Revision History

November 1990	First printing	New for Simulink 1
December 1996	Second printing	Revised for Simulink 2
January 1999	Third printing	Revised for Simulink 3 (Release 11)
November 2000	Fourth printing	Revised for Simulink 4 (Release 12)
July 2002	Fifth printing	Revised for Simulink 5 (Release 13)
April 2003	Online only	Revised for Simulink 5.1 (Release 13SP1)
April 2004	Online only	Revised for Simulink 5.1.1 (Release 13SP1+)
June 2004	Sixth printing	Revised for Simulink 5.0 (Release 14)
October 2004	Seventh printing	Revised for Simulink 6.1 (Release 14SP1)
March 2005	Online only	Revised for Simulink 6.2 (Release 14SP2)
September 2005	Eighth printing	Revised for Simulink 6.3 (Release 14SP3)
March 2006	Online only	Revised for Simulink 6.4 (Release 2006a)
March 2006	Ninth printing	Revised for Simulink 6.4 (Release 2006a)
September 2006	Online only	Revised for Simulink 6.5 (Release 2006b)
March 2007	Online only	Revised for Simulink 6.6 (Release 2007a)
September 2007	Online only	Revised for Simulink 7.0 (Release 2007b)
March 2008	Online only	Revised for Simulink 7.1 (Release 2008a)
October 2008	Online only	Revised for Simulink 7.2 (Release 2008b)
March 2009	Online only	Revised for Simulink 7.3 (Release 2009a)
September 2009	Online only	Revised for Simulink 7.4 (Release 2009b)
March 2010	Online only	Revised for Simulink 7.5 (Release 2010a)
September 2010	Online only	Revised for Simulink 7.6 (Release 2010b)
April 2011	Online only	Revised for Simulink 7.7 (Release 2011a)
September 2011	Online only	Revised for Simulink 7.8 (Release 2011b)
March 2012	Online only	Revised for Simulink 7.9 (Release 2012a)
September 2012	Online only	Revised for Simulink 8.0 (Release 2012b)
March 2013	Online only	Revised for Simulink 8.1 (Release 2013a)
September 2013	Online only	Revised for Simulink 8.2 (Release 2013b)
March 2014	Online only	Revised for Simulink 8.3 (Release 2014a)
October 2014	Online only	Revised for Simulink 8.4 (Release 2014b)
March 2015	Online only	Revised for Simulink 8.5 (Release 2015a)
September 2015	Online only	Revised for Simulink 8.6 (Release 2015b)
October 2015	Online only	Rereleased for Simulink 8.5.1 (Release 2015aSP1)
March 2016	Online only	Revised for Simulink 8.7 (Release 2016a)
September 2016	Online only	Revised for Simulink 8.8 (Release 2016b)
March 2017	Online only	Revised for Simulink 8.9 (Release 2017a)
September 2017	Online only	Revised for Simulink 9.0 (Release 2017b)

Introduction to Simulink

Simulink Basics

The following sections explain how to perform basic tasks when using the Simulink product.

Start the Simulink Software

To build models, use the Simulink Editor and the Library Browser.

Start the MATLAB Software

Before you start Simulink, start MATLAB®. See “Startup and Shutdown” (MATLAB).

Configure MATLAB to Start Simulink

The first model that you open in a MATLAB session takes longer to open than subsequent models because, by default, MATLAB starts Simulink when opening the first model. This just-in-time starting of Simulink reduces MATLAB startup time and avoids unnecessary system memory use.

To speed up opening the first model, you can configure MATLAB startup to also start Simulink. To start Simulink without opening models or the Library Browser, use `start_simulink`.

Depending on how you start MATLAB, use the command:

- In the MATLAB `startup.m` file
- At the operating system command line, with the `matlab` command and the `-r` switch

For example, to start Simulink when MATLAB starts on a computer running the Microsoft® Windows® operating system, create a desktop shortcut with this target:

```
matlabroot\bin\win64\matlab.exe -r start_simulink
```

On Macintosh and Linux® computers, use this command to start Simulink when you start MATLAB:

```
matlab -r start_simulink
```

Open the Simulink Editor

To open the Simulink Editor, you can:

- Create a model. On the MATLAB **Home** tab, click **Simulink** and choose a model template.

Alternatively, if you already have the Library Browser open, click the **New Model** button  . For additional ways to create a model, see "Create a Model" on page 1-5.

- Open an existing model. To open recent models, on the MATLAB **Home** tab, click **Simulink**.

  Alternatively, if you know the name of the model you want, at the MATLAB command prompt, enter the name, such as `vdp`. For additional ways to open a model, see "Open a Model" on page 1-9.

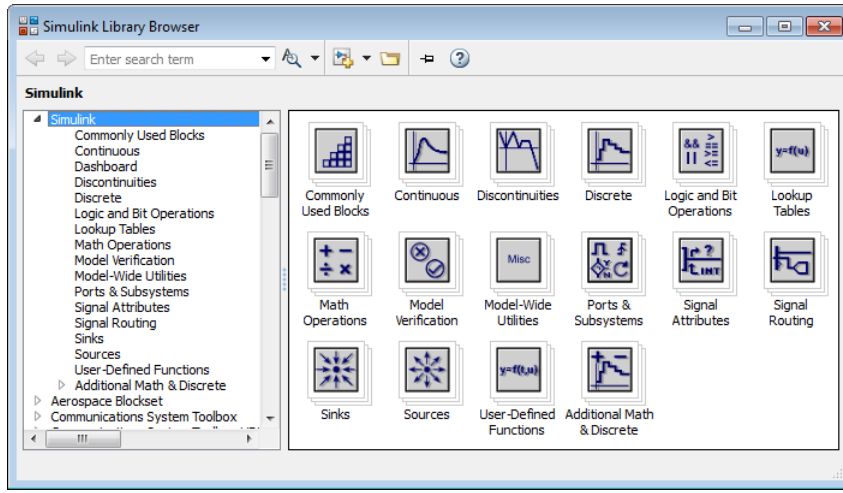
Tip The Simulink Editor opens on top of the MATLAB desktop. To move the MATLAB desktop on top, in the Simulink Editor, select **View > MATLAB Desktop**.

Open the Library Browser

Use any of these techniques to open the Simulink Library Browser from MATLAB:

- On the **Home** tab, click **Simulink**, and choose a model template. In the new model, click the **Library Browser** button  .
- At the command prompt, enter `slLibraryBrowser`.

The Library Browser opens and displays a tree view of the Simulink block libraries on your system. As you click libraries in the tree, the contents of the library appear in the right pane.



Note Simulink comes with block libraries in addition to the Simulink library. These libraries support simulating supplied example models that contain blocks from those libraries. However, you can generate code or modify these blocks only with the relevant product licenses.

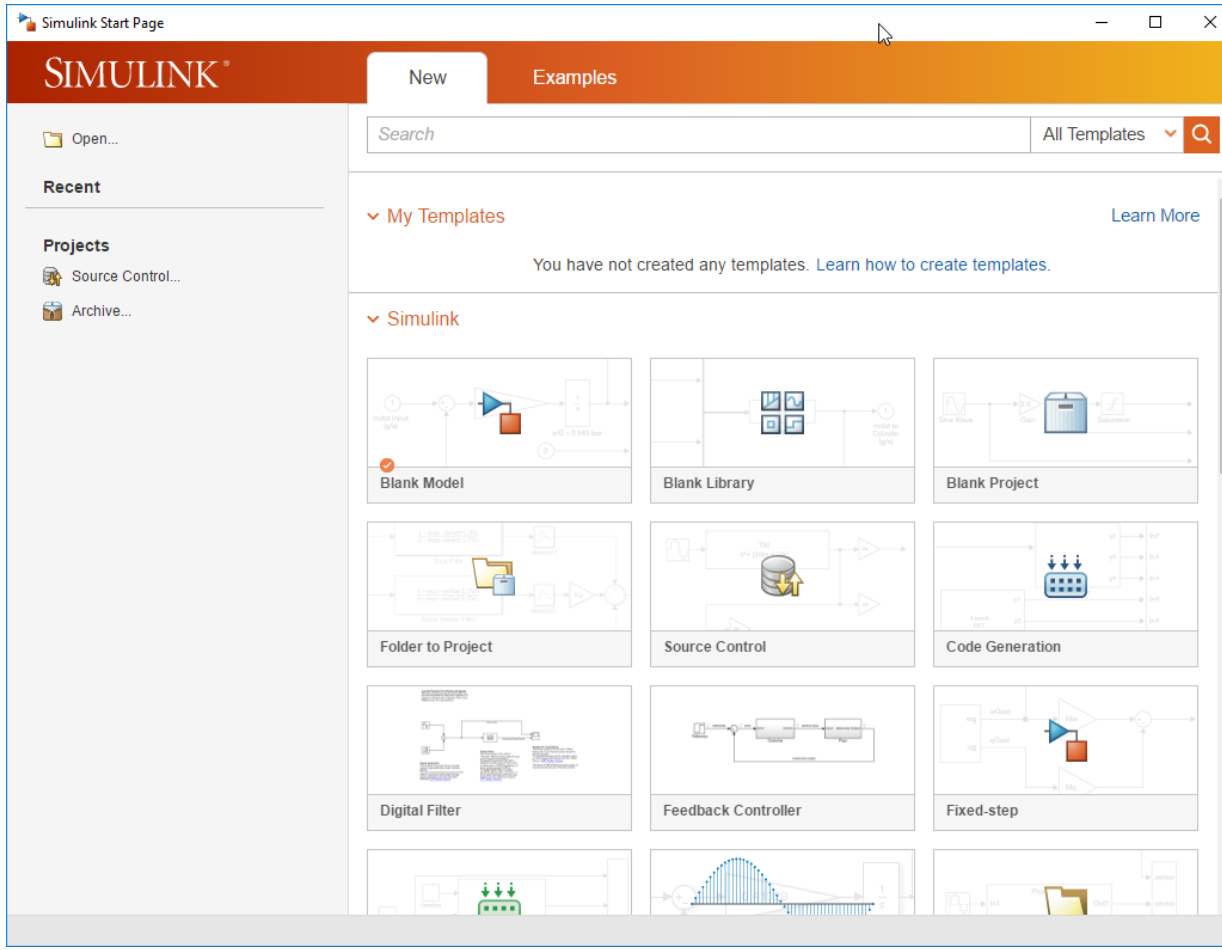
Create and Open Models

In this section...

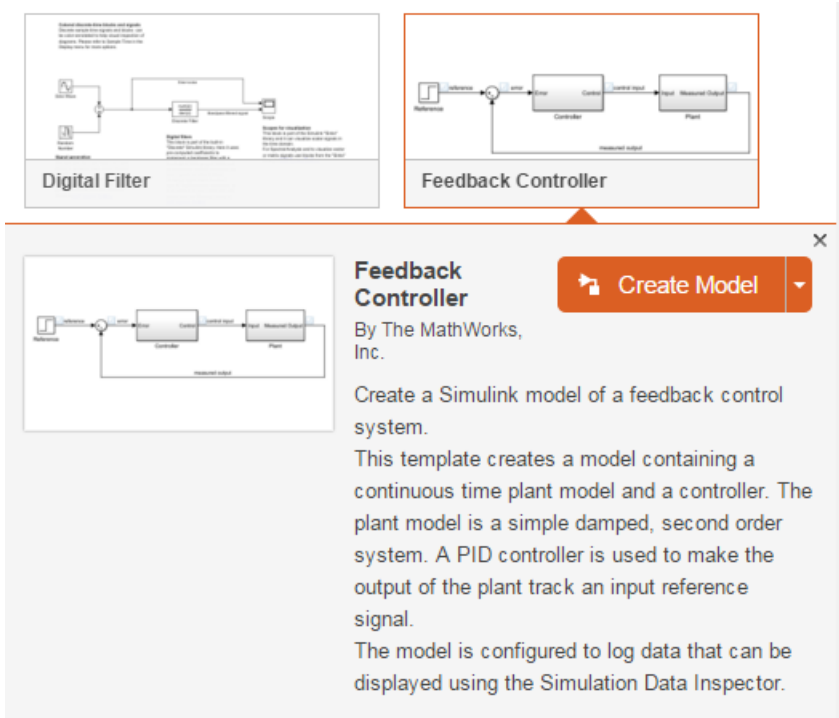
Create a Model

1. On the MATLAB **Home** tab, click **Simulink**.
2. In the Simulink start page, choose a template or search the templates.

   Model templates are starting points to apply common modeling approaches. They help you reuse settings and block configurations and share knowledge. Use model and project templates to apply best practices and take advantage of previous modeling solutions.



Click the title of a template to read the description.



To locate templates that are not on the MATLAB search path, click **Open**. Model templates have the extension `.sltx`.

3 After selecting the template you want, click **Create Model**.

To use a template without reading the description, click the template image. Alternatively, press **Ctrl+N** to use your default template. To set a default template, see "Use Customized Settings When Creating New Models" on page 1-8.

A new model using the template settings and contents opens in the Simulink Editor. For next steps, see "Build and Edit a Model in the Simulink Editor" on page 1-23.

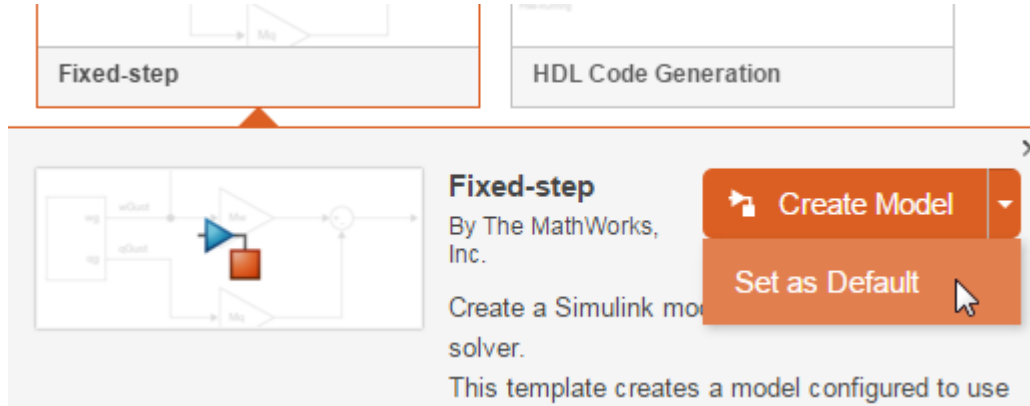
If the built-in templates do not meet your needs, try searching on the **Examples** tab, or you can create your own templates. See "Create a Template from a Model" on page 4-2. On the **Examples** tab, enter search terms to find examples titles and descriptions of interest, or open further examples on the web by clicking **View All** next to a product name.

Use Customized Settings When Creating New Models

You can specify a model template to use for all new models.

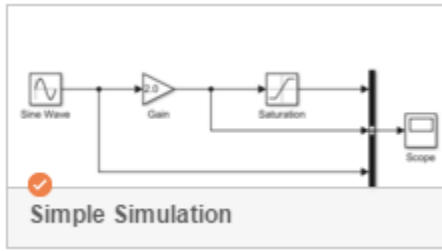
1. Create a model with the configuration settings and blocks you want, then export the model to a template. See “Create a Template from a Model” on page 4-2.
2. To reuse these settings in every new model, make the new template your default model template using the Simulink start page or the `Simulink.defaultModelTemplate` function.

   In the start page, click the title of a template to expand the description, then click the down arrow next to **Create Model** and select **Set As Default**.



After you set a default model template, every new model uses that template, for example, when you press **Ctrl+N**, when you use new model buttons, or when you use `new_system`. In the Simulink Editor, your default template name is at the top of the list when you select **File** > **New** > ***`MyDefaultTemplateName`***.

The default template shows a tick mark in the start page.



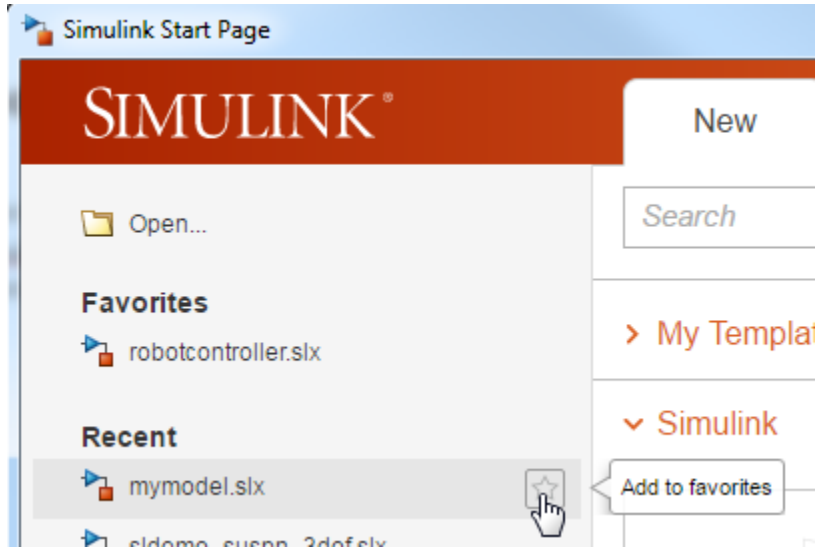
Open a Model

Opening a model loads the model into memory and displays it in the Simulink Editor. Use any of these techniques:

- On the MATLAB **Home** tab, click **Simulink**. In the Simulink Start Page, select a recent model or project from the list, or click **Open**.
- In the Simulink Editor, select **File** > **Open Recent** and choose a recent model.
- At the MATLAB command prompt, enter the name of the model without a file extension, for example, `vdp`. The model must be in the current folder or on the MATLAB search path.
- In the Simulink Library Browser, click the **Open model or library** button .
- Open the model using the Current Folder browser or your operating system file browser.

Tip Set favorites to easily get back to your favorite models and projects in the start page.

In the Simulink start page recent files list, you can add files to favorites. The Favorites list then appears above recent files in the start page, so that you can easily reopen your favorite models and projects.



To edit or clear the list of recent files in the start page, right-click a recent file and use the context menu.

Note To open a model created in a later version of Simulink software in an earlier version, first export the model to the earlier version. See "Export a Model to a Previous Simulink Version" on page 1-43.

Load Variables When Opening a Model

As you build models, you sometimes define variables for a model. For example, suppose that you have a model that contains a Gain block. You can specify the variable `K` as the gain rather than setting the value on the block. When you use this approach, you must define the variable `K` for the model to simulate.

You can use a model callback to load variables when you open a model.

1. In a model that uses the Gain block, set the block **Gain** value to `K`.
2. Define the variable in a MATLAB script. In MATLAB, select **New > Script**. In the script, enter your variable definitions:

   ```
   K=27
   ```

3. Save the script as `loadvar.m`.
4. In the model, open the Property Inspector. Select **View > Property Inspector**. With no selection at the top level of a model, you can use the Property Inspector to set model properties. Otherwise, use **File > Model Properties**.
5. In the **Callbacks** section of the model properties, select `PreLoadFcn` as the callback that you want to define. In the pane, enter `loadvar`.
6. Save the model.

The next time that you open the model, the `PreloadFcn` callback loads the variables into the MATLAB workspace.

To learn about callbacks, see "Callbacks for Customized Model Behavior" on page 4-44. To define a callback for loading variables programmatically, see "Programmatically Load Variables When Opening a Model" on page 1-14.

Open a Model with Different Character Encoding

If you open an MDL file that uses a particular character set encoding in a MATLAB session that uses a different encoding, a warning appears. For example, suppose that you create an MDL file in a MATLAB session configured for `Shift_JIS` and open it in a session configured for `US_ASCII`. The warning message shows the encoding of the current session and the encoding used to create the model.

SLX files do not warn because they can store characters from any encoding.

If you encounter any problems with corrupted characters, for example when using MATLAB files associated with the model, then try using the `slCharacterEncoding` function to change the character encoding of the current MATLAB session to match the model character encoding.

Simulink can check if models contain characters unsupported in the current locale. For more details, see "Check model for foreign characters" and "Save Models with Different Character Encodings" on page 1-41.

Simulink Model File Types

New models that you create have the `.slx` extension by default. Models created before R2012b have the extension `.mdl`. Models you can edit can have the `.slx` or `.mdl` extension, depending on when they were created or whether you converted them. See "Save Models in the SLX File Format" on page 1-39.

`.slxp` and `.mdlp` extensions denote protected models that you cannot open and edit. See "Protected Model" on page 8-95. Model templates have the extension `.sltx`.

Simulink libraries also use the `.slx` extension, but you cannot simulate them. To learn more, see "Create a Custom Library" on page 40-4.

More About

- “Search Path” (MATLAB)

Programmatic Modeling Basics

In this section...

You can perform most Simulink modeling basics programmatically at the MATLAB command prompt. The commands that correspond to basic modeling operations, such as creating models, adding blocks to models, and setting parameters, are listed in the Functions section of “Model Editing Fundamentals”. These examples show some of these commands and how you can use them.

Load a Model

Loading a model brings it into memory but does not open it in the Simulink Editor for editing. After you load a model, you can work with it programmatically. You can use the Simulink Editor to edit the model only if you open the model.

To load a system, use the `load_system` command. For example, to load the `vdp` model, at the MATLAB command prompt, enter:

```
load_system('vdp')
```

Create a Model and Specify Parameter Settings

You can write a function that creates a model and uses the settings that you prefer. For example, this function creates a model that has a green background and uses the ode3 solver:

```
function new_model(modelname)
% NEW_MODEL Create a new, empty Simulink model
```

```
%    NEW_MODEL('MODELNAME') creates a new model with
%    the name 'MODELNAME'. Without the 'MODELNAME'
%    argument, the new model is named 'my_untitled'.

if nargin == 0
     modelname = 'my_untitled';
end

% create and open the model
open_system(new_system(modelname));

% set default screen color
set_param(modelname,'ScreenColor','green');

% set default solver
set_param(modelname,'Solver','ode3');

% save the model
save_system(modelname);
```

Programmatically Load Variables When Opening a Model

If you assign a variable as a block parameter value, you must define the value of the variable in the model. See “Load Variables When Opening a Model” on page 1-10. You can define the variable programmatically using the `PreloadFcn` callback with the `set_param` function. Use the function in this form:

```
set_param('mymodel','PreloadFcn','expression')
```

`expression` is a MATLAB command or a MATLAB script on your MATLAB search path. This command sets the model `PreloadFcn` callback to the value that you specify. Save the model to save the setting.

For example, when you define the variables in a MATLAB script `loadvar.m` for the model `modelname.slx`, use this command:

```
set_param('modelname','PreloadFcn','loadvar')
```

To assign the variable `K` the value `15`, use this command:

```
set_param('modelname','PreloadFcn','K=15')
```

After you save the model, the `PreloadFcn` callback executes when you next open the model.

Programmatically Add and Connect Blocks

This example shows how to use functions to add blocks and connect the blocks programmatically. Once you have added blocks to the model, you use three different approaches to connect them: routed lines, port handles, and port IDs. Routed lines allow you to specify the exact (x,y) coordinates of all connecting line segment endpoints. Port handles and port IDs allow connecting lines to block ports without having to know the port location coordinates.

Create and open a blank model named '`mymodel`'.

Add blocks, including a subsystem block. Use the `position` array in the `set_param` function to set the size and position of the blocks. Set the upper left and lower right block corners using (x,y) coordinates.

```
add_block('simulink/Sources/Sine Wave','mymodel/Sine1');
set_param('mymodel/Sine1','position',[140,80,180,120]);
add_block('simulink/Sources/Pulse Generator','mymodel/Pulse1');
set_param('mymodel/Pulse1','position',[140,200,180,240]);
add_block('simulink/Ports & Subsystems/Subsystem','mymodel/Subsystem1');
set_param('mymodel/Subsystem1','position',[315,120,395,200]);
add_block('simulink/Sinks/Scope','mymodel/Scope1');
set_param('mymodel/Scope1','position',[535,140,575,180]);
```

Inside `Subsystem1`, delete the default connection between `In1` and `Out1`. Also, add a second input port by copying and renaming `In1` from the block library.

```
delete_line('mymodel/Subsystem1','In1/1','Out1/1');
add_block('simulink/Sources/In1','mymodel/Subsystem1/In2');
```

Reposition the internal input and output port blocks inside `Subsystem1`.

```
set_param('mymodel/Subsystem1/In1','position',[50,50,90,70]);
set_param('mymodel/Subsystem1/In2','position',[50,130,90,150]);
set_param('mymodel/Subsystem1/Out1','position',[500,80,540,100]);
```

Insert and position an `Add` block inside `Subsystem1`.

```
add_block('simulink/Math Operations/Add','mymodel/Subsystem1/Add1');
set_param('mymodel/Subsystem1/Add1','position',[250,80,290,120]);
```

Next, add lines to connect all the blocks in the model. Start by connecting the `Sine1` and `Pulse1` blocks using routed lines.

Find the (x,y) coordinates of the `Sine1` output port.

```
Sine1_Port = get_param('mymodel/Sine1','PortConnectivity')

Sine1_Port =

  struct with fields:

       Type: '1'
    Position: [185 100]
    SrcBlock: []
     SrcPort: []
    DstBlock: [1×0 double]
     DstPort: [1×0 double]
```

`get_param` shows that the port Position is [185 100].

Find the (x,y) coordinates of the `Pulse1` output port.

```
Pulse1_Port = get_param('mymodel/Pulse1','PortConnectivity')

Pulse1_Port =

  struct with fields:

       Type: '1'
    Position: [185 220]
    SrcBlock: []
     SrcPort: []
    DstBlock: [1×0 double]
     DstPort: [1×0 double]
```

`get_param` shows that the port position is [185 220].

Connect the output of `Sine1` to the first input of `Subsystem1` using three segments of routed line.

```
add_line('mymodel', [185 100; 275 100]);
add_line('mymodel', [275 100; 275 140]);
add_line('mymodel', [275 140; 310 140]);
```

Connect the output of `Pulse1` to the second input of `Subsystem1` using three segments of routed line.

```
add_line('mymodel', [185 220; 275 220]);
add_line('mymodel', [275 220; 275 180]);
add_line('mymodel', [275 180; 310 180]);
```

Use `get_param` to get the port handles of the blocks being connected. Then use the block port handles to connect the output of `Subsystem1` to the input of `Scope1`.

```
SubsysPortHandles = get_param('mymodel/Subsystem1','PortHandles');
ScopePortHandles = get_param('mymodel/Scope1','PortHandles');
add_line('mymodel',SubsysPortHandles.Outport(1),...
ScopePortHandles.Inport(1));
```

Use port names and IDs to connect the `Add1` block inside `Subsystem1` to the subsystem inputs and outputs. Simulink uses the most direct path to connect the ports.

```
add_line('mymodel/Subsystem1','In1/1','Add1/1');
add_line('mymodel/Subsystem1','In2/1','Add1/2');
add_line('mymodel/Subsystem1','Add1/1','Out1/1');
```

Name a Signal Programmatically

1. Select the block that is the source for the signal line.
2. Use `get_param` to assign the port handle of the currently selected block to the variable *p*. Use `get_param` to assign the name of the signal line from that port to the variable *l*. Then set the name of the signal line to `'s9'`.

```
p = get_param(gcb,'PortHandles')
l = get_param(p.Outport,'Line')
set_param(l,'Name','s9')
```

Open the Same Model in Multiple Windows

When you open a model, the model appears in a Simulink Editor window. For example, if you have one model open and then you open a second model, the second model appears in a second window.

To open the same model in two Simulink Editor windows, at the MATLAB command prompt, enter the `open_system` command and use the `window` argument. For example, if you have the `vdp` model open, to open another instance of the `vdp` model, enter:

```
open_system('vdp','window')
```

Get a Simulink Identifier

Every block in your model has a Simulink Identifier (SID), a unique and unmodifiable identifier. The SID persists for the lifetime of the object and is saved with a model. If the name of the object changes, the SID stays the same. The SID has the form `model_name:number`. For details, see "Locate Diagram Components Using Simulink Identifiers" on page 1-18.

Locate Diagram Components Using Simulink Identifiers

A Simulink Identifier (SID) is a unique designation automatically assigned to a Simulink block, model annotation, or Stateflow® object within a Stateflow chart. The SID helps to identify specific instances of these components in your diagram, especially when sharing models between people within a team.

To highlight a component visually within the model, get the SID and use it with the `Simulink.ID.hilite` function.

The SID has these characteristics:

- Persistent within the lifetime of a Simulink block, model annotation, or Stateflow object
- Saved in the model file
- Remains the same if the block or object name changes
- Cannot be modified

The SID format is:

```
model_name:sid_number
```

- `model_name` is the name of the model where the block, annotation, or Stateflow object resides.
- `sid_number` is a unique number within the model, assigned by Simulink.

Highlight Block

1 To open the model `vdp`, enter `vdp` at the MATLAB command prompt.

2 Get the SID of the `Mu` block.

```
Simulink.ID.getSID('vdp/Mu')
```

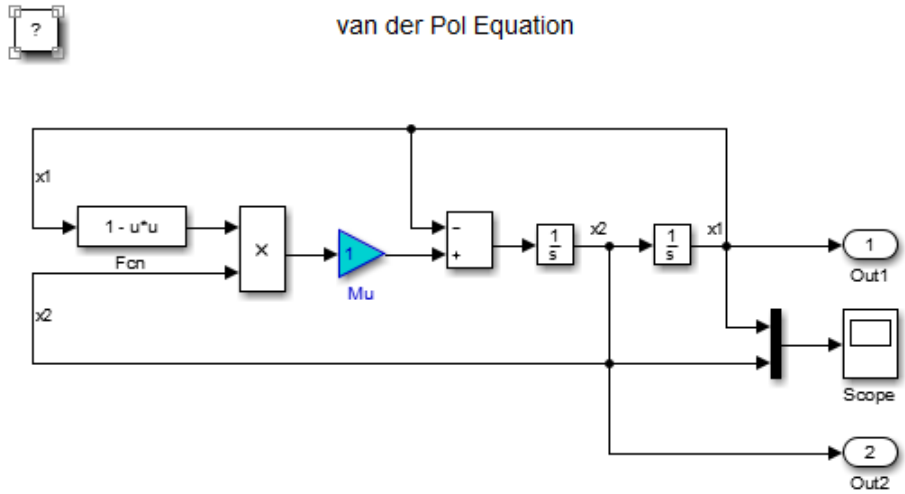
```
ans =

vdp:4
```

3 Use the SID to highlight the block.

```
Simulink.ID.hilite('vdp:4')
```

The block appears highlighted in the model:



Highlight Annotation

1 Open the model `vdp`.

2 Select the annotation at the top of the diagram.

3 Get the annotation object for the selected annotation.

```
ann = getSelectedAnnotations('vdp')
```

```
ann =
```

```
Simulink.Annotation
```

4 Get the SID of the annotation.

```
ann.SIDFullString
```

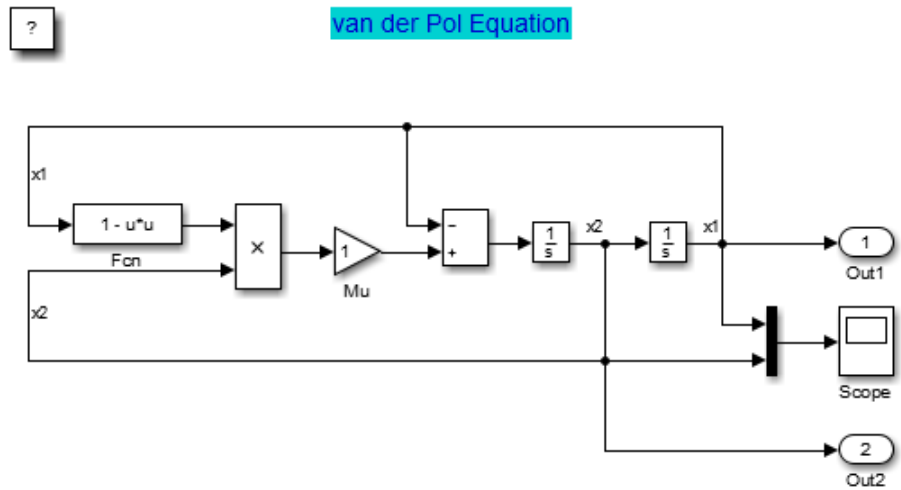
```
ans =

vdp:13
```

5 Use the SID to highlight the annotation.

```
Simulink.ID.hilite('vdp:13')
```

The annotation appears highlighted in the model:



Highlight Stateflow Object

1 Open the model `sf_resolve_signal_object`.

2 Get the SID of the Signal Object Chart Stateflow object:

```
Simulink.ID.getSID('sf_resolve_signal_object/Signal Object Chart')
```

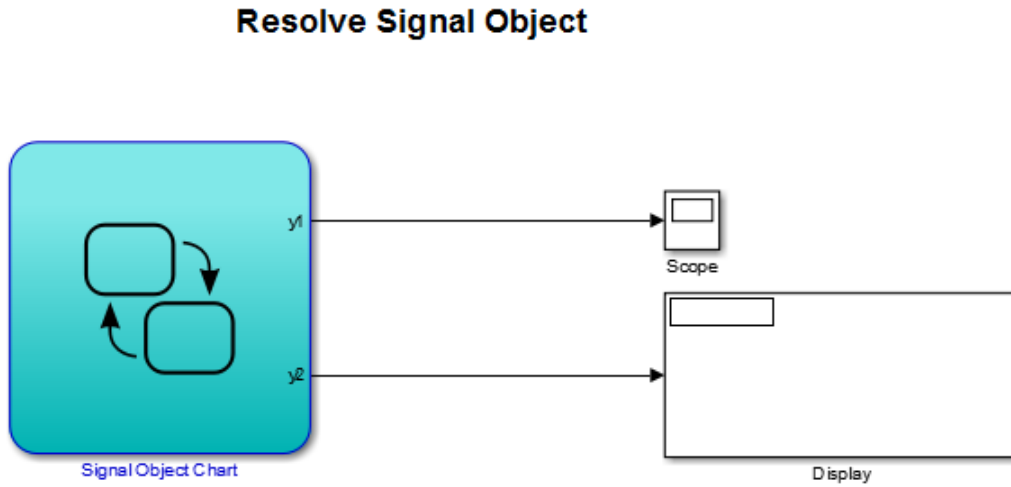
```
ans =
```

```
sf_resolve_signal_object:1
```

3 Use the SID to highlight the object.

```
Simulink.ID.hilite('sf_resolve_signal_object:1')
```

The object appears highlighted in the model.



Specify Colors Programmatically

You can use the `set_param` command at the MATLAB command line or in a MATLAB program to set parameters that determine the background color of a diagram and the background color and foreground color of diagram elements. The following table summarizes the parameters that control block diagram colors.

Parameter	Determines
`ScreenColor`	Block diagram background
`BackgroundColor`	Block and annotation background
`ForegroundColor`	Block and annotation foreground

Set the color parameter to either a named color or an RGB value.

- Named color: `'black'`, `'white'`, `'red'`, `'green'`, `'blue'`, `'cyan'`, `'magenta'`, `'yellow'`, `'gray'`, `'lightBlue'`, `'orange'`, `'darkGreen'`
- RGB value: `'[r,g,b]'`

  where `r`, `g`, and `b` are the red, green, and blue components of the color normalized to the range `0.0` to `1.0`.

For example, the following command sets the background color of the currently selected system or subsystem to a light green color:

```
set_param(gcs,'ScreenColor','[0.3, 0.9, 0.5]')
```

Build and Edit a Model in the Simulink Editor

In this section...

This example shows the basics of how to create a model, add blocks to it, connect blocks, and simulate the model. You also learn how to organize your model with subsystems, name parts of a model, and modify a model.

Start Simulink and Create a Model

1. On the MATLAB **Home** tab, click **Simulink**.
2. In the Simulink Start Page, click the **Blank Model** template.

   A new model based on the template opens in the Simulink Editor.
3. Open the Library Browser so that you can access the blocks you need to create your model. In the Simulink Editor, click the **Library Browser** button  .

Add Blocks to the Model

A minimal model takes an input signal, operates on it, and outputs the result. In the Library Browser, the Sources library contains blocks that represent input signals. The Sinks library has blocks that you can use to capture and display outputs. The other libraries contain blocks you can use for a variety of purposes, such as math operations.

In this basic model, the input is a sine wave, the operation is a gain (which increases the signal value by multiplying), and you output the result to a scope. Try different techniques to explore the library and to add blocks to your model.

The Editor names blocks as you add them. For example, it names the first Gain block that you add Gain, the next Gain1, and so on. By default, these names are hidden. However, you can see the name by selecting the block. You can also explicitly name a block so that the name appears. You can display all names given by the Editor by selecting **Display** and clearing the **Hide Automatic Names** check box. For more information on displaying block names, see "Manage Block Names" on page 35-10.

1. Open the Sources library. In the tree view of the Library Browser, click the **Sources** library.
2. In the right pane, hover over the Sine Wave block to see a tooltip describing its purpose.
3. Add a block to your model using a context menu. Right-click the Sine Wave block and select **Add block to model untitled**. (To learn more about the block, select **Help** from the context menu.)
4. Add a block to your model by dragging. In the library tree view, click **Math Operations**. In the Math Operations library, locate the Gain block and drag it to your model to the right of the Sine Wave block.
5. In the library tree view, click **Simulink** to view the sublibraries as icons in the right pane. This view is an alternative way to navigate the library structure. Double-click the **Sinks** library icon.
6. In the Sinks library, locate the Scope block and add it to your model using the context menu or by dragging it.

   The figure shows your model so far.

Align and Connect Blocks

Connect the blocks to create the relationships between model elements that you need to make the model operate. Reading the model is easier when you line up the blocks

according to how they interact with each other. Shortcuts help you to align and connect the blocks.

1 Drag the Gain block so it lines up with the Sine Wave block. An alignment guide appears when the blocks line up horizontally. Release the block, and a blue arrow appears as a preview of the suggested connection. The block name appears while the block is selected.

2 To make the connection, click the end of the arrow. A solid line appears in place of the guide.

3 Line up and connect the Scope block to the Gain block using the same technique.

Tip Use the **Diagram > Arrange** menu for additional alignment options.

Set Block Parameters

You can set parameters on most blocks. Parameters help you to specify how a block operates in your model. You can use the default values or you can set values as needed. Use the Property Inspector to set parameters. Alternatively, you can double-click most blocks to set the parameters using a block dialog box. To understand when to use each approach, see “Setting Properties and Parameters” on page 1-50.

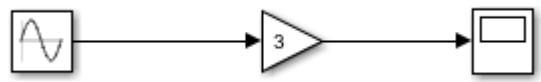
In your model, set the sine wave amplitude and the gain value.

1 Display the Property Inspector. Select **View > Property Inspector**.

2 Select the Sine Wave block.

3 In the Property Inspector, set the **Amplitude** parameter to `2`.

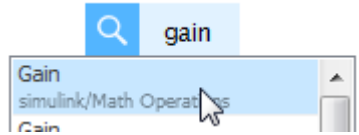
4 Select the Gain block and set the **Gain** parameter to `3`. The value appears on the block.



Add More Blocks

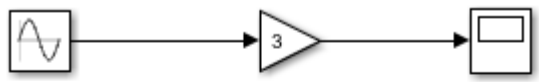
Suppose that you want to perform another gain but on the absolute value of the output from the Sine Wave block. Add blocks for this purpose, trying different techniques for locating blocks in the library and adding them to your model.

1. If you know the name of the block that you want to add, you can use a shortcut. Double-click where you want to add the block, and type the block name, in this case Gain. A list of possible blocks appears.



2. Click the block name or, with the block name highlighted, press **Enter**. You can use the arrow keys to highlight the block name if it is not first in the list.
3. Some blocks display a prompt for you to enter a value for one of the block parameters. The Gain block prompts you to enter the **Gain** value. Type `3` and press **Enter**.
4. To get an absolute value, add an Abs block. Suppose you do not know the library a block is in or the full name of the block. You can search for it using the search box in the Library Browser. Enter `abs` in the search box and press **Enter**. When you find the Abs block, add it to the left of the new Gain block.
5. Add another Scope block. You can right-click the existing Scope block and drag to create the copy or use **Edit > Copy** and **Edit > Paste**.

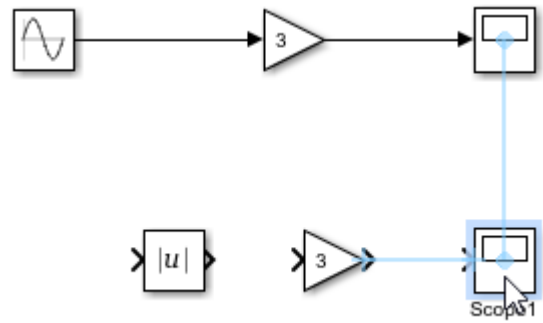
   The figure shows the current state of your model.



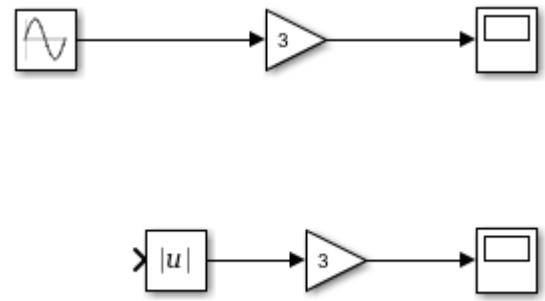
Branch a Connection

The input to the second Gain block is the absolute value of the output from the Sine Wave block. To use a single Sine Wave block as the input to both gain operations, create a branch from the Sine Wave block output signal.

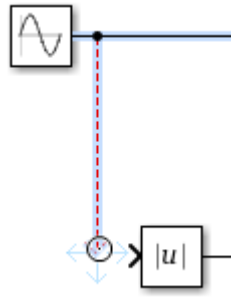
1 For the first set of blocks in your model, you used the horizontal alignment guides to help you align and connect them. You can also use guides to align blocks vertically. Drag the second Scope block so that it lines up under the first one. Release it when the vertical alignment guide shows that the blocks are aligned.



2 Align and connect the Abs and Gain blocks as shown.

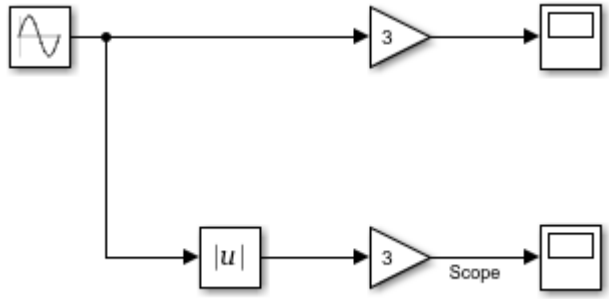


3 Create a branch from the Sine Wave block output to the Abs block. With your cursor over the output signal line from the Sine Wave block, press **Ctrl** and drag down. Drag the branch until the end is to next to the Abs block.



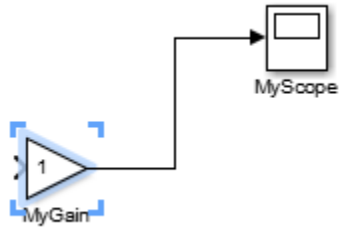
4 Drag toward the Abs block until the line connects to it. Move the vertex as needed to straighten the line. (A circle appears over the vertex.)

5 Name signals. Double-click the signal between the lower Gain block and the Scope block and type `Scope`. Double-click the line and not a blank area of the canvas. For other techniques that you can use with signal names, see "Signal Name and Label Actions" on page 1-93.

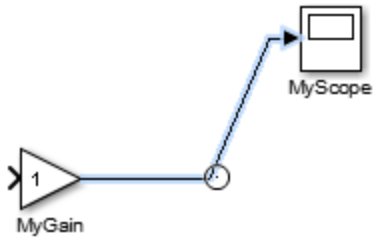


Try these methods to connect blocks:

- Drag a connection from the output of one block to the input of the other block. Use this technique when your blocks are already aligned, that is, no guideline appears.
- Select the first block and **Ctrl**+click the block you want to connect it to. This technique is useful when you want to connect blocks that have multiple inputs and outputs, such as multiple blocks to a bus or two subsystems with multiple ports. This technique is also useful when you do not want the blocks to align. The connection line bends as needed to make the connection, as shown in the figure.



To approximate a diagonal line from line segments, press **Shift** and drag a vertex.

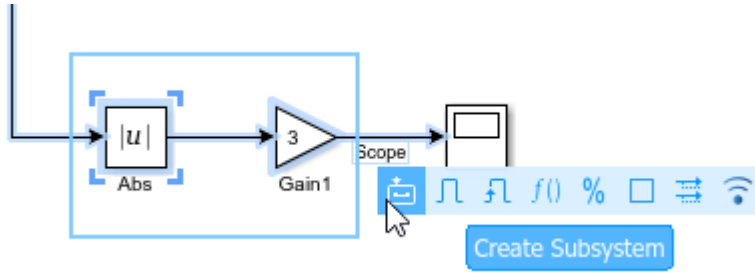


Tip To improve the shape of a signal line, select the line and, from the ellipsis menu, select **Autoroute Line**. The line redraws if a better route between model elements is possible. You can select **Autoroute Lines** from the ellipsis menu to improve lines with a single block selected or with multiple model elements selected by dragging a selection box.

Organize Your Model

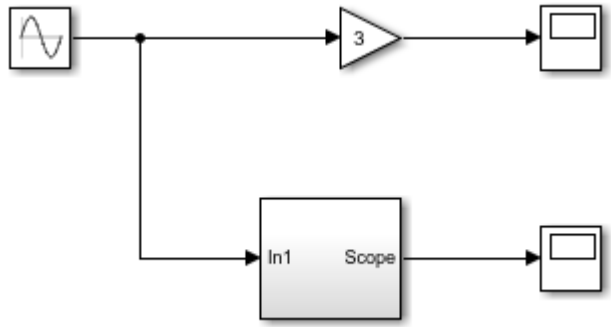
You can group blocks in subsystems and label blocks, subsystems, and signals. For more information about subsystems, see “Create a Subsystem” on page 4-17.

1. Drag a selection box around the Abs block and the Gain block next to it.
2. Move the cursor over the ellipses that appear at the corner of the box where you ended the selection. From the ellipsis menu, select **Create Subsystem**.



A subsystem block appears in the model in place of the selected blocks. The output signal name from the Gain block becomes the name of the output port on the subsystem.

To resize the subsystem block for the best fit in your model, drag the block handles.



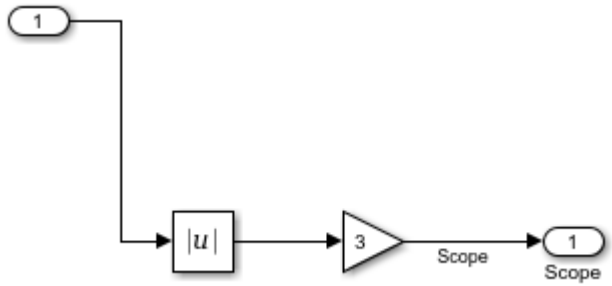
3 Give the subsystem a meaningful name. Select the block, double-click the name, and type `Absolute Value`. Naming a block causes the name to appear in the model.

4 Open the Absolute Value subsystem by double-clicking it.

Tip To use the Explorer Bar to navigate the model hierarchy, right-click the subsystem and select **Open in New Tab**.

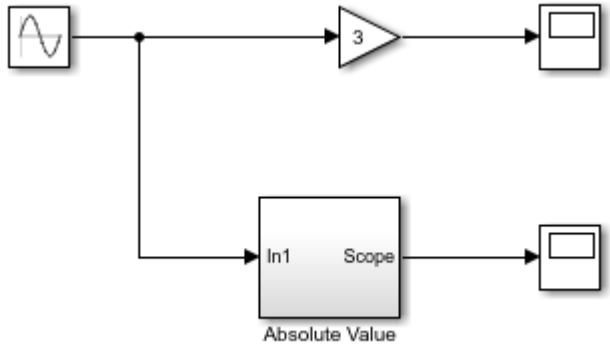
The subsystem contains the blocks and signal that you selected as the basis of the subsystem. They are connected in sequence to two new blocks: an Inport block and an Outport block. Inport and Outport blocks correspond to the input and output

ports on the subsystem. Creating the subsystem from a selection that includes a named signal adds the name of the signal to the corresponding inport or outport.



5 Click the **Up to Parent** button to return to the top level of the model.

6 The figure shows the model after you create the subsystem and name it.



Simulate Model and View Results

1 You can simulate a model using the **Simulation > Run** command (**Ctrl+T**) or the **Run** button . Simulate the model using the technique that you prefer.

In this example, simulation runs for 10 seconds, the default setting.

2 Double-click both Scope blocks to open them and view the results.

The figure shows the two results. In the second plot, as expected, the absolute value of the sine wave is always positive.

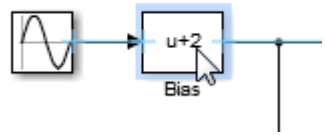
Modify the Model

You can add blocks to a signal, remove blocks from models, and redraw connections. To modify this model, add a bias to the input to both branches of your model. Also, replace one of the scopes with a different sink. Add more blocks to the subsystem and another output.

For some blocks, connecting a line to it adds an input port or output port. For example, a port appears on a subsystem when you connect a line to it. Additional blocks that add ports include the Bus Creator, Scope, and Add, Sum, and Product blocks. For more information, see “Automatic Port Creation: Add inports and outports to blocks when routing signals”.

1. Add a Bias block to the model and set the **Bias** parameter to `2`.
2. Drag the block onto the signal line after the Sine Wave block but before the branch. If you need to make room for the block, drag the Sine Wave block to the left or move the end of the branch by dragging it to the right.

When you drag the block onto the signal line, the block connects to the signal line at both ends. Release the block when you are satisfied with the position.



3 Remove the top Scope block. Press **Shift** and drag the block if you want to disconnect it from the model but do not want to delete it. Cut or delete it using the **Edit** menu commands or a keystroke. The broken connection appears as a red dotted line.

Tip When you delete a block that has one input and one output, a prompt appears between the broken connection lines. Click the prompt to connect the signals.

---

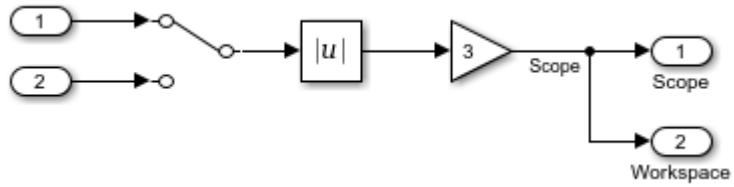
4 Add a To Workspace block to the model at the end of the broken connection. The To Workspace block outputs the results to a variable in the MATLAB workspace.

5 Add a Sine Wave block to the model and set the amplitude to `5`. Place it to the left of the subsystem.

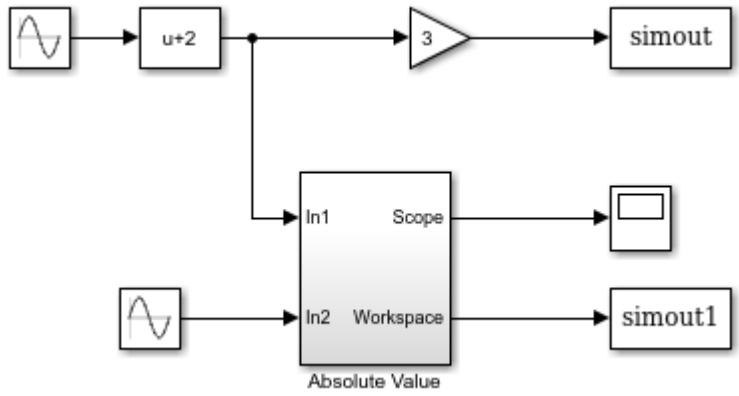
6 Add another input to the subsystem. Drag a line from the new Sine Wave block to the left side of the subsystem. A new port, In2, appears on the subsystem.

7 Add an output to the subsystem. Add another To Workspace block to the model and place it to the right of the subsystem. Drag a line from its input port to the right side of the subsystem. A new port, Out2, appears on the subsystem.

8 Open the subsystem and rename the Out2 block Workspace. Add a Manual Switch block to the subsystem. Resize it and connect it as shown. Branch the signal after the Gain block to direct the output to the To Workspace block.



Then, return to the top level of the model. The figure shows the current model.



9 Simulate the model.

- The `simout` and `simout1` variables appear in the MATLAB workspace. Double-click each variable to explore the results.
- If you want to use the second sine wave as input to the subsystem algorithm, open the subsystem and double-click the switch. The input changes to In2. Simulate again.

Tip To toggle between simulating the model with and without the effects of the Bias block, right-click the Bias block and select **Comment Through**. The block stays in the model but does not affect the operation. Right-click the Bias block and select **Uncomment** to enable the block. The **Comment Out** command comments out the block's output signal, so signal data does not pass through. Try each of these commands to better understand their effects.

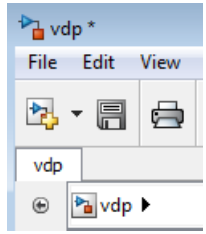
Save a Model

In this section...

How to Tell If a Model Needs Saving

To tell whether a model needs saving, look at the title bar in the Simulink Editor. If the model needs saving, an asterisk appears next to the model name in the title bar (known as the dirty flag: *).



To determine programmatically whether a model needs saving, use the model parameter `Dirty`. For example:

```
if strcmp(get_param(gcs,'Dirty'),'on')
    save_system;
end
```

Save a Model

To save a model for the first time, in the Simulink Editor, select **File > Save**. Provide a location and name for the model file. For name requirements, see “Model Names” on page 1-38.

To save a previously saved model:

- To replace the file contents, in the Simulink Editor, select **File > Save**.
- To save the model with a new name or location, or to change from MDL to SLX format, in the Simulink Editor, select **File > Save As**.

Note For details about the SLX format, see "Upgrade Models to SLX" on page 1-40.

- To save the model in a format compatible with the earlier version, select **File > Export Model to > Previous Version**. See "Export a Model to a Previous Simulink Version" on page 1-43.

Model Names

Model file names must start with a letter and can contain letters, numbers, and underscores. The file name must not be:

- A language keyword (e.g., `if`, `for` , `end`)
- A reserved name: `'simulink'`, `'sl'`, `'sf'`
- A MATLAB software command

The total number of characters in the model name must not be greater than a certain maximum, usually 63 characters. To find out whether the maximum for your system is greater than 63 characters, use the MATLAB `namelengthmax` command.

Note Copying and pasting blocks whose names follow numeric order (Gain1, Gain2, and so on) creates names that follow standard sorting order conventions for ASCII characters. This sorting order can result in a sequence of numbers on the block names that is hard to understand. If the numbering scheme is important to you, name your blocks explicitly such that copying and pasting them creates names that follow a typical reading order. To do so, use a leading zero in the block names, for example Gain001, Gain002, and so on.

To understand how MATLAB determines which function to call when you specify a model name, see "Function Precedence Order" (MATLAB).

What Happens When You Save a Model?

Simulink saves the model (block diagram) and block properties in the model file.

If you have any pre- or post-save functions, they execute in this order:

1. All block `PreSaveFcn` callback routines execute first, then the model `PreSaveFcn` callback routine executes.
2. Simulink writes the model file.
3. All block `PostSaveFcn` callback routines execute, then the model `PostSaveFcn` executes.

During the save process, Simulink maintains a temporary backup copy (named *`modelname`*`.bak`) for restoring in case of an error. If an error occurs during saving or during any callback during the save process, Simulink:

- Restores the original file
- Writes any content saved before the error occurred in a file named *`modelname`*`.err`
- Issues an error message

When saving a model loaded from an SLX file, the original SLX file must still be present. Simulink performs incremental loading and saving of SLX files, so if the original file is missing at save-time, Simulink warns that it cannot reconstruct the file fully.

Save Models in the SLX File Format

Save New Models as SLX

Simulink saves new models and libraries in the SLX format by default, with file extension `.slx`. SLX is a compressed package that conforms to the Open Packaging Conventions (OPC) interoperability standard. SLX stores model information using Unicode® UTF-8 in XML and other international formats. Saving Simulink models in the SLX format:

- Typically reduces file size compared to MDL. The file size reduction between MDL and SLX varies depending on the model.
- Solves some problems in previous releases with loading and saving MDL files containing Korean and Chinese characters.
- Enables incremental loading and saving. Simulink optimizes performance and memory usage by loading only required parts of the model and saving only modified parts of the model.

You can specify your file format for saving new models and libraries with the Simulink preference “File format for new models and libraries”.

Upgrade Models to SLX

If you upgrade an MDL file to SLX file format, the file contains the same information as the MDL file, and you always have a backup file. All functionality and APIs that currently exist for working with models, such as the `get_param` and `set_param` commands, are also available when using the SLX file format. If you upgrade an MDL file to SLX file format without changing the model name or location, then Simulink creates a backup file by renaming the MDL (if writable).

If you save an existing MDL file using **File > Save**, Simulink respects the file's current format and saves your model in MDL format.

To save an existing MDL file in the SLX file format:

1. Select **File > Save As**.
2. Leave the default **Save as type** as SLX, and click **Save**.

   Simulink saves your model in SLX format, and creates a backup file by renaming the MDL (if writable) to `mymodel.mdl.`*`releasename`*, e.g., `mymodel.mdl.R2010b`.

Alternatively, use `save_system`:

```
save_system mymodel mymodel.slx
```

This command creates `mymodel.slx`, and if the existing file `mymodel.mdl` is writable it is renamed `mymodel.mdl.`*`releasename`*.

SLX files take precedence over MDL files, so if both exist with the same name and you do not specify a file extension, you load the SLX file.

Simulink Projects can help you migrate files to SLX. For an example, see “Upgrade Model Files to SLX and Preserve Revision History” on page 17-19.

Caution If you use third-party source control tools, be sure to register the model file extension `.slx` as a binary file format. If you do not, these third-party tools might corrupt SLX files when you submit them.

Operations with Possible Compatibility Considerations when using SLX	What Happens	Action
Hard-coded references to file names with extension `.mdl`.	Scripts cannot find or process models saved with new file extension `.slx`.	Make your code work with both the `.mdl` and `.slx` extension. Use functions like `which` and `what` instead of file names.
Third-party source control tools that assume a text format by default.	Binary format of SLX files can cause third-party tools to corrupt the files when you submit them.	Register `.slx` as a binary file format with third-party source control tools. Also recommended for `.mdl` files. See "Register Model Files with Source Control Tools" on page 19-10.
Changing character encoding.	Some cases are improved, e.g., SLX solves some problems in previous releases with loading and saving MDL files containing Korean and Chinese characters. However, sharing models between different locales remains problematic.	See "SLX Files and Character Encodings" on page 1-42.

The format of content within MDL and SLX files is subject to change. To operate on model data, use documented APIs (such as `get_param`, `find_system`, and `Simulink.MDLInfo`.

Save Models with Different Character Encodings

- "MDL Files and Character Encodings" on page 1-42
- "SLX Files and Character Encodings" on page 1-42

MDL Files and Character Encodings

When you save a model, the current character encoding is used to encode the text stored in the model file. With MDL files, this can lead to model corruption if you save a model whose original encoding differs from current encoding.

If you change character encoding, it is possible to introduce characters that cannot be represented in the current encoding. If this is the case, the model is saved as *`model`*`.mdl.err`, where *`model`* is the model name, leaving the original model file unchanged. Simulink also displays an error message that specifies the line and column number of the first character which cannot be represented.

To recover from this error, either:

- Save the model in SLX format (see "Save Models in the SLX File Format" on page 1-39).
- Locate and remove characters one by one.

  1. Use a text editor to find the character in the `.err` file at the position specified by the save error message.
  2. Find and delete the corresponding character in the open model and resave the model.
  3. Repeat this process until you are able to save the model without error.

It's possible that your model's original encoding can represent all the text changes made in the current session, albeit incorrectly. For example, suppose you open a model whose original encoding is A in a session whose current encoding is B. Further suppose that you edit the model to include a character that has different encodings in A and B and then save the model. If in addition the encoding for x in B is the same as the encoding for y in A, and if you insert x in the model while B is in effect, save the model, and then reopen the model with A in effect the Simulink software will display x as y. To alert you to the possibility of such corruptions, a warning message appears whenever you save a model in which the current and original encoding differ but the original encoding can encode, possibly incorrectly, all of the characters to be saved in the model file.

SLX Files and Character Encodings

Saving Simulink models in the SLX format typically reduces file size and solves some problems in previous releases with loading and saving MDL files containing Korean and Chinese characters.

Considerations for choosing a model file format:

- Use SLX if you are loading and saving models with Korean or Chinese characters
- Use SLX if you would benefit from a compressed model file
- Whether you use SLX or MDL, Simulink can detect and warn if models contain characters unsupported in the current locale. For SLX, you can use the Model Advisor to help you, see “Check model for foreign characters”.

Export a Model to a Previous Simulink Version

You can export (save) a model created with the latest version of the Simulink software in a format used by an earlier version. For example, to share a model with colleagues who only have access to a previous version of the Simulink product.

To export a model in an earlier format:

1. In the Simulink Editor, select **File > Save**. This saves a copy in the latest version of Simulink. This step avoids compatibility problems.
2. Simulink Editor, select **File > Export Model to > Previous Version**.

   The Export to Previous Version dialog box appears.
3. In the dialog box, from the **Save as type** list, select the previous version to which to export the model. The list supports 7 years of previous releases.
4. Click the **Save** button.

When you export a model to a previous version’s format, the model is saved in the earlier format, regardless of whether the model contains blocks and features that were introduced after that version. If the model does contain blocks or use features that postdate the earlier version, the model might not give correct results when you run it in the earlier version of Simulink software. In addition, Simulink converts blocks that postdate an earlier version into yellow empty masked Subsystem blocks. For example, if you use `save_system` to export a model to Release R2007b, and the model contains Polynomial blocks, Simulink converts the Polynomial blocks into yellow empty masked Subsystem blocks. Simulink also removes any unsupported functionality from the model. See `save_system`.

Save from One Earlier Simulink Version to Another

You can open a model created in an earlier version of Simulink and export that model to a different earlier version. To prevent compatibility problems, use the following procedure if you need to save a model from one earlier version to another earlier version.

1. Use the current version of Simulink to open the model created with the earlier version.
2. Before you make any changes, save the model in the current version by selecting **File > Save**.

   After saving the model in the current version, you can change and resave it as needed.
3. Save the model in the earlier version of Simulink by selecting **File > Export Model to > Previous Version**.
4. Start the earlier Simulink version and use it to open the model that you exported to that earlier version.
5. Save the model in the earlier version by selecting **File > Save**.

You can now use the model in the earlier version of Simulink exactly as you could if it had been created in that version.

See also the Simulink preferences that can help you work with models from earlier versions:

- "Do not load models created with a newer version of Simulink"
- "Save backup when overwriting a file created in an older version of Simulink"

Model Editing Environment

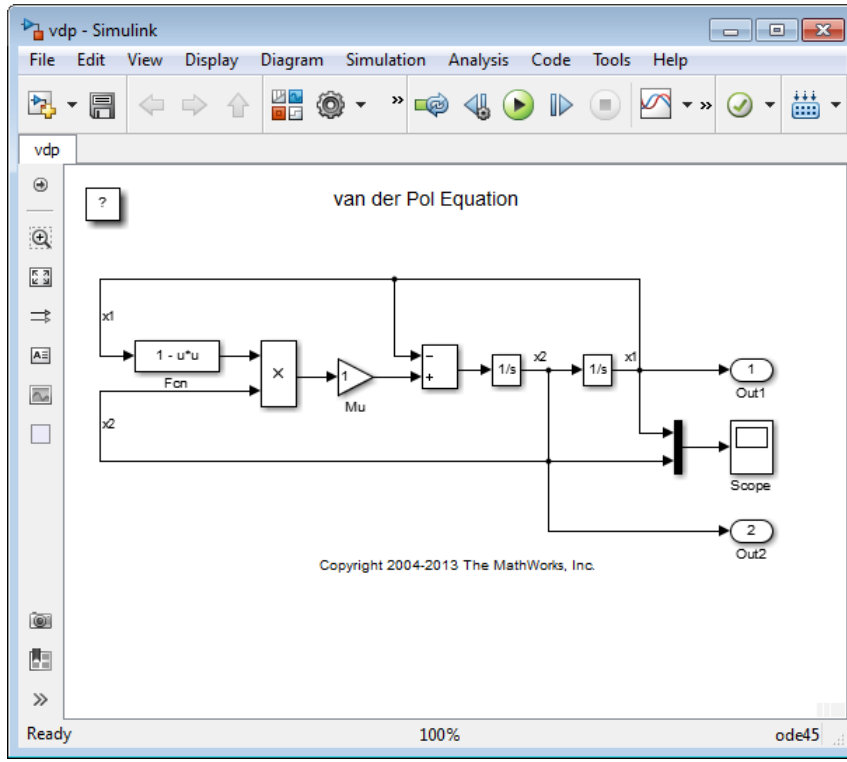
In this section...

The Simulink model editing environment consists of two main tools: the Simulink Editor and the Library Browser. You find the blocks for your model in the Library Browser and build the model by adding and connecting the blocks in the Simulink Editor.

Simulink Editor

The Simulink Editor is an intuitive tool for building models. In addition to providing standard methods for working with diagrams in a vector graphics editor, the editor provides shortcuts that help you to add and connect blocks. The Simulink Editor also gives you access to the tools you need for technical operations such as importing data, simulating your model, and analyzing model performance.

The figure shows the Simulink Editor with the example model `vdp` open.



The Simulink Editor has menus of commands and a toolbar of shortcuts for performing frequent operations or opening tools. Tooltips appear when you hover over the toolbar buttons. Commands also appear on context menus. Context menus appear when you right-click a model element or a blank area of the editor. For example, right-click a block, and the menus display the commands relevant for working on blocks, such as clipboard and alignment operations. Some commands appear only on a context menu.

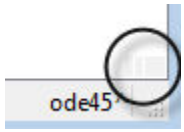
Palette

The palette along the left side of the editor provides more shortcuts. The palette shortcuts have to do with the model appearance and how you navigate the model rather than how you build and operate it. For example, the palette includes a shortcut for adding annotations and other visuals, like boxed-in areas for labeling the model. It also provides a zoom button for zooming on a particular part of the model.

The **Hide/Show Explorer Bar** button displays a bar that shows where you are in the model hierarchy as you navigate. The **Hide/Show Model Browser** button displays a hierarchical view of the model that you can use to navigate. See “Explore the Model Hierarchy Using the Model Browser” on page 12-47.

Additional Model Views

The control in the lower-right corner opens additional views of the model. One such view is the interface view, which helps you to trace model interfaces. Click the control to see these views.



Interactive Model Building

When you build a model in the Simulink Editor, you use common techniques for working with graphics objects. Some of these actions include:

- Selection using click, shift-click, and dragging
- Resizing objects using handles and moving objects by dragging
- Clipboard operations, that is, cut, copy, and paste
- Undo/redo (up to 101 operations)

Note After you undo or redo block parameter changes, a visual cue appears that shows the current values of the affected parameters. Some parameter changes are not affected by the Undo or Redo commands. After you undo or redo changes to block parameters, use the cue to see the parameters affected.

A small subset of parameters do not support Undo. Changing these parameters clears the Undo history, whether you make the change in the Property Inspector or in the block dialog box.

You zoom and scroll the editing area using familiar methods, such as the commands on the **View > Zoom** menu. If you are using a supported touch display platform, you can pinch to zoom and swipe to scroll. The supported touch display devices include Microsoft Windows platforms with a Windows 7 certified or Windows 8 certified touch display and Macintosh platforms with an Apple Magic Trackpad.

The editor supports additional shortcuts for scrolling that are unique to Simulink. Shortcuts and the other interactive model building techniques are summarized in “Keyboard and Mouse Actions for Simulink Modeling” on page 1-91. For a tutorial, see “Build and Edit a Model in the Simulink Editor” on page 1-23.

Model Design Error Detection

The Simulink Editor can provide you with visual cues for some model design issues. In the model editor, highlighted blocks alert you to issues while you edit. To see a description of the issue, hover over a highlighted block and click the error or warning symbol.

Simulink can detect block errors and warnings, such as:

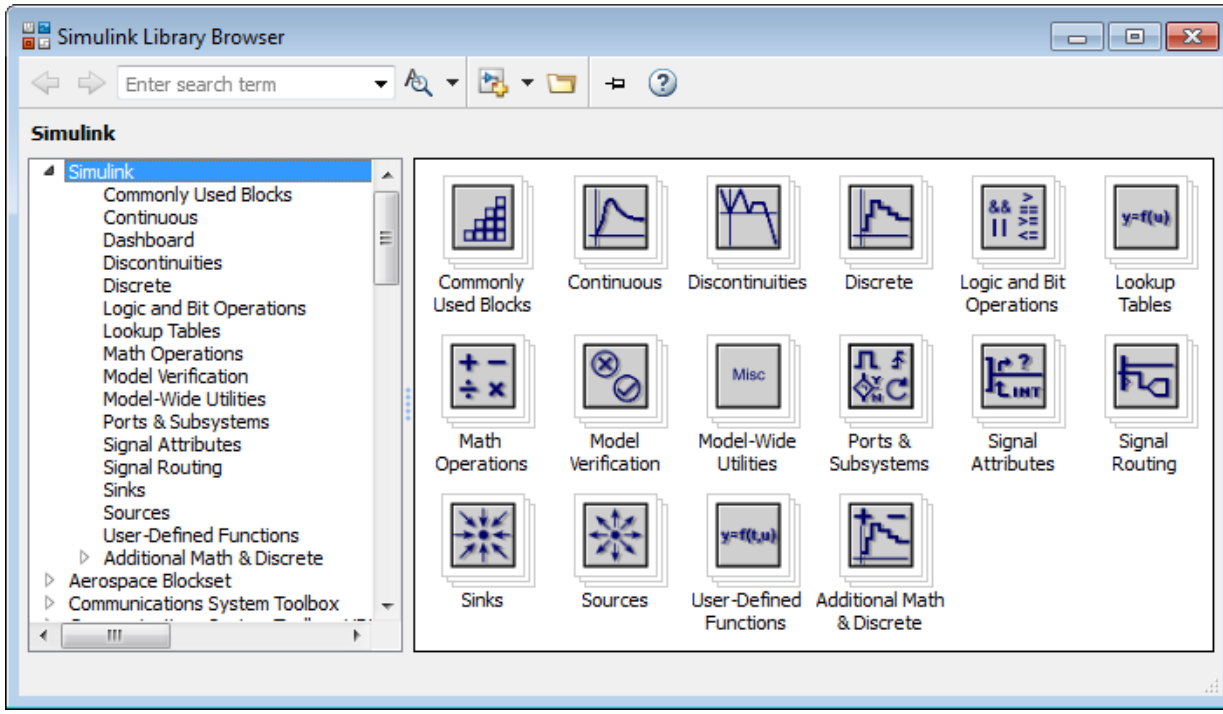
- Goto and From block mismatches.
- Duplicate data store blocks. The value of the Duplicate data store names parameter determines if there is a visual cue, and if the cue is an error or warning.

The **Errors and Warnings** option is enabled by default. To turn off this option, deselect **Display** > **Errors & Warnings**.

Library Browser

Use the Library Browser to locate blocks and visuals (annotations) to add to your model. Navigate the libraries using the tree structure in the left pane or by double-clicking sublibraries in the right pane. Sublibraries, blocks, and text and image annotations can appear in the right pane. Hover over any item to see a description.

When you find the item you are looking for, you can drag it into your model, or you can select it and use the context menu to add it.



Tip The Recently Used Blocks structure at the bottom of the tree contains the blocks and libraries from the supplied libraries that you used most recently.

You can search for blocks and annotations using the search controls. To use regular expressions, whole word search, or case-sensitive search, use the **Search for subsystems, blocks, and annotations** button arrow . For annotations, you can search for any of the text in the annotation or any part of its description.

By default, library contents appear in alphabetical order. Subsystems appear first, then blocks, and then annotations. If you prefer to view the contents of the libraries in the order set by the developer of the library, right-click the right pane and select **Sort in library model order**. This setting stays in effect from session to session.

To return to the alphabetical order, right-click and select **Sort in alphabetical order**. Depending on how the library designer set up the library, some items might not appear

in alphabetical order. For example, in the **Simulink** library, the Additional Math & Discrete library appears as the last item regardless of the sorting option you choose.

You can create your own libraries and, optionally, have them appear in the Library Browser. See “Create a Custom Library” on page 40-4.

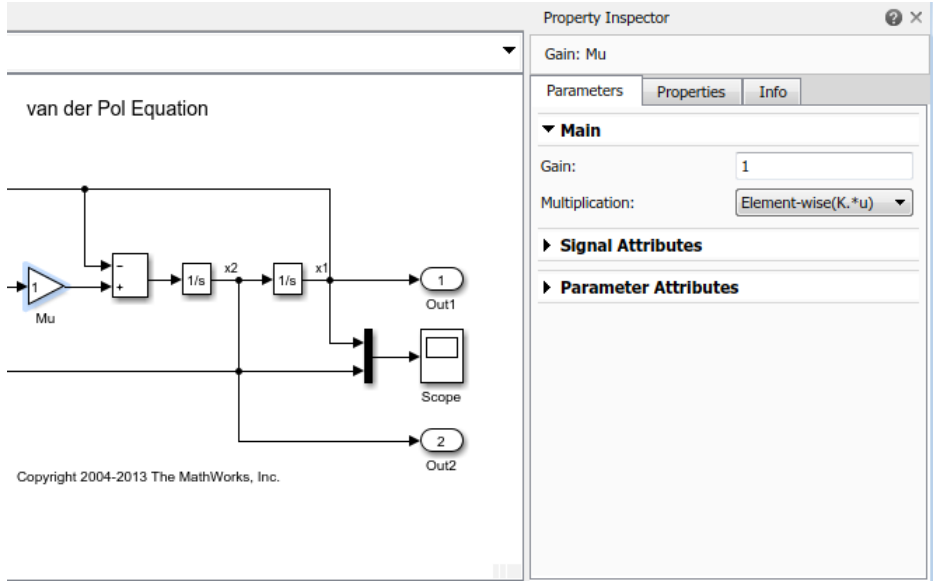
Setting Properties and Parameters

As you build a model, you can set parameters and properties on model elements. For example, you can set parameters and properties for blocks that affect how the block functions. You can also set properties on Stateflow charts, signal lines, visual elements such as annotations, and on the model.

Based on your workflow and goals, set parameters and properties using:

- The Property Inspector, which stays open in the editor as you work and updates based on the current selection
- A dialog box that is associated with an element, such as a specific block
- The Model Data Editor, which stays open and displays information about signals, states, and algorithmic block praameters (for instances, gains and filter coefficients) in a table

When you select **View > Property Inspector**, the interface appears in the Simulink Editor on the right. You can drag it from the default location and dock it in another location in the editor. The figure shows a block selected with the Property Inspector displayed.



The Property Inspector is useful when you are setting parameters and properties as you work, because it is always open and available for setting values for the current selection. Values take effect as soon as you set them. This workflow simplifies your interaction with the interface.

You can alternatively open a dialog box for a selected model element using an item on the **Diagram** menu, such as **Properties** and, for blocks, **Block Parameters**. You can also use the context menu. Double-clicking a block generally opens a block dialog box. (Use one of the menu commands on Subsystem and Model blocks.) For more information on setting block properties and parameters, see “Block Parameters and Properties in Simulink” on page 1-54.

The Property Inspector and the dialog boxes operate on a single selection. The main difference is that the Property Inspector updates with each selection and the dialog box shows the settings only for the element you opened it from. For this reason, the dialog box is useful if:

- You are moving through the model hierarchy and want to see or set an element’s parameters or properties as you navigate the model.
- You want to compare the parameters or properties of similar elements.

- The settings are advanced and appear only in the dialog box.

With the Model Data Editor (**View > Model Data**), you can configure multiple signals, states, and algorithmic parameters at once. You can set only certain parameters and properties such as data types, initial values, and physical units. Open the Property Inspector to work with one model element at a time and perform batch operations with the Model Data Editor.

For more information about setting block properties and parameters, see “Specify Signal Properties” on page 64-4. To learn to use the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 59-141.

Parts of a Model

In this section...

You create a Simulink model by adding blocks, specifying block behavior, and using signal lines to connect the blocks to each other according to the dynamics of the system that you want to simulate.

About Blocks

Blocks are the main elements that you use to build models in Simulink. Generally, you add blocks from the supplied Simulink libraries to perform specific operations, such as math, as shown in “Build and Edit a Model in the Simulink Editor” on page 1-23.

You can further classify blocks in Simulink.

- Virtual blocks — These blocks help to organize a model and do not affect simulation. See “Nonvirtual and Virtual Blocks” on page 35-2.
- Subsystem blocks — Subsystems help you to organize your models hierarchically. You use a Subsystem block to encapsulate related parts of a model, that is, a representation of a system within the larger system that you are modeling. See “Model Hierarchy”.
- Masked blocks — You can add a mask to any block in a model. A mask is a custom interface that enables you to show only the block parameters and settings that you want the user of the block to have access to. A mask also provides an interface for setting parameters on blocks inside a subsystem without having to navigate the hierarchy. You can change the block appearance using a mask. See “Block Masks”.
- Referenced models — A model reference is a way to include a model in another model. You use a Model block to reference a model. See “Model Referencing”.
- Linked blocks — A linked block is an instance of a block from a custom library that links to the library block. You can create a library of blocks that you configure for your specific purposes. For example, you can create subsystems and masked blocks and store them in a library for reuse. When you add a block to a model from a library

that you created, the block keeps a link to the library version, called a library link. You can modify a linked block only by disabling the link. See “Libraries”.

Block Parameters and Properties in Simulink

For most blocks, you can specify parameters that determine how the block works. For example, in the Trigonometric Function block, you specify the trigonometry function that you want the block to perform. For some blocks, you can specify the number of inputs or outputs. Whether the block has parameters that you can set and the nature of those parameters is specific to each block. For detailed information on parameter values, see “Set Block Parameter Values” on page 36-2.

You set block parameters in the Property Inspector or in a block dialog box.

- To open the Property Inspector, select **View > Property Inspector**. Select the block whose parameters you want to view or set. The parameters appear in the **Parameters** tab.
- To open the block dialog box, select **Diagram > Block Parameters** or, for most blocks, double-click the block. You can also use the context menu.
- To open the Model Data Editor, select **View > Model Data**. Inspect the **Parameters** tab.

To understand the differences between these approaches, see “Setting Properties and Parameters” on page 1-50. If you cannot access the block parameters from the Property Inspector or by double-clicking the block, select **Block Parameters** from the block context menu.

Some block parameters do not appear in the Property Inspector or in the Model Data Editor. For example, some advanced parameters do not appear in the Property Inspector while the Model Data Editor shows only algorithmic parameters such as gains and coefficients. When the Property Inspector cannot display the parameters, an **Open** button appears in the Property Inspector. Click **Open** to open the block dialog box, where you can set the parameters.

See the documentation for your product to learn more about setting block parameters in the Property Inspector.

Blocks also have properties that are not specific to the block. Block properties enable you to configure the block to execute code when you perform actions such as opening the block or starting simulation. For example, you can set up a MATLAB script to perform

tasks such as loading or defining variables for a block or any other callback functions. See “Callbacks for Customized Model Behavior” on page 4-44. Block properties also enable you to annotate the block and define callback functions. See “Specify Block Properties” on page 35-4.

You can set block properties on the **Properties** tab of the Property Inspector. Alternatively, you can use the Block Properties dialog box.

Additional Parameters and Properties

Simulink has these additional types of parameters and properties.

- Programmatically accessible parameters — Blocks and models have parameters whose value you do not set explicitly in the editor. For example, each block has a position parameter that is based on where you place the block in the model. There is no single interface to these parameters, but you can query and set any of them programmatically. You can also set any of the block-specific parameters programmatically. See “Common Block Properties” and “Model Parameters”.
- Model configuration parameters — Use configuration parameters (**Simulation > Model Configuration Parameters**) to specify simulation conditions, such as the solver to use, the types of errors and warnings to display, and how you want to store simulation data. See “Configuration Parameters Dialog Box Overview”.
- Model properties — Model properties help you to define callbacks for the model. They also enable you to add a description and specify data to load or scripts to run, along with other settings. You can view and set model properties in the Property Inspector when there is no selection in the top level of a model. Otherwise, use **File > Model Properties**. See “Manage Model Properties” on page 4-63.

Note Simulink preferences (**File > Simulink Preferences**) help you to customize your model editing environment, such as how your scroll wheel functions and saving options. See “Set Simulink Preferences”.

Setting Parameter Values in Workspaces

Simulink gives you access to two workspaces where you can set values for parameters. Workspaces enable you to set parameters by using variables rather than setting every value on every block in a model. This approach is especially useful when your model is large and complex because you do not need to locate every block whose parameter value you want to set or change. Instead, assign a variable as the value of a parameter and

define the variable in a workspace. This mechanism also allows you to use different sets of parameter values for the same model.

In the MATLAB base workspace, you can define parameters using any MATLAB mechanism for defining a variable. For example, you can use a MAT-file and load the variables when you open the model. Using the MATLAB base workspace or a Simulink data dictionary to define variables is useful when you are using the same set of parameters for more than one model.

You can also define parameters by assigning values to variables in a model workspace. You define a set of parameters that are specific to the model and save them with the model.

For more information about using workspace variables to set parameter values, see "Share and Reuse Block Parameter Values by Creating Variables" on page 36-12.

Signals

As you can see in "Build and Edit a Model in the Simulink Editor" on page 1-23, you use signal lines to connect blocks in a model. At a minimum, a model takes an input signal, operates on it, and outputs the result. In the Library Browser, the Sources library contains blocks that represent input signals. The Sinks library contains blocks for capturing and displaying outputs.

Simulink represents signals as lines. The line style varies with the type of signal. You create signals between the output port of one block and the input port of another block by drawing or using shortcuts.

For more on signals, see "Signals" and "Block and Signal Line Shortcuts and Actions" on page 1-92.

Preview Content of Hierarchical Items

In this section...

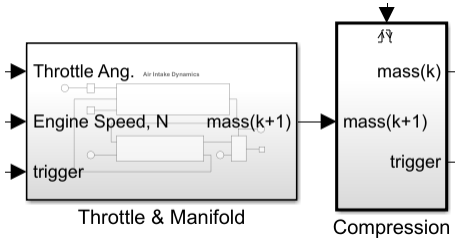
What Is Content Preview?

Content preview displays a representation of the contents of a hierarchical item, such as a subsystem, on the block. Content preview helps you to understand at a glance the kind of processing performed by the hierarchical item.

Hierarchical items that support content preview are:

- Subsystem blocks (but not masked subsystems)
- Model blocks (for referenced models)
- Stateflow charts, subcharts, and graphical functions

By default, the Simulink Editor displays models without content preview. Enable or disable content preview for each block or subsystem. For example, in this model, the Throttle & Manifold subsystem has content preview enabled, and the Compression subsystem does not.



Content preview displays a representation of the contents of a hierarchical item. For details, see “What Content Preview Displays” on page 1-59.

A slight delay can occur in drawing models that contain many hierarchical items that enable content preview if those items contain many blocks.

Enable Content Preview

Content preview settings apply across Simulink sessions.

1. In the Simulink or Stateflow Editor, select the Subsystem or Model blocks or charts whose content you want to preview. To enable content preview for multiple instances of the same referenced model, select each Model block.
2. From the context menu, select **Format > Content Preview**.
3. To see the content preview for a Model block, open the block.

Tip To apply content preview to the whole model, use **Edit > Select All** before enabling content preview.

Enable for Model Blocks

Enabling content preview for Model blocks requires opening the referenced model.

1. In the Simulink Editor, right-click the Model block.
2. Select **Format > Content Preview**.
3. Open the Model block.

What Content Preview Displays

Simulink scales the content preview to fit the size of the block. To improve the readability of the content preview, you can:

- Zoom.
- Resize the block.

In addition to block icons and signals, content preview displays the following, if present in the system:

- Block labels
- Signal labels
- Highlighted blocks for signals with **Highlight Signal to Source** or **Highlight Signal to Destination** enabled
- Sample time color coding

- Stateflow animation

Simulink does not display content preview for:

- Masked blocks
- Hierarchical block icons when they are smaller than their default size in the Library Browser
- Subsystem blocks when they have the **Read/Write permissions** block parameter set to `NoReadOrWrite`.
- Protected Model blocks
- Model blocks whose referenced models are not loaded
- Models that have **Simulink Preferences > Editor Preferences > Use classic diagram theme** enabled.

The content preview image does not show:

- Block icon graphics, including masked block images
- The content of other hierarchical items contained in the content preview
- Signal line styles (for example, for buses)
- Port information such as port values

Use Viewmarks to Save Views of Models

In this section...

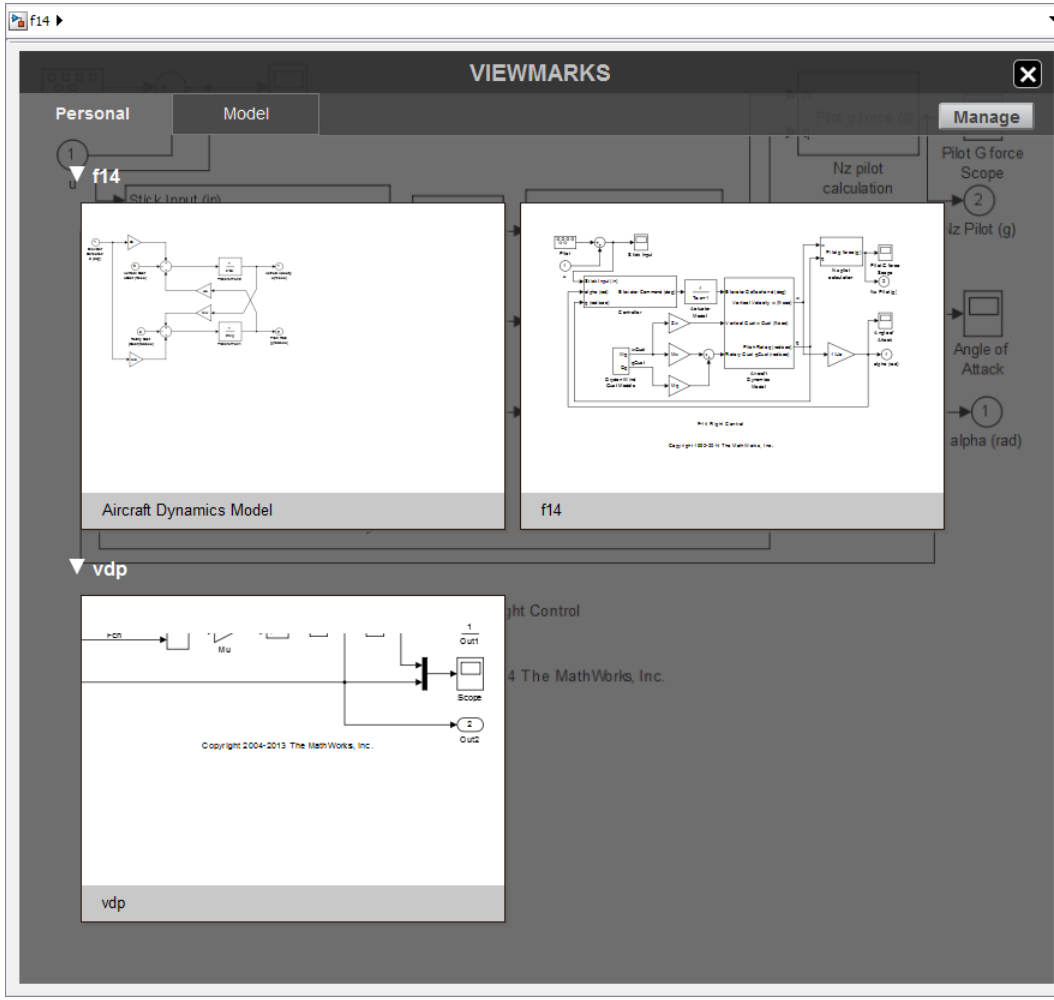
What Are Viewmarks?

Viewmarks are bookmarks to parts of a model. Use viewmarks to capture graphical views of a model so you can navigate directly to that view. You can capture viewmarks for specific levels in a model hierarchy. You can also pan and zoom to capture a point of interest.

Some examples of ways you can use viewmarks include:

- Navigate to specific locations in complex models without opening multiple Simulink Editor tabs or windows.
- Review model designs.
- Visually compare versions of a model.
- Share views of a model by storing viewmarks within the model.

You manage viewmarks in the viewmarks gallery. By default, viewmarks are stored locally on your computer. If you want to include a viewmark to share with a model, see “Save a Viewmark with the Model” on page 1-64. The figure shows the viewmark gallery.



Create a Viewmark

1. Navigate to the part of the model that you want to capture in a viewmark.
2. Pan and zoom to the part of the system that you want to capture.
3. Resize the Simulink Editor window so that it frames the part of the model you want to capture.

4 In the palette, click the **Viewmark This View** button  .

The viewmark displays briefly and becomes part of the viewmarks gallery.

Open and Navigate Viewmarks

The viewmarks gallery has two tabs. The **Personal** tab consists of viewmarks that you created in a model and are stored locally on your computer. The **Model** tab consists of viewmarks that are saved in the Simulink model file.

1 In the Simulink Editor palette, click the **Viewmarks** button  .

2 Select the tab (**Personal** or **Model**) that contains your viewmark, and then click the viewmark.

The Simulink Editor opens the model, if necessary, and displays the part of the model captured in the viewmark.

Manage Viewmarks

In the viewmarks gallery, you can rename viewmarks, add or edit a description for viewmark, and delete viewmarks. You also use the viewmarks gallery to save viewmarks with the model. You can manage viewmarks only in models saved in SLX format. In models saved in MDL format, the **Manage** button appears dimmed.

- To rename a viewmark, click the name and edit it.
- To add a description, click the viewmark Description button  and enter a description.
- To delete a viewmark, click the **Delete** button  on the viewmark. To delete all the viewmarks for a model, hover over the model name and click **Delete**.

You can replace the generated viewmark name.

1 Place the cursor in the viewmark name edit box.

2 Enter the new name.

You can also add a viewmark description. For example, you can add a description of the part of the model in the viewmark or add review comments.

1. Hover over the viewmark.
2. Click the **Description** button  .
3. In the description edit box, enter the description.

Save a Viewmark with the Model

1. In the Simulink Editor palette, click the **Viewmarks** button  .
2. In the viewmarks gallery, click **Manage**.
3. Select the check box in the viewmarks you want to copy to the model.
4. Click the **Add viewmarks to model** button  .

These viewmarks become part of the model and are saved with the model.

Refresh a Viewmark

A viewmark is a static view of a part of a model. For currently loaded models, you can refresh a viewmark so that it reflects the current model. Open the viewmark gallery and click the **Refresh** button  on the viewmark.

If the viewmark shows a subsystem that has been removed, then the viewmark appears dimmed.

Update Diagram and Run Simulation

Updating the Diagram

You can leave many attributes of a block diagram, such as signal data types and sample times, unspecified. The Simulink software then infers the values of block diagram attributes, based on the block connectivity and attributes that you specify. The process that Simulink uses is known as *updating the diagram*.

Simulink attempts to infer the most appropriate values for attributes that you do not specify. If Simulink cannot infer an attribute, it halts the update and displays an error.

Simulation Updates the Diagram

Simulink updates the diagram at the start of a simulation. The updated diagram provides the simulation with the results of the latest changes that you have made to a model.

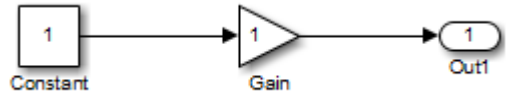
Update Diagram While Editing

As you create a model, at any point you can update the diagram. Updating the diagram periodically can help you to identify and fix potential simulation issues as you develop the model. This approach can make it easier to identify the sources of problems by focusing on a set of recent changes. Also, the update diagram processing takes less time than performing a simulation, so you can identify issues more efficiently.

To update the diagram select **Simulation > Update Diagram**, or press **Ctrl+D**.

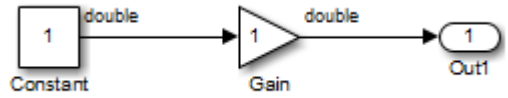
This example shows the effects of updating the diagram.

1 Create the following model.



2 Select **Display > Signals & Ports > Port Data Types**.

The data types of the output ports of the Constant and Gain blocks appear. The data type of both ports is `double`, the default value.



3 In the Constant block dialog box, set **Output data type** to `single`.

The output port data type displays on the block diagram do not show this change.

4 Select **Simulation** > **Update Diagram**.

The updated block diagram shows the changes to the output data types of the Constant and Gain blocks.

When you update a block diagram, by default, a Gain block chooses an output data type based on the data types of the input signal and the **Gain** parameter. In this example, the block chooses the same data type as the input signal.

Simulate a Model

For any type of model you build in Simulink, you need to know how to simulate. Simulating performs the operations specified by the blocks in the model and its specific configuration and produces results. See “Simulation” for complete information, such as how to configure your model for simulation.

Use any of these methods to simulate a model:

- Select **Simulation** > **Run**.
- Press **Ctrl+T**.
- Click the **Run** button  .

Print Model Diagrams

In this section...

Print Interactively or Programmatically

You can print a block diagram:

- Interactively in the Simulink Editor, by selecting **File > Print**
- Programmatically, by using the MATLAB `print` command

To control some additional aspects of printing a block diagram, use the `set_param` command with model parameters. You can use `set_param` with the interactive and programmatic printing interface.

Printing Options

In addition to printing a model using default settings, you can:

- “Select the Systems to Print” on page 1-74.
- “Specify the Page Layout and Print Job” on page 1-77
- “Print Multiple Pages for Large Models” on page 1-79
- “Print Using Print Frames” on page 68-13
- “Print to a PDF” on page 1-86
- “Add a Log of Printed Models” on page 1-80
- “Add a Sample Time Legend” on page 1-81
- “Print Models to Image File Formats” on page 1-90

Canvas Color

By default, the canvas (background) of the printed model is white. To match the color of the model, set the **Simulink Preferences > General > Print** preference.

More About

- “Tiled Printing” on page 1-78
- “Print Frames” on page 68-2

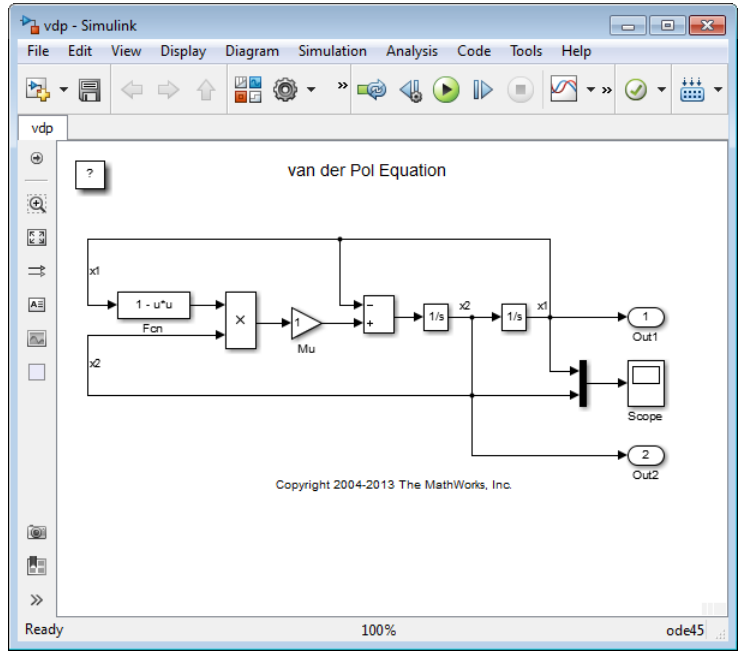
Basic Printing

In this section...

Print the vdp Model Using Default Settings

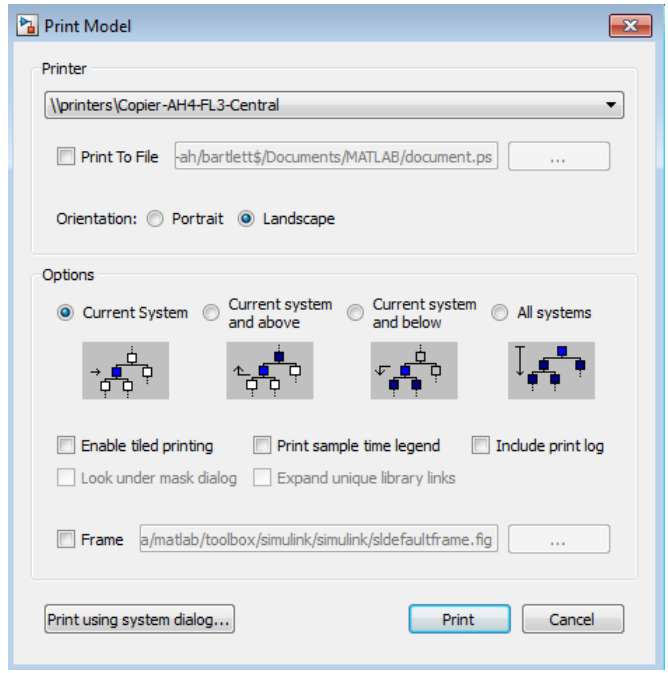
The default print settings produce good quality printed output for quickly capturing a model in printed form.

1 Open the `vdp` model.

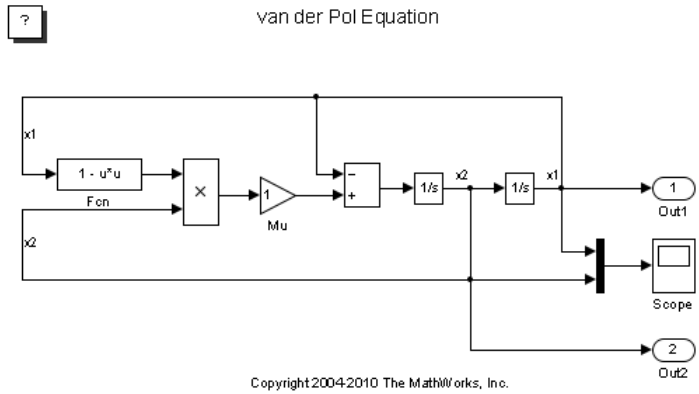


2 In the Simulink Editor, select **File** > **Print** > **Print**.

3 In the Print Model dialog box, use the default settings. Click **Print**.



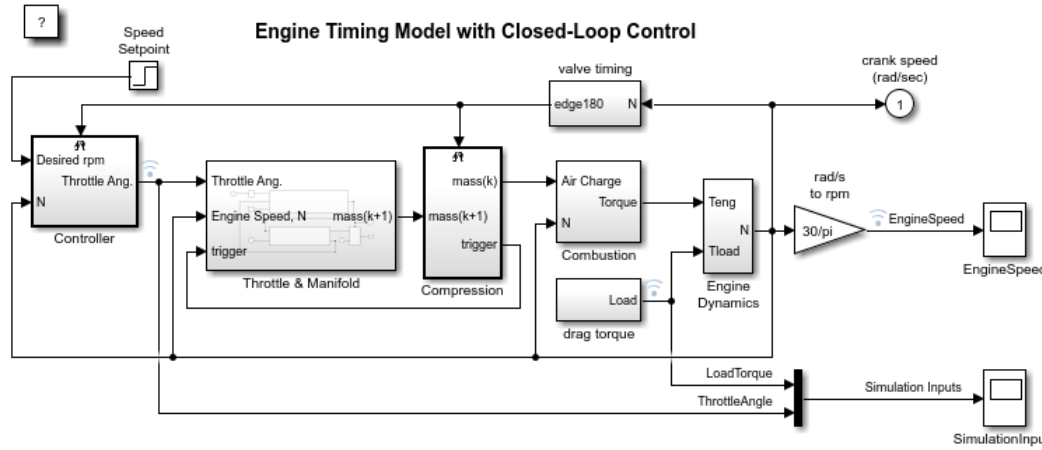
The output looks like this. The model, as it appears in the Simulink Editor, prints on a single page, using portrait orientation and not using a print frame.



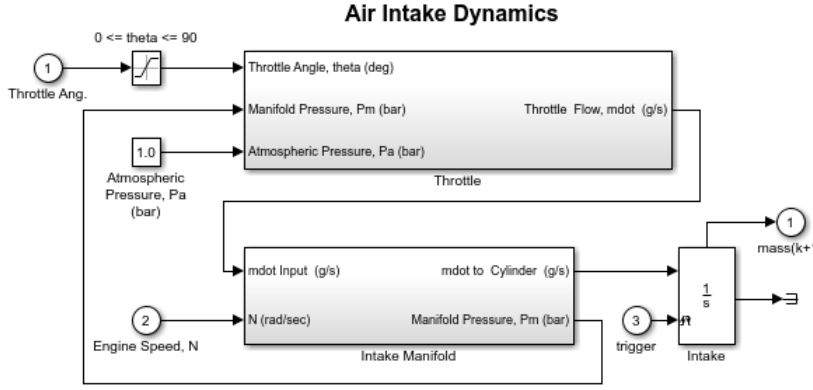
Print a Subsystem Hierarchy

You can print levels in nested subsystems.

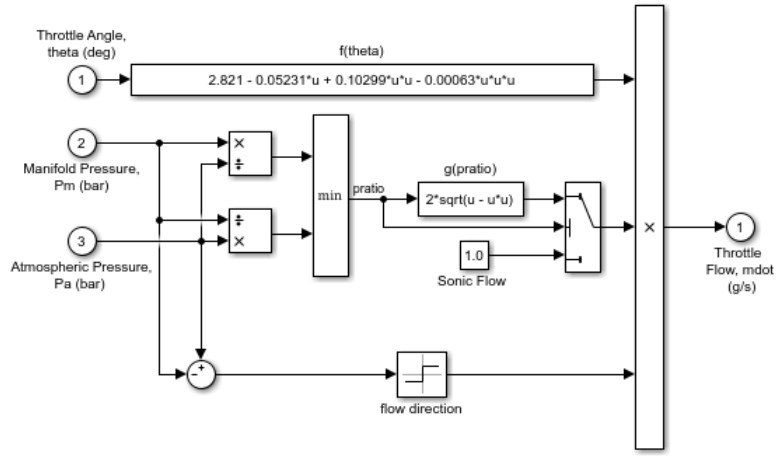
1 Open the `sldemo_enginewc` model.



2 Open the Throttle & Manifold subsystem.



3 Open the Throttle subsystem.



4 In the Simulink Editor, select **File > Print > Print**.

5 In the Print Model dialog box, click **Current system and above** and click **Print**.

The printed output shows the Throttle subsystem (the current system) and the two levels above it in the subsystem hierarchy.

More About

- "Print Model Diagrams" on page 1-68

Select the Systems to Print

In this section...

Print Current System

To select a specific system in a model to print, display that system in the currently open Simulink Editor tab and select **File** > **Print** > **Print**.

Print Subsystems

For models with subsystems, use the Simulink Editor and the Print Model dialog box to specify the systems in the model to print.

By default, Simulink does not print masked subsystems or library links. For information about masked subsystem and library link printing, see “Print Masked Subsystems and Library Links” on page 1-75.

Print All Subsystems in a Model

Use this procedure to print all of the subsystems in a model, including hierarchies of subsystems.

1. Display the top-level model in the currently open Simulink Editor tab.
2. In the Simulink Editor, select **File** > **Print** > **Print**.
3. In the Print Model dialog box, select **All systems**.
4. Click **Print**.

Print the Contents of a Specific Subsystem

In the currently open Simulink Editor tab, display the subsystem that you want to print and click **Print**.

Print a Subsystem Hierarchy

Use this procedure to print nested subsystems.

1. In the current tab of the Simulink Editor, display the subsystem level that you want to use as the starting point for printing the subsystem hierarchy.
2. In the Print Model dialog box, select one of the following:
   - **Current system and below**
   - **Current system and above**
3. Click **Print**.

Simulink prints the hierarchy for all of the subsystems in the current tab.

Print Masked Subsystems and Library Links

To print the contents of masked subsystems, in the Print Model dialog box, click **Look under mask dialog**.

To print the contents of library links, in the Print Model dialog box, click **Expand unique library links**. Simulink prints one copy, regardless of how many copies of the block the model contains.

If a subsystem is both a masked subsystem and a library link, Simulink uses the **Look under mask dialog** setting and ignores the **Expand unique library links** setting.

Print a Model Referencing Hierarchy

To print a model referencing hierarchy, open each level of the hierarchy and print that level.

Clicking **All systems** does not print different levels in the model referencing hierarchy.

You cannot print the contents of protected models.

See Also

More About

- “Model Hierarchy”

Specify the Page Layout and Print Job

In this section...

Page and Print Job Setup

Use the Print Model dialog box to specify the page orientation (portrait or landscape) for the current printing session.

To open the print dialog box for your operating system, in the Print Model dialog box, click **Print using system dialog**. The operating system print dialog box provides additional printing options for models, such as page range, copies, double-sided printing, printing in color (if your print driver supports color printing), and nonstandard paper sizes.

Set Paper Size and Orientation Without Printing

To specify paper size and orientation without printing, use the Page Setup dialog box. To open the dialog box, select **File** > **Print** > **Page Setup**.

Only the paper size and orientation are used.

See Also

Related Examples

- “Basic Printing” on page 1-70

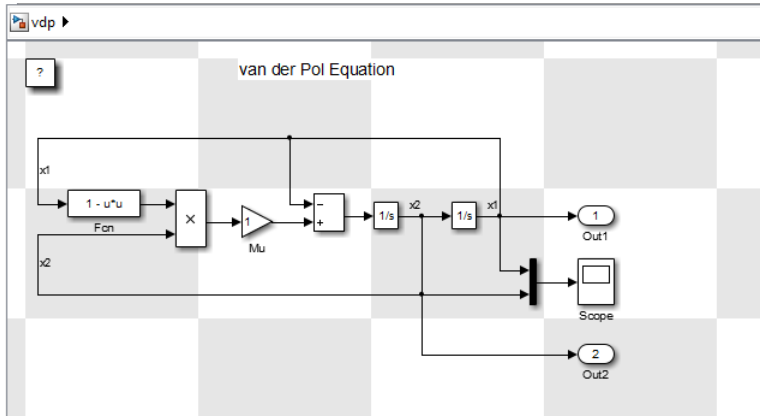
More About

- “Print Model Diagrams” on page 1-68

Tiled Printing

By default, each block diagram is scaled during the printing process so that it fits on a single page. In the case of a large diagram, this automatic scaling can make the printed image difficult to read.

Tiled printing enables you to print even the largest block diagrams without sacrificing clarity and detail. Tiled printing allows you to distribute a block diagram over multiple pages. For example, you can use tiling to divide a model as shown in the figure, with each white box and each gray box representing a separate printed page.



You can control the number of pages over which Simulink prints the block diagram.

Also, you can set different tiled-print settings for each of the systems in your model.

Note If you enable the print frame option, then Simulink does not use tiled printing.

See Also

Related Examples

- “Print Using Print Frames” on page 68-13
- “Print Multiple Pages for Large Models” on page 1-79

Print Multiple Pages for Large Models

1. In the Simulink Editor, open the model in the current tab.
2. Select **File** > **Print** > **Print**.
3. In the Print Model dialog box, click **Enable tile printing**.

   The default Enable tile printing setting in the Print Model dialog box is the same as the **File** > **Print** > **Enable Tiled Printing** setting. If you change the Print Model dialog box **Enable tile printing** setting, the Print Model dialog box setting takes precedence.
4. Confirm that tiling divides the model into separate pages the way you want it to appear in the printed pages. In the Simulink Editor, select **File** > **Print** > **Show Page Boundaries**. The gray and white squares indicate the page boundaries.
5. Optionally, from the MATLAB command line, specify the model scaling, tile margins, or both. See "Set Tiled Page Scaling and Margins" on page 1-84.
6. Optionally, specify a subset of pages to print. In the Print Model dialog box, specify the **Page Range**.
7. Click **Print**.

- "Tiled Printing" on page 1-78

Add a Log of Printed Models

A print log lists the blocks and systems printed. To print the print log when you print a model:

1. In the Simulink Editor, open the model whose print job you want to log.
2. Select **File** > **Print** > **Print**.
3. In the Print Model dialog box, click **Include print log**.
4. Click **Print**.

The print log appears on the last page.

For example, here is the print log for the `sldemo_enginewc` model, with **All systems** enabled and **Enable tiled printing** cleared.

```
   Page       System Name
-----------------------------------------------------------------
--------------
      1       sldemo_enginewc
      2       sldemo_enginewc/Combustion
      3       sldemo_enginewc/Compression
      4       sldemo_enginewc/Controller
      5       sldemo_enginewc/Engine Dynamics
      6       sldemo_enginewc/More Info
      7       sldemo_enginewc/Throttle & Manifold
      8       sldemo_enginewc/Throttle & Manifold/Intake Manifold
      9       sldemo_enginewc/Throttle & Manifold/Throttle
     10       sldemo_enginewc/drag torque
     11       sldemo_enginewc/valve timing
     12       sldemo_enginewc/valve timing/TDC and BDC detection
     13       sldemo_enginewc/valve timing/positive edge to dual
edge conversion
```

- “Print Model Diagrams” on page 1-68

Add a Sample Time Legend

You can print a legend that contains sample time information for your entire system, including any subsystems. The legend appears on a separate page from the model. To print a sample time legend:

1. In the Simulink Editor, select **Simulation** > **Update diagram**.
2. Select **File** > **Print** > **Print**.
3. In the Print Model dialog box, click **Print sample time legend**.
4. Click **Print**.

A sample time legend appears on the last page. For example, here is the sample time legend for the `sldemo_enginewc` model, with **All systems** enabled.

Sample Times for 'sldemo_enginewc'

Color	Description	Value
	Continuous	0
	Fixed in Minor Step	[0,1]
	Constant	Inf
	Triggered	Source: FiM

More About

- “Print Model Diagrams” on page 1-68

Print from the MATLAB Command Line

In this section...

Printing Commands

The MATLAB `print` command provides several options for printing Simulink models. For example, print the `Compression` subsystem in the `sldemo_enginewc` model to your default printer:

```
open_system('sldemo_enginewc');
print -sCompression
```

Tip When you use the `print` command, you can print only one system. To print multiple levels in a model, use multiple `print` commands, one for each system that you want to print. To print multiple systems in a model, consider using the Print Model dialog box in the Simulink Editor. For details, see "Select the Systems to Print" on page 1-74.

You can use `set_param` to specify printing options for models. For details, see "Model Parameters".

You can use `orient` to control the paper orientation.

Print Systems with Multiline Names or Names with Spaces

To print a system whose name appears on multiple lines, assign the newline character to a variable and use that variable in the `print` command. This example shows how to print a subsystem whose name, `Aircraft Dynamics Model`, appears on three lines.

```
open_system('f14');
open_system('f14/Aircraft Dynamics Model');
```

```
sys = sprintf('f14/Aircraft\nDynamics\nModel');
print (['-s' sys])
```

To print a system whose name includes one or more spaces, specify the name as a character vector. For example, to print the Throttle & Manifold subsystem, enter:

```
open_system('sldemo_enginewc');
open_system('sldemo_enginewc/Throttle & Manifold');
print (['-sThrottle & Manifold'])
```

Set Paper Orientation and Type

To set just the paper orientation, use the MATLAB `orient` command.

You can also set the paper orientation by using `set_param` with the `PaperOrientation` model parameter. Set the paper type with the `PaperType` model parameter.

Position and Size a System

To position and size the model diagram on the printed page, use `set_param` command with the `PaperPositionMode` and `PaperPosition` model parameters.

The value of the `PaperPosition` parameter is a vector of form `[left bottom width height]`. The first two elements specify the bottom-left corner of a rectangular area on the page, measured from the bottom-left corner. The last two elements specify the width and height of the rectangle.

If you set the `PaperPositionMode` parameter to `manual`, Simulink positions (and scales, if necessary) the model to fit inside the specified print rectangle. If `PaperPositionMode` is `auto`, Simulink centers the model on the printed page, scaling the model, if necessary, to fit the page.

For example, to print the `vdp` model in the lower-left corner of a U.S. letter-size page in landscape orientation:

```
open_system('vdp');
set_param('vdp', 'PaperType', 'usletter');
set_param('vdp', 'PaperOrientation', 'landscape');
set_param('vdp', 'PaperPositionMode', 'manual');
set_param('vdp', 'PaperPosition', [0.5 0.5 4 4]);
print -svdp
```

Use Tiled Printing

Enable Tiled Printing

1. Use `set_param` to set the `PaperPositionMode` parameter to `tiled`.
2. Use the `print` command with the `-tileall` argument.

For example, to enable tiled printing for the `Compression` subsystem in the `sldemo_enginewc` model:

```
open_system('sldemo_enginewc');
set_param('sldemo_enginewc/Compression', 'PaperPositionMode', ...
'tiled');
print('-ssldemo_enginewc/Compression', '-tileall')
```

Display Tiled Page Boundaries

To display the page boundaries programmatically, use the `set_param` command, with the model parameter `ShowPageBoundaries` set to `on`. For example:

```
open_system('sldemo_enginewc');
set_param('sldemo_enginewc', 'ShowPageBoundaries', 'on')
```

Set Tiled Page Scaling and Margins

To scale the block diagram so that more or less of it appears on a single tiled page, use `set_param` with the `TiledPageScale` parameter. By default, the value is 1. Values greater than 1 proportionally scale the model to use a smaller percentage of the tiled page, while values between 0 and 1 proportionally scale the model to use a larger percentage of the tiled page. For example, a `TiledPageScale` of `0.5` makes the printed diagram appear twice its size on a tiled page, while a `TiledPageScale` value of `2` makes the printed diagram appear half its size on a tiled page.

By decreasing the margin sizes, you can increase the printable area of the tiled pages. To specify the margin sizes associated with tiled pages, use `set_param` with the `TiledPaperMargins` parameter. Each margin to 0.5 inches by default. The value of `TiledPaperMargins` is a vector that specifies margins in this order: `[left top right bottom]`. Each element specifies the size of the margin at a particular edge of the page. The value of the `PaperUnits` parameter determines the units of measurement for the margins.

Specify Range of Tiled Pages to Print

To specify a range of tiled page numbers programmatically, use `print` with the `-tileall` argument and the `-pages` argument. Append to `-pages` a two-element vector that specifies the range.

Note Simulink uses a row-major scheme to number tiled pages. For example, the first page of the first row is 1, the second page of the first row is 2, and so on.

For example, to print the second, third, and fourth pages:

```
open_system('vdp');
print('-svdp','-tileall','-pages[2 4]')
```

Print to a PDF

You can print a model to a `.pdf` file. Simulink creates one file for all of the systems in the model.

1. In the Simulink Editor, select **File** > **Print** > **Print**.
2. Select the **Print to File** check box.
3. Specify a location and file name to save the new `.pdf` file. Include the extension `.pdf` in the file name.
4. Click **Print**.

Print Model Reports

A model report is an HTML document that describes the structure and content of a model. The report includes block diagrams of the model and its subsystems and the settings of its block parameters.

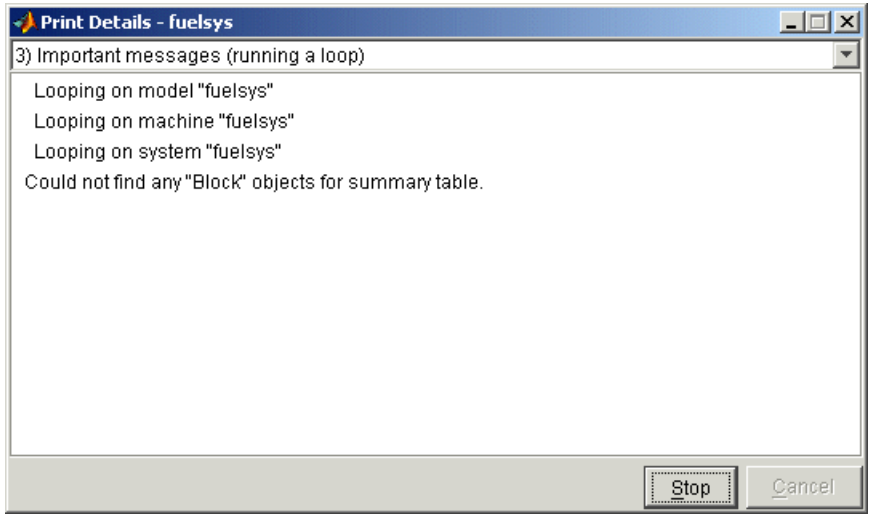
Tip If you have the Simulink Report Generator™ installed, you can generate a detailed report about a system. To do so, in the Simulink Editor, select **File > Reports > System Design Description**. For more information, see "System Design Description" (Simulink Report Generator).

To generate a model report for the current model:

1. In the Simulink Editor, select **File > Print > Print Details**.
2. In the Print Details dialog box, select report options. For details, see "Model Report Options" on page 1-88.
3. Select **Print**.

The Simulink software generates the HTML report and displays the report in your default HTML browser.

While generating the report, Simulink displays status messages on a messages pane that replaces the options pane on the Print Details dialog box.



Select the detail level of the messages from the list at the top of the messages pane. When the report generation process begins, the **Print** button changes to a **Stop** button. To stop the report generation, click **Stop**. When the report generation process finishes, the **Stop** button changes to an **Options** button. Clicking this button redisplays the report generation options, allowing you to generate another report without having to reopen the Print Details dialog box.

Model Report Options

Use the Print Details dialog box allows you to specify the following report options.

Directory

The folder where the HTML report is stored. The options include your system's temporary folder (the default), your system's current folder, or another folder whose path you specify in the adjacent edit field.

Increment filename to prevent overwriting old files

Creates a unique report file name each time you generate a report for the same model in the current session. This preserves each report.

Current object

Include only the currently selected object in the report.

Current and above

Include the current object and all levels of the model above the current object in the report.

Current and below

Include the current object and all levels below the current object in the report.

Entire model

Include the entire model in the report.

Look under mask dialog

Include the contents of masked subsystems in the report.

Expand unique library links

Include the contents of library blocks that are subsystems. The report includes a library subsystem only once even if it occurs in more than one place in the model.

Print Models to Image File Formats

To print the current view of your model to an image file format such as `.png` or `.jpeg`, use the `-device` argument with the MATLAB `print` command. For example, to print the `vdp` model to a `.png` format, use this command:

```
print -dpng -svdp vdp_model.png
```

By default, the canvas (background) of the exported model matches the color of the model. To use a white or transparent canvas for model files that you export to another file format, set the **Simulink Preferences** > **Export** preference.

Copy Model Views to Third-Party Applications

On Microsoft Windows platforms, you can copy the current view of your model in either bitmap or metafile format. You can then paste the clipboard image to a third-party application such as word processing software.

On Macintosh platforms, when you copy a model view to the clipboard, Simulink saves the model in a scalable format, in addition to a bitmap format. When you paste from the clipboard to an application, the application selects the format that best meets its requirements.

By default, the canvas (background) of the copied model matches the color of the model. To use a white or transparent canvas for model files that you copy to another application, set the **Simulink Preferences** > **Clipboard** preference.

1. To copy a Simulink model to the operating system clipboard, in the Simulink Editor select **Edit** > **Copy Current View to Clipboard**.
2. Paste the model from the clipboard to a third-party application.

Keyboard and Mouse Actions for Simulink Modeling

In this section...

Note On Macintosh platforms, use the **command** key instead of **Ctrl**.

Object Selection and Clipboard Operations

Objects include blocks, signal lines, signal labels, and annotations.

Task	Action
Select an object	Click
Select additional objects	**Shift**+click
Select all objects	**Ctrl+A**
Copy object	Drag with right mouse button **Ctrl**+drag
Move any object, including signal labels	Drag
Delete selected object	**Delete** or **Backspace** **Edit** > **Clear**
Cut	**Ctrl+X**
Paste	**Ctrl+V**

Task	Action
Duplicate object	**Ctrl+C**, **Ctrl+V**
Undo	**Ctrl+Z**
Redo	**Ctrl+Y**

Block and Signal Line Shortcuts and Actions

Task	Action
Set the main parameter for selected block	**Alt+Enter**
Open or hide the Property Inspector	**Ctrl+Shift+I**
Copy block or model from another Simulink Editor window	Drag between windows
Move block	Arrow keys
Resize block, keeping same ratio of width and height	**Shift**+drag handle
Resize block from the center	**Ctrl**+drag handle
Rotate block clockwise	**Ctrl+R**
Rotate block counterclockwise	**Ctrl+Shift+R**
Flip block	**Ctrl+I**
Connect blocks	Select first block, **Ctrl**+click second block Drag from port to port
Draw branch line	**Ctrl**+drag line Right-mouse button+drag
Route lines around blocks	**Shift**+drag while drawing
Disconnect block	**Shift**+drag block
Create subsystem from selected blocks	**Ctrl+G**
Open selected subsystem	**Enter**

Task	Action
Go to parent of selected subsystem	**Esc**
Find block	**Ctrl+F**
Mask subsystem	**Ctrl+M**
Look under block mask	**Ctrl+U**
Comment through a block	**Ctrl+Shift+Y**
Comment out/uncomment a block	**Ctrl+Shift+X**
Refresh Model blocks	**Ctrl+K**
For a linked block, go to the library of the parent block	**Ctrl+L**
Open Model Explorer	**Ctrl+H**

Signal Name and Label Actions

The signal name appears in a label on the signal line.

Task	Action
Name a signal line	Double-click signal and type name
Name a branch of a named signal line	Double-click the branch
Name every branch of a signal	Right-click the signal, select **Properties**, and use the dialog box
Delete signal label and name	Delete characters in label or delete name in Signal Properties dialog box.
Delete signal label only	Right-click label and select **Delete Label**.
Open signal label text box for edit	Double-click signal line Click label
Move signal label	Drag label to a new location on same signal line
Copy signal label	**Ctrl**+drag signal label
Change the label font	Select the signal line (not the label) and use **Diagram** > **Format** > **Font Style**

Simulation Keyboard Shortcuts

Task	Action
Open Configuration Parameters dialog box	**Ctrl+E**
Update diagram	**Ctrl+D**
Start simulation	**Ctrl+T**
Stop simulation	**Ctrl+Shift+T**
Build model (for code generation)	**Ctrl+B**

Debugging and Breakpoints Keyboard Shortcuts

Task	Action
Step	**F10**
Step in	**F11**
Step out	**Shift** + **F11**
Run	**F5**
Set/Clear breakpoint	**F12**

Zooming and Scrolling Shortcuts

Task	Action
Zoom in	**Ctrl++**
Zoom out	**Ctrl+-**
Zoom to normal (100%)	**Ctrl+0** or **Alt+1**
Zoom with mouse	**Ctrl**+scroll wheel Select the **File > Simulink Preferences > Editor Preferences > Scroll wheel controls zooming** preference to zoom using just the scroll wheel.
Zoom in on object	Drag the **Zoom** button  from the palette to the object
Fit diagram to screen	**Spacebar**

Task	Action
Scroll view	Arrow keys **Shift**+arrow for larger pans
Scroll with mouse	**Spacebar**+drag Hold the scroll wheel down and drag the mouse

Library Browser Shortcuts

Task	Shortcut
Open a model	**Ctrl+O**
Open Library Browser from a model	**Ctrl+Shift+L**
Move selection down in the Blocks or Libraries pane	**Down arrow**
Move selection up in the Blocks or Libraries pane	**Up arrow**
Expand a node in the Libraries pane	**Right arrow**
Collapse a node in the Libraries pane	**Left arrow**
Refresh Libraries pane	**F5**
Show parent library in Blocks pane	**Esc**
Select a block found with the search tool in the Blocks pane	**Ctrl+R**
Insert the selected block in a new model	**Ctrl+I**
Increase zoom in the Blocks pane	**Ctrl++**
Decrease zoom in the Blocks pane	**Ctrl+-**
Reset zoom to default in the Blocks pane	**Alt+1**
Find a block	**Ctrl+F**

Task	Shortcut
Close	**Ctrl+W**

File Operations

Task	Action
Open model	**Ctrl+O**
Create a model	**Ctrl+N**
Print	**Ctrl+P**
Save	**Ctrl+S**
Close model	**Ctrl+W**

Simulation Stepping

How Simulation Stepper Helps With Model Analysis

Simulation Stepper enables you to step through major time steps of a simulation. Using discrete time steps, you can step forward or back to a particular instant in simulation time. At each time step, Stepper displays all of the simulation data the model produces.

Use Simulation Stepper to analyze your model in these ways:

- Step forward and back through a simulation.
- Pause a simulation in progress and step back.
- Continue running a simulation after stepping back.
- Analyze plotted data in your model at a particular moment in simulation time.
- Set conditions before and during simulation to pause a simulation.

How Stepping Through a Simulation Works

In this section...

These topics explain how Simulation Stepper steps through a simulation.

Simulation Snapshots

When you set up Simulation Stepper, you specify:

- The number of time steps where Stepper creates ‘snapshots’
- The number of steps to skip between snapshots
- The total number of snapshots stored

A simulation snapshot contains simulation state (SimState) and information related to logged data and visualization blocks. Simulation Stepper stores simulation states in snapshots at the specified interval of time steps when it steps forward through a simulation.

It is important to understand the difference between a Simulation Stepper step and a simulation time step. A simulation time step is the fixed amount of time by which the simulation advances. A Simulation Stepper step is where Simulation Stepper creates a snapshot. Each step (that Simulation Stepper takes) consists of one or more simulation time steps (that you specify).

When you step back through a simulation, the software uses simulation snapshots, stored as SimStates, to display previous states of the simulation. The model does not simulate in reverse when stepping back. Therefore, to enable the step back capability, you must first simulate the model or step it forward to save snapshots.

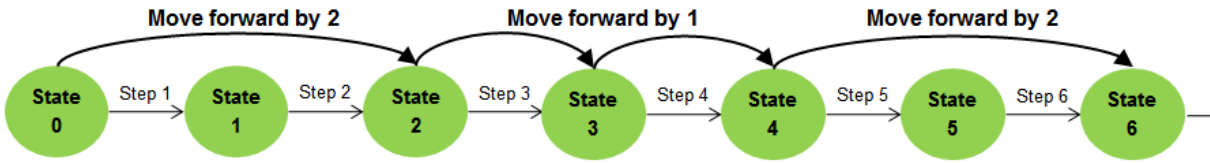
Keep in mind that snapshots for stepping back are available only during a single simulation. The Simulation Stepper does not save the steps from one simulation to the next.

How Simulation Stepper Uses Snapshots

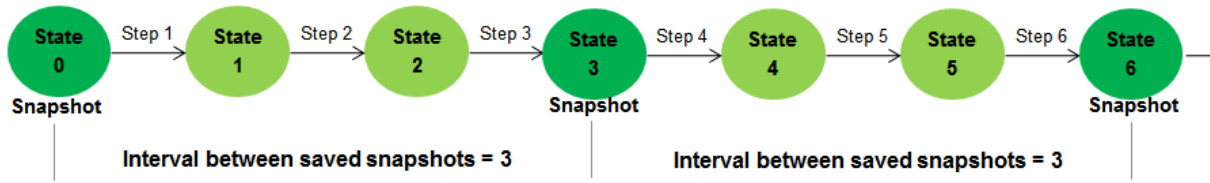
A simulation snapshot captures all the information required to continue a simulation from that point. When you set up simulation stepping, you specify:

- The maximum number of snapshots to capture while simulating forward. The greater the number, the more memory the simulation uses and the longer the simulation takes to run.
- The number of time steps to skip between snapshots. This setting enables you to save snapshots of simulation state when stepping forward at periodic intervals, such as every three steps. This interval is independent of the number of forward or backward time steps taken. Because taking simulation snapshots affects simulation speed, saving snapshots less frequently can improve simulation speed.

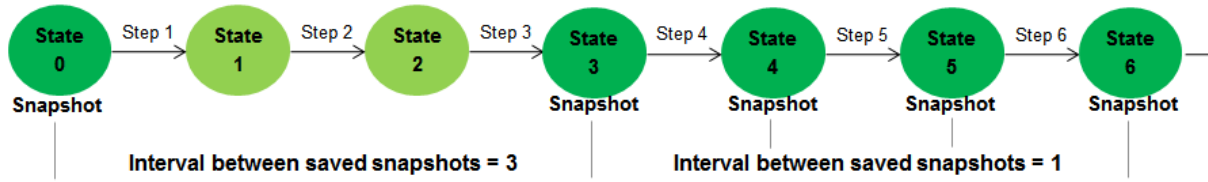
The figure shows how you can step through a simulation depending on how you set the parameters in the Simulation Stepping Options dialog box. Because you can change the stepping parameters as you step through the simulation, you can step through a simulation as shown in this figure: sometimes by single steps and sometimes by two or more steps.



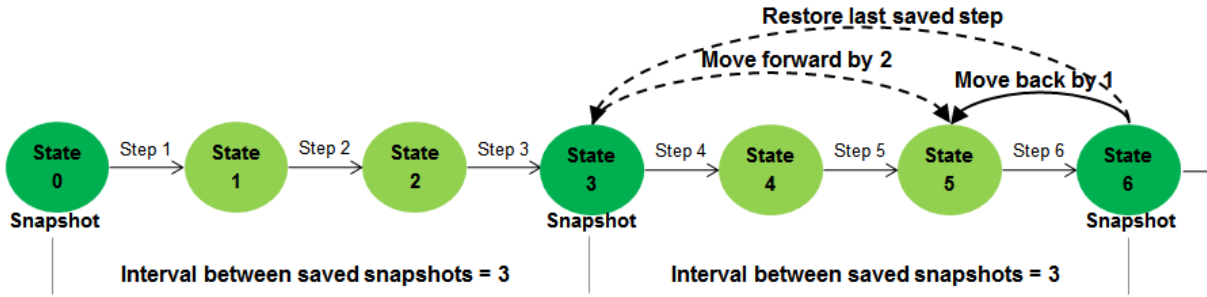
In the figure, the interval for snapshot captures is three.



This next figure shows the advantage of changing the stepping options while stepping forward. At the fourth step, the interval between stored steps changed the snapshot steps from three to one. This enables you to capture more snapshots around a simulation time of interest.



The next figure shows how the snapshot settings of Simulation Stepper can change what happens when stepping back. Suppose that the interval between snapshots is set to three, and starting at state six, the stepper **Move back/forward by** setting is set to one. The stepper first restores the simulation state to the last saved snapshot (state three), and then simulates two major times steps to arrive at the desired state (state five).



Thus, when you step back to a particular time step in a simulation, Simulation Stepper restores the last saved snapshot before that time step. Then, it steps forward to the time step you specify. This capability is helpful for memory usage and simulation performance.

How Simulation Stepper Differs from Simulink Debugger

Simulation Stepper and Simulink Debugger both enable you to start, stop, and step through a model simulation. Both tools allow you to use breakpoints as part of a debugging session. However, you use Simulation Stepper and Simulink Debugger for different purposes. The table shows the actions you can perform with each tool.

Action	Simulation Stepper	Simulink Debugger
Look at state of system after executing a major time step.	✓	✓

Action	Simulation Stepper	Simulink Debugger
Observe dynamics of the entire model from step to step.	✓	
Step simulation back.	✓	
Pause across major steps.	✓	
Control a Stateflow debugging session.	✓	
Step through simulation by major steps.	✓	
Monitor single block dynamics (for example, output and update) during a single major time step.		✓
Look at state of system while executing a major time step.		✓
Observe solver dynamics during a single major step.		✓
Show various stages of Simulink simulation.		✓
Pause within a major step.		✓
Step through a simulation block by block.		✓
Access via a command-line interface.		✓

Understanding the simulation process can help you to better understand the differences between Simulation Stepper and Simulink Debugger.

Use Simulation Stepper

In this section...

Simulation Stepper Access

You run Simulation Stepper and access the settings from the Simulink Editor toolbar .

Click the Stepping Options button to open the Simulation Stepping Options dialog box.

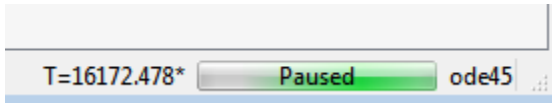
Use the dialog box to enable stepping back through a simulation. When stepping back is enabled, after you start the simulation, the Stepping Options button changes to , and then you can use it to step back. In that case, you can access the dialog box again only by using **Simulation > Stepping Options**.

If you clear the **Enable previous stepping** check box, the software clears the stored snapshot cache.

Simulation Stepper Pause Status

The status bar at the bottom of the Simulink Editor displays the simulation time of the last completed simulation step. While a simulation is running, the editor updates the time display to indicate the simulation progress. This display is approximate because the status bar updates only at every major time step and not at every simulation time step.

When you pause a simulation, the status bar display time catches up to the actual time of the last completed step.



The value (the time of the last completed step) that is displayed on the status bar is not always the same as the time of the solver. This happens because different solvers use different ways to propagate the simulation time in a single iteration of the simulation loop. Simulation Stepper pauses at a single position within the simulation loop. Some solvers perform their time advance before Simulation Stepper pauses. However, other solvers perform their time advance after Simulation Stepper pauses, and the time advance then becomes part of the next step. As a result, for continuous and discrete solvers, the solver time is always one major step ahead of the time of the last model output.

When this condition occurs, and the simulation is paused, the status bar time displays an asterisk. The asterisk indicates that the solver in this simulation has already advanced past the displayed time (which is the time of the last completed simulation step).

Tune Parameters

While using Simulation Stepper, when the simulation is paused, you can change tunable parameters, including some solver settings. However, changes to the solver step size take effect when the solver advances the simulation time. For some solvers, this occurs after the next simulation step is taken.

Simulation Stepper takes into account the size of a movement (**Move back/forward by**) and the frequency of saving steps (**Interval between stored back steps**). If you specify a frequency that is larger than the step size, Simulation Stepper first steps back to the last saved step and then simulates forward until the total step count difference reaches the size of the desired movement. Simulation Stepper applies values for tunable parameters when simulating forward. For this reason, if you change any tunable parameter before stepping back, the resulting simulation output might not match the previous simulation output at that step before the parameter change. This can cause unexpected results when stepping forward from the snapshot to the chosen time step.

For example, assume a snapshot save frequency of three and a step size of one. The stepper first steps back to the last saved step, up to three steps, and then simulates forward until the total step count difference reaches one. If you change tunable

parameters before stepping back, the resulting simulation output might not match the previous simulation output at that step.

Referenced Models

When using Simulation Stepper and the Model block, the referenced model shares the stepping options of the top model throughout a simulation. As a result, changing Simulation Stepper settings for the referenced model during simulation changes the Simulation Stepper settings of the top model. When the simulation ends, the settings of the referenced model revert to the original values; the Stepper settings of the top model stay at the changed settings.

- When the model is not simulating, the top model and referenced model retain their own independent stepping options.
- When the model is simulating and you change a referenced model stepping option, the top model stepping option changes to the same value.
- When the model is simulating and you change a top model stepping option, the referenced model stepping option changes to the same value.
- When the model stops simulating, the referenced model stepping options revert to how they were set before simulation started; the top model keeps the values set during simulation.

Simulation Stepper and Interval Logging

When you change the logging interval of a simulation before rolling back, Simulink does not log data for time steps that were outside the original logging interval until the first forward step after a rollback operation. For more information, see “Logging intervals”.

Simulation Stepper and Stateflow Debugger

When you debug a Stateflow chart (for example, when the simulation stops at a Stateflow breakpoint), Simulation Stepper adds buttons to control the Stateflow debugging session. When the Stateflow debugging session ends, the Simulation Stepper interface returns to the default. For more information about controlling the Stateflow debugger using the Simulink Editor toolbar, see “Control Chart Execution from the Stateflow Editor” (Stateflow).

- “Simulation Stepper Limitations” on page 2-12

Simulation Stepper Limitations

In this section...

Interface

- There is no command-line interface for Simulation Stepper.

Model Configuration

- Simulation stepping (forward and backward) is available only for Normal and Accelerator modes.
- The step back capability relies on SimState technology for saving and restoring the state of a simulation. As a result, the step back capability is available only for models that support SimState. For more information, see “Save and Restore Simulation State as SimState” on page 24-37.
- Simulation Stepper steps through the major time steps of a simulation without changing the course of a simulation. Choosing a refine factor greater than unity produces loggable outputs at times between the major time steps of the solver. These times are not major time steps, and you cannot step to a model state at those times.
- If you run a simulation with stepping back enabled, the Simulink software checks whether the model can step back. If it cannot, a warning appears at the MATLAB command prompt. For some simulations, Simulink cannot step back. The step back capability is then disabled until the end of that simulation. Then the setting resets to the value you requested.
- When you place custom code in **Configuration Parameters > Simulation Target > Custom Code > Initialize function** in the **Model Configuration Parameters** dialog box, this gets called only during the first simulation in Simulation Stepper.

Blocks

- Some blocks do not support stepping back for reasons other than SimState support. These blocks are:

  - S-functions that have P-work vectors but do not declare their SimState compliance level or declare it to be unknown or disallowed (see “S-Function Compliance with the SimState”)
  - Simscape™ Multibody™ First Generation blocks
  - Model blocks configured for Accelerator mode
  - Legacy (pre-R2016a) SimEvents® blocks
- MATLAB Function blocks generally support stepping back. However, the use of certain constructs in the MATLAB code of these blocks can prevent the block from supporting stepping back. These scenarios prevent the MATLAB Function blocks from stepping back:
  - Persistent variables of opaque data type. Attempts to step back under this condition cause an error message based on the specific variable type.
  - Extrinsic functions calls that can contain state (such as properties of objects or persistent data of functions). No warnings or error messages appear, but the result likely will be incorrect.
  - Calls to custom C code (through MEX function calls) that do not contain static variables. No warnings or error messages appear, but the result likely will be incorrect.
- Some visualization blocks do not support stepping back. Because these blocks are not critical to the state of the simulation, no errors or warnings appear when you step back in a model that contains these blocks:
  - `XY Graph`
  - `Auto Correlator`
  - `Cross Correlator`
  - `Spectrum Analyzer`
  - `Averaging Spectrum Analyzer`
  - `Power Spectral Density`
  - `Averaging Power Spectral Density`
  - `Floating Bar Plot`
  - `3Dof Animation`
  - `MATLAB Animation`
  - `VR Sink`

- Any blocks that implement custom visualization in their output method (for example, an S-function that outputs to a MATLAB figure) are not fully supported for stepping back because the block method `Output` does not execute while stepping back. While the state of such blocks remains consistent with the simulation time (if the blocks comply with SimState), the visualization component is inconsistent until the next step forward in the simulation.

Because these blocks do not affect the numerical result of a simulation, stepping back is not disabled for these blocks. However, the values these blocks output are inaccurate until the simulation steps forward again.

Step Through a Simulation

Step Forward and Back

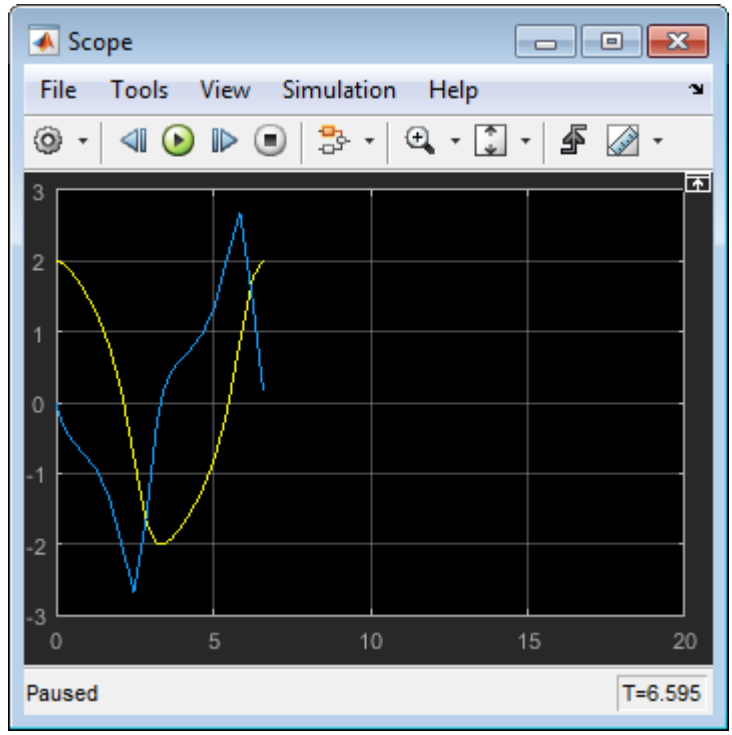
This example shows how to step forward and back through a simulation.

1. At the MATLAB prompt, type

   ```
   vdp
   ```

2. In the Simulink Editor for the `vdp` model, click  to open the Simulation Stepping Options dialog box.
3. In the dialog box, select the **Enable stepping back** check box, and then click **OK**.
4. In the Simulation toolbar, click the **Step Forward** button  one time.

   The simulation simulates one step, and the software stores a simulation snapshot for that step.
5. Click the Step Forward button again to step forward again and store simulation data. A total of 25 forward steps produces these simulation results:



6 You must step forward to create the simulation state that the step backward operation requires. This means you must first step forward before you can step backward through the same steps.

In the Simulation toolbar, click the **Step Back** button  four times to step backward to the simulation snapshot shown below.

Set Conditional Breakpoints for Stepping a Simulation

A conditional breakpoint is triggered based on a specified expression evaluated on a signal. When the breakpoint is triggered, the simulation pauses.

Set conditional breakpoints to stop Simulation Stepper when a specified condition is met. One example of a use for conditional breakpoints is when you want to examine results after a certain number of iterations in a loop.

Simulation Stepper allows you to set conditional breakpoints for scalar signals. These breakpoints appear for signals:

Breakpoint	Description
	Enabled breakpoint. Appears when you add the conditional breakpoint.
	Enabled breakpoint hit. Appears when the simulation reaches the condition specified and triggers the breakpoint.
	Disabled breakpoint. Appears when you disable a conditional breakpoint.
	Invalid breakpoint. Appears when the software determines that a breakpoint is invalid for the signal. An enabled breakpoint image changes to this one when, during simulation, the software determines that the conditional breakpoint is invalid.

When setting conditional breakpoints, keep in mind that:

- When simulation arrives at a conditional breakpoint, simulation does not stop when the block is executed. Instead, simulation stops after the current simulation step completes.
- You can add multiple conditional breakpoints to a signal line.

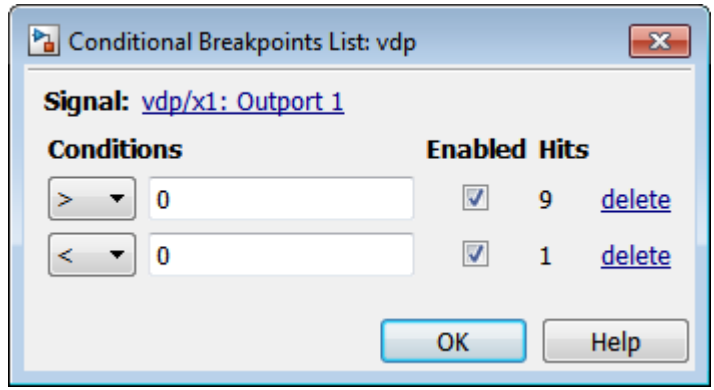
Add and Edit Conditional Breakpoints

1. In a model, right-click a signal and select **Add Conditional Breakpoint**.
2. In the **Add Conditional Breakpoint** dialog box, from the drop-down list, select the condition for the signal. For example, select greater than or less than.
3. Enter the signal value where you want simulation to pause and click **OK**. For the condition values:

- Use numeric values. Do not use expressions.
- Do not use `NaN`.

The affected signal line displays a conditional breakpoint icon: .

4 Click the breakpoint to view and edit all conditions set for the signal.



5 Simulate the model and notice that the model pauses as simulation steps through the conditional breakpoints.

Conditional Breakpoints Limitations

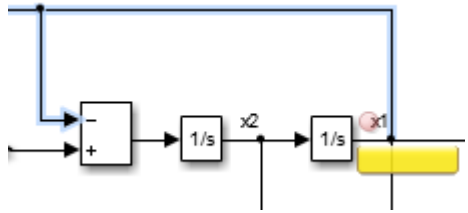
- You can set conditional breakpoints only on real scalar signals of these data types:
  - double
  - single
  - int
  - bool
  - fixed point (based on the converted double value)
- You cannot set conditional breakpoints (or port value display labels) on non-Simulink signals, such as Simscape or SimEvents signals.
- Conditional breakpoints also have the limitations that port value display have(“Port Value Display Limitations” on page 35-25).

Observe Conditional Breakpoint Values

To observe a conditional breakpoint value of a block signal, use data tips to display block port values. You can add data tips before or after you add conditional breakpoints.

1 Enable the value display for a signal. Right-click the signal line that has a conditional breakpoint and select **Show Value Label of Selected Port**.

The data tip for the value display appears.



2 Simulate the model and observe the conditional breakpoint and data tip when the simulation triggers the breakpoint.

How Simulink Works

How Simulink Works

Simulink is a software package that enables you to model, simulate, and analyze systems whose outputs change over time. Such systems are often referred to as dynamic systems. The Simulink software can be used to explore the behavior of a wide range of real-world dynamic systems, including electrical circuits, shock absorbers, braking systems, and many other electrical, mechanical, and thermodynamic systems. This section explains how Simulink works.

Simulating a dynamic system is a two-step process. First, a user creates a block diagram, using the Simulink model editor, that graphically depicts time-dependent mathematical relationships among the system's inputs, states, and outputs. The user then commands the Simulink software to simulate the system represented by the model from a specified start time to a specified stop time.

Modeling Dynamic Systems

In this section...

Block Diagram Semantics

A classic block diagram model of a dynamic system graphically consists of blocks and lines (signals). The history of these block diagram models is derived from engineering areas such as Feedback Control Theory and Signal Processing. A block within a block diagram defines a dynamic system in itself. The relationships between each elementary dynamic system in a block diagram are illustrated by the use of signals connecting the blocks. Collectively the blocks and lines in a block diagram describe an overall dynamic system.

The Simulink product extends these classic block diagram models by introducing the notion of two classes of blocks, nonvirtual blocks and virtual blocks. Nonvirtual blocks represent elementary systems. Virtual blocks exist for graphical and organizational convenience only: they have no effect on the system of equations described by the block diagram model. You can use virtual blocks to improve the readability of your models.

In general, blocks and lines can be used to describe many “models of computations.” One example would be a flow chart. A flow chart consists of blocks and lines, but one cannot describe general dynamic systems using flow chart semantics.

The term “time-based block diagram” is used to distinguish block diagrams that describe dynamic systems from that of other forms of block diagrams, and the term block diagram (or model) is used to refer to a time-based block diagram unless the context requires explicit distinction.

To summarize the meaning of time-based block diagrams:

- Simulink block diagrams define time-based relationships between signals and state variables. The solution of a block diagram is obtained by evaluating these relationships over time, where time starts at a user specified “start time” and ends at a user specified “stop time.” Each evaluation of these relationships is referred to as a time step.
- Signals represent quantities that change over time and are defined for all points in time between the block diagram's start and stop time.
- The relationships between signals and state variables are defined by a set of equations represented by blocks. Each block consists of a set of equations (block methods). These equations define a relationship between the input signals, output signals and the state variables. Inherent in the definition of a equation is the notion of parameters, which are the coefficients found within the equation.

Creating Models

The Simulink product provides a graphical editor that allows you to create and connect instances of block types selected from libraries of block types (see “Block Libraries”) via a library browser. Libraries of blocks are provided representing elementary systems that can be used as building blocks. The blocks supplied with Simulink are called built-in blocks. Users can also create their own block types and use the Simulink editor to create instances of them in a diagram. User-defined blocks are called custom blocks.

Time

Time is an inherent component of block diagrams in that the results of a block diagram simulation change with time. Put another way, a block diagram represents the instantaneous behavior of a dynamic system. Determining a system's behavior over time thus entails repeatedly solving the model at intervals, called time steps, from the start of the time span to the end of the time span. The process of solving a model at successive time steps is referred to as *simulating* the system that the model represents.

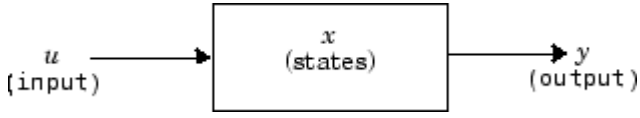
States

Typically the current values of some system, and hence model, outputs are functions of the previous values of temporal variables. Such variables are called states. Computing a model's outputs from a block diagram hence entails saving the value of states at the current time step for use in computing the outputs at a subsequent time step. This task is performed during simulation for models that define states.

Two types of states can occur in a Simulink model: discrete and continuous states. A continuous state changes continuously. Examples of continuous states are the position and speed of a car. A discrete state is an approximation of a continuous state where the state is updated (recomputed) using finite (periodic or aperiodic) intervals. An example of a discrete state would be the position of a car shown on a digital odometer where it is updated every second as opposed to continuously. In the limit, as the discrete state time interval approaches zero, a discrete state becomes equivalent to a continuous state.

Blocks implicitly define a model's states. In particular, a block that needs some or all of its previous outputs to compute its current outputs implicitly defines a set of states that need to be saved between time steps. Such a block is said to have states.

The following is a graphical representation of a block that has states:



Blocks that define continuous states include the following standard Simulink blocks:

- Integrator
- State-Space
- Transfer Fcn
- Variable Transport Delay
- Zero-Pole

The total number of a model's states is the sum of all the states defined by all its blocks. Determining the number of states in a diagram requires parsing the diagram to determine the types of blocks that it contains and then aggregating the number of states defined by each instance of a block type that defines states. This task is performed during the Compilation phase of a simulation.

Working with States

The following facilities are provided for determining, initializing, and logging a model's states during simulation:

- The `model` command displays information about the states defined by a model, including the total number of states defined by the model, the block that defines each state, and the initial value of each state.
- The Simulink debugger displays the value of a state at each time step during a simulation, and the Simulink debugger's `states` command displays information about the model's current states (see “Simulink Debugger”).
- The **Data Import/Export** pane of a model's Configuration Parameters dialog box (see “State Information” on page 61-258) allows you to specify initial values for a model's states, and to record the values of the states at each time step during simulation as an array or structure variable in the MATLAB workspace.
- The Block Parameters dialog box (and the `ContinuousStateAttributes` parameter) allows you to give names to states for those blocks (such as the Integrator) that employ continuous states. This can simplify analyzing data logged for states, especially when a block has multiple states.

  The Two Cylinder Model with Load Constraints model illustrates the logging of continuous states.

Continuous States

Computing a continuous state entails knowing its rate of change, or derivative. Since the rate of change of a continuous state typically itself changes continuously (i.e., is itself a state), computing the value of a continuous state at the current time step entails integration of its derivative from the start of a simulation. Thus modeling a continuous state entails representing the operation of integration and the process of computing the state's derivative at each point in time. Simulink block diagrams use Integrator blocks to indicate integration and a chain of blocks connected to an integrator block's input to represent the method for computing the state's derivative. The chain of blocks connected to the integrator block's input is the graphical counterpart to an ordinary differential equation (ODE).

In general, excluding simple dynamic systems, analytical methods do not exist for integrating the states of real-world dynamic systems represented by ordinary differential equations. Integrating the states requires the use of numerical methods called ODE solvers. These various methods trade computational accuracy for computational

workload. The Simulink product comes with computerized implementations of the most common ODE integration methods and allows a user to determine which it uses to integrate states represented by Integrator blocks when simulating a system.

Computing the value of a continuous state at the current time step entails integrating its values from the start of the simulation. The accuracy of numerical integration in turn depends on the size of the intervals between time steps. In general, the smaller the time step, the more accurate the simulation. Some ODE solvers, called variable time step solvers, can automatically vary the size of the time step, based on the rate of change of the state, to achieve a specified level of accuracy over the course of a simulation. The user can specify the size of the time step in the case of fixed-step solvers, or the solver can automatically determine the step size in the case of variable-step solvers. To minimize the computation workload, the variable-step solver chooses the largest step size consistent with achieving an overall level of precision specified by the user for the most rapidly changing model state. This ensures that all model states are computed to the accuracy specified by the user.

Discrete States

Computing a discrete state requires knowing the relationship between its value at the current time step and its value at the previous time step. This is referred to this relationship as the state's update function. A discrete state depends not only on its value at the previous time step but also on the values of a model's inputs. Modeling a discrete state thus entails modeling the state's dependency on the systems' inputs at the previous time step. Simulink block diagrams use specific types of blocks, called discrete blocks, to specify update functions and chains of blocks connected to the inputs of discrete blocks to model the dependency of a system's discrete states on its inputs.

As with continuous states, discrete states set a constraint on the simulation time step size. Specifically, the step size must ensure that all the sample times of the model's states are hit. This task is assigned to a component of the Simulink system called a discrete solver. Two discrete solvers are provided: a fixed-step discrete solver and a variable-step discrete solver. The fixed-step discrete solver determines a fixed step size that hits all the sample times of all the model's discrete states, regardless of whether the states actually change value at the sample time hits. By contrast, the variable-step discrete solver varies the step size to ensure that sample time hits occur only at times when the states change value.

Modeling Hybrid Systems

A hybrid system is a system that has both discrete and continuous states. Strictly speaking, any model that has both continuous and discrete sample times is treated as a

hybrid model, presuming that the model has both continuous and discrete states. Solving such a model entails choosing a step size that satisfies both the precision constraint on the continuous state integration and the sample time hit constraint on the discrete states. The Simulink software meets this requirement by passing the next sample time hit, as determined by the discrete solver, as an additional constraint on the continuous solver. The continuous solver must choose a step size that advances the simulation up to but not beyond the time of the next sample time hit. The continuous solver can take a time step short of the next sample time hit to meet its accuracy constraint but it cannot take a step beyond the next sample time hit even if its accuracy constraint allows it to.

You can simulate hybrid systems using any one of the integration methods, but certain methods are more effective than others. For most hybrid systems, `ode23` and `ode45` are superior to the other solvers in terms of efficiency. Because of discontinuities associated with the sample and hold of the discrete blocks, do not use the `ode15s` and `ode113` solvers for hybrid systems.

Block Parameters

Key properties of many standard blocks are parameterized. For example, the Constant value of the Simulink Constant block is a parameter. Each parameterized block has a block dialog that lets you set the values of the parameters. You can use MATLAB expressions to specify parameter values. Simulink evaluates the expressions before running a simulation. You can change the values of parameters during a simulation. This allows you to determine interactively the most suitable value for a parameter.

A parameterized block effectively represents a family of similar blocks. For example, when creating a model, you can set the Constant value parameter of each instance of the Constant block separately so that each instance behaves differently. Because it allows each standard block to represent a family of blocks, block parameterization greatly increases the modeling power of the standard Simulink libraries. See “Block Parameters” on page 3-8 and “Block Libraries” for more information.

Tunable Parameters

Many block parameters are tunable. A *tunable parameter* is a parameter whose value can be changed without recompiling the model (see “Model Compilation” on page 3-17 for more information on compiling a model). For example, the gain parameter of the Gain block is tunable. You can alter the block's gain while a simulation is running. If a parameter is not tunable and the simulation is running, the dialog box control that sets the parameter is disabled.

When you change the value of a tunable parameter, the change takes effect at the start of the next time step. See “Block Parameters” on page 3-8 and “Tune and Experiment with Block Parameter Values” on page 36-38 for more information.

Block Sample Times

Every Simulink block has a sample time which defines when the block will execute. Most blocks allow you to specify the sample time via a `SampleTime` parameter. Common choices include discrete, continuous, and inherited sample times.

Common Sample Time Types	Sample Time	Examples
Discrete	[T_s, T_o]	Unit Delay, Digital Filter
Continuous	[0, 0]	Integrator, Derivative
Inherited	[–1, 0]	Gain, Sum

For discrete blocks, the sample time is a vector [Ts, To] where Ts is the time interval or period between consecutive sample times and To is an initial offset to the sample time. In contrast, the sample times for nondiscrete blocks are represented by ordered pairs that use zero, a negative integer, or infinity to represent a specific type of sample time (see “View Sample Time Information” on page 7-9). For example, continuous blocks have a nominal sample time of [0, 0] and are used to model systems in which the states change continuously (e.g., a car accelerating). Whereas you indicate the sample time type of an inherited block symbolically as [–1, 0] and Simulink then determines the actual value based upon the context of the inherited block within the model.

Note that not all blocks accept all types of sample times. For example, a discrete block cannot accept a continuous sample time.

For a visual aid, Simulink allows the optional color-coding and annotation of any block diagram to indicate the type and speed of the block sample times. You can capture all of the colors and the annotations within a legend (see “View Sample Time Information” on page 7-9).

For a more detailed discussion of sample times, see “Sample Time”

Custom Blocks

You can create libraries of custom blocks that you can then use in your models. You can create a custom block either graphically or programmatically. To create a custom block

graphically, you draw a block diagram representing the block's behavior, wrap this diagram in an instance of the Simulink Subsystem block, and provide the block with a parameter dialog, using the Simulink block mask facility. To create a block programmatically, you create a MATLAB file or a MEX-file that contains the block's system functions (see “S-Function Basics”). The resulting file is called an S-function. You then associate the S-function with instances of the Simulink S-Function block in your model. You can add a parameter dialog to your S-Function block by wrapping it in a Subsystem block and adding the parameter dialog to the Subsystem block. See “Block Creation” for more information.

Systems and Subsystems

A Simulink block diagram can consist of layers. Each layer is defined by a subsystem. A subsystem is part of the overall block diagram and ideally has no impact on the meaning of the block diagram. Subsystems are provided primarily to help with the organizational aspects of a block diagram. Subsystems do not define a separate block diagram.

The Simulink software differentiates between two different types of subsystems: virtual and nonvirtual. The primary difference is that nonvirtual subsystems provide the ability to control when the contents of the subsystem are evaluated.

Virtual Subsystems

Virtual subsystems provide graphical hierarchy in models. Virtual subsystems do not impact execution. During model execution, the Simulink engine flattens all virtual subsystems, i.e., Simulink expands the subsystem in place before execution. This expansion is very similar to the way macros work in a programming language such as C or C++. Roughly speaking, there will be one system for the top-level block diagram which is referred to as the root system, and several lower-level systems derived from nonvirtual subsystems and other elements in the block diagram. You will see these systems in the Simulink Debugger. The act of creating these internal systems is often referred to as *flattening the model hierarchy*.

Nonvirtual Subsystems

Nonvirtual subsystems, which are drawn with a bold border, provide execution and graphical hierarchy in models. Nonvirtual subsystems are executed as a single unit (atomic execution) by the Simulink engine. You can create conditionally executed subsystems that are executed only when a precondition—such as a trigger, an enable, a function-call, or an action— occurs (see “Conditionally Executed Subsystems”). Simulink

always computes all inputs used during the execution of a nonvirtual subsystem before executing the subsystem. Simulink defines the following nonvirtual subsystems.

Atomic subsystems

The primary characteristic of an atomic subsystem is that blocks in an atomic subsystem execute as a single unit. This provides the advantage of grouping functional aspects of models at the execution level. Any Simulink block can be placed in an atomic subsystem, including blocks with different execution rates. You can create an atomic subsystem by selecting the **Treat as atomic unit** option on a virtual subsystem (see the Atomic Subsystem block for more information).

Enabled subsystems

An enabled subsystem behaves similarly to an atomic subsystem, except that it executes only when the signal driving the subsystem enable port is greater than zero. To create an enabled subsystem, place an Enable port block within a Subsystem block. You can configure an enabled subsystem to hold or reset the states of blocks within the enabled subsystem prior to a subsystem enabling action. Simply select the **States when enabling** parameter of the Enable port block. Similarly, you can configure each output port of an enabled subsystem to hold or reset its output prior to the subsystem disabling action. Select the **Output when disabled** parameter in the Outport block.

Triggered subsystems

You create a triggered subsystem by placing a trigger port block within a subsystem. The resulting subsystem executes when a rising or falling edge with respect to zero is seen on the signal driving the subsystem trigger port. The direction of the triggering edge is defined by the `Trigger type` parameter on the trigger port block. Simulink limits the type of blocks placed in a triggered subsystem to blocks that do not have explicit sample times (i.e., blocks within the subsystem must have a sample time of -1) because the contents of a triggered subsystem execute in an aperiodic fashion. A Stateflow chart can also have a trigger port which is defined by using the Stateflow editor. Simulink does not distinguish between a triggered subsystem and a triggered chart.

Function-call subsystems

A function-call subsystem is a subsystem that another block can invoke directly during a simulation. It is analogous to a function in a procedural programming language. Invoking a function-call subsystem is equivalent to invoking the output and update methods of the blocks that the subsystem contains in sorted order. The block that invokes a function-call subsystem is called the function-call initiator. Stateflow, Function-Call Generator, and S-function blocks can all serve as function-call initiators.

To create a function-call subsystem, drag a Function-Call Subsystem block from the Ports & Subsystems library into your model and connect a function-call initiator to the function-call port displayed on top of the subsystem. You can also create a function-call subsystem from scratch by first creating a Subsystem block in your model and then creating a Trigger block in the subsystem and setting the Trigger block `Trigger type` to `function-call`.

You can configure a function-call subsystem to be triggered (the default) or periodic by setting its `Sample time type` to be `triggered` or `periodic`, respectively. A function-call initiator can invoke a triggered function-call subsystem zero, once, or multiple times per time step. The sample times of all the blocks in a triggered function-call subsystem must be set to inherited (-1).

A function-call initiator can invoke a periodic function-call subsystem only once per time step and must invoke the subsystem periodically. If the initiator invokes a periodic function-call subsystem aperiodically, Simulink halts the simulation and displays an error message. The blocks in a periodic function-call subsystem can specify a noninherited sample time or inherited (-1) sample time. All blocks that specify a noninherited sample time must specify the same sample time, that is, if one block specifies .1 as its sample time, all other blocks must specify a sample time of .1 or -1. If a function-call initiator invokes a periodic function-call subsystem at a rate that differs from the sample time specified by the blocks in the subsystem, Simulink halts the simulation and displays an error message.

Enabled and triggered subsystems

You can create an enabled and triggered subsystem by placing a Trigger Port block and an Enable port block within a Subsystem block. The resulting subsystem is essentially a triggered subsystem that executes when the subsystem is enabled and a rising or falling edge with respect to zero is seen on the signal driving the subsystem trigger port. The direction of the triggering edge is defined by the `Trigger type` parameter on the trigger port block. Because the contents of a triggered subsystem execute in an aperiodic fashion, Simulink limits the types of blocks placed in an enabled and triggered subsystem to blocks that do not have explicit sample times. In other words, blocks within the subsystem must have a sample time of `-1`).

Resettable subsystems

A resettable subsystem computes its outputs at every sample time hit but also resets the states of the subsystem on triggering. The resettable subsystem resets the states of all blocks within it, triggered by a rising or falling edge with respect to zero. On triggering, the resettable subsystem resets its states and also computes the outputs.

The resettable subsystem supports only single sample time for all the blocks it contains. Different sample times for different blocks within the subsystem result in an error. For more information, see Resettable Subsystem.

Action subsystems

Action subsystems can be thought of as an intersection of the properties of enabled subsystems and function-call subsystems. Action subsystems are restricted to a single sample time (e.g., a continuous, discrete, or inherited sample time). Action subsystems must be executed by an action subsystem initiator. This is either an If block or a Switch Case block. All action subsystems connected to a given action subsystem initiator must have the same sample time. An action subsystem is created by placing an Action Port block within a Subsystem block. The subsystem icon will automatically adapt to the type of block (i.e., If or Switch Case block) that is executing the action subsystem.

Action subsystems can be executed at most once by the action subsystem initiator. Action subsystems give you control over when the states reset via the `States when execution is resumed` parameter on the Action Port block. Action subsystems also give you control over whether or not to hold the outport values via the `Output when disabled` parameter on the outport block. This is analogous to enabled subsystems.

Action subsystems behave very similarly to function-call subsystems because they must be executed by an initiator block. *Function-call subsystems can be executed more than once at any given time step whereas action subsystems can be executed at most once*. This restriction means that a larger set of blocks (e.g., periodic blocks) can be placed in action subsystems as compared to function-call subsystems. This restriction also means that you can control how the states and outputs behave.

While iterator subsystems

A while iterator subsystem will run multiple iterations on each model time step. The number of iterations is controlled by the While Iterator block condition. A while iterator subsystem is created by placing a While Iterator block within a subsystem block.

A while iterator subsystem is very similar to a function-call subsystem in that it can run for any number of iterations at a given time step. The while iterator subsystem differs from a function-call subsystem in that there is no separate initiator (e.g., a Stateflow Chart). In addition, a while iterator subsystem has access to the current iteration number optionally produced by the While Iterator block. A while iterator subsystem also gives you control over whether or not to reset states when starting via the `States when starting` parameter on the While Iterator block.

For iterator subsystems

A for iterator subsystem will run a fixed number of iterations at each model time step. The number of iterations can be an external input to the for iterator subsystem or specified internally on the For Iterator block. A for iterator subsystem is created by placing a For Iterator block within a subsystem block.

A for iterator subsystem has access to the current iteration number that is optionally produced by the For Iterator block. A for iterator subsystem also gives you control over whether or not to reset states when starting via the `States when starting` parameter on the For Iterator block. A for iterator subsystem is very similar to a while iterator subsystem with the restriction that the number of iterations during any given time step is fixed.

For each subsystems

The for each subsystem allows you to repeat an algorithm for individual elements (or subarrays) of an input signal. Here, the algorithm is represented by the set of blocks in the subsystem and is applied to a single element (or subarray) of the signal. You can configure the decomposition of the subsystem inputs into elements (or subarrays) using the For Each block, which resides in the subsystem. The For Each block also allows you to configure the concatenation of individual results into output signals. An advantage of this subsystem is that it maintains separate sets of states for each element or subarray that it processes. In addition, for certain models, the for each subsystem improves the code reuse of the code generated by Simulink Coder™.

Signals

The term *signal* refers to a time varying quantity that has values at all points in time. You can specify a wide range of signal attributes, including signal name, data type (e.g., 8-bit, 16-bit, or 32-bit integer), numeric type (real or complex), and dimensionality (one-dimensional, two-dimensional, or multidimensional array). Many blocks can accept or output signals of any data or numeric type and dimensionality. Others impose restrictions on the attributes of the signals they can handle.

On the block diagram, signals are represented with lines that have an arrowhead. The source of the signal corresponds to the block that writes to the signal during evaluation of its block methods (equations). The destinations of the signal are blocks that read the signal during the evaluation of the block's methods (equations).

A good way to understand the definition of a signal is to consider a classroom. The teacher is the one responsible for writing on the white board and the students read what

is written on the white board when they choose to. This is also true of Simulink signals: a reader of the signal (a block method) can choose to read the signal as frequently or infrequently as so desired.

For more information about signals, see “Signals”.

Block Methods

Blocks represent multiple equations. These equations are represented as block methods. These block methods are evaluated (executed) during the execution of a block diagram. The evaluation of these block methods is performed within a simulation loop, where each cycle through the simulation loop represents the evaluation of the block diagram at a given point in time.

Method Types

Names are assigned to the types of functions performed by block methods. Common method types include:

- Outputs

  Computes the outputs of a block given its inputs at the current time step and its states at the previous time step.

- Update

  Computes the value of the block's discrete states at the current time step, given its inputs at the current time step and its discrete states at the previous time step.

- Derivatives

  Computes the derivatives of the block's continuous states at the current time step, given the block's inputs and the values of the states at the previous time step.

Method Naming Convention

Block methods perform the same types of operations in different ways for different types of blocks. The Simulink user interface and documentation uses dot notation to indicate the specific function performed by a block method:

```
BlockType.MethodType
```

For example, the method that computes the outputs of a Gain block is referred to as

```
Gain.Outputs
```

The Simulink debugger takes the naming convention one step further and uses the instance name of a block to specify both the method type and the block instance on which the method is being invoked during simulation, e.g.,

```
g1.Outputs
```

Model Methods

In addition to block methods, a set of methods is provided that compute the model properties and its outputs. The Simulink software similarly invokes these methods during simulation to determine a model's properties and its outputs. The model methods generally perform their tasks by invoking block methods of the same type. For example, the model Outputs method invokes the Outputs methods of the blocks that it contains in the order specified by the model to compute its outputs. The model Derivatives method similarly invokes the Derivatives methods of the blocks that it contains to determine the derivatives of its states.

Simulation Phases in Dynamic Systems

In this section...

Model Compilation

The first phase of simulation occurs when the system’s model is open and you simulate the model. In the Simulink Editor, select **Simulation** > **Run**. Running the simulation causes the Simulink engine to invoke the model compiler. The model compiler converts the model to an executable form, a process called compilation. In particular, the compiler:

- Evaluates the model's block parameter expressions to determine their values.
- Determines signal attributes, e.g., name, data type, numeric type, and dimensionality, not explicitly specified by the model and checks that each block can accept the signals connected to its inputs.
- A process called attribute propagation is used to determine unspecified attributes. This process entails propagating the attributes of a source signal to the inputs of the blocks that it drives.
- Performs block reduction optimizations.
- Flattens the model hierarchy by replacing virtual subsystems with the blocks that they contain (see “Solvers” on page 3-21).
- Determines the block sorted order (see “Control and Display the Sorted Order” on page 35-28 for more information).
- Determines the sample times of all blocks in the model whose sample times you did not explicitly specify (see “How Propagation Affects Inherited Sample Times” on page 7-39).

These events are essentially the same as what occurs when you update a diagram (“Update Diagram and Run Simulation” on page 1-65). The difference is that the Simulink software starts model compilation as part of model simulation, where compilation leads directly into the linking phase, as described in “Link Phase” on page 3-18. In contrast, you start an explicit model update as a standalone operation on a model.

Link Phase

In this phase, the Simulink engine allocates memory needed for working areas (signals, states, and run-time parameters) for execution of the block diagram. It also allocates and initializes memory for data structures that store run-time information for each block. For built-in blocks, the principal run-time data structure for a block is called the SimBlock. It stores pointers to a block's input and output buffers and state and work vectors.

Method Execution Lists

In the Link phase, the Simulink engine also creates method execution lists. These lists list the most efficient order in which to invoke a model's block methods to compute its outputs. The block sorted order lists generated during the model compilation phase is used to construct the method execution lists.

Block Priorities

You can assign update priorities to blocks (see “Assign Block Priorities” on page 35-42). The output methods of higher priority blocks are executed before those of lower priority blocks. The priorities are honored only if they are consistent with its block sorting rules.

Simulation Loop Phase

Once the Link Phase completes, the simulation enters the simulation loop phase. In this phase, the Simulink engine successively computes the states and outputs of the system at intervals from the simulation start time to the finish time, using information provided by the model. The successive time points at which the states and outputs are computed are called time steps. The length of time between steps is called the step size. The step size depends on the type of solver (see “Solvers” on page 3-21) used to compute the system's continuous states, the system's fundamental sample time (see “Sample Times in Systems” on page 7-29), and whether the system's continuous states have discontinuities (see “Zero-Crossing Detection” on page 3-24).

The Simulation Loop phase has two subphases: the Loop Initialization phase and the Loop Iteration phase. The initialization phase occurs once, at the start of the loop. The iteration phase is repeated once per time step from the simulation start time to the simulation stop time.

At the start of the simulation, the model specifies the initial states and outputs of the system to be simulated. At each step, new values for the system's inputs, states, and outputs are computed, and the model is updated to reflect the computed values. At the

end of the simulation, the model reflects the final values of the system's inputs, states, and outputs. The Simulink software provides data display and logging blocks. You can display and/or log intermediate results by including these blocks in your model.

Loop Iteration

At each time step, the Simulink engine:

1 Computes the model's outputs.

   The Simulink engine initiates this step by invoking the Simulink model Outputs method. The model Outputs method in turn invokes the model system Outputs method, which invokes the Outputs methods of the blocks that the model contains in the order specified by the Outputs method execution lists generated in the Link phase of the simulation (see “Solvers” on page 3-21).

   The system Outputs method passes the following arguments to each block Outputs method: a pointer to the block's data structure and to its SimBlock structure. The SimBlock data structures point to information that the Outputs method needs to compute the block's outputs, including the location of its input buffers and its output buffers.

2 Computes the model's states.

   The Simulink engine computes a model's states by invoking a solver. Which solver it invokes depends on whether the model has no states, only discrete states, only continuous states, or both continuous and discrete states.

   If the model has only discrete states, the Simulink engine invokes the discrete solver selected by the user. The solver computes the size of the time step needed to hit the model's sample times. It then invokes the Update method of the model. The model Update method invokes the Update method of its system, which invokes the Update methods of each of the blocks that the system contains in the order specified by the Update method lists generated in the Link phase.

   If the model has only continuous states, the Simulink engine invokes the continuous solver specified by the model. Depending on the solver, the solver either in turn calls the Derivatives method of the model once or enters a subcycle of minor time steps where the solver repeatedly calls the model's Outputs methods and Derivatives methods to compute the model's outputs and derivatives at successive intervals within the major time step. This is done to increase the accuracy of the state computation. The model Outputs method and Derivatives methods in turn invoke

their corresponding system methods, which invoke the block Outputs and Derivatives in the order specified by the Outputs and Derivatives methods execution lists generated in the Link phase.

3 Optionally checks for discontinuities in the continuous states of blocks.

A technique called zero-crossing detection is used to detect discontinuities in continuous states. See “Zero-Crossing Detection” on page 3-24 for more information.

4 Computes the time for the next time step.

Steps 1 through 4 are repeated until the simulation stop time is reached.

- “Simulate a Model Interactively” on page 24-2

Solvers

A dynamic system is simulated by computing its states at successive time steps over a specified time span, using information provided by the model. The process of computing the successive states of a system from its model is known as solving the model. No single method of solving a model suffices for all systems. Accordingly, a set of programs, known as *solvers*, are provided that each embody a particular approach to solving a model. The Configuration Parameters dialog box allows you to choose the solver most suitable for your model (see “Solver Classification Criteria” on page 24-11).

Fixed-Step Solvers Versus Variable-Step Solvers

The solvers provided in the Simulink software fall into two basic categories: fixed-step and variable-step.

Fixed-step solvers solve the model at regular time intervals from the beginning to the end of the simulation. The size of the interval is known as the step size. You can specify the step size or let the solver choose the step size. Generally, decreasing the step size increases the accuracy of the results while increasing the time required to simulate the system.

Variable-step solvers vary the step size during the simulation, reducing the step size to increase accuracy when a model's states are changing rapidly and increasing the step size to avoid taking unnecessary steps when the model's states are changing slowly. Computing the step size adds to the computational overhead at each step but can reduce the total number of steps, and hence simulation time, required to maintain a specified level of accuracy for models with rapidly changing or piecewise continuous states.

Continuous Versus Discrete Solvers

The Simulink product provides both continuous and discrete solvers.

Continuous solvers use numerical integration to compute a model's continuous states at the current time step based on the states at previous time steps and the state derivatives. Continuous solvers rely on the individual blocks to compute the values of the model's discrete states at each time step.

Mathematicians have developed a wide variety of numerical integration techniques for solving the ordinary differential equations (ODEs) that represent the continuous states of dynamic systems. An extensive set of fixed-step and variable-step continuous solvers

are provided, each of which implements a specific ODE solution method (see "Solver Classification Criteria" on page 24-11).

Discrete solvers exist primarily to solve purely discrete models. They compute the next simulation time step for a model and nothing else. In performing these computations, they rely on each block in the model to update its individual discrete states. They do not compute continuous states.

Note You must use a continuous solver to solve a model that contains both continuous and discrete states. You cannot use a discrete solver because discrete solvers cannot handle continuous states. If, on the other hand, you select a continuous solver for a model with no states or discrete states only, Simulink software uses a discrete solver.

Two discrete solvers are provided: A fixed-step discrete solver and a variable-step discrete solver. The fixed-step solver by default chooses a step size and hence simulation rate fast enough to track state changes in the fastest block in your model. The variable-step solver adjusts the simulation step size to keep pace with the actual rate of discrete state changes in your model. This can avoid unnecessary steps and hence shorten simulation time for multirate models (see "Sample Times in Systems" on page 7-29 for more information).

Minor Time Steps

Some continuous solvers subdivide the simulation time span into major and minor time steps, where a minor time step represents a subdivision of the major time step. The solver produces a result at each major time step. It uses results at the minor time steps to improve the accuracy of the result at the major time step.

Shape Preservation

Usually the integration step size is only related to the current step size and the current integration error. However, for signals whose derivative changes rapidly, you can obtain a more accurate integration results by including the derivative input information at each time step. To do so, enable the **Model Configuration Parameters > Solver > Shape Preservation** option.

Zero-Crossing Detection

A variable-step solver dynamically adjusts the time step size, causing it to increase when a variable is changing slowly and to decrease when the variable changes rapidly. This behavior causes the solver to take many small steps in the vicinity of a discontinuity because the variable is rapidly changing in this region. This improves accuracy but can lead to excessive simulation times.

The Simulink software uses a technique known as *zero-crossing detection* to accurately locate a discontinuity without resorting to excessively small time steps. Usually this technique improves simulation run time, but it can cause some simulations to halt before the intended completion time.

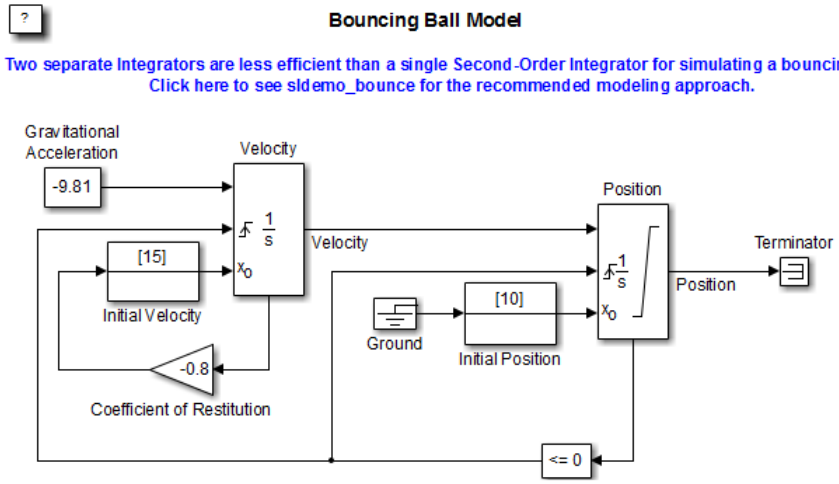
Two algorithms are provided in the Simulink software: Nonadaptive and Adaptive. For information about these techniques, see "Zero-Crossing Algorithms" on page 3-31.

Demonstrating Effects of Excessive Zero-Crossing Detection

The Simulink software comes with three models that illustrate zero-crossing behavior: `sldemo_bounce_two_integrators`, `sldemo_doublebounce`, and `sldemo_bounce`.

- The `sldemo_bounce_two_integrators` model demonstrates how excessive zero crossings can cause a simulation to halt before the intended completion time unless you use the adaptive algorithm.
- The `sldemo_bounce` model uses a better model design than `sldemo_bounce_two_integrators`.
- The `sldemo_doublebounce` model demonstrates how the adaptive algorithm successfully solves a complex system with two distinct zero-crossing requirements.

The Bounce Model with Two Integrators



1 At the MATLAB command prompt, type `sldemo_bounce_two_integrators` to load the example.

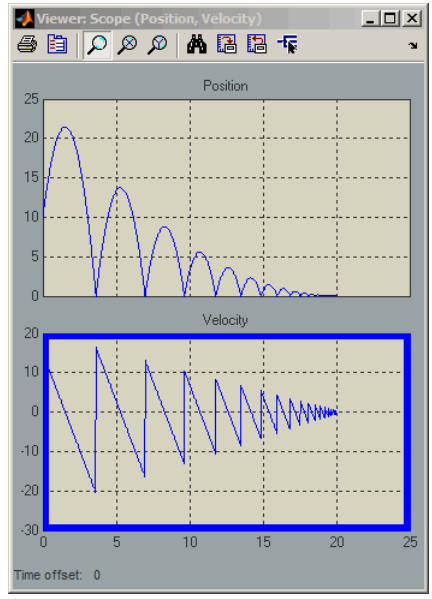
2 Once the block diagram appears, set the **Model Configuration Parameters** > **Solver** > **Algorithm** parameter to `Nonadaptive`.

3 Also in the **Solver** pane, set the **Stop time** parameter to 20 s.

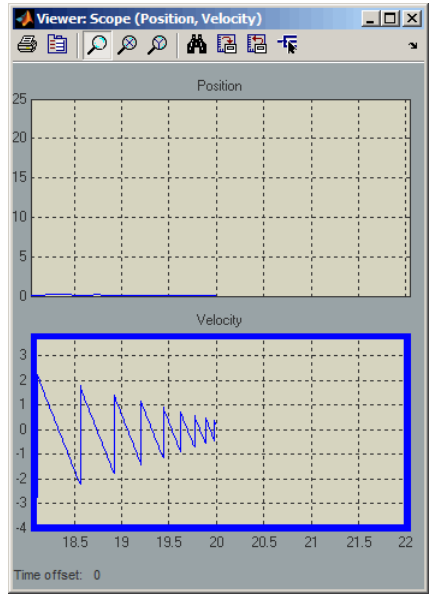
4 Run the model. In the Simulink Editor, select **Simulation** > **Run**.

5 After the simulation completes, click the Scope block window to see the results.

You may need to click on **Autoscale** to view the results in their entirety.



6 Use the scope zoom controls to closely examine the last portion of the simulation. You can see that the velocity is hovering just above zero at the last time point.



7 Change the simulation **Stop time** edit box in the Simulink Editor toolbar to 25 seconds, and run the simulation again.

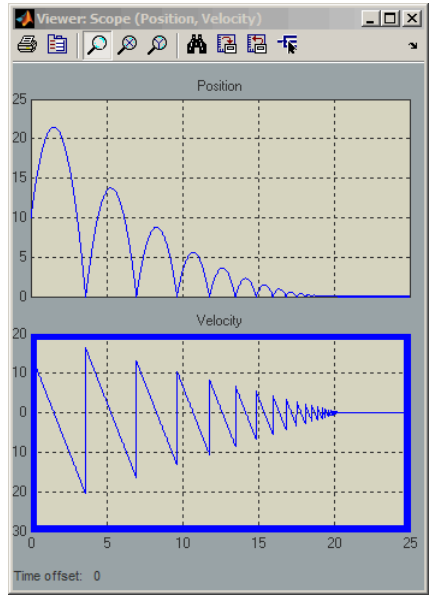
8 This time the simulation halts with an error shortly after it passes the simulated 20 second time point.

Excessive chattering as the ball repeatedly approaches zero velocity has caused the simulation to exceed the default limit of 1000 for the number of consecutive zero crossings allowed. Although you can increase this limit by adjusting the **Model Configuration Parameters > Solver > Number of consecutive zero crossings** parameter. In this case, making that change does not allow the simulation to simulate for 25 seconds.

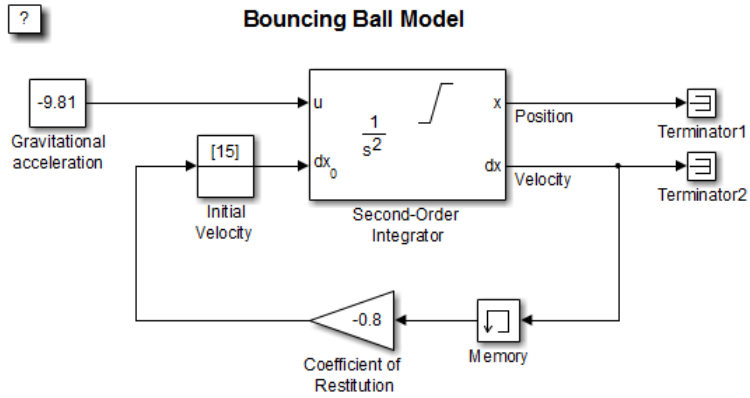
9 Also in the **Solver** pane, from the **Algorithm** pull down menu, select the **Adaptive** algorithm.

10 Run the simulation again.

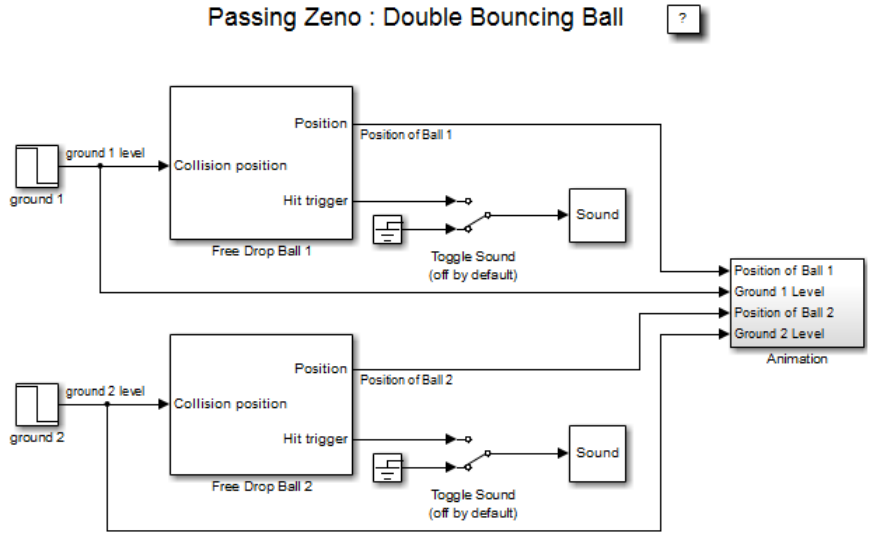
11 This time the simulation runs to completion because the adaptive algorithm prevented an excessive number of zero crossings from occurring.



Bounce Model with a Second-Order Integrator



The Double-Bounce Model



1 At the MATLAB command prompt, type `sldemo_doublebounce` to load the example. The model and an animation window open. In the animation window, two balls are resting on two platforms.

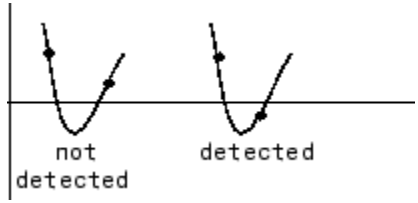
2. In the animation window, click the **Nonadaptive** button to run the example using the nonadaptive algorithm. This is the default setting used by the Simulink software for all models.
3. The ball on the right is given a larger initial velocity. Consequently, the two balls hit the ground and recoil at different times.
4. The simulation halts after 14 seconds because the ball on the left exceeded the number of zero crossings limit. The ball on the right is left hanging in mid air.
5. An error message dialog opens. Click **OK** to close it.
6. Click on the **Adaptive** button to run the simulation with the adaptive algorithm.
7. Notice that this time the simulation runs to completion, even after the ground shifts out from underneath the ball on the left at 20 seconds.

How the Simulator Can Miss Zero-Crossing Events

The bounce and double-bounce models show that high-frequency fluctuations about a discontinuity ('chattering') can cause a simulation to prematurely halt.

It is also possible for the solver to entirely miss zero crossings if the solver error tolerances are too large. This is possible because the zero-crossing detection technique checks to see if the value of a signal has changed sign after a major time step. A sign change indicates that a zero crossing has occurred, and the zero-crossing algorithm will then hunt for the precise crossing time. However, if a zero crossing occurs within a time step, but the values at the beginning and end of the step do not indicate a sign change, the solver steps over the crossing without detecting it.

The following figure shows a signal that crosses zero. In the first instance, the integrator steps over the event because the sign has not changed between time steps. In the second, the solver detects change in sign and so detects the zero-crossing event.



Preventing Excessive Zero Crossings

Use the following table to prevent excessive zero-crossing errors in your model.

Make this change...	How to make this change...	Rationale for making this change...
Increase the number of allowed zero crossings	Increase the value of the **Number of consecutive zero crossings**. option on the **Solver** pane in the Configuration Parameters dialog box.	This may give your model enough time to resolve the zero crossing.
Relax the **Signal threshold**	Select **Adaptive** from the **Algorithm** pull down and increase the value of the **Signal threshold** option on the **Solver** pane in the Configuration Parameters dialog box.	The solver requires less time to precisely locate the zero crossing. This can reduce simulation time and eliminate an excessive number of consecutive zero-crossing errors. However, relaxing the **Signal threshold** may reduce accuracy.
Use the **Adaptive** Algorithm	Select **Adaptive** from the **Algorithm** pull down on the **Solver** pane in the Configuration Parameters dialog box.	This algorithm dynamically adjusts the zero-crossing threshold, which improves accuracy and reduces the number of consecutive zero crossings detected. With this algorithm you have the option of specifying both the **Time tolerance** and the **Signal threshold**.
Disable zero-crossing detection for a specific block	1 Clear the **Enable zero-crossing detection** check box on the block's parameter dialog box. 2 Select `Use local settings` from the **Zero-crossing control** pull down on the **Solver** pane of the Configuration Parameters dialog box.	Locally disabling zero-crossing detection prevents a specific block from stopping the simulation because of excessive consecutive zero crossings. All other blocks continue to benefit from the increased accuracy that zero-crossing detection provides.

Make this change...	How to make this change...	Rationale for making this change...
Disable zero-crossing detection for the entire model	Select `Disable all` from the **Zero-crossing control** pull down on the **Solver** pane of the Configuration Parameters dialog box.	This prevents zero crossings from being detected anywhere in your model. A consequence is that your model no longer benefits from the increased accuracy that zero-crossing detection provides.
If using the `ode15s` solver, consider adjusting the order of the numerical differentiation formulas	Select a value from the `Maximum order` pull down on the **Solver** pane of the Configuration Parameters dialog box.	For more information, see "Maximum order".
Reduce the maximum step size	Enter a value for the `Max step size` option on the **Solver** pane of the Configuration Parameters dialog box.	This can insure the solver takes steps small enough to resolve the zero crossing. However, reducing the step size can increase simulation time, and is seldom necessary when using the Adaptive algorithm.

Zero-Crossing Algorithms

The Simulink software includes two zero-crossing detection algorithms: Nonadaptive and Adaptive.

To choose the algorithm, either use the **Algorithm** option in the Solver pane of the Configuration Parameter dialog box, or use the `ZeroCrossAlgorithm` command. The command can either be set to `'Nonadaptive'` or `'Adaptive'`.

The Nonadaptive algorithm is provided for backwards compatibility with older versions of Simulink and is the default. It brackets the zero-crossing event and uses increasingly smaller time steps to pinpoint when the zero crossing has occurred. Although adequate for many types of simulations, the Nonadaptive algorithm can result in very long simulation times when a high degree of 'chattering' (high frequency oscillation around the zero-crossing point) is present.

The Adaptive algorithm dynamically turns the bracketing on and off, and is a good choice when:

- The system contains a large amount of chattering.
- You wish to specify a guard band (tolerance) around which the zero crossing is detected.

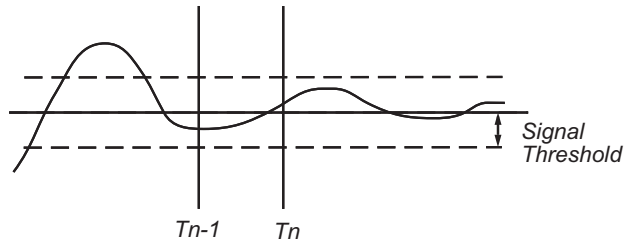
The Adaptive algorithm turns off zero-crossing bracketing (stops iterating) if either of the following are satisfied:

- The zero crossing error is exceeded. This is determined by the value specified in the **Signal threshold** option in the Solver pane of the Configuration Parameters dialog box. This can also be set with the `ZCThreshold` command. The default is `Auto`, but you can enter any real number greater than zero for the tolerance.
- The system has exceeded the number of consecutive zero crossings specified in the **Number of consecutive zero crossings** option in the Solver pane of the Configuration Parameters dialog box. Alternatively, this can be set with the `MaxConsecutiveZCs` command.

Understanding Signal Threshold

The Adaptive algorithm automatically sets a tolerance for zero-crossing detection. Alternatively, you can set the tolerance by entering a real number greater than or equal to zero in the Configuration Parameters Solver pane, `Signal threshold` pull down. This option only becomes active when the zero-crossing algorithm is set to `Adaptive`.

This graphic shows how the Signal threshold sets a window region around the zero-crossing point. Signals falling within this window are considered as being at zero.



The zero-crossing event is bracketed by time steps T_{n-1} and T_n. The solver iteratively reduces the time steps until the state variable lies within the band defined by the signal threshold, or until the number of consecutive zero crossings equals or exceeds the value in the Configuration Parameters Solver pane, `Number of consecutive zero crossings` pull down.

It is evident from the figure that increasing the signal threshold increases the distance between the time steps which will be executed. This often results in faster simulation times, but might reduce accuracy.

How Blocks Work with Zero-Crossing Detection

A block can register a set of zero-crossing variables, each of which is a function of a state variable that can have a discontinuity. The zero-crossing function passes through zero from a positive or negative value when the corresponding discontinuity occurs. The registered zero-crossing variables are updated at the end of each simulation step, and any variable that has changed sign is identified as having had a zero-crossing event.

If any zero crossings are detected, the Simulink software interpolates between the previous and current values of each variable that changed sign to estimate the times of the zero crossings (that is, the discontinuities).

Note The Zero-Crossing detection algorithm can bracket zero-crossing events only for signals of data type double

Blocks That Register Zero Crossings

The following table lists blocks that register zero crossings and explains how the blocks use the zero crossings:

Block	Description of Zero Crossing
Abs	One: to detect when the input signal crosses zero in either the rising or falling direction.
Backlash	Two: one to detect when the upper threshold is engaged, and one to detect when the lower threshold is engaged.
Compare To Constant	One: to detect when the signal equals a constant.
Compare To Zero	One: to detect when the signal equals zero.
Dead Zone	Two: one to detect when the dead zone is entered (the input signal minus the lower limit), and one to detect when the dead zone is exited (the input signal minus the upper limit).
Enable	One: If an Enable port is inside of a Subsystem block, it provides the capability to detect zero crossings. See the Enable Subsystem block for details “Enabled Subsystems” on page 10-10.
From File	One: to detect when the input signal has a discontinuity in either the rising or falling direction
From Workspace	One: to detect when the input signal has a discontinuity in either the rising or falling direction
Hit Crossing	One or two. If there is no output port, there is only one zero crossing to detect when the input signal hit the threshold value. If there is an output port, the second zero crossing is used to bring the output back to 0 from 1 to create an impulse-like output.
If	One: to detect when the If condition is met.
Integrator	If the reset port is present, to detect when a reset occurs. If the output is limited, there are three zero crossings: one to detect when the upper saturation limit is reached, one to detect when the lower saturation limit is reached, and one to detect when saturation is left.
MinMax	One: for each element of the output vector, to detect when an input signal is the new minimum or maximum.

Block	Description of Zero Crossing
Relational Operator	One: to detect when the specified relation is true.
Relay	One: if the relay is off, to detect the switch-on point. If the relay is on, to detect the switch-off point.
Saturation	Two: one to detect when the upper limit is reached or left, and one to detect when the lower limit is reached or left.
Second-Order Integrator	Five: two to detect when the state x upper or lower limit is reached; two to detect when the state dx/dt upper or lower limit is reached; and one to detect when a state leaves saturation.
Sign	One: to detect when the input crosses through zero.
Signal Builder	One: to detect when the input signal has a discontinuity in either the rising or falling direction
Step	One: to detect the step time.
Switch	One: to detect when the switch condition occurs.
Switch Case	One: to detect when the case condition is met.
Trigger	One: If a Triggered port is inside of a Subsystem block, it provides the capability to detect zero crossings. See the Triggered Subsystem block for details: “Triggered Subsystems” on page 10-20.
Enabled and Triggered Subsystem	Two: one for the enable port and one for the trigger port. See the Enabled and Triggered Subsystem block for details: “Enabled and Triggered Subsystems” on page 10-25

Note Zero-crossing detection is also available for a Stateflow chart that uses continuous-time mode. See “Configure a Stateflow Chart to Update in Continuous Time” (Stateflow) in the Stateflow documentation for more information.

Implementation Example: Saturation Block

An example of a Simulink block that registers zero crossings is the Saturation block. Zero-crossing detection identifies these state events in the Saturation block:

- The input signal reaches the upper limit.
- The input signal leaves the upper limit.

- The input signal reaches the lower limit.
- The input signal leaves the lower limit.

Simulink blocks that define their own state events are considered to have *intrinsic zero crossings*. Use the Hit Crossing block to receive explicit notification of a zero-crossing event. See “Blocks That Register Zero Crossings” on page 3-34 for a list of blocks that incorporate zero crossings.

The detection of a state event depends on the construction of an internal zero-crossing signal. This signal is not accessible by the block diagram. For the Saturation block, the signal that is used to detect zero crossings for the upper limit is `zcSignal = UpperLimit - u`, where `u` is the input signal.

Zero-crossing signals have a direction attribute, which can have these values:

- *rising* — A zero crossing occurs when a signal rises to or through zero, or when a signal leaves zero and becomes positive.
- *falling* — A zero crossing occurs when a signal falls to or through zero, or when a signal leaves zero and becomes negative.
- *either* — A zero crossing occurs if either a rising or falling condition occurs.

For the Saturation block's upper limit, the direction of the zero crossing is *either*. This enables the entering and leaving saturation events to be detected using the same zero-crossing signal.

Algebraic Loops

In this section...

What Is an Algebraic Loop?

In a Simulink model, an algebraic loop occurs when a signal loop exists with only direct feedthrough blocks within the loop. Direct feedthrough means that the block output depends on the value of an input port; the value of the input directly controls the value of the output.

Some blocks have input ports with direct feedthrough. Simulink cannot compute the output of these blocks without knowing the values of the signals entering the blocks at these input ports at the current time step.

Some examples of blocks with direct feedthrough inputs are:

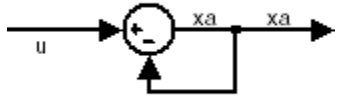
- Math Function
- Gain
- Product

- State-Space, when the D matrix coefficient is nonzero
- Sum
- Transfer Fcn, when the numerator and denominator are of the same order
- Zero-Pole, when the block has as many zeros as poles

Nondirect feedthrough blocks maintain a State variable. Two examples are Integrator and Unit Delay.

Tip To determine if a block has direct feedthrough, read the **Characteristics** section of the block reference page.

The figure shows an example of an algebraic loop (for demonstration only, not a recommended modeling pattern). The Sum block is an algebraic variable x_a that is constrained to equal the first input u minus x_a (for example, $x_a = u - x_a$).



The solution of this simple loop is $x_a = u/2$.

Interpretations of Algebraic Loops

Mathematical Interpretation

Simulink contains a suite of numerical solvers for simulating ordinary differential equations (ODEs), which are systems of equations that you can write as

$$\dot{x} = f(x,t),$$

where:

- x is the state vector.
- t is the independent time variable.

Some systems of equations contain additional constraints that involve the independent variable and the state vector, but not the derivative of the state vector. Such systems are differential algebraic equations (DAEs), not ODEs.

The term algebraic refers to equations that do not involve any derivatives. You can express DAEs that arise in engineering in the semi-explicit form

$$\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x}, \mathbf{x_a}, t)$$
$$0 = \mathbf{g}(\mathbf{x}, \mathbf{x_a}, t),$$

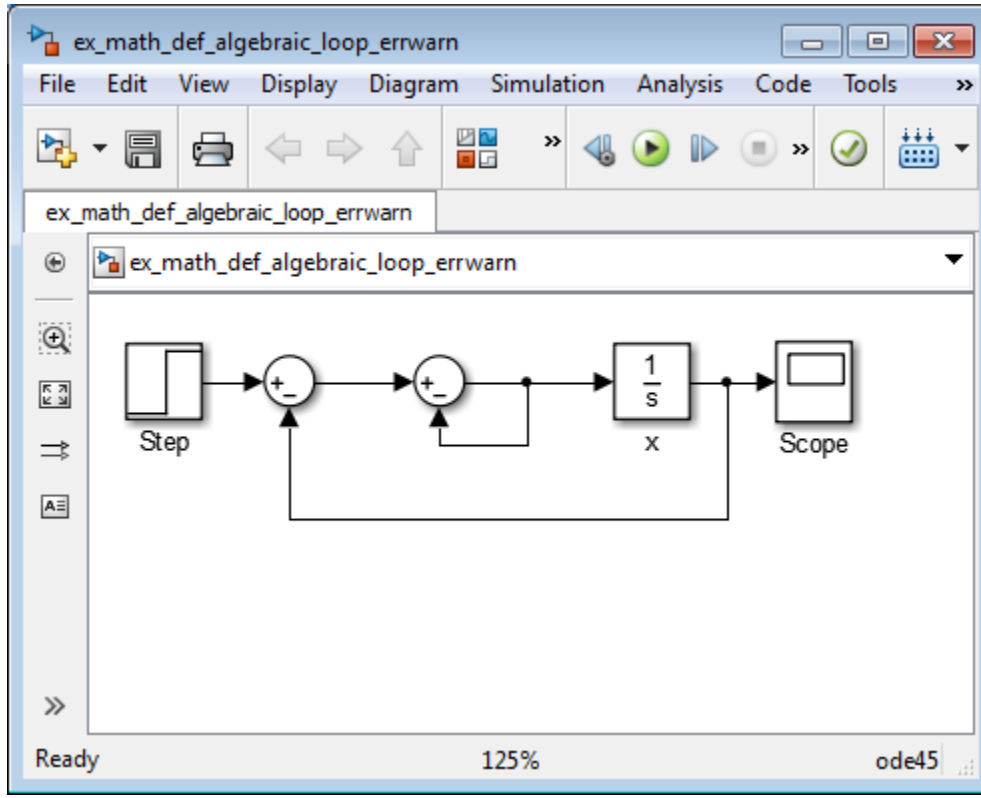
where:

- **f** and **g** can be vector functions.
- The first equation is the differential equation.
- The second equation is the algebraic equation.
- The vector of differential variables is **x**.
- The vector of algebraic variables is $\mathbf{x_a}$.

In Simulink models, algebraic loops are algebraic constraints. Models with algebraic loops define a system of differential algebraic equations. Simulink does not solve DAEs directly. Simulink solves the algebraic equations (the algebraic loop) numerically for x_a at each step of the ODE solver.

The model in the figure is equivalent to this system of equations in semi-explicit form:

$$\dot{x} = f(x, x_a, t) = x_a$$
$$0 = g(x, x_a, t) = -x + u - 2x_a.$$



At each step of the ODE solver, the algebraic loop solver must solve the algebraic constraint for x_a before calculating the derivative $\dot{x}$.

Physical Interpretation

Algebraic constraints:

- Occur when modeling physical systems, often due to conservation laws, such as conservation of mass and energy
- Occur when you choose a particular coordinate system for a model
- Help impose design constraints on system responses in a dynamic system

Use Simscape to model systems that span mechanical, electrical, hydraulic, and other physical domains as physical networks. Simscape constructs the DAEs that characterize

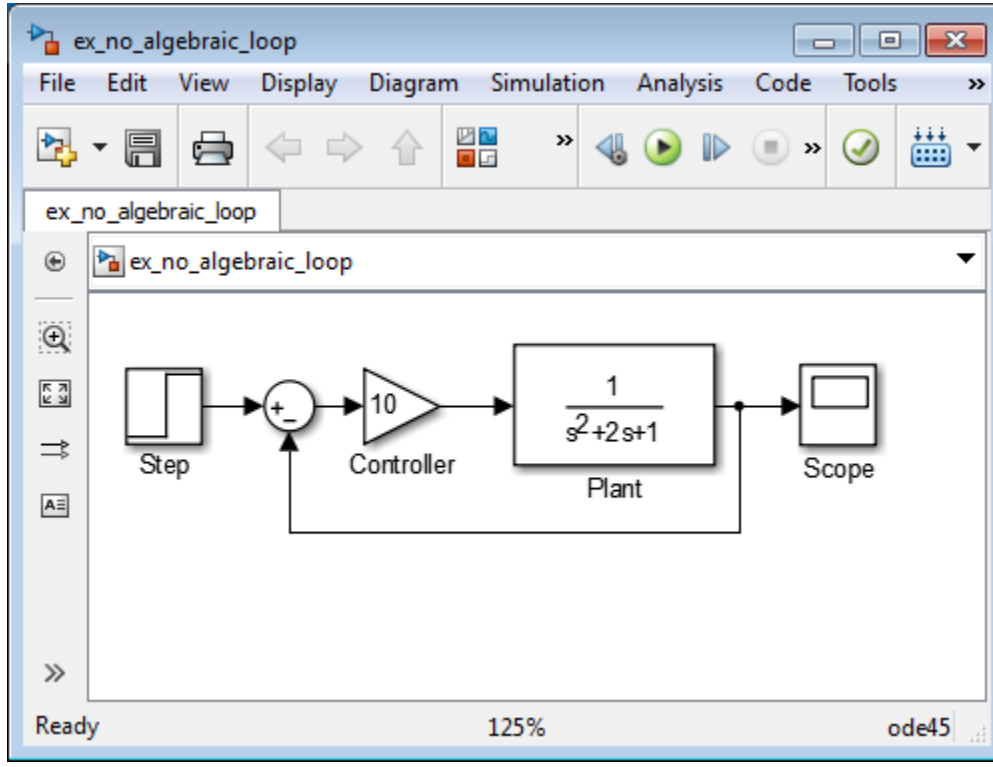
the behavior of a model. The software integrates these equations with the rest of the model and then solves the DAEs directly. Simulink solves the variables for the components in the different physical domains simultaneously, avoiding problems with algebraic loops.

What is an Artificial Algebraic Loop?

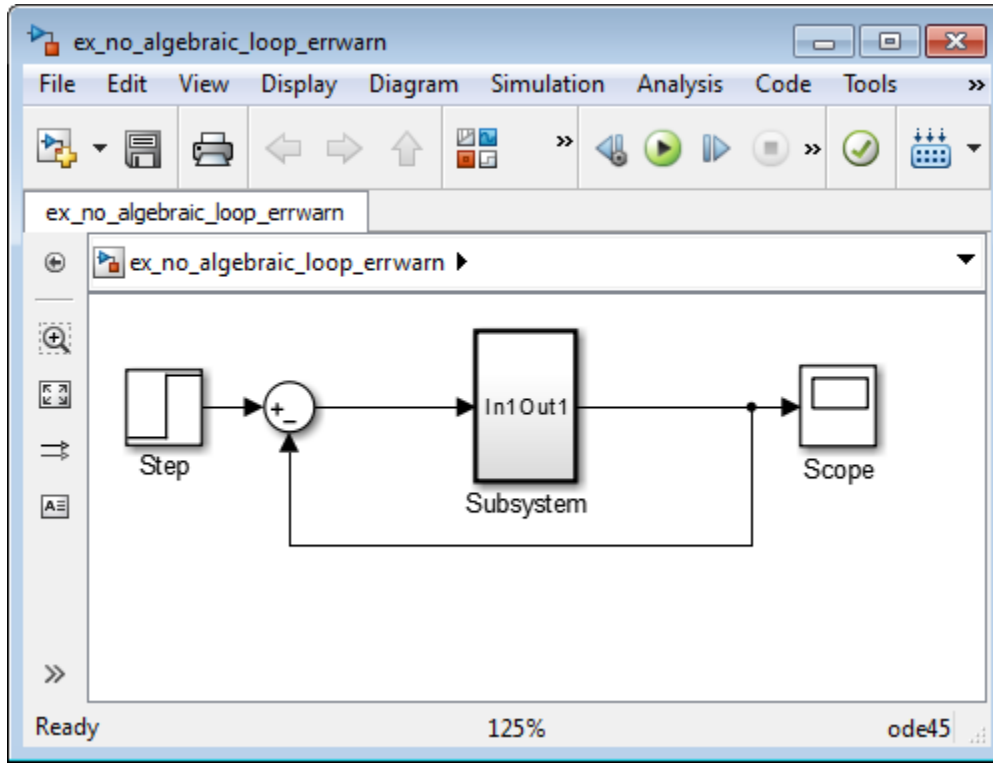
An artificial algebraic loop occurs when an atomic subsystem or Model block causes Simulink to detect an algebraic loop, even though the contents of the subsystem do not contain an algebraic constraint. When you create an atomic subsystem, all Inport blocks are direct feedthrough, resulting in an algebraic loop.

Example of an Artificial Algebraic Loop

Start with this model, which does not contain an algebraic loop. It simulates without error.



1. Enclose the Controller and Plant blocks in a subsystem.
2. In the subsystem block dialog box, select **Treat as atomic unit** to make the subsystem atomic.
3. In the **Diagnostics** pane of Model Configuration Parameters, set the **Algebraic loop** parameter to `error`.



When simulating this model, an algebraic loop occurs because the subsystem is direct feedthrough, even though the path within the atomic subsystem is not direct feedthrough. Simulation stops with an algebraic loop error.

Why Algebraic Loops Are Undesirable

If your model contains an algebraic loop:

- You cannot generate code for the model.
- The Simulink algebraic loop solver might not be able to solve the algebraic loop.
- While Simulink is trying to solve the algebraic loop, the simulation can execute slowly.

  For most models, the algebraic loop solver is computationally expensive for the first time step. Simulink solves subsequent time steps rapidly because a good starting point for x_a is available from the previous time step.

Identify Algebraic Loops in Your Model

Use these techniques to search for algebraic loops in your model:

- "Highlight Algebraic Loops in the Model" on page 3-43
- "Use The Algebraic Loop Diagnostic" on page 3-44
- "Use The ashow Debugger Command" on page 3-45

Highlight Algebraic Loops in the Model

Use `getAlgebraicLoops` to identify algebraic loops in a model and highlight them in the Simulink Editor. With this approach:

- You can traverse multiple layers of model hierarchy to locate algebraic loops.
- You can identify real and artificial algebraic loops.
- You can visualize all loops in your model simultaneously.
- You do not need to drill in and out of the model, across boundaries.
- You do not need to detect loops in serial order. Also, you do not need to compile the model every time you detect and solve a loop. Therefore you can solve loops quickly.

You perform algebraic loop highlighting on an entire model, not on specific subsystems.

1. Open the model.
2. In the **Diagnostics** pane of Model Configuration Parameters, set **Algebraic loop** to `none` or `warning`. Setting this parameter to `error` prevents the model from compiling.
3. Compile the model without any errors. The model must compile before you can highlight any algebraic loops.

4 At the MATLAB command prompt, enter:

```
Simulink.BlockDiagram.getAlgebraicLoops(bdroot)
```

The `getAlgebraicLoops` function highlights algebraic loops in the model, including algebraic loops in subsystems. It also creates a report with information about each loop:

- Solid lines represent real algebraic loops.
- Dotted lines represent artificial algebraic loops.
- A red highlight appears around a block assigned with an algebraic variable.
- The **Loop ID** helps you identify the system that contains a particular loop.

Customize the report by selecting or clearing the **Visible** checkbox for a loop.

Once you have identified algebraic loops in a model, you can remove them by editing the model. Close the highlight report and make changes to the model. You can edit the model only after you close the report. For information on removing real algebraic loops, see “Remove Algebraic Loops” on page 3-50.

Simulink does not save loop highlighting. Closing the model or exiting the display removes the loop highlighting.

Use The Algebraic Loop Diagnostic

Simulink detects algebraic loops during simulation initialization, for example, when you update your diagram. You can set the **Algebraic loop** diagnostic to report an error or warning if the software detects any algebraic loops in your model.

In the **Diagnostics** pane of the Model Configuration Parameters, set the **Algebraic loop** parameter.

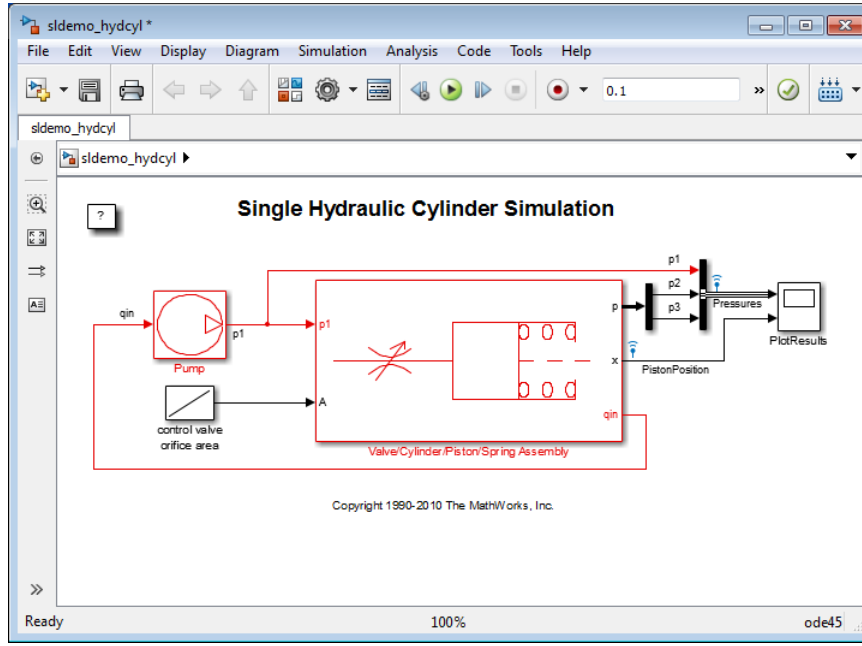
Setting	Simulation Response
`none`	Simulink tries to solve the algebraic loop; reports an error only if the algebraic loop cannot be solved.
`warning`	Algebraic loops result in warnings. Simulink tries to solve the algebraic loop; reports an error only if the algebraic loop cannot be solved.
`error`	Algebraic loops stop the initialization. Review the loop manually before Simulink tries to solve the loop.

This example shows how to use the algebraic loop diagnostic to highlight algebraic loops in the `sldemo_hydcyl` model.

1. Open the sldemo_hydcyl model.
2. In the **Diagnostics** pane of the Model Configuration Parameters, set the **Algebraic loop** parameter to `error`.
3. Simulate the model.

   When Simulink detects an algebraic loop during initialization, the simulation stops. The Diagnostic Viewer displays an error message and lists all the blocks in the model that are part of that algebraic loop.

   In the model, red highlights show the blocks and signals that make up the loop.



4. Close the Diagnostic Viewer to remove the highlights.
5. Close `sldemo_hydcyl` model. Do not save the changes.

Use The ashow Debugger Command

Use the `ashow` command in the Simulink debugger to highlight algebraic loops and step through a simulation.

1. Open the sldemo_hydcyl model.

   By default, the **Algebraic loop** parameter for this model is set to `none`.

2. Start the Simulink debugger. Select **Simulation** > **Debug** > **Debug Model**.

   Run the debugger.

3. In the MATLAB command prompt, enter:

   ```
   ashow
   ```

   The command returns the algebraic loop in `sldemo_hydcyl` and the number of blocks in the loop.

   ```
   Found 1 Algebraic loop(s):
   System number#Algebraic loop id, number of blocks in loop
   - 0#1, 9 blocks in loop
   ```

4. To list the blocks in this algebraic loop, at the MATLAB command prompt, enter:

   ```
   ashow 0#1
   ```

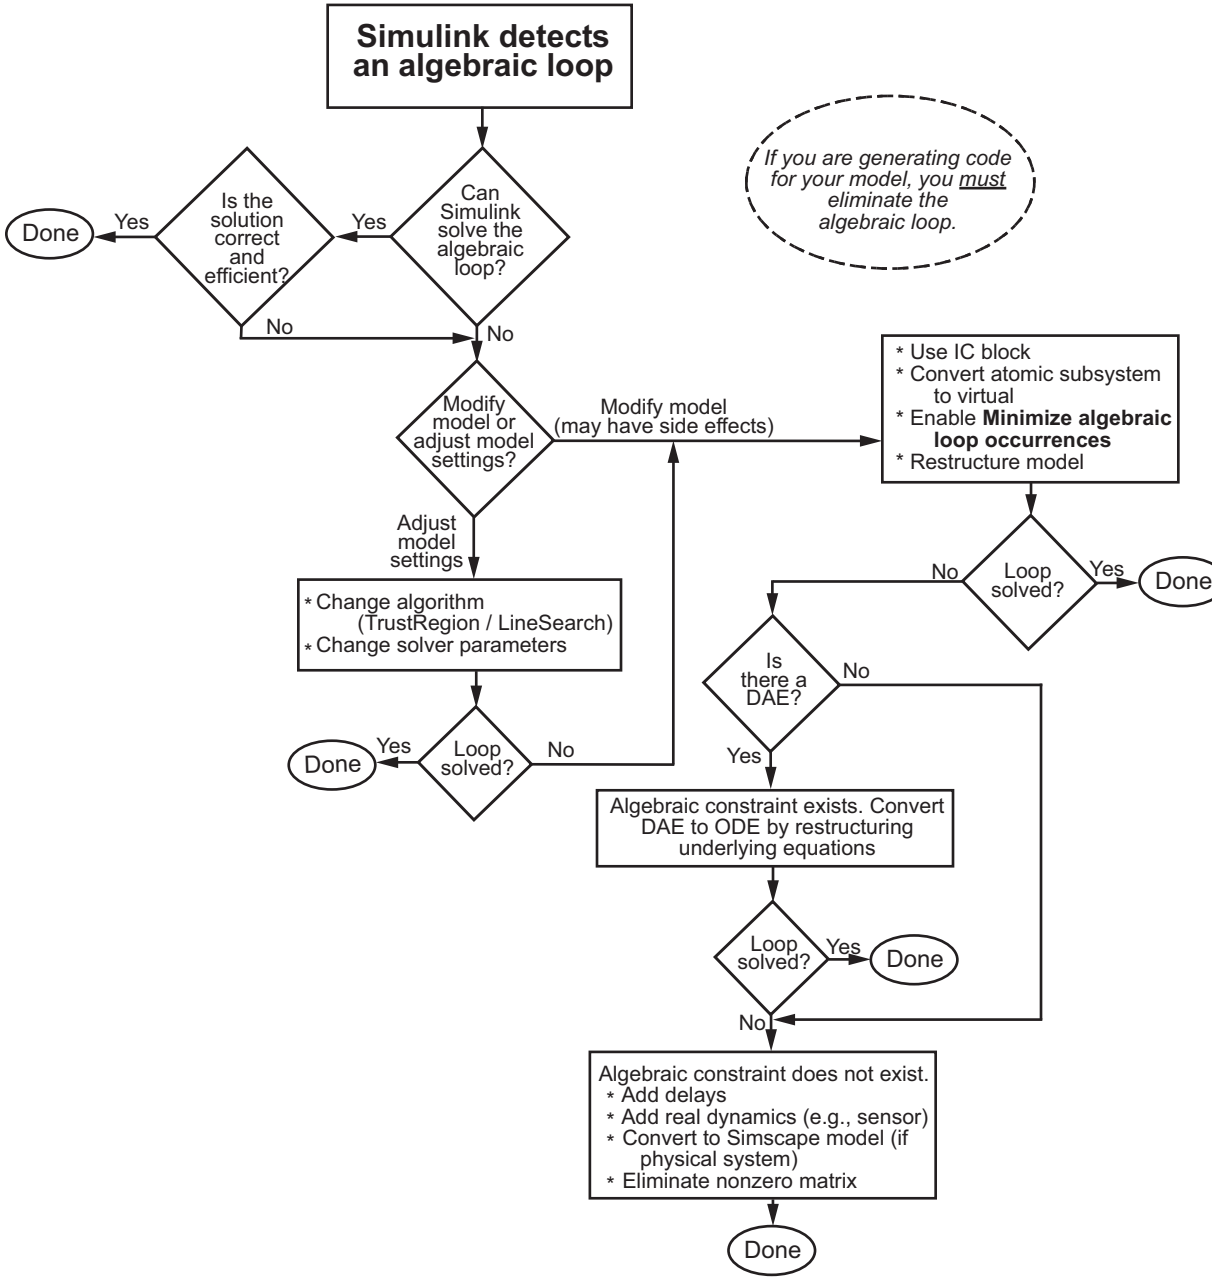
   The Control Valve Flow subsystem in the Valve/Cylinder/Piston/Spring Assembly subsystem opens with the algebraic loop in the model highlighted. The function lists the nine blocks in the algebraic loop:

   ```
   - sldemo_hydcyl/Valve//Cylinder//Piston//Spring Assembly/Control Valve Flow/IC
   - sldemo_hydcyl/Valve//Cylinder//Piston//Spring Assembly/Control Valve Flow/signed sqrt
   - sldemo_hydcyl/Valve//Cylinder//Piston//Spring Assembly/Control Valve Flow/Product
   - sldemo_hydcyl/Valve//Cylinder//Piston//Spring Assembly/laminar flow pressure drop
   - sldemo_hydcyl/Valve//Cylinder//Piston//Spring Assembly/Sum7
   - sldemo_hydcyl/Pump/IC
   - sldemo_hydcyl/Valve//Cylinder//Piston//Spring Assembly/Control Valve Flow/
   Sum1 (algebraic variable)
   - sldemo_hydcyl/Pump/Sum1
   - sldemo_hydcyl/Pump/leakage (algebraic variable)
   ```

How to Handle Algebraic Loops in a Model

If Simulink reports an algebraic loop in your model, the algebraic loop solver may be able to solve the loop. If Simulink cannot solve the loop, there are several techniques to eliminate the loop.

Use this workflow to decide how you want to eliminate an algebraic loop.



Simulink detects an algebraic loop
Can Simulink solve the algebraic loop?
Yes
Is the solution correct and efficient?
Yes
Done
No
No
If you are generating code for your model, you must eliminate the algebraic loop.
Modify model or adjust model settings?
Modify model (may have side effects)
* Use IC block
* Convert atomic subsystem to virtual
* Enable Minimize algebraic loop occurrences
* Restructure model
Loop solved?
No
Yes
Done
Adjust model settings
* Change algorithm (TrustRegion / LineSearch)
* Change solver parameters
Loop solved?
Yes
Done
No
Is there a DAE?
No
Yes
Algebraic constraint exists. Convert DAE to ODE by restructuring underlying equations
Loop solved?
Yes
Done
No
Algebraic constraint does not exist.
* Add delays
* Add real dynamics (e.g., sensor)
* Convert to Simscape model (if physical system)
* Eliminate nonzero matrix
Done

How the Algebraic Loop Solver Works

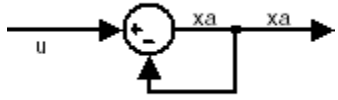
When a model contains an algebraic loop, Simulink uses a nonlinear solver at each time step to solve the algebraic loop. The solver performs iterations to determine the solution to the algebraic constraint, if there is one. As a result, models with algebraic loops can run more slowly than models without algebraic loops.

Simulink uses a dogleg trust region algorithm to solve algebraic loops. The tolerance used is smaller than the ODE solver `Reltol` and `Abstol`. This is because Simulink uses the "explicit ODE method" to solve Index-1 differential algebraic equations (DAEs).

For the algebraic loop solver to work,

- There must be one block where the loop solver can break the loop and attempt to solve the loop.
- The model should have real double signals.
- The underlying algebraic constraint must be a smooth function

For example, suppose your model has a Sum block with two inputs—one additive, the other subtractive. If you feed the output of the Sum block to one of the inputs, you create an algebraic loop where all of the blocks include direct feedthrough.



The Sum block cannot compute the output without knowing the input. Simulink detects the algebraic loop, and the algebraic loop solver solves the loop using an iterative loop. In the Sum block example, the software computes the correct result this way:

$x_a(t) = u(t) / 2$.

The algebraic loop solver uses a gradient-based search method, which requires continuous first derivatives of the algebraic constraint that correspond to the algebraic loop. As a result, if the algebraic loop contains discontinuities, the algebraic loop solver can fail.

For more information, see Solving Index-1 DAEs in MATLAB and Simulink [1]

Trust-Region and Line-Search Algorithms in the Algebraic Loop Solver

The Simulink algebraic loop solver uses one of two algorithms to solve algebraic loops:

- Trust-Region
- Line-Search

By default, the algebraic loop solver uses the trust-region algorithm.

If the algebraic loop solver cannot solve the algebraic loop with the trust-region algorithm, try simulating the model using the line-search algorithm.

To switch to the line-search algorithm, at the MATLAB command line, enter:

```
set_param(model_name, 'AlgebraicLoopSolver', 'LineSearch');
```

To switch back to the trust-region algorithm, at the MATLAB command line, enter:

```
set_param(model_name, 'AlgebraicLoopSolver', 'TrustRegion');
```

Limitations of the Algebraic Loop Solver

Algebraic loop solving is an iterative process. The Simulink algebraic loop solver is successful only if the algebraic loop converges to a definite answer. When the loop fails to converge, or converges too slowly, the simulation exits with an error.

3. Rabinowitz, Philip, ed. *Numerical Methods for Nonlinear Algebraic Equations*, New York: Gordon and Breach Science Publishers, 1970.

The algebraic loop solver cannot solve algebraic loops that contain any of the following:

- Blocks with discrete-valued outputs
- Blocks with nondouble or complex outputs
- Discontinuities
- Stateflow charts

Remove Algebraic Loops

Use these techniques to remove algebraic loops in a model.

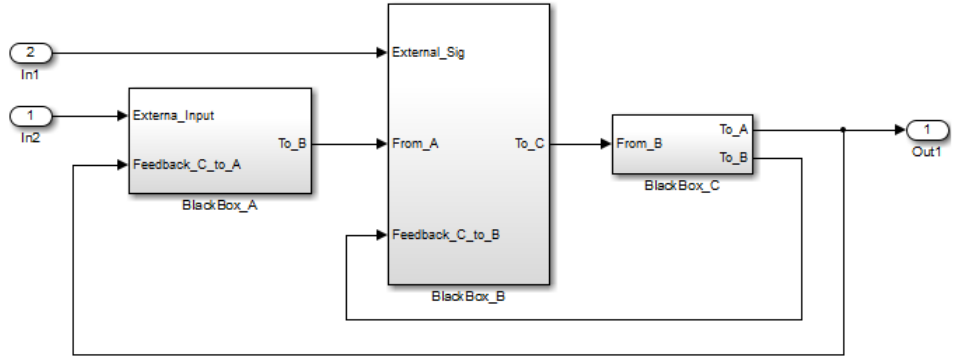
- "Introduce a Delay" on page 3-50
- "Solve Algebraic Loops Manually" on page 3-52
- "Create Initial Guesses Using the IC and Algebraic Constraint Blocks" on page 3-53

Introduce a Delay

Algebraic loops can occur in large models when atomic subsystems create feedback loops.

In the generic model here, there are two algebraic loops that involve subsystems.

- BlackBox_A —> BlackBox_B —> BlackBox_C —> BlackBox_A
- BlackBox_B —> BlackBox_C —> BlackBox_B



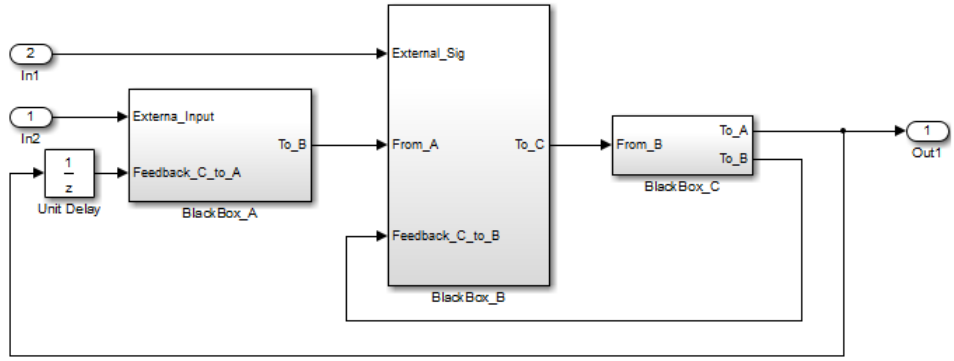
When you update this model, Simulink detects the loop BlackBox_A —> BlackBox_B —> BlackBox_C —> BlackBox_A.

Since you do not know the contents of these subsystems, break the loops by adding a Unit Delay block outside the subsystems. There are three ways to use the Unit Delay block to break these loops:

- Add a Unit Delay between `BlackBox_A` and `BlackBox_C`.
- Add a Unit Delay between `BlackBox_B` and `BlackBox_C`.
- Add Unit Delay blocks to both algebraic loops.

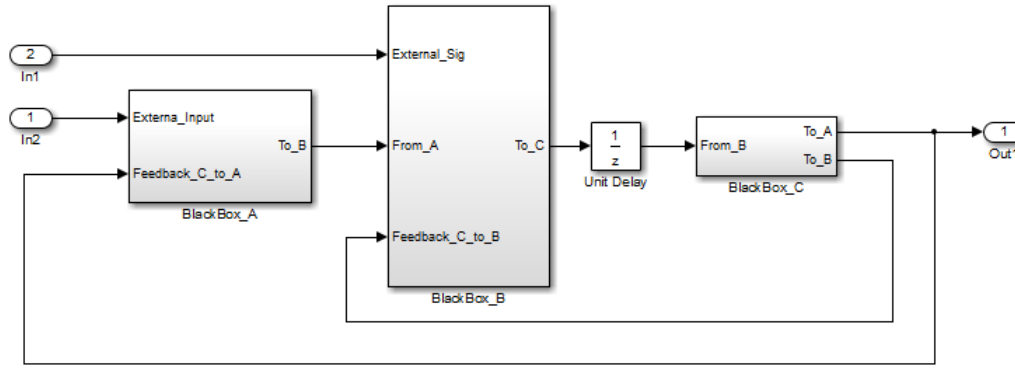
Add a unit delay between BlackBox_A and BlackBox_C

If you add a unit delay on the feedback signal between the subsystems BlackBox_A and BlackBox_C, you introduce the minimum number of unit delays (1) to the system. By introducing the delay before BlackBox_A, BlackBox_B and BlackBox_C use data from the current time step.



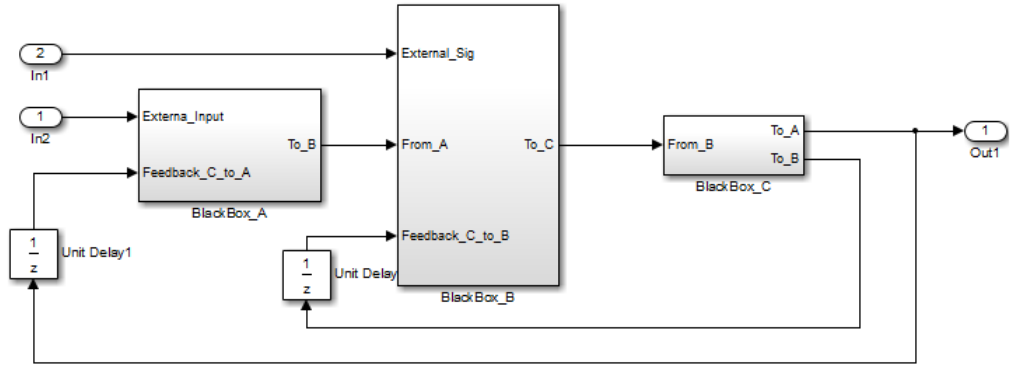
Add a unit delay between BlackBox_B and BlackBox_C

If you add a unit delay between the subsystems BlackBox_B and BlackBox_C, you break the algebraic loop between BlackBox_B and BlackBox_C. In addition, you break the loop between BlackBox_A and BlackBox_C, because that signal completes the algebraic loop. By inserting the Unit Delay block before BlackBox_C, BlackBox_C now works with data from the previous time step only.



Add unit delays to both algebraic loops

In the example here, you insert Unit Delay blocks to break both algebraic loops. In this model, BlackBox_A and BlackBox_B use data from the previous time step. BlackBox_C uses data from the current time step.



Solve Algebraic Loops Manually

If Simulink cannot solve the algebraic loop, the software reports an error. Use one of these techniques to solve the loop manually:

- Restructure the underlying DAEs using techniques such as differentiation or change of coordinates. These techniques put the DAEs in a form that is easier for the algebraic loop solver to solve.
- Convert the DAEs to ODEs, which eliminates any algebraic loops.

Create Initial Guesses Using the IC and Algebraic Constraint Blocks

Your model might contain loops for which the loop solver cannot converge without a good, initial guess for the algebraic states. You can specify an initial guess for the algebraic state variables, but use this technique only when you think the loop is legitimate.

There are two ways to specify an initial guess:

- Place an IC block in the algebraic loop.
- Specify an initial guess for a signal in an algebraic loop using an Algebraic Constraint block.

Remove Artificial Algebraic Loops

Use these techniques to remove artificial algebraic loops in a model:

Eliminate Artificial Algebraic Loops Caused by Atomic Subsystems

If an atomic subsystem causes an artificial algebraic loop, convert the atomic subsystem to a virtual subsystem. This change has no effect on the behavior of the model. When the subsystem is atomic and you simulate the model, Simulink invokes the algebraic loop solver. The solver terminates after one iteration. The algebraic loop is automatically solved because there is no algebraic constant. After you make the subsystem virtual, Simulink does not invoke the algebraic loop solver during simulation.

To convert an atomic subsystem to a virtual subsystem:

1. Open the model that contains the atomic subsystem.
2. Right-click the atomic subsystem and select **Subsystem Parameters**.
3. Clear the **Treat as atomic unit** parameter.
4. Save the changes.

If you replace the atomic subsystem with a virtual subsystem and the simulation still fails with an algebraic loop error, examine the model for one of these:

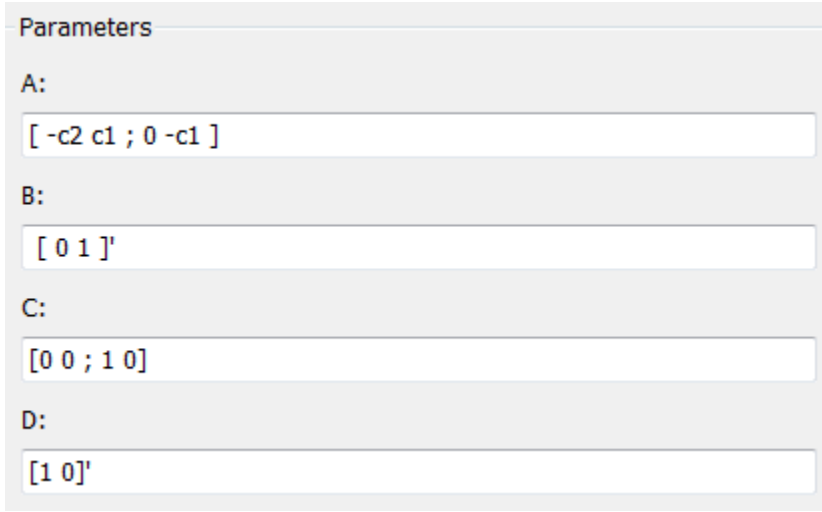
- An algebraic constraint
- An artificial algebraic loop that was not caused by this atomic subsystem

Bundled Signals That Create Artificial Algebraic Loops

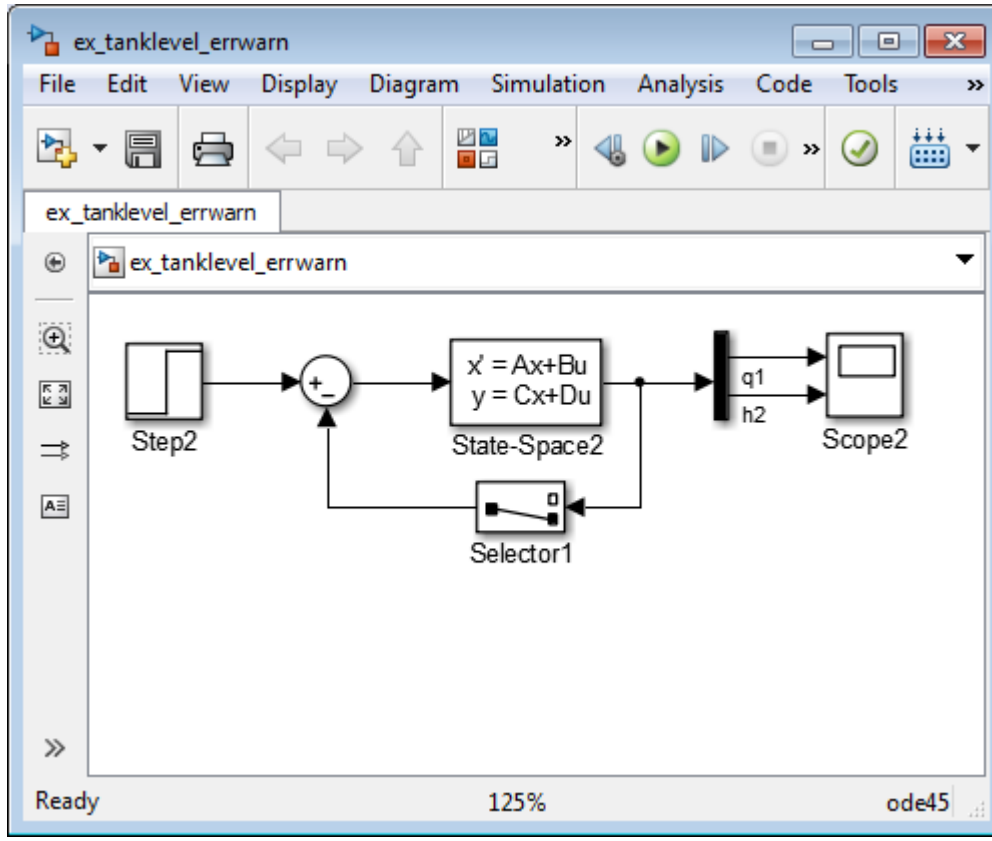
Some models bundle signals together. This bundling can cause Simulink to detect an algebraic loop, even when an algebraic constraint does not exist. If you redirect one or more signals, you may be able to remove the artificial algebraic loop.

In this example, a linearized model simulates the dynamics of a two-tank system fed by a single pump. In this model:

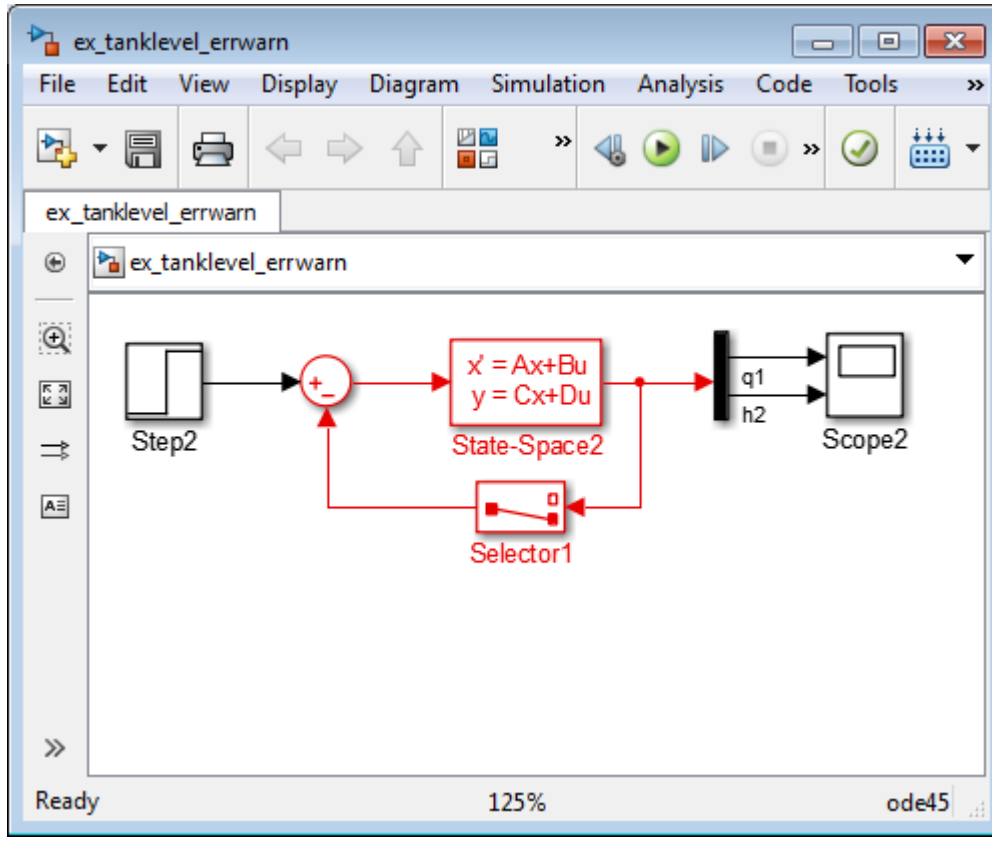
- Output `q1` is the rate of the fluid flow into the tank from the pump.
- Output `h2` is the height of the fluid in the second tank.
- The State-Space block defines the dynamic response of the tank system to the pump operation:



- The output from the State-Space block is a vector that contains `q1` and `h2`.

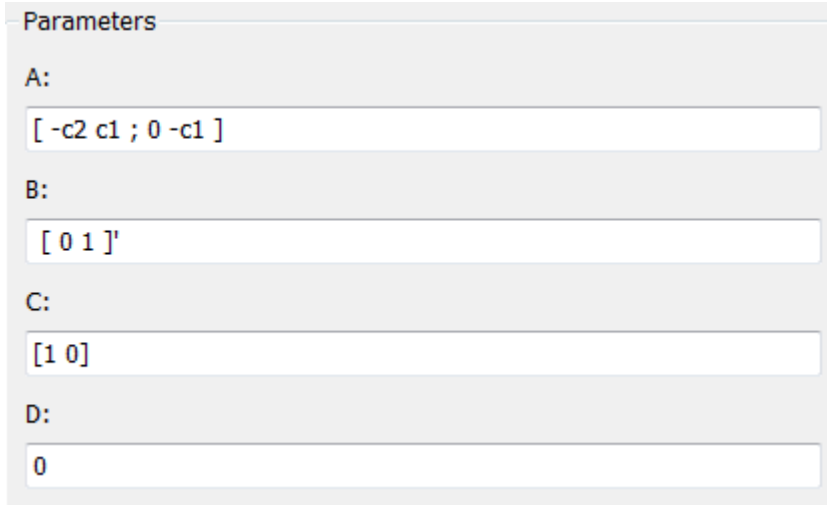


If you simulate this model with the **Algebraic loop** parameter set to `warn` or `error`, Simulink identifies the algebraic loop.



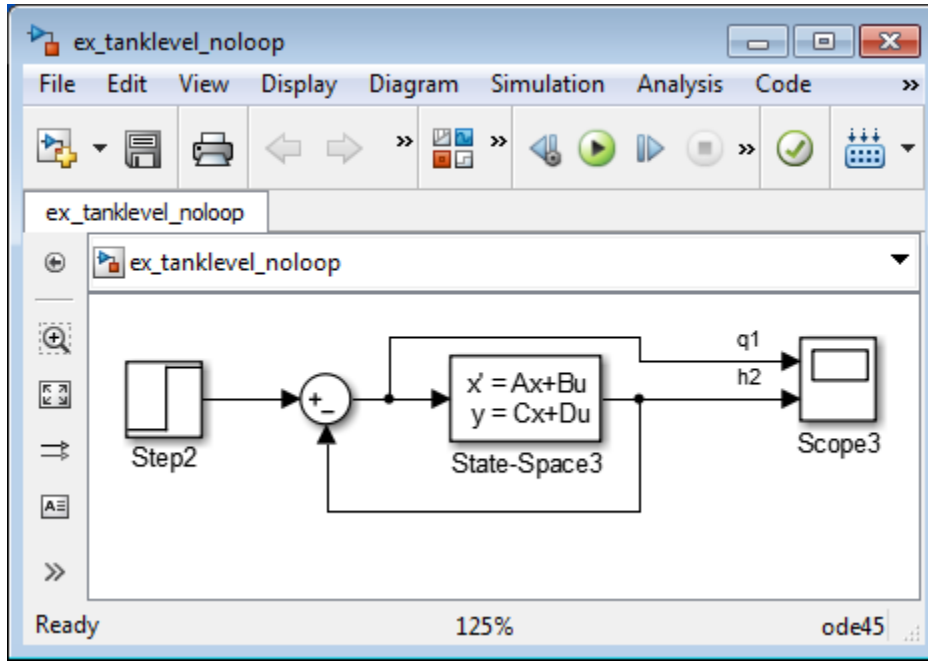
To eliminate this algebraic loop:

1 Change the `C` and `D` matrices as follows:



2 Pass `q1` directly to the Scope instead of through the State-Space block.

Now, the input (`q1`) does not pass directly to the output (the `D` matrix is 0), so the State-Space block no longer has direct feedthrough. The feedback signal has only one element now, so the Selector block is no longer necessary, as you can see in the following model.



Model and Block Parameters to Diagnose and Eliminate Artificial Algebraic Loops

There are two parameters to consider when you think that your model has an artificial algebraic loop:

- **Minimize algebraic loop occurrences** parameter — Specify that Simulink try to eliminate any artificial algebraic loops for:
  - Atomic subsystems — In the Subsystem Parameters dialog box, select **Minimize algebraic loop occurrences**.
  - Model blocks — For the referenced model, in the **Model Referencing** pane of Configuration Parameters, select **Minimize algebraic loop occurrences**.
- **Minimize algebraic loop** parameter — Specifies what diagnostic action Simulink takes if the **Minimize algebraic loop occurrences** parameter has no effect.

  The **Minimize algebraic loop** parameter is in the **Diagnostics** pane of Configuration Parameters. The diagnostic actions for this parameter are:

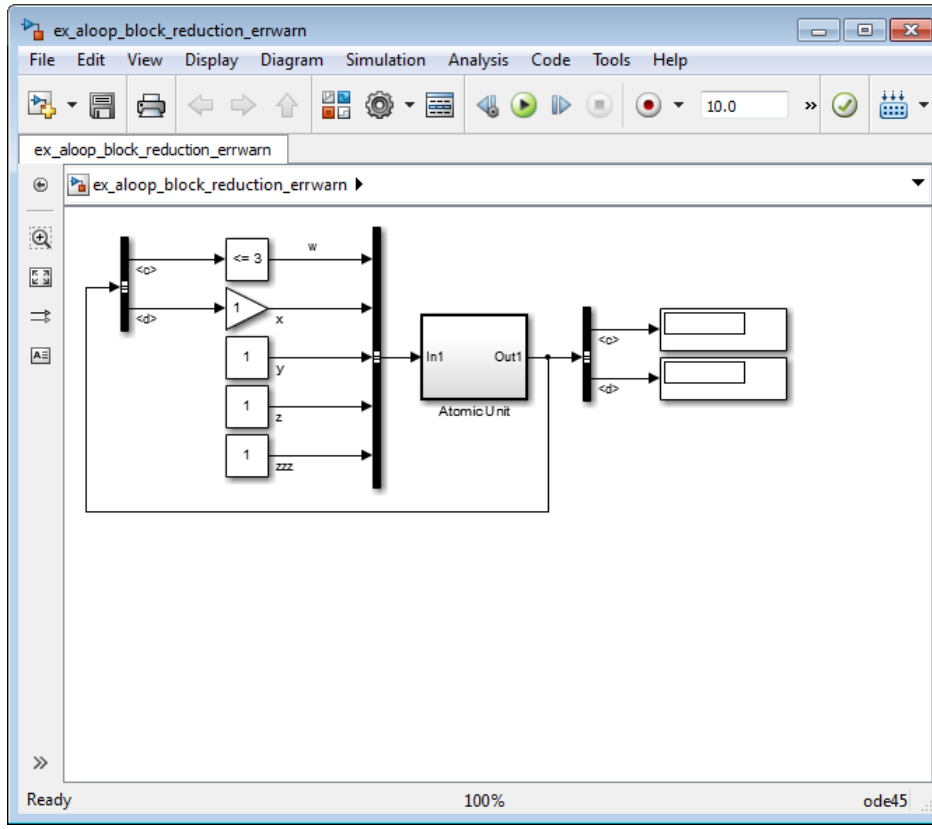
Setting	Simulation Response
`none`	Simulink takes no action.
`warning`	Simulink displays a warning that the **Minimize algebraic loop occurrences** parameter has no effect.
`error`	Simulink terminates the simulation and displays an error that the **Minimize algebraic loop occurrences** parameter has no effect.

Block Reduction and Artificial Algebraic Loops

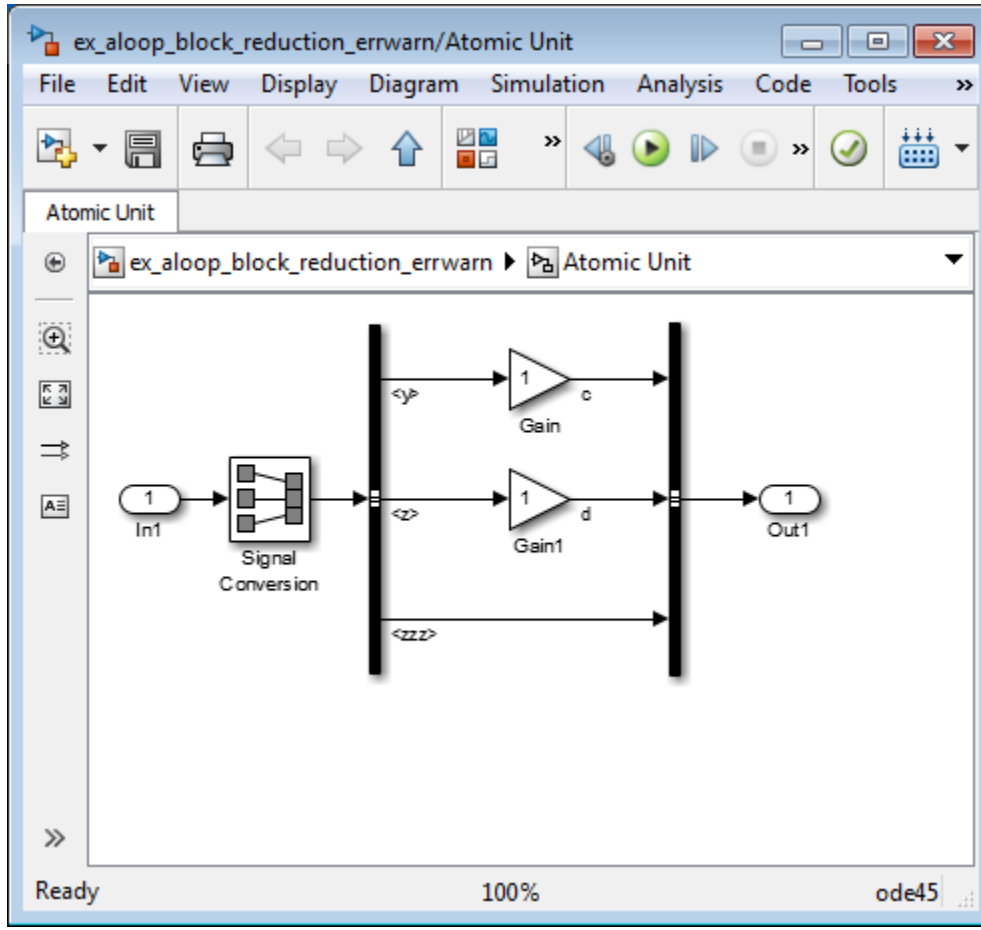
When you enable the **Block reduction** optimization in Model Configuration Parameters, Simulink collapses certain groups of blocks into a single, more efficient block, or removes them entirely. Enabling block reduction results in faster execution during model simulation and in generating code.

Enabling block reduction can also help Simulink solve artificial algebraic loops.

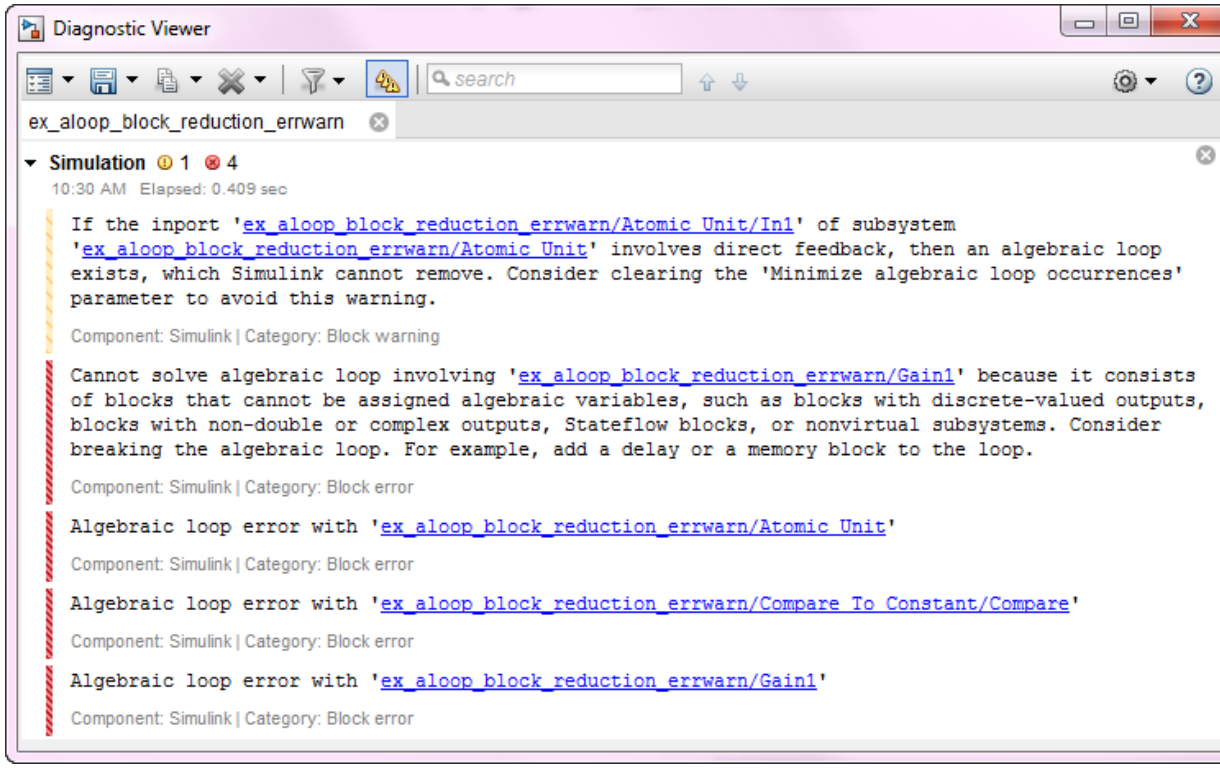
Consider the following example model.



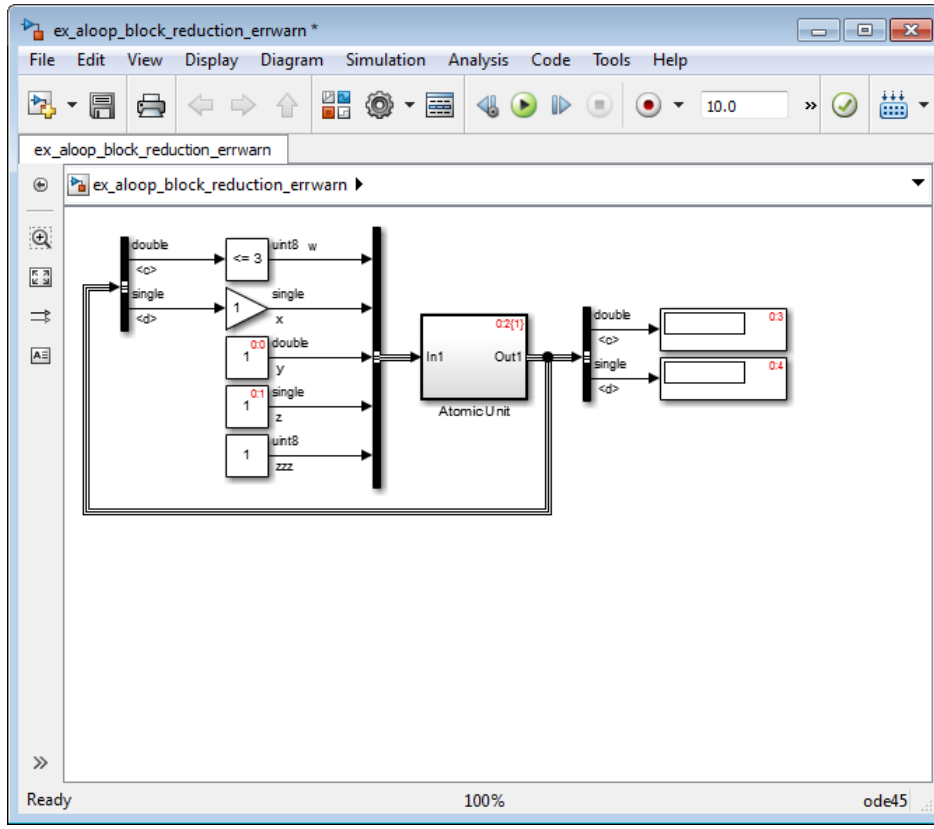
ex_aloop_block_reduction_errwarn
File Edit View Display Diagram Simulation Analysis Code Tools Help
10.0
ex_aloop_block_reduction_errwarn
ex_aloop_block_reduction_errwarn
<c>
<d>
<= 3
w
1
x
1
y
1
z
1
zzz
In1
Out1
Atomic Unit
<c>
<d>
Ready
100%
ode45



Initially, block reduction is turned off. When you simulate this model, the Atomic Unit subsystem and Gain and Compare to Constant blocks are part of an algebraic loop that Simulink cannot solve.



If you enable block reduction and sorted order, and resimulate the model, Simulink does not display the sorted order for blocks that have been reduced. You can now quickly see which blocks have been reduced.



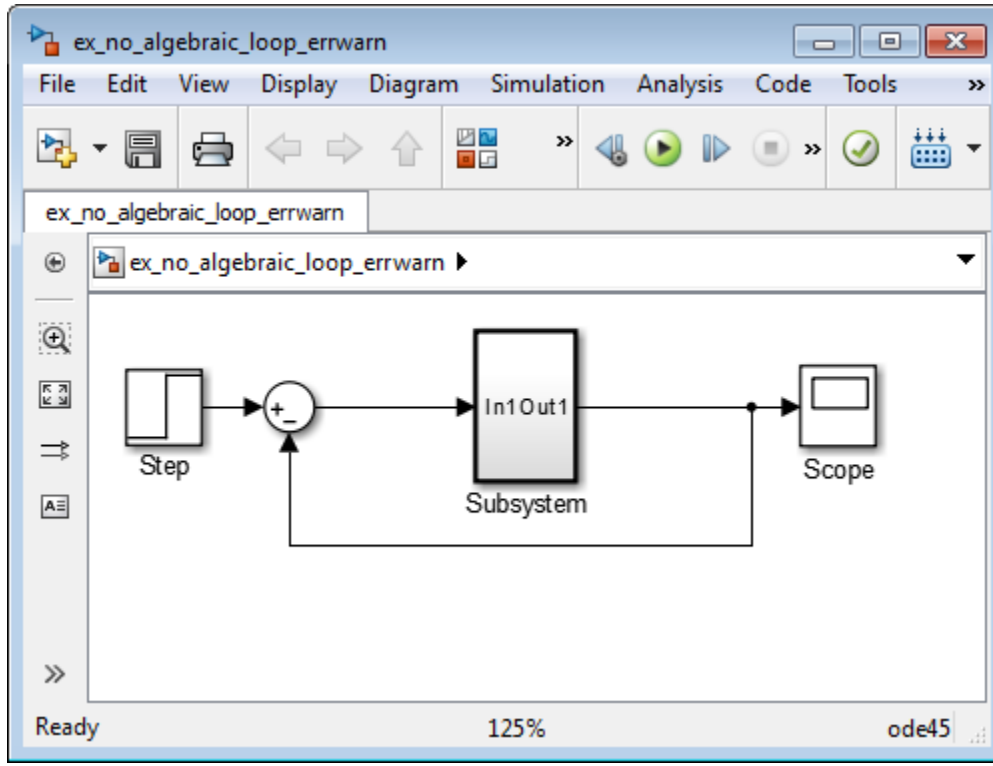
The Compare to Constant and Gain blocks have been eliminated from the model, so they no longer generate an algebraic loop error. The Atomic Unit subsystem generates a warning:

```
Warning: If the inport 'ex_aloop_block_reduction_errwarn/
Atomic Unit/In1' of subsystem 'ex_aloop_block_reduction_errwarn/
Atomic Unit' involves direct feedback, then an algebraic loop
exists, which Simulink cannot remove. Consider clearing the
'Minimize algebraic loop occurrences' parameter to avoid this
warning.
```

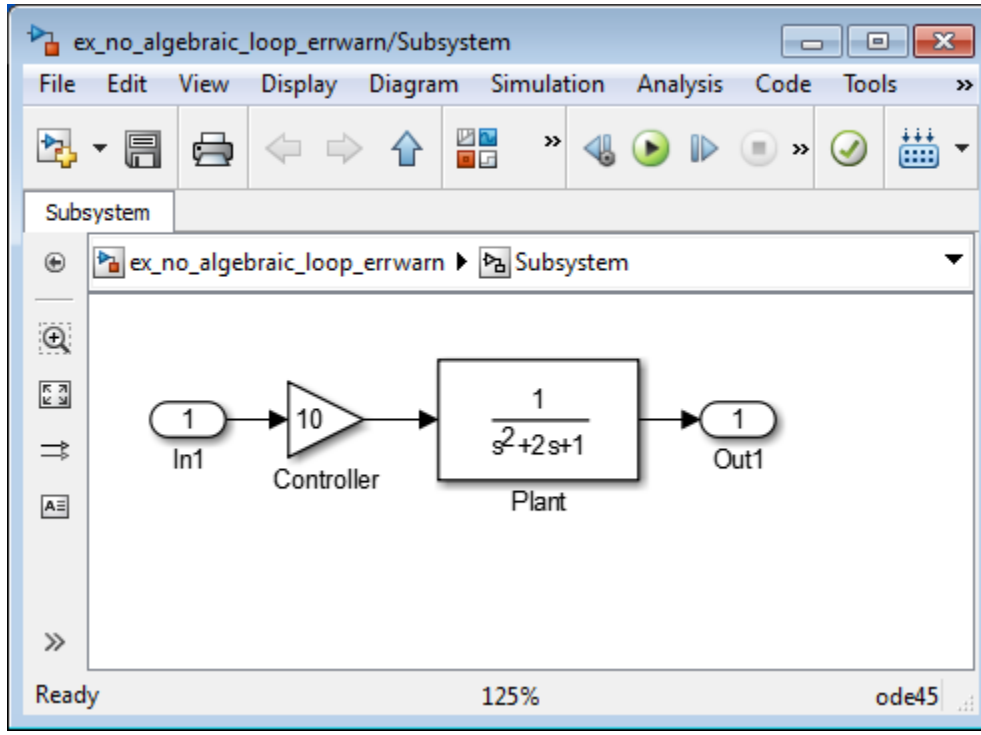
Tip Use Bus Selector blocks to pass only the required signals into atomic subsystems.

How Simulink Eliminates Artificial Algebraic Loops

When you enable **Minimize algebraic loop occurrences**, Simulink tries to eliminate artificial algebraic loops. In this example, the model contains an atomic subsystem that causes an artificial algebraic loop.



The contents of the atomic subsystem are not direct feedthrough, but Simulink identifies the atomic subsystem as direct feedthrough.



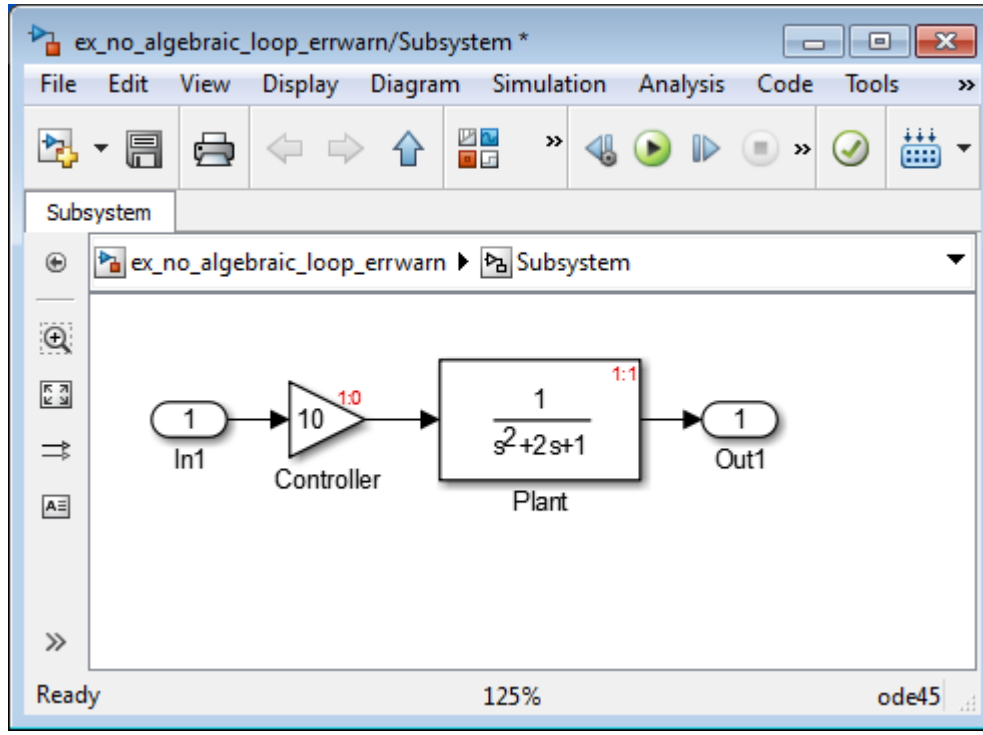
If the **Algebraic loop** diagnostic is set to `error`, simulating the model results in an error because the model contains an artificial algebraic loop involving its atomic subsystem.

To eliminate this algebraic loop,

1. Create the model from the preceding graphics, with the atomic subsystem that causes the artificial algebraic loop.
2. In the **Diagnostics** pane of Model Configuration Parameters, set the **Algebraic loop** parameter to `warning` or `none`.
3. In the **Data Import/Export** pane, make sure the **Signal logging** parameter is disabled. If signal logging is enabled, Simulink cannot eliminate artificial algebraic loops.
4. To display the sorted order for this model and the atomic subsystem, select **Display > Blocks > Sorted Execution Order**.

Reviewing the sorted order can help you understand how to eliminate the artificial algebraic loop.

All the blocks in the subsystem execute at the same level: 1. (0 is the lowest level, indicating the first blocks to execute.)

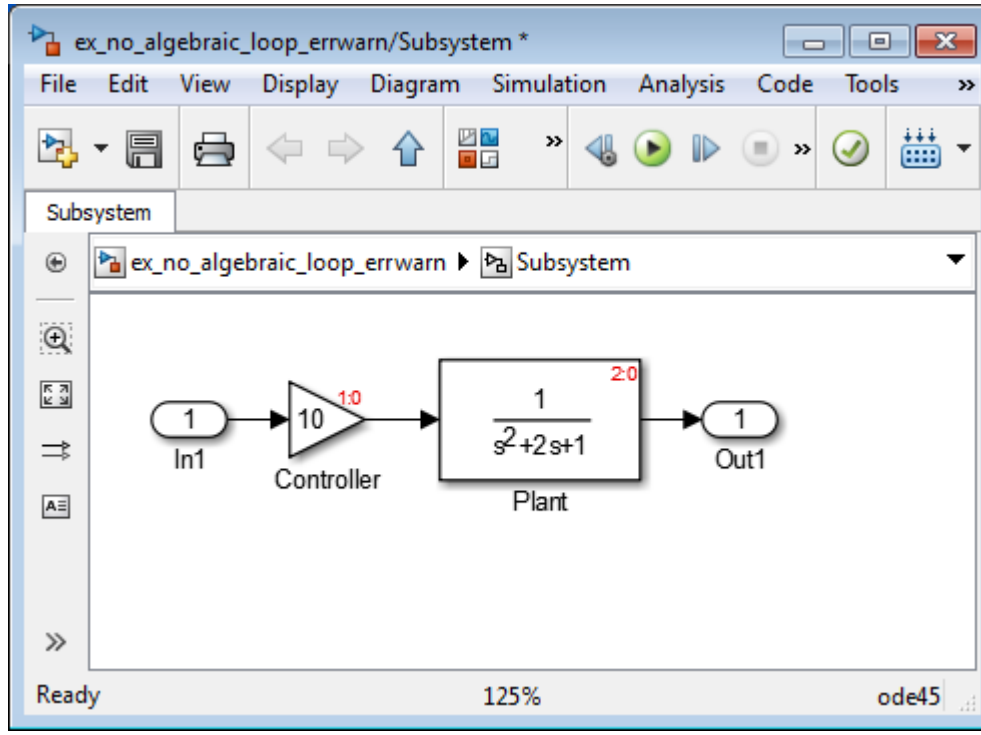


Note For more information about sorted order, see "Control and Display the Sorted Order" on page 35-28.

5 In the top-level model's **Subsystem Parameters** dialog box, select **Minimize algebraic loop occurrences**. This parameter directs Simulink to try to eliminate the algebraic loop that contains the atomic subsystem, when it simulates the model. Save the changes.

6 Click **Simulation** > **Update Diagram** to recalculate the sorted order.

Now there are two levels of sorted order inside the subsystem: 1 and 2.

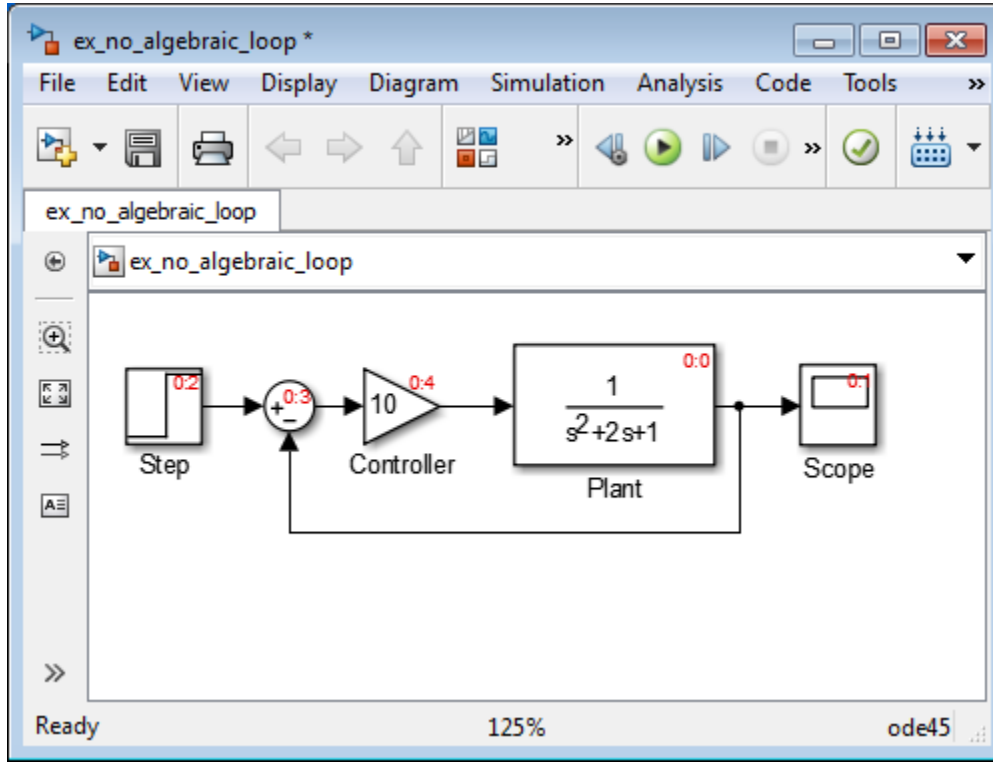


To eliminate the artificial algebraic loop, Simulink tries to make the input of the subsystem or referenced model non-direct feedthrough.

When you simulate a model, all blocks execute methods in this order:

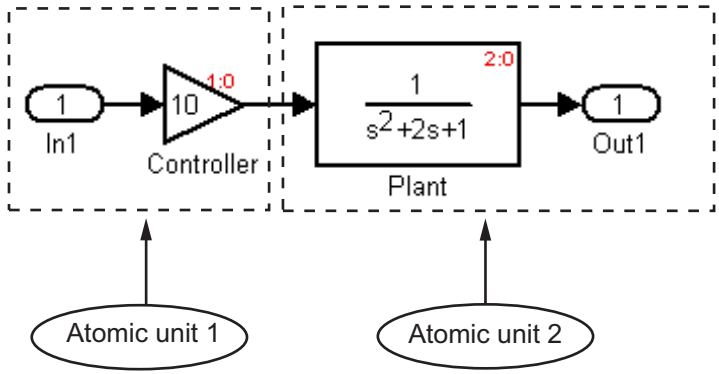
1. `mdlOutputs`
2. `mdlDerivatives`
3. `mdlUpdate`

In the original version of this model, the execution of the `mdlOutputs` method starts with the Plant block because the Plant block is non-direct feedthrough. The execution finishes with the Controller block.



Note For more information about these methods, see "Block Methods" on page 3-15.

If you enable the **Minimize algebraic loop occurrences** parameter for the atomic subsystem, Simulink divides the subsystem into two atomic units.



These conditions are true:

- Atomic unit 2 is not direct feedthrough.
- Atomic unit 1 has only a `mdlOutputs` method.

Only the `mdlDerivatives` or `mdlUpdate` methods of Atomic unit 2 need the output of Atomic unit 1. Simulink can execute what normally would have been executed during the `mdlOutput` method of Atomic unit 1 in the `mdlDerivatives` methods of Atomic unit 2.

The new execution order for the model is:

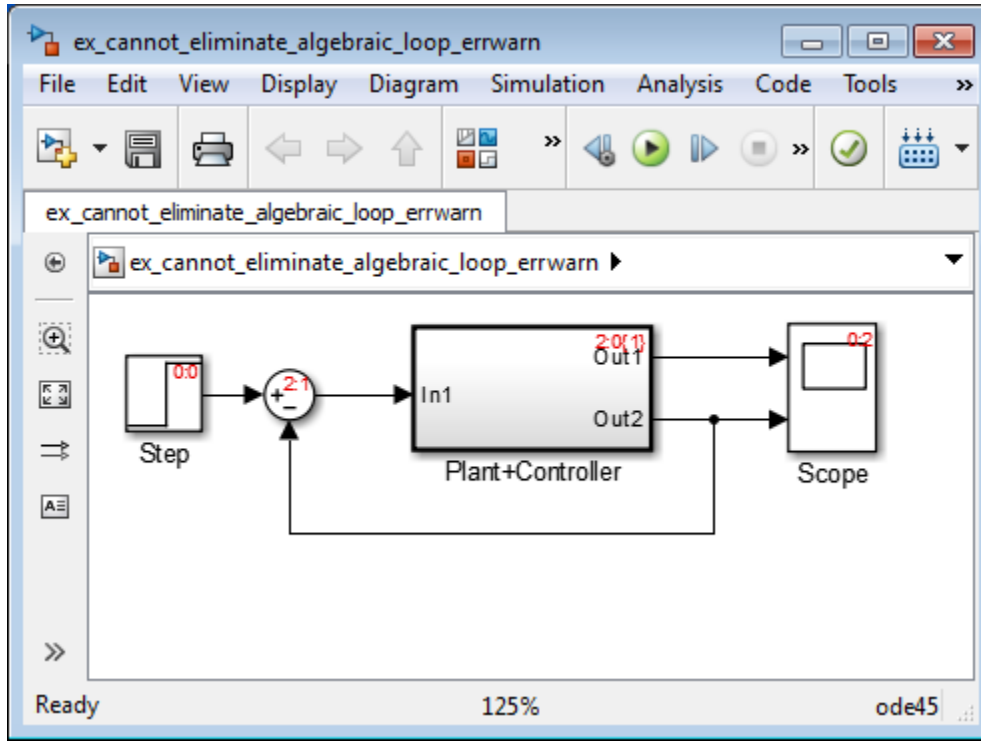
1. `mdlOutputs` method of model
   a. `mdlOutputs` method of Atomic unit 2
   b. `mdlOutputs` methods of other blocks
2. `mdlDerivatives` method of model
   a. `mdlOutputs` method of Atomic unit 1
   b. `mdlDerivatives` method of Atomic unit 2
   c. `mdlDerivatives` method of other blocks

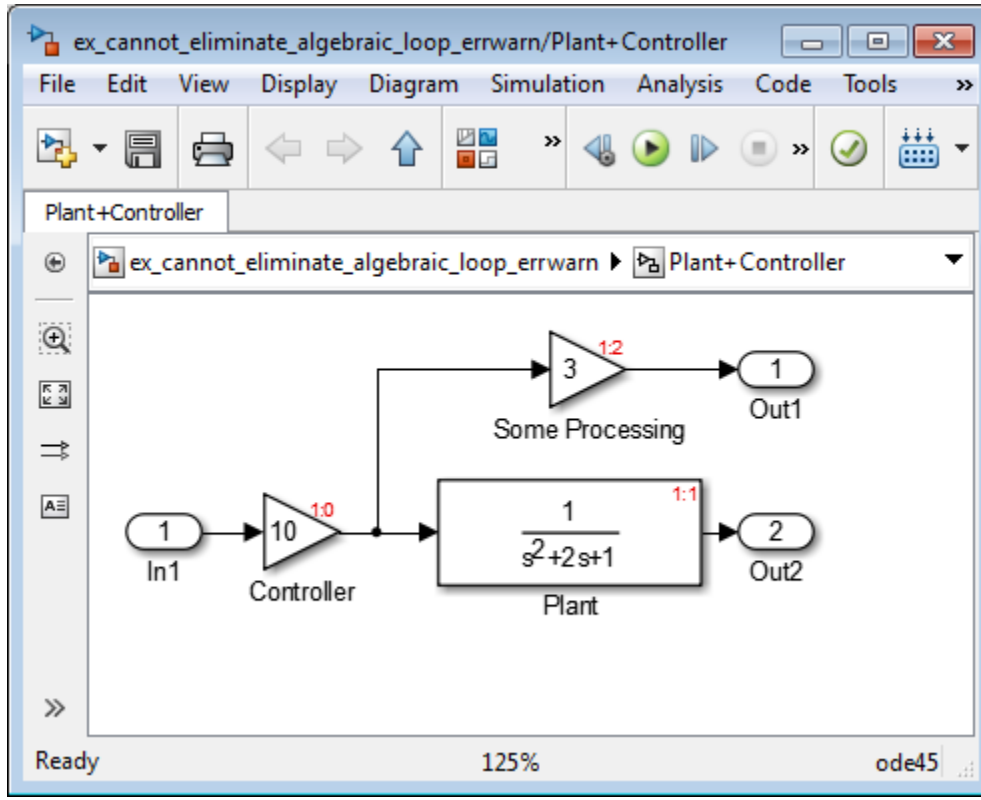
For the **Minimize algebraic loop occurrences** technique to be successful, the subsystem or referenced model must have a non-direct-feedthrough block connected directly to an Inport. Simulink can then set the `DirectFeedthrough` property of the block Inport to `false` to indicate that the input port does not have direct feedthrough.

When Simulink Cannot Eliminate Artificial Algebraic Loops

Setting the **Minimize algebraic loop occurrences** parameter does not always work. Simulink cannot change the `DirectFeedthrough` property of an Inport for an atomic subsystem if the Inport is connected to an Outport only through direct-feedthrough blocks.

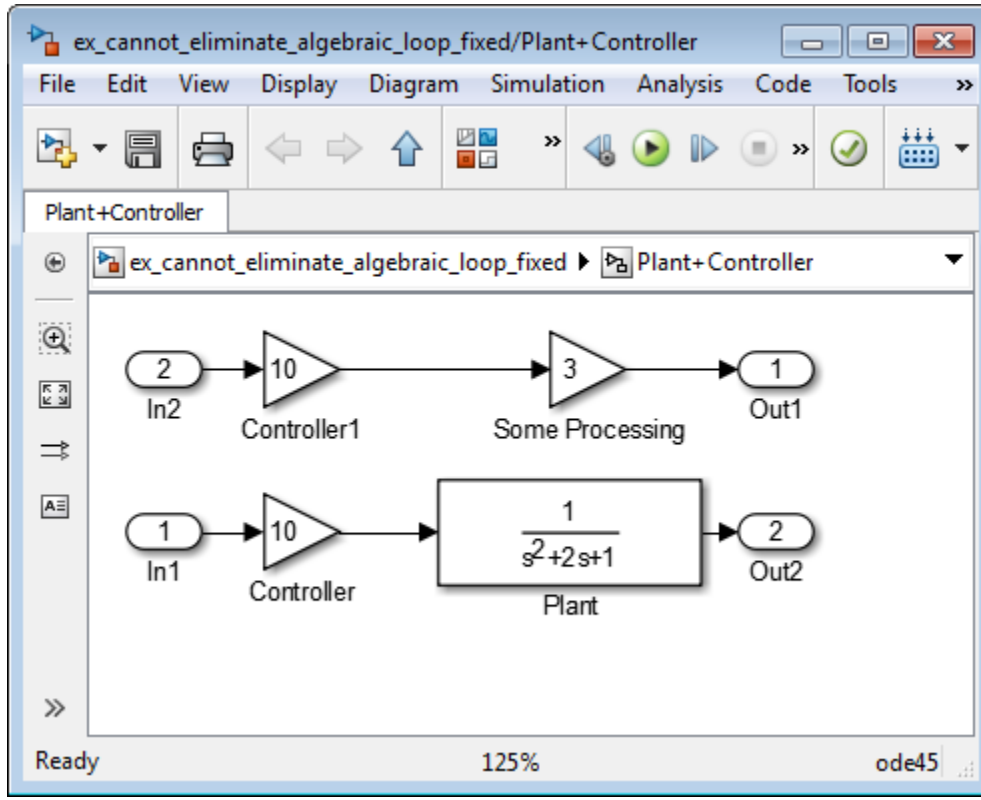
In this model, the subsystem Plant+Controller causes an algebraic loop, but it has an extra Gain block and an extra output.





Simulink cannot move the `mdlOutputs` method of the Controller block to the `mdlDerivative` method of an Atomic unit 1 because the output of the atomic subsystem depends on the output of the Controller block. You cannot make the subsystem non-direct-feedthrough.

You can modify this model to eliminate the artificial algebraic loop by redefining the atomic subsystem by adding additional Inport and Gain blocks, as you can see in the model here. Doing so makes In1 non-direct-feedthrough and In2 direct feedthrough, thus breaking the algebraic loop.



Managing Large Models with Artificial Algebraic Loops

Adopt these design techniques for large models with algebraic loops:

- Avoid creating loops that contain discontinuities or nondouble data types. The Simulink algebraic loop solver is gradient-based and must solve algebraic constraints to high precision.
- Develop a scheme for clearly identifying atomic subsystems as direct feedthrough or not direct feedthrough. Use a visual scheme such as coloring the blocks or defining a block-naming convention.
- If you plan to generate code for your model, enable the **Minimize algebraic loop occurrences** parameter for all atomic subsystems. When possible, make sure that

the input ports for the atomic subsystems are connected directly to non-direct-feedthrough blocks.

- Avoid combining non-direct-feedthrough and direct-feedthrough paths using the Bus Creator or Mux blocks. Simulink may not be able to eliminate any resulting artificial algebraic loops. Instead, consider clustering the non-direct-feedthrough and direct-feedthrough objects in separate subsystems.

  Use Bus Selector blocks to pass only the required signals into atomic subsystems.

Model Blocks and Direct Feedthrough

When a Model block is part of a cycle, and the block is a direct feed through block, an algebraic loop can result. An algebraic loop in a model is not necessarily an error, but it can give unexpected results. See:

- "Highlight Algebraic Loops in the Model" on page 3-43 for information about seeing algebraic loops graphically.
- "Display Algebraic Loop Information" on page 33-31 for information about tracing algebraic loops in the debugger.
- The "Model Configuration Parameters: Diagnostics" pane "Algebraic loop" option for information on detecting algebraic loops automatically.

Direct Model Block Feedthrough Caused by Submodel Structure

A Model block can be a direct feed through block due to the structure of the referenced model. Where direct feed through results from sub model structure, and causes an unwanted algebraic loop, you can:

- Automatically eliminate the algebraic loop using techniques described in:
  - "Minimize algebraic loop"
  - "Minimize algebraic loop occurrences"
  - "Remove Algebraic Loops" on page 3-50
- Manually insert the number of Unit Delay blocks needed to break the algebraic loop.

Direct Model Block Feedthrough Caused by Model Configuration

Generic Real Time (`grt`) and Embedded Real Time (`ert`) based targets provide the **Single output/update function** option on the **Configuration Parameters** dialog.

This option controls whether generated code has separate output and update functions, or a combined output/update function. See:

- "Entry-Point Functions and Scheduling" (Simulink Coder) for information about separate and combined output and update functions.
- "Single output/update function" (Simulink Coder) for information about specifying whether code has separate or combined functions.

When **Single output/update function** is enabled (default), a Model block has a combined output/update function. The function makes the block a direct feed through block for all inports, regardless of the structure of the referenced model. Where an unwanted algebraic loop results, you can:

- Disable **Single output/update function**. The code for the Model block then has separate output and update functions, eliminating the direct feed through and hence the algebraic loop.
- Automatically eliminate the algebraic loop using techniques described in:
  - "Minimize algebraic loop"
  - "Minimize algebraic loop occurrences"
  - "Remove Algebraic Loops" on page 3-50
- Manually insert one or more Unit Delay blocks as needed to break the algebraic loop.

Changing Block Priorities When Using Algebraic Loop Solver

During the updating phase of simulation, Simulink determines the simulation execution order of block methods. This block invocation ordering is the sorted order.

If you assign priorities to nonvirtual blocks to indicate to Simulink their execution order relative to other blocks, the algebraic loop solver does not honor these priorities when attempting to solve any algebraic loops.

Modeling Dynamic Systems

Creating a Model

Create a Template from a Model

Create a Simulink template from a model to reuse or share the settings and contents of the model without copying the model each time. Create templates only from models that do not have external file dependencies (for example, model references, data dictionary, scripts, S-functions, or other file dependencies). If you want to include other dependent files, use a project template instead. See "Using Templates to Create Standard Project Settings" on page 16-42.

1. In the model, select **File** > **Export Model to** > **Template**.
2. In the Export *`modelname`* to Model Template dialog box, edit the template title and enter a description of the template.

   When you use the template, the Simulink start page displays this title and description.
3. In the **Template file** box, select a file name and location for the template SLTX file.

   Tip Save the template on the MATLAB path to make it visible in the Simulink start page. If you save in a location that is not on the path, the new template is visible in the start page only in the current MATLAB session. Saving the template does not add the destination folder to the path.
4. (Optional) Specify a thumbnail image for the template by clicking **Change** and selecting an image file.
5. Click **Export**.

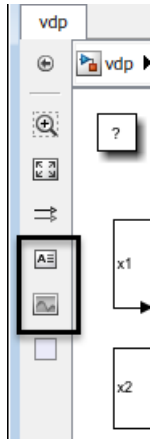
Describe Models Using Annotations

Annotations are visual elements that you can use to add descriptive notes and callouts to your model. You can also add annotations that perform an action when you click them. Shortcuts on the Simulink Editor palette help you to create annotations.



Text annotations can contain any combination of:

- Text
- Images
- Equations using TeX commands
- Hyperlinks that open a website or perform MATLAB functions

Also, you can create an annotation that can hold only an image.

Add a Text Annotation

To create a text annotation, use one of these options:

- Double-click the canvas where you want to create the annotation and select **Create Annotation** from the menu.
- Click the annotation box  on the palette and then click the canvas.
- Drag the annotation box to the canvas.

After you add the text annotation, you can:

- Apply formatting changes to text or insert an image or a table using the formatting toolbar.
- Apply additional formatting, using the **Paragraph** menu on the context menu. For example, you can create bullet and numbered lists from this menu.
- Add hyperlinks using the context menu. You can use hyperlinks to open a website or make an annotation interactive using MATLAB commands.
- Apply properties using the Property Inspector. To view the Property Inspector, select **View > Property Inspector**.

Resize an Annotation

An annotation resizes as you enter content. You can also resize an annotation by dragging the corners. For example, you can hold **Shift** as you drag to resize proportionally.

After you resize an annotation, the annotation stays that size until you resize it again, regardless of the content size. To revert to the original height or width of the annotation, in the Property Inspector, under **Appearance**, clear the **Fixed height** or **Fixed width** check box.

Make an Annotation Interactive

To make the annotation interactive, use a hyperlink on any content of a text annotation.

1. In the annotation, select the content that you want to make interactive. To make the entire annotation interactive, select all the content.
2. Right-click and select **Hyperlink** from the context menu.
3. In the Hyperlink dialog box, either:
   - Select **URL Address** as the target and enter the web address in the **Code** box.
   - Select **MATLAB Code** as the target and enter MATLAB functions in the **Code** box.
4. Click **OK**.

For an alternative approach, see “Add an Annotation Callback” on page 4-9

Add an Image Annotation

You can add an annotation that contains only an image. Add an image annotation when you want to be able to resize or move the image independently of text. For example, you can put your company logo in an image and size and position it at a particular location in the model. You can also associate MATLAB functions with a click on the image.

Tip To include an image such as a logo in every new model, add the image to your default template. See "Create a Template from a Model" on page 4-2.

1. From the Simulink Editor palette, drag an **Image** box into the model.
2. Add an image to the box. You can either:
   - Double-click the image box and browse to an image.
   - Paste an image from the clipboard. Right-click the image box and select **Paste Image**.

Tip If you resize the image, you can reset it to its original size. Right-click the image and select **Format > Restore Size**.

To associate an action with an image:

1. Select the image.
2. In the Property Inspector, under **ClickFcn**, add the MATLAB functions that you want to invoke with a click on the image.

Use TeX Commands in an Annotation

You can add TeX formatting commands to your annotation for mathematical and other symbols and Greek letters. For the supported TeX commands, see "TeX for Simulink Model Annotations" on page 4-14.

1. Add supported TeX commands to your annotation. For example, add this text:

   ```
   \sigma \kappa \mu
   ```

2. With the annotation selected, or with the text cursor in the annotation, in the Property Inspector, under **Appearance**, select **Enable TeX commands**.

When you click outside the annotation, the TeX commands appear as symbols in the annotation.

Add Lines to Connect Annotations to Blocks

You can add connector lines between an annotation and a block in the model. The connector is similar to a callout, identifying the block that an annotation applies to. If you move the annotation or block, the connector moves or resizes to keep the connection.

1. Place the cursor over the annotation outline where you want the connector to start.
2. When the cursor is a cross hair, drag the connector line to the block you want to connect to.

Tip To specify the color or width of the connector, right-click it and use the **Format** menu.

- “Add an Annotation Callback” on page 4-9

Show or Hide Annotations

In this section...

By default, all annotations appear in the model. To hide an annotation, first configure it for hiding by converting it to markup. Then select **Display** > **Hide Markup**.

Configure an Annotation for Hiding

You can configure an annotation so that you can hide or display it.

1. Right-click the annotation.
2. From the context menu, select **Convert to Markup**.

A markup annotation has a light-blue background, regardless of the background color you set. If you change a markup annotation back to a regular annotation, the annotation returns to the background color you set.

To change a markup annotation to a regular annotation (one that you cannot hide), from the annotation context menu, select **Convert to Annotation**.

Hide Markup Annotations

To hide all markup annotations, select **Display** > **Hide Markup**.

To display hidden markup annotations, select **Display** > **Show Markup**.

Note In a model reference hierarchy, **Show Markup** and **Hide Markup** apply only to the current model reference level.

Add an Annotation Callback

In this section...

Annotation Callback Functions

You can associate these callback functions with annotations.

Click Function

You can make an annotation interactive using a link. Alternatively, you can make an annotation interactive by adding a click function callback. A click function is a MATLAB function that Simulink invokes when you click an annotation.

You can add a click function callback programmatically or interactively. To create a click function programmatically, see `Simulink.Annotation`. To create one interactively, see “Associate a Click Function with an Annotation” on page 4-9.

The text for annotations associated with a click function appears in blue.

Load Function

Simulink invokes a load function when you load the model that contains the associated annotation. To associate a load function with an annotation, set the `LoadFcn` property of the annotation to the desired function (see `Simulink.Annotation`).

Delete Function

A delete function is invoked before you delete an annotation. To associate a delete function with an annotation, set the `DeleteFcn` property of the annotation to the desired function (see `Simulink.Annotation`).

Associate a Click Function with an Annotation

You can interactively associate a click function with an annotation.

1. Add an annotation.
2. Open the Annotation Properties dialog box. Right-click the annotation and select **Properties**.
3. Open the **ClickFcn** tab. In the text box under **ClickFcn**, enter the MATLAB code that defines the click function, and click **OK**.

Tip Alternatively, you can use the annotation text as the click function. Then, in the Annotation Properties dialog box, select the **Use annotation text as click callback** check box.

Select and Edit Click-Function Annotations

If you associate an annotation with a click function, clicking invokes the function rather than selecting the annotation. To select it instead, drag a selection box around it. To edit it, right-click it and select **Edit Text** or **Properties**.

- "Describe Models Using Annotations" on page 4-3

Create an Annotation Programmatically

In this section...

Annotations API

Use MATLAB code to get and set the properties of annotations.

- `Simulink.Annotation` class

  Set the properties of annotations.
- `getCallbackAnnotation` function

  Get the `Simulink.Annotation` object for the annotation associated with the currently executing annotation callback function. Use this function to determine which annotation invoked the current callback. This function is also useful if you write a callback function in a separate MATLAB file that contains multiple callback calls.

Create Annotations Programmatically

Alternatively, you can use a `Simulink.Annotation` object to create an annotation. For example:

```
open_system('vdp')
note = Simulink.Annotation('vdp/This is an annotation');
note.position = [10,50]
```

Delete an Annotation Programmatically

To delete an annotation programmatically, use the `find_system` function to get the annotation handle. Then use the `delete` function to delete the annotation. For example:

```
delete(find_system(gcs, 'FindAll', 'on', 'type', 'annotation',...
'text', 'programmatically created'));
```

Find Annotations in a Model

Use command such as this to find all of the annotations in a model.

```
open_system('vdp')
annotations = find_system(gcs,'FindAll','on','Type','annotation')
```

```
annotations =

   34.0004
   33.0009
```

See the `find_system` documentation for specifying levels of the model to search.

To identify the annotation handle of annotations, enter:

```
get_param(annotations,'Name')
```

```
ans =

    'Copyright 2004-2014 The MathWorks, Inc.'
    'van der Pol Equation'
```

Show or Hide Annotations Programmatically

When you create an annotation, by default it appears in the model. You can configure an annotation to be a markup annotation, which you can hide.

To find out whether the first annotation is a markup annotation, use commands such as this:

```
open_system('vdp')
annotations = find_system(gcs,'FindAll','on','Type','annotation')
get_param(annotations(1),'MarkupType')
```

To configure the first annotation in a model so that it can be hidden, use a commands such as this:

```
set_param(annotations(1),'MarkupType','markup')
```

To reconfigure that annotation to always appear, use this command:

```
set_param(annotations(1),'MarkupType','model')
```

To find out whether a model is configured to show or hide markup annotations, use a command such as this for the `vdp` model:

```
get_param(vdp,'ShowMarkup')
```

To configure a model to hide markup annotations, use a command such as this for the `vdp` model:

```
set_param(vdp,'ShowMarkup','off')
```

Create a Subsystem

In this section...

Subsystem Advantages

Subsystems allow you to create a hierarchical model comprising many layers. A subsystem is a set of blocks that you replace with a single Subsystem block. As your model increases in size and complexity, you can simplify it by grouping blocks into subsystems. Using subsystems:

- Establishes a hierarchical block diagram, where a Subsystem block is on one layer and the blocks that make up the subsystem are on another
- Keeps functionally related blocks together
- Helps reduce the number of blocks displayed in your model window

When you make a copy of a subsystem, that copy is independent of the source subsystem. To reuse the contents of a subsystem across a model or across models, use either model referencing or a library.

Ways to Create a Subsystem

You can create a subsystem using these approaches:

- Add a Subsystem block to your model, and then open the block and add blocks to the subsystem window. “Create a Subsystem in a Subsystem Block” on page 4-18.
- Select the blocks that you want in the subsystem, and from the right-click context menu, select **Create Subsystem from Selection**. “Create a Subsystem from Selected Blocks” on page 4-19.
- Copy a model to a subsystem. In the Simulink Editor, copy and paste the model into a subsystem window, or use `Simulink.BlockDiagram.copyContentsToSubsystem`.

- Copy an existing Subsystem block to a model.
- Drag a box around the blocks you want in a subsystem, and select the type of subsystem you want from the context options. “Create a Subsystem Using Context Options” on page 4-20.

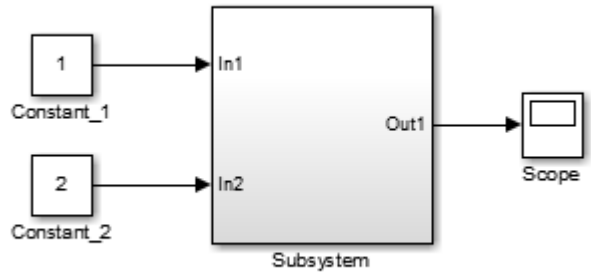
Create a Subsystem in a Subsystem Block

Add a Subsystem block to the model, and then add the blocks that make up the subsystem.

1. Copy the Subsystem block from the Ports & Subsystems library into your model.
2. Open the Subsystem block by double-clicking it.
3. In the empty subsystem window, create the subsystem contents. Use Inport blocks to represent input from outside the subsystem and Outport blocks to represent external output.

   For example, this subsystem includes a Sum block and Inport and Outport blocks to represent input to and output from the subsystem.

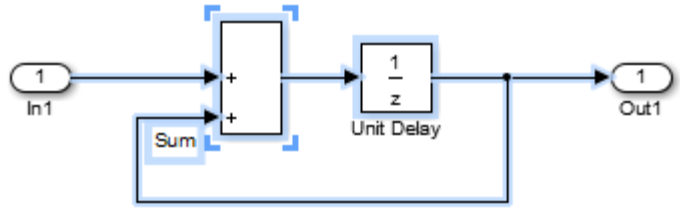
   When you close the subsystem window, the Subsystem block includes a port for each Inport and Outport block.



Create a Subsystem from Selected Blocks

1 Select the blocks that you want to include in a subsystem. To select multiple blocks in one area of the model, drag a bounding box that encloses the blocks and connecting lines that you want to include in the subsystem.

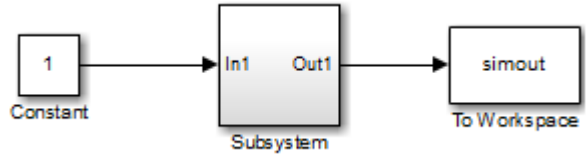
The figure shows a model that represents a counter. The bounding box selects the Sum and Unit Delay blocks.



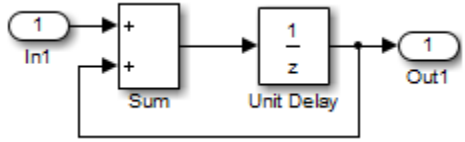
2 Select **Diagram > Subsystems & Model Reference > Create Subsystem from Selection**.

A Subsystem block appears, which encloses the selected blocks.

Tip Resize the Subsystem block so the port labels are readable.



To edit the subsystem contents, open the Subsystem block. For example:

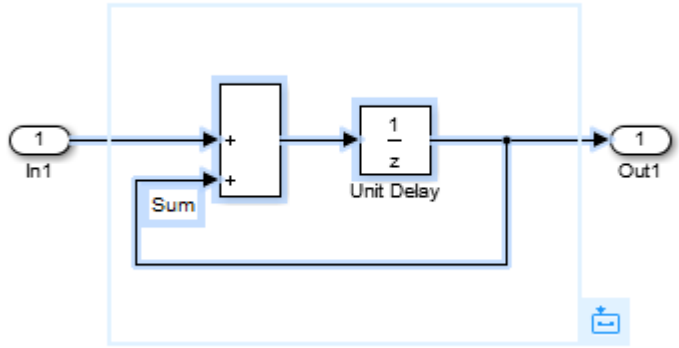


adds Inport and Outport blocks to represent input from and output to blocks outside the subsystem.

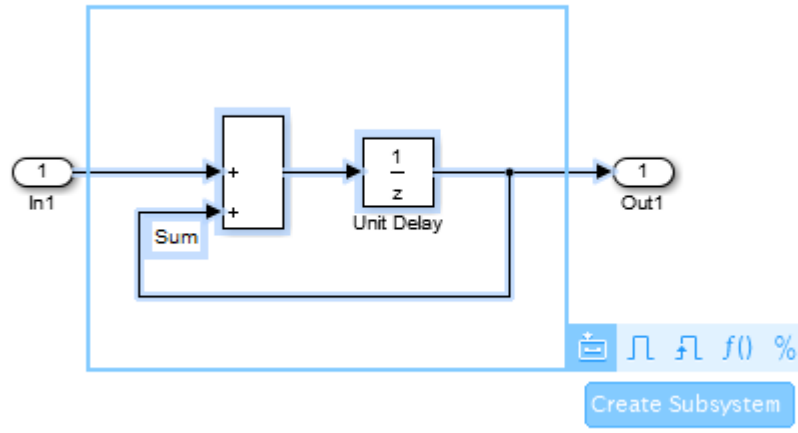
You can change the name of the Subsystem block and modify the block the way that you do with any other block (for example, you can mask the subsystem).

Create a Subsystem Using Context Options

1 Drag a box around the blocks you want in your subsystem.



2 View the subsystems you can create with these blocks by hovering over the first context option that appears.



3 Select the type of subsystem you want to create from these options.

A Subsystem block appears, which encloses the selected blocks.

Note You can create only enabled, triggered, virtual, and function-call subsystems using this method.

- “Conditionally Executed Subsystems”

Configure a Subsystem

In this section...

Subsystem Execution

You can configure a subsystem to execute either conditionally or unconditionally.

- An unconditionally executed subsystem always executes.
- A conditionally executed subsystem executes based on the value of an input signal. For details, see “Conditionally Executed Subsystems”.

Label Subsystem Ports

By default, Simulink labels ports on a Subsystem block. The labels are the names of the Inport and Outport blocks that connect the subsystem to blocks outside of the subsystem.

You can specify how Simulink labels the ports of a subsystem.

1. Select the Subsystem block.
2. Select one of the labeling options from **Diagram** > **Format** > **Port Labels** menu (for example, `From Port Block Name`).

Control Access to Subsystems

You can control user access to subsystems. For example, you can prevent a user from viewing or modifying the contents of a library subsystem while still allowing the user to employ the subsystem in a model.

Note This method does not necessarily prevent a user from changing the access restrictions. To hide proprietary information that is in a subsystem, consider using protected model referencing models (see “Protected Model” on page 8-95).

To restrict access to a library subsystem, open the subsystem parameter dialog box and set **Read/Write permissions** to one of these values:

- `ReadOnly`: A user can view the contents of the library subsystem but cannot modify the reference subsystem without disabling its library link or changing its **Read/Write permissions** to `ReadWrite`.
- `NoReadOrWrite`: A user cannot view the contents of the library subsystem, modify the reference subsystem, or change reference subsystem permissions.

Both options allow a user to use the library subsystem in models by creating links (see "Libraries"). For more information about subsystem access options, see the Subsystem block.

Note You do not receive a response if you attempt to view the contents of a subsystem whose **Read/Write permissions** parameter is set to `NoReadOrWrite`. For example, when double-clicking such a subsystem, Simulink does not open the subsystem and does not display any messages.

Control Subsystem Behavior with Callbacks

You can use block callbacks to perform actions in response to subsystem modeling actions such as:

- Handling an error
- Deleting a block or line in a subsystem
- Closing a subsystem

For details, see "Specify Block Callbacks" on page 35-5.

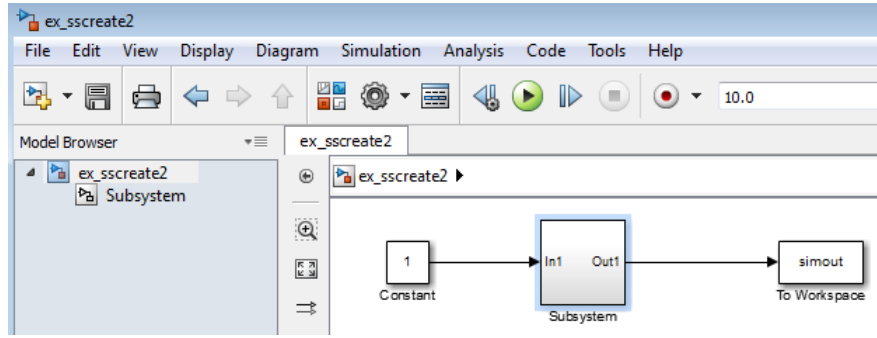
Navigate Subsystems in the Model Hierarchy

Open a Subsystem

Subsystems allow you to create a hierarchical model comprising many layers. You can navigate this hierarchy using the “Explore the Model Hierarchy Using the Model Browser” on page 12-47 or with Simulink Editor model navigation commands.

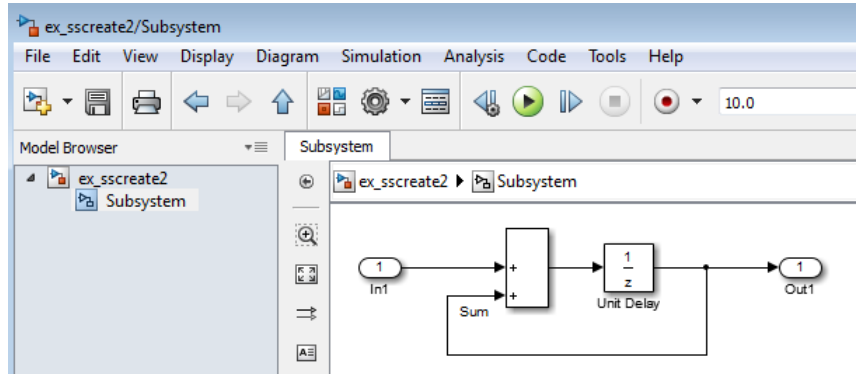
To open a subsystem using the Simulink Editor context menu for the Subsystem block:

1 In the Simulink Editor, right-click the Subsystem block.

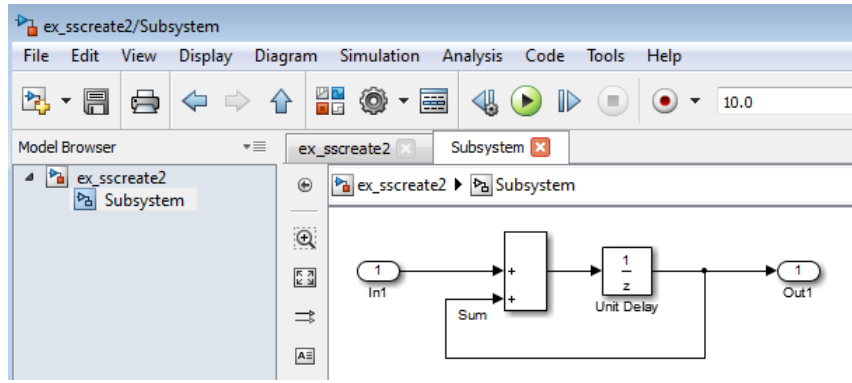


2 From the context menu, select one of these options:

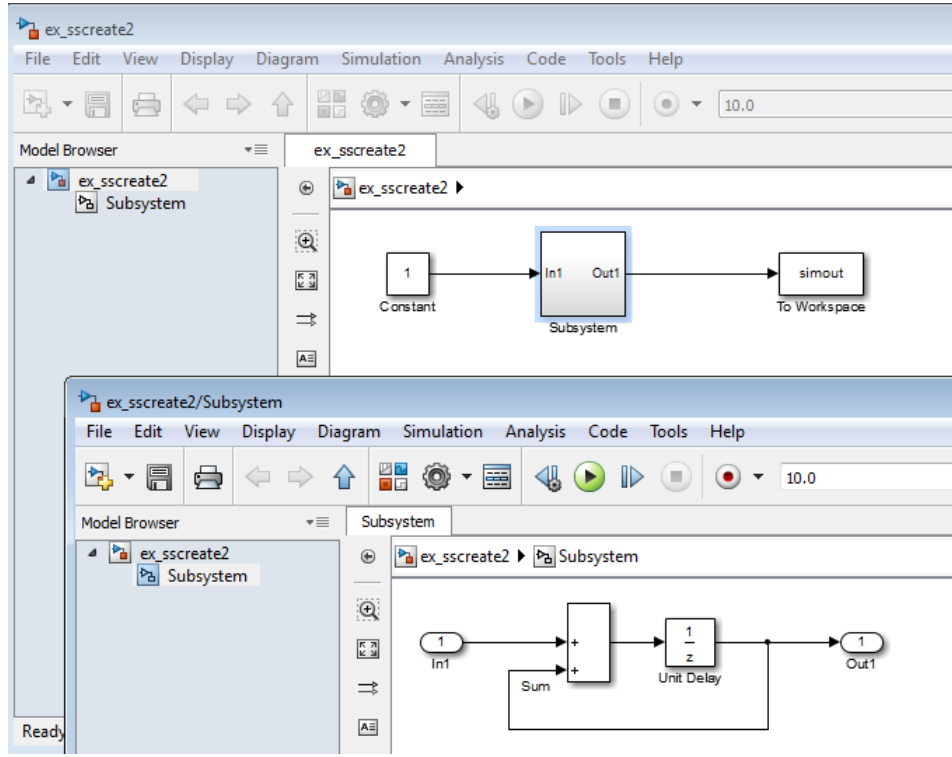
- **Open** — Open the subsystem, in the same window and tab as used for the top model.



- **Open In New Tab** — Open the subsystem, creating an additional tab for the subsystem.



- **Open In New Window**— Open the subsystem, opening a new Simulink Editor window.



For any operation to open a subsystem, you can use a keyboard shortcut to have the subsystem open in a new tab or window:

Where to Open the Subsystem	Keyboard Shortcut
In a new tab	Hold the **CTRL** key while opening the subsystem.
In a new window	Hold the **SHIFT** key while opening the subsystem.

Tip To navigate up and out of a subsystem, select **View > Navigate > Up to Parent**. The subsystem you navigated from appears highlighted so you can identify where you came from.

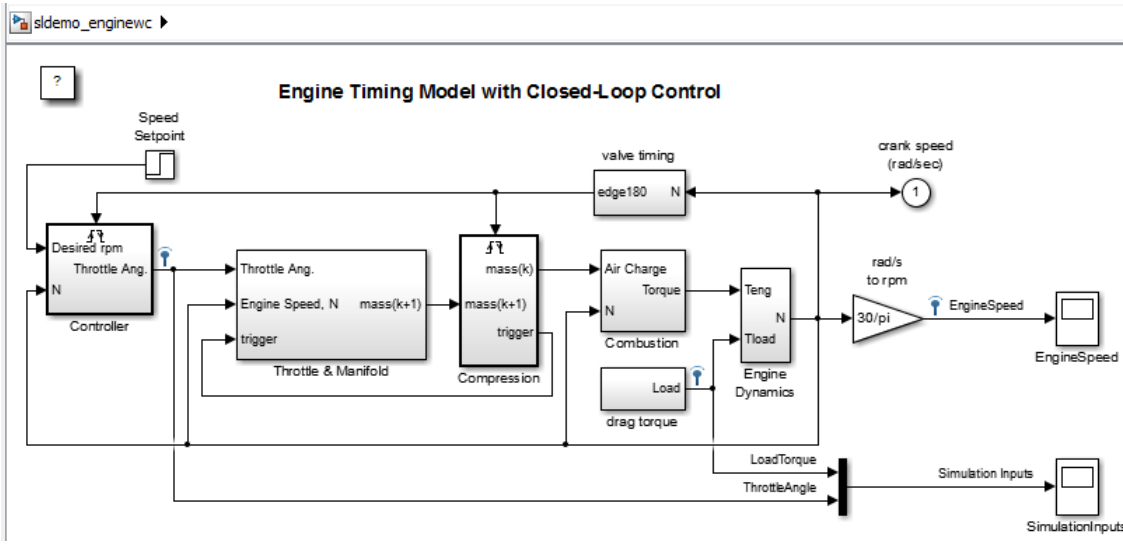
Subsystem Expansion

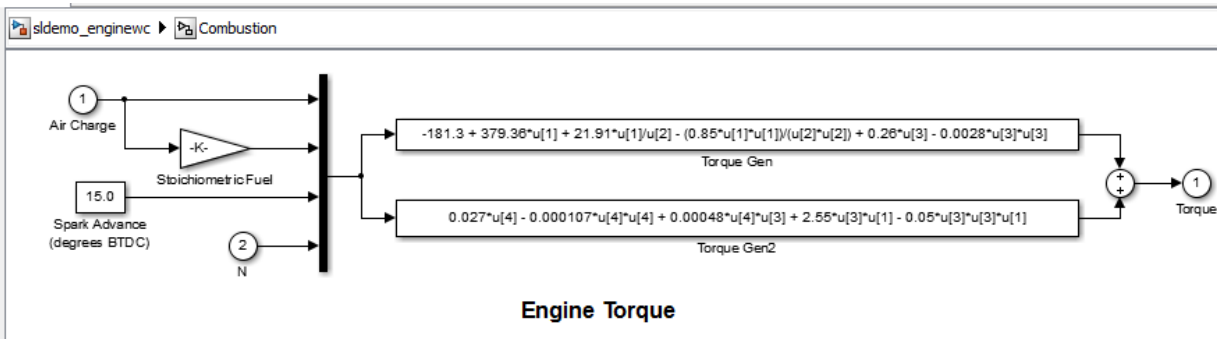
In this section...

What Is Subsystem Expansion?

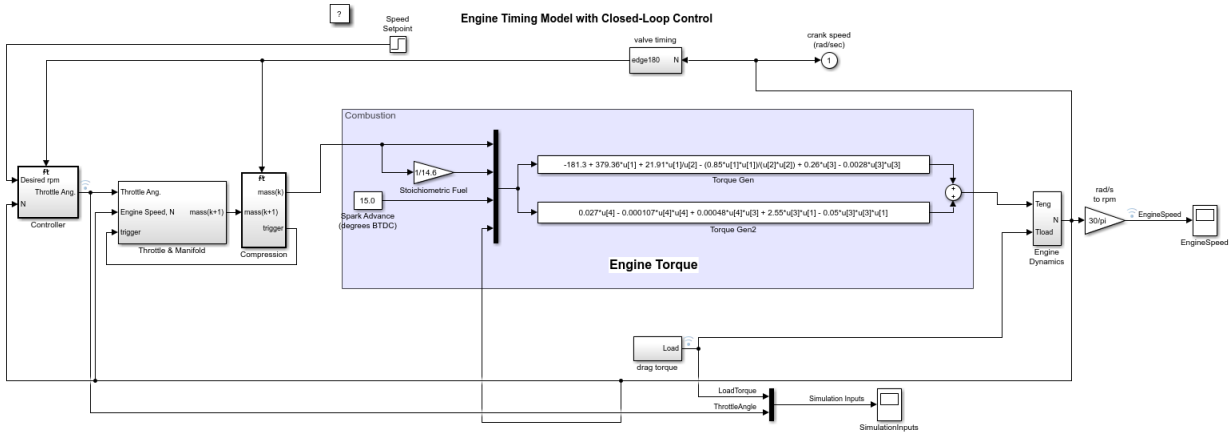
Subsystem expansion involves moving the contents of a virtual subsystem into the system that contains that subsystem.

For example, the `sldemo_enginewc` model includes the Combustion subsystem.





After you expand the Combustion subsystem, the top level of the `sldemo_enginewc` model includes the blocks and signals of the Combustion subsystem. The expansion removes the Subsystem block and the Inport and Outport blocks.



Why Expand a Subsystem?

Expand a subsystem if you want to flatten a model hierarchy by bringing the contents of a subsystem up one level.

Expanding a subsystem is useful when refactoring a model. Flattening a model hierarchy can be the end result, or just one step in refactoring. For example, you could pull a set of blocks up to the parent system by expanding the subsystem, deselect the blocks that you want to leave in the parent, and then create a subsystem from the remaining selected blocks.

Subsystems That You Can Expand

You can expand virtual subsystems that are not masked, linked, or commented.

Subsystems That You Can Automatically Modify to Enable Expansion

If you try to expand one of these subsystems using the Simulink Editor, a message gives you the option of having Simulink modify the subsystem so that you can then expand it.

Kind of Subsystem	Modification
Masked subsystem	Removes all masking information
Library links	Breaks the link
Commented-out subsystem	Removes the comment-out setting

Subsystems That You Cannot Expand

You cannot expand these subsystems:

- Atomic subsystems
- Conditional subsystems
- Configurable subsystems
- Variant subsystems
- Subsystems in a referenced model
- Subsystems with the **Read/Write permissions** parameter set to `ReadOnly` or `NoReadWrite`
- Subsystems with an `InitFcn`, `StartFcn`, `PauseFcn`, `ContinueFcn`, or `StopFcn` callback
- Subsystems with linked requirements (using Simulink Requirements™ software)

Results of Expanding a Subsystem

When you expand a subsystem, Simulink:

- Removes the Subsystem block
- Removes the root Inport, root Outport, and Simscape Connection Port blocks that were in the subsystem
- Connects the signal lines that went to the input and output ports of the subsystem directly to the ports of the blocks in the model that connected to the subsystem

Block Paths

The paths for blocks that were in the subsystem that you expanded change. After expansion, update scripts and test harnesses that rely on the hierarchical paths to blocks that were in the subsystem that you expanded.

Signal Names and Properties

If you expand a subsystem with a missing connection on the outside or inside of the subsystem, Simulink keeps the line labels, but uses the signal name and properties from just one of the lines. For lines corresponding to:

- A subsystem input port, Simulink uses the signal name and properties from the signal in the system in which the subsystem exists
- A subsystem output port, Simulink uses the signal name and properties from the subsystem

Display Layers

The display layers of blocks (in other words, which blocks appear in front or in back for overlapping blocks) does not change after expansion. Blocks in front of the Subsystem block remain above the expanded contents, and blocks below the Subsystem block remain under the expanded contents.

Sorted Order and Block Priorities

When you compile a model, Simulink sorts the blocks in terms of the order of block execution. Expanding a subsystem can change block path names, which, in rare cases, can impact the block execution order.

If you explicitly set block execution order by setting block priorities within a subsystem, Simulink removes those block priority settings when you expand that subsystem.

Data Stores

Expanding a subsystem that contains a Data Store Memory block that other subsystems read from or write to can change the required data store write and read sequence. You may need to restructure your model. For details, see “Order Data Store Access” on page 62-25.

- “Expand Subsystem Contents” on page 4-33

Expand Subsystem Contents

In this section...

Expand a subsystem to flatten a model hierarchy by bringing the contents of a subsystem up one level.

Expand a Subsystem

1. In the Simulink Editor, right-click the Subsystem block for the subsystem that you want to expand.
2. From the context menu, select **Subsystem & Model Reference** > **Expand Subsystem**.

   Expand Subsystem is disabled for subsystems that you cannot convert. For some kinds of subsystems, you have the option of having Simulink modify the subsystem so that you can then expand it. For details, see “Subsystems That You Can Automatically Modify to Enable Expansion” on page 4-30.
3. If necessary, modify the model layout for readability.

   Simulink distributes blocks and routes signals for readability, but you can refine the model layout to enhance readability. Also, you may want to modify the model to adjust for how the subsystem expansion handles aspects of the model such as signal naming. For details, see “Results of Expanding a Subsystem” on page 4-30.
4. Update scripts and test harnesses that rely on the hierarchical paths to blocks that were in the subsystem that you expanded.

Nested Subsystems

Subsystem expansion applies to the currently selected subsystem level. Simulink does not expand other subsystems in a nested subsystem hierarchy.

To improve readability when you expand nested subsystems, start by expanding the highest-level subsystem that you want to expand, and then work your way down the hierarchy as far as you want to expand.

Expand a Subsystem from the Command Line

To expand a subsystem programmatically, use the `Simulink.BlockDiagram.expandSubsystem` function.

Use Control Flow Logic

In this section...

What is a Control Flow Subsystem

A *control flow subsystem* executes one or more times at the current time step when enabled by a control flow block. A control flow block implements control logic similar to that expressed by control flow statements of programming languages (e.g., `if-then`, `while-do`, `switch`, and `for`).

Equivalent C Language Statements

You can use block diagrams to model control flow logic equivalent to the following C programming language statements:

- `for`
- `if-else`
- `switch`
- `while`

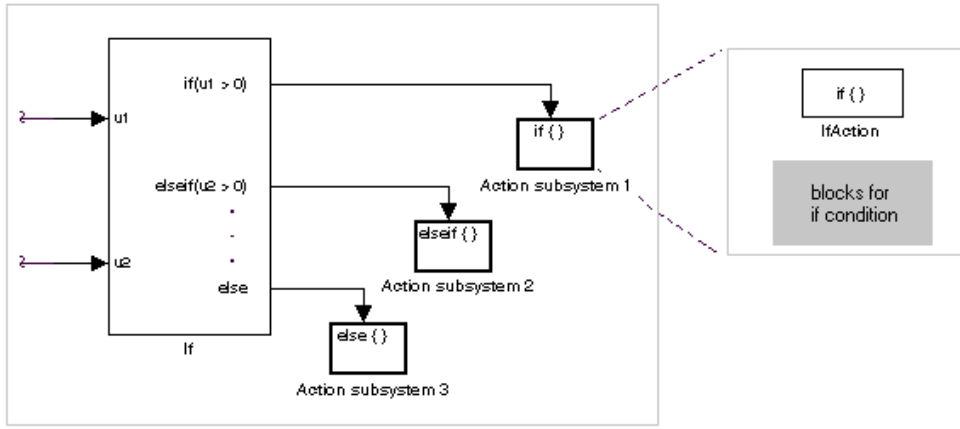
Conditional Control Flow Logic

You can use the following blocks to perform conditional control flow logic.

