Specify the initial values of the square root inverse covariance matrix of the input signal. This property must be either a scalar or a square matrix with each dimension equal to the `Length` property value. If you set a scalar value, the `SquareRootInverseCovariance` property is initialized to a diagonal matrix with diagonal elements equal to that scalar value. This property applies only when the `Method` property is set to `Householder RLS` or `Householder sliding-window RLS`. The default value is `sqrt(1000)`. This property is tunable.

### **InitialSquareRootCovariance**

Initial square root covariance

Specify the initial values of the square root covariance matrix of the input signal. This property must be either a scalar or a square matrix with each dimension equal to the `Length` property value. If you set a scalar value, the `SquareRootCovariance` property is initialized to a diagonal matrix with diagonal elements equal to the scalar value. This property applies only when the `Method` property is set to `QR-decomposition RLS`. The default value is `sqrt(1/1000)`. This property is tunable.

### **LockCoefficients**

Lock coefficient updates

Specify whether the filter coefficient values should be locked. When you set this property to `true`, the filter coefficients are not updated and their values remain the same. The default value is `false` (filter coefficients continuously updated). This property is tunable.

## Methods

msesim	Mean-square error for RLS filter
reset	Reset the internal states of a System object
step	Process inputs using RLS filter

Common to All System Objects	
release	Allow System object property value changes

## Examples

### System Identification of an FIR Filter

Use the RLS filter System object™ to determine the signal value.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```

rsl1 = dsp.RLSFilter(11, 'ForgettingFactor', 0.98);
filt = dsp.FIRFilter('Numerator', fir1(10, .25)); % Unknown System
x = randn(1000,1); % input signal
d = filt(x) + 0.01*randn(1000,1); % desired signal
[y,e] = rsl1(x, d);
w = rsl1.Coefficients;
subplot(2,1,1), plot(1:1000, [d,y,e]);
title('System Identification of an FIR filter');
legend('Desired', 'Output', 'Error');
xlabel('time index'); ylabel('signal value');
subplot(2,1,2); stem([filt.Numerator; w].');
legend('Actual', 'Estimated');
xlabel('coefficient #'); ylabel('coefficient value');

```

### Noise Cancellation

```

rls2 = dsp.RLSFilter('Length', 11, 'Method', 'Householder RLS');
filt2 = dsp.FIRFilter('Numerator', fir1(10, [.5, .75]));
x = randn(1000,1); % Noise
d = filt2(x) + sin(0:.05:49.95); % Noise + Signal
[y, err] = rls2(x, d);
subplot(2,1,1), plot(d), title('Noise + Signal');
subplot(2,1,2), plot(err), title('Signal');

```

## Algorithms

The `dsp.RLSFilter` System object, when `Conventional` RLS is selected, recursively computes the least squares estimate (RLS) of the FIR filter weights. The System object estimates the filter weights or coefficients, needed to convert the input signal into the desired signal. The input signal can be a scalar or a column vector. The desired signal must have the same data type, complexity, and dimensions as the input signal. The corresponding RLS filter is expressed in matrix form as  $\mathbf{P}(n)$  :

$$\mathbf{k}(n) = \frac{\lambda^{-1}\mathbf{P}(n-1)\mathbf{u}(n)}{1 + \lambda^{-1}\mathbf{u}^H(n)\mathbf{P}(n-1)\mathbf{u}(n)}$$

$$y(n) = \mathbf{w}^T(n-1)\mathbf{u}(n)$$

$$e(n) = d(n) - y(n)$$

$$\mathbf{w}(n) = \mathbf{w}(n-1) + \mathbf{k}(n)e(n)$$

$$\mathbf{P}(n) = \lambda^{-1}\mathbf{P}(n-1) - \lambda^{-1}\mathbf{k}(n)\mathbf{u}^H(n)\mathbf{P}(n-1)$$

where  $\lambda^{-1}$  denotes the reciprocal of the exponential weighting factor. The variables are as follows:

Variable	Description
$n$	The current time index
$\mathbf{u}(n)$	The vector of buffered input samples at step $n$
$\mathbf{P}(n)$	The inverse correlation matrix at step $n$
$\mathbf{k}(n)$	The gain vector at step $n$
$\mathbf{w}(n)$	The vector of filter tap estimates at step $n$
$y(n)$	The filtered output at step $n$
$e(n)$	The estimation error at step $n$
$d(n)$	The desired response at step $n$
$\lambda$	The forgetting factor

$\mathbf{u}$ ,  $\mathbf{w}$ , and  $\mathbf{k}$  are all column vectors.

## **mstesim**

**System object:** dsp.RLSFilter

**Package:** dsp

Mean-square error for RLS filter

### **Syntax**

```
MSE = mstesim(sysObj,X,D)
[MSE,MEANW,W,TRACEK] = mstesim(sysObj,X,D)
[...] = mstesim(sysObj,X,D,M)
```

### **Description**

`MSE = mstesim(sysObj,X,D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE,MEANW,W,TRACEK] = mstesim(sysObj,X,D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `sysObj`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(sysObj.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `sysObj`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[...] = mstesim(sysObj,X,D,M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If `M > 1`, every `Mth` predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

# reset

**System object:** dsp.RLSFilter

**Package:** dsp

Reset the internal states of a System object

## Syntax

```
reset(rlsFilt)
```

## Description

`reset(rlsFilt)` resets the internal states of the System object, `rlsFilt`, to their initial values.

For many System objects, this method is nonoperational. Objects that have internal states describe in their **help** what the reset method does for that object. The `reset` method is always nonoperational for unlocked System objects, as states may not be allocated when the object is not locked.

# step

**System object:** dsp.RLSFilter

**Package:** dsp

Process inputs using RLS filter

## Syntax

```
y = step(rlsFilt,x,d)
[y,e] = step(rlsFilt,x,d)
```

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`y = step(rlsFilt,x,d)` recursively adapts the reference input, `x`, to match the desired signal, `d`, using the System object, `rlsFilt`. The desired signal, `d` is the signal desired plus some undesired noise. `[y,e] = step(rlsFilt,x,d)` shows the output of the RLS filter along with the error, `e`, between the reference input and the desired signal. The filters adapts its coefficients until the error, `e` is minimized. You can access these coefficients by accessing the 'Coefficients' property of the object. You must access this property after calling the `step` method on the object. For example, you can access the optimized coefficients of `rlsFilt` filter object through `rlsFilt.Coefficients`, after calling the `step` method on this object.

# dsp.RMS System object

**Package:** dsp

Root mean square of vector elements

## Description

The RMS object computes the root mean square (RMS) value.

To compute the RMS value of your input:

- 1 Define and set up your RMS calculation. See “Construction” on page 4-1511.
- 2 Call `step` to compute the RMS value for an input according to the properties of `dsp.RMS`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

---

**Note** The Running mode in the `dsp.RMS` System object will be removed in a future release. To compute the running RMS in MATLAB, use the `dsp.MovingRMS` System object instead.

---

## Construction

`rms = dsp.RMS` returns a System object, `rms`, that computes the root mean square (RMS) of an input or a sequence of inputs over the specified `Dimension`.

`rms = dsp.RMS('PropertyName',PropertyValue,...)` returns an RMS System object, `rms`, with each specified property set to the specified value.

## Properties

### RunningRMS

Enable calculating RMS over time

Set this property to `true` to enable calculating the RMS over successive calls to the `step` method.

**Default:** `false`

### ResetInputPort

Enable resetting in running RMS mode

Set this property to `true` to enable resetting the running RMS. When the property is set to `true`, you must specify a reset input to the `step` method to reset the running RMS. This property applies when you set the `RunningRMS` property to `true`.

**Default:** `false`

### ResetCondition

Reset condition for running RMS mode

Specify the event to reset the running RMS as one of `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`. `Non-zero` resets the running RMS each time a nonzero sample is acquired. See “Rising and Falling Edges” on page 4-1514 for definitions of rising and falling edges. This property applies when you set the “ResetInputPort” on page 4-0 property to `true`.

**Default:** `Non-zero`

### Dimension

Dimension to compute RMS value along

Specify the dimension along which to calculate the RMS as one of `All`, `Row`, `Column`, or `Custom`. This property applies only when you set the `RunningRMS` property to `false`. Specifying the `Dimension` property as `All` computes the RMS value over the entire input.

**Default:** `Column`

## CustomDimension

Numerical dimension to operate along

Specify the dimension (one-based scalar integer value) of the input signal, along which the RMS is computed. The cannot exceed the number of dimensions in the input signal. This property applies when you set the “Dimension” on page 4-0 property to Custom.

**Default:** 1

## Methods

reset      Reset the running root mean square object  
 step        Root mean square of input

Common to All System Objects	
release	Allow System object property value changes

## Examples

### RMS Value of Vector Input

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Compute the RMS value of a vector consisting of the integers 1 to 10.

```
x = 1:10;
rms = dsp.RMS('Dimension','row');
rmsval = rms(x)

rmsval = 6.2048
```

### RMS Value of Matrix Input

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Compute the RMS value of a matrix with the `Dimension` property set to `'All'`.

```
in2 = magic(4);  
rms2d = dsp.RMS;  
rms2d.Dimension = 'All';  
y_rms2 = rms2d(in2)  
  
y_rms2 = 9.6695
```

The output is equivalent to reshaping the 4-by-4 matrix into a 16-by-1, or 1-by-16 vector and computing the RMS value for the vector.

## Definitions

### Root-Mean-Square Level

The root-mean-square level of a vector,  $X$ , is

$$x_{\text{RMS}} = \sqrt{\frac{1}{N} \sum_{n=1}^N |x_n|^2},$$

with the summation performed along the specified dimension.

### Rising and Falling Edges

A rising edge:

- Rises from a negative value to a positive value or zero.
- Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

A falling edge:

- Falls from a positive value to a negative value or zero.
- Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the RMS block reference page. The object properties correspond to the Simulink block parameters, except:

- **Treat sample-based row input as a column** block parameter is not supported by the dsp.RMS object.

- **Reset Port** block parameter corresponds to both the `ResetCondition` and the `ResetInputPort` object properties.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Moving RMS | Moving Standard Deviation | Moving Variance | RMS | Standard Deviation | Variance

### Introduced in R2012a

## reset

**System object:** dsp.RMS

**Package:** dsp

Reset the running root mean square object

## Syntax

`reset(rms)`

## Description

`reset(rms)` resets the running root mean square (RMS) for the object `rms`.

# step

**System object:** dsp.RMS

**Package:** dsp

Root mean square of input

## Syntax

`Y = step(rms,X)`

`Y = step(rms,X,R)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(rms,X)` computes the root mean square (RMS) output, `Y`, of input vector `X`. When the `RunningRMS` property is true, `Y` corresponds to the RMS of the input elements over successive calls to the `step` method.

`Y = step(rms,X,R)` resets the running RMS state based on the value of `R`, the reset signal, and the `ResetCondition` property. This computation is possible when you set both the `RunningRMS` and the `ResetInputPort` properties to `true`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## **dsp.SampleRateConverter System object**

**Package:** dsp

Multistage sample rate converter

### **Description**

The `SampleRateConverter` System object converts the sample rate of an incoming signal.

To convert the sample rate of a signal:

- 1 Define and set up your sample rate converter. See “Construction” on page 4-1520.
- 2 Call `step` to convert the sample rate according to the properties of `dsp.SampleRateConverter`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### **Construction**

`src = dsp.SampleRateConverter` creates a multistage FIR sample rate converter System object, `src`, that converts the sample rate of each channel of an input signal.

`src = dsp.SampleRateConverter(Name,Value)` returns a multistage FIR sample rate converter System object, `src`, with properties and options specified by one or more `Name,Value` pair arguments.

## Properties

### **Bandwidth — Two-sided bandwidth of interest**

40 kHz (default) | positive scalar

Specify the two-sided bandwidth of interest (after rate conversion) as a positive scalar expressed in hertz. This property is the two-sided bandwidth of the information-carrying portion of the signal that you wish to retain. The default is 40 kHz.

### **InputSampleRate — Sample rate of input signal**

192 kHz (default) | positive scalar

Specify the sample rate of the input signal as a positive scalar expressed in hertz. The input sample rate must be greater than the bandwidth of interest. The default is 192 kHz.

### **OutputRateTolerance — Maximum allowed tolerance for output sample rate**

0 (default) | positive scalar

Specify the maximum allowed tolerance for the sample rate of the output signal as a positive scalar between 0 and 1. The default is 0.

The output rate tolerance allows for a simpler design in many cases. The actual output sample rate varies but is within the specified range. For example, if `OutputRateTolerance` is specified as 0.01, then the actual output sample rate is in the range given by `OutputSampleRate ± 1%`.

### **OutputSampleRate — Sample rate of output signal**

44.1 kHz (default) | positive scalar

Specify the sample rate of the output signal as a positive scalar expressed in hertz. The output sample rate must be greater than the bandwidth of interest. The default is 44.1 kHz.

### **StopbandAttenuation — Minimum dB attenuation for aliased components**

80 dB (default) | positive scalar

Specify the stopband attenuation as a positive scalar expressed in decibels. This property is the minimum amount by which any aliasing involved in the process is attenuated. The default is 80 dB.

## Methods

cost	Compute implementation cost
freqz	Frequency response
getFilters	Obtain single-stage filters
getActualOutputRate	Get actual output rate
getRateChangeFactors	Overall interpolation and decimation factors
info	Display information about sample rate converter
reset	Reset internal states of multistage sample rate converter
step	Convert sample rate of signal
visualizeFilterStages	Visualize filter stages

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Convert Sample Rate of Audio Signal

Convert the sample rate of an audio signal from 44.1 kHz (CD quality) to 96 kHz (DVD quality).

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
fs1 = 44.1e3;  
fs2 = 96e3;
```

```
SRC = dsp.SampleRateConverter('Bandwidth',40e3,...  
    'InputSampleRate',fs1,'OutputSampleRate',fs2);
```

```
[L,M] = getRateChangeFactors(SRC);  
FrameSize = 10*M;
```

```
AR = dsp.AudioFileReader('guitar10min.ogg', ...
    'SamplesPerFrame',FrameSize);
AW = dsp.AudioFileWriter('guitar10min_96k.wav', ...
    'SampleRate',fs2);
```

Run the system for 15 s. Release all objects.

```
tic
while toc < 15
    x = AR();
    y = SRC(x);
    AW(y);
end
```

```
release(AR);
release(AW);
release(SRC);
```

Plot the input and output signals. Use a different set of axes for each signal. Shift the output to compensate for the delay introduced by the filter.

```
t1 = 0:1/fs1:1/30-1/fs1;
t2 = 0:1/fs2:1/30-1/fs2;

delay = 114;

e11 = 1:length(t1)-delay;

e12 = 1:length(t2);
e12(1:delay) = [];

subplot(2,1,1)
plot(t1(1:length(e11)),x(e11,1))
hold on
plot(t1(1:length(e11)),x(e11,2))
title('Input')

subplot(2,1,2)
plot(t2(1:length(e12)),y(e12,1))
hold on
plot(t2(1:length(e12)),y(e12,2))
xlabel('Time (s)')
title('Output')
```

Zoom in to see the difference in sample rates. Use a different set of axes for each channel.

figure

```
subplot(2,1,1)
plot(t1(1:length(e1)),x(e1,1),'o-')
hold on
plot(t2(1:length(e2)),y(e2,1),'d--')
xlim([0.01 0.0103])
title('First channel')

subplot(2,1,2)
plot(t1(1:length(e1)),x(e1,2),'o-')
hold on
```

```

plot(t2(1:length(e12)),y(e12,2),'d--')
xlim([0.01 0.0103])
xlabel('Time (s)')
title('Second channel')

```

### Tolerance Cost in Sample Rate Conversion

A signal output from an A/D converter is sampled at 98.304 MHz. The signal has a bandwidth of 20 MHz. Reduce the sample rate of the signal to 22 MHz, which is the bandwidth of 802.11 channels. Make the conversion exactly and then redo it with an output rate tolerance of 1%.

```
SRC1 = dsp.SampleRateConverter('Bandwidth',20e6, ...  
    'InputSampleRate',98.304e6,'OutputSampleRate',22e6, ...  
    'OutputRateTolerance',0);  
SRC2 = dsp.SampleRateConverter('Bandwidth',20e6, ...  
    'InputSampleRate',98.304e6,'OutputSampleRate',22e6, ...  
    'OutputRateTolerance',0.01);
```

Use the `cost` method to determine the cost of each sample rate conversion. The zero-tolerance process requires more than 500 times as many coefficients as the 1% process.

```
c1 = cost(SRC1)
```

```
c1 = struct with fields:  
    NumCoefficients: 84779  
    NumStates: 133  
    MultiplicationsPerInputSample: 27.0422  
    AdditionsPerInputSample: 26.0684
```

```
c2 = cost(SRC2)
```

```
c2 = struct with fields:  
    NumCoefficients: 150  
    NumStates: 127  
    MultiplicationsPerInputSample: 22.6667  
    AdditionsPerInputSample: 22.1111
```

Find the integer upsampling and downsampling factors used in each conversion.

```
[L1,M1] = getRateChangeFactors(SRC1)
```

```
L1 = 1375
```

```
M1 = 6144
```

```
[L2,M2] = getRateChangeFactors(SRC2)
```

```
L2 = 2
```

```
M2 = 9
```

Compute the actual sample rate of the output signal when the sample rate conversion has a tolerance of 1%.

```
getActualOutputRate(SRC2)
```

ans = 2.1845e+07

## Algorithms

- The general multistage sample rate converter performs a multistage decimation, a single-stage sample rate conversion, and a multistage interpolation, in that order. Actual designs include at most two of those steps.
- The procedure determines automatically the optimal number of decimation or interpolation stages. In special cases, the decimation or the interpolation can be performed in a single stage.
- The algorithm always attempts to start by reducing the sample rate. This decreases the amount of computation required. The decimation step is designed so that no intermediate sample rate goes below the bandwidth of interest. This ensures that no information is filtered out.
- Each individual stage uses halfband or Nyquist filters to minimize the number of nonzero coefficients.
- Transition-band aliasing is allowed because it decreases the implementation cost. The signal within the bandwidth of interest is kept alias free up to the value specified by the `StopbandAttenuation` property.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

The `getRateChangeFactors` function supports C and C++ code generation.

**Introduced in R2014b**

# cost

**System object:** `dsp.SampleRateConverter`

**Package:** `dsp`

Compute implementation cost

## Syntax

```
c = cost(src)
```

## Description

`c = cost(src)` returns a structure, `c`, whose fields contain information about the computational cost of implementing a multistage sample rate converter, `src`.

## Input Arguments

**src** — **Multistage sample rate converter**

`SampleRateConverter` System object

Multistage sample rate converter, specified as a `SampleRateConverter` System object.

## Output Arguments

**c** — **Output structure**

structure

Output structure with information about the computational cost of `src`:

- The number of coefficients,
- The number of states,
- The number of multiplications per unit sample, and

- The number of additions per unit sample.

## Examples

### Computational Cost of a Sample Rate Converter

Create `src`, a multistage sample rate converter with default values. `src` combines three filter stages to convert from 192 kHz to 44.1 kHz. Determine its computational cost: the number of coefficients, the number of states, the number of multiplications per unit sample, and the number of additions per unit sample.

```
src = dsp.SampleRateConverter;
cst = cost(src)

cst = struct with fields:
    NumCoefficients: 8631
    NumStates: 138
    MultiplicationsPerInputSample: 27.6672
    AdditionsPerInputSample: 26.6875
```

Repeat the computation allowing a tolerance of 10% in the output sample rate.

```
src.OutputRateTolerance = 0.1;
ctl = cost(src)

ctl = struct with fields:
    NumCoefficients: 44
    NumStates: 80
    MultiplicationsPerInputSample: 14.2500
    AdditionsPerInputSample: 13.5000
```

# freqz

**System object:** dsp.SampleRateConverter

**Package:** dsp

Frequency response

## Syntax

`[h, f] = freqz(src, n, range)`

`[h, f] = freqz(src, f)`

## Description

`[h, f] = freqz(src, n, range)` returns the complex frequency response, `h`, of the multistage sample rate converter, `src`, evaluated at the `n` frequencies returned in `f`. `range` is the frequency range over which the response is computed. The sample rate is taken to be the largest of `InputSampleRate` and `OutputSampleRate`.

`[h, f] = freqz(src, f)` returns the complex frequency response evaluated at the frequency points specified in the vector `f`. `f` is assumed to be expressed in hertz.

## Input Arguments

**src** — Multistage sample rate converter

SampleRateConverter System object

Multistage sample rate converter, specified as a SampleRateConverter System object.

**n** — Number of evaluation points

512 (default) | positive integer

Number of frequencies for response evaluation, specified as a positive integer scalar. If `n` is not specified, it defaults to 512.

**range — Range of frequencies**

'half' (default) | 'whole'

Range considered when computing the frequency response, specified as either 'half' (from 0 to  $\pi$ ) or 'whole' (from 0 to  $2\pi$ ). If range is not specified, it defaults to 'half'.

## Output Arguments

**h — Complex frequency response**

vector

Complex frequency response, returned as a vector.

**f — Frequencies**

vector

Frequencies at which the response is evaluated, returned as a vector.

## Examples

**Frequency Response of Default Converter**

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz. Compute and display the frequency response.

```
src = dsp.SampleRateConverter;  
[H,f] = freqz(src);  
plot(f,20*log10(abs(H)))
```

Compute and display the frequency response over the range between 20 Hz and 44.1 kHz.

```
f = 20:10:44.1e3;  
[H,f] = freqz(src,f);  
plot(f,20*log10(abs(H)))
```

## getFilters

**System object:** dsp.SampleRateConverter

**Package:** dsp

Obtain single-stage filters

## Syntax

```
c = getFilters(src)
```

## Description

`c = getFilters(src)` returns the multirate filters cascaded together in `src` to perform the overall sample rate conversion. The result is a `FilterCascade` structure, `c`. Each field of `c` holds the filter used at a particular stage and gives access to its coefficients and rate-change factors.

## Input Arguments

**src** — Multistage sample rate converter

`SampleRateConverter` System object

Multistage sample rate converter, specified as a `SampleRateConverter` System object.

## Output Arguments

**c** — Single-stage filters

`FilterCascade` structure

Single-stage filters, returned as a `FilterCascade` structure.

## Examples

### Single-Stage Filters

Create `src`, a multistage sample rate converter with default properties. `src` converts between 192 kHz and 44.1 kHz. Find the individual filters that are cascaded together to perform the conversion.

```
src = dsp.SampleRateConverter;  
c = getFilters(src);
```

Visualize the frequency response of the decimator used in the first stage of the process.

```
m = c.Stage1;  
  
[h,w] = freqz(m);  
plot(w/pi,20*log10(abs(h)))  
xlabel('\omega / \pi')  
ylabel('Magnitude (dB)')
```

# getActualOutputRate

**System object:** dsp.SampleRateConverter

**Package:** dsp

Get actual output rate

## Syntax

```
fsout = getActualOutputRate(src)
```

## Description

`fsout = getActualOutputRate(src)` returns the actual output sample rate yielded by a `SampleRateConverter` System object. The computation takes into account the `OutputRateTolerance` parameter.

## Input Arguments

**src** — **Multistage sample rate converter**

`SampleRateConverter` System object

Multistage sample rate converter, specified as a `SampleRateConverter` System object.

## Output Arguments

**fsout** — **Actual output sample rate**

scalar

Actual output sample rate, returned as a scalar expressed in hertz.

## Examples

### Output Sample Rate with Given Tolerance

Get the actual output sample rate for conversion between 192 kHz and 44.1 kHz when given a tolerance of 1%.

```
src = dsp.SampleRateConverter;  
src.OutputRateTolerance = 0.01;  
FsOut = getActualOutputRate(src)
```

```
FsOut = 4.4308e+04
```

# getRateChangeFactors

**System object:** dsp.SampleRateConverter

**Package:** dsp

Overall interpolation and decimation factors

## Syntax

[L,M] = getRateChangeFactors(src)

## Description

[L,M] = getRateChangeFactors(src) returns the overall interpolation factor, L, and the overall decimation factor, M, corresponding to the multistage sample rate converter, src. The overall decimation factor affects the allowable frame size of the input signal, which must be an integer multiple of M.

This function supports C and C++ code generation.

## Input Arguments

**src** — Multistage sample rate converter

SampleRateConverter System object

Multistage sample rate converter, specified as a SampleRateConverter System object.

## Output Arguments

**L** — Overall interpolation factor

scalar

Overall interpolation factor, returned as a scalar.

### **M — Overall decimation factor**

scalar

Overall decimation factor, returned as a scalar.

## **Examples**

### **Default Resampling Factors**

Create `src`, a multistage sample rate converter with default properties. `src` combines three filter stages to convert from 192 kHz to 44.1 kHz. Determine its overall interpolation and decimation factors.

```
src = dsp.SampleRateConverter;  
[L,M] = getRateChangeFactors(src)
```

```
L = 147
```

```
M = 640
```

## info

**System object:** dsp.SampleRateConverter

**Package:** dsp

Display information about sample rate converter

## Syntax

```
info(src)
```

## Description

`info(src)` displays information about the multistage `SampleRateConverter` System object, `src`.

## Input Arguments

**src — Multistage sample rate converter**

`SampleRateConverter` System object

Multistage sample rate converter, specified as a `SampleRateConverter` System object.

## Examples

### Default Multistage Sample Rate Converter

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz. Display information about the design.

```
src = dsp.SampleRateConverter
```

```
src =  
  dsp.SampleRateConverter with properties:
```

```
      InputSampleRate: 192000  
      OutputSampleRate: 44100  
      OutputRateTolerance: 0  
      Bandwidth: 40000  
      StopbandAttenuation: 80
```

```
info(src)
```

```
ans =  
'Overall Interpolation Factor    : 147  
Overall Decimation Factor       : 640  
Number of Filters                : 3

,
```

## reset

**System object:** dsp.SampleRateConverter

**Package:** dsp

Reset internal states of multistage sample rate converter

## Syntax

```
reset(src)
```

## Description

`reset(src)` resets the internal states of a multistage `SampleRateConverter` System object, `src`, to their initial values.

## Input Arguments

**src** — Multistage sample rate converter

`SampleRateConverter` System object

Multistage sample rate converter, specified as a `SampleRateConverter` System object.

## Examples

### Reset a Sample Rate Converter

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz. Determine its overall decimation and interpolation factors.

```
src = dsp.SampleRateConverter;
```

```
[L,M] = getRateChangeFactors(src);
```

Create a two-channel random signal. Specify a number of samples equal to the decimation factor. Apply the `step` method twice on the signal.

```
x = randn(M,2);
```

```
y1 = src(x);
```

```
y2 = src(x);
```

```
no = all(y2==y1)
```

```
no = 1x2 logical array
```

```
0 0
```

The output is different because the internal states of `src` have changed. Use `reset` to reset the converter and call the converter again. Verify that the output is unchanged.

```
reset(src)
```

```
y3 = src(x);
```

```
yes = all(y3==y1)
```

```
yes = 1x2 logical array
```

```
1 1
```

# step

**System object:** dsp.SampleRateConverter

**Package:** dsp

Convert sample rate of signal

## Syntax

`y = step(src,x)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`y = step(src,x)` returns a signal, `y`, corresponding to the input signal, `x`, with sample rate converted by `src`.

## Input Arguments

**src** — Multistage sample rate converter

SampleRateConverter System object

Multistage sample rate converter, specified as a SampleRateConverter System object.

**x** — Input signal

vector | matrix

Input signal, specified as a vector or matrix. The row length of `x` must be a multiple of the overall decimation factor. Each column of `x` is treated as a separate channel.

## Output Arguments

### **y** — Resampled signal

vector | matrix

Resampled signal, returned as a vector or matrix.

## Examples

### Convert the Sample Rate of a Sinusoid

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a multistage sample rate converter with default properties. The converter converts from 192 kHz to 44.1 kHz in three stages.

```
src = dsp.SampleRateConverter;
```

Use `src` to convert the sample rate of a noisy sinusoid. The sinusoid has a frequency of 20 kHz and is sampled for 0.1 s.

```
f = 20e3;
```

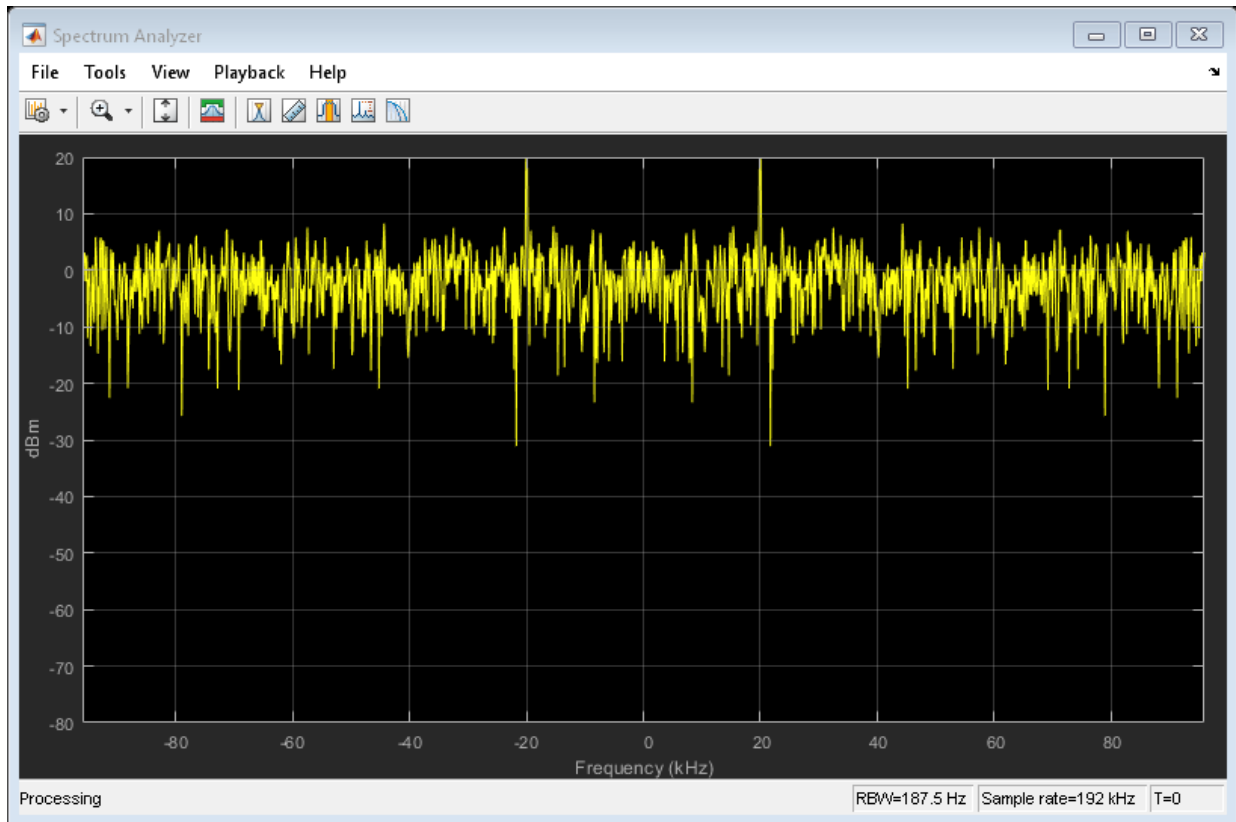

```
FsIn = src.InputSampleRate;  
FsOut = src.OutputSampleRate;
```

```
t1 = (0:1/FsIn:0.1-1/FsIn)';
```

```
sIn = sin(2*pi*f*t1) + randn(size(t1));
```

Estimate the power spectral density of the input.

```
hsa = dsp.SpectrumAnalyzer('SampleRate',FsIn);  
hsa(sIn)
```

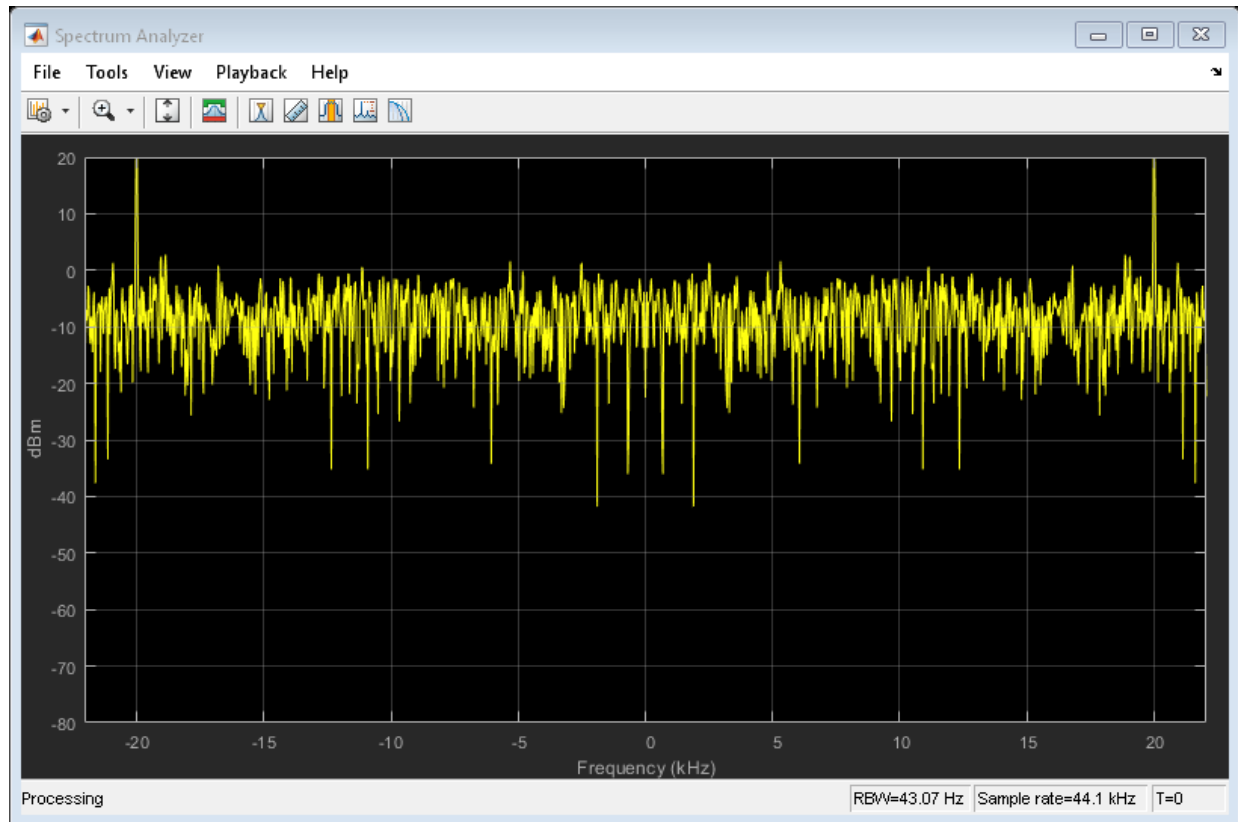

Convert the sample rate of the signal. Estimate the power spectral density of the output.

```
s0out = src(sIn);
```

```
hsb = dsp.SpectrumAnalyzer('SampleRate',FsOut);  
hsb(s0out)
```

## 4 System Objects — Alphabetical List

# visualizeFilterStages

**System object:** dsp.SampleRateConverter

**Package:** dsp

Visualize filter stages

## Syntax

```
visualizeFilterStages(src)
```

## Description

`visualizeFilterStages(src)` shows the response of each individual filter stage of `src` using FVTool.

## Input Arguments

**src** — **Multistage sample rate converter**

SampleRateConverter System object

Multistage sample rate converter, specified as a SampleRateConverter System object.

