the Bus Assignment block adds ports.

The signals that you assign values to can be nonbus or bus signals. The signals must match the attributes of the signals in the original bus.

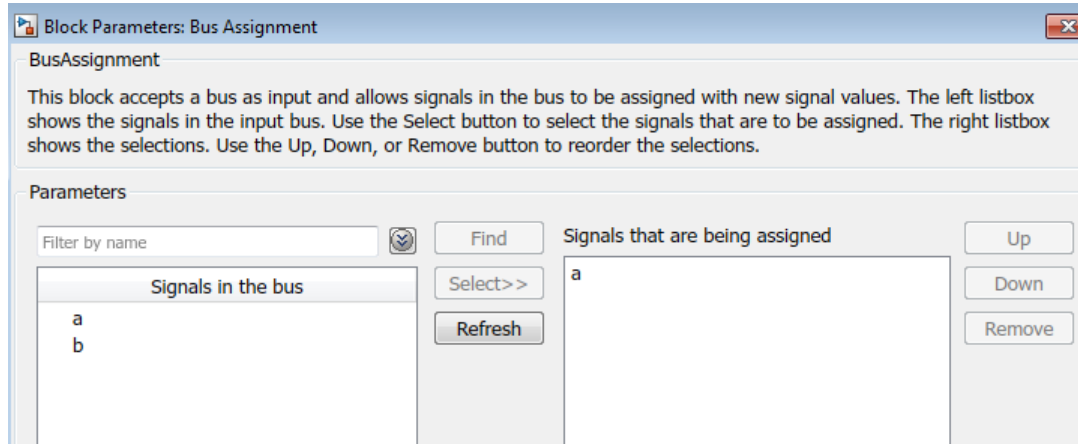
Update a Bus Element

This simple example illustrates the mechanics of using the Bus Assignment block. In more complex models, using a Bus Assignment block simplifies updating a bus to reflect the processing that occurs in a separate component, such as a subsystem or referenced model. Here is the model after you simulate it.



Some key steps in constructing this model are:

1. Connect two Constant blocks to a Bus Creator block. The value of signal `a` is 1, and the value of signal `b` is 2.
2. Connect the Bus Creator output signal `const_bus` to the first port of a Bus Assignment block. The bus elements `a` and `b` are available to assign new values to them.
3. Connect the Constant block output signal `c` to the second port of the Bus Assignment block.
4. For the Bus Assignment block, in the Block Parameters dialog box **Signals in the bus** list, select the `a` signal and click **Select>>**.



5. Use a Bus Selector to select signals `a` and `b` from the `const_bus` signal and connect those signals to Display blocks.
6. Simulate the model. The Display blocks show that the value of signal `a`, which was 1 when the `const_bus` bus was created, is now 3, reflecting the assignment of the `c` signal from the `Const3` block.

Correct Buses Used as Vectors

Using a bus signal as an input to a block that requires vector input makes a model less robust. Configuring a model to avoid using bus signals as vectors:

- Improves loop handling
- Produces clear error messages
- Contributes to consistent edit and compile-time behavior

Avoiding the use of bus signals as vectors also allows you to update your model to take advantage of several features that otherwise you could not use, such as

- Nonzero initialization of bus signals
- Bus support for blocks such as Constant, From File, and several others
- Arrays of buses

Three Approaches

The three approaches that you can use to correct bus signals used as vectors (muxes) to avoid an error are:

- “Use the Model Advisor” on page 65-56
- “Explicitly Add Bus to Vector Blocks” on page 65-57
- “Reorganize the Model” on page 65-58

Generally, using the Model Advisor is the most efficient approach.

Use the Model Advisor

1. In the Simulink Editor, select **Analysis > Model Advisor > Model Advisor**.
2. Select and run the Simulink “Check bus signals treated as vectors” check.

   The Model Advisor reports any cases of bus signals treated as vectors.
3. Follow the Model Advisor suggestions for correcting errors reported by the check.

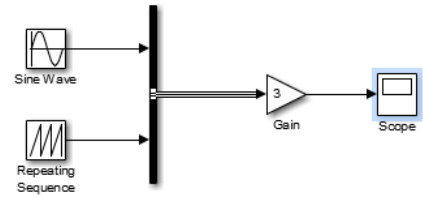
For additional information about using the Model Advisor, see “Select and Run Model Advisor Checks” on page 5-2.

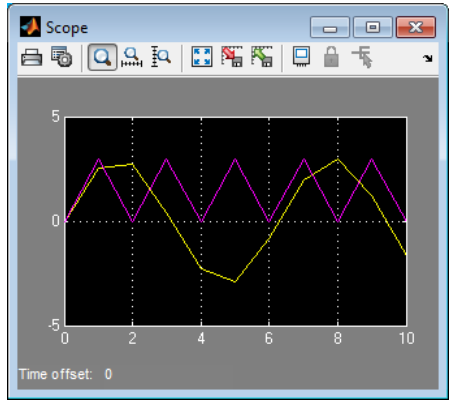
Explicitly Add Bus to Vector Blocks

You can explicitly add Bus to Vector blocks to convert the bus signal to a mux (vector), using one of these approaches:

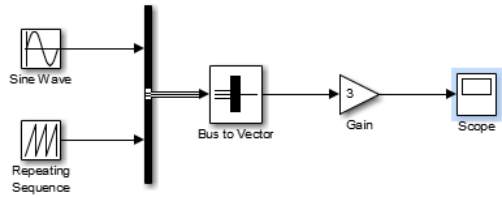
- To convert the bus to a vector explicitly, insert the Bus to Vector block into any bus used implicitly as a vector.
- Use the `Simulink.BlockDiagram.addBusToVector` function, which automatically inserts Bus to Vector blocks wherever needed.

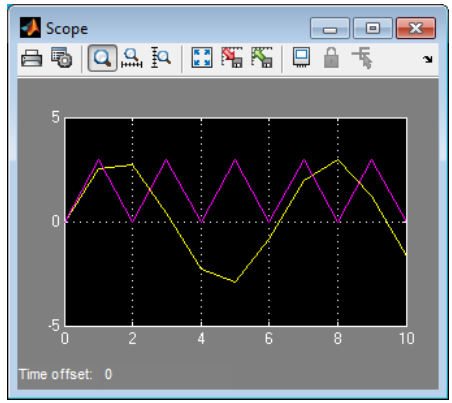
For example, this model treats a bus signal as a vector signal by using the bus as an input to a Gain block. The Scope block shows the simulation results.





This figure shows the same model, rebuilt after inserting a Bus to Vector block after the Bus Creator block.



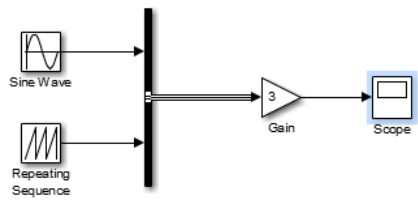


The results of simulation are the same in either case, but adding the Bus to Vector block avoids an error. The Bus to Vector block is virtual, and does not affect simulation results, code generation, or performance.

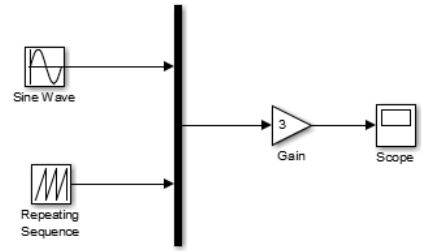
Reorganize the Model

You can replace blocks manually. Change the sources for a block that require vector inputs to avoid feeding a bus signal into a block that requires vector input.

For example, in the following model, the Gain block requires a vector signal. However, the input signal is a bus signal created by a Bus Creator block.



To provide the required vector signal for the Gain block, change the Bus Creator block to a Mux block.



Challenges with reorganizing the model manually include:

- It can be difficult to identify all the occurrences in a model. (The Model Advisor check identifies all occurrences in the model and helps you to correct them.)
- Dealing with many occurrences in a model is time-consuming and error-prone.
- Reorganizing the model to address this issue can interfere with other aspects of the model.

Bus to Vector Block Compatibility Issues

If you use **Save As** for a model in a version of the Simulink product before R2007a, Simulink replaces each Bus to Vector block with a null subsystem that outputs nothing. Before you can use the model, reconnect or otherwise correct each signal that used to contain a Bus to Vector block but now is interrupted by a null subsystem.

Specify Bus Signal Sample Times

In this section...

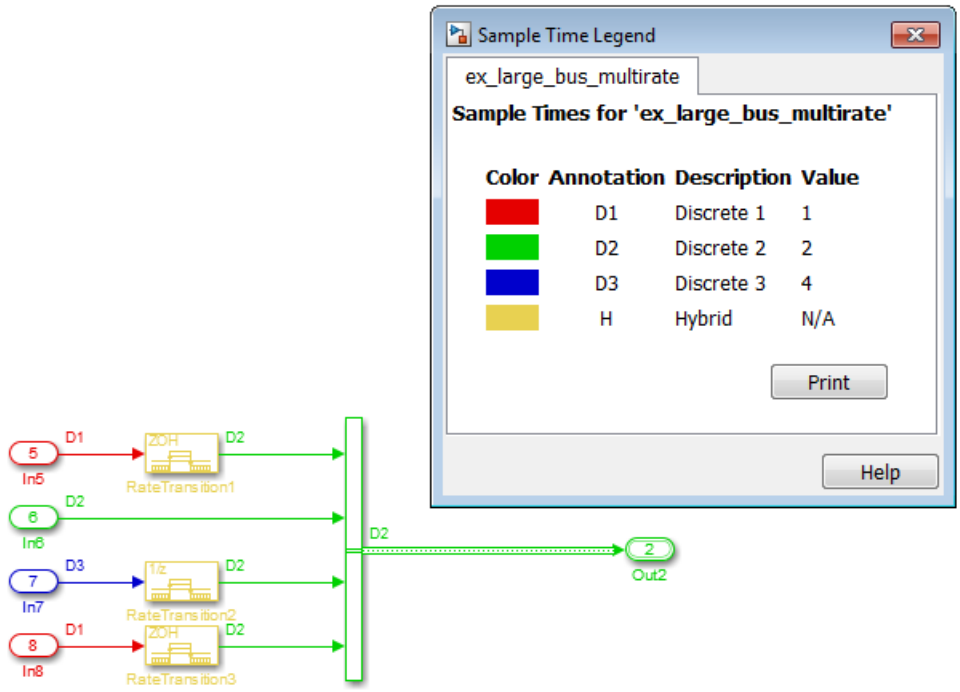
The technique that you use to combine signals that use different sample times depends on the virtuality of the bus.

- Virtual buses can combine signals that have different sample times.
- Nonvirtual buses require that every element signal has the same sample time.

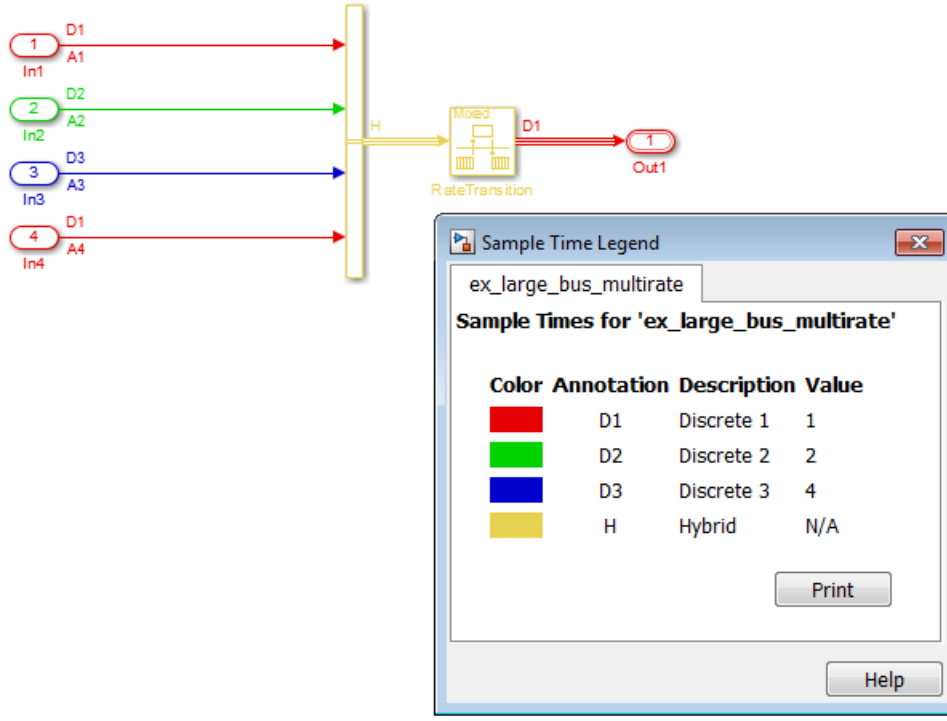
Sample Times for Nonvirtual Buses

All signals in a nonvirtual bus must have the same sample time, even if the elements of the associated bus object specify inherited sample times. Any bus operation that results in a nonvirtual bus that violates this requirement generates an error. All buses and signals input to a Bus Creator block that outputs a nonvirtual bus must have the same sample time.

To include signals or a bus in a nonvirtual bus that has elements with different sample times, you can change the sample time of bus element signals by inserting Rate Transition blocks upstream of the Bus Creator block.



However, some blocks automatically convert virtual buses to nonvirtual buses. Examples of these kinds of blocks include as root-level Outport and Inport blocks, MATLAB Function, and S-Function blocks. You can use a single Rate Transition block after a Bus Creator block to transition all the signal elements to a single sample time.



For more information about automatic conversion of virtual buses to nonvirtual buses, see “Bus Conversion” on page 65-153.

Specify Sample Times for Signal Elements

To control the sample time of each signal element in a bus, specify the sample time in the Block Parameters dialog box of the block that generates the signal element.

To specify a sample time for a signal in a `Simulink.Bus` object, a best practice is to use the default `SampleTime` value of -1.

When to Use Bus Objects

In this section...

A bus can have an associated bus object, which provides properties that Simulink uses to validate the bus signal. Bus objects are optional for virtual buses, but required for nonvirtual buses.

A bus object specifies only the architectural properties of a bus, as distinct from the values of the signals it contains. For example, a bus object can specify the number of elements in a bus, the order of those elements, whether and how elements are nested, and the data types of constituent signals; but not the signal values. A bus object is analogous to a structure definition in C: it defines the members of the bus but does not create a bus. Another way of thinking of a bus object is that it is similar to a cable connector. The connector defines all the pins and their configuration and controls what types of wires can be connected to it. Similarly, a bus object defines the configuration and properties of the signals that the associated bus must have.

A bus object is an instance of class `Simulink.Bus` that can be stored in a location such as the base workspace. The object defines the structure of the bus and the properties of its elements, such as nesting, data type, and size.

A bus object serves as the root of an ordered hierarchy of bus elements, which are instances of class `Simulink.BusElement`. Each element completely specifies the properties of a signal in a bus, such as its name, data type, and dimensionality. The order of the elements contained in the bus object defines the order of the signals in the bus. A bus object can also specify properties that were not defined by constituent signals, but were left to be inherited.

You can use the Simulink Bus Editor to create and manage bus objects, as described in “Create Bus Objects with the Bus Editor” on page 65-69, or you can use the Simulink API, as described in “Create Bus Objects Programmatically” on page 65-81. After you create a bus object and specify its attributes, you can associate it with any block that needs to use the bus definition that the object provides.

You can save bus objects as MATLAB code or as a MAT-file.

Required Uses of Bus Objects

You must use bus objects for these modeling configurations:

- Bus data across model reference boundaries on page 65-150
- MATLAB Function on page 65-78 block or Stateflow charts that input or output buses
- S-function or Legacy Code Tool interface with external code

Optional Uses of Bus Object

If you use Bus Creator block parameters to specify bus signal properties, all blocks downstream from the bus inherit the same properties.

You can use Bus Creator block parameters to define virtual buses and perform limited error checking. To perform thorough error checking on a bus, associate a bus object with that bus. Using bus objects to check bus signals for errors is important when you want to create reusable and shareable model components.

To make it easier to trace the correspondence between the model and the generated code for a bus, use a nonvirtual bus. The generated code for a nonvirtual bus produces a structure, but also can result in multiple copies of some bus signals.

Bus Object Use with Blocks

You can associate a bus object with several blocks. Some blocks require that you specify a bus object if the block has a bus input or bus output. When a bus object governs a signal output by a block, the signal is a bus that has exactly the properties specified by the object. When a bus object governs a signal input by a block, the signal must be a bus that has exactly the properties specified by the object. Any variance causes an error.

Block	Requires Bus Object for Bus Input or Output
Argument Inport	
Argument Outport	
Bus Creator	

Block	Requires Bus Object for Bus Input or Output
Constant	✓
Data Store Memory	✓
Data Store Read	✓
Data Store Write	✓

Outport (root-level)	✓
Permute Dimensions	
Prelookup	✓
Probe	
Reshape	
S-Function	✓
Signal Conversion	
Signal Specification	
State Reader	✓
Unit Delay	

To associate a block with a bus, in the Block Parameters dialog box, set **Data type** to `Bus: <object name>` and replace `<object name>` with the bus object name.

If a subsystem that is in a library contains a block that uses a bus object, all instances of that block must match the bus object specification.

Note Do not set the minimum and maximum values for bus data on blocks with bus object data type. Simulink ignores these settings. Instead, set the minimum and maximum values for bus elements of the bus object specified as the data type. The values should be finite real double scalar.

For information on the `Minimum` and `Maximum` properties of a bus element, see `Simulink.BusElement`.

Bus Object Workflow

Using bus objects in a model involves performing these tasks, in many cases iteratively.

1. Determine where you need or want to use bus objects.
2. Determine how you want to manage the bus objects, to keep track of the bus objects used by a model and the models that use the bus objects.
3. Create the bus objects in the MATLAB base workspace.
4. Export the bus objects from the base workspace to a MATLAB code file or a MAT-file.
5. Import bus objects from files to models that use the bus objects.

Create Bus Objects with the Bus Editor

In this section...

To create a bus object and its elements interactively, use the Simulink Bus Editor. The bus objects that you create with the Bus Editor are stored in the MATLAB base workspace. To simulate a block that uses a bus object, the bus object must be in the base workspace or in a data dictionary. To save bus object definitions to associate with models, export the bus objects from the base workspace into a MATLAB code file or MAT-file (see "Save and Import Bus Objects" on page 65-90).

You can specify the bus object to be the data type of a block either before or after defining the bus object. However, before you simulate the model, the bus object and the corresponding bus signal must have the same number of bus elements, in the same order. Also, each bus element in the bus object and in the corresponding signal in the model must have the same attributes.

During model development, you can modify bus signals to match bus objects or modify bus objects to match buses.

Tip This example is a simple model that walks through the basics of bus object definition and use. For examples that show bus object definitions for models that require bus objects, see "Use Nonvirtual Buses with MATLAB Function Block" on page 65-78 and `sldemo_mdlref_bus`.

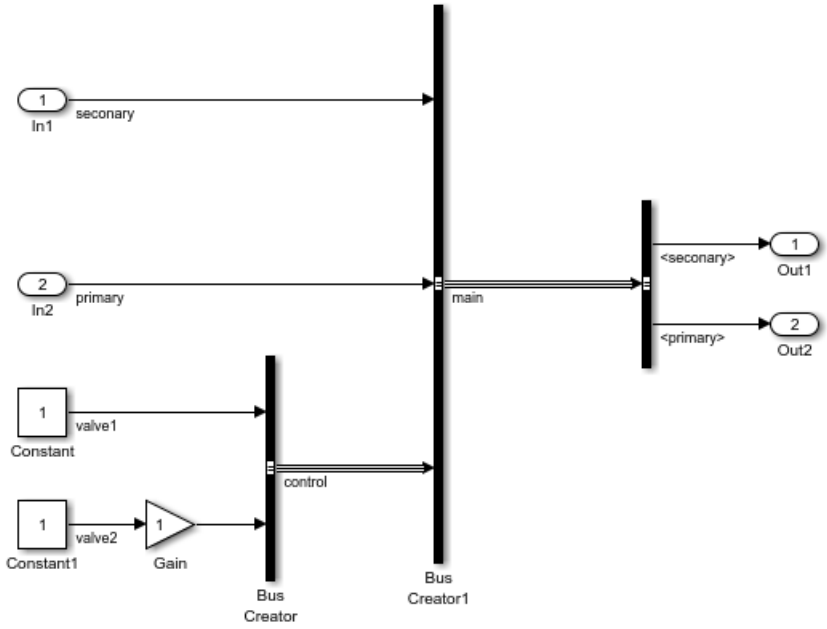
Open the Bus Editor

Open the Bus Editor using one of these approaches, depending on your modeling task.

Modeling Task	Approach
Create a model	In the Simulink Editor, select **Edit > Bus Editor**.
Create bus objects outside of model context	At the MATLAB command line, enter `buseditor`.
Explore and update a model	In the Model Explorer, in a bus object dialog box, click the **Launch Bus Editor** button.

Create Bus Objects

Suppose that your model has two buses, with one bus nested inside the other bus.



This example shows how to create bus objects corresponding to the `control` and `main` bus signals. To complete the definition of the bus objects and use those objects, also perform the steps in these examples:

- "Create Bus Elements for the Bus Object" on page 65-71

- "Nest Bus Object Definitions" on page 65-74
- "Use Bus Objects to Create Nonvirtual Buses" on page 65-77

1. Open the model.
2. In the Simulink Editor, select **Edit > Bus Editor**.
3. In the Bus Editor, select **File > Add Bus**.

   This action creates a bus object with a default name and properties. The object appears in the **Hierarchy** pane and its properties appear in the **Dialog** pane.
4. Specify the name for the bus object, using the **Name** property. To make it easier to see how the bus object is used in a model, use a name that reflects the bus signal associated with the bus object. The bus signal that combines the valve inputs is named `control`, therefore, name the bus object `CONTROL`.
5. You can provide documentation about the bus object by using the **Description** property. Enter `Combines two valve signals`.
6. Click **Apply**.
7. Create the second bus object. In the **Hierarchy** pane, select the `CONTROL` bus object and in the toolbar select the **Add Bus** button ().
8. In the **Dialog** pane, set **Name** to `MAIN` and **Description** to `Defines a bus object for a bus that contains three signals, including the control bus signal`.
9. Click **Apply**.

   The **Hierarchy** pane displays bus objects in alphabetical order.

Do not close MATLAB without exporting the bus objects to a MATLAB code file or MAT-file. Otherwise, you lose the bus object definitions.

To define bus element objects for the bus objects, perform the steps in "Create Bus Elements for the Bus Object" on page 65-71.

Create Bus Elements for the Bus Object

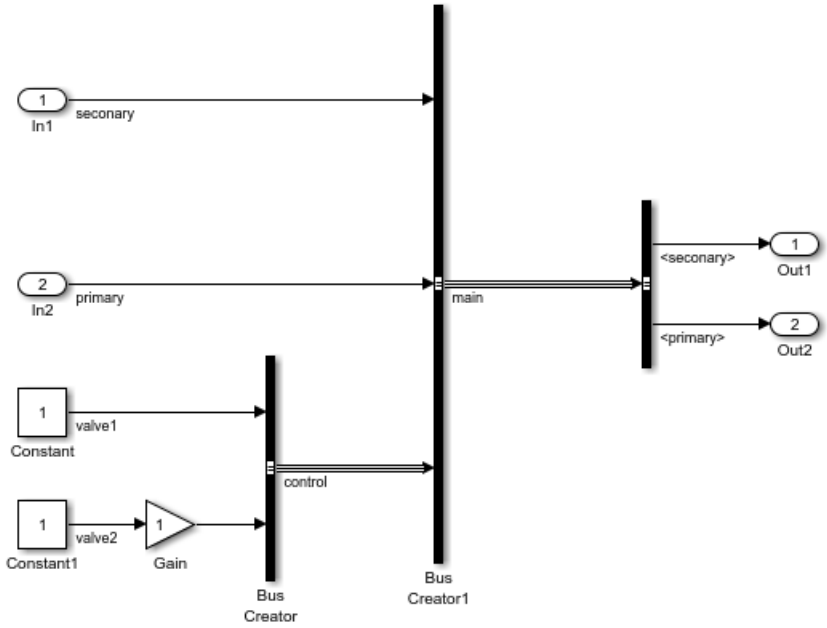
This example builds on bus objects that you created in "Create Bus Objects" on page 65-70. The example shows how to define the bus element objects for the `CONTROL` and `MAIN` bus objects for the model.

Note In this example, the name for the bus element and the corresponding signals are different, to try to highlight that they are distinct entities. If you change the default value for the **Element name mismatch** diagnostic to error, then the signal name and corresponding bus element name must match exactly to run on all platforms.

Also, the Bus Creator blocks in this model use the default setting for the **Override bus signal names from inputs** block parameter. The default setting of `On` propagates the signal names of the signals in model, not of the names of the bus elements in the bus object.

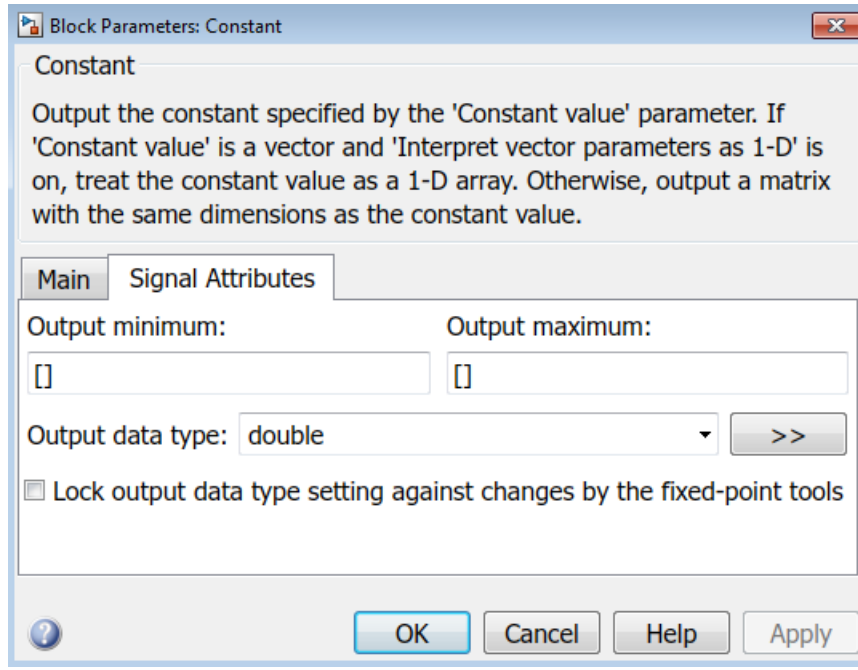
To complete the definition of the bus objects and use those objects, also perform the steps in these examples:

- "Nest Bus Object Definitions" on page 65-74
- "Use Bus Objects to Create Nonvirtual Buses" on page 65-77



1. In the Bus Editor **Hierarchy** pane, select the `CONTROL` bus object.
2. Select **File** > **Add/Insert BusElement**.

   A new bus element with a default name and properties is created in the `CONTROL` bus object. The bus element appears in the **Hierarchy** pane below the `CONTROL` bus object.
3. In the **Dialog** pane, set **Name** to `VALVE1`, to reflect the name of the top signal in the bus.
4. For the `Constant` block, open the Block Parameters dialog box and select the **Signal Attributes** tab.



5. In the Bus Editor **Dialog** pane, set **DataType** property to `double`, to match the **Output data type** block parameter setting for the `Constant` block. Use the default setting for the other bus element object properties.
6. Click **Apply**.

7. Create a second bus element object that corresponds to the `valve2` bus element signal. In the **Hierarchy** pane, select the `VALVE1` bus element object and click the **Add/Insert Bus Element** button ().

   Set the bus object name to `VALVE2`.

8. For the `Constant1` block, open Block Parameters dialog box and select the **Signal Attributes** tab.

   The **Output data type** is `int8`.

9. In the Bus Editor **Dialog** pane, for the `VALVE2` bus element object, set **DataType** property to `int8`. Use the default setting for the other bus element object properties.

10. Click **Apply**.

11. Create a bus element object for the `secondary` bus element signal of the `main` bus. In the **Hierarchy** pane, select the `MAIN` bus object and click the **Add/Insert Bus Element** button.

12. Set the **Name** property to `SECONDARY` and the **Data type** property to `int32`, matching the `In1` block output signal data type. Click **Apply**.

13. Create a bus element object for the `primary` bus element signal of the `main` bus. In the **Hierarchy** pane, select the `SECONDARY` bus element object and click the **Add/Insert Bus Element** button.

14. Set the **Name** property to `PRIMARY` and the **Data type** property to `boolean`, matching the `In2` block output signal data type. Click **Apply**.

To define a bus element object for the control bus, which is the third bus element of the main bus, perform the steps in “Nest Bus Object Definitions” on page 65-74.

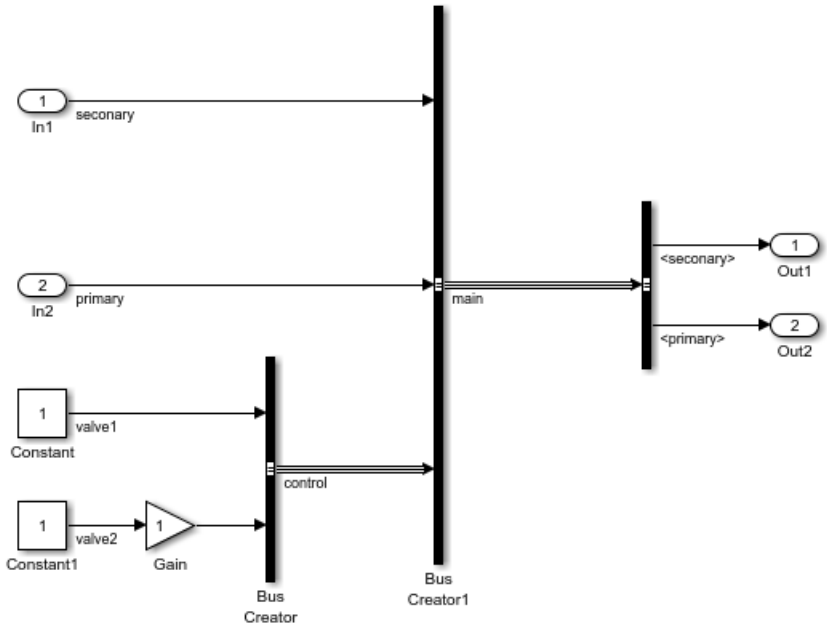
Nest Bus Object Definitions

Any signal in a bus can be another bus, which can in turn contain subordinate buses, to any depth. Describing nested buses with bus objects requires nesting the bus object definitions that the objects provide.

Every bus object defines a data type whose properties are specified by the object. To nest one bus object definition in another, assign to a bus element of one bus object a data type that is defined by another bus object. The bus element object represents a nested bus. The bus object that specifies the data type of the bus element object defines the nested bus elements.

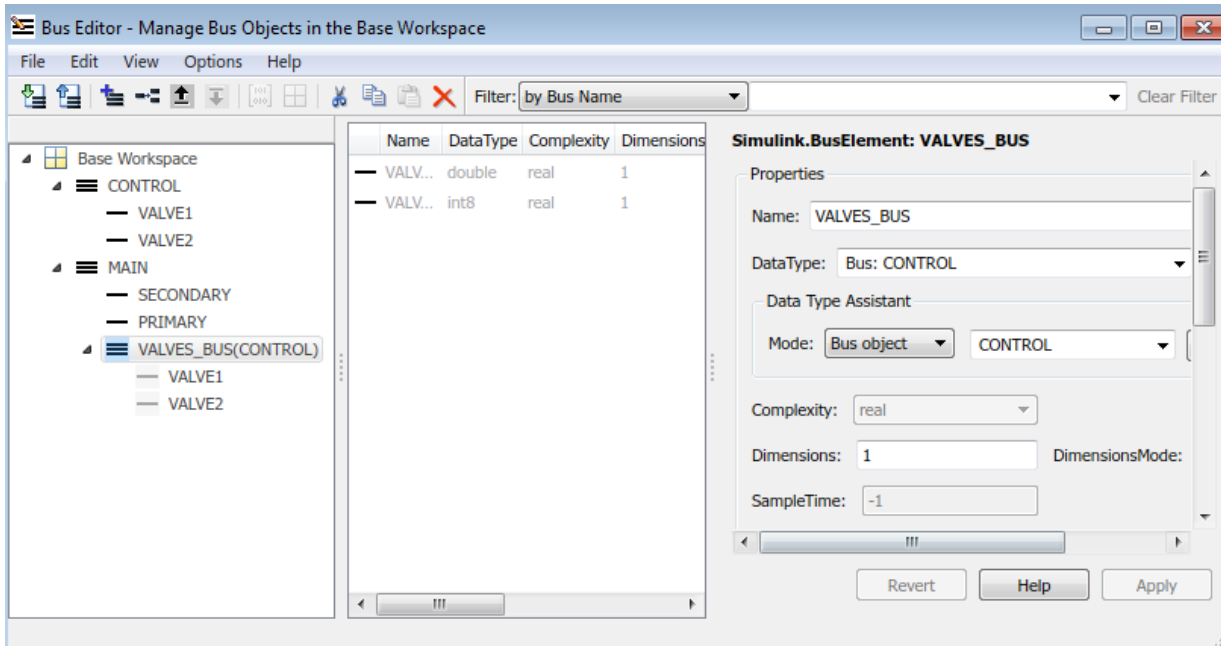
A data type defined by a bus object is called a *bus type*. Nesting buses by assigning bus types to elements allows the same bus definition to be used conveniently in multiple contexts without unwanted interactions.

This example builds on the bus objects and bus elements that you created for the model in "Create Bus Objects" on page 65-70 and "Create Bus Elements for the Bus Object" on page 65-71.



1. In the Bus Editor **Hierarchy** pane, select the `PRIMARY` bus element object and click the **Add/Insert Bus Element** button.
2. In the **Dialog** pane, set the **Name** property to `VALVES_BUS`.
3. For the **Data type** property, use the `Bus: <object name>` template, replacing `<object name>` with `CONTROL`, which is the name of the bus object for the `control` bus.
4. Click **Apply**.

If you expand the `VALVES_BUS` bus element object, you see the two bus element objects for the `CONTROL` bus object, `VALVE1` and `VALVE2`.



5 You have finished defining bus objects for this example. Consider exporting the bus objects to a MATLAB code file. In the Bus Editor, select **File > Export to File**. In the Export dialog box, specify a file name for the bus object MAT-file.

To use the bus objects to create nonvirtual buses, perform the steps in “Use Bus Objects to Create Nonvirtual Buses” on page 65-77.

Avoid Circular Nested Bus Object Definitions

You can nest a bus object in as many different bus objects as desired, and as many times in the same bus object as desired. You can nest bus objects to any depth, but you cannot define a circular structure by directly or indirectly nesting a bus object within itself.

If you define a circular structure, the Bus Editor posts a warning and sets the data type of the element that would have completed the cycle to `double`. Click **OK** to close the warning and continue using the editor.

Use Bus Objects to Create Nonvirtual Buses

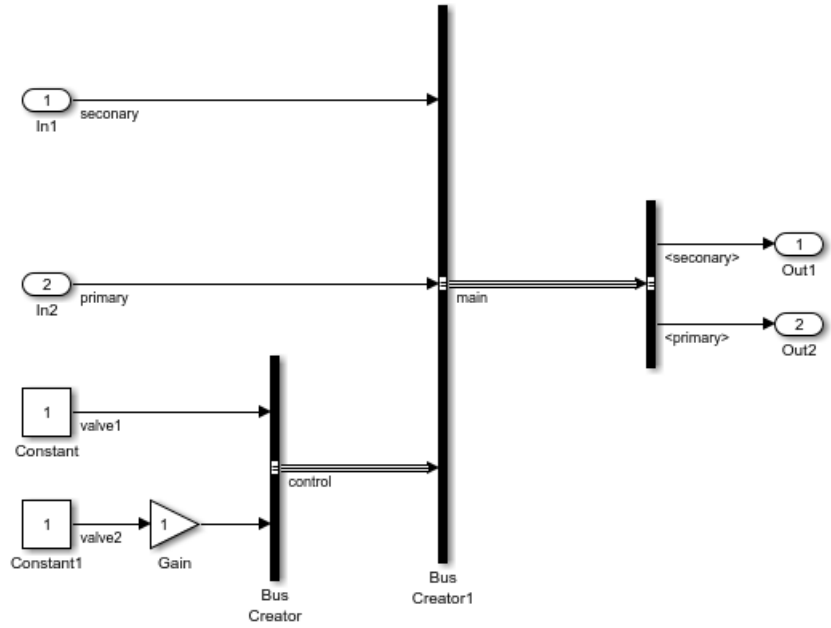
The buses in the `ex_bus_object_tutorial` model that you defined in the "Create Bus Objects" on page 65-70 example and its associated examples are virtual buses. To use the bus objects you defined in those examples to change the virtual buses to nonvirtual buses:

1. Open the Bus Creator block parameters dialog box. Set **Output data type** to `Bus: CONTROL` and select **Output as nonvirtual bus**.

   Note You can use a bus object to specify the data type for a block without specifying that the bus is a nonvirtual bus. You must specify a bus object for a nonvirtual bus, but it is optional for a virtual bus.

2. Open the `Bus Creator1` Block Parameters dialog box. Set **Output data type** to `Bus: MAIN` and select **Output as nonvirtual bus**.
3. Add another Outport block after the `Bus Creator1` block and connect it to the `main` signal.
4. Open the `Out3` Block Parameters dialog box. In the **Signal Attributes** tab, set the **Data type** to `Bus: MAIN` and select **Output as nonvirtual bus in parent model**.

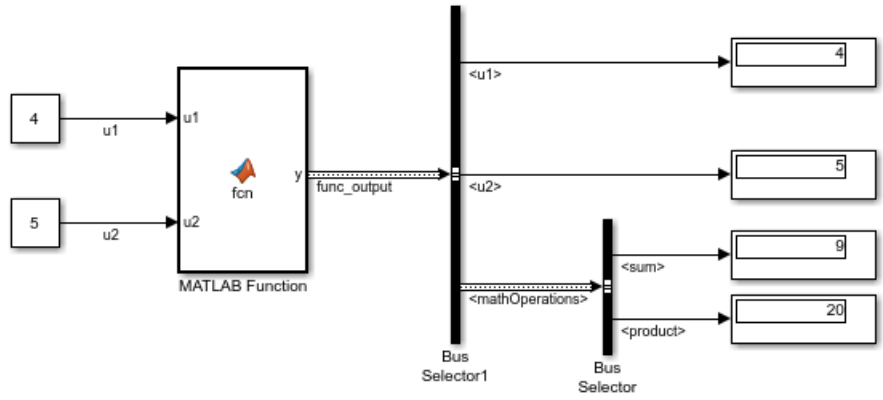
The model uses the bus objects that you defined. When you simulate the model, you see that the buses are now nonvirtual.