C Statement	Equivalent Blocks
`if-else`	If, If Action Subsystem
`switch`	Switch Case, Switch Case Action Subsystem

If-Else Control Flow

The following diagram represents `if-else` control flow.



Construct an `if-else` control flow diagram as follows:

1. Provide data inputs to the If block for constructing if-else conditions.

   In the If block parameters dialog box, set inputs to the If block. Internally, the inputs are designated as `u1, u2,..., un` and are used to construct output conditions.

2. In the If block parameters dialog box, set output port if-else conditions for the If block.

   In the If block parameters dialog box, set Output ports. Use the input values `u1, u2, ..., un` to express conditions for the if, elseif, and else condition fields in the dialog box. Of these, only the if field is required. You can enter multiple elseif conditions and select a check box to enable the else condition.

3. Connect each condition output port to an Action subsystem.

   Connect each if, elseif, and else condition output port on the If block to a subsystem to be executed if the port's case is true.

   Create these subsystems by placing an Action Port block in a subsystem. This creates an atomic Action subsystem with a port named Action, which you then connect to a condition on the If block.

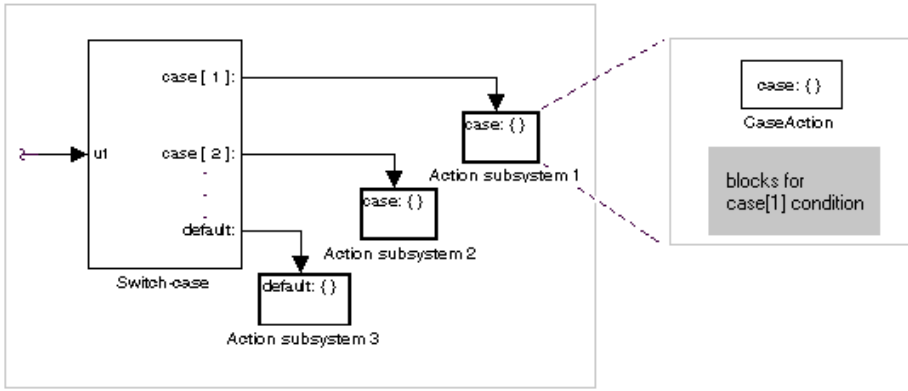
   Once connected, the subsystem takes on the identity of the condition it is connected to and behaves like an enabled subsystem.

For more detailed information, see the If and Action Port blocks.

Note All blocks in an Action subsystem driven by an If or Switch Case block must run at the same rate as the driving block.

Switch Control Flow

The following diagram represents `switch` control flow.



Construct a `switch` control flow statement as follows:

1. Provide a data input to the argument input of the Switch Case block.

   The input to the Switch Case block is the argument to the `switch` control flow statement. This value determines the appropriate case to execute. Noninteger inputs to this port are truncated.

2. Add cases to the Switch Case block based on the numeric value of the argument input.

   Using the parameters dialog box of the Switch Case block, add cases to the Switch Case block. Cases can be single or multivalued. You can also add an optional default case, which is true if no other cases are true. Once added, these cases appear as output ports on the Switch Case block.

3. Connect each Switch Case block case output port to an Action subsystem.

   Each case output of the Switch Case block is connected to a subsystem to be executed if the port's case is true. You create these subsystems by placing an Action Port block in a subsystem. This creates an atomic subsystem with a port named Action, which you then connect to a condition on the Switch Case block. Once connected, the

subsystem takes on the identity of the condition and behaves like an enabled subsystem. Place all the block programming executed for that case in this subsystem.

For more detailed information, see documentation for the Switch Case and Action Port blocks.

Note After the subsystem for a particular case executes, an implied break executes, which exits the `switch` control flow statement altogether. Simulink `switch` control flow statement implementations do not exhibit the "fall through" behavior of C `switch` statements.

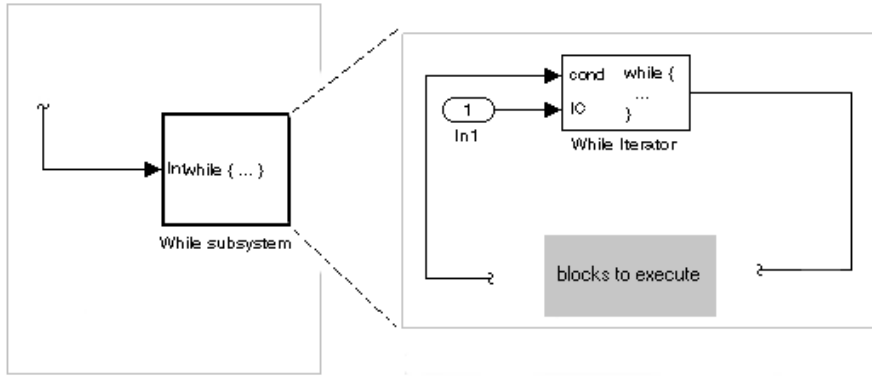
While and For Loops

Use the following blocks to perform `while` and `for` loops.

C Statement	Equivalent Blocks
`do-while`	While Iterator Subsystem
`for`	For Iterator Subsystem
`while`	While Iterator Subsystem

While Loops

The following diagram illustrates a `while` loop.



In this example, Simulink repeatedly executes the contents of the While subsystem at each time step until a condition specified by the While Iterator block is satisfied. In particular, for each iteration of the loop specified by the While Iterator block, Simulink invokes the update and output methods of all the blocks in the While subsystem in the same order that the methods would be invoked if they were in a noniterated atomic subsystem.

Note Simulation time does not advance during execution of a While subsystem's iterations. Nevertheless, blocks in a While subsystem treat each iteration as a time step. As a result, in a While subsystem, the output of a block with states (that is, a block whose output depends on its previous input), reflects the value of its input at the previous iteration of the `while` loop. The output does *not* reflect that block's input at the previous simulation time step. For example, a Unit Delay block in a While subsystem outputs the value of its input at the previous iteration of the `while` loop, not the value at the previous simulation time step.

Construct a `while` loop as follows:

1. Place a While Iterator block in a subsystem.

   The host subsystem label changes to `while {...}`, to indicate that it is modeling a while loop. These subsystems behave like triggered subsystems. This subsystem is host to the block programming that you want to iterate with the While Iterator block.

2. Provide a data input for the initial condition data input port of the While Iterator block.

   The While Iterator block requires an initial condition data input (labeled `IC`) for its first iteration. This must originate outside the While subsystem. If this value is nonzero, the first iteration takes place.

3. Provide data input for the conditions port of the While Iterator block.

   Conditions for the remaining iterations are passed to the data input port labeled `cond`. Input for this port must originate inside the While subsystem.

4. (Optional) Set the While Iterator block to output its iterator value through its properties dialog.

   The iterator value is 1 for the first iteration and is incremented by 1 for each succeeding iteration.

5 (Optional) Change the iteration of the While Iterator block to `do-while` through its properties dialog.

   This changes the label of the host subsystem to `do {...} while`. With a `do-while` iteration, the While Iteration block no longer has an initial condition (IC) port, because all blocks in the subsystem are executed once before the condition port (labeled `cond`) is checked.

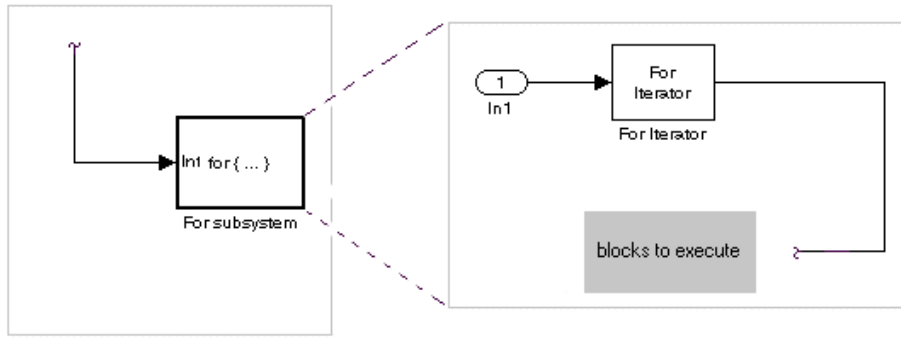
6 Create a block diagram in the subsystem that defines the subsystem's outputs.

Note The diagram must not contain blocks with continuous states (for example, blocks from the Continuous block library). The sample times of all the blocks must be either inherited (`-1`) or constant `(inf)`.

For more information, see the While Iterator block.

Modeling For Loops

The following diagram represents a `for` loop:



In this example, Simulink executes the contents of the For subsystem multiples times at each time step. The input to the For Iterator block specifies the number of iterations . For each iteration of the `for` loop, Simulink invokes the update and output methods of all the blocks in the For subsystem in the same order that it invokes the methods if they are in a noniterated atomic subsystem.

Note Simulation time does not advance during execution of a For subsystem's iterations. Nevertheless, blocks in a For subsystem treat each iteration as a time step. As a result,

in a For subsystem, the output of a block with states (that is, a block whose output depends on its previous input) reflects the value of its input at the previous iteration of the `for` loop. The output does *not* reflect that block's input at the previous simulation time step. For example, a Unit Delay block in a For subsystem outputs the value of its input at the previous iteration of the `for` loop, not the value at the previous simulation time step.

Construct a `for` loop as follows:

1. Drag a For Iterator Subsystem block from the Library Browser or Library window into your model.
2. (Optional) Set the For Iterator block to take external or internal input for the number of iterations it executes.

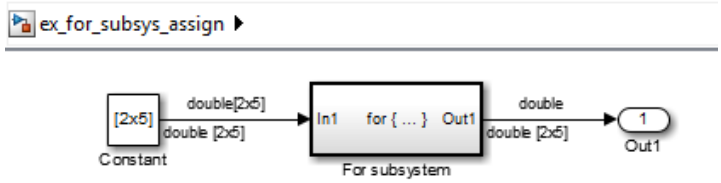
   Through the properties dialog of the For Iterator block you can set it to take input for the number of iterations through the port labeled `N`. This input must come from outside the For Iterator Subsystem.

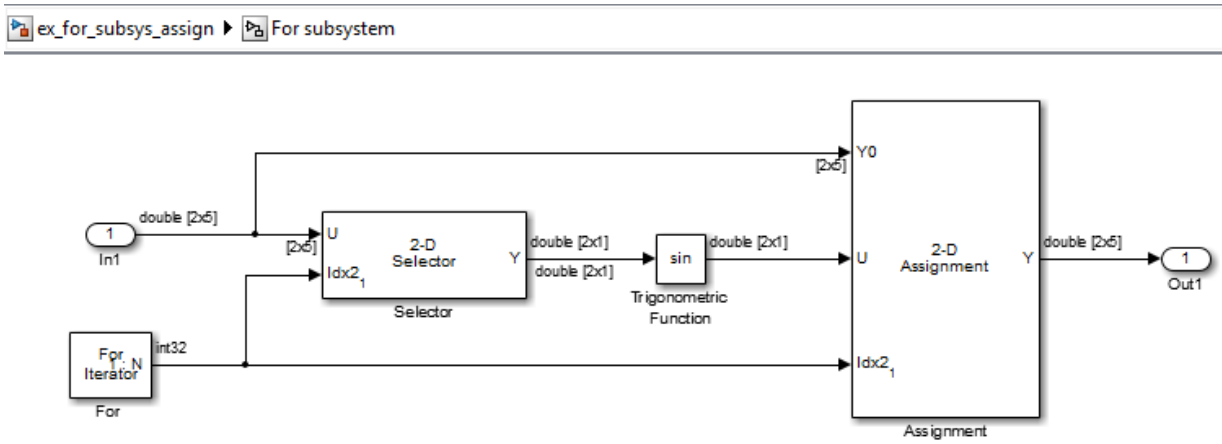
   You can also set the number of iterations directly in the properties dialog.
3. (Optional) Set the For Iterator block to output its iterator value for use in the block programming of the For Iterator Subsystem.

   The iterator value is 1 for the first iteration and is incremented by 1 for each succeeding iteration.
4. Create a block diagram in the subsystem that defines the subsystem's outputs.

   Note The diagram must not contain blocks with continuous states (for example, blocks from the Continuous block library). The sample times of all the blocks must be either inherited (`-1`) or constant `(inf)`.

The For Iterator block works well with the Assignment block to reassign values in a vector or matrix. The following example shows the use of a For Iterator block. Note the matrix dimensions in the data being passed.





The above example outputs the sine value of an input 2-by-5 matrix (2 rows, 5 columns) using a For subsystem containing an Assignment block. The process is as follows.

1. A 2-by-5 matrix is input to the Selector block and the Assignment block.
2. The Selector block strips off a 2-by-1 matrix from the input matrix at the column value indicated by the current iteration value of the For Iterator block.
3. The sine of the 2-by-1 matrix is taken.
4. The sine value 2-by-1 matrix is passed to an Assignment block.
5. The Assignment block, which takes the original 2-by-5 matrix as one of its inputs, assigns the 2-by-1 matrix back into the original matrix at the column location indicated by the iteration value.

   The rows specified for reassignment in the property dialog for the Assignment block in the above example are [1,2]. Because there are only two rows in the original matrix, you could also have specified -1 for the rows, (that is, all rows).

Note The Trigonometric Function block is already capable of taking the sine of a matrix. The above example uses the Trigonometric Function block only as an example of changing each element of a matrix with the collaboration of an Assignment block and a For Iterator block.

Callbacks for Customized Model Behavior

In this section...

Model, Block, and Port Callbacks

Callbacks are commands you can define that execute in response to a specific modeling action, such as opening a model or stopping a simulation. Callbacks define MATLAB expressions that execute when the block diagram or a block is acted upon in a particular way.

Simulink provides model, block, and port callback parameters that identify specific kinds of model actions. You provide the code for a callback parameter. Simulink executes the callback code when the associated modeling action occurs.

For example, the code that you specify for the `PreLoadFcn` model callback parameter executes before the model loads. You can provide code for `PreLoadFcn` that loads the variables that model uses into the MATLAB workspace.

What You Can Do with Callbacks

Callbacks are a powerful way to customize your Simulink model. A callback executes when you perform actions on your model, such as double-clicking a block or starting a simulation. You can use callbacks to execute MATLAB code. You can use model, block, or port callbacks to perform common tasks, such as:

- “Load Variables When Opening a Model” on page 1-10
- “Specify Block Callbacks” on page 4-52
- “Automate Simulation Tasks Using Block Callbacks” on page 25-9

Avoid run Commands in Callback Code

Do not call the `run` command from within model or block callback code. Doing so can result in unexpected behavior (such as errors or incorrect results) if you load, compile, or simulate a Simulink model.

- "Callback Tracing" on page 4-61
- "Model Methods and Callbacks in Fast Restart" on page 70-12

Model Callbacks

In this section...

Model callbacks execute at specified action points, for example after you load or save the model. You can set most of the same callbacks for libraries. Only the callbacks that can execute for a library are available to set. For example, you cannot set the `InitFcn` callback for a library, which is called as part of simulation, because you cannot simulate a library.

Create Model Callbacks

1. In the Simulink Editor, open the Property Inspector. Select **View** > **Property Inspector**.
2. With no selection at the top level of your model, in the **Properties** tab, in the **Callbacks** section, select the callback you want to set.
3. In the box, enter the functions you want the callback to perform.

To create a model callback programmatically, use the `set_param` function to assign MATLAB code to a model callback parameter. See “Model Callback Parameters” on page 4-48

Referenced Model Callbacks

The execution of callbacks for model referencing reflects the order in which the top model and the model it references execute their callbacks. For example, suppose:

- Model A references model B.
- Model A has a `PostLoadFcn` callback that creates variables in the MATLAB workspace.
- Model B has a `CloseFcn` callback that clears the MATLAB workspace.

Simulating model A triggers rebuilding the referenced model B.

When Simulink rebuilds model B, it opens and closes model B and invokes the model B `CloseFcn` callback. `CloseFcn` clears the MATLAB workspace, including the variables created by the model A `OpenFcn` callback.

Instead of using a `CloseFcn` callback for model B, you can use a `StopFcn` callback in model A to clear the variables used by the model from the MATLAB workspace.

If a model references multiple instances of the same model in normal mode, callbacks execute for each instance.

Model Callback Parameters

Model Loading and Closing Callback Parameters

Model Callback Parameter	When Executed

`PreLoadFcn`	This callback is executed before the model is loaded.
	
	Do not use model parameters in a `PreLoadFcn` model callback because parameters are loaded after the model is loaded. Instead, use a `PostLoadFcn` callback to work with model parameters when the model is loaded.
	
	Defining a callback code for this parameter is useful for loading variables that the model uses.
	
	If you want to call your model from a MATLAB file without opening your model, use the `load_system` function so that the `PreLoadFcn` executes.
	
	For examples, see:
	
	• "Load Variables When Opening a Model" on page 1-10
	• "Introduction to Managing Data with Model Reference"
	• "Model Reference Simulation Targets" on page 8-54
	
	Limitations include:
	
	• For the `PreLoadFcn` callback, `get_param` does not return the model parameter values because the model is not yet loaded. Instead, `get_param` returns:
	  • The default value for a standard model parameter such as `solver`
	  • An error message for a model parameter added with `add_param`
	• Programmatic access to Scopes is not supported.

Model Callback Parameter	When Executed
`PostLoadFcn`	After the model is loaded. Defining callback code for this parameter may be useful for generating an interface requiring a loaded model. Limitations include: • If you make structural changes with `PostLoadFcn`, the function does not set the model `Dirty` flag to indicate unsaved changes. When you close the model, Simulink does not prompt you to save. • Programmatic access to Scopes is not supported.
`CloseFcn`	Before the block diagram is closed. Any `ModelCloseFcn` and `DeleteFcn` callbacks set on blocks in the model are called prior to the model `CloseFcn` callback. The `DestroyFcn` callback of any blocks in the model is called after the model `CloseFcn` callback.

Model Saving Callback Parameters

Model Callback Parameter	When Executed
`PreSaveFcn`	Before the model is saved.
`PostSaveFcn`	After the model is saved. **Note** If you make structural changes with `PostSaveFcn`, the function does not set the model `Dirty` flag to indicate unsaved changes. When you close the model, Simulink does not prompt you to save.

Model Simulation Callback Parameters

Model Callback Parameter	When Executed
`InitFcn`	Called during update phase before block parameters are evaluated. This is called during model update and simulation. For examples, see: • "Create Programmatic Hyperlinks" on page 24-64 • "Track Object Using MATLAB Code" on page 41-180 **Note** • An `InitFcn` callback in a top model cannot change parameters used by referenced models. • During model compilation, Simulink evaluates variant objects before calling the model `InitFcn` callback. Do not modify the condition of the variant object in the `InitFcn` callback. For more information, see "Define, Configure, and Activate Variants" on page 11-35.
`StartFcn`	Called before the simulation phase. This is not called during model update. For an example, see "Automate Simulation Tasks Using Block Callbacks" on page 25-9.
`PauseFcn`	After the simulation pauses.
`ContinueFcn`	Before the simulation continues.
`StopFcn`	After the simulation stops. Output is written to workspace variables and files before the `StopFcn` is executed.

- “Model Methods and Callbacks in Fast Restart” on page 70-12

Block Callbacks

In this section...

Specify Block Callbacks

1. Open the Property Inspector. Select **View > Property Inspector**.
2. Select the block whose callback you want to specify. In the **Properties** tab of the Property Inspector, in the **Callbacks** section, select the callback you want to define.
3. In the box, enter the functions you want the callback to perform.

To specify a block callback programmatically, use `set_param` to assign MATLAB code to the block callback parameter.

Block Callback Parameters

If a block callback executes before or after a modeling action takes place, that callback occurs immediately before or after the action.

Block Opening Callback Parameters

Block Callback Parameter	When Executed
`OpenFcn`	When the block is opened. Generally, use this parameter with Subsystem blocks. The callback executes when you double-click the block or when you use `open_system` with the block as an argument. The `OpenFcn` parameter overrides the normal behavior associated with opening a block, which is to display the block dialog box or to open the subsystem. Examples of tasks that you can use `OpenFcn` for include defining variables for a block, making a call to MATLAB to produce a plot of simulated data, or generating a graphical user interface. After you add an `OpenFcn` callback to a block, double-clicking the block does not open the block dialog box. Also, the block parameters do not appear in the Property Inspector when the block is selected. To set the block parameters, select **Block Parameters** from the block context menu. For examples of using `OpenFcn` with model referencing, see: • In the Introduction to Managing Data with Model Reference example, click the question mark block at the top and then select `Detailed Workflow for Managing Data with Model Reference`. • "Model Reference Simulation Targets" on page 8-54
`LoadFcn`	After the block diagram is loaded. For Subsystem blocks, the `LoadFcn` callback is performed for any blocks in the subsystem (including other Subsystem blocks) that have a `LoadFcn` callback defined.

Block Editing Callback Parameters

Block Callback Parameter	When Executed
`MoveFcn`	When the block is moved or resized.

Block Callback Parameter	When Executed
`NameChangeFcn`	After a block name or path changes. When a Subsystem block path changes, the Subsystem block calls the `NameChangeFcn` callback of its descendant blocks and then calls the `NameChangeFcn` callback on itself.
`PreCopyFcn`	Before a block is copied. The `PreCopyFcn` is also executed if `add_block` is used to copy the block. If you copy a Subsystem block that contains a block for which the `PreCopyFcn` callback is defined, that callback executes also. The block `CopyFcn` callback is called after all `PreCopyFcn` callbacks are executed, unless `PreCopyFcn` invokes the `error` command, either explicitly or via a command used in any `PreCopyFcn`.
`CopyFcn`	After a block is copied. The callback is also executed if `add_block` is used to copy the block. If you copy a Subsystem block that contains a block for which the `CopyFcn` parameter is defined, the callback is also executed.
`ClipboardFcn`	When the block is copied or cut to the system clipboard.
`PreDeleteFcn`	Before a block is graphically deleted (for example, when you graphically delete the block or invoke `delete_block` on the block). The `PreDeleteFcn` is not called when the model containing the block is closed. The block's `DeleteFcn` is called after the `PreDeleteFcn`, unless the `PreDeleteFcn` invokes the `error` command, either explicitly or via a command used in the `PreDeleteFcn`.

Block Callback Parameter	When Executed
`DeleteFcn`	After a block is graphically deleted (for example, when you graphically delete the block, invoke `delete_block` on the block, or close the model containing the block). When the `DeleteFcn` is called, the block handle is still valid and can be accessed using `get_param`. If the block is graphically deleted by invoking `delete_block` or by closing the model, after deletion the block is destroyed from memory and the block's `DestroyFcn` is called. For Subsystem blocks, the `DeleteFcn` callback is performed for any blocks in the subsystem (including other Subsystem blocks) that have a `DeleteFcn` callback defined.
`DestroyFcn`	When the block has been destroyed from memory (for example, when you invoke `delete_block` on either the block or a subsystem containing the block or close the model containing the block). If the block was not previously graphically deleted, the block`DeleteFcn` callback is called prior to the `DestroyFcn`. When the `DestroyFcn` is called, the block handle is no longer valid.
`UndoDeleteFcn`	When a block deletion is undone.

Block Compilation and Simulation Callback Parameters

Block Callback Parameter	When Executed
`InitFcn`	Before the block diagram is compiled and before block parameters are evaluated.
`StartFcn`	After the block diagram is compiled and before the simulation starts. In the case of an S-Function block, `StartFcn` executes immediately before the first execution of the block's `mdlProcessParameters` function. For more information, see "S-Function Callback Methods".
`ContinueFcn`	Before the simulation continues.

Block Callback Parameter	When Executed
`PauseFcn`	After the simulation pauses.
`StopFcn`	At any termination of the simulation. In the case of an S-Function block, `StopFcn` executes after the block's `mdlTerminate` function executes. For more information, see “S-Function Callback Methods”.

Block Saving and Closing Callback Parameters

Block Callback Parameter	When Executed
`PreSaveFcn`	Before the block diagram is saved. For Subsystem blocks, the `PreSaveFcn` callback is performed for any blocks in the subsystem (including other Subsystem blocks) that have a `PreSaveFcn` callback defined.
`PostSaveFcn`	After the block diagram is saved. For Subsystem blocks, the `PostSaveFcn` callback is performed for any blocks in the subsystem (including other Subsystem blocks) that have a `PostSaveFcn` callback defined.
`CloseFcn`	When the block is closed using `close_system`. The `CloseFcn` is not called when you interactively close the block parameters dialog box, when you interactively close the subsystem or model containing the block, or when you close the subsystem or model containing a block using `close_system`. For example, to close all open MATLAB windows, use a command such as: `set_param('my_model','CloseFcn','close all')`

Block Callback Parameter	When Executed
`ModelCloseFcn`	Before the block diagram is closed. When the model is closed, the block's `ModelCloseFcn` is called prior to its `DeleteFcn`. For Subsystem blocks, the `ModelCloseFcn` callback is performed for any blocks in the subsystem (including other Subsystem blocks) that have a `ModelCloseFcn` callback defined.

Subsystem Block Callback Parameters

You can use the other block callback parameters with Subsystem blocks, but the callback parameters in this table are specific to Subsystem blocks.

Note A callback for a masked subsystem cannot directly reference the parameters of the masked subsystem (see "Block Masks"). Simulink evaluates block callbacks in the MATLAB base workspace, whereas the mask parameters reside in the masked subsystem's private workspace. A block callback, however, can use `get_param` to obtain the value of a mask parameter. For example, here `gain` is the name of a mask parameter of the current block:

```
get_param(gcb, 'gain')
```

Block Callback Parameter	When Executed
`DeleteChildFcn`	After a block or line is deleted in a subsystem. If the block has a `DeleteFcn` or `DestroyFcn` callback, those callbacks execute prior to the `DeleteChildFcn` callback.

Block Callback Parameter	When Executed

`ErrorFcn`	When an error has occurred in a subsystem.
	
	Use the following form for the callback code for the `ErrorFcn` parameter:
	
	`newException = errorHandler(subsys, ... errorType, originalException)`
	
	where
	
	• `errorHandler` is the name of the function.
	• `subsys` is a handle to the subsystem in which the error occurred.
	• `errorType` is a character vector indicating the type of error that occurred.
	• `originalException` is an MSLException (see "Error Handling in Simulink Using MSLException" on page 25-28).
	• `newException` is an MSLException specifying the error message to be displayed to the user.
	
	If you provide the original exception, then you do not need to specify the subsystem and the error type.
	
	The following command sets the `ErrorFcn` of the subsystem `subsys` to call the `errorHandler` callback:
	
	`set_param(subsys,'ErrorFcn','errorHandler')`
	
	In such calls to `set_param`, do not include the input arguments of the callback code. Simulink displays the error message returned by the callback.

Block Callback Parameter	When Executed
`ParentCloseFcn`	Before closing a subsystem containing the block or when the block is made part of a new subsystem using either: • The `new_system` function • In the Simulink Editor, the **Diagram > Subsystem & Model Reference > Create Subsystem from Selection** option When you close the model, Simulink does not call the `ParentCloseFcn` callbacks of blocks at the root model level.

- "Callback Tracing" on page 4-61
- "Model Methods and Callbacks in Fast Restart" on page 70-12

Port Callbacks

Block input and output ports have a single callback parameter, `ConnectionCallback`. This parameter allows you to set callbacks on ports that are triggered every time the connectivity of these ports changes. Examples of connectivity changes include adding a connection from the port to a block, deleting a block connected to the port, and deleting, disconnecting, or connecting branches or lines to the port.

Use `get_param` to get the port handle of a port and `set_param` to set the callback on the port. The callback code must have one input argument that represents the port handle. The input argument is not included in the call to `set_param`.

For example, suppose the currently selected block has a single input port. The following code sets `foo` as the connection callback on the input port:

```
phs = get_param(gcb, 'PortHandles');
set_param(phs.Inport, 'ConnectionCallback', 'foo');
```

where, `foo` is defined as:

```
function foo(portHandle)
```

- “Model Methods and Callbacks in Fast Restart” on page 70-12

Callback Tracing

Use callback tracing to determine the callbacks that Simulink invokes and the order that it invokes them when you open, edit, or simulate a model.

To enable callback tracing, do one of the following:

- In the Simulink Preferences dialog box, select the **Callback tracing** preference.
- Execute `set_param(0, 'CallbackTracing', 'on')`.

  The `CallbackTracing` parameter causes the callbacks to appear in the MATLAB Command Window as they are invoked. This option applies to all Simulink models, not just models that are open when you enable the preference.

Manage Model Versions and Specify Model Properties

In this section...

How Simulink Helps You Manage Model Versions

In Simulink, you can manage multiple versions of a model using these techniques:

- Use Simulink Projects to manage your project files, connect to source control, review modified files, and compare revisions. See “Project Management”.
- Use model file change notification to manage work with source control operations and multiple users. See “Model File Change Notification” on page 4-62.
- As you edit a model, Simulink generates version information about the model, including a version number, who created and last updated the model, and an optional comments history log. Simulink saves these version properties with the model.
  - View and edit some of the version information stored in the model and specify history logging in the model properties.
  - The Model Info block lets you display version information as an annotation block in a model diagram.
  - You can access Simulink version parameters programmatically.
- See `Simulink.MDLInfo` to extract information from a model file without loading the block diagram into memory. You can use `MDLInfo` to query model version and Simulink version, find the names of referenced models without loading the model into memory, and attach arbitrary metadata to your model file.

Model File Change Notification

You can use a Simulink preference to specify whether to notify you if the model has changed on disk. You can receive this notification when updating or simulating the

model, first editing the model, or saving the model. The model can change on disk, for example, with source control operations and multiple users.

In the Simulink Editor, select **File > Simulink Preferences**. In the **Model File** pane, under **Change Notification**, select the appropriate action.

- If you select **First editing the model**, the file has changed on disk, and the block diagram is unmodified in Simulink:
  - Any interactive operation that modifies the block diagram (e.g., adding a block) causes a warning to appear.
  - Any command-line operation that modifies the block diagram (such as a call to `set_param`) causes a warning to appear.
- If you select **Saving the model**, and the file has changed on disk:
  - Saving the model in the Simulink Editor causes a message to appear.
  - The `save_system` function reports an error, unless you use the `OverwriteIfChangedOnDisk` option.

To programmatically check whether the model has changed on disk since it was loaded, use the function `slIsFileChangedOnDisk`.

For more options that help you work with source control and multiple users, see "Project Management".

Manage Model Properties

You can use the Property Inspector to view and edit model version properties, description history, and callback functions. To open the Property Inspector, select **View > Property Inspector**. Model properties or, if you are in a library model, library properties, appear in the Property Inspector when nothing is selected at the top level of a model.

Specify the Current User

When you create or update a model, your name is logged in the model for version control purposes. Simulink assumes that your name is specified by at least one of the `USER`, `USERNAME`, `LOGIN`, or `LOGNAME` environment variables. If your system does not define any of these variables, Simulink does not update the user name in the model.

UNIX® systems define the `USER` environment variable and set its value to the name you use to log in to your system. Thus, if you are using a UNIX system, you do not have to take further action for Simulink to identify you as the current user.

Windows systems can define environment variables for user name that Simulink expects, depending on the version of Windows installed on your system and whether it is connected to a network. Use the MATLAB function `getenv` to determine which of the environment variables is defined. For example, at MATLAB command prompt, enter:

```
getenv('user')
```

This function determines whether the `USER` environment variable exists on your Windows system. If it does not, set it.

Model Information and History

The **Info** tab summarizes information about the current version of the model, such as modifications, version, and last saved date. You can view and edit model information and enable, view, and edit the model's change history.

Use the **Description** section to enter a description of the model. You can then view the model description by entering `help` followed by the model name at the MATLAB command prompt.

The **History** section displays model history information.

- **Model version**

  Version number for this model, incremented by 1 each time you save the model.
- **Created by**

  Name of the person who created this model based on the value of the `USER` environment variable when the model is created.
- **Created on**

  Date and time this model was created. Do not change this value.
- **Last saved by**

  Name of the person who last saved this model based on the value of the `USER` environment variable when the model is saved.

- **Last saved on**

  Date that this model was last saved, based on the system date and time.

The **Model history** box displays the history of the model. For more information on updating model history, see “Log Comments History” on page 4-65.

Properties

You can view the source file location, specify where to save model design data, and define callbacks in the **Properties** tab of the model properties.

Note Library properties also enable you to specify the mapping from old library blocks to new library blocks. For information on using forwarding tables for this purpose, see “Forwarding Tables” on page 40-39.

Define Location of Design Data

Use the **Design Data** section to specify the location of the design data that your model uses. You can define design data in the base workspace or in a data dictionary. See “Migrate Single Model to Use Dictionary” on page 63-6.

Callbacks

Use the **Callbacks** section to specify functions to invoke at specific points in the simulation of the model. Select the callback from the list. In the box, enter the function you want to invoke for the selected callback. For information on these callbacks. see “Create Model Callbacks” on page 4-46.

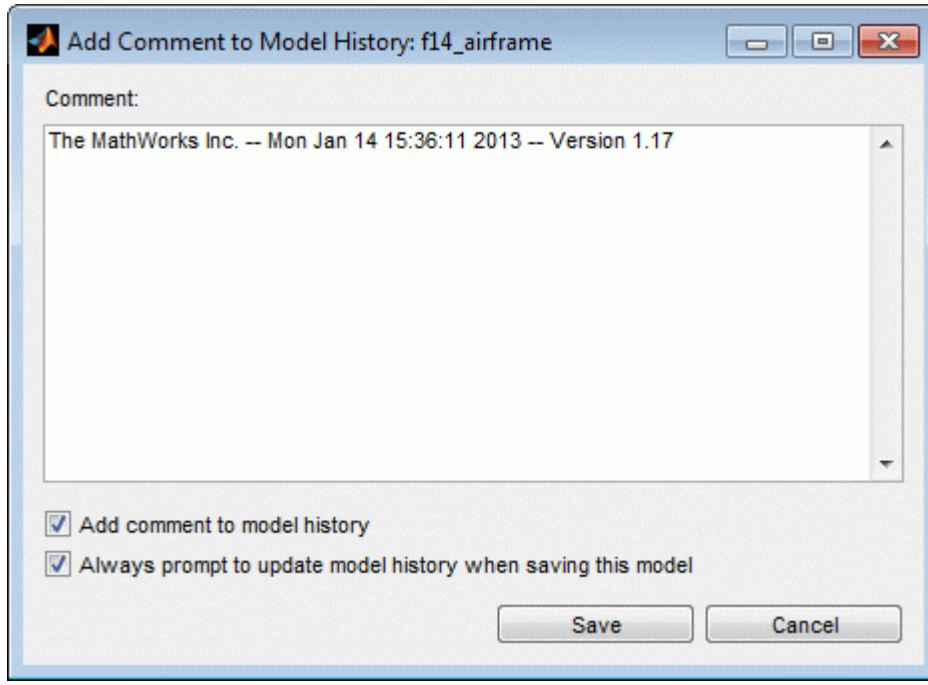
Log Comments History

You can create and store a record of changes with the model. Simulink compiles the history from comments that you or other users enter when saving changes to a model. For more flexibility adding labels and comments to models and submissions, see “Project Management”.

Logging Changes

To enable comment logging, in the **Info** tab of the model properties, in the **History** section, set **Prompt to update model history** to `When saving model`.

The next time you save the model, the Add Comment to Model History dialog box prompts you to enter a comment.



For example, describe the changes you have made to the model since the last time you saved it. To add an item to the model's change history, enter it in the **Comment** box and click **Save**. The information is stored in the model's change history log.

If you do not want to enter an item for this session, clear the **Add comment to model history** check box.

To discontinue change logging, you can either:

- Clear the **Always prompt to update model history when saving this model** check box.
- Change the **Prompt to update model history** model property to `Never`.

Version Information Properties

Some version information is stored as model parameters in a model. You can access this information programmatically using the Simulink `get_param` function.

The table describes the model parameters used by Simulink to store version information.

Property	Description
Created	Date created.
Creator	Name of the person who created this model.
Description	User-entered description of this model. Enter or edit a description on the Description tab of the Model Properties dialog box. You can view the model description by typing `help 'mymodelname'` at the MATLAB command prompt.
LastModifiedBy	Name of the user who last saved the model.
LastModifiedDate	Date when the model was last saved.
ModifiedByFormat	Format of the `ModifiedBy` parameter. The value can include the tag `%<Auto>`. The Simulink software replaces the tag with the current value of the `USER` environment variable.
ModifiedDateFormat	Format used to generate the value of the `LastModifiedDate` parameter. The value can include the tag `%<Auto>`. Simulink replaces the tag with the current date and time when saving the model.
ModifiedComment	Comment entered by user who last updated this model.
ModifiedHistory	History of changes to this model.
ModelVersion	Version number.

Property	Description
ModelVersionFormat	Format of model version number. The value can contain the tag `%<AutoIncrement:#>` where `#` is an integer. Simulink replaces the tag with `#` when displaying the version number. It increments `#` when saving the model.

`LibraryVersion` is a block parameter for a linked block. `LibraryVersion` is the `ModelVersion` of the library at the time the link was created.

For source control version information, see instead “Project Management”.

Model Discretizer

In this section...

What Is the Model Discretizer?

Model Discretizer selectively replaces continuous Simulink blocks with discrete equivalents. Discretization is a critical step in digital controller design and for hardware in-the-loop simulations.

You can use the Model Discretizer to:

- Identify a model's continuous blocks
- Change a block's parameters from continuous to discrete
- Apply discretization settings to all continuous blocks in the model or selected blocks
- Create configurable subsystems that contain multiple discretization candidates along with the original continuous block(s)
- Switch among the different discretization candidates and evaluate the resulting model simulations

Requirements

To use Model Discretizer

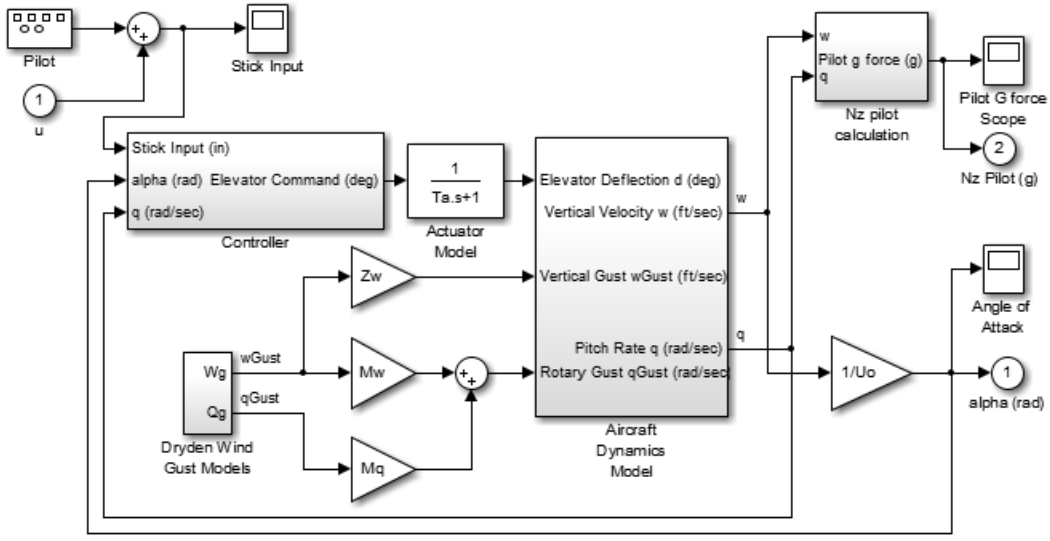
- You must have a Control System Toolbox™ license, Version 5.2 or later.
- Make sure your model does not contain any obsolete blocks and is upgraded to the current Simulink version. For more information, see “Model Upgrades”
- Make sure your model does not contain any masked subsystems. For more information, see “Block Masks”.

Discretize a Model with the Model Discretizer

To discretize a model:

- Start the Model Discretizer
- Specify the Transform Method
- Specify the Sample Time
- Specify the Discretization Method
- Discretize the Blocks

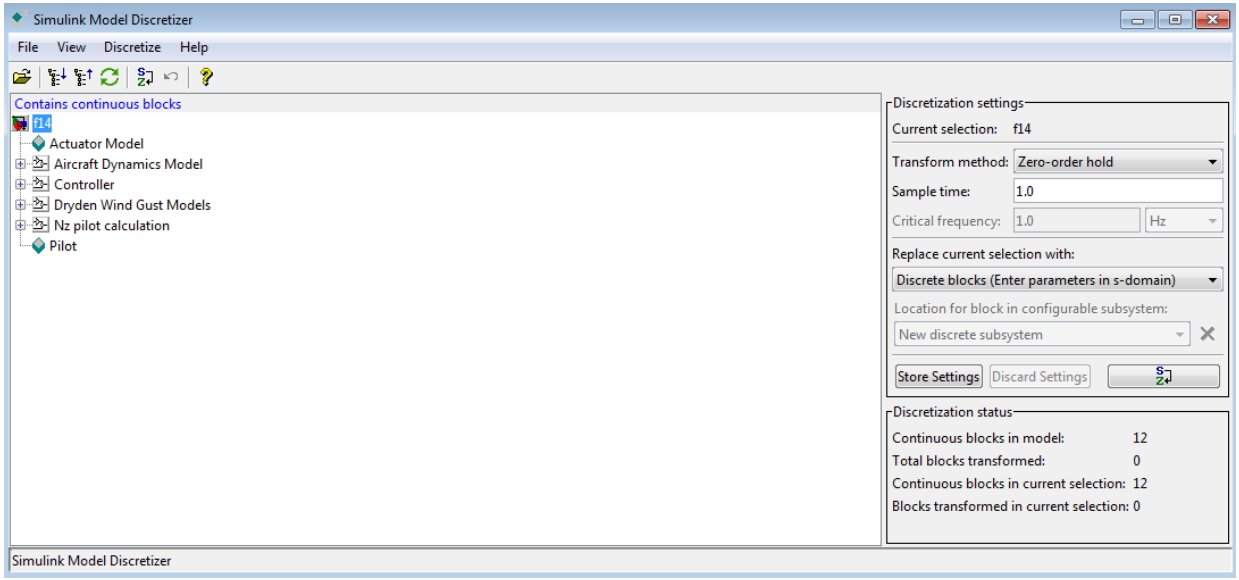
The `f14` model shows the steps in discretizing a model.



Start Model Discretizer

To open the tool, in the Simulink Editor, select **Analysis > Control Design > Model Discretizer**.

The **Simulink Model Discretizer** opens.



Alternatively, you can open Model Discretizer from the MATLAB Command Window using the `slmdldiscui` function.

The following command opens the **Simulink Model Discretizer** window with the `f14` model:

```
slmdldiscui('f14')
```

To open a new model or library from Model Discretizer, select **File** > **Load model**.

Specify the Transform Method

The transform method specifies the type of algorithms used in the discretization. For more information on the different transform methods, see the Control System Toolbox.

The **Transform method** list contains the following options:

- `Zero-order hold`

  Zero-order hold on the inputs.
- `First-order hold`

  Linear interpolation of inputs.

- `Tustin`

  Bilinear (Tustin) approximation.
- `Tustin with prewarping`

  Tustin approximation with frequency prewarping.
- `Matched pole-zero`

  Matched pole-zero method (for SISO systems only).

Specify the Sample Time

Enter the sample time in the **Sample time** field.

You can specify an offset time by entering a two-element vector for discrete blocks or configurable subsystems. The first element is the sample time and the second element is the offset time. For example, an entry of [1.0 0.1] would specify a 1.0 second sample time with a 0.1 second offset. If no offset is specified, the default is zero.

You can enter workspace variables when discretizing blocks in the s-domain. See “Discrete blocks (Enter parameters in s-domain)” on page 4-73.

Specify the Discretization Method

Specify the discretization method in the **Replace current selection with** field. The options are

- “Discrete blocks (Enter parameters in s-domain)” on page 4-73

  Creates a discrete block whose parameters are retained from the corresponding continuous block.
- “Discrete blocks (Enter parameters in z-domain)” on page 4-74

  Creates a discrete block whose parameters are “hard-coded“ values placed directly into the block's dialog.
- “Configurable subsystem (Enter parameters in s-domain)” on page 4-75

  Create multiple discretization candidates using s-domain values for the current selection. A configurable subsystem can consist of one or more blocks.
- “Configurable subsystem (Enter parameters in z-domain)” on page 4-76

Create multiple discretization candidates in z-domain for the current selection. A configurable subsystem can consist of one or more blocks.

Discrete blocks (Enter parameters in s-domain)

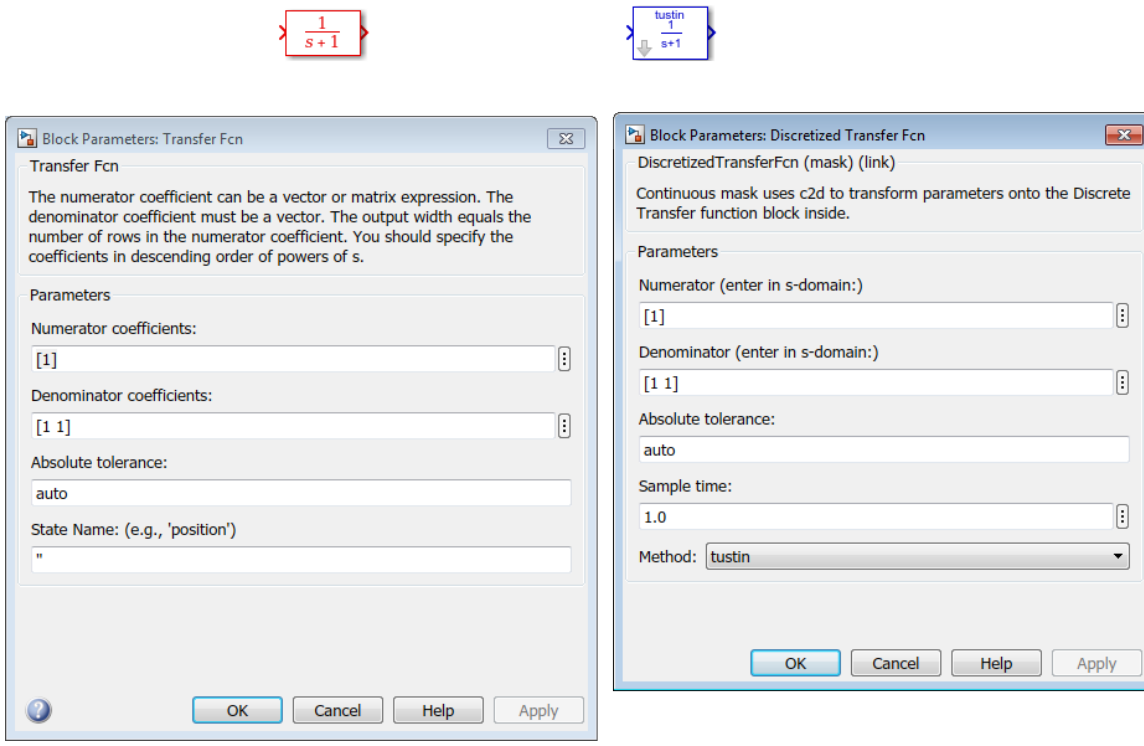
Creates a discrete block whose parameters are retained from the corresponding continuous block. The sample time and the discretization parameters are also on the block's parameter dialog box.

The block is implemented as a masked discrete block that uses `c2d` to transform the continuous parameters to discrete parameters in the mask initialization code.

These blocks have the unique capability of reverting to continuous behavior if the sample time is changed to zero. Entering the sample time as a workspace variable (`'Ts'`, for example) allows for easy changeover from continuous to discrete and back again. See "Specify the Sample Time" on page 4-72.

Note If you generated code from a model, parameters are not tunable when **Default parameter behavior** is set to `Inlined` in the model's Configuration Parameters dialog box.

The following figure shows a continuous Transfer Function block next to a Transfer Function block that has been discretized in the s-domain. The block parameters dialog box for each block appears below the block.



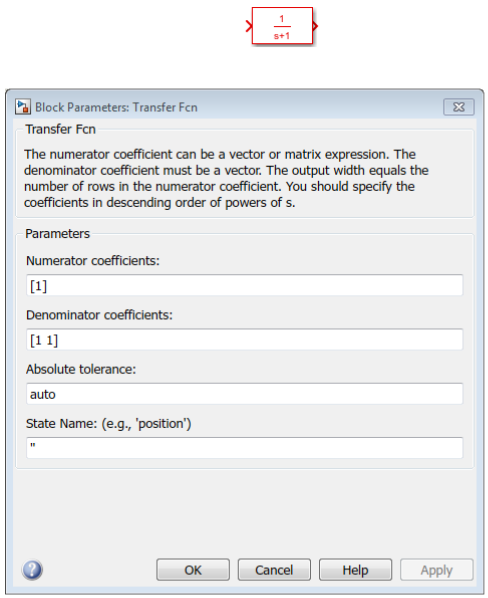
Discrete blocks (Enter parameters in z-domain)

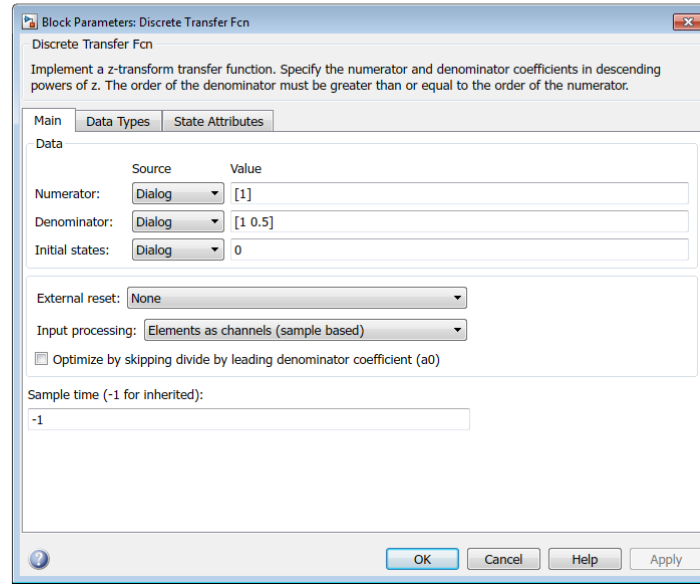
Creates a discrete block whose parameters are “hard-coded” values placed directly into the block's dialog box. Model Discretizer uses the `c2d` function to obtain the discretized parameters, if needed.

For more help on the `c2d` function, type the following in the Command Window:

```
help c2d
```

The following figure shows a continuous Transfer Function block next to a Transfer Function block that has been discretized in the z-domain. The block parameters dialog box for each block appears below the block.





Note If you want to recover exactly the original continuous parameter values after the Model Discretization session, you should enter parameters in the s-domain.

Configurable subsystem (Enter parameters in s-domain)

Create multiple discretization candidates using s-domain values for the current selection. A configurable subsystem can consist of one or more blocks.

The **Location for block in configurable subsystem** field becomes active when this option is selected. This option allows you to either create a new configurable subsystem or overwrite an existing one.

Note The current folder must be writable in order to save the library or libraries for the configurable subsystem option.

Configurable subsystem (Enter parameters in z-domain)

Create multiple discretization candidates in z-domain for the current selection. A configurable subsystem can consist of one or more blocks.

The **Location for block in configurable subsystem** field becomes active when this option is selected. This option allows you to either create a new configurable subsystem or overwrite an existing one.

Note The current folder must be writable in order to save the library or libraries for the configurable subsystem option.

Configurable subsystems are stored in a library containing the discretization candidates and the original continuous block. The library will be named `<model name>_disc_lib` and it will be stored in the current . For example a library containing a configurable subsystem created from the `f14` model will be named `f14_disc_lib`.

If multiple libraries are created from the same model, then the filenames will increment accordingly. For example, the second configurable subsystem library created from the `f14` model will be named `f14_disc_lib2`.

You can open a configurable subsystem library by right-clicking on the subsystem in the model and selecting **Library Link > Go to library block** from the context menu.

Discretize the Blocks

To discretize blocks that are linked to a library, you must either discretize the blocks in the library itself or disable the library links in the model window.

You can open the library from Model Discretizer by selecting **Load model** from the **File** menu.

You can disable the library links by right-clicking on the block and selecting **Library Link > Disable Link** from the context menu.

There are two methods for discretizing blocks.

Select Blocks and Discretize

1 Select a block or blocks in the Model Discretizer tree view pane.

To choose multiple blocks, press and hold the **Ctrl** button on the keyboard while selecting the blocks.

Note You must select blocks from the Model Discretizer tree view. Clicking blocks in the editor does not select them for discretization.

2 Select **Discretize current block** from the **Discretize** menu if a single block is selected or select **Discretize selected blocks** from the **Discretize** menu if multiple blocks are selected.

You can also discretize the current block by clicking the **Discretize** button, shown below.

Store the Discretization Settings and Apply Them to Selected Blocks in the Model

1 Enter the discretization settings for the current block.

2 Click **Store Settings**.

This adds the current block with its discretization settings to the group of preset blocks.

3 Repeat steps 1 and 2, as necessary.

4 Select **Discretize preset blocks** from the **Discretize** menu.

Deleting a Discretization Candidate from a Configurable Subsystem

You can delete a discretization candidate from a configurable subsystem by selecting it in the **Location for block in configurable subsystem** field and clicking the **Delete** button.

Undoing a Discretization

To undo a discretization, click the **Undo discretization** button.

Alternatively, you can select **Undo discretization** from the **Discretize** menu.

This operation undoes discretizations in the current selection and its children. For example, performing the undo operation on a subsystem will remove discretization from all blocks in all levels of the subsystem's hierarchy.

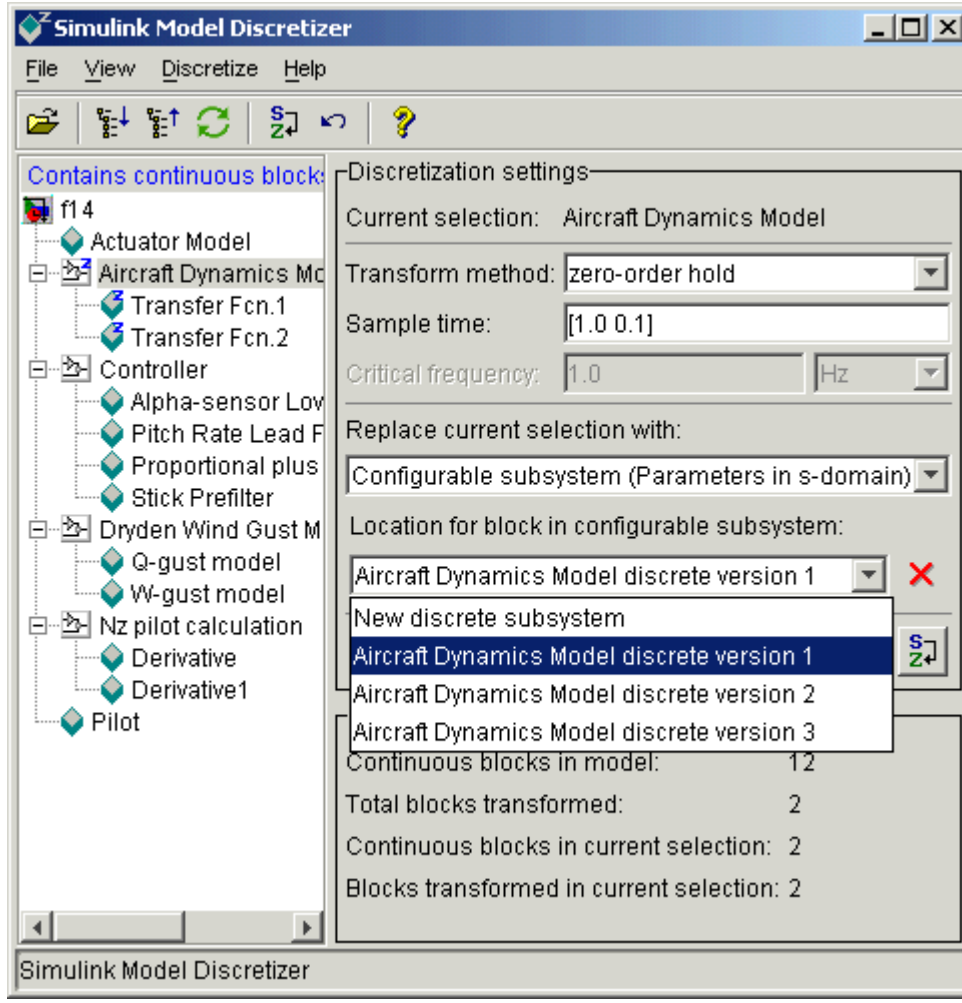
View the Discretized Model

Model Discretizer displays the model in a hierarchical tree view.

Viewing Discretized Blocks

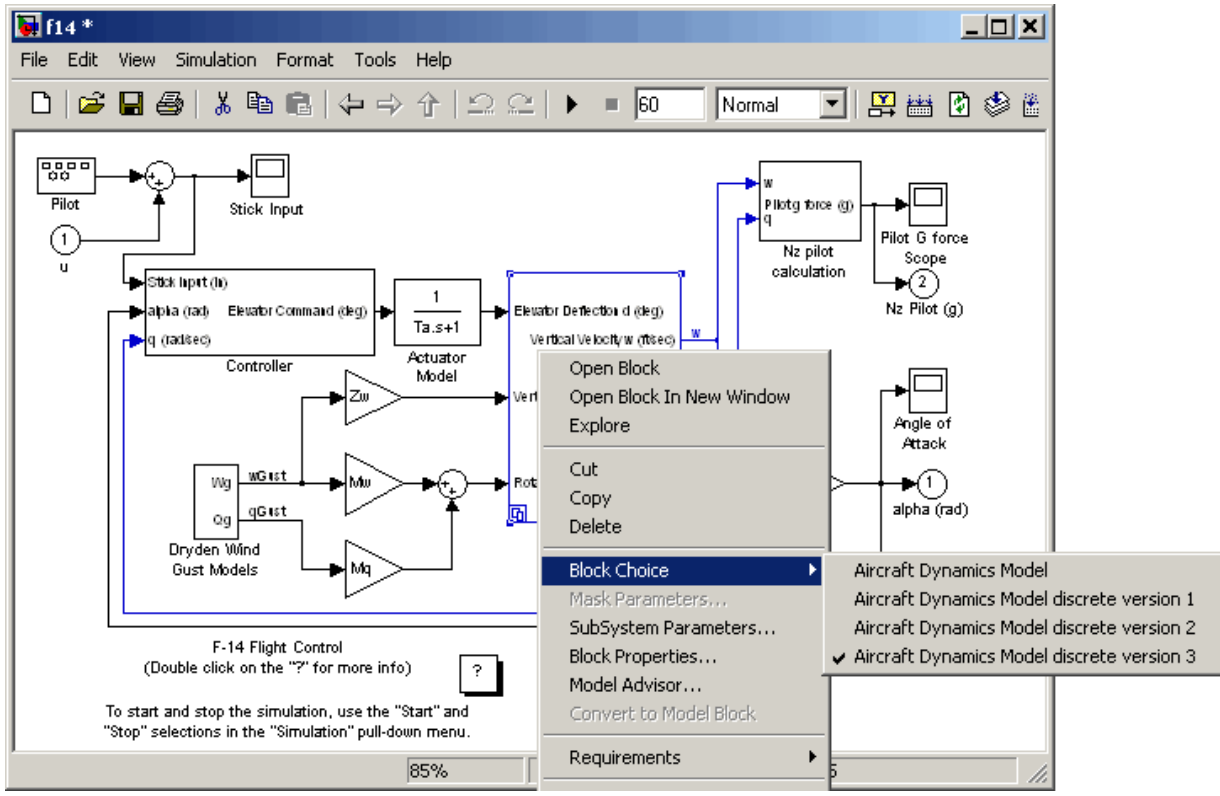
The block's icon in the tree view becomes highlighted with a "**z**" when the block has been discretized.

The following figure shows that the Aircraft Dynamics Model subsystem has been discretized into a configurable subsystem with three discretization candidates.

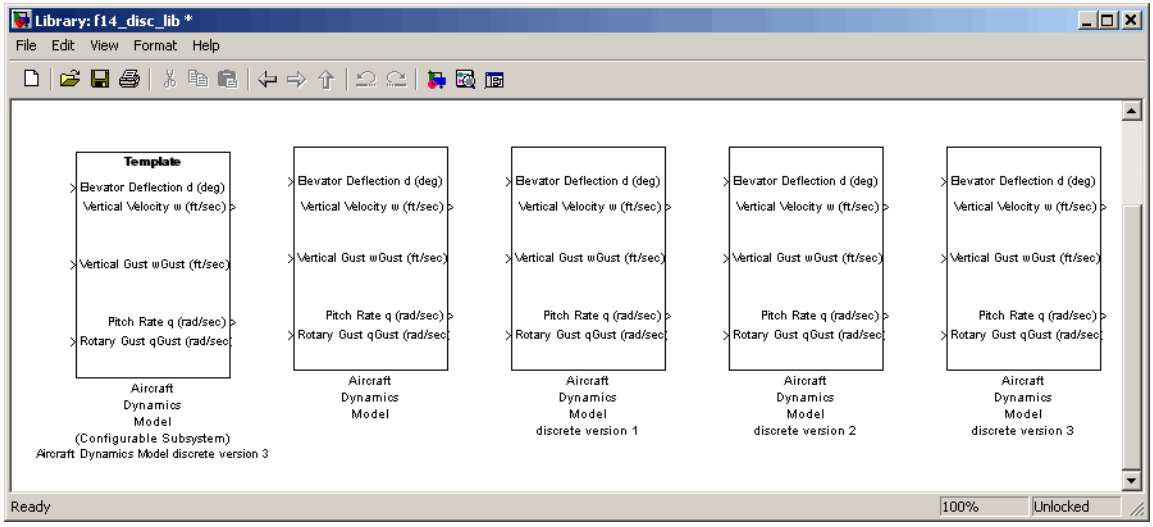


The other blocks in this `f14` model have not been discretized.

The following figure shows the Aircraft Dynamics Model subsystem of the `f14` example model after discretization into a configurable subsystem containing the original continuous model and three discretization candidates.



The following figure shows the library containing the Aircraft Dynamics Model configurable subsystem with the original continuous model and three discretization candidates.



Refreshing Model Discretizer View of the Model

To refresh Model Discretizer's tree view of the model when the model has been changed, click the **Refresh** button.

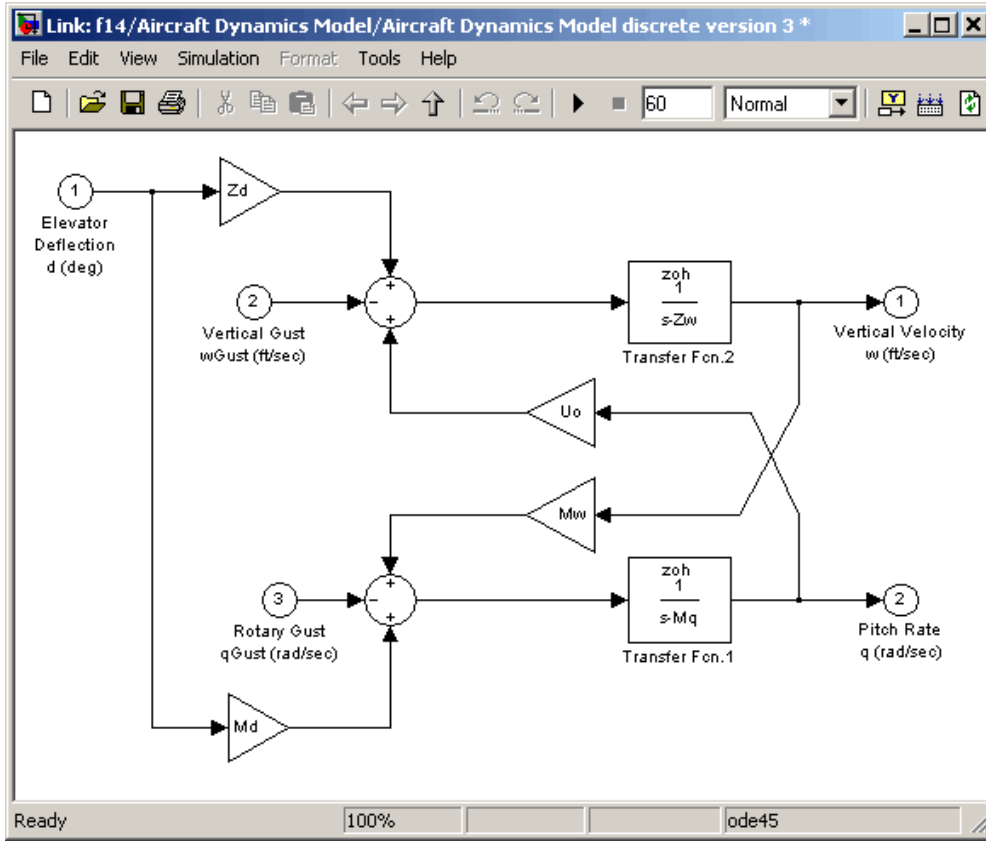
Alternatively, you can select **Refresh** from the **View** menu.

Discretize Blocks from the Simulink Model

You can replace continuous blocks in a Simulink software model with the equivalent blocks discretized in the s-domain using the Discretizing library.

The procedure below shows how to replace a continuous Transfer Fcn block in the Aircraft Dynamics Model subsystem of the `f14` model with a discretized Transfer Fcn block from the Discretizing Library. The block is discretized in the s-domain with a zero-order hold transform method and a two second sample time.

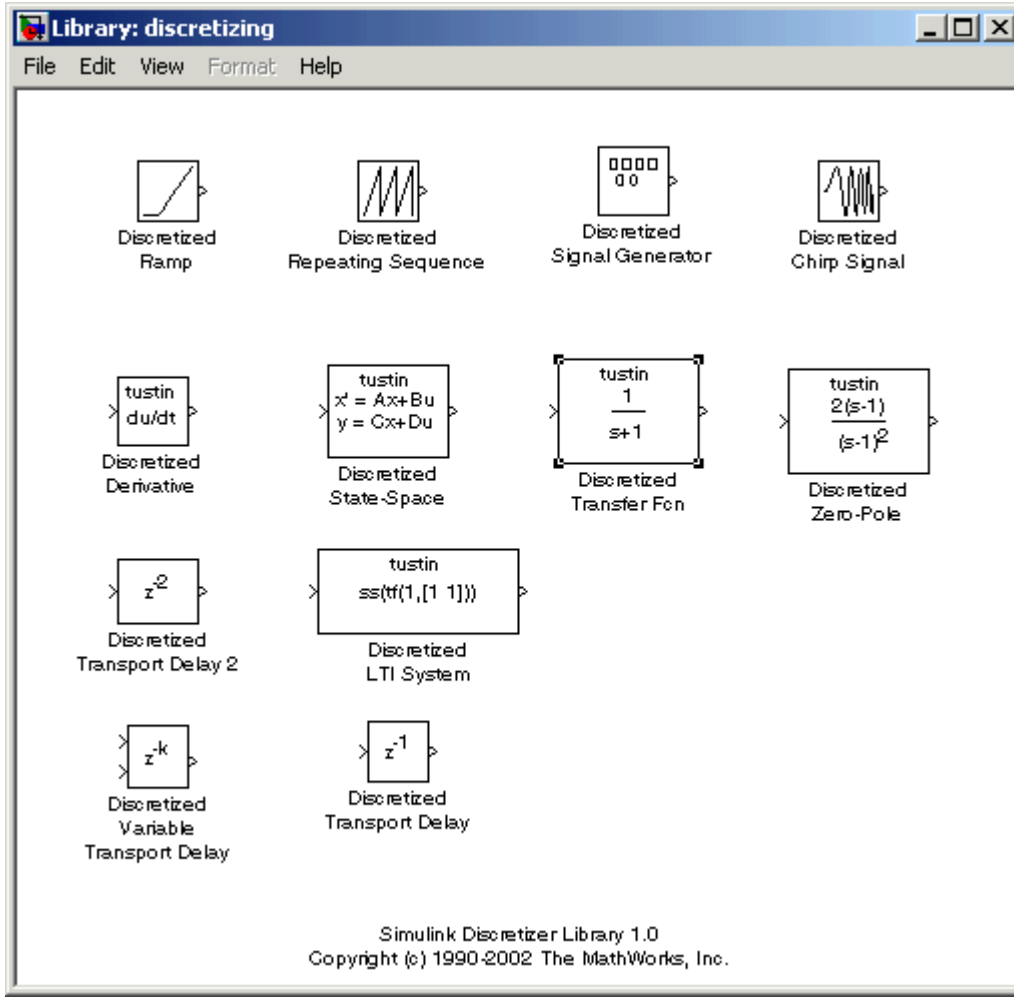
1. Open the `f14` model.
2. Open the Aircraft Dynamics Model subsystem in the `f14` model.



3 Open the Discretizing library window.

Enter `discretizing` at the MATLAB command prompt.

The **Library: discretizing** window opens.

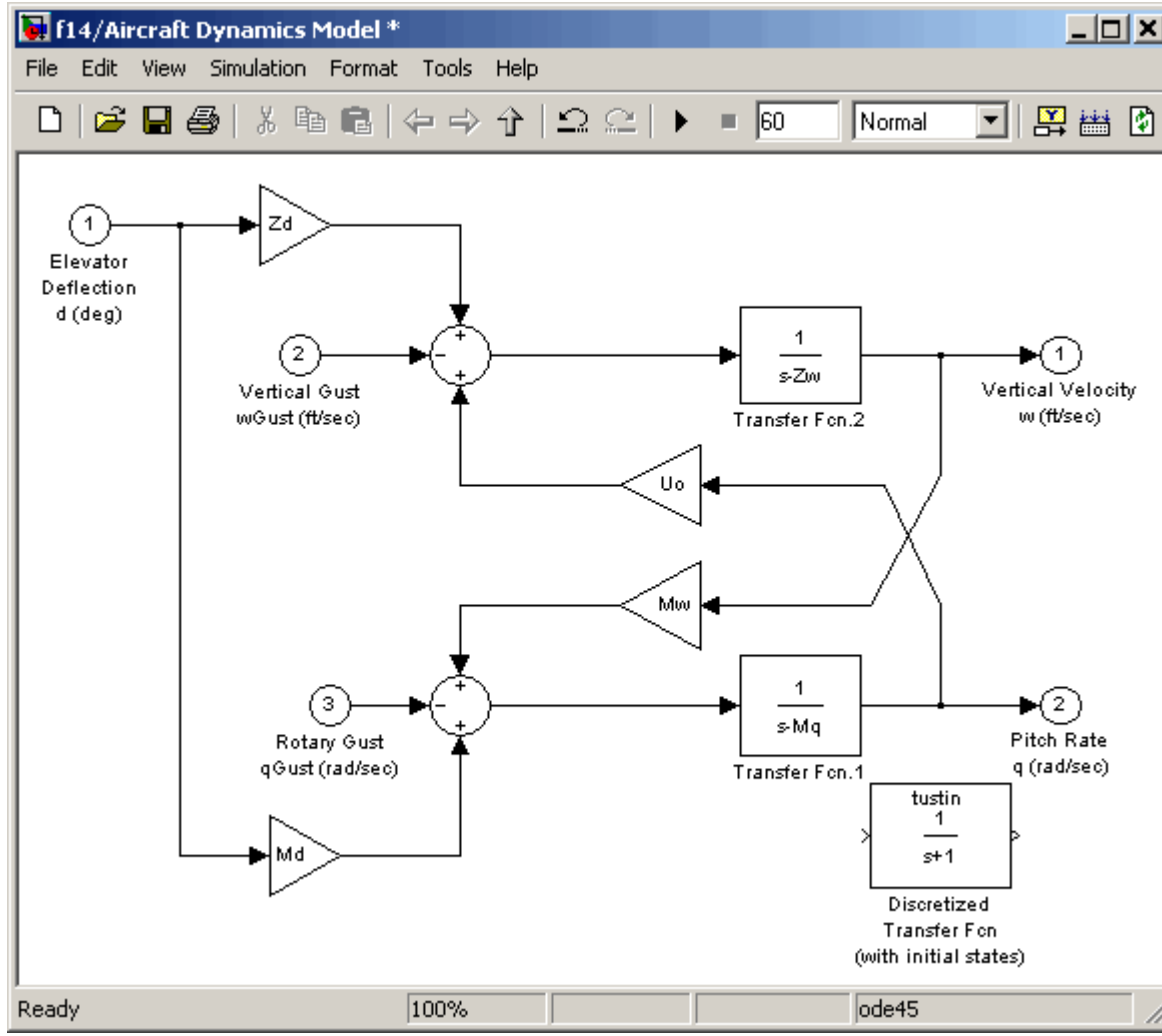


This library contains s-domain discretized blocks.

4 Add the Discretized Transfer Fcn (with initial states) block to the **f14/Aircraft Dynamics Model** window.

   a Click the Discretized Transfer Fcn block in the **Library: discretizing** window.

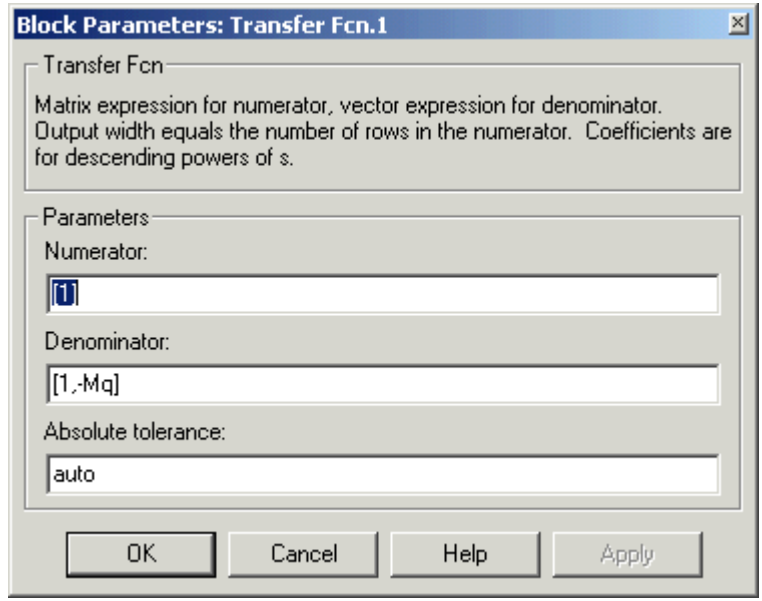
   b Drag it into the **f14/Aircraft Dynamics Model** window.



5 Open the parameter dialog box for the Transfer Fcn.1 block.

Double-click the Transfer Fcn.1 block in the **f14/Aircraft Dynamics Model** window.

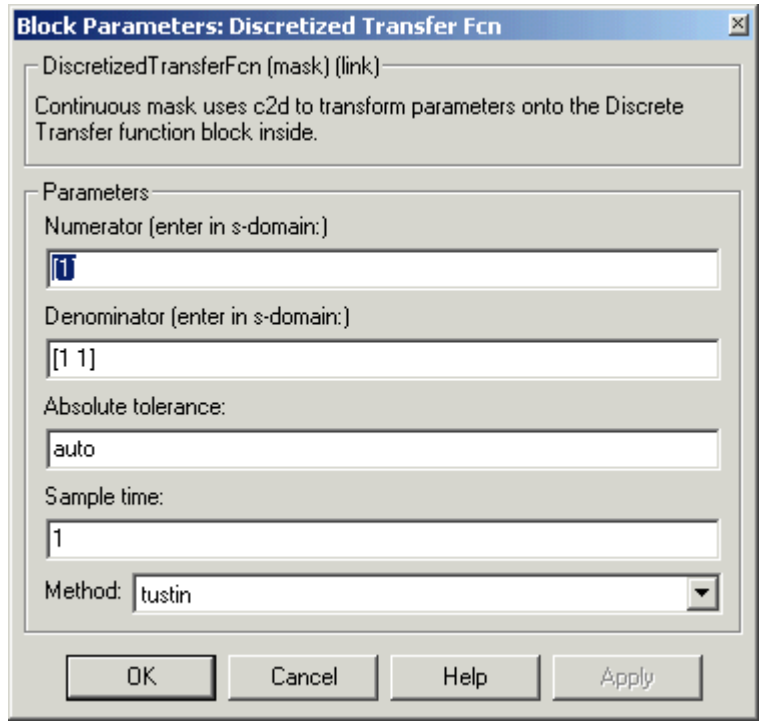
The Block Parameters: Transfer Fcn.1 dialog box opens.



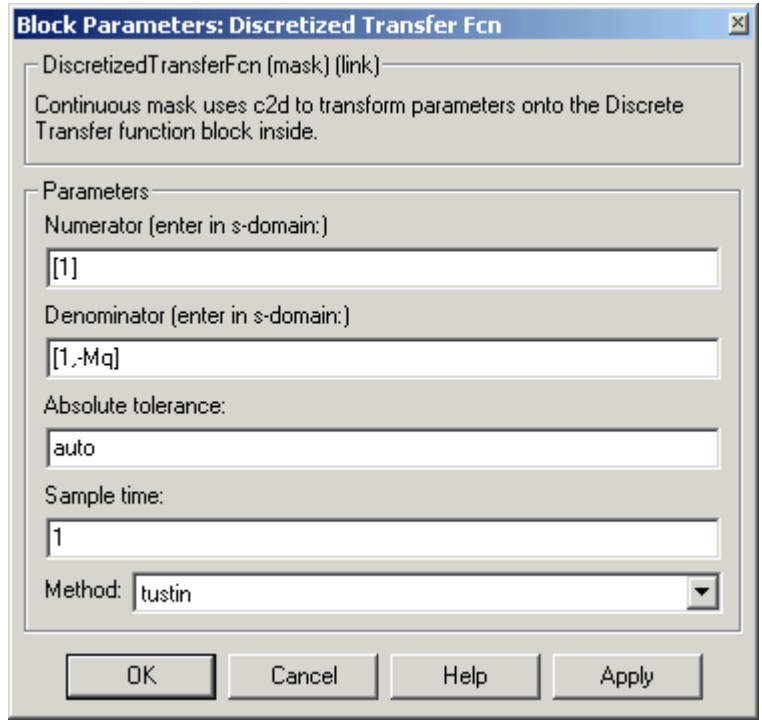
6 Open the parameter dialog box for the Discretized Transfer Fcn block.

Double-click the Discretized Transfer Fcn block in the **f14/Aircraft Dynamics Model** window.

The Block Parameters: Discretized Transfer Fcn dialog box opens.



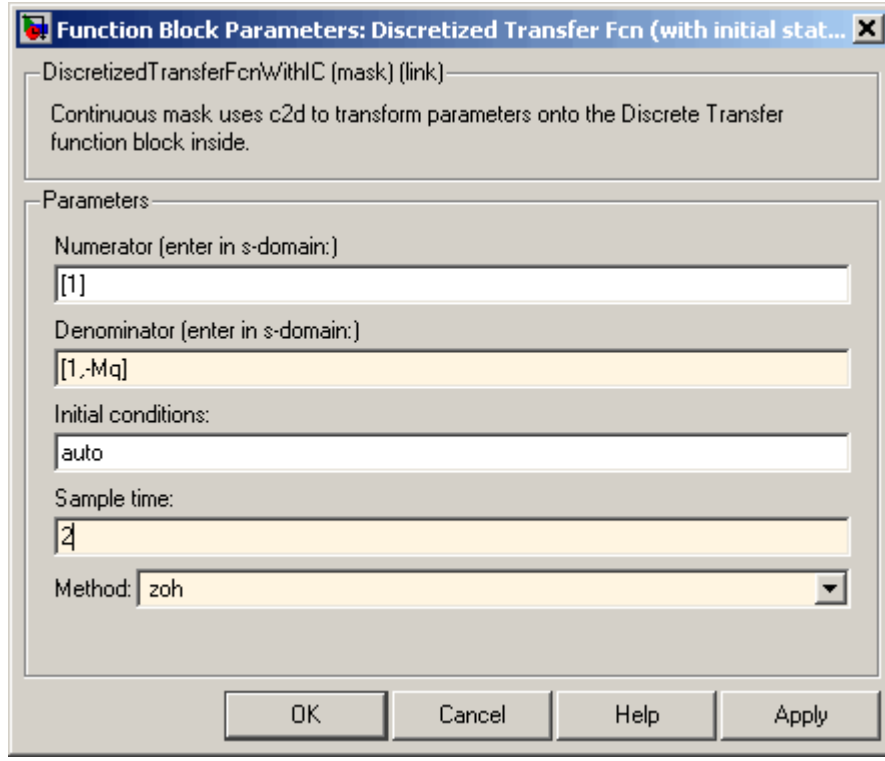
Copy the parameter information from the Transfer Fcn.1 block's dialog box to the Discretized Transfer Fcn block's dialog box.



7 Enter `2` in the **Sample time** field.

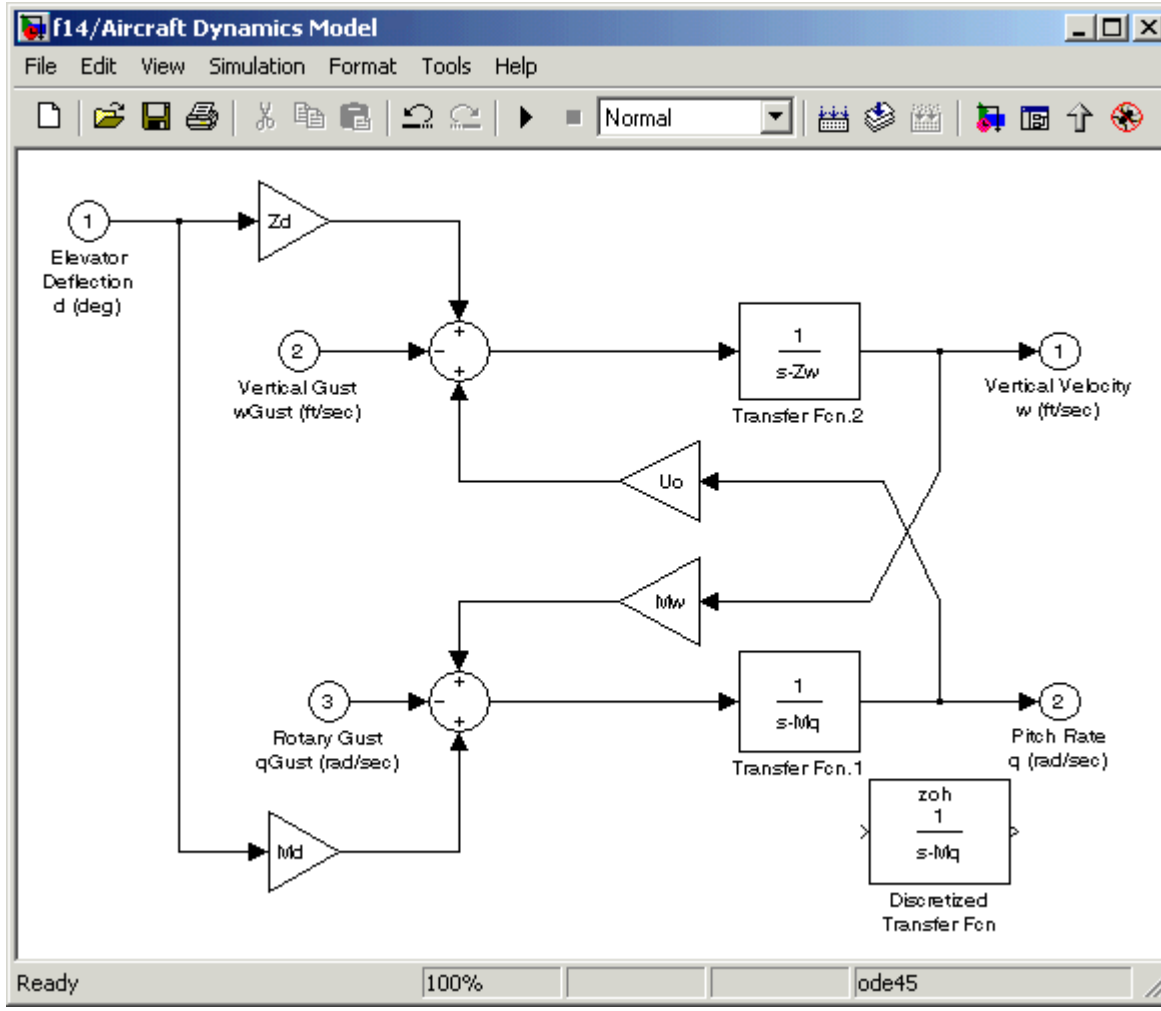
8 Select `zoh` from the **Method** drop-down list.

The parameter dialog box for the Discretized Transfer Fcn now looks like this.



9 Click **OK**.

The **f14/Aircraft Dynamics Model** window now looks like this.

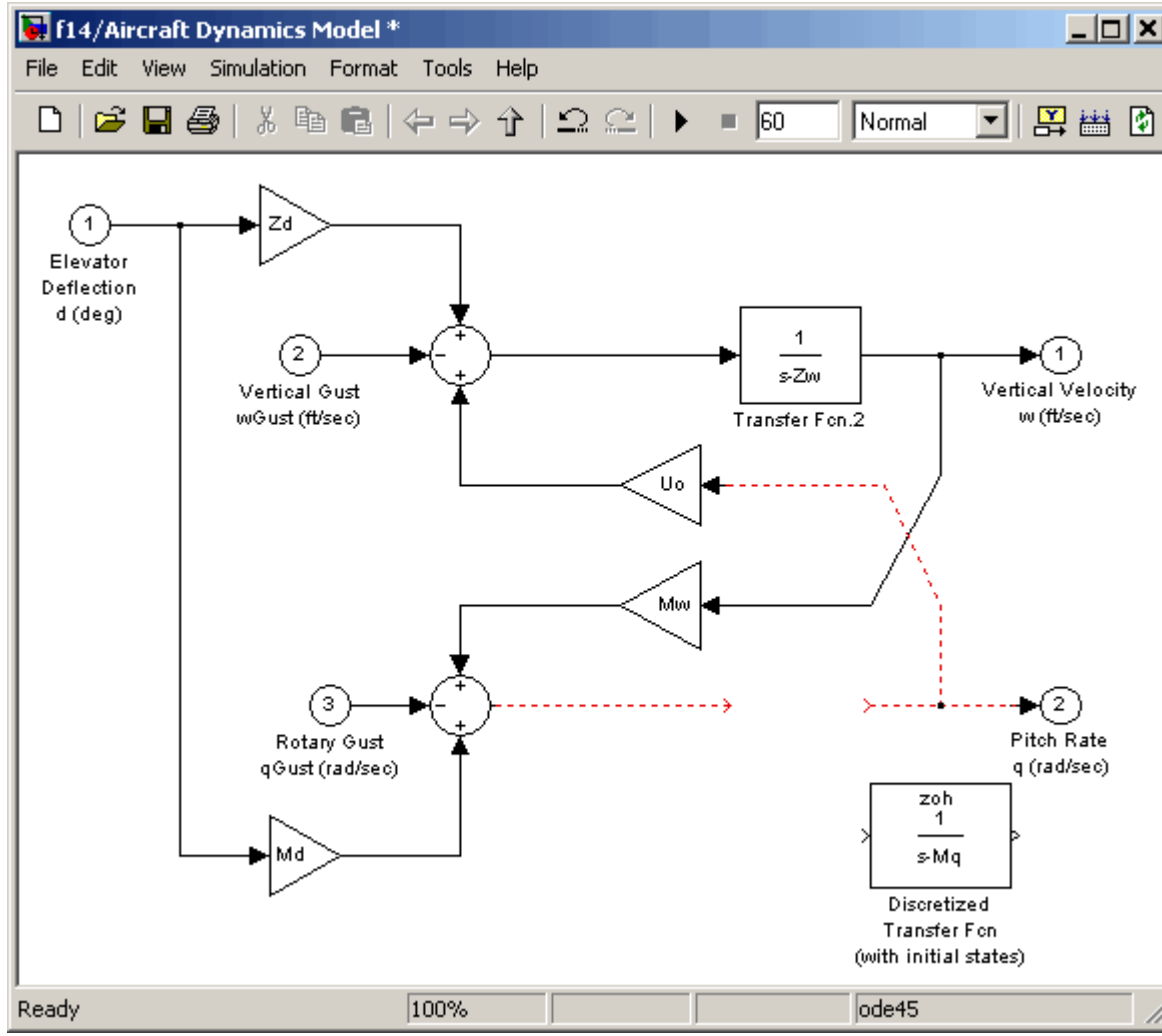


10 Delete the original Transfer Fcn.1 block.

a Click the Transfer Fcn.1 block.

b Press the **Delete** key.

The **f14/Aircraft Dynamics Model** window now looks like this.

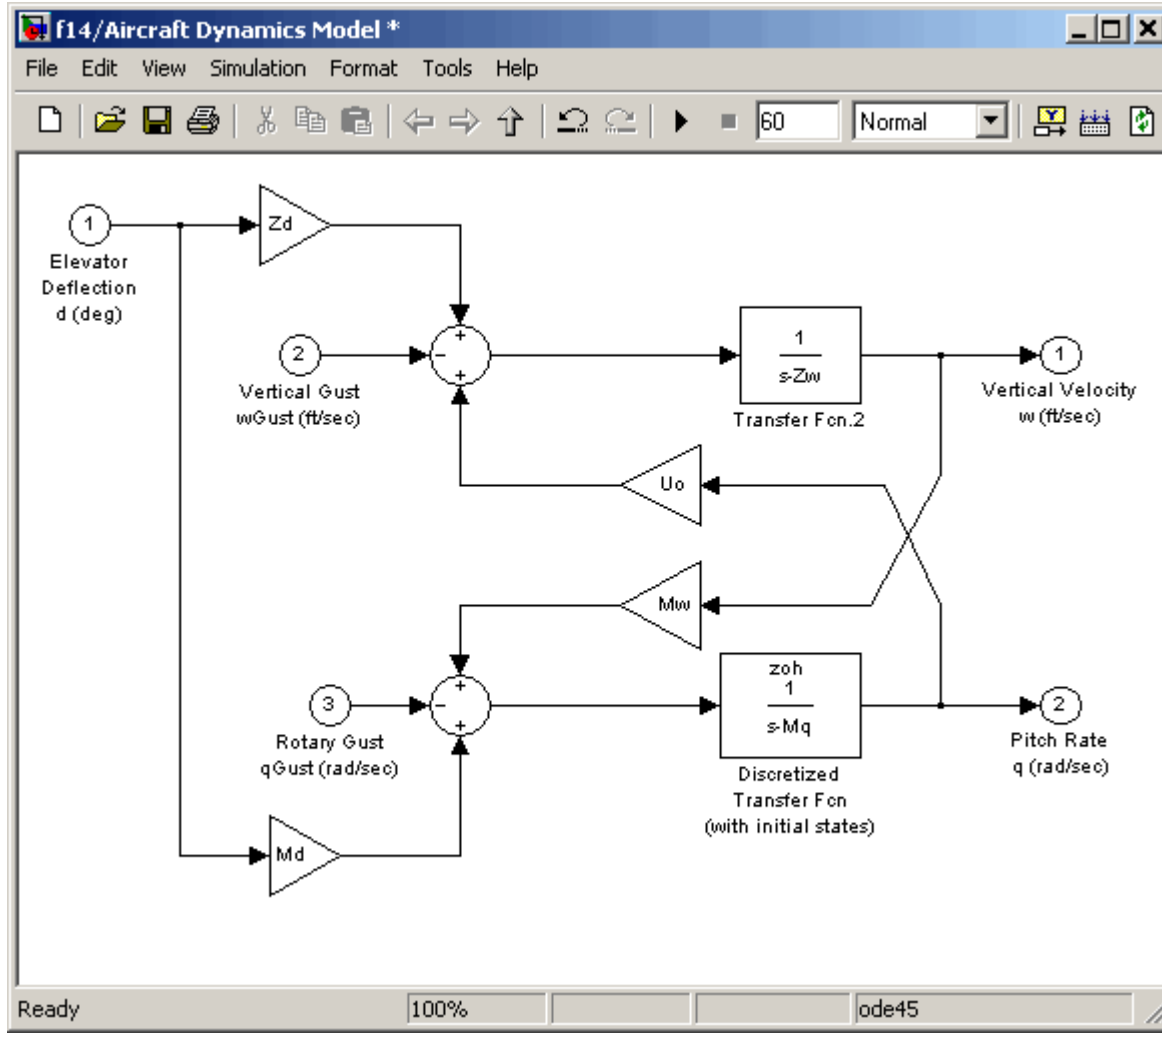


11 Add the Discretized Transfer Fcn block to the model.

a Click the Discretized Transfer Fcn block.

b Drag the Discretized Transfer Fcn block into position to complete the model.

The **f14/Aircraft Dynamics Model** window now looks like this.



Discretize a Model with the sldiscmdl Function

Use the `sldiscmdl` function to discretize Simulink software models from the MATLAB Command Window. You can specify the transform method, the sample time, and the discretization method with the `sldiscmdl` function.

For example, the following command discretizes the `f14` model in the s-domain with a 1-second sample time using a zero-order hold transform method:

```
sldiscmdl('f14',1.0,'zoh')
```

Model Advisor

Select and Run Model Advisor Checks

Model Advisor Overview

The Model Advisor checks a model or subsystem for conditions and configuration settings including conditions that cause inaccurate or inefficient simulation of the system that the model represents. If you have Simulink Coder or Simulink Check™, the Model Advisor can check for model settings that cause generation of inefficient code or code unsuitable for safety-critical applications. If you have Simulink Design Verifier™, the Model Advisor can check for design errors. If an error is reported, you can view a test case that reproduces the error.

The Model Advisor produces a report that lists the suboptimal conditions or settings that it finds, and proposes better model configuration settings where appropriate.

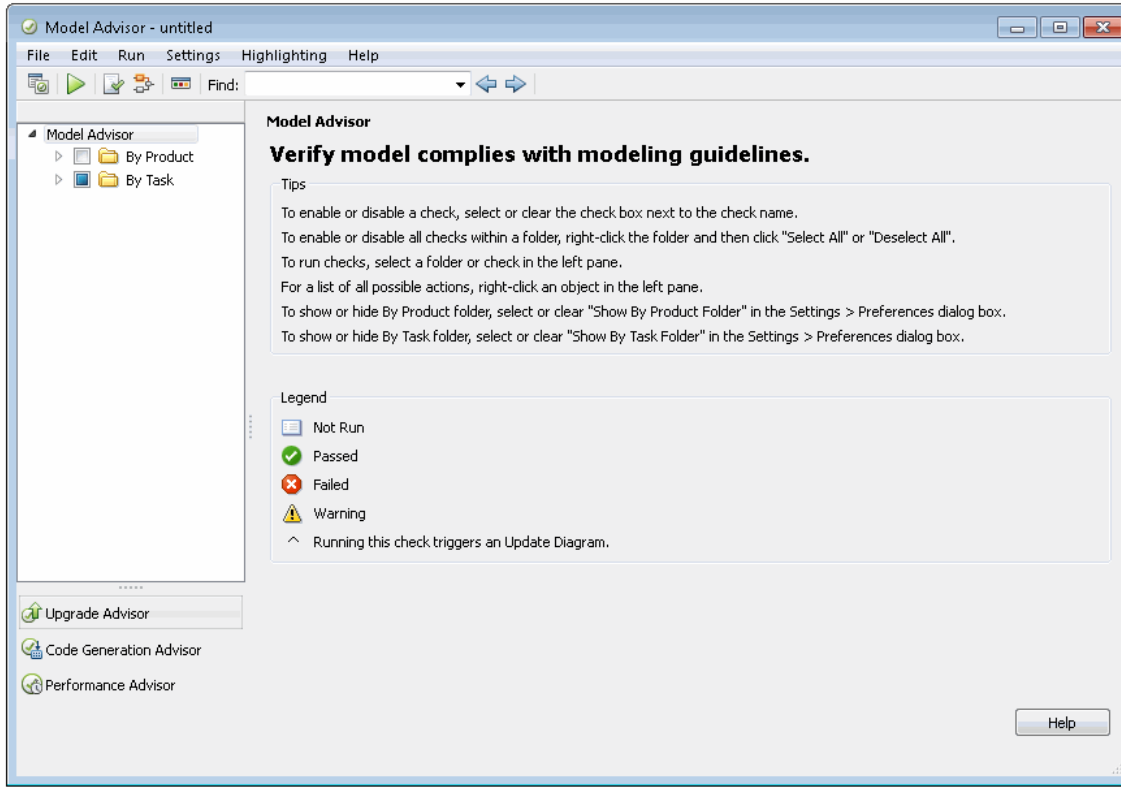
Software is inherently complex and may not be completely free of errors. Model Advisor checks might contain bugs. MathWorks® reports known bugs brought to its attention on its Bug Report system at http://www.mathworks.com/support/bugreports/. The bug reports are an integral part of the documentation for each release. Examine periodically all bug reports for a release as such reports may identify inconsistencies between the actual behavior of a release you are using and the behavior described in this documentation.

While applying Model Advisor checks to your model increases the likelihood that your model does not violate certain modeling standards or guidelines, their application cannot guarantee that the system being developed will be safe or error-free. It is ultimately your responsibility to verify, using multiple methods, that the system being developed provides its intended functionality and does not include any unintended functionality.

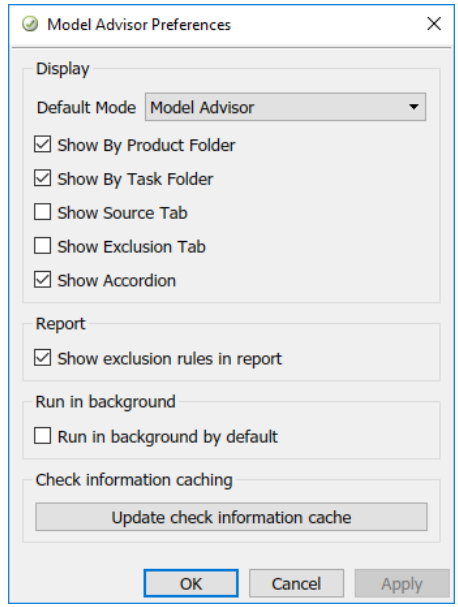
Run Model Advisor Checks

1. Open the Model Advisor example model `sldemo_mdladv`.
2. Start the Model Advisor. In the Model Editor, select **Analysis** > **Model Advisor** > **Model Advisor** or **Model Advisor Dashboard**. The dashboard preserves the checks used in the previous analysis. You can run these same checks without reloading them, saving analysis time.
3. In the Model Explorer, in the **Contents** pane, select **Advice for** ***`model`***. ***`model`*** is the name of the model that you want to check.

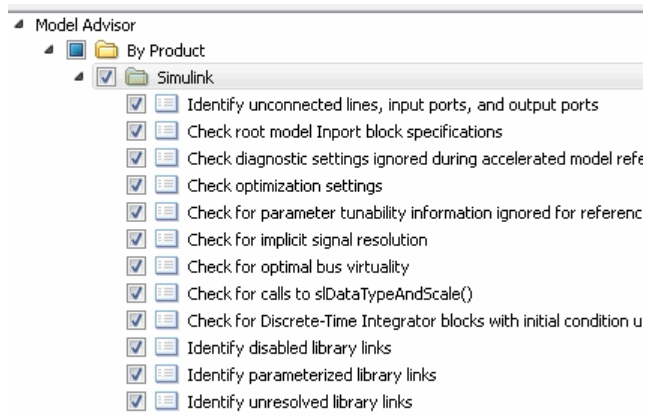
4. In the Model Editor, right-click the subsystem that you want to check, and in the context menu select **Model Advisor**.
5. At the command prompt, enter `modeladvisor('sldemo_mdladv')`.
6. In the System Selector dialog box, select the model or system that you want to analyze, for example, `sldemo_mdladv`. Click **OK**.
7. In the left pane of the Model Advisor, expand the **By Product** and **By Task** folders to display the subfolders. The **By Task** folders display checks related to specific tasks. For example, to run checks to determine if your model is configured for simulation accuracy, select checks in the **Simulation Accuracy** folder.



8. The **By Product** folders display checks available with specific products.
9. Select **Settings** > **Preferences** to control the folders that are displayed.



10 In the left pane, select the checks to run on your model. For example, select the checks in the **By Product > Simulink** folder.



Display Check Results

To display an HTML report of check results:

1 In the right pane of the Model Advisor, select **Show report after run**.

2 On the toolbar, click **Run Selected Checks** or  . After the Model Advisor runs the checks, the results appear in a browser if you selected the option to show the report.

After reviewing the check results in the Model Advisor window, you can choose to fix warnings or failures.

Set Model Advisor Window Preferences

To open the Model Advisor Preferences dialog box, on the toolbar, select **Settings** > **Preferences**.

Action	Select
Display the check available for each product.	**Show By Product Folder**
Display checks related to specific tasks.	**Show By Task Folder**
Display the check Title, TitleId, and location of the MATLAB source code for the check.	**Show Source Tab**. The **Source** tab displays check source information.
Display checks that are excluded from the Model Advisor analysis.	**Show Exclusion tab**. The **Exclusions** tab displays checks that are excluded from the Model Advisor analysis.

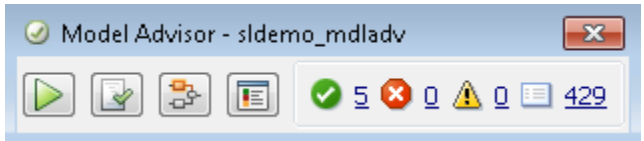
Display and Run Checks

Action	Model Advisor Options
Display checks related to specific tasks.	Select **By Task**.
Display the check available for each product.	Select **By Product**.
Find checks and folders.	In the **Find:** field, enter text and click the **Find Next** button (). The Model Advisor searches in check names, folder names, and analysis descriptions.

Action	Model Advisor Options
Reset the status of the checks to not run.	In the left pane, right-click **Model Advisor** and select `Reset`.
Select some or all of the checks.	Select the check and folder check boxes.
Run the selected checks.	On the toolbar of the Model Advisor window, click **Run selected checks** ().

Run the Same Set of Checks Consistently

To consistently run the same set of checks on your model, use the Model Advisor dashboard.



Action	Option
Select and view checks.	In the Model Advisor window, click the **Switch to standard view** toggle () button.
Run checks.	Click **Run checks** ().
View the report in a separate browser window.	Click **Open Report**.
View highlighted results.	Click the **Enable highlighting** toggle () button.

Run Model Checks Programmatically

If you have Simulink Check, you can create MATLAB scripts and functions so that you can run the Model Advisor programmatically. For example, you can create a `ModelAdvisor.run` function to check whether your model passes a specified set of the Model Advisor checks every time that you open the model and start a simulation. If you have Simulink Coder, the function can generate code from the model.

Access Other Advisors

You can use the Model Advisor window to access other Advisors.

Action	Select
Configure your model to meet code generation objectives.	**Code Generation Advisor**. See "Application Objectives Using Code Generation Advisor" (Simulink Coder).
Upgrade and improve models with the current release.	**Upgrade Advisor**. See "Consult the Upgrade Advisor" on page 6-2.
Improve the simulation performance of your model.	**Performance Advisor**. See "Improve Simulation Performance Using Performance Advisor" on page 31-2.

More About

- "Model Advisor Limitations" on page 5-8
- "Optimization Tools and Techniques" (Simulink Coder)
- "Create Model Advisor Checks" (Simulink Check)

Model Advisor Limitations

When you use the Model Advisor to check systems, these limitations apply:

- If you rename a system, you must restart the Model Advisor to check that system.
- In systems that contain a variant subsystem, the Model Advisor checks only the active subsystem.
- Model Advisor does not analyze commented blocks.
- Checks do not search in Model blocks or Subsystem blocks with the block parameter **Read/Write** set to `NoReadorWrite`. However, on a check-by-check basis, Model Advisor checks do search in library blocks and masked subsystems.
- Unless specified in the documentation for a check, the Model Advisor, by default, does not analyze the contents of a Model Reference block.

For limitations that apply to specific checks, see the "Capabilities and Limitations" section in the check documentation. For example, for capabilities that apply to the **Identify unconnected lines, input ports, and output ports** check, see "Capabilities and Limitations".

More About

- "Model Advisor Overview" on page 5-2

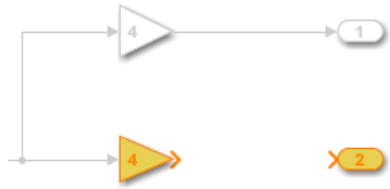
Save Model Analysis Time

You can save analysis time by consistently running the same set of checks on your model by using the Model Advisor dashboard. When you use the dashboard, the Model Advisor does not reload the checks before executing them, saving analysis time.

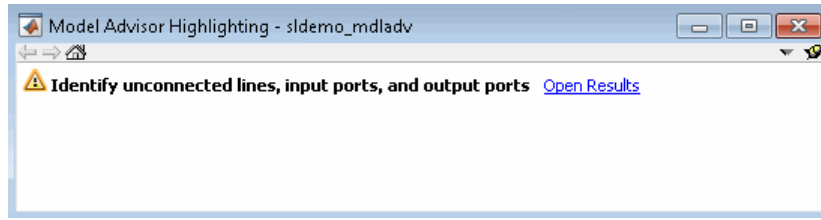
1. Open your model. For example, open the Model Advisor model, `sldemo_mdladv`.
2. Open the Model Advisor dashboard.
   a. From the Simulink Editor, select **Analysis > Model Advisor > Model Advisor Dashboard** .

      Alternatively, from the Simulink Editor toolbar  drop-down list, select `Model Advisor Dashboard`.
   b. In the System Selector window, select the model or system that you want to review. For example, `sldemo_mdladv`. Click **OK**.
3. Optionally, to select or view checks to run on your model, click the **Switch to standard view** toggle () button.
   a. In the Model Advisor window, open the **By Product** folder and select checks:
      Identify unconnected lines, input ports, and output ports
      Check root model Inport block specifications

      If the **By Product** folder is not displayed in the Model Advisor window, select **Show By Product Folder** in the **Settings > Preferences** dialog box.
   b. Return to the Model Advisor dashboard by clicking the **Switch to Model Advisor Dashboard** toggle () button.
4. On the Model Advisor dashboard, click **Run checks** ().
5. To view highlighted results, click the **Enable Highlighting** toggle ().
   - In the model window, the blocks causing the **Identify unconnected lines, input ports, and output ports** check warning are highlighted in yellow.



- The Model Advisor Highlighting information window opens with a link to the Model Advisor window. In the Model Advisor window, you can find more information about the check results and how to fix the warning condition.



6 After reviewing the check results, you can choose to fix warnings or failures. For example, to fix the **Identify unconnected lines, input ports, and output ports** check warning:

a Connect model blocks `Gain2` and `Out4`.

b On the Model Advisor dashboard, click **Run checks** () to rerun the checks.

The **Identify unconnected lines, input ports, and output ports** check passes.

Run Model Checks in Background

If you have Parallel Computing Toolbox, you can run the Model Advisor in the background, so that you can continue working on your model during analysis. When you start a Model Advisor analysis run in the background, Model Advisor takes a snapshot of your model. The analysis does not reflect changes that you make to your model while Model Advisor is running in the background.

1. Open your model.
2. Start the Model Advisor.
   a. From the Simulink Editor, select **Analysis > Model Advisor > Model Advisor**.
   b. In the System Selector window, select the model or system that you want to review.
3. In the Model Advisor window, click the **Run checks in background** toggle ().
4. In the left pane of the Model Advisor window, select the checks that you want to run.
5. In the Model Advisor window, select **Run selected checks** () button.

   Alternatively, you can use the Model Advisor dashboard to run the checks. In the Model Advisor window, switch to the Model Advisor dashboard by clicking the **Switch to Model Advisor Dashboard** toggle (). On the Model Advisor dashboard, click **Run selected checks** ().

   The Model Advisor starts an analysis on a parallel processor.
6. To stop running checks in the background, in the Model Advisor window, click **Stop background run** (). In the lower-left pane, you see a status of the analysis.

The **Explore Result** option is not available for checks that are run in the background.

- “Address Model Check Results” on page 5-13

Address Model Check Results

To find warnings or failures in your model:

- Open the model `sldemo_mdladv`. From the toolbar, select **Analysis > Model Advisor > Model Advisor**. Select checks **By Product > Simulink**.
- On the toolbar of the Model Advisor window, click **Run selected checks** (). The Model Advisor finds warnings or failures in the model.

Address Model Check Results with Highlighting

To indicate the analysis results for individual Model Advisor checks, use color highlighting on the model diagram. Highlighting is available for Simulink blocks and Stateflow charts. Blocks that pass a check, fail a check, or cause a check warning are highlighted in color in the model window. On the toolbar of the Model Advisor window, click **Enable highlighting** (), select **Highlighting > Enable Highlighting**.

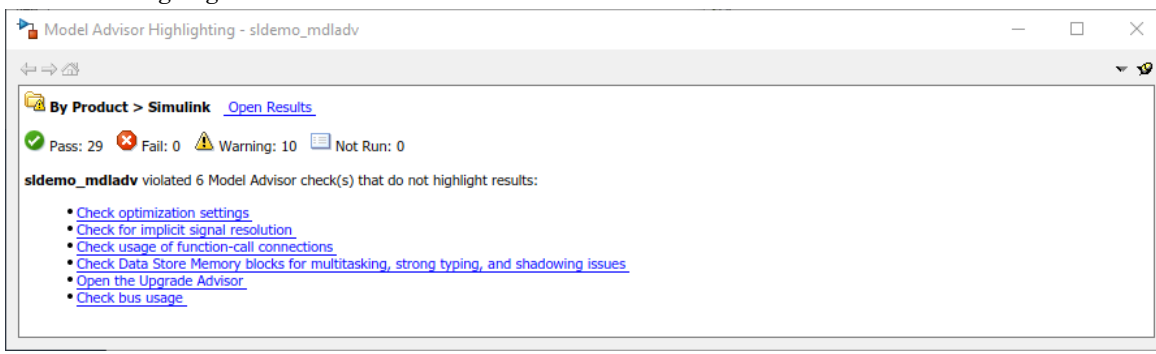
After selecting the highlighting feature, the model window and a Model Advisor Highlighting information window open. The Model Advisor Highlighting information window provides a link to the Model Advisor window where you can review the check results.

Yellow with orange border		Blocks that cause the check failure or warning.
White with orange border		Subsystem with blocks that cause the check warning or failure.
White with gray border		Blocks or subsystems without highlighting.
Gray with black border		Blocks that are excluded from the check.

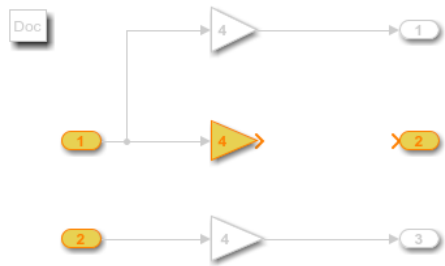
White with black border		Subsystems that are excluded from the check.

If a check warns or fails, and the model window highlights blocks in gray, closely examine the results in the Model Advisor window. A Model Advisor check can fail or warn due to your parameter or diagnostic settings.

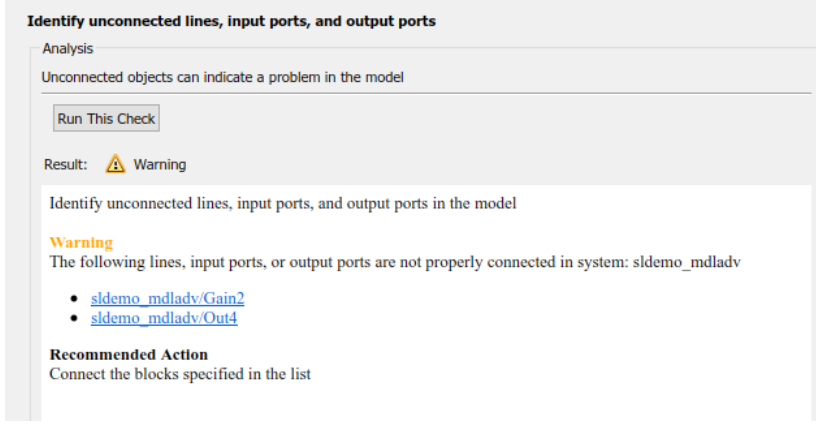
After you run a Model Advisor analysis and select the highlighting feature, checks with highlighted results are indicated with an  icon in the Model Advisor window. Highlighting is not available for some checks. Selecting **By Product > Simulink** displays Model Advisor checks in the Model Advisor Highlighting window that do not highlight results.



In the left pane of the Model Advisor window, select the highlighted check **Identify unconnected lines, input ports, and output ports**. In the model editor window, the Model Advisor highlights the blocks or components related to the warning. In this case, the Model Advisor finds a `Gain` block and an `Outport` block not properly connected to the model.



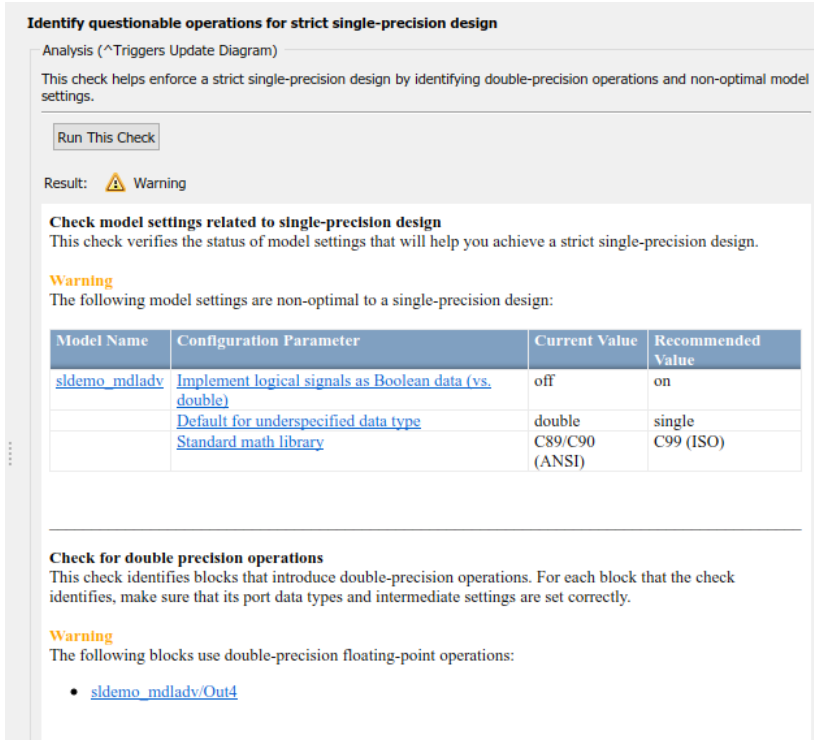
In the right pane of the Model Advisor window, there is further information about the warning.



The **Recommended Action** suggests how to fix the warning or error. In this case, connect the disconnected blocks.

In the left pane of the Model Advisor window, select the highlighted check **Identify questionable operations for strict single-precision design**. In the model editor window, the Model Advisor highlights the blocks or components related to the warning. In this case, the Model Advisor finds an `Outport` block that uses double precision due to a setting of the **Configuration Parameter Default for underspecified data type**.

In the right pane of the Model Advisor window, you see further detail on the single-precision warning.



The default input of the `Outport` block is set to `double`. Model Advisor generates a warning because the `Outport` block is not connected to another block. After reviewing the check results in the model window and the Model Advisor window, you can choose to fix warnings or failures.

To view model blocks that are excluded from the Model Advisor checks, on the Model Advisor window toolbar, select **Highlighting** > **Highlight Exclusions**. If you have Simulink Check, you can create or modify exclusions to the Model Advisor checks.

Fix a Model Check Warning or Failure

When a model or referenced model has a suboptimal condition, checks can fail. A warning result is informational. You can fix the reported issue or move on to the next task. For more information on why a specific check does not pass, see the documentation for that check.

Manually Fix Warnings or Failures

To manually fix warnings or failures, checks have an Analysis Result box that describes the recommended actions.

1. Optionally, save a model and data restore point so that you can undo your changes.
2. In the Analysis Result box, review the recommended actions to make changes to your model.
3. To verify that the check passes, rerun the check.

   When you fix a warning or failure, rerun all checks to update the results of all checks. If you do not rerun all checks, the Model Advisor can report an invalid check result.

Automatically Fix Warnings or Failures

Some checks have an Action box that you can use to automatically fix failures. The action box applies all of the recommended actions listed in the Analysis Result box.

1. Optionally, save a model and data restore point so that you can undo your changes.
2. In the Action box, click **Modify All** or **Modify**.

   The Action Result box displays a table of changes.
3. To verify that the check passes, rerun the check.

   When you fix a warning or failure, rerun all checks to update the results of all checks. If you do not rerun all checks, the Model Advisor can report an invalid check result.

Batch-Fix Warnings or Failures

Some checks have an **Explore Result** button that opens the Model Advisor Result Explorer. With the Model Advisor Result Explorer, you can quickly locate, view, and change elements of a model.

The Model Advisor Result Explorer helps you to modify only the items that the Model Advisor is checking.

If a check does not pass and you want to explore the results and make batch changes:

1. Optionally, save a model and data restore point so that you can undo your changes.

2 In the Analysis box, click **Explore Result**.

3 In the Model Advisor Result Explorer, you can modify block parameters.

4 In the Model Advisor window, rerun the check to verify that it passes.

When you fix a warning or failure, rerun all checks to update the results of all checks. If you do not rerun all checks, the Model Advisor can report an invalid check result.

Revert Changes

The Model Advisor provides a model and a data restore point capability for reverting changes that you made in response to recommendations from the Model Advisor. You can also restore the default configuration of the Model Advisor. A restore point is a snapshot in time of the model, base workspace, and Model Advisor. The Model Advisor maintains restore points for the model or subsystem through multiple sessions of MATLAB.

Note A restore point saves only the current working model, base workspace variables, and the Model Advisor tree. It does not save other items, such as libraries and referenced models.

Restore Default Configuration

In the Model Advisor window, select **Settings > Restore Default Configuration**.

Save a Restore Point

You can save a restore point and give it a name and description. Or, the Model Advisor can name the restore point.

1 In the Model Advisor window, select **File > Save Restore Point As**.

2 In the **Name** field, enter a name for the restore point.

3 In the **Description** field, you can optionally add a description to help identify the restore point.

4 Click **Save**.

The Model Advisor saves a restore point of the current model, base workspace, and Model Advisor status.

To quickly save a restore point, in the Model Advisor window, select **File > Save Restore Point**. The Model Advisor saves a restore point with the name `autosaven`. *n* is the sequential number of the restore point. If you use this method, you cannot change the name of, or add a description to, the restore point.

Load a Restore Point

1. Optionally, save a model and data restore point so that you can undo your changes.
2. Select **File > Load Restore Point**.
3. In the Load Model and Data Restore Point dialog box, select the restore point that you want.
4. Click **Load**.

   The Model Advisor issues a warning that the restoration removes changes that you made after saving the restore point.
5. To load the restore point that you selected, click **Load**.

   The Model Advisor reverts the model, base workspace, and Model Advisor status.

- “Check Your Model Interactively” (Simulink Check)

Save and View Model Advisor Reports

When the Model Advisor runs checks, it generates an HTML report of check results. By default, the HTML report is in the `slprj/modeladvisor/model_name` folder.

If you have Simulink Check, you can generate reports in Adobe® PDF and Microsoft Word .docx formats.

Save Model Advisor Reports

The Model Advisor uses the `slprj` folder in the code generation folder to store reports and other information. If the `slprj` folder does not exist in the code generation folder, the Model Advisor creates it.

You can save a Model Advisor report to a new location.

1. In the Model Advisor window, navigate to the folder with the checks that you ran.
2. Select the folder. The right pane of the Model Advisor window displays information about that folder. The pane includes a **Report** box.
3. In the Report box, click **Generate Report**.
4. In the Generate Model Advisor Report dialog box, enter the path to the folder where you want to generate the report. Provide a file name.
5. Click **OK**. The Model Advisor saves the report in HTML format to the location that you specified.

If you rerun the Model Advisor, the report is updated in the working folder, not in the location where you archived the original report.

The full path to the report is in the title bar of the report window.

View Model Advisor Reports

Access a report by selecting a folder and clicking the link in the **Report** box. Or, before a Model Advisor analysis, in the right pane of the Model Advisor window, select **Show report after run**.

Tip Use the options in the Model Advisor window to interactively fix warnings and failures. Model Advisor reports are best for viewing a summary of checks.

As you run checks, the Model Advisor updates the reports with the latest information for each check in the folder. When you run the checks at different times, an informational message appears in the report. Timestamps indicate when checks have been run. The time of the current run appears at the top right of the report. Checks that occurred during previous runs have a timestamp following the check name.

Goal	Action
Display results for checks that pass, warn, or fail.	Use the **Filter checks** check boxes. For example, to display results for only checks that warn, in the left pane of the report, select the Warning check box. Clear the **Passed**, **Failed**, and **Not Run** check boxes.
Display results for checks with keywords or phrases in the check title.	Use the **Keywords** field. Results for checks without the keyword in the check title are not displayed in the report. For example, to display results for checks with only "setting" in the check title, in the **Keywords** field, enter "setting".
Quickly navigate to sections of the report.	Select the links in the table-of-contents navigation pane.
Expand and collapse content in the check results.	Click **Show/Hide check details**.
Scroll to the top of the report.	Click **Scroll to top**.
Minimize folder results in the report.	Click the minus sign next to the folder name.

Printed versions of the report do not contain:

- Filtering checks, Navigation, or View panes.
- Content hidden due to filtering or keyword searching.

Some checks have input parameters specified in the right pane of the Model Advisor. For example, **Check Merge block usage** has an input parameter for **Maximum analysis time (seconds)**. When you run checks with input parameters, the Model Advisor displays the values of the input parameters in the HTML report. For more information, see the `EmitInputParametersToReport` property of the `Simulink.ModelAdvisor` class.

Upgrade Advisor

Consult the Upgrade Advisor

Use the Upgrade Advisor to help you upgrade and improve models with the current release. The Upgrade Advisor can identify cases where you can benefit by changing your model to use new features and settings in Simulink. The Advisor provides advice for transitioning to new technologies, and upgrading a model hierarchy.

The Upgrade Advisor can also help identify cases when a model will not work because changes and improvements in Simulink require changes to a model.

The Upgrade Advisor offers options to perform recommended actions automatically or instructions for manual fixes.

You can open the Upgrade Advisor in the following ways:

- From the Model Editor, select **Analysis > Model Advisor > Upgrade Advisor**
- From the MATLAB command line, use the `upgradeadvisor` function:

  ```
  upgradeadvisor modelname
  ```
- Alternatively, from the Model Advisor, click **Upgrade Advisor**. This action closes the Model Advisor and opens the Upgrade Advisor.

In the Upgrade Advisor, you create reports and run checks in the same way as when using the Model Advisor.

- Select the top Upgrade Advisor node in the left pane to run all selected checks and create a report.
- Select each individual check to open a detailed view of the results in the right pane. View the analysis results for recommended actions to manually fix warnings or failures. In some cases, the Upgrade Advisor provides mechanisms for automatically fixing warnings and failures.

Caution When you fix a warning or failure, rerun all checks to update the results of all checks. If you do not rerun all checks, the Upgrade Advisor might report an invalid check result.

You must run upgrade checks in this order: first the checks that do not require compile time information and do not trigger an Update Diagram, then the compile checks. To guide you through upgrade checks to run both non-compile and compile checks, run the

check **Analyze model hierarchy and continue upgrade sequence**. See "Analyze model hierarchy and continue upgrade sequence".

For more information on individual checks, see

- "Model Upgrades" for upgrade checks only
- "Simulink Checks" for all upgrade and advisor checks

Upgrade Programmatically

To analyze and upgrade models programmatically, use the `upgradeadvisor` function.

Tip For an example showing how to upgrade a whole project programmatically, see "Upgrade Simulink Models Using a Simulink Project".

Upgrade Advisor Checks

For advice on upgrading and improving models with the current release, use the following Model Advisor checks in the Upgrade Advisor.

- "Check model for block upgrade issues"
- "Check usage of function-call connections"
- "Identify Model Info blocks that can interact with external source control tools"
- "Check for calls to slDataTypeAndScale"
- "Identify masked blocks that specify tabs in mask dialog using MaskTabNames parameter"
- "Check that the model is saved in SLX format"
- "Check model for SB2SL blocks"
- "Check Model History properties"
- "Identify Model Info blocks that use the Configuration Manager"
- "Identify configurable subsystem blocks for converting to variant subsystem blocks"
- "Check and update masked blocks in library to use promoted parameters"
- "Check and update mask image display commands with unnecessary imread() function calls"

Working with Sample Times

What Is Sample Time?

The sample time of a block is a parameter that indicates when, during simulation, the block produces outputs and if appropriate, updates its internal state. The internal state includes but is not limited to continuous and discrete states that are logged.

Note Do not confuse the Simulink usage of the term sample time with the engineering sense of the term. In engineering, sample time refers to the rate at which a discrete system samples its inputs. Simulink allows you to model single-rate and multirate discrete systems and hybrid continuous-discrete systems through the appropriate setting of block sample times that control the rate of block execution (calculations).

For many engineering applications, you need to control the rate of block execution. In general, Simulink provides this capability by allowing you to specify an explicit `SampleTime` parameter in the block dialog or at the command line. Blocks that do not have a `SampleTime` parameter have an implicit sample time. You cannot specify implicit sample times. Simulink determines them based upon the context of the block in the system. The Integrator block is an example of a block that has an implicit sample time. Simulink automatically sets its sample time to `0`.

Sample times can be port based or block based. For block-based sample times, all of the inputs and outputs of the block run at the same rate. For port-based sample times, the input and output ports can run at different rates. To learn more about rates of execution, see “Types of Sample Time” on page 7-16.

See Also

“Specify Sample Time” on page 7-3 | “Types of Sample Time” on page 7-16 | “Sample Times in Systems” on page 7-29 | “Sample Times in Subsystems” on page 7-27

Specify Sample Time

In this section...

Designate Sample Times

Simulink allows you to specify a block sample time directly as a numerical value or symbolically by defining a sample time vector. In the case of a discrete sample time, the vector is [T_s, T_o] where T_s is the sampling period and T_o is the initial time offset. For example, consider a discrete model that produces its outputs every two seconds. If your base time unit is seconds, you can directly set the discrete sample time by specifying the numerical value of `2` as the `SampleTime` parameter. Because the offset value is zero, you do not need to specify it; however, you can enter `[2,0]` in the **Sample time** field.

For nondiscrete blocks, the components of the vector are symbolic values that represent one of the types in "Types of Sample Time" on page 7-16. The following table summarizes these types and the corresponding sample time values. The table also defines the explicit nature of each sample time type and designates the associated color and annotation. Because an *inherited sample time* is explicit, you can specify it as `[-1, 0]` or as `-1`. Whereas, a triggered sample time is implicit; only Simulink can assign the sample time of `[-1, -1]`. (For more information about colors and annotations, see "View Sample Time Information" on page 7-9.)

Designations of Sample Time Information

Sample Time Type	Sample Time	Color	Annotation	Explicit
Discrete	[T_s, T_o]	In descending order of speed: red, green, blue, light blue, dark green, orange	D1, D2, D3, D4, D5, D6, D7,... Di	Yes
Continuous	[0, 0]	black	Cont	Yes
Fixed in minor step	[0, 1]	gray	FiM	Yes
Inherited	[–1, 0]	N/A	N/A	Yes
Constant	[Inf, 0]	magenta	Inf	Yes
Variable	[–2,T_{vo}]	brown	V1, V2,... Vi	No
Variable Discrete	[base, -2i], i = 0, 1, 2, …,	brown	VD1, VD2, VD3, …. VDi	Yes
Hybrid	N/A	yellow	N/A	No
Triggered	`Source: D`1, Source: D2, ...Source: Di	cyan	T1, T2,... Ti	No
Asynchronous	[–1, –n]	purple	A1, A2,... Ai	No

The color that is assigned to each block depends on its sample time relative to other sample times in the model. This means that the same sample time may be assigned different colors in a parent model and in models that it references. (See “Model Referencing”.)

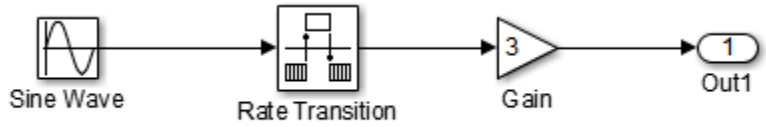
For example, suppose that a model defines three sample times: `1`, `2`, and `3`. Further, suppose that it references a model that defines two sample times: `2` and `3`. In this case, blocks operating at the `2` sample rate appear as green in the parent model and as red in the referenced model.

It is important to note that Mux and Demux blocks are simply grouping operators; signals passing through them retain their timing information. For this reason, the lines emanating from a Demux block can have different colors if they are driven by sources having different sample times. In this case, the Mux and Demux blocks are color coded as hybrids (yellow) to indicate that they handle signals with multiple rates.

Similarly, Subsystem blocks that contain blocks with differing sample times are also colored as hybrids, because there is no single rate associated with them. If all the blocks within a subsystem run at a single rate, the Subsystem block is colored according to that rate.

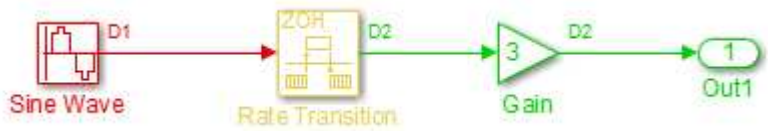
You can use the explicit sample time values in this table to specify sample times interactively or programmatically for either block-based or port-based sample times.

The following model, `ex_specify_sample_time`, serves as a reference for this section.



ex_specify_sample_time

In this example, set the sample time of the input sine wave signal to `0.1`. The goal is to achieve an output sample time of `0.2`. The Rate Transition block serves as a zero-order hold. The resulting block diagram after setting the sample times and simulating the model is shown in the following figure. (The colors and annotations indicate that this is a discrete model.)



Sample Time 0.1 Sample Time 0.2

ex_specify_sample_time after Setting Sample Times

Specify Block-Based Sample Times Interactively

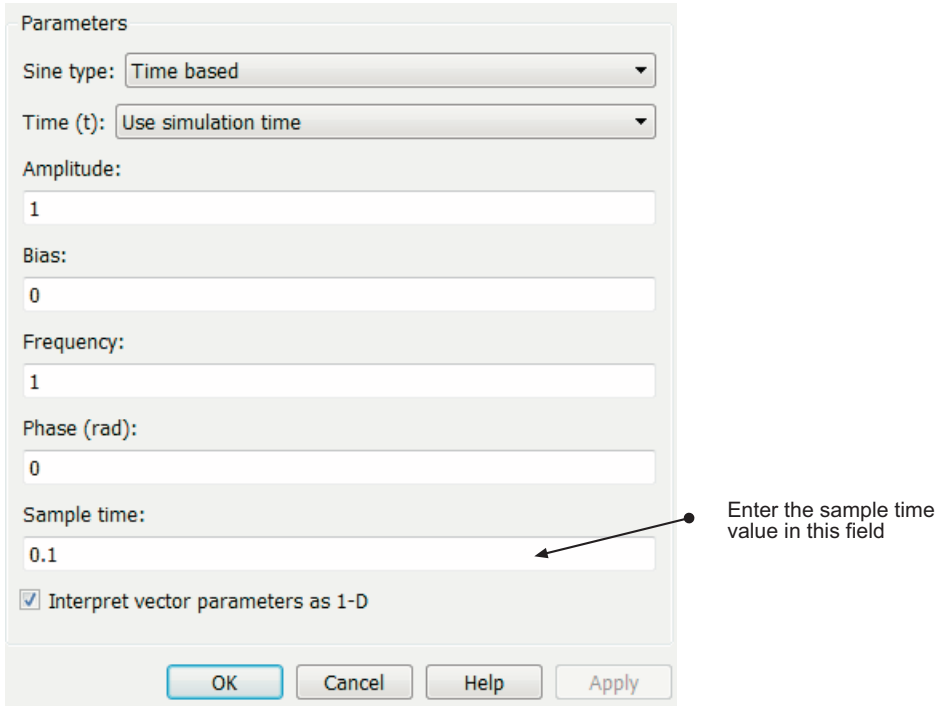
To set the sample time of a block interactively:

1 In the Simulink model window, double-click the block. The block parameter dialog box opens.

2 Enter the sample time in the **Sample time** field.

3 Click **OK**.

Following is a figure of a parameters dialog box for the Sine Wave block after entering `0.1` in the **Sample time** field.

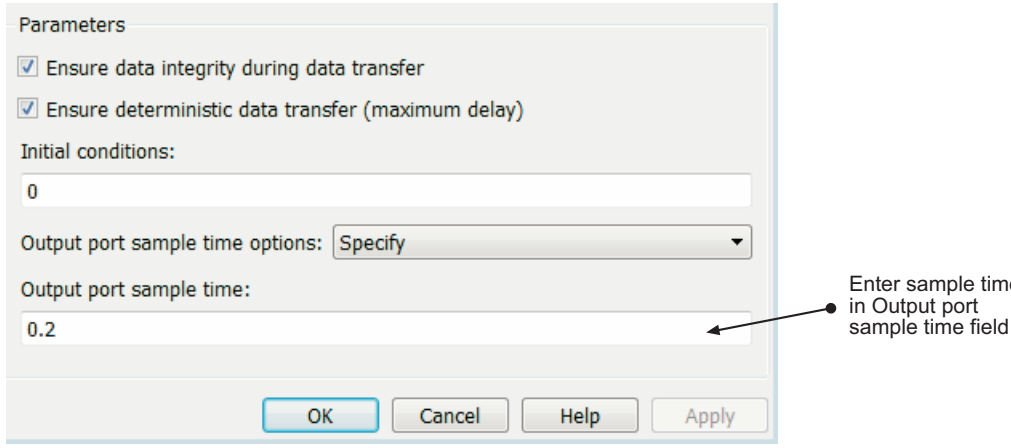


To specify and inspect block-based sample times throughout a model, consider using the Model Data Editor (**View > Model Data**). On the **Inports/Outports**, **Signals**, and **Data Stores** tabs, set the **Change view** drop-down list to `Design` and use the **Sample Time** column. For more information about the Model Data Editor, see "Configure Data Properties by Using the Model Data Editor" on page 59-141.

Specify Port-Based Sample Times Interactively

The Rate Transition block has port-based sample times. You can set the output port sample time interactively by completing the following steps:

1. Double-click the Rate Transition block. The parameters dialog box opens.
2. Leave the drop-down menu choice of the **Output port sample time options** as `Specify`.
3. Replace the `-1` in the **Output port sample time** field with `0.2`.



4. Click **OK**.

For more information about the sample time options in the Rate Transition parameters dialog box, see the Rate Transition reference page.

Specify Block-Based Sample Times Programmatically

To set a block sample time programmatically, set its `SampleTime` parameter to the desired sample time using the `set_param` command. For example, to set the sample time of the Gain block in the "Specify_Sample_Time" model to inherited (`-1`), enter the following command:

```
set_param('Specify_Sample_Time/Gain','SampleTime','[-1, 0]')
```

As with interactive specification, you can enter just the first vector component if the second component is zero.

```
set_param('Specify_Sample_Time/Gain','SampleTime','-1')
```

Specify Port-Based Sample Times Programmatically

To set the output port sample time of the Rate Transition block to `0.2`, use the `set_param` command with the parameter `OutPortSampleTime`:

```
set_param('Specify_Sample_Time/Rate Transition',...
'OutPortSampleTime', '0.2')
```

Access Sample Time Information Programmatically

To access all sample times associated with a model, use the API `Simulink.BlockDiagram.getSampleTimes`.

To access the sample time of a single block, use the API `Simulink.Block.getSampleTimes`.

Specify Sample Times for a Custom Block

You can design custom blocks so that the input and output ports operate at different sample time rates. For information on specifying block-based and port-based sample times for S-functions, see "Sample Times" in *Writing S-Functions* of the Simulink documentation.

Determining Sample Time Units

Since the execution of a Simulink model is not dependent on a specific set of units, you must determine the appropriate base time unit for your application and set the sample time values accordingly. For example, if your base time unit is second, then you would represent a sample time of `0.5` second by setting the sample time to `0.5`.

Change the Sample Time After Simulation Start Time

To change a sample time after simulation begins, you must stop the simulation, reset the `SampleTime` parameter, and then restart execution.

See Also

"What Is Sample Time?" on page 7-2 | "Types of Sample Time" on page 7-16

View Sample Time Information

In this section...

View Sample Time Display

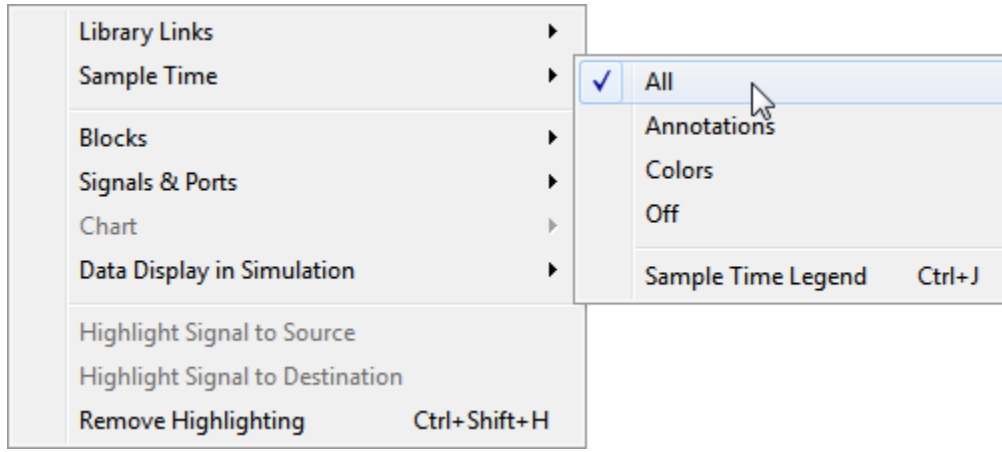
Simulink models can display color coding and annotations that represent specific sample times. As shown in the table Designations of Sample Time Information, each sample time type has one or more colors associated with it. You can display the blocks and signal lines in color, the annotations in black, or both the colors and the annotations. To choose one of these options:

1. In the Simulink model window, select **Display > Sample Time**.
2. Select **Colors**, **Annotations**, or **All**.

Selecting **All** results in the display of both the colors and the annotations. Regardless of your choice, Simulink performs an **Update Diagram** automatically. To turn off the colors and annotations:

1. Select **Display** > **Sample Time**.
2. Select **Off**.

Simulink performs another **Update Diagram** automatically.



Your Sample Time Display choices directly control the information that the Sample Time Legend displays.

Note The discrete sample times in the table Designations of Sample Time Information represent a special case. Five colors indicate the fastest through the fifth fastest discrete rate. A sixth color, orange, represents all rates that are slower than the fifth discrete rate. You can distinguish between these slower rates by looking at the annotations on their respective signal lines.

Sample Time Legend

You can view the Sample Time Legend for an individual model or for multiple models. Additionally, you can prevent the legend from automatically opening when you select options on the **Sample Time** menu.

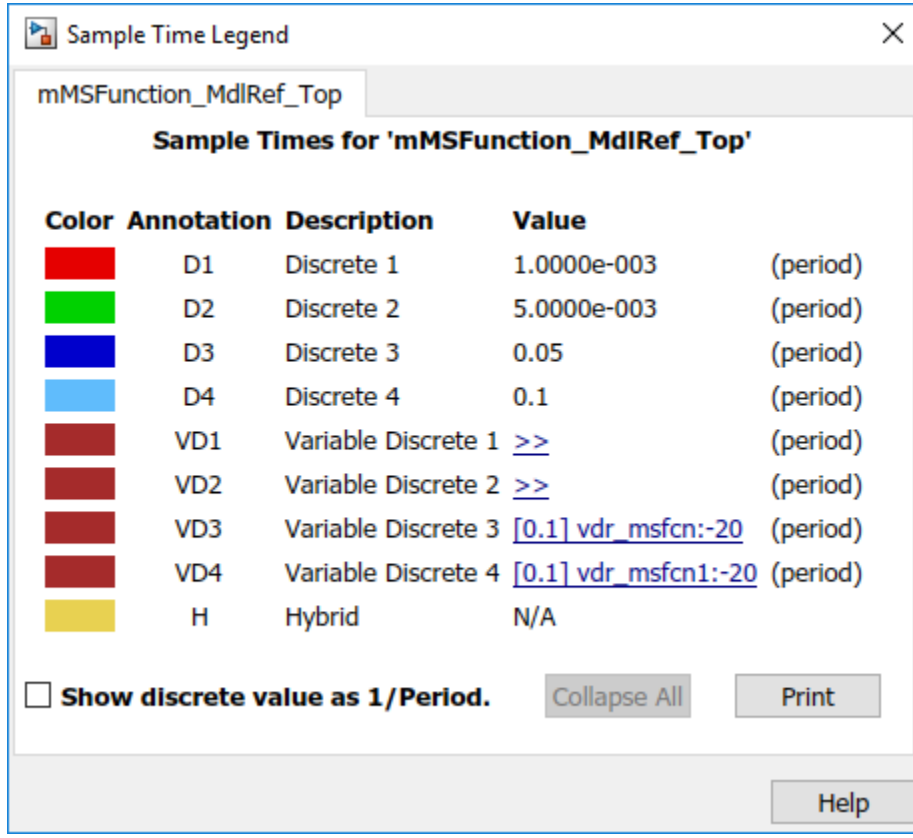
Viewing the Legend

To assist you with interpreting your block diagram, a sample time legend contains the sample time color, annotation, description, and value for each sample time in the model. You can use one of three methods to view the legend, but first update the diagram.

1. In the Simulink model window, select **Simulation > Update Diagram**.
2. Select **Display > Sample Time > Sample Time Legend** or press **Ctrl + J**.

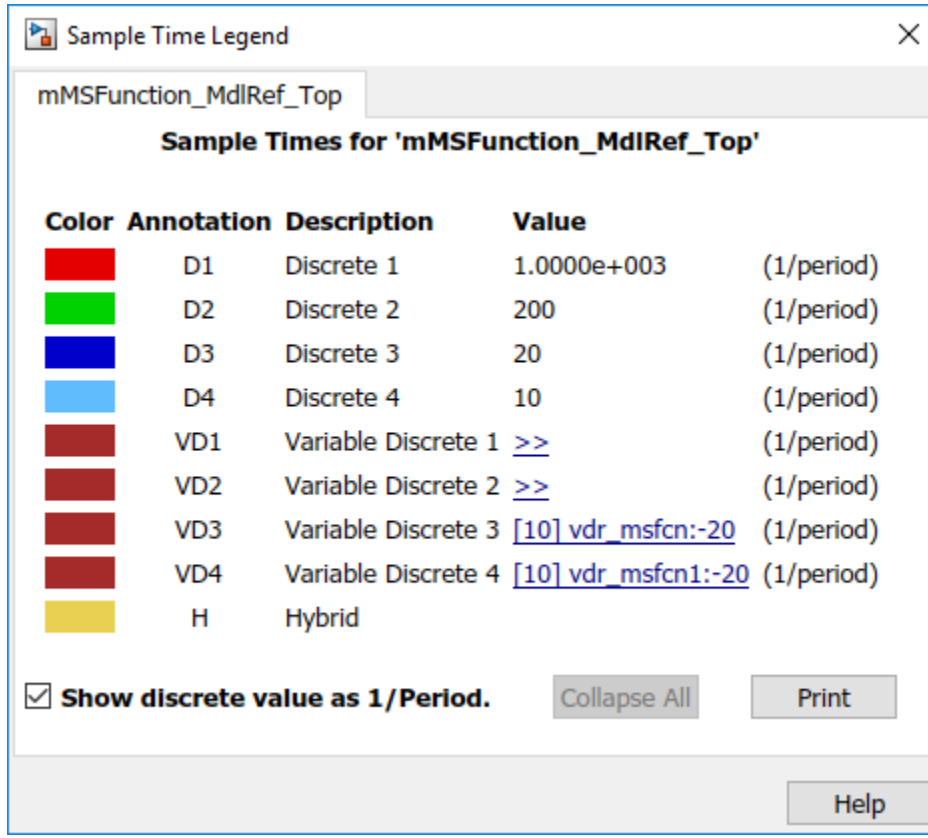
In addition, when you select **Colors**, **Annotations**, or **All** from the **Sample Time** menu, Simulink updates the model diagram and opens the legend by default. The legend contents reflect your **Sample Time Display** choices. By default or if you have selected **Off**, the legend contains a description of the sample time and the sample time value. If you turn colors on, the legend displays the appropriate color beside each description. Similarly, if you turn annotations on, the annotations appear in the legend.

The legend does not provide a discrete rate for all types of sample times. For asynchronous and variable sample times, the legend displays a link to the block that controls the sample time in place of the sample time value. Clicking one of these links highlights the corresponding block in the block diagram. The checkbox to show discrete value as 1/period is enabled in presence of the discrete rate.



The rate listed under hybrid and asynchronous hybrid models is Not Applicable because these blocks do not have a single representative sample time.

When checked, the discrete period is displayed as 1/period, for a non zero offset displays as offset/period. For variable sample times, the legend uses >> to indicate that the controller block of the sample time is in a model reference hierarchy. Click >> to drill down to that block



Note The Sample Time Legend displays all of the sample times in the model, including those that are not associated with any block. For example, if the fixed step size is 0.1 and all of the blocks have a sample time of 0.2, then both rates (i.e., 0.1 and 0.2) appear in the legend.

For subsequent viewings of the legend, update the diagram to access the latest known information.

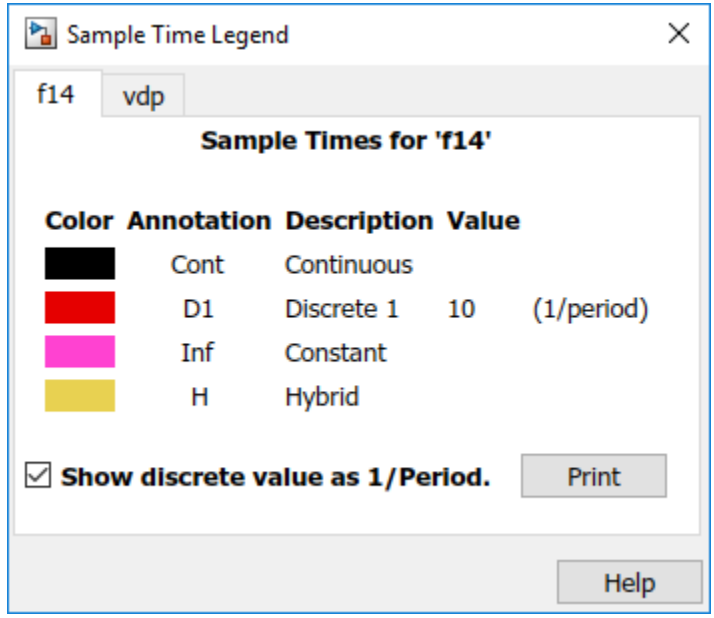
Turning the Legend Off

If you do not want to view the legend upon selecting **Sample Time Display**:

1. In the Simulink Editor, select **File > Simulink Preferences**
2. In the **General** pane, clear **Open the sample time legend when the sample time display is changed** and click **Apply**.

Viewing Multiple Legends

If you have more than one model open and you view the **Sample Time Legend** for each one, a single legend window appears with multiple tabs. Each tab contains the name of the model and the respective legend information. The following figure shows the tabbed legends for the `f14` and `vdp` models.



Inspect Sample Times Throughout a Model

The Model Data Editor (**View > Model Data**) shows information about model data (signals, parameters, and states) in a sortable, searchable table. The **Sample Time**

column shows you the sample time specified for each signal in a model. After you update the block diagram, the column also shows you the specific sample that each signal uses (for example, for signals for which you specify inherited sample time, `-1`). You can also use the column to specify sample times.

For more information about the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 59-141.

See Also

“What Is Sample Time?” on page 7-2 | “Specify Sample Time” on page 7-3 | “Print Sample Time Information” on page 7-15

Print Sample Time Information

You can print the sample time information in the Sample Time Legend by using either of these methods:

- In the Sample Time Legend window, click **Print**.
- Print the legend from the **Print Model** dialog box:

  1. In the model window, select **File** > **Print**.
  2. Under **Options**, select the check box beside **Print Sample Time Legend**.
  3. Click **OK**.

Types of Sample Time

In this section...

Discrete Sample Time

Given a block with a discrete sample time, Simulink executes the block output or update method at times

$$t_n = nT_s + |T_o|$$

where the sample time period T_s is always greater than zero and less than the simulation time, T_{sim}. The number of periods (n) is an integer that must satisfy:

$$0 \le n \le \frac{T_{sim}}{T_s}$$

As simulation progresses, Simulink computes block outputs only once at each of these fixed time intervals of t_n. These simulation times, at which Simulink executes the output method of a block for a given sample time, are referred to as *sample time hits*. Discrete sample times are the only type for which sample time hits are known *a priori*.

If you need to delay the initial sample hit time, you can define an offset, T_o.

The Unit Delay block is an example of a block with a discrete sample time.

Continuous Sample Time

Unlike the discrete sample time, continuous sample hit times are divided into major time steps and minor time steps, where the minor steps represent subdivisions of the major steps (see "Minor Time Steps" on page 3-22). The ODE solver you choose integrates all continuous states from the simulation start time to a given major or minor time step. The solver determines the times of the minor steps and uses the results at the minor time steps to improve the accuracy of the results at the major time steps. However, you see the block output only at the major time steps.

To specify that a block, such as the Derivative block, is continuous, enter `[0, 0]` or `0` in the **Sample time** field of the block dialog.

Fixed-in-Minor-Step

If the sample time of a block is set to [`0, 1`], the block becomes *fixed-in-minor-step*. For this setting, Simulink does not execute the block at the minor time steps; updates occur only at the major time steps. This process eliminates unnecessary computations of blocks whose output cannot change between major steps.

While you can explicitly set a block to be fixed-in-minor-step, more typically Simulink sets this condition as either an inherited sample time or as an alteration to a user specification of `0` (continuous). This setting is equivalent to, and therefore converted to, the fastest discrete rate when you use a fixed-step solver.

Inherited Sample Time

If a block sample time is set to `[-1, 0]` or `-1`, the sample time is *inherited* and Simulink determines the best sample time for the block based on the block context within the model. Simulink performs this task during the compilation stage; the original inherited setting never appears in a compiled model. Therefore, you never see inherited ([–1, 0]) in the Sample Time Legend. (See "View Sample Time Information" on page 7-9.)

There are some blocks in which the sample time is inherited (-1) by default. For these blocks, the parameter is not visible on the block dialog box unless it is set to a noninherited value. Examples of these blocks include the Gain and Rounding Function blocks. As a good modeling practice, do not change the **Sample time** parameter for these blocks. For more information, see "Blocks for Which Sample Time Is Not Recommended" on page 7-21.

All inherited blocks are subject to the process of sample time propagation, as discussed in "How Propagation Affects Inherited Sample Times" on page 7-39

Constant Sample Time

In Simulink, a constant is a symbolic name or expression whose value you can change only outside the algorithm or through supervisory control. Blocks, like the constant block, whose outputs do not change during normal execution of the model, are always considered to be constant.

Simulink assigns constant sample time to these blocks. They run their block output method:

- At the start of a simulation.
- In response to runtime changes in the environment, such as tuning a parameter.

For constant sample time, the block sample time assignment is `[inf,0]` or `[inf]`.

For a block to allow constant sample time, these conditions hold:

- The block has no continuous or discrete states.
- The block does not drive an output port of a conditionally executed subsystem (see "Enabled Subsystems" on page 10-10).

S-Function Blocks

The Simulink block library includes several blocks, such as the MATLAB S-Function block, the Level-2 MATLAB S-Function block, and the C S-Function block, whose ports can produce outputs at different sample rates. It is possible for some of the ports of these blocks to have a constant sample time.

Variable Sample Time

Blocks that use a variable sample time have an implicit `SampleTime` parameter that the block specifies; the block tells Simulink when to run it. The compiled sample time is [–2, T_{vo}] where T_{vo} is a unique variable offset.

The Pulse Generator block is an example of a block that has a variable sample time. Since Simulink supports variable sample times for variable-step solvers only, the Pulse Generator block specifies a discrete sample time if you use a fixed-step solver.

To learn how to write your own block that uses a variable sample time, see "C MEX S-Function Examples".

Variable Discrete Sample Time

Blocks that use a variable discrete sample time with a resolution D_b run at a subset of the sample hits of D_b. The block tells Simulink when it (the block) runs. The resolution D_b need not be the same value as the **Fixed-step size (fundamental sample time)** which is specified in the model's Configuration Parameters.

Triggered Sample Time

If a block is inside of a triggered-type (e.g., function-call, enabled and triggered, or iterator) subsystem, the block may be constant or have a triggered sample time. You cannot specify the triggered sample time type explicitly. However, to achieve a triggered type during compilation, you must set the block sample time to inherited (–1). Simulink then determines the specific times at which the block computes its output during simulation. One exception is if the subsystem is an asynchronous function call, as discussed in the following section.

Asynchronous Sample Time

An asynchronous sample time is similar to a triggered sample time. In both cases, it is necessary to specify an inherited sample time because the Simulink engine does not regularly execute the block. Instead, a run-time condition determines when the block executes. For the case of an asynchronous sample time, an S-function makes an asynchronous function call.

The differences between these sample time types are:

- Only a function-call subsystem can have an asynchronous sample time. (See "Using Function-Call Subsystems" on page 10-29.)
- The source of the function-call signal is an S-function having the option SS_OPTION_ASYNCHRONOUS.
- The asynchronous sample time can also occur when a virtual block is connected to an asynchronous S-function or an asynchronous function-call subsystem.
- The asynchronous sample time is important to certain code-generation applications. (See "Asynchronous Events" (Simulink Coder) in the *Simulink Coder User's Guide*.)

- The sample time is [–1,–*n*].

For an explanation of how to use blocks to model and generate code for asynchronous event handling, see “Rate Transitions and Asynchronous Blocks” (Simulink Coder) in the *Simulink Coder User's Guide*.

Blocks for Which Sample Time Is Not Recommended

In this section...

Some blocks do not enable you to set the **Sample Time** parameter by default. However, you can see and set the **Sample Time** parameter for these blocks in an existing model if the sample time is set to a value other than the default of `-1` (inherited sample time). The **Sample Time** parameter is not available on certain blocks because specifying a sample time that is not `-1` on blocks such as the Gain, Sum, and n-D Lookup Table causes sample rate transition to be implicitly mixed with block algorithms. This mixing can often lead to ambiguity and confusion in Simulink models.

In most modeling applications, you specify rates for a model on the boundary of your system instead of on a block within the subsystem. You specify the system rate from incoming signals or the rate of sampling the output. You can also decide rates for events you are modeling that enter the subsystem as trigger, function-call, or enable/disable signals. Some global variables (such as Data Store Memory blocks) might need additional sample time specification. If you want to change rate within a system, use a Rate Transition block, which is designed specifically to model rate transitions.

In a future release, you might not be able see or set this parameter on blocks where it is not appropriate.

Best Practice to Model Sample Times

Use these approaches instead of setting the **Sample Time** parameter in the blocks where it is not appropriate:

- Adjust your model by specifying **Sample Time** only in the blocks listed in “Appropriate Blocks for the Sample Time Parameter” on page 7-22, and set **Sample Time** to `-1` for all other blocks. To change the sample time for multiple blocks simultaneously, use Model Explorer. For more information, see “Editing Object Properties” on page 12-22.
- Use the Rate Transition block to model rate transitions in your model.

- Use the Signal Specification block to specify sample time in models that don't have source blocks, such as algebraic loops.
- Specify the simulation rate independently from the block sample times, using the Model Parameter dialog box.

Once you have completed these changes, verify whether your model gives the same outputs as before.

Appropriate Blocks for the Sample Time Parameter

Specify sample time on the boundary of a model or subsystem, or in blocks designed to model rate transitions. Examples include:

- Blocks in the Sources library
- Blocks in the Sinks library
- Trigger ports (if **Trigger type** is set to `function-call`) and Enable ports
- Data Store Read and Data Store Write blocks, as the Data Store Memory block they link to might be outside the boundary of the subsystem
- Rate Transition block
- Signal Specification block
- Blocks in the Discrete library
- Message Receive block
- Function Caller block

Specify Sample Time in Blocks Where Hidden

You can specify sample time in the blocks that do not display the parameter on the block dialog box. If you specify value other than `-1` in these blocks, no error occurs when you simulate the model. However, a message appears on the block dialog box advising to set this parameter to `-1` (inherited sample time). If you promote the sample time block parameter to a mask, this parameter is always visible on the mask dialog box.

To change the sample time in this case, use the `set_param` command. For example, select a block in the Simulink Editor and, at the command prompt, enter:

```
set_param(gcb,'SampleTime','2');
```

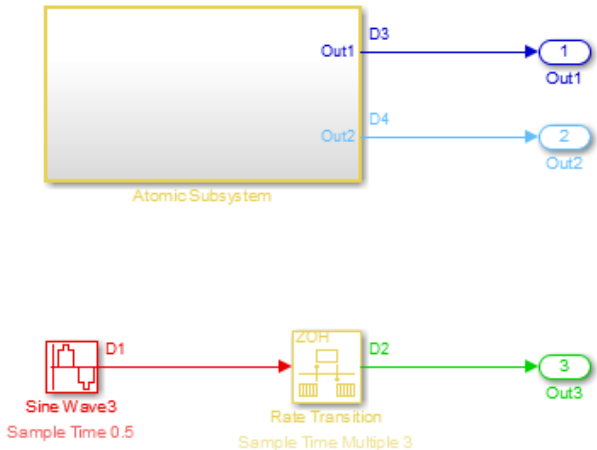
Block Compiled Sample Time

During the compilation phase of a simulation, Simulink determines the sample time of a block from the `SampleTime` parameter (if the block has an explicit sample time), the block type (if it has an implicit sample time), or by the model content. This compiled sample time determines the sample rate of a block during simulation. You can determine the compiled sample time of any block in a model by first updating the model and then getting the block `CompiledSampleTime` parameter, using the `get_param` command.

For example, consider the model `ex_compiled_sample_new`.



Use `get_param` to obtain the block `CompiledSampleTime` parameter for each of the blocks in this example.

```
get_param('model_name/block_name','CompiledSampleTime');
```

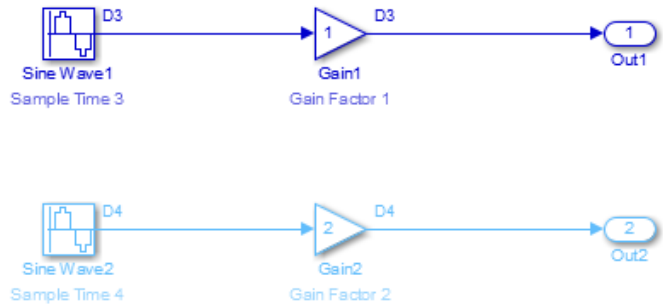
For the Sine Wave3 block,

```
get_param('ex_compiled_sample_new/Sine Wave3','CompiledSampleTime');
```

displays

```
0.5000    0
```

The atomic subsystem contains sine wave blocks with sample times of 3 and 4.



When calculating the block `CompiledSampleTime` for this subsystem, Simulink returns a cell array of the sample times present in the subsystem.

```
3    0
4    0
```

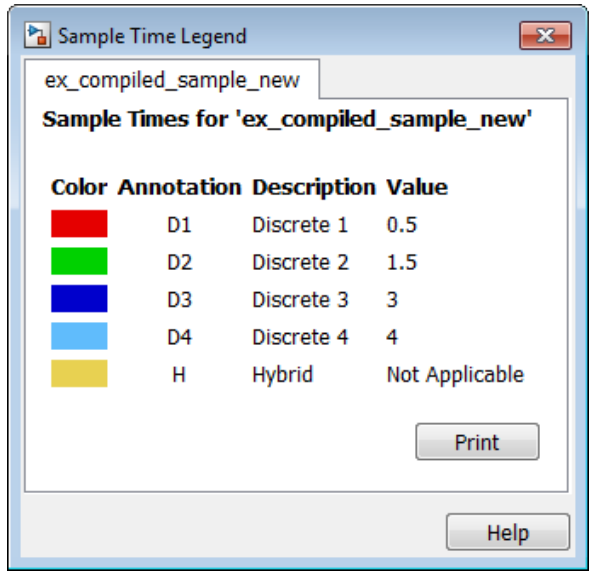
The greatest common divisor (GCD) of the two rates is 1. However, this is not necessarily one of the rates in the model.

The Rate Transition block in this model serves as a Zero-Order Hold. Since the `Sample Time Multiple` parameter is set to 3, the input to the rate transition block has a sample rate of 0.5 while the output has a rate of 1.5.

```
rt=get_param('ex_compiled_sample_new/Rate Transition',...
'CompiledSampleTime');
rt{:}

0.5000    0
1.5000    0
```

The Sample Time Legend shows all of the sample rates present in the model.



To inspect compiled sample times throughout a model, you can use the Model Data Editor (**View > Model Data**). After you update the block diagram, the right side of the **Sample Time** column shows compiled sample times for signals and data stores. For more information about the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 59-141.

Sample Times in Subsystems

Subsystems fall into two categories: triggered and non-triggered. For triggered subsystems, in general, the subsystem gets its sample time from the triggering signal. One exception occurs when you use a Trigger block to create a triggered subsystem. If you set the block **Trigger type** to **function-call** and the **Sample time type** to **periodic**, the `SampleTime` parameter becomes active. In this case, *you* specify the sample time of the Trigger block, which in turn, establishes the sample time of the subsystem.

There are four non-triggered subsystems:

- Virtual
- Enabled
- Atomic
- Action

Simulink calculates the sample times of virtual and enabled subsystems based on the respective sample times of their contents.

The atomic subsystem is a special case in that the subsystem block has a `SystemSampleTime` parameter. Moreover, for a sample time other than the default value of –1, the blocks inside the atomic subsystem can have only a value of `Inf`, –1, or the identical (discrete) value of the subsystem `SampleTime` parameter. If the atomic subsystem is left as inherited, Simulink calculates the block sample time in the same manner as the virtual and enabled subsystems. However, the main purpose of the subsystem `SampleTime` parameter is to allow for the simultaneous specification of a large number of blocks, within an atomic subsystem, that are all set to inherited. To obtain the sample time set on an atomic subsystem, use this command at the command prompt:

```
get_param(AtomicSubsystemBlock,'SystemSampleTime');
```

Finally, the sample time of the action subsystem is set by the If block or the Switch Case block.

For non-triggered subsystems where blocks have different sample rates, Simulink returns the Compiled Sample Time for the subsystem as a cell array of all the sample rates present in the subsystem. To see this, use the `get_param` command at MATLAB prompt.

```
get_param(subsystemBlock,'CompiledSampleTime')
```

Sample Times in Systems

In this section...

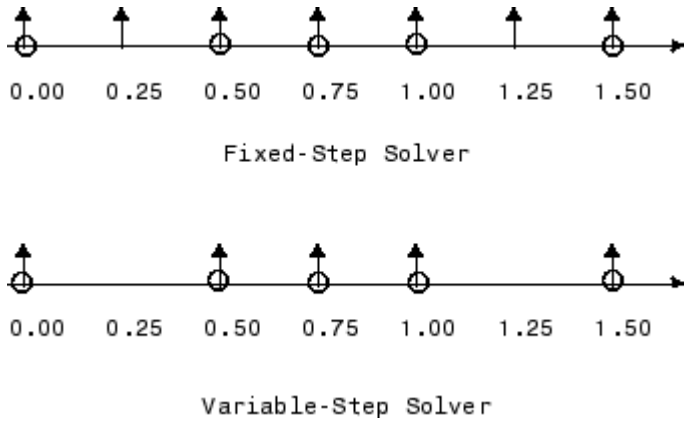
Purely Discrete Systems

A purely discrete system is composed solely of discrete blocks and can be modeled using either a fixed-step or a variable-step solver. Simulating a discrete system requires that the simulator take a simulation step at every sample time hit. For a *multirate discrete system*—a system whose blocks Simulink samples at different rates—the steps must occur at integer multiples of each of the system sample times. Otherwise, the simulator might miss key transitions in the states of the system. The step size that the Simulink software chooses depends on the type of solver you use to simulate the multirate system and on the fundamental sample time.

The *fundamental sample time* of a multirate discrete system is the largest double that is an integer divisor of the actual sample times of the system. For example, suppose that a system has sample times of 0.25 and 0.50 seconds. The fundamental sample time in this case is 0.25 seconds. Suppose, instead, the sample times are 0.50 and 0.75 seconds. The fundamental sample time is again 0.25 seconds.

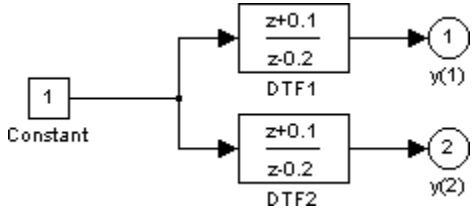
The importance of the fundamental sample time directly relates to whether you direct the Simulink software to use a fixed-step or a variable-step discrete solver to solve your multirate discrete system. A fixed-step solver sets the simulation step size equal to the fundamental sample time of the discrete system. In contrast, a variable-step solver varies the step size to equal the distance between actual sample time hits.

The following diagram illustrates the difference between a fixed-step and a variable-step solver.



In the diagram, the arrows indicate simulation steps and circles represent sample time hits. As the diagram illustrates, a variable-step solver requires fewer simulation steps to simulate a system, if the fundamental sample time is less than any of the actual sample times of the system being simulated. On the other hand, a fixed-step solver requires less memory to implement and is faster if one of the system sample times is fundamental. This can be an advantage in applications that entail generating code from a Simulink model (using Simulink Coder). In either case, the discrete solver provided by Simulink is optimized for discrete systems; however, you can simulate a purely discrete system with any one of the solvers and obtain equivalent results.

Consider the following example of a simple multirate system. For this example, the DTF1 Discrete Transfer Fcn block's **Sample time** is set to `[1 0.1]` [], which gives it an offset of `0.1`. The **Sample time** of the DTF2 Discrete Transfer Fcn block is set to `0.7` , with no offset. The solver is set to a variable-step discrete solver.

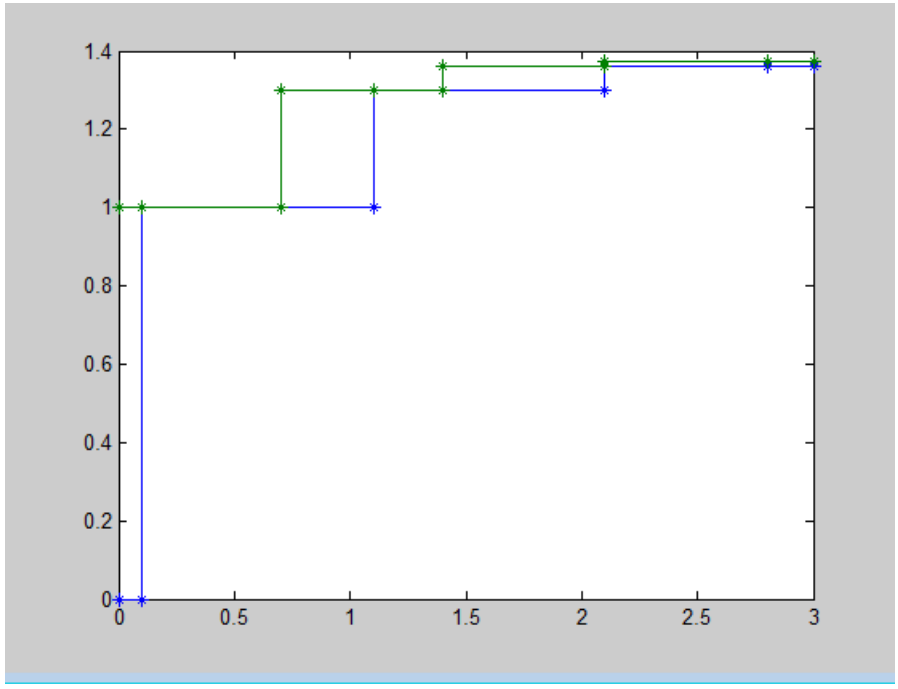


Running the simulation and plotting the outputs using the `stairs` function

```
simOut = sim('ex_dtf','StopTime', '3');
t = simOut.find('tout')
```

```
y = simOut.find('yout')
stairs(t,y, '-*')
```

produces the following plot.



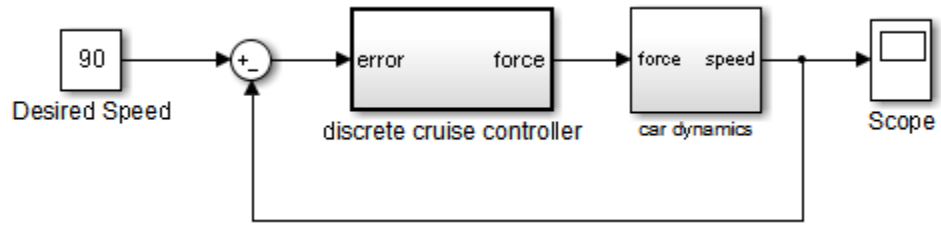
(For information on the `sim` command. see “Run Simulations Programmatically” on page 25-2.)

As the figure demonstrates, because the DTF1 block has a `0.1` offset, the DTF1 block has no output until `t = 0.1`. Similarly, the initial conditions of the transfer functions are zero; therefore, the output of DTF1, y(1), is zero before this time.

Hybrid Systems

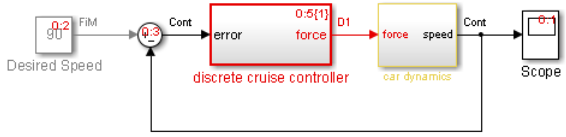
Hybrid systems contain both discrete and continuous blocks and thus have both discrete and continuous states. However, Simulink solvers treat any system that has both continuous and discrete sample times as a hybrid system. For information on modeling hybrid systems, see “Modeling Hybrid Systems” on page 3-7.

In block diagrams, the term hybrid applies to both hybrid systems (mixed continuous-discrete systems) and systems with multiple sample times (multirate systems). Such systems turn yellow in color when you perform an **Update Diagram** with Sample Time Display **Colors** turned 'on'. As an example, consider the following model that contains an atomic subsystem, "Discrete Cruise Controller", and a virtual subsystem, "Car Dynamics". (See `ex_execution_order`.)

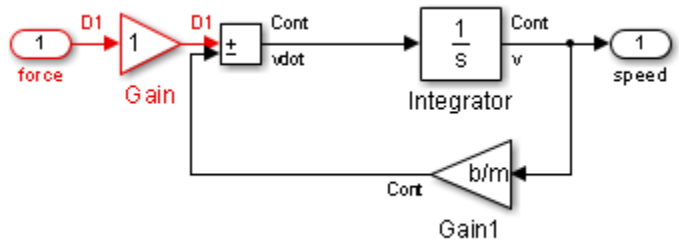


Car Model

With the **Sample Time** option set to **All**, an **Update Diagram** turns the virtual subsystem yellow, indicating that it is a hybrid subsystem. In this case, the subsystem is a true hybrid system since it has both continuous and discrete sample times. As shown below, the discrete input signal, D1, combines with the continuous velocity signal, v, to produce a continuous input to the integrator.

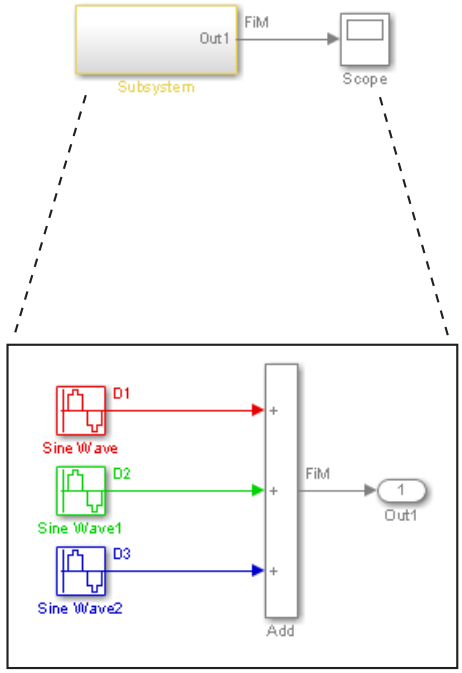


Car Model after an Update Diagram



Car Dynamics Subsystem after an Update Diagram

Now consider a multirate subsystem that contains three Sine Wave source blocks, each of which has a unique sample time — 0.2, 0.3, and 0.4, respectively.



Multirate Subsystem after an Update Diagram

An **Update Diagram** turns the subsystem yellow because the subsystem contains more than one sample time. As shown in the block diagram, the Sine Wave blocks have discrete sample times D1, D2, and D3 and the output signal is fixed in minor step.

In assessing a system for multiple sample times, Simulink does not consider either constant [inf, 0] or asynchronous [–1, –n] sample times. Thus a subsystem consisting of one block that outputs constant value and one block with a discrete sample time will not be designated as hybrid.

The hybrid annotation and coloring are very useful for evaluating whether or not the subsystems in your model have inherited the correct or expected sample times.

"Blocks for Which Sample Time Is Not Recommended" on page 7-21 | "View Sample Time Information" on page 7-9

Resolve Rate Transitions

In general, a rate transition exists between two blocks if their sample times differ, that is, if either of their sample-time vector components are different. The exceptions are:

- Blocks that output constant value never have a rate transition with any other rate.
- A continuous sample time (black) and the fastest discrete rate (red) never has a rate transition if you use a fixed-step solver.
- A variable sample time and fixed in minor step do not have a rate transition.

You can resolve rate transitions manually by inserting rate transition blocks and by using two diagnostic tools. For the single-tasking execution mode, the **Single task rate transition** diagnostic allows you to set the level of Simulink rate transition messages. The **Multitask rate transition** diagnostic serves the same function for multitasking execution mode. These execution modes directly relate to the type of solver in use: Variable-step solvers are always single-tasking; fixed-step solvers may be explicitly set as single-tasking or multitasking.

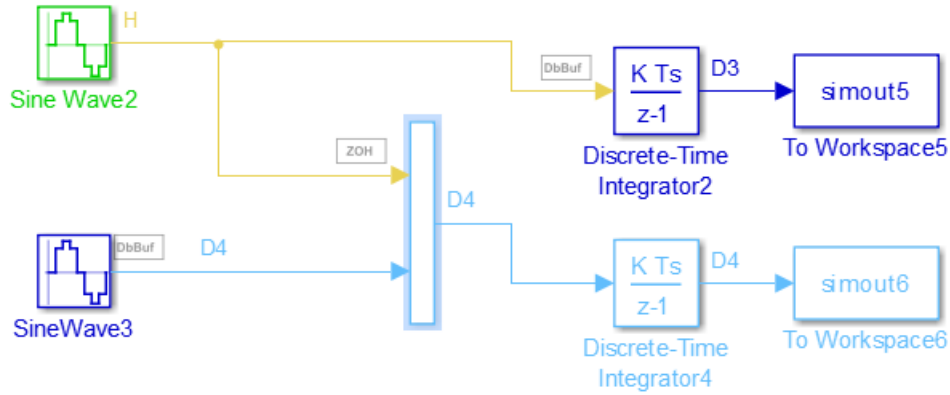
Automatic Rate Transition

Simulink can detect mismatched rate transitions in a multitasking model during an update diagram and automatically insert Rate Transition blocks to handle them. To enable this, in the **Solver** pane of model configuration parameters, select **Automatically handle rate transition for data transfer**. The default setting for this option is off. When you select this option:

- Simulink handles transitions between periodic sample times and asynchronous tasks.
- Simulink inserts hidden Rate Transition blocks in the block diagram.
- Automatically inserted Rate Transition blocks operate in protected mode for periodic tasks and asynchronous tasks. You cannot alter this behavior. For periodic tasks, automatically inserted Rate Transition blocks operate with the level of determinism specified by the **Deterministic data transfer** parameter in the **Solver** pane. The default setting is `Whenever possible`, which enables determinism for data transfers between periodic sample-times that are related by an integer multiple. For more information, see “Deterministic data transfer”. To use other modes, you must insert Rate Transition blocks and set their modes manually.

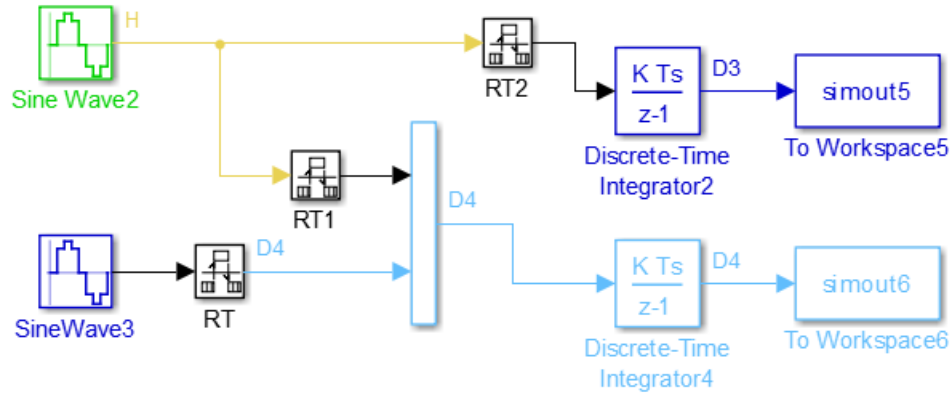
Visualize Inserted Rate Transition Blocks

When you select the **Automatically handle rate transition for data transfer** option, Simulink inserts Rate Transition blocks in the paths that have mismatched transition rates. These blocks are hidden by default. To visualize the inserted blocks, update the diagram. Badge labels appear in the model and indicate where Simulink inserted Rate Transition blocks during the compilation phase. For example, in this model, three Rate Transition blocks were inserted between the two Sine Wave blocks and the Multiplexer and Integrator when the model compiled. The ZOH and DbBuf badge labels indicate these blocks.



You can show or hide badge labels using the **Display > Signals and Ports > Hidden Rate Transition Block Indicators** setting.

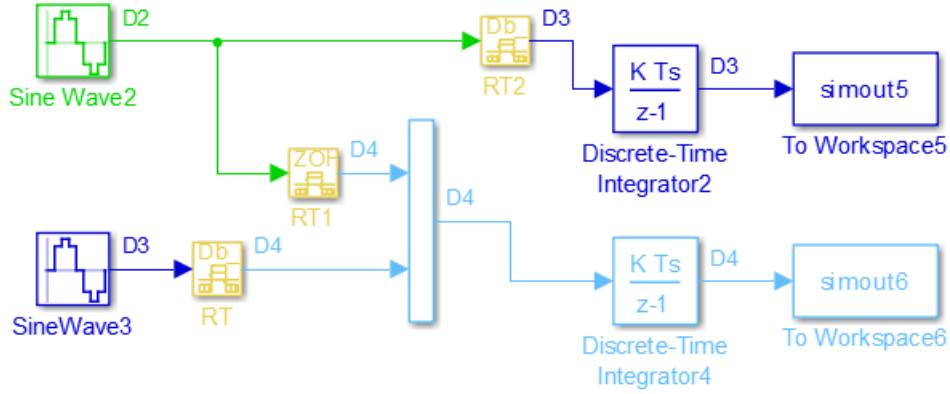
To configure the hidden Rate Transition blocks, right click on a badge label and click on **Insert rate transition block** to make the block visible.



When you make hidden Rate Transition blocks visible:

- You can see the type of Rate Transition block inserted as well as the location in the model.
- You can set the **Initial Conditions** of these blocks.
- You can change data transfer and sample time block parameters.

Validate the changes to your model by updating your diagram.



Displaying inserted Rate Transition blocks is not compatible with:

- Concurrent execution environment
- Export-function models

To learn more about the types of Rate Transition blocks, see Rate Transition.

Note Suppose you automatically insert rate transition blocks and there is a virtual block specifying sample time upstream of the block you insert. You cannot click the badge of the inserted block to configure the block and make it visible because the sample time on the virtual block causes a rate transition as well. In this case, manually insert a rate transition block before the virtual block. To learn more about virtual blocks, see "Nonvirtual and Virtual Blocks" on page 35-2.

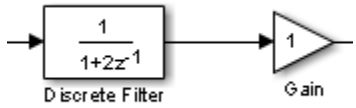
How Propagation Affects Inherited Sample Times

During a model update, for example at the beginning of a simulation, Simulink uses a process called sample time propagation to determine the sample times of blocks that inherit their sample times. The figure below illustrates a Discrete Filter block with a sample time period T_s driving a Gain block.



Because the output of the Gain block is the input multiplied by a constant, its output changes at the same rate as the filter. In other words, the Gain block has an effective sample rate equal to the sample rate of the filter. The establishment of such effective rates is the fundamental mechanism behind sample time propagation in Simulink.

Process for Sample Time Propagation

Simulink uses the following basic process to assign sample times to blocks that inherit their sample times:

1. Propagate known sample time information forward.
2. Propagate known sample time information backward.
3. Apply a set of heuristics to determine additional sample times.
4. Repeat until all sample times are known.

Simulink Rules for Assigning Sample Times

A block having a block-based sample time inherits a sample time based on the sample times of the blocks connected to its inputs, and in accordance with the following rules:

Rule	Action
All of the inputs have the same sample time and the block can accept that sample time	Simulink assigns the sample time to the block

Rule	Action
The inputs have different discrete sample times and all of the input sample times are integer multiples of the fastest input sample time	Simulink assigns the sample time of the fastest input to the block . (This assignment assumes that the block can accept the fastest sample time.)
The inputs have different discrete sample times, some of the input sample times are not integer multiples of the fastest sample time, and the model uses a variable-step solver	Simulink assigns a fixed-in-minor-step sample time to the block.
The inputs have different discrete sample times, some of the input sample times are not integer multiples of the fastest sample time, the model uses a fixed-step solver, and Simulink can compute the greatest common integer divisor (GCD) of the sample times coming into the block	Simulink assigns the GCD sample time to the block. Otherwise, Simulink assigns the fixed step size of the model to the block.
The sample times of some of the inputs are unknown, or if the block cannot accept the sample time	Simulink determines a sample time for the block based on a set of heuristics.

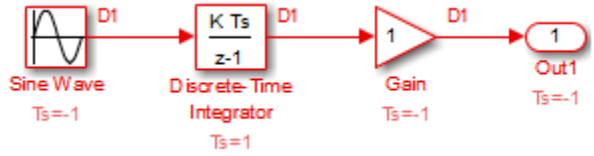
More About

- "Backpropagation in Sample Times" on page 7-41

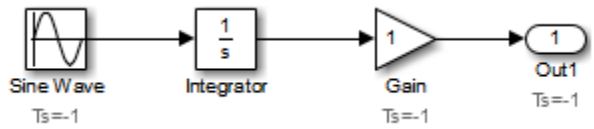
Backpropagation in Sample Times

When you update or simulate a model that specifies the sample time of a source block as inherited (–1), the sample time of the source block may be backpropagated; Simulink may set the sample time of the source block to be identical to the sample time specified by or inherited by the block connected to the source block. For example, in the model below, the Simulink software recognizes that the Sine Wave block is driving a Discrete-Time Integrator block whose sample time is `1`; so it assigns the Sine Wave block a sample time of `1`.



You can verify this sample time setting by selecting **Sample Time > Colors** from the Simulink **Display** menu and noting that both blocks are red. Because the Discrete-Time Integrator block looks at its input only during its sample hit times, this change does not affect the results of the simulation, but does improve the simulation performance.

Now replacing the Discrete-Time Integrator block with a continuous Integrator block, as shown in the model below, causes the Sine Wave and Gain blocks to change to continuous blocks. You can test this change by selecting **Simulation > Update Diagram** to update the colors; both blocks now appear black.



Note Backpropagation makes the sample times of model sources dependent on block connectivity. If you change the connectivity of a model whose sources inherit sample times, you can inadvertently change the source sample times. For this reason, when you update or simulate a model, by default, Simulink displays warnings at the command line if the model contains sources that inherit their sample times.

Referencing a Model

Overview of Model Referencing

In this section...

Reference One Model from Another Model

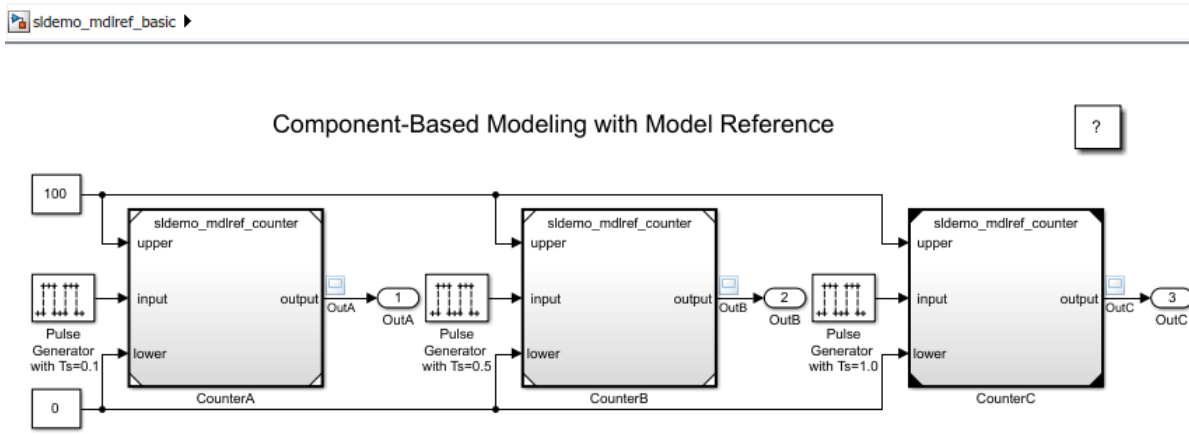
You can include one model in another by using Model blocks. Each instance of a Model block represents a reference to another model, called a referenced model. For simulation and code generation, the referenced model effectively replaces the Model block that references it. The model that contains a referenced model is its parent model. A collection of parent and referenced models constitute a *model reference hierarchy*.

The interface of a referenced model consists of its:

- Input and output ports (and control ports, in the case of a conditional referenced model)
- Parameter arguments

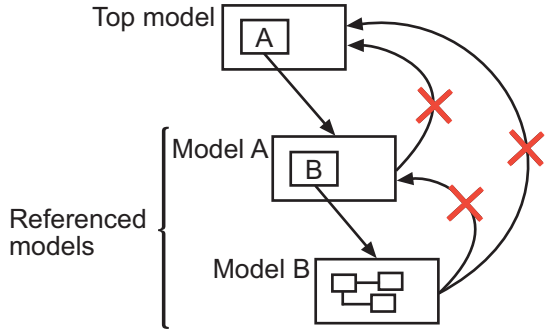
A Model block displays inputs and outputs corresponding to the root-level inputs and outputs of the model it references. These ports enable you to incorporate the referenced model into the block diagram of the parent model. The interface of the referenced model, not the context from which the model is referenced, defines the attributes of blocks in the referenced model. For example, attributes such as dimensions and data types do not propagate across Model block boundaries. To set the interface attributes, use the root Inport of the referenced model.

For example, the `sldemo_mdlref_basic` model includes Model blocks that reference three instances of the same referenced model, `sldemo_mdlref_counter`.



Model Reference Hierarchies

A referenced model can itself contain Model blocks and thus reference lower-level models, to any depth. The top model is the topmost model in a hierarchy of referenced models. Where only one level of model reference exists, the parent model and top model are the same. To prevent cyclic inheritance, a Model block cannot refer directly or indirectly to a model that is superior to it in the model reference hierarchy. This figure shows cyclic inheritance.



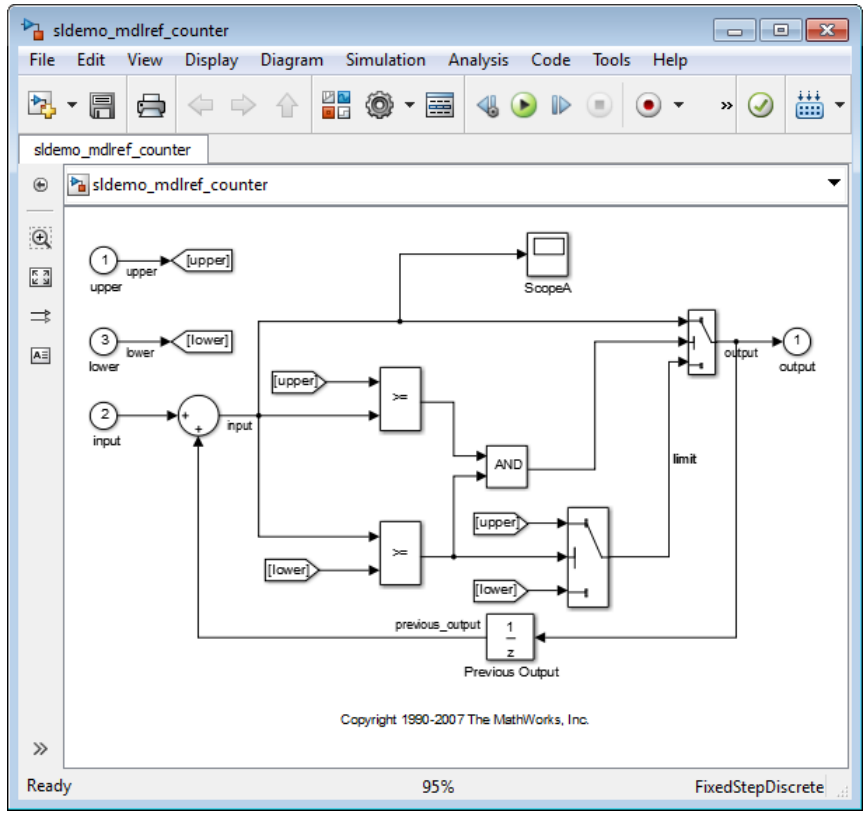
A parent model can contain multiple Model blocks that reference the same referenced model as long as the referenced model does not define global data. The referenced model can also appear in other parent models at any level. You can parameterize a referenced model to provide tunability for all instances of the model. Also, you can parameterize a referenced model to let different Model blocks specify different values for variables that

define the behavior of the referenced model. See “Parameterize Instances of a Reusable Referenced Model” on page 8-72 for details.

Model Block and Referenced Model Ports

To connect the referenced model to other elements of the parent model, use the ports on a Model block. Connecting a signal to a Model block port has the same effect as connecting the signal to the corresponding port in the referenced model. For example, the Model block CounterA has three inputs: two Constant blocks and a Pulse Generator block with a sample time of .1. The Model block CounterB also has three inputs: the same two Constant blocks, and a Pulse Generator block with a sample time of .5. Each Model block has an output to a separate Scope block.

The referenced model includes Inport and Outport blocks (and possibly Trigger or Enable blocks) to connect to the parent model. The `sldemo_mdlref_counter` model has three Inport blocks (upper, input, and lower) and one Outport block (output).



Using Referenced Models as Standalone Models

If a referenced model does not depend on data that is available only from a higher-level model, you can use a referenced model as a standalone model. An appropriately configured model can function as both a standalone model and a referenced model, without changing the model or any entities derived from it.

Examples of Models That Use Model Referencing

Simulink includes several models that illustrate model referencing.

The `Introduction to Managing Data with Model Reference` example introduces the basic concepts and workflow related to managing data with model

referencing. To explore these topics in more detail, select the `Detailed Workflow for Managing Data with Model Reference` example.

In addition, the `sldemo_absbrake` model represents a wheel speed calculation as a Model block within the context of an anti-lock braking system (ABS).

Simulation of Model Referencing Models

You can simulate a referenced model either interpretively (in normal mode) or by compiling the referenced model to code and executing the code (in accelerator mode). For details, see “Simulate Model Reference Hierarchies” on page 8-35.

Code Generation for Referenced Models

To learn about considerations when generating code for a referenced model, see “Referenced Models” (Simulink Coder).

When to Use Model Referencing

In this section...

Referenced Model Advantages

Like subsystems, referenced models allow you to organize large models hierarchically. Model blocks can represent major subsystems. Like libraries, referenced models allow you to use the same capability repeatedly without having to redefine it. Referenced models provide several advantages that are unavailable with subsystems and/or library blocks. Several of these advantages result from Simulink compiling a referenced model independent of the context of the referenced model.

- **Modular development**

  You can develop a referenced model independently from the models that use it.
- **Model Protection**

  You can obscure the contents of a referenced model, allowing you to distribute it without revealing the intellectual property that it embodies.
- **Inclusion by reference**

  You can reference a model multiple times without having to make redundant copies, and multiple models can reference the same model.
- **Incremental loading**

  Simulink loads a referenced model when it is needed, which speeds up model loading.
- **Accelerated simulation**

  Simulink can convert a referenced model to code and simulate the model by running the code, which is faster than interactive simulation.
- **Incremental code generation**

  Accelerated simulation requires code generation only if the model has changed since the code was previously generated.

- **Independent configuration sets**

  The configuration set used by a referenced model can differ from the configuration set of its parent or other referenced models.

For a video summarizing advantages of model referencing, see Modular Design Using Model Referencing.

Compare Model Referencing to Other Componentization Techniques

Model referencing provides many benefits for componentization of a model. However, using subsystems or libraries can meet some modeling requirements better than model referencing. You can use all three componentization techniques in the same model.

For additional information about how model referencing compares to other Simulink componentization techniques, see “Componentization Guidelines” on page 15-29.

- “Model Referencing Limitations” on page 8-105

Create a Referenced Model

A model becomes a referenced model when a Model block in some other model references it. Any model can function as a referenced model, and can continue to function as a separate model.

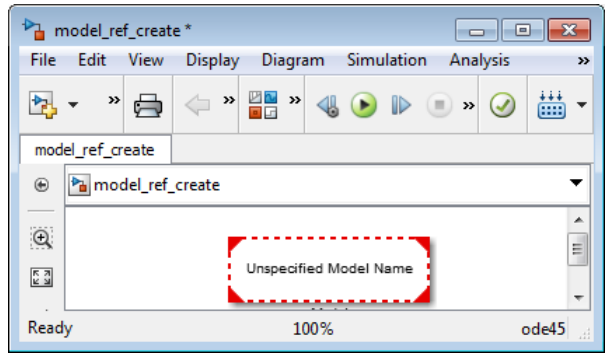
For a video explaining how to create model references, see Getting Started with Model Referencing.

Note If the Simulink block references a model that contains Assignment blocks that are not in an iterator subsystem, you cannot place a Model block in an iterator subsystem.

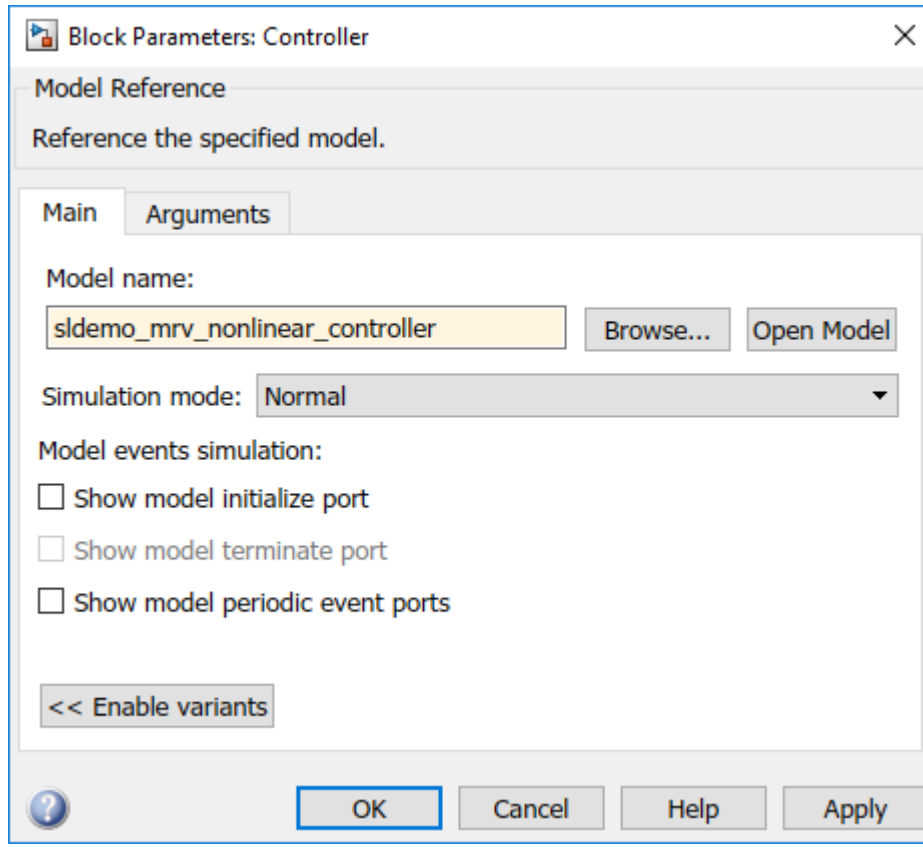
In a configurable subsystem with a Model block, during model update, do not change the subsystem that the configurable subsystem selects.

To create a reference to a model (referenced model) in another model (parent model):

1. If the folder containing the referenced model you want to reference is not on the MATLAB path, add the folder to the MATLAB path.
2. In the referenced model:
   - Set **Configuration Parameters Model Referencing Total number of instances allowed per top model** to:
     - `One`, if the hierarchy uses the model at most once.
     - `Multiple`, to use the model more than once per top model. To reduce overhead, specify `Multiple` only when necessary.
     - `Zero`, which precludes referencing the model.
3. Create an instance of the Model block in the parent model by dragging a Model block instance from the Ports & Subsystems library to the parent model. The new block is initially unresolved (specifies no referenced model).



4 Double-click the Model block to open the parameter dialog box



5 Enter the name of the referenced model in the **Model name** field. This name must contain fewer than 60 characters, exclusive of the `.slx` or `.mdl` suffix.

   - For information about **Model Arguments**, see "Specify Different Value for Each Instance of Reusable Model" on page 8-72.
   - For information about the **Simulation mode**, see "Simulate Model Reference Hierarchies" on page 8-35.

6 Click **OK** or **Apply**.

If the referenced model contains any root-level inputs or outputs, Simulink displays corresponding input and output ports on the Model block instance that you have created. Use these ports to connect the referenced model to other ports in the parent model.

A signal that connects to a Model block is functionally the same signal outside and inside the block. Therefore, that signal is subject to the restriction that a given signal can have at most one associated signal object. See `Simulink.Signal` for more information. For information about connecting a bus signal to a referenced model, see "Bus Usage Requirements" on page 8-28.

Specify Reusability of Referenced Models

To reuse an algorithm (a set of connected blocks that perform a repeatable function), instead of copying and pasting the blocks, you can encapsulate the algorithm in a referenced model and refer to that model with multiple Model blocks. Each Model block is an instance of the algorithm.

Encapsulating a reusable algorithm in a referenced model:

- Decreases the effort of maintance—to change the algorithm, you make the modifications only once.
- Makes models easier to understand at a glance—the Model blocks indicate that they refer to the same algorithm (the same referenced model).
- Helps prepare your model for efficient code generation (Simulink Coder)—the generated code calls a reentrant function instead of repeating the algorithm operations line by line.

To enable reuse of a referenced model, set **Configuration Parameters > Model Referencing > Total number of instances allowed per top model** to `Multiple` (the default setting).

Alternatively, to reuse an algorithm, you can create a custom library subsystem. To decide which technique to use, see “Componentization Guidelines” on page 15-29. To iteratively repeat an algorithm over multiple similar signals in the same model, consider using a For Each subsystem. See “Repeat an Algorithm Using a For Each Subsystem” on page 65-139.

Share Data Between Instances

By default, each instance (each Model block) reads from and writes to a separate copy of the signals and block states in the model. Therefore, the instances do not interact with each other through shared signal or state data.

To share a piece of data between all of the instances (for example, an accumulator or a fault indicator), model the data as a data store.

- To restrict access to the data so that only the blocks in the referenced model can read from and write to it, use a Data Store Memory block in the model and select the **Share across model instances** parameter. For an example, see “Share Data Between Instances of a Reusable Algorithm”.
- To allow access to the data outside the referenced model (for example, in the parent model or in other sibling referenced models), use a global data store, which is a `Simulink.Signal` object in the base workspace or a data dictionary.

For more information about data stores, see “Model Global Data by Creating Data Stores” on page 62-13.

Use Different Parameter Value for Each Instance

For some applications, you can reuse an algorithm only if you can configure each instance to use a different value for a block parameter (such as the setpoint of a controller or a filter coefficient). The instances differ only in the value of the parameter.

By default, a block parameter has the same value in each instance (each Model block) of a reusable referenced model. To specify a different value for each instance, define a model argument. For more information, see “Parameterize Instances of a Reusable Referenced Model” on page 8-72.

Reusability Limitations

If a referenced model has any of these characteristics, the model must specify **Configuration Parameters Model Referencing Total number of instances**

allowed per top model as `One`. No other instances of the model can exist in the hierarchy.

- The model contains any To File blocks.
- The model references another model that is set to single instance.
- The model contains a state or signal with a non-auto storage class.
- The model uses one of these Stateflow constructs:
  - Stateflow graphical functions
  - Machine-parented data
- The referenced model executes in accelerator mode and has any of these characteristics:
  - A subsystem that is marked as a function
  - An S-function that is either not inlined or is inlined but does not set the option `SS_OPTION_WORKS_WITH_CODE_REUSE`
- A function-call subsystem that Simulinkforces to be a function and is called by a wide signal

An error occurs in either of these cases:

- You do not set the parameter correctly.
- Another instance of the model is in the hierarchy, in either normal mode or accelerator mode.

Masking Referenced Models

You can mask a model and reference the masked model from a Model block. With a model mask, you can control the appearance of corresponding Model blocks and customize the way the blocks display model arguments. For more information about block masks, see “Introduction to Model Mask” on page 38-64.

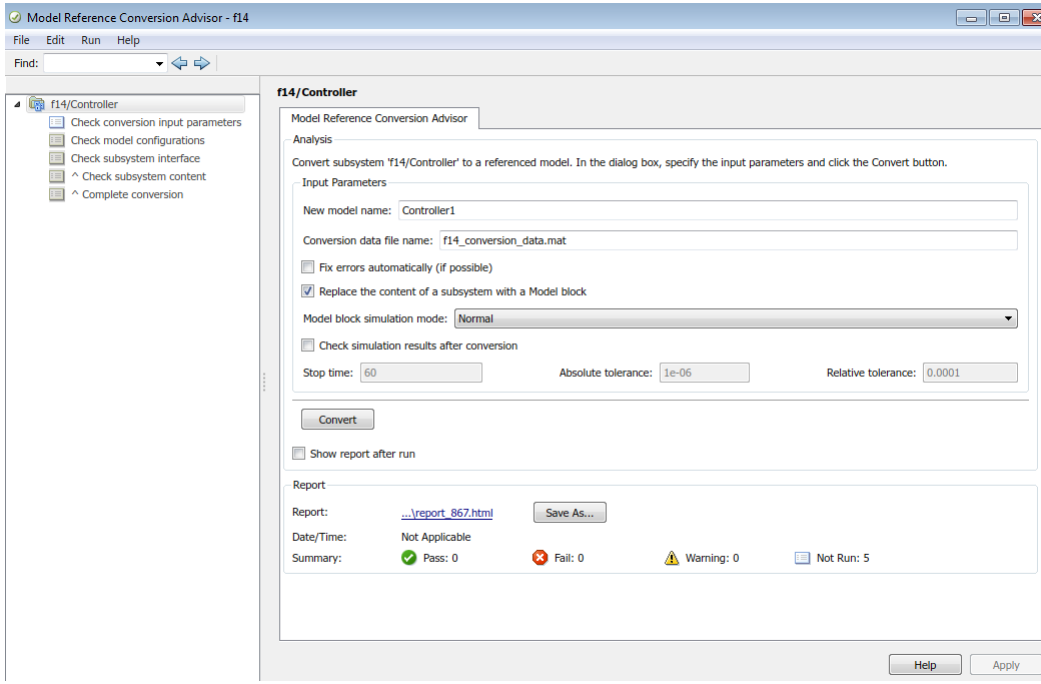
Convert a Subsystem to a Referenced Model

In this section...

Conversion Process

The general process for converting a subsystem to a referenced model involves the following tasks. For details, see "Convert a Subsystem to a Referenced Model" on page 8-15.

1. Determine whether converting the subsystem to a referenced model meets your modeling requirements.
2. Optionally, prepare the model before converting the subsystem.
3. To create a referenced model, run the Model Reference Conversion Advisor. Address any issues that the advisor reports and continue the conversion until the advisor reports no issues.



4 Optionally, have the advisor compare the results of simulating the model before and after the conversion. Set up signal logging for key signals. Check the consistency of the top model simulation results.

5 After you complete the conversion, update the model as necessary.

Determine Whether to Convert the Subsystem

Before you convert a subsystem to model referencing, consider whether model referencing is the approach to use to meet your modeling requirements.

Model referencing offers several benefits for modeling large, complex systems and for team-based development. However, subsystems or libraries are better suited for some modeling goals than model referencing. Many large models involve using a combination of subsystems and referenced models. For information to help you to decide whether to convert a subsystem to a referenced model, see “Componentization Guidelines” on page 15-29.

Confirm that the subsystem you want to convert is a type of subsystem that you can convert. See “Limitations on Subsystems That You Can Convert” on page 8-17.

Limitations on Subsystems That You Can Convert

You cannot convert to a referenced model Subsystem with Simscape Multibody components.

To convert a masked subsystem, use the `Simulink.SubSystem.convertToModelReference` function.

To create a referenced model that accepts asynchronous function calls, see “Asynchronous Support Limitations” (Simulink Coder).

Update the Model Before Converting the Subsystem

Tip Before you perform the conversion, make sure that the model containing the subsystem that you want to convert compiles successfully.

The advisor fixes or guides you through fixing issues. However, if you are converting a large, complex subsystem, consider taking steps before you convert the model. Preparing the model and subsystem can eliminate or reduce the number of issues the advisor identifies. It can be more efficient to address issues in the model editing environment than to switch repeatedly between the advisor and the Simulink Editor.

Note You can use Model Reference Conversion Advisor **Fix** option to have the advisor fix some conversion issues.

1. Set the **Configuration Parameters > Diagnostics > Data Validity > Signal resolution** parameter to `Explicit only` or `None`.

   You can use the Model Reference Conversion Advisor **Fix** option to address this issue automatically.
2. Configure these subsystem interfaces to the model.

Subsystem Interface	What to Look For	Model Modification
Goto or From blocks	Crossing of subsystem boundaries	Use an Inport block to replace From blocks that have a corresponding GoTo block that crosses the subsystem boundary. Use an Outport block to replace each GoTo block that has corresponding From blocks that cross the subsystem boundary. Connect the Inport and Outport blocks to the corresponding subsystem ports. You can use the Model Reference Conversion Advisor **Fix** option to address this issue.
Data stores	Data Store Memory blocks accessed by Data Store Read or Data Store Write blocks from outside of the subsystem	Replace the Data Store Memory block with a global data store. Define a global data store using a `Simulink.Signal` object. For details, see “Data Stores with Signal Objects” on page 62-20. You can use the Model Reference Conversion Advisor **Fix** option to address this issue.

Subsystem Interface	What to Look For	Model Modification
Tunable parameters	Global tunable parameters in the dialog box opened using the **Configuration Parameters > Optimization > Signals and Parameters > Configure** button	Use `tunablevars2parameterobjects` to create a `Simulink.Parameter` object for each tunable parameter. The `Simulink.Parameter` objects must have a storage class other than Auto. For more information, see "Parameterize Instances of a Reusable Referenced Model" on page 8-72 and "Tunable Parameters" on page 3-8. You can use the Model Reference Conversion Advisor **Fix** option to address this issue.

3 Configure the subsystem and its contents.

Subsystem Configuration	What to Look For	Model Modification
Inactive subsystem variants	Variant Subsystem blocks.	Make the subsystem variant that you want to convert active. The advisor does not convert inactive subsystem variants. To have the new Model block behave similar to the subsystem variant, convert each variant subsystem separately and then use a Model Variants block. For more information, see "Set up Model Variants Using a Model Block" on page 11-49.

Subsystem Configuration	What to Look For	Model Modification
Function calls	Function-call signals that cross virtual subsystem boundaries.	Move the Function-Call Generator block into the subsystem that you want to convert. **Note** If you convert an export-function subsystem, then you do not need to move the Function-Call Generator block.
	Function-call outputs.	Change the function-call outputs to data triggers.
	Wide function-call ports.	Eliminate wide signals for function-call subsystems.
Sample times	Sample time of an Inport block that does not match the sample time of the block driving the Inport.	Insert Rate Transition blocks where appropriate.
Inport blocks	Merged Inport blocks.	Configure the model to avoid merged Inport blocks. See the Merge block documentation.
Constant blocks	Constant blocks that input to subsystems.	Consider moving the Constant blocks into the subsystem.
Buses	Bus signals that enter and exit a subsystem.	Match signal names and bus element names for blocks inside the subsystem. Consider using the **Configuration Parameters > Diagnostics > Connectivity > Signal label mismatch** diagnostic.
	Duplicate signal names in buses.	Make signal names of the bus elements unique.

Subsystem Configuration	What to Look For	Model Modification
	Signal names that are not valid MATLAB identifiers. A valid identifier is a character vector that meets these conditions: • The name contains letters, digits, or underscores. • The first character is a letter. • The length of the name is less than or equal to the value returned by the `namelengthmax` function.	Change any invalid signal names to be valid MATLAB identifiers.

Run the Model Reference Conversion Advisor

Note As an alternative to running the Model Reference Conversion Advisor, you can use the `Simulink.SubSystem.convertToModelReference` function. You can convert multiple subsystems using one `Simulink.SubSystem.convertToModelReference` command.

Before you run the advisor, make sure that the model containing the subsystem that you want to convert compiles successfully.

1. Open the model and locate the subsystem that you want to convert.
2. For improved conversion performance, close any open Scope block windows.
3. Start the Model Reference Conversion Advisor. In the Simulink Editor, right-click the subsystem that you want to convert. Select **Subsystem & Model Reference** > **Convert Subsystem to** > **Referenced Model**.

4 In the Model Reference Conversion Advisor dialog box, review the default settings under **Input Parameters**. Modify the parameters for running the advisor as needed and click **Apply**.

   You can have the advisor fix all conversion issues that it can fix. In the **Check Conversion Input Parameters** check, select **Fix errors automatically (if possible)**. This option can make the conversion process faster, but you do not control the fixes that the advisor makes.

   The advisor can compare simulation results for the top model for the referenced model to the results for the baseline model containing the subsystem. Select **Check simulation results after conversion**. For details, see "Compare Simulation Results Before and After Conversion" on page 8-22.

   Tip The advisor provides context-sensitive help for checks. In the advisor, right-click the check (such as **Check conversion input parameters**) and select `What's This?`.

5 Click **Convert**.

6 Address any issues that the advisor reports. For some issues, the advisor provides a **Fix** button to address an issue.

7 After you address each issue, click **Continue** until all the checks pass.

Compare Simulation Results Before and After Conversion

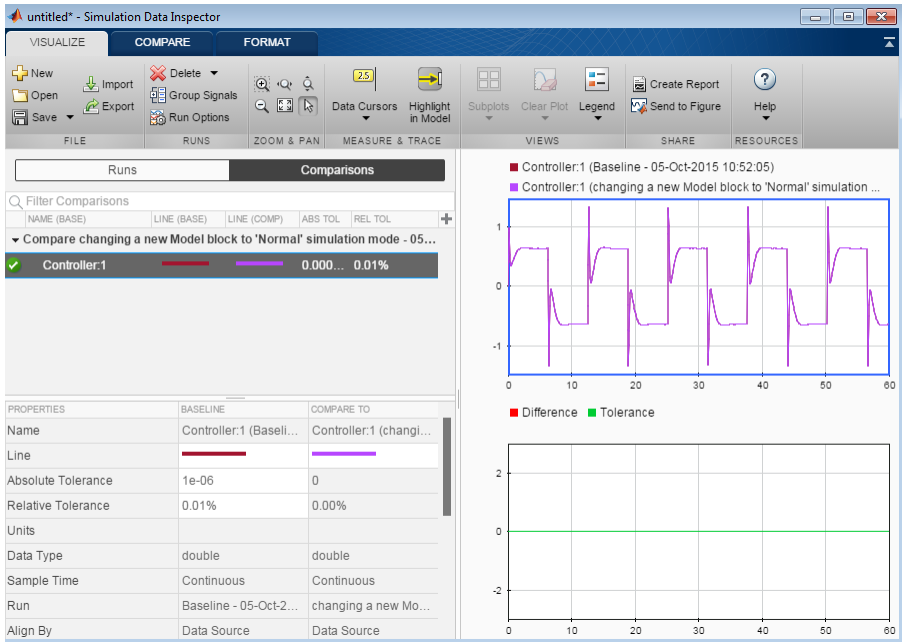
The advisor can compare simulation results before and after the conversion.

Before you convert the subsystem:

- In the Model Reference Conversion Advisor, under **Input Parameters**, select **Replace subsystem with a Model block** and **Check simulation results after conversion**.
- Set these options:
  - **Stop time**
  - **Absolute tolerance**
  - **Relative tolerance**
- Enable signal logging for the subsystem output signals of interest.

- Set the **Model block simulation mode** option in the advisor to the same simulation mode as the original model.

After you convert the model, select **View comparison results**. The results display in the Simulation Data Inspector. A green check mark indicates that the simulation results are the same for the baseline model and the model with the referenced model.



For more information about the Simulation Data Inspector, see “View and Analyze Simulation Results”.

Conversion Results

After the advisor runs all the checks successfully, it:

- Creates a referenced model from the subsystem
- Creates the bus objects, signal objects, and tunable parameters that the referenced model requires
- Adds a Model block (by default)
- Inserts the Model block in a wrapper subsystem when the automatic fixes modify the Model block interface by adding ports.

- Creates a conversion summary report
- Checks the consistency of simulation results before and after conversion (if you select that option)

The advisor copies the following elements from the original model to the new referenced model.

- **Configuration set** — If the referencing model uses:
  - A configuration set that is not a referenced configuration set, the advisor copies the entire configuration set to the referenced model.
  - A referenced configuration set, then both the referencing and referenced models use the same referenced configuration set.
- **Variables** — The advisor copies into the model workspace of the referenced model only the model workspace variables that the subsystem used in the original model.

  If the model that contains the subsystem uses a data dictionary, then the referenced model uses the same data dictionary.
- **Requirements links** — Requirements links created with the Simulink Requirements software (for example, requirements links to blocks and signals) are copied. The advisor transfers the requirements links from the subsystem to the new Model block.

The conversion summary report describes the elements that it copies.

Conversion Report

The advisor creates an HTML report in the `slprj` folder that it uses while performing the conversion. The report summarizes the results of the conversion process, including the results of the fixes that the advisor performed.

Revert the Conversion Results

If you are not satisfied with the conversion results, you can restore the model to its initial state. Use one of these approaches:

- At any point during the conversion, select **File > Load Restore Point**.
- After you successfully run the **Complete conversion** check, select **Click here to restore the original model**.

Integrate the Referenced Model into the Parent Model

After you complete the conversion, update the model as necessary to meet your modeling requirements.

Add a Model Block, If Necessary

If, before the conversion, you cleared the **Replace the content of a subsystem with a Model block** option, then add a Model block to the parent model manually.

1. Delete the Subsystem block.
2. Copy the new Model block into the model, where the subsystem was.

Note If you enable the **Replace the content of a subsystem with a Model block** option, the advisor action depends on whether you use the automatic fix options.

- If you use the automatic fixes, then the advisor replaces the Subsystem block with a Model block unless the automatic fixes change the input or output ports. If the ports change, then the advisor includes the contents of the subsystem in a Model block that is inserted in the Subsystem block.
- If you do not use the automatic fixes, then the advisor replaces the Subsystem block with a Model block.

Inspect Root Inport Blocks in the Referenced Model

If you want to simulate the model with external data, check that the root Inport blocks in the new referenced model have the appropriate **Interpolate data** parameter setting. For details, see the documentation for the **Interpolate data** parameter of the Inport block.

Convert Each Variant Subsystem

If you convert an active variant subsystem, convert each of the variant subsystems to referenced model. Converting each variant subsystem to a referenced model produces similar results to using the Variant Subsystem block.

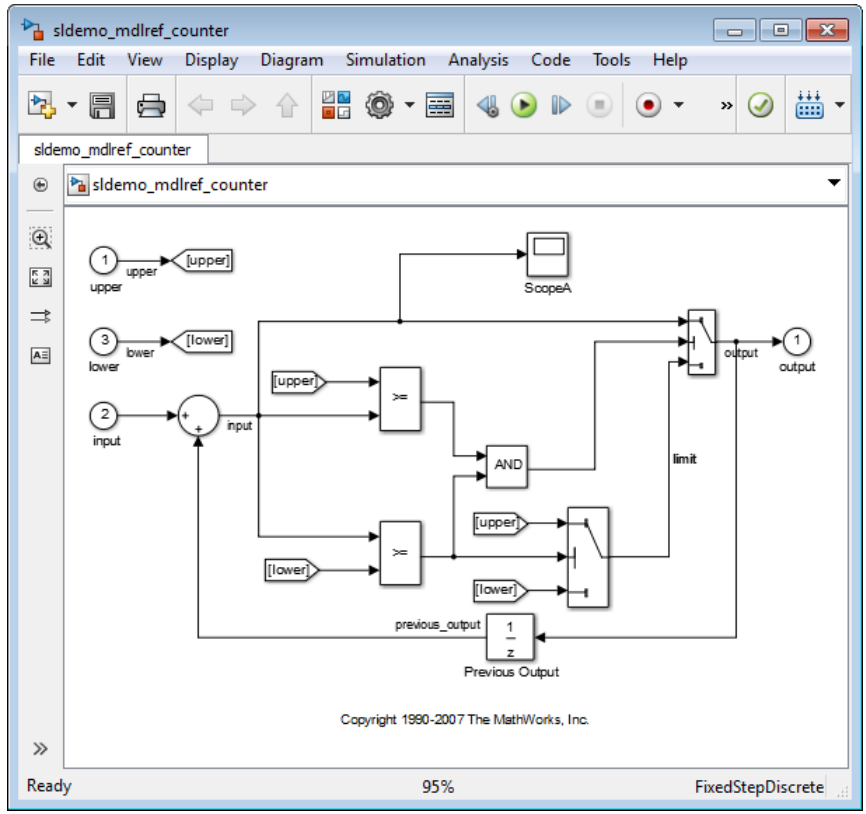
Define Referenced Model Inputs and Outputs

In this section...

The referenced model includes Inport and Outport blocks (and possibly Trigger or Enable blocks) to get input from the parent model and to provide output to the parent model. The Model block that references the model has input and output ports that correspond to the root-level input and output blocks of the referenced model. The signals entering the Model block need to be valid for the corresponding input blocks of the referenced model and the output signals from the Model block are the referenced model root-level Outport block signals. The `sldemo_mdlref_counter` model has three Inport blocks (upper, input, and lower) and one Outport block (output).



Signal Propagation Requirements

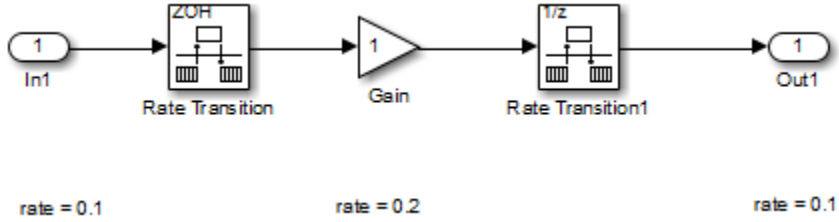
The signal name must explicitly appear on any signal line connected to an Outport block of a referenced model. A signal connected to an unlabeled line of an Outport block of a referenced model cannot propagate out of the Model block to the parent model.

Bus Usage Requirements

For bus signals that cross model reference boundaries, use the same bus object to specify the properties of the bus in both the parent and the referenced model. For details, see “Bus Data Crossing Model Reference Boundaries” on page 65-150. For an example of a model referencing model that uses buses, see `sldemo_mdref_bus`.

Sample Time Requirements

The first nonvirtual block connected to a root-level Inport or Outport block of a referenced model must have the same sample time as the port to which it connects. Use Rate Transition blocks to match input and output sample times, as shown in the following diagram.



User-Defined Data Types

A referenced model can input or output only those user-defined data types that are fixed-point or that `Simulink.DataType` or `Simulink.Bus` objects define.

Inherit Sample Times for Model Referencing

In this section...

How Sample-Time Inheritance Works for Model Blocks

The sample times of a Model block are the sample times of the model that it references. If the referenced model must run at specific rates, the model specifies the required rates. Otherwise, the referenced model inherits its sample time from the parent model.

Placing a Model block in a triggered, function call, or iterator subsystem relies on the ability to inherit sample times. Also, allowing a Model block to inherit sample time maximizes its reuse potential. For example, a model can fix the data types and dimensions of all its input and output signals. You could reuse the model with different sample times (for example, discrete at 0.1 or discrete at 0.2, triggered).

Conditions for Inheriting Sample Times

A referenced model inherits its sample time if the model:

- Does not have any continuous states
- Specifies a fixed-step solver and the **Fixed-step size** is `auto`
- Contains no blocks that specify sample times (other than inherited or constant)
- Does not contain any S-functions that use their specific sample time internally
- Has only one sample time (not counting constant and triggered sample time) after sample time propagation
- Does not contain any blocks, including Stateflow charts, that use absolute time, as listed in "Blocks That Depend on Absolute Time" on page 8-31

- Does not contain any blocks whose outputs depend on inherited sample time, as listed in "Blocks Whose Outputs Depend on Inherited Sample Time" on page 8-32.

You can use a referenced model that inherits its sample time anywhere in a parent model. By contrast, you cannot use a referenced model that has intrinsic sample times in a triggered, function call, or iterator subsystem. To avoid rate transition errors, ensure that blocks connected to a referenced model with intrinsic samples times operate at the same rates as the referenced model.

Note A continuous sample time cannot be propagated to a Model block that is sample-time independent.

For more information, see "Blocks Whose Outputs Depend on Inherited Sample Time" on page 8-32.

Determining Sample Time of a Referenced Model

To determine whether a referenced model can inherit its sample time, set the **Periodic sample time constraint** configuration parameter to `Ensure sample time independent`. If the model is unable to inherit sample times, this setting causes Simulink to display an error message when building the model. See "Periodic sample time constraint" for more about this option.

To determine the intrinsic sample time of a referenced model, or the fastest intrinsic sample time for multirate referenced models:

1. Update the model that references the model
2. Select a Model block within the parent model
3. Enter the following at the MATLAB command line:

```
get_param(gcb, 'CompiledSampleTime')
```

Blocks That Depend on Absolute Time

The following Simulink blocks depend on absolute time, and therefore preclude a referenced model from inheriting sample time:

- Backlash (only when the model uses a variable-step solver and the block uses a continuous sample time)

- Chirp Signal
- Clock
- Derivative
- Digital Clock
- Discrete-Time Integrator (only when used in triggered subsystems)
- From File
- From Workspace
- Pulse Generator
- Ramp
- Rate Limiter
- Repeating Sequence
- Signal Generator
- Sine Wave (only when the **Sine type** parameter is `Time-based`)
- `stateflow` (when the chart uses absolute-time temporal logic, or the reserved word `t` to reference time)
- Step
- To File
- To Workspace (only when logging to `Timeseries` or `Structure With Time` format)
- Transport Delay
- Variable Time Delay
- Variable Transport Delay

Some blocks other than Simulink blocks depend on absolute time. See the documentation for the blocksets that you use.

Blocks Whose Outputs Depend on Inherited Sample Time

Using a block whose output depends on an inherited sample time in a referenced model can cause simulation to produce unexpected or erroneous results. When building a referenced model that does not need a specified rate, Simulink checks for blocks whose outputs are functions of the inherited sample time. This checking includes examining S-Function blocks. If Simulink finds any such blocks, it specifies a default sample time. If you have set the **Configuration Parameters > Solver > Periodic sample time**

constraint to `Ensure sample time independent`,Simulink displays an error. See "Periodic sample time constraint" for more about this option.

The outputs of the following built-in blocks depend on inherited sample time. The outputs of these blocks preclude a referenced model from inheriting its sample time from the parent model:

- Discrete-Time Integrator
- From Workspace (if it has input data that contains time)
- Probe (if probing sample time)
- Rate Limiter
- Sine Wave

Simulink assumes that the output of an S-function does not depend on inherited sample time unless the S-function explicitly declares the contrary. See "Sample Times" for information on how to create S-functions that declare whether their output depends on their inherited sample time.

In referenced models that inherit their sample time, avoid S-functions in referenced models that fail to declare whether output depends on inherited sample time. Excluding those kinds of S-functions helps to avoid simulation errors. By default, Simulink warns you if your model contains such blocks when you update or simulate the model. See "Unspecified inheritability of sample time" for details.

Sample Time Consistency

Use consistent sample time rates to promote the reliable use of a model referenced by another model. Make the rates of root Inport and Outport blocks in a referenced model consistent with the rates of blocks reading from and writing to those blocks. Simulink generates an error when there are sample time mismatches between:

- The sample times of root Inport blocks and the sample times of blocks to which the Inport block inputs.
- The sample times of root Outport blocks and the sample times of blocks that input to the Outport block.

To address an error that flags a sample time inconsistency in a referenced model, you can use one of these approaches.

Root Inport or Output Block Sample Time is Different From	Possible Solution
All the blocks to which it connects, and those blocks all have the same sample time as each other	Set the sample time of the Inport or Outport block so that it matches the sample time of the block to which it connects.
One or more blocks and the same as one or more blocks	For blocks that do not match the Inport or Outport block, insert Rate Transition blocks on the signal that connects to the Inport or Outport block.

Simulate Model Reference Hierarchies

In this section...

Simulating a model that uses model referencing differs in some ways from simulating a standalone model that does not use model referencing.

There are some limitations for simulating model reference hierarchies. For details, see “Simulation Limitations” on page 8-106 and “Signal Limitations” on page 8-106.

Simulate a Top Model

Simulink executes the top model in a model reference hierarchy the same way that it executes models without model referencing. All the Simulink simulation modes are available to the top model. To achieve faster execution of a top model in a model reference hierarchy, you can use Simulink accelerator or rapid accelerator mode. For details about accelerator mode, see the “Acceleration” documentation. For information about rapid accelerator mode, see “Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File” (Simulink Coder).

When you execute a top model in Simulink accelerator or rapid accelerator mode, all referenced models execute in accelerator mode.

Referenced Model Simulation

You can simulate a referenced model in one of these modes:

- Normal
- Accelerator
- Software-in-the-loop (SIL)

- Processor-in-the-loop (PIL)

For more information about using these simulation modes for referenced models, see “Comparison of Simulation Modes for Referenced Models” on page 8-36.

The simulation modes used for referenced models depend on the simulation mode of the parent model. For details, see “Parent and Referenced Model Simulation Modes” on page 8-39.

Specify the Simulation Mode for Referenced Models

The Model block for each instance of a referenced model controls the simulation mode of the instance. To set or change the simulation mode for a referenced model:

1. Access the block parameter dialog box for the Model block.
2. Set the **Simulation mode** parameter.
3. Click **OK** or **Apply**.

Comparison of Simulation Modes for Referenced Models

You can use rapid accelerator mode for the top model in a model reference hierarchy, but not for referenced models.

The different simulation modes for referenced models share many capabilities and techniques, but they have different implementations, requirements, and limitations.

Tip Accelerator mode execution of a referenced model is different from:

- Accelerator mode execution of a freestanding or top model, as described in “Acceleration”.
- Rapid Accelerator mode execution of a freestanding or top model, as described in “Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File” (Simulink Coder).

For more information about Accelerator mode execution of a referenced model, see “Model Reference Simulation Targets” on page 8-54.

Simulation Mode	Description	When to Use

Normal	Executes referenced model interpretively.	Simulink executes a normal mode referenced model interpretively. Compared to other simulation modes, normal mode:
		• Executes more slowly.
		• Requires no delay for code generation or compilation.
		• Works with more Simulink and Stateflow tools, supporting tools such as:
		  • Scopes, port value display, and other output viewing tools.
		  • Model coverage analysis.
		  • Stateflow debugging and animation.
		• Provides more accurate linearization analysis.
		• Supports more S-functions than accelerator mode does.
		You can use normal mode with multiple instances of a referenced model. For details, see “Simulate Models with Multiple Referenced Model Instances” on page 8-44.

Accelerator	Executes the referenced model by creating a MEX-file (a simulation target) for the referenced model, then running the MEX-file. For more information, see “Model Reference Simulation Targets” on page 8-54.	• Executes faster than normal mode. • Takes time for code generation and code compilation. • Does not fully support some Simulink tools, such as Model Coverage and the Simulink Debugger. • Supports Scope blocks, but requires using the Signal & Scope Manager and adding test points to signals. Adding or removing a test point requires rebuilding the SIM target for a model.

Simulation Mode	Description	When to Use
SIL	Executes referenced model by generating production code. This code is compiled for, and executed on, the host platform. Requires Embedded Coder® software. For more information, see "SIL and PIL Limitations" (Embedded Coder) and "Numerical Equivalence Testing" (Embedded Coder).	• Verifies generated source code without modifying the original model. • Supports the reuse of test harnesses for the original model with the generated source code. SIL mode provides a convenient alternative to PIL simulation when the target hardware is not available.
PIL	Executes referenced model by generating production code. This code is cross-compiled for, and executed on, a target processor or an equivalent instruction set simulator. Requires Embedded Coder software. For more information, see "SIL and PIL Limitations" (Embedded Coder) and "Numerical Equivalence Testing" (Embedded Coder).	• Verifies deployment object code on target processors without modifying the original model. • Supports the reuse of test harnesses for the original model with the generated source code.

Note Simulation results for a given model are nearly identical in normal and accelerator modes. Trivial differences can occur, depending on differences in the optimizations and libraries that you use.

Configuration parameter setting requirements and behavior can vary depending on the simulation mode. For details, see .

Diagnostic Configuration Parameters Ignored in Accelerator Mode

For models referenced in accelerator mode, Simulink ignores the values of these configuration parameter settings if you set them to a value other than `None`:

- **Array bounds exceeded** (`ArrayBoundsChecking`)
- **Inf or NaN block output** (`SignalInfNanChecking`)
- **Simulation range checking** (`SignalRangeChecking`)
- **Division by singular matrix** (`CheckMatrixSingularityMsg`)
- **Wrap on overflow** (`IntegerOverflowMsg`)

Also, for models referenced in accelerator mode, Simulink ignores these configuration parameters when you set them to a value other than `Disable all`. For details, see "Data Store Diagnostics" on page 62-3.

- **Detect read before write** (`ReadBeforeWriteMsg`)
- **Detect write after read** (`WriteAfterReadMsg`)
- **Detect write after write** (`WriteAfterWriteMsg`)

You can use the Model Advisor to identify models referenced in accelerator mode for which Simulink ignores these configuration parameters.

1. In the Simulink Editor, select **Analysis > Model Advisor**.
2. Select **By Task**.
3. Run the **Check diagnostic settings ignored during accelerated model reference simulation** check.

To see the results of running the identified diagnostics with settings to produce warnings or errors, simulate the model in normal mode. Inspect the diagnostic warnings and then simulate in accelerator mode.

Parent and Referenced Model Simulation Modes

The simulation modes you can use for a referenced model depend on the simulation mode of its parent model.

Parent Model Simulation Mode	Referenced Model Simulation Modes
Normal	• Referenced models can use normal, accelerator, SIL, or PIL mode. • If every model that is superior to a referenced model in the model reference hierarchy also executes in normal mode, that referenced model can execute in normal mode.
Accelerator	• All subordinate models must also execute in accelerator mode. • When a normal mode model is subordinate to an accelerator mode model, Simulink returns a warning and temporarily overrides the normal mode specification. • When a SIL-mode or PIL-mode model is subordinate to an accelerator mode model that is not the top model, an error occurs.
SIL	• If their simulation modes are normal, accelerator, or SIL, all subordinate models also execute in SIL mode. Otherwise, an error occurs. See “Simulation Mode Override Behavior in Model Reference Hierarchy” (Embedded Coder). • Multiple Model blocks, starting at the top of a model reference hierarchy, can execute in SIL mode. However, if code coverage or code execution profiling is enabled, only one Model block can execute at a time in SIL mode.
PIL	• If their simulation modes are normal, accelerator, or PIL, all subordinate models also execute in PIL mode. Otherwise, an error occurs. See “Simulation Mode Override Behavior in Model Reference Hierarchy” (Embedded Coder). • Multiple Model blocks, starting at the top of a model reference hierarchy, can execute in PIL mode. However, if code coverage or code execution profiling is enabled, only one Model block can execute at a time in PIL mode.

Faster Simulations Using Simulink Cache Files

The first time that you simulate or perform an update diagram for a model that builds a Simulink accelerator target, a rapid accelerator target, or a referenced model simulation (SIM) target, the build process creates a Simulink cache file to store the build artifacts. Use the cache files to:

- Speed up first-time builds for later use by yourself or others.
- Avoid rebuild costs for a subset of referenced models without using variants that enable placeholder models.
- Speed up parallel simulations.
- Use the same cache file on different platforms (for example, UNIX and Windows), after creating the cache file on each platform.
- Avoid manual updates associated with setting the **Rebuild** configuration parameter to `Never`. That setting prevents building of SIM target and updating the cache files.

For details, see “Reuse Simulation Builds for Faster Simulations” on page 8-63.

Simulate Conditional Referenced Models

You can run a standalone simulation of a conditional referenced model. A standalone simulation is useful for unit testing because it provides consistent data across simulations in terms of data type, dimension, and sample time. Use normal, accelerator, or rapid accelerator mode to simulate a conditional model.

Triggered, Enabled, and Triggered and Enabled Models

Triggered, enabled, and triggered and enabled models require an external input to drive the Trigger or Enable blocks. In the **Signal Attributes** pane of the Trigger or Enable block dialog box, specify values for the signal data type, dimension, and sample time.

To run a standalone simulation, specify the inputs using the **Configuration Parameters > Data Import/Export > Input** parameter. For details about how to specify the input, see “Comparison of Signal Loading Techniques” on page 61-128. The following conditions apply when you use the “Input” parameter for trigger and enable block inputs:

- Use the last data input for the trigger or enable input. For a triggered and enabled model, use the last data input for the trigger input.
- If you do not provide any input values, the simulation uses zero as the default values.

You can log data to determine which signal caused the model to run. For the Trigger or Enable block, in the **Main** pane of the Block Parameters dialog box, select **Show output port**.

Function-Call Models

When you simulate a function-call model, it simulates as if a function call at the fastest rate for the system drives the function-call block. You can also configure the model to calculate output at specific times using a variable-step solver (see “Samples to Export for Variable-Step Solvers” on page 61-67).

Set Diagnostics and Debug Model Reference Hierarchies

You can enable or suppress warning messages about mismatches between a Model block and its referenced model by setting diagnostics on the **Diagnostics Pane: Model Referencing**.

Working with the Simulink Debugger in a parent model, you can set breakpoints at Model block boundaries. Setting breakpoints allows you to look at the input and output values of the Model block. However, you cannot set a breakpoint inside the model that the Model block references. See “Simulink Debugger” for more information.

Index Information Propagation

In two cases, Simulink does not propagate 0-based or 1-based indexing information to referenced-model root-level ports connected to blocks that:

- Accept indexes (such as the Assignment block)
- Produce indexes (such as the For Iterator block)

An example of a block that accepts indexes is the Assignment block. An example of a block that produces indexes is the For Iterator block.

The two cases result in a lack of propagation that can cause Simulink to fail to detect incompatible index connections. These two cases are:

- If a root-level input port of the referenced model connects to index inputs in the model that have different 0-based or 1-based indexing settings, Simulink does not set the 0-based or 1-based indexing property of the root-level Inport block.
- If a root-level output port of the referenced model connects to index outputs in the model that have different 0-based or 1-based indexing settings, Simulink does not set the 0-based or 1-based indexing property of the root-level Outport block.

Simulate Models with Multiple Referenced Model Instances

In this section...

Normal Mode Visibility

All instances of a normal mode referenced model are part of the simulation. However, Simulink displays only one instance in a model window. Normal mode visibility includes the display of Scope blocks and data port values.

You set normal mode visibility by selecting in the top model the **Diagram > Subsystem & Model Reference > Model Block Normal Mode Visibility**. The normal mode visibility setting determines the instance that is displayed. If you do not specify normal mode visibility for a specific instance of a referenced model, Simulink picks one instance of the referenced model to display.

After a simulation, if you try to open a referenced model from a Model block that does not have normal mode visibility, Simulink displays a warning.

To set up your model to control which instance of a referenced model in normal mode has visibility and to ensure proper simulation of the model, see "Specify the Instance Having Normal Mode Visibility" on page 8-47.

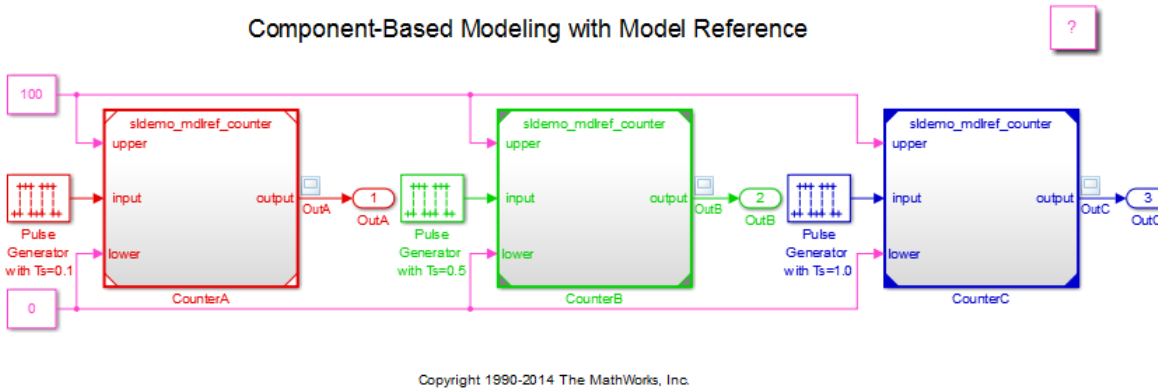
Example Models with Multiple Referenced Model Instances

The `sldemo_mdlref_basic` model and the "Visualizing Model Reference Architectures" featured example show the use of models containing multiple instances of a referenced model.

sldemo_mdlref_basic

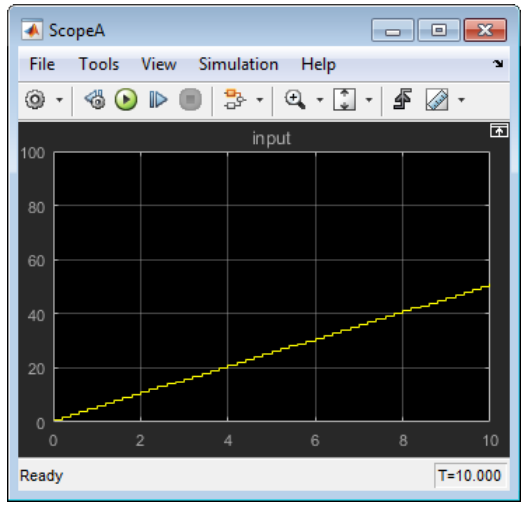
The `sldemo_mdlref_basic` model has three Model blocks (`CounterA`, `CounterB`, and `CounterC`) that each reference the `sldemo_mdlref_counter` model.

If you update the diagram, the `sldemo_mdlref_basic` displays different icons for each of the three Model blocks that reference `sldemo_mdlref_counter`.



Model Block	Icon Corners	Simulation Mode and Normal Mode Visibility Setting
`CounterA`	White	Normal mode, with normal mode visibility enabled
`CounterB`	Gray corners	Normal mode, with normal mode visibility disabled
`CounterC`	Black corner	Accelerator mode (normal mode visibility is not applicable)

Open and simulate `sldemo_mdlref_basic`. Double-click the CounterA model and open the ScopeA block.



That `ScopeA` block reflects the results of simulating the `CounterA` Model block, which has normal mode visibility enabled.

If you try to open `mdlref_counter` model by double-clicking the `CounterB` Model block, ScopeA in `mdlref_counter` still shows the results of the `CounterA` Model block because that block has normal mode visibility enabled.

Visualizing Model Reference Architectures

The featured example `Visualizing Model Reference Architectures` shows the use of the Model Dependency Viewer for a model (`sldemo_mdlref_depgraph`) that references multiple instances of a referenced model in normal mode. The example shows how to set up a model with multiple referenced instances in normal mode.

Configure Models with Multiple Referenced Model Instances

1. Set the **Configuration Parameters > Model Referencing > Total number of instances allowed per top model** parameter to `Multiple`.
2. Set each instance of the referenced model so that it uses normal mode. In the block parameters dialog box for the Model block that references the instance, set the **Simulation Mode** parameter to `Normal`. Ensure that all the ancestors in the hierarchy for that Model block are in normal mode.

The corners of icons for Model blocks that are in normal mode can be white (empty). The corners turn gray after you update the diagram or simulate the model.

3. If necessary, modify S-functions used by the model so that they work with multiple instances of referenced models in normal mode. For details, see "Supporting the Use of Multiple Instances of Referenced Models That Are in Normal Mode".

By default, Simulink assigns normal mode visibility to one of the instances. After you complete the configuration steps, you can specify a non-default instance to have normal mode visibility.

For more information about encapsulating a reusable algorithm in a referenced model, see "Specify Reusability of Referenced Models" on page 8-11.

Specify the Instance Having Normal Mode Visibility

Determine Which Instance Has Normal Mode Visibility

To determine which instance currently has normal mode visibility:

1. To apply the normal mode visibility setting, update the diagram and make no other changes to the model.
2. Examine the Model blocks that reference the model that you are interested in. The Model block that has white corners has normal mode visibility enabled, navigate through the model hierarchy.

When you are editing a model or during compilation, after updating the diagram, use the `ModelReferenceNormalModeVisibilityBlockPath` parameter. The result is a `Simulink.BlockPath` object that is the block path for the Model block that references the model that has normal mode visibility enabled. For example:

```
get_param('sldemo_mdlref_basic',...
 'ModelReferenceNormalModeVisibilityBlockPath')

ans =

   Simulink.BlockPath
   Package: Simulink

   Block Path:
      'sldemo_mdlref_basic/CounterA'
```

For a top model that you are simulating or that is in a compiled state, you can use the `CompiledModelBlockInstancesBlockPath` parameter. For example:

```
a = get_param('sldemo_mdlref_depgraph',...
 'CompiledModelBlockInstancesBlockPath')

a =

         sldemo_mdlref_F2C: [1x1 Simulink.BlockPath]
      sldemo_mdlref_heater: [1x1 Simulink.BlockPath]
sldemo_mdlref_outdoor_temp: [1x1 Simulink.BlockPath]
```

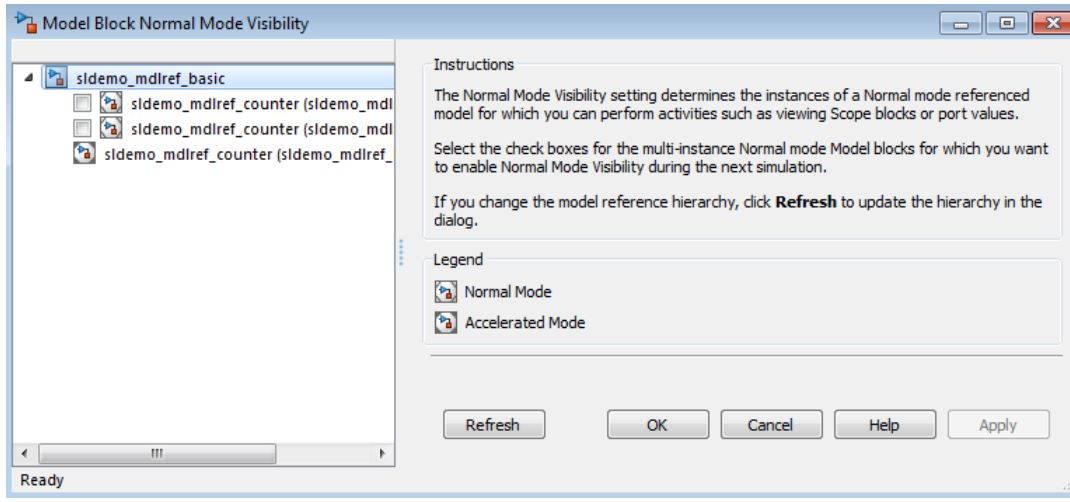
Enable Normal Mode Visibility for an Instance

Note You cannot change normal mode visibility during simulation.

To enable normal mode visibility for a different instance of the referenced model than the instance that currently has normal mode visibility:

1. Navigate to the top model.
2. In the Simulink Editor, select the **Diagram** > **Subsystem & Model Reference** > **Model Block Normal Mode Visibility**.

   The Model Block Normal Mode Visibility dialog box appears. For example, here is the dialog box for the `sldemo_mdlref_basic` model, with the hierarchy pane expanded:



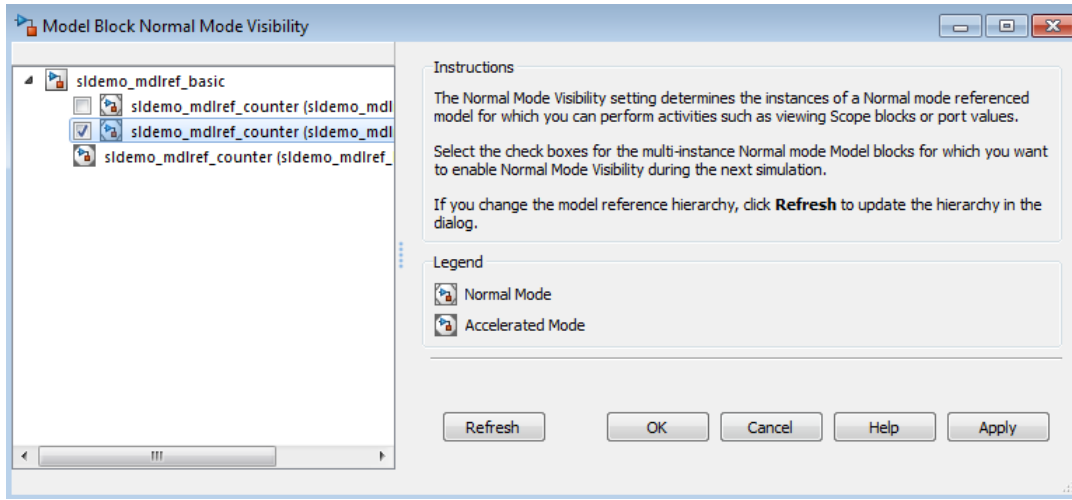
The model hierarchy pane shows a partial model hierarchy for the model from which you opened the dialog box. The hierarchy stops at the first Model block that is not in normal mode. The model hierarchy pane does not display Model blocks that reference protected models.

The dialog box shows the complete model block hierarchy for the top model. The normal mode instances of referenced models have check boxes.

Tip To have the model hierarchy pane of the Model Block Normal Mode Visibility dialog box reflect the current model hierarchy, click **Refresh**.

---

3 Select the instance of the model that you want to have normal mode visibility.



Simulink selects all ancestors of the model and clears all other instances of that model. When a model is cleared, Simulink clears all children of that model.

Tip To open a model from the Model Block Normal Mode Visibility dialog box, right-click the model in the model hierarchy pane and then click **Open**.

4 To apply the normal mode visibility setting, simulate the top model in the model reference hierarchy.

As an alternative to using the Model Block Normal Mode Visibility dialog box, at the MATLAB command line you can use the `ModelReferenceNormalModeVisibility` parameter. For input, you can specify one of these values:

- An array of `Simulink.BlockPath` objects. For example:

```
bp1 = Simulink.BlockPath({'mVisibility_top/Model',  ...
'mVisibility_mid_A/Model'});
bp2 = Simulink.BlockPath({'mVisibility_top/Model1', ...
'mVisibility_mid_B/Model1'});
 bps = [bp1, bp2];
 set_param(topMdl,'ModelBlockNormalModeVisibility',bps);
```

- A cell array of cell arrays of character vectors, with the character vectors being paths to individual blocks and models. This example produces the same effect as the object array example:

```
p1 = {'mVisibility_top/Model','mVisibility_mid_A/Model'};
p2 = {'mVisibility_top/Model1','mVisibility_mid_B/Model1'};
set_param(topMdl,'ModelBlockNormalModeVisibility',{p1, p2});
```

- An empty array, to specify the use of the Simulink default selection of the instance that has normal mode visibility. For example:

  ```
  set_param(topMdl, 'ModelBlockNormalModeVisibility', []);
  ```

  Using an empty array is equivalent to clearing all the check boxes in the Model Block Normal Mode Visibility dialog box.

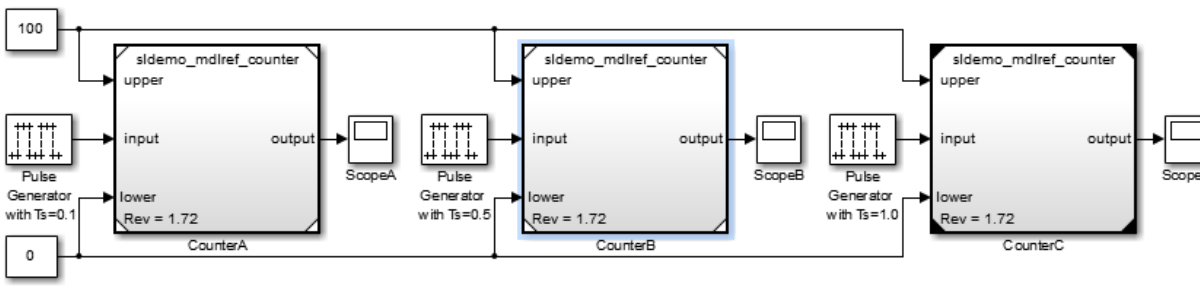
View Model Referencing Hierarchies

Simulink provides tools and functions that you can use to examine a model reference hierarchy:

- Content preview displays a representation of the contents of a referenced model, without opening the Model block. Content preview helps you to understand at a glance the kind of processing performed by the referenced model. For details, see "Preview Content of Hierarchical Items" on page 1-58.
- **Model Dependency Viewer** — Shows the structure of the hierarchy and lets you open constituent models. The Referenced Model Instances view displays Model blocks differently to indicate normal, accelerator, and PIL modes. See "Model Dependency Viewer" on page 12-56 for more information.
- **`view_mdlrefs` function** — Invokes the Model Dependency Viewer to display a graph of model reference dependencies.
- **`find_mdlrefs` function** — Finds all models directly or indirectly referenced by a given model.

Display Version Numbers

To display the version numbers of the models referenced by a model, for the parent model, choose **Display > Blocks > Block Version for Referenced Models**. Simulink displays the version numbers in the icons of the corresponding Model block instances.



The version number displayed on a Model block icon refers to the version of the model used to either:

- Create the block

- Refresh the block most recently changed

See “Manage Model Versions and Specify Model Properties” on page 4-62 and “Refresh Model Blocks” on page 8-99 for more information.

Model Reference Simulation Targets

In this section...

Simulation Targets

A simulation target, or SIM target, is a MEX-file that implements a referenced model that executes in accelerator mode. Simulink invokes the simulation target as needed during simulation to compute the behavior and outputs of the referenced model. Simulink uses the same simulation target for all accelerator mode instances of a given referenced model anywhere in a reference hierarchy.

If you have a Simulink Coder license, be careful not to confuse the simulation target of a referenced model with any of these other types of target:

- Hardware target — A platform for which Simulink Coder generates code
- System target — A file that tells Simulink Coder how to generate code for particular purpose
- Rapid Simulation target (RSim) — A system target file supplied with Simulink Coder
- Model reference target — A library module that contains Simulink Coder code for a referenced model

Simulink creates a simulation target only for a referenced model that has one or more accelerator mode instances in a reference hierarchy. A referenced model that executes only in normal mode always executes interpretively and does not use a simulation target. When one or more instances of a referenced model executes in normal mode, and one or more instances executes in accelerator mode:

- Simulink creates a simulation target for the accelerator mode instances.
- The normal mode instances do not use that simulation target.

Because accelerator mode requires code generation, it imposes some requirements and limitations that do not apply to normal mode. Aside from these constraints, you can

generally ignore simulation targets and their details when you execute a referenced model in accelerator mode. See “Simulation Limitations” on page 8-106 for details.

Build Simulation Targets

Simulink by default generates the needed target from the referenced model:

- If a simulation target does not exist at the beginning of a simulation
- When you perform an update diagram for a parent model

If the simulation target exists, then by default Simulink checks whether the referenced model has structural changes since the target was last generated. If so, Simulink regenerates the target to reflect changes in the model. For details about how Simulink detects whether to rebuild a model reference target, see the “Rebuild” parameter documentation.

You can change this default behavior to modify the rebuild criteria or specify that Simulink always or never rebuilds targets. See “Rebuild” for details.

To generate simulation targets interactively for accelerator mode referenced models, do one of these steps:

- Update the diagram on a model that directly or indirectly references the model that is in accelerator mode
- Execute the `slbuild` command with appropriate arguments at the MATLAB command line

While generating a simulation target, Simulink displays status messages at the MATLAB command line to enable you to monitor the target generation process. Target generation entails generating and compiling code and linking the compiled target code with compiled code from standard code libraries to create an executable file.

Reduce Change Checking Time

You can reduce the time that Simulink spends checking whether any or all simulation targets require rebuilding by setting configuration parameter values as follows:

- In all referenced models throughout the hierarchy, set the **Signal resolution** configuration parameter to `Explicit only` or `None`. (See “Signal resolution”.)

- To minimize change detection time, consider setting the **Rebuild options** configuration parameter to `If any changes in known dependencies detected` on the top model. See "Rebuild".

These parameter values exist in the configuration set of a referenced model, not in the individual Model block. Setting either value for any instance of a referenced model sets it for all instances of that model.

Simulation Target Output File Control

Simulink creates simulation targets in the `slprj` subfolder of the working folder. If `slprj` does not exist, Simulink creates it.

Note Simulink Coder code generation also uses the `slprj` folder. Subfolders in `slprj` provide separate places for simulation code, Simulink Coder code, and other files. For details, see "Manage Build Process Folders" (Simulink Coder).

By default, the files generated by Simulink diagram updates and model builds are placed in a build folder, the root of which is the current working folder (`pwd`). However, in some situations, you might want the generated files to go to a root folder outside the current working folder. For example:

- Keep generated files separate from the models and other source materials used to generate them.
- You want to reuse or share previously built simulation targets without having to set the current working folder back to a previous working folder.

You can separate generated simulation artifacts from generated production code.

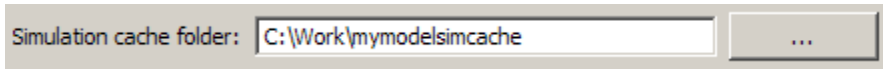
To allow you to control the output locations for the files generated by diagram updates and model builds, you can specify the simulation cache folder build folder separately. The simulation cache folder is the root folder in which to place artifacts used for simulation.

To specify the simulation cache folder, use *one* of these approaches:

- Use the `CacheFolder` MATLAB session parameter.
- In the **Simulink Preferences > General** dialog box, use the **Simulation cache folder** preference. This preference provides the initial defaults for the MATLAB session parameters.

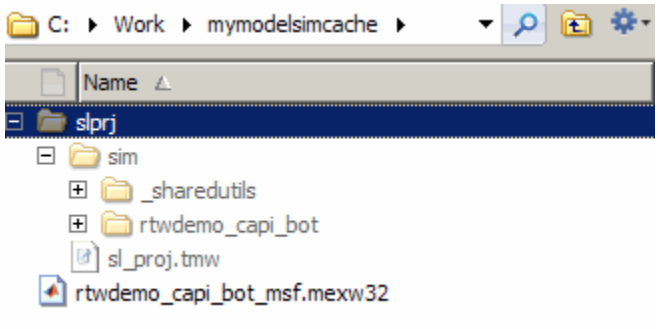
Control Output Location for Model Simulation Build Artifacts

To control the output location for files generated by Simulink diagram updates, in the **Simulink Preferences > General** dialog box, use the **Simulation cache folder** preference. To specify the root folder location for files generated by Simulink diagram updates, set the preference value by entering or browsing to a folder path, for example:



The folder path that you specify provides the initial default for the MATLAB session parameter `CacheFolder`. When you initiate a Simulink diagram update, generated files are placed in a build folder at the root location specified by `CacheFolder`, rather than in the current working folder (`pwd`).

For example, using a 32-bit Windows host platform, if you set the **Simulation cache folder** to `'C:\Work\mymodelsimcache'` and then simulate the model `rtwdemo_capi`, files are generated into the specified folder as follows:



As an alternative to using the Simulink preferences to set **Simulation cache folder**, you also can get and set the preference value from the command line using `get_param` and `set_param`. For example,

```
>> get_param(0, 'CacheFolder')

ans =

     ''

>> set_param(0, 'CacheFolder', fullfile('C:','Work','mymodelsimcache'))
>> get_param(0, 'CacheFolder')

ans =

C:\Work\mymodelsimcache
```

Also, you can choose to override the **Simulation cache folder** preference value for the current MATLAB session.

Override Build Folder Settings

The Simulink preferences **Simulation cache folder** and **Code generation folder** provide the initial defaults for the MATLAB session parameters `CacheFolder` and `CodeGenFolder`, which determine where files generated by Simulink diagram updates and model builds are placed. However, you can override these build folder settings during the current MATLAB session, using the `Simulink.fileGenControl` function. This function allows you to manipulate the MATLAB session parameters (for example, overriding or restoring the initial default values) directly. The values you set using `Simulink.fileGenControl` expire at the end of the current MATLAB session. For more information and detailed examples, see the `Simulink.fileGenControl` function reference page.

Reduce Update Time for Referenced Models

Parallel Building for Large Model Reference Hierarchies

In a parallel computing environment, you can increase the speed of diagram updates for models containing large model reference hierarchies by building referenced models that are configured in accelerator mode in parallel whenever conditions allow. For example, if you have Parallel Computing Toolbox software, updating of each referenced model can be distributed across the cores of a multicore host computer. Also, if you have MATLAB Distributed Computing Server™ software, updating of each referenced model can be distributed across remote workers in your MATLAB Distributed Computing Server configuration.

The performance gain realized by using parallel builds for updating referenced models depends on several factors, including:

- How many models can be built in parallel for a given model referencing hierarchy
- The size of the referenced models

- The parallel computing resources, such as number of local or remote workers available and the hardware attributes of the local and remote machines (amount of RAM, number of cores, and so on)

For configuration requirements that can apply to your parallel computing environment, see "Parallel Building Configuration Requirements" on page 8-59.

For a description of the general workflow for building referenced models in parallel whenever conditions allow, see "Update Models in a Parallel Computing Environment" on page 8-59.

Parallel Building Configuration Requirements

These requirements apply to using parallel builds for updating model reference hierarchies:

- For local pools, the host machine needs an appropriate amount of RAM available for supporting the number of local workers (MATLAB sessions) that you plan to use. For example, using `parpool(4)` to create a parallel pool with four workers results in five MATLAB sessions on your machine, each using approximately 120 MB of memory at startup.
- Remote MATLAB Distributed Computing Server workers participating in a parallel build must use a common platform and compiler.
- Set up a consistent MATLAB environment for each MATLAB worker session and the MATLAB client session. For example, use consistent shared base workspace variables, MATLAB path settings, and so forth. One approach is to use the `PreLoadFcn` callback of the top model. If you configure your model to load the top model with each MATLAB worker session, its preload function can be used for any MATLAB worker session setup.

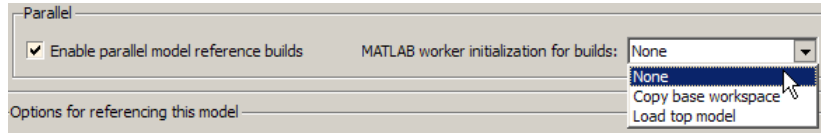
Update Models in a Parallel Computing Environment

To take advantage of parallel building for a model reference hierarchy:

1. Set up a pool of local and/or remote MATLAB workers in your parallel computing environment.
   a. Make sure that Parallel Computing Toolbox software is licensed and installed.
   b. To use remote workers, make sure that MATLAB Distributed Computing Server software is licensed and installed.

c Issue MATLAB commands to set up the worker pool, for example, `parpool(4)`.

2 From the top model of the model reference hierarchy, open the Configuration Parameters dialog box. Go to the **Model Referencing** pane and select the **Enable parallel model reference builds** option. This selection enables the parameter **MATLAB worker initialization for builds**.



For **MATLAB worker initialization for builds**, select one of the following values:

- `None` – The software performs no special worker initialization. Specify this value if the child models in the model reference hierarchy do not rely on anything in the base workspace beyond what they explicitly set up (for example, with a model load function).
- `Copy base workspace` – The software attempts to copy the base workspace to each worker. Specify this value if you use a setup script to prepare the base workspace for multiple models to use.
- `Load top model` – The software loads the top model on each worker. Specify this value if the top model in the model reference hierarchy handles all the base workspace setup (for example, with a model load function).

Note Set **Enable parallel model reference builds** only for the top model of the model reference hierarchy to which it applies.

3 Optionally, turn on verbose messages for simulation builds. If you select verbose builds, the build messages report the progress of each parallel build with the name of the model.

To turn on verbose messages for simulation target builds, go to the Configuration Parameters dialog box and select **Verbose accelerator builds**.

The **Verbose accelerator builds** option controls the verbosity of build messages both in the MATLAB Command Window and in parallel build log files.

4 Optionally, inspect the model reference hierarchy to determine, based on model dependencies, which models will build in parallel. For example, you can use the Model Dependency Viewer from the Simulink **Analysis > Model Dependencies** menu.

5 Update your model. Messages in the MATLAB command window record when each parallel or serial build starts and finishes.

If you need more information about a parallel build, for example, if a build fails, see "Locate Parallel Build Logs" on page 8-61.

Locate Parallel Build Logs

When you update a model for which referenced models are built in parallel, if verbose builds are turned on, messages in the MATLAB Command Window record when each parallel or serial build starts and finishes. For example,

```
### Initializing parallel workers for parallel model reference build.
### Parallel worker initialization complete.
### Starting parallel model reference SIM build for 'bot_model001'
### Starting parallel model reference SIM build for 'bot_model002'
### Starting parallel model reference SIM build for 'bot_model003'
### Starting parallel model reference SIM build for 'bot_model004'
### Finished parallel model reference SIM build for 'bot_model001'
### Finished parallel model reference SIM build for 'bot_model002'
### Finished parallel model reference SIM build for 'bot_model003'
### Finished parallel model reference SIM build for 'bot_model004'
```

To obtain more detailed information about a parallel build, you can examine the parallel build log. For each referenced model built in parallel, the build process generates a file named *model*`_buildlog.txt`, where *model* is the name of the referenced model. This file contains the full build log for that model.

If a parallel build completes, you can find the build log file in the build subfolder corresponding to the referenced model. For example, for a build of referenced model `bot_model004`, look for the build log file `bot_model004_buildlog.txt` in the referenced model subfolder *build_folder*`/slprj/sim/bot_model004`.

If a parallel builds fails, you can see output similar to the following:

```
### Initializing parallel workers for parallel model reference build.
### Parallel worker initialization complete.
### Starting parallel model reference SIM build for 'bot_model002'
### Starting parallel model reference SIM build for 'bot_model003'
### Finished parallel model reference SIM build for 'bot_model002'
### Finished parallel model reference SIM build for 'bot_model003'
### Starting parallel model reference SIM build for 'bot_model001'
### Starting parallel model reference SIM build for 'bot_model004'
### Finished parallel model reference SIM build for 'bot_model004'
### The following error occurred during the parallel model reference SIM build for
'bot_model001':

Error(s) encountered while building model "bot_model001"

### Cleaning up parallel workers.
```

If a parallel build fails, you can find the build log file in a referenced model subfolder under the build subfolder `/par_mdl_ref/`*`model`*. For example, for a failed parallel build of model `bot_model001`, look for the build log file `bot_model001_buildlog.txt` in the subfolder *`build_folder`*`/par_mdl_ref/bot_model001/slprj/sim/bot_model001`.

Reuse Simulation Builds for Faster Simulations

In this section...

The first time that you simulate or perform an update diagram for a model that builds a Simulink accelerator target, a rapid accelerator target, or a referenced model simulation (SIM) target, the build process creates a Simulink cache file to store the build artifacts. Simulink creates:

- A Simulink accelerator target for the top model
- A rapid accelerator target for the top model
- A SIM target for a referenced model that has one or more accelerator mode instances in a reference hierarchy

Use the cache files to:

- Speed up first-time build for later use by yourself or others.
- Speed up parallel simulations.
- Use the same cache file on different platforms (for example, UNIX and Windows), after creating the cache file on each platform.
- Avoid manual updates associated with setting the **Rebuild** configuration parameter to `Never`. That setting prevents building of SIM target and updating the cache files.

Examples of Using Simulink Cache Files

For team development of large models that use model referencing, Simulink cache files are useful for a sync and design workflow. For example, suppose this model development environment:

- A team of 20 people is working on a model hierarchy containing 100 models.
- All the referenced models simulate in accelerator mode.
- The team uses Linux for development.
- The team uses a source control system for their models.

The team workflow involves using Simulink cache files:

1. The team has a pool of parallel worker machines (Linux) that does an update diagram on the model hierarchy every night based on the latest version of the models in the source control system and Simulink cache files in a location available to all team members.
2. After the update diagram is complete, the updated models and Simulink cache files are committed into the repository
3. The next morning, a developer named Tom gets the latest version of all models and the Simulink cache files for the complete model hierarchy from the repository into his desktop.
4. Tom opens the top model of the hierarchy and clicks **Run**. During simulation, the necessary files are extracted from the cache files and then the simulation begins without any builds.
5. Tom makes changes to some models in the hierarchy and simulates, which rebuilds models as needed. During the update diagram, Simulink updates the cache files for those models as needed.
6. At the end of the day, Tom commits his changes to the repository by submitting the changed models.
7. At night, the latest version of the model hierarchy in the repository is built with Tom's changes.
8. The next day, another developer, Edna, gets the latest version of all models and the corresponding cache files into her work area.
9. Edna simulates the top model. The necessary artifacts are extracted from the cache files without a build.

Another example of using Simulink cache files is for parallel simulations.

Simulink Cache Files

Simulink cache files are container files that include the build artifacts for SIM targets and rapid accelerator targets. For a model reference hierarchy, there is a cache file for each referenced model that generates those targets. The cache file name is the name of the model plus the file extension `.slxc`.

The cache files are stored in the folder specified by the **Simulation cache folder** preference. You can change the default location, but it must be on the MATLAB path to

use the cache file with the model. To preserve a version of a cache file, use one of these approaches:

- Use a version control system such as Git.
- Manually move the cache file outside of the folder specified with the **Simulation cache folder** preference.
- Specify a different folder with the **Simulation cache folder** preference before doing a rebuild.

Simulink creates a cache file the first time you perform an update model or simulate a model that produces the targets. When you modify a model and perform an update diagram or simulate the model, Simulink determines whether a rebuild is needed, based on the **Rebuild** configuration parameter setting for the model. For a rebuild, Simulink updates the build artifacts on disk and updates the cache file.

Share Simulink Cache Files

If your referenced model is part of a large model developed by a team, sharing Simulink cache files with team members saves them the first-time build overhead when they use your model.

When your model is ready to share, consider including its cache files in a Simulink project. When you create a new project from a top model, the project includes associated cache files for the model and its referenced models.

- To include cache files in the share operation, use the **Simulink Project** tab **Share** button.
- To display cache files and highlight missing cache files, in the project tree, click the **Dependency Analysis** node.
- To identify out-of-date targets, use the **Simulink Project** tab **Share** button.

If you do not use a Simulink project, save the cache files in a location that is accessible to the people who are sharing the files. Alternatively, you can attach the cache files to an email.

If you send an out-of-date cache file to someone, when that person simulates the model, Simulink detects that it needs to perform a build.

Set Configuration Parameters for Model Referencing

In this section...

A referenced model uses a configuration set in the same way that any other model does, as described in “Manage a Configuration Set” on page 13-11. By default, every model in a hierarchy has its own configuration set. Each model uses its configuration set the same way that it would if the model executed independently.

Because each model can have its own configuration set, configuration parameter values can be different in different models. Furthermore, some parameter values are intrinsically incompatible with model referencing. The Simulink response to an inconsistent or unusable configuration parameter depends on the parameter:

- Where an inconsistency has no significance, or a trivial resolution without risk exists, Simulink ignores or resolves the inconsistency without posting a warning.
- Where a nontrivial and possibly acceptable solution exists, Simulink resolves the conflict silently, resolves it with a warning, or generates an error. See “Diagnostics That Are Ignored in Accelerator Mode” on page 8-70 for details.
- Where no acceptable resolution is possible, Simulink generates an error. Change some or all parameter values to eliminate the problem.

Manage Configuration Parameters by Using Configuration References

Manually eliminating all configuration parameter incompatibilities can be tedious when:

- A model reference hierarchy contains many referenced models that have incompatible parameter values
- A changed parameter value must propagate to many referenced models

You can control or eliminate such overhead by using configuration references to assign an externally stored configuration set to multiple models. See “Manage a Configuration Reference” on page 13-18 for details.

Configuration Requirements for All Referenced Model Simulation

Some configuration parameter options can cause problems if set:

- In certain ways, as indicated in the tables
- Differently in a referenced model than in a parent model

Where possible, Simulink resolves violations of these requirements automatically, but most cases require changes to the parameters in some or all models.

Dialog Box Pane	Option	Requirement
Solver	**Start time**	The start time of the top model and all referenced models must be the same, but need not be zero.
	Stop time	Simulink uses **Stop time** of the top model for simulation, overriding any differing **Stop time** in a referenced model.
	Type **Solver**	The **Type** and **Solver** of the top model apply throughout the hierarchy. See “Solver Settings” on page 8-69.
Data Import/Export	**Initial state**	Can be `on` for the top model, but must be `off` for a referenced model.
Optimization	**Default parameter behavior**	If the parent model has this option set to `Inlined`, then the referenced model cannot be set to `Tunable`.
	Application lifespan (days)	For code generation, must be the same for parent and referenced models. For simulation, the setting can be different for the parent and referenced models.

Dialog Box Pane	Option	Requirement
Model Referencing	**Total number of instances allowed per top model**	Must not be `Zero` in a referenced model. Specifying `One` rather than `Multiple` is preferable or required sometimes. See "Number of Model Instances Setting" on page 8-69.

Solver Settings

Model referencing works with both fixed-step and variable-step solvers. All models in a model reference hierarchy use the same solver, which is always the solver specified by the top model. An error occurs if the solver type specified by the top model is incompatible with the solver type specified by any referenced model.

Top Model Solver Type	referenced model Solver Type	Compatibility
Fixed step	Fixed step	Allowed
Variable step	Variable Step	Allowed
Variable step	Fixed step	Allowed unless the referenced model is multirate and specifies both a discrete sample time and a continuous sample time
Fixed Step	Variable step	Error

If an incompatibility exists between the top model solver and any referenced model solver, one or both models must change to use compatible solvers. For information about solvers, see "Solvers" on page 3-21 and "About Solvers" on page 24-7.

Number of Model Instances Setting

A referenced model must specify that it is available to be referenced, and whether it can be referenced at most once or can have multiple instances. The **Configuration Parameters > Model Referencing > Total number of instances allowed per top model** parameter provides this specification. See "Total number of instances allowed per top model" for more information. The possible values for this parameter are:

- `Zero` — A model cannot reference this model. An error occurs if a reference to the model occurs in another model.
- `One` — A model reference hierarchy can reference the model at most once. An error occurs if more than one instance of the model exists. This value is sometimes preferable or required.
- `Multiple` — A model hierarchy can reference the model more than once, if it contains no constructs that preclude multiple reference. An error occurs if the model cannot be multiply referenced, even if only one reference exists.

Setting **Total number of instances allowed per top model** to `Multiple` for a model that is referenced only once can reduce execution efficiency slightly. However, this setting does not affect data values that result from simulation or from executing code Simulink Coder generates. Specifying `Multiple` when only one model instance exists avoids having to change or rebuild the model when reusing the model:

- In the same hierarchy
- Multiple times in a different hierarchy

Some model properties and constructs require setting **Total number of instances allowed per top model** to `One`. For details, see "Specify Reusability of Referenced Models" on page 8-11.

Diagnostics That Are Ignored in Accelerator Mode

For models referenced in accelerator mode, Simulink ignores the values of these configuration parameter settings if you set them to a value other than `None`:

- **Array bounds exceeded** (`ArrayBoundsChecking`)
- **Inf or NaN block output** (`SignalInfNanChecking`)
- **Simulation range checking** (`SignalRangeChecking`)
- **Division by singular matrix** (`CheckMatrixSingularityMsg`)
- **Wrap on overflow** (`IntegerOverflowMsg`)

Also, for models referenced in accelerator mode, Simulink ignores these **Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block** parameters if you set them to a value other than `Disable all`. For details, see "Data Store Diagnostics" on page 62-3.

- **Detect read before write** (`ReadBeforeWriteMsg`)
- **Detect write after read** (`WriteAfterReadMsg`)
- **Detect write after write** (`WriteAfterWriteMsg`)

You can use the Model Advisor to identify models referenced in accelerator mode for which Simulink ignores the configuration parameters listed above.

1. In the Simulink Editor, select **Analysis > Model Advisor**.
2. Select **By Task**.
3. Run the **Check diagnostic settings ignored during accelerated model reference simulation** check.

To see the results of running the identified diagnostics with settings to produce warnings or errors, simulate the model in normal mode. Inspect the diagnostic warnings and then simulate in accelerator mode.

Accelerated Simulation and Code Generation Changes Settings

Note Configuration parameters on the **Code Generation** pane of the Configuration Parameters dialog box do not affect simulation in either normal or accelerator mode. **Code Generation** parameters affect only code generation by Simulink Coder itself. Accelerated mode simulation requires code generation to create a simulation target. Simulink uses default values for all **Code Generation** parameters when generating the target, and restores the original parameter values after code generation is complete.

During model referencing simulation in accelerator and rapid accelerator mode, Simulink temporarily sets several **Configuration Parameters > Diagnostics > Data Validity** parameter settings to `None`, if they are set to `Warning` or `Error`. You can use the Model Advisor to check for parameters that change. For details, see “Diagnostic Configuration Parameters Ignored in Accelerator Mode” on page 8-39.

If the **Configuration Parameters > Code Generation > Symbols** parameters hold identifier information about the name of a referenced model and do not use a `$R` token, code generation prepends the `$R` token to the name of the model. You can use the Model Advisor to check for changed model names. See .

Parameterize Instances of a Reusable Referenced Model

When you use model referencing to break a large system into components, each component is a separate model. You can reuse a component by referring to it with multiple Model blocks. Each Model block is an instance of the component. You can then configure a block parameter (such as the **Gain** parameter of a Gain block) to use either the same value or a different value for each instance of the component. To use different values, create and use a model argument to set the value of the block parameter.

For information about setting block parameter values in reusable components, see "Parameter Interfaces for Reusable Components" on page 36-20.

Specify Different Value for Each Instance of Reusable Model

For a block parameter in a reusable referenced model, to specify a different value for each instance of the model:

1. Create a MATLAB variable or `Simulink.Parameter` object in the model workspace of the referenced model.

   Use a MATLAB variable for ease of maintenance. Use a `Simulink.Parameter` object for greater control over the minimum and maximum value, the data type, and other properties of the model argument.
2. Set the block parameter value in the model by using the variable or parameter object. Optionally, use the same variable or object to set other block parameter values.
3. Configure the variable or object as a model argument. On the Model Data Editor **Parameters** tab, select the check box in the **Argument** column. Alternatively, in the Model Explorer, inspect the variable or object in the model workspace and in the **Contents** pane, select the check box in the **Argument** column.

   When you simulate this model directly, the block parameters use the value that the variable or object stores in the model workspace. Otherwise, including when you simulate a parent model, the value in the model workspace has no significance.
4. In each Model block that refers to the reusable model, specify an instance-specific value for the model argument. To set the value, you can use the common techniques for setting block parameter values (see "Set Block Parameter Values" on page 36-2).

Combine Multiple Arguments into a Structure

When you configure a model to use multiple model arguments, consider using a structure instead of separate variables in the model workspace. This technique reduces the effort of maintenance when you want to add, rename, or delete arguments. Instead of manually synchronizing the arguments in the model workspace with the argument values in Model blocks, you modify structures by using the Variable Editor or the command prompt.

If you have Simulink Coder, this technique can also reduce the ROM consumed by the formal parameters of the referenced model functions, such as the output (`step`) function.

For basic information about creating and using structures to set block parameter values, see “Organize Related Block Parameter Definitions in Structures” on page 36-22.

Parameterize a Referenced Model

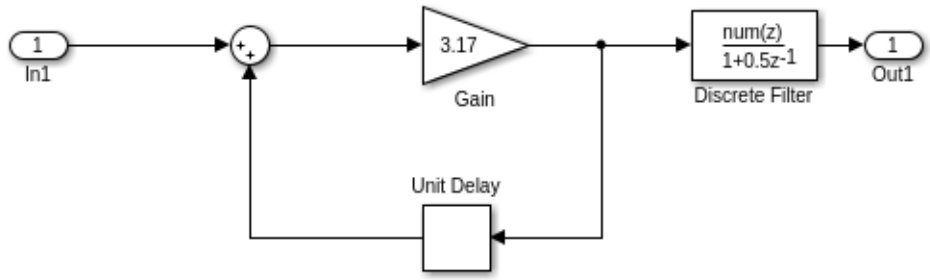
This example shows how to configure multiple instances of a referenced model to use different values for the same block parameter.

For an example that involves code generation, see “Specify Instance-Specific Parameter Values for Reusable Referenced Model” (Simulink Coder).

Configure Referenced Model to Use Model Arguments

Create the model `ex_model_arg_ref`. This model represents a reusable algorithm.

```
open_system('ex_model_arg_ref')
```



In the model, select **View** > **Model Data**.

In the Model Data Editor, select the **Parameters** tab.

In the model, select the Gain block.

In the Model Data Editor, use the **Value** column to set the value of the **Gain** parameter to `gainArg`.

Next to `gainArg`, click the action button ⋮ and select **Create**.

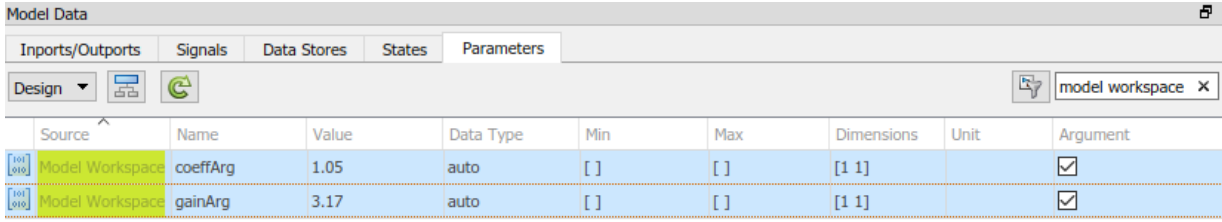
In the Create New Data dialog box, set **Value** to `Simulink.Parameter` and **Location** to `Model Workspace`. Click **Create**.

In the property dialog box, set **Value** to a number, for example, `3.17`. Click **OK**.

Use the Model Data Editor to set the **Numerator** parameter of the Discrete Filter block by using a `Simulink.Parameter` object named `coeffArg` whose value is `1.05`. As with `gainArg`, store the parameter object in the model workspace.

In the Model Data Editor, click the **Show/refresh additional information** button.

Use the **Filter contents** box to find each parameter object (`gainArg` and `coeffArg`). For each object, select the check box in the **Argument** column.



Save the `ex_model_arg_ref` model.

Alternatively, at the command prompt, you can use these commands to configure the blocks and the parameter objects:

```
set_param('ex_model_arg_ref/Gain','Gain','gainArg')
modelWorkspace = get_param('ex_model_arg_ref','ModelWorkspace');
assignin(modelWorkspace,'gainArg',Simulink.Parameter(3.17));

set_param('ex_model_arg_ref/Discrete Filter','Numerator','coeffArg')
assignin(modelWorkspace,'coeffArg',Simulink.Parameter(1.05));

set_param('ex_model_arg_ref','ParameterArgumentNames','coeffArg,gainArg')

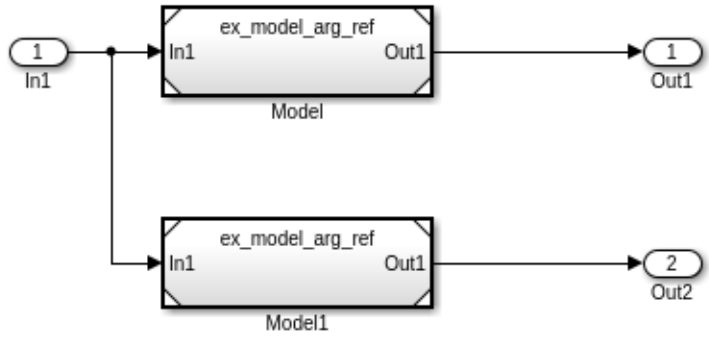
save_system('ex_model_arg_ref')
```

When you simulate the `ex_model_arg_ref` model by itself, the parameter objects in the model workspace use the values that you specified in the `Value` property. The block parameters also use these values.

Set Model Argument Values in Parent Model

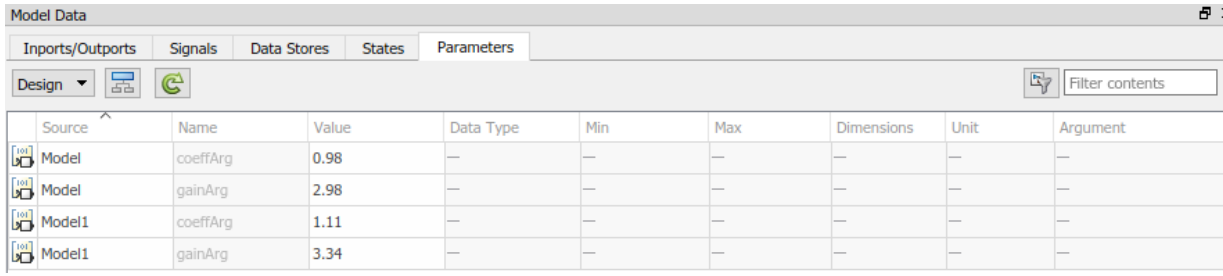
Create the model `ex_model_arg`. This model represents a system model that uses multiple instances of the reusable algorithm.

```
open_system('ex_model_arg')
```



In the model, open the Model Data Editor **Parameters** tab (**View** > **Model Data**). The Model Data Editor shows four rows that correspond to the model arguments, `coeffArg` and `gainArg`, that you can specify for the two Model blocks.

Use the Model Data Editor to set values for the model arguments. For example, use the values in the figure.



Alternatively, at the command prompt, you can use these commands to set the values:

```
set_param('ex_model_arg/Model','ParameterArgumentValues',...
    struct('coeffArg','0.98','gainArg','2.98'))

set_param('ex_model_arg/Model1','ParameterArgumentValues',...
    struct('coeffArg','1.11','gainArg','3.34'))
```

When you simulate the `ex_model_arg` model, each instance of `ex_model_arg_ref` (each Model block) passes the argument values that you specified to the parameter objects in the `ex_model_arg_ref` model workspace. For example, in the upper instance of `ex_model_arg_ref`, the parameter object `gainArg` uses the value `2.98`.

Group Multiple Model Arguments into Single Structure

At the command prompt, create a structure. Add one field for each of the parameter objects in the `ex_model_arg_ref` workspace.

```
structForInst1.gain = 3.17;
structForInst1.coeff = 1.05;
```

Store the structure in a `Simulink.Parameter` object.

```
structForInst1 = Simulink.Parameter(structForInst1);
```

Open the Model Explorer. In the referenced model, `ex_model_arg_ref`, select **View** > **Model Explorer** > **Model Explorer**.

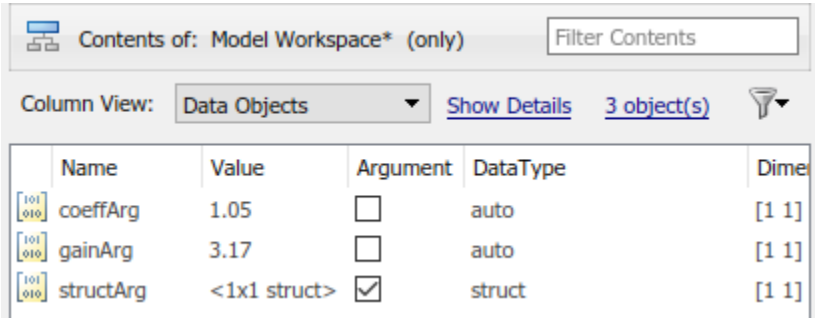
Use the Model Explorer to copy the parameter object from the base workspace into the `ex_model_arg_ref` model workspace.

In the model workspace, rename `structForInst1` as `structArg`.

```
assignin(modelWorkspace,'structArg',copy(structForInst1));
```

In the **Contents** pane, configure `structArg` as the only model argument.

```
set_param('ex_model_arg_ref','ParameterArgumentNames','structArg')
```



In the `ex_model_arg_ref` model, inspect the Model Data Editor **Parameters** tab.

Use the Model Data Editor to set the value of the **Gain** parameter to `structArg.gain` and the value of the **Numerator** parameter to `structArg.coeff`. Save the model.

```
set_param('ex_model_arg_ref/Gain','Gain','structArg.gain')
set_param('ex_model_arg_ref/Discrete Filter',...
    'Numerator','structArg.coeff')

save_system('ex_model_arg_ref')
```

At the command prompt, copy the existing structure as `structForInst2`.

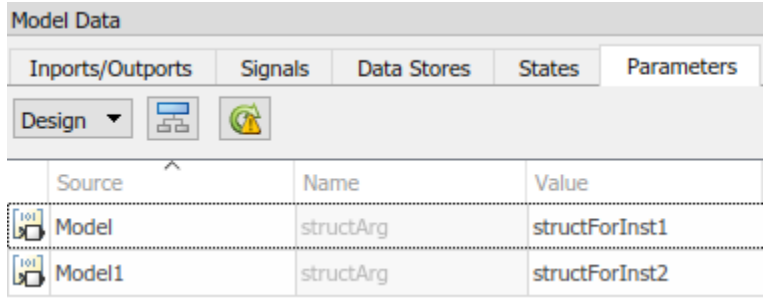
```
structForInst2 = copy(structForInst1);
```

Set the field values in the two structures by using the same numbers that you used to set the model argument values in the Model blocks.

```
structForInst1.Value.gain = 2.98;
structForInst1.Value.coeff = 0.98;

structForInst2.Value.gain = 3.34;
structForInst2.Value.coeff = 1.11;
```

In the top model, `ex_model_arg`, use the Model Data Editor to set the argument values according to the figure.



```
set_param('ex_model_arg/Model','ParameterArgumentValues',...
    struct('structArg','structForInst1'))
set_param('ex_model_arg/Model1','ParameterArgumentValues',...
    struct('structArg','structForInst2'))
```

With the structures, the mathematical functionality of the models is the same.

Use Bus Object as Data Type of Structures

Optionally, use a `Simulink.Bus` object as the data type of the structures. The object makes sure that the characteristics of the instance-specific structures, such as the names and order of fields, match the characteristics of the structure in the model workspace.

At the command prompt, use the function `Simulink.Bus.createObject` to create a `Simulink.Bus` object. The hierarchy of elements in the object matches the hierarchy of the structure fields. The default name of the object is `slBus1`.

```
Simulink.Bus.createObject(structForInst1.Value);
```

Rename the bus object as `myParamStructType` by copying it.

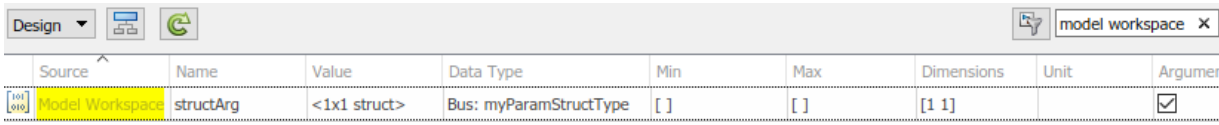
```
myParamStructType = copy(slBus1);
```

In the Model Data Editor for `ex_model_arg`, click the **Show/refresh additional information** button. The Model Data Editor now contains rows that correspond to the parameter objects in the base workspace, `structForInst1` and `structForInst2`.

Use the **Data Type** column to set the data type of `structForInst1` and `structForInst2` to `Bus: myParamStructType`.

```
structForInst1.DataType = 'Bus: myParamStructType';
structForInst2.DataType = 'Bus: myParamStructType';
```

In the Model Data Editor for `ex_model_arg_ref`, use the Model Data Editor to set the data type of `structArg` to `Bus: myParamStructType`.



```
temp = getVariable(modelWorkspace,'structArg');
temp = copy(temp);
temp.DataType = 'Bus: myParamStructType';
assignin(modelWorkspace,'structArg',copy(temp));
```

Rename Model Argument

To rename a model argument in the context of the referenced model:

- Find all Model blocks that refer to the model and save the argument values that each block specifies. Use the `get_param` function to query the `ParameterArgumentValues` parameter of each block, which is a structure with a field that corresponds to the argument that you want to rename.

  You must save the argument values because the renaming operation discards the values in the Model blocks.
- In the Model Explorer, right-click the variable or object in the model workspace of the referenced model and select **Rename All**. The renaming operation changes the name of the variable or object and changes references to it throughout the model. For more information, see “Create, Edit, and Manage Workspace Variables” on page 59-105.
- Reapply the argument values to the Model blocks by using the new name of the argument. See “Programmatically Change Specific Argument Value in a Model Block” on page 8-79.

Programmatically Change Specific Argument Value in a Model Block

To programmatically set argument values in a Model block, you set the value of the programmatic block parameter `ParameterArgumentValues` by using a structure. To modify an argument value or values that you already set, consider setting `ParameterArgumentValues` by using a partial structure, which has fields that correspond only to the arguments whose values you want to set.

In the example “Parameterize a Referenced Model” on page 8-73, for the model `ex_model_arg_ref`, you define two model arguments named `coeffArg` and `gainArg`. In a Model block that refers to `ex_model_arg_ref`, you set values for both arguments by using `ParameterArgumentValues`. Later, to change the value of `coeffArg` from `0.98` to `1.15` for that Model block, you can use a partial structure that targets only `coeffArg`:

```
set_param('ex_model_arg/Model','ParameterArgumentValues',struct('coeffArg','1.15'))
```

The other argument, `gainArg`, retains its value.

Customize User Interface for Reusable Component

When you design a reusable referenced model for use by other members of a team, you can apply a mask to the entire referenced model. You can then customize the way that your users interact with Model blocks, including setting model argument values.

Using this technique also makes it easier to programmatically specify argument values. If you create and use a mask parameter named `gainMask`, to programmatically set the argument value to `0.98` for an instance of the model (Model block) named `myModelBlock`, your users can use this command at the command prompt:

```
set_param('myModelBlock','gainMask','0.98')
```

If you do not mask the model, to set the argument value, your users must locate the value in the Model Data Editor or in the table of argument values in the Model block dialog box.

For information about masking models, see “Introduction to Model Mask” on page 38-64.

Specify Argument Values for a Model Block That Contains Model Variants

When you refer to a model as a variant in a Model block (by selecting **Enable variants** in the block), instead of using a table, specify argument values by using the technique described in “Model Arguments for Model Blocks That Contain Model Variants” on page 8-85.

Configure Instance-Specific Data for Lookup Tables

When you use `Simulink.LookupTable` objects to store and configure lookup table data for ASAP2 or AUTOSAR code generation (for example, STD_AXIS or CURVE), you can configure the objects as model arguments. You can then specify unique table data and breakpoint data for each instance of a component.

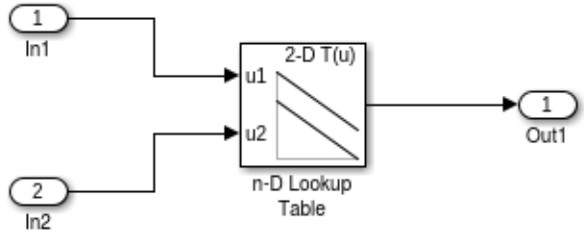
1. In the referenced model workspace, create `Simulink.LookupTable` objects. In lookup table blocks that are in the model, use the objects to set the table and breakpoint data.
2. Configure the objects as model arguments by using the **Argument** check box in the Model Explorer.
3. Create `Simulink.LookupTable` objects to store the instance-specific data. For example, if you configure a single `Simulink.LookupTable` object in the referenced model workspace as a model argument, to store instance-specific data for two instances of the referenced model (Model blocks in the parent model), create two `Simulink.LookupTable` objects in the base workspace or a data dictionary.
4. Configure all of the `Simulink.LookupTable` objects to use the same structure type name. In the property dialog box, under **Struct Type definition**, set **Name** to the same value.
5. Use the instance-specific objects to set argument values in Model blocks. For example, in each Model block, use one of the instance-specific `Simulink.LookupTable` objects from the base workspace.

You cannot use `Simulink.Breakpoint` objects or `Simulink.LookupTable` objects that refer to `Simulink.Breakpoint` objects as model arguments.

Create Example Models

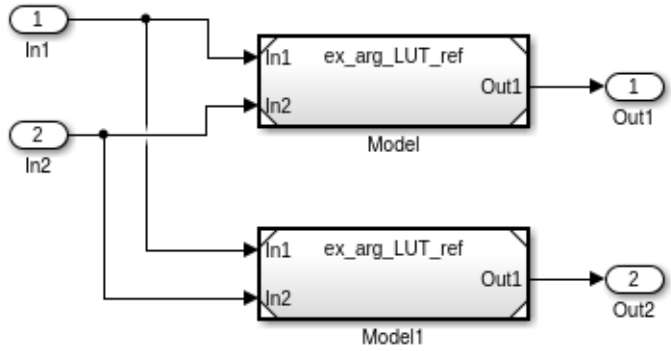
Create the example model `ex_arg_LUT_ref`, which represents a reusable algorithm.

```
open_system('ex_arg_LUT_ref')
```



Create the example model `ex_arg_LUT`, which uses the reusable algorithm twice.

```
open_system('ex_arg_LUT')
```



Configure Model Arguments in Referenced Model

Use the Model Explorer to create a `Simulink.LookupTable` object in the referenced model workspace (`ex_arg_LUT_ref`). Name the object `LUT_arg`.

In the Dialog pane (the right pane) of the Model Explorer, set **Number of table dimensions** to `2`. Under **Table** and **Breakpoints**, specify values for the table and breakpoint data. When you simulate or generate code directly from `ex_arg_LUT_ref`, the model uses these values.

Under **Struct Type definition**, set **Name** to `LUT_arg_Type`.

Click **Apply**.

In the **Contents** pane, for `LUT_arg`, select the check box in the **Argument** column.

In the referenced model, in the n-D Lookup Table block, set **Data specification** to `Lookup table object`. Set **Name** to `LUT_arg`.

Save the referenced model.

Alternatively, at the command prompt, you can use these commands to create and configure the object.

```
temp = Simulink.LookupTable;
temp.Table.Value = [3 4; 1 2];
temp.Breakpoints(1).Value = [1 2];
temp.Breakpoints(2).Value = [3 4];
temp.StructTypeInfo.Name = 'LUT_arg_Type';
mdlwks = get_param('ex_arg_LUT_ref','ModelWorkspace');
assignin(mdlwks,'LUT_arg',copy(temp))
set_param('ex_arg_LUT_ref','ParameterArgumentNames','LUT_arg')
set_param('ex_arg_LUT_ref/n-D Lookup Table',...
    'DataSpecification','Lookup table object','LookupTableObject','LUT_arg')
save_system('ex_arg_LUT_ref')
```

Create Instance-Specific Argument Values

At the command prompt, create two `Simulink.LookupTable` objects in the base workspace.

```
LUTForInst1 = Simulink.LookupTable;
LUTForInst2 = Simulink.LookupTable;
```

Specify breakpoint and table data for each object.

```
LUTForInst1.Table.Value = [8 7; 6 5];
LUTForInst1.Breakpoints(1).Value = [5 6];
LUTForInst1.Breakpoints(2).Value = [3 4];

LUTForInst2.Table.Value = [9 8; 7 7];
LUTForInst2.Breakpoints(1).Value = [3 4];
LUTForInst2.Breakpoints(2).Value = [5 6];
```

Specify a structure type name. Match this name with the name specified by the object in the referenced model workspace.

```
LUTForInst1.StructTypeInfo.Name = 'LUT_arg_Type';
LUTForInst2.StructTypeInfo.Name = 'LUT_arg_Type';
```

In the `ex_arg_LUT` model, in the top Model block, on the **Arguments** tab, set the value of **LUT_arg** to `LUTForInst1`.

In the bottom Model block, set **LUT_arg** to `LUTForInst2`.

Alternatively, at the command prompt, you can use these commands to configure the Model blocks.

```
set_param('ex_arg_LUT/Model','ParameterArgumentValues',...
    struct('LUT_arg','LUTForInst1'))
set_param('ex_arg_LUT/Model1','ParameterArgumentValues',...
    struct('LUT_arg','LUTForInst2'))
```

Each instance of `ex_arg_LUT_ref` uses the table and breakpoint data stored in one of the `Simulink.LookupTable` objects in the base workspace.

Model Arguments for Model Blocks That Contain Model Variants

To parameterize instances (Model blocks) of the same model so that each instance can behave differently, you use model arguments. Without model arguments, a block parameter or variable in the referenced model has the same value in every instance of the model.

When you use a Model block that contains model variants (by selecting **Enable variants** in the block), you specify argument values by using a different technique than for standard Model blocks. You specify a comma-separated list of argument values instead of specifying the values in a table.

For basic information about model arguments, see "Parameterize Instances of a Reusable Referenced Model" on page 8-72.

Note For new models, use model variants only if you need to use variants that are conditionally executed models (models with control ports). Model variants are supported for backward compatibility. However, support for model variants will be removed in a future release.

For more information, see Model.

Configure Model Arguments in Referenced Model

No matter how you use Model blocks to refer to a model, you define model arguments by using the same technique. Later, the technique you use to specify values for the arguments differs depending on how you use Model blocks.

1. Open the referenced model for which you want to define model arguments.
2. Open the Model Explorer. In the Simulink Editor, select **View** > **Model Explorer** > **Model Explorer**.
3. In the Model Explorer **Model Hierarchy** pane, select the **Model Workspace** node for the model.
4. Add variables or `Simulink.Parameter` objects to the model workspace. Optionally, rename the variables or objects. Each variable or object represents one model argument.

   For example, from the **Add** menu, select **MATLAB Variable**.

5 For the new variables or objects, select the check box in the **Argument** column.

Now, you can use the variables or objects to set block parameter values in the referenced model.

Assign Model Argument Values

If a model defines model arguments, assign values to those arguments in each Model block that references the model. Failing to assign a value to a model argument causes an error. The value of the model argument does *not* default to the value of the corresponding MATLAB variable in the model workspace. That value is available only to a standalone or top model.

1 In the parent model, open the block parameters dialog box of the Model block that contains model variants. Under **Variant choices**, select the target referenced model.

Under **Model parameters for chosen variant in table**, the **Model arguments** field displays the same MATLAB variables that you configured as model arguments in the referenced model. The Model block field **Model arguments** is not editable. It indicates the model arguments that you need to assign values to, and the order of the arguments.

2 In the **Model argument values** field, enter a comma-delimited list of values for the model arguments that appear in the **Model arguments** field. Simulink assigns the values to arguments in positional order, so they must appear in the same order as the corresponding arguments.

You can enter literal values, variable names, MATLAB expressions, or `Simulink.Parameter` objects. Any symbols used resolve to values as described in “Symbol Resolution Process” on page 59-136. All values must be numeric (including objects with numeric values).

The value for each argument must have the same dimensions and complexity as the MATLAB variable that defines the model argument in the model workspace. The data types need not match. If necessary, the Simulink software casts a model argument value to the data type of the corresponding variable.

3 Click **OK** or **Apply** to confirm the values for the Model block.

When the model executes in the context of that Model block, the model arguments have the values specified in the **Model argument values** field of the Model block.

Use Masked Blocks in Referenced Models

You can use masked blocks in a referenced model (see “Block Masks”). Also, you can mask a referenced model (see “Create and Reference a Masked Model” on page 38-65).

Block Mask Limitations in Referenced Models

- Mask callbacks cannot add Model blocks. Also, mask callbacks cannot change the Model block name or simulation mode. These invalid callbacks generate an error.
- If a mask specifies the name of the model that a Model block references, the mask must provide the name of the referenced model directly. You cannot use a workspace variable to provide the name.
- The mask workspace of a Model block is not available to the model that the mask block references. Any variable that the referenced model uses must resolve to either of these workspaces:
  - A workspace that the referenced model defines
  - The MATLAB base workspace
- To use a masked subsystem in a referenced model that uses model arguments, do not create in the mask workspace a variable that derives its value from a mask parameter. Instead, use blocks under the masked subsystem to perform the calculations for the mask workspace variable.

Create and Reference Conditional Referenced Models

In this section...

Conditional Referenced Models

You can set up referenced models so that they execute conditionally, similar to conditional subsystems. For information about conditional subsystems, see “Conditional Subsystems” on page 10-3.

You can use these conditionally executed referenced models.

Conditional Referenced Model	Description
Enabled	Use an Enable block to insert an enable port in a model. Add an enable port to a model if you want a referenced model to execute at each simulation step for which the control signal has a positive value. To see an example of an enabled *subsystem*, see `enablesub`. A corresponding enabled referenced model uses the same blocks as are in the enabled subsystem.
Triggered	Use a Trigger block to insert a trigger port in a model. To use an external signal to trigger the execution of a model, add a trigger port to the model. You can add a trigger port to a root-level model or to a subsystem. To view a model that illustrates how you can use trigger ports in referenced models, see the Introduction to Managing Data with Model Reference example. In that example, see the “Top Model: Scheduling Calls to the Referenced Model” section.

Conditional Referenced Model	Description
Triggered and Enabled	If the enable control signal has a positive value at the time step for which a trigger event occurs, a triggered and enabled model executes once.
Function-Call	Simulink allows certain blocks to control execution of a referenced model during a time step, using a function-call signal. Examples of such blocks are a Function-Call Generator or an appropriately configured custom S-function. See "Using Function-Call Subsystems" on page 10-29 for more information. For an example of a function-call model, see the `sldemo_mdlref_fcncall` model.

Each kind of conditionally executed model has some model creating requirements. For details, see "Requirements for Conditional Models" on page 8-92.

Create Conditional Models

1 At the root level of the referenced model, insert one of the following blocks:

Type of Model	Blocks to Insert
Enabled	Enable
Triggered	Trigger
Triggered and Enabled	Trigger and Enable
Function-Call	Trigger

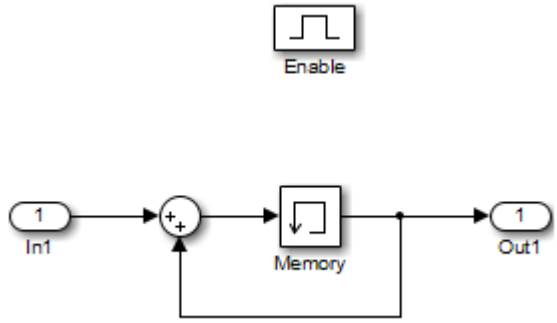
For an enabled model, go on to Step 3.

2 For the Trigger block, set the **Trigger type** parameter, based on the kind of model:

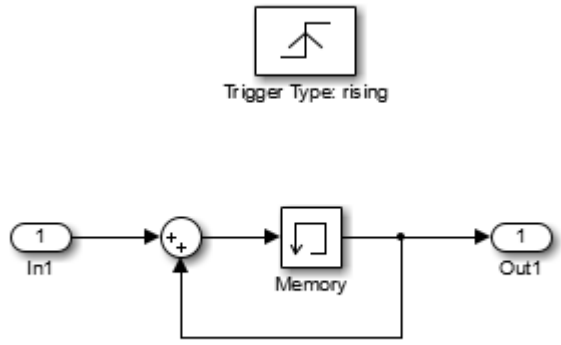
Type of Model	Trigger Type Parameter Setting
Triggered Triggered and enabled	One of the following: • `rising` • `falling` • `either`
Function-Call	`function-call`

3 Create and connect other blocks to implement the model.

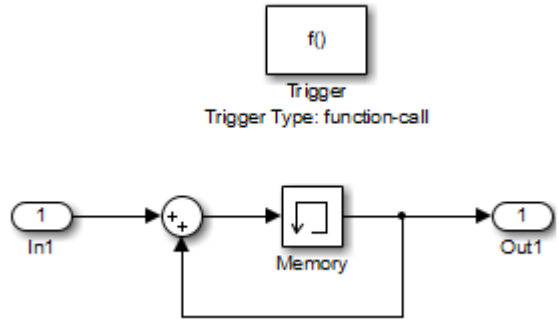
Enabled model example:



Triggered model example:



Function-call model example:



4 Ensure that the model satisfies the requirements for a conditional model. See the appropriate section:

- “Enabled Model Requirements” on page 8-92
- “Triggered Model Requirements” on page 8-92
- “Function-Call Model Requirements” on page 8-93

Requirements for Conditional Models

Conditional models must meet the requirements for:

- Conditional subsystems (see “Conditionally Executed Subsystems”)
- Referenced models (see “Create a Referenced Model” on page 8-9)

In addition, conditional models must meet the requirements specific to each type of conditional model.

Enabled Model Requirements

- Multi-rate enabled models cannot use multi-tasking solvers. Use single-tasking.
- For models with enable ports at the root, if the model uses a fixed-step solver, the fixed-step size of the model must not exceed the rate for any block in the model.
- The signal attributes of the enable port in the referenced model must be consistent with the input that the Model block provides to that enable port.

Triggered Model Requirements

The signal attributes of the trigger port in the referenced model must be consistent with the input that the Model block provides to that trigger port.

Function-Call Model Requirements

- A function-call model cannot have an outport driven only by Ground blocks, including hidden Ground blocks inserted by Simulink. To meet this requirement, do the following:

  1. Insert a Signal Conversion block into the signal connected to the outport.
  2. Enable the **Exclude this block from 'Block reduction' optimization** option of the inserted block.

- The referencing model must trigger the function-call model at the rate specified by the **Configuration Parameters** > **Solver** `'Fixed-step size'` option if the function-call model meets both these conditions:

  - It specifies a fixed-step solver
  - It contains one or more blocks that use absolute or elapsed time

  Otherwise, the referencing model can trigger the function-call model at any rate.

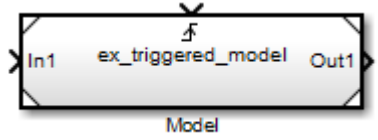
- A function-call model must not have direct internal connections between its root-level input and output ports. Simulink does not honor the `None` and `Warning` settings for the **Invalid root Inport/Outport block connection** diagnostic for a referenced function-call model. It reports all invalid root port connections as errors.
- If the **Sample time type** is `periodic`, the sample-time period must not contain an offset.
- The signal connected to a function-call port of a Model block must be scalar.

Reference Conditional Models

To create a reference to a conditional model:

1. Add a Model block to the model that you want to reference the triggered model. See “Create a Referenced Model” on page 8-9 for details.

   The top of the Model block displays an icon that corresponds to the kind of port used in the referenced model. For example, for a triggered model, the top of the Model block displays the following icon.



For enabled, triggered, and triggered and enabled models, go to Step 3.

2. For a function-call model, connect a Stateflow chart, Function-Call Generator block, or other function-call-generating block to the function-call port of the Model block. The signal connected to the port must be scalar.
3. Create and connect other blocks to implement the parent model.
4. Ensure that the referencing model satisfies the conditions for model referencing. See "Model Referencing Limitations" on page 8-105 for details.

Protected Model

A protected model provides the ability to deliver a model without revealing the intellectual property of the model. A protected model is a referenced model that hides all block and line information. It does not use encryption technology unless you use the optional password protection available for read-only view, simulation, and code generation. If you choose password protection for one of these options, the software protects the supporting files using AES–256 encryption. Creating a protected model requires a Simulink Coder license. A third party that receives a protected model must match the platform and the version of Simulink for which the protected model was generated.

Simulating a protected model requires that the protected model:

- Be available somewhere on the MATLAB path.
- Be referenced by a Model block in a model that executes in normal, accelerator, or rapid accelerator mode.
- Receives from the Model block the values needed by any defined model arguments.
- Connects via the Model block to input and output signals that match the input and output signals of the protected model.

To locate protected models in your model:

- The MATLAB Folder Browser shows a small image of a lock on the node for the protected model file.
- A Model block that references a protected model shows a small image of a shield in the lower left corner of the Model block.

Note Protected models do not appear in the model hierarchy in the Model Explorer.

If you use a protected model for operations like viewing a Web view, simulation, or code generation, then the licenses used in the protected model will be checked out before those operations begin. The creator of the protected model can view the licenses of a protected model that will be checked out by looking at the protected model report. To open the report, right-click the protected-model badge icon and select **Display Report**. In the **Summary** of the report, the **Licenses** table lists the licenses required to use the protected model.

For more information, see “Use Protected Model in Simulation” on page 8-97. For more information about creating protected referenced models, see “Protect a Referenced Model” (Simulink Coder).

Related Examples

- “Use Protected Model in Simulation” on page 8-97

Use Protected Model in Simulation

When you receive a protected model, it might be included in a protected model package. The package could include additional files, such as a harness model and a MAT-file. A protected model file has an `.slxp` extension. A typical workflow for using a protected model on page 8-95 in a simulation is:

1. If necessary, unpack the files according to any accompanying directions.
2. If there is a MAT-file containing workspace definitions, load that MAT-file.
3. If there is a harness model, copy the Model block referencing the protected model into your model.
4. If the protected model is password protected, then right-click the protected-model badge icon and select **Authorize**. Enter the required passwords, and then click **OK**.
5. If a protected model report was generated when the protected model was created, right-click the protected-model badge icon and select **Display Report** to open it. In the **Summary** of the report, check that your Simulink version and platform match the software and platform used to create the protected model.
6. Connect signals to the Model block that match its input and output port requirements.
7. Provide any needed model argument values. See "Parameterize a Referenced Model" on page 8-73.

There are also other ways to include the protected model into your model:

- Use your own Model block rather than the Model block in the harness model.

  Note When you change a Model block to reference a protected model, the **Simulation mode** of the block is set to `Accelerator`. You cannot change this mode. Furthermore, you cannot use the protected reference model block in External mode.

- Start with the harness model, add more constructs to it, and use it in your model.
- Use the protected model as a variant in a Model Variant block, as described in "Set up Model Variants Using a Model Block" on page 11-49.
- Apply a mask to the Model block that references the protected model. See "Block Masks".
- Configure a callback function, such as **LoadFcn**, to load the MAT-file automatically. See "Callbacks for Customized Model Behavior" on page 4-44.

Now you can simulate the model that includes the protected model. Because the protected model is set to accelerator mode, the simulation produces the same outputs that it did when used in accelerator mode in the source model.

Protected Model Web View

The Web view is a read-only reference of the protected model. If the Web view functionality is enabled during creation, you can see this read-only view of a protected model. It is platform independent so you can view it on platforms other than the platform for which you created the protected model. To open the Web view of a protected model, use one of the following methods:

- Right-click the protected-model badge icon and select **Show Web view**.
- Use the `Simulink.ProtectedModel.open` function. For example, to display the Web view for protected model `sldemo_mdlref_counter`, you can call:

  ```
  Simulink.ProtectedModel.open('sldemo_mdlref_counter', 'webview');
  ```

- Double-click the `.slxp` protected model file in the Current Folder browser.
- In the Block Parameter dialog box for the protected model, click **Open Model**.

Hover over a block in the model Web view to show the parameter values.

If the Web view is password protected, then right-click the protected-model badge icon and select **Authorize**. In the **Model view** box, enter the password, and then click **OK**.

More About

- “Protected Model” on page 8-95

Refresh Model Blocks

Refreshing a Model block updates its internal representation to reflect changes in the interface of the model that it references.

Examples of when to refresh a Model block include:

- Refresh a Model block that references model that has gained or lost a port.
- Refresh all the Model blocks that reference a model whose interface has changed.

If changes to a referenced model interface do not affect how the referenced model interfaces to its parent, you do not need to refresh a Model block .

To update a specific Model block, from the context menu of the Model block, select **Subsystem & Model Reference > Refresh Selected Model Block**.

To refresh all Model blocks in a model (as well as linked blocks in a library or model), in the Simulink Editor select **Diagram > Refresh Blocks**. You can also refresh a model by starting a simulation or generating code.

You can use Simulink diagnostics to detect changes in the interfaces of referenced models that could require refreshing the Model blocks that reference them. The diagnostics include:

- **Model block version mismatch**
- **Port and parameter mismatch**

Use S-Functions with Referenced Models

In this section...

S-Function Support for Model Referencing

Each kind of S-function provides its own level of support for model referencing.

Type of S-Function	Support for Model Referencing
Level-1 MATLAB S-function	Not supported
Level-2 MATLAB S-function	• Supports normal and accelerator mode • Accelerator mode requires a TLC file
Handwritten C MEX S-function	• Supports normal and accelerator mode • Can be inlined with TLC file
S-Function Builder	Supports normal and accelerator mode
Legacy Code Tool	Supports normal and accelerator mode

Sample Times

Simulink assumes that the output of an S-function does not depend on an inherited sample time unless the S-function explicitly declares a dependence on an inherited sample time.

You can control inheriting sample time by using `ssSetModelReferenceSampleTimeInheritanceRule` in different ways, depending on whether an S-function permits or precludes inheritance. For details, see “Inherited Sample Time for Referenced Models” (Simulink Coder).

S-Functions with Accelerator Mode Referenced Models

For a referenced model that executes in accelerator mode, set the **Configuration Parameters > Model Referencing > Total number of instances allowed per top model** to `One` if the model contains an S-function that is either:

- Inlined, but has not set the `SS_OPTION_WORKS_WITH_CODE_REUSE` flag
- Not inlined

Inlined S-Functions with Accelerator Mode Referenced Models

For accelerator mode referenced models that contain an S-function that requires inlining using a Target Language Compiler file, the S-function must use the `ssSetOptions` macro to set the `SS_OPTION_USE_TLC_WITH_ACCELERATOR` option in its `mdlInitializeSizes` method. The simulation target does not inline the S-function unless the S-function sets this option.

A referenced model cannot use noninlined S-functions in the following cases:

- The model uses a variable-step solver.
- Simulink Coder generated the S-function.
- The S-function supports use of fixed-point numbers as inputs, outputs, or parameters.
- The model is referenced more than once in the model reference hierarchy. To work around this limitation, use normal mode or:

  1. Make copies of the referenced model.
  2. Assign different names to the copies.
  3. Reference a different copy at each location that needs the model.
- The S-function uses character vector parameters.

Using C S-Functions in Normal Mode Referenced Models

Under certain conditions, when a C S-function appears in a referenced model that executes in normal mode, successful execution is impossible. For details, see "S-Functions in Normal Mode Referenced Models".

Use the `ssSetModelReferenceNormalModeSupport` SimStruct function to specify whether an S-function can be used in a normal mode referenced model.

You might need to modify S-functions that are used by a model so that the S-functions work with multiple instances of referenced models in normal mode. The S-functions must indicate explicitly that they support multiple `exec` instances. For details, see "Supporting the Use of Multiple Instances of Referenced Models That Are in Normal Mode".

Protected Models

A protected model cannot use noninlined S-functions directly or indirectly.

Simulink Coder Considerations

A referenced model in accelerator mode cannot use S-functions generated by the Simulink Coder software.

Noninlined S-functions in referenced models are supported when generating Simulink Coder code.

The Simulink Coder S-function target does not support model referencing.

For general information about using Simulink Coder and model referencing, see "Referenced Models" (Simulink Coder).

Buses in Referenced Models

To have bus data cross model reference boundaries, use a bus object (`Simulink.Bus`) to define the bus.

For more information, see “Bus Data Crossing Model Reference Boundaries” on page 65-150. For an example of a model referencing model that uses buses, see `sldemo_mdref_bus`.

Log Signals in Referenced Models

In a referenced model, you can log any signal configured for signal logging. Use the Signal Logging Selector to select a subset or all the signals configured for signal logging in a model reference hierarchy. For details, see “Models with Model Referencing: Overriding Signal Logging Settings” on page 61-99.

You can use the Simulation Data Inspector to view and analyze signals logged in referenced models. You can view signals on multiple plots, zoom, and use data cursors to understand and evaluate the data. Also, you can compare signal data from multiple simulations. For an example of viewing signals with referenced models, see “Viewing Signals in Model Reference Instances”.

Model Referencing Limitations

In this section...

Model Architecture Limitations

Limitation	Details
Reusability in accelerator mode	See “Specify Reusability of Referenced Models” on page 8-11.
Block masks	See “Use Masked Blocks in Referenced Models” on page 8-88.
S-Functions	“Use S-Functions with Referenced Models” on page 8-100
Goto and From blocks	Goto and From blocks cannot cross model reference boundaries.
Iterator and configurable subsystems	If the Model block references a model that contains Assignment blocks that are not in an iterator subsystem, you cannot place a Model block in an iterator subsystem. In a configurable subsystem with a Model block, during model update, do not change the subsystem that the configurable subsystem selects.
`InitFcn` callback	An `InitFcn` callback in a top model cannot change parameters used by referenced models.
MATLAB Function block	A MATLAB Function block in a referenced model that executes in accelerator mode cannot call MATLAB functions that are declared extrinsic for code generation.

Limitation	Details
Stateflow charts	You cannot reference a model multiple times in the same model reference hierarchy if that model that contains a Stateflow chart that: • Contains exported graphical functions • Is part of a Stateflow model that contains machine-parented data

Signal Limitations

Limitation	Details
0-based or 1-based indexing information propagation	See “Index Information Propagation” on page 8-42.
Asynchronous rates	Referenced models can only use asynchronous rates if the model meets *both* of these conditions: • An external source drives the asynchronous rate through a root-level Inport block. • The root-level Inport block outputs a function-call signal. See Asynchronous Task Specification.
User-defined data type input or output	A referenced model can input or output only the user-defined data types that are fixed point or that `Simulink.DataType` or `Simulink.Bus` objects define.
Referenced model cannot access signals in multirate bus	A referenced model cannot directly access the signals in a multirate bus. To overcome this limitation, see “Connect Multirate Buses to Referenced Models” on page 65-150.

Simulation Limitations

Limitation	Details
Continuous sample time propagation	A continuous sample time cannot be propagated to a Model block that is sample-time independent.

Limitation	Details
State initialization	To initialize the states of a model that references other models with states, specify the initial states in structure or structure with time format. For more information, see "State Information for Referenced Models" on page 61-262.
Parameter tunability	When you simulate a model that references other models, under some circumstances, you lose some tunability of block parameters (for example, the **Gain** parameter of a Gain block). For more information, see "Tunability Considerations and Limitations for Other Modeling Goals" on page 36-45.
0-based or 1-based indexing information propagation	See "Index Information Propagation" on page 8-42.
Normal mode visibility for multiple instances of referenced model	You can simulate a model that has multiple instances of a referenced model that are in normal mode. All the instances of the referenced model are part of the simulation. However, Simulink displays only one of the instances in a model window. The normal mode visibility setting determines which instance Simulink displays. Normal mode visibility includes the display of Scope blocks and data port values. To set up your model to control which instance of a referenced model in normal mode has visibility and to ensure proper simulation of the model, see "Configure Models with Multiple Referenced Model Instances" on page 8-46.
Save before using accelerator mode	When you create a model, you cannot use that model as an accelerator mode referenced model until you have saved the model to disk. You can work around this limitation by setting the model to normal mode. See "Simulate Model Reference Hierarchies" on page 8-35.

Limitation	Details
Diagnostic configuration parameters in accelerator mode	For models referenced in accelerator mode, Simulink ignores certain runtime diagnostics that you set to a value other than `none` or `Disable all`. For details, see "Diagnostic Configuration Parameters Ignored in Accelerator Mode" on page 8-39.
Blocks with runtime checks in accelerator mode	Some blocks include runtime checks that are disabled when you include the block in a referenced model in accelerator mode. Examples of these blocks include Assignment, Selector, and MATLAB Function blocks).
`sim` command in accelerator mode	When the `sim` command executes a referenced model in accelerator mode, the source workspace is always the MATLAB base workspace.
Data logging and visualization in accelerator mode	These logging methods have limitations when specified for referenced models executing in accelerator mode. • To Workspace blocks —Logs data only if you use Timeseries format. • Scope, Floating Scope, and Scope Viewer blocks — No data is displayed. • Runtime display — Simulation data values, such as port values, do not display.
Reusability in accelerator mode	See "Specify Reusability of Referenced Models" on page 8-11.
Linearization of discrete states in accelerator mode	In accelerator mode, discrete states of model references are not exposed to linearization. These discrete states are not perturbed during linearization and, therefore, are not truly free in the trimming process.
Trimming in accelerator mode	The outputs of random blocks are not kept constant during trimming. Outputs that are not kept constant can affect the optimization process.
External mode in accelerator mode	Accelerator mode does not support the **External mode** option. If you enable the **External mode** option, accelerator mode ignores it.