## Examples

### Sample Rate Converter Stages

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz. Visualize the stages.

```
src = dsp.SampleRateConverter;  
visualizeFilterStages(src)
```

# dsp.ScalarQuantizerDecoder System object

**Package:** dsp

Convert each index value into quantized output value

## Description

The `ScalarQuantizerDecoder` object converts each index value into a quantized output value. The specified codebook defines the set of all possible quantized output values or codewords. Input index values less than 0 are set to 0 and index values greater  $N - 1$  are set to  $N - 1$ .  $N$  is the length of the codebook vector.

To convert an index value into a quantized output value:

- 1 Define and set up your scalar quantizer decoder. See “Construction” on page 4-1551.
- 2 Call `step` to convert the index value according to the properties of `dsp.ScalarQuantizerDecoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`sqdec = dsp.ScalarQuantizerDecoder` returns a scalar quantizer decoder System object, `sqdec`, that transforms zero-based input index values into quantized output values.

`sqdec = dsp.ScalarQuantizerDecoder('PropertyName',PropertyValue,...)` returns a scalar quantizer decoder object, `sqdec`, with each specified property set to the specified value.

## Properties

### CodebookSource

How to specify codebook values

Specify how to determine the codebook values as `Property` or `Input port`. The default is `Property`.

### Codebook

Codebook

Specify the codebook as a vector of quantized output values that correspond to each index value. The default is `1:10`. This property is tunable.

### OutputDataType

Data type of codebook and quantized output

Specify the data type of the codebook and quantized output values as `Same as input`, `double`, `single` or `Custom`. The default is `double`.

### Fixed-Point Properties

#### CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a signed or unsigned `numericType` object. This property applies only when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numericType(true,16)`.

## Methods

`step` Decode using scalar quantization

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Quantize a Signal

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Given a codebook and index values as inputs, determine the corresponding output quantized values.

```
codebook = single([-2.1655 -1.3238 -0.7365 -0.2249 0.2726, ...  
    0.7844 1.3610 2.1599]);  
indices = uint8([1 3 5 7 6 4 2 0]);  
sqdec = dsp.ScalarQuantizerDecoder;  
sqdec.CodebookSource = 'Input port';  
qout = sqdec(indices, codebook);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Scalar Quantizer Decoder block reference page. The object properties correspond to the block parameters, except:

There is no object property that directly corresponds to the **Action for out of range index value** block parameter. The object sets any index values less than 0 to 0 and any index values greater than or equal to  $N$  to  $N - 1$ .

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

## step

**System object:** dsp.ScalarQuantizerDecoder

**Package:** dsp

Decode using scalar quantization

## Syntax

`Q = step(sqdec, I)`

`Q = step(sqdec,I,C)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Q = step(sqdec, I)` returns the quantized output values `Q` corresponding to the input indices `I`. The data type of `I` can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The `OutputDataType` property determines the data type for `Q`.

`Q = step(sqdec,I,C)` uses input `C` as the codebook values when you set the `CodebookSource` property to `Input port`. The data type of `C` can be `double`, `single`, or `fixed-point`. The output `Q` has the same data type as the codebook input `C`.

## dsp.ScalarQuantizerEncoder System object

**Package:** dsp

Associate input value with index value of quantization region

### Description

The `ScalarQuantizerEncoder` object encodes each input value by associating that value with the index value of the quantization region. Then, the object outputs the index of the associated region.

To encode an input value by associating it with an index value of the quantization region:

- 1 Define and set up your scalar quantizer encoder. See “Construction” on page 4-1556.
- 2 Call `step` to encode the input value according to the properties of `dsp.ScalarQuantizerEncoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`sqenc = dsp.ScalarQuantizerEncoder` returns a scalar quantizer encoder System object, `sqenc`. This object maps each input value to a quantization region by comparing the input value to the user-specified boundary points.

`sqenc = dsp.ScalarQuantizerEncoder('PropertyName',PropertyValue,...)` returns a scalar quantizer encoder object, `sqenc`, with each specified property set to the specified value.

## Properties

### BoundaryPointsSource

Source of boundary points

Specify how to determine the boundary points and codebook values as `Property` or `Input port`. The default is `Property`.

### Partitioning

Quantizer is bounded or unbounded

Specify the quantizer as `Bounded` or `Unbounded`. The default is `Bounded`.

### BoundaryPoints

Boundary points of quantizer regions

Specify the boundary points of quantizer regions as a vector. The vector values must be in ascending order. Let  $[p_0 \ p_1 \ p_2 \ p_3 \ \dots \ p_N]$  denote the boundary points property in the quantizer. If the quantizer is bounded, the object uses this property to specify  $[p_0 \ p_1 \ p_2 \ p_3 \ \dots \ p_N]$ . If the quantizer is unbounded, the object uses this property to specify  $[p_1 \ p_2 \ p_3 \ \dots \ p_{(N-1)}]$  and sets  $p_0 = -\text{Inf}$  and  $p_N = +\text{Inf}$ . This property applies when you set the `BoundaryPointsSource` property to `Property`. The default is `1:10`. This property is tunable.

### SearchMethod

Find quantizer index by linear or binary search

Specify whether to find the appropriate quantizer index using a linear search or a binary search as one of `Linear` or `Binary`. The computational cost of the linear search method is of the order  $P$  and the computational cost of the binary search method is of the order

$$\log_2(P)$$

where  $P$  is the number of boundary points. The default is `Linear`.

### TiebreakerRule

Behavior when input equals boundary point

Specify whether the input value is assigned to the lower indexed region or higher indexed region when the input value equals boundary point by selecting `Choose the lower index` or `Choose the higher index`. The default is `Choose the lower index`.

### **CodewordOutputPort**

Enable output of codeword value

Set this property to `true` to output the codeword values that correspond to each index value. The default is `false`.

### **QuantizationErrorOutputPort**

Enable output of quantization error

Set this property to `true` to output the quantization error for each input value. The quantization error is the difference between the input value and the quantized output value. The default is `false`.

### **Codebook**

Codebook

Specify the codebook as a vector of quantized output values that correspond to each region. If the `Partitioning` property is `Bounded` and the boundary points vector has length  $N$ , you must set this property to a vector of length  $N-1$ . If the `Partitioning` property is `Unbounded` and the boundary points vector has length  $N$ , you must set this property to a vector of length  $N+1$ . This property applies when you set the `BoundaryPointsSource` property to `Property` and either the `CodewordOutputPort` property or the `QuantizationErrorOutputPort` property is `true`. The default is `1.5:9.5`. This property is tunable.

### **ClippingStatusOutputPort**

Enable output of clipping status

Set this property to `true` to output the clipping status. The output is a 1 when an input value is outside the range defined by the `BoundaryPoints` property. When the value is inside the range, the exception output is a 0. This property applies when you set the `Partitioning` property to `Bounded`. The default is `false`.

## OutputIndexDataType

Data type of the index output

Specify the data type of the index output from the object as: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`. The default is `int32`.

## Fixed-Point Properties

### RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest` or `Zero`. The default is `Floor`.

### OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

## Methods

`step`      Encode using scalar quantization

### Common to All System Objects

<code>release</code>	Allow System object property value changes
----------------------	--

## Examples

### Quantize the Varying Fractional Inputs

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Quantize the varying fractional inputs between zero and five to the closest integers, and then plot the results.

```
sqenc = dsp.ScalarQuantizerEncoder;  
sqenc.BoundaryPoints = [-.001 .499 1.499 ...  
    2.499 3.499 4.499 5.001];  
sqenc.CodewordOutputPort = true;  
sqenc.Codebook = [0 1 2 3 4 5];  
input = (0:0.02:5)';  
[index, quantizedValue] = sqenc(input);  
plot(1:length(input), [input quantizedValue]);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Scalar Quantizer Encoder block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

### See Also

`dsp.ScalarQuantizerDecoder` | `dsp.VectorQuantizerEncoder`

**Introduced in R2012a**

# step

**System object:** dsp.ScalarQuantizerEncoder

**Package:** dsp

Encode using scalar quantization

## Syntax

```
INDEX= step(sqenc,INPUT)
[...] = step(sqenc,INPUT,BPOINTS)
[...] = step(sqenc,INPUT,BPOINTS,CODEBOOK)
[... ,CODEWORD] = step(sqenc, ...)
[... , QERR] = step(sqenc, ...)
[... ,CLIPSTATUS] = step(sqenc, ...)
```

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`INDEX= step(sqenc,INPUT)` returns the `INDEX` of the quantization region to which the `INPUT` belongs. The input data, boundary points, codebook values, quantized output values, and the quantization error must have the same data type whenever they are present.

`[...] = step(sqenc,INPUT,BPOINTS)` when the `BoundaryPointsSource` property is `Input port`, uses input `BPOINTS` as the boundary points .

`[...] = step(sqenc,INPUT,BPOINTS,CODEBOOK)` uses input `BPOINTS` as the boundary points and input `CODEBOOK` as the codebook when the `BoundaryPointsSource` property is `Input port` and either the

CodewordOutputPort property or the QuantizationErrorOutputPort property is true.

[..., CODEWORD] = step(sqenc, ...) outputs the CODEWORD values that corresponds to each index value when the CodewordOutputPort property is true.

[..., QERR] = step(sqenc, ...) outputs the quantization error QERR for each input value when the QuantizationErrorOutputPort property is true.

[..., CLIPSTATUS] = step(sqenc, ...) also returns output CLIPSTATUS as the clipping status output port for each input value when the Partitioning property is Bounded and the ClippingStatusOutputPort property is true. If an input value is outside the range defined by the BoundaryPoints property, CLIPSTATUS is true. If an input value is inside the range, CLIPSTATUS is false.

---

**Note** obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

---

## dsp.SignalSink System object

**Package:** dsp

Log simulation data in buffer

### Description

The `SignalSink` object logs MATLAB simulation data. This object accepts any numeric data type.

To log MATLAB simulation data :

- 1 Define and set up your signal sink. See “Construction” on page 4-1564.
- 2 Call `step` to log the simulation data according to the properties of `dsp.SignalSink`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = dsp.SignalSink` returns a signal sink, `H`, that logs 2-D input data in the object.

`H = dsp.SignalSink('PropertyName',PropertyValue,...)` returns a signal sink, `H`, with each specified property set to the specified value.

### Properties

#### BufferLength

Maximum number of input frames to log

Specify the maximum number of frames to log. The object always preserves the most recent data in the buffer. When you specify a buffer length that is greater than the input length, the object pads the end of the logged data with zeros. To capture all input data without extra padding, set the `BufferLength` property to `inf`. The default is `inf`.

### Decimation

Decimation factor

Setting this property to any positive integer  $d$  causes the signal sink to write data at every  $d$ th sample. The default is 1.

### FrameHandlingMode

Output dimensionality for frame-based inputs

Set the dimension of the output array for frame-based inputs as 2-D array (concatenate) or 3-D array (separate). Concatenation occurs along the first dimension for 2-D array (concatenate). The default is 2-D array (concatenate).

### Buffer

Logged Data (read only)

The signal sink writes simulation data into a buffer. Specify the maximum length of the buffer with the `BufferLength` property.

## Methods

`reset`      Reset internal states of signal logger object  
`step`        Store signal in buffer

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Log Input Data

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
hlog = dsp.SignalSink;  
for i=1:10  
    y = sin(i);  
    hlog(y);  
end  
log = hlog.Buffer;  
display(log);
```

```
log = 10x1  
  
    0.8415  
    0.9093  
    0.1411  
   -0.7568  
   -0.9589  
   -0.2794  
    0.6570  
    0.9894  
    0.4121  
   -0.5440
```

### Algorithms

This object implements the algorithm, inputs, and outputs described on the To Workspace block reference page. The object properties correspond to the block properties, except: The object always generates fixed-point output for fixed-point input.

---

`step(H,Y)` buffers the signal `Y`. The buffer may be accessed at any time from the `Buffer` property of `H`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.SignalSource System object

**Package:** dsp

Import variable from workspace

## Description

The `SignalSource` object imports a variable from the MATLAB workspace.

To import a variable from the MATLAB workspace:

- 1 Define and set up your signal source. See “Construction” on page 4-1569.
- 2 Call `step` to import the variable according to the properties of `dsp.SignalSource`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

---

## Construction

`src = dsp.SignalSource` returns a signal source System object, `src`, that outputs the variable one sample or frame at a time.

`src = dsp.SignalSource('PropertyName',PropertyValue,...)` returns a signal source object, `src`, with each specified property set to the specified value.

`src = dsp.SignalSource(signal,spf,'PropertyName',PropertyValue,...)` returns a signal source object, `src`, with the `Signal` property set to `signal`, the “SamplesPerFrame” on page 4-0 property set to `spf`, and other specified properties set to the specified values.

## Properties

### Signal

Variable or expression containing the signal

Specify the name of the workspace variable from which to import the signal, or a valid expression specifying the signal. The default is [1:10].

### SamplesPerFrame

Number of samples per output frame

Specify the number of samples to buffer into each output frame. This property must be 1 when you specify a 3-D array in the `Signal` property. The default is 1.

### SignalEndAction

Action after final signal values are generated

Specify the output after all of the specified signal samples have been generated as one of `Set to zero`, `Hold final value`, or `Cyclic repetition`. The default is `Set to zero`.

## Methods

<code>isDone</code>	End-of-file status for signal reader object
<code>reset</code>	Reset internal states of signal reader object
<code>step</code>	Read one sample or frame of signal

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

## Create a Signal Source

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject()` becomes `step(myObject)`.

Create a signal source to output one sample at a time.

```
src1 = dsp.SignalSource;  
src1.Signal = randn(1024, 1);  
y1 = zeros(1024,1);  
idx = 1;  
while(~isDone(src1))  
    y1(idx) = src1();  
    idx = idx+1;  
end
```

Create a signal source to output vectors.

```
src2 = dsp.SignalSource(randn(1024, 1), 128);  
y2 = src2(); % y2 is a 128-by-1 frame of samples
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Signal From Workspace block reference page. The object properties correspond to the block parameters, except:

The object does not have properties that correspond to the **Sample time** or **Warn when frame size does not evenly divide input length** block parameters.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

## **See Also**

`dsp.SignalSink`

**Introduced in R2012b**

# isDone

**System object:** dsp.SignalSource

**Package:** dsp

End-of-file status for signal reader object

## Syntax

isDone(src)

## Description

isDone(src) returns a logical value indicating whether or not the SignalSource object, src, has reached the end of the imported signal. If the SignalEndAction property is set to `Cyclic repetition`, this method will return true every time the reader reaches the end.

## **reset**

**System object:** dsp.SignalSource

**Package:** dsp

Reset internal states of signal reader object

## **Syntax**

`reset(src)`

## **Description**

`reset(src)` resets the signal reader object `src`, to start reading from the beginning of the imported signal.

---

## step

**System object:** dsp.SignalSource

**Package:** dsp

Read one sample or frame of signal

## Syntax

$Y = \text{step}(\text{src})$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

---

$Y = \text{step}(\text{src})$  outputs one sample or frame of data,  $Y$ , from each column of the imported signal. The imported signal is the variable or expression you specify for the `Signal` property of the `SignalSource` System object `src`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## **dsp.SineWave System object**

**Package:** dsp

Generate discrete sine wave

### **Description**

The `dsp.SineWave` System object generates a real or complex, multichannel sinusoidal signal with independent amplitude, frequency, and phase in each output channel.

For both real and complex sinusoids, the “Amplitude” on page 4-0 , “Frequency” on page 4-0 , and “PhaseOffset” on page 4-0 properties can be scalars or length- $N$  vectors, where  $N$  is the number of channels in the output. When you specify at least one of these properties as a length- $N$  vector, scalar values specified for the other properties are applied to each of the  $N$  channels.

To generate a discrete-time sinusoidal signal:

- 1 Create the `dsp.SineWave` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

### **Creation**

### **Syntax**

```
sine = dsp.SineWave
sine = dsp.SineWave(Name,Value)
sine = dsp.SineWave(amp,freq,phase,Name,Value)
```

## Description

`sine = dsp.SineWave` creates a sine wave object that generates a real-valued sinusoid with an amplitude of 1, a frequency of 100 Hz, and a phase offset of 0. By default, the sine wave object generates only one sample.

`sine = dsp.SineWave(Name, Value)` creates a sine wave object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `sine = dsp.SineWave('Amplitude',2);`

`sine = dsp.SineWave(amp, freq, phase, Name, Value)` creates a sine wave object with the “Amplitude” on page 4-0 property set to `amp`, “Frequency” on page 4-0 property set to `freq`, “PhaseOffset” on page 4-0 property set to `phase`, and any other specified properties set to the specified values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

### Amplitude — Amplitude of sine wave

1 (default) | scalar | vector

Amplitude of the sine wave, specified as one of the following:

- scalar -- A scalar applies to all channels.
- vector -- A length- $N$  vector contains the amplitudes of the sine waves in each of the  $N$  output channels. The vector length must be the same as that specified for the “Frequency” on page 4-0 and “PhaseOffset” on page 4-0 properties.

**Tunable:** Yes

### Dependencies

This property is tunable only when you set “Method” on page 4-0 to either 'Trigonometric function' or 'Differential'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### Frequency — Frequency of sine wave

100 (default) | scalar | vector

Frequency of the sine wave in Hz, specified as one of the following:

- `scalar` -- A scalar applies to all channels.
- `vector` -- A length- $N$  vector contains the frequencies of the sine waves in each of the  $N$  output channels. The vector length must be the same as that specified for the “Amplitude” on page 4-0 and “PhaseOffset” on page 4-0 properties.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### PhaseOffset — Phase offset of sine wave

0 (default) | scalar | vector

Phase offset of the sine wave in radians, specified as one of the following:

- `scalar` -- A scalar applies to all channels.
- `vector` -- A length- $N$  vector contains the phase offsets of the sine waves in each of the  $N$  output channels. The vector length must be the same as that specified for the “Amplitude” on page 4-0 and “Frequency” on page 4-0 properties.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### ComplexOutput — Flag that indicates whether waveform is real or complex

`false` (default) | `true`

Flag that indicates whether the waveform is real or complex, specified as either:

- `false` -- The waveform output is real.
- `true` -- The waveform output is complex.

**Method — Method used to generate sinusoids**

'Trigonometric function' (default) | 'Table lookup' | 'Differential'

Method used to generate sinusoids, specified as one of the following:

- 'Trigonometric function' -- The object computes the sinusoid by sampling the continuous-time function.
- 'Table lookup' -- The object precomputes the unique samples of every output sinusoid at the start of the simulation, and recalls the samples from memory as needed.
- 'Differential' -- The object uses an incremental algorithm. This algorithm computes the output samples based on the output values computed at the previous sample time and precomputed update terms.

**TableOptimization — Optimize table of sine values for speed or memory**

'Speed' (default) | 'Memory'

Optimize table of sine values for speed or memory, specified as either:

- 'Speed' -- The table contains  $k$  elements, where  $k$  is the number of input samples in one full period of the sine wave. The period of each sinusoid must be an integer multiple of  $1/F_s$ , where  $F_s$  is the value of the "SampleRate" on page 4-0 property value. That is, each element of the "Frequency" on page 4-0 property must be of the form  $F_s/m$ , where  $m$  is an integer greater than 1.
- 'Memory' -- The table contains  $k/4$  elements.

**Dependencies**

This property applies only when you set the Method property to 'Table lookup'.

**SampleRate — Sample rate of output signal**

1000 (default) | positive scalar

Sample rate of output signal in Hz, specified as a positive scalar.

Example: 44100

Example: 22050

**SamplesPerFrame — Number of samples per frame**

1 (default) | positive integer

Number of consecutive samples from each sinusoid to buffer into the output frame, specified as a positive integer.

Example: 1000

Example: 5000

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **OutputDataType — Data type of the sine wave output**

`'double'` (default) | `'single'` | `'Custom'`

Data type of the sine wave output, specified as `'double'`, `'single'`, or `'Custom'`.

### **Fixed-Point Properties**

#### **CustomOutputDataType — Output word and fraction lengths**

`numerictype([],16)` (default) | `numerictype([],32,30)`

Output word and fraction lengths, specified as an autosigned numeric type with a word length of 16.

Example: `numerictype([],32,30)`

Example: `numerictype([],16,15)`

### **Dependencies**

This property applies only when you set the “Method” on page 4-0 property to `'Table lookup'` and the “OutputDataType” on page 4-0 property to `'Custom'`.

## **Usage**

## **Syntax**

```
sineOut = sine()
```

## **Description**

`sineOut = sine()` creates the sine wave output, `sineOut`.

## Output Arguments

### **sineOut** — Sine wave output

vector | matrix

Sine wave output, returned as a vector or matrix. The “SamplesPerFrame” on page 4-0 property determines the number of rows in the output matrix. If the “Frequency” on page 4-0 or the “PhaseOffset” on page 4-0 property is a vector, the length of the vector determines the number of columns (channels) in the output matrix. If the Frequency or the PhaseOffset properties is a scalar, then the number of channels in the output matrix is 1.

The “OutputDataType” on page 4-0 property sets the data type of the output.

Data Types: `single` | `double` | `fi`

---

**Note** For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

---

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### Generate a Sine Wave Signal

**Note:** If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Generate a sine wave with an amplitude of 2, frequency of 10 Hz, and an initial phase of 0.

```
sine1 = dsp.SineWave(2,10);  
sine1.SamplesPerFrame = 1000;  
y = sine1();  
plot(y)
```

Generate two sine waves offset by a phase of  $\pi/2$  radians.

```
sine2 = dsp.SineWave;  
sine2.Frequency = 10;  
sine2.PhaseOffset = [0 pi/2];  
sine2.SamplesPerFrame = 1000;  
y = sine2();  
plot(y)
```

## Definitions

### Sinusoid

A real-valued, discrete-time sinusoid is defined as:

$$y(n) = A \sin(2\pi fn + \phi)$$

where  $A$  is the amplitude,  $f$  is the frequency in Hz, and  $\phi$  is the initial phase, or phase offset, in radians.

A complex sinusoid is defined as:

$$y(n) = Ae^{j(2\pi fn + \phi)}$$

## Algorithms

### Trigonometric Function

The trigonometric function method computes the sinusoid in the  $i$ th channel,  $y_i$ , by sampling the continuous function

$$y_i = A_i \sin(2\pi f_i t + \phi_i) \quad (\text{real})$$

or

$$y_i = A_i e^{j(2\pi f_i t + \phi_i)} \quad (\text{complex})$$

with a period of  $T_s$ , where you specify  $T_s$  in the sample time.

At each sample time, the algorithm evaluates the sine function at the appropriate time value *within the first cycle* of the sinusoid. By constraining trigonometric evaluations to

the first cycle of each sinusoid, the algorithm avoids the imprecision of computing the sine of very large numbers. This constraint also eliminates the possibility of discontinuity during extended operations, when an absolute time variable might overflow. This method therefore avoids the memory demands of the table lookup method at the expense of many more floating-point operations.

## Table Lookup

The table lookup method precomputes the *unique* samples of every output sinusoid at the start of the simulation, and recalls the samples from memory as needed. Because a table of finite length can only be constructed when all output sequences repeat, the method requires that the period of every sinusoid in the output be evenly divisible by the sample period. That is,  $1/(f_i T_s) = k_i$  must be an integer value for every channel  $i = 1, 2, \dots, N$ .

When the algorithm optimizes the table of sine values for **Speed**, the table constructed for each channel contains  $k_i$  elements. When the optimization is for **Memory**, the table constructed for each channel contains  $k_i/4$  elements.

For long output sequences, the table lookup method requires far fewer floating-point operations than any of the other methods. However, the method can demand considerably more memory, especially for high sample rates (long tables). This method is recommended for models that are intended to emulate or generate code for DSP hardware, which need to be optimized for execution speed.

---

**Note** The lookup table for this object is constructed from double-precision floating-point values. When you use the **Table Lookup** computation mode, the maximum amount of precision you can achieve in your output is 53 bits. Setting the word length of the output data type to values greater than 53 bits does not improve the precision of your output.

---

## Differential

The differential method uses an incremental algorithm. This algorithm computes the output samples based on the output values computed at the previous sample time (and precomputed update terms) by making use of the following identities.

$$\begin{aligned}\sin(t + T_s) &= \sin(t)\cos(T_s) + \cos(t)\sin(T_s) \\ \cos(t + T_s) &= \cos(t)\cos(T_s) - \sin(t)\sin(T_s)\end{aligned}$$

The update equations for the sinusoid in the  $i$ th channel,  $y_i$ , can therefore be written in matrix form as

$$\begin{bmatrix} \sin\{2\pi f_i(t + T_s) + \phi_i\} \\ \cos\{2\pi f_i(t + T_s) + \phi_i\} \end{bmatrix} = \begin{bmatrix} \cos(2\pi f_i T_s) & \sin(2\pi f_i T_s) \\ -\sin(2\pi f_i T_s) & \cos(2\pi f_i T_s) \end{bmatrix} \begin{bmatrix} \sin(2\pi f_i t + \phi_i) \\ \cos(2\pi f_i t + \phi_i) \end{bmatrix}$$

where you specify  $T_s$  in the sample time. Since  $T_s$  is constant, the right-hand matrix is a constant and can be computed once at the start of the simulation. The value of  $A_i \sin[2\pi f_i(t + T_s) + \phi_i]$  is then computed from the values of  $\sin(2\pi f_i t + \phi_i)$  and  $\cos(2\pi f_i t + \phi_i)$  by a simple matrix multiplication at each time step.

This mode offers reduced computational load, but is subject to drift over time due to cumulative quantization error. Because the method is not contingent on an absolute time value, there is no danger of discontinuity during extended operations, when an absolute time variable might overflow.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- This object has no tunable properties for code generation.

## **dsp.SpectrumAnalyzer System object**

**Package:** dsp

Display frequency spectrum of time-domain signals

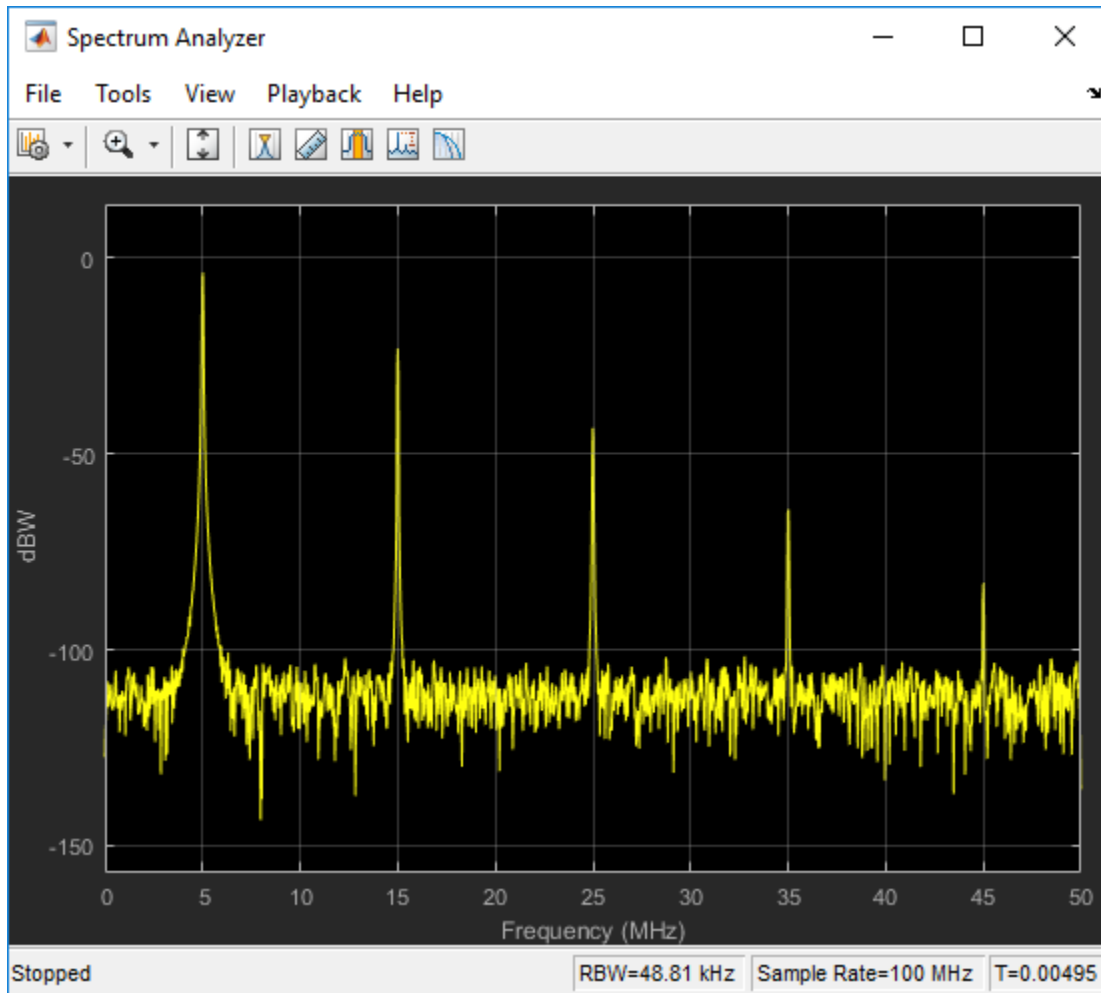

### **Description**

The Spectrum Analyzer System object displays the frequency spectrum of time-domain signals. This scope supports variable-size input, which allows the input frame size to change. Frame size is the first dimension of the input vector. The number of input channels must remain constant.

To display the spectra of signals in the Spectrum Analyzer:

- 1** Create the `dsp.SpectrumAnalyzer` object and set its properties.
- 2** Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

## Creation

## Syntax

```
scope = dsp.SpectrumAnalyzer
```

```
scope = dsp.SpectrumAnalyzer(ports)
scope = dsp.SpectrumAnalyzer(Name,Value)
```

### Description

`scope = dsp.SpectrumAnalyzer` creates a Spectrum Analyzer System object. This object displays the frequency spectrum of real- and complex-valued floating- and fixed-point signals.

`scope = dsp.SpectrumAnalyzer(ports)` creates a Spectrum Analyzer object and sets the `NumInputPorts` property to the value of `ports`.

`scope = dsp.SpectrumAnalyzer(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects* (MATLAB).

### Frequently Used

#### **NumInputPorts — Number of input ports**

1 (default) | integer between [1, 96]

Number of input ports, specified as a positive integer. Each signal coming through a separate input becomes a separate channel in the scope. You must invoke the scope with the same number of inputs as the value of this property.

#### **InputDomain — Domain of the input signal**

Time (default) | Frequency

The domain of the input signal you want to visualize. If you visualize time-domain signals, the signal is transformed to the frequency spectrum based on the algorithm specified by the `Method` parameter.

**UI Use**

Open the **Spectrum Settings**. In the **Main options** section, set **Input Domain**.

**SampleRate — Sample rate of input**

10000 (default) | finite scalar

Specify the sample rate, in hertz, of the input signals as a finite numeric scalar.

**UI Use**

Open the **Spectrum Settings**. In the **Main options** section, set **Sample rate (Hz)**.

**SpectrumType — Type of spectrum to show**

'Power' (default) | 'Power density' | 'RMS'

Specify the spectrum type to display.

'Power' — Power spectrum

'Power density' — Power spectral density. The power spectral density is the magnitude squared of the spectrum normalized to a bandwidth of 1 hertz.

'RMS' — Root mean square. The root-mean-square shows the square root of the sum of the squared means. This option is useful when viewing the frequency of voltage or current signals.

**Tunable:** Yes

**UI Use**

Open the **Spectrum Settings**. In the **Main options** section, set **Type**.

**ViewType — Viewer type**

'Spectrum' (default) | 'Spectrogram' | 'Spectrum and spectrogram'

Specify the spectrum type as one of 'Spectrum', 'Spectrogram', or 'Spectrum and spectrogram'.

- 'Spectrum' — shows the power spectrum.

- 'Spectrogram' — shows frequency content over time. Each line of the spectrogram is one periodogram. Time scrolls from the bottom to the top of the display. The most recent spectrogram update is at the bottom of the display.
- 'Spectrum and Spectrogram' — shows a dual view of a spectrum and spectrogram.

**Tunable:** Yes

### UI Use

Open the **Spectrum Settings**. In the **Main options** section, set **View**.

### Method — Spectrum estimation method

'Welch' (default) | 'Filter Bank'

Specify the spectrum estimation method as Welch or Filter bank.

### Dependency

To enable this property, set InputDomain to 'Time'.

### UI Use

Open the **Spectrum Settings**. In the **Main options** section, set **Method**.

### NumTapsPerBand — Number of filter taps per frequency band

12 (default) | positive even scalar

Specify the number of filter taps or coefficients for each frequency band. This number must be a positive even integer. This value corresponds to the number of filter coefficients per polyphase branch. The total number of filter coefficients is equal to NumTapsPerBand + FFTLength.

### Dependency

To enable this property, set Method to 'Filter Bank'

### UI Use

Open the **Spectrum Settings**. In the **Main options** section, set **Taps per band**.

### SpectralAverages — Number of spectral averages

1 (default) | positive integer

The Spectrum Analyzer computes the current power spectrum estimate by computing a running average of the last  $N$  power spectrum estimates. This property defines  $N$ .

**Tunable:** Yes

#### **Dependency**

To enable this property, set `ViewType` to `'Spectrum'`.

#### **UI Use**

Open the **Spectrum Settings**. In the **Trace options** section, set **Averages**.

#### **PlotAsTwoSidedSpectrum — Two-sided spectrum flag**

`true` (default) | `false`

- `true` — Compute and plot two-sided spectral estimates. When the input signal is complex-valued, you must set this property to `true`.
- `false` — Compute and plot one-sided spectral estimates. If you set this property to `false`, then the input signal must be real-valued.

When this property is `false`, Spectrum Analyzer uses power-folding. The y-axis values are twice the amplitude that they would be if this property were set to `true`, except at  $0$  and the Nyquist frequency. A one-sided power spectral density (PSD) contains the total power of the signal in the frequency interval from DC to half of the Nyquist rate. For more information, see `pwelch`.

#### **UI Use**

Open the **Spectrum Settings**. In the **Trace options** section, select **Two-sided spectrum**.

#### **FrequencyScale — Frequency scale**

`'Linear'` (default) | `'Log'`

- `'Log'` — displays the frequencies on the x-axis on a logarithmic scale. To use the `'Log'` setting, you must also set the `PlotAsTwoSidedSpectrum` property to `false`.
- `'Linear'` — displays the frequencies on the x-axis on a linear scale. To use the `'Linear'` setting, you must also set the `PlotAsTwoSidedSpectrum` property to `true`.

**Tunable:** Yes

### UI Use

Open the **Spectrum Settings**. In the **Trace options** section, set **Scale**.

### AxesScaling — Axes scaling mode

'Auto' (default) | 'Manual' | 'OnceAtStop' | 'Updates'

Specify when the scope automatically scales the axes. Valid values are:

- 'Auto' — The scope scales the axes as-needed to fit the data, both during and after simulation.
- 'Manual' — The scope does not scale the axes automatically.
- 'OnceAtStop' — The scope scales the axes when the simulation stops.
- 'Updates' — The scope scales the axes once after 10 updates.

### UI Use

Select **Tools > Axes Scaling**.

## Advanced

### FrequencyResolutionMethod — Frequency resolution method

'RBW' (default) | 'WindowLength' | 'NumFrequencyBands'

Specify the frequency resolution method of the Spectrum Analyzer.

- 'RBW' - the RBWSource and RBW properties control the frequency resolution (in Hz) of the analyzer. The FFT length is the window length that results from achieving the specified RBW value or 1024, whichever is larger.
- 'WindowLength' - applies only when the Method property is set to 'Welch'. The WindowLength property controls the frequency resolution. You can control the number of FFT points only when the FrequencyResolutionMethod property is 'WindowLength'.
- 'NumFrequencyBands' - applies only when the Method property is set to 'Filter Bank'. The FFTLengthSource and FFTLength properties control the frequency resolution.