For another example of defining bus objects and using nonvirtual buses in a model, see “Use Nonvirtual Buses with MATLAB Function Block” on page 65-78.

Use Nonvirtual Buses with MATLAB Function Block

If a MATLAB Function block outputs a structure, then you need to use a bus object to define a bus output. In the `ex_bus_object_matlab_func` model, the MATLAB Function block includes MATLAB code that creates a structure. Here is the model after simulation.

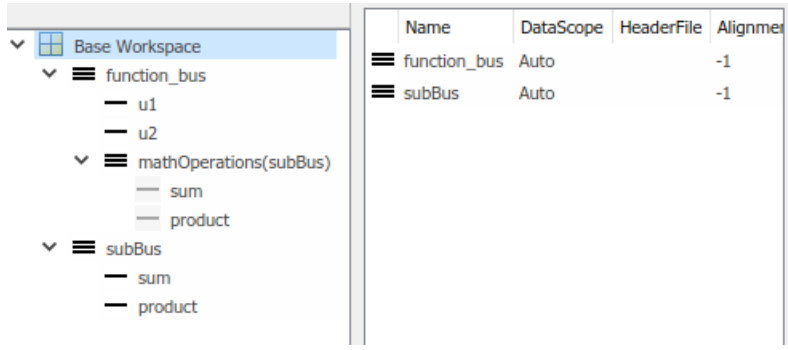


To see the structure definition, double-click the MATLAB Function block .

```
function y = fcn(u1,u2)

y.u1 = u1;
y.u2 = u2;
y.mathOperations.sum     = u1+u2;
y.mathOperations.product = u1*u2;
```

Open the Bus Editor and expand the bus object definition that represents the structure.



To see how the bus object is used to define the bus output for the MATLAB Function , in the MATLAB Editor, click **Edit Data** and then click `y`. The output **Type** is defined as the `function_bus` object.

- “Map Bus Objects to Models” on page 65-96

Create Bus Objects Programmatically

To create a bus object and its bus elements programmatically from scratch or based on a block, data, or C code.

- "Create Simulink.Bus and Simulink.BusElement Objects Directly" on page 65-81 — Construct a `Simulink.Bus` object and define its properties. Construct `Simulink.BusElement` objects for the elements of the bus.
- "Create Bus Objects from Blocks" on page 65-82 — Create a bus object and its bus element objects based on a block in a model.
- "Create Bus Objects from MATLAB Data" on page 65-82 — Create a bus object and its bus elements based on a MATLAB structure or cell array.
- "Create Bus Objects from External C Code" on page 65-95 — Create a bus object and its bus elements based on your external C code (`struct`). Use the `Simulink.importExternalCTypes` function.

As you create bus objects programmatically, you can store them in either the MATLAB workspace or in a MATLAB code file. After you create a bus object, you can use MATLAB commands to save the bus objects to a MAT-file (see "Save and Load Workspace Variables" (MATLAB)). To simulate a block that uses a bus object, that bus object must be in the base workspace or in a data dictionary.

You can specify the bus object to be the data type of a block either before or after defining the bus object. However, before you simulate the model, the bus object and the corresponding bus signal must have the same number of bus elements, in the same order. Also, each bus element in the bus object and in the corresponding bus element signal must have the same data type and dimensions.

During model development, you can modify bus signals to match bus objects or modify bus objects to match buses.

Create Simulink.Bus and Simulink.BusElement Objects Directly

You can create a `Simulink.Bus` object and its `Simulink.BusElement` objects programmatically. The bus objects are stored in the base workspace. For each bus element object, specify the name, dimensions, and data type. The other bus element object properties are optional. For the bus object, specify the bus elements. The other bus object properties are optional. For example, this code creates two bus element objects that are then used as the elements of the `CONTROL` bus object.

```
clear elems;
elems(1) = Simulink.BusElement;
elems(1).Name = 'VALVE1';
elems(1).Dimensions = 1;
elems(1).DimensionsMode = 'Fixed';
elems(1).DataType = 'double';
elems(1).SampleTime = -1;
elems(1).Complexity = 'real';

elems(2) = Simulink.BusElement;
elems(2).Name = 'VALVE2';
elems(2).Dimensions = 1;
elems(2).DimensionsMode = 'Fixed';
elems(2).DataType = 'double';
elems(2).SampleTime = -1;
elems(2).Complexity = 'real';

CONTROL = Simulink.Bus;
CONTROL.Elements = elems;
```

This script is similar to the file you get if you save a bus object to a MATLAB file and choose the `Object` format. For information about saving bus objects, see “Save and Import Bus Objects” on page 65-90.

Create Bus Objects from Blocks

You can create a bus object and its bus elements programmatically based on a block in a model. Use the `Simulink.Bus.createObject` function and specify the model and blocks for which to create bus objects for. Before you use the function, the model must be compilable. For example, if you specify a Bus Creator block that is at the highest level of a nested bus hierarchy, the function creates bus objects for all of the buses in the hierarchy. You can specify to have the bus objects created in the base workspace or to save them in a MATLAB code file.

Create Bus Objects from MATLAB Data

You can create a bus object from cell arrays of bus information in MATLAB, using the `Simulink.Bus.cellToObject` function. Each cell subordinate cell array represents a bus object and includes the following data, reflecting `Simulink.Bus` object properties:

```
{BusName,HeaderFile,Description,DataScope,Alignment,Elements}
```

The `Elements` field is a cell array defining these properties for each `Simulink.BusElement` object:

```
{ElementName,Dimensions,DataType,SampleTime,Complexity,DimensionsMode,Min,Max,Units,Description}
```

You can create a bus object from a MATLAB structure of `timeseries` objects, using the `Simulink.Bus.createObject` function. Alternatively, you can specify a numeric MATLAB structure. You can specify to have the bus objects created in the base workspace or to save them in a MATLAB code file.

Related Examples

- “When to Use Bus Objects” on page 65-64
- “Create Bus Objects with the Bus Editor” on page 65-69
- “Save and Import Bus Objects” on page 65-90
- “Modify Bus Objects” on page 65-84
- “Map Bus Objects to Models” on page 65-96

Modify Bus Objects

In this section...

Modify a bus object or its bus element objects if you change the associated bus signal to:

- Add or delete a bus element signal.
- Reorder bus element signals.
- Change the data type or dimensions of a bus element signal.

If you modify a bus object to reflect changes to a bus signal, confirm that the bus object continues to work in other places it is used. To find where a bus object is used in a model, see “Finding Blocks That Use a Specific Variable” on page 59-114.

If you do not want to change the bus object, you can:

- Create a bus object that matches the changes to the bus signal and use the new bus object for the blocks that the changed bus connects to.
- Revert the bus signal changes so that the bus signal continues to match the associated bus object.

You can use the Bus Editor to change and delete existing bus objects and bus elements. The Bus Editor displays all the bus objects in the base workspace. Changes that create, reorder, or delete entities take effect immediately in the base workspace. Changes to properties take effect when you apply them. The Bus Editor does not provide an undo capability.

If you have saved a bus object in a MATLAB code file, you can edit it programmatically. For details, see “Create Simulink.Bus and Simulink.BusElement Objects Directly” on page 65-81.

Edit Bus Objects

1. Open the Bus Editor.
2. In the **Hierarchy** pane, expand **Base Workspace** (if necessary) and select the bus object to edit.

   Tip If the base workspace contains many bus objects, you can reduce the number of displayed bus objects by using a Bus Editor filter. For details, see "Filter Displayed Bus Objects" on page 65-86.
3. In the **Dialog** pane, edit the bus object properties.
4. Click **Apply**.

Edit Bus Element Objects

1. Open the Bus Editor.
2. In the **Hierarchy** pane, expand **Base Workspace** (if necessary) and select the bus object whose bus element object you want to modify.
3. In the **Contents** pane, select the bus element whose properties you want to edit. You can make the edits in the **Dialog** pane or in the **Contents** pane. To make the same edit to a property in multiple bus elements, use the **Contents** pane. Hold the **Ctrl** key while you select multiple bus elements and enter the new value in the property for one of the selected bus elements. The change applies to all the selected bus elements.
4. If you made edits in the **Dialog** pane, click **Apply**.

Copy and Paste Bus Objects and Elements

You can use the Bus Editor to copy and paste bus objects or bus element objects. Right-click an object and use the context menu to copy and paste the bus object. Copying a bus object also copies its bus elements. The copied objects have the same property values as the original objects. Change the name of the objects and modify other properties as necessary.

Change the Order of Bus Elements

To change the order of bus elements in a bus object, in the **Hierarchy** pane, select a bus element and move it up or down in the list, using the **Move Element Up**

or the **Move Element Down**  button.

Delete Bus Objects and Bus Elements

To delete a bus object, in the **Hierarchy** pane, select the bus object and click the **Delete**  button or **Delete** key. Deleting a bus object deletes its bus element objects.

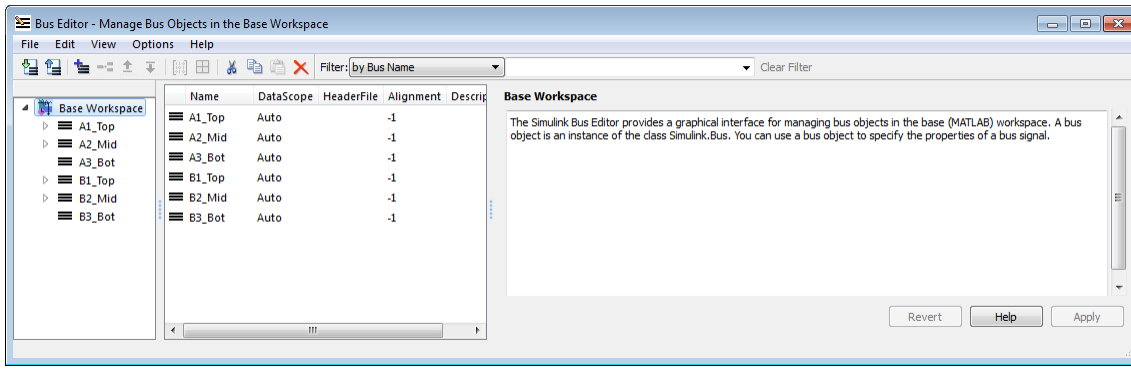
If you delete a bus object, in the Simulink Editor, update any blocks that use that bus object. To find where a bus object is used in a model, see “Finding Blocks That Use a Specific Variable” on page 59-114.

Filter Displayed Bus Objects

By default, the Bus Editor displays all bus objects that exist in the base workspace, in alphabetical order. When there are many bus objects, you can have the Bus Editor display only those bus objects that have:

- Names that match a given search term or regular expression
- A specified relationship to a specified bus object

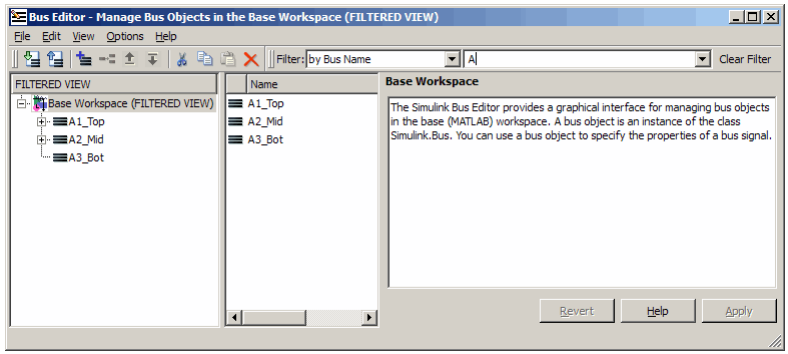
To set a filter, specify values in the **Filter** boxes to the right of the tools in the toolbar. Depending on the specified type of filtering, one or two boxes appear to the right of the **Filter Type** box. In this example, the Bus Editor displays the bus objects that are in the base workspace:



The bus objects shown form two disjoint hierarchies. `A1_Top` is the parent of `A2_Mid`, which is the parent of `A3_Bot`. Similarly, `B1_Top` > `B2_Mid` > `B3_Bot`.

Filter by Name

Set **Filter Type** to `by Bus Name` and in **Object Name**, enter a character vector. See "Regular Expressions" (MATLAB) for complete information about MATLAB regular expression syntax. As you type, the Bus Editor updates dynamically to show only the bus objects whose names match the expression that you have typed. The comparison is case-sensitive. For example, entering `A` displays:



Filter by Relationship

Set **Filter Type** box to `by Bus Object Dependency`. In the **Relationship** box, select the type of relationship to display:

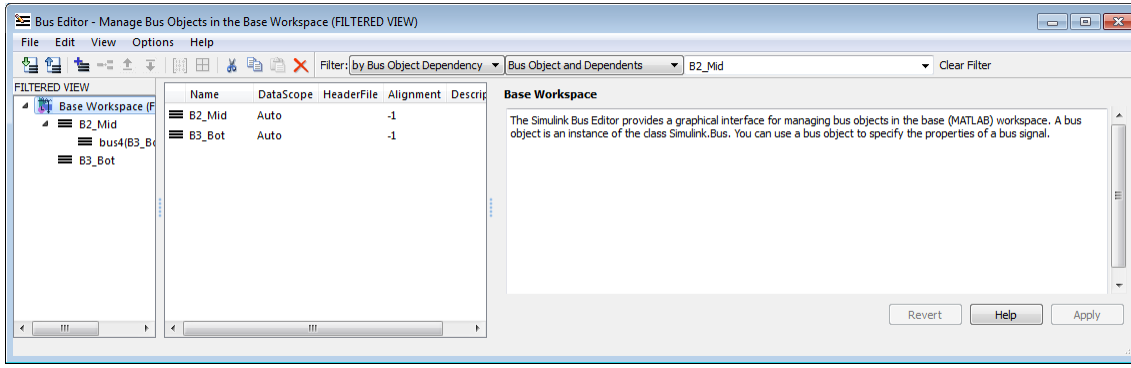
- `Bus Object and Parents` — Show a specified bus object and all superior bus objects in the hierarchy (default).
- `Bus Object and Dependents` — Show a specified bus object and all subordinate bus objects in the hierarchy.
- `Bus Object and Related Objects` — Show a specified bus object and all superior and subordinate bus objects.

In **Object Name**, specify a bus object by name, using a character vector. Use the list to select any existing bus object name, or type a name. As you type, the editor:

- Dynamically completes the field to indicate the first bus object that alphabetically matches what you have typed

- Updates the display panes to show only the specified object and any objects that have the specified relationship to it

For example, assuming that `A1_Top` is the parent of `A2_Mid`, which is the parent of `A3_Bot`, if you enter `B2`, the Bus Editor displays for `Bus Object and Dependents`:



Change Filtered Objects

You can work with any bus object that is visible in a filtered display exactly as in an unfiltered display. If you change the name or dependency of an object so that it no longer passes the current filter, the object disappears from the display. Conversely, if some activity outside the Bus Editor changes a filtered object so that it passes the current filter, the object immediately becomes visible.

If you create a bus object but do not see it in the editor, check the filter. The new object (whose name always begins with `BusObject`) can exist but be invisible. Bus objects created or imported from outside the Bus Editor are not visible until you reopen the Bus Editor, regardless of whether a filter is in effect.

Operations performed in the **Hierarchy** pane on the **Base Workspace** affect only visible objects. An object that is invisible because a filter is being used is unaffected by the operation. To act on all existing bus objects, clear the filter by clicking **Clear Filter**.

- “When to Use Bus Objects” on page 65-64

Save and Import Bus Objects

In this section...

When you create bus objects in the base workspace, before you close MATLAB, save (export) the bus objects to one of these locations:

- Data dictionary
- MATLAB code file
- MAT-file
- Database or other external files

If you do not save the bus objects, then when you reopen the model that uses the bus objects, you need to recreate the bus objects.

The technique you use for creating a bus object determines where the bus object is stored initially.

Bus Creation Technique	Initial Storage Location
Bus Editor	Base workspace
`Simulink.Bus` and `Simulink.BusElement` object definition	Base workspace
`Simulink.Bus.cellToObject`	Base workspace
`Simulink.createObject`	Base workspace or MATLAB code file

When you save bus objects using the Bus Editor, you can save them in a MAT-file or MATLAB code file. When you save bus objects using the `Simulink.Bus.save` or `matlab.io.saveVariablesToScript` function, the bus objects in the base workspace are saved in a MATLAB code file in object form. You can use any MATLAB technique that saves the contents of the base workspace. However, the resulting file contains everything in the base workspace, not just bus objects.

Tip You can configure the Bus Editor so that closing it posts a reminder to save bus objects. To enable the reminder, select **Options > Always Warn Before Closing**. When you select this option and try to close the Bus Editor, a reminder appears about saving bus objects before closing. You can disable the reminder by clearing **Options > Always Warn Before Closing**.

You can customize bus object export and import by providing a custom function that writes to or reads from a location outside MATLAB. For example, the exported bus objects could be saved as records in a corporate database. See "Customize Bus Object Import and Export" on page 65-98 for details.

When you import and modify bus objects, resave them and possibly modify the mechanism (such as a model callback) that you use for importing them.

Locations for Saving Bus Objects

Before you choose where to save bus objects, consider how you want to associate bus objects with models. For more information, see "Map Bus Objects to Models" on page 65-96.

Location	Usage Considerations
Data dictionary	Use for large model componentization. When you save to a data dictionay from the base workspace, you get all the variables used by the model, not just the bus objects. Before you save to a data dictionary, read "Considerations before Migrating to Data Dictionary" on page 63-9.
MATLAB code file	Use for when you want to use MATLAB for traceability and model differencing.
MAT-file	Use for faster bus object saving and loading.
Database or other external files	Use for comparing bus interface information with design documents stored in an external data source.

Data Dictionary

Save Bus Objects

To save bus objects (and other base workspace variables used by the model) to a data dictionary:

1. Link the model to a data dictionary, using the **Model Properties** dialog box.
2. Create a data dictionary.
3. Migrate data from the base workspace to the data dictionary.

For an example showing the complete procedure, see "Migrate Single Model to Use Dictionary" on page 63-6.

MATLAB Code File

Save Bus Objects

To use the Bus Editor to export all bus objects from the base workspace to a MATLAB code file:

1. In the Bus Editor, choose **File > Export to File**.
2. In the Export dialog box, specify the name for the export file. You do not have to specify a file extension.
3. Set **Save as type** to `MATLAB files (*.m)`.
4. Click **Save**.
5. In the dialog box that appears, select the format:
   - `Cell` — Stores the bus objects in a compressed format.
   - `Object` — Store the bus objects in `Simulink.Bus` object format, which is easier to read and edit.

All the bus objects that are in the base workspace, and nothing else, are exported to the specified MATLAB code file.

Note Operations performed on the **Base Workspace** in the **Hierarchy** pane, such as exporting bus objects, affect only visible objects. An object that is invisible because a

filter is being used is unaffected by the operation. To export all existing bus objects, before performing the export, clear any filter that is in use.

To export only selected bus objects from the base workspace to a file:

1. In the Bus Editor **Contents** pane, select one or more bus objects and right-click.
2. To export only the selected bus objects, in the context menu, select **Export to File**. To include nested bus objects used by the selected objects, select **Export with Dependent Bus Objects to File**.
3. Use the Export dialog box to export the selected bus objects.

When you create bus objects using `Simulink.Bus.createObject`, you can specify a MATLAB code file to store the bus objects. If you store the bus objects in a file, by default the objects are stored in cell format, which is a compressed format. To store the objects in a more readable format, use `'object'` as the last argument, after the file name. For example:

```
Simulink.Bus.createObject('busdemo','busdemo/Bus Creator2',...
'bus_objs','object'),
```

Import Bus Objects

You can use a model callback, using the `load` function, to load the MATLAB code file.

If a model uses only a few bus objects, consider copying the bus object code directly into the callback, instead of loading a file. For an example, open the model and examine the callback.

You can use the Bus Editor to import the definitions from a MAT-file to the base workspace. The import loads the complete contents of the file, not just the bus objects.

1. Choose **File > Import into Base Workspace**.
2. Use the Open File dialog box to navigate to and import the desired file.

MAT-File

Save Bus Objects

To export all bus objects from the base workspace to a MAT-file using the Bus Editor:

1. In the Bus Editor, choose **File > Export to File**.
2. In the Export dialog box, specify the name for the export file. You do not have to specify a file extension.
3. Set **Save as type** to `MAT—files (*.mat)`.
4. Click **Save**.

All bus objects in the base workspace, and nothing else, are exported to the specified MAT-file.

Note Operations performed on the **Base Workspace** in the **Hierarchy** pane, such as exporting bus objects, affect only visible objects. An object that is invisible because a filter is in use is unaffected by the operation. To export all existing bus objects, before performing the export, clear any filter that is in effect.

To export only selected bus objects from the base workspace to a file:

1. In the Bus Editor **Contents** pane, select one or more bus objects and right-click.
2. To export only the selected bus objects, in the context menu select **Export to File**. To export any nested bus objects used by the selected objects, select **Export with Dependent Bus Objects to File**.
3. Use the Export dialog box to export the selected bus objects.

When you create bus objects using `Simulink.Bus.createObject` or `Simulink.Bus.cellToObject`, you can save the bus objects as a MATLAB code file. When you use the `Simulink.saveVars` function to save variables from the base workspace, the objects are saved in a MATLAB code file.

Import Bus Objects

You can use a model callback, using the `load` function to load the MAT-file.

You can use the Bus Editor to import the definitions from a MAT-file to the base workspace. Importing the file loads the complete contents of the file, not just the bus objects.

1. Choose **File > Import into Base Workspace**.
2. Use the Open File dialog box to navigate to and import the desired file.

Database or Other External Files

Save Bus Objects

You can capture bus interface information in a database or other external source, and use scripts and Database Toolbox™ functionality to read that information into MATLAB.

Import Bus Objects

You can use `sl_customization.m` to customize the Bus Editor to import bus data from a database or other external source. For details, see "Customize Bus Object Import and Export" on page 65-98.

Create Bus Objects from External C Code

You can create a bus object that corresponds to a structure type (`struct`) that your existing C code defines. Then, in preparation for integrating existing algorithmic C code for simulation (for example, by using the Legacy Code Tool), you can use the bus object to package signal or parameter data according to the structure type. To create the object, use the `Simulink.importExternalCTypes` function.

Map Bus Objects to Models

As models become complex, it is important to identify the bus objects that a model uses and the models that use a specific bus object.

Before you simulate a model, all the bus objects it uses must be loaded into the base workspace. For automation and consistency across models, it is important to map bus objects to models.

- By identifying all of the bus objects a model needs, you can ensure that those objects are loaded before model execution.
- By identifying all models that use a bus object, you can ensure that changes to a bus object do not cause unexpected changes in any of the models that use that bus object.

To map bus objects to models, consider:

- Keeping the bus objects in a data dictionary, which you use to store variables and objects for one or more models. To share a bus object between models, you can link each model to a dictionary and create a common referenced dictionary to store the object. For an example, see “Partition Dictionary Data Using Referenced Dictionaries” on page 63-34.
- Using Simulink Projects:

  1. Serialize the files that contain the bus objects as part of a project.
  2. Loading that data upon project open.

  For details, see “Project Management”.
- Capturing the mapping information in an external data source, such as a database.

To find where a bus object is used in an open model, see “Finding Blocks That Use a Specific Variable” on page 59-114.

Use a Rigorous Naming Convention

Using a rigorous and standard naming convention is very helpful for mapping bus object usage. For example, consider the model and data required for an actuator control function. Naming the model `Actuator` and the input and output ports `Actuator_bus_in` and `Actuator_bus_out`, respectively, makes the connection between the bus objects and the model clear.

Note that this approach can cause issues if the output from one model reference is fed directly to another model reference. In this case, the naming mismatch results in an error.

Customize Bus Object Import and Export

In this section...

You can use the Bus Editor to import bus objects to the base workspace and to export bus objects from the base workspace, as described in “Save and Import Bus Objects” on page 65-90. By default, the Bus Editor can save bus objects to, and import bus objects from, a MATLAB code file or MAT-file. The files must be in a location that is accessible using an ordinary **Open** or **Save** dialog box.

You can write customized MATLAB functions that provide alternative import or export (or both) functionality. For example, you can write a customized function that stores the objects as records in a database, in a format that your organization uses.

After you design and implement a custom bus object import or export function, use the Simulink Customization Manager to register the function. The registration process establishes custom import and export functions as callbacks for the Bus Editor **Import to Base Workspace** and **Export to File** commands. The callbacks replace the default capabilities of the Bus Editor. Customizing the Bus Editor import and export capabilities has no effect on other MATLAB or Simulink functions. Canceling import or export customization restores the default Bus Editor capabilities for that operation without affecting the other.

To create bus objects from external C code, you do not need to make customizations. See “Create Bus Objects from External C Code” on page 65-95.

Required Background Knowledge

Customizing bus object import or export requires that you understand:

- MATLAB language and programming techniques
- Simulink bus object syntax

- The proprietary format into which you translate bus objects, and the techniques necessary to access the facility that stores the objects.
- Any platform-specific techniques for obtaining data from the user, such as the name of the location in which to store or access bus objects.

Write a Bus Object Export Function

A custom bus object export function requires at least one argument. You can use additional arguments to handle special actions by the function. The value of the first argument is a cell array containing the names of all bus objects that the Bus Editor has selected. You can use functions, global variables, or any other MATLAB technique, to provide values for any additional arguments. The general algorithm of a customized export function is:

1. Iterate over the list of object names in the first argument.
2. Obtain the bus object corresponding to each name.
3. Translate the bus object to the proprietary syntax.
4. Save the translated bus object in the local repository.

This example shows the syntactic shell of such an export callback function is:

```
function myExportCallBack(selectedBusObjects)
disp('Custom export was called!');
for idx = 1:length(selectedBusObjects)
    disp([selectedBusObjects{idx} ' was selected for export.']);
end
```

Although this function does not export any bus objects, it is syntactically valid and can be registered. It accepts a cell array of bus object names, iterates over them, and prints each name. An operational export function:

- Uses each name to retrieve the corresponding bus object from the base workspace
- Converts the object to proprietary format
- Stores the converted object

The additional logic is enterprise-specific.

Write a Bus Object Import Function

A custom bus object import function can take zero or more arguments to perform its task. You can use functions, global variables, or any other MATLAB technique to provide

argument values. Also, the function can poll the user for information, such as a designation of where to obtain bus object information. The general algorithm of a custom bus object import function is:

1. Obtain bus object information from the local repository.
2. Translate each bus object definition to a `Simulink.Bus` object.
3. Save each bus object to the MATLAB base workspace.

This example shows the syntactic shell of an import callback function is:

```
function myImportCallBack
disp('Custom import was called!');
```

Although this function does not import any bus objects, it is syntactically valid and can be registered with the Simulink Customization Manager. An operational import function:

- Gets a designation of where to obtain the bus objects to import
- Converts each bus object to a `Simulink.Bus` object
- Stores the object in the base workspace

The additional logic is enterprise-specific.

Register Customizations

To customize bus object import or export, provide a customization registration function that inputs and configures the Customization Manager whenever you start Simulink software or refresh Simulink customizations. The steps for using a customization registration function are:

1. Create a file named `sl_customization.m` to contain the customization registration function. Alternatively, you can use an existing customization file.
2. At the top of the file, create a function named `sl_customization` that takes a single argument (or use the customization function in an existing file). When the function is invoked, the value of this argument is the Customization Manager.
3. Configure the `sl_customization` function to set `importCallbackFcn` and `exportCallbackFcn` to be function handles that specify your customized bus object import and export functions.

4 If `sl_customization.m` is a new customization file, put it anywhere on the MATLAB search path. Two frequently used locations are `matlabroot` and the current working folder. Alternatively, you can extend the search path.

Here is a simple example of a customization registration function:

```
function sl_customization(cm)
disp('My customization file was loaded.');
cm.BusEditorCustomizer.importCallbackFcn = @myImportCallBack;
cm.BusEditorCustomizer.exportCallbackFcn = @(x)myExportCallBack(x);
```

When Simulink starts up, it traverses the MATLAB search path looking for files named `sl_customization.m`. Simulink loads each such file that it finds (not just the first file) and executes the `sl_customization` function at its top, establishing the customizations that the function specifies.

Executing the example customization function displays a message (which an actual function probably would not). The function establishes that the Bus Editor uses a function named `myImportCallBack()` to import bus objects, and a function named `myExportCallBack(x)` to export bus objects.

The function corresponding to a handle that appears in a callback registration can be undefined when the registration occurs. However, it must be defined when the Bus Editor calls the function. The same latitude and requirement applies to any functions or global variables used to provide the values of additional arguments.

Other functions can also exist in the `sl_customization.m` file. However, the Simulink software ignores files named `sl_customization.m`, except when it starts up or refreshes customizations. Any changes to functions in the customization file are ignored until one of those events occurs. By contrast, changes to other MATLAB code files on the MATLAB path take effect immediately.

For more information, see “Registering Customizations” on page 67-28.

Change Customizations

You can change the handles established in the `sl_customization` function by:

- Changing the function to specify the changed handles
- Saving the function

- Refreshing customizations by executing `sl_refresh_customizations`

Simulink traverses the MATLAB path and reloads all `sl_customization.m` files that it finds, executing the first function in each one, just as it did on Simulink startup.

You can revert to default import or export behavior by setting in the `sl_customization` function the appropriate `BusEditorCustomizer` element to `[]` and then refreshing customizations. Alternatively, you can eliminate both customizations in one operation by executing:

```
cm.BusEditorCustomizer.clear
```

where `cm` was previously set to a customization manager object (see "Register Customizations" on page 65-100).

Changes to the import and export callback functions themselves, as distinct from changes to the handles that register them as customizations, take effect immediately, unless they are in the `sl_customization.m` file itself. If the callback functions are in the `sl_customization.m` file, they take effect next time you refresh customizations. Keeping the callback functions in separate files usually provides more flexible and modular results.

Use Buses with Inport and Outport Blocks

In this section...

You need to perform some special configuration steps to have a model:

- Produce a bus signal as an output of a root-level Inport block
- Accept a virtual bus as an input to a root-level Outport block
- Accept a bus as an input to a nonvirtual Inport block in an atomic subsystem

Use Buses with Root-Level Inports

To produce a bus signal as an output of a root-level Inport block, in the Block Parameters dialog box of the Inport block:

- Set the **Data type** parameter to `Bus: <object name>`
- Replace `<object name>` with the name of the bus object name that defines the bus that the Inport produces.

Root-level Inport blocks convert virtual buses to nonvirtual buses. All signals in a nonvirtual bus must have the same sample time. For details, see “Specify Bus Signal Sample Times” on page 65-60.

For information about importing data to root-level Inport blocks, see “Load Bus Data to Root-Level Input Ports” on page 61-170.

Use Buses with Root-Level Outports

A root level Outport block of a model can accept a virtual bus only if all elements of the bus have the same data type. The Outport block automatically converts the bus to a vector having the same number of elements as the bus, and outputs that vector.

To use a bus signal that contains mixed data types as an input to a root-level Outport block, in the Block Parameters dialog box of the Outport block:

- Set **Data type** to `Bus: <object name>`.
- Replace `<object name>` with the name of the bus object name that defines the bus that the Outport produces.

Root-level Outport blocks convert virtual buses to nonvirtual buses. All signals in a nonvirtual bus must have the same sample time. For details, see "Specify Bus Signal Sample Times" on page 65-60.

In a model reference hierarchy, if the bus signal in a top-level model is virtual, the signal is converted to nonvirtual (see "Bus Conversion" on page 65-153). For information about using buses as inputs to, or outputs from, a referenced model, see "Bus Data Crossing Model Reference Boundaries" on page 65-150.

Buses for Atomic Subsystem Nonvirtual Inports

By default, an Inport block is a virtual on page 35-2 block and accepts a bus as input. However, an Inport block is nonvirtual on page 35-2 if both of these conditions exist:

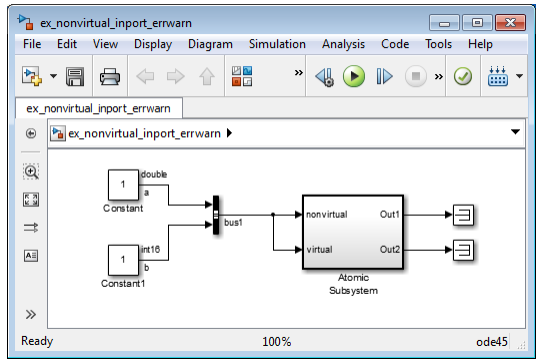
- The Inport block is in an atomic subsystem on page 3-11.
- The signal or any of its elements (if the signal is a bus) are directly connected to the output of the subsystem.

The Inport block can accept a bus when either of these conditions is true:

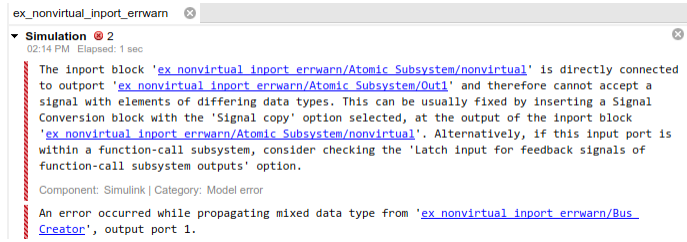
- All elements of the bus can be converted to a vector (all the elements must have the same data type).
- The bus is a nonvirtual bus.

If the first condition is violated (that is, the bus elements have different data types), attempting to simulate the model halts the simulation and produces an error message. To avoid this problem without changing the semantics of your model, insert a Signal Conversion block between the Inport block and the Outport block to which it was originally connected.

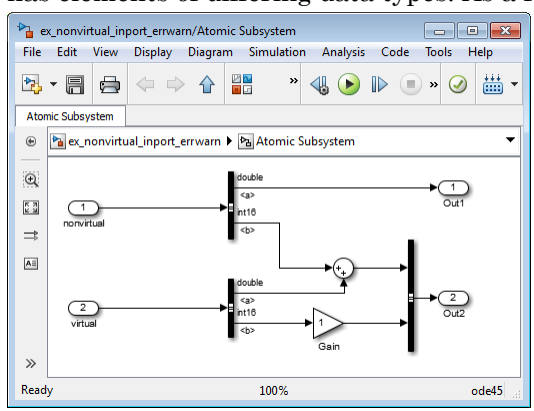
For example, the following model, which includes an atomic subsystem, does not simulate.



Starting the simulation generates the following error messages:



In the subsystem, the Inport block labeled `nonvirtual` is nonvirtual because it resides in an atomic subsystem and one of its bus elements (labeled `a`) is directly connected to one of the subsystem outputs. Further, the bus (`bus1`) connected to the subsystem inputs has elements of differing data types. As a result, you cannot simulate this model.



To break the direct connection to the subsystem output, after the nonvirtual Inport block, insert a Signal Conversion block. Set the Signal Conversion block **Output** parameter to `Signal copy`. Inserting the Signal Conversion block enables you to simulate the model.

- “Specify Initial Conditions for Bus Signals” on page 65-108
- “When to Use Bus Objects” on page 65-64

Specify Initial Conditions for Bus Signals

In this section...

Bus signal initialization is a special form of signal initialization. For general information about initializing signals, see “Initialize Signals and Discrete States” on page 64-53. For details about initializing array of buses signals, see “Initialize Arrays of Buses” on page 65-132.

Bus signal initialization specifies the bus element values that Simulink uses for the first execution of a block that uses that bus signal. By default, the initial value for a bus element is the ground value (represented by `0`). Bus initialization involves specifying nonzero initial conditions (ICs).

You can use bus signal initialization features to:

- Specify initial conditions for signals that have different data types.
- Apply a different initial condition for each signal in the bus.
- Specify initial conditions for a subset of signals in a bus without specifying initial conditions for all the signals.
- Use the same initial conditions for multiple blocks, signals, or models.

Blocks That Support Bus Signal Initialization

You can initialize bus signal values that input to a block if that block meets both of these conditions:

- Has an initial value or initial condition block parameter
- Supports bus signals

These blocks support bus signal initialization:

- Data Store Memory
- Memory
- Merge
- Outport (when the block is inside a conditionally executed context)
- Rate Transition
- Unit Delay

For example, the Unit Delay block is a bus-capable block. Its Block Parameters dialog box has an **Initial conditions** parameter.

You cannot initialize a bus that has:

- Variable-size signals
- Frame-based signals

Set Diagnostics to Support Bus Initialization

To enable bus signal initialization, before you start a simulation, set the "Underspecified initialization detection" configuration parameter to `simplified`.

Create Initial Condition Structures

You can create partial or full initial condition (IC) structures to represent initial values for a bus signal. To create an IC structure, use one of these approaches:

- Define a MATLAB structure in the MATLAB base or Simulink model workspace. You can manually define the structure, or alternatively for full structures, you can use the `Simulink.Bus.createMATLABstruct` function.
- In the Block Parameters dialog box for a block that supports bus signal initialization, for the initial condition parameter specify an expression that evaluates to a structure.

For information about defining MATLAB structures, see "Create Structure Array" (MATLAB).

The field that you specify in an IC structure must match these data attributes of the bus element exactly:

- Name
- Dimension
- Complexity

For example, if you define a bus element to be a real [2x2] double array, then in the IC structure, define the value to initialize that bus element to be a real [2x2] double array.

Explicitly specify fields in the IC structure for every bus element that has an enumerated (`enum`) data type.

Control Data Types of Structure Fields

If any of the signal elements of the target bus use a data type other than `double`, you can use different techniques to control the data types of the fields of initial condition structures. The technique that you choose can influence the efficiency and readability of the generated code. See “Control Data Types of Initial Condition Structure Fields” on page 65-156.

Create Full Structures for Initialization

A full initial condition structure provides an initial value for every element of a bus signal. The IC structure mirrors the bus hierarchy and reflects the attributes of the bus elements.

Specifying full structures during code generation offers these advantages:

- Generates more readable code
- Supports a modeling style that explicitly initializes all signals

Use the `Simulink.Bus.createMATLABStruct` function to streamline the creation of a full MATLAB initial condition structure with the same hierarchy, names, and data attributes as a bus signal. This function fills all of the elements that you do not specify with ground values for those elements.

You can use several different kinds of input with the function, including:

- A bus object name
- An array of port handles

You can invoke the function from the Bus Editor. Select the bus object for which you want to create a a full MATLAB structure, and then select the **File > Create a MATLAB structure** menu item.

To detect when structure parameters are not consistent in shape (hierarchy and names) with the associated bus signal, in the Simulink Editor, use the **Analysis > Model Advisor > By Product > Simulink** "Check structure parameter usage with bus signals" check. This check identifies partial IC structures.