Limitation	Details
Sim viewing device in rapid accelerator mode	In rapid accelerator mode, Simulink does not update a Model block with a sim viewing device.
SIL and PIL mode	See “Simulation Mode Override Behavior in Model Reference Hierarchy” (Embedded Coder).

Tools Limitations

Limitation	Details
Simulink Debugger breakpoints	Working with the Simulink Debugger in a parent model, you can set breakpoints at Model block boundaries. Setting the breakpoints allows you to look at the input and output values of the Model block. However, you cannot set a breakpoint inside the model that the Model block references. See “Simulink Debugger” for more information.
Simulink Profiler	In Normal mode, enabling the Simulink Profiler on a parent model does not enable profiling for referenced models. Enable profiling separately for each referenced model. See “How Profiler Captures Performance Data” on page 30-5.
Simulink tools that access internal data or model configurations	Simulink tools that require access to the internal data or the configuration of a model have no effect on referenced models executing in accelerator mode. Specifications made and actions taken by such tools are ignored. Examples of tools that require access to model internal data or configuration include: • Model Coverage • Simulink Report Generator • Simulink Debugger • Simulink Profiler
Printing referenced models	You cannot print a referenced model from a top model.

Code Generation Limitations

Limitation	Details
Configuration parameters	See “Configuration Parameter Requirements” (Simulink Coder).
Atomic subsystems	If you generate code for an atomic subsystem as a reusable function, when you use accelerator mode, the inputs or outputs that connect the subsystem to a referenced model can affect code reuse. See “Generate Reentrant Code from Subsystems” (Simulink Coder) for details.
Data type replacement	Simulation target code generation for referenced models in accelerator mode does not support data type replacement.

Simulink Units

Unit Specification in Simulink Models

Simulink enables you to specify physical units as attributes on signals at the boundaries of model components. Such components can be:

- Subsystems
- Referenced Simulink models
- Simulink-PS Converter and PS-Simulink Converter blocks that interface between Simulink and components developed in Simscape and its associated physical modeling products
- Stateflow charts, state transition tables, or truth tables
- MATLAB Function blocks

By specifying, controlling, and visualizing signal units, you can ensure the consistency of calculations across the various components of your model. For example, this added degree of consistency checking is useful if you are integrating many separately developed components into a large, overall system model.

In Simulink models, you specify units from a unit database. The unit database comprises units from the following unit systems:

- `SI` — International System of Units
- `SI (extended)` — International System of Units (extended)
- `English` — English System of Units
- `CGS` — Centimetre-gram-second System of Units

Based on the type of system you are modeling, you can use any combination of units from these supported unit systems. For more information about supported unit systems and the units they contain, see Allowed Units.

You can assign units to signals through these blocks:

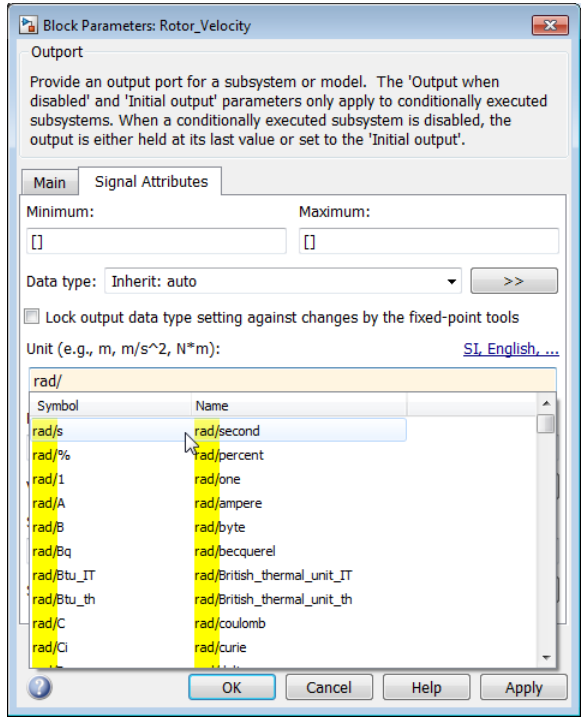
- Inport
- Outport
- Signal Specification
- MATLAB Function
- Stateflow Chart

and these objects:

- `Simulink.Signal`
- `Simulink.BusElement`
- `Simulink.Parameter`

When you add a supported block to your model, the **Unit** parameter on the block is set to `inherit` by default. This setting means that the block inherits the unit from a connecting signal that has an explicitly specified unit.

You can explicitly specify units for signals using the **Unit** parameter of a supported block. For this parameter, the dialog box provides matching suggestions to help you:



If you do not provide a correctly formed unit expression, you get an error. Correctly formed unit expressions are a combination of unit names or symbols with properly balanced parentheses and `*`, `/`, and `^` characters. Special characters such as `[`, `]`, `{`, `}`, `<`, `>`, `\`, `"`, `&`, and so forth are not supported.

By default, a block port has an empty (that is, unspecified) unit and the **Unit** parameter is set to `inherit`. When you specify a unit for one port, Simulink checks the unit setting of any port connected to it. If a port has an empty unit, you can connect it to another port that has any supported unit. If a port unit parameter is set to `inherit`, it inherits the unit from a connected port that has a specified unit.

Specify Physical Quantities

When you model a physical system, it is possible to use the same unit expression for two or more signals that represent different physical quantities. For example, a unit expression of `N*m` can represent either torque or energy. To prevent mistaken connection of two ports with the same unit but representing different physical quantities, you can add a physical quantity to the unit expression. For example, for the same unit of `N*m`, you can specify different physical quantities of `N*m@torque` and `N*m@energy`. Similar to units, the dialog box provides suggestions as you type the names of physical quantities.

Physical quantities help you to enforce an extra degree of unit consistency checking between connected ports. When you attempt to connect ports with different physical quantities, the model displays a warning.

Specify Units in Objects

By default, `Simulink.Signal`, `Simulink.BusElement`, and `Simulink.Parameter` objects have empty units. In the case of a:

- `Simulink.Signal` object, the empty unit means that the corresponding signal can inherit a unit from an upstream or downstream port.
- `Simulink.BusElement` object, the empty unit means that the corresponding bus element signal also has an empty unit. You can connect the signal to a port with any unit, but the signal does not inherit a unit from the port.
- `Simulink.Parameter` object, the object does not attach a unit to the corresponding parameter value.

If you specify a unit in a `Simulink.Signal` or `Simulink.BusElement` object, Simulink applies the attribute to the corresponding signal line when:

- The `Simulink.Signal` object resolves to a signal in the model
- You use a bus element signal that is associated with a `Simulink.Bus` object with a Bus Creator, Bus Selector, or Bus Assignment block.

If you use either of these objects with a Data Store block, Simulink does not display any unit attribute.

For the `Simulink.Parameter` object, Simulink does not apply any attribute. For all objects, if the **Unit** parameter has a value that is not formed correctly, you see an error. If the unit is formed correctly but is undefined, you see a warning when you compile the model. If the unit expression contains special characters such as `[`, `]`, `{`, `}`, `<`, `>`, `\`, `"`, `&`, and so forth, Simulink replaces them with underscores (_).

Custom Unit Properties

Notes on the `Unit` and `DocUnits` properties starting in R2016a:

- The `DocUnits` property is now `Unit` for `Simulink.Parameter` or `Simulink.Signal` objects. If, in a previous release, you used the `DocUnits` parameter of a `Simulink.Parameter` or `Simulink.Signal` object to contain text that does not now comply with units specifications, simulation returns a warning when the model simulates.

  To suppress these warnings, set the configuration parameter "Units inconsistency messages" to `none`. This setting suppresses all units inconsistency check warnings.

- If you have a class that derives from `Simulink.Parameter`, `Simulink.Signal`, or `Simulink.BusElement` with a previously defined `Unit` property, Simulink returns an error like the following:

  ```
  Cannot define property 'Unit' in class 'classname' because
   the property has already been defined in the superclass 'superclass'.
  ```

  If you use this property to represent the physical unit of the signal, delete the `Unit` property from the derived class in the R2016a or later release. Existing scripts continue to work, unless you are assigning incorrectly formed unit expressions to the `Unit` field. In this case, replace the use of `Unit` with `DocUnits` to continue to be able to assign the unit expression.

Note If you store existing data in a MAT- or `.sldd` file, in a release prior to R2016a, copy the contents of the `Unit` property to the `DocUnits` first. Then, save the file in the earlier release before loading the model in R2016a or later release.

Specify Units for Temperature Signals

When modeling absolute temperature quantities, use units such as `K`, `degC`, `degF`, and `degR`. When modeling temperature *difference* quantities, use units such as `deltaK`, `deltadegC`, `deltadegF`, and `deltadegR`. If you connect a signal that has a temperature difference unit to a block that specifies an *absolute* temperature unit, Simulink detects the mismatch.

Specify Units in MATLAB Function Blocks

You can specify units for input and output data of MATLAB Function blocks by using the **Unit** parameter on the Ports and Data Manager.

During model update, Simulink checks for inconsistencies in units between input or output data ports and the corresponding signals.

Specify Units for Logging and Loading Signal Data

You can include units in signal data that you log or load.

You specify units for logging and loading using `Simulink.SimulationData.Unit` objects. When you log using `Dataset` or `Timeseries` format, Simulink stores the unit information using `Simulink.SimulationData.Unit` objects. If you create MATLAB timeseries data to load, you can specify `Simulink.SimulationData.Unit` object for the `Units` property of the `timeseries` object.

For details, see “Log Signal Data That Uses Units” on page 61-39 and “Load Signal Data That Uses Units” on page 61-243.

Restricting Unit Systems

By default, you can specify units from any of the supported unit systems. However, in large modeling projects, to enforce consistency, you might want to restrict the unit systems that certain components of your model can use. To specify available unit systems for a model, in the configuration parameter **Allowed unit systems**, enter `all` or a comma-separated list containing one or more of `SI`, `SI (extended)`, `CGS`, and `English`. Do not use quotation marks. If your model contains referenced models, you can use the **Allowed unit systems** to restrict units in each of those referenced models. If your model contains subsystems, you can use the Unit System Configuration block to restrict units

in the subsystems. You can also optionally use a Unit System Configuration block in a model. In this case, the settings in the Unit System Configuration block override whatever you specify in **Allowed unit systems**.

To restrict unit systems in a model:

1. In the **Unit** parameter of the Inport, Outport, or Signal Specification block, click the link.

   If a Unit System Configuration block exists in your model, this link opens the block dialog box. Otherwise, the link opens the **Allowed unit systems** configuration parameter.

2. Specify one or more the desired unit systems, `SI`, `SI (extended)`, `English`, or `CGS`, in a comma-delimited list, or `all`, without quotation marks.

In a parent-child relationship (for example, a top model with a referenced model or subsystem), you can specify different unit systems for each component. However, if a child propagates a unit into a parent that is not in the unit systems specified for the parent, you get a warning.

To check whether there are unit mismatches caused by restricted unit systems in your model hierarchy:

- Press **Ctrl+D** and visually inspect the model for warning badges.
- Use the Model Advisor check **Identify disallowed unit systems**.

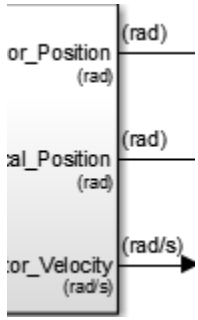
More About

Displaying Units

To display signal units in your model, select **Display > Signals & Ports > Port Units**. To select this option programmatically, use the command-line property `ShowPortUnits`.



With this option selected, the model dynamically updates port and signal labels to show any changes that you make to units. You do not need to press **Ctrl+D** to update the model. When you simulate your model, the Scope block displays units for connected signals as *y*-axis labels.

Note When you explicitly specify units on inport or outport blocks, block port labels and signal lines display those units. If a port is set to inherit units or has empty units, port labels and signal lines do not show labels.

Note With the option to display units cleared, you do not see port and signal labels, even when you press **Ctrl+D** to update your model. However, you do see warning or error badges for any unit inconsistency problems that exist in the model.

You can also see units in the interface view of your model. Select **Display > Interface**.

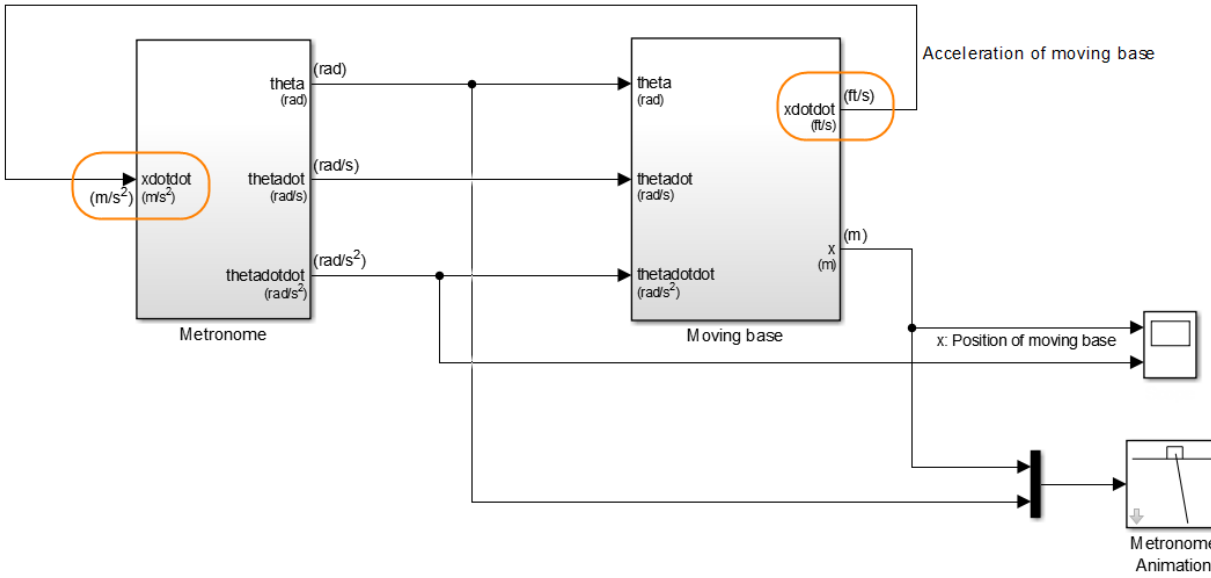
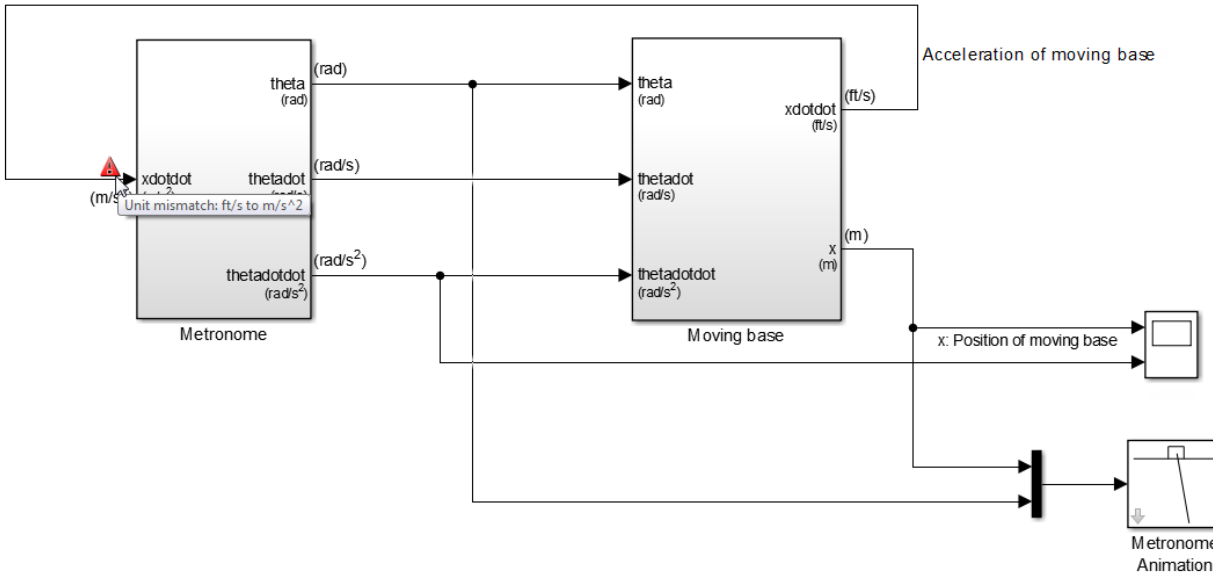
- “Converting Units” on page 9-16
- “Troubleshooting Units” on page 9-26

Unit Consistency Checking and Propagation

Simulink performs unit consistency checking between components. Ports that you connect together — sometimes via intermediate blocks that propagate units — must have the same units. For example, you cannot connect a port with unit `ft/s` to a port with unit `m/s^2`.



By default, Simulink shows the mismatch warning when it detects a mismatch in units between two connected ports. You can press **Ctrl+D** to show mismatched units in your model.



To make this connection valid, you can:

- Explicitly set both port units to the same unit.
- Set the **Unit** parameter of one of the connecting ports to `inherit`.
- Insert a Unit Conversion block between the mismatched units if they are separated by a scaling factor or offset, or if they are inverse units. These units are convertible. For more information, see "Converting Units" on page 9-16.
- Select the **Allow automatic unit conversions** configuration parameter. For more information, see "Converting Units" on page 9-16.

Note Simulink supports variations on unit expressions. For example, one port can have a unit of `m/s^2` and a connected port can have a unit of `m/s/s`. In these cases, Simulink does not display a warning for mismatched units.

When Simulink detects one of these conditions, it displays the inconsistency warning :

- Disallowed unit system
- Undefined unit

Simulink checks the consistency of unit settings and propagates units across component boundaries. In a model that contains a referenced model, Simulink compiles the referenced model independently of the top model. This independent compilation means that the referenced model cannot inherit units from the top model.

If a port in a referenced model has **Unit** set to `inherit`, it can inherit a unit from any upstream or downstream block in the referenced model. If the port does not inherit a unit from an upstream or downstream block, you can connect it to a port in the top model with any unit.

Simulink passes units through the following blocks that do not change data, known as noncomputation blocks:

- Bus Creator
- Bus Selector
- Bus to Vector
- Data Type Conversion
- Demux
- From
- Goto
- Inport
- Merge
- Model
- Mux
- Outport
- Rate Transition
- Signal Conversion
- Signal Specification
- Subsystem
- Variant Sink
- Variant Source

Note If you supply two or more signals with different units to a Mux block, Simulink applies empty units to the vector signal that the Mux block outputs. Vector signals must have a common unit.

Note If you have a nonvirtual bus in your model (see "Virtual and Nonvirtual Buses" on page 65-4), Simulink sets the unit of the bus to empty. A nonvirtual bus cannot have a unit. However, if the bus element signals themselves have units, Simulink does not change these.

Simulink does not propagate units through blocks that produce new data as output. When signals with units pass through these blocks, the units of these signals become empty. Examples of blocks that do not preserve units because they produce new data as an output include:

- Sum
- Gain
- Filter
- Product

Unit Propagation Between Simulink and Simscape

When modeling physical systems, you might want to integrate components developed in Simulink with components developed in Simscape and its associated physical modeling products. Simscape components use physical signals instead of regular Simulink signals. Therefore, you need Simulink-PS Converter and PS-Simulink Converter converter blocks to connect signals between Simulink and Simscape components.

To specify units for the input and output signals of your Simscape component, you can explicitly specify the units on the converter blocks. When you specify units on a PS-Simulink Converter block that converts a signal from Simscape to Simulink, Simulink propagates the unit settings to the connected Simulink port. However, Simulink cannot propagate a signal unit from Simulink into your Simscape component. To do that, you must explicitly specify the unit on the Simulink-PS Converter block. For more information, see "Physical Units" (Simscape) in the Simscape documentation.

Converting Units

Simulink can convert units between ports when it detects discrepancies that have known mathematical relationships such as:

- Scaling factors
- Conversion factors and offsets, such as `F` (Fahrenheit) to `C` (Celsius)
- Scaled, inverse units, such as `mpg` (miles per gallon) and `L/km` (liters per kilometer).

For example, if you connect one port with a unit of `cm` to one with a unit of `mm`, Simulink can automatically scale one unit to work with the other.

To enable Simulink to convert unit mismatches in your model automatically, select the **Allow automatic unit conversions** configuration parameter.

- When Simulink successfully converts signal units at a block port, it displays  .
- When Simulink detects that an automatic conversion is not possible, it displays  .

To manually convert units separated by a conversion factor or offset:

1. Clear the **Allow automatic unit conversions** configuration parameter.
2. Insert a Unit Conversion block between the ports whose units you want to convert.

Tip Automatic conversion of units is a convenience. For better control of units, when Simulink detects a mismatch, consider modifying the units specified at one or the other of the two connected ports.

Automatic Unit Conversion Limitations

Simulink does not support automatic conversion:

- At the boundaries of virtual subsystems. Virtual subsystems have the **Treat as atomic unit** parameter cleared. For more information, see “Nonvirtual and Virtual Blocks” on page 35-2.
- At the root level of models configured for concurrent execution or export-function models. For more information, see “Configure Your Model for Concurrent Execution” on page 14-23 and “Export-Function Models” on page 10-76.

- For fixed-point and integer signals.
- At an input port of a Merge block.
- At any port of an asynchronous Rate Transition block.
- At an input port of a function-call subsystem.
- For bus signals.

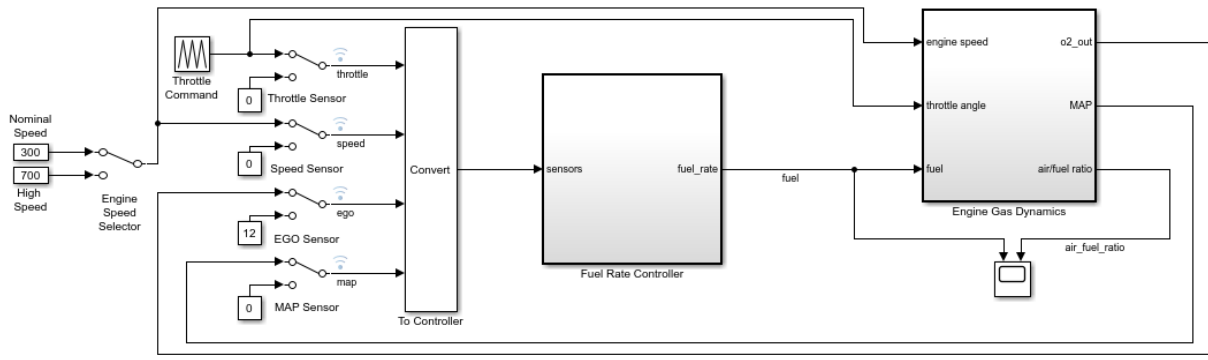
Update an Existing Model to Use Units

This example shows how to add units to an existing model. You see how to:

- Use an incremental workflow to add units to components in your model
- Integrate components that use different unit systems
- Specify units for individual elements of a bus object
- Troubleshoot unit mismatch problems

The model in the example is a fuel control system. The controller (Fuel Rate Controller) and plant (Engine Gas Dynamics) components of the model are nonvirtual subsystems. Nonvirtual subsystems have the **Treat as atomic unit** parameter selected. You introduce units to the plant before introducing units to the controller and connecting signals. You also specify units for the individual elements of a bus object in the model.

Open the `ex_units_fuelsys` example model.



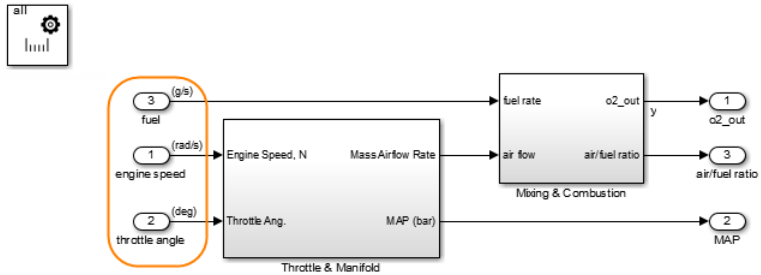
For the top model, the **Allowed unit systems** configuration parameter determines the unit systems the model can use. For each of the plant and controller subsystems, a Unit System Configuration block determines the allowed unit systems.

Component	Allowed Unit Systems
Top model	`SI`
Fuel Rate Controller subsystem (controller)	`all`
Engine Gas Dynamics subsystem (plant)	`all`

In the plant subsystem, on the **Signal Attributes** tab of each inport block dialog box, set the **Unit** parameter to a value appropriate for the connected physical signal.

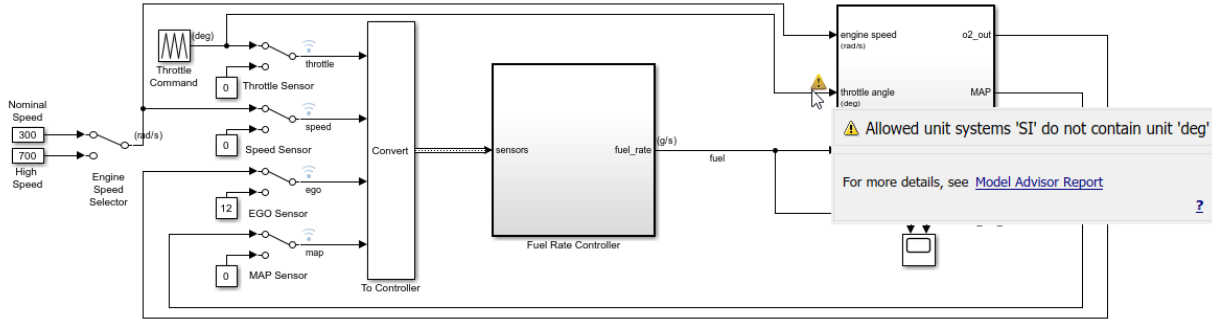
Block	Physical Signal	Unit Parameter Setting
1	engine speed	`rad/s` (radians per second)
2	throttle angle	`deg` (degrees)
3	fuel rate	`g/s` (grams per second)

To display units on ports and signals in the model, select **Display** > **Signals & Ports** > **Port Units**.



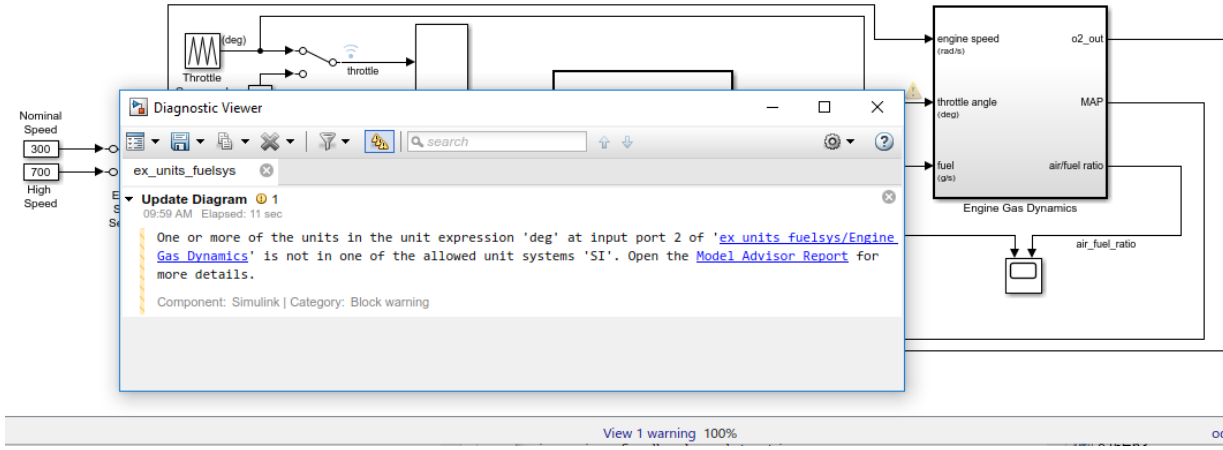
In the plant subsystem, you see units on the inport blocks and connected signals.

Navigate back to the top model. To compile the model, press **Ctrl+D**, which also performs unit consistency checking.



The model displays a warning to indicate that there is a disallowed unit for the `throttle angle` signal. Clicking the warning icon displays a link to a Model Advisor report that gives you more detail.

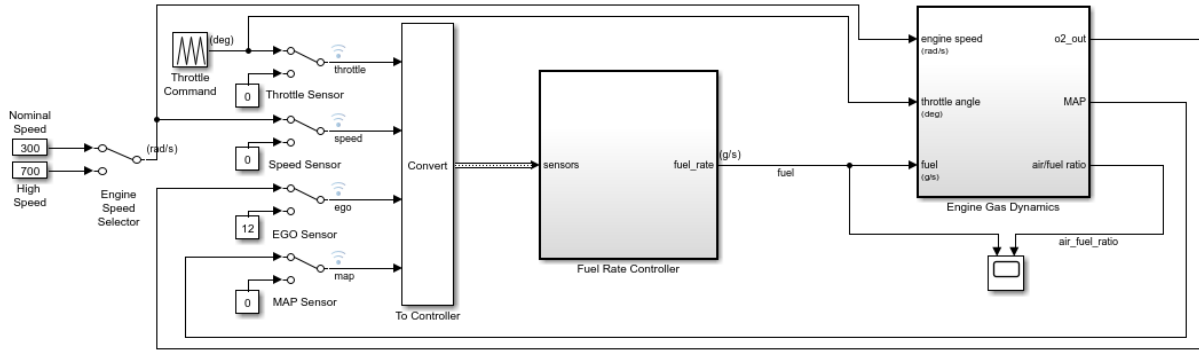
The model also displays the warning at the bottom of the model editing window.



In the plant subsystem, you specified a unit of `deg` (degrees) for the `throttle angle` signal. However, the warning message indicates that degrees are not in the SI unit system. As determined by the **Allowed unit systems** configuration parameter, SI is the only unit system that the top model currently allows. To resolve this warning, you have two options:

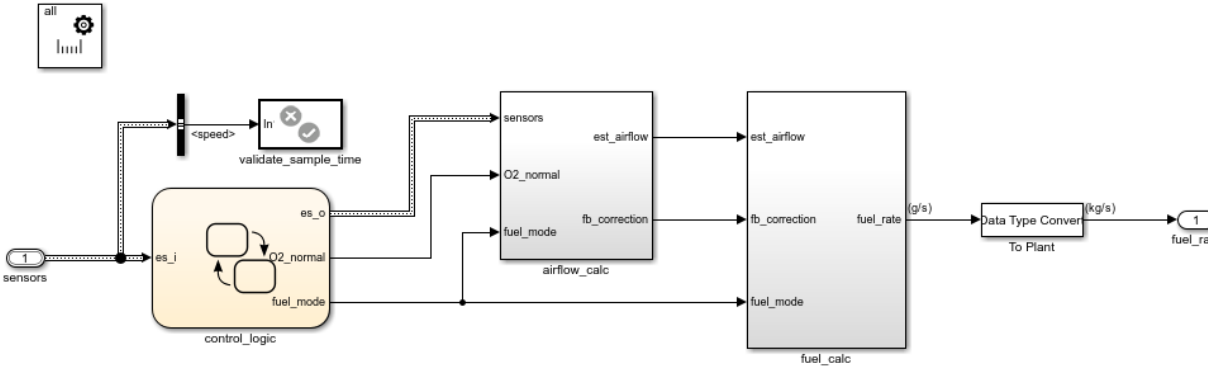
- In the plant subsystem, specify a unit for the `throttle angle` signal that the SI unit system supports. For more information about supported unit systems and the units they contain, see Allowed Units.
- In the top model, change the **Allowed unit systems** configuration parameter to expand the set of allowed unit systems.

In this case, a unit of `deg` for the `throttle angle` signal is appropriate. Instead, to resolve the warning, expand the set of allowed unit systems for the top model. Set the **Allowed unit systems** configuration parameter of the top model to `all`. To recompile the model, press **Ctrl+D**.

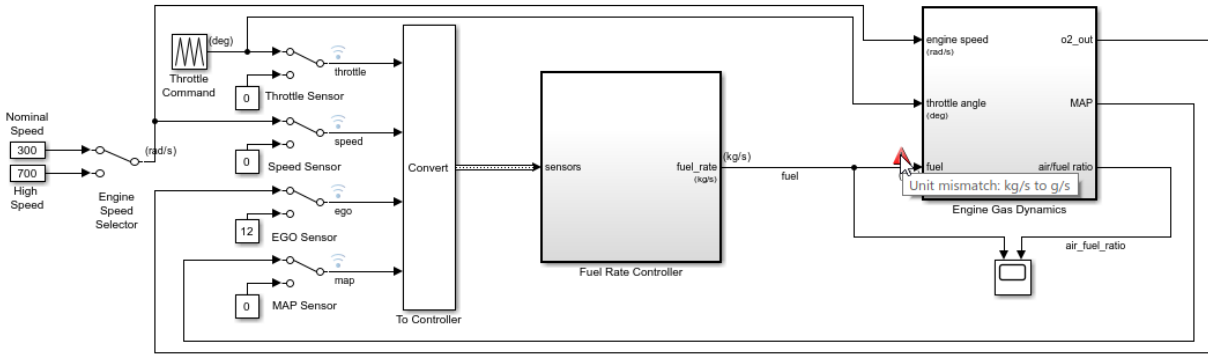


The top model no longer displays warnings.

Now that you have introduced units to the plant and successfully resolved unit inconsistency problems, you can add units to the controller. In the Fuel Rate Controller subsystem, set the **Unit** parameter of the fuel_rate outport block to `kg/s` (kilograms per second).



Navigate back to the top model. To recompile it, press **Ctrl+D**.

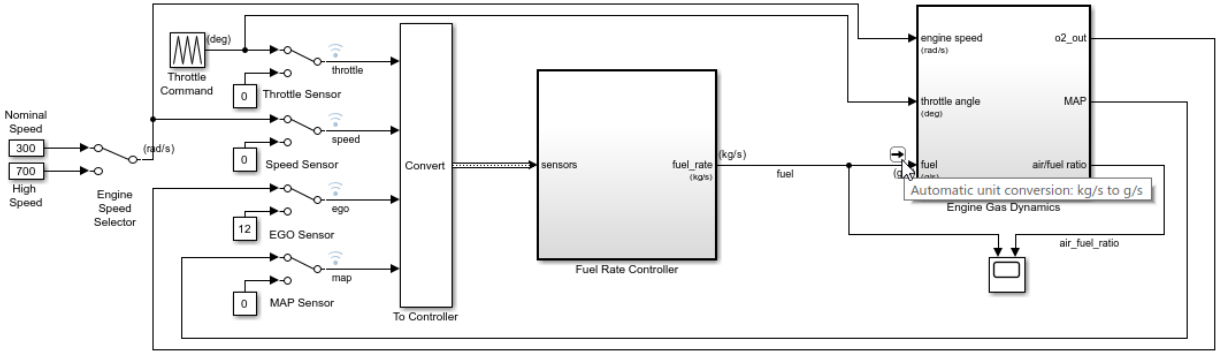


The top model now shows a warning for mismatched units between the controller and plant. To resolve this error, you can:

- Explicitly insert a Unit Conversion block between the two components.
- Select the **Allow automatic unit conversions** configuration parameter.

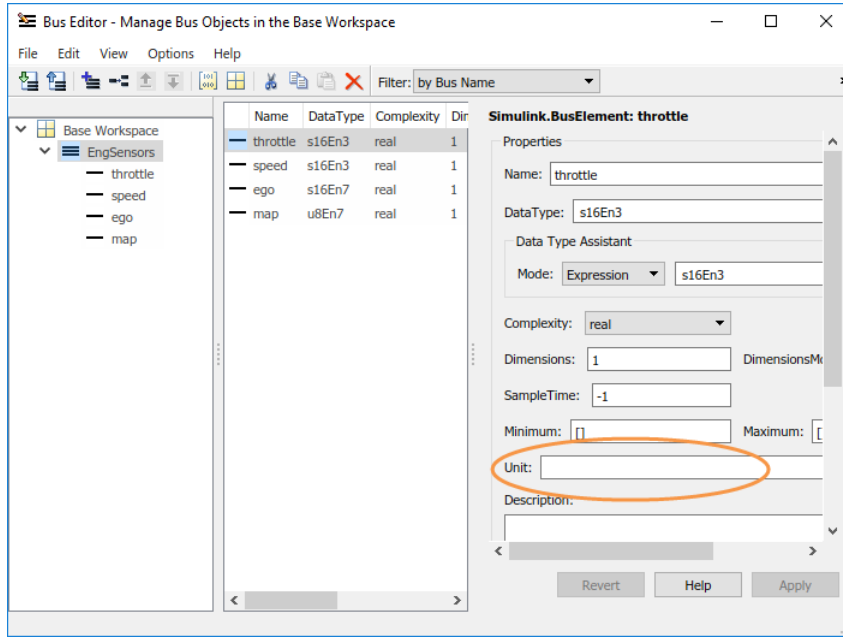
Both options convert units in the same way. A situation in which you might disallow automatic conversions and insert conversion blocks instead is when you are integrating many components in a large system model. In that case, manually inserting conversion blocks can give you an added degree of control of unit conversions in the model. Also, with a conversion block, you can control the data type of the converted signal. This is useful, for instance, when you are modeling for fixed-point precision.

In this case, to enable Simulink to resolve the unit mismatch automatically, select **Allow automatic unit conversions**. To recompile the model, press **Ctrl+D**.



Simulink automatically converts units between the controller and the plant. An automatic conversion icon replaces the warning.

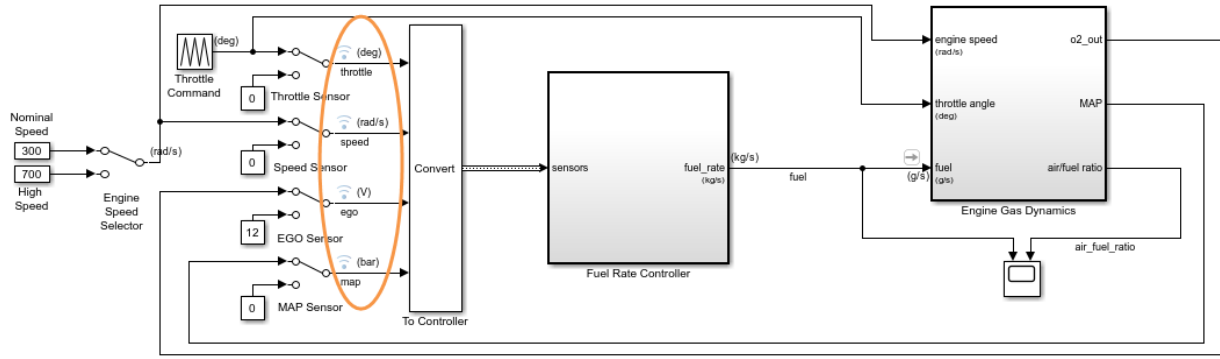
The top model includes a `EngSensors` bus object that passes various sensor signals as a composite signal to the controller. To use the Bus Editor to add units to individual elements of the bus object, select **Edit** > **Bus Editor**.



For the `EngSensors` bus object, set the **Unit** parameter of each element.

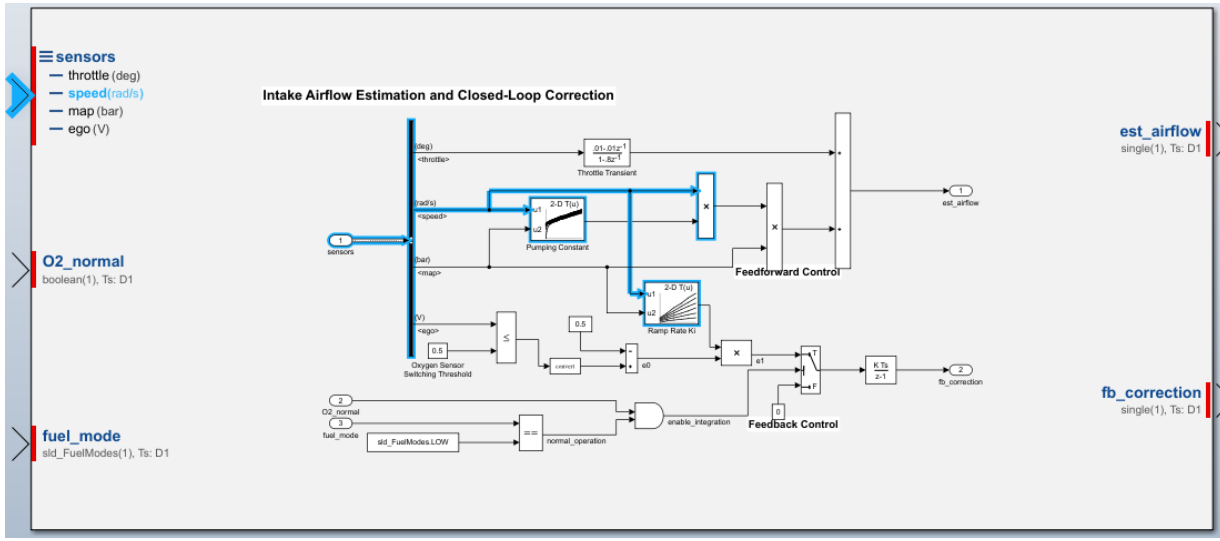
Signal	Unit Parameter Setting
`throttle`	`deg` (degrees)
`speed`	`rad/s` (radians per second)
`ego`	`V` (volts)
`map`	`bar` (bars)

To recompile the model, press **Ctrl+D**.



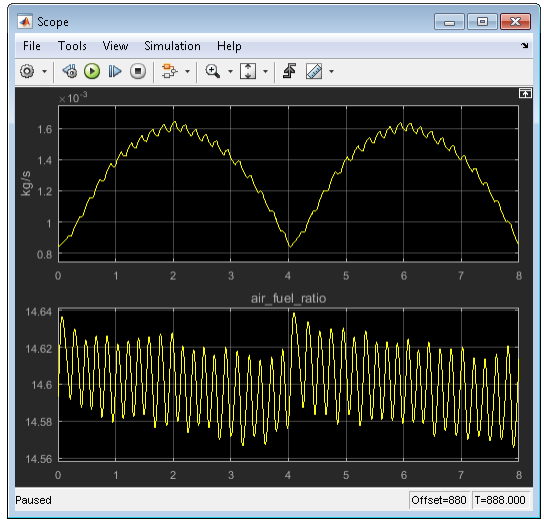
The model shows units on the individual elements of the bus object.

You can also see the units in the interface view of your model. Select **Display** > **Interface**.



The airflow_calc block of the controller subsystem displays units on the individual elements of the bus object, both at the component interface and within the component.

After you introduce units incrementally and resolve inconsistency and mismatch issues, you can simulate the model.



For the `fuel` signal that is connected to the scope, the plot window displays the associated units of `kg/s` as a *y*-axis label.

Troubleshooting Units

In this section...

To help you troubleshoot issues with unit settings, Simulink uses Model Advisor checks to generate a report useful for larger models.

By default, Simulink flags unit usage issues, such as mismatched units, with warnings. Warnings enable you to continue working despite mismatched units. You can reduce the number of warnings you see by setting the configuration parameter **Units inconsistency messages** to `none`.

Undefined Units

Simulink does not support custom unit specifications. For more information about supported unit systems and the units they contain, see Allowed Units.

The Model Advisor check “Identify undefined units in the model” identifies undefined units.

Overflow and Underflow Errors or Warning

You can get overflow and underflow errors or warnings when using the Unit Conversion block. If you get:

- Overflow messages, change the data type at the output port to one with a better range
- Underflow messages, change the data type at the output port to one with better precision

Mismatched Units Detected

At the boundary of a component, Simulink detects if the units of two ports do not match. To see the tooltip, hover over the warning badge. If the unit is convertible, Simulink displays advice on fixing the issue.

The Model Advisor check “Identify unit mismatches in the model” identifies mismatched units.

Mismatched Units Detected While Loading

At the boundary of a component, Simulink detects if the units of two ports do not match. To see the tooltip, hover the warning badge. When possible, Simulink displays advice on fixing the issue.

The Model Advisor check “Identify unit mismatches in the model” identifies mismatched units.

Disallowed Unit Systems

Simulink supports only the unit systems listed in the tables of allowed units.

The Model Advisor check “Identify disallowed unit systems in the model” identifies unit systems that are not allowed in the configured units systems.

Automatic Unit Conversions

If the **Allow automatic unit conversions** configuration parameter is set, Simulink supports the automatic conversion of units. Simulink flags automatically converted units with the badge.

For a list of the automatic unit conversions, use the Model Advisor check “Identify automatic unit conversions in the model”.

Unsuccessful Automatic Unit Conversions

If the **Allow automatic unit conversions** configuration parameter is set, Simulink supports the automatic conversion of units. If Simulink cannot perform the automatic unit conversion, Simulink returns a warning (). In such cases, consider manually specifying the unit.

Tip Automatic unit conversion is a convenience. For better control of units, you can manually set the units for two connecting ports.

Simscape Unit Specification Incompatible with Simulink

If these are true:

- You define a new unit to your unit registry by using the `pm_addunit` function.
- You use the new unit with the Simulink-PS Converter or PS-Simulink Converter block.
- Your new unit conflicts with an existing one in the Simulink database.

Simulink returns a warning about a potential incorrect calculation ().

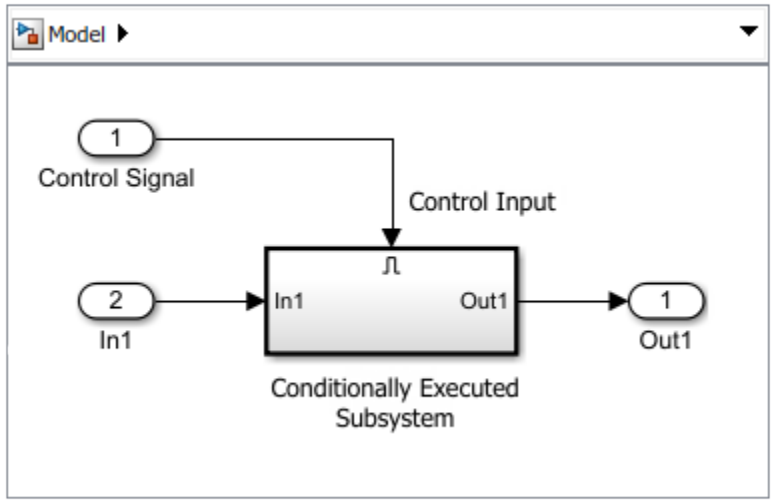
Conditional Subsystems

Conditional Subsystems

A conditionally executed subsystem is an atomic subsystem that allows you to control its execution with an external signal. The external signal, called the control signal, is attached to the control input port. Conditional subsystems are useful when you create complex models that contain components whose execution depends on other components.



Simulink supports these types of conditional subsystems:

- Enabled Subsystem — Executes at each time step while the control signal is positive. Execution starts at the time step when the control signal crosses zero from the negative to the positive direction. See “Enabled Subsystems” on page 10-10.
- Triggered Subsystem — Executes each time a trigger event occurs. A trigger event can occur on the rising or falling edge of a continuous or discrete trigger signal. See “Triggered Subsystems” on page 10-20.
- Enabled and Triggered Subsystem — Executes once at the time step when a trigger event occurs and the enable control signal has a positive value. See “Enabled and Triggered Subsystems” on page 10-25.
- Function-Call subsystem — Executes each time a function-call event occurs. A Stateflow chart, Function-Call Generator block, or an S-function block can provide function call events. See “Using Function-Call Subsystems” on page 10-29.

More About

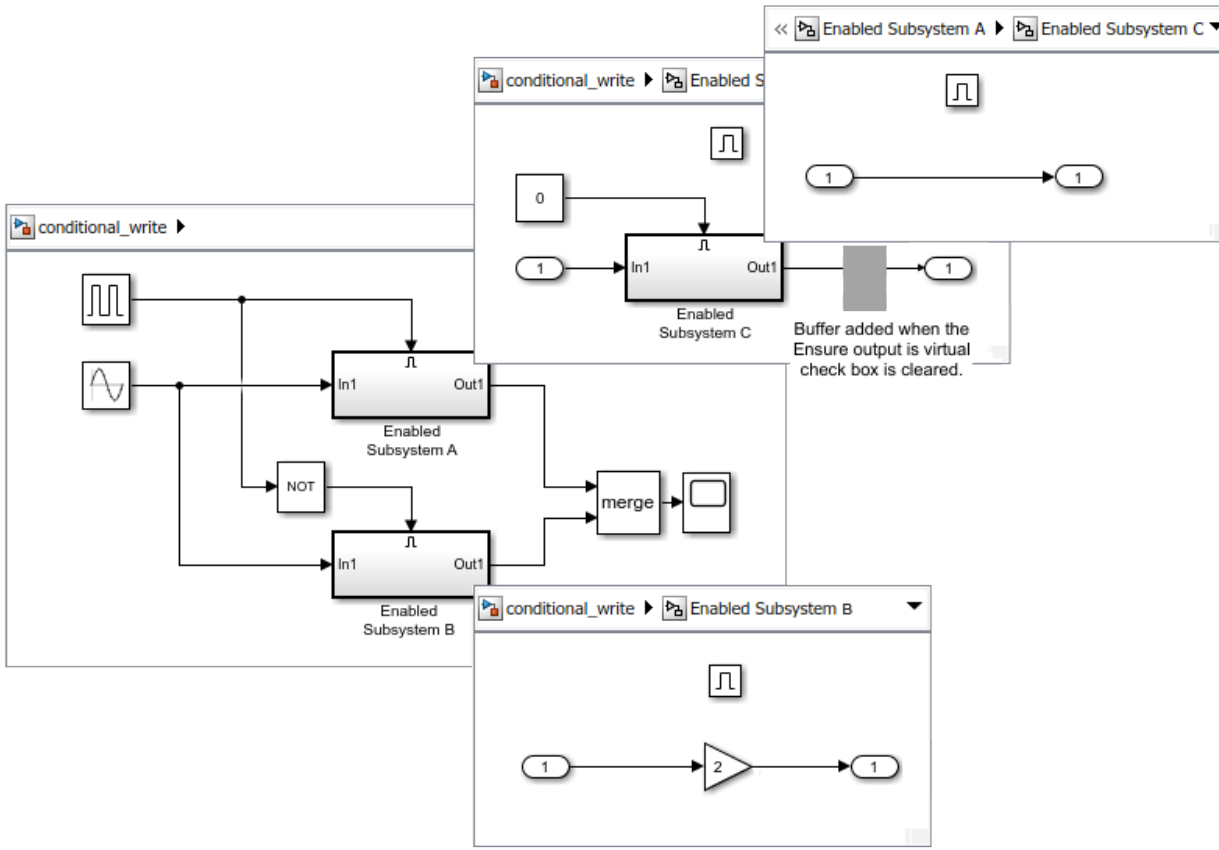
- “Conditional Subsystem Initial Output Values” on page 10-33
- “Conditional Subsystem Output Values When Disabled” on page 10-52

Ensure output is virtual

The parameter **Ensure output is virtual** is an option on a conditional subsystem Outport block or a root-level Outport block. Select this option when you are concerned with conditioanal or partial writers.

Conditional Writes

Consider the following model.



The Merge block combines its inputs into a single signal whose value at any time is equal to the most recently computed output of its driving blocks.

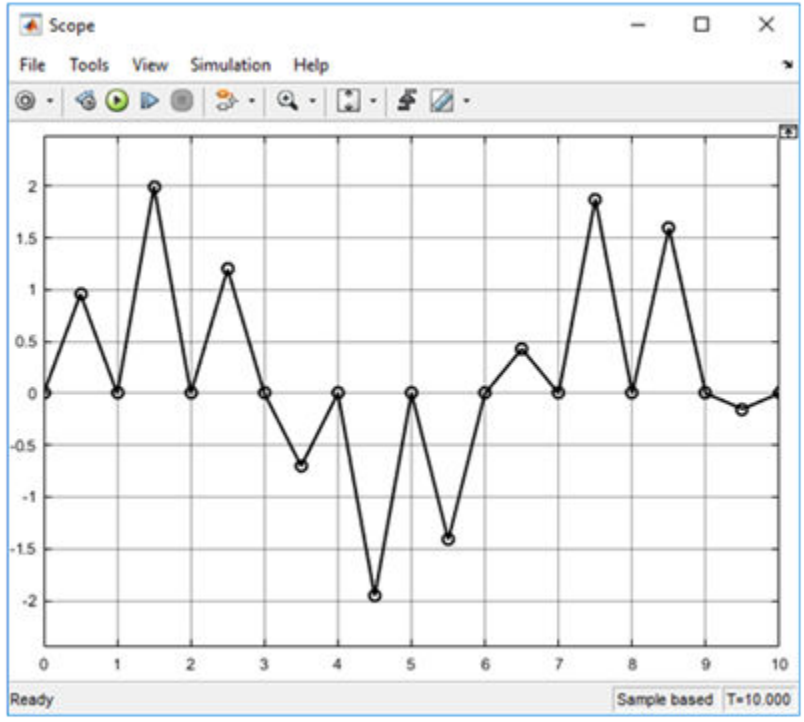
For the case with most models, clear (uncheck) the **Ensure output is virtual** check box on the Outport block connected to Enabled Subsystem C.

- The outpout block follows non-virtual semantics with a hidden buffer inserted if needed before the Outport block.
- The buffer provides consistent initialization of the Outport block signal.

Time 0: A runs, C does not run, but because the buffer is in A, it runs and copies the initial value of zero to the Outport block. B does not run. The merge signal is zero from the output from A.

Time 0.5: A does not run. B runs and outputs a sine wave. The merge signal is the sine wave from B.

Time 1. A runs, C does not run, but the buffer again runs and copies over the initial value of zero to the Outport block. B does not run. The merge signal is again the initial value of A, not the last value from B.



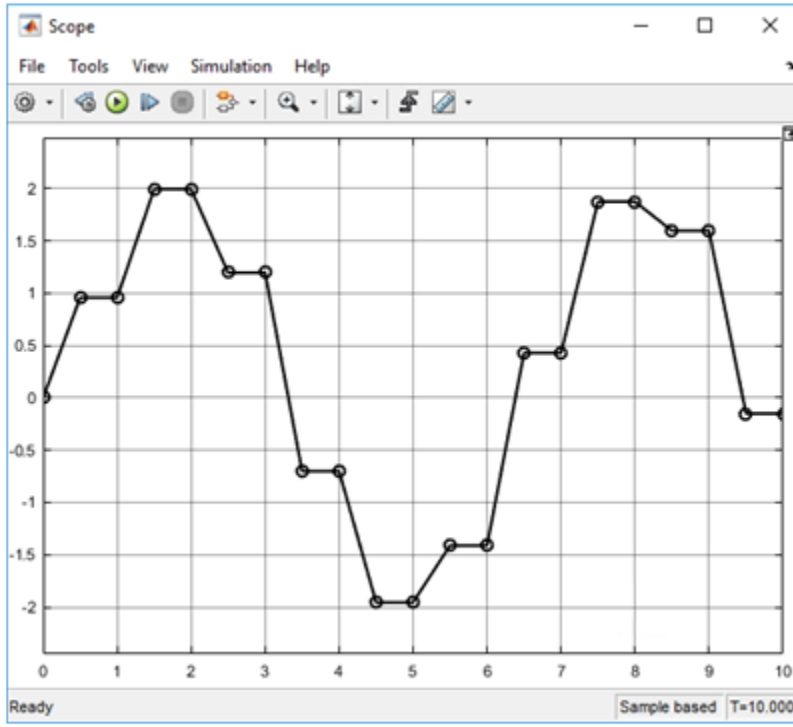
For the case where you are concerned with conditional and partial writers, select (check) the **Ensure output is virtual** check box on the Outport block connected to Enabled Subsystem C.

- The Outport block follows virtual semantics.
- A hidden buffer is not inserted before the Outport block of the Subsystem.
- If Simulink determines a buffer is needed, an error is displayed.

Time 0: A runs, C does not run. B does not run. Merge signal is the initial value of the signal.

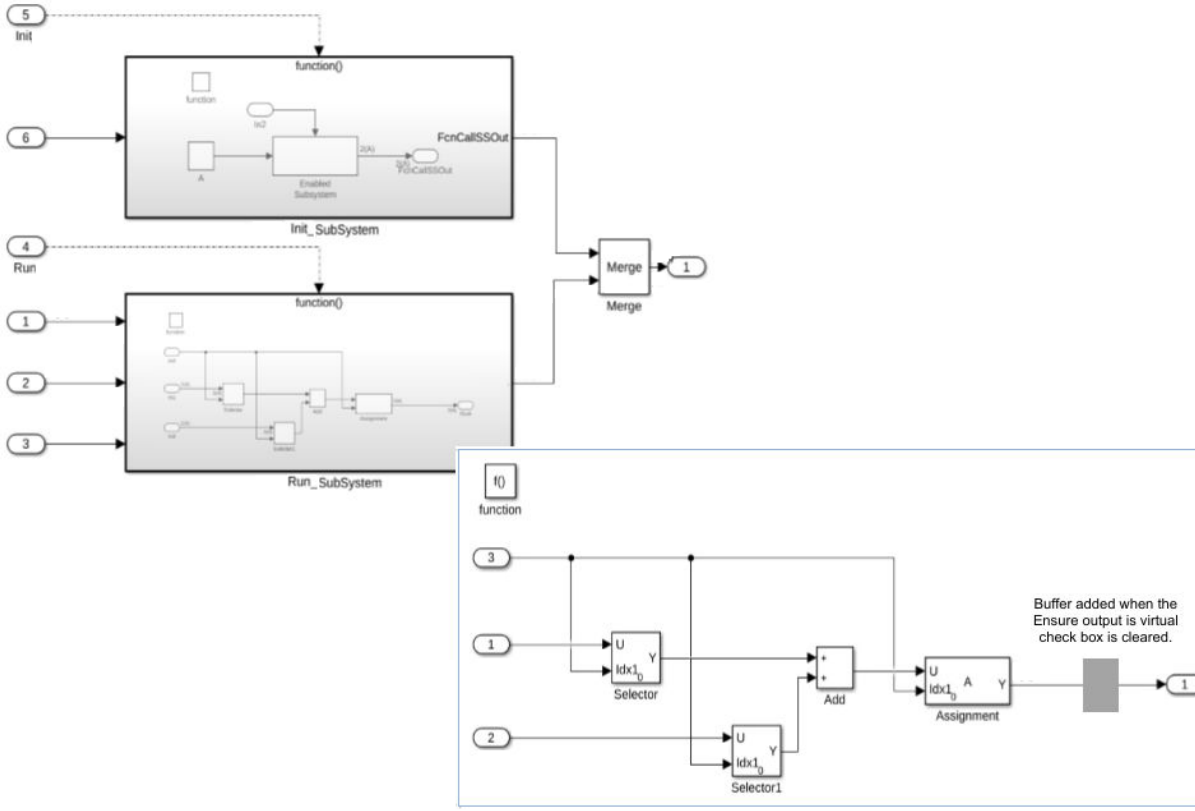
Time 0.5 sec: A does not run. B runs and outputs a sine wave. The merge signal is the value of the sine wave from B.

Time 1: A runs, C does not run. B does not run. The merge signal is the most recently computed output which was the sine wave from B.



Partial Writes

Consider the following model. Input blocks 1 and 2 are vector signals.



For the case for most models, clear (uncheck) the **Ensure output is virtual** check box on the Output block 1 in Run_SubSystem,

- The output block follows non-virtual semantics with a buffer inserted after the Assignment block and before the Outport block.
- The buffer copies the entire vector over to the Outport block. The signal is no longer partial.

For the case where you are concerned with partinal writes, select (check) the **Ensure output is virtual** check box on Output block 1.

- The Outport block behaves like a virtual block, without any additional buffering.
- Partial vector is copied over to the root Outport block thrugh the Mirge block.

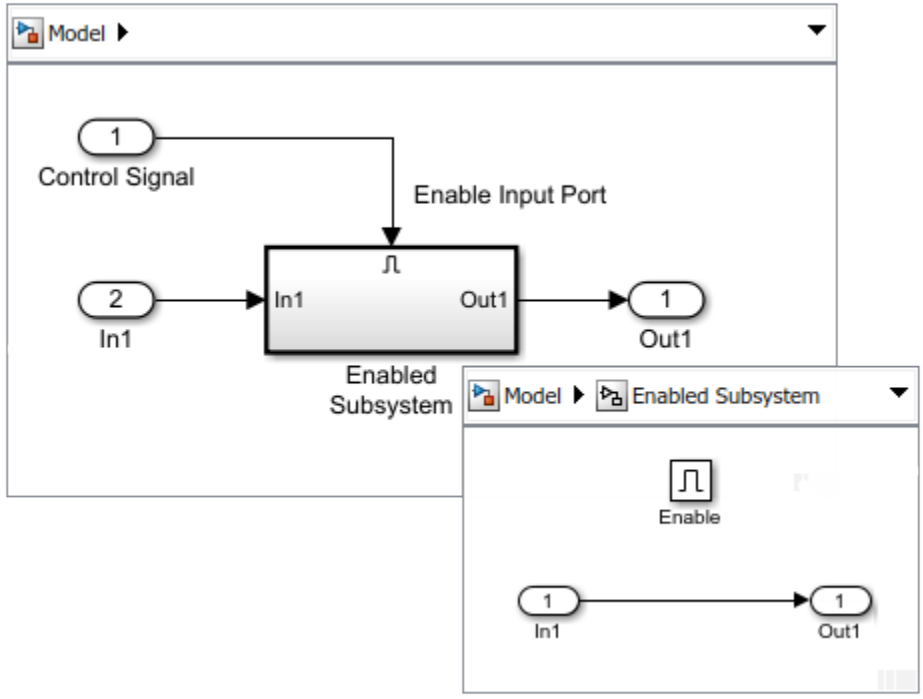
Enabled Subsystems

In this section...

An enabled subsystem is a conditionally executed subsystem that runs once at each major time step while the control signal has a positive value. If the signal crosses zero during a minor time step, the subsystem is not enabled or disabled until the next major time step.

The control signal can be either a scalar or a vector.

- If a scalar value is greater than zero, the subsystem executes.
- If any one of the vector element values is greater than zero, the subsystem executes.

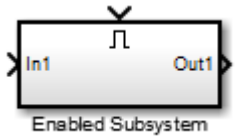


Create an Enabled Subsystem

To create an enabled subsystem:

1. Add an Enabled Subsystem block to your model.

   - Copy a block from the Simulink Ports & Subsystems library to your model.
   - Click the model diagram, start typing `enabled`, and then select Enabled Subsystem.

2. Set initial and disabled values for the Outport blocks. See “Conditional Subsystem Initial Output Values” on page 10-33 and “Conditional Subsystem Output Values When Disabled” on page 10-52.
3. Specify how subsystem states are handled when the subsystem is enabled.

   Open the subsystem block, and then open the parameter dialog box for the Enable port block. From the **States when enabling** drop-down list, select:

   - `held` — States maintain their most recent values.
   - `reset` — If the subsystem is disabled for at least one time step, states revert to their initial conditions .

     In simplified initialization mode (default), the subsystem elapsed time is always reset during the first execution after becoming enabled. This reset happens regardless of whether the subsystem is configured to reset on being enabled. See “Underspecified initialization detection”.

   For nested subsystems whose Enable blocks have different parameter settings, the settings for the child subsystem override the settings inherited from the parent subsystem.
4. Output the control signal from the Enable block.

   In the parameter dialog box for the Enable Block, select the **Show output port** check box.

Selecting this parameter allows you to pass the control signal into the enabled subsystem. You can use this signal with an algorithm that depends on the value of the control signal.

Blocks in Enabled Subsystems

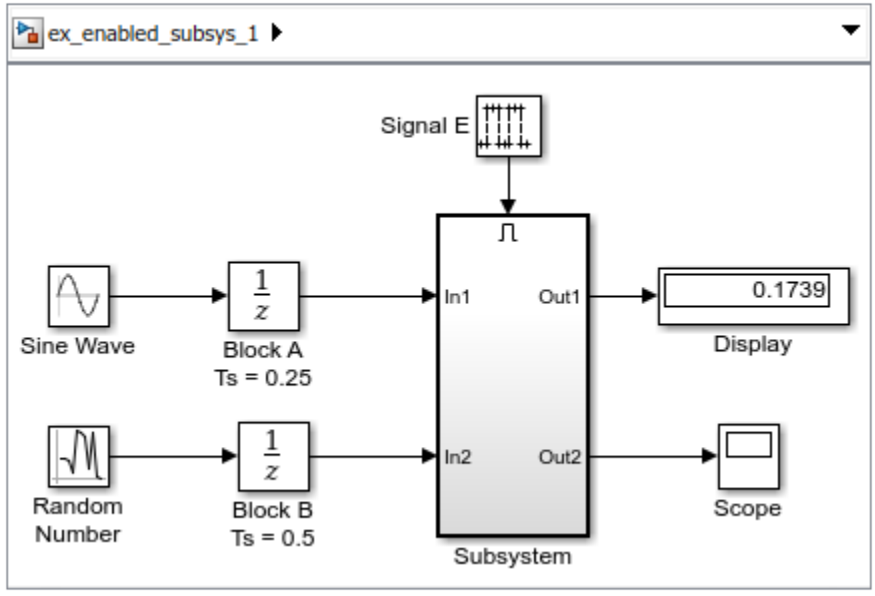
Discrete Blocks

Discrete blocks in an enabled subsystem execute only when the subsystem executes, and only when their sample times are synchronized with the simulation sample time.

Consider the ex_enabled_subsys_1 model, which contains four discrete blocks and a control signal. The discrete blocks are:

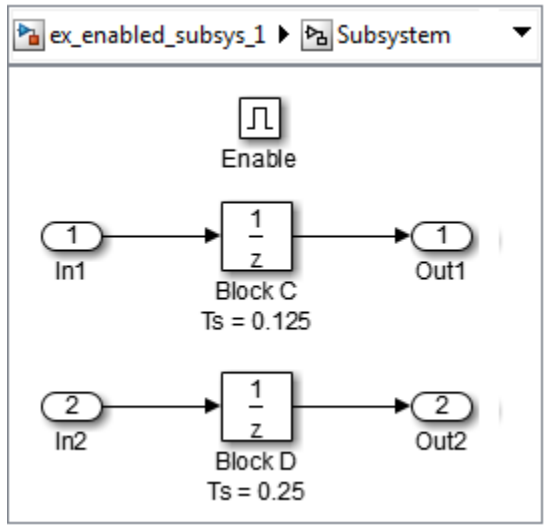
- Block A, with the sample time of 0.25 seconds
- Block B, with the sample time of 0.5 seconds

Signal E is the enable control signal generated by a Pulse Generator with a sample time of 0.125. Its output changes value from 0 to 1 at 0.375 seconds and returns to 0 at 0.875 seconds.

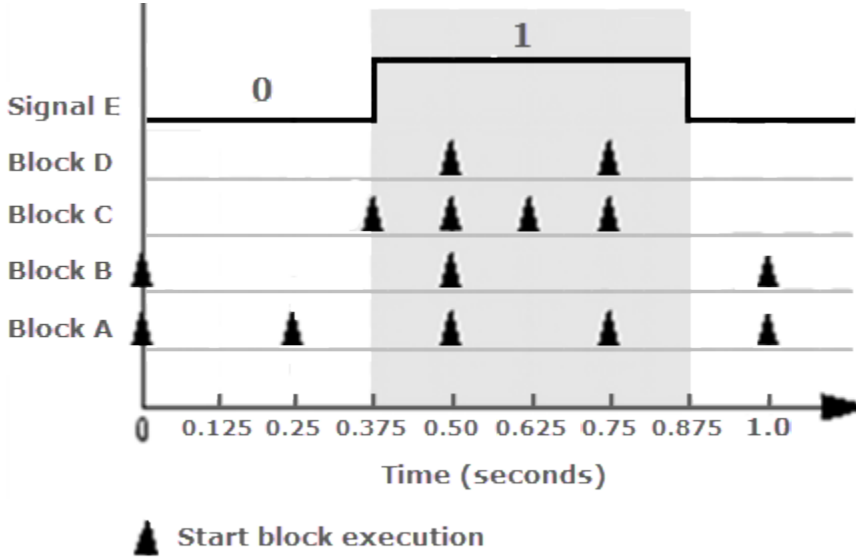


The discrete blocks in the enabled subsystem are:

- Block C, within the enabled subsystem, with the sample time of 0.125 seconds
- Block D, also within the enabled subsystem, with the sample time of 0.25 seconds



Discrete blocks execute at sample times shown.



Blocks A and B execute independently of the enable control signal because they are not part of the enabled subsystem. When the enable control signal becomes positive, blocks C and D execute at their assigned sample rates until the enable control signal becomes zero again. Block C does not execute at 0.875 seconds when the enable control signal changes to zero.

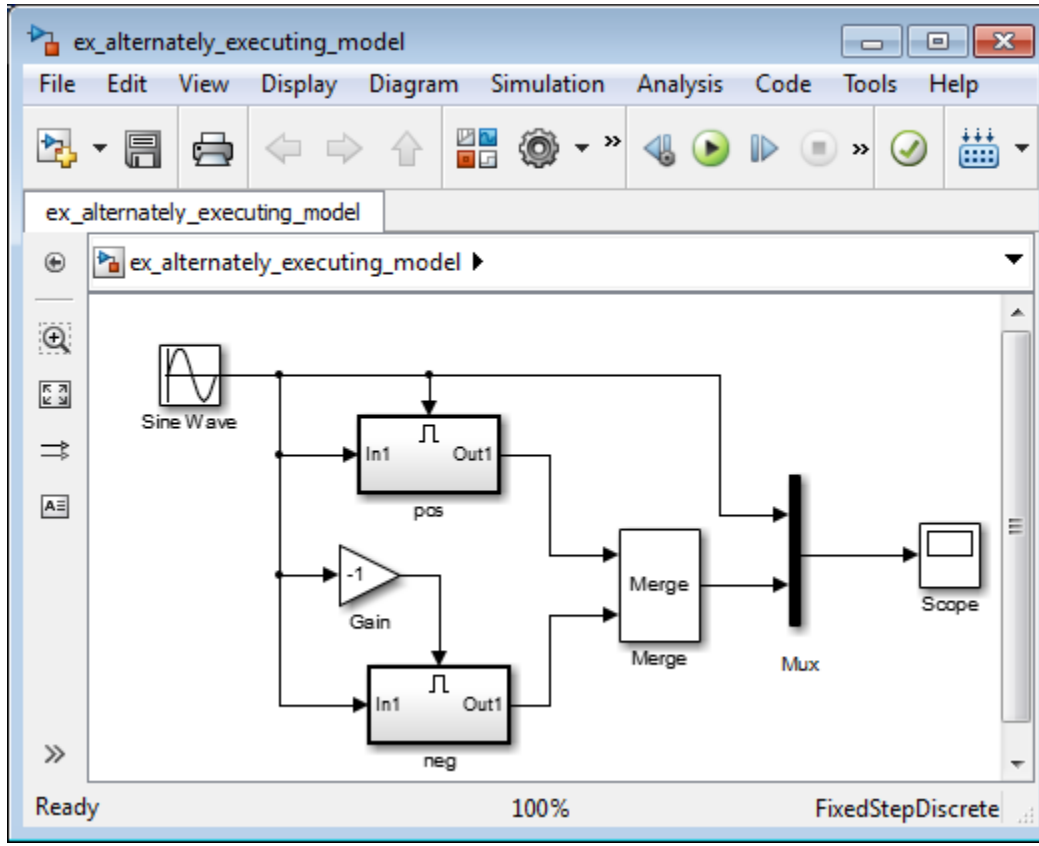
Goto Blocks

Enabled subsystems can contain Goto blocks. However, only output ports for blocks with state can connect to Goto blocks. See the `Locked` subsystem in the model `sldemo_clutch`, for an example of using Goto blocks in an enabled subsystem.

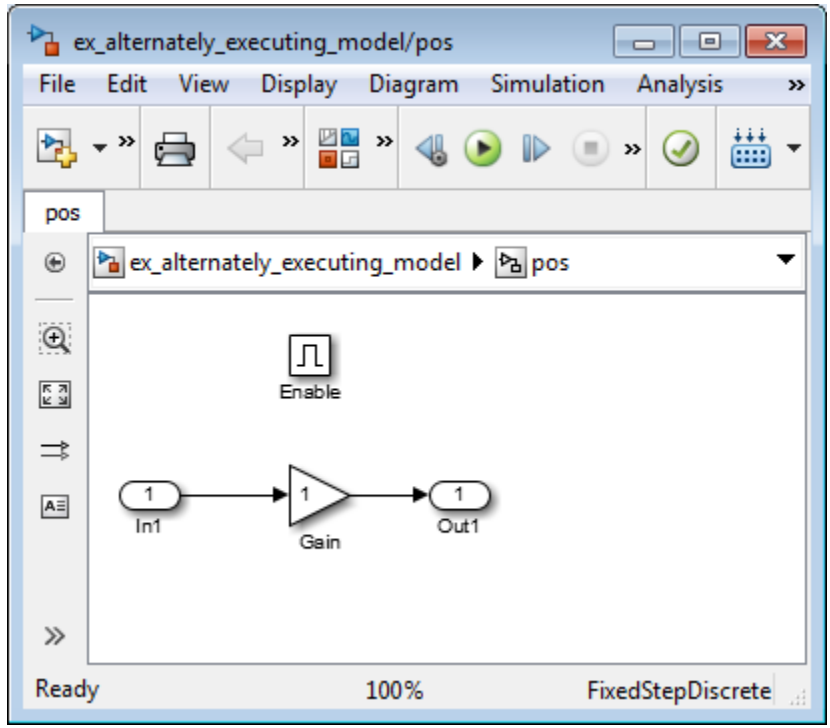
Alternately Executing Enabled Subsystems

You can use conditional subsystems with Merge blocks to create sets of subsystems that execute alternately, depending on the current state of the model.

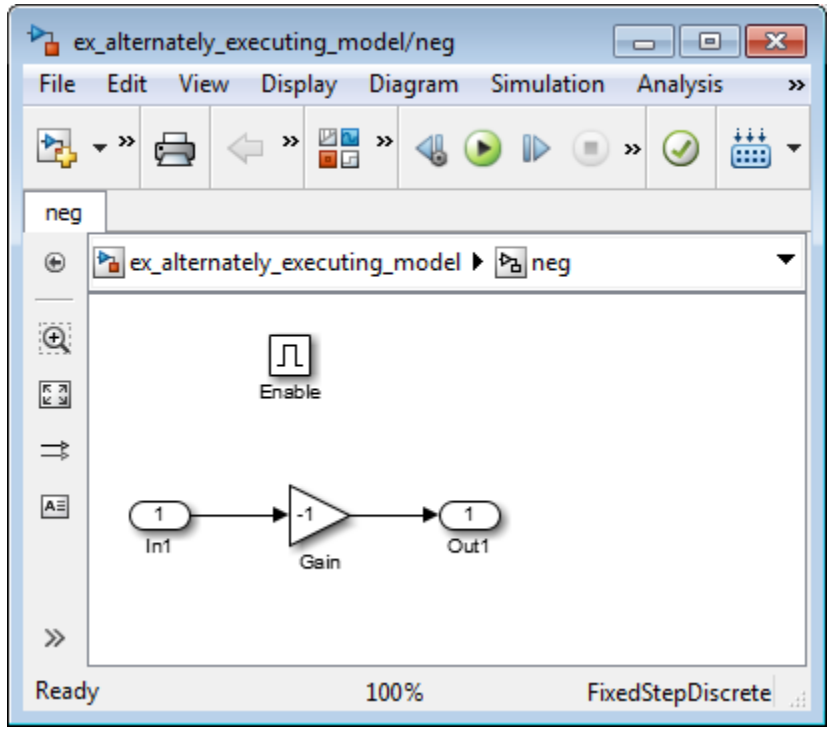
Consider a model that uses two Enabled Subsystem blocks and a Merge block to model a full-wave rectifier (a device that converts AC current to pulsating DC current).



Open the `pos` subsystem. The subsystem is enabled when the AC waveform is positive and passes the waveform unchanged to its output.



Open the `neg` subsystem. The subsystem is enabled when the waveform is negative and inverts the waveform.



The Merge block passes the output of the currently enabled subsystem along with the original waveform to the Scope block.

Running a simulation and then opening the Scope block shows the following result.

More About

- “Conditional Subsystems” on page 10-3
- “Conditional Subsystem Initial Output Values” on page 10-33

- “Conditional Subsystem Output Values When Disabled” on page 10-52
- “Comparison of Resettable Subsystems and Enabled Subsystems” on page 10-99

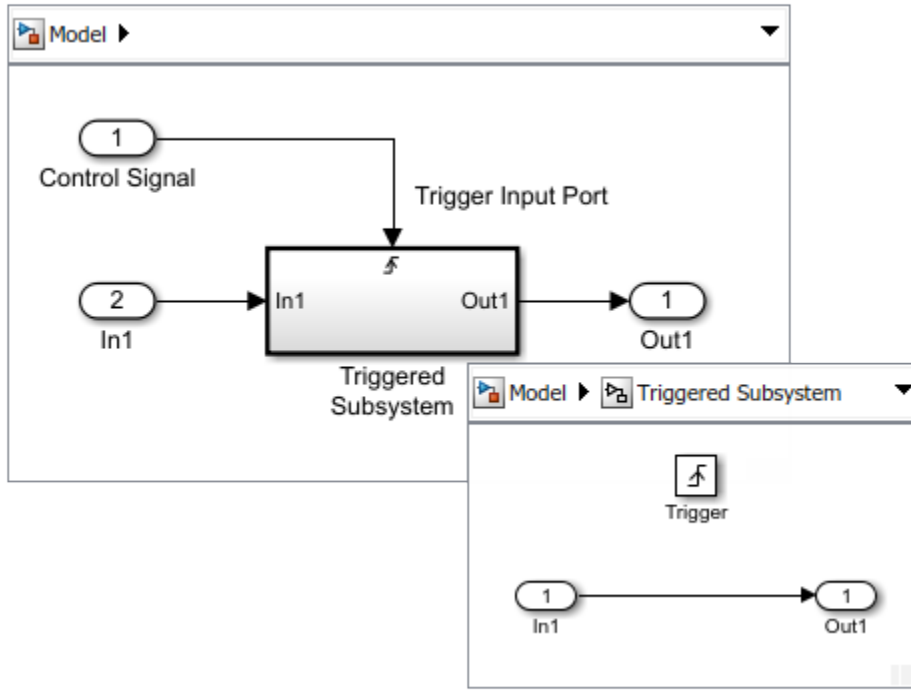
Triggered Subsystems

In this section...

A triggered subsystem is a conditionally executed atomic subsystem that runs each time the trigger input port receives a trigger event.

Trigger events can occur when the control signal:

- Either rises from a negative value to a positive value or zero, or rises from a zero value to a positive value.
- Either falls from a positive value to a negative value or zero, or falls from a zero value to a negative value.
- Rises or falls through or to a zero value.



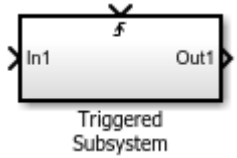
Unlike an Enabled Subsystem block, a Triggered Subsystem block always holds its outputs at the last value between triggering events. Also, triggered subsystems cannot reset block states when triggered; the states of any discrete block are held between trigger events.

Create a Triggered Subsystem

To create a triggered subsystem:

1 Add a Triggered Subsystem block to your model.

- Copy a block from the Simulink Ports & Subsystems library to your model.
- Click the model diagram, start typing `trigger`, and then select Triggered Subsystem.



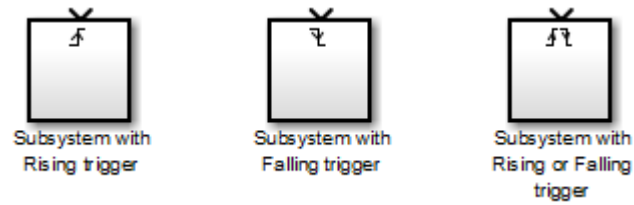
2 Set initial and disabled values for the Outport blocks. See “Conditional Subsystem Initial Output Values” on page 10-33 and “Conditional Subsystem Output Values When Disabled” on page 10-52.

3 Set how the control signal triggers execution.

Open the subsystem block, and then open the parameter dialog box for the Trigger port block. From the **Trigger type** drop-down list, select:

- `rising` — Trigger execution of the subsystem when the control signal rises from a negative or zero value to a positive value.
- `falling` — Trigger execution of the subsystem when the control signal falls from a positive or zero value to a negative value.
- `either` — Trigger execution of the subsystem with either a rising or falling control signal.

Different symbols appear on the Trigger and Subsystem blocks to indicate rising and falling triggers.



4 Output the enable control signal from the Trigger port block. Open the Trigger port block. Select the **Show output port** check box to pass the control signal into the triggered subsystem.

You can use this signal with an algorithm that depends on the value of the control signal.

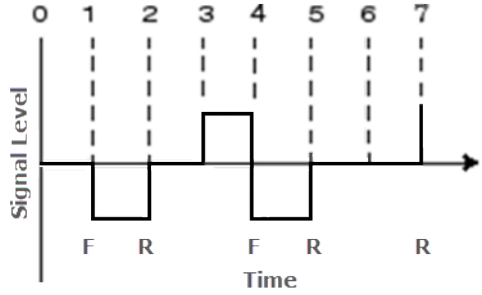
5 From the **Output data type** drop-down list, select `auto`, `int8`, or `double`.

The `auto` option causes the data type of the output signal to be the data type (either `int8` or `double`) of the block port connected to the signal.

Triggering with Discrete Time Systems

For a discrete time system, the trigger control signal must remain at zero for more than one time step. This triggering strategy eliminates false triggers caused by control signal sampling.

In the following timing diagram for a discrete system, a rising trigger event (R) does not occur at time step 3. The trigger signal remains at zero for only one time step before the signal increases from zero.



Triggered Model Versus a Triggered Subsystem

You can place a Trigger port block in a Model block (referenced model) to simplify your model design instead of using one of these blocks:

- A Triggered Subsystem block in a Model block.
- A Model block in a Triggered Subsystem block.

For information about using Trigger port blocks in referenced models, see “Create and Reference Conditional Referenced Models” on page 8-89.

To convert a subsystem to use model referencing, see “Convert a Subsystem to a Referenced Model” on page 8-15.

Blocks in a Triggered Subsystem

All blocks in a triggered subsystem must have **Sample time** set to inherited (`-1`) or constant (`inf`). This requirement allows the blocks in a triggered subsystem to run only when the triggered subsystem itself runs. This requirement also means that a triggered subsystem cannot contain continuous blocks, such as an Integrator block.

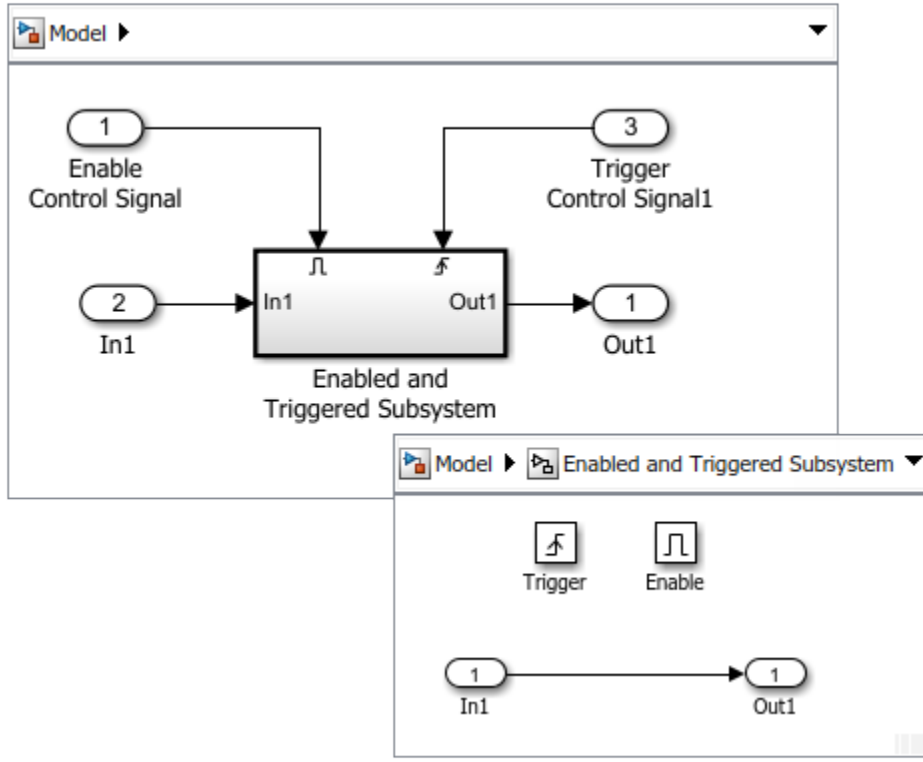
Enabled and Triggered Subsystems

In this section...

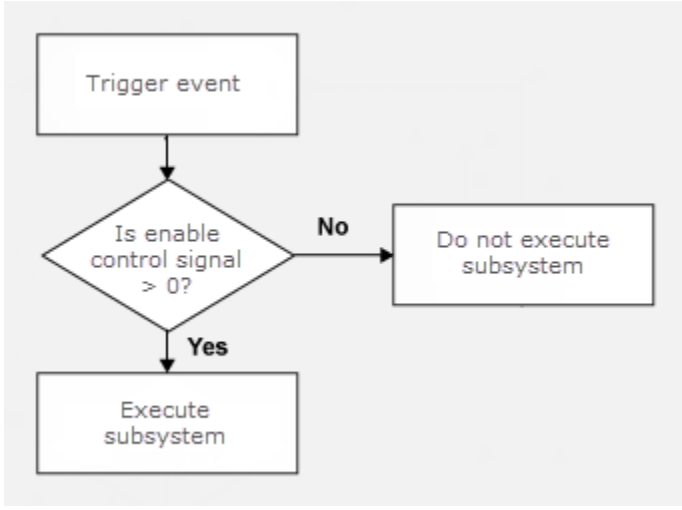
An Enabled and Triggered Subsystem is a conditionally executed subsystem that runs once at each simulation time step when both these conditions apply:

- Enabled control signal has a positive value.
- Trigger input port receives a trigger event.



An Enabled and Triggered Subsystem block contains both an Enable port block and a Trigger port block. When a trigger event occurs, the enable input port is checked to

evaluate the enable control signal. If its value is greater than zero, the subsystem is executed. When both inputs are vectors, the subsystem executes if at least one element of each vector is nonzero.

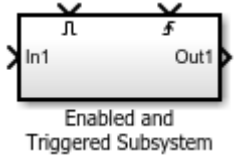


Creating an Enabled and Triggered Subsystem

To create an enabled and triggered subsystem:

1 Add an Enabled and Triggered Subsystem block to your model.

- Copy a block from the Simulink Ports & Subsystems library to your model.
- Click the model diagram, start typing `enabled`, and then select Enabled and Triggered Subsystem.



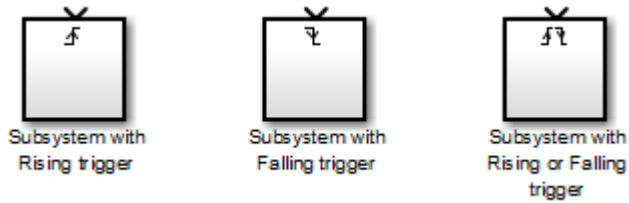
2 Set initial and disabled values for the Outport blocks. See “Conditional Subsystem Initial Output Values” on page 10-33 and “Conditional Subsystem Output Values When Disabled” on page 10-52.

3 Set how the control signal triggers execution.

Open the subsystem block, and then open the block parameters dialog box for the Trigger port block. From the **Trigger type** drop-down list, select:

- `rising` — Trigger execution of the subsystem when the control signal rises from a negative or zero value to a positive value.
- `falling` — Trigger execution of the subsystem when the control signal falls from a positive or zero value to a negative value.
- `either` — Trigger execution of the subsystem with either a rising or falling control signal.

Different symbols appear on the Trigger and Subsystem blocks to indicate rising and falling triggers.



4 Specify how subsystem states are handled when enabled.

Open the subsystem block, and then open the Enable port block. From the **States when enabling** drop-down list, select:

- `held` — States maintain their most recent values.
- `reset` — States revert to their initial conditions if the subsystem is disabled for at least one time step.

In simplified initialization mode, the subsystem elapsed time is always reset during the first execution after becoming enabled. This reset happens regardless of whether the subsystem is configured to reset on being enable. See “Underspecified initialization detection”.

For nested subsystems whose Enable blocks have different parameter settings, the settings for the child subsystem override the settings inherited from the parent subsystem.

Blocks in an Enabled and Triggered Subsystem

All blocks in an enabled and triggered subsystem must have **Sample time** set to inherited (`-1`) or constant (`inf`). This requirement allows the blocks in a triggered subsystem to run only when the triggered subsystem itself runs. This requirement also means that a triggered subsystem cannot contain continuous blocks, such as an Integrator block.

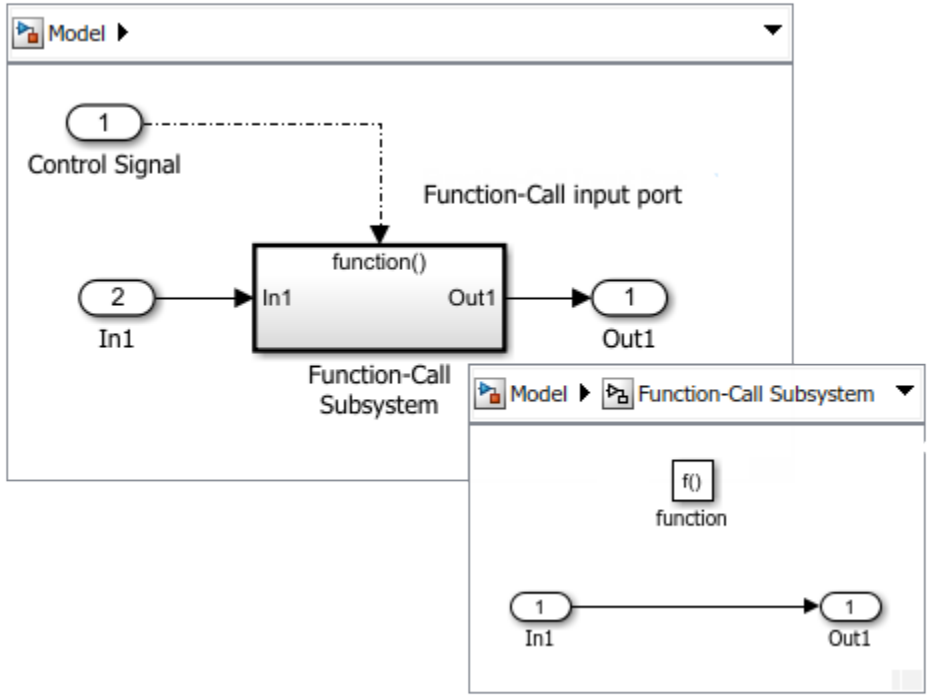
Using Function-Call Subsystems

In this section...

A Function-Call Subsystem block is a conditionally executed subsystem that runs each time the control signal has a function-call event. A Stateflow chart, Function-Call Generator block, or an S-function block can provide function call events.



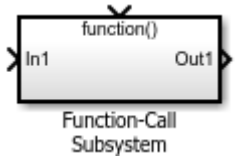
A function-call subsystem is analogous to a function in a procedural programming language. Invoking a function-call subsystem executes the output methods of the blocks within the subsystem in sorted order. For an explanation of Function-Call Subsystem blocks parameters, see Subsystem, Atomic Subsystem, Nonvirtual Subsystem, CodeReuse Subsystem

Creating a Function-Call Subsystem

To create a function-call subsystem:

1. Add an Function-Call Subsystem block to your model.

   - Copy a block from the Simulink Ports & Subsystems library to your model.
   - Click the model diagram, start typing `function-call`, and then select Function-Call Subsystem.



2. Set initial and disabled values for the Outport blocks. See "Conditional Subsystem Initial Output Values" on page 10-33 and "Conditional Subsystem Output Values When Disabled" on page 10-52.
3. Set how subsystem states are handled when executed.

   Open the subsystem block, and then open the block parameters dialog box for the Trigger block. From the **States when enabling** drop-down list, select:

   - `held` — States maintain their most recent values.
   - `reset` — States set to their initial conditions.
   - `inherit` — Use the held or reset setting from the parent subsystem initiating the function-call.

   For nested subsystems whose Function-Call Subsystem blocks have different parameter settings, the settings for the child subsystem override the settings inherited from the parent subsystem.
4. Attach a function-call initiator to the function-call input port.

   If you attach an Inport block, open the block, select the Signal Attributes pane, and then select the **Output function call** check box.

You can also create a function-call subsystem from scratch. First, add a Subsystem block in your model, and then add a Trigger block in the subsystem. Next, open the Trigger block dialog box and set the **Trigger type** to `function-call`.

Sample Time Propagation in a Function-Call Subsystem

Configure a Function-Call Subsystem block by setting the **Sample time type** of its Trigger port block to `triggered` or `periodic`.

- A triggered function-call subsystem can execute zero, one, or multiple times during a time step.

  If a function-call subsystem is triggered by a root Inport block with a discrete sample time, multiple function-calls during a time step are not allowed. To allow multiple function-calls, set **Sample time** to `-1`.

  You must set the sample time for all the blocks in a triggered function-call subsystem to inherited (`-1`).
- A periodic function-call subsystem executes once during a time step and must receive periodic function-calls. If the function-calls are aperiodic, the simulation stops and an error message is displayed.

  You can specify a noninherited sample time or inherited (`-1`) sample time. All blocks that specify a noninherited sample time must specify the same sample time. For example, if one block specifies `0.1` as the sample time, all other blocks must specify a sample time of `0.1` or `-1`. If function-calls are at a rate that differs from the sample time specified by the blocks in the subsystem, the simulation stops and an error message is displayed.

Note During range checking, the minimum and maximum parameter settings are back-propagated to the actual source port of the function-call subsystem, even when the function-call subsystem is not enabled.

To prevent this back propagation:

1. Add a Signal Conversion block and a Signal Specification block after the source port.
2. Set the **Output** of the Signal Conversion block to `Signal copy`.
3. Specify the minimum and maximum values for the Signal Specification block instead of specifying them on the source port.

Conditional Subsystem Initial Output Values

In this section...

To initialize the output values of a conditional subsystem, initialize its Outport blocks by using one of these methods:

- Inherit initial output values from input signals.
- Specify initial output values using Outport block parameters.

Note If the conditional subsystem is driving a Merge block in the same model, you do not need to specify an initial condition for the subsystem Outport block.

Inherit Initial Output Values from Input Signals

By default, Simulink uses subsystem input signals to initialize output values to Output port blocks. Other valid sources for initial output values are:

- Output ports from another conditionally executed subsystem
- Output ports from a Model block with a Trigger block set to function-call
- Merge blocks
- Constant blocks
- IC (initial condition) blocks
- Simulink signal object attached to the signal line connected to the Output block. If the `InitialValue` parameter is defined, Simulink uses this value.
- Stateflow chart

If the input signal is from a block that is not listed here, the Outport block uses the default initial value of the output data type.

To Specify output values with input signals:

1 Open the dialog box for an Outport block in a conditional subsystem.

2 From the **Source of initial output value** drop-down list, select `Input signal`.

Note If you are using classic initialization mode, selecting `Input signal` causes an error. To inherit the initial output value from an input signal, set the **Source of initial output value** parameter to `Dialog`, set **Outut when disabled** to `held`, and set **Initial output** to the empty matrix `[]`.

Specify Initial Output Values

Explicitly set the initial output values in cases where you want to:

- Test the behavior of a model with various initial values.
- Set initial values to steady state and reduce simulation time.
- Eliminate having to trace input signals to determine the initial output values.

To specify initial output values:

1 Open the dialog box for an Output block in a conditional subsystem.
2 From the **Source of initial output value** drop-down list, select `Dialog`.
3 In the **Initial output** box, enter the initial value.

Explicitly

Explicitly Schedule Execution of Subsystems and Models

In this section...

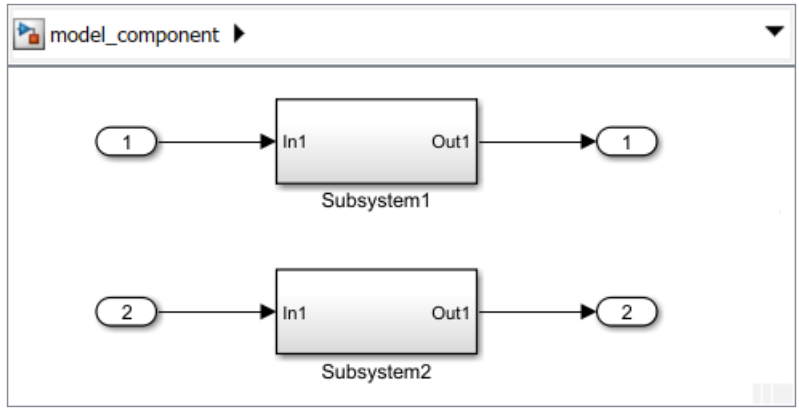
You can control the execuition of model components by using export-function models or rate-based models. Benefits of scheduling components are :

- Full control over secheduling of model components rather than letting Simulink implicitly schedule the components.
- No need to deal with data dependency issues between components. That is, there are only data transfers.

This topic describes how to create a rate-based model with explicitly scheduled subsystems, reference the model in a test model, and then add periodic event ports to the test model for simulation. For information about using export-function models, see“Export-Function Models” on page 10-76.

Create Rate-Based Model

This example starts with two subsystems. Subsystem1 multiples its input by 2 while Subsystem2 multiples its input by 4. Using Continuous time blocks such as Intergrator blocks are not allowed. Instead use discrete time equivalent blocks.



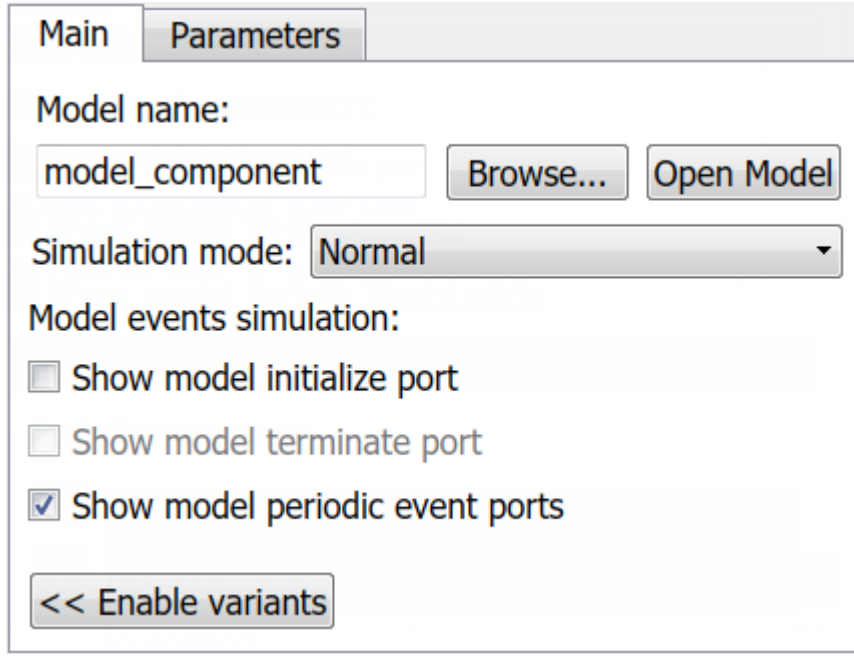
1. Open the Inport 1 dialog box. On the Signal Attributes tab, set the **Sample time** to `0.2`.
2. Open the Inport 2 dialog box. On the Signal Attributes tab, set the **Sample time** to `0.4`.
3. If a rate-based model has multiple rates, single tasking is not allowed. Select the Configuration Parameter check box for **Treat each discrete rate as a separate task**.

Create Test Model That References a Rate-Based Model

Testing a rate-based model includes referencing the model from a Model block in a test model, adding periodic event ports to the Model block, and then connecting function-calls to the ports.

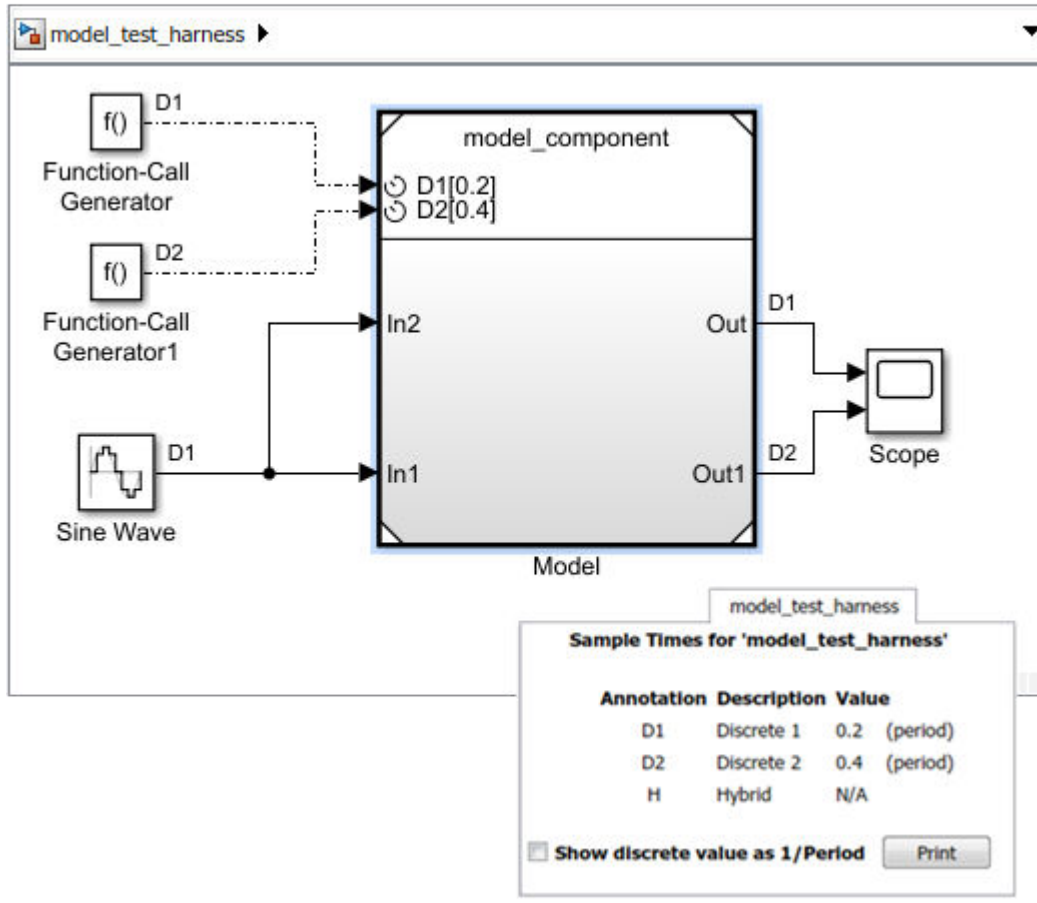
1. Create a new Simulink model.
2. Add a Model block and open the block parameters dialog box.
3. In the **Model name** box, enter the file name for the rate-based model.
4. Select the **Show model periodic event ports** check box.

   Periodic event ports are added to the Model block with the **Sample times** you specified for the Inport blocks connected to the Subsystem blocks.



5 Specify the execution rate using function-call initiators (Function-Call Generator blocks or Stateflow charts). The function-call events and scheduling of the events are located outside of the Model block referencing the rate-based model.

In this example, add Function-Call Generator blocks. Open the block dialog box for the blocks and specify **Sample time**.



Subsystems or referenced models in a rate-based model with the same sample time must have a common rate initiator. This includes periodic scheduled subsystems and event driven Function-Call Subsystem blocks with the same rate.

6 Use a fixed-step solver for simulation. Set the Configuration Parameters **Type** to `Fixed-step`, Solver to `auto`, and **Fixed-step size** to `auto`.

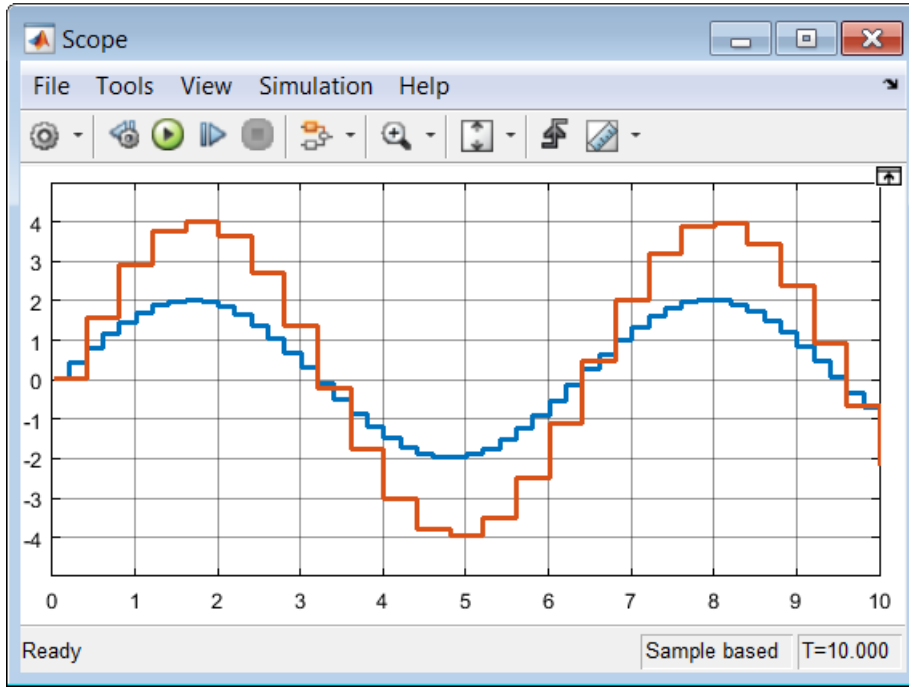
Simulate Rate-Based Model

Simulate the behavior of a rate-based model from the test model.

1 Run a simulation. Some common compile and run time errors are cause by:

- A periodic event port that is not connected to a function-call initiator with the same specified sample time.
- A scheduled Inport block (**Sample time** parameter set to a value) in the referenced component model that doesn't specify one of the periodic event port rates (sample times specified in the **Port discrete rates** table).

2 Observe the behavior of the component model. Open the Scope block.

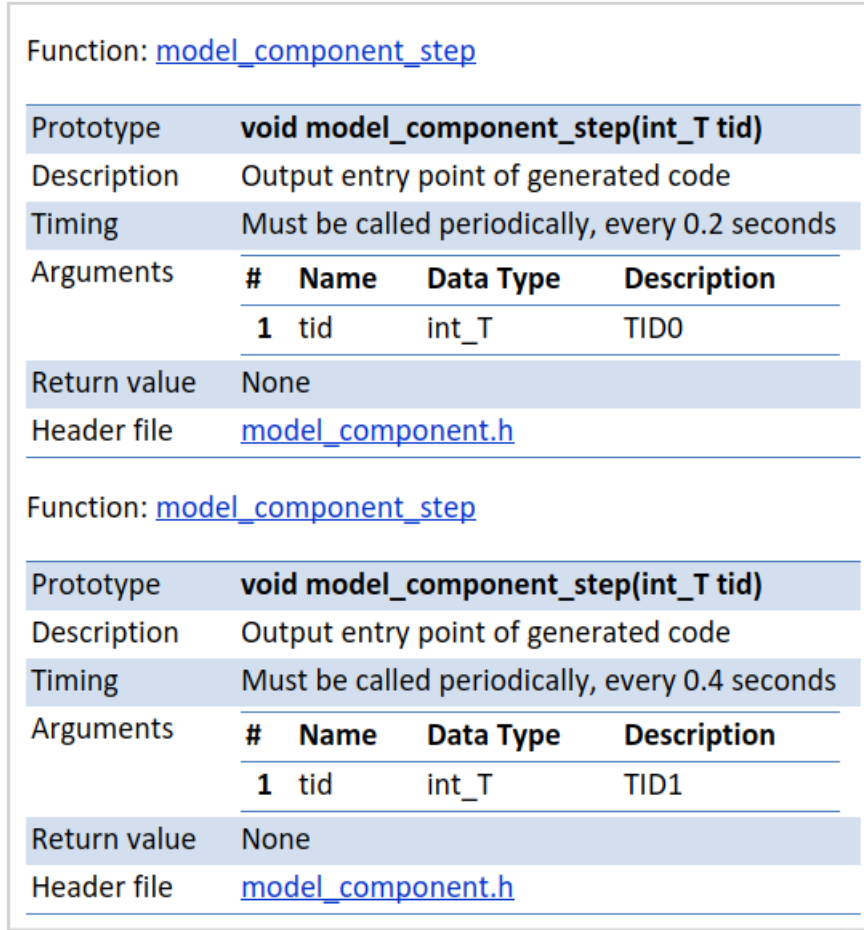


Generate Code from Rate-Based Model

Generate code from the rate-based model, not from the model test harness. For scheduled subsystems with different discrete rates, multi-tasking is required and the resulting code has separate entry points.

1 Generate code for the component model. From the menu, select Code > C/C++ Code > Build Model

2 Open the code generation report. From the menu, select Code > C/C++ Code > Code Generation Report > Open Model Report.



Function: model_component_step

Prototype	**void model_component_step(int_T tid)**
Description	Output entry point of generated code
Timing	Must be called periodically, every 0.2 seconds

More About

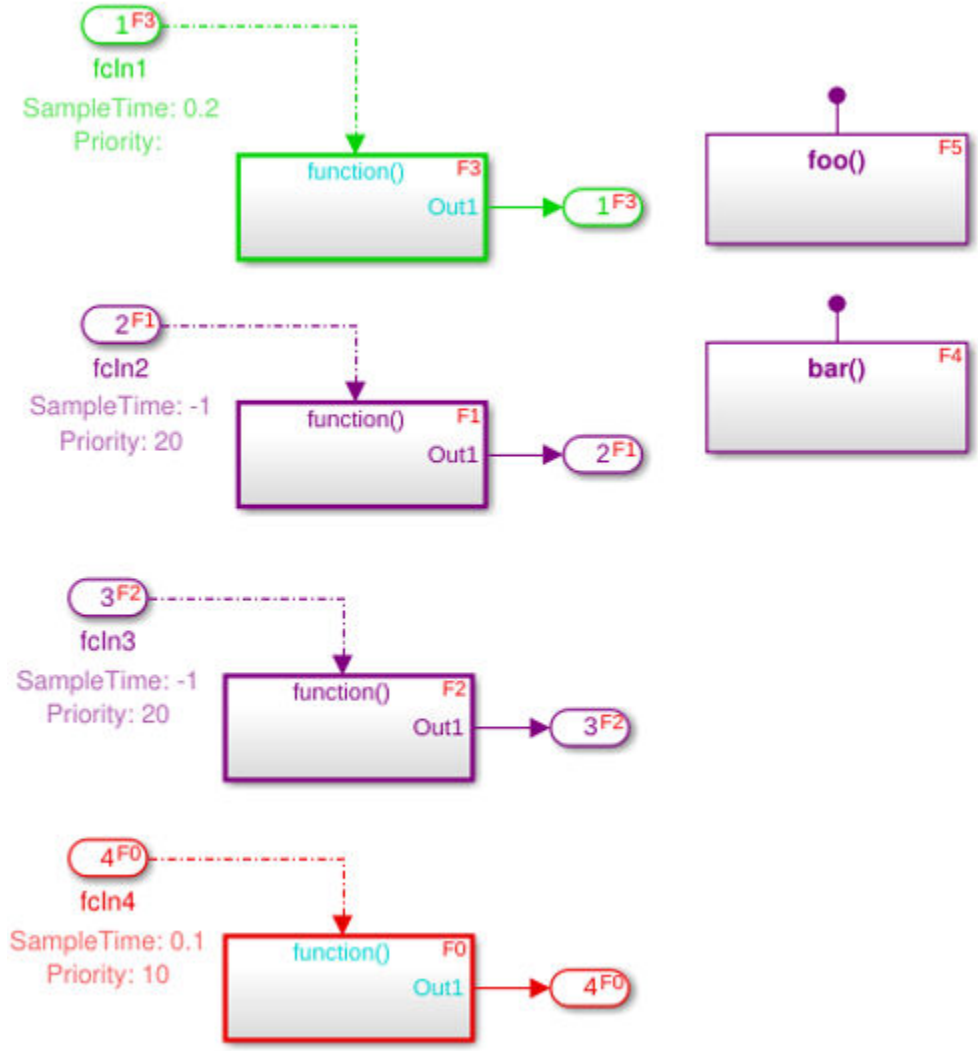
- “Sorting Rules for Scheduled Components” on page 10-42

Sorting Rules for Scheduled Components

Simulink determines the sorted order for model components (subsystems and referenced models).

Export-Function Models

Export-Function Models include Function-Call Subsystem blocks, function-call models, and S-Function blocks invoked by function-call root Inport blocks. Also, Simulink Function blocks at the root level.



Root function-call Inport blocks are sorted with the following rules:

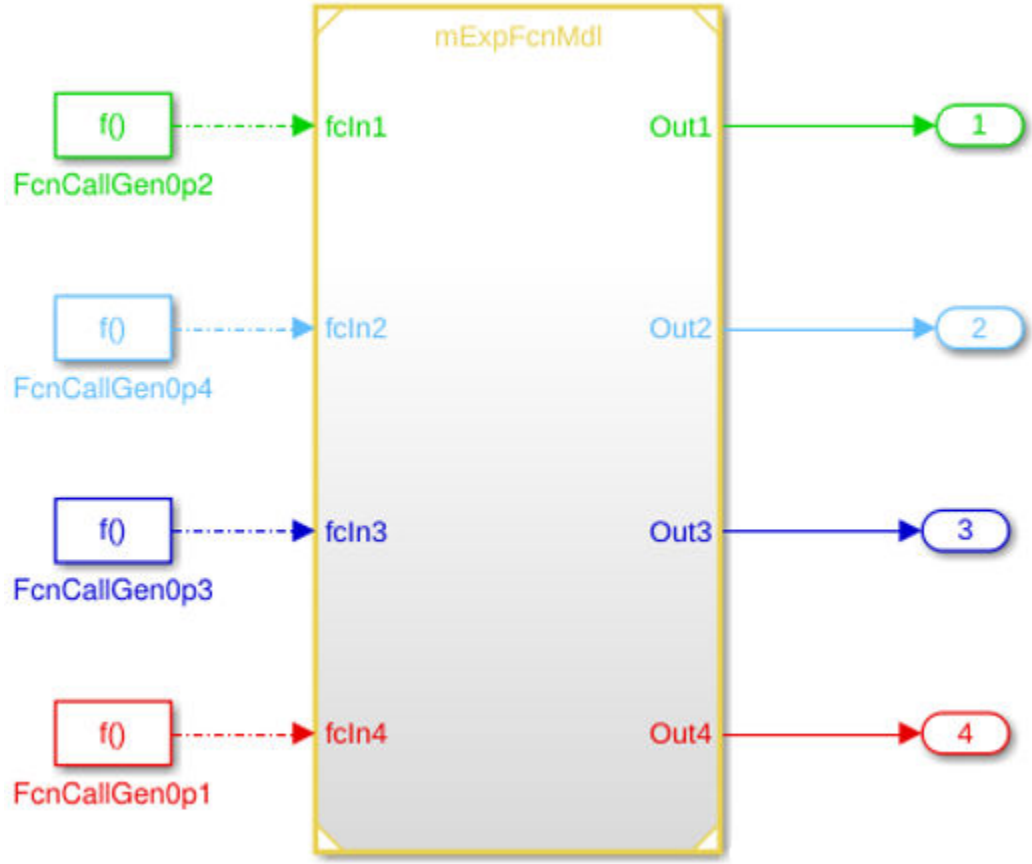
- First compare block priorities. The block with the highest priority (a small value) is sorted before the others.

- If block priorities are the same, compare their sample times. The block with a faster rate (a smaller sample time value) is sorted before the other.
- If the sample times are the same, compare the Input port numbers. The block with the smaller port number is sorted before the other.

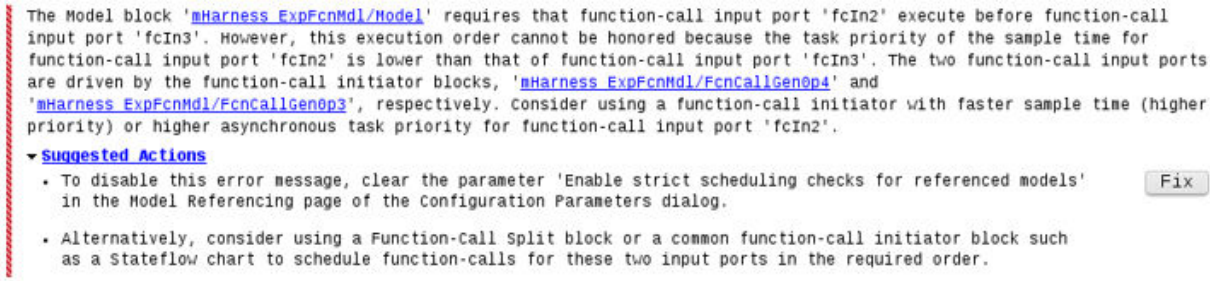
Root Simulink Function blocks are sorted after root function-call Inport blocks.

Test Harness for ExportFunction Models with Strick Scheduling

Reference the export-function model in a test harness and connect ports to Function Generator blocks.

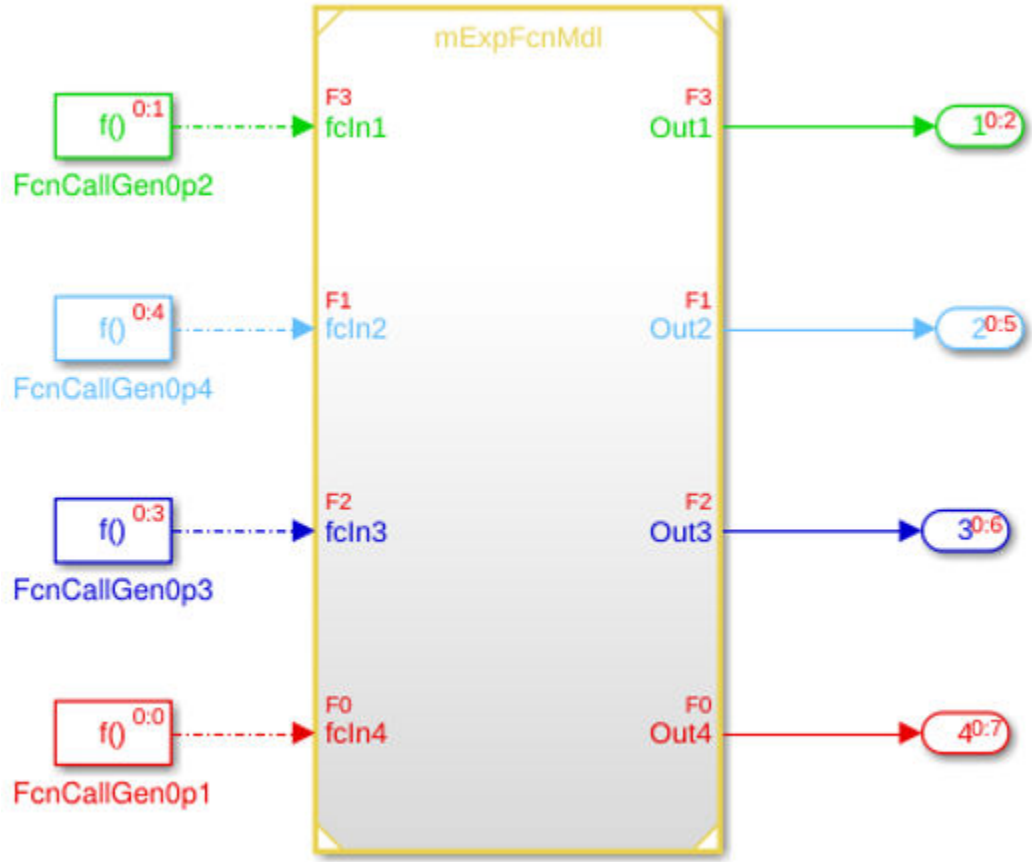


If you select the Configuration Parameter **Enable strick scheduling checks for a referenced model**, both compile time and run time checks ensure initiators will invoke function-calls based on the pre-defined scheduling order. Initiators are sorted based on their sample time priorities. For this example, the scheduling order and the sample time priorities do not match. The model mharness_ExpFcnMdl displays an error.



Test Harness for Export-Function Models without Strick Scheduling

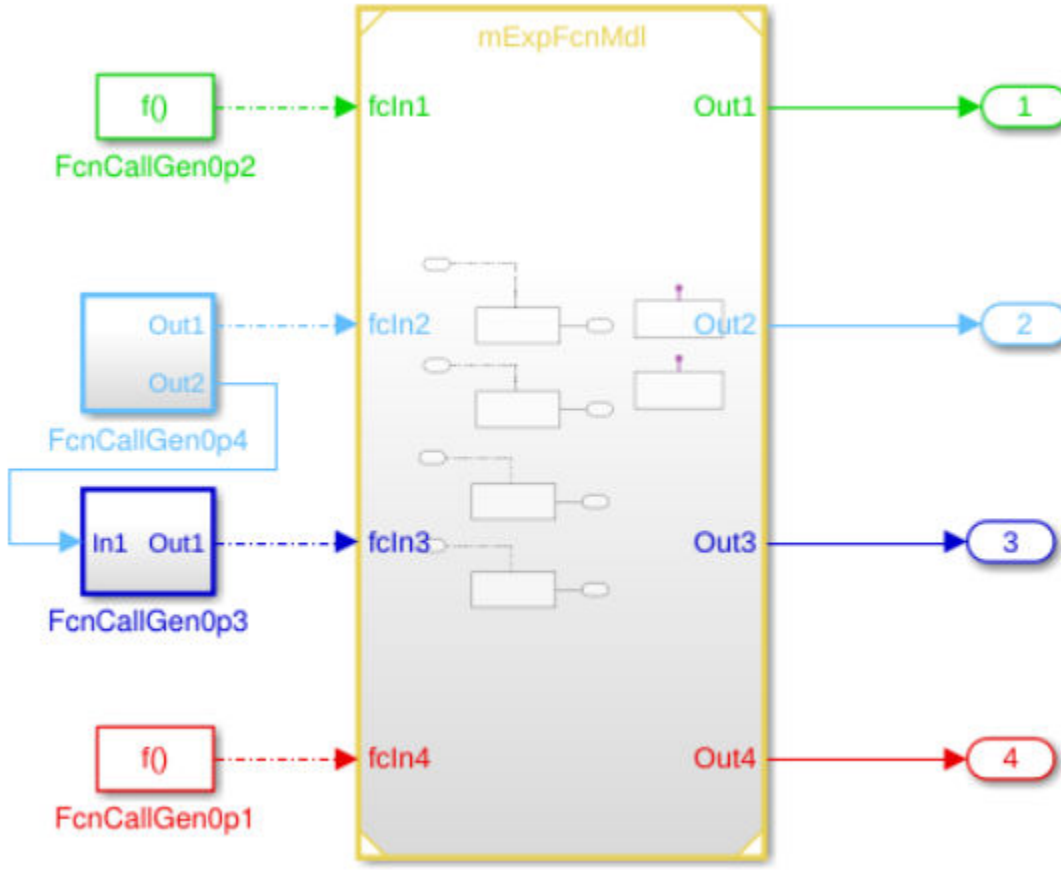
Reference the export-function model in a test harness and connect ports to Function Generator blocks.



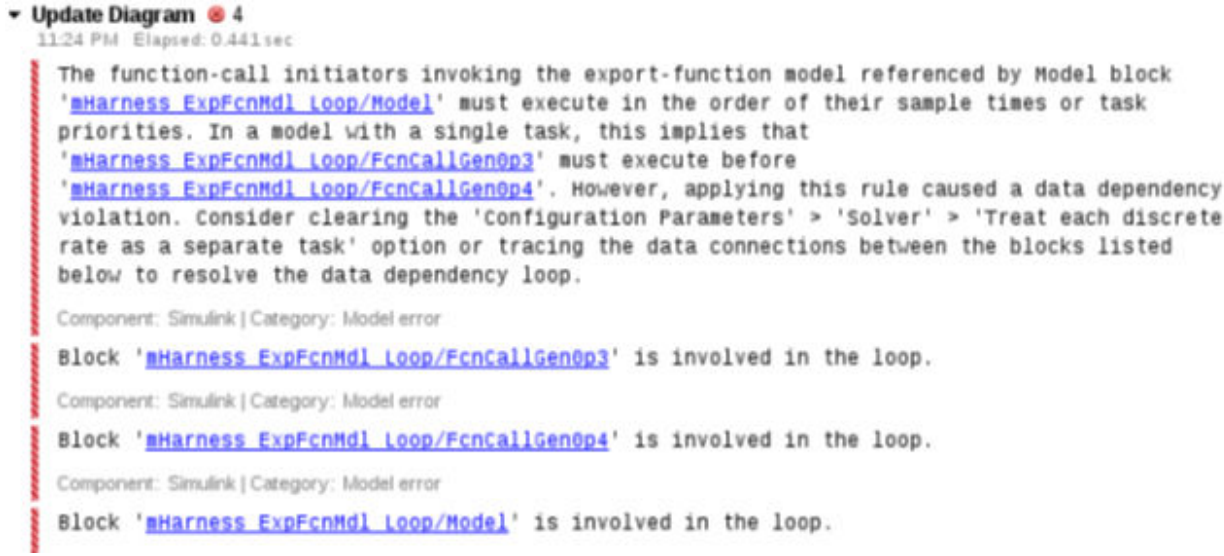
If you clear the Configuration Parameter **Enable strick scheduling checks for a referenced model** and the test harness model is in signal taking mode. The function-call initiators are sorted based on their sample time priorities. For this example, the sorted order is `FcnCallGen0p1` > `FcnCallGen0p2` > `FcnCallGen0p3` > `FcnCallGen0p1`.

Data Dependency Error Caused by Data Sorting Rules

Condider a model where the output from one function-call initiator is the input to another.



The function-call initiator `FcnCallGen0p3` should be sorted before `FcnCallGen0p4`. However, because `FcnCallGen0p4` is also a source for `FcnCallGen0p3` a data dependency occurs and Simulink displays an error.



Test Harness for Models with Initialize, Reset, and Terminate Function Blocks

If a Model block references a model that has initialize, reset, or terminate ports, the function-call initiators connected to these ports have a higher prority than other function-call input ports. For example, export-function models, rate-based models, and JMAB-B models can have other function-call input ports. Simulink sorts function-call intiators in the follow order:

- Initialize, reset, and then terminate ports.
- lf there is more than one reset port, initiators to those reset ports are not sorted. For example, if a model has one initialize port driven by block `A`, two reset ports driven by blocks `B` and `C`, and one terminate port driven by block `D`, then Simulink sorts in the order A, B or C, and then D. B and C are sorted using general sorting rules.

Initiators for a Model Block in a Test Harness

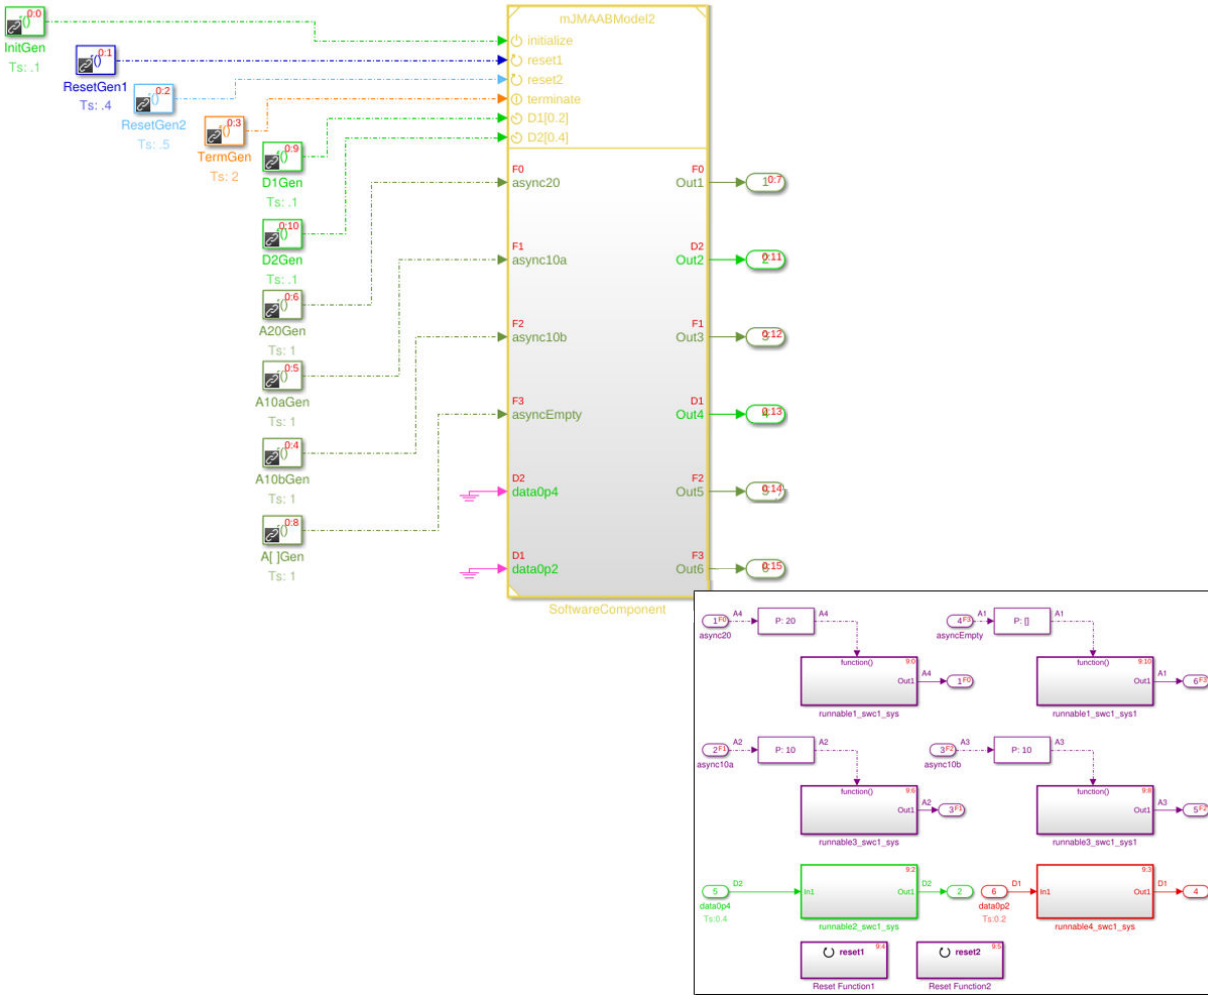
Add event ports to a Model block in a test harness that references a rate-based model or JMAAB-B model by selecting the Model block parameter **Show model periodic event ports**.

In a single tasking model, all discrete rates are in the same task. In a multi-tasking model, discrete rates with the same value execute in the same task. Simulink sorts test harness initiators in the same task in the following order:

- Initialize, reset, and then terminate ports.
- Function-call input ports mapped to asynchronous function-call root Inport blocks if adapted model is a JMAAB-B model. Among those "async" function-call input ports, use the task priotiries specified by the Asychronous Task Specification block connected to the function-call root Inport block inside the referenced model to compare ports. In the follow cases, do not compare ports:
  - For two 'async" function-call input ports with the same task priotity.
  - For 'async" function-call input ports with an empty (unspecified) task priority
- Periodic event input ports mapped to discrete rates. Use rate monotonic scheduling (RMS) rules to compare.

In a single tasking model, all initiators are in the same task:

- `InitGen` > `ResetGen1` or `ResetGen2` > `TermGen` > `A10aGen` or `A10bGen` or `A[]Gen` > `D1Gen` > `D2Gen`
- `A10aGen` or `A10bGen` > `A20Gen`
- Could swap relative ordering of (`ResetGen1`, `ResetGen2`) or (`A10aGen`, `A10bGen`), or (`A[]Gen`, `A20Gen`), etc.



In a multi-tasking model, initiators of the same color are in the same task.

- InitGen > D1Gen > D2Gen
- A10aGen or A10bGen > A20Gen

Conditional Subsystem Output Values When Disabled

Although a conditional subsystem does not execute while it is disabled, the output signal is still available to other blocks. When a conditional subsystem is disabled and you have specified to not inherit initial conditions from an input signal, you can hold the subsystem outputs at their previous values or reset them to their initial conditions.

To specify output values when disabled:

1. Open the dialog box for an Outport block in a conditional subsystem.
2. From the **Source of initial output value** drop-down list, select `Dialog`.
3. From the **Output when disabled** drop-down list, select one of these options:
   - `held` — Maintain the most recent value.
   - `reset` — Use the initial condition when enabled.

   Note If you are connecting the output of a conditionally executed subsystem to a Merge block, set **Output when disabled** to `held` to ensure consistent simulation results.

   If you are using simplified initialization mode, you must select `held` when connecting a conditionally executed subsystem to a Merge block. For more information, see "Underspecified initialization detection".
4. In the **Initial output** box, enter the initial value.

Note If an Outport block in an Enabled Subsystem resets its output when disabled at a different rate from the execution of the subsystem contents, both the disabled and execution outputs write to the subsystem output. This behavior can cause unexpected results.

Simplified Initialization Mode

In this section...

Initialization mode controls how Simulink handles:

- Initialization values for conditionally executed subsystems.
- Initial values for Merge blocks.
- Discrete-Time Integrator blocks.
- Subsystem elapsed time.

The default initialization mode for a model is simplified. This mode uses enhanced processing to improve consistency of simulation results and helps to:

- Attain the same simulation results with the same inputs when using the same blocks in a different model.
- Avoid unexpected changes to simulation results as you modify a model.

When to Use Simplified Initialization

Use simplified initialization mode for models that contain one or more of the following blocks:

- Conditional subsystem blocks.
- Merge blocks. If a root Merge block has an empty matrix (`[]`) for its initial output value, simplified mode uses the default ground value of the output data type.
- Discrete-Time Integrator blocks. Simplified mode always uses the initial value as both the initial and reset value for output from a Discrete-Time Integrator block.

Use simplified mode if your model uses features that require simplified initialization mode, such as:

- Specify a structure to initialize a bus.
- Branch merged signals inside a conditional subsystem.

Set Initialization Mode to Simplified

Simplified mode is the default initialization mode when creating a new Simulink model. If your model is using classic mode, you might need to make changes after you select simplified mode. See “Convert from Classic to Simplified Initialization Mode” on page 10-74.

1. Open the Configuration Parameters dialog box.
2. In the search box, enter **Underspecified initialization detection**.
3. From the drop-down list, select `Simplified`.

More About

- “Conditional Subsystems” on page 10-3

Classic Initialization Mode

In this section...

When to Use Classic Initialization

Initialization mode controls how Simulink handles the initialization values for conditionally executed subsystems.

`Classic` mode was the default initialization mode for Simulink models created in R2013b or before. You can continue to use classic mode if:

- The model does not include any modeling elements affected by simplified mode.
- The behavior and requirements of simplified mode do not meet your modeling goals.
- The work involved in converting to simplified mode is greater than the benefits of simplified mode. See “Convert from Classic to Simplified Initialization Mode” on page 10-74.

Set Initialization Mode to Classic

To set classic initialization mode:

1. Open the Configuration Parameters dialog box.
2. In the search box, enter **Underspecified initialization detection**.
3. From the drop-down list, select `Classic`.

Classic Initialization Issues

Using classic initialization mode can result in one or more of the following issues. You can address these issues by using simplified mode. The description of each issue includes

an example of the behavior in classic mode, the behavior when you use simplified mode, and a summary of the changes you must make to use simplified mode.

- "Identity Transformation Can Change Model Behavior" on page 10-57.

  Conditional subsystems that include identical subsystems can display different initial values before the first execution if both of these apply:

  - The model uses classic initialization mode.
  - One or more of the identical subsystems outputs to an identity transformation block.
- "Discrete-Time Integrator or S-Function Block Can Produce Inconsistent Output" on page 10-61

  Conditional subsystems that use classic initialization mode and whose output connects to a Discrete-Time Integrator block or S-Function block can produce inconsistent output.
- "Sorted Order Can Affect Merge Block Output" on page 10-64

  The sorted order of conditional subsystems that used classic mode initialization, when connected to a Merge block, can affect the output of that Merge block. A change in block execution order can produce unexpected results.
- When you rename the Merge block source subsystem blocks, the initial output of the Merge block can change.

  When two or more subsystems are feeding different initial output values to a Merge block that does not specify its own initial output value, renaming one of the subsystems can affect the initial output of the Merge block in classic initialization mode.

For additional information about the tasks involved to convert a model from classic to simplified mode, see "Convert from Classic to Simplified Initialization Mode" on page 10-74.

Identity Transformation Can Change Model Behavior

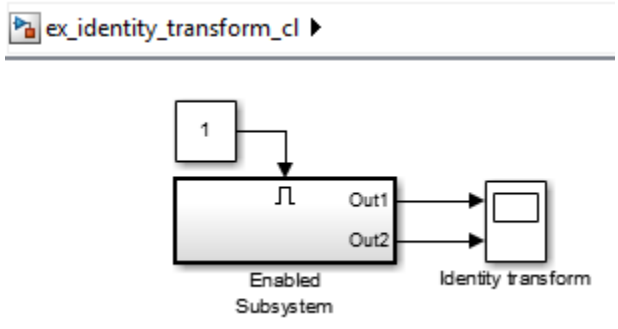
Conditional subsystems that include identical subsystems can display different initial values before the first execution if both of these apply:

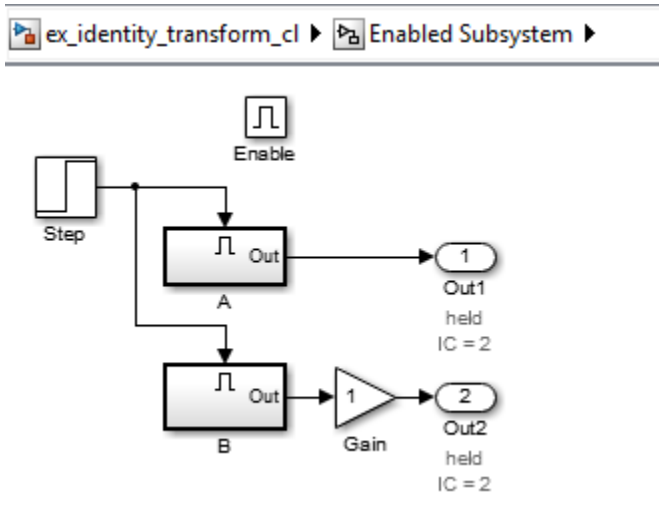
- The model uses classic initialization mode.

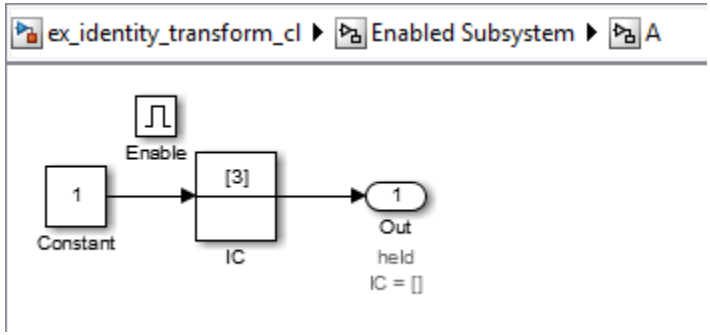
- One or more of the identical subsystems outputs to an identity transformation block.

An identity transformation block is a block that does not change the value of its input signal. Examples of identify transform blocks are a Signal Conversion block or a Gain block with a value of 1.

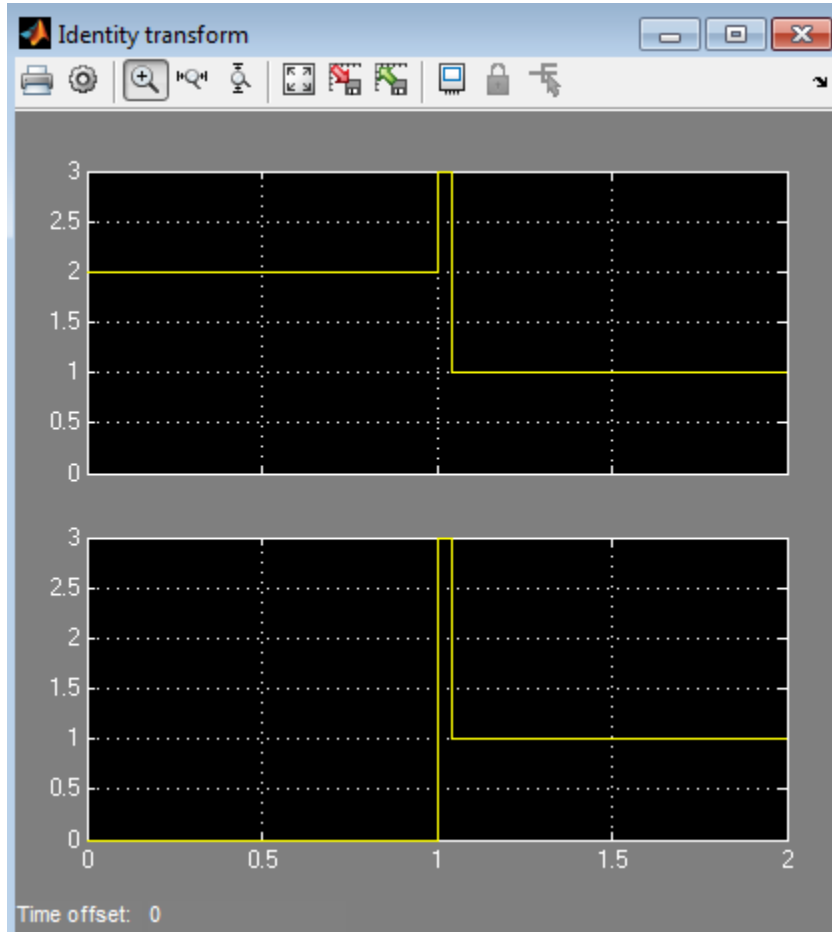
In the `ex_identity_transform_cl` model, subsystems A and B are identical, but B outputs to a Gain block, which in turn outputs to an Outport block.







When you simulate the model, the initial value for A (the top signal in the Scope block) is 2, but the initial value of B is 0, even though the subsystems are identical.

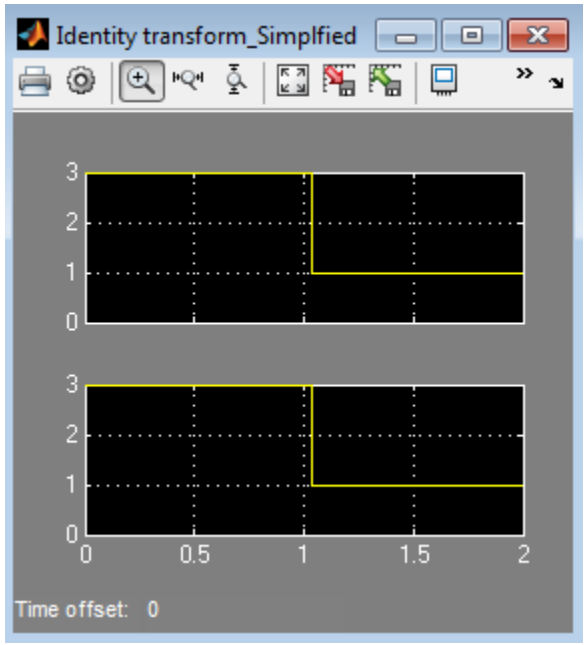


If you update the model to use simplified initialization mode (see `ex_identity_transform_simpl`), the model looks the same. The steps required to convert `ex_identity_transform_cl` to `ex_identity_transform_simpl` are:

1. Set **Underspecified initialization detection** to `Simplified`.
2. For the Outport blocks in subsystems A and B, set the **Source of initial output value** parameter to `Input signal`.

   You can also get the same behavior by setting the **Source of initial output value** parameter to `Dialog` and the **Initial output** parameter to `3`.

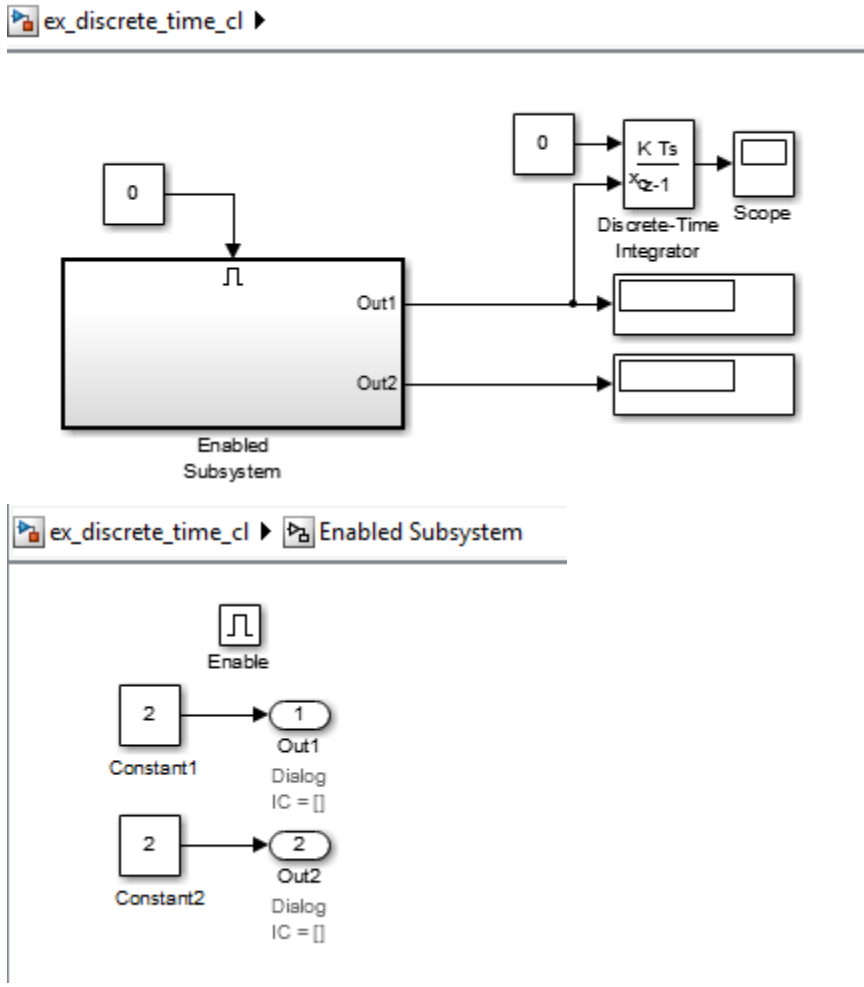
When you simulate the updated model, the connection of an identity transformation does not change the result. The output is consistent in both cases.



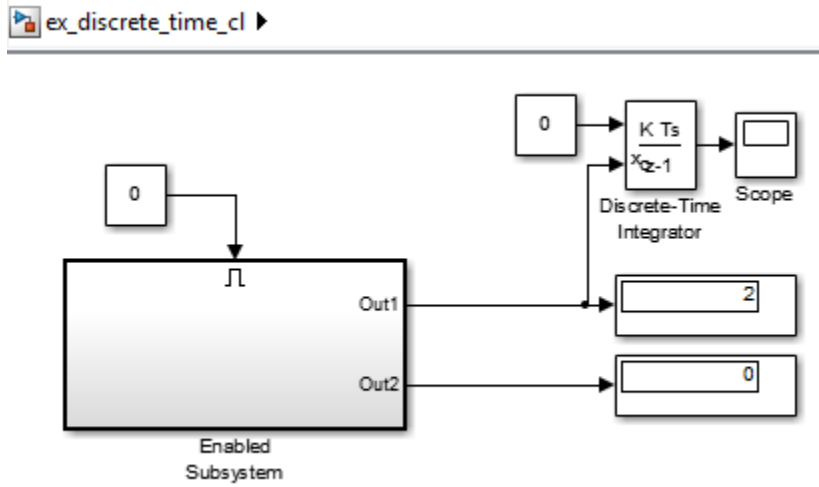
Discrete-Time Integrator or S-Function Block Can Produce Inconsistent Output

Conditional subsystems that use classic initialization mode and whose output connects to a Discrete-Time Integrator block or S-Function block can produce inconsistent output.

In the `ex_discrete_time_cl` model, the enabled subsystem includes two Constant blocks and outputs to a Discrete-Time Integrator block. The enabled subsystem outputs to two Display blocks.



When you simulate the model, the two display blocks show different values.



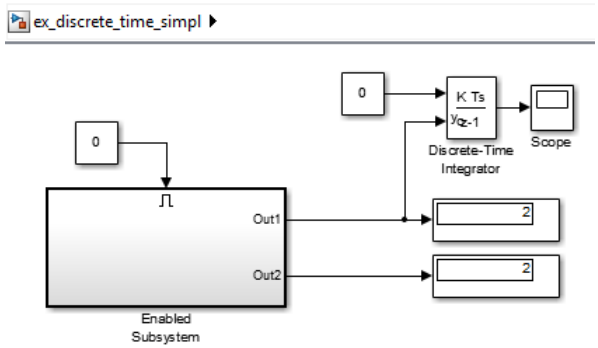
The Constant1 block, which is connected to the Discrete-Time Integrator block, executes, even though the conditional subsystem is disabled. The top Display block shows a value of 2, which is the value of the Constant1 block. The Constant2 block does not execute, so the bottom Display block shows a value of 0.

If you update the model to use simplified initialization mode (see `ex_discrete_time_simpl`), the model looks the same. The updated model corrects the inconsistent output issue by using simplified mode. The steps required to convert `ex_discrete_time_cl` to `ex_discrete_time_simpl` are:

1. Set **Underspecified initialization detection** to `Simplified`.
2. For the Outport blocks Out1 and Out2, set the **Source of initial output value** parameter to `Input signal`. This setting explicitly inherits the initial value, which in this case is 2.

   You can also get the same behavior by setting the **Source of initial output value** parameter to `Dialog` and the **Initial output** parameter to `2`.

When you simulate the updated model, the Display blocks show the same output. The output value is 2 because both Outport blocks inherit their initial value.

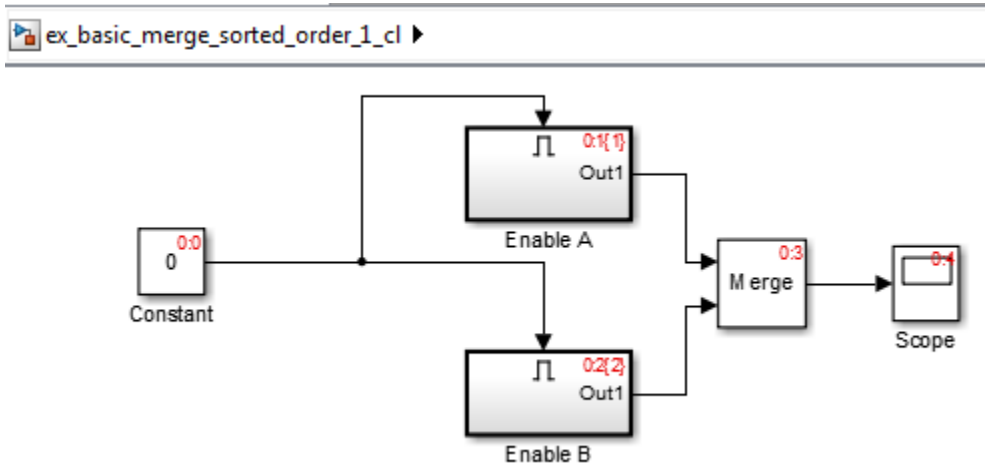


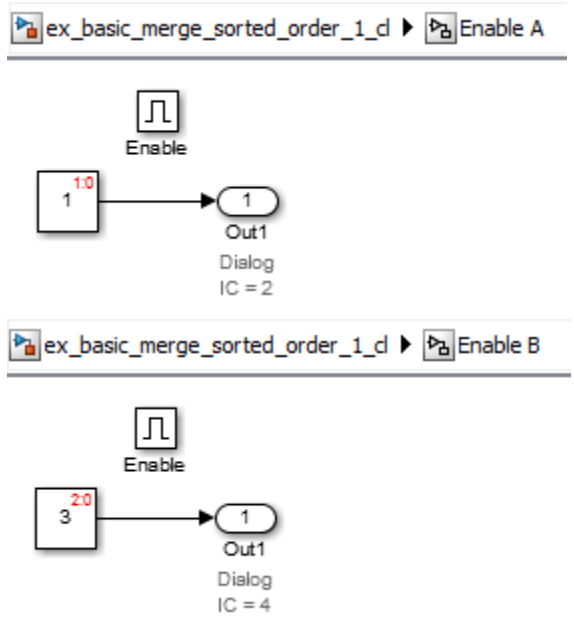
Sorted Order Can Affect Merge Block Output

The sorted order of conditional subsystems that used classic mode initialization, when connected to a Merge block, can affect the output of that Merge block. A change in block execution order can produce unexpected results. The behavior depends on how you set the **Output When Disabled** parameter.

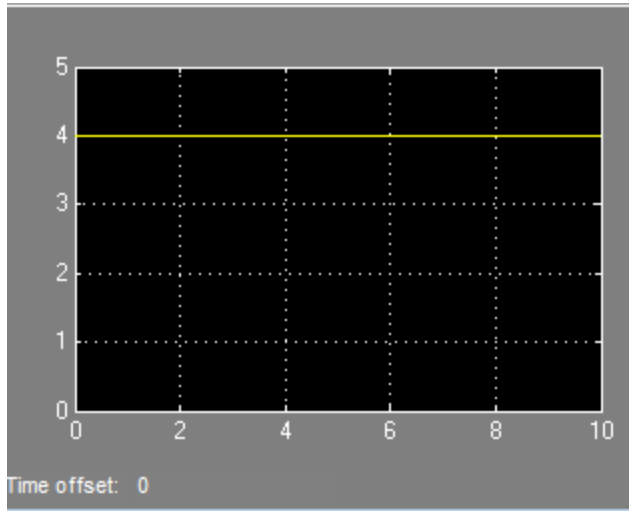
Example Using Default Setting for the Output When Disabled Parameter

The `ex_basic_merge_sorted_order_1_cl` model has two identical enabled subsystems (Enable A and Enable B) that connect to a Merge block. When you simulate the model, the red numbers show the sorted execution order of the blocks.



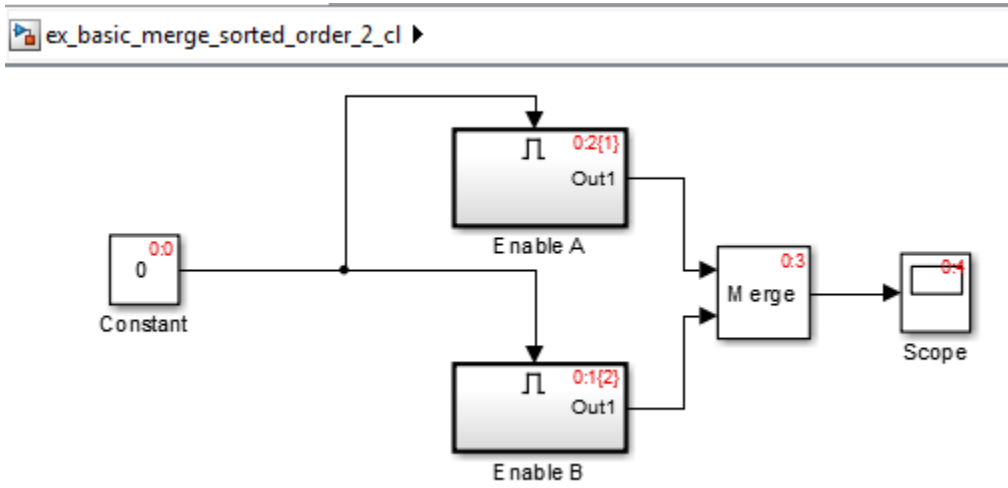


When you simulate the model, the Scope block looks like this:

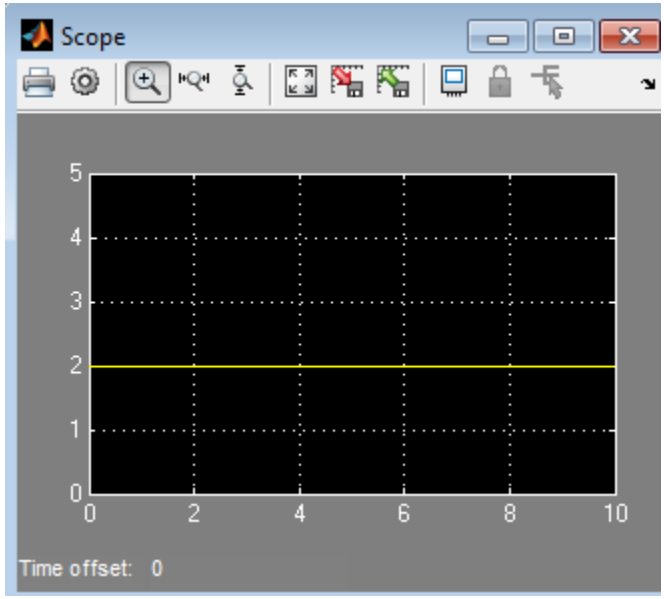


The `ex_basic_merge_sorted_order_2_cl` model is the same as `ex_merge_sorted_1_cl`, except that the block execution order is the reverse of the default execution order. To change the execution order:

1. Open the Properties dialog box for the Enable A subsystem and set the **Priority** parameter to `2`.
2. Set the **Priority** of the Enable B subsystem to `1`.



When you simulate the model using the different execution order, the Scope block looks like this:

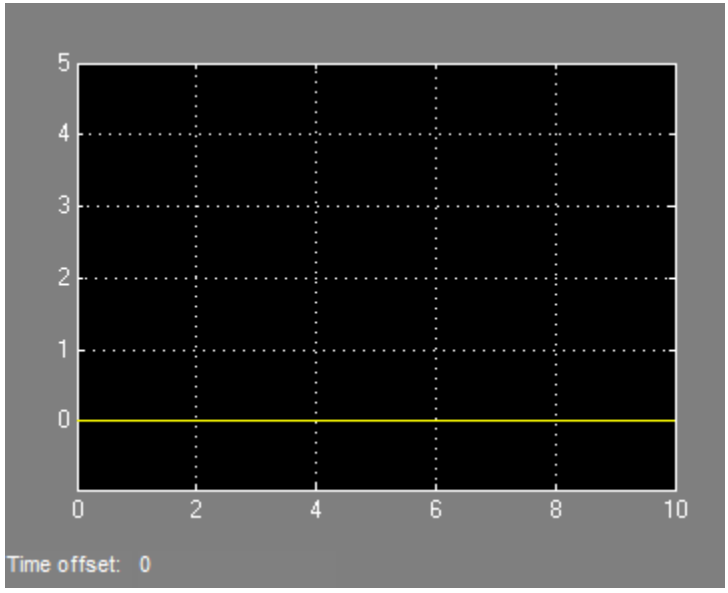


The change in sorted order produces different results from identical conditional subsystems.

To update the models to use simplified initialization mode, (see `ex_basic_merge_sorted_order_1_simpl` and `ex_basic_merge_sorted_order_2_simpl`):

1 Set **Underspecified initialization detection** to `Simplified`.

The **Initial Output** parameter of the Merge block is an empty matrix, `[]`, by default. Hence, the initial output value is set to the default initial value for this data type, which is 0. For information on default initial value, see “Initializing Signal Values” on page 64-17. When you simulate each simplified mode model, both models produce the same results.



Example Using Output When Disabled Parameter Set to Reset

The `ex_merge_sorted_1_cl` model has two enabled subsystems (Enable A and Enable B) that connect to a Merge block. When you simulate the model, the red numbers show the sorted execution order of the blocks.

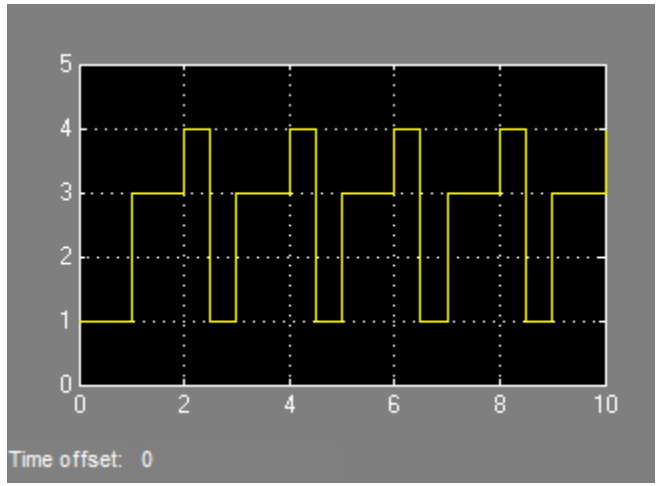
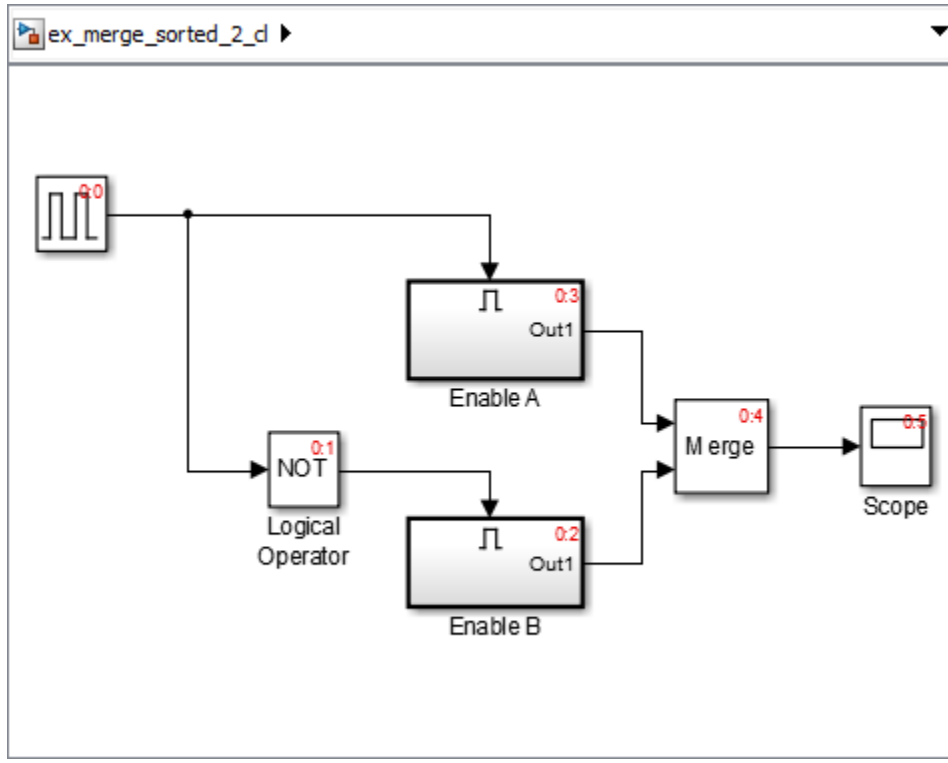
When you simulate the model, the Scope block looks like this:

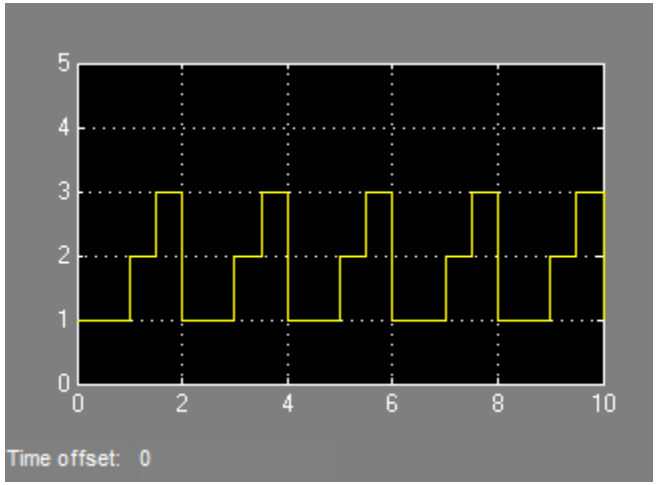


The `ex_merge_sorted_2_cl` model is the same as `ex_merge_sorted_1_cl`, except that the block execution order is the reverse of the default execution order. To change the execution order:

1. Open the Properties dialog box for the Enable A subsystem and set the **Priority** parameter to `2`.
2. Set the **Priority** of the Enable B subsystem to `1`.



When you simulate the model using the different execution order, the Scope block looks like this:



The change in sorted order produces different results from identical conditional subsystems.

To update the models to use simplified initialization mode (see `ex_merge_sorted_1_simpl` and `ex_merge_sorted_2_simpl`):

1. Set **Underspecified initialization detection** to `Simplified`.
2. For the Outport blocks in Enable A and Enable B, set the **Output when disabled** parameter to `held`. Simplified mode does not support `reset` for outports of conditional subsystems driving Merge blocks.

When you simulate each simplified mode model, both models produce the same results.

Convert from Classic to Simplified Initialization Mode

If you switch the initialization mode from classic to simplified mode, you can encounter several issues that you must fix. For most models, the following approach helps you to address conversion issues more efficiently.

1. Save the existing model and simulation results for the model.

   Because you might need to make several changes to your model during the conversion process, it is helpful to have the original model for reference and for comparing simulation results.
2. Simulate the model and address any warnings.
3. In the Model Advisor, in the Simulink checks section, run the checks in the folder "Migrating to Simplified Initialization Mode Overview".
4. Address the issues that Model Advisor identifies.
5. Simulate the model to make sure that there are no errors.
6. Rerun the Model Advisor checks in the folder "Migrating to Simplified Initialization Mode Overview" check to confirm that the modified model addresses the issues related to initialization.

For examples of models that have been converted from classic initialization mode to simplified initialization mode, see "Classic Initialization Issues" on page 10-56.

Blocks to Consider

Discrete-Time Integrator Blocks

Discrete-Time Integrator block behaves differently in simplified mode than it does in classic mode. The changes for simplified mode promote more robust and consistent model behavior. For details, see "Behavior in Simplified Initialization Mode" in the Discrete-Time Integrator block reference documentation.

Library Blocks

Simulink creates a library assuming that classic mode is in effect. If you use a library block that is affected by simplified mode in a model that uses simplified mode, then use the Model Advisor to identify changes you must make so that the library block works with simplified mode.

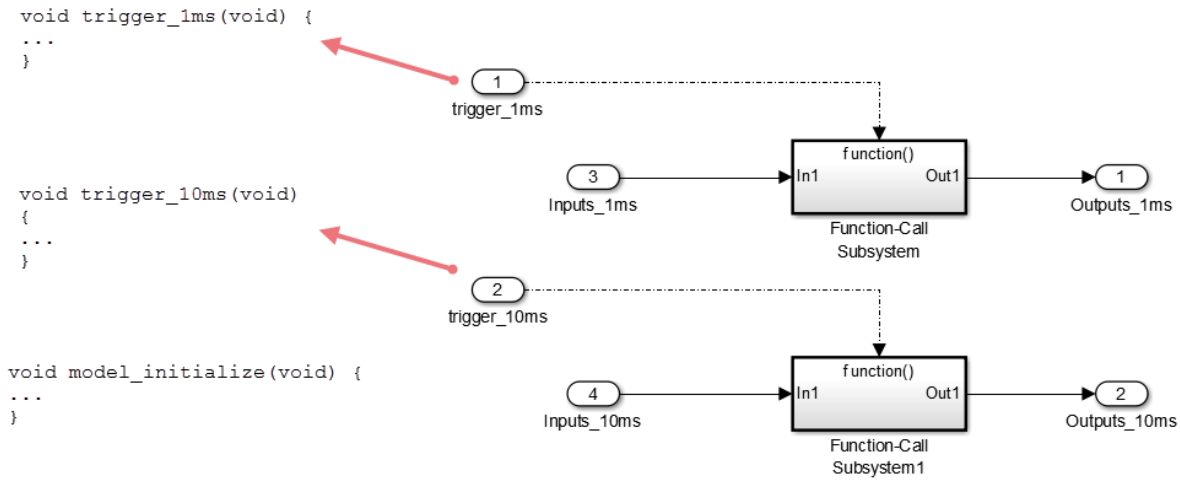
Export-Function Models

In this section...

About Export-Function Models

Simulink provides the capability to export functions from Simulink models that are invoked by controlling logic that is outside the model. Such models are called export-function models, and their functional blocks are made up exclusively of function-call subsystems, function-call model blocks or other export-function models. These blocks are invoked using function-call triggers passed via root-level Inport blocks. Execute these functions by providing model inputs through root-level Inport blocks or by referencing this model in a top model to invoke the function-calls. The execution of these functions is subject to the guidelines described in "Requirements for Export-Function Models" on page 10-77.

The figure shows an export-function model and the resulting generated functions.



Requirements for Export-Function Models

To set up a model to export functions, first meet these requirements. These requirements ensure that the executable components of the model are made up only of function-call blocks.

- The model solver must be a fixed-step discrete solver.
- Configure each root-level Inport block triggering a function-call subsystem to output a function-call trigger. These Inport blocks cannot be connected to an Asynchronous Task Specification block.
- Export-function models generate functions to be integrated with an external environment. Simulink does not generate a step function or a terminate function, and all blocks in these models must be executed in a function-call context. Thus, the model must contain only the following blocks at root level:
  - Function-call blocks, such as Function-Call Subsystem, S-functions, and Simulink Function blocks. Function-call Model blocks can be placed at the root-level only if their model parameter **Configuration Parameters > Solver > Tasking and sample time options > Periodic sample time constraint** is set to `Ensure sample time independent`.
  - Inport and Outport blocks

  - Blocks with a sample time of `Inf`
  - Merge and Data Store Memory blocks
  - Virtual connection blocks (Function-Call Split, Mux, Demux, Bus Creator, Bus Selector, Signal Specification, and any virtual subsystem that contains any of the blocks listed.)
- Blocks inside function-call subsystems must support code generation. These blocks can use absolute or elapsed time if they are inside a periodic function-call subsystem with a discrete sample time specified on the corresponding function-call root-level Inport block.
- Data signals connected to root-level Inport and root-level Outport blocks cannot be a virtual bus.
- Data logging and signal-viewer blocks, such as the Scope block, are not allowed at the root level and within the function-call blocks.

Sample Time for Function-Call Subsystems in Export-Function Models

There are two blocks for each function-call subsystem in export-function models where you must specify the sample time. These blocks are the function-call root-level Inport block and the Trigger block inside the function-call subsystem. The table shows how to specify these sample times.

	Function-call root-level Inport block with inherited sample time (`-1`) specified	**Function-call root-level Inport block with discrete sample time specified**

Trigger block of function-call subsystem has sample time type set to `Periodic`	Configuration not allowed.	Set sample time of Trigger block to inherited (`-1`) or the sample time of the function-call root-level Inport block. The subsystem executes at the specified rate. Periodic function-call run-time checks apply if the export-function model is used as a referenced model in normal simulation mode. These subsystems can contain blocks that use elapsed time (e.g., Discrete-Time Integrator) and blocks that use absolute time (e.g., Digital Clock). You cannot set the model configuration parameter **Fixed-step size (fundamental sample time)** to `auto`.
Trigger block of function-call subsystem has sample time type set to `Triggered`	No sample time specification.	No sample time specification. The subsystem executes at the specified rate. You cannot set the model configuration parameter **Fixed-step size (fundamental sample time)** to `auto`.

Sample Time in Top Model Function-Call Initiators

The blocks that output function-call signals to the function-call root-level Inport blocks of the export-function models are called function-call initiators. When a top model

references an export-function model, the blocks that supply the function-call inputs to the referenced model are the function-call initiators in the top model.

Top model function-call initiators that drive function-call blocks in the referenced export-function model can have different sample times. You can also mux function-call initiator blocks with different sample times before feeding them to the referenced export-function model. In the Solver pane of the Configuration Parameters dialog box, when you clear the **Treat each discrete rate as a separate task** check box, function-call initiator blocks with smaller sample times execute first.

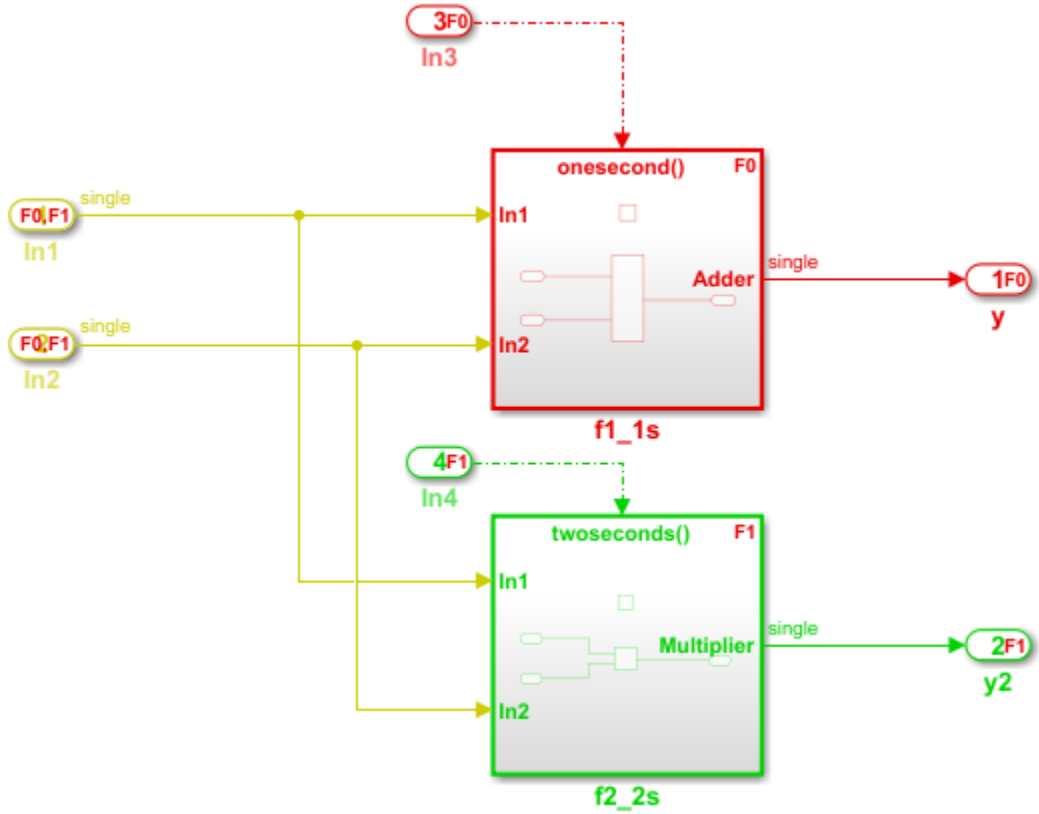
The sample time of function-call initiators must be an integer multiple of the sample time of the corresponding data inputs to the export-function model. The initiators must invoke a function-call subsystem in an export-function model at simulation times that are integer multiples of the sample time of the function-call root-level Inport block of the subsystem.

When you mux function-call initiator blocks in the top-level model, the function-call blocks they invoke do not receive the name of the initiator.

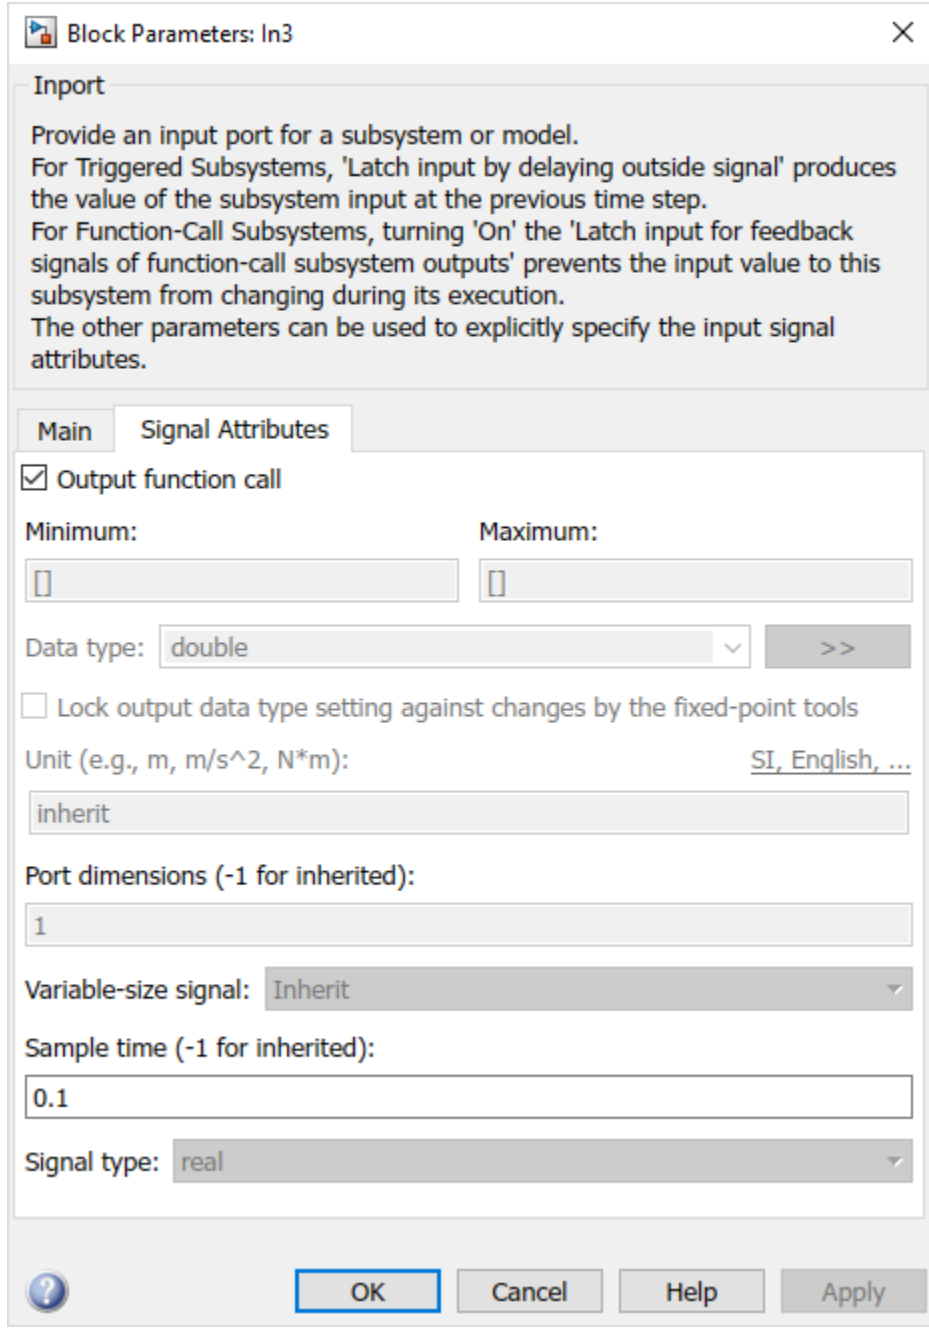
Control Export Function Scheduling Using Sample Time

You can use the sample time of each export function call in your model to control the scheduling of triggers. In the following example, the order of the function-call triggers is determined by the sample times of their corresponding export-function blocks.

In this example, the function calls are scheduled based on the sample time specified on the function-call port. Based on the color coded display, `onesecond` (F0) executes every `0.1` time steps while function `twoseconds` (F1) executes every `0.2` time steps.



You specify the sample time on the root-level function-call input ports.



Block Parameters: In3
Inport
Provide an input port for a subsystem or model.
For Triggered Subsystems, 'Latch input by delaying outside signal' produces the value of the subsystem input at the previous time step.
For Function-Call Subsystems, turning 'On' the 'Latch input for feedback signals of function-call subsystem outputs' prevents the input value to this subsystem from changing during its execution.
The other parameters can be used to explicitly specify the input signal attributes.
Main
Signal Attributes
Output function call
Minimum:
Maximum:
[]
[]
Data type:
double
>>
Lock output data type setting against changes by the fixed-point tools
Unit (e.g., m, m/s^2, N*m):

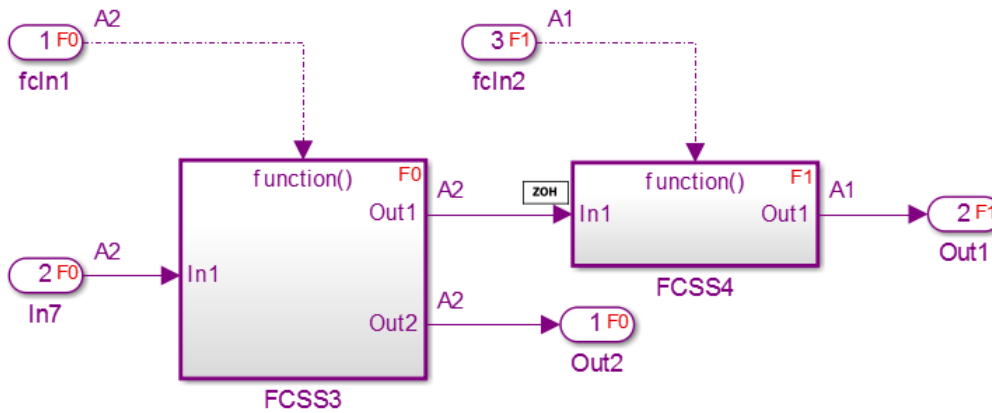
Apply

Using the sample time, you can have more fine-grained control over how function-call triggers are scheduled in your model.

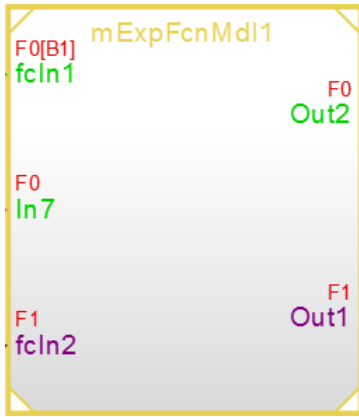
When two blocks have different values for the **Sample time** parameter, the block with the lower priority executes first. If the **Priority** parameter is equal, the block with the faster rate executes first. If **Priority** and sample time are the same for both of the blocks, the block with the lower port number executes first.

Execution Order for Function-Call Root-Level Inport Blocks

You can display the sorted execution order to interpret simulation results. This display has no impact on generated code. To display the sorted execution order, select **Display** > **Blocks** > **Sorted Execution Order**. In the following example, notice the sorted order for both the function-call triggers. Based on sorted order display labels, `fcIn1` (F0) executes before `fcIn2` (F1) when both have a sample hit at the same time step.



The referenced export-function model in the top model shows the local execution order of the Inport and Outport blocks in the model.



Simulink compares Inport block properties to determine their relative execution order. Simulink checks the block properties in this order:

1. Priority (lower priority executes first)
2. Sample time (smaller sample time executes first)
3. Port number (smaller port number executes first)

When two blocks have different values for the **Priority** parameter, the block with the lower priority executes first. If the **Priority** parameter is equal, the block with the faster rate executes first. If **Priority** and sample time are the same for both of the blocks, the block with the lower port number executes first. This example shows how relative execution order is calculated.

Note When the simulation mode of the top model is `Accelerator` or `Rapid Accelerator`, Simulink does not perform run-time checks for the execution order of function-call root-level Inport blocks inside referenced export-function models.

Example 10.1. Determine Relative Execution Order

Suppose that an export function model has five function-call root-level Inport blocks, A to E, with block properties as shown in the table. To determine their relative execution order, Simulink compares their sample times (if distinct and noninherited), **Priority** parameter, and port number, in order.

function-call root-level Inport	A	B	C	D	E
Priority	10	30	40	40	30
Sample Time	–1	0.2	0.1	0.1	–1
Port Number	5	4	3	2	1

Block A has the lowest priority of all five blocks. A executes first.

Using the same logic, B and E execute after A but before C and D. Since B and E have the same priority, Simulink compares their sample time to determine execution order. E has a sample time of `-1` (inherited), which is smaller than `0.2`, the sample time of B. E executes before B.

C and D have the same priority and the same distinct, noninherited sample times. The port number for D (2) is smaller than C (3), D executes before C.

The relative execution order of these Inport blocks, then, is A, E, B, D, and C.

Scheduling Restrictions for Referenced Export-Function Models

If a top model references an export-function model, there are restrictions on function-call subsystems within the export-function model. These restrictions ensure consistency with standalone simulation results.

- In the top model, the same function-call initiator must output function-calls originating with the same sample time. You cannot use two function-call initiators with the same sample time. You cannot disable this restriction.
- The function-call inputs from the top model must follow the execution order of the function-call Inport blocks in the referenced export-function model. You can disable this restriction.
- The sample time of the function-call root-level Inport block must be inherited (`-1`) or match the sample time of the function-call initiator block that drives it. If you disable this restriction, the sample time of the function-call root-level Inport block must be inherited (`-1`) or an integer multiple of the sample time of the function-call initiator block.

To disable the restrictions, clear the check box **Model Configuration Parameters > Model Referencing > Enable strict scheduling checks for referenced models**.

An error appears if the top model calls the referenced model functions out of order at any time step. For information on sorted execution order, see “Control and Display the Sorted Order” on page 35-28.

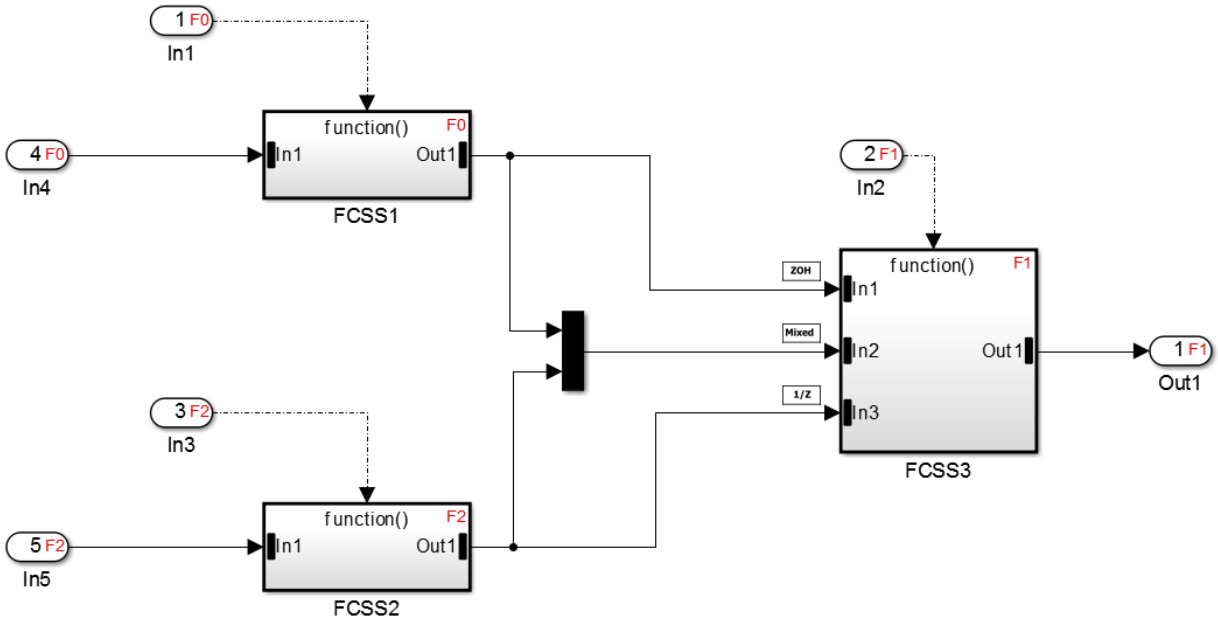
Data Transfer Between Function-Call Subsystems

You must know the timing of the data being transferred between function-call subsystems to understand and interpret simulation results.

To display which subsystem executes first during simulation, the signal lines are annotated with different symbols at the input ports of the subsystems:

- **ZOH** indicates that all source function-call subsystems execute before the function-call block reading this signal.
- **1/z** indicated that all source function-call subsystems execute after the function-call block reading this signal.
- **Mixed** indicates that some source function-call subsystems execute before and some function-call subsystems execute after the function-call block reading this signal.

In the block diagram, notice the sorted execution order for each block. We can see that for the input port **In1** of subsystems **FCSS3** (F1), the source subsystem **FCSS1** (F0) executes before **FCSS3** (F1). Hence, a badge of **ZOH** is added next to **In1**. Similarly, **FCSS2** (F2) executes after **FCSS3** (F1). Hence, Simulink adds a badge of **1/z** next to **In3** of subsystem **FCSS3** (F1). Port **In2** inputs signals from both **FCSS1** (F0) and **FCSS2** (F2). Hence, it has a badge **Mixed** next to it.



You can latch Inport blocks in function-call subsystems to ensure data integrity. If your function-call subsystems have Inport blocks that are latched, then the root-level data Inport block of the export-function model is latched only if all the data Inport blocks it is feeding to are latched. For more information, see "Latch input for feedback signals of function-call subsystem outputs".

When referencing an export function model or a model with asynchronous function-call inputs, the data input to the referenced model is latched if all function-call block inputs it feeds inside the referenced model are latched.

Note Data transfer signals are unprotected in the generated code by default. You must prevent data corruption in these signals due to pre-emption in the target environment or implementing protection using custom storage classes.

Workflows for Export-Function Models

The most common workflow is to test function-call behavior through simulation and generate the functions using standalone code generation.

Standalone Simulation

When function-call sequencing is simple enough to be specified as a model input, standalone simulation is the preferred workflow. For a standalone simulation, create data sets for the function-call and data root-level Inport blocks. For more information on function-call inputs, see “Specifying Function-Call Inputs” on page 10-88.

You can also specify the execution order for function-call subsystems. For more information, see “Execution Order for Function-Call Root-Level Inport Blocks” on page 10-83.

Specifying Function-Call Inputs

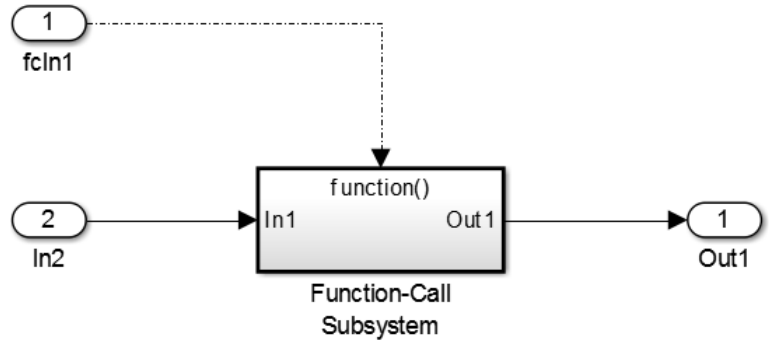
You can create data sets for the function-call and data root-level Inport blocks in **Simulation > Model Configuration Parameters > Data Import/Export > Input**.

For function-call inputs, specify a time-vector indicating when events occur.

- The time vector data type must be double and monotonically increasing.
- All time data must be integer multiples of the model sample time.
- To specify multiple function-calls at a given time step, repeat the time value accordingly. For example, to specify three events at t = 1 and 2 events at t = 9, list 1 three times and 9 twice in your time vector, `t = [1 1 1 9 9]'`.

The normal data input can use any other supported format as described in “Forms of Input Data” on page 61-157.

Consider the following export-function model with one function-call input port **fcIn1** and one data input **In2**.



In the **Configuration Parameters > Data Import/Export** pane, set the **Input** parameter to `t, tu`.

`t` is a column vector containing the times of events for the Inport block. `tu` is a table of input values versus time for the `In2` block.

The table describes how to specify the vector `t`.

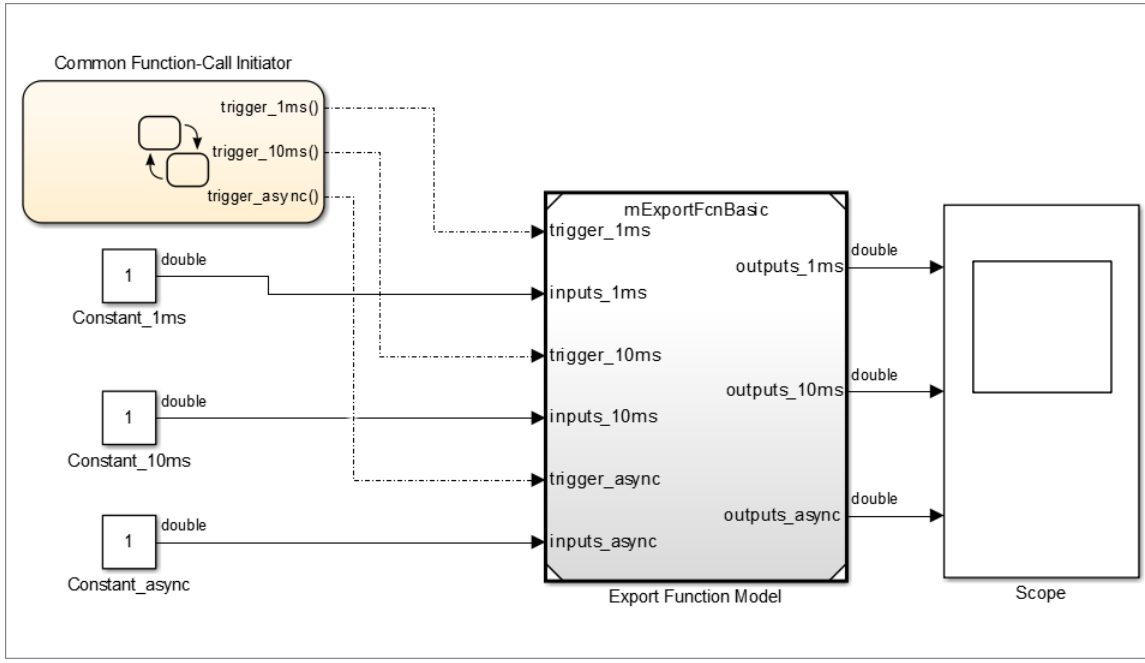
	Root-level Inport block with inherited sample time (`-1`) specified	Root-level Inport block with discrete sample time specified
Function-call subsystem trigger port sample time type is `Periodic`	Not applicable	Use an empty matrix(`[]`). The function-call subsystem executes at every sample time hit of the root-level Inport block invoking it.

	Root-level Inport block with inherited sample time (`-1`) specified	Root-level Inport block with discrete sample time specified
Function-call subsystem trigger port sample time type is `Triggered`	Use a nondecreasing column vector. Each element in the column vector must be an integral multiple of the fundamental sample time of the model. The function-call subsystem executes at the times specified by the column vector. If you specify an empty matrix (`[]`), the function-call subsystem does not execute.	Use a nondecreasing column vector. Each element in the column vector must be an integral multiple of discrete sample time of the function-call root-level Inport block. The function-call subsystem executes at the times specified by the column vector. Alternatively, specify an empty matrix (`[]`), and the function-call subsystem executes at every sample time hit.

Top-Model Simulation Using Model Reference

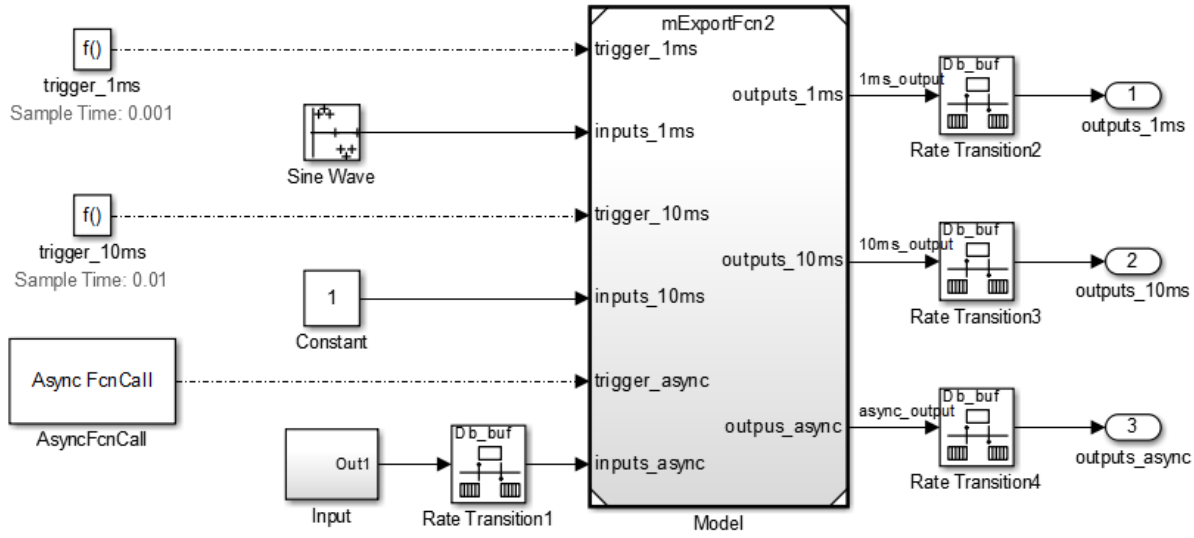
The more common simulation workflow of export-function models is by referencing export-function models. When function-call sequencing is too complicated to specify with data sets in a standalone simulation, create a harness top model to mimic target environment behavior. Use this top model to give inputs to the export-function model. There are two forms to mimic behavior of the scheduling environment:

- Common function-call initiator, in which you fully control the scheduling process. Use Stateflow or S-functions to create arbitrary call sequences.



Note Simulink does not simulate pre-empting function-calls.

- Multiple function-call initiators with distinct sample times: Use Simulink scheduling for simulation, which is useful when the rate monotonic scheduling behavior in Simulink is similar to the target OS behavior.



Note When using export-function models in top-model simulations, do not change the enable/disable status of the model during the simulation. Enable it at the start of the simulation and use function-calls to call it.

Standalone Code Generation

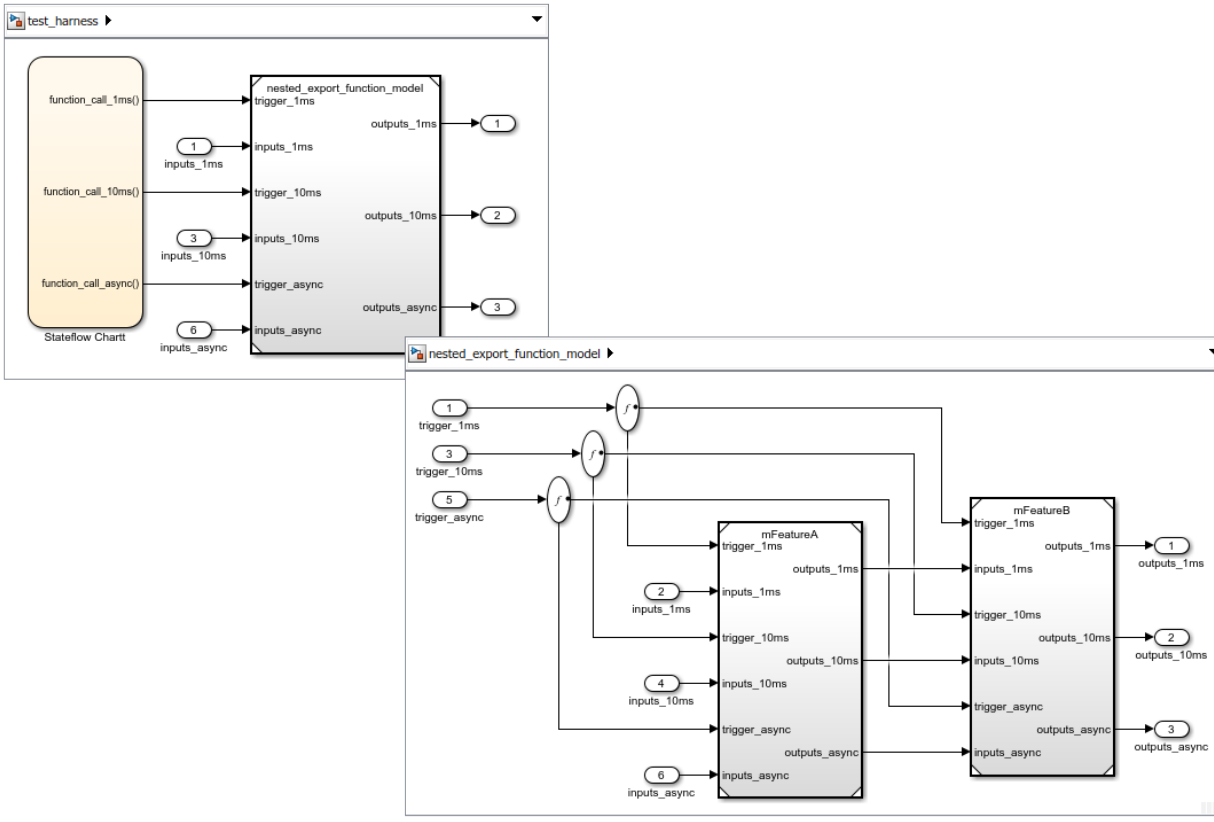
For standalone code generation, specify an ERT code-generation target, such as `ert.tlc`, and select **Code > C/C++ Code > Build Model** to generate code. In the generated code, each function-call root Inport generates a void-void function. The function name for each function-call root Inport block is the name of the output function-call signal of the block. If there is no signal name, then the function name is derived from the name of the root Inport block. Building the model generates a model initialization function but does not generate a model step function or an enable/disable function.

To customize the model initialize function name for the referenced export-function model, open the top model and complete these steps:

- Select **Model Configuration Parameters** > **Code Generation** > **Interface**.
- Click **Configure Model Functions**.
- In the Model Interface dialog box, set **Function specification** to `Model specific C prototypes` and click **Validate**.
- Type the function name in the **Initialize function** name text box and click **Apply**.
- Generate code again to see the new function name.

Nested Export-Function Models

Nested export-function models provide an additional layer of organization for your model. The following model shows how the you can export functions at the component level or the individual feature level.



Note An export-function model cannot contain a model with asynchronous function-call inputs, but can contain function-call subsystems and function-call models. A model with asynchronous function-call inputs can contain an export-function model, function-call subsystem, or a function-call model.

Comparison Between Export-Function Models and Models with Asynchronous Function-Call Inputs

An export-function models capability is available for models with asynchronous function-call inputs. You use these models primarily in the Simulink environment where the Simulink scheduler calls generated functions.

	Export-Function Models	Models with Asynchronous Function-Call Inputs
Definition	These models have function-call root-level Inport blocks that are not connected to an Asynchronous Task Specification block. These Inport blocks trigger function-call subsystems or referenced models with function-call trigger inputs.	These models have function-call root-level Inport blocks connected to Asynchronous Task Specification blocks. These Inport blocks trigger function-call subsystems or referenced models with function-call trigger inputs.
Root-level blocks	Only blocks executing in a function-call context are allowed at the root level.	Blocks executing in a non-function-call context are also allowed.
Data transfer	Use data transfer indicators to interpret simulation results. Data transfer in export-function models is not protected by default in generated code. For more details, see “Data Transfer Between Function-Call Subsystems” on page 10-86.	Use Rate Transition blocks to protect data transferred between function-call subsystems running at different rates. For more information, see Rate Transition.
Simulation support	These models support standalone simulation and top-model simulation in all simulation modes.	These models support top-model simulation in all simulation modes and standalone simulation in normal, accelerator, and rapid accelerator modes.

	Export-Function Models	Models with Asynchronous Function-Call Inputs
Code generation support	Top-model and standalone code generation is supported.	Top-model and standalone code generation is supported.

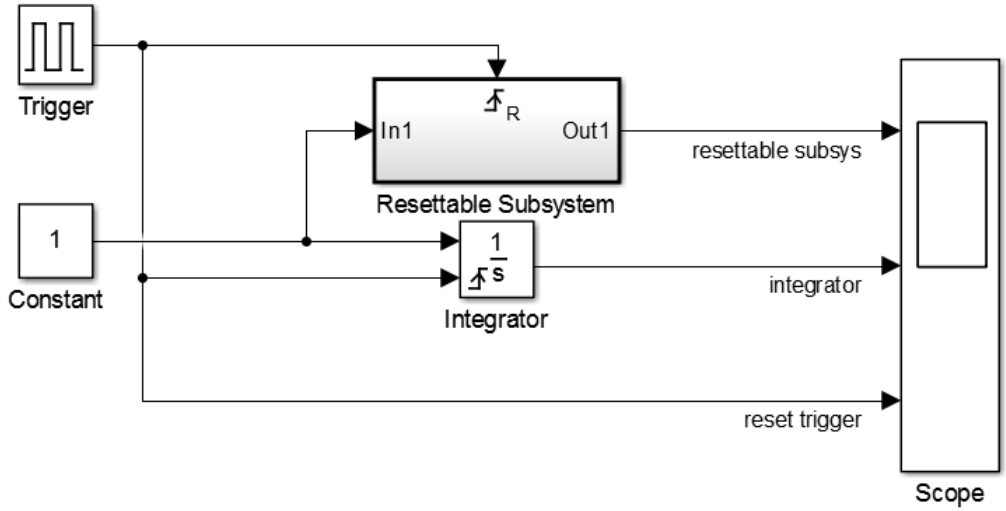
Resettable Subsystems

In this section...

Behavior of Resettable Subsystems

Use resettable subsystems when you want to conditionally reset the states of all blocks within a subsystem to their initial condition. A resettable subsystem executes at every time step but conditionally resets the states of blocks within it when a trigger event occurs at the reset port. This behavior is similar to the reset behavior of blocks with reset ports, except that a resettable subsystem resets the states of all blocks inside it.



Using resettable subsystems over other methods of resetting states of your block or subsystem has these advantages:

- When you want to reset the states of multiple blocks in a subsystem, displaying and connecting the reset port of each block is cumbersome and makes the block diagram hard to read. Instead, place all the blocks in a resettable subsystem and configure the Reset block in the subsystem.

- Some blocks, such as the Discrete State-Space block, have states but do not have reset ports. You cannot reset these blocks individually, and you must reset the subsystem they are inside. In such cases, it is useful to place these blocks in a resettable subsystem.
- You can also reset blocks in enabled subsystems by setting the **States when enabling** parameter on the enable port to `reset`. However, for this behavior, you must disable the subsystem and then reenable it at a later time step. To reset your block states at the same time step, use resettable subsystems. For more information, see "Comparison of Resettable Subsystems and Enabled Subsystems" on page 10-99.

All blocks in a resettable subsystem must have the same sample time, and they execute at every sample time hit of the subsystem. Resettable subsystems and the model use a common clock.

This model shows that the behavior of block reset ports and resettable subsystems is the same. A resettable subsystem enables you to reset the states of all blocks inside it. The resettable subsystem contains an integrator block that is configured similar to the root-level Integrator block, but the block does not have a reset port. The subsystem resets the states of the integrator block inside it in the same manner as the reset port of the Integrator block. You can see this behavior by running the model and viewing the output in the scope.

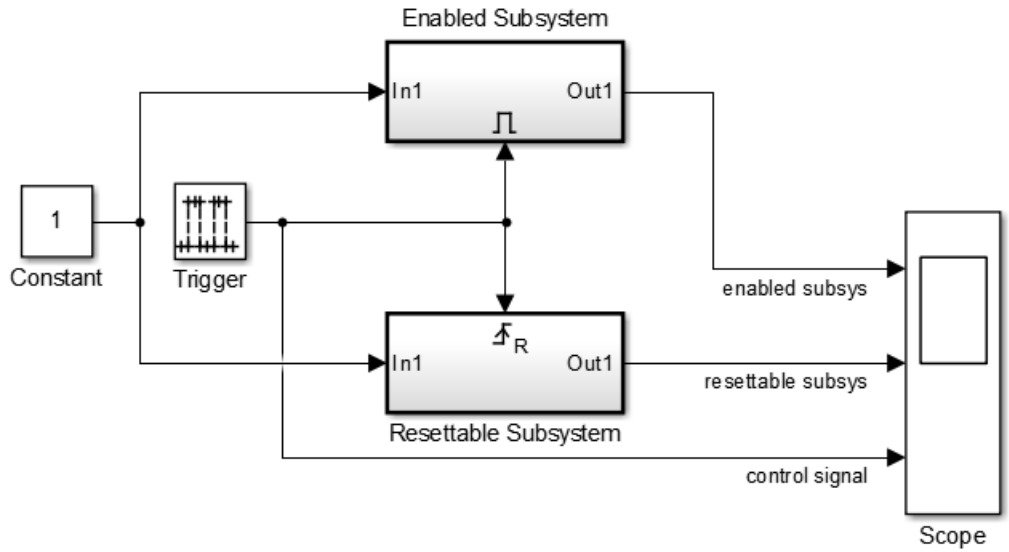
Comparison of Resettable Subsystems and Enabled Subsystems

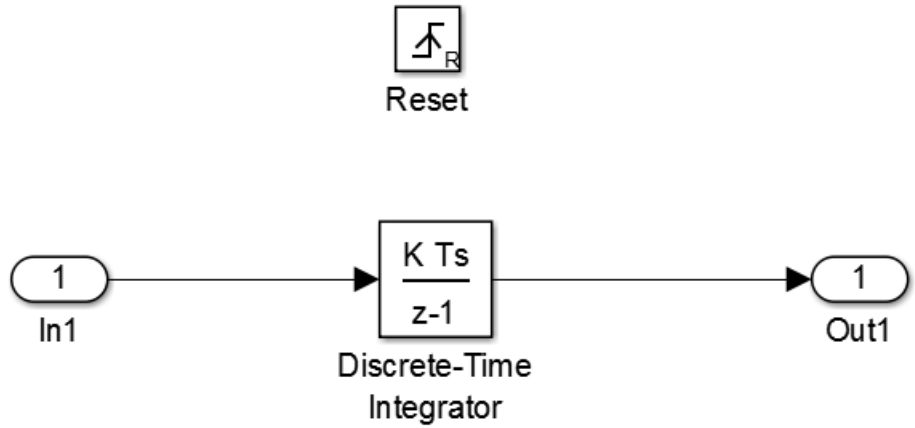
If you set **States when enabling** for the Enable block to `reset`, the enabled subsystem resets the states of all blocks in the subsystem. However, you must disable the subsystem for at least one time step and then reenable it for the states to reset.

In contrast, resettable subsystems always execute and reset the states of their blocks instantaneously.

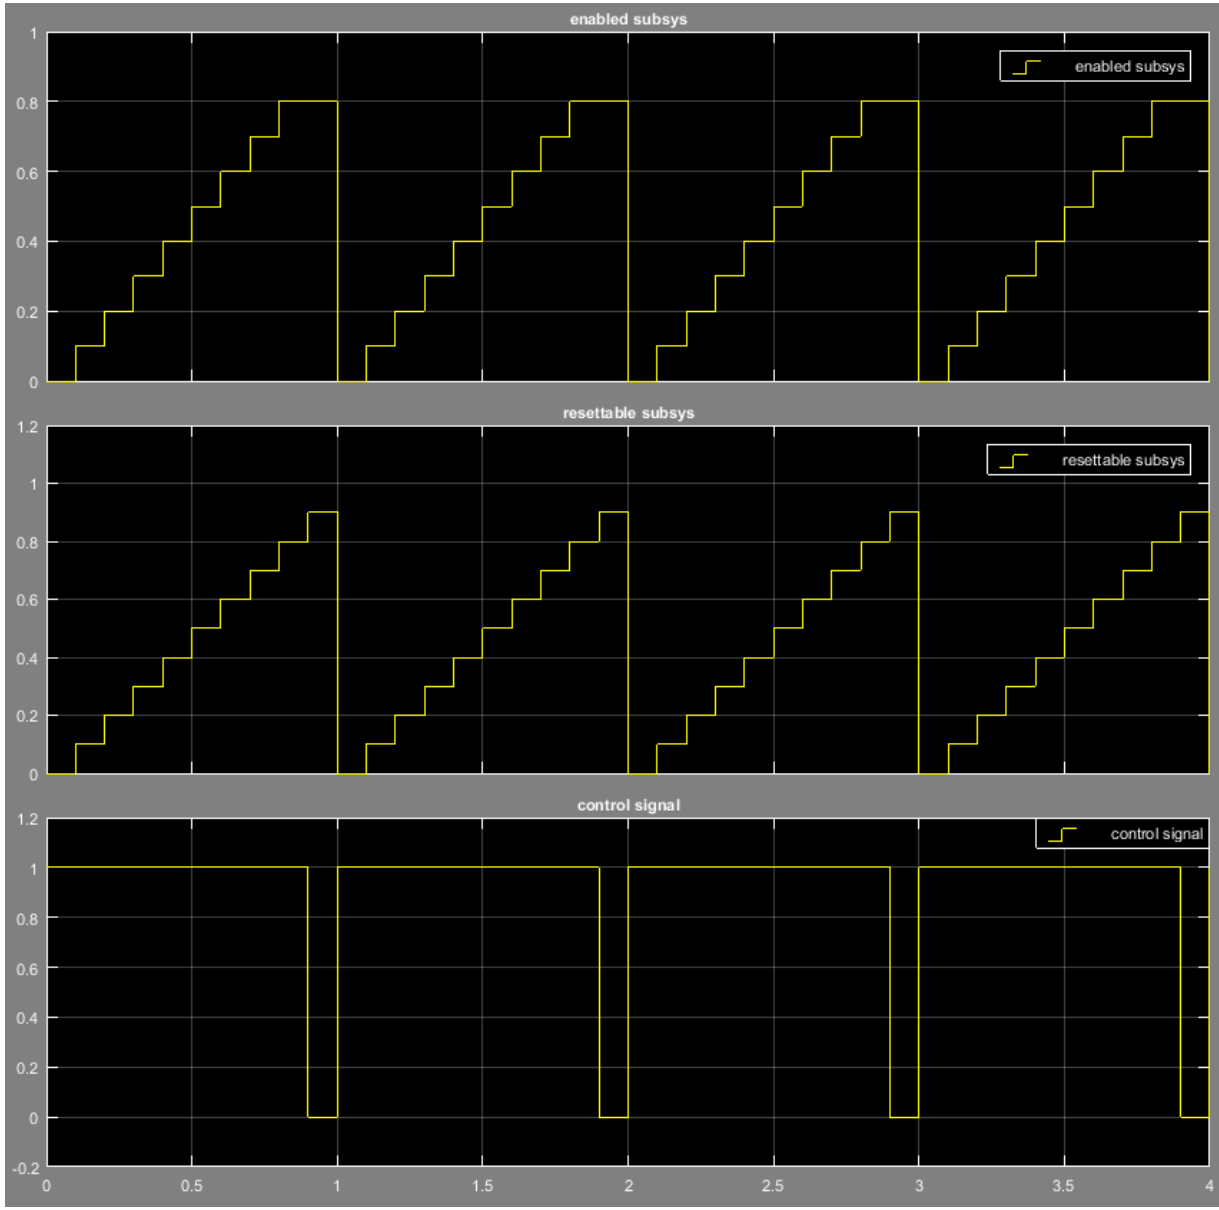
This model shows the difference in the execution behavior of these subsystems. It contains an enabled subsystem and a resettable subsystem whose control ports are connected to pulse generator. The resettable subsystem is set to reset on the rising edge of the control signal, and the enabled subsystem has the **States when enabling** parameter set to `reset` in the enable port.



The subsystems contain identical Discrete-Time Integrator blocks, whose input is the Constant block at the root level of the model. The figure shows the contents of the resettable subsystem.



The figure shows the simulation output.



When the control signal is 0, the enabled subsystem is disabled and the integrator does not change its output while the resettable subsystem is executing. The rising edge of the

control signal triggers the reset port of the resettable subsystem and enables the enabled subsystem. Both subsystems reset their states at this time step.

Notice that the enabled subsystem is disabled for at least one time step before its states can are reset. The resettable subsystem does not have this limitation.

Action Subsystem

In this section...

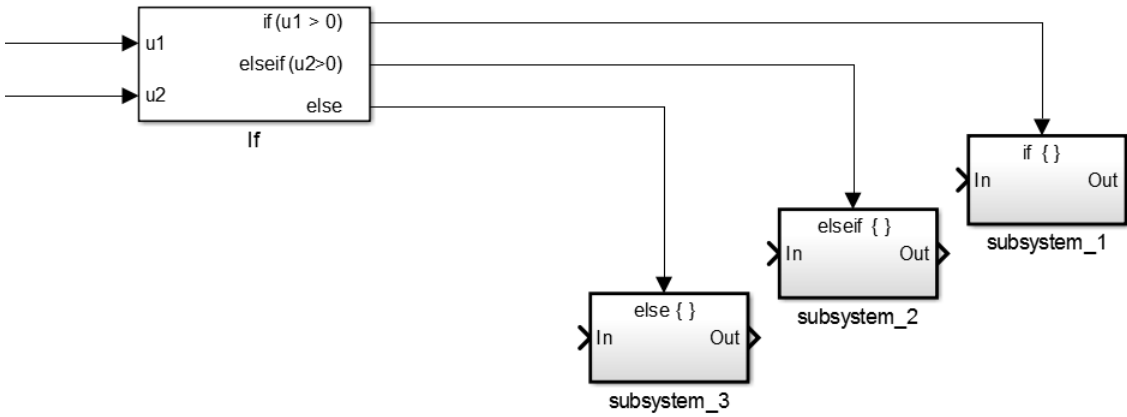
What Are Action Subsystems?

Action subsystems are subsystems that execute in response to a conditional output from an If block or a Switch Case block. In essence, they are subsystems with an Action port, which allow for block execution based on conditional inputs from an If block or Switch Case block.

Simulink has two types of action subsystems, based on the type of block they receive conditional input from.

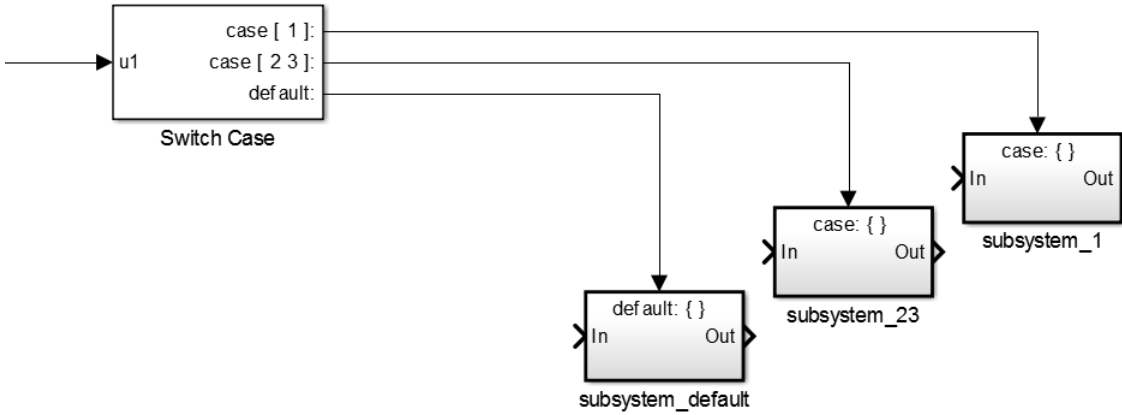
If Action Subsystem

An If Action Subsystem is preconfigured to serve as a starting point for creating a subsystem whose execution is triggered by an If block. To implement an if-else condition, connect If Action Subsystem blocks to the outputs of an If block.



Switch Case Action Subsystem

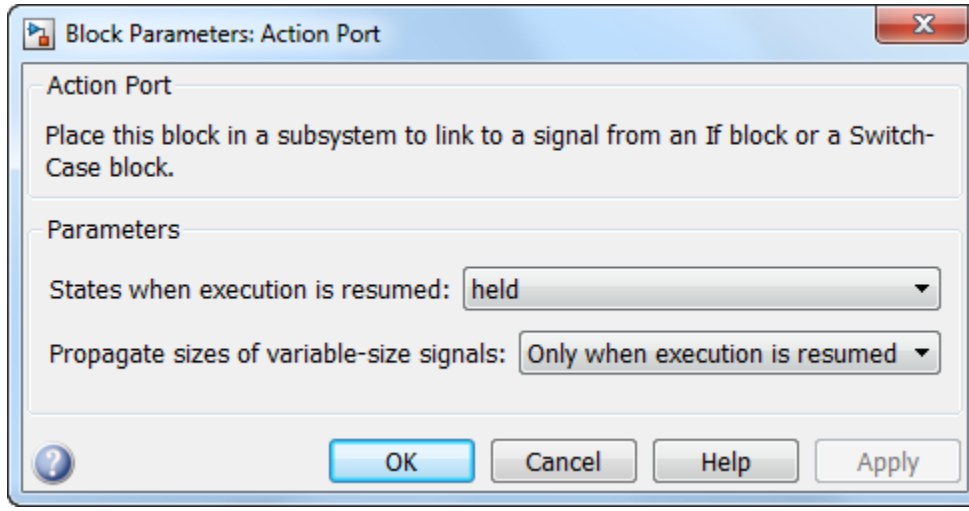
The Switch Case Action Subsystem is preconfigured to serve as a starting point for creating a subsystem whose execution is triggered by a Switch Case block. To implement a switch condition, connect Switch Case Action Subsystem blocks to the outputs of a Switch Case block.



Set States When an Action Subsystem Executes

When an action subsystem is triggered to execute, you can choose whether to hold the subsystem states at their previous values or reset them to their initial conditions.

1. Open the Action Port block inside the action subsystem.
2. Select one of the following for the **States when execution is resumed** parameter:
   - `held` if you want the states to maintain their most recent values
   - `reset` if you want the states to revert to their initial conditions



Note For nested subsystems whose Action Port blocks have different parameter settings, the settings on the child subsystem dialog box override those setting inherited from the parent subsystem.

Simulink Functions

In this section...

What Are Simulink Functions?

A Simulink function is a computational unit that calculates a set of outputs when provided with a set of inputs. The function header uses a notation similar to programming languages such as MATLAB and C++. You can define and implement a Simulink function in several ways:

- **Simulink Function block** — Function defined using Simulink blocks within a Simulink Function block. See Simulink Function block reference.
- **Exported Stateflow graphical function** — Function defined with state transitions within a Stateflow chart, and then exported to a Simulink model.
- **Exported Stateflow MATLAB function** — Function defined with MATLAB language statements within a Stateflow chart, and then exported to a Simulink model.

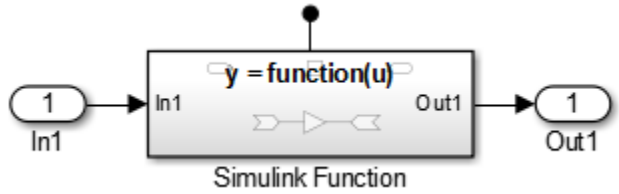
What Are Simulink Function Callers?

A Simulink function caller invokes the execution of a Simulink function from anywhere in a model or chart hierarchy.

- **Function Caller block** — In a Simulink model, calls a function defined in Simulink or exported from Stateflow. See Function Caller block reference.
- **Stateflow chart transition** — In a Stateflow chart, calls a function defined in Simulink or exported from Stateflow.
- **MATLAB Function block** — In a Simulink model, calls a function from a MATLAB language script.

Connect to Local Signals

In addition to Argument Inport and Argument Outport blocks, a Simulink Function block can interface to signals in the local environment of the block through Inport or Outport blocks. These signals are hidden from the caller. You can use port blocks to connect and communicate between two Simulink Function blocks or connect to root Inport and Outport blocks that represent external I/O.

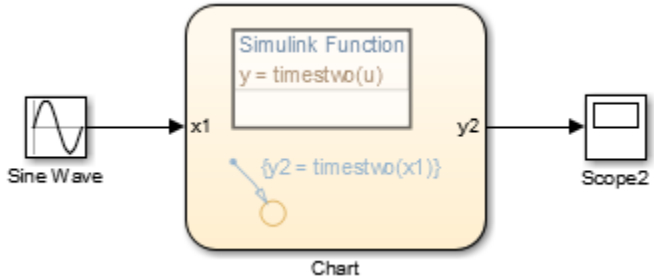


You can also connect the Outport blocks to sink blocks that include logging (To File, To Workspace) and viewing (Scope, Display) blocks. However, these blocks execute last after all other blocks.

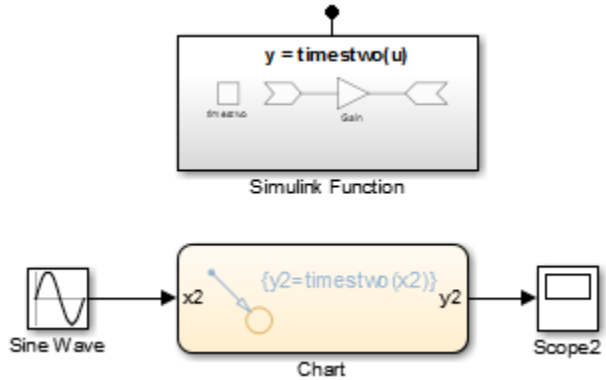
A Simulink Function block can output a function-call signal to an Output port block.

Reusable Logic with Functions

Use functions when you need reusable logic across a model hierarchy. Consider an example where a Simulink Function with reusable logic is defined in a Stateflow chart.



You can move the reusable logic from inside the Stateflow chart to a Simulink Function block. The logic is then reusable by function callers in Simulink subsystems (Subsystem and Model blocks) and in Stateflow charts at any level in the model hierarchy.



The result is added flexibility for structuring your model for reuse.

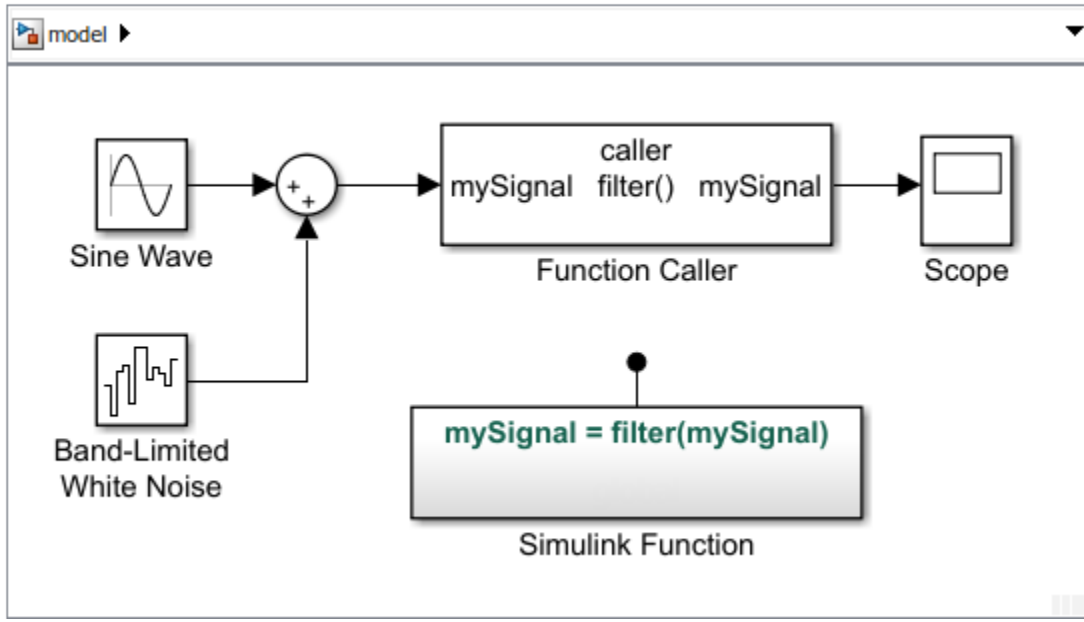
Note Input and output argument names (`x2`, `y2`) for calling a function from a Stateflow chart do not have to match the argument names in the function prototype (`u`, `y`) of a Simulink Function block.

Input/Output Argument Behavior

The function prototype for a Simulink Function block can have identical input and output arguments. For example, a function that filters noise could input a signal and then return the signal after filtering.

```
mySignal = filter(mySignal)
```

You can call the function with a Function Caller block and add noise to a test signal to verify the function algorithm.



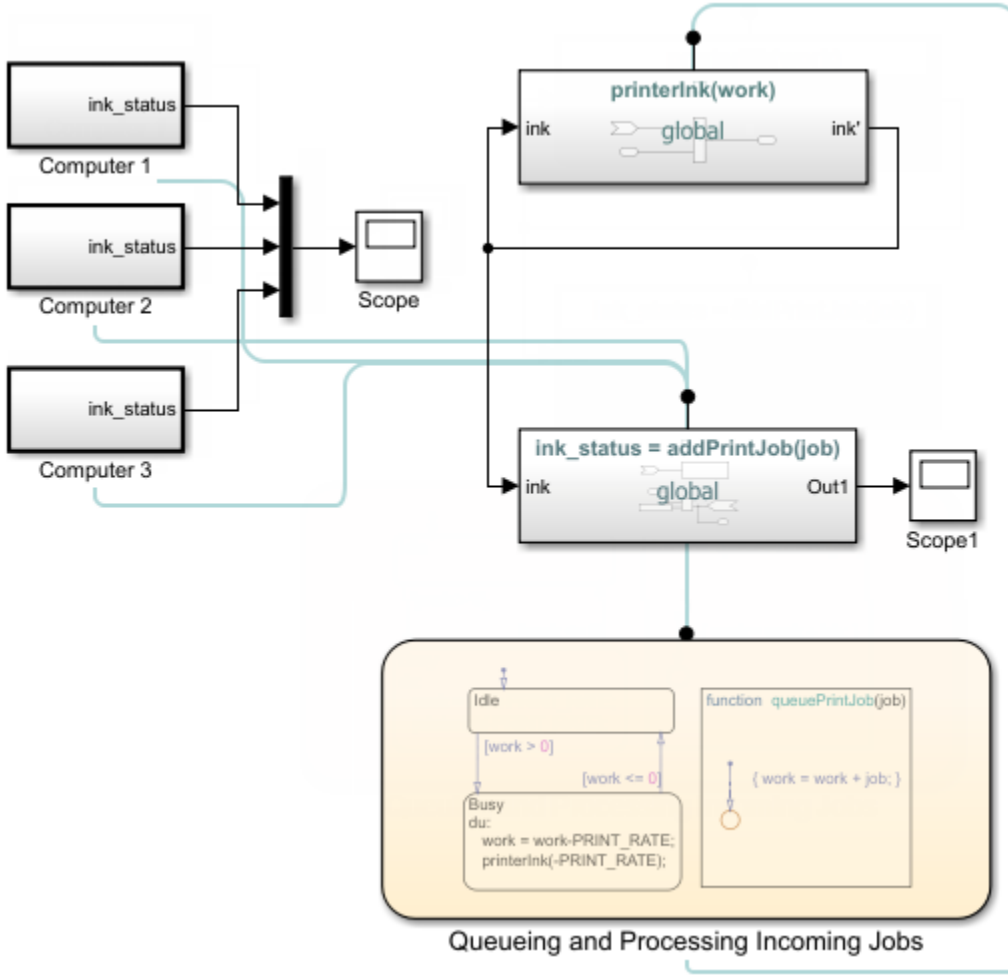
When generating code for this model, the input argument for the Simulink Function block passes a pointer to the signal, not a copy of the signal value.

```
void filter(real_T *rtuy_mySignal)
{
        . . .

        *rtuy_mySignal = model_P.DiscreteFilter_NumCoef * DiscreteFilter_tmp;
    }
```

Shared Resources with Functions

Use functions when you model a shared resource, such as a printer. The model `slexPrinterExample` uses Simulink Function blocks as a common interface between multiple computers and a single Stateflow chart that models a printer process.



How a Function Caller Identifies a Function

The function interface uses MATLAB syntax to define the name of a function and its input and output arguments. The model hierarchy can contain only one function definition with the identified function name. Simulink verifies that:

- The arguments in the **Function prototype** parameter for a Function Caller block matches the arguments specified in the function. For example, a function with two input arguments and one output argument appears as:

  ```
  y = MyFunction(u1, u2)
  ```

- The data type, dimension, and complexity of the arguments must agree. For a Function Caller block, you can set the **Input argument specifications** and **Output argument specifications** parameters, but usually you do not need to specify these parameters manually. Simulink derives the specification from the function.

  The only case where you must specify the argument parameters is when the Function Caller block cannot find the function in the model or in any child model it references. This situation can happen when the Functions Caller block and called function are in separate models that referenced by a common parent model. See “Simulink Functions in Referenced Models” on page 10-140and “Argument Specification for Simulink Functions” on page 10-135.

Reasons to Use a Simulink Function Block

Function-Call Subsystem blocks with direct signal connections for triggering provide better signal traceability than Simulink Function blocks, but Simulink Function blocks have other advantages.

- **Eliminate routing of signal lines.** The Function Caller block allows you to execute functions defined with a Simulink Function block without a connecting signal line. In addition, functions and their callers can reside in different models or subsystems. This approach eliminates signal routing problems through a hierarchal model structure and allows greater reuse of model components.
- **Use multiple callers to the same function.** Multiple Function Caller blocks or Stateflow charts can call the same function. If the function contains state (e.g., a Unit Delay block), the state is shared between the different callers.
- **Separate function interface from function definition.** Functions separate their interface (input and output arguments) from their implementation. Therefore, you can define a function using a Simulink Function block, an exported graphical function from Stateflow, or an exported MATLAB function from Stateflow. The caller does not need to know how or where the function was implemented.

Choose a Simulink Function or Reusable Subsystem

A consideration for using a Simulink Function block or a Subsystem block has to do with shared state between function calls. A Simulink Function block has shared state while a Subsystem block, even if specified as a reusable function, does not.

- For a Simulink Function block, when one block has multiple callers, code is always generated for one function. If the Simulink Function block contains blocks with state (for example, Delay or Memory), the state is persistent and shared between function callers. In this case, the order of calls is an important consideration.
- For a Subsystem block, when a block has multiple instances and is configured as a reusable function, code is usually generated for one function as an optimization. If the Subsystem block contains blocks with state, code is still generated for one function, but a different state variable is passed to the function. State is not shared between the instances.

When Not to Use a Simulink Function Block

Simulink Function blocks allow you to implement functions graphically, but sometimes using a Simulink Function block is not the best solution.

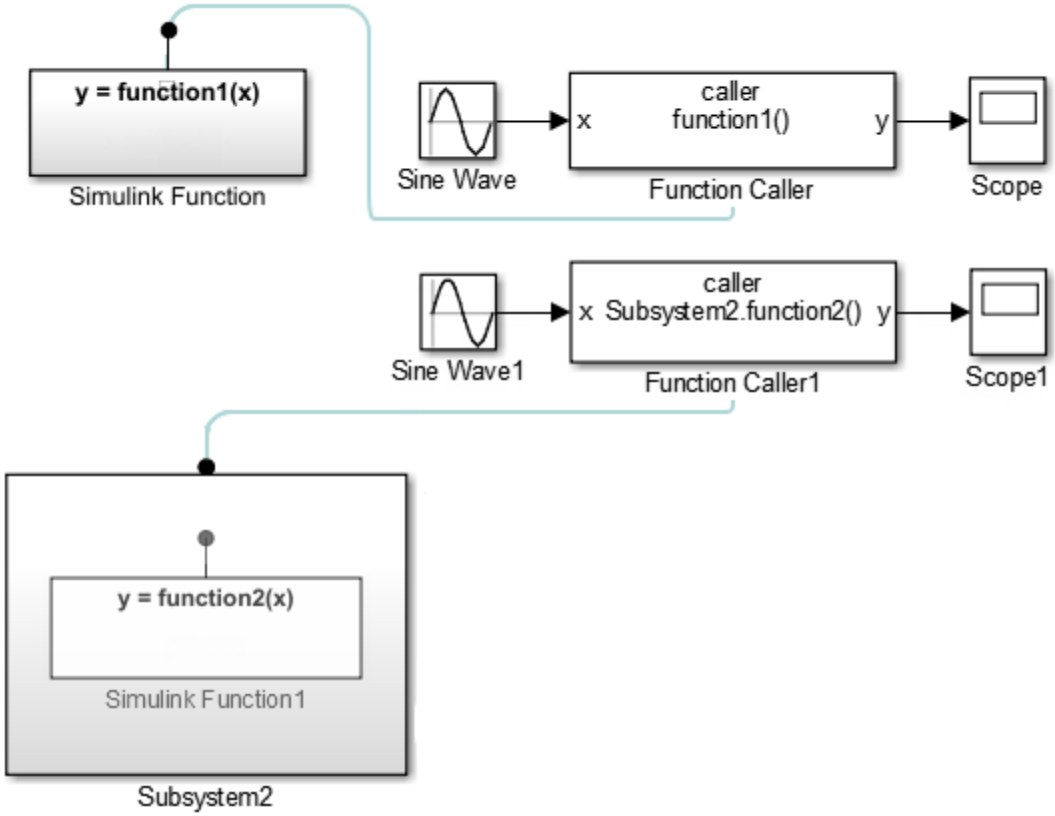
For example, when modeling a PID controller or a digital filter and you have to model the equations defining the dynamic system. Use an S-Function, Subsystem, or Model block to implement systems of equations, but do not use a Simulink Function block, because these conditions can occur:

- **Persistence of state between function calls.** If a Simulink Function block contains any blocks with state (for example, Unit Delay or Memory), then their state values are persistent between calls to the function. If there are multiple calls to that function, the state values are also persistent between the calls originating from different callers. For more on this topic, see “Call a Simulink Function Block from Multiple Sites” on page 10-131.
- **Inheriting continuous sample time.** A Simulink Function block cannot inherit a continuous sample time. Therefore, do not use this block in systems that use continuous sample times to model continuous system equations.

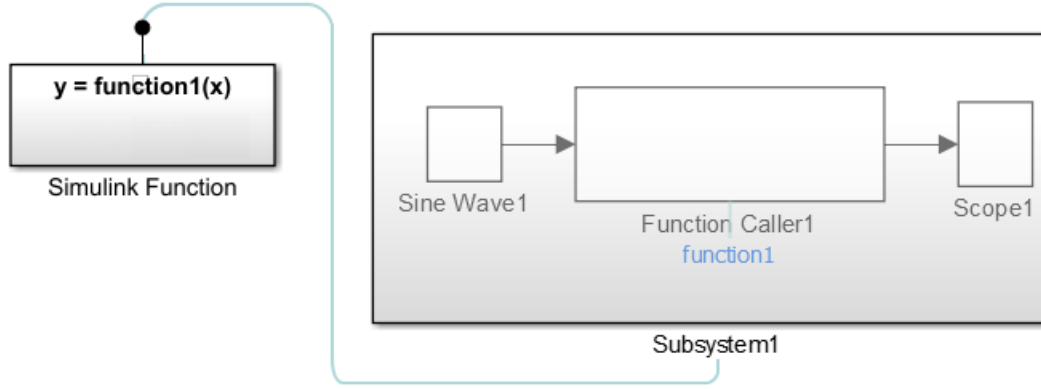
Tracing Simulink Functions

Visually display connections between a Simulink function and their callers with lines that connect callers to functions:

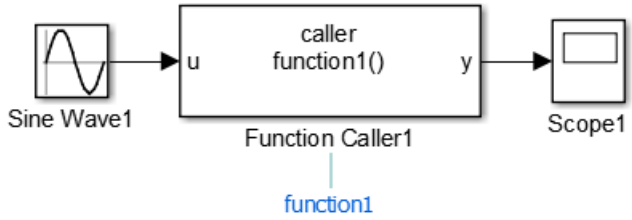
- Turning on/off tracing lines — From the Simulink Editor menu, select **Display** > **Function Connectors**.
- Direction of tracing lines — Lines connected at the bottom of a block are from a function caller. Lines connected at the top of a block are to a Simulink function or a subsystem containing the function.



- Navigation to functions — A function caller can be within a subsystem.



Navigate from a caller in a subsystem to a function by first opening the subsystem, and then clicking a link to the function.



If the function is at the root level of a model, the function opens. If the function is within a subsystem, the subsystem containing the function opens.

Monitor Ink Status on a Shared Printer Using Simulink Functions

After selecting **Display** > **Function Connectors**, the model slexPrinterExample shows the relationships between callers and functions.

In this example, the Function Caller in the Simulink Function block `addPrintJob`, calls the exported Stateflow function `queuePrintJob`. The subchart `Busy` calls the Simulink Function block `printerInk`. Tracing lines are drawn into and out of the Stateflow chart.

Simulink Functions in Models

In this section...

Simulink Functions in a Simulink Model

Simulink functions have an interface with input and output arguments similar to programming languages. You create the function definitions:

- Graphically, using Simulink blocks in a Simulink Function block, or Stateflow state transitions in a graphical function exported from a Stateflow chart.
- Textually, using MATLAB code in a MATLAB function exported from a Stateflow chart.

Simulink Function Block

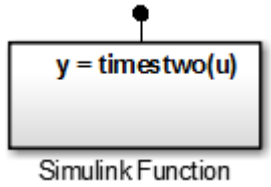
Set up a Simulink Function block to receive data through an input argument from a function caller. Multiply the input argument by 2, and then pass the calculated value back through an output argument.

1 Add a Simulink Function block from the User-Defined Functions library into your model.

Open the Library Browser by selecting the Library Browser toolbar button  .

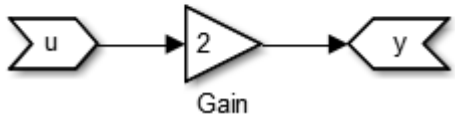
2 On the block, enter this function prototype to set the function name to `timestwo`, the input argument to `u`, and the output argument to `y`:

```
y = timestwo(u)
```



3 Double-click the block to open the subsystem defining the function.

4 Add a Gain block and set the **Gain** parameter to `2`.



Export Graphical Function from Stateflow Chart

Set up a graphical function in a Stateflow chart to receive data through an input argument from a function caller. Multiply the input argument by 2, and then pass the calculated value back through an output argument. Set chart parameters to export the function to a Simulink model.

Define a Graphical Function

Create a graphical function in a Stateflow chart. Define the function interface and function definition.

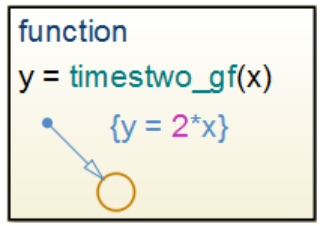
1 Add a Stateflow Chart to your Simulink model. From the Simulink Editor menu, select **File > New > Chart**.

2 Drag the new chart to your model. Double-click the chart to open it.

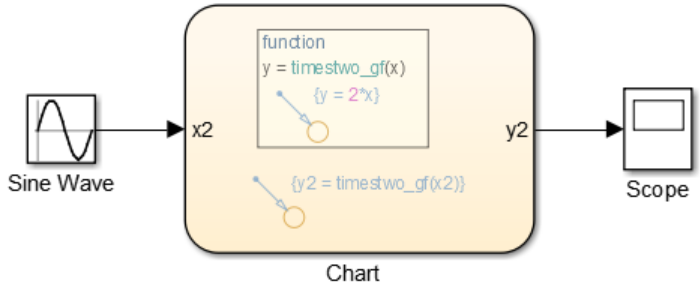
3 Add a graphical function. From the left-side toolbar, click and drag the graphical function icon  onto the chart.

4 Define the function interface. In the function box, replace the `?` with the function interface `y = timestwo_gf(x)`.

5 Define the function. Click the transition arrow and replace the `?` with the MATLAB code `{y = 2*x}`.



6 Add a transition in the chart. Connect the chart input to a Sine Wave input and the output to a Scope.

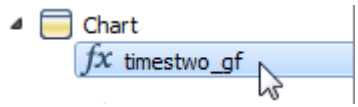


7 Run a simulation to test the function.

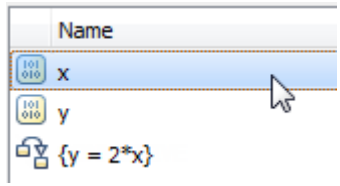
Set Argument Parameters for a Graphical Function

Specify the size, complexity, and type of the function input and output arguments. A chart can export only functions with fully specified prototypes.

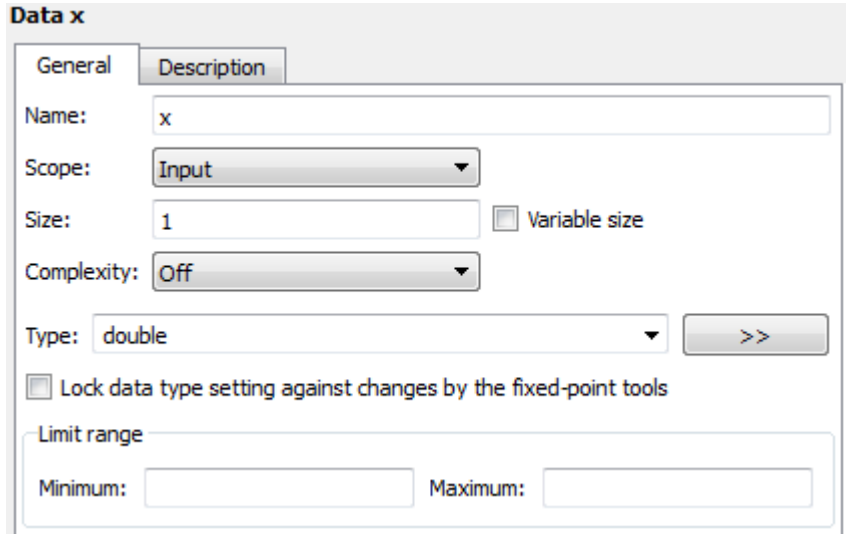
1 Open Model Explorer. In the left pane, select the graphical function.



2 From the **Column View** list in the middle pane, select `Stateflow`. Select the filter icon  , and then select **All Stateflow Objects**. From the table at the bottom of the pane, select an input or output argument.



3 In the right pane, enter `1` (scaler) for Size, select `Off` (real number) for **Complexity**, and select `double` for **Type**.

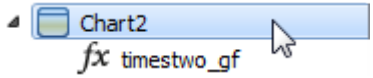


4 Repeat steps `2` and `3` with the remaining function arguments.

Set Export Function Parameters for a Graphical Function

Set parameters to export the graphical function during a simulation.

1 From the left pane, select the chart containing the graphical function.



Alternatively, open the chart and from the menu, select **Chart > Properties**.

2 In the property dialog box, select **Export Chart Level Functions (Make Global)** and **Allow exported functions to be called by Simulink** check boxes.

If you are calling the exported graphical function from another Stateflow chart (not the chart that exported the graphical function), you do not need to select the **Allow exported functions to be called by Simulink** check box.

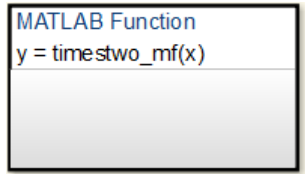
Export MATLAB Function from Stateflow Chart

Set up a MATLAB function in a Stateflow chart to receive data through an input argument from a function caller. Multiply the input argument by 2, and then pass the calculated value back through an output argument. Set chart parameters to export the function to a Simulink model.

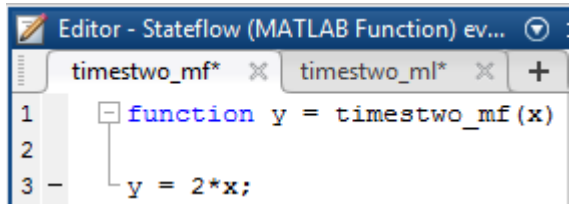
Define MATLAB Function

Create a graphical function in a Stateflow chart. Define the function interface and function definition.

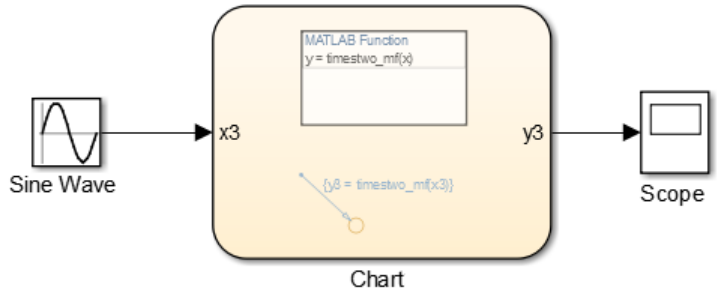
1. Add a Stateflow Chart to your Simulink model. From the Simulink Editor menu, select **File** > **New** > **Chart**. A new chart opens in a new model.
2. Drag the new chart to your model. Double-click the chart to open it.
3. Add a graphical function. From the left-side toolbar, click and drag the graphical function icon  onto the chart.
4. Define the function interface. In the function box, replace the `?` with the function interface `y = timestwo_ml(x)`.



5. Double-click the function box to open the MATLAB code editor. Define the function with the MATLAB code.



6 Add a transition to test the MATLAB function. Add a Sine Wave input and connect the output to a Scope.

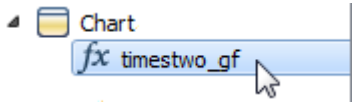


7 Run a simulation to test the function.

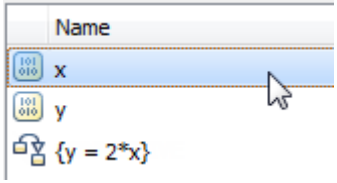
Set Argument Parameters

Specify the size, complexity, and type of the function input and output arguments. A chart can export only functions with fully specified prototypes.

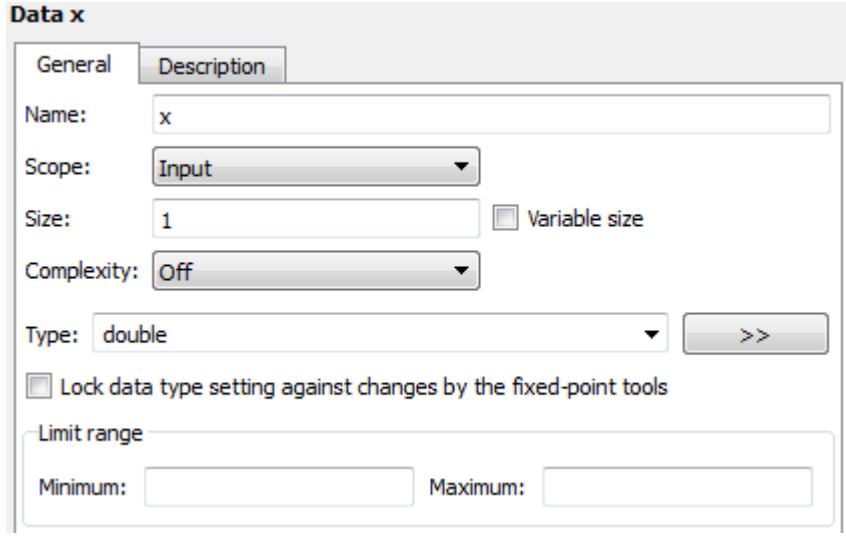
1 Open Model Explorer. In the left pane, select the MATLAB function.



2 In the middle pain, from the **Column View** list, select `Stateflow`. From the table, select an input or output argument.



3 In the right pane, enter `1` (scaler) for **Size**, select `Off` (real number) for **Complexity**, and select `double` for **Type**.

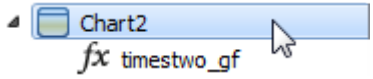


4 Repeat steps 2 and 3 with the remaining function arguments.

Set Export Function Parameters

Set parameters to export the MATLAB function during a simulation.

1 From the left pane, select the chart containing the graphical function.



Alternatively, open the chart and from the menu, select **Chart** > **Properties**.

2 In the property dialog box, select **Export Chart Level Function (Make Global)** and **Allow exported functions to be called by Simulink** check boxes.

If you are calling the exported graphical function from another Stateflow chart (not the chart that exported the graphical function), you do not need to select the **Allow exported functions to be called by Simulink** check box.

Call Simulink Functions with a Function Caller Block

The following examples show how to use a Function Caller block to call:

- Simulink Function block.
- Exported Graphical function from a Stateflow chart.
- Exported MATLAB function from a Stateflow chart.

The functions multiply a value from the caller by `2`, and then send the calculated value back to the caller.

Because the Function Caller block cannot determine function arguments at compile time, you have to name the Function Caller block input and output arguments. The argument names in the **Function prototype** must match the function argument names.

Function Caller Block to Call Simulink Function Block

Set up a Function Caller block to send data through an input argument to a Simulink Function block. Receive data back from the function through an output argument. Points to consider:

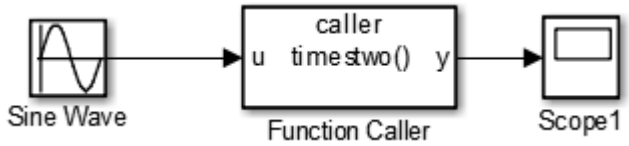
- The input and output argument names for the Simulink Function block and the prototype for a Function Caller block much match exactly.
- If the Function Caller block is within a Model block (referenced model), you must define the **Input argument specification** and **Output argument specification**. See "Simulink Functions in Referenced Models" on page 10-140and "Argument Specification for Simulink Functions" on page 10-135.

To add a Function Caller block.

1. Add a Function Caller block from the User-Defined Functions library into your model.
2. In the Function Caller dialog box, in the **Function prototype** box, enter `y = timestwo(u)`. This function prototype creates an input port `u` and output port `y` on the Function Caller block.

   Note Typing in a blank text box displays a list of previously created function prototypes that match the text you're typing.

3. Add a Sine Wave block to the input and a Scope block to the output.

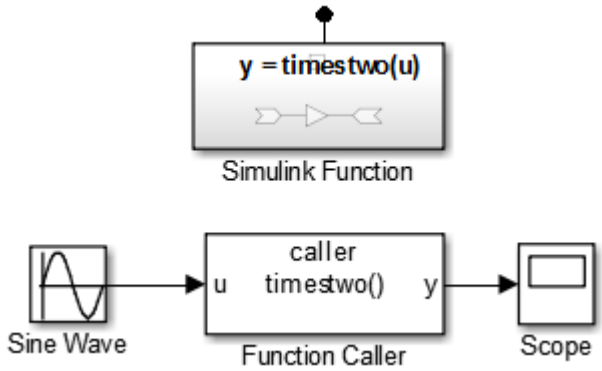


4 Set up a Simulink Function block as described in “Simulink Function Block” on page 10-117.

Simulate the Model

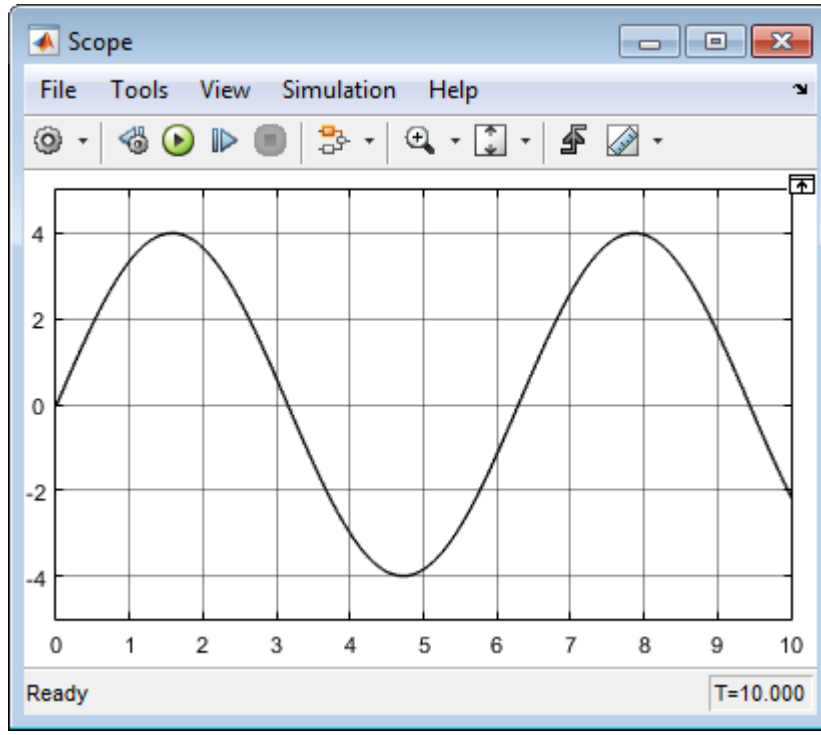
After you create a function using a Simulink Function block and setup a call to that function using a Function Caller block, you can simulate the model.

1 Return to the top level of the model.



2 Run a simulation.

3 To view the signal results, double-click the Scope block. The input sine wave with an amplitude of 2 is doubled.



Function Caller Block to Call Exported Graphical Function

Calling an exported graphical function from Stateflow is no different than calling a Simulink Function block. Points to consider:

- The input and output argument names for an exported function and the prototype for a Function Caller block much match exactly.
- If the Function Caller block is within a Model block (referenced model), you must define the **Input argument specification** and **Output argument specification**. See “Simulink Functions in Referenced Models” on page 10-140and “Argument Specification for Simulink Functions” on page 10-135.

To create an exported graphical function, see “Export Graphical Function from Stateflow Chart” on page 10-118.

Function Caller Block to Call Exported MATLAB Functions

Calling an exported MATLAB function from Stateflow is no different than calling a Simulink Function block. Points to consider:

- The input and output argument names for an exported function and the prototype for a Function Caller block must match exactly.
- If the Function Caller block is within a Model block (referenced model), you must define the **Input argument specification** and **Output argument specification**. See "Simulink Functions in Referenced Models" on page 10-140and "Argument Specification for Simulink Functions" on page 10-135.

To create an exported MATLAB function, see "Export MATLAB Function from Stateflow Chart" on page 10-121.

Call Simulink Functions from a MATLAB Function Block

A MATLAB Function block can call another function. The following examples show how to use a MATLAB Function block to call:

- Simulink Function block.
- Exported Graphical function from a Stateflow chart.
- Exported MATLAB function from a Stateflow chart.

The functions multiply a value from the caller by `2`, and then send the calculated value back to the caller.

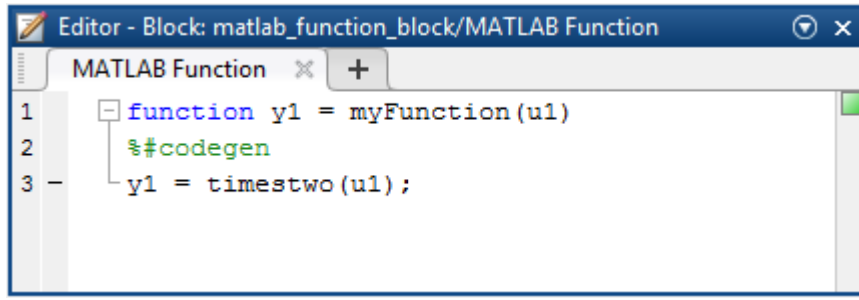
MATLAB Function blocks only support discrete and fixed-in-minor sample times. When using a Sine Wave block as an input signal, setup the model and block parameters for a sample time compatible with the MATLAB Function block:

- Discrete — Open the model Configuration Parameters dialog box to the Solver pane. Set **Type** to Fixed-step and enter a value for **Fixed-step size** (fundamental sample time). Open the Sine Wave Block Parameters dialog box and set **Sample time** to the model sample time you entered.
- Fixed-In-Minor step — Open the Sine Wave Block Parameters dialog box. In the **Sample time** box, enter `[0 1]`.

MATLAB Function Block to Call Simulink Function Block

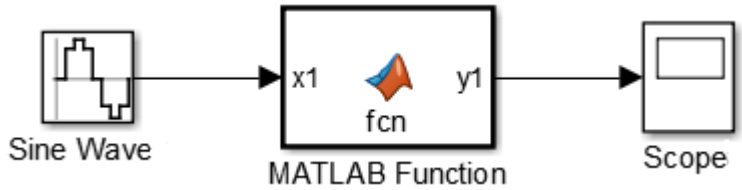
Set up a MATLAB Function block to send data through an input argument to a Simulink Function block. Receive data back from the function through an output argument.

1. Add a MATLAB Function block to your model.
2. Double-click the block, which opens the MATLAB editor. Enter the function call `y1 = timestwo(u1)`.



Note The argument names for the function you define in the MATLAB Function block do not have to match the argument names for the function that you define in the Simulink Function block. For a Function Caller block that calls a Simulink Function block, argument names must match.

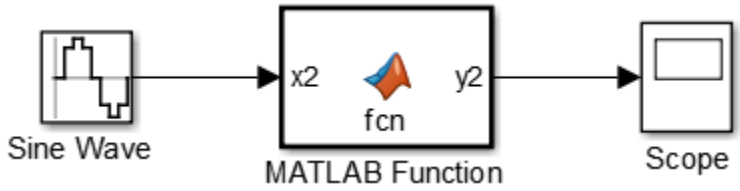
3. Add a Sine Wave block for an input signal and a Scope block to view the output signal.



4. For the Sine Wave block, set the **Sample time** to `0.01`. For the model, open the Configuration Parameters dialog box to the solver pane. Set **Type** to `Fixed-step` and **Fixed-step size** to `0.01`.
5. Set up a Simulink Function block as described in “Simulink Function Block” on page 10-117.

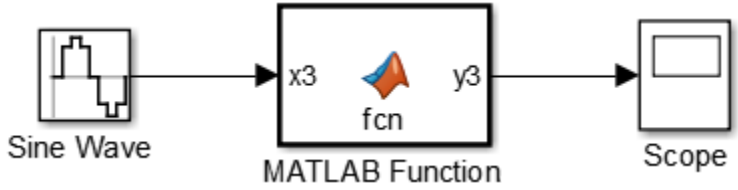
MATLAB Function Block to Call Exported Graphical Function

Calling an exported graphical function from a MATLAB Function block is the same as calling a Simulink Function block. See “MATLAB Function Block to Call Simulink Function Block” on page 10-128.



MATLAB Function Block to Call Exported MATLAB Function

Calling an exported MATLAB function from a MATLAB Function block is the same as calling a Simulink Function block. See “MATLAB Function Block to Call Simulink Function Block” on page 10-128.



Call Simulink Functions from a Stateflow Chart

The following examples show how to use a Stateflow chart to call functions external to the chart but accessible in a Simulink model:

- Simulink Function block
- Exported Stateflow graphical function
- Exported Stateflow MATLAB function

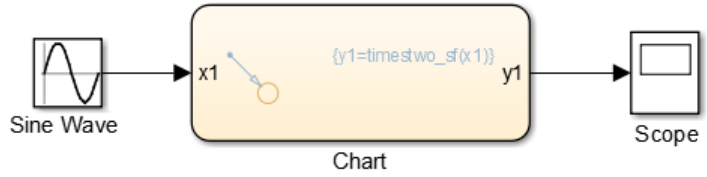
There are no limitations to a function call from a Stateflow chart:

- Caller argument names can be different from the function argument names.
- Input signals to a Stateflow chart can be either continuous or discrete.

Create Stateflow Chart with a Transition

1. Add a Stateflow Chart to your Simulink model. From the Simulink Editor menu, select **File > New > Chart**. A new chart opens in a new model.
2. Drag the new chart to your model. Double-click the chart to open it.
3. Add a graphical function. From the left-side toolbar, click and drag the transition icon  onto the chart.
4. Add input port.
   a. From the menu, select **Chart > Add Inputs & Outputs > Data Input From Simulink**.
   b. In the Data dialog box, set **Name** to `x1`.
5. Add output port.
   a. From the menu, select **Chart > Add Inputs & Outputs > Data Output To Simulink**.
   b. In the Data dialog box, set **Name** to `y1`.
6. Add a Sine Wave block and connect signal output to the chart input port. Add a Scope block and connect input to the chart output port.
7. Edit transition code to call a function. For example, to call the Simulink Function block, enter:

```
{y1=timestwo_sf(x1);}
```



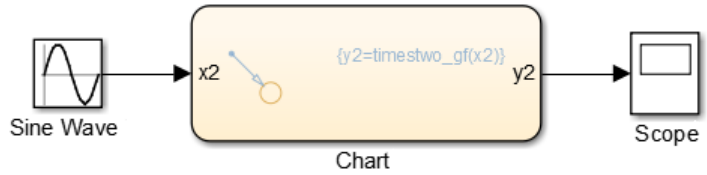
8. Set up a Simulink Function block as described in “Simulink Function Block” on page 10-117.

Stateflow Chart to Call Exported Graphical Function

Calling an exported graphical function from a Stateflow chart is the same as calling a Simulink Function block. See “Call Simulink Functions from a Stateflow Chart” on page 10-129.

1. Open a Stateflow chart.
2. Click transition and enter

```
{y2=timestwo_gf(x2);}
```

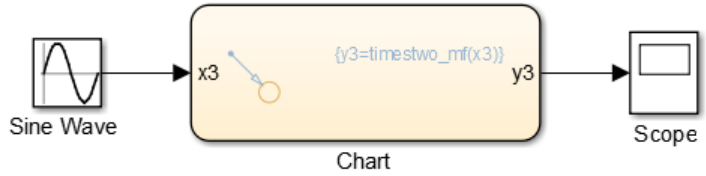


Stateflow Chart to Call Exported MATLAB Functions

Calling an exported MATLAB function from a Stateflow chart is the same as calling a Simulink Function block. See “Call Simulink Functions from a Stateflow Chart” on page 10-129.

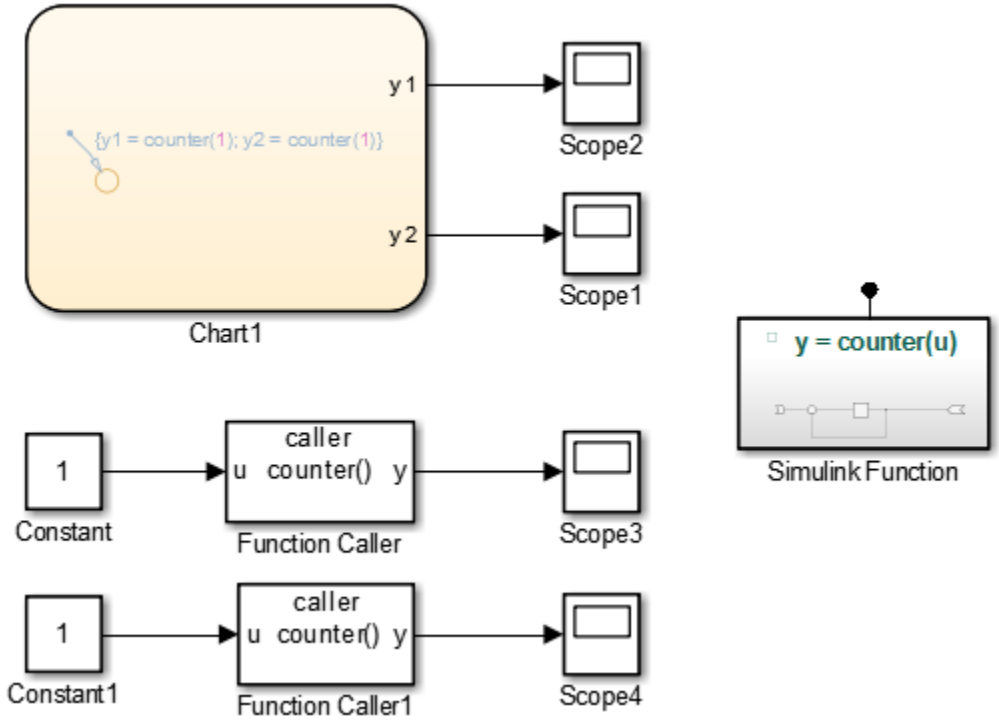
1. Open Stateflow chart.
2. Click transition and enter:

```
{y3=timestwo_sf(x3);}
```

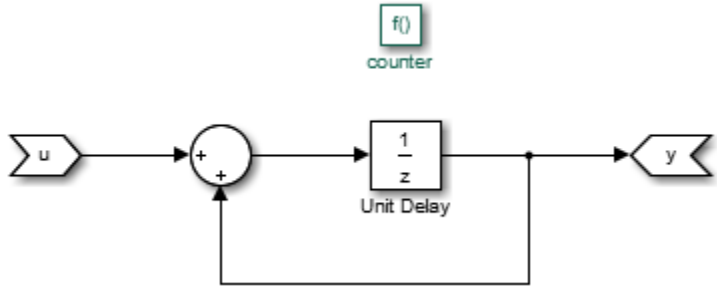


Call a Simulink Function Block from Multiple Sites

If you call a Simulink Function block from multiple sites, all call sites share the state of the function. For example, suppose that you have a Stateflow chart with two calls and two Function Caller blocks with calls to the same function.



A function defined with a Simulink Function block is a counter that increments by `1` each time it is called with an input of `1`.

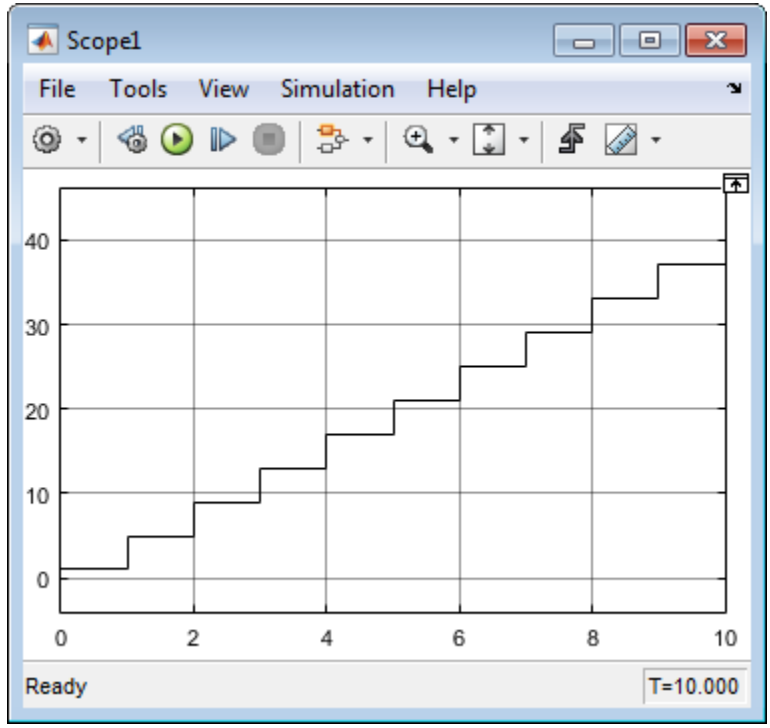


The Unit Delay block has state because the block value is persistent between calls from the two Function Caller blocks and the Stateflow chart. Conceptually, you can think of this function being implemented in MATLAB code:

```
function y = counter(u)
persistent state;
if isempty(state)
      state = 0;
end
y = state;
state = state + u;
```

Simulink initializes the state value of the Unit Delay block at the beginning of a simulation. After that, each time the function is called, the state value is updated.

In this example, the output observed in Scope1 increments by `4` at each time step. Scope2, Scope3, and Scope4 show a similar behavior. The only difference is a shift in the observed signal due to the execution sequence of the function calls.



“Create Stateflow Chart with a Transition” on page 10-130

Diagnostic Settings With Multiple Callers

For multiple callers that share a function and have different sample time rates, data integrity and consistency of real-time code might be a problem. Consider controlling the severity of diagnostics.

Select a **Fixed-step** solver. Set the **Treat each discrete rate as a separate task** to:

- Clear (single–tasking), and then set **Single task rate transition** parameter to `none` (default), `warning`, or `error`.
- Select (multi-tasking), and then set **Multitask rate transition** parameter to `error` (default) or `warning`.

Argument Specification for Simulink Functions

In this section...

When a Simulink Function block is within the scope of a Function Caller block, you do not have to specify the parameters. In such a case, the Function Caller block can determine the input and output argument specifications.

You specify arguments when a Simulink Function block is outside the scope of a Function Caller block. A Simulink Function block is considered to be out of scope of a Function Caller block when the two blocks are in separate models referenced by a common parent model.

Example Argument Specifications for Data Types

This table lists possible input and output argument specifications.

Simulink Function Block Data Type	Function Caller Block Expression	Description
`double`	`double(1.0)`	Double-precision scalar.
`double`	`double(ones(12,1))`	Double-precision column vector of length 12.
`single`	`single(1.0)`	Single-precision scalar.
`int8`, `int16`, `int32`	`int8(1)`, `int16(1)`, `int32(1)`	Integer scalars.
	`int32([1 1 1])`	Integer row vector of length 3.
	`int32(1+1i)`	Complex scalar whose real and imaginary parts are 32-bit integers.
`uint8`, `int16`, `int32`	`uint8(1)`, `uint16(1)`, `uint32(1)`	Unsigned integer scalers.

Simulink Function Block Data Type	Function Caller Block Expression	Description
`boolean`	`boolean(true),boolean(false)`	Booleans, initialized to true (1) or false (0).

`fixdt(1,16)`
 	
`fixdt (signed, word_length)`
	`fi(0,1,16)`
	
	`fi (value, signed, word_length)`
		16-bit fixed-point signed scalar with binary point set to zero.
		
		Fixed-point numbers can have a word size up to 128 bits.

`fixdt(1,16,4)`	`fi(0,1,16,4)`	16-bit fixed-point signed scalar with binary point set to 4.
`fixdt(1,16,2^0,0)`	`fi(0,1,16,2^0,0)`	16-bit fixed-point signed scalar with slope set to `2^0` and bias set to 0.
`Bus: <object name>`	`parameter object name`	`Simulink.Parameter` object with the `Value` parameter set to a MATLAB structure for the bus.
`Enum: <class name>`	`parameter object name`	`Simulink.Parameter` object with the `Value` parameter set to an enumerated value.
`<alias name>`	`parameter object name`	`Simulink.Parameter` object with the `DataType` parameter set to a `Simulink.AliasType` object and the `Value` parameter set to a value.

Input Argument Specification for Bus Data Type

Create a bus with two signals, and then specify the **Input argument specification** parameter for a Function Caller block. The Function Caller block calls a Simulink Function block that accepts the bus as input.

A bus input to a Function Caller block must be a nonvirtual bus using a bus object.

1 Create a Simulink bus object `myBus`.

```
myBus = Simulink.Bus;
```

2 Add elements `A` and `B`.

```
myBus.Elements(1).Name = 'A';
myBus.Elements(2).Name = 'B';
```

3 Create a MATLAB structure `myBus_MATLABstruct` with fields `A` and `B`.

```
myBus_MATLABStruct.A = 0;
myBus_MATLABStruct.B = 0;
```

4 Create a Simulink parameter object `myBus_parameter` and assign the MATLAB structure to the `Value` parameter.

```
myBus_parameter = Simulink.Parameter;
myBus_parameter.DataType = 'Bus: myBus';
myBus_parameter.Value = myBus_MATLABStruct;
```

5 For the Function Caller block dialog box, set the **Input argument specification** parameter to `myBus_parameter`.

6 For the Argument In block dialog box of the Simulink Function block, set the **Data type** parameter to `Bus: myBus`.

Input Argument Specification for Enumerated Data Type

Create an enumerated data type for the three primary colors, and then specify the **Input argument specification** parameter for a Function Caller block. The Function Caller block calls a Simulink Function block that accepts a signal with the enumerated type as input.

1 Create a MATLAB file for saving the data type definition. On the MATLAB toolstrip, select **New > Class**.

2 In the MATLAB editor, define the elements of an enumerated data type. The class `BasicColors` is a subclass of the class `Simulink.IntEnumType`.

```
classdef BasicColors < Simulink.IntEnumType
  enumeration
    Red(0)
    Yellow(1)
    Blue(2)
  end
end
```

3. Save the class definition in a file named `BasicColors.m`.
4. Create a Simulink parameter object `myEnum_parameter` and assign one of the enumerated values to the `Value` parameter.

```
myEnum_parameter = Simulink.Parameter;
myEnum_parameter.Value = BasicColors.Red;
```

5. For the Function Caller block dialog box, set the **Input argument specification**. to `myEnum_parameter`.
6. For the Argument In block dialog box within a Simulink Function block, set the **Data type** parameter to `Enum: BasicColors`.

Input Argument Specification for an Alias Data Type

Create an alias name for the data type single, and then specify the **Input argument specification** parameter for a Function Caller block. The Simulink Function block called by the Function Caller block also uses the alias name to define the input data type.

1. Create a Simulink alias data type object `myAlias`.

```
myAlias = Simulink.AliasType;
```

2. Assign a data type.

```
myAlias.BaseType = 'single';
```

3. Create a Simulink parameter object `myAlias_parameter` and assign the alias name to the `DataType` parameter.

```
myAlias_parameter = Simulink.Parameter;
myAlias_parameter.DataType = 'myAlias';
myAlias_parameter.Value = 1;
```

4. For the Function Caller block dialog box, set the **Input argument specification** parameter to `myAlias_parameter`.
5. For the Argument In block dialog box within a Simulink Function block, set the **Data type** parameter to `myAlias`.

- “Simulink Functions” on page 10-106

Simulink Functions in Referenced Models

In this section...

You can place Simulink Function blocks and function callers (such as Function Caller blocks and Stateflow charts) in a referenced model, but doing so requires some special considerations:

- The referenced model must follow export-function model rules. See “Export-Function Models” on page 10-76.
- Sometimes, you must explicitly define the argument data types for a Function Caller block.

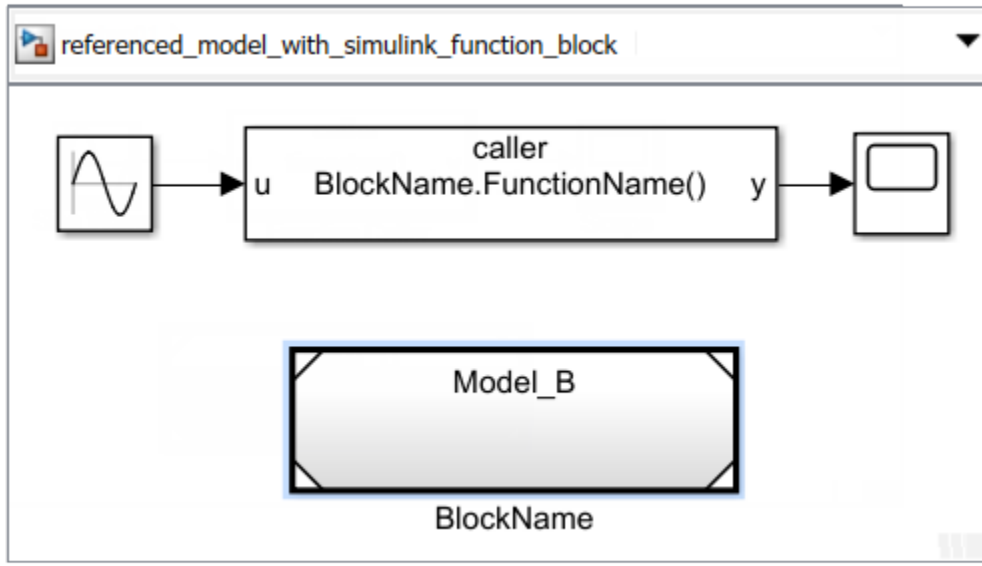
These examples show four relationships between Function Caller blocks, Simulink Function blocks, and referenced models.

Simulink Function Block in Referenced Model

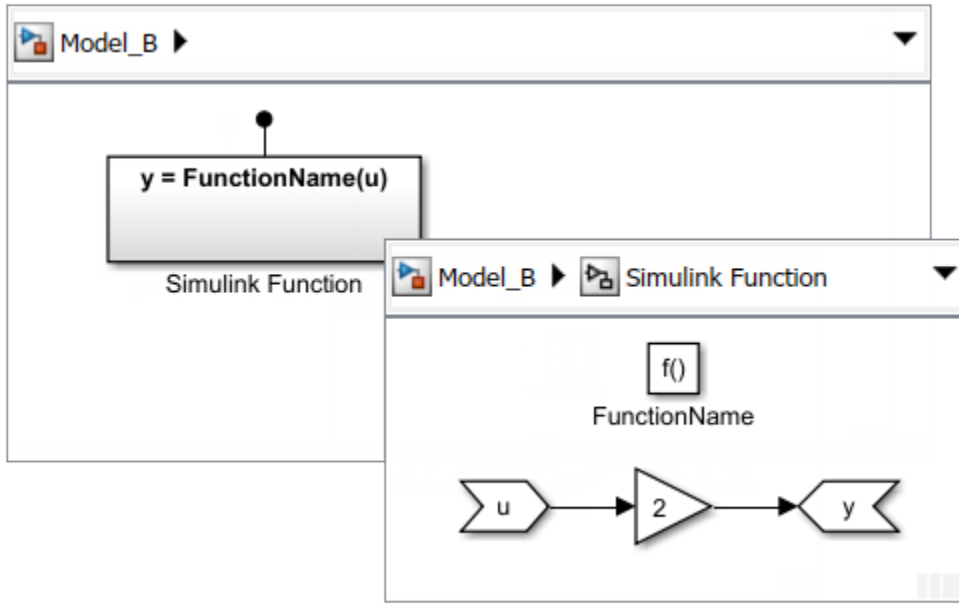
In this example, the parent model contains a Function Caller block, and the referenced model, `Model_B`, contains a Simulink Function block. `Model_B` must follow export-function model rules.

The Function Caller block can determine the argument data types of the function. In the Function Caller block, you do not need to define the **Input argument specification** and **Output argument specification** parameters.

But since, by default, the Simulink Function block is scoped to the model, you need to qualify a call to the function name with the Model block name.



`Model_B` contains a Simulink Function block that defines a function for multiplying the input by 2. Because this model contains only a Simulink Function block, it satisfies export-function model rules. See “Export-Function Models” on page 10-76.



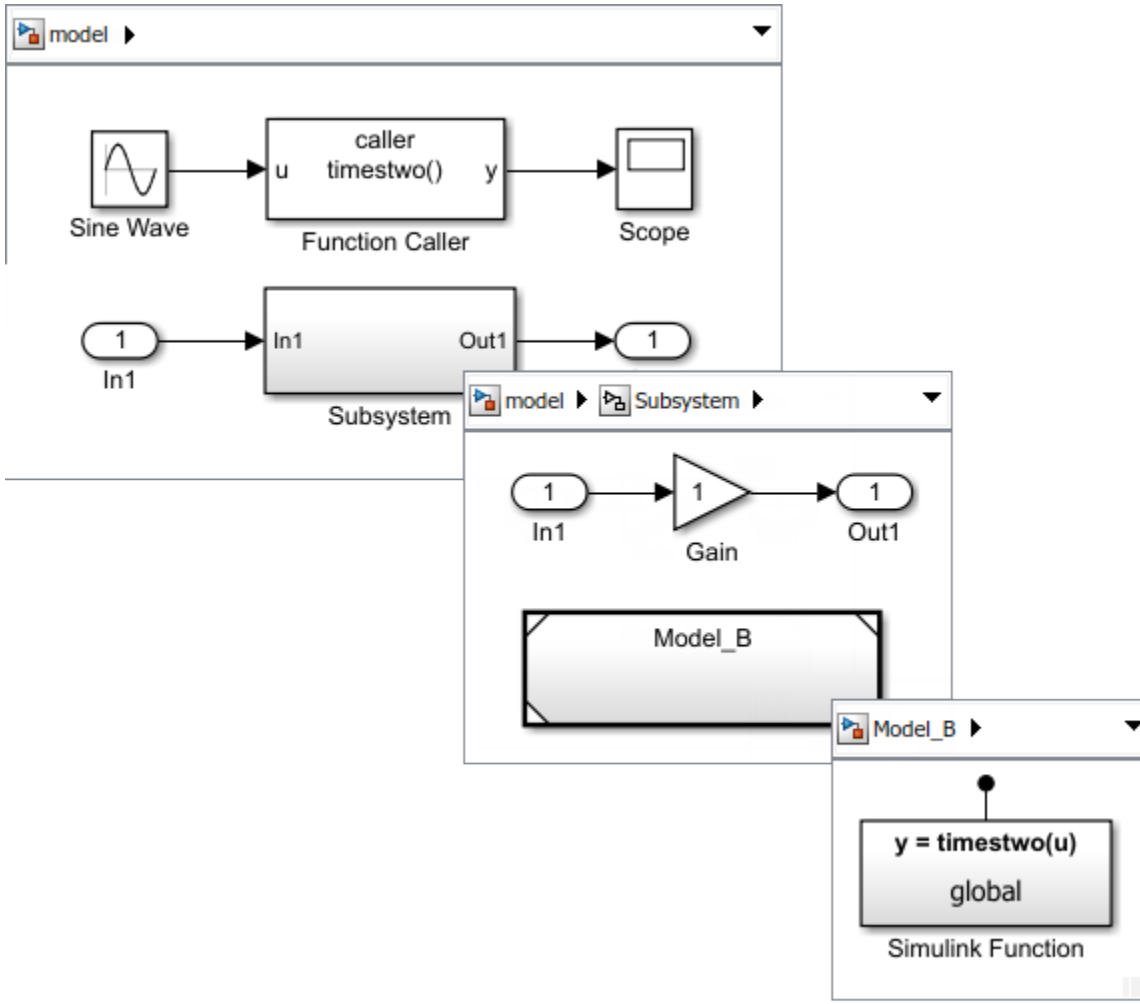
For `Model_B`, set the Configuration Parameters for the solver to satisfy export-function model rules:

- **Type**: `Fixed-step`.
- **Solver**: `discrete (no continuous states)`.

Simulink Function in Referenced Model Placed in Subsystem

Once the Simulink Function block is identified as global by placing at it at the root level of a referenced model there are no limitations on where this referenced model can be placed.

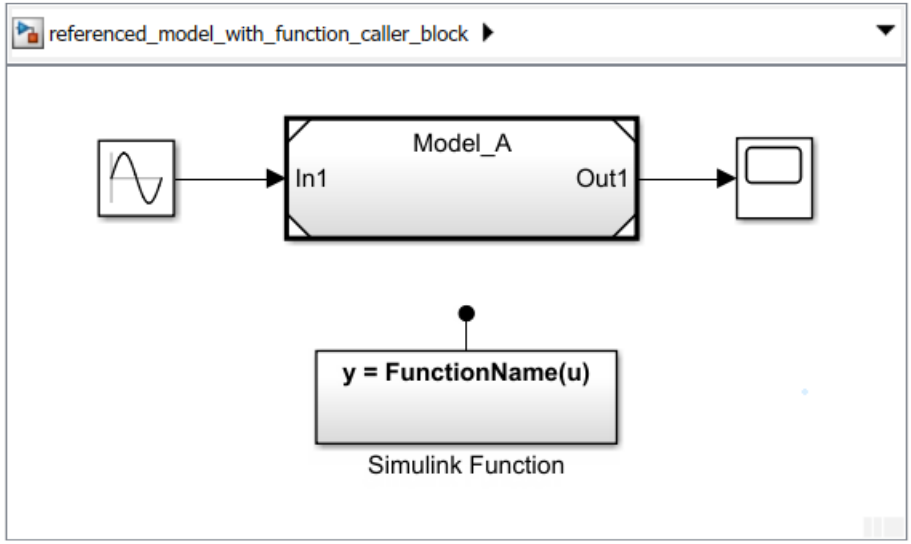
For example, you could place `Model_B` with a Simulink Function block in a Subsystem block.



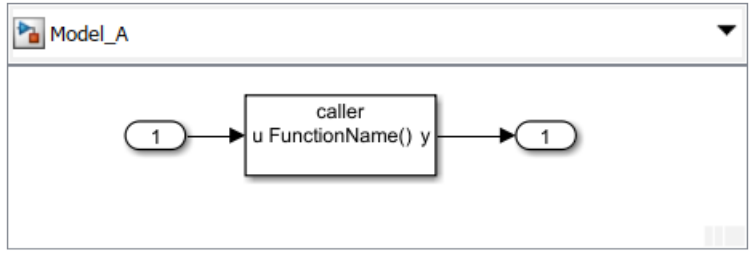
Function Caller Block in Referenced Model

In this example, the parent model contains a Simulink Function block, and a referenced model, `Model_A`, contains a Function Caller block. If you want to use this modeling pattering, the **Function visibility** parameter for the Trigger port block in the Simulink Function block can be set to `scoped` or `global`.

For the parent model, set the solver type to `Variable-step` or `Fixed-step`.



`Model_A` contains a Function Caller block.



Since the Function Caller block cannot find the function in `Model_A` you must provide the argument specification in one of two ways. Set the **Function visibility** parameter for the Trigger block to :

(1) `scoped` and qualify the function name in the Function Caller block **Function prototype** parameter. Add the name of the model file (not the Model block name) where the function is expected to be resolved. For example,

```
y = ModelFileName.FunctionName(u)
```

(2) `global` and specify the Function Caller block argument parameters:

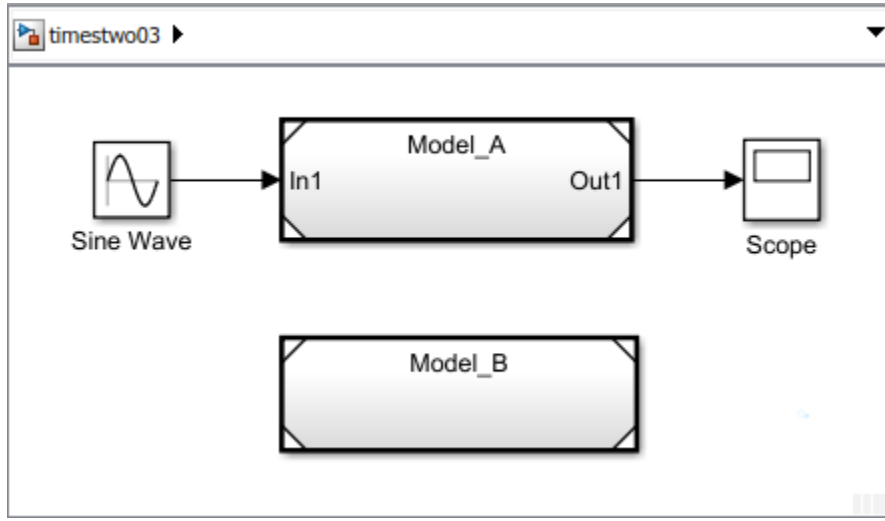
- **Input argument specification**: Specify to match the Simulink Function block input argument data types, for example, `double(1.0)`.

  Specify the argument specification for a Simulink Function block with the **Data type** parameter in the Input Argument and Output Argument blocks.
- **Output argument specification**: Specify to match the Simulink Function block output argument data types, for example, `double(1.0)`.

Function and Function Caller in Separate Models

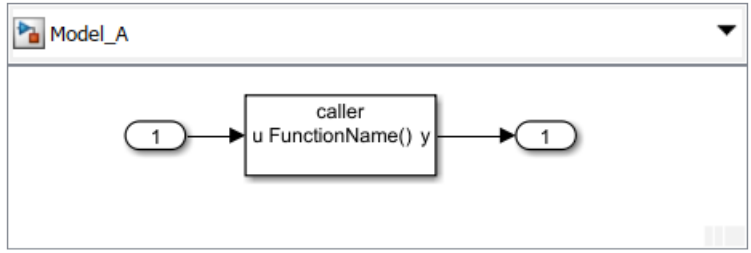
In this example, the parent model contains two referenced models. `Model_A` is a referenced model with a Function Caller block. `Model_B` is a referenced model with a Simulink Function block. Only `Model_B` with a Simulink Function block must follow export-function rules.

For `Model_A`, provide the argument specification as you do for the referenced model in "Function Caller Block in Referenced Model" on page 10-143. For `Model_B`, specify parameters as you do for the referenced model in "Simulink Function Block in Referenced Model" on page 10-140.

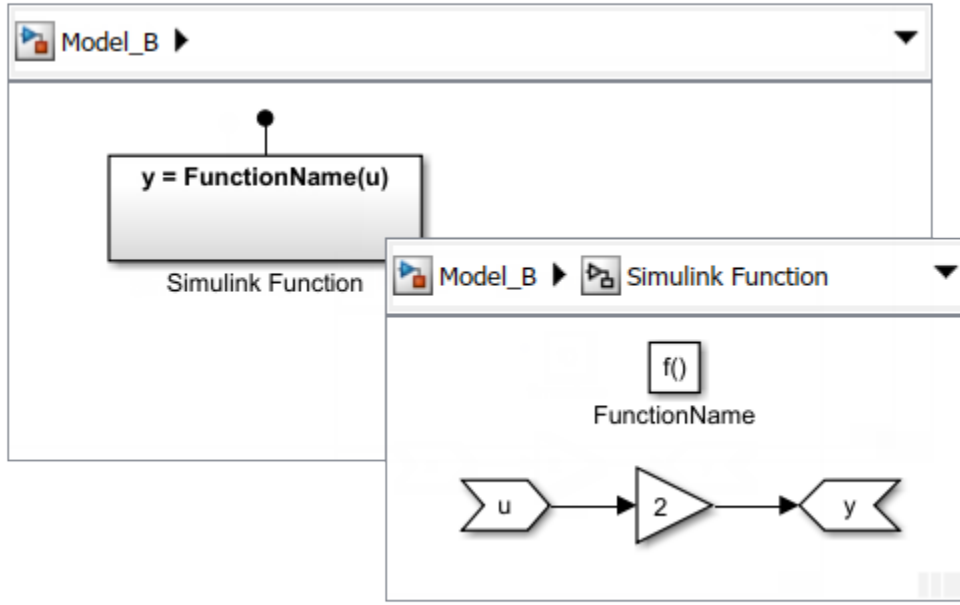


`Model_A` contains a Function Caller block. If the function is se to `global`, define the Input and Output Argument Specification parameters. If the function is set to `scoped`,

provide the file name of the model where the function is expected to be resolved to as `y = Model_B.FunctionName(u)`.

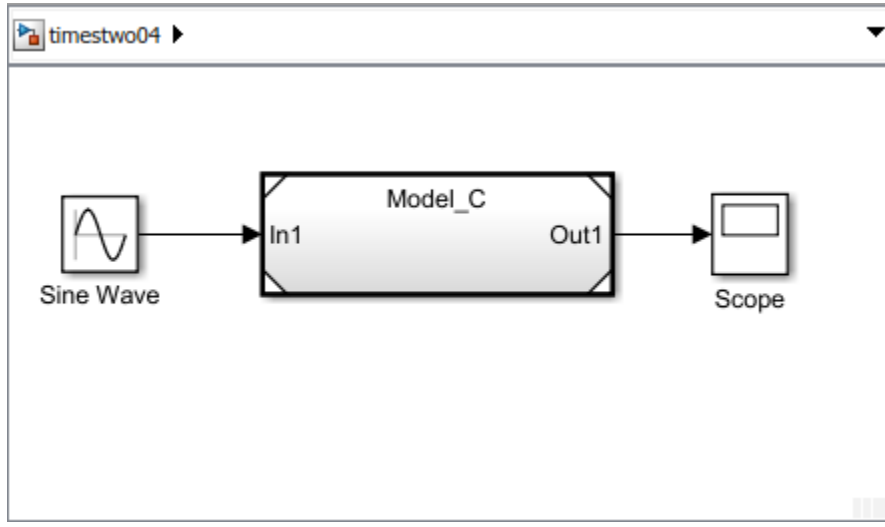


`Model_B` contains a Simulink Function block that defines a function for multiplying the input by 2. Because this model contains only a Simulink Function block, it satisfies export-function model rules. See “Export-Function Models” on page 10-76.



Function and Function Caller in the Same Model

In this example, the parent model contains one referenced model, `Model_C`, with both a Function Caller block and a Simulink Function block. Because both function and caller are in the same model, `Model_C` does not need to follow export-function rules.



`Model_C` contains both a Function Caller block and a Simulink Function block.

Scoped and Global Simulink Function Blocks

Defining the visibility of functions will help you to avoid namespace conflicts when integrating your submodels. A Simulink Function block defines the visibility of its function in relationship to the subsystem or model containing the block.

By default, the parameter **Function visibility** for the Trigger block in the Simulink Function block is set to `scoped`. The function visibility is limited to the subsystem or model where you can refer the function using the function name.

- *Function Visibility*. A scoped function is visible in its hierarchy. This means that a function caller located at the same level as the function, or one or more levels below can refer to the function. A global function is visible across a model hierarchy. This means that a function caller located anywhere in the current model or in the parent model hierarchy can refer to the function.
- *Function accessibility* is determined by the visibility of a function and the location of the function caller relative to the Simulink Function block. For function callers one hierarchical level above the function, qualify the function name with the virtual subsystem block name or model block name.
- *Function exporting* refers to functions exported from models. A function with global visibility, placed anywhere in an export function model, is exported to the top-level of a model hierarchy in addition to the model interface. A function with scoped visibility at the root level of an export function model is exported to the model interface. In both these cases, you can access the exported function outside of the model.

Summary of Simulink Function block visibility and access

	Virtual Subsystem		Atomic Subsystem		Model	
Function visibility	scoped Function name does not have to be unique	global Function name must be unique	scoped Function name does not have to be unique	global visibility not allowed	scoped Function name does not have to be unique	global Function name must be unique
Function accessibility	function caller inside hierarchy or at parent level. function caller inside hierarchy – unqualified, `fcn()` function caller at parent level – qualified with subsystem name,`subsystem.fcn()`	function caller at any level of hierarchy down or up. function caller at any level of hierarchy – unqualified, `fcn()`	function caller only inside hierarchy function caller inside hierarchy – unqualified, `fcn()` function caller at parent level – not allowed	not allowed	function caller inside hierarchy or at parent level. function caller inside hierarchy – unqualified, `fcn()` function caller at parent level - qualified with model block name,`model.fcn()`	function caller at any level of hierarchy down or up. function caller at any level of hierarchy – unqualified, `fcn()`

	Virtual Subsystem		Atomic Subsystem		Model	
Function exporting	na	Function at any level of model exported to the global name space of the top-level model	na	na	Function at the root level of a model exported to the model interface	Function at any level of model exported to the global name space of the top-level model

Use Cases

Placing a virtual subsystem at the root level of a model and setting **Function visibility** to `scoped`, allows you to create a library of Simulink functions. The functions are accessible from anywhere in your model.

Scoping Simulink Functions in Subsystems

The scope of a Simulink function is defined in its parent subsystem within the context of a model. If you place a function in a model at the root level, the function is scoped to the model by default. If you place a function in any Subsystem block, access to the function from outside the model is prohibited by default. In both cases, the Trigger block parameter **Function visibility** is set to `scoped`. The function can be placed:

- In a virtual subsystem — Call the function from within the subsystem without qualifying the function name, or call the function from outside the subsystem by qualifying the function name with the subsystem name.
- In an atomic or non-virtual subsystem — Call the function from within the subsystem by resolving hierarchically. Access to the function from outside of the subsystem is prohibited.

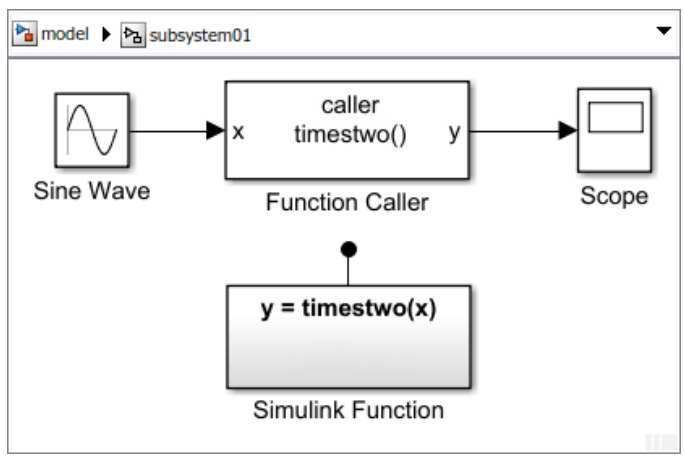
Resolve to a Function Hierarchically

Placing a Simulink Function block within any subsystem block limits access to the function and removes the function name from the global namespace. You can call the function from inside the subsystem without qualification. For example:

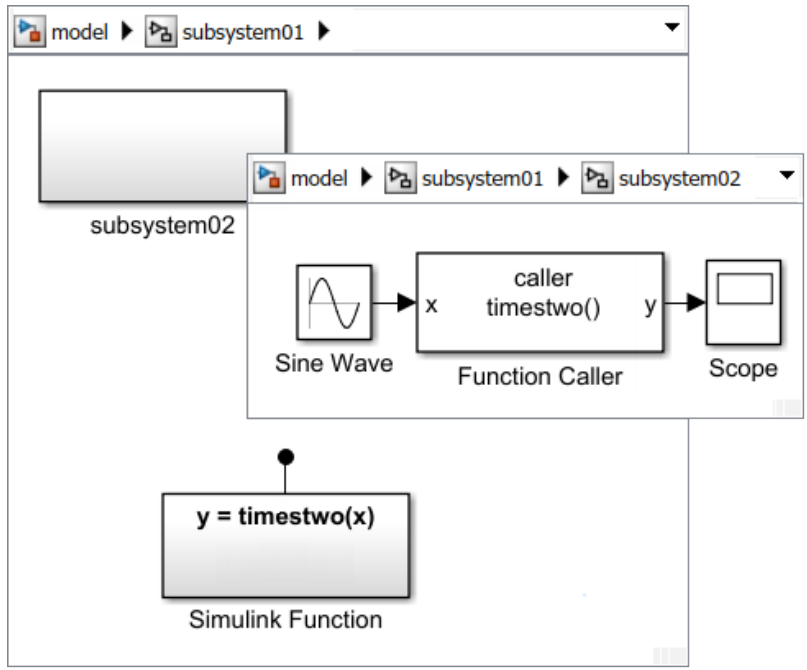
```
y = function_name(x)
```

The function caller can be:

- At the same hierarchic level as the function.



- In a subsystem one or more levels below the hierarchic level of the function.



You can also call a Simulink Function block in a Subsystem block without qualification from a MATLAB Function block or a Stateflow chart within the subsystem.

Resolve to a Function by Qualification

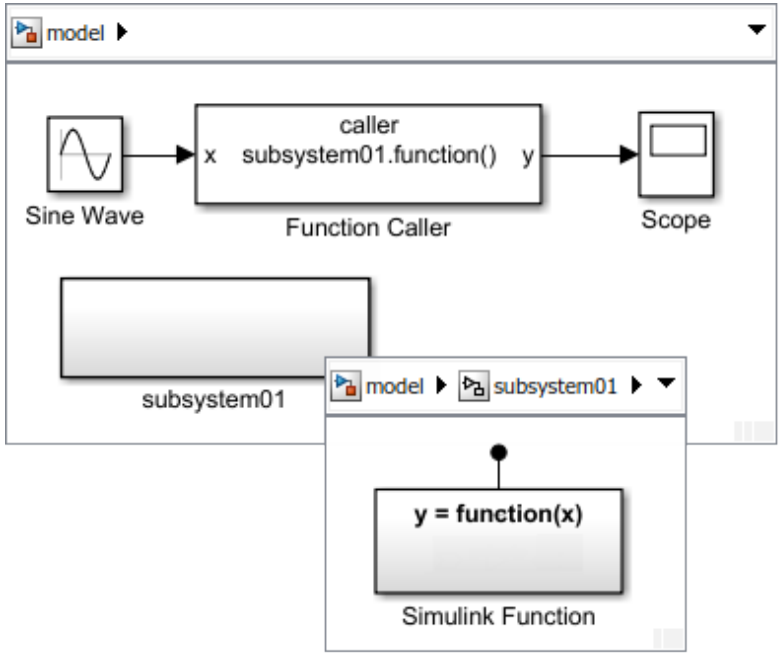
When you place a Simulink Function block in a virtual Subsystem block, the function name is not visible outside of the subsystem. However, you can call the function by qualifying the function name with the subsystem name. For example:

```
y = subsystem01.function(x)
```

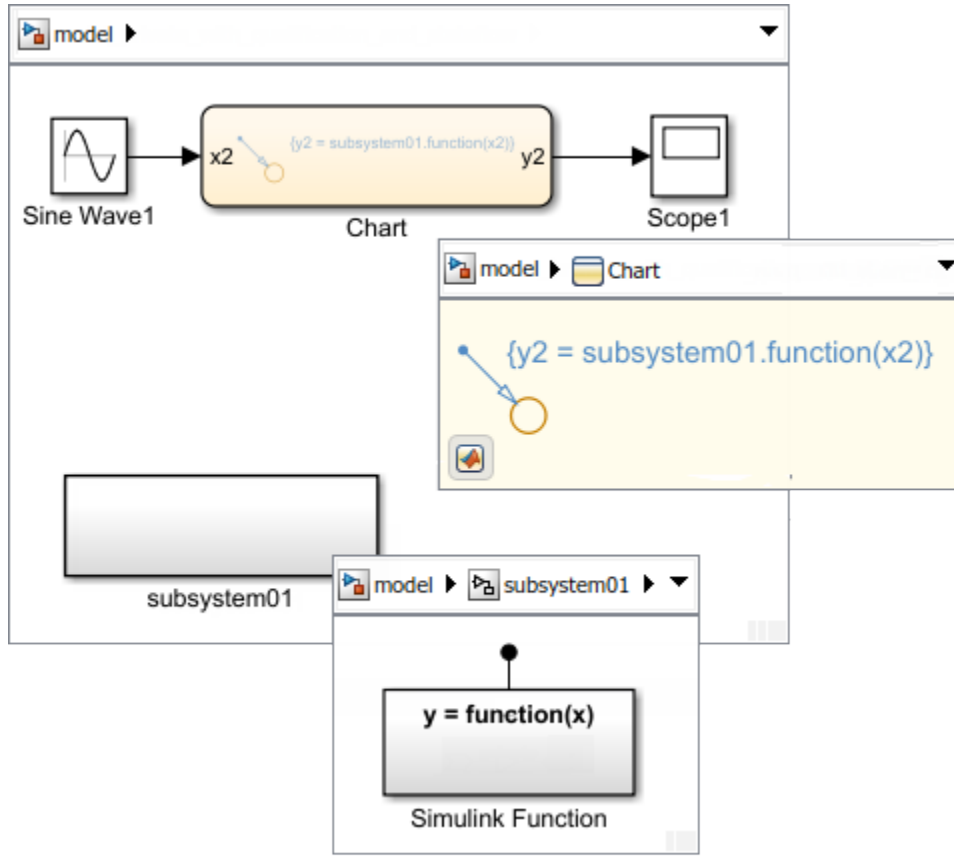
A function caller must be in a hierarchical branch and at a level where it can resolve to the subsystem containing the function:

- Outside the subsystem one hierarchic level above the function.

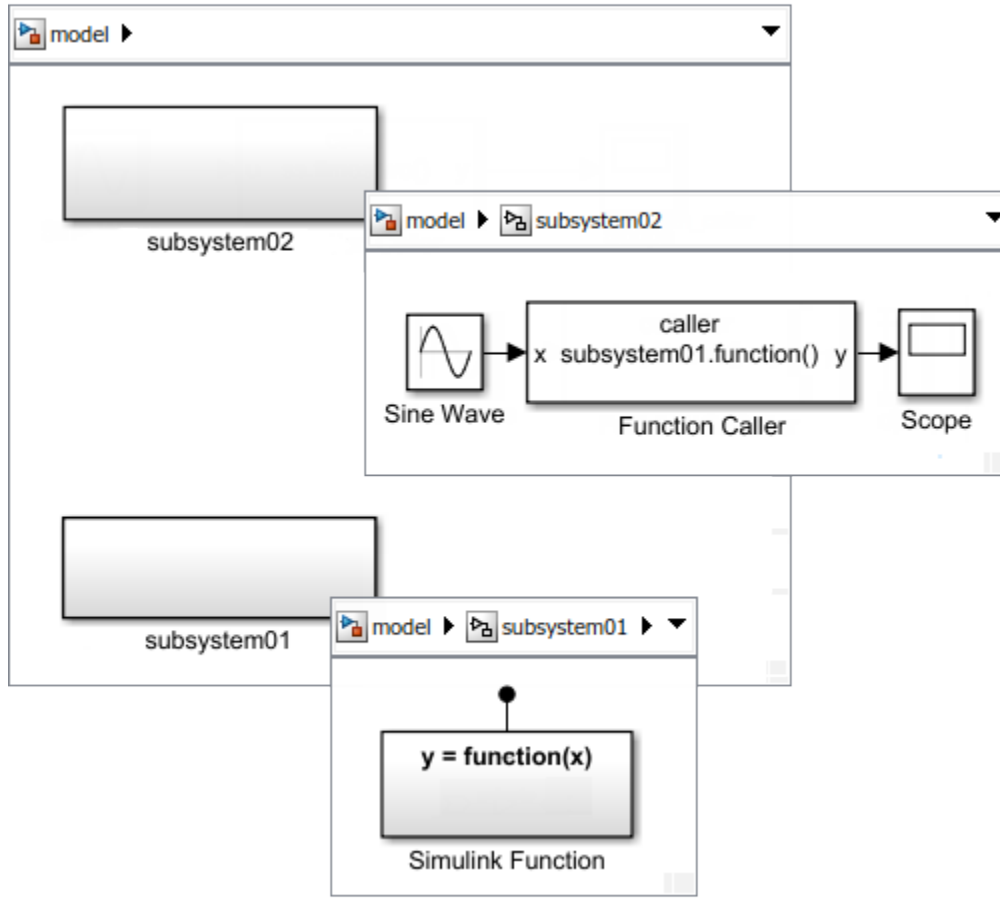
  Calling the function from a Function Caller block.



Calling the function from a Stateflow chart.



- In another subsystem at the same hierarchic level as the function.



- In another subsystem one or more levels below the hierarchic level of the function.

- “Export Stateflow Functions for Reuse” (Stateflow)

Scope Simulink Functions in Models

The scope of a Simulink function is defined in the context of a model. If you place a function at the root level of a model, the function is scoped to the model by default. The Trigger block parameter **Function visibility** is set to `scoped`, and access to the function from outside the model is possible using qualificaton.

Access the function from:

- Within the model without qualifying the function name.
- Outside the model by qualifying the function name with the model instance name.

Setting **Function visibility** for a Simulink Function block to `global` allows you to access the function from anywhere in a model or the parent model. As a result, models with a Simulink Function block set to global cannot be multi-instanced because function names must be unique.

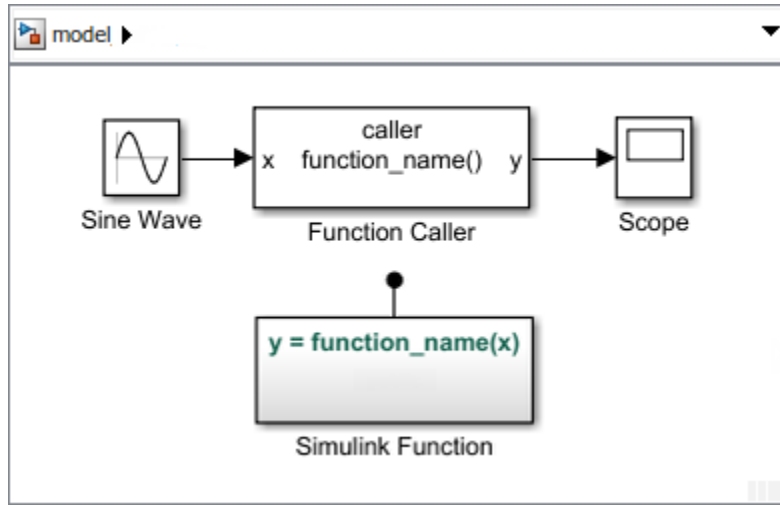
Resolve to a Function Hierarchically

Placing a Simulink Function block within a model at the root level limits access to the function and removes the function name from the global namespace. You can call the function from inside the model without qualification. For example:

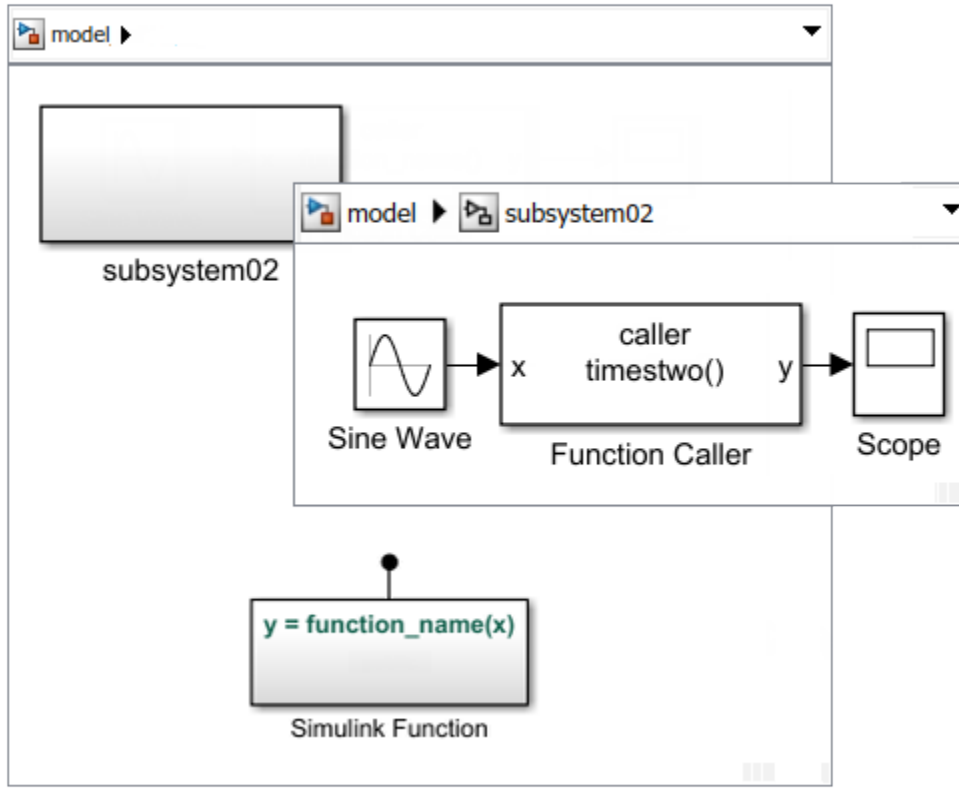
```
y = function_name(x)
```

The function caller can be:

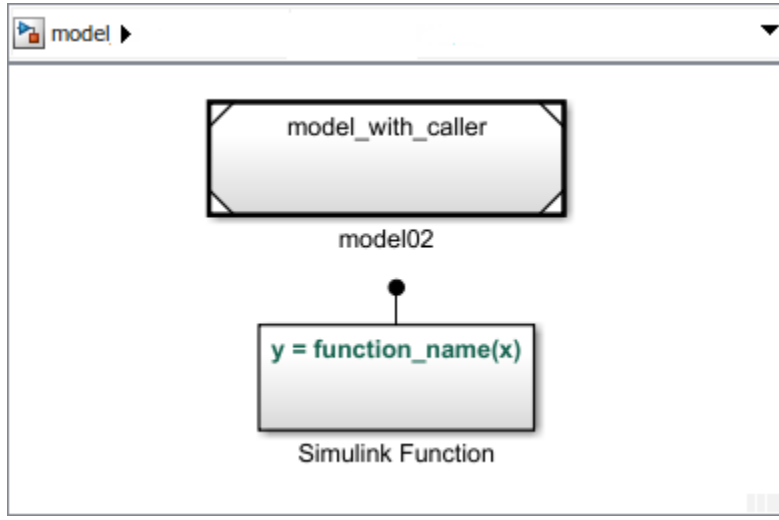
- At the same hierarchic level as the function



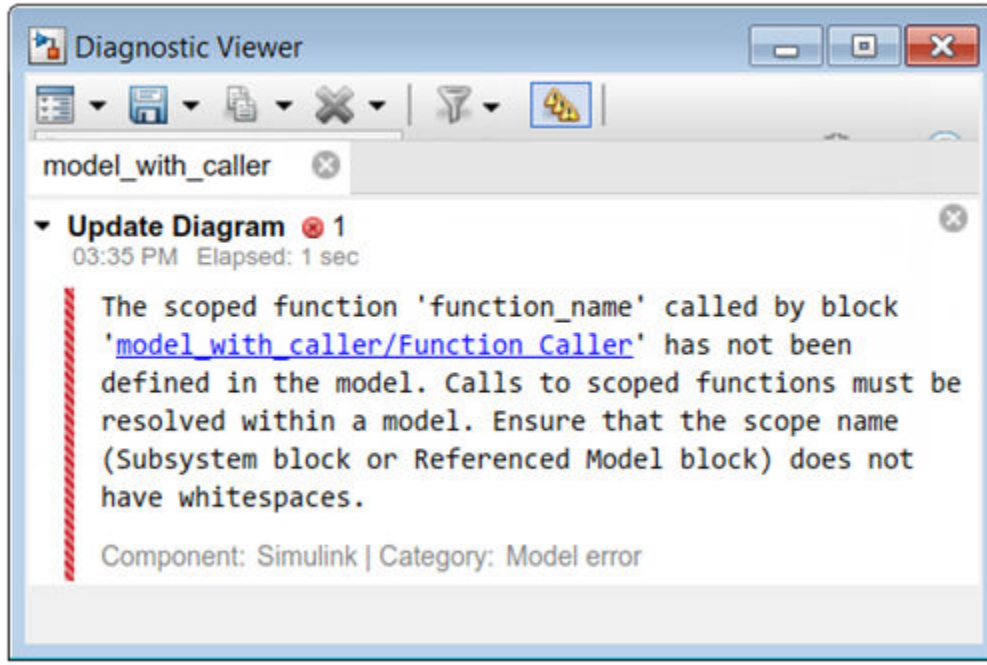
- In a subsystem or model one or more levels below the hierarchic level of the function



- You cannot place a function caller inside a Model block and the Simulink Function block in the parent model,



If you place a function caller inside a Model block, Simulink displays an error. This error occurs because the model containing the caller does not know the name of the function.



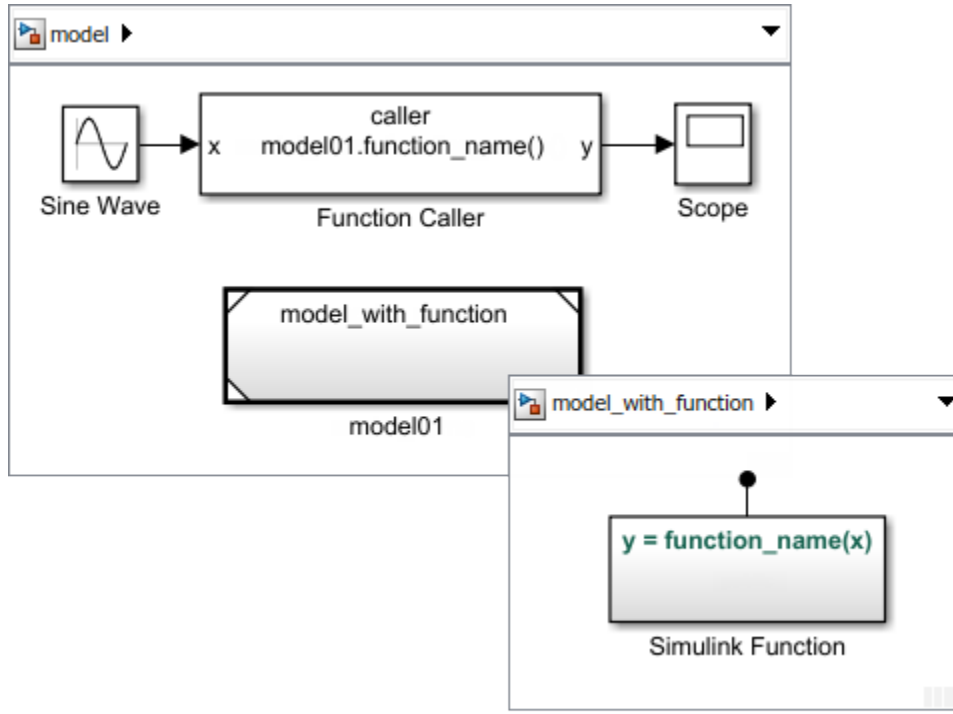
Resolve to a Function by Qualification

When you place a Simulink Function block in a Model block, the function name is not accessable outside the model. To call the function from outside the model, qualify the function name with the model block name in the parent model. For example:

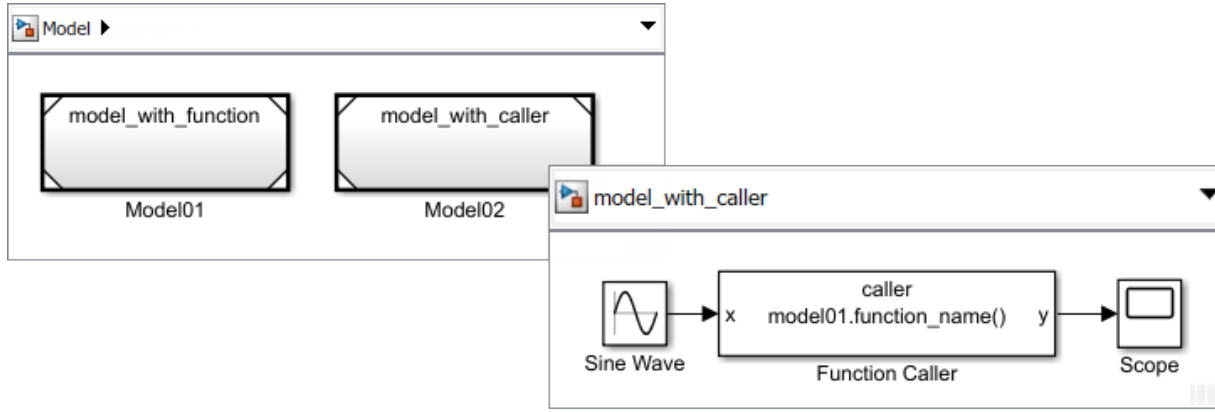
```
y = model01.function_name(x)
```

A function caller can be at a level where it can hierarchically resolve to the model instance containing the function:

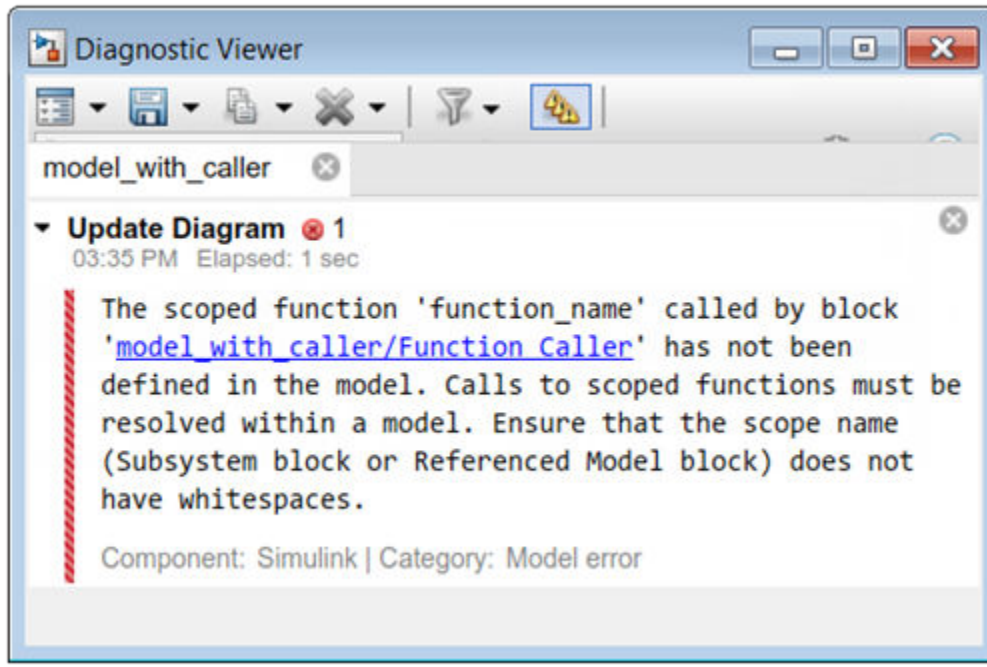
- The function caller can be outside the model one hierarchic level above the function.