**Tunable:** Yes

**Dependency**

To enable this property, set `InputDomain` to `'Time'`.

**UI Use**

Open the **Spectrum Settings**. In the **Main options** section, set the frequency resolution method by selecting the **RBW (Hz)** dropdown.

**RBWSource — Source of resolution bandwidth value**

`'Auto'` (default) | `'Property'`

Specify the source of the resolution bandwidth (RBW) as either `'Auto'` or `'Property'`.

- `'Auto'` — The Spectrum Analyzer adjusts the spectral estimation resolution to ensure that there are 1024 RBW intervals over the defined frequency span.
- `'Property'` — Specify the resolution bandwidth directly using the RBW property.

**Tunable:** Yes

**Dependency**

To enable this property, set either:

- `InputDomain` to `'Time'` and `FrequencyResolutionMethod` to `'RBW'`.
- `InputDomain` to `'Frequency'`.

**UI Use**

Open the **Spectrum Settings**. In the **Main options** section, set **RBW (Hz)**.

**RBW — Resolution bandwidth**

9.76 (default) | real positive scalar

RBW controls the spectral resolution of Spectrum Analyzer. Specify the resolution bandwidth in hertz as a real positive scalar. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. Thus, the ratio of the overall span to RBW must be greater than two:

$$\frac{\textit{span}}{\textit{RBW}} > 2$$

You can specify the overall span in different ways based on how you set the FrequencySpan property.

### Dependency

To enable, set:

- RBWSource to 'Property'

### UI Use

Open the **Spectrum Settings**. In the **Main options** section, set **RBW (Hz)**.

### FrequencyVectorSource — Source of frequency vector

'Auto' (default) | 'Property'

- Auto — The frequency vector is calculated from the length of the input. See “Frequency Vector” on page 4-1632.
- Property — Enter a custom vector as the frequency vector.

### Dependency

To enable this property, set InputDomain to 'Frequency'.

### UI Use

Open the **Spectrum Settings**. In the **Frequency input options** section, set **Frequency (Hz)**.

### FrequencyVector — Custom frequency vector

[-5000 5000] (default) | monotonically increasing vector

Set the frequency vector which determines the x-axis of the display. The vector must be monotonically increasing and of the same size as the input frame size.

### Dependency

To enable this property, set FrequencyVectorSource to 'Property'.

### UI Use

Open the **Spectrum Settings**. In the **Frequency input options** section, set **Frequency (Hz)**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **WindowLength** — Window length

1024 (default) | integer greater than 2

Control the frequency resolution by specifying the window length, in samples used to compute the spectral estimates. The window length must be an integer scalar greater than 2.

**Tunable:** Yes

#### **Dependencies**

To enable this property, set:

- FrequencyResolutionMethod to 'WindowLength', which controls the frequency resolution based on your window length setting
- Method to 'Welch'

#### **UI Use**

Open the **Spectrum Settings**. Change the **RBW (Hz)** dropdown to Window length.

### **FFTLengthSource** — Source of the FFT length

'Auto' (default) | 'Property'

- 'Auto' - sets the FFT length to the window length specified in the WindowLength property or 1024, whichever is larger.
- 'Property' - number of FFT points using the FFTLength property. FFTLength must be greater than WindowLength.

**Tunable:** Yes

#### **Dependency**

To enable this property, set FrequencyResolutionMethod to 'WindowLength'.

#### **UI Use**

Open the **Spectrum Settings**. In the **Main options** section, next to the **RBW (Hz)** option, enter a number or select Auto.

### **FFTLength — Length of FFT**

1024 (default) | positive integer

Specify the length of the FFT that the Spectrum Analyzer uses to compute spectral estimates.

If `FrequencyResolutionMethod` is 'RBW', the FFT length is set as the window length required to achieve the specified resolution bandwidth value or 1024, whichever is larger.

**Tunable:** Yes

#### **Dependencies**

To use this property, the following must be true:

- `FrequencyResolutionMethod` is set to 'WindowLength' or 'NumFrequencyBands'
- `FFTLength` is greater than or equal to the `WindowLength`.
- `FFTLengthSource` is set to 'Property'.

#### **UI Use**

Open the **Spectrum Settings**. In the **Main options** section, next to the **RBW (Hz)** option, enter a number or select Auto.

### **FrequencyOffset — Frequency offset**

0 (default) | scalar | vector

- **Scalar** — Apply the same frequency offset to all channels, specified in hertz as a character vector.
- **Vector** — apply a specific frequency offset for each channel, specify a vector of frequencies. The vector length must be equal to number of input channels.

The frequency-axis values are offset by the values specified in this property. The overall span must fall within the “Nyquist frequency interval” on page 4-1631. You can control the overall span in different ways based on how you set the `FrequencySpan` property.

**Tunable:** Yes

#### **UI Use**

Open the **Spectrum Settings**. In the **Trace options** section, set **Offset (Hz)**.

**FrequencySpan — Frequency span mode**

'Full' (default) | 'Span and center frequency' | 'Start and stop frequencies'

- 'Full' - The Spectrum Analyzer computes and plots the spectrum over the entire “Nyquist frequency interval” on page 4-1631.
- 'Span and center frequency' - The Spectrum Analyzer computes and plots the spectrum over the interval specified by the Span and CenterFrequency properties.
- 'Start and stop frequencies' - The Spectrum Analyzer computes and plots the spectrum over the interval specified by the StartFrequency and StopFrequency properties.

**Tunable:** Yes

**UI Use**

Open the **Spectrum Settings**. In the **Main options** section, select **Full frequency span** for 'Full'. Otherwise, clear the **Full frequency span** check box and choose between Span or FStart.

**StartFrequency — Start frequency to compute spectrum**

-5e3 (default) | real scalar

Start of the frequency interval over which spectrum is computed, specified in hertz as a real scalar. The overall span, which is defined by this property and StopFrequency, must fall within the “Nyquist frequency interval” on page 4-1631.

**Tunable:** Yes

**Dependency**

To enable this property, set FrequencySpan to 'Start and stop frequencies'.

**UI Use**

Open the **Spectrum Settings**. In the **Main options** section, clear the **Full frequency span** and change Span to FStart. Set **FStart (Hz)**.

**StopFrequency — Stop frequency to compute spectrum**

5e3 (default) | real scalar

End of the frequency interval over which spectrum is computed, specified in hertz as a real scalar. The overall span, which is defined by this property and the StartFrequency property, must fall within the Nyquist frequency interval on page 4-1631.

**Tunable:** Yes

**Dependency**

To enable this property, set FrequencySpan to 'Start and stop frequencies'.

**UI Use**

Open the **Spectrum Settings**. In the **Main options** section, clear the **Full frequency span** and change Span to FStart. Set **FStop (Hz)**.

**CenterFrequency — Center of frequency span**

0 (default) | real scalar

Specify in hertz the center frequency of the span over which the Spectrum Analyzer computes and plots the spectrum. The overall frequency span, defined by the Span and this property, must fall within the “Nyquist frequency interval” on page 4-1631.

**Tunable:** Yes

**Dependency**

To enable this property, set FrequencySpan to 'Span and center frequency'.

**UI Use**

Open the **Spectrum Settings**. In the **Main**, clear **Full frequency span** and set **CF (Hz)**.

**Span — Frequency span to compute spectrum**

10e3 (default) | real positive scalar

Specify the frequency span, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. The overall span, defined by this property and the CenterFrequency property, must fall within the “Nyquist frequency interval” on page 4-1631.

**Tunable:** Yes

**Dependency**

To enable this property, set FrequencySpan to 'Span and center frequency'.

**UI Use**

Open the **Spectrum Settings**. In the **Main options** section, clear the **Full frequency span** check box and set Span.

**TimeResolutionSource — Source of the time resolution value**

'Auto' (default) | 'Property'

Specify the source for the time resolution of each spectrogram line as either 'Auto' or 'Property'. The TimeResolution property shows the time resolution for the different frequency resolution methods and time resolution properties.

**Tunable:** Yes

**Dependency**

To enable this property, set ViewType to 'Spectrogram' or 'Spectrum and spectrogram'.

**UI Use**

Open the **Spectrum Settings**. In the **Spectrogram options** section, set **Time res (s)**.

**TimeResolution — Time resolution**

0.001 (default) | positive scalar

Specify the time resolution of each spectrogram line as a positive scalar, expressed in seconds.

The time resolution value is determined based on frequency resolution method, the RBW setting, and the time resolution setting.

Method	Frequency Resolution Method	Frequency Resolution Setting	Time Resolution Setting	Resulting Time Resolution in Seconds
Welch or Filter Bank	RBW (Hz)	Auto	Auto	1/RBW
Welch or Filter Bank	RBW (Hz)	Auto	Manually entered	Time Resolution

<b>Method</b>	<b>Frequency Resolution Method</b>	<b>Frequency Resolution Setting</b>	<b>Time Resolution Setting</b>	<b>Resulting Time Resolution in Seconds</b>
Welch or Filter Bank	RBW (Hz)	Manually entered	Auto	1/RBW
Welch or Filter Bank	RBW (Hz)	Manually entered	Manually entered	Must be equal to or greater than the minimum attainable time resolution, 1/RBW. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW.
Welch	Window length	—	Auto	1/RBW
Welch	Window length	—	Manually entered	Must be equal to or greater than the minimum attainable time resolution. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW.

Method	Frequency Resolution Method	Frequency Resolution Setting	Time Resolution Setting	Resulting Time Resolution in Seconds
Filter Bank	Number of frequency bands	—	Auto	1/RBW
Filter Bank	Number of frequency bands	—	Manually entered	Must be equal to or greater than the minimum attainable time resolution, 1/RBW.

**Tunable:** Yes

#### Dependency

To enable this property, set:

- ViewType to 'Spectrogram' or 'Spectrum and spectrogram'
- TimeResolutionSource to 'Property'.

#### UI Use

Open the **Spectrum Settings**. In the **Spectrogram options** section, in the **Time res (s)** box, enter a number.

#### TimeSpanSource — Source of time span value

'Auto' (default) | 'Property'

Specify the source for the time span of the spectrogram as either 'Auto' or 'Property'. If you set this property to 'Auto', the spectrogram displays 100 spectrogram lines at any given time. If you set this property to 'Property', the spectrogram uses the time duration you specify in seconds in the TimeSpan property.

**Tunable:** Yes

#### Dependency

To enable this property, set ViewType to 'Spectrogram' or 'Spectrum and spectrogram'.

### UI Use

Open the **Spectrum Settings**. In the **Spectrogram options** section, set **Time span (s)**.

### TimeSpan — Time span

0.1 (default) | positive scalar

Specify the time span of the spectrogram display in seconds. You must set the time span to be at least twice as large as the duration of the number of samples required for a spectral update.

**Tunable:** Yes

### Dependency

To enable this property, set:

- ViewType to 'Spectrogram' or 'Spectrum and spectrogram'.
- TimeSpanSource to 'Property'.

### UI Use

Open the **Spectrum Settings**. In the **Spectrogram options** section, in the **Time span (s)** box, enter a number.

### OverlapPercent — Overlap percentage

0 (default) | real, scalar value

The percentage overlap between the previous and current buffered data segments, specified as a real, scalar value. The overlap creates a window segment that is used to compute a spectral estimate. The value must be greater than or equal to zero and less than 100.

**Tunable:** Yes

### UI Use

Open the **Spectrum Settings**. In the **Window options** section, set **Overlap (%)**.

### Window — Window function

'Hann' (default) | 'Rectangular' | 'Chebyshev' | 'Flat Top' | 'Hamming' | 'Kaiser' | 'Blackman-Harris' | 'Custom'

Specify a window function for the spectral estimator. The following table shows preset windows. For more information, follow the link to the corresponding function reference in the Signal Processing Toolbox documentation.

Window Option	Corresponding Signal Processing Toolbox Function
'Rectangular'	rectwin
'Chebyshev'	chebwin
'Flat Top'	flattopwin
'Hamming'	hamming
'Hann'	hann
'Kaiser'	kaiser
'Blackman-Harris'	blackmanharris

To set your own spectral estimation window, set this property to 'Custom' and specify a custom window function in the CustomWindow property.

**Tunable:** Yes

#### UI Use

Open the **Spectrum Settings**. In the **Window options** section, set **Window**.

#### CustomWindow — Custom window function

'hann' (default) | character array | string

Specify a custom window function as a character array or string. The custom window function name must be on the MATLAB path. This property is useful if you want to customize the window using additional properties available with the Signal Processing Toolbox version of the window function.

**Tunable:** Yes

#### Example

Define and use a custom window function.

```
function w = my_hann(L)
    w = hann(L, 'periodic')
end
```

```
scope.Window = 'Custom';  
scope.CustomWindow = 'my_hann'
```

### Dependency

To use this property, set Window to 'Custom'.

### UI Use

Open the **Spectrum Settings**. In the **Window options** section, in the **Window** option box, enter a custom window function name.

### SidelobeAttenuation — Sidelobe attenuation of window

60 (default) | real positive scalar

The window sidelobe attenuation, in decibels (dB). The value must be greater than or equal to 45.

**Tunable:** Yes

### Dependency

To enable this property, set Window to 'Chebyshev' or 'Kaiser'.

### UI Use

Open the **Spectrum Settings**. In the **Window options** section, set **Attenuation (dB)**.

### InputUnits — Units of frequency input

'dBm' (default) | 'dBV' | 'dBW' | 'Vrms' | 'Watts'

Select the units of the frequency-domain input. This property allows the Spectrum Analyzer to scale frequency data if you choose a different display unit with the “Units” on page 2-0 property.

### Dependency

This option is only available for InputDomain set to Frequency.

### UI Use

Open the **Spectrum Settings**. In the **Frequency input options** section, set **Input units**.

**SpectrumUnits — Units of the spectrum**

'Auto' (default) | 'dBm' | 'dBFS' | 'dBV' | 'dBW' | 'Vrms' | 'Watts'

Specify the units in which the Spectrum Analyzer displays power values.

**Tunable:** Yes

**Dependency**

The available spectrum units depend on the value of SpectrumType.

InputDomain	SpectrumType	Allowed SpectrumUnits
Time	Power or Power density	'dBFS', 'dBm', 'dBW', 'Watts'
	RMS	'Vrms', 'dBV'
Frequency	—	'dBm', 'dBV', 'dBW', 'Vrms', 'Watts',

**UI Use**

Open the **Spectrum Settings**. In the **Trace options** section, set **Units**.

**FullScaleSource — Source of full scale**

'Auto' (default) | 'Property'

Specify the source of the dBFS scaling factor as either 'Auto' or 'Property'.

- 'Auto' - The Spectrum Analyzer adjusts the scaling factor based on the input data.
- 'Property' - Specify the full-scale scaling factor using the FullScale property.

**Dependency**

To enable this property, set SpectrumUnits to 'dBFS'.

**UI Use**

Open the **Spectrum Settings**. In the **Trace options** section, set **Full scale** to Auto or enter a number.

**FullScale — Full scale**

1 (default) | positive scalar

Specify a real positive scalar for the dBFS full scale.

**Tunable:** Yes

**Dependency**

To enable this option set:

- SpectrumUnits to 'dBFS'
- FullScaleSource to 'Property'

**UI Use**

Open the **Spectrum Settings**. In the **Trace options** section, set **Full scale** to Auto or enter a number.

**ReferenceLoad — Reference load**

1 (default) | real positive scalar

The load the scope uses as a reference to compute power levels.

**Tunable:** Yes

**UI Use**

Open the **Spectrum Settings**. In the **Trace options** section, set **Reference load**.

**PlotNormalTrace — Normal trace flag**

true (default) | false

Set this property to `false` to remove the display of the normal traces. These traces display the free-running spectral estimates. Even when the traces are removed from the display, the Spectrum Analyzer continues its spectral computations.

**Tunable:** Yes

**Dependency**

To enable this property, set ViewType to 'Spectrum' or 'Spectrum and spectrogram'.

**UI Use**

Open the **Spectrum Settings**. In the **Trace options** section, select **Normal trace**.

**PlotMaxHoldTrace — Max-hold trace flag**

false (default) | true

To compute and plot the maximum-hold spectrum of each input channel, set this property to `true`. The maximum-hold spectrum at each frequency bin is computed by keeping the maximum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its maximum-hold computations.

**Tunable:** Yes

**Dependency**

To enable this property, set `ViewType` to `'Spectrum'` or `'Spectrum and spectrogram'`.

**UI Use**

Open the **Spectrum Settings**. In the **Trace options** section, select **Max-hold trace**.

**PlotMinHoldTrace — Min-hold trace flag**

`false` (default) | `true`

To compute and plot the minimum-hold spectrum of each input channel, set this property to `true`. The minimum-hold spectrum at each frequency bin is computed by keeping the minimum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its minimum-hold computations.

**Tunable:** Yes

**Dependency**

To enable this property, set `ViewType` to `'Spectrum'` or `'Spectrum and spectrogram'`.

**UI Use**

Open the **Spectrum Settings**. In the **Trace options** section, select **Min-hold trace**.

**SpectralMask — Spectral mask lines**

`SpectralMaskSpecification` object

Specify whether to display upper and lower spectral mask lines on a spectrum plot. This property uses `SpectralMaskSpecification` properties to enable and configure the spectral masks. The `SpectralMaskSpecification` properties are:

- `EnabledMasks` — Masks to enable, specified as a character vector or string. Valid values are `'None'`, `'Upper'`, `'Lower'`, or `'Upper and lower'`.

Default: 'None'

- **UpperMask** — Upper limit spectral mask, specified as a scalar or two-column matrix. If **UpperMask** is a scalar, the upper limit mask uses the power value of the scalar for all frequency values applicable to the Spectrum Analyzer. If **UpperMask** is a matrix, the first column contains the frequency values (Hz), which correspond to the x-axis values. The second column contains the power values, which correspond to the associated y-axis values. To apply offsets to the power and frequency values, use **ReferenceLevel** and **MaskFrequencyOffset** property values, respectively.

Default: Inf

- **LowerMask** — Lower limit spectral mask, specified as a scalar or two-column matrix. If **LowerMask** is a scalar, the lower limit mask uses the power value of the scalar for all frequency values applicable to the Spectrum Analyzer. If **LowerMask** is a matrix, the first column contains the frequency values (Hz), which correspond to the x-axis values. The second column contains the power values, which correspond to the associated y-axis values. To apply offsets to the power and frequency values, use **ReferenceLevel** and **MaskFrequencyOffset** property values, respectively.

Default: -Inf

- **ReferenceLevel** — Reference level for mask power values, specified as either 'Custom' or 'Spectrum peak'. When **ReferenceLevel** is 'Custom', the **CustomReferenceLevel** property value is used as the reference to the power values, in dBm, in the **UpperMask** and **LowerMask** properties. When **ReferenceLevel** is 'Spectrum peak', the peak value of the current spectrum of the **SelectedChannel** is used.

Default: 'Custom'

- **CustomReferenceLevel** — Custom reference level, specified as a real value, in the same units as the power units. The reference level is the value to which to reference the power values in the **UpperMask** and **LowerMask** properties. This property applies when **ReferenceLevel** is set to 'Custom'. This property uses the same units as the **PowerUnits** property of the Spectrum Analyzer.

Default: 0

- **SelectedChannel** — Input channel with peak spectrum to use as the mask reference level, specified as an integer. This property applies when **ReferenceLevel** is set to 'Spectrum peak'.

Default: 1

- **MaskFrequencyOffset** — Frequency offset, specified as a finite, numeric scalar. Frequency offset is the amount of offset to apply to frequency values in the **UpperMask** and **LowerMask** properties.

Default: 0

All **SpectralMaskSpecification** properties are tunable.

Masks are overlaid on the spectrum. If the mask is green, the signal is passing the mask limitations. If the mask is red, the signal is failing the mask limits.

You can check the status of the spectral mask using one of the following methods:

- To modify the spectral mask and see the spectral mask status, in the scope toolbar, select the spectral mask button, . In the Spectral Mask panel that opens, you can modify the masks and see details about what percentage of the time the mask is succeeding, which mask is failing, how many times the mask failed, and which channels are causing the failure.
- To get the current status of the spectral masks, call the function `getSpectralMaskStatus`.
- To perform an action every time the mask fails, use the `MaskTestFailed` event. To trigger a function when the mask fails, create a listener to the `MaskTestFailed` event and define a callback function to trigger. For more details about using events, see “Events” (MATLAB).

**Tunable:** Yes

### UI Use

Open the **Spectral Mask** panel and modify the **Settings** options.

## Visualization

### Name — Window name

'Spectrum Analyzer' (default) | character vector | string

Title of the scope window.

**Tunable:** Yes

### Position — Window position

screen center (default) | [left bottom width height]

Spectrum Analyzer window position in pixels, specified by the size and location of the scope window as a four-element double vector of the form [left bottom width height]. You can place the scope window in a specific position on your screen by modifying the values to this property.

By default, the window appears in the center of your screen with a width of 800 pixels and height of 450 pixels. The exact center coordinates depend on your screen resolution.

**Tunable:** Yes

### **PlotType** — Plot type for normal traces

'Line' (default) | 'Stem'

Specify the type of plot to use for displaying normal traces as either 'Line' or 'Stem'. Normal traces are traces that display free-running spectral estimates.

**Tunable:** Yes

### **Dependency**

To enable this property, set:

- ViewType to 'Spectrum' or 'Spectrum and spectrogram'
- PlotNormalTrace to true

### **UI Use**

Open the **Style** properties and set **Plot type**.

### **ReducePlotRate** — Improve performance with reduced plot rate

true (default) | false

The simulation speed is faster when this property is set to true.

- true — the scope logs data for later use and updates the display at fixed intervals of time. Data occurring between these fixed intervals might not be plotted.
- false — the scope updates every time it computes the power spectrum. Use the false setting when you do not want to miss any spectral updates at the expense of slower simulation speed.

**Tunable:** Yes

**UI Use**

Select **Playback > Reduce plot rate to improve performance**.

**Title — Display title**

' ' (default) | character vector | string

Specify the display title as a character vector or string. To use the input name as the display title, enter '%<SignalLabel>'.

**Tunable:** Yes

**UI Use**

Open the **Configuration Properties**. On the **Display** tab, set **Title**.

**ShowLegend — Show legend**

false (default) | true

To show a legend with the input names, set this property to `true`.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** dialog box. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name. To show all signals, press **Esc**.

**Tunable:** Yes

**UI Use**

Open the **Configuration Properties**. On the **Display** tab, select **Show legend**.

**ChannelNames — Channel names**

empty cell (default) | cell array of character vectors

Specify the input channel names as a cell array of character vectors. The names appear in the legend, **Style** dialog box, and **Measurements** panels. If you do not specify names, the channels are labeled as Channel 1, Channel 2, etc.

**Tunable:** Yes

**Dependency**

To see channel names, set ShowLegend to `true`.

### UI Use

On the legend, double-click the channel name.

### ShowGrid — Grid visibility

false (default) | true

Set this property to true to show gridlines on the plot.

**Tunable:** Yes

### UI Use

Open the **Configuration Properties**. On the **Display** tab, set **Show grid**.

### YLimits — Y-axis limits

[-80, 20] (default) | [ymin ymax]

Specify the y-axis limits as a two-element numeric vector, [ymin ymax].

Example: `scope.YLimits = [-10,20]`

**Tunable:** Yes

### Dependencies

- To enable this property, set the ViewType property to 'Spectrum' or 'Spectrum and spectrogram'.
- The units directly depend upon the SpectrumUnits property.

### UI Use

Open the **Configuration Properties**. Set **Y-limits (maximum)** and **Y-limits (minimum)**.

### ColorLimits — Scale spectrogram color limits

[-80, 20] (default) | [colorMin colorMax]

Control the color limits of the spectrogram using a two-element numeric vector, [colorMin colorMax].

Example: `scope.ColorLimits = [-10,20]`

**Dependencies**

- To enable this property, set the `ViewType` property to 'Spectrogram' or 'Spectrum and spectrogram'.
- The units directly depend upon the `SpectrumUnits` property.

**UI Use**

Open the **Configuration Properties**. Set **Color-limits (minimum)** and **Color-limits (maximum)**.

**YLabel — Y-axis label**

' ' (default) | character vector | string

Specify the text for the scope to display to the left of the y-axis.

Regardless of this property, Spectrum Analyzer always displays power units as one of the `SpectrumUnits` values.

**Tunable:** Yes

**Dependency**

To enable this property, set `ViewType` to 'Spectrum' or 'Spectrum and spectrogram'.

**UI Use**

Open the **Configuration Properties**. Set **Y-label**.

**AxesLayout — Orientation of the spectrum and spectrogram**

'Vertical' (default) | 'Horizontal'

Specify the layout type as 'Horizontal' or 'Vertical'. A vertical layout stacks the spectrum above the spectrogram. A horizontal layout puts the two views side-by-side.

**Tunable:** Yes

**Dependency**

To enable this property, set `ViewType` to 'Spectrum and spectrogram'.

**UI Use**

Open the **Spectrum Settings**. Set **Axes layout**.

# Usage

**Note** For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

# Syntax

```
scope(signal)  
scope(signal1,signal2,...,signalN)
```

# Description

`scope(signal)` updates the spectrum of the signal in the spectrum analyzer.

`scope(signal1,signal2,...,signalN)` displays multiple signals in the spectrum analyzer. The signals must have the same frame length, but can vary in number of channels. You must set the `NumInputPorts` property to enable multiple input signals.

# Input Arguments

**signal** — Input signal or signals to visualize

scalar | vector | matrix

Specify one or more input signals to visualize in the `dsp.SpectrumAnalyzer`. Signals can have a different number of channels, but must have the same frame length.

Example: `scope(signal1, signal2)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `string` | `struct` | `table` | `cell` | `categorical` | `datetime` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to dsp.SpectrumAnalyzer

<code>getSpectralMaskStatus</code>	Get test results of current spectral mask
<code>getSpectrumData</code>	Save spectrum data shown in spectrum analyzer
<code>isNewDataReady</code>	Check spectrum analyzer for new data

### Specific to Scopes

<code>show</code>	Display scope window
<code>hide</code>	Hide scope window
<code>isVisible</code>	Determine visibility of scope

### Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### Spectrum Analyzer for One-Sided Power Spectrum

View a one-sided power spectrum made from the sum of fixed real sine waves with different amplitudes and frequencies.

```
Fs = 100e6; % Sampling frequency
fSz = 5000; % Frame size

sin1 = dsp.SineWave(1e0, 5e6,0, 'SamplesPerFrame', fSz, 'SampleRate', Fs);
sin2 = dsp.SineWave(1e-1, 15e6,0, 'SamplesPerFrame', fSz, 'SampleRate', Fs);
sin3 = dsp.SineWave(1e-2, 25e6,0, 'SamplesPerFrame', fSz, 'SampleRate', Fs);
sin4 = dsp.SineWave(1e-3, 35e6,0, 'SamplesPerFrame', fSz, 'SampleRate', Fs);
```

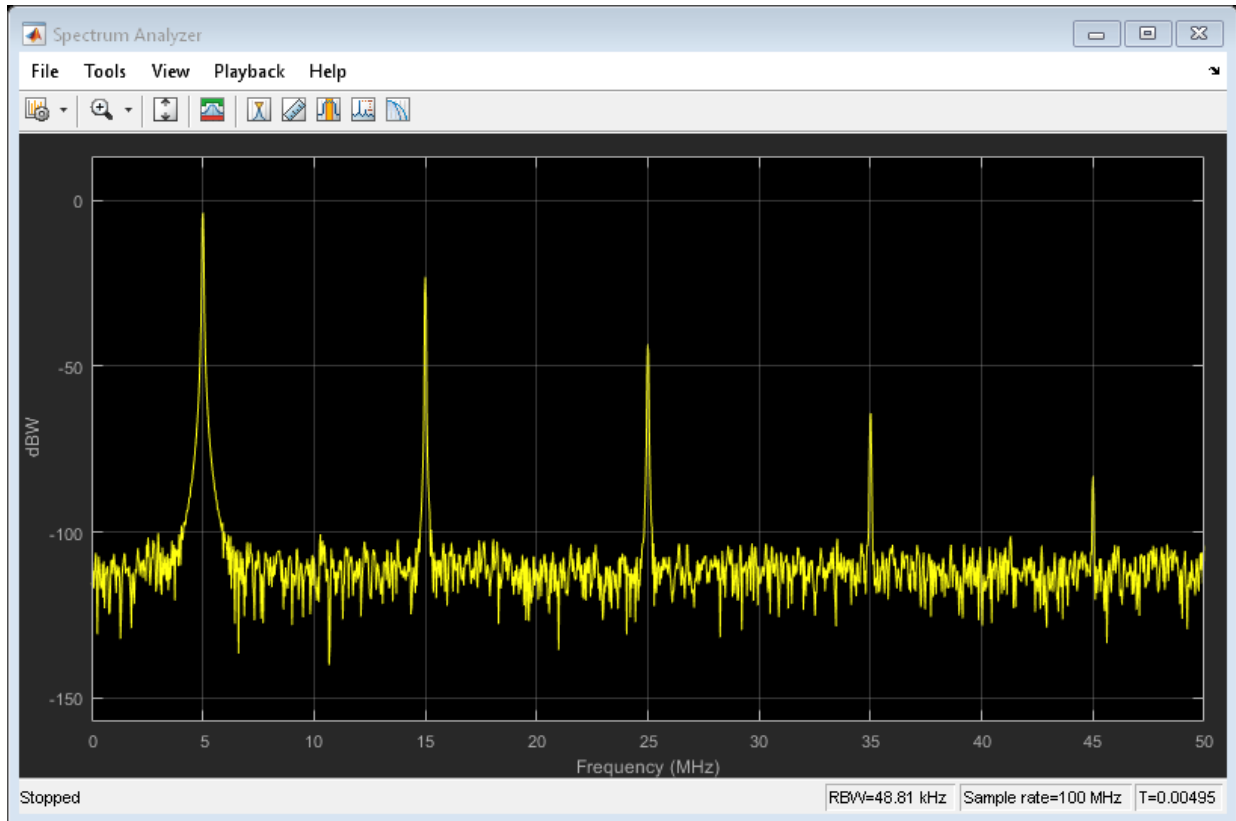

```
sin5 = dsp.SineWave(1e-4,45e6,0, 'SamplesPerFrame', fSz, 'SampleRate', Fs);

scope = dsp.SpectrumAnalyzer;
scope.SampleRate = Fs;
scope.SpectralAverages = 1;
scope.PlotAsTwoSidedSpectrum = false;
scope.RBWSource = 'Auto';
scope.PowerUnits = 'dBW';
for idx = 1:1e2
    y1 = sin1();
    y2 = sin2();
    y3 = sin3();
    y4 = sin4();
    y5 = sin5();
    scope(y1+y2+y3+y4+y5+0.0001*randn(fSz,1));
end
```

Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(scope)
```

Run the `clear` function to close the Spectrum Analyzer window.

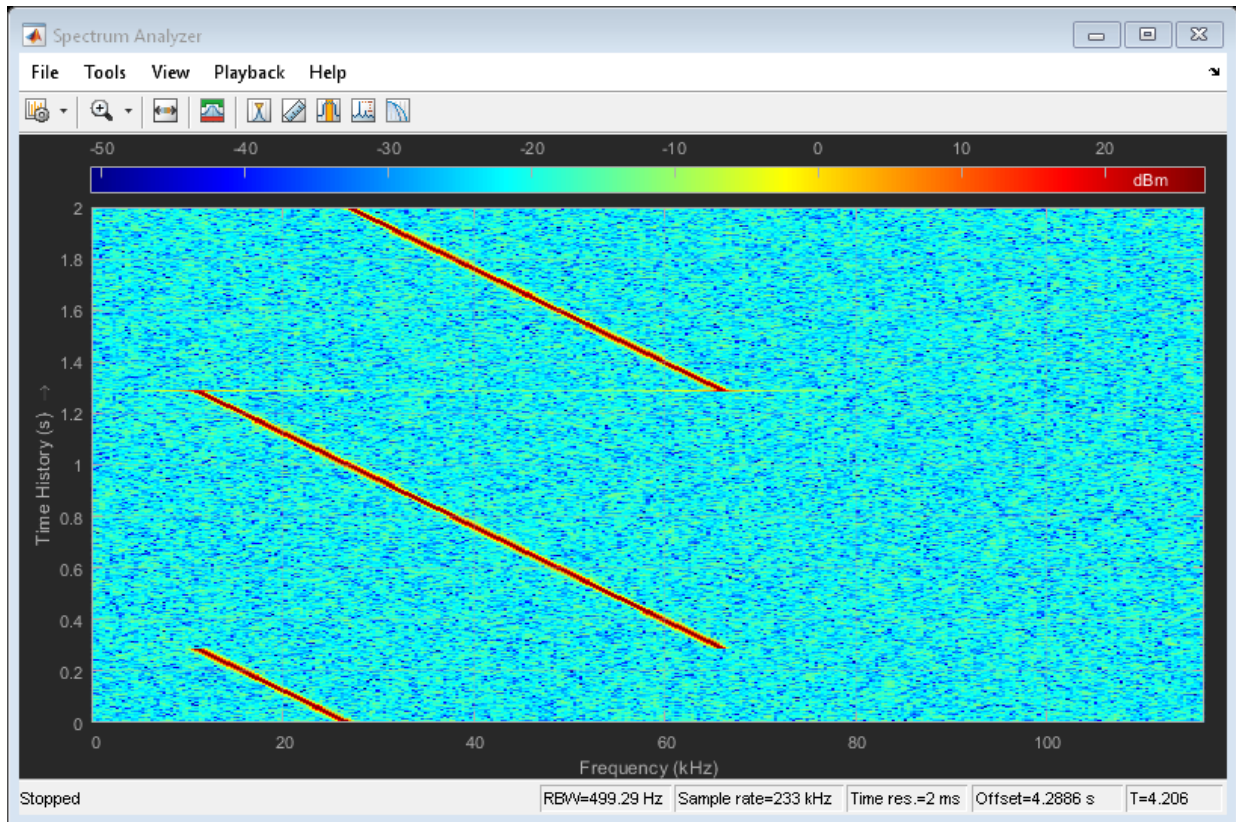

```
clear('scope');
```

### Spectrogram of Chirp Signal

This example shows the spectrogram for a chirp signal with added random noise.