After you create the structure, you can edit it in the MATLAB Editor.

Create Partial Structures for Initialization

A partial IC structure provides initial values for a subset of the elements of a bus signal. If you use a partial IC structure, during simulation, Simulink creates a full IC structure to represent all the bus signal elements. Simulink assigns the respective ground value to each element for which the partial IC structure does not explicitly assign a value.

Specifying partial structures for block parameter values can be useful during the iterative process of creating a model. Partial structures enable you to focus on a subset of signals in a bus. When you use partial structures, Simulink initializes unspecified signals implicitly.

When you define a partial IC structure:

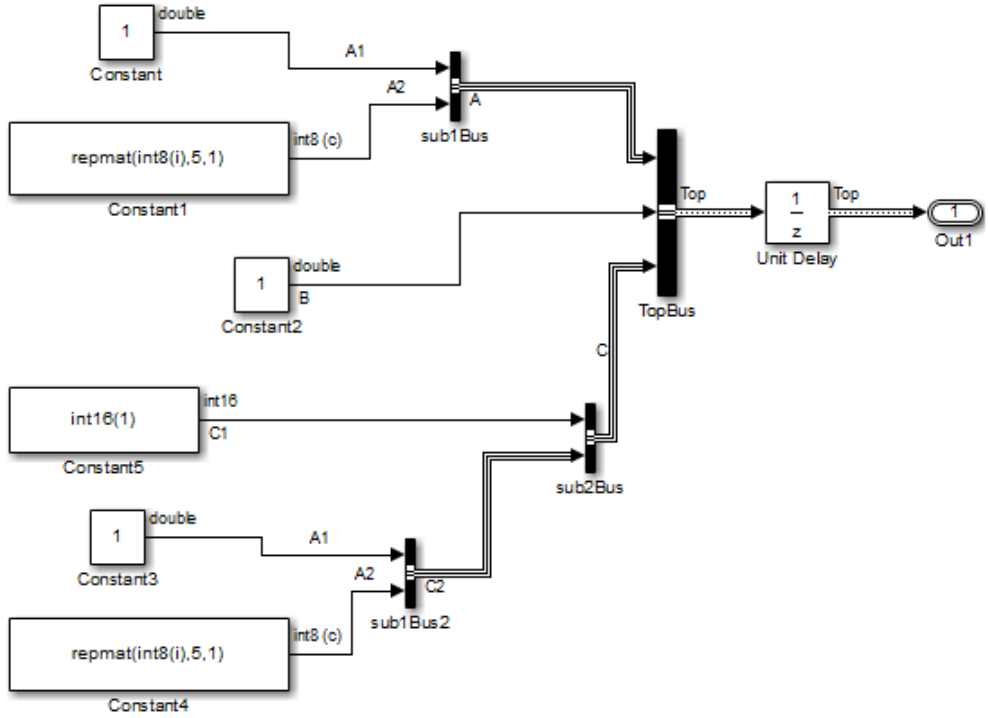
- Include only fields that are in the bus.
- Omit one or more fields that are in the bus.
- Make the field in the IC structure correspond to the nesting level of the bus element.
- Within the same nesting level in both the structure and the bus, optionally specify the structure fields in a different order than the bus elements.

Note The value of an IC structure must lie within the design minimum and maximum range of the corresponding bus element. Simulink performs this range checking when you do an update diagram or simulate the model.

Suppose that you have a bus, `Top`, composed of three elements: `A`, `B`, and `C`, with these characteristics:

- `A` is a nested bus, with two signal elements.
- `B` is a single signal.
- `C` is a nested bus that includes bus `A` as a nested bus.

The `ex_busic` model includes the nested `Top` bus. This is how the model appears after it has been updated. .



Here is a summary of the `Top` bus hierarchy and the data type, dimension, and complexity of the bus elements.

```
Top
   A (sub1)
      A1 (double)
      A2 (int8, 5x1, complex)
   B (double)
   C (sub2)
      C1 (int16)
```

```
C2 (sub1)
   A1 (double)
   A2 (int8, 5x1, complex)
```

In these examples, `K` is an IC structure specified for the initial value of the Unit Delay block. The IC structure corresponds to the `Top` bus in the `ex_busic` model. Here are some valid initial condition specifications.

Valid Syntax	Description
`K.A.A1 = 3`	Initialize the bus element `Top.A.A1` using the value `3`.
`K = struct('C',struct('C1',int16(4)))`	The bus element `Top.C.C1` is `int16`. The corresponding structure field explicitly specifies `int16(4)`. Alternatively, you could specify the field value as `4` without specifying an explicit data type.
`K = struct('B',3,'A',struct('A1',4))`	Bus elements `Top.B` and `Top.A` are at the same nesting level in the bus. For bus elements at the same nesting level, the order of corresponding structure fields does not matter.

Invalid Partial IC Structures

In the following examples, `K` is an IC structure specified for the initial value of the Unit Delay block. The IC structure corresponds to the `Top` bus in the `ex_busic` model.

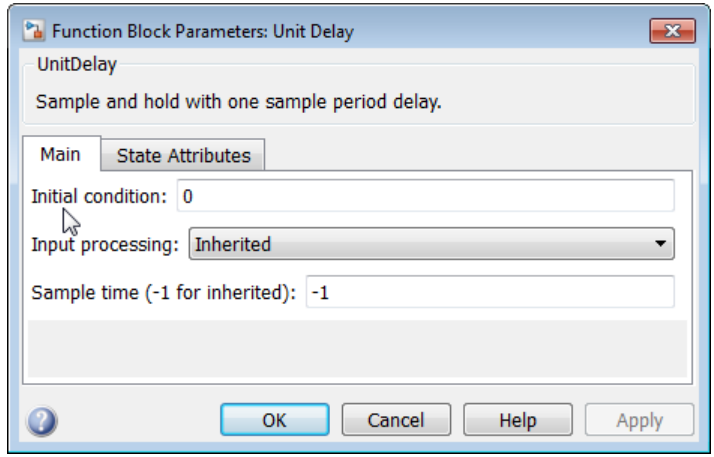
These three initial condition specifications are *not* valid:

Invalid Syntax	Reason the Syntax Is Invalid
`K.A.A2 = 3`	Value dimension and complexity do not match. The bus element `Top.A.A2` is `5x1`, but `K.A.A2` is `1x1`; `Top.A.A2` is complex, but `K.A.A2` is real.
`K.C.C2 = 3`	You cannot use a scalar value to initialize IC substructures.
`K = struct('B',3,'X',4)`	You cannot specify fields that are not in the bus (`X` does not exist in the bus).

Initialize Bus Signals Using Block Parameters

Initialize a bus signal by setting the initial condition parameter for a block that receives a bus signal as input and that supports bus initialization (see “Blocks That Support Bus Signal Initialization” on page 65-108).

For example, the Block Parameters dialog box for the Unit Delay block has an **Initial conditions** parameter.



For a block that supports bus signal initialization, you can replace the default value of `0` using one of these approaches:

- “MATLAB Structure for Initialization” on page 65-115
- “MATLAB Variable for Initialization” on page 65-115
- “Simulink.Parameter For Initialization” on page 65-116

All three approaches require that you define an IC structure (see “Create Initial Condition Structures” on page 65-109). You cannot specify a nonzero scalar value or any other type of value other than `0`, an IC structure, or `Simulink.Parameter` object to initialize a bus signal.

Defining an IC structure as a MATLAB variable, rather than specifying the IC structure directly in the Block Parameters dialog box offers several advantages, including:

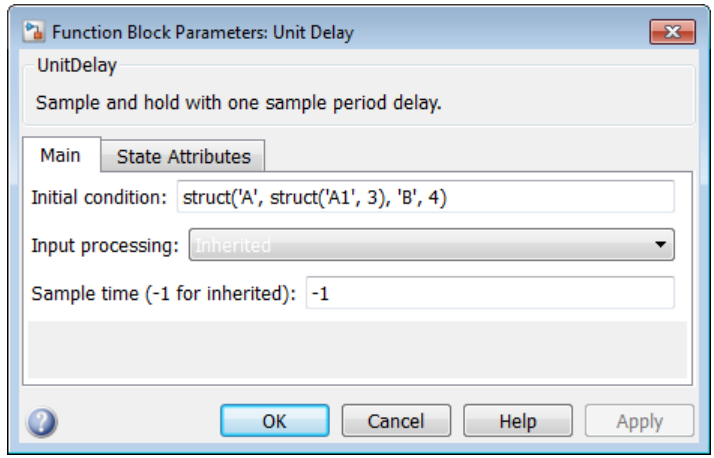
- Reuse of the IC structure for multiple blocks

- Using the IC structure as a tunable parameter in the generated code

MATLAB Structure for Initialization

You can initialize a bus signal using a MATLAB structure that explicitly defines the initial conditions for the bus signal.

For example, in the **Initial conditions** parameter of the Unit Delay block, you could type in a structure.



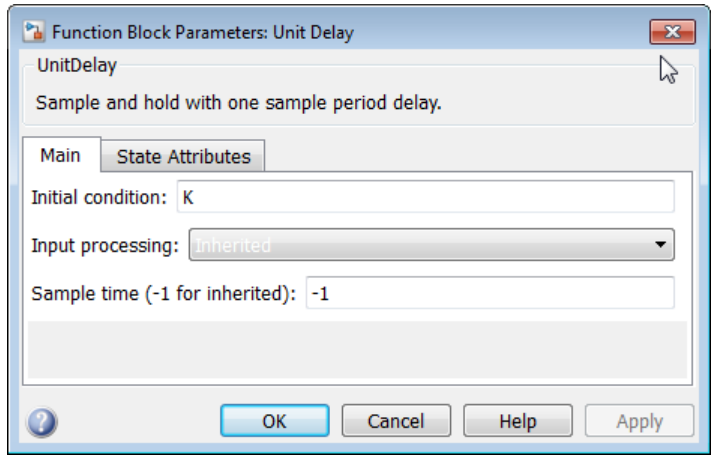
MATLAB Variable for Initialization

You can initialize a bus signal using a MATLAB variable that you define as an IC structure with the appropriate values.

For example, you could define the following partial structure in the base workspace:

```
K = struct('A', struct('A1', 3), 'B', 4);
```

You can then specify the `K` structure as the **Initial conditions** parameter of the Unit Delay block:



Simulink.Parameter For Initialization

You can initialize a bus signal using a `Simulink.Parameter` object that uses an IC structure for the `Value` property.

For example, you could define the partial structure `P` in the base workspace (reflecting the `ex_busic` model discussed in the previous section):

```
P = Simulink.Parameter;
P.DataType = 'Bus: Top';
P.Value = Simulink.Bus.createMATLABStruct('Top');
P.Value.A.A1 = 3;
P.Value.B = 5;
```

You can then specify the `P` structure as the **Initial conditions** parameter of the Unit Delay block:

Combine Buses into an Array of Buses

In this section...

Tip Simulink provides several techniques for combining signals into a composite signal. For a comparison of techniques, see “Composite Signal Techniques” on page 65-3.

What Is an Array of Buses?

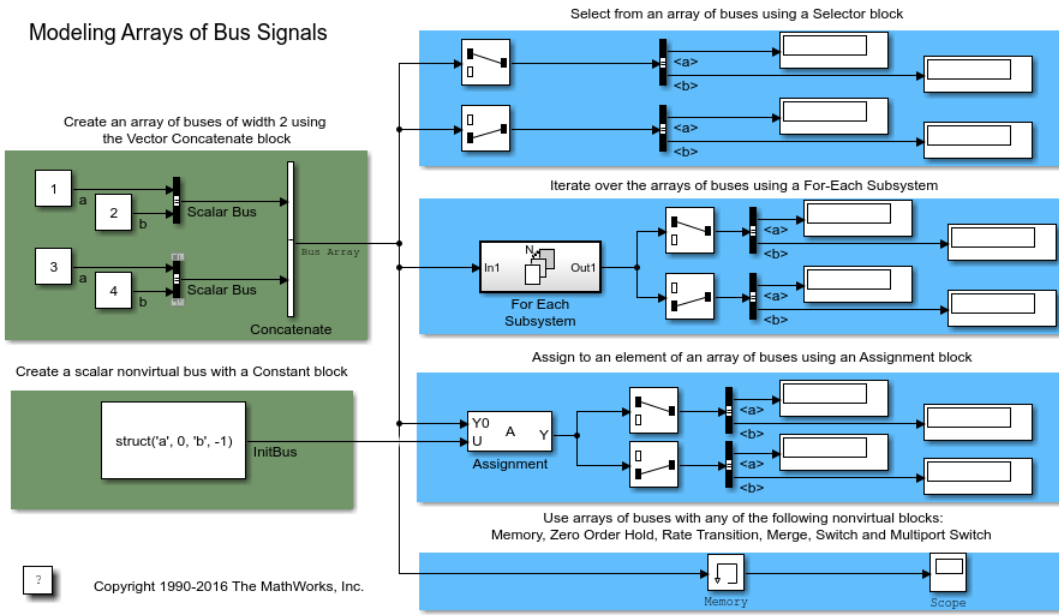
An array of nonvirtual buses is an array whose elements are buses. Each bus object has the same signal name, hierarchy, and attributes for its bus elements.

An example of using an array of buses is to model a multi-channel system, such as a communications system. You can model all the channels using the same bus object, although each of the channels could have a different value.

To use an arrays of buses:

- Use a bus object as a data type (see “Specify a Bus Object Data Type” on page 59-49).
- Specify dimensions for the bus and bus elements.

For an example of a model that uses an array of buses, open the `sldemo_bus_arrays` model. In this example, the nonvirtual bus input signals connect to a Vector Concatenate or Matrix Concatenate block that creates an array of bus signals. Here is the diagram after you update it:



The model uses the array of buses with:

- An Assignment block, to assign a bus in the array
- A For Each Subsystem block, to perform iterative processing over each bus in the array
- A Memory block, to output the array of buses input from the previous time step

Benefits of an Array of Buses

Use an array of buses to:

- Represent structured data compactly.
  - Reduce model complexity.
  - Reduce maintenance by centralizing algorithms used for processing multiple buses.
- Streamline iterative processing of multiple buses of the same type, for example, by using a For Each Subsystem with the array of buses.

- Simplify changing the number of buses, without your having to restructure the rest of the model or make updates in multiple places in the model.
- Use built-in blocks, such as the Assignment or Selector blocks, to manipulate arrays of buses just like arrays of any other type. Using a array of buses avoids the need for you to create custom S-functions to manage packing and unpacking structure signals.
- Use the combined bus data across subsystem boundaries, model reference boundaries, and into or out of a MATLAB Function block.
- Keep all the logic in the Simulink model, rather than splitting the logic between C code and the Simulink model. This approach supports integrated consistency and correctness checking, maintaining metadata in the model, and avoids the need to manage model components in two different environments.
- Generate code that has an array of C structures, which you can integrate with legacy C code that uses arrays of structures. This approach simplifies indexing into an array for Simulink computations, using a `for` loop on indexed structures.

Define an Array of Buses

For information about the kinds of buses that you can combine into an array of buses, see "Bus Requirements" on page 65-123.

To define an array of buses, use a Concatenate block. The table describes the array of buses input requirements and output for each of the Vector Concatenate and the Matrix Concatenate versions of the Concatenate block.

Block	Bus Signal Input Requirement	Output
Vector Concatenate	Vectors, row vectors, or columns vectors	If any of the inputs are row or column vectors, output is a row or column vector.
Matrix Concatenate	Signals of any dimensionality (scalars, vectors, and matrices)	Trailing dimensions are assumed to be 1 for lower dimensionality inputs. Concatenation is on the dimension that you specify with the **Concatenate dimension** parameter.

Note Do not use a Mux block or a Bus Creator block to define an array of buses. Instead, use a Bus Creator block to create scalar bus signals.

1. Define *one* bus object for *all* of the buses that you want to combine into an array of buses. For information about defining bus objects, see “Create Bus Objects” on page 65-70.

   The `sldemo_bus_arrays` model defines an `sldemo_bus_arrays_busobject` bus object, which both of the Bus Creator blocks use for the input bus signals (`Scalar Bus`) for the array of buses.

2. Add a Vector Concatenate or Matrix Concatenate block to the model and open the Block Parameters dialog box.

   The `sldemo_bus_arrays_busobject` model uses a Vector Concatenate block, because the inputs are scalars.

3. Set the **Number of inputs** parameter to be the number of buses that you want to be in the array of buses.

   The block icon displays the number of input ports that you specify.

4. Set the **Mode** parameter to match the type of the input bus data.

   In the `sldemo_bus_arrays` model, the input bus data is scalar, so the **Mode** setting is `Vector`.

5. If you use a Matrix Concatenation block, set the **Concatenate dimension** parameter to specify the output dimension along which to concatenate the input arrays. Enter one of the following values:

   - `1` — concatenate input arrays vertically
   - `2` — concatenate input arrays horizontally
   - A higher dimension than 2 — perform multidimensional concatenation on the inputs

6. Connect to the Concatenate block all the buses that you want to be in the array of buses.

Use Arrays of Buses in Models

In this section...

Array of Buses Requirements and Limitations

Bus Requirements

All buses combined into an array of buses must:

- Be nonvirtual
- Have the same bus type (that is, same name, hierarchies, and attributes for the bus elements)
- Have no variable-size signals or frame-based signals

Supported Blocks

You can use arrays of buses with these blocks:

- Virtual blocks
- Several nonvirtual blocks, such as:
  - Some signal routing blocks (for example, Data Store Memory, Merge, and Switch)
  - Rate Transition and Zero-Order Hold blocks
- Several additional blocks, such as Assignment, MATLAB Function, and Signal Conversion

For a complete list, see “Blocks That Support Arrays of Buses” on page 65-124. That section describes requirements for using the supported blocks.

Structure Parameter Requirements

To initialize an array of buses with structure parameters, you can use:

- The number `0`. In this case, all the individual signals in the array of buses use the initial value `0`.

- A scalar `struct` that represents the same hierarchy of fields and field names as the bus type. In this case, the scalar structure expands to initialize each of the individual signals in the array of buses.
- An array of structures that specifies an initial value for each of the individual signals in the array of buses.

  If you use an array of structures, all the structures in the array must have the same hierarchy of fields. Each field in the hierarchy must have the same characteristics across the array:

  - Field name
  - Numeric data type, such as `single` or `int32`
  - Complexity
  - Dimensions

You cannot use partial structures.

For more information about specifying initial conditions for bus signals, see “Initialize Arrays of Buses” on page 65-132.

Signal Logging Limitation

Simulink does not log array of buses signals inside referenced models in rapid accelerator mode.

Stateflow Limitations

Stateflow action language does not support arrays of buses.

Blocks That Support Arrays of Buses

The following blocks support arrays of buses:

- Virtual blocks (see “Nonvirtual and Virtual Blocks” on page 35-2)
- These nonvirtual blocks:
  - Data Store Memory
  - Data Store Read
  - Data Store Write

  - Memory
  - Merge
  - Multiport Switch
  - Rate Transition
  - Switch
  - Unit Delay
  - Zero-Order Hold
- Assignment
- MATLAB Function
- Matrix Concatenate
- Selector
- Signal Conversion
- Vector Concatenate
- Width
- Two-Way Connection (a Simscape block)

Note You can use an array of buses as an input to an In Bus Element block, but you cannot use that block to select individual buses. The block passes through the whole array of buses signal.

Block Parameter Settings

Using an array of buses signal with some blocks requires specific block parameter settings.

This information is also in the reference pages for each of these blocks. For usage information for bus-related blocks, see “Work with Array of Buses Signals” on page 65-128.

Block	Block Parameters Settings
Memory	**Initial condition** — You can specify this parameter with: • The value `0`. In this case, all the individual signals in the array of buses use the initial value `0`. • An array of structures that specifies an initial condition for each of the individual signals in the array of buses. • A single scalar structure that specifies an initial condition for each of the elements that the bus type defines. Use this technique to specify the same initial conditions for each of the buses in the array.

Merge	• **Allow unequal port widths** — Clear this parameter.
	• **Number of inputs** — Set to a value of 2 or greater.
	• **Initial condition** — You can specify this parameter with:
	  • The value `0`. In this case, all the individual signals in the array of buses use the initial value `0`.
	  • An array of structures that specifies an initial condition for each of the individual signals in the array of buses.
	  • A single scalar structure that specifies an initial condition for each of the elements that the bus type defines. Use this technique to specify the same initial conditions for each of the bus signals in the array.

Multiport Switch	**Number of data ports** — Set to a value of 2 or greater.
Signal Conversion	**Output** — Set to `Signal copy`.
Switch	**Threshold** — Specify a scalar threshold.

Signal Line Style

After model simulation, the line style for the array of buses signal is a thicker version of the signal line style for a nonvirtual bus signal.

For example, in the `sldemo_bus_arrays` model, the `Scalar Bus` signal is a nonvirtual bus signal, and the `Bus Array` output signal of the Concatenate block is an array of buses signal.

Work with Array of Buses Signals

In this section...

To select a signal within an array of buses, use a:

1. Selector block to find the appropriate bus within the array of buses.
2. Bus Selector block to select the signal.

To assign a value to a signal within an array of buses, use:

1. A Bus Assignment block to assign a value to a bus element
2. An Assignment block to assign the bus to the array of buses

Bus Selector and Bus Assignment blocks can only accept scalar buses, not arrays of buses.

A Bus Creator block can accept an array of buses as input, but cannot have an array of buses as output.

Set Up Model for Arrays of Buses

Setting up a model to use an array of buses usually involves these basic tasks:

1. Define the array of buses (see “Define an Array of Buses” on page 65-120).
2. Add a subsystem for performing iterative processing on each element of the array of buses. For example, use a For Each Subsystem block or an Iterator block. Connect the array of buses signal from the Concatenate block to the iterative processing subsystem. See “Perform Iterative Processing” on page 65-129.

3 Model your scalar algorithm within the iterative processing subsystem (for example, a For Each subsystem).

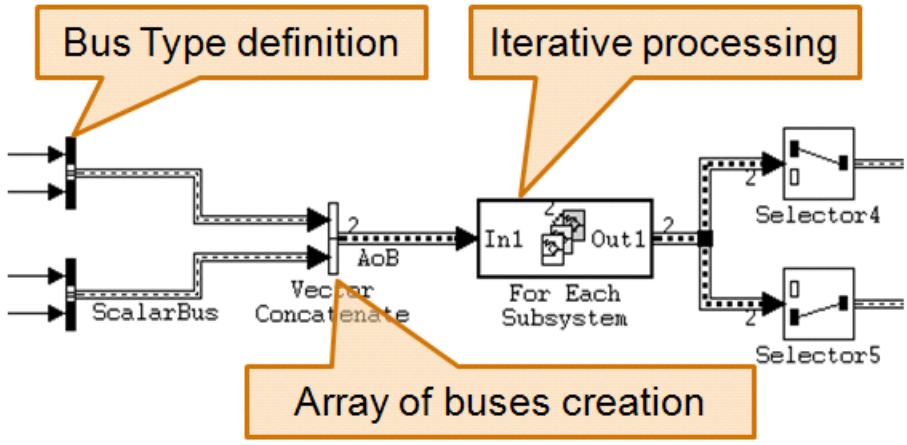
   a Operate on the array of buses (using Selector and Assignment blocks).

   b Use the Bus Selector and Bus Assignment blocks to select elements from, or assign elements to, a scalar bus within the subsystem.

   See “Assign Values into an Array of Buses” on page 65-130 and “Select Bus Elements from an Array of Buses” on page 65-130.

4 Optionally, import or log array of buses data. See “Import Array of Buses Data” on page 65-131 and “Log Array of Buses Signals” on page 65-131

The resulting model includes these components.



Perform Iterative Processing

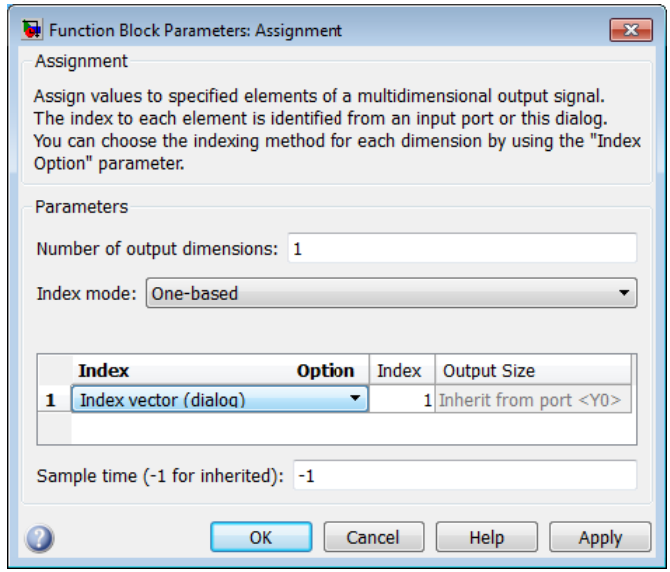
You can perform iterative processing on the bus signal data of an array of buses using blocks such as a For Each Subsystem block, a While Iterator Subsystem block, or a For Iterator Subsystem block. You can use one of these blocks to perform the same kind of processing on:

- Each bus in the array of buses
- A selected subset of buses in the array of buses

Assign Values into an Array of Buses

Use an Assignment block to assign values to specified elements in a bus array.

For example, in the `sldemo_bus_arrays` model, the Assignment block assigns the value to the first element of the array of buses.

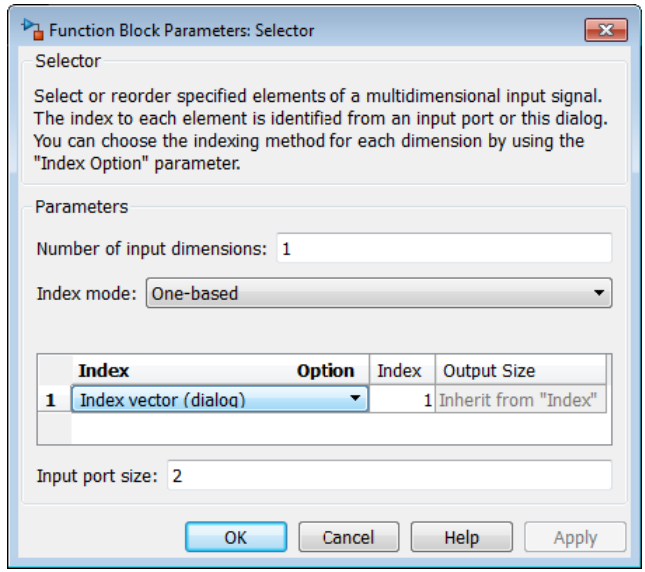


To assign bus elements within a bus signal, use the Bus Assignment block. The input for the Bus Assignment block must be a scalar bus signal.

Select Bus Elements from an Array of Buses

Use a Selector block to select elements of an array of buses. The input array of buses can have any dimension. The output bus signal of the Selector block is a selected or reordered set of elements from the input array of buses.

For example, the `sldemo_bus_arrays` model uses Selector blocks to select elements from the array of buses signal that the Assignment and For Each Subsystem blocks outputs. In this example, here is the Block Parameters dialog box for the Selector block that selects the first element:



To select bus elements within a bus signal, use the Bus Selector block. The input for the Bus Selector block must be a scalar bus signal.

Import Array of Buses Data

Use a root Inport block to import (load) an array of structures of MATLAB `timeseries` objects for an array of buses. You can import partial data into the array of buses.

For details, see “Import Array of Buses Data” on page 61-175.

You cannot use a From Workspace or From File block to import data for an array of buses.

Log Array of Buses Signals

To export an array of buses signal, mark the signal for signal logging. For more information, see “Save Runtime Data from Simulation”.

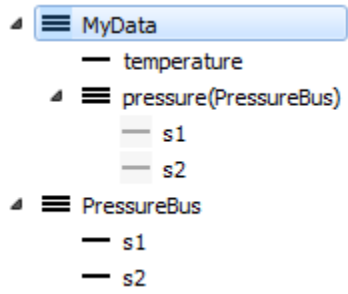
Note Simulink does not log signals inside referenced models in rapid accelerator mode.

To access the signal logging data for a specific signal in an array of buses, navigate through the structure hierarchy and specify the index to the specific signal. For details, see “Access Array of Buses Signal Logging Data” on page 61-33.

Initialize Arrays of Buses

To specify a unique initial value for each of the individual signals in an array of buses, you can use an array of initial condition structures. Each structure in the array initializes one of the buses.

Here is an example that shows how to initialize an array of buses. Suppose that you define the bus types `MyData` and `PressureBus`.



Suppose that you set the data type of the signal element `temperature` to `int16`, and the data type of the elements `s1` and `s2` to `double`.

To specify initial conditions for an array of buses, you can create a variable whose value is an array of initial condition structures.

```
initValues(1).temperature = int16(5);
initValues(1).pressure.s1 = 9.87;
initValues(1).pressure.s2 = 8.71;

initValues(2).temperature = int16(20);
initValues(2).pressure.s1 = 10.21;
initValues(2).pressure.s2 = 9.56;

initValues(3).temperature = int16(35);
initValues(3).pressure.s1 = 8.98;
initValues(3).pressure.s2 = 9.17;
```

The variable `initValues` provides initial conditions for a signal that is an array of three buses. You can use `initValues` to specify the **Initial condition** parameter of a block such as Unit Delay.

Alternatively, you can use a single scalar structure to specify the same initial conditions for all the buses in the array.

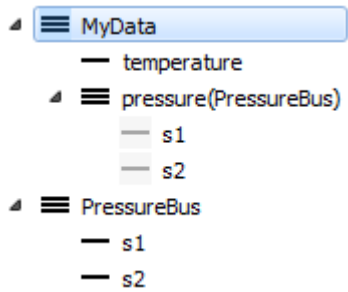
```
initStruct.temperature = int16(15);
initStruct.pressure.s1 = 10.32;
initStruct.pressure.s2 = 9.46;
```

If you specify `initStruct` in the **Initial condition** parameter of a block, each bus in the array uses the same initial value, `15`, for the signal element `temperature`. Similarly, the buses use the initial value `10.32` for the element `pressure.s1` and the value `9.46` for the element `pressure.s2`.

To create an array of structures for a bus that uses a large hierarchy of signal elements, consider using the function `Simulink.Bus.createMATLABStruct`.

This example shows how to initialize a nested array of buses. Create an initial condition structure for a complicated signal hierarchy that includes nested arrays of buses.

1. In the Bus Editor, create the bus objects `MyData` and `PressureBus`.



2. In the hierarchy pane, select the bus element `pressure`. Set the **Dimensions** property to `[1 3]`.
3. Create an array of four initialization structures by using the function `Simulink.Bus.createMATLABStruct`. Store the array in the variable `initStruct`. Initialize all the individual signals to the ground value, `0`.

```
initStruct=Simulink.Bus.createMATLABStruct('MyData',[],[1 4]);
```

4 In the base workspace, double-click the variable `initStruct` to view it in the variable editor.

   The four structures in the array each have the fields `temperature` and `pressure`.

5 To inspect a `pressure`, double-click one of the fields.

   The value of each of the four `pressure` fields is an array of three substructures. Each substructure has the fields `s1` and `s2`.

6 To provide unique initialization values for the signals in an array of buses, you can specify the values manually using the variable editor.

   Alternatively, you can write a script. For example, to access the field `s1` of the second substructure `pressure` in the third structure of `initStruct`, use this code:

```
initStruct(3).pressure(2).s1 = 15.35;
```

Code Generation

Code generation for array of buses signals produces structures with a specific format. See “Code Generation for Arrays of Buses” on page 65-163.

Convert Models to Use Arrays of Buses

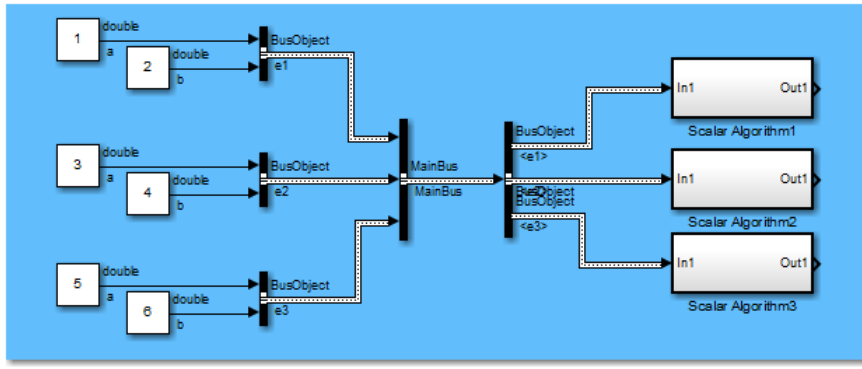
There are several reasons to convert a model to use an array of buses (see “Benefits of an Array of Buses” on page 65-119). For example:

- The model was developed before Simulink supported arrays of buses (introduced in R2010b), and the model contains many subsystems that perform the same kind of processing.
- The model has grown in complexity.

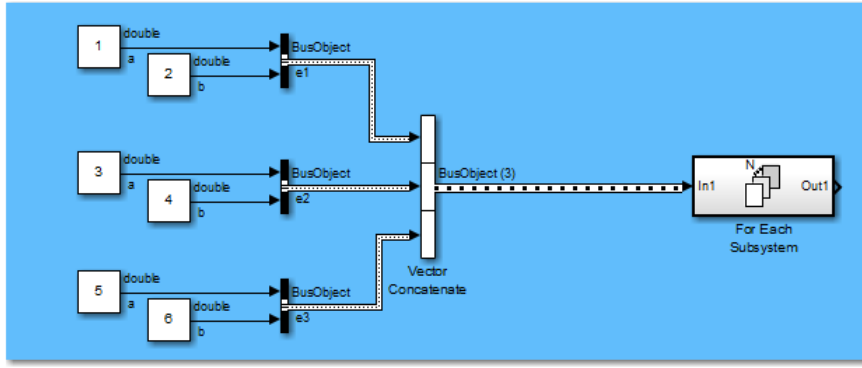
General Conversion Approach

Here is a general approach for converting a model that contains buses to a model that uses an array of buses. The method that you use depends on your model. For details about these techniques, see “Combine Buses into an Array of Buses” on page 65-118 and “Use Arrays of Buses in Models” on page 65-123.

This workflow refers to a stylized example model. The example shows the original modeling pattern and a new modeling pattern that uses an array of buses.



Original modeling pattern



New modeling pattern

In the original modeling pattern:

- The target bus signal to be converted is named `MainBus`, and it has three elements, each of type `BusObject`.
- The `ScalarAlgorithm1`, `ScalarAlgorithm2`, and `ScalarAlgorithm3` subsystems encapsulate the algorithms that operate on each of the bus elements. The subsystems all have the same content.
- A Bus Selector block picks out each element of `MainBus` to drive the subsystems.

The construction in the original modeling pattern is inefficient for two reasons:

- A copy of the subsystem that encapsulates the algorithm is made for each element of the bus that is to be processed.
- Adding another element to `MainBus` involves changing the bus object definition and the Bus Selector block, and adding a subsystem. Each of these changes is a potential source of error.

To convert the original modeling pattern to use an array of buses:

1. Identify the target bus and associated algorithm that you want to convert. Typically, the target bus signal is a bus of buses, where each element bus signal is of the same type.

   - The bus that you convert must be a nonvirtual bus. If all elements of the target bus have the same sample time (or if the sample time is inherited), you can convert a virtual bus to a nonvirtual bus.
   - The target bus cannot have variable-dimensioned and frame-based elements.

2. Use a Concatenate block to convert the original bus of buses signal to an array of buses.

   In the example, the new modeling pattern uses a Vector Concatenate block to replace the Bus Creator block that creates the `MainBus` signal. The output of the Vector Concatenate block is an array of buses, where the type of the bus signal is `BusObject`. The new model eliminates the wrapper bus signal (`MainBus`).

3. Replace all identical copies of the algorithm subsystem with a single For Each subsystem that encapsulates the scalar algorithm. Connect the array of buses signal to the For Each subsystem.

   The new model eliminates the Bus Selector blocks that separate out the elements of the `MainBus` signal in the original model.

4. Configure the For Each Subsystem block to iterate over the input array of buses signal and concatenate the output bus signal.

   The scalar algorithm within the For Each subsystem cannot have continuous states. For additional limitations, see the For Each Subsystem block documentation.

Repeat an Algorithm Using a For Each Subsystem

If you repeat algorithms in a diagram by copying and pasting blocks and subsystems, maintaining the model can become difficult. Individual signal lines and subsystems can crowd the diagram, reducing readability and making simple changes difficult. At the same time, many variables can crowd workspaces, reducing model portability. A model can develop these efficiency issues as you add to the design over time.

To repeat an algorithm, you can iterate the algorithm over signals, subsystems, and parameters that are grouped into arrays and structures. This example shows how to convert an inefficiently complex repetitive algorithm into a compact form that is easier to manage.

In this section...

Explore Example Model

1. Open the example model `ex_repeat_algorithm`. The model creates about 30 variables in the base workspace.
2. Inspect the subsystem Burner_1_Analysis. This subsystem executes an algorithm by using the base workspace variables as parameters in blocks such as Constant and Discrete-Time Integrator.
3. Inspect the subsystems Burner_2_Analysis and Burner_3_Analysis. All three subsystems execute the same algorithm but use different workspace variables to parameterize the blocks.
4. Inspect the three Analysis_Delay subsystems. These subsystems repeat a different algorithm from the one in the Analysis subsystems.
5. Return to the top level of the model. The Memory blocks delay the input signals before they enter the Analysis_Delay subsystems.
6. Look at the **Data Import/Export** pane of the Configuration Parameters dialog box. The model uses the variables `SensorsInput` and `t` as simulation inputs.

During simulation, each of the nine columns in the matrix variable `SensorsInput` provides input data for an Inport block at the top level of the model.

Reduce Signal Line Density with Buses

You can use buses to group related signals into a single structured signal, reducing line density and improving model readability.

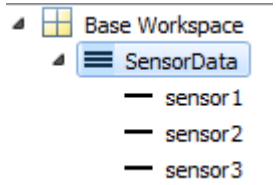
Each subsystem in the example model requires three signal inputs. You can combine each group of three signals into a single bus.

You could modify all the subsystems in the example model to use buses. However, because some of the subsystems are identical, you can delete them and later replace them with For Each Subsystem blocks.