- You cannot place a Simulink Function block in one Model block and the function caller in another Model block..



If you place a Simulink Function block in a referenced model and a function caller in another referenced model, Simulink displays an error. This error occurs because the qualified function name using the Model block name is not visible to the model containing the caller.

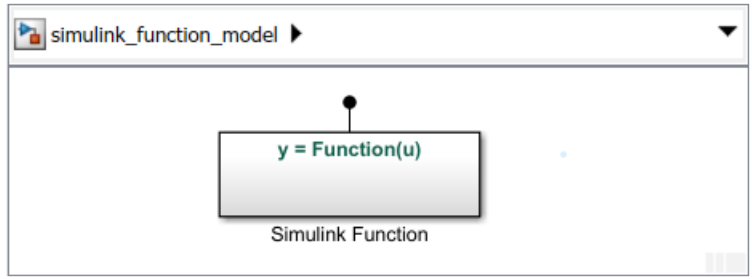


If you want to access the function using this modeling pattern, see the section Function Caller Block in Referenced Model and Function and the section Function Caller in Seperate Models in the topic “Simulink Functions in Referenced Models” on page 10-140.

Multi-Instance Modeling with Simulink Functions

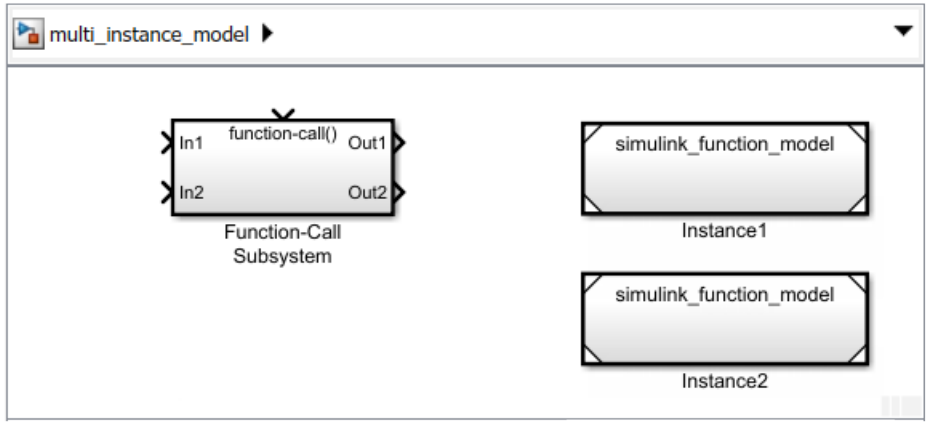
Setting **Function visibility** for a Simulink Function block to `scoped` allows you to multi-instance a model containing the function. This model behavior is allowed because the function is encapsulated within the model. Adding the model instance name to the function name creates a qualified function name that is unique within the parent model.

1 Create a model containing Simulink Function blocks.

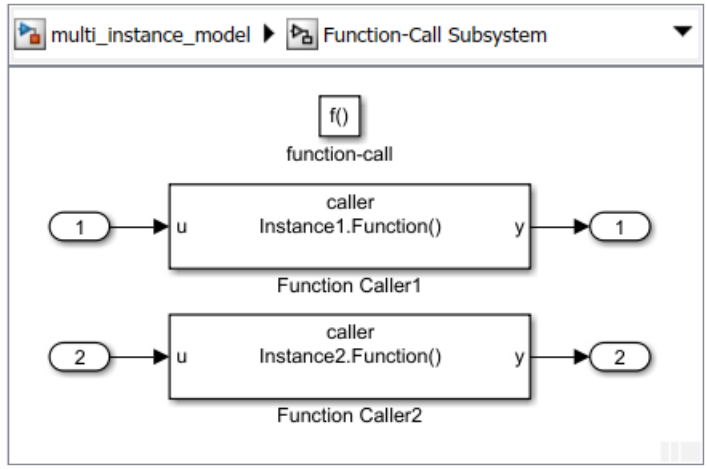


By default, the **Function visibility** parameter for the Trigger block within the Simulink Function block is set to `scoped`.

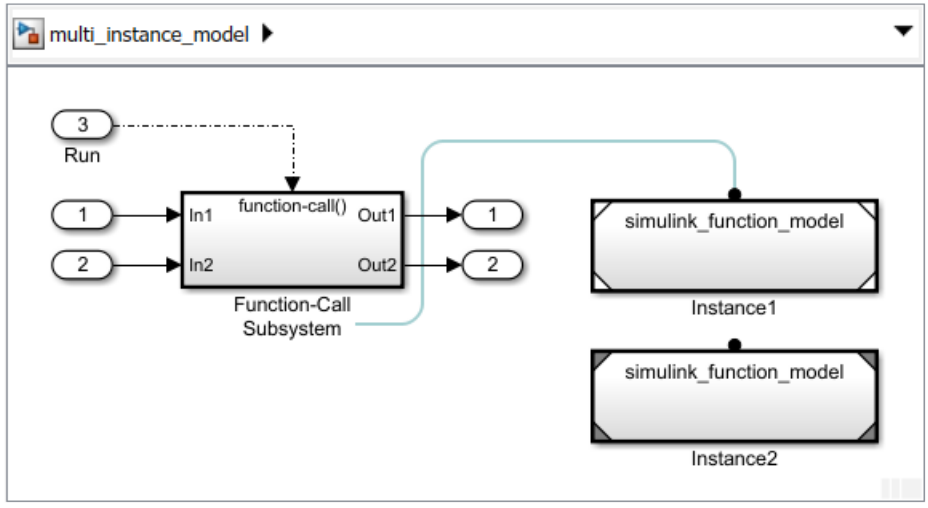
2 Reference the model with Simulink functions from multiple Model blocks. Add a Function-Call Subsystem block to schedule calls to the functions.



3 Add Function Caller blocks to the Function-Call Subsystem block. Access the function in separate model instances by qualifying the function name with the block name.



4 From the **Display** menu, select **Function Connectors**. Tracing lines are drawn to help you navigate from a function caller to the function.



For a model using Simulink Function blocks with multiple instances, see “Modeling Reusable Components Using Multiply Instanced Simulink Functions”.

Diagnostics Using a Client-Server Architecture

In this section...

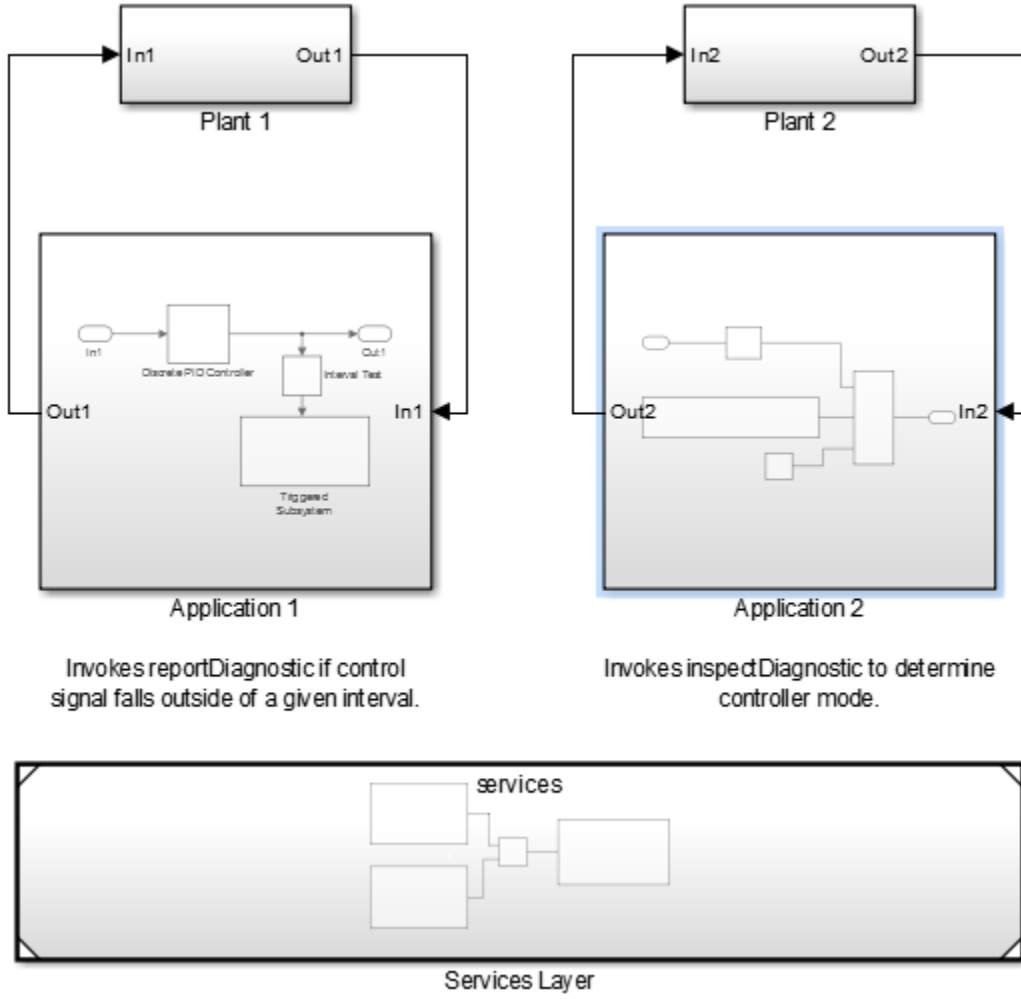
Diagnostic Messaging with Simulink Functions

Use Simulink functions when you define a diagnostic service where callers pass an error code. The service tracks error codes for all errors that occur. One-way to implement this service is to use an indexed Data Store Memory block. A diagnostic monitoring system can then periodically check for the occurrence of specific errors and modify system behavior accordingly.

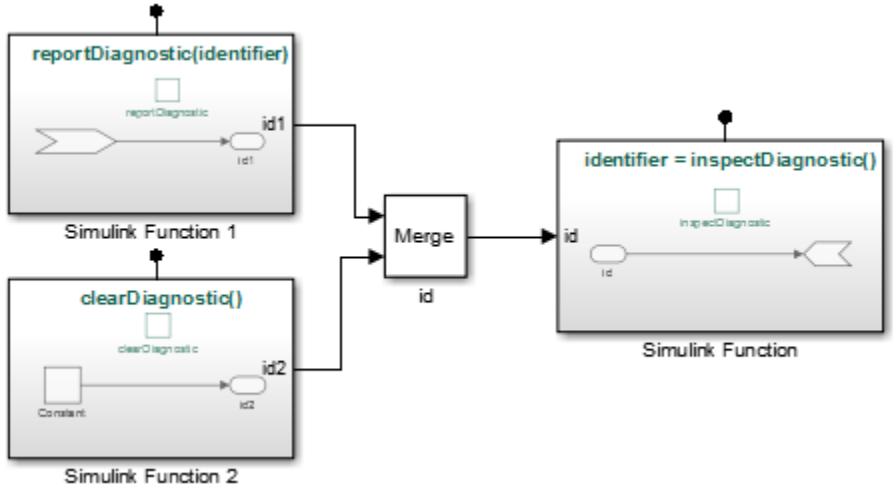
Client-Server Architecture

You can use Simulink Function blocks and Function Caller blocks to model client-server architectures. Uses for this architecture include memory storage and diagnostics.

As an example, create a model of a simple distributed system consisting of multiple control applications (clients), each of which can report diagnostics throughout execution. Since client-server architectures are typically constructed in layers, add a service layer to model the diagnostic interface.



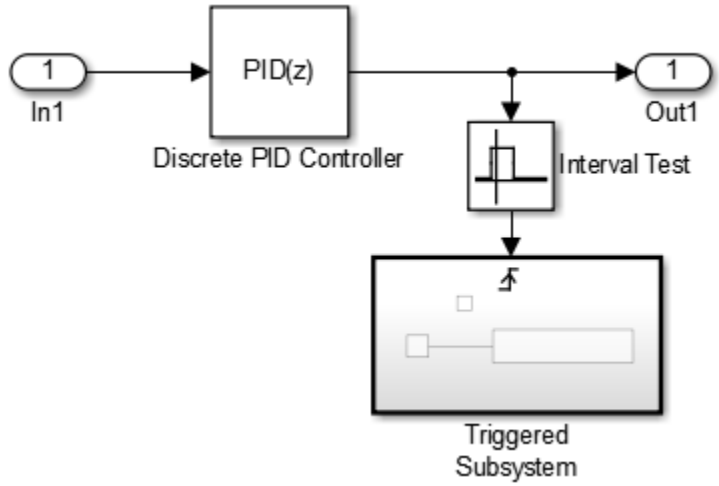
The services (servers), modeled using Simulink Function blocks, are in a separate model. Add the service model to your system model as a referenced model.



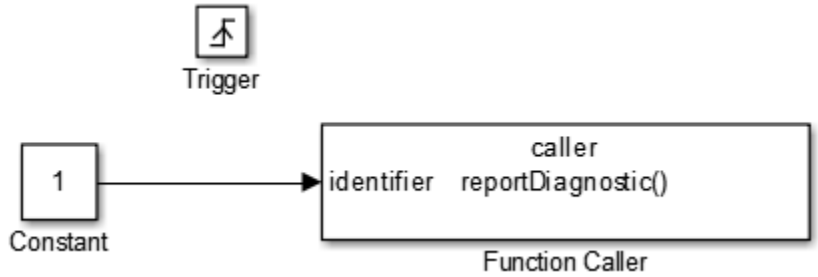
The control applications (clients) interact with the diagnostic interface using Function Caller blocks.

Modifier Pattern

Application 1 reports a diagnostic condition by invoking the `reportDiagnostic` interface within the service layer. The application calls this function while passing in a diagnostic identifier.



The interval test determines when to create a diagnostic identifier.

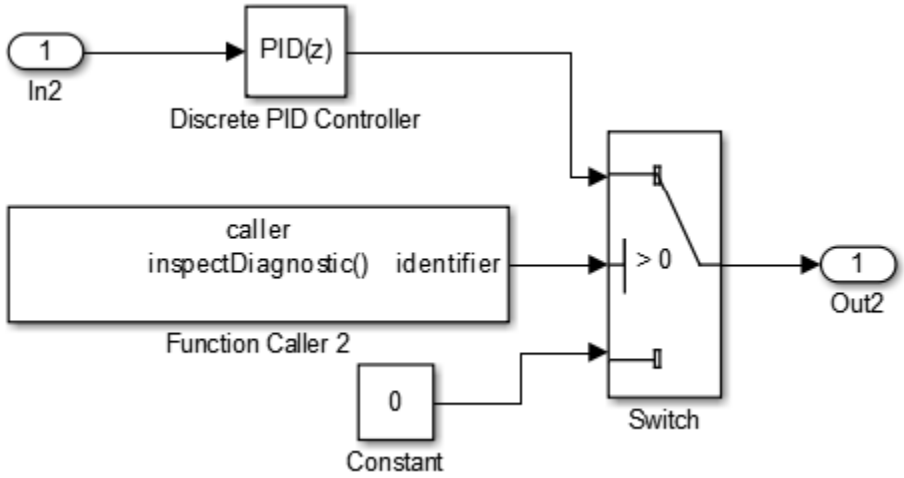


The implementation of the function (Simulink Function 1) tracks the passed-in identifier by transferring the value to a graphical output of the function. A graphical output is a server-side signal that is not part of the server interface but facilitates communication between service functions through function arguments. The value of graphical outputs is held between function invocations.

The `reportDiagnostic` function is an example of a modifier pattern. This pattern helps to communication of data from the caller to the function and later computations based on that data.

Observer Pattern

Application 2 invokes the `inspectDiagnostic` interface within the service layer to inspect whether diagnostics were reported.



The implementation of the function (Simulink Function) uses a graphical input (`id`) to observe the last reported diagnostic and transfer this value as an output argument (`identifier`) to the caller. A graphical input is a server-side signal that is not part of the server interface.

The `inspectDiagnostic` function is an example of an observer pattern. This pattern helps to communication of data from the function to the caller.

Initialize, Reset, and Terminate Function Limitations

In this section...

Unsupported Blocks

Initialize, Reset, and Terminate Function blocks do not support:

- Model blocks
- Custom code blocks
- Stateflow charts
- Resettable Subsystem blocks
- Conditional Subsystem blocks with an output port
- Blocks with state, for example, Unit Delay blocks
- Blocks with absolute time, for example, Clock blocks
- MATLAB Function blocks or MATLAB System blocks with states. However, MATLAB Function blocks without persistent and global data and MATLAB Function blocks that do not use Signal Objects are supported.

Initialize, Reset, and Terminate Function blocks cannot call Simulink Function blocks with:

- Input or output ports
- An Initialize Function, Reset Function, or Terminate Function block
- Unsupported blocks

Unsupported Features

Initialize, Reset, and Terminate Function blocks do not support:

- Using variable-size signals

- Logging signals from Inport and Outport blocks

Component I/O Blocks

The input and output ports of a model component containing Initialize Function, Reset Function, or Terminate Function blocks must connect to root Inport and Outport blocks without intervening blocks.

In this example, an Initialize Function block is placed in a Subsystem block. The model containing the Subsystem block is referenced from a model that is referenced from the root level model. Only the root level model with the **Show model initialize port** parameter selected can have blocks between the input and output ports.

Create Model to Initialize, Reset, and Terminate State

In this section...

Some blocks maintain state information that they use during a simulation. For example, the Unit Delay block uses the current state of the block to calculate the output signal value for the next simulation time step.

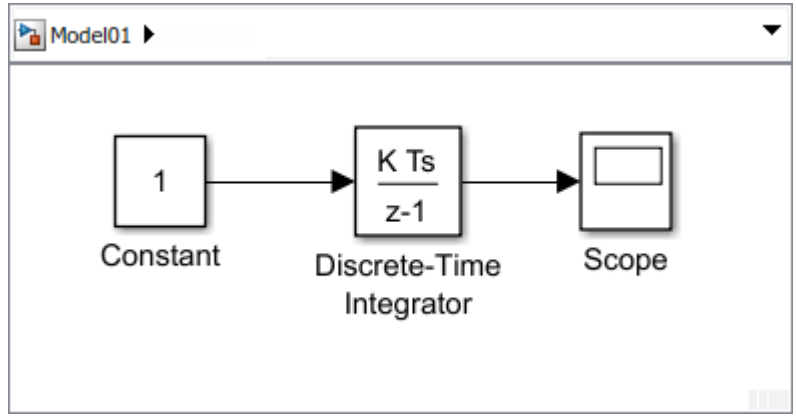
Subsystem blocks have default initialize and termination routines. You can add custom routines to the default routines using Initialize Function and Terminate Function blocks to change or read block states. These function blocks contain:

- Event Listener blocks that trigger the execution of the combined routines when receiving an initialize or terminate function-call signal.
- State Writer blocks to initialize the block state and State Reader blocks to read the state.

Create Model Component with State

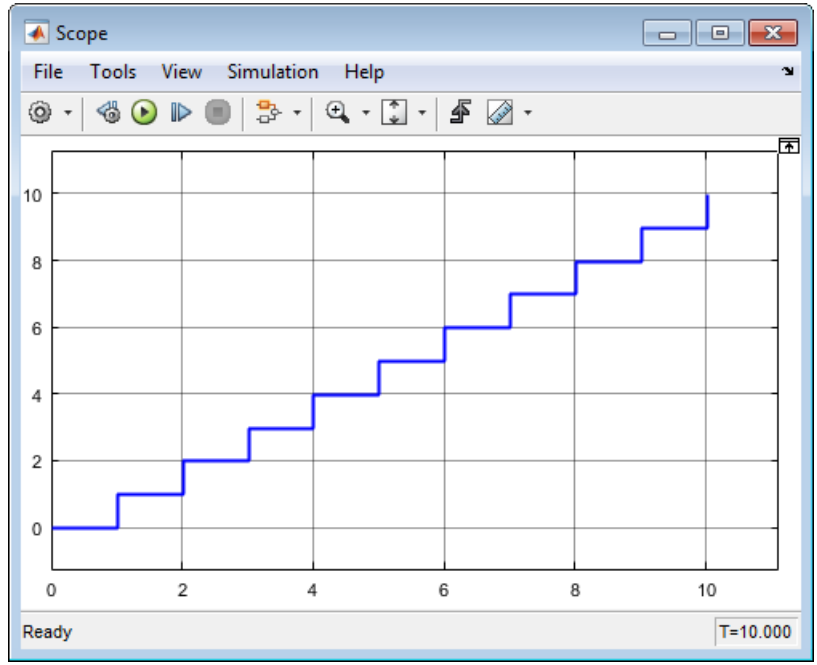
You can define model algorithms using Simulink blocks. In this example, a single Discrete-Time Integrator block defines the algorithm for integrating an input signal.

1. Open a new Simulink model. Save this model with the name `Model01`.
2. Add a Discrete-Time Integrator block. Verify the default parameter values are `1.0` for **Gain value**, `0` for **Initial condition**, `State (most efficient)` for **Initial condition setting**, and `-1` for **Sample time**.
3. Connect a Constant block to the input of the Discreate-Time Integrator block to model an input signal. Connect a Scope block to the output signal.



4 Open the Configuration Parameters dialog box. Set the simulation parameters for the Solver **Type** to `Fixed-step`, **Solver** to `auto`, and **Fixed-step size** to `1`.

5 Open the Scope block, and then run simulation. The output signal increases by `1` at each time step.



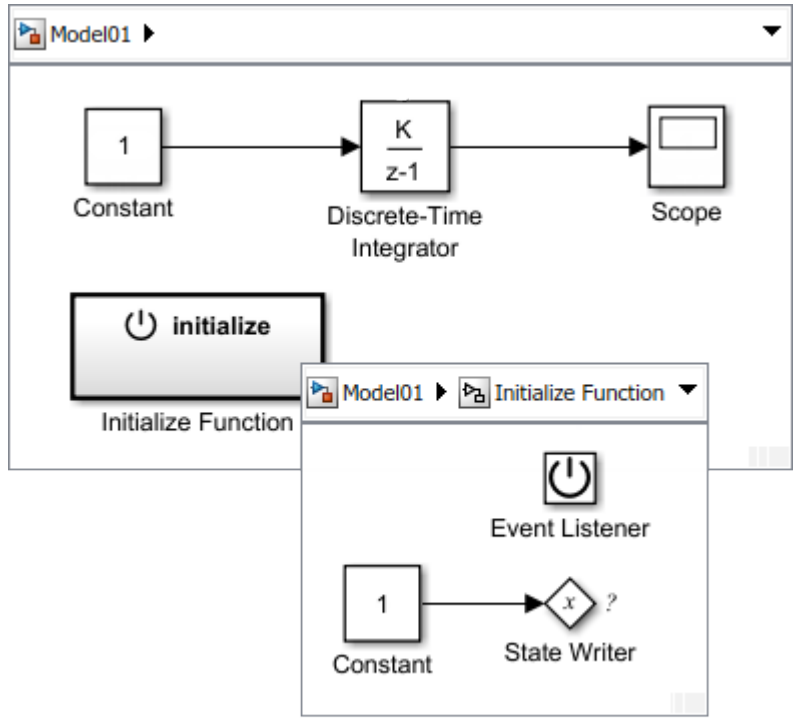
Initialize Block State

Some model algorithms contain states that you can initialize. For example, with an algorithm that reads a sensor value, you can perform a computation to set the initial sensor state.

At the beginning of a simulation, initialize the state of a block using a State Writer block. To control when initialization occurs, use an Initialize Function block that includes the State Writer block.

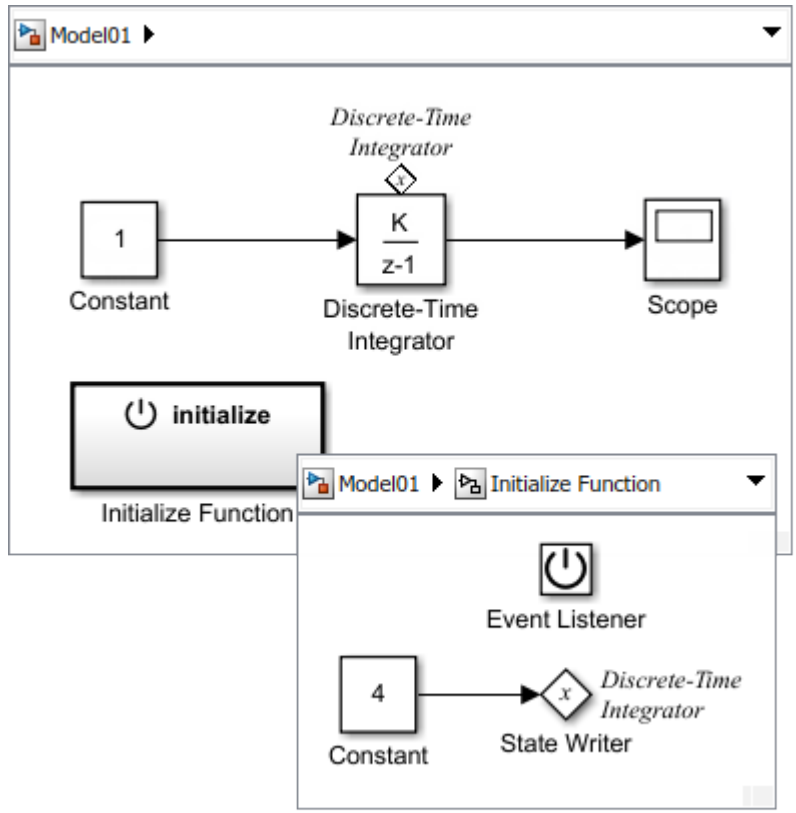
1 Add an Initialize Function block.

By default, the Initialize Function block includes an Event Listener block with the **Event type** parameter set to `Initialize`. The block also includes a State Writer block, and a Constant block as a placeholder for the source of the initial state value.



2 Model initial conditions. In this example, set the **Constant value** parameter for the Constant block to `4`.

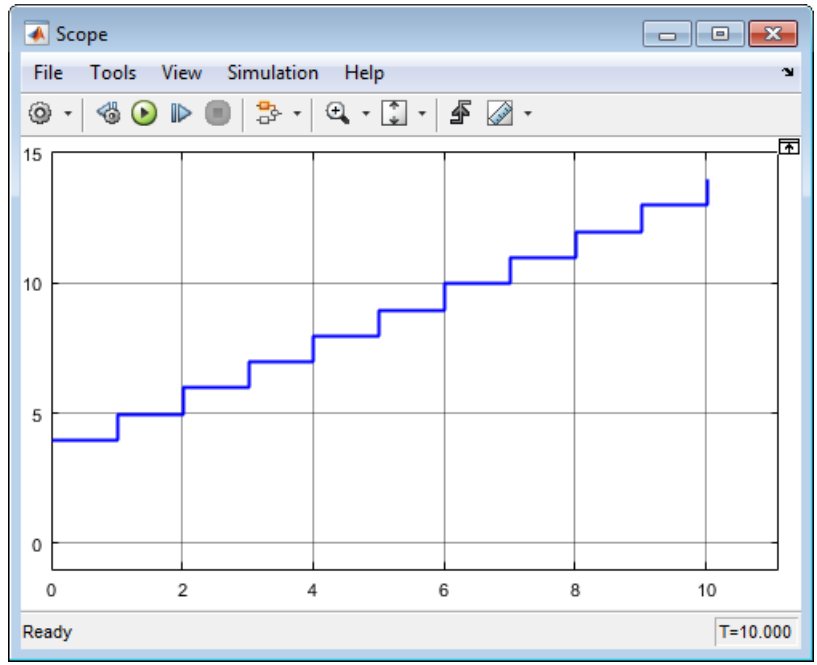
3 Connect the state writer with the state owner. Open the State Writer dialog box. Expand the State Owner Selector Tree, select `Discrete-Time Integrator`, and then click **Apply**.



The State Writer block displays the name of the state owner block. The state owner block displays a tag indicating a link to a State Writer block. If you click the label above the tag, a list opens with a link for navigating to the State Writer block.

4 Run simulation to confirm that your model simulates without errors.

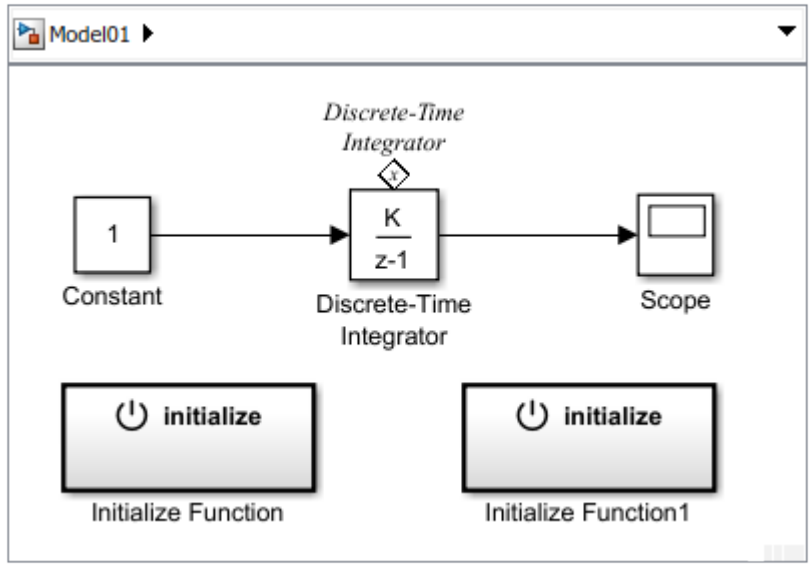
The Initialize Function block executes at the beginning of a simulation. The output signal starts at the initial value of `4` and then increases by `1` until the end of the simulation.



Reset Block State

During a simulation, you can reset the state of a block using a State Writer block. To control when reset occurs, use an Initialize Function block that you reconfigure to a Reset Function block.

1 Add an Initialize Function block.



2 Open the new Initialize Function block.

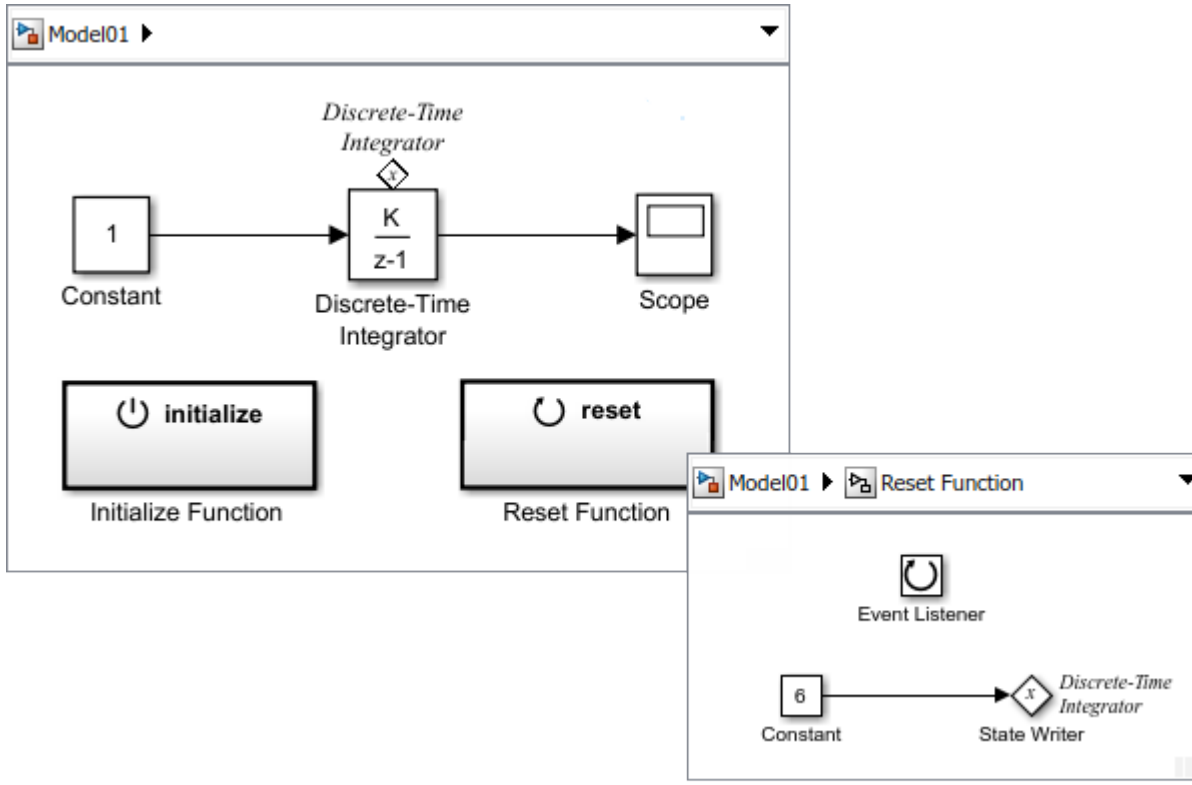
3 Configure block for reset. Open the Block Parameter dialog box for the Event Listener block. From the **Event type** drop-down list, select `Reset`. In the **Event name** box, enter an event name. For example, enter `reset`. Close the dialog box.

4 Model reset conditions. In this example, set the **Constant value** parameter for the Constant block to `6`.

5 Connect state writer with the state owner. Open the State Writer dialog box. Expand the State Owner Selector Tree, select `Discrete-Time Integrator`, and then click **Apply**.

6 Navigate to the top level of `Model01`. Rename the block from `Initialize Function1` to `Reset Function`.

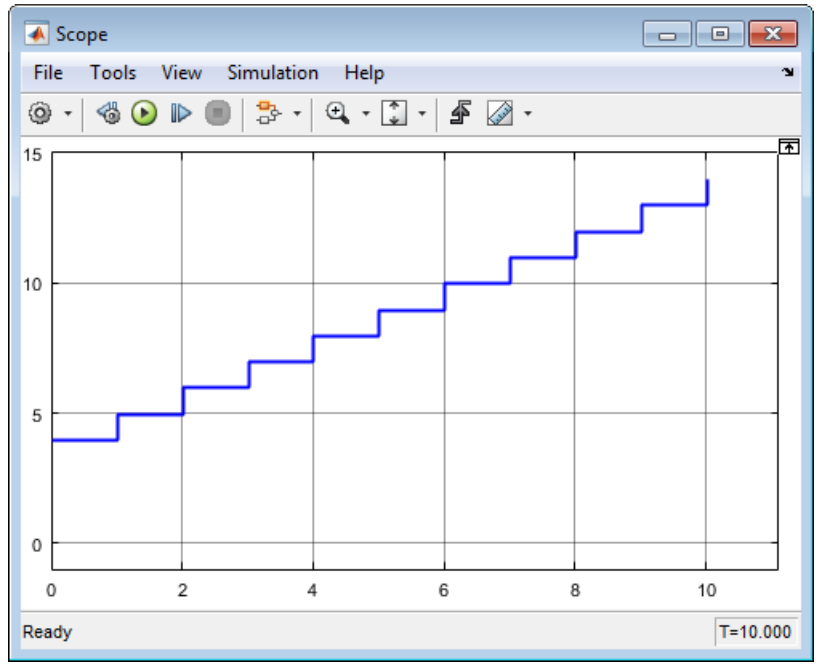
After updating your model, the event name for the Reset Function block is displayed on the face of the block.



If you click above the tag, a list opens with a link for navigating to the State Writer blocks located in the Initialize Function block and the Reset Function block.

7 Run a simulation to confirm that your model simulates without errors.

The Reset Function block does not execute during the simulation. It needs an event signal.

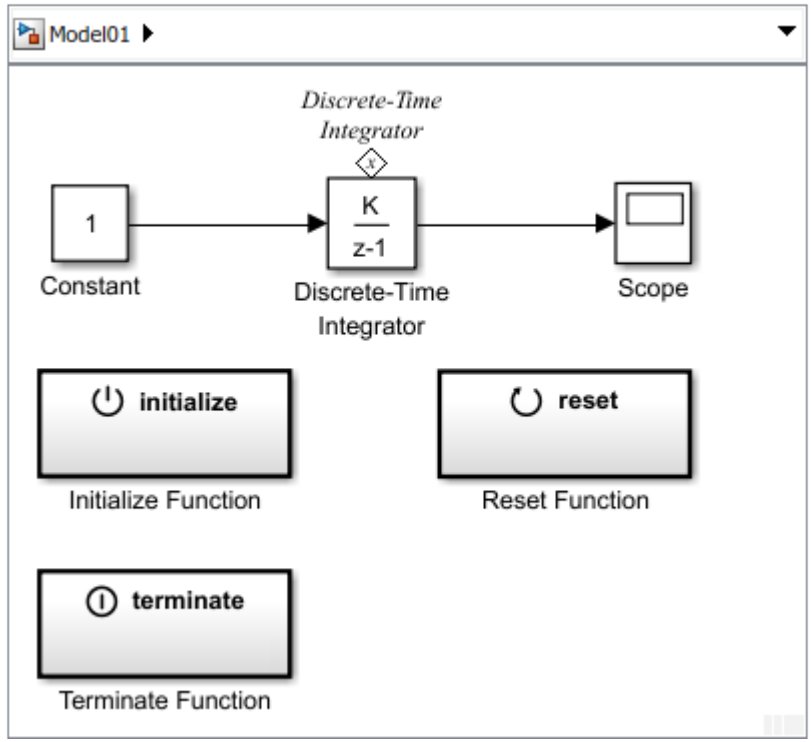


Read and Save Block State

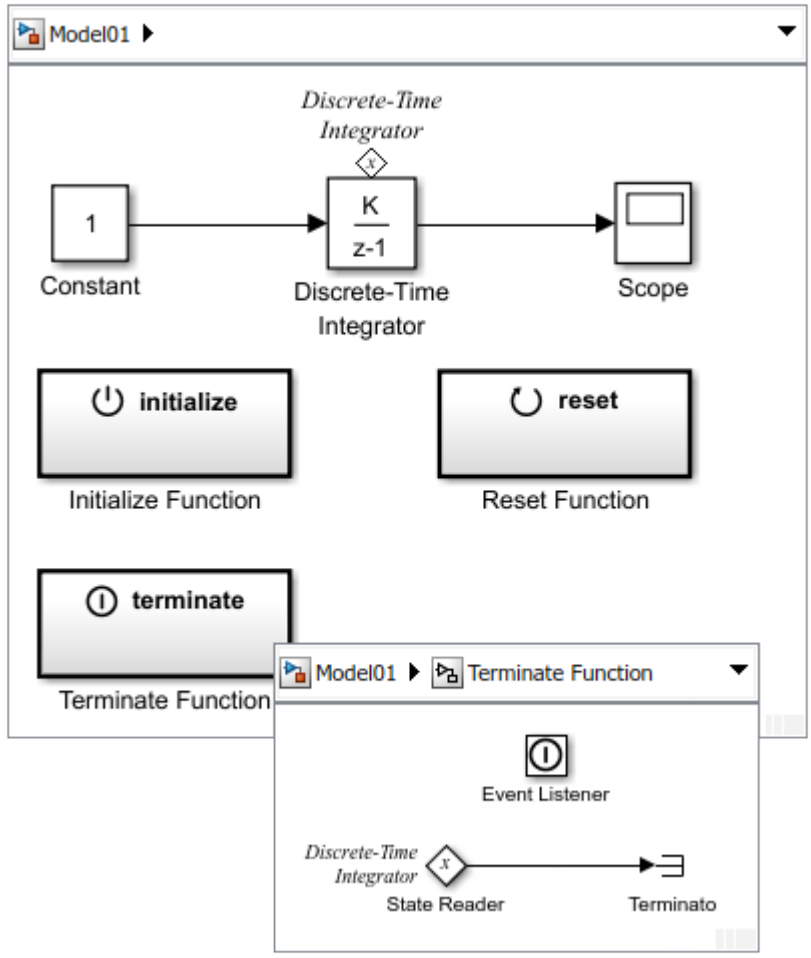
At the end of a simulation, you can read the state of a block, and save that state.

1 Add a Terminate Function block.

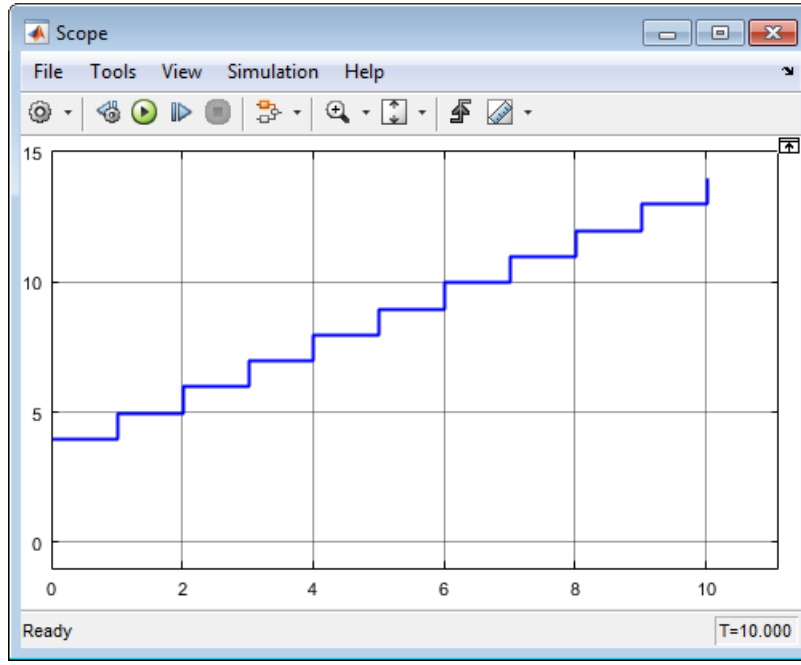
By default, the Terminate Function block includes an Event Listener block with the parameter **Event type** set to `Terminate`. The block also includes a State Reader block, and a Terminator block as a placeholder for saving the state value.



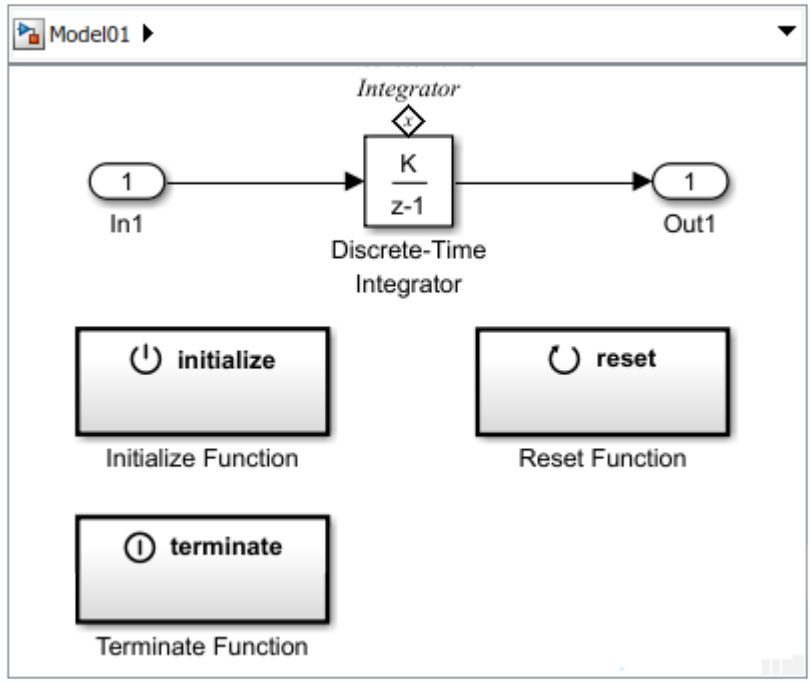
2 Connect the state reader with the state owner. Open the State Reader dialog box. From the State Owner Selector Tree, select `Discrete-Time Integrator`, and then click **Apply**.



3 Run a simulation to confirm that your model simulates without errors. The Terminate Function block executes at the end of a simulation.



4 Delete the blocks that you added for testing. Replace the Constant block with an Inport block and the Scope block with an Outport block.



Prepare Model Component for Testing

Make the following changes to avoid simulation errors when the component model is placed in an Export-Function Model for simulation testing.

1. Open the Block Parameters dialog box for the Discrete-Time Integrator block. Set **Integrator method** to `Accumulation:Forward Euler`.
2. Open the Model Configuration Parameters dialog box. Confirm the solver **Type** is set to `Fixed-step` and **Solver** is set to `auto`. Change the **Fixed-step size** from `1` to `auto`.

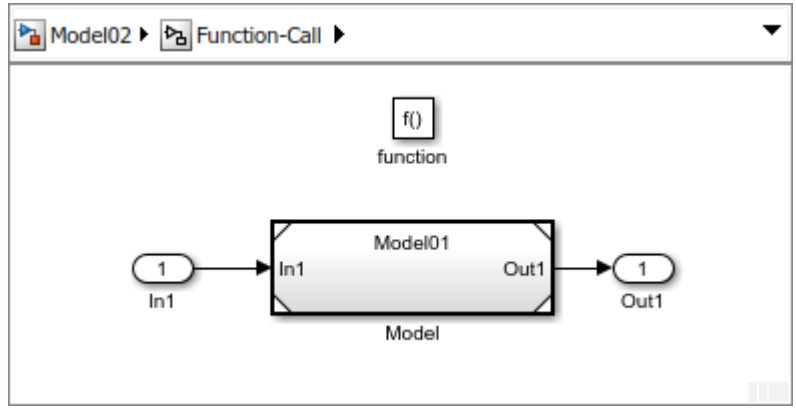
   This change avoids a simulation error caused by having multiple sample times in a Function-Call Subsystem.

Create an Export-Function Model

Placing a model component in a test harness for testing the initialize, reset, and terminate functions requires the model to follow export-function rules. See "Export-Function Models" on page 10-76 and "Create Test Harness to Generate Function Calls" on page 10-192.

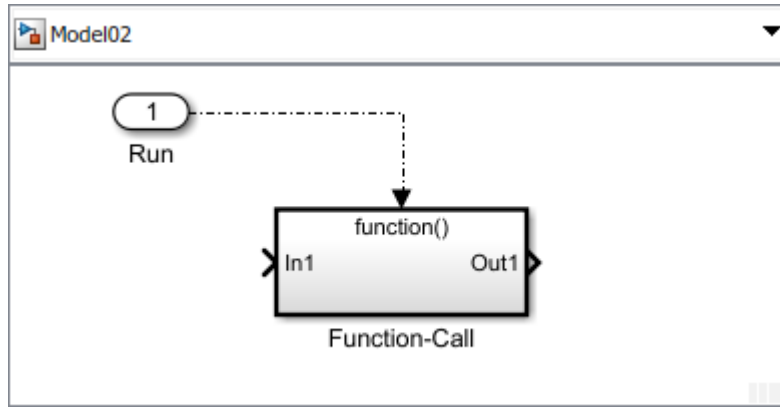
To create an export-function model, place the model component in a Function-Call Subsystem block using a Model block. Connect input and output ports from the model to the subsystem input and output ports.

1. Create a Simulink model. Save this model with the name `Model02`.
2. Open the Configuration Parameters dialog box. Set the simulation parameter for the Solver **Type** to `Fixed-step`. Confirm **Solver** is set to `auto` and **Fixed-step size** is set to `auto`.
3. Add a Function-Call Subsystem block. Open the subsystem by double-clicking the block.
4. Add a Model block to the subsystem and set **Model name** to `Model01`. Add Inport and Outport blocks.



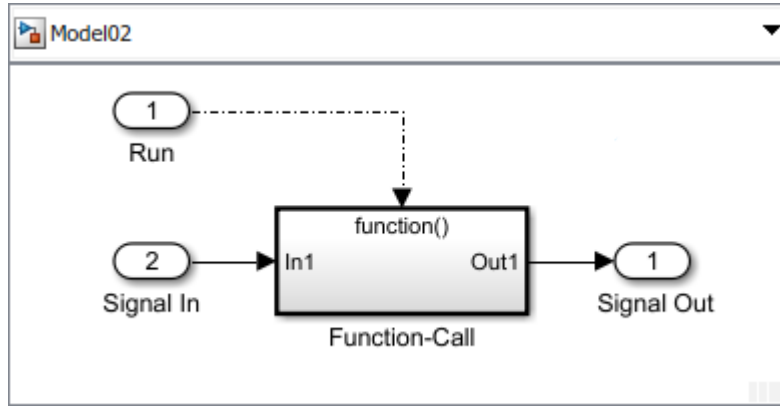
5. Navigate to the top level of the model.
6. Add an Inport block. This block is the control signal for executing the subsystem. Change the block name to `Run` and connect it to the `function()` port.

   Open the Inport block dialog box and on the Signal Attributes tab, select the **Output function call** check box.



7 Add a second Inport block and rename it to `Signal In`. Connect it to the `In1` port of the subsystem. This block is the signal for the integration algorithm.

Add an Outport block, rename it to `Signal Out`, and then connect it to the `Out1` port of the subsystem. This block is the integrated signal.



8 Open the Configuration Parameters dialog box. On the Model Referencing pane, set the **Total number of instances allowed per top model** to `one`.

Since logging root-level Outport blocks or signals in `Dataset` format are not supported, on the Data Import/Export pane, clear the **Time** and **Output** check boxes.

9 Update your model and confirm that there are no errors by pressing **Ctrl-D**.

The next step is create a test harness. See “Create Test Harness to Generate Function Calls” on page 10-192.

Create Test Harness to Generate Function Calls

In this section...

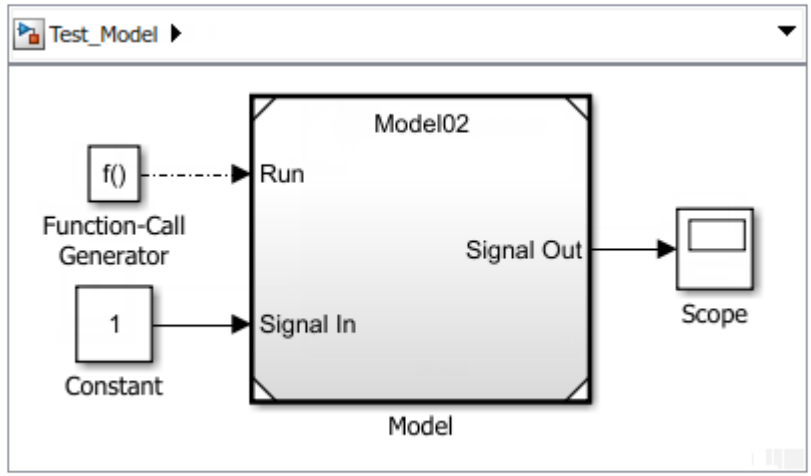
After you create a model component to initialize, reset, and terminate the state of blocks (see “Create Model to Initialize, Reset, and Terminate State” on page 10-177), you can place the model in a simulation test harness. A test harness is a Simulink model that you use to develop, test, and debug a model component.

To create the test harness, reference the export-function model containing the model component in a new model, and then add a Stateflow chart to model an event scheduler.

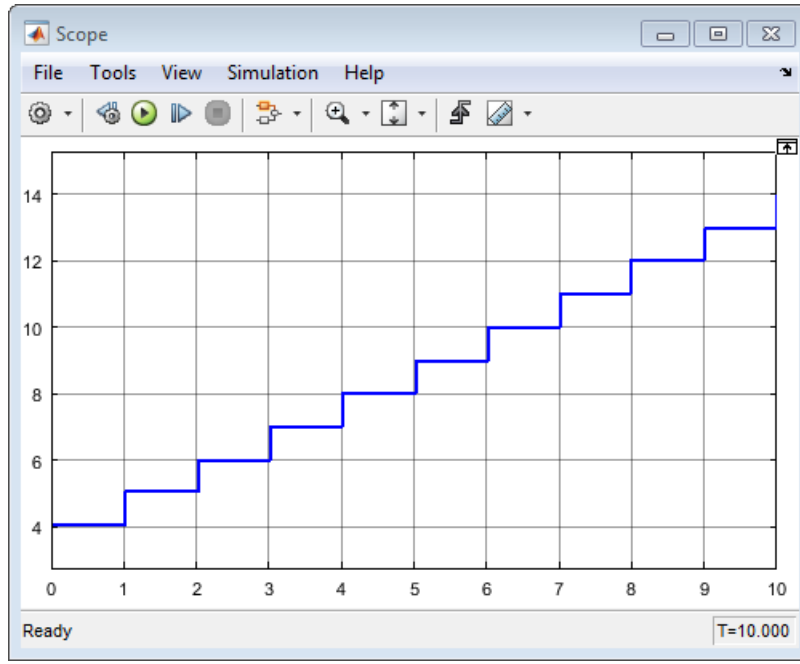
Reference the Export-Function Model

The export-function model contains the model component for testing. To create the export function model, see “Create an Export-Function Model” on page 10-189.

1. Create a new Simulink model. Save this model with the name `Test_Model`.
2. Set Model Configuration Parameters for solver **Type** to `Fixed-step`, Solver to `auto`, and **Fixed-step size** to `1`.
3. Add a Model block. Open the Block Parameters dialog box. In the **Model name** text box, enter the name of your export-function model. In this example, enter `Model02`.
4. Test the referenced model component by connecting a Function-Call Generator block to the `Run` port. Connect a Constant block to the `Signal In` port and a Scope block to the `Signal Out` port.

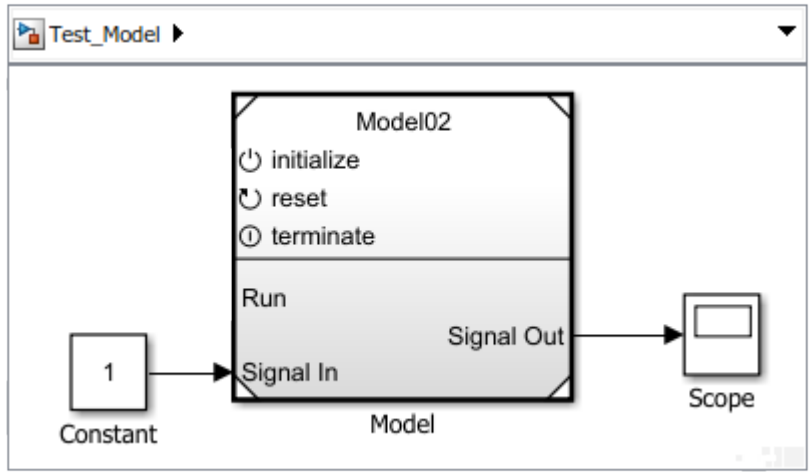


5 Run simulation to verify your model simulates correctly from the parent model. When the model is simulated without event ports, the Initialize Function block executes at the beginning of a simulation and the Terminate Function block executes at the end of the simulation.



6 Expose function-call ports on the model block. Right-click the Model block and select **Block Parameters**. In the Block Parameters dialog box, select the **Show model initialize port**, **Show model reset port**, and **Show model terminate port** check boxes.

7 Delete the Function-Call Generator block and update the model by pressing **Ctr-D**.



When you activate the initialize function-call port on a Model block, the model has to receive an initialize function call on the `initialize` port before it can execute. The reception of a function call triggers the execution of the default model initialize routine, and then the execution of the Initialize Function block contents.

The reception of a function call on the `Reset` port triggers the execution of the Reset Function block contents.

The reception of a function call on the `Terminate` port triggers the execution of the Terminate Function block contents, and then the execution of the default model terminate routine. The model then stops running. To execute the model again, you have to reinitialize the model by sending an event signal to the `initialize` port.

Model an Event Scheduler

Use a Stateflow chart to model an event schedule and generate the initialize and terminate function call signals.

1. Add a Stateflow Chart. Click the model diagram and start typing `Chart`. From the search list, select 
.
2. Open the chart and add two state blocks, one above the other.
3. Add a default transition and connect it to the top state block. Edit the label:

```
{step = 0}
```

4 Add a transition from the top block to the bottom block. Edit the label:

```
[step == 2]/{Initialize}
```

5 Add a transition from the bottom block to top block. Edit the label:

```
[step == 5]/{Reset}
```

6 Add a transition from the bottom block and back to the bottom block. Edit the label:

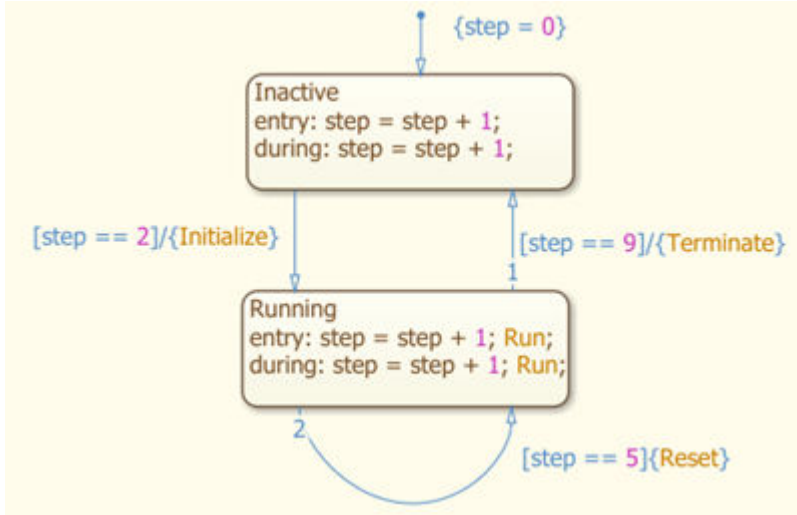
```
[step == 9]/{Terminate}
```

7 Edit the content of the top block:

```
Inactive
entry: step = step + 1;
during: step = step + 1;
```

8 Edit the content of the bottom block:

```
Running
entry: step = step + 1; Run;
during: step = step + 1; Run;
```



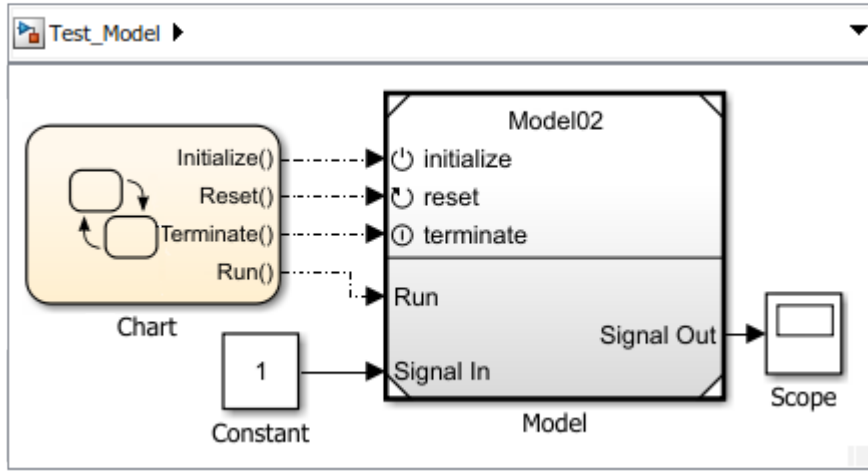
Connect Chart to Test Model

Create function-call ports on the chart to control and run the model component.

1. Open Model Explorer. **View** > **Model Explorer** > **Model Explorer**.
2. Create index variable. From the menu, select **Add** > **Data**. In the Data dialog box, enter `Step` for the **Name**.
3. Create function-call ports. For each event you create, select **Add** > **Event** and in the Event dialog box, enter, and select the following values.

Enter in Event text box	Set Scope	Set Trigger
`Initialize`	`Output to Simulink`	`Function call`
`Reset`	`Output to Simulink`	`Function call`
`Terminate`	`Output to Simulink`	`Function call`
`Run`	`Output to Simulink`	`Function call`

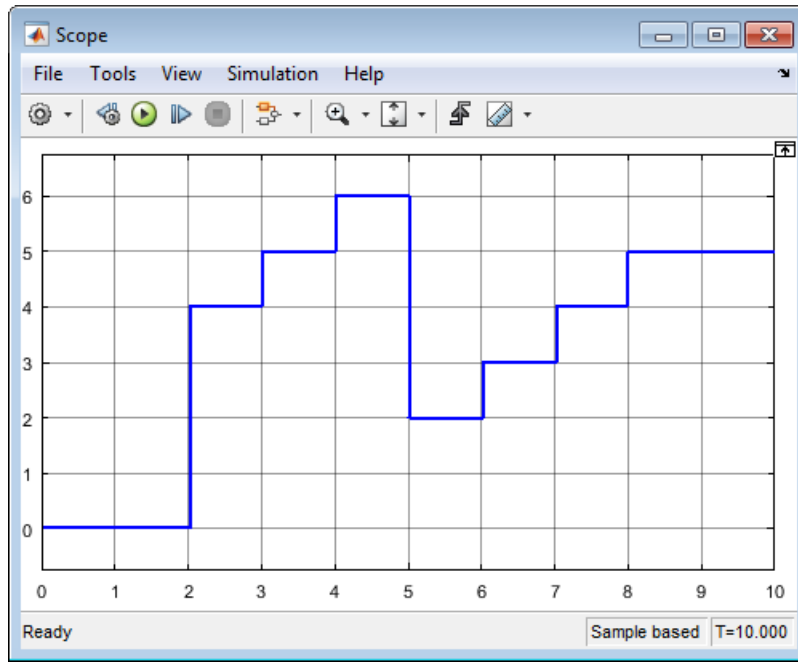
4. Navigate to the top level of the model. Connect the `Initialize`, `Reset`, `Terminate`, and `Run` ports on the chart to the `initialize`, `reset`, `terminate`, and `Run` input ports on the Model block.



5. Run simulation.

   The model cannot execute until the second time step, when the block state is initialized to 4. At the fifth time step, a reset function call to the reset port triggers

the Reset Function block to execute. At the ninth time step, the subsystem stops executing, and the block state remains constant.



If the model receives a function call to run before an initialize function call, a simulation error occurs.

Modeling Variant Systems

What Are Variants and When to Use Them

In this section...

What Are Variants?

In Simulink, you can use the variant blocks to create a single model that caters to multiple variant requirements. Such models have a fixed common structure and a finite set of variable components. The variable components are activated depending on the variant choice that you select. Thus, the resultant active model is a combination of the fixed structure and the variable components based on the variant choice.

The use of variant blocks in a model helps in reusability of the model for different conditional expressions called variant choices. This approach helps you to meet diverse customer requirements based on application, cost, or operational considerations.

You can use these variants blocks depending on the model design:

- Variant Subsystem: For hierarchical model structure. The block is a template with two Subsystem blocks to use as variant systems. You can add Subystem blocks, as well as Model blocks, for variants.
- Variant Model: For hierarchical model structure. The block is a template with two Model blocks to use as variant systems. You can add Model blocks, as well as Subsystem blocks, for variants.
- Inline Variants: For flat model structure.
    - Variant Source
    - Variant Sink
    - Manual Variant Source

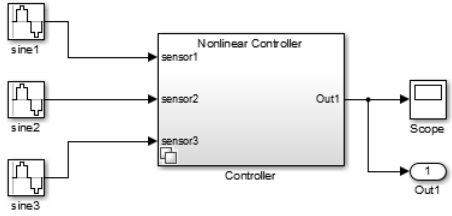
  - Manual Variant Sink
- Model

Note For new models, use a Model block for model variants only if you need to use variants that are conditionally executed models (models with control ports). Model variants are supported for backward compatibility. However, support for model variants will be removed in a future release. Use of a Variant Subsystem block provides these advantages:

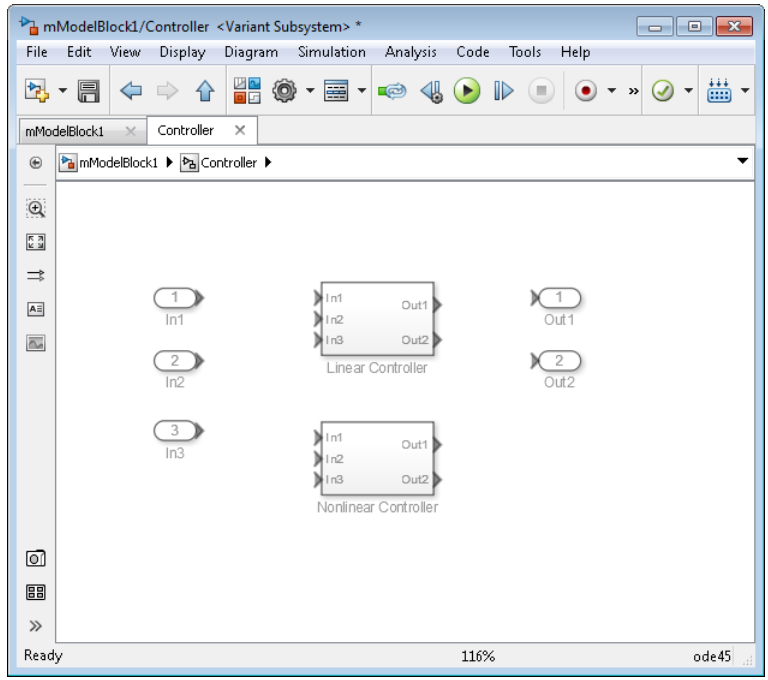
- Allows you to mix Model and Subsystem blocks as variant systems
- Supports flexible I/O, so that all variants do not need to have the same number of input and output ports

To convert a Model block that contains variant models to a Variant Subsystem block that contains Model blocks that reference the variant models, right-click the Model block and select **Subsystems & Model Reference > Convert to > Variant Subsystem**. Alternatively, you can use the `Simulink.VariantManager.convertToVariant` function. Specify the Model block name or block handle.The converted model produces the same results as the original model.

Suppose you want to simulate a model that represents an automobile with several configurations. These configurations, although similar in several aspects, can differ in properties such as fuel consumption, engine size, or emission standard. Instead of designing multiple models that together represent all possible configurations, you can use variants to model only the varying configurations. This approach keeps the common components fixed.



This model contains two variant choices inside a single Variant Subsystem block. Variant choices are two or more configurations of a component in your model.



Advantages of Using Variants

Using variants in Model-Based Design provides several advantages:

- Variants provide you a way to design one model for many systems.
- You can rapidly prototype design possibilities as variants without having to comment out sections of your model.
- Variants help you develop modular design platforms that facilitate reuse and customization. This approach improves workflow speed by reducing complexity.
- If a model component has several alternative configurations, you can efficiently explore these varying alternatives without altering the fixed, unvarying components.
- You can use different variant configurations for simulation or code generation from the same model.
- You can simulate every design possibility in a combinatorial fashion for a given test suite.

- If you are working with large-scale designs, you can distribute the process of testing these designs on a cluster of multicore computers. Alternatively, you can map different test suites to design alternatives for efficiently managing design-specific tests.
- You can generate a reduced model with a subset of configuration from a master model with many variants.

When to Use Variants

Variants help you specify multiple implementations of a model in a single, unified block diagram. Here are three scenarios where you can use variants:

- Models that represent multiple simulation, code generation, or testing workflows.

Figure 1. Model of an ideal actuator for basic simulation.

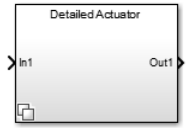


Figure 2. Detailed actuator for simulating customizations.

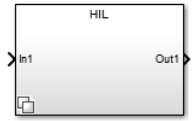

Figure 3. Model that is configured for Hardware-in-the-Loop simulation.

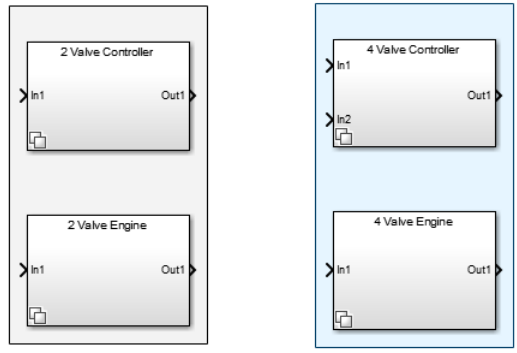
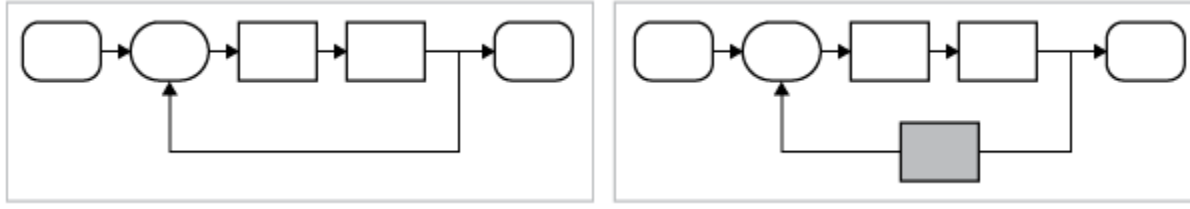
- Models that contain multiple design choices at the component level.



Subsystem blocks representing variant choices can have inports and outports that differ in number from the inports and outports in the parent Variant Subsystem block. See “Mapping Inports and Outports of Variant Choices” on page 11-8.

- Models that are mostly similar but have slight variations, such as in cases where you want to separate a test model from a debugging model.

  The test model on the left has a fixed design. On the right, the same test model includes a variant that is introduced for debugging purposes.



Simulink selects the active variant during update diagram time and during code compile time.

Options for Representing Variants in Simulink

You can represent one or more variants as variant choices inside these blocks.

Note For new models, use a Model block for model variants only if you need to use variants that are conditionally executed models (models with control ports). Using a

Model block for variant models is supported for backward compatibility. However, support for using a Model block to contain model variants will be removed in a future release. For an example of a model that uses a Variant Subsystem block as a container for variant models, see "Model Reference Variants".

	Variant Source and Variant Sink blocks	Variant Subsystem and Variant Model blocks	Model block
Variant choice representation	Number of ports	Subsystem or Model block	Only Model block
Allows choice hierarchy	No	Yes	Yes
Mismatched number of inports and outports among variant choices	Simulink disables inactive ports	Simulink disables inactive ports	Requires manual resolution of disconnected signal lines
Option to specify default variant	Yes	Yes	No
Supports control ports	No	No	Yes
Can be saved as standalone file	No	No	Yes
Supports physical modeling connection ports	No	Partially	No
Comment choice	Yes	No	No

In addition, you can represent variant choices using Variant Source and Variant Sink block. These blocks enable the propagation of variant conditions and they allow you to visualize variant choices in a single layer of your model.

You can create variants at several levels inside your model hierarchy.

Mapping Inports and Outports of Variant Choices

A Variant Subsystem is a container of variants choices that are represented as Subsystem or Model blocks. The inputs that the Variant Subsystem block receives from upstream models components map to the inports and outports of the variant choices.

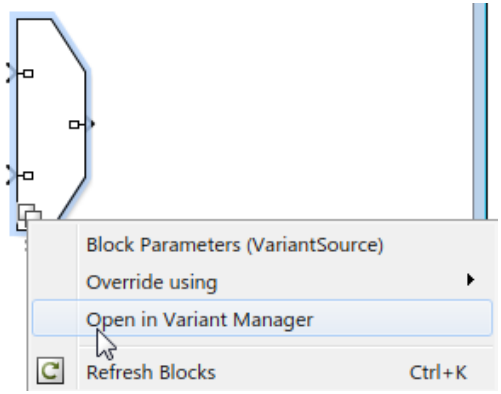
Subsystem and Model blocks representing variant choices can have inports and outports that differ in number from the inports and outports in the parent Variant Subsystem block. However, the following conditions must be satisfied:

- The names of the inports of a variant choice are a subset of the inport names used by the parent variant subsystem.
- The names of the outports of a variant choice are a subset of the outport names used by the parent variant subsystem.

During simulation, Simulink disables the inactive ports in a Variant Subsystem block. If you are specifying variant choices in a Model Variant block, resolve any disconnected signal lines manually when you switch between choices.

Variant Badges

Each Variant block has a badge associated with it. The color and icon of a Variant badge indicate the status of the Variant block. It also provides quick access to few Variant commands. You can right-click the Variant badge to access these commands.



Variant Badge	Variant Source	Variant Sink	Variant Subsystem
Default Variant badge when no option is selected.			
Variant block with **Override variant conditions and use the following variant** option selected.			
Variant block with **Allow zero active variant controls** option selected.			
Variant block with **Analyze all choices during update diagram and generate preprocessor conditionals** option selected.			

Variant Badge	Variant Source	Variant Sink	Variant Subsystem
Variant block with **Propagate conditions outside of variant subsystem** option selected.	Not applicable	Not applicable	
Variant block with **Analyze all choices during update diagram and generate preprocessor conditionals** and **Allow zero active variant controls** option selected.			
Variant block with **Analyze all choices during update diagram and generate preprocessor conditionals** and **Propagate conditions outside of variant subsystem** option selected.	Not applicable	Not applicable	

Comment Out and Comment Through

Consider when you want to simulate a Simulink model by excluding some of its blocks from simulation and without physically removing the blocks from the model. The **Comment Out** and **Comment Through** commands in Simulink provide you with an option to exclude blocks from simulation. Depending on your modeling requirement, you can use these options:

- **Comment Out**: Excludes the selected block from simulation. The signals are terminated and grounded.
- **Comment Through**: Excludes the selected block from simulation. The signals are passed through. To comment through a block, the number of input ports and the output ports for the block must be same.

To access the **Comment Out** or the **Comment Through** options, right-click the block and in the context menu either select **Comment Out** or **Comment Through** based on your modeling requirement.

Alternatively, you can also select the block and press **Cltr+Shift+X** to comment out or press **Cltr+Shift+Y** to comment through.

You can use `get_param` and `set_param` commands to view or change the commented state of a block programmatically. For example,

- `get_param(gcb,'commented'); % To view the commented state of the block`
- `set_param(gcb,'commented','on'); % To comment out a block`
- `set_param(gcb,'commented','through'); % To comment through a block`
- `set_param(gcb,'commented','off'); % To uncomment a block`

When you comment out a block, the signal names at the output port of the block are ignored. To include such signals during simulation, the signal name must be added at the input port of the block.

Comment Out and **Comment Through** are not supported with these blocks: Inport, Outport, Duplicate Port, Connection ports, Argument Inport, Argument Outport, Data Store Memory, Signal Generator, Goto Tag Visibility, For, and While blocks.

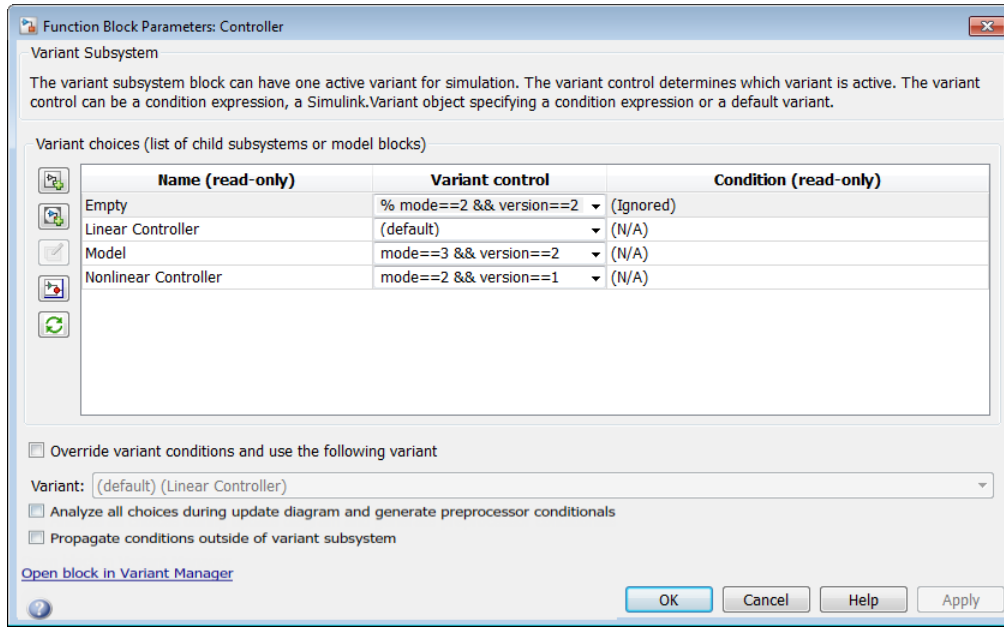
Working with Variant Choices

In this section...

Each variant choice in your model is associated with a conditional expression called variant control. The way you specify your variant controls determines the active variant choice.

This image shows the block parameters dialog box of a Variant Subsystem block that contains four variant choices:

- The first choice is empty and has been commented out by adding the `%` symbol before the variant control.
- The second choice is the default and is activated when no variant control evaluates to `true`.
- The third choice is activated when the expression `mode==3 && version==2` evaluates to `true`.
- The fourth choice is activated when the expression `mode==2 && version==1` evaluates to `true`.



Default Variant Choice

You can specify at most one variant choice as the default for the model. As shown in the image above, the `Linear Controller` subsystem is defined as the default variant choice. During model compilation, if Simulink finds that no variant control evaluates to `true`, it uses the default choice.

In the dialog box, select the variant choice and change its **Variant control** property to `(default)`.

Active Variant Choice

While each variant choice is associated with a variant control, only one variant control can evaluate to `true` at a time. When a variant control evaluates to `true`, Simulink activates the variant choice that corresponds to that variant control.

In this example, you can activate either the `Model` variant choice or the `Nonlinear Controller` variant choice by specifying appropriate values for `mode` and `version`.

Value of `mode`	Value of `version`	Active variant choice
2	1	`Nonlinear Controller`
3	2	`Model`

You can specify the values of `mode` and `version` at the MATLAB Command Window.

You can also override the active variant choice with another variant choice. Right-click the active variant block in the Simulink Editor, and select **Variant > Override using**. Then select your variant choice.

Inactive Variant Choice

When a variant control activates one variant choice, Simulink considers the other variant choices to be inactive. Simulink ignores inactive variant choices during simulation. However, Simulink continues to execute block callbacks inside the inactive variant choices.

Empty Variant Choice

When you are prototyping variant choices, you can create empty Subsystem blocks with no inputs or outputs inside the Variant Subsystem block. The empty subsystem recreates the situation in which that subsystem is inactive without the need for completely modeling the variant choice.

For an empty variant choice, you can either specify a variant activation condition or comment out the variant condition by placing a `%` symbol before the condition.

If this variant choice is active during simulation, Simulink ignores the empty variant choice. However, Simulink continues to execute block callbacks inside the empty variant choices.

Open Active Variant

When you open a model, variant blocks display the name of the variant that was active the last time that you saved your model. Use the **Variant** menu to open the active variant. Right-click the block and select **Variant > Open**. Then select the active variant.

Use this command to find the current active choice:

```
get_param(gcb,'ActiveVariant')
```

Use this command to find the path to the current active choice:

```
get_param(gcb,'ActiveVariantBlock')
```

Note The `ActiveVariantBlock` parameter is supported only for the Variant Subsystem block.

Introduction to Variant Controls

In this section...

The components of a Simulink model that contain Variants are activated or deactivated based on the variant choice that you select.

Each variant choice in your model is associated with a conditional expression called variant control. Variant controls determine which variant choice is active. By changing the value of a variant control, you can switch the active variant choice.

While each variant choice is associated with a variant control, only one variant control can evaluate to true. When a variant control evaluates to true, Simulink activates the variant choice that corresponds to that variant control.

A variant control is a Boolean expression that activates a specific variant choice when it evaluates to `true`.

Note You can specify variant controls in the MATLAB workspace or a data dictionary.

You can specify variant controls as `Simulink.Variant` objects or as expressions that contain one or more of these operands and operators.

Operands

- Variable names that resolve to MATLAB variables or `Simulink.Parameter` objects with integer or enumerated data type and scalar literal values
- Variable names that resolve to `Simulink.Variant` objects
- Scalar literal values that represent integer or enumerated values

Operators

- Parentheses for grouping
- Arithmetic, relational, logical, or bitwise operators

For more information, see “Operators and Operands in Variant Condition Expressions” on page 11-25.

When you compile the model, Simulink determines that a variant choice is active if its variant control evaluates to `true`.

Approaches for Specifying Variant Controls

You can use many approaches for switching between variant choices—from options to use while prototyping to options required for generating code from your model.

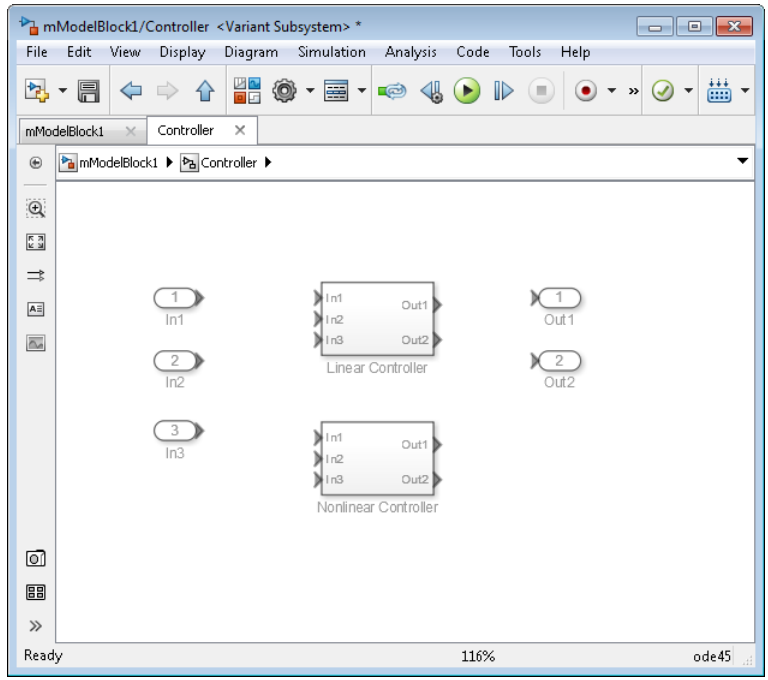
Specification	Purpose	Example
Scalar variable	Rapid prototyping	`A == 1`
`Simulink.Variant` object	Reuse variant conditions	`LinearController = Simulink.Variant('FUEL ==2 && EMIS==1');`
`Simulink.Parameter` object	Generate preprocessor conditionals for code generation	`mode == 1`, where `mode` is a `Simulink.Parameter` object
Enumerated type	Improved code readability because condition values are represented as meaningful names instead of integers	`LEVEL == Level.Advanced`

You can convert MATLAB variables in variant control expressions into `Simulink.Parameter` object using the function `Simulink.VariantManager.findVariantControlVars`.

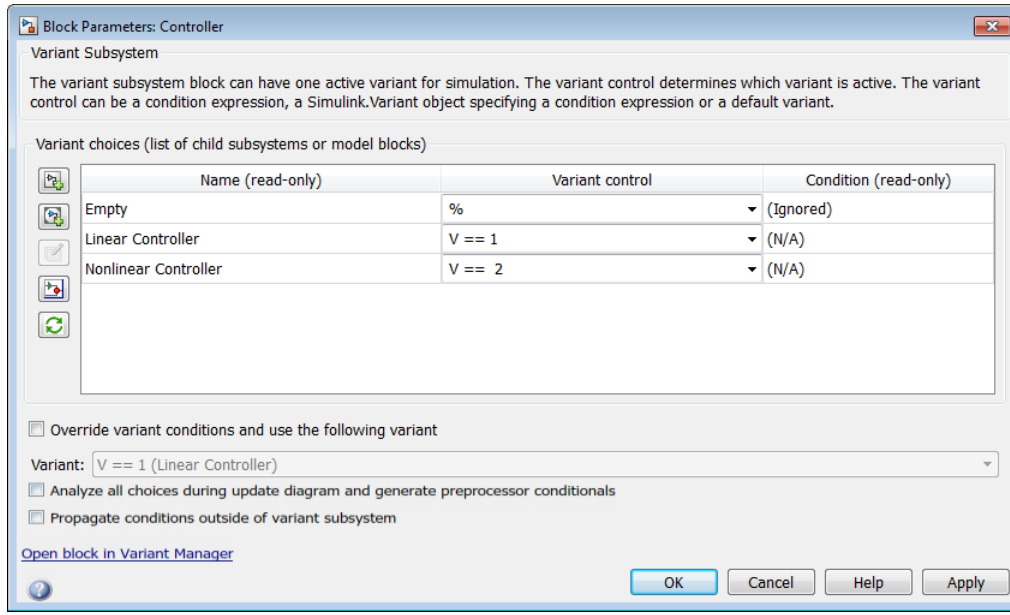
Scalar Variables for Rapid Prototyping

Scalar MATLAB variables allow you to rapidly prototype variant choices when you are still building your model. They help you focus more on building your variant choices than on developing the expressions that activate those choices.

Consider a model that contains two variant choices, each represented by a Variant Subsystem block.



You can specify variant controls in their simplest form as scalar variables in the block parameters dialog box of the Variant Subsystem block.

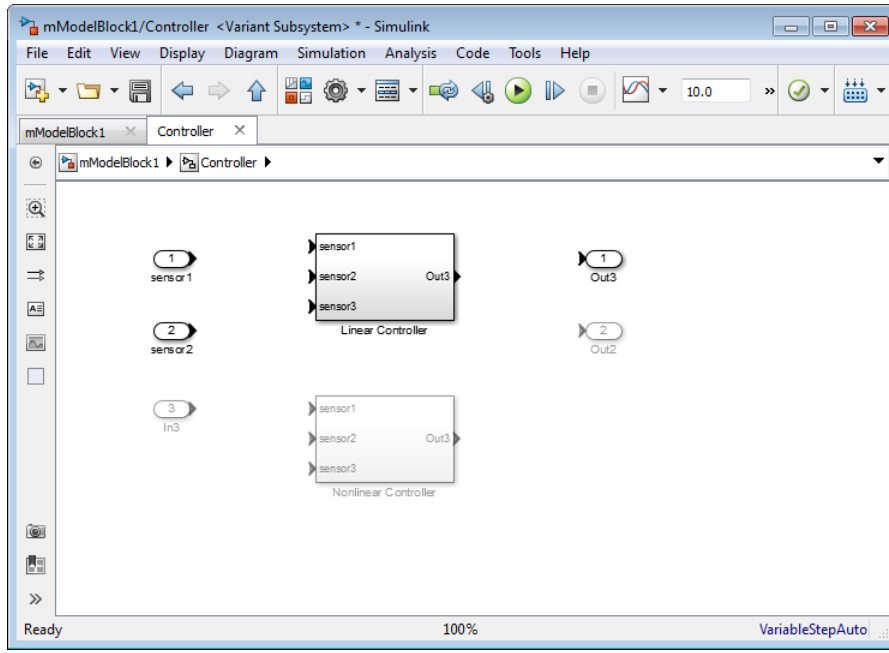


The **Condition** field for both the `Linear Controller` and `Nonlinear Controller` are `N/A`, because the variant control itself is the condition.

You can activate one of the variant choices by defining a scalar variable `V` and setting its value to `1` at the MATLAB Command Window.

```
V = 1;
```

This condition activates the `Linear Controller` variant choice.



Similarly, if you change the value of `V` to `2`, Simulink activates the `Nonlinear Controller` variant choice.

Simulink.Variant Objects for Variant Condition Reuse

After identifying the variant choices that your model requires, you can construct complex variant conditions to control the activation of your variant choices. Define variant conditions as `Simulink.Variant` objects.

`Simulink.Variant` objects enable you to reuse common variant conditions across models and help you encapsulate complex variant condition expressions.

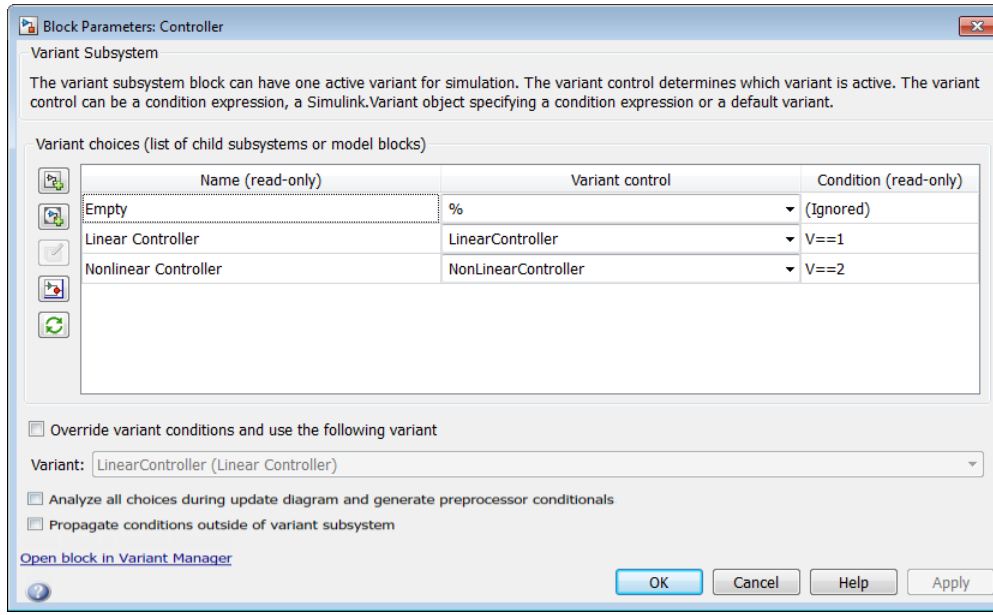
Consider an example where variant controls are already defined in the base workspace.

```
V=1;
V=2;
```

You can convert these controls into condition expressions encapsulated as `Simulink.Variant` objects.

```
LinearController=Simulink.Variant('V==1');
NonLinearController=Simulink.Variant('V==2');
```

You can then specify these `Simulink.Variant` objects as the variant controls in the block parameters dialog box of the Variant Subsystem block.



The **Condition** field now reflects the encapsulated variant condition. Using this approach, you can develop complex variant condition expressions that are reusable.

Simulink.Parameter Objects for Code Generation

If you intend to generate code for a model containing variant choices, specify variant control variables as `Simulink.Parameter` objects. In addition to enabling parameter value specification, `Simulink.Parameter` objects allow you to specify other attributes (such as data type) that are required for generating code.

```
VSSMODE = Simulink.Parameter;
VSSMODE.Value = 1;
VSSMODE.DataType = 'int32';
VSSMODE.CoderInfo.StorageClass = 'Custom';
VSSMODE.CoderInfo.CustomStorageClass = 'ImportedDefine';
VSSMODE.CoderInfo.CustomAttributes.HeaderFile =...
'rtwdemo_importedmacros.h';
```

Variant control variables defined as `Simulink.Parameter` objects can have one of these storage classes:

- `Define` or `ImportedDefine` with header file specified
- `CompilerFlag`
- `SystemConstant (AUTOSAR)`
- Your own custom storage class that defines data as a macro

You can also convert a scalar variant control variable into a Simulink.Parameter object. See "Convert Variant Control Variables into Simulink.Parameter Objects" on page 11-44.

Enumerated Types for Improving Code Readability

Use enumerated types to give meaningful names to integers used as variant control values.

1 In the MATLAB Editor, define the classes that map enumerated values to meaningful names.

```
classdef sldemo_mrv_CONTROLLER_TYPE < Simulink.IntEnumType
        enumeration
        NONLINEAR (1)
        SECOND_ORDER (2)
        end
end

classdef sldemo_mrv_BUILD_TYPE < Simulink.IntEnumType
        enumeration
        PROTOTYPE (1)
        PRODUCTION (2)
        end
end
```

2 Define `Simulink.Variant` objects for these classes in the base workspace.

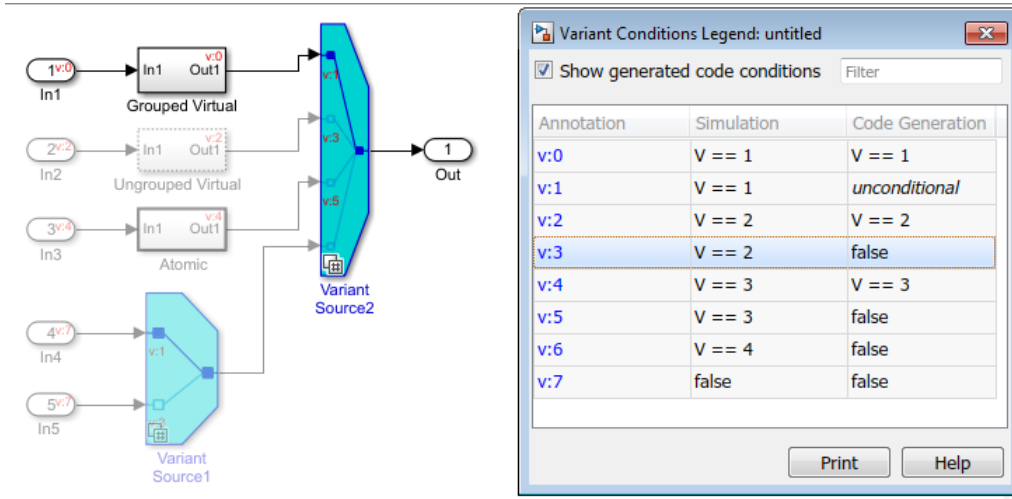
```
VE_NONLINEAR_CONTROLLER = Simulink.Variant...
('E_CTRL==sldemo_mrv_CONTROLLER_TYPE.NONLINEAR')
VE_SECOND_ORDER_CONTROLLER =Simulink.Variant...
('E_CTRL==sldemo_mrv_CONTROLLER_TYPE.SECOND_ORDER')
VE_PROTOTYPE =Simulink.Variant...
('E_CURRENT_BUILD==sldemo_mrv_BUILD_TYPE.PROTOTYPE')
VE_PRODUCTION =Simulink.Variant...
('E_CURRENT_BUILD==sldemo_mrv_BUILD_TYPE.PRODUCTION')
```

Using enumerated types simplifies the generated code because it contains the names of the values rather than integers.

Viewing Variant Conditions

The **Variant Condition Legend** helps you visualize the variant conditions associated with a model. To view the **Variant Condition Legend**, click **Display > Blocks > Variant Condition Legend**.

Note The **Variant Condition Legend** is available only when **Display > Blocks > Variant Condition** is active.



By default, the **Variant Condition Legend** displays the variant condition annnotation and the variant condition during simulation. To view the variant condition in the generated code, select the **Show generated code conditions** option on the **Variant Condition Legend**.

In the **Variant Condition Legend**, the variant conditions on the blocks are annotated as `v:c`, where `v` is the variant semantic indicator and `c` represents the variant condition index. You can click through the hyperlinked variant annotations to observe which parts of the model the condition corresponds to.

When you hover over a block that has a variant condition, the tooltip displays the variant annotation and the related variant condition for the block. To view the variant condition annotation tooltip, the **Variant Condition** option must be selected.

To view the **Variant Condition Legend** programmatically, use the `Simulink.VariantManager.VariantLegend` function in the MATLAB command window.

Operators and Operands in Variant Condition Expressions

Simulink evaluates condition expressions within variant controls to determine the active variant choice. You can include the following operands in a condition expression:

- Scalar variables
- `Simulink.Parameter` objects that are not structures and that have data types other than `Simulink.Bus` objects
- Enumerated types
- Parentheses for grouping

Variant condition expressions can contain MATLAB operators, provided the expression evaluates to a boolean value. In these examples, `A` and `B` are expressions that evaluate to an integer, and `x` is a constant integer literal.

MATLAB Expressions That Support Generation of Preprocessor Conditionals	Equivalent Expression in C Preprocessor Conditional
Arithmetic	
• `A + B` • `+A`	• `A + B` • `A`
• `A - B` • `-A`	• `A - B` • `-A`
`A * B`	`A * B`
`idivide(A,B)`	`A / B` If the value of the second operand (`B`) is `0`, the behavior is undefined.

MATLAB Expressions That Support Generation of Preprocessor Conditionals	Equivalent Expression in C Preprocessor Conditional
`rem(A,B)`	`A % B` If the value of the second operand (`B`) is `0`, the behavior is undefined.
Relational	
`A == B`	`A == B`
`A ~= B`	`A != B`
`A < B`	`A < B`
`A > B`	`A > B`
`A <= B`	`A <= B`
`A >= B`	`A >= B`
Logical	
`~A`	`!A`, where `A` is not an integer
`A && B`	`A && B`
`A || B`	`A || B`
Bitwise (`A` and `B` cannot both be constant integer literals)	
`bitand(A,B)`	`A & B`
`bitor(A,B)`	`A | B`
`bitxor(A,B)`	`A ^ B`
`bitcmp(A)`	`~A`
`bitshift(A,x)`	`A << x`
`bitshift(A,-x)`	`A >> x`

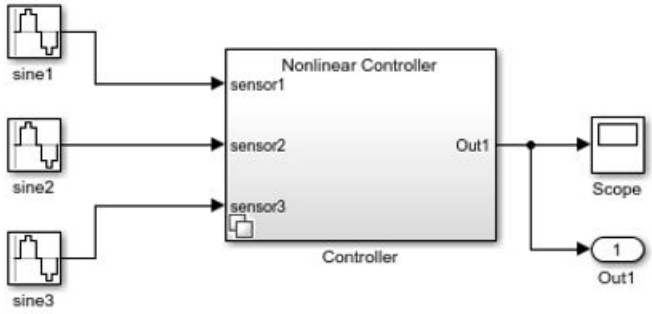
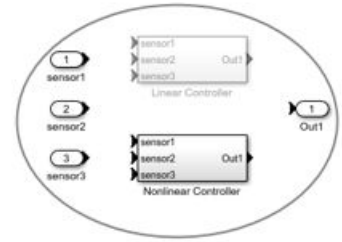
More About

- “Create a Simple Variant Model” on page 11-28

Create a Simple Variant Model

1 Create a model that contains variant blocks. For example, see sldemo_variant_subsystems that contains a Variant Subsystem block (`Controller`).



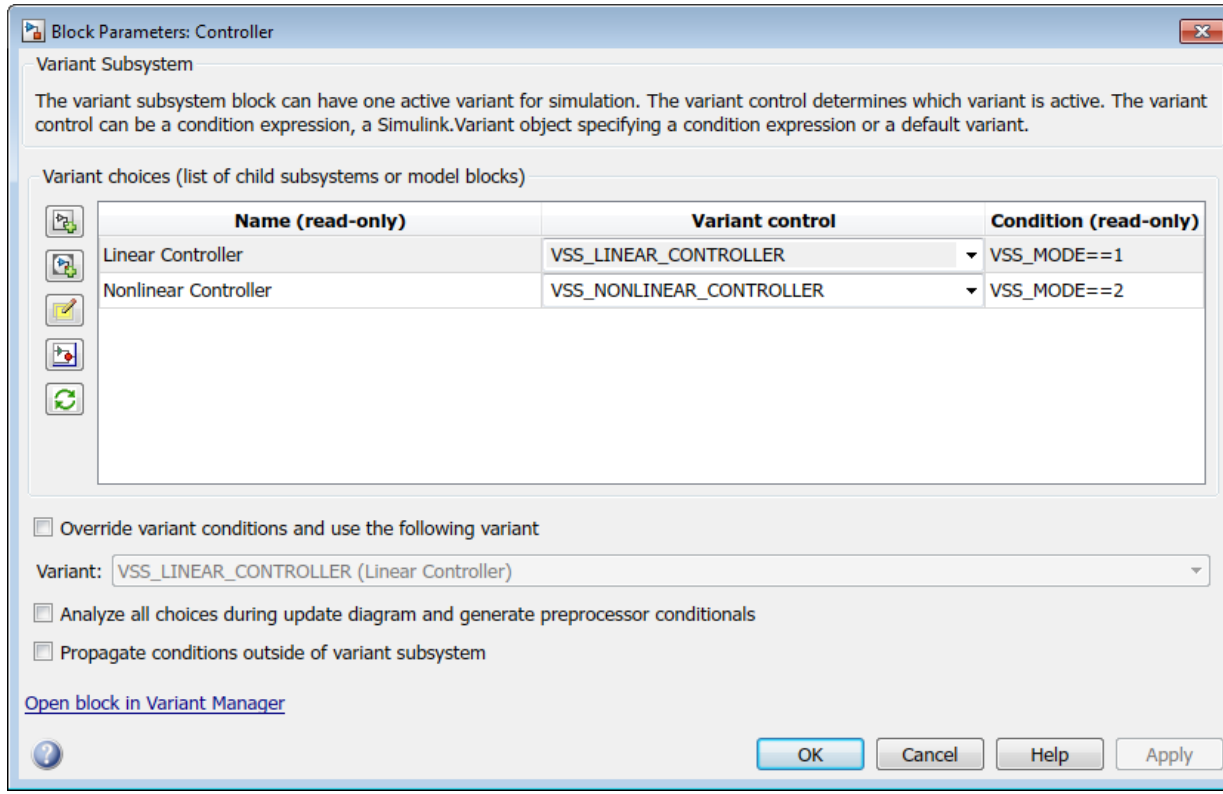


Components of 'Controller' block

2 Define variant control variables that determine the condition under which a variant choice is active.

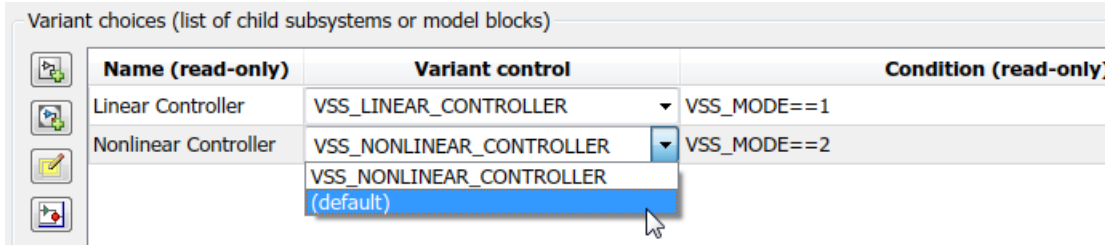
   a Right-click the variant block and click **Block Parameters**. The Block Parameters dialog box for the variant block opens.

   b Use the options available on the Block Parameter dialog box to add variant controls and its corresponding variant condition.



Note The variables used to specify the variant control and variant condition must be defined in the base workspace or data dictionary for the model.

3 Specify a default variant condition to be used when there is no active variant choice. Use the **Variant control** dropdown menu to specify the default.



4. To activate a variant choice, type the variant choice in MATLAB command window. For example, type `VSS_MODE = 2`.
5. To simulate the model, click **Simulation > Run**. The model simulates for the specified active choice.
6. Modify the active choice and simulate the model again, if necessary.
7. Generate code for the variants model with preprocessor conditionals.

   Note You must have Embedded Coder license to generate code.

   a. In the Block Parameters dialog box, select the **Analyze all choices during update diagram and generate preprocessor conditionals** check box.
   b. In the **Code Generation** section of Configuration Parameters dialog box, specify the **System target file** as `ert.tlc`.
   c. In Model Explorer, define the variables used to specify the variant choice as a `Simulink.Parameter`. The data type of the variable can be of type `Integer`, `Boolean`, or `Enumerated` and the storage class can be either `importedDefine(Custom)`, `Define(Custom)`, or `CompilerFlag`.
8. For the variants that are defined in the base workspace, export the control variables to a MAT-file. For example, type the following in theMATLAB command window:

   a. `save <MAT-File Name> <Variable Name>`
   b. `PostLoadCallback > load MAT-File Name>`

Note To update or refresh active models that contain Variant Subsystem blocks, click **Diagram > Refresh Blocks** (Ctrl + K) or **Simulink > Update Diagram** (Ctrl + D) in Simulink.

Create Variant Controls Programmatically

In this section...

Create and Export Variant Controls

Create control variables, define variant conditions, and export control variables.

1 Create control variables in the base workspace or a data dictionary.

```
FUEL=2;
EMIS=1;
```

2 Use the control variables to define the control condition using a `Simulink.Variant` object.

```
LinearContoller=Simulink.Variant('FUEL==2 && EMIS==1');
```

Note Before each simulation, define `Simulink.Variant` objects representing the variant conditions.

3 If you saved the variables in the base workspace, select the control variables to export. Right-click and click **Save As** to specify the name of a MAT-file.

Reuse Variant Conditions

If you want to reuse common variant conditions across models, specify variant control conditions using `Simulink.Variant` objects.

Reuse `Simulink.Variant` objects to change the model hierarchy dynamically to reflect variant conditions by changing the values of the control variables that define the condition expression.

The example models `AutoMRVar` and `AutoSSVar` show the use of `Simulink.Variant` objects to define variant control conditions.

Enumerated Types as Variant Controls

Use enumerated types to give meaningful names to integers used as variant control values.

1 In the MATLAB Editor, define the classes that map enumerated values to meaningful names.

```
classdef sldemo_mrv_CONTROLLER_TYPE < Simulink.IntEnumType
        enumeration
        NONLINEAR (1)
        SECOND_ORDER (2)
        end
end

classdef sldemo_mrv_BUILD_TYPE < Simulink.IntEnumType
        enumeration
        PROTOTYPE (1)
        PRODUCTION (2)
        end
end
```

2 Define `Simulink.Variant` objects for these classes in the base workspace.

```
VE_NONLINEAR_CONTROLLER = Simulink.Variant...
('E_CTRL==sldemo_mrv_CONTROLLER_TYPE.NONLINEAR')
VE_SECOND_ORDER_CONTROLLER =Simulink.Variant...
('E_CTRL==sldemo_mrv_CONTROLLER_TYPE.SECOND_ORDER')
VE_PROTOTYPE =Simulink.Variant...
('E_CURRENT_BUILD==sldemo_mrv_BUILD_TYPE.PROTOTYPE')
VE_PRODUCTION =Simulink.Variant...
('E_CURRENT_BUILD==sldemo_mrv_BUILD_TYPE.PRODUCTION')
```

Using enumerated types simplifies the generated code because it contains the names of the values rather than integers.

Define, Configure, and Activate Variants

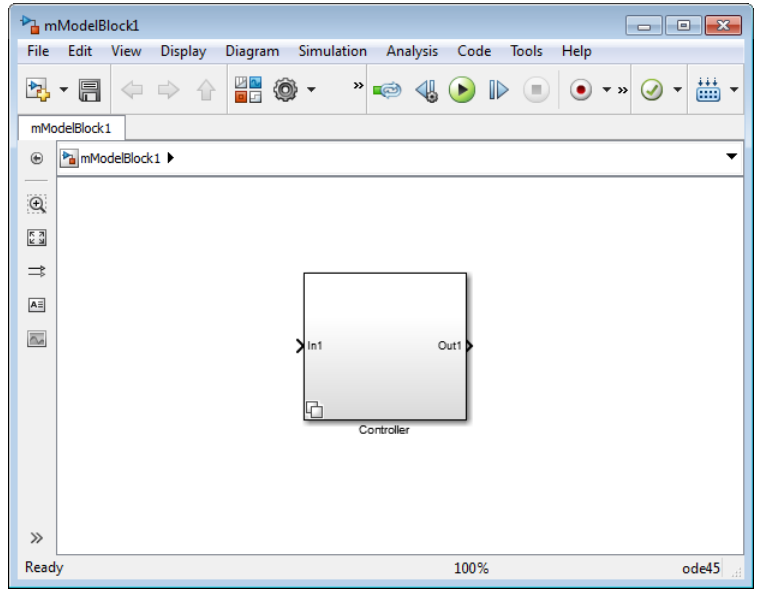
In this section...

Represent Variant Choices

Variant choices are two or more configurations of a component in your model. This example shows how to represent variant choices inside a Variant Subsystem block in your model. For other ways to represent design variants, see “Options for Representing Variants in Simulink” on page 11-6.

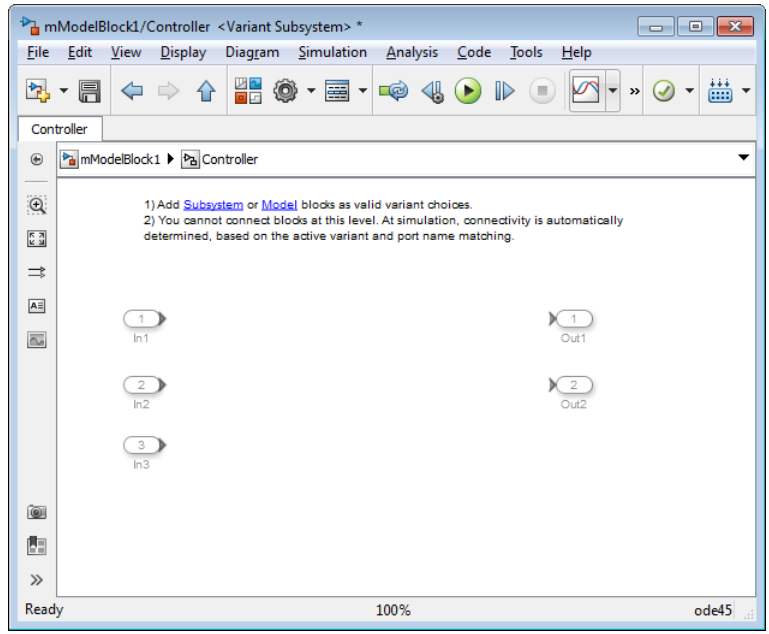
1 Add a Variant Subsystem block to your model and name it.

This block serves as the container for the variant choices.



2 Double-click the Variant Subsystem block. Add inport and outport blocks so that they match the inputs into and outputs from this block.

Note You can add only Inport, Outport, Subsystem, and Model blocks inside a Variant Subsystem block.

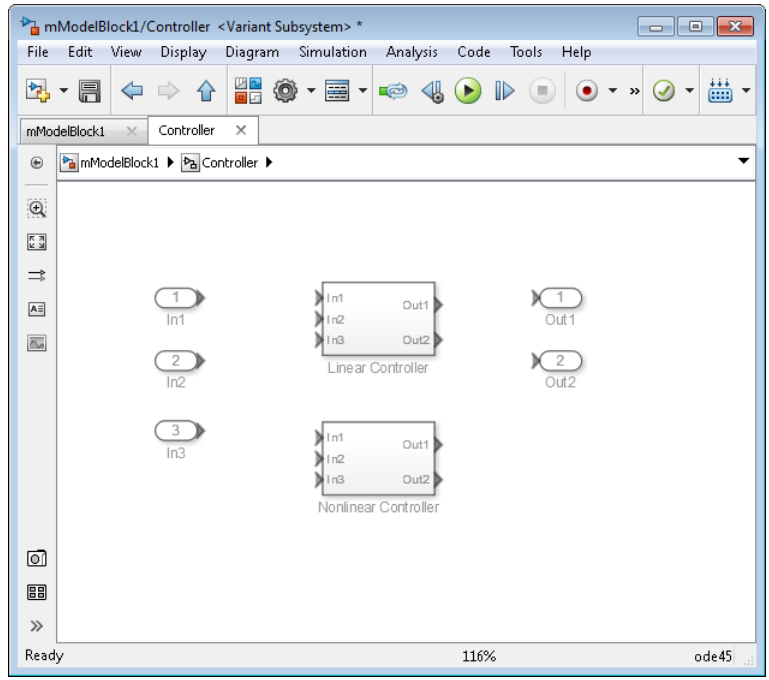


3 Right-click the badge on the Variant Subsystem block and select **Block Parameters (Subsystem)**.

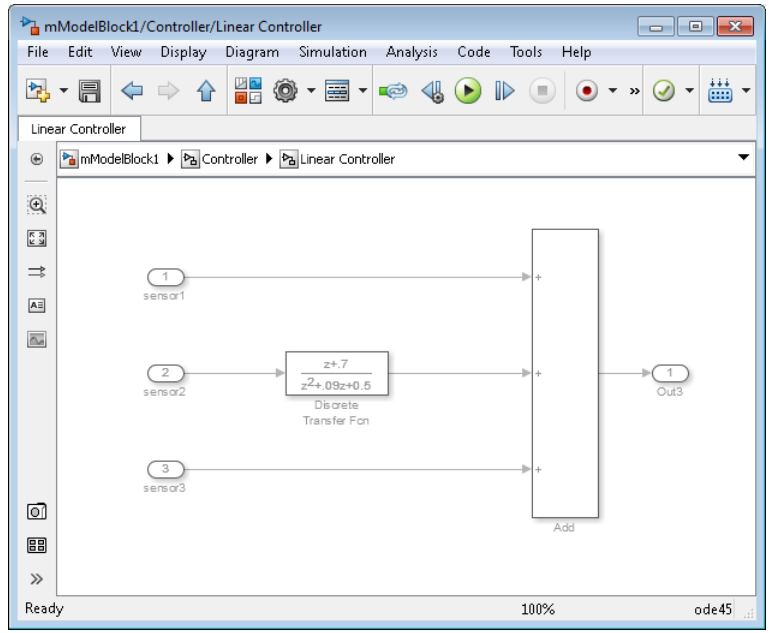
4 In the block parameters dialog box, click the  button for each subsystem variant choice you want to add.

Simulink creates empty Subsystem blocks inside the Variant Subsystem block. The new blocks have the same number of inports and outports as the containing Variant Subsystem block.

Tip (If your variant choices have different numbers of inports and outports, see “Mapping Inports and Outports of Variant Choices” on page 11-8.)

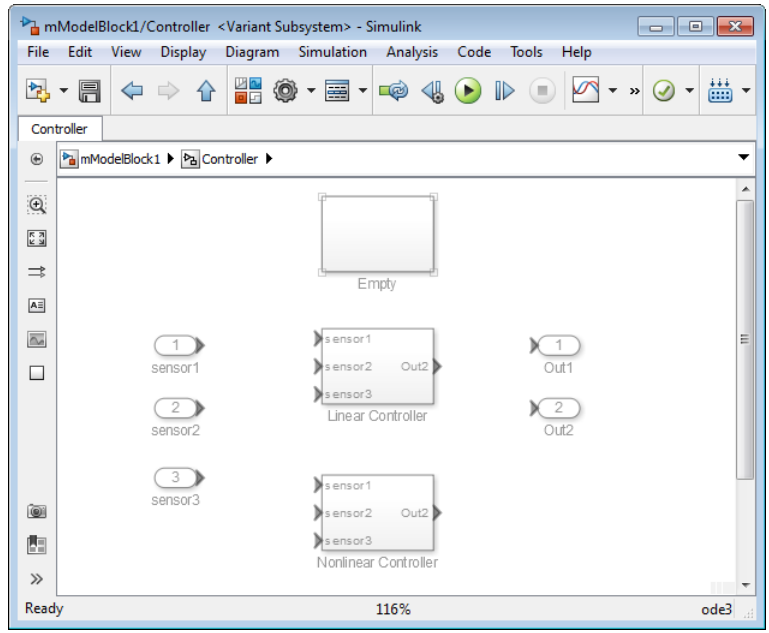


5 Open each Subsystem block and create the model that represents a variant choice.



6 When you are prototyping variants, you can create empty Subsystem blocks with no inputs or outputs inside the Variant Subsystem block. The empty subsystem recreates the situation in which a subsystem is inactive without the need for completely modeling the variant. For an empty variant choice, either specify a variant activation condition or comment out the variant condition by placing a `%` symbol before the condition.

If the empty variant choice is active during simulation, Simulink ignores it.

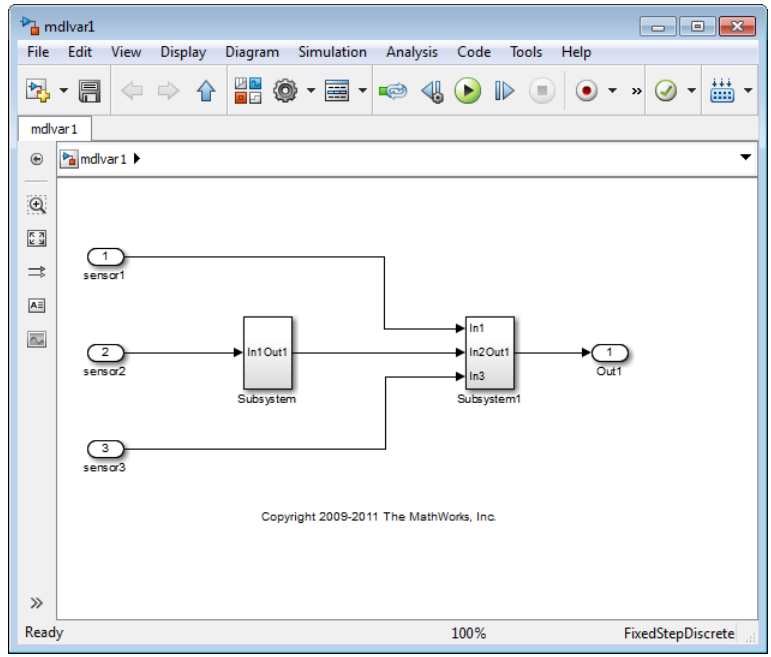


Include Simulink Model as Variant Choice

You can include a Simulink model as a variant choice inside a Variant Subsystem block.

1 Create a model that you want to include as a variant choice. Make sure that it has the same number of inports and outports as the containing Variant Subsystem block.

Note If your model has different numbers of inports and outports, see “Mapping Inports and Outports of Variant Choices” on page 11-8.

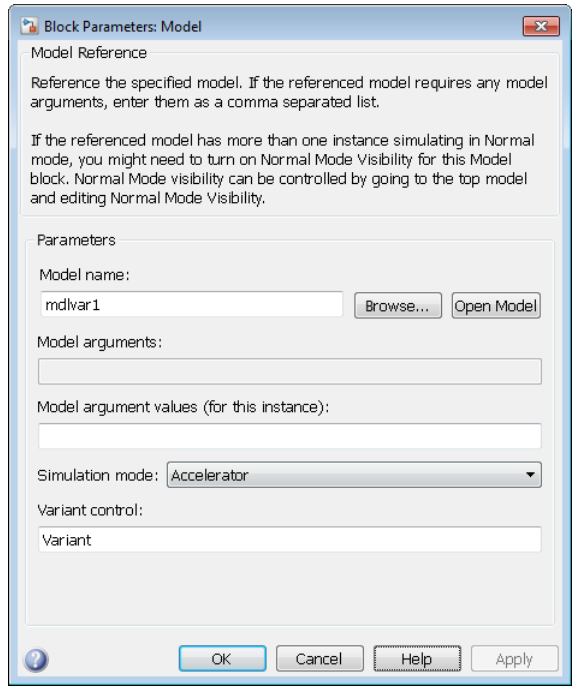


2 In your model, right-click the Variant Subsystem block that contains variant choices and select **Block Parameters (Subsystem)**.

3 In the block parameters dialog box, click the  button to add a Model block as variant choice.

Simulink creates an unresolved model reference block in the Variant Subsystem block.

4 Double-click the unresolved model block. In the **Model name** box, enter the name of the model you want to use as a model variant choice and click **OK**.



Configure Variant Controls

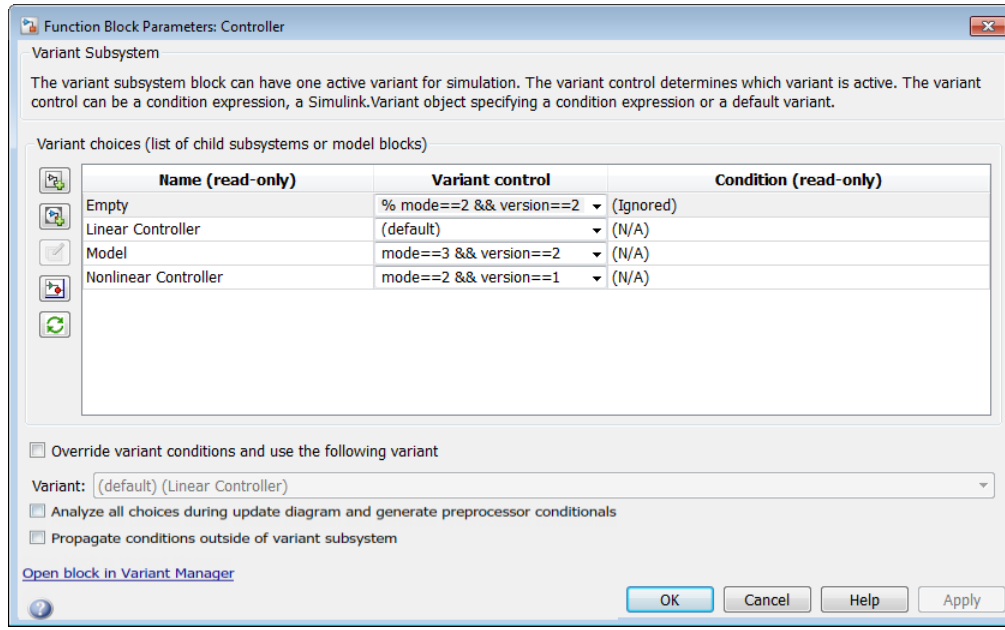
You can specify the conditions for activating a variant choice using variant controls. You can also specify at most one variant choice as the default.

1. At the MATLAB command prompt, specify the control variables that create an activation condition when combined.

   ```
   mode = 3;
   version = 2;
   ```

2. Right-click the Variant Subsystem block that is the container for variant choices in your model and select **Block Parameters (Subsystem)**.
3. In the block parameters dialog box, in the **Variant control** column, select `(default)` next to one of the choices.

   Simulink verifies that only one variant choice is active for simulation. When the control condition does not activate a variant, Simulink uses the default variant for simulation.



4 Specify a variant condition each of the other choices. If you are using an empty variant choice, specify a variant condition for the choice. You can also comment out an existing activation condition by prefixing it with a `%` symbol.

5 Click **Apply**; otherwise, your changes are not saved.

Convert to Variants

Note For new models, use a Variant Subsystem block instead of a Model block to contain model variants, unless you need to use variants that are conditionally executed models (models with control ports). Support for using a Model block to contain model variants will be removed in a future release.

In the Simulink Editor, you can convert these blocks to a Variant Subsystem block:

- Subsystem block
- Model block
- Model Variants block (for models created in versions earlier than R2017b)

To do so, right-click the block, then in the context menu, click **Subsystem & Model Reference > Convert to > Variant Subsystem**.

You can also convert these block to Variant Subsystem block programmatically. To do so, use any of these syntaxes:

- `Simulink.VariantManager.convertToVariant(gcb)`
- `Simulink.VariantManager.convertToVariant(gcbh)`

For example,

```
open_system('sldemo_variant_subsystems');
Simulink.VariantManager.convertToVariant('sldemo_variant_subsystems/Controller');
```

If you convert model variants to subsystem variants, note that the behavior of the Model block parameter **Generate preprocessor conditionals** is different than the Subsystem Variants block parameter **Analyze all choices during update diagram and generate preprocessor conditionals**. For model variants, enabling the parameter causes simulation and update diagram to compile the active variant only. For subsystem variants, enabling the parameter compiles all the variants, which can make simulation and updates slower.

Converting model variants to subsystem variants can require that you update scripts that use the `Variants` command-line parameter.

Prepare Variant-Containing Model for Code Generation

In this section...

Using Embedded Coder, you can generate code from Simulink models containing one or more variant choices. The generated code contains preprocessor conditionals that control the activation of each variant choice.

Convert Variant Control Variables into Simulink.Parameter Objects

MATLAB variables allow you to rapidly prototype variant control expressions when you are building your model. However, if you want to generate preprocessor conditionals for code generation, convert MATLAB variables into `Simulink.Parameter` objects.

In addition to enabling parameter value specification, `Simulink.Parameter` objects allow you to specify other attributes (such as data type) that are required for generating code.

1. Specify the model in which you want to replace MATLAB variant control variables with `Simulink.Parameter` objects.

```
model = 'my_model_containing_variant_choices';
open_system(model);
```

2. Get the variables that are referenced in variant control expressions.

```
vars = Simulink.VariantManager.findVariantControlVars(model)

vars =

4x1 struct array with fields:

    Name
    Value
    Exists
    Source
    SourceType
```

3. Create an external header file for specifying variant control values so that the variable definitions are imported when the code runs.

```
headerFileName = [model '_importedDefines.h'];
headerPreamble = strrep(upper(headerFileName),'.','_');

fid = fopen(headerFileName,'w+');
fidErr = (fid == -1);
if (fidErr)
    fprintf('There was an error creating header file %s:...
\n', headerFileName);
else
    fprintf('+++ Creating header file ''%s'' with variant control...
        variable definitions.\n\n', headerFileName);
    fprintf(fid, '#ifndef %s\n', headerPreamble);
    fprintf(fid, '#define %s\n', headerPreamble);
end
```

Variant control variables defined as `Simulink.Parameter` objects can have one of these storage classes.

- `Define` or `ImportedDefine` with header file specified
- `CompilerFlag`
- `SystemConstant (AUTOSAR)`
- Your own custom storage class that defines data as a macro

4 Loop through all the MATLAB variables to convert them into `Simulink.Parameter` objects.

```
count = 0;
for countVars = 1:length(vars)
    var = vars(countVars).Name;
    val = vars(countVars).Value;
    if isa(val, 'Simulink.Parameter')
        % Do nothing
        continue;
    end
    count = count+1;

% Create and configure Simulink.Parameter objects
% corresponding to the control variable names.
% Specify the custom storage class as Define (Custom).
    newVal = Simulink.Parameter(val);
    newVal.DataType = 'int16';
    newVal.CoderInfo.StorageClass = 'Custom';
    newVal.CoderInfo.CustomStorageClass = 'Define (Custom)';
    newVal.CoderInfo.CustomAttributes.HeaderFile = headerFileName;
```

```
            Simulink.data.assigninGlobal(model, var, newVal);

            if ~fidErr
                fprintf(fid, '#endif\n');
                fclose(fid);
            end
    end
```

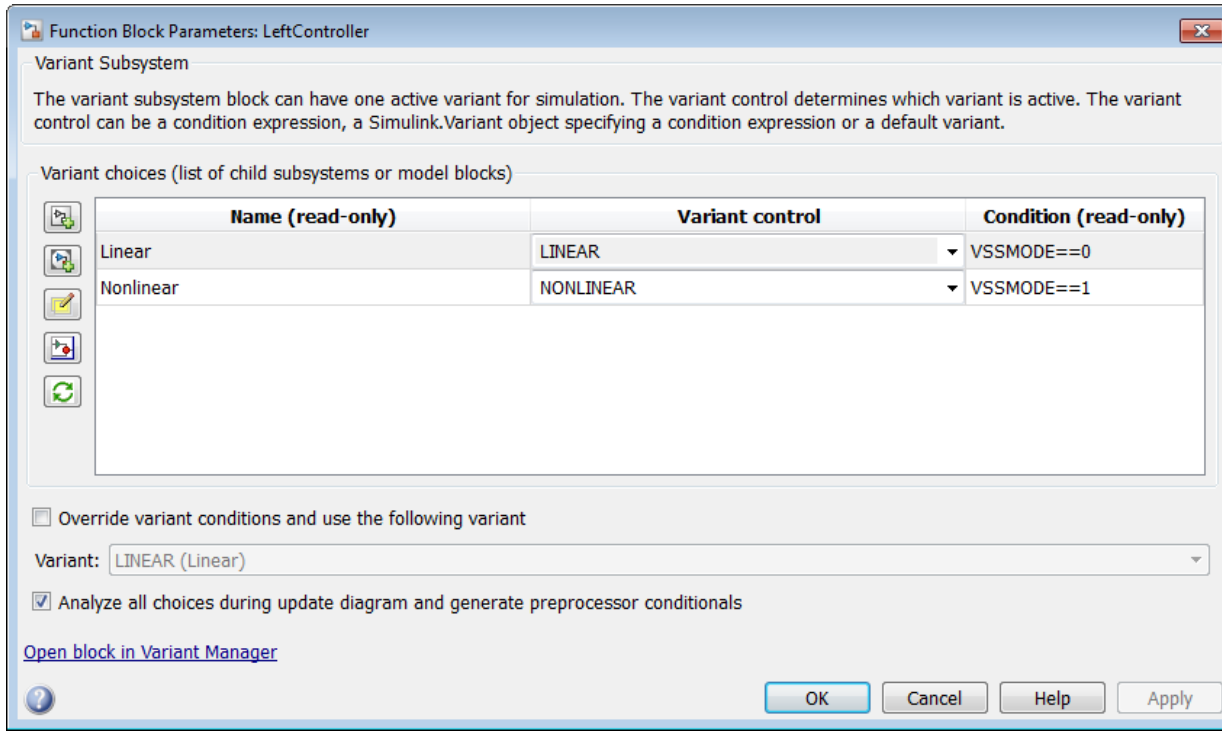
Configure Model for Generating Preprocessor Conditionals

If you represent variant choices inside a Variant Subsystem block or a Model Variant block, code generated for each variant choice is enclosed within C preprocessor conditionals `#if`, `#else`, `#elif`, and `#endif`.

If you represent variant choices using a Variant Source block or a Variant Sink block, code generated for each variant choice is enclosed within C preprocessor conditionals `#if` and `#endif`.

Therefore, the active variant is selected at compile time and the preprocessor conditionals determine which sections of the code to execute.

1. In the Simulink editor, select **Simulation > Model Configuration Parameters**.
2. Select the **Code Generation** pane, and set **System target file** to `ert.tlc`.
3. In the **Report** pane, select **Create code generation report**.
4. Select the **Code Generation** pane, and clear **Ignore custom storage classes** and **Apply**.
5. In your model, right-click the block containing the variant choices (Variant Subsystem, Variant Source, Variant Sink, or Model Variant) and select **Block Parameters**.
6. Select the option **Analyze all choices during update diagram and generate preprocessor conditionals**.



Simulink analyzes all variant choices during an update diagram or simulation. This analysis provides early validation of the code generation readiness for all variant choices.

7 Clear the option **Override variant conditions and use following variant**.

8 Build the model.

Set up Model Variants Using a Model Block

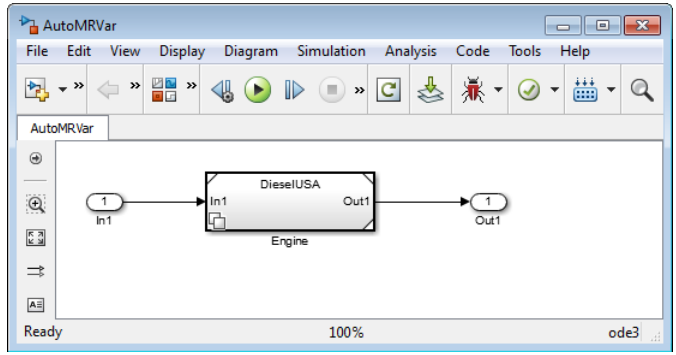
In this section...

Note For new models, use a Variant Model or Variant Subsystem block instead of a Model block to contain model variants, unless you need to use variants that are conditionally executed models (models with control ports). Support for using a Model block to contain model variants will be removed in a future release. For an example of a model that uses a Variant Subsystem block as a container for variant models, see “Model Reference Variants”.

To convert a Model block that contains variant models to a Variant Subsystem block, right-click the Model block and select **Subsystems & Model Reference** > **Convert to** > **Variant Subsystem**. Alternatively, you can use the `Simulink.VariantManager.convertToVariant` function, specifying the Model block path or block handle.

Open the example `AutoMRVar` model.

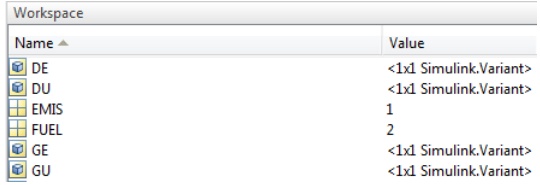
```
addpath([docroot '/toolbox/simulink/ug/examples/variants/mdlref/']);
open('AutoMRVar');
```



The symbol appears in the lower-left corner of the block to indicate that it uses variants. The name of the variant that was active the last time you saved the model appears on the block.

When you change the active variant, the variant block refreshes. The name changes to reflect the current active variant.

When you open the example model, the `load` function loads a MAT-file that populates the base workspace with the variables and objects used by the model.



The example shows the use of variants for the following cases:

- The automobile can use a diesel or a gasoline engine.
- Each engine must meet the European or United States (USA) emission standard.

`AutoMRVar` implements the automobile application using the Model block named `Engine`. The Engine block specifies four referenced models. Each referenced model represents one permutation of engine fuel and emission standards. The table shows the variant choices.

Model Name	Variant Control	Condition (read only)
`GasolUSA`	`GU`	`FUEL==1 && EMIS==1`
`GasolEuro`	`GE`	`FUEL==1 && EMIS==2`
`DieselUSA`	`DU`	`FUEL==2 && EMIS==1`
`DieselEuro`	`DE`	`FUEL==2 && EMIS==2`

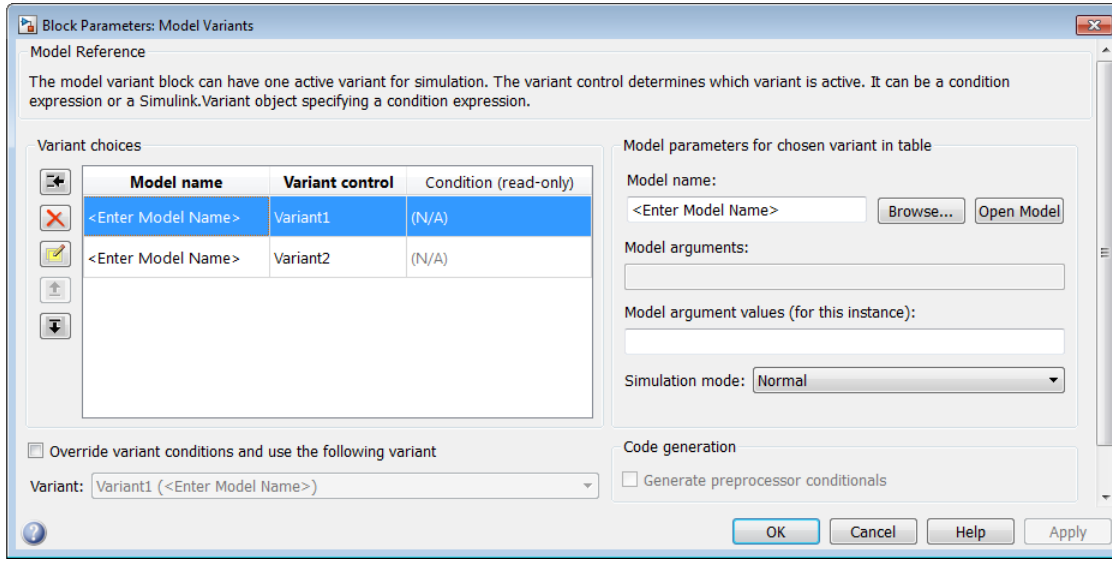
Note You can use condition expressions directly in the **Variant control** field. You do not need to create `Simulink.Variant` objects.

Configure the Model Block

A Model block and its variants must satisfy model referencing requirements and limitations. on page 8-105. For information on requirements and limitations that apply to *code generation* see "Represent Subsystem and Model Variants in Generated Code" (Embedded Coder).

To configure a Model block and specify your variant choices:

1. Create a model.
2. From the **Ports & Subsystems** library, add a Model block to the model.
3. Right-click the Model block and select **Block Parameters (ModelReference)** from the context menu.



4. Under **Variant choices**, specify the model choices in the **Model name** column. To specify a protected model, use the extension `.slxp` or `.mdlp`. For more information, see "Protected Model" on page 8-95.

> **Note** You cannot specify a model as the default variant if that model is a variant choice in a Model block. Instead, you can add that model as a variant choice in a Subsystem block, and then specify that model as the default variant.

5 For each model choice, specify the variant control in the **Variant control** column. Use a Boolean condition expression or a `Simulink.Variant` object representing a Boolean condition expression.

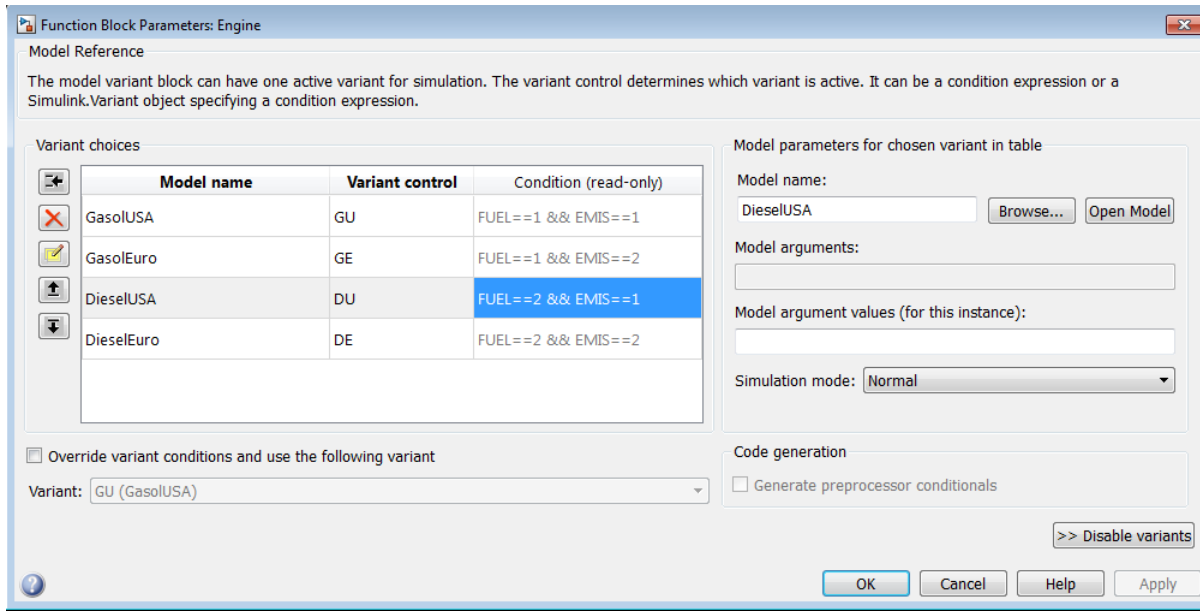
   Populate the **Variant control** column for each choice. You cannot comment out (`%`) variant control values for the Model block. However, for Variant Subsystem blocks, you can comment out variant choices.

6 To edit the condition that determines the active variant choice, click the **Create/Edit selected variant** button  . In the dialog box, enter the condition and click **OK**.

7 If you want, specify the model arguments and the **Simulation mode**. All simulation modes work with model variants. For more information, see "Parameterize Model Variants" on page 11-53 and "Simulate Model Reference Hierarchies" on page 8-35.

8 If you want to add more variant choices, click the **Add a new variant** button  .

9 After you have specified referenced models and added variant choices, click **OK**.



For next steps, see "Working with Variant Choices" on page 11-13.

Disable and Enable Model Variants

You can disable model variants without losing your variant settings. After you enable variants, they remain enabled until you explicitly disable them.

Disabling variants:

- Hides and ignores the content of the **Variant choices** section of the dialog box
- Retains the active variant as the model name
- Ignores subsequent changes to variant control variables and other models, other than the current model

To disable variants from a Model block:

1. Right-click the block and select **Block Parameters (ModelReference)** to open the block parameters dialog box.
2. Click **Disable Variants**.

   To enable variants, click **Enable Variants**. The Model block selects an active variant according to the current base workspace variables and conditions.

Parameterize Model Variants

You can apply a parameter to a variant control. Parameter values are the same as for a referenced model.

1. In the block parameters dialog box, under **Variant choices**, select the row for the variant control that you want to parameterize.
2. In the **Model argument values (for this instance)** text box, specify the parameter.
3. Click **Apply**.

For more information, see “Model Arguments for Model Blocks That Contain Model Variants” on page 8-85.

Log Model Variants

A Model block can log only those signals that the referenced model specifies as logged. If a model is a variant model, or contains a variant model, then you can either log all

signals marked for logging or log no logged signals. The Signal Logging Selector configuration for the model must be in one of these states. For details, see “Models with Model Referencing: Overriding Signal Logging Settings” on page 61-99.

- The **Logging Mode** is set to `Log all signals as specified in model`.
- The **Logging Mode** is set to `Override signals` and the check box for the model block is either checked () or empty (). The check box cannot be filled ().

Additional Examples

For additional examples of model reference variants, in the Help browser, select **Simulink > Examples > Modeling Features > Model Reference > Model Reference Variants**.

The example `sldemo_mdlref_variants` shows a Variant Subsystem block that contains referenced models as variants.

Visualize Variant Implementations in a Single Layer

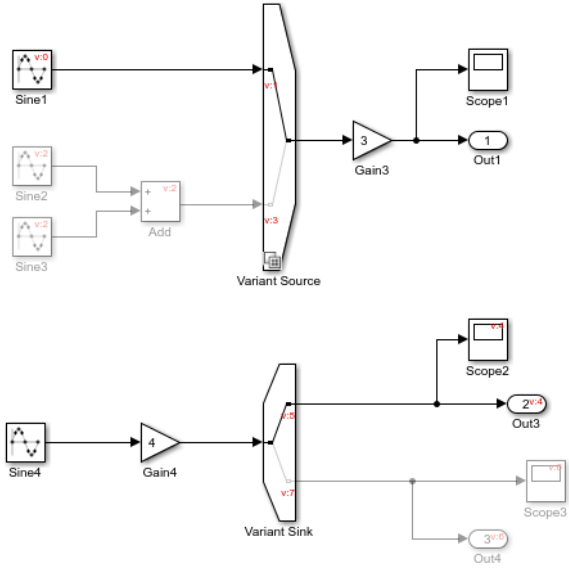
Simulink provides two blocks that you can use to visualize all possible implementations of variant choices in a model. These blocks are called Variant Source and Variant Sink.

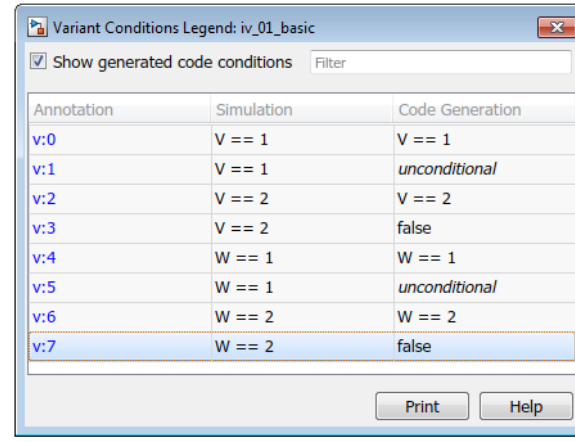
When you compile the model, Simulink determines which variant control evaluates to `true`. Simulink then deactivates blocks that are not tied to the variant control being `true` and visualizes the active connections.

How Variant Sources and Sinks Work

The Variant Source block has one or more input ports and one output port. You can define variant choices as blocks that are connected to the input port so that, at most, one choice is active. The active choice is connected directly to the output port of the Variant Source and the inactive choices are eliminated during simulation.

The Variant Sink block has one input port and one or more output ports. You can define variant choices as blocks that are connected to the output port so that, at most, one choice is active. The active choice is connected directly to the input port of the Variant Sink, and the inactive choices are eliminated during simulation.





Connect one or more blocks to the input port of the Variant Source block or the output port of the Variant Sink block. Then, you define variant controls for each variant choice entering the Variant Source block and exiting the Variant Sink block. For more information, see “Variant Condition Propagation with Variant Sources and Sinks” on page 11-63.

Advantages of Using Variant Sources and Sinks

Using Variant Source and Variant Sink blocks in Model-Based Design provides these advantages:

- The blocks enable the propagation of variant conditions and allow you to visualize variant choices in a single layer of your model.
- By visualizing all possible implementations of variant choices, you can improve the readability of your model.
- During model compilation, Simulink eliminates inactive blocks throughout the model, improving the runtime performance of your model.
- Variant sources and sinks provide variant component interfaces that you can use to quickly model variant choices.

Limitations of Using Variant Sources and Sinks

- Variant Source and Variant Sink blocks work with time-based, function-call, or action signals. You cannot use SimEvents, Simscape Multibody, or other non-time-based signals with these blocks.
- The code generation variant report does not contain Variant Source and Variant Sink blocks.

More About

- “Variant Condition Propagation with Variant Sources and Sinks” on page 11-63

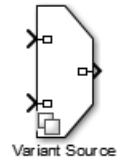
Define and Configure Variant Sources and Sinks

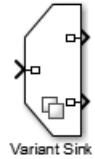
Simulink provides two blocks that you can use to visualize all possible implementations of variant choices in a model graphically. These blocks are called Variant Source and Variant Sink.

When you compile the model, Simulink determines which variant control evaluates to `true`. Simulink then deactivates blocks that are not tied to the variant control being `true` and visualizes the active connections.

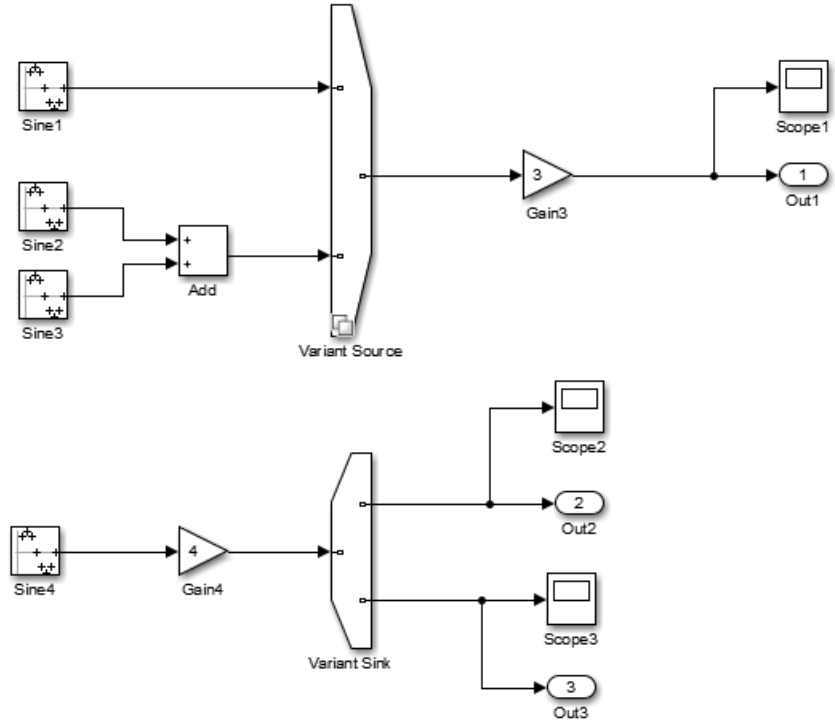
1 Add Variant Source and Variant Sink blocks to your model.

  These blocks enable ports that activate variant choices.





2 Using blocks from the Simulink Library Browser, create sources and sinks that represent variant choices. Connect choices to the input and output ports of the Variant Source and Variant Sink blocks.



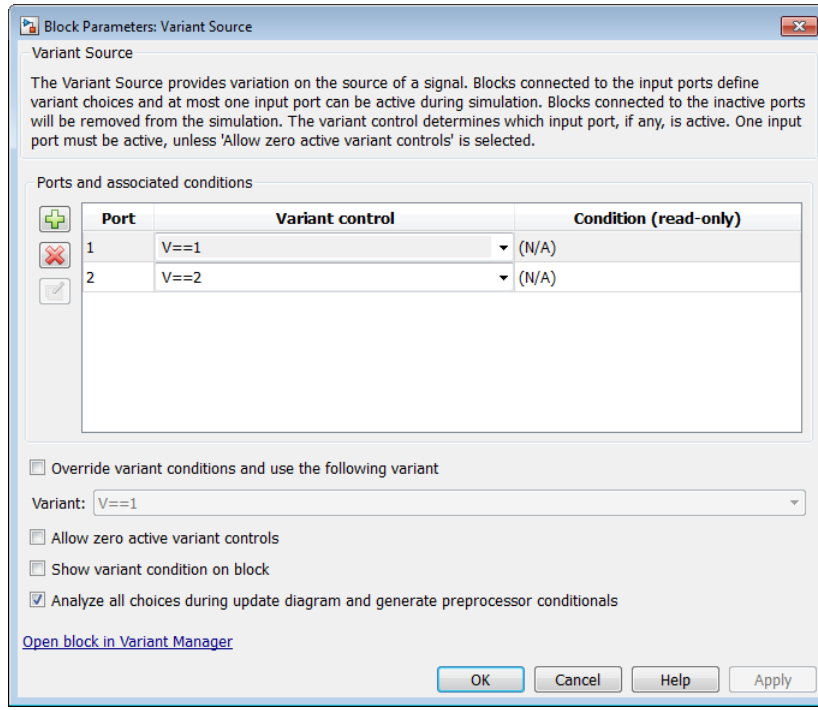
3 At the MATLAB command prompt, specify the control variable that creates an activation condition for the variant source.

```
V = Simulink.Parameter(1);
```

4 Right-click the Variant Source block and select **Block Parameters (VariantSource)**.

5 In the block parameters dialog box, in the **Variant control** column, type `V==1` next to one of the choices and `V==2` next to the other. Click **Apply**; otherwise, your changes are not saved.

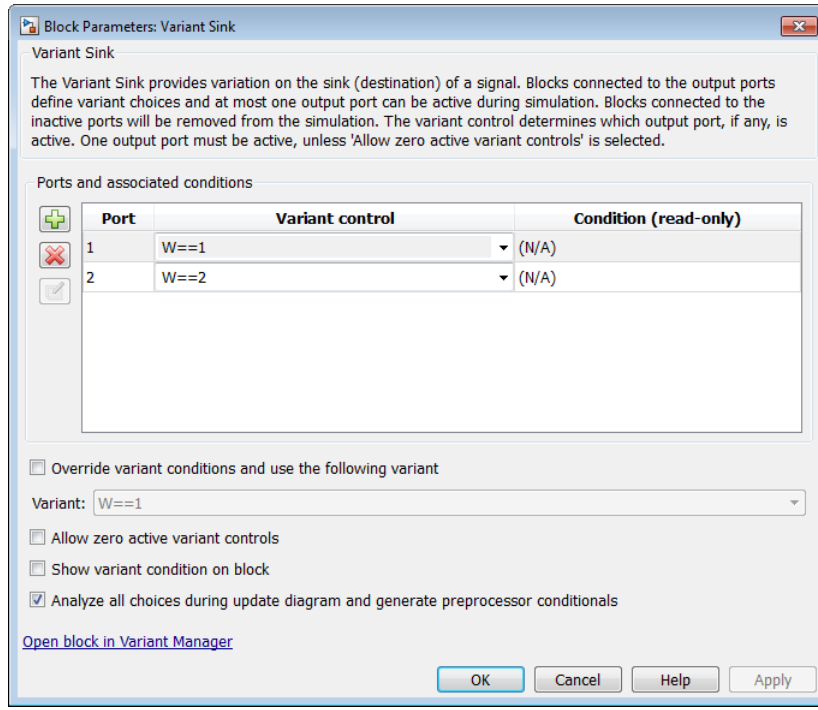
Simulink verifies that only one variant is active for simulation. When the control condition does not activate a variant, Simulink uses the default variant for simulation.



6 At the MATLAB command prompt, specify the control variable that creates an activation condition for the variant sink.

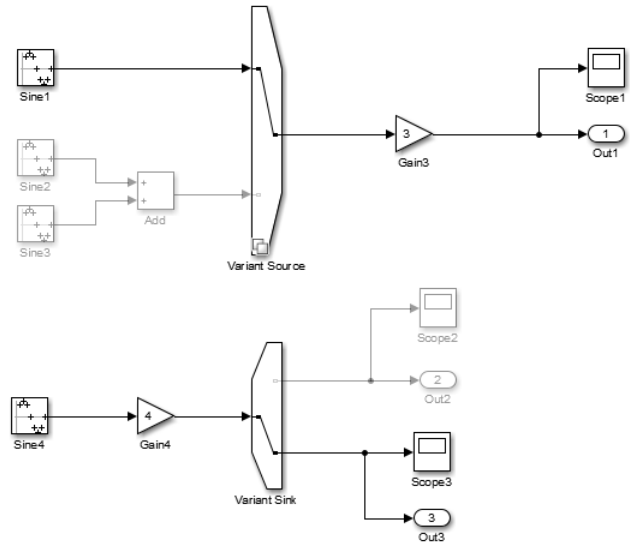
```
W = Simulink.Parameter(2);
```

7 Double-click the Variant Sink. In the block parameters dialog box, in the **Variant control** column, type `W==1` next to one of the choices and `W==2` next to the other.

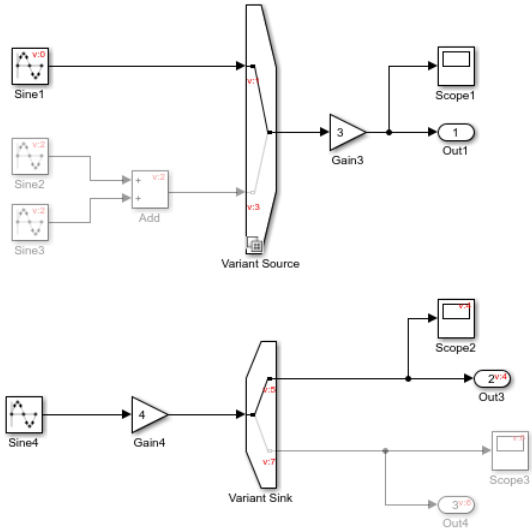


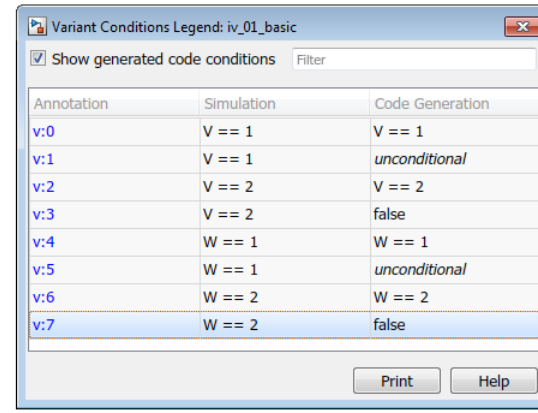
8 Click **Apply**; otherwise, your changes are not saved.

9 Simulate the model. Simulink propagates the variant conditions to identify which model components to activate.



10 You can visualize the conditions that activate each variant choice by selecting **Display > Blocks > Variant Conditions**.





11 In the Variant Condition Legend dialog box, click through the hyperlinked variant condition annotations to observe which parts of the model each condition activates.

Variant Condition Propagation with Variant Sources and Sinks

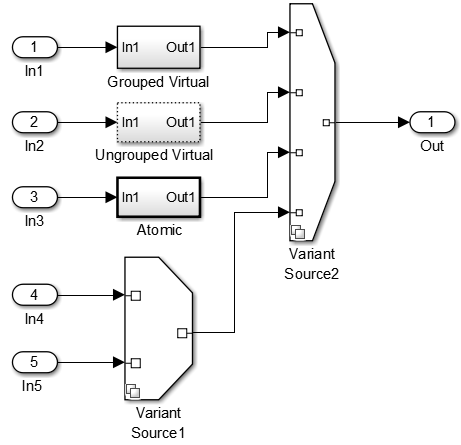
When you specify variant conditions in models containing Variant Source and Variant Sink blocks, Simulink propagates these conditions to determine which components of the model are active during simulation.

In this section...

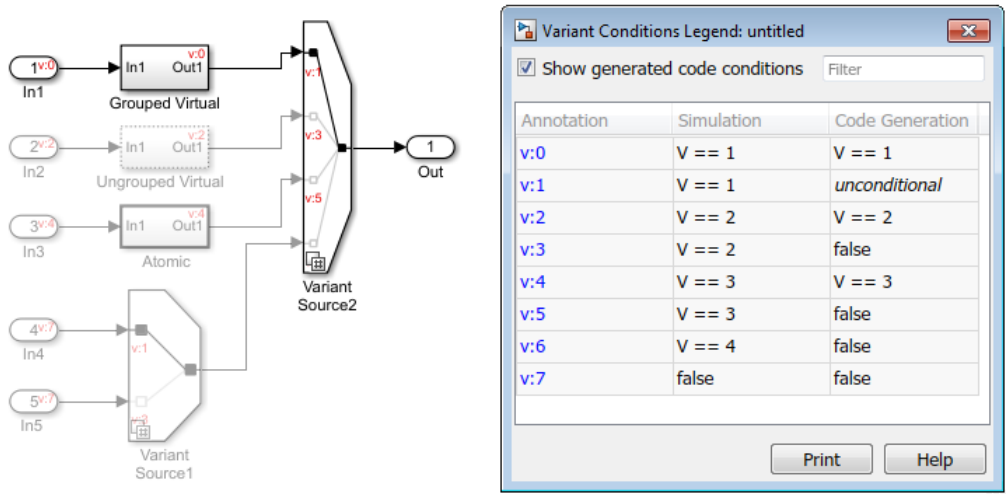
View Variant Condition Annotations

When you develop a model that contains Variant Source or Variant Sink blocks, you can visualize the conditions that activate each variant choice. Simulink annotates these models with their corresponding variant conditions.

Consider this model containing multiple variant choices feeding into Variant Source blocks. A specific variant condition activates each variant choice.

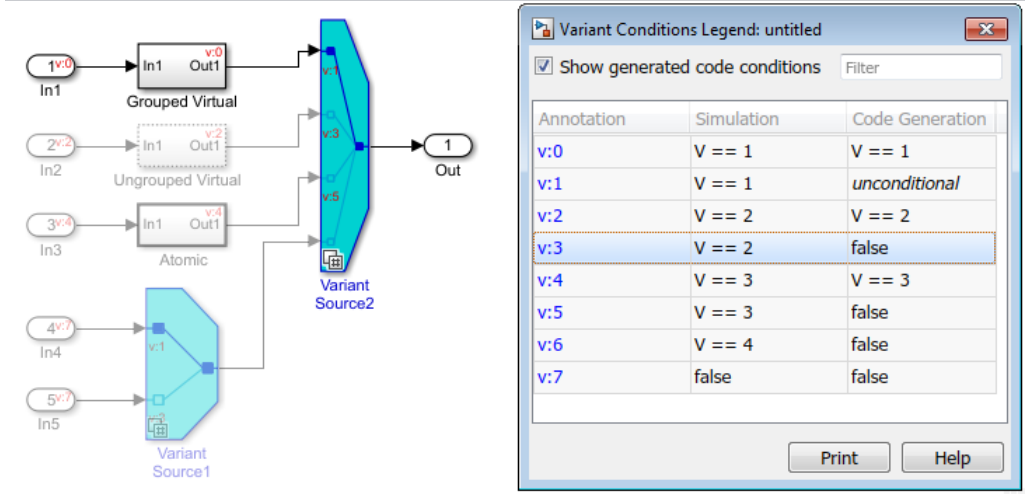


To visualize the variant conditions, select **Display > Blocks > Variant Conditions**.



The **Variant Condition Legend** dialog box appears. Variant conditions on blocks are annotated as `v:C`, where `v` is the variant semantic indicator and `C` represents the variant condition index. The dialog box also shows the expression associated with each condition.

In the **Variant Condition Legend** dialog box, you can click through the hyperlinked variant annotations to observe which parts of the model each condition activates. For example, if you click `v:3`, Simulink highlights the parts of the model that are activated when the condition `V==3` evaluates to `true`.



Variant condition annotations have these properties:

- There are no annotations on unconditional blocks. Therefore, the `Out` block is not annotated.
- To reduce clutter, the legend only displays the final computed conditions. For example, if you enter a variant condition in a Variant Source block, that condition appears in the annotations only when you apply your changes.
- The conditions in the legend are sorted during display.
- In the legend, a condition is set to `false` if Simulink assesses that the blocks associated with that condition are never active.

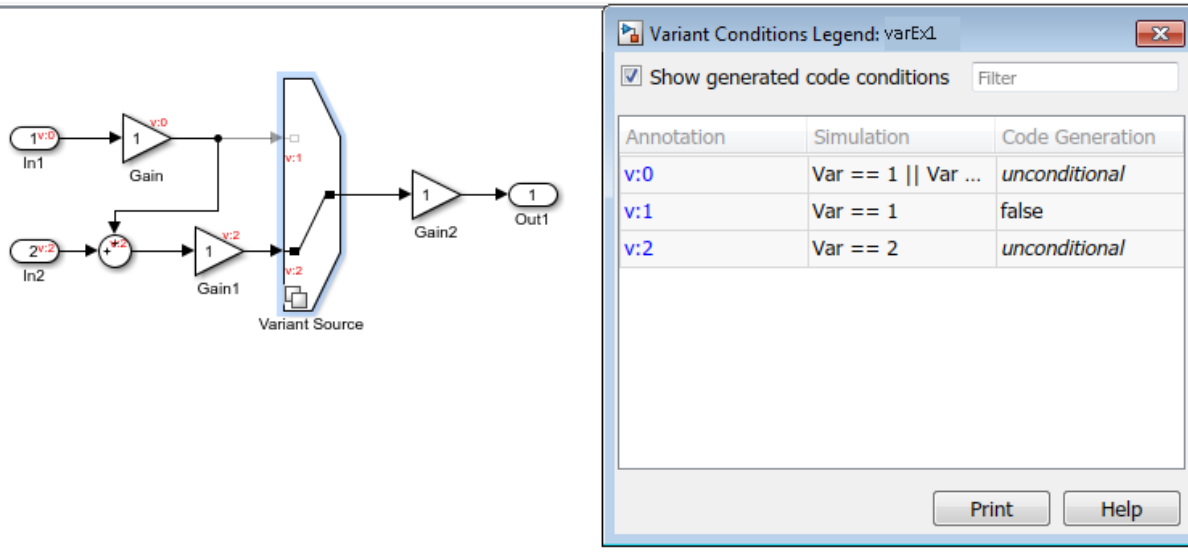
  For example, the `In4` block is connected to the `Variant Source1` block, whose condition is `V==1`. `Variant Source1` is connected to the `Variant Source2` block, which activates `Variant Source1` only when `V==4`. Therefore, `In4` can only be active when `V==1 && V==4`, a condition that is always `false`.

How Variant Condition Propagation Works

When you compile a model containing Variant Source or Variant Sink blocks, Simulink determines which variant control evaluates to `true`. Simulink then deactivates blocks that are not tied to the variant control being `true` and visualizes the active connections.

Cross-Coupling of Inputs and Outputs

In this model, two inputs feed the Variant Source block. The first input is active when `Var == 1`, and it branches into the second input before connecting to the Variant Source block. The second input is the default variant choice.

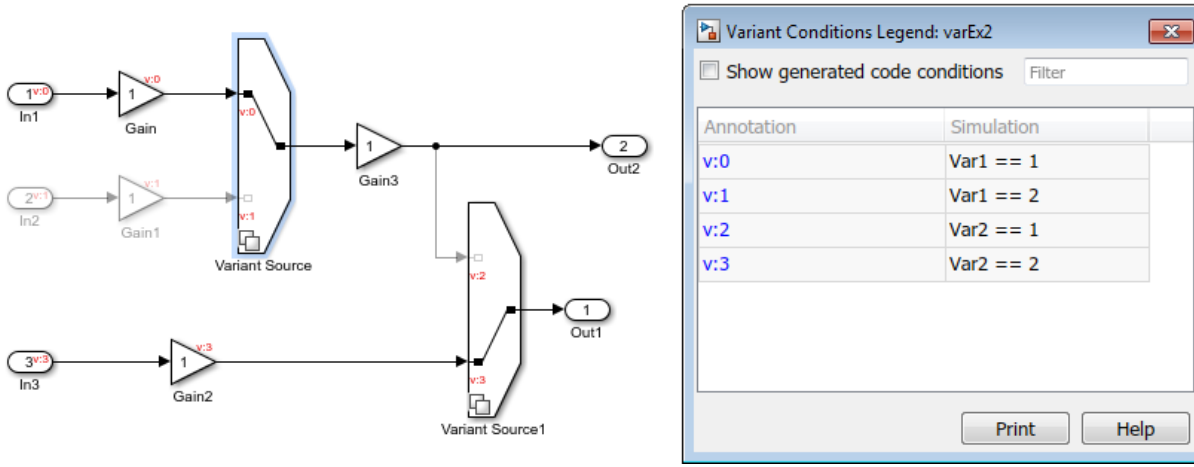


During simulation, this model exhibits three modes of operation:

- When `Var == 1`, the first input is active and its branch into the second input is inactive.
- When `Var == 1 || Var == 2`, the second input is active and the branch of the first input is active.
- When `Var == 2`, the second input is active and the output is active.

Cascading Blocks and Compounding Conditions

In this model, two Variant Source blocks, each fed by two input ports, are connected in a cascading manner. The inputs to `Variant Source` are active when `Var1 == 1` or `Var1 == 2`. The output of `Variant Source` branches into one of the inputs of `Variant Source1`. The inputs to`Variant Source1` are active when `Var2 == 1` or `Var2 == 2`.



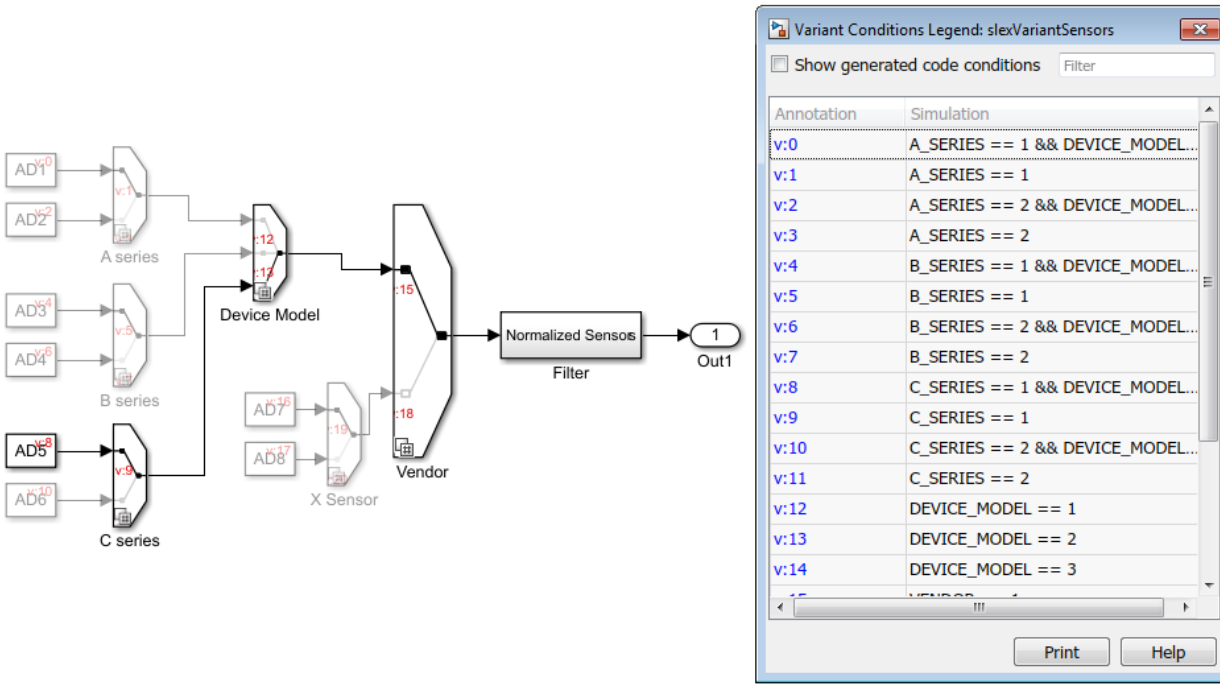
During simulation, this model exhibits eight modes of operation:

- When `Var1 == 1 && Var2 == 1`, the first inputs of `Variant Source` and `Variant Source` are active.
- When `Var1 == 1 && Var2 == 2`, the first input of `Variant Source` and the second input of `Variant Source1` are active.
- When `Var1 == 2 && Var2 == 1`, the second input of `Variant Source` and the first input of `Variant Source1` are active.
- When `Var1 == 2 && Var2 == 2`, the second inputs of `Variant Source` and `Variant Source1` are active.
- When `Var1 == 1 && Var2 != (1,2)`, only the first input of `Variant Source` is active.
- When `Var1 == 2 && Var2 != (1,2)`, only the second input of `Variant Source` is active.
- When `Var1 != (1,2) && Var2 == 1`, none of the inputs or outputs is active.
- When `Var1 != (1,2) && Var2 == 2`, only the second input of `Variant Source1` is active.
- When `Var1 != (1,2) && Var2 != (1,2)`, none of the inputs or outputs is active.

Hierarchical Nesting of Sources or Sinks

In this model, multiple Variant Source blocks are used to create hierarchical nesting of variant choices. Choices are first grouped by series: `A Series`, `B Series`, and `C Series`. A combination of one or more series is provided as input for a device model. The resulting device model is provided as input to the vendor by including or excluding a sensor selection.

Simulink propagates complex variant control conditions to determine which model components are active during compilation.



For more information, see Variant Sensors.

Condition Propagation with Subsystems

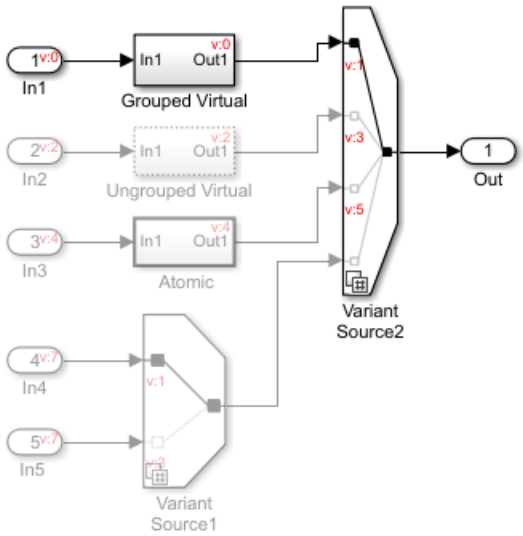
A Subsystem can either be a virtual (grouped or ungrouped) or an atomic subsystem depending on the selections made in its **Block Parameters** dialog box. For,

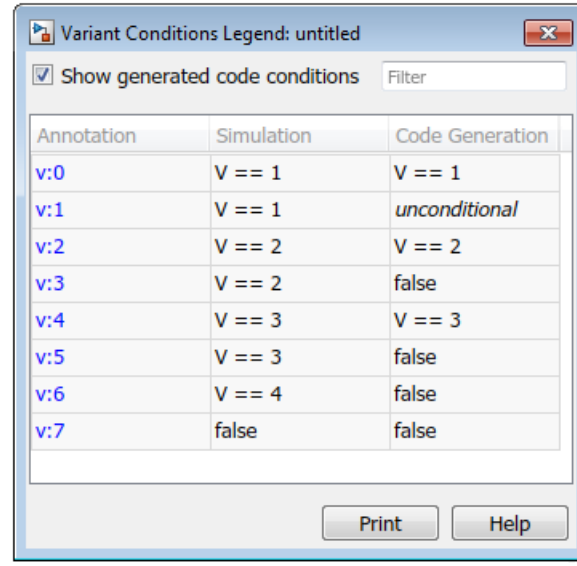
- Grouped Virtual: Select the **Treat as grouped when propagating variant conditions** check box. A grouped virtual subsystem has a continuous line.
- Ungrouped Virtual: Clear the **Treat as grouped when propagating variant conditions** check box. An ungrouped virtual subsystem has a dotted line.
- Atomic: Select the **Treat as atomic unit** check box. An atomic virtual subsystem has a solid line.

Simulink propagates variant conditions differently to these Subsystem types.

In this model, three types of subsystems are provided as input to the block `Variant Source2`.

- The grouped virtual subsystem is activated when `V == 1`. Simulink propagates the variant activation condition to all the blocks in the subsystem.
- The ungrouped virtual subsystem is activated when `V == 2`. Simulink propagates the variant activation condition to the blocks that were available in the subsystem while marking the subsystem virtual.
- The atomic subsystem is activated when `V == 3`. Simulink does not propagate the variant activation condition into this subsystem





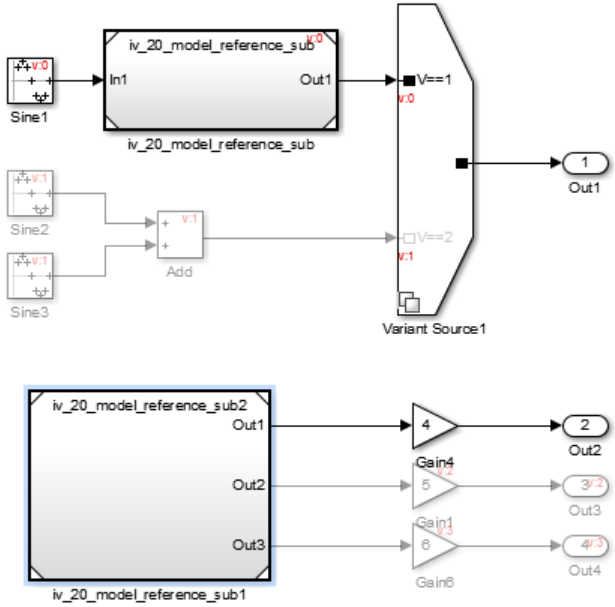
For more information, see “Propagating Variant Conditions to Subsystems” on page 11-114.

Condition Propagation with Other Simulink Blocks

Variant Condition Propagation with Model Block

Simulink compiles referenced models before propagating variant conditions. A variant condition can activate or deactivate a Model block, but variant conditions cannot propagate into the referenced model. A Model block can propagate variant conditions from its output port, if that variant condition originates at a port inside the model.

In this example, variant condition `V==1` activates the model block `iv_20_model_reference_sub`. However, the condition does not propagate into the model referenced by the block. Model block `iv_20_model_reference_sub2` propagates the same variant condition from its output port.

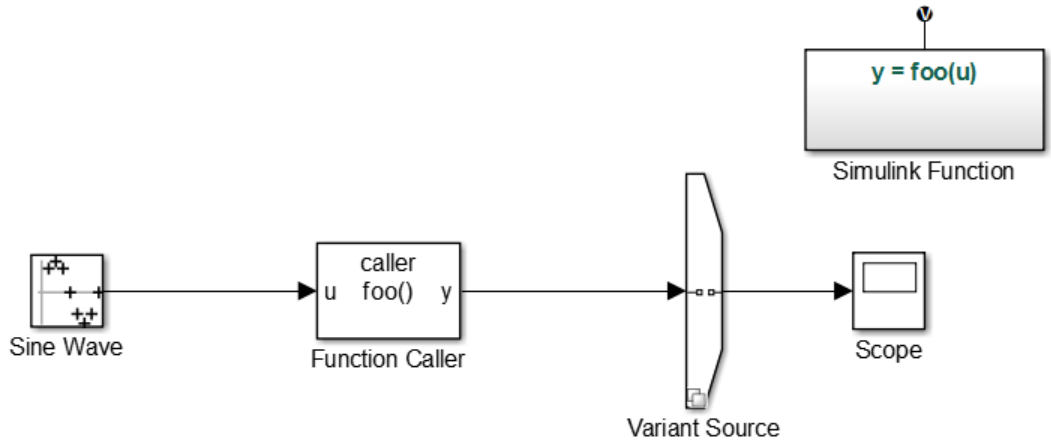


Variant Condition Propagation with Simulink Function block

Argument Inport and Argument Outport blocks interfacing with Simulink Function blocks cannot be connected to Variant Source or Variant Sink blocks. One variant condition must control the entire Simulink Function.

Consider the model slexVariantSimulinkFunction.

In this example, the function-call port block within the Simulink Function block has the **Enable variant condition** option selected. The `(inherit)` keyword is used to specify the value for the **Variant control** parameter. As a result, the Simulink Function block inherits the variant condition from the corresponding Function Caller blocks in the model. The **Generate preprocessor conditionals** parameter value is also inherited.

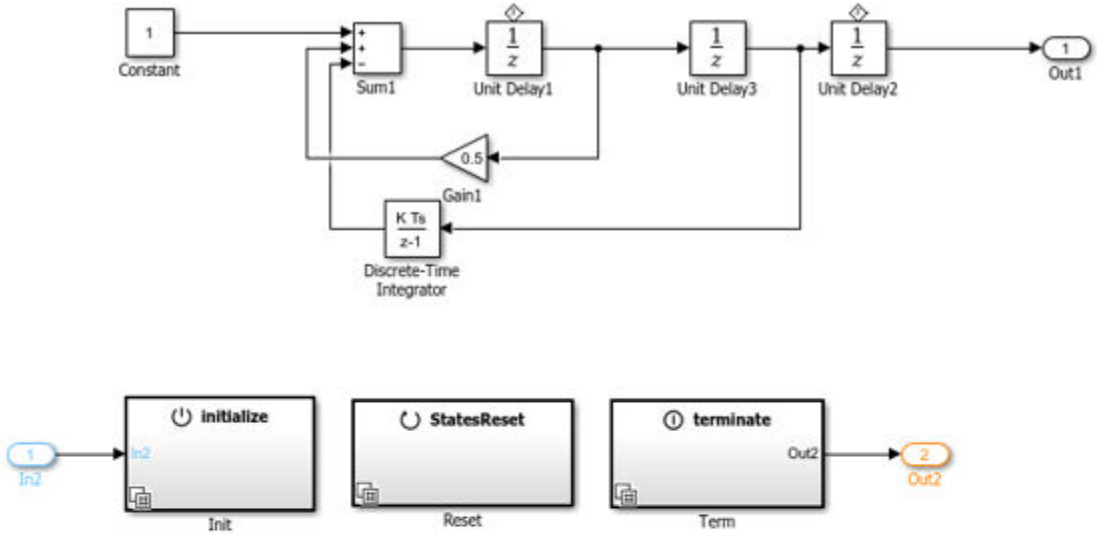


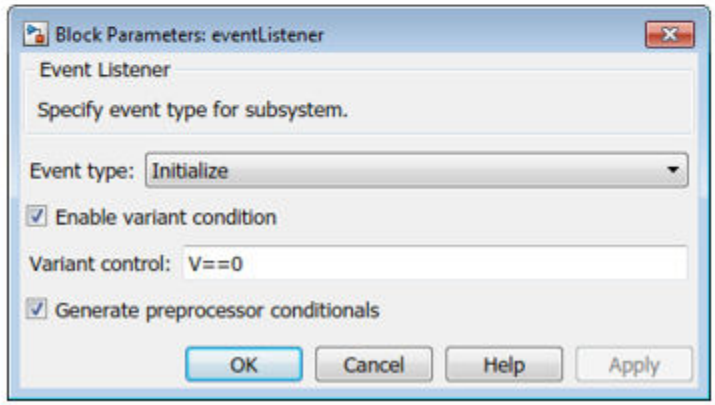
Note The **Configure Model Functions** button on the **Code Generation** > **Interface** pane provides you flexible control over the model function prototypes that are generated for a model. If the inport and the outport share an argument name and have propagated variant conditions, the flexible control over the model function prototypes is not supported.

Variant Condition Propagation with Initialize, Reset, and Terminate Blocks

The Initialize, Reset, and Terminate function blocks are pre-configured subsystem blocks that execute during model initialize, reset, and terminate events. Similar to a Simulink Function block these blocks support variant condition propagation.

In this example, the `Event Listener` block within the `Init`, `Reset`, and `Term` blocks have the **Enable variant condition** option selected. The **Variant control** parameter of the `Event Listener` block is specified as `V==0`. If you change the value of `V`, the `Init`, `Reset`, and `Term` blocks become inactive.





Variant Condition Propagation with Subsystem Block

A variant condition can activate or deactivate a Subsystem block, but variant conditions cannot propagate into the subsystem. A Subsystem block can propagate variant conditions from its output port if that variant condition originates at a port inside the subsystem.

For more information, see “Propagating Variant Conditions to Subsystems” on page 11-114.

Variant Condition Propagation with Bus

A Variant Source block can accept either virtual or nonvirtual bus inputs. When generating code with preprocessor conditionals, the bus types and hierarchies of all bus inputs must be the same. In addition, all elements of a bus signal must have the same variant condition. Elements of a bus cannot have different variant conditions.

Similarly, all elements of a Mux, Demux, or a Vector Concatenate block signal must have the same variant condition.

Known Limitations

- Variant condition propagation from Simulink Function inside Stateflow block is not supported.
- Variant condition propagation to Bus element port is not supported.
- When you simulate an Inline variants model with Simscape blocks, the Simscape blocks become unconditional.
- C++ code generation is not supported for models that contain propagated variant conditions.

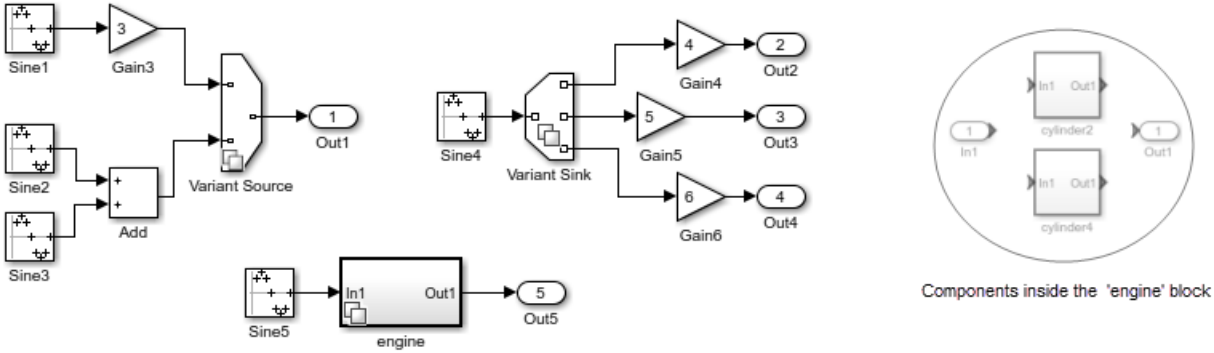
Create and Validate Variant Configurations

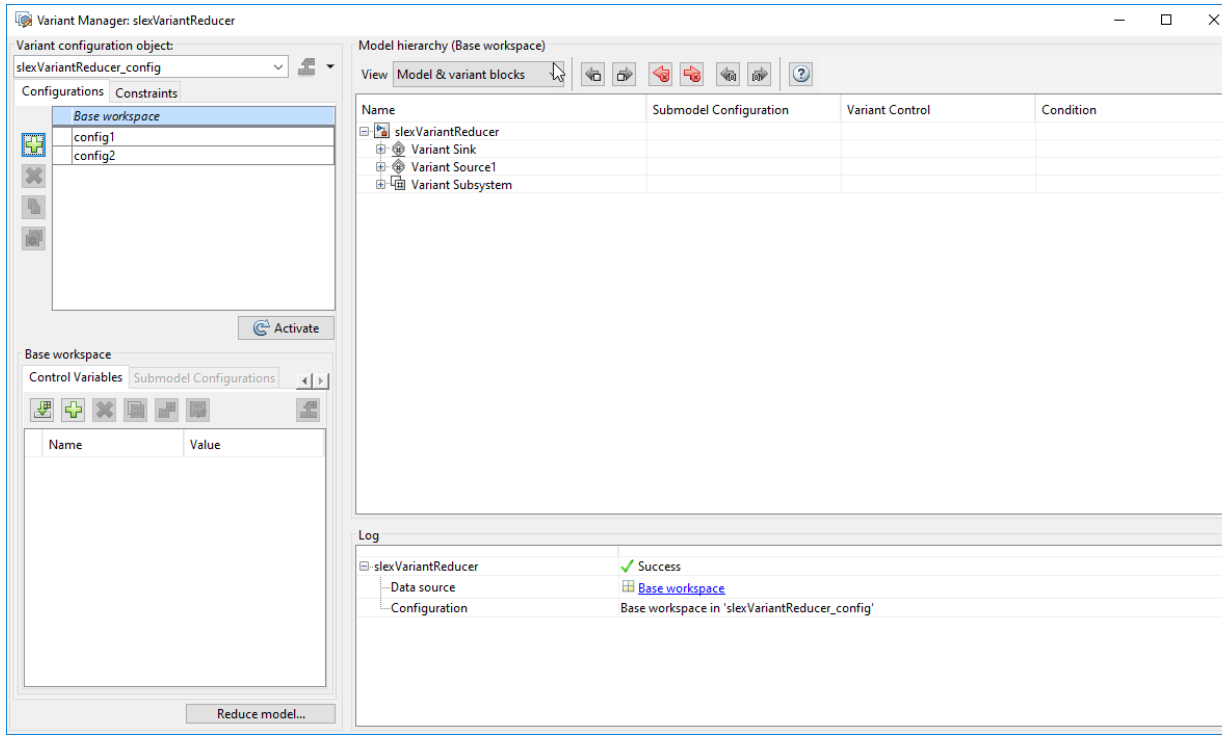
This example shows how to create and validate variant configurations for a model.

Step 1: Open Variant Manager

1 Open the model in which you want to create variant configurations. For example, consider a model containing a Variant Source, Variant Sink, and a Variant Subsystem block.



2 Right-click the variant badge and select **Open in Variant Manager**.



Step 2: Define Variant Configuration

You can use the **Variant configuration data** pane to define and store a variant configuration. For detailed information on each pane, see “Variant Manager Overview”.

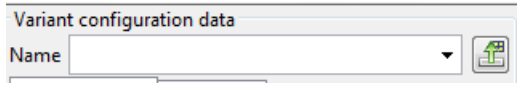
1 In the variant configuration data pane, click the **Configurations** tab.

2 Click  . A variant configuration is added. Type a name for this configuration in the **Name** column.

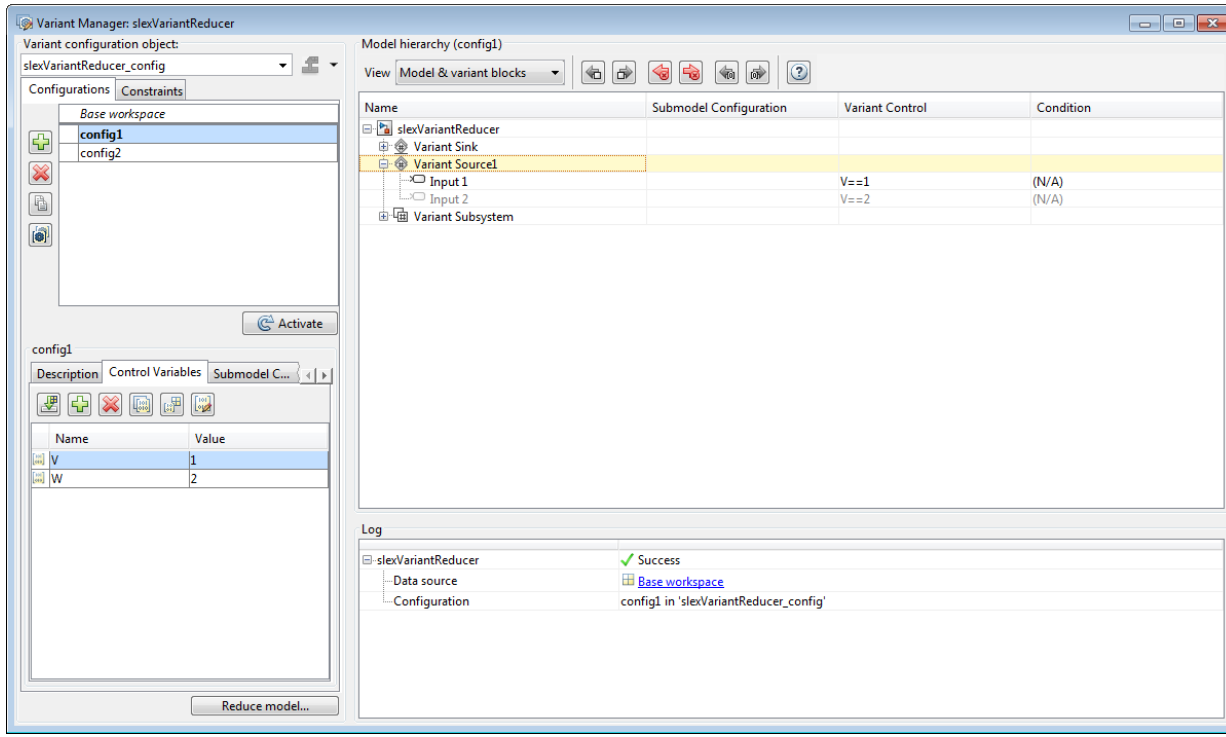
3 Click the **Control Variables** tab in the controls section of the **Configurations** pane.

4 To import the control variables for the variant configuration from the global workspace, click  or  to add new control variables to the model.

5 Type a name for the variant configuration in the **Name** box available at the top-left of Variant Manager.



6 To export the variant configuration information to the global workspace, click  . The variant configuration for the model is now created.



Step 3: Activate and Validate Variant Configuration

To activate a variant configuration, select a configuration from the **Configurations** section and click the **Activate** button. The **Activate** button validates and applies the selected configuration on the model.

Note To reduce a model based on a variant condition, click **Reduce model**. For more information, see “Reduce Models Containing Variant Blocks” on page 11-86

More About

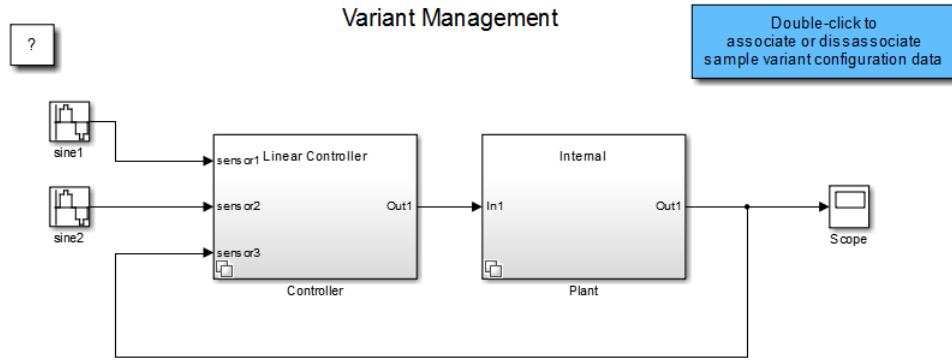
- “Approaches for Specifying Variant Controls” on page 11-18

Import Control Variables to Variant Configuration

This example shows how to import control variables to a variant configuration and associate a configuration with a referenced submodel.

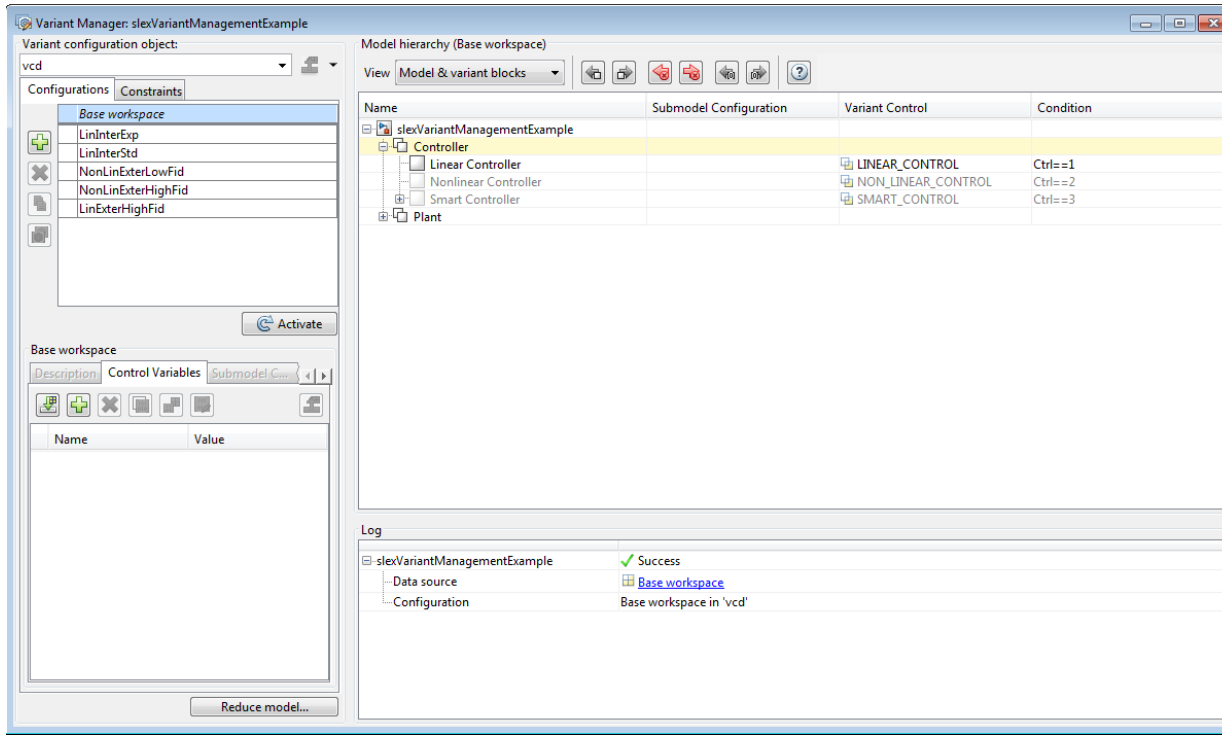
Step 1: Open Variant Manager

1 Open slexVariantManagementExample, which contains the variant configurations.



2 Double-click the blue block at the top to associate variant configuration data with the model.

3 Select **View > Variant Manager**.

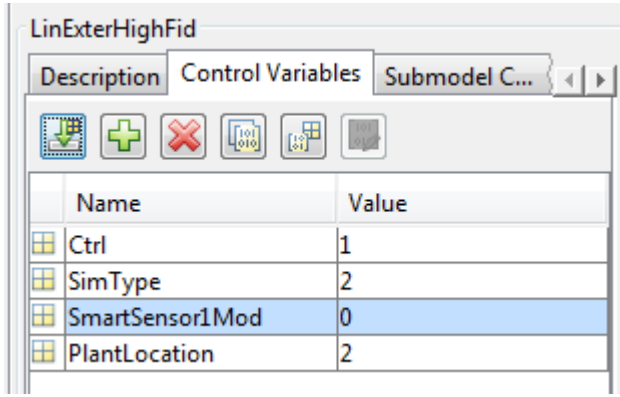


Variant configuration data `vcd` is associated with the model.

Step 2: Import Variant Configuration

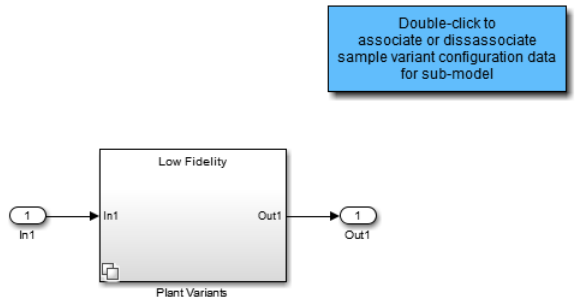
1. In the Variant Manager, in the **Configurations** tab, select `LinExterHighFid`.
2. In the **Control Variables** tab, click the **Import control variables from the base workspace** button  .

   The variables are imported.



Step 3: View Submodel Configuration

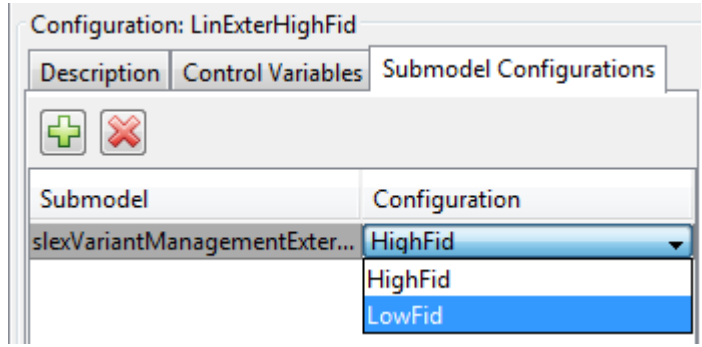
1 Open the referenced model slexVariantManagementExternalPlantMdlRef.



2 Double-click the blue block at the top to associate variant configuration data with the referenced model.

3 In the Variant Manager that is opened from `slexVariantManagementExample`, select `slexVariantManagementExternalPlantMdlRef` under the **Submodel Configurations** tab.

4 Select the `LowFid` configuration from the dropdown menu.



5 To validate the model using the `LinExterHighFid` variant configuration, select `LinExterHighFid` from the **Configurations** list and click **Activate**.

Simulink validates the new configuration against the model and returns the validation results.

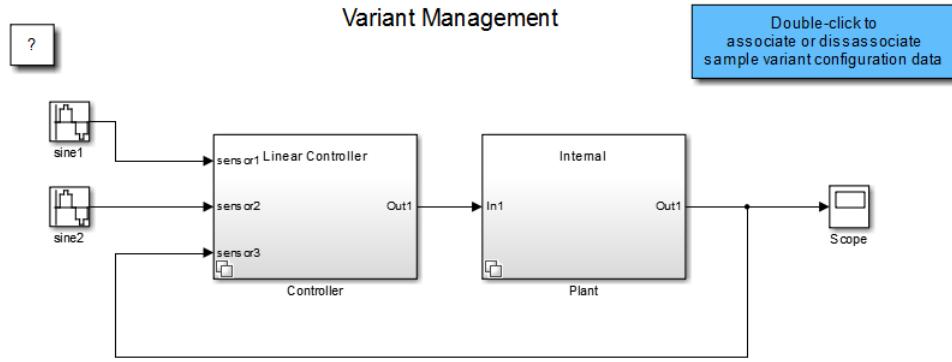
More About

- “Introduction to Variant Controls” on page 11-17

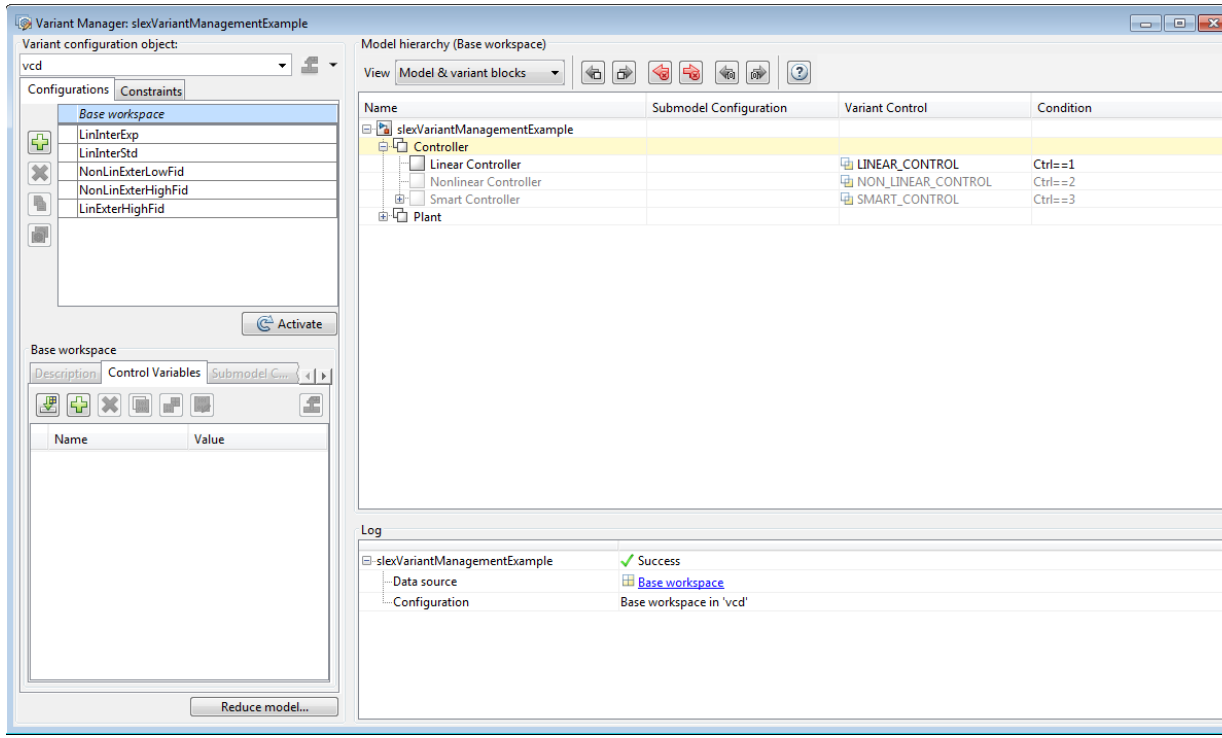
Define Constraints

This example shows how to define constraints that must evaluate to true for a variant configuration to become active.

1 Open slexVariantManagementExample.

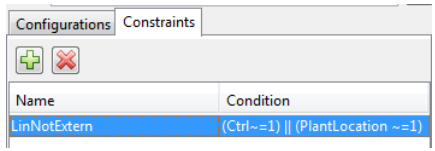


2 Select **View** > **Variant Manager**.



3 In the Variant Manager, in the **Constraints** tab, click  .

4 Enter `LinNotExtern` as the **Name** and `(Ctrl~=1) || (PlantLocation ~=1)` as the **Condition** for the constraint.



This constraint activates variants that do not use the Linear Controller and External Plant Controller configurations.

5 To activate and validate the constraint, click the **Activate** button.

Reduce Models Containing Variant Blocks

Note You require a Simulink Design Verifier license to reduce your model.

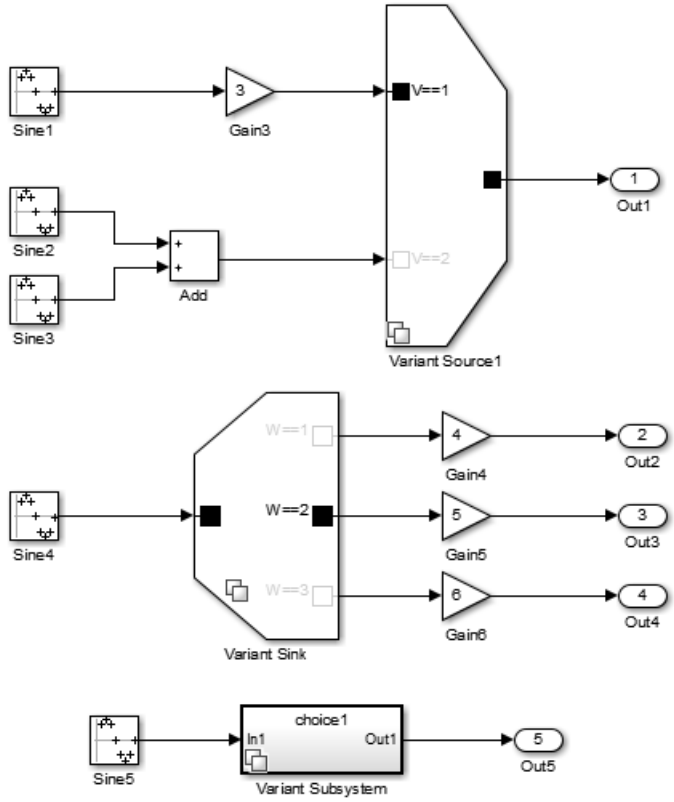
A variant model can contain multiple variable structure and a single fixed structure. The combination of the variable structure and the fixed structure to create a model depends on different combinations of the variant choices that you select. Each combination of the variant choices can be stored as a variant configuration.

Variant models can be reduced to simplified, standalone model depending on the selected variant configurations.

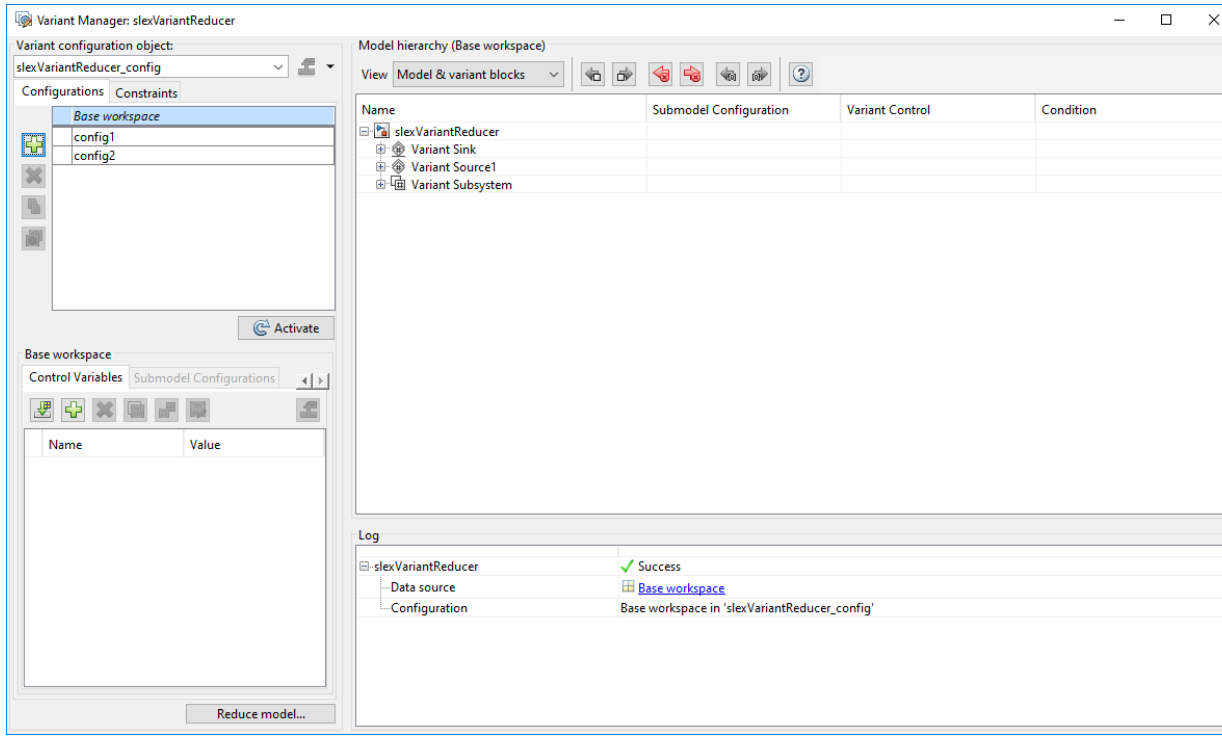
Consider the model Variant Reducer. The model contains a Variant Source block, a Variant Sink block, and a Variant Subsystem block with these variant choices:

- Variant Source: `V==1` and `V==2`
- Variant Sink: `W==1`, `W==2`, and `W==3`
- Variant Subsystem: `V==1` and `V==2`

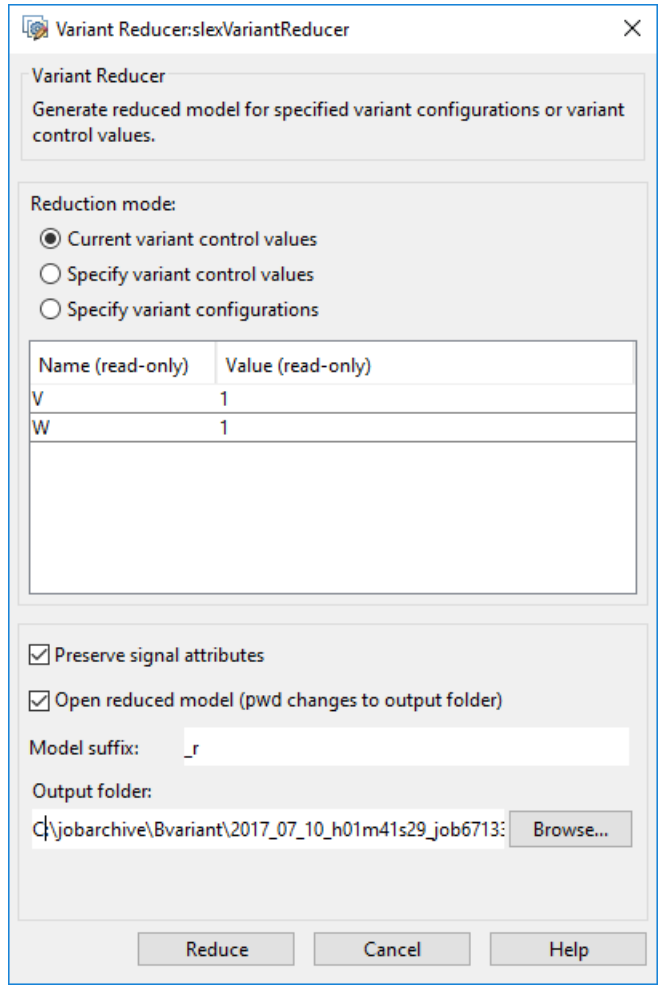
Assume that the model has two predefined variant configurations, named `config1` (`V==1 && W==2`) and `config2` (`V==2 && W==2`). These configurations are saved in a variant configuration data object, `varConfig`.



1 Right-click the variant badge, and select **Open in Variant Manager**. The Variant Manager opens displaying the predefined configurations.

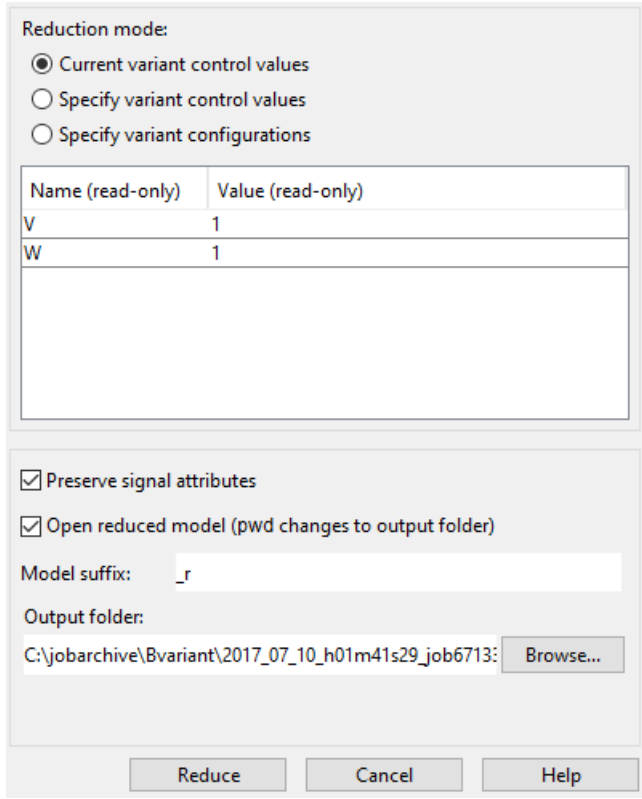


2 Click **Reduce model**. The Variant Reducer dialog box opens.

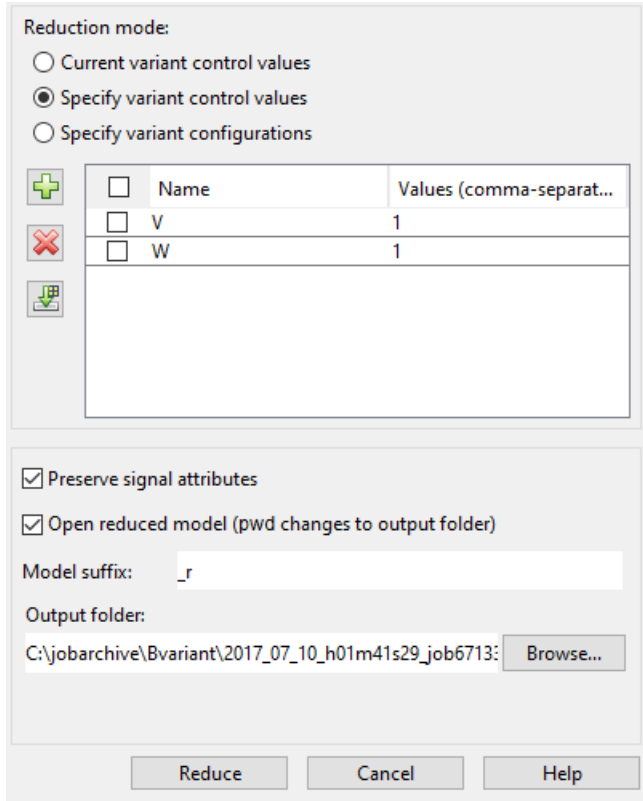


3 In the **Reduction mode** section, select:

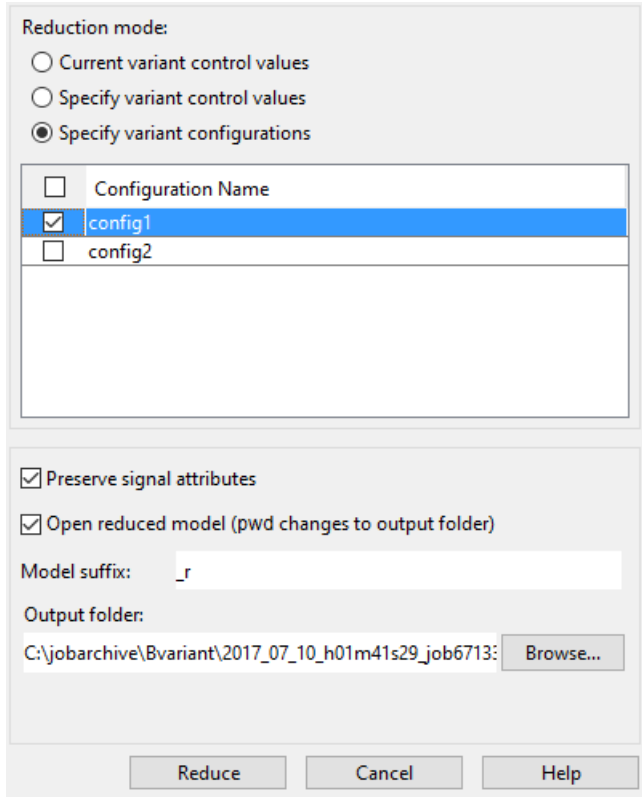
- **Current variant control values** (default) : To reduce the model based on its variant control variable values in the global workspace.



- **Specify variant control values**: To reduce the model based on the variant control variable values specified as a comma separated list.



- **Specify variant configurations**: To reduce the model that is associated with a variant configuration data object and configurations to be retained in the reduced model.



Note During reduction, the control variable values from the last selected configuration are stored in the global workspace.

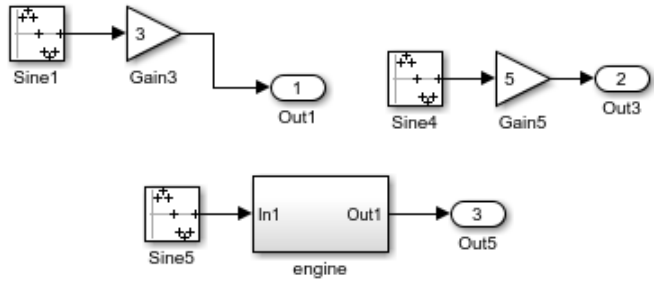
4 Select **Preserve signal attributes** to preserve the compiled signal attributes between the original and reduced model. When this option is selected, the Variant Reducer tries to preserve the compiled signal attributes between the original and reduced models by adding signal specification blocks at appropriate block ports in the reduced model. Compiled signal attributes include signal data types, signal dimensions, compiled sample times, and so on.

5 Specify a value as the suffix in the **Model suffix** field. The model suffix value is appended to the reduced models and the releated artifacts. By default, `_r` is the suffix.

6 Specify the output folder to store the reduced model.

Note To make the output folder as current working folder, select the **Open reduced model** check box

7 Click **Reduce**. The reduced model for the required configuration is now created. If the model contains resolved library links or referenced models, the corresponding parent is reduced for the specified configuration and is referenced in the model. The reduced model, reduced referenced model, and the reduced library get their names from the corresponding model, referenced model, or the library with `_r` (**Model suffix**) appended to it.



Consider a Variant model that contains a Simulink Function block with Variant condition on the Simulink Function block as `V==1 || V==2 || V==3 || V==4`. If the model is reduced for any or a combination of the available Variant conditions, the Simulink Function block in the reduced model is unconditional. For example, if the model is reduced for Variant condition, `V=1, V=2, and V=3`, theSimulink Function block in the reduced model is unconditional. Whereas, if the model is reduced for Variant condition, `V=1, V=2, and V=5`, theSimulink Function block in the reduced model remains conditional with `V=1 and V=2` as the Variant condition.

Reduce Model Programmatically

To reduce a model programmatically by using the below syntax:

```
Simulink.VariantManager.reduceModel(model,<Configuration>,<OutputFolder>)
```

For example,

- To reduce the model based on its variant control variable values in the global workspace.

  ```
  Simulink.VariantManager.reduceModel('sldemo_variant_subsystems')
  ```

- To reduce the model based on its variant control variable values in the global workspace to a specified folder.

```
Simulink.VariantManager.reduceModel('sldemo_variant_subsystems, [], 'outdir')
```

- To reduce the model that is associated with a variant configuration data object and configurations to be retained in the reduced model.

  ```
  Simulink.VariantManager.reduceModel('slexVariantManagementExample',...
  {'LinInterStd','NonLinExterHighFid'})
  ```

- To reduce the model by specifying configurations in the form of a structure of variant control variables.

  ```
  Simulink.VariantManager.reduceModel('iv_model', struct('V', 1, 'W', [1 2]))
  ```

  Here, two configurations are specified corresponding to `{V=1, W=1}` and `{V=1, W=2}`, respectively.

For more information on reducing model programmatically, see `Simulink.VariantManager.reduceModel`.

Considerations and Limitations

- The output folder to store the reduced model must not be in `matlabroot`.
- If the model has dependencies on files that are located in `matlabroot`, these files are not modified or copied to the output folder during model reduction. File dependency can include files from the Simulink libraries, `.m` files, `.mat` files, `.sldd` files. Such models must be copied to a location that is not in `matlabroot` and then reduced.
- If the output folder contains the `variant_reducer.log` file from the previous model reduction, the reducer overwrites all the files available in that output for any subsequent reduction.
- Callback code (For example, model callbacks, mask initialization code and mask parameter callback codes) are not modified during model reduction and must be modified manually.
- Additional blocks are added automatically to the reduced model to ensure consistent simulation semantics. The additional blocks can include Signal Specification blocks for consistent signal attributes (data type, dimensions, complexity) or the Ground and the Terminator blocks for unconnected signals.
- During model reduction, commented blocks present on the active path are retained while the commented blocks presented on an inactive path are deleted.

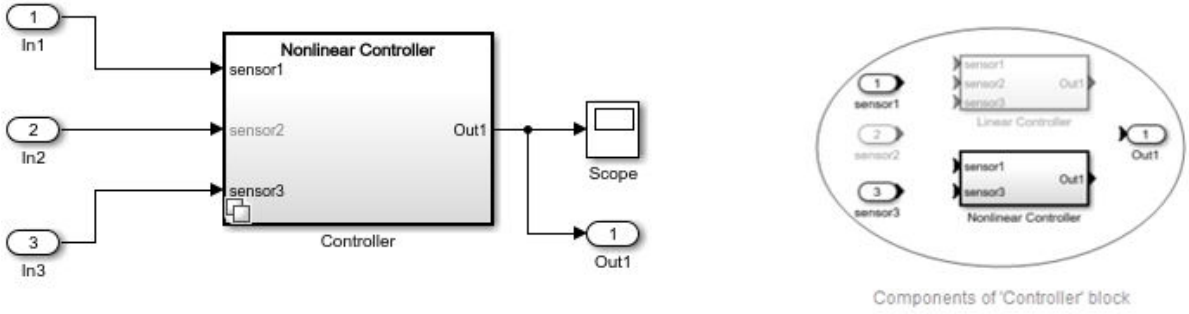
Condition Propagation with Variant Subsystem

When you specify variant conditions in models containing Variant Subsystem blocks, Simulink propagates these conditions to determine which components of the model are active during simulation. A variant condition can be a condition expression or a variant object.

The variant condition annotations help you visualize the propagated conditions. To view the variant condition annotations, click **Display > Blocks > Variant Condition Legend**.

Note The **Variant Condition Legend** option is available only when **Display > Blocks > Variant Condition** is active.

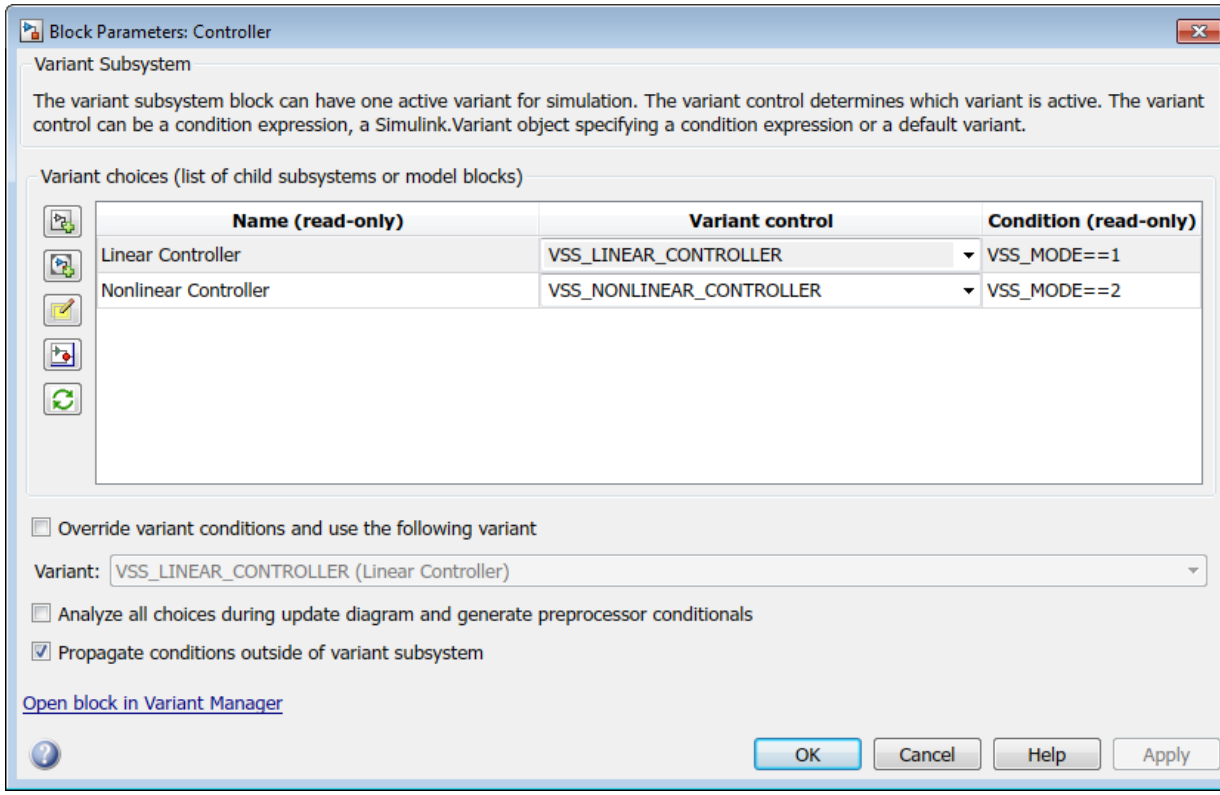
Consider this model containing a Variant Subsystem block with variant choices. A specific variant condition activates each block.



In the Variant Subsystem (`Controller`), `sensor1` and `sensor3` are used both in the Linear Controller and Nonlinear Controllers but `sensor2` is used only in the Linear Controller. Hence, the `sensor2` block is executed only when the Linear Controller choice is active and is not executed for any other choice. To ensure that the components outside of the Variant Subsystem (`Controller`) are aware of the active or inactive state of blocks with the Variant Subsystem, the block condition must propagate outside of the Variant Subsystem.

Propagate Conditions Without Generate Preprocessor Conditionals

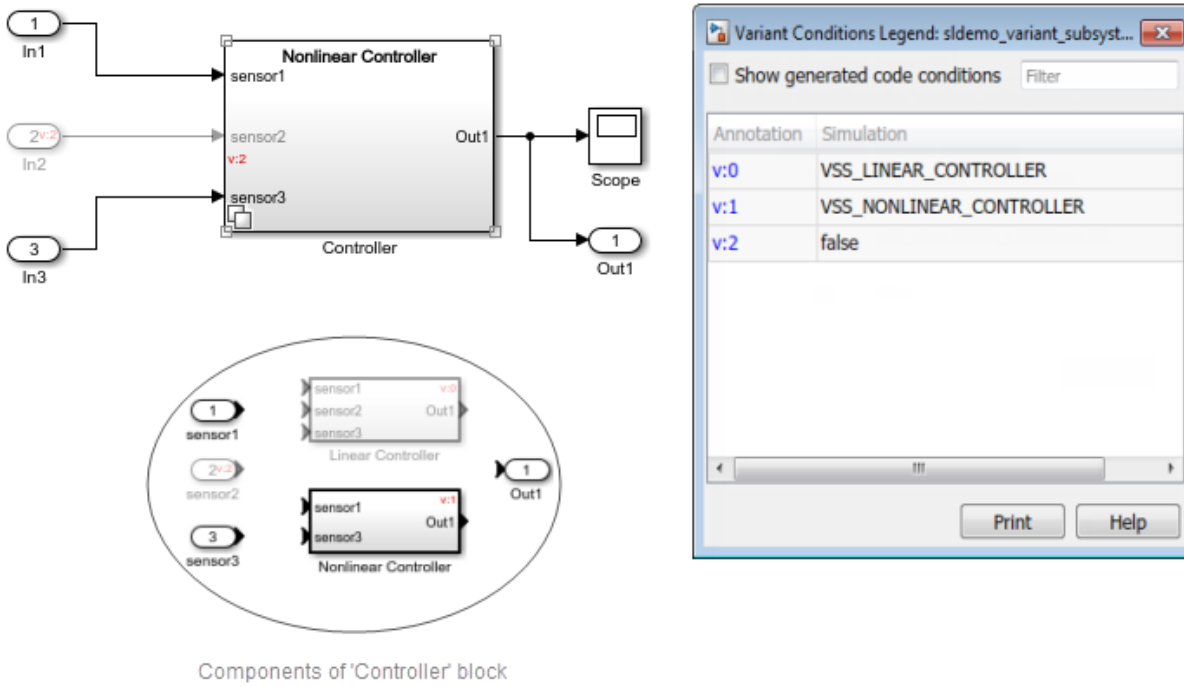
To propagate conditions outside of Variant Subsystems without generate preprocessor conditionals, select the **Propagate conditions outside of variant subsystem** check box in the **Block Parameter** dialog box of the Variant Subsystem block. By default, **Propagate conditions outside of variant subsystem** is not selected.



When you simulate the model with the active choice as Nonlinear Controller and the **Propagate condition outside of variant subsystem** selected, only the active choice is analyzed. Notice that the **Analyze all choices during update diagram and generate preprocessor conditional** check box is not selected.

The **Variant Condition Legend** displays the inactive conditions as `false`. Here, `sensor2` is inactive with variant choice as Nonlinear Controller and is marked as `false`.

The annotations are displayed on the `sensor2` port and the inactive block that is connected to `sensor2`.



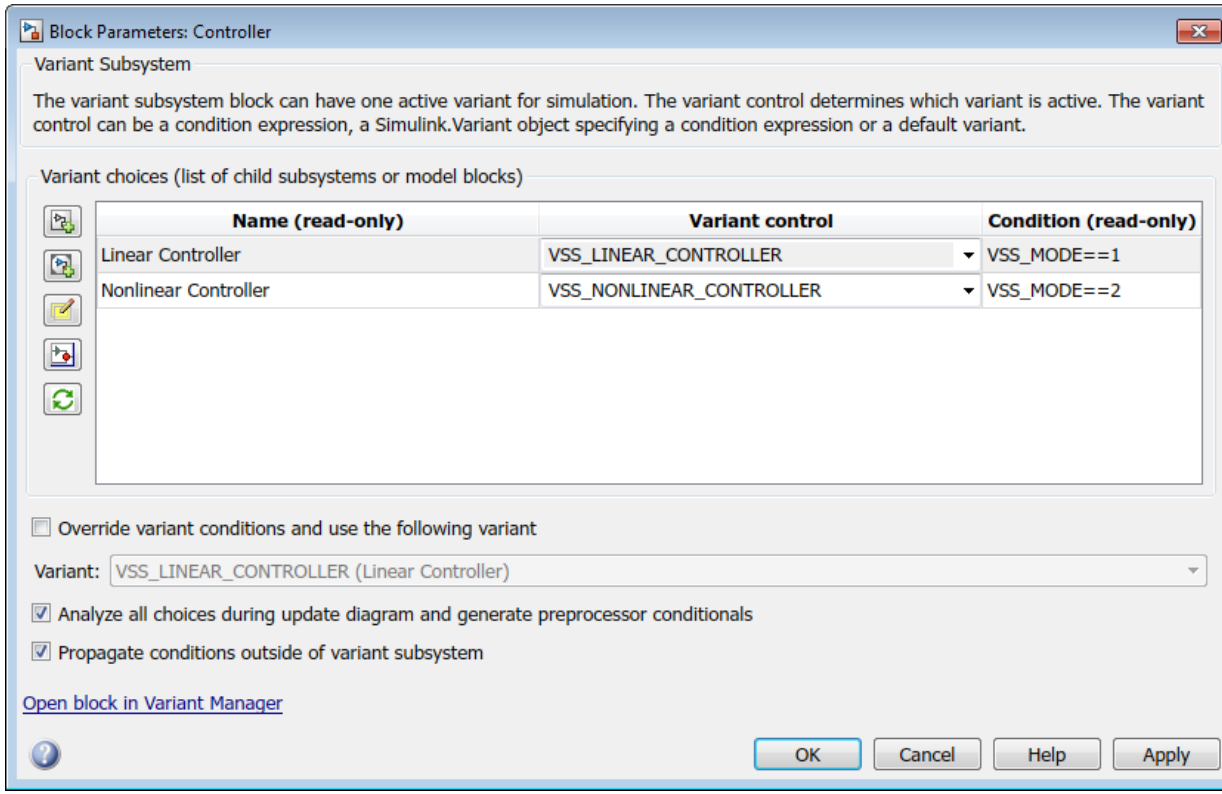
Components of 'Controller' block

When you generate code for condition propagation without generate preprocessor conditionals, the inactive blocks are ignored. In this example, the input port `In2` is not shown in the generated code.

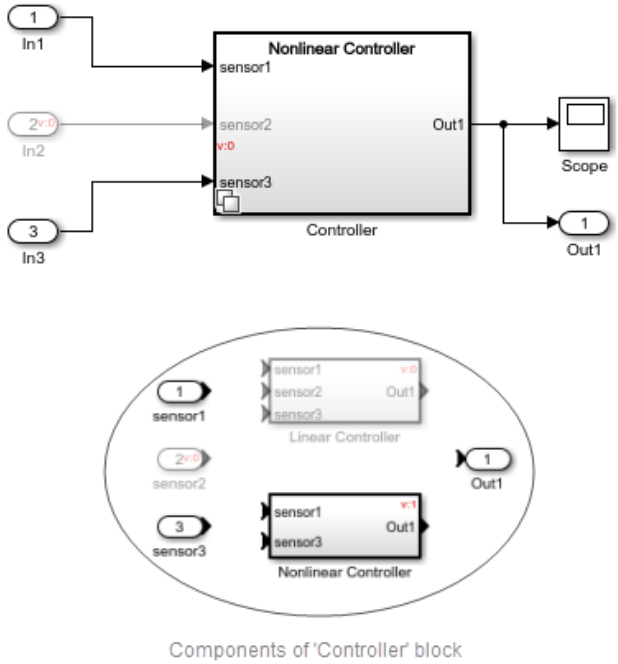
```
/* External inputs (root inport signals with auto storage) */
typedef struct {
  real_T In1;                          /* '<Root>/In1' */
  real_T In3;                          /* '<Root>/In3' */
} EXTU_variant_subsystem_propagate_T;
```

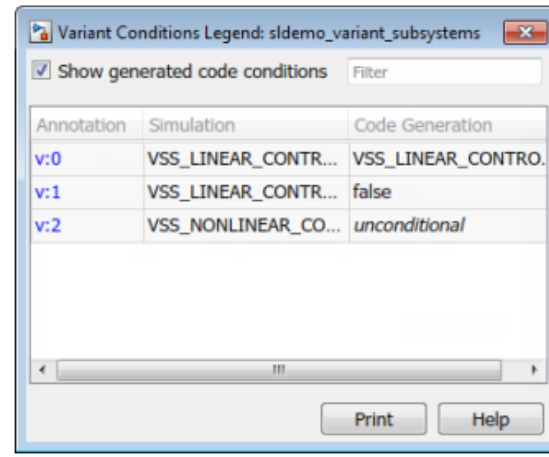
Propagate Conditions with Generate Preprocessor Conditionals

To propagate conditions outside of Variant Subsystem with generate preprocessor conditionals, select the **Propagate conditions outside of variant subsystem** check box and the **Analyze all choices during update diagram and generate preprocessor conditionals** check box in the **Block Parameter** dialog box of the Variant Subsystem.



When you simulate the model with active choice as Nonlinear Controller and **Propagate conditions outside of variant subsystem** check box and the **Analyze all choices during update diagram and generate preprocessor conditionals** check box selected, all the variant choices are analyzed. The **Variant Condition Legend** displays the variant conditions associated with the model.





When you generate code for condition propagation with generate preprocessor conditionals, the model is analyzed for all the choices. In this example, the input port `In2` is guarded with necessary conditions.

```
/* External inputs (root inport signals with auto storage) */
typedef struct {
  real_T In1;                          /* '<Root>/In1' */

#if VSS_LINEAR_CONTROLLER

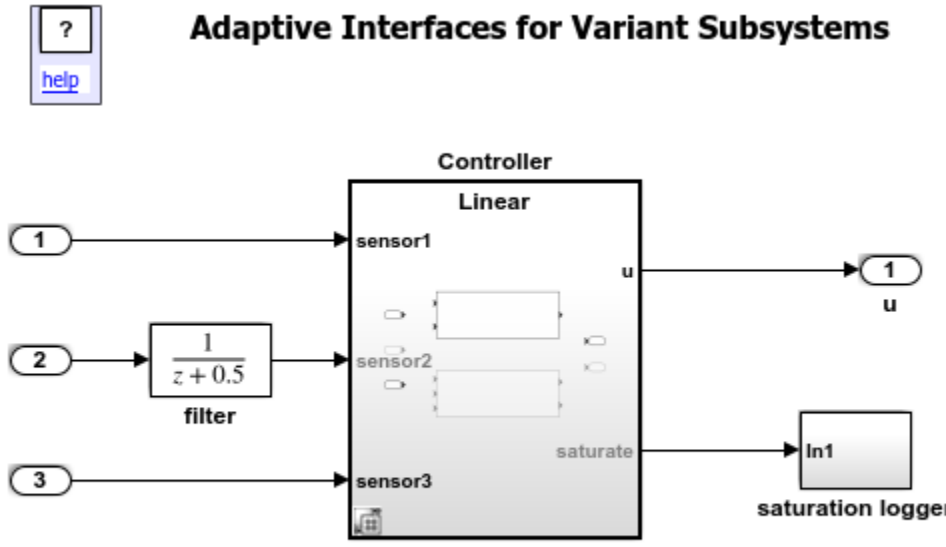
  real_T In2;                          /* '<Root>/In2' */

#define   EXTU_VARIANT_SUBSYSTEM_PROPAGATE_T_VARIANT_EXISTS
#endif                                 /* VSS_LINEAR_CONTROLLER */

  real_T In3;                          /* '<Root>/In3' */
} EXTU_variant_subsystem_propagate_T;
```

Adaptive Interface for Variant Subsystems

When you select the **Propagate conditions outside of variant subsystem** check box in the **Block Parameters** dialog box, the Variant Subsystem adapts its interface to the connected blocks. Consider this model.



The Controller block is a Variant Subsystem that provides a `Linear` and a `Nonlinear` choice. The `Linear` choice is active when `V = 1`, and the `Nonlinear` choice is active when `V = 2`. Here, `V` is a variant control variable of the `Simulink.Parameter` type. Select the Controller block and, in Simulink click **Diagram > Block Parameters** (Subsystem). Verify that the **Propagate condition outside of variant subsystem** check box is selected.

To change the value of the variant control variable, in the MATLAB command window, type `V.Value = 1` or `V.Value = 2`.

Double-click the Controller block to view its contents. The `Linear` choice is using `sensor1` and `sensor3` inputs of the Controller (Variant Subsystem block). It is not using `sensor2` and, therefore, does not produce a `saturate` output.

When you simulate this model, the Variant Subsystem block adapts its interface such that the condition `V = 2` (`v:1 V=2`) propagates the `In2`, the `filter`, and the `saturation logger` blocks.

Known Limitations

- Propagated variant conditions from variant subsystems cannot be set on blocks in Simscape domain or Stateflow based blocks.
- C++ code generation is not supported for models that contain propagated conditions outside of a Variant Subsystem.
- The propagated conditions to a Variant Subsystem choice block must be a subset of the variant condition on the variant subsystem block itself.

Propagate Conditions Programmatically

To propagate conditions outside of Variant Subsystem programmatically, use one of these syntaxes:

- Propagate conditions without generate preprocessor conditionals:

  ```
  set_param(VariantSubsystemName, 'PropagateVariantConditions','on')
  ```

  For example,

  ```
  set_param('sldemo_variant_subsystems/Controller','PropagateVariantConditions','on')
  ```

- Propagate conditions with generate preprocessor conditionals:

  ```
  set_param(VariantSubsystemName,'PropagateVariantConditions',...
  'on','GeneratePreprocessorConditionals','on')
  ```

  For example,

  ```
  set_param('sldemo_variant_subsystems/Controller','PropagateVariantConditions','on',...
  'GeneratePreprocessorConditionals','on')
  ```

Use Subsystem Variants To Generate Code That Uses C Preprocessor Conditionals

This example shows how to use Simulink® variant subsystems to generate C preprocessor conditionals that control which child subsystem of the variant subsystem is active in the generated code produced by the Simulink® Coder™.

Overview of Variant Subsystems

A Variant Subsystem block contains two or more child subsystems where one child is active during model execution. The active child subsystem is referred to as the *active variant*. You can programmatically switch the active variant of the Variant Subsystem block by changing values of variables in the base workspace, or by manually overriding variant selection using the Variant Subsystem block dialog. The *active variant* is programmatically wired to the Inport and Outport blocks of the Variant Subsystem by Simulink® during model compilation.

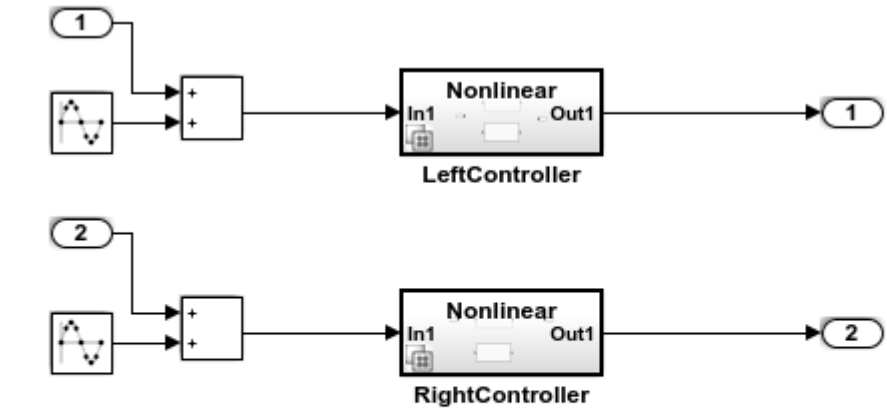
To programmatically control variant selection, a `Simulink.Variant` object is associated with each child subsystem in the Variant Subsystem block dialog. `Simulink.Variant` objects are created in the MATLAB® base workspace. These objects have a property named `Condition`, an expression, which evaluates to a Boolean value and is used to determine the active variant child subsystem.

When you generate code, you can only generate code for the active variant. You can also generate code for all variants of a Variant Subsystem block and defer the choice of active variant until it is time to compile the generated code.

Specifying Variants for a Subsystem Block

Opening the example model `rtwdemo_preprocessor_subsys` will run the **PostLoadFcn** defined in the "File: ModelProperties: Callbacks" dialog. This will populate the base workspace with the variables for the Variant Subsystem blocks.

```
open_system('rtwdemo_preprocessor_subsys')
```

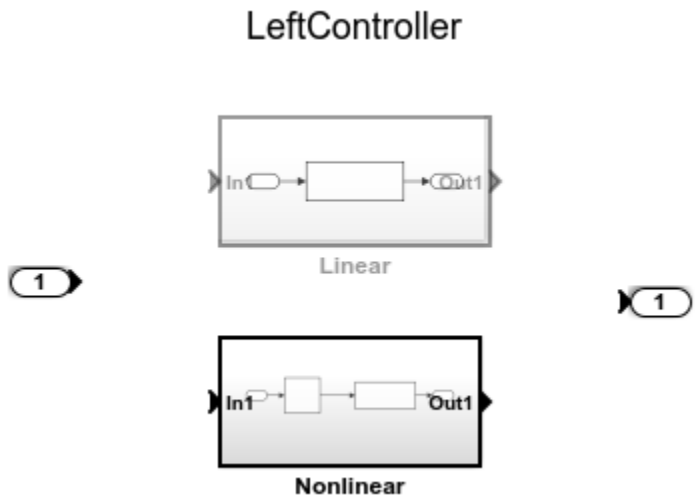


This model shows the generation of preprocessor conditionals for variant subsystems.

The LeftController variant subsystem contains two child subsystems: Linear and Nonlinear. The LeftController/Linear child subsystem executes when the Simulink.Variant object LINEAR evaluates to `true`, and the LeftController/Nonlinear child subsystem executes when the Simulink.Variant object NONLINEAR evaluates to `true`.

Simulink.Variant objects are specified for the LeftController subsystem by right-clicking the LeftController subsystem and selecting `Subsystem Parameters`, which will open the LeftController subsystem block dialog.

```
open_system('rtwdemo_preprocessor_subsys/LeftController');
```



The LeftController subsystem block dialog creates an association between the Linear and Nonlinear subsystems with the two Simulink.Variant objects, `LINEAR` and `NONLINEAR`, that exist in the base workspace. These objects have a property named `Condition`, an expression, which evaluates to a Boolean value and determines the active variant child subsystem (Linear or Nonlinear). The condition is also shown in the subsystem block dialog. In this example, the conditions of `LINEAR` and `NONLINEAR` are 'VSSMODE == 0' and 'VSSMODE == 1', respectively.

In this example, the Simulink.Variant objects are created in the base workspace.

```
LINEAR = Simulink.Variant;
LINEAR.Condition = 'VSSMODE==0';
NONLINEAR = Simulink.Variant;
NONLINEAR.Condition = 'VSSMODE==1';
```

Specifying a Variant Control Variable

Variant objects allow you to reuse arbitrarily complex conditions throughout a model. Multiple Variant Subsystem blocks can use the same Simulink.Variant objects, allowing you to toggle the activation of subsystem variants as a set. You can toggle the set prior to simulation by changing the value of `VSSMODE` in the MATLAB environment or when compiling the generated code, as explained in the next section. In this example,

LeftController and RightController reference the same variant objects, so that you can toggle them simultaneously.

The nonlinear controller subsystems implement hysteresis, while the linear controller subsystems act as simple low-pass filters. Open the subsystem for the left channel. The subsystems for the right channel are similar.

The generated code accesses the variant control variable `VSSMODE` as a user-defined macro. In this example, `rtwdemo_importedmacros.h` supplies `VSSMODE`. Within the MATLAB environment, you specify `VSSMODE` using a `Simulink.Parameter` object. Its value will be ignored when generating code including preprocessor conditionals. However, the value is used for simulation. The legacy header file specifies the value of the macro to be used when compiling the generated code, which ultimately activates one of the two specified variants in the embedded executable.

Variant control variables can be defined as `Simulink.Parameter` objects with one of these storage classes:

- `Define` or `ImportedDefine` with header file specified
- `CompilerFlag`
- `SystemConstant (AUTOSAR)`
- User-defined custom storage class that defines data as a macro in a specified header file

```
VSSMODE = Simulink.Parameter;
VSSMODE.Value = 1;
VSSMODE.DataType = 'int32';
VSSMODE.CoderInfo.StorageClass = 'Custom';
VSSMODE.CoderInfo.CustomStorageClass = 'ImportedDefine';
VSSMODE.CoderInfo.CustomAttributes.HeaderFile = 'rtwdemo_importedmacros.h';
```

Simulating the Model with Different Variants

Because you set the value of `VSSMODE` to 1, the model uses the nonlinear controllers during simulation.

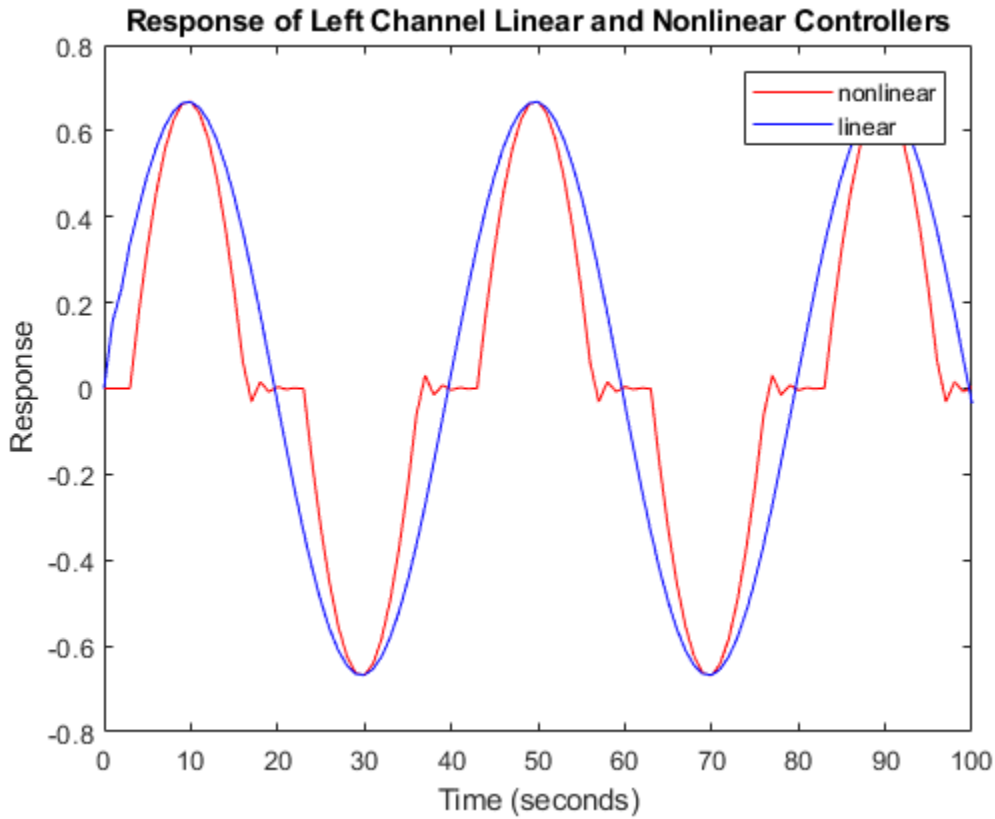
```
sim('rtwdemo_preprocessor_subsys')
youtnl = yout;
```

If you change the value of `VSSMODE` to 0, the model uses the linear controllers during simulation.

```
VSSMODE.Value = int32(0);
sim('rtwdemo_preprocessor_subsys')
youtl = yout;
```

You can plot and compare the response of the linear and nonlinear controllers:

```
figure('Tag','CloseMe');
plot(tout, youtnl.signals(1).values, 'r-', tout, youtl.signals(1).values, 'b-')
title('Response of Left Channel Linear and Nonlinear Controllers');
ylabel('Response');
xlabel('Time (seconds)');
legend('nonlinear','linear')
axis([0 100 -0.8 0.8]);
```



Using C Preprocessor Conditionals

This example model has been configured to generate C preprocessor conditionals. You can generate code for the model by selecting **Code > C/C++ Code > Build Model**.

To activate code generation of preprocessor conditionals, check whether the following conditions are true:

- Select an Embedded Coder® target in **Code Generation > System target file** in the Configuration Parameters dialog box
- In the Variant Subsystem block parameter dialog box, clear the option to **Override variant conditions and use following variant**
- In the Variant Subsystem block parameter dialog box, Select the option to **Analyze all choices during update diagram and generate preprocessor conditionals**.

The Simulink® Coder™ code generation report contains sections in the Code Variants report dedicated to the subsystems that have variants controlled by preprocessor conditionals.

In this example, the generated code includes references to the Simulink.Variant objects `LINEAR` and `NONLINEAR`, as well as the definitions of macros corresponding to those variants. Those definitions depend on the value of `VSSMODE`, which is supplied in an external header file `rtwdemo_importedmacros.h`. The active variant is determined by using preprocessor conditionals (#if) on the macros (#define) `LINEAR` and `NONLINEAR`.

The macros `LINEAR` and `NONLINEAR` are defined in the generated `rtwdemo_preprocessor_subsys_types.h`, header file:

```
#ifndef LINEAR
#define LINEAR      (VSSMODE == 0)
#endif

#ifndef NONLINEAR
#define NONLINEAR   (VSSMODE == 1)
#endif
```

In the generated code, the code related to the variants is guarded by C preprocessor conditionals. For example, in `rtwdemo_preprocessor_subsys.c`, the calls to the step and initialization functions of each variant are conditionally compiled:

```
/* Outputs for atomic SubSystem: '<Root>/LeftController' */
#if LINEAR
```

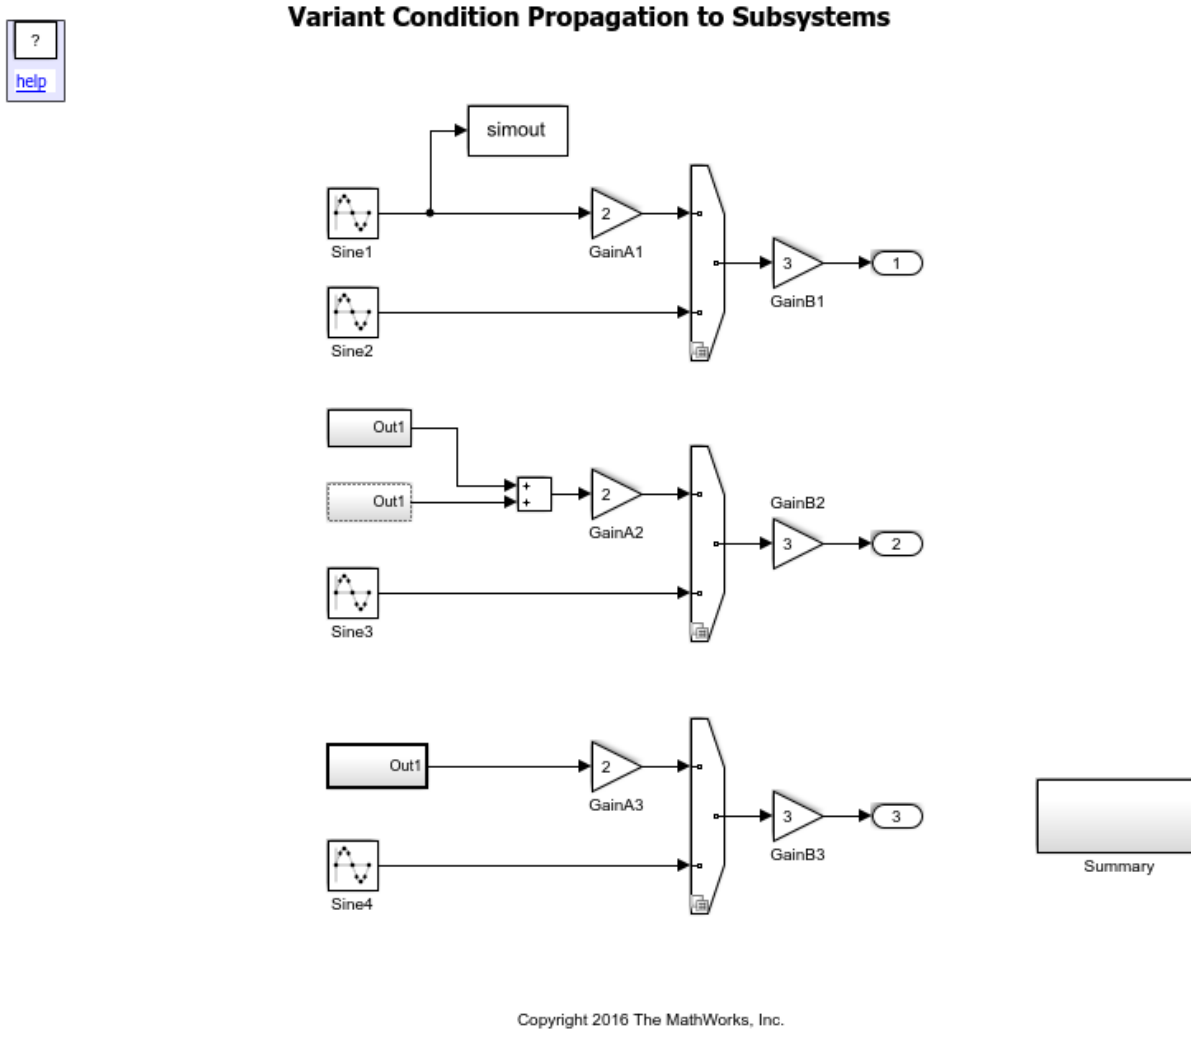
```
    /* Output and update for atomic system: '<S1>/Linear' */
#elif NONLINEAR
    /* Output and update for atomic system: '<S1>/Nonlinear' */
#endif
```

Close the model, figure, and workspace variables from the example.

```
bdclose('rtwdemo_preprocessor_subsys')
close(findobj(0,'Tag','CloseMe'));
clear LINEAR NONLINEAR VSSMODE
clear tout yout youtl youtnl
```

Propagating Variant Conditions to Subsystems

A Subsystem can be virtual or atomic. Simulink propagates variant conditions differently to such Subsystems. This example shows the propagation of variant conditions from Inline variants to Subsystem blocks. Consider a model as shown:



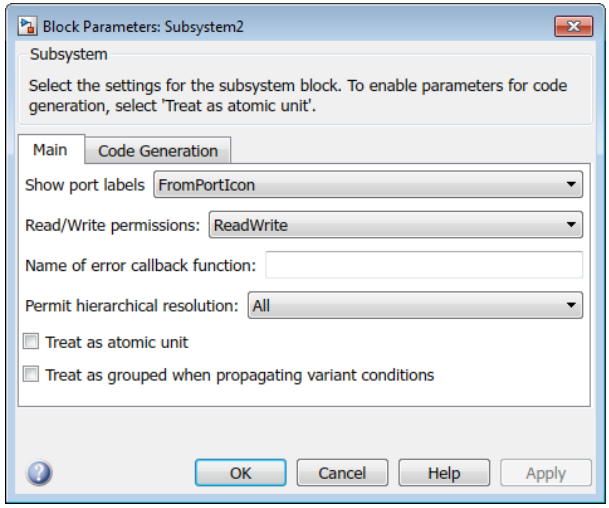
Click **Simulation** > **Run** to simulate this model and see the variant conditions being propagated from the Variant Source blocks to the blocks connected to it.

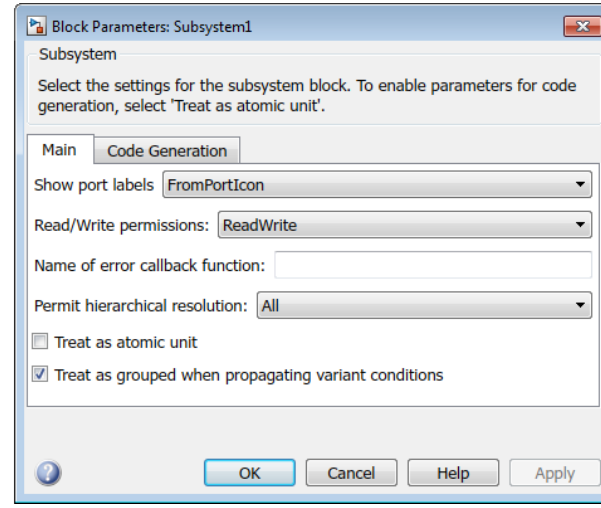
The variant condition annotation helps you visualize the propagated conditions. To be able to view the variant condition annotation, click **Display** > **Blocks** > **Variant Condition Legend**.

The model contains three Variant Source blocks: `Variant Source1` , `Variant Source2` , and `Variant Source3` , respectively.

`Variant Source1` contains conditions `V = 1` and `V = 2` at inport. The variant condition `V = 1` propagates to `GainA1` while `V = 2` propagates to `Sine2` . The `Sine1` block does not get any propagated variant conditions because it is connected to an unconditional block `To Workspace1` . If the `To Workspace block1` did not exist or was commented-out before simulating the model, variant condition `V = 1` propagates to `Sine1` .

`Variant Source2` is connected to virtual subsystems `Subsystem1` and `Subsystem2` that have identical contents, a `Sine Wave` block connected to a `To Workspace` and an `Output` blocks. `Subsystem1` is a grouped virtual subsystem (**Treat as grouped when propagating variant conditions** is selected) while Subsystem2 (**Treat as grouped when propagating variant conditions** is clear) is an ungrouped virtual subsystem.





A Subsystem block becomes a grouped virtual subsystem when you select the **Treat as grouped when propagating variant conditions** checkbox in the block parameters dialog box. When the **Treat as grouped when propagating variant conditions** checkbox is clear, the Subsystem is an ungrouped virtual subsystem.

A grouped subsystem represents a system of equation and hence the propagated conditions also apply to the blocks within this system. A grouped subsystem has a continuous boundary line. An ungrouped subsystem does not represent a system of equation and the blocks within it have ungrouped semantics. An ungrouped subsystem has a dotted boundary line and the conditions are propagated into the subsystem.

The variant condition `V = 1` propagates to `Subsystem1` and further to the blocks within it as `Subsystem1` is a grouped virtual subsystem (represents a system of equation).

`Subsystem2` that is an ungrouped virtual subsystem (does not represent a system of equation) also receives `V = 1` as the propagated condition, and the propagated variant condition `V = 1` propagates into `Subsystem 2` as if the subsystem were expanded.

`Variant Source3` is connected to a nonvirtual (atomic) subsystem with `V = 1` as the propagated variant condition. A nonvirtual (atomic) subsystem always represents a system of equations. An atomic subsystem has a continuous solid boundary line. The variant condition does not propagate inside of a nonvirtual subsystem. Instead, it stays on the boundary. The nonvirtual subsystem behaves as an entity.

Variant Subsystems

This model illustrates Simulink® variant subsystems. Variant subsystems let you provide multiple implementations for a subsystem where only one implementation is active during simulation. You can programmatically swap out the active implementation and replace it with one of the other implementations without modifying the model.

Overview of Variant Subsystems

A Variant Subsystem block contains two or more child subsystems where one child is active during model execution. The active child subsystem is referred to as the *active variant*. You can programmatically switch the active variant of the Variant Subsystem block by changing values of variables in the base workspace, or by manually overriding variant selection using the Variant Subsystem block dialog. The *active variant* is programmatically wired to the Inport and Outport blocks of the Variant Subsystem by Simulink during model compilation.

To programmatically control variant selection, a `Simulink.Variant` object is associated with each child subsystem in the Variant Subsystem block dialog. `Simulink.Variant` objects are created in the MATLAB® base workspace. These objects have a property named `Condition`, which is an expression, that evaluates to a boolean value and is used to determine the active variant child subsystem. For example, defining

```
VSS_LINEAR_CONTROLLER=Simulink.Variant('VSS_MODE==1');
```

in the base workspace creates a `Simulink.Variant` object where the constructor argument `('VSS_MODE==1')` defines when the variant is active. Using the Variant Subsystem dialog, you then associate `VSS_LINEAR_CONTROLLER` with one of the child subsystems within the Variant Subsystem. Defining

```
VSS_MODE=1
```

in the base workspace, activates the `VSS_LINEAR_CONTROLLER` variant. The condition argument can be a *simple expression* consisting of scalar variables, enumerations, equality, inequality, &&, , and ~. Parenthesis () can be used for precedence grouping.

Using Variant Subsystems

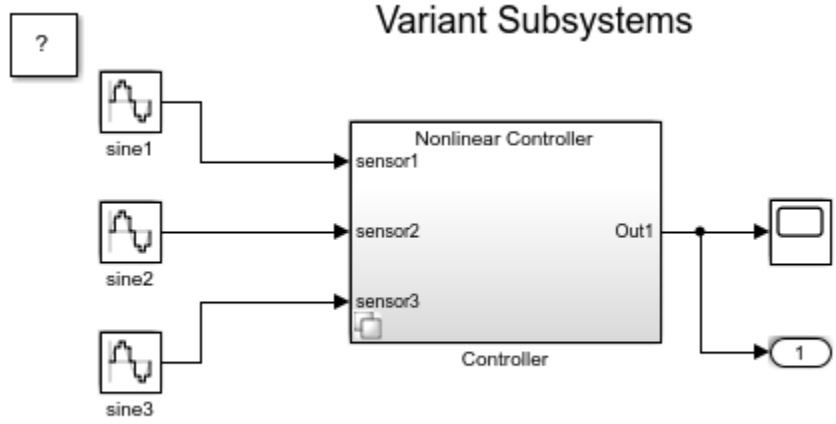
The model in this example uses the following variant objects and variant control variable, which are defined in the MATLAB base workspace:

```
VSS_LINEAR_CONTROLLER=Simulink.Variant('VSS_MODE==1');
```

```
VSS_NONLINEAR_CONTROLLER=Simulink.Variant('VSS_MODE==2');

VSS_MODE=2;
```

Opening the example model `sldemo_variant_subsystems` runs the **PreLoadFcn** defined in `File -> ModelProperties -> Callbacks`. This populates the base workspace with the variables for the Variant Subsystem block named Controller:



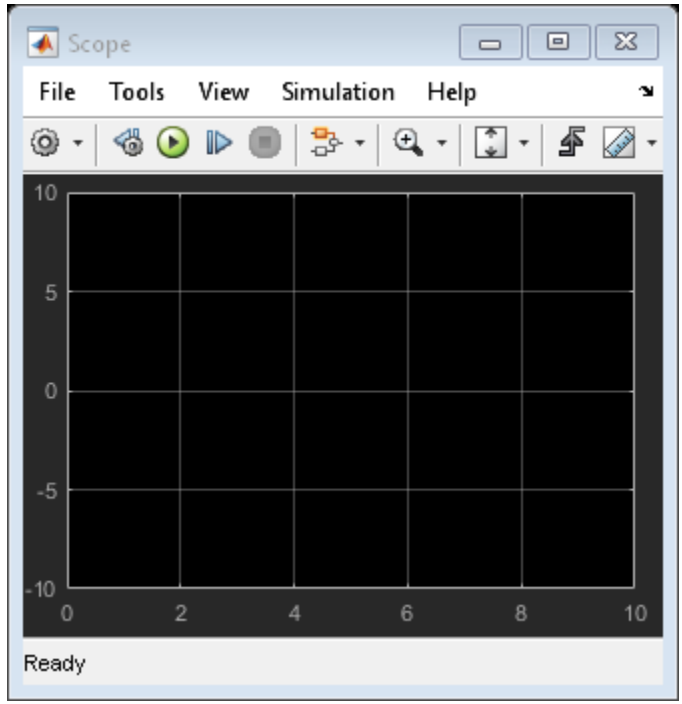


Figure 1: The example model, `sldemo_variant_subsystems`

To specify the `Simulink.Variant` objects association for the Controller subsystem, right-click on the Controller subsystem and select `Subsystem Parameters`, which will open the Controller subsystem block dialog.

The Controller subsystem block dialog specifies two potential variants. The two variants are in turn associated with the two `Simulink.Variant` objects `VSS_LINEAR_CONTROLLER` and `VSS_NONLINEAR_CONTROLLER`, which exist in the base workspace. These objects have a property named **Condition**, an expression that evaluates to a boolean and that determines which variant is active. The condition is also shown in the Variant Subsystem block dialog. In this example, the Condition properties of `VSS_LINEAR_CONTROLLER` and `VSS_NONLINEAR_CONTROLLER` are `VSS_MODE == 1` and `VSS_MODE == 2`, respectively. The variable `VSS_MODE` resides in the base workspace, and can be a standard MATLAB variable or a `Simulink.Parameter`.

If there is no associated variant object or a '%' (comment) character prefixes the variant object in the Variant Subsystem parameters dialog box, then the child subsystem is considered commented out and is not used during model execution.

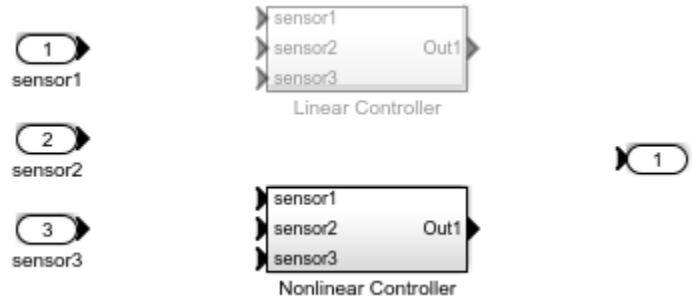

Figure 2: Contents of the Controller subsystem block

Within a Variant Subsystem block, you can place Inport, Outport, and Subsystem blocks. In this example, the `Linear Controller` Subsystem block is associated with the variant object, `VSS_LINEAR_CONTROLLER`, and the `Nonlinear Controller` Subsystem block is associated with the variant object, `VSS_NONLINEAR_CONTROLLER`.

Signal connections are not allowed in the Variant Subsystem. Simulink programmatically wires up the Inport and Outport blocks to the active variant when simulating the model.

Switching Active Variants

To simulate using the `Linear Controller` variant, define:

```
VSS_MODE=1
```

in the base workspace and then simulate the model.

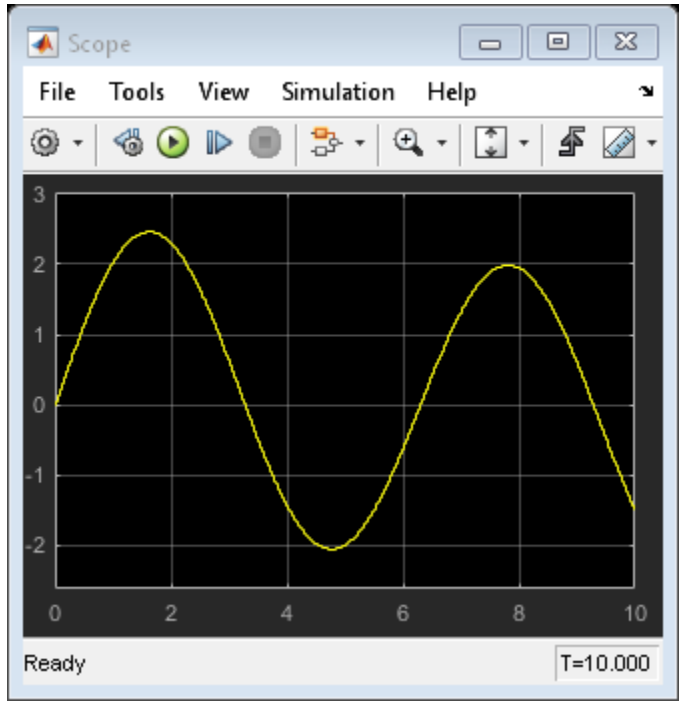

Figure 3: Simulation using the `Linear Controller` variant

To simulate using the `Nonlinear Controller`, define

```
VSS_MODE=2
```

in the base workspace and then simulate the model.

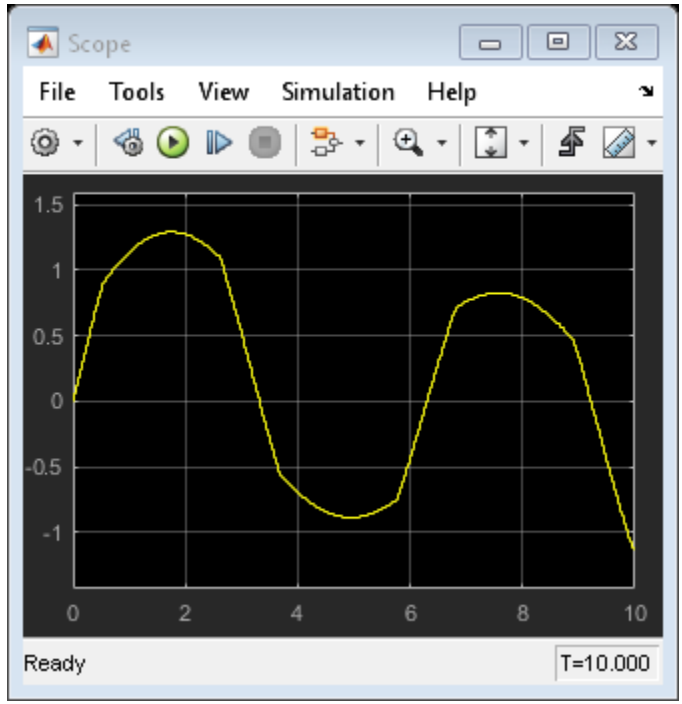

Figure 4: Simulation using the `Nonlinear Controller` variant

Enumerations and Reuse

The `sldemo_variant_subsystems_enum` model illustrates the following `Simulink.Variant` capabilities:

1. **Enumerations:** MATLAB enumeration classes can be used to improve readability in the conditions of the variant object.

2. **Reuse:** `Simulink.Variant` objects can be reused in different Variant Subsystem blocks.

This example uses the following variables which are defined in the MATLAB base workspace:

```
VSSE_LINEAR_CONTROLLER=Simulink.Variant( ...
'VSSE_MODE==sldemo_vss_CONTROLLER_TYPE.LINEAR')
```

```
VSSE_NONLINEAR_CONTROLLER=Simulink.Variant( ...
'VSSE_MODE==sldemo_vss_CONTROLLER_TYPE.NONLINEAR')

VSSE_MODE=sldemo_vss_CONTROLLER_TYPE.LINEAR

VSSE_PROTOTYPE=Simulink.Variant( ...
'VSSE_MODE_BUILD==sldemo_vss_BUILD_TYPE.PROTOTYPE')

VSSE_PRODUCTION=Simulink.Variant( ...
'VSSE_MODE_BUILD==sldemo_vss_BUILD_TYPE.PRODUCTION')

VSSE_MODE_BUILD=sldemo_vss_BUILD_TYPE.PRODUCTION
```

In these `Simulink.Variant` objects, we use the enumeration classes, sldemo_vss_BUILD_TYPE.m, and sldemo_vss_CONTROLLER_TYPE.m to define the `Simulink.Variant` **Condition** parameters which improves readability.

The three filter Variant Subsystems blocks, Filter1, Filter2, and Filter3 all use the `VSSE_PROTOTYPE` and `VSSE_PRODUCTION` `Simulink.Variant` objects.

Opening the example model `sldemo_variant_subsystems_enum` runs the **PreLoadFcn** defined in `File -> ModelProperties -> Callbacks`. This populates the base workspace with variables for the Variant Subsystem blocks:

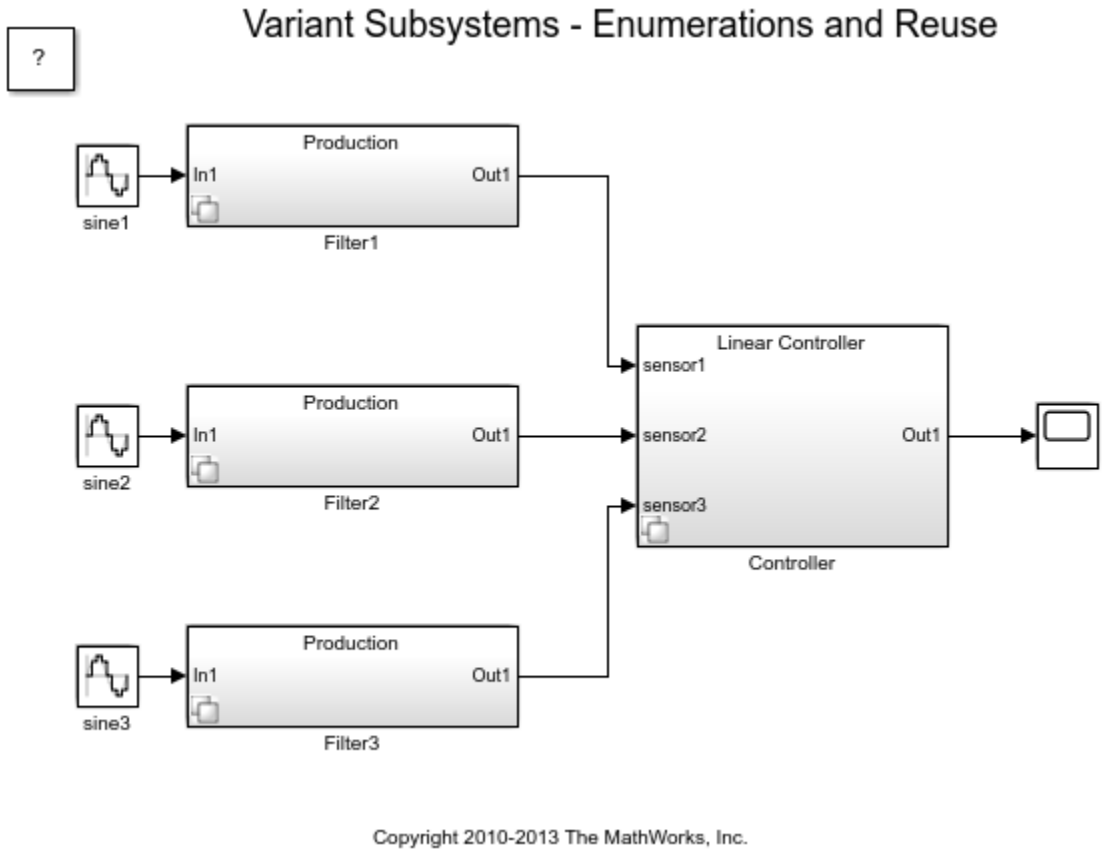

Figure 5: The example model, `sldemo_variant_subsystems_enum`

Code Generation

You can use the Simulink® Coder™ to generate code from a model containing Variant Subsystem blocks. By default the generated code contains only the active variant. Alternatively, you can generate code for all variants guarded by C preprocessor conditionals (`#if`, `#elif`, `#endif`) when using the Embedded Coder™.

To generate preprocessor conditionals, the types of blocks that you can place within the child subsystems of a Variant Subsystem block are limited. During the code generation process, one Merge block is placed at the input of each Outport block within the variant

subsystem and connected to the child subsystems within the variant subsystem. Thus, the restrictions placed on Merge blocks apply to the contents of Variant Subsystem blocks. The restriction checks are only performed when generating code. In addition, the child subsystems of the Variant Subsystem block must be Atomic subsystems, which are created by selecting the **Treat as atomic unit** parameter of the Subsystem parameters dialog box.

Code generation of preprocessor conditionals is active when

1. Embedded Coder target is selected on the Code Generation pane of the Configuration Parameters dialog box.
2. The **Override variant conditions and use following variant** is *not* selected on the Variant Subsystem block parameter dialog box.

When code generation of preprocessor conditionals is active, the generated code contains all child subsystems of the Variant Subsystem blocks protected by C preprocessor conditionals. In this case, the selection of the active variants is deferred until compile-time of the generated code. Only one variant object which is encoded in C macros, must evaluate to true (be active).

In addition, the variant control variables (such as `VSS_MODE` and `VSSE_MODE` above) must be `Simulink.Parameter` objects that specify how the `#define`'s for the variant control variables are managed in the generated code. For the `sldemo_variant_subsystems`, you can clear the `VSS_MODE` double from the base workspace. Use `Model Explorer -> Simulink Root -> Base Workspace` to add a new `Simulink.Parameter` named `VSS_MODE`. Specify the parameter **Value** as `1` or `2`, the **Data Type** as `int32`, and **Storage class** as `ImportedDefine (Custom)` with **Custom attributes Header file** as `sldemo_variant_subsystems_vdef.h`. You should then create this header in the current working directory:

```
/* File: sldemo_variant_subsystems_vdef.h */
#ifndef SLDEMO_VARIANT_SUBSYSTEM_VDEF_H
#define SLDEMO_VARIANT_SUBSYSTEM_VDEF_H
#define VSS_MODE 1
#endif
```

See the Embedded Coder documentation for more information on code generation for variant subsystems.

Model Reference Variants

This example shows how to use model reference variants. A Model block is used to reference one Simulink® model from another Simulink model. A Variant Subsystem block can contain Model blocks as variants. A *variant* describes one of N possible modes a Variant Subsystem block can operate in. Each variant references a specific model with its associated model-specific arguments. Only one variant is active for simulation. You can switch the active variant by changing the values of variables in the base workspace, or by manually overriding variant selection using the Variant Subsystem block dialog.

For new models, use a Variant Subsystem block instead of a Model block to contain model variants, unless you need to use variants that are conditionally executed models (models with control ports). Support for using a Model block to contain model variants will be removed in a future release.

Example Requirements

During this example, Simulink and Simulink® Coder™ may generate code in the code generation folder in the current working folder. If you do not want to (or cannot) generate files in this folder, you should change the working folder.

Overview of Model Variants

A Model block is used to reference one Simulink model (the *child model*) from another Simulink model (the *parent model*). A Variant Subsystem block can have Model blocks as variants. The variants comprise a set of models that have the potential to be referenced by the Variant Subsystem block. In this example, there are two models that are potentially referenced by the Variant Subsystem block named Controller.

Each *variant* is associated with a `Simulink.Variant` object. `Simulink.Variant` objects are created in the MATLAB® base workspace. For example:

```
V_LINEAR_CONTROLLER=Simulink.Variant('CTRL==1');
```

where the constructor argument `('CTRL==1')` defines the condition when the variant is active. In this case, defining:

```
CTRL=1
```

in the base workspace would activate the `V_LINEAR_CONTROLLER` variant. The condition argument can be a *simple expression* consisting of scalar variables, enumerations, equality, inequality, &&, , and ~. Parenthesis () can be used for precedence grouping.

For a given Variant Subsystem block, one variant is active during simulation. The *active variant* is determined by evaluating the variant object conditions in the MATLAB base workspace. Alternatively, you can instruct the Variant Subsystem block to use a specific variant by selecting the **Override variant conditions and use following variant** checkbox.

Specifying Variants

The model used in this example requires the following variables be defined in the MATLAB base workspace:

```
V_LINEAR_CONTROLLER=Simulink.Variant('CTRL==1');

V_NONLINEAR_CONTROLLER=Simulink.Variant('CTRL==2');

CTRL=2;
```

Opening the model `sldemo_mdlref_variants` runs the **PreLoadFcn** defined in `File -> ModelProperties -> Callbacks`. This callback populates the base workspace with the variables for the Variant Subsystem block named Controller:

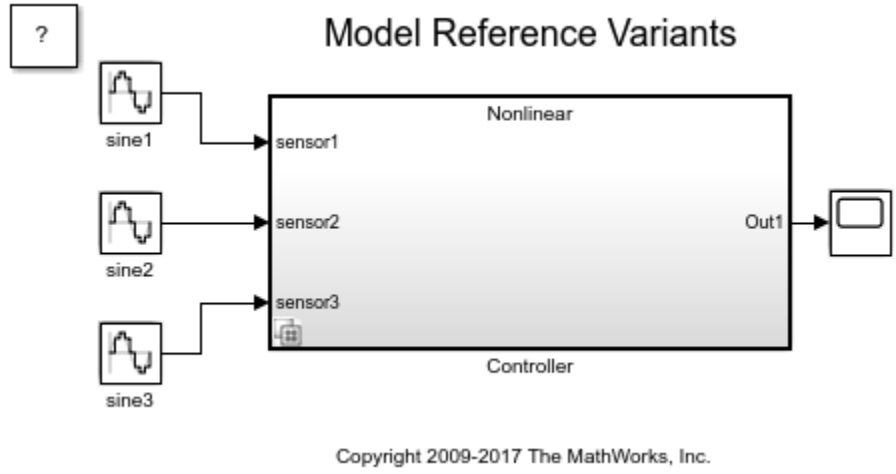

Figure 1: The top model, `sldemo_mdlref_variants`

Right-click the Variant Subsystem block Controller and select the menu item **Block Parameters (Subsystem)** to open the block dialog box.

The dialog box specifies two potential variants. The two variants are in turn associated with the two `Simulink.Variant` objects `V_LINEAR_CONTROLLER` and `V_NONLINEAR_CONTROLLER`, which exist in the base workspace. These objects have a property named **Condition**, an expression that evaluates to a boolean and that determines which variant is active. The **Condition** is also shown in the Variant Subsystem block dialog. In this example, the condition of `V_LINEAR_CONTROLLER` and `V_NONLINEAR_CONTROLLER` are `CTRL == 1` and `CTRL == 2`, respectively. The variable `CTRL` resides in the base workspace, and may be a standard MATLAB variable or a `Simulink.Parameter`.

Switching Active Variants

To simulate using the `sldemo_mrv_linear_controller`, define:

```
CTRL=1
```

in the base workspace and then simulate the model.

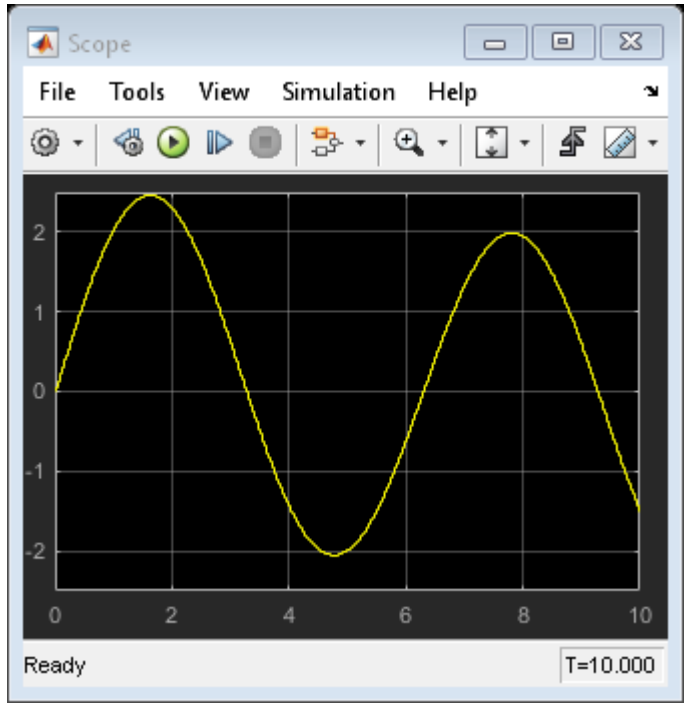

Figure 2: Simulation using the `sldemo_mrv_linear_controller` variant

To simulate using the `sldemo_nonlinear_controller`, define

```
CTRL=2
```

in the base workspace and then simulate the model.

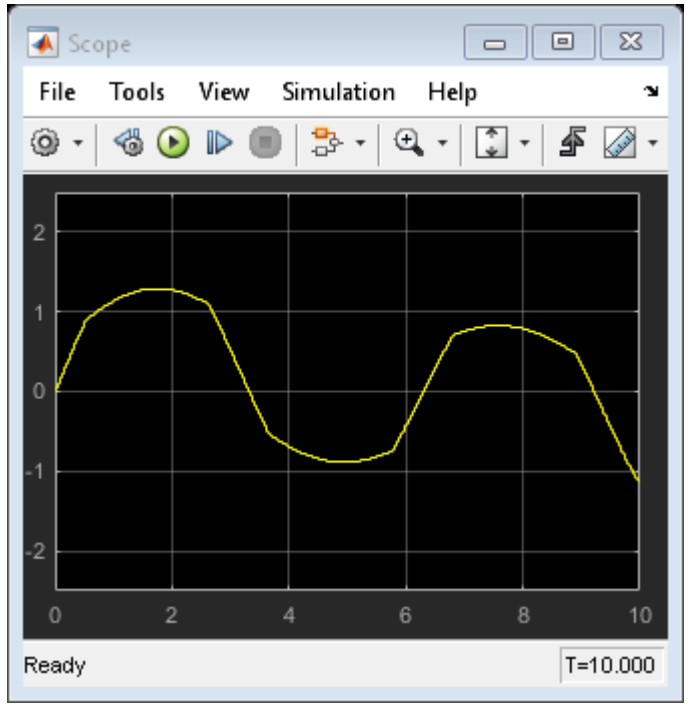

Figure 3: Simulation using the `sldemo_mrv_nonlinear_controller` variant

Enumerations and Reuse

The sldemo_mdlref_variants_enum model illustrates `Simulink.Variant` capabilities:

1. **Enumerations:** MATLAB enumeration classes can be used to improve readability in the conditions of the variant object.

2. **Reuse:** `Simulink.Variant` objects can be reused in different Variant Subsystem blocks.

This example requires the following variables be defined in the MATLAB base workspace:

```
VE_LINEAR_CONTROLLER=Simulink.Variant('E_CTRL==sldemo_mrv_CONTROLLER
_TYPE.LINEAR')

VE_NONLINEAR_CONTROLLER=Simulink.Variant('E_CTRL==sldemo_mrv_CONTROL
LER_TYPE.NONLINEAR')

E_CTRL=sldemo_mrv_CONTROLLER_TYPE.LINEAR

VE_PROTOTYPE=Simulink.Variant('E_CURRENT_BUILD==sldemo_mrv_BUILD_TYP
E.PROTOTYPE')

VE_PRODUCTION=Simulink.Variant('E_CURRENT_BUILD==sldemo_mrv_BUILD_TY
PE.PRODUCTION')

E_CURRENT_BUILD=sldemo_mrv_BUILD_TYPE.PRODUCTION
```

In these Simulink.Variant objects we use the enumeration classes sldemo_mrv_BUILD_TYPE.m and sldemo_mrv_CONTROLLER_TYPE.m within the `Simulink.Variant` **Condition** properties to improve readability.

The `VE_PROTOTYPE` and `VE_PRODUCTION` `Simulink.Variant` objects are reused across the three filter Variant Subsystem blocks, Filter1, Filter2, and Filter3.

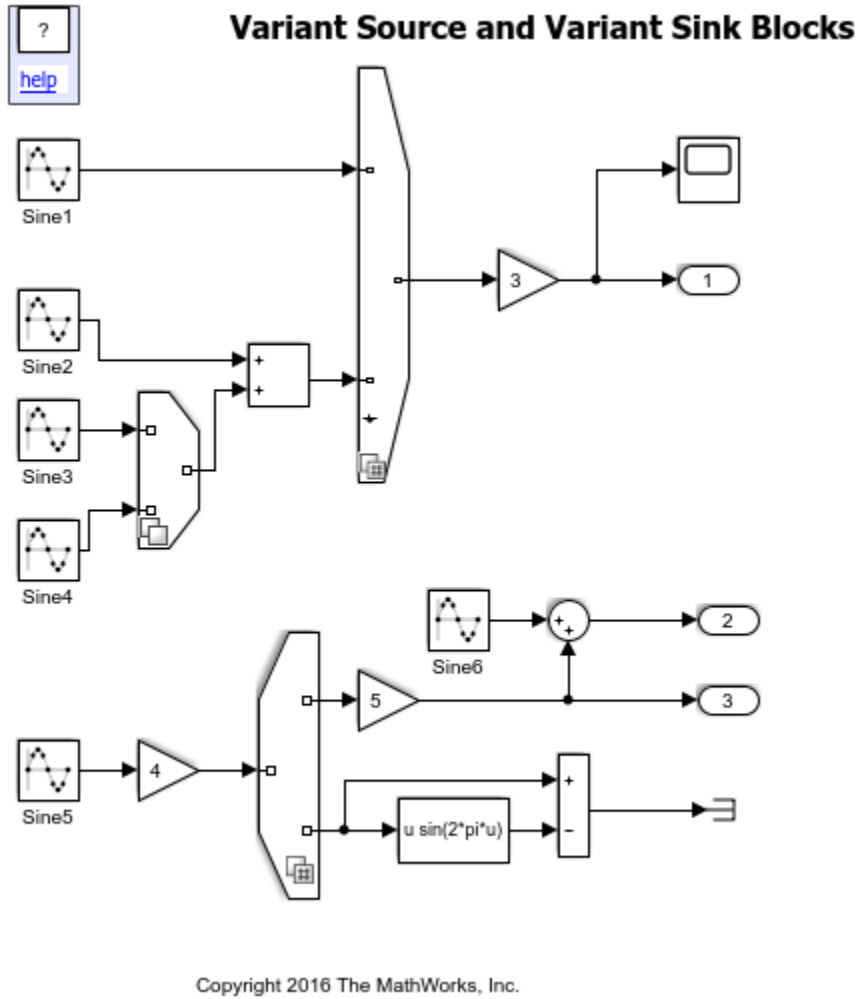
Opening the model `sldemo_mdlref_variants_enum` runs the **PreLoadFcn** defined in `File -> ModelProperties -> Callbacks`. This callback populates the base workspace with variables for the Variant Subsystem blocks, which are displayed in the MATLAB Command Window:

Variant Source and Variant Sink Blocks

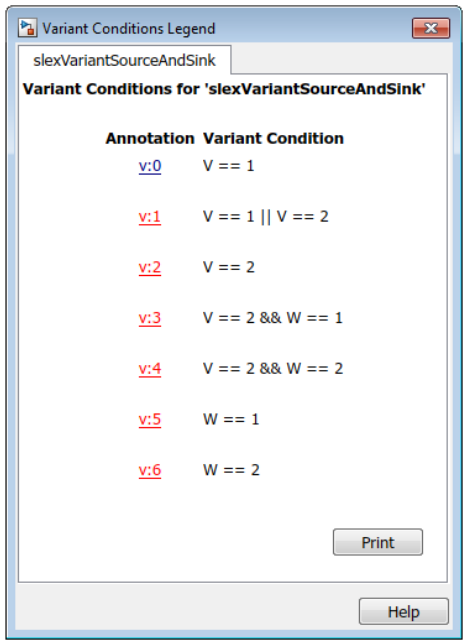
Define variant choice regions in the Variant Source and Sink blocks based on the block connectivity. The variant choice regions are computed by Simulink when you update diagram (**Simulation > Update Diagram**).

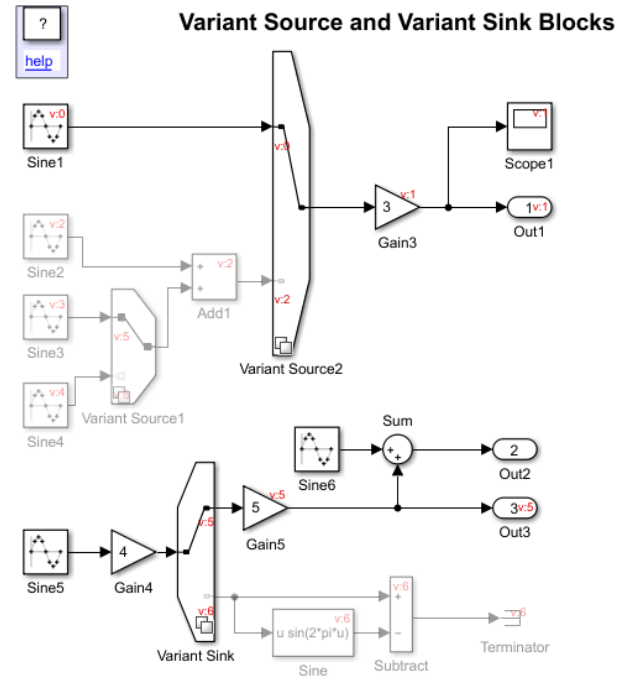
The process of computing the variant choice regions is called `variant condition propagation` . The Variant Source block provides variation on the source of a signal, and the Variant Sink blocks provides variation on the destination (sink) of a signal.

Consider a model containing two Variant Source blocks (`Variant Source1` , `Variant Source2`) and a Sink block (`Variant Sink`).



The variant conditions at the inports and outports of Variant Source and Sink blocks, respectively, determine the activation and deactivation of the blocks connected to them. To view the annotations and the variant conditions, click **Display > Blocks > Variant Conditions**.





Let's analyze the variant conditions and the block activation state.

- In `Variant Source1`, when `W==1`, the `Sine3` block is active, and when `W==2`, the `Sine4` block is active.
- In `Variant Source2`, when `V==1`, the Sine1 block is active, and when `V==2`, the `Add1` block is active.
- At `Add1` block the condition propagation continues making `Variant Source1` block to be active only when the `V==2`. This further propagates to `Sine3` block and `Sine4` block, making the `Sine3` block active at `V==2 && W==1` and the `Sine4` block active at `V==2 && W==2`, respectively.
- The `Gain3` block is active when either `V==1` or `V==2`, and hence the condition `V==2 || V==1`. The variant condition is further propagated to `Scope1` and `Out1`.
- The blocks connected to the outport of `Variant Sink` are active when `W==1` (`Gain5`), or `W==2` (`Sine`, `Subtract`, `Terminator`).

- The `Sum` block illustrates two key concepts in variant condition propagation: Signals are only variant if explicitly marked or when all paths can be proven to be variant. To make the `Sine6`, `Sum`, `Out2` variant, place a Single-Input Single-Output Variant Source before Out2 (or after the `Sine6`). Reading an inactive signal is equivalent to reading ground. When `W ~= 1`, then the bottom input to the `Sum` block is inactive and `Out2 = Sine6 + ground`.

If you select the **Analyze all choices during update diagram and generate preprocessor conditionals** parameter for the Variant Source and Variant Sink block, the generated code contains the code for the active and the inactive (`#if COND`). If this parameter is not selected, then code is generated only for the active choices.

If you select the **Allow zero active variant controls** parameter for the Variant Source and Variant Sink block, you can simulate the variant model without an active variant. In such cases, Simulink disables the blocks connected to the input and output stream of Variant Source and Variant Sink. These disabled blocks are ignored from update diagram or simulation.

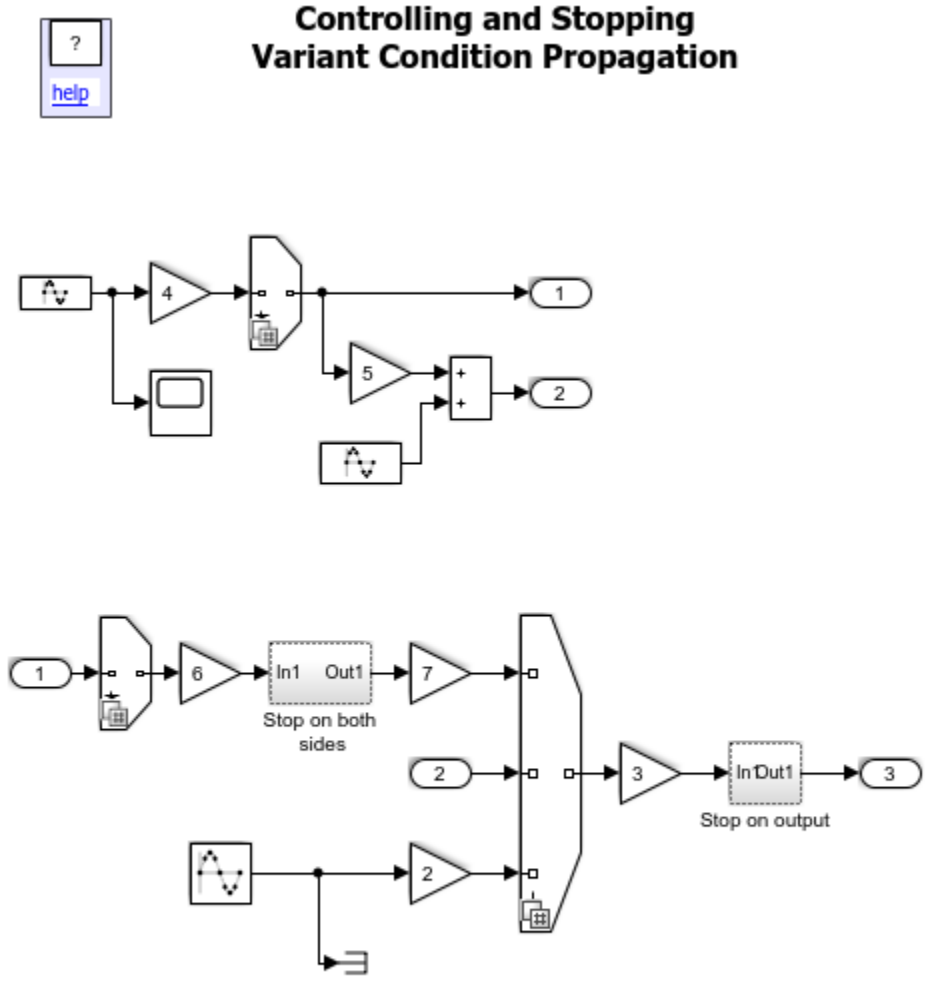
More About

- “Define and Configure Variant Sources and Sinks” on page 11-57

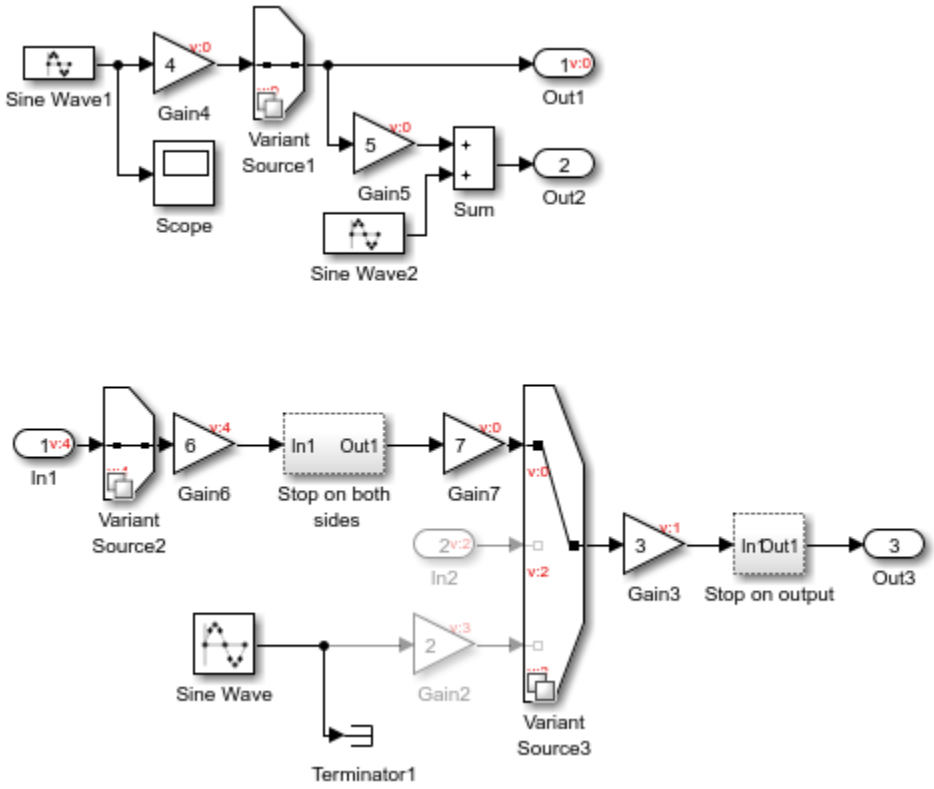
Control Variant Condition Propagation

During variant condition propagation, Simulink automatically assigns conditions to blocks. You can control how the variant condition propagates upstream and downstream in a model.

Consider this model.



In Simulink, click **Simulation** > **Run** to view the variant condition propagation to blocks.



The `Variant Source1` block has the `A==1` condition, which propagates backward and forward to the blocks connected to `Variant Source1` block. The variant condition propagates to `Gain4` block but does not propagate to the `Sine Wave1` block.

The `Scope` block is unconditional and receives its inputs from the `Sine Wave1` block. Therefore, the `Sine Wave1` block is unconditional. If you remove the `Scope` block, the variant condition propagates to the `Sine Wave1` block.

If you replace the `Scope` block with any other block (including the `Terminator` block), the `Sine Wave1` block remains unconditional.

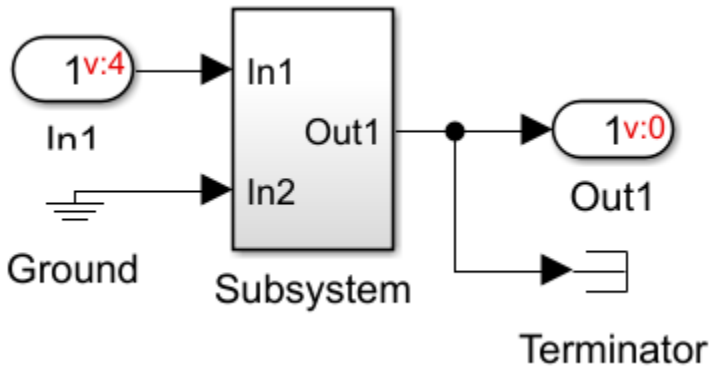
A block is unconditional if at least one of its inputs is unconditional. The input side of the `Sum` block is connected to `Gain5` (conditional) block and to the `Sine Wave2` (unconditional) block. Therefore, the `Sum` block is unconditional.

You can use these concepts to create a Subsystem block that controlls the propagation of variant conditions to both sides or to one side.

Stop Propagation of Variant Condition Upstream and Downstream

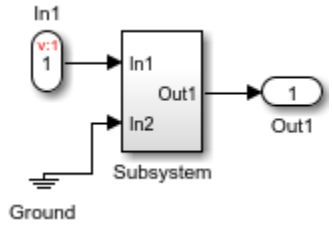
Consider the section of the model that is connected to the `Variant Source2` and `Variant Source3` blocks. When you simulate the model, the Variant condition from the `Variant Source2` block and the `Variant Source3` blocks propagates upstream and downstream.

The `Stop on both sides` block between `Gain6` and the `Gain7` block, prevents the Variant condition from propagating upstream or downstream. Double-click the `Stop on both sides` block to view its components.



The `Stop on both sides` block uses a `Terminator` to stop the variant condition propagation on upstream of the `Subsystem` block. To stop the condition propagation on the downstream side of the `Subsystem` block, one of the inports is connected to `Ground` (unconditional). Therefore, this arrangement stops the variant condition propagation upstream and downstream. Similarly, you can selectively stop the condition propagation of variant condition at upstream or downstream for a model. For example, if you remove the `Terminator` block, variant condition propagated upstream but is stopped downstream.

Stop Propagation of Variant Condition Downstream



Here, one input port of the Subsystem block is unconditional making the Subsystem block unconditional at input side and thus stopping the propagation of variant condition downstream.

More About

- “Define and Configure Variant Sources and Sinks” on page 11-57

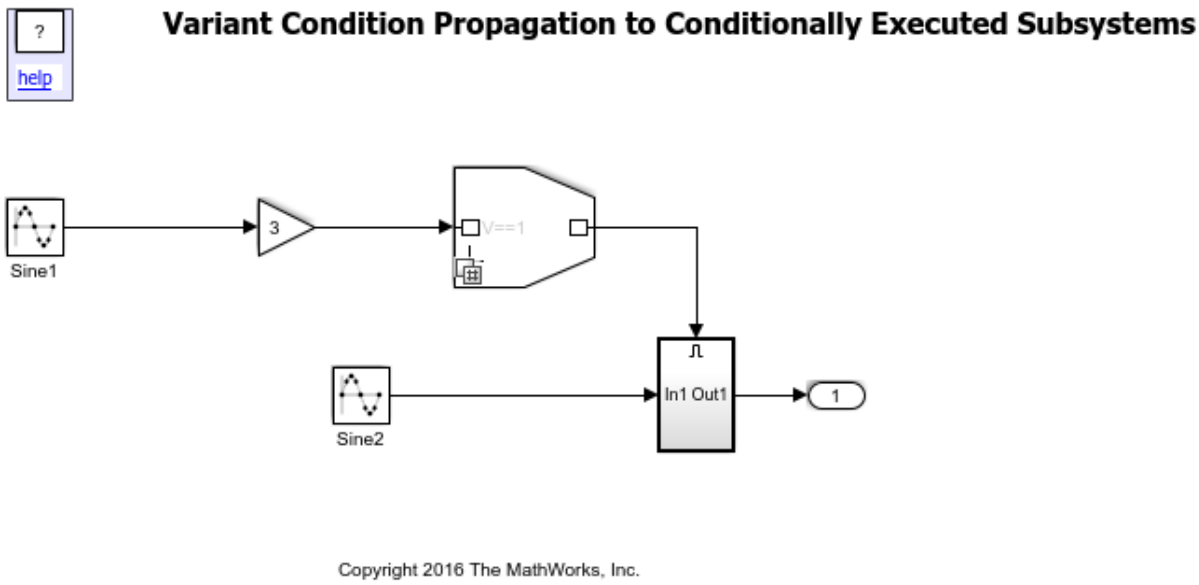
Propagate Variant Condition to Conditional Subsystem

A conditional subsystem (also known as a conditionally executed subsystem) is a type of subsystem where you can control the execution using an external signal.

Enabled, Triggered, and Function-Call Subsystems are examples of conditional subsystems. The signal that controls a conditional subsystem is called the *control signal* and the port from which the signal enters the block is called the *control port*. For more information on conditional subsystems, see “Conditional Subsystems” on page 10-3.

You can use a Variant block to control the execution of a conditional subsystem blocks.

Consider this model.



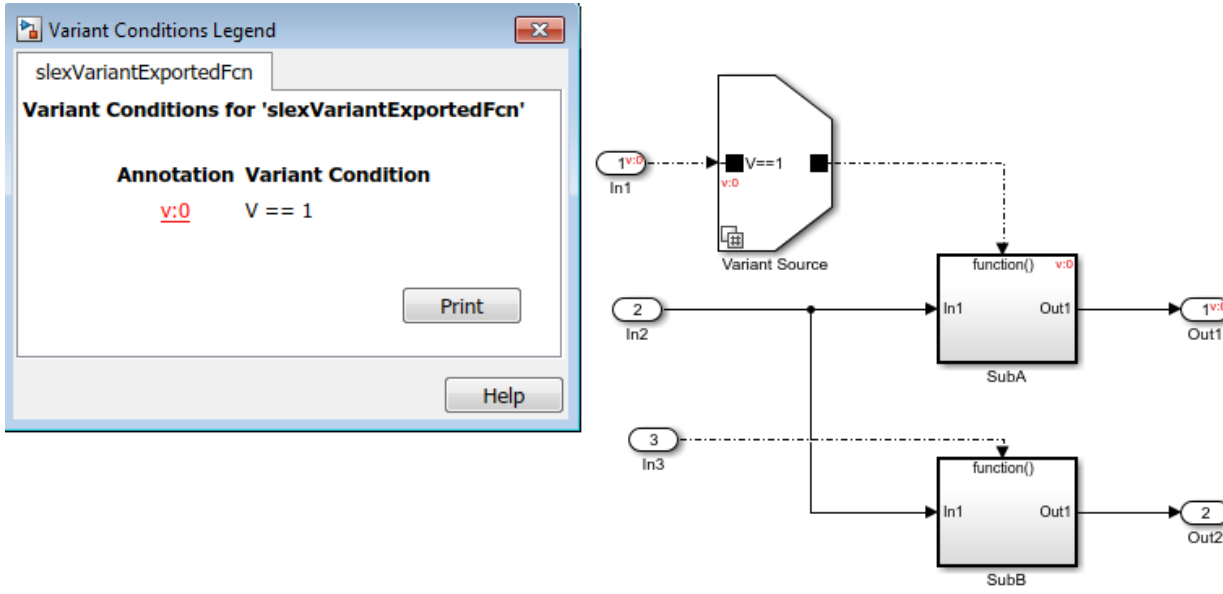
`Variant Source1` is a single-input/single-output Variant Source block with variant condition as `V==1`. When you simulate this model, the variant condition from the `Variant Source1` block propagates to the control port of the `Subsystem` block and then to the blocks connected to its inports and outports.

For example, when `V=1`, `Variant Source1` is active and the Variant condition propagates to the control port of the `Subsystem` block. Therefore, the `Subsystem` block is also active and the variant condition propagates to the blocks connected to the input and output ports of the `Subsystem` block.

Propagate Variant Condition to Function-Call Subsystem

A `Function-Call Subsystem` block is a subsystem that another block can invoke directly during simulation. The `Function-Call Subsystem` block is analogous to a function in procedural programming language. For more information, see "Using Function-Call Subsystems" on page 10-29.

You can use a single-input/single-output variant block to make the `Function-Call Subsystem` block conditional.



The `Variant Source` block has condition `V==1`, where `V` is a `Simulink.Parameter`.

When you simulate this model, the variant condition from the Variant Source block propagates to the control port of the `SubA` subsystem block and further propagates to the blocks connected to its inports and outports.

For example, when `V=1`, the `SubA` block is active and the variant condition propagates backward and forward to the blocks connected to the input (`In1`) and output (`Out1`) ports.

When `V~=1` (for example, `V=0`), `SubA` becomes inactive, making `Out1` to be inactive. `In2` remains active as it is connected to `SubB`, which is active.

If `In2` is not connected to `SubB`, `In2` becomes inactive when `V~=1`.

Note: If the `Function-Call Subsystem` is placed inside a virtual grouped subsystem, the variant condition triggering the `Function-Call Subsystem` must match the corresponding condition on the input of the higher level subsystem block.

- "Define and Configure Variant Sources and Sinks" on page 11-57

Exploring, Searching, and Browsing Models

Search and Edit Using Model Explorer

In this section...

What You Can Do Using the Model Explorer

Use the Model Explorer to view, modify, and add elements of Simulink models, Stateflow charts, and workspace variables. The Model Explorer lets you focus on specific elements (for example, blocks, signals, and properties) without navigating through the model or chart.

Use the Model Explorer to search for:

- Variables in workspaces and data dictionaries
- Variable usage in a model
- Instances of a type of block
- Block parameters and parameter values

You can combine search criteria and iteratively refine the results. Search in Model Explorer for model elements, starting with the node you select in the model hierarchy. You can search the entire model, in a particular system, or in a system and all the systems below it in the hierarchy. For details on the options, see "Search Bar Controls" on page 12-4.

For an example showing how to search for a parameter, see “Search Using Model Explorer” on page 12-52.

Using your search results, you can apply changes to multiple elements at once.

To manipulate model data (block parameters, signals, and states) in a searchable, sortable table, consider using the Model Data Editor. You can specify data attributes such as parameter values, signal names, and initial values for states. See “Configure Data Properties by Using the Model Data Editor” on page 59-141.

To create, modify, and view the entries in a data dictionary, use the Model Explorer. See “Edit and Manage Workspace Variables by Using Model Explorer” on page 59-111 and “View and Revert Changes to Dictionary Data” on page 63-27.

Open the Model Explorer and Edit Object Properties

To open the Model Explorer, use one of these approaches:

- From the Simulink Editor **View** menu, select **Model Explorer** or select the Model Explorer icon  from the toolbar.
- In an open model in the Simulink Editor, right-click a block and from the context menu, select **Explore**.
- In an open Stateflow chart, right-click in the drawing area and from the context menu, select **Explore**.
- At the MATLAB command line, enter `daexplr`.

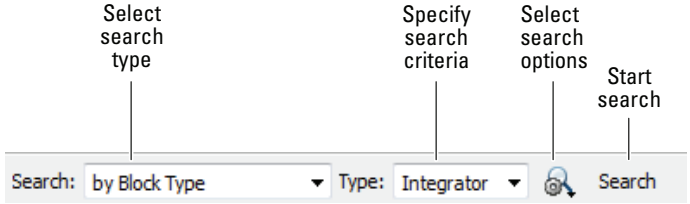
Use this workflow to view and edit object properties:

1. To specify whether to display only the current system or the whole system hierarchy, select the model in the **Model Hierarchy** pane.
2. Control the model information the **Contents** pane displays:
   - Control which property columns to display using the **View > Column View** option.
   - Control which types of objects to display using the **View > Row Filter** option.
   - Directly manipulate column headings
3. Identify model elements with specific values using the search bar.

4 Edit the values for model elements, in either the **Contents** pane or the **Dialog** pane. To edit workspace variables, you can use the Variable Editor.

Search Bar Controls

The search bar includes these controls:



Search Type

Use the **Search Type** control to specify the type of objects or properties to include in the search.

Search Type Option	Description
`by Name`	Searches a model or chart for all objects that have the specified string in the name of the object. See “Search Strings” on page 12-6.
`by Property Name`	Searches for objects that have a specified property. Specify the target property name from a list of properties that objects in the search domain can have.
`by Property Value`	Searches for objects with a property value that matches the value you specify. Specify the name of the property, the value to be matched, and the type of match (for example, equals, less than, or greater than). See “Search Strings” on page 12-6.
`by Block Type`	Searches for blocks of a specified block type. Select the target block type from the list of types contained in the currently selected model.
`by Stateflow Type`	Searches for Stateflow objects of a specified type.

Search Type Option	Description
`for Variable Usage`	Searches for blocks that use variables defined in a workspace. Select the base workspace or a model workspace (model name) and, optionally, the name of a variable. See “Search Strings” on page 12-6.
`for Referenced Variables`	Searches for variables that a model or block uses. Specify the name of the model or block in the **by System** field. The model or block must be in the **Model Hierarchy** pane.
`for Unused Variables`	Searches for variables that are defined in a workspace but not used by any model or block. Select the name of the workspace from the drop-down list for the **in Workspace** field.
`for Library Links`	Searches for library links in the current model.
`by Class`	Searches for Simulink objects of a specified class.
`for Fixed Point Capable`	Searches a model for all blocks that support fixed-point computations.
`for Model References`	Searches a model for references to other models.
`by Dialog Prompt`	Searches a model for all objects whose dialogs contain the prompt you specify. See “Search Strings” on page 12-6.
`by String`	Searches a model for all objects in which the string you specify occurs. See “Search Strings” on page 12-6.

Search Options

Use the **Search Options** control to specify the scope and how to apply search strings.

Search Option	Description
Match Whole String	Do not allow partial string matches (for example, do not allow `sub` to match `substring`).
Match Case	Considers case when matching strings (for example, `Gain` does not match `gain`).

Search Option	Description
Regular Expression	Considers a string to be matched as a regular expression.
Evaluate Property Values During Search	Applies only for searches by property value. If enabled, Model Explorer evaluates the value of each property as a MATLAB expression and compares the result to the search value. If this option is disabled (the default), the Model Explorer compares the unevaluated property value to the search value.
Refine Search	Initiates a secondary search that provides additional search criteria to refine the initial search results. The second search operation searches for objects that meet both the original and the new search criteria.

For an example showing how to search for a parameter, see “Search Using Model Explorer” on page 12-52.

Search Strings

By default, search strings are case-insensitive and are treated as regular expressions.

By default, the search allows partial string matches. You cannot use wildcard characters in search strings. For example, if you enter `*1` as a name search string, you get no search results unless there is an item whose name starts with the two characters `*1`. If there is an `out1` item, the search results do not include that item.

Model Explorer Components

By default, the Model Explorer opens with three panes (**Model Hierarchy**, **Contents**, and **Dialog**), a main toolbar, and a search bar.

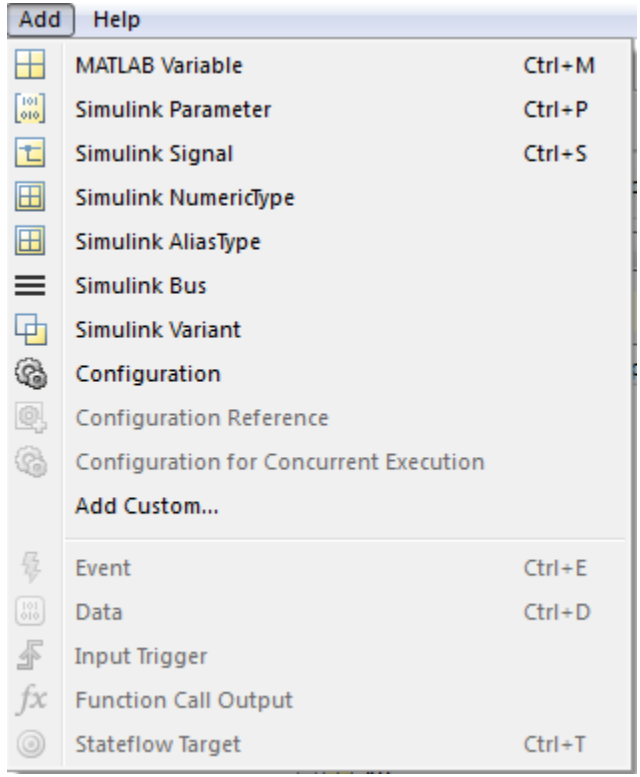
Component	Purpose	Documentation
Main toolbar	Execute Model Explorer commands	Most toolbar buttons perform actions that you can also perform using Model Explorer menu items, except to bring MATLAB to the front or open the Simulink Library Browser. If you have Simulink Requirements installed, you can use additional toolbar buttons relating to requirements links.
Search bar	Perform a search within the context of the selected node in **Model Hierarchy** pane.	"Search Bar Controls" on page 12-4
Model Hierarchy pane	Navigate and explore model, chart, and workspace nodes	"Model Explorer: Model Hierarchy Pane" on page 12-10
Contents pane	Display and modify model or chart objects	"Model Explorer: Contents Pane" on page 12-18
Dialog pane	View and change the details of object properties	"Model Explorer: Property Dialog Pane" on page 12-36

Add Objects to a Model, Chart, or Workspace

You can use the Model Explorer to add many kinds of objects to a model, chart, or workspace. The types of objects that you can add depend on the node you select in the **Model Hierarchy** pane. Use toolbar buttons or the **Add** menu to add objects. The **Add** menu lists the types of objects you can add.



Focus on Specific Elements of a Model or Chart

As you explore a model or chart, you might want to narrow the contents that you see in the Model Explorer to particular elements of a model or chart. You can use several different techniques. The table summarizes techniques for controlling the content the Model Explorer displays and how the contents appear.

Technique	When to Use	Documentation
Show partial or whole model hierarchy contents	To control how much of a hierarchical model to display	"Display Partial or Whole Model Hierarchy Contents" on page 12-12
Use the Row Filter option	To focus on, or hide, a specific kind of a model object, such as signals	"Use the Row Filter Option" on page 12-31

Technique	When to Use	Documentation
Search	To find objects that might not be currently displayed	"Search Using Model Explorer" on page 12-52
Filter contents	To focus on specific objects in the **Contents** pane, based on a search string	"Filtering Contents" on page 12-33

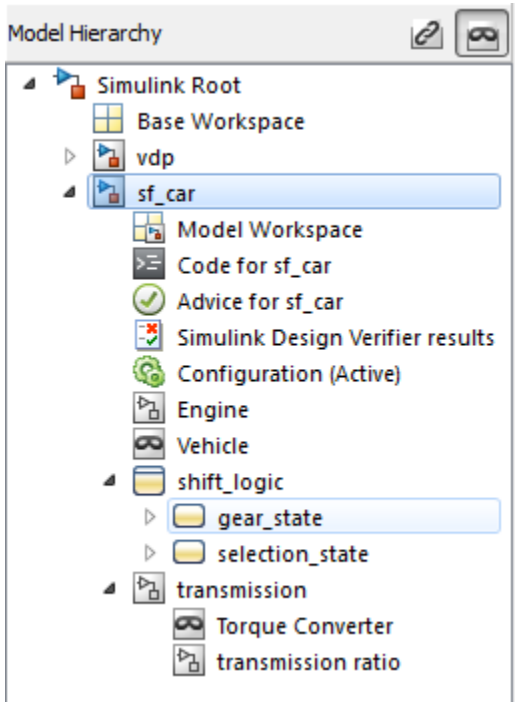
Once you have the general set of data that you are interested in, you can use the following techniques to organize the display of contents.