```
Fs = 233e3;  
frameSize = 20e3;  
chirp = dsp.Chirp('SampleRate',Fs,...  
    'SamplesPerFrame',frameSize,...
```

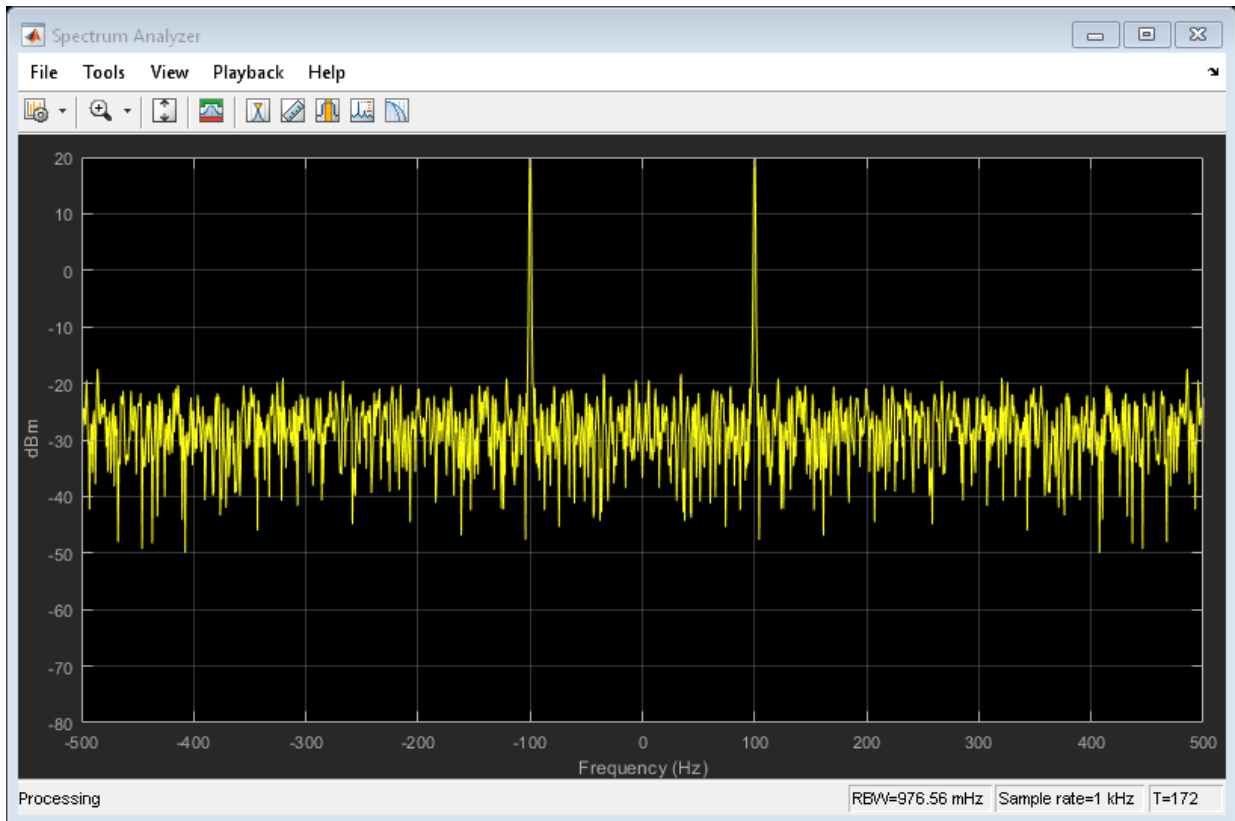

```
    'InitialFrequency',11e3,...  
    'TargetFrequency',11e3+55e3);  
  
scope = dsp.SpectrumAnalyzer('SampleRate',Fs);  
scope.SpectrumType = 'Spectrogram';  
scope.RBWSource = 'Property';  
scope.RBW = 500;  
scope.TimeSpanSource = 'Property';  
scope.TimeSpan = 2;  
scope.PlotAsTwoSidedSpectrum = false;  
  
for idx = 1:50  
    y = chirp()+ 0.05*randn(frameSize,1);  
    scope(y);  
end  
release(scope)
```

### Spectrum Analyzer For Two-Sided Power Spectrum

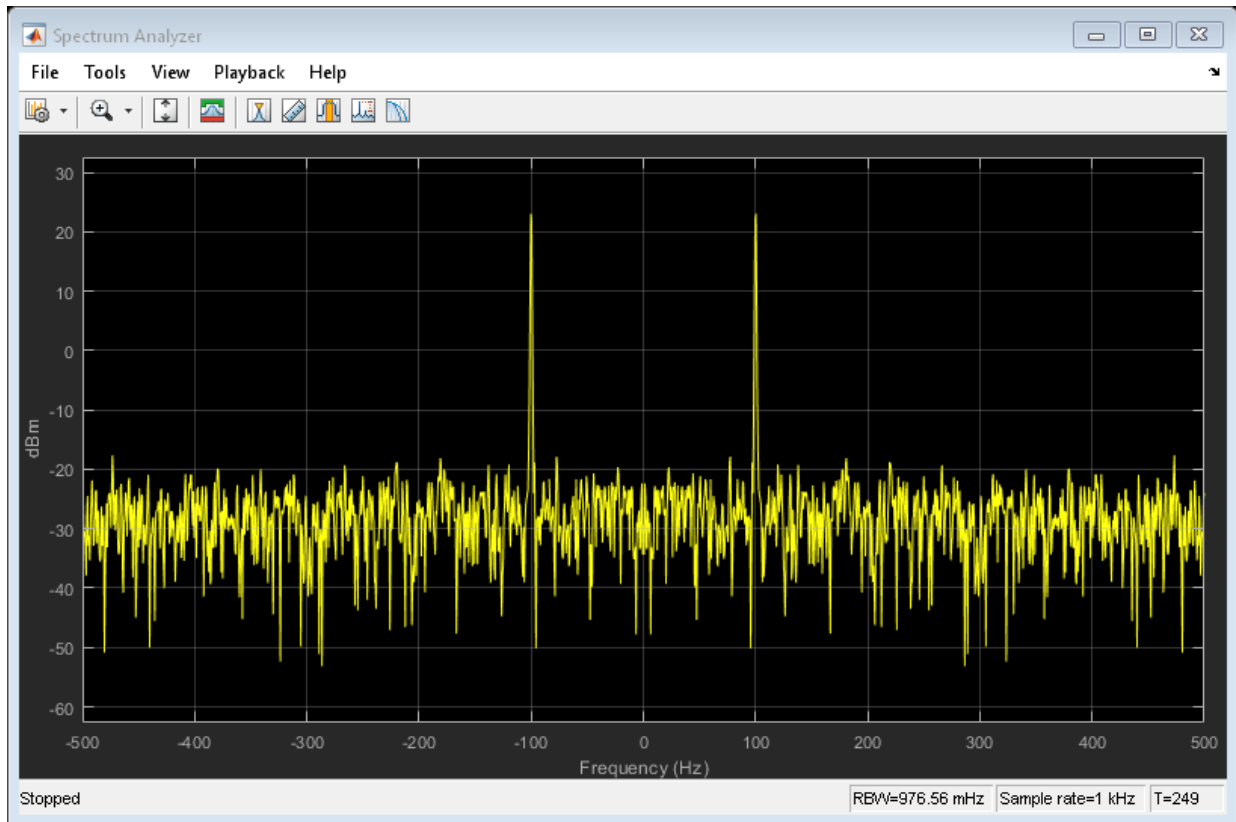

View a two-sided power spectrum of a sine wave with noise on the Spectrum Analyzer.

```
sin = dsp.SineWave('Frequency',100,'SampleRate',1000);  
sin.SamplesPerFrame = 1000;  
scope = dsp.SpectrumAnalyzer('SampleRate',sin.SampleRate);  
for ii = 1:250  
    x = sin() + 0.05*randn(1000,1);  
    scope(x);  
end
```

Run the `release` method to change property values and input characteristics. The scope automatically scales the axes. It updates the display one more time if any data is in the internal buffer.

```
release(scope);
```

Run the MATLAB `clear` function to close the Spectrum Analyzer window.

```
clear('scope');
```

### Display Frequency Input from Spectral Estimation

Use the Spectrum Analyzer to display frequency input from spectral estimates of sinusoids embedded in white Gaussian noise.

#### Initialization

Initialize two `dsp.SpectrumEstimator` objects to display. One estimator uses the Welch-based spectral estimation technique with a Hann window, the other estimator use a filter bank estimation. Specify a noisy sine wave input signal with 4 sinusoids at 0.16, 0.2,

0.205, and 0.25 cycles/sample. View the spectral estimate using a spectrum analyzer set to process frequency input.

```

FrameSize = 420;
Fs = 1;
Frequency = [0.16 0.2 0.205 0.25];
sinegen = dsp.SineWave('SampleRate',Fs,'SamplesPerFrame',FrameSize,...
    'Frequency',Frequency,'Amplitude',[2e-5 1 0.05 0.5]);
NoiseVar = 1e-10;
numAves = 8;

hannEstimator = dsp.SpectrumEstimator('PowerUnits','dBm',...
    'Window','Hann','FrequencyRange','onesided',...
    'SpectralAverages',numAves,'SampleRate',Fs);

filterBankEstimator = dsp.SpectrumEstimator('PowerUnits','dBm',...
    'Method','Filter bank','FrequencyRange','onesided',...
    'SpectralAverages',numAves,'SampleRate',Fs);

spectrumPlotter = dsp.SpectrumAnalyzer('InputDomain','Frequency',...
    'SampleRate',Fs/FrameSize,...
    'SpectrumUnits','dBm','YLimits',[-120,40],...
    'PlotAsTwoSidedSpectrum',false,...
    'ChannelNames',{'Hann window','Filter bank'},'ShowLegend',true);

```

## Streaming

Stream the input. Compare the spectral estimates in the spectrum analyzer.

```

for i = 1:1000
    x = sum(sinegen(),2) + sqrt(NoiseVar)*randn(FrameSize,1);
    Pse_hann = hannEstimator(x);
    Pfb = filterBankEstimator(x);
    spectrumPlotter([Pse_hann,Pfb])
end

```

- “Estimate the Power Spectrum in MATLAB”
- “Spectral Analysis”

### Tips

- To close the scope window and clear its associated data, use the MATLAB `clear` function.
- To hide or show the scope window, use the `hide` and `show` functions.
- Use the MATLAB `mcc` function to compile code containing a Spectrum Analyzer.

You cannot open Spectrum Analyzer configuration dialog boxes if you have more than one compiled component in your application.

## Algorithms

### Welch's Method

When you set the **Method** property to **Welch**, the following algorithms apply. The Spectrum Analyzer uses the **RBW** or the **Window Length** setting in the **Spectrum Settings** pane to determine the data window length. Then, it partitions the input signal into a number of windowed data segments. Finally, Spectrum Analyzer uses the modified periodogram method to compute spectral updates, averaging the windowed periodograms for each segment.

Spectrum Analyzer requires that a minimum number of samples to compute a spectral estimate. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly related to resolution bandwidth, **RBW**, by the following equation, or to the window length, by the equation shown in step 2.

$$N_{samples} = \frac{\left(1 - \frac{O_p}{100}\right) \times NENBW \times F_s}{RBW}$$

The normalized effective noise bandwidth, **NENBW**, is a factor that depends on the windowing method. Spectrum Analyzer shows the value of **NENBW** in the **Window Options** pane of the **Spectrum Settings** pane. Overlap percentage,  $O_p$ , is the value of the **Overlap %** parameter in the **Window Options** pane of the **Spectrum Settings** pane.  $F_s$  is the sample rate of the input signal. Spectrum Analyzer shows sample rate in the **Main Options** pane of the **Spectrum Settings** pane.

- 1 When in **RBW (Hz)** mode, the window length required to compute one spectral update,  $N_{window}$ , is directly related to the resolution bandwidth and normalized effective noise bandwidth:

$$N_{window} = \frac{NENBW \times F_s}{RBW}$$

When in **Window Length** mode, the window length is used as specified.

- 2 The number of input samples required to compute one spectral update,  $N_{samples}$ , is directly related to the window length and the amount of overlap by the following equation.

$$N_{samples} = \left(1 - \frac{O_p}{100}\right) N_{window}$$

When you increase the overlap percentage, fewer new input samples are needed to compute a new spectral update. For example, if the window length is 100, then the number of input samples required to compute one spectral update is given as shown in the following table.

$O_p$	$N_{samples}$
0%	100
50%	50
80%	20

- 3 The normalized effective noise bandwidth,  $NENBW$ , is a window parameter determined by the window length,  $N_{window}$ , and the type of window used. If  $w(n)$  denotes the vector of  $N_{window}$  window coefficients, then  $NENBW$  is given by the following equation.

$$NENBW = N_{window} \frac{\sum_{n=1}^{N_{window}} w^2(n)}{\left[\sum_{n=1}^{N_{window}} w(n)\right]^2}$$

- 4 When in **RBW (Hz)** mode, you can set the resolution bandwidth using the value of the **RBW (Hz)** parameter on the **Main options** pane of the **Spectrum Settings** pane. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two:

$$\frac{span}{RBW} > 2$$

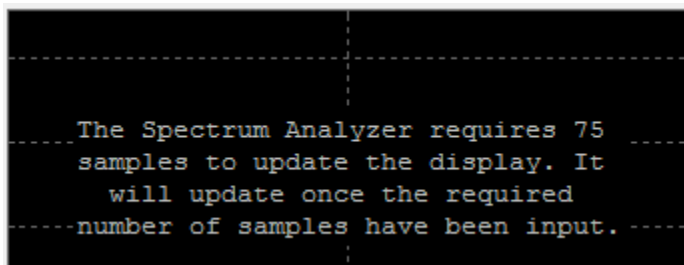

By default, the **RBW (Hz)** parameter on the **Main options** pane is set to Auto. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified frequency span. When you set **RBW (Hz)** to Auto,  $RBW$  is calculated as:

$$RBW_{auto} = \frac{span}{1024}$$

- 5 When in **Window Length** mode, you specify  $N_{window}$  and the resulting  $RBW$  is:

$$\frac{NENBW * F_s}{N_{window}}$$

Sometimes, the number of input samples provided are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer displays a message:

Spectrum Analyzer removes this message and displays a spectral estimate when enough data has been input.

---

**Note** The number of FFT points ( $N_{fft}$ ) is independent of the window length ( $N_{window}$ ). You can set them to different values if  $N_{fft}$  is greater than or equal to  $N_{window}$ .

---

## Filter Bank

When you set the **Method** property to **Filter Bank**, the following algorithms apply. The Spectrum Analyzer uses the **RBW (Hz)** or the **Number of frequency band** property in the **Spectrum Settings** pane to determine the input frame length.

Spectrum Analyzer requires a minimum number of samples to compute a spectral estimate. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly related to resolution bandwidth,  $RBW$ , by the following equation.

$$N_{samples} = \frac{F_s}{RBW}$$

$F_s$  is the sample rate of the input signal. Spectrum Analyzer shows sample rate in the **Main Options** pane of the **Spectrum Settings** pane.

- 1 When in **RBW (Hz)** mode, you can set the resolution bandwidth using the value of the **RBW (Hz)** parameter on the **Main options** pane of the **Spectrum Settings** pane. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two:

$$\frac{span}{RBW} > 2$$

By default, the **RBW** parameter on the **Main options** pane is set to Auto. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified frequency span. Thus, when you set **RBW**

to Auto, it is calculated by the following equation.  $RBW_{auto} = \frac{span}{1024}$

- 2 When in **Number of frequency bands** mode, you specify the input frame size. When the number of frequency bands is Auto, the resulting RBW is:

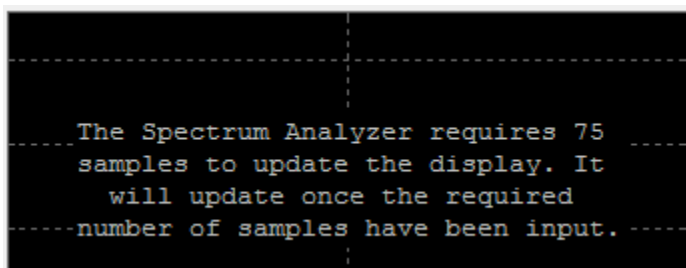

$$RBW = \frac{F_s}{\text{Input Frame Size}}$$

When the number of frequency bands is manually specified, the resulting RBW is:

$$RBW = \frac{F_s}{FTLength}$$

For more information about the filter bank algorithm, see “Polyphase Implementation” on page 2-199.

Sometimes, the number of input samples provided are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer displays a message:

Spectrum Analyzer removes this message and displays a spectral estimate when enough data has been input.

## Nyquist frequency interval

When the `PlotAsTwoSidedSpectrum` property is set to `true`, the interval is

$$\left[ -\frac{\text{SampleRate}}{2}, \frac{\text{SampleRate}}{2} \right] + \text{FrequencyOffset} \text{ hertz.}$$

When the `PlotAsTwoSidedSpectrum` property is set to `false`, the interval is

$$\left[ 0, \frac{\text{SampleRate}}{2} \right] + \text{FrequencyOffset} \text{ hertz.}$$

## Periodogram and Spectrogram

Spectrum Analyzer calculates and plots the power spectrum, power spectrum density, and RMS computed by the modified Periodogram estimator. For more information about the Periodogram method, see `periodogram`.

**Power Spectral Density** — The power spectral density (PSD) is given by the following equation.

$$PSD(f) = \frac{1}{P} \sum_{p=1}^P \frac{\left| \sum_{n=1}^{N_{FFT}} x^{(p)}[n] e^{-j2\pi f(n-1)T} \right|^2}{F_s \times \sum_{n=1}^{N_{window}} w^2[n]}$$

In this equation,  $x[n]$  is the discrete input signal. On every input signal frame, Spectrum Analyzer generates as many overlapping windows as possible, with each window denoted as  $x^{(p)}[n]$ , and computes their periodograms. Spectrum Analyzer displays a running average of the  $P$  most current periodograms.

*Power Spectrum* — The power spectrum is the product of the power spectral density and the resolution bandwidth, as given by the following equation.

$$P_{\text{spectrum}}(f) = PSD(f) \times RBW = PSD(f) \times \frac{F_s \times NENBW}{N_{\text{window}}} = \frac{1}{P} \sum_{p=1}^P \frac{\left| \sum_{n=1}^{N_{FFT}} x^{(p)}[n] e^{-j2\pi f(n-1)T} \right|^2}{\left[ \sum_{n=1}^{N_{\text{window}}} w[n] \right]^2}$$

*Spectrogram* — You can plot any power as a spectrogram. Each line of the spectrogram is one periodogram. The time resolution of each line is  $1/RBW$ , which is the minimum attainable resolution. Achieving the resolution you want may require combining several periodograms. You then use interpolation to calculate noninteger values of  $1/RBW$ . In the spectrogram display, time scrolls from bottom to top, so the most recent data is shown at the bottom of the display. The offset shows the time value at which the center of the most current spectrogram line occurred.

## Frequency Vector

When set to **Auto**, the frequency vector for frequency-domain input is calculated by the software.

When the `PlotAsTwoSidedSpectrum` property is set to true, the frequency vector is:

$$\left[ -\frac{\text{SampleRate}}{2}, \frac{\text{SampleRate}}{2} \right]$$

When the `PlotAsTwoSidedSpectrum` property is set to false, the frequency vector is:

$$\left[ 0, \frac{\text{SampleRate}}{2} \right]$$

## Occupied BW

The *Occupied BW* is calculated as follows.

- 1 Calculate the total power in the measured frequency range.
- 2 Determine the lower frequency value. Starting at the lowest frequency in the range and moving upward, the power distributed in each frequency is summed until this result is

$$\frac{100 - \text{Occupied BW } \%}{2}$$

of the total power.

- 3 Determine the upper frequency value. Starting at the highest frequency in the range and moving downward, the power distributed in each frequency is summed until the result reaches

$$\frac{100 - \text{Occupied BW } \%}{2}$$

of the total power.

- 4 The bandwidth between the lower and upper power frequency values is the occupied bandwidth.
- 5 The frequency halfway between the lower and upper frequency values is the center frequency.

## Distortion Measurements

The *Distortion Measurements* are computed as follows.

- 1 Spectral content is estimated by finding peaks in the spectrum. When the algorithm detects a peak, it records the width of the peak and clears all monotonically decreasing values. That is, the algorithm treats all these values as if they belong to the peak. Using this method, all spectral content centered at DC (0 Hz) is removed from the spectrum and the amount of bandwidth cleared ( $W_0$ ) is recorded.
- 2 The fundamental power ( $P_1$ ) is determined from the remaining maximum value of the displayed spectrum. A local estimate ( $Fe_1$ ) of the fundamental frequency is made by computing the central moment of the power near the peak. The bandwidth of the

fundamental power content ( $W_1$ ) is recorded. Then, the power from the fundamental is removed as in step 1.

- 3 The power and width of the higher-order harmonics ( $P_2, W_2, P_3, W_3$ , etc.) are determined in succession by examining the frequencies closest to the appropriate multiple of the local estimate ( $Fe_1$ ). Any spectral content that decreases monotonically about the harmonic frequency is removed from the spectrum first before proceeding to the next harmonic.
- 4 Once the DC, fundamental, and harmonic content is removed from the spectrum, the power of the remaining spectrum is examined for its sum ( $P_{remaining}$ ), peak value ( $P_{maxspur}$ ), and median value ( $P_{estnoise}$ ).
- 5 The sum of all the removed bandwidth is computed as  $W_{sum} = W_0 + W_1 + W_2 + \dots + W_n$ .

The sum of powers of the second and higher-order harmonics are computed as  $P_{harmonic} = P_2 + P_3 + P_4 + \dots + P_n$ .

- 6 The sum of the noise power is estimated as:

$$P_{noise} = (P_{remaining} \cdot dF + P_{est.noise} \cdot W_{sum}) / RBW$$

Where  $dF$  is the absolute difference between frequency bins, and  $RBW$  is the resolution bandwidth of the window.

- 7 The metrics for SNR, THD, SINAD, and SFDR are then computed from the estimates.

$$THD = 10 \cdot \log_{10} \left( \frac{P_{harmonic}}{P_1} \right)$$

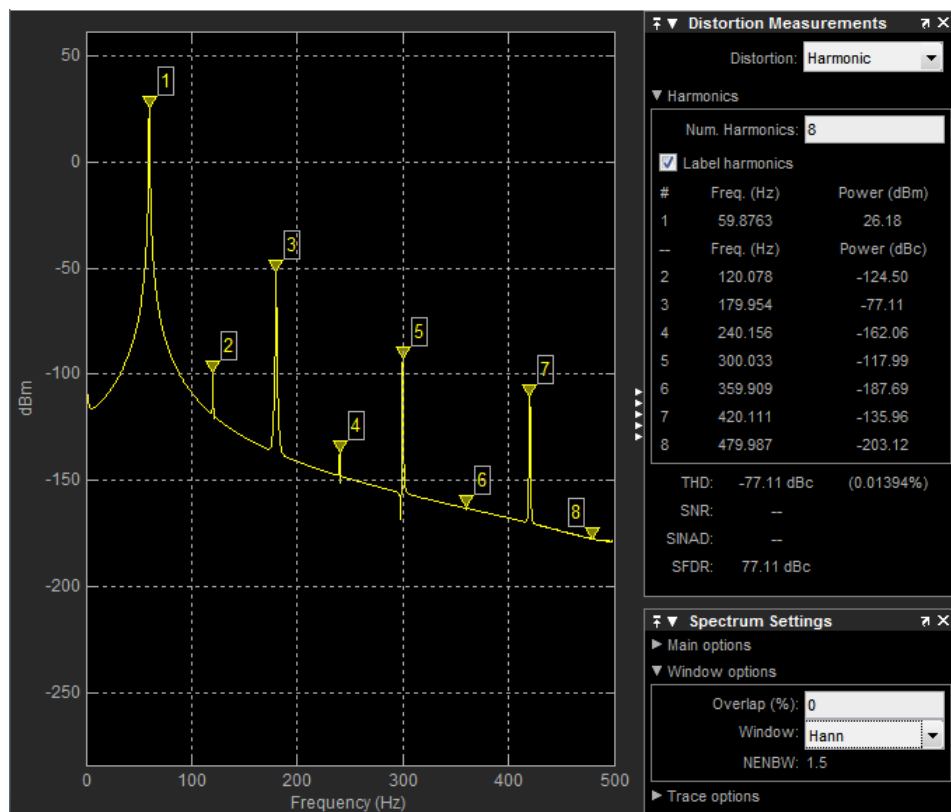

$$SINAD = 10 \cdot \log_{10} \left( \frac{P_1}{P_{harmonic} + P_{noise}} \right)$$

$$SNR = 10 \cdot \log_{10} \left( \frac{P_1}{P_{noise}} \right)$$

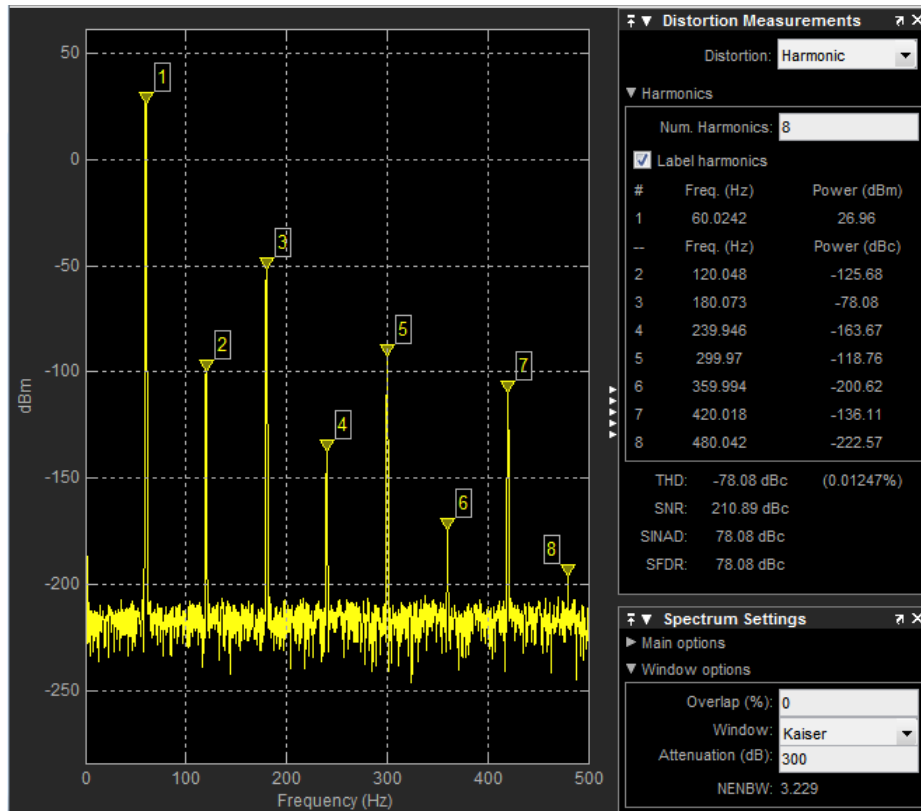

$$SFDR = 10 \cdot \log_{10} \left( \frac{P_1}{\max(P_{maxspur}, \max(P_2, P_3, \dots, P_n))} \right)$$

## Harmonic Measurements

- 1 The harmonic distortion measurements use the spectrum trace shown in the display as the input to the measurements. The default Hann window setting of the Spectrum Analyzer may exhibit leakage that can completely mask the noise floor of the measured signal.

The harmonic measurements attempt to correct for leakage by ignoring all frequency content that decreases monotonically away from the maximum of harmonic peaks. If the window leakage covers more than 70% of the frequency bandwidth in your spectrum, you may see a blank reading (-) reported for **SNR** and **SINAD**. If your application can tolerate the increased equivalent noise bandwidth (ENBW), consider using a Kaiser window with a high attenuation (up to 330 dB) to minimize spectral leakage.

- 2 The DC component is ignored.
- 3 After windowing, the width of each harmonic component masks the noise power in the neighborhood of the fundamental frequency and harmonics. To estimate the noise power in each region, Spectrum Analyzer computes the median noise level in the nonharmonic areas of the spectrum. It then extrapolates that value into each region.
- 4  $N$ th order intermodulation products occur at  $A*F1 + B*F2$ ,  
 where  $F1$  and  $F2$  are the sinusoid input frequencies and  $|A| + |B| = N$ .  $A$  and  $B$  are integer values.
- 5 For intermodulation measurements, the third-order intercept (TOI) point is computed as follows, where  $P$  is power in decibels of the measured power referenced to 1 milliwatt (dBm):

- $TOI_{lower} = P_{F1} + (P_{F2} - P_{(2F1-F2)})/2$
- $TOI_{upper} = P_{F2} + (P_{F1} - P_{(2F2-F1)})/2$
- $TOI = + (TOI_{lower} + TOI_{upper})/2$

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supports MEX code generation by treating the calls to the object as extrinsic. Does not support code generation for standalone applications.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

## **dsp.SpectrumEstimator System object**

**Package:** dsp

Estimate power spectrum or power density spectrum

### **Description**

The `dsp.SpectrumEstimator` computes the power spectrum or the power density spectrum of a signal, using the Welch algorithm and the filter bank approach.

When you choose the Welch method, the object computes the averaged modified periodograms to compute the spectral estimate. When you choose the filter bank approach, an analysis filter bank splits the broadband input signal into multiple narrow subbands. The object computes the power in each narrow frequency band and the computed value is the spectral estimate over the respective frequency band. For signals with relatively small FFT lengths, the filter bank approach produces a spectral estimate with a higher resolution, a more accurate noise floor, and peaks more precise than the Welch method, with low or no spectral leakage. These advantages come at the expense of increased computation and slower tracking.

The spectrum can be expressed in Watts or in decibels. This object can also estimate the max-hold and min-hold spectra of the signal.

To estimate the power density spectrum:

- 1 Define and set up your spectrum estimator object. See “Construction” on page 4-1639.
- 2 Call `step` to estimate the power density spectrum according to the properties of the object.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`SE = dsp.SpectrumEstimator` returns a System object, SE, that computes the frequency power spectrum or the power density spectrum of real or complex signals. This System object uses the Welch's averaged modified periodogram method and filter bank based spectral estimation method.

`SE = dsp.SpectrumEstimator('PropertyName',PropertyValue,...)` returns a Spectrum Estimator System object, SE, with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1, ..., NameN,ValueN).

## Properties

### SampleRate

Sample rate of input

Specify the sample rate of the input in, hertz, as a finite numeric scalar. The default value is 1 Hz. The sample rate is the rate at which the signal is sampled in time.

### SpectrumType

Spectrum type

Specify the spectrum type as one of 'Power' | 'Power density'. When the spectrum type is 'Power', the power density spectrum is scaled by the equivalent noise bandwidth of the window (in Hz). The default value is 'Power'. This property is tunable.

### SpectralAverages

Number of spectral averages

Specify the number of spectral averages as a positive, integer scalar. The Spectrum Estimator computes the current power spectrum or power density spectrum estimate by averaging the last N estimates. N is the number of spectral averages defined in the SpectralAverages property. The default value is 8.

### FFTLengthSource

Source of the FFT length value

Specify the source of the FFT length value as one of 'Auto' | 'Property'. The default value is 'Auto'. If you set this property to 'Auto', the Spectrum Estimator sets the FFT length to the input frame size. If you set this property to 'Property', then you specify the number of FFT points using the FFTLength property.

### **FFTLength**

FFT Length

Specify the length of the FFT that the Spectrum Estimator uses to compute spectral estimates as a positive, integer scalar. This property applies when you set the FFTLengthSource property to 'Property'. The default value is 128.

### **Method**

Welch or filter bank

Specify the spectral estimation method as one of 'Welch' | 'Filter bank'.

- 'Welch' — The object uses Welch's averaged modified periodograms method.
- 'Filter bank' — An analysis filter bank splits the broadband input signal into multiple narrow subbands. The object computes the power in each narrow frequency band and the computed value is the spectral estimate over the respective frequency band.

The default is 'Welch'.

### **NumTapsPerBand**

Number of filter taps per frequency band

Specify the number of filter coefficients, or taps, for each frequency band. This value corresponds to the number of filter coefficients per polyphase branch. The total number of filter coefficients is given by NumTapsPerBand × FFTLength. This property applies when you set Method to 'Filter bank'. The default is 12.

### **Window**

Window function

Specify a window function for the spectral estimator as one of 'Rectangular' | 'Chebyshev' | 'Flat Top' | 'Hamming' | 'Hann' | 'Kaiser'. The default value is 'Hann'.

## SidelobeAttenuation

Side lobe attenuation of window

Specify the side lobe attenuation of the window as a real, positive scalar, in decibels (dB). This property applies when you set the `Window` property to `'Chebyshev'` or `'Kaiser'`. The default value is `60` dB.

## FrequencyRange

Frequency range of the spectrum estimate

Specify the frequency range of the spectrum estimator as one of `'twosided'` | `'onesided'` | `'centered'`.

If you set the `FrequencyRange` to `'onesided'`, then the Spectrum Estimator computes the one-sided spectrum of a real input signal. When the FFT length, `NFFT`, is even, the spectrum estimate has length  $(NFFT/2) + 1$  and is computed over the frequency range  $[0 \text{ SampleRate}/2]$ , where `SampleRate` is the sample rate of the input signal. When `NFFT` is odd, the spectrum estimate has length  $(NFFT + 1)/2$  and is computed over the frequency range  $[0 \text{ SampleRate}/2]$ .

If you set the `FrequencyRange` to `'twosided'`, then the Spectrum Estimator computes the two-sided spectrum of a complex or real input signal. The length of the spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range  $[0 \text{ SampleRate})$ , where `SampleRate` is the sample rate of the input signal.

If you set the `FrequencyRange` to `'centered'`, then the Spectrum Estimator computes the centered two-sided spectrum of a complex or real input signal. The length of the spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range  $(-\text{SampleRate}/2 \text{ SampleRate}/2]$  when the FFT length is even and  $(-\text{SampleRate}/2 \text{ SampleRate}/2)$  when the FFT length is odd.

The default value is `'twosided'`.

## PowerUnits

Power units

Specify the units used to measure power as one of `'Watts'` | `'dBW'` | `'dBm'`. The default value is `'Watts'`.

### ReferenceLoad

Reference load

Specify the load that the spectrum estimator uses as a reference to compute power values as a real, positive scalar in ohms. The default value is 1 ohm.

### OutputMaxHoldSpectrum

Output max-hold spectrum

Set this property to `true` so that the Spectrum Estimator computes and outputs the max-hold spectrum of each input channel. The max-hold spectrum is computed by keeping, at each frequency bin, the maximum value of all the power spectrum estimates. The default is `false`.

### OutputMinHoldSpectrum

Output min-hold spectrum

Set this property to `true` so that the Spectrum Estimator computes and outputs the min-hold spectrum of each input channel. The min-hold spectrum is computed by keeping, at each frequency bin, the minimum value of all the power spectrum estimates. The default is `false`.

## Methods

<code>getFrequencyVector</code>	Get the vector of frequencies at which the spectrum is estimated
<code>getRBW</code>	Get the resolution bandwidth of the spectrum
<code>reset</code>	Reset the internal states of the spectrum estimator
<code>step</code>	Estimate the power spectrum or power-density spectrum of a signal

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

## Spectral Estimation Using Filter Bank

Compare spectral estimates of sinusoids embedded in white Gaussian noise using a Hann window based Welch method and filter bank method.

### Initialization

Initialize two `dsp.SpectrumEstimator` objects. Specify one estimator to use the Welch-based spectral estimation technique with a Hann window. Specify the other estimator to use an analysis filter bank to perform the spectral estimation. Specify a noisy sine wave input signal with 4 sinusoids at 0.16, 0.2, 0.205, and 0.25 cycles/sample. View the spectral estimate using an array plot.