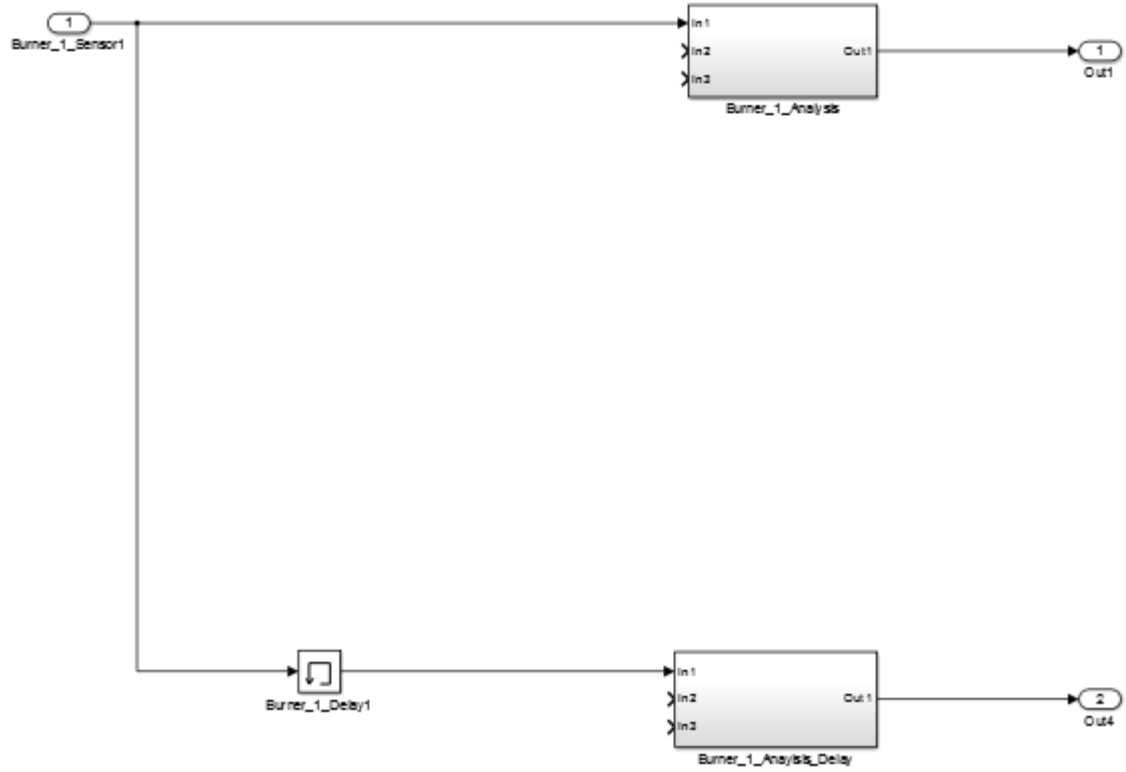
1 Open the Bus Editor.

```
buseditor
```

2 Create a bus type `SensorData` with three signal elements: `sensor1`, `sensor2`, and `sensor3`.



3 Delete the blocks as shown in the figure, leaving only the Burner_1_Sensor1 and Burner_1_Delay1 blocks as inputs to the two remaining subsystems.



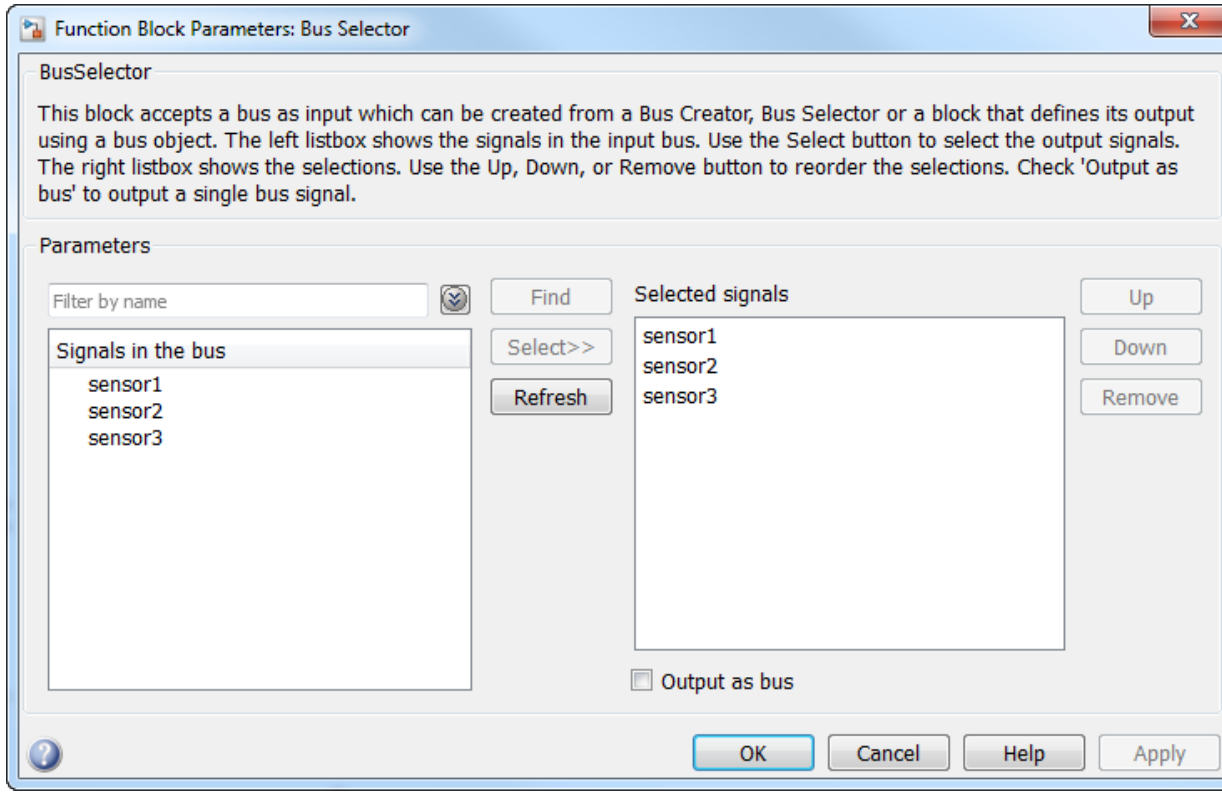
4 On the **Signal Attributes** tab of the Burner_1_Sensor1 Inport block dialog box, set **Data type** to `Bus: SensorData`.

   The output of the block is a bus signal that contains the three signal elements `sensor1`, `sensor2`, and `sensor3`.

5 Open the subsystem Burner_1_Analysis. Delete the signal output lines of the three Inport blocks. Delete the In2 and In3 Inport blocks.

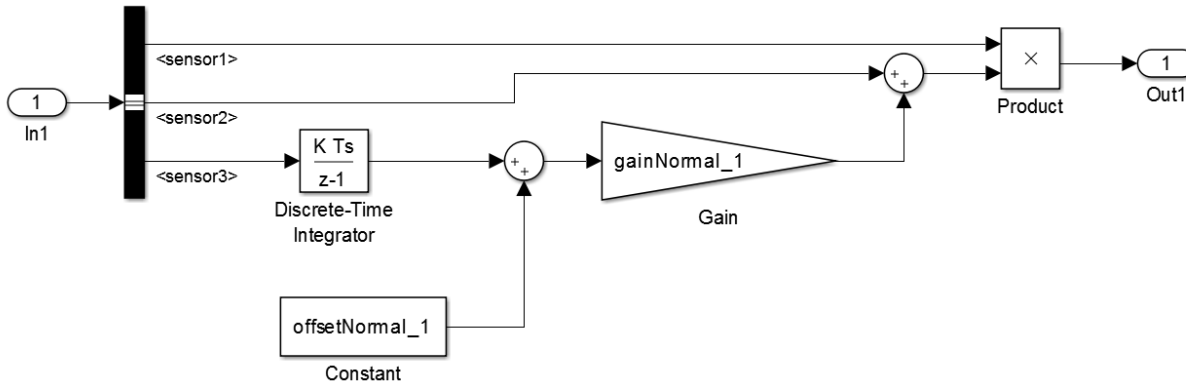
6 Add a Bus Selector block to the right of the In1 Inport block. Connect the Inport block output to the Bus Selector block.

7 In the Bus Selector block dialog box, select the signals `sensor1`, `sensor2`, and `sensor3`.



The Bus Selector block extracts the three signal elements from the input bus. Other blocks in the model can use the extracted signal elements.

8 In the subsystem, connect the blocks as shown.



9 In the subsystem Burner_1_Analysis_Delay, use a Bus Selector block to extract the signals in the bus. Use the same technique as you did in the subsystem Burner_1_Analysis.

Repeat an Algorithm

A For Each Subsystem block partitions an input signal, and sequentially executes an algorithm on each partition. For example, if the input to the subsystem is an array of six signals, you can configure the subsystem to execute the same algorithm on each of the six signals.

You can use For Each subsystems to repeat an algorithm in an iterative fashion. This approach improves model readability and makes it easy to change the repeated algorithm .

1 Add two For Each Subsystem blocks to the model. Name one of the subsystems Burner_Analysis. Name the other subsystem Burner_Analysis_Delay.

2 Copy the contents of the subsystem Burner_1_Analysis into the subsystem Burner_Analysis. Before you paste the blocks, delete the Inport and Outport blocks in the For Each subsystem.

3 In the For Each block dialog box in the Burner_Analysis subsystem, select the check box to partition the input `In1`.

4 Copy the contents of the subsystem Burner_1_Analysis_Delay into the subsystem Burner_Analysis_Delay.

5 In the For Each block dialog box in the Burner_Analysis_Delay subsystem, select the check box to partition the input `In1`.

6 At the top level of the model, delete the subsystems Burner_1_Analysis and Burner_1_Analysis_Delay. Connect the new For Each Subsystem blocks in their place.

7 On the **Signal Attributes** tab of the Burner_1_Sensor1 Inport block dialog box, set **Port dimensions** to `3`.

The block output is a three-element array of buses. The For Each subsystems in the model repeat an algorithm for each of the three buses in the array.

8 Create a `Simulink.SimulationData.Dataset` object that the Inport block can use to import the simulation data. You can use this code to create the object and store it in the variable `SensorsInput`.

```
% First, create an array of structures whose field values are
% timeseries objects.

for i = 1:3 % Burner number

    % Sensor 1
    eval(['tempInput(1,' num2str(i) ').sensor1 = ' ...
        'timeseries(t,SensorsInput(:,' num2str(3*(i-1)+1) '));'])

    % Sensor 2
    eval(['tempInput(1,' num2str(i) ').sensor2 = ' ...
        'timeseries(t,SensorsInput(:,' num2str(3*(i-1)+2) '));'])

    % Sensor 3
    eval(['tempInput(1,' num2str(i) ').sensor3 = ' ...
        'timeseries(t,SensorsInput(:,' num2str(3*(i-1)+3) '));'])

end

% Create the Dataset object.

SensorsInput = Simulink.SimulationData.Dataset;
SensorsInput = addElement(SensorsInput,tempInput,'element1');

clear tempInput t i
```

The code first creates a variable `tempInput` that contains an array of three structures. Each structure has three fields that correspond to the signal elements in

the bus type `SensorData`, and each field stores a MATLAB `timeseries` object. Each `timeseries` object stores one of the nine columns of data from the variable `SensorsInput`, which stored the simulation input data for each of the sensors.

The code then overwrites `SensorsInput` with a new `Simulink.SimulationData.Dataset` object, and adds `tempInput` as an element of the object.

9 Set the **Input** configuration parameter to `SensorsInput`.

Since `SensorsInput` provides simulation input data in the form of `timeseries` objects, you do not need to specify a variable that contains time data.

10 Create an array of structures that initializes the remaining Memory block, and store the array in the variable `initForDelay`. Specify the structure fields with the values of the existing initialization variables such as `initDelay_1_sensor1`.

```
for i = 1:3 % Burner number

    % Sensor 1
    eval(['initForDelay(' num2str(i) ').sensor1 = ' ...
        'initDelay_' num2str(i) '_sensor1;'])

    % Sensor 2
    eval(['initForDelay(' num2str(i) ').sensor2 = ' ...
        'initDelay_' num2str(i) '_sensor2;'])

    % Sensor 3
    eval(['initForDelay(' num2str(i) ').sensor3 = ' ...
        'initDelay_' num2str(i) '_sensor3;'])
end
```

To view the contents of the new variable `initForDelay`, double-click the variable name in the base workspace. The variable contains an array of three structures that each has three fields: `sensor1`, `sensor2`, and `sensor3`.

initForDelay

1x3 struct with 3 fields

Fields	sensor1	sensor2	sensor3
1	17.5000	13.2000	27.8000
2	5.2000	6.9000	1.7000
3	19.4000	14.9000	22.3000

11 In the Memory block dialog box, set **Initial condition** to `initForDelay`.

The Memory block output is an array of buses that requires initialization. Each signal element in the array of buses acquires an initial value from the corresponding field in the array of structures.

Organize Parameters into Arrays of Structures

The base workspace contains many variables that the example model uses for block parameters. To reduce the number of workspace variables, package them into arrays of structures, and use the individual structure fields to specify block parameters.

A For Each Subsystem block can partition an array of values that you specify as a mask parameter. Each iteration of the subsystem uses a single partition of the array to specify block parameters. If you specify the parameter as an array of structures, each iteration of the subsystem can use one of the structures in the array.

1 Create an array of structures that parameterizes the Burner_Analysis For Each subsystem, and store the array in the variable `paramsNormal`. Specify the structure fields by using the values of existing parameter variables such as `gainNormal_1`, `offsetNormal_1`, and `initDelayed_1`.

```
for i = 1:3
    eval(['paramsNormal(' num2str(i) ').gain = gainNormal_' num2str(i) ';'])
    eval(['paramsNormal(' num2str(i) ').offset = offsetNormal_' num2str(i) ';'])
    eval(['paramsNormal(' num2str(i) ').init = initNormal_' num2str(i) ';'])
end
```

The variable contains an array of three structures that each has three fields: `gain`, `offset`, and `init`.

2 In the model, right-click the Burner_Analysis For Each subsystem and select **Mask > Create Mask**.

3. On the **Parameters & Dialog** pane of the dialog box, under **Parameter**, click **Edit**. For the new mask parameter, set **Prompt** to `Parameter structure` and **Name** to `paramStruct`. Click **OK**.
4. In the mask for the Burner_Analysis subsystem, set **Parameter structure** to `paramsNormal`.
5. Open the subsystem. In the For Each block dialog box, on the **Parameter Partition** pane, select the check box to partition the parameter `paramStruct`. Set **Partition dimension** to `2`.
6. For the blocks in the subsystem, set these parameters.

Block	Parameter Name	Parameter Value
Gain	**Gain**	`paramStruct.gain`
Discrete-Time Integrator	**Initial condition**	`paramStruct.init`
Constant	**Constant value**	`paramStruct.offset`

7. Create an array of structures that parameterizes the Burner_Analysis_Delay For Each subsystem, and store the array in the variable `paramsForDelay`.

```
for i = 1:3
    eval(['paramsForDelay(' num2str(i) ').gain = gainDelayed_' num2str(i) ';'])
    eval(['paramsForDelay(' num2str(i) ').offset = offsetDelayed_' num2str(i) ';'])
    eval(['paramsForDelay(' num2str(i) ').init = initDelayed_' num2str(i) ';'])
end
```

8. At the top level of the model, right-click the Burner_Analysis_Delay For Each subsystem and select **Mask > Create Mask**.
9. On the **Parameters & Dialog** pane of the dialog box, under **Parameter**, click **Edit**. For the new mask parameter, set **Prompt** to `Parameter structure` and **Name** to `paramStruct`. Click **OK**.
10. In the mask for the For Each Subsystem block, set **Parameter structure** to `paramsForDelay`.
11. Open the subsystem. In the For Each block dialog box, on the **Parameter Partition** pane, select the check box to partition the parameter `paramStruct`. Set **Partition dimension** to `2`.
12. For the blocks in the subsystem, set these parameters.

Block	Parameter Name	Parameter Value
Gain	**Gain**	`paramStruct.gain`

Block	Parameter Name	Parameter Value
Discrete-Time Integrator	**Initial condition**	`paramStruct.init`
Constant	**Constant value**	`paramStruct.offset`

13 Clear the unnecessary variables from the base workspace.

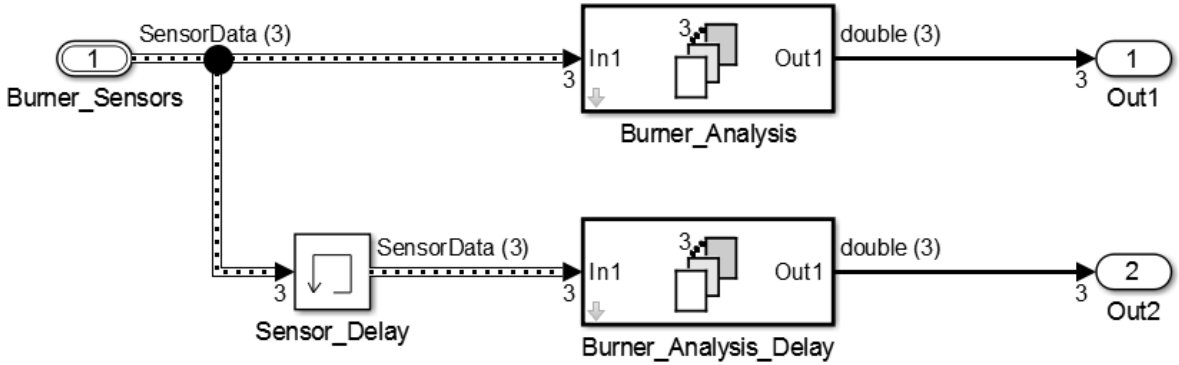
```
% Clear the old parameter variables that you replaced
% with arrays of structures
clear -regexp _

% Clear the iteration variables
clear i
```

The model requires few variables in the base workspace.

Inspect the Converted Model

To view the new signal and subsystem organization, update the diagram.



The model input is an array of three bus signals. The model uses two For Each subsystems to execute the two algorithms on each of the three bus signals in the input array.

In the base workspace, arrays of structures replace the many variables that the model used. Mathematically, the modified model behaves the same way it did when you started because the arrays of structures contain the values of all the old variables.

To view the completed model, open the example model `ex_repeat_algorithm_complete`.

Tip You can log nonbus signals in a For Each subsystem. However, you cannot use signal logging for bus or array of buses signals from within a For Each subsystem. Either use a Bus Selector block to select the bus element signals that you want to log or add an Outport block outside of the subsystem and then log that signal. For details, see "Log Signals in For Each Subsystems" on page 61-114.

Bus Data Crossing Model Reference Boundaries

A model reference boundary refers to the boundary between a model that contains a Model block and the referenced model. If you have bus data in a model that is passed to a Model block, then that data crosses the boundary to the referenced model. You need to set up your model so that the bus data input to the Model block is consistent with the bus data that the referenced model requires.

For bus data that crosses model reference boundaries:

1. Use a bus object (`Simulink.Bus`) to define the bus. For details, see "When to Use Bus Objects" on page 65-64 and "Create Bus Objects" on page 65-70.

   You can use a nonvirtual or a virtual bus as an input to a referenced model.
2. Decide whether to use a virtual or nonvirtual bus. Using a nonvirtual bus provides a well-defined data interface for code generation. See "Virtual and Nonvirtual Buses" on page 65-4.

To use a multirate bus signal across a model referenced boundary requires a specific configuration of parameters in the parent and referenced models.

Connect Multirate Buses to Referenced Models

You can input a single-rate bus to a referenced model. To input the signals in a multirate bus to a referenced model, insert blocks into the parent and referenced model as follows:

1. **In the parent model:** To convert the multirate bus to a single-rate bus, insert a Rate Transition block. The Rate Transition block must specify a rate in its **Block Parameters** > **Output port sample time** field unless one of the following is true:
   - The **Configuration Parameters** > **Solver** pane specifies a rate with these settings:
     - The **Periodic sample time constraint** parameter is set to `Specified`.
     - The **Sample time properties** parameter contains the specified rate.
   - The Inport block that accepts the bus in the referenced model specifies a rate in its**Block Properties** > **Signal Attributes** > **Sample time** field.
2. **In the referenced model:** Use a Bus Selector block to pick out signals of interest, and use Rate Transition blocks to convert the signals to the desired rates.

Model Referencing Limitations for Virtual Buses

If you use a bus signal as an input to or an output from a referenced model:

- The bus cannot contain a variable-size signal element.

  As a workaround, use a nonvirtual bus instead.
- For code generation, you cannot configure the `I/O arguments step method` style of C++ class interface for the referenced model.

  As a workaround, use a nonvirtual bus instead. Alternatively, use the `Default` style of C++ class interface.
- For code generation, you cannot configure function prototype control for the referenced model.

  As a workaround, use a nonvirtual bus instead.

Use the Upgrade Advisor to fix models saved before R2016a that engage these limitations. See “Update Models Saved Before R2016a” on page 65-151.

Update Models Saved Before R2016a

The behavior of models that meet these criteria is different than it is in R2016a and later releases:

- The model was saved in a release earlier than R2016a.
- The model has referenced models with bus inputs and outputs configured to be treated as virtual buses.

Use the Upgrade Advisor **Check for virtual bus across model reference boundaries** check to avoid errors that the behavior differences can trigger. Run the **Analyze model hierarchy and continue upgrade sequence** check on the top-level model and then down through the model reference hierarchy.

Bus Conversion

When updating a diagram prior to simulation or code generation, Simulink automatically converts a virtual bus to a nonvirtual bus (and nonvirtual buses to virtual buses) in cases such as when the virtual bus is an input to, or output from:

- An S-Function block
- A Stateflow chart

When you pass a bus signal into a referenced model, Simulink makes the bus a virtual or nonvirtual bus to match the type of bus specified for the Inport block it feeds. Bus signal outputs are virtual or nonvirtual, based on the specification for the Outport block. For bus signals driving a root-level Outport block, Simulink performs a similar conversion. For more information, see “Bus Data Crossing Model Reference Boundaries” on page 65-150.

The conversion consists of inserting hidden Signal Conversion blocks into the model where needed. If no bus object is specified at the port to which the virtual bus connects, conversion to a nonvirtual bus fails.

To avoid the need for automatic bus conversion, manually insert a Signal Conversion block. For details, see the Signal Conversion documentation.

Buses and Libraries

When you define a library block, the block can input, process, and output buses just as an ordinary subsystem can.

Provide the appropriate input bus signal if:

- You have a bus routing block (Bus Creator, Bus Selector, or Bus Assignment) block that is in a library.
- That block depends on signals that are input to the library.

To change that block in a library, perform these steps. For details about modifying library links, see “Libraries”.

1. Copy the library block that uses that block to a model that connects an input bus.
2. Disable the link to the library block in this model.
3. Edit the bus routing block within the context of the outside model.
4. Resolve the link to the library.
5. In the Link Tool, in **Push/Restore Mode**, select `Push` to place the edited content into the library.
6. Save the library.

Alternatively, to have the library supply an appropriate bus signal, use a bus object to lock in the data type at the interface of a library subsystem block.

Generate Code for Bus Signals

If you have Simulink Coder, the various techniques for defining buses are essentially equivalent for simulation, but the techniques can make a significant difference in the efficiency, size, and readability of generated code. For example, a nonvirtual bus appears as a structure in generated code, and only one copy exists of any algorithm that uses the bus. The use of a structure in the generated code can be helpful when tracing the correspondence between the model and the code. For example, here is the generated code for the Bus Creator block in the `ex_bus_logging` model.

```
50
51      /* BusCreator: '<Root>/COUNTERBUSCreator' incorporates:
52       *  BusCreator: '<Root>/LIMITBUSCreator'
53       *  Constant: '<Root>/lower_ saturation_ limit'
54       *  Constant: '<Root>/upper_saturation_limit'
55       */
56      ex_bus_logging_B.COUNTERBUS_n.data = rtb_data;
57      ex_bus_logging_B.COUNTERBUS_n.limits.upper_saturation_limit = 40;
58      ex_bus_logging_B.COUNTERBUS_n.limits.lower_saturation_limit = 0;
59
```

A virtual bus does not appear as a structure or any other coherent unit in generated code. A separate copy of any algorithm that manipulates the bus exists for each element. In general, virtual buses do not affect the generated code.

To group signals into structures in the generated code, use nonvirtual buses. See “Group Signals into Structures in the Generated Code Using Buses” (Simulink Coder).

When you create a MATLAB structure to initialize a bus that contains non-double signal elements, you need to set the values of structure fields. The technique that you choose to set the values can influence the efficiency and readability of the generated code. See “Control Data Types of Initial Condition Structure Fields” on page 65-156.

When you generate code for a bus signal that is input to or output from a referenced model, there are some code generation limitations. See “Limitations for Virtual Buses Crossing Model Reference Boundaries” on page 65-162.

Code generation for array of buses signals produces structures with a specific format. See “Code Generation for Arrays of Buses” on page 65-163.

Control Data Types of Initial Condition Structure Fields

You can use a MATLAB structure to initialize the signal elements in a bus. See "Specify Initial Conditions for Bus Signals" on page 65-108.

If the signal elements of the target bus use numeric data types other than `double`, in general:

- To avoid manually matching the field data types with the data types of the signal elements, use untyped expressions to set the field values. As you develop and rapidly prototype a model, use this technique for convenience.
- To generate more efficient production code and to avoid floating-point storage in the code, match the data types of the structure fields with the data types of the corresponding signal elements.

The technique that you choose can influence the efficiency and readability of the generated code.

For examples and more information about tunable initial conditions in the generated code, see "Control Signal and State Initialization in the Generated Code" (Simulink Coder).

Inline Numeric Values of Structure Fields in the Generated Code

If you set the **Default parameter behavior** configuration parameter to `Inlined`, by default, the field values of the initial condition structure appear in the generated code as inlined numbers (non-tunable). For these structures, use untyped expressions to set the field values in Simulink. The field values do not require data types because the structure is not tunable in the generated code.

However, if you later set **Default parameter behavior** to `Tunable` or apply a storage class to the structure by using a `Simulink.Parameter` object, the code can contain floating-point storage and inefficient explicit typecasts and bit shifts. To avoid these issues, consider matching the data types of the structure fields with the data types of the corresponding signal elements.

Generate Tunable Structure Specified Directly in a Block Dialog Box

Suppose that you specify an initial condition structure directly in a block dialog box, or in a `Simulink.Signal` object, with an expression such as `struct('signal1', 5,'signal2',7.2)` (instead of storing the structure in a variable or

`Simulink.Parameter` object). In this case, to generate a tunable structure in the code, you set **Default parameter behavior** to `Tunable`.

Use the table to decide how to control the data types of the fields in these initial condition structures.

Goal		Technique
Use a nonvirtual bus.		Use untyped expressions to set the field values.
Use a virtual bus.	Avoid manually matching the field data types with those of the signal elements.	Use untyped expressions to set the field values.
	Generate more efficient code and avoid floating-point storage.	Match the structure field data types with the signal element types. Store the data type information in the `struct` by using typed expressions to set the field values.

Generate Tunable Structure Stored in a Variable or Parameter Object

Suppose that you store an initial condition structure in a variable or `Simulink.Parameter` object that you create in the base workspace or a data dictionary. For example, you use this technique to share the structure between multiple blocks, or to generate a tunable structure when you set **Default parameter behavior** to `Inlined`. In this case, use the table to decide how to control the data types of the fields in the initial condition structure.

Goal	Technique
Avoid manually matching the field data types with those of the signal elements.	Use untyped expressions to set the field values. In the generated code, the structure fields use the data type `double`. The generated algorithm uses explicit typecasts to reconcile the data type mismatches.

Goal	Technique
Generate more efficient code and avoid floating-point storage.	Match the structure field data types with the signal element types. Store the data type information in the structure fields or use a `Simulink.Bus` object to control the data types of the fields and the signal elements simultaneously. To use the Model Advisor to check your model for potentially expensive data type mismatches, see "Check structure parameter usage with bus signals".
Initialize an array of buses in a referenced model by using an array of structures. Pass the array of structures to the referenced model as the value of a model argument in the Model block.	Match the structure field data types with the signal element types. Store the data type information in the structure fields or use a `Simulink.Bus` object to control the data types of the structure fields and the signal elements simultaneously. If you do not pass the structure to the referenced model as a model argument, follow the other guidelines for nonvirtual buses to decide how to control the data types.

Use Untyped Expressions to Set Field Values

You can use untyped expressions to set the structure field values. The fields implicitly use the data type `double`. Set the field values to represent the ideal, real-world initialization values.

You avoid manually matching the field data types with the data types of the corresponding signal elements. However, depending on the virtuality of the bus signal, the method that you use to apply the initial condition, and other factors, you can introduce floating-point storage and potentially inefficient typecasts in the generated code.

Suppose that you create a bus signal `myBusSig` with these signal elements. Each element uses a specific data type.

```
myBusSig
   signalElement1 (int32)
   signalElement2 (boolean)
   signalElement3 (single)
```

Create an initial condition structure `initStruct`. Use untyped expressions to specify the field values. Optionally, to enhance readability of the Boolean field `signalElement2`, use the value `false` instead of `0`.

```
initStruct.signalElement1 = 3;
initStruct.signalElement2 = false;
initStruct.signalElement3 = 17.35;
```

If you use the function `Simulink.Bus.createMATLABStruct` to create the structure, the function stores data type information in the structure fields. After you create the structure, you can optionally use untyped expressions to change the field values. See "Use Simulink.Bus.createMATLABStruct to Create Structure" on page 65-160.

Store Data Type Information in Structure Fields

To store data type information in the structure fields, use typed expressions to set the field values, or use the function `Simulink.Bus.createMATLABStruct` to create the structure. Use these techniques to generate efficient code by eliminating floating-point storage and potentially inefficient explicit typecasts.

To avoid manually applying new data types to the structure fields when you change the data types of the corresponding signal elements, consider using a `Simulink.Bus` object to control the data types in the structure and the bus simultaneously.

Use Typed Expressions to Set Field Values

Suppose that you create a bus signal `myBusSig` with this hierarchy of signal elements. Each element uses a specific data type.

```
myBusSig
   signalElement1 (int32)
   signalElement2 (boolean)
   signalElement3 (single)
```

Create an initial condition structure `initStruct` by using typed expressions to set the field values. Match the data types of the fields with the data types of the corresponding signal elements.

```
initStruct.signalElement1 = int32(3);
initStruct.signalElement2 = false;
initStruct.signalElement3 = single(17.35);
```

The structure fields store data type information. If you later change the data type of a signal element, manually apply the new data type to the corresponding structure field.

To match a fixed-point data type, set the field value by using a `fi` object.

Change Field Value by Preserving Data Type Information

Suppose that you change the value of a field in an existing initial condition structure. To preserve the data type information in the field you can use subscripted assignment, with the syntax `(:)`.

```
initStruct.signalElement3(:) = 16.93;
```

If you do not use subscripted assignment, you must remember to preserve the data type by using a typed expression.

```
initStruct.signalElement3 = single(16.93);
```

If you do not use either of these techniques, the field loses the data type information.

```
initStruct.signalElement3 = 16.93; % Field data type is now 'double'.
```

Use Simulink.Bus.createMATLABStruct to Create Structure

You can use the function `Simulink.Bus.createMATLABStruct` to create a structure whose fields all have ground values, typically `0`. If you configure the data types of the signal elements before using the function, for example by setting the output data types of the blocks that generate the signal elements, each field in the output structure uses the same data type as the corresponding signal element. The fields store the data type information as if you use typed expressions to set the values.

You can initialize some of the signal elements with a value other than ground by passing a partial structure to the function. When you create this partial structure, match the data type of each field with the data type of the corresponding signal element by using typed expressions. For more information and examples, see `Simulink.Bus.createMATLABStruct`.

When you later change the value of a field in the structure, choose one of these techniques to set the new value:

- Untyped expression. The field value no longer stores the data type information.
- Typed expression or subscripted assignment. The field value continues to store the data type information.

Use Bus Object as Data Type of Initial Condition Structure

Whether you store data type information in the structure fields or use untyped expressions to set the field values, you can use a `Simulink.Bus` object as the data type of the entire initial condition structure. You can then manage the field values and data types independently.

If you use this technique, consider using untyped expressions to set the field values. Then, you do not need to match the field data types manually when you change the data types of the signal elements. To control the data types of the fields and the signal elements, use the `DataType` property of the elements in the bus object.

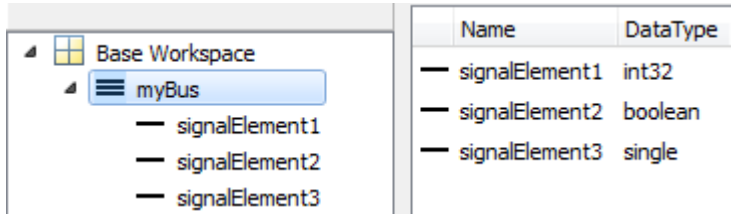
Suppose that you use a Bus Creator block to create a bus signal `myBusSig` with these signal elements.

```
myBusSig
   signalElement1 (int32)
   signalElement2 (boolean)
   signalElement3 (single)
```

1 Open the Bus Editor.

```
buseditor
```

2 Create a bus object, `myBus`, that corresponds to the bus signal.



3 Create an initial condition structure `initStruct`. Used untyped expressions to set the field values. To enhance readability of the field `signalElement2`, use the Boolean value `false` instead of `0`.

```
initStruct.signalElement1 = 3;
initStruct.signalElement2 = false;
initStruct.signalElement3 = 17.35;
```

4 To represent the structure, create a `Simulink.Parameter` object.

```
initStruct = Simulink.Parameter(initStruct);
```

5 Use the parameter object to specify an initial condition for the bus signal. For example, in a Unit Delay block dialog box, set **Initial condition** to `initStruct`.

6 Use the bus object to specify the data type of the parameter object.

```
initStruct.DataType = 'Bus: myBus';
```

7 Use the bus object to specify the data type of the bus signal. For example, in the Bus Creator block dialog box, set **Output data type** to `Bus: myBus`.

During simulation and in the generated code, the structure fields and the signal elements use the data types that you specify in the bus object. Before simulation and code generation, the parameter object casts the structure fields to the data types that you specify in the bus object.

For basic information about bus objects, see "When to Use Bus Objects" on page 65-64.

Configure Data Types for Existing Structure

To remove data type information from all the fields of a structure, you can write a custom function that replaces the field values with `double` numbers. Use the example function `castStructToDbl` as a template.

To convert a structure that uses doubles to one that stores data type information, you can create a reference structure using the function `Simulink.Bus.createMATLABStruct`. You can then write a custom function to cast the field values to the data types in the reference structure. Use the example function `castStructFromDbl` as a template.

Check for Mismatched Data Types with Model Advisor

To detect when the data types of structure fields are not consistent with the associated bus signal elements, in the Simulink Editor, use the **Analysis > Model Advisor > By Product > Simulink** "Check structure parameter usage with bus signals" check.

Limitations for Virtual Buses Crossing Model Reference Boundaries

If you use a bus signal as an input to or an output from a referenced model (Model block):

- You cannot configure the `I/O arguments step method` style of C++ class interface for the referenced model.

  As a workaround, use a nonvirtual bus instead. Alternatively, use the `Default` style of C++ class interface.

- You cannot configure function prototype control for the referenced model.

  As a workaround, use a nonvirtual bus instead.

For more information about using buses as inputs to or outputs from a referenced model, see “Bus Data Crossing Model Reference Boundaries” on page 65-150. For more information about bus virtuality, see “Virtual and Nonvirtual Buses” on page 65-4.

Code Generation for Arrays of Buses

When you generate code for a model that includes an array of buses, a `typedef` that represents the underlying bus type appears in the `*_types.h` file.

Code generation produces an array of C structures that you can integrate with legacy C code that uses arrays of structures. As necessary, code for bus variables (arrays) is generated in the following structures:

- Block IO
- States
- External inputs
- External outputs

Here is a simplified example of some generated code for an array of buses.

```
typedef struct {
  real_T a;
  real_T b;
} BusObject;
```

```
/* Block signals (auto storage) */
typedef struct {
  BusObject ForEachSubsystem_IterInp_0[2];
} BlockIO_aob1;
```

For basic information about code generation for nonvirtual buses, which appear in the code as structures, see “Group Signals into Structures in the Generated Code Using Buses” (Simulink Coder).

Working with Variable-Size Signals

Variable-Size Signal Basics

In this section...

About Variable-Size Signals

A Simulink signal can be a scalar, vector (1-D), matrix (2-D), or N-D. For information about these types of signals, see “Signal Basics” on page 64-2 in the *Simulink User's Guide*.

A Simulink variable-size signal is a signal whose size (the number of elements in a dimension), in addition to its values, can change during a model simulation. However, during a simulation, the number of dimensions cannot change. This capability allows you to model systems with varying resources, constraints, and environments.

Creating Variable-Size Signals

You can create variable-size signals in your Simulink model by using:

- Switch or Multiport Switch blocks with different input ports having fixed-size signals with different sizes. The output is a variable-size signal.
- A selector block and the `Starting and ending indices (port)` indexing option. The index port signal can specify different subregions of the input data signal which produce an output signal of variable size as the simulation progresses.
- The S-function block with the output port configured for a variable-size signal. The output includes not only the values but also the dimension of the signal.

How Variable-Size Signals Propagate

In the Simulink environment, variable-size signals can change their size during model execution in one of two ways:

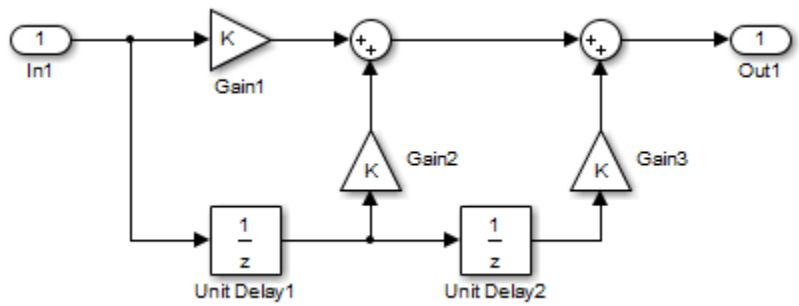
- **At every step of model execution.**

  Various blocks in the model modify the sizes of the signals during execution of the output method.

- **Only during initialization of conditionally executed subsystems.**

  Size changes occur during distinct mode-switching events in subsystems such as Action, Enable, and Function-Call subsystems.

You can see the key difference by considering a Discrete 2-Tap Filter block with states.



Discrete 2-Tap Filter

Assume that the input signal dimension to this filter changes from 4 to 1 during simulation. It is ambiguous when and how the states of the Unit Delay blocks should adapt from 4 to 1 to continue processing the input. To ensure consistency, both Unit Delay blocks must change their state behavior synchronously. To prevent ambiguity, Simulink generally disallows blocks whose number of states depends on input signal sizes in contexts where signal sizes change at any point during execution.