Technique	When to Use	Documentation
Sort	To quickly organize data for a property in ascending or descending order	"Sort Column Contents" on page 12-23
Group by property column	To logically group data based on values for a property	"How to Group by a Property Column" on page 12-25
Use column views	To display a named subset of property columns to apply to different kinds of nodes in the **Model Hierarchy** pane	"Customize Model Explorer Views" on page 12-38
Add, delete, or rearrange property table columns	To customize property columns	"Organize Data Display in Model Explorer" on page 12-23

Model Explorer: Model Hierarchy Pane

- “Cut, Copy, and Paste Objects Between Workspaces” on page 12-17

The **Model Hierarchy** pane displays a tree-structured view of the Simulink model and Stateflow chart hierarchy. Use the **Model Hierarchy** pane to navigate to the part of the model and chart hierarchy that you want to explore.



Select the object in the **Model Hierarchy** pane whose contents you want to display in the **Contents** pane.

Simulink Root

The first node in the hierarchy represents the Simulink root. Expand the root node to display nodes representing the MATLAB workspace, Simulink models, and Stateflow charts that are in the current session.

Base Workspace

This node represents the MATLAB workspace. The MATLAB workspace is the base workspace for Simulink models and Stateflow charts. Variables defined in this workspace are visible to all open models and charts.

For information about exporting and importing workspace variables, see “Export Workspace Variables” on page 59-120 and “Importing Workspace Variables” on page 59-122.

Work With Model Workspace Variables and Configuration Sets

Expanding a model or chart node in the **Model Hierarchy** pane displays nodes representing the following elements, as applicable for the models and charts you have open.

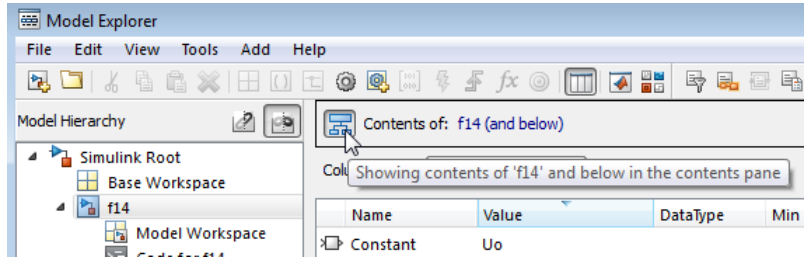
Node	Description
Model workspace	For information about how to use the Model Explorer to work with model workspace variables, see the following sections: • “Finding Variables That Are Used by a Model or Block” on page 59-111 • “Finding Blocks That Use a Specific Variable” on page 59-114 • “Editing Workspace Variables” on page 59-117 • “Export Workspace Variables” on page 59-120 • “Importing Workspace Variables” on page 59-122 • “Model Workspaces” on page 59-124
Configuration sets	For information about adding, deleting, saving, and moving configuration sets, see “Manage a Configuration Set” on page 13-11.
Top-level subsystems	Expand a node representing a subsystem to display underlying subsystems, if any.
Model blocks	Expand model blocks to show contents of referenced models (see “Expand and Edit Model References” on page 12-15).
Stateflow charts	• Expand a node representing a Stateflow chart to display the top-level states of the chart. • Expand a node representing a state to display its substates.

Display Partial or Whole Model Hierarchy Contents

By default, the Model Explorer displays objects for the system that you select in the **Model Hierarchy** pane. It does not display data for child systems. You can override that default, so that the Model Explorer displays objects for the whole hierarchy of the

currently selected system. To toggle between displaying only the current system and displaying the whole system hierarchy of the current system, use one of these techniques:

- Select **View > Show Current System and Below**.
- Click the **Show Current System and Below** button ( ) at the top of the **Contents** pane.



When you select the **Show Current System and Below** option:

- The **Model Hierarchy** pane highlights in pale blue the current system and its child systems.
- After the path in the **Contents of** field, the text `(and below)` appears.
- The appearance of the **Show Current System and Below** button at the top of the **Contents** pane and in the **View** menu changes.
- The status bar indicates the scope of the displayed objects when you hover over the **Show Current System and Below** button.

Loading very large models for the current system and below can be slow. To stop the loading process at any time, either click the **Show Current System and Below** button or click another node in the tree hierarchy.

If you show the current system and below, you might want to change the view to better reflect the displayed system contents. For details about views, see “Customize Model Explorer Views” on page 12-38.

The setting for the **Show Current System and Below** option is persistent across Simulink sessions.

Display Linked Library Subsystems and Masked Subsystems

By default, the Model Explorer does not display the contents of linked library subsystems or masked subsystems in the **Model Hierarchy** pane. To display the contents of linked library subsystems, use one of these approaches:

- At the top of the **Model Hierarchy** pane, click the **Show/Hide Library Links** button () or the **Show/Hide Masked Subsystems** button () .
- From the **View** menu, select **Show Library Links** or **Show Masked Subsystems**.

Library-linked subsystems and masked subsystems are visible in the **Contents** pane, regardless of how you configure the **Model Hierarchy** pane.

Note Search does not find elements in linked library or masked subsystems that are not displayed in the **Model Hierarchy** pane.

For subsystems that are both library-linked and masked, how you set the linked library subsystems and masked subsystems options affects which subsystems appear in the **Model Hierarchy** pane, as described in the following table.

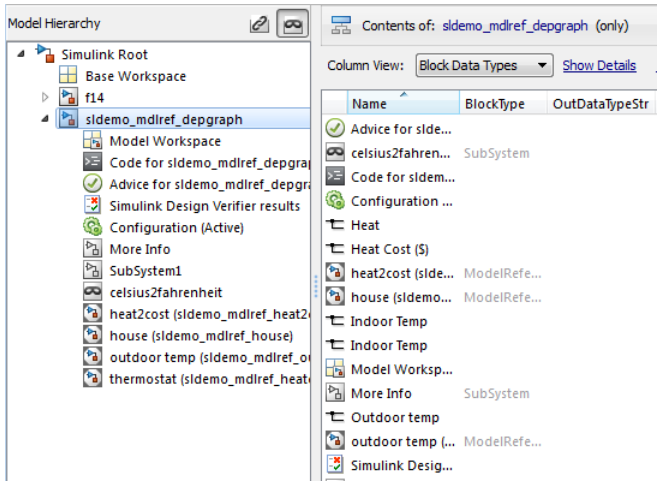
Settings	Subsystems Displayed in the Model Hierarchy Pane
Show Library Links **Hide Masked Subsystems**	Only library-linked, unmasked subsystems
Hide Library Links **Show Masked Subsystems**	Only masked subsystems that are not library-linked subsystems
Show Library Links **Show Masked Subsystems**	All library-linked or masked subsystems

Navigating to the Block Diagram

To open a graphical object (for example, a model, subsystem, or chart) in an editor window, right-click the object in the **Model Hierarchy** pane. From the context menu, select **Open**.

Expand and Edit Model References

To browse a model that includes Model blocks, you can expand the **Model Hierarchy** pane nodes of the Model blocks. For example, the `sldemo_mdlref_depgraph` model includes Model blocks that reference other models. If you open the `sldemo_mdlref_depgraph` model and expand that model node in the **Model Hierarchy** pane, you see that the model contains several Model blocks, including `heat2cost`.

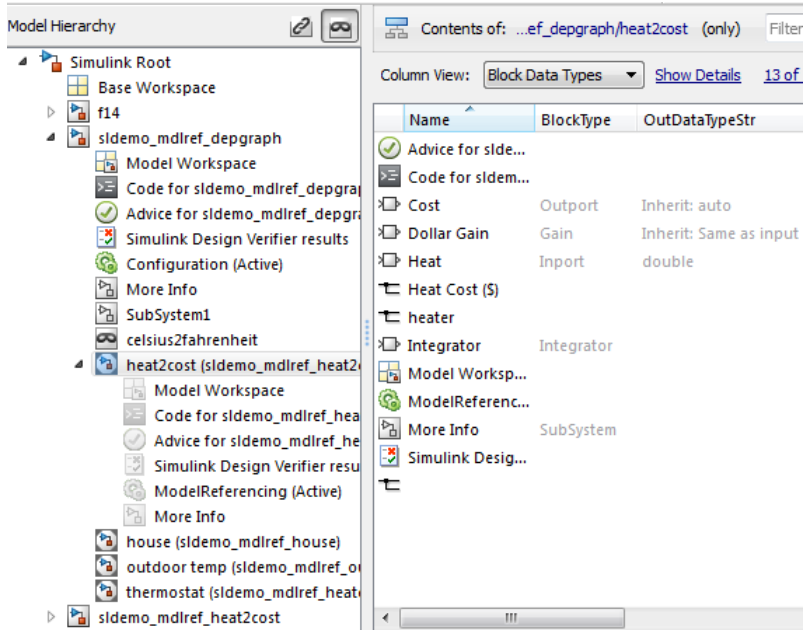


To browse a model referenced by a Model block:

1. Right-click the referenced model node in the **Model Hierarchy** pane.
2. From the context menu, choose **Open Model**.

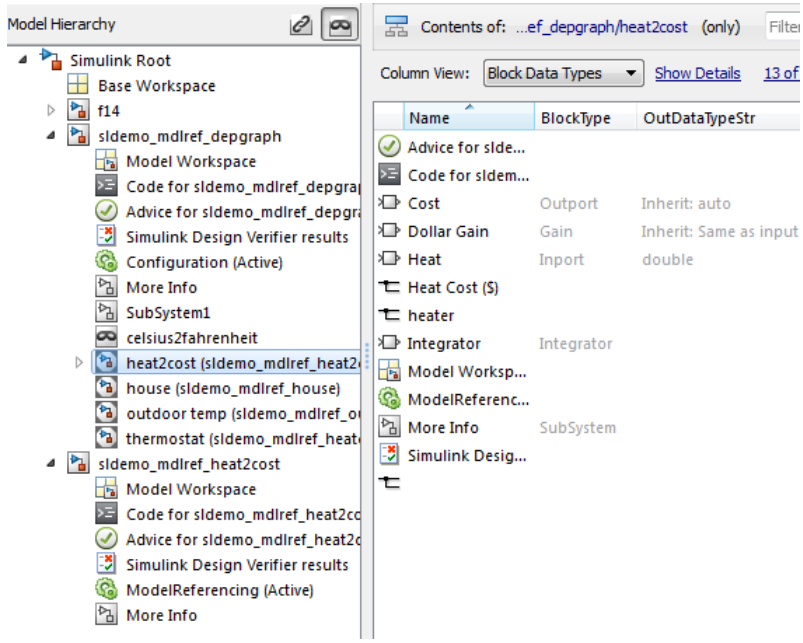
   - The referenced model opens.
   - The **Model Hierarchy** pane indicates that you can expand the Model block node.
   - The **Model Hierarchy** pane displays a separate expandable node for the referenced model (read-only).
   - The **Contents** pane displays objects corresponding to the Model block node (read-only).

For example, if you right-click the `heat2cost` Model block node and select the **Open Model** option, the **Contents** pane displays the objects corresponding to the `heat2cost` Model block. You can expand the `heat2cost` node.



You can browse the contents of the referenced model, but you cannot edit the model objects that are underneath the Model block.

To edit the referenced model, expand the referenced model node in the **Model Hierarchy** pane, then you can edit the properties of objects in the referenced model. For example, expand the `sldemo_mdlref_heat2cost` node:



For information about referenced models, see “Model Referencing”.

Cut, Copy, and Paste Objects Between Workspaces

To cut, copy, and paste workspace objects from one workspace into another workspace:

1. In the **Contents** pane, right-click on the workspace object you want to cut or copy.
2. From the context menu, select **Cut** or **Copy**.
   - You can also cut a workspace object by selecting in the **Contents** pane **Edit** > **Cut** or by clicking the **Cut** button ( ).
   - You can also copy a workspace object by selecting **Edit** > **Copy** or by clicking the **Copy** button ( ).
3. If you want to paste the workspace object that you cut or copied, in the **Model Hierarchy** pane, right-click the workspace into which you want to paste the object, and select **Paste**.
   - You can also paste the object by selecting **Edit** > **Paste** or by clicking the **Paste** button ( ).

You can also perform cut, copy, and paste operations by selecting an object and performing drag and drop operations.

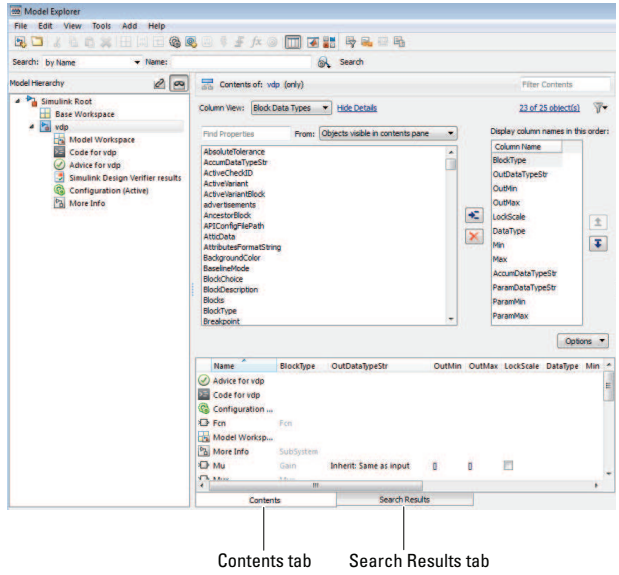
Model Explorer: Contents Pane

Contents Pane Tabs

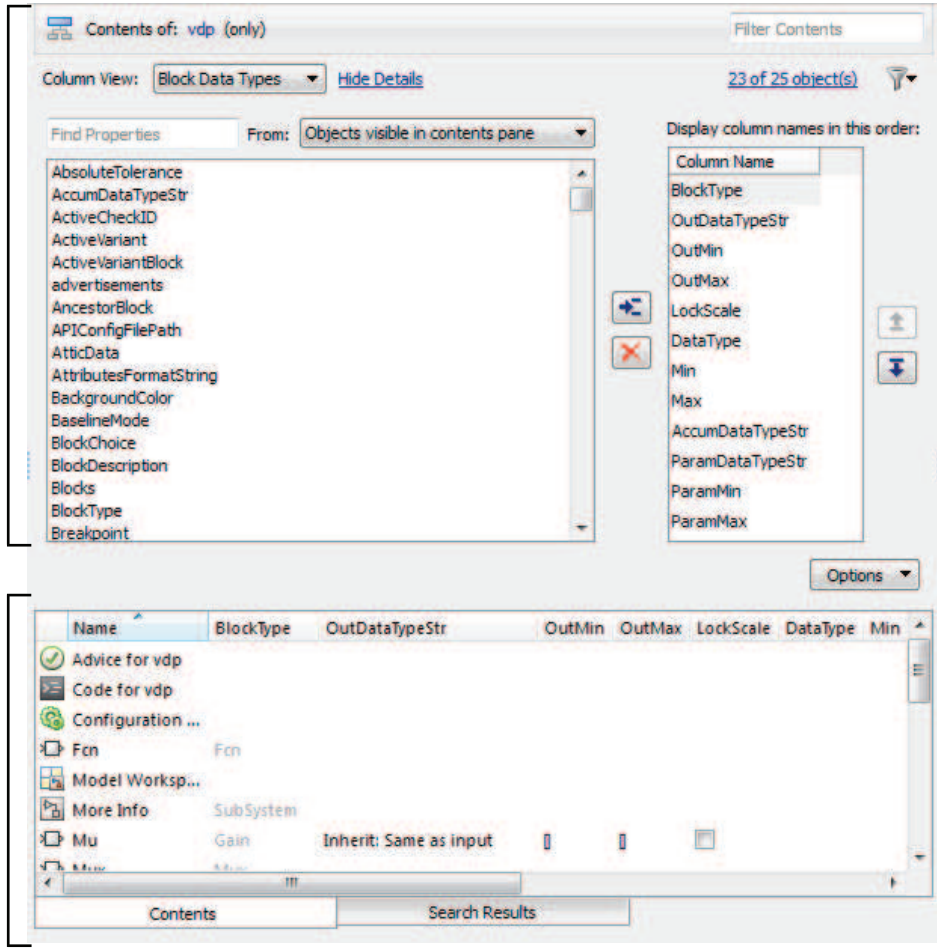
The **Contents** pane displays one of two tables containing information about models and charts, depending on the tab that you select:

- The **Contents** tab displays an object property table for the node that you select in the **Model Hierarchy** pane.
- The **Search Results** tab displays the search results table (see "Search Using Model Explorer" on page 12-52).

Optionally, you can also open a column view details section in the **Contents** pane. The following graphic shows the **Contents** pane with the column view details section opened.



To open the column view details section, click **Show Details**, at the top of the **Contents** pane.



Column View Details section

Object Property Table section

The **Column view details** section provides an interface for customizing the column view (hidden by default).

The **Object property table** section displays a table of model and chart object data (open by default).

Data Displayed in the Contents Pane

In the object property table section of the **Contents** tab and in the **Search Results** tab:

- Table columns correspond to object properties (for example, `Name` and `BlockType`).

  The object property table displays the first two columns (the object icon and the `Name` property) persistently, so that these columns remain visible regardless of how far you scroll to the right.
- Table rows correspond to objects (for example, blocks, and states).

The objects and properties displayed in the **Contents** pane depend on:

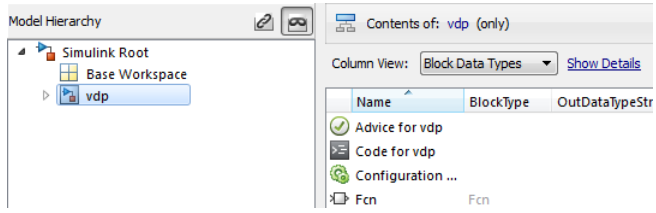
- The column view that you select in the **Contents** pane
- The node that you select in the **Model Hierarchy** pane
- The kind of object (for example, subsystem, chart, or configuration set) that you select in the **Model Hierarchy** pane
- The **View** > **Row Filter** options that you select

For more information about controlling which objects and properties to display in the **Contents** pane, see:

- “Customize Model Explorer Views” on page 12-38
- “Organize Data Display in Model Explorer” on page 12-23
- “Filter Objects in the Model Explorer” on page 12-31

Link to the Currently Selected Node

The **Contents of** link at the top left side of the **Contents** pane links to the currently selected node in the **Model Hierarchy** pane. The model data displayed in the Contents pane reflects the setting of the **Current System and Below** option. In the following example, **Contents of** links to the `vdp` model, which is the currently selected node.



Working with the Contents Pane

The following table summarizes the key tasks to control what is displayed in the **Contents**.

Task	Documentation
Control which kinds of objects to display.	"Use the Row Filter Option" on page 12-31
Search within the selected set of objects.	"Search Using Model Explorer" on page 12-52
Specify a set of properties to display based on the kind of node.	"Customize Model Explorer Views" on page 12-38
Group data based on unique values in a property column.	"Group by a Property" on page 12-24
Manage views (for example, save and export a view).	"Managing Views" on page 12-42
Add, remove, or rearrange columns.	"Organize Data Display in Model Explorer" on page 12-23
Edit object property values.	"Editing Object Properties" on page 12-22

Editing Object Properties

To open a properties dialog box for an object in the **Model Hierarchy** pane, right-click the object, and from the context menu, select **Properties**. Alternatively, click an object and from the **Edit** menu, select **Properties**.

You can change modifiable properties in the **Contents** pane (for example, a block name) by editing the displayed value. To edit a value, first select the row that contains the value, and then click the value. An edit control replaces the value (for example, an edit field for text values or a list for a range of values). For workspace variables that are arrays or structures, you can use the Variable Editor. Use the edit control to change the value of the selected property.

To assign the same property value to multiple objects in the **Contents** pane, select the objects and then change one of the selected objects to have the new property value. An edit control replaces the value with `<edit>`, indicating that you are doing batch editing. The Model Explorer assigns the new property value to the other selected objects, as well.

You can also change property values using the **Dialog** pane. See "Model Explorer: Property Dialog Pane" on page 12-36.

Organize Data Display in Model Explorer

You can control how the object property table and **Search Results** pane organize the layout of property information by:

- Sorting column contents
- Grouping by a property
- Changing the order of property columns
- Adding a property column
- Hiding and removing property columns

Sort Column Contents

To sort the column contents in ascending order, click the heading of the property column. A triangle pointing up appears in the column heading. To change the order from ascending to descending, or from descending to ascending, click the heading of the column again.

For example, if properties are in ascending order, based on the `Name` property (the default), click the heading of the `Name` column to display objects by name, in descending order.

By default, the **Contents** pane displays its contents in ascending order, based on the name of the object. Objects that have no values in any property columns appear at the end of the object property table.

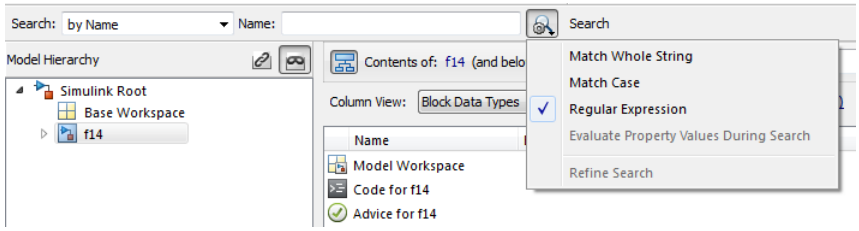
Note When you group by property, the Model Explorer applies sorting of column contents within each group.

Group by a Property

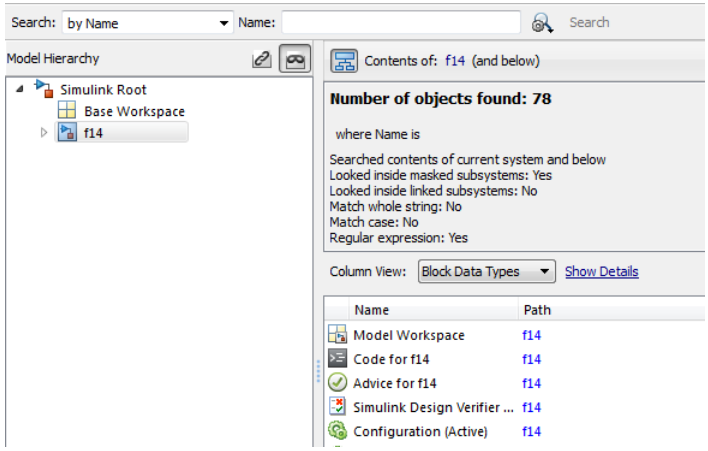
Organizing Contents by Property Values

When you explore a model, you might want to focus on all objects with the same property value. One approach is to group data by a property column.

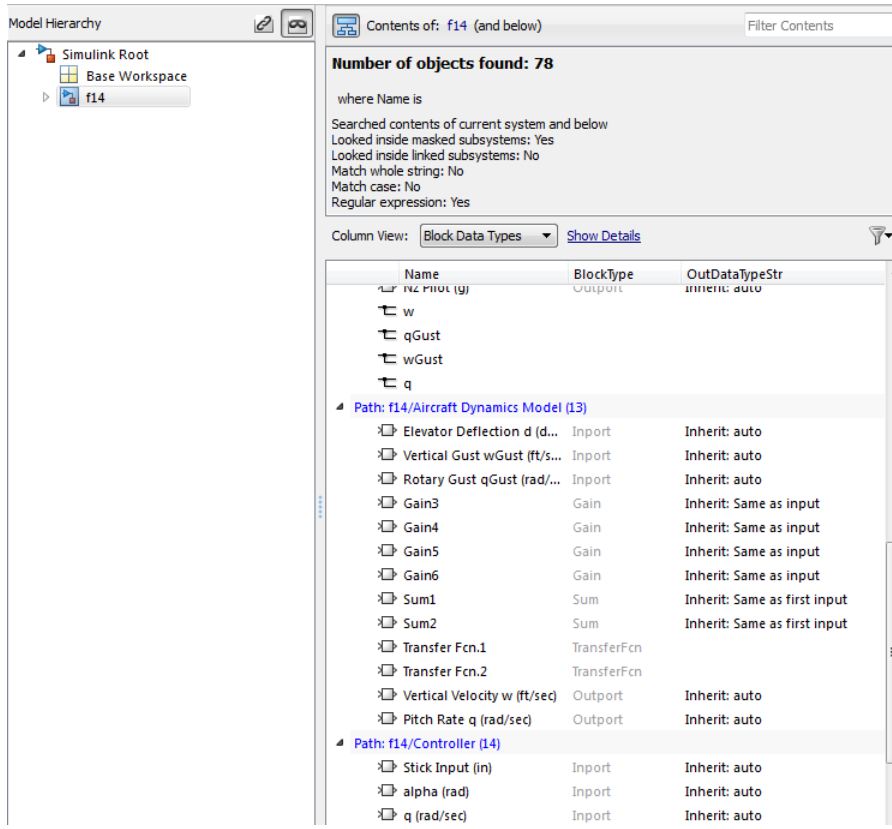
For example, suppose that you want to see all of the blocks in the `f14` model. You could perform the following search.



The search results obscure the whole path name for lower-level nodes:



By grouping on the `Path` property column, you see the whole path for lower-level nodes.



You can also collapse groups to focus on specific portions of a model.

How to Group by a Property Column

To group by a property:

1. In the object property table, right-click the column heading of the property by which you want to group contents.

   You can group by object icons, such as a block icon (), which represents a type of object. Right-click the empty column heading in the first column.
2. From the context menu, select the **Group By This Column** menu item.

Sorting with Grouped Data

When you group by property, the Model Explorer applies sorting of column contents within each group.

Expanding and Collapsing Grouped Data

By default, Model Explorer displays groups in expanded form. That is, all the objects in each group are visible. You can collapse and expand groups.

- To collapse the contents of a group, click the minus sign icon for that group.
- To expand a group, click the plus sign.
- To collapse or expand all the groups, right-click the column heading and select either the **Collapse All Groups** menu item (**Shift+C**) or **Expand All Groups** menu item (**Shift+E**).

Hiding the Group Column

By default, the property column that you use for grouping appears in the property table. That property also appears in the top row for each group.

To hide the group column in the property table, use one of the following approaches:

- From the **View** menu, clear the **Show Group Column** check box.
- Right-click a column heading in the property table and clear the **Show Group Column** check box.

Persistence of Grouped Data Settings

If you group by a property, that grouping is saved as part of the view definition.

When you select a different node in the **Model Hierarchy** pane, the contents for the new node are grouped by that same property. However, all groups are expanded, even if you had collapsed all groups before switching nodes.

Group Search Results

You can use grouping to organize the **Search Results** pane. The grouping that you apply to the **Search Results** pane also applies to the object property table, if that property is in the table. If the search results include a property that is not in the object property table, and you group on that property, then the Model Explorer removes the grouping setting that was in effect in the object property table.

Change the Order of Property Columns

Object Icon and Name Columns Are Always First

The first two columns of every object property table are the object icon column (the column with a blank column heading) and the `Name` property column. You cannot hide, remove, or change the location of the first two columns.

How to Change the Order of Property Columns

To change the order of property columns in the object property table, use one of these approaches:

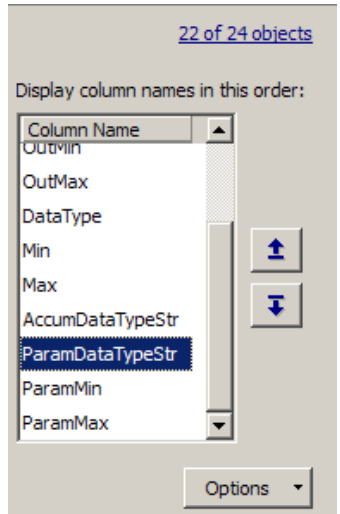
- In the object property table, select a column heading and drag it to a new location in the table.

  This approach avoids opening the column view details section and makes it easier to move a column a short distance to the right or left.
- In the column view details section, select one or more property columns and move them up or down in the list, using the arrow buttons to the right of the list.

  This approach allows you to move several property columns in one step, but it moves the selected columns right or left by only one column at a time.

  To move a property column by using the view details interface:

  1 In the **Display column names in this order** list on the right side of the column view details section, select one or more property columns that you want to move.

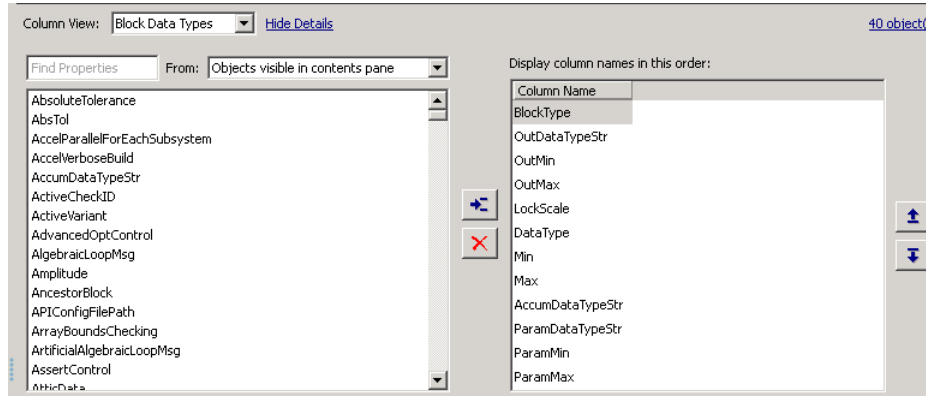


2 Click the **Move column left in view** button ( ) or the **Move column right in view** button ( ).

Add Property Columns

To add property columns to a view:

1 If you do not have the column view details section of the **Contents** pane already open, then at the top of the **Contents** pane, select **Show Details**.



2 In the list of properties on left side of the column view details section, select one or more properties that you want to add.

   - The list displays property names in alphabetical order. You can use the **Find Properties** search box in the column view details section to search for properties that contain the text string that you enter. You can specify the scope of the search with the **From** list to the right of the search box.

3 In the list of column names on the right side, select the property column that you want to be to the left of the property columns you insert.

4 Click the **Display property as column in view** button ()

Adding a Path Property Column

The Model Explorer provides a shortcut for adding a `Path` property column to a view. To add a `Path` property column:

1 Right-click the column heading in the object property table to the right of which you want to insert a `Path` column.

2 From the context menu, select **Insert Path**.

Hide or Remove Property Columns

You can choose between two approaches to hide (remove) a property column from the object property table. Hiding and removing a column both have the same result. You can:

- Hide a column using the context menu for a column heading. This approach avoids needing to open the column view details section.
- Remove a column using the column view details interface. This approach allows you to delete several properties in one step.

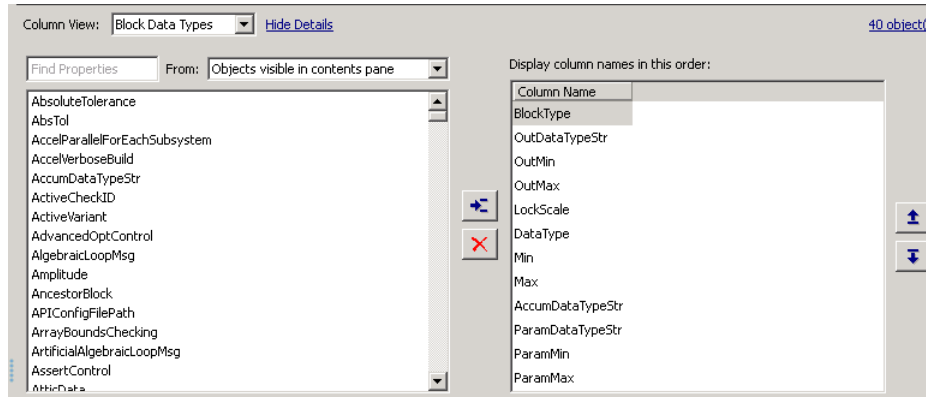
Hiding a Column Using the Column Heading Context Menu

1 Right-click the column heading of the column that you want to remove.

2 From the context menu, select **Hide**.

Removing a Column Using the Column View Details Interface

1 If you do not have the column view details section of the **Contents** pane already open, then at the top of the **Contents** pane, select **Show Details**.



2 In the column view details section of the **Contents** pane, in the **Display column names in this order** list, select one or more properties that you want to remove.

3 Click the **Remove column from view** button ( ) or the **Delete** key.

Inserting Recently Hidden or Removed Columns

The Model Explorer maintains a list of columns you hide or remove for each view during a Simulink session.

To add a recently hidden or removed column back into a view:

1 Right-click the column heading of the column to the right of which you want to insert a recently hidden column.

2 From the context menu, select **Insert Recently Hidden Columns**.

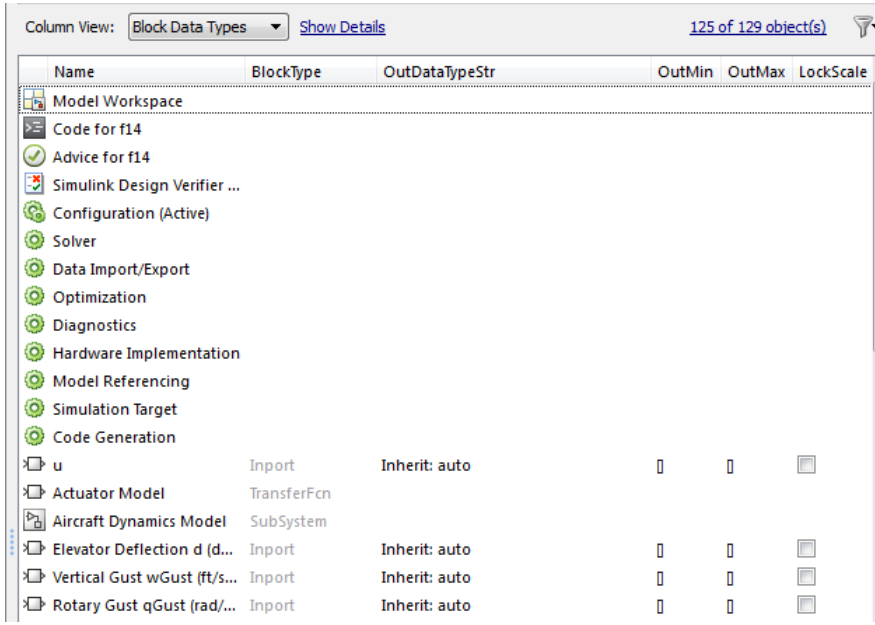
3 Select the column that you want to insert.

See “Hide or Remove Property Columns” on page 12-29.

Mark Nonexistent Properties

Usually, some of the properties that the **Contents** pane displays do not apply to all the displayed objects (in other words, some objects do not have values set). By default, the Model Explorer displays a dash (–) to mark properties that do not have a value.

If you want the Model Explorer to display a blank (instead of the default dash) in property cells that have no values, clear the **View > Show Nonexistent Properties as “–”** option. The **Contents** pane looks similar to the following graphic:



Filter Objects in the Model Explorer

- "Use the Row Filter Option" on page 12-31
- "Filtering Contents" on page 12-33

Two techniques that you can use to control the set of objects that the **Contents** pane displays are:

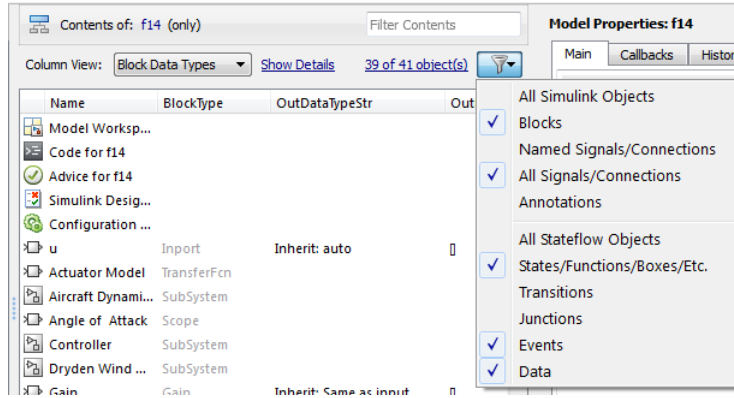
- Using the Row Filter option
- Filtering contents

For a summary of other techniques, see "Focus on Specific Elements of a Model or Chart" on page 12-9.

Use the Row Filter Option

You can filter the kinds of objects that the **Contents** pane displays:

1 Open the **Row Filter** options menu. In the Model Explorer, at the top-right corner of the **Contents** pane, click the **Row Filter** button.

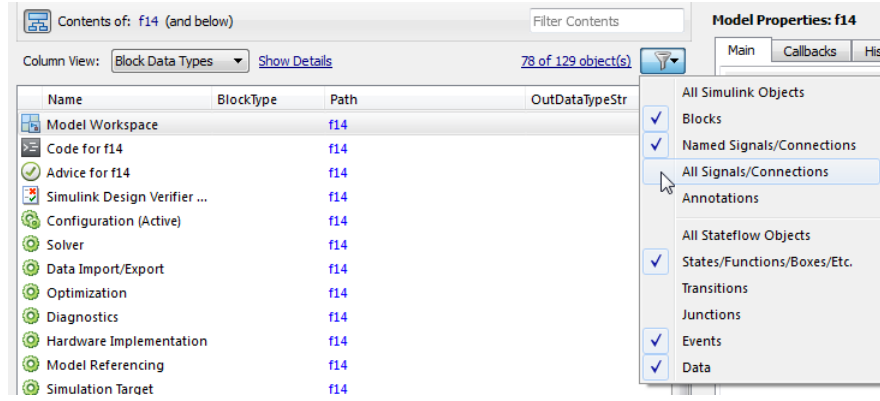


An alternative way to open the Row Filter menu is to select **View** > **Row Filter**.

By default, the **Contents** pane displays these kinds of objects for the selected node:

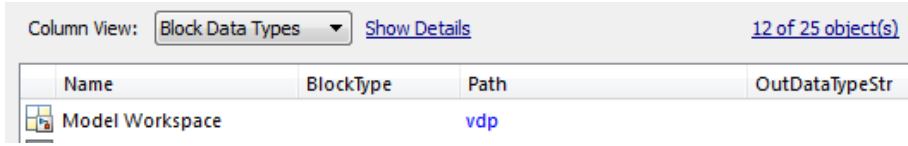
- Blocks
- Signals and connections
- Stateflow states, functions, and boxes
- Stateflow events
- Stateflow data

2 Clear the kinds of objects that you do not want to display in the **Contents** pane, or enable any cleared options to display more kinds of objects. For example, clear **All Signals/Connections** to prevent the display of signal and connection objects in the **Contents** pane.



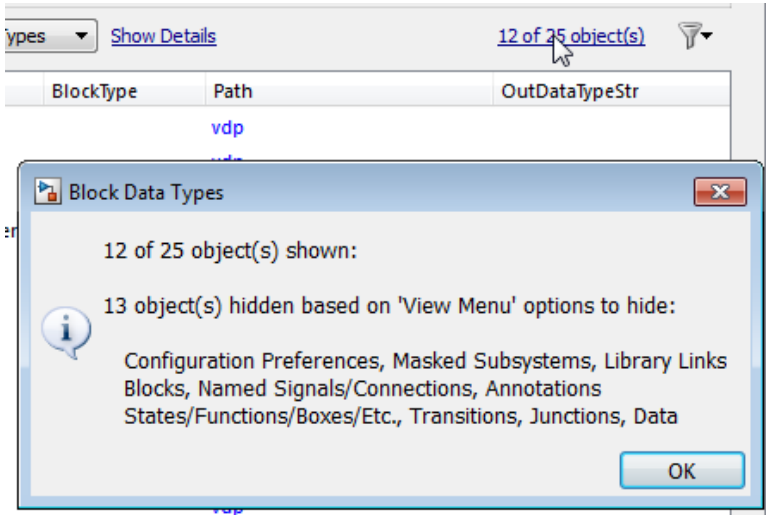
Object Count

The top-right portion of the **Contents** pane includes an object counter, indicating how many objects the **Contents** pane is displaying.



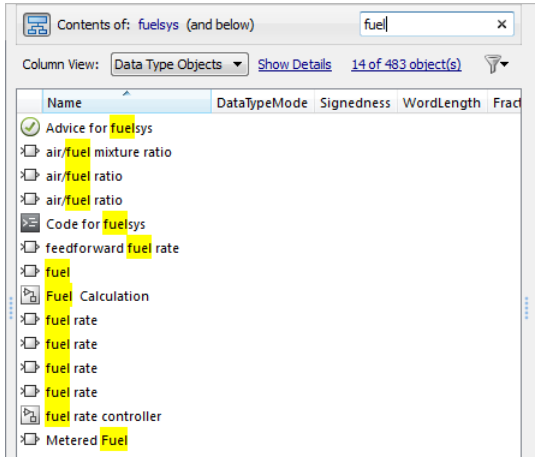
When you use the **Row Filter** option to filter objects, the object count indicator reflects that the **Contents** pane displays a subset of all the model and chart objects.

To view an explanation of the current object count, click the object count link (for example, `12 of 25 objects`). That link displays a pop-up information box:



Filtering Contents

To refine the display of objects that are currently displayed in the **Contents** pane, you can use the **Filter Contents** text box at the top of the **Contents** pane to specify search strings for filtering a subset of objects.



Using the **Filter Contents** text box can help you to find specific objects within the set of objects, based on a particular object name, property value, or property that is of interest to you. For example, if you enter the text string `fuel` in the **Filter Contents** edit box, the Model Explorer displays results similar to those shown above. The results highlight the text string that you specified.

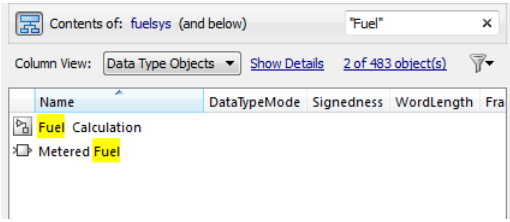
Specifying Filter Text Strings

As you enter text in the **Filter Contents** text box, the Model Explorer performs a dynamic search, displaying results that reflect the text as you enter it.

The text strings you enter must be in the format consistent with the guidelines described in the following sections.

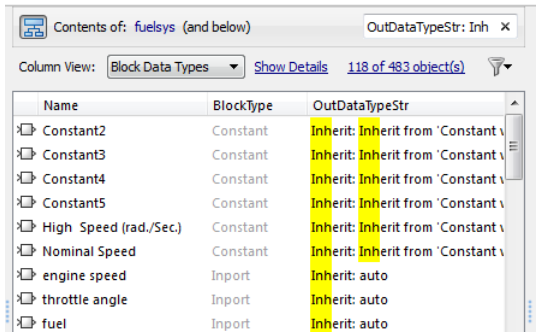
Case Sensitivity — By default, the Model Explorer ignores case as it performs the filtering.

To specify that you want the Model Explorer to respect case sensitivity for a text string that you enter, put that text string in quotation marks. For example, if you want to restrict the filtering to display only objects that include the text `Fuel` (with a capital `F`), enter `"Fuel"` (with quotation marks).



Specifying Properties and Property Values — To restrict the filtering to apply to objects with a specific property, specify the property name followed by a colon (:). The **Contents** pane displays objects that have that property.

To filter for a objects for which a specific property has a specific value, specify the property name followed by a colon (:) and then the value. For example, to filter the contents to display only objects whose `OutDataTypeStr` property has a value that includes `Inherit`, enter `OutDataTypeStr: Inherit` (alternatively, you could put the whole string in quotation marks to enforce case sensitivity):



Wildcards and MATLAB Expressions Not Supported — The Model Explorer does not recognize wildcard characters, such as an asterisk (*), as having any special meaning. For example, if you enter `fuel*` in the **Filter Contents** text box, you get no results, even if several objects contain the text string `fuel`.

Also, if you specify a MATLAB expression, in the **Filter Contents** text box, the Model Explorer interprets that string as literal text, not as a MATLAB expression.

Clearing the Filtered Contents

To redisplay the object property table as it appeared before you filtered the contents, click the **X** in the **Filter Contents** text box.

Filtering Removes Grouping

If you have set up grouping on a column, then when you filtering contents, the Model Explorer does not retain that grouping.

Model Explorer: Property Dialog Pane

- "Showing and Hiding the Dialog Pane" on page 12-36
- "Editing Properties in the Dialog Pane" on page 12-36

Use the **Dialog** pane to view and change properties of objects that you select in the **Model Hierarchy** pane or in the **Contents** pane.

Showing and Hiding the Dialog Pane

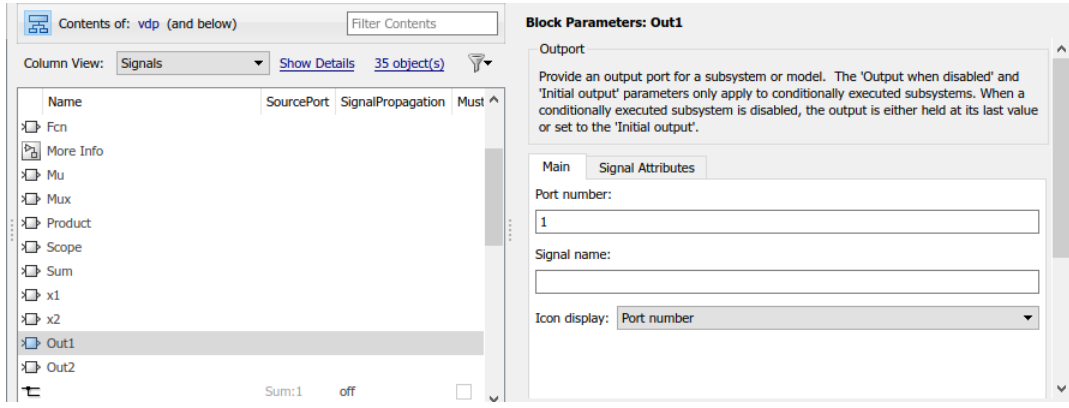
By default, the **Dialog** pane appears in the Model Explorer, to the right of the **Contents** pane. To show or hide the **Dialog** pane, use one of these approaches:

- From the **View** menu, select **Show Dialog Pane**.
- From the main toolbar, click the **Dialog View** button ( ).

Editing Properties in the Dialog Pane

To edit property values using the **Dialog** pane:

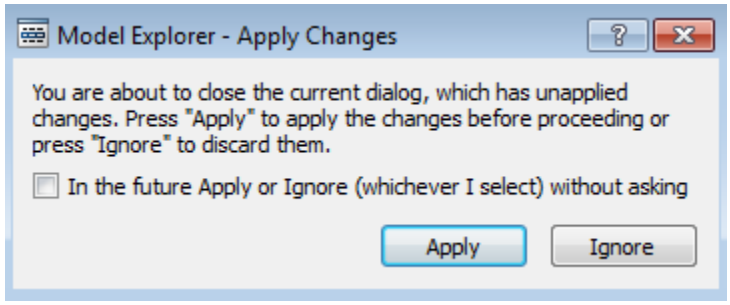
1 In the **Contents** pane, select an object (such as a block or signal). The **Dialog** pane displays the properties of the object you selected.



2 Change a property (for example, the port number of an Outport block) in the **Dialog** pane.

3 Click **Apply** to accept the change, or click **Revert** to return to the original value.

By default, clicking outside a dialog box with unapplied changes causes the Apply Changes dialog box to appear:



Click **Apply** to accept the changes or **Ignore** to revert to the original settings.

To prevent display of the **Apply Changes** dialog box:

1 In the dialog box, click the **In the future Apply or Ignore (whichever I select) without asking** check box.

2 If you want Simulink to apply changes without warning you, press **Apply**. If you want Simulink to ignore changes without warning you, press **Ignore**.

To restore display of the **Apply Changes** dialog box, from the **Tools** menu, select **Prompt if dialog has unapplied changes**.

Customize Model Explorer Views

In this section...

Using Views

What Is a Column View?

A view in the Model Explorer is a named set of properties.

The Model Explorer uses views to specify sets of property columns to display in the **Contents** pane.

For each kind of node in the **Model Hierarchy** pane, certain properties are most relevant for the objects displayed in the **Contents** pane. For example, for a Simulink model node, such as a model or subsystem, some properties that are useful to display include:

- `BlockType` (block type)
- `OutDataTypeStr` (output data type)
- `OutMin` (minimum value for the block output)

Generally, a column view does not contain the total set of properties for all the objects in a node. Specifying a subset of properties to display can streamline the task of exploring and editing model and chart object properties and increase the density of the data displayed in the **Contents** pane.

What You Can Capture in a View

You can use a view to capture the following characteristics of the model information to show in the Model Explorer:

- Properties that you want to display in the **Contents** pane (see “Customizing Views” on page 12-41)

- Layout of the **Contents** pane (for example, grouping by property, the order of property columns, and sorting), as described in "Organize Data Display in Model Explorer" on page 12-23.

Use Standard Views or Customized Views

You can use views in the following ways:

- Use the standard views shipped with the Model Explorer
- Customize the standard views
- Create your own views

Automatically Applied Views

The first time you open the Model Explorer, the software automatically applies one of the standard views to the node you select in the **Model Hierarchy** pane. The Model Explorer applies a view based on the kind of node you select.

The Model Explorer assigns one of four categories of nodes in the **Model Hierarchy** pane. The Model Explorer initially associates a default view with each node category. The four node categories are:

Node Category	Kinds of Hierarchy Nodes Included	Initial Associated View
Simulink	Models, subsystems, and root level models	`Block Data Types`
Workspace	Base and model workspace objects	`Data Objects`
Stateflow	Stateflow charts and states	`Stateflow`
Other	Objects that do not fit into one of the first three categories; for example, configuration sets	`Default`

The **Column View** field at the top of the **Contents** pane displays the view that the Model Explorer is currently using.

If you select a view

In the **Contents** pane, from the **Column View** list, you can select a different view. If you select a different view, then the Model Explorer associates that view with the

category of the current node. For example, suppose the selected node in the **Model Hierarchy** pane is a Simulink model, and the current view is `Data Objects`. If you change the view to `Signals`, then when you select another Simulink model node, the Model Explorer uses the `Signals` view. See “Selecting a View Manually” on page 12-40.

Selecting a View Manually

By default, the Model Explorer automatically applies a view, based on the category of node that you select and the last view used for that node. You can manually select a view from the **Column View** list that better meets your current task.

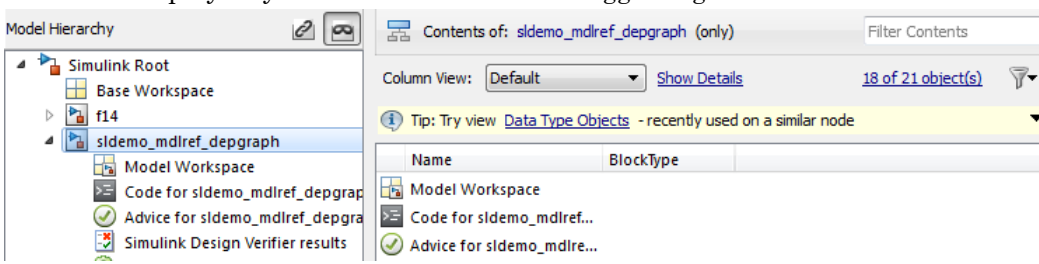
You can shift from the default mode of having the Model Explorer automatically apply views to a mode in which you must manually select a view to change views.

To enable the manual view selection mode:

1. Select **View** > **Column View** > **Manage Views**.

   The View Manager dialog box opens.
2. In the View Manager dialog box, click the **Options** button and clear **Change View Automatically**.

In the manual view selection mode, if you switch to a different kind of node in the **Model Hierarchy** pane that has a different view associated with it, the **Contents** pane displays a yellow informational bar suggesting a view to use.



Tip interface

The tip interface appears immediately above the object property table.

The tip does not appear if you use automatic view selection.

To hide the currently displayed tip, from the menu button on the right-hand side of the tip bar, select **Hide This Tip**.

The tip interface displays a link for changing the current view to a suggested view. To choose the suggested view displayed in the tip bar, click the link.

Initially, the suggested view is the default view associated with a node. If you associate a different view with a node category, then the tip suggests the most recently selected view when you select similar nodes.

To change from manual specification of views to automatic specification, from the tip interface, select the down arrow and then the **Change View Automatically** menu item.

Customizing Views

If a standard view does not meet your needs, you can either modify the view or create a new view.

You can customize the object property table represented by the current view in several ways, as described in these sections:

- "Add Property Columns" on page 12-28
- "Hide or Remove Property Columns" on page 12-29
- "Change the Order of Property Columns" on page 12-27

How the Model Explorer Saves Your Customizations

As you modify the object property table, you change the current view definition.

The Model Explorer saves the following changes to the object property table as part of the column view definition:

- Grouping by property
- Sorting in a column
- Changing the order of property columns
- Adding a property column
- Hiding and removing property columns

When you change from one view to another view, the Model Explorer saves any customizations that you have made to the previous view.

For example, suppose you use the `Block Data Types` view and you remove the `LockScale` property column. If you then switch to use the `Data Objects` view, and

later use the `Block Data Types` view again, the `Block Data Types` view no longer includes the `LockScale` column that you deleted.

At the end of a Simulink session, the Model Explorer saves the view customizations that you made during that session. When you reopen the Model Explorer, Simulink uses the customized view, reflecting any changes that you made to the view in the previous session.

Controlling the Font Size

You can change the font size in the Model Explorer panes:

- To increase the font size, press the **Ctrl + Plus Sign** (+).

  Alternatively, from the Model Explorer **View** menu, select **Increase Font Size**.
- To decrease the font size, press the **Ctrl + Minus Sign** (-).

  Alternatively, from the Model Explorer **View** menu, select **Decrease Font Size**.

Note The changes remain in effect for the Model Explorer and in the Simulink dialog boxes across Simulink sessions.

Managing Views

If a standard view does not meet your needs, you can either modify the view or create a new view. See “Customizing Views” on page 12-41.

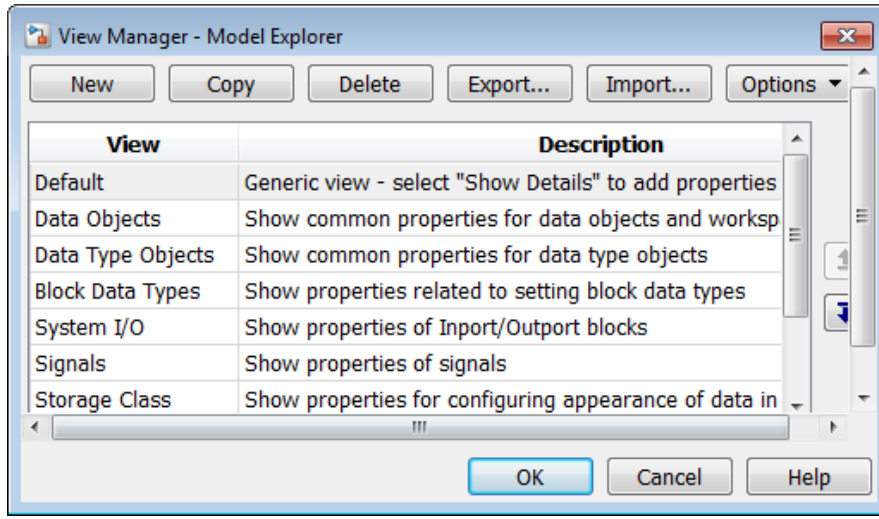
You can manage views (for example, create a new view or export a view) using the View Manager dialog box.

Opening the View Manager Dialog Box

To open the View Manager dialog box, select the **Manage Views** option from either:

- The **View > Column View** menu
- The options listed when you click the **Options** button in the column view details section

The View Manager dialog box displays a list of defined views and provides tools for you to manage views.



You can manage views in several ways, including:

- "Creating a New View" on page 12-43
- "Deleting Views" on page 12-44
- "Reordering Views" on page 12-44
- "Exporting Views" on page 12-45
- "Importing Views" on page 12-45
- "Resetting Views to Factory Settings" on page 12-46

Creating a New View

To create a new view that has a new name, you can use one of these approaches:

- Copy an existing view, rename it, and customize the view.
- Create a completely new view.

After you create a new view, you can customize the view as described in "Customizing Views" on page 12-41.

Copying and renaming an existing view

You can build a new view by copying an existing view, renaming it, and optionally customizing the renamed view. In the View Manager dialog box:

1. Select the view that you want to use as the starting point for your new view.
2. Click the **Copy** button.

   A new row appears at the bottom of the View Manager table of views. The new row contains the name of the view you copied, followed by a number in parentheses. For example, if you copy the `Stateflow` view, the initial name of the copied view is `Stateflow (1)`.

Creating a completely new view

To create a completely view, in the View Manager dialog box, click the **New** button. A new view row appears at the bottom of the View Manager dialog box list of views.

Naming and describing a new view

Once you create a view, you can name the view and provide a description of the view:

1. Double-click `New View` in the left column of the table of views and replace the text with a name for the view.
2. Double-click `Description` in the table and replace the text with a description of the view.
3. Click **OK**.

Deleting Views

To delete a view from the **Column View** list of views:

1. In the View Manager dialog box, select one or more views that you want to remove from the list.
2. Click the **Delete** button or the **Delete** key.
3. Click **OK**.

Deleting a view using the View Manager dialog box permanently deletes that view from the Model Explorer interface.

If you think you or someone else might want to use a view again, consider exporting the view before you delete it (see “Exporting Views” on page 12-45).

Reordering Views

To change the position of a view in the **Column View** list, in the View Manager dialog box:

1. Select one or more views that you wish to move up or down one row in the table of views.
2. Click the up or down arrow buttons to the right of the table of views. Repeat this step until the view appears where you want it to be in the table.
3. Click **OK**.

Exporting Views

To export views that you or others can then import, in the View Manager dialog box:

1. In the View Manager dialog box, select one or more views that you want to export.
2. Click the **Export** button.

   An Export Views dialog box opens, with check marks next to the views that you selected.
3. Click **OK**.

   An Export to File Name dialog box opens.
4. Navigate to the folder to which you want to export the view.

   By default, the Model Explorer exports views to the MATLAB current folder.
5. Specify the file name for the exported view.

   The file format is `.mat`.
6. Click **OK**.

Importing Views

To import view files from another location for use by the Model Explorer:

1. In the View Manager dialog box, click the **Import** button.

   The Select `.mat` File to Import dialog box opens.
2. Navigate to the folder from which you want to import the view.
3. Select the MAT-file containing the view that you want to import and then click **Open**.

   A confirmation dialog box opens. Click **OK** to import the view.

The imported view appears at the bottom of the **Column View** list of views.

The Model Explorer automatically renames the view if a name conflict occurs.

Resetting Views to Factory Settings

You can reset (restore) the original definition of a specific standard view (that is, a view shipped with the Model Explorer) if that view is the current view. To do so, click the **Options** button in the column view details section and select **Reset This View to Factory Settings**.

To reset the factory settings for *all* standard views in one step, in the View Manager dialog box, click the **Options** button and select **Reset All Views to Factory Settings**.

Note When you reset all views, the Model Explorer removes all the custom views you have created. Before you reset views to factory settings, export any views that you will want to use in the future.

More About

- “Search and Edit Using Model Explorer” on page 12-2

Find Model Elements in Simulink Models

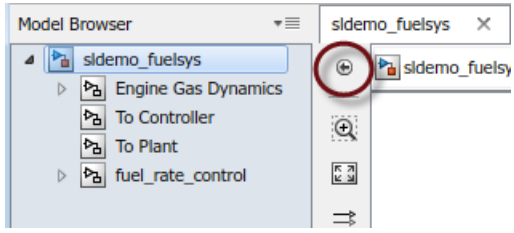
As you build and modify your model, it helps when you can understand your model structure and can locate specific model elements. Simulink Editor tools simplify these tasks. Use the tool that is appropriate for your model size and complexity.

- Use the model browser to view and navigate the structure of your model. You can find an element using the model browser by navigating to it through the model hierarchy. This approach works well for a smaller model whose structure you are familiar with. See “Explore the Model Hierarchy Using the Model Browser” on page 12-47.
- Use **Edit** > **Find** to locate model elements that match search criteria. You can search in a selected system and optionally include all systems below it. You can also narrow your results based on search criteria. See “Search for Model Elements Using Find” on page 12-48.
- Use the Model Explorer to search the model hierarchy using advanced criteria. You can use it to search the model hierarchy and search for variables. The Model Explorer also enables you to search in and apply a change to multiple model elements at once. See “Search Using Model Explorer” on page 12-52.
- Use project-wide search to search across all your models and supporting files in one place. You can find matches inside model files, MATLAB files, and other project files such as PDF and Microsoft Word files. See “Project-Wide Search” on page 17-4.

Explore the Model Hierarchy Using the Model Browser

Use the model browser to navigate a model hierarchy using a tree structure. The browser helps you to understand the organization of your model and explore systems within systems.

To display the model browser, in the Simulink Editor, select **View** > **Model Browser** > **Show Model Browser**. You can also use the **Hide/Show Model Browser** control on the palette to toggle the browser display.



You can use the commands on the **View > Model Browser** menu to specify whether to include in the browser blocks that are linked to a library and masked subsystems. For information on these types of blocks, see “Linked Blocks” on page 40-15 and “Masking Fundamentals” on page 38-2.

Search for Model Elements Using Find

You can search in Simulink models using **Edit > Find**. Use Find and the Finder interface to locate, navigate to, and select any element that matches the search string that you enter. Searching can match the string anywhere in the element, such as in the name and in parameter values. You can customize the search to look only in certain types of elements or when specific parameters are set a certain way.

Default Search	Search Options
In the current system	Specify to search the current system and all systems below it in the model hierarchy.
In all model elements, including all types of Simulink and Stateflow objects	Narrow your search to include only the elements you are interested in, such as blocks, annotations, or signals.
In parameters	Specify to omit parameter values from the search.
Case-insensitive, partial matches	Search for an exact match and use regular expressions.
In referenced models but not in linked blocks or masked systems	You can turn each of these options off and on.

Perform a Basic Search

Search in the current level of the model `sldemo_fuelsys` for any model element that contains the number `2`.

Tip Open the Property Inspector to see the properties and parameters of the current selection. Select **View > Property Inspector**.

1. Open the model `sldemo_fuelsys`.
2. Select **Edit > Find**.

3 In the search box, enter `2` and press **Enter**.

Nine model elements appear highlighted. The first element found, the copyright annotation, has a stronger highlight to show that it is the current match.

4 To move to the next element, click the search box down arrow. In this example, the current selection highlight moves to a Constant block. The block name does not appear in the model. Look in the Property Inspector to see the block name, Constant2.

5 Use the up and down arrows to move through the rest of the elements found.

Perform an Advanced Search

You can narrow your search by specifying search criteria. For an example, see "Specify Search Criteria and Sort Results" on page 12-50.

1 Select **Edit** > **Find**.

2 Enter the search string. Alternatively, you can add the search string later.

3 Click **View Details**.

4 Click the **Configure advanced search settings** button.

5 In the Advanced Search Settings dialog box, for each criterion you want to set, click the **Add property and value** button. Select the property and enter the value for each criterion.

6 Set any other advanced search settings, and then click **OK**.

7 If you entered a search string, the search executes. Alternatively, you can enter the search string after you specify the criteria, or enter an asterisk (*) to search for any model element that matches the advanced criteria.

Tip You can cancel a search and view partial search results. In the Finder interface, click the **Stop Search** button.

Search for a Property Value

Using the search box, you can specify a property and value to search for. Enter the search string in the form `Property:Value`. For example, to search for all **Constant value** parameters whose value is `throttle_sw` , type `Value:throttle_sw` and press **Enter**. To search for all Constant blocks, enter `BlockType:Constant`. To search for text that appears in the description of the block, use the form `Description:textstring`.

- Search using the programmatic name of the property. To find the programmatic name, in the Property Inspector, hover over the property.
- Enter the full property name, case insensitive. You cannot use regular expressions or partial matches for the property name.
- By default, the value search is case insensitive and finds partial matches. Use the advanced search settings to make the search case sensitive, specify verbatim matches, or search using regular expressions.

To search for a string that has a colon and prevent the text before the colon from being treated as a property, use one of these approaches:

- Escape the colon using a backslash, for example, `Earth\: a planet`.
- Use single or double quotes around the expression, for example, `'Earth: a planet'` or `"Earth: a planet"`.

Specify Search Criteria and Sort Results

You can specify criteria for your search and sort the results using the Finder interface. In this example, you search for all elements that contain the string `fuel`. You then use the Finder interface to narrow your results.

Tip Use the model browser with the Finder interface to select the starting point for your search.

---

1. Open the model `sldemo_fuelsys`.
2. Select **Edit** > **Find**. Next to the search box, click **View Details**.

3. To expand the scope of the search, in the Finder interface, click the **Click to search in current system and below** button .
4. Search for any elements that include the string `fuel`. In the search box, enter `fuel` and press **Enter**.

   The model has many elements with `fuel` in the name or in a parameter or property value, including blocks, annotations, signals (data), and Stateflow charts.

   Use the Finder interface to make your results more meaningful. For example, you can sort by any of the headings and double-click an item in the list to go to and select the element in the model. Click an item in the list to make it the current match in the model if it is displayed.
5. When a search returns too many results, use the advanced search settings. Next to the search box, click the **Configure advanced search settings** button .
6. Search only for blocks. In the Advanced Search Settings dialog box, under **Object Type**, clear the **Stateflow** check box. Expand the **Simulink** list and clear the **Annotations** and **Signals** check boxes.
7. Narrow the search further to look only in blocks whose description contains the word `input`. Under **Property : Value**, from the property list, select `BlockDescription`. In the value box, enter `input`, and then click the **Add property and value** button. Click **OK**.
8. Searching returns fewer blocks. You can add more property values to narrow the search further. For example, you can specify the type of blocks to search in. Open the Advanced Search Settings dialog box. Under **Property : Value**, add another property-value pair. Set the property to `BlockType` and the value to `MultiPortSwitch`. Click the **Add property and value** button and click **OK**.

   One block appears in the list.
9. Clear the advanced search criteria. Click the arrow on the **Configure advanced search settings** button and select **Clear advanced settings**.

Search Using Model Explorer

Model Explorer helps you to explore and modify your model using advanced techniques. Use the Model Explorer for to search for:

- Variables in workspaces and data dictionaries
- Variable usage in a model
- Instances of a type of block
- Block parameters and parameter values

You can combine search criteria and iteratively refine the results. Search in Model Explorer for model elements, starting with the node you select in the model hierarchy. You can search the entire model, in a particular system, or in a system and all the systems below it in the hierarchy. For details on the options, see “Search Bar Controls” on page 12-4.

Using your search results, you can apply changes to multiple elements at once.

To modify algorithmic block parameters such as the **Gain** parameter of a Gain block, consider using the Model Data Editor. See “Configure Data Properties by Using the Model Data Editor” on page 59-141.

Search for a Parameter and Refine Results

In this example, you search for model elements that have an **Integer rounding mode** parameter. You then refine the results to include only n-D Lookup table blocks. You can use the search results to find out more about how these values are set or make batch changes to the model elements found by the search.

1 Open the model `sldemo_fuelsys`.
2 Open Model Explorer. Select **View** > **Model Explorer** > **Model Explorer**.

   By default, the Model Explorer searches the current system and below. You can use the model hierarchy tree in combination with the **Show contents** button  to specify the scope of the search. For example, you can select a node and set the search to **current system only** to keep the search only at that level. Set the search to **current system and below** to search the current system and all the subsystems within it.

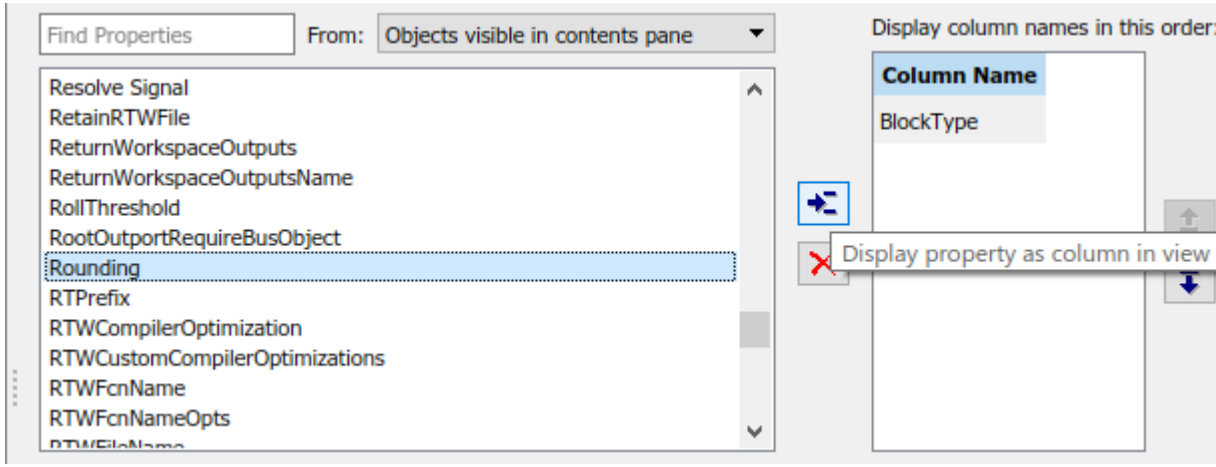
3. For this example, leave the search scope set to search the current system and below, starting with the top level of the model. Specify your search criteria. In the search bar, set:

   - **Search** to `by Property Name`
   - **Property** to `Rounding`

   `Rounding` is the programmatic name for the **Integer rounding mode** parameter. For a list of these names, see "Block-Specific Parameters".
4. Click **Search**. In the **Search Results** box, 43 results appear. You can go to an item by clicking the link to the path.
5. Refine the search. In the search bar, click **Search Options** and select **Refine Search**.

   The search button label changes to **Refine**. With this label in effect, additional search criteria act on the previous set of results.
6. Set **Search** to `by Block Type` and set **Type** to `Lookup_n-D`. Click **Refine**.

   The search returns 5 items.
7. To work further with the values, click **Show Details**.
8. The property you are interested in learning more about or acting on is `Rounding`. First add a column for it in the search results. Select `Rounding` from the list (you can enter it in the **Find Properties** box to locate it quickly), and click the **Display property as column in view** button.



A column for `Rounding` appears in the search results. For any parameter or property that appears in a column, you can view, sort, and change values for multiple items. For example, to change the `Rounding` values on all n-D Lookup Table blocks you find by searching, select all the items in the list. In the **Rounding** column, click one cell and select a new value from the list (for example, `Floor`).

Tip To view a summary of the search options that you used, expand the **Number of objects found** box by clicking the **Show Search Details** button .

- To create, modify, and view the entries in a data dictionary, use the Model Explorer. See “Edit and Manage Workspace Variables by Using Model Explorer” on page 59-111 and “View and Revert Changes to Dictionary Data” on page 63-27.
- For general information about Model Explorer and its uses, see “Search and Edit Using Model Explorer” on page 12-2.

Model Dependency Viewer

In this section...

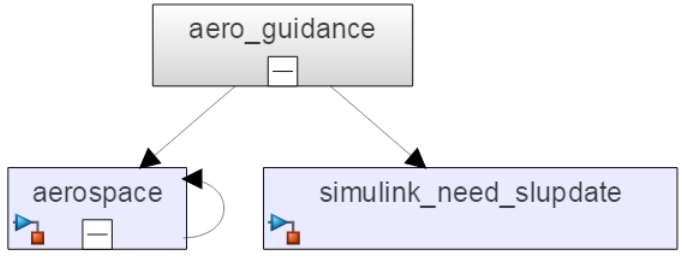
Model Dependency Views

The Model Dependency Viewer displays a dependency view of a model. The dependency view is a graph of all the models and libraries referenced directly or indirectly by the model. You can use the dependency view to find and open referenced libraries and models. To identify and package all required files instead, see “Analyze Model Dependencies” on page 18-25.

The Model Dependency Viewer allows you to choose between the file dependency view and the model instances view.

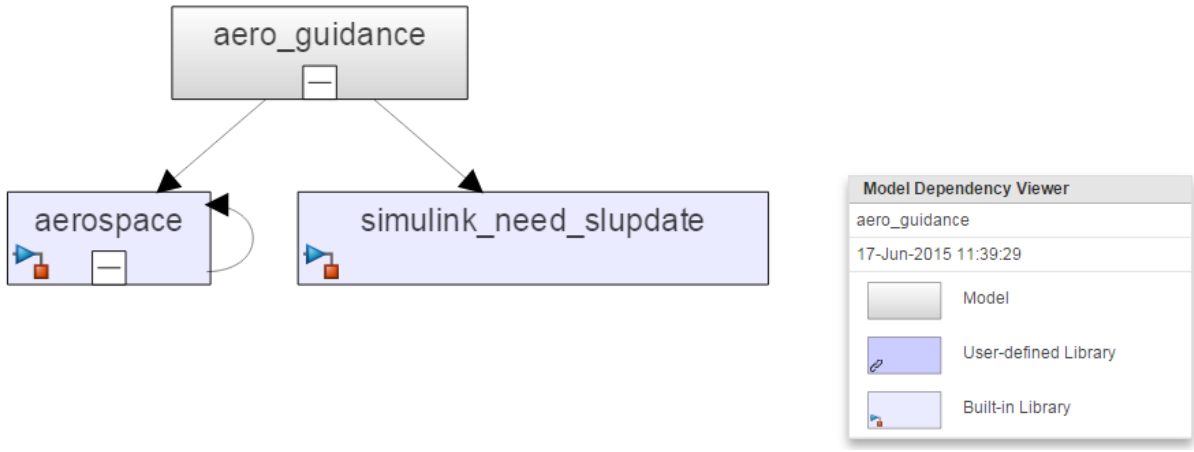
File Dependency View

The file dependency view shows the model and library files referenced by a top model. A referenced model or library appears only once in the view even if it is referenced more than once in the model. The figure shows a dependency view. Gray blocks represent model files and blue boxes represent libraries. Arrows represent dependencies. For example, the arrows in this view indicate that the `aero_guidance` model references two libraries: `aerospace` and `simulink_need_slupdate`.



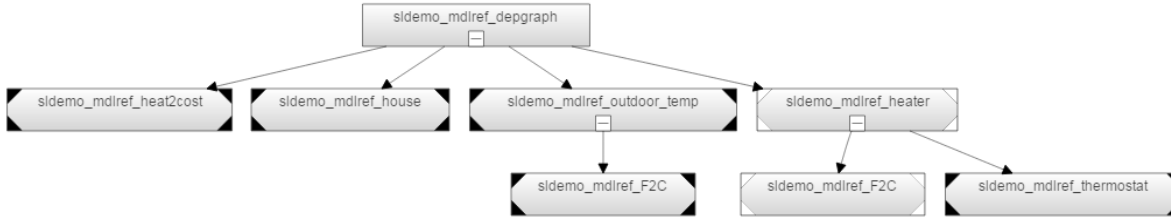
An arrow from a library that points to itself indicates that the library references itself. Blocks in the library reference other blocks in that same library. The example view shows that the `aerospace` library references itself.

A file dependency view can include a legend that identifies the model in the view and the date and time the view was created.



Model Instances View

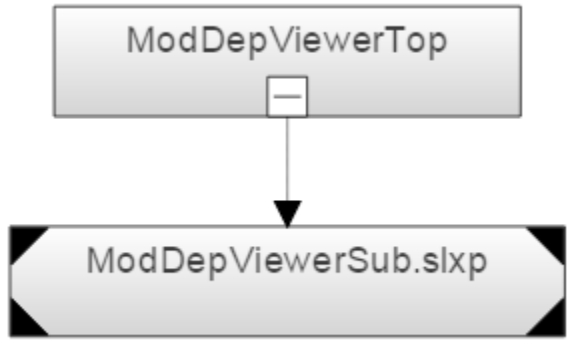
The model instances view shows every reference to a model in a model reference hierarchy (see "Model Referencing") with the top model at the root of the hierarchy. If a model hierarchy references the same model more than once, the referenced model appears multiple times in the instance view, once for each reference. For example, this view indicates that the model reference hierarchy for `sldemo_mdlref_depgraph` contains two references to the model `sldemo_mdlref_F2C`.



In an instance view, boxes represent a top model and model references. Boxes representing accelerated-mode instances (see "Simulate Model Reference Hierarchies" on page 8-35) have filled triangles in their corners; boxes representing normal-mode instances have empty triangles in their corners. For example, the previous diagram

shows that one of the references to `sldemo_mdlref_F2C` operates in normal mode, and the other operates in accelerated mode.

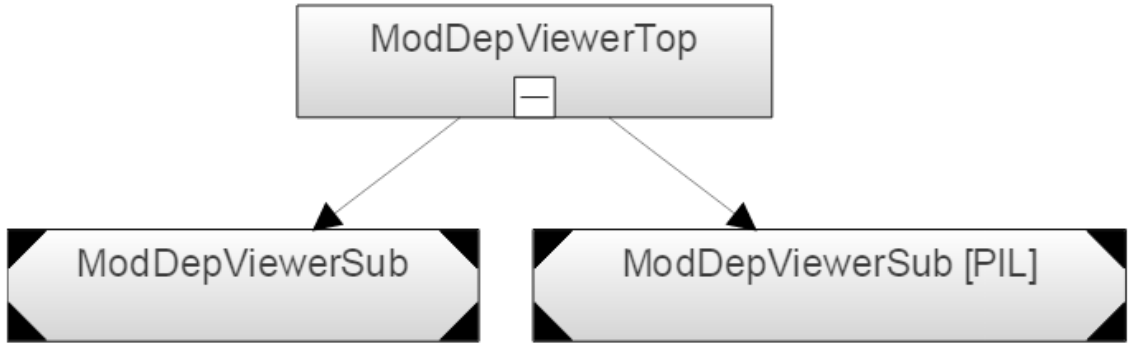
Boxes representing protected referenced models on page 8-95 show the protected models `.slxp` extension. You cannot expand protected reference models.



An instance view displays information icons on instance boxes to indicate an override in simulation mode for that instance. For example, if a referenced model is configured to run in normal mode and it runs in accelerator mode, its simulation mode is overridden. This override occurs because another referenced model that runs in accelerator mode directly or indirectly references it.

Processor-in-the-Loop Mode Indicator

An instance view appends PIL to the names of models that run in processor-in-the-loop mode (see "Simulate Model Reference Hierarchies" on page 8-35). For example, this dependency instance view indicates one instance of the referenced model `ModDepViewerSub` runs in processor-in-the-loop mode.



View Model File and Library Dependencies

This example shows how to use Model Dependency Viewer to view model file and library dependencies of the model. To identify and package all required files instead, see "Analyze Model Dependencies" on page 18-25.

1. Open the model `sldemo_mdlref_depgraph`.
2. To open the Model Dependency Viewer in file dependency view, select **Analysis > Model Dependencies > Model Dependency Viewer > Models Only**.
3. Select the **User-Defined Libraries** check box. The viewer shows dependencies on user-defined libraries, if such dependencies exist.

   You can open this view directly from the Simulink Editor by selecting **Analysis > Model Dependencies > Model Dependency Viewer > Models & Libraries**.
4. Select the **Built-In Libraries** check box to show dependencies on MathWorks built-in libraries.
5. To view the dependencies laid out horizontally, click **Options** and, under **Layout**, select **Horizontal**.
6. Collapse the dependencies of `sldemo_mdlref_outdoor_temp`. Click – on the box for `sldemo_mdlref_outdoor_temp`.
7. Hide the dependency viewer legend. Click **Options** and, under **Display**, select the **Legend** check box.
8. Click **Model Instances** to open the model instance view.

You can open this view directly from the Simulink editor by selecting **Analysis > Model Dependencies > Model Dependency Viewer > Referenced Model Instances**.

9 To display full paths in the boxes representing the instances, click **Options** and, under **Display**, select the **Full path** check box. Each box in the instance view displays the path of the Model block corresponding to the instance. The name of the referenced model appears in parentheses.

10 Select the box for `sldemo_mdlref_heat2cost` and click **Highlight Box**. The corresponding block in the `sldemo_mdlref_depgraph` model appears highlighted.

11 In the dependency viewer, double-click the `sldemo_mdlref_heat2cost` box to open the model in the Simulink Editor.

View Linked Requirements in Models and Blocks

In this section...

Requirements Traceability in Simulink

If your Simulink model has links to requirements in external documents, you can review these links. To identify which model objects satisfy certain design requirements, use the following requirements features available in Simulink software:

- Highlighting objects in your model that have links to external requirements
- Viewing information about a requirements link
- Navigating from a model object to its associated requirement
- Filtering requirements highlighting based on specified keywords

Having a Simulink Requirements license enables you to perform the following additional tasks, using the Requirements Management Interface (RMI):

- Adding new requirements
- Changing existing requirements
- Deleting existing requirements
- Applying user tags to requirements
- Creating reports about requirements links in your model
- Checking the validity of the links between the model objects and the requirements documents

Highlight Requirements in a Model

You can highlight a model to identify which objects in the model have links to requirements in external documents. Both the Simulink Editor and the Model Explorer provide this capability.

- "Highlight a Model Using the Simulink Editor" on page 12-62
- "Highlight a Model Using the Model Explorer" on page 12-63

Note If your model contains a Model block whose referenced model contains requirements, those requirements are not highlighted. If you have Simulink Requirements, you can view this information only in requirements reports. To generate requirements information for referenced models and then see highlighted snapshots of those requirements, follow the steps in "Report for Requirements in Model Blocks" (Simulink Requirements).

Highlight a Model Using the Simulink Editor

If you are working in the Simulink Editor and want to see which model objects in the `slvnvdemo_fuelsys_officereq` model have requirements, follow these steps:

1. Open the example model:

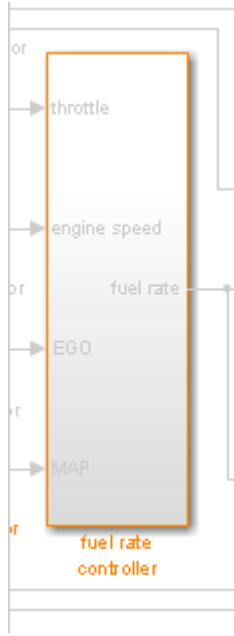
   ```
   slvnvdemo_fuelsys_officereq
   ```

2. Select **Analysis > Requirements Traceability > Highlight Model**.

   Two types of highlighting indicate model objects with requirements:

   - Yellow highlighting indicates objects that have requirements links for the object itself.

     
   - Orange outline indicates objects, such as subsystems, whose child objects have requirements links.



Objects that do not have requirements are colored gray.

3 To remove the highlighting from the model, select **Analysis > Requirements Traceability > Unhighlight Model**. Alternatively, you can right-click anywhere in the model, and select **Remove Highlighting**.

While a model is highlighted, you can still manage the model and its contents.

Highlight a Model Using the Model Explorer

If you are working in Model Explorer and want to see which model objects have requirements, follow these steps:

1 Open the example model:

```
slvnvdemo_fuelsys_officereq
```

2 Select **View > Model Explorer**.

3 To highlight all model objects with requirements, click the **Highlight items with requirements on model** icon ().

The Simulink Editor window opens, and all objects in the model with requirements are highlighted.

Note If you are running a 64-bit version of MATLAB, when you navigate to a requirement in a PDF file, the file opens at the beginning of the document, not at the specified location.

View Information About a Requirements Link

Using Simulink, you can view detailed information about a requirements link, such as identifying the location and type of document that contains the requirement.

Note You can modify the requirements information only if you have a Simulink Requirements license.

For example, to view information about the requirements link from the MAP Sensor block in the `slvnvdemo_fuelsys_officereq` example model, follow these steps:

1 Open the example model:

```
slvnvdemo_fuelsys_officereq
```

2 Right-click the MAP sensor block, and select **Requirements > Edit/Add Links**.

The Requirements dialog box opens and displays the following information about the requirements link:

- The description of the link (which is the actual text of the requirement).
- The Microsoft Excel® workbook named `slvnvdemo_FuelSys_TestScenarios.xlsx`, which contains the linked requirement.
- The requirements text, which appears in the named cell `Simulink_requirement_item_2` in the workbook.

- The user tag `test`, which is associated with this requirement.

Navigate to Requirements from a Model

Navigate from the Model Object

You can navigate directly from a model object to that object's associated requirement. When you take these steps, the external requirements document opens in the application, with the requirements text highlighted.

1. Open the example model:

   ```
   slvnvdemo_fuelsys_officereq
   ```

2. Open the fuel rate controller subsystem.
3. To open the linked requirement, right-click the Airflow calculation subsystem and select **Requirements Traceability > 1. "Mass airflow estimation"**.

   The Microsoft Word document `slvnvdemo_FuelSys_DesignDescription.docx`, opens with the section **2.1 Mass airflow estimation** selected.

Note If you are running a 64-bit version of MATLAB, when you navigate to a requirement in a PDF file, the file opens at the top of the page, not at the bookmark location.

Navigate from a System Requirements Block

Sometimes you want to see all the requirements links at a given level of the model hierarchy. In such cases, you can insert a System Requirements block to collect all requirements links in a model or subsystem. The System Requirements block lists requirements links for the model or subsystem in which it resides; it does not list requirements links for model objects inside that model or subsystem, because those are at a different level of the model hierarchy.

In the following example, you insert a System Requirements block at the top level of the `slvnvdemo_fuelsys_officereq` model, and navigate to the requirements using the links inside the block.

1. Open the example model:

   ```
   slvnvdemo_fuelsys_officereq
   ```

2. In the Simulink Editor, select **Analysis** > **Requirements Traceability** > **Highlight Model**.
3. Open the fuel rate controller subsystem.

   The Airflow calculation subsystem has a requirements link.
4. Open the Airflow calculation subsystem.
5. In the Simulink Editor, select **View** > **Library Browser**.
6. On the **Libraries** pane, select **Simulink Requirements**.

   This library contains only one block—the System Requirements block.
7. Drag a System Requirements block into the Airflow calculation subsystem.

   The RMI software collects and displays any requirements links for that subsystem in the System Requirements block.
8. In the System Requirements block, double-click **1. "Mass airflow subsystem"**.

   The Microsoft Word document, `slvnvdemo_FuelSys_DesignDescription.docx`, opens, with the section **2.1 Mass airflow estimation** selected.

Filter Requirements in a Model

Filtering Requirements Highlighting by User Tag

Some requirements links in your model can have one or more associated user tags. User tags are keywords that you create to categorize a requirement, for example, `design` or `test`.

For example, in the `slvnvdemo_fuelsys_officereq` model, the requirements link from the MAP sensor block has the user tag `test`.

To highlight only all the blocks that have a requirement with the user tag `test`:

1. Open the example model:

   ```
   slvnvdemo_fuelsys_officereq
   ```

2 In the Simulink Editor, select **Analysis** > **Requirements** > **Settings**.

The Requirements Settings dialog box opens. If you do not have a Simulink Requirements license, the **Filters** tab is the only option available.

By default, your model has no requirements filtering enabled.

3 Select **Filter links by user tags when highlighting and reporting requirements**.

4 In the **Include links with any of these tags** text box, delete `design`, and enter `test`.

5 Press **Enter**.

6 Highlight the `slvnvdemo_fuelsys_officereq` model for requirements. Select **Analysis** > **Requirements** > **Highlight Model**.

In the top-level model, only the MAP sensor block and the Test inputs block are highlighted.

7 To disable the filtering by user tag, select **Analysis** > **Requirements** > **Settings**, and clear **Filter links by user tags when highlighting and reporting requirements**.

The model highlighting updates immediately.

Filtering Options for Highlighting Requirements

On the **Filters** tab, you select options that designate which objects with requirements are highlighted. The following table describes these settings, which apply to all requirements in your model for the duration of your MATLAB session.

Option	Description
Filter links by user tags when highlighting and reporting requirements	Enables filtering for highlighting and reporting, based on specified user tags.
Include links with any of these tags	Highlights all objects whose requirements match at least one of the specified user tags. The tag names must match exactly. Separate multiple user tags with commas or spaces.

Option	Description
Exclude links with any of these tags	Excludes from the highlighting all objects whose requirements match at least one of the specified user tags. The tag names must match exactly. Separate multiple user tags with commas or spaces.
Apply same filters in context menus	Disables navigation links in context menus for all objects whose requirements do not match at least one of the specified user tags.
Under **Link type filters**, **Disable DOORS surrogate item links in context menus**	Disables links to IBM® Rational® DOORS® surrogate items from the context menus when you right-click a model object. This option does not depend on current user tag filters.

Trace Connections Using Interface Display

In this section...

How Interface Display Works

In the Simulink Editor, you can turn on and off the display of interfaces in a model. When you are building large, complex models, you can connect or add signal lines between blocks or buses that are at different levels. The interface view allows you to trace signals through the nested levels. This capability helps you to:

- Identify inputs and outputs.
- Trace signal lines and bus elements to sources and terminations.
- Annotate signal characteristics such as data type, dimensions, and sample time.
- View units associated with signals, where applicable.

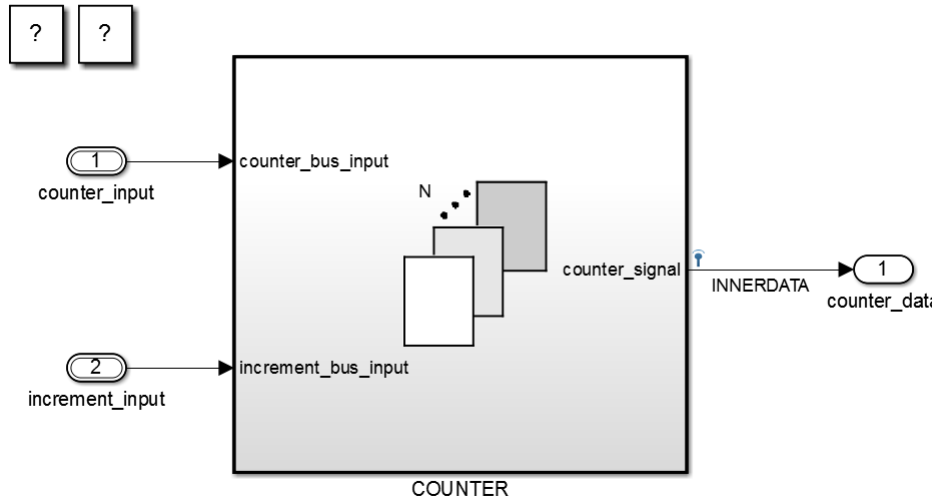
When you build a model, transition block pairs such as Inport and Outport and From and Goto help you to simplify connections of the crossovers among many signal lines. The interface view enables you to trace the hand-off and receipt between such blocks by way of colored highlights.

Trace Connections in a Subsystem

This example shows how to use the display of model interfaces to examine, trace, and understand the flow of signals and buses. This model propagates bus signals into referenced models.

1 Open the model `sldemo_mdlref_counter_bus`.

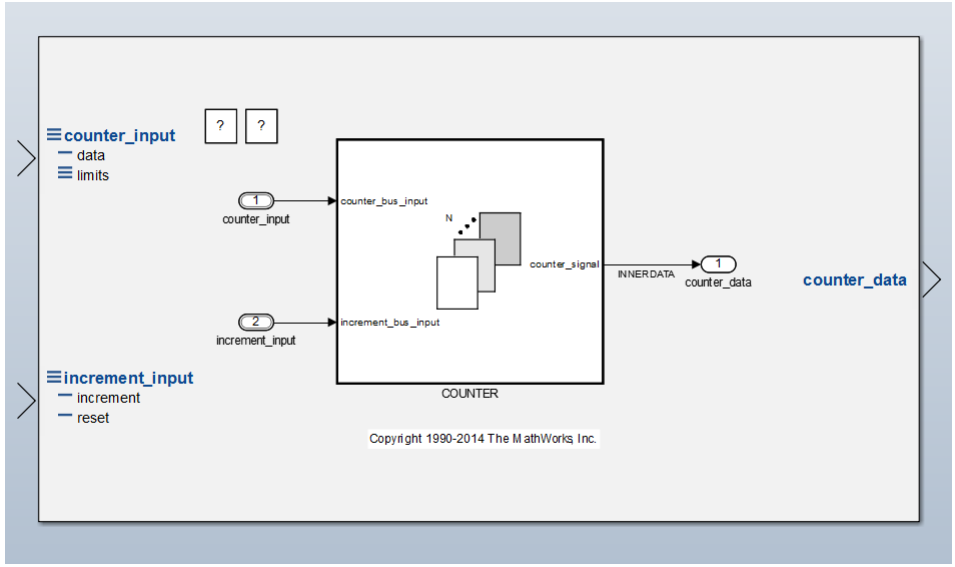
The counter_bus_input port channels the data and saturation limits of the counter to count and sets the upper and lower limit values. The increment_bus_input port channels a bus signal to change the increment and reset the counter.



2 Select **Display** > **Interface** to enable the interface view.

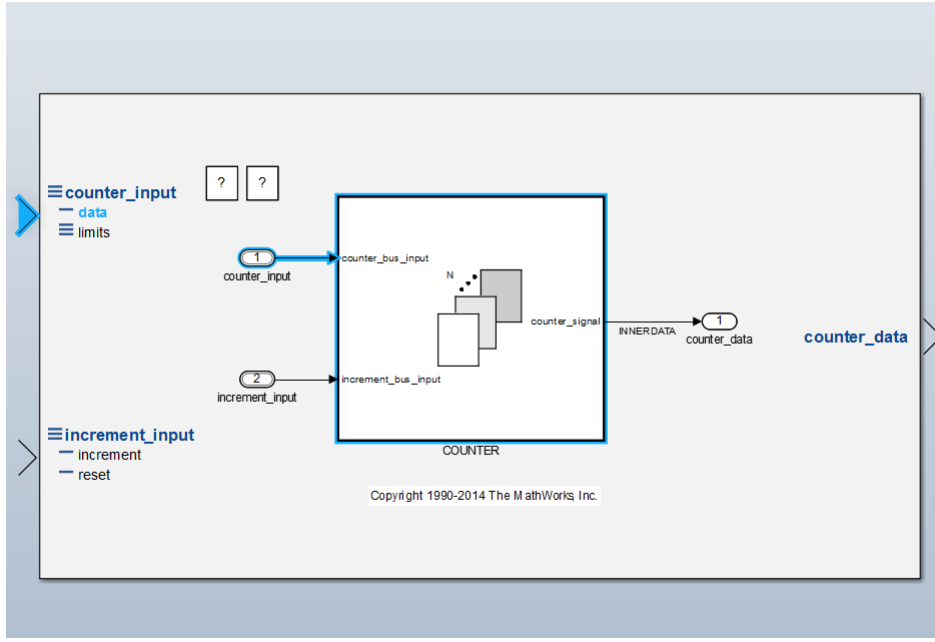
Tip Use the perspectives control in the lower-right corner of the model to toggle the display of interfaces.

The three bars next to the `counter_input` and `increment_input` interfaces indicate the bus input signals. The single bars indicate data lines, such as counts per second, or command lines, such as reset, to start a new counting sequence. The three bars next to `limits` indicate that bus signals are nested inside the COUNTER subsystem.



3 Under `counter_input`, click `data`.

The path for the data appears in blue. The COUNTER subsystem is highlighted, indicating the path continues within it.



4 Double-click the COUNTER subsystem.

The continuation of the path for the data signal appears in blue.

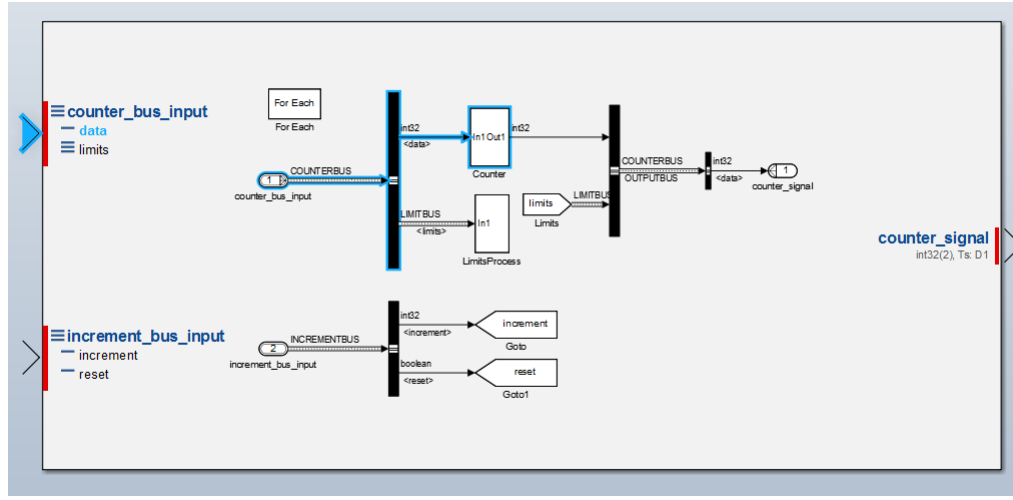
5 Select **Simulation** > **Update Diagram**.

Note This model requires values from a parent model to simulate completely.

The `counter_signal` interface displays these signal attributes, which help you to synchronize signals between blocks during simulation:

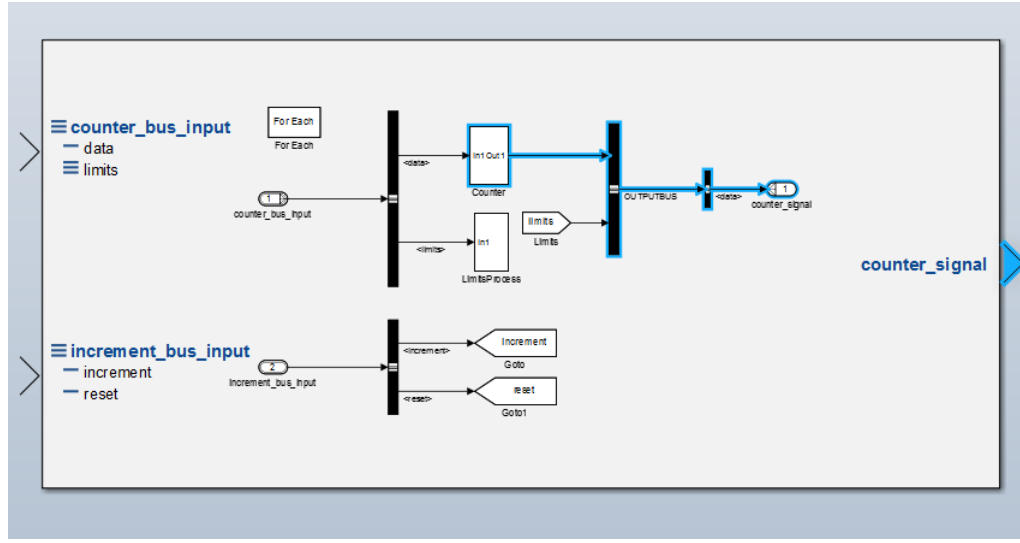
- Data type: int32 (signed 32-bit integer)
- Dimensions: (2) (a 1-D Simulink representation of a scalar)
- Sample time: Ts:D1 (a discrete sample time of D1, which is the highest speed)

In addition, when you update the diagram with interfaces displayed, the model displays the color code for sample time at each interface. For example, this model displays a red bar at each interface to indicate a sample time of D1.



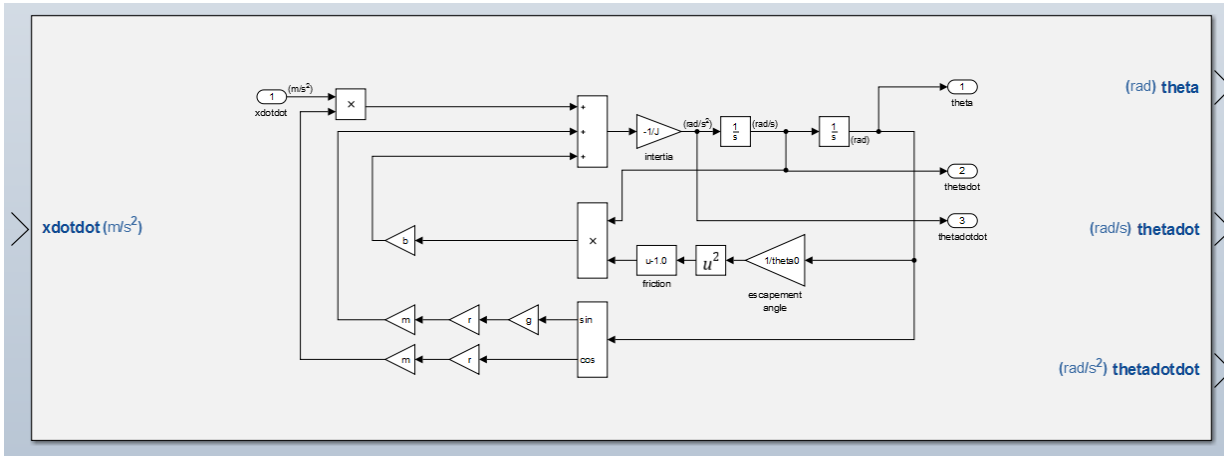
Tip To display a legend of the meaning of sample time colors, select **Display > Sample Time > Colors**.

6 Click the `counter_signal` output interface to see the output of the bus outlined in blue, where the path ends.



7 If you want to print this diagram with the interfaces displayed, select **File** > **Print** > **Print**.

When signals in your model have units associated with them, you see the units in the interface view. For example, in the model `sldemo_metro`, the Metronome1 subsystem shows units for inputs and outputs of the subsystem in the interface view.



To modify the attributes of the existing interface (such as signal names, data types, and dimensions), consider using the Model Data Editor (**View** > **Model Data**). For information about the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 59-141.

See Also

More About

- “Interface Design” on page 22-14
- “What Is Sample Time?” on page 7-2
- “Buses” on page 65-3

Display Signal Attributes at Model Load Time

When working with multiple model components in large models, consider displaying signal attributes at load time without compiling the model. To enable the display, select **Display** > **Signals & Ports** > **Port Data Types** and save the model. The next time you load the model, it displays the data type and complexity signal attributes.

You can use the `ShowPortDataTypes` property to toggle the display of the data type and complexity signal attributes:

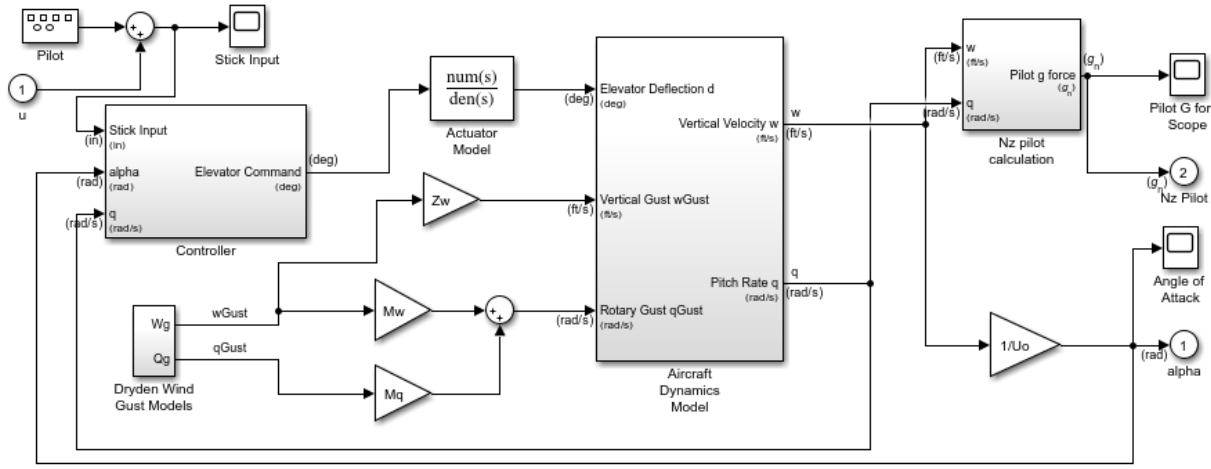
```
set_param(bdroot,'ShowPortDataTypes','on')
set_param(bdroot,'ShowPortDataTypes','off')
```

the `ShowLineDimensions` and `ShowPortUnits` properties then display dimensions and units at load time.

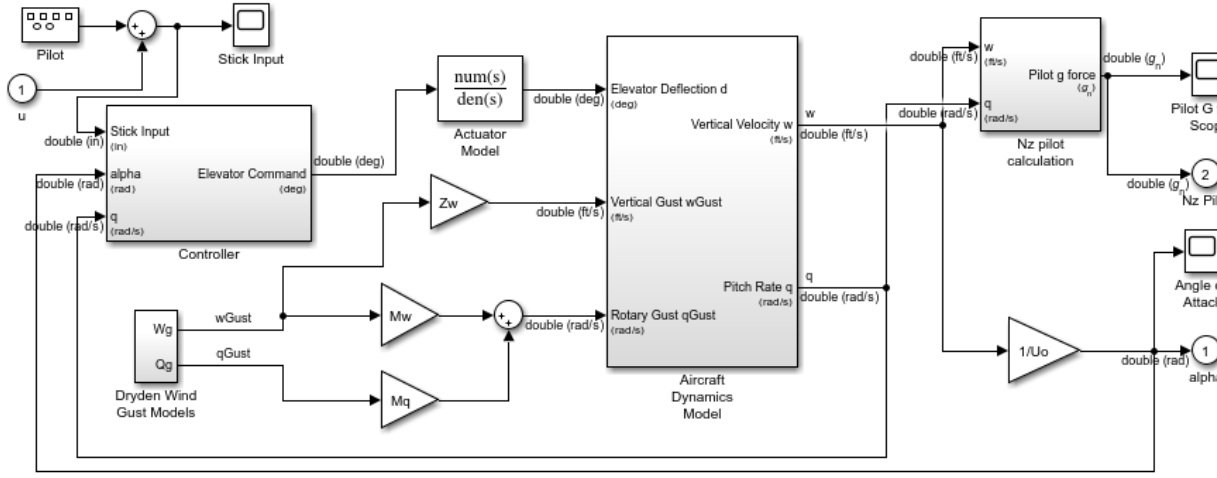
These blocks support the display of signal attributes:

- Inport
- Outport
- Subsystem
- Model
- Signal Specification
- Bus Creator

For example, this model has the show port data types capability disabled.



And this is the same model after the show port data types capability is enabled.



Managing Model Configurations

About Model Configurations

A model configuration is a named set of values for the parameters of a model. It is referred to as a *configuration set on page 13-26*. Every new model is created with a default configuration set, called `Configuration`, that initially specifies default values for the model parameters. You can change the default values for new models by setting the Model Configuration Preferences. For more information, see "Model Configuration Pane".

You can subsequently create and modify additional configuration sets and associate them with the model. The configuration sets associated with a model can specify different values for any or all configuration parameters. For more information, see "About Configuration Sets" on page 13-26. For examples on how to use configuration sets, see:

- "Multiple Configuration Sets in a Model" on page 13-3
- "Manage a Configuration Set" on page 13-11

By default, a configuration set resides within a single model so that only that model can use it. Alternatively, you can store a configuration set independently, so that other models can use it. A configuration set that exists outside any model is a freestanding configuration set on page 13-27. Each model that uses a freestanding configuration set defines a configuration reference on page 13-29 that points to the freestanding configuration set. A freestanding configuration set allows you to single-source a configuration set for several models. For more information, see "About Configuration References" on page 13-29. For examples on how to use configuration references, see:

- "Share a Configuration for Multiple Models" on page 13-4
- "Share a Configuration Across Referenced Models" on page 13-6
- "Manage a Configuration Reference" on page 13-18

- "Hardware Implementation Pane"

Multiple Configuration Sets in a Model

A model can include many different configuration sets. This capability is useful if you want to compare the difference in simulation output after changing the values of several parameters. Attaching additional configuration sets allows you to quickly switch the active configuration.

1. To create additional configuration sets in your model, in the Model Explorer, select your model node in the Model Hierarchy pane and do one of the following:
   - Right-click the model node and select **Configuration > Add Configuration**.
   - Right-click an existing configuration set. In the context menu, select **Copy**.
2. To import a previously saved configuration set, right-click the model node and select **Configuration > Import**. In the Import Configuration From File dialog box, select a configuration file.
3. To modify the newly added configuration set, in the Model Hierarchy pane, select the configuration node. In the **Contents** pane, select a component, and then modify any parameters which are displayed in the right pane.
4. To make the new configuration set the active configuration, in the configuration set context menu, select **Activate**. In the Model Hierarchy pane, the new configuration set name is now displayed as `(Active)`.
5. To simulate your model using a different configuration set, switch the active configuration by repeating step 4.

See Also

Related Examples

- "Manage a Configuration Set" on page 13-11
- "Model Configuration Command Line Interface" on page 13-33

Share a Configuration for Multiple Models

With configuration references, multiple models can share a configuration set. To share a configuration set between models, store the configuration set as a configuration set object in the base workspace. Then create a configuration reference in your model that references the configuration set object. You can create configuration references in other models that also point to the same configuration set object.

Note Before saving and closing your models, follow the instructions to "Save a Referenced Configuration Set" on page 13-23. If you do not save the referenced configuration set from the base workspace, when you reopen your model, the configuration reference is unresolved.

Convert an Existing Configuration Set to a Configuration Reference

To convert an existing configuration set in your model to a configuration reference:

1. Open the Model Explorer.
2. In the Model Hierarchy pane, right-click the active configuration set to share.
3. In the configuration set context menu, select **Convert to Configuration Reference**, which opens a dialog box. Alternatively, you can right-click the model node and select **Configuration > Convert Active Configuration to Reference**.
4. In the Convert Active Configuration to Reference dialog box, use the default configuration set object name, `configSetObj`, or type a name.
5. Click **OK**, which creates a configuration reference in the model and a configuration set object in the base workspace. The configuration reference points to the configuration set object, which has the same values as the original active configuration set. The configuration reference name in the Model Hierarchy is now marked as `(Active)`.
6. To change the name of the configuration reference, select it in the Model Hierarchy, and in the right pane, change the **Name** field.

Create a Configuration Reference in Another Model

To share the preceding configuration set, which is stored as `configSetObj` in the base workspace, create a configuration reference in another model:

1. In the Model Hierarchy pane, right-click the model node.
2. In the context menu, select **Configuration > Add Configuration Reference**.
3. The Create Configuration Reference dialog box opens. Specify the name of the configuration set object, `configSetObj`, in the base workspace.
4. To make the new configuration reference the active configuration, in the Model Hierarchy, right-click the configuration reference. In the context menu, select **Activate**.

Both models now contain a configuration reference that points to the same configuration set object in the base workspace. To set up your model to automatically load the configuration set object, see "Callbacks for Customized Model Behavior" on page 4-44.

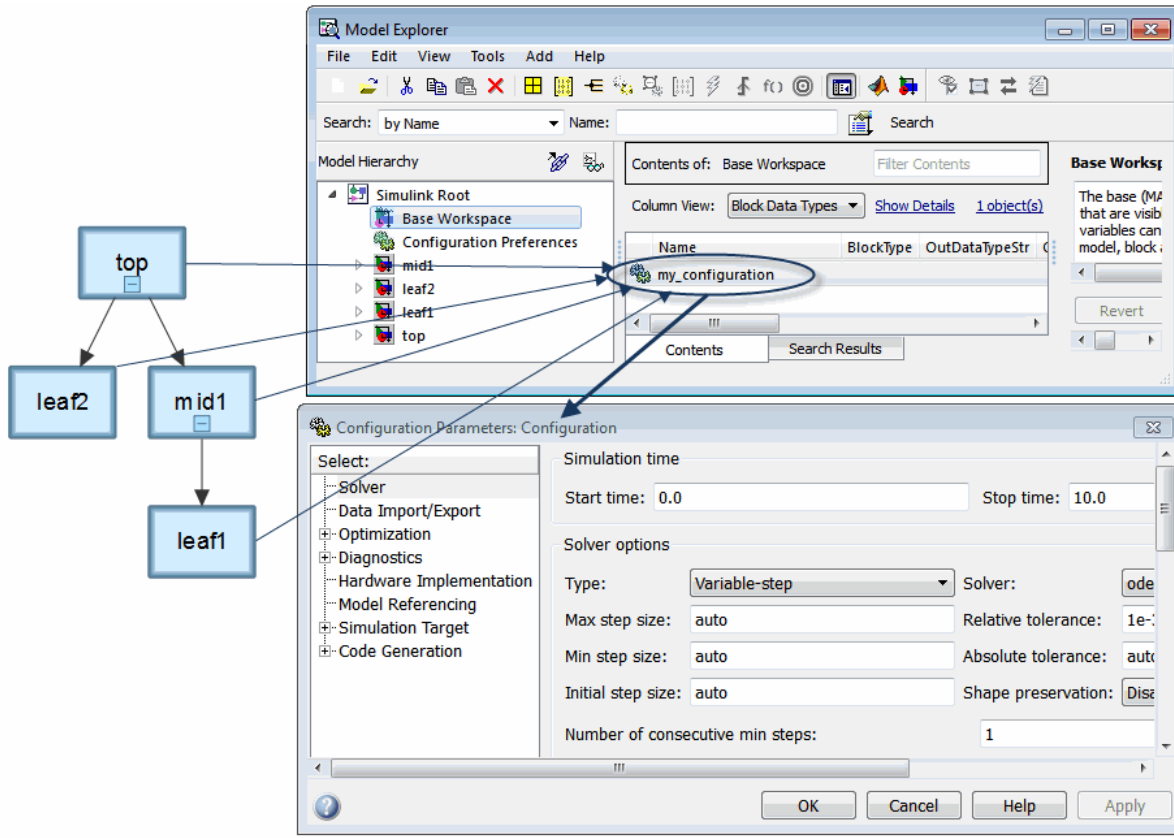
- "Share a Configuration Across Referenced Models" on page 13-6

More About

- "About Configuration References" on page 13-29

Share a Configuration Across Referenced Models

This example shows how to share the same configuration set for the top model and referenced models in a model reference hierarchy. You can use a configuration reference in each of the models to reference the same configuration set object in the base workspace.

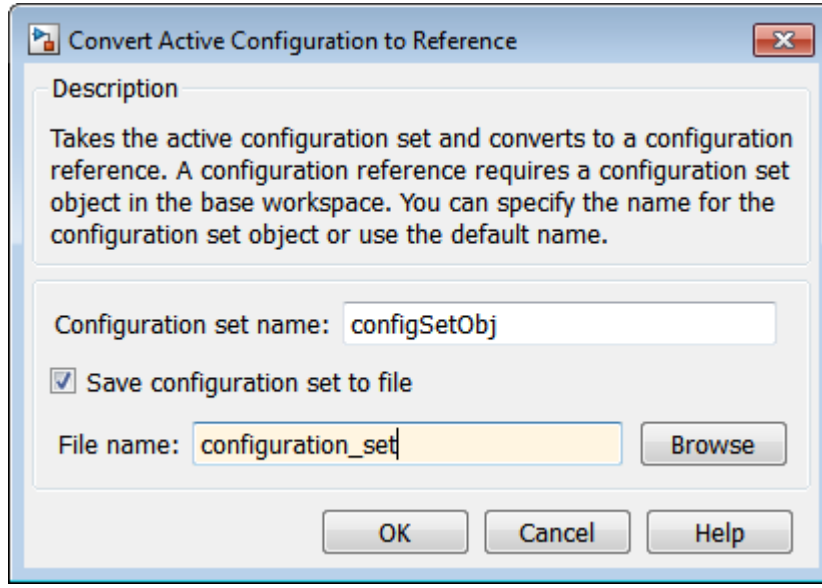


In the diagram, each model shown in the Model Dependency Viewer specifies the configuration reference, `my_configuration`, as its active configuration set. `my_configuration` points to the freestanding configuration set, `Configuration`. Therefore, the parameter values in `Configuration` apply to all four models. Any parameter change in `Configuration` applies to all four models.

Convert Configuration Set to Configuration Reference

In the top model, you must convert the active configuration set to a configuration reference:

1. Open the `sldemo_mdlref_depgraph` model and the Model Explorer.
2. In the Model Hierarchy pane, expand the top model, `sldemo_mdlref_depgraph`. In the list, right-click `Configuration (Active)`. In the context menu, select **Convert to Configuration Reference**.
3. In the **Configuration set name** field, specify a name for the configuration set object, or use the default name, `configSetObj`. This configuration set object is stored in the base workspace.
4. Optionally, you can save the configuration set to a MAT-file. Select **Save configuration set to file**. This enables the **File name** parameter.
5. In the **File name** field, specify a name for the MAT-file.



6. Click **OK**.

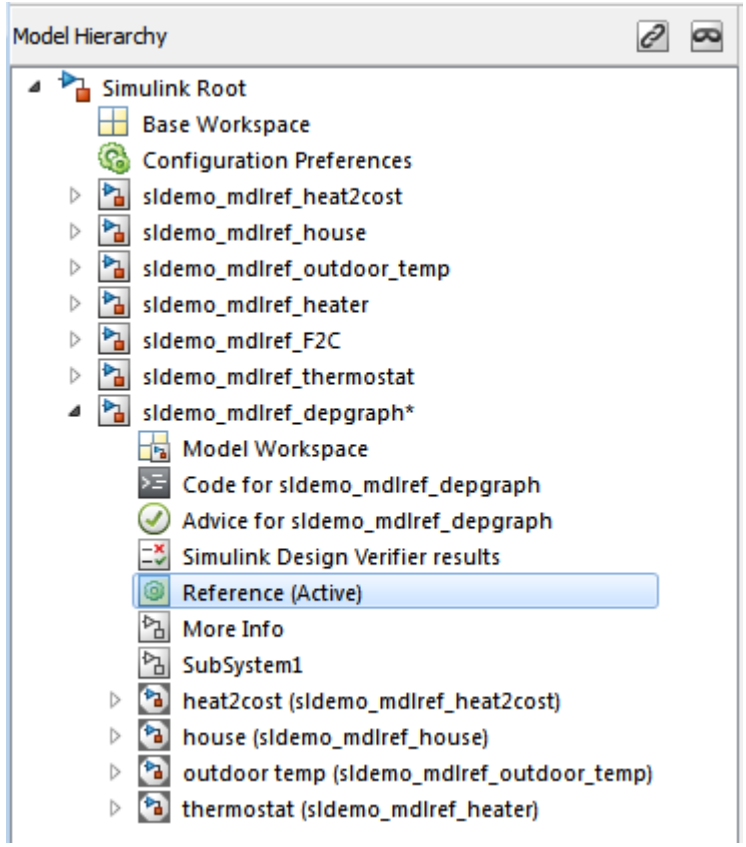
The original configuration set is now stored as a configuration set object, `configSetObj`, in the base workspace. The configuration set is also stored in a MAT-file, `configuration_set.mat`. The active configuration for the top model is now a

configuration reference. This configuration reference points to the configuration set object in the base workspace.

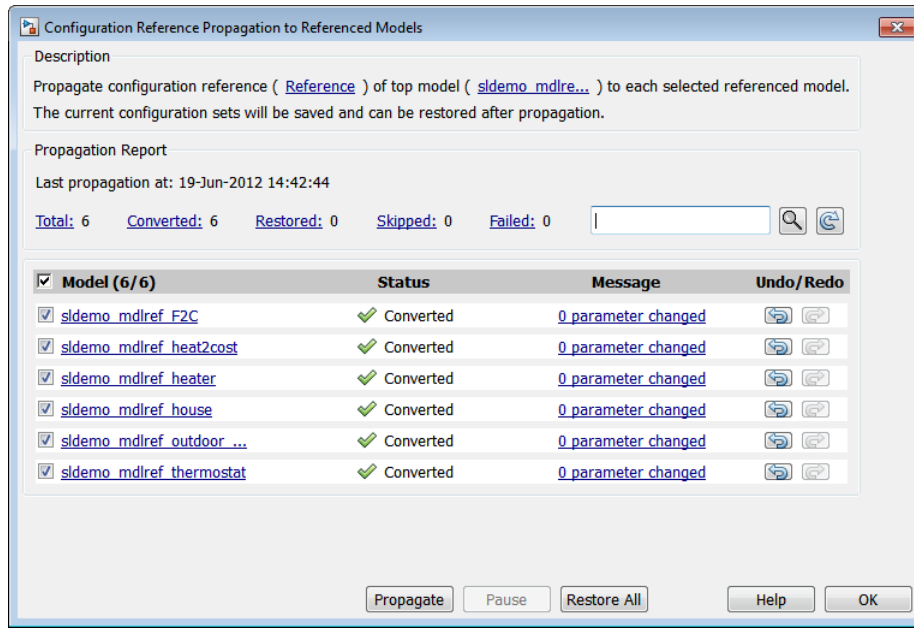
Propagate a Configuration Reference

Now that the top model contains an active configuration reference, you can propagate this configuration reference to all of the child models. Propagation creates a copy of the top model configuration reference in each referenced model. For each referenced model, the configuration reference is now the active configuration. The configuration references point to the configuration set object, `configSetObj`, in the base workspace.

1 In the Model Explorer, in the Model Hierarchy pane, expand the `sldemo_mdlref_depgraph` node.



2. Right-click the active configuration reference, **Reference (Active)**. In the context menu, select **Propagate to Referenced Models**.
3. In the Configuration Reference Propagation dialog box, select the check box for each referenced model. In this example, they are already selected.
4. Verify that your current folder is a writable folder. The propagation mechanism saves the original configuration parameters for each referenced model so that you can undo the propagation. Click **Propagate**.
5. In the Propagation Confirmation dialog box, click **OK**.
6. In the Configuration Reference Propagation dialog box, the Propagation Report is updated and the **Status** for each referenced model is marked as `Converted`.



Undo a Configuration Reference Propagation

After propagating a configuration reference from a top model to the referenced models, you can undo the propagation for all referenced models by clicking **Restore All**. If you want to undo the propagation for individual referenced models, in the **Undo/Redo** column, click the **Undo** button. The Propagation Report is updated and the **Status** for the referenced model is set to `Restored`.

Related Examples

- “Manage a Configuration Reference” on page 13-18
- “Model Configuration Command Line Interface” on page 13-33

More About

- “About Configuration References” on page 13-29

Manage a Configuration Set

In this section...

Create a Configuration Set in a Model

1. Open the Model Explorer.
2. In the Model Hierarchy pane, select the model name.
3. You can create a new configuration set in any of the following ways:
   - From the **Add** menu, select **Configuration**.
   - On the toolbar, click the **Add Configuration** button  .
   - In the Model Hierarchy pane, right-click an existing configuration set and copy and paste the configuration set.

Create a Configuration Set in the Base Workspace

1. Open the Model Explorer.
2. In the Model Hierarchy pane, select **Base Workspace**.
3. You can create a new configuration set object in the following ways:
   - From the **Add** menu, select **Configuration**

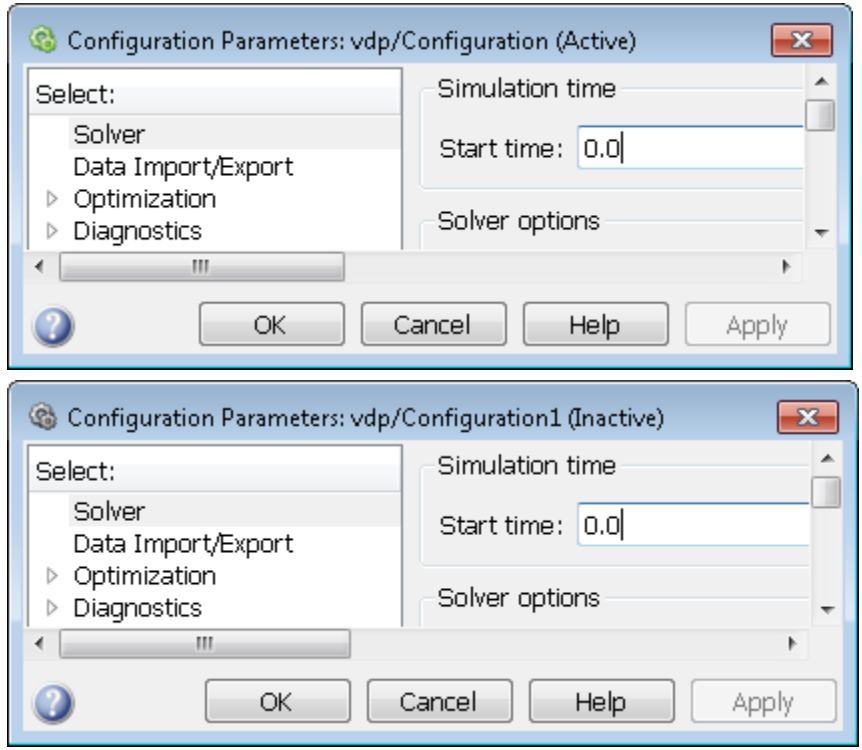
- In the toolbar, click the **Add Configuration** button 

4 The configuration set object appears in the Contents pane, with the default name, `ConfigSet`.

Open a Configuration Set in the Configuration Parameters Dialog Box

In the Model Explorer, to open the Configuration Parameters dialog box for a configuration set, right-click the configuration set's node to display the context menu, then select **Open**. You can open the Configuration Parameters dialog box for any configuration set, whether or not it is active.

The title bar of the dialog box indicates whether the configuration set is active or inactive.



Note Every configuration set has its own Configuration Parameters dialog box. As you change the state of a configuration set, the title bar of the dialog box changes to reflect the state.

Activate a Configuration Set

Only one configuration set associated with a model is active at any given time. The active set determines the current values of the model parameters. You can change the active or inactive set at any time (except when executing the model). In this way, you can quickly reconfigure a model for different purposes, for example, testing and production, or apply standard configuration settings to new models.

To activate a configuration set, right-click the configuration set node to display the context menu, then select **Activate**.

Set Values in a Configuration Set

To set the value of a parameter in a configuration set, in the Model Explorer:

1. In the Model Hierarchy, select the configuration set node.
2. In the Contents pane, select the component from where the parameter resides.
3. In the Dialog pane, edit the parameter value.

Copy, Delete, and Move a Configuration Set

You can use edit commands on the Model Explorer **Edit** or context menus or object drag-and-drop operations to delete, copy, and move configuration sets among models displayed in the **Model Hierarchy** pane.

For example, to copy a configuration set from one model to another:

1. In the **Model Hierarchy** pane, right-click the configuration set node that you want to copy.
2. Select **Copy** in the configuration set context menu.
3. Right-click the model node in which you want to create the copy.
4. Select **Paste** from the model context menu.

To copy the configuration set using object drag-and-drop, hold down the right mouse button and drag the configuration set node to the node of the model in which you want to create the copy.

To move a configuration set from one model to another using drag-and-drop, hold the left mouse button down and drag the configuration set node to the node of the destination model.

Note You cannot move or delete an active configuration set from a model.

Save a Configuration Set

You can save the settings of configuration sets as MATLAB functions or scripts. Using the MATLAB function or script, you can share and archive model configuration sets. You can also compare the settings in different configuration sets by comparing the MATLAB functions or scripts of the configuration sets.

To save an active or inactive configuration set from the Model Explorer:

1. Open the model.
2. Open the Model Explorer.
3. Save the configuration set:
   a. In the **Model Hierarchy** pane:
      - Right-click the model node and select **Configuration > Export Active Configuration Set**.
      - Right-click a configuration set and select **Export**.
      - Select the model. In the **Contents** pane, right-click a configuration set and select **Export**.
   b. In the Export Configuration Set to File dialog box, specify the name of the file and the file type. If you specify a `.m` extension, the file contains a function that creates a configuration set object. If you specify a `.mat` extension, the file contains a configuration set object.

      Note Do not specify the name of the file to be the same as a model name. If the file and model have the same name, the software cannot determine which file contains the configuration set object when loading the file.

c Click **Save**. The Simulink software saves the configuration set.

Load a Saved Configuration Set

You can load configuration sets that you previously saved as MATLAB functions or scripts.

To load a configuration set from the Model Explorer:

1 Open the model.

2 Open the Model Explorer.

3 In the **Model Hierarchy** pane, right-click the model and select **Configuration > Import**.

4 In the Import Configuration Set From File dialog box, select the `.m` file that contains the function to create the configuration set object, or the `.mat` file that contains the configuration set object.

5 Click **Open**. The Simulink software loads the configuration set.

Note

- If you load a configuration set object that contains an invalid custom target, the software sets the "System target file" (Simulink Coder) parameter to `ert.tlc`.
- If you load a configuration set that contains a component that is not available on your system, the parameters in the missing component are reset to their default values.

---

6 Optionally, activate the configuration set. For more information, see "Activate a Configuration Set" on page 13-13.

Copy Configuration Set Components

To copy a configuration set component from one configuration set to another:

1 Select the component in the Model Explorer **Contents** pane.

2 From either the Model Explorer **Edit** menu or the component context menu, select **Copy**.

3 Select the configuration set into which you want to copy the component.

4 From either the Model Explorer **Edit** menu or the component context menu, select **Paste**.

Note The copy replaces the component of the same name in the destination configuration set. For example, if you copy the Solver component of configuration set A and paste it into configuration set B, the copy replaces the existing Solver component in B.

Compare Configuration Sets

You can visually compare two configuration sets using the `visdiff` function. This function opens the Comparison Tool and presents the differences between the two files. Alternatively, you can select a pair of models to compare. See "Compare Simulink Models" on page 21-7.

1 Get the first configuration set for a model.

```
cs = getConfigSet('model_name','config_set_1_name');
```

2 Save the configuration set to a MAT-file.

```
save('configSet1.mat','cs');
```

3 Get the second configuration set for the model.

```
cs = getConfigSet('model_name','config_set_2_name');
```

4 Save the second configuration set to a MAT-file.

```
save('configSet2.mat','cs');
```

5 Compare the files.

```
visdiff('configSet1.mat','configSet2.mat');
```

For more information on using the Comparison Tool to compare MAT-files, see "Comparing MAT-Files" (MATLAB).

Manage a Configuration Reference

In this section...

Create and Attach a Configuration Reference

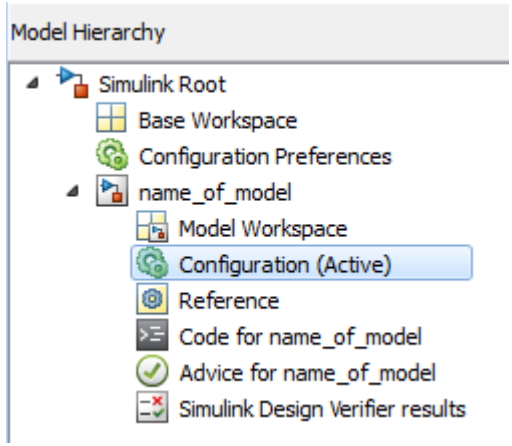
To use a configuration reference on page 13-29, it must point to freestanding configuration set on page 13-27. Create a freestanding configuration set before creating a configuration reference, see “Create a Configuration Set in the Base Workspace” on page 13-11.

To create a configuration reference:

1. In the Model Explorer, in the Model Hierarchy pane, select the model.
2. Click the **Add Reference** tool  or select **Add** > **Configuration Reference**. The Create Configuration Reference dialog box opens.
3. Specify the **Configuration set name** of the configuration set object in the base workspace to be referenced.
4. Click **OK**. If you chose to create a configuration reference without first creating a configuration set object, a dialog box opens asking if you would like to continue. If you choose:

   - **Yes**, an unresolved configuration reference is created. For more information, see “Unresolved Configuration References” on page 13-30. Follow the instructions in “Resolve a Configuration Reference” on page 13-19.
   - **No**, then the configuration reference is not created. Follow the instructions in “Create a Configuration Set in the Base Workspace” on page 13-11, and then return to step 1 above.

5 A new configuration reference appears in the Model Hierarchy under the selected model. The default name of the new reference is `Reference`.



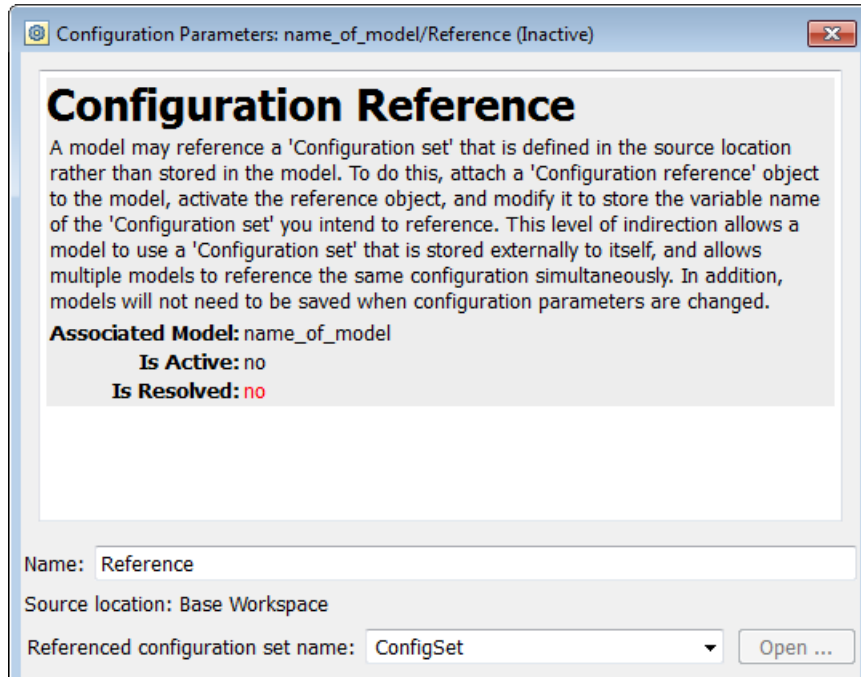
Resolve a Configuration Reference

An unresolved configuration reference on page 13-30 is a configuration reference that is not pointing to a valid configuration set object.

To resolve a configuration reference:

1 In the Model Hierarchy pane, select the unresolved configuration reference or right-click the configuration reference, and select **Open** from the context menu.

The Configuration Reference dialog box opens in the Dialog pane or a separate window.

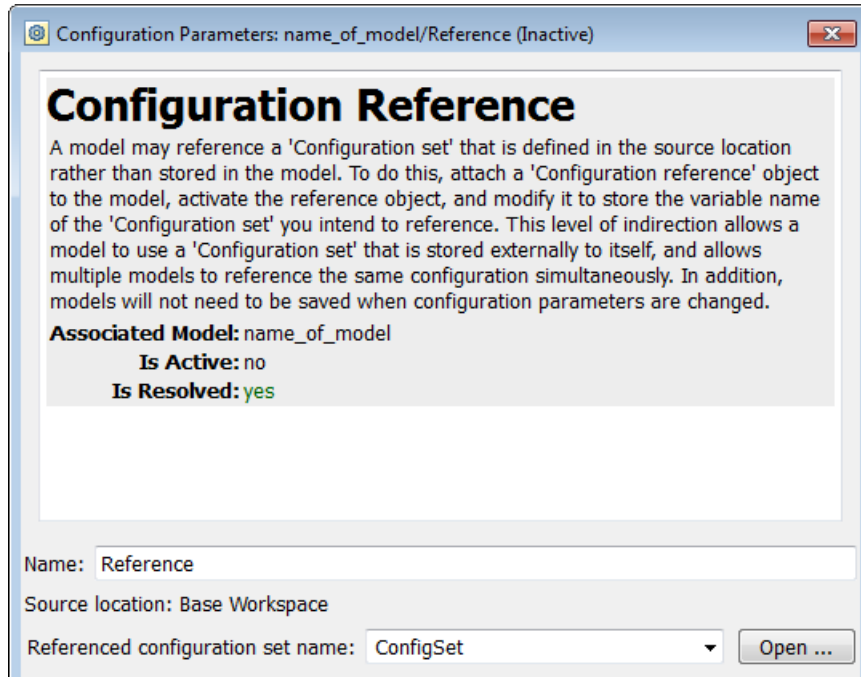


2 Specify the **Referenced configuration** set to be a configuration set object already in the base workspace. If one does not exist, see "Create a Configuration Set in the Base Workspace" on page 13-11.

Tip Do not specify the name of a configuration reference. If you nest a configuration reference, an error occurs.

3 Click **OK** or **Apply**.

If you specified a Referenced configuration that exists in the base workspace, the **Is Resolved** field in the dialog box changes to `yes`.

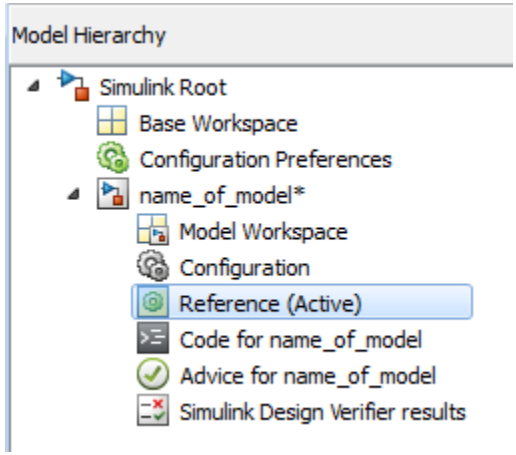


Activate a Configuration Reference

After you create a configuration reference and attach it to a model, you can activate it so that it is the active configuration.

- In the GUI, from the context menu of the configuration reference, select **Activate**.
- From the API, execute `setActiveConfigSet`, specifying the configuration reference as the second argument.

When a configuration reference is active, the **Is Active** field of the Configuration Reference dialog box changes to `yes`. Also, the Model Explorer shows the name of the reference with the suffix `(Active)`.



The freestanding configuration set of the active reference now provides the configuration parameters for the model.

Manage Configuration Reference Across Referenced Models

In a model hierarchy, you can share a configuration reference across referenced models. Using the Configuration Reference Propagation dialog box, you can propagate a configuration reference of a top model to an individual referenced model or to all referenced models in the model hierarchy. The dialog box provides:

- A list of referenced models in the top model.
- The ability to select only specific referenced models for propagation.
- After propagation, the status for the converted configuration for each referenced model.
- A view of the changed parameters after the propagation.
- The ability to undo the configuration reference and restore the previous configuration settings for a referenced model.

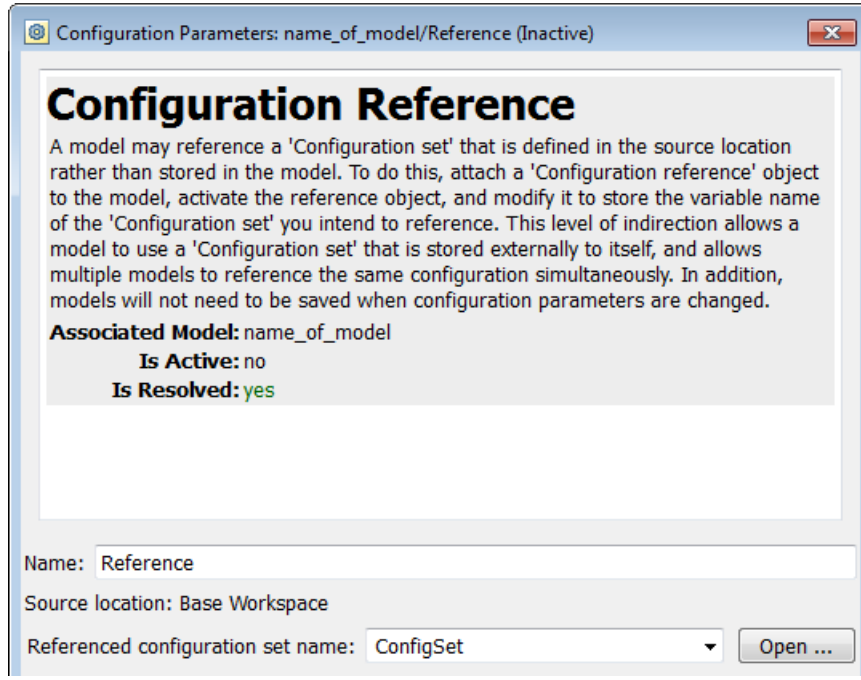
To open the dialog box, in the Model Explorer, in the model hierarchy pane, right-click the configuration reference node of a model. In the context menu, select `Propagate to Referenced Models`. For an example, see “Share a Configuration Across Referenced Models” on page 13-6.

Change Parameter Values in a Referenced Configuration Set

To obtain a referenced configuration set:

1 In the Model Hierarchy pane, select the configuration reference, or right-click the configuration reference, and select **Open** from the context menu.

The Configuration Reference dialog box appears in the Dialog pane or in a separate window.



2 To the right of the **Referenced configuration** field, click **Open**. The Configuration Parameters dialog box opens. You can now change and apply parameter values as you would for any configuration set.

Save a Referenced Configuration Set

If your model uses a configuration reference to specify the model configuration, before closing your model, you need to save the referenced configuration set to a MAT-file or MATLAB script.

1. In the Model Explorer, in the Model Hierarchy, select **Base Workspace**.
2. In the Contents pane, right-click the name of the referenced configuration set object.
3. From the context menu, select **Export Selected**.
4. Specify the filename for saving the configuration set as either a MAT-file or a MATLAB script.

Tip When you reopen the model you must load the saved configuration set, otherwise, the configuration reference is unresolved. To set up your model to automatically load the configuration set object, see "Callbacks for Customized Model Behavior" on page 4-44.

Load a Saved Referenced Configuration Set

If your model uses a configuration reference to specify the model configuration, you need to load the referenced configuration set from a MAT-file or MATLAB script to the base workspace.

1. In the Model Explorer, in the Model Hierarchy, right-click **Base Workspace**.
2. From the context menu, select **Import**.
3. Specify the filename for the saved configuration set and select OK. The configuration set object appears in the base workspace.

Tip When you reopen the model you must load the saved configuration set, otherwise, the configuration reference is unresolved. To set up your model to automatically load the configuration set object, see "Callbacks for Customized Model Behavior" on page 4-44.

More About

- “About Configuration References” on page 13-29

About Configuration Sets

In this section...

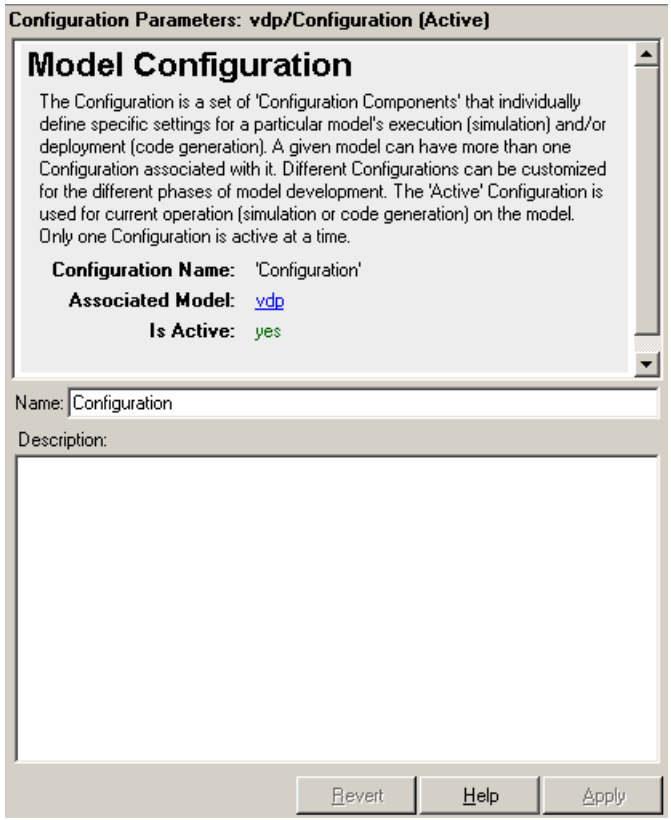
What Is a Configuration Set?

A configuration set comprises groups of related parameters called components. Every configuration set includes the following components:

- Solver
- Data Import/Export
- Optimization
- Diagnostics
- Hardware Implementation
- Model Referencing
- Simulation Target

Some MathWorks products that work with Simulink, such as Simulink Coder, define additional components. If such a product is installed on your system, the configuration set also contains the components that the product defines.

When you select any model configuration, the Model Configuration dialog appears in the Model Explorer **Dialog** pane. In this location, you can edit the name and description of your configuration.



Tip If you want to reuse the same configuration settings in new models, use a model template. See "Use Customized Settings When Creating New Models" on page 1-8.

What Is a Freestanding Configuration Set?

A freestanding configuration set is a configuration set object, `Simulink.ConfigSet`, stored in the base workspace. To use a freestanding configuration set as the configuration for a model, you must create a configuration reference in the model that references it. You can create a freestanding configuration set in the base workspace in these ways:

- Create a new configuration set object.

- Copy a configuration set that resides within a model to the base workspace.
- Load a configuration set from a MAT-file.

You can store any number of configuration sets in the base workspace by assigning each set to a different MATLAB variable.

Note Although you can store a configuration set in a model and point to it with a base workspace variable, such a configuration set is not freestanding. Using it in a configuration reference causes an error.

About Configuration References

In this section...

What Is a Configuration Reference?

A configuration reference in a model is a reference to a configuration set object in the base workspace. A model that has a configuration reference that points to a freestanding configuration set on page 13-27 uses that configuration set when configuration reference is active. The model then has the same configuration parameters as if the referenced configuration set resides directly in the model.

You can attach any number of configuration references to a model. Each reference must have a unique name. For more information, see “Why Use Configuration References?” on page 13-29. For an example on how to use configuration references, see “Share a Configuration for Multiple Models” on page 13-4 or “Create and Attach a Configuration Reference” on page 13-18.

Tip Save or export the configuration set object. Otherwise, when you reopen your model the configuration reference is unresolved. To set up your model to automatically load the configuration set object, see “Callbacks for Customized Model Behavior” on page 4-44.

Why Use Configuration References?

You can use configuration references and freestanding configuration sets to:

- **Assign the same configuration set to any number of models**

  Each model that uses a given configuration set contains a configuration reference that points to a MATLAB variable. The value of that variable is a freestanding

configuration set. All the models share that configuration set. Changing the value of any parameter in the set changes it for every model that uses the set. Use this feature to reconfigure many referenced models quickly and ensure consistent configuration of parent models and referenced models.

- **Replace the configuration sets of any number of models without changing the model files**

  When multiple models use configuration references to access a freestanding configuration set, assigning a different set to the MATLAB variable assigns that set to all models. Use this feature to maintain a library of configuration sets and assign them to any number of models in a single operation.

- **Use different configuration sets for a referenced model used in different contexts without changing the model file**

  A referenced model that uses different configuration sets in different contexts contains a configuration reference that specifies the referenced model configuration set as a variable. When you call an instance of the referenced model, Simulink software assigns that variable a freestanding configuration set for the current context.

Unresolved Configuration References

When a configuration reference does not reference a valid configuration set, the **Is Resolved** field of the Configuration Reference dialog box has the value `no`. If you activate an unresolved configuration reference, no warning or error occurs. However, an unresolved configuration reference that is active provides no configuration parameter values to the model. Therefore:

- Fields that display values known only by accessing a configuration parameter, like Stop Time in the model window, are blank.
- Trying to build the model, simulate it, generate code for it, or otherwise require it to access configuration parameter values, causes an error.

For more information, see “Resolve a Configuration Reference” on page 13-19.

Configuration Reference Limitations

- You cannot nest configuration references. Only one level of indirection is available, so a configuration reference cannot link to another configuration reference. Each reference must specify a freestanding configuration set on page 13-27.

- If you activate a configuration reference when using a custom target, the `ActivateCallback` function does not trigger to notify the corresponding freestanding configuration set. Likewise, if a freestanding configuration set switches from one target to another, the `ActivateCallback` function does not trigger to notify the new target. This behavior occurs, even if an active configuration reference points to that target. For more information about `ActivateCallback` functions, see "rtwgensettings Structure" (Simulink Coder) in the Simulink Coder documentation.

Configuration References for Models with Older Simulation Target Settings

Suppose that you have a nonlibrary model that contains one of these blocks:

- MATLAB Function
- Stateflow chart
- Truth Table
- Attribute Function

In R2008a and earlier, this type of nonlibrary model does not store simulation target (or `sfun`) settings in the configuration parameters. Instead, the model stores the settings outside any configuration set.

When you load this older type of model, the simulation target settings migrate to parameters in the active configuration set.

- If the active configuration set resides internally with the model, the migration happens automatically.
- If the model uses an active configuration reference to point to a configuration set in the base workspace, the migration process is different.

The following sections describe the two types of migration for nonlibrary models that use an active configuration reference.

Default Migration Process That Disables the Configuration Reference

Because multiple models can share a configuration set in the base workspace, loading a nonlibrary model cannot automatically change any parameter values in that configuration set. By default, these actions occur during loading of a model to ensure that simulation results are the same, no matter which version of the software that you use:

- A copy of the configuration set in the base workspace attaches to the model.
- The simulation target settings migrate to the corresponding parameters in this new configuration set.
- The new configuration set becomes active.
- The old configuration reference becomes inactive.

A warning message appears in the MATLAB Command Window to describe those actions. Although this process ensures consistent simulation results for the model, it disables the configuration reference that links to the configuration set in the base workspace.

Model Configuration Command Line Interface

In this section...

Overview

An application programming interface (API) lets you create and manipulate configuration sets at the command line or in a script. The API includes the `Simulink.ConfigSet` and `Simulink.ConfigSetRef` classes and the following functions:

- `attachConfigSet`
- `attachConfigSetCopy`
- `detachConfigSet`
- `getConfigSet`
- `getConfigSets`
- `setActiveConfigSet`
- `getActiveConfigSet`
- `openDialog`
- `closeDialog`
- `Simulink.BlockDiagram.saveActiveConfigSet`
- `Simulink.BlockDiagram.loadActiveConfigSet`

These functions, along with the methods and properties of `Simulink.ConfigSet` class, allow you to create a script to:

- Create and modify configuration sets.
- Attach configuration sets to a model.
- Set the active configuration set for a model.
- Open and close configuration sets.
- Detach configuration sets from a model.
- Save configuration sets.
- Load configuration sets.

For examples using the preceding functions and the `Simulink.ConfigSet` class, see the function and class reference pages.

Load and Activate a Configuration Set at the Command Line

To load a configuration set from a MATLAB function or script:

1. Use the `getActiveConfigSet` or `getConfigSet` function to get a handle to the configuration set that you want to update.
2. Call the MATLAB function or execute the MATLAB script to load the saved configuration set.
3. Optionally, use the `attachConfigSet` function to attach the configuration set to the model. To avoid configuration set naming conflicts, set *`allowRename`* to `true`.
4. Optionally, use the `setActiveConfigSet` function to activate the configuration set.

Alternatively, to load a configuration set at the command line and make it the active configuration set:

1. Open the model.
2. Use the `Simulink.BlockDiagram.loadActiveConfigSet` function to load the configuration set and make it active.

Note If you load a configuration set with the same name as the:

- Active configuration set, the software overwrites the active configuration set.

- Inactive configuration set that is associated with the model, the software detaches the inactive configuration from the model.

Save a Configuration Set at the Command Line

To save an active or inactive configuration set as a MATLAB function or script:

1. Use the `getActiveConfigSet` or `getConfigSet` function to get a handle to the configuration set.
2. Use the `saveAs` method of the `Simulink.Configset` class to save the configuration set as a function or script.

Alternatively, to save the active configuration set:

1. Open the model.
2. Use the `Simulink.BlockDiagram.saveActiveConfigSet` function to save the active configuration set.

Create a Freestanding Configuration Set at the Command Line

Copy a Configuration Set Stored in a Model

Create a freestanding configuration set on page 13-27 to be referenced by a configuration reference in several models. You must copy any configuration set obtained from an existing model, otherwise, *`cset`* refers to the existing configuration set stored in the model, rather than a new freestanding configuration set in the base workspace. For example, use one of the following:

- `cset = copy (getActiveConfigSet(model))`
- `cset = copy (getConfigSet(model, ConfigSetName))`

`model` is any open model, and *`ConfigSetName`* is the name of any configuration set attached to the model.

Read a Configuration Set from a MAT-File

To use a freestanding configuration set across multiple MATLAB sessions, you can save it to a MAT-file. To create the MAT-file, you first copy the configuration set to a base workspace variable, then save the variable to the MAT-file:

```
save (workfolder/ConfigSetName.mat, cset)
```

workfolder is a working folder, *ConfigSetName*.mat is the MAT-file name, and *cset* is a base workspace variable whose value is the configuration set to save. When you later reopen your model, you can reload the configuration set into the variable:

```
load (workfolder/ConfigSetName.mat)
```

To execute code that reads configuration sets from MAT-files, use one of these techniques:

- The preload function of a top model
- The MATLAB startup script
- Interactive entry of `load` statements

Create and Attach a Configuration Reference at the Command Line

To create and populate a configuration reference, `Simulink.ConfigSetRef`, using the API:

1. Create the reference:

   ```
   cref = Simulink.ConfigSetRef
   ```

2. Change the default name if desired:

   ```
   cref.Name = 'ConfigSetRefName'
   ```

3. Specify the referenced configuration set:

   ```
   cref.SourceName = 'cset'
   ```

   Tip Do not specify the name of a configuration reference. If you nest a configuration reference, an error occurs.

4. Attach the reference to a model:

   ```
   attachConfigSet(model, cref, true)
   ```

   The third argument is optional and authorizes renaming to avoid a name conflict.

Using a configuration reference with an invalid configuration set, `SourceName`, generates an error and is called an unresolved configuration reference. The GUI

equivalent of `SourceName` is **Referenced configuration**. You can later use the API or GUI to provide the name of a freestanding configuration set. For more information, see "Unresolved Configuration References" on page 13-30.

Note A `Simulink.ConfigSetRef` object cannot be saved to a MATLAB file. To save the configuration, call the `Simulink.ConfigSetRef.getRefConfigSet` method. Then save the `Simulink.ConfigSet` object that the method returns. For more information, see "Save a Configuration Set at the Command Line" on page 13-35.

Attach a Configuration Reference to Multiple Models at the Command Line

After you create a configuration reference and attach it to a model, you can attach copies of the reference to any other models. Each model has its own copy of any configuration reference attached to it, just as each model has its own copy of any attached configuration set.

If you use the GUI, attaching an existing configuration reference to another model automatically attaches a distinct copy to the model. If necessary to prevent name conflict, the GUI adds or increments a digit at the end of the name of the copied reference. If you use the API, be sure to copy the configuration reference explicitly before attaching it, with statements like:

```
cref = copy (getConfigSet(model, ConfigSetRefName))
attachConfigSet (model, cref,  true)
```

If you omit the `copy` operation, *`cref`* becomes a handle to the original configuration reference, rather than a copy of the reference. Any attempt to use *`cref`* causes an error. If you omit the argument `true` to `attachConfigSet`, the operation fails if a name conflict exists.

The following example shows code for obtaining a freestanding configuration set and attaching references to it from two models. After the code executes, one of the models contains an internal configuration set and a configuration reference that points to a freestanding copy of that set. If the internal copy is an extra copy, you can remove it with `detachConfigSet`, as shown in the last line of the example.

```
open_system('model1')
% Get handle to local cset
```

```
cset = getConfigSet('model1', 'Configuration')

% Create freestanding copy; original remains in model
cset1 = copy(cset)

% In the original model, create a configuration
% reference to the cset copy
cref1 = Simulink.ConfigSetRef
cref1.SourceName = 'cset1'

% Attach the configuration reference to the model
attachConfigSet('model1', cref1, true)

% In a second model, create a configuration
% reference to the same cset
open_system('model2')
% Rename if name conflict occurs
attachConfigSetCopy('model2', cref1, true)

% Delete original cset from first model
detachConfigSet('model1', 'Configuration')
```

Get Values from a Referenced Configuration Set

You can use `get_param` on a configuration reference to obtain parameter values from the linked configuration set, as if the reference object were the configuration set itself. Simulink software retrieves the referenced configuration set and performs the indicated `get_param` on it.

For example, if configuration reference *`cref`* links to configuration set *`cset`*, the following operations give identical results:

```
get_param (cset, 'StopTime')
get_param (cref, 'StopTime')
```

Change Values in a Referenced Configuration Set

By operating on only a configuration reference, you cannot change the referenced configuration set parameter values. If you execute:

```
set_param (cset, 'StopTime', '300')
set_param (cref, 'StopTime', '300')          % ILLEGAL
```

the first operation succeeds, but the second causes an error. Instead, you must obtain the configuration set itself and change it directly, using the GUI or the API.

To obtain a referenced configuration set using the API:

1. Follow the instructions in "Obtain a Configuration Reference Handle" on page 13-39.
2. Obtain the configuration set *cset* from the configuration reference *cref*:

   ```
   cset = cref.getRefConfigSet
   ```

   You can now use `set_param` on *cset* to change parameter values. For example:

   ```
   set_param (cset, 'StopTime', '300')
   ```

   Tip If you want to change parameter values through the GUI, execute:

   ```
   cset.openDialog
   ```

   The Configuration Parameters dialog box opens on the specified configuration set.

Obtain a Configuration Reference Handle

Most functions and methods that operate on a configuration reference take a handle to the reference. When you create a configuration reference:

```
cref = Simulink.ConfigSetRef
```

the variable *cref* contains a handle to the reference. If you do not already have a handle, you can obtain one by executing:

```
cref = getConfigSet(model, 'ConfigSetRefName')
```

ConfigSetRefName is the name of the configuration reference as it appears in the Model Explorer, for example, `Reference`. You specify this name by setting the **Name** field in the Configuration Reference dialog box or executing:

```
cref.Name = 'ConfigSetRefName'
```

The technique for obtaining a configuration reference handle is the same technique you use to obtain a configuration set handle. Wherever the same operation applies to both

configuration sets and configuration references, applicable functions and methods overload to perform correctly with either class.

Configuring Models for Targets with Multicore Processors

Concepts in Multicore Programming

In this section...

Basics of Multicore Programming

Multicore programming helps you create concurrent systems for deployment on multicore processor and multiprocessor systems. A *multicore processor system* is a single processor with multiple execution cores in one chip. By contrast, a *multiprocessor system* has multiple processors on the motherboard or chip. A multiprocessor system might include a Field-Programmable Gate Array (FPGA). An FPGA is an integrated circuit containing an array of programmable logic blocks and a hierarchy of reconfigurable interconnects. A *processing node* processes input data to produce outputs. It can be a processor in a multicore or multiprocessor system, or an FPGA.

The multicore programming approach can help when:

- You want to take advantage of multicore and FPGA processing to increase the performance of an embedded system.
- You want to achieve scalability so your deployed system can take advantage of increasing numbers of cores and FPGA processing power over time.

Concurrent systems that you create using multicore programming have multiple tasks executing in parallel. This is known as *concurrent execution*. When a processor executes multiple parallel tasks, it is known as *multitasking*. A CPU has firmware called a scheduler, which handles the tasks that execute in parallel. The CPU implements tasks using operating system threads. Your tasks can execute independently but have some data transfer between them, such as data transfer between a data acquisition module and controller for the system. Data transfer between tasks means that there is a *data dependency*.

Multicore programming is commonly used in signal processing and plant-control systems. In signal processing, you can have a concurrent system that processes multiple frames in parallel. In plant-control systems, the controller and the plant can execute as

two separate tasks. Using multicore programming helps to split your system into multiple parallel tasks, which run simultaneously, speeding up the overall execution time.

To model a concurrently executing system, see “Partitioning Guidelines” on page 14-36.

Types of Parallelism

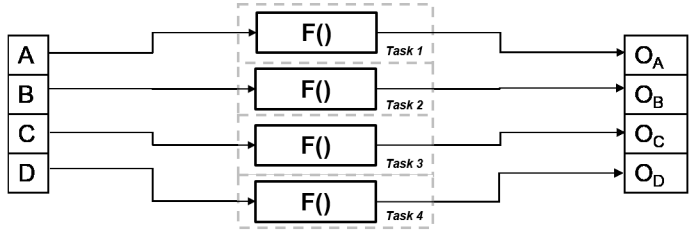
The concept of multicore programming is to have multiple system tasks executing in parallel. Types of parallelism include:

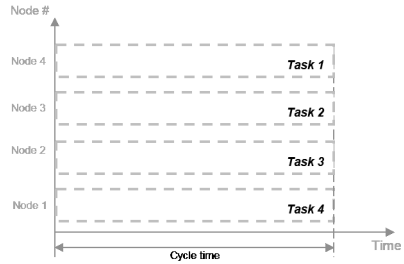
- Data parallelism
- Task parallelism
- Pipelining

Data Parallelism

Data parallelism involves processing multiple pieces of data independently in parallel. The processor performs the same operation on each piece of data. You achieve parallelism by feeding the data in parallel.

The figure shows the timing diagram for this parallelism. The input is divided into four chunks, A, B, C, and D. The same operation `F()` is applied to each of these pieces and the output is O_A, O_B, O_C, and O_D respectively. All four tasks are identical, and they run in parallel.





The time taken per processor cycle, known as cycle time, is

t = tF.

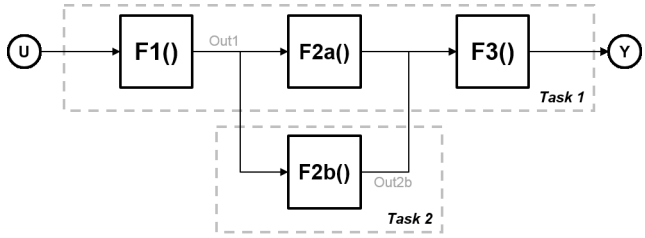
The total processing time is also `tF`, since all four tasks run simultaneously. In the absence of parallelism, all four pieces of data are processed by one processing node. The cycle time is `tF` for each task but the total processing time is `4*tF`, since the pieces are processed in succession.

You can use data parallelism in scenarios where it is possible to process each piece of input data independently. For example, a web database with independent data sets for processing or processing frames of a video independently are good candidates for data parallelism.

Task Parallelism

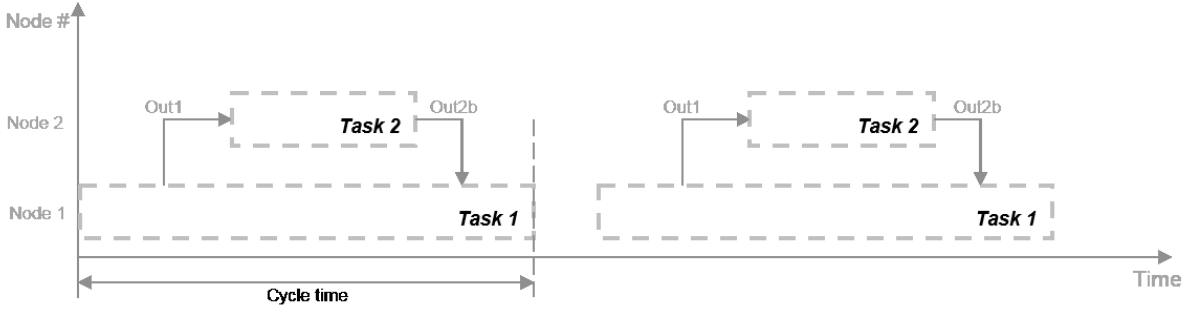
In contrast to data parallelism, task parallelism doesn't split up the input data. Instead, it achieves parallelism by splitting up an application into multiple tasks. Task parallelism involves distributing tasks within an application across multiple processing nodes. Some tasks can have data dependency on others, so all tasks do not run at exactly the same time.

Consider a system that involves four functions. Functions F2a() and F2b() are in parallel, that is, they can run simultaneously. In task parallelism, you can divide your computation into two tasks. Function F2b() runs on a separate processing node after it gets data Out1 from Task 1, and it outputs back to F3() in Task 1.



The figure shows the timing diagram for this parallelism. Task 2 does not run until it gets data Out1 from Task 1. Hence, these tasks do not run completely in parallel. The time taken per processor cycle, known as cycle time, is

$t = tF1 + \max(tF2a, tF2b) + tF3$.

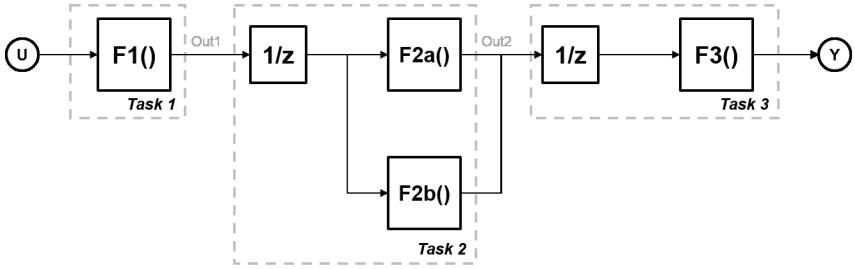


You can use task parallelism in scenarios such as a factory where the plant and controller run in parallel.

Model Pipeline Execution (Pipelining)

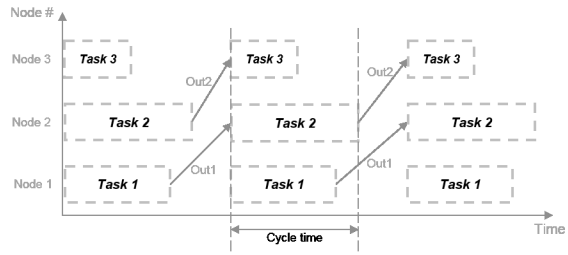
Use model pipeline execution, or pipelining, to work around the problem of task parallelism where threads do not run completely in parallel. This approach involves modifying your system model to introduce delays between tasks where there is a data dependency.

In this figure, the system is divided into three tasks to run on three different processing nodes, with delays introduced between functions. At each time step, each task takes in the value from the previous time step by way of the delay.



Each task can start processing at the same time, as this timing diagram shows. These tasks are truly parallel and they are no longer serially dependent on each other in one processor cycle. The cycle time does not have any additions but is the maximum processing time of all the tasks.

t = max(Task1, Task2, Task3) = max(tF1, tF2a, tF2b, tF3).



You can use pipelining wherever you can introduce delays artificially in your concurrently executing system. The resulting overhead due to this introduction must not exceed the time saved by pipelining.

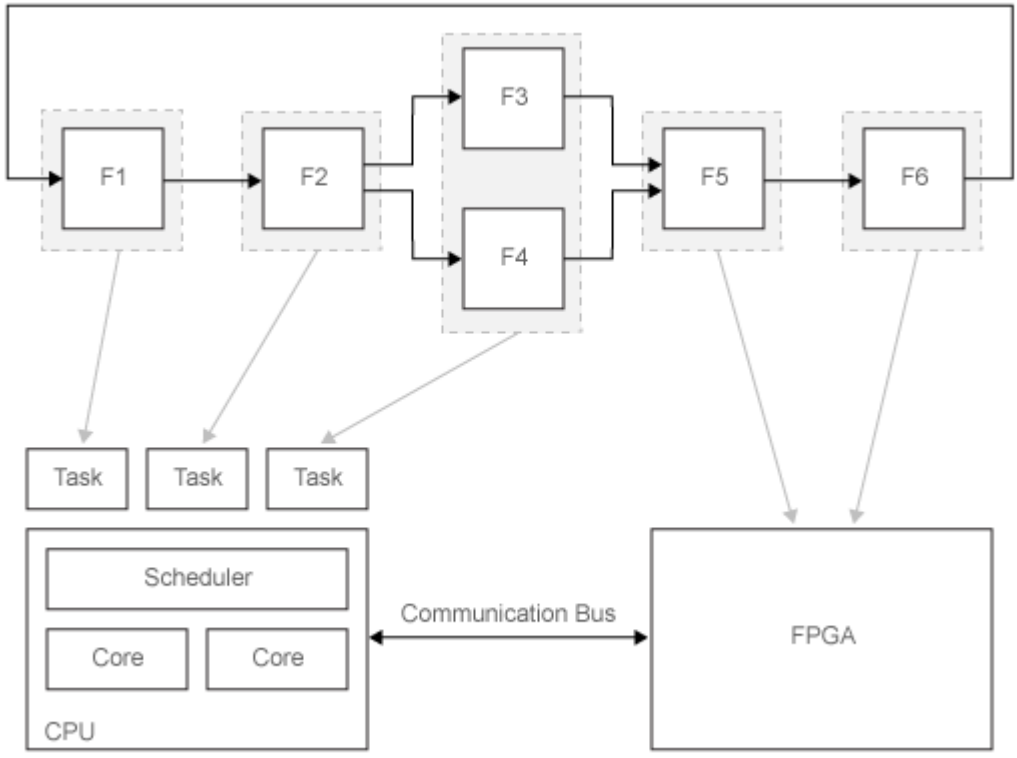
System Partitioning for Parallelism

Partitioning methods help you to designate areas of your system for concurrent execution. Partitioning allows you to create tasks independently of the specifics of the target system on which the application is deployed.

Consider this system. F1–F6 are functions of the system that can be executed independently. An arrow between two functions indicates a data dependency. For example, the execution of F5 has a data dependency on F3.

Execution of these functions is assigned to the different processor nodes in the target system. The grey arrows indicate assignment of the functions to be deployed on the CPU

or the FPGA. The CPU scheduler determines when individual tasks run. The CPU and FPGA communicate via a common communication bus.



The figure shows one possible configuration for partitioning. In general, you test different configurations and iteratively improve until you get the optimal distribution of tasks for your application.

Challenges in Multicore Programming

Manually coding your application onto a multicore processor or an FPGA poses challenges beyond the problems caused by manual coding. In concurrent execution, you must track:

- Scheduling of the tasks that execute on the embedded processing system multicore processor

- Data transfers to and from the different processing nodes

Simulink manages the implementation of tasks and data transfer between tasks. It also generates the code that is deployed for the application. For more information, see "Multicore Programming with Simulink" on page 14-10.

In addition to these challenges, there are challenges when you want to deploy your application to different architectures and when you want to improve the performance of the deployed application.

Portability: Deployment to Different Architectures

The hardware configuration that runs the deployed application is known as the architecture. It can contain multicore processors, multiprocessor systems, FPGAs, or a combination of these. Deployment of the same application to different architectures can require effort due to:

- Different number and types of processor nodes on the architecture
- Communication and data transfer standards for the architecture
- Standards for certain events, synchronization, and data protection in each architecture

To deploy the application manually, you must reassign tasks to different processing nodes for each architecture. You might also need to reimplement your application if each architecture uses different standards.

Simulink helps overcome these problems by offering portability across architectures. For more information, see "How Simulink Helps You to Overcome Challenges in Multicore Programming" on page 14-11.

Deployment Efficiency

You can improve the performance of your deployed application by balancing the load of the different processing nodes in the multicore processing environment. You must iterate and improve upon your distribution of tasks during partitioning, as mentioned in "System Partitioning for Parallelism" on page 14-6. This process involves moving tasks between different processing nodes and testing the resulting performance. Since it is an iterative process, it takes time to find the most efficient distribution.

Simulink helps you to overcome these problems using profiling. For more information, see "How Simulink Helps You to Overcome Challenges in Multicore Programming" on page 14-11.

Cyclic Data Dependency

Some tasks of a system depend on the output of other tasks. The data dependency between tasks determines their processing order. Two or more partitions containing data dependencies in a cycle creates a data dependency loop, also known as an *algebraic loop*.

Simulink identifies loops in your system before deployment. For more information, see "How Simulink Helps You to Overcome Challenges in Multicore Programming" on page 14-11.

Multicore Programming with Simulink

In this section...

Using the process of partitioning, mapping, and profiling in Simulink, you can address common challenges of designing systems for concurrent execution.

Partitioning enables you to designate regions of your model as tasks, independent of the details of the embedded multicore processing hardware. This independence enables you to arrange the content and hierarchy of your model to best suit the needs of your application.

In a partitioned system, mapping enables you to assign partitions to processing elements in your embedded processing system. Use the Simulink mapping tool to represent and manage the details of executing threads, HDL code on FPGAs, and the work that these threads or FPGAs perform. While creating your model, you do not need to track the partitions or data transfer between them because the tool does this work. Also, you can reuse your model across multiple architectures.

Profiling simulates deployment of your application under typical computational loads. It enables you to determine the partitioning and mapping for your model that gives the best performance, before you deploy to your hardware.

Basic Workflow

To deploy your model to the target.

1 Set up your model for concurrent execution.

- If you are using a desktop target, you need to configure your model. For more information, see “Configure Your Model for Concurrent Execution” on page 14-23.
- If you are not using a desktop target, you need to configure your model, specify a target, and explicitly partition your model. Additionally, you may want to change the default mapping of blocks to tasks in explicit partitioning. To set up your model for concurrent execution, see “Configure Your Model for Concurrent

Execution” on page 14-23. To specify the target architecture, see “Specify a Target Architecture” on page 14-24. For explicit partitioning of a model, see “Partition Your Model Using Explicit Partitioning” on page 14-30

2 Generate code and deploy it to your target. You can choose to deploy onto multiple targets.

- To build and deploy on a desktop target, see “Build on Desktop” on page 14-45.
- To deploy onto embedded targets using Embedded Coder, see “Deployment” (Embedded Coder).
- To deploy onto FPGAs using HDL Coder™, see “Deployment” (HDL Coder).
- To build and deploy on a real-time target using Simulink Real-Time™, see “Standalone Operation” (Simulink Real-Time).

3 Optimize your design. This step is optional, and includes iterating over the design of your model and mapping to get the best performance, based on your metrics. One way to evaluate your model is to profile it and get execution times.

Product	Information
Desktop target	“Profile and Evaluate on a Desktop” on page 14-48
Simulink Real-Time	“Execution Profiling for Real-Time Applications” (Simulink Real-Time)
Embedded Coder	“Perform Execution-Time Profiling for IDE and Toolchain Targets” (Embedded Coder)
HDL Coder	“Speed and Area Optimization” (HDL Coder)

How Simulink Helps You to Overcome Challenges in Multicore Programming

Manually programming your application for concurrent execution poses challenges beyond the typical challenges with manual coding. With Simulink, you can overcome the challenges of portability across multiple architectures, efficiency of deployment for an architecture, and cyclic data dependencies between application components. For more information on these challenges, see “Challenges in Multicore Programming” on page 14-7

Portability

Simulink enables you to determine the content and hierarchical needs of the modeled system without considering the target system. While creating model content, you do not need to keep track of the number of cores in your target system. Instead, you select the partitioning methods that enable you to create model content. Simulink generates code for the architecture you specify.

You can select an architecture from the available supported architectures or add a custom architecture. When you change your architecture, Simulink generates only the code that needs to change for the second architecture. The new architecture reuses blocks and functions. For more information, see “Supported Targets For Multicore Programming” on page 14-56 and “Specify a Target Architecture” on page 14-24.

Deployment Efficiency

To improve the performance of the deployed application, Simulink allows you to simulate it under typical computational loads and try multiple configurations of partitioning and mapping the application. Simulink compares the performance of each of these configurations to provide the optimal configuration for deployment. This is known as profiling. Profiling helps you to determine the optimum partition configuration before you deploy your system to the desired hardware.

You can create a mapping for your application in which Simulink maps the application components across different processing nodes. You can also manually assign components to processing nodes. For any mapping, you can see the data dependencies between components and remap accordingly. You can also introduce and remove data dependencies between different components.

Cyclic Data Dependency

Some tasks of a system depend on the output of other tasks. The data dependency between tasks determines their processing order. Two or more partitions containing data dependencies in a cycle creates a data dependency loop, also known as an *algebraic loop*. Simulink does not allow algebraic loops to occur across potentially parallel partitions because of the high cost of solving the loop using parallel algorithms.

In some cases, the algebraic loop is artificial. For example, you can have an artificial algebraic loop because of Model-block-based partitioning. An algebraic loop involving Model blocks is artificial if removing the use of Model partitioning eliminates the loop. You can minimize the occurrence of artificial loops. In the Configuration Parameter

dialog boxes for the models involved in the algebraic loop, select **Model Referencing** > **Minimize algebraic loop occurrences**.

Additionally, if the model is configured for the Generic Real-Time target (`grt.tlc`) or the Embedded Real-Time target (`ert.tlc`) in the Configuration Parameters dialog box, clear the **Single output/update function** check box.

If the algebraic loop is a true algebraic condition, you must either contain all the blocks in the loop in one Model partition, or eliminate the loop by introducing a delay element in the loop.

The following examples show how to implement different types of parallelism in Simulink. These examples contain models that are partitioned and mapped to a simple architecture with one CPU and one FPGA.

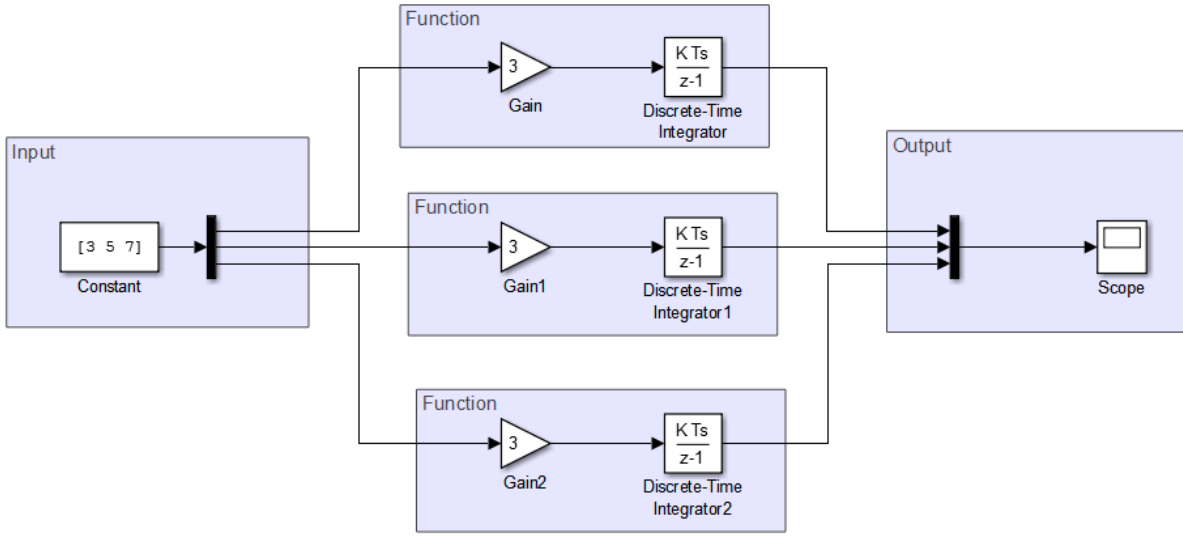
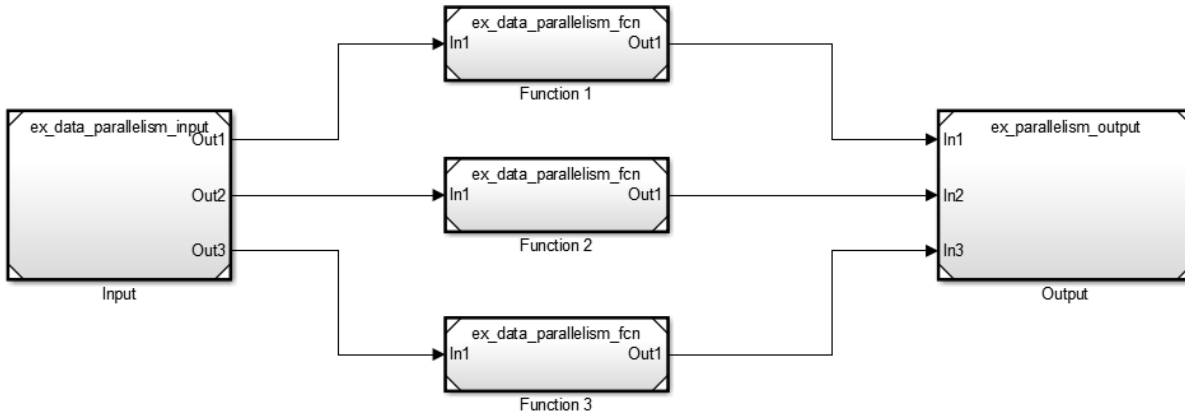
Implement Data Parallelism in Simulink

This example shows how to implement data parallelism for a system in a Simulink model. The model consists of an input, a functional component that applies to each input, and a concatenated output. For more information on data parallelism, see “Types of Parallelism” on page 14-3.



Set up this model for concurrent execution. To see the completed model, open ex_data_parallelism_top.

1 Convert areas in this model to referenced models. Use the same referenced model to replace each of the functional components that process the input. The figure shows a sample configuration.



2. Open the model configuration parameters for the top level model. Clear the **MAT-file logging** check box.
3. On the **Solver** pane, set **Type** to `Fixed-step` and click **Apply**. Also ensure that the the **Periodic sample time constraint** is set to `Unconstrained`. Under **Additional options**, select **Allow tasks to execute concurrently on target** and click **Configure Tasks**.
4. In the Concurrent Execution dialog box, in the right pane, select the **Enable explicit model partitioning for concurrent behavior** check box. With explicit partitioning, you can partition your model manually.
5. In the selection pane, select **CPU**. Click **Add task**  four times to add four new tasks.
6. In the selection pane, select **Tasks and Mapping**. On the **Map block to tasks** pane:

   - Under **Block: Input**, click `select task` and select `Periodic: Task`.
   - Under **Block: Function 1**, select `Periodic: Task1`.
   - Under **Block: Function 2**, select `Periodic: Task2`.
   - Under **Block: Function 3**, select `Periodic: Task3`.
   - Under **Block: Output**, select `Periodic: Task`.

   This maps your partitions to the tasks you created. The Input and Output model blocks are on one task. Each functional component is assigned a separate task.

7 In the selection pane, select **Data transfer**. In the **Data Transfer Options** pane, set the parameter **Periodic signals** to `Ensure deterministic transfer (minimum delay)`. Click **Apply** and close the Concurrent Execution dialog box.

8 Apply these configuration parameters to all referenced models. For more information, see "Share a Configuration for Multiple Models" on page 13-4.

Update your model to see the tasks mapped to individual model blocks.

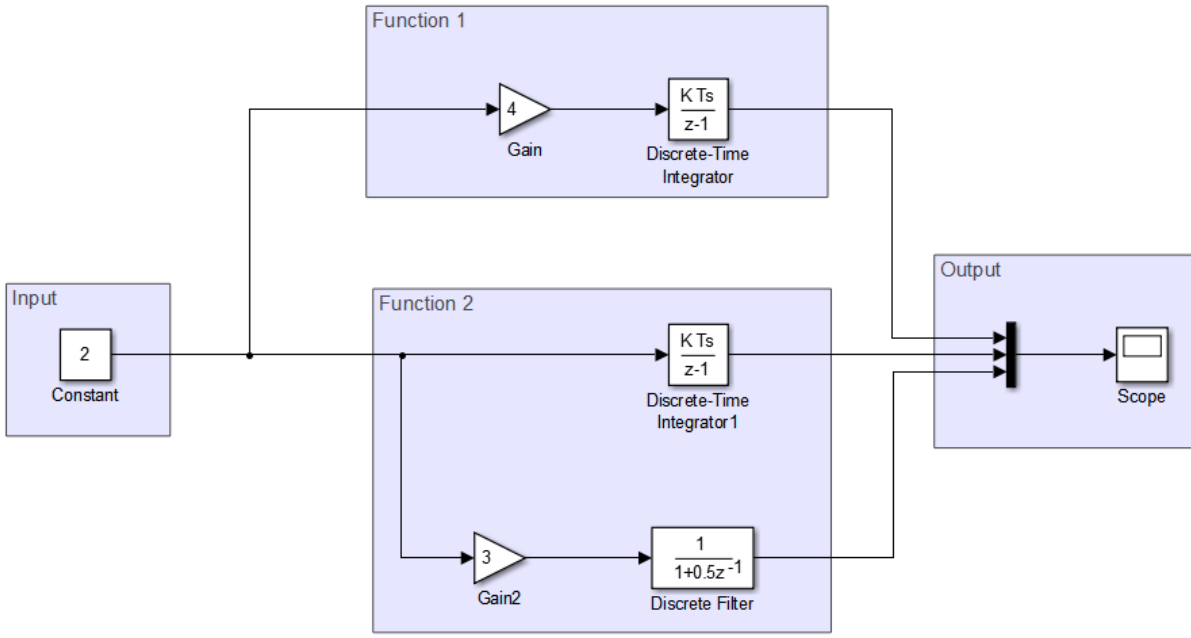
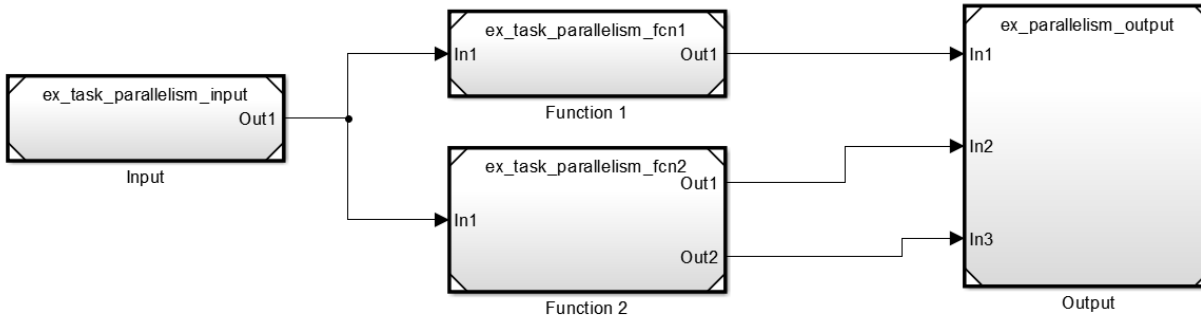
Implement Task Parallelism in Simulink

This example shows how to implement task parallelism for a system in a Simulink model. The model consists of an input, functional components applied to the same input, and a concatenated output. For more information on Task Parallelism, see “Types of Parallelism” on page 14-3.



Set up the model for concurrent execution. To see the completed model, open ex_task_parallelism_top.

1 Convert areas in this model to referenced models. Use the same referenced model to replace each of the functional components that process the input. The figure shows a sample configuration.



2 Open the model configuration parameters for the top level model. Clear the **MAT-file logging** check box.

3 On the **Solver** pane, set **Type** to `Fixed-step` and click **Apply**. Also ensure that the **Periodic sample time constraint** is set to `Unconstrained`. Under **Additional options**, select **Allow tasks to execute concurrently on target** and click **Configure Tasks**.

4 In the Concurrent Execution dialog box, in the right pane, select the **Enable explicit model partitioning for concurrent behavior** check box. With explicit partitioning, you can partition your model manually.

5 In the selection pane, select **CPU**. Click **Add task**  three times to add new tasks.

6 In the selection pane, select **Tasks and Mapping**. To map partitions to the tasks you created, on the **Map block to tasks** pane:

- Under **Block: Input**, click `select task` and select `Periodic: Task`.
- Under **Block: Function 1**, select `Periodic: Task1`.
- Under **Block: Function 2**, select `Periodic: Task2`.
- Under **Block: Output**, select `Periodic: Task`.

The Input and Output model blocks are on one task. Each functional component is assigned a separate task.

7 In the selection pane, select **Data transfer**. In the **Data Transfer Options** pane, set the parameter **Periodic signals** to `Ensure deterministic transfer (minimum delay)`. Click **Apply** and close the Concurrent Execution dialog box.

8 Apply these configuration parameters to all referenced models. For more information, see “Share a Configuration for Multiple Models” on page 13-4.

Update your model to see the tasks mapped to individual model blocks.

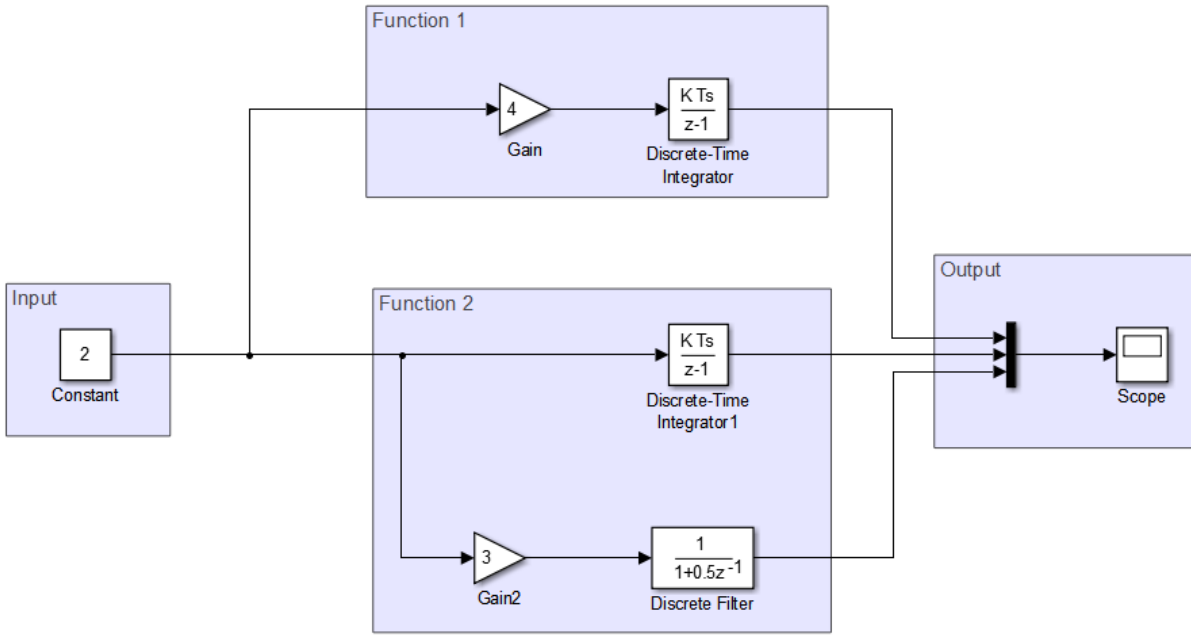
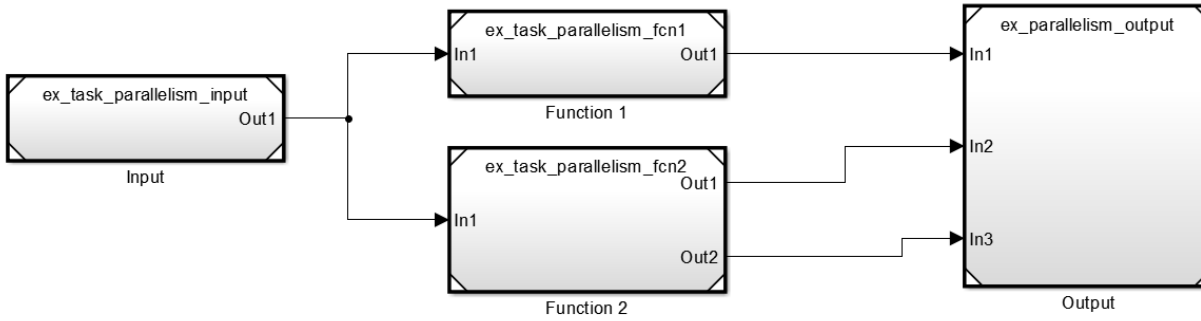
Implement Pipelining in Simulink

This example shows how to implement pipelining for a system in a Simulink model. The model consists of an input, functional components applied to the same input, and a concatenated output. For more information on pipelining, see “Types of Parallelism” on page 14-3.



Setup this model for concurrent execution. To see the completed model, open ex_pipelining_top.

1 Convert areas in this model to referenced models. Use the same referenced model to replace each of the functional components that process the input. The figure shows a sample configuration.

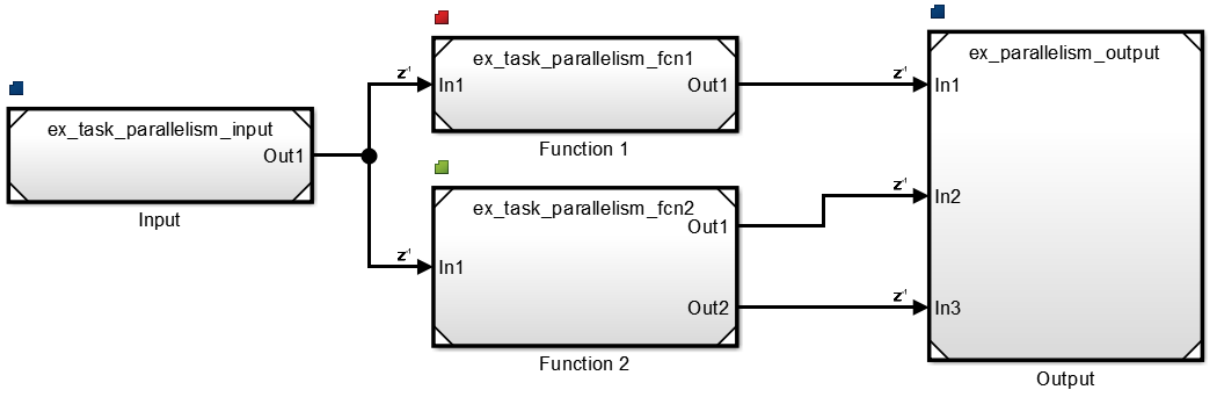


2. Open the model configuration parameters for the top level model. Clear the **MAT-file logging** check box.
3. On the **Solver** pane, set **Type** to `Fixed-step` and click **Apply**. Also ensure that the the **Periodic sample time constraint** is set to `Unconstrained`. Under **Additional options**, select **Allow tasks to execute concurrently on target** and click **Configure Tasks**.
4. In the Concurrent Execution dialog box, in the right pane, select the **Enable explicit model partitioning for concurrent behavior** check box. With explicit partitioning, you can partition your model manually.
5. In the selection pane, select **CPU**. Click **Add task**  three times to add three new tasks.
6. In the selection pane, select **Tasks and Mapping**. On the **Map block to tasks** pane:

   - Under **Block: Input**, click `select task` and select `Periodic: Task`.
   - Under **Block: Function 1**, select `Periodic: Task1`.
   - Under **Block: Function 2**, select `Periodic: Task2`.
   - Under **Block: Output**, select `Periodic: Task`.

   This maps your partitions to the tasks you created. The Input and Output model blocks are on one task. Each functional component is assigned a separate task.
7. Close the Concurrent Execution dialog box.
8. Apply these configuration parameters to all referenced models. For more information, see “Share a Configuration for Multiple Models” on page 13-4.

Update your model to see the tasks mapped to individual model blocks.



Note Notice that delays are introduced between different tasks, indicated by the z-1 badge. Introducing these delays may cause different model outputs in Simulink. Ensure that your model has an expected output on simulating the parallelized model.

Configure Your Model for Concurrent Execution

Follow these steps to configure your Simulink model to take advantage of concurrent execution.

1. Open your model.
2. Open the **Simulation** menu and select **Configuration Settings**.
3. In **Configuration Parameters** > **Solver** > **Solver options**, choose `Fixed-step` for the **Type** and `auto (Automatic solver selection)` for the **Solver**.
4. Select the **Allow tasks to execute concurrently on target** check box in the **Solver** pane under **Additional Parameters**. Selecting this check box is optional for models referenced in the model hierarchy. When you select this option for a referenced model, Simulink allows each rate in the referenced model to execute as an independent concurrent task on the target processor.
5. Clear the **MAT-file logging** check box.

Once you have a model that executes concurrently on your computer, you can further configure your model in the following ways:

- "Specify a Target Architecture" on page 14-24
- "Partition Your Model Using Explicit Partitioning" on page 14-30.
- "Configure Data Transfer Settings Between Concurrent Tasks" on page 14-39

Specify a Target Architecture

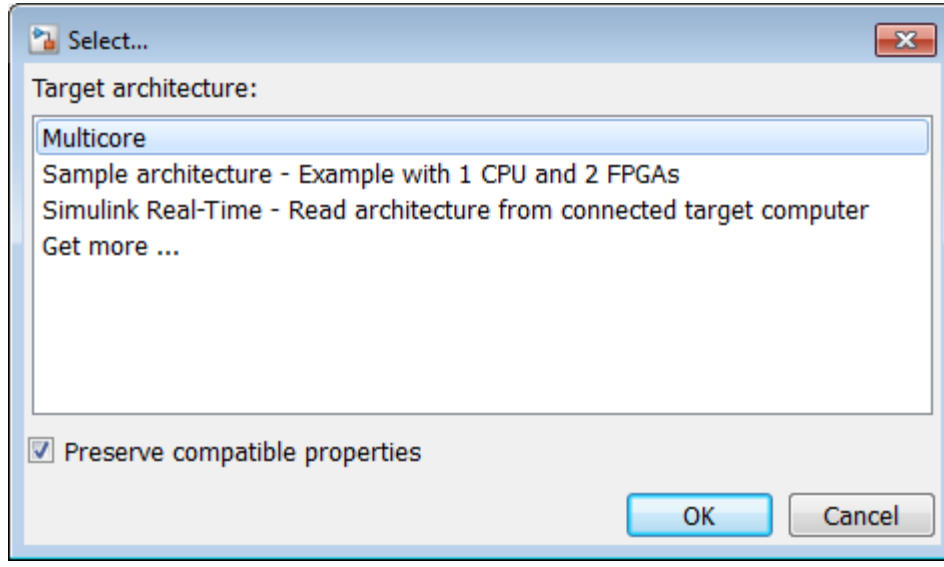
In this section...

For models configured for concurrent execution, you can choose the architecture to which you want to deploy your model. Choose from a set of predefined architectures in Simulink, or you can create an interface for a custom architecture. After selecting your architecture, you can use explicit partitioning to specify which tasks run on it. For more information, see “Partition Your Model Using Explicit Partitioning” on page 14-30.

Choose from Predefined Architectures

You can choose from the predefined architectures available in Simulink, or you can download support packages for different available architectures.

1 In the Concurrent Execution dialog box, in the **Concurrent Execution** pane, click **Select**. The concurrent execution target architecture selector appears.



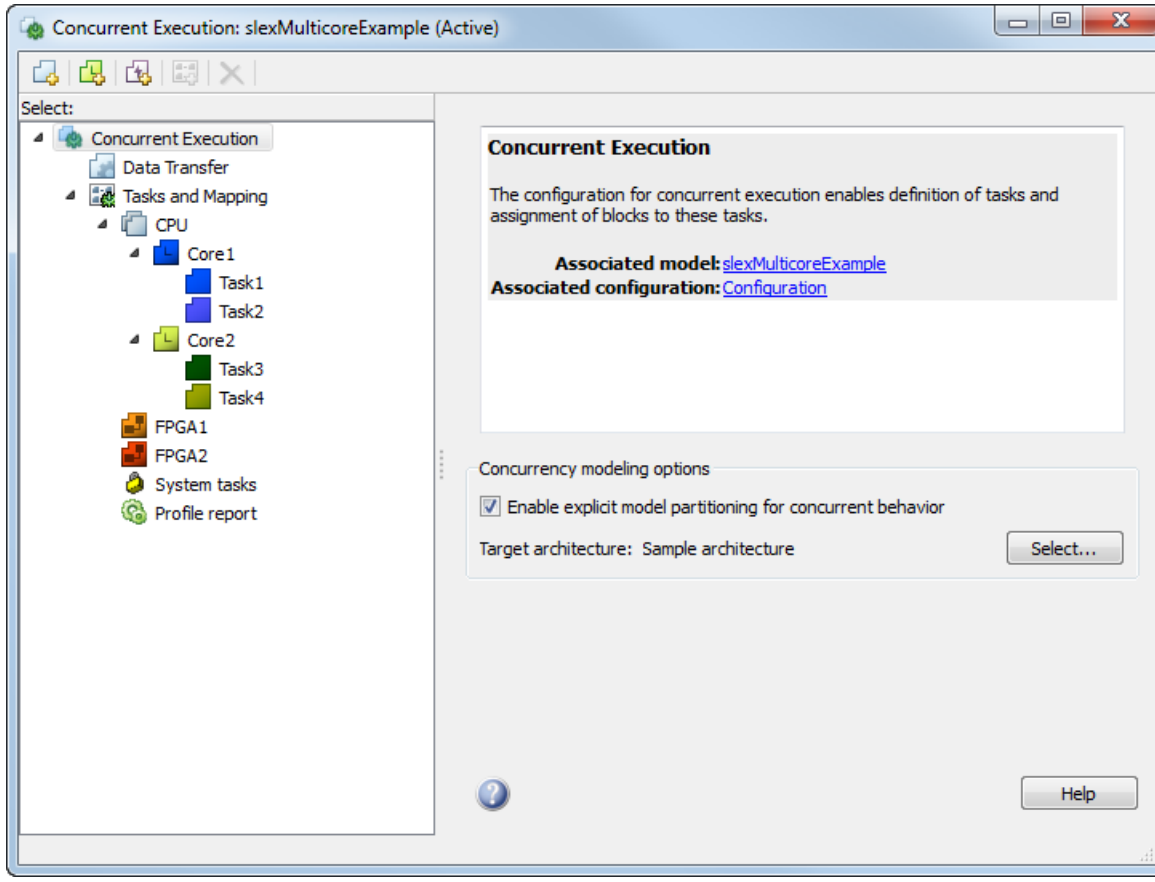
2 Select your target.

Property	Description
`Multicore`	Single CPU with multiple cores.
`Sample Architecture`	Single CPU with multiple cores and two FPGAs.
`Simulink Real-Time`	Simulink Real-Time target.
`Get more ...`	Click OK to start the Support Package Installer. From the list, select the target and follow the instructions.

3 In the Target architecture window, clear the **Preserve compatible properties** check box to reset existing target property settings to their default. Alternatively, select the **Preserve compatible properties** check box to preserve existing target property settings.

4 Click **OK**.

Simulink adds the corresponding software and hardware nodes to the configuration tree hierarchy. For example, the following illustrates one software node and two hardware nodes added to the configuration tree when you select `Sample architecture` as the target architecture.



Define a Custom Architecture File

A custom architecture file is an XML file that allows you to define custom target properties for tasks and triggers. For example, you may want to define custom properties to represent threading APIs. Threading APIs are necessary to take advantage of concurrency on your target processor.

The following is an example custom architecture file:

```
<architecture brief="Multicore with custom threading API"
              format="1.1"  revision="1.1"
              uuid="MulticoreCustomAPI"  name="MulticoreCustomAPI">
<configurationSet>
```

```
     <parameter name="SystemTargetFile" value="ert.tlc"/>
     <parameter name="SystemTargetFile" value="grt.tlc"/>
</configurationSet>
<node name="MulticoreProcessor" type="SoftwareNode" uuid="MulticoreProcessor"/>
<template name="CustomTask" type="Task" uuid="CustomTask">
     <property name="affinity" prompt="Affinity:" value="1" evaluate="true"/>
     <property name="schedulingPolicy" prompt="Scheduling policy:" value="Rate-monotonic">
           <allowedValue>Rate-monotonic</allowedValue>
           <allowedValue>Round-robin</allowedValue>
        </property>
   </template>
</architecture>
```

An architecture file must contain:

- The architecture element that defines basic information used by Simulink to identify the architecture.
- A `configurationSet` element that lists the system target files for which this architecture is valid.
- One node element that Simulink uses to identify the multicore processing element.

  Note The architecture must contain exactly one node element that identifies a multicore processing element. You cannot create multiple nodes identifying multiple processing elements or an architecture with no multicore processing element.

- One or more template elements that list custom properties for tasks and triggers.
  - The type attribute can be `Task`, `PeriodicTrigger`, or `AperiodicTrigger`.
  - Each property is editable and has the default value specified in the `value` attribute.
  - Each property can be a text box, check box, or combo box. A check box is one where you can set the `value` attribute to `on` or `off`. A combo box is one where you can optionally list `allowedValue` elements as part of the property.
  - Each text box property can also optionally define an `evaluate` attribute. This lets you place MATLAB variable names as the value of the property.

  Assuming that you have saved the custom target architecture file in `C:\custom_arch.xml`, register this file with Simulink using the `Simulink.architecture.register` function.

For example:

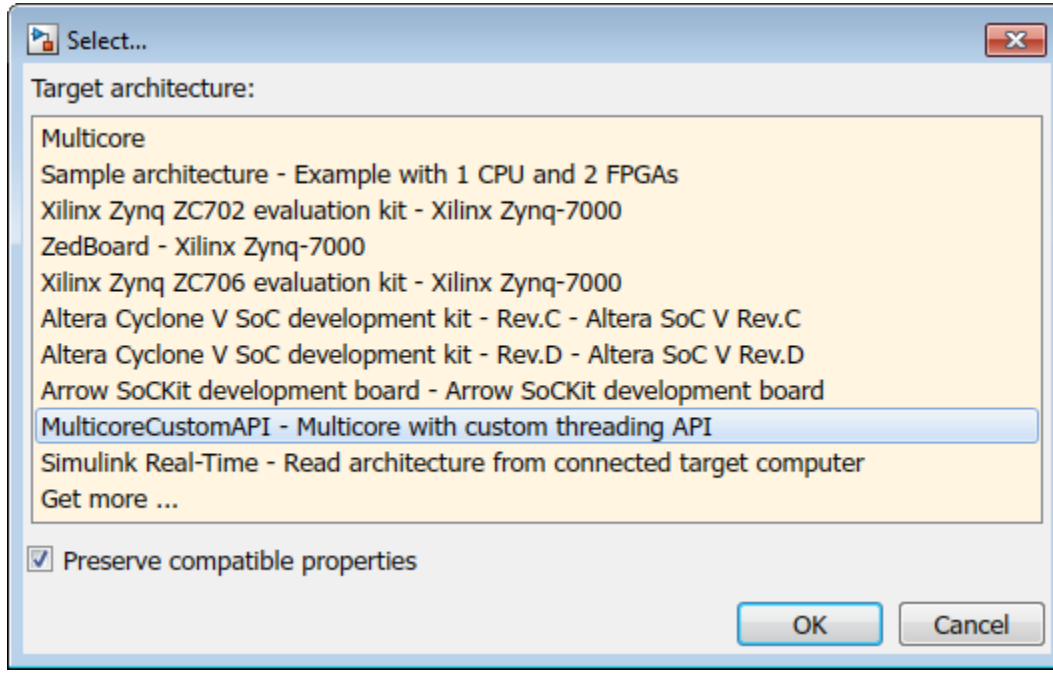
1. Save the contents of the listed XML file in `custom_arch.xml`.
2. In the MATLAB Command Window, type:

   ```
   Simulink.architecture.register('custom_arch.xml')
   ```

3. In the MATLAB Command Window, type:

   ```
   slexMulticoreSolverExample
   ```

4. In the Simulink editor, open the **Configuration Parameters** > **Solver** pane and click **Configure Tasks**. The Concurrent Execution dialog box displays.
5. In the **Concurrent Execution** pane, click **Select...** under **Target Architecture**. The Target architecture window displays.
6. Select `MulticoreCustomAPI` and click **OK**.



Your Concurrent Execution dialog box updates to contain Code Generation properties for the tasks as shown. These are the properties defined in the XML file.

- "Configure Your Model for Concurrent Execution" on page 14-23
- "Partition Your Model Using Explicit Partitioning" on page 14-30
- "Implicit and Explicit Partitioning of Models" on page 14-36

Partition Your Model Using Explicit Partitioning

When you have a model that is configured for concurrent execution, you can add tasks, create partitions, and map individual tasks to partitions using explicit partitioning. This enables you to execute different parts of your model to different parts of your architecture. For more information, see “Implicit and Explicit Partitioning of Models” on page 14-36.

In this section...

Prerequisites for Explicit Partitioning

To use explicit partitioning, you must meet the following prerequisites:

1. Set up your model for concurrent execution. For more information, see “Configure Your Model for Concurrent Execution” on page 14-23.
2. Convert all blocks at the root level of your model into MATLAB System blocks or models that are referenced using Model blocks. For more information, see “Implicit and Explicit Partitioning of Models” on page 14-36.

   Note When using referenced models, replicate the model configuration parameters of the top model to the referenced models. Consider using a single configuration reference to use for all of your referenced models. For more information, see “Configuration Reuse”.
3. Select the target architecture on which to deploy your model. For more information, see “Specify a Target Architecture” on page 14-24.

Add Periodic Triggers and Tasks

Add periodic tasks for components in your model that you want to execute periodically. To add aperiodic tasks whose execution is trigger based, see “Add Aperiodic Triggers and Tasks” on page 14-31.

If you want to explore the effects of increasing the concurrency on your model execution, you can create additional periodic tasks in your model.

1. In the Concurrent Execution dialog box, right-click the **Periodic** node and select **Add task**.

   A task node appears in the Configuration Execution hierarchy.
2. Select the task node and enter a name and period for the task, then click **Apply**.

   The task node is renamed to the name you enter.
3. Optionally, specify a color for the task. The color illustrates the block-to-task mapping. If you do not assign a color, Simulink chooses a default color. If you enable sample time colors for your model, the software honors the setting.
4. Click **Apply** as necessary.

To create more periodic triggers, click the **Add periodic trigger** symbol. You can also create multiple periodic triggers with their own trigger sources.

Note Periodic triggers let you represent multiple periodic interrupt sources such as multiple timers. The periodicity of the trigger is either the base rate of the tasks that the trigger schedules, or the period of the trigger. Data transfers between triggers can only be `Ensure Data Integrity Only` types. With blocks mapped to periodic triggers, you can only generate code for `ert.tlc` and `grt.tlc` system target files.

To delete tasks and triggers, right-click them in the pane and select **Delete**.

When the periodic tasks and trigger configurations are complete, configure the aperiodic (interrupt) tasks as necessary. If you do not need aperiodic tasks, continue to "Map Blocks to Tasks, Triggers, and Nodes" on page 14-33.

Add Aperiodic Triggers and Tasks

Add aperiodic tasks for components in your model whose execution is interrupt-based. To add periodic tasks whose execution is periodic, see "Add Periodic Triggers and Tasks" on page 14-30.

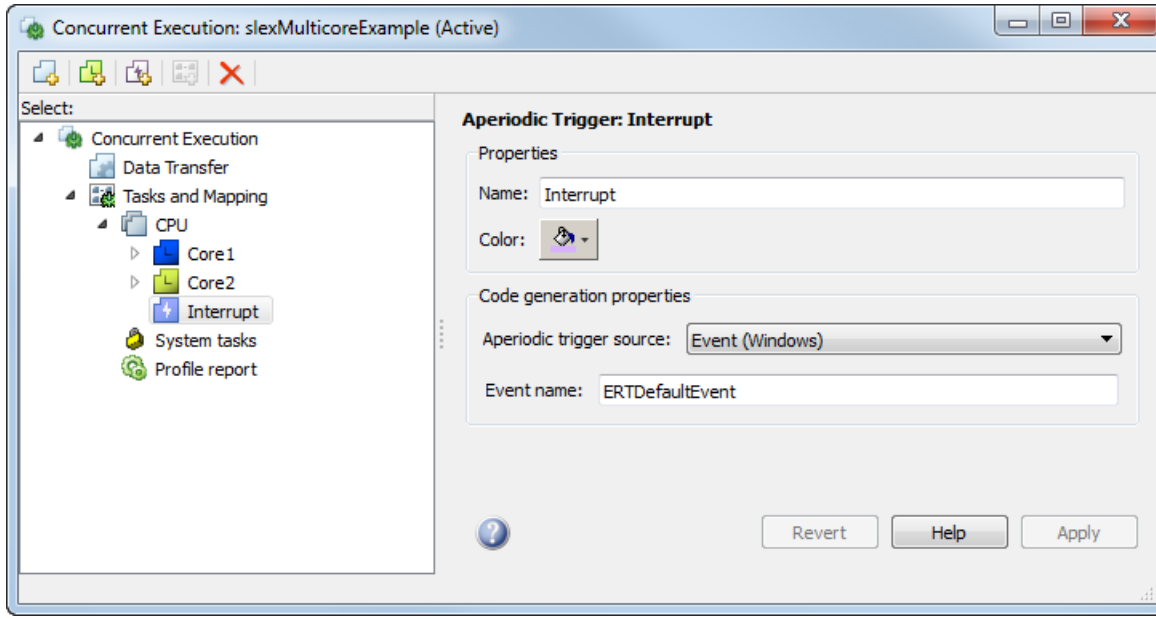
1. To create an aperiodic trigger, in the Concurrent Execution dialog box, right-click the **Concurrent Execution** node and click the **Add aperiodic trigger** symbol.

A node named **Interrupt***N* appears in the configuration tree hierarchy, where *N* is an integer.

2 Select **Interrupt**.

This node represents an aperiodic trigger for your system.

3 Specify the name of the trigger and configure the aperiodic trigger source. Depending on your deployment target, choose either `Posix Signal (Linux/VxWorks 6.x)` or `Event (Windows)`. For POSIX® signals, specify the signal number to use for delivering the aperiodic event. For Windows events, specify the name of the event.



4 Click **Apply**.

The software services aperiodic triggers as soon as possible. If you want to process the trigger response using a task:

1 Right-click the **Interrupt** node and select **Add task**.

A new task node appears under the **Interrupt** node.

2 Specify the name of the new task node.

3 Optionally, specify a color for the task. The color illustrates the block-to-task mapping. If you do not assign a color, Simulink chooses a default color.

4 Click **Apply**.

To delete tasks and triggers, right-click them in the pane and select **Delete**.

Once you have created your tasks and triggers, map your execution components to these tasks. For more information, see “Map Blocks to Tasks, Triggers, and Nodes” on page 14-33.

Map Blocks to Tasks, Triggers, and Nodes

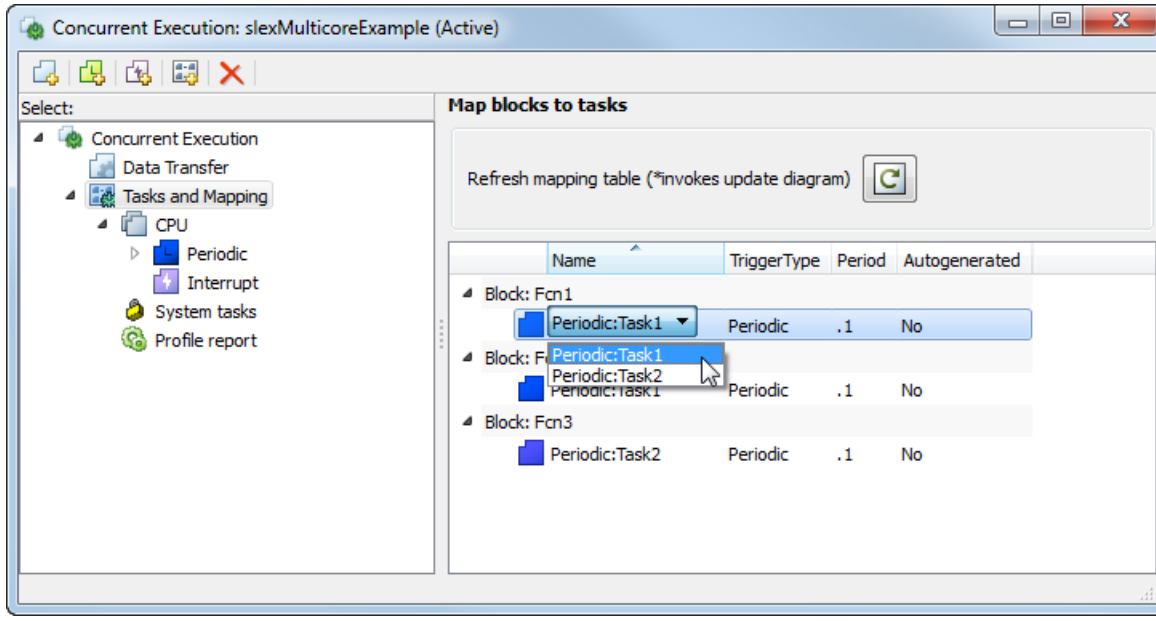
After you create the tasks and triggers, you can explicitly assign partitions to these execution elements.

1 In the Concurrent Execution dialog box, click the **Tasks and Mapping** node.

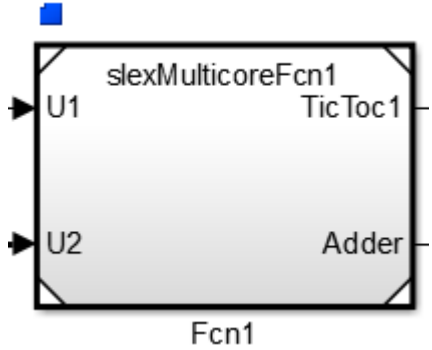
The **Tasks and Mapping** pane appears. If you add a Model block to your model, the new block appears in the table with a **select task** entry under it.

2 If you want to add a task to a block, in the **Name** column, right-click a task under the block and select **Add new entry**.

3 To assign a task for the entry, click the box in the **Name** column and select an entry from the list. For example:



The block-to-task mapping symbol appears on the top-left corner of the Model block. For example:



If you assign a Model block to multiple tasks, multiple task symbols are displayed in the top-left corner.

To display the Concurrent Execution dialog box from the block, click the block-to-task mapping symbol.

4 Click **Apply**.

Note

- System tasks allow you to perform mapping incrementally. This means that if there is only one periodic trigger, Simulink assigns any Model blocks or MATLAB System blocks that you have not explicitly mapped to a task, trigger, or hardware node to a task created by the system. Simulink creates at most one system task for each rate in the model. If there are multiple periodic triggers created, explicitly map the Model block partitions or MATLAB System blocks to a task, trigger, or hardware node.
- Map Model block partitions that contain continuous blocks to the same periodic trigger.
- You can map only Model blocks to hardware nodes. Also, if you map the Model block to a hardware node, and the Model block contains multiple periodic sample times, clear the **Allow tasks to execute concurrently on target** check box in the **Solver** pane of the Configuration Parameters dialog box.

When the mapping is complete, simulate the model again.

Implicit and Explicit Partitioning of Models

When implementing multicore programming for your application in Simulink, there are two ways to partition your model for running on individual processing nodes. If you are new to multicore programming in Simulink, use the default (implicit partitioning) for your first iteration of implementing multicore programming.

The automated way of creating tasks and mapping them to your processing nodes is called implicit partitioning. Simulink partitions your model based on the sample time of blocks at the root level. Each sample time in your model corresponds to a partition, and all blocks of a single rate or sample time belong to the same partition. Simulink maps these partitions to tasks that run on your processor. Implicit partitioning assumes your architecture to be a single multicore CPU. The CPU task scheduler handles all the partitioned tasks.

If you want to specify how to partition your model, use explicit partitioning. In explicit partitioning, you create partitions in the root-level model by using referenced models, MATLAB system blocks, and so on. For example, if your model has data acquisition and a controller, partition your model by putting these components in two referenced models at the model root-level. Each sample time in a referenced model or a system block is a partition. You can add tasks to run on processing nodes in the Concurrent Execution dialog box and assign your partitions to these tasks. If some partitions are left unassigned, Simulink automatically assigns them to tasks.

In explicit partitioning, you can specify your own architecture. The default architecture is a multicore CPU, the same as the assumed architecture in implicit partitioning. Explicit partitioning has more restrictions on your root-level model than implicit partitioning. For more information, see “Limitations with Multicore Programming in Simulink” on page 14-58.

Partitioning Guidelines

There are multiple ways to partition your model for concurrent execution in Simulink. Rate-based and model-based approaches give you primarily graphical means to represent concurrency for systems that are represented using Simulink and Stateflow blocks. You can partition MATLAB code using the MATLAB System block. You can also partition models of physical systems using multisolver methods.

Each method has additional considerations to help you decide which to use.

Goal	Valid Partitioning Methods	Considerations
Increase the performance of a simulation on the host computer.	No partitioning method	Simulink tries to optimize the host computer performance regardless of the modeling method you use. For more information on the ways that Simulink helps you to improve performance, see "Performance".
Increase the performance of a plant simulation in a multicore HIL (hardware-in-the-loop) system.	You can use any of the partitioning methods and their combinations.	The processing characteristics of the HIL system and the embedded processing system can vary greatly. Consider partitioning your system into more units of work than there are number of processing elements in the HIL or embedded system. This convention allows flexibility in the mapping process.
Create a valid model of a multirate concurrent system to take advantage of a multicore processing system.	You can use any of the partitioning methods and their combinations.	Partitioning can introduce signal delays to represent the data transfer requirements for concurrent execution. For more information, see "Configure Data Transfer Settings Between Concurrent Tasks" on page 14-39.
Create a valid model of a heterogeneous system to take advantage of multicore and FPGA processing.	• Multicore processing: Use any of the partitioning methods. • FPGA processing: Partition your model using Model blocks.	Consider partitioning for FPGA processing where your computations have bottlenecks that could be reduced using fine-grained hardware parallelism.

Configure Data Transfer Settings Between Concurrent Tasks

Data dependencies arise when a signal originates from one block in one partition and is connected to a block in another partition. To create opportunities for parallelism, Simulink provides multiple options for handling data transfers between concurrently executing partitions. These options help you trade off computational latency for numerical signal delays.

Use the **Data Transfer Options** pane to define communications between tasks. Set the values for the `Use global setting` option of the Data Transfer tab in the Signal Properties dialog box. The table provides the model-level options that you can apply to each signal that requires data transfer in the system.

Data Transfer Options

Goal	Data Transfer Type	Simulation	Deployment
• Create opportunity for parallelism. • Reduce signal latency.	Ensure data integrity only.	Data transfer is simulated using a one-step delay.	Simulink Coder ensures data integrity during data transfer. Simulink generates code to operate with maximum responsiveness and data integrity. However, the implementation is interruptible, which can lead to loss of data during data transfer. Use a deterministic execution schedule to achieve determinism in the deployment environment.
• Create opportunity for parallelism. • Produce numeric results that are repeatable with each run of the generated code.	Ensure deterministic transfer (maximum delay).	Data transfer is simulated using a one-step delay, which can have impact on the numeric results. To compensate, you might need to specify an initial condition for these delay elements.	Simulink Coder ensures data integrity during data transfer. In addition, Simulink Coder ensures that data transfer is identical with simulation.

Goal	Data Transfer Type	Simulation	Deployment
• Enforce data dependency. • Produce numeric results that are repeatable with each run of the generated code.	Ensure deterministic transfer (minimum delay).	Data transfer occurs within the same step.	

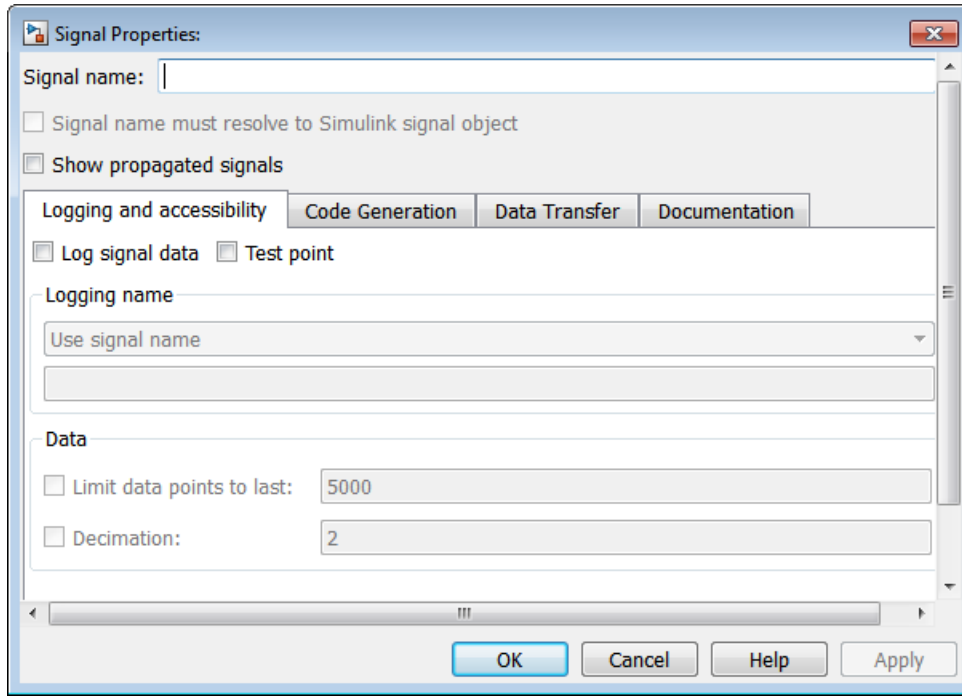
You can also override these options for each signal from the **Data Transfer** pane of the Signal Properties dialog box. For more information, see "Data Transfer Options for Concurrent Execution".

For example, consider a control application in which a controller that reads sensory data at time T must produce the control signals to the actuator at time $T+\Delta$.

- If the sequential algorithm meets the timing deadlines, consider using option 3.
- If the embedded system provides deterministic scheduling, consider using option 2.
- Otherwise, use option 1 to create opportunities for parallelism by introducing signal delays.

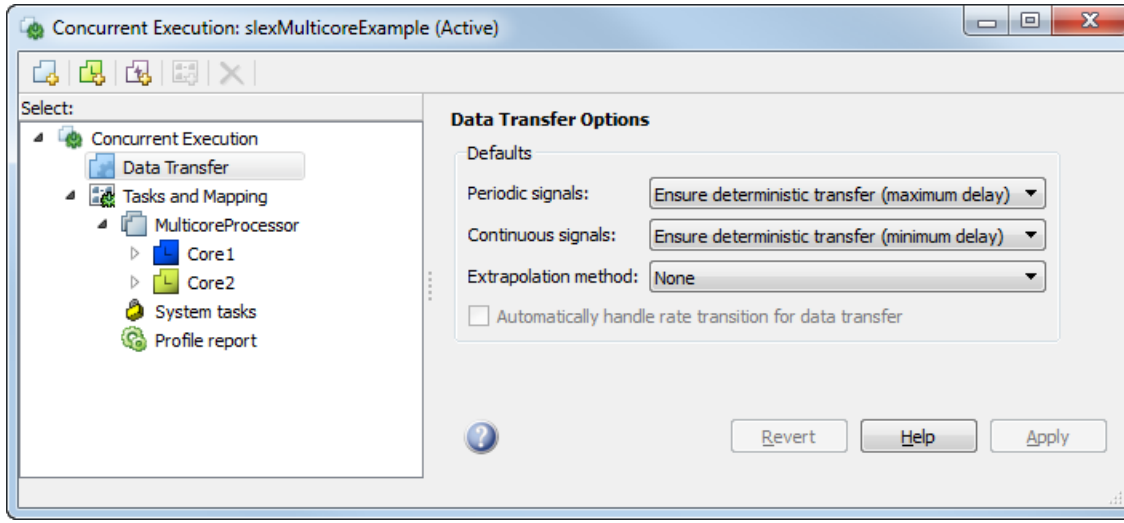
For continuous signals, Simulink uses extrapolation methods to compensate for numerical errors that were introduced due to delays and discontinuities in data transfer.

To avoid numerical errors in signals configured for `Ensure Data Integrity Only` and `Ensure deterministic transfer (maximum delay)` data transfers, you may need to provide an initial condition. You can specify this initial condition in the **Data Transfer** tab of the Signal Properties dialog box. To access this dialog box, right-click the signal line and select **Properties** from the context menu. A dialog box like the following is displayed.



1 From the Data Transfer Options table, determine how you want your tasks to communicate.

2 In the Concurrent Execution dialog box, select Data Transfer defaults and apply the settings from step 1.



3 Apply your changes.

- “Implicit and Explicit Partitioning of Models” on page 14-36

Optimize and Deploy on a Multicore Target

In this section...

This topic shows you how to use a model that is configured for concurrent execution using explicit partitioning and deploy it onto a target. To set up your model for concurrent execution, see “Configure Your Model for Concurrent Execution” on page 14-23. To specify the target architecture, see “Specify a Target Architecture” on page 14-24. To use explicit partitioning in a model that is set up for concurrent execution, see “Partition Your Model Using Explicit Partitioning” on page 14-30.

Generate Code

To generate code for a model that is configured for concurrent execution, in the Simulink editor window, select **Code > C/C++ Code > Build Model**. The resulting code includes:

- C code for parts of the model that are mapped to tasks and triggers in the Concurrent Execution dialog box. C code generation requires a Simulink Coder license. For more information, see “Code Generation” (Simulink Coder) in the Simulink Coder documentation and “Code Generation from Simulink Models” (Embedded Coder) in the Embedded Coder documentation.
- HDL code for parts of the model that are mapped to hardware nodes in the Concurrent Execution dialog box. HDL code generation requires an HDL Coder license. For more information, see “HDL Code Generation from Simulink” (HDL Coder).
- Code to handle data transfer between the concurrent tasks and triggers and to interface with the hardware and software components.

The generated C code contains one function for each task or trigger defined in the system. The task and trigger determines the name of the function:

```
void <TriggerName>_TaskName(void);
```

The content for each such function consists of target-independent C code, except for:

- Code corresponding to blocks that implement target-specific functionality
- Customizations, including those derived from “Custom Storage Classes” (Embedded Coder) or “Code Replacement Libraries” (Simulink Coder)
- Code that is generated to handle how data is transferred between tasks. In particular, Simulink Coder uses target-specific implementations of mutual exclusion primitives and data synchronization semaphores to implement the data transfer as described in the following table of pseudocode.

Data Transfer	Initialization	Reader	Writer

Data Integrity Only	`BufferIndex = 0;`
	`Initialize Buffer[1] with IC`
		`Begin mutual exclusion`
		`Tmp = 1 - BufferIndex;`
		`End mutual exclusiton`
		`Read Buffer[ Tmp ];`
			`Write Buffer[ BufferIndex ];`
			`Begin mutual exclusion`
			`BufferIndex = 1 - BufferIndex;`
			`End mutual exclusion`

Ensure Determinism (Maximum Delay)	`WriterIndex = 0;`
	`ReaderIndex = 1;`
	`Initialize Buffer[1] with IC`
		`Read Buffer[ ReaderIndex ];`
		`ReaderIndex = 1 - ReaderIndex;`
			`Write Buffer[ WriterIndex ]`
			`WriterIndex = 1 - WriterIndex;`

Ensure Determinism (Minimum Delay)	N/A	`Wait dataReady;`
		`Read data;`
		`Post readDone;`
			`Wait readDone;`
			`Write data;`
			`Post dataReady;`

Data Integrity Only C-HDL interface	The Simulink Coder and HDL Coder products both take advantage of target-specific communication implementations and devices to handle the data transfer between hardware and software components.		

The generated HDL code contains one HDL project for each hardware node.

Build on Desktop

Simulink Coder and Embedded Coder targets provide an example target to generate code for Windows, Linux and Mac OS operating systems. It is known as the native threads example, which is used to deploy your model to a desktop target. The desktop may not be your final target, but can help to profile and optimize your model before you deploy it on another target.

If you have specified an Embedded Coder target, make the following changes in the Configuration Parameters dialog box.

1. Select the **Code Generation > Templates > Generate an example main program** check box.
2. From the **Code Generation > Templates > Target Operating System** list, select `NativeThreadsExample`.
3. Click **OK** to save your changes and close the Configuration Parameters dialog box.
4. Apply these settings to all referenced models in your model.

Once you have set up your model, press **Ctrl-B** to build and deploy it to your desktop. The native threads example illustrates how Simulink Coder and Embedded Coder use target-specific threading APIs and data management primitives, as shown in "Threading APIs Used by Native Threads Example" on page 14-46. The data transfer between concurrently executing tasks behaves as described in Data Transfer Options. The coder products use the APIs on supported targets for this behavior, as described in "Data Protection and Synchronization APIs Used by Native Threads Example" on page 14-47.

Threading APIs Used by Native Threads Example

Aspect of Concurrent Execution	Linux Implementation	Windows Implementation	Mac OS Implementation
Periodic triggering event	POSIX timer	Windows timer	Not applicable
Aperiodic triggering event	POSIX real-time signal	Windows event	POSIX non-real-time signal
Aperiodic trigger	For blocks mapped to an aperiodic task: thread waiting for a signal For blocks mapped to an aperiodic trigger: signal action	Thread waiting for an event	For blocks mapped to an aperiodic task: thread waiting for a signal For blocks mapped to an aperiodic trigger: signal action
Threads	POSIX	Windows	POSIX

Aspect of Concurrent Execution	Linux Implementation	Windows Implementation	Mac OS Implementation
Threads priority	Assigned based on sample time: fastest task has highest priority	Priority class inherited from the parent process. Assigned based on sample time: fastest task has highest priority for the first three fastest tasks. The rest of the tasks share the lowest priority.	Assigned based on sample time: fastest task has highest priority
Example of overrun detection	Yes	Yes	No

Data Protection and Synchronization APIs Used by Native Threads Example

API	Linux Implementation	Windows Implementation	Mac OS Implementation
Data protection API	• pthread_mutex_init • `pthread_mutex_-destroy` • `pthread_mutex_lock` • `pthread_mutex_-unlock`	• `CreateMutex` • `CloseHandle` • `WaitForSingleObject` • `ReleaseMutex`	• `pthread_mutex_init` • `pthread_mutex_-destroy` • `pthread_mutex_lock` • `pthread_mutex_-unlock`
Synchronization API	• `sem_init` • `sem_destroy` • `sem_wait` • `sem_post`	• `CreateSemaphore` • `CloseHandle` • `WaitForSingle-Object` • `ReleaseSemaphore`	• `sem_open` • `sem_unlink` • `sem_wait` • `sem_post`

Profile and Evaluate on a Desktop

Profile the execution of your code on the multicore target using the **Profile Report** pane of the Concurrent Execution dialog box. You can profile using Simulink Coder (GRT) and Embedded Coder (ERT) targets. Profiling helps you identify the areas in your model that are execution bottlenecks. You can analyze the execution time of each task and find the task that takes most of the execution time. For example, you can compare the average execution times of the tasks. If a task is computation intensive, or does not satisfy real-time requirements and overruns, you can break it into tasks that are less computation intensive and that can run concurrently.

When you generate a profile report, the software:

1. Builds the model.
2. Generates code for the model.
3. Adds tooling to the generated code to collect data.
4. Executes the generated code on the target and collects data.
5. Collates the data, generates an HTML file (`model_name_ProfileReport.html`) in the current folder, and displays that HTML file in the **Profile Report** pane of the Concurrent Execution dialog box.

Note If an HTML profile report exists for the model, the **Profile Report** pane displays that file. To generate a new profile report, click  .

Section	Description
Summary	Summarizes model execution statistics, such as total execution time and profile report creation time. It also lists the total number of cores on the host machine.
Task Execution Time	Displays the execution time, in microseconds, for each task in a pie chart color coded by task. Visible for Windows, Linux, and Mac OS platforms.

Section	Description
Task Affinitization to Processor Cores	Platform-dependent. For each time step and task, Simulink displays the processor core number the task started executing on at that time step, color coded by processor. If there is no task scheduled for a particular time step, `NR` is displayed. Visible for Windows and Linux platforms.

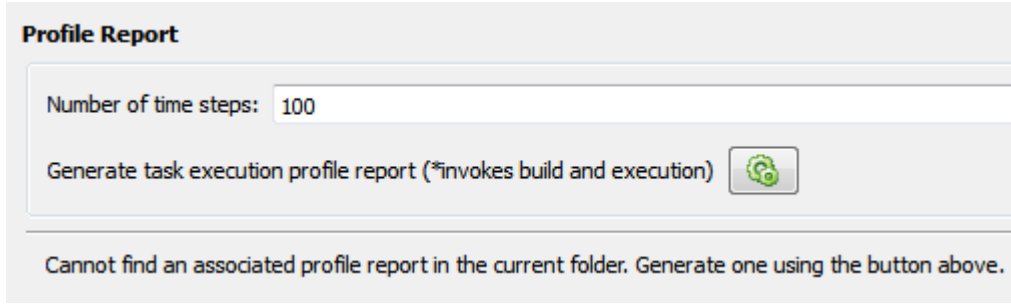
After you analyze the profile report, consider changing the mapping of Model blocks to efficiently use the concurrency available on your multicore system (see "Map Blocks to Tasks, Triggers, and Nodes" on page 14-33).

Generate Profile Report

This topic assumes a previously configured model ready to be profiled for concurrent execution. For more information, see "Configure Your Model for Concurrent Execution" on page 14-23.

1 In the Concurrent Execution dialog box, click the **Profile report** node.

The profile tool looks for a file named *model_name*`_ProfileReport.html`. If such a file does not exist for the current model, the **Profile Report** pane displays the following.



Note If an HTML profile report exists for the model, the **Profile Report** pane displays that file. To generate a new profile report, click  .

2 Enter the number of time steps for which you want the profiler to collect data for the model execution.

3 Click the **Generate task execution profile report** button.

This action builds the model, generates code, adds data collection tooling to the code, and executes it on the target, which also generates an HTML profile report. This process can take several minutes. When the process is complete, the contents of the profile report appear in the **Profile Report** pane. For example:

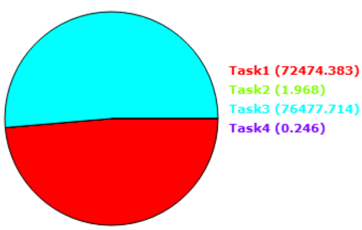
Task Execution Profiling Report for slexMulticoreExample

1. Summary

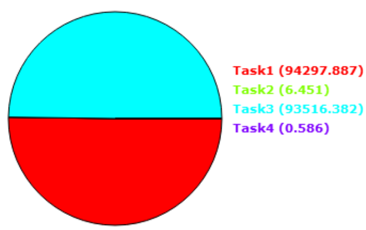
Total simulation time [seconds]	9.9
Profile data created	Thu Nov 12 16:47:52 2015
Model name	slexMulticoreExample
Number of processor cores on the host machine	12

2. Task Execution Time

Average Turnaround Time [microseconds]



Maximum Turnaround Time [microseconds]



3. Task Affinitization to Processor Cores

Clock Tick / Task	0										10										20										30										40									
Task1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Task2	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Task3	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR
Task4	1	NR	NR	NR	1	NR	NR	NR	1	NR	NR	NR	1	NR	NR	NR	1	NR	NR	NR	1	NR	NR	NR	1	NR	NR	NR	1	NR	NR	NR	1	NR	NR	NR	1	NR	NR	NR	1	NR	NR	NR	1	NR	NR	NR	1	NR

Legend

NR - Not scheduled to run

The profiling report shows the summary, execution time for each task, and the mapping of each task to processor cores. We see that tasks 1 and 2 run on core 0, where tasks 3 and 4 run on core 1. The **Task Execution Time** section of the report indicates that task 1 and task 3 take the most amount of time to run. Note that the

period of task 3 is twice that of tasks 1 and 2, and the period of task 4 is twice that of task 3.

4 Analyze the profile report. Create and modify your model or task mapping if needed, and regenerate the profile report.

Generate Profile Report at Command Line

Alternatively, you can generate a profile report for a model configured for concurrent execution at the command line. Use the `Simulink.architecture.profile` function.

For example, to create a profile report for the model `slexMulticoreSolverExample`:

```
Simulink.architecture.profile('slexMulticoreSolverExample');
```

To create a profile report with a specific number of samples (100) for the model `slexMulticoreSolverExample`:

```
Simulink.architecture.profile('slexMulticoreSolverExample',120);
```

The function creates a profile report named `slexMulticoreSolverExample_ProfileReport.html` in your current folder.

Customize the Generated C Code

The generated code is suitable for many different applications and development environments. To meet your needs, you can customize the generated C code as described in "Target Development" (Embedded Coder). In addition to those customization capabilities, for multicore and heterogeneous targets you can further customize the generated code as follows:

- You can register your preferred implementation of mutual exclusion and data synchronization primitives using the code replacement library.
- You can define a custom target architecture file that allows you to specify target specific properties for tasks and triggers in the Concurrent Execution dialog box. For more information, see "Define a Custom Architecture File" on page 14-26.

Programmatic Interface for Concurrent Execution

Use these functions to configure models for concurrent execution.

To	Use
Create or convert configuration for concurrent execution.	`Simulink.architecture.config`
Add triggers to the software node or add tasks to triggers.	`Simulink.architecture.add`
Delete triggers or tasks.	`Simulink.architecture.delete`
Find objects with specified parameter values.	`Simulink.architecture.find_system`
Get configuration parameters for target architecture.	`Simulink.architecture.get_param`
Import and select architecture.	`Simulink.architecture.importAndSelect`
Generate profile report for model configured for concurrent execution.	`Simulink.architecture.profile`
Add custom target architecture.	`Simulink.architecture.register`
Set properties for a concurrent execution object (such as task, trigger, or hardware node).	`Simulink.architecture.set_param`
Configure concurrent execution data transfers.	`Simulink.GlobalDataTransfer`

Map Blocks to Tasks

To map blocks to tasks, use the `set_param` function.

Map a block to one task:

```
set_param(block,'TargetArchitectureMapping',[bdroot 'CPU/PeriodicTrigger1/Task1']);
```

Map a block to multiple tasks:

```
set_param(block,'TargetArchitectureMapping',...
{[bdroot 'CPU/PeriodicTrigger1/Task1'];...
[bdroot 'CPU/PeriodicTrigger1/Task2']});
```

Get the current mapping of a block:

```
get_param(block,'TargetArchitectureMapping');
```

Supported Targets For Multicore Programming

Supported Multicore Targets

You can build and download concurrent execution models for the following multicore targets using system target files:

- Linux, Windows, and Mac OS using `ert.tlc` and `grt.tlc`.
- Simulink Real-Time using `slrt.tlc`.
- `idelink_ert.tlc`, `idelink_grt.tlc`, and `ert.tlc`, if it is supported for your hardware board.

Note

- To build and download your model, you must have Simulink Coder software installed.
- To build and download your model to a Simulink Real-Time system, you must have Simulink Real-Time software installed. You must also have a multicore target system supported by the Simulink Real-Time product.
- Deploying to an embedded processor that runs Linux and VxWorks® operating systems requires the Embedded Coder product.

Supported Heterogeneous Targets

In addition to multicore targets, Simulink also supports building and downloading partitions of a model to heterogeneous targets that contain a multicore target and one or more field-programmable gate arrays (FPGAs).

Select the heterogeneous architecture using the Target architecture option in the Concurrent Execution dialog box **Concurrent Execution** pane:

Item	Description
`Sample Architecture`	Example architecture consisting of single CPU with multiple cores and two FPGAs. You can use this architecture to model for concurrent execution.

Item	Description
`Simulink Real-Time`	Simulink Real-Time target containing FPGA boards.
`Xilinx Zynq ZC702 evaluation kit`	Xilinx® Zynq® ZC702 evaluation kit target.
`Xilinx Zynq ZC706 evaluation kit`	Xilinx Zynq ZC706 evaluation kit target.
`Xilinx Zynq Zedboard`	Xilinx Zynq ZedBoard™ target.
`Altera Cyclone V SoC development kit Rev. C`	Altera® Cyclone® SoC Rev. C development kit target.
`Altera Cyclone V SoC development kit Rev. D`	Altera Cyclone SoC Rev. D development kit target.
`Arrow SoCKit development board`	Arrow® SoCKit development board target.

Note Building HDL code and downloading it to FPGAs requires the HDL Coder product. You can generate HDL code if:

- You have an HDL Coder license
- You are building on Windows or Linux operating systems

You cannot generate HDL code on Macintosh systems.

Limitations with Multicore Programming in Simulink

The following limitations apply when partitioning a model for concurrent execution.

- Configure the model to use the fixed-step solver.
- Do not use the following modes of simulation for models in the concurrent execution environment:
  - External mode
  - Logging to MAT-files (**MAT-file logging** check box selected). However, you can use the To Workspace and To File blocks.
  - If you are simulating your model using Rapid Accelerator mode, the top-level model cannot contain a root level Inport block that outputs function calls.
  - In the Configuration Parameters dialog box, set the **Diagnostics > Sample Time > Multitask conditionally executed subsystem** and **Diagnostics > Data Validity > Multitask data store** parameters to `error`.
  - In addition, use the model-level control to handle data transfer for rate transition or if you use Rate Transition blocks, then:
    - Select the **Ensure data integrity during data transfer** check box.
    - Clear the **Ensure deterministic data transfer (maximum delay)** check box.
- If you want to use explicit partitioning, your model must consist entirely of Model blocks, MATLAB System blocks, and virtual connectivity blocks at the root-level. The following are valid virtual connectivity blocks:
  - Goto and From blocks
  - Ground and Terminator blocks
  - Inport and Outport blocks
  - Virtual subsystem blocks that contain permitted blocks

Modeling Best Practices

General Considerations when Building Simulink Models

In this section...

Avoiding Invalid Loops

You can connect the output of a block directly or indirectly (i.e., via other blocks) to its input, thereby, creating a loop. Loops can be very useful. For example, you can use loops to solve differential equations diagrammatically (see “Model a Continuous System” on page 15-8) or model feedback control systems. However, it is also possible to create loops that cannot be simulated. Common types of invalid loops include:

- Loops that create invalid function-call connections or an attempt to modify the input/output arguments of a function call (see “Using Function-Call Subsystems” on page 10-29 for a description of function-call subsystems)
- Self-triggering subsystems and loops containing non-latched triggered subsystems (see “Triggered Subsystems” on page 10-20 in the Using Simulink documentation for a description of triggered subsystems and Inport in the Simulink reference documentation for a description of latched input)
- Loops containing action subsystems

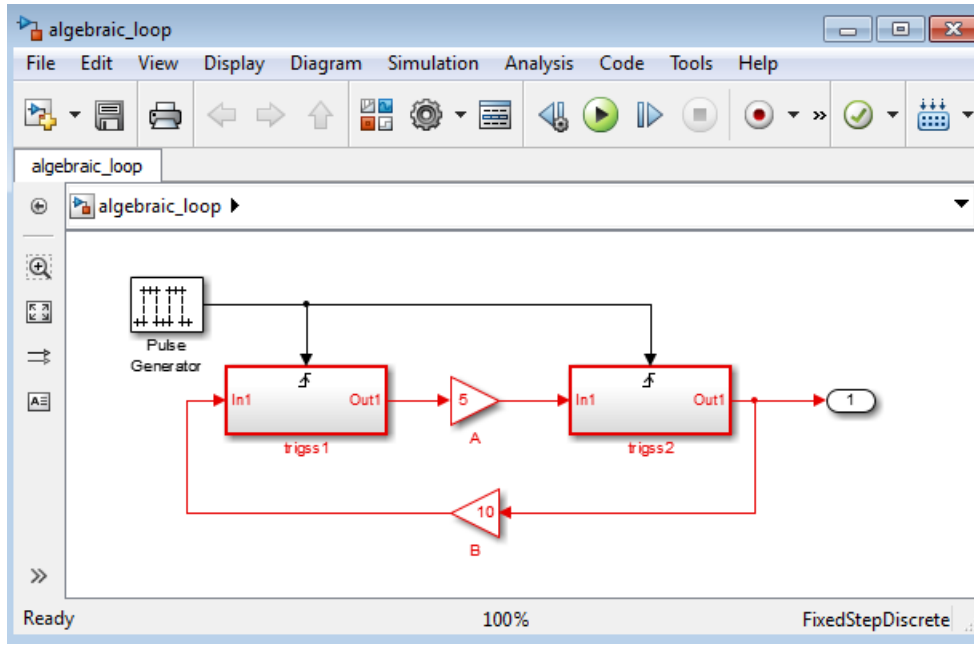
The Subsystem Examples block library in the Ports & Subsystems library contains models that illustrates examples of valid and invalid loops involving triggered and function-call subsystems. Examples of invalid loops include the following models:

- `simulink/Ports&Subsystems/sl_subsys_semantics/Triggered subsystem/sl_subsys_trigerr1` (`sl_subsys_trigerr1`)
- `simulink/Ports&Subsystems/sl_subsys_semantics/Triggered subsystem/sl_subsys_trigerr2` (`sl_subsys_trigerr2`)
- `simulink/Ports&Subsystems/sl_subsys_semantics/Function-call systems/sl_subsys_fcncallerr3` (`sl_subsys_fcncallerr3`)

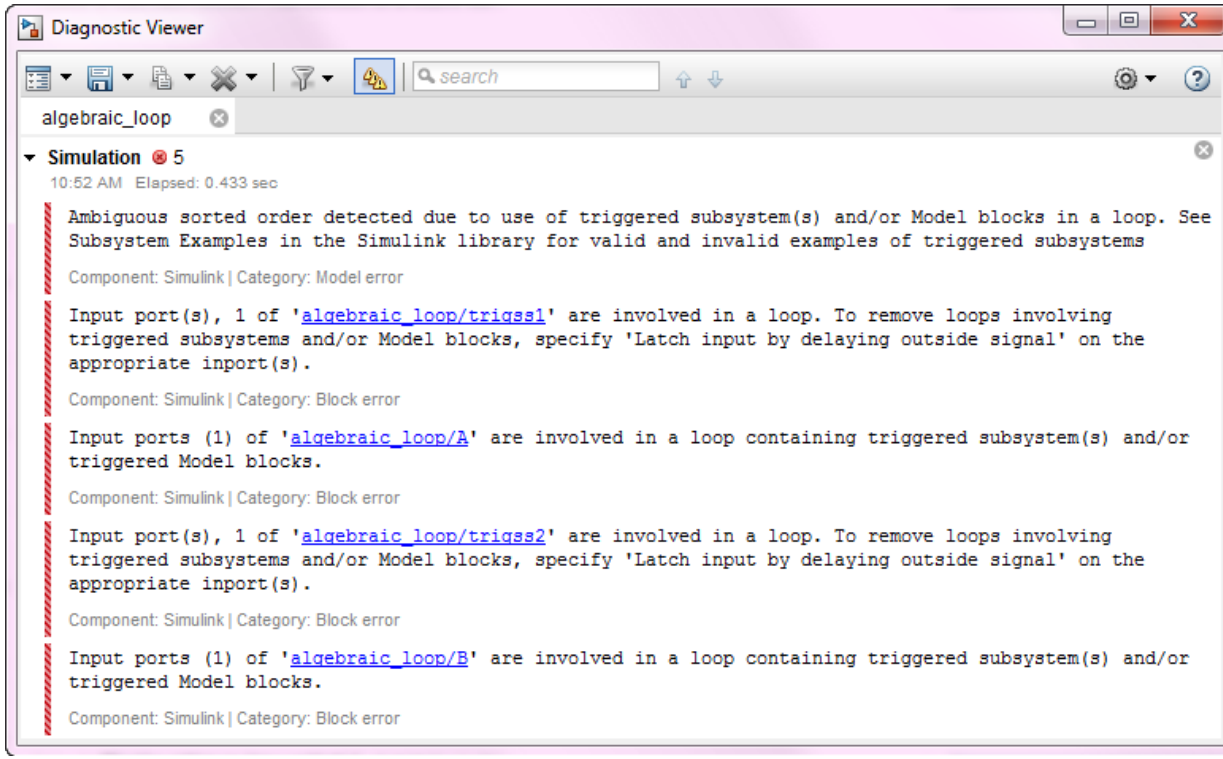
You might find it useful to study these examples to avoid creating invalid loops in your own models.

Detecting Invalid Loops

To detect whether your model contains invalid loops, select **Update Diagram** from the model's **Simulation** menu. If the model contains invalid loops, the invalid loops are highlighted. This is illustrated in the following model ,



and displays an error message in the Diagnostic Viewer.



Shadowed Files

If there are two Model files with the same name (e.g. `mylibrary.slx`) on the MATLAB path, the one higher on the path is loaded, and the one lower on the path is said to be "shadowed".

Tip To help avoid problems with shadowed files, turn on the Simulink preference **Do not load models that are shadowed on the MATLAB path**. See “Do not load models that are shadowed on the MATLAB path”.

The rules Simulink software uses to find Model files are similar to those used by MATLAB software. See “What Is the MATLAB Search Path?” (MATLAB) in the MATLAB documentation. However, there is an important difference between how

Simulink block diagrams and MATLAB functions are handled: a loaded block diagram takes precedence over any unloaded ones, regardless of its position on the MATLAB path. This is done for performance reasons, as part of the Simulink software's incremental loading methodology.

The precedence of a loaded block diagram over any others can have important implications, particularly since a block diagram can be loaded without the corresponding Simulink window being visible.

Making Sure the Correct Block Diagram Is Loaded

When using libraries and referenced models, you can load a block diagram without showing its window. If the MATLAB path or the current MATLAB folder changes while block diagrams are in memory, these block diagrams can interfere with the use of other files of the same name.

For example, open a model with a library called `mylib`, change to another folder, and then open another model with a library also called `mylib`. When you run the first model, it uses the library associated with the second model.

This can lead to problems including:

- Simulation errors
- "Unresolved Link" icons on blocks that are library links
- Wrong results

Detecting and Fixing Problems

To help avoid problems with shadowed files, you can turn on the Simulink preference **Do not load models that are shadowed on the MATLAB path**. See "Do not load models that are shadowed on the MATLAB path".

When updating a block diagram, the Simulink software checks the position of its file on the MATLAB path and will issue a warning if it detects that another file of the same name exists and is higher on the MATLAB path. The warning reads:

```
The file containing block diagram 'mylibrary' is shadowed
by a file of the same name higher on the MATLAB path.
```

This may indicate that the wrong file called `mylibrary.slx` is being used. To see which file called `mylibrary.slx` is loaded into memory, enter:

```
 which mylibrary

C:\work\Model1\mylibrary.slx
```

To see all the files called `mylibrary` which are on the MATLAB path, including MATLAB scripts, enter:

```
which -all mylibrary

C:\work\Model1\mylibrary.slx
C:\work\Model2\mylibrary.slx  % Shadowed
```

To close the block diagram called `mylibrary` and let the Simulink software load the file which is highest on the MATLAB path, enter:

```
close_system('mylibrary')
```

Model Building Tips

Here are some model-building hints you might find useful:

- Memory issues

  In general, more memory will increase performance.
- Using hierarchy

  More complex models often benefit from adding the hierarchy of subsystems to the model. Grouping blocks simplifies the top level of the model and can make it easier to read and understand the model. For more information, see “Create a Subsystem” on page 4-17. The Model Browser provides useful information about complex models (see “Explore the Model Hierarchy Using the Model Browser” on page 12-47).
- Cleaning up models

  Well organized and documented models are easier to read and understand. Signal labels and model annotations can help describe what is happening in a model. For more information, see “Signal Names and Labels” on page 64-4 and “Describe Models Using Annotations” on page 4-3.
- Modeling strategies

  If several of your models tend to use the same blocks, you might find it easier to save these blocks in a model. Then, when you build new models, just open this model and

copy the commonly used blocks from it. You can create a block library by placing a collection of blocks into a system and saving the system. You can then access the system by typing its name in the MATLAB Command Window.

Generally, when building a model, design it first on paper, then build it using the computer. Then, when you start putting the blocks together into a model, add the blocks to the model window before adding the lines that connect them. This way, you can reduce how often you need to open block libraries.

Model a Continuous System

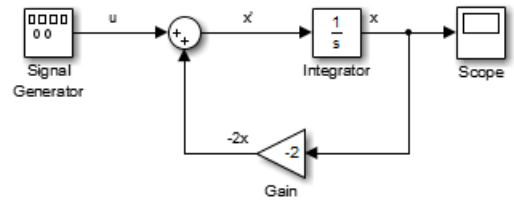
To model the differential equation

$x' = -2x(t)+u(t)$,

where $u(t)$ is a square wave with an amplitude of `1` and a frequency of `1` rad/sec, use an integrator block and a gain block. The Integrator block integrates its input x' to produce x. Other blocks needed in this model include a Gain block and a Sum block. To generate a square wave, use a Signal Generator block and select the Square Wave form but change the default units to radians/sec. Again, view the output using a Scope block. Gather the blocks and define the gain.

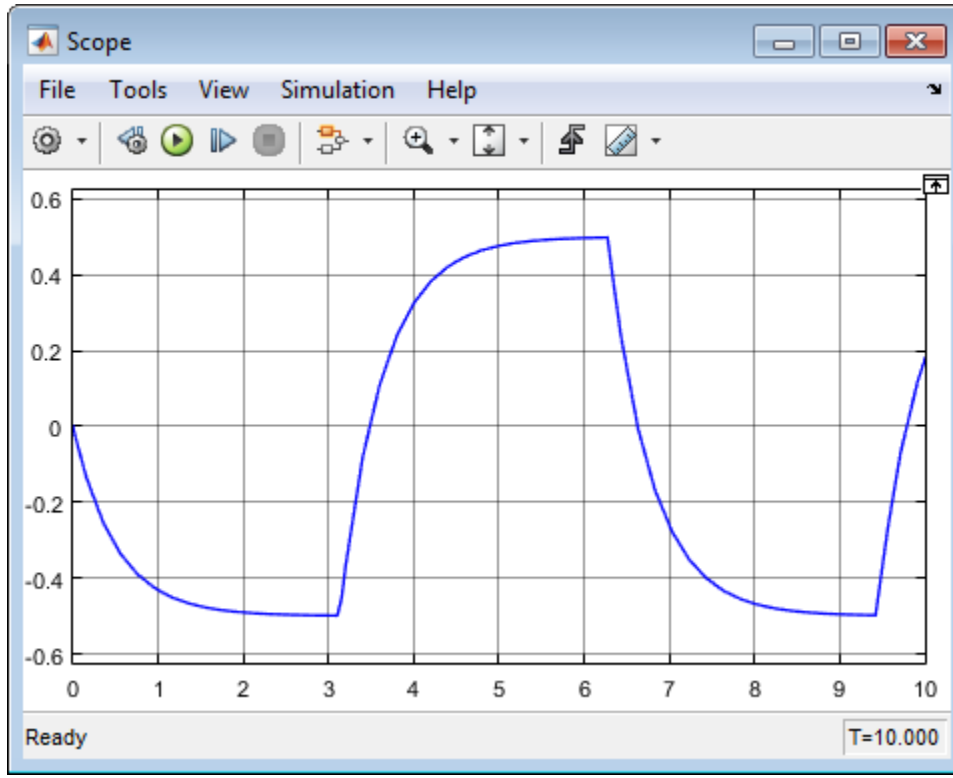
In this model, to reverse the direction of the Gain block, select the block, then use the **Diagram > Rotate & Flip > Flip Block** command. To create the branch line from the output of the Integrator block to the Gain block, hold down the **Ctrl** key while drawing the line. For more information, see "Branch a Connection" on page 1-27.

Now you can connect all the blocks.



An important concept in this model is the loop that includes the Sum block, the Integrator block, and the Gain block. In this equation, x is the output of the Integrator block. It is also the input to the blocks that compute x', on which it is based. This relationship is implemented using a loop.

The Scope displays x at each time step. For a simulation lasting 10 seconds, the output looks like this:



The equation you modeled in this example can also be expressed as a transfer function. The model uses the Transfer Fcn block, which accepts u as input and outputs x. So, the block implements x/u. If you substitute sx for x' in the above equation, you get

$$sx = -2x + u.$$

Solving for x gives

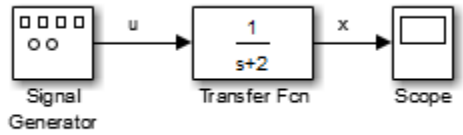
$$x = u/(s + 2)$$

or,

$$x/u = 1/(s + 2).$$

The Transfer Fcn block uses parameters to specify the numerator and denominator coefficients. In this case, the numerator is `1` and the denominator is `s+2`. Specify both terms as vectors of coefficients of successively decreasing powers of `s`.

In this case the numerator is `[1]` (or just `1`) and the denominator is `[1 2]`.



The results of this simulation are identical to those of the previous model.

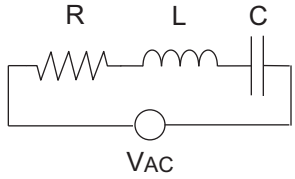
Best-Form Mathematical Models

In this section...

Series RLC Example

You can often formulate the mathematical system you are modeling in several ways. Choosing the best-form mathematical model allows the simulation to execute faster and more accurately. For example, consider a simple series RLC circuit.



According to Kirchoff's voltage law, the voltage drop across this circuit is equal to the sum of the voltage drop across each element of the circuit.

$$V_{AC} = V_R + V_L + V_C$$

Using Ohm's law to solve for the voltage across each element of the circuit, the equation for this circuit can be written as

$$V_{AC} = Ri + L\frac{di}{dt} + \frac{1}{C}\int_{-\infty}^{t} i(t)dt$$

You can model this system in Simulink by solving for either the resistor voltage or inductor voltage. Which you choose to solve for affects the structure of the model and its performance.

Solving Series RLC Using Resistor Voltage

Solving the RLC circuit for the resistor voltage yields

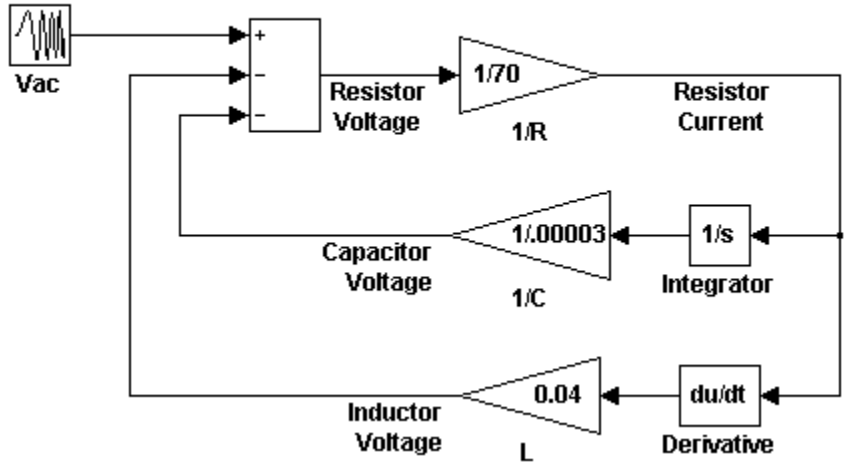
$$V_R = Ri$$

$$Ri = V_{AC} - L\frac{di}{dt} - \frac{1}{C}\int_{-\infty}^{t} i(t)dt$$

Circuit Model

The following diagram shows this equation modeled in Simulink where R is `70`, C is `0.00003`, and L is `0.04`. The resistor voltage is the sum of the voltage source, the capacitor voltage, and the inductor voltage. You need the current in the circuit to calculate the capacitor and inductor voltages. To calculate the current, multiply the resistor voltage by a gain of $1/R$. Calculate the capacitor voltage by integrating the current and multiplying by a gain of $1/C$. Calculate the inductor voltage by taking the derivative of the current and multiplying by a gain of L.

Series RLC Circuit: Formulated to solve for resistor current



This formulation contains a Derivative block associated with the inductor. Whenever possible, you should avoid mathematical formulations that require Derivative blocks as they introduce discontinuities into your system. Numerical integration is used to solve the model dynamics though time. These integration solvers take small steps through time to satisfy an accuracy constraint on the solution. If the discontinuity introduced by the Derivative block is too large, it is not possible for the solver to step across it.

In addition, in this model the Derivative, Sum, and two Gain blocks create an algebraic loop. Algebraic loops slow down the model's execution and can produce less accurate simulation results. See “Algebraic Loops” on page 3-37 for more information.

Solving Series RLC Using Inductor Voltage

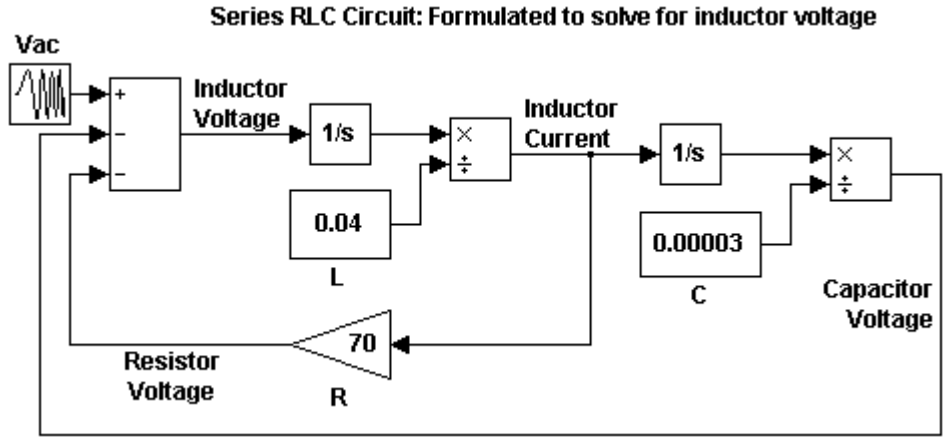
To avoid using a Derivative block, formulate the equation to solve for the inductor voltage.

$$V_L = L\frac{di}{dt}$$

$$L\frac{di}{dt} = V_{AC} - Ri - \frac{1}{C}\int_{-\infty}^{t} i(t)dt$$

Circuit Model

The following diagram shows this equation modeled in Simulink. The inductor voltage is the sum of the voltage source, the resistor voltage, and the capacitor voltage. You need the current in the circuit to calculate the resistor and capacitor voltages. To calculate the current, integrate the inductor voltage and divide by *L*. Calculate the capacitor voltage by integrating the current and dividing by *C*. Calculate the resistor voltage by multiplying the current by a gain of *R*.



This model contains only integrator blocks and no algebraic loops. As a result, the model simulates faster and more accurately.

Model a Simple Equation

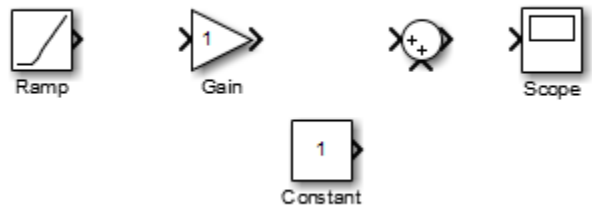
To model the equation that converts Celsius temperature to Fahrenheit

$$T_F = 9/5(T_C) + 32$$

First, consider the blocks needed to build the model:

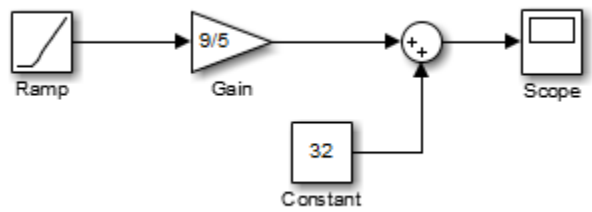
- A Ramp block to input the temperature signal, from the Sources library
- A Constant block to define a constant of 32, also from the Sources library
- A Gain block to multiply the input signal by 9/5, from the Math Operations library
- A Sum block to add the two quantities, also from the Math Operations library
- A Scope block to display the output, from the Sinks library

Next, gather the blocks into your model window.



Assign parameter values to the Gain and Constant blocks by opening (double-clicking) each block and entering the appropriate value. Then, click the **OK** button to apply the value and close the dialog box.

Now, connect the blocks.



The Ramp block inputs Celsius temperature. Open that block and change the **Initial output** parameter to 0. The Gain block multiplies that temperature by the constant 9/5. The Sum block adds the value 32 to the result and outputs the Fahrenheit temperature.

Open the Scope block to view the output. Now, choose **Run** from the **Simulation** menu to run the simulation. The simulation runs for 10 seconds.

Model Differential Algebraic Equations

In this section...

Overview of Robertson Reaction Example

Robertson [1] on page 15-27 created a system of autocatalytic chemical reactions to test and compare numerical solvers for stiff systems. The reactions, rate constants (k), and reaction rates (V) for the system are given as follows:

$$A \xrightarrow{k_1} B \qquad k_1 = 0.04 \qquad V_1 = k_1[A]$$

$$B + B \xrightarrow{k_2} C + B \qquad k_2 = 3 \cdot 10^7 \qquad V_2 = k_2[B][B]$$

$$B + C \xrightarrow{k_3} A + C \qquad k_3 = 1 \cdot 10^4 \qquad V_3 = k_3[B][C]$$

Because there are large differences between the reaction rates, the numerical solvers see the differential equations as stiff. For stiff differential equations, some numerical solvers cannot converge on a solution unless the step size is extremely small. If the step size is extremely small, the simulation time can be unacceptably long. In this case, you need to use a numerical solver designed to solve stiff equations.

Simulink Model from ODE Equations

A system of ordinary differential equations (ODE) has the following characteristics:

- All of the equations are ordinary differential equations.
- Each equation is the derivative of a dependent variable with respect to one independent variable, usually time.
- The number of equations is equal to the number of dependent variables in the system.

Using the reaction rates, you can create a set of differential equations describing the rate of change for each chemical species. Since there are three species, there are three differential equations in the mathematical model.

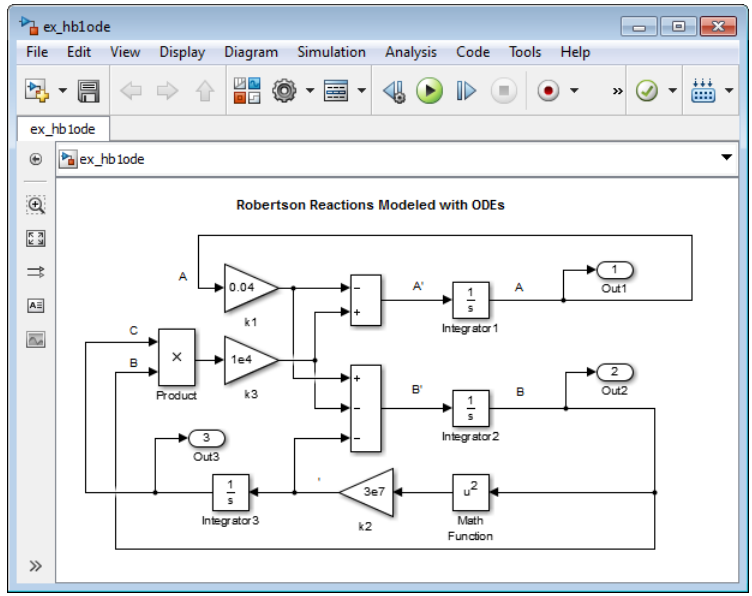
$$A' = -0.04A + 1 \cdot 10^4 BC$$
$$B' = 0.04A - 1 \cdot 10^4 BC - 3 \cdot 10^7 B^2$$
$$C' = 3 \cdot 10^7 B^2$$

Initial conditions: $A = 1$, $B = 0$, and $C = 0$.

Build the Model

Create a model, or open the model `ex_hb1ode`.

1. Add three Integrator blocks to your model. Label the inputs `A'`, `B'`, and `C'`, and the outputs `A`, `B`, and `C` respectively.
2. Add Sum, Product, and Gain blocks to solve each differential variable. For example, to model the signal `C'`,
   a. Add a Math Function block and connect the input to signal `B`. Set the **Function** parameter to `square`.
   b. Connect the output from the Math Function block to a Gain block. Set the **Gain** parameter to `3e7`.
   c. Continue to add the remaining differential equation terms to your model.
3. Model the initial condition of `A` by setting the **Initial condition** parameter for the `A` Integrator block to `1`.
4. Add Out blocks to save the signals `A`, `B`, and `C` to the MATLAB variable `yout`.



Simulate the Model

Create a script that uses the `sim` command to simulate your model. This script saves the simulation results in the MATLAB variable `yout`. Since the simulation has a long time interval and `B` initially changes very fast, plotting values on a logarithmic scale helps to visually compare the results. Also, since the value of `B` is small relative to the values of `A` and `C`, multiply `B` by $1 \cdot 10^4$ before plotting the values.

1. Enter the following statements in a MATLAB script. If you built your own model, replace `ex_hblode` with the name of your model.

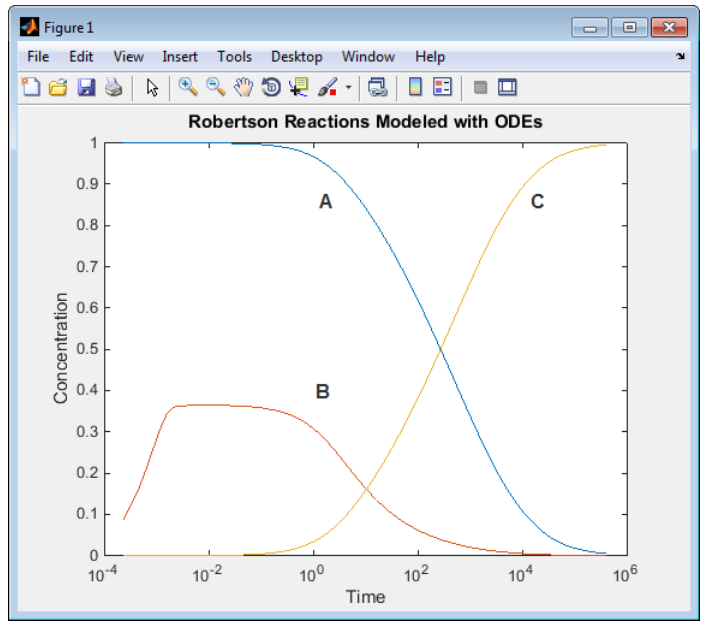
```
sim('ex_hb1ode')
yout(:,2) = 1e4*yout(:,2);
figure;
semilogx(tout,yout);
xlabel('Time');
ylabel('Concentration');
title('Robertson Reactions Modeled with ODEs')
```

2. From the Simulink Editor menu, select **Simulation > Model Configuration Parameters**:

— In the Solver pane, set the **Stop time** to `4e5` and the **Solver** to `ode15s (stiff/NDF)`.

— In the Data Import pane, select the **Time** and **Output** check boxes.

3 Run the script. Observe that all of `A` is converted to `C`.



Simulink Model from DAE Equations

A system of differential algebraic equations (DAE) has the following characteristics:

- It contains both ordinary differential equations and algebraic equations. Algebraic equations do not have any derivatives.
- Only some of the equations are differential equations defining the derivatives of some of the dependent variables. The other dependent variables are defined with algebraic equations.
- The number of equations is equal to the number of dependent variables in the system.

Some systems contain constraints due to conservation laws, such as conservation of mass and energy. If you set the initial concentrations to $A = 1$, $B = 0$, and $C = 0$, the total

concentration of the three species is always equal to 1 since $A+B+C=1$. You can replace the differential equation for C' with the following algebraic equation to create a set of differential algebraic equations (DAEs).

$$C = 1 - A - B$$

The differential variables `A` and `B` uniquely determine the algebraic variable `C`.

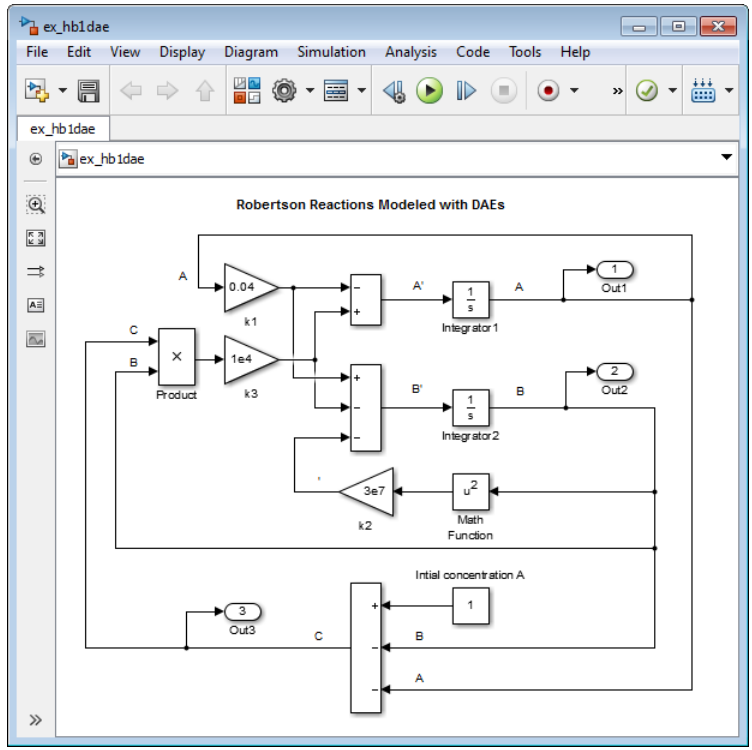
$$A' = -0.04A + 1 \cdot 10^4 BC$$
$$B' = 0.04A - 1 \cdot 10^4 BC - 3 \cdot 10^7 B^2$$
$$C = 1 - A - B$$

Initial conditions: $A = 1$ and $B = 0$.

Build the Model

Make these changes to your model or to the model `ex_hb1ode`, or open the model `ex_hb1dae`.

1. Delete the Integrator block for calculating `C`.
2. Add a Sum block and set the **List of signs** parameter to +– –.
3. Connect the signals `A` and `B` to the minus inputs of the Sum block.
4. Model the initial concentration of `A` with a Constant block connected to the plus input of the Sum block. Set the **Constant value** parameter to `1`.
5. Connect the output of the Sum block to the branched line connected to the Product and Out blocks.



Simulate the Model

Create a script that uses the `sim` command to simulate your model.

1 Enter the following statements in a MATLAB script. If you built your own model, replace `ex_hbldae` with the name of your model.

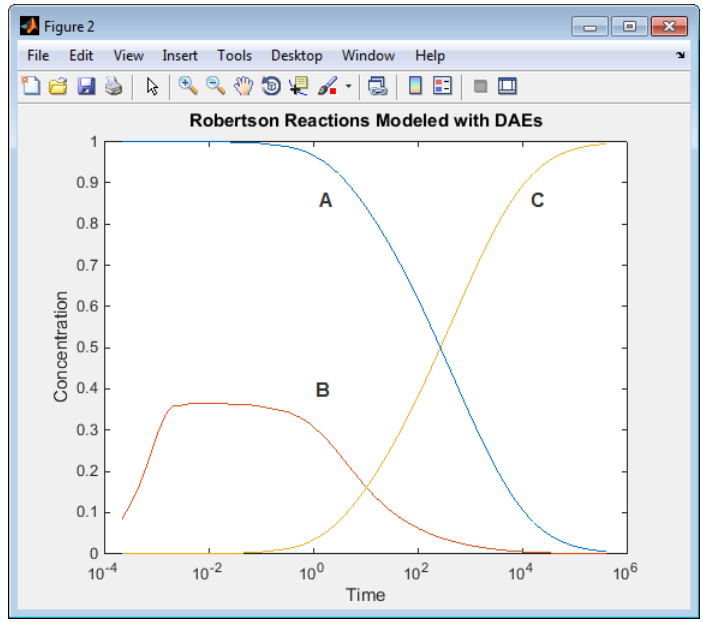
```
sim('ex_hb1dae')
yout(:,2) = 1e4*yout(:,2);
figure;
semilogx(tout,yout);
xlabel('Time');
ylabel('Concentration');
title('Robertson Reactions Modeled with DAEs')
```

2 From the Simulink Editor menu, select **Simulation** > **Model Configuration Parameters**:

— In the Solver pane, set the **Stop time** to `4e5` and the **Solver** to `ode15s (stiff/NDF)`.

— In the Data Import pane, select the **Time** and **Output** check boxes.

3 Run the script. The simulation results when you use an algebraic equation are the same as for the model simulation using only differential equations.



Simulink Model from DAE Equations Using Algebraic Constraint Block

Some systems contain constraints due to conservation laws, such as conservation of mass and energy. If you set the initial concentrations to $A = 1$, $B = 0$, and $C = 0$, the total concentration of the three species is always equal to 1 since $A + B + C = 1$.

You can replace the differential equation for C' with an algebraic equation modeled using an Algebraic Constraint block and a Sum block. The Algebraic Constraint block constrains its input signal F(z) to zero and outputs an algebraic state z. In other words, the block output is a value needed to produce a zero at the input. Use the following algebraic equation for input to the block.

$$0 = A + B + C - 1$$

The differential variables `A` and `B` uniquely determine the algebraic variable `C`.

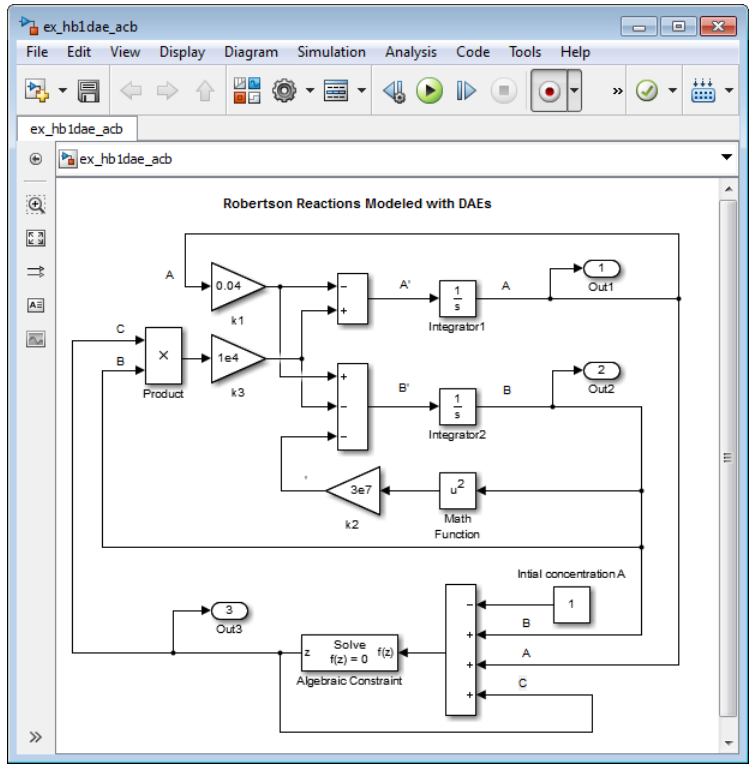
$$A' = -0.04A + 1 \cdot 10^4 BC$$
$$B' = 0.04A - 1 \cdot 10^4 BC - 3 \cdot 10^7 B^2$$
$$C = 1 - A - B$$

Initial conditions: $A = 1$, $B = 0$, and $C = 1 \cdot 10^{-3}$.

Build the Model

Make these changes to your model or to the model `ex_hb1ode`, or open the model `ex_hb1dae_acb`.

1. Delete the Integrator block for calculating `C`.
2. Add an Algebraic Constraint block. Set the **Initial guess** parameter to `1e-3`.
3. Add a Sum block. Set the **List of signs** parameter to `–+++`.
4. Connect the signals `A` and `B` to plus inputs of the Sum block.
5. Model the initial concentration of `A` with a Constant block connected to the minus input of the Sum block. Set the **Constant value** parameter to `1`.
6. Connect the output of the Algebraic Constraint block to the branched line connected to the Product and Out block inputs.
7. Create a branch line from the output of the Algebraic Constraint block to the final plus input of the Sum block.



Simulate the Model

Create a script that uses the `sim` command to simulate your model.

1 Enter the following statements in a MATLAB script. If you built your own model, replace `ex_hbl_acb` with the name of your model.

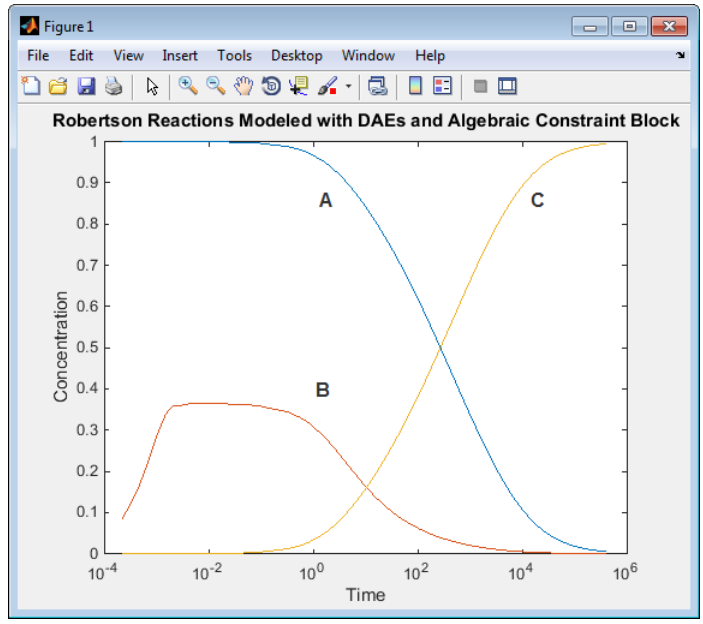
```
sim('ex_hb1dae_acb')
yout(:,2) = 1e4*yout(:,2);
figure;
semilogx(tout,yout);
xlabel('Time');
ylabel('Concentration');
title('Robertson Reactions Modeled with DAEs and Algebraic Constraint Block')
```

2 From the Simulink Editor menu, select **Simulation > Model Configuration Parameters**:

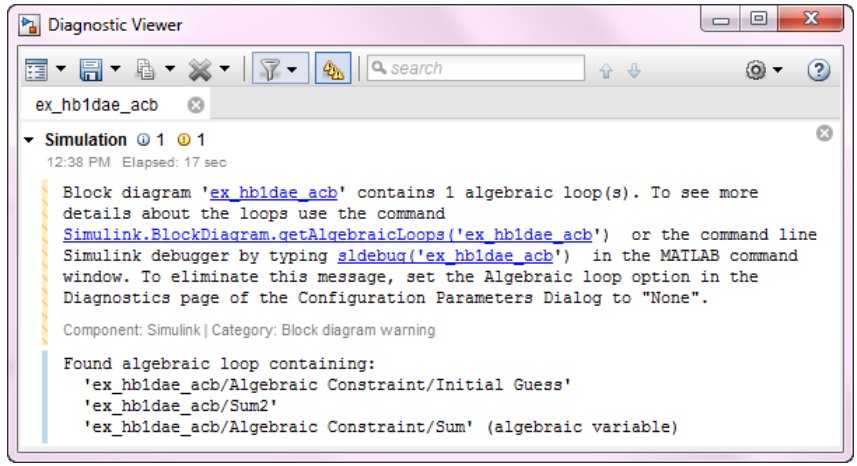
— In the Solver pane, set the **Stop time** to `4e5` and the **Solver** to `ode15s (stiff/NDF)`.

— In the Data Import pane, select the **Time** and **Output** check boxes.

3 Run the script. The simulation results when you use an Algebraic Constraint block are the same as for the model simulation using only differential equations.



Using an Algebraic Constraint block creates an algebraic loop in a model, If you set the **Algebraic Loop** parameter to `warning` (**Simulation > Model Configuration Parameters > Diagnostics > Algebraic Loop**), the following message displays in the Diagnostic Viewer during simulation.



For this model, the algebraic loop solver was able to find a solution for the simulation, but algebraic loops don't always have a solution, and they are not supported for code generation. For more information about algebraic loops in Simulink models and how to remove them, see "Algebraic Loops" on page 3-37.

Componentization Guidelines

Componentization

A component is a piece of your design, a unit level item, or a subassembly, that you can work on without needing the higher level parts of the model.

Componentization involves organizing your model into components. Componentization provides many benefits for organizations that develop large Simulink models that consist of many functional pieces. The benefits include:

- Meeting development process requirements, such as:
  - Component reuse
  - Team-based development
  - Intellectual property protection
  - Unit testing
- Improving performance for:
  - Model loading
  - Simulation speed
  - Memory usage

Componentization Techniques

Key componentization techniques that you can use with Simulink include:

- Subsystems
- Libraries
- Model referencing

These componentization techniques support a wide range of modeling requirements for models that vary in size and complexity. Most large models use a combination of componentization techniques. For example, you can include subsystems in referenced models, and include referenced models in subsystems. As another example, a large model might use model reference Accelerator blocks at the top level component partitions and blend model reference Accelerator and atomic subsystem libraries at lower levels.

Simulink provides tools to convert from subsystems to model referencing. Because of the differences between subsystems and model referencing, switching from subsystems to model referencing can involve several steps (see Converting a Subsystem to a Referenced Model on page 8-15). Consider scalability and support for anticipated future modeling requirements, such as how a model is likely to grow in size and complexity and possible code generation requirements. Designing a scalable architecture can avoid later conversion costs.

General Componentization Guidelines

This table provides high-level guidelines about the kinds of modeling goals and models for which subsystems, libraries, and model referencing are each particularly well suited.

Componentization Technique	Modeling Goals for Which the Technique Is Well Suited
Subsystems	• Add hierarchy to organize and visually simplify a model. • Maximize design reuse with inherited attributes for context-dependent behavior.
Libraries	• Provide a frequently used, and infrequently changed, modeling utility. • Reuse components repeatedly in a model or in multiple models.

Componentization Technique	Modeling Goals for Which the Technique Is Well Suited
Model referencing	• Develop a referenced model independently from the models that use it. • Obscure the contents of a referenced model, allowing you to distribute it without revealing the intellectual property that it embodies. • Reference a model multiple times without having to make redundant copies. • Facilitate changes by multiple people, with defined interfaces for top-level components. • Improve the overall performance by using incremental model loading, update diagram, simulation, and code generation for large models (for example, a model with 10,000 blocks). • Perform unit testing. • Simplify debugging for large models. • Generate code that reflects the model structure.

For a more detailed comparison of these modeling techniques, see “Summary of Componentization Techniques” on page 15-31.

Summary of Componentization Techniques

This section compares subsystems, libraries, and model referencing. The table includes recommendations and notes about a range of modeling requirements and features.

To see more information about a specific requirement or feature, click a link in a table cell.

Modeling Requirement or Feature	Subsystems	Libraries	Model Referencing
Code generation	Supported, with limitations	Supported, with limitations	Well suited

For each modeling technique, you can see a summary table that includes the more detailed information included in the links in the above summary table of componentization techniques:

- “Subsystems Summary” on page 15-33
- “Libraries Summary” on page 15-36
- “Model Referencing Summary” on page 15-40

Subsystems Summary

This section provides guidelines for using subsystems for each of the modeling requirements and features highlighted in the “Summary of Componentization Techniques” on page 15-31.

For additional information about subsystems, see:

- Creating Subsystems on page 4-17
- “Conditionally Executed Subsystems”

Modeling Requirement or Feature	Guidelines for Subsystems
Development Process	
Component reuse	**Not supported** • Copy a subsystem to reuse it in a model. • Subsystem copies are independent of each other. • Save a subsystem by saving the model that contains the subsystem. • Configuration management for subsystems is difficult.

Modeling Requirement or Feature	Guidelines for Subsystems
Team-based development	**Not supported** • For subsystems in a model, Simulink provides no direct interface with source control tools. • To create or change a subsystem, you need to open the parent model's file. This can lead to file contention when multiple people want to work on multiple subsystems in a model.
Intellectual property protection	**Not supported** Use model referencing protected models instead.
Unit testing	**Supported, with limitations** • For coverage testing, use Signal Builder and source blocks. • Each time a subsystem changes, you need to copy the subsystem to a harness model. • The test harness may have different Simulink sort orders, due to virtual boundaries. • Test harness files require configuration management overhead.
Performance	
Model loading speed	**Supported, with limitations** Loading a model loads all subsystems at one time. There is no incremental loading.
Simulation speed for large models	**Supported, with limitations** • To speed simulation, use Accelerator or Rapid Accelerator simulation mode. • Simulation mode applies to the whole model. Model referencing provides a finer level of control for simulation modes.

Modeling Requirement or Feature	Guidelines for Subsystems
Memory	**Supported, with limitations** Memory use for simulation and code generation is comparable for subsystems and libraries. For models with over 500 blocks, model reference Accelerator mode can significantly reduce memory usage for simulation and code generation.
Artificial algebraic loop avoidance	**Well suited** • Virtual subsystems avoid artificial algebraic loops. • For nonvirtual subsystems, consider enabling the Subsystem block parameter **Minimize algebraic loop occurrences**.
Features	
Signal property inheritance	**Well suited** • Inheriting signal properties from outside the subsystem boundary avoids your having to specify properties for every signal. • Propagation of signal properties can lead to Simulink using signal properties that you did not anticipate.
State initialization	**Well suited** You can initialize states of subsystems.
Tunability	**Well suited** • Tune subsystems using a block parameterization or masked subsystems. • Control tunability in generated code using **Configuration Parameters > Optimization > Signals and Parameters > Default parameter behavior**.
Buses	**Well suited** Subsystems do not require the use of bus objects for virtual buses.

Modeling Requirement or Feature	Guidelines for Subsystems
S-functions	**Well suited** Subsystems support inlined or noninlined S-functions.
Model configuration settings	**Well suited** A subsystem uses the model configuration settings of the model that contains the subsystem.
Tools	**Well suited** Subsystems provide extensive support for Simulink tools.
Code generation	**Supported, with limitations** • To generate code for a subsystem by itself, right-click the Subsystem block and select a code generation option. • As an optimization, Simulink attempts to recognize identical subsystems. For detected identical subsystems, the generated code includes only one copy of code for the multiple subsystems. • For virtual subsystems, you cannot specify file or function code partitions for code generation.

Libraries Summary

This section provides guidelines for using libraries for each of the modeling requirements and features highlighted in the “Summary of Componentization Techniques” on page 15-31.

For additional information about libraries, see “Libraries”.

Modeling Requirement or Feature	Guidelines for Libraries
Development Process	

Modeling Requirement or Feature	Guidelines for Libraries
Component reuse	**Well suited** • Access a collection of well-defined utility blocks. • Create a component once and reuse it in models. • Link to the same library block multiple times without creating multiple copies. • Link to the same library block from multiple models. • Restrict write access to library components. • Maintain one truth: propagate changes from a single library block to all blocks that link to that library. • Disable a link to allow independent changes to a linked block. • Managing library links adds some overhead. • Save library in a file similar to a Simulink model, but you cannot simulate the file contents. • Share data between instances by defining the data outside the component (for example, a data store in a common parent subsystem).
Team-based development	**Supported, with limitations** • Place library files in source control for version control and configuration management. • Maintain one truth: propagate changes from a single library block to all blocks that link to that library. • To reduce file contention, use one subsystem per library. • Link to the same library block from multiple models. • Restrict write access to library component. • See General Reusability Limitations on page 8-11.
Intellectual property protection	**Not supported** Use model referencing protected models instead.

Modeling Requirement or Feature	Guidelines for Libraries
Unit testing	**Supported, with limitations** • For coverage testing, use Signal Builder and source blocks. • Test harness may have different Simulink sort orders, due to virtual boundaries. • Test harness files require configuration management overhead.
Performance	
Model loading speed	**Well suited** Simulink incrementally loads a library at the point needed during editing, updating a diagram, or simulating a model.
Simulation speed for large models	**Supported, with limitations** • To speed simulation, use Accelerator or Rapid Accelerator simulation mode. • Simulation mode applies to the whole model. Model referencing provides a finer level of control for simulation modes.
Memory	**Supported, with limitations** • Simulink incrementally loads libraries at the point needed during editing, updating a diagram, or simulating a model. • Simulink duplicates library block instances during block update. • Memory usage for simulation and code generation is comparable for subsystems and libraries. For models with over 500 blocks, model reference Accelerator mode can significantly reduce memory usage for simulation and code generation.

Modeling Requirement or Feature	Guidelines for Libraries
Artificial algebraic loop avoidance	**Well suited** • Virtual subsystems avoid artificial algebraic loops. • For nonvirtual subsystems, consider enabling the Subsystem block parameter **Minimize algebraic loop occurrences**.
Features	
Signal property inheritance	**Well suited** • Inheriting signal properties from outside the library block boundary avoids your having to specify properties for every signal. • Propagation of signal properties can lead to Simulink using signal properties that you did not anticipate.
State initialization	**Well suited** You can initialize states of library blocks.
Tunability	**Well suited** • Tune library blocks using block parameterization or masked subsystems. • Control tunability in generated code using **Configuration Parameters > Optimization > Signals and Parameters > Default parameter behavior**.
Buses	**Well suited** Libraries do not require the use of bus objects for virtual buses.
S-functions	**Well suited** Libraries support inlined and noninlined S-functions.

Modeling Requirement or Feature	Guidelines for Libraries
Model configuration settings	**Well suited** • Library models do not have model configuration settings. • A referenced library block uses the model configuration setting of the model that contains that block.
Tools	**Supported, with limitations** There are some limitations for using some Simulink tools, such as the Model Advisor, with libraries.
Code generation	**Supported, with limitations** • As an optimization, Simulink attempts to recognize identical subsystems. For detected identical subsystems, the generated code includes only one copy of code for the multiple subsystems. • For virtual subsystems, you cannot specify file or function code partitions for code generation.

Model Referencing Summary

This section provides guidelines for using model referencing for each of the modeling requirements and features highlighted in the “Summary of Componentization Techniques” on page 15-31.

For additional information about model referencing, see:

- “Model Referencing”
- “Create a Referenced Model” on page 8-9
- Model Referencing Limitations on page 8-105

Modeling Requirement or Feature	Guidelines for Model Referencing
Development Process Requirements	

Modeling Requirement or Feature	Guidelines for Model Referencing
Component reuse	**Well suited** • Create a standalone component once and reuse it in multiple models. • Reference the same model multiple times without creating multiple copies. • Reference the same model from multiple models. • Model referencing uses specified boundaries for preserving component integrity. • Share data between instances (Model blocks) by creating a data store inside the model. See “Specify Reusability of Referenced Models” on page 8-11.
Team-based development	**Well suited** • For version control and configuration management, you can place model reference files in a source control system. • Design, create, simulate, and test a referenced model independently from the model that references it. • Link to the same model reference from multiple models. • Changes made to a referenced model apply to all instances of that referenced model. • Simulink does not limit access for changing a model reference. • You save a referenced model in a separate file from the model that references it. Using separate files helps to avoid file contention.
Intellectual property protection	**Well suited** • Use the protected model feature to obscure contents of a referenced model in a distributed model. • Creating a protected model feature requires a Simulink Coder license. Using a protected model does *not* require a Simulink Coder license.

Modeling Requirement or Feature	Guidelines for Model Referencing
Unit testing	**Well suited** • Test components independently to isolate behaviors, by simulating them standalone. • You can eliminate unit retest for unchanged components. • Use a data-defined test harness, with MATLAB test vectors and direct coverage collection. • For coverage testing, use root inports and outports.
Performance	
Model loading speed	**Well suited** • Simulink incrementally loads a referenced model at the point needed during editing, updating a diagram, or simulating a model. • If a simulation target build is required, first-time loading can be slow.
Simulation speed for large models	**Well suited** • Simulate a referenced model standalone. • The Model block has an option for specifying the simulation mode. • You can improve rebuild performance by selecting the appropriate setting for the **Configuration Parameters** > **Model Referencing** > **Rebuild** parameter. • Simulation through code generation can have a slow start-up time, which might be undesirable during prototyping. • See “Simulation Limitations” on page 8-106.

Modeling Requirement or Feature	Guidelines for Model Referencing
Memory	**Well suited** • Simulink loads a referenced model at the point that model is needed for navigation during editing, updating a diagram, or simulating a model. • Use model reference Accelerator mode to reduce memory usage, incrementally loading a compiled version of a referenced model.
Artificial algebraic loop avoidance	**Supported, with limitations** Consider enabling **Configuration Parameters > Model Referencing > Minimize algebraic loop occurrences**.
Features	
Signal property inheritance	**Supported, with limitations** • Inherit sample time when the referenced model is sample-time independent. You cannot propagate a continuous sample time to a Model block that is sample-time independent. • Model block is context-independent, so it cannot inherit signal properties. Explicitly set input and output signal properties. • Use a bus object to define the signal data type of a bus signal that is passed into a referenced model. • Goto and From block lines cannot cross model referencing boundaries. • See Index Base Limitations on page 8-42.

Modeling Requirement or Feature	Guidelines for Model Referencing
State initialization	**Supported, with limitations** • You can initialize states from the top model. • Use either the structure format or structure with time format to initialize the states of a top model and the models that it references. • To use the `SimState` (simulation state) feature with model referencing, simulate all Model blocks in Normal mode. • See "State Information for Referenced Models" on page 61-262.
Tunability	**Supported, with limitations** • To have each instance of a referenced model use different values, use model arguments in the Model block. • To have each instance of a referenced model use the same values, use `Simulink.Parameter` objects. • By default, all other parameters are inlined in generated code.
Buses	**Supported, with limitations** You must use bus objects for bus signals that cross referenced model boundaries (for example, global data stores, root inports, root outports).
S-functions	**Supported, with limitations** Model referencing generally supports inlined or noninlined S-functions. See "Use S-Functions with Referenced Models" on page 8-100.

Modeling Requirement or Feature	Guidelines for Model Referencing
Model configuration settings	**Supported, with limitations** • To apply the same model configuration settings to all models in a model hierarchy, use a referenced configuration set. • Configuration settings for the root model and referenced models must be consistent. However, not all configuration settings need to be the same across the model hierarchy.
Tools	**Supported, with limitations** • There are some limitations for using some Simulink tools, such as the Simulink Debugger, with model referencing. • For details, see “Tools Limitations” on page 8-109.
Code generation	**Well suited** • By default, model referencing generates code incrementally. • You can improve rebuild performance by selecting the appropriate setting for the **Configuration Parameters** > **Model Referencing** > **Rebuild** parameter. • Model referencing requires the use of bus objects. For information, see “Bus Data Crossing Model Reference Boundaries” on page 65-150.

Model Complex Logic

To model complex logic in a Simulink model, consider using Stateflow software.

Stateflow extends Simulink with a design environment for developing state transition diagrams and flow charts. Stateflow provides the language elements required to describe complex logic in a natural, readable, and understandable form. It is tightly integrated with MATLAB and Simulink products, providing an efficient environment for designing embedded systems that contain control, supervisory, and mode logic.

For more information on Stateflow software, see “Stateflow”.

Model Physical Systems

To model physical systems in the Simulink environment, consider using Simscape software.

Simscape extends Simulink with tools for modeling systems spanning mechanical, electrical, hydraulic, and other physical domains as physical networks. It provides fundamental building blocks from these domains to let you create models of custom components. The MATLAB based Simscape language enables text-based authoring of physical modeling components, domains, and libraries.

For more information on Simscape software, see “Simscape”.

Model Signal Processing Systems

To model signal processing systems in the Simulink environment, consider using DSP System Toolbox™ software.

DSP System Toolbox provides algorithms and tools for the design and simulation of signal processing systems. These capabilities are provided as MATLAB functions, MATLAB System objects, and Simulink blocks. The system toolbox includes design methods for specialized FIR and IIR filters, FFTs, multirate processing, and DSP techniques for processing streaming data and creating real-time prototypes. You can design adaptive and multirate filters, implement filters using computationally efficient architectures, and simulate floating-point digital filters. Tools for signal I/O from files and devices, signal generation, spectral analysis, and interactive visualization enable you to analyze system behavior and performance. For rapid prototyping and embedded system design, the system toolbox supports fixed-point arithmetic and C or HDL code generation.

For more information on DSP System Toolbox software, see “DSP System Toolbox”.

Simulink Project Setup

Organize Large Modeling Projects

You can use Simulink Projects to help you organize your work. To get started with managing your files in a project:

1. Try an example project to see how the tools can help you organize your work. See “Explore Simulink Project Tools with the Airframe Project” on page 16-5.
2. Create a new project. See “Create a New Project From a Folder” on page 16-17.
3. Use the Dependency Analysis view to analyze your project and check required files. See “Run Dependency Analysis” on page 18-4.
4. Explore views of your files. See “Work with Project Files” on page 17-8.
5. Create shortcuts to save and run frequent tasks. See “Use Shortcuts to Find and Run Frequent Tasks” on page 16-40.
6. Run custom task operations on batches of files. See “Run a Simulink Project Custom Task and Publish Report” on page 17-43.
7. If you use a source control integration, you can use the **Modified Files** view to review changes, compare revisions, and commit modified files. If you want to use source control with your project, see “About Source Control with Projects” on page 19-2.

For guidelines on structuring projects, see “Componentization Guidelines” on page 15-29.

What Are Simulink Projects?

You can use Simulink Projects to help you organize your work. Find all your required files; manage and share files, settings, and user-defined tasks; and interact with source control.

If your work involves any of the following:

- More than one model file
- More than one model developer
- More than one model version

— then Simulink Projects can help you organize your work. You can manage all the files you need in one place — all MATLAB and Simulink files, and any other file types you need such as data, requirements, reports, spreadsheets, tests, or generated files.

Projects can promote more efficient team work and individual productivity by helping you:

- Find all the files that belong with your project.
- Create standard ways to initialize and shut down a project.
- Create, store, and easily access common operations.
- View and label modified files for peer review workflows.
- Share projects using built-in integration with Subversion® (SVN) or Git™, external source control tools.

See the Web page `https://www.mathworks.com/discovery/simulink-projects.html` for the latest information, downloads, and videos.

To get started with managing your files in a project:

1. Try an example project to see how the tools can help you organize your work. See “Explore Simulink Project Tools with the Airframe Project” on page 16-5.
2. Create a new project. See “Create a New Project From a Folder” on page 16-17.
3. Analyze your project and check required files by using the Dependency Analysis view. See “Run Dependency Analysis” on page 18-4.
4. Explore views of your files. See “Work with Project Files” on page 17-8.

5 Create shortcuts to save and run frequent tasks. See “Use Shortcuts to Find and Run Frequent Tasks” on page 16-40.

6 Run custom task operations on batches of files. See “Run a Simulink Project Custom Task and Publish Report” on page 17-43.

7 If you use a source control integration, you can use the **Modified Files** view to review changes, compare revisions, and commit modified files. If you want to use source control with your project, see “About Source Control with Projects” on page 19-2.

For guidelines on structuring projects, see “Large-Scale Modeling”.

Explore Simulink Project Tools with the Airframe Project

In this section...

Explore the Airframe Project

Try an example Simulink project to see how the tools can help you organize your work. Projects can help you manage:

- Your design (model and library files, `.m`, `.mat`, and other files, source code for S-functions, and data)
- A set of actions to use with your project (run setup code, open models, simulate, build, and run shutdown code)
- Working with files under source control (check out, compare revisions, tag or label, and check in)

The Airframe example shows how to:

1. Set up and browse some example project files under source control.
2. Examine project shortcuts to access frequently used files and tasks.
3. Analyze dependencies in the example project and locate required files that are not yet in the project.
4. Modify some project files, find and review modified files, compare to an ancestor version, and commit modified files to source control.
5. Explore views of project files only, modified files, and all files under the project root folder.

Set Up Project Files and Open Simulink Project

Run this command to create a working copy of the project files and open the project:

```
sldemo_slproject_airframe_svn
```

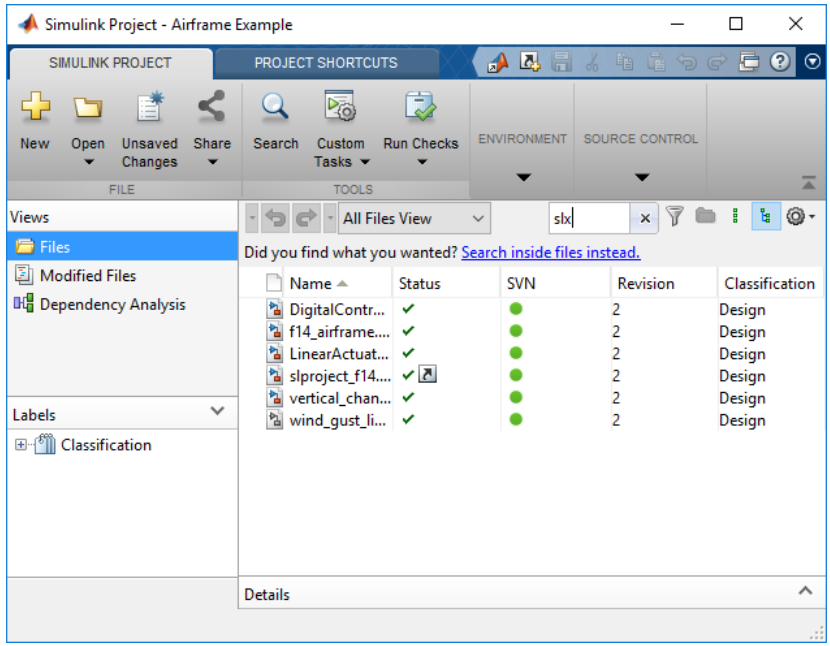
The project example copies files to your temporary folder so that you can edit them and put them under SVN source control.

The Simulink Project opens and loads the project. The project is configured to run some startup tasks, including changing the current working folder to the project root folder.

Note Alternatively, you can try this example project using Git source control, by specifying `sldemo_slproject_airframe_git`. The following example shows the options when using SVN.

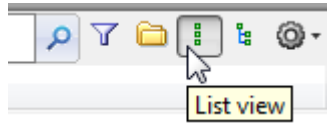
View, Search, and Sort Project Files

1. In Simulink Project, examine the **Files** view to manage the files within your project. When **Project Files View** is selected, only the files in your project are shown.
2. To see all the files in your sandbox, click the **Project Files View** button and select **All Files View**. This view shows all the files that are under the project root, not just the files that are in the project. This view is useful for adding files to the project from your sandbox.
3. To find particular files or file types, in any file view, type in the search box or click the Filter button. You can also search inside files.



Click the x to clear the search.

4 To view files as a list instead of a tree, click the List view button.



5 To sort files and to customize the columns, click the Organize view button at the far right of the search box.

6 You can dock and undock the Simulink Project into the MATLAB Desktop. If you want to maximize space for viewing your project files, undock the Simulink Project. Drag the title bar to undock it.

Open and Run Frequently Used Files

You can use shortcuts to make scripts easier to find in a large project. View and run shortcuts on the Project Shortcuts toolstrip. You can organize the shortcuts into groups.

In this example, the script that regenerates S-functions is set as a shortcut so that a new user of the project can easily find it. You can also make the top-level model, or models, within a project easier to find. In this example, the top-level model, `slproject_f14.mdl`, is a shortcut.

Regenerate the S-functions.

1. On the Project Shortcuts tab in the toolstrip, click the shortcut **Rebuild Project's S-functions**.

   The shortcut file builds a MEX-file. If you do not have a compiler set up, follow the instructions to choose a compiler.
2. Open the `rebuild_s_functions.m` file to explore how it works.

Open the top model.

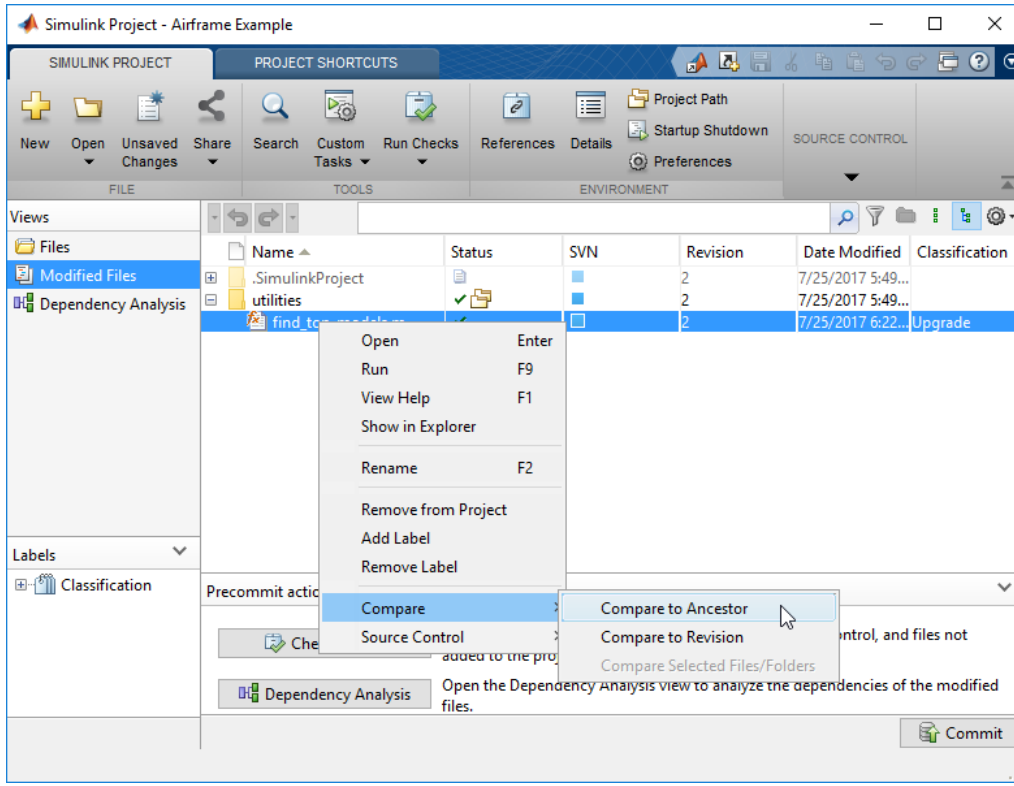
- On the Project Shortcuts tab, click the shortcut **F14 Model** to open the root model for this project.
- To create shortcuts to access frequently used files, select the **Files** view, right-click a file, and select **Create Shortcut**.

You can also specify files to run at startup and shutdown. See “Automate Startup Tasks” on page 16-34.

Review Changes in Modified Files

Open and make changes to files and review changes.

1. Select **Project Files View**. View folders using the tree view button, and then expand the `utilities` folder.
2. Either double-click to open the `find_top_models` file for editing from the Simulink Project, or right-click and select **Open**.
3. Make a change in the Editor, such as adding a comment, and save the file.
4. Under **Files**, select the **Modified Files** view. The files you changed appear in the list.
5. To review changes, right-click the `find_top_models` file in the **Modified Files** view and select **Compare** > **Compare to Ancestor**.



The MATLAB Comparison Tool opens a report comparing the modified version of the file in your sandbox against its ancestor stored in the version control tool. The comparison report type can differ depending on the file you select.

If you select a Simulink model to **Compare** > **Compare to Ancestor**, this command runs a Simulink model comparison.

To compare models, try the following example.

1. Select the **Files** view and expand the `models` folder.
2. Either double-click to open the `AnalogControl` file for editing from the Simulink Project, or right-click and select **Open**.
3. Make a change in the model, such as opening a block and changing some parameters, and then save the model.

4 To review changes, right-click the file in the **Modified Files** view and select **Compare > Compare to Ancestor**.

The Comparison Tool opens a report.

Run Project Integrity Checks

In the **Modified Files** view, under **Precommit actions**, click **Check Project** to run the project integrity checks. The checks look for missing files, files to add to source control or retrieve from source control, and other issues. The checks dialog box can offer automatic fixes to problems found.

When you click a **Details** button in the Checks dialog box, you can view recommended actions and decide whether to make the changes.

For an example using the project checks to fix issues, see "Upgrade Model Files to SLX and Preserve Revision History" on page 17-19.

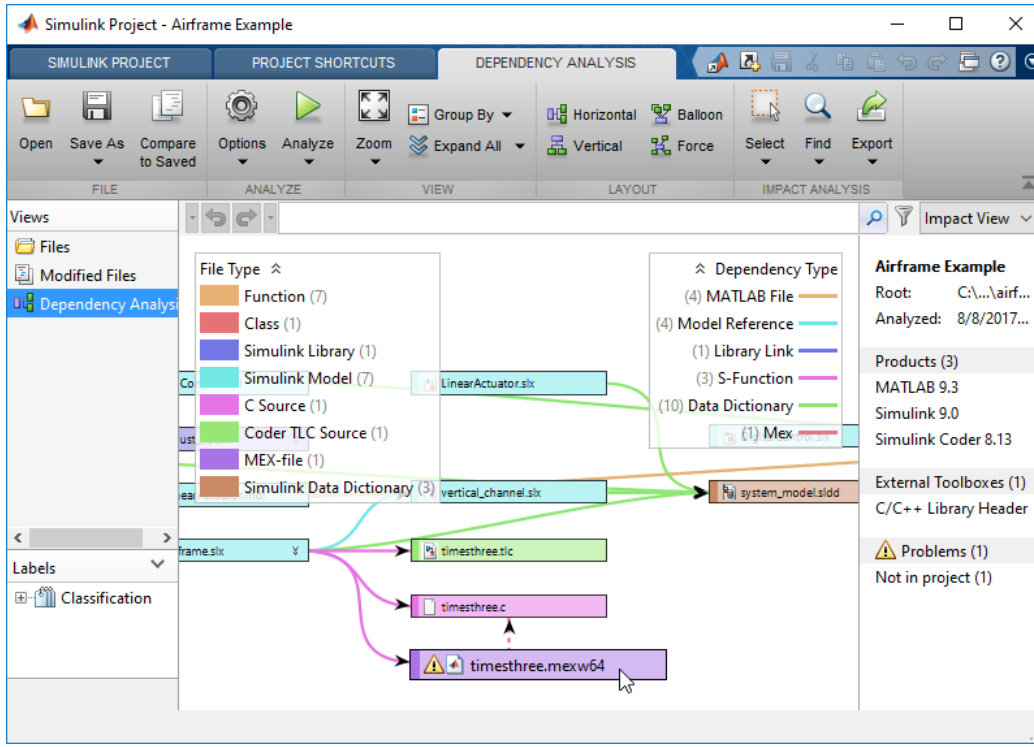
Run Dependency Analysis

To check that all required files are in the project, run a file dependency analysis on the modified files in your project.

1 From the Simulink Project tree, select **Dependency Analysis**.

2 Click **Analyze**.

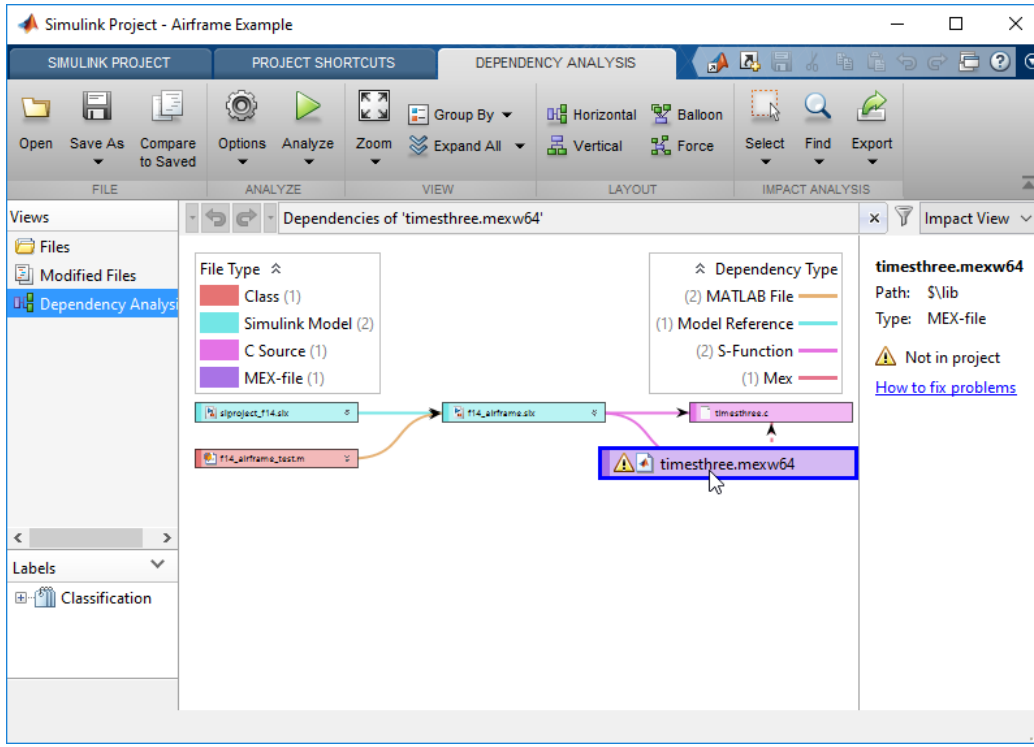
The Impact graph displays the structure of all analyzed dependencies in the project. The right pane lists required toolboxes and any problem files.



3 To view the files that use a problem file, hover over the messages under **Problems** and click **Find All**.

   The graph updates to display only the problem file, and the problem message in the right panel. The file is not in the project. To view the dependencies of the problem file, on the Dependency Analysis tab, select **Find** > **All Dependencies of Selection**.

4 Observe that `timesthree.mexw64` is an S-function binary file required by `f14_airframe.slx`. You can add binary files to your project or, as in this project, provide a utility script that regenerates them from the source code that is part of the project.



5 To remove the file from the problem files list, right-click the file and select **Add External File**. The next time you run a dependency analysis, the file does not appear as a problem file.

   In this example, you do not want to add the binary file to the project, but instead use the script to regenerate the binary file from the source code in the project. Use **Add External File** to stop such files being marked as problems.

6 On the **Dependency Analysis** tab, in the **Impact Analysis** section, select **Find** > **All Files**.

7 In the **Impact Analysis** section, choose **Select** > **Modified Files**.

8 To view dependencies of the modified files, in the **Impact Analysis** section, select **Find** > **All Dependencies of Selection**.

Commit Modified Files

After you modify files and you are satisfied with the results of the checks, you can commit your changes to the source control repository.

1. In the **Modified Files** view, under **Precommit actions**, click **Check Project** to make sure that your changes are ready to commit.
2. Observe that the Modified Files list includes a `.SimulinkProject` folder. The files stored in the `.SimulinkProject` folder are internal project definition files generated by your changes. These definition files allow you to add a label to a file without checking it out. You do not need to view the definition files directly unless you need to merge them, but they are listed so you know about all the files being committed to the source control system. See “Project Definition Files” on page 19-44.
3. To commit your changes to source control, click **Commit**.
4. Enter a comment for your submission, and click **Submit**.

   Watch the messages in the status bar as the source control commits your changes.

View Project and Source Control Information

- To view and edit project details, on the **Simulink Project** tab, in the **Environment** section, click **Details**. View and edit details such as the name, description, project root, startup folder, and generated files folders such as the `slprj` folder.
- To view details about the source control integration and repository location, on the Simulink Project tab, in the Source Control section, click **SVN Details**. This Airframe example project is under the control of the SVN source control tool.

Alternatively, use the project API to get the current project and the root folder:

```
project = simulinkproject;
projectRoot = project.RootFolder;
```

You can use the project API to get all the project details and manipulate the project at the command line. See `simulinkproject`.

For next steps, see “Project Management”.

- “About Source Control with Projects” on page 19-2

Create a Project from a Model

Create a project to organize your model and any dependent files. Use **Create Project from Model** to run a dependency analysis on your top model to identify required files.

Tip For a simpler option that automates more steps for you, see instead "Create a New Project From a Folder" on page 16-17.