```

FrameSize = 420;
Fs = 1;
sinegen = dsp.SineWave('SampleRate',Fs,...
    'SamplesPerFrame',FrameSize,...
    'Frequency',[0.16 0.2 0.205 0.25],...
    'Amplitude',[2e-5 1 0.05 0.5]);
NoiseVar = 1e-10;
numAvg = 8;

hannEstimator = dsp.SpectrumEstimator('PowerUnits','dBm',...
    'Window','Hann','FrequencyRange','onesided',...
    'SpectralAverages',numAvg,'SampleRate',Fs);

filterBankEstimator = dsp.SpectrumEstimator('PowerUnits','dBm',...
    'Method','Filter bank','FrequencyRange','onesided',...
    'SpectralAverages',numAvg,'SampleRate',Fs);

spectrumPlotter = dsp.ArrayPlot(...
    'PlotType','Line','SampleIncrement',Fs/FrameSize,...
    'YLimits',[-250,50],'YLabel','dBm',...
    'ShowLegend',true,'ChannelNames',{'Hann window','Filter bank'});

```

### Streaming

Stream the input. Compare the spectral estimates computed using the Hann window and the analysis filter bank

```

for i = 1:1000
    x = sum(sinegen(),2) + sqrt(NoiseVar)*randn(FrameSize,1);
    Pse_hann = hannEstimator(x);
    Pfb = filterBankEstimator(x);
end

```

```
spectrumPlotter([Pse_hann,Pfb]);  
end
```

The Hann window misses the peak at 0.205 cycles/sample. In addition, the window has a significant spectral leakage that makes the peak at 0.16 cycles/sample hard to distinguish, and the noise floor is not correct.

The filter bank estimate has a very good resolution with no spectral leakage.

## Power and Max-Hold Spectra of Noisy Sine Wave

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Generate a sine wave.

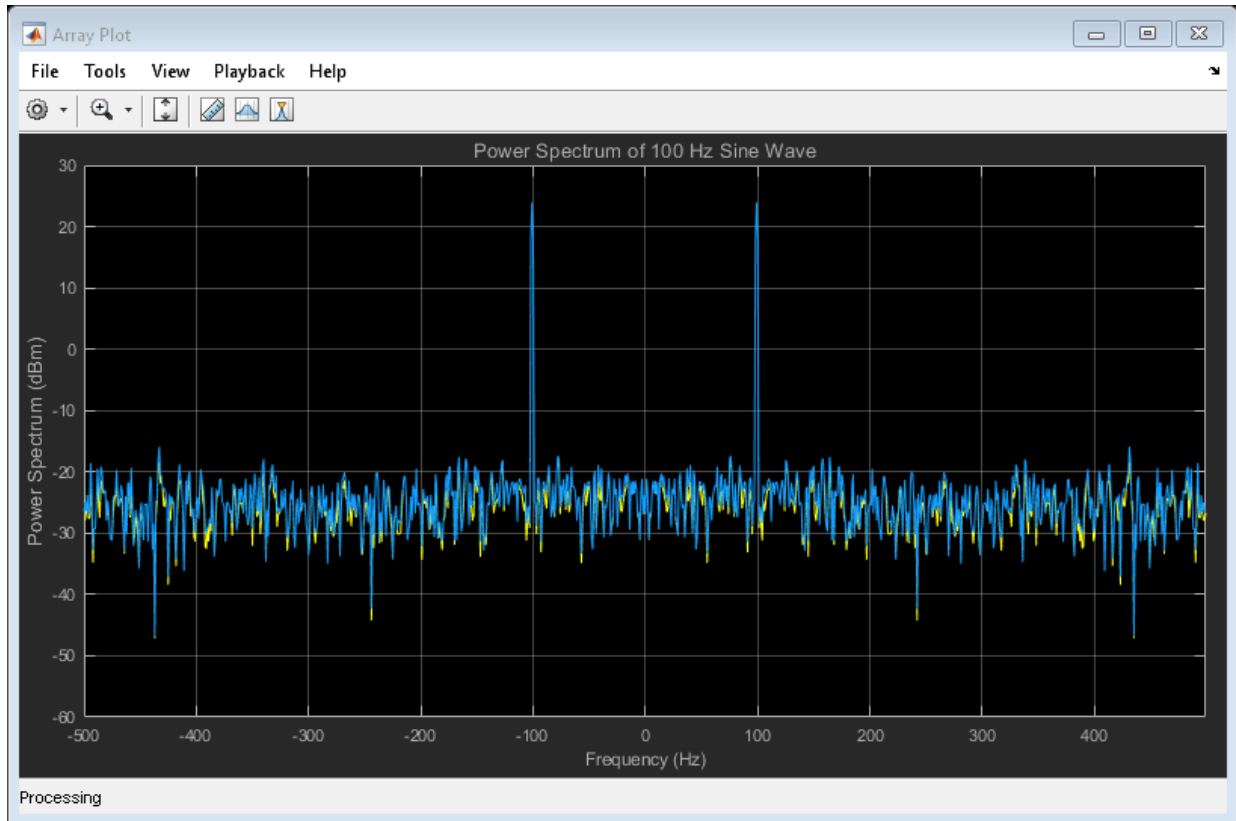

```
SINE = dsp.SineWave('Frequency',100,'SampleRate',1000, ...
    'SamplesPerFrame',1000);
```

Use the Spectrum Estimator to compute the power spectrum and the max-hold spectrum of the sine wave. Use the Array Plot to display the spectra.

```
SE = dsp.SpectrumEstimator('SampleRate',SINE.SampleRate, ...
    'SpectrumType','Power','PowerUnits','dBm', ...
    'FrequencyRange','centered','OutputMaxHoldSpectrum',true);
PLOTTER = dsp.ArrayPlot('PlotType','Line','XOffset',-500, ...
    'YLimits',[-60 30], 'Title','Power Spectrum of 100 Hz Sine Wave', ...
    'YLabel','Power Spectrum (dBm)','XLabel','Frequency (Hz)');
```

Add random noise to the sine wave. Stream in the data, and plot the power spectrum of the signal.

```
for ii = 1:10
    x = SINE() + 0.05*randn(1000,1);
    [Pxx,Pmax] = SE(x);
    PLOTTER([Pxx Pmax]);
end
```

## Algorithms

### Welch's Method of Averaged Modified Periodograms

When you choose the Welch method, the power spectrum estimate is averaged modified periodograms.

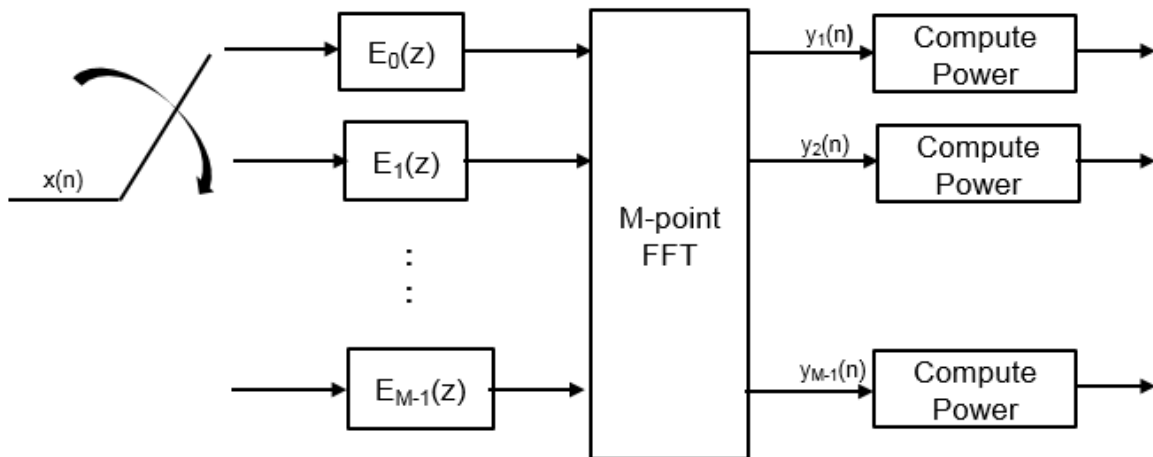

Let  $x$  be the input frame. Multiply  $x$  by the window and scale the result by the window power. Take the FFT of the signal,  $Y$ , and take the square magnitude using  $Z = Y \cdot \text{conj}(Y)$ . Compute the current power spectrum estimate by averaging the last  $N$   $Z$ s and scaling the answer by the sample rate.  $N$  is the number of spectral averages.

For further information refer to the “Algorithms” on page 2-1597 section in Spectrum Analyzer, which uses the same algorithm.

## Filter Bank

The spectrum estimator uses an analysis filter bank to estimate the power spectrum. The number of taps per frequency band specifies the number of filter coefficients for each frequency band of the filter bank. The total number of filter coefficients is equal to number of taps per band times the FFT length.

The filter-bank-based spectrum estimator splits the broadband input signal,  $x(n)$ , into multiple narrow bands and computes the power in each band. Each value becomes the estimate of the power over that narrow frequency band. The power in all the narrow bands forms the spectral estimate vector.

For more information on the analysis filter bank and how it is implemented, see the “Definitions” on page 4-286 and the “Algorithm” on page 4-289 sections in dsp.Channelizer.

`dsp.TransferFunctionEstimator`

#### Blocks

Spectrum Estimator

#### Introduced in R2013b

# getFrequencyVector

**System object:** dsp.SpectrumEstimator

**Package:** dsp

Get the vector of frequencies at which the spectrum is estimated

## Syntax

getFrequencyVector(SE)

## Description

getFrequencyVector(SE) returns the vector of frequencies at which the spectrum is estimated.

If you set the FrequencyRange to 'onesided' and the FFT length, NFFT, is even, the frequency vector is of length  $NFFT/2+1$ , and covers the interval  $[0, SampleRate/2]$ . If you set the FrequencyRange to 'onesided' and NFFT is odd, the frequency vector is of length  $(NFFT+1)/2$  and covers the interval  $[0, SampleRate/2]$ . If you set the FrequencyRange to 'twosided', the frequency vector is of length NFFT and covers the interval  $[0, SampleRate]$ . If you set the FrequencyRange to 'centered', the frequency vector is of length NFFT and covers the range  $[-SampleRate/2, SampleRate/2]$  and  $[-SampleRate/2, SampleRate/2]$  for even and odd length NFFT, respectively.

# getRBW

**System object:** dsp.SpectrumEstimator

**Package:** dsp

Get the resolution bandwidth of the spectrum

## Syntax

getRBW(SE)

## Description

getRBW(SE) returns the resolution bandwidth of the spectrum.

The resolution bandwidth, RBW, is the smallest positive frequency, or frequency interval, that can be resolved. It is equal to  $ENBW \cdot \text{SampleRate} / L$ , where  $L$  is the input length, and ENBW is the two-sided equivalent noise bandwidth of the window (in Hz). For example, if  $\text{SampleRate}=100$ ,  $L=1024$ , and  $\text{Window}='Hann'$ ,  $RBW=enbw(hann(1024)) \cdot 100/1024$ .

## reset

**System object:** dsp.SpectrumEstimator

**Package:** dsp

Reset the internal states of the spectrum estimator

## Syntax

```
reset(sysObj)
```

## Description

`reset(sysObj)` resets the internal states of the System object, `sysObj`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

## step

**System object:** dsp.SpectrumEstimator

**Package:** dsp

Estimate the power spectrum or power-density spectrum of a signal

## Syntax

```
pxx = step(SE,x)
[pxx,pmax] = step(SE,x)
[pxx,pmin] = step(SE,x)
[pxx,pmax,pmin] = step(SE,x)
```

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`pxx = step(SE,x)` computes the power spectrum or power-density spectrum, `pxx`, of the input signal, `x`. The System object treats the columns of `x` as independent channels.

`[pxx,pmax] = step(SE,x)` also computes the max-hold frequency spectrum, `pmax`, of `x`. To determine the max-hold spectrum, the method keeps the maximum of all the power spectrum estimates computed at each frequency bin. Set `OutputMaxHoldSpectrum` to `true` to obtain the max-hold spectrum.

`[pxx,pmin] = step(SE,x)` also computes the min-hold frequency spectrum, `pmin`, of `x`. To determine the min-hold spectrum, the method keeps the minimum of all the power spectrum estimates computed at each frequency bin. Set `OutputMinHoldSpectrum` to `true` to obtain the min-hold spectrum.

`[pxx,pmax,pmin] = step(SE,x)` computes the power spectrum or power-density spectrum, the max-hold spectrum, and the min-hold spectrum of `x`. Set

OutputMaxHoldSpectrum and OutputMinHoldSpectrum to true to obtain the max-hold and min-hold spectra.

## Input Arguments

### **SE — Frequency spectrum estimator**

SpectrumEstimator System object

Frequency spectrum estimate, specified as a SpectrumEstimator System object

### **x — Input signal**

vector | matrix

Input signal, specified as a vector or matrix with floating point or fixed-point precision. The row length of  $x$  is the frame size or channel length. Each column of  $x$  is treated as a separate channel. The column length of  $x$  is the number of channels.

## Output Arguments

### **pxx — Power or power-density spectrum estimate**

vector | matrix

Power or power-density spectrum estimate, returned as a vector or matrix of the same size, data type, and complexity as the input signal,  $x$ . By default, the unit is 'Watts'. You can also specify the spectrum to be in 'dBm' or 'dBW' through the PowerUnits property of the SpectrumEstimator System object.

### **pmax — Max-hold spectrum estimate**

vector | matrix

Max-hold spectrum estimate, returned as a vector or matrix of the same size, data type, and complexity as the input signal,  $x$ .

### **pmin — Min-hold spectrum estimate**

vector | matrix

Min-hold spectrum estimate, returned as a vector or matrix of the same size, data type, and complexity as the input signal,  $x$ .

## Examples

### Power Spectrum of Multichannel Sinusoidal Signal

Generate a three-channel sinusoid sampled at 1 kHz. Specify sinusoidal frequencies of 100, 200, and 300 Hz. The second and third channels have their phases offset from the first by  $\pi/2$  and  $\pi/4$ , respectively.

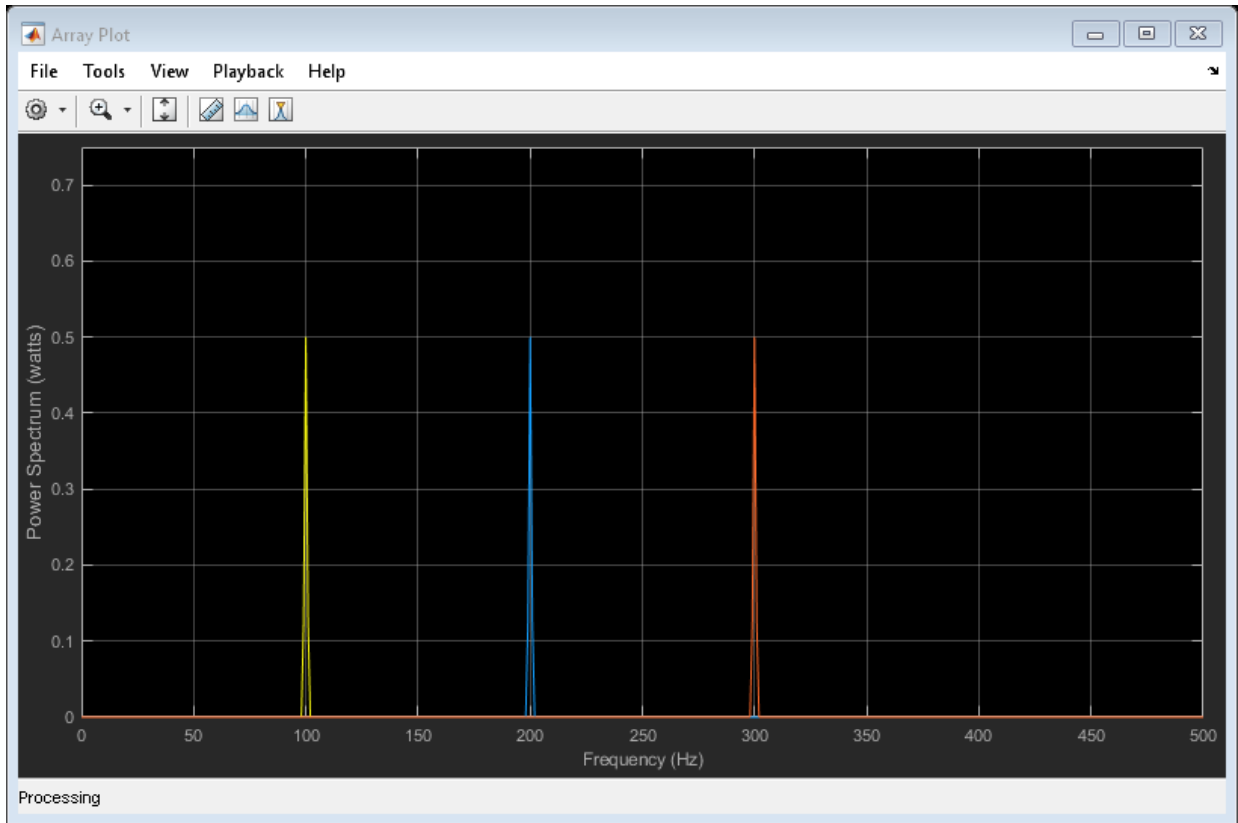

```
SINE = dsp.SineWave('SamplesPerFrame',1000,'SampleRate',1000, ...  
    'Frequency',[100 200 300],'PhaseOffset',[0 pi/2 pi/4]);
```

Estimate and plot the one-sided spectrum of the signal. Use the Spectrum Estimator for the computation and the Array Plot for the plotting.

```
SE = dsp.SpectrumEstimator('FrequencyRange','onesided');  
PLOTTER = dsp.ArrayPlot('PlotType','Line','YLimits',[0 0.75], ...  
    'YLabel','Power Spectrum (watts)','XLabel','Frequency (Hz)');
```

Step through to obtain the data streams and display the spectra of the three channels.

```
y = step(SINE);  
pxx = step(SE,y);  
step(PLOTTER,pxx)
```

## dsp.StandardDeviation System object

**Package:** dsp

Standard deviation of input or sequence of inputs

### Description

The `dsp.StandardDeviation` object computes the standard deviation for an input or sequence of inputs.

To compute the standard deviation for an input or sequence of inputs:

- 1 Define and set up your standard deviation object. See “Construction” on page 4-1656.
- 2 Call `step` to compute the standard deviation according to the properties of `dsp.StandardDeviation`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

---

**Note** The Running mode in the `dsp.StandardDeviation` System object will be removed in a future release. To compute the running standard deviation in MATLAB, use the `dsp.MovingStandardDeviation` System object instead.

---

### Construction

`std = dsp.StandardDeviation` returns a standard deviation System object, `std`, that computes the standard deviation for the columns of input.

`std = dsp.StandardDeviation('PropertyName',PropertyValue,...)` returns a standard deviation System object, `std`, with each specified property set to the specified value.

## Properties

### RunningStandardDeviation

Enable calculation over successive calls to the `step` method

Set this property to `true` to enable the calculation of standard deviation over successive calls to the `step` method. The default is `false`.

### ResetInputPort

Enable resetting in running standard deviation mode

Set this property to `true` to enable resetting for the running standard deviation. When the property is set to `true`, you must specify a reset input to the `step` method to reset the running standard deviation. This property applies only when you set the `RunningStandardDeviation` property to `true`. The default is `false`.

### ResetCondition

Reset condition for running standard deviation mode

Specify event to reset the running standard deviation as one of `Rising edge` | `Falling edge` | `Either edge` | `Non-zero` |. This property applies only when you set the “ResetInputPort” on page 4-0 property to `true`. The default is `Non-zero`.

### Dimension

Dimension to operate along

Specify how the standard deviation calculation is performed over the data as one of `All` | `Row` | `Column` | `Custom` |. This property applies only when you set the `RunningStandardDeviation` property to `false`. The default is `Column`.

### CustomDimension

Numerical dimension to operate along

Specify the dimension (one-based value) of the input signal, over which the object computes the standard deviation. The cannot exceed the number of dimensions for the input signal. This property applies when you set the “Dimension” on page 4-0 property to `Custom`. The default is `1`.

### Methods

- reset    Reset states for running standard deviation computation
- step    Calculate standard deviation of input

Common to All System Objects	
release	Allow System object property value changes

### Examples

#### Running Standard Deviation

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Compute the running standard deviation of a signal using `dsp.StandardDeviation` object. To activate this mode, set the `RunningStandardDeviation` property to `true`.

```
std2 = dsp.StandardDeviation;  
std2.RunningStandardDeviation = true;  
x = randn(100,1);  
y = std2(x);
```

`y(i)` is the standard deviation of the `i`th input sample with respect to all the past input samples.

### Algorithms

This object implements the algorithm, inputs, and outputs described on the Standard Deviation block reference page. The object properties correspond to the block parameters, except:

- The **Reset port** block parameter corresponds to the `ResetInputPort` and `ResetCondition` object properties.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

**Introduced in R2012a**

## **reset**

**System object:** dsp.StandardDeviation

**Package:** dsp

Reset states for running standard deviation computation

## **Syntax**

`reset(std)`

## **Description**

`reset(std)` sets the internal states of the `StandardDeviation` object `std` to their initial values when computing the running standard deviation.

---

## step

**System object:** dsp.StandardDeviation

**Package:** dsp

Calculate standard deviation of input

## Syntax

$Y = \text{step}(\text{std}, X)$

$Y = \text{step}(\text{std}, X, R)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(\text{std}, X)$  computes the standard deviation,  $Y$ , of input  $X$ . The object computes the standard deviation over successive calls to the `step` method when the `RunningStandardDeviation` property is true.

$Y = \text{step}(\text{std}, X, R)$  resets its state based on the value of reset signal  $R$  and the `ResetCondition` property. You can use this option only when the `RunningStandardDeviation` property is true.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.StateLevels System object

**Package:** dsp

State-level estimation for bilevel rectangular waveform

## Description

The `StateLevels` object estimates the state levels of a bilevel rectangular waveform.

To estimate the state levels of a bilevel waveform:

- 1 Define and set up your state-level estimation. See “Construction” on page 4-1663.
- 2 Call `step` to estimate the state levels for an input vector according to the properties of `dsp.StateLevels`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`sl = dsp.StateLevels` creates a state-level estimation System object, `sl`, that estimates state levels in a bilevel rectangular waveform using the histogram method with 100 bins.

`sl = dsp.StateLevels('PropertyName',PropertyValue,...)` returns an `StateLevels` System object, `sl`, with each specified property set to the specified value.

## Properties

### HistogramBounds

Minimum and maximum levels of the histogram. Specify the range of the histogram as a 2-element real-valued row vector. Signal values outside the range defined by this

property are ignored. This property applies when you set the `Method` property to 'Histogram mode' or 'Histogram mean', and either `RunningStateLevels` is true, or the `HistogramBoundsSource` property is set to 'Property'.

**Default:** [0 5]

### **HistogramBoundsSource**

Source of histogram bounds. Specify how to determine the histogram bounds as one of 'Auto' or 'Property'. When you set this property to 'Auto', the histogram bounds are determined by the minimum and maximum input values. When you set this property to 'Property', the histogram bounds are determined by the value of the `HistogramBounds` property. This property applies when you set the `Method` property to 'Histogram mode' or 'Histogram mean', and the `RunningStateLevels` property is false.

**Default:** 'Auto'

### **HistogramNumBins**

Number of bins in the histogram. Specify the number of bins in the histogram. This property applies when you set the `Method` property to 'Histogram mode' or 'Histogram mean'.

**Default:** 100

### **HistogramOutputPort**

Enable histogram output. Set this property to true to output the histogram used in the computation of the state levels. This property applies when you set the `Method` property to 'Histogram mode' or 'Histogram mean'.

**Default:** false

### **Method**

Algorithm used to compute state levels. Specify the method used to compute state levels as one of 'Histogram mean', 'Histogram mode', or 'Peak to peak'.

**Default:** 'Histogram mode'

## RunningStateLevels

Calculation over successive calls to `step`. Set this property to `true` to enable computation of the state levels over successive calls to the `step`. Otherwise, compute the state levels of the current input. When you set the `RunningStateLevels` property to `false` and you are using a histogram to compute your state levels, you must set the `HistogramBoundsSource` property to `'Property'`.

## State

A particular level, which can be associated with an upper and lower state boundary. States are ordered from the most negative to the most positive. In a bilevel waveform, the most negative state is the low state. The most positive state is the high state.

## State-Level Tolerances

Each state level can have associated lower- and upper-state boundaries. These state boundaries are defined as the state level plus or minus a scalar multiple of the difference between the high state and low state. To provide a useful tolerance region, the scalar is typically a small number such as 2/100 or 3/100. In general, the  $\alpha\%$  tolerance region for the low state is defined as

$$S_1 \pm \frac{\alpha}{100}(S_2 - S_1)$$

where  $S_1$  is the low-state level and  $S_2$  is the high-state level. Replace the first term in the equation with  $S_2$  to obtain the  $\alpha\%$  tolerance region for the high state.

The following figure illustrates lower and upper 2% state boundaries (tolerance regions) for a positive-polarity bilevel waveform. The estimated state levels are indicated by a dashed red line.

## Methods

- plot     Plot signal, state levels, and histogram
- reset    Reset internal states of state levels object
- step     Estimate state levels for bilevel rectangular waveform

### Common to All System Objects

release	Allow System object property value changes
---------	--

## Examples

### State Levels of 2.3 V Underdamped Noisy Clock

Compute and plot the state levels of a 2.3 V underdamped noisy clock. Load the clock data in the variable, `x`, and the sampling instants in the variable `t`.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
load('clockex.mat', 'x', 't');
```

Estimate the state levels.

```
sl = dsp.StateLevels;  
levels = sl(x);
```

Plot the clock data along with the estimated state levels and histograms.

```
plot(sl)
```

### Algorithms

The `StateLevels` System object uses the histogram method to estimate the states of a bilevel waveform. The histogram method is described in [1]. To summarize the method:

- 1 Determine the maximum and minimum amplitudes and amplitude range of the data.
- 2 For the specified number of histogram bins, determine the bin width as the ratio of the amplitude range to the number of bins.
- 3 Sort the data values into the histogram bins.
- 4 Identify the lowest-indexed histogram bin,  $i_{low}$ , and highest-indexed histogram bin,  $i_{high}$ , with nonzero counts.
- 5 Divide the histogram into two subhistograms. The lower-histogram bins are  $i_{low} \leq i \leq 1/2(i_{high} - i_{low})$ .

The upper-histogram bins are  $i_{low} + 1/2(i_{high} - i_{low}) \leq i \leq i_{high}$ .

- 6 Compute the state levels by determining the mode or mean of the lower and upper histograms.

### Extended Capabilities

#### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

## **See Also**

dsp.PulseMetrics | dsp.TransitionMetrics

**Introduced in R2012a**

# plot

**System object:** dsp.StateLevels

**Package:** dsp

Plot signal, state levels, and histogram

## Syntax

```
plot(sl)
```

## Description

`plot(sl)` plots the signal and state levels computed in the last call to the `step` method. If the `Method` property of the state levels object is set to `'Histogram mode'` or `'Histogram Mean'`, the histogram is plotted in a subplot below the signal.

## reset

**System object:** dsp.StateLevels

**Package:** dsp

Reset internal states of state levels object

## Syntax

reset(sl)

## Description

reset(sl) resets the state levels object, sl, to clear information accumulated from previous calls to step.

## step

**System object:** dsp.StateLevels

**Package:** dsp

Estimate state levels for bilevel rectangular waveform

## Syntax

LEVELS = step(sl,X)

[LEVELS,HISTOGRAM] = step(sl,X)

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

LEVELS = step(sl,X) returns a 2-element row vector, LEVELS, containing the estimated state levels for X. X is a real-valued column vector.

[LEVELS,HISTOGRAM] = step(sl,X) returns a double-precision column vector, HISTOGRAM, containing the histogram of the sample values in X. You can obtain this output only when you set the Method property to either 'Histogram mean' or 'Histogram mode', and you set the HistogramOutputPort property to true.

# dsp.SubbandAnalysisFilter System object

**Package:** dsp

Decompose signal into high-frequency and low-frequency subbands

## Description

The `SubbandAnalysisFilter` object decomposes a signal into high-frequency and low-frequency subbands.

To decompose a signal into high-frequency and low-frequency subbands:

- 1 Define and set up your two-channel subband analysis filter. See “Construction” on page 4-1673.
- 2 Call `step` to decompose the signal according to the properties of `dsp.SubbandAnalysisFilter`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`subAna = dsp.SubbandAnalysisFilter` returns a two-channel subband analysis filter, `subAna`, that decomposes the input signal into a high-frequency subband and a low-frequency subband, each with half the bandwidth of the input.

`subAna = dsp.SubbandAnalysisFilter('PropertyName',PropertyValue,...)` returns a two-channel subband analysis filter, `subAna`, with each specified property set to the specified value.

`subAna = dsp.SubbandAnalysisFilter(lpc,hpc,`

`'PropertyName', PropertyValue, ...`) returns a two-channel subband analysis filter, `subAna`, with the “LowpassCoefficients” on page 4-0 property set to `lpc`, the `HighpassCoefficients` property set to `hpc`, and other specified properties set to the specified values.

## Properties

### LowpassCoefficients

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of  $z$ . For the lowpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the `HighpassCoefficients` property. The default values of this property specify a filter based on a third-order Daubechies wavelet.

### HighpassCoefficients

Highpass FIR filter coefficient

Specify a vector of highpass FIR filter coefficients, in descending powers of  $z$ . For the highpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the “LowpassCoefficients” on page 4-0 property. The default values of this property specify a filter based on a third-order Daubechies wavelet.

### Fixed-Point Properties

#### FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

**RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`. This property applies only if the object is not in full precision mode.

**OverflowAction**

Action to take when integer input is out of range

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`. This property applies only if the object is not in full precision mode.

**CoefficientsDataType**

Data type of the coefficients

Specify the FIR filter coefficients fixed-point data type as one of | `Same word length as input` | `Custom` |. The default is `Same word length as input`.

**CustomCoefficientsDataType**

Coefficients word and fraction lengths

Specify the FIR filter coefficients fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `CoefficientsDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

**ProductDataType**

Data type of product

Specify the product data type as one of | `Full precision` | `Same as input` | `Custom` |. The default is `Full precision`.

**CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

### **AccumulatorDataType**

Data type of accumulator

Specify the accumulator data type as one of `Full precision` | `Same as input` | `Same as product` | `Custom` |. The default is `Full precision`.

### **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

### **OutputDataType**

Data type of output

Specify the output data type as one of | `Same as accumulator` | `Same as product` | `Same as input` | `Custom` |. The default is `Same as accumulator`.

### **CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numericType([], 16, 14)`.

## **Methods**

- `reset`    Reset filter states of subband analysis filter object
- `step`    Decompose signal into high- and low-frequency subbands

<b>Common to All System Objects</b>	
<code>release</code>	Allow System object property value changes

## Examples

### Decompose and Reconstruct a Signal

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Decompose a signal into low frequency and high frequency subbands using the subband analysis filter. Reconstruct the signal using the subband synthesis filter.

```
load dspwlets; % load the filter coefficients lod, hid, lor and hir
subAna = dsp.SubbandAnalysisFilter(lod, hid);
subSynth = dsp.SubbandSynthesisFilter(lor, hir);
u = randn(128,1);
```

```
[hi, lo] = subAna(u); % Two channel analysis
y = subSynth(hi, lo); % Two channel synthesis
```

Plot difference between original and reconstructed signals with filter latency compensated.

```
plot(u(1:end-7)-y(8:end));
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Two-Channel Analysis Subband Filter block reference page. The object properties correspond to the block parameters, except:

- The `SubbandAnalysisFilter` object does not have a property that corresponds to the **Input processing** parameter of the Two-Channel Analysis Subband Filter block. The object assumes the input is frame based and always maintains the input frame rate.

- The **Rate options** block parameter is not supported by the `dsp.SubbandAnalysisFilter` object.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

`dsp.DyadicAnalysisFilterBank` | `dsp.SubbandSynthesisFilter`

**Introduced in R2012a**

# reset

**System object:** dsp.SubbandAnalysisFilter

**Package:** dsp

Reset filter states of subband analysis filter object

## Syntax

```
reset(subAna)
```

## Description

`reset(subAna)` sets the filter states of the `SubbandAnalysisFilter` object `subAna` to 0.

---

## step

**System object:** dsp.SubbandAnalysisFilter

**Package:** dsp

Decompose signal into high- and low-frequency subbands

## Syntax

[HI,L0] = step(subAna,SIG)

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

[HI,L0] = step(subAna,SIG) decomposes the input signal, SIG, into a high-frequency subband, HI, and a low-frequency subband, L0.

---

**Note** obj specifies the System object on which to run this step method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## **dsp.SubbandSynthesisFilter System object**

**Package:** dsp

Reconstruct signal from high-frequency and low-frequency subbands

### **Description**

The `SubbandSynthesisFilter` object reconstructs a signal from high-frequency and low-frequency subbands.

To reconstruct a signal from high-frequency and low-frequency subbands:

- 1 Define and set up your two-channel subband synthesis filter. See “Construction” on page 4-1682.
- 2 Call `step` to reconstruct the signal according to the properties of `dsp.SubbandSynthesisFilter`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### **Construction**

`subSyn = dsp.SubbandSynthesisFilter` returns a two-channel subband synthesis filter, `subSyn`, that reconstructs a signal from its high-frequency subband and low-frequency subband. Each subband contains half the bandwidth of the original signal.

`subSyn = dsp.SubbandSynthesisFilter('PropertyName',PropertyValue,...)` returns a two-channel subband synthesis filter, `subSyn`, with each specified property set to the specified value.

`subSyn = dsp.SubbandSynthesisFilter(lpc,hpc,`

`'PropertyName',PropertyValue,...`) returns a two-channel subband synthesis filter, `subSyn`. The object has the “LowpassCoefficients” on page 4-0 property set to `lpc`, the `HighpassCoefficients` property set to `hpc`, and other specified properties set to the specified values.

## Properties

### LowpassCoefficients

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of  $z$ . For the lowpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the `HighpassCoefficients` property. The default values of this property specify a filter based on a third-order Daubechies wavelet.

### HighpassCoefficients

Highpass FIR filter coefficients

Specify a vector of highpass FIR filter coefficients, in descending powers of  $z$ . For the highpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the `LowpassCoefficients` property. The default values of this property specify a filter based on a third-order Daubechies wavelet.

### Fixed-Point Properties

#### FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`. This property applies only if the object is not in full precision mode.

### **OverflowAction**

Action to take when integer input is out of range

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`. This property applies only if the object is not in full precision mode.

### **CoefficientsDataType**

Data type of the coefficients

Specify the FIR filter coefficients fixed-point data type as one of | `Same word length as input` | `Custom` |. The default is `Same word length as input`.

### **CustomCoefficientsDataType**

Coefficient word and fraction lengths

Specify the FIR filter coefficients fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `CoefficientsDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

### **ProductDataType**

Data type of product

Specify the product data type as one of | `Full precision` | `Same as input` | `Custom` |. The default is `Full precision`.

### **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

### AccumulatorDataType

Data type of accumulator

Specify the accumulator data type as one of | Full precision | Same as input | Same as product | Custom|. The default is Full precision.

### CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

### OutputDataType

Data type of output

Specify the output data type as one of | Same as accumulator | Same as product | Same as input | Custom|. The default is Same as accumulator.

### CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numericType([],16,14)`.

## Methods

- `reset`    Reset internal states of subband synthesis filter object
- `step`    Reconstruct signal from high- and low-frequency subbands

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Decompose and Reconstruct a Signal

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Decompose a signal into low frequency and high frequency subbands using the subband analysis filter. Reconstruct the signal using the subband synthesis filter.

```
load dspwlets; % load the filter coefficients lod, hid, lor and hir
subAna = dsp.SubbandAnalysisFilter(lod, hid);
subSynth = dsp.SubbandSynthesisFilter(lor, hir);
u = randn(128,1);
```

```
[hi, lo] = subAna(u); % Two channel analysis
y = subSynth(hi, lo); % Two channel synthesis
```

Plot difference between original and reconstructed signals with filter latency compensated.

```
plot(u(1:end-7)-y(8:end));
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Two-Channel Synthesis Subband Filter block reference page. The object properties correspond to the block parameters, except:

- The `SubbandSynthesisFilter` object does not have a property that corresponds to the **Input processing** parameter of the Two-Channel Synthesis Subband Filter block. The object only performs sample-based processing and always maintains the input frame rate.

- The **Rate options** block parameter is not supported by the `SubbandSynthesisFilter` object.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

### See Also

`dsp.DyadicSynthesisFilterBank` | `dsp.SubbandAnalysisFilter`

**Introduced in R2012a**

## reset

**System object:** dsp.SubbandSynthesisFilter

**Package:** dsp

Reset internal states of subband synthesis filter object

## Syntax

reset(subSyn)

## Description

reset(subSyn) sets the internal states of the SubbandSynthesisFilter object subSyn to their initial values.