In contrast, consider the same Discrete 2-Tap Filter block in a Function-Call subsystem. Assume that this subsystem is using the second way to propagate variable-size signals. In this case, the size of the input signal changes from 4 to 1 only at the initialization of the subsystem. At initialization, the subsystem resets all of its states (including the

states of the two Unit Delay blocks) to their initial values. Resetting the subsystem ensures no ambiguity on the assignment of states to the input signal of the filter.

"Mode-Dependent Variable-Size Signals" on page 66-14 shows how you can use the two ways of propagating variable-size signals in a complementary fashion to model complex systems.

Programmatically Determine Whether Signal Line Has Variable Size

This example shows how to use commands at the command prompt or in a script to determine whether a signal line has a variable size. In a large model or hierarchy of subsystems or referenced models, use this technique to determine whether a signal has a variable size due to an upstream block.

The example model `sldemo_varsize_basic` contains a signal `a` that is downstream of a Switch block. Use commands at the command prompt to determine whether `a` has a variable size.

1. Open the example model.
2. Select the Sum block whose output signal is labeled `a`.
3. At the command prompt, set the model to a compiled state (similar to a diagram update).

   ```
   sldemo_varsize_basic([],[],[],'compile')
   ```

4. Get a handle to the block output port.

   ```
   portHandles = get_param(gcb,'portHandles');
   outPortHandle = portHandles.Outport;
   ```

5. Query the programmatic parameter `CompiledPortDimensionsMode` of the output port.

   ```
   varSize = get_param(outPortHandle,'CompiledPortDimensionsMode')
   ```

   ```
   varSize =

        1
   ```

   The value of the variable `varSize` is `1`, which indicates that the signal `a` has variable size.

   The value `0` indicates that a signal does not have variable size.

6 Terminate the model compilation.

```
sldemo_varsize_basic([],[],[],'term')
```

Empty Signals

An empty signal is a signal with a length of `0`. For example, signals with size `[0]`, `[0x3]`, `[2x0]`, and `[2x0x3]` are all empty signals. Simulink allows empty signals with variable-size signals and supports most element-wise operations. However, Simulink does not support empty signals for blocks that modify signal dimensions. Unsupported blocks include Reshape, Permute, and Sum along a specified dimension.

Subsystem Initialization of Variable-Size Signals

The initial signal size from an Outport block in a conditionally executed subsystem varies depending on the parameters you select.

If you set the **Propagate sizes of variable-size signals** parameter in the parent subsystem to `During execution`, the **Initial output** parameter for the Output block must not exceed the maximum size of the input port. If the **Initial output** parameter value is:

Initial output parameter	Initial output signal size
A nonscalar matrix	The initial output signal size is the size of the **Initial output** parameter.
A scalar	The initial output signal size is a scalar.
The default []	The initial output size is an empty signal (dimensions are all zeros).

If you set the **Propagate sizes of variable-size signals** parameter in the parent subsystem to `Only when enabling`, the **Initial output** parameter for the Output block must be a scalar value.

- When size is repropagated for the input of the Outport block, the initial output value is set using scalar expansion from the scalar parameter value.
- If the **Initial output** parameter is the default value `[]`, Simulink treats the initial output as a grounded value.

- If the model does not activate the parent subsystem at start time (`t = 0`), the current size of the subsystem output corresponding to the Outport block is set to maximum size.
- When its parent subsystem repropagates signal sizes, the values of the subsystem variable-size output signals are also reset to their initial output parameter values.

Simulink Models Using Variable-Size Signals

In this section...

Variable-Size Signal Generation and Operations

This example model shows how to create a variable-size signal from multiple fixed-size signals and from a single data signal. It also shows some of the operations you can apply to variable-size signals.

For a complete list of blocks that support variable-size signals, see "Simulink Block Support for Variable-Size Signals" on page 66-24.

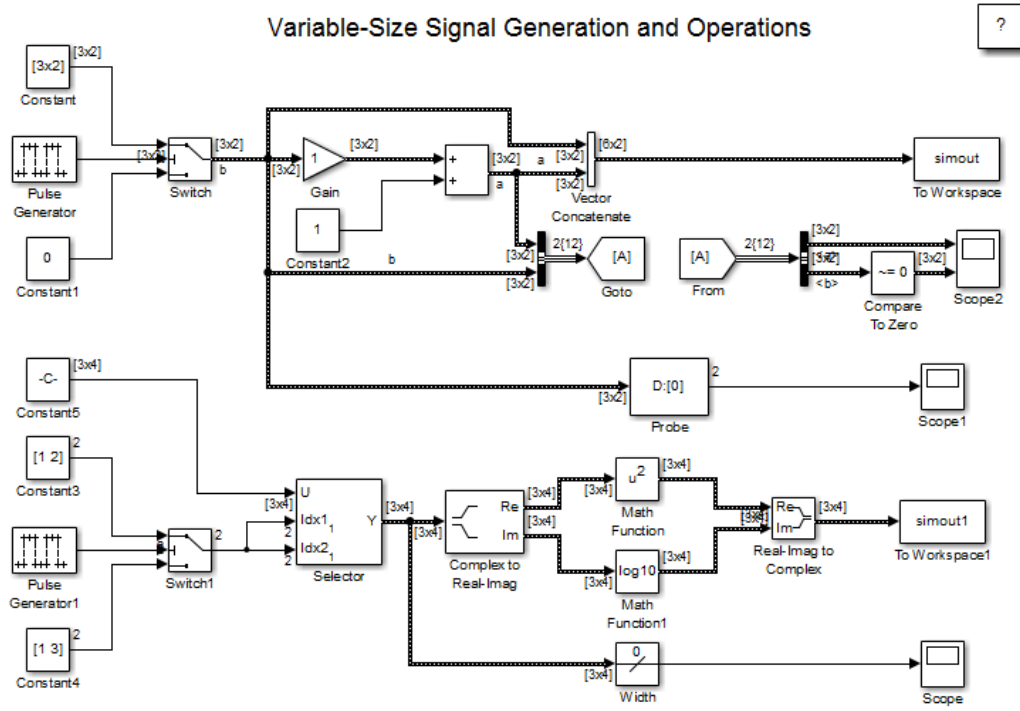
1 In the MATLAB Command Window, type

```
sldemo_varsize_basic
```

2 In the Simulink Editor, select **Display > Signals & Ports > Signal Dimensions**. Run a simulation or press `Ctrl-D`.

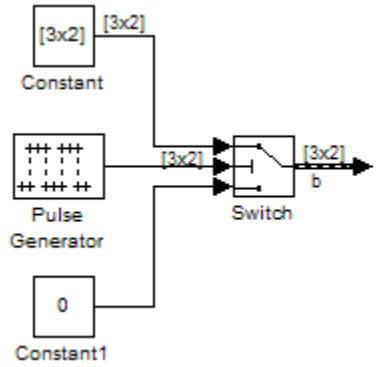
The Simulink Editor displays the signal dimensions and line styles. See "Signal Basics" on page 64-2 for an interpretation of signal line styles.

3 So that you can see the names of the blocks in the model, clear **Display > Hide Automatic Names**.



Creating a Variable-Size Signal from Fixed-Size Signals

One way to create a variable-size signal is to use the Switch block. The input signals to the Switch block can differ in their number of dimensions and in their size.



Output from the Switch block is a 2-D variable-size signal with a maximum size of `3x2`. When you select the **Allow different data input sizes** parameter on the Switch block, Simulink does not expand the scalar value from the Constant1 block.

Saving Variable-Size Signal Data

You could add a To Workspace block to the output from the Switch block. Since the model already has a To Workspace block, the second To Workspace block would save data to a signal array named `simout2` The `values` field logs the actual signal values. If logged signal data is smaller than the maximum size, values are padded with NaNs or appropriate values. To obtain these signal values, type:

```
simout2.signals.values

ans(:,:,1) =

     1    -1
    -2     2
    -3     3

ans(:,:,2) =

     1    -1
    -2     2
    -3     3

ans(:,:,3) =

     0   NaN
   NaN   NaN
   NaN   NaN
```

The `valueDimensions` field logs the dimensions of a variable-size signal. To obtain the dimensions, type:

```
simout2.signals.valueDimensions
```

The signal dimensions for the first three time steps are shown.

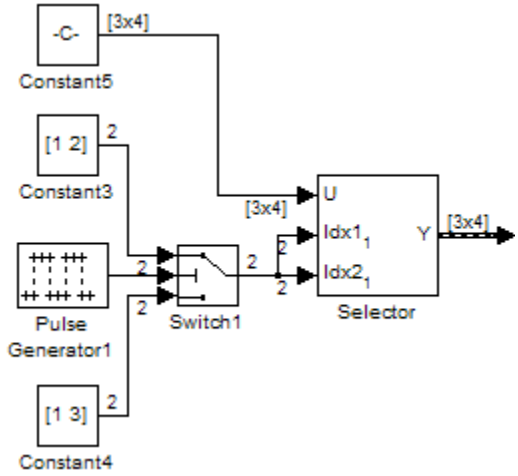
```
ans =

     3     2
```

```
     3     2
     1     1
```

Creating a Variable-Size Signal from a Single Data Signal

The data signal (Constant5) is a `3x4` matrix. The Pulse Generator represents a control signal that selects a starting and ending index value (`[1 2]` or `[1 3]`). The Selector block then uses the index values to select different parts of the data signal at each time step and output a variable-size signal.



Viewing Changes in Signal Size

The output from the Selector block is either a `2x2` or `3x3` matrix. Because the maximum dimension for a variable-size signal is the `3x4` matrix from the data signal, the logged output signals are padded with NaNs.

Use the Probe or Width blocks to inspect the current dimensions and width of a variable-size signal. In addition, you can display variable-size signals on Scope blocks and save variable-size signals to the workspace using the To Workspace block.

Processing Variable-Size Signals

The remainder of the model shows various operations that are possible with variable-size signals. Operations include using the Gain block, the Sum block, the Math Function block, the Matrix Concatenate block. You can connect variable-size signals with the From, Goto, Bus Assignment, Bus Creator, and Bus Selector blocks.

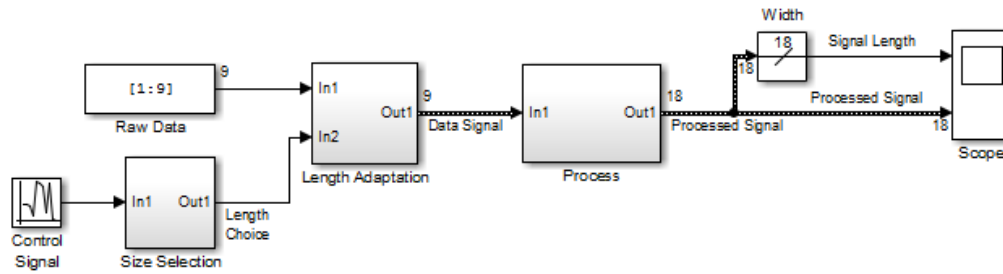
Variable-Size Signal Length Adaptation

This example model corresponds to a hypothetical system where the model adapts the length of a signal over time. Length adaptation is based on the value of a control signal. When the control signal falls within one of three predefined ranges, the fixed-size raw data signal changes to a variable-size data signal.

The variable-size signal connects to a processing block, where blocks that support variable-size signals operate on it. A MATLAB Function block with both input and output signals of variable size allow more flexibility than other blocks supporting variable-size signals. See "Simulink Block Support for Variable-Size Signals" on page 66-24.

To open the example model, in the MATLAB Command Window, type:

```
sldemo_varsize_dataLengthAdapt
```



So that you can see the names of the blocks, in the model, clear **Display** > **Hide Automatic Names**.

Creating a Variable-Size Signal by Adapting the Length of a Data Signal

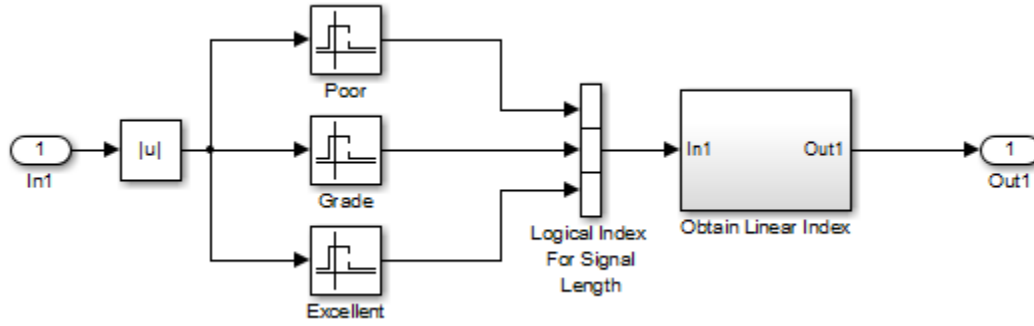
This model generates a data signal and converts the signal to a variable-size signal. The size of the signal depends on the value of a control signal. The raw data signal is a column vector with values from `1` to `9`.

```
[1:9].'

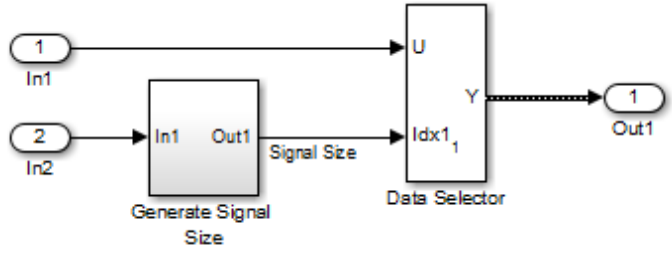
ans =
     1
     2
```

3
4
5
6
7
8
9

The Size Selection subsystem determines the quality of the data signal and outputs a quality value (1, 2, or 3). This value helps to select the length of the data signal in the Length Adaptation subsystem.

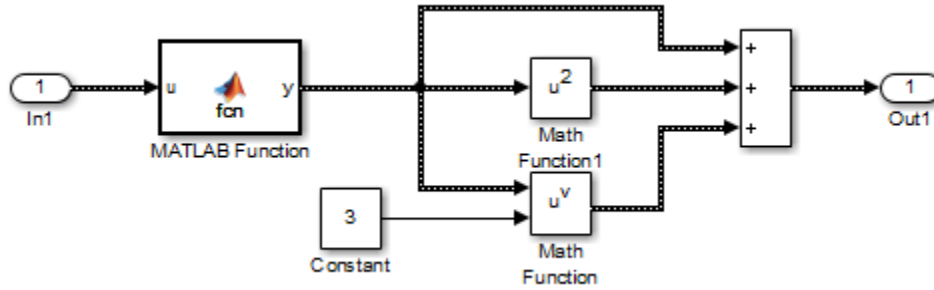


In the Length Adaptation subsystem, the Signal Size subsystem generates an index based on the quality value from the Size Selection subsystem (In2). The Data Selector block uses the starting and ending indices to adapt the length of the data signal (In1) and output a variable-size signal.



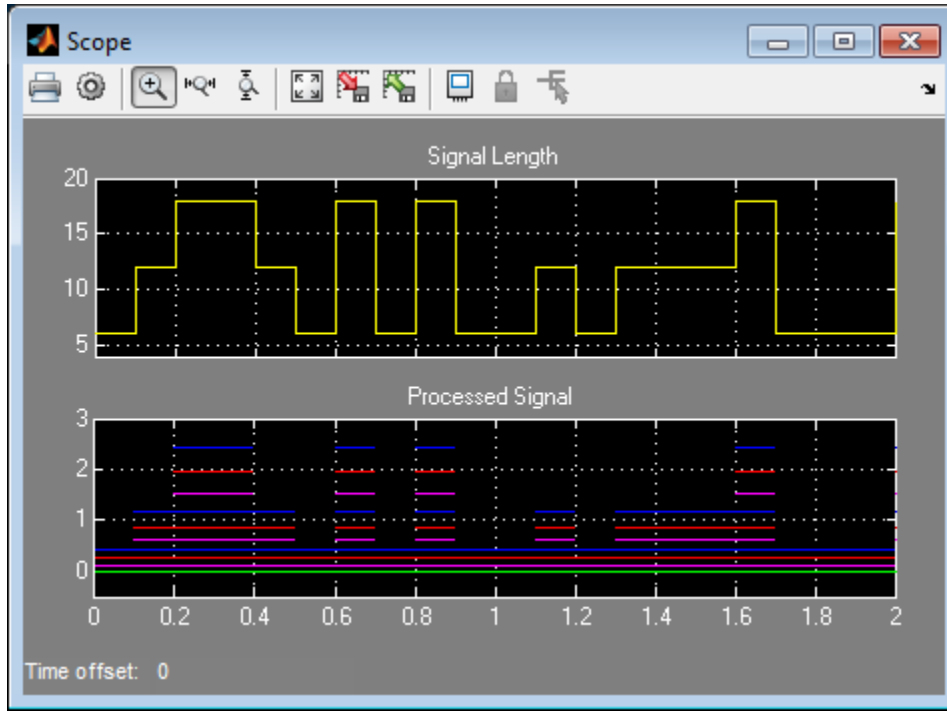
Processing a Variable-Size Signal

The center section of the model processes the variable-size signal. The MATLAB Function block adds zeros between the data values in a way that is similar to upsampling a signal. The dimension of the signal changes from `9` to `18`. The Math Function blocks shows various manipulations you can do with variable-size signals.



Visualizing a Variable-Size Signal

The right section of the model determines the signal width (size) and uses a scope to visualize the width and the processed data signal.



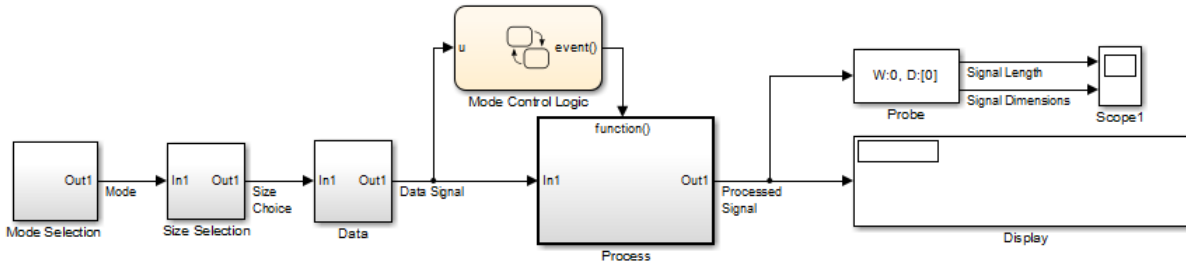
Mode-Dependent Variable-Size Signals

This example model represents a system that has three operation modes. For each mode, the data signal to process has a different size.

The Process subsystem in this model receives a variable-size signal where the size of the signal depends on the operation mode of the system. For each mode change, the Stateflow chart, Mode Control Logic, detects when the data signal size changes. It then generates a function call to reset the blocks in the Process subsystem.

To open the model, In the MATLAB Command Window, type:

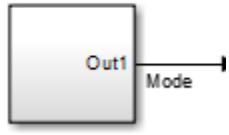
```
sldemo_varsize_multimode
```



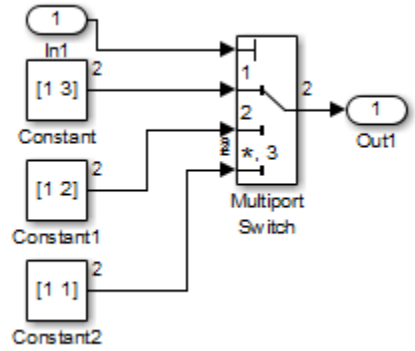
So that you can see the names of the blocks, in the model, clear **Display > Hide Automatic Names**.

Creating a Variable-Size Signal Based on Mode

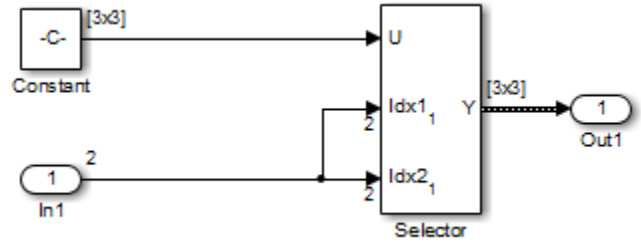
The Mode Selection subsystem determines the mode for processing a data signal and outputs a mode value (1, 2, or 3). This value helps to select the length of the data signal using the Size Selection and Data subsystems.



The Size Selection subsystem creates an index value from the mode value. In this example, the index values are `[1 3]`, `[1 2]`, and `[1 1]`.



The Data subsystem takes a data signal (Constant block) and selects part of the data signal dependent on the mode. The output is a variable-size signal with a matrix size of `3x3`, `2x2`, and `1x1`.



The dimensions of the raw data signal (Constant block) is a `3x3`. After connecting a To Workspace block to a signal line, you can view the signal in the MATLAB Command Window by typing:

```
simout.signals.values

ans(:,:,1) =

     1     4     7
     2     5     8
     3     6     9
```

The variable-size signal generated from the Data subsystem is also a `3x3` matrix. For shorter signals, the matrix is padded with NaNs.

```
simout.signals.values

ans(:,:,1) =

     1   NaN   NaN
   NaN   NaN   NaN
   NaN   NaN   NaN

ans(:,:,2) =

     1     4   NaN
     2     5   NaN
   NaN   NaN   NaN

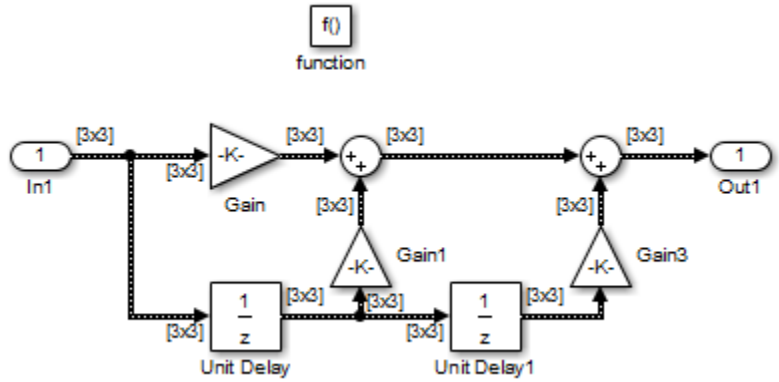
ans(:,:,3) =

     1     4     7
     2     5     8
     3     6     9
```

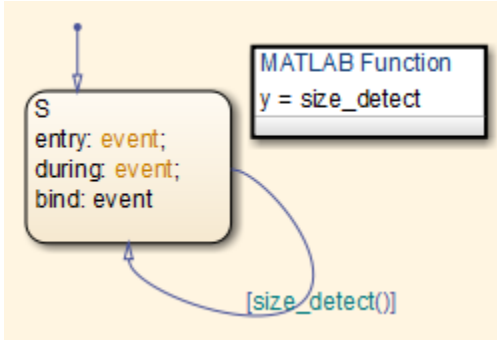
Processing a Variable-Size Signal with a Conditionally Executed Subsystem

Because the Process subsystem contains a Delay block, the subsystem resets and repropagates the signal at each time step. This model uses a Stateflow chart to detect a signal size change and reset the Process subsystem.

In the function block dialog, and from the **Propagate sizes of variable-size signals** list, choose `Only when enabling`. When the model enables this subsystem, selecting this option directs the Simulink software to propagate sizes for variable-size signals inside the conditionally executed subsystem. Signal sizes can change only when they transition from disabled to enabled. For an explanation of handling signal-size changes with blocks containing states, see “How Variable-Size Signals Propagate” on page 66-3.

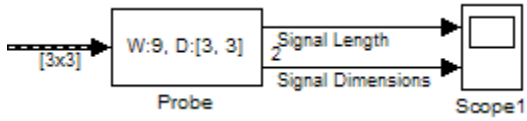


The Stateflow chart determines if there is a change in the size of the signal. The function `size_detect` calculates the width of the variable-size signal at each time step, and compares the current width to the previous width. If there is a change in signal size, the chart outputs a function-call output event that resets and repropagates the signal sizes within the Process subsystem.

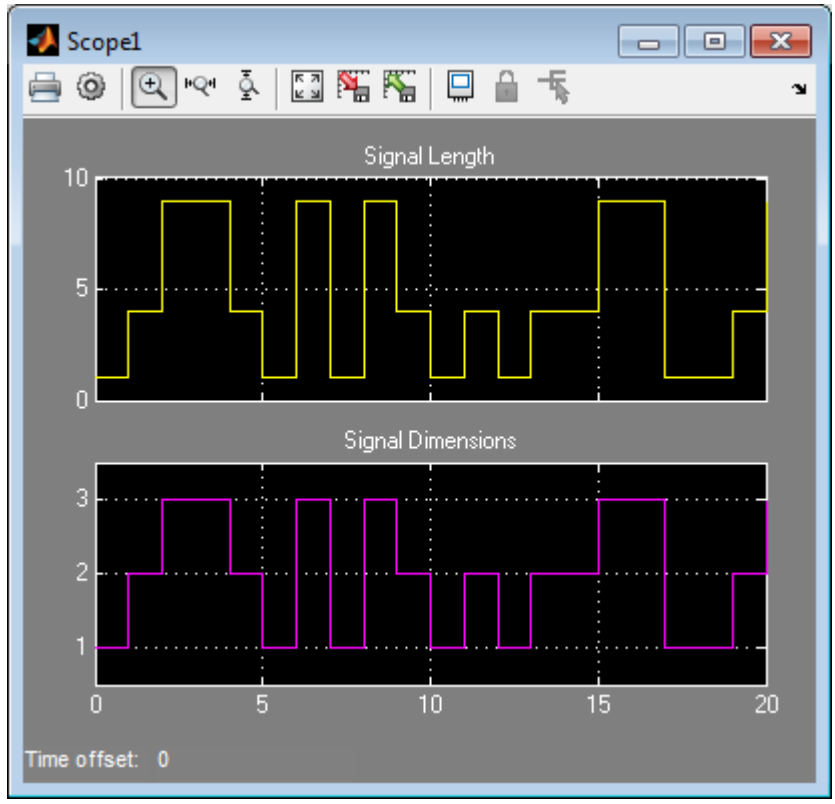


Visualizing Data

Use the Probe block to visualize signal size and signal dimension.



Since the signals are `n x n` matrices, the signal dimension lines overlap in the Scope display.



You can use a Display block and the Simulink Debugger to visualize signal values at each time step.

S-Functions Using Variable-Size Signals

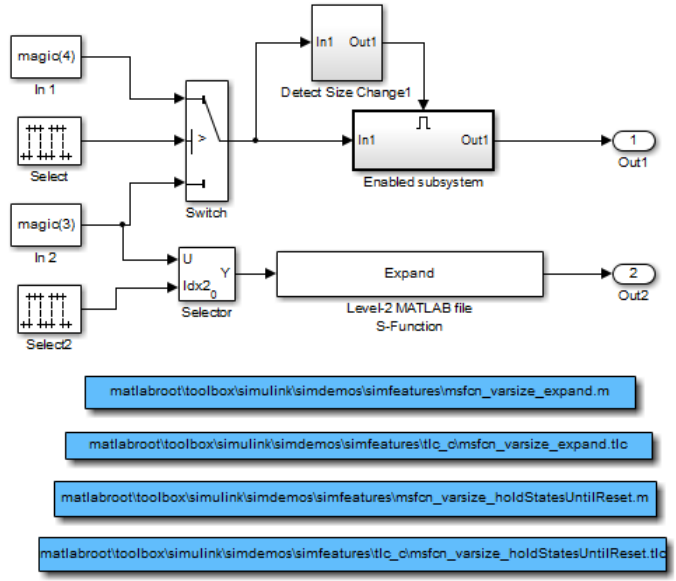
In this section...

Level-2 MATLAB S-Function with Variable-Size Signals

Both Level-2 MATLAB S-Functions and C S-Functions support variable-size signals when you set the **DimensionMode** for the output port to `Variable`. You also need to consider the current dimension of the input and output signals in the input and output update methods.

To open this example model, in the MATLAB Command Window, type:

```
msfcndemo_varsize
```



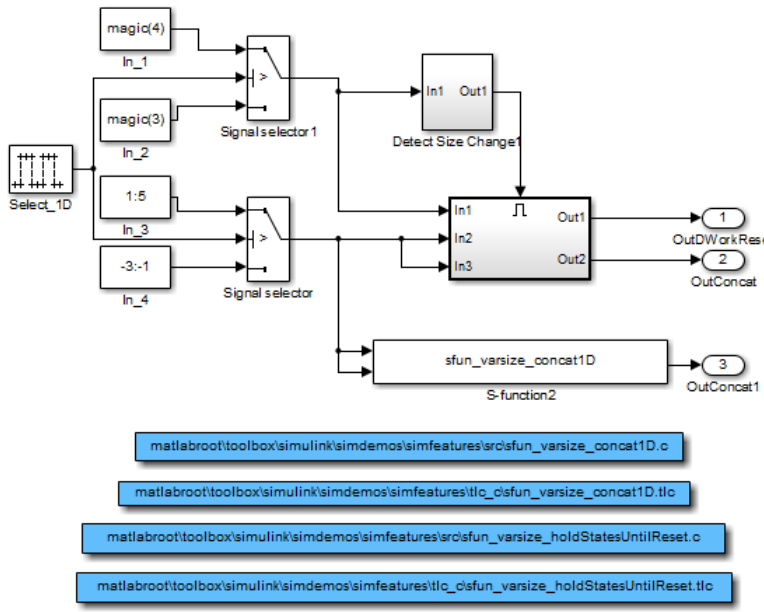
The Enabled subsystem includes a Level-2 MATLAB S-Function which shows how to implement a block that holds its states until reset. Because this block contains states and delays the input signal, the input size can change only when a reset occurs.

The Expand block is a Level-2 MATLAB S-Function that takes a scalar input and outputs a vector of length indicated by its input value. The output is by `1:n` where `n` is the input value.

C S-Function with Variable-Size Signals

To open this example model, in the MATLAB Command Window, type:

```
sfcndemo_varsize
```



The enabled subsystems have two S-Functions:

- sfun_varsize_holdStatesUntilReset is a C S-Function that has states and requires its DWorks vector to reset whenever the sizes of the input signal changes.

- sfun_varsize_concat1D is a C S-function that implements the concatenation of two unoriented vectors. You can use this function within an enabled subsystem by itself.

Simulink Block Support for Variable-Size Signals

In this section...

Simulink Block Data Type Support

The Simulink Block Data Type Support table includes a complete list of blocks that support variable-size signals.

To view the table:

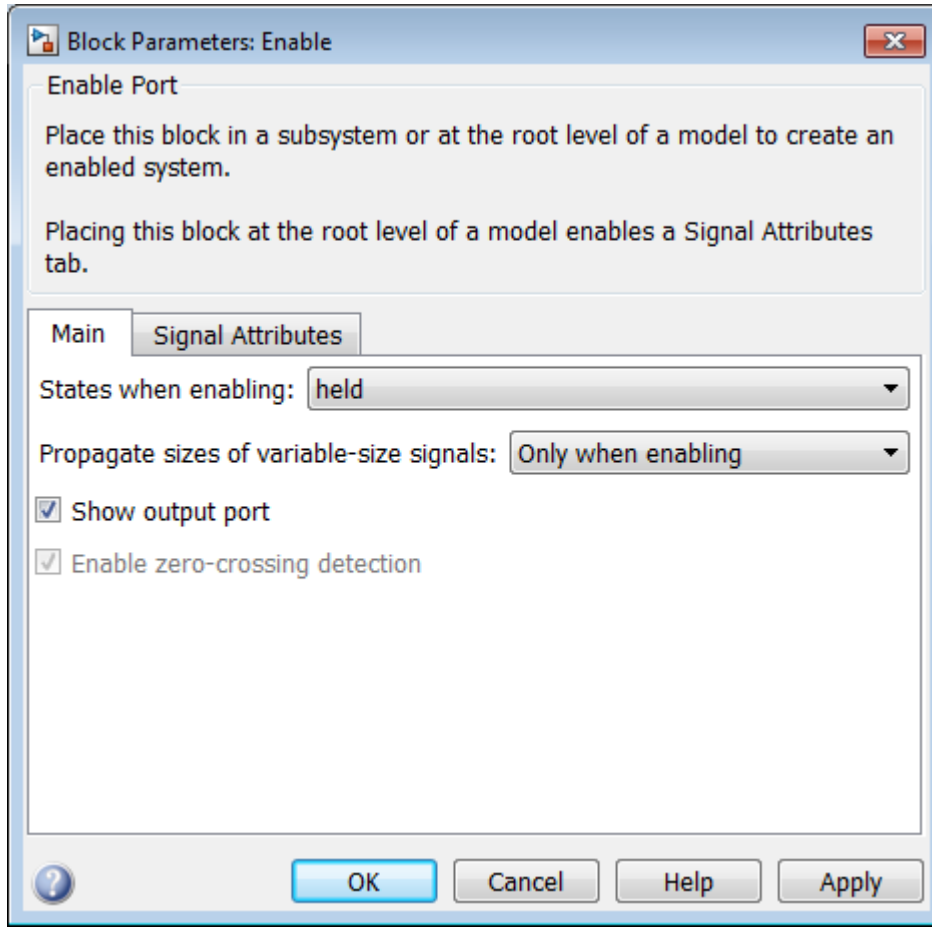
1. Open a Simulink model.
2. Select **Help > Simulink > Block Data Types & Code Generation Support > Simulink**.

An `X` in the **Variable-Size Support** column indicates support for that block.

Tip You can also view the table by entering `showblockdatatypetable` at the command prompt.

Conditionally Executed Subsystem Blocks

Control port blocks are in conditionally executed subsystems. You can set the **Propagate sizes of variable-size signals** parameter for these blocks to `During execution`, `Only when execution is resumed` (Action Port), and `Only when enabling` (Enable and Trigger or Function-Call).

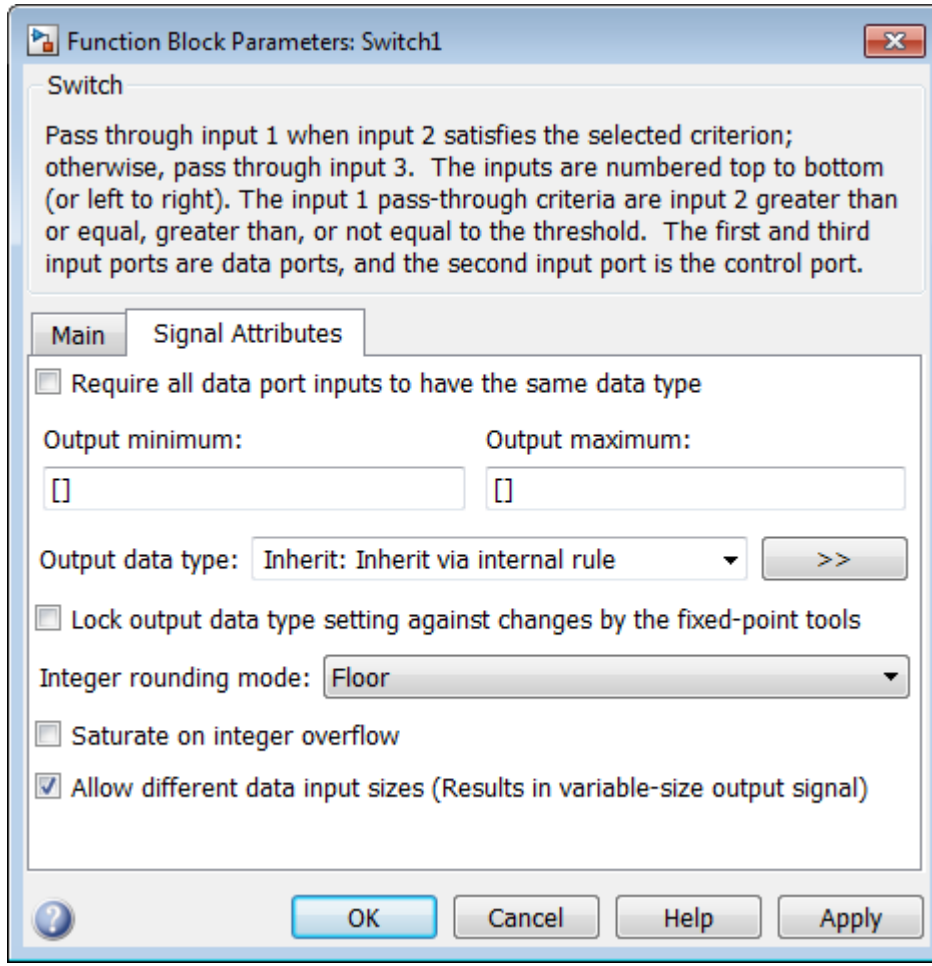


- Action Port
- Enable
- Trigger — **Trigger type** set to `function-call`

Switching Blocks

Switching blocks support variable-size signals by allowing input signals with different sizes and propagating the size of the input signal to the output signal. You can set the

Allow different data input sizes parameter for these blocks on the Signal Attributes pane to either on or off.



- Switch
- Multiport Switch
- Manual Switch

- "Variable-Size Signal Limitations" on page 66-28

Variable-Size Signal Limitations

The following table is a list of known limitations and workarounds.

Limitation	Workaround
Array format logging does not support variable-size signals.	Use a `Structure` or `Structure With Time` format for logging variable-size signals.
Right-click signal logging does not support variable-size signals.	Use a To Workspace block (with `Structure` or `Structure With Time` format) or a root Outport block for logging variable-size signals.
A frame-based variable-size signal cannot change the frame length (first dimension size), but it can change the second dimension size (number of channels). Using frame-based signals requires DSP System Toolbox software.	Use the Frame Conversion block to convert a signal into sample-based signal.
Variable-size signals must have a discrete sample time.	—
Embedded Coder does not support variable-size signals with ERT S-functions, custom storage classes, function prototype control, the AUTOSAR, C++ interface, and the ERT reusable code interface.	—
Simulink does not support variable-size parameter or DWork vectors.	—
Rapid accelerator mode does not support models having root-level input ports with variable-size signals.	—

Limitation	Workaround
Virtual buses that you use as inputs to or outputs from a referenced model (Model block) do not support variable-size signals.	Configure the bus signal as nonvirtual. For more information about using buses as inputs to or outputs from a referenced model, see "Bus Data Crossing Model Reference Boundaries" on page 65-150. For more information about controlling bus virtuality, see "Virtual and Nonvirtual Buses" on page 65-4.
You cannot apply a storage class to a root-level Outport block (see "Use Model Data Editor to Configure Data Interface" (Simulink Coder)) if the signal that enters the block has a variable size.	Apply the storage class to the signal line instead of the Outport block.

Customizing Simulink Environment and Printed Models

Customizing the Simulink User Interface

Add Items to Model Editor Menus

In this section...

About Adding Items

You can add commands and submenus to these menu locations for the Simulink Editor and Stateflow Editor:

- The end of top-level menus
- The menu bar
- The beginning or end of a context menu

To add an item to an editor menu:

- For each item, create a function, called a schema function, that defines the item (see “Define Menu Items” on page 67-4).
- Register the menu customizations with the Simulink customization manager at startup, e.g., in an `sl_customization.m` file on the MATLAB path (see “Register Menu Customizations” on page 67-9).
- Create callback functions that implement the commands triggered by the items that you add to the menus.