Simulink projects can help you organize your work and collaborate in teams. The project can help you to:

- Find all your required files
- Manage and share files, settings, and user-defined tasks
- Interact with source control.

1. In a Simulink model, select **File > Simulink Project > Create Project from Model**.

   Simulink runs dependency analysis on your model to identify required files and a project root location that contains all dependencies.
2. In the New Simulink Project dialog box, edit any settings you want to change:

   - **Project name** — By default, the name of the suggested project root folder. Edit if desired.
   - **Project folder** — A folder that dependency analysis identified to contain all dependencies. If you want, click to select a different folder in the file system hierarchy between the file system root and the model folder.
   - **Files to include** — Files to include in the project. Files with selected check boxes are identified by dependency analysis. Select check boxes to specify all the files you want to include.

     Any external dependencies are listed. If required files are outside your project root, then you cannot add these files to your project. An external dependency might not indicate a problem if the file is on your path and is a utility or other resource that is not part of your project.
   - If you do not want to make a shortcut to the top-level file, or add all the folders to the project path, under **More Options**, clear the check boxes. Alternatively, you can edit these project settings later.

3 Click **Create** to create the Simulink project containing your model and any other specified files.

For an example showing what you can do with projects, see “Explore Simulink Project Tools with the Airframe Project” on page 16-5.

Create a New Project From a Folder

If you have many files that you want to organize into a project, with or without source control, use the following steps to create a new project.

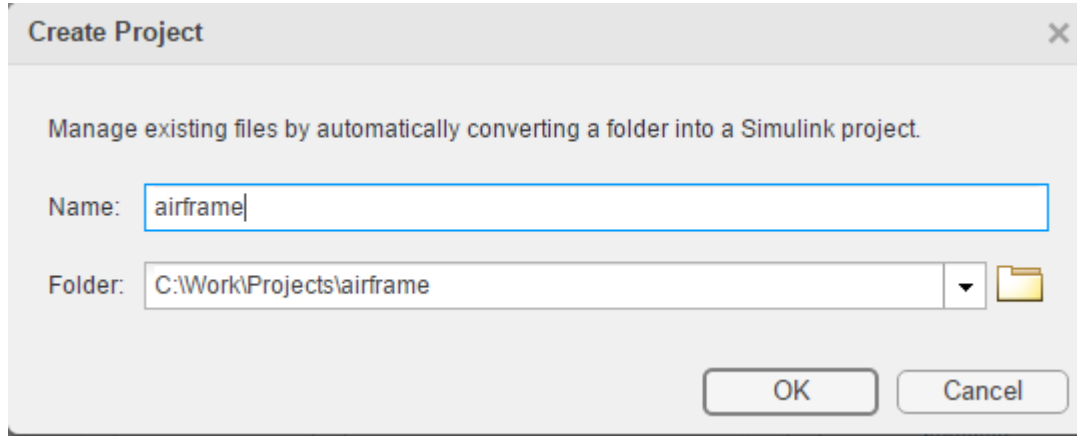
Note If you want to retrieve a project from a source control repository, see instead "Retrieve a Working Copy of a Project from Source Control" on page 19-29.

Easily convert a folder of files into a Simulink project by using the **Folder to Project** template in the Simulink start page. The template automatically adds your files to the project and prompts you to set up the path and startup files. This simple, quick process sets up your project to manage your files and introduces you to project features. When you open the project, it automatically puts the folders you need on the path, and runs any setup operations to configure your environment. Startup files automatically run (.m and .p files), load (.mat files), and open (Simulink models) when you open the project.

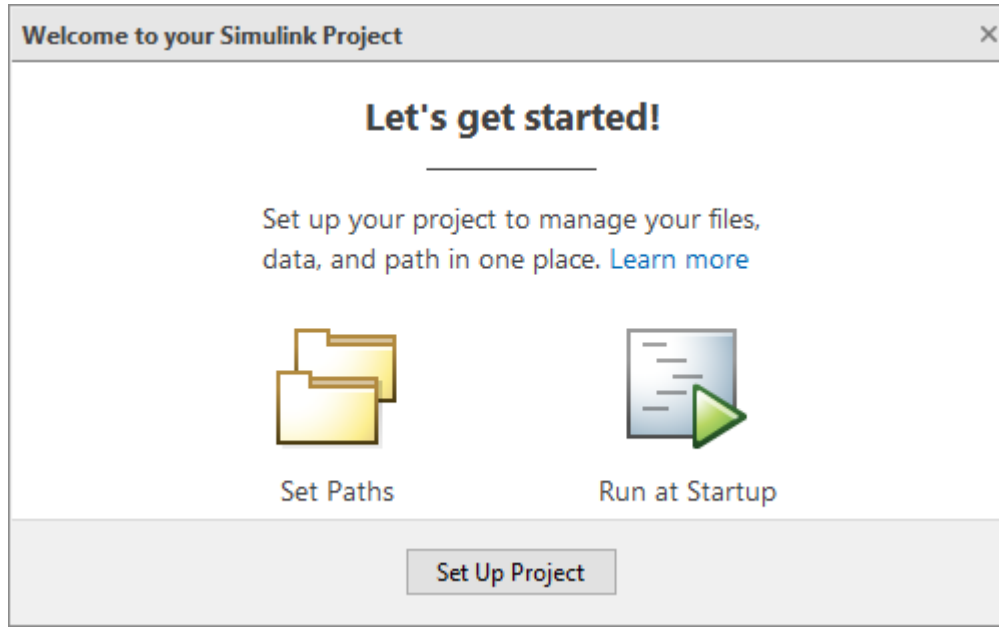
To create a new project to manage your files:

- On the MATLAB **Home** tab, click **Simulink** or select **New** > **Simulink Project**.
- From the Model Editor, select **File** > **New** > **Project**.

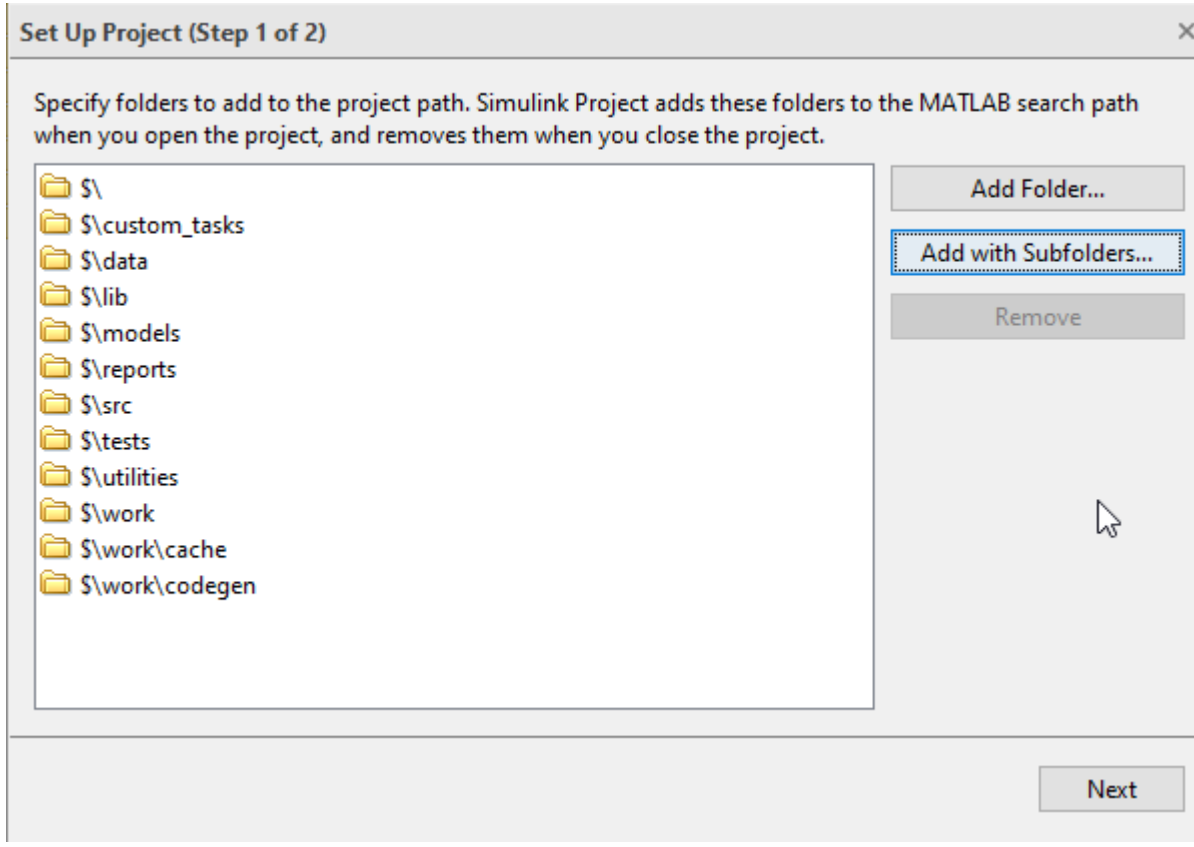
1. In the Simulink start page, click the **Folder to Project** template.
2. In the Create Project dialog box, enter a project name, browse to select the folder containing your files, and click **OK**.



3 In the Welcome to your Simulink Project dialog box, click **Set Up Project** to continue.



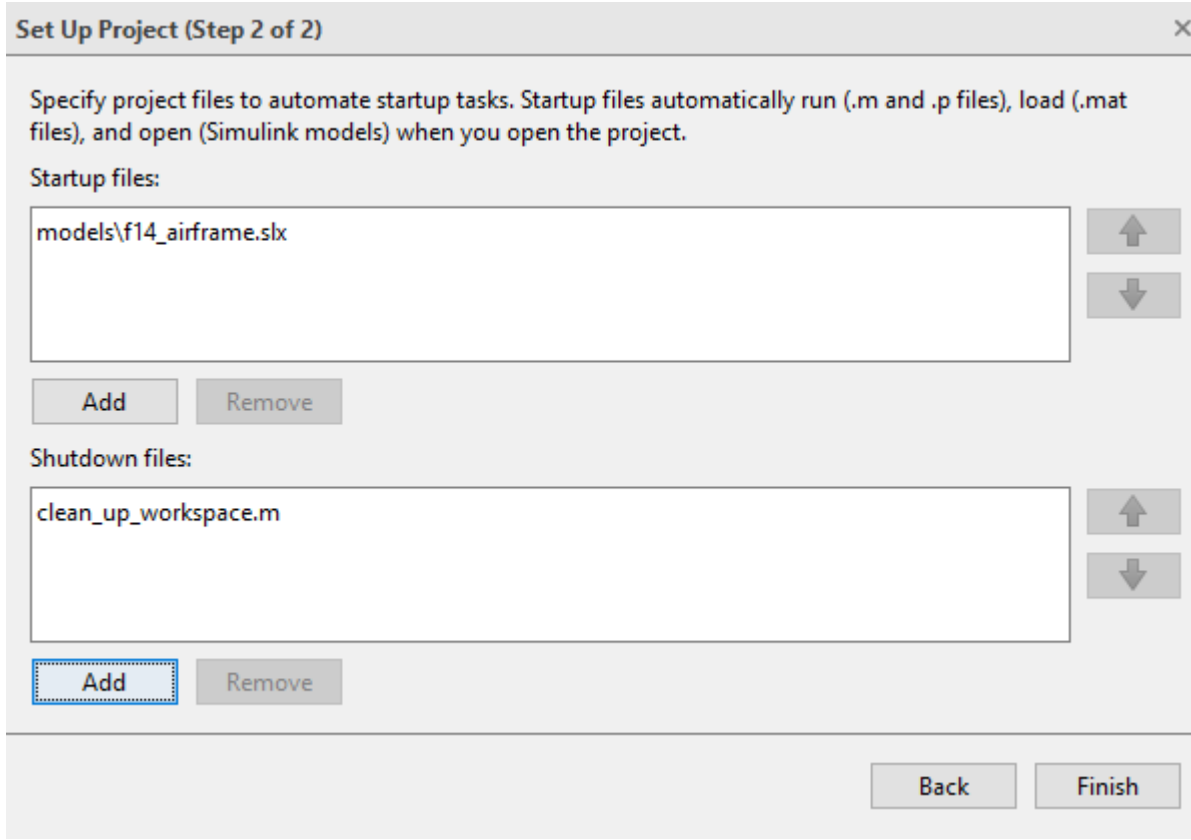
4 In the Set Up Project (Step 1 of 2) dialog box, optionally choose folders to add to the project path. When you open the project, it adds these folders to your MATLABsearch path, and removes them when you close the project. Add project folders to ensure dependency analysis detects project files. To add all project folders, click **Add with Subfolders** and then select the project folder containing all your subfolders. Alternatively, you can set up the project path later. Click **Next**.



5 In the Set Up Project (Step 2 of 2) dialog box, optionally specify startup and shutdown files.

- Use startup files to configure settings when you open the project. Startup files automatically run (`.m` and `.p` files), load (.mat files), or open (Simulink models) when you open the project.
- Use shutdown files to specify MATLAB code to run as the project shuts down. You do not need to use shutdown files to close models when you close a project, because it automatically closes any project models that are open, unless they are dirty. The project prompts you to save or discard changes.

Click **Add** to specify startup or shutdown files. Alternatively, you can setup these files later.



6 Click **Finish** and your new project opens. The **Folder to Project** template automatically adds all your files to the project. The template does not add derived files to your project.

For next steps, try dependency analysis to visualise the structure of your project, or consider adding source control to help you manage versions. For details, see "Run Dependency Analysis" on page 18-4 or "Add a Project to Source Control" on page 19-6.

As alternatives to the **Folder to Project** template, you can:

- Create a project from a model by analysing it for dependent files that you want to put in a project. See "Create a Project from a Model" on page 16-15

- Create projects manually, but then you need to add files to the project and configure the path, startup, and shutdown files. To examine the alternative templates. or to use your own templates:

  1. In the Simulink start page, click templates in the list to read the descriptions. If you selected a new project option to open the start page, the list shows only project templates, or you can filter the list for Project Templates using the list next to the Search box.

     - Select the `Blank Project` template if you are creating a project in a folder with existing files and want to set up the project manually. The `Blank Project` template creates a Simulink project in your selected folder and leaves any other files untouched. You must manually set up the project, for example by adding files to the project, configuring startup files, configuring the project path, etc.
     - Try the `Simple Project` template if you are creating a project in a new folder and want a blank model. The `Simple Project` template creates a simple Simulink project containing a blank model and some utilities. The model is a shortcut so you can open it from the toolstrip. The project manages your path and the location of the temporary files (slprj folder) when you open and close the project. You can modify any of these files, folders, and settings later.
     - You can create your own templates. See “Using Templates to Create Standard Project Settings” on page 16-42.

  2. In the start page, select a template and click **Create Project**.
  3. In the Create Project dialog box, specify your project folder and edit the project name, and click **Create Project**. You can control the default folder for new projects using the project preferences.

     The Simulink Project displays the Project Files view for the specified project root. You need to add files to the project. See “Add Files to the Project” on page 16-23.

For next steps using your new project, try dependency analysis to visualise the structure of your files.

More About

- “What Can You Do With Project Shortcuts?” on page 16-33

Add Files to the Project

After creating a new Simulink Project, unless you created the project from a model, then the **Files** node in the **Project** tree shows the empty Project Files view. Files under your chosen project root are not included in your project until you add them. If you created your project from a model, you already specified initial files to include in the project.

To display all files in your project folder (or `projectroot`), in the **Files** view, click the **Project Files View** button and select **All Files View** You might not want to include all files in your project. For example, you might want to exclude some files under `projectroot` from your project, such as SVN or CVS source control folders.

To add existing files to your project, use any of these methods:

- In **All Files View**, select files or folders, right-click, and select **Add to Project** or **Add to Project (including child files)**.
- To add files to your project, cut and paste or drag and drop files from a file browser or the Current Folder browser onto the **Project Files** view. If you drag a file from outside the project root, this moves the file and adds it to your project. You can drag files within project root to move them.
- Add and remove project files at the command line using `addFile`.

To create new files or folders in the project, right-click a white space in the **Files** view and select **New Folder** or **New File**. The new files are added to the project.

To learn how to set up your project with all required files, see “Run Dependency Analysis” on page 18-4.

To add or remove project folders from the MATLAB search path, see “Specify Project Path” on page 16-31.

To configure your project to automatically run startup and shutdown tasks, see “Automate Startup Tasks” on page 16-34.

You can access your recent projects direct from MATLAB. See “Open Recent Projects” on page 16-28.

If you want to add source control, see “Add a Project to Source Control” on page 19-6.

More About

- “What Can You Do With Project Shortcuts?” on page 16-33

Create a New Project from an Archived Project

To create a new project from an archived project:

1. From MATLAB, on the **Home** tab, in the **File** section, select **New** > **Simulink Project**.
2. In the start page, under **Projects** in the left list, click **Archive**.
3. In the Extract Project from Zip File dialog box, specify:
   - In the **Zip file** field, the location of the archived project.
   - In the **Project folder** field, the location of the new project. For example, `C:\myNewProject`.
4. Click **Extract**.

   The new project opens. The current working folder, for example, `C:\myNewProject`, contains the imported project folders.

   If the archived project contains referenced projects, Simulink Project imports files into two subfolders, `mains` and `refs`. The current working folder, for example, `C:\myNewProject\main` contains the project folders and `C:\myNewProject\refs` contains the referenced project folders.

Create a New Project Using Templates

In Simulink Project, you can use templates to create and reuse a standard project structure.

1. To browse for templates, click **Simulink** on the MATLABHome tab, or on the Simulink Project tab, click **New**.
2. In the Simulink start page, click a template in the list to read the description. For example, click `Simple Project`.
3. The start page shows all project templates (`*.sltx`) on the MATLAB path. If your templates do not appear, locate them by clicking **Open**. In the Open dialog box, make `*.sltx` files visible by changing the file type list `Model Files` to `All MATLAB files`, and browse to your template.
4. In the start page, select a template and click **Create Project**.

   Templates created in R2017b or later warn you if required products are missing. Click the links to open Add-On Explorer and install required products.
5. In the Create Project dialog box, specify your project folder and edit the project name, and click **Create Project**.

Use Project Templates from R2014a or Before

To use project templates created in R2014a or earlier (`.zip` files), upgrade them to `.sltx` files using `Simulink.exportToTemplate`.

After you upgrade the templates to `.sltx` and put them on the MATLAB path, you can use the templates from the start page.

Open Recent Projects

Note You can have one project open at a time, to avoid conflicts. If you open another project, any currently open project closes.

You can use any of these methods to open recent Simulink projects:

- On the MATLAB **Home** tab, click **Simulink**, and select your project in the recent projects list.

  If you select a recent model that is part of a project, you can choose to also open the project.
- On the MATLAB **Home** tab, click the **Open** arrow and select your project under the **Recent Simulink Projects** list.
- From the Current Folder browser, double-click the `.prj` file.
- In the Simulink Editor, if an open model, library, or chart belongs to a project, you can select **File > Simulink Project > Open Project**.

Alternatively, open Simulink Project by entering `simulinkproject`, or in the Simulink Editor, select **View > Simulink Project**. When Simulink Project is open, you can open projects with these methods:

- On the **Simulink Project** tab, click the **Open** arrow and select your project under the **Recent** list.
- For projects created or saved in Release 2012b or later, select **Open > Open Project File**. Browse and select your project `.prj` file.
- For projects saved in Release 2012a or earlier, select **Open > Open Project by Folder**. Navigate to the folder containing the `.SimulinkProject` folder, and click **OK** to load the project. After you load this project once, then you can use **Open Project File** to open the project.

Tip Create a MATLAB shortcut for opening or giving focus to the Simulink Project by dragging this command to the toolstrip from the Command History or Command Window:

```
simulinkproject
```

When you open a project, you are prompted if loaded files shadow your project model files. To avoid working on the wrong files, close the shadowing files. See “Manage Shadowed and Dirty Model Files” on page 17-11.

Specify Project Details, Startup Folder, and Derived Files Folders

On the Simulink Project tab, in the Environment section, click **Details**. Use the Project Details dialog box for the following tasks:

- Edit the project name or add a description.
- View the **Project root** folder. You can change your project root by moving your entire project on your file system, and reopening your project in its new location. All project file paths are stored as relative paths. To change the current working folder to your project root, click **Set As Current Folder**.
- View or edit the **Start Up** folder. By default, this is set to the project root. When you open the project, the current working folder changes to the project root folder. You can specify a different startup folder or click **Clear**.

  You can also configure startup scripts that set the current folder and perform other setup tasks. If you configure startup files to set the current folder, your startup setting takes precedence over the startup folder at the Project Details dialog box. To set up startup files, see “Automate Startup Tasks” on page 16-34.
- View or edit the **Generated Files** folders. You can set the **Simulink cache folder** and **Code generation folder**. For details, see “Manage Build Process Folders” (Simulink Coder).
- If you edit any project details, then click **OK** to save your changes.

If you are looking for source control information for your project, see instead the details button for your source control in the Source Control section of the Simulink Project tab, e.g., **SVN Details**. See “Add a Project to Source Control” on page 19-6.

Specify Project Path

When Simulink Project:

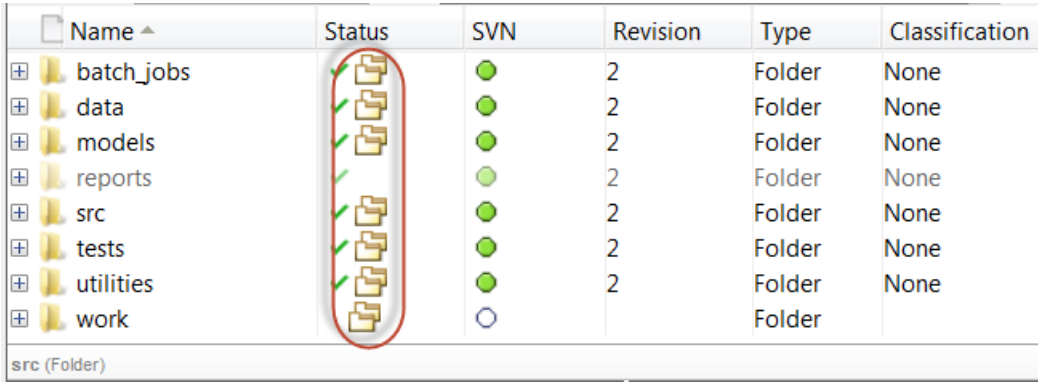
- Opens your project, it adds the project path to the MATLAB search path before applying startup shortcuts.
- Closes your project, it removes the project path from the MATLAB search path after applying shutdown shortcuts.

You can add or remove folders from the project path. Add project folders to ensure dependency analysis detects project files. On the **Simulink Project** tab, in the **Environment** section, click **Project Path**:

- To add a folder (without subfolders) to the project path, click **Add Folder**. If you want to add a folder and its subfolders, click **Add with Subfolders** instead. Then use the Open dialog box to add the new folder.
- To remove a folder from the project path, from the display list, select the folder. Then click **Remove**.

In the **Project** > **Files** view, you can use the context menu to add or remove folders from the project path. Right-click a folder and select **Project Path** > **Add to Project Path**, or **Add to the Project Path (Including Subfolders)**, or one of the options to remove the folder from the path.

Folders on the project path display the project path icon in the **Status** column.



If you want to set the startup folder, see the check box option at the root project node: **Change current folder to project root on start up**.

- “What Can You Do With Project Shortcuts?” on page 16-33

What Can You Do With Project Shortcuts?

In Simulink Project, use shortcuts to make it easy for any project user to find and access important files and operations. You can use shortcuts to make top models or scripts easier to find in a large project. You can group shortcuts to organize them by type and annotate them to use meaningful names instead of cryptic file names.

Using the Project Shortcuts tab in the toolstrip, you can execute, group, or annotate shortcuts. Run shortcuts by clicking them in the Project Shortcuts tab or execute them manually from the context menu.

To automate tasks, use startup and shutdown files instead. You can use startup files to help you set up the environment for your project, and shutdown shortcuts to help you clean up the environment for the current project when you close it.

- “Automate Shutdown Tasks” on page 16-36
- “Specify Project Path” on page 16-31

Automate Startup Tasks

In Simulink Project, startup files help you set up the environment for your project.

Startup files are automatically run (`.m` and `.p` files), loaded (`.mat` files), and opened (Simulink models) when you open the project.

Note Startup scripts can have any name. You do not need to use `startup.m`

You can use a file named `startup.m` on the MATLAB path which runs when you start MATLAB. If your `startup.m` file calls the project with `simulinkproject`, an error appears because no project is loaded yet. To avoid the error, rename `startup.m` and use it as a project startup file instead.

Configure an existing file to run when you open your project.

- Right-click the file and select **Run at Startup** .
- Alternatively, on the Simulink Project tab, click **Startup Shutdown**. In the Manage Project Startup and Shutdown dialog box, you can add and remove startup and shutdown files. If execution order is important, change the order using the arrow buttons.

In the files view, the **Status** column displays an icon and tooltip indicating the file will run at startup.

Note Startup file settings are included when you commit modified files to source control. Any startup tasks you create run for all other project users.

To stop a file running at startup, change back by right-clicking it and selecting **Remove from Startup**.

When you open the project, the startup files run. Also, the current working folder changes to the project startup folder. If you want to set the startup folder, on the Simulink Project tab, click **Details** and edit the **Start Up** folder. See “Specify Project Details, Startup Folder, and Derived Files Folders” on page 16-30.

You can create new startup and shutdown files interactively in the Simulink Project or at the command line. For details, see `addStartupFile`.

Automate Shutdown Tasks

In Simulink Project, shutdown files help you clean up the environment for the current project when you close it. Shutdown files should undo the settings applied in startup files.

Configure an existing file to run when you close your project.

1 Right-click the file and select **Run at Shutdown**.

The **Status** column displays an icon and tooltip indicating the file will run at shutdown.

Note Shutdown files are included when you commit modified files to source control. Any shutdown files you set run for all other project users.

To stop a file running at shutdown, change it back by right-clicking it and selecting **Remove from Shutdown**.

More About

- “What Can You Do With Project Shortcuts?” on page 16-33

Create Shortcuts to Frequent Tasks

In this section...

Create Shortcuts

In Simulink Project, create shortcuts for common project tasks and to make it easy to find and access important files and operations. For example, find and open top models, run code (for example, to load data), and simulate models. To run startup or shutdown code, see instead “Automate Startup Tasks” on page 16-34.

To configure an existing project file as a shortcut, use any of the following methods:

- In the **Files** view, right-click the project file and select **Create Shortcut**. In the Create New Shortcut dialog box, you can edit the shortcut name, choose an icon, and select a group if you have created a shortcut group you want to use. You can change shortcut group later. Click **OK**.
- Click **New Shortcut** on the Project Shortcuts tab on the toolstrip and browse to select a file.

The shortcut appears on the Project Shortcuts tab on the toolstrip.

In the files view, the **Status** column displays an icon and tooltip indicating the file is a shortcut.

Note Shortcuts are included when you commit your modified files to source control, so you can share shortcuts with other project users.

Group Shortcuts

You can group shortcuts to organize them by type. For example, you can group shortcuts for loading data, opening models, generating code, and running tests.

You can select a shortcut group when creating shortcuts, or manage groups later on the Project Shortcuts toolstrip tab.

Create new shortcut groups to organize your shortcuts:

- On the Project Shortcuts tab, click **Organize Groups**.
- Click **Create**, enter a name for the group and click **OK**.

  The new shortcut group appears on the Project Shortcuts tab.

To organize your shortcuts by group, either:

- Select a group when creating a shortcut.
- In the **Project Files View**, right-click a file and select **Edit Shortcut**.
- On the Project Shortcuts tab, right-click a file and select **Edit Shortcut**.

The shortcuts are organized by group in the Project Shortcuts toolstrip tab.

Annotate Shortcuts to Use Meaningful Names

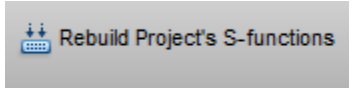
Annotating shortcuts makes their purpose visible, without changing the file name or location of the script or model the shortcut points to. For example, you can change a cryptic file name to a descriptive name for the shortcut. To put shortcuts in a workflow order on the toolstrip, prefix the shortcut names with numbers.

When creating a shortcut, edit the **Name**. The shortcut name does not affect the file name or location.

Your specified shortcut name appears on the Project Shortcuts tab, to make it easier to find your shortcuts.

Customize Shortcut Icons

You can specify an icon to use for your shortcut buttons on the Project Shortcuts tab. Icons such as "build" can aid other project users to recognize frequent tasks.



1 When creating a shortcut, choose an icon.

2 Select an image file. Images must be exactly 16 pixels square, and a `png` or a `gif` file.

More About

- "What Can You Do With Project Shortcuts?" on page 16-33

Use Shortcuts to Find and Run Frequent Tasks

In Simulink Project, use shortcuts to make it easy for any project user to find and access important files and operations. You can use shortcuts to make top models or scripts easier to find in a large project. Shortcuts are available from any file view via the toolstrip.

If your project does not yet contain any shortcuts, see “Create Shortcuts to Frequent Tasks” on page 16-37.

To use shortcuts:

- In the Project Shortcuts toolstrip tab, click the shortcut. Clicking a shortcut in the toolstrip performs the default action for the file type, for example, run `.m` files, load `.mat` files, and open models. Hover over a shortcut to view the full path.

Choose which behavior you want when running shortcuts:

- If the script is not on the path, and you want to switch to the parent folder and run the script without being prompted, then click the shortcut in the Project Shortcuts toolstrip tab. If you use this option, the result of `pwd` in the script is the parent folder of the script.
- If you select **Run** in the **Files** view context menu, and the script is not on the path, then MATLAB asks if you want to change folder or add the folder to the path. This is the same behavior as running from the Current Folder browser. If you use this option, the result of `pwd` in the script is the current folder when you run the script.

Create Templates for Standard Project Settings

In this section...

Using Templates to Create Standard Project Settings

In Simulink Project, use templates to create and reuse a standard project structure. Templates help you make consistent projects across teams. You can use templates to create new projects that:

- Use a standard folder structure.
- Set up a company standard environment, for example, with company libraries on the path.
- Have access to tools such as company Model Advisor checks.
- Use company standard startup and shutdown scripts.
- Share labels and categories.

You can use templates to share information and best practices. You or your colleagues can create templates.

Create a template from a project when it is useful to reuse or share with others. You can use the template when creating new projects.

Create a Template from the Current Project

In Simulink Project, when you create a template, it contains the structure and all the contents of the current project, enabling you to reuse scripts and other files for your standard project setup. You can choose whether to include the contents of referenced projects in the template.

1 Before creating the template, create a copy of the project, and edit the copy to contain only the files you want to reuse. Use the copy as the basis for the template.

Note If the project is under version control, see instead "Create a Template from a Project Under Version Control" on page 16-43.

2. On the **Simulink Project** tab, in the **File** section, select **Share** > **Template**.
3. On the Create Project Template dialog box, edit the name and author, add a description to help template users.
4. If you have referenced projects and want to export the referenced project files, then select the **Include referenced projects** check box.
5. Click **Save As**. Choose a file location and click **Save**

Create a Template from a Project Under Version Control

1. Get a new working copy of the project. See "Retrieve a Working Copy of a Project from Source Control" on page 19-29.
2. To avoid accidentally committing changes to your project meant only for the template, stop using source control with this sandbox as you work on the template. In the Source Control view, under **Available Source Control Integrations**, select `No Source Control Integration` and click **Reload**.
3. Remove the files that you do not want in the template. For example, you might want to reuse only the utility functions, startup and shutdown scripts, and labels. In the **Files** view, right-click unwanted files and select **Remove from Project**.
4. On the **Simulink Project** tab, in the **File** section, select **Share** > **Template** and use the dialog box to name and save the file.

To verify that your template behaves as you expect, create a new project that uses your new template. See "Create a New Project Using Templates" on page 16-26.

Edit a Template

1. Create a new project that uses the template you want to modify. See "Create a New Project Using Templates" on page 16-26.
2. Make the changes.
3. On the **Simulink Project** tab, in the **File** section, select **Share** > **Template**.

   Use the dialog box to create a new template or overwrite the existing one.

Explore the Example Templates

Example templates are supplied with Simulink Project. You can use these templates as example structures for a new project.

You can explore the templates using the Simulink start page. To search for templates, use the start page search box. See “Create a New Project Using Templates” on page 16-26 and “Create a New Project From a Folder” on page 16-17.

See Also

Related Examples

Simulink Project File Management

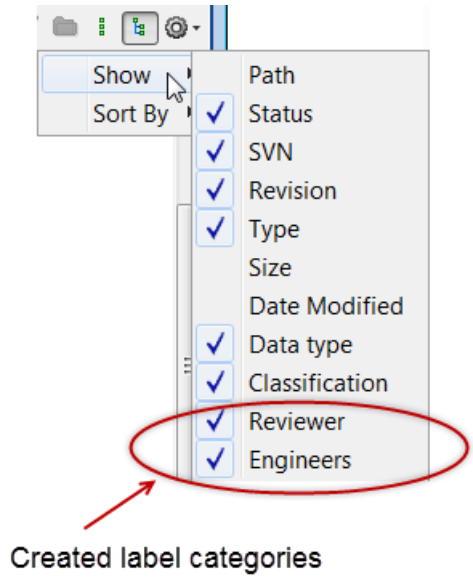
Group and Sort File Views

In Simulink Project, to group and sort the views in the Files view:

- Use the List view or Tree view buttons to switch between a flat list of files and a hierarchical tree of files.

  In a list view, you can click the **Hide Folders** button if you want to view only files.

- Click the Actions button  to specify display columns and sort order. For example, you can display columns for label categories that you created and sort files by label category.



See Also

Related Examples

- “Search Inside Project Files and Filter File Views” on page 17-4

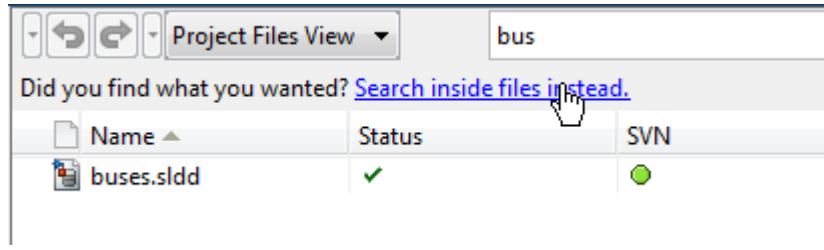
Search Inside Project Files and Filter File Views

In this section...

Project-Wide Search

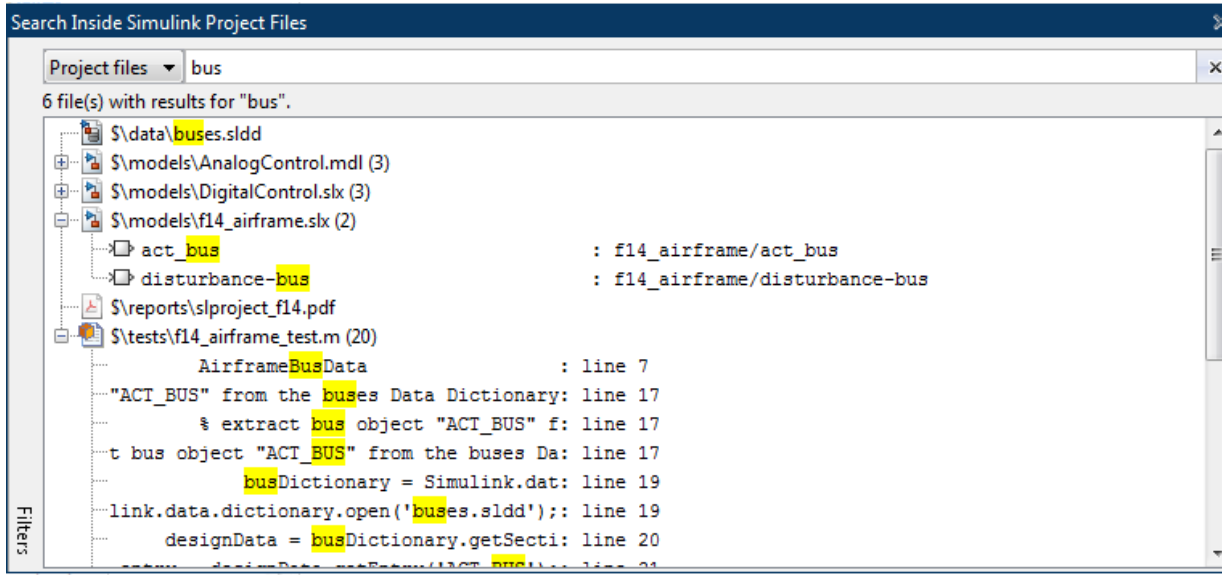
In Simulink Project, you can search inside all your models and supporting files. You can find matches inside model files, MATLAB files, and other project files such as PDF and Microsoft Word files. You search only the current project. If you want to search referenced project files, open the referenced project.

1 On the Simulink Project tab, click **Search**. Alternatively, type in the file filter box, and the project provides a link to try searching inside files instead.

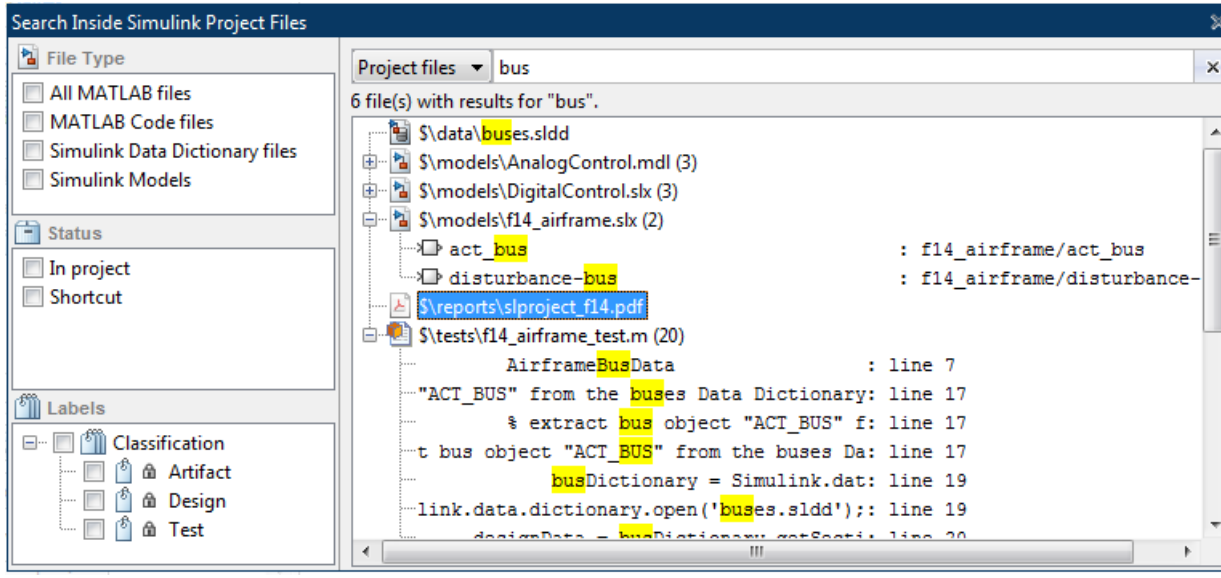


2 In the Search Inside Simulink Project Files dialog box, enter some characters to search for. Do not use quotes around phrases, or hyphens.

3 Expand files in the list to see results inside the file. Double-click results to locate specific items, e.g., highlight blocks in Simulink models, or highlight specific lines in MATLAB files.



4 Click **Filters** to refine results by file type, status, or label.



Filter Project File Views

In the Simulink Project Files and Dependency Analysis views, and in the Custom Task dialog box, you can use the search box and filtering tools to specify file display.

- To view files, select the **Files** node. When **Project Files View** is selected, only the files in your project are shown. To see all the files in your sandbox, click the **Project Files View** button and select **All Files View**. This view shows all the files that are under the project root, not just the files that are in the project.
- To search, type a search term in the search box, for example, part of a file name or a file extension. You can use wildcards, for example, `*.m`, or `*.m*`.

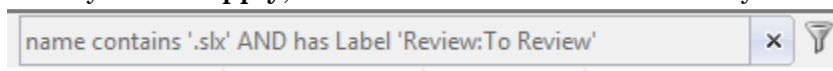
  Click **X** to clear the search.
- To build a filter for the current view, click the filter button  .

  
  In the Filter Builder dialog box you can select multiple filter criteria to apply using names, file types, project status, and labels.

  The dialog box reports the resulting filter at the bottom, for example:

  ```
  Filter = file type is 'Model files (*.slx, *.mdl)' AND project status
   is 'In project' AND has label 'Engine Type:Diesel'
  ```

  When you click **Apply**, the search box shows the filter that you are applying.

More Ways to Search

You can also search:

- Model contents without loading the models into memory. On the MATLAB **Home** tab, in the **File** section, click **Find Files**. You can search a folder or the entire path. However, you cannot highlight results in models from the results in the Find Files dialog box the same way you do with project search. See “Advanced Search for Files” (MATLAB).
- A model hierarchy. In the Simulink Editor, select **Edit > Find**. Select options to look inside masks, links, and references. This search loads the models into memory. See “Find Model Elements in Simulink Models” on page 12-47
- For variables, block parameter values, or search a model hierarchy and contents using more options, using the Model Explorer. This search loads the models into memory. Use the Model Explorer to search for variables in workspaces and data dictionaries, and variable usage in a model. See “Edit and Manage Workspace Variables by Using Model Explorer” on page 59-111

Work with Project Files

In Simulink Project, in the **Files** view, use the context menus to perform actions on the files that you are viewing. Right-click a file (or selected multiple files) to perform project options such as:

- Open files.
- Add and remove files from the project.
- Add, change, and remove labels. See “Add Labels to Files” on page 17-26.
- Create entry point shortcuts (for example, code to run at startup or shutdown, open models, simulate, or generate code). See “Create Shortcuts to Frequent Tasks” on page 16-37.
- If a source control interface is enabled, you can also:
  - Refresh source control status.
  - Update from source control.
  - Check for modifications.
  - Revert.
  - Compare against revision (select a version to compare).

  See “About Source Control with Projects” on page 19-2.

In the **Files** view, if you select, for example a model file, the bottom right-hand pane displays file information, a model preview, and file labels.

Manage Shadowed and Dirty Model Files

In this section...

Identify Shadowed Project Files When Opening a Project

If there are two model files with the same name on the MATLAB path, then the one higher on the path is loaded, and the one lower on the path is shadowed. This shadowing applies to all models and libraries (SLX and MDL files).

A loaded model always takes precedence over unloaded ones, regardless of its position on the MATLAB path. Loaded models can interfere when you try to use other files of the same name, especially when models are loaded but not visible. Simulink warns when you try to load a shadowed model, because the other model is already loaded and can cause conflicts. Simulink Project checks for shadowed files when you open a project.

1. When you open a Simulink project, it warns you if any models of the same names as your project models are already loaded. This check enables you to find and avoid shadowed files before opening any project models.

   The Configuring Project Environment dialog box reports the **Identify shadowed project files** check fails. Click **Details**.
2. In the dialog box, you can choose to show or close individual files, or close all potentially shadowing files, by clicking the hyperlinks. To avoid working on the wrong files, close the loaded models.
3. After deciding whether to show or close the loaded models, click **OK** to return to the Configuring Project Environment dialog box.
4. Inspect the other project loading tasks, then click **Continue** to view the project.

Tip To help avoid problems with shadowed files, turn on the Simulink preference **Do not load models that are shadowed on the MATLAB path**. See “Do not load models that are shadowed on the MATLAB path”.

To learn more about shadowed files, see “Shadowed Files” on page 15-4.

Find Models and MATLAB Files With Unsaved Changes

You can check your project for models and MATLAB files with unsaved changes. On the **Simulink Project** tab, in the **Tools** section, click **Unsaved Changes**.

In the Unsaved Changes dialog box, you can see all dirty project models and MATLAB files. If you have referenced projects, files are grouped by project. You can save or discard all changes.

Manage Open Models When Closing a Project

When you close a project, it closes any project models that are open, unless they are dirty.

When you close a project, if there are model files with unsaved changes, a message prompts you to save or discard changes. You can see all dirty files, grouped by project if you have referenced projects. To avoid losing work, you can save or discard changes by file, by project, or globally.

Control this behavior using the Simulink project shutdown preferences.

See Also

Related Examples

- “Do not load models that are shadowed on the MATLAB path”
- “Shadowed Files” on page 15-4

Move, Rename, Copy, or Delete Project Files

In this section...

Move or Add Files

To move or add project files, you can drag them to Simulink Project, or use clipboard operations.

- To add files to your project, you can paste files or drag them from your operating system file browser or the MATLAB Current Folder browser onto the Project Files View in Simulink Project. When you drag a file to the Project Files View, you add the file to the project. For projects under source control, you also add the file to source control.
- To move files within your project, cut and paste or drag files in the Simulink Project.

See also “Add Files to the Project” on page 16-23.

Automatic Updates When Renaming, Deleting, or Removing Files

When you rename, delete, or remove files or folders in a Simulink project, the project checks for impact in other project files. You can find and fix impacts such as changed library links, model references, and model callbacks. You can avoid refactoring pain tracking down other affected files. Automatic renaming helps to prevent errors that result from changing names or paths manually and overlooking or mistyping one or more instances of the name.

For example:

- When renaming a library, the project offers to automatically update all library links to the renamed library.
- When renaming a class, the project offers to automatically update all classes that inherit from it. If you rename a `.m` or `.mlx` file, the project offers to automatically update any files and callbacks that call it.
- When deleting files or removing them from the project, the project prompts you if other files refer to them. You must decide how to fix the affected files manually.

- When renaming a C file, the project prompts you to update the S-function that uses it.

To use automatic updates:

1. Rename a model, library, or MATLAB file in a Simulink project.

   The project runs a dependency analysis to look for impacts in other files.
2. In the Rename dialog box, you can examine impacted files, choose to rename and update, just rename, or cancel renaming the file.
3. If you choose automatic updates, you can examine the results in updated files.

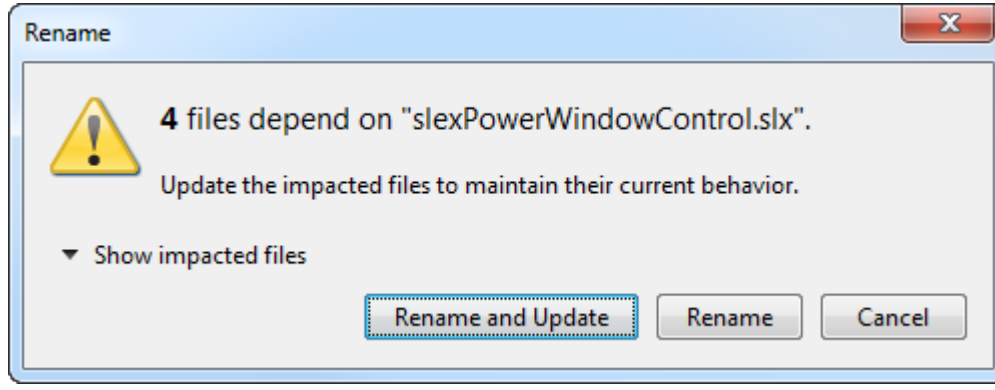
Automatic Renaming Using the Power Window Project

1. Open the power window example project by entering in MATLAB:

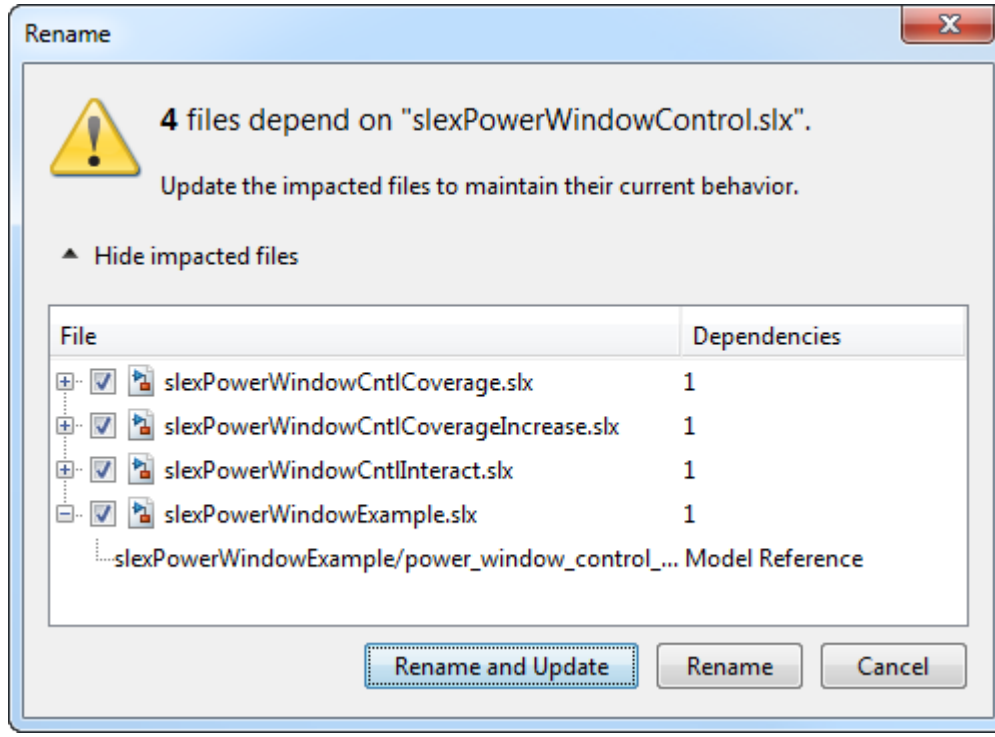
   ```
   slexPowerWindowStart
   ```

   The project opens the top model, some scopes, and an animation window.
2. In Simulink Project, expand the `model` folder, and rename the `slexPowerWindowControl.slx` model to `slexPowerWindowControlSystem.slx`.

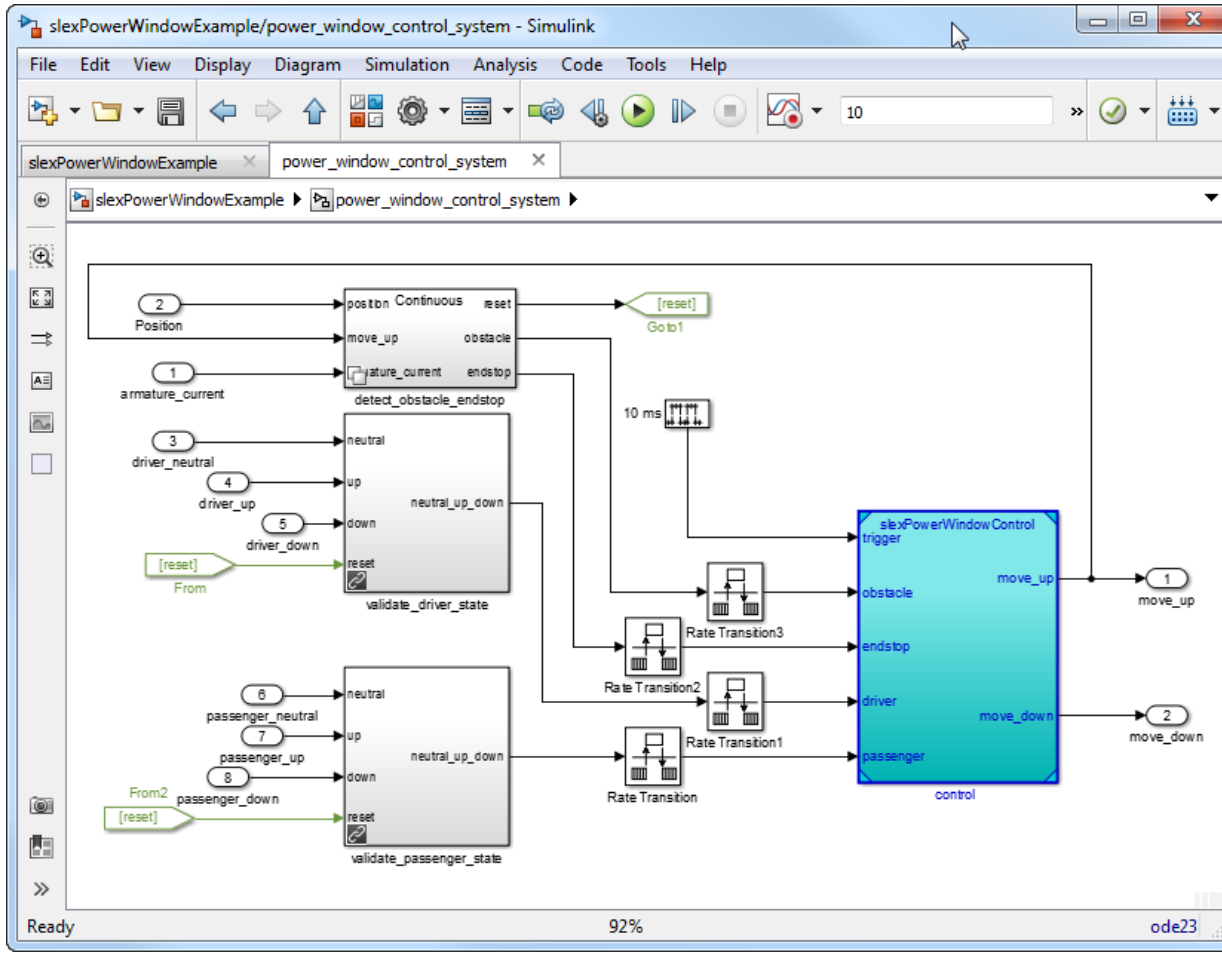
   The project runs a dependency analysis to look for impacts in other files, and then the Rename dialog box reports impacted files.



3. In the Rename dialog box, click **Show impacted files**. Expand the last impacted file to view the dependency, which is a model reference.

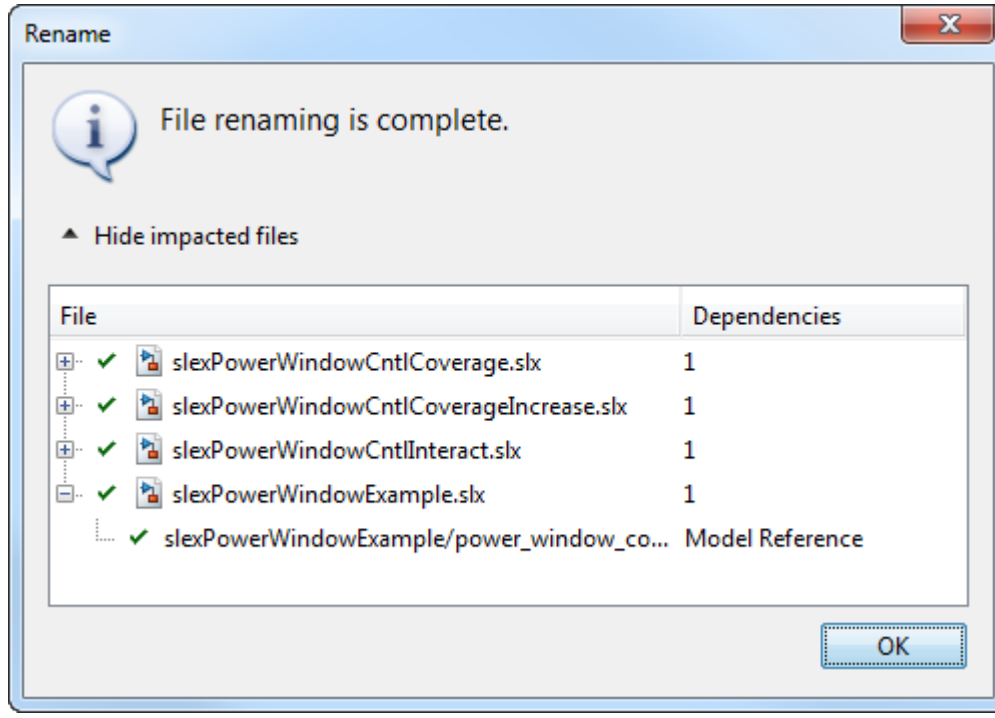


4 To view the dependency highlighted in the model, double-click the last **Model Reference** line in the Rename dialog box. Observe the model name on the highlighted control block, `slexPowerWindowControl`.



5 In the Rename dialog box, click **Rename and Update**.

The project updates the impact files to use the new model name in model references. When the project can automatically rename items, it reports success with a check mark. With some impacts, you must decide how to fix the affected files manually.



6 Examine the results by double-clicking items in the Rename dialog box. Double-click the last **Model Reference** line. Check if the model name on the highlighted control block is updated to `slexPowerWindowControlSystem`.

Related Examples

- “Work with Project Files” on page 17-8

Back Out Changes

Similar to many applications, Simulink Project enables you to Undo and Redo, to back out recent changes.

1. Click the arrow next to the Undo or Redo button.
2. Select the actions you want to undo or redo. You can select multiple actions. Hover over each action to view details in a tooltip.

If you are using source control, you can revert to particular versions of files or projects. See “Revert Changes” on page 19-53.

Upgrade Model Files to SLX and Preserve Revision History

In this section...

Project Tools for Migrating Model Files to SLX

Simulink Project helps you upgrade model files from MDL format to SLX format. You can use the project integrity checks to automatically add the new SLX file to your project, remove the MDL file from the project, and preserve the revision history of your MDL file with the new SLX file. You can then commit your changes to source control and maintain the continuity of your model file history.

The following example shows how to use project checks to fix your project after manually saving a model as SLX.

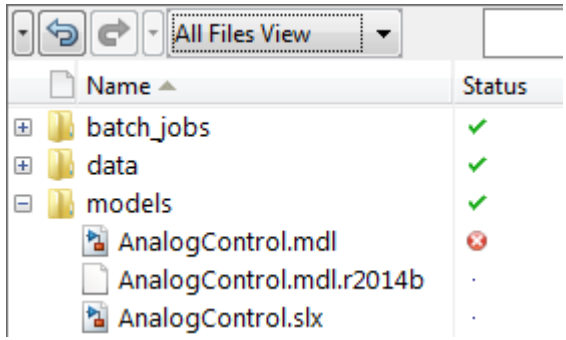
Upgrade the Model and Commit the Changes

1. Open a new copy of the `airframe` project.

   ```
   sldemo_slproject_airframe
   ```

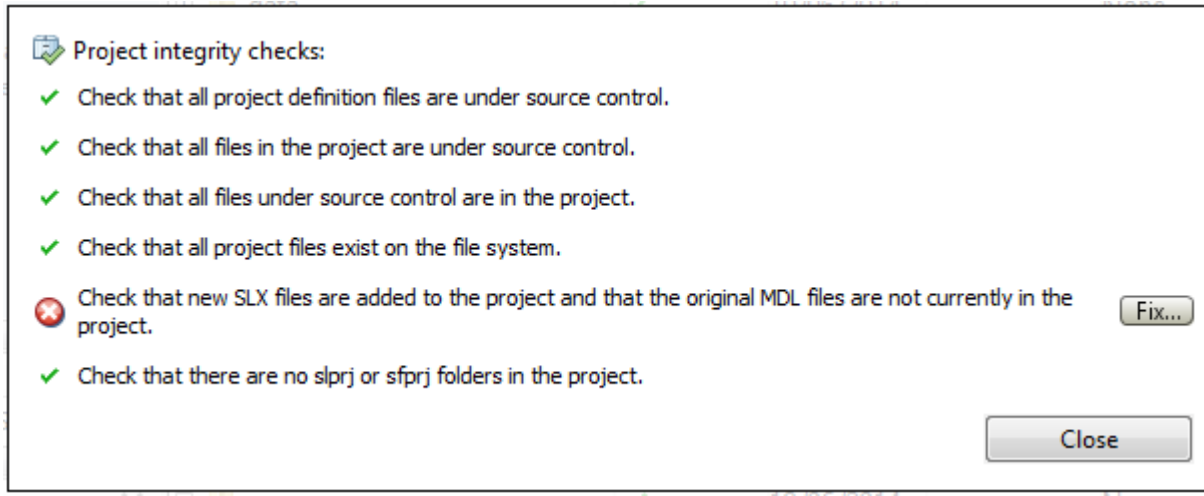
2. In the Project Files View, right-click the model file `AnalogControl.mdl`, and select **Open**.
3. Select **File** > **Save As**.
4. Ensure that **Save as type** is SLX, and click **Save**. SLX is the default unless you change your preferences.
5. To see the results, in the Files view, click the **Project Files View** button and change the selection to the **All Files View**. Expand the `models` folder.

   Simulink saves the model in SLX format, and creates a backup file by renaming the MDL file to `AnalogControl.mdl.`*`releasename`*. The project also reports the original name of the MDL file as missing.



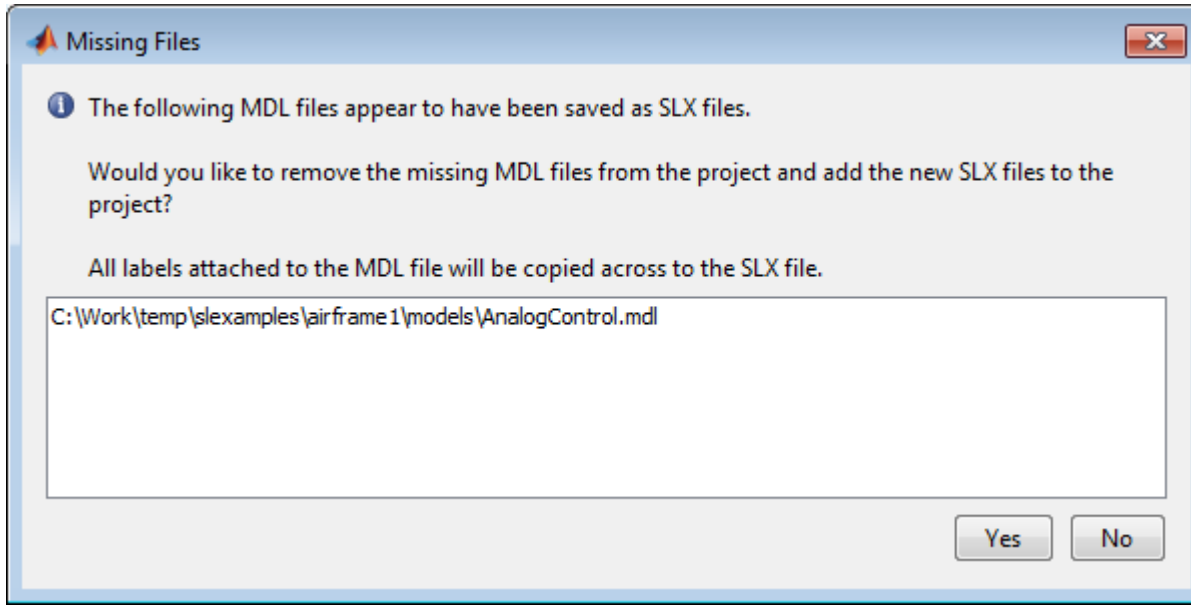
6 To resolve these issues, on the Simulink Project tab, click **Check Project** to run the project integrity checks. The checks look for MDL files converted to SLX, and offer automatic fixes if that check fails.

7 Click the **Fix** button to view recommended actions and decide whether to make the changes.

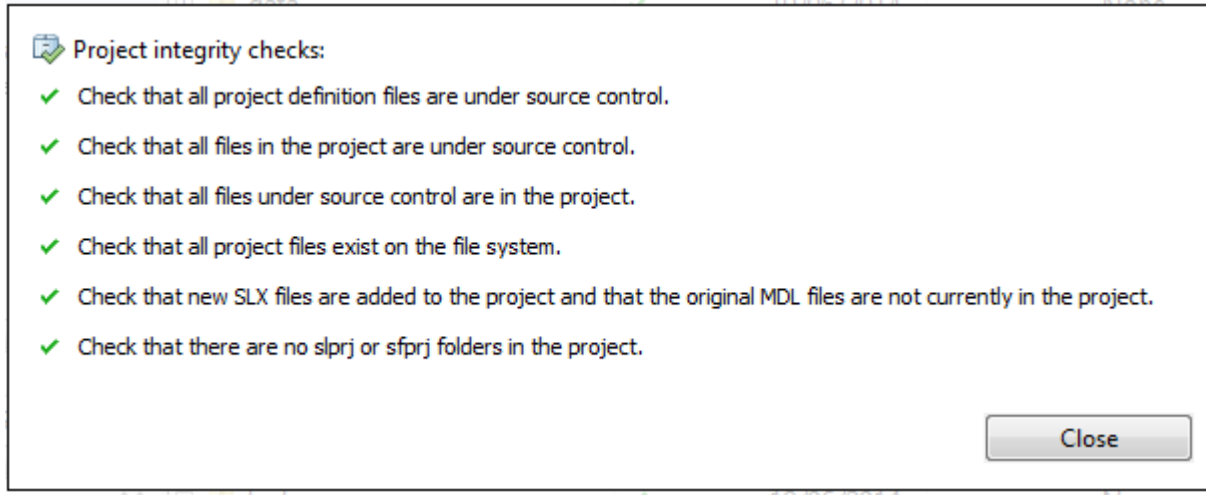


When you click **Fix**, the Missing Files dialog box offers to remove the missing MDL file from the project and add the new SLX file to the project.

8 Click **Yes** to perform the fix.

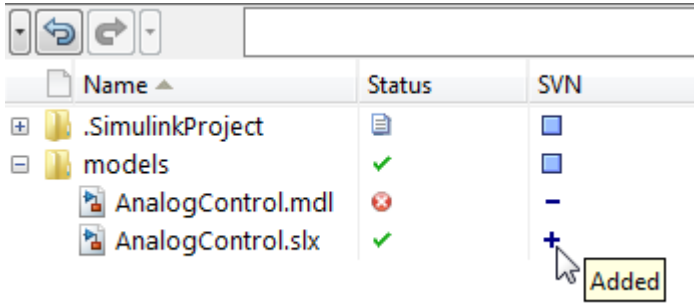


Project checks rerun after you click **Yes** to perform the fix.



Close the Project Integrity Checks dialog box.

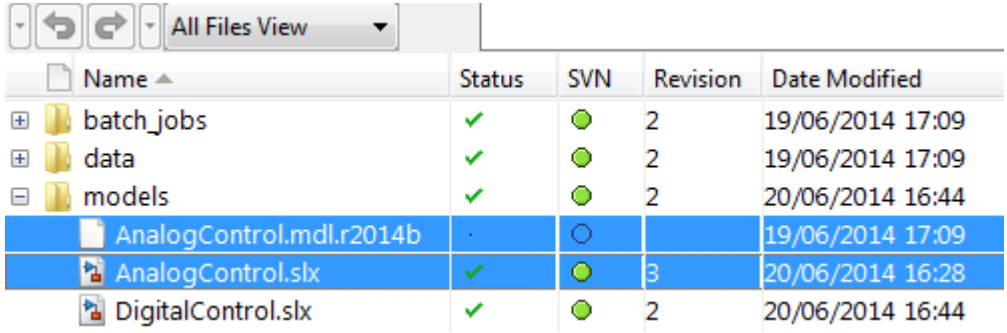
9 Select the Modified Files view. Expand the `models` folder and check the Modifications column to see that the newly created SLX file has been added to the project, and the original MDL file is scheduled for removal.



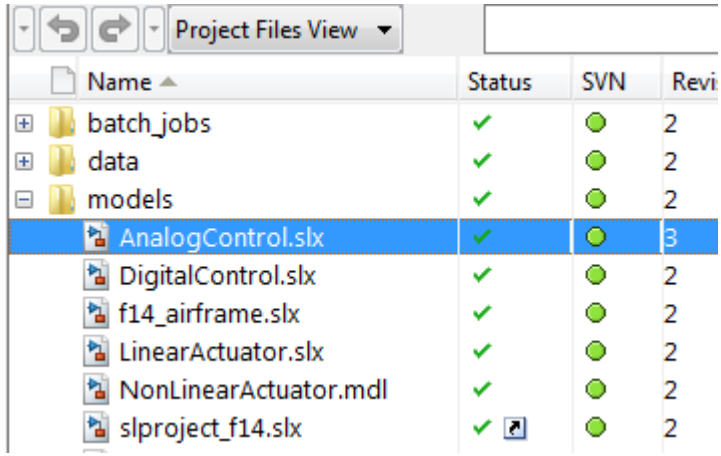
10 Click **Commit Modified Files**. Enter a comment for your submission in the dialog box, for example, `Convert to SLX`, and click **Submit**.

Verify Changes After Upgrade to SLX

1 In the Files view, ensure the **All Files View** is selected. Check that the backup file `AnalogControl.mdl.r2012b` is still present, along with the new SLX file. Click the Actions button to customize the columns to show, such as **Date Modified**.



2 In the Files view, click the **All Files View** button and change the selection to the **Project Files View**. Check that only the new SLX file is included in the project, and the backup file is not included in the project.



3 Right-click the model file `AnalogControl.slx` and select **Show Revisions**.

4 In the File Revisions dialog box, verify that the previous revision is `AnalogControl.mdl`. The revision history of the previous model file is preserved with the new SLX file.

For an example showing commands to find and upgrade all model files in the project to SLX, see Converting from MDL to SLX Model File Format in a Simulink Project.

Note For an example showing how to programmatically upgrade a whole project using `upgradeadvisor`, see instead:

```
sldemo_slproject_upgrade
```

Create Labels

In Simulink Project, use labels to organize files and communicate information to project users. You can create these types of label categories:

- Single-valued — You can attach only one label from the category to a file.
- Multi-valued — You can attach multiple labels from the category to a file.

The **Labels** tree has built-in labels in the single-valued **Classification** category:

- You cannot rename or delete **Artifact**, **Convenience**, **Derived**, **Design**, **None**, **Test**, and **Other**.
- You can rename or delete **Utility**.
- You cannot annotate built-in labels.

To create a label category:

1. In Simulink Project, right-click the **Labels** pane. Then select **Create New Category**.
2. In the Create Category dialog box, enter a name for the new category.
3. If you require a single-valued label category, select the **Single Valued** check box. The default is multi-valued.
4. If you want to specify a data type for the label other than `String`, from the **Type** list, select `Double`, `Integer`, `Logical`, or `None`.
5. Click **Create**.

To create a label in a category:

1. In the **Labels** pane, right-click the label category and select **Create New Label**.
2. In the Create Label dialog box, enter a name for the new label and click **OK**.

To rename or delete a category or label, right-click it and select **Rename** or **Remove**.

To create new labels at the command line, see “Automate Simulink Project Tasks Using Scripts” on page 17-29.

See Also

Related Examples

- "Add Labels to Files" on page 17-26
- "View and Edit Label Data" on page 17-27

Add Labels to Files

In Simulink Project, use labels to organize files and communicate information to project users.

To add a label to a file, use one of these methods:

- Drag the label from the **Labels** pane onto the file.
- In the Files view, select the file. Then, drag the label from the **Labels** pane into the label editor.

To add a label to multiple files, in the Files view or Impact graph, select the files that require the label. Then right-click and select **Add Label**. Use the dialog box to specify the label.

To add labels programmatically, for example, in custom task functions, see "Automate Simulink Project Tasks Using Scripts" on page 17-29.

Note After you add a label to a file, the label persists across file revisions.

After you add labels, you can organize files by label in the Files view and Impact graph. See "Group and Sort File Views" on page 17-2 and "Perform Impact Analysis" on page 18-7.

If the project is under SVN source control, adding tags to all your project files enables you to mark versions. See "Tag and Retrieve Versions of Project Files" on page 19-35.

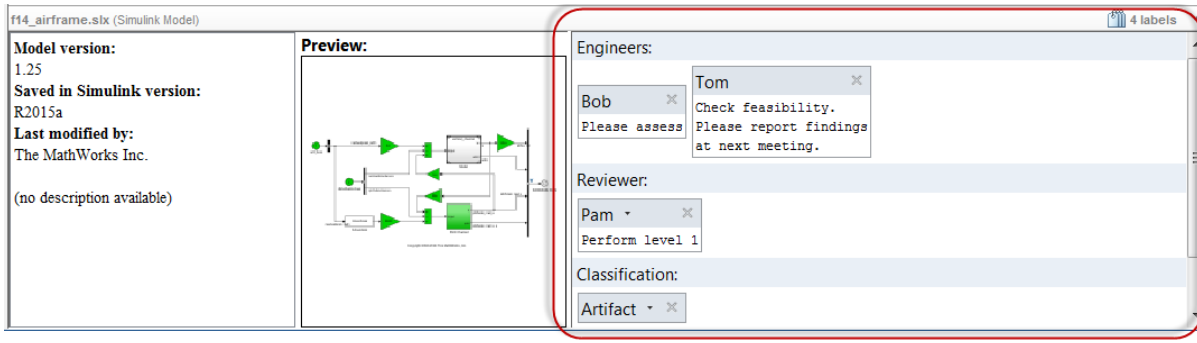
Related Examples

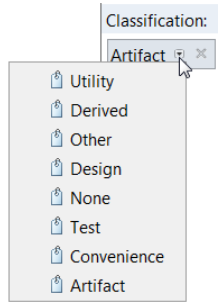
- "Create Labels" on page 17-24
- "View and Edit Label Data" on page 17-27

View and Edit Label Data

When you select a file in the Simulink Project Files view, the file labels appear in the label editor view.



To change a label that belongs to a single-valued category, select the new value from the label list.



You can annotate labels from categories that you create. In the label, insert or modify text. Then, click **Apply**.

Automate Simulink Project Tasks Using Scripts

This example shows how to use the Simulink project API to automate project tasks manipulating files, including working with modified files, dependencies, shortcuts, and labels.

Get Simulink Project at the Command Line

Open the Airframe project and use simulinkproject to get a project object to manipulate the project at the command line. You must open a project in Simulink Project to perform command-line operations on the project.

```
sldemo_slproject_airframe
proj = simulinkproject
```

```
Creating sandbox for project.
Created example files in "C:\slexamples\airframe21"
Initializing: Project Path
Identifying shadowed project files
Running: C:\slexamples\airframe21\utilities\set_up_project.m
Building with 'MinGW64 Compiler  C '.
MEX completed successfully.

proj =

  ProjectManager with properties:

                Name: 'Simulink Project Airframe Example'
         Information: [1×1 slproject.Information]
        Dependencies: [1×1 slproject.Dependencies]
           Shortcuts: [1×9 slproject.Shortcut]
         ProjectPath: [1×7 slproject.PathFolder]
   ProjectReferences: [1×0 slproject.ProjectReference]
          Categories: [1×1 slproject.Category]
               Files: [1×33 slproject.ProjectFile]
          RootFolder: 'C:\slexamples\airframe21'
```

Find Project Commands

Find out what you can do with your project.

```
methods(proj)
```

```
Methods for class slproject.ProjectManager:

addFile                         isLoaded
addFolderIncludingChildFiles    listModifiedFiles
close                           refreshSourceControl
createCategory                  reload
export                          removeCategory
findCategory                    removeFile
findFile
getFilesRequiredBy
```

Examine Project Files

After you get a project object, you can examine project properties such as files.

```
files = proj.Files
```

```
files =

  1×33 ProjectFile array with properties:

    Path
    Labels
    Revision
    SourceControlStatus
```

Use indexing to access files in this list. The following command gets file number 14. Each file has properties describing its path and attached labels.

```
proj.Files(14)
```

```
ans =

  ProjectFile with properties:

                  Path: 'C:\slexamples\airframe21\models\AnalogControl.mdl'
                Labels: [1×1 slproject.Label]
              Revision: '2'
    SourceControlStatus: Unmodified
```

Examine the labels of the 14th file.

```
proj.Files(14).Labels
```

```
ans =

  Label with properties:

           File: 'C:\slexamples\airframe21\models\AnalogControl.mdl'
       DataType: 'none'
           Data: []
           Name: 'Design'
   CategoryName: 'Classification'
```

Get a particular file by name.

```
myfile = findFile(proj, 'models/AnalogControl.mdl')
```

```
myfile =

  ProjectFile with properties:

                 Path: 'C:\slexamples\airframe21\models\AnalogControl.mdl'
               Labels: [1×1 slproject.Label]
             Revision: '2'
   SourceControlStatus: Unmodified
```

Find out what you can do with the file.

```
methods(myfile)
```

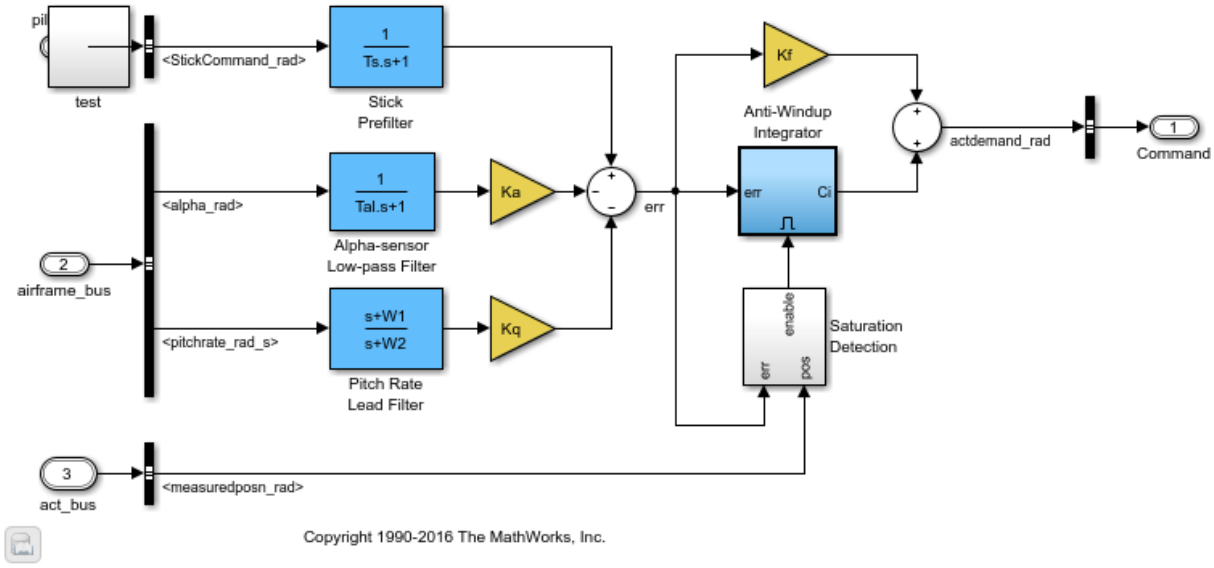
```
Methods for class slproject.ProjectFile:

addLabel     findLabel    removeLabel
```

Get Modified Files

Modify a project model file by adding an arbitrary block.

```
open_system('AnalogControl')
add_block('built-in/SubSystem', 'AnalogControl/test')
save_system('AnalogControl')
```



Get all the modified files in the project. Observe two modified files. Compare with the Modified Files view in Simulink Project, where you can see a modified model file, and the corresponding .SimulinkProject definition file.

```
modifiedfiles = listModifiedFiles(proj)
```

```
modifiedfiles =

  1×2 ProjectFile array with properties:

    Path
    Labels
    Revision
    SourceControlStatus
```

Get the second modified file. Observe the file `SourceControlStatus` property is Modified. Similarly, `listModifiedFiles` returns any files that are added, conflicted, deleted, etc., that show up in the Modified Files view in Simulink Project.

```
modifiedfiles(2)
```

```
ans =

  ProjectFile with properties:

                  Path: 'C:\slexamples\airframe21\models\AnalogControl.mdl'
                Labels: [1×1 slproject.Label]
              Revision: '2'
    SourceControlStatus: Modified
```

Refresh source control status before querying individual files. You do not need to do before using `listModifiedFiles` .

```
refreshSourceControl(proj)
```

Get all the project files with a particular source control status. For example, get the files that are `Unmodified` .

```
proj.Files(ismember([proj.Files.SourceControlStatus], matlab.sourcecontrol.Status.Unmod
```

```
ans =

  1×32 ProjectFile array with properties:

    Path
    Labels
    Revision
    SourceControlStatus
```

Get File Dependencies

Update the file dependencies. The project runs a dependency analysis to update the known dependencies between project files.

```
update(proj.Dependencies)
```

Examine the dependencies in the project object. The dependencies property of the project object contains the graph of dependencies between project files in a MATLAB digraph object. You can view the same dependency analysis graph in the Impact view of Simulink Project. If you want to plot the graph, instead of working with the digraph object, save the impact view to an image file.

```
proj.Dependencies
```

```
ans =

  Dependencies with properties:

    Graph: [1×1 digraph]
```

Get the graph dependencies. You can use digraph methods to get information from the graph.

```
g = proj.Dependencies.Graph
```

```
g =

  digraph with properties:

    Edges: [24×1 table]
    Nodes: [25×1 table]
```

Get the files required by a model.

```
requiredFiles = bfsearch(g, which('AnalogControl'))
```

```
requiredFiles =

  3×1 cell array

    'C:\slexamples\airframe21\models\AnalogControl.mdl'
    'C:\slexamples\airframe21\data\controller.sldd'
    'C:\slexamples\airframe21\data\buses.sldd'
```

Get the top-level files of all types in the graph.

```
top = g.Nodes.Name(indegree(g)==0);
```

Get the top-level files that have dependencies.

```
top = g.Nodes.Name(indegree(g)==0 & outdegree(g)>0)
```

```
top =

  7×1 cell array

    'C:\slexamples\airframe21\models\DigitalControl.slx'
    'C:\slexamples\airframe21\models\LinearActuator.slx'
    'C:\slexamples\airframe21\models\slproject_f14.slx'
    'C:\slexamples\airframe21\tests\f14_airframe_test.m'
    'C:\slexamples\airframe21\utilities\rebuild_s_functions.m'
    'C:\slexamples\airframe21\utilities\set_up_project.m'
    'C:\slexamples\airframe21\utilities\upgrade_project.m'
```

Find impacted (or "upstream") files by creating a transposed graph.

```
transposed   = flipedge(g)
impacted = bfsearch(transposed, which('vertical_channel'))
```

```
transposed =

  digraph with properties:

    Edges: [24×1 table]
    Nodes: [25×1 table]

impacted =

  4×1 cell array

    'C:\slexamples\airframe21\models\vertical_channel.slx'
    'C:\slexamples\airframe21\models\f14_airframe.slx'
    'C:\slexamples\airframe21\models\slproject_f14.slx'
    'C:\slexamples\airframe21\tests\f14_airframe_test.m'
```

Find files impacted by a data dictionary.

```
impacted2 = bfsearch(transposed, which('buses.sldd'))
```

```
impacted2 =

  11×1 cell array

    'C:\slexamples\airframe21\data\buses.sldd'
    'C:\slexamples\airframe21\data\controller.sldd'
    'C:\slexamples\airframe21\data\system_model.sldd'
    'C:\slexamples\airframe21\tests\f14_airframe_test.m'
    'C:\slexamples\airframe21\models\AnalogControl.mdl'
    'C:\slexamples\airframe21\models\DigitalControl.slx'
    'C:\slexamples\airframe21\models\f14_airframe.slx'
    'C:\slexamples\airframe21\models\LinearActuator.slx'
    'C:\slexamples\airframe21\models\NonLinearActuator.mdl'
    'C:\slexamples\airframe21\models\slproject_f14.slx'
    'C:\slexamples\airframe21\models\vertical_channel.slx'
```

Get information on your files, such as the number of dependencies and orphans.

```
averageNumDependencies = mean(outdegree(g));
numberOfOrphans = sum(indegree(g)+outdegree(g)==0);
```

If you want to make changes to a model hierarchy, starting from the bottom up, find the topological order.

```
ordered = g.Nodes.Name(flip(toposort(g)));
```

Query Shortcuts

Examine the project's Shortcuts property. You can automate startup and shutdown tasks using shortcuts, or use them to save frequent tasks and frequently accessed files.

```
shortcuts = proj.Shortcuts
```

```
shortcuts =

  1×9 Shortcut array with properties:

    File
    RunAtStartup
    RunAtShutdown
```

Examine a shortcut in the array.

```
shortcuts(9)
```

```
ans =

  Shortcut with properties:

             File: 'C:\slexamples\airframe21\utilities\set_up_project.m'
     RunAtStartup: 1
    RunAtShutdown: 0
```

The RunAtStartup property is set to 1, so this shortcut file is set to run at project startup. At the command line, you can view but not change the RunAtStartup and RunAtShutdown properties. To set these properties, use the shortcut tools Simulink Project. Get the file path of a shortcut.

```
shortcuts(6).File
```

```
ans =

  1×50 char array

C:\slexamples\airframe21\reports\slproject_f14.pdf
```

Examine all the files in the shortcuts cell array.

```
{shortcuts.File}'
```

```
ans =

  9×1 cell array

    'C:\slexamples\airframe21\batch_jobs\billOfMaterials.m'
    'C:\slexamples\airframe21\batch_jobs\checkCodeProblems.m'
    'C:\slexamples\airframe21\batch_jobs\runUnitTest.m'
    'C:\slexamples\airframe21\batch_jobs\saveModelFiles.m'
    'C:\slexamples\airframe21\models\slproject_f14.slx'
    'C:\slexamples\airframe21\reports\slproject_f14.pdf'
    'C:\slexamples\airframe21\utilities\clean_up_project.m'
```

```
    'C:\slexamples\airframe21\utilities\rebuild_s_functions.m'
    'C:\slexamples\airframe21\utilities\set_up_project.m'
```

Create a logical array that shows the shortcuts set to run at startup.

```
idx = [shortcuts.RunAtStartup]

idx =

  1×9 logical array

   0   0   0   0   0   0   0   0   1
```

Use the logical array to get only the startup shortcuts.

```
startupshortcuts = shortcuts(idx)

startupshortcuts =

  Shortcut with properties:

             File: 'C:\slexamples\airframe21\utilities\set_up_project.m'
     RunAtStartup: 1
    RunAtShutdown: 0
```

Get the path of the startup shortcut by accessing the File property.

```
startupshortcuts.File

ans =

  1×51 char array

C:\slexamples\airframe21\utilities\set_up_project.m
```

Label files

Create a new category of labels, of type char. In Simulink Project, the new Engineers category appears in the Labels pane.

```
createCategory(proj, 'Engineers', 'char')
```

```
ans =

  Category with properties:

                Name: 'Engineers'
        SingleValued: 0
            DataType: 'char'
    LabelDefinitions: [1×0 slproject.LabelDefinition]
```

Find out what you can do with the new category.

```
category = findCategory(proj, 'Engineers');
methods(category)
```

```
Methods for class slproject.Category:

createLabel  findLabel    removeLabel
```

Define a new label in the new category.

```
createLabel(category, 'Bob');
```

Get a label definition.

```
ld = findLabel(category, 'Bob')
```

```
ld =

  LabelDefinition with properties:

            Name: 'Bob'
    CategoryName: 'Engineers'
```

Attach a label to the retrieved file, myfile. If you select the file in Simulink Project, you can see this label in the label editor pane.

```
addLabel(myfile, 'Engineers', 'Bob');
```

Get a particular label and attach data to it, for example, some text.

```
label = findLabel(myfile, 'Engineers', 'Bob');
label.Data = 'Please assess'
```

```
label =

  Label with properties:

           File: 'C:\slexamples\airframe21\models\AnalogControl.mdl'
       DataType: 'char'
           Data: 'Please assess'
           Name: 'Bob'
   CategoryName: 'Engineers'
```

You can specify a variable for the label data, for example:

```
mydata = label.Data
```

```
mydata =

  1×13 char array

Please assess
```

Create a new label category with numeric data type.

```
createCategory(proj, 'Assessors', 'double');
category = findCategory(proj, 'Assessors');
createLabel(category, 'Sam');
```

Attach the new label to a specified file and assign data value 2 to the label.

```
myfile = proj.Files(14);
addLabel(myfile, 'Assessors', 'Sam', 2)
```

```
ans =

  Label with properties:

           File: 'C:\slexamples\airframe21\models\AnalogControl.mdl'
```

```
        DataType: 'double'
            Data: 2
            Name: 'Sam'
    CategoryName: 'Assessors'
```

Close Project

Closing the project at the command line is the same as closing the project using the Simulink Project tool. For example, the project runs shutdown scripts ad checks for unsaved models.

```
close(proj)
```

```
Running: C:\slexamples\airframe21\utilities\clean_up_project.m
Closing Project Models
Clearing: Project Path
```

More Information

For more details on using the API, enter: `doc simulinkproject`.

To automate start and shutdown tasks, see “Automate Startup Tasks” on page 16-34.

Create a Custom Task Function

In Simulink Project, you can create functions and run them on selected project files.

For example custom task functions, see “Running Custom Tasks with a Simulink Project”.

To create a custom task function:

1. In Simulink Project, select **Custom Tasks > Manage Custom Tasks**.
2. In the Manage Custom Tasks dialog box, select **Add > Add Using New Script** or **Add Using Existing Script** .

   Either browse to an existing script, or name and save the new file on your MATLAB path. Simulink Project adds the file to the project.
3. The MATLAB Editor opens the new file containing a simple example custom task function for you to edit. Edit the function to perform the desired action on each file. The instructions guide you to create a custom task with the correct function signature. Save the file.
4. To run your task, in Simulink Project, click **Custom Tasks**. In the Custom Task dialog box, select project files to include using the check boxes, select your custom task in the list, and click **Run Task**.
5. After your custom task function runs, view the results in the Custom Task Report.
6. To save the results in a file, click **Publish Report**.

See Also

Related Examples

- “Run a Simulink Project Custom Task and Publish Report” on page 17-43

Run a Simulink Project Custom Task and Publish Report

1. In Simulink Project, click **Custom Tasks**, and then select the check boxes of project files you want to include in the custom task.

   Tip If the function can identify the files to operate on, include all files. For example, the custom task function `saveModelFiles` in the `airframe` project checks that the file is a Simulink model and does nothing if it is not.

   To select multiple files, **Shift** or **Ctrl**+click, and then right-click a file and select **Include** or **Exclude**.

2. Specify the custom task function to run in the **Custom task** box. Enter the name, or click **Browse**, or choose from a list of custom tasks.

   If your project does not yet contain any custom task functions, see "Create a Custom Task Function" on page 17-42.

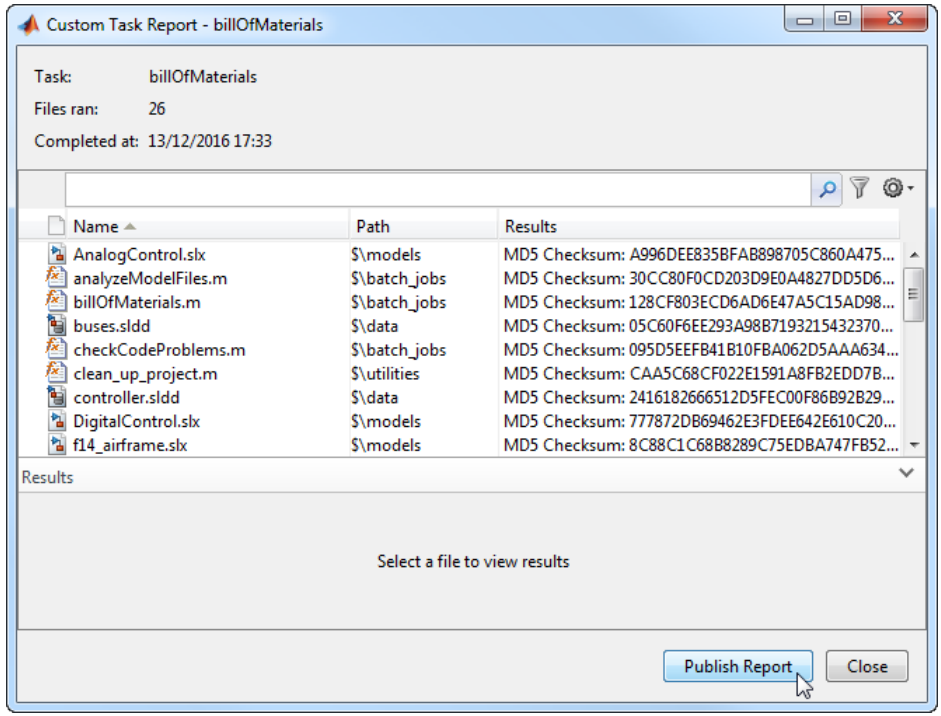
3. Click **Run Task**.

   Simulink Project displays the results.

4. To view details of results for the currently selected file, click a file and check the Results pane.

You can publish a report of your custom task results. For example, try this custom task:

1. Open an example project by entering `sldemo_slproject_customtasks`.
2. In Simulink Project, click **Custom Tasks**.
3. In the Custom Task dialog box, click the **Custom task** drop-down arrow to choose from a list of tasks, and select **Generate Bill of Materials Report**.
4. Click **Run Task**. Results appear.



5 Click **Publish Report**.

6 In the file browser, specify a name and location for the report, and choose a file type from HTML or Microsoft Word. If you have MATLAB Report Generator, you can also choose PDF.

7 View the results in the report.

The example custom task function **Generate Bill of Materials Report** creates a list of project files, their source control status, revision numbers, and MD5 checksums. You can view the code for this custom task in the file `billOfMaterials.m`.

8 To see the report file and add it to your project, switch to the **All Files View**.

Tip To try example custom tasks in a project, see the example “Running Custom Tasks with a Simulink Project”.

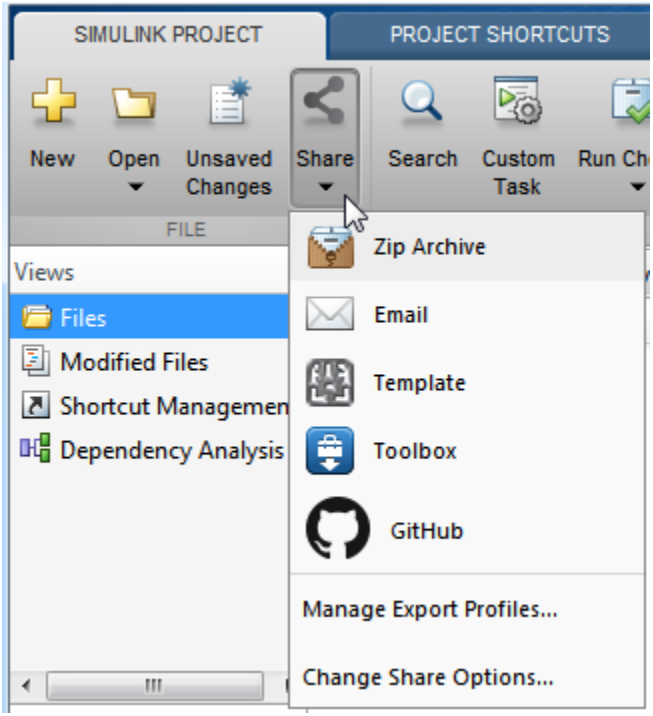
Sharing Simulink Projects

Simulink projects help you collaborate. Use the **Share** menu to share your project in these ways:

- Archive your project in a zip file.
- Share your project by email (Windows only).
- Create a template from your project.
- Package your project as a MATLAB toolbox.
- Make your project publicly available on GitHub.



You can also collaborate by using source control within Simulink projects.

- “Create Templates for Standard Project Settings” on page 16-42
- “Share Project by Email” on page 17-48
- “Share Project as a MATLAB Toolbox” on page 17-49
- “Share Project on GitHub” on page 17-50

More About

- “About Source Control with Projects” on page 19-2

Share Project by Email

To package and share Simulink project files on Windows, you can email your project as a zip file attachment. For example, you can share the project with people who do not have access to the connected source control tool.

1. With a project loaded, on the **Simulink Project** tab, select **Share** > **Email**.
2. (Optional) To export only the specified files, choose an **Export profile**. To exclude files with particular labels, select **Manage Export Profiles** and create an export profile.
3. If you have referenced projects and want to export the referenced project files, then select the **Include referenced projects** check box.
4. Click **Attach to Email**. The project opens a new email in your default email client with the project attached as a zip file.
5. Edit and send the email.

Share Project as a MATLAB Toolbox

To package and share Simulink project files, you can create a MATLAB toolbox from your project.

1. With a project loaded, on the **Simulink Project** tab, select **Share** > **Toolbox**.

   The packager adds all project files to the toolbox and opens the Package a Toolbox dialog box.
2. The **Toolbox Information** fields are populated with the project name, author, and description. Edit the information if needed.
3. If you want to include files not already included in the project files, edit the excluded files and folders.
4. Click **Package**.

More About

- "Sharing Simulink Projects" on page 17-46

Share Project on GitHub

To share your Simulink project, you can make your project publicly available on GitHub. First, create a login on GitHub.

You can share any project. Sharing adds Git source control to the open project. If your project is already under source control, sharing replaces the source control configuration with Git, and the project's remote repository is GitHub.

Note If you do not want to change your current source control in the open project, share a copy of the project instead. To create a copy to share, see "Archive Projects in Zip Files" on page 17-52.

---

1. With a project loaded, on the **Simulink Project** tab, select **Share** > **Change Share Options**.
2. Add the **GitHub** option to your **Share** menu. In the Manage Sharing dialog box, select **GitHub** and click **Close**.
3. Select **Share** > **GitHub**.
4. In the Create GitHub Repository dialog box, enter your GitHub user name and password, and edit the name for the new repository. Click **Create**.

   A warning prompts you to confirm that you want to create a public repository and modify the current project's remote repository location. To continue, click **Yes**.
5. The Create GitHub Repository dialog box displays the URL address for your new repository. Click the link to view the new repository on the GitHub website. The repository contains the initial check-in of your project files.
6. The source control in your current project now references the new repository on GitHub as the remote repository. To use the project with the new repository, in the Create GitHub Repository dialog box, click **Reload Project**.

In the project, you can find the URL address for your remote repository on the Simulink Project tab, under **Source Control**, using the **SVN Details** or **Git Details** button.

If you have not already set up Git, you need some additional setup steps before you can merge branches. You can use other Git functionality without any additional installation. See "Set Up Git Source Control" on page 19-20.

More About

- “Sharing Simulink Projects” on page 17-46

Archive Projects in Zip Files

To package and share project files, you can export all project files to a zip file. For example, you can share a zipped project with people who do not have access to the connected source control tool.

1. With a project loaded, on the **Simulink Project** tab, select **Share** > **Zip Archive**.
2. (Optional) To export only the specified files, choose an **Export profile**.
3. If you have referenced projects and want to export the referenced project files, then select the **Include referenced projects** check box.
4. Click **Save As**.
5. Use the file browser to specify a file path in the **Zip file** field. By default, the file *myProjectName*`.zip` is created in the current working folder.

If you want to exclude files from the archive, create an export profile to exclude files with particular labels.

1. Create labels and add them to the project files you want to exclude. See "Create Labels" on page 17-24.
2. Specify an export profile. On the **Simulink Project** tab, select **Share** > **Manage Export Profiles**.
   a. Click **+** and specify a name for the export profile.
   b. In the Files pane, click **+** and select the labels for the files you do not want to export, and click **OK**. You can also choose not to export custom labels.
   c. Click **Apply** and close the Manage Export Profiles dialog box.
3. When you share the project to an archive, in the **Export profile** list, select the name of your export profile to export only the specified files.

Before sharing projects with other users, it can be useful to examine the required toolboxes for your project. See "Find Required Toolboxes" on page 18-9.

More About

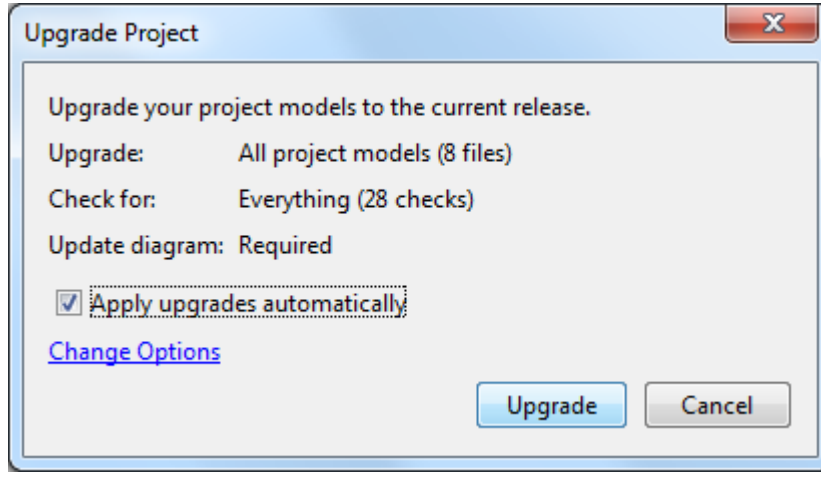
- “Sharing Simulink Projects” on page 17-46

Upgrade All Project Models and Libraries

Tip Before upgrading, if you put your project under source control, you can easily revert changes later if you want. See “Add a Project to Source Control” on page 19-6.

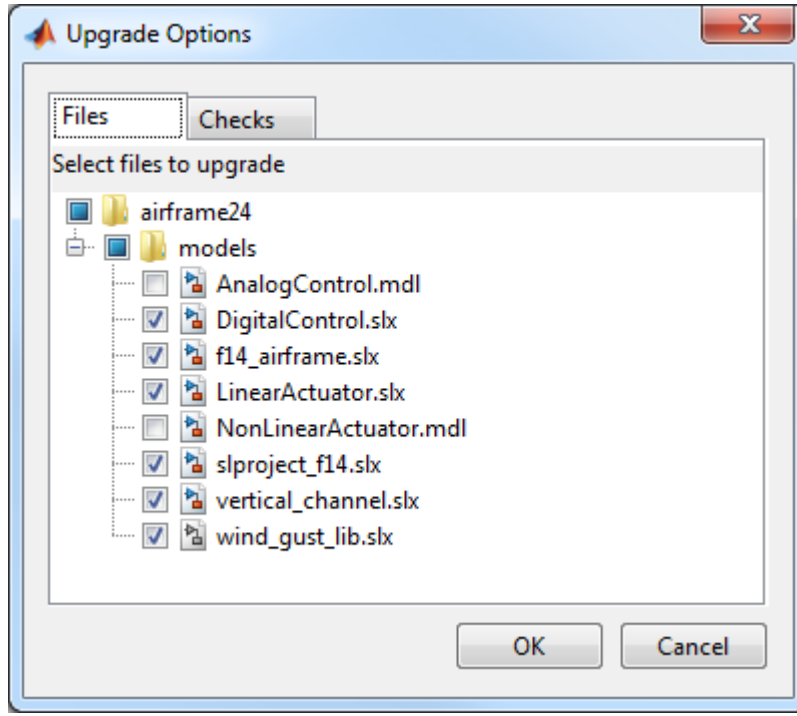
Upgrade all models and libraries in your Simulink project to the latest release using a simple workflow. The Upgrade Project tool can apply all fixes automatically when possible, upgrade all model hierarchies in the project at once, and produce a report. You do not need to open the Upgrade Advisor.

1 On the Simulink Project tab, select **Run Checks** > **Upgrade**.



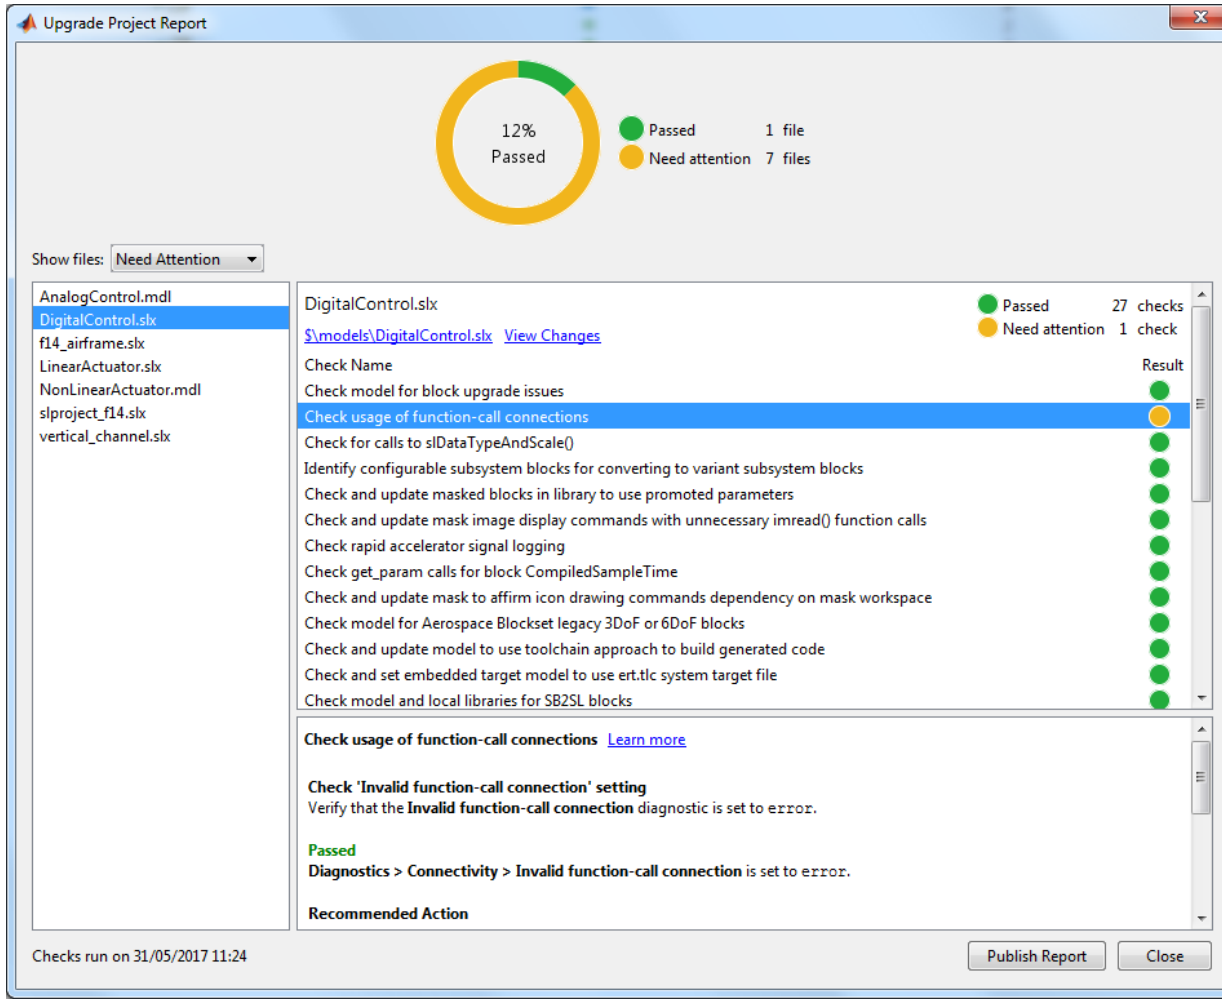
2 In the Upgrade Project dialog box, to upgrade all models, run all checks, and apply fixes automatically where possible, click **Upgrade**. If you want to change the settings, use these options before clicking **Upgrade**:

- If you want to run upgrade checks but not apply fixes automatically where possible, clear the check box **Apply upgrades automatically**.
- If you want to change which models to upgrade and which checks to run, click **Change Options**. In the Upgrade Options dialog box, clear check boxes for models and checks you want to exclude from the upgrade. For example, you might want to exclude checks that require an **Update Diagram**.



When you click **Upgrade**, the tool runs the checks and applies fixes if specified. Upgrading can take several minutes.

3 Examine the Upgrade Project Report. The summary at the top shows how many files passed and how many files require attention.



a Select files in the left list to view check results on the right. By default, the left list shows any files that need attention. Show instead all files, files that passed, or files that passed with fixes, by using the **Show files** control.

b Select checks in the right list to read details of results and any applied fixes in the lower pane. Examine checks marked as needing attention, with an orange circle in the **Result** column. For details of upgrading libraries, see “Upgrade Libraries” on page 17-57.

c If your project is under source control, you can examine the upgrade changes in your files using a comparison report. To see the differences before and after upgrade, in the Upgrade Project Report, click **View Changes**.

4 To save a report of the upgrade results, click **Publish Report** and choose a file name and location.

5 To close the interactive report, click **Close**.

Upgrade Libraries

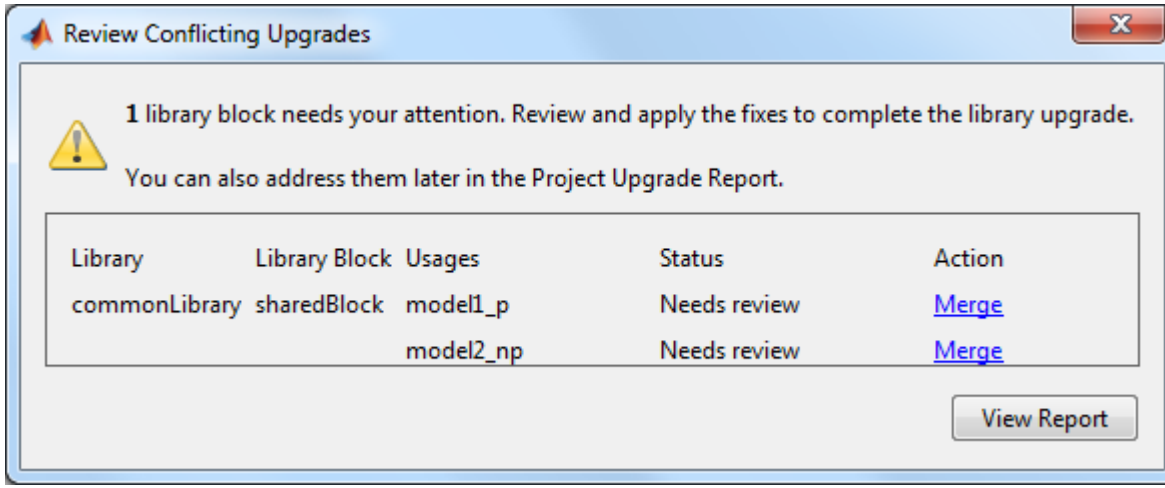
The project automatically runs all upgrade checks on multiple libraries, including any checks that require an Update Diagram.

You cannot run Update Diagram on a library, so project upgrade runs the Update Diagram checks in the models where the library blocks are used. This means that project upgrade can only fully upgrade library blocks that are used in a model. If the library block is used in a model, project upgrade automatically runs all checks, including Update Diagram checks, and then upgrades the block in the library.

If a library block is not used in any project model, then the check **Run checks that require Update Diagram on library blocks** is marked as needing attention, with an orange circle in the **Result** column. Select the check and in the details pane you see the message `Unable to upgrade blocks unused by a model`.

- To upgrade unused library blocks, use the blocks in a model and then upgrade.
- If you want to upgrade library blocks that use forwarding tables, disable the library link and save the model before upgrading, upgrade and then restore the link.

The upgrade of library blocks depends on the model context. The same library block might be used in multiple models. Linked library blocks inherit attributes from the surrounding models, such as data types and sample rate. The blocks' behavior can differ depending on the context where they are used, and this can lead to conflicting upgrades for Update Diagram checks. If models require a different upgrade of the same library block, you are prompted to view and resolve the upgrade conflict.



If you need to review conflicting upgrades, click **Merge**. Alternatively you can review conflicting upgrades later from the report. Review changes in the comparison report and choose which upgrades to save.

Simulink Project Dependency Analysis

What Is Dependency Analysis?

Project Dependency Analysis

In Simulink Project, you can analyze project structure and discover files required by your project in the Dependency Analysis view.

- To help you set up your project with all required files, you can use dependency analysis.

  In a Simulink model, select **File > Simulink Project > Create Project from Model**.

  Simulink runs dependency analysis on your model to identify required files and a project root location that contains all dependencies. See “Create a Project from a Model” on page 16-15.

  Alternatively, you can manually add models to your project, analyze the model dependencies, and then add all dependent files to your project. See “Run Dependency Analysis” on page 18-4.
- You can use the Impact graph view of a dependency analysis to analyze the structure of a project visually. You can perform impact analysis to find the impact of changing particular files. In the graph, you can examine your project structure; find required toolboxes for the whole project or for selected files; open, edit, and run files; add labels and export files. See “Perform Impact Analysis” on page 18-7.

  Impact analysis can show you how a change affects other files before you make the change. For example:

  - Investigate the potential impact of a change in requirements by finding the design files linked to the requirements document.
  - Investigate change set impact by finding upstream and downstream dependencies of modified files before committing the changes. Finding these dependencies can help you identify design and test files that need modification and help you find the tests you need to run.
- You can run dependency analysis at any point in your workflow when you want to check that the project has all required files. For example, check dependencies before submitting a version of your project to source control. To work with results, see “Check Dependency Results and Resolve Problems” on page 18-17.

- You can search for requirements documents in a project. See “Find Requirements Documents in a Project” on page 18-22.
- After performing dependency analysis, you can open or label the files, export the results as workspace variables, images, or reloadable files, or send files for custom task processing. Exporting the results enables further processing or archiving of impact analysis results. You can add the exported list of files to reports or artifacts that describe the impact of a change. See “Save, Open, and Compare Dependency Analysis Results” on page 18-23.

Tip For an example showing how to perform file-level impact analysis to find and run the tests affected by modified files, see Perform Impact Analysis with a Simulink Project.

Model Dependency Analysis

Simulink Project can analyze file dependencies for your entire project. For detailed dependency analysis of a *specific* model, use the manifest tools to control more options. Use the manifest tools if you want to:

- Analyze a model that is not in a project.
- Save the list of the model dependencies to a manifest file.
- Create a report to identify where dependencies arise.
- Control the scope of dependency analysis.

See “Analyze Model Dependencies” on page 18-25.

- “Perform Impact Analysis” on page 18-7
- “Find Requirements Documents in a Project” on page 18-22
- “Analyze Model Dependencies” on page 18-25

Run Dependency Analysis

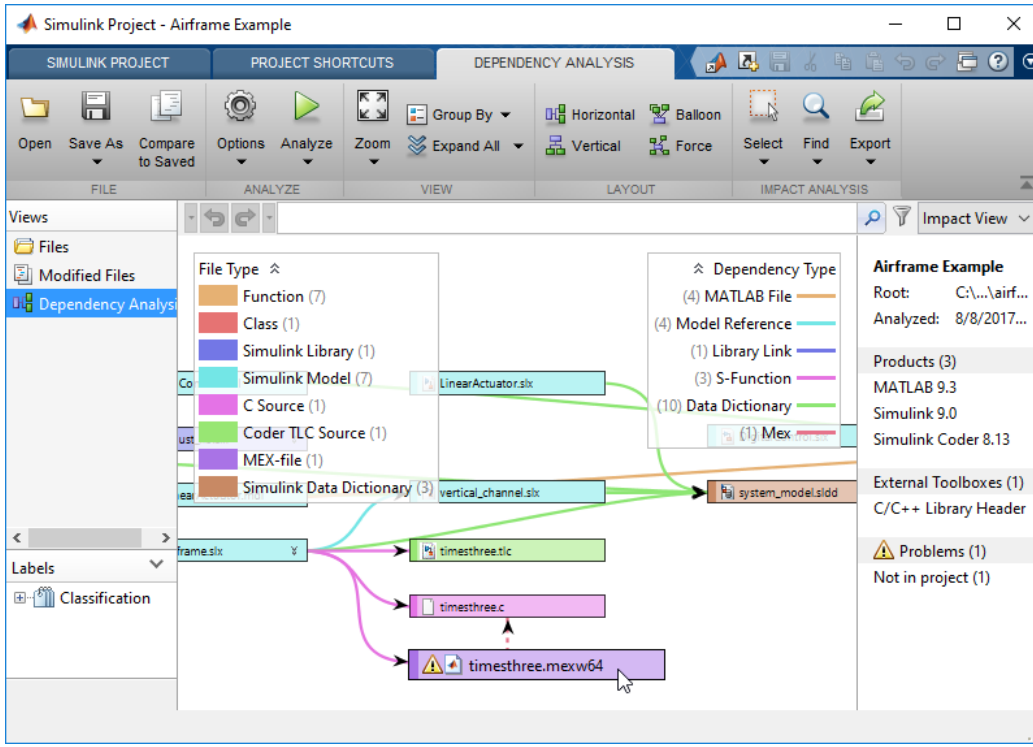
Note You can analyze only files that are in your Simulink project. If your project is new, add files to the project before running a dependency analysis. See "Add Files to the Project" on page 16-23.

1. In the Simulink Project tree, select **Dependency Analysis**.
2. If you want to analyze the dependencies of external toolboxes, select **Options** > **Analyze External Toolboxes**.

   After you run the first dependency analysis of your project, subsequent analyses are incremental updates. However, if you update external toolboxes and want to discover dependency changes in them, you must perform a complete analysis. In this case, turn off **Options** > **Perform Incremental Updates** before running the dependency analysis.
3. To analyze all files in your project, on the **Dependency Analysis** tab or view, select **Analyze**.

   
   If you want to analyze specific files, on the **Dependency Analysis** tab, click **Analyze** > **Select Files to Analyze**. In the Dependency Analysis dialog box, select files for analysis, and click **Analyze**.

Note In the Simulink Editor, if an open model, library, or chart belongs to a project, you can find file dependencies. Select **File** > **Simulink Project** > **Find Dependencies**. Simulink Project analyzes the whole project and shows upstream and downstream dependencies for the file.



For next steps, see:

- “Find Required Toolboxes” on page 18-9
- “Find Dependencies of Selected Files” on page 18-12
- “Select, Edit, and Export File Dependencies” on page 18-13
- “Check Dependency Results and Resolve Problems” on page 18-17

Tip To try a dependency analysis on example files, see Perform Impact Analysis with a Simulink Project.

Perform Impact Analysis

In this section...

About Impact Analysis

In Simulink Project, you can use impact analysis to find out the impact of changing particular files. Investigate dependencies visually and explore the structure of your project. Analyze selected or modified files to find their required files and the files they affect. Impact analysis can show you how a change affects other files before you make the change. For example, you can:

- Investigate the potential impact of a change in requirements by finding the design files linked to the requirements document.
- Investigate change set impact by finding upstream and downstream dependencies of modified files before committing the changes. Finding these dependencies can help you identify design and test files that need modification, and help you find the tests you need to run.

After performing dependency analysis, you can open or label the files, export the results as workspace variables, images, or reloadable files, or send files for custom task processing. Exporting the results enables further processing or archiving of impact analysis results. You can add the exported list of files to reports or artifacts that describe the impact of a change.

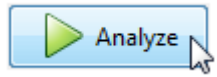
Tip For an example showing how to perform file-level impact analysis to find and run the tests affected by modified files, see Perform Impact Analysis with a Simulink Project.

Run Dependency Analysis

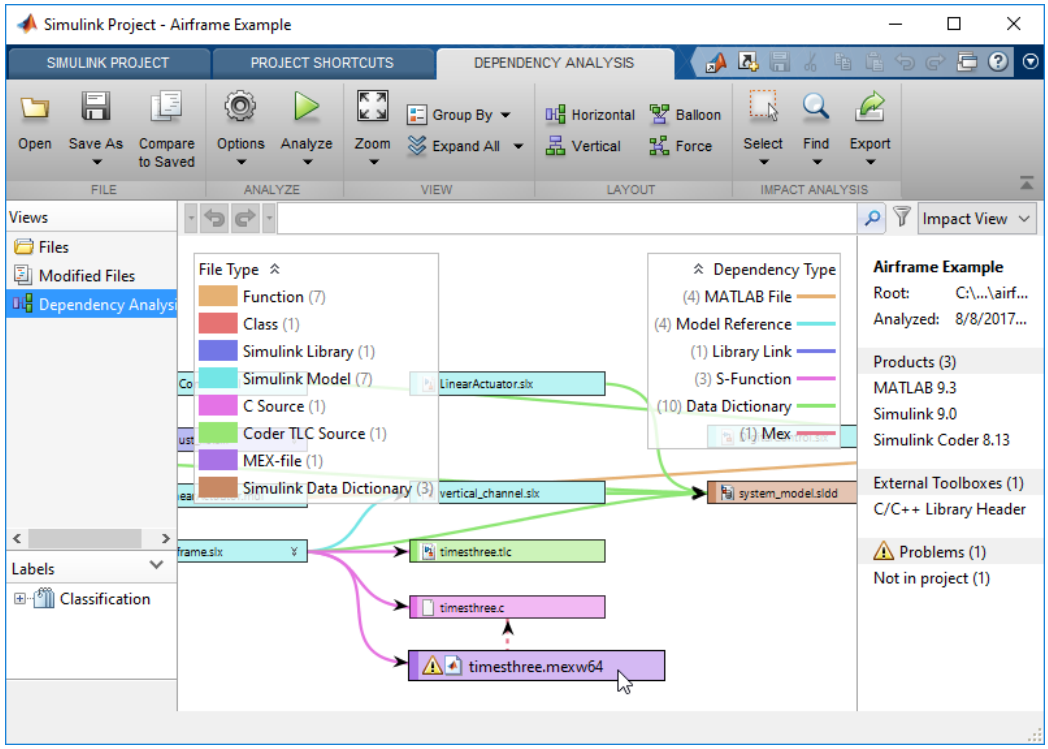
To investigate dependencies, run a dependency analysis on your project.

1 In the Simulink Project tree, select **Dependency Analysis**. If you want to analyze the dependencies of external toolboxes, select **Options** > **Analyze External Toolboxes**.

2 Click **Analyze**.



The **Impact View** graph displays the structure of all analyzed dependencies in the project. Project files that are not detectable dependencies of the analyzed files do not appear on the graph.



After you run the first dependency analysis of your project, clicking **Analyze** again produces incremental updates. If you want to analyze changes in external toolboxes, turn off the incremental update option.

After performing dependency analysis, the Impact view shows:

- A graph of your project structure and its file dependencies, showing how files such as models, libraries, functions, data files, and source and derived files relate to each other.
- Required products and toolboxes.
- Relationships between source and derived files (such as `.m` and `.p` files, `.slx` and `.slxp`, `.ssc` and `.sscp`, `.c` and `.mex` files), and between C/C++ source and header files.
- Warnings about problem files, such as missing files, files not in the project, unsaved changes, and out-of-date derived files.

For next steps:

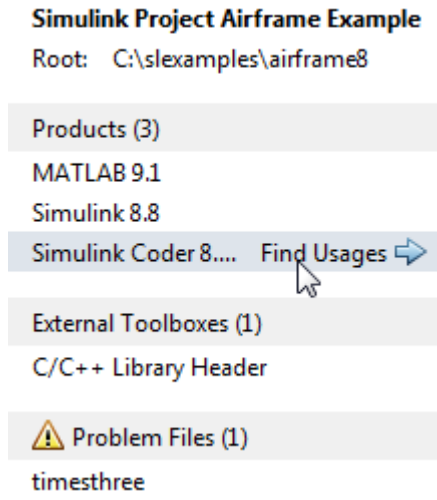
- "Find Required Toolboxes" on page 18-9
- "Find Dependencies of Selected Files" on page 18-12
- "Select, Edit, and Export File Dependencies" on page 18-13
- "Check Dependency Results and Resolve Problems" on page 18-17

Tip To try a dependency analysis on example files, see Perform Impact Analysis with a Simulink Project.

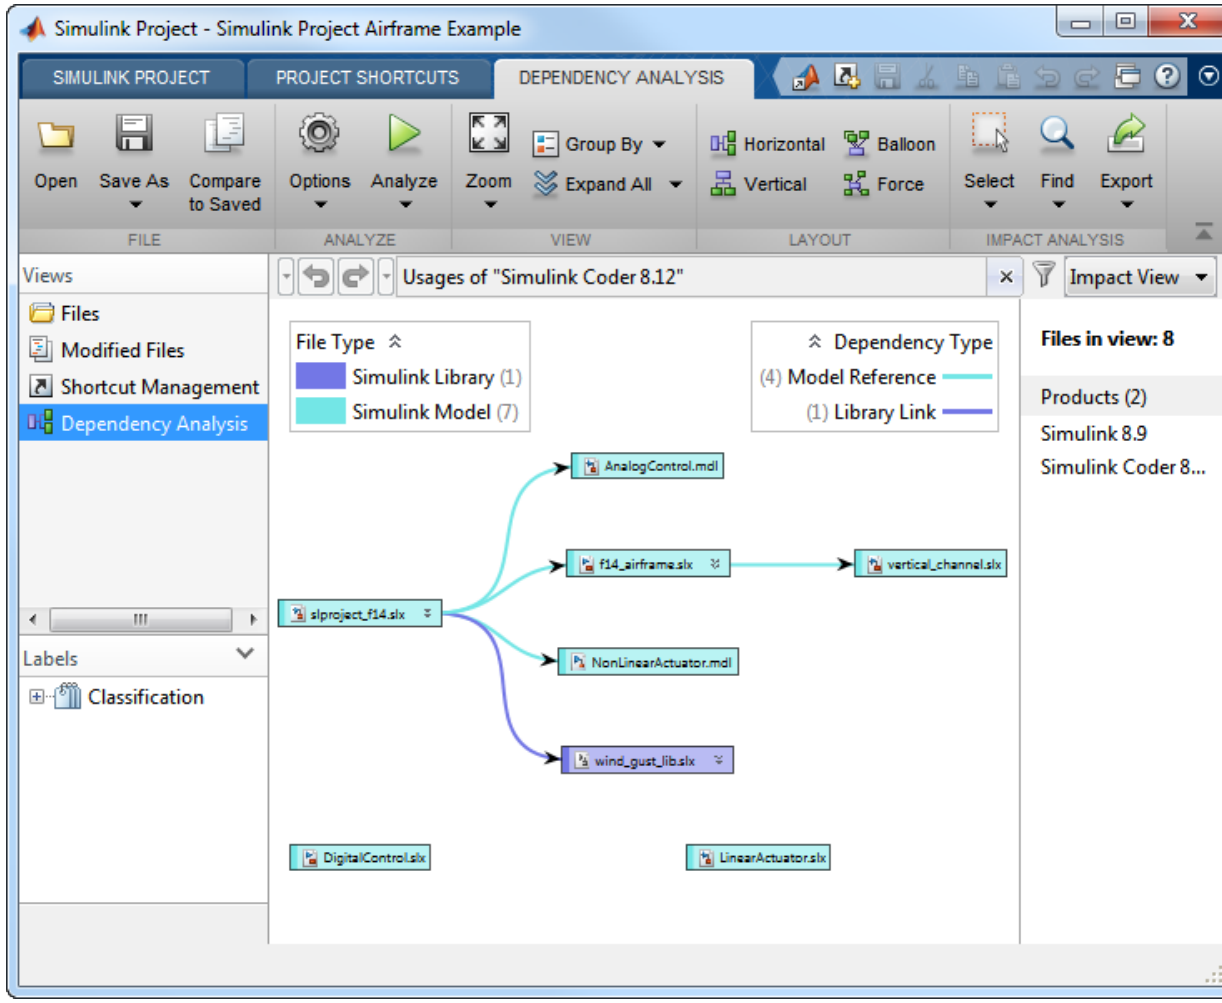
Find Required Toolboxes

After running dependency analysis in a Simulink project, the Impact view shows the required toolboxes for the whole project or for selected files. You can see which products a new team member requires to use the project, or find which file is introducing a product dependency.

1. After running dependency analysis, view the required products for the whole project listed in the right pane.
2. To find which file is introducing a product dependency, hover over the product name and click **Find Usages**.



The graph updates to show only the files using the selected product.



To return to the full project view, clear the filter in the search box (e.g., **Usages of** "*productname*").

3 To view required products of selected files, select some files by clicking the graph or a legend.

If a required product is missing, the product list labels it **Missing**. See "Check Dependency Results and Resolve Problems" on page 18-17.

Find Dependencies of Selected Files

After a dependency analysis, to find out the impact of particular files, in the **Impact View** use the context menu, or use controls in the **View** and **Impact Analysis** sections of the **Dependency Analysis** tab.

1 Select files to investigate using one of these methods:

- Select files in the graph or select groups of files by clicking the legend. For example, select all model files by clicking **Simulink Model** in the **File Type** legend. Change the legend, in the **View** section of the toolstrip, using the **Group By** menu, for example to show problem types, status, or labels.
- To select modified files, problem files or external files, use the **Select** menu in the **Impact Analysis** section of the toolstrip.

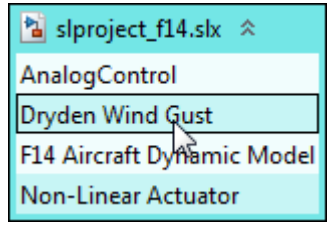
2 To find dependencies, right-click selected files and use the context menu. Select **Find All Dependencies**, **Find Impacted Files**, or **Find Required Files**.

Alternatively, select files and then use the **Dependency Analysis** tab. In the **Impact Analysis** section, select **Find** and then specify the range of dependencies you want to display: **All Dependencies of Selection**, **Files Impacted by Selection**, or **Files Required by Selection**.

The graph shows the selected files and their file dependencies.

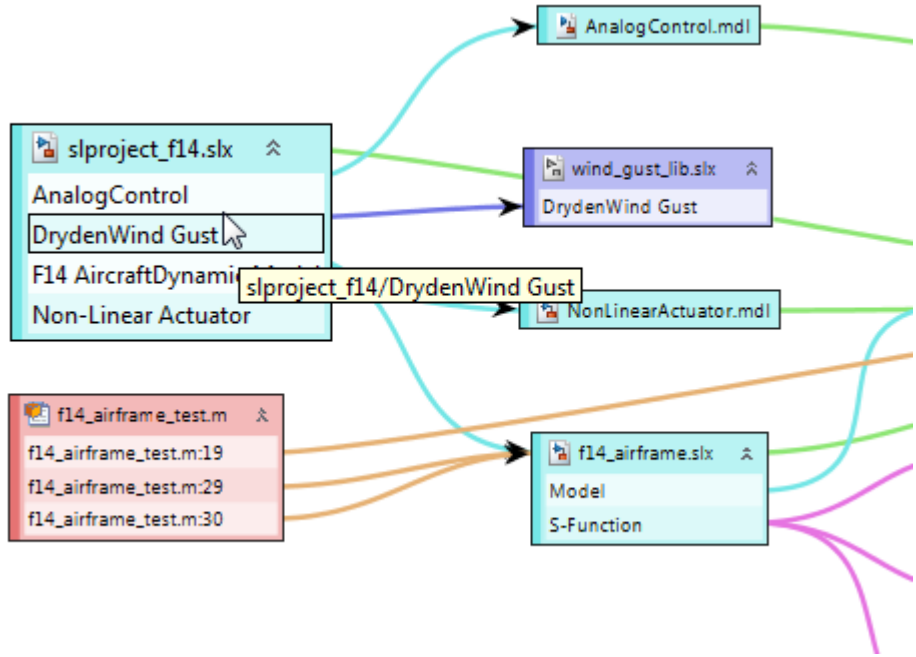
3 To see the blocks that have dependencies, expand individual files in the graph by clicking the arrows next to the file names.

The Impact graph expands the dependent file. You can see the subsystems that have dependencies. You can view dependent blocks, models, libraries, and library blocks.



To highlight a dependent block in the model, double-click the block name in the expanded file.

To expand all files in the graph, in the **View** section, click **Expand All**.



4 To investigate changes in modified files, right-click and select **Compare to Ancestor** or **Compare to Revision**. See “Compare Revisions” on page 19-46.

Tip To reset the graph to show all analyzed dependencies in the project, on the **Dependency Analysis** tab, in the **Impact Analysis** section, select **Find** > **All Files**.

Select, Edit, and Export File Dependencies

To highlight or select groups of files:

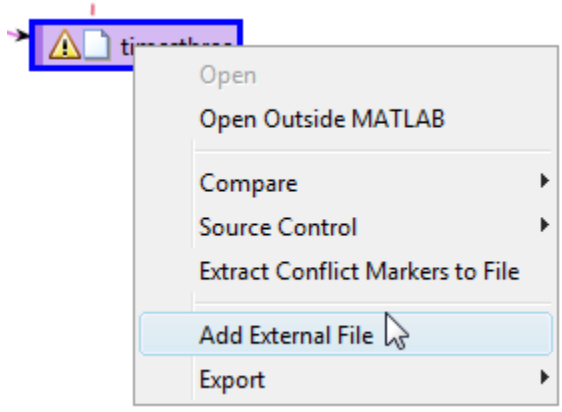
- Click a legend item to select all files of that type. For example, to select all model files, in the **File Type** legend, click **Simulink Model**. Selected files display a blue box.
- To choose a legend, on the **Dependency Analysis** tab, in the **View** section, use the **Group By** control. Choose a category such as file type, project status, source control status, labels, project, and problem type. Files in the graph are colored to indicate the legend category on each file.

For example:

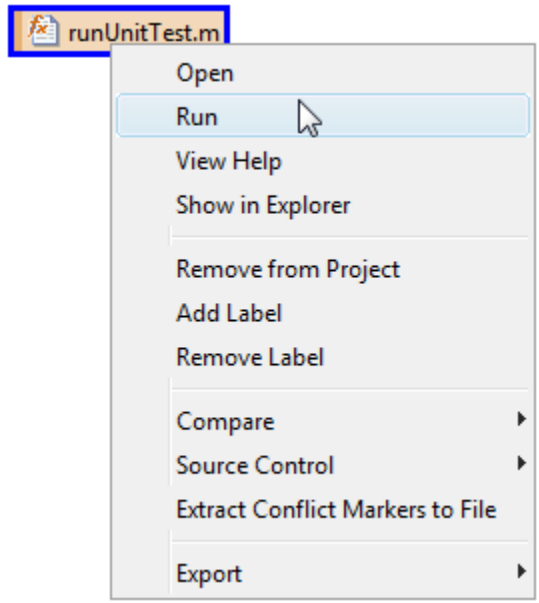
- If your project is under source control, to show modified files, select **Group By** > **SVN** (or **Git**).
- To identify whether files are in your project or a referenced project, select **Group By** > **Project**.

To perform file operations:

- Take actions to resolve problem files. For example, right-click a problem file and select **Add to Project** or **Add External File**. For advice on resolving problem files, see "Check Dependency Results and Resolve Problems" on page 18-17.



- Hover over a file to read the file name in the tooltip at any zoom level. Double-click to open the file. Expand or collapse files in the graph by clicking the arrows next to the file names. View dependent blocks under an expanded file, and double-click a dependent block to highlight it in the model.
- Right-click files in the graph to use commands such as **Open**, **Compare**, or **Source Control** operations.



You can perform file operations on multiple files. To fit the view to the currently selected files, press **F**.

- Export selected files using the **Export** menu. You can switch to the files or custom task views with the files selected, or send the file paths to a workspace variable. You can also save and reload graph layouts, and save the graph as an image file, using **Save As**. Your graph layout is saved with the project. See "Save, Open, and Compare Dependency Analysis Results" on page 18-23.

  Alternatively, you can work with the graph information programmatically. See "Automate Simulink Project Tasks Using Scripts" on page 17-29.

- “Automate Simulink Project Tasks Using Scripts” on page 17-29
- Perform Impact Analysis with a Simulink Project

Check Dependency Results and Resolve Problems

In the Simulink Project tree, select **Dependency Analysis**. If you have not yet run an analysis, click **Analyze**. After you run a dependency analysis, you see the Impact graph for the whole project in **Impact View**. The project dependency analysis identifies problems, such as missing files, files not in the project, unsaved changes, and out-of-date derived files. You can examine problem files and resolve issues using the **Impact View** or the **Table View**.

To show only problem files, hover over the **Problems** heading in the right pane of the Impact view and click **Find All**.

Problem Message	Description	Fix
Not in project	The file is not in the project.	Add it to the project. You do not need to add all required file the project. For example, you can exclu derived S-Function binary files that th source code in your project generates. “Work with Derived Files in Projects” 19-71. To remove a file from the problem list without adding it to the project, right- the file and select **Add External File**
Missing project file	The file is in the project but does not exist on disk.	Create the file, or recover it using sour control.

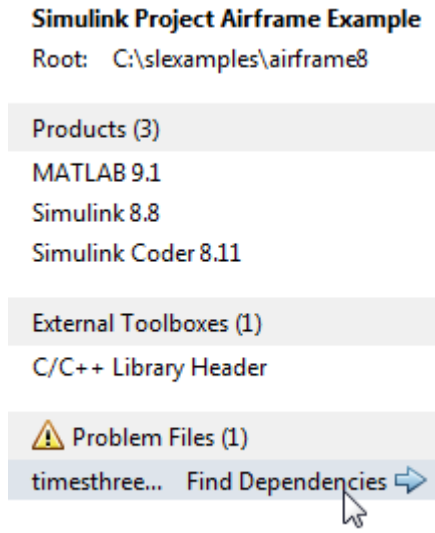
Problem Message	Description	Fix
Outside project root	The file is outside the project root folder.	If this is OK, set the file as an externa Otherwise move it under the project ro If you need a file that is outside the pr root to be in your project, copy or move file within the project root, and add it project and the path. Remove the origi location from the path. If required files are outside your projec you cannot add these files to your proj This dependency might not indicate a problem if the file is on your path and utility or resource that is not part of yo project. Use dependency analysis to en that you understand the design dependencies.
In unreferenced project	The file is within a project that is not referenced by the current project.	Add the project containing the file as a project reference.
Missing file	The file or variable could not be found.	If this status is acceptable, set the file external file.
Unsaved changes	The file has unsaved changes in the MATLAB or Simulink editors	Save the file.
Derived file out of date	The derived file is older than the source file it was derived from.	Regenerate the derived file. If it is a P you can regenerate automatically by ru the project checks. On the Simulink Project tab, click **Che Project** and follow prompts to rebuild If you rename a source file, the project detects impact in the derived file and prompts you to update it.

Problem Message	Description	Fix
Missing product	The project has a dependency on a missing product.	Fix models by installing missing produ If you open a model that contains built blocks or library links from missing pr you see labels and links to help you fix problem. • Blocks are labeled with missing pro (for example, **SimEvents not inst** • Tooltips include the name of the mi product • Messages provide links to open Add Explorer and install the missing pr To find a link to open Add-On Explore install the product: • For built-in blocks, open the Diagn Viewer, and click the link in the wa • For unresolved library links, doubl the block to view details and click t link. Product dependencies can occur in ma other ways, for example in callbacks, s this case you cannot easily see where t missing product is referenced. Fix mod installing missing products.

Investigate Problem Files in Impact View

Use the **Impact View** to investigate your project dependencies graphically.

1. In the Impact view, to see problem files for the whole project, clear any file selections by clicking a blank area of the graph. View any problem files listed in the right panel.
2. To view the files that use a problem file, hover over the problem file and click **Find Dependencies**.



The graph updates to display only the problem file and its dependencies, and the problem message in the right panel.

3 Take actions to resolve the problem file. For example, right-click the file and select **Add to Project** or **Add External File**.

4 Click a problem file and check the path shown on the right. Check if required files are outside your project root.

5 Examine or edit dependencies by opening referencing components (such as a block or line of MATLAB code that references a problem file). To open a referencing component, expand a file in the graph, and double-click an item in the list.

MATLAB files open in the MATLAB Editor, and Simulink models open in the Simulink Editor with the referencing component block highlighted.

6 To return to the full project view, clear the filter in the search box (e.g., **Dependencies of** "`filename`").

For more ways to work with the Impact view, see "Perform Impact Analysis" on page 18-7.

Investigate Problem Files in Table View

1. Select **Table View** and sort by the Problem Description column.
2. Click each file in the problem list.

   The lower pane, under **Upstream Dependencies: *`filename`***, displays the files that use the selected file.

   Check the message in the **Problem Description** column.
3. In the dependencies table, check the problem description and project status of dependent files.
4. To open the referencing component for editing, right-click a file **Upstream Dependencies: *`filename`*** table and select **Open**.
5. Check the path, where `$` indicates the project root. Check if required files are outside your project root.
6. To remove a file from the problem list without adding it to the project, right-click the file and select **Add External File**. The file disappears from the problem list. The next time you run a dependency analysis, this file does not appear in the problem list.
7. Clear the search box to view all identified dependencies, not just problem files.

- “Save, Open, and Compare Dependency Analysis Results” on page 18-23

Find Requirements Documents in a Project

In Simulink Project, a dependency analysis finds requirements documents linked using the Requirements Management Interface.

- You can view and navigate to and from the linked requirements documents.
- You can create or edit Requirements Management links only if you have Simulink Requirements.

1. From the Simulink Project tree, select **Dependency Analysis**.
2. Click the **Analyze** button.

   The Impact graph displays the structure of all analyzed dependencies in the project. Project files that are not detectable dependencies of the analyzed files are not visible in the graph.
3. To highlight requirements documents in the graph, in the Dependency Type legend, click **Requirements Link** . Arrows connect requirements documents to the files with the requirement links.
4. To find the specific block containing a requirement link, expand the model file in the graph. Click **Expand All** or click the arrows next to the file name. View the arrow connecting the block containing the requirement link to the requirements document file.
5. To open a requirements document, double-click the document in the graph.

- “View Linked Requirements in Models and Blocks” on page 12-61

Save, Open, and Compare Dependency Analysis Results

In Simulink Project, you can save the results of a dependency analysis. You can view the saved results later, without having to repeat the analysis. You can also save results separately in named files and reload them.

Save, open, and compare dependency analysis results from the **File** section of the **Dependency Analysis** tab.

- To save your results as a `.graphml` file, click **Save As** and choose a file name and location.
- To open saved dependency analysis results, click **Open**.
- To compare results with previously saved results, click **Compare to Saved**. Select a `.graphml` file. Inspect the differences in the comparison report.

You can save reports that include more detailed results by using model dependency analysis. For more information about choosing model or project dependency analysis, see “What Is Dependency Analysis?” on page 18-2.

Export Impact Graph Results to Files or Images

To export impact analysis results, on the **Dependency Analysis** tab, in the **Impact Analysis** section, use the **Export** controls, or use the **Export** context menu on selected files.

Select Files to Export

To export all the files in the current view, check that no files are selected. (Click the graph background to clear the selection on all files.) Click **Export** to display **Files in view:** *`number of files`*.

Select a subset of files in the graph to export. Click **Export** to see how many files are selected: **Selected files:** *`number of files`*.

Export Files

- To save the selected file paths to a variable, select **Export > Save to Workspace**.
- To open the Custom Task dialog box with the files selected, select **Export > Send to Custom Task**.

- To switch to the Files view with the files selected, select **Export > Show in Files View**.

Export Graph to Image File

To export the Impact graph as an image file for sharing or archiving, you can either:

- Save an image file. On the **Dependency Analysis** tab, in the **File** section, select **Save As > Save As Image**. Use the Save dialog box to specify the name, file type, and location. The default file type is SVG, which supports image scaling.
- Copy the image to the clipboard using the keyboard. You can paste the clipboard contents into other documents.

Export Reloadable Results

To export the impact results to a `.graphml` file that you can reload in Simulink Project, click **Save As** and choose a file name and location..

Analyze Model Dependencies

In this section...

What Are Model Dependencies?

Each Simulink model requires a set of files to run successfully. These files can include referenced models, data files, S-functions, and other files the model cannot run without. These required files are called model dependencies.

Dependency Analysis Requirements	Tools to Choose
Find required files for an entire project.	Use dependency analysis from the Simulink Project. See “Dependency Analysis”.
Perform dependency analysis of a specific model with control of more options.	Use the manifest tools from your model. See “Generate Manifests” on page 18-26. Generate a manifest if you want to: • Analyze a model that is not in a project. • Save the list of the model dependencies to a manifest file. • Create a report to identify where dependencies arise. • Control the scope of dependency analysis.

After you generate a manifest for a model to determine its dependencies, you can:

- View the files required by your model in a manifest file.
- Trace dependencies using the report to understand why a particular file or toolbox is required by a model.
- Package the model with its required files into a zip file to send to another Simulink user.
- Compare older and newer manifests for the same model.
- Save a specific version of the model and its required files in a revision control system.

You can also view the libraries and models referenced by your model in a graphical format using the Model Dependency Viewer. See "Model Dependency Viewer" on page 12-56.

Generate Manifests

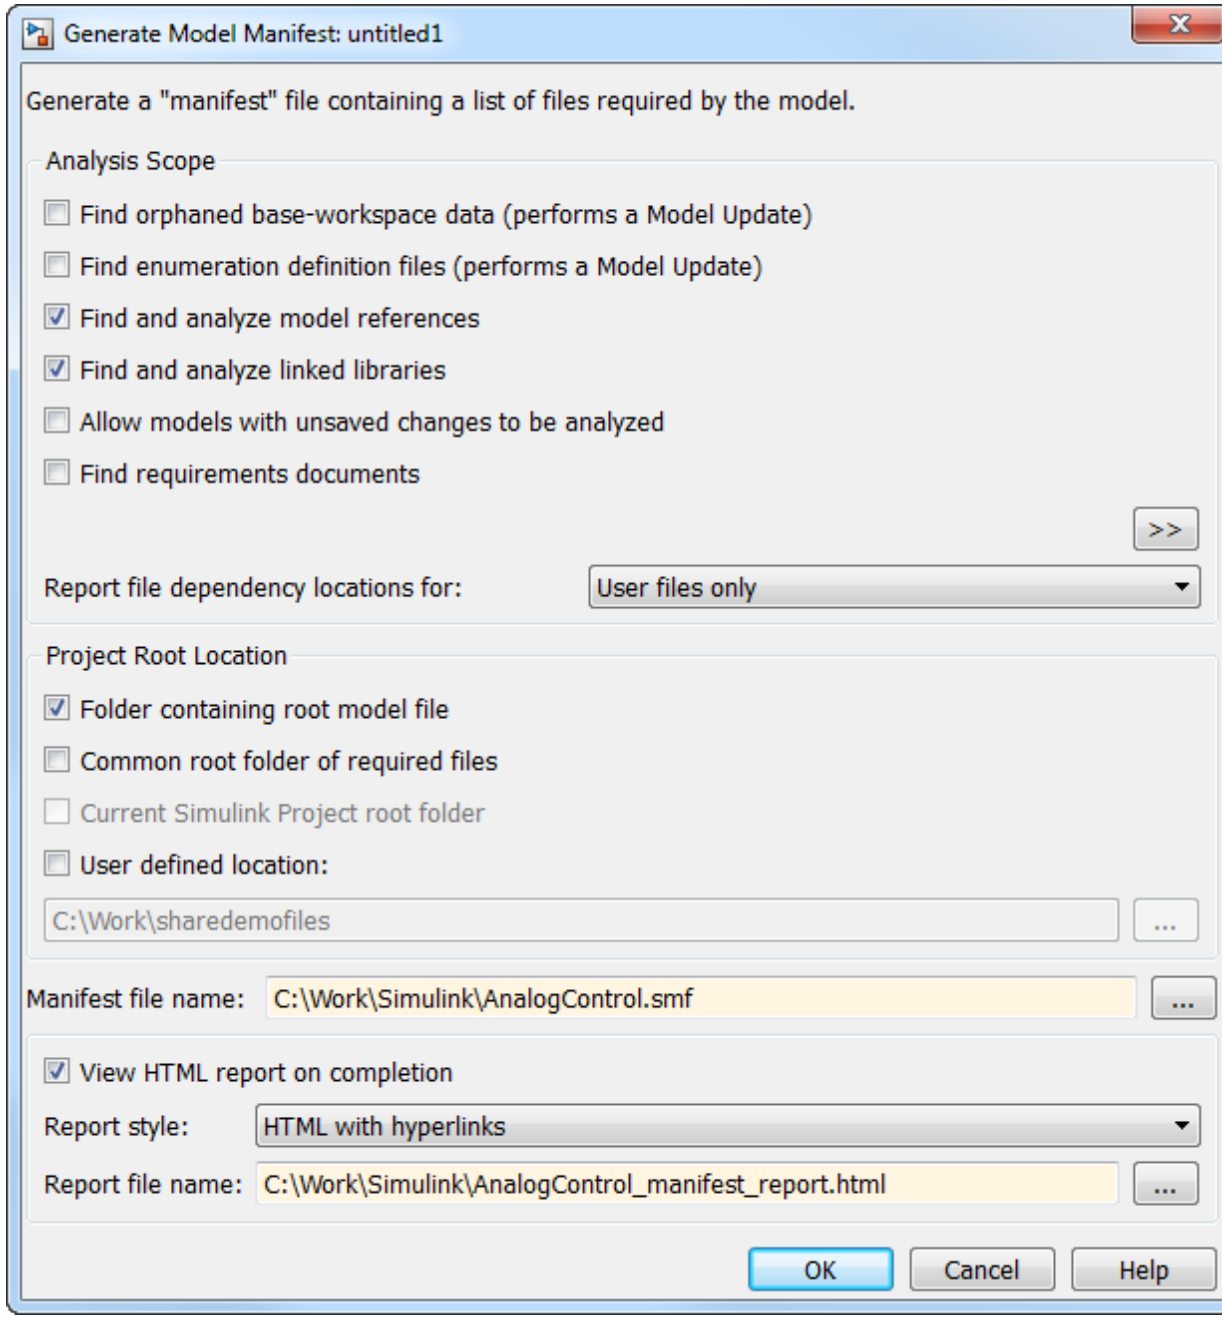
Generating a manifest performs the dependency analysis and saves the list of model dependencies to a manifest file. You must generate the manifest before using any of the other Simulink Manifest Tools.

Note The model dependencies identified in a manifest depend upon the **Analysis Scope** options you specify. For example, performing an analysis without selecting **Find Library Links** might not find all the Simulink blocksets that your model requires, because they are often included in a model as library links. See "Manifest Analysis Scope Options" on page 18-29.

To generate a manifest:

1 Select **Analysis > Model Dependencies > Generate Manifest**.

The Generate Model Manifest dialog box appears.



Generate Model Manifest: untitled1
Generate a "manifest" file containing a list of files required by the model.
Analysis Scope
Find orphaned base-workspace data (performs a Model Update)
Find enumeration definition files (performs a Model Update)
Find and analyze model references
Find and analyze linked libraries
Allow models with unsaved changes to be analyzed
Find requirements documents

Help

2 Click **OK** to generate a manifest and report using the default settings.

Alternatively you can first change the following settings:

- Select the **Analysis scope** check boxes to specify the type of dependencies you want to detect (see "Manifest Analysis Scope Options" on page 18-29).
- Control whether to report file dependency locations by selecting **Report file dependency locations for**:
  - `User files only` (default) — only report locations where dependencies are upon user files. Use this option if you want to understand the interdependencies of your own code and do not care about the locations of dependencies on MathWorks products. This option speeds up report creation and streamlines the report.
  - `All files` — report all locations where dependencies are introduced, including all dependencies on MathWorks products. This is the slowest option and the most verbose report. Use this option if you need to trace all dependencies to understand why a particular file or toolbox is required by a model. If you need to analyze many references, it can be helpful to sort the results by clicking the report column headers.
  - `None` — do not report any dependency locations. This is the fastest option and the most streamlined report. Use this option if you want to discover and package required files and do not require all the information about file references.
- If desired, change the **Project Root Location**. If the model is in a project, you can select **Current Simulink Project root folder**. Other check box options are: **Folder containing root model file** (the default), **Common root folder of required files**, or **User-defined location** — for this option, enter a path in the edit box, or browse to a location.
- If desired, edit the **Manifest file name** and location in which to save the file.
- Use the check box **View HTML report on completion** to specify if you want to generate a report when you generate the manifest. You can edit the **Report file name** or leave the default, *`mymodelname`*`_manifest_report.html`. You can set the **Report style** to `Plain HTML` or `HTML with Hyperlinks`.

When you click **OK** Simulink generates a manifest file containing a list of the model dependencies. If you selected **View HTML report on completion**, the Model Manifest Report appears after Simulink generates the manifest. See "Use the Model Manifest Report" on page 18-43 for an example.

The manifest is an XML file with the extension `.smf` located (by default) in the same folder as the model itself.

Manifest Analysis Scope Options

The Simulink Manifest Tools allow you to specify the scope of analysis when generating the manifest. The dependencies identified by the analysis depend upon the scope you specify.

Tip You can select analysis options that perform a Model Update. If Model Update fails you see an error message. Either clear those analysis options to generate a manifest without a Model Update, or try a manual Model Update to find out more about the problem. For example your model might require variables that are not present in the workspace (for example, if a block parameter defines a variable that you forgot to load manually).

The following table describes the Analysis Scope options.

Check Box Option	Description
Find orphaned base workspace data (performs a Model Update)	Searches for base workspace variables the model requires, that are not defined in any file in this Manifest.
Find enumeration definition files (performs a Model Update)	Searches for enumeration definition files. Turn on this option to detect enumerated datatypes used as part of a bus object definition.
Find and analyze model references	Searches for Model blocks in the model, and identifies any referenced models as dependencies.
Find and analyze linked libraries	Searches for links to library blocks in the model, and identifies any library links as dependencies.
Allow models with unsaved changes to be analyzed	Select this check box only if you want to allow analysis of unsaved changes.

Check Box Option	Description
Find requirements documents	Searches for requirements documents linked using the Requirements Management Interface. Note that requirements links created with IBM Rational DOORS software are not included in manifests. For more information, see "Find Requirements Documents in a Project" on page 18-22 and "Requirements Management Interface Setup" (Simulink Requirements) in the Simulink Requirements documentation.
Click the >> button on the right to show the following advanced analysis options.	
Find S-functions	Searches for S-Function blocks in the model, and identifies S-function files (MATLAB code and C) as dependencies. See the source code item in "Special Cases" on page 18-41.
Analyze model and block callbacks (including Interpreted MATLAB Function blocks)	Searches for file dependencies introduced by the code in Interpreted MATLAB Function blocks, block callbacks, and model callbacks. For more detail on how callbacks are analyzed, see "Code Analysis" on page 18-40.
Find files required for code generation	Searches for file dependencies introduced by Simulink Coder custom code, and Embedded Coder templates. If you do not have a code generation product, this check is off by default, and produces a warning if you select it. This includes analysis of all configuration sets (not just the Active set) and *STF*`_make_rtw_hook` functions, and locates system target files and Code Replacement Library definition files (.m or .mat). See also "Required Toolboxes" on page 18-45, and the source code item in "Special Cases" on page 18-41.
Find data files (e.g. in "From File" blocks)	Searches for explicitly referenced data files, such as those in From File blocks, and identifies those files as dependencies. See "Special Cases" on page 18-41.

Check Box Option	Description
Analyze Stateflow charts	Searches for file dependencies introduced by using syntax such as `ml.mymean(myvariable)` in models that use Stateflow.
Analyze code in MATLAB Functions blocks	Searches for MATLAB Function blocks in the model, and identifies any file dependencies (outside toolboxes) introduced in the code. Toolbox dependencies introduced by a MATLAB Function block are not detected.
Analyze files in "user toolboxes"	Searches for file dependencies introduced by files in user-defined toolboxes. See "Special Cases" on page 18-41.
Analyze MATLAB files	Searches for file dependencies introduced by MATLAB files called from the model. For example, if this option is selected and you have a callback to `mycallback.m`, then the referenced file `mycallback.m` is also analyzed for further dependencies. See "Code Analysis" on page 18-40.
Store MATLAB code analysis warnings in manifest	Saves any warnings in the manifest.

See also "Scope of Dependency Analysis" on page 18-39 for more information.

Command-Line Dependency Analysis

Check File Dependencies

To programmatically check for file dependencies, use the function `dependencies.fileDependencyAnalysis` as follows.

```
[files, missing, depfile, manifestfile] =
dependencies.fileDependencyAnalysis('modelname', 'manifestfile')
```

This returns the following:

- *`files`* — a cell array of character vectors containing the full-paths of all existing files referenced by the model *`modelname`*.

- *missing* — a cell array of character vectors containing the names all files that are referenced by the model *modelname*, but cannot be found.
- *depfile* — returns the full path of the user dependencies (`.smd`) file, if it exists, that stores the names of any files you manually added or excluded. Simulink uses the `.smd` file to remember your changes the next time you generate a manifest. See "Edit Manifests" on page 18-34.
- *manifestfile* — (optional input) specify the name of the manifest file to create. The suffix `.smf` is always added to the user-specified name.

  If you specify the optional input, *manifestfile*, then the command creates a manifest file with the specified name and path *manifestfile*. *manifestfile* can be a full-path or just a file name (in which case the file is created in the current folder).

If you try this analysis on an example model, it returns an empty list of required files because the standard MathWorks installation includes all the files required for the example models.

Check Toolbox Dependencies

To check which toolboxes are required, use the function `dependencies.toolboxDependencyAnalysis` as follows:

```
[names,dirs] = dependencies.toolboxDependencyAnalysis(files_in)
```

files_in must be a cell array of character vectors containing `.m` or model files on the MATLAB path. Simulink model names (without file extension) are also allowed.

This returns the following:

- *names* — a cell-array of toolbox names required by the files in *files_in*.
- *dirs* — a cell-array of the toolbox folders.

Note The method `toolboxDependencyAnalysis` looks for toolbox dependencies of the files in `files_in` but does *not* analyze any subsequent dependencies.

If you want to find all detectable toolbox dependencies of your model *and* the files it depends on:

1. Call `fileDependencyAnalysis` on your model.

   For example:

   ```
   [files, missing, depfile, manifestfile] = dependencies.fileDependencyAnalysis('mymodel')

   files =
       'C:\Work\manifest\foo.m'
       'C:\Work\manifest\mymodel'
   missing =
        []
   depfile =
        []
   manifestfile =
        []
   ```

2. Call `toolboxDependencyAnalysis` on the `files` output of step 1.

   For example:

   ```
   tbxes = dependencies.toolboxDependencyAnalysis(files)

   tbxes =
   [1x24 char]    'MATLAB'    'Simulink Coder'    'Simulink'
   ```

   To view long product names examine the `tbxes` cell array as follows:

   ```
   tbxes{:}

   ans =
   Image Processing Toolbox

   ans =
   MATLAB

   ans =
   Simulink Coder

   ans =

   Simulink
   ```

For command-line dependency analysis, the analysis uses the default settings for analysis scope to determine required toolboxes. For example, if you have code generation products, then the check **Find files required for code generation** is on by default and Simulink Coder is always reported as required. See “Required Toolboxes” on page 18-45

for more examples of how your installed products and analysis scope settings can affect reported toolbox requirements.

Edit Manifests

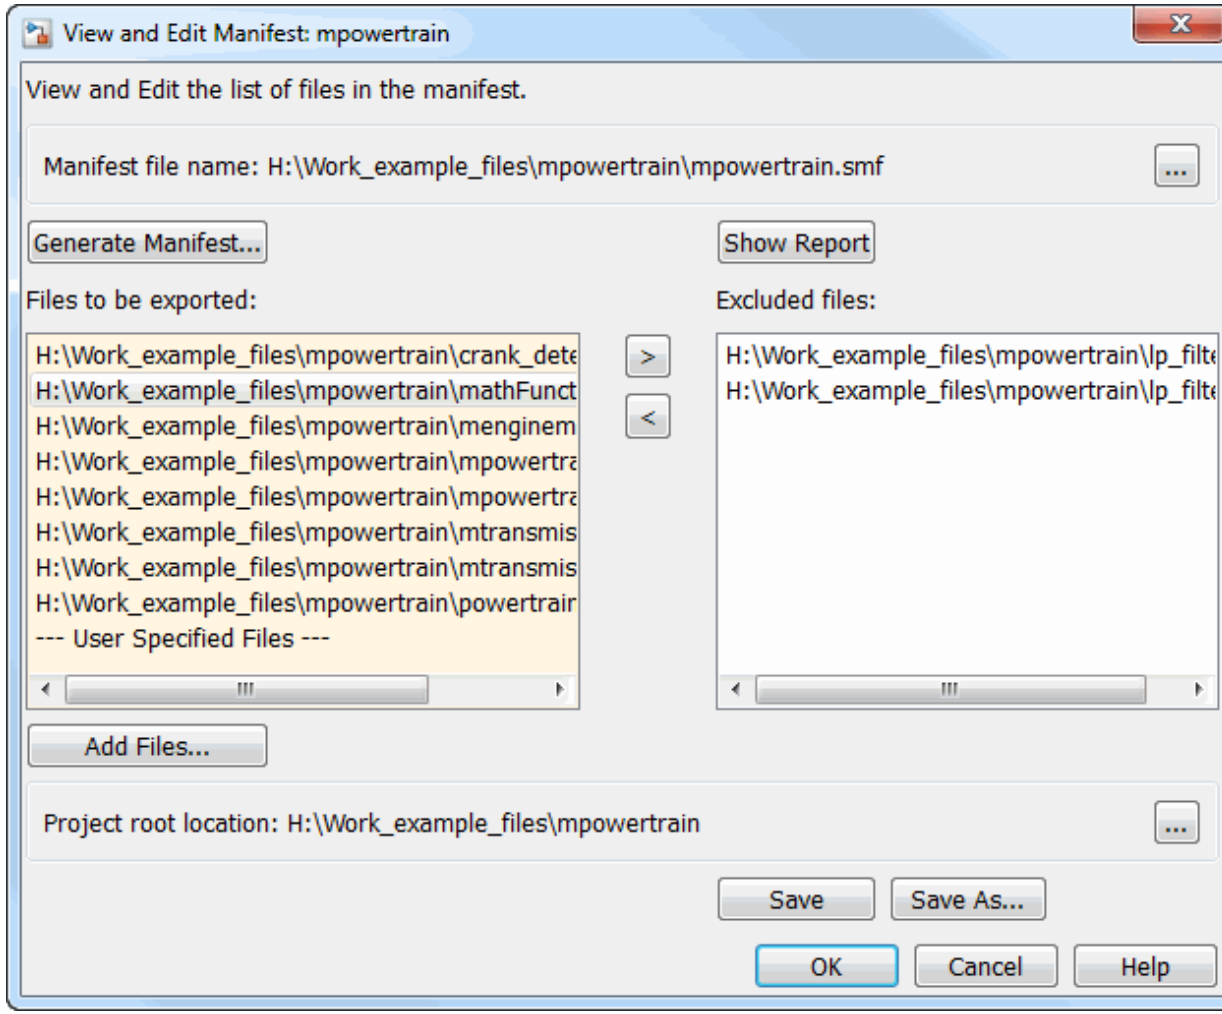
After you generate a manifest, you can view the list of files identified as dependencies, and manually add or delete files from the list.

To edit the list of required files in a manifest:

1 Select **Analysis > Model Dependencies > Edit Manifest Contents**.

Alternatively, if you are viewing a manifest report you can click **Edit** in the top **Actions** box, or you can click **View and Edit Manifest** in the Export Manifest dialog box.

The View and Edit Manifest dialog box appears, showing the latest manifest for the current model.



Note You can open a different manifest by clicking the Browse for manifest file button ... . If you have not generated a manifest, select **Generate Manifest** to open the Generate Model Manifest dialog box (see "Generate Manifests" on page 18-26).

2 Examine the **Files to be exported** list on the left side of the dialog box. This list shows the files identified as dependencies.

3 To add a file to the manifest:

   a Click **Add Files**.

   The Add Files to Manifest dialog box opens.

   b Select the file you want to add, then click **Open**.

   The selected file is added to the **Files to be exported** list.

4 To remove a file from the manifest:

   a Select the file you want to remove from the **Files to be exported** list.

   b Click the Exclude selected files button  .

   The selected file is moved to the **Excluded files** list.

   Note If you add a file to the manifest and then exclude it, that file is removed from the dialog box (it is not added to the **Excluded files** list). Only files detected by the Simulink Manifest Tools are included in the Excluded files list.

5 If desired, change the **Project Root Location**.

6 Click **Save** to save your changes to the manifest file.

   Simulink saves the manifest (`.smf`) file, and creates a user dependencies (`.smd`) file that stores the names of any files you manually added or excluded. Simulink uses the `.smd` file to remember your changes the next time you generate a manifest, so you do not need to repeat manual editing. For example, you might want to exclude source code or include a copyright document every time you generate a manifest for exporting to a customer. The user dependencies (`.smd`) file has the same name and folder as the model. By default, the user dependencies (`.smd`) file is also included in the manifest.

   Note If the user dependencies (`.smd`) file is read-only, a warning is displayed when you save the manifest.

7 To view the Model Manifest Report for the updated manifest, click **Show Report**.

An updated Model Manifest Report appears, listing the required files and toolboxes, and details of references to other files. See “Use the Model Manifest Report” on page 18-43 for an example.

8 When you are finished editing the manifest, click **OK**.

Compare Manifests

You can compare two manifests to see how the list of model dependencies differs between two models, or between two versions of the same model. You can also compare a manifest with a folder or a ZIP file.

To compare manifests:

1 From the Current Folder browser, right-click a manifest file and select **Compare Against > Choose**.

Alternatively, from your model, select **Analysis > Model Dependencies > Compare Manifests**.

The dialog box Select Files or Folders for Comparison appears.

2 In the dialog box Select Files or Folders for Comparison, select files to compare, and the comparison type.

a Use the drop-down lists or browse to select manifest files to compare.

b Select the **Comparison type**. For two manifests you can select:

- `Simulink manifest comparison` — Select for a manifest file list comparison reporting new, removed, and changed files. The report contains links to open files and compare files that differ. You can use a similar file `List comparison` for comparing a manifest to a folder or a ZIP file.
- `Simulink manifest comparison (printable)` — Select for a printable Model Manifest Differences Report without links. The report provides details about each manifest file, and lists the differences between the files.

3 View the report in the Comparison Tool comparing the file names, dates, and sizes stored in the manifests.

Be aware the details stored in the manifest might differ from the files on disc. If you click a “compare” link in the report, you see warnings if there are problems such as size mismatches, or if the tool cannot find those files on disc.

For more information on the Comparison Tool, see “Comparing Files and Folders” (MATLAB) in the MATLAB Data and File Management documentation.

Export Files in a Manifest

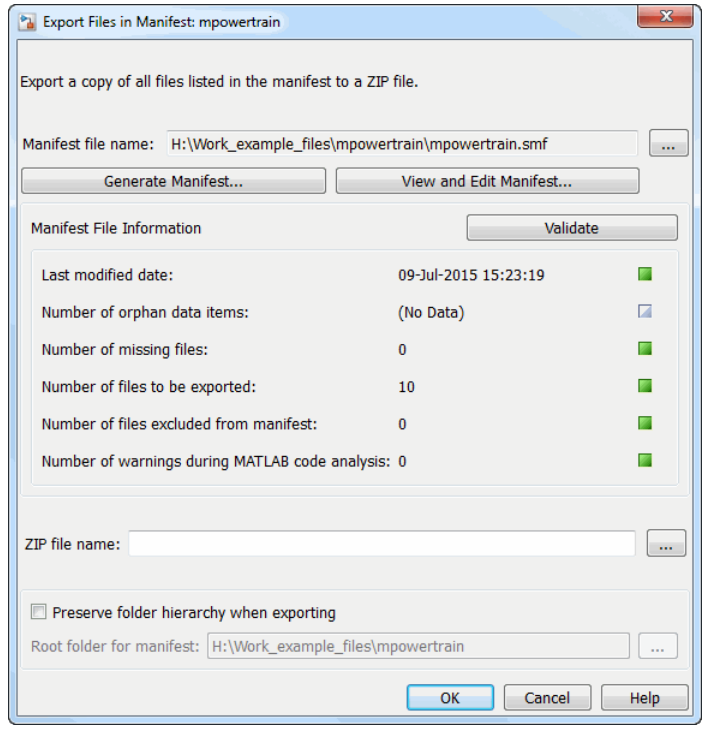
You can export copies of the files listed in the manifest to a ZIP file. Exporting the files allows you to package the model with its required files into a single ZIP file, so you can easily send it to another user or save it in a revision control system.

To export your model with its required files:

1 Select **Analysis > Model Dependencies > Export Files in Manifest**.

Alternatively, if you are viewing a manifest report you can click **Export** in the top **Actions** box.

The Export Files in Manifest dialog box appears, showing the latest manifest for the current model.



Note You can export a different manifest by clicking the Browse for manifest file button  . If you have not generated a manifest, select **Generate Manifest** to open the Generate Model Manifest dialog box (see "Generate Manifests" on page 18-26).

2. If you want to view or edit the manifest before exporting it, click **View and Edit Manifest** to view or change the list of required files. See "Edit Manifests" on page 18-34. When you close the View and Edit Manifest dialog box, you return to the Export Files in Manifest dialog box.
3. Click **Validate** to check the manifest. Validation reports information about possible problems such as missing files, warnings, and orphaned base workspace data.
4. Enter the ZIP file name to which you want to export the model.
5. Select **Preserve folder hierarchy when exporting** if you want to keep folder structure for your exported model and files. Then, select the root folder to use for this structure (usually the same as the **Project Root Location** on the Generate Manifest dialog box).

   Note You must select **Preserve folder hierarchy** if you are exporting a model that uses an `.m` file inside a MATLAB class (to maintain the folder structure of the class), or if the model refers to files in other folders (to ensure the exported files maintain the same relative paths).
6. Click **OK**.

   The model and its file dependencies are exported to the specified ZIP file.

Scope of Dependency Analysis

The Simulink Manifest Tools identify required files and list them in an XML file called a manifest. When Simulink generates a manifest file, it performs a static analysis on your model, which means that the model does not need to be capable of performing an "update diagram" operation (see "Update Diagram and Run Simulation" on page 1-65). The only exception to this is when you select the analysis option **Find orphaned base workspace data (performs a Model Update)**.

You can specify the type of dependencies you want to detect when you generate the manifest. See "Manifest Analysis Scope Options" on page 18-29.

For more information on what the tool analyzes, refer to the following sections:

- "Analysis Limitations" on page 18-40
- "Code Analysis" on page 18-40
- "Special Cases" on page 18-41

Analysis Limitations

The analysis might not find all files required by your model (for examples, see "Code Analysis" on page 18-40).

The analysis might not report certain blocksets or toolboxes required by a model. You should be aware of this limitation when sending a model to another user. Blocksets that do not introduce dependence on any files (such as Fixed-Point Designer™) cannot be detected. Some SimEvents blocks do not introduce a detectable dependence on SimEvents.

To include dependencies that the analysis cannot detect, you can add additional file dependencies to a manifest file using the View/Edit Manifest Contents option (see "Edit Manifests" on page 18-34).

Code Analysis

When the Simulink dependency analysis encounters MATLAB code, for example in a model or block callback, or in a `.m` file S-function, the analysis attempts to identify the files it references. If those files contain MATLAB code, *and* the analysis scope option **Analyze MATLAB files** is selected, the referenced files are also analyzed. This function is similar to `matlab.codetools.requiredFilesAndProducts` but with some enhancements:

- Character vectors passed into calls to `eval`, `evalc`, and `evalin` are analyzed.
- File names passed to `load`, `fopen`, `xlsread`, `importdata`, `dlmread`, and `imread` are identified.

Files that are in MathWorks toolboxes are not analyzed.

File names passed to `load`, etc., are identified only if they are literal character vectors, for example:

```
load('mydatafile')
load mydatafile
```

If you define a file name as a variable and pass that to a function, the file is a hidden dependency. The following example, and anything more complicated, does not identify the dependency because the file name is inside a variable:

```
str = 'mydatafile';
load(str);
```

Similarly, arguments to `eval`, etc., are analyzed only if they are literal character vectors.

The Simulink dependency analysis looks inside MAT-files to find the names of variables to be loaded. This enables them to distinguish reliably between variable names and function names in block callbacks.

If a model depends upon a file for which both `.m` and `.p` files exist, then the manifest reports both, and, if the **Analyze MATLAB files** option is selected, the `.m` file is analyzed.

Special Cases

The following list contains more information about specific cases:

- If your model references a data class created using MATLAB syntax, for example called *`MyPackage.MyClass`*, all files inside the folder *`MyPackage`* and its subfolders are added to the manifest.

  Warning The analysis adds all files in the class, which includes any source control files such as `.svn` or `.cvs`. You might want to edit the manifest to remove these files.

- A user-defined toolbox must have a properly configured `Contents.m` file. The Simulink Manifest Tools search user-defined toolboxes as follows:

  - If you have a `Contents.m` file in folder `X`, any file inside a subfolder of `X` is considered part of your toolbox.
  - If you have a `Contents.m` file in folder `X/X`, any file inside all subfolders of the "outer" folder `X` is considered part of your toolbox.

    For more information on the format of a `Contents.m` file, see `ver`.

- If your S-functions require TLC files, these are detected.
- If you have Simscape, your Simscape components are analyzed. See also "Required Toolboxes" on page 18-45 for other effects of your installed products on manifests.

- If you create a UI using GUIDE and add this to a model callback, then the dependency analysis detects the `.m` and `.fig` file dependencies.
- If you have a dependence on source code, such as `.c`, `.h` files, these files are not analyzed at all to find any files that they depend upon. For example, subsequent `#include` calls inside `.h` files are not detected. To make such files detectable, you can add them as dependent files to the "header file" section of the Custom Code pane of the Simulink Coder section of the Configuration Parameters dialog box (or specify them with `rtwmakecfg`). Alternatively, to include dependencies that the analysis cannot detect, you can add additional file dependencies to a manifest file using the View/Edit Manifest Contents option (see “Edit Manifests” on page 18-34).
- Various blocksets and toolboxes can introduce a dependence on a file through their additional source blocks. If the analysis scope option **Find data files (e.g. in “From File” blocks)** is selected, the analysis detects file dependencies introduced by the following blocks:

Product	Blocks
DSP System Toolbox	From Wave File (Obsolete) block (Microsoft Windows operating system only) From Multimedia File block (Windows only)
Computer Vision System Toolbox™	Image From File block Read Binary File block
Simulink 3D Animation™	VR Sink block

The option **Find data files** also detects dependencies introduced by setting a "Model Workspace" for a model to either `MAT-File` or `MATLAB Code`, and model dependencies specified on the Model Referencing pane of the Configuration Parameters dialog box.

Best Practices for Dependency Analysis

The starting point for dependency analysis is the model itself. Make sure that the model refers to any data files it needs, even if you would normally load these manually. For example, add code to the model's `PreLoadFcn` to load them automatically, like this example:

```
load mydatafile
load('my_other_data_file.mat')
```

This way, the Simulink Manifest Tools can add them to the manifest. For more detail on callback analysis, see the notes on code analysis (see “Code Analysis” on page 18-40).

More generally, ensure that the model creates or loads any variables it uses, either in model callbacks or in scripts called from model callbacks. This reduces the possibility of the Simulink Manifest Tools confusing variable names with function names when analyzing block callbacks.

If you plan to export the manifest after creating it, ensure that the model does not refer to any files by their absolute paths, for example:

```
load C:\mymodel\mydata\mydatafile.mat
```

Absolute paths can become invalid when you export the model to another machine. If referring to files in other folders, do it by relative path, for example:

```
load mydata\mydatafile.mat
```

Select **Preserve folder hierarchy** when exporting, so that the exported files are in the same locations relative to each other. Also, choose a root folder so that all the files listed in the manifest are inside it. Otherwise, any files outside the root are copied into a new folder called `external` underneath the root, and relative paths to those files become invalid.

If you are exporting a model that uses a `.m` file inside a MATLAB class (in a folder called `@myclass`, for example), you must select the **Preserve folder hierarchy** check box when exporting, to maintain the folder structure of the class.

Always test exported ZIP files by extracting the contents to a new location on your computer and testing the model. Be aware that in some cases required files might be on your path but not in the ZIP file, if your path contains references to folders other than MathWorks toolboxes.

Use the Model Manifest Report

Report Sections

If you selected **View HTML report on completion** in the Generate Model Manifest dialog box, the Model Manifest Report appears after Simulink generates the manifest. The report shows:

- Analysis date
- **Actions** pane — Provides links to regenerate, edit, or compare the manifest, and export the files in the manifest to a ZIP file.
- **Model Reference and Library Link Hierarchy** — Links you can click to open models.
- **Files used by this model** — Required files, with paths relative to the `projectroot`.

  You can sort the results by clicking the report column headers.
- **Toolboxes required by this model**. For details, see “Required Toolboxes” on page 18-45.
- **References in this model** — This section provides details of references to other files so you can identify where dependencies arise. You control the scope of this section with the **Report file dependency locations** options on the Generate Manifest dialog box. You can choose to include references to user files only, all files, or no files. See “Generate Manifests” on page 18-26. Use this section of the report to trace dependencies to understand why a particular file or toolbox is required by a model. If you need to analyze many references, it can be helpful to sort the results by clicking the report column headers.
- **Folders referenced by this model**
- **Orphaned base workspace variables** — If you selected the analysis option **Find orphaned base workspace data**, this section reports any base workspace variables the model requires that are not defined in a file in this manifest.
- **Warnings generated while analyzing MATLAB code** — You can opt out of this section by clearing the **Store MATLAB code analysis warnings in manifest** analysis option.
- **Dependency analysis settings** — Records the details of the analysis scope options.

See the examples shown in “Example Model Manifest Report” on page 18-45.

Required Toolboxes

In the report, the "Toolboxes required by this model" section lists all products required by the model *that the analysis can detect*. Be aware that the analysis might not report certain blocksets or toolboxes required by a model, e.g., blocksets that do not introduce dependence on any files (such as Fixed-Point Designer) cannot be detected. Some MathWorks files under toolbox/shared can report only requiring MATLAB instead of their associated toolbox.

The results reported can be affected by your analysis scope settings and your installed products. For example:

- If you have code generation products and select the scope option "**Find files required for code generation**", then:
  - Simulink Coder software is always reported as required.
  - If you also have an `.ert` system target file selected, then Embedded Coder software is always reported as required.
- If you clear the **Find library links** option, then the analysis cannot find a dependence on, for example, *`someBlockSet`*, and so no dependence is reported upon the block set.
- If you clear the **Analyze MATLAB files** option, then the analysis cannot find a dependence upon `fuzzy.m`, and so no dependence is reported upon the Fuzzy Logic Toolbox™.

Example Model Manifest Report

You should always check the **Dependency analysis settings** section in the Model Manifest Report to see the scope of analysis settings used to generate it.

Following are portions of a sample report.

Model Manifest Report:mpowertrain

Actions

- Re-generate this manifest
- Edit this manifest
- Compare this manifest with another one
- Export the files in this manifest to a ZIP file

Analysis performed:09-Jul-2013 14:30:49

Simulink Project Source Control

About Source Control with Projects

You can use Simulink Project to work with source control. You can perform operations such as update, commit, merge changes, and view revision history directly from the Simulink Project environment.

Simulink Project has interfaces to:

- Subversion (SVN) — See “Set Up SVN Source Control” on page 19-11.
- Git— See “Set Up Git Source Control” on page 19-20.
- Software Development Kit (SDK) — You can use the SDK to integrate Simulink Projects with third-party source control tools. See “Write a Source Control Integration with the SDK” on page 19-28.

Tip You can check for updated source control integration downloads on the Simulink Projects Web page: `https://www.mathworks.com/discovery/simulink-projects.html`

To use source control in your project, use any of the following workflows:

- Add source control to a project. See “Add a Project to Source Control” on page 19-6.
- Retrieve files from an existing repository and create a new project. See “Retrieve a Working Copy of a Project from Source Control” on page 19-29.
- Create a new project in a folder already under source control and click **Detect**. See “Create a New Project From a Folder” on page 16-17.
- Make your project publicly available on GitHub. See “Share Project on GitHub” on page 17-50.

When your project is under source control, you can:

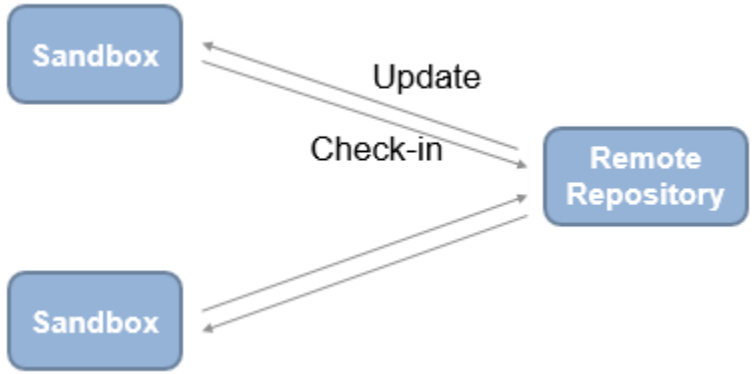
- “Retrieve a Working Copy of a Project from Source Control” on page 19-29
- “Compare Revisions” on page 19-46
- “Commit Modified Files to Source Control” on page 19-51

Caution Before using source control, you must register model files with your source control tools to avoid corrupting models. See “Register Model Files with Source Control Tools” on page 19-10.

To view an example project under source control, see “Explore Simulink Project Tools with the Airframe Project” on page 16-5.

Classic and Distributed Source Control

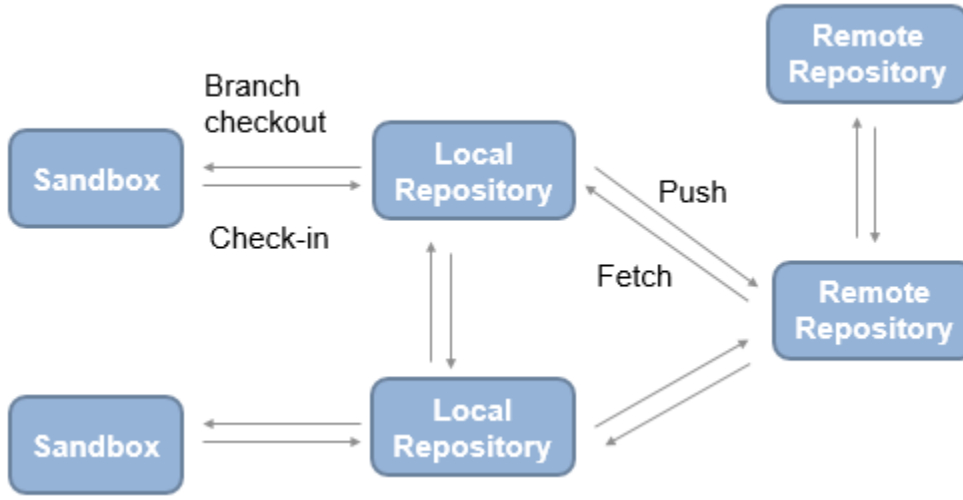
This diagram represents the classic source control workflow (for example, using SVN).



Benefits of classic source control:

- Locking and user permissions on a per-file basis (e.g., you can enforce locking of model files)
- Central server, reducing local storage needs
- Simple and easy to learn

This diagram represents the distributed source control workflow (for example, using Git).



Benefits of distributed source control:

- Offline working
- Local repository, which provides full history
- Branching
- Multiple remote repositories, enabling large-scale hierarchical access control

To choose classic or distributed source control, consider these tips.

Classic source control can be helpful if:

- You need file locks.
- You are new to source control.

Distributed source control can be helpful if:

- You need to work offline, commit regularly, and need access to the full repository history.
- You need to branch locally.

Add a Project to Source Control

In this section...

Add a Project to Git Source Control

If you want to add version control to your Simulink project files without sharing with another user, it is quickest to create a local Git repository in your sandbox.

1. On the Simulink Project tab, in the Source Control section, click **Use Source Control**.
2. In the Source control information dialog box, click **Add project to source control**.
3. In the Add to Source Control dialog box, in the **Source control integration** list, select `Git` to use the Git source control integration provided by Simulink Project.
4. Click **Convert** to finish adding the project to source control.

   Git creates a local repository in your sandbox project root folder. The project runs integrity checks.
5. Click **Open Project** to return to your project.

   The Project node displays the source control name `Git` and the repository location `Local Repository: yoursandboxpath`.
6. Select the Modified Files view and click **Commit** to commit the first version of your files to the new repository.

   In the dialog box, enter a comment if you want, and click **Submit**.

You need some additional setup steps only if you want to merge branches with Git. See “Install Command-Line Git Client” on page 19-22.

Tip If you want to use Git and share with other users:

- To clone an existing remote Git repository, see “Retrieve a Working Copy of a Project from Source Control” on page 19-29.

- To connect an existing project to a remote repository, on the Simulink Project tab, in the Source Control section, click **Remote** and specify a single remote repository for the origin branch.
- To make your project publicly available on GitHub, see "Share Project on GitHub" on page 17-50.

Add a Project to SVN Source Control

Caution Before you start, check that your sandbox folder is on a local hard disc. Using a network folder with SVN is slow and unreliable.

This procedure adds a project to the built-in SVN integration that comes with Simulink Project. If you want to use a different version of SVN, see "Set Up SVN Source Control" on page 19-11.

1. On the Simulink Project tab, in the Source Control section, click **Use Source Control**.
2. In the Source control information dialog box, click **Add project to source control**.
3. In the Add to Source Control dialog box, leave the default **Source control integration** selected to use `Built-In SVN Integration`.
4. Next to **Repository path**, click **Change**.
5. In the Specify SVN Repository URL dialog box, select an existing repository or create a new one.

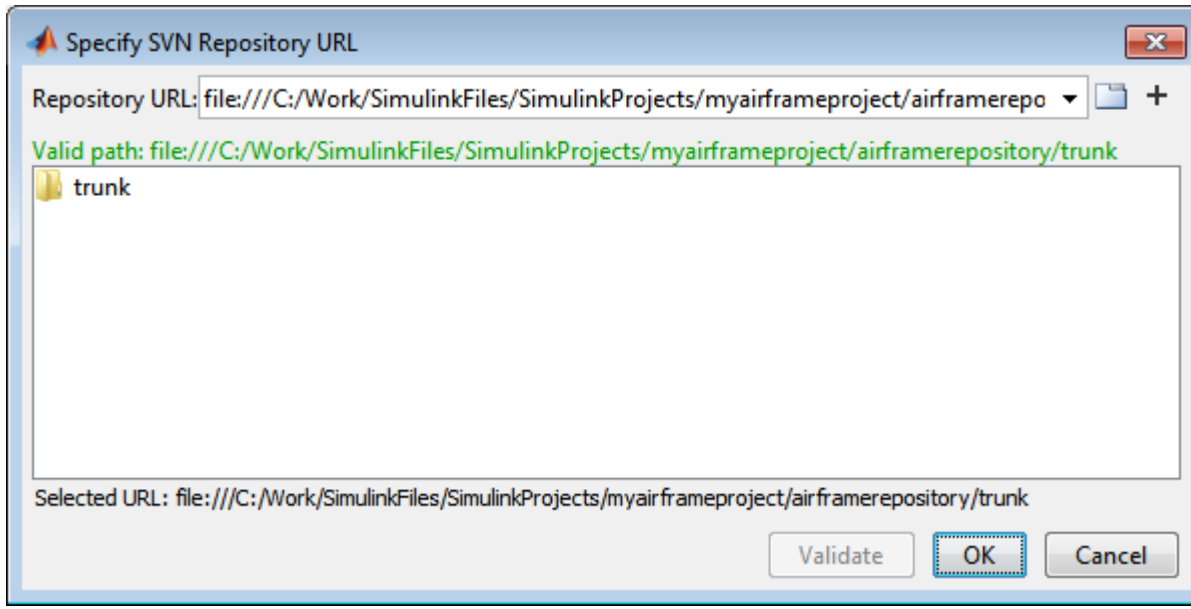
   - To specify an existing repository, click Generate URL from folder  to browse for your repository, paste a URL into the box, or use the list to select a recent repository.
   - To create a new repository, click Create an SVN repository in a folder  . Using the file browser, create a folder where you want to create the new repository and click **Select Folder**. Do not place the new repository inside the existing project folder.

     Simulink Project creates a repository in your folder, and you return to the Specify SVN Repository URL dialog box. The URL of the new repository is in the **Repository URL** box, and the project automatically selects the `trunk` folder.

Caution Specify `file://` URLs and create new repositories for single users only. For multiple users, see "Share a Subversion Repository" on page 19-17.

6 Click **Validate** to check the path to the selected repository.

When the path is valid, you can browse the repository folders. For example, select the `trunk` folder, and verify the selected URL at the bottom of the dialog box, as shown.



7 Click **OK** to return to the Add to Source Control dialog box.

If your repository has a file URL, a warning appears that file URLs are for single users. Click **OK** to continue.

8 Click **Convert** to finish adding the project to source control.

The project runs integrity checks.

9 After the integrity checks run, click **Open Project** to return to your project.

The Project node displays details of the current source control tool and the repository location.

10 If you created a new repository, select the Modified Files view and click **Commit** to commit the first version of your files to the new repository. In the dialog box, enter a comment if you want, and click **Submit**.

Caution Before using source control, you must register model files with your source control tools to avoid corrupting models. See "Register Model Files with Subversion" on page 19-13.

More About

- "About Source Control with Projects" on page 19-2

Register Model Files with Source Control Tools

If you use third-party source control tools, you must register your model file extensions (`.mdl` and `.slx`) as binary formats. If you do not, these third-party tools can corrupt your model files when you submit them, by changing end-of-line characters, expanding tokens, substituting keywords, or attempting to automerge. Corruption can occur whether you use the source control tools outside of Simulink or if you try submitting files from Simulink Project without first registering your file formats.

Also check that other file extensions are registered as binary to avoid corruption at check-in for files such as `.mat`, `.mlx`, `.mdlp`, `.slxp`, `.sldd`, `.p`, MEX-files, `.xlsx`, `.jpg`, `.pdf`, `.docx`, etc.

For instructions with SVN, see “Register Model Files with Subversion” on page 19-13. You must register model files if you use SVN, including the `Built-In SVN Integration` provided by Simulink Project.

For instructions with Git, see “Register Model Files with Git” on page 19-23.

- “Register Model Files with Git” on page 19-23

Set Up SVN Source Control

In this section...

Set Up SVN Integration Provided with Simulink Project

Simulink Project provides `Built-In SVN Integration` for use with Subversion (SVN) sandboxes and repositories at version 1.8. You do not need to install SVN to use this integration because it includes an implementation of SVN.

Note This integration ignores any existing SVN installation.

The `Built-In SVN Integration` supports secure logins.

To use the version of SVN provided with Simulink Project, when you add a project to source control or retrieve from source control, select `Built-In SVN Integration` in the **Source control integration** list. For instructions, see

- “Add a Project to Source Control” on page 19-6, or
- “Retrieve a Working Copy of a Project from Source Control” on page 19-29.

Caution Place your project sandbox folder on a local hard disc. Using a network folder with SVN is slow and unreliable. If you use a Windows network drive, SVN move operations can result in incorrect "not existing" status for files visible in file browsers.

When you create a new sandbox using the Simulink Project `Built-In SVN Integration`, the new sandbox uses the latest version of SVN provided by Simulink Project.

When your project is under source control, you can use these project features:

- "Retrieve a Working Copy of a Project from Source Control" on page 19-29
- "Compare Revisions" on page 19-46
- "Commit Modified Files to Source Control" on page 19-51

You can check out from a branch, but the project Built-In SVN Integration does not support branch merging. Use an external tool such as TortoiseSVN to perform branch merging. You can use the project tools for comparing and merging by configuring TortoiseSVN to generate an XML comparison report when you perform a diff on model files. See "Merge Simulink Models from the Comparison Report" on page 21-16.

Set Up SVN Integration for SVN Version Already Installed

If you want to use Simulink Project with an earlier SVN version you already have installed, create a new project in a folder already under SVN source control. The project detects SVN.

For example:

1. Create the sandbox using TortoiseSVN from Windows Explorer.
2. Use Simulink Project to create a new project in that folder. The project detects the existing source control. If the sandbox is version 1.6, for example, it remains a version 1.6 sandbox.

Note Before using source control, you must register model files with the tools. See "Register Model Files with Subversion" on page 19-13.

Set Up SVN Integration for SVN Version Not Yet Provided with Simulink Project

If you need to use a later version of SVN than 1.8, you can use `Command-Line SVN Integration (compatibility mode)`, but you must also install a command-line SVN client.

Note Select `Command-Line SVN Integration (compatibility mode)` only if you need to use a later version of SVN than 1.8. Otherwise, use `Built-In SVN Integration` instead, for more features, improved performance, and no need to install an additional command-line SVN client.

Command-line SVN integration communicates with any Subversion (SVN) client that supports the command-line interface.

1 Install an SVN client that supports the command-line interface.

   Note TortoiseSVN does not support the command-line interface unless you choose the option to install command-line tools. Alternatively, you can continue to use TortoiseSVN from Windows Explorer after installing another SVN client that supports the command-line interface. Ensure that the major version numbers match, for example, both clients are SVN 1.7.

   You can find Subversion clients on this Web page:

   `http://subversion.apache.org/packages.html`

2 In Simulink Project, select `Command-Line SVN Integration (compatibility mode)`.

With `Command-Line SVN Integration (compatibility mode)`, if you try to rename a file in a project and the folder name contains an @ character, an error appears because command-line SVN treats all characters after the @ symbol as a peg revision value.

Tip You can check for updated source control integration downloads on the Simulink Projects Web page: `https://www.mathworks.com/discovery/simulink-projects.html`

Register Model Files with Subversion

You must register model files if you use SVN, including the `Built-In SVN Integration` provided by Simulink Project.

If you do not register your model file extension as binary, SVN might add annotations to conflicted Simulink files and attempt automerge. This corrupts model files so you cannot load the models in Simulink.

To avoid this problem when using SVN, register file extensions.

1 Locate your SVN `config` file. Look for the file in these locations:

   - `C:\Users\`*`myusername`*`\AppData\Roaming\Subversion\config` or `C:\Documents and Settings\`*`myusername`*`\Application Data\Subversion\config` on Windows
   - In `~/.subversion` on Linux or Mac OS X

2 If you do not find a `config` file, create a new one. See "Create SVN Config File" on page 19-14.

3 If you find an existing `config` file, you have previously installed SVN. Edit the `config` file. See "Update Existing SVN Config File" on page 19-15.

Create SVN Config File

1 If you do not find an SVN `config` file, create a text file containing these lines:

```
[miscellany]
enable-auto-props = yes
[auto-props]
*.mdl = svn:mime-type=application/octet-stream
*.mat = svn:mime-type=application/octet-stream
*.slx = svn:mime-type= application/octet-stream
*.mlx = svn:mime-type=application/octet-stream
```

2 Check for other file types you use in your projects that you also need to register as binary to avoid corruption at check-in. Check for files such as `.mat`, `.mdlp`, `.slxp`, `.p`, MEX-files (`.mexa64`, `.mexmaci64`, , `.mexw64`), `.xlsx`, `.jpg`, `.pdf`, `.docx`, etc. Add a line to the attributes file for each file type you need. Examples:

```
*.mdlp  = svn:mime-type=application/octet-stream
*.slxp  = svn:mime-type=application/octet-stream
*.sldd  = svn:mime-type=application/octet-stream
*.p  = svn:mime-type=application/octet-stream
*.mexa64  = svn:mime-type=application/octet-stream
*.mexw64  = svn:mime-type=application/octet-stream
*.mexmaci64  = svn:mime-type=application/octet-stream
```

```
*.xlsx  = svn:mime-type=application/octet-stream
*.docx  = svn:mime-type=application/octet-stream
*.pdf  = svn:mime-type=application/octet-stream
*.jpg  = svn:mime-type=application/octet-stream
*.png  = svn:mime-type=application/octet-stream
```

3 Name the file `config` and save it in the appropriate location:

- `C:\Users\`*`myusername`*`\AppData\Roaming\Subversion\config` or `C:\Documents and Settings\`*`myusername`*`\Application Data\Subversion\config` on Windows
- `~/.subversion` on Linux or Mac OS X

After you create the SVN config file, SVN treats new model files as binary.

If you already have models in repositories, see "Register Models Already in Repositories" on page 19-16.

Update Existing SVN Config File

If you find an existing `config` file, you have previously installed SVN. Edit the `config` file to register files as binary.

1 Edit the `config` file in a text editor.

2 Locate the `[miscellany]` section, and verify the following line enables `auto-props` with `yes`:

```
enable-auto-props = yes
```

Ensure that this line is not commented (that is, that it does not start with a #). Config files can contain example lines that are commented out. If there is a # character at the beginning of the line, delete it.

3 Locate the `[auto-props]` section. Ensure that `[auto-props]` is not commented. If there is a # character at the beginning, delete it.

4 Add the following lines at the end of the `[auto-props]` section:

```
*.mdl = svn:mime-type= application/octet-stream
*.mat = svn:mime-type=application/octet-stream
*.slx = svn:mime-type= application/octet-stream
*.mlx = svn:mime-type=application/octet-stream
```

These lines prevent SVN from adding annotations to MATLAB and Simulink files on conflict and from automerging.

5 Check for other file types you use in your projects that you also need to register as binary to avoid corruption at check-in. Check for files such as `.mat`, `.mdlp`, `.slxp`, `.p`, MEX-files (`.mexa64`, `.mexmaci64`, `.mexw64`), `.xlsx`, `.jpg`, `.pdf`, `.docx`, etc. Add a line to the `config` file for each file type you need.

Examples:

```
*.mdlp  = svn:mime-type=application/octet-stream
*.slxp  = svn:mime-type=application/octet-stream
*.sldd  = svn:mime-type=application/octet-stream
*.p  = svn:mime-type=application/octet-stream
*.mexa64  = svn:mime-type=application/octet-stream
*.mexw64  = svn:mime-type=application/octet-stream
*.mexmaci64  = svn:mime-type=application/octet-stream
*.xlsx  = svn:mime-type=application/octet-stream
*.docx  = svn:mime-type=application/octet-stream
*.pdf  = svn:mime-type=application/octet-stream
*.jpg  = svn:mime-type=application/octet-stream
*.png  = svn:mime-type=application/octet-stream
```

6 Save the `config` file.

After you create or update the SVN config file, SVN treats new model files as binary.

If you already have models in repositories, register them as described next.

Register Models Already in Repositories

Caution Changing your SVN config file does not affect model files already committed to an SVN repository. If a model is not registered as binary, use `svn propset` to manually register models as binary.

To manually register a file in a repository as binary, use the following command with command-line SVN:

```
svn propset svn:mime-type application/octet-stream modelfilename
```

If you need to install a command-line SVN client, see “Set Up SVN Integration for SVN Version Not Yet Provided with Simulink Project” on page 19-12.

Enforce SVN Locking Model Files Before Editing

To ensure users remember to get a lock on model files before editing, you can configure SVN to make specified file extensions read only. To locate your SVN config file, see "Register Model Files with Subversion" on page 19-13.

After this setup, SVN sets model files to read only when you open the project, so you need to select **Source Control > Get File Lock** before you can edit them. Doing so helps prevent editing of models without getting the file lock. When the file has a lock, other users know the file is being edited, and you can avoid merge issues.

1. To make SLX files read only, add a property to your SVN config file. Find this line in the `[auto-props]` section that registers slx files as binary:

   ```
   *.slx = svn:mime-type= application/octet-stream
   ```

2. Add the `needs-lock` property to the end of the existing `slx` line, separated by a semicolon, so the line looks like this:

   ```
   *.slx = svn:mime-type=application/octet-stream;svn:needs-lock=yes
   ```

   You can combine properties in any order, but multiple entries (e.g., for `slx`) must be on a single line separated by semicolons.

3. Recreate the sandbox for the config to take effect.
4. You need to select **Get File Lock** before you can edit model files. See "Get SVN File Locks" on page 19-41.

If you need to resolve merge issues, see "Resolve Conflicts" on page 19-66.

Share a Subversion Repository

You can specify a repository location using the `file://` protocol. However, Subversion documentation strongly recommends only single users access a repository directly via `file://` URLs. See the Web page:

`http://svnbook.red-bean.com/en/1.7/svn-book.html#svn.serverconfig.choosing.recommendations`

Caution Do not allow multiple users to access a repository directly via `file://` URLs or you risk corrupting the repository. Use `file://` URLs only for single-user repositories.

Be aware of this caution with these workflows:

- If you specify a repository with a `file://` URL, or
- If you use Simulink Projects to create a repository, this uses the `file://` protocol. Creating new repositories is provided for local single-user access only, for testing and debugging.

Also, accessing a repository via `file://` URLs is slower than using a server.

When you want to share a repository, you need to set up a server. You can use `svnserve` or the Apache SVN module. See the Web page references:

```
http://svnbook.red-bean.com/en/1.7/svn-book.html#svn.serverconfig.svnserve
http://svnbook.red-bean.com/en/1.7/svn-book.html#svn.serverconfig.httpd
```

Standard Repository Structure

Create your repository with the standard `tags`, `trunk`, and `branches` folders, and check out files from `trunk`. The Subversion project recommends this structure. See the Web page:

```
http://svn.apache.org/repos/asf/subversion/trunk/doc/user/svn-best-practices.html
```

If you use Simulink Project to create an SVN repository, it creates the standard repository structure. To enable tagging, the repository must have `trunk/` and `tags/` folders.

After you create a repository with this structure, to add tags to all your project files, on the Simulink Project tab, in the Source Control section, click **Tag**. See “Tag and Retrieve Versions of Project Files” on page 19-35.

Manage SVN Externals

To get files into your project from another repository or from a different part of the same repository, use SVN externals.

1. In Simulink Project, right-click a project folder and select **Source Control** > **Manage Externals**.
2. In the Manage Externals dialog box, click **Add entry**. You can browse to and validate a repository location, specify the relative reference format, specify the subfolder, choose the revision, e.g., the `HEAD` node, etc.
3. After specifying the externals, click **OK**. The project displays the externals definition in the Manage Externals dialog box.

Alternatively, enter or paste an `svn:external` definition in the Manage Externals dialog box. The project applies an SVN version 1.6 compliant externals definition.

4. Click **Set** to validate and apply your changes.
5. To retrieve the external files, click **Update** to update the sandbox.

If two users modify the `svn:external` for a folder, you can get a conflict. To resolve the conflict, in the All Files View, locate the `.prej` file and examine the conflict details. Open the Manage Externals dialog box and specify the desired `svn:external`, mark the folder conflict resolved, and then commit the changes.

More About

- “About Source Control with Projects” on page 19-2

Set Up Git Source Control

In this section...

About Git Source Control

If you want to manage your models and source code using Git, you can integrate with Simulink Project.

Git integration with Simulink Project provides distributed source control with support for creating and merging branches. Git is a distributed source control tool, so you can commit changes to a local repository and later synchronize with other remote repositories.

Git supports distributed development because every sandbox contains a complete repository. The full revision history of every file is saved locally. This enables working offline, because you do not need to contact remote repositories for every local edit and commit, only when pushing batches of changes. In addition, you can create your own branches and commit local edits. Doing so is fast, and you do not need to merge with other changes on each commit.

Capabilities of Git source control:

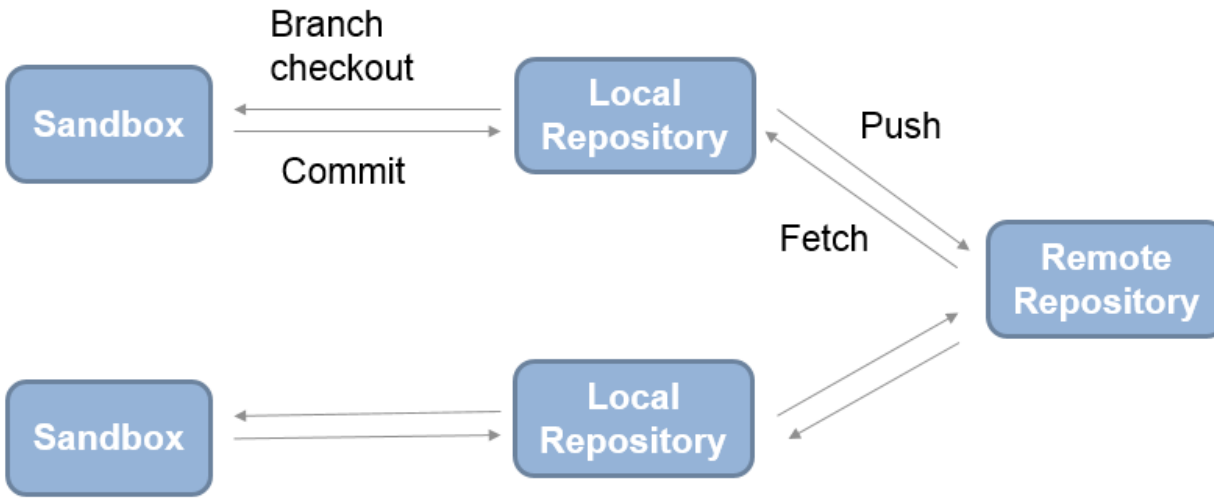
- Branch management
- Local full revision history
- Local access that is quicker than remote access
- Offline working
- Tracking of file names and contents separately
- Enforcing of change logs for tracing accountability
- Integration of batches of changes when ready

These capabilities do not suit every situation. If your project is not appropriate for offline working or your repository is too large for a full local revision history, for example, Git is not the ideal source control. In addition, if you need to enforce locking of files before editing, Git does not have this ability. In that situation, SVN is the better choice.

When you use Git in Simulink Project, you can:

- Create local Git repositories.
- Pull and fetch files from remote Git repositories.
- Create and switch branches.
- Merge branches locally.
- Commit locally.
- Push files to remote Git repositories.

This diagram represents the distributed Git workflow.



Use Git Source Control in Simulink Project

To use the version of Git provided with Simulink Project, when you add a project to source control or retrieve from source control, select `Git` in the **Source control integration** list.

- If you add an existing project to Git source control, you create a local Git repository in that sandbox. You can specify a remote repository later. See “Add a Project to Source Control” on page 19-6
- If you want to clone a remote Git repository to create a project, select **New > Simulink Project** on the MATLAB Home tab, and then in the start page, click **Source Control**. After you specify a remote repository to retrieve from, a local repository is created. You can also pull, fetch, and push changes from and to the remote repository. See “Retrieve a Working Copy of a Project from Source Control” on page 19-29.

  Note You cannot add empty folders to Git source control. Use **Check Project** instead. See “Pull, Push, and Fetch Files with Git” on page 19-56.

  To use a Git server for your remote repository, you can set up your own Apache Git server or use a Git server hosting solution. If you cannot set up a server and must use a remote repository via the file system using the `file:///` protocol, make sure that it is a bare repository with no checked out working copy.
- To make your project publicly available on GitHub, see “Share Project on GitHub” on page 17-50. Sharing adds Git source control to the open project and the project’s remote repository is GitHub.

Install Command-Line Git Client

If you want to use Git to merge branches in Simulink Project, you must also install a command-line Git client that is available systemwide. You can use other Git functionality without any additional installation.

Some clients are not available systemwide, including the `mingw32` environment provided by GitHub (**Git Shell** on the **Start** menu). Installing command-line Git makes it available systemwide, and then Simulink Project can locate standard `ssh` keys.

Check if Git is available by using the command `!git` in MATLAB. If Git is not available, install it.

On Windows:

1 Download the Git installer and run it. You can find command-line Git at:

```
http://msysgit.github.io/
```

2. In the section on adjusting your PATH, choose the install option to **Use Git from the Windows Command Prompt**. This option adds Git to your `PATH` variable, so that the Simulink Project can communicate with Git.
3. In the section on configuring the line-ending conversions, choose the option **Checkout as-is, commit as-is** to avoid converting any line endings in files.

On Linux, Git is available for most distributions. Install Git for your distribution. For example, on Debian®, install Git by entering:

```
sudo apt-get install git
```

On Mac, on Mavericks (10.9) or above, try to run `git` from the Terminal. If you do not have Git installed already, it will prompt you to install Xcode Command Line Tools. For more options, see `http://git-scm.com/doc`.

If you are working with long path files, run this command in MATLAB:

```
!git config --global core.longpaths true
```

Caution To avoid corrupting models, before using Git to merge branches, register model files. See "Register Model Files with Git" on page 19-23.

Register Model Files with Git

After you install a command-line Git client, you can prevent Git from corrupting your Simulink models by inserting conflict markers. To do so, edit your `.gitattributes` file to register model files as binary. For details, see:

```
http://git-scm.com/docs/gitattributes
```

1. If you do not already have a `.gitattributes` file in your project root folder, create one by entering in MATLAB:

   ```
   edit .gitattributes
   ```

2. Add these lines to the `.gitattributes` file:

   ```
   *.slx -crlf -diff -merge
   *.mdl -crlf -diff -merge
   *.mat -crlf -diff -merge
   *.mlx -crlf -diff -merge
   ```

These lines specify not to try automatic line feed, diff, and merge attempts for MATLAB and Simulink files.

3 Check for other file types you use in your projects that you also need to register as binary to avoid corruption at check-in. Check for files such as `.mat`, `.mdlp`, `.slxp`, `.p`, MEX-files (`.mexa64`, `.mexmaci64`, `.mexw64`), `.xlsx`, `.jpg`, `.pdf`, `.docx`, etc. Add a line to the attributes file for each file type you need.

Examples:

```
*.mdlp -crlf -diff -merge
*.slxp -crlf -diff -merge
*.sldd -crlf -diff -merge
*.p -crlf -diff -merge
*.mexa64 -crlf -diff -merge
*.mexw64 -crlf -diff -merge
*.mexmaci64 -crlf -diff -merge
*.xlsx -crlf -diff -merge
*.docx -crlf -diff -merge
*.pdf -crlf -diff -merge
*.jpg -crlf -diff -merge
*.png -crlf -diff -merge
```

4 Restart MATLAB so you can start using the Git client with Simulink Project.

After you have installed a command-line Git client and registered your model files as binary, you can use the merging features of Git in Simulink Project.

Add Git Submodules

To reuse code from another repository, you can specify Git submodules to include in your project.

To clone an external Git repository as a submodule:

1 On the Simulink Project tab, in the Source Control section, click **Submodules**.

2 In the Submodules dialog box, click the **+** button.

3 In the Add Submodule dialog box, in the **Remote** box, specify a repository location. Optionally, click **Validate**.

4 In the **Path** box, specify a location for the submodule in your project and click **OK**. The Submodules dialog box displays the status and details of the submodule.

5 Check the status message, and click **Close** to return to your project.

Use Fetch to Get Latest Submodule Version

When you want to manage the added submodule, open the Submodules dialog box.

1 To get the latest version of a submodule, in the Submodules dialog box, click **Fetch**.

2 After fetching, you must merge. Check the **Status** message in the Submodules dialog box for information about your current branch relative to the remote tracking branch in the repository. When you see the message `Behind`, you need to merge in changes from the repository to your local branch.

3 Click **Branches** and merge in the origin changes to your local branch using the Branches dialog box. See "Pull, Fetch, and Merge" on page 19-57.

Use Push to Send Changes to the Submodule Repository

If you make changes in your submodule and want to send changes back to the repository:

1 Perform a local commit in the parent project.

2 Open the Submodules dialog box and click **Push**.

If you want other project users to obtain your changes in the submodule when they clone the parent project, make sure the index and head match.

1 In the Submodules dialog box, check the index and head values. The index points to the head commit at the time you first cloned the submodule, or when you last committed the parent project repository. If the index and head do not match, you must update the index.

2 To update the index, commit your changes in the parent project, and then click **Push** in the Submodules dialog box. This action makes the index and head the same.

Disable Source Control

Disabling source control is useful when you are preparing a project to create a template from it, and you want to avoid accidentally committing unwanted changes.

1. On the Simulink Project tab, in the Source Control section, click the **Details** button for your source control. For example, **SVN Details** or **Git Details**.
2. Change the selection from the current source control to `No source control integration`.
3. Click **Reload**.

Note Source control tools create files in the project folders (for example, SVN creates an `.svn` folder), so you can put the project back under the same source control only by selecting your previous source control from the list.

See Also

Related Examples

- “Change Source Control” on page 19-27

- “Add a Project to Source Control” on page 19-6

Change Source Control

Changing source control is useful when you want to create a new local repository for testing and debugging.

1. Prepare your project by checking for any updates from the existing source control tool repository and committing any local changes.
2. On the **Simulink Project** tab, click **Share** > **Zip Archive** to save a zip file containing the project without any source control information.
3. On the **Simulink Project** tab, click **New**, and then in the start page, click **Archive** to create a new project from the archived project.
4. On the Simulink Project tab, in the Source Control section, click **Use Source Control**.
5. Click **Add project to source control** and then select a new source control. For details, see "Add a Project to Source Control" on page 19-6.

Tip To avoid accidentally committing changes to the previous source control, delete the original sandbox.

Write a Source Control Integration with the SDK

Tip You can check for updated source control integration downloads on the Simulink Projects Web page: `https://www.mathworks.com/discovery/simulink-projects.html`

The file exchange provides a Software Development Kit (SDK) that you can use to integrate Simulink Projects with third-party source control tools. See http://www.mathworks.com/matlabcentral/fileexchange/61483-source-control-integration-software-development-kit.

The SDK provides instructions for writing an integration to a source control tool that has a published API you can call from Java®.

You must create a `.jar` file that implements a collection of Java interfaces and a Java Manifest file, that defines a set of required properties.

The SDK provides example source code, Javadoc, and files for validating, building, and testing your source control integration. Build and test your own interfaces using the example as a guide. Then you can use your source control integration with Simulink Projects. Download the SDK and follow the instructions.

After you write a source control integration, see “Add a Project to Source Control” on page 19-6.

More About

- “About Source Control with Projects” on page 19-2

Retrieve a Working Copy of a Project from Source Control

Create a new local copy of a project by retrieving files from source control.

1. From MATLAB, on the **Home** tab, click **Simulink**, or select **New** > **Simulink Project**.

   Alternatively, on the **Simulink Project** tab, in the **File** section, click **New**.

2. In the start page, click the **Source Control** template. Click the title to read the description, then click **Create Project**.

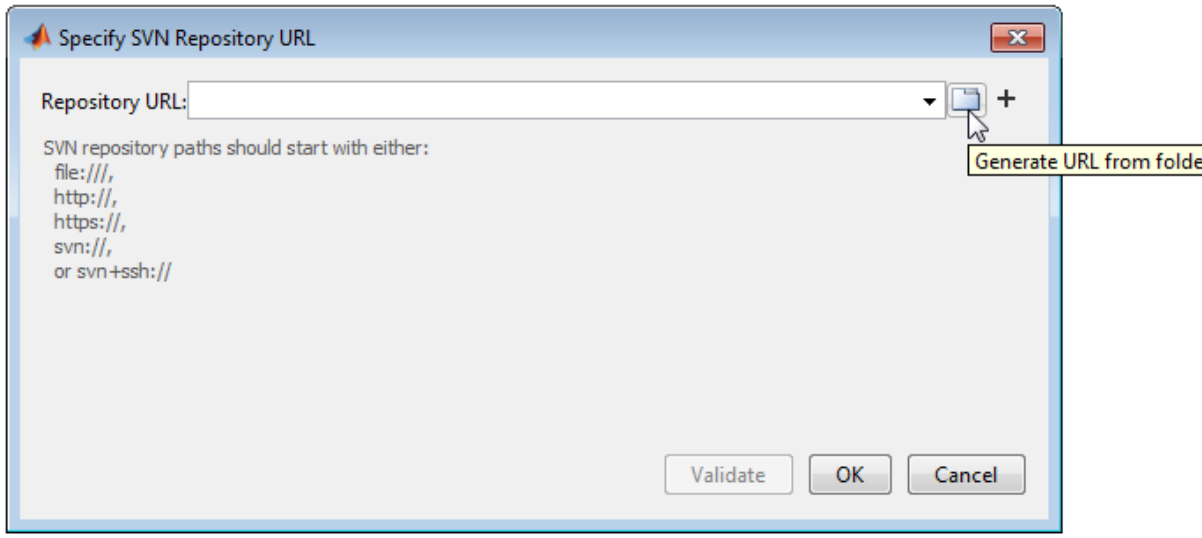
   Alternatively, in the start page, under **Projects** in the left list, click **Source Control**.

3. In the Project Retriever dialog box, select the source control interface from the **Source control integration** list.

   - To use SVN, leave the default `Built-In SVN Integration`.
   - To use Git, select `Git`.

4. If you know your repository location, you can paste it into the **Repository Path** box and proceed to step 8. Click **Change** to browse for and validate the repository path to retrieve files from.

5 In the dialog box, specify the repository URL by entering or pasting a URL in the box, using the list of recent repositories, or by using the **Generate URL from folder** button .



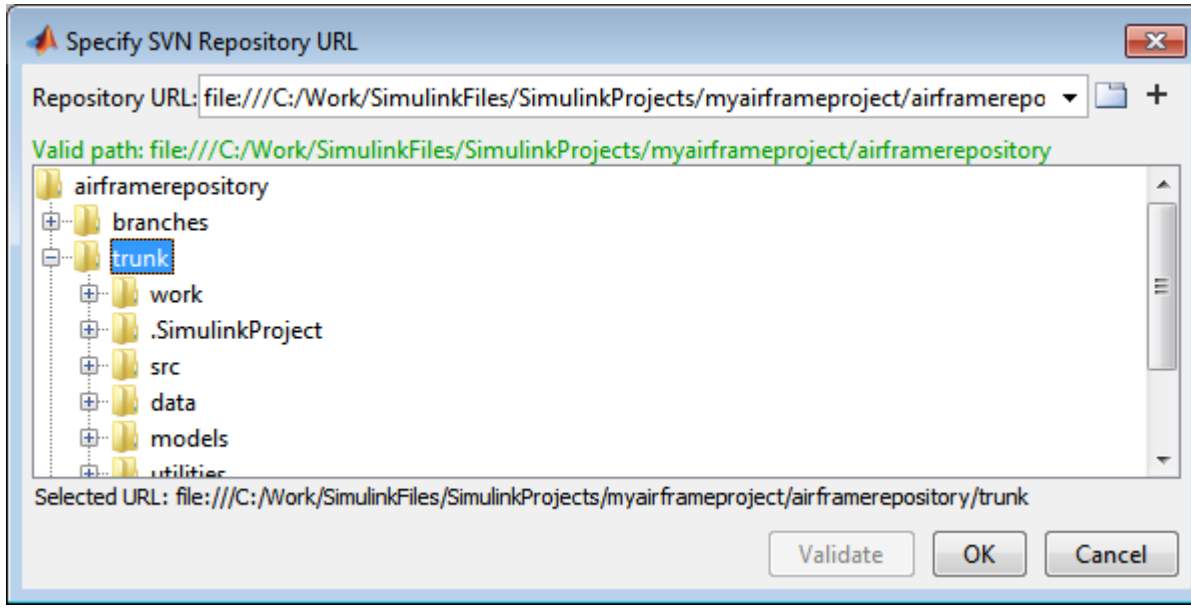
Caution Use `file://` URLs only for single-user repositories. For more information, see "Share a Subversion Repository" on page 19-17.

6 Click **Validate** to check the repository path.

If the path is invalid, check the URL against your source control repository browser.

7 If you see an authentication dialog box for your repository, enter login information to continue.

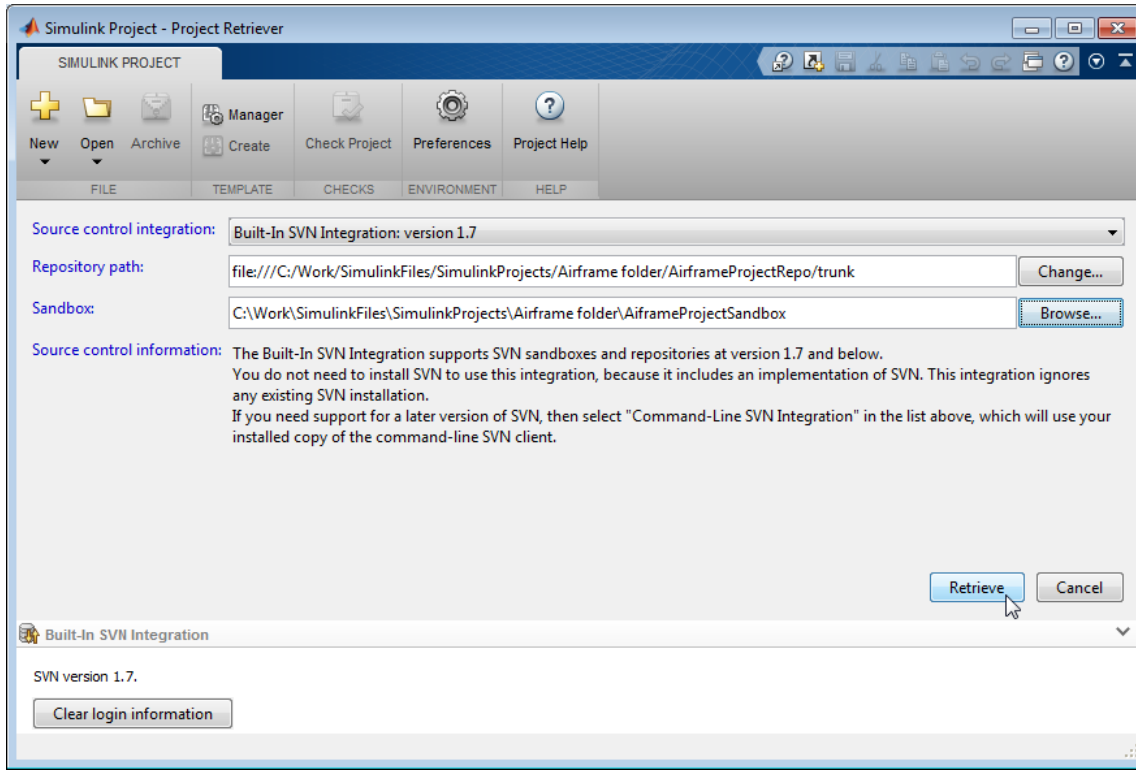
8 If necessary, select a deeper folder in the repository tree. You might want to check out from `trunk` or from a branch folder under `tags`, if your repository contains tagged versions of files. The example shows `trunk` selected, and the **Selected URL** displays at the bottom of the dialog box. The retriever uses this URL when you click **OK**.



9 When you have finished specifying the URL path you want to retrieve, click **OK**.

10 In the Project Retriever, select the sandbox folder where you want to put the retrieved files for your new project, and click **Retrieve**.

Caution Use local sandbox folders. Using a network folder with SVN is slow.



The source control pane (for example, **Built-In SVN Integration** or **Git**) displays messages as the project retrieves the files from source control.

If your repository already contains a Simulink project, the project is ready when the tool finishes retrieving files to your selected sandbox folder.

11 If your sandbox does not yet contain a Simulink project, then a dialog box prompts you to check whether you want to create a project in the folder. Click **Yes** to continue creating the project.

The new project controls appear.

a In the new project controls, enter a project name.

b Click **Create** to finish creating the new project in your new sandbox.

Simulink Project displays the empty Project Files list for the chosen project root. The project does not yet contain any files. For next steps, see “Add Files to the Project” on page 16-23.

Note To update an existing project sandbox from source control, see “Update Revisions of Project Files” on page 19-39.

Troubleshooting

If you encounter errors like `OutOfMemoryError: Java heap space`, for example when cloning big Git repositories, then edit your MATLAB preferences to increase the heap size.

1. On the **Home** tab, in the **Environment** section, click **Preferences**.
2. Select **MATLAB > General > Java Heap Memory**.
3. Move the slider to increase the heap size, and then click **OK**.
4. Restart MATLAB.

More About

- “About Source Control with Projects” on page 19-2

Tag and Retrieve Versions of Project Files

With SVN, you can use tags to identify specific revisions of all project files. Not every source control has the concept of tags. To use tags with SVN, you need the standard folder structure in your repository and you need to check out your files from `trunk`. See "Standard Repository Structure" on page 19-18.

1. On the Simulink Project tab, in the Source Control section, click **Tag**.
2. Specify the tag text and click **OK**. The tag is added to every project file.

   Errors appear if you do not have a `tags` folder in your repository.

Note You can retrieve a tagged version of your project files from source control, but you cannot tag them again with a new tag. You must check out from `trunk` to create new tags.

To retrieve the tagged version of your project files from source control:

1. On the **Simulink Project** tab, click **New**, and then in the start page, click **Source Control**.
2. Click **Change** to select the Repository Path that you want to retrieve files from.

   The Specify Repository URL dialog box opens.

   a. Select a recent repository from the **Repository URL** list, or click the **Generate URL from folder** button  to browse for the repository location.

   b. Click **Validate** to show the repository browser.

   c. Expand the `tags` folder in the repository tree, and select the tag version you want. Verify there is a `.SimulinkProject` folder under the chosen tag subfolder.

   d. Click **OK** to continue and return to the Project Retriever.
3. Select the sandbox folder to receive the tagged files. You must use an empty sandbox folder. (If you try to retrieve tagged files into an existing sandbox, an error appears.)
4. Click **Retrieve**.

Alternatively, you can use labels to apply any metadata to files and manage configurations. You can group and sort by labels, and create batch jobs to export files by label. See “Add Labels to Files” on page 17-26.

With Git, you can switch branches. See “Branch and Merge Files with Git” on page 19-61.

Refresh Status of Project Files

To check for locally modified project files, on the Simulink Project tab, in the Source Control section, click **Refresh**.

Refresh queries the local sandbox state and checks for changes made with another tool outside of MATLAB.

Note For SVN, **Refresh** does not contact the repository. To check the repository for later revisions, use **Check for Modifications** instead. To get the latest revisions, use **Update** instead. See "Check for Modifications" on page 19-38 and "Update Revisions of Project Files" on page 19-39.

The buttons in the Source Control section of the Simulink Project tab apply to the whole project.

Refresh refreshes the view of the source control status for all files under `projectroot`. Clicking **Refresh** updates the information shown in the **Revision** column and the source control status column (for example, **SVN**, or **Git** columns). Hover over the icon to see the tooltip showing the source control status of a file, e.g., **Modified**.

See Also

Related Examples

- "Check for Modifications" on page 19-38
- "Update Revisions of Project Files" on page 19-39
- "Revert Changes" on page 19-53

Check for Modifications

To check the status of individual files for modifications, right-click files in Simulink Project and select **Source Control > Check for Modifications**. Use this to find out if the repository version has moved ahead.

With SVN, this option contacts the repository to check for external modifications. Simulink Project compares the revision numbers of the local file and the repository version. If the revision number in the repository is larger than that in the local sandbox folder, then Simulink Project displays `(not latest)` next to the revision number of the local file.

If your local file is not the latest version, get the latest revisions from the repository by clicking **Update**. See “Update Revisions of Project Files” on page 19-39. You might need to resolve conflicts after updating. See “Resolve Conflicts” on page 19-66 and “Compare Revisions” on page 19-46.

To check for locally modified files, use **Refresh** instead. See “Refresh Status of Project Files” on page 19-37.

Update Revisions of Project Files

In this section...

Update Revisions with SVN

In Simulink Project, to get the latest revisions of all project files from the source control repository, click **Update** in the source control section of the Simulink Project tab.

Use **Update** to get other people's changes from the repository and find out about any conflicts. If you want to back out local changes, use **Revert Project** instead. See "Discard Local Changes" on page 19-53.

After you update, the project displays a dialog box listing all the files that have changed on disk. You can control this behavior using the project preference **Show changes on source control update**.

When your project uses SVN source control, **Update** calls `svn update` to bring changes from the repository into your working copy. If there are other people's changes in your modified files, SVN adds conflict markers to the file. SVN preserves your modifications.

Caution Ensure you have registered SLX files as binary with SVN before using **Update**. If you do not, SVN conflict markers can corrupt your SLX file. Simulink Project warns you about this when you first click **Update** to ensure you protect your model files. See "Register Model Files with Subversion" on page 19-13.

You must resolve any conflicts before you can commit. See "Resolve Conflicts" on page 19-66.

Update Revisions with Git

If you are using Git source control, click **Pull** in the source control pane.

Caution Ensure you have registered SLX files as binary with Git before using **Pull**. If you do not, conflict markers can corrupt your SLX file. See "Set Up Git Source Control" on page 19-20.

Pull fetches the latest changes and merges them into your current branch. If you are not sure what is going to come in from the repository, use fetch to examine the changes first and then merge the changes manually.

Pull might fail if you have conflicts. With a complicated change you might want to create a branch from the origin, make some compatibility changes, then merge that branch into the main tracking branch. For next steps, see "Pull, Push, and Fetch Files with Git" on page 19-56.

Update Selected Files

To update selected files, right-click and select the **Update** command for the source control system you are using. For example, if you are using SVN, select **Source Control > Update from SVN** to get fresh local copies of the selected files from the repository.

Get SVN File Locks

To ensure users remember to get a lock on model files before editing, you can configure SVN to make model files read only. Follow the steps in "Enforce SVN Locking Model Files Before Editing" on page 19-17. After you configure SVN to make files with certain extensions read only, then users must get a lock on these read-only files before editing.

1. In Simulink Project, in any Files view, select the files you want to check out.
2. Right-click the selected files and select **Source Control > Get File Lock**.

   Get File Lock is for SVN. This option does not modify the file in your local sandbox. Git does not have locks.

   A lock symbol appears in the SVN source control column. Other users cannot see the lock symbol in their sandboxes, but they cannot get a file lock or check in a change when you have the lock.

Note To get a fresh local copy of the file from the repository, select **Update from SVN**.

In the Simulink Editor, if an open model belongs to a project under SVN, you can get a lock by selecting **File > Simulink Project > Get File Lock**.

If you see an SVN message reporting a `working copy locked` error, remove stale locks by clicking **SVN Cleanup** in the Source Control section on the Simulink Project tab. SVN uses working copy locks internally and they are not the file locks you control using **Get File Lock**.

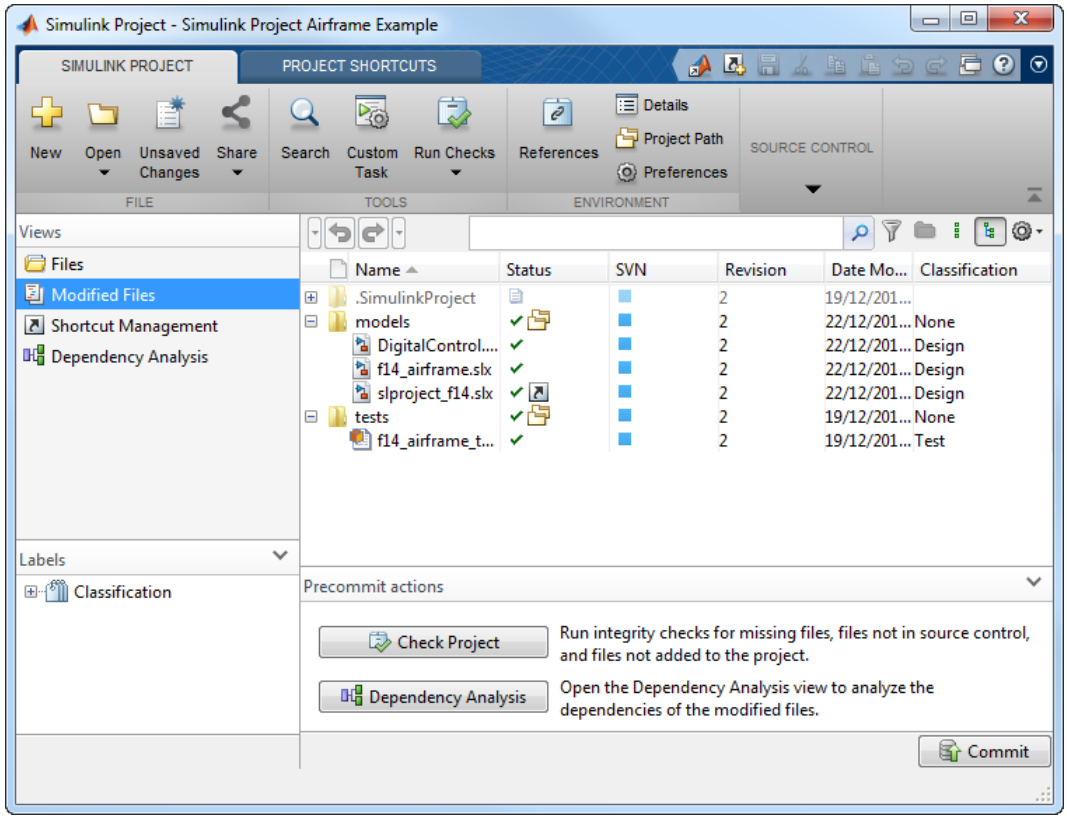
- "Commit Modified Files to Source Control" on page 19-51

More About

- “About Source Control with Projects” on page 19-2

View Modified Files

In Simulink Project, select the Modified Files view. The Modified Files node is visible only if you are using source control integration with your project.



If you need to update the modified files list, click **Refresh** in the source control section of the Simulink Project tab.

Use the Modified Files view to review, analyze, label, and commit modified files. Lists of modified files are sometimes called changesets. You can perform the same operations in the Modified Files view as you can in other file views.

Tip In the Modified Files view, it can be useful to switch to List view by clicking the List button 

You can identify modified or conflicted folder contents using the source control summary status. In the Files views, folders display rolled-up source control status. This makes it easier to locate changes in files, particularly conflicted files. You can hover over the source control status (e.g., the **SVN** or **Git** column) for a folder to view a tooltip displaying how many files inside are modified, conflicted, added or deleted.

Project Definition Files

The files in `.SimulinkProject` are project definition files generated by your changes. The project definition files allow you to add metadata to files without checking them out, for example, by creating shortcuts, adding labels, and adding a project description. Project definition files also define the files that are added to your project.

Any changes you make to your project (for example, to shortcuts, labels, categories, or files in the project) generate changes in the `.SimulinkProject` folder. These files store the definition of your project in XML files whose format is subject to change.

You do not need to view project definition files directly, except when the source control tool requires a merge. The files are shown so that you know about all the files being committed to the source control system. See “Resolve Conflicts” on page 19-66.

If you want to change project definition file from the type used when the project was created, see `export`.

If you want to use projects with configurations that do not allow folder names to start with “.”, then you can choose an underscore instead. Use the project preferences to change the project definition folder for new projects to `_SimulinkProject`.

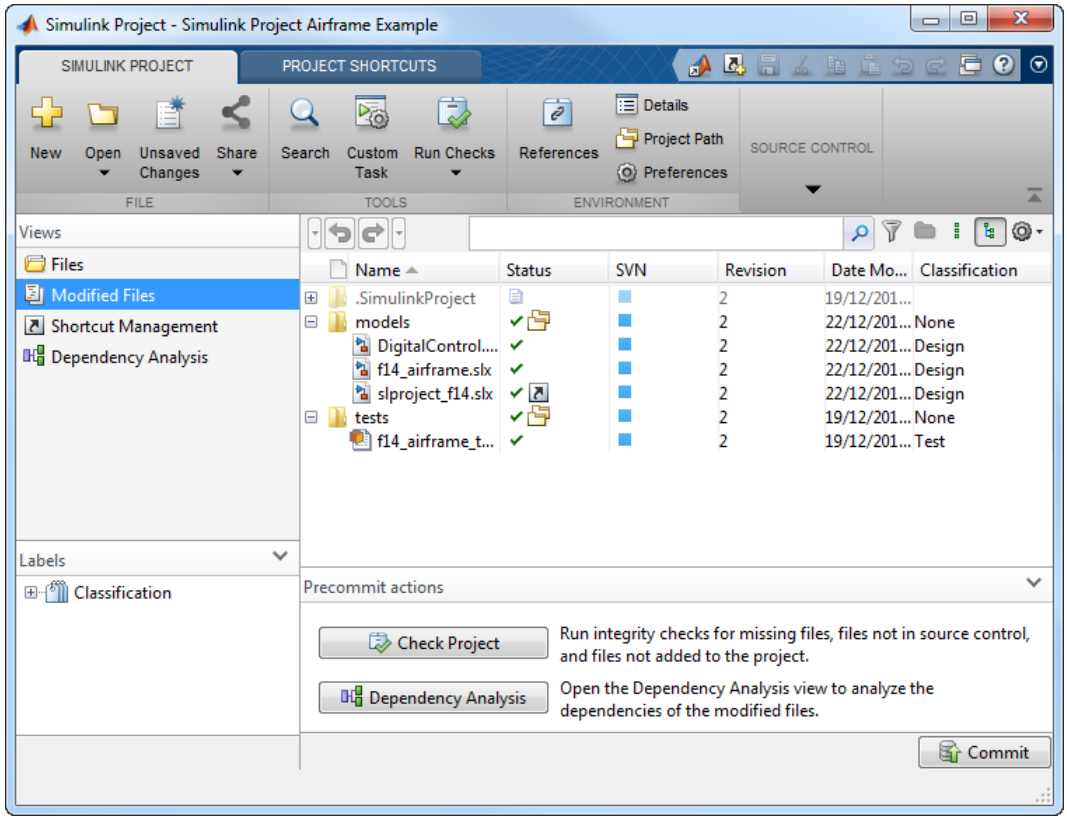
- “Commit Modified Files to Source Control” on page 19-51

More About

- “About Source Control with Projects” on page 19-2

Compare Revisions

To review changes in modified files in Simulink Project, select the Modified Files view.



If you need to update the modified files list, click **Refresh** in the source control section of the Simulink Project tab.

To review changes in modified files, right-click selected files in any view in Simulink Project and:

- Select **Compare** > **Compare to Ancestor** to run a comparison with the last checked-out version in the sandbox (SVN) or against the local repository (Git). The Comparison Tool displays a report.
- To compare other revisions of a file, select **Compare** > **Compare to Revision**. In the Compare to Revisions dialog box, you can view information about who previously

committed the file, when they committed it, and the log messages. To view a comparison report, select the revisions you want to compare. You can either:

  - Select a revision and click **Compare to Local**.
  - Select two revisions and click **Compare Selected**.
- To browse the revision history of a file, select **Source Control > Show Revisions**. In the File Revisions dialog box, view information about who previously committed the file, when they committed it, and the log messages.

Note In the Simulink Editor, if an open model, library, or chart belongs to a project under source control, you can view changes by selecting **File > Simulink Project > Compare to Ancestor** or **Compare to Revision**.

When you compare to a revision or ancestor, the MATLAB Comparison Tool opens a report comparing the modified version of the file in your sandbox with the selected revision or against its ancestor stored in the version control tool.

Comparison type depends on the file you select. If you select a Simulink model, this command runs a Simulink model comparison.

When reviewing changes, you can merge Simulink models from the Comparison Tool report. See “Merge Text Files” on page 19-68 and “Merge Models” on page 19-69.

To examine the dependencies of modified files, see “Perform Impact Analysis” on page 18-7.

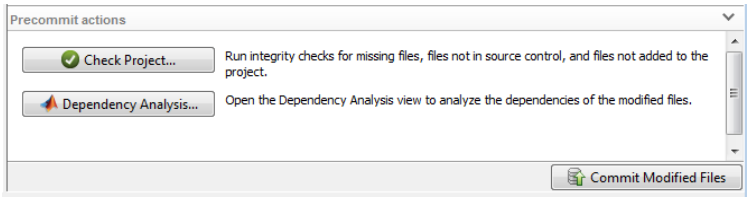
Run Project Checks

In Simulink Project, you can run checks from any project view by clicking **Run Checks** > **Check Project** on the **Simulink Project** tab. The project checks can find problems with project integrity such as missing files, unsaved files, or files not under source control.

For details on problems the checks can fix, see "Work with Derived Files in Projects" on page 19-71, "Upgrade Model Files to SLX and Preserve Revision History" on page 17-19, and "Check Dependency Results and Resolve Problems" on page 18-17.

The Precommit actions pane in the Modified Files view contains tools to use before committing your changes to source control, including **Check Project**.



- Click **Check Project** to check the integrity of the project. For example, is everything under source control in the project? Are all project files under source control? A dialog box reports results. You can click for details and follow prompts to fix problems.

  For an example showing how the checks can help you, see "Upgrade Model Files to SLX and Preserve Revision History" on page 17-19.
- If you want to check for required files, click **Dependency Analysis** to analyze the dependencies of the modified files.

  Use the dependency tools to analyze the structure of your project. See "Perform Impact Analysis" on page 18-7.

Note The files in `.SimulinkProject` are project definition files generated by your changes. See "Project Definition Files" on page 19-44.

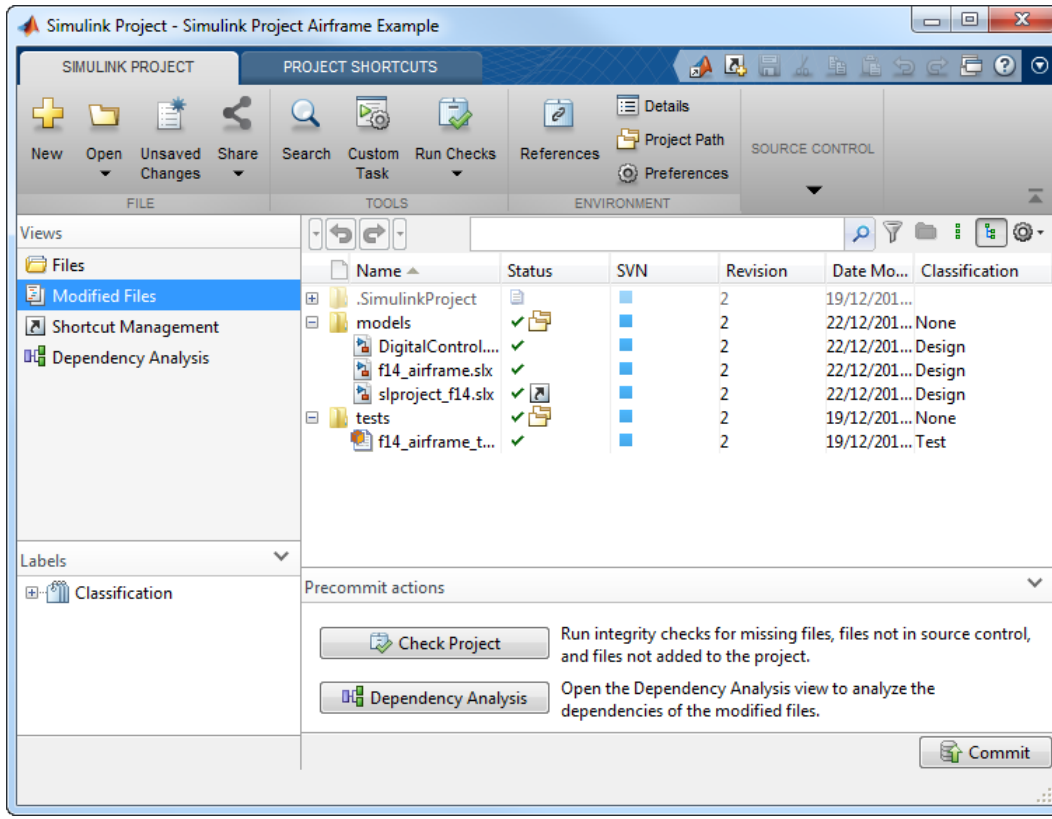
Commit Modified Files to Source Control

Before you commit modified files, review changes and consider precommit actions. See “Compare Revisions” on page 19-46 and “Run Project Checks” on page 19-49.

1 In Simulink Project, select the Modified Files view.



If you need to update the modified files list, click **Refresh** in the source control section of the Simulink Project tab.

2 Click **Commit** to check in all files in the modified files list. You can click **Commit** in either the modified files view or on the Simulink Project tab.

If you are using SVN source control, this commits changes to your repository.

If you are using Git source control, this commits to your local repository. To commit to the remote repository, see “Pull and Push” on page 19-56.

3 Enter comments in the dialog box if you want, and click **Submit**.

4 A message appears if you cannot commit because the repository has moved ahead. Before you can commit the file, you must update its revision up to the current HEAD revision. If you are using SVN source control, click **Update**. If you are using Git source control, click **Pull**. Resolve any conflicts before you commit.

Note You can commit individual files using the context menu, by selecting **Source Control** > **Commit**. However if you commit individual files, you risk not committing the related project definition files that keep track of your files. Instead, use the Modified Files view to commit all related changes.

More About

- “About Source Control with Projects” on page 19-2

Revert Changes

In this section...

Discard Local Changes

With SVN, if you want to roll back local changes in a particular file, in Simulink Project, right-click the file and select **Source Control > Discard Local Changes and Release Locks** to release locks and revert to the version in the last sandbox update (that is, the last version you synchronized or retrieved from the repository).

In the Simulink Editor, if an open model belongs to a project under source control, you can revert changes by selecting **File > Simulink Project > Discard Local Changes and Release Locks**.

To abandon all local changes, in Simulink Project select all the files in the Modified Files list, then right-click and select **Discard Local Changes and Release Locks**.

With Git, right-click a file and select **Source Control > Revert Local Changes**. Git does not have locks. To remove all local changes, click **Branches** in the **Git** pane and click **Revert to Head**.

Revert a File to a Specified Revision

1. Right-click a file and select **Source Control > Revert using SVN** or **Source Control > Revert using Git**.
2. In the Revert Files dialog box, choose a revision to revert to. Select a revision to view information about the change such as the author, date, log message, and the list of modified files also in the change set.
3. Click **Revert**.

   Simulink Project reverts the selected file.
4. If you revert a file to an earlier revision and then make changes, you cannot commit the file until you resolve the conflict with the repository history.

With SVN, if you try to commit the file, you see a message that it is out of date. Before you can commit the file, you must update its revision up to the current HEAD revision. click **Update** in the source control section on the Simulink Project tab.

The project marks the file as conflicted because you have made changes to an earlier version of the file than the version in the repository.

5 With either SVN or Git, to examine conflicts, right-click and select **View Conflicts**.

Decide how to resolve the conflict or to keep your changes to the reverted file. See "Resolve Conflicts" on page 19-66.

6 After you have resolved the conflict, mark the conflict resolved, either by using the merge tool or manually by right-clicking the file and selecting **Source Control** > **Mark Conflict Resolved**.

7 Select the Modified Files view and click **Commit**.

Revert the Project to a Specified Revision

With SVN, inspect the project revision information by clicking **Show Log** in the in Source Control section on the Simulink Project tab. In the Log dialog box, each revision in the list is a change set of modified files. Select a revision to view information about the change such as the author, date, log message and the list of modified files.

To revert the project:

1 On the Simulink Project tab, in the Source Control section, click **Revert Project**.

2 In the Revert Files dialog box, choose a revision to revert to.

Each revision in the list is a change set of modified files. Select a revision to view information about the change such as the author, date, log message and the list of modified files.

3 Click **Revert**.

Simulink Project displays progress messages in the SVN pane as it restores the project to the state it was in when the selected revision was committed. Depending on the change set you selected, all files do not necessarily have a particular revision number or matching revision numbers. For example, if you revert a project to revision 20, all files will show their revision numbers when revision 20 was committed (20 or lower).

With Git, you can switch branches. See “Branch and Merge Files with Git” on page 19-61.

Related Examples

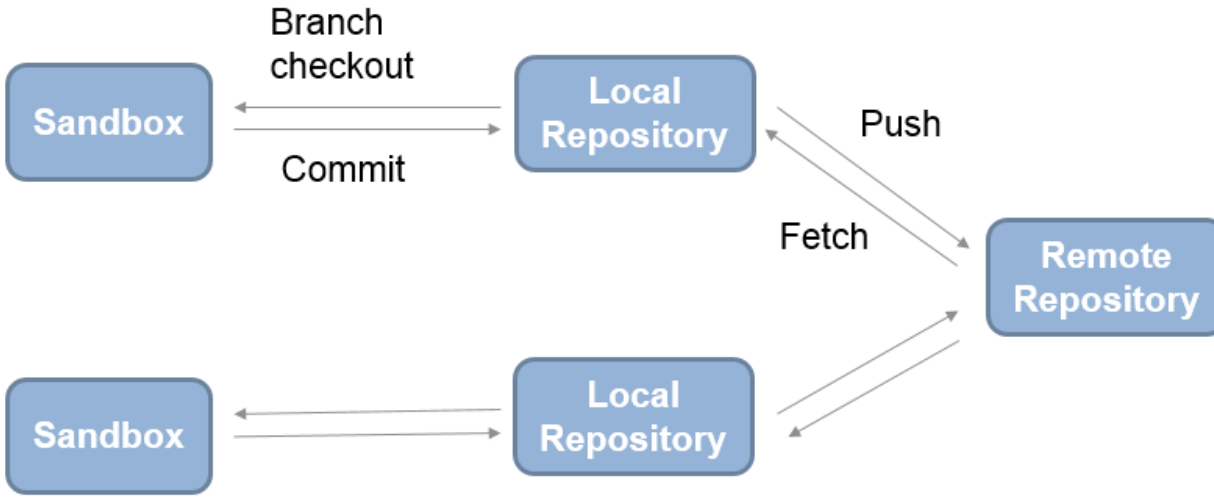
- “Resolve Conflicts” on page 19-66

Pull, Push, and Fetch Files with Git

In this section...

Pull and Push

Use this workflow to work with a Git project connected to a remote repository. With Git, there is a two-step workflow: commit local changes, and then push to the remote repository. In Simulink Project, the only access to the remote repository is through the **Pull**, **Push**, and **Fetch** buttons. All other actions use the local repository (such as **Check for Modifications**, **Compare to Ancestor**, and **Commit**). This diagram represents the Git workflow.



1 To get the latest changes, on the Simulink Project tab, in the Source Control section, click **Pull**. Pull fetches the latest changes and merges them into your current branch.

Note Before you can merge, you must install command-line Git on your system path and register model files as binary to prevent Git from inserting conflict markers. See "Install Command-Line Git Client" on page 19-22.

2. To create branches to work on, on the Simulink Project tab, in the Source Control section, click **Branches**. Create branches in the Branches dialog box, as described in "Branch and Merge Files with Git" on page 19-61.
3. When you want to commit changes, select the Modified Files view and click **Commit**. The changes are committed to your current branch in your local repository. Check the **Git** pane for information about the current branch. You see the message `Ahead` when you commit local changes that have moved ahead of the remote tracking branch.

   ```
   Current branch: master
   Branch status: SAFE
   Ahead of /origin/master
   ```

4. To send your local commits to the remote repository, on the Simulink Project tab, in the Source Control section, click **Push**.
5. A message appears if you cannot push your changes directly because the repository has moved on. Click **Fetch** to fetch changes from the remote repository. Merge branches and resolve conflicts, and then you can push your changes. See "Pull, Fetch, and Merge" on page 19-57.

Pull, Fetch, and Merge

Use **Fetch** to get changes and merge manually. Use **Pull** instead to fetch the latest changes and merge them into your current branch.

Note Before you can merge branches, you must install command-line Git on your system path and register model files as binary to prevent Git from inserting conflict markers. See "Install Command-Line Git Client" on page 19-22.

Pull fetches the latest changes and merges them into your current branch. If you are not sure what is going to come in from the repository, use fetch instead to examine the changes, and then merge the changes manually.

Pull might fail if you have conflicts. With a complicated change you might want to create a branch from the origin, make some compatibility changes, then merge that branch into the main tracking branch.

To fetch changes from the remote repository, click **Fetch** on the Simulink Project tab.

Fetch updates all of the origin branches in the local repository.

Note When you click **Fetch**, your sandbox files are not changed. To see others' changes, you need to merge in the origin changes to your local branches.

Check the Git pane for information about your current branch relative to the remote tracking branch in the repository. When you see the message `Behind`, you need to merge in changes from the repository to your local branch.

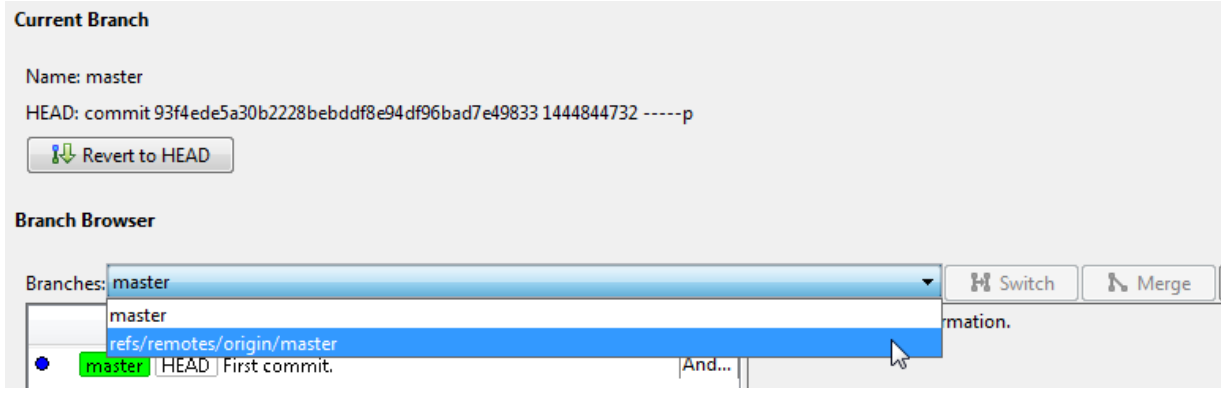
For example, if you are on the master branch and want to get changes from the master branch in the remote repository:

1. Click **Fetch**.

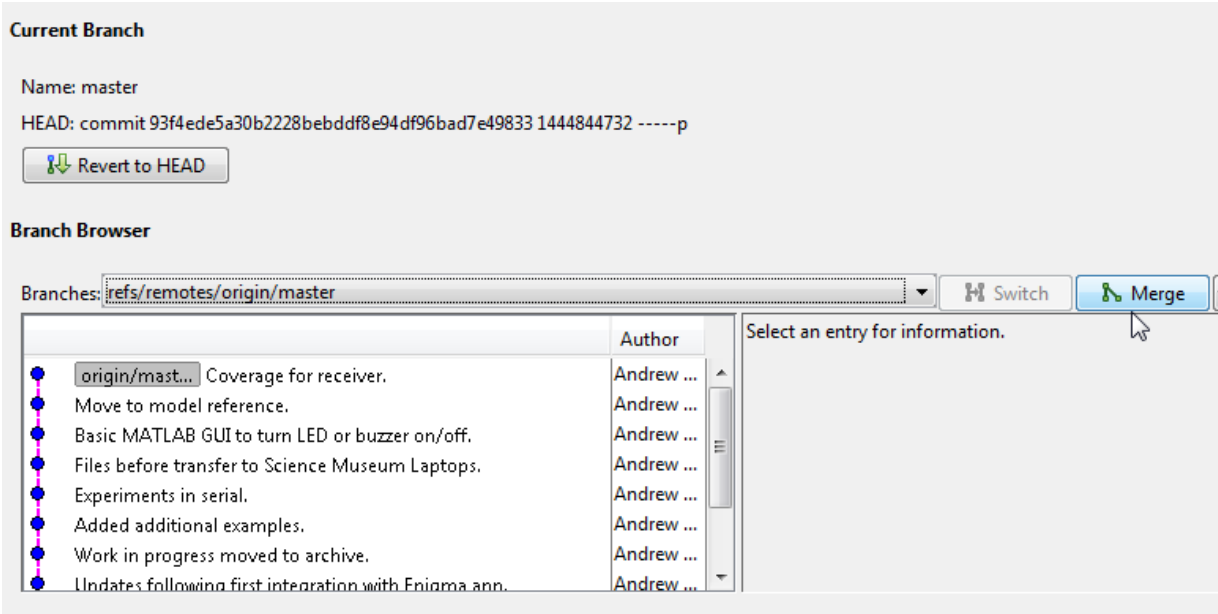
   Observe the message in the Git pane, `Behind /origin/master`. You need to merge in the changes from the repository to your local branch, using **Branches**.

   Current branch: master
   Branch status: SAFE
   Behind /origin/master

2. Click **Branches**.
3. In the Branches dialog box, in the **Branches** list, select **origin/master**.



4. Click **Merge**. This merges the origin branch changes into the master branch in your sandbox.



5 Close the Branches dialog box. Observe the message in the Git pane now says `Coincident with /origin/master`. You can now view the changes fetched and merged from the remote repository in your local sandbox files.

When you fetch and merge, you might need to resolve conflicting changes. If the branch merge causes a conflict that Git cannot resolve automatically, an error dialog box reports that automatic merge failed. Resolve the conflicts before proceeding. See “Resolve Conflicts” on page 19-66.

Push Empty Folders

Using Git, you cannot add empty folders to source control, so you cannot select **Push** and then clone an empty folder. You can create an empty folder in Simulink Project, but if you push changes and then sync a new sandbox, then the empty folder does not appear in the new sandbox. You can instead run **Check Project** which creates the empty folder for you.

Alternatively, to push empty folders to the repository for other users to sync, create a `gitignore` file in the folder and then push your changes.

Branch and Merge Files with Git

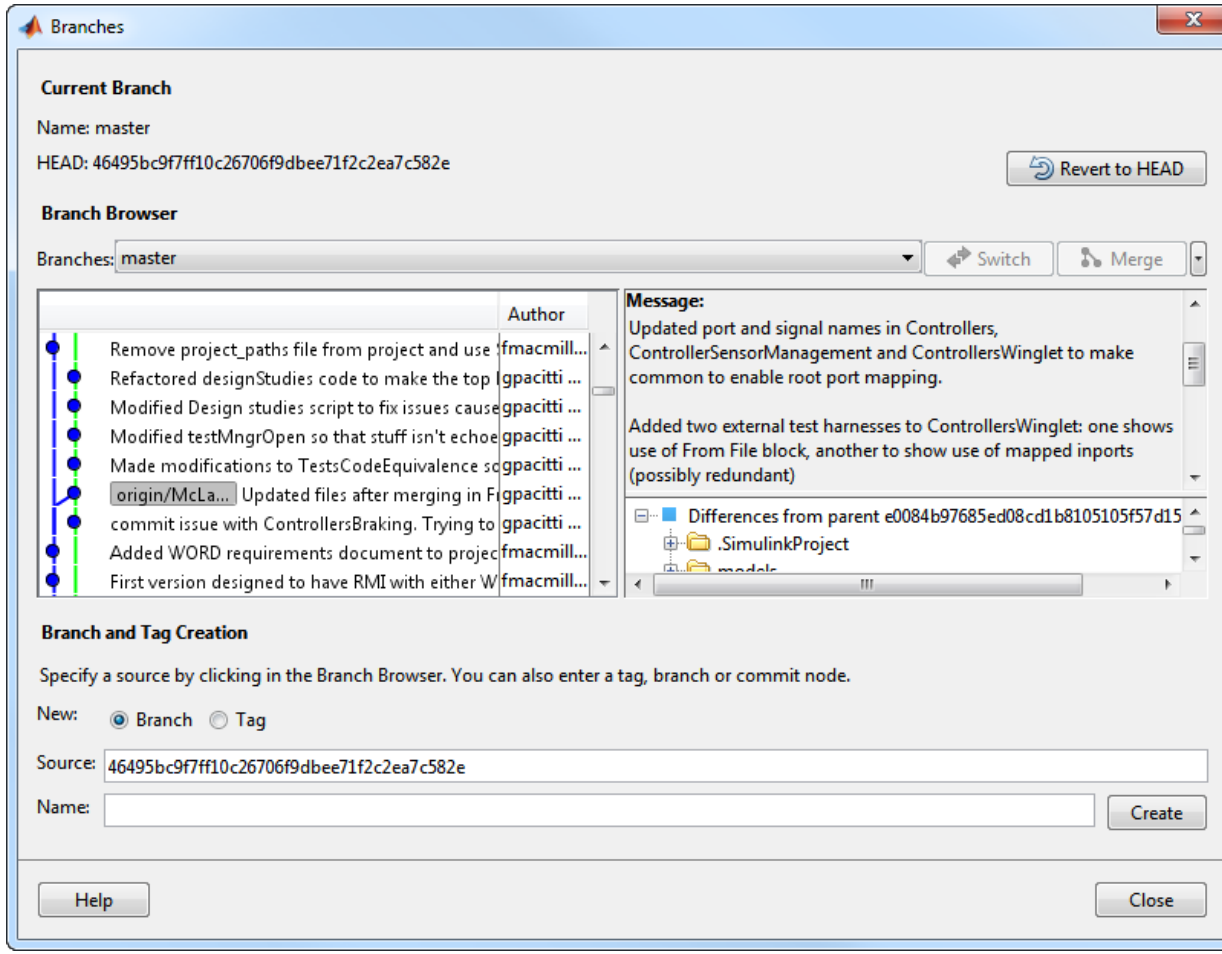
In this section...

Create a Branch

1 In a Simulink Project using Git source control, click **Branches** on the Simulink Project tab. The Branches dialog box appears, where you can view, switch, create, and merge branches.

Tip You can inspect information about each commit node. Select a node in the Branch Browser diagram to view the author, date, commit message, and changed files.

The **Branches** pane in this figure shows an example branch history.



2 Select a source for the new branch. Click a node in the Branch Browser diagram, or enter a unique identifier in the Source text box. You can enter a tag, branch name, or a unique prefix of the SHA1 hash (for example, `73c637` to identify a specific commit). Leave the default to create a branch from the head of the current branch.

3 Enter a name in the **Branch name** text box and click **Create**.

4 To work on the files on your new branch, switch your project to the branch.

In the **Branches** drop-down list, select the branch you want to switch to and click **Switch**.

5 Close the Branches dialog box to return to Simulink Project and work on the files on your branch.

For next steps, see "Pull, Push, and Fetch Files with Git" on page 19-56.

Switch Branch

1 In Simulink Project, click **Branches**.

2 In the Branches dialog box, select the branch you want to switch to in the **Branches** list and click **Switch**.

3 Close the Branches dialog box to return to Simulink Project and work on the files on the selected branch.

Compare Branches and Save Copies

In the Branches dialog box, to examine differences from the parent, right-click a file in the tree under `Differences from parent` and select **Show Difference**. The project opens a comparison report.

If you want to examine added or deleted files, or to test how the code ran in previous versions, you can save a copy of the selected or parent files. Right-click a file and select **Save As** or **Save Parent As**.

Merge Branches

Before you can merge branches, you must install command-line Git on your system path and register model files as binary to prevent Git from inserting conflict markers. See "Install Command-Line Git Client" on page 19-22.

Tip After you use **Fetch**, you must merge. See "Pull, Fetch, and Merge" on page 19-57.

To merge any branches:

1 In Simulink Project, click **Branches**.

2 In the Branches dialog box, from the **Branches** drop-down list, select a branch you want to merge into the current branch, and click **Merge**.

3 Close the Branches dialog box to return to Simulink Project and work on the files on the current branch.

If the branch merge causes a conflict that Git cannot resolve automatically, an error dialog box reports that automatic merge failed. The Branch status in the **Git** pane displays `MERGING`. Resolve the conflicts before proceeding.

Caution Do not move or delete files outside of MATLAB because this can cause errors on merge.

Keep Your Version

1 To keep your version of the file, right-click the file and select **Mark Conflict Resolved**. The Branch status in **Git** pane displays `MERGE_RESOLVED`. The Modified Files list is empty, because you have not changed any file contents. The local repository index version and your branch version are identical.

2 Click **Commit** to commit your change that marks the conflict resolved.

View Conflicts in Branch Versions

If you merge a branch and there is a conflict in a model file, Git marks the file as conflicted and does not modify the contents. Right-click the file and select **View Conflicts**. Simulink Project opens a comparison report showing the differences between the file on your branch and the branch you want to merge into. Decide how to resolve the conflict. See “Resolve Conflicts” on page 19-66.

Revert to Head

To remove all local changes, in the Branches dialog box, click **Revert to Head**.

Delete Branches

1 In the Branches dialog box, from the **Branches** drop-down list, select a branch you want to delete. You cannot delete the current branch.

2 On the far right, click the down arrow and select **Delete Branch**.

Caution You cannot undo deleting a branch.

More About

- “About Source Control with Projects” on page 19-2

Resolve Conflicts

In this section...

Resolve Conflicts

If you and another user change the same file in different sandboxes or on different branches, a conflict message appears when you try to commit your modified files. Extract conflict markers if necessary, compare the differences causing the conflict, and resolve the conflict.

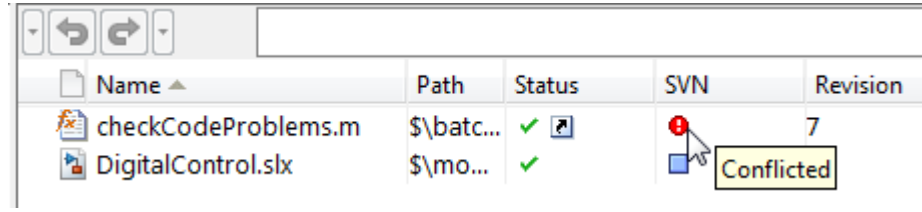
1 Look for conflicted files in the Modified Files view.

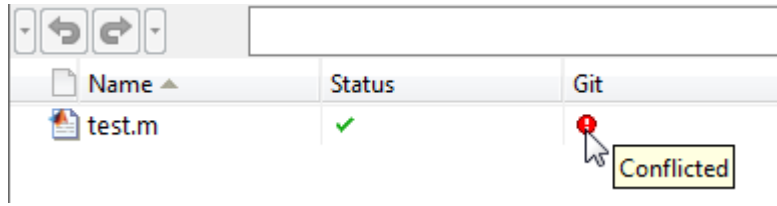
Identify conflicted folder contents using source control summary status. Folders display rolled-up source control status. This makes it easier to locate changes in files, particularly conflicted files. You can hover over the source control status for a folder to view a tooltip displaying how many files inside are modified, conflicted, added or deleted.

Tip Use the List view  to view files without needing to expand folders.

---

2 Check the source control status column (**SVN** or **Git**) for files with a red warning symbol, which indicates a conflict.





3 Right-click the conflicted file and select **View Conflicts** to compare versions.

4 Examine the conflict. Simulink Project opens a comparison report showing the differences between the conflicted files.

- For SVN, the comparison shows the differences between the file and the version of the file in conflict.
- For Git, the comparison shows the differences between the file on your branch and the branch you want to merge into.
- For model files, see "Merge Simulink Models from the Comparison Report" on page 21-16.

5 Use the comparison report to determine how to resolve the conflict.

To resolve conflicts you can:

- Use the report to merge changes between revisions.
- Decide to overwrite one set of changes with the other.
- Make changes manually from the project by editing files, changing labels, or editing the project description.

For details on using the Comparison Tool to merge changes between revisions, see "Merge Text Files" on page 19-68 and "Merge Models" on page 19-69.

6 When you have resolved the changes and want to commit the version in your sandbox, in Simulink Project, right-click the file and select **Source Control > Mark Conflict Resolved**. You can use the merge tool to mark the conflict resolved, or you can choose to manually mark the conflict resolved in the project.

For Git, the Branch status in the **Git** pane changes from `MERGING` to `SAFE`.

7 Select the Modified Files view and click **Commit**.

Merge Text Files

When comparing text files, you can merge changes from one file to the other. Merging changes is useful when resolving conflicts between different versions of files.

Conflict markers appear in a text comparison report like this:

```
<<<<<<< .mine
```

If your comparison report contains conflict markers, extract them before merging, as described in “Extract Conflict Markers” on page 19-69.

Tip You can merge only from left to right. When comparing to another version in source control, the right file is the version in your sandbox. The left file is either a temporary copy of the previous version or another version causing a conflict (e.g., *`filename`*`_theirs`). Observe the file paths of the left and right file at the top of the comparison report. Merge differences from the left (temporary copy) file to the right file to resolve conflicts.

---

1. In the Comparison Tool report, select a difference in the report and click **Merge**. The selected difference is copied from the left file to the right file.

   
   Merged differences display gray row highlighting and a green merge arrow.

   
   The merged file name at the top of the report displays the dirty flag (*`filename`*`.m*`) to show you that the file contains unsaved changes.

2. Click **Save Merged File** to save the file on the right. Check the file path of the right file in the comparison report. (To save to a different file, select **Save Merged File** > **Save Merged File As**). To resolve conflicts, save the merged file over the conflicted file.

3. If you want to inspect the files in the editor, click the line number links in the report.

Note If you make any further changes in the editor, the comparison report does not update to reflect changes and report links can become incorrect.

4 After merging to resolve conflicts, mark the conflict resolved and commit the changes, as described in "Resolve Conflicts" on page 19-66.

Merge Models

In the Comparison Tool report, you can merge changes between revisions. For details, see "Merge Simulink Models from the Comparison Report" on page 21-16.

After merging to resolve conflicts, the merge tool can mark the conflict resolved for you, or you can choose to manually mark the conflict resolved. Then commit the changes, as described in "Resolve Conflicts" on page 19-66.

Extract Conflict Markers

What Are Conflict Markers?

Source control tools can insert conflict markers in files that you have not registered as binary (e.g., text files). You can use Simulink Project tools to extract the conflict markers and compare the files causing the conflict. This process helps you to decide how to resolve the conflict.

Caution Register model files with source control tools to prevent them from inserting conflict markers and corrupting models. See "Register Model Files with Source Control Tools" on page 19-10. If your model already contains conflict markers, the project tools can help you to resolve the conflict, but only if you open the model from the project. Opening a model that contains conflict markers from the Current Folder or from a file explorer can fail because Simulink does not recognize conflict markers.

Conflict markers have the following form:

```
<<<<<<<["mine" file descriptor]
["mine" file content]
=======
```

```
["theirs" file content]
<<<<<<<["theirs" file descriptor]
```

If you try to open a file marked conflicted that contains conflict markers, the Conflict Markers Found dialog box opens. Follow the prompts to fix the file by extracting the conflict markers. After you extract the conflict markers, resolve the conflicts as described in "Resolve Conflicts" on page 19-66.

To view the conflict markers, in the Conflict Markers Found dialog box, click **Load File**. Do not try to load model files, because Simulink does not recognize conflict markers. Instead, click **Fix File** to extract the conflict markers.

By default, the project checks only conflicted files for conflict markers. You can change this preference to check all files or no files. Click **Preferences** in the Simulink Project tab to change the setting.

Extract Conflict Markers

When you open a conflicted file or select **View Conflicts**, the project checks files for conflict markers and offers to extract the conflict markers. The project checks only conflicted files for conflict markers unless you change your preferences setting.

However, some files that are not marked conflicted can still contain conflict markers. This can happen if you or another user marked a conflict resolved without removing the conflict markers and then committed the file. If you see conflict markers in a file that is not marked conflicted, you can remove the conflict markers.

1. In Simulink Project, right-click the file and select **Source Control > Extract Conflict Markers to File**.
2. Leave the default option to copy the "mine" revision over the conflicted file. Leave the **Compare** check box selected. Click **Extract**.
3. Use the Comparison Tool report as usual to continue to resolve the conflict.

Work with Derived Files in Projects

Best practice is to omit derived and temporary files from your project or exclude them from source control. Use **Check Project** in the Precommit Actions pane or the **Simulink Project** tab to check the integrity of the project. If you add the `slprj` folder to a project, the project checks advise you to remove this from the project and offer to make the fix.

Best practice is to exclude derived files, such as `.mex*`, the contents of the `slprj` folder, `sccprj` folder, or other code generation folders from source control, because they can cause problems. For example:

- With a source control that can do file locking, you can encounter conflicts. If `slprj` is under source control and you generate code, most of the files under `slprj` change and become locked. Other users cannot generate code because of file permission errors. The `slprj` folder is also used for simulation via code generation (for example, with model reference or Stateflow), so locking these files can have an impact on a team. The same problems arise with binaries, such as `.mex*`.
- Deleting `slprj` is often required. However, deleting `slprj` causes problems such as "not a working copy" errors if the folder is under some source control tools (for example, SVN).
- If you want to check in the generated code as an artifact of the process, it is common to copy some of the files out of the `slprj` cache folder and into a separate location that is part of the project. That way, you can delete the temporary cache folder when you need to. See `packNGo` to discover the list of generated code files, and use the project API to add to the project with appropriate metadata.
- The `slprj` folder can contain many small files. This can affect performance with some source control tools when each of those files is checked to see if it is up-to-date.

Customize External Source Control to Use MATLAB for Diff and Merge

You can customize external source control tools to use the MATLAB Comparison Tool for diff and merge. If you want to compare MATLAB files such as live scripts, MAT, SLX, or MDL files from your source control tool, then you can configure your source control tool to open the MATLAB Comparison Tool.

MATLAB Comparison Tool provides useful merge tools for MathWorks files and is compatible with all popular software configuration management and version control systems.

Set up your source control tool to use MATLAB as the application for diff and merge for the file extensions you want, for example, `.mlx`, `.mat`, `.slx`, or `.mdl`, by following these steps:

1 To get the required file paths and set the preference to reuse open MATLAB sessions, run this command in MATLAB:

```
comparisons.ExternalSCMLink.setup()
```

This command sets the MATLAB preference, under **Comparison**, called **Allow external source control tools to use open MATLAB sessions for diffs and merges**.

The command also displays the file paths you will copy and paste into your source control tool setup:

- On Windows:

  matlabroot\bin\win64\mlDiff.exe

  matlabroot\bin\win64\mlMerge.exe

- On Linux:

  matlabroot/bin/glnxa64/mlDiff

  matlabroot/bin/glnxa64/mlMerge

  On Mac:

  matlabroot/bin/maci64/mlDiff

matlabroot/bin/maci64/mlMerge

Where *matlabroot* is replaced with the full path to your installation, for example, `C:\Program Files\MATLAB\R2016b`.

2. Set up diff.

   a. In the MATLAB Command Window, copy the file path to `mlDiff`, for example, `C:\Program Files\MATLAB\R2016b\bin\win64\mlDiff.exe`.

   b. In your source control tool, locate the diff setting, and add an entry to specify what to do with a particular file extension (for example, `.slx`). Paste in the file path to `mlDiff` that you copied from the MATLAB Command Window.

   c. After the path to the script, or in the arguments box, add arguments to specify the input files. Look up the argument names specific to your source control tool. Specify the inputs for diffs, in this order: *leftFile*, *rightFile*.

      For example, for Tortoise SVN:

      ```
      "C:\Program Files\MATLAB\R2016b\bin\win64\mlDiff.exe" %base %mine
      ```

      For Perforce® P4V:

      ```
      "C:\Program Files\MATLAB\R2016b\bin\win64\mlDiff.exe" %1 %2
      ```

3. Set up merge.

   a. In the MATLAB Command Window, copy the file path to `mlMerge`.

   b. In your source control tool, locate the merge setting, and add an entry to specify what to do with a particular file extension (for example, `.slx`). Paste in the file path to `mlMerge` that you copied from the MATLAB Command Window.

   c. After the path to the script, or in the arguments box, add arguments to specify the input files. Look up the argument names specific to your source control tool. Specify the inputs for merges, in this order: *base*, *mine*, *theirs*, and *merged* target file.

      For example, for Tortoise SVN:

      ```
      "C:\Program Files\MATLAB\R2016b\bin\win64\mlMerge.exe" %base %mine %theirs %merged
      ```

      For Perforce P4V:

      ```
      "C:\Program Files\MATLAB\R2016b\bin\win64\mlMerge.exe" %b %2 %1 %r
      ```

4. After this setup, when you use diff or merge, your external source control tool opens a report in MATLAB Comparison Tool. Use the report to view changes and resolve merges.

Your diff and merge operations use open MATLAB sessions if available, and only open MATLAB when necessary.The comparison only uses the specified MATLAB installation.

Project Reference

Componentization Using Referenced Projects

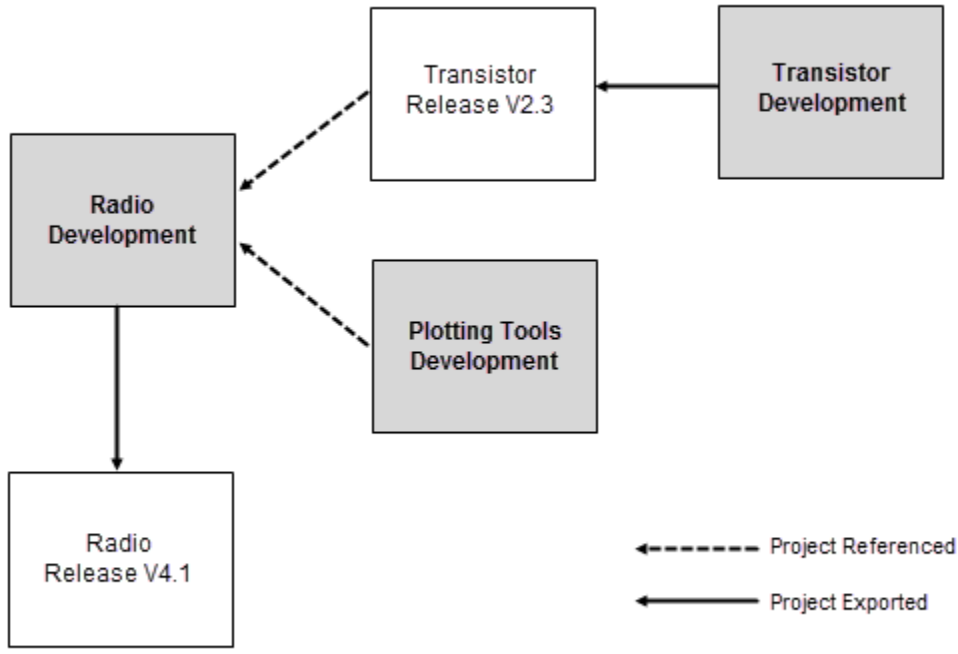
For a large modeling project, organizing the project into components facilitates:

- Component reuse
- Modular, team-based development
- Unit testing
- Independent release of components

Simulink Project supports large-scale project componentization by allowing you to reference other projects from a parent project. A collection of parent and referenced projects constitutes a project reference hierarchy. Project referencing provides these benefits:

- A parent project has access to a referenced project's project paths, entry-point shortcuts, and source control information. For example, from a parent project, you can use referenced project shortcuts to view and run files that belong to the referenced project.
- Through a referenced project, your team can develop a component independent of other components.
- In a referenced project, you can test the component separately.
- In a parent project, you can set a checkpoint and then compare the referenced project against the checkpoint to detect any changes.

This project hierarchy illustrates the use of parent and referenced projects as components of a large project.



Through the Transistor Development project, a team independently creates and tests a library of blocks. The team makes the library available to other developers by exporting release versions, for example, version 2.3.

Through the Radio Development project, another team develops and tests the Radio system. This team requires:

- Version 2.3 of the Transistor component. The team sets up the Radio Development project to reference the Transistor Release V2.3 project.
- Tools to plot signals, for example, MATLAB files that are not distributed to customers. The team sets up the Radio Development project to reference the Plotting Tools Development project.

When the Radio system is ready for customers, the team exports a release version, for example, version 4.1.

- Airframe Project Reference Example

Add or Remove a Reference to Another Project

Add new components to your project by referencing other projects. The addition of referenced projects creates a project hierarchy. When Simulink Project loads a referenced project in a project hierarchy, it:

- Adds project paths from the referenced project to the MATLAB search path.
- Runs startup shortcuts from the referenced project.

To reference a project:

1. On the Simulink Project tab, in the **Environment** section, click **References**.
2. In the Referenced Projects dialog box, click the **Add a reference to another project** button  .
   - If your project hierarchy has a well-defined root relative to your project root, for example, a folder under source control, select **Add Relative Reference**.
   - If the project you want to reference is in a location accessible to your computers, for example, a network drive, select **Add Absolute Reference**.
3. Using the Open dialog box, navigate to the project location and select the project folder.

On the **Project Shortcuts** tab, the **Referenced Projects** section displays the newly added project.

To remove a referenced project from your project hierarchy:

1. On the Simulink Project tab, in the **Environment** section, click **References**.
2. In the Referenced Projects dialog box, select the project that you want to remove and click the **Remove reference to selected project** button  .

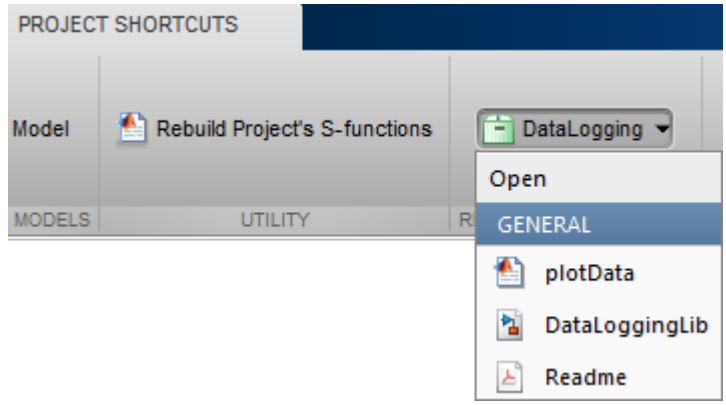
Related Examples

- “Componentization Using Referenced Projects” on page 20-2

View or Run Referenced Project Files

In a Simulink Project hierarchy, from a parent project, use referenced project shortcuts to view and run files that belong to the referenced project.

1. Within the referenced project, create shortcuts for the files that you want to view or run from the parent project.
2. From the parent project, on the **Project Shortcuts** tab, in the **Referenced Projects** section, click the referenced project button arrow.



3. From the list, select the file that you want to view or run.

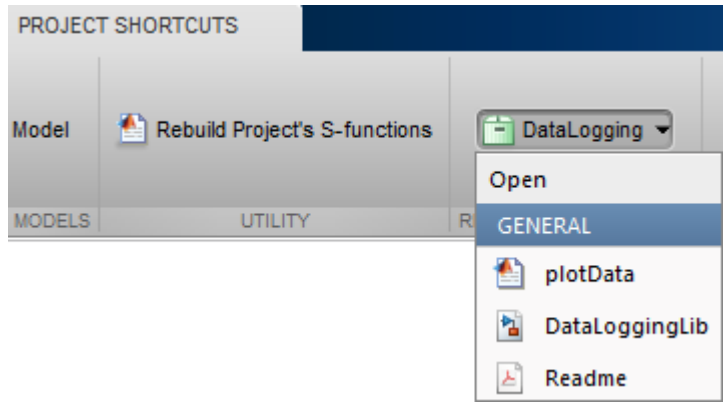
Open a Referenced Project

In Simulink Project, you can open a referenced project from a parent project.

Note Opening a referenced project closes the parent project.

1 On the **Project Shortcuts** tab, in the **Referenced Projects** section, click the referenced project button arrow.



2 From the list, select **Open**.

3 In the Warning dialog box, click **Continue**.

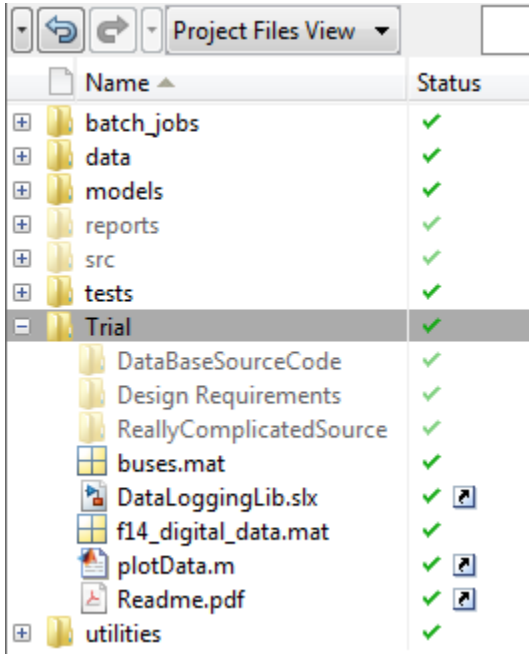
- "Extract a Folder to Create a Referenced Project" on page 20-9
- Airframe Project Reference Example

Extract a Folder to Create a Referenced Project

In Simulink Project, you can partition a large project into components through the use of project references.

Consider the Airframe example project. Suppose you create a folder `Trial` and carry out development work within the folder. You produce:

- Shortcuts to a Simulink library, a MATLAB file, and a `Readme` document
- Design and source code folders
- Data files



For easier management, you want to convert the `Trial` folder into a separate component. In addition, you want access to the folder contents, for example, shortcuts to key files. To fulfill these requirements, extract the folder from the project and convert the folder into a referenced project.

1 With `Project Files View` selected, right-click the `Trial` folder and select **Extract to Referenced Project**.

2 In the Extract Folder to New Project dialog box, specify these options:

- **New Project Name** — For example, `DataLogging`.
- **New Project Location** – For example, `C:\Work\DataLogging`.
- **Reference Type** – The default is `Relative reference`. Use the default if you specify the new project location with reference to the current project root. If you specify the full path for the new location, which is, for example, on a network drive, select `Absolute reference`.

3 Click **More Options**. If you want to disable any of the default content migration actions, clear the corresponding check box.

4 Click **Extract**.

5 In the Warning dialog box, click **Continue**.

The folder `Trial` and its contents are removed from the project. On the **Project Shortcuts** tab, the **Referenced Projects** section displays a new `DataLogging` button.

- Airframe Project Reference Example

Manage Referenced Project Changes Using Checkpoints

In Simulink Project, you can create a checkpoint for a referenced project. You can then compare the referenced project against the checkpoint to detect any changes.

1. In a Simulink Project containing referenced projects, on the Simulink Project tab, click **References**.
2. In the Referenced Projects dialog box, select a referenced project, and click **Set Checkpoint**.

   The Referenced Projects dialog box displays the timestamp of the checkpoint.
3. In future, to detect changes in the referenced project, click **Show Changes** in the Referenced Projects dialog box. The Difference to Checkpoint dialog box shows files that have changed on disk since you set the checkpoint.

Compare Simulink Models

About Simulink Model Comparison

In this section...

Creating Model Comparison Reports

In Simulink, you can compare Simulink models.

You can use models from any version of Simulink. Use the comparison report to explore the differences, view the changes highlighted in the original models, and merge differences.

You can access the comparison tool from:

- The MATLAB Current Folder browser context menu
- The MATLAB Comparison Tool
- The MATLAB command line
- The Simulink Editor **Analysis** menu
- The Simulink Project view

You can use the comparison tool with both model file formats, SLX and MDL. If the selected files are `.mdl` files, or SLX files saved in a previous version, then the comparison tool first exports the `.mdl` files to SLX files in a temporary directory, and produces a comparison report based on the SLX files.

For more information on creating reports, see “Select Simulink Models to Compare” on page 21-4.

Examples of Model Comparison

For examples with instructions, see:

- `slxml_compare_merge`
- `slxml_sfcar`
- `slxml_three_way_merge`

For more information on using and understanding the comparison reports, see “Compare Simulink Models” on page 21-7.

Using Model Comparison Reports

You can display comparison reports in the Comparison Tool. In the interactive report, you can click items in the report to display the corresponding items highlighted in the original models.

The comparison report shows a hierarchical view of the portions of the two files that differ. The report does not show sections of the files that are identical.

If the files are identical you see a message reporting there are no differences.

If files have not been saved, you see an error message informing you that you must save modified or newly created models before running a comparison.

Note It might not be possible for the analysis to detect matches between previously corresponding sections of files that have diverged too much.

Change detection is based on a scoring algorithm. Items match if their score is above a threshold. The tool's algorithm uses a comparison pattern that defines the thresholds assigned to particular node types (e.g., block).

For more information on using the report, see “Compare Simulink Models” on page 21-7.

To control highlighting, see “Display Differences in Original Models” on page 21-14.

To merge differences, see “Merge Simulink Models from the Comparison Report” on page 21-16.

For more information about the Comparison Tool, see “Comparing Files and Folders” (MATLAB).

Select Simulink Models to Compare

To learn what you can do with comparison reports, see "About Simulink Model Comparison" on page 21-2.

Select Files from the Simulink Editor

To compare files using the Simulink Editor:

1. Select **Analysis > Compare To...**.

   The Select Files or Folders for Comparison dialog box opens.
2. If the Editor currently displays a model, the current model name and path appear automatically selected in the **First file or folder** edit box. Use the browse buttons to locate and select files for the first and second model files.
3. When you click **Compare**, the comparison tool performs the analysis, and displays the resulting report in the Comparison Tool.

Select Files from the Current Folder Browser

To compare two files from the Current Folder browser:

- For two files in the same view, select two files, right-click and select **Compare Selected Files/Folders**.
- Alternatively, you can browse to select the second file to compare:

  1. Select a file, right-click and select **Compare Against**
  2. Select the second file to compare in the Select Files or Folders for Comparison dialog box.
  3. Leave the default **Comparison type**, `Simulink XML text comparison`.
  4. Click **Compare**.

For more information about comparisons of other file types (e.g., text, MAT, or binary) with the Comparison Tool, see "Comparing Files and Folders" (MATLAB).

Select Files from a Simulink Project

If you have a Simulink Project using source control, you can create a model comparison report from the Modified Files view of the Simulink Project Tool. For details, see "Project Management".

Select Files from the Comparison Tool

To compare files using the Comparison Tool, from the MATLAB Toolstrip, in the **File** section, select the **Compare** button. In the dialog box select files to compare.

Select Files from the Command Line

To compare XML files from the command line, enter

```
visdiff(filename1, filename2)
```

where `filename1` and `filename1` are XML files or Simulink models.

`visdiff` produces a report in the Comparison Tool.

To create an `xmlcomp.Edits` object at the command line without opening the Comparison Tool, enter:

```
Edits = slxmlcomp.compare(modelname_A,modelname_B)
```

See "Export Results to the Workspace" on page 21-24 for information about the `xmlcomp.Edits` object.

Choose a Comparison Type

To change comparison type, either create a new comparison from the Comparison Tool, or use the **Compare Against** option from the Current Folder browser. You can change comparison type in the Select Files or Folders for Comparison dialog box. For example, if you want the MATLAB text differences report for XML or model files, change the comparison type to `Text comparison` in the dialog before clicking **Compare**. Alternatively, see the `visdiff` function.

Compare Simulink Models

In this section...

Navigate the Simulink Model Comparison Report

You can compare models from any version of Simulink. The comparison tool produces a comparison report based on the SLX files, resaved in the current version if necessary. Use the report to explore the differences, view the changes highlighted in the original models, and merge differences.

The Comparison report shows changes only, not the entire file contents. The report shows a hierarchical view of the portions of the files that differ, and does not show sections of the files that are identical. To learn about the report, see "About Simulink Model Comparison" on page 21-2.

To *step through differences*, on the **Comparison** tab, in the **Navigate** section, click **Next** or **Previous**. See "Step Through Changes" on page 21-9.

You can also click to select items in the hierarchical trees and observe the following display features:

- Selected items appear highlighted in a box.
- If the selected item is part of a matched pair it is highlighted in a box in both left and right trees.

- When you select an item, the original model displays and the corresponding item is highlighted. See “Explore Changes in the Original Models” on page 21-9.

Report item highlighting indicates the nature of each difference as follows:

Type of report item	Highlighting	Notes
Modified	Purple	Modified items are matched pairs that differ between the two files. When you select a modified item it is highlighted in a box in both trees. Changed parameters for the selected pair are displayed underneath.
Inserted	Blue	When you select an unmatched item it is highlighted in a box in one tree only.
Deleted	Orange	
Container	None	Rows with no highlighting indicate a container item that contains other modified or unmatched items.

Icons indicate the category of item, for example: model, subsystem, Stateflow machine or chart, block, line, parameter, etc.

To expand or filter the tree view, use the toolstrip for the following functions:

- **Filter** — Opens the Filter list. Select items to enable or disable display of categories of changes in the report. Use the filters to show only the changes you are interested in. By default the report hides all nonfunctional changes, such as repositioning of items. Turn off filters to explore *all* differences including nonfunctional changes. See “Filter Out Differences” on page 21-11.

- **Find** — Opens the Find dialog box where you can search for items.

- If you want to swap the files, on the **Comparison** tab, select **Swap Sides**. The report swaps the sides and reruns the comparison. **Refresh** also runs the analysis again.

To create a new report, see “Select Simulink Models to Compare” on page 21-4.

For examples with instructions, see also “Examples of Model Comparison” on page 21-2.

Step Through Changes

On the **Comparison** tab, in the **Navigate** section, when you click the **Next** arrow button (or press the Down key when the report has focus), you step through groups of changes in the report, in the following order:

1. The first time you click **Next**, it selects the first changed (purple) or inserted (blue) node.
2. Step through the differences with the **Next** button.
   - When selected items have a match in the right tree then they are also highlighted.
   - Next skips white nodes with no color background, if they have no parameter changes underneath. White nodes are parts of the hierarchy that contain no differences.
   - If there is an insertion or deletion with child nodes, **Next** skips the child nodes if they are all also insertions or deletions. For example, if you insert a subsystem, **Next** selects the top subsystem node, then skips all the nodes inside the subsystem (if they are all also insertions) and selects the next difference.
   - **Next** minimizes context switching when highlighting in models. When you click **Next**, the report steps through all differences at the same level of the model, subsystem, or chart, in both left and right trees in the report, before moving to the next level of the report. For example, you step through all differences in a subsystem in the left and right trees, before moving to another subsystem.
3. When you have stepped through all changes, **Next** stops at the end.

If you click an item in the report, the **Next**/**Previous** controls will step through changes from the point you selected.

Explore Changes in the Original Models

When you compare Simulink models, you can choose to display the corresponding items in the original models when you select report items. You can use this highlighting function to explore the changes in the original models. When you select an item, the report highlights the corresponding item in the model.

Control the display by using the **Highlight Now** button and the **Always Highlight in Models** check box.

For details, see “Display Differences in Original Models” on page 21-14.

Merge Differences

To merge, on the **Comparison** tab, click **Merge**. The Target pane appears at the bottom of the report. Use the buttons to select differences to keep in the target. For more information, see “Merge Simulink Models from the Comparison Report” on page 21-16.

Open Child Comparison Reports for Selected Nodes

If additional comparisons are available for particular parameters, you see a **Compare** button to open a report for that pair of nodes. For example, if there are differences in the Model Workspace, you can click **Compare** to open a new report to explore differences in variables.

- You can open a new comparison for parameters when the report cannot display all the details, e.g., long strings or a script.
- If the original models contain MATLAB Function block components, and if differences are found, click the **Compare** button at the end of the MATLAB Function block report items to open new comparisons in the Comparison Tool, showing the text difference reports for the MATLAB Function block components. You can merge differences in MATLAB Function block code from the text comparison report. See “Merge Simulink Models from the Comparison Report” on page 21-16.
- If the original models contain truth tables, and if differences are found:
  - Click the **Compare** button at the end of the MATLAB Function node to see a summary of all changes.
  - Click the `truthtable` node to reverse annotate and display both truthtable editors.
  - Click the **Compare** button on the parameter to open a new text comparison showing only Condition table differences.
  - Similarly click the **Compare** button for `Action Table` to view only Action changes.

Understand the Report Hierarchy and Matching

Note It might not be possible for the analysis to detect matches between previously corresponding sections of files that have diverged too much.

If you cannot see changes you expected to see in the report, on the **View** tab, click the **Filter** button to turn off filters and see *all* identified changes. See "Filter Out Differences" on page 21-11.

Filter Out Differences

You can use the **Filter** button on the **View** tab to control display of categories of changes. Turn off filtering to view *all* identified changes.

In the **Filter** list, select check boxes to enable or disable display of categories of changes in the report. Use the filters to show only the changes you are interested in. By default the report hides all nonfunctional changes, such as repositioning of items. Turn off filters to explore all differences including nonfunctional changes. Try this if you cannot see changes you expected to see in the report.

Categories for filtering include:

- **Hide Changes in Lines**. Hide all changes to signal lines including functional changes.
- **Hide Nonfunctional Changes**. The report processing identifies certain items in the model file as nonfunctional, for example, items representing parameters such as block, system, chart or label positions, font and color settings for blocks and lines, and system print and display settings.
- **Hide Changes in Block Parameter Defaults**. Hiding changes in defaults can avoid duplication in the report, as any changes in blocks are also reported as functional changes where you can use highlighting. Block parameter defaults are an undocumented part of the Simulink model file that store the default parameters for the blocks used in a model.

Exceptions

The report does *not* filter out changes to Block and System names, annotations, and Stateflow Notes as nonfunctional, even though changes to these items do not affect the

outcome of simulation. The report always displays these changes to facilitate review of code changes, because they can contain important information about users' intentions.

In certain rare cases the report filters out changes that can impact the behavior of the design. By default moves are filtered as nonfunctional, but in the following cases moves can change design behavior:

- Moving blocks can in some cases change the execution order.
- In a Stateflow chart, if you move states or junctions so that they intersect, the model fails to simulate.

To view these types of changes in the report, turn off the filter for nonfunctional changes.

Change Color Preferences

You can change and save your diff color preferences for the Comparison tool. You can apply your color preferences to all comparison types.

1. On the MATLAB Home tab, click **Preferences**.
2. In the Preferences dialog box, under **MATLAB**, click **Comparison**.
3. Edit color settings as desired for differences and merges. View the colors in the **Sample** pane.

   The **Active Settings** list displays **Default (modified)**.
4. To use your modified settings in the comparison, click **Apply** and refresh the comparison report.
5. To return to the default color settings, in the Preferences dialog box, click **Reset** and click **Apply**. Refresh the comparison report.
6. If you want to save your modified color preferences for use in future MATLAB sessions, click **Save As**. Enter a name for your color settings profile and click **OK**.

   After saving settings, you can select them in the **Active Settings** list.

Save Comparison Results

To save your comparison results, use these **Comparison** tab buttons:

- **Publish > HTML** or **Word** — Open the Save dialog box, where you can choose to save a printable version of the comparison report. See “Save Printable HTML Report” on page 21-24.
- **Publish > Workspace Variable** — Export comparison results to workspace. See “Export Results to the Workspace” on page 21-24.

Examples of Model Comparison

Display Differences in Original Models

In this section...

Highlighting in Models

When you compare Simulink models, you can choose to display the corresponding items in the original models when you select report items. You can use this highlighting to explore the changes in the original models. When you select an item, the report highlights the corresponding item in the model.

Click a report entry to view the highlighted item (or its parent) in the model:

- If the item occurs in both models, they both appear with highlighting.
- When there is no match in the other model, the report highlights the first matched ancestor to show the context of the missing item.
- If the comparison tool cannot highlight an item directly (e.g., configuration parameters), then it highlights the nearest ancestor of the selected node.

Try highlighting items in original models using the example slxml_sfcar.

Control Highlighting in Models

To control highlighting in models, in the Comparison Tool, select or clear the check box **Always Highlight in Models**. You can click the **Highlight Now** button to highlight the currently selected report node at any time. This can be useful if you turn off automatic highlighting and only want to display specific nodes.

By default, models display to the right of the comparison report, with the model corresponding to the left side of the report on top, and the right below. If you move or resize the models your position settings are respected by subsequent model highlighting operations within the same session. The tool remembers your window positions.

If you want to preserve window positions across sessions, position the window, and then enter:

```
slxmlcomp.storeWindowPositions
```

This preserves the placement of any Simulink windows, Stateflow windows, and truth table windows.

To stop storing window positions and return to the defaults, enter:

```
slxmlcomp.clearWindowPositions
```

View Changes in Model Configuration Parameters

You can use the report to explore differences in the model Configuration Parameters. If you select a Configuration Parameter item, the report displays the appropriate root node pane, if possible, of both Configuration Parameters dialog boxes.

Parameters display the label text from the dialog controls (or the parameter name if it is command line only), and the parameter values. You can merge selected parameters using merge mode.

Merge Simulink Models from the Comparison Report

In this section...

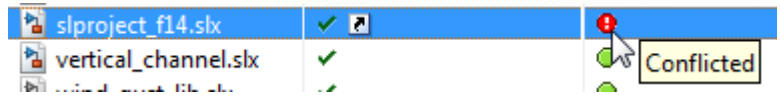
Merge tools enable you to:

- Resolve conflicts in model files under source control using three-way merge. Open by selecting **View Conflicts**.
- Merge any two model files using two-way merge. Open by selecting **Compare** context menu items.
- Merge MATLAB Function block code using text comparison reports.

Resolve Conflicts Using Three-Way Model Merge

If you have a conflicted model file under source control in Simulink Project or in the Current Folder browser, right-click and select **View Conflicts**. You can resolve the conflicts in the Three-Way Model Merge tool. Examine your local file compared to the conflicting revision and the base ancestor file, and decide which changes to keep. You can resolve the conflict and submit your changes.

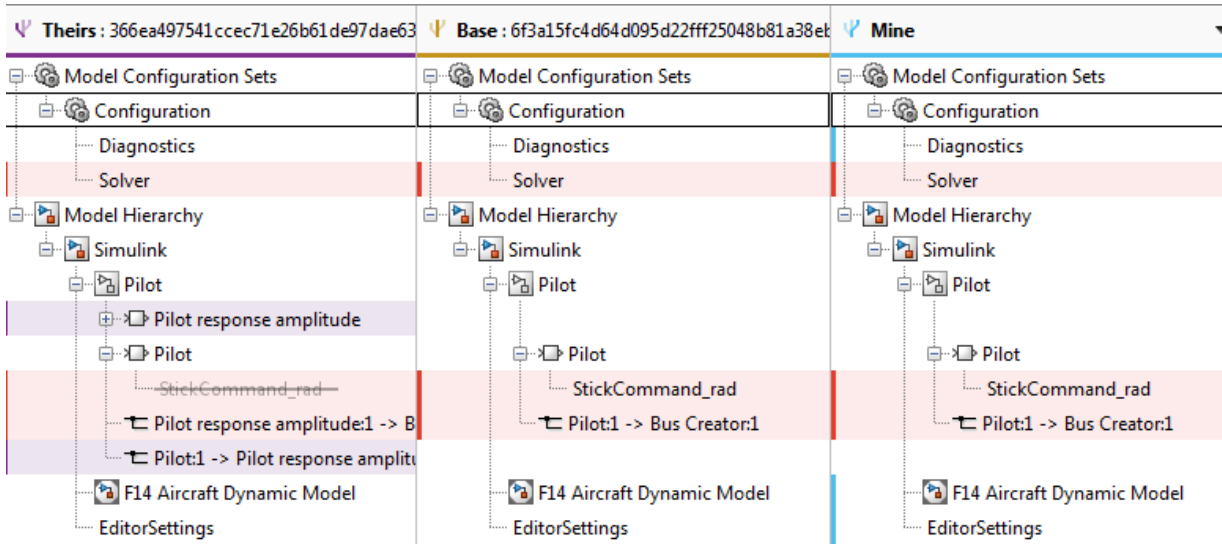
1. To try an example three-way merge, enter `slxml_three_way_merge`.
2. In the Simulink Project locate the conflicted model file, right-click and select **View Conflicts**. You can only see **View Conflicts** in the context menu if your file is marked conflicted by the source control.



The Merge tool automatically resolves every difference that it can, and shows the results in the **Target** pane. Review the automerge choices, edit if desired, and decide how to resolve any remaining conflicts.

1 Examine the Merge report columns.

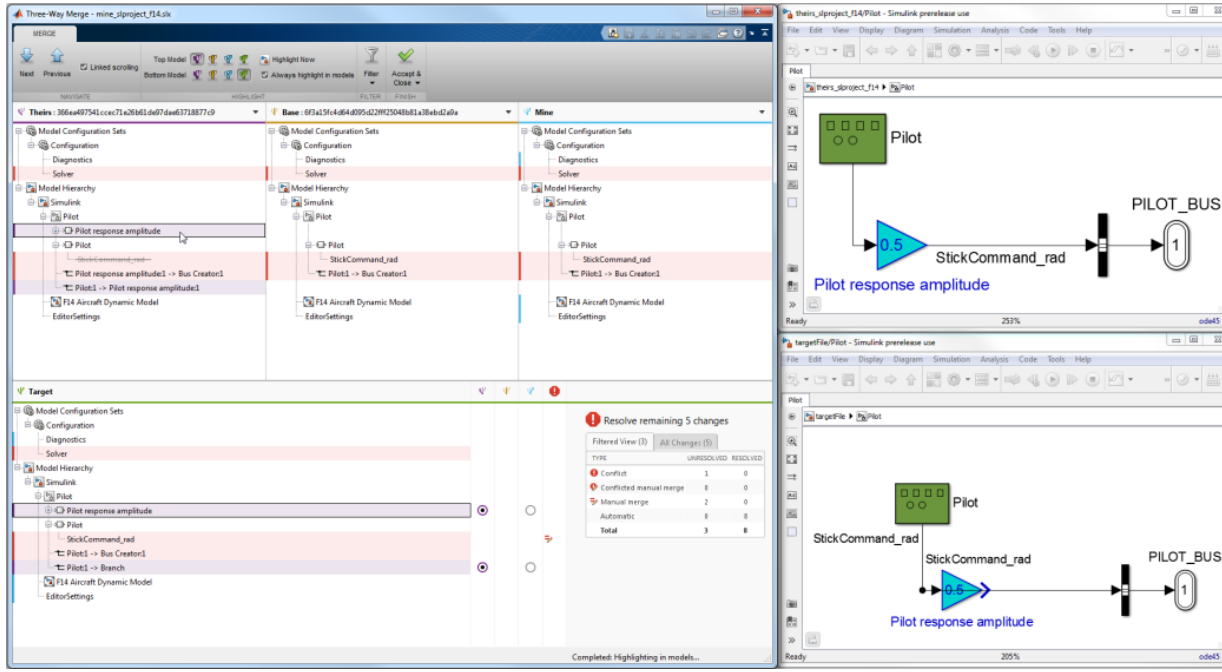
- At the top, **Theirs**, **Base**, and **Mine** columns show the differences in the conflicting revision, your revision, and the base ancestor of both files.
- Underneath, the **Target** shows the local file in your sandbox that you will merge changes into. The Merge tool already automerged the differences it can merge.



2 Examine a difference by clicking **Next** or by clicking a row in the **Theirs**, **Base**, and **Mine** columns.

The merge tool displays two models (or if you selected a configuration setting, you see two model Configuration Parameters dialog boxes). By default, you see **Theirs**

and **Target** models.

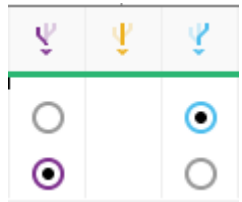


3 Choose the models to display with the toolstrip buttons on the **Merge** tab: **Top Model** or **Bottom Model**. View the models to help you decide what to merge.

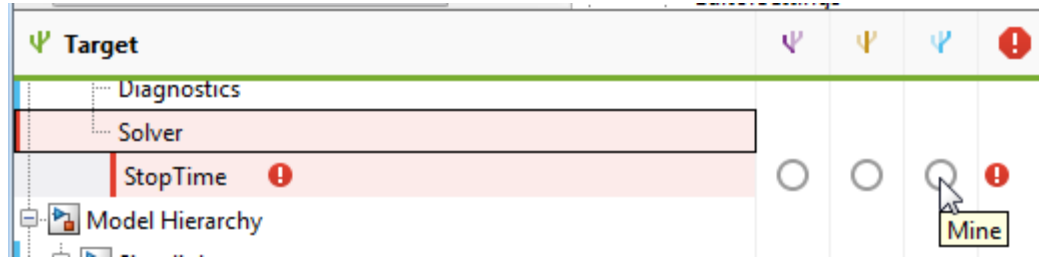
Note If you open the merge tool using **View Conflicts**, then the models **Theirs**, **Base**, and **Mine** are temporary files showing the conflicting revisions. Examine them to decide how to merge. The **Target** model is a copy of **Mine** containing the results of your merges in the report.

4 Select a version to keep for each change by clicking the buttons in the **Target** pane. You can merge modified, added, or deleted nodes, and you can merge individual

parameters. The Merge tool selects a choice for every difference it could resolve automatically. Review the selections and change them if you want.

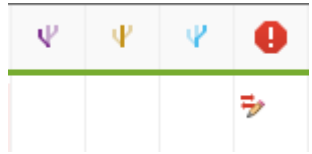


Look for warnings in the Conflicts column. Select a button to use **Theirs**, **Base**, or **Mine** for each conflicted item.



Tip Merge blocks before lines, and merge states and junctions before merging transitions. Merge tool then attempts to connect all lines to blocks for you.

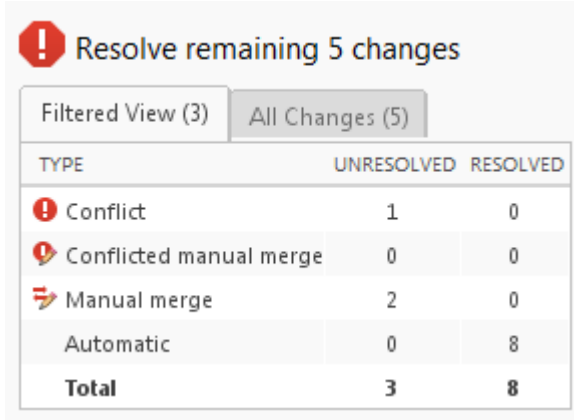
5 Some differences you must merge manually. In the **Target** pane, look for the manual merge icon in the Conflicts column that shows you must take action.



Make manual changes in the Editor. The comparison report cannot update to show any changes that you make in the Editor, so try to make manual changes after addressing all the simpler merges in the report.

After you have resolved the conflict using the Editor, in the **Target** pane, select the check option to mark the node as complete.

6 Examine the summary table to see the number of automatic merges and remaining conflicts you need to resolve.



Check for changes that are filtered out of the current view by looking at the summary table tab titles. The Filtered View and All Changes tab titles show the number of changes. By default the report hides all nonfunctional changes. Turn off active filters to view all identified changes.

7 When you are happy with your merge selections and any manual merges in the **Target** file, click **Accept and Close**. This action saves the target file with all your merges and marks the conflicted file resolved in the source control tool.

To save and not mark the conflict resolved, select **Accept and Close > Save and Close**.

To learn more about resolving conflicts in a change list of modified files in a Simulink project, see “Resolve Conflicts” on page 19-66.

Use Three-Way Merge with External Source Control Tools

If you are using source control outside of MATLAB, then you can customize external source control tools to open Three-Way Merge (or two-way merge for diffs).

For instructions, see “Customize External Source Control to Use MATLAB for Diff and Merge” on page 19-72.

Open Three-Way Merge Without Using Source Control

If you are not using source control or you want to choose three files to merge, then you can open Three-Way Merge using the function `slxmlcomp.slMerge`. Specify the files to merge, for example:

```
slxmlcomp.slMerge(baseFile, mineFile, theirsFile, targetFile);
```

Three-Way Merge opens, where you can merge the changes in `baseFile`, `mineFile`, and `theirsFile` into the `targetFile`.

Two-Way Model Merge

You can merge two Simulink models from a comparison report. The **Compare** context menu items from Simulink Project or the Current Folder browser open a two-way model merge. If you are using source control and want to resolve conflicts using a three-way model merge instead, see “Resolve Conflicts Using Three-Way Model Merge” on page 21-16.

The merge feature enables you to merge two versions of a design modeled in Simulink. You can merge individual parameters, blocks, or entire subsystems. Entire subsystems can only be merged as a whole if they are fully inserted or deleted subsystems.

1. On the **Comparison** tab, click **Merge**. The Target pane appears at the bottom of the report.
2. Use the same workflow as three-way merge. Use the buttons to select the differences to keep in the target file.

   Tip Merge blocks before lines, and merge states and junctions before merging transitions. See “Merging Tips” on page 21-22.
3. View the results in the report and the models. Click **Save File**. **Save File** copies the temporary target file over the right file in the comparison and reruns the comparison.
4. (Optional) To revert all merge operations, click **Close Merge** without saving the file.

5 Inspect your merge changes in the Simulink Editor. If necessary, connect any lines that the software did not connect automatically. The comparison report does not update to show any changes that you make in the Editor.

Merging Tips

- You must merge blocks before lines in the Simulink part of the report. You must merge states and junctions before merging transitions, or the report cannot make the connections.

  For an example showing how to merge a change involving multiple nodes, see `slxml_sfcar`.
- Not all parameters can be merged. In this case, only one radio button is shown in the target pane indicating the version that is in the target model.
- For information on merging between models with identical names, see "Comparing Models with Identical Names" on page 21-26.

Merge MATLAB Function Block Code

1 To merge differences in MATLAB Function block code, create a comparison report for the parent models.

2 Next to the `script` parameter under a MATLAB Function block node in the comparison report, click the **Merge** button. To compare, click the **Compare** button next to the script parameter instead.

  A new text comparison report opens.

3 In the text comparison report, select a difference in the code and click **Merge** to copy the selected difference from the left block to the right block.

4 After you finish merging differences, save the parent target model in the Editor.

Export, Print, and Save Model Comparison Results

In this section...

Save Printable HTML Report

To save a printable version of a model comparison report,

1. On the **Comparison** tab, select **Publish** > **HTML** or **Word**.

   The Save dialog box opens, where you can choose to save a printable version of the model comparison report.
2. Select a file name and location to save the report.

The report is a noninteractive document of the differences detected by the algorithm for printing, sharing, or archiving a record of the comparison. If you have applied filters, your filtered results appear in the printable report.

Export Results to the Workspace

To export the comparison results to the MATLAB base workspace,

1. On the **Comparison** tab, select **Publish** > **Workspace Variable**.

   The Input Variable Name dialog box appears.
2. Specify a name for the export object in the dialog and click **OK**. This action exports the results of the XML comparison to an `xmlcomp.Edits` object in the workspace.

The `xmlcomp.Edits` object contains information about the comparison including file names, filters applied, and hierarchical nodes that differ between the two files.

To create an `xmlcomp.Edits` object at the command line without opening the Comparison Tool, enter:

```
Edits = slxmlcomp.compare(modelname_A,modelname_B)
```

Property of `xmlcomp.Edits`	Description
`Filters`	Array of filter structure arrays. Each structure has two fields, Name and Value.
`LeftFileName`	File name of left model.
`LeftRoot`	`xmlcomp.Node` object that references the root of the left tree.
`RightFileName`	File name of right model.
`RightRoot`	`xmlcomp.Node` object that references the root of the right tree.
`TimeSaved`	Time when results exported to the workspace.
`Version`	MathWorks release-specific version number of `xmlcomp.Edits` object.
Property of `xmlcomp.Node`	**Description**
`Children`	Array of `xmlcomp.Node` references to child nodes, if any.
`Edited`	Boolean — If `Edited = true` then the node is either inserted (green) or part of a modified matched pair (pink).
`Name`	Name of node.
`Parameters`	Array of parameter structure arrays. Each structure has two fields, Name and Value.
`Parent`	`xmlcomp.Node` reference to parent node, if any.
`Partner`	If matched, `Partner` is an `xmlcomp.Node` reference to the matched partner node in the other tree. Otherwise empty `[]`.

Comparing Models with Identical Names

You can compare model files of the same name. To complete the operation, the comparison tool copies one of the models to a temporary folder, because Simulink cannot have two models of the same name in memory at the same time. The comparison tool creates a read-only copy of one model named *modelname*_TEMPORARY_COPY, and compares the resulting XML files.

Warning When you use highlighting from the report, one of the models displayed is a temporary copy with a new name. The temporary copy is read-only, to avoid making changes that can be lost.

Alternatively, you can run the comparison by renaming or copying one of the files.

If one of the models is open when you try to compare them, a dialog box appears where you can click **Yes** to close the file and proceed, or **No** to abort. You must close open models before the comparison tool can compare two models with the same name. The problem requiring you to close the loaded model is called "shadowed files". In some cases, another model with the same name might be in memory, but not visible. See "Shadowed Files" on page 15-4 for more information.

If you want to automatically close open models of the same name when comparing them and not see the dialog box again, run these commands:

```
opt = slxmlcomp.options
opt.setCloseSameNameModel(true)
```

This is persistent across MATLAB sessions. To revert to default behavior and be prompted whether or not to close the open model every time, enter:

```
opt = slxmlcomp.options
opt.setCloseSameNameModel(false)
```

If you open a comparison report from Simulink Project (for example, using **Compare to Revision**), the project handles files of the same name and does not prompt you to close models.

Work with Referenced Models and Library Links

The model comparison report applies only to the currently selected models, and does not include changes to any referenced models or linked libraries. The comparison report shows only changes in the files selected for comparison.

Tip If you want to examine your whole hierarchy instead, try using a Simulink Project, where you can examine modified files and dependencies across your whole project, and compare to selected revisions. See "Project Management".

If you are comparing models that contain referenced models with the same name, then your MATLAB path can affect the results. For example, this can happen if you generate a model comparison report for the current version of your model and a previous baseline. Make sure that your referenced models are not on your MATLAB path before you generate the report.

The reason why results can change is that Simulink records information in the top model about the interface between the top model and the child model. This interface information in the top model enables incremental loading and diagnostic checks without any need to load child models.

When you load a model (for example, to compare) then Simulink refreshes the interface information for referenced models if it can find the child model. Simulink can locate the child model if it is on the path. If another model of the same name is higher on the path, Simulink updates the interface information for that other model before comparing. This can produce entries for interface changes for model reference blocks in the comparison report. Make sure your referenced models are not on your path before you generate the report, to avoid these interface changes in the results. If both model versions are off the path, the interface information in the top model is not refreshed during the comparison process. Instead the cached information is used, resulting in a valid comparison report.

With library links, Simulink does not update the cached interface information when comparing, and so the report correctly captures library interfaces. However with both referenced models and library links, Simulink updates the information when displaying the model. When displaying report items in original models, you may see that Simulink finds another model or library that is higher in the path. To obtain the clearest results, make sure that the models and associated libraries are temporarily removed from the path. By removing the files from the path you will see unresolved library links and

referenced models when you view the original models, but their interfaces will be correct and will correctly align with the comparison report.

Compare Models Managed with Subversion

In this section...

Note The functionality on this page will be removed in a future release. Instead, use either of these approaches:

- Built-in SVN source control integration in Simulink Project. See “Project Management”.
- “Customize External Source Control to Use MATLAB for Diff and Merge” on page 19-72

Work with Subversion

Simulink Projects provide built-in Subversion source control integration. You can create a model comparison report from the Modified Files view of the Simulink Project Tool. See “Project Management”.

Note Alternatively, you can customize your external Configuration Management tools to call the comparison functionality in Simulink. The functionality below on this page describes a previous approach and will be removed in a future release. Instead, use the instructions here:“Customize External Source Control to Use MATLAB for Diff and Merge” on page 19-72.

Comparing two versions of the same file is a common workflow when using Configuration Management tools. If your Configuration Management tool is configurable, you can customize your Diff operations on Simulink model files from your Configuration Management tool to call the model comparison functionality in Simulink. This allows you to compare two versions of the same model file and generate a report of the differences.

TortoiseSVN and Subversion are a popular suite of open-source version control tools. The following example describes how to configure TortoiseSVN to use the Simulink model

comparison. You can register the model comparison function with TortoiseSVN as an extension-specific diff program to use for model files. When you perform a TortoiseSVN diff on a model file, TortoiseSVN uses the model comparison to generate a report. This workflow describes a typical usage of Subversion on a Windows PC.

1. Configure TortoiseSVN to use the `fileComparisonDriver` function for model files.
2. When you perform a TortoiseSVN diff on a model file, the `fileComparisonDriver` function invokes the `visdiff` function to generate a model comparison report.

Optionally, you can also configure TortoiseSVN to use the same function to call the Comparison Tool for `.mat` files and for Simulink manifest files (`.smf` files).

Configure TortoiseSVN

This example is compatible with Release 2008b+ onwards and was tested with Subversion 1.7.7 on Windows 7 Enterprise.

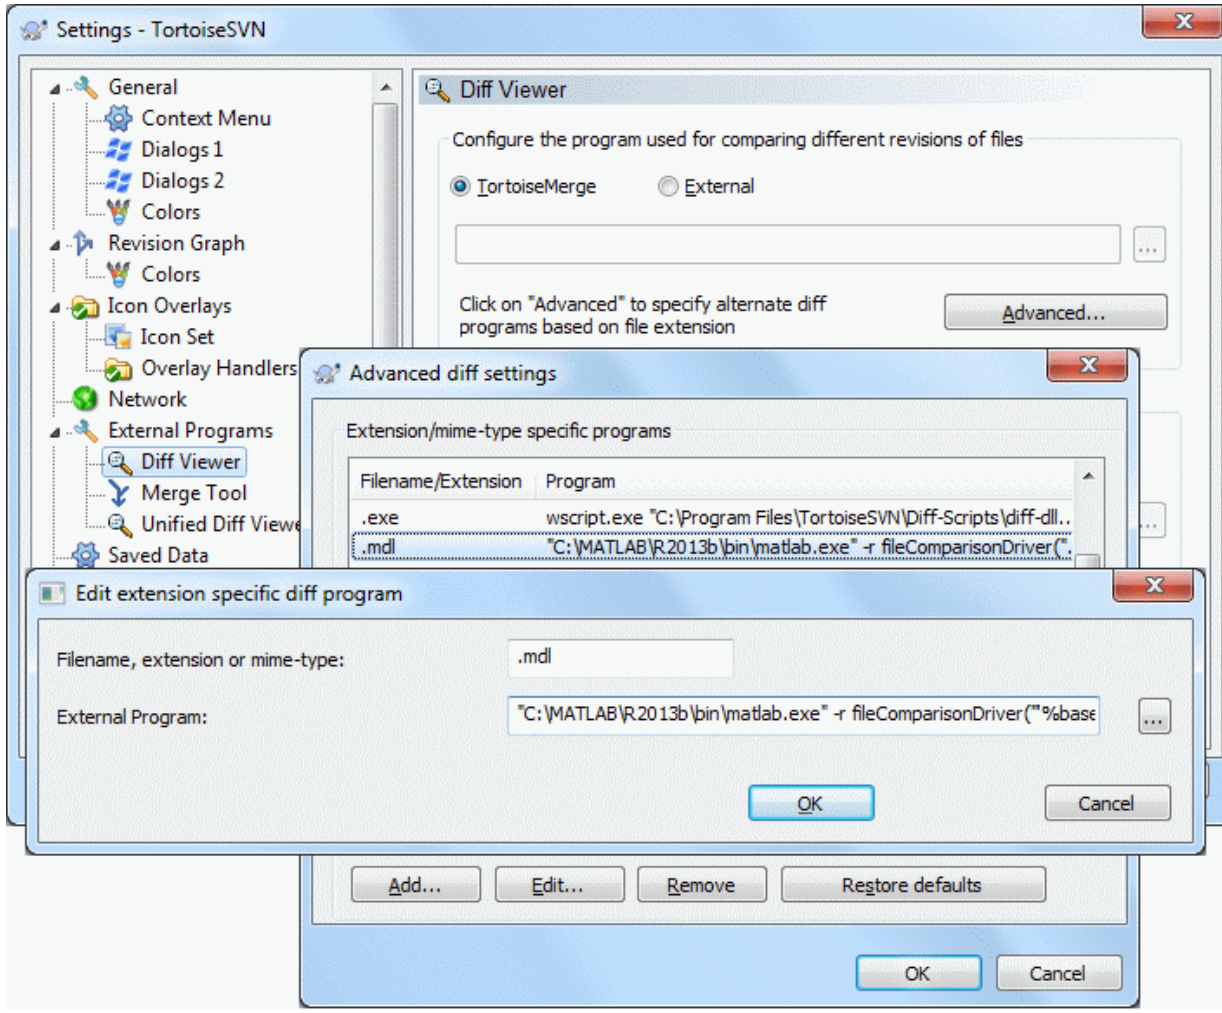
Configure TortoiseSVN to use the XML comparison tool for model files, as follows:

1. Right-click a file in Windows Explorer and select **TortoiseSVN > Settings**.
2. In the TortoiseSVN Settings dialog box, click **Diff Viewer** under **External Programs** in the tree, then click the **Advanced** button.
3. In the Advanced Diff settings dialog box, add an entry to specify what to do with model files by clicking **Add**.
4. In the Add extension specific diff program dialog box, enter `.mdl` or `.slx` for the **Extension** and enter the following command in the **External Program** edit box:

   ```
   "matlabroot\bin\matlab.exe" -r fileComparisonDriver("'%base'","'%mine'") -nosplash
   ```

   Replace *`matlabroot`* with the path to the specific location on your computer for your MATLAB installation, for example, `C:\Program files\MATLAB\R2009a`.