# step

**System object:** dsp.SubbandSynthesisFilter

**Package:** dsp

Reconstruct signal from high- and low-frequency subbands

## Syntax

$Y = \text{step}(\text{subSyn}, \text{HI}, \text{LO})$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(\text{subSyn}, \text{HI}, \text{LO})$  reconstructs a signal from a high-frequency subband, `HI`, and a low-frequency subband, `LO`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# **dsp.TimeScope System object**

**Package:** dsp

Time domain signal display and measurement

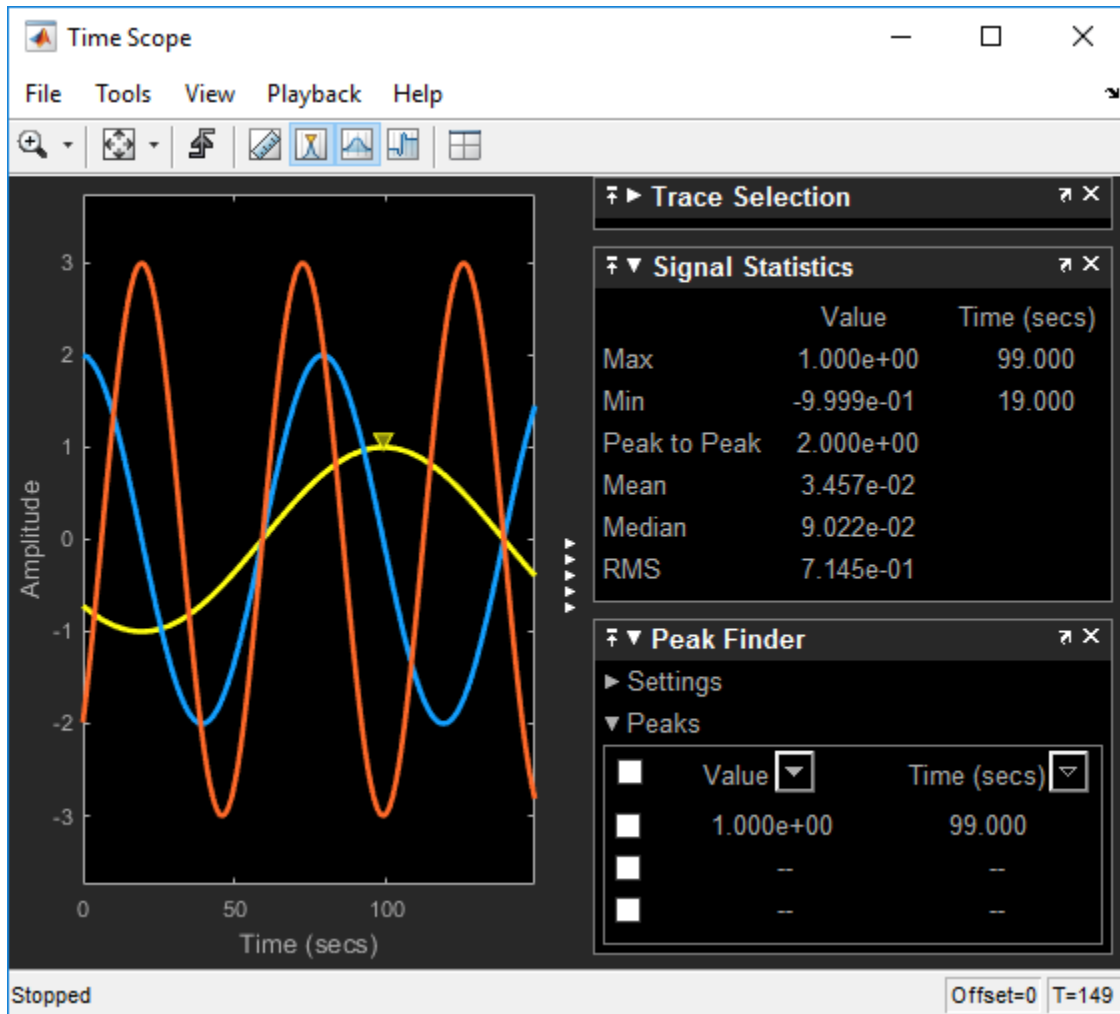

## **Description**

The `dsp.TimeScope` System object displays time-domain signals. You can use the scope to measure signal values, find peaks, display bilevel measurements and statistics.

To see time-domain signals in the scope:

- 1** Create the `dsp.TimeScope` object and set its properties.
- 2** Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

Oscilloscope features:

- Triggers — Set triggers to sync repeating signals and pause the display when events occur.
- Cursor Measurements — Measure signal values using vertical and horizontal cursors.
- Signal Statistics — Display the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal.

- Peak Finder — Find maxima, showing the  $x$ -axis values at which they occur.
- Bilevel Measurements — Measure transitions, overshoots, undershoots, and cycles.

For information on measurements and triggers, see “Configure Time Scope”.

Scope display features:

- Multiple signals — Plot multiple signals on the same  $y$ -axis (display) using multiple input ports.
- Multiple  $y$ -axes (displays) — Display multiple  $y$ -axes. All the  $y$ -axes have a common time range on the  $x$ -axis.
- Modify parameters — Modify scope parameter values before and during a simulation.
- Axis autoscaling — Autoscaling during or at the end of a simulation. Margins are drawn at the top and bottom of the axes.

## Creation

## Syntax

```
scope = dsp.TimeScope  
scope = dsp.TimeScope(numInputs, sampleRate)  
scope = dsp.TimeScope( ____, Name, Value)
```

## Description

`scope = dsp.TimeScope` returns a Time Scope System object, `scope`. This object displays real- and complex-valued floating and fixed-point signals in the time domain.

`scope = dsp.TimeScope(numInputs, sampleRate)` creates a Time Scope and sets the `NumInputPorts` property to `numInputs` and the `SampleRate` property to `sampleRate`.

`scope = dsp.TimeScope( ____, Name, Value)` sets properties specified as `Name, Value` pairs.

# Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects (MATLAB)*.

## Frequently Used

### **NumInputPorts** — Number of input ports

1 (default) | integer between [1, 96]

Number of input ports, specified as a positive integer. Each signal coming through a separate input becomes a separate channel in the scope. You must invoke the scope with the same number of inputs as the value of this property.

### **SampleRate** — Sample rate of inputs

1 (default) | scalar | vector

Specify the sample rate, in hertz, of the input signals.

You can specify a scalar or a numeric vector with length equal to the value of `NumInputPorts`. The inverse of the sample rate determines the spacing between points on the time axis in the displayed signal. When you set `SampleRate` to a scalar value and `NumInputPorts` is greater than 1, the object uses the same sample rate for all inputs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **TimeSpan** — Time span

10 (default) | positive scalar

Specify the time span, in seconds, as a positive, numeric scalar value. The time-axis limits are calculated as follows.

- Minimum time-axis limit = `min(TimeDisplayOffset)`
- Maximum time-axis limit = `max(TimeDisplayOffset) + TimeSpan`

**Tunable:** Yes

### Dependencies

To use this property, set `FrameBasedProcessing` to `false`, or set `FrameBasedProcessing` to `true` and `TimeSpanSource` to `'Property'`.

### UI Use

Open the **Configuration Properties**. On the **Time** tab, set **Time Span**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### TimeSpanOverrunAction — Wrap or scroll when TimeSpan is overrun

`'Wrap'` (default) | `'Scroll'`

Specify how the scope displays new data beyond the visible time span.

- **Wrap** — In this mode, the scope displays new data until the data reaches the maximum time-axis limit. When the data reaches the maximum time-axis limit of the scope window, the scope clears the display. The scope then updates the time offset value and begins displaying subsequent data points starting from the minimum time-axis limit.
- **Scroll** — In this mode, the scope scrolls old data to the left to make room for new data on the right side of the scope display. This mode is graphically intensive and can affect run-time performance. However, it is beneficial for debugging and monitoring time-varying signals.

**Tunable:** Yes

### UI Use

Open the **Configuration Properties**. On the **Time** tab, set **Time Span overrun action**.

### TimeSpanSource — Source of time span

`'Property'` (default) | `'Auto'`

Specify the source of the time span for frame-based input signals as:

- `'Property'` - The object derives the x-axis limits from the `TimeDisplayOffset` and `TimeSpan` properties.
- `'Auto'` - The time-axis limits are derived from the `TimeDisplayOffset` and `SampleRate` properties and the `FrameSize` (number of rows in each input signal). The limits are calculated as:

- Minimum time-axis limit = `min(TimeDisplayOffset)`
- Maximum time-axis limit = `max(TimeDisplayOffset) + max(1/SampleRate.*FrameSize)`

**Tunable:** Yes

### Dependencies

To use this property, set `FrameBasedProcessing` to `true`.

### UI Use

Open the **Configuration Properties**. On the **Time** tab, set **Time Span**.

### AxesScaling — Axes scaling mode

'OnceAtStop' (default) | 'Auto' | 'Manual' | 'Updates'

Specify when the scope scales the axes. Valid values are:

- 'Auto' — The scope scales the axes as needed to fit the data, both during and after simulation.
- 'Manual' — The scope does not scale the axes automatically.
- 'OnceAtStop' — The scope scales the axes when the simulation stops.
- 'Updates' — The scope scales the axes once and only once after 10 updates.

### UI Use

Select **Tools > Axes Scaling**.

## Advanced

### Name — Window name

'Time Scope' (default) | character vector | string

Specify the name of the scope as a character vector or string. This name appears as the title of the scope's figure window. To specify a title of a scope plot, use the `Title` property.

**Tunable:** Yes

Data Types: `char` | `string`

### Position — Window position

screen center (default) | [`left bottom width height`]

Scope window position in pixels, specified by the size and location of the scope window as a 4-element vector of the form `[left bottom width height]`. You can place the scope window in a specific position on your screen by modifying the values to this property.

By default, the window appears in the center of your screen with a width of 410 pixels and height of 300 pixels. The exact position value depends on your screen resolution.

**Tunable:** Yes

### **ReduceUpdates — Reduce updates to improve performance**

`true` (default) | `false`

- `true` — The scope logs data for later use and updates the window periodically.
- `false` — The scope updates every time the scope is called.

The simulation speed is faster when this property is set to `true`.

**Tunable:** Yes

#### **UI Use**

Select **Simulation > Reduce Updates to Improve Performance**.

### **LayoutDimensions — Display layout grid dimensions**

`[1,1]` (default) | `[numberOfRows, numberOfColumns]`

Specify the layout grid dimensions as a 2-element vector: `[numberOfRows, numberOfColumns]`. You can use up to 16 rows and 16 columns.

Example: `scope.LayoutDimensions = [2,4]`

**Tunable:** Yes

#### **UI Use**

Select **View > Layout**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **PlotType — Control the type of plot**

`'Line'` (default) | `'Stairs'`

Specify the type of plot to use.

- **Line** — Line graph, similar to the `line` or `plot` function.
- **Stairs** — Stair-step graph, similar to the `stairs` function. Stair-step graphs are useful for drawing time history graphs of digitally sampled data.

**Tunable:** Yes

### UI Use

Open the **Style** properties. Set **Plot type**.

### BufferLength — Length of buffer used for each input signal

5000 (default) | scalar

Specify the size of the buffer that the scope holds in its memory cache. Memory is limited by available memory on your system. If your signal has  $M$  rows of data and  $N$  data points in each row,  $M \times N$  is the number of data points per time step. Multiply this result by the number of time steps for your model to obtain the required buffer length. For example, if you have 10 rows of data with each row having 100 data points and your run will be 10 time steps, you should enter 10,000 ( $10 \times 100 \times 10$ ) as the buffer length.

### UI Use

Open the **Data History Properties**. Set **Buffer length**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### FrameBasedProcessing — Process input in frames

true (default) | false

- `true` — Enable frame-based processing.
- `false` — Enable sample-based processing.

### UI Use

Open the **Configuration Properties**. On the **Main** tab, set **Input processing**.

### TimeUnits — Units of time axis

'Metric' (default) | 'Seconds' | 'None'

Specify the units used to describe the time axis. You can select one of the following options:

- **Metric** — In this mode, the scope converts the times on the time axis to the most appropriate measurement units. These units include milliseconds, microseconds, nanoseconds, minutes, days, etc. The scope chooses the appropriate measurement units based on the minimum time-axis limit and the maximum time-axis limit of the scope window.
- **Seconds** — In this mode, the scope always displays the units on the time axis as seconds.
- **None** — In this mode, the scope does not display any units on the time axis. The scope only shows the word **Time** on the time axis.

**Tunable:** Yes

#### **UI Use**

Open the **Configuration Properties**. On the **Time** tab, set **Time units**.

#### **TimeDisplayOffset — Offset x-axis limits**

0 (default) | scalar | vector

Specify, in seconds, how far to move the data on x-axis. The signal value does not change, only the displayed x-axis.

If you specify this property as a scalar, then that value is the time display offset for all channels.

If you specify a vector, each vector element is the time offset for the corresponding channel. For vectors with length less than the number of input channels, the time display offsets for the remaining channels are set to 0. If a vector has a length greater than the number of input channels, the extra vector elements are ignored.

**Tunable:** Yes

#### **UI Use**

Open the **Configuration Properties**. On the **Time** tab, set **Time display offset**.

#### **TimeAxisLabels — Time-axis labels**

'All' (default) | 'Bottom' | 'None'

Specify how time-axis labels should appear in the scope displays as:

- **'All'** — Time-axis labels appear in all displays.

- 'Bottom' — Time-axis labels appear in the bottom display of each column.
- 'None' — No labels appear in any display.

**Tunable:** Yes

### UI Use

Open the **Configuration Properties**. On the **Time** tab, set **Time-axis labels**.

### MaximizeAxes — Maximize axes control

'Auto' (default) | 'On' | 'Off'

Specify whether to display the scope in maximized-axes mode. In this mode, the axes are expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- 'Auto' — The axes appear maximized in all displays only if the Title and YLabel properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- 'On' — The axes appear maximized in all displays. Any values entered into the Title and YLabel properties are hidden.
- 'Off' — None of the axes appear maximized.

**Tunable:** Yes

### UI Use

Open the **Configuration Properties**. On the **Main** tab, set **Maximize axes**.

## Display

### ActiveDisplay — Active display for setting properties

1 (default) | integer

Specify the active display, by integer display number, to get and set relevant properties. The number of a display corresponds to its column-wise placement index. Set this property to control which display has its axes colors, line properties, marker properties, and visibility changed.

**Tunable:** Yes

**UI Use**

Open the **Configuration Properties**. On the **Display** tab, set **Active Display**.

**Title — Display title**

' ' (default) | character vector | string

Specify the display title as a character vector or string. To use the input name as the display title, enter '%<SignalLabel>'.

**Tunable:** Yes

**UI Use**

Open the **Configuration Properties**. On the **Display** tab, set **Title**.

**ShowLegend — Show legend**

false (default) | true

To show a legend with the input names, set this property to `true`.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** dialog box. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name. To show all signals, press **Esc**.

**Tunable:** Yes

**UI Use**

Open the **Configuration Properties**. On the **Display** tab, select **Show legend**.

**ShowTimeAxisLabel — Show legend on display**

true (default) | false

When you set this property to `true`, the scope displays the time-axis label. When you set this property to `false`, the scope does not display the time-axis label, but still displays tick marks and other time-axis items. This property applies only if the `TimeAxisLabels` property is `All` or `Bottom`.

**Tunable:** Yes

**Dependency**

To control which display's axis is labeled, use the `ActiveDisplay` property.

### UI Use

Open the **Configuration Properties**. On the **Time** tab, set **Show time-axis label**.

### ChannelNames — Channel names

empty cell (default) | cell array of character vectors

Specify the input channel names as a cell array of character vectors. The names appear in the legend, **Style** dialog box, and **Measurements** panels. If you do not specify names, the channels are labeled as Channel 1, Channel 2, etc.

**Tunable:** Yes

### Dependency

To see channel names, set ShowLegend to true.

### UI Use

On the legend, double-click the channel name.

### ShowGrid — Grid visibility

false (default) | true

Set this property to true to show gridlines on the plot.

**Tunable:** Yes

### UI Use

Open the **Configuration Properties**. On the **Display** tab, set **Show grid**.

### PlotAsMagnitudePhase — Plot signal as magnitude and phase

false (default) | true

When you set this property to true, the scope plots the magnitude and phase of the input signal on two separate axes within the same active display. When you set this property to false, the scope plots the real and imaginary parts of the input signal on two separate axes within the same active display.

This property is useful for complex-valued input signals. Turning on this property affects the phase for real-valued input signals. When the amplitude of the input signal is nonnegative, the phase is 0 degrees. When the amplitude of the input signal is negative, the phase is 180 degrees.

**Tunable:** Yes

#### UI Use

Open the **Configuration Properties**. On the **Display** tab, select **Plot signals as magnitude and phase**.

#### YLimits — y-axis limits

`[-10,10]` (default) | `[ymin, ymax]`

Specify the y-axis limits as a two-element numeric vector, `[ymin, ymax]`.

If `PlotAsMagnitudePhase` is `false`, the default is `[-10,10]`. If `PlotAsMagnitudePhase` is `true`, the default is `[0,10]`.

**Tunable:** Yes

#### Dependencies

When `PlotAsMagnitudePhase` is `true`, this property specifies the y-axis limits of only the magnitude plot. The y-axis limits of the phase plot are always `[-180,180]`.

#### UI Use

Open the **Configuration Properties**. On the **Display** tab, set **Y-limits (Minimum)** and **Y-limits (Maximum)**.

#### YLabel — y-axis label

`'Amplitude'` (default) | character vector | string

Specify the text for the scope to display to the left of the y-axis.

**Tunable:** Yes

#### Dependencies

This property applies only when `PlotAsMagnitudePhase` is `false`. When `PlotAsMagnitudePhase` is `true`, the two y-axis labels are read-only values. The y-axis labels are set to `'Magnitude'` and `'Phase'` for the magnitude plot and the phase plot, respectively.

#### UI Use

Open the **Configuration Properties**. On the **Display** tab, set **Y-Label**.

Data Types: char | string

## Usage

**Note** For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Syntax

```
scope(signal)
scope(signal,signal2,...,signalN)
```

## Description

`scope(signal)` displays the signal, `signal`, in the time scope display.

`scope(signal,signal2,...,signalN)` displays the signals `signal`, `signal2`,...,`signalN` in the time scope display when you set the `NumInputPorts` property to `N`. In this case, `signal1`, `signal2`,...,`signalN` can have different data types and dimensions.

## Input Arguments

### **signal** — Input signal or signals to visualize

scalar | vector | matrix

Specify one or more input signals to visualize in the `dsp.TimeScope`. Signals can have different data types and dimensions.

Example: `scope(signal1,signal2)`

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | string | struct | table | cell | categorical | datetime | fi

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to Scopes

`show`      Display scope window  
`hide`      Hide scope window  
`isVisible` Determine visibility of scope

### Common to All System Objects

`step`      Run System object algorithm  
`release`   Release resources and allow changes to System object property values and input characteristics  
`reset`     Reset internal states of System object

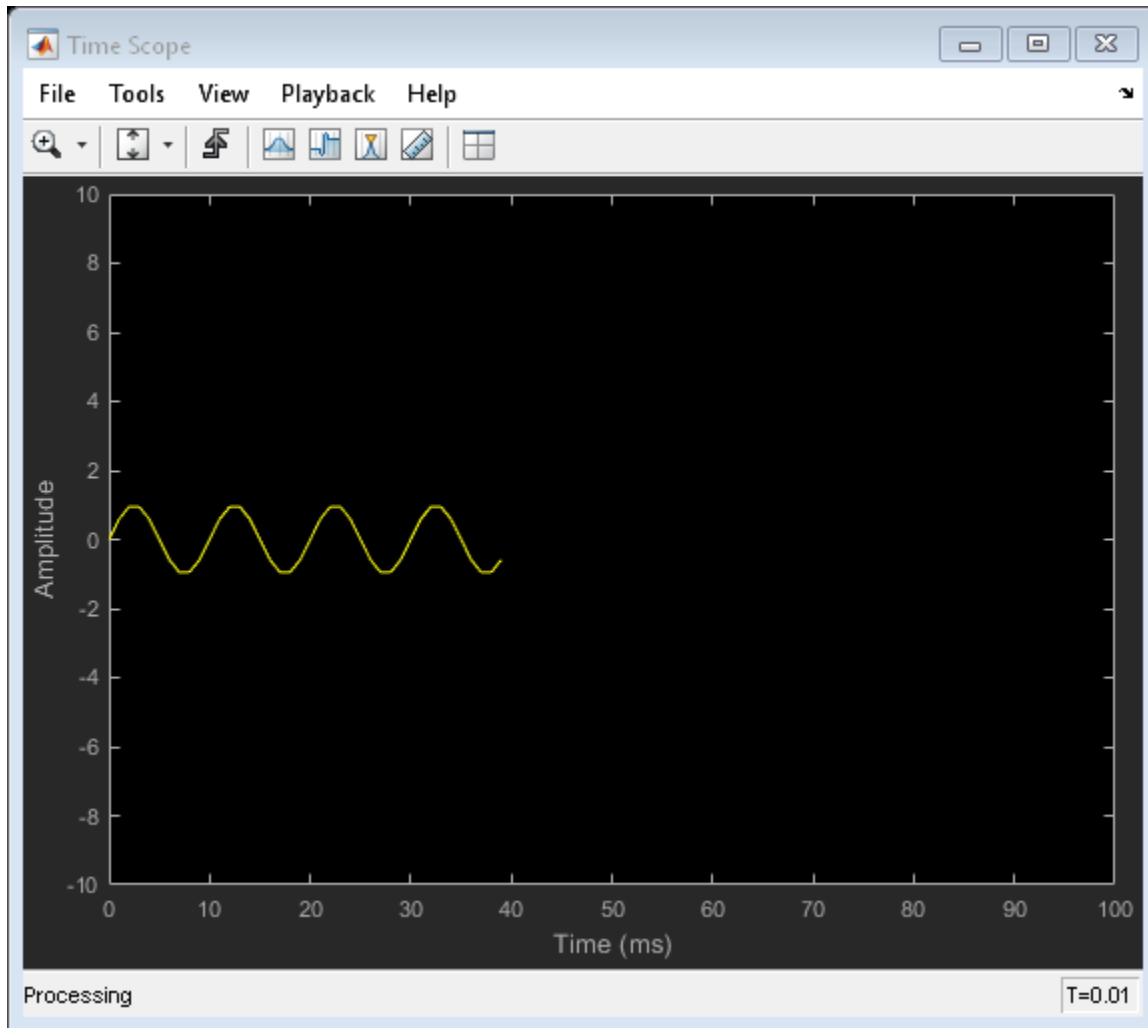

If you want to restart the simulation from the beginning, call `reset` to clear the scope window displays. Do not call `reset` after calling `release`.

## Examples

### Display Simple Sine Wave Input Signal

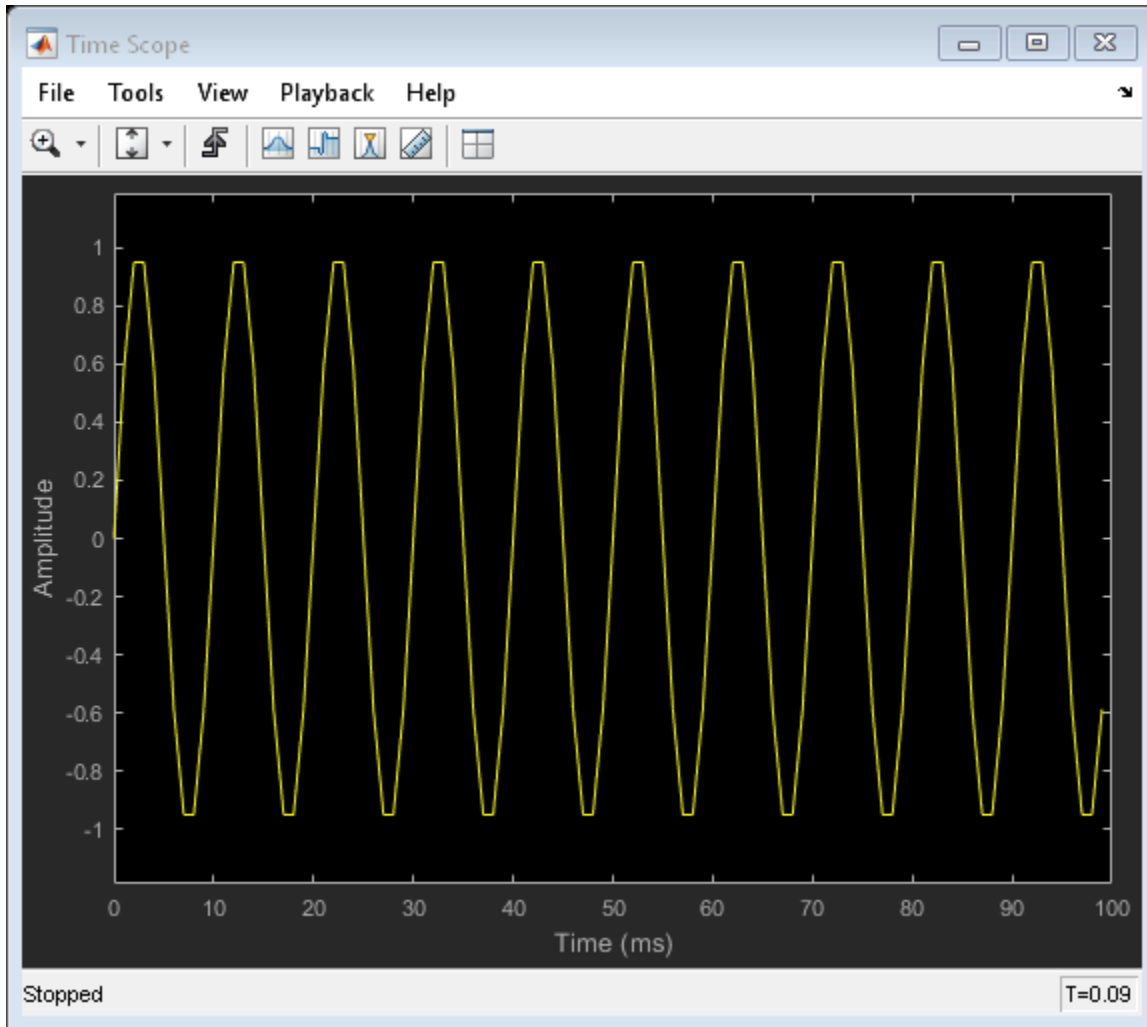

Create `dsp.SineWave` and `dsp.TimeScope` objects. Run the scope to display the signal

```
sine = dsp.SineWave('Frequency',100,'SampleRate',1000);  
sine.SamplesPerFrame = 10;  
scope = dsp.TimeScope('SampleRate',sine.SampleRate,'TimeSpan',0.1);  
for ii = 1:10  
    x = sine();  
    scope(x);  
end
```

Run the `release` method to allow changes to property values and input characteristics. The scope automatically scales the axes.

```
release(scope)
```

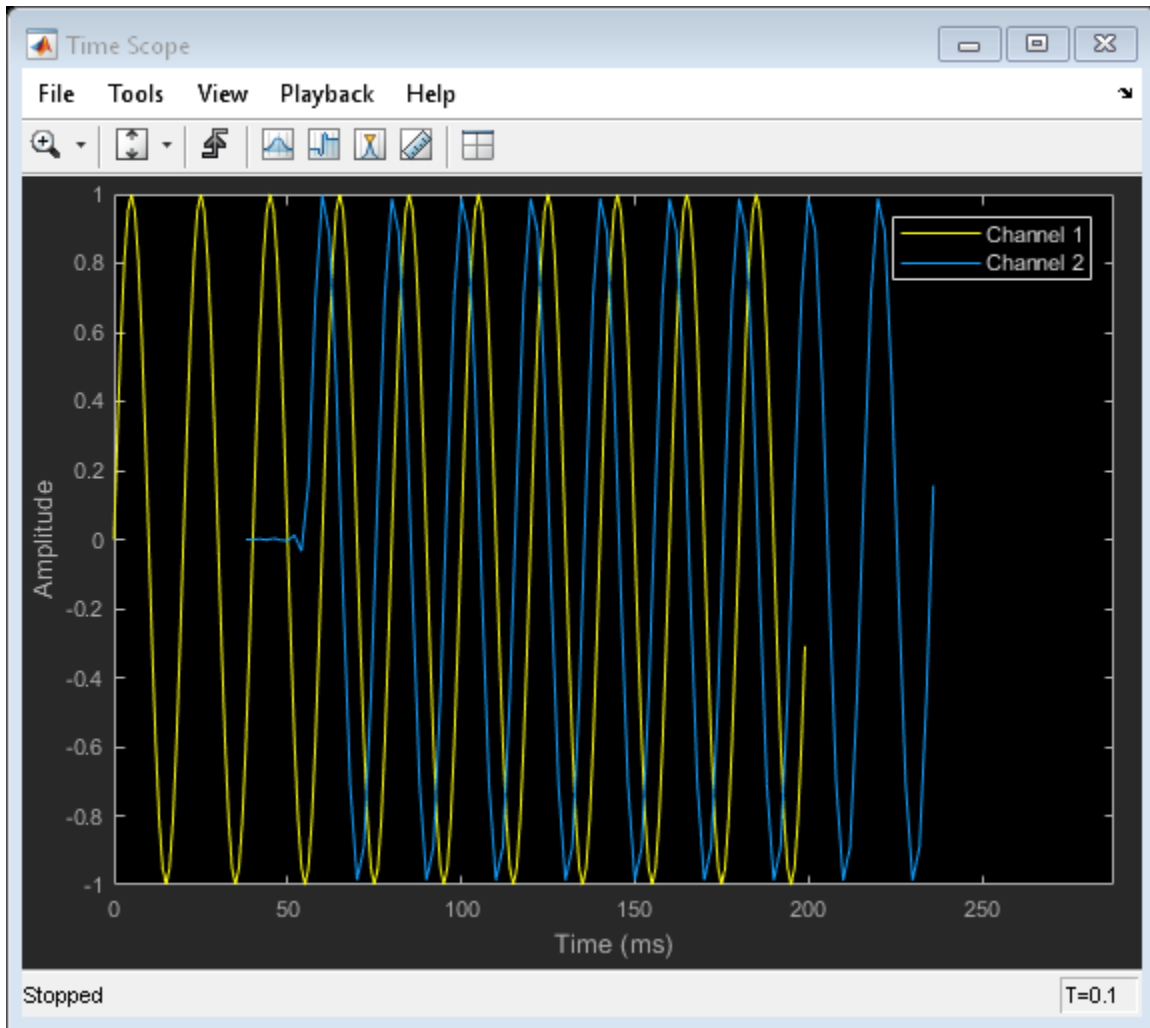

### View Sine Wave Input Signals at Different Sample Rates and Offsets

Create a `dsp.SineWave` with a 1000 Hz sampling frequency. Create a `dsp.FIRDecimator` object to decimate the sine wave by 2. Create a `dsp.TimeScope` object with two input ports.

```
Fs = 1000; % Sampling frequency
sine = dsp.SineWave('Frequency',50,...
    'SampleRate',Fs, ...
    'SamplesPerFrame',100);
decimate = dsp.FIRDecimator; % To decimate sine by 2
scope = dsp.TimeScope(2,[Fs Fs/2], ...
    'TimeDisplayOffset',[0 38/Fs], ...
    'TimeSpan',0.25, ...
    'YLimits',[-1 1], ...
    'ShowLegend', true);
```

Call the `dsp.SineWave` object to create a sine wave signal. Use the `dsp.FIRDecimator` object to create a second signal that equals the original signal, but decimated by a factor of 2. Display the signals by calling the `dsp.TimeScope` object.

```
for ii = 1:2
    xsine = sine();
    xdec = decimate(xsine);
    scope(xsine,xdec)
end
release(scope)
```

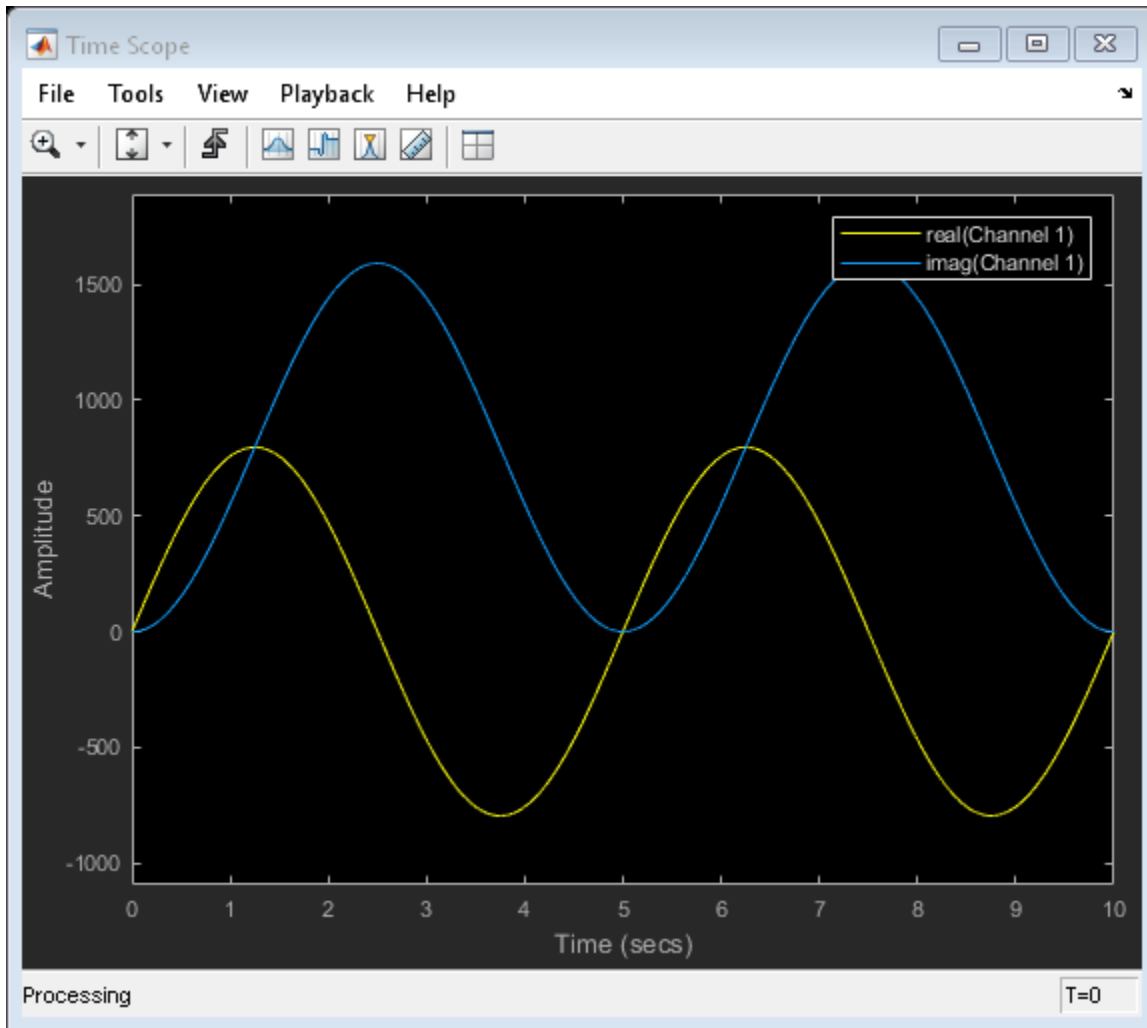

Close the Time Scope window and clear the variables.

```
clear scope Fs sine decimate ii xsine xdec
```

### Display Complex-Valued Input Signal

Create a vector representing a complex-valued sinusoidal signal, and create a `dsp.TimeScope` object. Call the scope to display the signal.