Code for Adding Menu Items

The following `sl_customization.m` file adds four items to the Simulink Editor’s **Tools** menu.

```
function sl_customization(cm)
```

```
  %% Register custom menu function.
  cm.addCustomMenuFcn('Simulink:ToolsMenu', @getMyMenuItems);
end

%% Define the custom menu function.
function schemaFcns = getMyMenuItems(callbackInfo)
  schemaFcns = {@getItem1,...
                        @getItem2,...
                        {@getItem3,3}... %% Pass 3 as user data to getItem3.
                        @getItem4};
end

%% Define the schema function for first menu item.
function schema = getItem1(callbackInfo)
  schema = sl_action_schema;
  schema.label = 'Item One';
  schema.userdata = 'item one';
  schema.callback = @myCallback1;
end

function myCallback1(callbackInfo)
  disp(['Callback for item ' callbackInfo.userdata ' was called']);
end

function schema = getItem2(callbackInfo)
  % Make a submenu label 'Item Two' with
  % the menu item above three times.
  schema = sl_container_schema;
  schema.label = 'Item Two';
    schema.childrenFcns = {@getItem1, @getItem1, @getItem1};
end

function schema = getItem3(callbackInfo)
  % Create a menu item whose label is
  % 'Item Three: 3', with the 3 being passed
  % from getMyItems above.

  schema = sl_action_schema;
  schema.label = ['Item Three: ' num2str(callbackInfo.userdata)];
end

function myToggleCallback(callbackInfo)
    if strcmp(get_param(gcs, 'ScreenColor'), 'red') == 0
        set_param(gcs, 'ScreenColor', 'red');
    else
        set_param(gcs, 'ScreenColor', 'white');
    end
end

%% Define the schema function for a toggle menu item.
function schema = getItem4(callbackInfo)
  schema = sl_toggle_schema;
  schema.label = 'Red Screen';
  if strcmp(get_param(gcs, 'ScreenColor'), 'red') == 1
    schema.checked = 'checked';
```

```
  else
    schema.checked = 'unchecked';
  end
  schema.callback = @myToggleCallback;
end
```

Define Menu Items

You define a menu item by creating a function that returns an object, called a *schema* object, that specifies the information needed to create the menu item. The menu item that you define may trigger a custom action or display a custom submenu. See the following sections for more information.

- "Defining Menu Items That Trigger Custom Commands" on page 67-4
- "Defining Custom Submenus" on page 67-7

Defining Menu Items That Trigger Custom Commands

To define an item that triggers a custom command, your schema function must accept a callback info object (see "Callback Info Object" on page 67-10) and create and return an action schema object (see "Action Schema Object" on page 67-5) that specifies the item's label and a function, called a *callback*, to be invoked when the user selects the item. For example, the following schema function defines a menu item that displays a message when selected by the user.

```
function schema = getItem1(callbackInfo)

  %% Create an instance of an action schema.
  schema = sl_action_schema;

%% Specify the menu item's label.
  schema.label = 'My Item 1';
  schema.userdata = 'item1';
  %% Specify the menu item's callback function.
  schema.callback = @myCallback1;

end

function myCallback1(callbackInfo)
  disp(['Callback for item ' callbackInfo.userdata
        ' was called']);
end
```

Action Schema Object

This object specifies information about menu items that trigger commands that you define, including the label that appears on the menu item and the function to be invoked when the user selects the menu item. Use the function `sl_action_schema` to create instances of this object in your schema functions. Its properties include:

- `tag`

  Optional character vector that identifies this action, for example, so that it can be referenced by a filter function.

- `label`

  Character vector specifying the label that appears on a menu item that triggers this action.

- `state`

  Property that specifies the state of this action. Valid values are `'Enabled'` (the default), `'Disabled'`, and `'Hidden'`.

- `statustip`

  Character vector specifying text to appear in the editor's status bar when the user selects the menu item that triggers this action.

- `userdata`

  Data that you specify. May be of any type.

- `accelerator`

  Character vector specifying a **Ctrl** and key combination to use to trigger this action. You can add a keyboard shortcut only for custom menu items that appear on menu bar menus and cannot redefine accelerators that come with the Simulink Editor. For example, **Ctrl+D** is an accelerator for **Update Diagram** in the Simulink Editor, so you cannot redefine it.

  To specify this value, use the form `'Ctrl+`*`K`*`'`, where *`K`* is the shortcut key. For example, use `'Ctrl+Alt+T'` for an accelerator invoked by holding down **Ctrl** and **Alt** and pressing **T**.

- `callback`

Character vector specifying a MATLAB expression to be evaluated or a handle to a function to be invoked when a user selects the menu item that triggers this action. This function must accept one argument: a callback info object.

- `autoDisableWhen`

  Property that controls when a menu item is automatically disabled.

Setting	When Menu Items Are Disabled
`'Locked'`	(default) When the active editor is locked or when the model is busy
`'Busy'`	Only if the model is busy
`'Never'`	Never

Toggle Schema Object

This object specifies information about a menu item that toggles some object on or off. Use the function `sl_toggle_schema` to create instances of this object in your schema functions. Its properties include:

- `tag`

  Optional character vector that identifies this toggle action, for example, so that it can be referenced by a filter function.

- `label`

  Character vector specifying the label that appears on a menu item that triggers this toggle action.

- `checked`

  Specify whether the menu item displays a check mark. Valid values are `'unchecked'` (default) and `'checked'`

- `state`

  State of this toggle action, specified as `'Enabled'` (default), `'Disabled'`, and `'Hidden'`.

- `statustip`

  Character vector specifying text to appear in the editor's status bar when the user selects the menu item that triggers this toggle action.

- `userdata`

  Data that you specify. May be of any type.

- `accelerator`

  Character vector specifying a **Ctrl** and key combination to use to trigger this action. You can add a keyboard shortcut only for custom menu items that appear on menu bar menus and cannot redefine accelerators that come with the Simulink Editor. For example, **Ctrl+D** is an accelerator for **Update Diagram** in the Simulink Editor, so you cannot redefine it.

  To specify this value, use the form `'Ctrl+`*`K`*`'`, where *`K`* is the shortcut key. For example, use `'Ctrl+Alt+T'` for an accelerator invoked by holding down **Ctrl** and **Alt** and pressing **T**.

- `callback`

  Character vector specifying a MATLAB expression to be evaluated or a handle to a function to be invoked when a user selects the menu item that triggers this action. This function must accept one argument: a callback info object.

- `autoDisableWhen`

  Property that controls when a menu item is automatically disabled.

Setting	When Menu Items Are Disabled
`'Locked'`	(default) When the active editor is locked or when the model is busy
`'Busy'`	Only if the model is busy
`'Never'`	Never

Defining Custom Submenus

To define a submenu, create a schema function that accepts a callback info object and returns a container schema object (see “Container Schema Object” on page 67-8) that specifies the schemas that define the items on the submenu. For example, the following schema function defines a submenu that contains three instances of the menu item defined in the example in “Defining Menu Items That Trigger Custom Commands” on page 67-4.

```
function schema = getItem2( callbackInfo )
    schema = sl_container_schema;
```

```
    schema.label = 'Item Two';
    schema.childrenFcns = {@getItem1, @getItem1, @getItem1};
end
```

Container Schema Object

A container schema object specifies a submenu's label and its contents. Use the function `sl_container_schema` to create instances of this object in your schema functions. Properties of the object include

- `tag`

  Optional character vector that identifies this submenu.

- `label`

  Character vector specifying the submenu's label.

- `state`

  Character vector that specifies the state of this submenu. Valid values are `'Enabled'` (the default), `'Disabled'`, and `'Hidden'`.

- `statustip`

  Character vector specifying text to appear in the editor's status bar when the user selects this submenu.

- `childrenFcns`

  Cell array that specifies the contents of the submenu. Each entry in the cell array can be

  - A pointer to a schema function that defines an item on the submenu (see "Define Menu Items" on page 67-4)
  - A two-element cell array whose first element is a pointer to a schema function that defines an item entry and whose second element is data to be inserted as user data in the callback info object (see "Callback Info Object" on page 67-10) passed to the schema function
  - `'separator'`, which causes a separator to appear between the item defined by the preceding entry in the cell array and the item defined in the following entry. The case is ignored for this entry (for example, `'SEPARATOR'` and `'Separator'` are both valid entries). A separator is also suppressed if it appears at the beginning or end of the submenu and separators that would appear successively

are combined into a single separator (for example, as a result of an item being hidden).

For example, the following cell array specifies two submenu entries:

```
{@getItem1, 'separator', {@getItem2, 1}}
```

In this example, a 1 is passed to `getItem2` via a callback info object.

- `generateFcn`

  Pointer to a function that returns a cell array defining the contents of the submenu. The cell array must have the same format as that specified for the container schema objects `childrenFcns` property.

  Note The `generateFcn` property takes precedence over the `childrenFcns` property. If you set both, the `childrenFcns` property is ignored and the cell array returned by the `generateFcn` is used to create the submenu.

- `userdata`

  Data of any type that is passed to `generateFcn`.

- `autoDisableWhen`

  Property that controls when a menu item is automatically disabled.

Setting	When Menu Items Are Disabled
`'Locked'`	(default) When the active editor is locked or when the model is busy
`'Busy'`	Only if the model is busy
`'Never'`	Never

Register Menu Customizations

You must register custom items to be included on a Simulink menu with the customization manager. Use the `sl_customization.m` file for a Simulink installation (see “Registering Customizations” on page 67-28) to perform this task. In particular, for each menu that you want to customize, your system's `sl_customization` function must invoke the customization manager's `addCustomMenuFcn` method. Each invocation should pass the tag of the menu (see “Menu Tags” on page 67-11) to be customized and a

custom menu function that specifies the items to be added to the menu (see “Creating the Custom Menu Function” on page 67-10) . For example, the following `sl_customization` function adds custom items to the Simulink Tools menu.

```
function sl_customization(cm)
  %% Register custom menu function.
  cm.addCustomMenuFcn('Simulink:ToolsMenu', @getMyItems);
```

Creating the Custom Menu Function

The custom menu function returns a cell array of schema functions that define custom items that you want to appear on the model editor menus (see “Define Menu Items” on page 67-4). The custom menu function returns a cell array similar to that returned by the `generateFcn` function.

Your custom menu function should accept a callback info object (see “Callback Info Object” on page 67-10) and return a cell array that lists the schema functions. Each element of the cell array can be either a handle to a schema function or a two-element cell array whose first element is a handle to a schema function and whose second element is user-defined data to be passed to the schema function. For example, the following custom menu function returns a cell array that lists three schema functions.

```
function schemas = getMyItems(callbackInfo)
  schemas = {@getItem1, ...
                @getItem2, ...
             {@getItem3,3} }; % Pass 3 as userdata to getItem3.
end
```

Callback Info Object

Instances of these objects are passed to menu customization functions. Methods and properties of these objects include:

- `uiObject`

  Method to get the handle to the owner of the menu for which this is the callback. The owner can be the Simulink Editor or the Stateflow Editor.

- `model`

  Method to get the handle to the model being displayed in the editor window.

- `userdata`

User data property. The value of this property can be any type of data.

Debugging Custom Menu Callbacks

On systems using the Microsoft Windows operating system, selecting a custom menu item whose callback contains a breakpoint can cause the mouse to become unresponsive or the menu to remain open and on top of other windows. To fix these problems, use the MATLAB code debugger keyboard commands to continue execution of the callback.

Menu Tags

A menu tag identifies a Simulink Editor or the Stateflow Editor menu bar or menu. You need to know a menu's tag to add custom items to it (see “Register Menu Customizations” on page 67-9). You can configure the editor to display all (see “Displaying Menu Tags” on page 67-13) but these tags.

Tag	What it adds
Simulink tags	
`Simulink:MenuBar`	Menu to Simulink Editor's menu bar
`Simulink:PreContextMenu`	Item to the beginning of Simulink Editor's context menu
`Simulink:ContextMenu`	Item to the end of Simulink Editor's context menu
`Simulink:FileMenu`	Item near the end of the Simulink Editor's **File** menu, but before the **Exit MATLAB** item
`Simulink:EditMenu`	Item to the end of the Simulink Editor's **Edit** menu
`Simulink:ViewMenu`	Item to the end of the Simulink Editor's **View** menu
`Simulink:DisplayMenu`	Item to the end of the Simulink Editor's **Display** menu
`Simulink:DiagramMenu`	Item to the end of the Simulink Editor's **Diagram** menu
`Simulink:SimulationMenu`	Item to the end of the Simulink Editor's **Simulation** menu

Tag	What it adds
`Simulink:AnalysisMenu`	Item to the end of the Simulink Editor's **Analysis** menu
`Simulink:CodeMenu`	Item to the end of the Simulink Editor's **Code** menu
`Simulink:ToolsMenu`	Item to the end of the Simulink Editor's **Tools** menu
`Simulink:HelpMenu`	Item to the end of Simulink Editor's **Help** menu
Stateflow tags	
`Stateflow:MenuBar`	Menu to Stateflow Editor's menu bar
`Stateflow:PreContextMenu`	Item to the beginning of Stateflow Editor's context menu.
`Stateflow:ContextMenu`	Items to the end of Stateflow Editor's context menu.
`Stateflow:FileMenu`	Item near the end of the Stateflow Editor's **File** menu, but before the **Exit MATLAB** item
`Stateflow:EditMenu`	Item to the end of Stateflow Editor's **Edit** menu
`Stateflow:ViewMenu`	Item to the end of the Stateflow Editor's **View** menu
`Stateflow:DisplayMenu`	Item to the end of the Stateflow Editor's **Display** menu
`Stateflow:ChartMenu`	Item to the end of the Stateflow Editor's **Chart** menu
`Stateflow:SimulationMenu`	Item to the end of the Stateflow Editor's **Simulation** menu
`Stateflow:AnalysisMenu`	Item to the end of the Stateflow Editor's **Analysis** menu
`Stateflow:CodeMenu`	Item to the end of the Stateflow Editor's **Code** menu
`Stateflow:ToolsMenu`	Item to the end of the Stateflow Editor's **Tools** menu
`Stateflow:HelpMenu`	Item to the end of the Stateflow Editor's **Help** menu

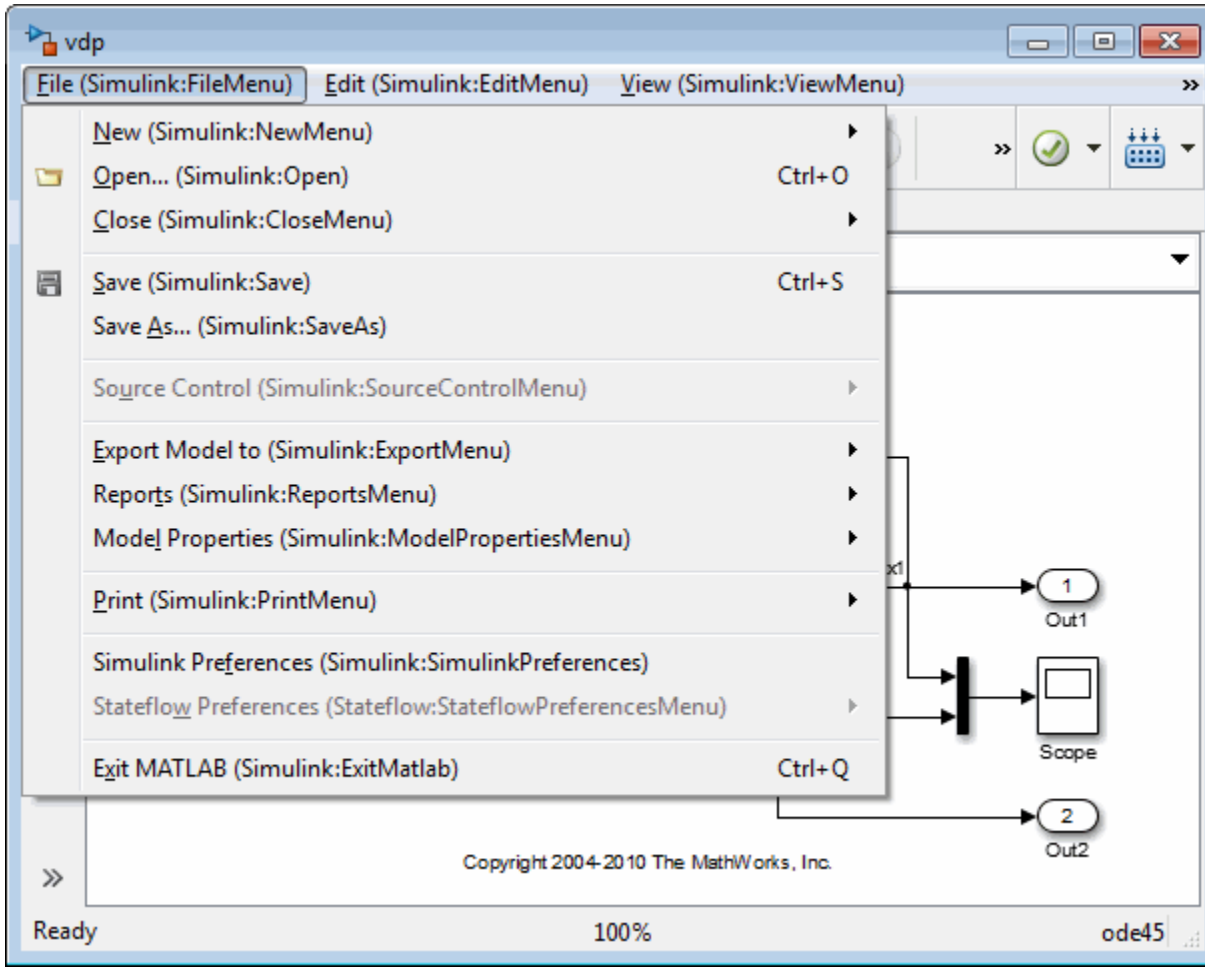
Displaying Menu Tags

You can configure the Simulink and Stateflow software to display the tag for a menu item next to the item's label, allowing you to determine at a glance the tag for a menu. The `Simulink:TagName` customizations appear only if the current editor is the Simulink Editor. The `Stateflow:TagName` customizations appear only if the current editor is the Stateflow Editor.

To configure the editor to display menu tags, at the MATLAB command line, set the customization manager's `showWidgetIdAsToolTip` property to `true`. For example:

```
cm = sl_customization_manager;
cm.showWidgetIdAsToolTip=true;
```

The tag of each menu item appears next to the item's label on the menu:



To turn off tag display, enter the following command at the command line:

```
cm.showWidgetIdAsToolTip=false;
```

Note Some menu items may not work while menu tag display is enabled. To ensure that all items work, turn off menu tag display before using the menus.

Simulink and Stateflow Editor Menu Customization

Use the same general procedures to customize Stateflow Editor menus as you use for Simulink Editor. The addition of custom menu functions to the ends of top-level menus depends on the active editor:

- Menus bound to `Simulink:FileMenu` only appear when the Simulink Editor is active.
- Menus bound to `Stateflow:FileMenu` only appear when the Stateflow Editor is active.
- To have a menu to appear in both of the editors, call `addCustomMenuFcn` twice, once for each tag. Check that the code works in both editors.

Disable and Hide Model Editor Menu Items

In this section...

About Disabling and Hiding Model Editor Menu Items

You can disable or hide items that appear on the Simulink Editor menus. To disable or hide a menu item, you must:

- Create a filter function that disables or hides the menu item (see “Creating a Filter Function” on page 67-16).
- Register the filter function with the customization manager (see “Registering a Filter Function” on page 67-17).

Example: Disabling the New Model Command on the Simulink Editor's File Menu

```
function sl_customization(cm)
  cm.addCustomFilterFcn('Simulink:NewModel',@myFilter);
end

function state = myFilter(callbackInfo)
  state = 'Disabled';
end
```

Creating a Filter Function

Your filter function must accept a callback info object and return the state that you want to assign to the menu item. Valid states are

- `'Hidden'`

- `'Disabled'`
- `'Enabled'`

Your filter function may have to compete with other filter functions and with Simulink itself to assign a state to an item. Who succeeds depends on the strength of the state that each assigns to the item. `'Hidden'` is the strongest state. If any filter function or Simulink assigns `'Hidden'` to the item, it is hidden. `'Enabled'` is the weakest state. For an item to be enabled, all filter functions and the Simulink or Stateflow products must assign `'Enabled'`to the item. The `'Disabled'` state is of middling strength. It overrides `'Enabled'` but is itself overridden by `'Hidden'`. For example, if any filter function or Simulink or Stateflow assigns `'Disabled'` to a menu item and none assigns `'Hidden'` to the item, the item is disabled.

Note The Simulink software does not allow you to filter some menu items, for example, the **Exit MATLAB** item on the Simulink **File** menu. An error message is displayed if you attempt to filter a menu item that you are not allowed to filter.

Registering a Filter Function

Use the customization manager's `addCustomFilterFcn` method to register a filter function. The `addCustomFilterFcn` method takes two arguments: a tag that identifies the menu or menu item to be filtered (see “Displaying Menu Tags” on page 67-13) and a pointer to the filter function itself. For example, the following code registers a filter function for the **New Model** item on the Simulink **File** menu.

```
function sl_customization(cm)
  cm.addCustomFilterFcn('Simulink:NewModel',@myFilter);
end
```

Disable and Hide Dialog Box Controls

In this section...

About Disabling and Hiding Controls

Simulink includes a customization API that allows you to disable and hide controls (also referred to as widgets), such as text fields and buttons, on most dialog boxes. The customization API allows you to disable or hide controls on an entire class of dialog boxes, for example, parameter dialog boxes, by way of a single method call.

Before you customize a Simulink dialog box or class of dialog boxes, first make sure that the dialog box or class of dialog boxes is customizable. Any dialog box that appears in the dialog pane of Model Explorer is customizable. In addition, any dialog box that has dialog and widget IDs is customizable. To determine whether a dialog box is customizable, open the dialog box, enable dialog and widget ID display (see "Widget IDs" on page 67-21), and hover over a widget. If a widget ID appears, you can customize the dialog box.

Once you have determined that a dialog box or class of dialog boxes is customizable, write MATLAB code to customize the dialog boxes. This entails writing callback functions that disable or hide controls for a specific dialog box or class of dialog boxes (see "Write Control Customization Callback Functions" on page 67-20) and registering the callback functions using the customization manager (see "Register Control Customization Callback Functions" on page 67-22). Simulink invokes the callback functions to disable or hide the controls whenever you open the dialog boxes.

Disable a Button on a Dialog Box

This `sl_customization.m` file disables the **Browse** button on the **Code Generation** pane of the Configuration Parameters dialog box for any model whose name contains `engine`.

```
function sl_customization(cm)

% Disable for standalone Configuration Parameters dialog box
configset.dialog.Customizer.addCustomization(@disableRTWBrowseButton,cm);

end

function disableRTWBrowseButton(dialogH)
  hSrc   = dialogH.getSource;  % Simulink.RTWCC
  hModel = hSrc.getModel;
  modelName   = get_param(hModel,'Name');

  if ~isempty(strfind(modelName,'engine'))
    % Takes a cell array of widget Factory ID.
    dialogH.disableWidgets({'STF_Browser'})
  end

end
```

To test this customization:

1. Save the `sl_customization.m` file on the MATLAB path.
2. Refresh the customizations by entering `sl_refresh_customizations` at the command line or by restarting MATLAB (see "Registering Customizations" on page 67-28).
3. Open the `sldemo_engine` model, for example, by entering the command `sldemo_engine` at the command prompt.
4. Open the Configuration Parameters dialog box and look at the **Code Generation** pane to see if the **Browse** button is disabled.

Write Control Customization Callback Functions

A callback function for disabling or hiding controls on a dialog box accepts one argument: a handle to the dialog box object that contains the controls you want to disable or hide. The dialog box object provides methods that the callback function can use to disable or hide the controls that the dialog box contains.

The dialog box object also provides access to objects containing information about the current model. Your callback function can use these objects to determine whether to disable or hide controls. For example, this callback function uses these objects to disable the **Browse** button on the **Code Generation** pane of the Configuration Parameters dialog box for any model whose name contains `engine`.

```
function disableRTWBrowseButton(dialogH)
```

```
hSrc = dialogH.getSource;  % Simulink.RTWCC
hModel = hSrc.getModel;
modelName = get_param(hModel,'Name');

if ~isempty(strfind(modelName,'engine'))
   % Takes a cell array of widget Factory ID.
   dialogH.disableWidgets({'STF_Browser'})
end
```

Dialog Box Methods

Dialog box objects provide these methods for enabling, disabling, and hiding controls:

- `disableWidgets(widgetIDs)`
- `hideWidgets(widgetIDs)`

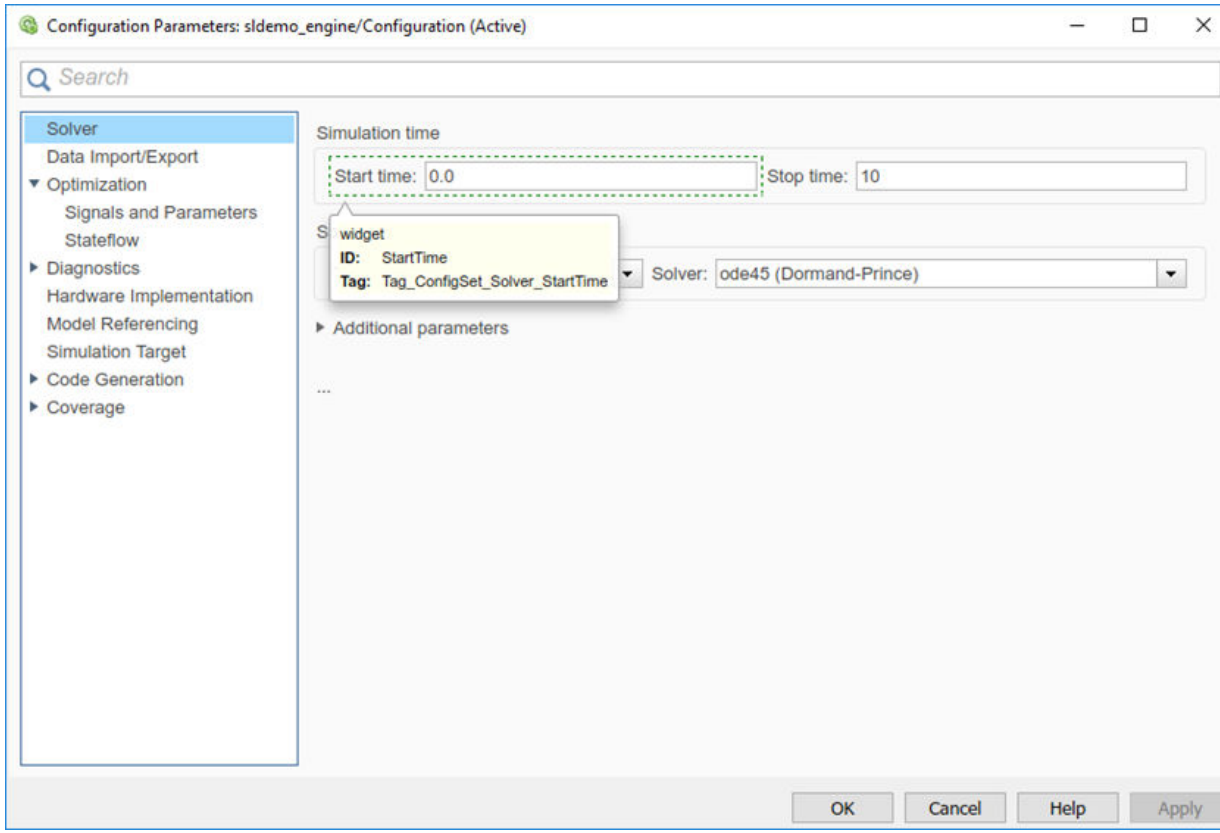
`widgetIDs` is a cell array of widget identifiers (see "Widget IDs" on page 67-21) that specify the widgets to disable or hide.

Widget IDs

Widget IDs identify a control on a Simulink dialog box. To determine the widget ID for a particular control, execute the following code at the command line:

```
cm = sl_customization_manager;
cm.showWidgetIdAsToolTip = true
```

Open the dialog box that contains the control and hover over the control to display a tooltip listing the widget ID. For example, hovering over the **Start time** field on the **Solver** pane of the Configuration Parameters dialog box shows that the widget ID for the **Start time** field is `StartTime`.



Note The tooltip displays `not customizable` for controls that are not customizable.

Register Control Customization Callback Functions

To register control customization callback functions for an installation of Simulink, include code in the installation's `sl_customization.m` file (see "Registering Customizations" on page 67-28) that invokes the `configset.dialog.Customizer.addCustomization` method on the callbacks.

This method takes as an argument a pointer to the callback function to register. Invoking this method causes the registered function to be invoked before the dialog box is opened.

This example registers a callback that disables the **Browse** button on the **Code Generation** pane of the Configuration Parameters dialog box (see "Write Control Customization Callback Functions" on page 67-20).

```
function sl_customization(cm)

% Disable for standalone Configuration Parameters dialog box
configset.dialog.Customizer.addCustomization(@disableRTWBrowseButton,cm);

end
```

Note Registering a customization callback causes Simulink to invoke the callback for every instance of the class of dialog boxes specified by the method's dialog box ID argument. You can therefore use a single callback to disable or hide a control for an entire class of dialog boxes. In particular, you can use a single callback to disable or hide the control for a parameter that is common to most built-in blocks. Most built-in block dialog boxes are instances of the same dialog box super class.

Customize Library Browser Appearance

In this section...

Reorder Libraries

A library’s name and sort priority determines its order in the tree view of the Library Browser. Libraries appear in ascending order of priority. Libraries that have the same priority are sorted alphabetically.

The Simulink library has a sort priority of `-1` by default. All other libraries have a sort priority of `0` by default. These sort priorities cause the Simulink library to display first in the Library Browser by default.

You can reorder libraries by changing their sort priorities. To change library sort priorities, add code in this form to an `sl_customization.m` file on the MATLAB path:

```
cm.LibraryBrowserCustomizer.applyOrder({'LIBNAME1',PRIORITY1, ...
                                        'LIBNAME2',PRIORITY2, ...
                                         .
                                         .
                                        'LIBNAMEN',PRIORITYN});
```

`LIBNAMEn` is the name of the library (or its model file) and `PRIORITYn` is an integer indicating the library's sort priority. For example, this code moves the Simulink Extras library to the top of the Library Browser’s tree view.

```
cm.LibraryBrowserCustomizer.applyOrder({'Simulink Extras',-2});
```

After adding or modifying the `sl_customization.m` file, enter `sl_refresh_customizations` at the MATLAB command prompt to see the customizations take effect.

For more information on the customization functions, see “Registering Customizations” on page 67-28.

Disable and Hide Libraries

To disable or hide libraries, sublibraries, or library blocks, insert code in this form in an `sl_customization.m` file (see "Registering Customizations" on page 67-28) on the MATLAB path. Blocks that you hide in a library also do not appear on the quick insert menu that you invoke in the model.

```
cm.LibraryBrowserCustomizer.applyFilter({'Item1','State', ...
                                         'Item2','State', ...
                                         .
                                         .
                                         'ItemN','State'});
```

- `ItemN` is the library, sublibrary, or block to disable or hide. Specify the item in the form `'LibraryName/Sublibrary/Block'`.
  - `LibraryName` is the library name as it appears in the browser. For a custom library, you set this value in the `slblocks.m` file with the `Browser.Name` property.
  - `Sublibrary` is the name of the sublibrary or, for a custom library, a `Subsystem` block. You can specify a block inside the subsystem in your library or in a library that you open by way of the subsystem's `OpenFcn` callback. See "Create a Custom Library" on page 40-4.
  - `Block` is the block name.
- `'State'` is `'Disabled'` or `'Hidden'`.

For example, this code hides the `Sources` sublibrary of the `Simulink` library and disables the `Sinks` sublibrary.

```
cm.LibraryBrowserCustomizer.applyFilter({'Simulink/Sources','Hidden'});
cm.LibraryBrowserCustomizer.applyFilter({'Simulink/Sinks','Disabled'});
```

This code disables the Sqrt block in the sublibrary opened by way of the Subsystem2 block in the custom library `'My Library'`.

```
cm.LibraryBrowserCustomizer.applyFilter(...
{'My Library/Subsystem2/Sqrt','Disabled'});
```

After adding or modifying the `sl_customization.m` file, enter `sl_refresh_customization` at the MATLAB command prompt to see the customizations take effect.

Expand or Collapse Library in Browser Tree

You can add a customization to expand or collapse any library in the Library Browser tree by default. For example, the `Simulink` library is expanded by default. You can specify to instead collapse it by default. Add code in this form to your `sl_customization.m` file:

```
cm.LibraryBrowserCustomizer.applyNodePreference(...
{'libraryName',logical});
```

Use `true` to expand the library and `false` to collapse it.

For example, this code collapses the `Simulink` library and expands the `Simscape` library:

```
function sl_customization(cm)
  cm.LibraryBrowserCustomizer.applyNodePreference(...
{'Simulink',false,'Simscape',true});
end
```

This code collapses a custom library named `'My Library'`.

```
function sl_customization(cm)
     cm.LibraryBrowserCustomizer.applyNodePreference(...
{'My Library',false});
end
```

After adding or modifying the `sl_customization.m` file, enter `sl_refresh_customizations` at the MATLAB command prompt to see the customizations take effect.

Registering Customizations

About Registering Customizations in Simulink

Register your customizations using the MATLAB function `sl_customization.m`. Place the function on the MATLAB path of the Simulink installation that you want to customize or in the current folder.

You can have more than one `sl_customization.m` file. The customizations in each file takes effect, with conflicts handled by each customization. For example, if you specify priorities for libraries in multiple `sl_customization` files, only one takes effect. If you add the same menu item twice, it appears twice. To ensure that customizations are loading as expected, refresh the customizations, as described in "Reading and Refreshing the Customization File" on page 67-29.

The `sl_customization` function accepts one argument: a handle to the customization manager object, that is, `cm`. For example:

```
function sl_customization(cm)
```

In your `sl_customization` function, use customization manager object properties and methods specific to your application to register customizations. You can use customization properties and methods to:

- "Add Items to Model Editor Menus" on page 67-2
- "Disable and Hide Model Editor Menu Items" on page 67-16
- "Disable and Hide Dialog Box Controls" on page 67-19
- "Add Libraries to the Library Browser" on page 40-10
- "Customize Library Browser Appearance" on page 67-24
- "Customize Bus Object Import and Export" on page 65-98
- "Import Lookup Table Data from MATLAB" on page 37-29

Additional MathWorks products use the customization manager object and the `sl_customization.m` file. Refer to your product documentation to learn about the methods and properties that apply to your product.

Reading and Refreshing the Customization File

The `sl_customization.m` file is read when Simulink starts. If you change the `sl_customization.m` file, either restart Simulink or enter this command to see the changes:

```
sl_refresh_customizations
```

This command runs all `sl_customization.m` files on the MATLAB path and in the current folder. Some side-effects of running `sl_refresh_customizations` include:

- Rebuilding all Simulink Editor menus and toolbars
- Rebuilding the Library Browser menus and toolbars
- Clearing the Library Browser cache and refreshing the Library Browser
- Reloading the Signal and Scope Manager data

Frames for Printed Models

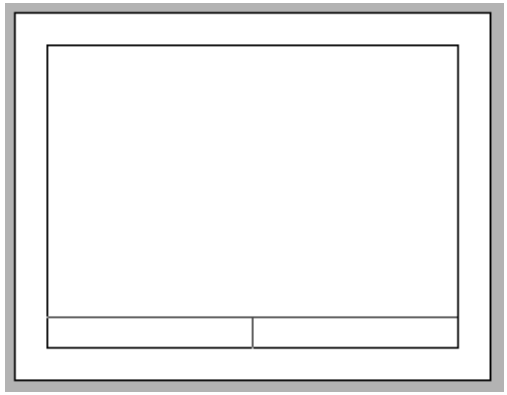
Print Frames

In this section...

What Are Print Frames?

Print frames are borders of a printed page that contain information about a block diagram, such as the model name or the date of printing. After you create a print frame, use the Simulink or Stateflow Editor to print a block diagram or chart with that print frame.

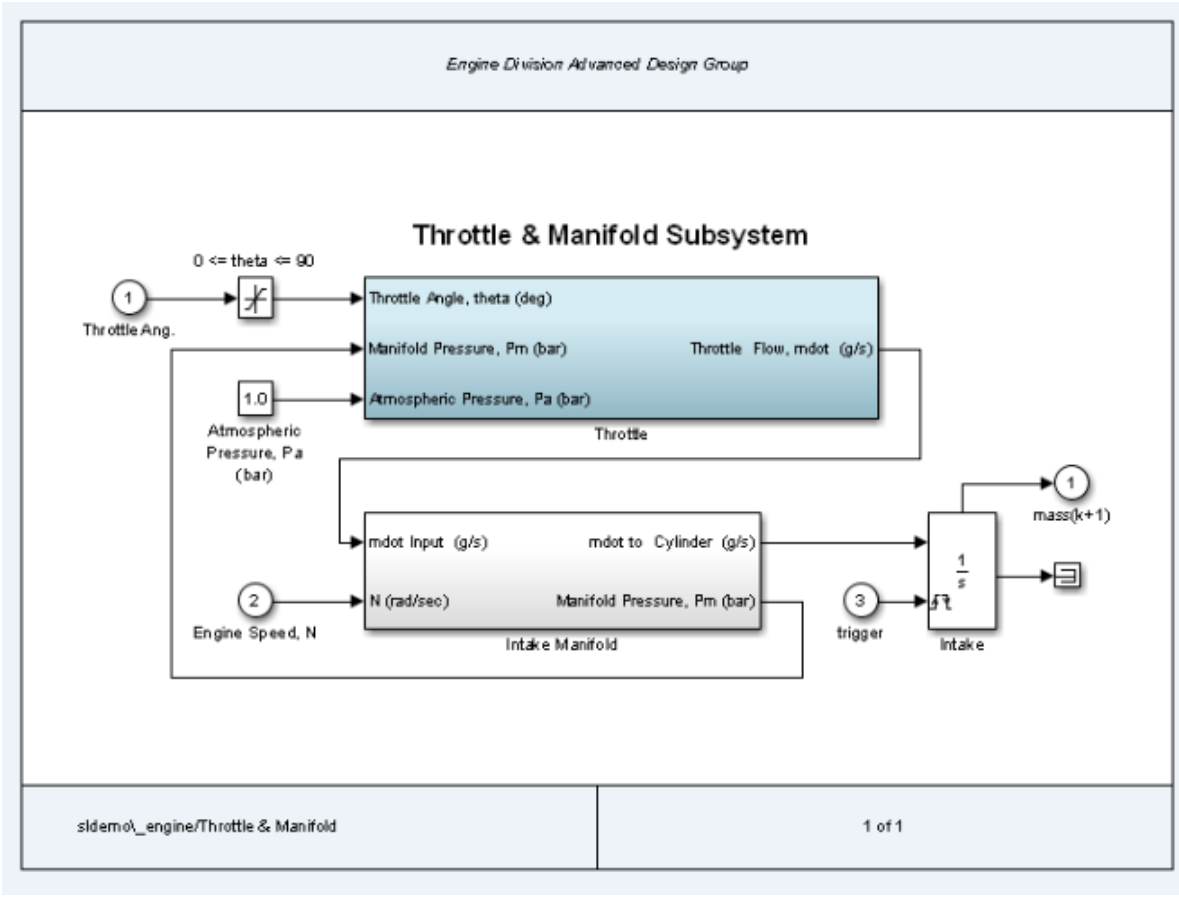
The default print frame has two rows:



Rows contain one or more cells. You can add content entries to cells. You can also add new rows and cells.