   The following example shows this setup on an R2013b installation.



5 Click **OK** to apply your changes and close all the Tortoise SVN dialog boxes.

6 If you also want to use the MATLAB Comparison Tool to compare MATLAB files, such as `.m` and `.mat` files, or Simulink manifest files (`.smf` files) you can repeat the steps to add exactly the same **External Program** command for `.m`, `.mat` and `.smf` files.

Test TortoiseSVN Setup

To test your setup, follow these steps:

1. Start MATLAB and open, modify, and save a Simulink model that is managed in a Subversion archive. This creates a local working copy that is different to the head repository copy.
2. In Windows Explorer, right-click your modified file, and select **TortoiseSVN > Diff**.

TortoiseSVN runs a new instance of MATLAB. MATLAB loads and runs the `fileComparisonDriver.m` file, located in the folder `matlab\toolbox\rptgenext\rptgenextdemos\slxmlcomp`. The `fileComparisonDriver` function performs these steps:

1. Creates temporary copies of the current working version of the Simulink model and the previously stored version of the model.
2. Compares both models and generates a comparison report displayed in the MATLAB Comparison Tool.

The function must preprocess the file names by creating renamed temporary copies because Subversion uses a temporary file naming convention that is not compatible with Simulink because of invalid delimiting characters. The branch and version information is embedded in the temporary model names. See also “Comparing Models with Identical Names” on page 21-26 for information about using the report and a warning to avoid losing work in the temporary models.

Other TortoiseSVN workflows using Diff operations are also supported, such as comparing two versions in an archive.

Compare Project or Model Templates

In this section...

Compare Project Templates

You can compare project templates (SLTX files). If you select two project template files to compare, you see a comparison report showing differences in template properties and project metadata. You can open a new report to investigate project file and folder differences.

- Click **Template Properties** to view differences in the Parameters, such as the description or date modified.
- Expand the **Project Metadata** node to view metadata differences such as label changes.
- Next to **Project Files**, click **Compare** to open a folder comparison where you can investigate changed, added, or removed files and folders.

Compare Model Templates

You can compare model templates (SLTX files). If you select two model template files to compare, you see a comparison report showing differences in template properties. You can open a new comparison report to compare the Simulink models.

- Click **Template Properties** to view differences in the Parameters, such as the description or date modified.
- Next to **Model**, click **Compare** to open a Simulink model comparison report where you can investigate differences.

Large-Scale Modeling

Design Partitioning

In this section...

When to Partition a Design

Partition a design when it becomes too complex for one person to know all of the details. Complexity increases with design size and team size, for example,

- Design size and complexity:
  - Thousands of blocks
  - Hundreds of logical decisions
  - Hundreds of inputs and outputs
  - Hundreds of times larger industry examples in some cases
  - Multiple variant configurations of the same functionality
- Team integration:
  - Multiple people working on the design
  - People located in different places
  - People from different companies

Partitioning your design into components helps you to work with large-scale designs. Partitioning a design into components gives modularity to help you reduce complexity, collaborate on development, test and reuse components, and to succeed with large-scale model-based design. Component-based modeling helps:

- Enable efficient and robust system development.

  - Reduce overall design complexity by solving smaller problems.
  - Gain performance benefits that scale.
  - Reuse components across multiple projects.
- Facilitate collaboration
  - Partition algorithms, physical models, and tests. Define architecture in terms of structural and functional partitioning of the design using defined interfaces.
  - Collaborate with teams across organizational boundaries on product development. Teams can elaborate individual components independently to do plant modeling, algorithm design, and developing of test harnesses.
  - Manage design with source control tools.
- Improved iteration, elaboration, and verification workflows
  - Iterate faster via more efficient testing and reuse.
  - Eliminate retesting for unchanged components.
  - Reuse environment models and algorithm designs in different projects.
  - Create variants of designs.
  - Elaborate components independently through well-defined interfaces.
  - Manage design evolution with configuration management tools.

Component-based modeling requires:

- Mechanisms for partitioning models and specifying interfaces
- Tools and processes for managing data, models, and environment

Use the following techniques for component-based modeling.

When Not to Partition a Design

Componentization provides benefits for large-scale designs, but is not needed for small designs. Partitioning your design into components requires design work and can increase time taken to update diagrams. Use separate components only when your design is large enough to benefit from componentization.

To decide whether your design needs partitioning, see the recommendations in “Guidelines for Component Size and Functionality” on page 22-4.

Plan for Componentization in Model Design

After models grow large and complex over time, it is difficult to split them into components to allow multiple engineers to work on them in parallel. Splitting a Simulink model into components is easier if the model is designed for componentization from the start. Designing for componentization in the first place can help you avoid these difficulties:

- If a single engineer develops a model from the bottom up, adding blocks and grouping them into subsystems as the model complexity increases, it is hard to later split the model into components. The subsystems within the model are often “virtual” and nonatomic. When you convert these to atomic subsystems and then to model reference components, you can introduce unwanted algebraic loops that are hard to diagnose and solve.
- Subsystems grown over time do not always represent the best way to partition the model. “Best” here might mean the most useful structure for reusable components in other models, or for generating code that integrates with legacy functionality, or for performing Hardware-in-the-Loop tests, etc.
- If you try to expand to parallel development without componentizing models, it is difficult to share work in teams without time-consuming and error-prone merging of subsystems.

These problems are analogous to taking a large piece of code (C, Java, or MATLAB code) and trying to break it down into a number of separate functions. Significant effort is required and can require extensive modifications to some parts of the code, if the code was not designed to be modular in the first place. The same is true for Simulink models.

Lack of componentization causes common failure modes when trying to place Simulink models into configuration management as they grow and you want more than one engineer to work on it in parallel. The best way to avoid these issues is to design for components from the start. You can use the following features of Simulink to design a model suitable for componentization.

If you already have a design that you want to divide into components, see “Partition an Existing Design” on page 22-11.

Guidelines for Component Size and Functionality

To set up your project for a team to work on, consider the following model architecture guidelines for components. Useful components:

- Have well-defined interface I/O boundaries.
- Perform a defined set of functions (actions), defined by requirements.
- Form part of a larger system.
- Have the “right” size:
  - Large enough to be reusable
  - Small enough to be tested
  - Only one engineer is likely to want to edit each model at a time

The right size can depend on team size. You can have larger components if only one person is working on each, but if you need to share components between several people, you probably need to divide the design into smaller logical pieces. This aids two goals: understanding the design, and reducing file contention and time spent on merging.

Recommendations:

- In most cases, if you have fewer than 100 blocks, do not divide the design into components. Instead, use subsystems if you want to create a visual hierarchy. For example, the example model `vdp` is not large enough to benefit from componentization.
- If you have 500–1000 blocks, consider creating a model reference to contain that component in a separate file. The cost of verification can reduce the size for components. For example, if you have a small component of 100 blocks with high testing costs and frequent changes, consider separating that component into a separate file to make verification easier.

Consider dividing the model based on:

- Physical components (e.g., plant and controller, for code generation)
- Algorithm logic
- Reusability in other models
- Testability, for example, for performing Hardware-in-the-Loop tests
- Sample rate; consider grouping components that have the same sample rate
- Simulation speed; using different solvers for components with different numerical properties can increase simulation speed
- Accessibility to other teams or others on your team.

While you cannot always plan on model size, if you expect multiple people to work on the design, you can benefit from componentization techniques. Consider controlling

configuration management using Simulink Project and partitioning the design using Model Reference so that the team can work on separate files concurrently.

Component Size	Recommended Componentization Techniques	Notes
Small <500 blocks	Create visual hierarchy using subsystems.	Small designs do not benefit from dividing into separate files. However, larger teams that cause file contention or high cost of verification can make it worth partitioning smaller components into separate files instead of using subsystems.
Large >500 blocks	Separate components into separate files using Model Reference or Libraries.	For multiple engineers or teams working on a design, best practice is one file per component. To reduce file contention, aim for components in which only one engineer needs to edit each model at a time.
Small <500 blocks, but expected to grow over time	Use atomic subsystems for functional block grouping instead of virtual subsystems. Atomic subsystems are easier to migrate to separate file components later.	If possible, plan your components from the start to avoid migration pain.

If your design or team is large enough to benefit from separating components into separate files, this table summarizes when to apply each technique.

Component Characteristics	Technique	Benefits	Costs
Small, low-level utility functions, reused in many places in a design	Library model containing a single reusable atomic subsystem	• Context-dependent: can adapt to various interfaces with different data types, sample time, and dimensions, in different contexts, without changing the design. • Can be reused in other models • Stored as a separate file, can apply version control, but each instance adapts to context of parent model, so generated code can differ in each instance.	• Cannot use independently to simulate or generate code. Requires a parent model. • Context adaptation not desirable for big components in large-scale models where interfaces are managed and locked down to specific data type and dimension. In these cases, you might not want code generated for the library block to differ in each instance. • Requires link management to avoid problems with broken, disabled, or parameterized links. See “Manage Components Using Libraries” on page 22-12.

Component Characteristics	Technique	Benefits	Costs
Groups of blocks for sharing among users	Library for grouping and storing Simulink blocks Library palette of links to components	• Libraries are useful for storing blocks to share among a number of users • To reduce file contention, use library palettes of links to individual components in separate files. Store each component in a model reference file or a single subsystem in a separate library.	• Causes file contention if multiple components reside in a single library file. File contention is a problem only if blocks need frequent updates or multi-user access. Palettes can help. • Requires link management to avoid problems with broken, disabled, or parameterized links. See “Manage Components Using Libraries” on page 22-12.

Component Characteristics	Technique	Benefits	Costs
Top-level components for large-scale models: >500 blocks Large components: starting at ~ 500–5000 blocks for one or a few reusable instances, or smaller if many instances Components at any level of model hierarchy where teams need to work independently	Model Referencing	• Components are independent model files and part of a larger model. You can simulate and generate code in the component. • Independent of context—good for large-scale model components where interfaces are managed and locked down. • Stored as a separate file—can apply version control to a component independently of the models that use it. • Possible to use Accelerator mode generated code to reduce memory requirements when loading models and increase simulation speed, compared to subsystems or libraries. Useful for top-level component partitions.	Performance can reduce slightly when updating a model (update diagram) because each reference model is checked for changes to enable incremental builds. When components are large enough (>500 blocks), update diagram is faster in most cases. See “Partition a Design Using Model Reference” on page 22-11.

Choose Components for Team-Based Development

To perform parallel development, you need component-based modeling. Best practice for successful team-based development is to partition the models within the project so that only one user works on each part at a time. Componentization enables you to avoid or minimize time-consuming merging. To set up your project for work by a team, consider the following model architecture guidelines.

This table compares subsystems, libraries, and model referencing for team-based development.

Modeling Development Process	Subsystems	Libraries	Model Referencing
Team-based development	Not supported For subsystems in a model, Simulink provides no direct interface with source control tools. To create or change a subsystem, you need to open the parent model's file. This can lead to file contention when multiple people want to work on multiple subsystems in a model. Merging subsystems is slow and errorprone, so best avoided as a workflow process. However, Simulink Report Generator provides tools to help you merge subsystems. See "Merge Simulink Models from the Comparison Report" on page 21-16.	Supported, with limitations You can place library files in source control for version control and configuration management. You can use Simulink Project to interact with source control. You can maintain one truth, by propagating changes from a single library block to all blocks that link to that library. To reduce file contention, use one subsystem per library. You can link to the same library block from multiple models. You can restrict write access to library components.	Well suited You can place model reference files in source control for version control and configuration management. You can use Simulink Project to interact with source control. You save a referenced model in a separate file from the model that references it. Using separate files helps to avoid file contention. You can design, create, simulate, and test a referenced model independently from the model that references it. Simulink does not limit access for changing a model reference.

Most large models use a combination of componentization techniques. No single approach is suitable for the wide range of users of Simulink. The following advice descibes some

typical processes to show what you can do with MathWorks tools to perform team-based development.

One File Per Component for Parallel Development

To perform efficient parallel development, break a large model into a number of individual files, so that team members can work independently and you can place each file under revision control. Componentization enables you to avoid or minimize time-consuming merging. To set up your project for work by a team, consider the advice in "Guidelines for Component Size and Functionality" on page 22-4.

A key goal of component-based modeling is to allow parallel development, where different engineers can work on components of a larger system in parallel. You can achieve this if each component is a single file. You can then control and trace the changes in each component using source control in Simulink Project. See "Configuration Management" on page 22-19.

Partition an Existing Design

If you already have a design that you want to divide into components, first decide where to partition the model. Existing subsystems that grow over time are not always the best way to partition the model. Consider dividing the model based on the advice in "Guidelines for Component Size and Functionality" on page 22-4.

Agreeing on an interface is a useful first step in deciding how to break down the functionality of a large system into subcomponents. You can group signals and partition data. See "Interface Design" on page 22-14.

After you decide how to partition your design, Simulink tools can help you divide an existing model into components.

Simulink can help you partition models by converting subsystems to files. You can convert to files using Model Reference or Libraries. See "Guidelines for Component Size and Functionality" on page 22-4 for suggestions on when to apply each technique.

Partition a Design Using Model Reference

Use Model Reference to divide the components into separate files so that the team can work on separate files concurrently. You can also reuse the models in other models. To partition a model using model reference, see "Create a Referenced Model" on page 8-9 or "Convert a Subsystem to a Referenced Model" on page 8-15.

Manage Components Using Libraries

- Use Libraries containing a single subsystem to contain a component in a single file. Use libraries to store blocks you can reuse in models. The linked blocks inherit attributes from the surrounding models, such as data types and sample rate. Using this technique for componentization has the management overhead of library links, described below.
- Use Libraries to reuse blocks in multiple models. Libraries work well for grouping and storing Simulink blocks to share. Best practice for libraries is to use them for storing blocks to share with multiple users, and blocks that are updated infrequently. As a rough guideline, it is appropriate to use a Simulink library if its contents are updated once every few months. If you update it more frequently, then the library is probably being used to perform configuration management. In this case, take care to avoid the common problems described in “Library Link Management” on page 22-12.
- To make library blocks available for reuse while reducing file contention and applying revision control, use library palettes. A palette is a library containing links to other components. If each component is a single subsystem in a separate library, or a model reference file, you can achieve the one-file-per-component best practice for component-based modeling. You can use separate version control for each component, and you can also control the palette.

  When you drag a block from the library palette into your model, Simulink follows the link back to the file where the subsystem or model reference is implemented. The models that use the component contain a link to the component and not to the palette.

Library Link Management

Library links can introduce management overhead if you use them for configuration management. Take care to manage:

- Disabled links — Can cause merge conflicts, and failure to update all instances of the same model component. In a hierarchy of links, you can accidentally disable all links without being aware of it, and only restore one link while leaving others disabled.
- Broken links — Accidentally broken links are a hard problem to solve, because, by design, you cannot detect what the broken link linked to previously.
- Parameterized link data — It can be useful to change the value of parameter data, such as the value of a gain within a gain block, without disabling the library link. This generates “link data” for that instance only. However for configuration management this can cause a problem, if you assume all instances are identical, as one now has different properties.

Simulink tools help you manage library links to avoid problems:

- Lock links to prevent editing. See “Lock Links to Blocks in a Library” on page 40-29.
- Use diagnostic options to check library link integrity whenever you save a model. You can set the checks to warn, error, or ignore that a model has disabled or parameterized library links. You select these settings per model. In the Configuration Parameters dialog box, see **Diagnostics > Saving**.

  See the diagnostic settings “Block diagram contains disabled library links” and “Block diagram contains parameterized library links”.
- Use Model Advisor checks to report on library link integrity. The advisor checks for disabled and parameterized links within a model. You can use the resulting report as an artifact to check into a configuration management system.

  See the Model Advisor checks:

  - “Identify disabled library links”
  - “Identify parameterized library links”
  - “Identify unresolved library links”
- Use the Links Tool to view and restore disabled and edited links. See “Restore Disabled or Parameterized Links” on page 40-31.

Caution These link management tools can detect link problems but cannot prevent editing the wrong files. If this is a problem, then use Model Reference as the partitioning mechanism to avoid the risks associated with disabled, broken, and parameterized links.

Interface Design

In this section...

Why Interface Definitions Are Important

Defining the “interface” of a software component, such as a C or MATLAB code function or a Simulink subsystem, is a key first step before others can use it, for these reasons:

- Agreeing on an interface is a useful first step in deciding how to break down the functionality of a large system into subcomponents.
- After you define interfaces between a number of components, you can develop the components in parallel. If the interface remains stable, then it is easy to integrate those components into a larger system.
- Changing the interface between components is expensive. It requires changes to at least two components (the source and any sinks) and to any test harnesses. It also makes all previous versions of those components incompatible with the current and future versions.

When you need to change an interface, doing so is much easier if the components are stored under configuration management. You can track configurations of compatible component versions to prevent incompatible combinations of components.

Recommendations for Interface Design

Suggestions for defining the interfaces of components for a new project:

- Base the boundaries of the components upon those of the corresponding real systems. This is especially useful when the model contains:
  - Both physical (plant and environment) and control systems
  - Algorithms that run at different rates

- Consider future model elaboration. If you intend to add models of sensors, then put them in from the start as an empty subsystem that passes signals straight through or performs a unit delay and/or name conversion.
- Consider future component reuse.
- Consider using a signal naming convention.
- Use data objects for :
  - Defining component interfaces
  - Precise control over data attributes
- Simplify interface design by grouping signals into buses. Signal buses are well suited for use at the high levels of models, where components often have a large number of signals going in and out, and do not use all the signals available. Using buses can simplify modifying the interface to a component. For example, if you need to add or remove signals used by a component, it can be simpler to modify a bus than to add or remove inports or outports to that component. However, using a bus that crosses model reference boundaries requires using a bus object.

  Best practices for using Simulink bus signals and bus objects:

  - Make buses virtual, except for model reference component boundaries.
  - Use nonvirtual buses when defining interfaces between components. However, this requires associating the bus with a bus object. Bus objects completely define the properties of the signals on a bus, giving an unambiguous interface definition.

    Include bus objects in a data dictionary, or save bus objects as a `.mat` or `.m` file, in order to place them under revision control.
  - Pass only required signals to each component to reduce costly passing of unnecessary data. Signal buses allow the full set of input and output signals to be defined, but not necessarily used or created.
  - Make sure that the interface specifies exactly what the component uses.
  - Use a rigorous naming convention for bus objects. Unless you use a data dictionary, bus objects are stored in the base workspace.
  - At the lower levels of a model, consider using inports and outports for each signal. At lower levels of a model, where components typically implement algorithms rather than serve as containers for other components, it can increase readability if you use individual inports and outports for components, instead of using signal buses. However, creating interfaces in this way has a greater risk of connection

problems, because it is difficult to check the validity of connections, other than their data type, size, etc.

- To package signals or parameters into structures that correspond to a `struct` type definition that your external C code defines, import the type as a bus object and use the object as a data type for bus signals and MATLAB structures. To create the object, use the `Simulink.importExternalCTypes` function.

Partitioning Data

Explicitly control the scope of data for your components. Some techniques:

- Global parameters — A common approach in the automotive world is to completely separate the problem of parameter storage from model storage. The parameters for a model come from a database of calibration data, and the specific calibration file used becomes part of the configuration. The calibration data is treated as global data, and resides in the base MATLAB workspace. You can migrate base workspace data to a data dictionary for more control.
- Nonglobal parameters — Combining a number of components that somehow store their own parameter data has the risk of parameter name collisions. If you do not use a naming convention for parameters or, alternatively, a list of unique parameter names and definitions, then there is the risk that two components use a parameter with the same name but with different meanings.

  Methods for storing local parameter data include:

  - Partition data into reference dictionaries for each component.
  - With Model Reference, you can use model workspaces.
  - Use parameter files (`.m` or `.mat`) and callbacks of the individual Simulink models (e.g., `preload` function).

    You can also automatically load required data using Simulink Project shortcuts.
  - Mask workspaces, with or without the use of mask initialization functions.
  - For subsystems, you can control the scope of data for a subsystem using the Subsystem Parameters, Permit Hierarchical Resolution dialog box.

Configure Data Interface for Component

Whether you use referenced models or subsystems to break a large system into components, the components can exchange signal data through Inport and Outport

blocks. You can explicitly configure design attributes (such as data type and numeric complexity) of the interface to prevent modeling errors and make integrating the components easier.

After you create the Inport and Outport blocks, you can use the Model Data Editor and the interface display to configure the design attributes (such as data type and numeric complexity) of the blocks. Use this technique to view the component interface in its entirety at once and to trace the pieces of the interface to usage points in the internal block algorithm. You can also use this technique to configure the interface of a component before you develop the internal algorithm, in which case the component contains unconnected Inport and Outport blocks.

The example model `sldemo_fuelsys_dd` contains two components which are referenced models:

- A plant component, `sldemo_fuelsys_dd_plant`.
- A controller component, `sldemo_fuelsys_dd_controller`.

Use the Model Data Editor and the interface display to examine and configure the interface of the plant component.

1. Open the plant component.

   ```
   sldemo_fuelsys_dd_plant
   ```

2. Select **Display** > **Interface**.
3. Select **View** > **Model Data**.

   By default, in the Model Data Editor, the **Inports/Outports** tab is selected. Each row in the table represents an Inport or Outport block. By default, the **Change view** drop-down list is set to `Design`.

   Tip To view only the Inport and Outport blocks at the root level of the model (by excluding the blocks inside the subsystems), deactivate the **Change Scope** button.

4. Use the columns in the Model Data Editor to explicitly configure the design attributes of the interface. For example, specify minimum and maximum values for each Inport and Outport block by using the **Min** and **Max** columns.

To configure code generation settings for the interface of a controller component, in the Model Data Editor, set the **Change view** drop-down list to `Code`.

For more information about using the interface display, see “Trace Connections Using Interface Display” on page 12-69. For more information about the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 59-141.

Configuration Management

In this section...

Manage Designs Using Source Control

Simulink projects can help you work with configuration management tools for team collaboration. You can use projects to help you manage all the models and associated files for model-based design.

You can control and trace the changes in each component using source control in Simulink Project. Using source control directly from Simulink Project provides these benefits:

- Engineers do not have to remember to use two separate tools, avoiding the common mistake of beginning work in Simulink without checking out the required files first.
- You can perform analysis within MATLAB and Simulink to determine the dependencies of files upon each other. Third-party tools are unlikely to understand such dependencies.
- You can compare revisions and use tools to merge models.

If each component is a single file, you can achieve efficient parallel development, where different engineers can work on the different components of a larger system in parallel. Componentization enables you to avoid or minimize time-consuming merging. See “One File Per Component for Parallel Development” on page 22-11. One file per component is not strictly necessary to perform configuration management, but it makes parallel development much easier.

If you break down a model into a number of components, it is easier to reuse those components in different projects. If the components are kept under revision control and configuration management, then you can reuse components in a number of projects simultaneously.

To find out about source control support in Simulink, see “Source Control in Simulink Project”.

Determine the Files Used by a Component

You can use Simulink Project to determine the set of files you need to place under configuration management. You can analyze the set of files that are required for the model to run, such as model references, library links, block and model callbacks (`preload` functions, `init` functions, etc.), S-functions, From Workspace blocks, etc. Any MATLAB code found is also analyzed to determine additional file dependencies. You can use the Simulink manifest tools to report which toolboxes are required by a model, which can be a useful artifact to store.

You can also perform a file dependency analysis of a model programmatically from MATLAB using `dependencies.fileDependencyAnalysis` to get a cell array of paths to required files.

For more information, see “Dependency Analysis”.

Manage Model Versions

Simulink can help you to manage multiple versions of a model.

- Use Simulink Projects to manage your project files, connect to source control, review modified files, and compare revisions. See “Project Management”.
- Simulink notifies you if a model has changed on disk when updating, simulating, editing, or saving the model. Models can change on disk, for example, with source control operations and multiple users. Control this notification with the Model File Change Notification preference. See “Model File Change Notification” on page 4-62.
- As you edit a model, Simulink generates version information about the model, including a version number, who created and last updated the model, and an optional comments history log. Simulink saves these version properties with the model.
  - Use the Model Properties dialog box to view and edit some of the version information stored in the model and specify history logging.
  - The Model Info block lets you display version information as an annotation block in a model diagram.
- Use `Simulink.MDLInfo` to extract information from a model file without loading the block diagram into memory. You can use `MDLInfo` to query model version and

Simulink version, find the names of referenced models without loading the model into memory, and attach arbitrary metadata to your model file.

Create Configurations

You can use Simulink Project to work with the revision control parts of the workflow: retrieving files, adding files to source control, checking out files, and committing edited files to source control.

To define configurations of files, you can label a number of files as a new mutually consistent configuration. Other users can get this set of files from the revision control system.

Configurations are different from revisions. Individual components can have revisions that work together only in particular configurations.

Tools for creating configurations in Simulink:

- Variant modeling. See “Variant Systems”.
- Tools in Simulink Project:
  - Label — Label project files. Use labels to apply metadata to files. You can group and sort by labels, label folders for adding to the path using shortcut functions, or create batch jobs to export files by label, for example, to manage files with the label `Diesel`. You cannot retrieve from source control by label, and labels persist across revisions.
  - Revision Log — Use Revert Project to choose a revision to revert to (SVN source control only).
  - Branch — Create branches of file versions, and switch to any branch in the repository (Git source control only).
  - Tag — You can tag all project files (SVN source control only) to identify a particular configuration of a project, and retrieve tagged versions from source control. However, continued development is limited. That is, you cannot tag again, and you must check out from `trunk` to apply tags.
  - Archive — Package all project files in a Zip file that you can create a new project from. However, this packaging removes all source control information, because archiving is for exporting, sharing, and changing to another source control. You can commit the new Zip file to source control.

Power Window Example

Power Window

In this section...

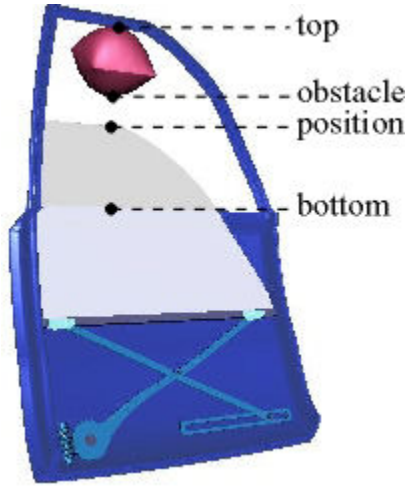
Study Power Windows

Automobiles use electronics for control operations such as:

- Opening and closing windows and sunroof
- Adjusting mirrors and headlights
- Locking and unlocking doors

These systems are subject to stringent operation constraints. Failures can cause dangerous and possibly life-threatening situations. As a result, careful design and analysis are needed before deployment.

This example focuses on the design of a power window system of an automobile, in particular, the passenger-side window. A critical aspect of this system is that it cannot exert a force of more than 100 N on an object when the window closes. When the system detects such an object, it must lower the window by about 10 cm.



As part of the design process, the example considers:

- Quantitative requirements for the window control system, such as timing and force requirements
- System requirements, captured in activity diagrams
- Data definitions for the signals used in activity diagrams

Other aspects of the design process that this example contains are:

- Managing the components of the system
- Building the model
- Validating the results of system simulation
- Generating code

MathWorks Software Used in This Example

In addition to Simulink, this example uses these additional MathWorks products:

- DSP System Toolbox
- Fixed-Point Designer
- Simscape Multibody

- Simscape Power Systems™
- Simscape
- Simulink 3D Animation
- Simulink Real-Time
- Simulink Coverage™
- Stateflow

Quantitative Requirements

Quantitative requirements for the control are:

- The window must fully open and fully close within 4 s.
- If the up is issued for between 200 ms and 1 s, the window must fully open. If the down command is issued for between 200 ms and 1 s, the window must fully close.
- The window must start moving 200 ms after the command is issued.
- The force to detect when an object is present is less than 100 N.
- When closing the window, if an object is in the way, stop closing the window and lower the window by approximately 10 cm.

Capturing Requirements in Activity and Context Diagrams

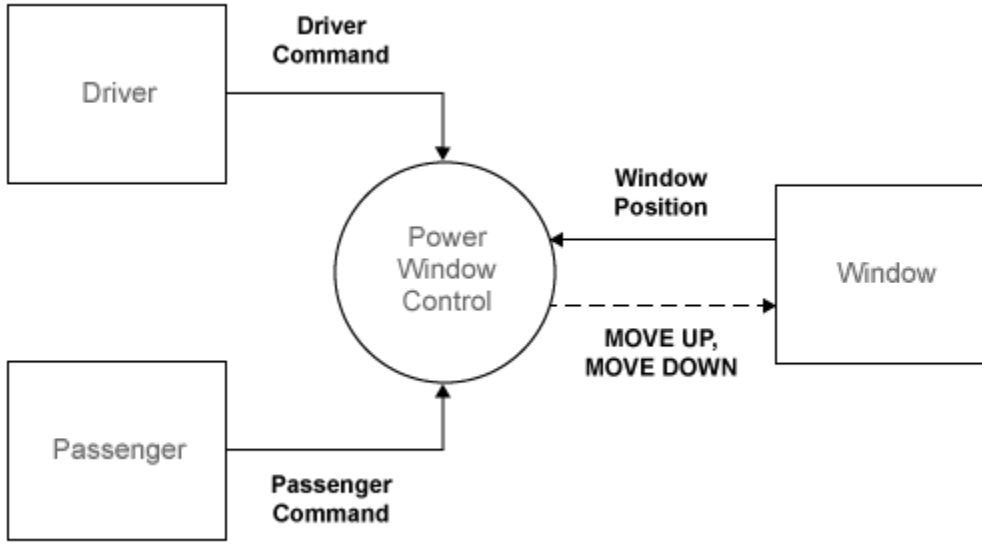
Activity diagrams help you graphically capture the specification and understand how the system operates. A hierarchical structure helps with analyzing even large systems. At the top level, a context diagram describes the system environment and its interaction with the system under study in terms of data exchange and control operations. Then you can decompose the system into an activity diagram with processes and control specifications (CSPEC).

The processes guide the hierarchical decomposition. You specify each process using another activity diagram or a primitive specification (PSPEC). You can specify a PSPEC in a number of representations with a formal semantic, such as a Simulink block diagram. In addition, context diagrams graphically capture the context of system operation.

Context Diagram: Power Window System

The figure represents the context diagram of a power window system. The square boxes capture the environment, in this case, the driver, passenger, and window. Both the driver

and passenger can send commands to the window to move it up and down. The controller infers the correct command to send to the window actuator (e.g., the driver command has priority over the passenger command). In addition, diagram monitors the state of the window system to establish when the window is fully opened and closed and to detect if there is an object between the window and frame.



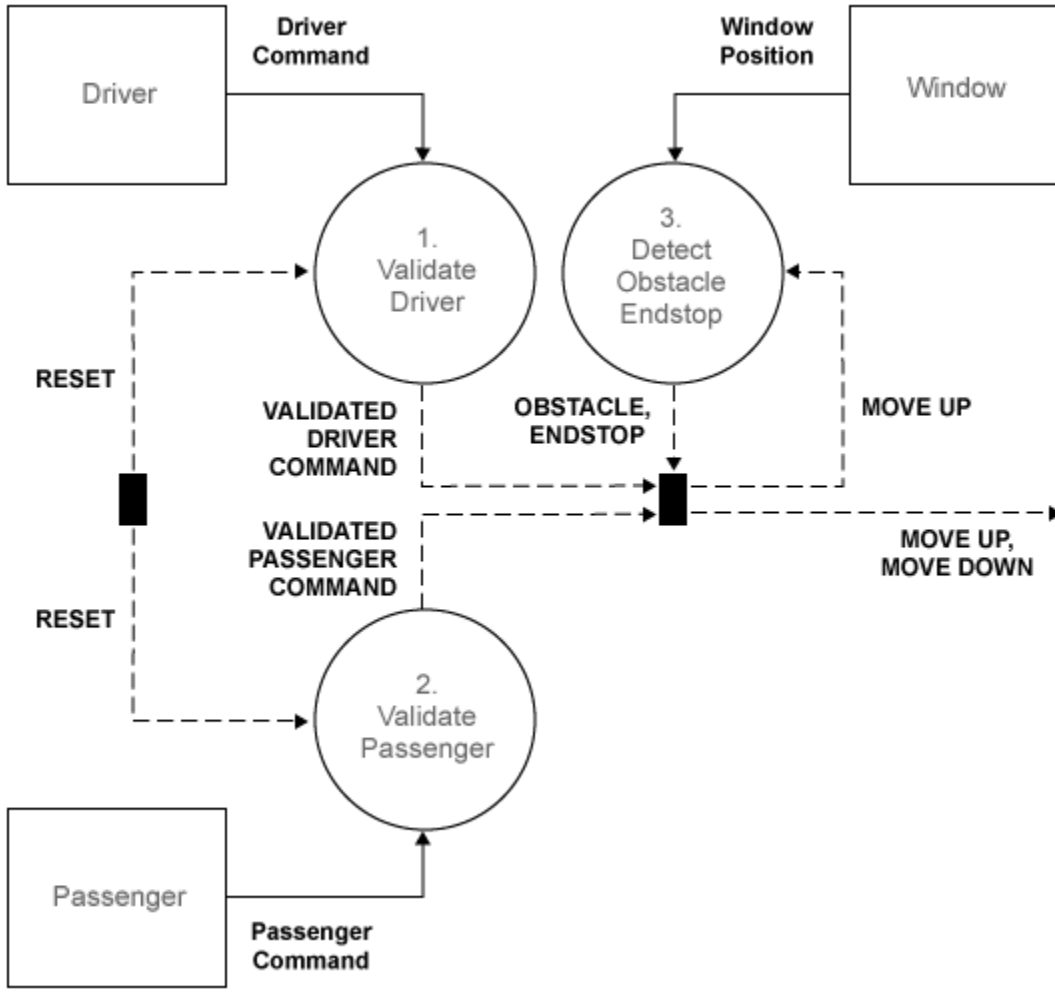
The circle (also known as a bubble) represents the power window controller. The circle is the graphical notation for a process. Processes capture the transformation of input data into output data. Primitive process might also generate. CSPECs typically consist of combinational or sequential logic to infer output control signals from input control.

For implementation in the Simulink environment, see “Implementation of Context Diagram: Power Window System” on page 23-34.

Activity Diagram: Power Window Control

The power window control consists of three processes and a CSPEC. Two processes validate the driver and passenger input to ensure that their input is meaningful given the state of the system. For example, if the window is completely opened, the `MOVE DOWN` command does not make sense. The remaining process detects if the window is completely opened or completely closed and if an object is present. The CSPEC takes the

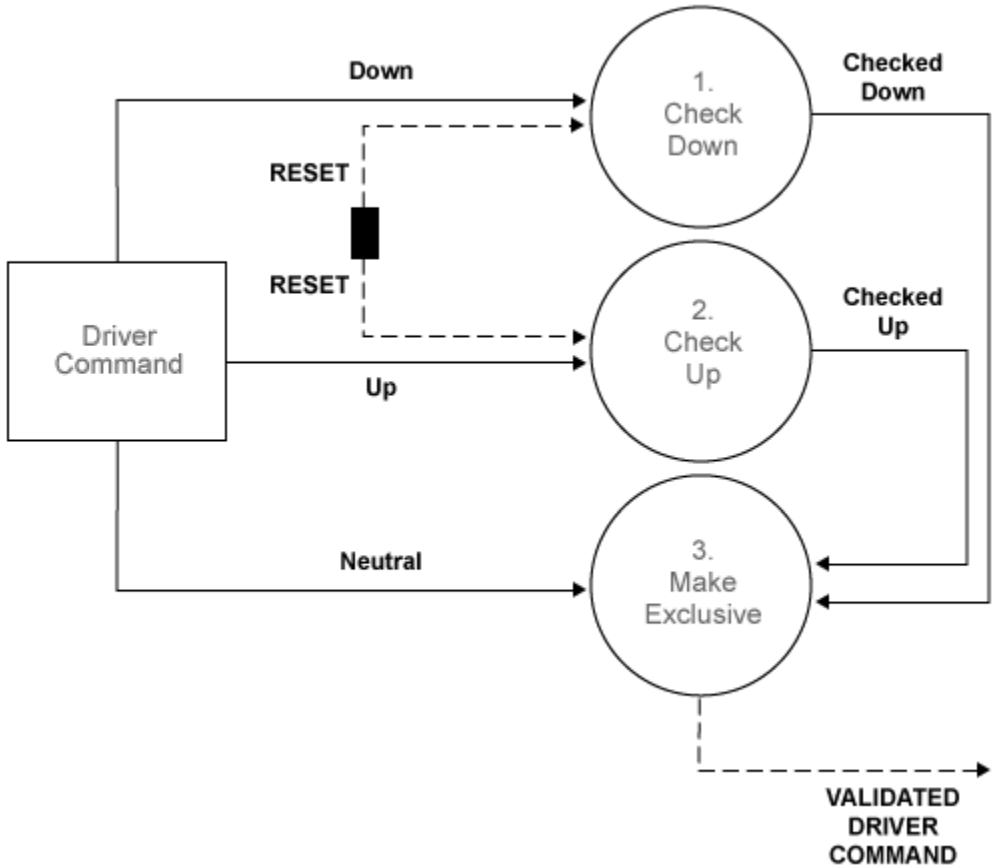
control signals and infers whether to move the window up or down (e.g., if an object is present, the window moves down for about one second or until it reaches an endstop).



For implementation in the Simulink environment, see “Implementation of Activity Diagram: Power Window Control” on page 23-15.

Activity Diagram: Validate Driver

Each process in the VALIDATE DRIVER activity chart is primitive and specified by the following PSPEC. In the MAKE EXCLUSIVE PSPEC, for safety reasons the `DOWN` command takes precedence over the `UP` command.



```
PSPEC 1.1.1: CHECK DOWN
  CHECKED_DOWN = DOWN and not RESET

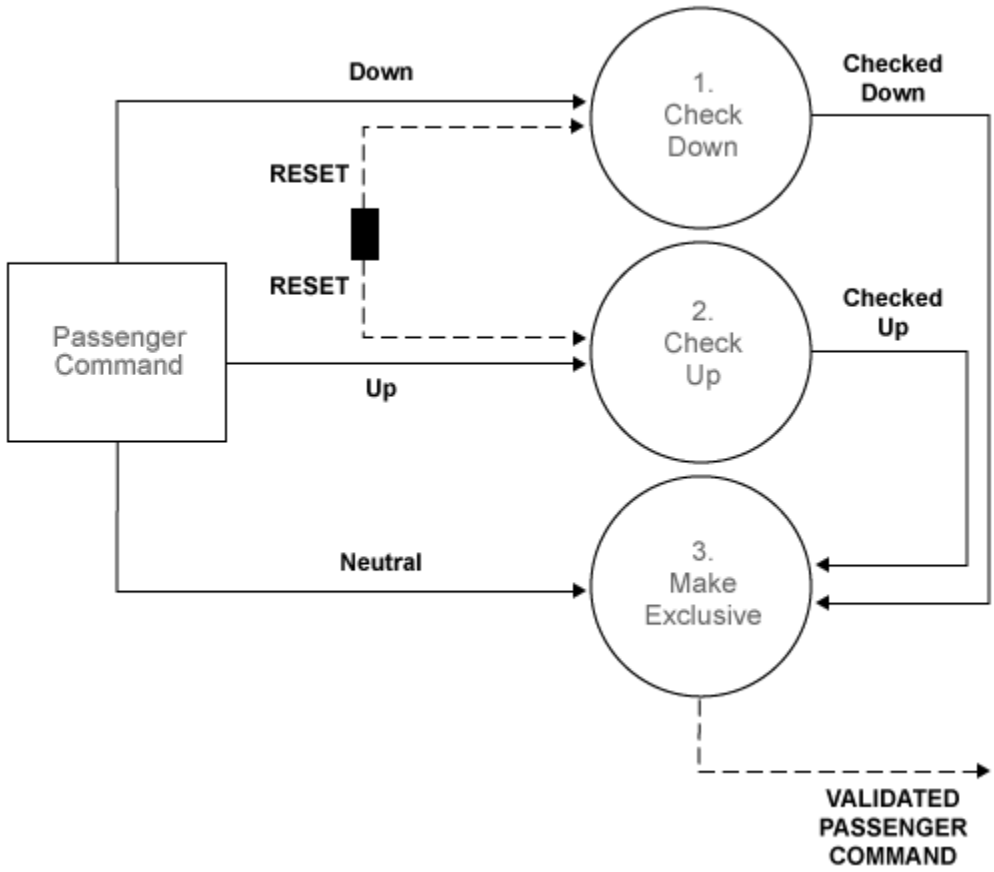
PSPEC 1.1.2: CHECK UP
  CHECKED_UP = UP and not RESET
```

```
PSPEC 1.1.3: MAKE EXCLUSIVE
  VALIDATED_DOWN    = CHECKED_DOWN
  VALIDATED_UP      = CHECKED_UP and not CHECKED_DOWN
  VALIDATED_NEUTRAL = (NEUTRAL and not (CHECKED_UP and not CHECKED_DOWN))
                        or not (CHECKED_UP or CHECKED_DOWN)
```

For implementation in the Simulink environment, see “Implementation of Activity Diagram: Validate” on page 23-36.

Activity Diagram: Validate Passenger

The internals of the VALIDATE PASSENGER process are the same as the VALIDATE DRIVER process. The only difference is the different input and output.



```
PSPEC 1.2.1: CHECK DOWN
  CHECKED_DOWN = DOWN and not RESET

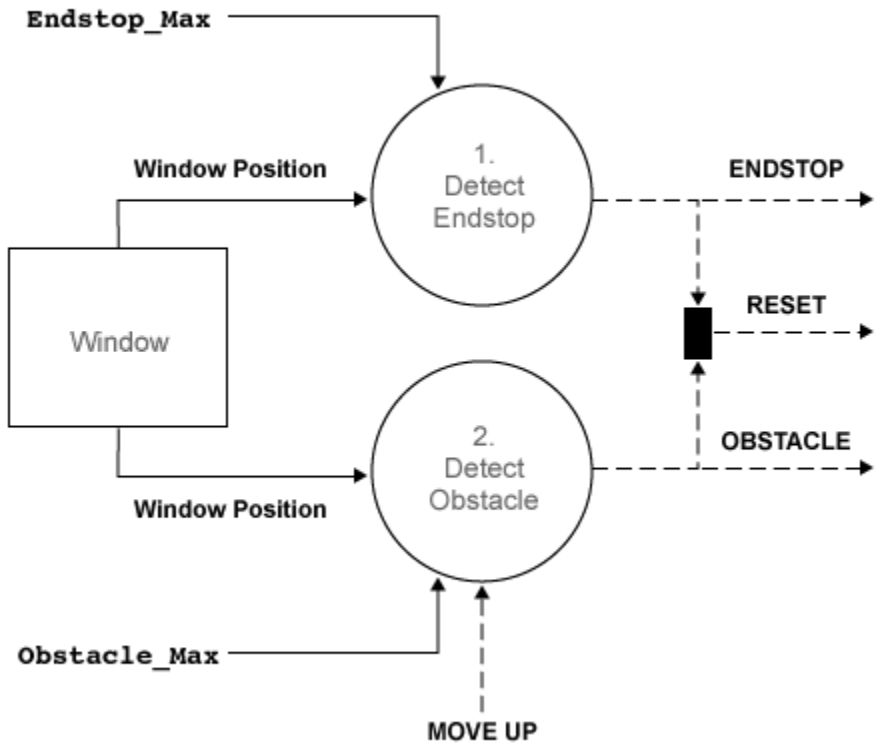
PSPEC 1.2.2: CHECK UP
  CHECKED_UP = UP and not RESET

PSPEC 1.2.3: MAKE EXCLUSIVE
  VALIDATED_DOWN    =  CHECKED_DOWN
  VALIDATED_UP      =  CHECKED_UP and not CHECKED_DOWN
  VALIDATED_NEUTRAL = (NEUTRAL and not (CHECKED_UP and not CHECKED_DOWN))
                        or not (CHECKED_UP or CHECKED_DOWN)
```

For implementation in the Simulink environment, see “Activity Diagram: Validate Passenger” on page 23-8.

Activity Diagram: Detect Obstacle Endstop

The third process in the POWER WINDOW CONTROL activity diagram detects the presence of an obstacle or when the window reaches its top or bottom (`ENDSTOP`). The detection mechanism is based on the armature current of the window actuator. During normal operation, this current is within certain bounds. When the window reaches its top or bottom, the electromotor draws a large current (more than 15 A or less than –15 A) to try and sustain its angular velocity. Similarly, during normal operation the current is about 2 A or –2 A (depending on whether the window is opening or closing). When there is an object, there is a slight deviation from this value. To keep the window force on the object less than 100 N, the control switches to its emergency operation when it detects a current that is less than –2.5 A. This operations is necessary only when the window is rolling up, which corresponds to a negative current in the particular wiring of this model. The DETECT OBSTACLE ENDSTOP activity diagram embodies this functionality.



```
CSPEC 1.3: DETECT OBSTACLE ENDSTOP
  RESET = OBSTACLE or ENDSTOP

PSPEC 1.3.1: DETECT ENDSTOP
  ENDSTOP = WINDOW_POSITION > ENDSTOP_MAX

PSPEC 1.3.2: DETECT OBSTACLE
  OBSTACLE = (WINDOW_POSITION > OBSTACLE_MAX) and MOVE_UP for 500 ms
```

For implementation in the Simulink environment, see “Activity Diagram: Detect Obstacle Endstop” on page 23-9.

Data Definitions

The functional decomposition unambiguously specifies each process by its decomposition or primitive specification (PSPEC). In addition, it must also formally specify the signals in the activity diagrams. Use data definitions for these specifications.

The following tables are data definitions for the signals used in the activity diagrams.

For the associated activity diagram, see "Context Diagram: Power Window System" on page 23-4.

Context Diagram: Power Window System Data Definitions

Signal	Information Type	Continuous/ Discrete	Data Type	Values
DRIVER_COMMAND	Data	Discrete	Aggregate	`Neutral`, `up`, `down`
PASSENGER_COMMAND	Data	Discrete	Aggregate	`Neutral`, `up`, `down`
WINDOW_POSITION	Data	Continuous	Real	0 to 0.4 m
MOVE_UP	Control	Discrete	Boolean	`'True'`, `'False'`
MOVE_DOWN	Control	Discrete	Boolean	`'True'`, `'False'`

For the associated activity diagram, see "Activity Diagram: Power Window Control" on page 23-5.

Activity Diagram: Power Window Control Data Definitions

Signal	Information Type	Continuous/ Discrete	Data Type	Values
DRIVER_COMMAND	Data	Discrete	Aggregate	`Neutral`, `up`, `down`
PASSENGER_COMMAND	Data	Discrete	Aggregate	`Neutral`, `up`, `down`
WINDOW_POSITION	Data	Continuous	Real	0 to 0.4 m
MOVE_UP	Control	Discrete	Boolean	`'True'`, `'False'`
MOVE_DOWN	Control	Discrete	Boolean	`'True'`, `'False'`

For the associated activity diagram, see “Activity Diagram: Validate Driver” on page 23-7.

Activity Diagram: Validate Driver Data Definitions

Signal	Information Type	Continuous/ Discrete	Data Type	Values
DRIVER_COMMAND	Data	Discrete	Aggregate	`Neutral`, `up`, `down`
PASSENGER_COMMAND	Data	Discrete	Aggregate	`Neutral`, `up`, `down`
WINDOW_POSITION	Data	Continuous	Real	0 to 0.4 m
MOVE_UP	Control	Discrete	Boolean	`'True'`, `'False'`
MOVE_DOWN	Control	Discrete	Boolean	`'True'`, `'False'`

For the associated activity diagram, see “Activity Diagram: Validate Passenger” on page 23-8.

Activity Diagram: Validate Passenger Data Definitions

Signal	Information Type	Continuous/ Discrete	Data Type	Values
NEUTRAL	Data	Discrete	Boolean	`'True'`, `'False'`
UP	Data	Discrete	Boolean	`'True'`, `'False'`
DOWN	Data	Discrete	Boolean	`'True'`, `'False'`
CHECKED_UP	Data	Discrete	Boolean	`'True'`, `'False'`
CHECKED_DOWN	Data	Discrete	Boolean	`'True'`, `'False'`

For the associated activity diagram, see “Activity Diagram: Detect Obstacle Endstop” on page 23-9.

Activity Diagram: Detect Obstacle Endstop Data Definitions

Signal	Information Type	Continuous/ Discrete	Data Type	Values
ENDSTOP_MIN	Data	Constant	Real	0.0 m
ENDSTOP_MAX	Data	Constant	Real	0.4 m
OBSTACLE_MAX	Data	Constant	Real	0.3 m

The model design iterates as we examine more detailed implementations. For information about how the model design iterates as you introduce more detail, see “Iterate on the Design” on page 23-46.

Simulink Power Window Controller in Simulink Project

MATLAB and Simulink support Model-Based Design for embedded control design, from initial specification to code generation. To organize large projects and share your work with others, use Simulink Projects.

The Power Window Control Project example shows how you can use MathWorks tools and the Model-Based Design process to go from concept through implementation for an

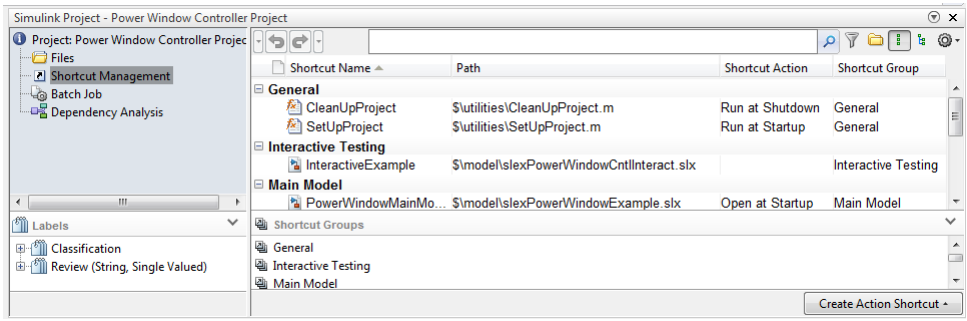
automobile power window system. It uses Simulink Projects to organize the files and other model components.

In addition, this example shows how to link models to system documentation.

Explore the Power Window Controller Project

1 To open the Power Window Controller project, in the MATLAB Command Window, type:

```
slexPowerWindowStart
```



2 Explore the project folders. In particular, note the **task** folders. This folder contains scripts that run frequent tasks for a model. For the Power Window Controller Project, these scripts:

- Set up the model to control window movement on a controller area network (CAN).
- Set up the model to use the Stateflow and Simulink software to model discrete-event reactive behavior and continuous time behavior, with a low-order plant model.
- Set up the model with a more detailed plant model that includes power effects in the electrical and mechanical domains. The plant model validates the force exerted by the window on a trapped object.
- Set up the model with a model that includes other effects that may change the model, such as quantization of the measurements.

Note These scripts also simulate the model. To only configure the model, see the scripts in the **configureModel** folder.

- Use the increase coverage model to generate the model coverage report.

3 The **Shortcut Management** section contains quick-access commands that you can double-click to perform common tasks such as:

- Set up and clean up projects.
- Add projects to MATLAB paths.
- Perform interactive testing.
- Validate model testing with model coverage.
- Open the main model.
- Simulate the model with various configurations.
- Generate a model coverage report for increased coverage of the model.
- Open the model used for increasing model coverage.

Simulink Power Window Controller

Implementation of Activity Diagram: Power Window Control

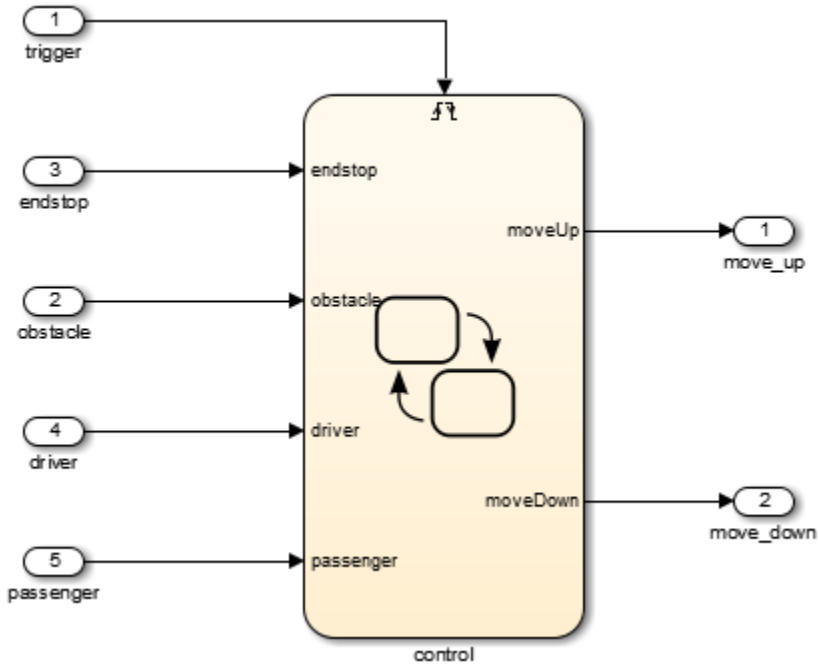
This topic describes the high-level discrete-event control specification for a power window control.

You can model the discrete-event control of the window with a Stateflow chart. A Stateflow chart is a finite state machine with hierarchy and parallelism. This state machine contains the basic states of the power window system: up, auto-up, down, auto-down, rest, and emergency. It models the state transitions and accounts for the precedence of driver commands over the passenger commands. It also includes emergency behavior that activates when the software detects an object between the window and the frame while moving up.

The initial Simulink model for the power window control, `slexPowerWindowControl`, is a discrete-event controller that runs at a given sample rate.

In this implementation, open the power window control subsystem and observe that the Stateflow chart with the discrete-event control forms the CSPEC, represented by the

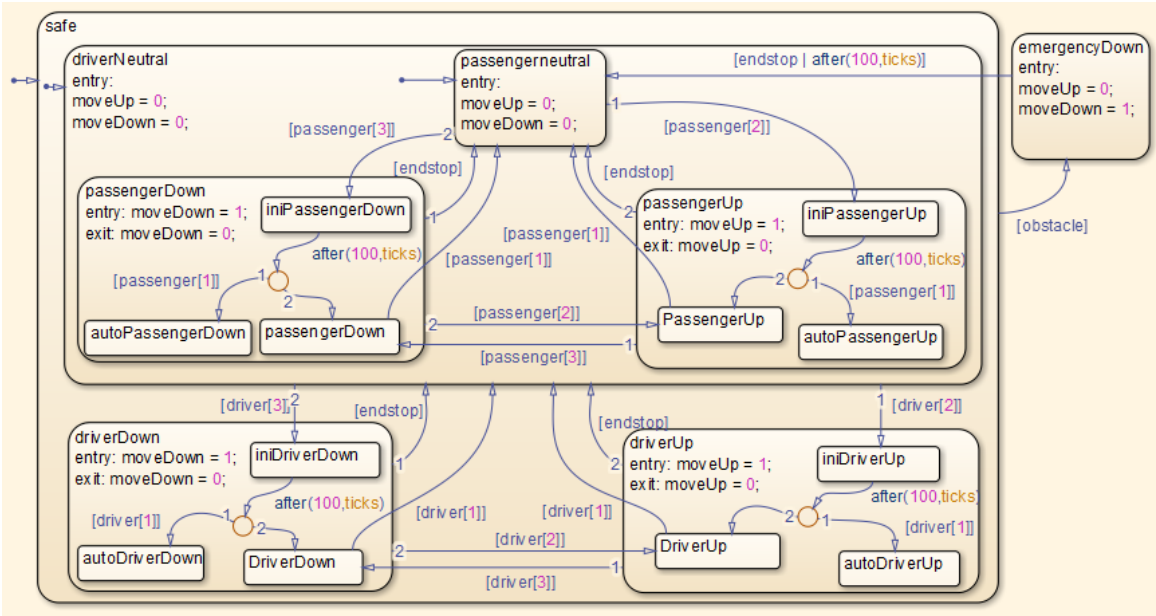
tilted thick bar in the bottom right corner. The detect_obstacle_endstop subsystem encapsulate the threshold detection mechanisms.



The discrete-event control is a Stateflow model that extends the state transition diagram notion with hierarchy and parallelism. State changes because of passenger commands are encapsulated in a *super state* that does not correspond to an active driver command.

Consider the control of the passenger window. The passenger or driver can move this window up and down.

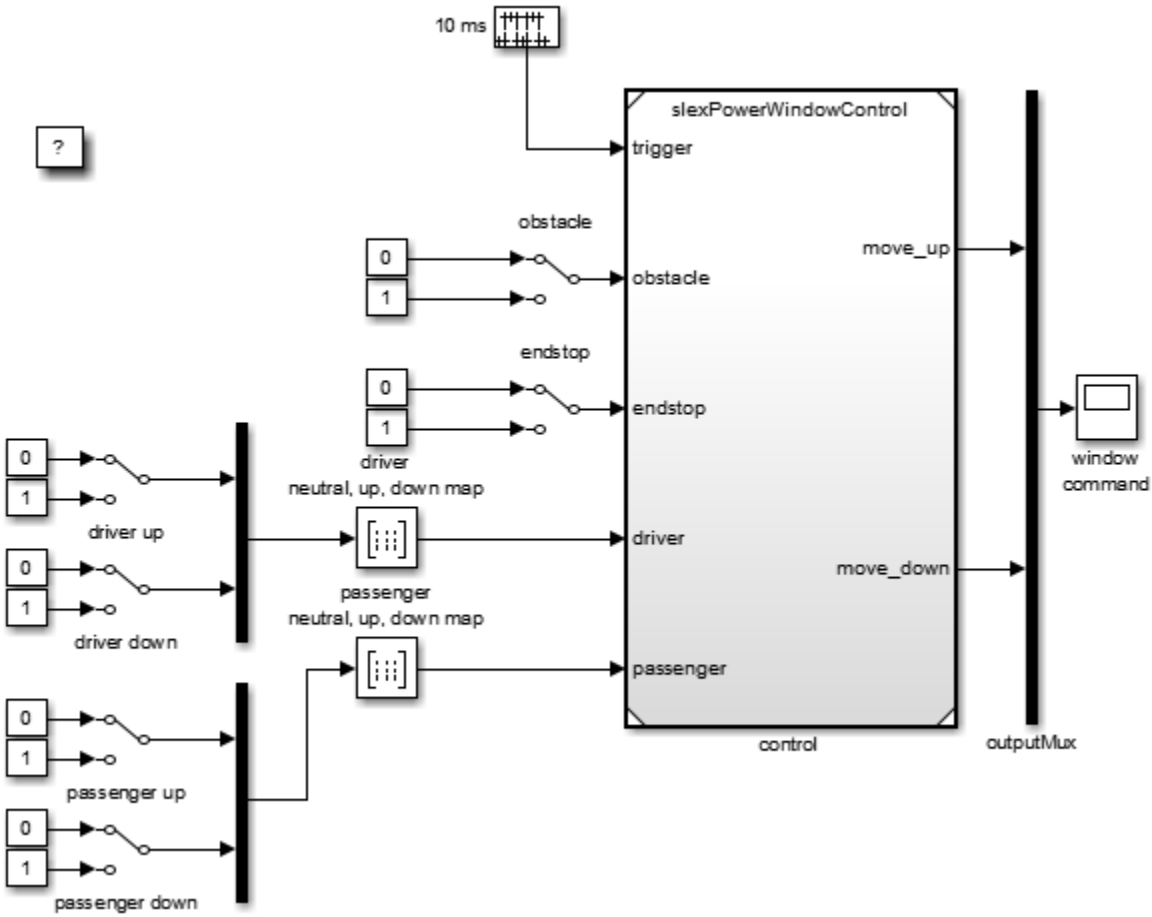
This state machine contains the basic states of the power window system: up, auto-up, down, auto-down, rest, and emergency.



Interactive Testing

Control Input

The `slexPowerWindowCntlInteract` model includes this control input as switches. Double-click these switches to manually operate them.



Test the state machine that controls a power window by running the input test vectors and checking that it reaches the desired internal state and generates output. The power window has the following external inputs:

- Passenger input
- Driver input
- Window up or down
- Obstacle in window

Each input consists of a vector with these inputs.

Passenger Input

Element	Description
`neutral`	Passenger control switch is not depressed.
`up`	Passenger control switch generates the up signal.
`down`	Passenger control switch generates the down signal.

Driver Input

Element	Description
`neutral`	Driver control switch is not depressed.
`up`	Driver control switch generates the up signal.
`down`	Driver control switch generates the down signal.

Window Up or Down

Element	Description
`0`	Window moves freely between top or bottom.
`1`	Window is stuck at the top or bottom because of physical limitations.

Obstacle in Window

Element	Description
`0`	Window moves freely between top or bottom.
`1`	Window has obstacle in the frame.

Generate the passenger and driver input signals by mapping the up and down signals according to this table:

Inputs		Outputs		
up	**down**	**up**	**down**	**neutral**
`0`	`0`	`0`	`0`	`1`

Inputs		Outputs		
up	down	up	down	neutral
0	1	0	1	0
1	0	1	0	0
1	1	0	0	1

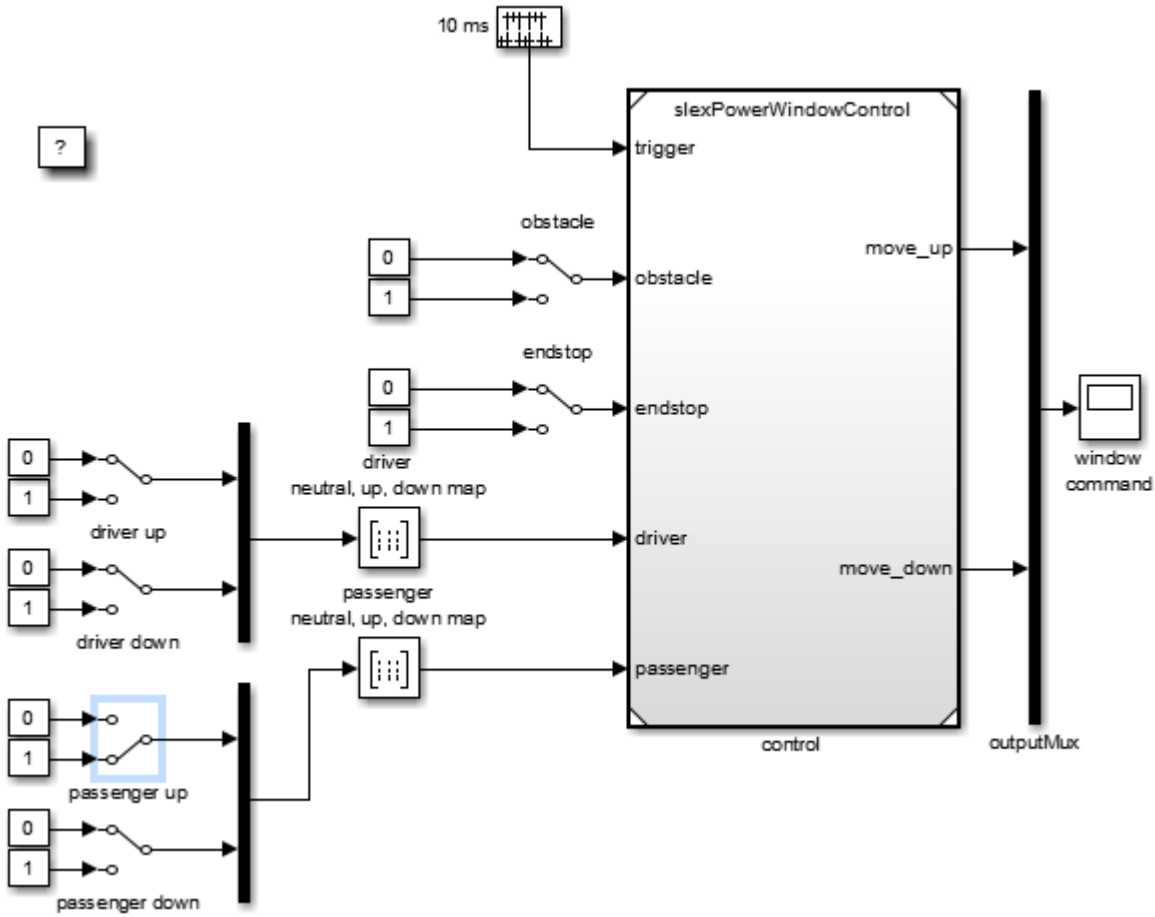
The inputs explicitly generate the `neutral` event from the `up` and `down` events, generated by pressing a power window control switch. The inputs are entered as a truth table in the passenger neutral, up, down map and the driver neutral, up, down map.

Experimental Results from Interactive Testing

Case 1: Window Up

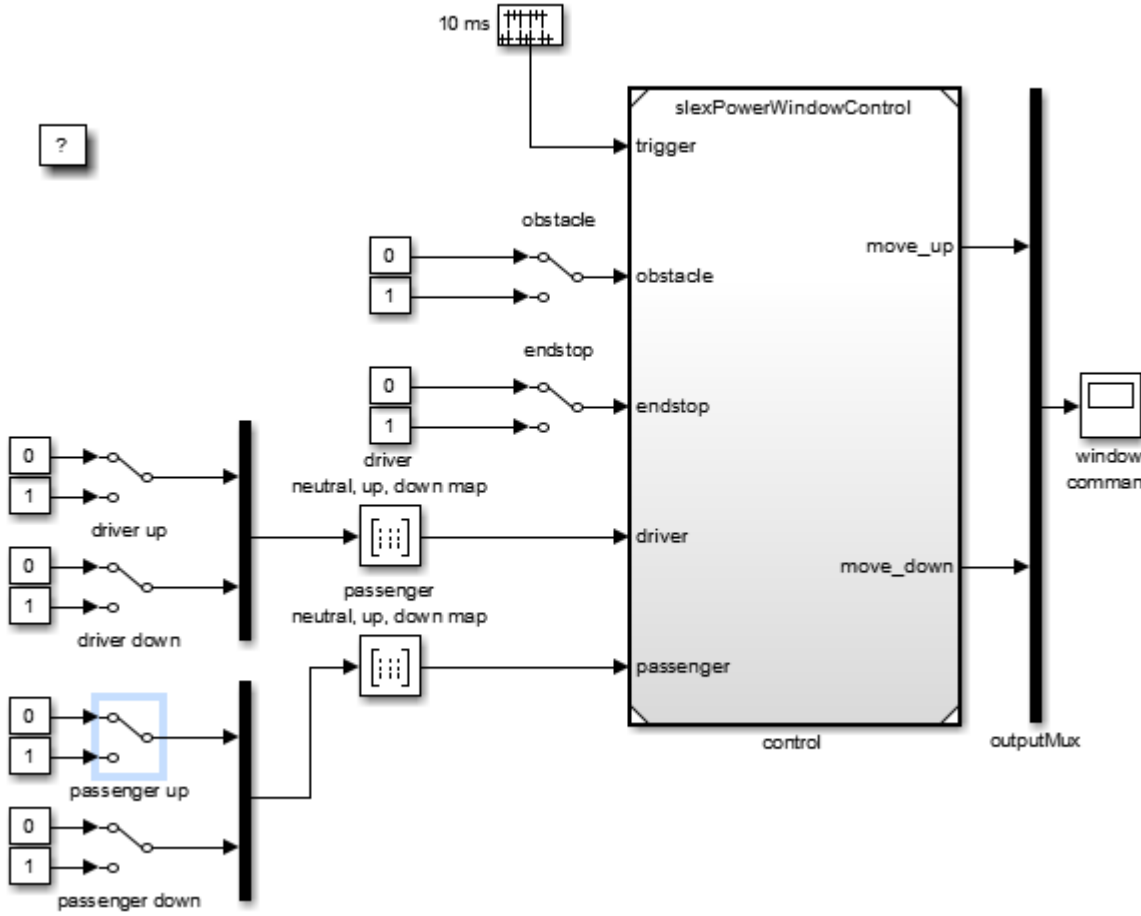
To observe the state machine behavior:

1. Open the `slexPowerWindowCntlInteract` model.
2. Run the simulation and then double-click the passenger up switch.



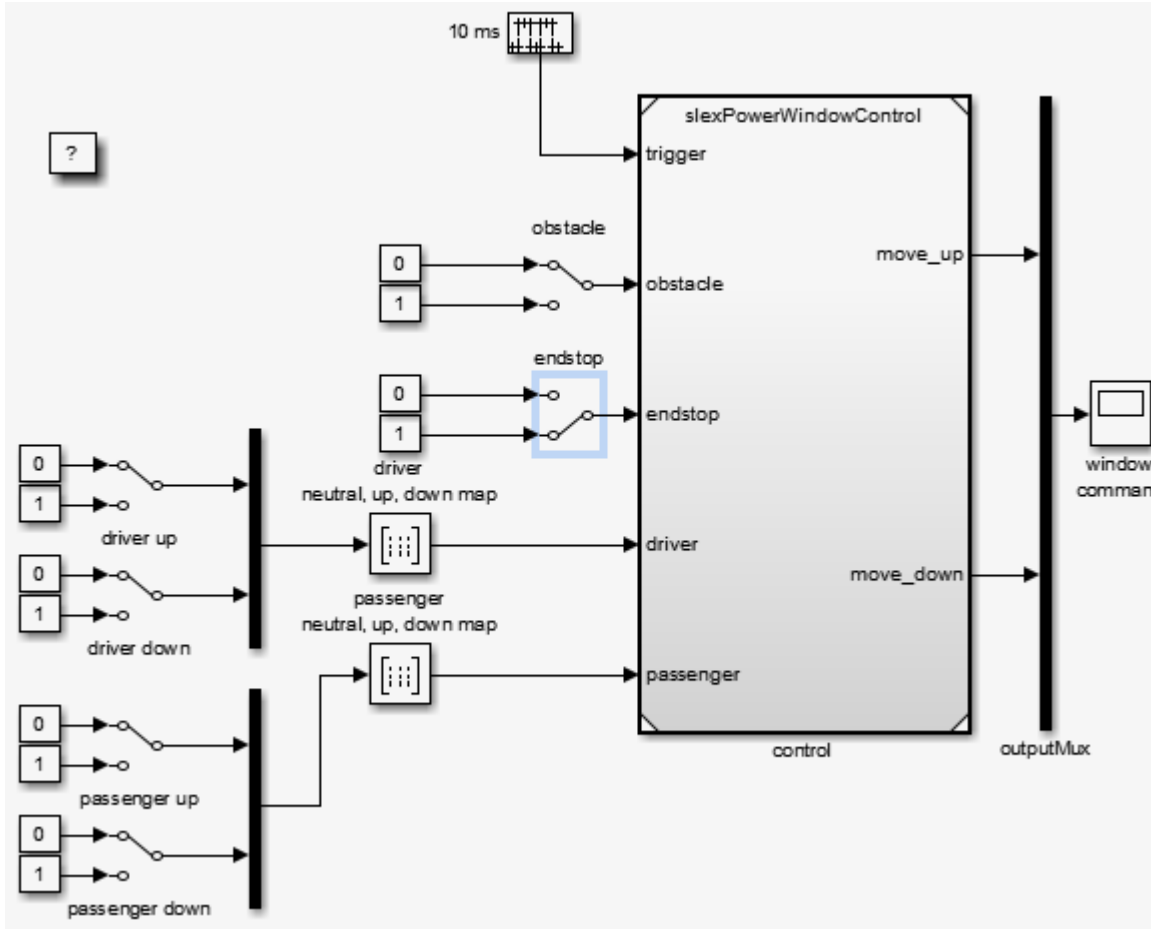
If you press the physical window switch for more than one second, the window moves up until the up switch is released (or the top of the window frame is reached and the `endstop` event is generated).

3 Double-click the selected passenger up switch to release it.



4 Simulate the model.

Setting the endstop switch generates the endstop event.

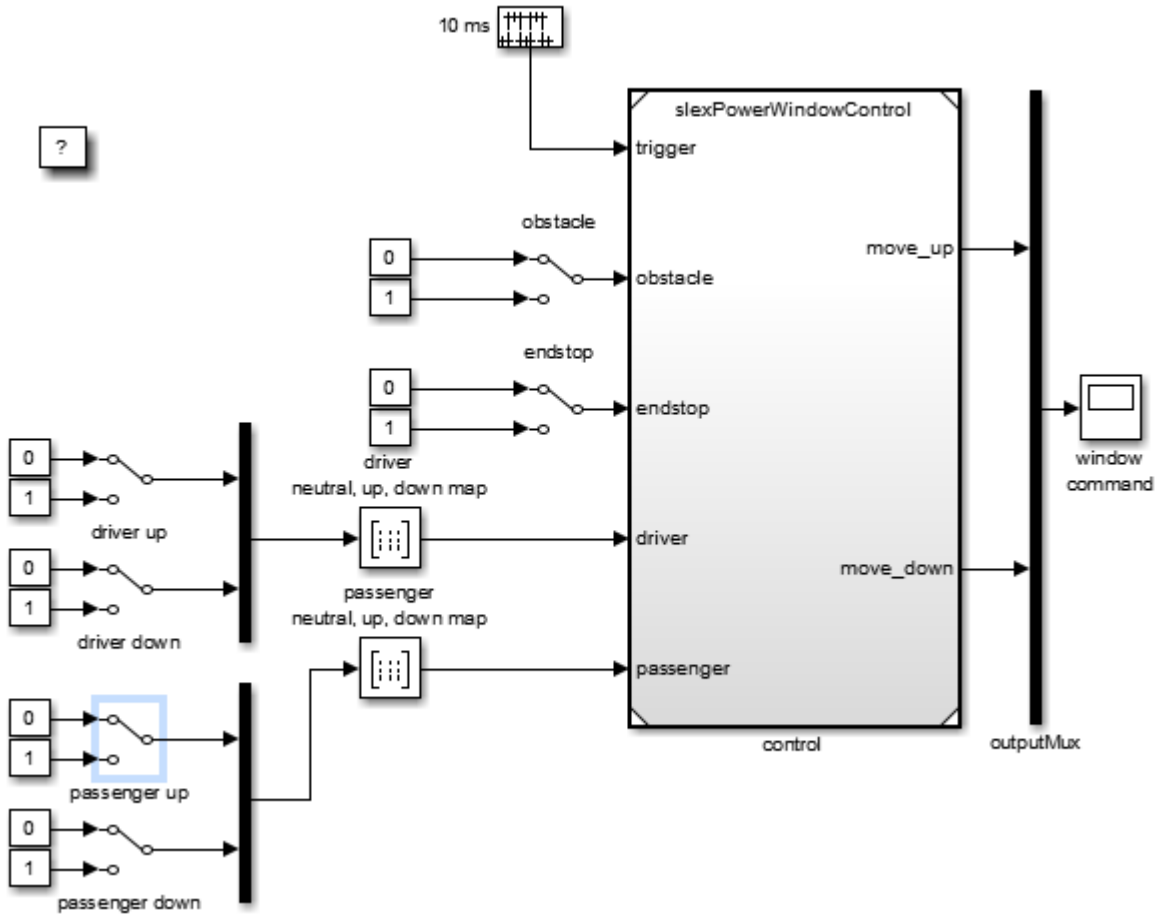


Case 2: Window Auto-Up

If you press the physical passenger window up switch for a short period of time (less than a second), the software activates auto-up behavior and the window continues to move up.

1 Press the physical passenger window up switch for a short period of time (less than a second).

   Ultimately, the window reaches the top of the frame and the software generates the `endstop` event. This event moves the state machine back to its neutral state.

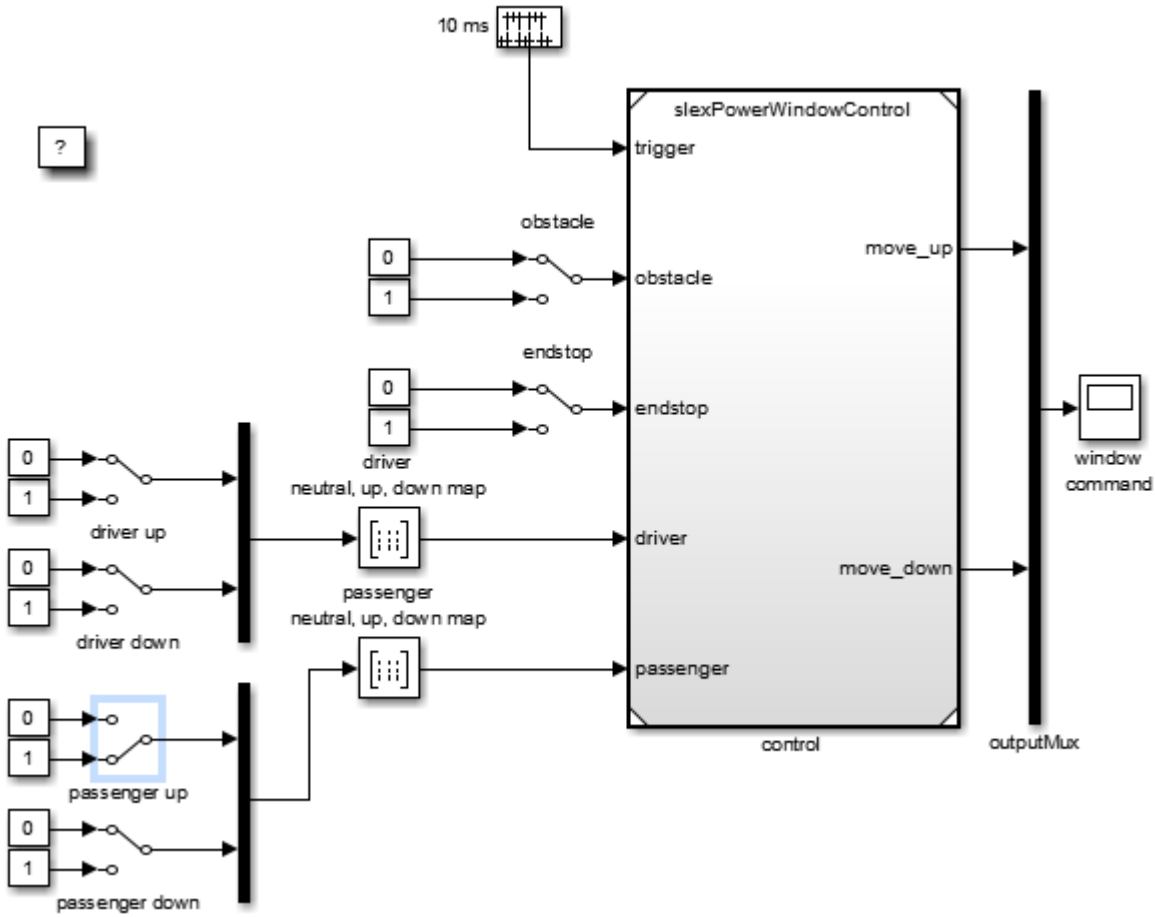


2 Simulate the model.

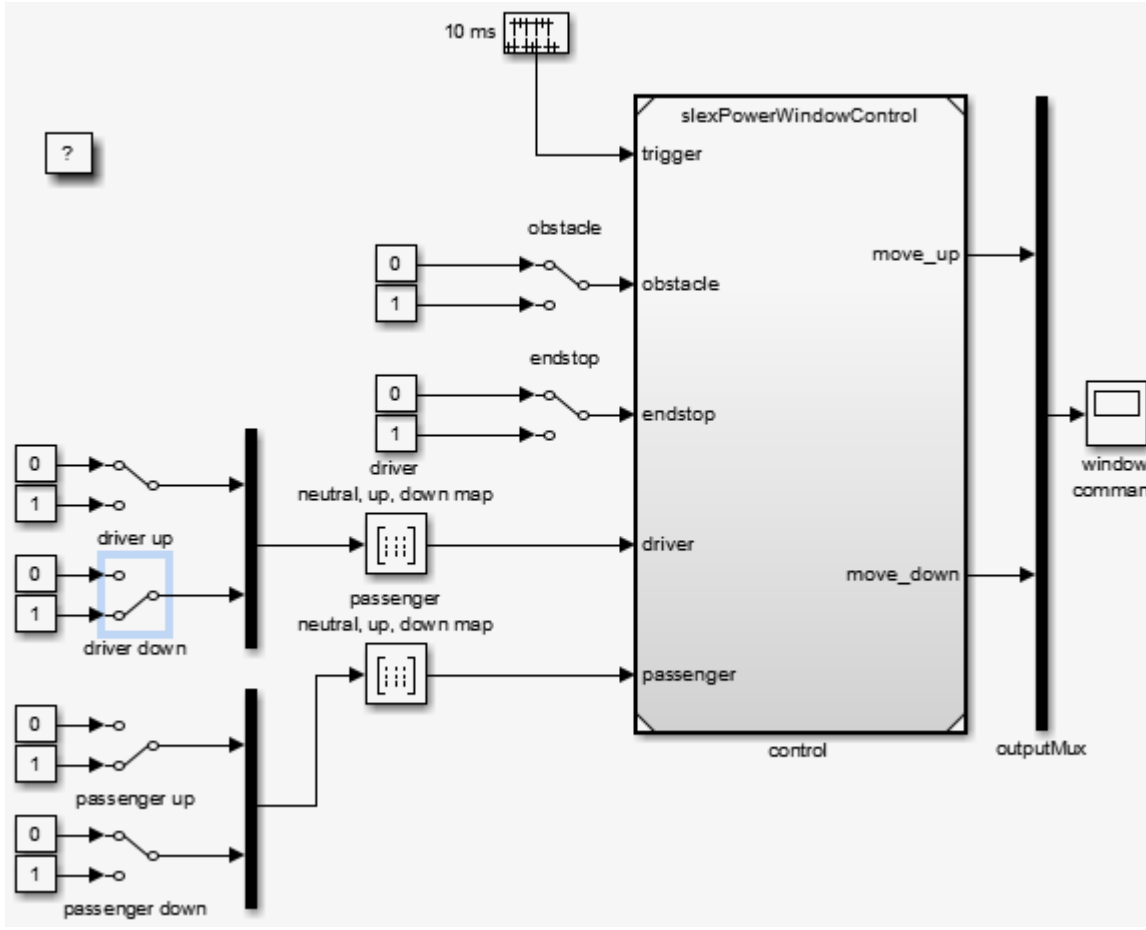
Case 3: Driver-Side Precedence

The driver switch for the passenger window takes precedence over the driver commands. To observe the state machine behavior in this case:

1 Run the simulation, and then move the system to the `passenger up` state by double-clicking the passenger window up switch.



2 Double-click the driver down switch.

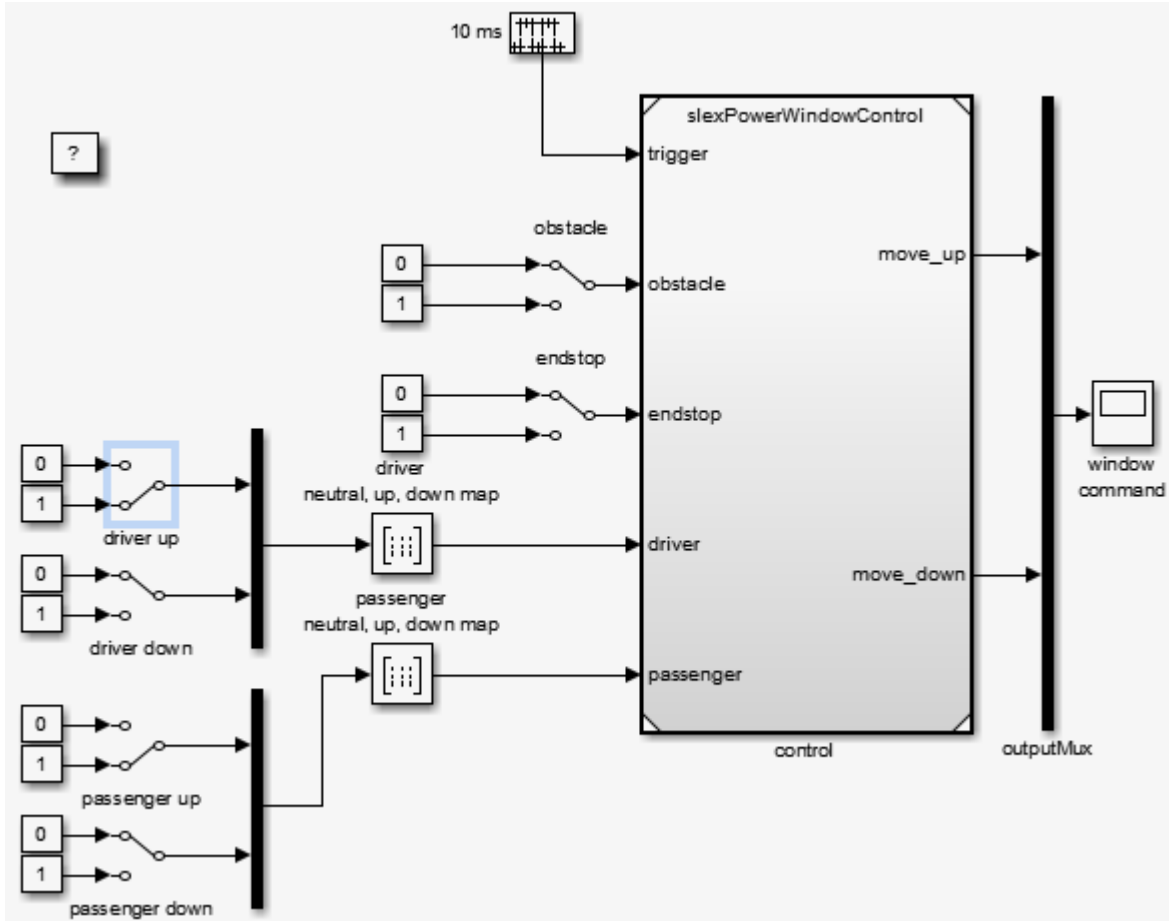


3 Simulate the model.

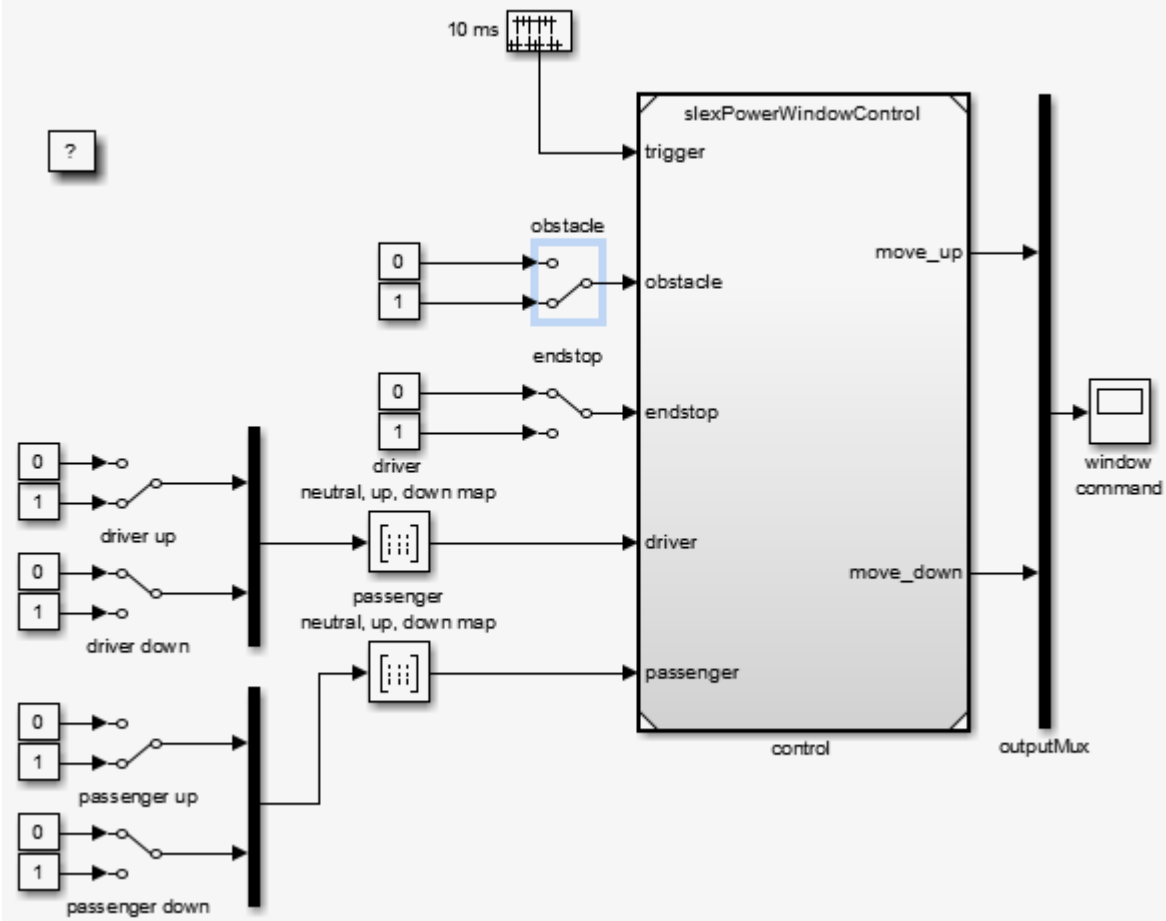
4 Notice how the state machine moves to the driver control part to generate the window down output instead of the window up output.

5 Double-click the driver control to driver up. Double-click the driver down switch.

The driver window up state is reached, which generates the window up output again, i.e., `windowUp = 1`.



6 To observe state behavior when an object is between the window and the frame, double-click the obstacle switch.



7 Simulate the model.

On the next sample time, the state machine moves to its `emergencyDown` state to lower the window a few inches. How far the software lowers the window depends on how long the state machine is in the `emergencyDown` state. This behavior is part of the next analysis phase.

If a driver or passenger window switch is still active, the state machine moves into the up or down states upon the next sample time after leaving the emergency state. If the obstacle switch is also still active, the software again activates the emergency state at the next sample time.

Model Coverage

Validation of the Control Subsystem

Validate the discrete-event control of the window using the model coverage tool. This tool helps you determine the extent to which a model test case exercises the conditional branches of the controller. It helps evaluate whether all transitions in the discrete-event control are taken, given the test case, and whether all clauses in a condition that enables a particular transition have become true. Multiple clauses can enable one transition, e.g., the transition from emergency back to neutral occurs when either 100 ticks have occurred or if the endstop is reached.

To achieve full coverage, each clause evaluates to true and false for the test cases used. The percentage of transitions that a test case exercises is called its model coverage. Model coverage is a measure of how thoroughly a test exercises a model.

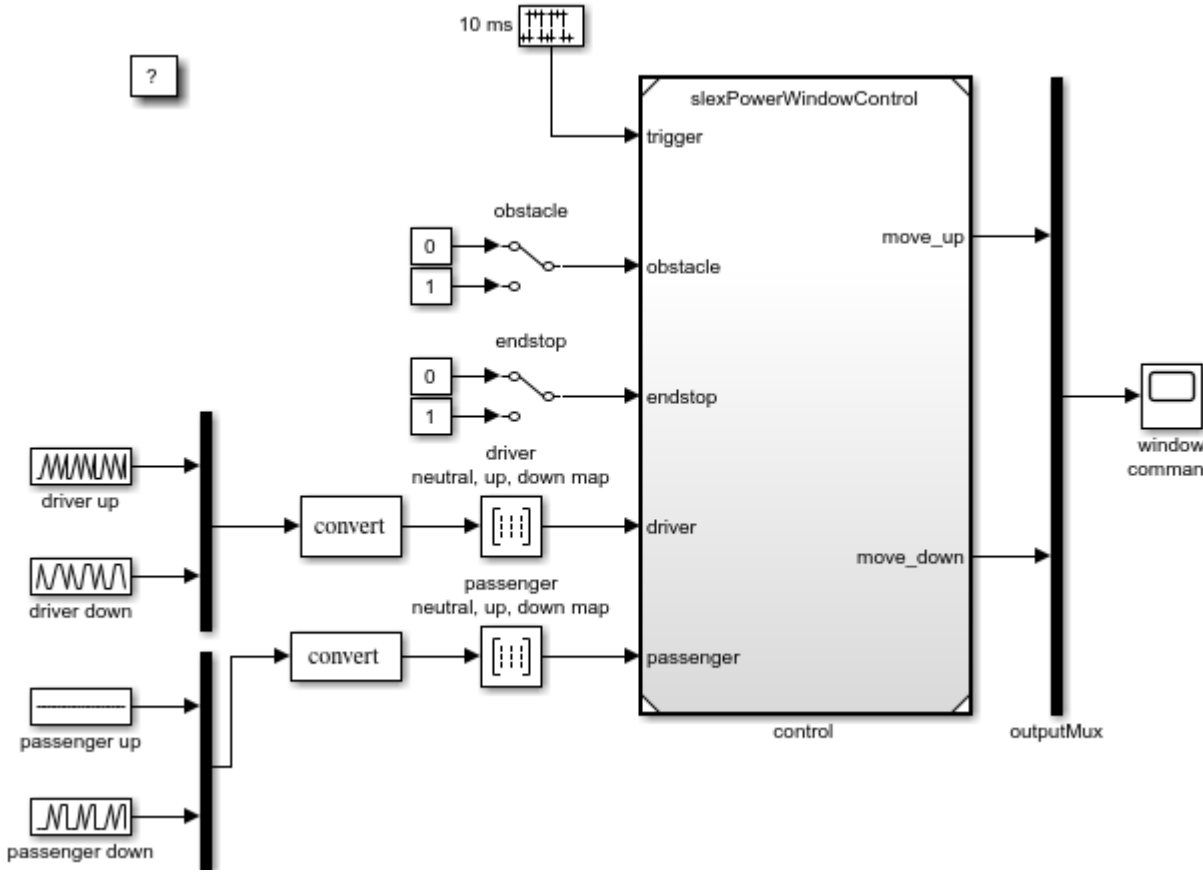
Using Simulink Coverage software, you can apply the following test to the power window controller.

Position	Step						
	0	1	2	3	4	5	6
Passenger up	0	0	0	0	0	0	0
Passenger down	0	0	0	1	0	1	1
Driver up	0	0	1	0	1	0	1
Driver down	0	1	0	0	1	1	0

With this test, all switches are inactive at time 0. At regular 1 s steps, the state of one or more switches changes. For example, after 1 s, the driver down switch becomes active. To automatically run these input vectors, replace the manual switches by prescribed sequences of input. To see the preconstructed model:

1 In the MATLAB Command Window, type:

```
slexPowerWindowCntlCoverage
```



2 Simulate the model to generate the Simulink Coverage coverage report.

For the `slexPowerWindowCntrlCoverage` model, the report reveals that this test handles 100% of the decision outcomes from the driver neutral, up, down map block. However, the test achieves only 50% coverage for the passenger neutral, up, down map block. This coverage means the overall coverage for `slexPowerWindowCntrlCoverage` is 45% while the overall coverage for the `slexPowerWindowControl` model is 42%. A few of the contributing factors for the coverage levels are:

- Passenger up block does not change.
- Endstop and obstacle blocks do not change.

Increase Model Coverage

To increase total coverage to 100%, you need to take into account all possible combinations of driver, passenger, obstacle, and endstop settings. When you are satisfied with the control behavior, you can create the power window system. For more information, see “Create Model Using Model-Based Design” on page 23-34.

This example increases the model coverage for the validation of the discrete-event control of the window. To start, the example uses inputs from `slexPowerWindowCntlCoverage` as a baseline for the model coverage. Next, to further exercise the discrete-event control of the window, it creates more input sets. The spreadsheet file, `inputCntlCoverageIncrease.xlsx`, contains these input sets using one input set per sheet.

In the example, the `slexPowerWindowSpreadsheetGeneration` utility function, which creates a spreadsheet template from the controller model, `slexPowerWindowControl`, creates the `inputCntlCoverageIncrease.xlsx`. In `inputCntlCoverageIncrease.xlsx`, the function uses the block names in the controller model as signal names. `slexPowerWindowSpreadsheetGeneration` defines the sheet names. The `slexWindowSpreadsheetAddInput` utility function populates `inputCntlCoverageIncrease.xlsx` with signal data.

The sheet names of these input sets and their descriptions are:

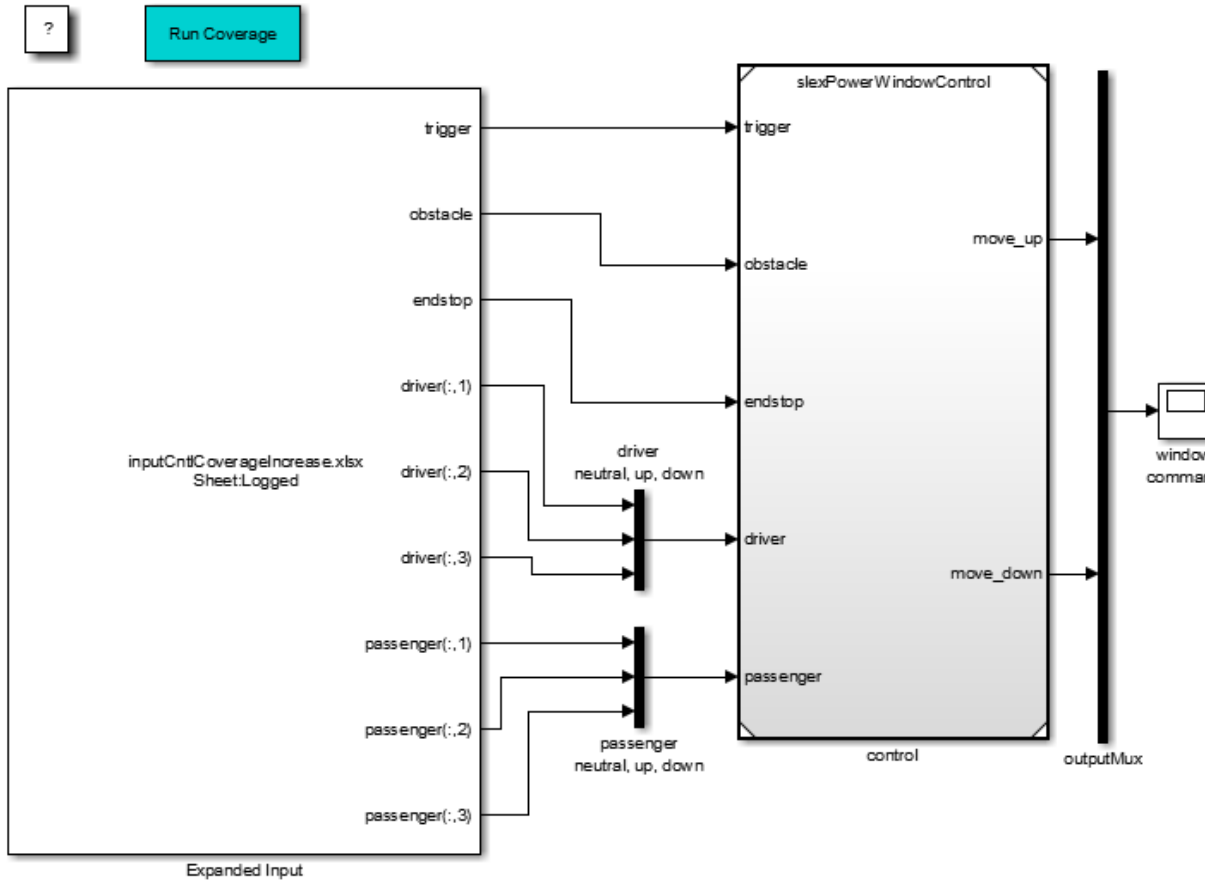
Sheet Name	Description
`Logged`	Inputs logged from `slexPowerWindowCntlCoverage`
`LoggedObstacleOffEndStopOn`	Inputs logged from `slexPowerWindowCntlCoverage` with ability to hit endstop
`LoggedObstacleOnEndStopOff`	Inputs logged from `slexPowerWindowCntlCoverage` with obstacle in window
`LoggedObstacleOnEndStopOn`	Inputs logged from `slexPowerWindowCntlCoverage` with obstacle in window and ability to hit endstop
`DriverLoggedPassengerNeutral`	Inputs logged from `slexPowerWindowCntlCoverage` for driver only and passenger takes no action
`DriverDownPassengerNeutral`	Driver is putting down window and passenger takes no action
`DriverUpPassengerNeutral`	Driver is putting up window and passenger takes no action

Sheet Name	Description
`DriverAutoDownPassengerNeutral`	Driver is putting down window for one second (auto-down) and passenger takes no action
`DriverAutoUpPassengerNeutral`	Driver is putting up window for one second (auto-up) and passenger takes no action
`PassengerAutoDownDriverNeutral`	Passenger is putting down window for one second (auto-down) and driver takes no action
`PassengerAutoUpDriverNeutral`	Passenger is putting up window for one second (auto-up) and driver takes no action

To automatically run these input vectors, replace the inputs to the discrete-event control with the From Spreadsheet block using the file, `inputCntlCoverageIncrease.xlsx`. This file contains the multiple input sets. To see the preconstructed model:

1 In the MATLAB Command Window, type:

```
slexPowerWindowCntlCoverageIncrease
```



2 To generate the Simulink Coverage coverage report for multiple input set, double click the Run Coverage subsystem in the model.

For the `slexPowerWindowCntrlCoverageIncrease` model, the report reveals that using multiple input sets has successfully raised the overall coverage for the `slexPowerWindowControl` model from 42% to 78%. Coverage levels are less than 100% because of missing input sets for:

- Passenger up state
- Driver up and down states
- Passenger automatic down and automatic up states

Create Model Using Model-Based Design

Why Use Model-Based Design?

In Model-Based Design, a system model is at the center of the development process, from requirements development, through design, implementation, and testing. Use Model-Based Design to:

- Use a common design environment across project teams.
- Link designs directly to requirements.
- Integrate testing with design to continuously identify and correct errors.
- Refine algorithms through multidomain simulation.
- Automatically generate embedded software code.
- Develop and reuse test suites.
- Automatically generate documentation for the model.
- Reuse designs to deploy systems across multiple processors and hardware targets.

For more information, see "Model-Based Design".

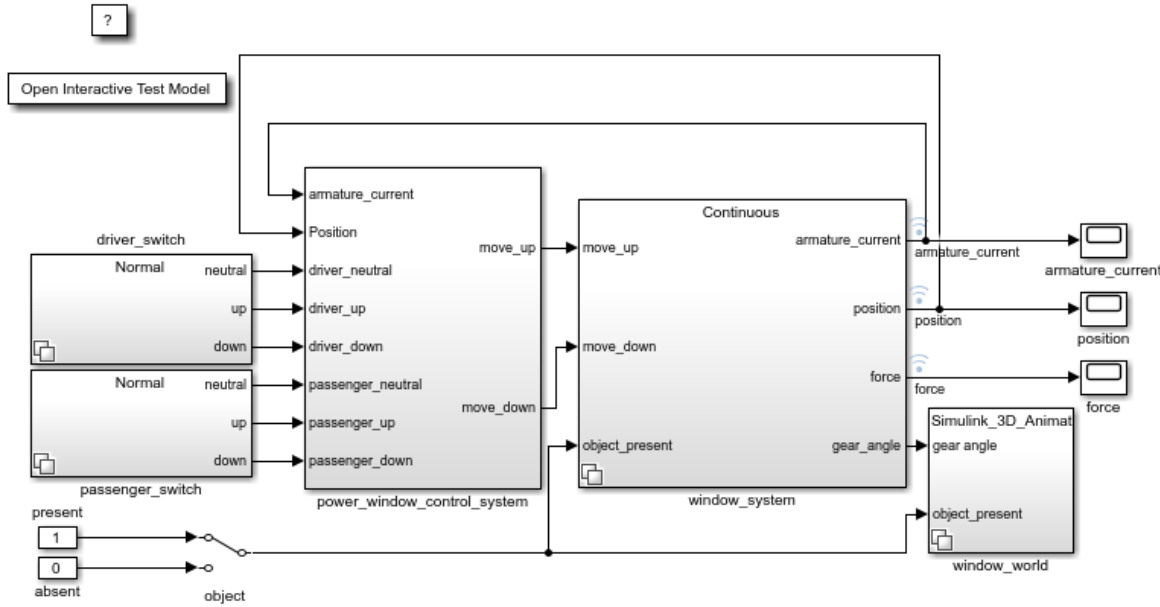
Implementation of Context Diagram: Power Window System

For requirements presented as a context diagram, see "Context Diagram: Power Window System" on page 23-4.

Create a Simulink model to resemble the context diagram.

1. Place the plant behavior into one subsystem.
2. Create two subsystems that contain the driver and passenger switches.
3. Add a control mechanism to conveniently switch between the presence and absence of the object.
4. Put the control in one subsystem.
5. Connect the new subsystems.
6. To see an implementation of this model, in the MATLAB Command Window, type:

```
slexPowerWindowStart
```



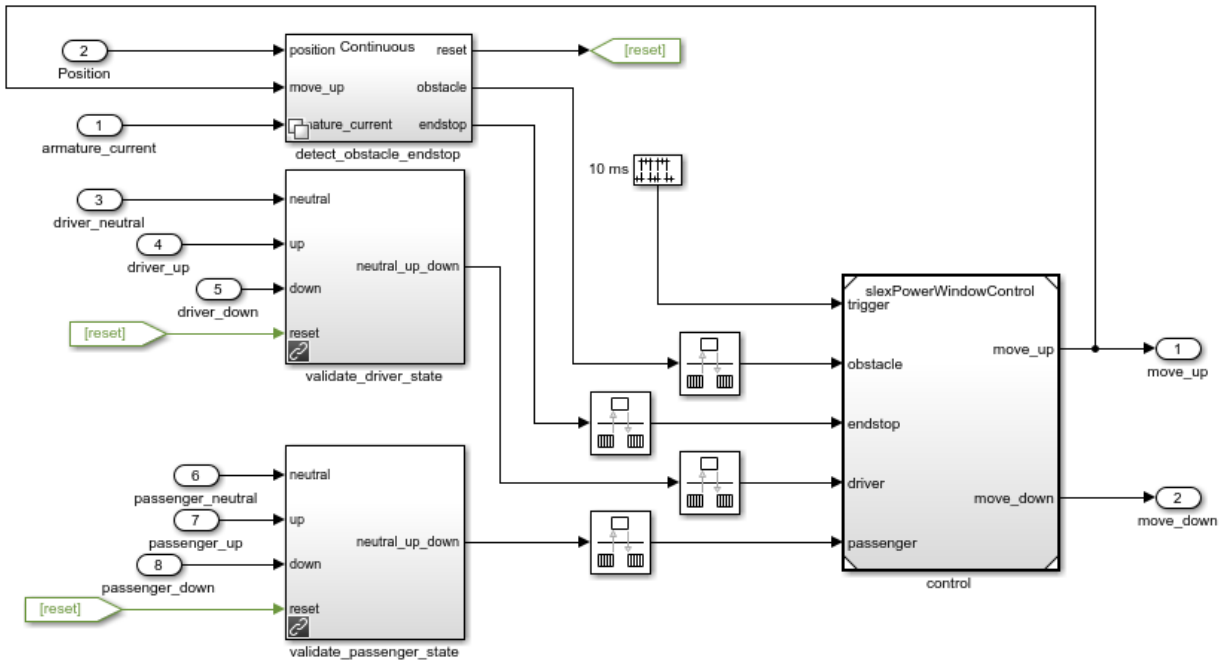
You can use the power window control activity diagram (“Activity Diagram: Power Window Control” on page 23-5) to decompose the power window controller of the context diagram into parts. This diagram shows the input and output signals present in the context diagram for easier tracing to their origins.

Implement Power Window Control System

To satisfy full requirements, the power window control must work with the validation of the driver and passenger inputs and detect the endstop.

For requirements presented as an activity diagram, see “Activity Diagram: Power Window Control” on page 23-5.

Double-click the slexPowerWindowExample/power_window_control_system block to open the following subsystem:



Implementation of Activity Diagram: Validate

For requirements presented as activity diagrams, see “Activity Diagram: Validate Driver” on page 23-7 and “Activity Diagram: Validate Passenger” on page 23-8.

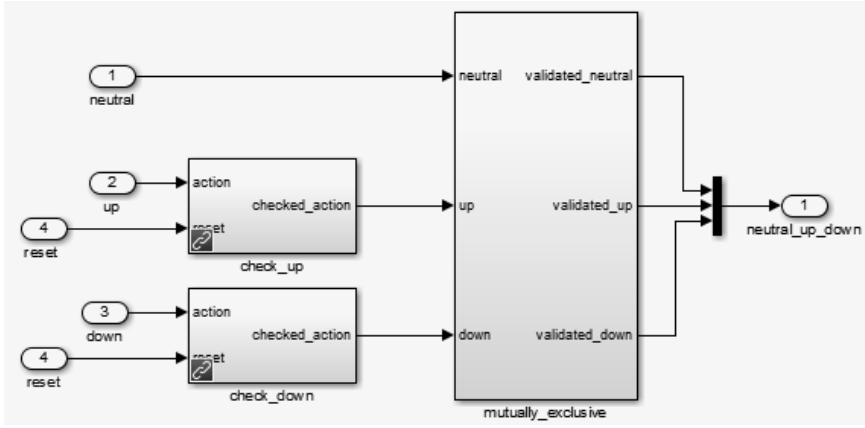
The activity diagram adds data validation functionality for the driver and passenger commands to ensure correct operation. For example, when the window reaches the top, the software blocks the `up` command. The implementation decomposes each validation process in new subsystems. Consider the validation of the driver commands (validation of

the passenger commands is similar). Check if the model can execute the `up` or `down` commands, according to the following:

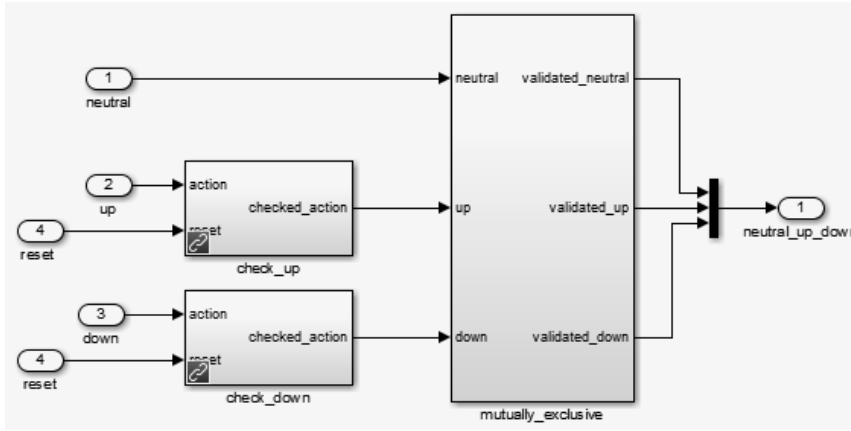
- The model allows the `down` command only when the window is not completely opened.
- The model allows the `up` command only when the window is not completely closed and no object is detected.

The third activity diagram process checks that the software sends only one of the three commands (`neutral`, `up`, `down`) to the controller. In an actual implementation, both `up` and `down` can be simultaneously true (for example, because of switch bouncing effects).

From the power_window_control_system subsystem, this is the validate_driver_state subsystem:



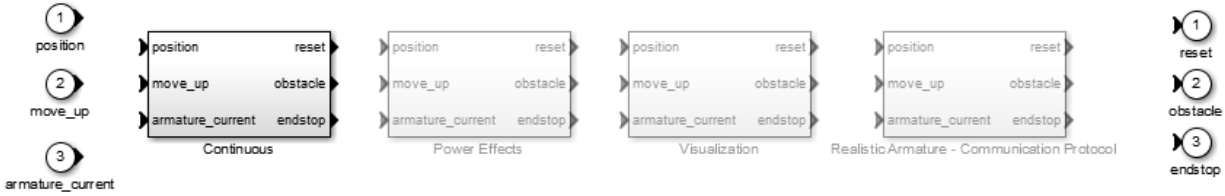
From the power_window_control_system subsystem, this is the validate_passenger_state subsystem:



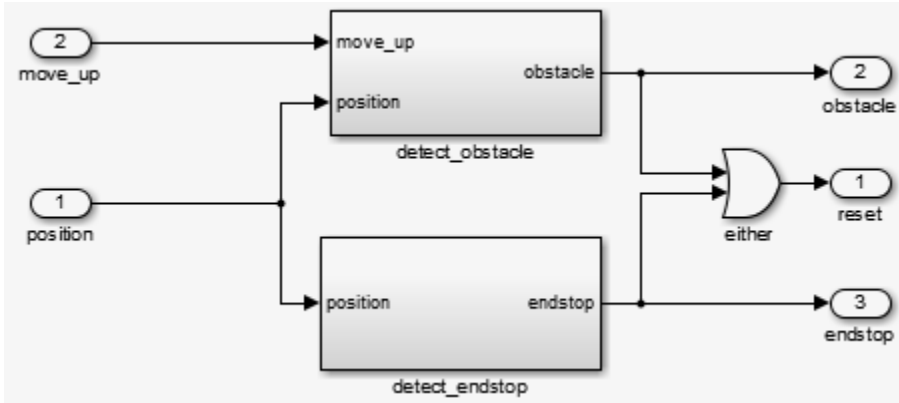
Implementation of Activity Diagram: Detect Obstacle Endstop

For requirements presented as an activity diagram, see “Activity Diagram: Detect Obstacle Endstop” on page 23-9.

In the `slexPowerWindowExample` model, the power_window_control_system/detect_obstacle_endstop block implements this activity diagram in the continuous variant of the Variant Subsystem block. During design iterations, you can add additional variants.



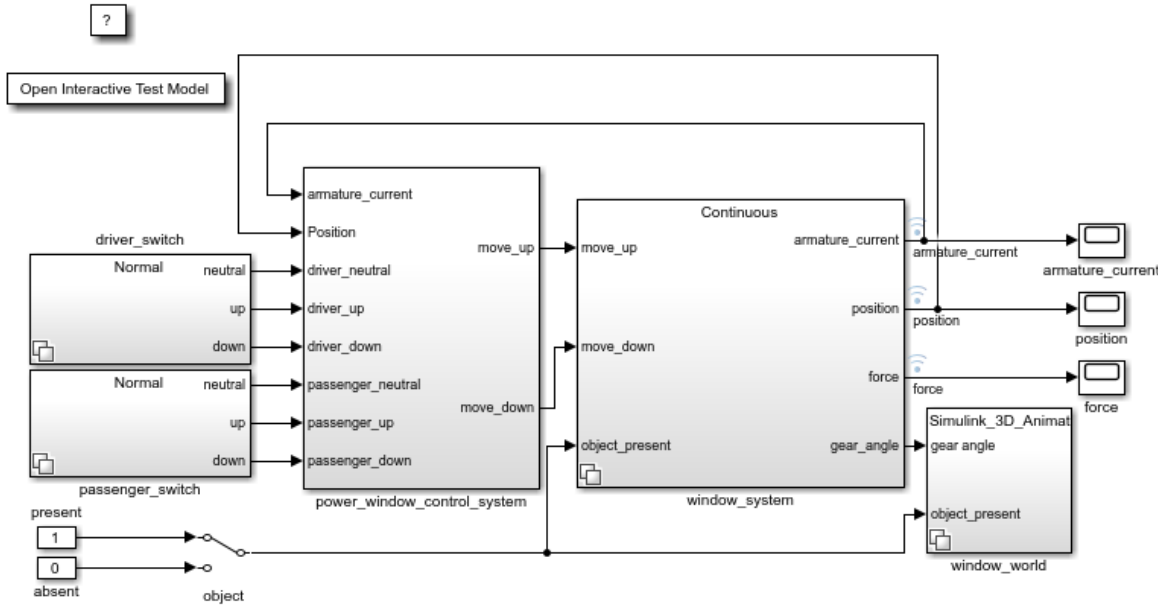
Double-click the `slexPowerWindowExample` model power_window_control_system/detect_obstacle_endstop/Continuous/verify_position block:



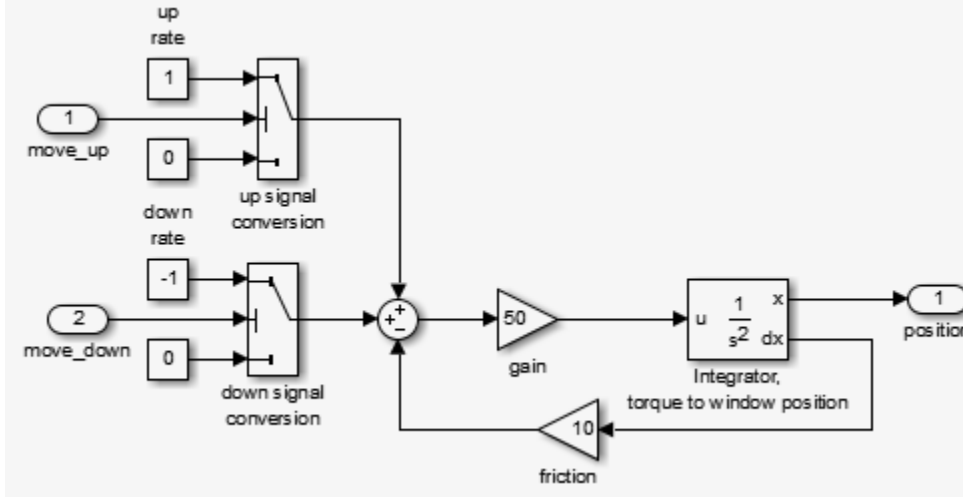
Hybrid Dynamic System: Combine Discrete-Event Control and Continuous Plant

After you have designed and verified the discrete-event control, integrate it with the continuous-time plant behavior. This step is the first iteration of the design with the simplest version of the plant.

In Simulink Project, navigate to **Files** and click **Project Files**. In the **configureModel** folder, run the `slexPowerWindowContinuous` utility to open and initialize the model.



The window_system block uses the Variant Subsystem block to allow for varying levels of fidelity in the plant modeling. Double-click the window_system/Continuous/ 2nd_order_window_system block to see the continuous variant.



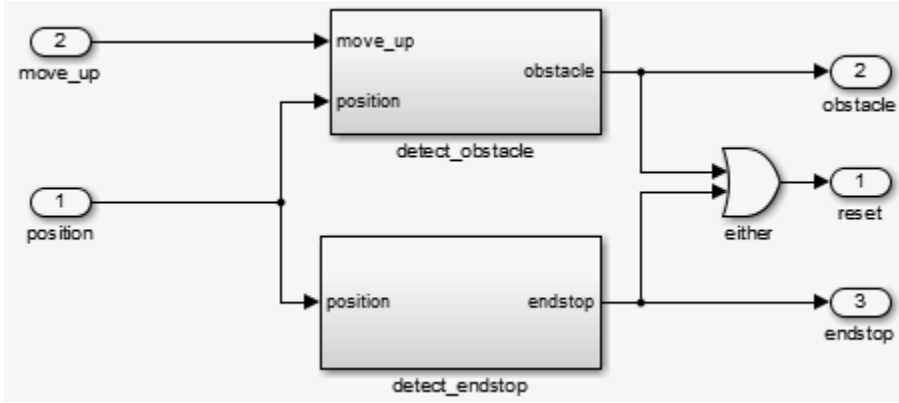
The plant is modeled as a second-order differential equation with step-wise changes in its input:

- When the Stateflow chart generates `windowUp`, the input is 1.
- When the Stateflow chart generates `windowDown`, the input is –1.
- Otherwise, the input is 0.

This phase allows analysis of the interaction between the discrete-event state behavior, its sample rate, and the continuous behavior of the window movement. There are threshold values to generate the window frame top and bottom:

- `endStop`
- Event when an obstacle is present, that is, `obstacle`
- Other events

Double-click the `slexPowerWindowExample` model power_window_control_system/-detect_obstacle_endstop/Continuous/verify_position block to see the continuous variant.



When you run the `slexPowerWindowContinuous` configureModel utility, the model uses the continuous time solver ode23 (Bogacki-Shampine).

A structure analysis of a system results in:

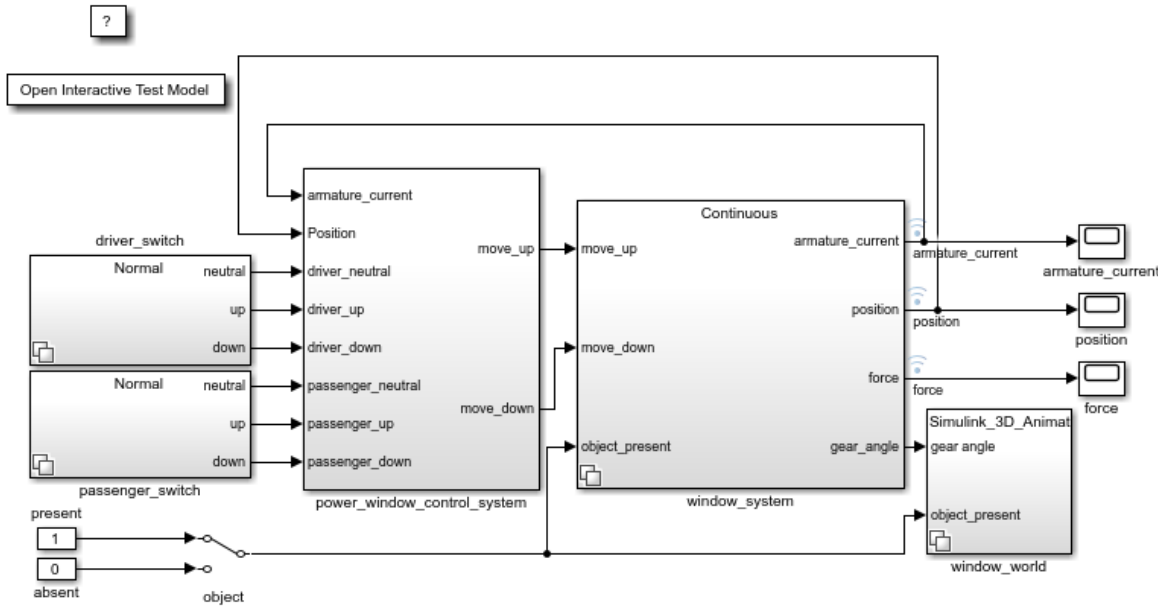
- A functional decomposition of the system
- Data definitions with the specifics of the system signals
- Timing constraints

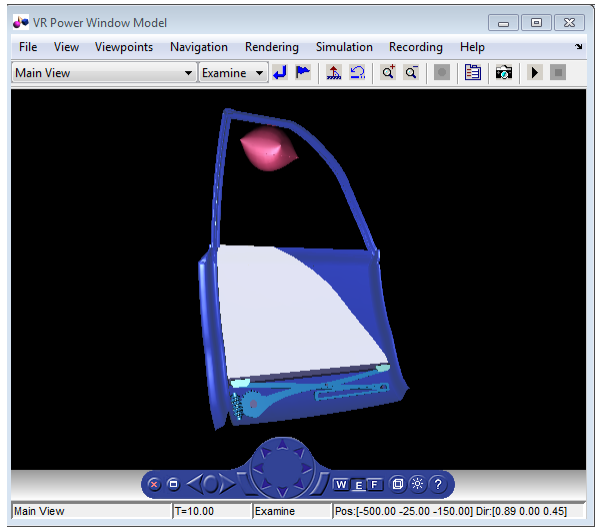
A structure analysis can also include the implementation architecture (outside the scope of this discussion).

The implementation also adds a control mechanism to conveniently switch between the presence and absence of the object.

Expected Controller Response

To view the window movement, in Simulink Project in the **PROJECT SHORTCUTS** section, double-click `SimHybridPlantLowOrder`. Alternatively, you can run the task `slexPowerWindowContinuousSim`.





The position scope shows the expected result from the controller. After 30 cm, the model generates the `obstacle` event and the Stateflow chart moves into its `emergencyDown` state. In this state, `windowDown` is output until the window lowers by about 10 cm. Because the passenger window up switch is still on, the window starts moving up again and this process repeats. Stop the simulation and open the position scope to observe the oscillating process. In case of an emergency, the discrete-event control rolls down the window approximately 10 cm.

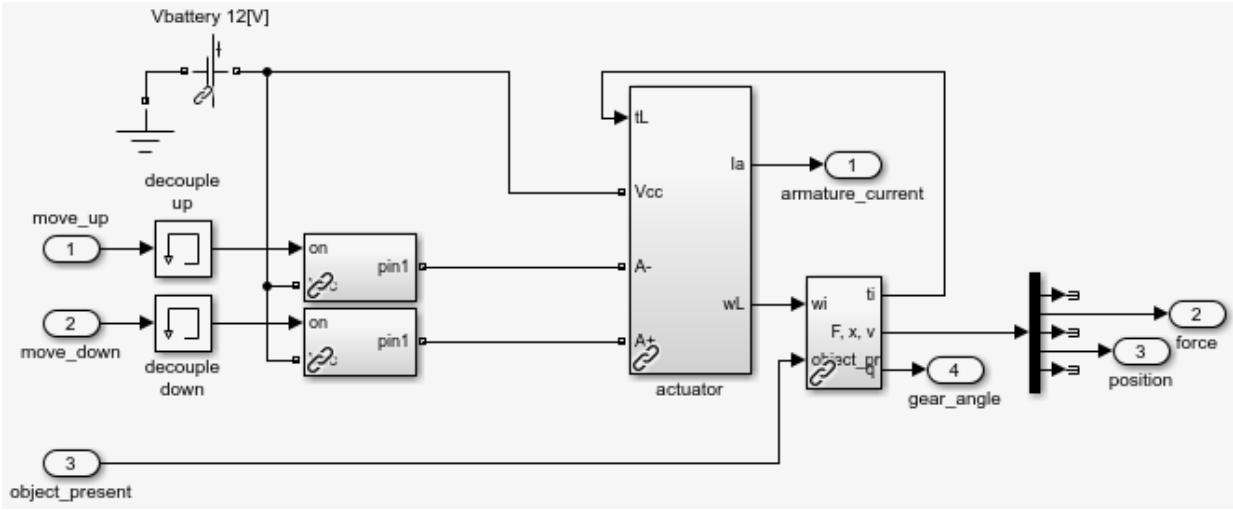
Detailed Modeling of Power Effects

After an initial analysis of the discrete-event control and continuous dynamics, you can use a detailed plant model to evaluate performance in a more realistic situation. It is best to design models at such a level of detail in the power domain, in other words, as energy flows. Several domain-specific MathWorks blocksets can help with this.

To take into account energy flows, add a more detailed variant consisting of power electronics and a multibody system to the window_system variant subsystem.

To open the model and explore the more detailed plant variant, in Simulink Project, run configureModel `slexPowerWindowPowerEffects`.

Double-click the `slexPowerWindowExample` model window_system/Power Effects - Visualization/detailed_window_system block.

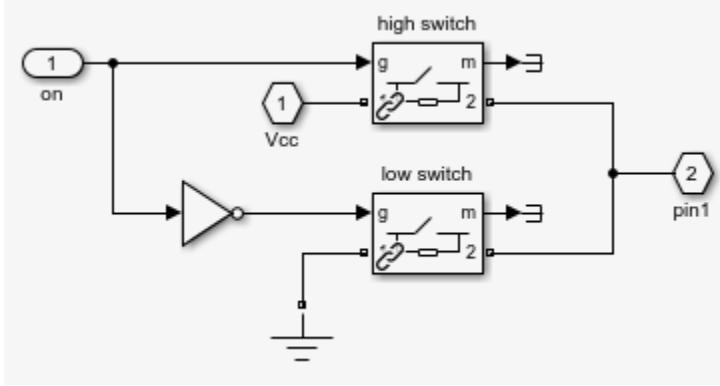


Power Electronics Subsystem

The model must amplify the control signals generated by the discrete-event controller to be powerful enough to drive the DC motor that moves the window.

The amplification modules model this behavior. They show that a switch either connects the DC motor to the battery voltage or ground. By connecting the battery in reverse, the system generates a negative voltage and the window can move up, down, or remain still. The window is always driven at maximum power. In other words, no DC motor controller applies a prescribed velocity.

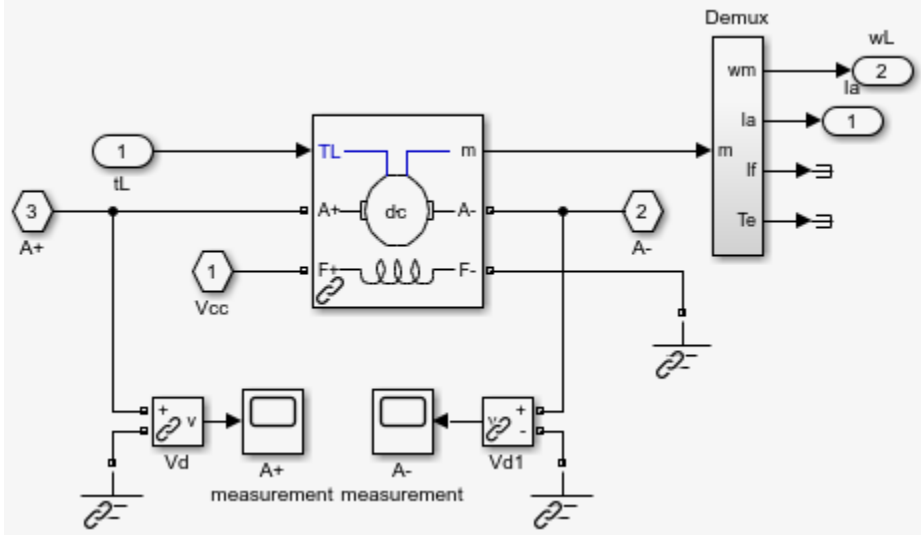
To see the implementation, double-click the `slexPowerWindowExample` model window_system/Power Effects - Visualization/detailed_window_system/amplification_up block.



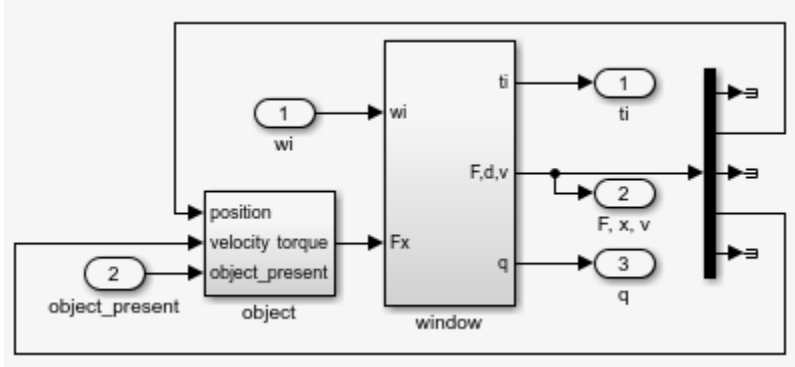
Multibody System

This implementation models the window using Simscape Multibody multibody blocks.

To see the actuator implementation, double-click the `slexPowerWindowExample` model window_system/Power Effects - Visualization/detailed_window_system/actuator block.



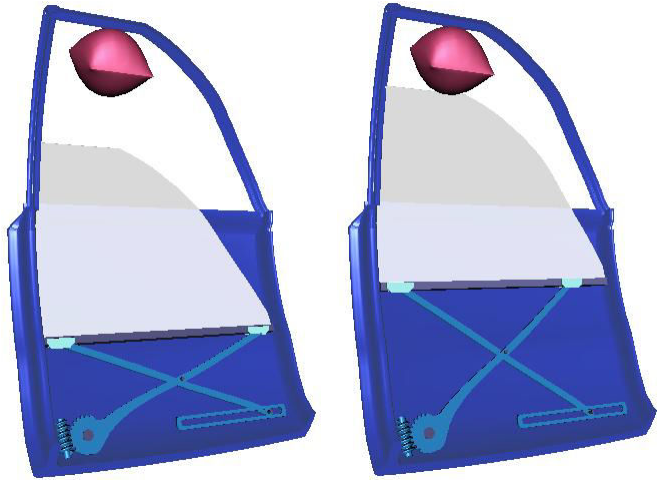
To see the window implementation, double-click the `slexPowerWindowExample` model window_system/Power Effects - Visualization/detailed_window_system/plant block.



This implementation uses Simscape Multibody multibody blocks for bodies, joints, and actuators. The window model consists of:

- A worm gear
- A lever to move the window holder in the vertical direction

The figure shows how the mechanical parts move.



Iterate on the Design

An important effect of the more detailed implementation is that there is no window position measurement available. Instead, the model measures the DC motor current and

uses it to detect the endstops and to see if an obstacle is present. The next stage of the system design analyzes the control to make sure that it does not cause excessive force when an obstacle is present.

In the original system, the design removes the obstacle and endstop detection based on the window position and replaces it with a current-based implementation. It also connects the process to the controller and position and force measurements. To reflect the different signals used, you must modify the data definition. In addition, observe that, because of power effects, the units are now amps.

```
PSPEC 1.3.1: DETECT ENDSTOP
  ENDSTOP = ARMATURE_CURRENT > ENDSTOP_MAX

PSPEC 1.3.2: DETECT OBSTACLE
  OBSTACLE = (ARMATURE_CURRENT > OBSTACLE_MAX) and MOVE_UP for 500 ms

PSPEC 1.3.3: ABSOLUTE VALUE
  ABSOLUTE_ARMATURE_CURRENT = abs(ARMATURE_CURRENT)
```

This table lists the additional signal for the Context Diagram: Power Window System data definitions.

Context Diagram: Power Window System Data Definition Changes

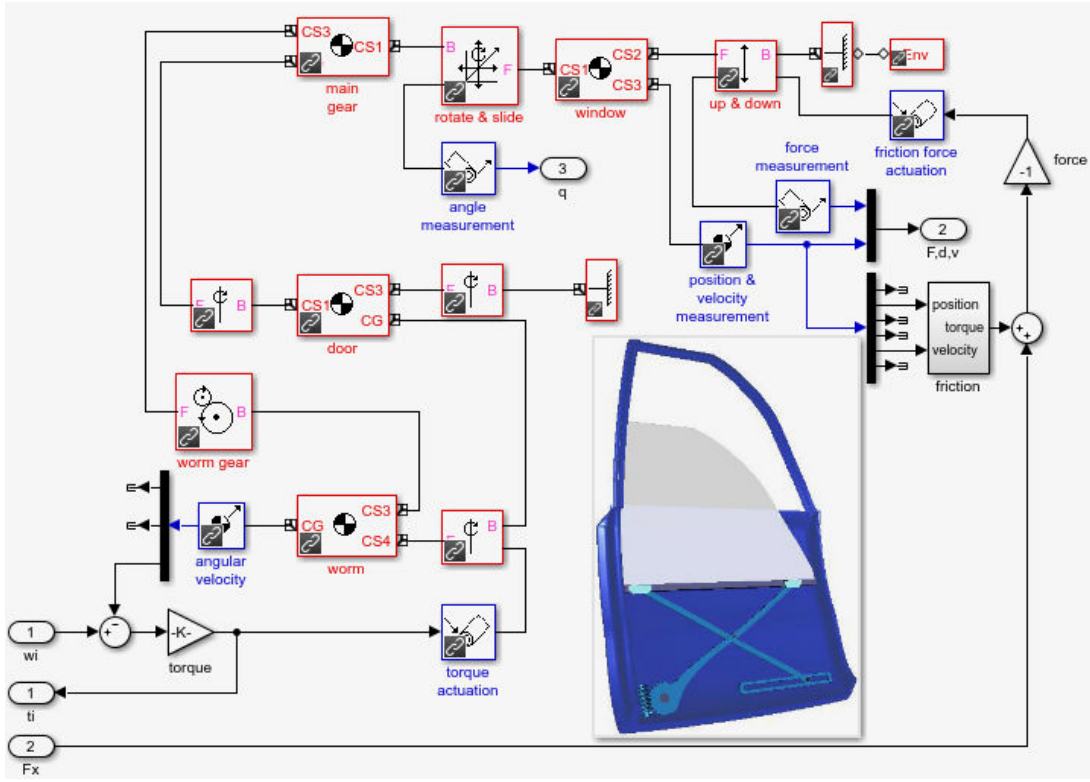
Signal	Information Type	Continuous/ Discrete	Data Type	Values
ARMATURE_CURRENT	Data	Continuous	Real	–20 to 20 A

This table lists the changed signals for the Activity Diagram: Detect Obstacle Endstop data definitions.

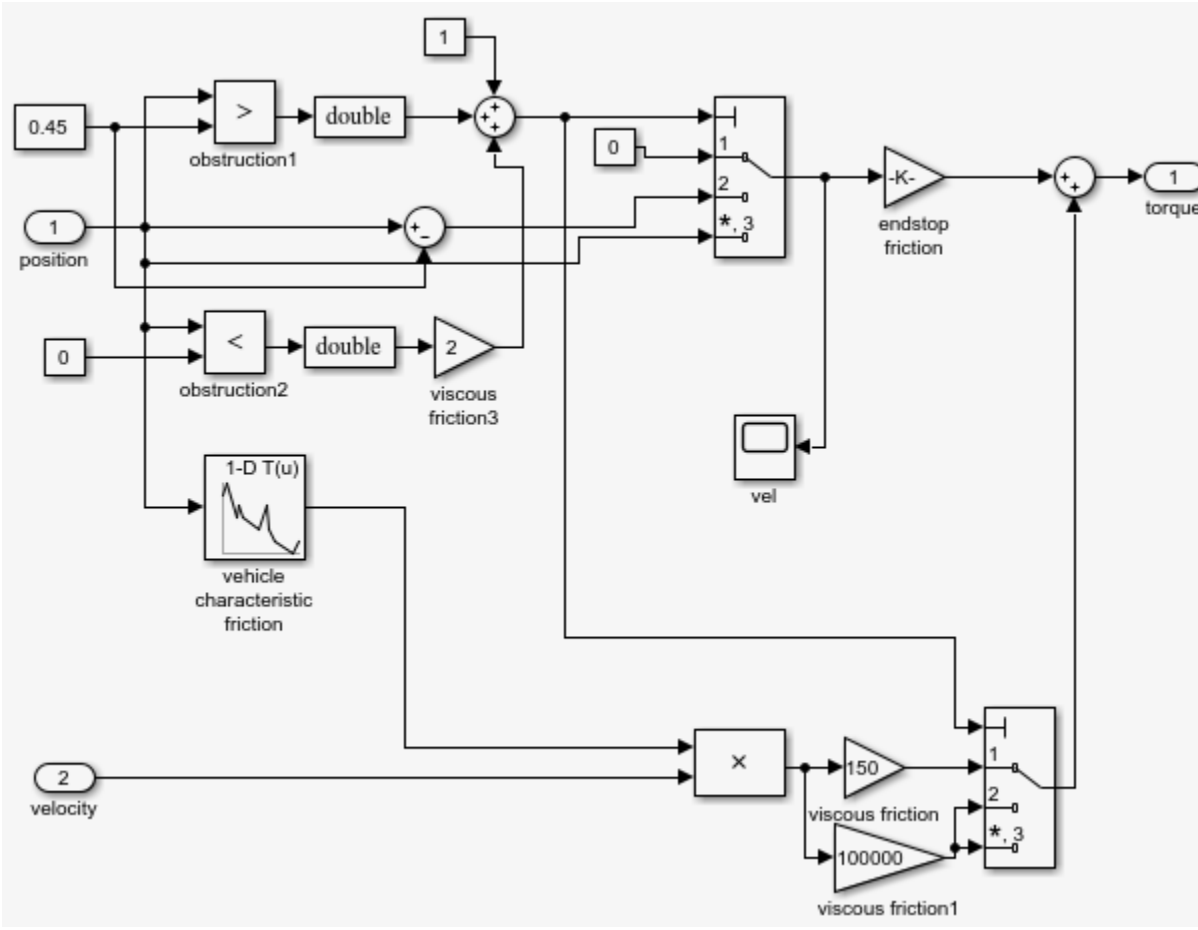
Activity Diagram: Detect Obstacle Endstop Data Definition Changes

Signal	Information Type	Continuous/ Constant	Data Type	Values
ABSOLUTE_ARMATURE_-CURRENT	Data	Continuous	Real	0 to 20 A
ENDSTOP_MAX	Data	Constant	Real	15 A
OBSTACLE_MAX	Data	Constant	Real	2.5 A

To see the window subsystem, double-click the `slexPowerWindowExample` model window_system/Power Effects - Visualization/detailed_window_system/plant/window block.



The implementation uses a lookup table and adds noise to allow evaluation of the control robustness. To see the implementation of the friction subsystem, double-click the `slexPowerWindowExample` model window_system/Power Effects - Visualization/ detailed_window_system/plant/window/friction block.



Control Law Evaluation

The idealized continuous plant allows access to the window position for `endStop` and `obstacle` event generation. In the more realistic implementation, the model must generate these events from accessible physical variables. For power window systems, this physical variable is typically the armature current, `Ia`, of the DC motor that drives the worm gear.

When the window is moving, this current has an approximate value of 2 A. When you switch the window on, the model draws a transient current that can reach a value of

approximately 10 A. When the current exceeds 15 A, the model activates endstop detection. The model draws this current when the angular velocity of the motor is kept at almost 0 despite a positive or negative input voltage.

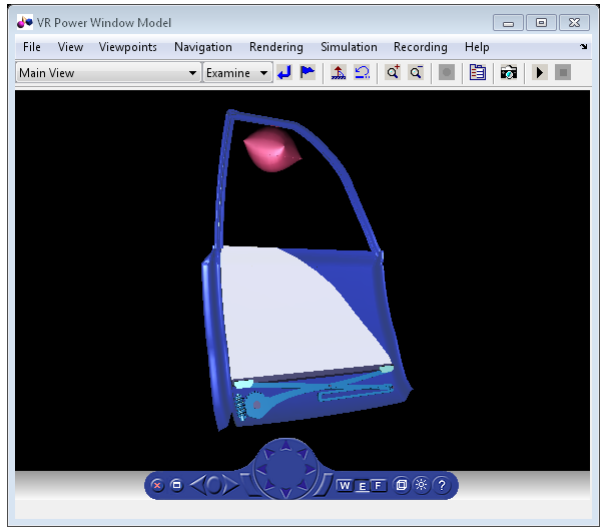
Detecting the presence of an object is more difficult in this setup. Because safety concerns restrict the window force to no more than 100 N, an armature current much less than 10 A should detect an object. However, this behavior conflicts with the transient values achieved during normal operation.

Implement a control law that disables object detection during achieved transient values. Now, when the system detects an armature current more than 2 A, it considers an object to be present and enters the `emergencyDown` state of the discrete-event control. Open the force scope window (measurements are in newtons) to check that the force exerted remains less than 100 N when an object is present and the window reverses its velocity.

In reality, far more sophisticated control laws are possible and implemented. For example, you can implement neural-network-based learning feedforward control techniques to emulate the friction characteristic of each individual vehicle and changes over time.

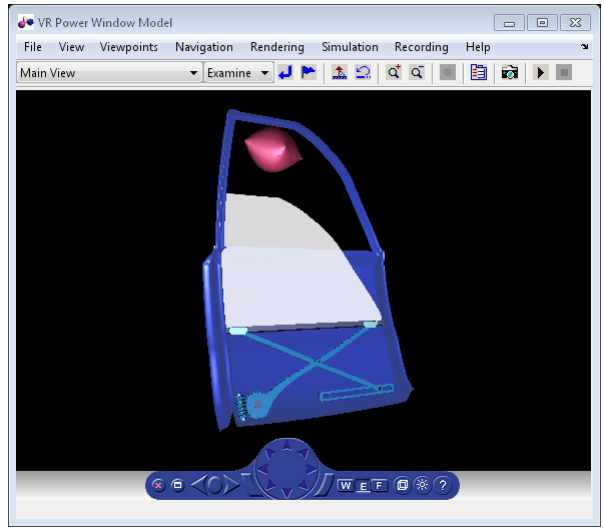
Visualization of the System in Motion

If you have Simulink 3D Animation software installed, you can view the geometrics of the system in motion via a virtual reality world. If the VR Sink block is not yet open, in the `slexPowerWindowExample/window_world/Simulink_3D_Animation View` model, double-click the VR Sink block.



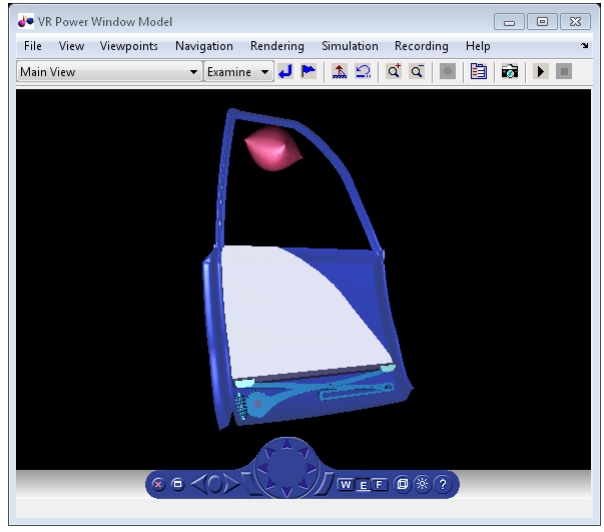
To simulate the model with a stiff solver:

1. In Simulink Project, run the task, `slexPowerWindowPowerEffectsSim`. This batch job sets the solver to ode23tb (stiff/TR-BDF2).
2. In the `slexPowerWindowExample` model passenger_switch/Normal block, set the passenger up switch to on.
3. In the `slexPowerWindowExample` model driver_switch/Normal block, set the driver up switch to off.
4. Simulate the model.
5. Between 10 ms and 1 s in simulation time, switch off the slexPowerWindowExample/passenger_switch/Normal block passenger up switch to initiate the auto-up behavior.



6 Observe how the window holder starts to move vertically to close the window. When the model encounters the object, it rolls the window down.

7 Double-click the `slexPowerWindowExample` model passenger_switch/Normal block driver down switch to roll down the window completely and then simulate the model. In this block, at less than one second simulation time, switch off the driver down switch to initiate the auto-down behavior.



8 When the window reaches the bottom of the frame, stop the simulation.

9 Look at the position measurement (in meters) and at the armature current (Ia) measurement (in amps).

Note The absolute value of the armature current transient during normal behavior does not exceed 10 A. The model detects the obstacle when the absolute value of the armature current required to move the window up exceeds 2.5 A (in fact, it is less than –2.5 A). During normal operation, this is about 2 A. You might have to zoom into the scope to see this measurement. The model detects the window endstop when the absolute value of the armature current exceeds 15 A.

Variation in the armature current during normal operation is due to friction that is included by sensing joint velocities and positions and applying window specific coefficients.

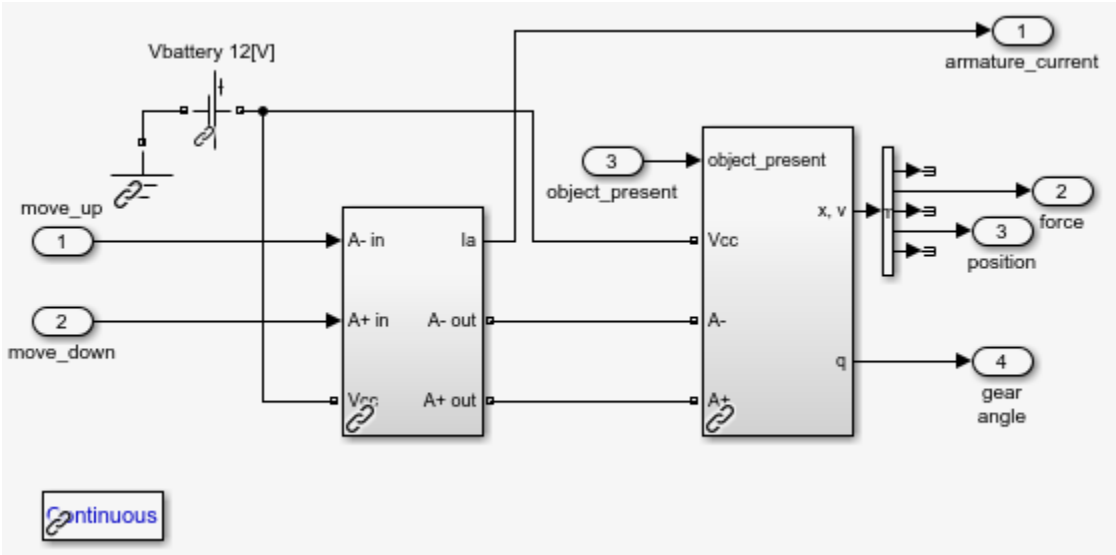
Realistic Armature Measurement

The armature current as used in the power window control is an ideal value that is accessible because of the use of an actuator model. In a more realistic situation, data acquisition components must measure this current value.

To include data acquisition components, add the more realistic measurement variant to the window_system variant subsystem. This realistic measurement variant contains a signal conditioning block in which the current is derived based on a voltage measurement.

To open a model and configure the realistic measurement, in Simulink Project, run the configureModel task `slexPowerWindowRealisticArmature`.

To view the contents of the Realistic Armature - Communications Protocol block, double-click the `SlexPowerWindowExample` model window_system/Realistic Armature - Communications Protocol/detailed_window_system_with_DAQ.



The measurement voltage is within the range of an analog-to-digital converter (ADC) that discretizes based on a given number of bits. You must scale the resulting value based on the value of the resistor and the range of the ADC.

Include these operations as fixed-point computations. To achieve the necessary resolution with the given range, 16 bits are required instead of 8.

Study the same scenario:

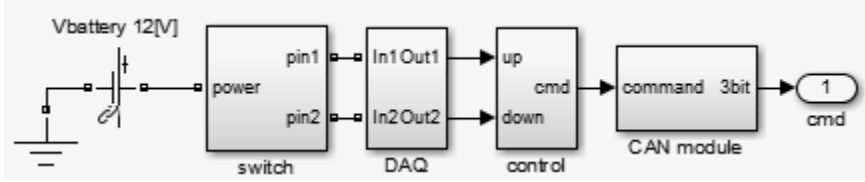
1. In the slexPowerWindowExample/passenger_switch/Normal block, set the passenger up switch.
2. Run the simulation.
3. After some time, in the slexPowerWindowExample/passenger_switch/Normal block, switch off the passenger up switch.
4. When the window has been rolled down, click the slexPowerWindowExample/passenger_switch/Normal block driver down switch.
5. After some time, switch off the slexPowerWindowExample/passenger_switch/Normal block driver down switch.
6. When the window reaches the bottom of the frame, stop the simulation.
7. Zoom into the armature_current scope window and notice the discretized appearance.

Communication Protocols

Similar to the power window output control, hardware must generate the input events. In this case, the hardware is the window control switches in the door and center control panels. Local processors generate these events and then communicate them to the window controller via a CAN bus.

To include these events, add a variant containing input from a CAN bus and switch components that generate the events delivered on the CAN bus to the driver switch and passenger switch variant subsystems. To open the model and configure the CAN communication protocols, run the configureModel task, `slexPowerWindowCommunicationProtocolSim`.

To see the implementation of the switch subsystem, double-click the slexPowerWindowExample/driver_switch/Communication Protocol/driver window control switch block.



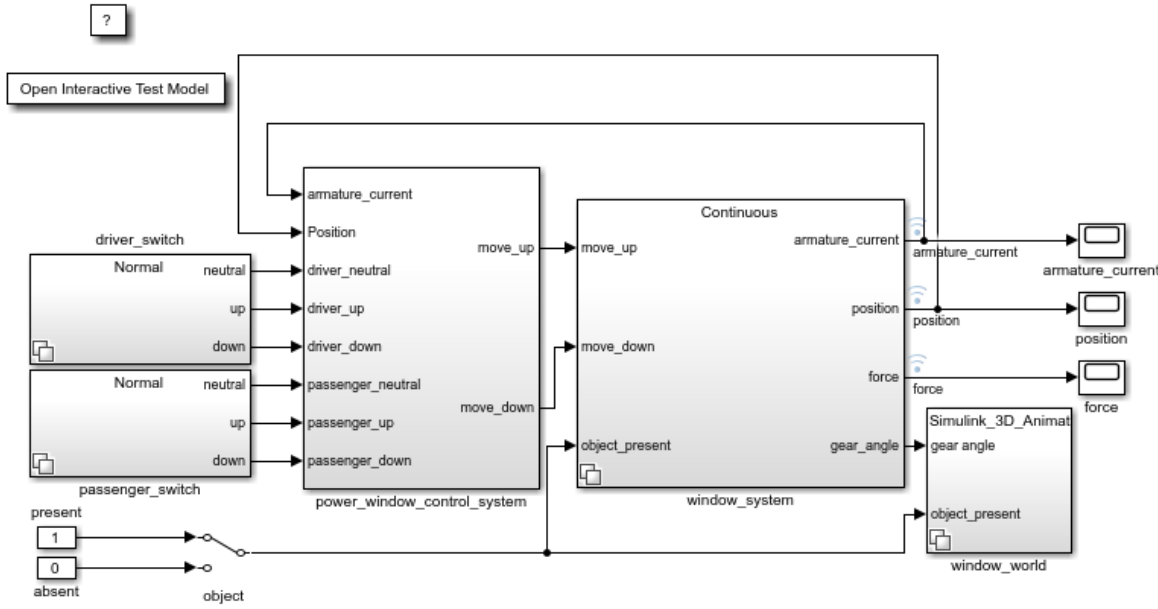
Observe a structure that is very similar to the window control system. This structure contains a:

- Plant model that represents the control switch
- Data acquisition subsystem that includes, among other things, signal conditioning components
- Control module to map the commands from the physical switch to logical commands
- CAN module to post the events to the vehicle data bus

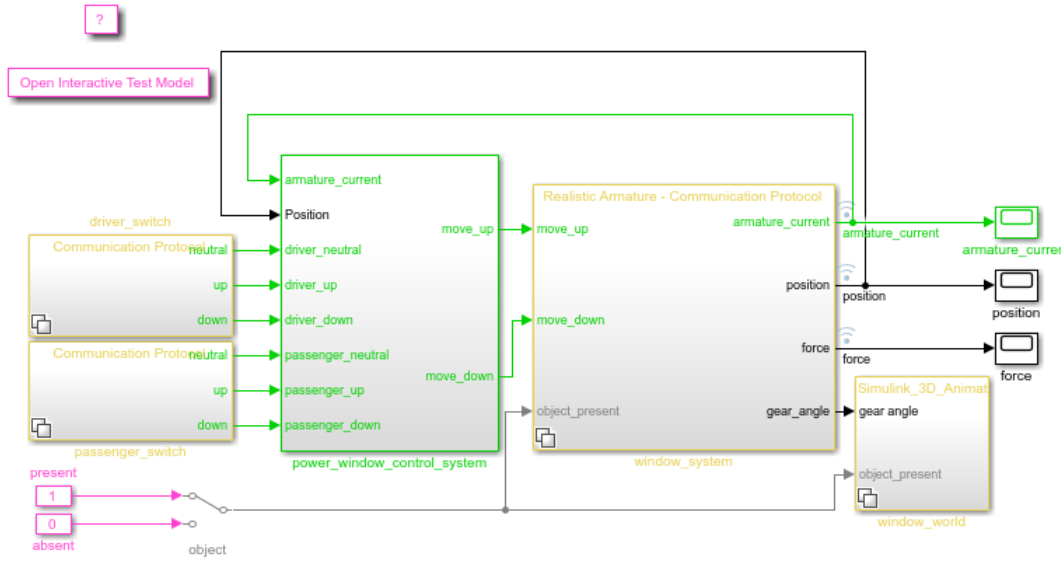
You can add communication effects, such as other systems using the CAN bus, and more realism similar to the described phases. Each phase allows analysis of the discrete-event controller in an increasingly realistic situation. When you have enough detail, you can automatically generate controller code for any specific target platform.

Automatic Code Generation for Control Subsystem

You can generate code for the designed control model, `slexPowerWindowExample`.



1 Display the sample rates of the controller. In the Simulink Editor, select **Display** > **Sample Time** > **Colors**. Observe that the controller runs at a uniform sample rate.



2 Right-click the power_window_control_system block and select **C/C++ Code** > **Build This Subsystem**.

Simulating Dynamic Systems

Running Simulations

Simulate a Model Interactively

Simulation Basics

You can simulate a model in the Simulink Editor using **Simulation** > **Run** or the **Run** button  on the toolbar. The **Run** button also appears in tools within the Simulink Editor. You can simulate from any tool that includes the button, such as the Scope viewer.

Before you start a simulation, you can specify options like simulation start time, stop time, and the solver for solving the model. (See “About Solvers” on page 24-7) You specify these options in the Configuration Parameters dialog box, which you can open from the **Simulation** menu or using the **Model Configuration Parameters** button  on the toolbar. These settings are saved with the model in a configuration set. You can create multiple configuration sets for each model and switch between them to see the effects of different settings. See “Configuration Reuse”.

After you set your model configuration parameters, you can start the simulation. You can pause, resume, and stop simulation using toolbar controls. You can also simulate more than one model at a time, so you can start another simulation while one is running.

During simulation, you cannot make changes to the structure of the model, such as adding or deleting lines or blocks. However, you can make these changes while a simulation is running:

- Modify some configuration parameters, including the stop time and the maximum step size.
- Modify the parameters of a block, as long as you do not cause a change in:
  - Number of states, inputs, or outputs
  - Sample time
  - Number of zero crossings
  - Vector length of any block parameters
  - Length of the internal block work vectors
  - Dimension of any signals

You can also examine the model visually as it simulates. For example, you can click a line to see the signal carried on that line on a Floating Scope or Display block. You can

also display port values as a model simulates. See “Display Port Values for Debugging” on page 35-17.

Run, Pause, and Stop a Simulation

To start simulating your model, click the **Run** button  . You can pause, resume, or stop a simulation using the corresponding controls on the toolbar.

The model starts simulating at the specified start time and runs until the specified end time. While the simulation is running, information at the bottom of the editor shows the percentage of simulation completed and the current simulation time.

- If an error occurs, simulation stops and a message appears. If a warning condition occurs, simulation completes. In both cases, click the diagnostics link at the bottom of the editor to see the message, which helps you to locate errors.
- Pausing takes effect after the current time step finishes executing. Resuming a paused simulation occurs at the next time step.
- If you stop a simulation, the current time step completes, and then simulation stops.
- If the model outputs to a file or to the workspace, stopping or pausing simulation writes the data.

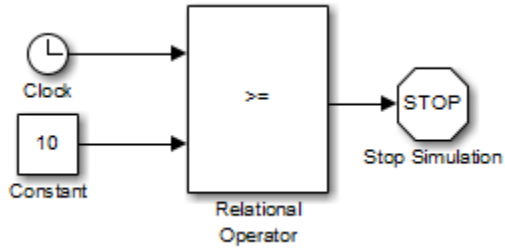
Use Blocks to Stop or Pause a Simulation

Stop Simulation Using Stop Simulation Blocks

You can use the Stop Simulation block to stop a simulation when the input to the block is nonzero. If the block input is a vector, any nonzero element stops the simulation.

1. Add a Stop Simulation block to your model.
2. Connect the Stop Simulation block to a signal whose value becomes nonzero at the specified stop time.

For example, this model stops the simulation when the simulation time reaches 10.



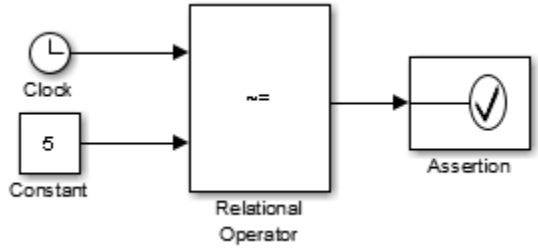
Pause Simulation Using Assertion Blocks

You can use an Assertion block to pause the simulation when the input signal to the block is zero. The Assertion block uses the `set_param` command to pause the simulation. See "Control Simulations Programmatically" on page 25-8 for more information on using the `set_param` command to control the execution of a Simulink model.

1. Add an Assertion block to your model.
2. Connect the Assertion block to a signal whose value becomes zero at the desired pause time.
3. In the Assertion block dialog box, clear the **Stop simulation when assertion fails** check box. Enter this command as the value of **Simulation callback when assertion fails**:

```
set_param(bdroot,'SimulationCommand','pause'),
disp(sprintf('\nSimulation paused.'))
```

This model uses an Assertion block with these settings to pause the simulation when the simulation time reaches 5.



When the simulation pauses, a message appears that shows the time the block paused the simulation.

You can resume the simulation using **Continue** as you can for any paused simulation.

More About

- “Run Individual Simulations Programmatically”
- “About Solvers” on page 24-7

Specify Simulation Start and Stop Time

By default, simulations start at 0.0 s and end at 10.0 s.

Note In the Simulink software, time and all related parameters (such as sample times) are implicitly in seconds. If you choose to use a different time unit, scale all parameters accordingly.

The **Solver** configuration pane allows you to specify other start and stop times for the currently selected simulation configuration. See "Solver Pane" for more information. On computers running the Microsoft Windows operating system, you can also specify the simulation stop time in the `Simulation` menu.

Note Simulation time and actual clock time are not the same. For example, if running a simulation for 10 s usually does not take 10 s as measured on a clock. The amount of time it actually takes to run a simulation depends on many factors including the complexity of the model, the step sizes, and the computer speed.

About Solvers

You simulate a dynamic system by computing its states at successive time steps over a specified time span. This computation uses information provided by a model of the system. The time steps are time intervals when the computation happens. The size of this time interval is called the step size. The process of computing the states of a model in this manner is known as solving the model. No single method of solving a model applies to all systems. Simulink provides a set of programs called solvers. Each solver embodies a particular approach to solving a model.

A solver applies a numerical method to solve the set of ordinary differential equations that represent the model. Through this computation, it determines the time of the next simulation step. In the process of solving this initial value problem, the solver also satisfies the accuracy requirements that you specify.

Solvers are broadly classified using these criteria:

- The type of step size used in the computation
  - Fixed-step solvers solve the model at step sizes from the beginning to the end of the simulation. You can specify the step size or let the solver choose the step size. Generally, decreasing the step size increases the accuracy of the results and increases the time required to simulate the system.
  - Variable-step solvers vary the step size during the simulation. They reduce the step size to increase accuracy when the states of a model change rapidly and during zero-crossing events. They increase the step size to avoid taking unnecessary steps when the states of a model change slowly. Computing the step size adds to the computational overhead at each step. However, it can reduce the total number of steps, and hence the simulation time required to maintain a specified level of accuracy for models with piecewise continuous or rapidly changing states.
- The nature of states in the model
  - Continuous solvers use numerical integration to compute continuous states of a model at the current time step based on the states at previous time steps and the state derivatives. Continuous solvers rely on individual blocks to compute the values of the discrete states of the model at each time step.
  - Discrete solvers are primarily for solving purely discrete models. They compute only the next simulation time step for a model. When they perform this

computation, they rely on each block in the model to update its individual discrete state. They do not compute continuous states.

When you choose a solver for simulating a model, consider:

- The dynamics of the system
- The stability of the solution
- The speed of computation
- The robustness of the solver

A solver might not completely satisfy all of your requirements, so use an iterative approach when choosing one. Compare simulation results from several solvers and select one that offers the best performance with minimal tradeoffs.

There are two ways to select a solver for your model:

- Use auto solver. New models have their solver selection set to auto solver by default. Auto solver recommends a fixed-step or variable-step solver for your model as well as maximum step size.
- If you are not satisfied with simulation results using auto solver, select a solver in the **Solver** pane in the model configuration parameters.

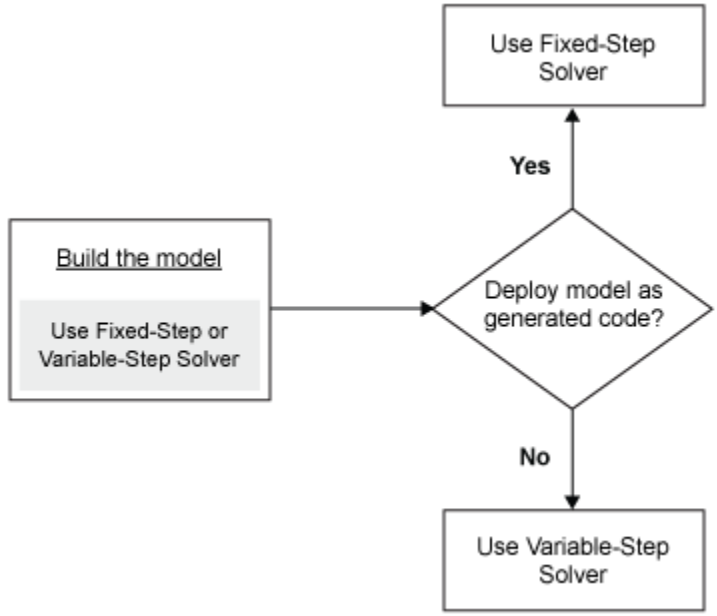
- “Choose a Solver” on page 24-9

Choose a Solver

In this section...

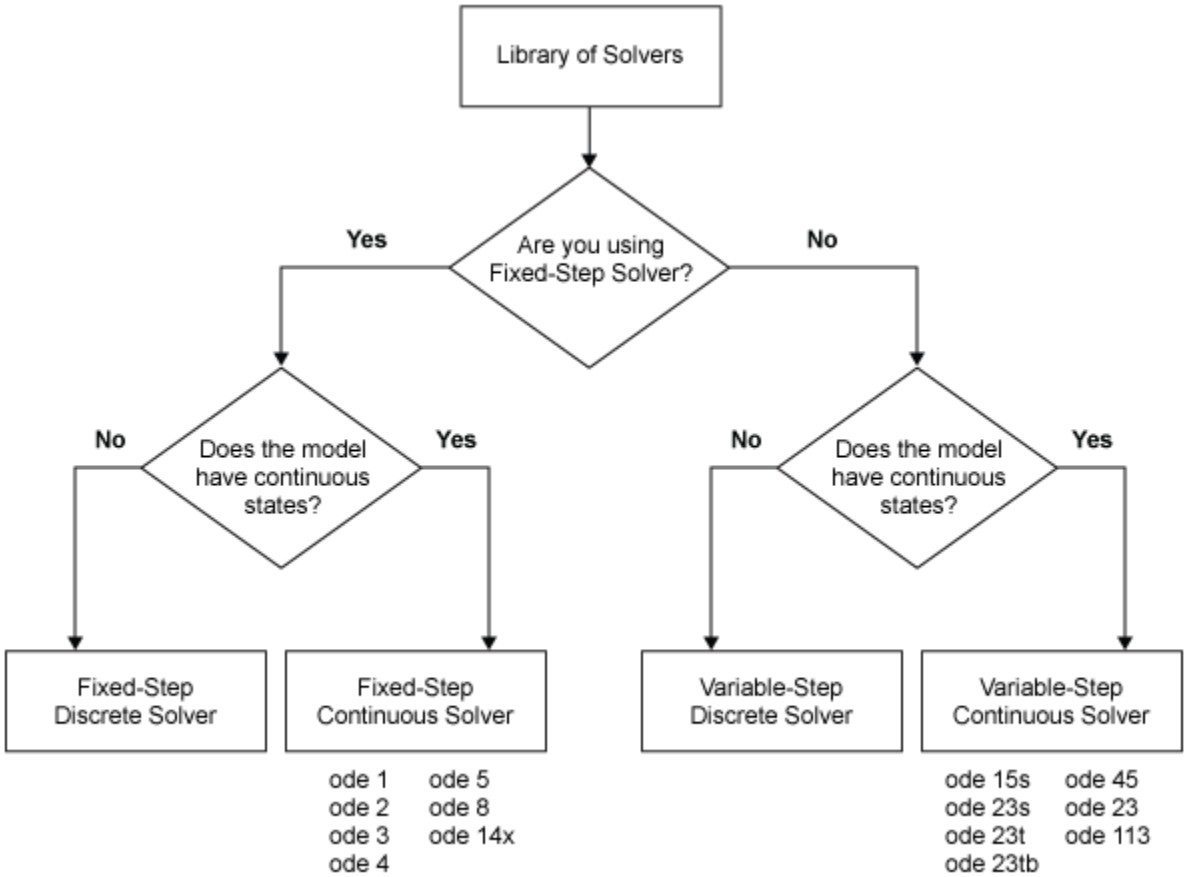
The Simulink library of solvers has two main types—fixed-step and variable-step solvers. You can see the solvers under each type in the **Solver** pane of model configuration parameters.

When you build and simulate a model, you can choose either type of solver based on the dynamics of the model. A model that contains several switches, like an inverter power system, needs a fixed-step solver. A variable-step solver is better suited for purely continuous models, like the dynamics of a mass spring damper system.



When you deploy a model as generated code, you can use only a fixed-step solver. If you selected a variable-step solver during simulation, use it to calculate the step size required for the fixed-step solver that you need at deployment.

This chart provides a broad classification of solvers in the Simulink library.



You can use auto solver to selects a solver for a model. Auto solver can pick a fixed-step or variable-step solver for your model and also suggest the maximum step size to use. For more information, see “Use Auto Solver to Select a Solver” on page 24-34.

To tailor the selected solver to your model, see “Check and Improve Simulation Accuracy” on page 30-12.

Ideally, the solver you select should:

- Solve the model successfully.
- Provide a solution within the tolerance limits you specify.
- Solve the model in a reasonable duration.

A single solver might not meet all of these requirements. Try simulating with several solvers before making a selection.

Solver Classification Criteria

The Simulink library provides several solvers, all of which can work with the algebraic loop solver.

		Discrete	Continuous	Variable-Order
Fixed-Step	Explicit	Not Applicable	"Fixed-Step Continuous Explicit Solvers" on page 24-17	Not Applicable
	Implicit	Not Applicable	"Fixed-Step Continuous Implicit Solvers" on page 24-19	Not Applicable
Variable-Step	Explicit	"Choose a Variable-Step Solver" on page 24-20	"Variable-Step Continuous Explicit Solvers" on page 24-21	"Single-Order Versus Variable-Order Continuous Solvers" on page 24-15
	Implicit		"Variable-Step Continuous Implicit Solvers" on page 24-22	"Single-Order Versus Variable-Order Continuous Solvers" on page 24-15

In the **Solver** pane of model configuration parameters, the Simulink library of solvers is divided into two major types. See "Fixed-Step Versus Variable-Step Solvers" on page 24-12.

You can further categorize the solvers of each type:

- "Discrete Versus Continuous Solvers" on page 24-13
- "Explicit Versus Implicit Continuous Solvers" on page 24-13

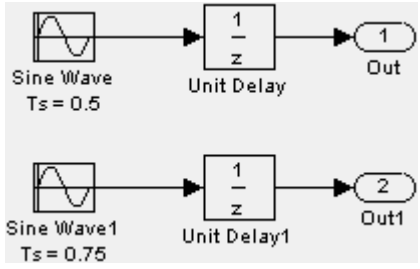
Fixed-Step Versus Variable-Step Solvers

Fixed-step and variable-step solvers compute the next simulation time as the sum of the current simulation time and a quantity known as the *step size*. The **Type** control on the **Solver** configuration pane allows you to select the type of solver. With a fixed-step solver, the step size remains constant throughout the simulation. With a variable-step solver, the step size can vary from step to step, depending on the model dynamics. In particular, a variable-step solver increases or reduces the step size to meet the error tolerances that you specify.

The choice between these types depends on how you plan to deploy your model and the model dynamics. If you plan to generate code from your model and run the code on a real-time computer system, choose a fixed-step solver to simulate the model. You cannot map the variable-step size to the real-time clock.

If you do not plan to deploy your model as generated code, the choice between a variable-step and a fixed-step solver depends on the dynamics of your model. A variable-step solver might shorten the simulation time of your model significantly. A variable-step solver allows this saving because, for a given level of accuracy, the solver can dynamically adjust the step size as necessary. This approach reduces the number of steps required. The fixed-step solver must use a single step size throughout the simulation, based on the accuracy requirements. To satisfy these requirements throughout the simulation, the fixed-step solver typically requires a small step.

This model shows how a variable-step solver can shorten simulation time for a multirate discrete model.



The model generates outputs at two different rates: every 0.5 s and every 0.75 s. To capture both outputs, the fixed-step solver must take a time step every 0.25 s (the *fundamental sample time* for the model).

```
[0.0 0.25 0.5 0.75 1.0 1.25 1.5 ...]
```

By contrast, the variable-step solver has to take a step only when the model generates an output.

```
[0.0 0.5 0.75 1.0 1.5 ...]
```

This scheme significantly reduces the number of time steps required to simulate the model.

Discrete Versus Continuous Solvers

When you select a solver type, you can also select a specific solver. Both sets of solvers include two types: discrete and continuous. Discrete and continuous solvers rely on the model blocks to compute the values of any discrete states. Blocks that define discrete states are responsible for computing the values of those states at each time step. However, unlike discrete solvers, continuous solvers use numerical integration to compute the continuous states that the blocks define. When choosing a solver, determine first whether to use a discrete solver or a continuous solver.

If your model has no continuous states, then Simulink switches to either the fixed-step discrete solver or the variable-step discrete solver. If your model has only continuous states or a mix of continuous and discrete states, choose a continuous solver from the remaining solver choices based on the dynamics of your model. Otherwise, an error occurs.

The solver library contains two discrete solvers—a fixed-step discrete solver and a variable-step discrete solver. The fixed-step solver by default chooses a step size and simulation rate fast enough to track state changes in the fastest block in your model. The variable-step solver adjusts the simulation step size to keep pace with the actual rate of discrete state changes in your model. This adjustment can avoid unnecessary steps and shorten simulation time for multirate models (see “Sample Times in Systems” on page 7-29 for more information.)

Note The fixed-step discrete solvers do not solve for discrete states. Each block calculates its discrete states independent of the solver.

Explicit Versus Implicit Continuous Solvers

You represent an explicit system by the system of equation

$\dot{x} = f(x)$

. For any given value of x, you can compute $\dot{x}$ by substituting x in $f(x)$ and evaluating the equation.

Equations of the form
$F(\dot{x},x) = 0$
are considered to be implicit. For any given value of x, you must solve this equation to calculate $\dot{x}$.

A linearly implicit system can be represented by the equation
$M(x).\dot{x} = f(x)$

. $M(x)$ is called the mass matrix and $f(x)$ is the forcing function. A system becomes linearly implicit when you use physical modeling blocks in the model.

While you can apply an implicit or explicit continuous solver to solve all these systems, implicit solvers are designed specifically for solving stiff problems. Explicit solvers solve nonstiff problems. An ordinary differential equation problem is said to be stiff if the desired solution varies slowly, but there are closer solutions that vary rapidly. The numerical method must then take small time steps to solve the system. Stiffness is an efficiency issue. The more stiff a system, the longer it takes to for the explicit solver to perform a computation. A stiff system has both slowly and quickly varying continuous dynamics.

When compared to explicit solvers, implicit solvers provide greater stability for oscillatory behavior. However, implicit solvers are also computationally more expensive. They generate the Jacobian matrix and solve the set of algebraic equations at every time step using a Newton-like method. To reduce this extra cost, the implicit solvers offer a `Solver Jacobian method` parameter that allows you to improve the simulation performance of implicit solvers. See “Choose a Jacobian Method for an Implicit Solver” on page 24-27 for more information. Implicit solvers are more efficient than explicit solvers when you solve a linearly implicit system.

One-Step Versus Multistep Continuous Solvers

The Simulink solver library provides both one-step and multistep solvers. The one-step solvers estimate $y(t_n)$ using the solution at the immediately preceding time point,

$y(t_{n-1})$, and the values of the derivative at multiple points between t_n and t_{n-1}. These points are minor steps.

The multistep solvers use the results at several preceding time steps to compute the current solution. Simulink provides one explicit multistep solver, `ode113`, and one implicit multistep solver, `ode15s`. Both are variable-step solvers.

Single-Order Versus Variable-Order Continuous Solvers

This distinction is based on the number of orders that the solver uses to solve the system of equation. Two variable-order solvers, `ode15s` and `ode113`, are part of the solver library. They use multiple orders to solve the system of equations. Specifically, the implicit, variable-step `ode15s` solver uses first-order through fifth-order equations while the explicit, variable-step `ode113` solver uses first-order through thirteenth-order. For `ode15s`, you can limit the highest order applied via the `Maximum Order` parameter. For more information, see “Maximum Order” on page 24-23.

Choose a Fixed-Step Solver

The Fixed-Step Discrete Solver

The fixed-step discrete solver computes the time of the next simulation step by adding a fixed step size to the current time. The accuracy and the length of time of the resulting simulation depends on the size of the steps taken by the simulation: the smaller the step size, the more accurate the results are but the longer the simulation takes. By default, Simulink chooses the step size or you can choose the step size yourself. If you choose the default setting of `auto`, and if the model has discrete sample times, then Simulink sets the step size to the fundamental sample time of the model. Otherwise, if no discrete rates exist, Simulink sets the size to the result of dividing the difference between the simulation start and stop times by 50.

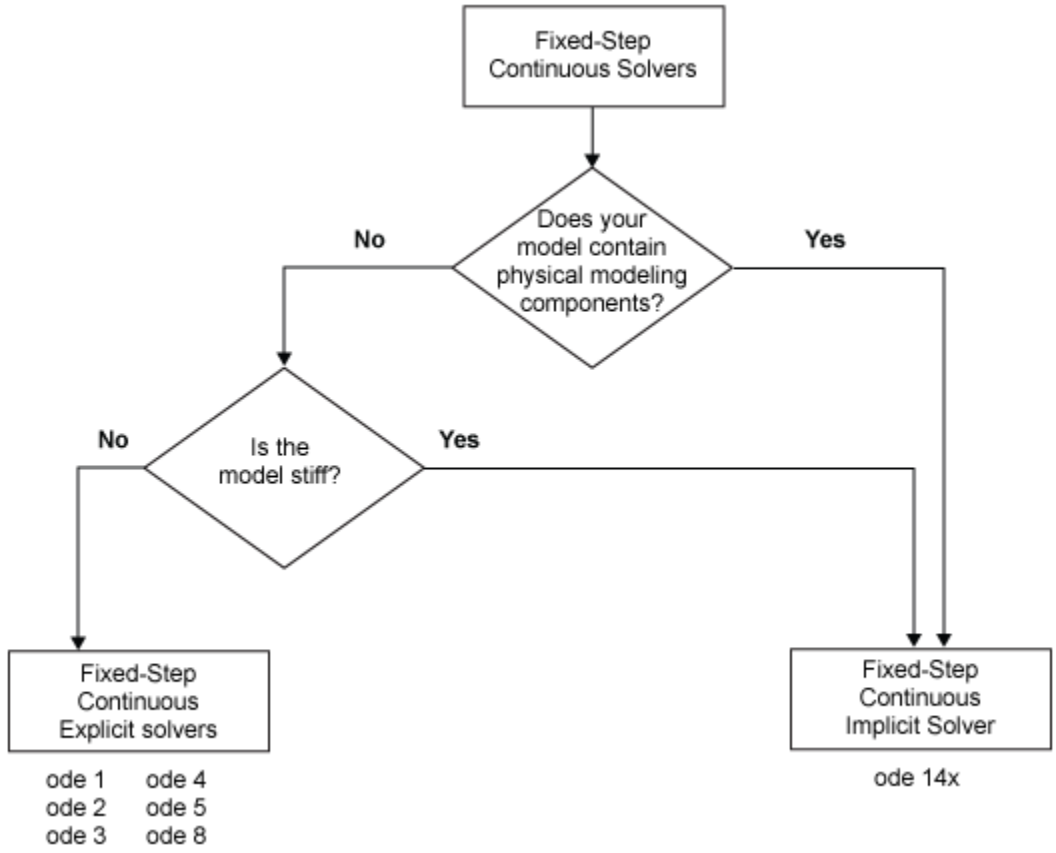
Note If you try to use the fixed-step discrete solver to update or simulate a model that has continuous states, an error message appears. Thus, selecting a fixed-step solver and then updating or simulating a model is a quick way to determine whether the model has continuous states.

Fixed-Step Continuous Solvers

The fixed-step continuous solvers, like the fixed-step discrete solver, compute the next simulation time by adding a fixed-size time step to the current time. For each of these steps, the continuous solvers use numerical integration to compute the values of the continuous states for the model. These values are calculated using the continuous states at the previous time step and the state derivatives at intermediate points (minor steps) between the current and the previous time step. The fixed-step continuous solvers can, therefore, handle models that contain both continuous and discrete states.

Note In theory, a fixed-step continuous solver can handle models that contain no continuous states. However, that would impose an unnecessary computational burden on the simulation. Consequently, Simulink uses the fixed-step discrete solver for a model that contains no states or only discrete states, even if you specify a fixed-step continuous solver for the model.

Simulink provides two types of fixed-step continuous solvers — explicit and implicit.



The difference between these two types lies in the speed and the stability. An implicit solver requires more computation per step than an explicit solver but is more stable. Therefore, the implicit fixed-step solver that Simulink provides is more adept at solving a stiff system than the fixed-step explicit solvers. For more information, see “Explicit Versus Implicit Continuous Solvers” on page 24-13.

Fixed-Step Continuous Explicit Solvers

Explicit solvers compute the value of a state at the next time step as an explicit function of the current values of both the state and the state derivative. A fixed-step explicit solver is expressed mathematically as:

$$x(n+1) = x(n) + h * Dx(n)$$

where x is the state, Dx is a solver-dependent function that estimates the state derivative, h is the step size, and n indicates the current time step.

Simulink provides a set of fixed-step continuous explicit solvers. The solvers differ in the specific numerical integration technique that they use to compute the state derivatives of the model. This table lists each solver and the integration technique it uses. The table lists the solvers in order of the computational complexity of the integration methods they use, from the least complex (`ode1`) to the most complex (`ode8`).

Solver	Integration Technique	Order of Accuracy
`ode1`	Euler's Method	First
`ode2`	Heun's Method	Second
`ode3`	Bogacki-Shampine Formula	Third
`ode4`	Fourth-Order Runge-Kutta (RK4) Formula	Fourth
`ode5`	Dormand-Prince (RK5) Formula	Fifth
`ode8`	Dormand-Prince RK8(7) Formula	Eighth

None of these solvers has an error control mechanism. Therefore, the accuracy and the duration of a simulation depend directly on the size of the steps taken by the solver. As you decrease the step size, the results become more accurate, but the simulation takes longer. Also, for any given step size, the more computationally complex the solver is, the more accurate are the simulation results.

If you specify a fixed-step solver type for a model, then by default, Simulink selects the `FixedStepAuto` solver. Auto solver then selects an appropriate fixed-step solver that can handle both continuous and discrete states with moderate computational effort. As with the discrete solver, if the model has discrete rates (sample times), then Simulink sets the step size to the fundamental sample time of the model by default. If the model has no discrete rates, Simulink automatically uses the result of dividing the simulation total duration by 50. Consequently, the solver takes a step at each simulation time at which Simulink must update the discrete states of the model at its specified sample rates. However, it does not guarantee that the default solver accurately computes the continuous states of a model. Therefore, you may need to choose another solver, a different fixed step size, or both to achieve acceptable accuracy and an acceptable simulation time.

Fixed-Step Continuous Implicit Solvers

An implicit solver computes the state at the next time step as an implicit function of the state at the current time step and the state derivative at the next time step. In other words:

$$x(n+1) - x(n) - h * Dx(n+1) = 0$$

Simulink provides one fixed-step implicit solver: `ode14x`. This solver uses a combination of Newton's method and extrapolation from the current value to compute the value of a state at the next time step. You can specify the number of Newton's method iterations and the extrapolation order that the solver uses to compute the next value of a model state (see "Fixed-step size (fundamental sample time)"). The more iterations and the higher the extrapolation order that you select, the greater the accuracy you obtain. However, you simultaneously create a greater computational burden per step size.

How to Choose a Fixed-Step Continuous Solver

Any of the fixed-step continuous solvers in the Simulink product can simulate a model to any desired level of accuracy, given a small enough step size. Unfortunately, it is not possible or practical to decide without trial, the combination of solver and step size that will yield acceptable results for the continuous states in the shortest time. Determining the best solver for a particular model generally requires experimentation.

To select a fixed-step continuous solver,

1. Choose error tolerances. For more information, see "Error Tolerances for Variable-Step Solvers" on page 24-25.
2. Use one of the variable-step solvers to simulate your model to the level of accuracy that you want. Start with `ode45`. If your model runs slowly, your problem may be stiff and need an implicit solver. The results of this step give a good approximation of the correct simulation results and the appropriate fixed step size.
3. Use `ode1` to simulate your model at the default step size for your model. Compare the simulation results for `ode1` with the simulation for the variable-step solver. If the results are the same for the specified level of accuracy, you have found the best fixed-step solver for your model, namely `ode1`. You arrive at this conclusion because `ode1` is the simplest of the fixed-step solvers and hence yields the shortest simulation time for the current step size.
4. If `ode1` does not give satisfactory results, repeat the preceding steps with the other fixed-step solvers until you find one that gives accurate results with the least

computational effort. The most efficient way to perform this task is to use a binary search technique:

a Try `ode3`.

b If `ode3` gives accurate results, try `ode2`. If `ode2` gives accurate results, it is the best solver for your model; otherwise, `ode3` is the best.

c If `ode3` does not give accurate results, try `ode5`. If `ode5` gives accurate results, try `ode4`. If `ode4` gives accurate results, select it as the solver for your model; otherwise, select `ode5`.

d If `ode5` does not give accurate results, reduce the simulation step size and repeat the preceding process. Continue in this way until you find a solver that solves your model accurately with the least computational effort.

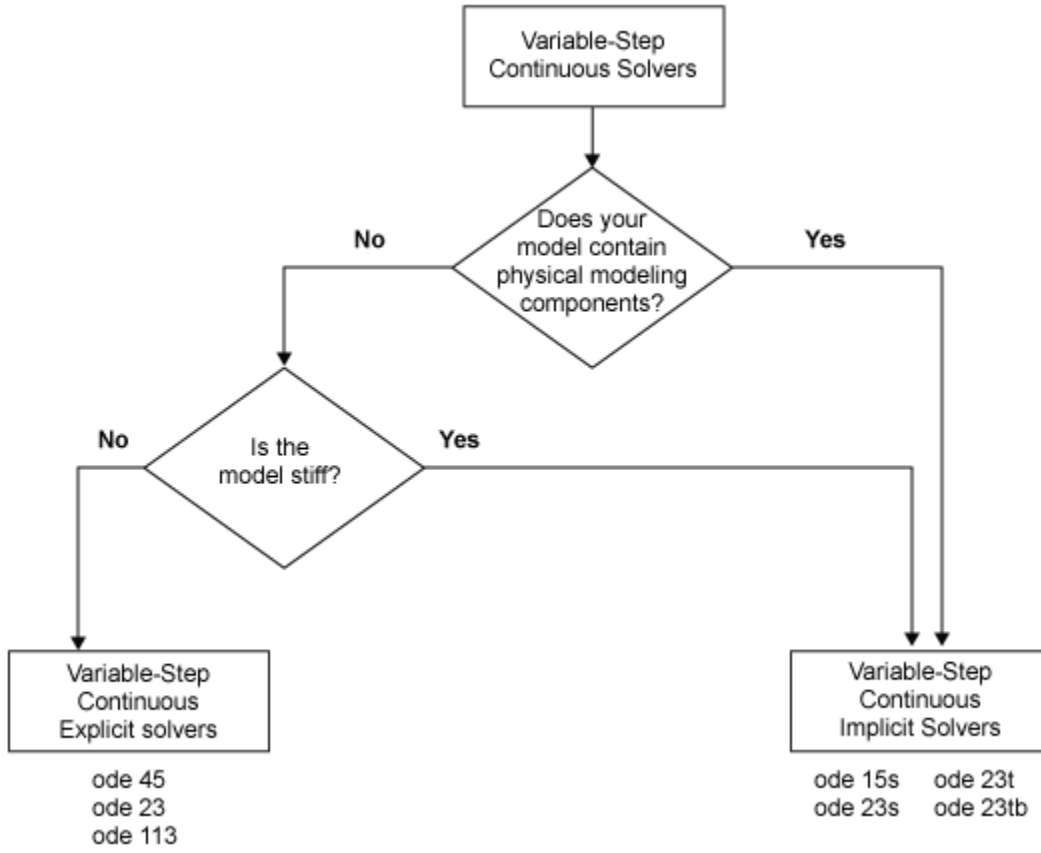
Choose a Variable-Step Solver

When you set the **Type** control of the **Solver** configuration pane to `Variable-step`, the **Solver** control allows you to choose one of the variable-step solvers. As with fixed-step solvers, the set of variable-step solvers comprises a discrete solver and a subset of continuous solvers. However, unlike the fixed-step solvers, the step size varies dynamically based on the local error.

The choice between the two types of variable-step solvers depends on whether the blocks in your model define states and, if so, the type of states that they define. If your model defines no states or defines only discrete states, select the discrete solver. If a model has no states or only discrete states, Simulink uses the discrete solver to simulate the model even if you specify a continuous solver. If the model has continuous states, the continuous solvers use numerical integration to compute the values of the continuous states at the next time step.

Variable-Step Continuous Solvers

Variable-step solvers dynamically vary the step size during the simulation. Each of these solvers increases or reduces the step size using its local error control to achieve the tolerances that you specify. Computing the step size at each time step adds to the computational overhead. However, it can reduce the total number of steps, and the simulation time required to maintain a specified level of accuracy.



You can further categorize the variable-step continuous solvers as: one-step or multistep, single-order or variable-order, and explicit or implicit. (See “Solver Classification Criteria” on page 24-11 for more information.)

Variable-Step Continuous Explicit Solvers

The variable-step explicit solvers are designed for nonstiff problems. Simulink provides three such solvers:

- `ode45`
- `ode23`
- `ode113`

ODE Solver	One-Step Method	Multistep Method	Order of Accuracy	Method
ode45	X		Medium	Runge-Kutta, Dormand-Prince (4,5) pair
ode23	X		Low	Runge-Kutta (2,3) pair of Bogacki & Shampine
ode113		X	Variable, Low to High	PECE Implementation of Adams-Bashforth-Moutlon

ODE Solver	Tips on When to Use
ode45	In general, the ode45 solver is the best to apply as a first try for most problems. For this reason, ode45 is the default solver for models with continuous states. This Runge-Kutta (4,5) solver is a fifth-order method that performs a fourth-order estimate of the error. This solver also uses a fourth-order "free" interpolant, which allows for event location and smoother plots. The ode45 is more accurate and faster than ode23. If the ode45 is computationally slow, your problem may be stiff and thus in need of an implicit solver.
ode23	The ode23 can be more efficient than the ode45 solver at crude error tolerances and in the presence of mild stiffness. This solver provides accurate solutions for "free" by applying a cubic Hermite interpolation to the values and slopes computed at the ends of a step.
ode113	For problems with stringent error tolerances or for computationally intensive problems, the Adams-Bashforth-Moulton PECE solver can be more efficient than ode45.

Variable-Step Continuous Implicit Solvers

If your problem is stiff, try using one of the variable-step implicit solvers:

- ode15s
- ode23s
- ode23t
- ode23tb

ODE Solver	One-Step Method	Multistep Method	Order of Accuracy	Solver Reset Method	Max. Order	Method
`ode15s`		X	Variable, Low to Medium	X	X	Numerical Differentiation Formulas (NDFs)
`ode23s`	X		Low			Second-order, modified Rosenbrock formula
`ode23t`	X		Low	X		Trapezoidal rule using a "free" interpolant
`ode23tb`	X		Low	X		TR-BDF2

Solver Reset Method

For three of the stiff solvers — `ode15s`, `ode23t`, and `ode23tb`— a drop-down menu for the `Solver reset method` appears on the **Solver** Configuration pane. This parameter controls how the solver treats a reset caused, for example, by a zero-crossing detection. The options allowed are `Fast` and `Robust`. `Fast` specifies that the solver does not recompute the Jacobian for a solver reset, whereas `Robust` specifies that the solver does. Consequently, the `Fast` setting is computationally faster but it may use a small step size in certain cases. To test for such cases, run the simulation with each setting and compare the results. If there is no difference, you can safely use the `Fast` setting and save time. If the results differ significantly, try reducing the step size for the fast simulation.

Maximum Order

For the `ode15s` solver, you can choose the maximum order of the numerical differentiation formulas (NDFs) that the solver applies. Since the `ode15s` uses first- through fifth-order formulas, the `Maximum order` parameter allows you to choose 1 through 5. For a stiff problem, you may want to start with order 2.

Tips for Choosing a Variable-Step Implicit Solver

The following table provides tips relating to the application of variable-step implicit solvers. For an example comparing the behavior of these solvers, see sldemo_solvers.

ODE Solver	Tips on When to Use
ode15s	`ode15s` is a variable-order solver based on the numerical differentiation formulas (NDFs). NDFs are related to, but are more efficient than the backward differentiation formulas (BDFs), which are also known as Gear's method. The `ode15s` solver numerically generates the Jacobian matrices. If you suspect that a problem is stiff, or if `ode45` failed or was highly inefficient, try `ode15s`. As a rule, start by limiting the maximum order of the NDFs to 2.
ode23s	`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it can be more efficient than `ode15s` at crude tolerances. Like `ode15s`, `ode23s` numerically generates the Jacobian matrix for you. However, it can solve certain kinds of stiff problems for which `ode15s` is not effective.
ode23t	The `ode23t` solver is an implementation of the trapezoidal rule using a "free" interpolant. Use this solver if your model is only moderately stiff and you need a solution without numerical damping. (Energy is not dissipated when you model oscillatory motion.)
ode23tb	`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with two stages. The first stage is a trapezoidal rule step while the second stage uses a backward differentiation formula of order 2. By construction, the method uses the same iteration matrix in evaluating both stages. Like `ode23s`, this solver can be more efficient than `ode15s` at crude tolerances.

Note For a *stiff* problem, solutions can change on a time scale that is very small as compared to the interval of integration, while the solution of interest changes on a much longer time scale. Methods that are not designed for stiff problems are ineffective on intervals where the solution changes slowly because these methods use time steps small enough to resolve the fastest possible change. For more information, see Shampine, L. F., *Numerical Solution of Ordinary Differential Equations*, Chapman & Hall, 1994.

Support for Zero-Crossing Detection

The variable-step discrete and continuous solvers use zero-crossing detection (see "Zero-Crossing Detection" on page 3-24) to handle continuous signals.

Error Tolerances for Variable-Step Solvers

Local Error

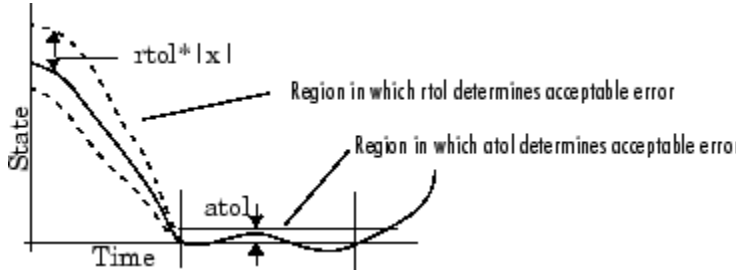
The variable-step solvers use standard control techniques to monitor the local error at each time step. During each time step, the solvers compute the state values at the end of the step and determine the *local error*—the estimated error of these state values. They then compare the local error to the *acceptable error*, which is a function of both the relative tolerance (*rtol*) and the absolute tolerance (*atol*). If the local error is greater than the acceptable error for *any one* state, the solver reduces the step size and tries again.

- The *Relative tolerance* measures the error relative to the size of each state. The relative tolerance represents a percentage of the state value. The default, 1e-3, means that the computed state is accurate to within 0.1%.
- *Absolute tolerance* is a threshold error value. This tolerance represents the acceptable error as the value of the measured state approaches zero.

  The solvers require the error for the `i`th state, e_i, to satisfy:

  $e_i \le \max(rtol \times |x_i|, atol_i)$.

The following figure shows a plot of a state and the regions in which the relative tolerance and the absolute tolerance determine the acceptable error.



Absolute Tolerances

Your model has a global absolute tolerance that you can set on the Solver pane of the Configuration Parameters dialog box. This tolerance applies to all states in the model. You can specify `auto` or a real scalar. If you specify `auto` (the default), Simulink initially sets the absolute tolerance for each state based on the relative tolerance. If the relative tolerance is larger 1e-3, `abstol` is initialized at 1e-6. However, for `reltol` smaller than 1e-3, `abstol` for the state is initialized at `reltol * 1e-3`. As the simulation progresses, the absolute tolerance for each state resets to the maximum value that the

state has assumed so far, times the relative tolerance for that state. Thus, if a state changes from 0 to 1 and `reltol` is 1e-3, `abstol` initializes at 1e-6 and by the end of the simulation reaches 1e-3 also. If a state goes from 0 to 1000, then `abstol` changes to 1.

Now, if the state changes from 0 to 1 and `reltol` is set at 1e-4, then `abstol`initializes at 1e-7 and by the end of the simulation reaches a value of 1e-4.

If the computed setting is not suitable, you can determine an appropriate setting yourself. You might have to run a simulation more than once to determine an appropriate value for the absolute tolerance.

Several blocks allow you to specify absolute tolerance values for solving the model states that they compute or that determine their output:

- Integrator
- Second-Order Integrator, Second-Order Integrator Limited
- Variable Transport Delay
- Transfer Fcn
- State-Space
- Zero-Pole

The absolute tolerance values that you specify for these blocks override the global settings in the Configuration Parameters dialog box. You might want to override the global setting if, for example, the global setting does not provide sufficient error control for all of your model states because they vary widely in magnitude. You can set the block absolute tolerance to:

- `auto`
- `–1` (same as `auto`)
- `positive scalar`
- `real vector` (having a dimension equal to the number of corresponding continuous states in the block)

Tips

If you do choose to set the absolute tolerance, keep in mind that too low of a value causes the solver to take too many steps in the vicinity of near-zero state values. As a result, the simulation is slower.

On the other hand, if you set the absolute tolerance too high, your results can be inaccurate as one or more continuous states in your model approach zero.

Once the simulation is complete, you can verify the accuracy of your results by reducing the absolute tolerance and running the simulation again. If the results of these two simulations are satisfactorily close, then you can feel confident about their accuracy.

Choose a Jacobian Method for an Implicit Solver

The Solver Jacobian

For implicit solvers, Simulink must compute the *solver Jacobian*, which is a submatrix of the Jacobian matrix associated with the continuous representation of a Simulink model. In general, this continuous representation is of the form:

$$\dot{x} = f(x,t,u)$$
$$y = g(x,t,u).$$

The Jacobian, J, formed from this system of equations is:

$$J = \begin{pmatrix} \frac{\partial f}{\partial x} & \frac{\partial f}{\partial u} \\ \frac{\partial g}{\partial x} & \frac{\partial g}{\partial u} \end{pmatrix} = \begin{pmatrix} A & B \\ C & D \end{pmatrix}.$$

In turn, the solver Jacobian is the submatrix, J_x.

$$J_x = A = \frac{\partial f}{\partial x}.$$

Sparsity of Jacobian

For many physical systems, the solver Jacobian J_x is *sparse*, meaning that many of the elements of J_x are zero.

Consider the following system of equations:

$$\dot{x}_1 = f_1(x_1, x_3)$$
$$\dot{x}_2 = f_2(x_2)$$
$$\dot{x}_3 = f_3(x_2).$$

From this system, you can derive a sparsity pattern that reflects the structure of the equations. The pattern, a Boolean matrix, has a 1 for each x_i that appears explicitly on the right-hand side of an equation. Therefore, you attain:

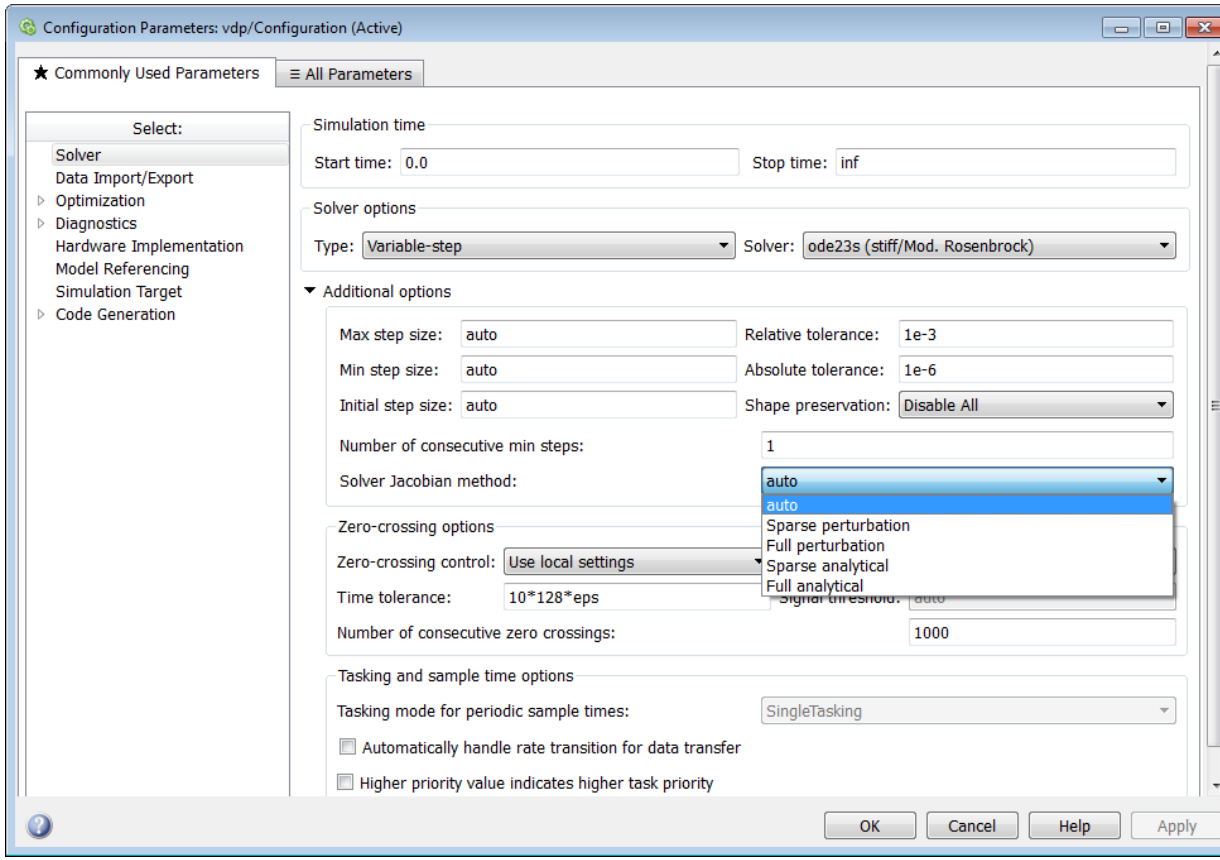
$$J_{x,pattern} = \begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \\ 0 & 1 & 0 \end{pmatrix}$$

As discussed in "Full and Sparse Perturbation Methods" on page 24-31 and "Full and Sparse Analytical Methods" on page 24-32 respectively, the Sparse Perturbation Method and the Sparse Analytical Method may be able to take advantage of this sparsity pattern to reduce the number of computations necessary and improve performance.

Solver Jacobian Methods

When you choose an implicit solver from the **Solver** pane of the configuration parameters dialog box, a parameter called `Solver Jacobian method` and a drop-down menu appear. This menu has five options for computing the solver Jacobian:

- **auto**
- **Sparse perturbation**
- **Full perturbation**
- **Sparse analytical**
- **Full analytical**



Note If you set **Automatic solver parameter selection** to `warning` or `error` in the Solver Diagnostics pane, and you choose a different solver method than Simulink, you may receive a warning or an error.

Limitations

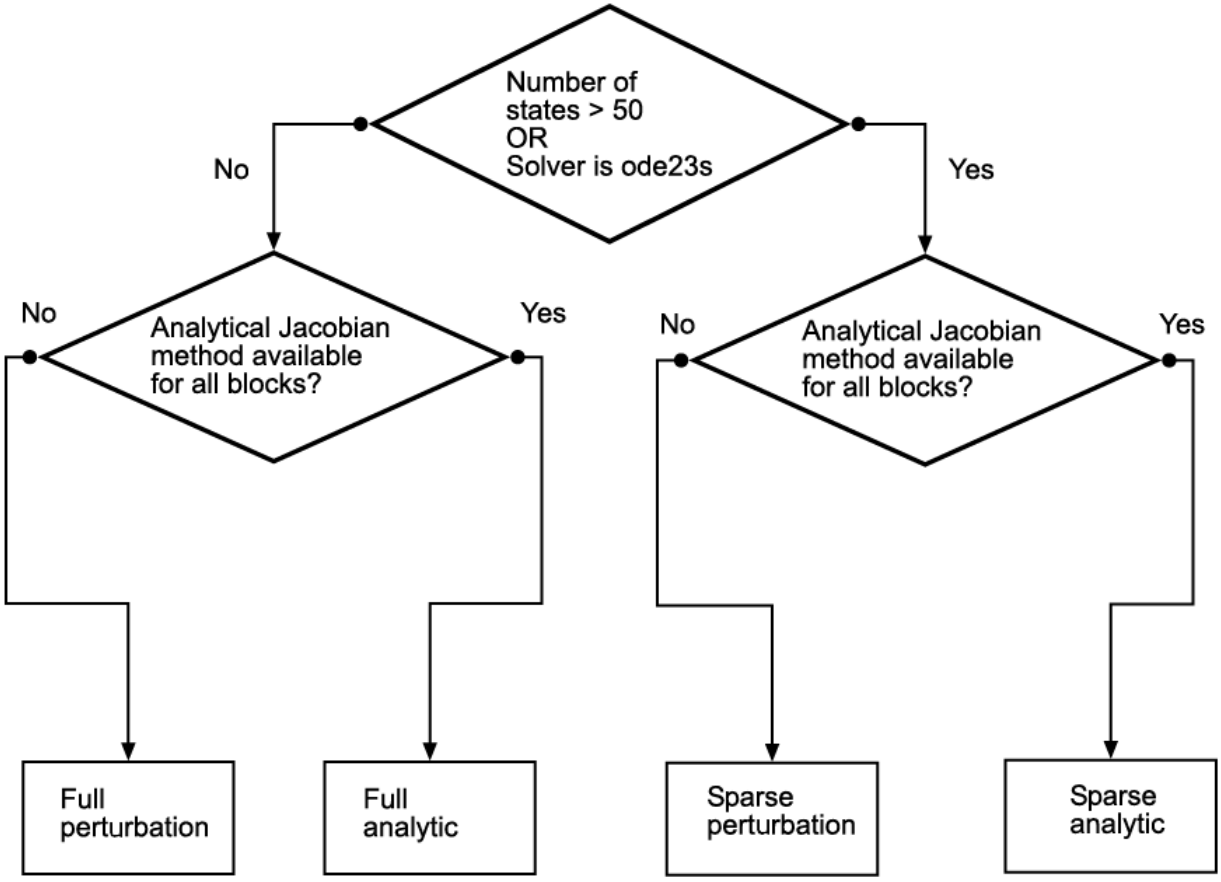
The solver Jacobian methods have the following limitations associated with them.

- If you select an analytical Jacobian method, but one or more blocks in the model do not have an analytical Jacobian, then Simulink applies a perturbation method.

- If you select sparse perturbation and your model contains data store blocks, Simulink applies the full perturbation method.

Heuristic 'auto' Method

The default setting for the `Solver Jacobian method` is `auto`. Selecting this choice causes Simulink to perform a heuristic to determine which of the remaining four methods best suits your model. This algorithm is depicted in the following flow chart.



Because sparse methods are beneficial for models having a large number of states, if 50 or more states exist in your model, the heuristic chooses a sparse method. The logic also leads to a sparse method if you specify `ode23s` because, unlike other implicit solvers,

`ode23s` generates a new Jacobian at every time step. A sparse analytical or a sparse perturbation method is, therefore, highly advantageous. The heuristic also ensures that the analytical methods are used only if every block in your model can generate an analytical Jacobian.

Full and Sparse Perturbation Methods

The full perturbation method was the standard numerical method that Simulink used to solve a system. For this method, Simulink solves the full set of perturbation equations and uses LAPACK for linear algebraic operations. This method is costly from a computational standpoint, but it remains the recommended method for establishing baseline results.

The sparse perturbation method attempts to improve the run-time performance by taking mathematical advantage of the sparse Jacobian pattern. Returning to the sample system of three equations and three states,

$$\dot{x}_1 = f_1(x_1, x_3)$$
$$\dot{x}_2 = f_2(x_2)$$
$$\dot{x}_3 = f_3(x_2).$$

The solver Jacobian is:

$$J_x = \begin{pmatrix} \frac{\partial f_1}{\partial x_1} & \frac{\partial f_1}{\partial x_2} & \frac{\partial f_1}{\partial x_3} \\ \frac{\partial f_2}{\partial x_1} & \frac{\partial f_2}{\partial x_2} & \frac{\partial f_2}{\partial x_3} \\ \frac{\partial f_3}{\partial x_1} & \frac{\partial f_3}{\partial x_2} & \frac{\partial f_3}{\partial x_3} \end{pmatrix}$$

$$= \begin{pmatrix} \frac{f_1(x_1+\Delta x_1, x_2, x_3) - f_1}{\Delta x_1} & \frac{f_1(x_1, x_2+\Delta x_2, x_3) - f_1}{\Delta x_2} & \frac{f_1(x_1, x_2, x_3+\Delta x_3) - f_1}{\Delta x_3} \\ \frac{f_2(x_1+\Delta x_1, x_2, x_3) - f_2}{\Delta x_1} & \frac{f_2(x_1, x_2+\Delta x_2, x_3) - f_2}{\Delta x_2} & \frac{f_2(x_1, x_2, x_3+\Delta x_3) - f_2}{\Delta x_3} \\ \frac{f_3(x_1+\Delta x_1, x_2, x_3) - f_3}{\Delta x_1} & \frac{f_3(x_1, x_2+\Delta x_2, x_3) - f_3}{\Delta x_2} & \frac{f_3(x_1, x_2, x_3+\Delta x_3) - f_3}{\Delta x_3} \end{pmatrix}$$

It is, therefore, necessary to perturb each of the three states three times and to evaluate the derivative function three times. For a system with n states, this method perturbs the states n times.

By applying the sparsity pattern and perturbing states x_1 and x_2 together, this matrix reduces to:

$$J_x = \begin{pmatrix} \frac{f_1(x_1+\Delta x_1, x_2+\Delta x_2, x_3)-f_1}{\Delta x_1} & 0 & \frac{f_1(x_1, x_2, x_3+\Delta x_3)-f_1}{\Delta x_3} \\ 0 & \frac{f_2(x_1+\Delta x_1, x_2+\Delta x_2, x_3)-f_2}{\Delta x_2} & 0 \\ 0 & \frac{f_3(x_1+\Delta x_1, x_2+\Delta x_2, x_3)-f_3}{\Delta x_2} & 0 \end{pmatrix}$$

The solver can now solve columns 1 and 2 in one sweep. While the sparse perturbation method saves significant computation, it also adds overhead to compilation. It might even slow down the simulation if the system does not have a large number of continuous states. A tipping point exists for which you obtain increased performance by applying this method. In general, systems having a large number of continuous states are usually sparse and benefit from the sparse method.

The sparse perturbation method, like the sparse analytical method, uses UMFPACK to perform linear algebraic operations. Also, the sparse perturbation method supports both RSim and Rapid Accelerator mode.

Full and Sparse Analytical Methods

The full and sparse analytical methods attempt to improve performance by calculating the Jacobian using analytical equations rather than the perturbation equations. The sparse analytical method, also uses the sparsity information to accelerate the linear algebraic operations required to solve the ordinary differential equations.

Sparsity Pattern

For details on how to access and interpret the sparsity pattern in MATLAB, see sldemo_metro.

Support for Code Generation

While the sparse perturbation method supports RSim, the sparse analytical method does not. Consequently, regardless of which sparse method you select, any generated code

uses the sparse perturbation method. This limitation applies to Rapid Accelerator mode as well.

Use Auto Solver to Select a Solver

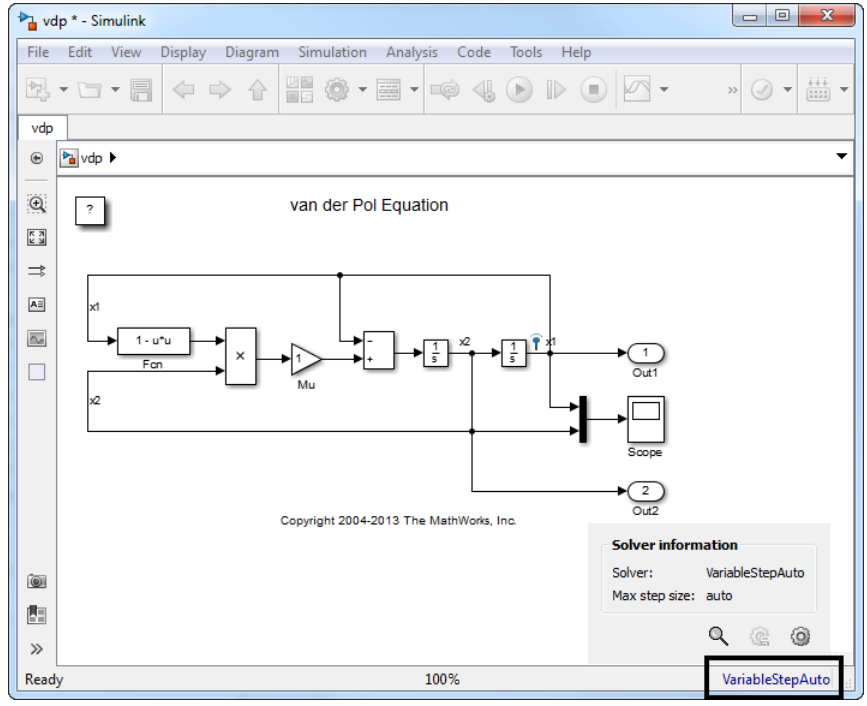
In this section...

When you want Simulink to select a solver for simulating the model, use auto solver. Auto solver chooses a suitable solver and sets the maximum step size of the simulation.

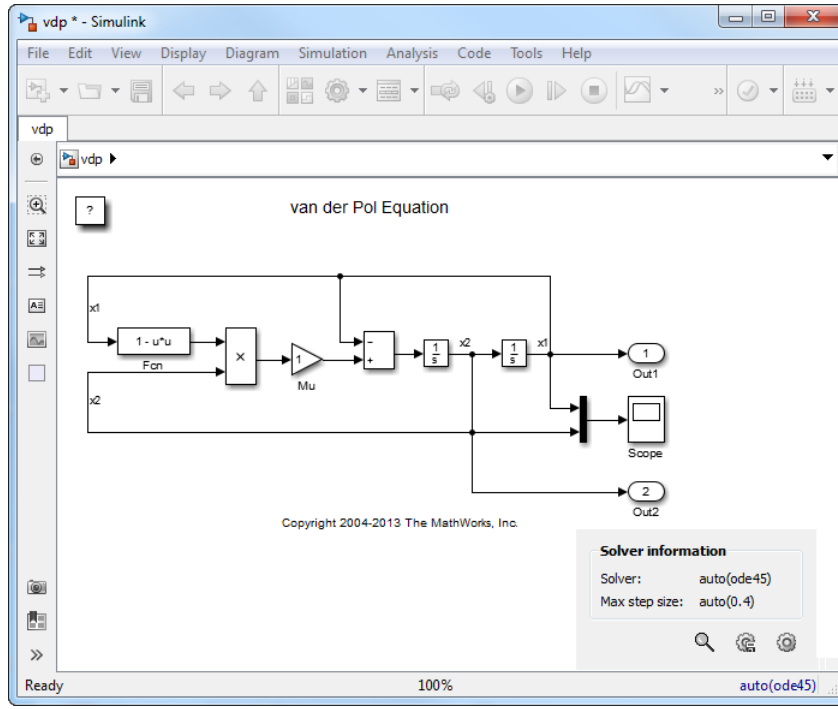
For new models, Simulink selects auto solver and sets the type to variable-step by default. For an existing model, you can use auto solver to select a solver.

Use Auto Solver with vdp Model

1 Open `vdp` and click the solver link in the lower-right corner. The **Solver information** pane opens.



2. In the pane, click the **View solver settings** button to open the **Solver** pane of the model configuration parameters.
3. Under **Solver options**, set **Type** to fixed or variable-step according to your preference and set **Solver** to `auto`.
4. When you simulate the model, auto solver selects a fixed-step or variable-step solver according to your preference and calculates the maximum step size it recommends. To see the results, open the **Solver information** pane.

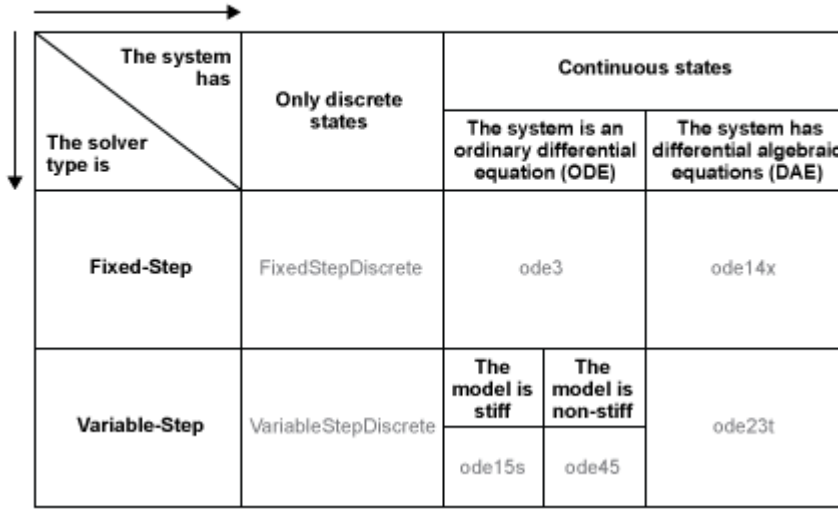


5. Click the **Accept suggested settings** button to apply the recommendations of auto solver. To select different settings, click the **View solver settings** button and make changes in the configuration parameters **Solver** pane.

Auto Solver Heuristics

This chart describes the heuristics of auto solver.

Auto Solver Heuristics



- For Simscape Power Systems models, auto solver selects `ode23tb`. These systems can have circuits with nonlinear models, especially circuit breakers and power electronics. Such nonlinear models require a stiff solver.
- If the number of continuous states in the model exceeds the `NumStatesForStiffnessChecking` value, auto solver uses `ode15s`. It does not calculate the stiffness of the model. The default value for this parameter is 1000. You can change this value using `set_param`.
- If the number of continuous states in the model is less than the `NumStatesForStiffnessChecking` value, auto solver calculates the stiffness of the model. A model is stiff if the stiffness exceeds the `StiffnessThreshold` value. The default value for this parameter is 1000. You can change this value using `set_param`.

Save and Restore Simulation State as SimState

In this section...

SimState and Repetitive Simulations

When designing a system, you simulate a model repeatedly to analyze the behavior of a system for different inputs, boundary conditions, or operating conditions. In many applications, a startup phase with significant dynamic behavior is common to multiple simulations. For example, the cold start takeoff of a gas turbine engine occurs before each set of aircraft maneuvers. Ideally, you:

1. Simulate the startup phase once.
2. Save the simulation state at the end of the start-up phase.
3. Use this state as the initial state for each set of conditions or maneuvers.

In this type of situation, use SimState to save the state of a simulation. For future simulations, you can restore the `SimState` and use it to set initial conditions for simulations going forward.

A `SimState` includes both the logged and internal states of every block (e.g., continuous states, discrete states, work vectors, zero-crossing states) and the internal state of the Simulink engine (e.g., the data of the ODE solver).

Note You can also use the **Final states** option in the Configuration Parameters **Data Import/Export** pane to save a simulation state. However, this option saves only *logged*

states—the continuous and discrete states of blocks. These states are only subsets of the complete simulation state of the model. They do not include information about hidden states of certain blocks — information that is not included in logged states but is still required for the proper execution of the block. Hence you cannot use **Final states** to save and restore the complete simulation state as the initial state of a new simulation.

Information Saved in a SimState

A `SimState` contains information about:

- Logged states
- State of the solver and execution engine
- Zero-crossing signals for blocks that register zero crossings
- Output values of certain blocks in the model

  Simulink analyzes block connections and other information to determine whether it is using the output values effectively as state information.

`SimState` also stores the hidden states of these blocks:

- Transport Delay
- Variable Transport Delay
- From Workspace
- For Each subsystem
- Conditionally executed subsystems
- Stateflow
- MATLAB System
- Simscape Multibody Second Generation

By storing this information, `SimState` ensures that the result of a simulation that starts from SimState is the same as a simulation that runs from the beginning.

Benefits of Using SimState

- When `SimState` saves the state of a simulation, it saves information in addition to the logged states in the model. You need to restore all of this information to ensure that the simulation matches the uninterrupted simulation. For example, if solver

information affected the simulation, then changing the state of a block without using `SimState` can produce different results.

- You can save several SimStates during a simulation. You can then resume a simulation from any of those states.
- `SimState` can help to restore the state of blocks such as the Transport Delay block, which is typically difficult to restore to a particular state. The state of the Transport Delay block is not saved in the structure format or the array format when you log data using the **Final states** configuration parameter without using Simstate. The blocks with hidden states are particularly difficult to restore, and SimState enables you to do so.

When You Can Save a SimState

You can save a `SimState`:

- At the final **Stop time**
- When you interrupt a simulation with the **Pause** or **Stop** button
- When you use `get_param` or a block, like the Stop block, to stop a simulation

Save SimState

Save a `SimState` at the beginning of the final step using one of these options.

Interactive

1. In the Configuration Parameters dialog box, in the **Data Import/Export** pane, select the **Final states** check box. The **Save complete SimState in final state** check box becomes available.
2. Select the **Save complete SimState in final state** check box.
3. In the **Final states** text box, enter a variable name for the `SimState`.
4. Simulate the model.

From the MATLAB Command Prompt

Use the `sim` command with `set_param`. Set the `SaveCompleteFinalSimState` parameter to `on`.

```
fuelsys
set_param('fuelsys','SaveFinalState','on','FinalStateName',...
```

```
'myOperPoint','SaveCompleteFinalSimState','on');
simOut = sim('fuelsys','StopTime','10')
set_param('fuelsys','SaveFinalState','off');
```

Restore SimState

The **Start time** does not change from the value in the simulation that generated SimState. It is a reference value for all time and time-dependent variables in both the original and the current simulation. For example, a block can save and restore the number of sample time hits that occurred since the beginning of simulation as its `SimState`.

Consider a model that you ran from 0–100 s and that you now want to run from 100–200 s. The **Start time** is 0 s for both the original simulation (0–100 s) and for the current simulation (100–200 s). The initial time of the current simulation is 100 s. Also, if the block had 10 sample time hits during the original simulation, Simulink recognizes that the next sample time hit is the 11th, relative to 0, not 100 s.

Note If you change **Start time** before restoring a `SimState`, Simulink overwrites the **Start time** with the value saved in the `SimState`.

Restore a `SimState` using one of these options.

Interactive

1. In the Configuration Parameters dialog box, in the **Data Import/Export** pane, under **Load from workspace**, select the **Initial state** check box. The text box becomes available.
2. Enter the name of the variable containing the `SimState` in the text box.
3. Set **Stop time** to a value greater than the time at which the SimState was saved.

From the MATLAB Command Prompt

To restore the SimState that you saved in the example “Save SimState” on page 24-39:

```
set_param('fuelsys','LoadInitialState','on','InitialState',...
'myOperPoint');
simOut.get('myOperPoint')
```

Restore SimState Saved in an Earlier Version of Simulink

You can use `SimState` objects saved in releases starting with R2010a to restore the `SimState` of a model. However, this option restores only the logged states of the model. To see the version of Simulink used to save the `SimState`, examine the **version** parameter of the `SimState` object.

Simulink detects if the `SimState` object you provided as the initial state was saved in the current release. By default, Simulink displays an error message if the `SimState` was not saved in the current release. You can configure the diagnostic to allow Simulink to display the message as a warning and try to restore as many of the values as possible.

To enable this best-effort restoration, in the Configuration Parameters dialog box set the message for **SimState object from earlier release** to `warning`.

Change the States of a Block Within SimState

- Use `loggedStates` to get or set the states of blocks. If `xout` is the state log that Simulink exports to the workspace, then the `loggedStates` field has the same structure as `xout.signals`.
- You cannot change the states that are not logged. Simulink does not allow this modification as it could cause the state to be inconsistent with the simulation.

S-Functions

You can use APIs for C and Level-2 MATLAB S-functions to enable S-functions to work with `SimState`. For information on how to implement these APIs within S-functions, see "S-Function Compliance with the SimState".

S-functions that have P-work vectors but do not declare their `SimState` compliance level or declare it to be unknown or disallowed do not support `SimState`. For more information, see "S-Function Compliance with the SimState".

Model Changes and SimState

- You cannot make any structural changes to the model between the time you save the `SimState` and the time you restore the simulation using the `SimState`. For example, you cannot add or remove a block after saving the `SimState` without repeating the simulation and saving the new `SimState`.

- The `SimState` interface checksum is primarily based on the configuration settings in a model. You can make some nonstructural changes to the model between saving and restoring a `SimState`. In the Configuration Parameters dialog box, in the **Diagnostics** pane, use the **SimState interface checksum mismatch** diagnostic to track such changes. You can then find out if the interface checksum of the restored `SimState` matches the current interface checksum.

  Mismatches can occur when you try to simulate using a solver that is different from the one that generated the saved `SimState`. Simulink permits solver changes. For example, you can use the `ode15s` solver to solve the initial stiff portion of a simulation and save the final `SimState`. You can then continue the simulation with the restored `SimState` using `ode45`. In other words, this diagnostic helps you see the solver changes but does not signal a problem with the simulation.
- When you use a variable-step solver with the maximum step size set to `auto`, Simulink uses the maximum step size from the restored `SimState` for the new simulation. To ensure that the concatenated `SimState` trajectory of two simulations matches that of an uninterrupted simulation, specify a value for the maximum step size.

Limitations of SimState

Note In some cases, saving partial state information avoids some of the limitations of using `SimState`. For a comparison of the two ways to save state data, see "Comparison of SimState and Final State Logging" on page 61-259.

Block Support

The following blocks do not support `SimState`:

- In the Stack and Queue blocks, the default setting for the **Push full stack** option is **Dynamic reallocation**. This default setting does not support `SimState`. Other settings (**Ignore**, **Warning** and **Error**) support `SimState`.
- Simscape Multibody First Generation blocks

Simulink tries to save the output of a block as part of a `SimState`. For S-functions, this happens even if the functions declare that no `SimState` is required. If the block output is of custom type, Simulink cannot save the `SimState` and displays an error. For more information about SimState use with S-functions, see "S-Functions" on page 24-41.

Model reference offers partial support for `SimState`. For details, see "Model Referencing" on page 24-43.

Simulation

- You can save `SimState` only at the final stop time or at the execution time at which you pause or stop the simulation.
- You can use only the Normal or the Accelerator simulation mode.
- You cannot save `SimState` in Normal mode and restore it in Accelerator mode, or vice versa.
- You cannot change the states of certain blocks that are not logged. For more information, see "Change the States of a Block Within SimState" on page 24-41.

Code Generation

The `SimState` feature does not support Simulink Coder or Embedded Coder code generation.

Model Referencing

- You cannot modify logged states of blocks that are inside a referenced model in Accelerator mode.
- The following blocks do not support SimState when included in a model referenced in Accelerator mode:
  - Level 2 MATLAB S-Function
  - MATLAB System
  - n-D Lookup Table
  - S-Function (with custom `SimState` or `PWork` vectors)
  - To File
  - Simscape blocks
- For additional information, see "State Information for Referenced Models" on page 61-262.

Model Function

You cannot input the `SimState` to the `model` function.

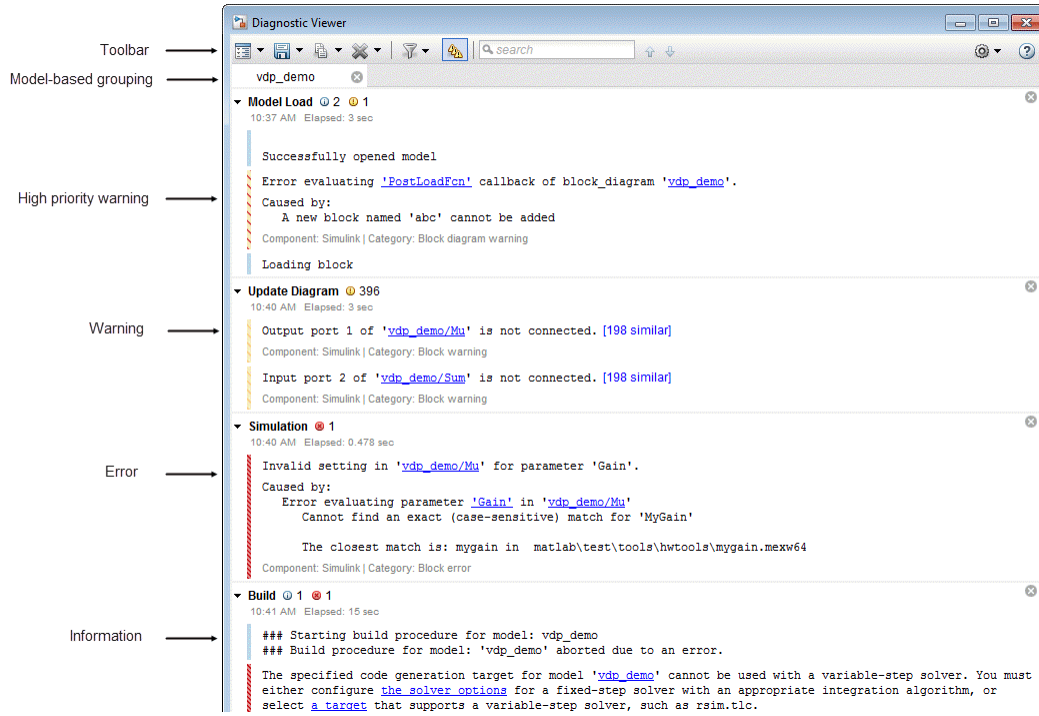
View Diagnostics

You can view and diagnose errors and warnings generated by your model using the **Diagnostic Viewer**. The **Diagnostic Viewer** displays three types of diagnostic messages: errors, warnings, and information. A model generates these messages during a runtime operation, like model load, simulation, or update diagram.



The diagnostic viewer window is divided into:

- Toolbar menu: Displays various commands to help you manage the diagnostic messages. For more information, see “Toolbar” on page 24-46.
- Diagnostic Message pane: Displays the error, warning, and information messages. For more information, see “Diagnostic Message Pane” on page 24-46.
- Suggested Actions: Displays suggestions and fixes to correct the diagnostic errors and warnings. For more information, see.“Suggested Actions” on page 24-48.

Toolbar

To manage the diagnostic messages, use the **Diagnostic Viewer** toolbar.

Button	Action
	Expand or collapse messages
	Save all or latest messages in a log file
	Copy all or latest messages
	Clear all or all but latest messages
	Filter out errors, warning, and information messages
	Group similar type of messages
	Search messages for specific keywords and navigate between messages
	Set maximum number of models to display in tabbed panes and the maximum number of events to display per model

Diagnostic Message Pane

The diagnostic message pane displays the error, warning, and information messages in a tabbed format. These messages are color-coded for distinction and are hierarchical.

A new stage is generated for each successive event, you can save or clear stage. Each stage represents a single event such as model load, update diagram, or simulation.

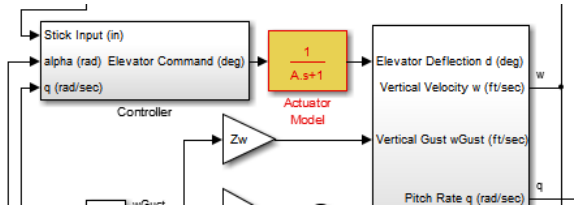
Different types of diagnostic messages are:

- Information message: Displays the information related to a model load. Information messages are marked as  .
- High priority warning: Displays the errors encountered during model load as a high priority warning. Any subsequent operation, like update on the model without

rectifying the high priority warning messages are marked as errors. High priority warnings are marked as  .

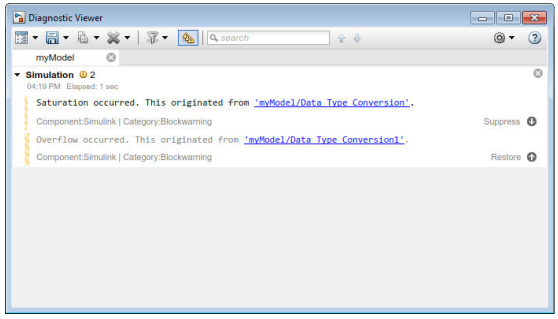
- Warning: Displays the warnings associated during an operation on a model. Warnings are marked as  .
- Error: Displays the errors associated during an operation on a model. Errors are marked as  .

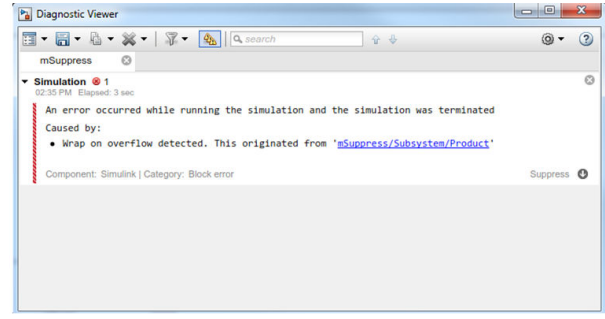
Tip To locate the source of error, click the hyperlink in the message. The source of error in the model is highlighted.



Suppress Warnings

The Diagnostic Viewer provides a **Suppress** button for certain diagnostics. This button allows you to suppress certain numerical diagnostics (for example, overflow, saturation, precision loss) for specific objects in your model. You can also suppress certain errors that have diagnostic level set to `Error` in the **Diagnostics** section of Model Configuration Parameters. To suppress the diagnostic from the specified source, click the **Suppress** button next to the diagnostic in the Diagnostic Viewer. You can restore the diagnostic from the source by clicking **Restore**. Diagnostic suppressions are saved with the model and persist across sessions.





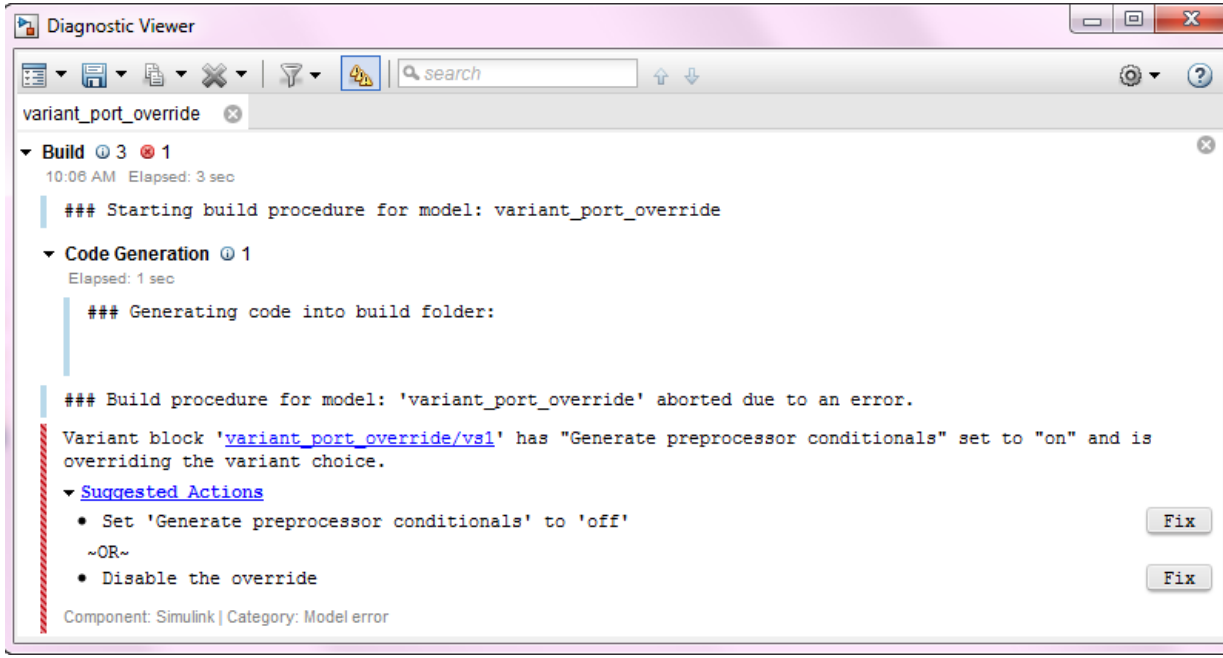
You can also control the suppression of diagnostics from the command line. For more information, see “Suppress Diagnostic Messages Programmatically” on page 24-54.

Suggested Actions

Diagnostic viewer provides suggestions and fixes for diagnostic error and warning messages. These suggestions and fixes are provided in the **Suggested Actions** section of diagnostic message pane.

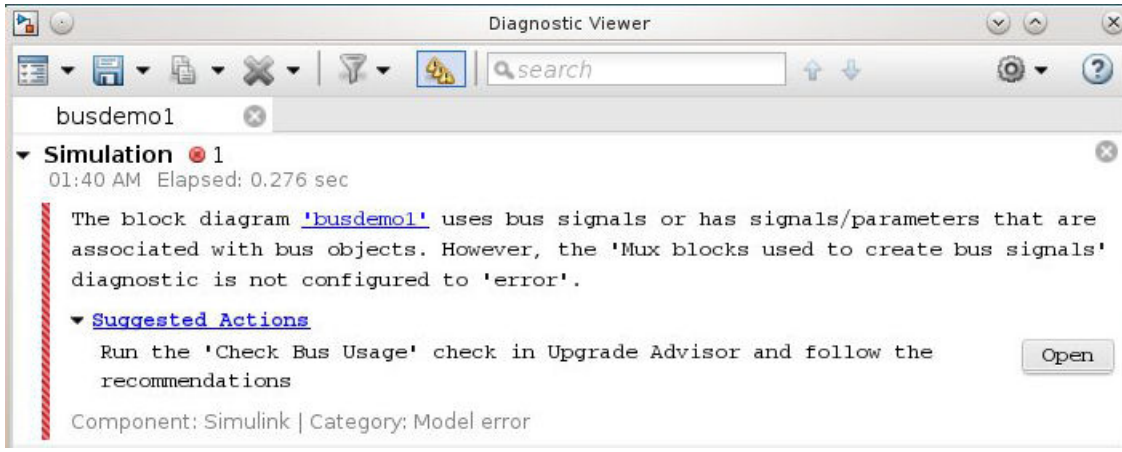
A diagnostic error or warning can have multiple fixes and suggestions. Each fix is associated with a **Fix** button.

You can click the **Fix** button for the most suitable fix to rectify the error automatically.



The **Fix** buttons for a diagnostic error or warning are no longer available after a fix is successfully applied. If a fix was unsuccessful, a failure message is displayed in the **Suggested Actions** section.

Suggestions are provided for errors and warnings that cannot be fixed automatically.



Note The **Suggested Actions** section is available only for the diagnostic errors or warnings that have a predefined fix.

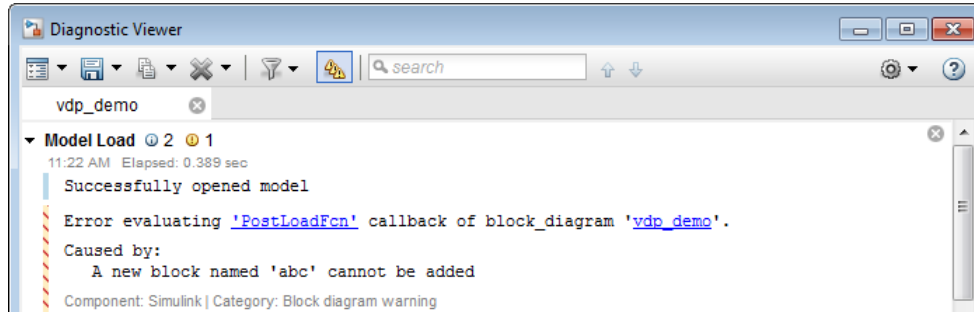
- "Customize Diagnostic Messages" on page 24-63
- "Report Diagnostic Messages Programmatically" on page 24-66

Systematic Diagnosis of Errors and Warnings

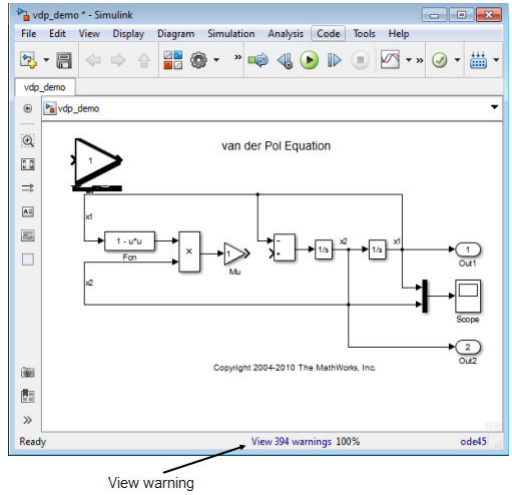
This example shows how to use the Diagnostic Viewer to identify and locate simulation errors and warnings systematically.

1 Open your model.

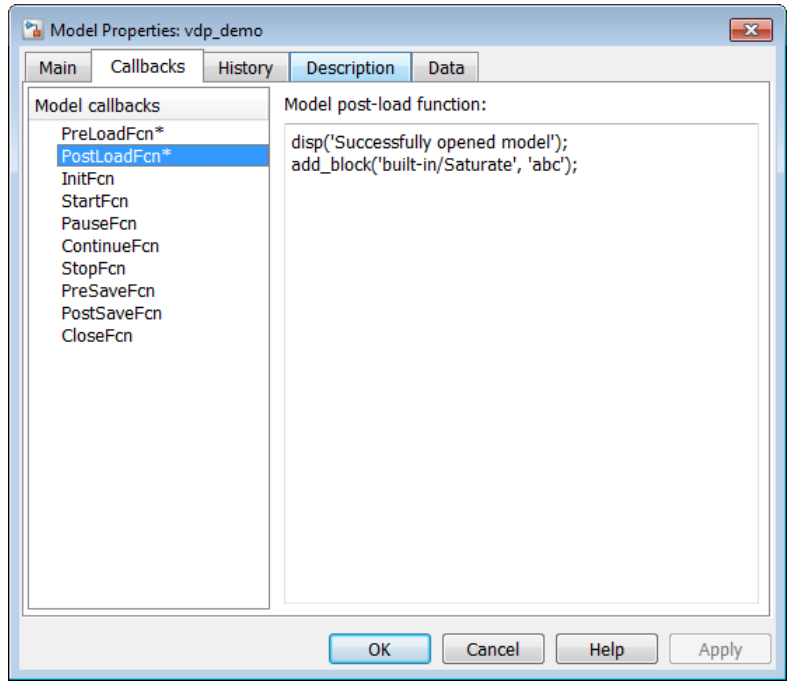
If your model contains errors related to callback functions, the **Diagnostic Viewer** opens and displays the following errors in **Model Load** stage.



Tip To open the **Diagnostic Viewer** window, click **View** > **Diagnostic Viewer** or click **View warnings** in the Simulink Editor.

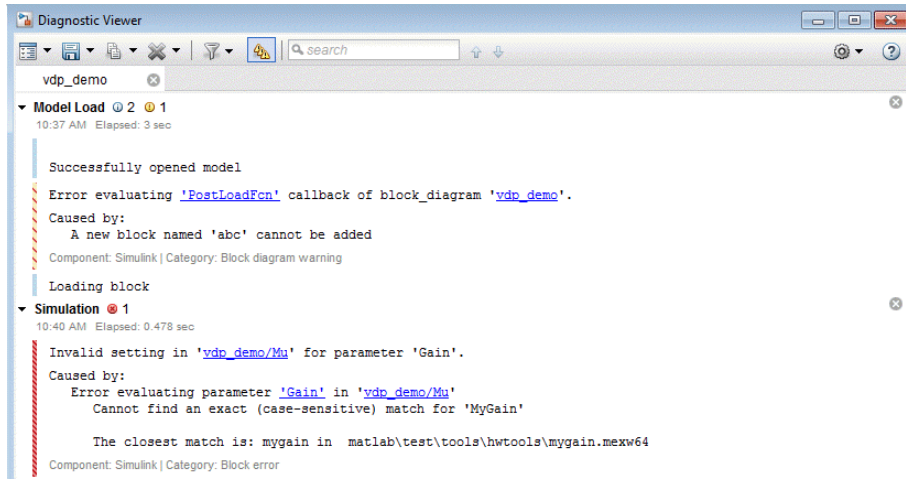


2 In the Simulink Editor, click **File** > **Model Properties** > **Model Properties**, and examine the callback error.



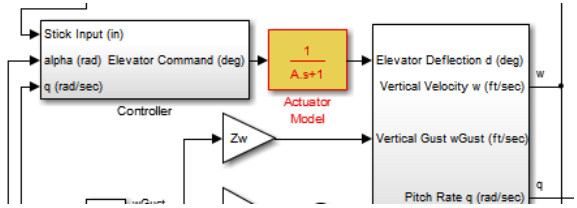
3 After fixing any callback errors, simulate the model to diagnose simulation errors and warnings.

Diagnostic Viewer lists errors and warnings in stages. Each stage in **Diagnostic Viewer** represents a single event such as model load, update diagram, simulation, or build.



4 Filter out warnings by clicking  so that you can address errors first.

5 To locate the source of the error, click the hyperlink in the message. The model in the source is highlighted. If a block has multiple ports, you can hover over each port to see the port number.



6 After fixing all errors, simulate your model again and view the **Diagnostic Viewer** to identify remaining problems.

Note If an error or warning has a predefined fix, the diagnostic message pane displays a **Suggested Actions** section. You can use the **Fix** button provided in this section to rectify the related error or warning. For more information see, “Suggested Actions” on page 24-48.

---

7 If an object in your model generates a warning that you do not want to be notified of, sometimes, you can suppress the warning from the specified source using the **Suppress** button. You can restore the warning from that source using the **Restore** button. For example, if a Counter Free-Running block generates an overflow warning that is intentional in your design, you can suppress only overflow warnings

from this particular block, without sacrificing notification of other overflows in your model.

8 To generate code for your model, click **Code > C/C++ Code > Build Model**.

Note If there is a failure during code generation, Diagnostic Viewer provides hyperlinks for easy navigation to the source of the error or warning message.

Suppress Diagnostic Messages Programmatically

The following examples show how to manage diagnostic suppressions programmatically.

In this section...

Suppress Diagnostic Messages Programmatically

This example shows how to access simulation metadata to manage diagnostic suppressions and to restore diagnostic messages programmatically.

Create a New Folder and Copy Relevant Files

1. Create a local working folder, for example, `c:\diadnostic_suppressor_demo`.
2. Change to the `docroot\toolbox\simulink\examples` folder. At the MATLAB command line, enter:

   ```
   cd(fullfile(docroot, 'toolbox', 'simulink', 'examples'))
   ```

3. Copy the `getDiagnosticObjects.m`, `suppressor_script.m`, and `Suppressor_CLI_Demo.slx` files to your local working folder.

   The `getDiagnosticObjects.m` function queries the simulation metadata to access diagnostics that were thrown during simulation. The `suppressor_script.m` script contains the commands for suppressing and restoring diagnostics to the `Suppressor_CLI_Demo` model.

   `getDiagnosticObjects.m`

   ```
   function y = getDiagnosticObjects(in)
   Warningdata = in.getSimulationMetadata.ExecutionInfo.WarningDiagnostics;
   Errordata = in.getSimulationMetadata.ExecutionInfo.ErrorDiagnostic;

   index = 1;

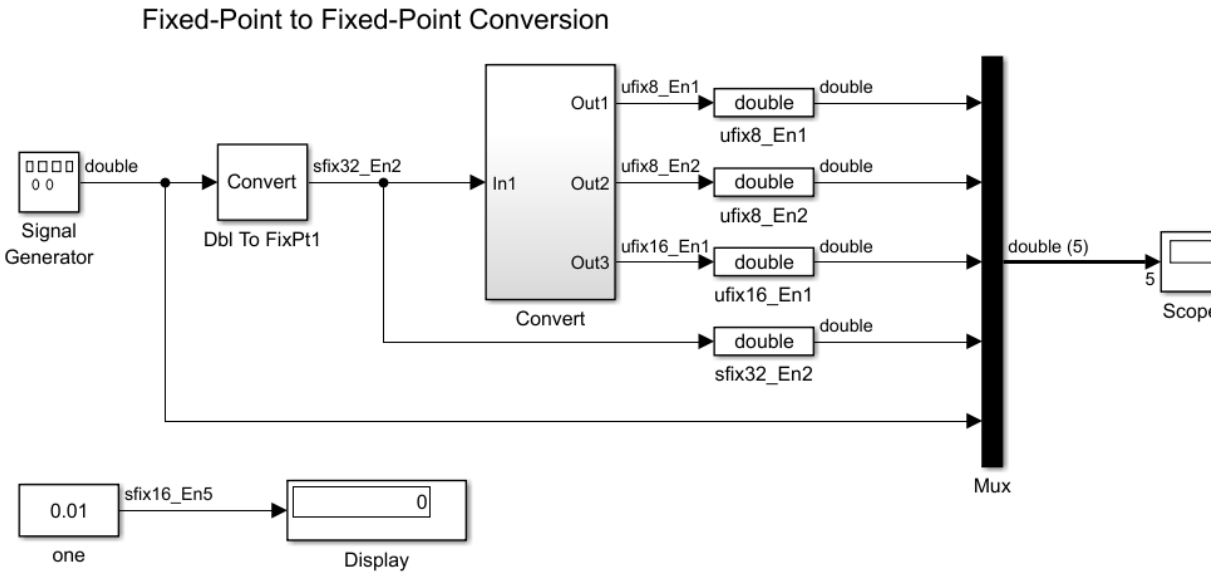
   for i = 1 : numel(Warningdata)
       y(index) = Warningdata(i).Diagnostic;
       index = index + 1;
   end
   ```

```
for i = 1 : numel(Errordata)
    y(index) = Errordata(i).Diagnostic;
    index = index + 1;
end
```

Open and Simulate the Model

Open the model. To access `Simulink.SimulationMetadata`, set the `ReturnWorkspaceOutputs` parameter value to `'on'`. Simulate the model.

```
model = 'Suppressor_CLI_Demo';
open_system(model);
set_param(model,'ReturnWorkspaceOutputs','on');
out = sim(model);
```



Get Message Identifiers from Simulation Metadata

Find the names of diagnostic message identifiers using the simulation metadata stored in the `MSLDiagnostic` object.

```
if (exist('out', 'var'))
    diag_objects = getDiagnosticObjects(out);
end
```

Several warnings were generated during simulation, including a saturation of the Data Type Converter block. Query the `diag_objects` variable to get more information on the identifiers.

```
diag_objects(5)
```

```
ans =

  MSLDiagnostic with properties:

    identifier: 'SimulinkFixedPoint:util:Saturationoccurred'
       message: 'Saturation occurred. This originated from 'Suppressor_CLI_Demo/Con…'
         paths: {'Suppressor_CLI_Demo/Convert/FixPt To FixPt3'}
         cause: {}
         stack: [0×1 struct]
```

Suppress Saturation Diagnostic on a Block

Use the `Simulink.suppressDiagnostic` function to suppress the saturation diagnostic on the data type conversion block only. Simulate the model.

```
Simulink.suppressDiagnostic('Suppressor_CLI_Demo/Convert/FixPt To FixPt3', ...
'SimulinkFixedPoint:util:Saturationoccurred');
set_param(model,'SimulationCommand','start');
```

Restore the Saturation Diagnostic

Use the `Simulink.restoreDiagnostic` function to restore the saturation diagnostic of the same block.

```
Simulink.restoreDiagnostic('Suppressor_CLI_Demo/Convert/FixPt To FixPt3',...
 'SimulinkFixedPoint:util:Saturationoccurred');
set_param(model,'SimulationCommand','start');
```

Suppress Multiple Diagnostics on a Source

You can suppress multiple warnings on a single source by creating a cell array of message identifiers. Suppress the precision loss and parameter underflow warnings of the Constant block, `one`, in the model.

```
diags = {'SimulinkFixedPoint:util:fxpParameterPrecisionLoss',...
 'SimulinkFixedPoint:util:fxpParameterUnderflow'};
```

```
Simulink.suppressDiagnostic('Suppressor_CLI_Demo/one',diags);
set_param(model,'SimulationCommand','start');
```

Restore All Diagnostics on a Block

Restore all diagnostics on a specified block using the`Simulink.restoreDiagnostic` function.

```
Simulink.restoreDiagnostic('Suppressor_CLI_Demo/one');
set_param(model,'SimulationCommand','start');
```

Suppress a Diagnostic on Many Blocks

You can suppress one or more diagnostics on many blocks. For example, use the `find_system` function to create a cell array of all Data Type Converter blocks in a system, and suppress all saturation warnings on the specified blocks.

```
dtc_blocks = find_system('Suppressor_CLI_Demo/Convert',...
 'BlockType', 'DataTypeConversion');
Simulink.suppressDiagnostic(dtc_blocks, 'SimulinkFixedPoint:util:Saturationoccurred');
set_param(model,'SimulationCommand','start');
```

Restore All Diagnostics Inside a Subsystem

You can also use the `Simulink.restoreDiagnostic` function to restore all diagnostics inside a specified subsystem.

```
Simulink.restoreDiagnostic('Suppressor_CLI_Demo/Convert',...
 'FindAll', 'On');
set_param(model,'SimulationCommand','start');
```

Add Comments and User Information to a Suppression

A `SuppressedDiagnostic` object contains information on the source of the suppression and the suppressed diagnostic message identifier. You can also include comments, and the name of the user who last modified the suppression.

```
Object = Simulink.SuppressedDiagnostic('Suppressor_CLI_Demo/Convert/FixPt To FixPt1',..
 'SimulinkFixedPoint:util:Saturationoccurred');
Object.Comments = 'Reviewed: John Doe';
Object.LastModifiedBy = 'Joe Schmoe'
set_param(model,'SimulationCommand','start');
```

```
Object =
```

```
  SuppressedDiagnostic with properties:

            Source: 'Suppressor_CLI_Demo/Convert/FixPt To FixPt1'
                Id: 'SimulinkFixedPoint:util:Saturationoccurred'
    LastModifiedBy: 'Joe Schmoe'
          Comments: 'Reviewed: John Doe'
      LastModified: '2016-Jun-21 18:23:01'
```

Get Suppression Data

To get suppression data for a certain subsystem or block, use the `Simulink.getSuppressedDiagnostics` function.

```
Object = Simulink.getSuppressedDiagnostics('Suppressor_CLI_Demo/Convert/FixPt To FixPt1
set_param(model,'SimulationCommand','start');
```

Restore All Diagnostics on a Model

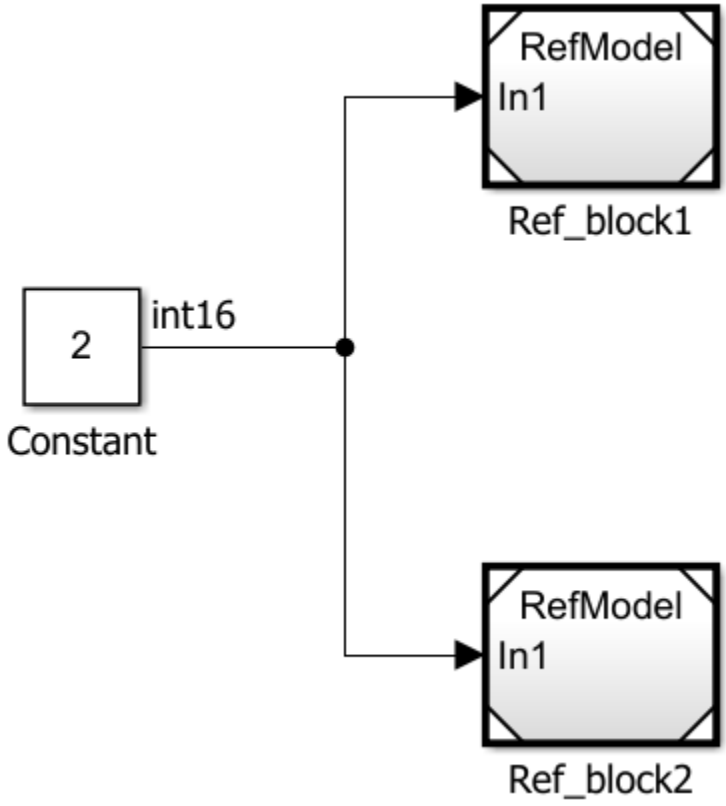
When a model contains many diagnostic suppressions, and you want to restore all diagnostics to a model, use the `Simulink.getSuppressedDiagnostics` function to return an array `Simulink.SuppressedDiagnostic` objects. Then use the `Simulink.SuppressedDiagnostic.restore` method as you iterate through the array.

```
Objects = Simulink.getSuppressedDiagnostics('Suppressor_CLI_Demo');
for iter = 1:numel(Objects)
    restore(Objects(iter));
end
set_param(model,'SimulationCommand','start');
```

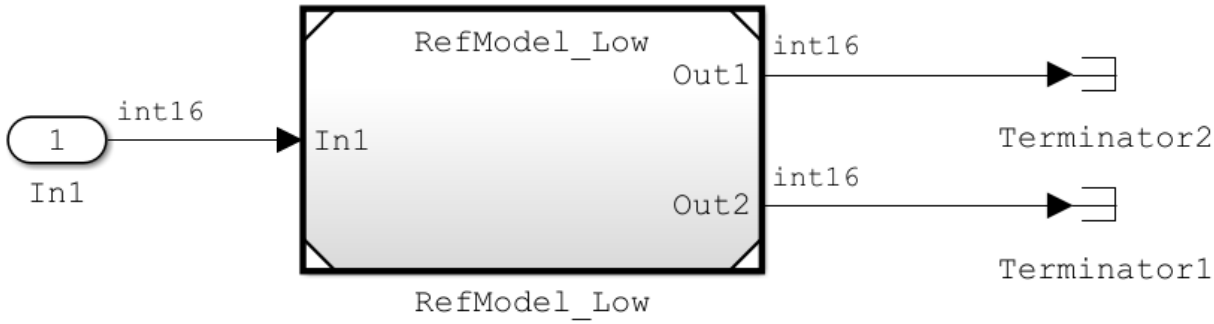
Suppress Diagnostic Messages of a Referenced Model

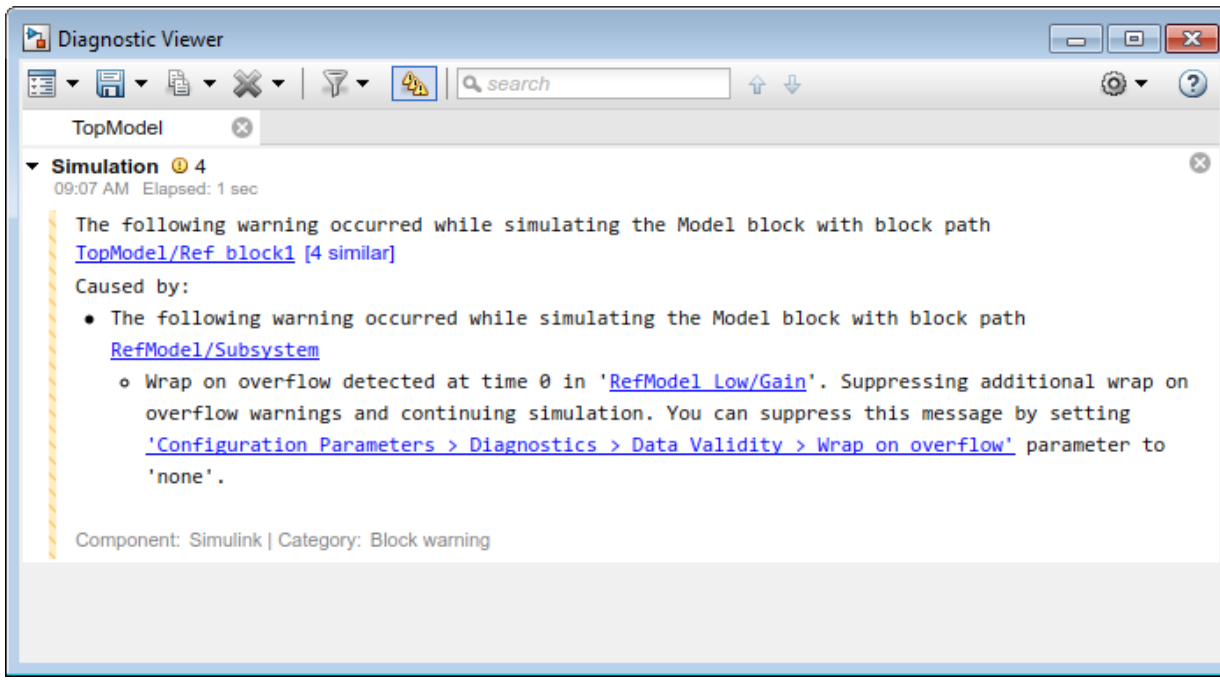
This example shows how to suppress a diagnostic when the diagnostic originates from a referenced model. By accessing the `MSLDiagnostic` object of the specific instance of the warning, you can suppress the warning only for instances when the referenced model is simulated from the specified top model.

This example model contains two instances of the same referenced model, `RefModel`. The model `RefModel` references yet another model, `RefModel_Low`. `RefModel_Low` contains two Gain blocks that each produce a wrap on overflow warning during simulation. Suppress one of the four instances of this warning in the model by accessing the `MSLDiagnostic` object associated with the wrap on overflow warning produced by one of the Gain blocks in the `RefModel_Low` model only when it is referenced by `Ref_block1`.



RefModel
In1
Ref_block1
2
int16
Constant
RefModel
In1
Ref_block2





Open the top model. Simulate the model and store the output in a variable, `out`.

```
out = sim('TopModel');
```

Access the simulation metadata stored in the `MSLDiagnostic` object.

```
diag = getDiagnosticObjects(out)
```

```
diag =

  1×4 MSLDiagnostic array with properties:

    identifier
    message
    paths
    cause
    stack
```

You can view the diagnostics and their causes in the Diagnostic Viewer or at the command-line.

```
for i = 1 : numel(diag)
    disp(diag(i));
    disp(diag(i).cause{1});
end
```

Suppress one of the wrap on overflow warnings from `RefModel_Low` only when it is simulated from `TopModel/Ref_block1` by accessing the specific diagnostic. Simulate the model.

```
Simulink.suppressDiagnostic(diag(1));
out = sim('TopModel')
```

Access the simulation metadata. This simulation produced only three warnings.

```
diag = getDiagnosticObjects(out)
```

```
diag =

  1×3 MSLDiagnostic array with properties:

    identifier
    message
    paths
    cause
    stack
```

Restore the diagnostic to the model.

```
Simulink.restoreDiagnostic(diag(1));
```

Customize Diagnostic Messages

In this section...

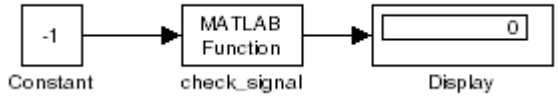
The **Diagnostic Viewer** displays the output of MATLAB error functions executed during simulation.

You can customize simulation error messages in the following ways by using MATLAB error functions in callbacks, S-functions, or MATLAB Function blocks.

Display Custom Text

This example shows how to can customize the MATLAB function `check_signal` to display the text `Signal is negative`.

1 Open the MATLAB Function for editing.



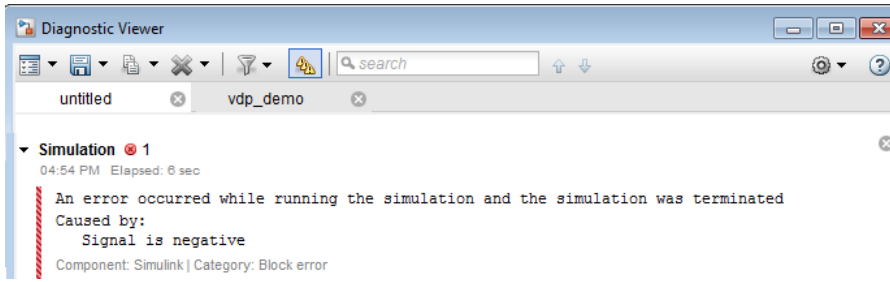
2 In the MATLAB Editor, create a function to display custom text.

```
function y = check_signal(x)
    if x < 0
        error('Signal is negative');
    else
        y = x;
    end
```

3 Simulate the model.

A runtime error appears and you are prompted to start the debugger. Click **OK**.

4 To view the following error in **Diagnostic Viewer**, close the debugger.



Create Hyperlinks to Files, Folders, or Blocks

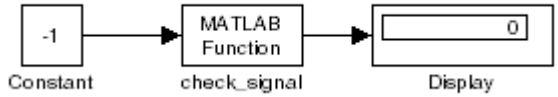
To create hyperlinks to files, folders, or blocks in an error message, include the path to these items within customized text.

Example error message	Hyperlink
`error ('Error reading data from "C:/Work/designData.mat"')`	Opens `designData.data` in the MATLAB Editor.
`error ('Could not find data in folder "C:/Work"')`	Opens a Command Window and sets `C:\Work` as the working folder.
`error ('Error evaluating parameter in block "myModel/Mu"')`	Displays the block `Mu` in model `myModel`.

Create Programmatic Hyperlinks

This example shows how to can customize the MATLAB function `check_signal` to display a hyperlink to the documentation for `find_system`.

1 Open the MATLAB Function for editing.



2 In the MATLAB Editor, create a function to display custom text.

```
function y = check_signal(x)
    if x < 0
        error('See help for <a href="matlab:doc find_system">find_system</a>');
    else
```

```
        y = x;
    end
```

3 Simulate the model.

A runtime error appears and you are prompted to start the debugger. Click **OK**.

4 To view the following error in **Diagnostic Viewer**, close the debugger.

- “Systematic Diagnosis of Errors and Warnings” on page 24-50
- “Report Diagnostic Messages Programmatically” on page 24-66

Report Diagnostic Messages Programmatically

The `sldiagviewer` functions enable you to generate, display, and log diagnostic messages in the Diagnostic Viewer.

You can use these functions to report the diagnostic messages programmatically:

- Function to create a stage: `sldiagviewer.createStage`
- Functions to report diagnostic messages:
  - `sldiagviewer.reportError`
  - `sldiagviewer.reportWarning`
  - `sldiagviewer.reportInfo`
- Function to log the diagnostics: `sldiagviewer.diary`

Create Diagnostic Stages

In the Diagnostic Viewer, errors, warnings, and information messages are displayed in groups based on the operation, such as model load, simulation, and build. These groups are called stages. The `sldiagviewer.createStage` function enables you to create stages. You can also create child stages for a stage object. A parent stage object must be active to create a child stage. When you create a stage object, Simulink initializes a stage. When you close the stage object, Simulink ends the stage. If you delete a parent stage object, the corresponding parent and its child stage close in the Diagnostic Viewer. The syntax for creating a stage is:

```
stageObject =
sldiagviewer.createStage(StageName,'ModelName',ModelNameValue)
```

In this syntax,

- `StageName` specifies the name of a stage and is a required argument, for example, `'Analysis'`.
- Use the `'ModelName'`, `ModelNameValue` pair to specify the model name of a stage, for example `'ModelName'`, `'vdp'`. All the child stages inherit the model name from their parent.

Example to Create Stage

```
my_stage = sldiagviewer.createStage('Analysis','ModelName','vdp');
```

Report Diagnostic Messages

You can use the `sldiagviewer` functions to report error, warning, or information messages in the Diagnostic Viewer. The syntaxes for reporting diagnostic messages are:

- `sldiagviewer.reportError(Message)`: Reports the error messages.
- `sldiagviewer.reportWarning(Message)`: Reports the warnings.
- `sldiagviewer.reportInfo(Message)`: Reports the information messages.

`Message` describes the error, warning, or build information and is a required argument. `Message` can have values in these formats:

- String
- `MSLException` or `MException` object

Optionally, you can use the `'Component'` argument and its corresponding value in the syntax to specify the component or product that generates the message, for example, `'Simulink'` and `'Stateflow'`.

Example to Report Diagnostics

```
% Create a Stage to display all the messages

my_stage = sldiagviewer.createStage('Analysis', 'ModelName', 'vdp');

% Catch the error introduced in vdp as an exception.

try
sim('vdp');
catch error
end

% Report the caught exception as warning

sldiagviewer.reportWarning(error);

% Report a custom info message to Diagnostic Viewer
```

```
sldiagviewer.reportInfo('My Info message');
```

Log Diagnostic Messages

You can use the `sldiagviewer.diary` function to log the simulation warning, error, and build information to a file. The syntaxes for generating log files are:

- `sldiagviewer.diary`: Intercepts the build information, warnings, and errors transmitted to the Diagnostic Viewer and logs them to a text file `diary.txt` in the current directory.
- `sldiagviewer.diary(filename)`: Toggles the logging state of the text file specified by `filename`.
- `sldiagviewer.diary(toggle)`: Toggles the logging ability. Valid values are `'on'` and `'off'`. If you have not specified a log file name, the toggle setting applies to the last file name that you specified for logging or to the `diary.txt` file.
- `sldiagviewer.diary(filename,'UTF-8')`: Specifies the character encoding for the log file.

In this syntax,

- `filename` specifies the file to log the data to.
- `toggle` specifies the logging state `'on'` or `'off'`.

Example to Log Diagnostic Messages

```
% Log messages using sldiagviewer.diary

sldiagviewer.diary
open_system('vdp')
rtwbuild('vdp')

% Open diary.txt to view logs.

### Starting build procedure for model: vdp
### Build procedure for model: 'vdp' aborted due to an error.
...
% Log messages using sldiagviewer.diary(filename)

sldiagviewer.diary('C:\MyLogs\log1.txt')
```

```
% Log messages using sldiagviewer.diary(toggle)

sldiagviewer.diary('C:\MyLogs\log1.txt') % Switch on logging and specify a log file.
open_system('vdp')
rtwbuild('vdp')

sldiagviewer.diary('off') % Switch off logging.
open_system('sldemo_fuelsys')
rtwbuild('sldemo_fuelsys')

sldiagviewer.diary('on') % Resume logging in the previously specified log file.

% Log messages using sldiagviewer.diary(filename,'UTF-8')

sldiagviewer.diary('C:\MyLogs\log1.txt','UTF-8')
```

Running a Simulation Programmatically

Run Simulations Programmatically

You can programmatically simulate a model with the `sim` function, using various techniques to specify parameter values. In addition to simulation using the `sim` function, these examples show you how to enable simulation timeouts, capture simulation errors, and access simulation metadata when your simulation is complete.

In this section...

Specify Parameter Name-Value Pairs

This example shows how to programmatically simulate a model, specifying parameters as name-value pairs.

Simulate the `vdp` model with parameter values specified as consecutive name-value pairs.

```
simOut = sim('vdp','SimulationMode','normal','AbsTol','1e-5',...
             'SaveState','on','StateSaveName','xout',...
             'SaveOutput','on','OutputSaveName','yout',...
 'SaveFormat', 'Dataset');
outputs = simOut.get('yout')

outputs =

  Simulink.SimulationData.Dataset
  Package: Simulink.SimulationData

  Characteristics:
              Name: 'yout'
    Total Elements: 2

  Elements:
    1 : 'x1'
```

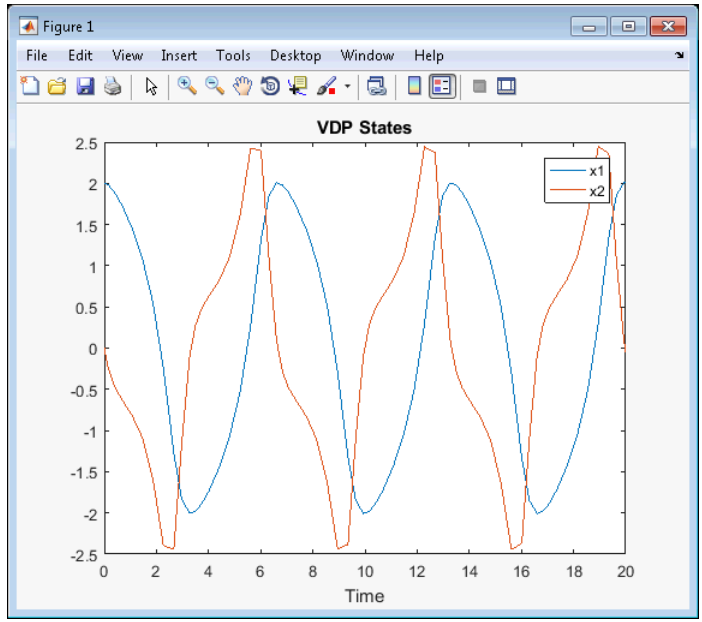
```
    2 : 'x2'

  -Use get or getElement to access elements by index or name.
  -Use addElement or setElement to add or modify elements.
```

You simulate the model in `Normal` mode, specifying an absolute tolerance for solver error. The `sim` function returns `SimOut`, a single `Simulink.SimulationOutput` object that contains all of the simulation outputs (logged time, states, and signals). The `sim` function *does not* return simulation values to the workspace.

Plot the output signal values against time.

```
x1=(outputs.get('x1').Values);
x2=(outputs.get('x2').Values);
plot(x1); hold on;
plot(x2);
title('VDP States')
xlabel('Time'); legend('x1','x2')
```



Specify a Configuration Set

This example shows how to specify parameter values in a new configuration set.

Create a new configuration set by copying the active configuration set and changing it using `set_param`. Then, use `sim` to simulate the model with the new configuration set.

```
model = 'vdp';
load_system(model)
cs = getActiveConfigSet(model);
model_cs = cs.copy;
set_param(model_cs,'AbsTol','1e-5',...
          'SaveState','on','StateSaveName','xout',...
          'SaveOutput','on','OutputSaveName','yout')
simOut = sim(model, model_cs);
```

Enable Simulation Timeouts

If you are running multiple simulations in a loop and are using a variable-step solver, consider using `sim` with the `timeout` parameter. If, for some reason, a simulation hangs

or begins to take unexpectedly small time steps, it will time out. Then, the next simulation can run. Example syntax is shown below.

```
N = 100;
simOut = repmat(Simulink.SimulationOutput, N, 1);
for i = 1:N
        simOut(i) = sim('vdp', 'timeout', 1000);
end
```

Capture Simulation Errors

If an error causes your simulation to stop, you can see the error in the simulation metadata. In this case, `sim` captures simulation data in the simulation output object up to the time it encounters the error, enabling you to do some debugging of the simulation without rerunning it. To enable this feature, use the `CaptureErrors` parameter with the `sim` function.

Example syntax and resulting output for capturing errors with `sim` is:

```
simOut = sim('my_model', 'CaptureErrors', 'on');
simOut.getSimulationMetadata.ExecutionInfo

ans =

  struct with fields:

              StopEvent: 'DiagnosticError'
          StopEventSource: []
    StopEventDescription: 'Division by zero in 'my_model/Divide''
         ErrorDiagnostic: [1×1 struct]
      WarningDiagnostics: [0×1 struct]
```

Another advantage of this approach is that the simulation error does not also cause `sim` to stop. Therefore, if you are using `sim` in a `for` loop for example, subsequent iterations of the loop will still run.

Access Simulation Metadata

This example shows you how to access simulation metadata once your simulation is complete.

Run the simulation as described in “Specify Parameter Name-Value Pairs” on page 25-2.

```
simOut = sim('vdp','SimulationMode','normal','AbsTol','1e-5',...
             'SaveState','on','StateSaveName','xoutNew',...
             'SaveOutput','on','OutputSaveName','youtNew',...
 'SaveFormat', 'StructureWithTime');
```

Access the `ModelInfo` property, which has some basic information about the model and solver.

```
simOut.getSimulationMetadata.ModelInfo
```

```
ans =

  struct with fields:

                 ModelName: 'vdp'
              ModelVersion: '1.6'
             ModelFilePath: 'C:\MyWork'
                    UserID: 'User'
               MachineName: 'MyMachine'
                  Platform: 'PCWIN64'
    ModelStructuralChecksum: [4×1 uint32]
          SimulationMode: 'normal'
               StartTime: 0
                StopTime: 20
              SolverInfo: [1×1 struct]
           SimulinkVersion: [1×1 struct]
              LoggingInfo: [1×1 struct]
```

Inspect the solver information.

```
simOut.getSimulationMetadata.ModelInfo.SolverInfo
```

```
ans =

  struct with fields:

          Type: 'Variable-Step'
        Solver: 'ode45'
    MaxStepSize: 0.4000
```

Review timing information for your simulation, such as when your simulation started and finished, and the time the simulation took to initialize, execute, and terminate.

```
simOut.getSimulationMetadata.TimingInfo
```

```
ans =

  struct with fields:

         WallClockTimestampStart: '2016-06-17 10:26:58.433686'
          WallClockTimestampStop: '2016-06-17 10:26:58.620687'
    InitializationElapsedWallTime: 0.1830
         ExecutionElapsedWallTime: 1.0000e-03
       TerminationElapsedWallTime: 0.0030
            TotalElapsedWallTime: 0.1870
```

Add notes to your simulation.

```
simOut=simOut.setUserString('Results from simulation 1 of 10');
simOut.getSimulationMetadata
```

```
ans =

  SimulationMetadata with properties:

       ModelInfo: [1×1 struct]
      TimingInfo: [1×1 struct]
    ExecutionInfo: [1×1 struct]
      UserString: 'Results from simulation 1 of 10'
        UserData: []
```

You can also add your own custom data using the `UserData` property.

Control Simulations Programmatically

These examples show you how to use `set_param` and `get_param` to programmatically control a model simulation, check the status of a running simulation, and control simulations using block callbacks.

In this section...

Control and Check Status of Simulation

This example shows how to use `set_param` to control and check the status of your simulation.

Start a simulation.

```
set_param('vdp','SimulationCommand','start')
```

When you start a simulation using `set_param` and the `'start'` argument, you must use the `'stop'` argument to stop it.

Pause, continue, and stop a simulation.

```
set_param('vdp','SimulationCommand','pause')
set_param('vdp','SimulationCommand','continue')
set_param('vdp','SimulationCommand','stop')
```

When you use `set_param` to pause or stop a simulation, the commands are requests for such actions and the simulation doesn’t execute them immediately. You can use `set_param` to start a simulation after the stop command and to continue a simulation after the pause command. Simulink first completes uninterruptable work, such as solver steps and other commands that preceded the `set_param` command. Then, simulation starts, pauses, continues or stops as specified by the `set_param` command.

Check the status of a simulation.

```
get_param('vdp','SimulationStatus')
```

The software returns `'stopped'`, `'initializing'`, `'running'`, `'paused'`, `'compiled'`, `'updating'`, `'terminating'`, or `'external'` (used with the Simulink Coder product).

Update changed workspace variables dynamically while a simulation is running.

```
set_param('vdp','SimulationCommand','update')
```

Write all data-logging variables to the base workspace.

```
set_param('vdp','SimulationCommand','WriteDataLogs')
```

Automate Simulation Tasks Using Block Callbacks

A callback executes when you perform various actions on your model, such as starting, pausing, or stopping a simulation. You can use callbacks to execute a MATLAB script or other MATLAB commands. For more information, see “Callbacks for Customized Model Behavior” on page 4-44 and “Block Callback Parameters” on page 4-52.

This example shows how to use the model `StartFcn` callback to automatically execute MATLAB code before the simulation starts.

Write a MATLAB script that finds Scope blocks in your model and opens them in the foreground when you simulate the model.

```
% openscopes.m
% Brings scopes to forefront at beginning of simulation.

blocks = find_system(bdroot,'BlockType','Scope');

% Finds all of the scope blocks in the top level of your
    % model. To find scopes in subsystems, provide the subsystem
    % names. Type help find_system for more on this command.

for i = 1:length(blocks)
  set_param(blocks{i},'Open','on')
end

% Loops through all of the scope blocks and brings them
    % to the forefront.
```

Set the `StartFcn` parameter for the model to call the script.

```
set_param('my_model','StartFcn','openscopes')
```

Run Parallel Simulations

Note Running parallel simulations using the `sim` function within a `parfor` loop is no longer recommended. To learn how to run parallel simulations using the `parsim` function, see "Run Multiple Simulations" on page 26-2.

In this section...

Overview of Calling sim from Within parfor

The `parfor` command allows you to run parallel (simultaneous) Simulink simulations of your model (design). In this context, parallel runs mean multiple model simulations at the same time on different workers. Calling `sim` from within a `parfor` loop often helps for performing multiple simulation runs of the same model for different inputs or for different parameter settings. For example, you can save simulation time performing parameter sweeps and Monte Carlo analyses by running them in parallel. Note that running parallel simulations using `parfor` does not currently support decomposing your model into smaller connected pieces and running the individual pieces simultaneously on multiple workers.

Normal, Accelerator, and Rapid Accelerator simulation modes are supported by `sim` in `parfor`. (See "Choosing a Simulation Mode" on page 34-12 for details on selecting a simulation mode and "Design Your Model for Effective Acceleration" on page 34-18 for

optimizing simulation run times.) For other simulation modes, you need to address any workspace access issues and data concurrency issues to produce useful results. Specifically, the simulations need to create separately named output files and workspace variables. Otherwise, each simulation overwrites the same workspace variables and files, or can have collisions trying to write variables and files simultaneously.

For information on code regeneration and parameter handling in Rapid Accelerator mode, see “Parameter Tuning in Rapid Accelerator Mode” on page 34-9.

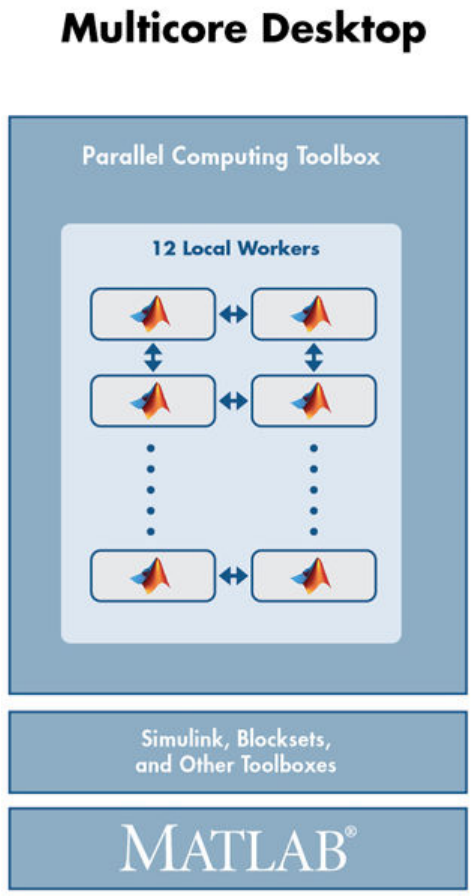
Also, see `parfor`.

Note If you open models inside a parfor statement, close them again using `bdclose all` to avoid leaving temporary files behind.

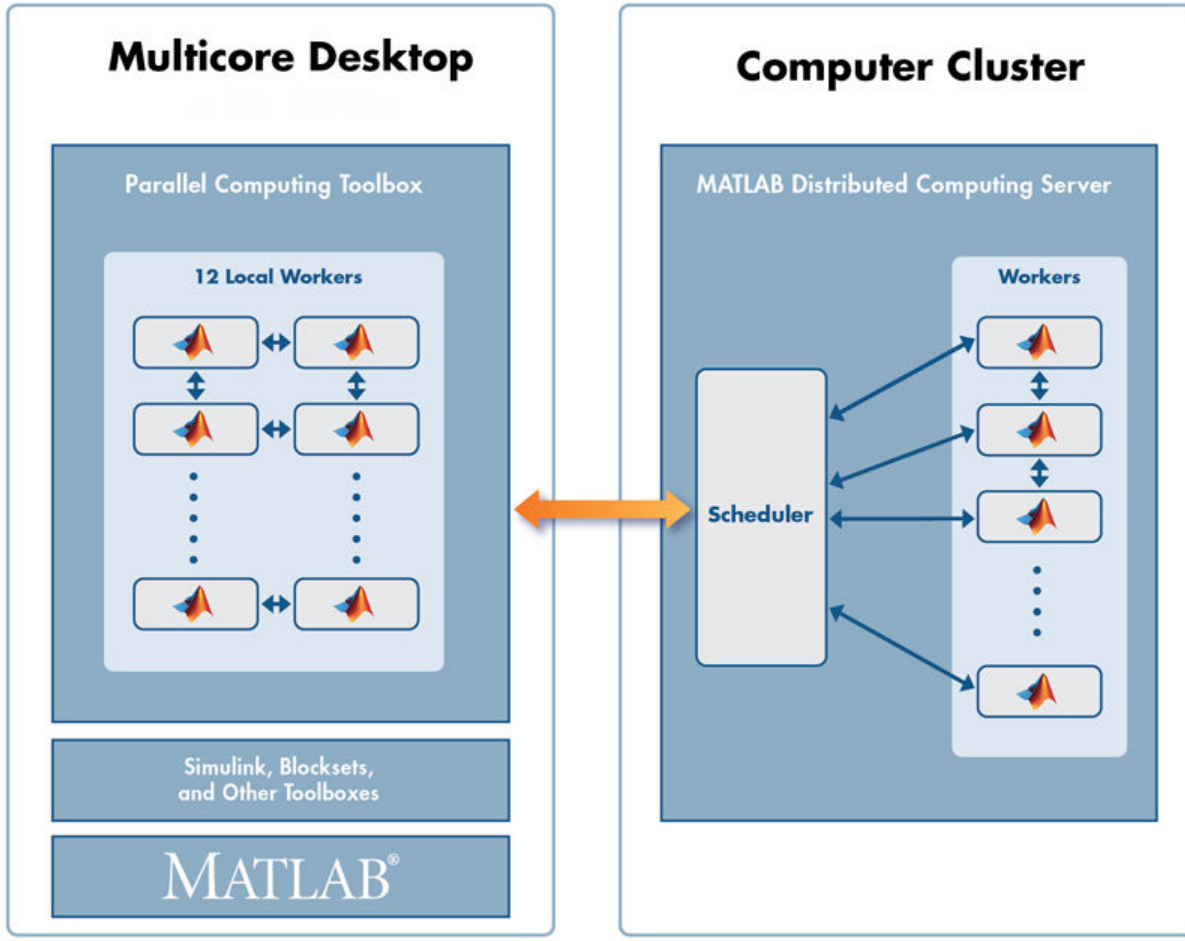
Computationally Intensive Simulations

To further improve the performance of multiple simulations of the same model, you can use:

- Multiple designated workers (MATLAB computational engines) using the Parallel Computing Toolbox software



- Multiple computer clusters, clouds, and grids using the MATLAB Distributed Computing Server software



To take advantage of these environments, you can:

1. Simulate your model on a single computer.
2. When satisfied with single simulation, run multiple simulations in parallel on multiple designated workers on a local multicore desktop.
3. When satisfied with multiple simulations on local multicore desktop, run simulations in parallel remotely on computer clusters, clouds, and grids.

Consider the following:

Action	Required Software*			
	MATLAB	Simulink	Parallel Computing Toolbox	MATLAB Distributed Computing Server
Run a single simulation.	✓	✓		
Run multiple simulations simultaneously on your computer.	✓	✓	✓	
Run multiple simulations remotely on a server.	✓	✓	✓	✓

* And other required and optional software

Simulink and Parallel Computing Toolbox Software

Before you run simulations in the Parallel Computing Toolbox environment, see "Parallel Computing Toolbox". You can use the Parallel Computing Toolbox software to run simulations on a local multicore computer or on multiple remote computers.

1. Have a Parallel Computing Toolbox license.
2. Run `sim` in `parfor` for your model.

For an example of using `sim` in `parfor` using Normal mode, see "sim in parfor with Normal Mode" on page 25-16.

For an example of using `sim` in `parfor` using Rapid Accelerator, see "sim in parfor with Rapid Accelerator Mode" on page 25-19.

Note Code generation operations for the same model overwrite each other. If you want each worker to generate its own copy of code, attach and distribute the folder to each worker.

You can also use Parallel Computing Toolbox software to run simulations on multiple remote computers or in a nonhomogeneous environment. For these cases, you can use the

Parallel Computing Toolbox software with the MATLAB Distributed Computing Server software.

Simulink and MATLAB Distributed Computing Server Software

Before you run simulations in the MATLAB Distributed Computing Server environment, see “MATLAB Distributed Computing Server”.

1. Have Parallel Computing Toolbox and MATLAB Distributed Computing Server licenses.
2. Select and configure your cluster configuration.
3. Use the “Parallel Computing Toolbox” software to create, import, and select a default parallel cluster profile.
4. Use the Parallel Computing Toolbox software to run `sim` in `parfor` for your model.

For an example of `sim` in `parfor` with Normal mode using MATLAB Distributed Computing Server software, see “sim in parfor with Normal Mode and MATLAB Distributed Computing Server Software” on page 25-18.

You can also use `sim` in `parfor` with Rapid Accelerator and MATLAB Distributed Computing Server software (see “sim in parfor with Rapid Accelerator Mode” on page 25-19). In that example, you build the code once and distribute that generated code to the other local workers. You can adapt “sim in parfor with Rapid Accelerator Mode” on page 25-19 example for a remote cluster environment by:

- Calling `parpool` with a cluster name as input
- Attaching required files

For an example of how to adapt to a remote cluster environment, see “sim in parfor with Normal Mode and MATLAB Distributed Computing Server Software” on page 25-18.

sim in parfor with Normal Mode

This code fragment shows how you can use `sim` and `parfor` in Normal mode. Save changes to your model before simulating in `parfor`. The saved copy of your model is distributed to parallel workers when simulating in `parfor`.

```
% 1) Load model and initialize the pool.
model = 'sldemo_suspn_3dof';
```

```
load_system(model);
parpool;

% 2) Set up the iterations that we want to compute.
Cf                  = evalin('base', 'Cf');
Cf_sweep            = Cf*(0.05:0.1:0.95);
iterations          = length(Cf_sweep);
simout(iterations)  = Simulink.SimulationOutput;

% 3) Need to switch all workers to a separate tempdir in case
% any code is generated for instance for StateFlow, or any other
% file artifacts are  created by the model.
spmd
    % Setup tempdir and cd into it
    currDir = pwd;
    addpath(currDir);
    tmpDir = tempname;
    mkdir(tmpDir);
    cd(tmpDir);
    % Load the model on the worker
    load_system(model);
end

% 4) Loop over the number of iterations and perform the
% computation for different parameter values.
parfor idx=1:iterations
    set_param([model '/Road-Suspension Interaction'],'MaskValues',...
        {'Kf',num2str(Cf_sweep(idx)),'Kr','Cr'});
    simout(idx) = sim(model, 'SimulationMode', 'normal');
end

% 5) Switch all of the workers back to their original folder.
spmd
    cd(currDir);
    rmdir(tmpDir,'s');
    rmpath(currDir);
    close_system(model, 0);
end

close_system(model, 0);
delete(gcp('nocreate'));
```

sim in parfor with Normal Mode and MATLAB Distributed Computing Server Software

This code fragment is identical to the one in “sim in parfor with Normal Mode” on page 25-16

. Modify it as follows for using `sim` and `parfor` in Normal mode:

- In item 1, modify the `parpool` command as follows to create an object and use it to call a cluster name.

  ```
  p = parpool('clusterProfile');
  % 'clusterProfile' is the name of the distributed cluster
  ```

- In item 1, find files on which the model depends and attach those files to the model for distribution to cluster workers on remote machines.

  ```
  files = dependencies.fileDependencyAnalysis(modelName);
  p.addAttachedFiles(files);
  ```

- If you do not have a MATLAB Distributed Computing Server cluster, use your local cluster. For more information, see “Discover Clusters and Use Cluster Profiles” (Parallel Computing Toolbox).

Start your cluster before running the code.

```
% 1) Load model and initialize the pool.
model = 'sldemo_suspn_3dof';
load_system(model);
parpool;

% 2) Set up the iterations that we want to compute.
Cf                  = evalin('base', 'Cf');
Cf_sweep            = Cf*(0.05:0.1:0.95);
iterations          = length(Cf_sweep);
simout(iterations)  = Simulink.SimulationOutput;

% 3) Need to switch all workers to a separate tempdir in case
% any code is generated for instance for StateFlow, or any other
% file artifacts are  created by the model.
spmd
    % Setup tempdir and cd into it
    addpath(pwd);
    currDir = pwd;
    addpath(currDir);
```

```
    tmpDir = tempname;
    mkdir(tmpDir);
    cd(tmpDir);
    % Load the model on the worker
    load_system(model);
end

% 4) Loop over the number of iterations and perform the
% computation for different parameter values.
parfor idx=1:iterations
    set_param([model '/Road-Suspension Interaction'],'MaskValues',...
        {'Kf',num2str(Cf_sweep(idx)),'Kr','Cr'});
    simout(idx) = sim(model, 'SimulationMode', 'normal');
end

% 5) Switch all of the workers back to their original folder.
spmd
    cd(currDir);
    rmdir(tmpDir,'s');
    rmpath(currDir);
    close_system(model, 0);
end

close_system(model, 0);
delete(gcp('nocreate'));
```

sim in parfor with Rapid Accelerator Mode

Running Rapid Accelerator simulations in `parfor` combines speed with automatic distribution of a prebuilt executable to the `parfor` workers. As a result, this mode eliminates duplication of the update diagram phase.

To run parallel simulations in Rapid Accelerator simulation mode using the `sim` and `parfor` commands:

- Configure the model to run in Rapid Accelerator simulation mode.
- Save changes to your model before simulating in `parfor`. The saved copy of your model is distributed to parallel workers when simulating in `parfor`.
- Ensure that the Rapid Accelerator target is already built and up to date.
- Disable the Rapid Accelerator target up-to-date check by setting the `sim` command option `RapidAcceleratorUpToDateCheck` to `'off'`.

To satisfy the second condition, you can change parameters only between simulations that do not require a model rebuild. In other words, the structural checksum of the model must remain the same. Hence, you can change only tunable block diagram parameters and tunable run-time block parameters between simulations. For a discussion on tunable parameters that do not require a rebuild subsequent to their modifications, see "Determine If the Simulation Will Rebuild" on page 34-9.

To disable the Rapid Accelerator target up-to-date check, use the `sim` command, as shown in this sample.

```
parpool;
% Load the model and set parameters
model = 'vdp';
load_system(model);
% Build the Rapid Accelerator target
rtp = Simulink.BlockDiagram.buildRapidAcceleratorTarget(model);
% Run parallel simulations
parfor i=1:4
   simOut{i} = sim(model,'SimulationMode', 'rapid',...
               'RapidAcceleratorUpToDateCheck', 'off',...
               'SaveTime', 'on',...
               'StopTime', num2str(10*i));
   close_system(model, 0);
end

close_system(model, 0);
delete(gcp('nocreate'));
```

In this example, the call to the `buildRapidAcceleratorTarget` function generates code once. Subsequent calls to `sim` with the `RapidAcceleratorUpToDateCheck` option `off` guarantees that code is not regenerated. Data concurrency issues are thus resolved.

When you set `RapidAcceleratorUpToDateCheck` to `'off'`, changes that you make to block parameter values in the model (for example, by using block dialog boxes, by using the `set_param` function, or by changing the values of MATLAB variables) do not affect the simulation. Instead, use `RapidAcceleratorParameterSets` to pass new parameter values directly to the simulation.

Workspace Access Issues

Workspace Access for MATLAB worker sessions

By default, to run `sim` in `parfor`, a parallel pool opens automatically, enabling the code to run in parallel. Alternatively, you can also first open MATLAB workers using the `parpool` command. The `parfor` command then runs the code within the `parfor` loop in these MATLAB worker sessions. The MATLAB workers, however, do not have access to the workspace of the MATLAB client session where the model and its associated workspace variables have been loaded. Hence, if you load a model and define its associated workspace variables outside of and before a `parfor` loop, then neither is the model loaded, nor are the workspace variables defined in the MATLAB worker sessions where the `parfor` iterations are executed. This is typically the case when you define model parameters or external inputs in the base workspace of the client session. These scenarios constitute workspace access issues.

Transparency Violation

When you run `sim` in `parfor` with `srcWorkspace` set to `current`, Simulink uses the `parfor` workspace, which is a transparent workspace. Simulink then displays an error for transparency violation. For more information on transparent workspaces, see "Ensure Transparency in parfor-Loops" (Parallel Computing Toolbox) .

Data Dictionary Access

When a model is linked to a data dictionary (see "What Is a Data Dictionary?" on page 63-2), to write code in `parfor` that accesses a variable or object that you store in the dictionary, you must use the functions `Simulink.data.dictionary.setupWorkerCache` and `Simulink.data.dictionary.cleanupWorkerCache` to prevent access issues. For an example, see "Sweep Variant Control Using Parallel Simulation" on page 25-23.

Resolving Workspace Access Issues

When a Simulink model is loaded into memory in a MATLAB client session, it is only visible and accessible in that MATLAB session; it is not accessible in the memory of the MATLAB worker sessions. Similarly, the workspace variables associated with a model that are defined in a MATLAB client session (such as parameters and external inputs) are not automatically available in the worker sessions. You must therefore ensure that

the model is loaded and that the workspace variables referenced in the model are defined in the MATLAB worker session by using the following two methods.

- In the `parfor` loop, use the `sim` command to load the model and to set parameters that change with each iteration. (Alternative: load the model and then use the `g(s)et_param` command(s) to set the parameters in the `parfor` loop)
- In the `parfor` loop, use the MATLAB `evalin` and `assignin` commands to assign data values to variables.

Alternatively, you can simplify the management of workspace variables by defining them in the model workspace. These variables will then be automatically loaded when the model is loaded into the worker sessions. There are, however, limitations to this method. For example, you cannot store signal objects that use a storage class other than `Auto` in a model workspace. For a detailed discussion on the model workspace, see "Model Workspaces" on page 59-124.

Specifying Parameter Values Using the sim Command

Use the `sim` command in the `parfor` loop to set parameters that change with each iteration.

```
%Specifying Parameter Values Using the sim Command

model = 'vdp';
load_system(model)

%Specifying parameter values.
paramName = 'StopTime';
paramValue = {'10', '20', '30', '40'};

% Run parallel simulations
parfor i=1:4
    simOut{i} = sim(model, ...
                    paramName, paramValue{i}, ...
                    'SaveTime', 'on'); %#ok
end

close_system(model, 0);
```

An equivalent method is to load the model and then use the `set_param` command to set the `paramName` in the `parfor` loop.

Specifying Variable Values Using the assignin Command

You can pass the values of model or simulation variables to the MATLAB workers by using the `assignin` or the `evalin` command. The following example illustrates how to use this method to load variable values into the appropriate workspace of the MATLAB workers.

```
parfor i = 1:4
    assignin('base', 'extInp', paramValue{i})%#ok
    % 'extInp' is the name of the variable in the base
    % workspace which contains the External Input data
    simOut{i} = sim(model, 'ExternalInput', 'extInp'); %#ok
end
```

Sweep Variant Control Using Parallel Simulation

To use parallel simulation to sweep a variant control (a `Simulink.Parameter` object whose value influences the variant condition of a `Simulink.Variant` object) that you store in a data dictionary, use this code as a template. Change the names and values of the model, data dictionary, and variant control to match your application.

To sweep block parameter values or the values of workspace variables that you use to set block parameters, use `Simulink.SimulationInput` objects instead of the programmatic interface to the data dictionary. See “Optimize, Estimate, and Sweep Block Parameter Values” on page 36-48.

You must have a Parallel Computing Toolbox license to perform parallel simulation.

```
% For convenience, define names of model and data dictionary
model = 'mySweepMdl';
dd = 'mySweepDD.sldd';

% Define the sweeping values for the variant control
CtrlValues = [1 2 3 4];

% Grant each worker in the parallel pool an independent data dictionary
% so they can use the data without interference
spmd
    Simulink.data.dictionary.setupWorkerCache
end

% Determine the number of times to simulate
numberOfSims = length(CtrlValues);
```

```
% Prepare a nondistributed array to contain simulation output
simOut = cell(1,numberOfSims);

parfor index = 1:numberOfSims
    % Create objects to interact with dictionary data
    % You must create these objects for every iteration of the parfor-loop
    dictObj = Simulink.data.dictionary.open(dd);
    sectObj = getSection(dictObj,'Design Data');
    entryObj = getEntry(sectObj,'MODE');
    % Suppose MODE is a Simulink.Parameter object stored in the data dictionary

    % Modify the value of MODE
    temp = getValue(entryObj);
    temp.Value = CtrlValues(index);
    setValue(entryObj,temp);

    % Simulate and store simulation output in the nondistributed array
    simOut{index} = sim(model);

    % Each worker must discard all changes to the data dictionary and
    % close the dictionary when finished with an interation of the parfor-loop
    discardChanges(dictObj);
    close(dictObj);
end

% Restore default settings that were changed by the function
% Simulink.data.dictionary.setupWorkerCache
% Prior to calling cleanupWorkerCache, close the model

spmd
    bdclose(model)
    Simulink.data.dictionary.cleanupWorkerCache
end
```

Note If data dictionaries are open, you cannot use the command `Simulink.data.dictionary.cleanupWorkerCache`. To identify open data dictionaries, use `Simulink.data.dictionary.getOpenDictionaryPaths`.

Data Concurrency Issues

Data concurrency issues refer to scenarios for which software makes simultaneous attempts to access the same file for data input or output. In Simulink, they primarily occur as a result of the nonsequential nature of the `parfor` loop during simultaneous execution of Simulink models. The most common incidences arise when code is generated or updated for a simulation target of a Stateflow, Model block or MATLAB Function block during parallel computing. The cause, in this case, is that Simulink tries to concurrently access target data from multiple worker sessions. Similarly, To File blocks may simultaneously attempt to log data to the same files during parallel simulations and thus cause I/O errors. Or a third-party blockset or user-written S-function may cause a data concurrency issue while simultaneously generating code or files.

A secondary cause of data concurrency is due to the unprotected access of network ports. This type of error occurs, for example, when a Simulink product provides blocks that communicate via TCP/IP with other applications during simulation. One such product is the HDL Verifier™ for use with the Mentor Graphics® ModelSim® HDL simulator.

Resolving Data Concurrency Issues

The core requirement of `parfor` is the independence of the different iterations of the `parfor` body. This restriction is not compatible with the core requirement of simulation via incremental code generation, for which the simulation target from a prior simulation is reused or updated for the current simulation. Hence during the parallel simulation of a model that involves code generation (such as Accelerator mode simulation), Simulink makes concurrent attempts to access (update) the simulation target . However, you can avoid such data concurrency issues by creating a temporary folder within the `parfor` loop and then adding several lines of MATLAB code to the loop to perform the following steps:

1. Change the current folder to the temporary, writable folder.
2. In the temporary folder, load the model, set parameters and input vectors, and simulate the model.
3. Return to the original, current folder.
4. Remove the temporary folder and temporary path.

In this manner, you avoid concurrency issues by loading and simulating the model within a separate temporary folder. Following are examples that use this method to resolve common concurrency issues.

A Model with Stateflow, MATLAB Function Block, or Model Block

In this example, either the model is configured to simulate in Accelerator mode or it contains a Stateflow, a MATLAB Function block, or a Model block (for example, `sf_bounce`, `sldemo_autotrans`, or `sldemo_mdlref_basic`). For these cases, Simulink generates code during the initialization phase of simulation. Simulating such a model in `parfor` would cause code to be generated to the same files, while the initialization phase is running on the worker sessions. As illustrated below, you can avoid such data concurrency issues by running each iteration of the `parfor` body in a different temporary folder.

```
parfor i=1:4
   cwd = pwd;
   addpath(cwd)
   tmpdir = tempname;
   mkdir(tmpdir)
   cd(tmpdir)
   load_system(model)
   % set the block parameters, e.g., filename of To File block
   set_param(someBlkInMdl, blkParamName, blkParamValue{i})
   % set the model parameters by passing them to the sim command
   out{i} = sim(model, mdlParamName, mdlParamValue{i});
   close_system(model,0);
   cd(cwd)
   rmdir(tmpdir,'s')
   rmpath(cwd)
end
```

Note the following:

- You can also avoid other concurrency issues due to file I/O errors by using a temporary folder for each iteration of the `parfor` body.
- On Windows platforms, consider inserting the `evalin('base', 'clear mex');` command before `rmdir(tmpdir, 's')`. This sequence closes MEX-files first before calling `rmdir` to remove `tmpdir`.

```
evalin('base', 'clear mex');
rmdir(tmpdir, 's')
```

A Model with To File Blocks

If you simulate a model with To File blocks from inside of a `parfor` loop, the nonsequential nature of the loop may cause file I/O errors. To avoid such errors during

parallel simulations, you can either use the temporary folder idea above or use the `sim` command in Rapid Accelerator mode with the option to append a suffix to the file names specified in the model To File blocks. By providing a unique suffix for each iteration of the `parfor` body, you can avoid the concurrency issue.

```
rtp = Simulink.BlockDiagram.buildRapidAcceleratorTarget(model);
       parfor idx=1:4
       sim(model, ...
           'ConcurrencyResolvingToFileSuffix', num2str(idx),...
           'SimulationMode', 'rapid',...
           'RapidAcceleratorUpToDateCheck', 'off');
        end
```

Error Handling in Simulink Using MSLException

Error Reporting in a Simulink Application

Simulink allows you to report an error by throwing an exception using the `MSLException` object , which is a subclass of the MATLAB `MException` class. As with the MATLAB `MException` object, you can use a `try-catch` block with a `MSLException` object construct to capture information about the error. The primary distinction between the `MSLException` and the `MException` objects is that the `MSLException` object has the additional property of handles. These handles allow you to identify the object associated with the error.

The MSLException Class

The `MSLException` class has five properties: `identifier`, `message`, `stack`, `cause`, and `handles`. The first four of these properties are identical to those of `MException`. For detailed information about them, see "Properties of the MException Class" (MATLAB). The fifth property, `handles`, is a cell array with elements that are double array. These elements contain the handles to the Simulink objects (blocks or block diagrams) associated with the error.

Methods of the MSLException Class

The methods for the `MSLException` class are identical to those of the `MException` class. For details of these methods, see `MException`.

Capturing Information about the Error

The structure of the Simulink `try-catch` block for capturing an exception is:

```
try
        Perform one or more operations
catch E
        if isa(E, 'MSLException')
...
end
```

If an operation within the `try` statement causes an error, the `catch` statement catches the exception (*E*). Next, an `if isa` conditional statement tests to determine if the

exception is Simulink specific, i.e., an `MSLException`. In other words, an `MSLException` is a type of `MException`.

The following code example shows how to get the handles associated with an error.

```
errHndls = [];
try
    sim('ModelName', ParamStruct);
catch e
    if isa(e,'MSLException')
            errHndls = e.handles{1}
    end
end
```

You can see the results by examining *e*. They will be similar to the following output:

```
e =

  MSLException

  Properties:
       handles: {[7.0010]}
    identifier: 'Simulink:Parameters:BlkParamUndefined'
       message: [1x87 char]
         cause: {0x1 cell}
         stack: [0x1 struct]

  Methods, Superclasses
```

To identify the name of the block that threw the error, use the `getfullname` command. For the present example, enter the following command at the MATLAB command line:

```
getfullname(errHndls)
```

If a block named Mu threw an error from a model named *vdp*, MATLAB would respond to the `getfullname` command with:

```
ans =
vdp/Mu
```

Multiple Simulations

Run Multiple Simulations

For workflows that involve multiple parallel simulations and logging of large amounts of data, you can create simulation sets by using an array of `Simulink.SimulationInput` objects. This is useful in scenarios like model testing, experiment design, Monte Carlo analysis, and model optimization.

Using arrays of `Simulink.SimulationInput` object simplifies the running of multiple simulations and running them in parallel. With the Parallel Computing Toolbox, you can use the `parsim` command to run the simulations in parallel. The `parsim` command distributes each simulation to your workers to decrease your overall simulation time. The `parsim` command automates the creation of a parallel pool, identifying file dependencies and managing build artifacts for accelerator and rapid accelerator simulations.

In the absence of a Parallel Computing Toolbox license, the `parsim` command behaves like the `sim` command. The simulations then run in serial.

You can make changes to your model using the `Simulink.SimulationInput` object and run a simulation in parallel with those changes. Changing the `Simulink.SimulationInput` object, overrides the values in the model. The simulation uses the values in the `Simulink.SimulationInput` object rather than the values defined in the model. This way, you can change the model without dirtying it. The `Simulink.SimulationInput` object allows you to change these settings in your model:

- Initial state
- External inputs
- Model parameters
- Block parameters
- Variables

Through the `Simulink.SimulationInput` object, you can also specify MATLAB functions to run at the start and the end of each simulation by using `PreSimFcn` and `PostSimFcn` respectively.

When you use `Simulink.SimulationInput` objects, the model's parameters are restored after the simulation ends. See "Parallel Simulations Workflow" on page 26-5.

Note When the pool is not already open and simulations are run for the first time, simulations take an additional time to start. Subsequent parallel simulations are faster.

Other Advantages

- Outputs errors in the simulation output object for easier debugging
- Compatible with rapid accelerator and fast restart
- Compatible with file logging (to facilitate big data)
- Compatible with MATLAB Distributed Computing Server in addition to local parallel pools
- Capable of transferring base workspace variables to workers
- Avoids transparency errors

Simulation Manager

The Simulation Manager allows you to monitor multiple parallel simulations. It shows the progress of the runs as they are running in parallel. You can view the details of every run such as parameters, elapsed time, and diagnostics. The Simulation Manager acts as a useful tool by giving you the option to analyze and compare your results in the Simulation Data Inspector. You can also select a run and apply its values to the model. For more information, see `Simulation Manager`.

Data Logging for Multiple Simulations

The resulting `Simulink.SimulationOutput` object, which contains the simulation outputs, captures error messages and the simulation metadata. When you select the **Data Import/Export > Log Dataset data to file** configuration parameter, Simulink creates a `Simulink.SimulationData.DatasetRef` object for each `Dataset` stored in the resulting MAT file. You can use the `DatasetRef` object to access the data for a `Dataset` element. For simulations that are run using the `Simulink.SimulationInput` objects, the `DatasetRef` object is returned as part of the `SimulationOutput` object. As a result, you have quicker access to and do not need to create them.

Parallel simulations can produce more logged data than the MATLAB memory can hold. Consider logging to persistent storage for parallel simulations to reduce the memory requirement. When you select the **Data Import/Export > Log Dataset data to file** configuration parameter (`LoggingToFile`), for parallel simulations in Simulink:

- Data is logged in Dataset format in a MAT-file
- A `Simulink.SimulationData.DatasetRef` object is created for each Dataset element (for example, `logsout`) for each simulation

You can use `DatasetRef` objects to access data for a specific signal. You can create `matlab.io.datasetore.SimulationDatastore` objects to use for streaming logged data from persistent storage in to a model.

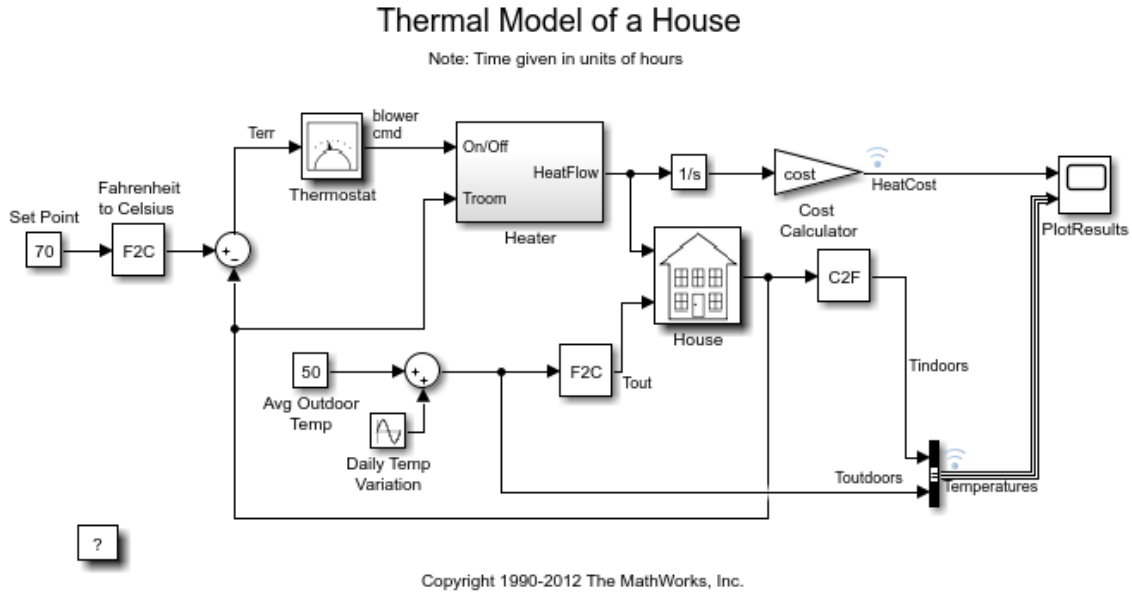
Parallel Simulations Workflow

This example shows how to use a `Simulink.SimulationInput` object to change block and model parameters and run simulations in parallel with those changes.

The example model `sldemo_househeat` is a system that models the thermal characteristics of a house, its outdoor environment, and a house heating system. This model calculates heating costs for a generic house.

Set Point block, Thermostat subsystem, Heater subsystem, House subsystem, and Cost Calculator component are the main components. For a detailed explanation of the model, see “Thermal Model of a House”.



Run Multiple Parallel Simulations with Different Set Points

This model uses a Constant block to specify a temperature set point that must be maintained indoors. The default value of set point value is 70 degrees Fahrenheit. This example shows you how to simulate the model in parallel using different values of `Set Point`.

Open the example model.

```
open_system('sldemo_househeat');
```

Define a set of values for `Set Point`.

```
SetPointValues = 65:2:85;
spv_length = length(SetPointValues);
```

Using the above values, initialize an array of `Simulink.SimulationInput` objects. Use these `Simulink.SimulationInput` objects to specify the`Set Point` values. In this step, to preallocate the array, the loop index is made to start from the largest value.

```
for i = spv_length:-1:1
    in(i) = Simulink.SimulationInput('sldemo_househeat');
    in(i) = in(i).setBlockParameter('sldemo_househeat/Set Point',...
        'Value',num2str(SetPointValues(i)));
end
```

This example produces an array of 10 `Simulink.SimulationInput` objects, each corresponding to a different value of `Set Point`.

Now, run these multiple simulations in parallel using the command `parsim`. To monitor and analyze the runs, open the `Simulation Manager` by setting the `ShowSimulationManager` argument to `on`. The `ShowProgress` argument when set to `on` shows the progress of the simulations.

```
out = parsim(in,'ShowSimulationManager','on''ShowProgress','on')
```

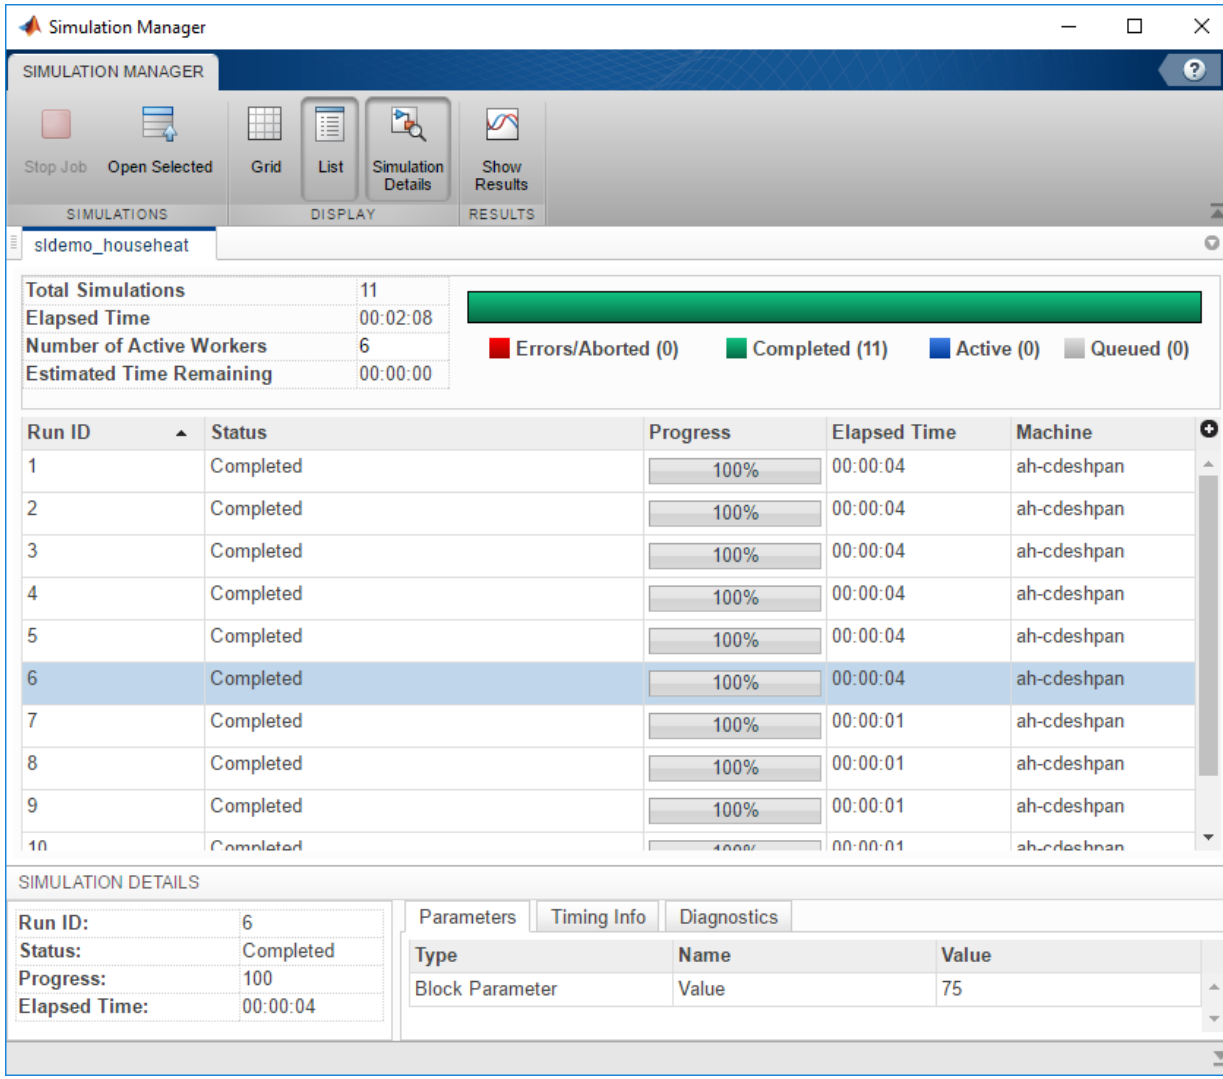
The output is generated as a `Simulink.SimulationOutput` object. To see all of the different set point values, open the plot of the Temperatures (Indoor and Outdoor) and the Heat Cost component. The constant block Avg Outdoor Temp specifies the average air temperature outdoors. The Daily Temp Variation Sine Wave block generates daily temperature fluctuations of outdoor temperature. The indoor temperature is derived from the House subsystem. The temperature outdoor varies sinusoidally, whereas the indoors temperature is maintained within 5 degrees Fahrenheit of the set point.

In the absence of the Parallel Computing Toolbox licenses, the `parsim` command behaves like the `sim` command. The simulations run in serial.