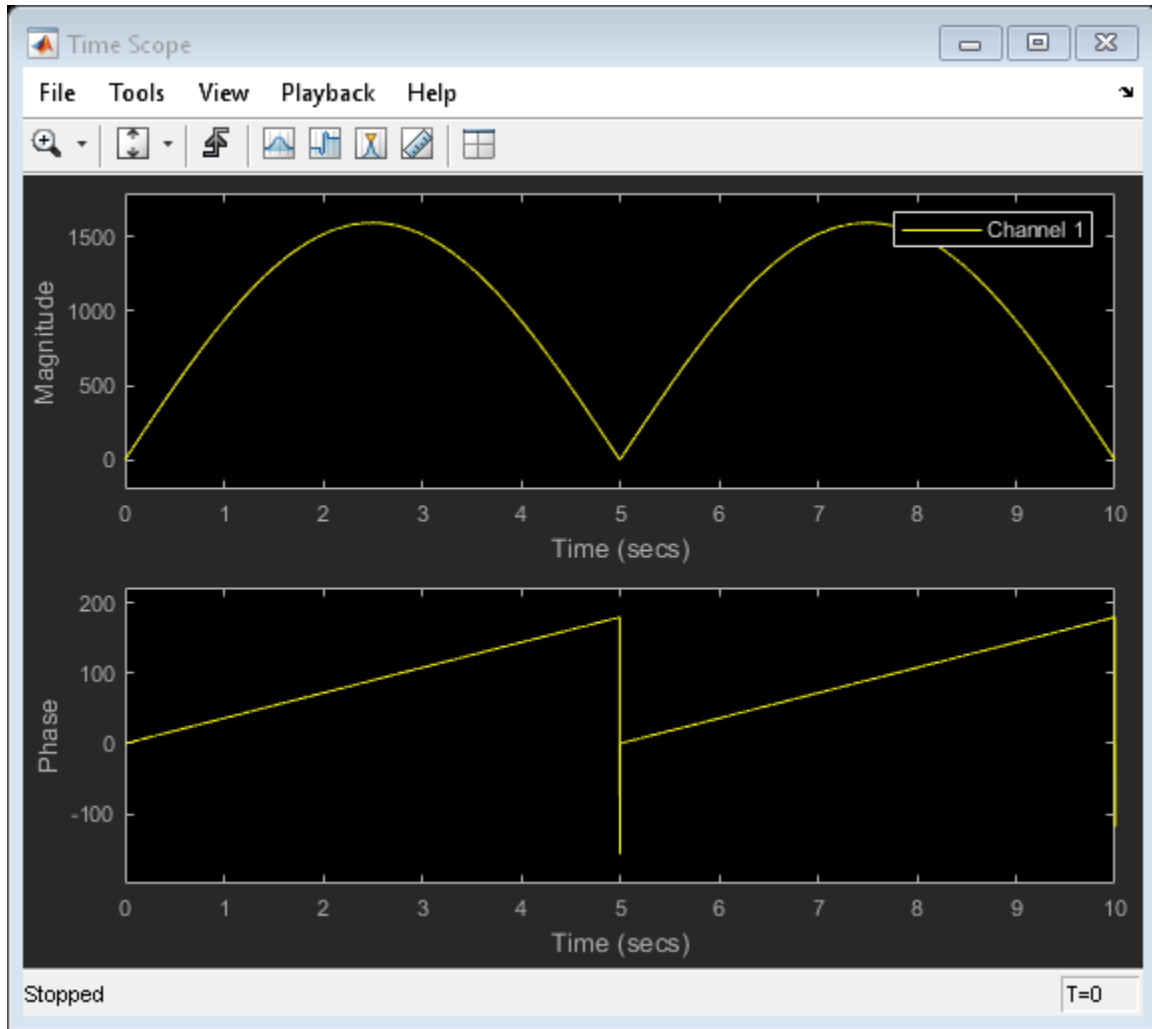

```
fs = 1000;  
t = (0:1/fs:10)';  
CxSine = cos(2*pi*0.2*t) + 1i*sin(2*pi*0.2*t);  
CxSineSum = cumsum(CxSine);  
scope = dsp.TimeScope(1,fs, 'TimeSpanSource', 'Auto', 'ShowLegend', 1);  
scope(CxSineSum);  
scope.AxesScaling = 'Auto';
```

By default, when the input is a complex-valued signal, Time Scope plots the real and imaginary portions on the same axes. These real and imaginary portions appear as different-colored lines on the same axes within the same active display.

Change the `PlotAsMagnitudePhase` property to `true` and call `release`.

```
scope.PlotAsMagnitudePhase = true;  
release(scope)
```

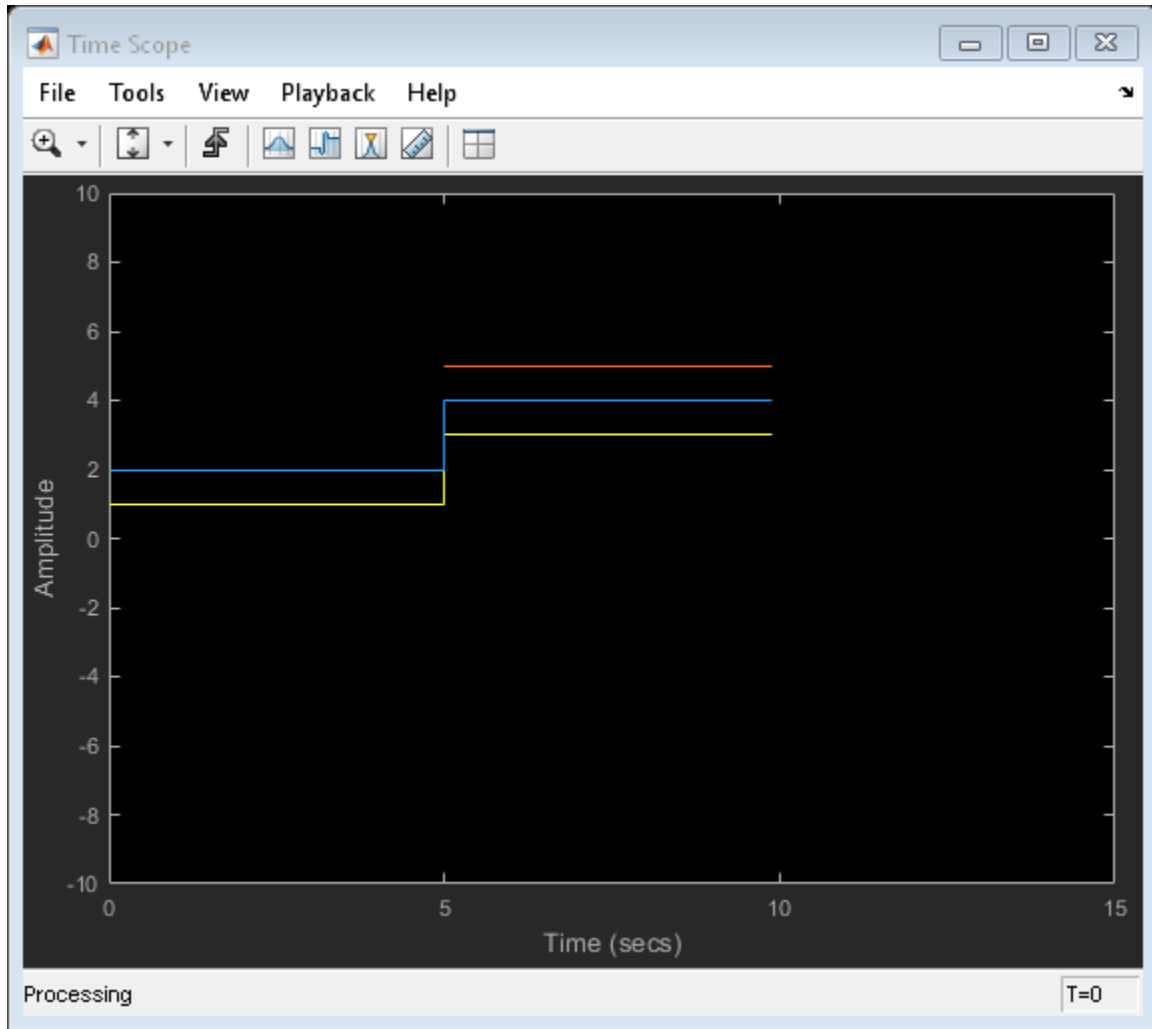

Time Scope now plots the magnitude and phase of the input signal on two separate axes within the same active display. The top axes display magnitude and the bottom axes display the phase, in degrees.

## Display Input Signal of Changing Size

Create a vector that represents a two-channel constant signal. Create another vector that represents a three-channel constant signal. Create a `dsp.TimeScope` object with two input ports. Call the scope to display the signal.

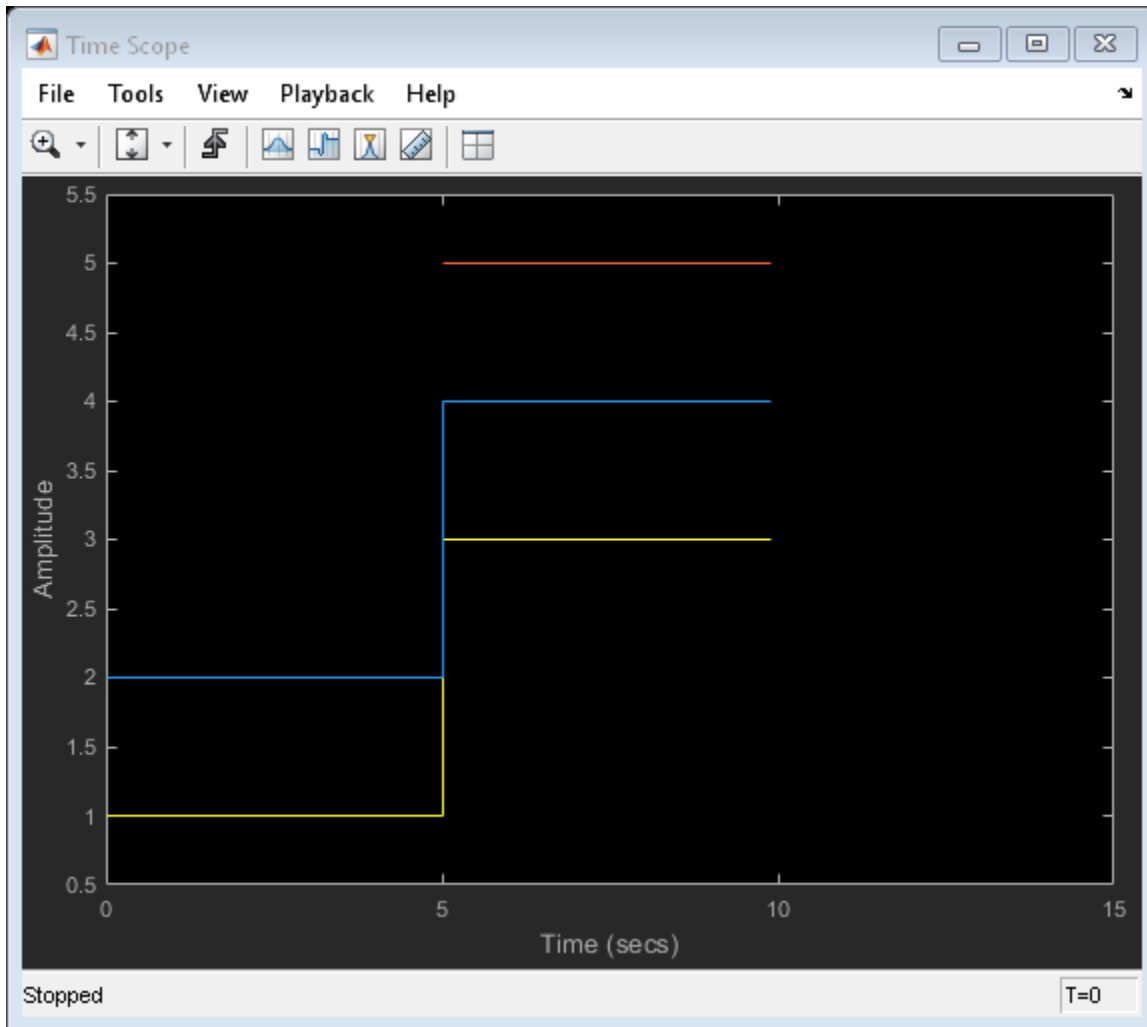

```
fs = 10;
sigdim2 = [ones(5*fs,1) 1+ones(5*fs,1)];           % 2-dim 0-5 s
sigdim3 = [2+ones(5*fs,1) 3+ones(5*fs,1) 4+ones(5*fs,1)]; % 3-dim 5-10 s
scope = dsp.TimeScope(2,fs,'TimeSpanSource','Property');
scope.PlotType = 'Stairs';
scope.TimeSpanOverrunAction = 'Scroll';
scope.TimeDisplayOffset = [0 0 5];
scope([sigdim2; sigdim3(:,1:2)], sigdim3(:,3));
```

In this example, the size of the input signal to the Time Scope block changes as the simulation progresses. When the simulation time is less than 5 seconds, Time Scope plots only the two-channel signal, `sigdim2`. After 5 seconds, Time Scope also plots the three-channel signal, `sigdim3`.

Run the `release` method to enable changes to property values and input characteristics. The scope automatically scales the axes.

```
release(scope)
```

Close the Time Scope window and remove the variables you created from the workspace.

```
clear scope fs sigdim2 sigdim3
```

### Use Bilevel Measurements Panel with Clock Input Signal

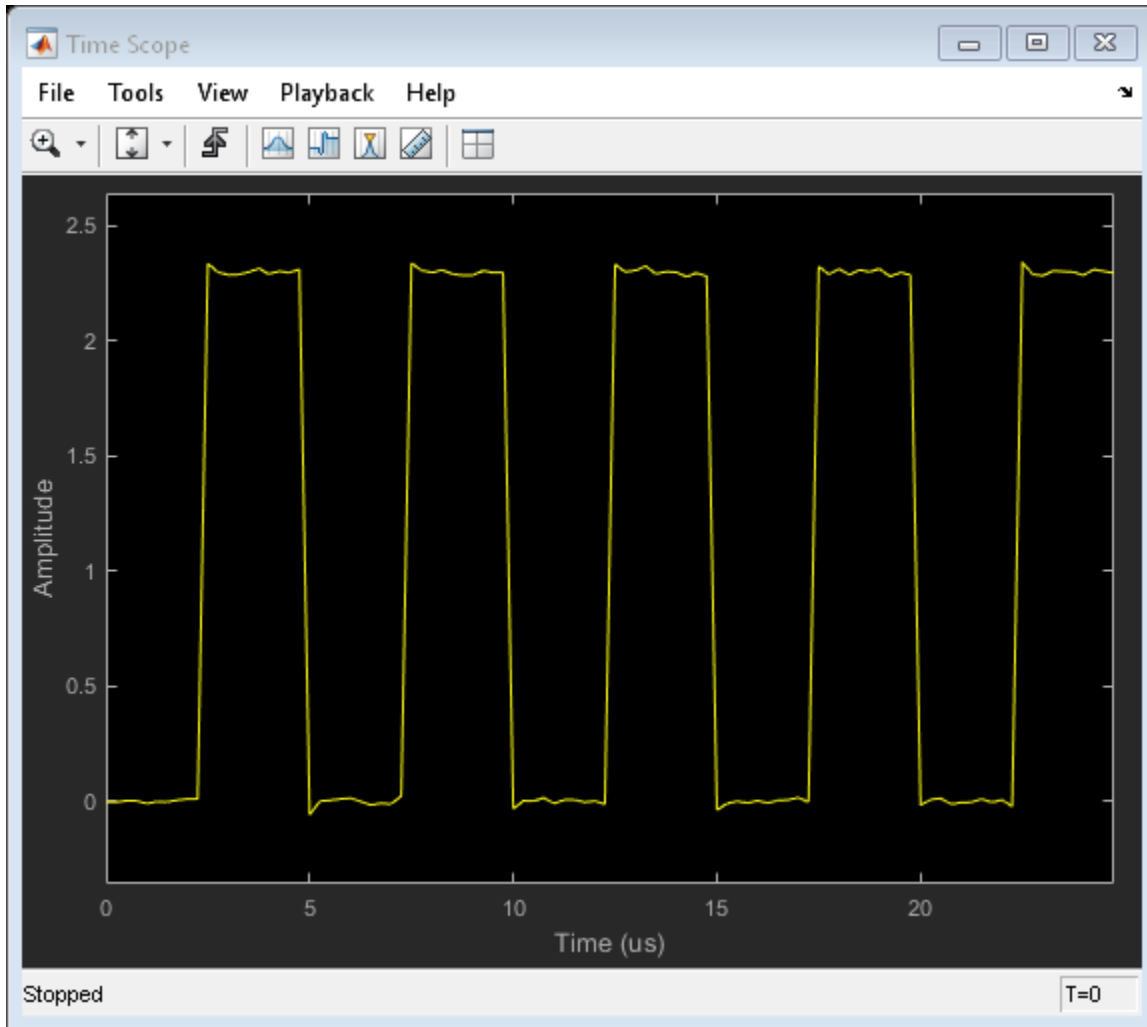

#### Create and Display Clock Input Signal

Load the clock data, `x` and `t`. Find the sample time, `ts`.

```
load clockex  
ts = t(2)-t(1);
```

Create a `dsp.TimeScope` object and call the object to display the signal. To autoscale the axes and enable changes to property values and input characteristics, call `release`.

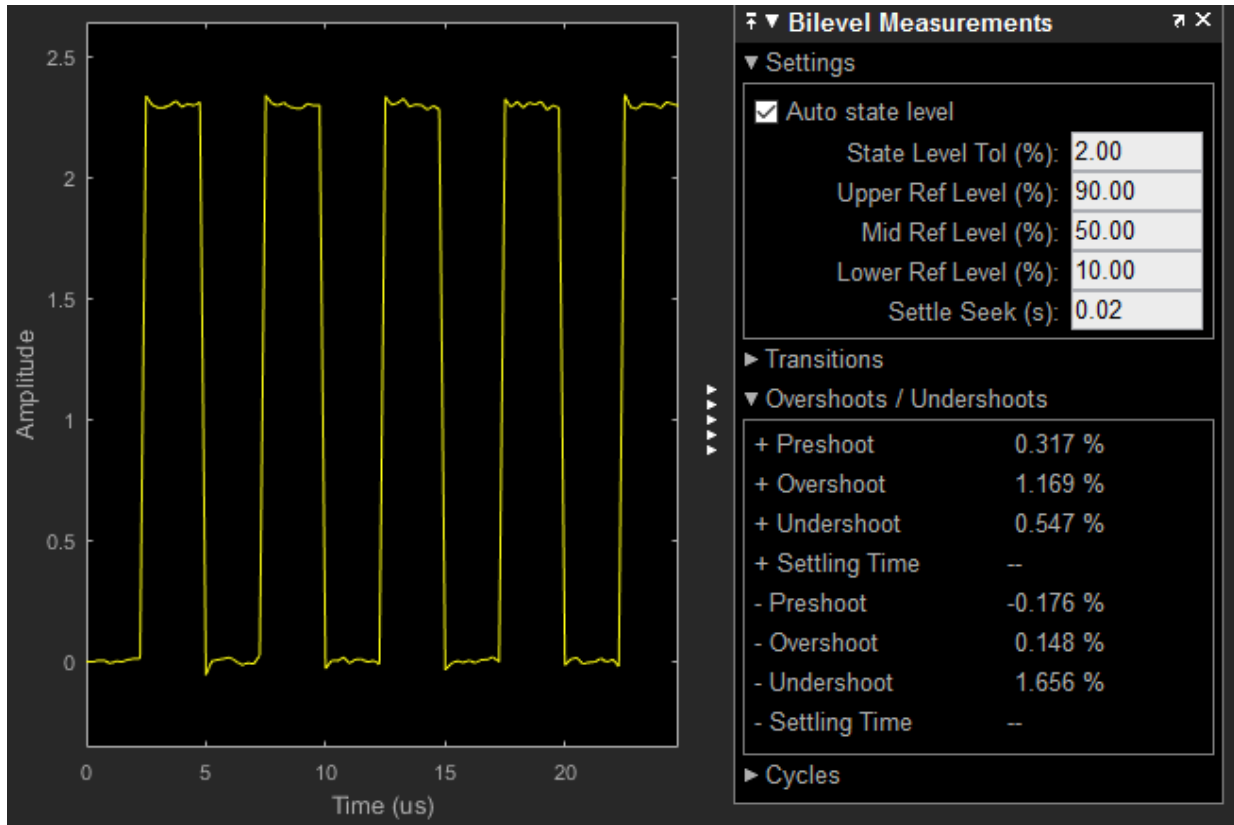

```
scope = dsp.TimeScope(1,1/ts, 'TimeSpanSource', 'Auto');  
scope(x);  
release(scope)
```

### Use Bilevel Measurements Panel to Find Settling Time

1. From the Time Scope menu, select **Tools > Measurements > Bilevel Measurements**.
2. Expand the **Settings** pane and the **Overshoots / Undershoots** pane.

Initially, the Time Scope does not display the rising edge **Settling Time** parameter. This absence occurs because the default value of the **Settle Seek** parameter is longer than the entire simulation duration.

3. In the **Settle Seek** box, enter  $2e-6$  and press **Enter**.

Time Scope now displays a rising edge **Settling Time** value of 118.392 ns.

This settling time value is actually the statistical average of the settling times for all five rising edges. To show the settling time for only one rising edge, you can zoom in on that transition.

4. In the Time Scope toolbar, click the arrow next to the Zoom button, and then click the Zoom X button.

5. Click the display near a value of 2 microseconds on the time axis.

6. Drag your cursor right and release it near a value of 4 microseconds on the time axis.

Time Scope updates the rising edge **Settling Time** value to reflect the new time window.

7. Close the Time Scope and remove the variables you created from the workspace.

```
clear scope x t ts
```

### Find Heart Rate Using Peak Finder Panel with ECG Input Signal

Use Peak Finder panel of the Time Scope to measure a heart rate.

### Create and Display ECG Signal

Create the electrocardiogram (ECG) signal. The custom `ecg` function helps generate the heartbeat signal.

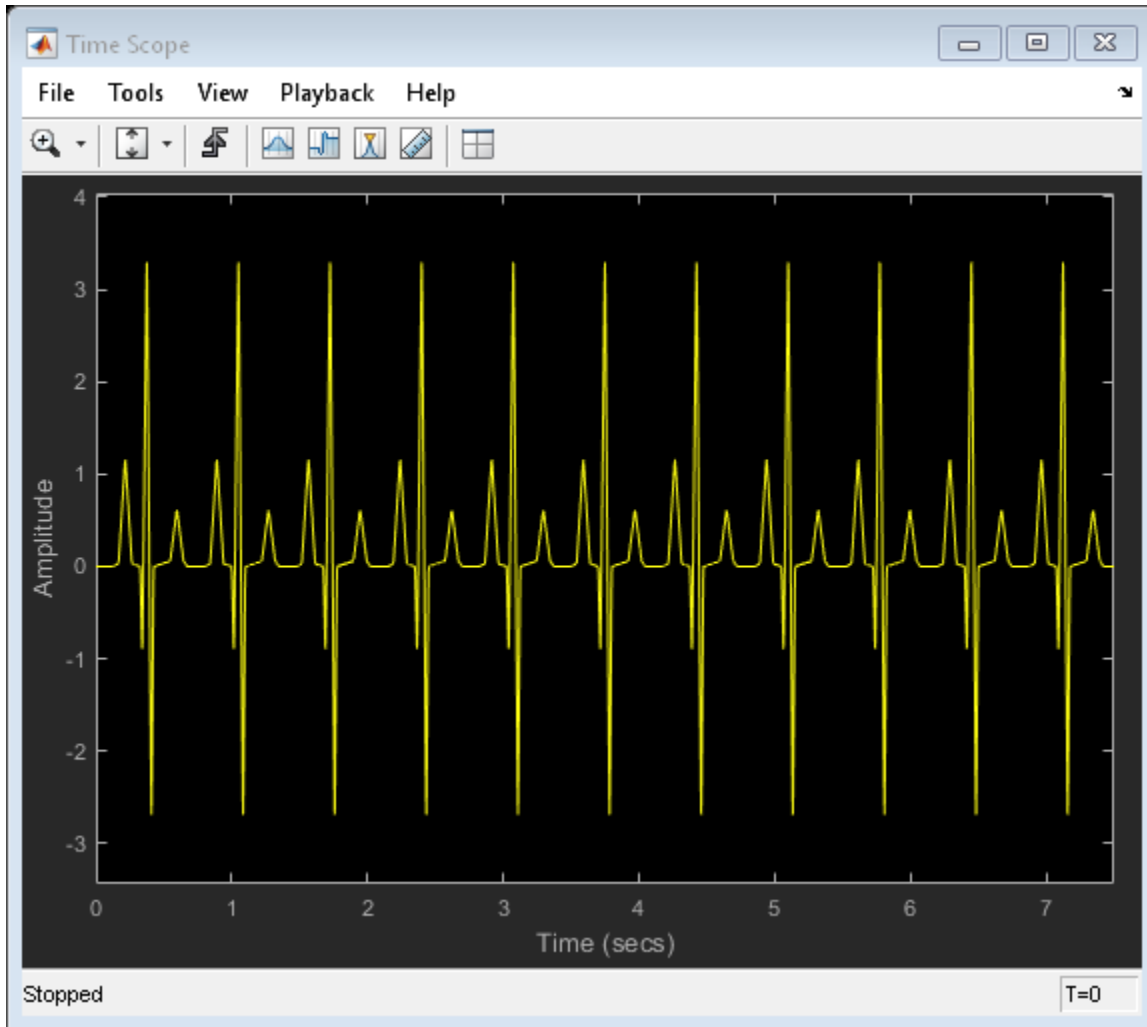

```
function x = ecg(L)
a0 = [0, 1, 40, 1, 0, -34, 118, -99, 0, 2, 21, 2, 0, 0, 0];
d0 = [0, 27, 59, 91, 131, 141, 163, 185, 195, 275, 307, 339, 357, 390, 440];
a = a0 / max(a0);
d = round(d0 * L / d0(15));
d(15) = L;
for i = 1:14
    m = d(i) : d(i+1) - 1;
    slope = (a(i+1) - a(i)) / (d(i+1) - d(i));
    x(m+1) = a(i) + slope * (m - d(i));
end
```

```
x1 = 3.5*ecg(2700).';
y1 = sgolayfilt(kron(ones(1,13),x1),0,21);
n = (1:30000)';
del = round(2700*rand(1));
mhb = y1(n + del);
ts = 0.00025;
```

Create a `dsp.TimeScope` object and call the object to display the signal. To autoscale the axes and enable changes to property values and input characteristics, call `release`.

```
scope = dsp.TimeScope(1,1/ts,'TimeSpanSource','Auto');
scope(mhb);
release(scope)
```

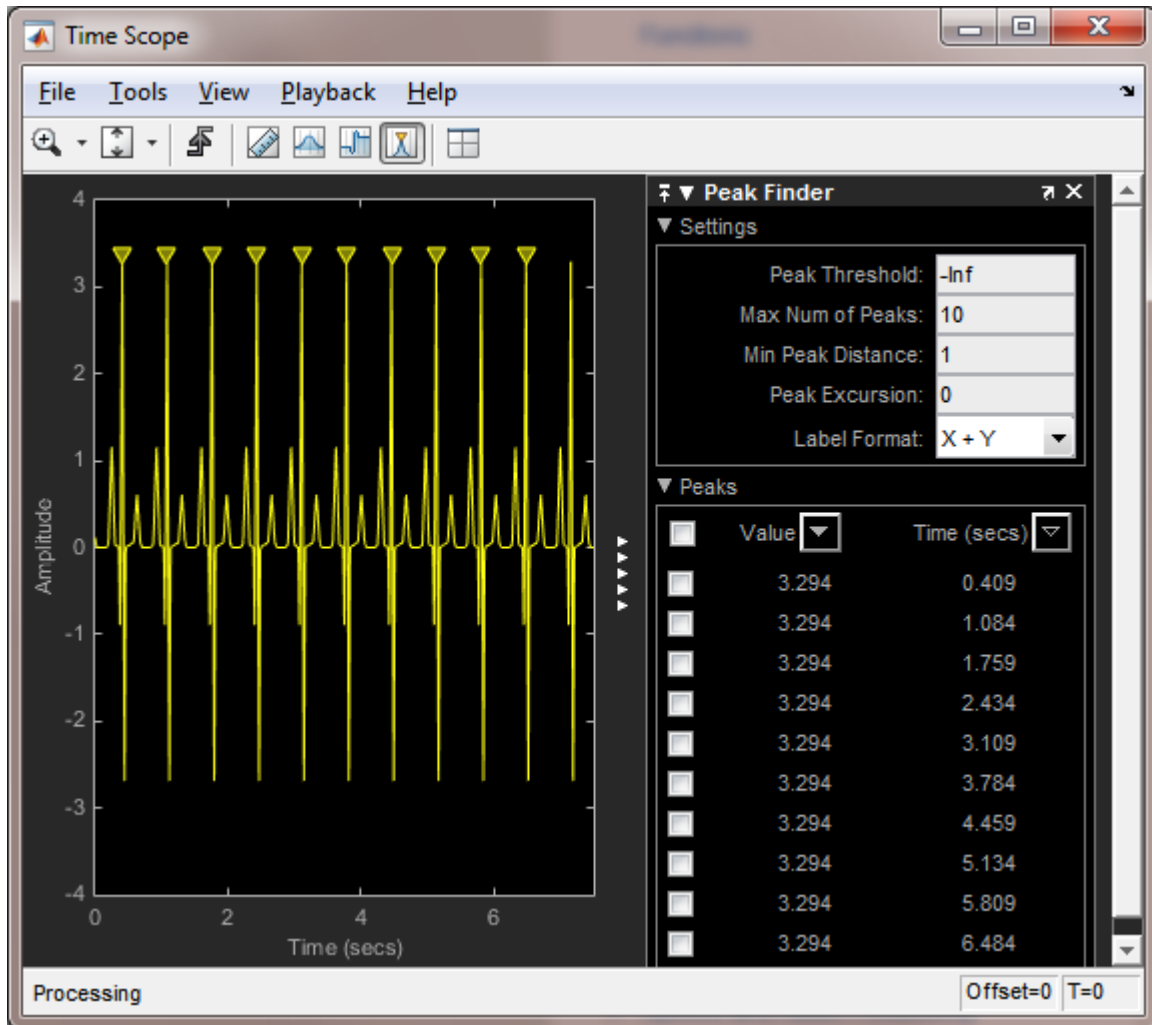

### Find Heart Rate

Use the Peak Finder measurements to measure the time between heart beats.

- 1 In the Time Scope menu, select **Tools > Measurements > Peak Finder**.
- 2 Expand the **Settings** pane.

3 In the **Max Num of Peaks** property, enter 10 and press **Enter**.

In the **Peaks** pane, Time Scope displays a list of ten peak amplitude values and the times at which they occur.

The list of peak values shows a constant time difference of 0.675 second between each heartbeat. Based on the following equation, the heart rate of this ECG signal is about 89 beats per minute.

$$\frac{60 \text{ s/min}}{0.675 \text{ s/beat}} = 88.89 \text{ bpm}$$

Close the Time Scope window and remove the variables you created from the workspace.

```
clear scope x1 y1 n del mhb ts
```

## Tips

- To close the scope window and clear its associated data, use the MATLAB `clear` function.
- To hide or show the scope window, use the `hide` and `show` functions.
- Use the MATLAB `mcc` function to compile code containing a scope.

You cannot open scope configuration dialogs if you have more than one compiled component in your application.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supports MEX code generation by treating the calls to the object as extrinsic. Does not support code generation for standalone applications.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

# dsp.TransferFunctionEstimator System object

**Package:** dsp

Estimate transfer function

## Description

The `dsp.TransferFunctionEstimator` computes the transfer function of a system, using the Welch algorithm and the Periodogram method.

To implement the transfer function estimation object:

- 1 Define and set up your transfer function estimator object. See “Construction” on page 4-1725.
- 2 Call `step` to implement the estimator according to the properties of `dsp.TransferFunctionEstimator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`tfe = dsp.TransferFunctionEstimator` returns a System object, `tfe`, that computes the transfer function of real or complex signals. This System object uses the periodogram method and Welch’s averaged, modified periodogram method.

`tfe = dsp.TransferFunctionEstimator('PropertyName', PropertyValue, ...)` returns a Transfer Function Estimator System object, `tfe`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

# Properties

## SpectralAverages

Number of spectral averages

Specify the number of spectral averages as a positive, integer scalar. The Transfer Function Estimator computes the current estimate by averaging the last *N* estimates. *N* is the number of spectral averages defined in the `SpectralAverages` property. The default value is 8.

## FFTLengthSource

Source of the FFT length value

Specify the source of the FFT length value as one of 'Auto' | 'Property'. The default value is 'Auto'. If you set this property to 'Auto', the Transfer function Estimator sets the FFT length to the input frame size. If you set this property to 'Property', then you specify the number of FFT points using the `FFTLength` property.

## FFTLength

FFT Length

Specify the length of the FFT that the Transfer Function Estimator uses to compute spectral estimates as a positive, integer scalar. This property applies when you set the `FFTLengthSource` property to 'Property'. The default value is 128.

## Window

Window function

Specify a window function for the Transfer Function estimator as one of 'Rectangular' | 'Chebyshev' | 'Flat Top' | 'Hamming' | 'Hann' | 'Kaiser'. The default value is 'Hann'.

## SideLobeAttenuation

Side lobe attenuation of window

Specify the side lobe attenuation of the window as a real, positive scalar, in decibels (dB). This property applies when you set the `Window` property to 'Chebyshev' or 'Kaiser'. The default value is 60 dB.

## FrequencyRange

Frequency range of the transfer function estimate

Specify the frequency range of the transfer function estimator as one of `'twosided'` | `'onesided'` | `'centered'`.

If you set the `FrequencyRange` to `'onesided'`, the transfer function estimator computes the onesided transfer function of real input signals, `x` and `y`. If the FFT length, `NFFT`, is even, the length of the transfer function estimate is  $NFFT/2+1$  and is computed over the interval  $[0, SampleRate/2]$ . If `NFFT` is odd, the length of the transfer function estimate is equal to  $(NFFT+1)/2$  and the interval is  $[0, SampleRate/2]$ .

If `FrequencyRange` is set to `'twosided'`, the transfer function estimator computes the twosided transfer function of complex or real input signals, `x` and `y`. The length of the transfer function estimate is equal to `NFFT` and is computed over  $[0, SampleRate]$ .

If you set the `FrequencyRange` to `'centered'`, the transfer function estimator computes the centered twosided transfer function of complex or real input signals, `x` and `y`. The length of the transfer function estimate is equal to `NFFT` and it is computed over  $[-SampleRate/2, SampleRate/2]$  for even lengths, and  $[-SampleRate/2, SampleRate/2]$  for odd lengths. The default value is `'Twosided'`.

## OutputCoherence

Magnitude squared coherence estimate

Specify `true` to compute and output the magnitude squared coherence estimate using Welch's averaged, modified periodogram method. The magnitude squared coherence estimate has values between 0 and 1 that indicate the correspondence at each frequency between two input signals. If you specify `false`, the magnitude squared coherence estimate is not computed. The default value is `false`.