For example, the print frame below includes:

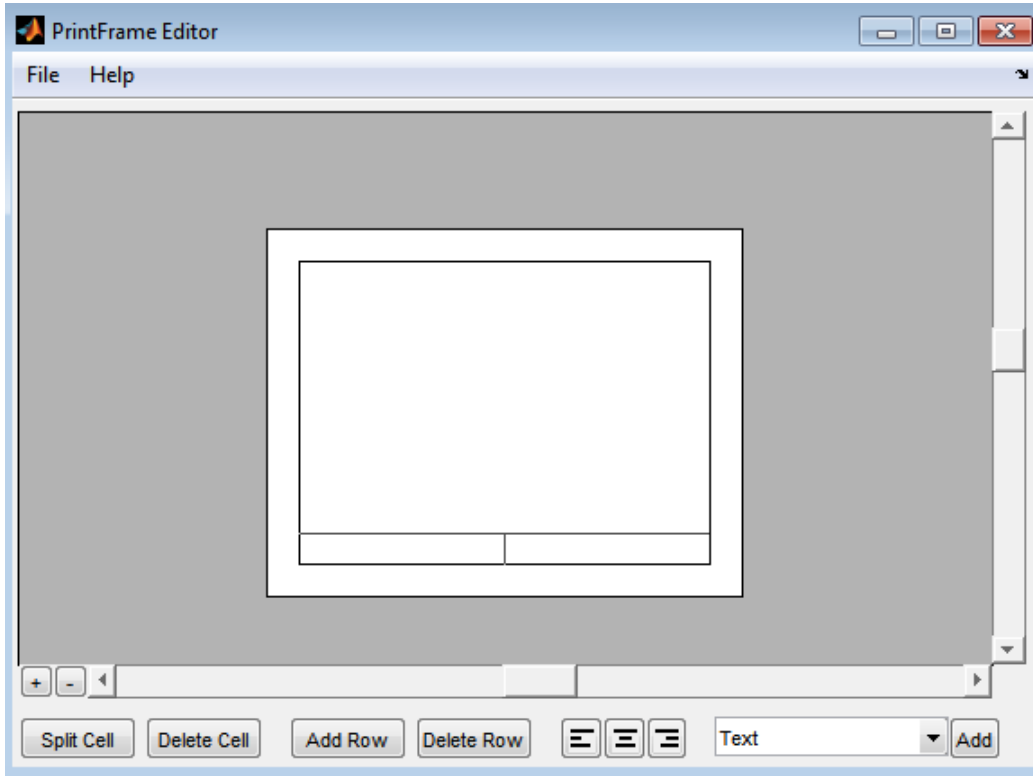
- An additional row at the top of the frame for a title
- A middle row, which includes the block diagram
- A bottom row, in which one cell has the path to the subsystem and another cell has the page number



PrintFrame Editor

Use the PrintFrame Editor to create and edit print frames.

To open the PrintFrame Editor, at the MATLAB command line, enter the `frameedit` command.



Use the PrintFrame Editor to:

- Set up the printed page
- Add or remove rows and cells in the print frame
- Add content to cells, such as text, the date, and page numbers
- Format cell content

To open an existing print frame, use `frameedit` command with the `filename` parameter, where `filename` is an existing print frame (a `.fig` file).

Single Use or Multiple Use Print Frames

You can design a print frame for one particular block diagram, or you can design a more generic print frame for printing multiple block diagrams.

Text and Variable Content

In cells, you can include text (such as the name and address of your organization) and variable content (such as the current date).

See Also

`frameedit`

Related Examples

- “Create a Print Frame” on page 68-6
- “Print Using Print Frames” on page 68-13

Create a Print Frame

1. At the MATLAB prompt, type `frameedit` to open the PrintFrame Editor.
2. In the PrintFrame Editor, select **File > Page Setup**.

   If necessary, change default page setup for the print frame, which is:

   - Paper type — usletter
   - Orientation — landscape

   Note The paper orientation you specify does not control the paper orientation used for printing. For example, assume you specify a landscape-oriented print frame in the PrintFrame Editor. If you want the printed page to have a landscape orientation, you must specify that using the Print Model dialog box.

   - Margins — .75 inches on all sides
3. Set up the layout of the print frame and add content. See:

   - “Add Rows and Cells to Print Frames” on page 68-7
   - “Add Content to Print Frame Cells” on page 68-9
4. Save the print frame as a `.fig` file. Select **File > Save As**.

More About

- “Print Frames” on page 68-2

Add Rows and Cells to Print Frames

In this section...

Tip Specify the print frame page setup before you create rows and cells or add content (see “Create a Print Frame” on page 68-6).

Add and Remove Rows

You can add a row above the row that you select.

1. Click in a cell to select a row.

   When you select a row, handles appear on all four corners. If you select only a line, handles appear on two corners.

2. Click **Add Row**.

   The new row appears above the row that you selected.

To remove a row, select the row and click **Delete Row**.

Add and Remove Cells

You can add cells within a row.

1. Select the cell that you want to split.
2. Click **Split Cell**.

   The cell splits into two cells.

To remove a cell, select the cell and click **Delete Cell**.

Resize Rows and Cells

You can change the dimensions of a row or cell by selecting the bordering line.

1. Click the line you want to move.

   A handle appears on both ends of the line.
2. Drag the line to resize the row or cell.

For example, to make a row taller, click on the top line that forms the row. Then drag the line up and the height of the row increases.

To change the overall dimensions of the print frame, see “Create a Print Frame” on page 68-6.

More About

- “Print Frames” on page 68-2

Add Content to Print Frame Cells

In this section...

Types of Content

You can add text or variables, or both, to a cell.

You must add a `Block Diagram` variable to one of the cells.

For details about the types of content, see:

- “Block Diagram” on page 68-10
- “Variables” on page 68-10
- “Text” on page 68-11

Add Content to Cells

1. Select the cell that you want to add content to.
2. From the list, select the type of content that you want to add.
3. Click **Add**.

   The type of content that you added appears in the cell.

   Tip If you click **Add** and nothing happens, it might be because you did not select a cell first.

4. If you add text, select the edit box and type in the text. For details, see “Text” on page 68-11.

Tip To make it easier to read and edit the content that you add, you can click the **Zoom in** + button.

Include Multiple Entries in a Cell

1. Select a cell that has a content entry.
2. Add another content type item from the list.

   The new entry is added after the last entry in that cell.

You can also add descriptive text to any of the variable entries without using the **Text** item.

1. Double-click in the cell.
2. Type text in the edit box before or after the entry.
3. To end editing mode, click outside of the cell.

Note You cannot include multiple entries or text in the cell that contains the `Block Diagram` variable. `%<blockdiagram>` must be the only content in that cell.

Block Diagram

Use the `Block Diagram` variable to indicate the cell in which to print the block diagram. Every print frame must include one `Block Diagram` variable. If you do not specify a `Block Diagram` in one of the cells, you cannot save the print frame and cannot print a block diagram with it.

Do not add any other content in a cell that contains a `Block Diagram` variable.

Variables

In addition to the `Block Diagram` variable, you can add other variables, such as the current date, to cells. Simulink supplies variable content at the time of printing.

Variable entries include:

- `Block Diagram` — Add this variable in the cell in which you want the block diagram to print. For details, see “Block Diagram” on page 68-10.

- `Date` — The date that the block diagram and print frame are printed, in `dd-mmm-yyyy` format.
- `Time` — The time that the block diagram and print frame are printed, in `hh:mm` format.
- `Page Number` — The page of the block diagram being printed.
- `Total Pages` — The total number of pages being printed for the block diagram, which depends on the printing options specified.
- `System Name` — The name of the block diagram being printed.
- `Full System Name` — The name of the block diagram being printed, including its position from the root system through the current system, for example, `engine/Throttle & Manifold`.
- `File Name` — The file name of the block diagram, for example, `sldemo_engine.mdl`.
- `Full File Name` — The full path and file name for the block diagram, for example, `\\matlab\toolbox\simulink\simdemos\automotive\sldemo_engine.mdl`.

When you enter a variable, the cell displays the type of content in brackets, <>, preceded by a percent sign, `%`. For example, if you add a `Page Number` variable, it appears as `%<page>`.

Note Do not edit the text of a variable entry, because then the variable content does not print. For example, if you accidentally remove the `%` from the `%<page>` entry, the text `<page>` prints, instead of the actual page number.

Text

For `Text` content, type the text that you want to include in that cell (for example, the name of your organization). To type additional text on a new line, press the **Enter** key. When you are finished editing, click outside of the edit box.

You can copy and paste text from another document into a cell. Any formatting of the copied text is lost.

To type special characters (for example, superscripts and subscripts, Greek letters, and mathematical symbols), use embedded TeX sequences. For a list of allowable sequences, see the `text` command `String` property (in Text).

Format Content in Cells

You can align cell contents using the left, center, and right alignment buttons. (Block diagrams are always center aligned.)

You can change font properties, such as size or style (for example, italics or bold). To change font properties, select the cell, then right-click the contents and use the context menu to format the text.

- “Print Using Print Frames” on page 68-13

More About

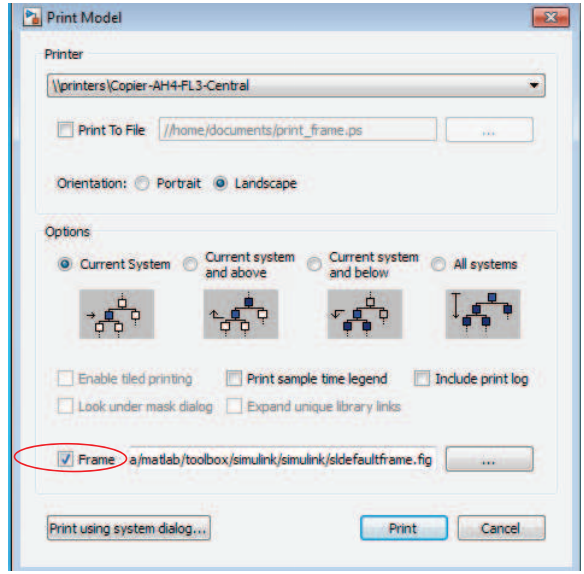
- “Print Frames” on page 68-2

Print Using Print Frames

To print using a print frame, you specify an existing print frame. If you want to build a print frame, see “Create a Print Frame” on page 68-6.

Note If you enable the print frame option, then Simulink does not use tiled printing.

1. In the Simulink Editor or Stateflow Editor, select **File** > **Print** > **Print**.
2. In the Print Model dialog box, select the **Frame** check box.



3. Supply the file name for the print frame you want to use. Either type the path and file name directly in the edit box, or click the **...** button and select a print frame file you saved using the PrintFrame Editor. The default print frame file name, `sldefaultframe.fig`, appears in the file name edit box until you specify a different file name.
4. Specify other printing options in the Print Model dialog box.

Note The paper orientation you specify with the PrintFrame Editor does not control the paper orientation used for printing. For example, assume you specify a

landscape-oriented print frame in the PrintFrame Editor. If you want the printed page to have a landscape orientation, you must specify that using the Print Model dialog box.

5 Click **OK**.

The block diagram prints with the print frame that you specify.

Running Models on Target Hardware

About Run on Target Hardware Feature

Simulink Supported Hardware

As of this release, Simulink supports the following hardware.

Support Package	Vendor	Earliest Release Available	Last Release Available
Android Devices	Android	R2014a	Current
Apple iOS Devices	Apple	R2015a	Current
Arduino Hardware	Arduino	R2012a	Current
BeagleBoard Hardware	BeagleBoard	R2012a	R2016a
LEGO MINDSTORMS NXT Hardware	LEGO	R2014a	R2016b
LEGO MINDSTORMS EV3 Hardware	LEGO	R2014a	Current
Raspberry Pi Hardware	Raspberry Pi	R2013a	Current
PARROT Minidrones	PARROT®	R2017a	Current

For a complete list of supported hardware, see Hardware Support.

Tune and Monitor Models Running on Target Hardware

In this section...

Overview of Using External Mode

You can use External mode to tune parameters and monitor a model running on your target hardware.

External mode enables you to tune model parameters and evaluate the effects of different parameter values on model results in real time. Doing so helps you find the optimal values to achieve desired performance. This process is called parameter tuning.

External mode accelerates parameter tuning because you do not have to rerun the model each time you change parameters. You can also use External mode to develop and validate your model using the actual data and hardware for which it is designed. This software-hardware interaction is not available solely by simulating a model.

This workflow lists the tasks usually required to tune parameters with External mode:

1. In the model on your host computer, enable External mode.
2. (Optional) Place one or more sink blocks in your model. For example, use Display or Scope blocks to visualize data, or use a To File block to log signal data.
3. Give the Simulink software command to run the model on the target hardware.
4. (Optional) Observe the data External mode sends from the target hardware to sink blocks in the model on the host computer.
5. Change and apply parameter values in the model on your host computer.
6. Find the optimal parameter values by making adjustments and observing the results.
7. Save the new parameter values, disable External mode, and save the model.

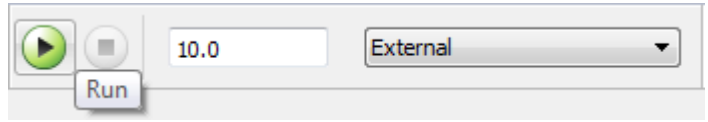
Run Your Simulink Model in External Mode

Note If you have the Embedded Coder or Simulink Coder software, you can use External mode with a model that contains Model blocks (uses the "Model reference").

1. Connect the target hardware to your host computer.

   Different types of target hardware can use different types of connections. Check the External mode topic for your target hardware to determine which type of connection to use.

2. On the model toolbar, set **Simulation mode** to `External`.



3. Set the **Simulation stop time** parameter, located to the left of **Simulation mode** on the model toolbar. The default value is `10.0` seconds. To run the model for an indefinite period, enter `inf`.

4. Click the **Run** button.

   If your model does not contain a sink block, the MATLAB Command Window displays a warning message. For example:

```
Warning: No data has been selected for uploading.
> In C:\Program Files (x86)\MATLAB\R2013a Student1\toolbox\
realtime\realtime\+realtime\extModeAutoConnect.p>
extModeAutoConnect at 17
In C:\Program Files (x86)\MATLAB\R2013a Student1\toolbox\
realtime\realtime\sl_customization.p>myRunCallback at 149
```

   You can disregard this warning or add a sink block to the model.

   After several minutes, Simulink starts running your model on the board.

5. Change parameter values in the model on your host computer.

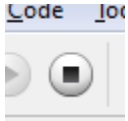
   Observe the corresponding changes in the model running on the hardware.

   Any Simulink Sinks blocks in your model receive data from the hardware and display it on your host computer.

Note External mode increases the processing burden of the model running on the board, and can cause overruns.

Stop External Mode

To stop the model running in External mode, click the black square Stop button located on the model toolbar, as shown here.



This action stops the process for the model running on the target hardware, and stops the model simulation running on your host computer.

If the **Simulation stop time** parameter is set to a specific number of seconds, External mode stops when that time elapses.

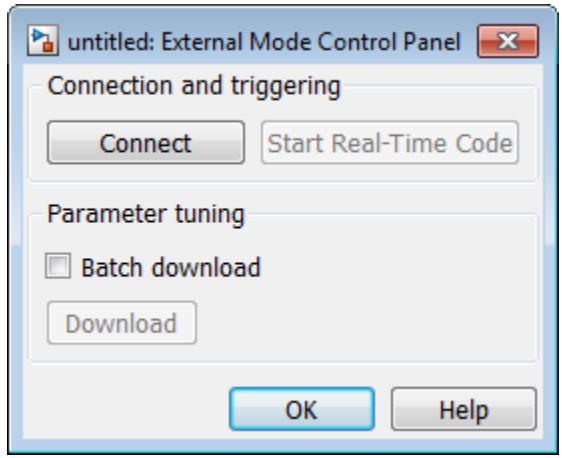
When you are finished using External mode, set **Simulation mode** back to `Normal`.

External Mode Control Panel

Using External Mode Control Panel provides additional control of External mode operations, including:

- Connect or disconnect the model on the host computer to/from the model running on the target hardware.
- Start and stop the model running on the target hardware.
- Gather changes to parameter values in a batch before applying them concurrently to the model running on the target hardware.

To open the External Mode Control Panel dialog box, in the model window, select **Code** > **External Mode Control Panel**.



The **Connect/Disconnect** button connects or disconnects the model on your host computer to/from the model running on the target hardware. If the model is not running on the target hardware, clicking **Connect** automatically deploys and runs the model on the target hardware.

- The **Start Real-Time Code/Stop Real-Time Code** button starts or stops the model running on the target hardware.
- **Batch download** enables you to gather changes before using the **Download** button to simultaneously apply those changes to the model running on the hardware:
  - While **Batch download** is disabled, clicking **OK** or **Apply** in a block dialog box sends updated block parameter values from the block to the model running on the target hardware.
  - When you enable **Batch download**, clicking **OK** or **Apply** in a block dialog box stores updated block parameter values on the host computer. You can complete a set of changes before clicking **Download** to simultaneously send all of the updated values to the model running on the target hardware. This feature is useful for avoiding error conditions when a model contains blocks whose parameter values must be changed concurrently.

External Mode Control Panel displays `Parameter changes pending...` to the right of the **Download** button until the model running on the target hardware has applied the new parameter values.

Block Produces Zeros or Does Nothing in Simulation

If you simulate a model on your host computer without running it on your target hardware:

- Input blocks produce zeros.
- Output blocks do nothing.

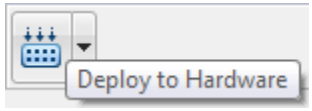
This is the expected behavior.

For example, in a model, if you select **Simulation** > **Mode** > **Normal** and then select **Simulation** > **Run**, the following happens:

- The sensor block and Digital Input block send zeros to the model.
- The Digital Output block does nothing.

To see the blocks work normally, run your model on target hardware or use External mode.

To run the model on target hardware, select **Tools** > **Run on Target Hardware** > **Prepare to Run**. Then, click the Deploy to Hardware button.



To use External mode, select **Simulation** > **Mode** > **External**. Then, select **Simulation** > **Run**.

Running Simulations in Fast Restart

How Fast Restart Improves Iterative Simulations

In the classic Simulink workflow, when you simulate a model, Simulink:

1. Compiles the model
2. Simulates the model
3. Terminates the simulation

While developing a model, you typically simulate a model repeatedly as you iterate the design. For example, you might calibrate input values or block parameters for a particular response. Changing these values or parameters does not always require compiling the model before simulating again. However, in the classic workflow, each simulation compiles the model, even if the changes do not alter the model structurally. Each compile slows down the process and increases overall simulation time.

Fast restart allows you to perform iterative simulations without compiling a model or terminating the simulation each time. Using fast restart, you compile a model only once. You can then tune parameters and root inputs and simulate the model again without spending time on compiling. Fast restart associates multiple simulation phases to a single compile phase to make iterative simulations more efficient.

Use fast restart when your workflow does not require structural changes to the model. Also, fast restart is better suited if the workflow involves any of these factors:

- The model requires multiple simulations in which simulation inputs or parameters change in every iteration.
- The compile time of the model is several seconds or longer.

You can use fast restart in normal and accelerator simulation modes. When you use fast restart in accelerator mode, you reduce simulation time and perform only a single compilation.

- “Factors Affecting Fast Restart” on page 70-16

Fast Restart Workflow

When you need to simulate a model iteratively to tune parameters, achieve a desired response, or automate testing, use fast restart to avoid compiling again.

1. Turn on fast restart using the **Fast restart** button on the Simulink Editor toolbar or from the command line.
2. Simulate the model. The first simulation requires the model to compile, initialize and save a `SimState`. Once the simulation is complete, it does not terminate. Instead, the model is initialized again in fast restart.
3. Perform any of these actions:

   - Change tunable parameters.
   - Tune root-level inputs.
   - Modify base workspace, model workspace variables and data dictionary entries that are referenced by tunable parameters.
   - Change inputs to From File and From Workspace blocks.
   - Change the **Initial state** parameter for the next simulation.
   - Using the Signal Builder block, change data, rename signals and signal groups, and add new groups.
   - Change the signal logging override values for the model programmatically by using the `set_param` command and the `DataLoggingOverride` parameter. See “Override Signal Logging Settings from MATLAB” on page 61-102.

   Once you have initialized a model in fast restart, you cannot

   - Change the dimension, type, or complexity of a signal or variable.
   - Make changes to a nontunable parameter such as sample time.
   - Make structural changes such as adding or deleting blocks or connections.

   These changes require you to compile the model again. To make changes like these, turn off fast restart, make your changes, and repeat this procedure.
4. Simulate the model. The model uses the new values of parameters and inputs that you provided but does not compile again.
5. Once you have achieved the desired response, turn off fast restart.

Note When you turn off fast restart, Simulink does not store any compile information for the model. The model compiles when you next simulate the model.

- “Factors Affecting Fast Restart” on page 70-16
- “Save and Restore Simulation State as SimState” on page 24-37

Get Started with Fast Restart

In this section...

Prepare a Model to Use Fast Restart

Before you simulate a model in fast restart, ensure that the model meets these requirements:

- If you have enabled callbacks in the model, make sure they do not attempt to make structural changes when the model is reinitialized. For example, callbacks such as mask initialization commands get called at the beginning of each simulation. Therefore, avoid using mask initialization code that makes structural changes to the model.
- All blocks in the model must support `SimState`.
- The simulation mode is Normal or Accelerator mode.

Caution When fast restart is on, you cannot save changes to the model after it compiles. Saving changes requires Simulink to discard information about the compiled state. To save any changes to the model, turn off fast restart first.

Enable Fast Restart

Use one of these methods to enable fast restart:

- Click the **Fast restart** button  on the Simulink Editor toolbar.
- At the MATLAB Command prompt, use `set_param` to enable fast restart. Type

  ```
  set_param(model,'FastRestart','on')
  ```

More About

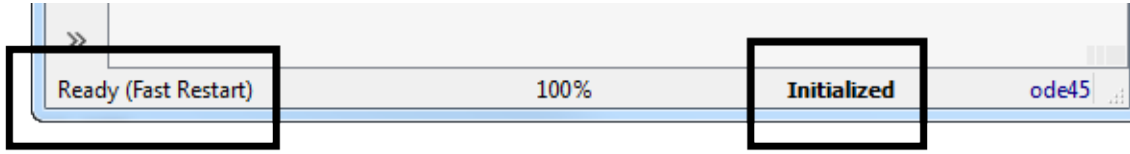
- “Fast Restart Methodology” on page 70-12
- “Factors Affecting Fast Restart” on page 70-16

Simulate a Model Using Fast Restart

After you load your model and turn on fast restart, simulate the model.

1. Simulate the model by calling `sim` or clicking the **Run** button in the Simulink Editor toolstrip. The first simulation in fast restart requires the model to compile and save a `SimState`.

   Once the simulation is complete, the status bar shows that the model is initialized in fast restart.



2. Adjust tunable parameters in the model, such as the gain value of a Gain block, or tune root-level input values. You can also make changes to base workspace variables. You cannot adjust nontunable parameters such as sample time, because doing so requires the model to compile once more.
3. Simulate the model again. This time, the model does not compile. When you click the **Play** button or step forward, Simulink updates blocks that have new values as well as blocks that reference workspace variables.
4. When you are satisfied with your results, turn off fast restart by clicking the **Fast restart** button off.
5. To keep your changes, save the model.

Note After a model is initialized in fast restart, Simulink displays a warning if you attempt to make a structural change to the model. To make such changes, you must turn off fast restart.

More About

- “Stop Simulation and Exit Fast Restart” on page 70-10
- “Fast Restart Methodology” on page 70-12

Stop Simulation and Exit Fast Restart

In this section...

Stop a Simulation

When you click **Stop** in the middle of a fast restart simulation:

- Simulation does not terminate.
- The model is in the initialized state.
- You can now change tunable parameters in the model
- You can terminate the simulation and exit fast restart by clicking the **Fast restart** button off.

Exit Fast Restart

You can exit fast restart only when the model is in the initialized state. After simulating, click the **Fast restart** button off. To do this programmatically, type:

```
set_param(model,'FastRestart','off')
```

- Simulink terminates simulation.
- Simulink discards any compiled information about the model.
- The model must compile again the next time you simulate.

More About

- “Fast Restart Methodology” on page 70-12

Fast Restart Methodology

In this section...

Simulation Modes

You can use fast restart in Normal and Accelerator simulation modes.

Tuning Parameters Between Simulations

- When a model is initialized in fast restart, in addition to block values and base workspace variables, you can tune parameters in the **Data Import/Export** and **Solver** panes in the **Simulation** > **Model Configuration Parameters** dialog box.
- Certain parameters are tunable between simulations only when the model is initialized in fast restart. They include:
  - **Initial Value** parameter of the IC block
  - **Initial Output** parameter of the Merge block
  - **Data** parameter of the From Workspace block
  - **Signal** parameter and signal groups of the Signal Builder block.

Model Methods and Callbacks in Fast Restart

When fast restart is on, Simulink calls model and block methods and callbacks as follows:

1. Call model `InitFcn` callback.
2. Call model `SetupRuntimeResources` method.
   a. Call `mdlSetupRuntimeResources` S-function method.

3. Call model `Start` method.
   a. Call `mdlStart` S-function method.
4. Call model `Initialize` method.
   a. Call `mdlInitializeConditions` S-function method.

   Note Use the `ssIsFirstInitCond` flag to guard code that should run only during the initialization phase of any simulation, including the first and subsequent initializations in fast restart.
5. Call model and block `StartFcn` callbacks.

Note Steps 1–5 apply to all simulations in Simulink (with or without fast restart).

6. For the first simulation in fast restart, capture a simulation snapshot. A simulation snapshot contains simulation state (`SimState`) and information related to logged data and visualization blocks. As part of the snapshot capture, call `mdlGetSimState` S-function method.
7. This is a standard execution phase of any simulation, with or without fast restart.
   - Call model `Outputs`.
   - Call model `Update`.
   - Call model `Derivatives`.
   - Repeat these steps in a loop until stop time or a stop is requested.
8. Call model `Terminate` method.
   a. Call `mdlTerminate` S-function method.
9. After simulation ends, call model and block `StopFcn` callbacks. This is a standard phase of any simulation, with or without fast restart.
10. Restore the simulation snapshot taken for fast restart. As part of the restore, call `mdlSetSimState` S-function method.
11. Wait in a reinitialized state until one of these actions:
    - To run another simulation (programmatically or using the Simulink Editor) in fast restart, return to step 3.
    - To end Fast Restart mode and uncompile the model:

a Call the model method `CleanupRuntimeResources` and the `mdlCleanupRuntimeResources` S-function method.

b Do not call `StopFcn` callbacks again at this point.

In some cases. the `Start` and `Terminate` methods are only called once and not for each successive Fast Restart simulation. In these cases, these method calls are combined with calls to `SetupRuntimeResources` and `CleanupRuntimeResources`, respectively. These cases are as follows:

- When an S-function contains custom `SimState` save and restore methods.
- When an S-function sets the flag `SS_OPTION_CALL_TERMINATE_ON_EXIT`.
- When an S-function is placed inside the accelerated mode of a referenced model.

For more information on model callbacks, see “Callbacks for Customized Model Behavior” on page 4-44.

SimState and Initial State Values

You can change initial state values, including `SimState`, in between fast restart simulations.

When a `SimState` object for initial state is used in fast restart, every new simulation resets to the start time of the model and not the snapshot time of each `SimState` object. Thereafter, on the first step forward, Simulink checks to see if a `SimState` has been specified. If yes, Simulink restores it before computing the next step. Thus, the first simulation step effectively fast forwards to the snapshot time of the specified `SimState` object.

Analyze Data Using the Simulation Data Inspector

Fast restart supports data logging using the Simulation Data Inspector. Every simulation in fast restart creates an SDI object with the name **<modelname> fast restart run <number>**. The value of `number` increments for each simulation.

Custom Code in the Initialize Function

When you place custom code in the **Configuration Parameters > Simulation Target > Custom Code > Initialize function** pane in the **Model Configuration Parameters** dialog box, this gets called only during the first simulation in fast restart.

Factors Affecting Fast Restart

There are some limitations to simulating in fast restart.

- Fast restart does not support these modes:
  - Rapid Accelerator
  - External
- When a model is in the reinitialized state, you cannot:
  - Make structural changes.
  - Make changes to nontunable parameters such as sample time.
  - Save changes to the model. You must turn off fast restart to save any changes to the model.
- You cannot turn on fast restart in a model if it contains blocks that do not support `SimState`. These blocks include:
  - Legacy (pre-R2016a) SimEvents blocks
  - Simscape Multibody First Generation blocks
  - MATLAB function blocks that contain system objects
  - S-functions that do not implement SimState `get` and `set` methods but have `Pwork` vectors declared
  - From Multimedia File
  - To Multimedia File
  - From Audio Device
  - To Audio Device
  - Multipath Rician Fading Channel
  - Multipath Rayleigh Fading Channel
  - Derepeat
  - DC Blocker
  - Stack
  - Queue
  - Read Binary File

  - Write Binary File
  - Video Viewer
  - Frame Rate Display
  - Video From Workspace
  - Video To Workspace
- Between simulations, fast restart does not handle changes to design data, such as bus properties.
- Parameter tunability limitations apply. See “Tunability Considerations and Limitations for Other Modeling Goals” on page 36-45.
- The Fixed-Point Tool provides limited support when a model is simulated in fast restart. You must exit fast restart to collect simulation and derived ranges, and propose data types.
- When fast restart is on, you cannot change the variant that a variant subsystem or variant model uses. This is because the inactive subsystems are not compiled in the first simulation.
- When there are multiple model references to the same submodel, you cannot change the model visibility when the model is in the reinitialized state.
- Fast restart is not compatible with these tools:
  - Simulink Profiler
  - Simulink Debugger
- When simulating a model in fast restart, you cannot run checks using Model Advisor.
- When you enable fast restart, the `sim` command supports only the single output `Simulink.SimulationOutput` form, regardless of the syntax you use in the command.
- When you enable fast restart, you cannot pass non-tunable parameters as arguments to `sim`.

Package Models to Share

Packaged Models

** This is a placeholder for an overview of packaged models ***

Model Component Testing

Component Verification

Component Verification

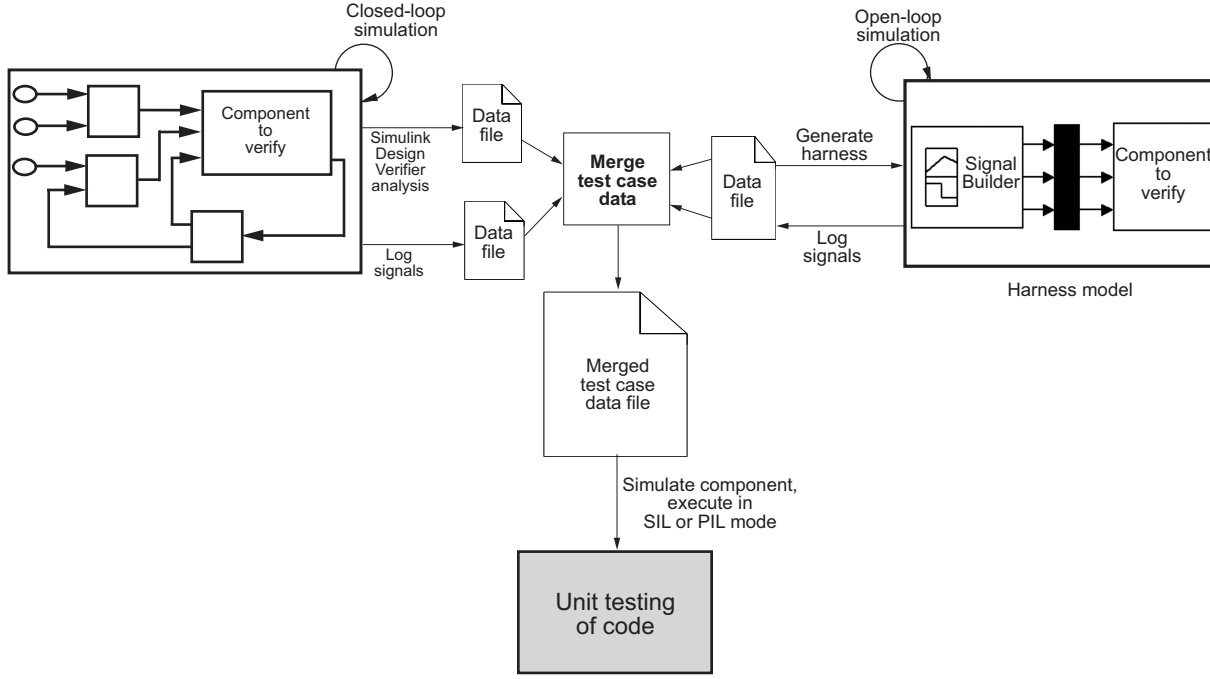
In this section...

You can test a component of your model in isolation, or as part of a larger model. Testing in isolation is useful for debugging the component algorithm and ensuring readiness for component reuse. Testing as part of a larger model considers component behavior in response to particular application inputs and outputs.

This topic is a broad overview of verification activities, including tools in additional products you can use in your verification workflow.

Workflow for Component Verification

This graphic illustrates component verification testing in closed- and open-loop configurations.



1 Choose your approach for component verification:

   - For closed-loop simulations, verify a component within the context of its container model by logging the signals to that component and storing them in a data file. If those signals do not constitute a complete test suite, generate a harness model and add or modify the test cases in the Signal Builder.
   - For open-loop simulations, verify a component independently of the container model by extracting the component from its container model and creating a harness model for the extracted component. Add or modify test cases in the Signal Builder and log the signals to the component in the harness model.

2 Prepare component for verification.

3 Create and log test cases. You can also merge the test case data into a single data file.

   The data file contains the test case data for simulating the component. If you cannot achieve the expected results with a certain set of test cases, add new test cases or modify existing test cases in the data file, and merge them into a single data file.

Continue adding or modifying test cases until you achieve a test suite that satisfies the goals of your analysis.

4 Execute the test cases in software-in-the-loop or processor-in-the-loop mode.

5 After you have a complete test suite, you can:

- Simulate the model and execute the test cases to:
  - Record coverage using Simulink Coverage.
  - Record output values to make sure that you get the expected results.
- Invoke the Code Generation Verification (CGV) API to execute the generated code for the model that contains the component in simulation, software-in-the-loop (SIL), or processor-in-the-loop (PIL) mode.

Note To execute a model in different modes of execution, you use the CGV API to verify the numerical equivalence of results. For more information about the CGV API, see "Programmatic Code Generation Verification" (Embedded Coder).

Test a Component in Isolation

This workflow illustrates common steps to test reusable components such as:

- Model blocks
- Atomic subsystems
- Stateflow atomic subcharts

1 Depending on the type of component, take one of the following actions:

- Model blocks — Open the referenced model.
- Atomic subsystems — Extract the contents of the subsystem into its own Simulink model.
- Atomic subcharts — Extract the contents of the Stateflow atomic subchart into its own Simulink model.

2 Create a harness model for:

- The referenced model
- The extracted model that contains the contents of the atomic subsystem or atomic subchart

3 Add or modify test cases in the Signal Builder in the harness model.
4 Log the input signals from the Signal Builder to the test unit.
5 Repeat steps 3 and 4 until you are satisfied with the test suite.
6 Merge the test case data into a single file.
7 Depending on your goals, take one of the following actions:

- Execute the test cases to:
  - Record coverage.
  - Record output values and make sure that they equal the expected values.
- Invoke the Code Generation Verification (CGV) API to execute the test cases in software-in-the-loop (SIL) or processor-in-the-loop (PIL) mode on the generated code for the model that contains the component.

If the test cases do not achieve the expected results, repeat steps 3 through 5.

Test a Model Block Included in a Larger Model

Use system analysis to:

- Verify aModel block in the context of the block's container model.
- Analyze a closed-loop controller.

1 Log the input signals to the component by simulating the container model or analyze the model using the Simulink Design Verifier software.
2 If you want to add test cases to your test suite or modify existing test cases, create a harness model with the logged signals.
3 Add or modify test cases in the Signal Builder in the harness model.
4 Log the input signals from the Signal Builder to the test unit.
5 Repeat steps 3 and 4 until you are satisfied with the test suite.
6 Merge the test case data into a single file.
7 Depending on your goals, do one of the following:

- Execute the test cases to:
  - Record coverage.

    - Record output values and make sure that they equal the expected values.
  - Invoke the Code Generation Verification (CGV) API to execute the test cases in software-in-the-loop (SIL) or processor-in-the-loop (PIL) mode on the generated code for the model.

If the test cases do not achieve the expected results, repeat steps 3 through 5.

Simulation Testing Using Model Verification Blocks

What Is the Verification Manager?

The Verification Manager is a graphical interface in the Signal Builder dialog box. You can use the Verification Manager to manage Model Verification blocks in your model.

Construct Simulation Tests Using the Verification Manager

In this section...

Model Verification Blocks and the Verification Manager

Simulink Model Verification library blocks assess time-domain signals in your model, according to the specifications that you assign to the blocks. For individual block reference information, see the “Model Verification” category.

Model Verification blocks return an assertion when signals fall outside the specified limit or range. During simulation, when the signal crosses the limit, the verification block can:

- Stop the simulation and bring immediate focus to that part of the model.
- Report the failure with a logical signal. If the signal does not fail, the signal output is `true`. If the simulation fails, the signal output is `false`.