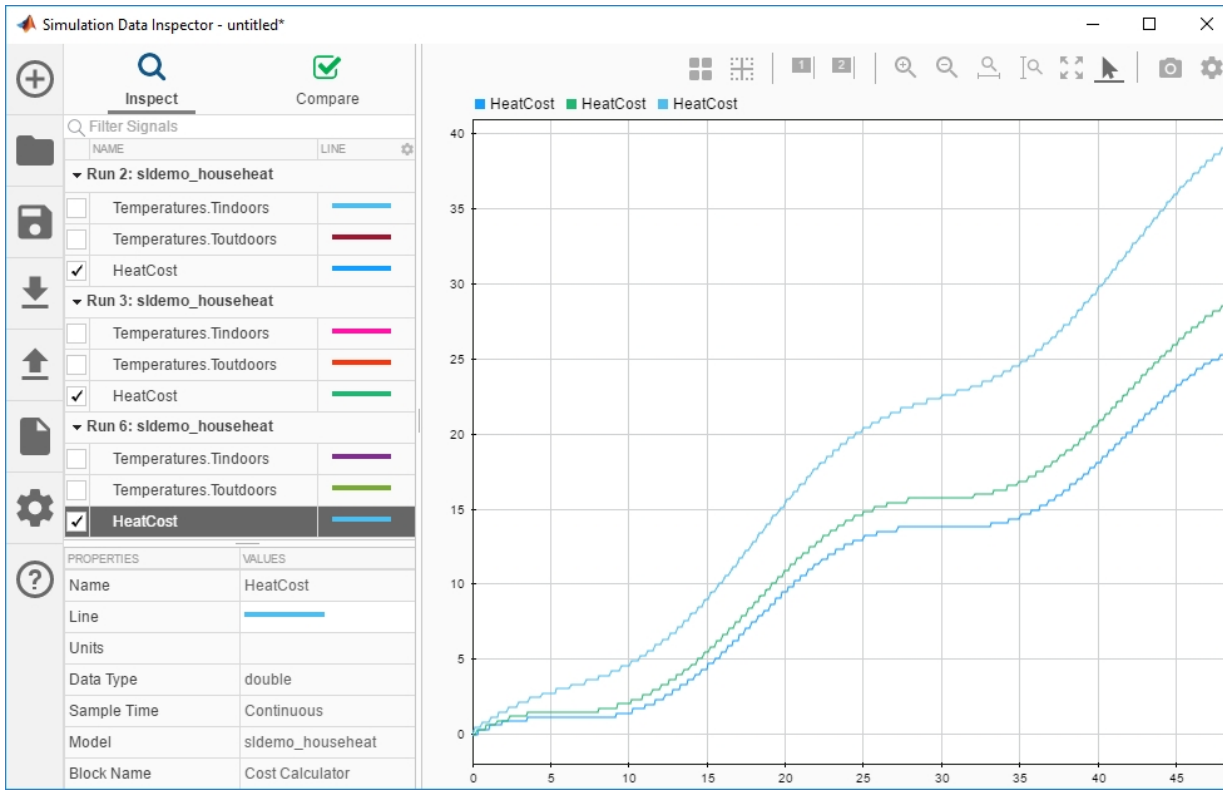
View the Runs in the Simulation Manager

Setting the `ShowSimulationManager` argument to `on` enables the Simulation Manager. For more information, see `Simulation Manager`.

You can view the status of all the runs and detailed information about them.



The Simulation Manager enables you to view your results in the Simulation Data Inspector, which in turn allows you to analyze and compare your data. You can view the plot of the Temperatures (Indoor and Outdoor) and the Heat Cost in Simulation Data Inspector. Select the runs for which you want to view the plot and click on  icon.



You can now see the heat cost for three simulations.

Using the Simulation Manager you can apply the parameters of any run to your model. Now, suppose you want to apply the parameters of Run 3 to your model. Select Run 3 and click on the  icon. Your parameters are applied to the model.

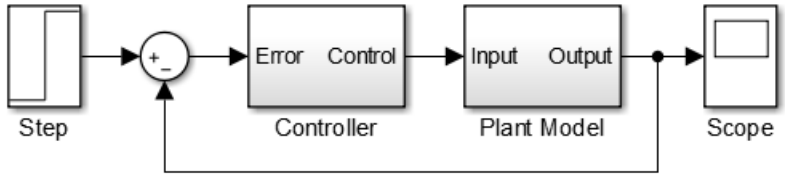
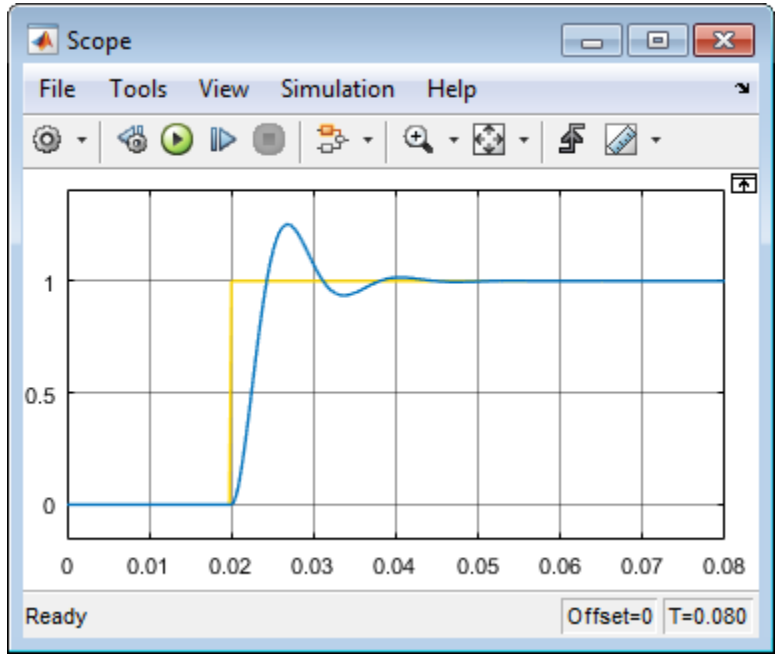
Visualizing and Comparing Simulation Results

Prototype and Debug Models with Scopes

Simulink Scope blocks and Scope viewers offer a quick and lightweight way to visualize your simulation data over time. If you are prototyping a model design, you can attach signals to a Scope block. After simulating the model, you can use the results to validate your design. See “Scope Blocks and Scope Viewer Overview” on page 27-8 and “Integrate a House Heating Model”.

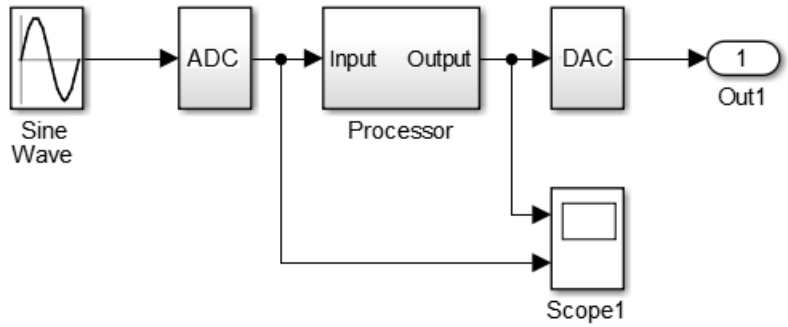


A Scope block or Scope viewer opens to a Scope window where you can display and evaluate simulation data.

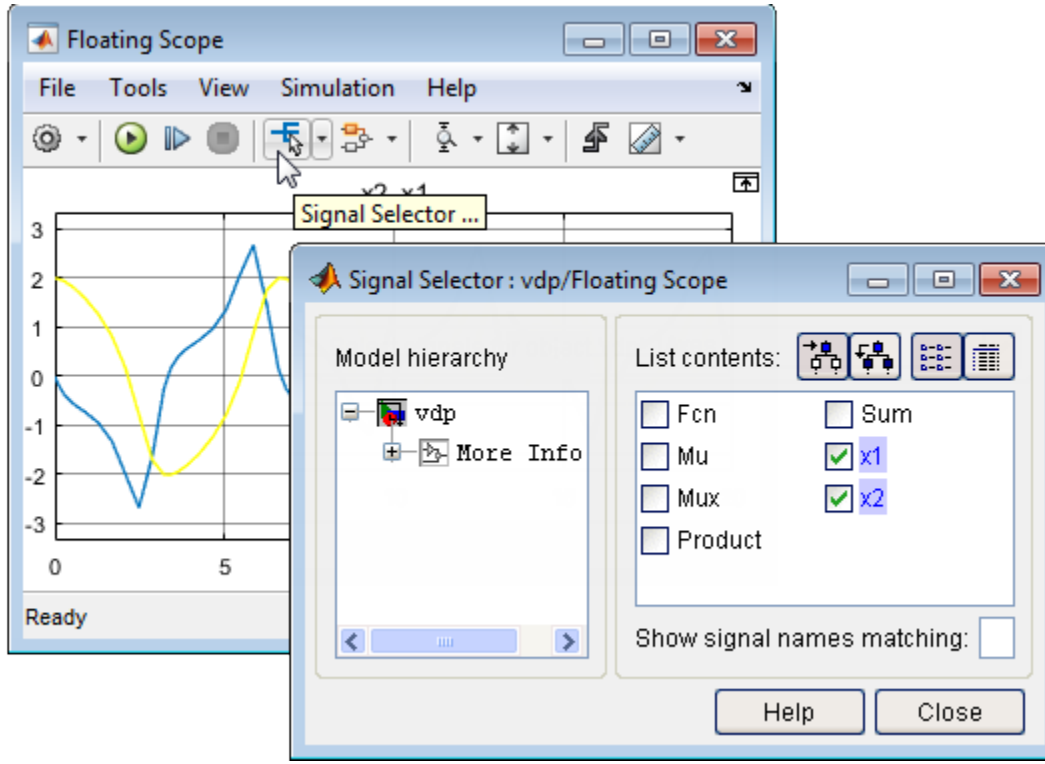


The toolbar contains controls for starting, stopping, and stepping forward through a simulation  . You can use these controls to debug a model by viewing signal data at each time interval. See "How Stepping Through a Simulation Works" on page 2-3.

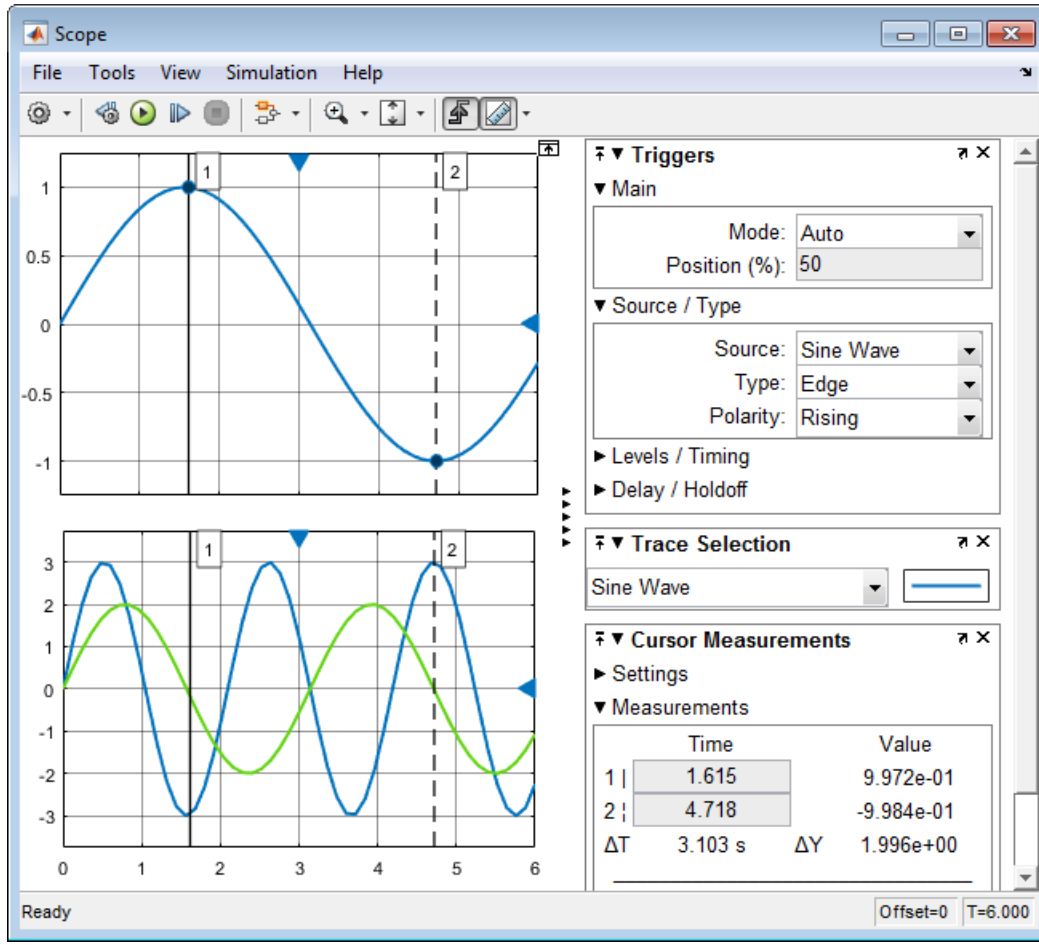
Connect signal lines to a Scope block using multiple input ports. See "Number of input ports" in Scope block reference.



Attach signals to a Floating Scope block or signal viewer using a signal selector tool that hierarchically displays all signals in a model. See "Signal Selector" on page 27-89.



Use the oscilloscope-like tools available with a scope to debug your model. Set triggers to capture events, use interactive cursors to measure signal values at various points, and review signal statistics such as maximum and mean values. See “Scope Triggers Panel” on page 27-16 and “Cursor Measurements Panel” on page 27-30.



Save or log signal data to the MATLAB workspace, and then plot data in a MATLAB figure widow. Use MATLAB functions or your own scripts to analyze the data. See “Save Simulation Data Using Floating Scope Block” on page 27-79.

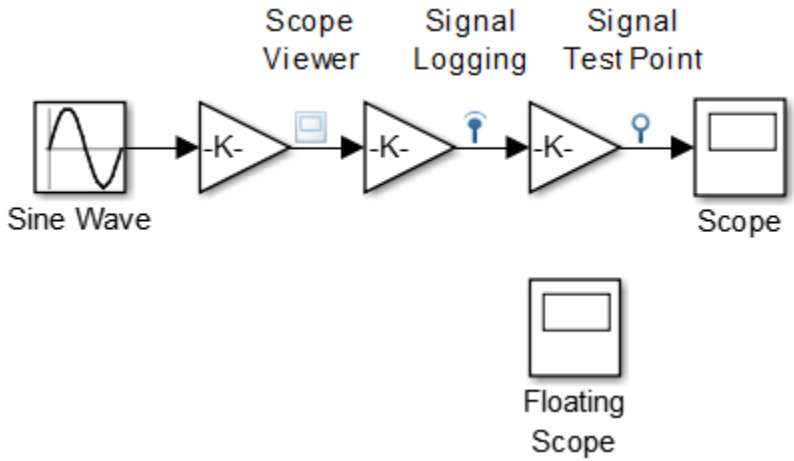
Scope Blocks and Scope Viewer Overview

In this section...

Overview of Methods

Simulink scopes provide several methods for displaying simulation data and capturing the data for later analysis. Symbols on your block diagram represent the various data display and data capture methods.



For more information about these methods:

- Scope and Floating Scope blocks — Scope, Floating Scope, “Common Scope Interactions” on page 27-63, “Floating Scope and Scope Viewer Tasks” on page 27-77.
- Scope Viewer — “Signal and Scope Manager” on page 27-85, “Floating Scope and Scope Viewer Tasks” on page 27-77.
- Signal Logging — “Save Simulation Data Using Floating Scope Block” on page 27-79.

- Signal Test Point — “Test Points” on page 64-62.

Simulink Scope Versus Floating Scope

Scope blocks and Floating Scope blocks both display simulation results, but they differ in how you attach signals and save data. Simulation behavior for a Floating Scope and a Scope Viewer is identical, but you manage them differently in your model.

Capability	Simulink Scope	Simulink Floating Scope	Simulink Scope Viewer
Attaching signals	Connect signal lines to a Scope block using input ports.	Attach signals using the Signal Selector. See “Signal Selector” on page 27-89. Attach signals interactively from the model before and during a simulation. See “View Signals on a Floating Scope Quickly” on page 27-81.	Attach signals using the Signal Selector or signal line context menu.
Access to signals	Because signals lines are connected to a Scope block, access signals at different levels of a model hierarchy using GoTo blocks.	Because signals are attached without signal lines, you do not have to route lines to a Floating Scope block. You can access most signals inside the model hierarchy, including referenced models and Stateflow charts. You cannot access optimized signals.	Scope viewers are attached to signal lines.

Capability	Simulink Scope	Simulink Floating Scope	Simulink Scope Viewer
Data logging	Save data to a MATLAB variable as an array, structure, or object.	Save data to a MATLAB variable as an object.	
Simulation control	Run, forward, and back toolbar buttons.	Run, forward, and back toolbar buttons.	Run, forward, and back toolbar buttons.
Scale axes after simulation	Toolbar buttons to Scale X-axis and Y-axis limits **Axes scaling** set to `Auto` for the X-axis and Y-axis.	Toolbar button to scale only the Y-axis limits, and **Axes scaling** set to `Auto` for only the Y-axis.	Toolbar buttons to Scale X-axis and Y-axis limits **Axes scaling** set to `Auto` for the X-axis and Y-axis.
Add to model	Add block from Simulink sinks library.	Add block from Simulink sinks library.	Add using Signal & Scope Manager. See “Signal and Scope Manager” on page 27-85.
Visual indication in model		Floating Scope block not attached to any signal lines.	Viewer icons located above signal lines for all attached signals.
Manage scopes centrally	No.	No.	Use the Signal & Scope Manager to add or delete viewers, and attach or remove signals.
Manage scopes locally	Attach signal lines to Scope block in ports.	Attach signals from the Floating Scope window.	Add viewers and attach additional signals within a model hierarchy using the context menus.
Simulink Report Generator support	Yes.	Yes.	No.

Capability	Simulink Scope	Simulink Floating Scope	Simulink Scope Viewer
Connecting Constant block with **Sample time** set to `inf` (constant sample time)		Plots all data values.	Plots the data value at the first time step and anytime you tune a parameter.

Simulink Scope Versus DSP System Toolbox Time Scope

If you have Simulink and a DSP System Toolbox license, you can use either the Simulink Scope or DSP System Toolbox Time Scope. Choose the scope based on your application requirements, how the blocks work, and the default values of each block.

If you have a DSP System Toolbox license and you have been using Time Scopes, continue to do so in your applications. Using the Time Scope block requires a DSP System Toolbox license.

Feature	Scope	Time Scope
Location in block library	Simulink Sinks library	DSP System Toolbox Sinks library
Trigger and measurement panels	With Simulink only: • Trigger • Cursor Measurement With DSP System Toolbox or Simscape license: • Signal Statistics • Bilevel Measurements • Peak Finder	• Trigger • Cursor Measurements • Signal Statistics • Bilevel Measurements • Peak Finder

Feature	Scope	Time Scope
Simulation mode support for block-based sample times For block-based sample times, all the inputs of the block run at the same rate.	• Normal • Accelerator • Rapid-Accelerator • External	• Rapid-Accelerator • External
Simulation mode support for port-based sample times For port-based sample times, the input ports can run at different rates.	No.	• Normal • Accelerator
Frame processing of signals	Included in Scope block with DSP System Toolbox license.	Included in Time Scope block.
Sample time propagation	If the different ports have different sample rates, the scope uses the greatest common divisor of the rates.	When using port-based sample times, the different ports of the Scope block inherit the different rates and plots the signals according to those rates.
Save model to previous Simulink release	If saving to a release before R2015a, the Scope block is converted to a scope with the features available in that release.	No change in features.

This table lists the differences in Configuration Property default values between the Scope and Time Scope blocks.

Property	Scope	Time Scope
Open at start of simulation	Cleared	Selected
Input processing	Elements as channels (sample based)	Columns as channels (frame based)
Maximize Axes	Off	Auto

Property	Scope	Time Scope
Time Units	None	Metric (based on Time Span)
Time-axis labels	Bottom displays only	All
Show time-axis label	Cleared	Selected
Plot Type	Auto	Line
Title	%<Signal Label>	No title
Y label	No label	Amplitude

Debugging a Model with Scope Blocks

There are different types of triggering techniques available in with a Scope block. You can choose one over the other depending on your application. Some of the important triggering techniques available in with a Scope include:

- Edge Trigger: Use edge triggering to stabilize a repetitive waveform and search for a occurrence of a particular pattern in the signal. Using the edge triggering technique, one can stabilize a repetitive signal based on occurrence of edge in a signal and then measure important attributes of a signal like Rise Time, Fall Time, Peak to peak voltage, RMS voltage etc.
- Pulse width triggering: Using this technique, you can set the Scope to trigger, for example, on the occurrence of a glitch – a pulse which is faster / slower than the reference pulse. This ability can help one investigate the properties of the glitch and do some investigation on the root cause of the glitch
- Runt triggering: Using the Runt Triggering, one can set the Scope to trigger for pulses whose amplitude crosses one of the two voltage threshold but not both and whose pulse width lies in a specific predefined time range. This is very useful in debugging the Runt Signals frequently encountered in troubleshooting Digital integrated Circuits.

  Runt signals are the signals which typically cross a voltage threshold level but fail to cross a second threshold before re-crossing the first threshold level. Runt signals are frequently encountered in digital circuits.

  To look for Runt signals, enable the Trigger, set the Trigger Mode to Normal, set the trigger type as Runt, adjust the voltage threshold and then view if the Scope detects and displays the presence of any runt signals in the incoming data stream.

Scope Triggers Panel

In this section...

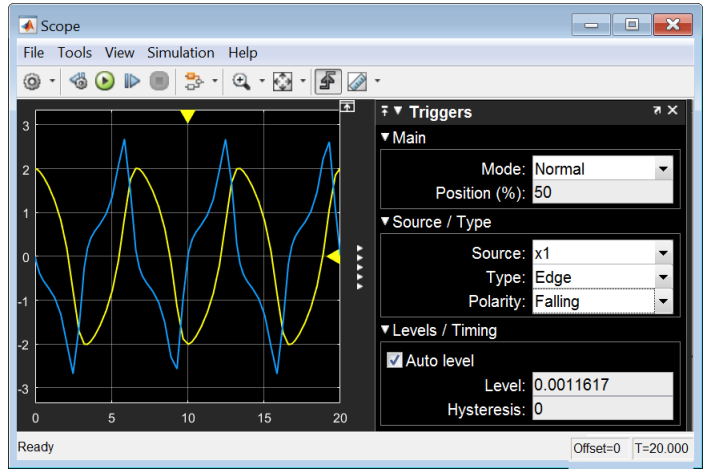
What Is the Trigger Panel

The Trigger panel defines a trigger event to synchronize simulation time with input signals. You can use trigger events to stabilize periodic signals such as a sine wave or capture non-periodic signals that occurs intermittently.

To open the Trigger panel:

1. Open a Scope block window.
2. On the toolbar, click the Triggers button  .
3. Run a simulation.

   Triangle trigger pointers indicate the trigger time and trigger level of an event. The marker color corresponds to the color of the source signal.



Main Pane

Mode — Specify when the display updates.

- **Auto** — Display data from the last trigger event. If no event occurs after one time span, display the last available data.

  Normal — Display data from the last trigger event. If no event occurs, the display remains blank.
- **Once** — Display data from the last trigger event and freeze the display. If no event occurs, the display remains blank. Click the **Rearm** button to look for the next trigger event.
- **Off** — Disable triggering.

Position (%) — Specify the position of the time pointer along the y-axis. You can also drag the time pointer to the left or right to adjust its position.

Source/Type and Levels/Timing Panes

Source — Select a trigger signal. For magnitude and phase plots, select either the magnitude or the phase.

Type — Select the type of trigger.

Trigger Type	Trigger Parameters
`Edge` — Trigger when the signal crosses a threshold.	**Polarity** — Select the polarity for an edge-triggered signal. • `Rising` — Trigger when the signal is increasing.  • `Falling` — Trigger when the signal value is decreasing.  • `Either` — Trigger when the signal is increasing or decreasing.

Trigger Type	Trigger Parameters
	Level — Enter a threshold value for an edge triggered signal. **Auto level** is 50% **Hysteresis** — Enter a value for an edge-triggered signal. See “Hysteresis of Trigger Signals” on page 27-27

Trigger Type	Trigger Parameters
`Pulse Width` — Trigger when the signal crosses a low threshold and a high threshold twice within a specified time.	**Polarity** — Select the polarity for a pulse width-triggered signal. • `Positive` — Trigger on a positive-polarity pulse when the pulse crosses the low threshold for a second time.  • `Negative` — Trigger on a negative-polarity pulse when the pulse crosses the high threshold for a second time. • `Either` — Trigger on both positive-polarity and negative-polarity pulses. **Note** A glitch-trigger is a special type of a pulse width-trigger. A glitch-Trigger occurs for a pulse or spike whose duration is less than a specified amount. You can implement a glitch trigger by using a pulse width-trigger and setting the **Max Width** parameter to a small value. **High** — Enter a high value for a pulse width-triggered signal. **Auto level** is 90%. **Low** — Enter a low value for a pulse width-triggered signal. **Auto level** is 10%.

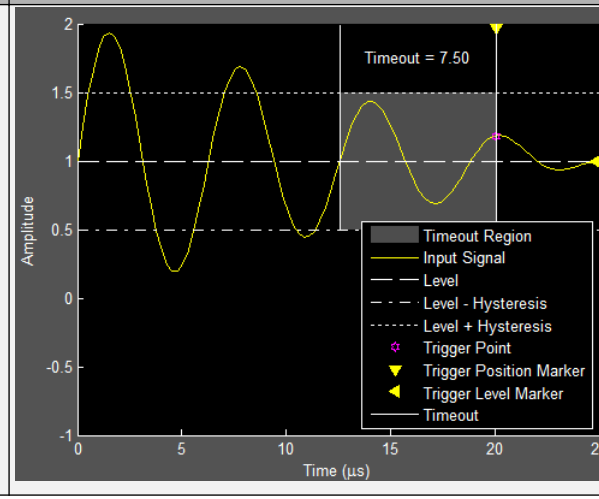
Trigger Type	Trigger Parameters
	Min Width — Enter the minimum pulse-width for a pulse width triggered signal. Pulse width is measured between the first and second crossings of the middle threshold. **Max Width** — Enter the maximum pulse width for a pulse width triggered signal.

Trigger Type	Trigger Parameters
`Transition` — Trigger on the rising or falling edge of a signal that crosses the high and low levels within a specified time range.	**Polarity** — Select the polarity for a transition-triggered signal. • `Rise Time` — Trigger on an increasing signal when the signal crosses the high threshold.  • `Fall Time` — Trigger on a decreasing signal when the signal crosses the low threshold. • `Either` — Trigger on an increasing or decreasing signal. **High** — Enter a high value for a transition-triggered signal. **Auto level** is 90%. **Low** — Enter a low value for a transition-triggered signal. **Auto level** is 10%. **Min Time** — Enter a minimum time duration for a transition-triggered signal. **Max Time** — Enter a maximum time duration for a transition-triggered signal.

Trigger Type	Trigger Parameters
`Runt`— Trigger when a signal crosses a low threshold or a high threshold twice within a specified time.	**Polarity** — Select the polarity for a runt-triggered signal. • `Positive` — Trigger on a positive-polarity pulse when the signal crosses the low threshold a second time, without crossing the high threshold.  • `Negative` — Trigger on a negative-polarity pulse. • `Either` — Trigger on both positive-polarity and negative-polarity pulses. **High** — Enter a high value for a runt-triggered signal. **Auto level** is 90%. **Low** — Enter a low value for a runt-triggered signal. **Auto level** is 10%. **Min Width** — Enter a minimum width for a runt-triggered signal. Pulse width is measured between the first and second crossing of a threshold. **Max Width** — Enter a maximum pulse width for a runt-triggered signal.

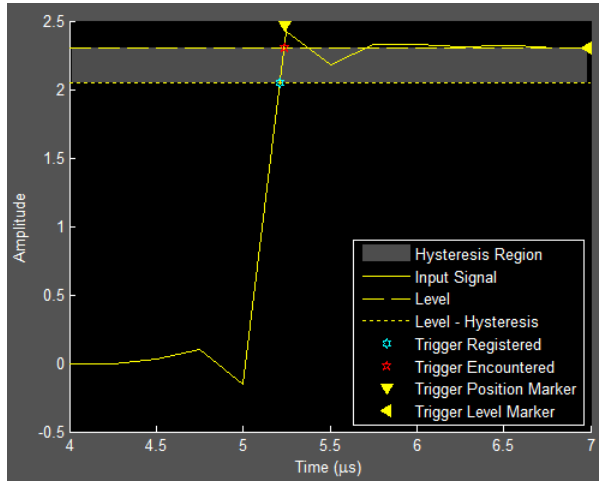
Trigger Type	Trigger Parameters
`Window` — Trigger when a signal stays within or outside a region defined by the high and low thresholds for a specified time.	**Polarity** — Select the region for a window-triggered signal. • `Inside` — Trigger when a signal leaves a region between the low and high levels.  • `Outside` — Trigger when a signal enters a region between the low and high levels. 
Trigger Type	Trigger Parameters
	• `Either` — Trigger when a signal leaves or enters a region between the low and high levels. **High** — Enter a high value for a window-triggered signal. **Auto level** is 90%. **Low** — Enter a low value for a window-trigger signal. **Auto level** is 10%. **Min Time** — Enter the minimum time duration for a window-triggered signal. **Max Time** — Enter the maximum time duration for a window-triggered signal.

Trigger Type	Trigger Parameters
`Timeout` — Trigger when a signal stays above or below a threshold longer than a specified time	**Polarity** — Select the polarity for a timeout-triggered signal. • `Rising` — Trigger when the signal does not cross the threshold from below. For example, if you set **Timeout** to 7.50 seconds, the scope triggers 7.50 seconds after the signal crosses the threshold.  • `Falling` — Trigger when the signal does not cross the threshold from above. • `Either` — Trigger when the signal does not cross the threshold from either direction **Level** — Enter a threshold value for a timeout-triggered signal. **Hysteresis** — Enter a value for a timeout-triggered signal. See “Hysteresis of Trigger Signals” on page 27-27. **Timeout** — Enter a time duration for a timeout-triggered signal. Alternatively, a trigger event can occur when the signal stays within the boundaries defined by the hysteresis for 7.50 seconds after the signal crosses the threshold.

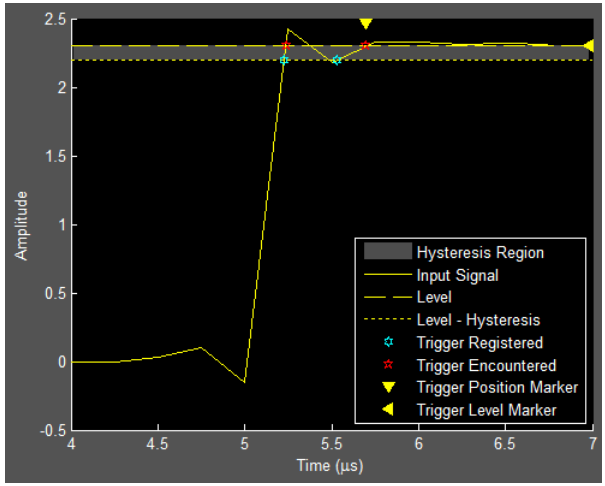
Trigger Type	Trigger Parameters
	


Hysteresis of Trigger Signals

Hysteresis (V) — Specify the hysteresis or noise reject value. This parameter is visible when you set **Type** to `Edge` or `Timeout`. If the signal jitters inside this range and briefly crosses the trigger level, the scope does not register an event. In the case of an edge trigger with rising polarity, the scope ignores the times that a signal crosses the trigger level within the hysteresis region.



You can reduce the hysteresis region size by decreasing the hysteresis value. In this example, if you set the hysteresis value to 0.07, the scope also considers the second rising edge to be a trigger event.



Delay/Holdoff Pane

Offset the trigger position by a fixed delay, or set the minimum possible time between trigger events.

- **Delay (s)** — Specify the fixed delay time by which to offset the trigger position. This parameter controls the amount of time the scope waits after a trigger event occurs before displaying a signal.
- **Holdoff (s)** — Specify the minimum possible time between trigger events. This amount of time is used to suppress data acquisition after a valid trigger event has occurred. A trigger holdoff prevents repeated occurrences of a trigger from occurring during the relevant portion of a burst.

Related Examples

- “Cursor Measurements Panel” on page 27-30

Cursor Measurements Panel

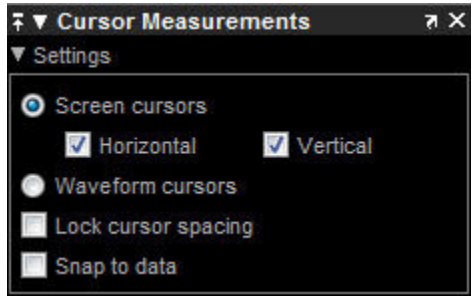
The **Cursor Measurements** panel displays screen cursors. The panel provides two types of cursors for measuring signals. Waveform cursors are vertical cursors that track along the signal. Screen cursors are both horizontal and vertical cursors that you can place anywhere in the display.

Note If a data point in your signal has more than one value, the cursor measurement at that point is undefined and no cursor value is displayed.

Display screen cursors with signal times and values. To open the Cursor measurements panel:

- From the menu, select **Tools > Measurements > Cursor Measurements**.
- On the toolbar, click the Cursor Measurements button.

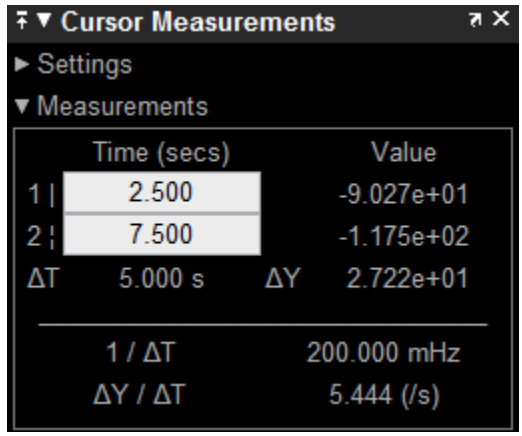
In the **Settings** pane, you can modify the type of screen cursors used for calculating measurements. When more than one signal is displayed, you can assign cursors to each trace individually.



- **Screen Cursors** — Shows screen cursors (for spectrum and dual view only).
- **Horizontal** — Shows horizontal screen cursors (for spectrum and dual view only).
- **Vertical** — Shows vertical screen cursors (for spectrum and dual view only).
- **Waveform Cursors** — Shows cursors that attach to the input signals (for spectrum and dual view only).
- **Lock Cursor Spacing** — Locks the frequency difference between the two cursors.

- **Snap to Data** — Positions the cursors on signal data points.

The Measurements pane displays time and value measurements.



- **1 |**— View or modify the time or value at cursor number one.
- **2 :**— View or modify the time or value at cursor number two.
- **Δt**— Shows the absolute value of the difference in the times between cursor number one and cursor number two.
- **ΔV**— Shows time difference. The absolute value of the difference in signal amplitudes between cursor number one and cursor number two.
- **1/Δt**— Shows the rate. The reciprocal of the absolute value of the difference in the times between cursor number one and cursor number two.
- **ΔV/Δt**— Shows the scope. The ratio of the absolute value of the difference in signal amplitudes between cursors to the absolute value of the difference in the times between cursors.

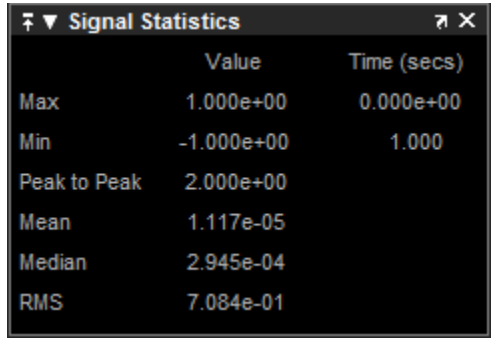
Scope Signal Statistics Panel

Note The Signal Statistics panel requires a DSP System Toolbox or Simscape license.

Display signal statistics for the signal selected in the **Trace Selection** panel. To open the Signal Statistics panel:

- From the menu, select **Tools** > **Measurements** > **Signal Statistics**.
- On the toolbar, click the Signal Statistics button.



The statistics shown are:

- **Max** — Maximum or largest value within the displayed portion of the input signal.
- **Min** — Minimum or smallest value within the displayed portion of the input signal.
- **Peak to Peak** — Difference between the maximum and minimum values within the displayed portion of the input signal.
- **Mean** — Average or mean of all the values within the displayed portion of the input signal.
- **Median** — Median value within the displayed portion of the input signal.
- **RMS** — Difference between the maximum and minimum values within the displayed portion of the input signal.

When you use the zoom options in the scope, the Signal Statistics measurements automatically adjust to the time range shown in the display. In the scope toolbar, click the **Zoom In** or**Zoom X** button to constrict the *x*-axis range of the display, and the

statistics shown reflect this time range. For example, you can zoom in on one pulse to make the **Signal Statistics** panel display information about only that particular pulse.

The Signal Statistics measurements are valid for any units of the input signal. The letter after the value associated with each measurement represents the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts. The SI prefixes are shown in the following table:

Scope Bilevel Measurements Panel

In this section...

Bilevel Measurements

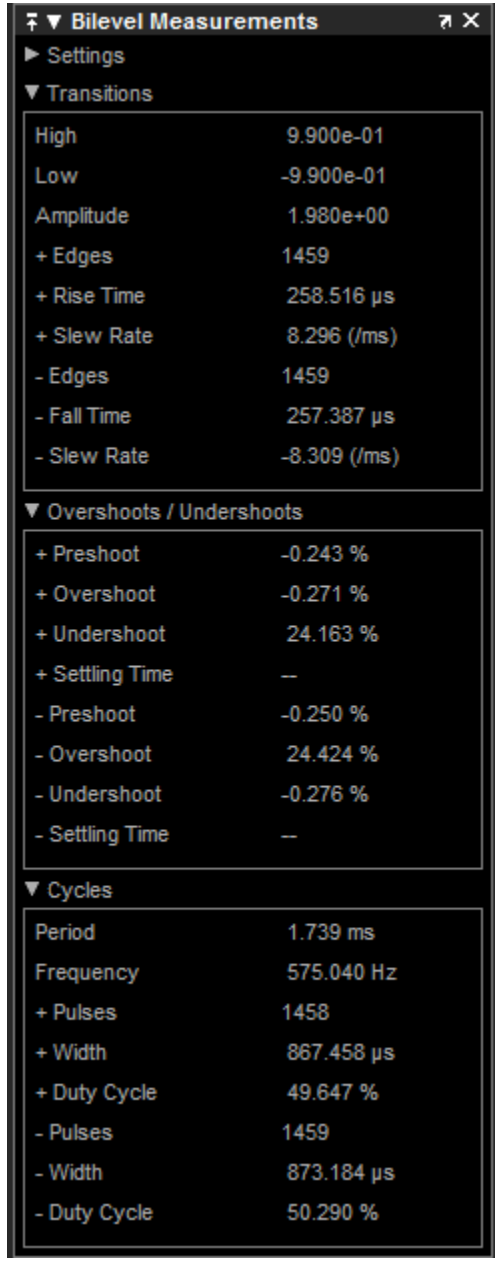
Note The Bilevel Measurements panel requires a DSP System Toolbox or Simscape license.

Display information about signal transitions, overshoots, undershoots, and cycles. To open the Bilevel Measurements panel:

- From the menu, select **Tools** > **Measurements** > **Bilevel Measurements**.
- On the toolbar, click the Bilevel Measurements  button.

Settings

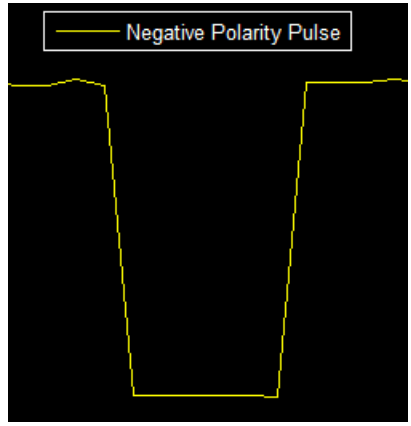
The **Settings** pane enables you to modify the properties used to calculate various measurements involving transitions, overshoots, undershoots, and cycles. You can modify the high-state level, low-state level, state-level tolerance, upper-reference level, mid-reference level, and lower-reference level.



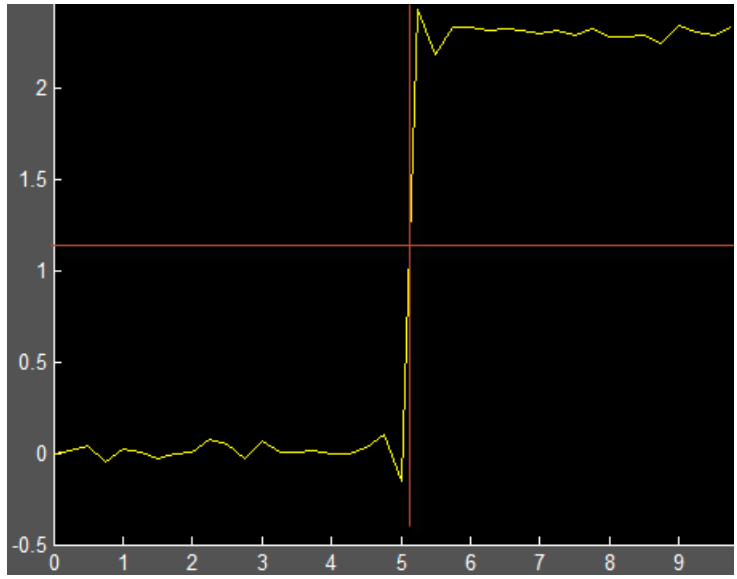
Bilevel Measurements
Settings
Transitions
High 9.900e-01
Low -9.900e-01
Amplitude 1.980e+00
+ Edges 1459
+ Rise Time 258.516 µs
+ Slew Rate 8.296 (/ms)
- Edges 1459
- Fall Time 257.387 µs
- Slew Rate -8.309 (/ms)
Overshoots / Undershoots
+ Preshoot -0.243 %
+ Overshoot -0.271 %
+ Undershoot 24.163 %
+ Settling Time --
- Preshoot -0.250 %
- Overshoot 24.424 %
- Undershoot -0.276 %
- Settling Time --
Cycles
Period 1.739 ms
Frequency 575.040 Hz
+ Pulses 1458
+ Width 867.458 µs
+ Duty Cycle 49.647 %
- Pulses 1459
- Width 873.184 µs
- Duty Cycle 50.290 %

- **Auto State Level** — When this check box is selected, the Bilevel measurements panel detects the high- and low- state levels of a bilevel waveform. When this check box is cleared, you can enter in values for the high- and low- state levels manually.
  - **High** — Used to specify manually the value that denotes a positive polarity, or high-state level.

  - **Low** — Used to specify manually the value that denotes a negative polarity, or low-state level.



- **State Level Tolerance** — Tolerance within which the initial and final levels of each transition must be within their respective state levels. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Upper Ref Level** — Used to compute the end of the rise-time measurement or the start of the fall time measurement. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Mid Ref Level** — Used to determine when a transition occurs. This value is expressed as a percentage of the difference between the high- and low- state levels. In the following figure, the mid-reference level is shown as the horizontal line, and its corresponding mid-reference level instant is shown as the vertical line.

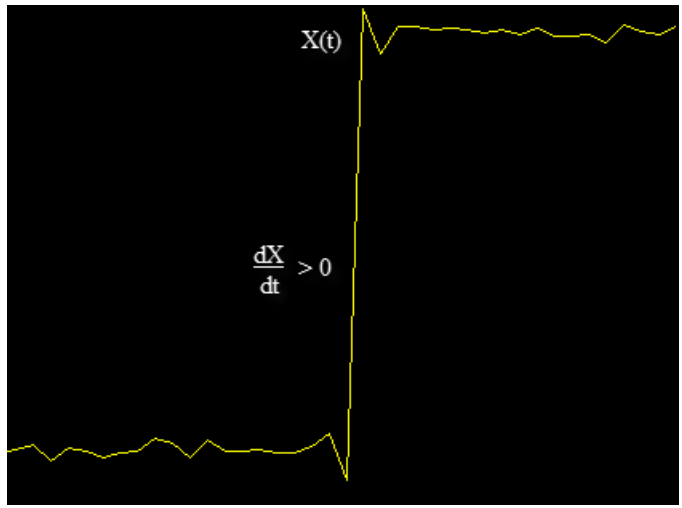


- **Lower Ref Level** — Used to compute the end of the fall-time measurement or the start of the rise-time measurement. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Settle Seek** — The duration after the mid-reference level instant when each transition occurs used for computing a valid settling time. This value is equivalent to the input parameter, `D`, which you can set when you run the `settlingtime` function. The settling time is displayed in the **Overshoots/Undershoots** pane.

Transitions Pane

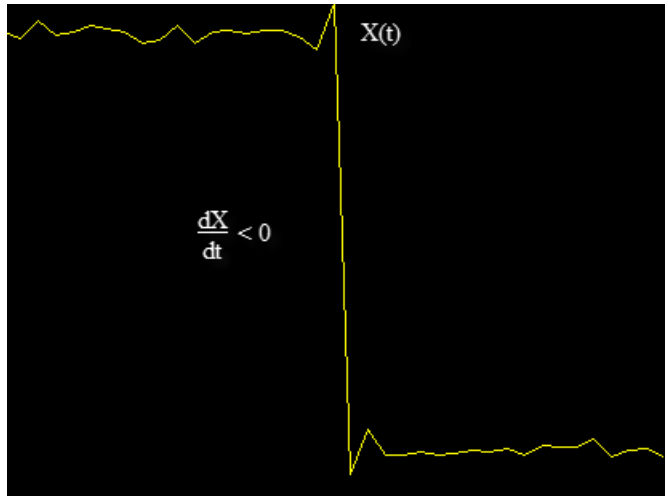
Display calculated measurements associated with the input signal changing between its two possible state level values, high and low.

A positive-going transition, or rising edge, in a bilevel waveform is a transition from the low-state level to the high-state level. A positive-going transition has a slope value greater than zero. The following figure shows a positive-going transition.



When here is a plus sign (+) next to a text label, the measurement is a rising edge, a transition from a low-state level to a high-state level.

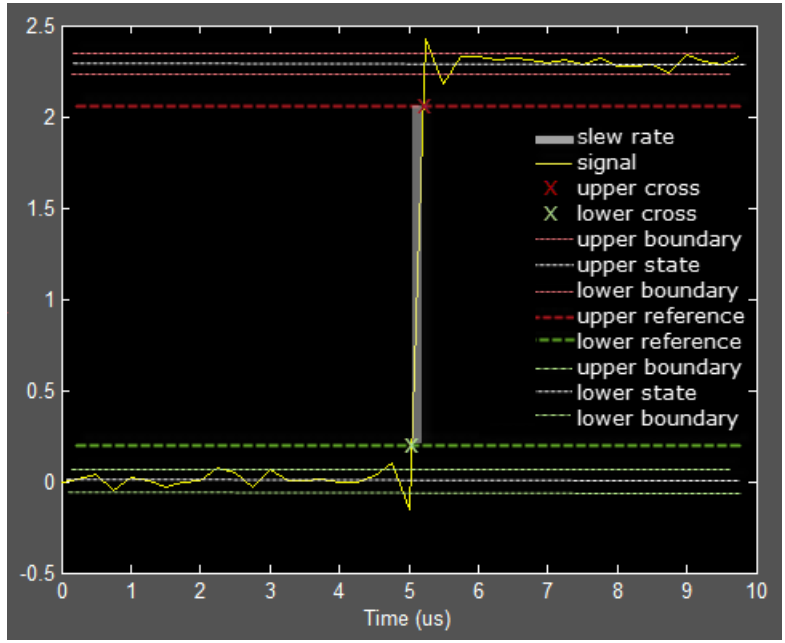
A negative-going transition, or falling edge, in a bilevel waveform is a transition from the high-state level to the low-state level. A negative-going transition has a slope value less than zero. The following figure shows a negative-going transition.



When there is a minus sign (–) next to a text label, the measurement is a falling edge, a transition from a high-state level to a low-state level.

The Transition measurements assume that the amplitude of the input signal is in units of volts. For the transition measurements to be valid, you must convert all input signals to volts.

- **High** — The high-amplitude state level of the input signal over the duration of the **Time Span** parameter. You can set **Time Span** in the **Main** pane of the Visuals—Time Domain Properties dialog box.
- **Low** — The low-amplitude state level of the input signal over the duration of the **Time Span** parameter. You can set **Time Span** in the **Main** pane of the Visuals—Time Domain Properties dialog box.
- **Amplitude** — Difference in amplitude between the high-state level and the low-state level.
- **+ Edges** — Total number of positive-polarity, or rising, edges counted within the displayed portion of the input signal.
- **+ Rise Time** — Average amount of time required for each rising edge to cross from the lower-reference level to the upper-reference level.
- **+ Slew Rate** — Average slope of each rising-edge transition line within the upper- and lower-percent reference levels in the displayed portion of the input signal. The region in which the slew rate is calculated appears in gray in the following figure.

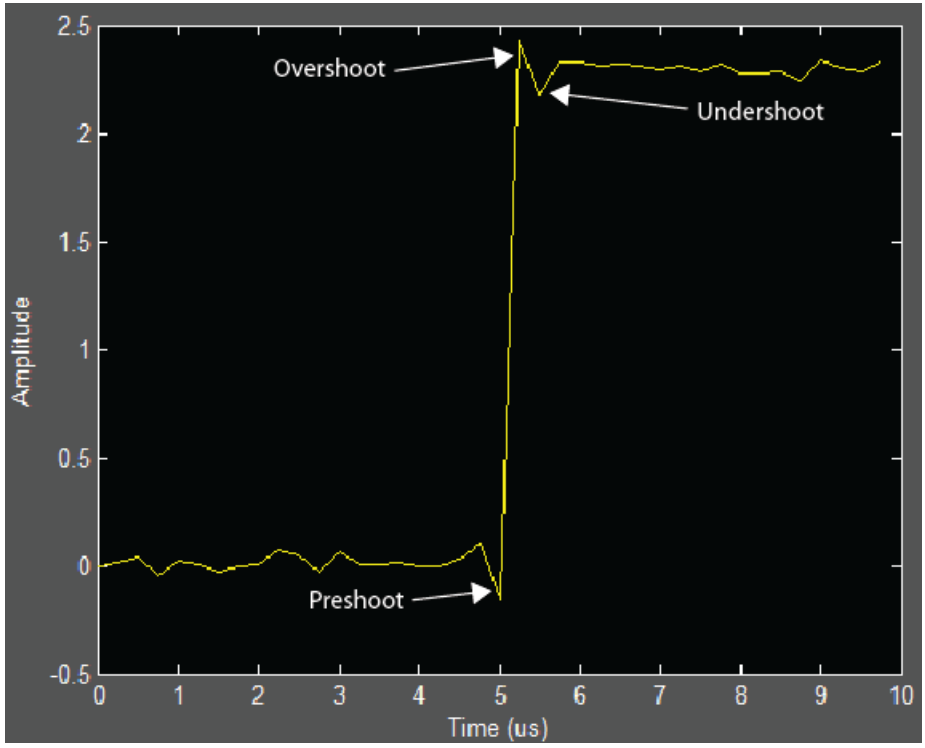


- – **Edges** — Total number of negative-polarity or falling edges counted within the displayed portion of the input signal.
- – **Fall Time** — Average amount of time required for each falling edge to cross from the upper-reference level to the lower-reference level.
- – **Slew Rate** — Average slope of each falling edge transition line within the upper- and lower-percent reference levels in the displayed portion of the input signal.

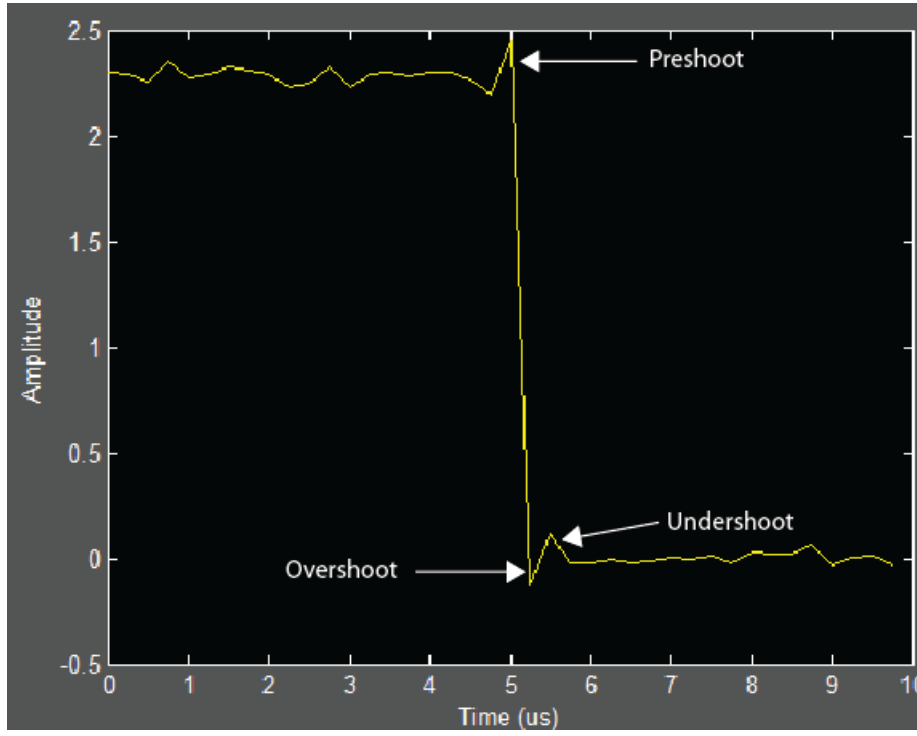
Overshoots / Undershoots Pane

The **Overshoots/Undershoots** pane displays calculated measurements involving the distortion and damping of the input signal. Overshoot and undershoot refer to the amount that a signal respectively exceeds and falls below its final steady-state value. Preshoot refers to the amount before a transition that a signal varies from its initial steady-state value.

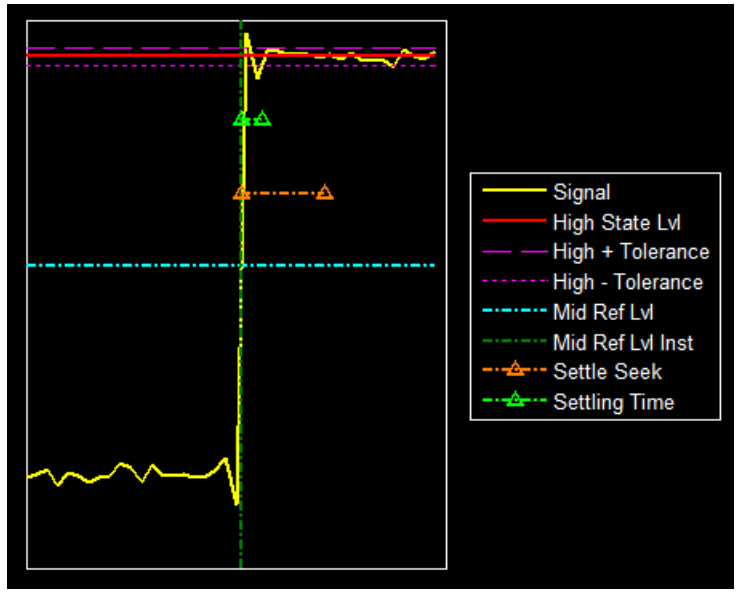
This figure shows preshoot, overshoot, and undershoot for a rising-edge transition.



The next figure shows preshoot, overshoot, and undershoot for a falling-edge transition.



- **+ Preshoot** — Average lowest aberration in the region immediately preceding each rising transition.
- **+ Overshoot** — Average highest aberration in the region immediately following each rising transition.
- **+ Undershoot** — Average lowest aberration in the region immediately following each rising transition.
- **+ Settling Time** — Average time required for each rising edge to enter and remain within the tolerance of the high-state level for the remainder of the settle-seek duration. The settling time is the time after the mid-reference level instant when the signal crosses into and remains in the tolerance region around the high-state level. This crossing is illustrated in the following figure.



You can modify the settle-seek duration parameter in the **Settings** pane.

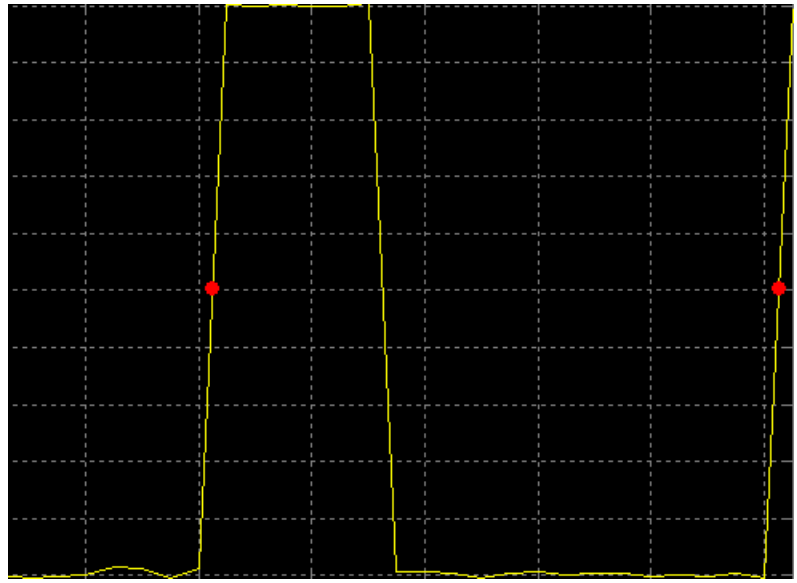
- – **Preshoot** — Average highest aberration in the region immediately preceding each falling transition.
- – **Overshoot** — Average highest aberration in the region immediately following each falling transition.
- – **Undershoot** — Average lowest aberration in the region immediately following each falling transition.
- – **Settling Time** — Average time required for each falling edge to enter and remain within the tolerance of the low-state level for the remainder of the settle-seek duration. The settling time is the time after the mid-reference level instant when the signal crosses into and remains in the tolerance region around the low-state level. You can modify the settle-seek duration parameter in the **Settings** pane.

Cycles Pane

The **Cycles** pane displays calculated measurements pertaining to repetitions or trends in the displayed portion of the input signal.

Properties to set:

- **Period** — Average duration between adjacent edges of identical polarity within the displayed portion of the input signal. The Bilevel measurements panel calculates period as follows. It takes the difference between the mid-reference level instants of the initial transition of each positive-polarity pulse and the next positive-going transition. These mid-reference level instants appear as red dots in the following figure.



- **Frequency** — Reciprocal of the average period. Whereas period is typically measured in some metric form of seconds, or seconds per cycle, frequency is typically measured in hertz or cycles per second.
- **+ Pulses** — Number of positive-polarity pulses counted.
- **+ Width** — Average duration between rising and falling edges of each positive-polarity pulse within the displayed portion of the input signal.
- **+ Duty Cycle** — Average ratio of pulse width to pulse period for each positive-polarity pulse within the displayed portion of the input signal.
- **– Pulses** — Number of negative-polarity pulses counted.
- **– Width** — Average duration between rising and falling edges of each negative-polarity pulse within the displayed portion of the input signal.
- **– Duty Cycle** — Average ratio of pulse width to pulse period for each negative-polarity pulse within the displayed portion of the input signal.

When you use the zoom options in the Scope, the bilevel measurements automatically adjust to the time range shown in the display. In the Scope toolbar, click the **Zoom In** or **Zoom X** button to constrict the *x*-axis range of the display, and the statistics shown reflect this time range. For example, you can zoom in on one rising edge to make the **Bilevel Measurements** panel display information about only that particular rising edge. However, this feature does not apply to the **High** and **Low** measurements.

Related Examples

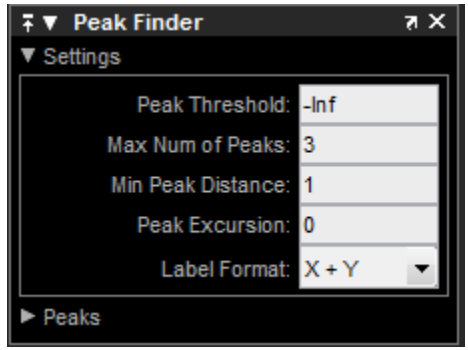
- “Scope Triggers Panel” on page 27-16

Peak Finder Measurements Panel

The **Peak Finder** panel displays the maxima, showing the *x*-axis values at which they occur. Peaks are defined as a local maximum where lower values are present on both sides of a peak. Endpoints are not considered peaks. This panel allows you to modify the settings for peak threshold, maximum number of peaks, and peak excursion.

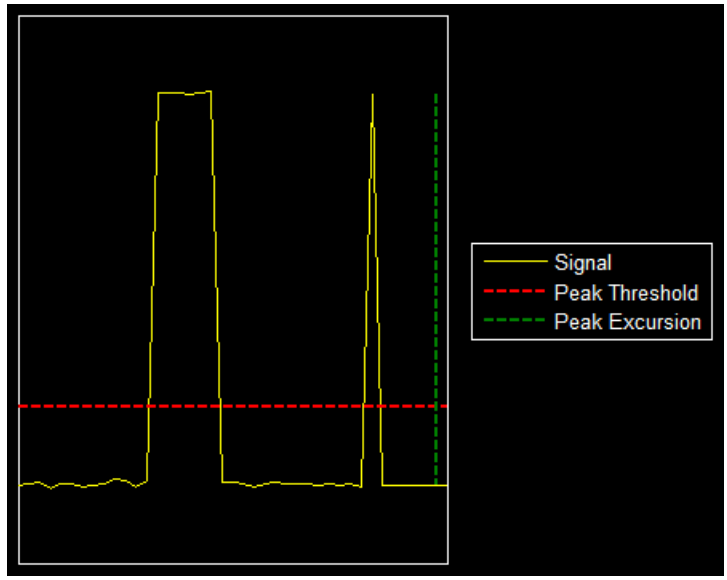
- From the menu, select **Tools** > **Measurements** > **Peak Finder**.
- On the toolbar, click the Peak Finder button.

The **Settings** pane enables you to modify the parameters used to calculate the peak values within the displayed portion of the input signal. For more information on the algorithms this pane uses, see the `findpeaks` function reference.



Properties to set:

- **Peak Threshold** — The level above which peaks are detected. This setting is equivalent to the `MINPEAKHEIGHT` parameter, which you can set when you run the `findpeaks` function.
- **Max Num of Peaks** — The maximum number of peaks to show. The value you enter must be a scalar integer from 1 through 99. This setting is equivalent to the `NPEAKS` parameter, which you can set when you run the `findpeaks` function.
- **Min Peaks Distance** — The minimum number of samples between adjacent peaks. This setting is equivalent to the `MINPEAKDISTANCE` parameter, which you can set when you run the `findpeaks` function.
- **Peak Excursion** — The minimum height difference between a peak and its neighboring samples. Peak excursion is illustrated alongside peak threshold in the following figure.



The peak threshold is a minimum value necessary for a sample value to be a peak. The peak excursion is the minimum difference between a peak sample and the samples to its left and right in the time domain. In the figure, the green vertical line illustrates the lesser of the two height differences between the labeled peak and its neighboring samples. This height difference must be greater than the **Peak Excursion** value for the labeled peak to be classified as a peak. Compare this setting to peak threshold, which is illustrated by the red horizontal line. The amplitude must be above this horizontal line for the labeled peak to be classified as a peak.

The peak excursion setting is equivalent to the `THRESHOLD` parameter, which you can set when you run the `findpeaks` function.

- **Label Format** — The coordinates to display next to the calculated peak values on the plot. To see peak values, you must first expand the **Peaks** pane and select the check boxes associated with individual peaks of interest. By default, both *x*-axis and *y*-axis values are displayed on the plot. Select which axes values you want to display next to each peak symbol on the display.

  - `X+Y` — Display both *x*-axis and *y*-axis values.
  - `X` — Display only *x*-axis values.
  - `Y` — Display only *y*-axis values.

The **Peaks** pane displays the largest calculated peak values. It also shows the coordinates at which the peaks occur, using the parameters you define in the **Settings** pane. You set the **Max Num of Peaks** parameter to specify the number of peaks shown in the list.

The numerical values displayed in the **Value** column are equivalent to the `pks` output argument returned when you run the `findpeaks` function. The numerical values displayed in the second column are similar to the `locs` output argument returned when you run the `findpeaks` function.

The Peak Finder displays the peak values in the **Peaks** pane. By default, the **Peak Finder** panel displays the largest calculated peak values in the **Peaks** pane in decreasing order of peak height.

Use the check boxes to control which peak values are shown on the display. By default, all check boxes are cleared and the **Peak Finder** panel hides all the peak values. To show or hide all the peak values on the display, use the check box in the top-left corner of the **Peaks** pane.

The Peaks are valid for any units of the input signal. The letter after the value associated with each measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

Related Examples

- “Scope Triggers Panel” on page 27-16

Spectrum Analyzer Cursor Measurements Panel

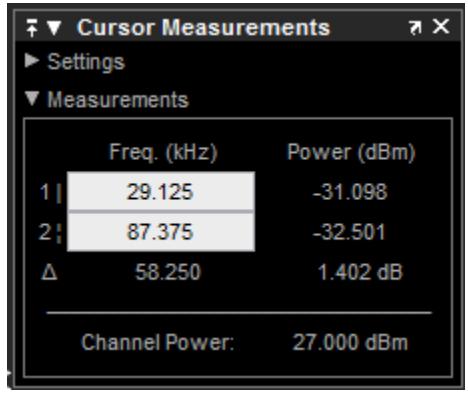
The **Cursor Measurements** panel displays screen cursors. The panel provides two types of cursors for measuring signals. Waveform cursors are vertical cursors that track along the signal. Screen cursors are both horizontal and vertical cursors that you can place anywhere in the display.

Note If a data point in your signal has more than one value, the cursor measurement at that point is undefined and no cursor value is displayed.

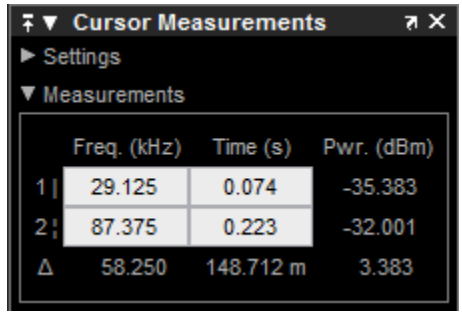
In the Scope menu, select **Tools** > **Measurements** > **Cursor Measurements**.

Alternatively, in the Scope toolbar, click the Cursor Measurements  button.

The **Cursor Measurements** panel for the spectrum and dual view:

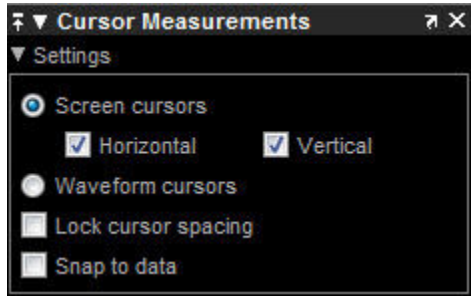


The **Cursor Measurements** panel for the spectrogram view. You must pause the spectrogram display before you can use cursors.



You can use the mouse or the left and right arrow keys to move vertical or waveform cursors and the up and down arrow keys for horizontal cursors.

In the **Settings** pane, you can modify the type of screen cursors used for calculating measurements. When more than one signal is displayed, you can assign cursors to each trace individually.



- **Screen Cursors** — Shows screen cursors (for spectrum and dual view only).
- **Horizontal** — Shows horizontal screen cursors (for spectrum and dual view only).
- **Vertical** — Shows vertical screen cursors (for spectrum and dual view only).
- **Waveform Cursors** — Shows cursors that attach to the input signals (for spectrum and dual view only).
- **Lock Cursor Spacing** — Locks the frequency difference between the two cursors.
- **Snap to Data** — Positions the cursors on signal data points.

Measurements Pane

The **Measurements** pane displays the frequency (Hz) , time (s), and power (dBm) value measurements. Time is displayed only in spectrogram mode. **Channel Power** shows the total power between the cursors.

- **1** — Shows or enables you to modify the frequency, time (for spectrograms only), or both, at cursor number one.
- **2** — Shows or enables you to modify the frequency, time (for spectrograms only), or both, at cursor number two.
- **Δ** — Shows the absolute value of the difference in the frequency, time (for spectrograms only), or both, and power between cursor number one and cursor number two.
- **Channel Power** — Shows the total power in the channel defined by the cursors.

The letter after the value associated with a measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix.

Spectrum Analyzer Channel Measurements Panel

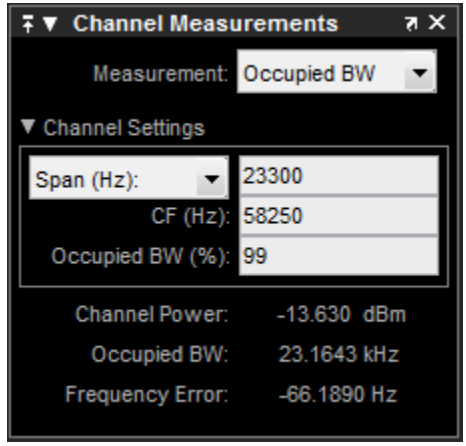
The **Channel Measurements** panel displays occupied bandwidth or adjacent channel power ratio (ACPR) measurements.

- From the menu, select **Tools** > **Measurements** > **Channel Measurements**.
- On the toolbar, click the Channel Measurements button.

In addition to the measurements, the **Channel Measurements** panel has an expandable **Channel Settings** pane.

- **Measurement** — The type of measurement data to display. Available options are `Occupied BW` or `ACPR`. See "Algorithms" (DSP System Toolbox) for information on how Occupied BW is calculated. ACPR is the adjacent channel power ratio, which is the ratio of the main channel power to the adjacent channel power.

When you select `Occupied BW` as the **Measurement**, the following fields appear.



- **Channel Settings** — Modify the parameters for calculating the channel measurements.

  ### Channel Settings for Occupied BW

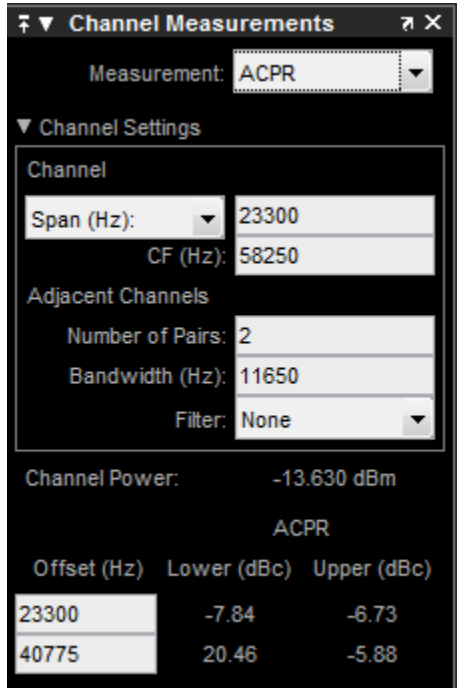
  - Select the frequency span of the channel, `Span (Hz)`, and specify the center frequency **CF (Hz)** of the channel. Alternatively, select the starting frequency,

`FStart(Hz)`, and specify the starting frequency and ending frequency (**FStop (Hz)**) values of the channel.

- **CF (Hz)** — The center frequency of the channel.
- **Occupied BW (%)** — The percentage of the total integrated power of the spectrum centered on the selected channel frequency over which to compute the occupied bandwidth.

- **Channel Power** — The total power in the channel.
- **Occupied BW** — The bandwidth containing the specified **Occupied BW (%)** of the total power of the spectrum. This setting is available only if you select `Occupied BW` as the **Measurement** type.
- **Frequency Error** — The difference between the center of the occupied band and the center frequency (**CF**) of the channel. This setting is available only if you select `Occupied BW` as the **Measurement** type.

When you select `ACPR` as the **Measurement**, the following fields appear.



- **Channel Settings** — Enables you to modify the parameters for calculating the channel measurements.

  ### Channel Settings for ACPR

  - Select the frequency span of the channel, `Span (Hz)`, and specify the center frequency **CF (Hz)** of the channel. Alternatively, select the starting frequency, `FStart(Hz)`, and specify the starting frequency and ending frequency (**FStop (Hz)**) values of the channel.
  - **CF (Hz)** — The center frequency of the channel.
  - **Number of Pairs** — The number of pairs of adjacent channels.
  - **Bandwidth (Hz)** — The bandwidth of the adjacent channels.
  - **Filter** — The filter to use for both main and adjacent channels. Available filters are `None`, `Gaussian`, and `RRC` (root-raised cosine).

- **Channel Power** — The total power in the channel.
- **Offset (Hz)** — The center frequency of the adjacent channel with respect to the center frequency of the main channel. This setting is available only if you select `ACPR` as the **Measurement** type.
- **Lower (dBc)** — The power ratio of the lower sideband to the main channel. This setting is available only if you select `ACPR` as the **Measurement** type.
- **Upper (dBc)** — The power ratio of the upper sideband to the main channel. This setting is available only if you select `ACPR` as the **Measurement** type.

Spectrum Analyzer Distortion Measurements Panel

The **Distortion Measurements** panel displays harmonic distortion and intermodulation distortion measurements.

- From the menu, select **Tools** > **Measurements** > **Distortion Measurements**.
- On the toolbar, click the Distortion Measurements  button.

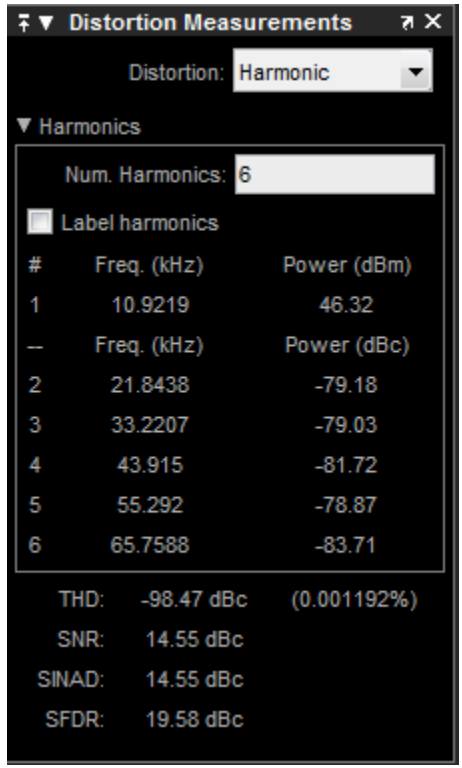
The **Distortion Measurements** panel has an expandable **Harmonics** pane, which shows measurement results for the specified number of harmonics.

Note For an accurate measurement, ensure that the fundamental signal (for harmonics) or primary tones (for intermodulation) is larger than any spurious or harmonic content. To do so, you may need to adjust the resolution bandwidth (`RBW`) of the spectrum analyzer. Make sure that the bandwidth is low enough to isolate the signal and harmonics from spurious and noise content. In general, you should set the RBW so that there is at least a 10dB separation between the peaks of the sinusoids and the noise floor. You may also need to select a different spectral window to obtain a valid measurement.

- **Distortion** — The type of distortion measurements to display. Available options are `Harmonic` or `Intermodulation`. Select `Harmonic` if your system input is a single sinusoid. Select `Intermodulation` if your system input is two equal amplitude sinusoids. Intermodulation can help you determine distortion when only a small portion of the available bandwidth will be used.

  See “Distortion Measurements” (DSP System Toolbox) for information on how distortion measurements are calculated.

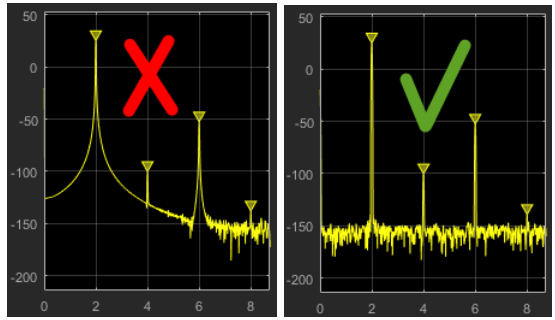
When you select `Harmonic` as the **Distortion**, the following fields appear.



The harmonic distortion measurement automatically locates the largest sinusoidal component (fundamental signal frequency). It then computes the harmonic frequencies and power in each harmonic in your signal. Any DC component is ignored. Any harmonics that are outside the spectrum analyzer's frequency span are not included in the measurements. Adjust your frequency span so that it includes all the desired harmonics.

Note To view the best harmonics, make sure that your fundamental frequency is set high enough to resolve the harmonics. However, this frequency should not be so high that aliasing occurs. For the best display of harmonic distortion, your plot should not show skirts, which indicate frequency leakage. Also, the noise floor should be visible.

For a better display, try a Kaiser window with a large sidelobe attenuation (e.g. between 100–300 db).



- **Num. Harmonics** — Number of harmonics to display, including the fundamental frequency. Valid values of **Num. Harmonics** are from `2` to `99`. The default value is `6`.
- **Label Harmonics** — Select **Label Harmonics** to add numerical labels to each harmonic in the spectrum display.
- **1** — The fundamental frequency, in hertz, and its power, in decibels of the measured power referenced to 1 milliwatt (dBm).
- **2, 3, ...** — The harmonics frequencies, in hertz, and their power in decibels relative to the carrier (dBc). If the harmonics are at the same level or exceed the fundamental frequency, reduce the input power.
- **THD** — The total harmonic distortion. This value represents the ratio of the power in the harmonics, *D*, to the power in the fundamental frequency, *S*. If the noise power is too high in relation to the harmonics, the THD value is not accurate. In this case, lower the resolution bandwidth or select a different spectral window.

  $$THD = 10 \cdot \log_{10}(D / S)$$

- **SNR** — Signal-to-noise ratio (SNR). This value represents the ratio of power in the fundamental frequency, *S*, to the power of all nonharmonic content, *N*, including spurious signals, in decibels relative to the carrier (dBc).

  $$SNR = 10 \cdot \log_{10}(S / N)$$

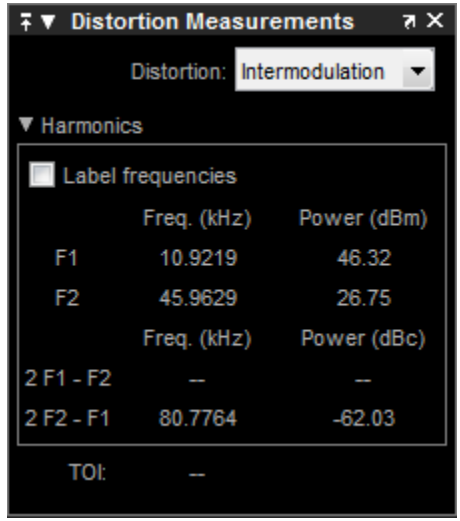
  If you see `--` as the reported SNR, the total non-harmonic content of your signal is less than 30% of the total signal.
- **SINAD** — Signal-to-noise-and-distortion. This value represents the ratio of the power in the fundamental frequency, *S* to all other content (including noise, *N*, and harmonic distortion, *D*), in decibels relative to the carrier (dBc).

$$SINAD = 10 \cdot \log_{10}\left(\frac{S}{N+D}\right)$$

- **SFDR** — Spurious free dynamic range (SFDR). This value represents the ratio of the power in the fundamental frequency, *S*, to power of the largest spurious signal, *R*, regardless of where it falls in the frequency spectrum. The worst spurious signal may or may not be a harmonic of the original signal. SFDR represents the smallest value of a signal that can be distinguished from a large interfering signal. SFDR includes harmonics.

  $$SNR = 10 \cdot \log_{10}(S / R)$$

When you select `Intermodulation` as the **Distortion**, the following fields appear.



The intermodulation distortion measurement automatically locates the fundamental, first-order frequencies (F1 and F2). It then computes the frequencies of the third-order intermodulation products (2*F1-F2 and 2*F2-F1).

- **Label frequencies** — Select **Label frequencies** to add numerical labels to the first-order intermodulation product and third-order frequencies in the spectrum analyzer display.
- **F1** — Lower fundamental first-order frequency
- **F2** — Upper fundamental first-order frequency

- **2F1 - F2** — Lower intermodulation product from third-order harmonics
- **2F2 - F1** — Upper intermodulation product from third-order harmonics
- **TOI** — Third-order intercept point. If the noise power is too high in relation to the harmonics, the TOI value will not be accurate. In this case, you should lower the resolution bandwidth or select a different spectral window. If the TOI has the same amplitude as the input two-tone signal, reduce the power of that input signal.

Spectrum Analyzer Spectral Mask

The **Spectral Mask** panel enables you to add upper and lower masks, modify the mask, and monitor mask statistics. Use spectral masks to:

- Enhance visualizing spectrum limits.
- Compare spectrum values to specification values.

To open the Spectral mask panel, in the toolbar, select the spectral mask button,  .

Set Up Spectral Masks

In the Spectrum Analyzer window:

1. In the Spectral Mask panel, select a **Masks** option.
2. In the **Upper limits** or **Lower limits** box, enter the mask limits as a constant scalar, an array, or a workspace variable name.
3. (Optional) Select additional properties:
   - **Reference level** — Set a reference level for the mask. Enter a specific value or select `Spectrum peak`.
   - **Channel** — Select a channel to use for the mask reference.
   - **Frequency offset** — Set a frequency offset for mask.

Check Spectral Masks

In the Spectrum Analyzer window, select the spectral mask button,  . In the **Spectral Mask** panel, the **Statistics** section shows statistics about how often the masks fail, which channels fail the mask, and which masks are failing. To perform an action every time the mask fails, use the `MaskTestFailed` event. To trigger a function when the mask fails, create a listener to the `MaskTestFailed` event and define a callback function to trigger. For more details about using events, see “Events” (MATLAB).

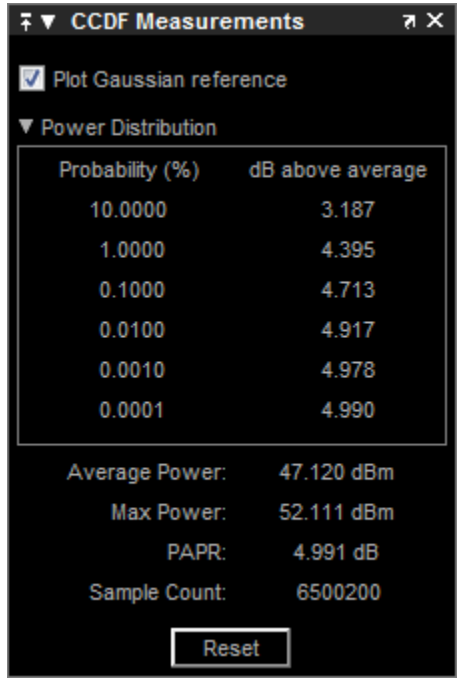
Spectrum Analyzer CCDF Measurements Panel

The **CCDF Measurements** panel displays complimentary cumulative distribution function measurements. CCDF measurements in this scope show the probability of a signal's instantaneous power being a specified level above the signal's average power. These measurements are useful indicators of a signal's dynamic range.

To compute the CCDF measurements, each input sample is quantized to 0.01 dB increments. Using a histogram 100 dB wide (10,000 points at 0.01 dB increments), the largest peak encountered is placed in the last bin of the histogram. If a new peak is encountered, the histogram shifts to make room for that new peak.

To open this dialog box:

- From the menu, select **Tools** > **Measurements** > **CCDF Measurements**
- In the toolbar, click the CCDF Measurements button.



- **Plot Gaussian reference** — Show the Gaussian white noise reference signal on the plot.
- **Probability (%)** — The percentage of the signal that contains the power level above the value listed in the **dB above average** column
- **dB above average** — The expected minimum power level at the associated **Probability (%)**.
- **Average Power** — The average power level of the signal since the start of simulation or from the last reset.

  Max Power — The maximum power level of the signal since the start of simulation or from the last reset.
- **PAPR** — The ratio of the peak power to the average power of the signal. PAPR should be less that 100 dB to obtain accurate CCDF measurements. If PAPR is above 100 dB, only the highest 100 dB power levels are plotted in the display and shown in the distribution table.
- **Sample Count** — The total number of samples used to compute the CCDF.
- **Reset** — Clear all current CCDF measurements and restart.

Common Scope Interactions

In this section...

To visualize your simulation results over time, use a Scope block, Time Scope block, or Time Scope System object™.

Connect Multiple Signals to Scope

To specify the number of input ports and the display layout:

1. Open a scope window.
2. On the Scope, toolbar, click the  button.
3. Click the **Main** tab. In the **Number of input ports** box, enter the number of signal lines you want to connect.
4. Connect signals from block output ports to the scope.

Nonvirtual Bus and Array of Buses Signals

You can connect nonvirtual bus and array of buses signals to a Scope block. To display the bus signals, use normal or accelerator simulation mode. The Scope block displays each bus element signal, in the order the elements appear in the bus, from the top to the bottom. Nested bus elements are flattened. For example, in this model the `nestedBus` signal has the `const`, `subSignal`, and `step` signals as elements. The `subSignal` subbus has the `chirp` and `sine` signals as its bus elements. In the Scope block, the two elements of the `subSignal` bus display between the `const` and `step` signals.

Save Simulation Data Using a Scope Block

This procedure uses the model vdp to demonstrate saving signals to the MATLAB Workspace.

1. Add a Scope block to your model. See “Add Scope and Time Scope Blocks to Model” on page 27-93.
2. Connect signals to scope input ports. See “Connect Multiple Signals to Scope” on page 27-63. For example, connect the signals `x1` and `x2` to a scope.
3. Open the Scope window. From the toolbar, click the Parameters button  .

4 Click the **Logging** tab, and then select the **Log data to workspace** check box. In the **Variable name** box, enter a variable name for saving the data or use the default name `ScopeData`. From the **Save format** list, select `Dataset`. Click **OK**.

   Alternatively, you can set **Save format** to format other than `Dataset` (for example, `Array`).

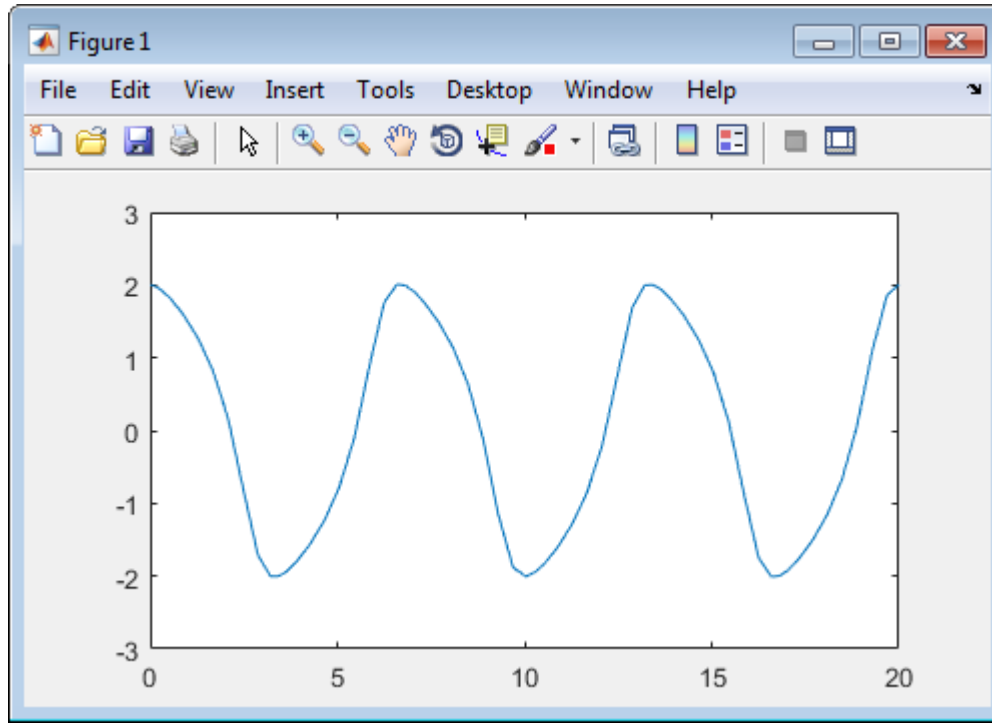
   When saving data from a Scope block, you do not have to select the **Log signal data** property for a signal or the **Signal logging** parameter on the **Model Configuration Parameters** > **Data Import/Export** pane.

   Note To log nonvirtual bus or array of buses signals attached to a Scope block, set the **Save format** parameter to `Dataset`.

5 Run a simulation. Simulink saves data to the MATLAB Workspace in a Dataset object with two elements, one element for each signal.

6 In the MATLAB Command Window, enter these commands to view the logged data from `ScopeData`, where `x1` is the name of a signal:

```
x1_data = ScopeData.getElement('x1').Values.Data
x1_time = ScopeData.getElement('x1').Values.Time
plot(x1_time,x1_data)
```

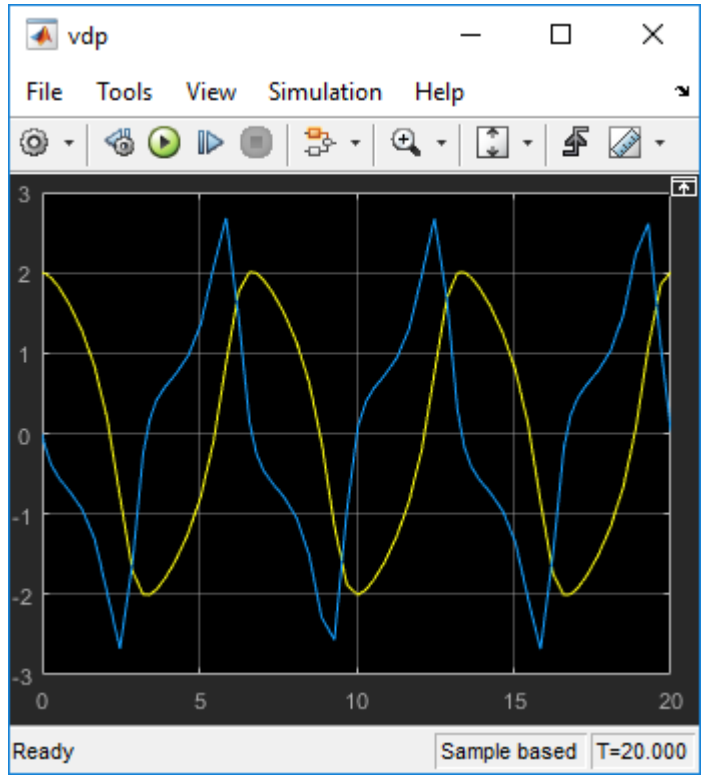


For information about the `Dataset` object, see `Simulink.SimulationData.Dataset`.

Share Scope Image

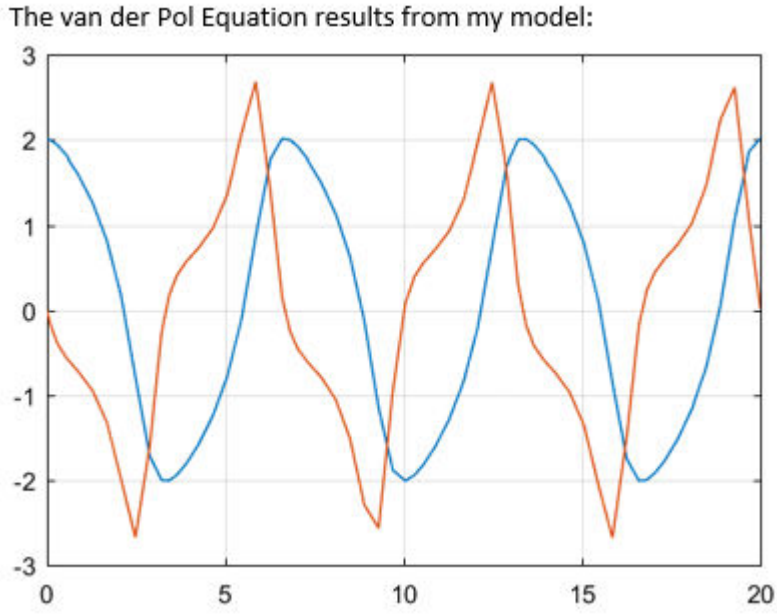
This example uses the model vdp to demonstrate how to copy and paste a scope image.

1. Add a Scope block to your model. See “Add Scope and Time Scope Blocks to Model” on page 27-93.
2. Connect signals to scope ports. See “Connect Multiple Signals to Scope” on page 27-63. For example, in the `vdp` model, connect the signals `x1` and `x2` to a scope.
3. Open the Scope window and run the simulation.



4 Select **File > Copy to Clipboard**.

5 Paste the image into a document. You paste a printer-friendly version of the scope with a white background and visible lines.

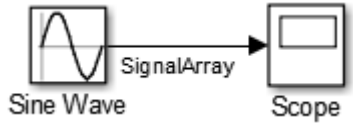


If you want to paste the exact scope plot displayed, select **View > Style**, then select the **Preserve colors for copy to clipboard** check box.

Plot an Array of Signals

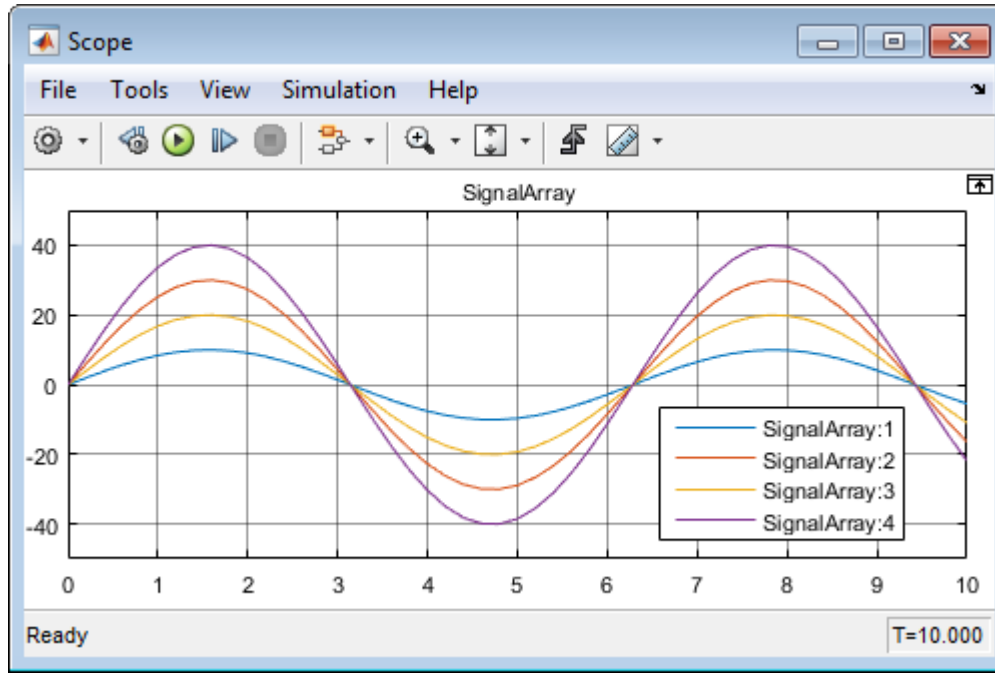
This example takes an array of four sine-wave signals and plots them on a Scope display.

1. Connect a Sine Wave block to a scope block.
2. Open the Scope Configuration Properties dialog box. On the Display pane, select the **Legends** check box.
3. Set the **Amplitude** parameter for the Sine Wave block to `[10 20;30 40]`.
4. Set the **Signal name** property for the signal to `SignalArray`.



5. Simulate the model.

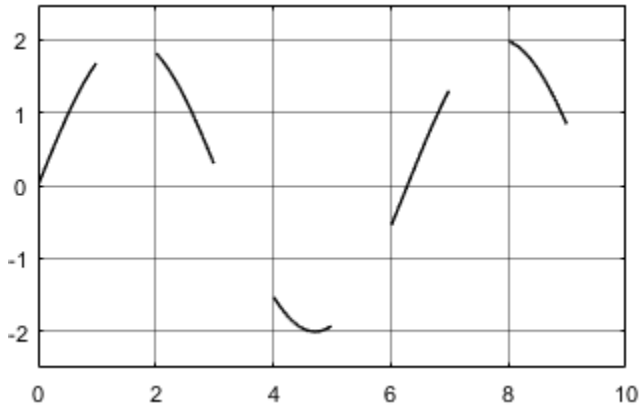
The Scope window displays the four signals in the matrix order (1,1), (2,1), (1,2), (2,2).



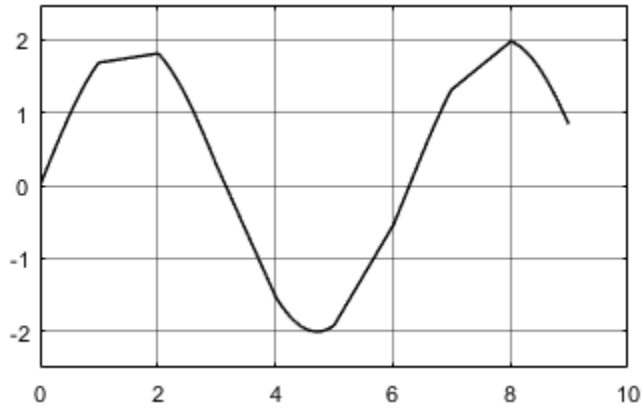
Scopes Within an Enabled Subsystem

When placed within an Enabled Subsystem block, Scope blocks and Scope Viewers behave differently depending on the simulation mode:

- Normal mode — Scope plots data when the subsystem is enabled. The display plot shows gaps when the subsystem is disabled.

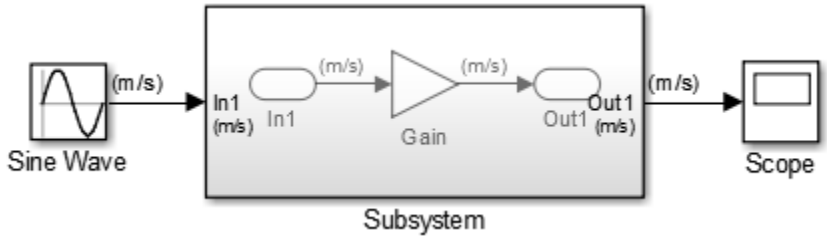


- External, Accelerator, and Rapid modes — Scope plots data when the subsystem is enabled. The display shows draw lines to connect the gaps.



Show Signal Units on a Scope Display

You can specify signal units at a model component boundary (Subsystem and Model blocks) using Inport and Outport blocks. See “Unit Specification in Simulink Models” on page 9-2 . You can then connect a Scope block to an Outport block or a signal originating from an Outport block. This example, the **Unit** property for the Out1 block was set to `m/s`.



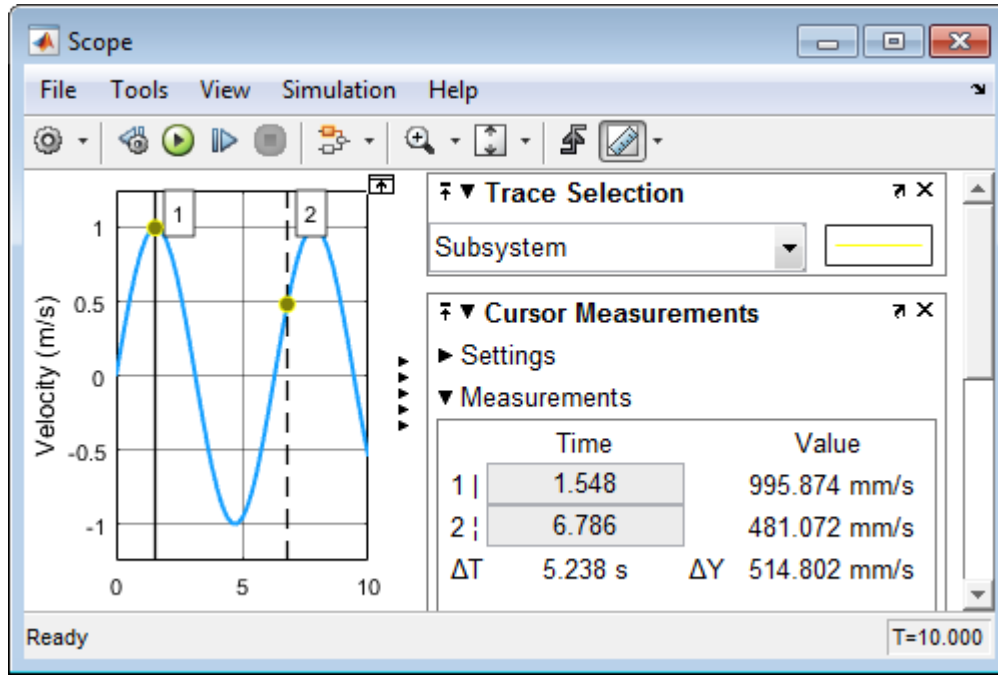
Show Units on a Scope Display

1. From the Scope window toolbar, select the Configuration Properties button  .
2. In the Configuration Properties: Scope dialog box, select the **Display** tab.
3. In the **Y-label** box, enter a title for the y-axis followed by `(%<SignalUnits>)`. For example, enter

   ```
   Velocity (%<SignalUnits>)
   ```

4. Click **OK** or **Apply**.

   Signal units display in the y-axis label as meters per second (`m/s`) and in the Cursor Measurements panel as millimeters per second (`mm/s`).



You can also select **Display > Signals & Ports > Ports Units**. You do not have to enter `(%<SignalUnits>)` in the **Y- Label** property.

Show Units on a Scope Display Programmatically

1 Get the scope properties. In the MATLAB Command Window, enter

```
load_system('my_model')
s = get_param('my_model/Scope','ScopeConfiguration');
```

2 Add a y-axis label to the first display.

```
s.ActiveDisplay = 1
s.YLabel = 'Velocity (%<SignalUnits>)';
```

You can also set the model parameter `ShowPortUnits` to `'on'`. All scopes in your model, with and without `(%<SignalUnits>)` in the **Y-Label** property, show units on the displays.

```
load_system('my_model')
get_param('my_model','ShowPortUnits')
```

```
ans =
off

set_param('my_model', 'ShowPortUnits','on')

ans =
on
```

Determine Units from Logged Data Object

When saving simulation data from a scope with the `Dataset` format, you can find unit information in the `DataInfo` field of the timeseries object.

Note Scope support for signal units is only for the `Dataset` logging format and not for the legacy logging formats `Array`, `Structure`, and `Structure With Time`.

1. From the Scope window toolbar, select the Configuration Properties button  .
2. In the Configuration Properties: Scope dialog box, select the **Logging** tab.
3. Select the **Log data to workspace** check box. In the text box, enter a variable name for saving simulation data. For example, enter `ScopeData`.
4. From the Scope window toolbar, select the Run button  .
5. In the MATLAB Command Window, enter

```
ScopeData.getElement(1).Values.DataInfo

Package: tsdata
Common Properties:
             Units: m/s (Simulink.SimulationData.Unit)
     Interpolation: linear (tsdata.interpolation)
```

Connect Signals with Different Units to a Scope

When there are multiple ports on a scope, Simulink ensures that each port receives data with only one unit. If you try to combine signals with different units, such as by using a Bus Creator block, Simulink returns an error.

Scopes show units depending on the number of ports and displays:

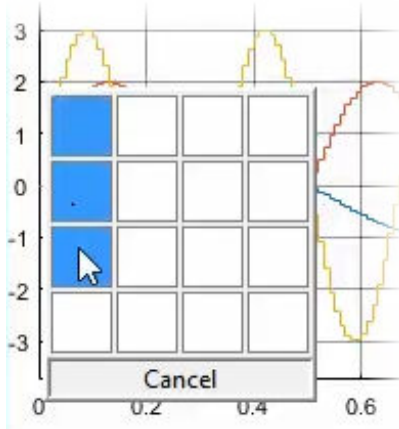
- **Number of ports equal to the number of displays** — One port is assigned to one display with units for the port signal shown on the *y-axis* label.

- **Greater than the number of displays** — One port is assigned to one display, with the last display assigned the remaining signals. Different units are shown on the last *y-axis* label as a comma-separated list.

Select Number of Displays and Layout

1. From a Scope window, select the Configuration Properties button .
2. In the Configuration Properties dialog box, select the **Main** tab, and then Select the **Layout** button.
3. Move your mouse pointer to select the number of displays and the layout you want.

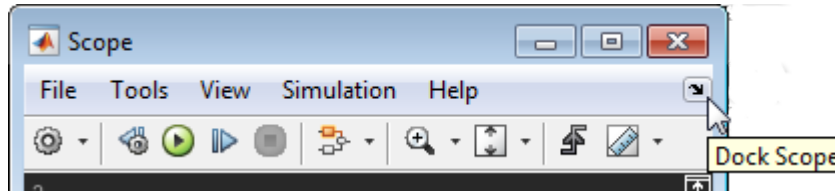
   You can select more than four displays in a row or column. Click within the layout, and then drag your mouse pointer to expand the layout to a maximum of 16 rows by 16 columns.



4. Click to apply the selected layout to the Scope window.

Dock and Undock Scope Window to MATLAB Desktop

1. In the right corner of a Scope window, click the Dock Scope button.



The Scope window is placed above the Command Window in the MATLAB desktop.

2 Click the Show Scope Actions button, and then click **Undock Scope**.

- "Floating Scope and Scope Viewer Tasks" on page 27-77

Floating Scope and Scope Viewer Tasks

In this section...

Add Floating Scope Block to Model

To add a Floating Scope block from the Simulink block library:

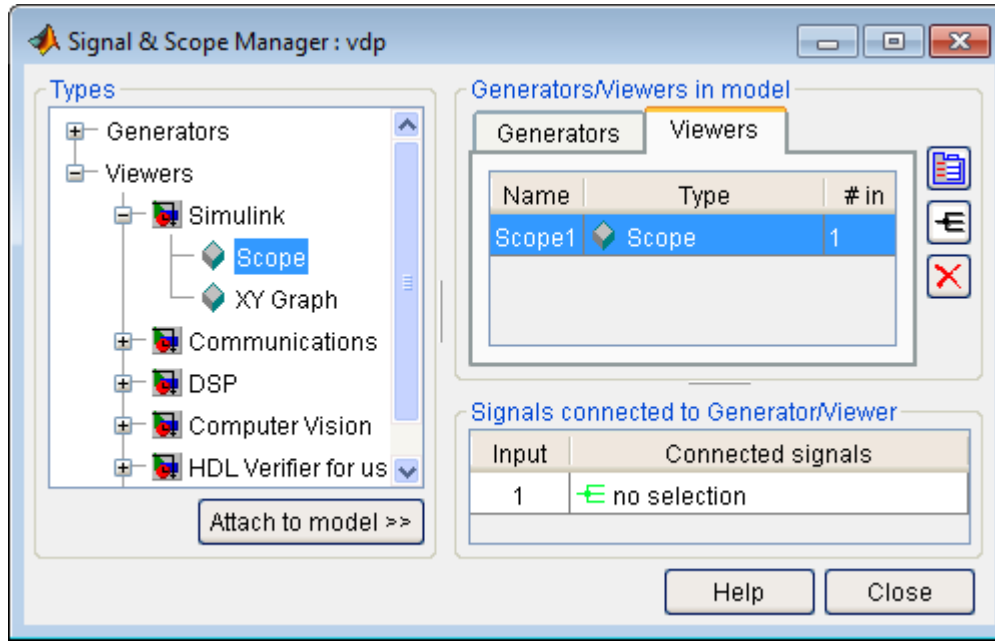
1. From the Simulink Editor menu, click the Library Browser button  .
2. From the Simulink Sinks library, drag a copy of the Floating Scope block to the Simulink Editor.

To add a Floating Scope block by searching from the model diagram:

1. In the Simulink Editor, click the model diagram, and then start typing `floating scope`.
2. From the list, select `Floating Scope Simulink/Sinks`.

Add Scope Viewer with Signal & Scope Manager

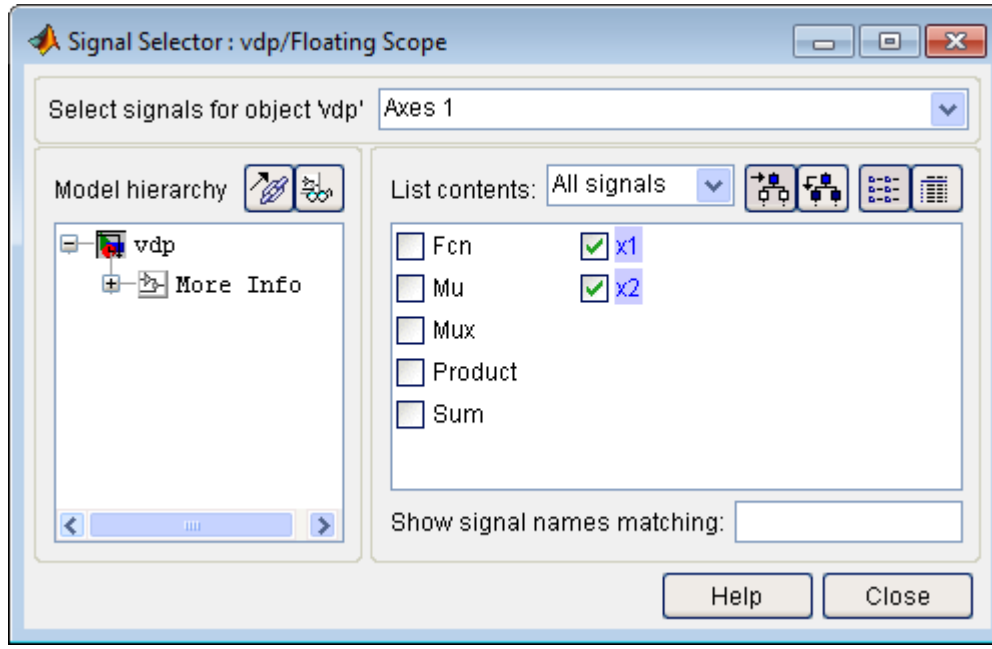
1. From the Simulink Editor menu, select **Diagram** > **Signals & Ports** > **Signal & Scope Manager**.
2. In the Signal & Scope Manager, in the **Types** pane and under the **Viewers** node, expand a product node to show the available viewers.
3. Select a **Scope**, and then click **Attach to model**. The viewer is added to a table on the **Viewers** tab in the **Generators/Viewers in model** pane.



Connect Signals to Floating Scope Block or Scope Viewer

Use the Signal Selector to connect signals to a Floating Scope block or Scope viewer.

1. Open a Scope window. In a Simulink model, double-click a Floating Scope block or Scope viewer icon .
2. Open the Signal Selector. On the Scope window toolbar, click the Signal Selector button .
3. For Scopes with multiple displays, select a display. In the Signal Selector dialog box, select a display from the **Select signals for object** drop-down list.
4. Select check boxes for the signals you want to view.



5 Click **Close** and then run a simulation.

Save Simulation Data Using Floating Scope Block

This procedure uses the model vdp to demonstrate saving signals to the MATLAB Workspace.

1 Add a Floating Scope or Scope Viewer to your model. See “Add Floating Scope Block to Model” on page 27-77or “Add Scope Viewer with Signal & Scope Manager” on page 27-77.

2 Connect signals using the Signal Selector. See “Connect Signals to Floating Scope Block or Scope Viewer” on page 27-78. For example, select the signals `x1` and `x2`.

3 Open a Floating Scope or Scope Viewer window. From the toolbar, click the Parameters button .

4 Click the **Logging** tab, and then select the **Log/Unlog Viewed Signals to Workspace** button.

This selection also sets the **Log signal data** parameter check box for the connected signals. The Simulink Editor places logging symbols on the signals.

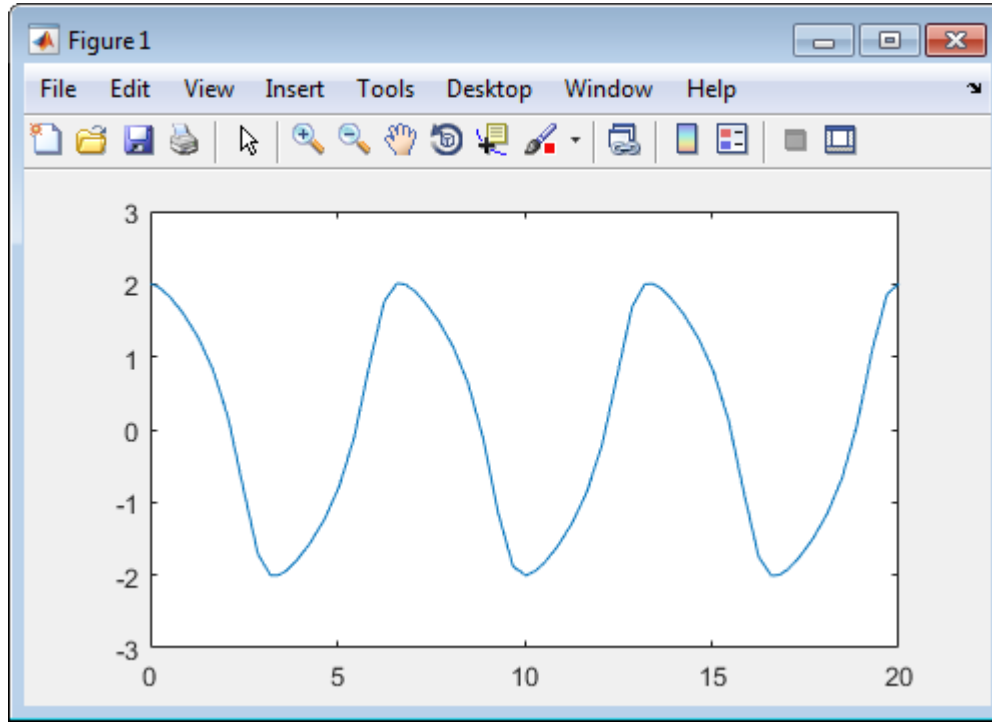
5 Open the **Configuration Parameters** dialog box. From the Simulink Editor menu, select **Simulation > Model Configuration Parameters > Data Import/Export**.

6 Select the **Signal logging** check box. Use the default Dataset object name `logsout` or enter your own name. Click **OK**.

7 Run a simulation. Simulink saves data to the MATLAB Workspace in a Dataset object with two elements, one element for each signal.

8 In the MATLAB Command Window, enter these commands to view the logged data from `logsout`, where `x1` is the name of a signal:

```
x1_data = logsout.get('x1').Values.Data
x1_time = logsout.get('x1').Values.Time
plot(x1_time,x1_data)
```



Run Simulation from Floating Scope Window

1 From a Simulink model, double-click a Floating Scope block.

2 From the toolbar, click the **Run** button .

For information on using toolbar buttons to control a simulation, see "Step Through a Simulation" on page 2-15.

Delete Scope Viewer

1 Right-click any signal line with a viewer attached or click the viewer symbol attached to a signal line.

2 Select **Delete Viewer**, and then select a viewer name.

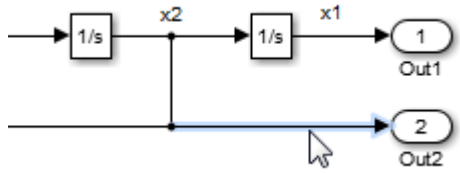
View Signals on a Floating Scope Quickly

1 Open a Floating Scope window.

2 On the toolbar, click the Lock button to unlock the Floating Scope.

Signals that you connected to this scope using the Signal Selector are removed.

3 On the model, click a signal line to select and highlight the signal line. To select multiple signals, hold down the **Shift** key while selecting signals.



4 Run a simulation.

Connect Scope Viewers Without Using Signal Selector

1 Right-click a signal line.

2 Select **Create & Connect Viewer** > **Simulink** > **Scope**.

The selected signal connects to the Scope Viewer, and a viewer symbol  is added to the signal line.

Connect additional signals using the Signal Selector.

Signal Generator Tasks

In this section...

Attach Signal Generator

Using the Context Menu

1. In the Simulink Editor, right-click the input to a block.
2. From the context menu, select **Create & Connect Generator**, the product, and then the generator you want as input to the block.

   The name of the generator you choose appears in a box connected to the block input.
3. Right-click the generator name and select **Generator Parameters**. In the Generator Parameters dialog box, enter values for parameters that are specific to this generator.

Using the Signal and Scope Manager

1. Right-click the input to a block and select **Signal & Scope Manager**.
2. In the **Types** pane and under the Generators node, expand a product node to show the available generators.
3. Select a generator and click **Attach to model**.

   The generator is added to a table in the **Generators** tab in the **Generators/ Viewers in model** section. The table lists the generators in your model.

Attach and Remove Signal Generator

1. Right-click a generator icon on a signal line.
2. From the context menu, select **Disconnect Generator**.

More About

- “Signal and Scope Manager” on page 27-85

Signal and Scope Manager

About the Signal & Scope Manager

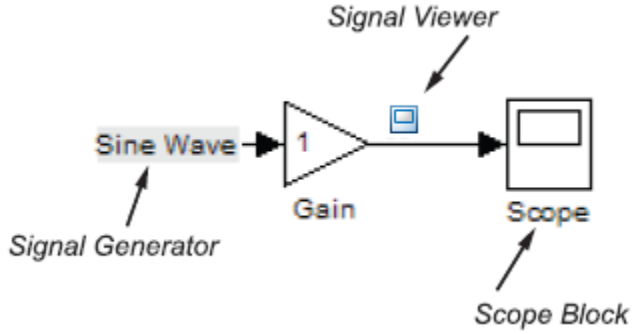
Using the Signal & Scope Manager you can manage viewers and generators from a central point.

Note The Signal and Scope Manager requires that you have Java enabled when you start MATLAB.

Viewer and Generator

Symbols identify a viewer attached to a signal line and signal names identify generators. Manage viewers and generators using the Signal & Scope Manager.

Viewers and generators are not blocks. Blocks are dragged from the Library browser and managed with block dialog boxes.



Change Scope Viewer Parameters

1. Open the Signal & Scope Manager. Right-click the input to a block and select **Signal & Scope Manager**.
2. To the right side of the **Generators** and **Viewers** pane, click the Parameters button  .

   - For a generator, the Generator Parameters dialog box opens.

- For a viewer, a Viewer opens. From the viewer toolbar, select the parameters button  . The Viewer parameters dialog box opens.

3 Review and change parameters.

Connect Viewers and Generators

Connect signals to new viewer or generator using the Signal & Scope Manager.

1 Open the Signal & Scope Manager window. Right-click a signal line, and then select **Signal & Scope Manager**.

2 From the **Types** pane, select a viewer or generator.

3 Click **Attach to model**.

4 Use the "Signal Selector" on page 27-89 to connect the viewer or generator to a signal.

View Test Point Data

Use a Scope viewer available from the Signal and Scope Manager to view any signal that is defined as a test point in a referenced model. A test point is a signal that you can always see when using a Scope viewer in a model.

Note With some viewers (for example, XY Graph, To Video Display, Matrix Viewer, Spectrum Scope, and Vector Scope), you cannot use the Signal Selector to select signals with test points in referenced models.

For more information, see "Test Points" on page 64-62.

Customize Signal & Scope Manager

You can add custom signal viewers or generators so that they appear in the Signal & Scope Manager. The following procedure assumes that you have a custom viewer named `newviewer` that you want to add.

1 Open a new Simulink library.

For example, open the Simulink browser and select **File > New > Library**.

2 Save the library.

   For example, save it as `newlib`.

3 In the MATLAB Command Window, set the library type for the library.

   For example, to set the library type of `newviewer` to `viewer`,

```
set_param('newlib','LibraryType','SSMgrViewerLibrary')
```

   To set library type for generators, use the type `'SSMgrGenLibrary'`.

   For example,

```
set_param('newlib','LibraryType','SSMgrGenLibrary')
```

4 Set the display name of the library.

   For example,

```
set_param('newlib','SSMgrDisplayString','My Custom Library')
```

5 Add the viewer or generator to the library.

Note If the viewer is a compound viewer, such as a subsystem with multiple blocks, make the top-level subsystem an atomic one.

---

6 Set the `iotype` of the viewer.

   For example,

```
set_param('newlib/newviewer','iotype','viewer')
```

7 Save the library `newlib`. In the Simulink window, select **File > Save**.

8 Using the MATLAB editor, create a file named `sl_customization.m`. In this file, enter a directive to incorporate the new library as a viewer library.

   For example, to save `newlib` as a viewer library, add the following lines:

```
function sl_customization(cm)
cm.addSigScopeMgrViewerLibrary('newlib')
%end function
```

   To add a library as a generator library, add a line like the following:

```
cm.addSigScopeMgrGeneratorLibrary('newlib')
```

9 Add a corresponding `cm.addSigScope` line for each viewer or generator library you want to add.

10 Save the `sl_customization.m` file on your MATLAB path. Edit this file to add new viewer or generator libraries.

11 To see the new custom libraries, restart MATLAB and start the Signal & Scope Manager.

Signal Selector

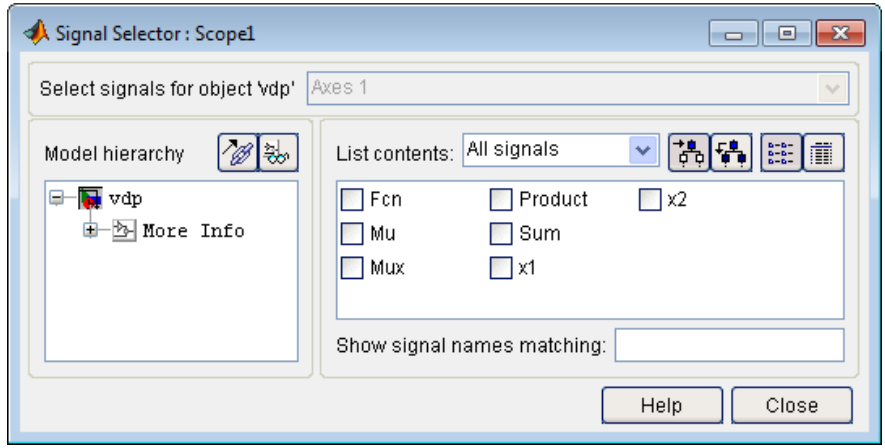
In this section...

About the Signal Selector

Use the Signal Selector to add signals to a Floating Scope or Scope viewer. See “Add Scope Viewer with Signal & Scope Manager” on page 27-77 . To open the Signal Selector,

- Open a Floating Scope. From the menu, select **Simulation > Signal Selector**, or on the toolbar, click the Signal Selector button  .
- Open a model. From the menu, select **Diagram > Signal & Ports > Signal & Scope Manager**. On the right side of the Signal & Scope Manager, click the Signal Selector button  .

The Signal Selector that appears when you click the **Edit signal selection** button applies only to the currently selected generator or viewer. If you want to connect blocks to another generator or viewer object, select the object in the Signal & Scope Manager and then open another instance of the Signal Selector.



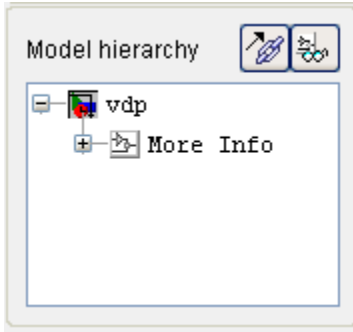
Select Signals

This list box allows you to select the owner output port (in the case of signal generators) or display axis (in the case of viewers) to which you want to connect blocks in your model.

The list box is enabled only if the signal generator has multiple outputs or the viewer has multiple axes.

Model Hierarchy

This tree-structured list lets you select any subsystem in your model.

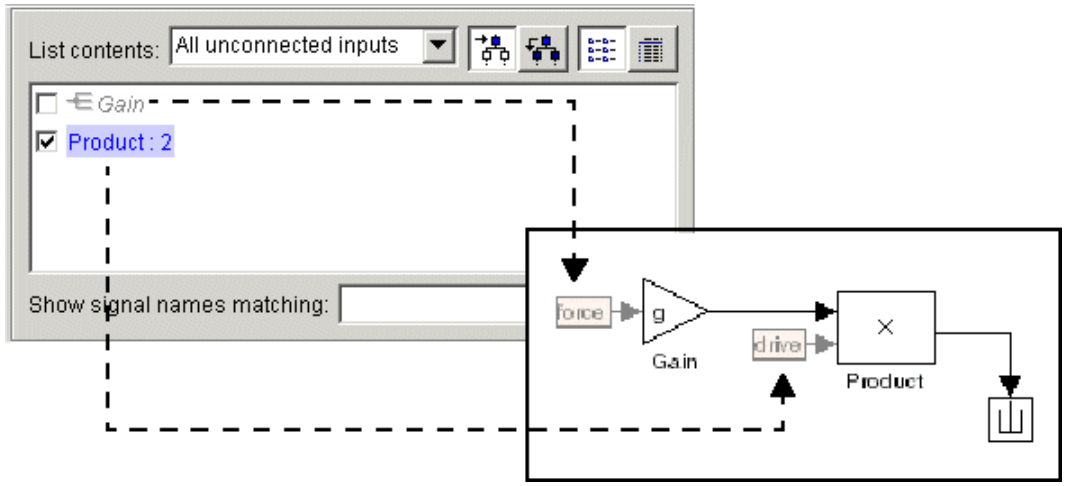


Selecting a subsystem causes the adjacent port list to display the ports available for connection in the selected subsystem. To display subsystems included as library links in your model, click the **Follow links** button at the top of the **Model hierarchy** control. To display subsystems contained by masked subsystems, click the **Look under masks** button at the top of the panel.

Inputs/Signals List

The contents of this panel displays input ports available for connection to the Signal Selector owner if the owner is a signal generator or signals available for connection to the owner if the owner is a viewer.

If the Signal Selector owner is a signal generator, the inputs/signals list by default lists each input port in the system selected in the model hierarchy tree that is either unconnected or connected to a signal generator.



The label for each entry indicates the name of the block of which the port is an input. If the block has more than one input, the label indicates the number of the displayed port. A greyed label indicates that the port is connected to a signal generator other than the Signal Selector owner. Selecting the check box next to a port entry in the list connects the Signal Selector owner to the port, replacing, if necessary, the signal generator previously connected to the port.

To display more information on each signal, click the **Detailed view** button at the top of the pane. The detailed view shows the path and data type of each signal and whether the signal is a test point. The controls at the top and bottom of the panel let you restrict the amount of information shown in the ports list.

- To show named signals only, select `Named signals only` from the **List contents** control at the top of the pane.
- To show only signals selected in the Signal Selector, select `Selected signals only` from the **List contents** control.
- To show test point signals only, select `Testpointed/Logged signals only` from the **List contents** control.
- To show only signals whose signals match a specified string of characters, enter the characters in the **Show signals matching** control at the bottom of the **Signals** pane and press the **Enter** key.

- To show the selected types of signals for all subsystems below the currently selected subsystem in the model hierarchy, click the **Current and Below** button at the top of the **Signals** pane.

To select or clear a signal in the **Signals** pane, click its entry or use the arrow keys to move the selection highlight to the signal entry and press the **Enter** key. You can also move the selection highlight to a signal entry by typing the first few characters of its name (enough to identify it uniquely).

Note You can continue to select and clear signals on the block diagram with the Signal Selector open. For example, shift-clicking a line in the block diagram adds the corresponding signal to the set of signals that you previously selected with the Signal Selector. If the Signal Selector owner is a Floating Scope block and a simulation is running when you open the Signal Selector, Simulink updates the Signal Selector to reflect signal selection changes you have made on the block diagram. However, the changes do not appear until you select the Signal Selector window itself. You can also use the Signal Selector before running a model. If no simulation is running, selecting a signal in the model does not change the Signal Selector.

Control Scopes Programmatically

In this section...

Use Simulink Configuration Object

Use a Scope Configuration object for programmatic access to scope parameters.

- Modify the title, axis labels, and axis limits
- Turn on or off the legend or grid
- Control the number of inputs
- Change the number of displays and which display is active

In this example, the variable `myConfiguration` stores the mask object obtained using `get_param`. The example also shows how to change the value of a Scope parameter.

Create a New Model

```
mdl='myModel';
new_system(mdl);
```

Add Scope and Time Scope Blocks to Model

```
add_block('simulink/Sinks/Scope', [mdl '/myScope']);
add_block('dspsnks4/Time Scope', [mdl '/myTimeScope']);
```

Get a Scope Configuration Object

Many of the scope configuration properties correspond to Scope block parameters.

```
myConfiguration = get_param([mdl '/myScope'],'ScopeConfiguration')
```

```
myConfiguration =

  Scope Configuration with properties:

                              Name: 'myScope'
                          Position: [680 390 560 420]
```

```
                          Visible: 0
                OpenAtSimulationStart: 0
                      DisplayFullPath: 0
    PreserveColorsForCopyToClipboard: 0
                       NumInputPorts: '1'
                    LayoutDimensions: [1 1]
                          SampleTime: '-1'
                FrameBasedProcessing: 0
                        MaximizeAxes: 'Off'
                    MinimizeControls: 0
                         AxesScaling: 'Manual'
                AxesScalingNumUpdates: '10'
                            TimeSpan: 'Auto'
                TimeSpanOverrunAction: 'Wrap'
                           TimeUnits: 'none'
                    TimeDisplayOffset: '0'
                       TimeAxisLabels: 'Bottom'
                    ShowTimeAxisLabel: 0
                        ActiveDisplay: 1
                                Title: '%<SignalLabel>'
                           ShowLegend: 0
                             ShowGrid: 1
                 PlotAsMagnitudePhase: 0
                              YLimits: [-10 10]
                               YLabel: ''
                          DataLogging: 0
              DataLoggingVariableName: 'ScopeData'
            DataLoggingLimitDataPoints: 0
                  DataLoggingMaxPoints: '5000'
              DataLoggingDecimateData: 0
                DataLoggingDecimation: '2'
                DataLoggingSaveFormat: 'Dataset'
```

Set a Property

```
myConfiguration.DataLoggingMaxPoints ='10000';
```

Find Scope and Time Scope Blocks

```
find_system(mdl,'LookUnderMasks','on','IncludeCommented','on', ...
'AllBlocks','on','BlockType','Scope')
```

```
ans =
    'myModel/myScope'
    'myModel/myTimeScope'
```

Find Only Simulink Scope Blocks

```
find_system(mdl,'LookUnderMasks','on','IncludeCommented','on',...
'AllBlocks','on','BlockType','Scope','DefaultConfigurationName',...
'Simulink.scopes.TimeScopeBlockCfg')
```

```
ans =
    'myModel/myScope'
```

Find Only DSP System Toolbox Time Scope Blocks

```
find_system(mdl,'LookUnderMasks','on','IncludeCommented','on',...
'AllBlocks','on','BlockType','Scope','DefaultConfigurationName',...
'spbscopes.TimeScopeBlockCfg')
```

```
ans =
    'myModel/myTimeScope'
```

Scope Configuration Properties

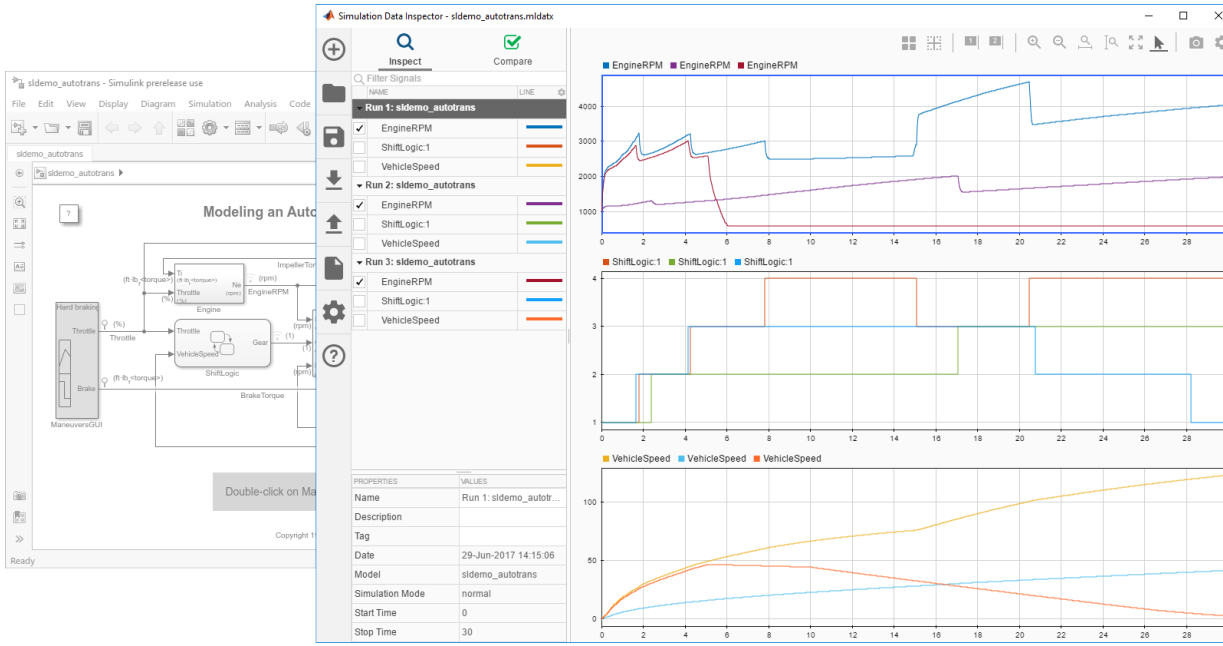
Inspecting and Comparing Simulation Data

Simulation Data Inspector in Your Workflow

The Simulation Data Inspector enables you to inspect and compare time series data at multiple stages of your workflow:

- Inspect and compare simulation data while iteratively modifying the model diagram, parameter values, or configuration.
- Compare simulation outputs for different inputs when testing your model.
- Compare simulation outputs to generated code outputs.



This example workflow shows how the Simulation Data Inspector fits in at several points of a design cycle:

1 “Populate the Simulation Data Inspector with Your Data” on page 28-4.

Run a simulation in a model configured to log data to the Simulation Data Inspector, or import data from the workspace or a MAT-file.

2 “Inspect Simulation Data” on page 28-31.

View signals on multiple plots, zoom in and out on specified plot axes, and use data cursors to understand and evaluate the data. “Create Plots Using the Simulation Data Inspector” on page 28-23 to tell your story.

3 “Compare Simulation Data” on page 28-47

You can compare individual signals or simulation runs and analyze your comparison results with relative, absolute, and time tolerances. The compare tools in the Simulation Data Inspector facilitate iterative design and allow you to highlight signals that do not meet you tolerance requirements. For more information about the comparison operation, see “How the Simulation Data Inspector Compares Data” on page 28-56.

4 “Save and Share Simulation Data Inspector Data and Views” on page 28-16.

Share your findings with others by saving Simulation Data Inspector data and views.

You can also harness the capabilities of the Simulation Data Inspector from the command line. For more information, see “Inspect and Compare Data Programmatically” on page 28-67.

Related Examples

- “Iterate Model Design with the Simulation Data Inspector” on page 28-9
- “Organize Your Simulation Data Inspector Workspace” on page 28-60
- “Keyboard Shortcuts for the Simulation Data Inspector” on page 28-78

Populate the Simulation Data Inspector with Your Data

The Simulation Data Inspector helps you visualize many kinds of data that you generate throughout your design process. The Simulation Data Inspector is empty until you populate it with data. To get your data into the Simulation Data Inspector, you can:

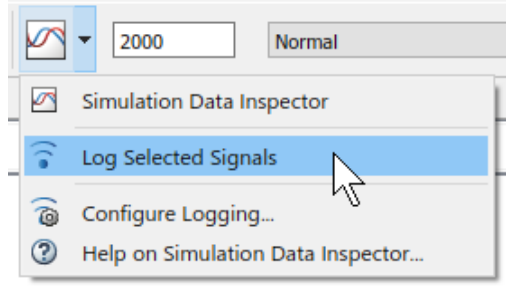
- Select signals to log, and simulate your model.
- Enable recording for logged data, and simulate your model.
- Import data from the base workspace or a MAT-file.
- Open a Simulation Data Inspector session.

Tip To work with data vectors, the Simulation Data Inspector requires at least an associated time vector for your data. In general, the `Array` and `Structure` data formats are not supported unless **Time** is logged. The `Timeseries` data format is preferred because some of the Simulation Data Inspector features work best with metadata that is missing from other formats.

Log Data to the Simulation Data Inspector

You can send data from your model to the Simulation Data Inspector by marking signals for logging. By default, Simulink sends data for logged signals to the workspace and directly to Simulation Data Inspector. To select signals to log:

1. Select one or more signals in the model.
2. On the Simulink Editor toolbar, click the **Simulation Data Inspector** drop-down and select **Log Selected Signals**.



The logging badge marks logged signals in the model.

Alternatively, you can select signals to log using one of the several methods described in Mark a Signal for Logging on page 61-75.

Tip For models with complex hierarchy and many signals of interest, the Model Data Editor can facilitate locating and selecting signals to log. See Inspect and Specify Design Attributes and Instrumentation for Model Data on page 59-141 for more information about the Model Data Editor.

After running one or more simulations with signals marked for logging, click the **Simulation Data Inspector** button on the Simulink editor toolbar and view your data.

To stop logging a signal, right-click the signal in the model and select **Stop Logging Selected Signals**. Alternatively, you can select one or more signals and then select **Stop Logging Selected Signals** from the **Simulation Data Inspector** drop-down on the Simulink Editor toolbar. The logging badge disappears from the signals.

If the simulation mode is set to `Normal`, you can log signals from within reference models.

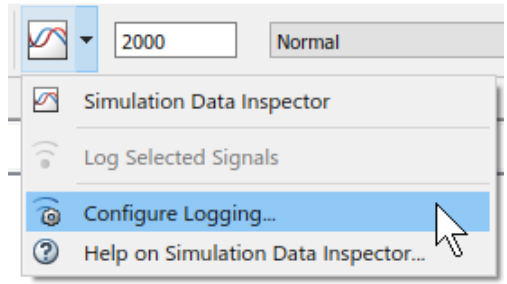
You can configure your model to log signals only to Simulation Data Inspector. To stop logging signal data to the workspace, clear the **Signal Logging** check box in the **Data Import/Export** section of the **Model Configuration Parameters**.

Record Data to the Simulation Data Inspector

States and Simscape data do not log directly to the Simulation Data Inspector and can be recorded instead. Recorded data accumulates during simulation and then automatically imports into the Simulation Data Inspector when the simulation pauses or completes.

States and Simscape data must be logged to the workspace to record to the Simulation Data Inspector. To configure logged data for recording:

1. Click the **Simulation Data Inspector** drop-down on the Simulink Editor toolbar and select **Configure Logging**.



2 In the **Data Import/Export** pane, select **Record logged workspace data in Simulation Data Inspector**.

Note To record **States**, `Dataset` is the recommended **Format**. You can also set **Format** to `Structure with time` or `Array`. If **Format** is configured as `Array`, you must also log **Time** for **States** to record to the Simulation Data Inspector.

3 Click **OK**.

To disable recording, navigate back to the **Data Import/Export** pane of the Configuration Parameters dialog box and clear the check box labeled **Record logged workspace data in Simulation Data Inspector**.

Once you have configured your model to record data, simulate the model to record a run. When the simulation completes, the **Simulation Data Inspector** button appears highlighted to indicate that new simulation data is available in the Simulation Data Inspector.

Import Data into the Simulation Data Inspector

You can import data from the base workspace or a MAT-file into the Simulation Data Inspector. The Simulation Data Inspector allows up to 8000 channels per signal in a run created from imported workspace data.

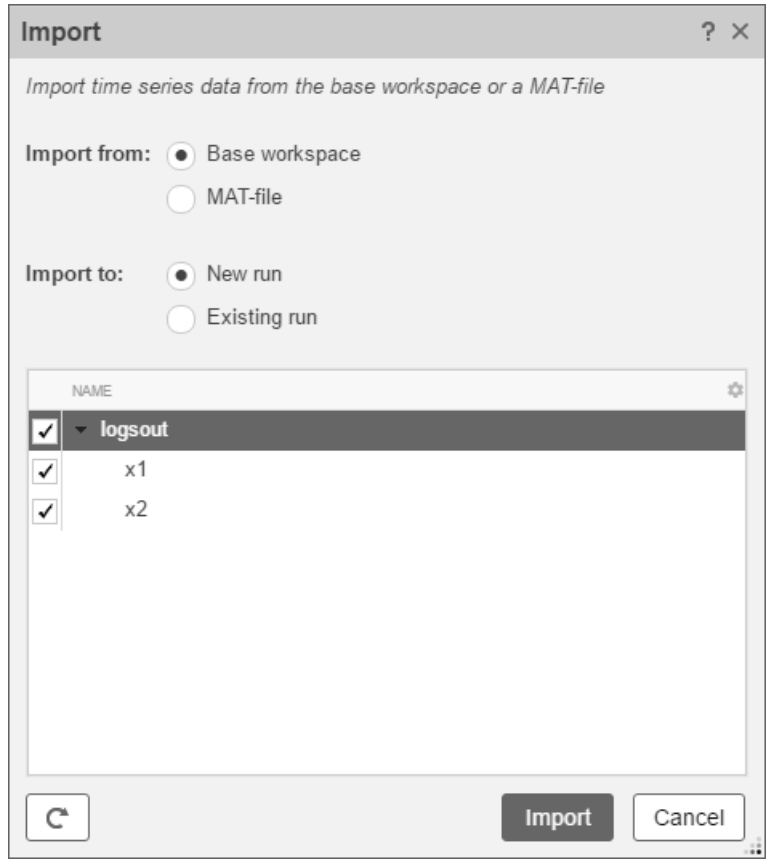
To import data, you have to open the Simulation Data Inspector. Type `Simulink.sdi.view` in the MATLAB Command Window, or you can click the **Simulation Data Inspector** button in the Simulink editor.

Then, to import data:

1 Click the Import button  on the left sidebar.

2 Select the origin of your data as either **Base workspace** or **MAT-file**.

Data available for import populates the table when the source is specified.



3 Select whether you would like to import the data as a new run or to an existing run. When you select the **Existing run** option, the Simulation Data Inspector adds the data to the existing run you select in the drop-down without overwriting any existing signals.

4 Select the signals you want to import.

5 Click **Import**.

The imported signals appear in the **Inspect** pane as a new run or as new signals appended to the specified existing run.

Open a Simulation Data Inspector Session

If you have a Simulation Data Inspector session file, double-click the file to view the data in the Simulation Data Inspector. Alternatively, from the Simulation Data Inspector click the Open button  on the left side bar. Browse to select the desired MLDATX-file, and then click **Open** to view the session file's contents in the Simulation Data Insepctor.

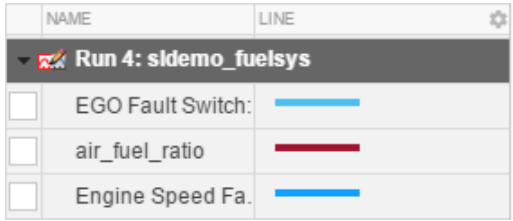
Iterate Model Design with the Simulation Data Inspector

The Simulation Data Inspector facilitates iterative debugging and optimization by providing fast and easy access to visualizations of logged data. You can use the Simulation Data Inspector to view data from your model during simulation and quickly optimize model parameters. Overwrite run mode and data cursors support iterative model and parameter optimization with the Simulation Data Inspector. Overwrite run mode helps prevent clutter, while data cursors facilitate quick and easy inspection of simulation data.

Overwrite Run Mode

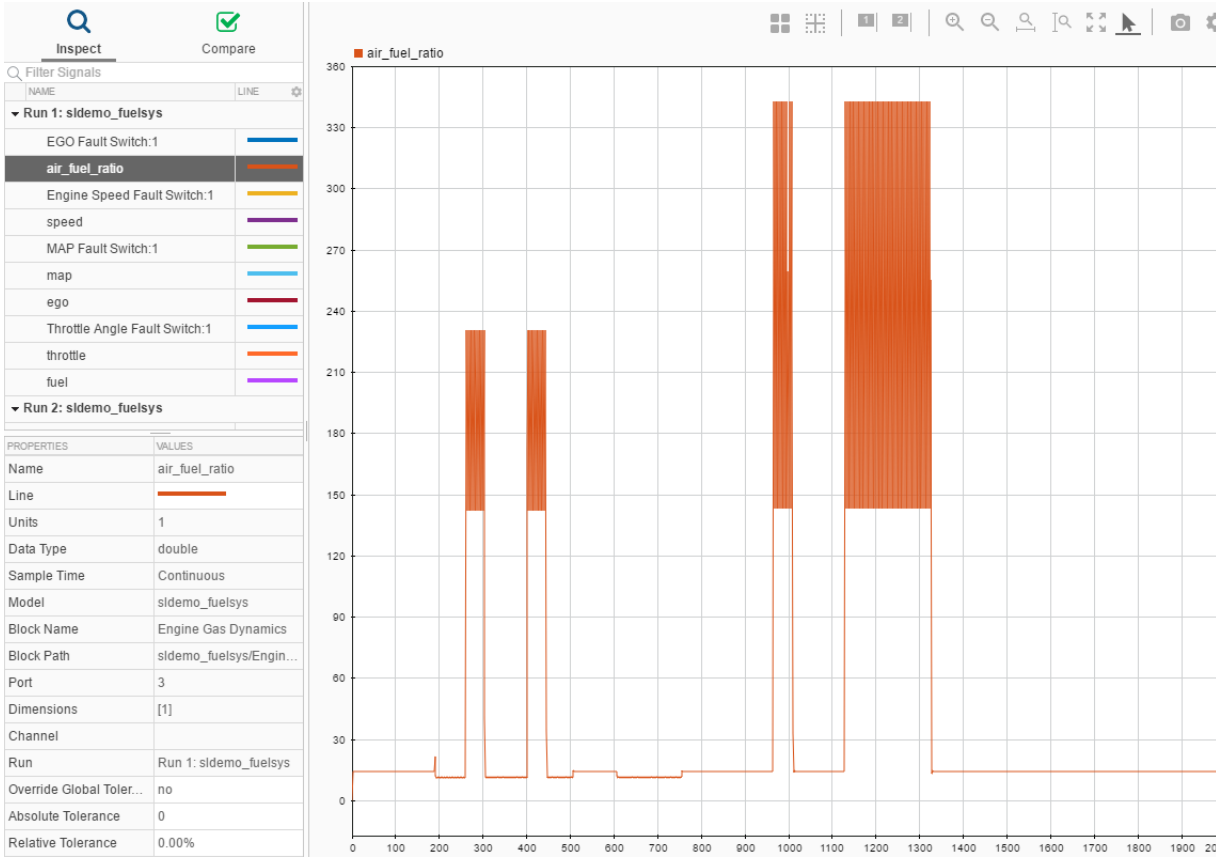
In overwrite run mode, the Simulation Data Inspector clears the data in the run at the start of a new simulation and replaces it with new data. Using overwrite run mode reduces the accumulation of runs in the **Inspect** pane. To enable overwrite run mode, right-click the run and select **Overwrite Run**. The overwrite symbol next to the run indicates that overwrite run mode is on.



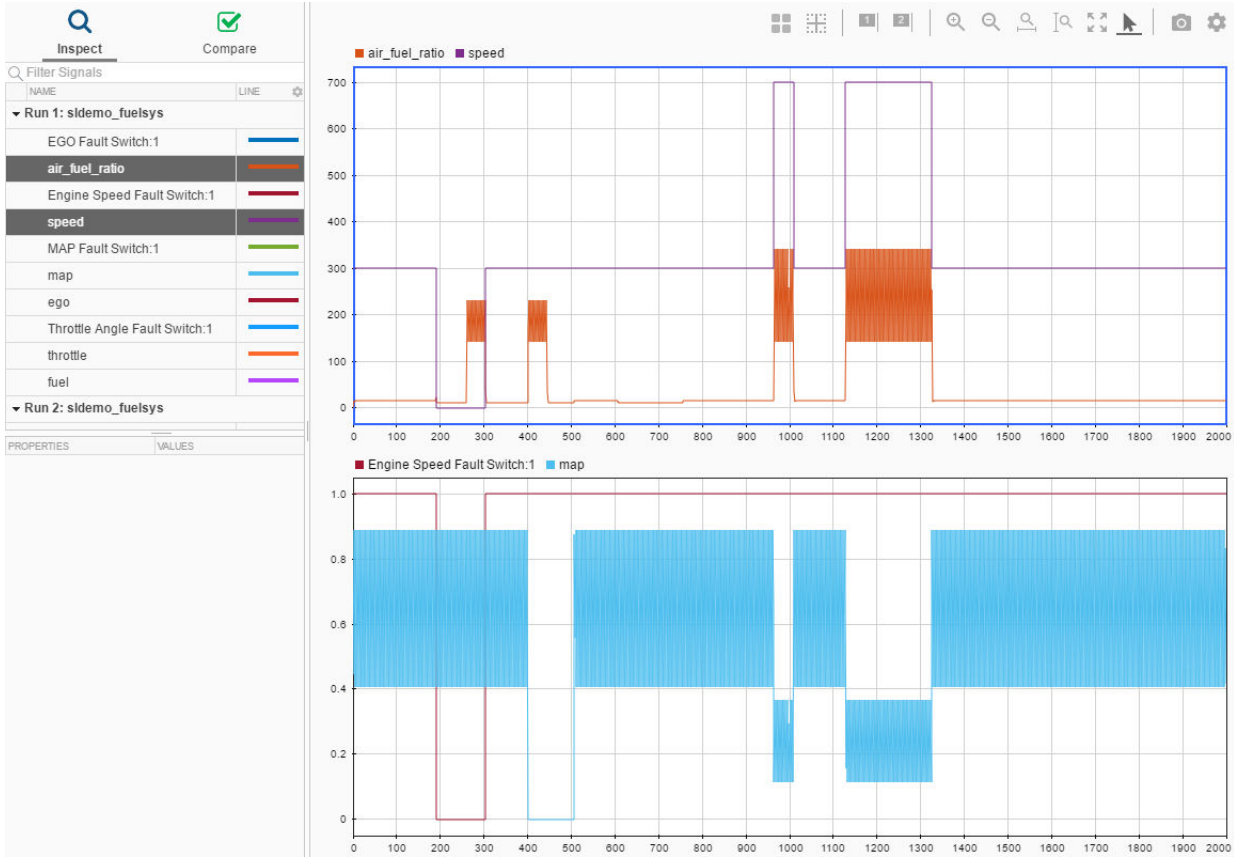
The Simulation Data Inspector plots the incoming data for plotted signals while the new simulation runs. The run remains in overwrite run mode until you disable it. To disable overwrite run mode, right-click the run in the **Inspect** pane and clear the **Overwrite Run** check box.

Browse Mode

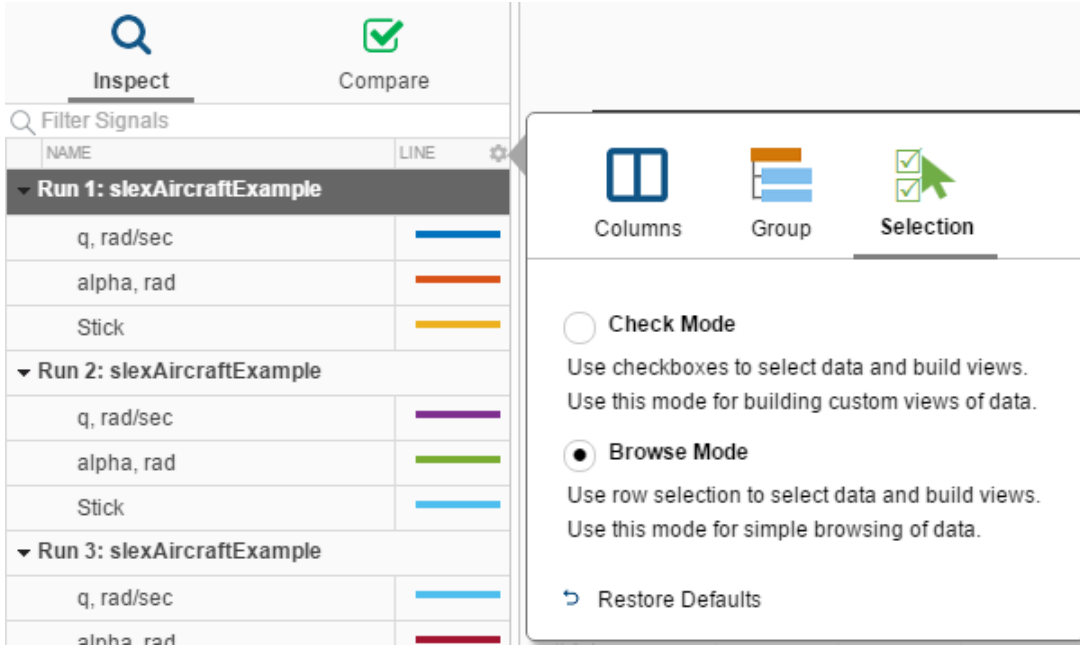
You can use **Browse Mode** to inspect logged signals quickly. In **Browse Mode**, signals selected in the navigation pane are plotted in the graphical viewing area. You can use the arrow keys on your keyboard to change the selected signals, and you can select multiple signals by holding the **Shift** or **Ctrl** keys. When you select a row for a run or hierarchical organization, no signals are displayed in the graphical viewing area.



You can also use plot layouts in **Browse Mode** to make more complex visualizations quickly. When the graphical viewing area contains multiple subplots, selecting new signals with the mouse or keyboard only changes the active plot.



To enable **Browse Mode**, click the gear icon in the navigation pane, and navigate to the **Selection** pane. Click the radio button next to **Browse Mode**.

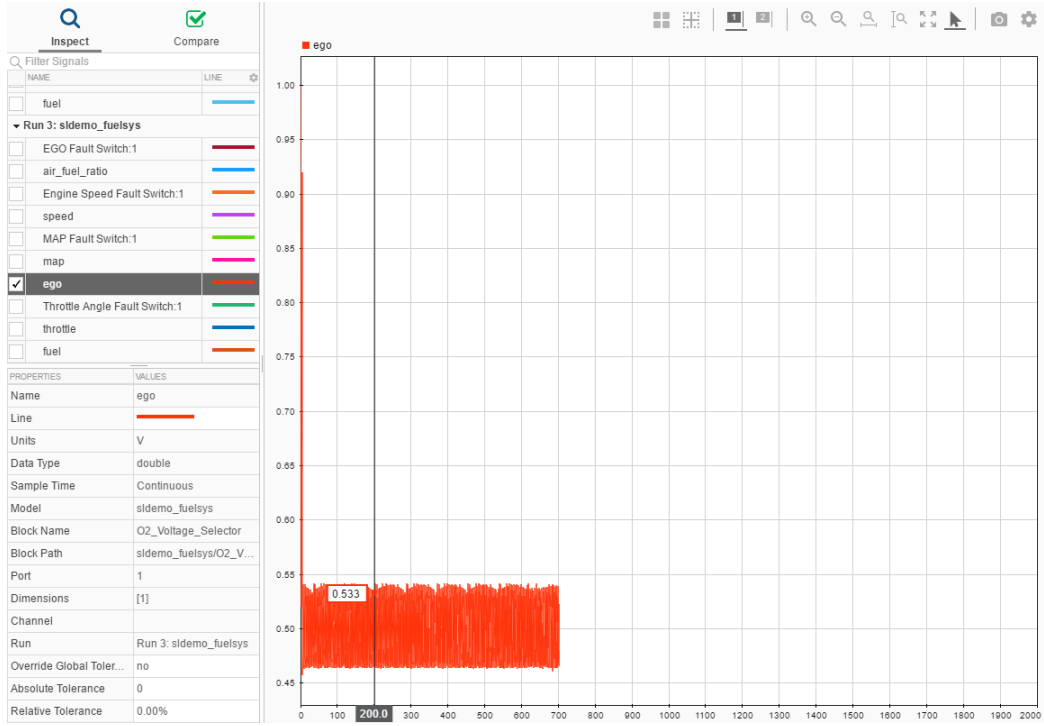


When you have finished browsing your simulation results, enable **Check Mode** to build plots that showcase your data. For more information about creating plots with the Simulation Data Inspector, see “Create Plots Using the Simulation Data Inspector” on page 28-23.

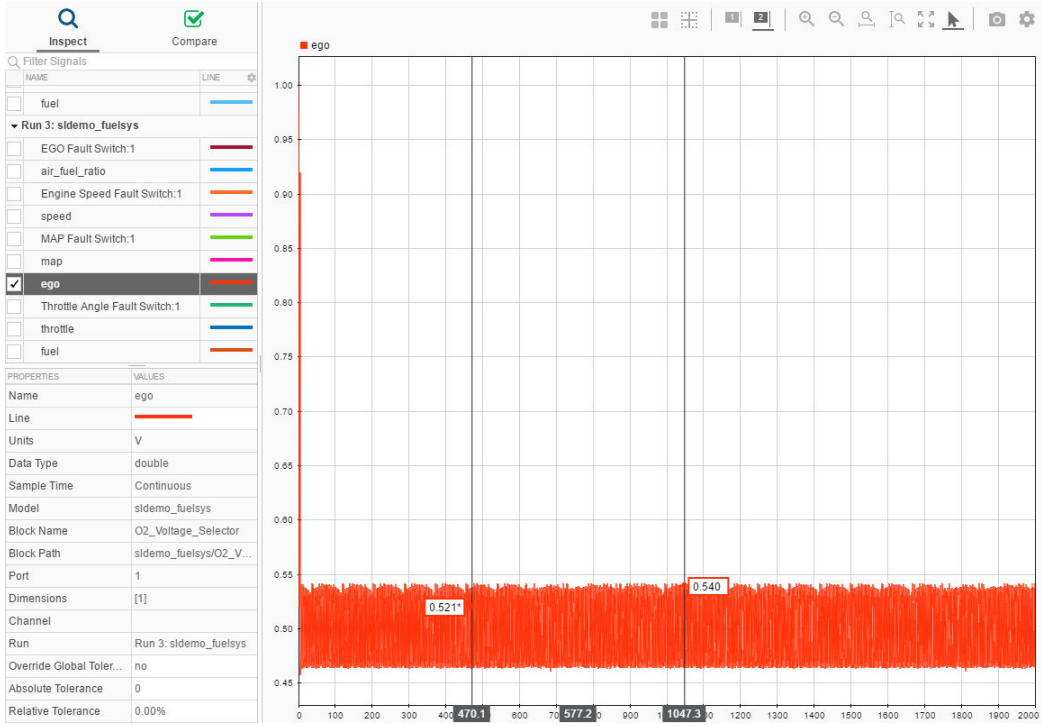
Data Cursors

Data cursors in the Simulation Data Inspector allow you to closely examine signals throughout design iteration. You can add a data cursor to the plot during simulation, while a simulation is paused, or after the simulation has finished. To add a data cursor, click the single cursor button 

. Drag the data cursor across the plot to inspect signal values. When you display multiple signals on a plot, the data cursor indicates the value for each signal in a color-coded box.



Click the two cursors button to add a second data cursor and explore temporal characteristics of your data. You can move each cursor independently, or you can move them together. The number between the two cursors displays the time difference between the cursors based on their current positions.



You can type directly into the box to specify a desired cursor separation. To move the cursors together, click and hold the middle number indicator, and drag it across the graphical viewing area to your desired position. For more information about using data cursors, see “Inspect Simulation Data” on page 28-31.

Save and Share Simulation Data Inspector Data and Views

After you inspect, analyze, or compare your data in the Simulation Data Inspector, you can share your results with others. The Simulation Data Inspector provides several ways for sharing and saving your data and results, depending on your needs. With the Simulation Data Inspector, you can:

- Save your data and layout modifications in a Simulation Data Inspector session.
- Share your layout modifications in a Simulation Data Inspector view.
- Share images and figures of plots you create in the Simulation Data Inspector.
- Create a Simulation Data Inspector report.
- Export your data from the Simulation Data Inspector.

Save and Load Simulation Data Inspector Sessions

If you want to archive or share data along with a configured view in the Simulation Data Inspector, save the Simulation Data Inspector session. You can save sessions as MAT- or MLDATX-files. The default format is MLDATX. When you save a Simulation Data Inspector session, the MLDATX-file contains:

- All runs, data, and properties from the **Inspect** pane.
- Plot display selection for signals in the **Inspect** pane.
- Subplot layout and line style and color selections.

Note Comparison runs and global tolerances are not saved in Simulation Data Inspector sessions.

To save a Simulation Data Inspector session:

1. Hover over the save icon on the left side bar. Then, click **Save As**.

2. Name the file.
3. Browse to the location where you want to save the session, and click **Save**.

For large datsets, a status overlay in the bottom right of the graphical viewing area displays information about the progress of the save operation and allows you to cancel the save operation at any time.

The **Save** tab of the Simulation Data Inspector preferences menu on the left side bar allows you to configure options related to save operations for MLDATX-files. You can set a limit as low as 50MB on the amount of memory used for the save operation. You can also select one of three **Compression** options:

- `None`, the default, applies no compression during the save operation.
- `Normal` creates the smallest file size.
- `Fastest` creates a smaller file size than you would get by selecting `None`, but provides a faster save time than `Normal`.

To load a Simulation Data Inspector session, click the open icon  on the left side bar. Then, browse to select the MLDATX-file you want to open, and click **Open**.

Alternatively, you can double-click the MLDATX-file. MATLAB and the Simulation Data Inspector open if they are not already open.

Share Simulation Data Inspector Views

When you have different sets of data that you want to visualize the same way, you can save a view. A view saves the layout and appearance characteristics of the Simulation Data Inspector without saving any of the data. Specifically, a view saves:

- Plot layout, axis ranges, linking characteristics, and normalized axes.
- Location of signals in the plots.
- Signal grouping and columns on display in the **Inspect** pane.
- Signal color and line styling.

To save a view:

1. Click the layout button  .
2. Click **Save current view**.

3 In the dialog box, specify a name for the view and browse to the location where you would like to save the MLDATX-file.

4 Click **Save**.

To load a view:

1 Click the layout button  .

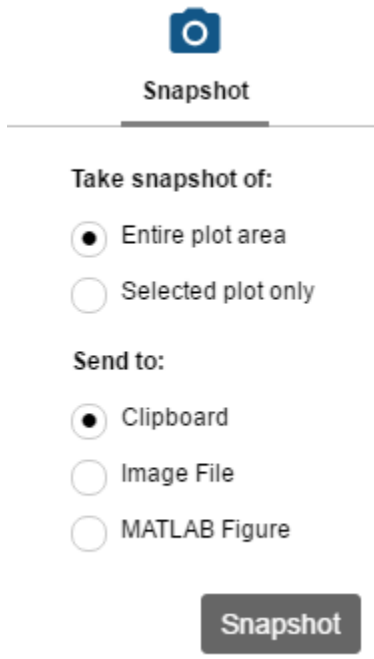
2 Click **Open saved view**.

3 Browse to the view you would like to load, and click **Open**.

Share Simulation Data Inspector Plots

Use the snapshot feature to share the plots you generate in the Simulation Data Inspector. You can export your plots to the clipboard to paste into a document, as an image file, or to a MATLAB figure. You can choose to capture the entire plot area, including all subplots in the plot area, or to capture only the selected subplot.

Click the camera icon  on the toolbar to access the snapshot menu. Use the radio buttons to select the area you want to share and how you want to share the plot. After you make your selections, click **Snapshot** to export the plot.



If you create an image, select where you would like to save the image in the file browser.

Create a Simulation Data Inspector Report

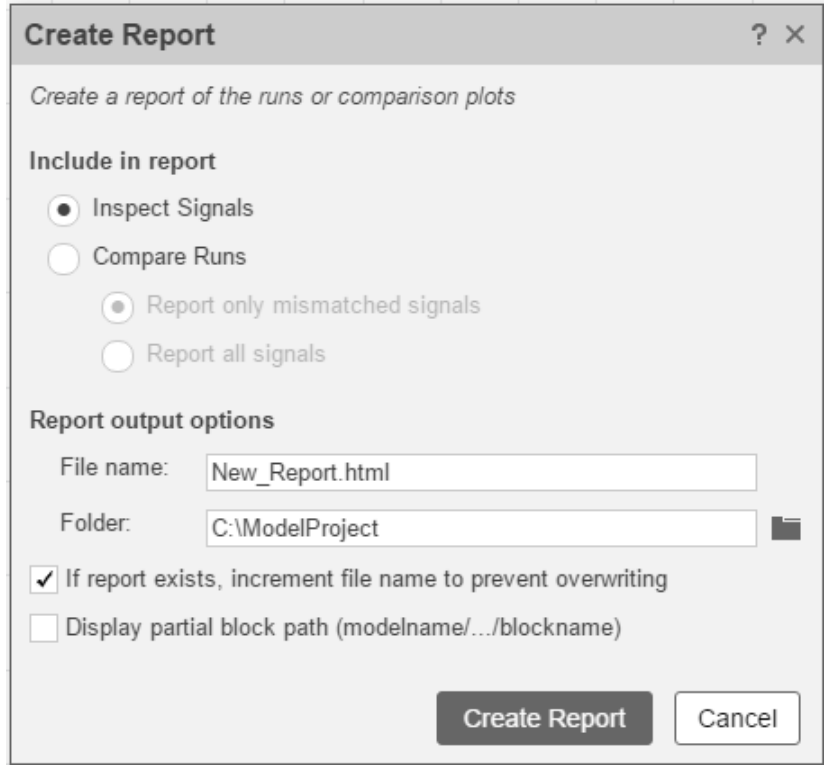
To generate documentation of your results quickly, create a Simulation Data Inspector report. You can create a report of your data in either the **Inspect** or the **Compare** pane. The report is an HTML file that includes information about all the signals and all plots in the active pane. The report includes all signal information displayed in the signal table in the navigation pane. For more information about configuring the table, see “Inspect Metadata” on page 28-41.

To generate a Simulation Data Inspector Report:

1. Click the create report icon  on the left side bar.

2 Under **Include in report**, specify the type of report you want to create.

- Select **Inspect Signals** to include the plots and signals from the **Inspect** pane.
- Select **Compare Runs** to include the data and plots from the **Compare** pane. When you generate a **Compare Runs** report, you can choose to **Report only mismatched signals** or to **Report all signals**. If you select **Report only mismatched signals**, the report shows only signal comparisons that are not within the specified tolerances.



3 Specify a **File name** for the report, and navigate to the **Folder** where you want to save the report.

4 Click **Create Report**.

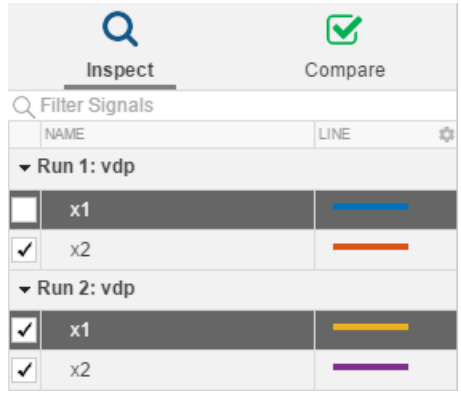
The generated report automatically opens in your default browser.

Export Data from the Simulation Data Inspector

You can use the Simulation Data Inspector to export data from the **Inspect** or **Compare** panes to the base workspace or a MAT-file. You can only export data from one pane at a time. When you export data from the Simulation Data Inspector to a MAT-file, the MAT-file contains the signal data and names and the interpolation method used to plot the signals. If you export multiple signals, the Simulation Data Inspector also saves the block path and port index for each signal. To export data:

1. Select all the signals and runs you want to export on either the **Inspect** or **Compare** pane.

   Only the selected runs and signals are exported. In this example, only the `x1` signals from Run 1 and Run 2 are exported. The check box selections for the plotting area do not affect whether a signal is exported.



2. 

   Either right-click a signal and select **Export Data** or click the export button on the left side bar.

3. In the Export dialog box, choose whether to export the selected data to the base workspace or a MAT-file.
4. Specify the variable name or the file name.
5. Click **Export**.

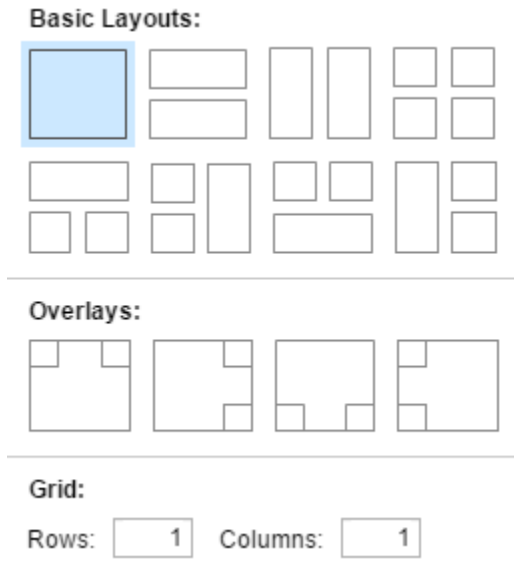
Create Plots Using the Simulation Data Inspector

Plots can help showcase important features or trends in your data and share your findings with others. The Simulation Data Inspector allows you to select from a variety of plot layouts and customize plot and signal appearances to present your data most effectively. This topic builds from the example in “Inspect Simulation Data” on page 28-31.

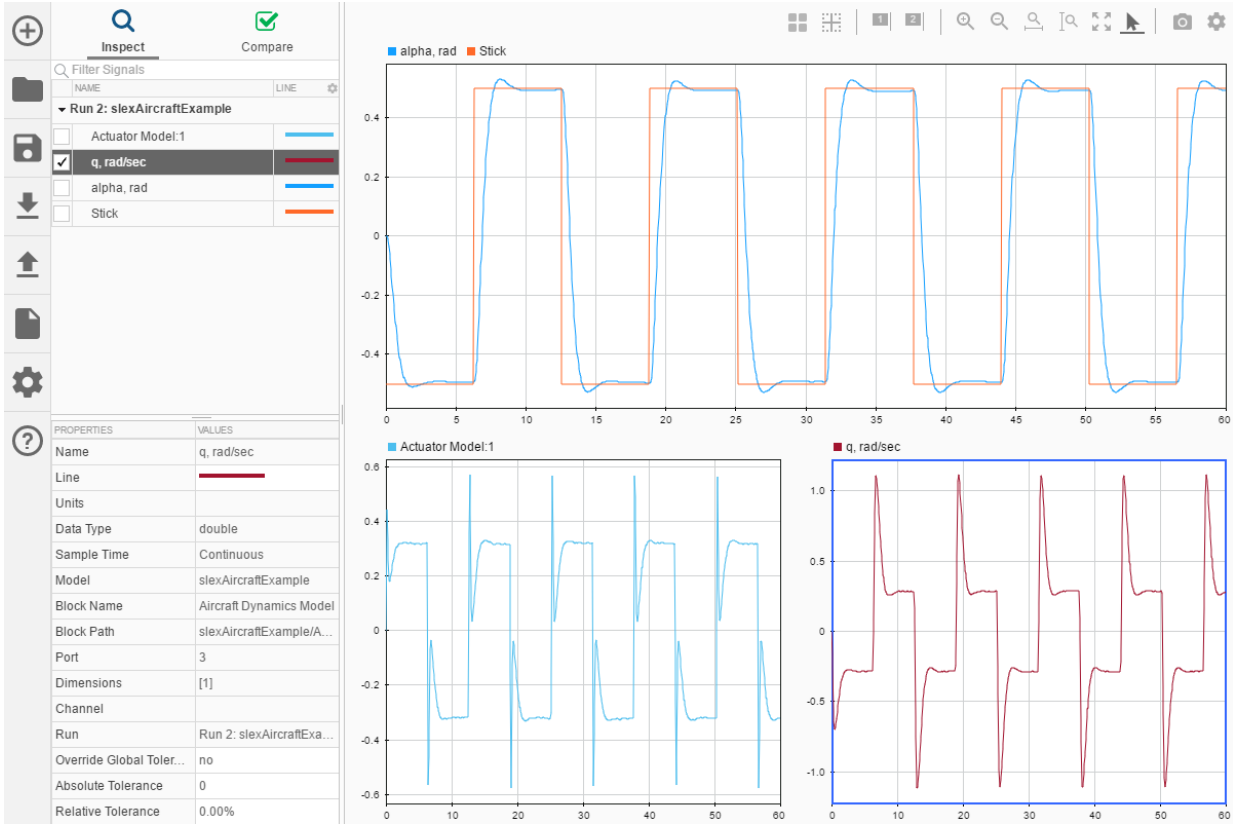
Plot Layouts

The Simulation Data Inspector allows you to select from three types of layouts under the plot layout menu  .



- **Basic Layouts** include templates for two or three subplot layouts.
- **Overlays** options have overlay subplots in two corners of the main plot.
- **Grid** layouts create a grid of subplots from `1×1` to `8×8`.

You can select the plot layout that best highlights the characteristics of your data. For example, with a basic three plot layout, you can use the large plot to show a main result and show intermediate signals on the smaller plots.



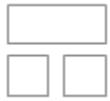
Moving Between Subplot Layouts

When you plot a signal on a subplot, the Simulation Data Inspector links the signal to the subplot, identifying the subplot with a number. As you move between subplot layouts, the association between the signal and subplot remains, even as the shape or visibility of the subplot may change. The **Basic Layouts** and **Overlays** subplot numbering are based on the columnwise numbering used for the grids layout.

Subplots of **Grid** layouts follow columnwise numbering, from `1` at the top left subplot to `8` in the bottom left, to `64` at the bottom right. The number system is fixed, regardless of which subplot configuration you select. For example, if you display four subplots in a `2×2` configuration, the bottom right subplot of the configuration is numbered `10`, not `4`. The

number is `10` because in the largest possible `8×8` matrix, that subplot is numbered `10` when you count the subplots in a columnwise manner.

Basic Layouts subplots also use the fixed `8×8` columnwise numbering as a base. For example, the top plot in this three-subplot layout is subplot `1`, and the two subplots below it are `2` and `10`.

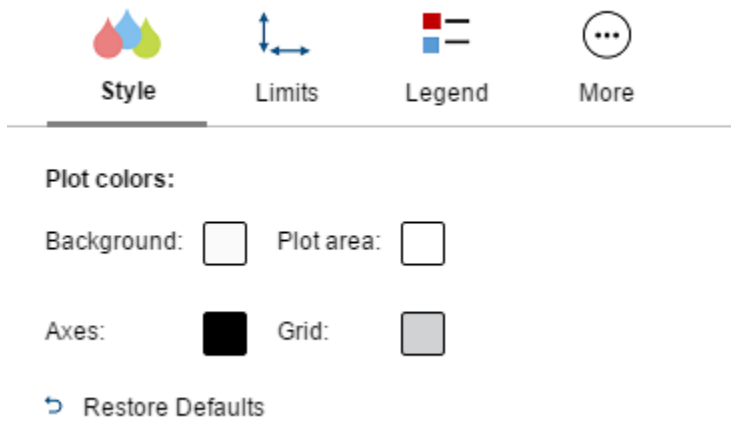


In this three-subplot layout, the index for the right subplot is `9`, and the indices for the two subplots on the left are `1` and `2`.

For the **Overlays** layouts, the index for the main plot is always `1`, and the indices for the overlaid plots are `2` and `9`.

Customize Plot Appearance

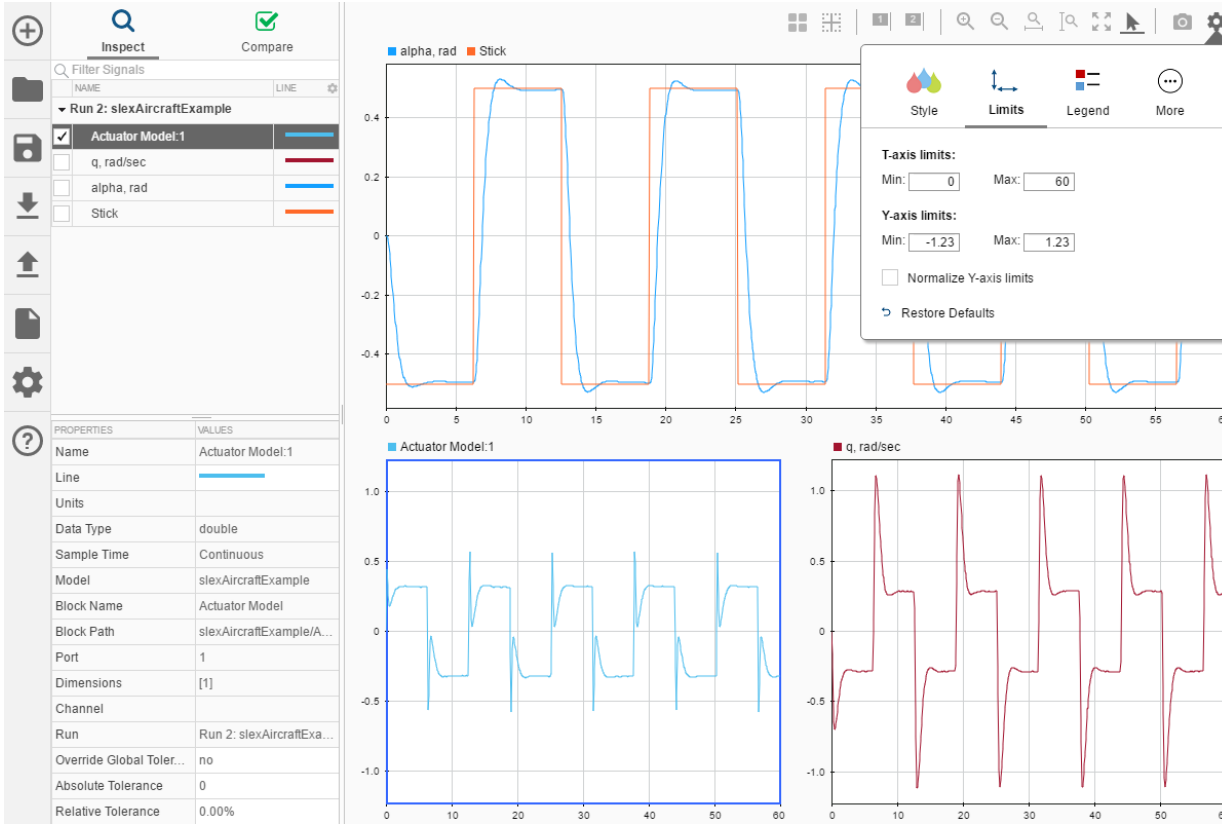
Once you have chosen a plot layout, you can customize the appearance of the Simulation Data Inspector plot area using the menus under the **Plot Area Settings** button .



On the **Style** tab, you can change the colors of plot features, such as the grid and axes. For example, you might change the **Background** of a plot you want to print to white to save printer ink.

The **Limits** tab gives you control over the limits of the *t*- and *y*-axes. You may also choose to normalize the *y*-axis. To improve the basic layout plot created in the previous section, change the *y*-axis limits of the left graph to match those on the right.

1. Select the `q, rad/sec` plot to view its y-axis limits in the **Limits** tab.
2. Select the `Actuator Model: 1` plot as the active plot.
3. On the **Limits** tab, change the y-axis limits of the `Actuator Model: 1` plot to match the limits of the `q, rad/sec` plot.



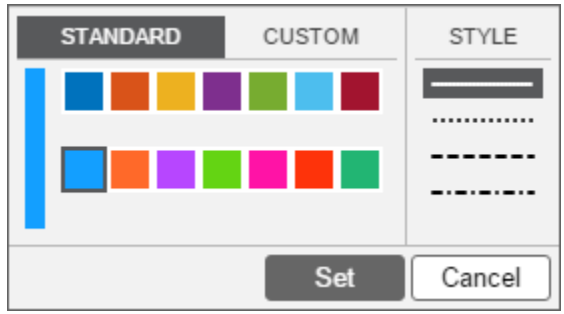
On the **Legend** tab, you can control the legend location and visibility. The selections on the **Legend** tab apply to all subplots.

On the **More** tab, you can choose whether to display data markers. The **Show Markers** selection applies to all plotted signals.

You can clear the active subplot or all subplots using the clear subplots menu on the toolbar. 

Customize Signal Appearance

The Simulation Data Inspector allows you to modify the color and style of each signal individually. For each signal, you can select from a palette of standard colors or specify a custom color with `RGB` values.



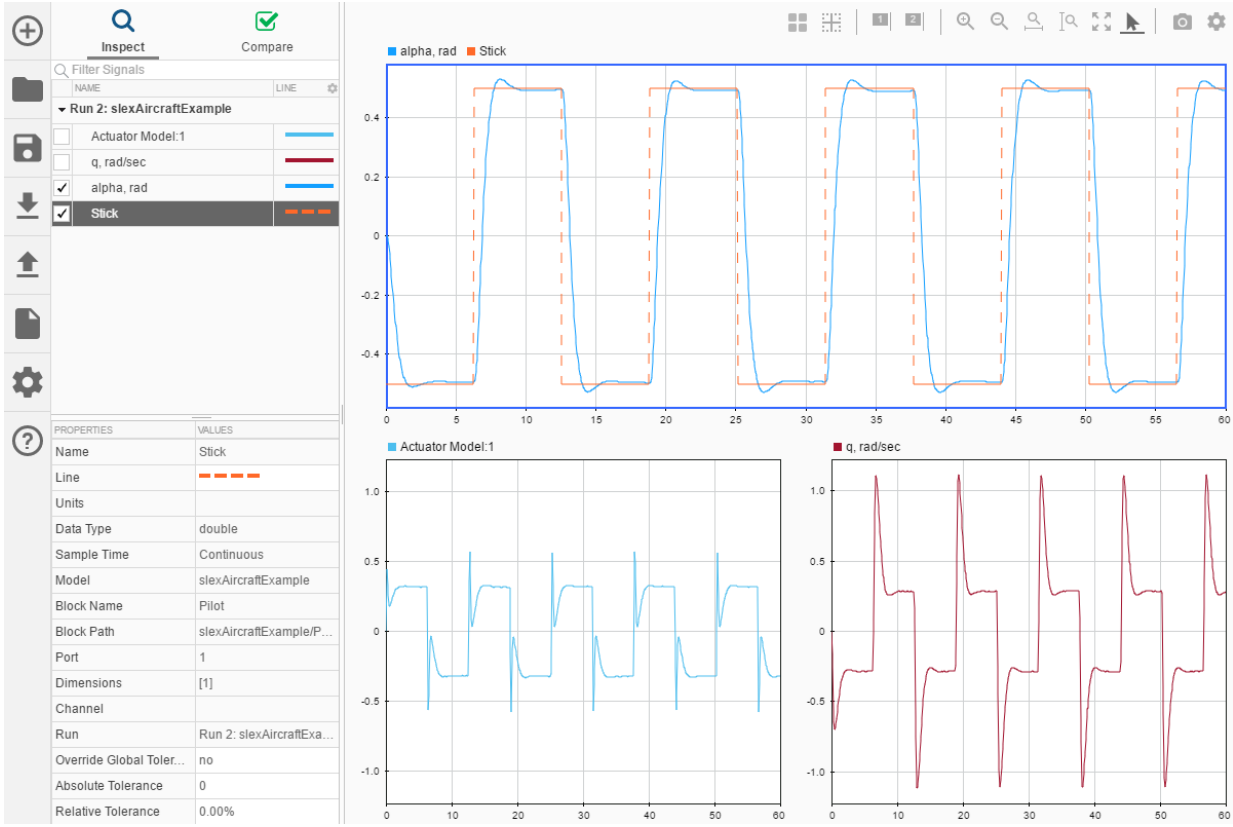
You can access the line style menu for a signal from several places:

- Click the graphic representation in the **Line** column of the navigation pane.
- From the Simulink Editor, right-click the logging badge, and select **Properties** to open the **Visualization Properties** dialog. Then, click the graphic representation of the **Line**.

  From the **Visualization Properties** dialog, you can also select subplots where you want to plot the signal. Changes made through the **Visualization Properties** dialog box take effect for subsequent simulations.

Line style customization can help emphasize differences between signals in your plot. For example, change the line style of the `Stick` signal to dashed to visually indicate that it is an ideal signal.

1. Click the **Line** column for the `Stick` signal.
2. Select the dashed option (third in the list).
3. Click **Set**.



The `alpha, rad` and `Actuator Model: 1` signals are very close in color. You can select bold, easily distinguishable colors for all of the signals in your plot.

1. Select the `Actuator Model: 1` signal in the navigation pane.
2. Click the **Line** row entry in the properties pane.
3. Specify your desired color.
4. Click **Set**.

More About

- “Save and Share Simulation Data Inspector Data and Views” on page 28-16
- “Inspect Simulation Data” on page 28-31
- “Compare Simulation Data” on page 28-47

Inspect Simulation Data

You can use the Simulation Data Inspector to view and inspect signals from simulations or from imported data. The Simulation Data Inspector provides a comprehensive view of your data by allowing you to group data from multiple simulations on multiple plots. You can also use data cursors for close examination of signal values.

This example shows you how to view and inspect signal data from the `slexAircraftExample` model using the Simulation Data Inspector.

Configure Signals for Logging

This example uses signal logging to send data to the Simulation Data Inspector. You can also record logged simulation data or import signal data from the base workspace or a MAT-file. For more information, see "Populate the Simulation Data Inspector with Your Data" on page 28-4. Open the `slexAircraftExample` model, mark signals for logging, and run a simulation.

1. To open the model, enter `slexAircraftExample` in the MATLAB Command Window.
2. To log the `q, rad/sec`, the `Stick`, and the `alpha, rad` signals to the Simulation Data Inspector, select the signals in the model. Then, click the **Simulation Data Inspector** drop-down, and select **Log Selected Signals**.

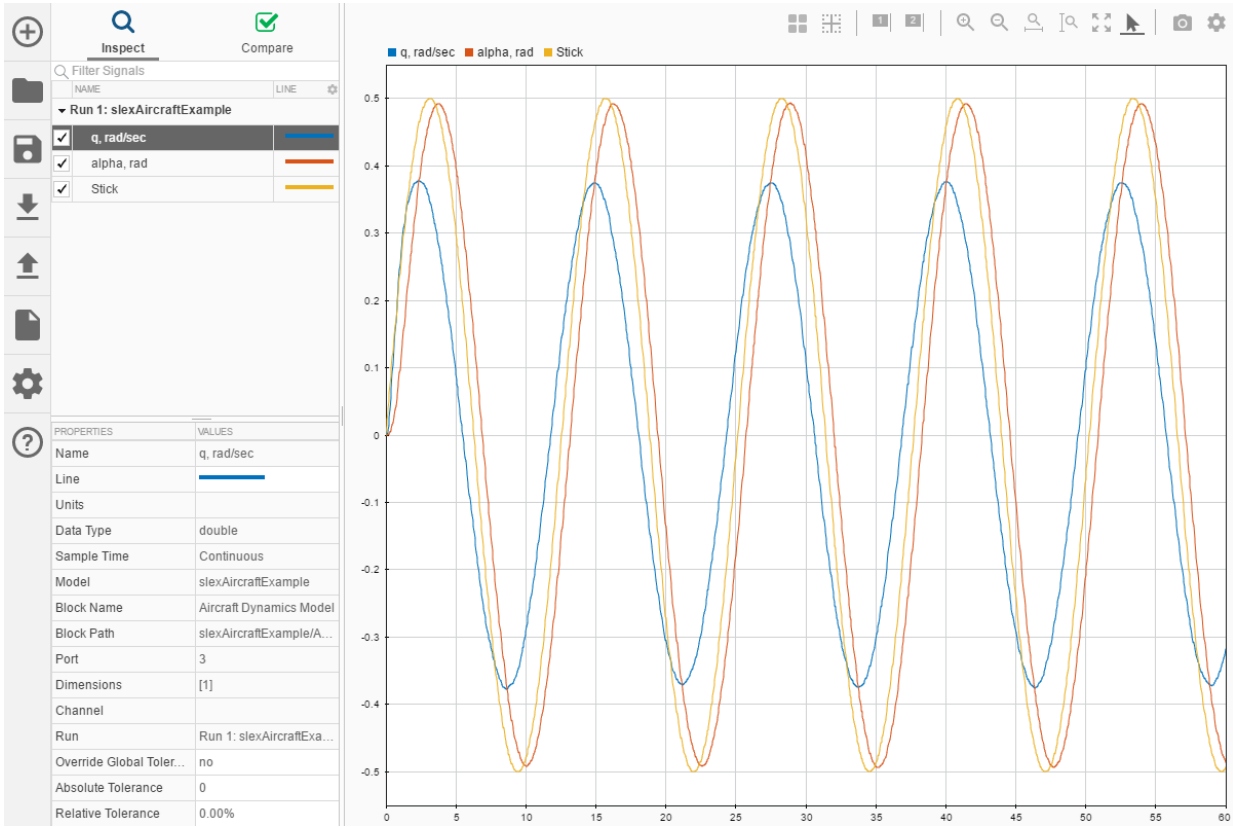
   The logging badge appears above each signal marked for logging.
3. Double-click the Pilot block. Set **Wave form** to `sine`, and click **OK**.
4. In the Simulink Editor, click the **Simulation Data Inspector** button to open the Simulation Data Inspector.

5 Simulate the model. A new run appears in the Simulation Data Inspector.

By default, the **Inspect** pane lists all logged signals in rows, organized by simulation run. You can expand or collapse any of the runs to view the signals in a run. For more information on signal grouping, see “Organize Your Simulation Data Inspector Workspace” on page 28-60.

View Signals

To select signals to view in the graphical viewing area, use the checkboxes next to the signals in the navigation pane. Select the check boxes next to the `q, rad/sec`, `Stick`, and `alpha, rad` signals.

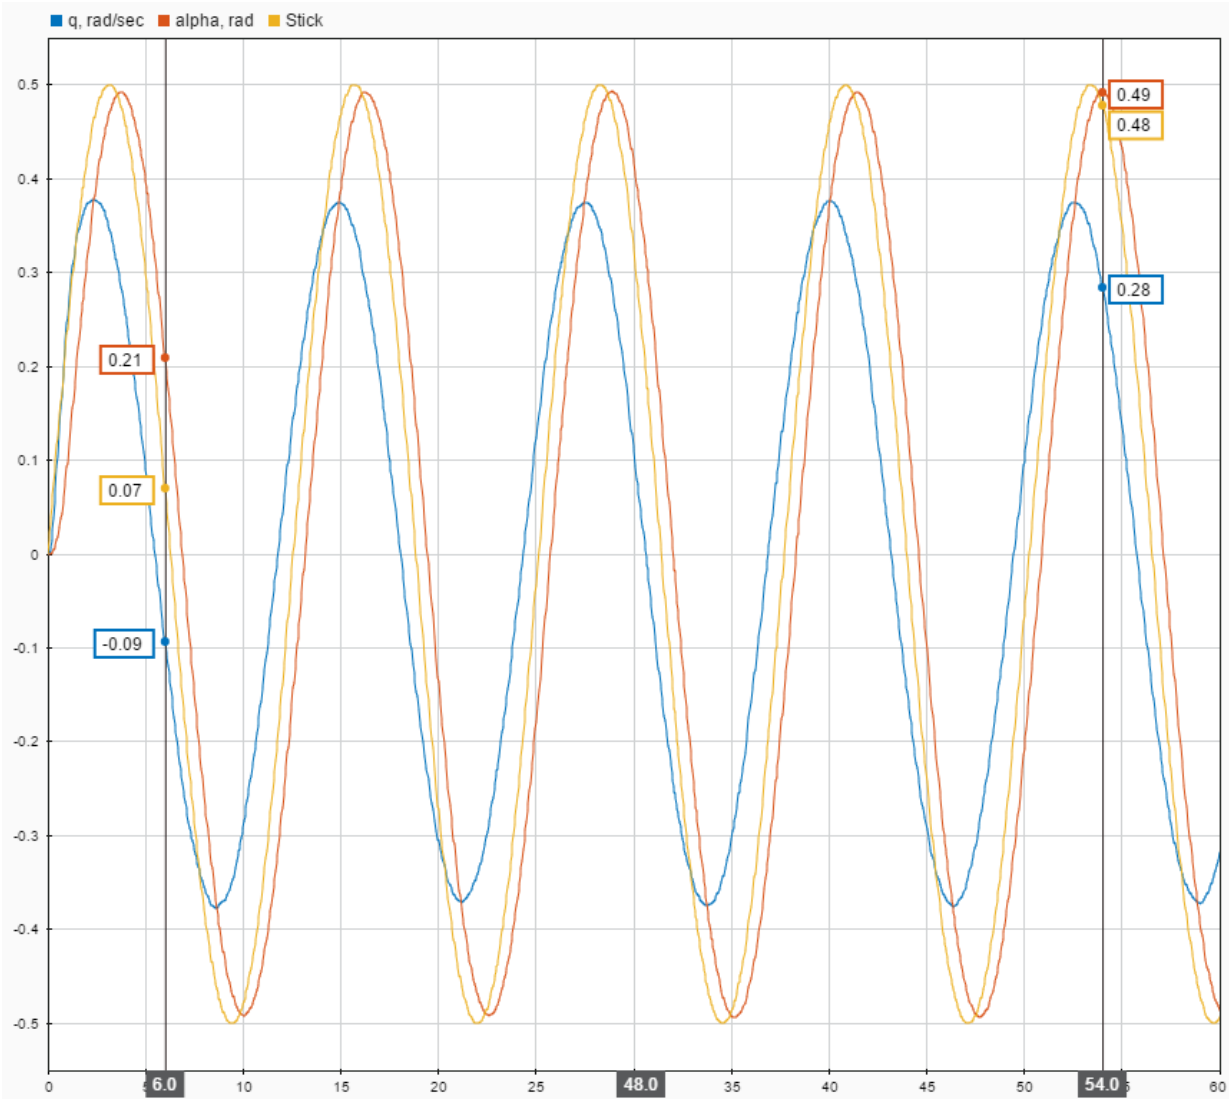


You can also use signal browsing mode to quickly view all the signals in your run.

Inspect Simulation Data with Cursors

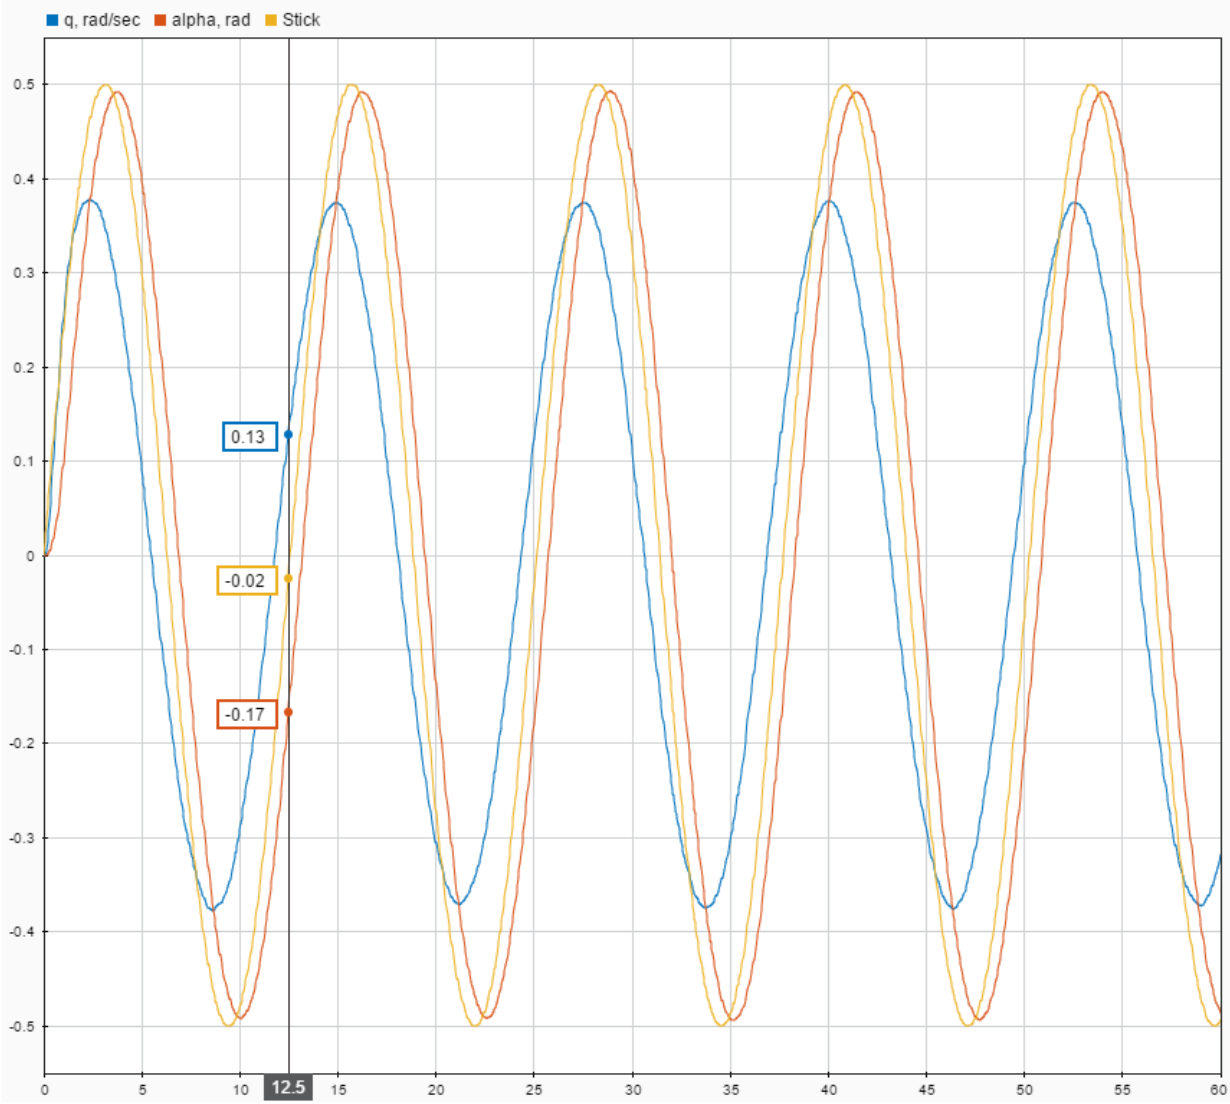
In the Simulation Data Inspector, you can inspect signals using data cursors. You can choose to use one or two data cursors.

With two data cursors, three time values are displayed: the time corresponding to each cursor position and the time spanned by the cursors. You can move the two cursors together by dragging the span label between the two cursors. You can also set the span by typing the desired value into the label field.



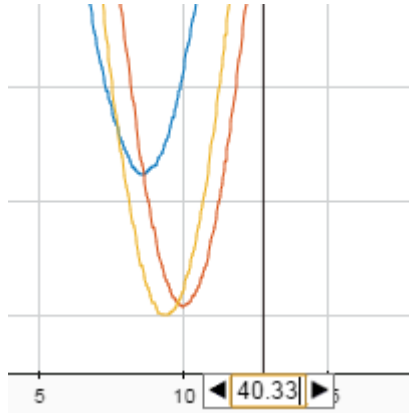
Practice inspecting data with cursors by adding one cursor to the plot.

1 To add a cursor to the plot, click the single cursor button.

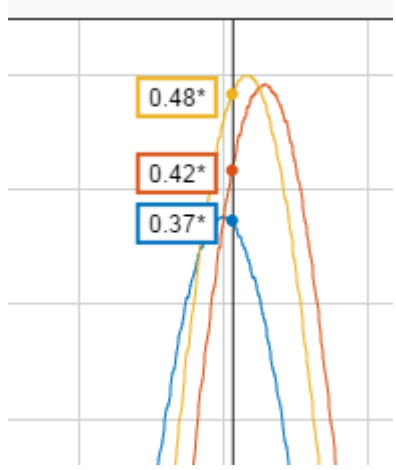


2 Drag the data cursor left or right to a point of interest. You can also use the arrow keys to move the data cursor.

To inspect the data at a specific point in time, click the data cursor time field and enter the desired time value, for example `40.33`.



If the signal does not have a sample value at the point of interest, the Simulation Data Inspector interpolates the value for the indicated time. An asterisk in the data cursor label indicates that the displayed value is interpolated. For information regarding interpolation methods, see “Interpolation Options in the Simulation Data Inspector” on page 28-58.



3 When you have finished inspecting the data, click the single cursor button to remove the cursor from the graphical viewing area.

Zoom and Pan

Zoom and pan to inspect signal values and the relationships between signals. The zoom and pan controls in the Simulation Data Inspector are on the toolstrip above the graphical viewing area. Each icon allows you to control the aspects of the plot your mouse controls.

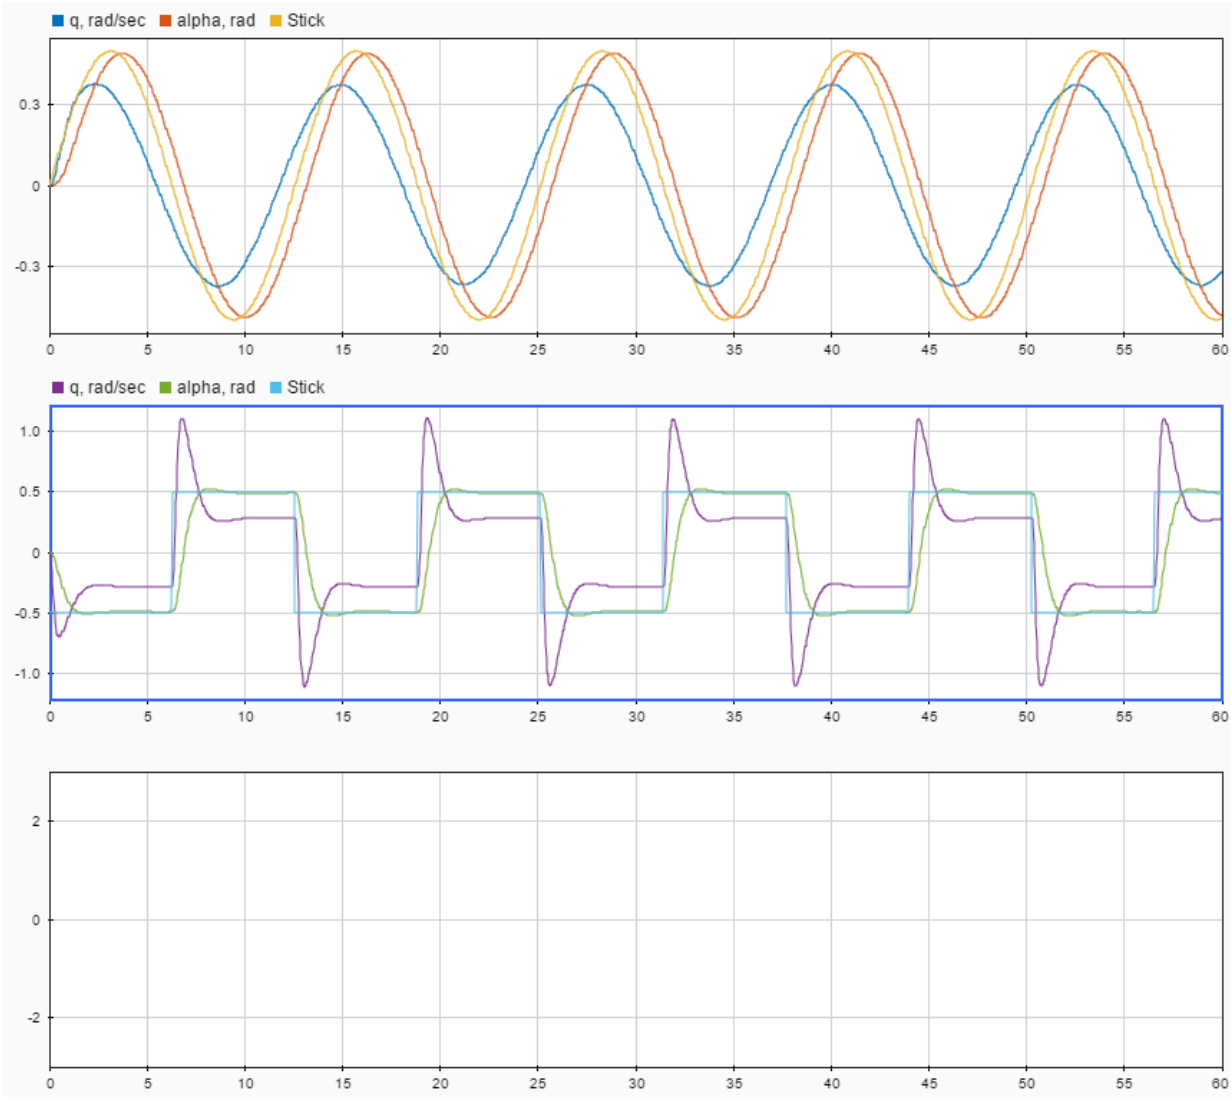
-  With the mouse pointer selected, you can select signals by clicking them and pan by clicking anywhere on the plot and dragging the mouse.
-  Click the fit-to-view option to scale the axes to accommodate your plotted data.
-  When you select the *y*-axis zoom option, all the mouse actions zoom on the *y*-axis. You can click in the graphical viewing area to zoom in a fixed amount. You can also click and drag to select a portion of the plot as the limits for the *y*-axis. Scrolling with the mouse wheel zooms in and out on the *y*-axis.
-  The *t*-axis zoom option makes all the mouse actions zoom on the *t*-axis. You can click the graphical viewing area to zoom in a fixed amount. You can click and drag the graphical viewing area to select a portion of the plot as the limits for the *t*-axis. Scrolling with the mouse wheel zooms in and out on the *t*-axis.
-  Click the zoom-out option to zoom out a fixed amount.
-  When you select the zoom-in option, all the mouse actions zoom in on both the *y*- and *t*-axes. You can click the graphical viewing area to zoom in a fixed amount on both axes. You can also click and drag to select an area to define the *y*- and *t*-axes. Scrolling with the mouse wheel zooms in and out on both axes.

View Signals on Multiple Plots

You can use subplot layouts to view groups of signals on different subplots. For example, you can group the same signal from different simulation runs or group signals that have a similar range of values.

1. In the model, double-click the Pilot block. Set **Wave form** to `square`, and click **OK**.
2. Simulate the model.
3. Click the **Layout** button and specify a `3×1` arrangement in the **Grid** section of the menu.
4. Click the middle subplot in the graphical viewing area. In the **Inspect** pane, select the check boxes for the `q, rad/sec`, `Stick`, and `alpha, rad` signals under `Run 2`.

   The check boxes in the **Inspect** pane indicate the signals plotted in the selected subplot, which is outlined in blue.

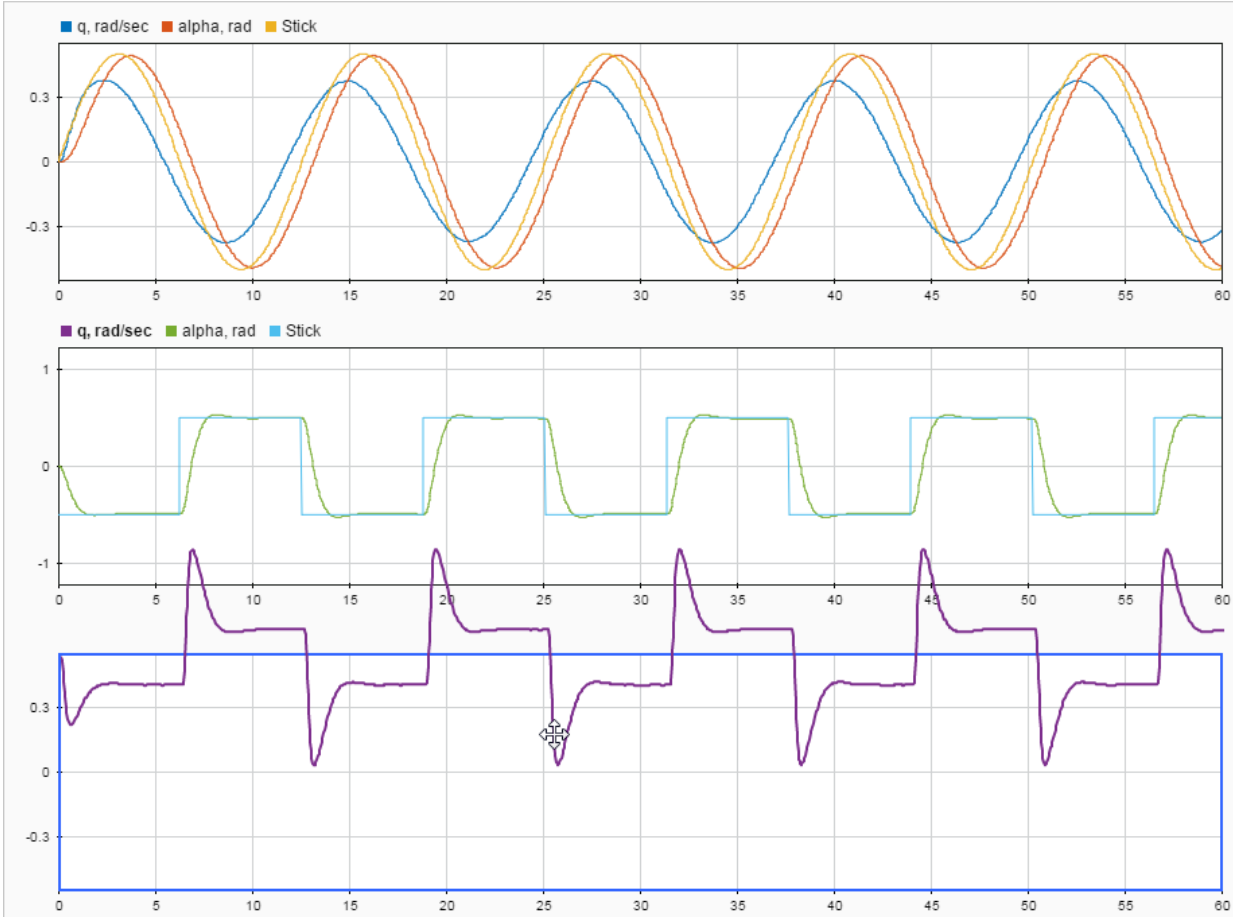


Move Signals Between Plots

You can also move plotted signals to other subplots graphically, rather than using the check boxes.

1 Select the signal you want to move.

2 Drag the signal to the plot where you want to plot it.



For more information on working with plots, see “Create Plots Using the Simulation Data Inspector” on page 28-23.

Linked Subplots

Subplots are linked by default, meaning that all plots in the graphical viewing area stay synchronized when you pan and zoom. Linked plots have a synchronized response when you:

- Click a plot and drag to pan
- Perform any zoom operation
- Fit to view

To pan and zoom independently in a subplot, you can unlink the subplot.

1. Select the subplot you want to unlink.
2. Click the settings button in the upper right of the graph.
3. On the **More** tab, click the check box labeled **Link Subplot**.

   The broken link symbol  appears on the unlinked subplot.

Inspect Metadata

The Simulation Data Inspector allows you to view run and signal metadata. You can view signal metadata in the properties pane or in the table of signals under each run. You can view run data only in the properties pane.

The properties pane displays the metadata for the selected run or signal. You can edit properties using the white box in the **Values** column. When you view a comparison, the Simulation Data Inspector highlights metadata differences in red.

PROPERTIES	VALUES
Name	q, rad/sec
Line	
Units	
Data Type	double
Sample Time	Continuous
Model	slexAircraftExample
Block Name	Aircraft Dynamics Model
Block Path	slexAircraftExample/A...
Port	3
Dimensions	[1]
Channel	
Run	Run 2: slexAircraftExa...
Override Global Toler...	no
Absolute Tolerance	0
Relative Tolerance	0.00%

Columns in the navigation pane allow you to display signal properties in the table of signals under each run. To add or remove columns in the table, select the columns you want to display from the list on the **Columns** tab of the navigation pane's **Preferences** menu. Columns appear in the table in the order in which you select them.

Property Descriptions

Property Name	Value
Line	Signal line style and color
Units	Signal measurement units
Data Type	Signal data type
Sample Time	Type of sampling
Model	Name of the model that generated the signal
Block Name	Name of the signal's source block
Block Path	Path to the signal's source block
Port	Index of the signal on the block's output port
Dimensions	Dimensions of the matrix containing the signal
Channel	Index of signal within matrix
Run	Name of the simulation run containing the signal
Absolute Tolerance	User-specified, positive-valued absolute tolerance for the signal
Relative Tolerance	User-specified, positive-valued relative tolerance for the signal
Override Global Tolerance	User-specified property that determines whether signal tolerances take priority over global tolerances
Time Tolerance	User-specified, positive-valued time tolerance for the signal
Interp Method	User-specified interpolation method used to plot the signal
Sync Method	User-specified synchronization method used to coordinate signals for comparison

Property Name	Value
Time Series Root	Name of the variable associated with signals imported from the MATLAB workspace
Time Source	Name of the array containing the time data for signals imported from the MATLAB workspace
Data Source	Name of the array containing the data for signals imported from the MATLAB workspace

On the **Compare** pane, many parameters have a Baseline column and a Compare To column that you can display independently. If the **Baseline** and **Compare to** signals both have a property, but you can only display one property column, the column shows the **Baseline** property. In addition to the parameters listed for the **Inspect** pane, the **Compare** pane has columns specific to comparisons.

- **Max Difference** – The maximum difference between the **Baseline** and **Compare to** signals
- **Align By** – Primary signal alignment criterion specified in the **Alignment** tab of the Simulation Data Inspector **Preferences** menu

By default, the table displays the baseline name column and a column indicating whether the comparisons passed or failed.

Inspect Event-Based Data

The Simulation Data Inspector visualizes data from event-based systems with stem plots. To plot event-based or message data, mark the signal for logging. When you simulate the model, the data appears in the Simulation Data Inspector as a stem plot for each event. The stem plot shows the number of events recorded for each sample time.

- “Save and Share Simulation Data Inspector Data and Views” on page 28-16

Compare Simulation Data

The Simulation Data Inspector compares the data and metadata for runs and individual signals. You can analyze comparison results with the difference plot and tolerance features. You can control the comparison through comparison settings. For more information on the comparison settings, see “How the Simulation Data Inspector Compares Data” on page 28-56.

Setup

This example continues from “Inspect Simulation Data” on page 28-31. You can also use this script to generate the data required for the example.

```
% Load system
load_system('slexAircraftExample')

% Configure signals to log
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Pilot', 1, 'on')
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Aircraft Dynamics Model', 3, '
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Aircraft Dynamics Model', 4, '

% Change Pilot signal to sine
set_param('slexAircraftExample/Pilot', 'WaveForm', 'sine')

% Simulate model
sim('slexAircraftExample')

% Change Pilog signal to square
set_param('slexAircraftExample/Pilot', 'WaveForm', 'square')

% Simulate Model
sim('slexAircraftExample')
```

Compare Signals

You can compare signals to analyze the relationship between your model's inputs and outputs. Compare the `Stick` input signal to the output observed at `alpha, rad`. Then, use the tolerance feature in the Simulation Data Inspector to analyze the result.

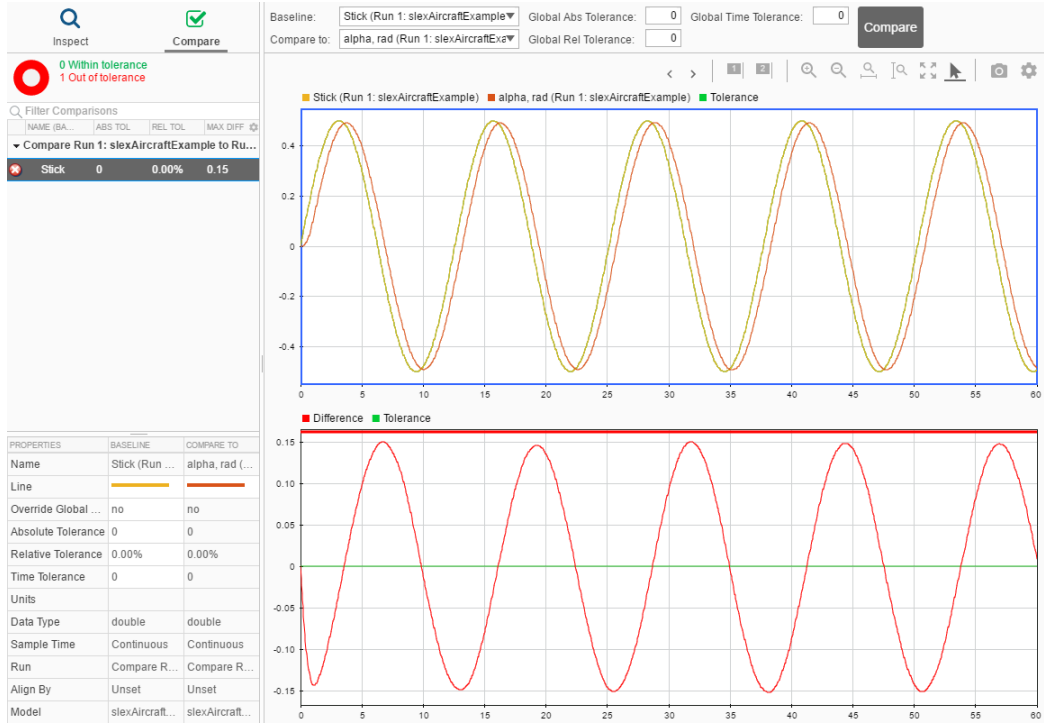
To compare the `alpha, rad` signal to the `Stick` signal:

1. Navigate to the **Compare** pane.
2. To view a list of signals available for comparison, click the **Baseline** text box, and select **Signals**.

3. Select `Stick (Run 1: slexAircraftExample)`.
4. Click the **Compare to** text box, and select **Signals**.
5. Select `alpha, rad (Run 1: slexAircraftExample)`.
6. Click **Compare**.

Alternatively, you can select the **Baseline** and **Compare to** signals through the context menu when you right-click a signal in the **Inspect** pane.

Here, the `alpha, rad` and `Stick` signals are compared from `Run 1`. The signals do not match within the absolute, relative, and time tolerances, all specified as 0 by default.



From a visual inspection of the signals, you can see `alpha, rad` lags `Stick`. Add a time tolerance to the `Stick` signal to account for the lag.

1. In the properties pane, click the **Override Global Tolerance** baseline value field, and select `yes` from the drop-down.

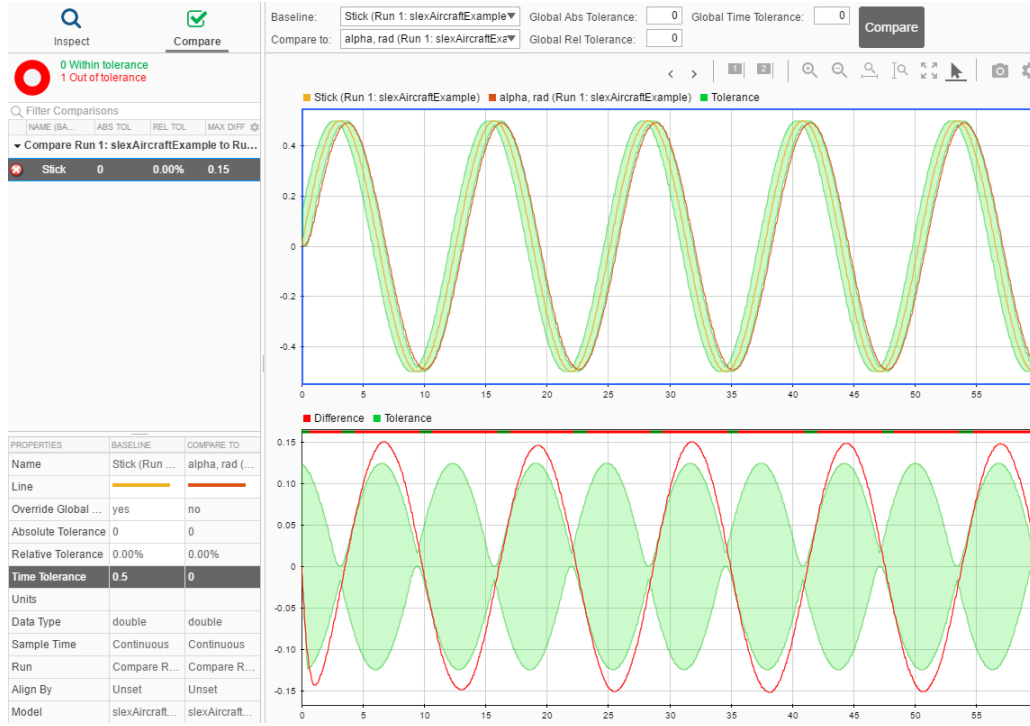
   When the **Override Global Tolerance** field is set to `yes`, the tolerance values in the signal properties are applied instead of the global tolerances specified above the graphical viewing area.

2. Enter `0.5` into the **Time Tolerance** field in the properties pane to the left of the graphical viewing area.

   The comparison automatically runs again, with the updated tolerance value.

   The Simulation Data Inspector draws the tolerance band around the plotted **Baseline** signal and around the signed difference signal displayed in the bottom

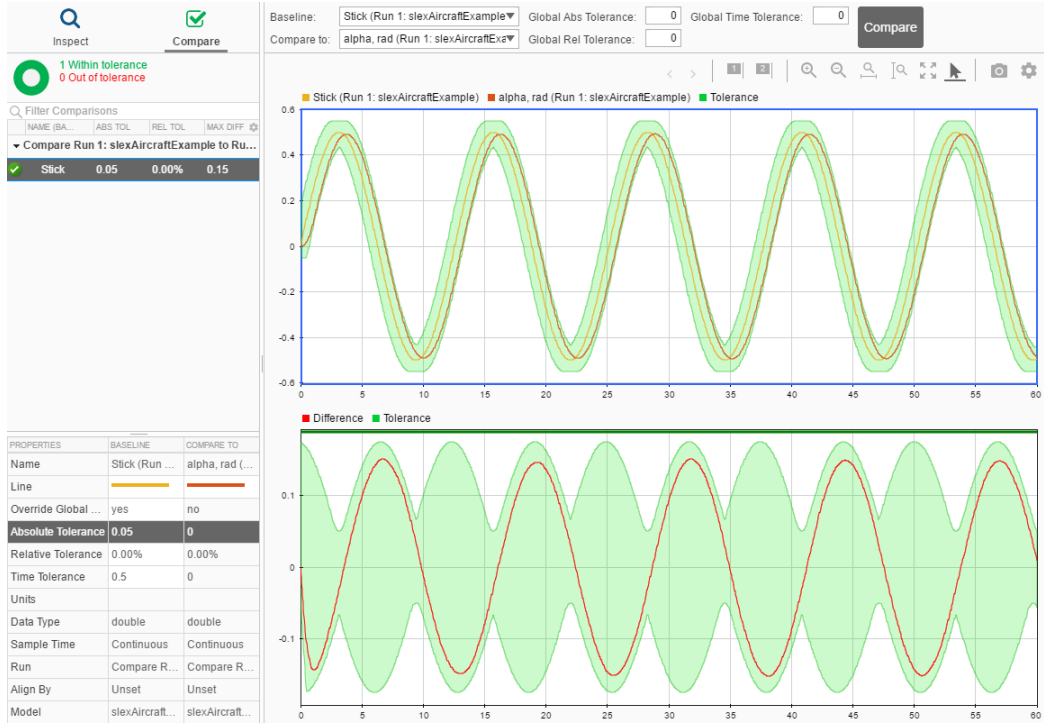
subplot. The bar along the top of the difference plot shows pass and out of tolerance regions for the comparison in green and red.



Note The Simulation Data Inspector draws the tolerance region with the most lenient interpretation of the specified tolerances for each point. For more information on tolerances, see “Tolerances in the Simulation Data Inspector” on page 28-58.

The time tolerance covers the phase difference between the two signals, but the comparison still does not pass due to the amplitude difference. To add an absolute tolerance to the `Stick` signal, enter `0.05` into the **Absolute Tolerance** field in the properties pane.

With the combination of the absolute and time tolerances, the signal comparison passes.



Compare Runs

You can also use the Simulation Data Inspector to compare all logged signals in a model at once by comparing runs. Run comparisons provide useful information about the effects of changing model parameters. For example, change the frequency cutoff of the filter for the control stick input signal. Then, evaluate the effect on the output signal with the Simulation Data Inspector.

1. Click the **Model Explorer** button  to access the **Model Workspace** variables.
2. Change the value of `Ts` in the **Model Workspace** from `0.1` to `1`.
3. Close the **Model Explorer**.
4. Simulate the model with the new filter.
5. In the Simulation Data Inspector, click **Compare** to switch to the **Compare** pane.

6 Click the **Baseline** text box, and select `Run 2: slexAircraftExample`.

7 Click the **Compare to** text box, and select `Run 3: slexAircraftExample`.

8 Click **Compare**.

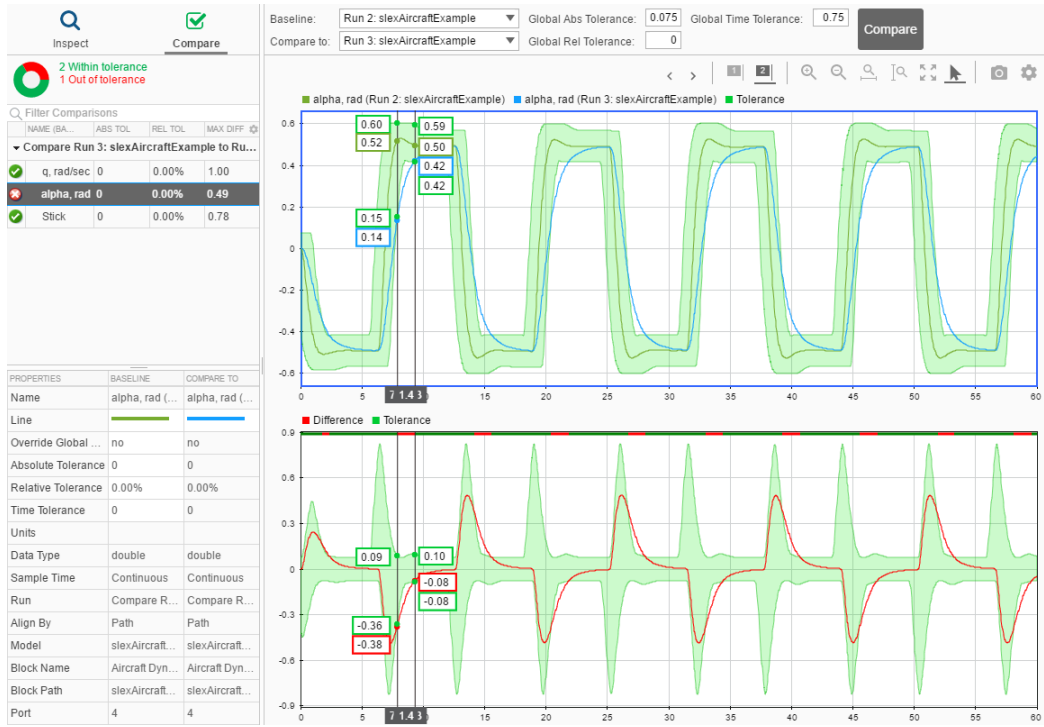
The **Compare** pane lists all signals from the runs with a comparison result. In this example, the comparison results of the aligned signals do not match. The signal differences are not within the specified tolerance values, all of which are set to zero.

Note The Simulation Data Inspector only compares signals from the **Baseline** run that align with a signal from the **Compare To** run. If a signal from the **Baseline** run does not align with a signal from the **Compare To** run, the signal is listed in the **Compare** pane with a warning. For more information on signal alignment, see "Signal Alignment in the Simulation Data Inspector" on page 28-56.

To plot comparison data, select the signal you want to see in the **Compare** pane. Here, the top plot shows the `q, rad/sec` signals from the **Baseline** and **Compare To** runs. The bottom plot shows the difference between the signals and a graphical representation of the tolerance.

To qualify signals in the run comparison, you can add global tolerances to the comparison using the global tolerance fields above the graphical viewing area. Enter one or more desired tolerance values, and click **Compare** to run the comparison again with the new tolerance values. Change the **Global Time Tolerance** to `0.75` and the **Global Abs Tolerance** to `0.075`, and run the comparison. The Simulation Data Inspector draws the tolerance band around the **Baseline** signal and on the signed difference plot on the lower half of the graphical viewing area. With the new tolerance values, the `Stick` and `q, rad/sec` signals pass the comparison.

View the `alpha, rad` signal to analyze the comparison's out of tolerance regions. Click the arrow buttons  in the tool strip to navigate to the comparison's out of tolerance regions. Two cursors on the plot show the beginning and end of the first out of tolerance region. You can use your mouse arrows to explore the signal and tolerance values. To view the next out of tolerance region, click the right arrow button in the tool strip.



To resolve the out of tolerance regions, you can choose to modify the global tolerance values or to add a signal specific tolerance to the `alpha, rad` signal using the signal properties.

How the Simulation Data Inspector Compares Data

You can tailor the Simulation Data Inspector comparison process to fit your requirements in multiple ways. When comparing runs, the Simulation Data Inspector:

1. Aligns signal pairs in the **Baseline** and **Compare To** runs based on the **Alignment** settings.

   The Simulation Data Inspector does not compare signals that it cannot align.
2. Synchronizes aligned signal pairs according to the specified **Sync Method**.

   Interpolates data in signal pairs as specified by the **Interpolation Method**.
3. Computes the difference of the signal pairs.
4. Compares the difference result against specified tolerances.

When the comparison run completes, the results of the comparison are added in the navigation pane.

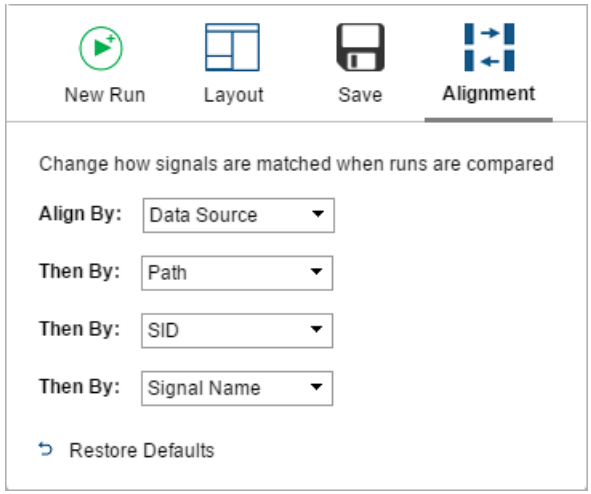
Status	Comparison Result
	• Signal aligns. • Data from two runs falls within the tolerance.
	• Signal aligns. • Data from two runs does not fall within the tolerance.
	Signal from **Baseline** does not align with a signal from **Compare To**.

When you compare signals of different lengths, the Simulation Data Inspector compares the signals on their overlapping interval.

Signal Alignment in the Simulation Data Inspector

Aligning the signals is the first step in a comparison. In the alignment step for a run comparison, the Simulation Data Inspector decides which signal from the **Compare To** run pairs with a given signal in the **Baseline** run. When you compare signals with the Simulation Data Inspector, you complete the alignment step by selecting the **Baseline** and **Compare To** signals.

The Simulation Data Inspector aligns signals using their properties. In the **Alignment** tab of the **Preferences** window, you can specify the priority order for each of the signal properties used for alignment. The **Align By** field specifies the highest priority property. The priority drops with each subsequent **Then By** field. Always specify a primary alignment property in the **Align By** field, but you can leave any number of the **Then By** fields blank.



From each drop-down, you can select `Data Source`, `Path`, `SID`, or `Signal Name`. By default, the Simulation Data Inspector is configured to first align signals by data source, then path, then SID, and then signal name.

Property	Description
Data Source	Path of the variable in the MATLAB workspace for data imported from the workspace
Path	Block path for the source of the data in the model
SID	Numeric signal identifier For more information about SIDs, see “Locate Diagram Components Using Simulink Identifiers” on page 1-18
Signal Name	Name of the signal in the model

Synchronization Options in the Simulation Data Inspector

You can choose how the Simulation Data Inspector synchronizes signals when their time vectors do not contain all the same sample times. You can select `union` or `intersection` as the synchronization method.

When you specify `union` synchronization, the Simulation Data Inspector builds a time vector that comprises every sample time represented between the two signals. For each sample time not originally present in either signal, the Simulation Data Inspector interpolates the value. When you specify `intersection` synchronization, the Simulation Data Inspector uses only the sample times present in both signals in the comparison.

Choosing between the two options is a trade off between speed and accuracy. The interpolation required by `union` synchronization takes time, but provides a more precise result. When you use `intersection` synchronization, the run completes quickly because the Simulation Data Inspector computes fewer data points and does not interpolate. However, some data is discarded in the process.

Interpolation Options in the Simulation Data Inspector

You can choose to interpolate your data with a zero-order hold (zoh) or a linear approximation. When you specify `zoh` in the **Interpolation Method**, the Simulation Data Inspector replicates the data of the previous sample for interpolated sample times. When you specify `linear` interpolation, the Simulation Data Inspector uses samples on either side of the interpolated point to linearly approximate the interpolated value.

Tolerances in the Simulation Data Inspector

You can specify absolute, relative, and time tolerances in the Simulation Data Inspector. You can specify all tolerances globally, at the top of the graphical viewing area, or on a signal by signal basis in the properties pane. To use a signal tolerance, change **Override Global Tol** to `yes`.

When you specify multiple tolerance, sometimes each tolerance yields a different answer for what the tolerance is at each point. The Simulation Data Inspector computes the overall tolerance band by selecting the most lenient tolerance result for each data point.

First, the Simulation Data Inspector computes the tolerance band using only the absolute and magnitude tolerances:

```
tolerance =
max(absoluteTolerance,relativeTolerance*abs(baselineData));
```

The upper boundary of the tolerance band is formed by adding `tolerance` to the **Baseline** signal. Similarly, the lower boundary of the tolerance band is formed by subtracting `tolerance` from the **Baseline** signal.

To apply the time tolerance, the Simulation Data Inspector looks at a time interval defined as `[(t-timeTol), (t+timeTol)]`. For the upper boundary of the tolerance band, the Simulation Data Inspector selects the maximum value on the interval for each data point. For the lower boundary of the tolerance band, the Simulation Data Inspector selects the minimum value on the interval for each data point.

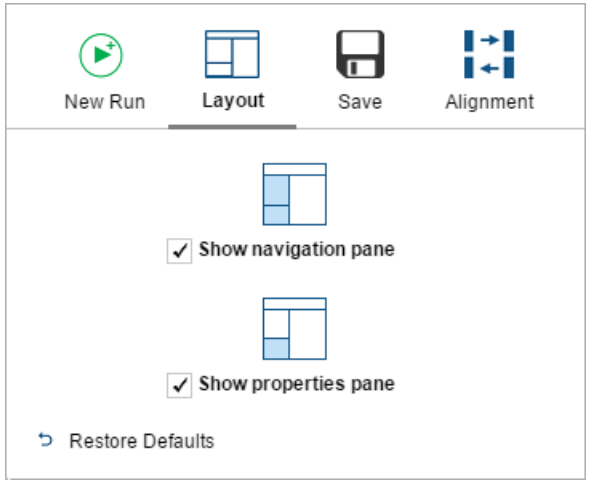
Organize Your Simulation Data Inspector Workspace

You can modify the layout and content of the panels in the Simulation Data Inspector to help you organize your data. You can set new run naming rules, change how runs are grouped in the navigation pane, and use filters to find the signal you want to inspect.

Modify the Layout

You can choose which panes are displayed in the Simulation Data Inspector. Click the gear icon on the side menu of the Simulation Data Inspector. Then, select the **Layout** tab. You can choose to hide or display the navigation and properties panes. When you hide the navigation pane, the properties pane is automatically hidden. The **Restore Defaults** option at the bottom of the pane restores the settings of the panel to the default configuration.

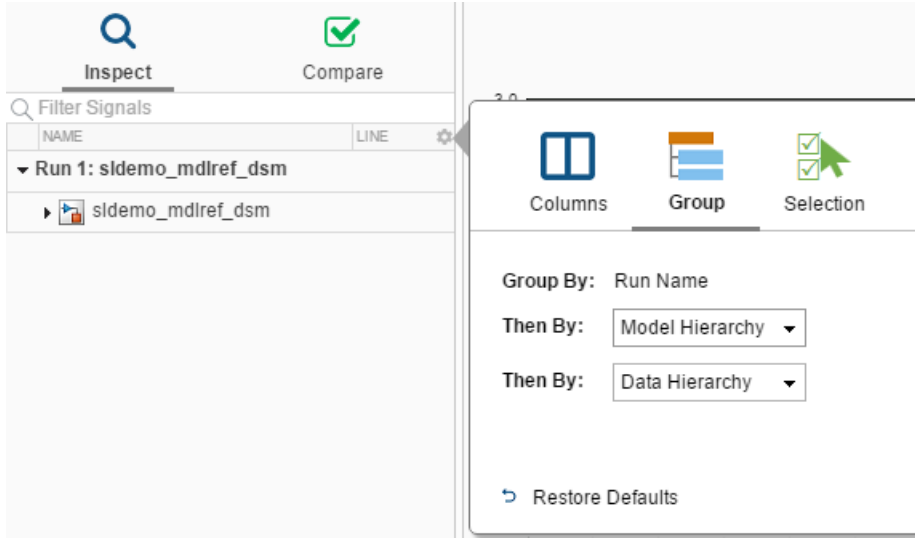


Modify Grouping in Inspect Pane

You can customize the hierarchy of your data in the **Inspect** pane. The data is grouped first by run name, which cannot be modified. You can then group your data by data or model hierarchy. Changes to signal grouping apply only to the **Inspect** pane. If you have a Simscape license, you can also group your data by physical system data hierarchy.

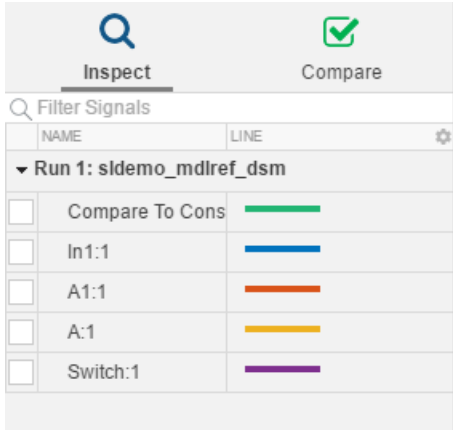
As an example, change the grouping in the **Inspect** pane to group by run name, then by model hierarchy, and then by data hierarchy.

1. Click the **Preferences** button in the upper right of the **Inspect** pane.
2. In the **Group** pane, select `Model Hierarchy` in the first **Then By** list.
3. In the second **Then By** list, select `Data Hierarchy`.

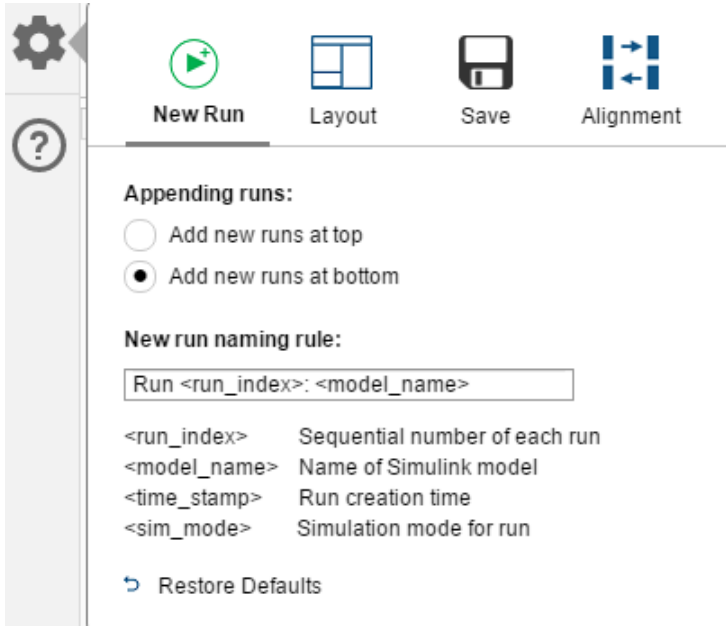


The **Inspect** pane groups the signals by run name, then by model hierarchy, and then by data hierarchy.

To remove the hierarchy and display a simple list of signals, select `None` from both **Then By** lists on the **Group** pane.



You can also specify whether to add new runs in the **Inspect** pane to the top or bottom of the runs list. The **New Run** tab in the **Preferences** window allows you to configure how new runs are added to the **Inspect** pane. The default configuration adds new runs to the bottom of the runs list.



Specify How the Simulation Data Inspector Names Runs

You can specify how existing and future runs are named in the Simulation Data Inspector.

To rename an existing run double-click the run row, type the new run name, and press **Enter**. Alternatively, you can select the run you want to rename and type the new name into the **Name** row of the properties pane.

To specify how you would like the Simulation Data Inspector to name future runs, open the **New Run** tab on the **Preferences**  menu. The default value for the **New run naming rule** is `Run <run_index>: <model_name>`.

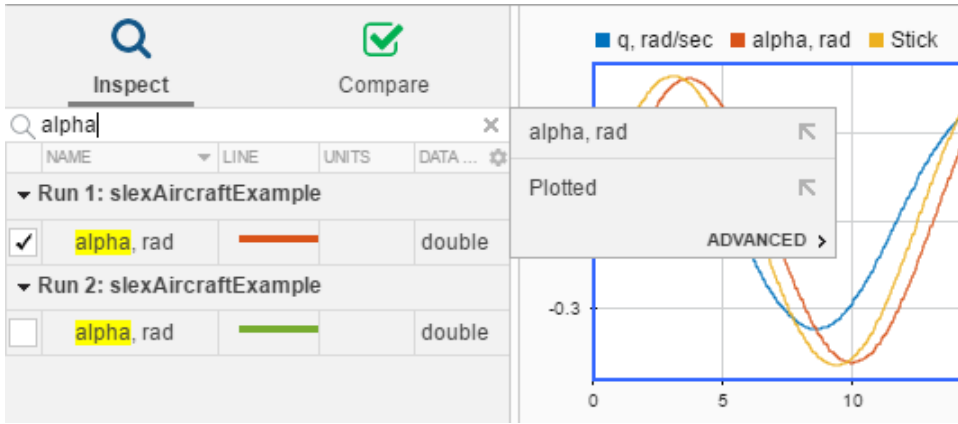
To change the run naming rule, enter your desired options from the list of available parameters along with any other regular characters. For example, to include the simulation mode in subsequent run names, enter `Run <run_index>: <model_name>: <sim_mode>` in the **New run naming rule** box. With this rule, simulating model

`slexAircraftExample` in `normal` mode, the name of the first run appears as `Run 1: slexAircraftExample: normal`.

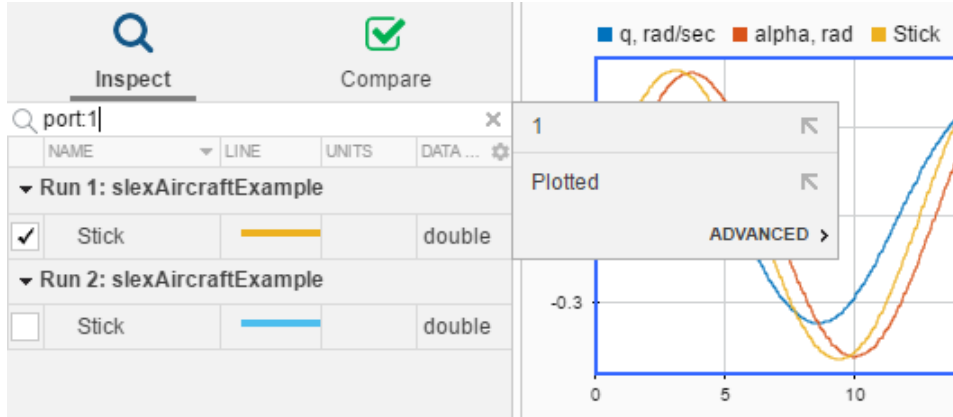
Filter Runs and Signals

You can filter runs and signals displayed in the **Inspect** and **Compare** panes to help search through large amounts of data in the Simulation Data Inspector. You can filter the data by text contained in the run or signal names and properties.

To show only signals named `alpha, rad`, type `alpha` into the filter signals text box. Matches for the search criteria are highlighted in the filter results displayed in the pane. The filter dialog box suggests completions for the text typed into the search query.



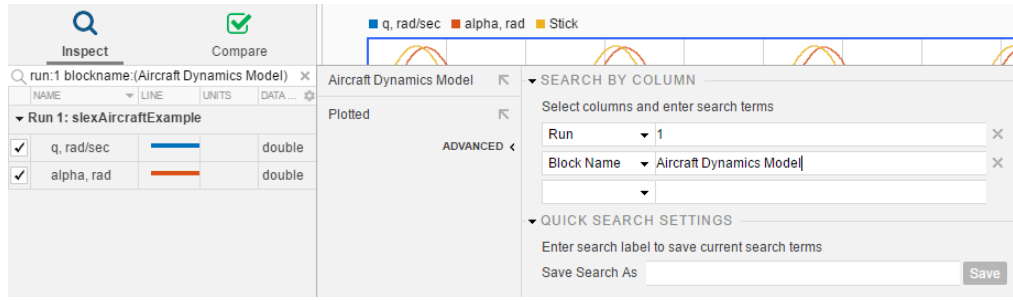
To filter for a signal or run property, use colons to separate the property name and filter value. For example, `port:1` filters for signals that use port 1 in the model. Because the property column is not visible in the **Inspect** pane, the result is not highlighted.



You can also construct more complicated filter queries that include multiple properties using the **Advanced** section of the filter dialog box.

1 Open the **Advanced** section of the filter dialog box.

2 Select a column to add to the filter, and enter the value.



Note Filters work by matching text. For example, an absolute tolerance filter for a value of `00.1` does not return signals with an absolute tolerance of `0.1`.

For convenience, you can save filter configurations. To save the filter, enter a name in the **Save Search As** box and click **Save** on the filter dialog box. Saved filters show as options in the filter list.

Inspect and Compare Data Programmatically

You can harness the capabilities of the Simulation Data Inspector from the MATLAB command line using the Simulation Data Inspector API.

The Simulation Data Inspector organizes data in runs and signals, assigning a unique numeric identification to each run and signal. Some Simulation Data Inspector API functions use the run and signal IDs to reference data, rather than accepting the run or signal itself as an input. To access the run IDs in the workspace, you can use `Simulink.sdi.getAllRunIDs` or `Simulink.sdi.getRunIDByIndex`. You can access signal IDs through a `Simulink.sdi.Run` object using the `Simulink.sdi.Run.getSignalIDByIndex` method.

The `Simulink.sdi.Run` and `Simulink.sdi.Signal` classes provide access to your data and allow you to view and modify run and signal metadata. You can modify the Simulation Data Inspector preferences using functions like `Simulink.sdi.setSubPlotLayout`, `Simulink.sdi.setRunNamingRule`, and `Simulink.sdi.setMarkersOn`. To restore the Simulation Data Inspector's default settings, use `Simulink.sdi.clearPreferences`.

Create a Run and View the Data

This example shows how to create a run, add data to it, and then view the data in the Simulation Data Inspector.

Create Data for the Run

This example creates `timeseries` objects for a sine and a cosine. To visualize your data, the Simulation Data Inspector requires at least a time vector that corresponds with your data.

```
% Generate timeseries data
time = linspace(0, 20, 100);

sine_vals = sin(2*pi/5*time);
sine_ts = timeseries(sine_vals, time);
sine_ts.Name = 'Sine, T=5';

cos_vals = cos(2*pi/8*time);
cos_ts = timeseries(cos_vals, time);
cos_ts.Name = 'Cosine, T=8';
```

Create a Simulation Data Inspector Run and Add Your Data

To give the Simulation Data Inspector access to your data, use the `create` method and create a run. This example modifies some of the run's properties to help identify the data. You can easily view run and signal properties with the Simulation Data Inspector.

```
% Create a run
run = Simulink.sdi.Run.create;
run.Name = 'Sinusoids';
run.Description = 'Sine and cosine signals with different frequencies';

% Add timeseries data to run
run.add('vars', sine_ts, cos_ts);
```

Plot Your Data Using the `Simulink.sdi.Signal` Object

The `getSignalByIndex` method returns a `Simulink.sdi.Signal` object that can be used to plot the signal in the Simulation Data Inspector. You can also programmatically control aspects of the plot's appearance, such as the color and style of the line representing the signal. This example customizes the subplot layout and signal characteristics.

```
% Get signal, modify its properties, and change Checked property to true
sine_sig = run.getSignalByIndex(1);
sine_sig.LineColor = [0 0 1];
sine_sig.LineDashed = '-.';
sine_sig.Checked = true;

% Add another subplot for the cosine signal
Simulink.sdi.setSubPlotLayout(2, 1);

% Plot the cosine signal and customize its appearance
cos_sig = run.getSignalByIndex(2);
cos_sig.LineColor = [0 1 0];
cos_sig.plotOnSubPlot(2, 1, true);

% View the signal in the Simulation Data Inspector
Simulink.sdi.view
```

Close the Simulation Data Inspector and Save Your Data

```
Simulink.sdi.close('sinusoids.mat')
```

Compare Signals Within a Simulation Run

This example uses the `slexAircraftExample` model to demonstrate the comparison of a control system's input and output signals. The example marks the signals for streaming then gets the run object for a simulation run. Signal IDs from the run object specify the signals to be compared.

```
% Load model slexAircraftExample, and mark signals for streaming
load_system('slexAircraftExample')
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Pilot', 1, 'on')
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Aircraft Dynamics Model', 4, '

% Simulate model slexAircraftExample
sim('slexAircraftExample')

% Get run IDs for most recent run
allIDs = Simulink.sdi.getAllRunIDs;
runID = allIDs(end);

%Get Run object
run = Simulink.sdi.getRun(runID);

% Get signal IDs
signalID1 = run.getSignalIDByIndex(1);
signalID2 = run.getSignalIDByIndex(2);

if (run.isValidSignalID(signalID1))
    % Change signal tolerance
    signal1 = Simulink.sdi.getSignal(signalID1);
    signal1.AbsTol = 0.1;
end

if (run.isValidSignalID(signalID1) && run.isValidSignalID(signalID2))
    % Compare signals
    diff = Simulink.sdi.compareSignals(signalID1, signalID2);

    % Check whether signals match within tolerance
    match = diff.match
end
```

```
match =

  logical

   0
```

Compare Simulation Data Inspector Runs Programmatically

This example shows how to compare runs of simulation data and access the comparison results with the Simulation Data Inspector API.

Generate Runs of Simulation Data

Simulate the model to create runs of simulation data to analyze with the Simulation Data Inspector API.

```
% Open model
load_system('ex_sldemo_absbrake')

% Set the desired slipratio to 0.24 and simulate
set_param('ex_sldemo_absbrake/Desired relative slip','Value','0.24')
sim('ex_sldemo_absbrake');

% Change the desired slip ratio to 0.25 and simulate
set_param('ex_sldemo_absbrake/Desired relative slip','Value','0.25')
sim('ex_sldemo_absbrake');
```

Compare Runs

Get the run IDs for the runs you just created with the `Simulink.sdi.getAllRunIDs` function.

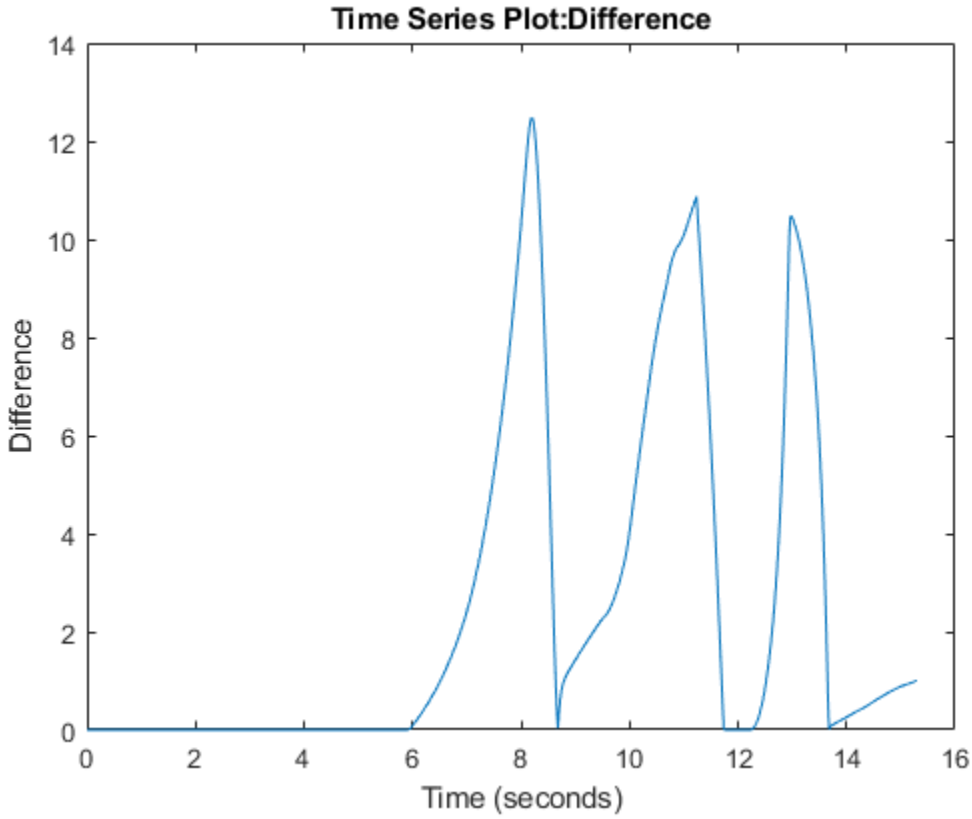
```
% Get run IDs for last two runs
runIDs = Simulink.sdi.getAllRunIDs;
runID1 = runIDs(end - 1);
runID2 = runIDs(end);

% Compare runs
runResult = Simulink.sdi.compareRuns(runID1, runID2);
```

Create a Plot of a Comparison Result

Use the `Simulink.sdi.DiffRunResult` object you created in the previous step with `Simulink.sdi.compareRuns` to access the data for the `Ww` signal result to plot it in a figure.

```
% Plot the |Ww| signal difference
signalResult_Ww = runResult.getResultByIndex(1);
figure(1)
plot(signalResult_Ww.Diff)
```



Analyze Simulation Data with Signal Tolerances

You can change tolerance values on a signal-by-signal basis to evaluate the effect of a model parameter change. This example uses the `slexAircraftExample` model and the Simulation Data Inspector to evaluate the effect of changing the time constant for the low-pass filter following the control input.

```
% Load example model
load_system('slexAircraftExample')

% Mark the alpha, rad signal for streaming
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Aircraft Dynamics Model', 4, '
```

```
% Simulate system
sim('slexAircraftExample')

% Change input filter time constant
modelWorkspace = get_param('slexAircraftExample', 'modelworkspace');
modelWorkspace.assignin('Ts', 0.2)

% Simulate again
sim('slexAircraftExample')

% Get run data
runIDs = Simulink.sdi.getAllRunIDs;
runID1 = runIDs(end - 1);
runID2 = runIDs(end);

% Compare runs
diffRun1 = Simulink.sdi.compareRuns(runID1, runID2);

% Get signal result
sigResult1 = diffRun1.getResultByIndex(1);

% Check whether signals matched
sigResult1.match

ans =

  logical

   0

% Get signal object for sigID1
run1 = Simulink.sdi.getRun(runID1);
sigID1 = run1.getSignalIDByIndex(1);
sig1 = Simulink.sdi.getSignal(sigID1);

% Change absolute tolerance to 0.2
sig1.absTol = 0.2;

% Run the comparison again
diffRun2 = Simulink.sdi.compareRuns(runID1, runID2);
sigResult2 = diffRun2.getResultByIndex(1);
```

```
% Check the result
sigResult2.match

ans =

  logical

   1
```

Generate a Simulation Data Inspector Report Programmatically

This example shows how to create reports using the Simulation Data Inspector programmatic interface. You can create a report for plotted signals in the Inspect pane or for comparison data in the Compare pane. This example first generates data by simulating a model, then shows how to create an `Inspect Signals` report. To run the example exactly as shown, ensure that the Simulation Data Inspector repository starts empty with the `Simulink.sdi.clear` function.

Generate Data

This example generates data using model `ex_sldemo_absbrake` with two different desired slip ratios.

```
% Ensure Simulation Data Inspector is empty
Simulink.sdi.clear

% Open model
load_system('ex_sldemo_absbrake')

% Set slip ratio and simulate model
set_param('ex_sldemo_absbrake/Desired relative slip','Value','0.24')
sim('ex_sldemo_absbrake')

% Set new slip ratio and simulate model again
set_param('ex_sldemo_absbrake/Desired relative slip','Value','0.25')
sim('ex_sldemo_absbrake')
```

Plot Signals in the Inspect Pane

The `Inspect Signals` report includes all signals plotted in the graphical viewing area of the Inspect pane and all displayed metadata for the plotted signals.

```
% Get Simulink.sdi.Run objects
runIDs = Simulink.sdi.getAllRunIDs;
runID1 = runIDs(end-1);
runID2 = runIDs(end);

run1 = Simulink.sdi.getRun(runID1);
run2 = Simulink.sdi.getRun(runID2);

% Get Simulink.sdi.Signal objects for slp signal
run1_slp = run1.getSignalByIndex(4);
run2_slp = run2.getSignalByIndex(4);

% Plot slp signals
run1_slp.plotOnSubPlot(1, 1, true)
run2_slp.plotOnSubPlot(1, 1, true)
```

Create a Report of Signals Plotted in Inspect Pane

You can include more data in the report by adding more columns using the Simulation Data Inspector UI, or you can specify the information you want in the report programmatically with Name-Value pairs and the enumeration class `Simulink.sdi.SignalMetaData`. This example shows how to specify the data in the report programmatically.

```
% Specify report parameters
reportType = 'Inspect Signals';
reportName = 'Data_Report.html';

signalMetadata = [Simulink.sdi.SignalMetaData.Run, ...
    Simulink.sdi.SignalMetaData.Line, ...
    Simulink.sdi.SignalMetaData.BlockName, ...
    Simulink.sdi.SignalMetaData.SignalName];

Simulink.sdi.report('ReportToCreate', reportType, 'ReportOutputFile', ...
    reportName, 'ColumnsToReport', signalMetadata);
```

Save and Restore a Set of Logged Signals

This example shows the capability of using the `Simulink.HMI.InstrumentedSignals` object to save a set of logged signals to restore after running a simulation with a different set of signals.

Load Model and Save Initial Configuration

Load the `sldemo_fuelsys` model, and save the initial set of logged signals.

```
% Load model
load_system sldemo_fuelsys

% Get Simulink.HMI.InstrumentedSignals object
initSigs = get_param('sldemo_fuelsys', 'InstrumentedSignals');

% Save logging configuration to file for future use
save initial_instSigs.mat initSigs
```

Remove All Logging Badges

Return to a baseline of no logged signals so you can easily select a different configuration of signals to log.

```
% Clear all logging signals
set_param('sldemo_fuelsys', 'InstrumentedSignals', [])
```

Restore Saved Logging Configuration

After working with a different set of logged signals, you can easily restore a saved configuration with the `Simulink.HMI.InstrumentedSignals` object.

```
% Load the saved configuration
load initial_instSigs.mat

% Restore logging configuration
set_param('sldemo_fuelsys', 'InstrumentedSignals', initSigs)
```

Keyboard Shortcuts for the Simulation Data Inspector

You can use several keyboard shortcuts to facilitate working with the Simulation Data Inspector. In the table, where the shortcut looks like **Ctrl+N**, to use the shortcut, you hold down the **Ctrl** key and then press the **N** key.

Note On Macintosh platforms, use the **command** key instead of **Ctrl**.

General Actions

Task	Shortcut
Start a new session	**Ctrl+N**
Open a session	**Ctrl+O**
Save a session	**Ctrl+S**
Compare	**Ctrl+E**
Link/Unlink a subplot	**Ctrl+U**
Delete a run or signal	**Delete**

Plot Zooming

Task	Shortcut
Zoom in T (time)	**Ctrl+Shift+T**
Zoom in Y	**Ctrl+Shift+Y**
Zoom in T and Y	**Ctrl++** (Numeric keypad only)
Zoom out	**Ctrl+-** (Numeric keypad only)
Fit to view	**Spacebar**
Cancel zoom operation or signal dragging	**Esc**

Data Cursors

Task	Shortcut
Show a data cursor	**Ctrl+I**
Hide all data cursors	**Shift+Del**
Move a selected data cursor to next data point	**Right arrow**
Move a selected data cursor to previous data point	**Left arrow**
Activate first (left) cursor	**Ctrl+1**
Activate second (right) cursor	**Ctrl+2**

Import Dialog Box

These actions pertain to the import table.

Task	Shortcut
Expand all nodes	**Ctrl+=**
Collapse all nodes	**Shift+Ctrl+=**
Select a node	**Space**
Expand a single node	**Right arrow**
Collapse a single node	**Left arrow**

Tune and Visualize Your Model with Dashboard Blocks

In this section...

The blocks in the Dashboard library help you control and visualize your Simulink model during simulation and while the simulation is paused. This example uses the Fault-Tolerant Fuel Control System model to showcase the control and visualization capabilities of Dashboard blocks.

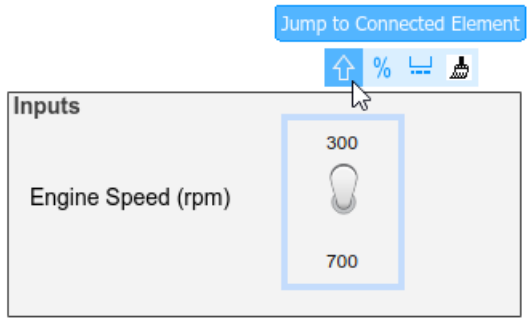
To open the model, enter `sldemo_fuelsys` into the MATLAB command window. To open the Dashboard subsystem, double-click it or click the Open the Dashboard link.

Note Dashboard blocks cannot connect to signals inside reference models.

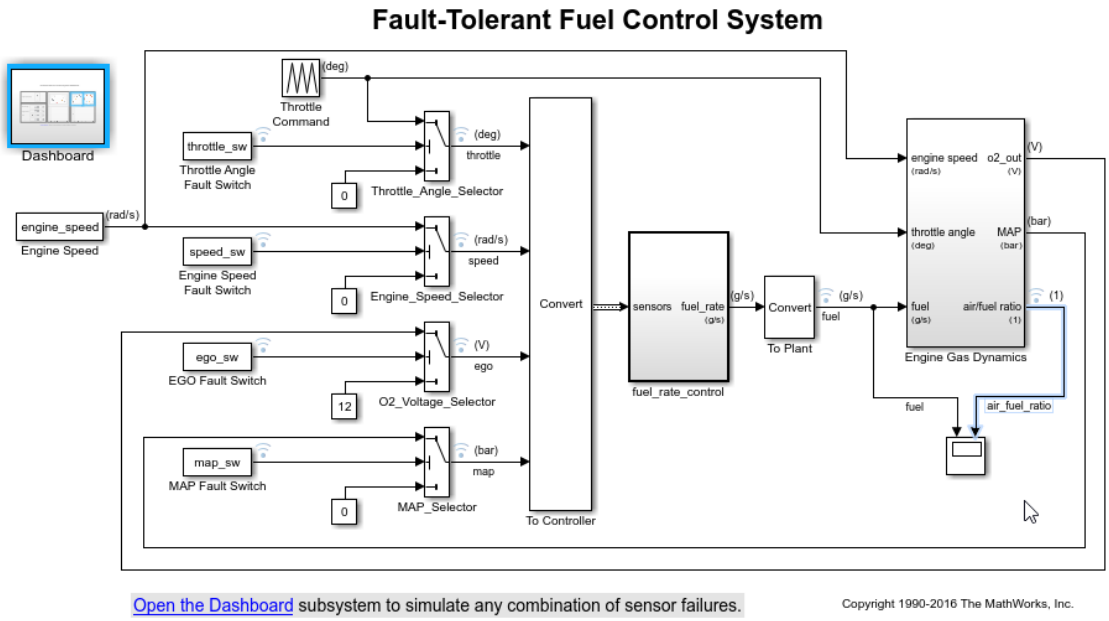
Explore Connections Within the Model

The Dashboard subsystem contains blocks for controlling and visualizing signals in the Fault-Tolerant Fuel Control System model. Explore the connections between the signals and Dashboard blocks. Click either a signal or a Dashboard block to highlight the connections.

From the Dashboard subsystem, click the Toggle Switch in the Fuel panel. Hover the mouse over the ellipsis above the block and then click the arrow above it to jump to the connected block or signal.



From the top level of the model, click the air_fuel_ratio signal and see the Dashboard subsystem, Quarter Gauge, and Half Gauge highlighted.



Note Connections with Dashboard Scope blocks are not highlighted.

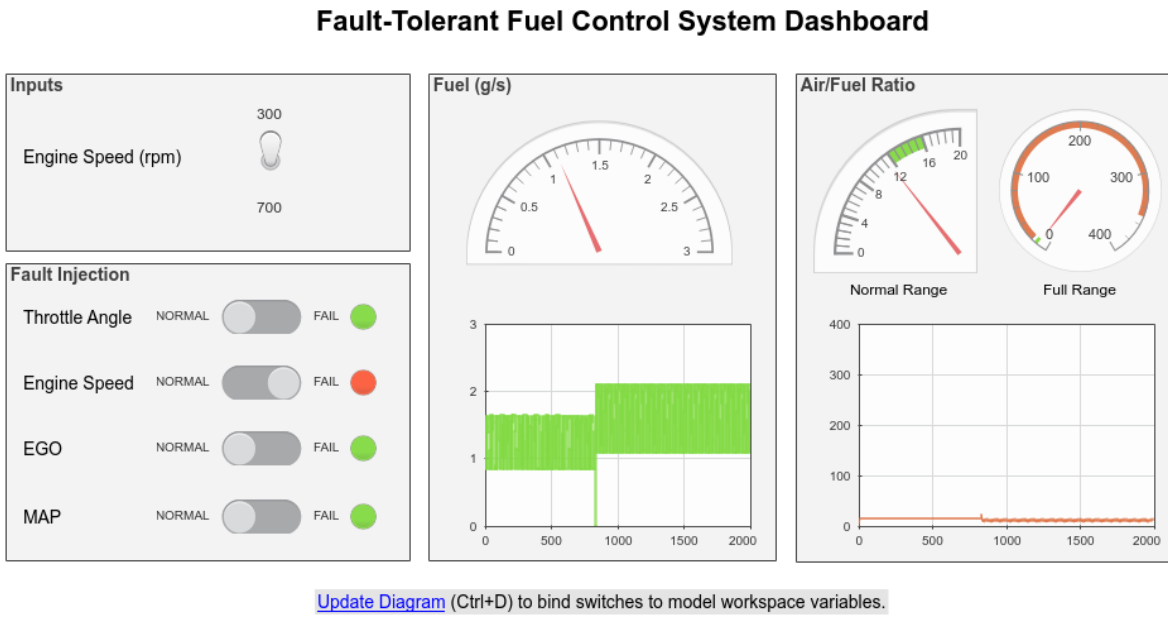
Simulate Changing Model States

In the Dashboard subsystem, switches provide control over the state of the throttle angle, engine speed, EGO, and MAP signals. For each sensor signal, the switch toggles between `normal` and `fail`, allowing you to simulate the system response to each single-point failure. Clicking any one of these switches before simulation, during simulation, or while a simulation is paused changes the state in the model.

Run the simulation and observe the control system response to each single-point failure.

1. Start the simulation.
2. As the simulation runs, click one of the switches to simulate a component failure.

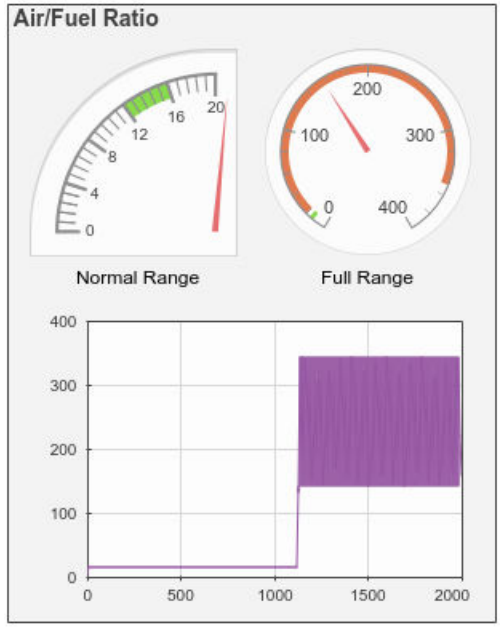
   Observe the changes in the `fuel` and `air_fuel_ratio` signals in the Dashboard Scope and Gauge blocks when you flip each switch.
3. Stop the simulation when you are finished.



View Signal Data

Dashboard blocks allow you to view signal data using gauges, lamps, and dashboard scopes. In this example, the Dashboard blocks provide visual feedback about the fuel input and air-to-fuel ratio during simulation, after simulation, and while a simulation is paused.

To capture different types of information and more effectively visualize a signal, connect multiple Dashboard blocks to a single signal. For example, you can visualize the `air_fuel_ratio` signal using the Gauge, Quarter Gauge, and Dashboard Scope blocks.



Use the Quarter Gauge block, labeled Normal Range in the example, to see small fluctuations in the instantaneous `air_fuel_ratio` signal while its value lies within the normal operational range. The Gauge block, labeled Full Range, allows you to see the behavior of the instantaneous `air_fuel_ratio` signal outside of the normal range. The Dashboard Scope block shows the variations of the `air_fuel_ratio` signal over time.

Note If you disable streaming for a signal connected to a Dashboard block Gauge or Dashboard Scope, the connection breaks, and signal data does not stream to the block. To view signal data again, double-click the Dashboard block and reconnect the signal.

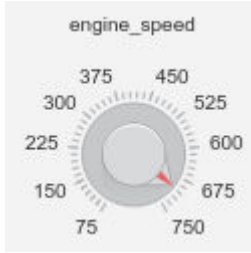
Tune Parameters During Simulation

Often, models include parameters that require tuning. Dashboard blocks allow you to tune these parameters during a simulation. To explore the tuning capability within the fuel system model, replace the engine speed Toggle Switch block with a Knob:

1. Delete the engine speed Toggle Switch.
2. Add a Knob block from the Dashboard library.
3. Double-click the Knob block to open its dialog box.
4. In the model, select the Engine Speed block. Engine Speed is a Constant block whose **Constant value** parameter you can tune with the Knob block.

   When you select Engine Speed, the name of the parameter you can tune appears in the connections table in the Knob block dialog box.

   Note Dashboard blocks cannot connect to blocks that are commented out.
5. Select the option button next to `engine_speed` in the connections table.
6. After you select the`engine_speed` parameter to tune, you can set the knob tick interval and range to values that make sense for your simulation. In this example, set **Minimum** to `75`, **Maximum** to `750`, and **Tick Interval** to `75`.
7. Click **OK** to connect the `engine_speed` parameter to the knob.



Simulate the model and tune the parameter using the Knob.

1. Start the simulation.
2. As the simulation runs, drag the pointer on the Knob to adjust the value of`engine_speed`.

   Notice as you use the Knob to adjust the value of `engine_speed`, the `air_fuel_ratio` value displayed on the Gauge blocks and in the Dashboard Scope block changes.
3. Stop the simulation when you are finished tuning parameters.

Analyzing Simulation Results

Decide How to Visualize Simulation Data

In this section...

Visualizing Simulation Data

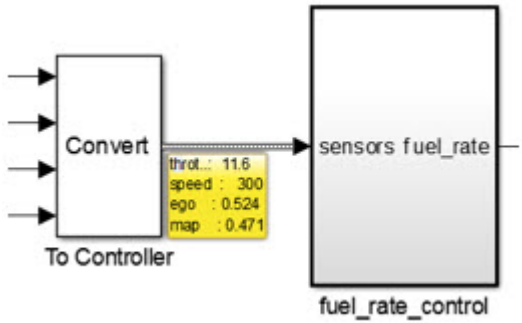
During the modeling process, you run simulations to learn about the behavior of your model. To observe that behavior, view and plot signal values during and after a simulation. Some common modeling tasks that include simulations are:

- Prototype — Quickly model a design and compare design alternatives.
- Validate — Compare simulated data with functional requirements to validate that you built your model correctly.
- Optimize — Compare simulated data between simulations to check if changes to your model remain within a specified design tolerance.
- Verify — Compare simulated data from a model with measured data from the modeled system to verify that your model gives the correct answer.

In Simulink you can view simulation data using several approaches. Some approaches display signal data during a simulation. Other approaches save signal data to the MATLAB workspace where you can post process the data. Learn about each of these approaches so you can choose one suitable for your application.

Port Value Displays

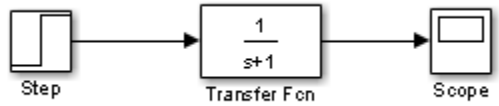
When debugging a model to isolate a particular issue, a common task is to observe signal values at each time step during a simulation. To observe a signal value, right-click a signal line, and then select **Show Value Label of Selected Port**.



Displaying port values for a bus signal allows you to monitor the signal values at each time step during a simulation.

Scope Blocks and Scope Viewers

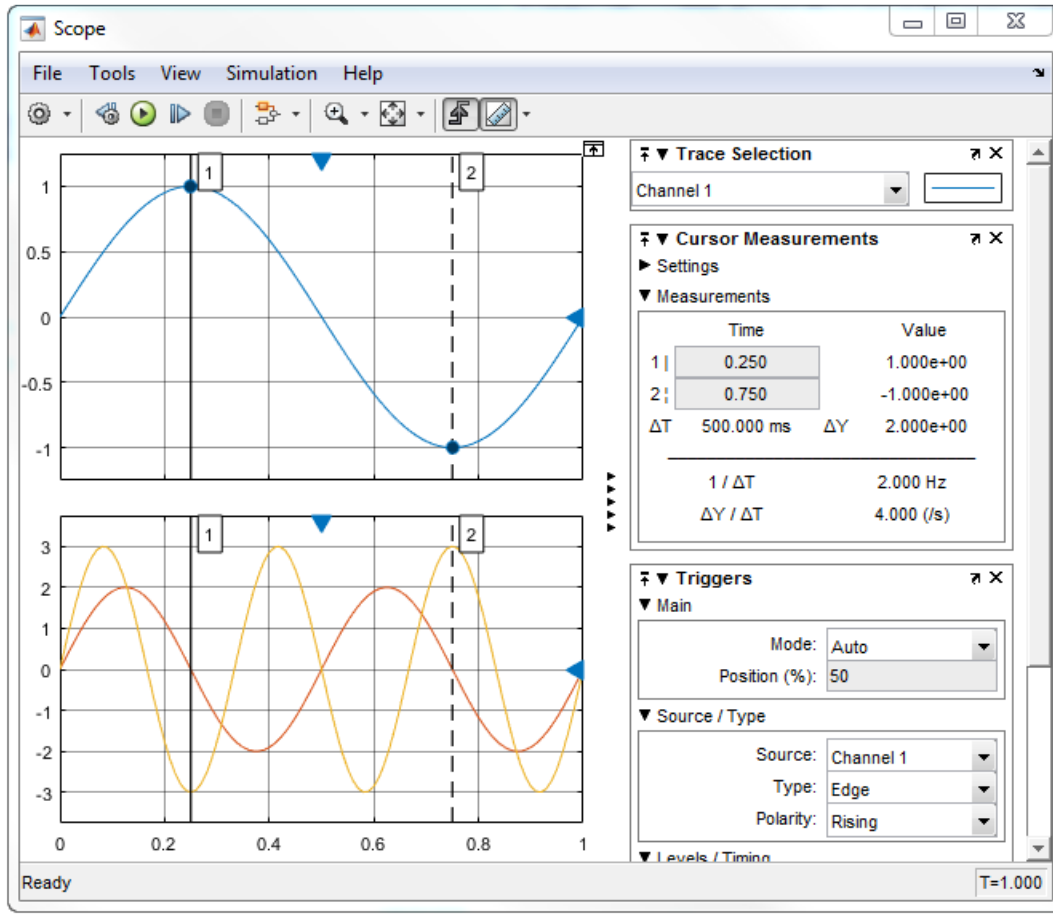
Scope blocks and scope viewers offer a way to visualize your simulation data over time. If you are prototyping a model design, you can attach signals to a Scope block, and then simulate your model to test and validate the design. Use the oscilloscope-like tools (triggers and measurements) available with a scope to debug your model.



A Scope block or scope viewer opens to a scope window where you can display and evaluate simulation data. In the Scope window, you can:

- Select signals — Connect signal lines to a Scope block using input ports. Attach signals to a Floating Scope block using the signal selector tool that hierarchically displays all signals in a model.
- View signals — Compare selected signals by grouping them on multiple displays.
- Prototype and debug — Set triggers to capture events, use interactive cursors to measure signal values at various points, and review signal statistics such as maximum and mean values. Also, control simulations and step through simulations to validate a design.
- Save signal data — Save signal data to the MATLAB workspace using a dataset object, array, or structure format.

- Supported data types — All data types supported by Simulink including variable-size, fixed-point, sample-based, and frame-based signals.



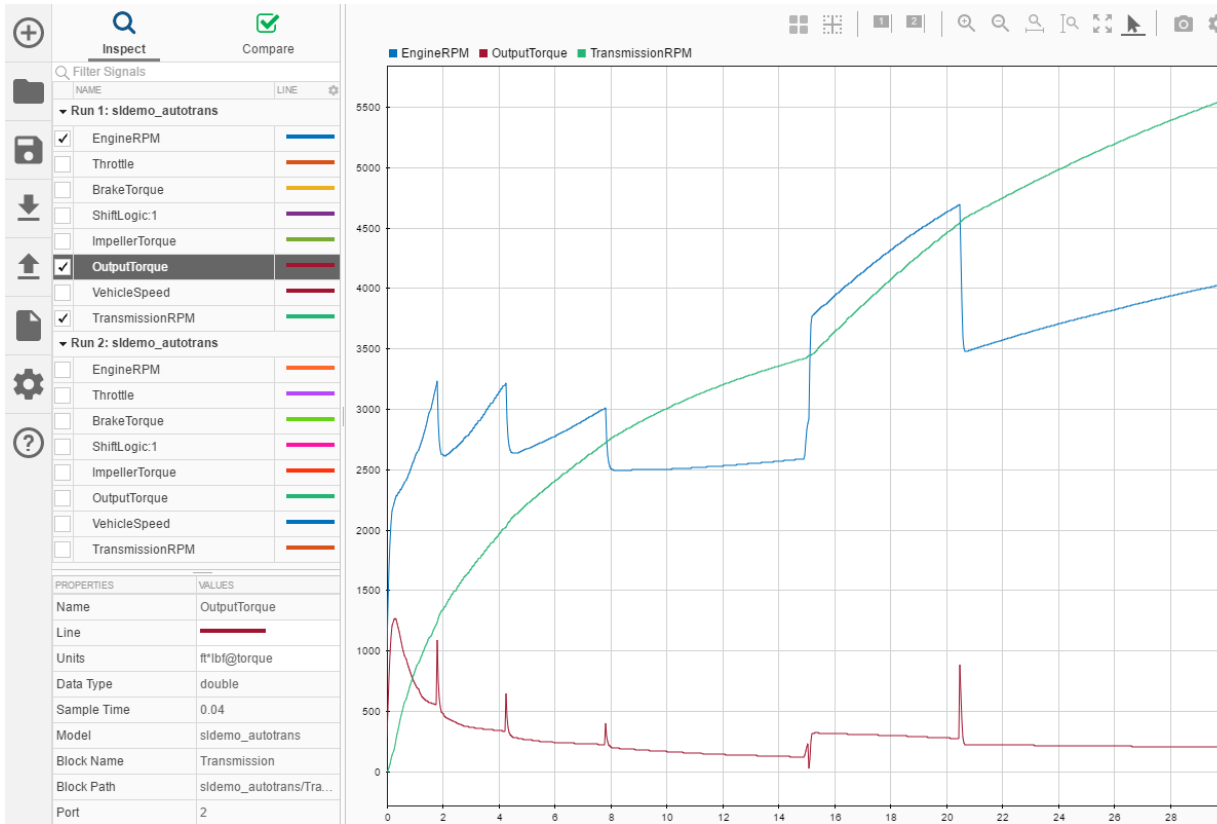
For more information, see “Scope Blocks and Scope Viewer Overview” on page 27-8.

Simulation Data Inspector

If you run your simulation more than once and want to inspect or compare data between simulations, you can use the Simulation Data Inspector. You can stream and store signals from the model and compare data between multiple simulations. For example,

you can check to see if the difference between two signals is within a certain design tolerance. In the Simulation Data Inspector, you can:

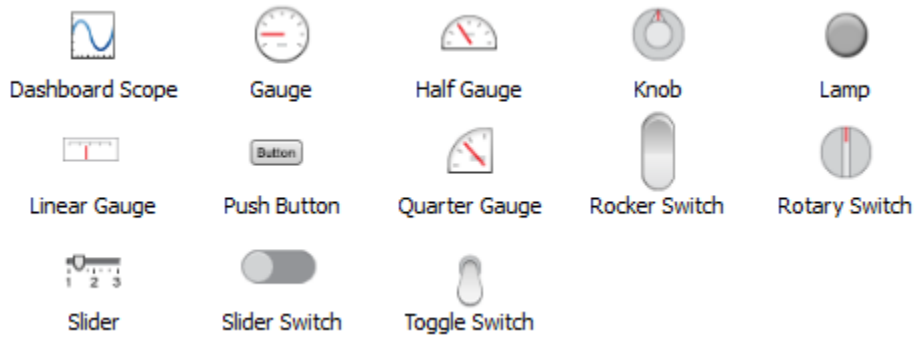
- View signals — Inspect signal data while your model is simulating.
- Import data — Import time series data from MAT-files or the base workspace.
- Compare signal data — Compare multiple simulation outputs to check the difference between runs.
- Export data and generate reports — Export plots and comparison data to share or archive results.



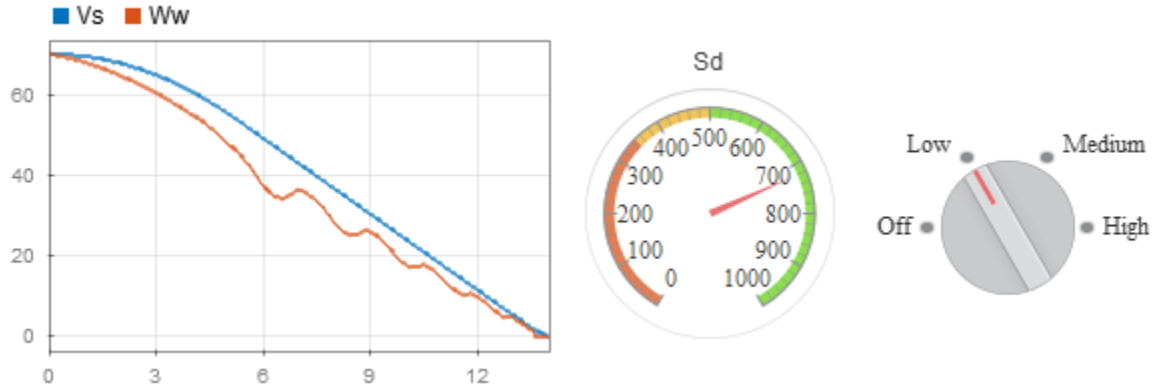
For more information, see “Simulation Data Inspector in Your Workflow” on page 28-2.

Dashboard Controls and Displays

Create an interactive display of controls and displays within your model diagram using blocks from the Dashboard library. Connect block parameters to control blocks (Knobs, Buttons, and Switches) and signals to displays blocks. (Scopes and Gauges).



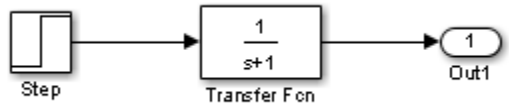
While a simulation is running, you can change parameter values using the controls. Signal values are updated continuously in the displays.



For more information, see “Tune and Visualize Your Model with Dashboard Blocks” on page 28-80.

Outport Block

Use Outport blocks to save simulation data from the top-level of your model to the MATLAB workspace. Select and define the variables for saving data in the **Data Import/Export** pane of the Configuration Parameters dialog box. For example, select the **Time** and **Output** check boxes.



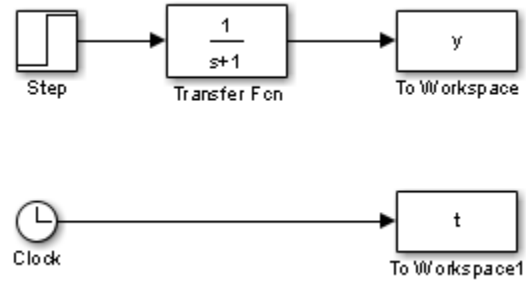
After running a simulation, you can use MATLAB plotting commands to display the simulation results. The variables `tout` and `yout` are the default variables returned by the solver after a simulation.

```
plot(tout,yout)
```

For more information, see "Model Configuration Parameters: Data Import/Export".

To Workspace Block

Use To Workspace blocks to save simulation data from anywhere in your model to the MATLAB workspace. Store a time vector by connecting a Clock block to a To Workspace block. You can also get a time vector using the `sim` command.



During a simulation, the blocks write data to an internal buffer. When you pause the simulation or it reaches the end time, data is written to the workspace and saved in the variables `y` and `t`.

For more information, see “Model Configuration Parameters: Data Import/Export”.

Signal Logging Without Blocks

You can save simulation data to the MATLAB workspace without using blocks.

1. Select signals for logging. Right-click a signal line, select **Properties**, and then select the **Log signal data** check box.
2. Enable signal logging during a simulation. In the **Data Import/Export** pane of the Configuration Parameters dialog box, select the **Signal logging** check box and enter a variable name.

For more information, see Export Signal Data Using Signal Logging on page 61-71.

Linearizing Models

In this section...

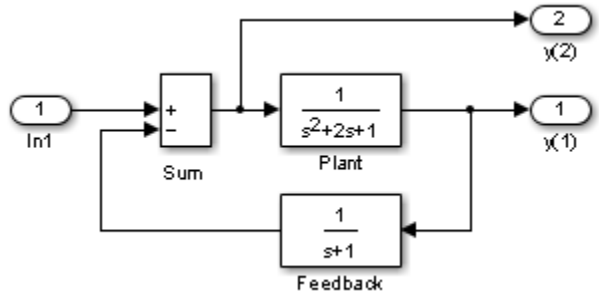
About Linearizing Models

The Simulink product provides the `linmod`, `linmod2`, and `dlinmod` functions to extract linear models in the form of the state-space matrices *A*, *B*, *C*, and *D*. State-space matrices describe the linear input-output relationship as

$$\dot{x} = Ax + Bu$$

$$y = Cx + Du,$$

where *x*, *u*, and *y* are state, input, and output vectors, respectively. For example, the following model is called `lmod`.



To extract the linear model of this system, enter this command.

```
[A,B,C,D] = linmod('lmod')

A =
   -2    -1    -1
    1     0     0
    0     1    -1
B =
```

```
     1
     0
     0
C =
     0     1     0
     0     0    -1
D =
     0
     1
```

Inputs and outputs must be defined using Inport and Outport blocks from the Ports & Subsystems library. Source and sink blocks do not act as inputs and outputs. Inport blocks can be used in conjunction with source blocks, using a Sum block. Once the data is in the state-space form or converted to an LTI object, you can apply functions in the Control System Toolbox product for further analysis:

- Conversion to an LTI object

  ```
  sys = ss(A,B,C,D);
  ```

- Bode phase and magnitude frequency plot

  ```
  bode(A,B,C,D) or bode(sys)
  ```

- Linearized time response

  ```
  step(A,B,C,D) or step(sys)
  impulse(A,B,C,D) or impulse(sys)
  lsim(A,B,C,D,u,t) or lsim(sys,u,t)
  ```

You can use other functions in the Control System Toolbox and the Robust Control Toolbox™ products for linear control system design.

When the model is nonlinear, an operating point can be chosen at which to extract the linearized model. Extra arguments to `linmod` specify the operating point.

```
[A,B,C,D] = linmod('sys', x, u)
```

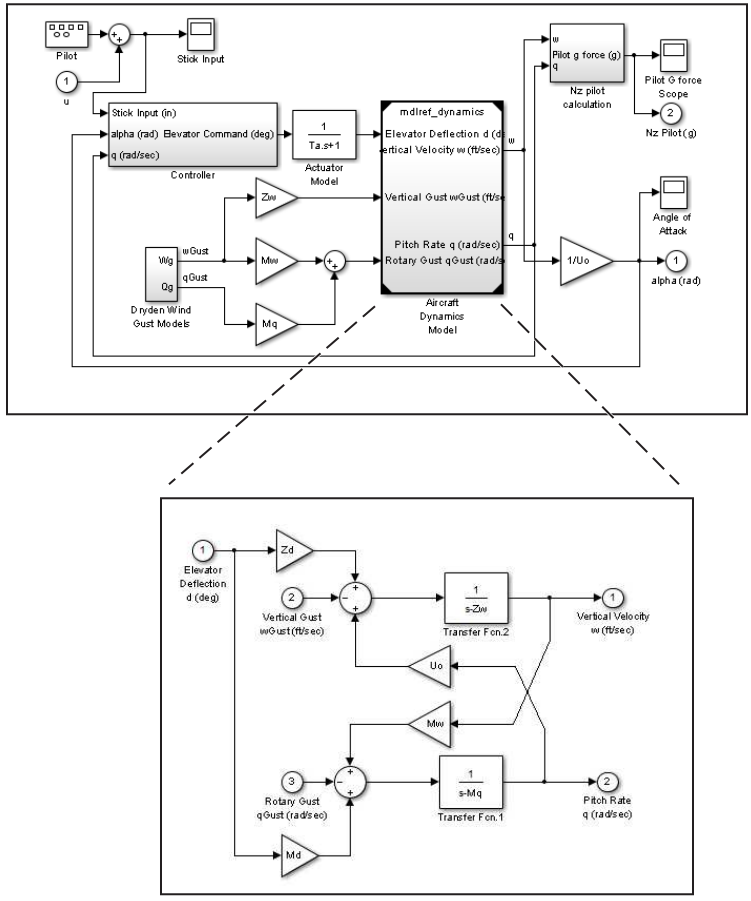
For discrete systems or mixed continuous and discrete systems, use the function `dlinmod` for linearization. This function has the same calling syntax as `linmod` except that the second right-hand argument must contain a sample time at which to perform the linearization.

Linearization with Referenced Models

You can use `linmod` to extract a linear model from a Simulink environment that contains Model blocks.

Note In Normal mode, the `linmod` command applies the block-by-block linearization algorithm on blocks inside the referenced model. If the Model block is in Accelerator mode, the `linmod` command uses numerical perturbation to linearize the referenced model. Due to limitations on linearizing multirate Model blocks in Accelerator mode, you should use Normal mode simulation for all models referenced by Model blocks when linearizing with referenced models. For an explanation of the block-by-block linearization algorithm, see the Simulink Control Design™ documentation.

For example, consider the `f14` model `mdlref_f14`. The Aircraft Dynamics Model block refers to the model `mdlref_dynamics`.



To linearize the `mdlref_f14` model, call the `linmod` command on the top `mdlref_f14` model as follows.

```
[A,B,C,D] = linmod('mdlref_f14')
```

The resulting state-space model corresponds to the complete `f14` model, including the referenced model.

You can call `linmod` with a state and input operating point for models that contain Model blocks. When using operating points, the state vector `x` refers to the total state vector for the top model and any referenced models. You must enter the state vector using the structure format. To get the complete state vector, call

```
x = Simulink.BlockDiagram.getInitialState(topModelName)
```

Linearization Using the 'v5' Algorithm

Calling the `linmod` command with the `'v5'` argument invokes the perturbation algorithm created prior to MATLAB software version 5.3. This algorithm also allows you to specify the perturbation values used to perform the perturbation of all the states and inputs of the model.

```
[A,B,C,D]=linmod('sys',x,u,para,xpert,upert,'v5')
```

Using `linmod` with the `'v5'` option to linearize a model that contains Derivative or Transport Delay blocks can be troublesome. Before linearizing, replace these blocks with specially designed blocks that avoid the problems. These blocks are in the Simulink Extras library in the Linearization sublibrary.

You access the Extras library by opening the Blocksets & Toolboxes icon:

- For the Derivative block, use the Switched derivative for linearization.

When using a Derivative block, you can also try to incorporate the derivative term in other blocks. For example, if you have a Derivative block in series with a Transfer Fcn block, it is better implemented (although this is not always possible) with a single Transfer Fcn block of the form

$$\frac{s}{s+a}.$$

In this example, the blocks on the left of this figure can be replaced by the block on the right.

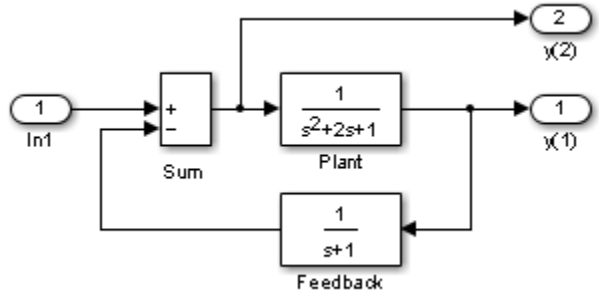
Finding Steady-State Points

The Simulink `trim` function uses a model to determine steady-state points of a dynamic system that satisfy input, output, and state conditions that you specify. Consider, for example, this model, called `ex_lmod`.



You can use the `trim` function to find the values of the input and the states that set both outputs to 1. First, make initial guesses for the state variables (`x`) and input values (`u`), then set the desired value for the output (`y`).

```
x = [0; 0; 0];
u = 0;
y = [1; 1];
```

Use index variables to indicate which variables are fixed and which can vary.

```
ix = [];      % Don't fix any of the states
iu = [];      % Don't fix the input
iy = [1;2];   % Fix both output 1 and output 2
```

Invoking `trim` returns the solution. Your results might differ because of roundoff error.

```
[x,u,y,dx] = trim('lmod',x,u,y,ix,iu,iy)

x =
   0.0000
   1.0000
   1.0000
u =
   2
y =
```

```
   1.0000
   1.0000
dx =
   1.0e-015 *
    -0.2220
    -0.0227
     0.3331
```

Note that there might be no solution to equilibrium point problems. If that is the case, `trim` returns a solution that minimizes the maximum deviation from the desired result after first trying to set the derivatives to zero. For a description of the `trim` syntax, see `trim`.

Improving Simulation Performance and Accuracy

How Optimization Techniques Improve Performance and Accuracy

The design of a model and choice of configuration parameters can affect simulation performance and accuracy. Solvers handle most model simulations accurately and efficiently with default parameter values. However, some models yield better results when you adjust solver parameters. Information about the behavior of a model can help you improve simulation performance, particularly when you provide this information to the solver. Use optimization techniques to better understand the behavior of your model and modify the model settings to improve performance and accuracy.

To optimize your model and achieve faster simulation automatically using Performance Advisor, see “Automated Performance Optimization”.

To learn more about accelerator modes for faster simulation, see “Acceleration”.

More About

- “Modeling Techniques That Improve Performance” on page 30-14

Speed Up Simulation

Several factors can slow simulation. Check your model for some of these conditions.

- Your model includes an Interpreted MATLAB Function block. When a model includes an Interpreted MATLAB Function block, the MATLAB execution engine is called at each time step, drastically slowing down the simulation. Use the built-in Fcn block or the Math Function block whenever possible.
- Your model includes a MATLAB file S-function. MATLAB file S-functions also call the MATLAB execution engine at each time step. Consider converting the S-function either to a subsystem or to a C-MEX file S-function.
- Your model includes a Memory block. Using a Memory block causes the variable-order solvers (`ode15s` and `ode113`) to reset back to order 1 at each time step.
- The maximum step size is too small. If you changed the maximum step size, try running the simulation again with the default value (`auto`).
- Your accuracy requirements are too high. The default relative tolerance (0.1% accuracy) is usually sufficient. For models with states that go to zero, if the absolute tolerance parameter is too small, the simulation can take too many steps around the near-zero state values. See the discussion of this error in "Maximum order""Maximum order" in the online documentation.
- The time scale is too long. Reduce the time interval.
- The problem is stiff, but you are using a nonstiff solver. Try using `ode15s`. For more information, see "Stiffness of System" on page 30-18.
- The model uses sample times that are not multiples of each other. Mixing sample times that are not multiples of each other causes the solver to take small enough steps to ensure sample time hits for all sample times.
- The model contains an algebraic loop. The solutions to algebraic loops are iteratively computed at every time step. Therefore, they severely degrade performance. For more information, see "Algebraic Loops" on page 3-37.
- Your model feeds a Random Number block into an Integrator block. For continuous systems, use the Band-Limited White Noise block in the Sources library.
- Your model contains a scope viewer that displays too many data points. Try adjusting the viewer property settings that can affect performance. For more information, see Scope Viewer.
- You need to simulate your model iteratively. You change tunable parameters between iterations but do not make structural changes to the model. Every iteration requires

the model to compile again, thus increasing overall simulation time. Use fast restart to perform iterative simulations. In this workflow, the model compiles only once and iterative simulations are tied to a single compile phase. See “How Fast Restart Improves Iterative Simulations” on page 70-2 for more information.

How Profiler Captures Performance Data

In this section...

How Profiler Works

Profiler captures performance data while your model simulates. It identifies the parts of your model that require the most time to simulate. Use the profiling information to decide where to focus your model optimization efforts.

Note You cannot use Profiler in Rapid Accelerator mode.

Simulink stores performance data in the *simulation profile report*. The data shows the time spent executing each function in your model.

The basis for Profiler is an execution model that this pseudocode summarizes.

```
Sim()
    ModelInitialize().
    ModelExecute()
        for t = tStart to tEnd
        Output()
        Update()
        Integrate()
            Compute states from derivs by repeatedly calling:
                MinorOutput()
                MinorDeriv()
            Locate any zero crossings by repeatedly calling:
                MinorOutput()
                MinorZeroCrossings()
        EndIntegrate
        Set time t = tNew.
    EndModelExecute
    ModelTerminate
EndSim
```

According to this conceptual model, Simulink runs a model by invoking the following functions zero, one, or many times, depending on the function and the model.

Function	Purpose	Level
`sim`	Simulate the model. This top-level function invokes the other functions required to simulate the model. The time spent in this function is the total time required to simulate the model.	System
`ModelInitialize`	Set up the model for simulation.	System
`ModelExecute`	Execute the model by invoking the output, update, integrate, etc., functions for each block at each time step from the start to the end of simulation.	System
`Output`	Compute the outputs of a block at the current time step.	Block
`Update`	Update the state of a block at the current time step.	Block
`Integrate`	Compute the continuous states of a block by integrating the state derivatives at the current time step.	Block
`MinorOutput`	Compute block output at a minor time step.	Block
`MinorDeriv`	Compute the state derivatives of a block at a minor time step.	Block
`MinorZeroCrossings`	Compute zero-crossing values of a block at a minor time step.	Block
`ModelTerminate`	Free memory and perform any other end-of-simulation cleanup.	System

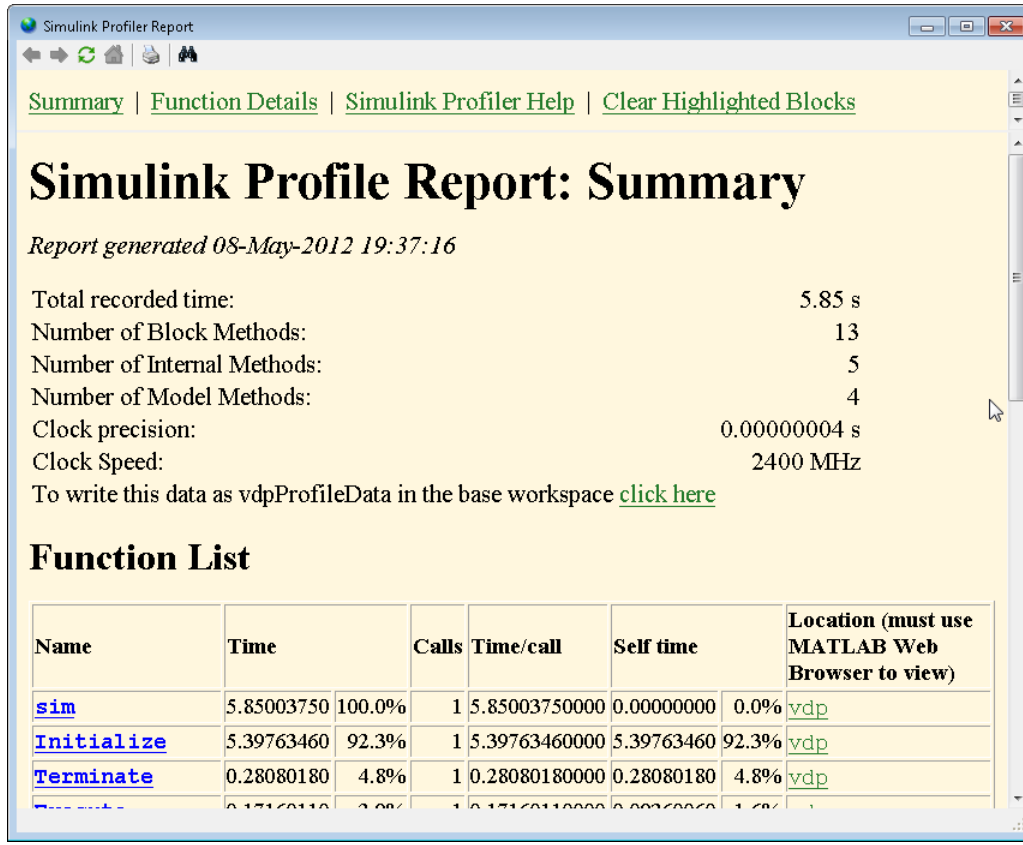
Function	Purpose	Level
`Nonvirtual Subsystem`	Compute the output of a nonvirtual subsystem at the current time step by invoking the output, update, integrate, etc., functions for each block that it contains. The time spent in this function is the time required to execute the nonvirtual subsystem.	Block

Profiler measures the time required to execute each invocation of these functions. After the model simulates, Profiler generates a report that describes the amount of simulation time spent on each function.

Start Profiler

1. Open the model.
2. Select **Analysis > Performance Tools > Show Profiler Report**.
3. Simulate the model.

When simulation is complete, Simulink generates and displays the simulation profile for the model in a MATLAB web browser.



Summary Section

The summary file displays the following performance totals.

Item	Description
Total Recorded Time	Total time required to simulate the model
Number of Block Methods	Total number of invocations of block-level functions (e.g., `Output()`)
Number of Internal Methods	Total number of invocations of system-level functions (e.g., `ModelExecute`)
Number of Model Methods	Number of methods called by the model

Item	Description
Number of Nonvirtual Subsystem Methods	Total number of invocations of nonvirtual subsystem functions
Clock Precision	Precision of the profiler's time measurement
Clock Speed	Speed of the profiler's time measurement

The function list shows summary profiles for each function invoked to simulate the model. For each function listed, the summary profile specifies this information.

Item	Description
Name	Name of function. This item is a hyperlink. Click it to display a detailed profile of this function.
Time	Total time spent executing all invocations of this function as an absolute value and as a percentage of the total simulation time.
Calls	Number of times this function was invoked.
Time/Call	Average time required for each invocation of this function, including the time spent in functions invoked by this function.
Self Time	Total time required to execute this function, excluding time spent in functions called by this function.
Location	Specifies the block or model executed for which this function is invoked. This item is a hyperlink. Click it to highlight the corresponding element in the model diagram.

Detailed Profile Section

This section of the report contains detailed profiles for each function that Simulink invoked to simulate the model. In addition to the information in the summary profile for the function, the detailed profile displays the function (parent function) that invoked the profiled function and the functions (child functions) invoked by the profiled function. Click the name of the parent or a child function to see the detailed profile for that function.

Note Enabling Profiler on a parent model does not enable profiling for referenced models. You must enable profiling separately for each referenced model. Profiling occurs only if the referenced model executes in Normal mode. See “Normal Mode” on page 34-4 for more information.

Reports for the referenced models are different from that of the parent model.

Save Profiler Results

You can save the Profiler report to a variable in the MATLAB workspace, and after that, to a `mat` file. At a later time, you can regenerate and review the report.

Save the Profiler report for a model `vdp` to the variable `profile1` and to the data file `report1.mat`.

1. In the **Simulink Profiler Report** window, in the **Summary** section, click **click here** link. Simulink saves the report data to the variable `vdpProfileData`.
2. Review the report. At the MATLAB command prompt, enter:

   ```
   slprofreport(vdpProfileData)
   ```
3. Save the data to a variable named `profile1` in the base workspace.

   ```
   profile1 = vdpProfileData;
   ```
4. Save the data to a `mat` file named `report1`.

   ```
   save report1 profile1
   ```

To view the report later, at the MATLAB command prompt, enter:

```
load report1
slprofreport(profile1);
```

Check and Improve Simulation Accuracy

Check Simulation Accuracy

1. Simulate the model over a reasonable time span.
2. Reduce either the relative tolerance to 1e-4 (the default is 1e-3) or the absolute tolerance.
3. Simulate the model again.
4. Compare the results from both simulations.

If the results are not significantly different, the solution has converged.

If the simulation misses significant behavior at the start, reduce the initial step size to ensure that the simulation does not step over that behavior.

Unstable Simulation Results

When simulation results become unstable over time,

- The system can be unstable.
- If you are using the `ode15s` solver, try restricting the maximum order to 2 (the maximum order for which the solver is A-stable). You can also try using the `ode23s` solver.

Inaccurate Simulation Results

If simulation results are not accurate:

- For a model that has states whose values approach zero, if the absolute tolerance parameter is too large, the simulation takes too few steps around areas of near-zero state values. Reduce this parameter value in the **Solver pane** of model configuration parameters or adjust it for individual states in the function block parameters of the Integrator block.
- If reducing the absolute tolerances does not improve simulation accuracy enough, reduce the size of the relative tolerance parameter. This change reduces the acceptable error and forces smaller step sizes and more steps.

Certain modeling constructs can also produce unexpected or inaccurate simulation results.

- A Source block that inherits sample time can produce different simulation results if, for example, the sample times of the downstream blocks are modified (see “How Propagation Affects Inherited Sample Times” on page 7-39).
- A Derivative block found in an algebraic loop can result in a loss in solver accuracy.

Modeling Techniques That Improve Performance

In this section...

Accelerate the Initialization Phase

Speed up a simulation by accelerating the initialization phase, using these techniques.

Simplify Graphics Using Mask Editor

Complex graphics and large images take a long time to load and render. Masked blocks that contain such images can make your model less responsive. Where possible, remove complex drawings and images from masked blocks.

If you want to keep the image, replace it with a smaller, low-resolution version. Use mask editor and edit the icon drawing commands to keep the image that is loaded by the call to `image()`.

For more information on mask editor, see “Mask Editor Overview”.

Consolidate Function Calls

When you open or update a model, Simulink runs the mask initialization code. If your model contains complicated mask initialization commands that contain many calls to `set_param`, consolidate consecutive calls into a single call with multiple argument pairs. Consolidating the calls can reduce the overhead associated with these function calls.

To learn more, see “Mask Callback Code” on page 38-18.

Load Data Using MAT-file

If you use MATLAB scripts to load and initialize data, you can improve performance by loading MAT-files instead. The data in a MAT-file is in binary and can be more difficult

to work with than a script. However, the load operation typically initializes data more quickly than the equivalent MATLAB script.

For more information, see “MAT-Files for Signal Data” on page 61-12.

Reduce Model Interactivity

In general, the more interactive a model is, the longer it takes to simulate. Use these techniques to reduce the interactivity of your model.

Disable Debugging Diagnostics

Some enabled diagnostic features can slow simulations considerably. Consider disabling them in the model configuration parameters **Diagnostics** pane.

Note Running **Array bounds exceeded** and **Solver data inconsistency** can slow down model runtime performance. For more information, see “Array bounds exceeded” and “Solver data inconsistency”.

Disable MATLAB Debugging

After verifying that your MATLAB code works correctly, disable these checks in the model configuration parameters **Simulation Target** pane.

- **Enable debugging/animation**
- **Detect wrap on overflow (with debugging)**
- **Echo expressions without semicolons**

For more information, see “Model Configuration Parameters: Simulation Target”.

Use BLAS Library Support

If your simulation involves low-level MATLAB matrix operations, use the Basic Linear Algebra Subprograms (BLAS) libraries to make use of highly optimized external linear algebra routines.

Disable Stateflow Animations

By default, Stateflow charts highlight the current active states in a model and animate the state transitions that take place as the model simulates. This feature is useful for debugging, but it slows the simulation.

To accelerate simulations, either close all Stateflow charts or disable the animation. Similarly, consider disabling animation or reducing scene fidelity when you use:

- Simulink 3D Animation
- Simscape Multibody visualization
- FlightGear
- Any other 3D animation package

To learn more, see “Speed Up Simulation” (Stateflow).

Adjust Scope Viewer Properties

If your model contains a scope viewer that displays a high rate of logging and you cannot remove the scope, adjust the viewer properties to trade off fidelity for rendering speed.

However, when you use decimation to reduce the number of plotted data points, you can miss short transients and other phenomena that you can see with more data points. To have more precise control over enabling visualizations, place viewers in enabled subsystems.

For more information, see Scope Viewer.

Reduce Model Complexity

Use these techniques to improve simulation performance by simplifying a model without sacrificing fidelity.

Replace Subsystems with Lower-Fidelity Alternatives

Replace a complex subsystem with one of these alternatives:

- A linear or nonlinear dynamic model that was created from measured input-output data using the System Identification Toolbox™.
- A high-fidelity, nonlinear statistical model that was created using the Model-Based Calibration Toolbox™.

- A linear model that was created using Simulink Control Design.
- A lookup table. For more information, see A lookup table.

You can maintain both representations of the subsystem in a library and use variant subsystems to manage them. Depending on the model, you can make this replacement without affecting the overall result. For more information, see “Optimize Generated Code for Lookup Table Blocks” on page 37-43.

Reduce Number of Blocks

When you reduce the number of blocks in your model, fewer blocks require updates during simulations and simulation is faster.

- Vectorization is one way to reduce your block count. For example, if you have several parallel signals that undergo a similar set of computations, try to combine them into a vector using a Mux block and perform a single computation.
- You can also enable the **Block Reduction** parameter in the **Configuration Parameters** dialog.

Use Frame-Based Processing

In frame-based processing, Simulink processes samples in batches instead of one at a time. If a model includes an analog-to-digital converter, for example, you can collect output samples in a buffer. Process the buffer in a single operation, such as a fast Fourier transform. Processing data in chunks this way reduces the number of times that the simulation needs to invoke blocks in your model.

In general, the scheduling overhead decreases as frame size increases. However, larger frames consume more memory, and memory limitations can adversely affect the performance of complex models. Experiment with different frame sizes to find one that maximizes the performance benefit of frame-based processing without causing memory issues.

Choose and Configure a Solver

Simulink provides a comprehensive library of solvers, including fixed-step and variable-step solvers, to handle stiff and nonstiff systems. Each solver determines the time of the next simulation step. A solver applies a numerical method to solve ordinary differential equations that represent the model.

The solver you choose and the solver options you select can affect simulation speed. Select and configure a solver that helps boost the performance of your model using these criteria. For more information, see “Choose a Solver” (Global Optimization Toolbox).

Stiffness of System

A stiff system has continuous dynamics that vary slowly and quickly. Implicit solvers are particularly useful for stiff problems. Explicit solvers are better suited for nonstiff systems. Using an explicit solver to solve a stiff system can lead to incorrect results. If a nonstiff solver uses a very small step size to solve a model, this is a sign that your system is stiff.

Model Step Size and Dynamics

When you are deciding between using a variable-step or fixed-step solver, keep in mind the step size and dynamics of your model. Select a solver that uses time steps to capture only the dynamics that are important to you. Choose a solver that performs only the calculations needed to work out the next time step.

You use fixed-step solvers when the step size is less than or equal to the fundamental sample time of the model. With a variable-step solver, the step size can vary because variable-step solvers dynamically adjust the step size. As a result, the step size for some time steps is larger than the fundamental sample time, reducing the number of steps required to complete the simulation. In general, simulations with variable-step solvers run faster than those that run with fixed-step solvers.

Choose a fixed-step solver when the fundamental sample time of your model is equal to one of the sample rates. Choose a variable-step solver when the fundamental sample time of your model is less than the fastest sample rate. You can also use variable-step solvers to capture continuous dynamics.

Decrease Solver Order

When you decrease the solver order, you reduce the number of calculations that Simulink performs to determine state outputs, which improves simulation speed. However, the results become less accurate as the solver order decreases. Choose the lowest solver order that produces results with acceptable accuracy.

Increase Solver Step Size or Error Tolerance

Increasing the solver step size or error tolerance usually increases simulation speed at the expense of accuracy. Make these changes with care because they can cause Simulink to miss potentially important dynamics during simulations.

Disable Zero-Crossing Detection

Variable-step solvers dynamically adjust the step size, increasing it when a variable changes slowly and decreasing it when a variable changes rapidly. This behavior causes the solver to take many small steps near a discontinuity because this is when a variable changes rapidly. Accuracy improves, but often at the expense of long simulation times.

To avoid the small time steps and long simulations associated with these situations, Simulink uses zero-crossing detection to locate such discontinuities accurately. For systems that exhibit frequent fluctuations between modes of operation—a phenomenon known as chattering—this zero-crossing detection can have the opposite effect and thus slow down simulations. In these situations, you can disable zero-crossing detection to improve performance.

You can enable or disable zero-crossing detection for specific blocks in a model. To improve performance, consider disabling zero-crossing detection for blocks that do not affect the accuracy of the simulation.

For more information, see “Zero-Crossing Detection” on page 3-24.

Save the Simulation State

In the classic workflow, a Simulink model simulates repeatedly for different inputs, boundary conditions, and operating conditions. In many situations, these simulations share a common startup phase in which the model transitions from the initial state to another state. For example, you can bring an electric motor up to speed before you test various control sequences.

Using `SimState`, you can save the simulation state at the end of the startup phase and then restore it for use as the initial state for future simulations. This technique does not improve simulation speed, but it can reduce total simulation time for consecutive runs because the startup phase needs to be simulated only once.

See “Save and Restore Simulation State as SimState” on page 24-37 for more information.

Performance Advisor

Improve Simulation Performance Using Performance Advisor

In this section...

Whatever the level of complexity of your model, you can make systematic changes that improve simulation performance. Performance Advisor checks for configuration settings that slow down your model simulations. It produces a report that lists the suboptimal conditions or settings it finds and suggests better configuration settings where appropriate.

You can use the Performance Advisor to fix some of these suboptimal conditions automatically or you can fix them manually.

Note Use Performance Advisor on top models. Performance Advisor does not traverse referenced models or library links.

To learn about faster simulation using acceleration modes, see “Acceleration”.

Performance Advisor Workflow

When the performance of a model is slower than expected, use Performance Advisor to help identify and resolve bottlenecks.

1. Prepare your model.
2. Create a baseline to compare measurements against.
3. Select the checks you want to run.
4. Run Performance Advisor with the selected checks and see recommended changes.
5. Make changes to the model. You can either:

- Automatically apply changes.
- Generate advice, and review and apply changes manually.

6 After applying changes, Performance Advisor performs a final validation of the model to see how performance has improved.

- If the performance improves, the selected checks were successful. The performance check is complete.
- If the performance is worse than the baseline, Performance Advisor reinstates the previous settings of the model.

7 Save your model.

Caution Performance Advisor does not automatically save your model after it makes changes. When you are satisfied with the changes to the model from Performance Advisor, save the model.

Prepare Your Model

Before running checks using Performance Advisor, complete the following steps:

- "Start Performance Advisor" on page 31-3
- "Enable Data Logging for the Model" on page 31-4
- "Select How Performance Advisor Applies Advice" on page 31-4
- "Select Validation Actions for the Advice" on page 31-4
- "Specify Runtime for Performance Advisor" on page 31-5

Start Performance Advisor

To get started with Performance Advisor:

1 Make a backup of the model.

2 Verify that the model can simulate without error.

3 Close all applications, including web browsers. Leave only the MATLAB Command Window, the model you want to analyze, and Performance Advisor running.

Running other applications can hinder the performance of model simulation and the ability of Performance Advisor to measure accurately.

4 Open Performance Advisor. In the Simulink Editor, select **Analysis > Performance Tools > Performance Advisor**.

Enable Data Logging for the Model

Make sure the model configuration parameters are set to enable data logging.

1 In the model, select **Simulation > Model Configuration Parameters**.

2 In the Configuration Parameters dialog box, click **Data Import/Export** in the left pane.

3 Set up signal logging. The model must log at least one signal for Performance Advisor to work. For example, select the **States** or **Output** check box.

4 Click **Configure Signals to Log** and select the signals to log.

> **Note** Select only the signals you are most interested in. Minimizing the number of signals to log can help performance. Selecting too many signals can cause Performance Advisor to run for a longer time.

5 Click **OK** in the Configuration Parameters dialog box.

6 Run the model once to make sure that the simulation is successful.

Select How Performance Advisor Applies Advice

Choose from these options to apply advice to the model:

- **Use check parameters**. Select the checks for which you want Performance Advisor to automatically apply advice. You can review the remaining checks and apply advice manually.
- **Automatically for all checks**. Performance Advisor automatically applies advice to all selected checks.
- **Generate advice only**. Review advice for each check and apply changes manually.

Select Validation Actions for the Advice

For the checks you want to run, validate an improvement in simulation time and accuracy by comparing against a baseline measurement. Each validation action requires the model to simulate. Use these validation options as global settings for the checks you select:

- **Use check parameters**. From the checks you want to run, select the ones for which you want to validate an improvement in performance. Specify validation action for fixes using individual settings for these checks.
- **For all checks**. Performance Advisor automatically validates an improvement in performance for the checks you select.
- **Do not validate**. Performance Advisor does not validate an improvement in performance. Instead, you can validate manually. When you select this option and also specify for Performance Advisor to apply advice automatically, a warning appears before Performance Advisor applies changes without validation.

These global settings for validation apply to all checks in the left pane except the Final Validation check. The Final Validation check validates the overall performance improvement in a model after you have applied changes. In case you do not want to validate changes resulting from other check results, you can run the Final Validation check to validate model changes for simulation time and accuracy.

Specify Runtime for Performance Advisor

You can specify a **Time Out** value in minutes if you want to limit the runtime duration of Performance Advisor. Use this option when running Performance Advisor on models with long simulation times.

If Performance Advisor times out before completing the checks you specify, in the left pane you can see the checks that failed.

Create a Performance Advisor Baseline Measurement

A baseline measurement is a set of simulation measurements that Performance Advisor measures check results against.

Note Before creating a baseline measurement, set the model configuration parameters to enable data logging. For more information, see “Enable Data Logging for the Model” on page 31-15.

---

1. In the model, select **Analysis > Performance Tools > Performance Advisor** to start Performance Advisor.
2. In the left pane, in the Baseline folder, select **Create Baseline**.

3 In the right pane, under **Input Parameters**, enter a value in the **Stop Time** field for the baseline.

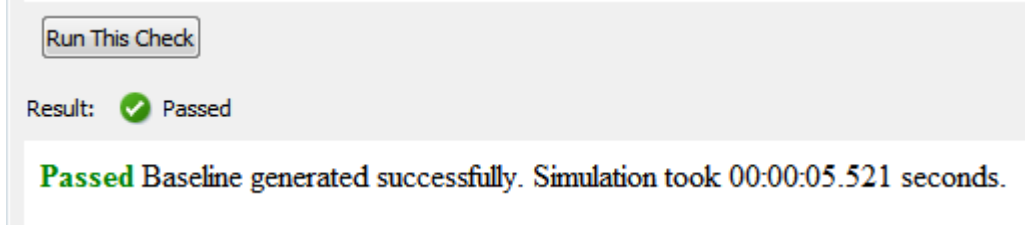
When you enter a Stop Time value in Performance Advisor, this overrides the value set in the model. A large stop time can create a simulation that runs longer.

If you do not enter a value, Performance Advisor uses values from the model. Performance Advisor uses values from the model that are less than 10. Performance Advisor rounds values from the model larger than 10 to 10.

4 Select the **Check to view baseline signals and set their tolerances** check box to start the Signal Data Inspector after Performance Advisor runs a check. Using the Signal Data Inspector, you can compare signals and adjust tolerance levels.

5 Click **Run This Check**.

When a baseline has been created, a message like the following appears under **Analysis**:



After the baseline has been created, you are can run Performance Advisor checks.

Run Performance Advisor Checks

1 After you have created a baseline measurement, select checks to run.

- In the left pane of Performance Advisor, expand a folder, such as **Simulation** or **Simulation Targets**, to display checks related to specific tasks.
- In the folder, select the checks you want to run using the check boxes.

Tip If you are unsure of which checks apply, you can select and run all checks. After you see the results, clear the checks you are not interested in.

2 Specify input parameters for selected checks. Use one of these methods:

- Apply global settings to all checks to take action, validate simulation time and validate simulation accuracy.
- Alternatively, for each check, in the right pane, specify input parameters.

Input Parameter	Description
Take action based on advice	`automatically` — Allow Performance Advisor to automatically make the change for you. `manually` — Review the change first. Then manually make the change or accept Performance Advisor recommendations.
Validate and revert changes if time of simulation increases	Select this check box to have Performance Advisor rerun the simulation and verify that the change made based on the advice improves simulation time. If the change does not improve simulation time, Performance Advisor reverts the changes.