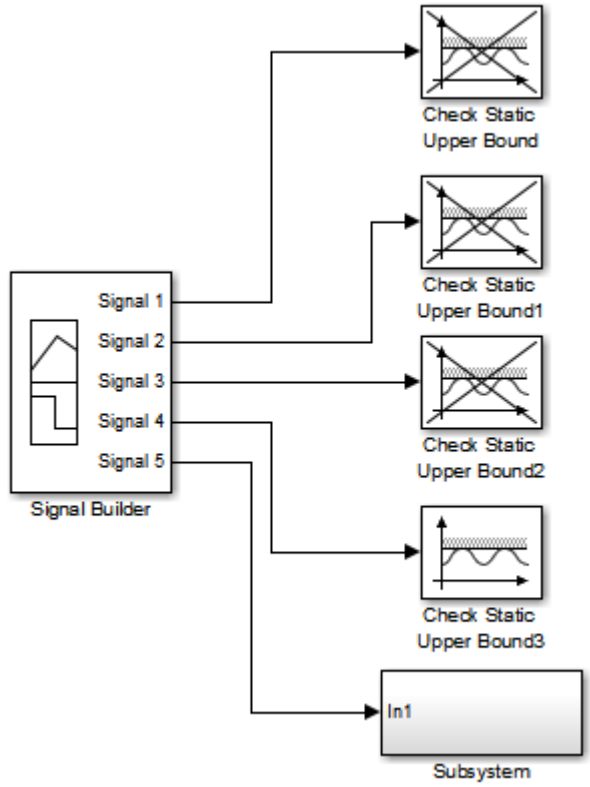
You can use the Verification Manager graphical interface in the Signal Builder dialog box to manage Model Verification blocks in your model.

If you have Simulink Control Design, you can also monitor frequency-domain characteristics such as gain and phase margins and peak magnitude. For more information, see “Model Verification” (Simulink Control Design).

View Model Verification Blocks

This example shows how to use the Verification Manager to enable and disable specific Model Verification blocks for certain Signal Builder groups.

1 Create a Simulink model that you can use to examine the Verification Manager. Create the following example model in a writable location on the MATLAB path.



In the example model, the contents of the subsystem are as follows.

a In the Signal Builder block, create a signal group with five signals in the group.

b Make two copies of the signal group, so that you have three signal groups: **Group 1**, **Group 2**, **Group 3**.

Note A Signal Builder block provides test signals for an entire model from one location. This model contains a Signal Builder block that feeds five test signals to the Model Verification blocks. The model sends the first four signals directly to Check Static Upper Bound blocks. The model sends the fifth signal to a subsystem that contains a Check Static Upper Bound block.

For more information on the Signal Builder block, see "Signal Groups" on page 64-72.

c To set each Check Static Upper Bound verification block to assert for an upper bound of 1, set the **Upper bound** parameter to `1`.

d For the following blocks, disable the assertion by clearing the **Enable assertion** parameter:

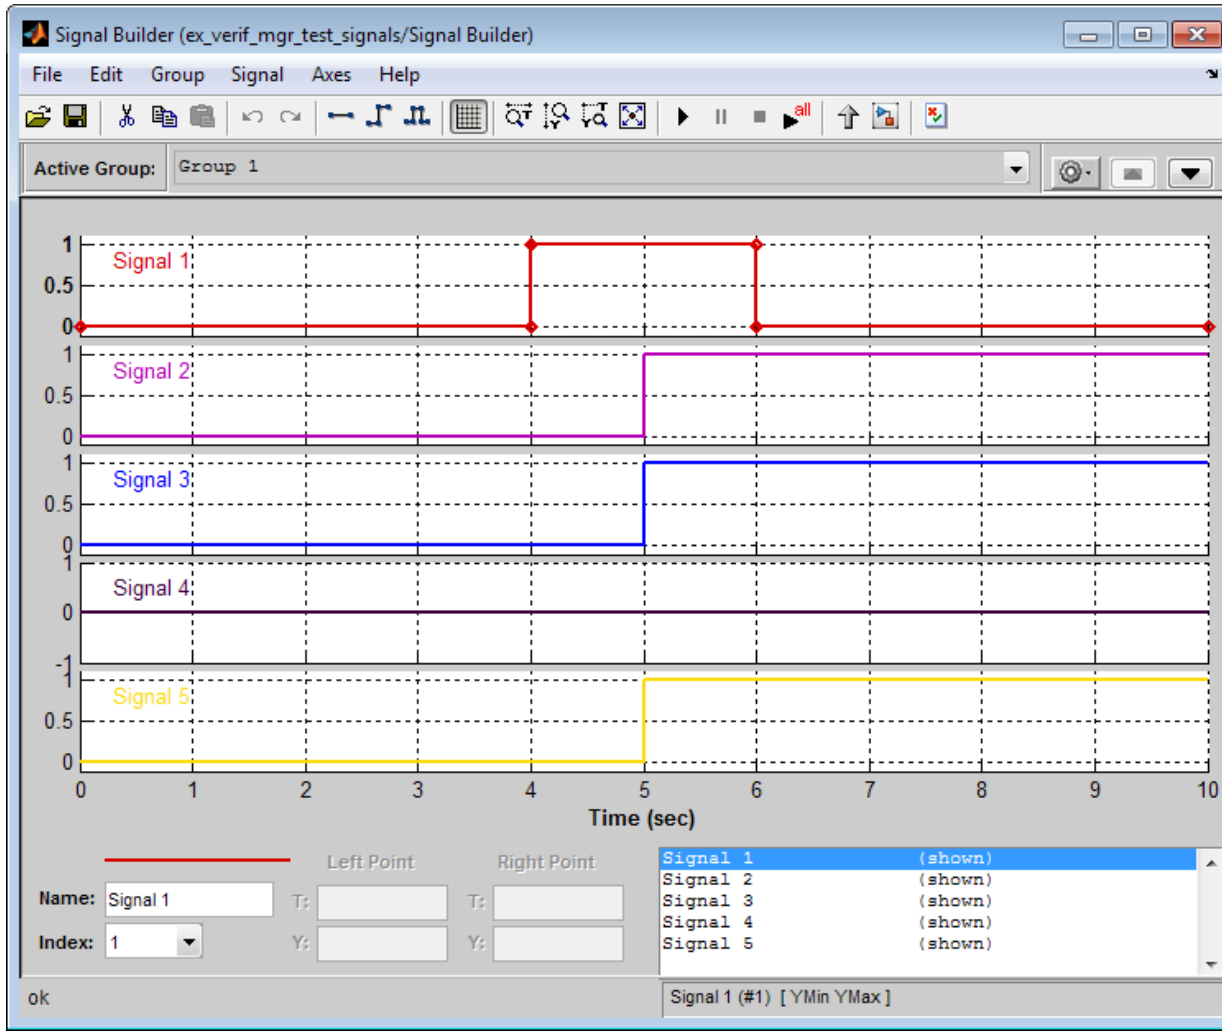
- Check Static Upper Bound
- Check Static Upper Bound1
- Check Static Upper Bound2
- Check Static Upper Bound in the subsystem

These blocks are crossed out in the model.

e To enable the Check Static Upper Bound3 block, select the **Enable assertion** parameter.

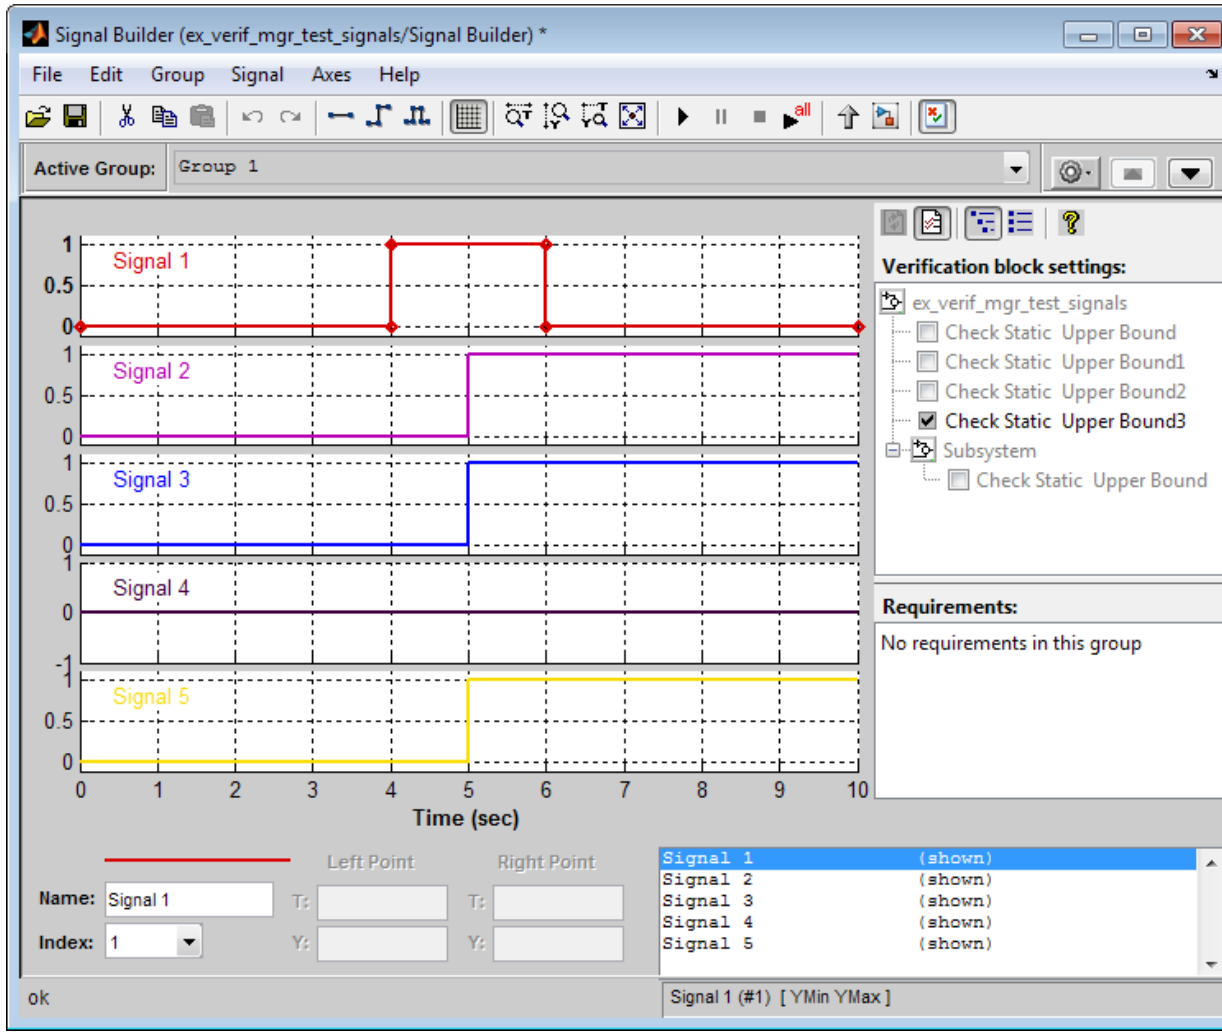
2 Save this model and name it `ex_verif_mgr_test_signals`.

3 To open the model Signal Builder dialog box, double-click the Signal Builder block. The signals in the first group (**Group 1** in this example) are displayed.



4 On the Signal Builder dialog box toolbar, select the Show Verification Settings tool .

The **Verification block settings** pane and the **Requirements** pane are displayed.



The **Verification block settings** pane lists all Model Verification blocks in the model, grouped by subsystem. If you right-click in this pane, you can select on of three options for viewing Model Verification blocks in this window:

- **Display > Tree format** — If enabled, lists the blocks as they appear in the model hierarchy.

- **Display > Overridden blocks only** — If enabled, lists only the blocks that have been disabled.
- **Display > Active blocks only** — If enabled, lists only the blocks that are enabled.

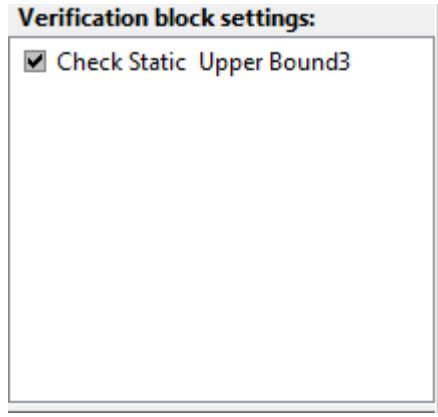
Note If both **Overridden blocks only** and **Active blocks only** are enabled, no Model Verification blocks appear. If both **Overridden blocks only** and **Active blocks only** are disabled, all Model Verification blocks appear.

In this example, the **Verification block settings** pane displays five Check Static Upper Bound blocks. Four are in the top level of the model, and one is in a subsystem.

The **Requirements** pane lists the requirements document links for the current signal group. For details on adding requirement document links in the Signal Builder dialog box, see "Link Test Cases to Requirements Documents Using the Verification Manager" on page 73-18.

5 For this example, select  to close the **Requirements** pane.

6 To display only the enabled Model Verification blocks for the current signal group, in the **Verification block settings** toolbar, select the List Enabled Verifications tool  .



7 To redisplay all Model Verification blocks for the current group, click the Show Verification Block Hierarchy tool  .

Enable and Disable Model Verification Blocks in a Model

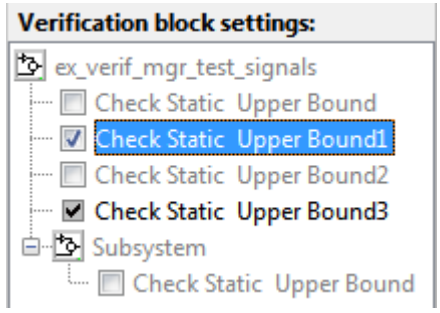
Use the Verification Manager to enable and disable individual Model Verification blocks in signal groups. To open the Verification Manager in the Signal Builder dialog box, click  .

The **Verification block settings** pane lists the Model Verification blocks in the model. Each verification block has a status node that indicates whether its assertion is enabled or disabled. Each verification block's status node also indicates whether the enabled or disabled setting applies universally or to the active group. The following table describes the different types of status nodes.

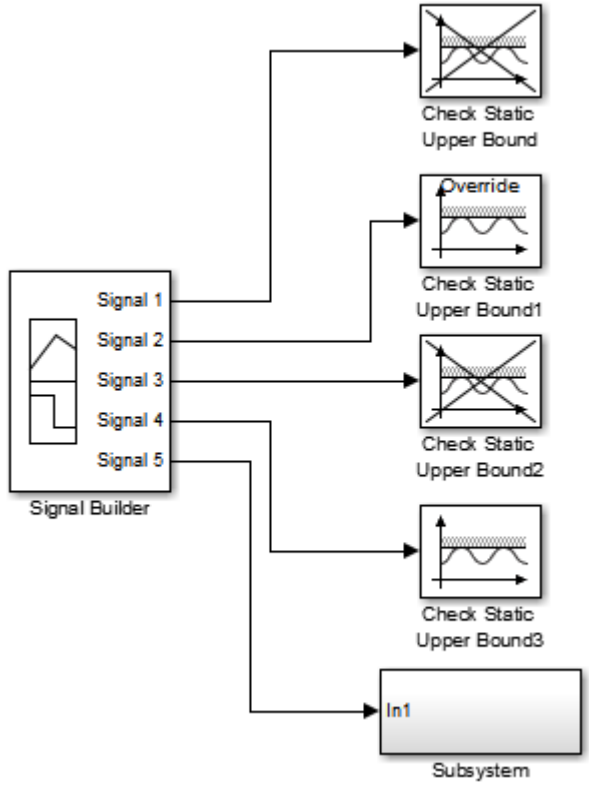
Node	Status
☐	Verification block is disabled for this group. Click to enable for the current group.
☑	Verification block is enabled for the current group. Click to disable for the current group.
☑	Verification block is enabled for all test groups.

Use the Verification Manager to enable or disable model verification blocks in the `ex_verif_mgr_test_signals` model that you created in “View Model Verification Blocks” on page 73-3.

1 In the Verification Manager, click the empty check box next to the Check Static Upper Bound1 node to enable that node for the current active group (**Group 1**).



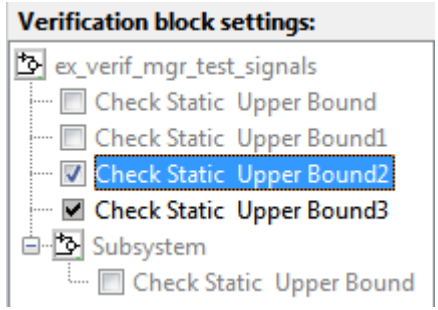
In the **Verification block settings** pane, when you enable a disabled block, you see the following change in how the block is displayed in the model.



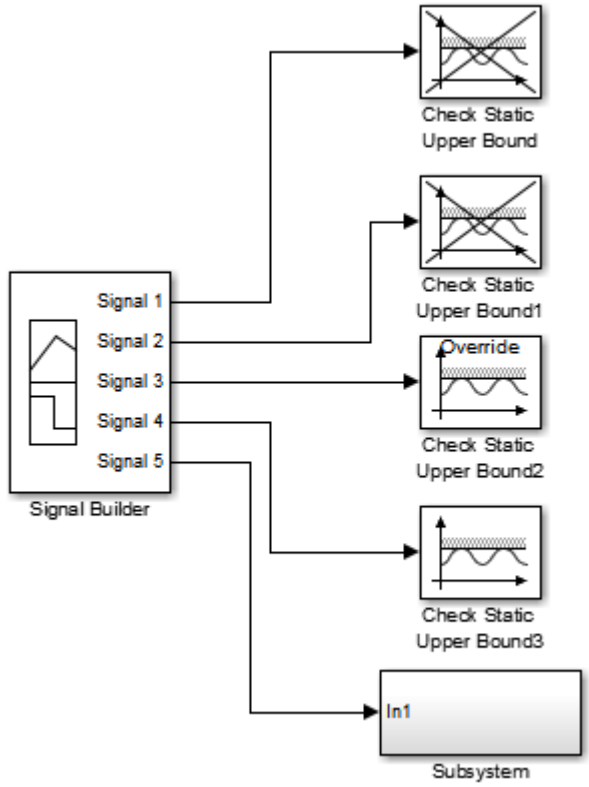
Because you enabled the Check Static Upper Bound1 block in the current group, an **Override** label is applied to the block and it is no longer crossed out.

2 In the Signal Builder, from the **Active Group** list, select `Group 2`.

3 Select the empty check box next to the Check Static Upper Bound2 node to enable that block for the current group (**Group 2**).



The Check Static Upper Bound2 block is no longer crossed out, indicating that the block is enabled for the current group. Check Static Upper Bound1, however, is crossed out because it is enabled in a different group.



4 Save the model with these changes.

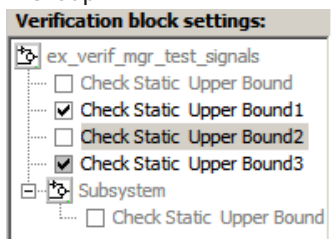
Enable and Disable Model Verification Blocks in a Subsystem

If you have a lot of verification blocks, it is tedious to enable and disable blocks individually. Using the Verification Manager, you can enable and disable blocks from context menu options. Depending on the status of the node, you have the following options.

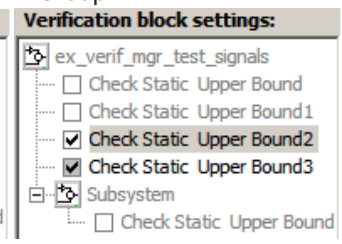
Node Status	Context Menu Options
	• Contents enable for all groups • Contents enable by group • Contents group enable • Contents group disable
	• Block enable by group
	• Block enable for all groups • Block group enable
	• Block enable for all groups • Block group disable

For example, assume that you define the following groups in the Verification Manager for a model with five Model Verification blocks.

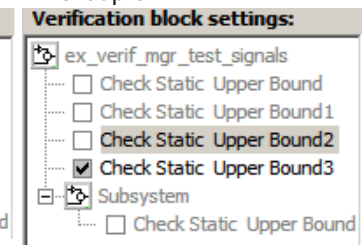
Group 1



Group 2

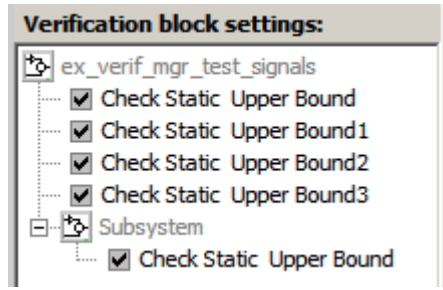


Group 3



1 In the Verification Manager window, right-click the `ex_verif_mgr_test_signals` node and select **Contents enable for all groups**.

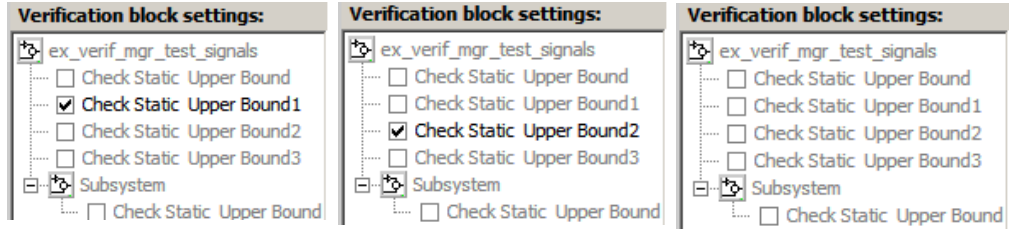
This option enables all verification blocks, for all test groups, in all subsystems; the settings for all groups look as follows:



2 Right-click `ex_verif_mgr_test_signals` and select **Contents enable by group**.

This option restores the individually enabled/disabled settings for each verification block in each group.

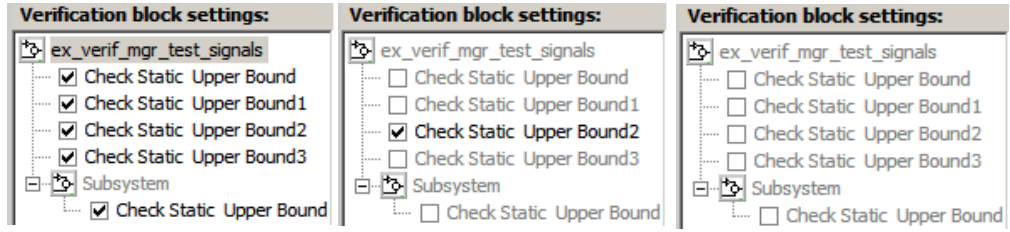
Group 1 Group 2 Group 3



3 From the **Active Group** list, select `Group 1`. Right-click `ex_verif_mgr_test_signals`, and select **Contents group enable**.

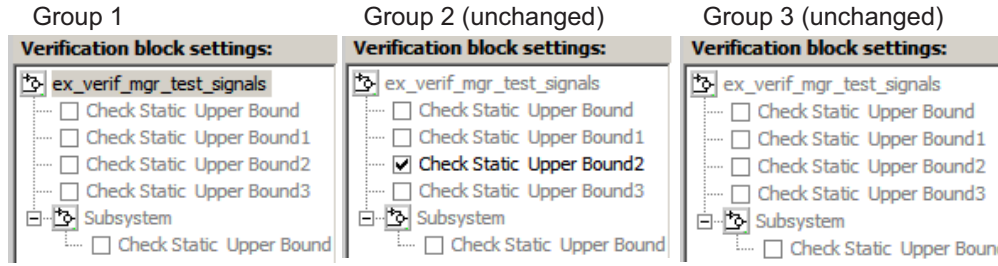
This option individually enables all contained blocks for only **Group 1**.

Group 1 Group 2 (unchanged) Group 3 (unchanged)



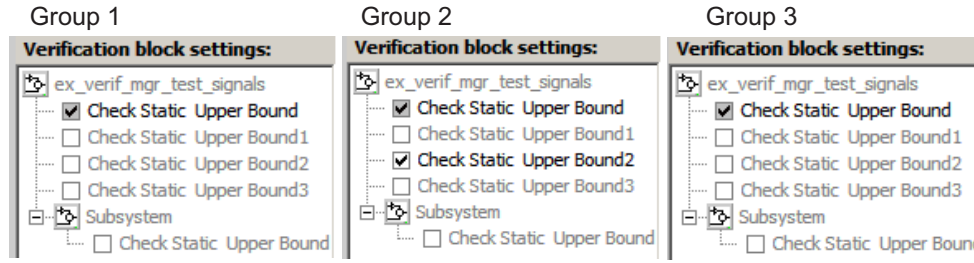
4 From the **Active Group** list, select `Group 1`. Right-click `ex_verif_mgr_test_signals` and select **Contents group disable**.

This option individually disables all contained blocks for only **Group 1**.



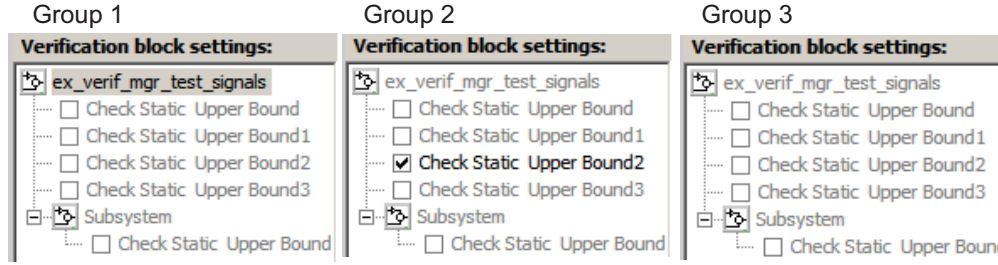
5 From the **Active Group** list, select `Group 1`. Right-click the Check Static Upper Bound node, and select **Block enable for all groups**.

This option enables the Check Static Upper Bound block for all groups.



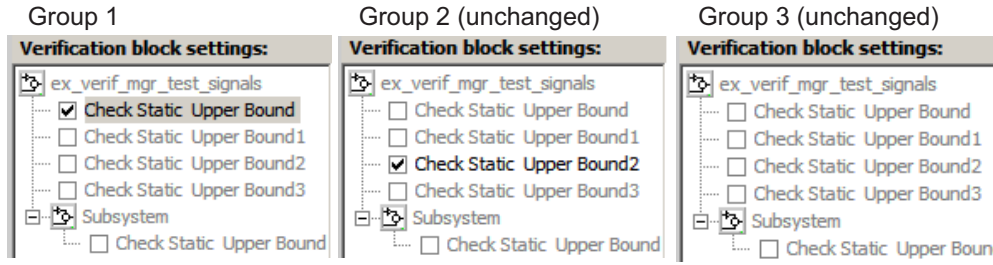
6 From the **Active Group** list, select `Group 1`. Right-click the Check Static Upper Bound node, and select **Block enable by group**.

This option restores the individually enabled/disabled state to this block for all groups. The **Block enable by group** option lets you enable or disable this node individually for each group.



7 From the **Active Group** list, select `Group 1`. Right-click the Check Static Upper Bound node, and select **Block group enable**.

This option enables the Check Static Upper Bound block for this group only.

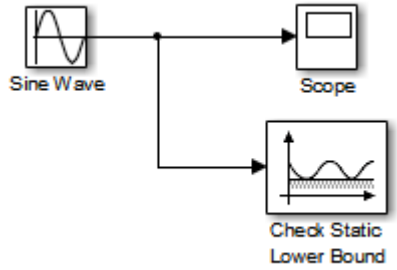


Selecting **Block group disable** disables the specified block for this group only.

Use Check Static Lower Bound Block to Check for Out-of-Bounds Signal

The following example uses a Check Static Lower Bound block to stop simulation when a signal from a Sine Wave block crosses its lower bound limit.

1 Attach a Check Static Lower Bound block to the signal from a Sine Wave block.



2 Set the Simulation stop time to 2 seconds.

3 Double-click the Sine Wave block and set the following parameters:

- Set the **Amplitude** to `1`.
- Set the **Frequency** to `pi` radians per second.

4 Double-click the Check Static Lower Bound block and set the **Lower bound** parameter to `-0.8`.

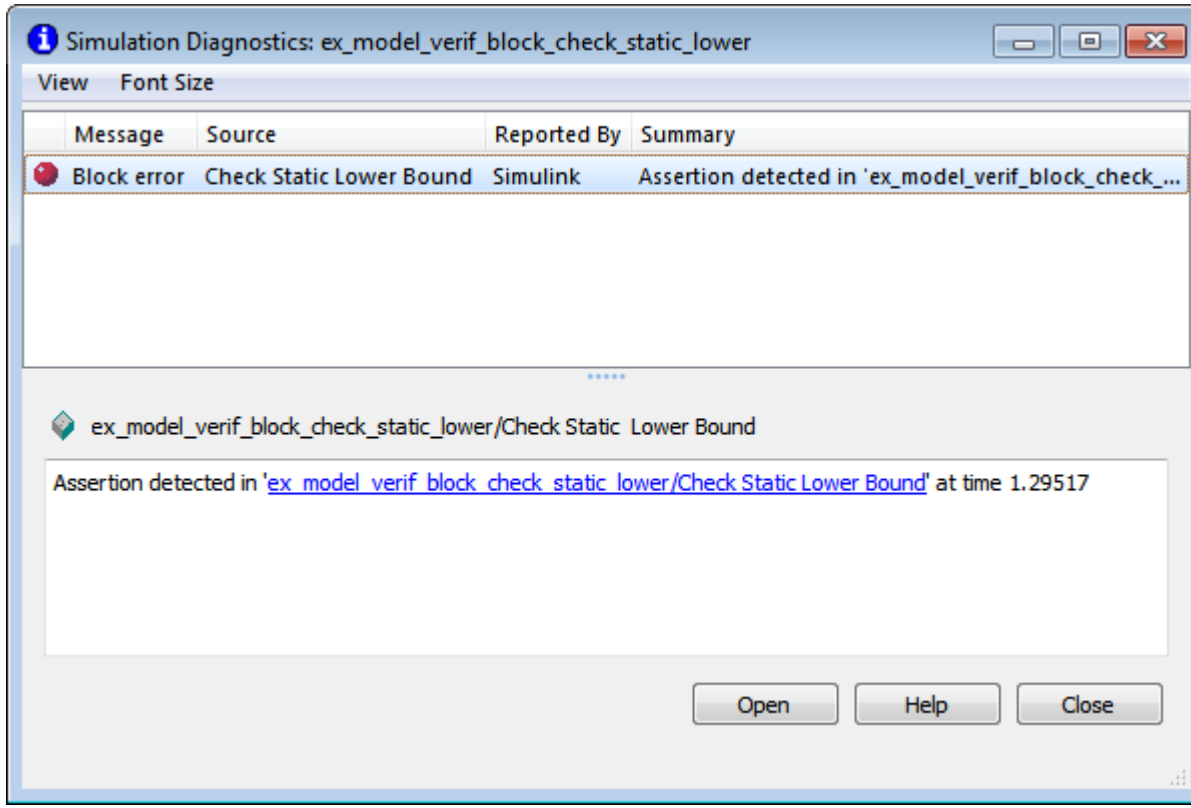
Enable assertion is the default. This parameter enables a verification block for an assertion. You set the Check Static Lower Bound block to detect a signal value of –

0.8 or lower. If the signal value reaches that value or falls below it, the simulation stops.

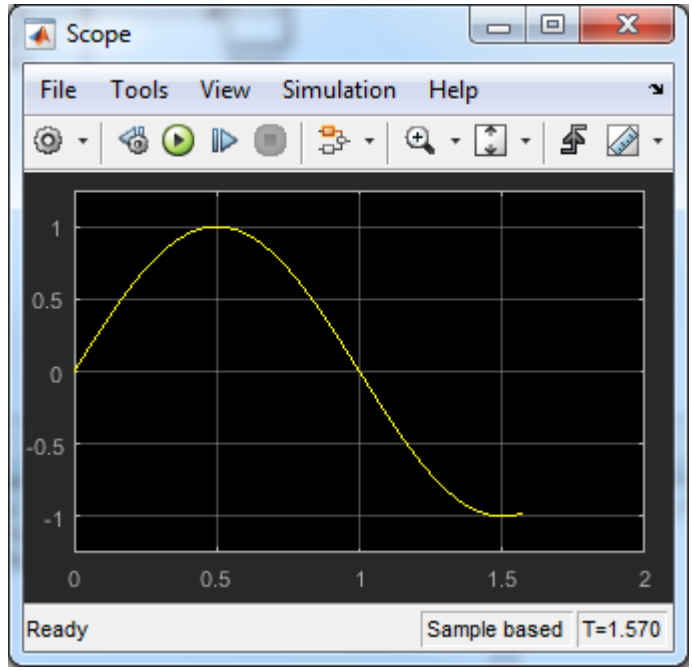
5 Run the simulation.

The model stops simulating after 1.295 seconds, when the output is –0.8. The software highlights the Check Static Lower Bound block.

When the simulation stops, you see the following diagnostic message.

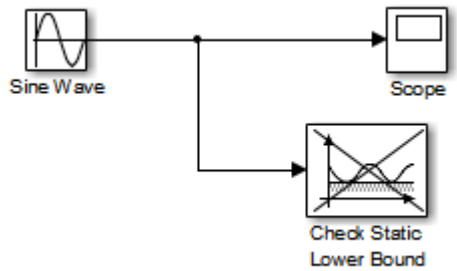


6 To verify the signal value, double-click the Scope block.



7 To disable the Check Static Lower Bound block from asserting its limit, clear the **Enable assertion** check box.

The block is crossed out in the model, as shown.



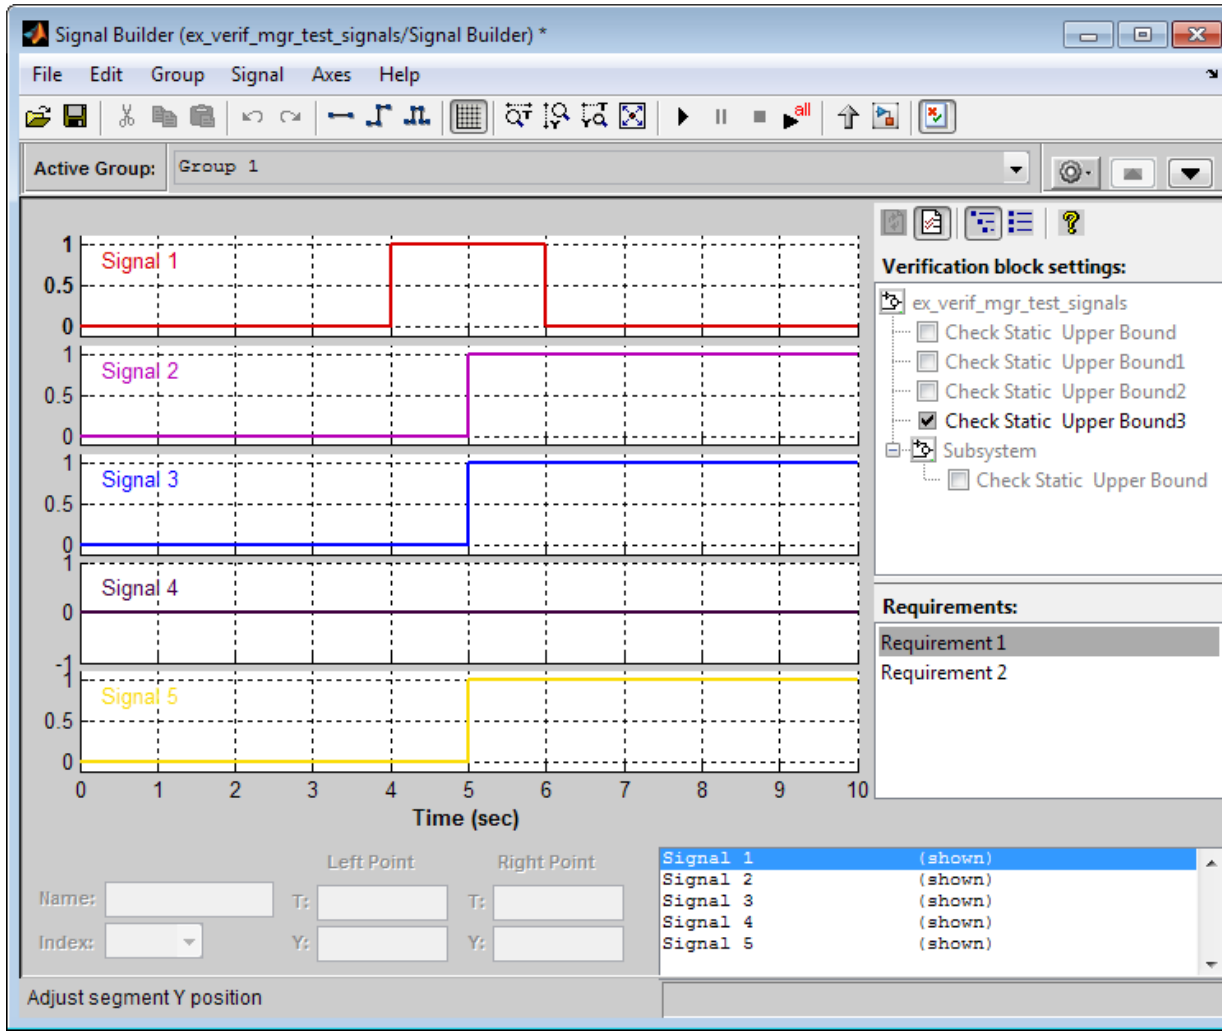
Link Test Cases to Requirements Documents Using the Verification Manager

With Simulink Requirements, you can link requirements documents to test cases and their corresponding Model Verification blocks through the Verification Manager **Requirements** pane in the Signal Builder.

1. To display the **Requirements** pane in the Signal Builder dialog box:
   a. Click the **Show verification settings** button ().
   b. Click the **Requirements display** button ().
2. In the **Requirements** pane, right-click anywhere.
3. From the context menu, select **Link Editor**.

   The Requirements dialog box opens.
4. When you browse and select a requirements document, the RMI stores the document path as specified by the **Document file reference** option on the Requirements Settings dialog box, **Selection Linking** tab.
5. Add links to requirements documents, as described in "Link to Requirements Document Using Selection-Based Linking" (Simulink Requirements).

   The names of the linked requirements appear in the **Requirements** pane.



6 To view the requirements document in its native editor, right-click a requirement link and select **View**.

7 Optionally, to delete a requirement link, right-click the link and select **Delete**.

Linear System Modeling Blocks in Simulink Control Design

If you have Simulink Control Design software, you can:

- Specify bounds on linear system characteristics.
- Check that the bounds are satisfied during simulation.

For example, you can check if the linearized behavior of your model satisfied upper and lower magnitude bounds on a Bode plot or gain and phase margins. For more information, see the individual block reference pages in “Model Verification” (Simulink Control Design).