## Methods

getFrequencyVector	Get vector of frequencies at which transfer function is estimated
getRBW	Get resolution bandwidth of transfer function
reset	Reset internal states of transfer function estimator
step	Estimate transfer function of system

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Estimate transfer function of a system represented by an order-64 FIR filter

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Generate a sine wave. Use the `dsp.TransferFunctionEstimator` System object to estimate the system transfer function, and the `dsp.ArrayPlot` System object to display it.

```
sin = dsp.SineWave('Frequency',100, 'SampleRate', 1000);
sin.SamplesPerFrame = 1000;
tfe = dsp.TransferFunctionEstimator('FrequencyRange','centered');
aplot = dsp.ArrayPlot('PlotType','Line','XOffset',-500,'YLimits',...
    [-120 5],'YLabel','Frequency Response (dB)',...
    'XLabel','Frequency (Hz)',...
    'Title','System Transfer Function');
```

Create an FIR Filter System object of order 64 and (normalized) cutoff frequency of 1/4. Add random noise to the sine wave. Step through the System objects to obtain the data streams, and plot the log of the magnitude of the transfer function.

```
firFilt = dsp.FIRFilter('Numerator',fir1(64,1/4));
for ii = 1:100
x = sin() + 0.05*randn(1000,1);
y = firFilt(x);
Txy = tfe(x,y);
```

```
aplot(20*log10(abs(Txy)))  
end
```

## Algorithms

Given two signals  $x$  and  $y$  as inputs. We first window the two inputs, and scale them by the window power. We then take FFT of the signals, calling them  $X$  and  $Y$ . This is followed by calculating  $P_{xx}$  which is the square magnitude of the FFT,  $X$ , and  $P_{yx}$  which is  $X$  multiplied by the conjugate of  $Y$ . The transfer function estimate is calculated by dividing  $P_{yx}$  by  $P_{xx}$ .

For further information refer to the **Algorithms** section in Spectrum Analyzer, which uses the same algorithm.

The magnitude squared coherence,  $C_{xy}$ , is defined as

$$C_{xy} = \frac{(\text{abs}(P_{xy}))^2}{(P_{xx} * P_{yy})}$$

where,  $x$  and  $y$  are input signals.  $P_{xx}$  and  $P_{yy}$  are the power spectral density (PSD) estimates of  $x$  and  $y$ , respectively.  $P_{xy}$  is the cross power spectral density (CPSD) estimate of  $x$  and  $y$ .

## getFrequencyVector

**System object:** dsp.TransferFunctionEstimator

**Package:** dsp

Get vector of frequencies at which transfer function is estimated

### Syntax

```
getFrequencyVector(tfe)
```

### Description

`getFrequencyVector(tfe)` returns the vector of frequencies at which the transfer function is estimated.

If you set the `FrequencyRange` to 'onesided' and the FFT length, `NFFT`, is even, the frequency vector is of length  $NFFT/2+1$ , and covers the interval  $[0, \text{SampleRate}/2]$ . If you set the `FrequencyRange` to 'onesided' and `NFFT` is odd, the frequency vector is of length  $(NFFT+1)/2$  and covers the interval  $[0, \text{SampleRate}/2]$ . If you set the `FrequencyRange` to 'twosided', the frequency vector is of length `NFFT` and covers the interval  $[0, \text{SampleRate}]$ . If you set the `FrequencyRange` to 'centered', the frequency vector is of length `NFFT` and covers the range  $[-\text{SampleRate}/2, \text{SampleRate}/2]$  and  $[-\text{SampleRate}/2, \text{SampleRate}/2]$  for even and odd length `NFFT`, respectively.

## getRBW

**System object:** dsp.TransferFunctionEstimator

**Package:** dsp

Get resolution bandwidth of transfer function

## Syntax

getRBW(tfe)

## Description

getRBW(tfe) returns the resolution bandwidth of the transfer function.

The resolution bandwidth, RBW, is the smallest positive frequency, or frequency interval, that can be resolved. It is equal to  $ENBW \cdot \text{SampleRate} / L$ , where  $L$  is the input length, and ENBW is the two-sided equivalent noise bandwidth of the window (in Hz). For example, if `SampleRate=100`, `L=1024`, and `Window='Hann'`,  $RBW = \text{enbw}(\text{hann}(1024)) \cdot 100 / 1024$ .

# reset

**System object:** dsp.TransferFunctionEstimator

**Package:** dsp

Reset internal states of transfer function estimator

## Syntax

```
reset(sysObj)
```

## Description

`reset(sysObj)` resets the internal states of the System object, `sysObj`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

---

## step

**System object:** dsp.TransferFunctionEstimator

**Package:** dsp

Estimate transfer function of system

## Syntax

```
Txy = step(tfe,x,y)
Y = step(sysObj,x)
[Y1,...,YN] = step(sysObj,x)
```

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Txy = step(tfe,x,y)` computes the transfer function, `Txy`, of the system with input `x` and output `y`. This computation uses the Welch's averaged periodogram method. `Txy` is the ratio of the Cross Power Spectral Density of `x` and `y`, and the Power Spectral Density of `x`. The columns of `x` and `y` are treated as independent channels.

`Y = step(sysObj,x)` processes the input data, `x`, to produce the output, `Y`, from the System object, `sysObj`. `[Y1,...,YN] = step(sysObj,x)` produces `N` outputs.

Every System object has a `step` method. The `step` method processes the input data according to the object algorithm. The number of input and output arguments depends on the algorithm, and may depend also on one or more property settings. The `step` method for some objects accepts fixed-point (fi) inputs.

Calling `step` on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.TransitionMetrics System object

**Package:** dsp

Transition metrics of bilevel waveforms

## Description

The `TransitionMetrics` object extracts information such as duration, slew rate, and reference-level crossings for each transition found in the bilevel waveform. The `TransitionMetrics` object can additionally return preshoot, postshoot and settling metrics for the regions immediately before and after each transition.

To obtain transition metrics for a bilevel waveform:

- 1 Define and set up your transition metrics. See “Construction” on page 4-1737.
- 2 Call `step` to calculate the transition metrics according to the properties of `dsp.TransitionMetrics`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`tm = dsp.TransitionMetrics` creates a transition metrics System object, `tm`. The object computes the rise time, fall time and width of a pulse. `TransitionMetrics` additionally computes cycle metrics such as pulse separations, periods, and duty cycles.

`tm = dsp.TransitionMetrics('PropertyName',PropertyValue,...)` returns a `TransitionMetrics` System object, `tm`, with each specified property set to the specified value.

## Properties

### **MaximumRecordLength**

Maximum samples to preserve between calls to `step`. This property requires a positive integer that specifies the maximum number of samples to save between calls to the `step` method. When the number of samples to be saved exceeds this length, the oldest excess samples are discarded. This property applies when `RunningMetrics` is `true` and is tunable.

**Default:** 1000

### **PercentReferenceLevels**

Lower-, middle-, and upper-percent reference levels. This property contains a 3-element numeric row vector that contains the lower-, middle-, and upper-percent reference levels. These reference levels are used as an offset between the low and high states of the waveform when computing the duration of each transition.

**Default:** [10 50 90]

### **PercentStateLevelTolerance**

Tolerance of the state level (in percent). This property requires a scalar that specifies the maximum deviation from either the low or high state before it is considered to be outside that state. The tolerance is expressed as a percentage of the waveform amplitude.

**Default:** 2

### **PostshootOutputPort**

Enable posttransition aberration metrics. If this property is set to `true`, overshoot and undershoot metrics are reported for a region defined immediately after each transition. The posttransition aberration region is defined as the waveform interval that begins at the end of each transition and whose duration is the value of `PostshootSeekFactor` times the computed transition duration. If a complete subsequent transition is detected before the interval is over, the region is truncated at the start of the subsequent transition. The metrics are computed for each transition that has a complete posttransition aberration region.

**Default:** `false`

**PostshootSeekFactor**

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately following each transition. The duration is expressed as a factor of the duration of the transition. This property is enabled only when the `PostshootOutputPort` property is set to `true` and is tunable.

**Default:** 3

**PreshootOutputPort**

Enable pretransition aberration metrics. If the `PreshootOutputPort` property is set to `true`, overshoot and undershoot metrics are reported for a region defined immediately before each transition. The pretransition aberration region is defined as the waveform interval that ends at the start of each transition and whose duration is `PreshootSeekFactor` times the computed transition duration.

**Default:** false

**PreshootSeekFactor**

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately preceding each transition. The duration is expressed as a factor of the duration of the transition. This property is enabled only when the `PreshootOutputPort` property is set to `true` and is tunable.

**Default:** 3

**RunningMetrics**

Enable metrics over all calls to `step`. If `RunningMetrics` is set to `false`, metrics are computed for each call to `step` independently. If `RunningMetrics` is set to `true`, metrics are computed across subsequent calls to `step`. If there are not enough samples to compute metrics associated with the last transition, posttransition aberration region, or settling seek duration in the current record, the object defers reporting all transition, aberration, and settling metrics associated with the last transition until a subsequent call to `step` is made with enough data to compute all enabled metrics for that transition.

**Default:** false

**SampleRate**

Sampling rate of uniformly-sampled signal. Specify the sample rate in hertz as a positive scalar. This property is used to construct the internal time values that correspond to the

input sample values. Time values start with zero. This property applies when the `TimeInputPort` property is set to `false`.

**Default:** 1

### **SettlingOutputPort**

Enable settling metrics. If `SettlingOutputPort` is set to `true`, settling metrics are reported for each transition. The region used to compute the settling metrics starts at the midcrossing and lasts until the `SettlingSeekDuration` has elapsed. If an intervening transition occurs, or the signal has not settled within the `PercentStateLevelTolerance` of the final level, `NaN` is returned for each metric. If there are not enough samples after the last transition to complete the `SettlingSeekDuration`, no metrics are reported for the last transition. The metrics are reported for the transition the next time step is called if the `RunningMetrics` property is set to `true`.

**Default:** `false`

### **SettlingSeekDuration**

Duration of time over which to search for settling. This property is a scalar that specifies the amount of time to inspect from the mid-reference level crossing (in seconds). If the transition has not yet settled, or a subsequent complete transition is detected within this duration, the `TransitionMetrics` object reports `NaN` for all settling metrics. This property is tunable and applies only when you set the `SettlingOutputPort` property to `true`.

**Default:** 0.02

### **StateLevels**

Low- and high-state levels. This property is a 2-element numeric row vector that contains the low and high state levels respectively. These state levels correspond to the nominal logic low and high levels of the pulse waveform. This property is tunable.

**Default:** [0 2.3]

### **StateLevelsSource**

Auto or manual state level computation. If the `StateLevelsSource` property is set to `'Auto'`, the first record sent to `step` is sent to `dsp.StateLevels` with the default

settings to determine the state levels of the incoming waveform. If this property is set to 'Property', the object uses the values the user specifies in the StateLevels property.

**Default:** 'Property'

### TimeInputPort

Add input to specify sample instants. Set TimeInputPort to true to enable an additional real input column vector to step to specify the sample instants that correspond to the sample values. If this property is false, the sample instants are built internally. The sample instants start at zero and increment by the reciprocal of the SampleRate property for subsequent samples. The sample instants continue to increment if the RunningMetrics property is set to true and no intervening calls to the reset or release methods are encountered.

**Default:** false

## Methods

plot     Plots signal and metrics computed in last call to step  
 reset    Reset the running transition metrics object  
 step     Transition metrics of bilevel waveform

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Transition and Preshoot Information of a 2.3 V Step Waveform

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent step syntax. For example, myObject(x) becomes step(myObject,x).

Compute transition and preshoot information of a 2.3 V step waveform sampled at 4 MHz. Load the data.

```
load('transitionex.mat', 'x');
```

Construct the `dsp.TransitionMetrics` object. Set the `SampleRate` property to 4 MHz, `StateLevelsSource` property to 'Auto' to estimate the state levels from the data. Set the `PreshootOutputPort` property to `true` to output pretransition aberration metrics when you call `step`.

```
tm = dsp.TransitionMetrics('SampleRate',4e6, ...  
                           'StateLevelsSource','Auto', ...  
                           'PreshootOutputPort',true)
```

```
tm =  
dsp.TransitionMetrics with properties:  
  
    StateLevelsSource: 'Auto'  
        StateLevels: [0 2.3000]  
PercentStateLevelTolerance: 2  
    PercentReferenceLevels: [10 50 90]  
        RunningMetrics: false  
        TimeInputPort: false  
        SampleRate: 4000000  
    PreshootOutputPort: true  
    PreshootSeekFactor: 3  
    PostshootOutputPort: false  
    SettlingOutputPort: false
```

Call `step` to compute the transition and preshoot information. Plot the result.

```
[transition, preshoot] = tm(x)  
  
transition = struct with fields:  
    Duration: 1.7800e-07  
    Polarity: 1  
    SlewRate: 1.0310e+07  
    MiddleCross: 5.1250e-06  
    LowerCross: 5.0360e-06  
    UpperCross: 5.2140e-06  
  
preshoot = struct with fields:  
    Overshoot: 4.8050  
    Undershoot: 6.1798  
    OvershootLevel: 0.1020  
    UndershootLevel: -0.1500
```

OvershootInstant: 4.7500e-06  
 UndershootInstant: 5.0000e-06

plot(tm)

### Transition, Postshoot, and Settling Information of a 2.3 V Step Waveform

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Compute transition, postshoot, and settling information of a 2.3 V step waveform sampled at 4 MHz. Load the data along with the sampling instants.

```
load('transitionex.mat', 'x', 't');
```

Construct the `dsp.TransitionMetrics` object. Set the `TimeInputPort` property to `true`, `StateLevels` property to `[0 2.3]` to match waveform statelevels. To output the postshoot information and settling information, set the `PostShootOutputPort` and `SettlingOutputPort` properties to `true`. Set the `SettlingSeekDuration` property to 2 ms.

```
tm = dsp.TransitionMetrics('TimeInputPort',true, ...  
                           'StateLevels',[0 2.3], ...  
                           'PostshootOutputPort',true, ...  
                           'SettlingOutputPort',true, ...  
                           'SettlingSeekDuration',2e-6)
```

```
tm =  
dsp.TransitionMetrics with properties:

**Introduced in R2012a**

# plot

**System object:** dsp.TransitionMetrics

**Package:** dsp

Plots signal and metrics computed in last call to `step`

## Syntax

```
plot(tm)
```

## Description

`plot(tm)` plots the signal and metrics resulting from the last call of the `step` method.

By default `plot` displays

- the low and high state levels and the state-level boundaries defined by the `PercentStateLevelTolerance` property.
- the lower-, middle-, and upper-reference levels.
- the locations of the mid-reference level crossings of the positive (+) and negative (-) transitions of each detected pulse.

When you set the `TransitionOutputPort` property to `true`, the locations of the upper and lower crossings are also plotted. When the `PreshootOutputPort` or `PostShootOutputPort` properties are set to `true`, the corresponding overshoots and undershoots are plotted as inverted or non-inverted triangles. When the `SettlingOutputPort` property is set to `true`, the locations where the signal enters and remains within the upper- and lower-state boundaries over the specified seek duration are plotted.

## reset

**System object:** dsp.TransitionMetrics

**Package:** dsp

Reset the running transition metrics object

## Syntax

reset(tm)

## Description

reset(tm) clears information from previous calls to step.

# step

**System object:** dsp.TransitionMetrics

**Package:** dsp

Transition metrics of bilevel waveform

## Syntax

```
PULSE = step(tm,X)
[PULSE,CYCLE] = step(tm,X)
[PULSE,TRANSITION] = step(tm,X)
[PULSE,PRESHOOT] = step(tm,X)
[PULSE,POSTSHOOT] = step(tm,X)
[PULSE,SETTLING] = step(tm,X)
[...] = step(tm,X,T)
```

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`PULSE = step(tm,X)` returns a structure array, `PULSE`, whose fields contain real-valued column vectors. The number of rows of each field corresponds to the number of complete pulses found in the real-valued column vector input, `X`. Each pulse starts with a transition of the polarity specified by the `Polarity` property and ends with a transition of the opposite polarity.

`PULSE` fields:

- `PositiveCross` — Instants where the positive-going transitions cross the mid-reference level of each pulse

- **NegativeCross** — Instants where the negative-going transitions cross the mid-reference level of each pulse
- **Width** — Absolute difference between **PositiveCross** and **NegativeCross** of each pulse
- **RiseTime** — Duration between the linearly-interpolated instants when the positive-going (rising) transition of each pulse crosses the lower- and upper-reference levels
- **FallTime** — Duration between the linearly-interpolated instants when the negative-going (falling) transition of each pulse crosses the upper- and lower-reference levels

[PULSE, CYCLE] = `step(tm, X)` returns a structure array, CYCLE, whose fields contain real-valued column vectors when you set the `CycleOutputPort` property to `true`. The number of rows of each field corresponds to the number of complete pulse periods found in the real-valued column vector input, X. You need at least three consecutive alternating polarity transitions that start and end with the same polarity as the value of the `Polarity` property if you want to compute cycle metrics. If the last transition found the input, X, does not match the polarity of the `Polarity` property, the pulse separation, period, frequency, and duty cycle are not reported for the last pulse. If the `RunningMetrics` property is set to `true` when this occurs, all pulse, cycle, transition, preshoot, postshoot, and settling metrics associated with the last pulse are deferred until a subsequent call to `step` detects the next transition.

CYCLE fields:

- **Period** — Duration between the first transition of the current pulse and the first transition of the next pulse
- **Frequency** — Reciprocal of the period
- **Separation** — Durations between the mid-reference level crossings of the second transition of each pulse and the first transition of the next pulse
- **Width** — Durations between the mid-reference level crossings of the first and second transitions of each pulse. This is equivalent to the width parameter of the PULSE structure.
- **DutyCycle** — Ratio of the width to the period for each pulse

[PULSE, TRANSITION] = `step(tm, X)` returns a structure array, TRANSITION, when you set the `TransitionOutputPort` property to `true`. The fields of TRANSITION contain real-valued matrices with two columns which correspond to the metrics of the first and second transitions. The number of rows corresponds to the number of pulses found in the input waveform.

TRANSITION fields:

- **Duration** — Amount of time between the interpolated instants where the transition crosses the lower- and upper-reference levels
- **SlewRate** — Ratio of absolute difference between the upper- and lower-reference levels to the transition duration
- **MiddleCross** — Linearly-interpolated instant where the transition first crosses the mid-reference level
- **LowerCross** — Linearly-interpolated instant where the signal crosses the lower-reference level
- **UpperCross** — Linearly-interpolated instant where the signal crosses the upper-reference level

[PULSE, PRESHOOT] = step(tm, X) returns a structure array, PRESHOOT, when you set the PreshootOutputPort property to true. The fields of PRESHOOT contain real-valued 2-column matrices whose row length corresponds to the number of transitions found in the input waveform. The field names are identical to those of the POSTSHOOT structure.

[PULSE, POSTSHOOT] = step(tm, X) returns a structure array, POSTSHOOT, when you set the PostshootOutputPort property to true. The fields of POSTSHOOT contain real-valued 2-column matrices whose row length corresponds to the number of transitions found in the input waveform.

PRESHOOT and POSTSHOOT fields:

- **Overshoot** — Overshoot of the region of interest expressed as a percentage of the waveform amplitude
- **Undershoot** — Undershoot of the region of interest expressed as a percentage of the waveform amplitude
- **OvershootLevel** — Level of the overshoot
- **UndershootLevel** — Level of the undershoot
- **OvershootInstant** — Instant that corresponds to the overshoot
- **UndershootInstant** — Instant that corresponds to the undershoot

[PULSE, SETTLING] = step(tm, X) returns a structure, SETTLING, when you set the SettlingOutputPort property to true. The fields of SETTLING correspond to the settling metrics for each transition. Each field is a column vector whose elements correspond to the individual settling durations, levels, and instants.

SETTLING fields:

- **Duration** — Amount of time from when the signal crosses the mid-reference level to the time where the signal enters and remains within the specified `PercentStateLevelTolerance` of the waveform amplitude over the specified settling seek duration
- **Instant** — Instant in time where the signal enters and remains within the specified tolerance
- **Level** — Level of the waveform where it enters and remains within the specified tolerance

The above operations can be used simultaneously, provided the System object properties are set appropriately. One example of providing all possible inputs and returning all possible outputs is :

```
[PULSE, CYCLE, TRANSITION, PRESHOOT, POSTSHOOT, SETTILING] = step(tm, X)
```

which returns the PULSE, CYCLE, TRANSITION, PRESHOOT, POSTSHOOT, and SETTILING structure arrays when the `CycleOutputPort`, `PreshootOutputPort`, `PostshootPort`, and `SettlingOutputPort` properties are `true`. You may enable or disable any combination of output ports. However, the output arguments are defined in the order shown here.

```
[...] = step(tm, X, T)
```

performs the above metrics with respect to a sampled signal, whose sample values, X, and sample instants, T, are real-valued column vectors of the same length. The additional input T applies only when you set the `TimeInputPort` property to `true`.

## **dsp.UDPReceiver System object**

**Package:** dsp

Receive UDP packets from the network

### **Description**

The `dsp.UDPReceiver` System object receives UDP packets over a UDP network from a remote IP address specified in the “RemoteIPAddress” on page 4-0 property. The object then saves the data to its internal buffer. The amount of data (number of elements) received in each UDP packet can vary. The maximum number of bytes the object can receive without losing data is set by the “ReceiveBufferSize” on page 4-0 property. The “MaximumMessageLength” on page 4-0 property specifies the maximum number of samples each data packet can contain. The “LocalIPPort” on page 4-0 on which the object receives the data is tunable in generated code but not tunable during simulation. For an example, see “Tune the UDP Port Number in MATLAB” on page 4-1758.

To receive UDP packets from the network:

- 1** Create the `dsp.UDPReceiver` object and set its properties.
- 2** Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

### **Creation**

#### **Syntax**

```
udpr = dsp.UDPReceiver  
udpr = dsp.UDPReceiver(Name,Value)
```

## Description

`udpr = dsp.UDPReceiver` returns a UDP receiver object that receives UDP packets from a specified port.

`udpr = dsp.UDPReceiver(Name, Value)` returns a UDP receiver object with each specified property set to the specified value. Enclose each property name in single quotes.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects (MATLAB)*.

### **LocalIPPort — Local port on which to receive data**

25000 (default) | [1 65535]

Port on which to receive the data, specified as a scalar in the range [1 65535]. This property is tunable in generated code but not tunable during simulation.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **RemoteIPAddress — Address from which to accept data**

'0.0.0.0' (default) | character vector containing a valid IP address

Address from which to accept data, specified as a character vector containing a valid IP address. Entering a specific IP address blocks UDP packets from other addresses. The default, '0.0.0.0', indicates that the data can be accepted from any remote IP address.

Data Types: `char`

### **ReceiveBufferSize — Size of internal buffer**

8192 bytes (default) | [1 67108864]

Size of the internal buffer that receives UDP packets, specified in bytes as a scalar in the range [1 67108864]. If the number of bytes received exceeds this value, the buffer overflows and the contents are truncated.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **MaximumMessageLength — Maximum size of output message**

255 (default) | [1 65507]

Maximum length of the output message, specified in samples as a positive scalar in the range [1 65507]. Set this property to a value equal to or greater than the data size of the UDP packet. If you receive more samples than specified in this property, the excess data is truncated.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **MessageDataType — Data type of the message**

'`uint8`' (default) | '`double`' | '`single`' | '`int8`' | '`int16`' | '`uint16`' | '`int32`' | '`uint32`' | '`logical`'

Data type of the vector elements in the message output, specified as a MATLAB built-in data type.

Match the data type with the data input used to create the UDP packets.

Data Types: `char`

## **Usage**

## **Syntax**

```
dataR = udpr()
```

## **Description**

`dataR = udpr()` receives one UDP packet from the network.

## Output Arguments

### **dataR** — Data received

scalar | vector

Data received from the network, returned as one packet. The “MaximumMessageLength” on page 4-0 property specifies the maximum number of bytes each data packet can contain. Length of the data received is the number of bytes received from the network.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### Byte Transmission Using UDP

Send and receive UDP packets using the `dsp.UDPSender` and `dsp.UDPReceiver` System objects. Calculate the number of bytes successfully transmitted.

**Note:** If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Set the `RemoteIPPort` of UDP sender and the `LocalIPPort` of the UDP receiver to 31000. Set the length of the data vector to 128 samples, which is less than the value of

the `MaximumMessageLength` property of the receiver. To prevent the loss of packets, call the `setup` method on the receiver object before the first call to the object algorithm.

```
udpr = dsp.UDPReceiver('LocalIPPort',31000);  
udps = dsp.UDPSender('RemoteIPPort',31000);
```

```
setup(udpr);
```

```
bytesSent = 0;  
bytesReceived = 0;  
dataLength = 128;
```

In each loop of iteration, send and receive a packet of data. At the end of the loop, use the `fprintf` function to print the number of bytes sent by the sender and the number of bytes received by the receiver.

```
for k = 1:20  
    dataSent = uint8(255*rand(1,dataLength));  
    bytesSent = bytesSent + dataLength;  
    udps(dataSent);  
    dataReceived = udpr();  
    bytesReceived = bytesReceived + length(dataReceived);  
end
```

```
release(udps);  
release(udpr);
```

```
fprintf('Bytes sent:      %d\n', bytesSent);
```

```
Bytes sent:      2560
```

```
fprintf('Bytes received: %d\n', bytesReceived);
```

```
Bytes received: 2560
```

### Tune the UDP Port Number in MATLAB

The local IP port number of the `dsp.UDPReceiver` object and the remote IP port number of the `dsp.UDPSender` object are tunable in the generated code. Generate a MEX file from the receiver function which contains the algorithm to receive sine wave data over

a UDP network. Change the remote IP port number of the UDP receiver without regenerating the MEX file. Verify the number of bytes sent and received over the network.

**Note:** This example runs only in R2017a or later.

The input to the `receiver` function is the local IP port number of the `dsp.UDPReceiver` System object™. The output of this function is the number of bytes received from the UDP network.

type `receiver`

```
function [bytesReceived] = receiver(portnumber)

persistent udpRx

if isempty(udpRx)
    udpRx = dsp.UDPReceiver('MessageDataType','double');
end

udpRx.LocalIPPort = portnumber;
dataReceived = udpRx();
bytesReceived = length(dataReceived);
```

The `dsp.UDPSender` object with `remoteIPPort` number set to 65000 sends the data over the UDP network. The `dsp.UDPReceiver` object with `LocalIPPort` number set to 65000 receives the data from the UDP network. The data is a sine wave containing 250 samples per frame.

```
portnumber = 65000;
udpSend = dsp.UDPSender('RemoteIPPort',portnumber);
sine = dsp.SineWave('SamplesPerFrame',250);

bytesSent = 0;
bytesReceived = 0;
dataLength = 250;

for i = 1:10
    dataSent = sine();
    bytesSent = bytesSent + dataLength;
    udpSend(dataSent);
    bytesReceived = bytesReceived + receiver(portnumber);
end
fprintf('Number of bytes sent: %d', bytesSent);

Number of bytes sent: 2500
```

```
fprintf('Number of bytes received: %d', bytesReceived);
```

```
Number of bytes received: 2250
```

The data is sent and received successfully over the UDP network. The initial data is dropped due to overhead.

Generate a MEX file from the `receiver.m` function.

```
codegen receiver -args {65000}
```

Release the sender and change the `RemoteIPPort` number to 25000. The `LocalIPPort` number of the receiver continues to be 65000. Since the port numbers are different, the data is not transmitted successfully.

```
release(udpSend)
portnumberTwo = 25000;
udpSend.RemoteIPPort = portnumberTwo;
bytesReceived = 0;
bytesSent = 0;
for i = 1:10
    dataSent = sine();
    bytesSent = bytesSent + dataLength;
    udpSend(dataSent);
    bytesReceived = bytesReceived + receiver_mex(portnumber);
end
fprintf('Number of bytes sent: %d', bytesSent);
```

```
Number of bytes sent: 2500
```

```
fprintf('Number of bytes received: %d', bytesReceived);
```

```
Number of bytes received: 0
```

Clear the MEX file and change the local IP port number of the receiver to 25000. Clearing the MEX enables the receiver port number to change without having to regenerate the MEX. The port numbers of the sender and receiver match. Verify if the data is transmitted successfully.

```
clear mex %#ok
bytesReceived = 0;
bytesSent = 0;
for i = 1:10
    dataSent = sine();
    bytesSent = bytesSent + dataLength;
```

```
udpSend(dataSent);
bytesReceived = bytesReceived + receiver_mex(portnumberTwo);
end
fprintf('Number of bytes sent: %d', bytesSent);

Number of bytes sent: 2500

fprintf('Number of bytes received: %d', bytesReceived);

Number of bytes received: 2250
```

The data is transmitted successfully over the UDP network. The initial data is dropped due to overhead.

- “Voice Over IP (VOIP)”

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- “System Objects in MATLAB Code Generation” (MATLAB Coder)
- The executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- The `LocalIPPort` property is tunable in generated code but not tunable during simulation.

# dsp.UDPSender System object

**Package:** dsp

Send UDP packets to network

## Description

The UDPSender object sends UDP packets to the network.

To send UDP packets to the network:

- 1 Define and set up your UDP sender. See “Construction” on page 4-1763.
- 2 Call `step` to send the packets according to the properties of `dsp.UDPSender`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`udps = dsp.UDPSender` returns a UDP sender object, `udps`, that sends UDP packets to a specified port.

`udps = dsp.UDPSender('PropertyName',PropertyValue, ...)` returns a UDP sender object, `udps`, with each property set to the specified value.

## Properties

### RemoteIPAddress

Remote address to which to send data

Specify the remote (that is, host) IP address to which the data is sent. The default is '127.0.0.1', which is the local host.

### **RemoteIPPort**

Remote port to which to send data

Specify the port at the remote IP address to which the data is sent. This property is tunable in generated code but not tunable during simulation. The default is 25000.

### **LocalIPPortSource**

Source of the LocalIPPort property

Specify how to determine the port on the host as | Auto | Property |. If you specify Auto, the object selects the port dynamically from the available ports. If you specify Property, the object uses the source specified in the LocalIPPort property. The default is Auto.

### **LocalIPPort**

Local port from which to send data

Specify the port from which to send data. This property applies when you set the LocalIPPortSource property to Auto. The default is 25000.

## **Methods**

step          Send a UDP packet to network

<b>Common to All System Objects</b>	
release	Allow System object property value changes

## **Examples**

## Byte Transmission Using UDP

Send and receive UDP packets using the `dsp.UDPSEnder` and `dsp.UDPReceiver` System objects. Calculate the number of bytes successfully transmitted.

**Note:** If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Set the `RemoteIPPort` of UDP sender and the `LocalIPPort` of the UDP receiver to 31000. Set the length of the data vector to 128 samples, which is less than the value of the `MaximumMessageLength` property of the receiver. To prevent the loss of packets, call the `setup` method on the receiver object before the first call to the object algorithm.

```
udpr = dsp.UDPReceiver('LocalIPPort',31000);
udps = dsp.UDPSEnder('RemoteIPPort',31000);
```

```
setup(udpr);
```

```
bytesSent = 0;
bytesReceived = 0;
dataLength = 128;
```

In each loop of iteration, send and receive a packet of data. At the end of the loop, use the `fprintf` function to print the number of bytes sent by the sender and the number of bytes received by the receiver.

```
for k = 1:20
    dataSent = uint8(255*rand(1,dataLength));
    bytesSent = bytesSent + dataLength;
    udps(dataSent);
    dataReceived = udpr();
    bytesReceived = bytesReceived + length(dataReceived);
end
```

```
release(udps);
release(udpr);
```

```
fprintf('Bytes sent:      %d\n', bytesSent);
```

```
Bytes sent:      2560
```

```
fprintf('Bytes received: %d\n', bytesReceived);
```

```
Bytes received: 2560
```

### Tune the UDP Port Number in MATLAB

The local IP port number of the `dsp.UDPReceiver` object and the remote IP port number of the `dsp.UDPSender` object are tunable in the generated code. Generate a MEX file from the `receiver` function which contains the algorithm to receive sine wave data over a UDP network. Change the remote IP port number of the UDP receiver without regenerating the MEX file. Verify the number of bytes sent and received over the network.

**Note:** This example runs only in R2017a or later.

The input to the `receiver` function is the local IP port number of the `dsp.UDPReceiver` System object™. The output of this function is the number of bytes received from the UDP network.

type `receiver`

```
function [bytesReceived] = receiver(portnumber)

persistent udpRx

if isempty(udpRx)
    udpRx = dsp.UDPReceiver('MessageDataType','double');
end

udpRx.LocalIPPort = portnumber;
dataReceived = udpRx();
bytesReceived = length(dataReceived);
```

The `dsp.UDPSender` object with `remoteIPPort` number set to 65000 sends the data over the UDP network. The `dsp.UDPReceiver` object with `LocalIPPort` number set to 65000 receives the data from the UDP network. The data is a sine wave containing 250 samples per frame.

```
portnumber = 65000;
udpSend = dsp.UDPSender('RemoteIPPort',portnumber);
sine = dsp.SineWave('SamplesPerFrame',250);

bytesSent = 0;
bytesReceived = 0;
dataLength = 250;
```

```

for i = 1:10
dataSent = sine();
bytesSent = bytesSent + dataLength;
udpSend(dataSent);
bytesReceived = bytesReceived + receiver(portnumber);
end
fprintf('Number of bytes sent: %d', bytesSent);

```

Number of bytes sent: 2500

```
fprintf('Number of bytes received: %d', bytesReceived);
```

Number of bytes received: 2250

The data is sent and received successfully over the UDP network. The initial data is dropped due to overhead.

Generate a MEX file from the receiver.m function.

```
codegen receiver -args {65000}
```

Release the sender and change the RemoteIPPort number to 25000. The LocalIPPort number of the receiver continues to be 65000. Since the port numbers are different, the data is not transmitted successfully.

```

release(udpSend)
portnumberTwo = 25000;
udpSend.RemoteIPPort = portnumberTwo;
bytesReceived = 0;
bytesSent = 0;
for i = 1:10
dataSent = sine();
bytesSent = bytesSent + dataLength;
udpSend(dataSent);
bytesReceived = bytesReceived + receiver_mex(portnumber);
end
fprintf('Number of bytes sent: %d', bytesSent);

```

Number of bytes sent: 2500

```
fprintf('Number of bytes received: %d', bytesReceived);
```

Number of bytes received: 0

Clear the MEX file and change the local IP port number of the receiver to 25000. Clearing the MEX enables the receiver port number to change without having to regenerate the

MEX. The port numbers of the sender and receiver match. Verify if the data is transmitted successfully.

```
clear mex %#ok
bytesReceived = 0;
bytesSent = 0;
for i = 1:10
    dataSent = sine();
    bytesSent = bytesSent + dataLength;
    udpSend(dataSent);
    bytesReceived = bytesReceived + receiver_mex(portnumberTwo);
end
fprintf('Number of bytes sent: %d', bytesSent);
```

```
Number of bytes sent: 2500
```

```
fprintf('Number of bytes received: %d', bytesReceived);
```

```
Number of bytes received: 2250
```

The data is transmitted successfully over the UDP network. The initial data is dropped due to overhead.

**Introduced in R2012a**

# step

**System object:** dsp.UDPSender

**Package:** dsp

Send a UDP packet to network

## Syntax

$Y = \text{step}(\text{udps}, \text{PACKET})$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(\text{udps}, \text{PACKET})$  sends one UDP packet, `PACKET`, to the network.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.UniformDecoder System object

**Package:** dsp

Decode integer input into floating-point output

## Description

The `UniformDecoder` object decodes integer input into floating-point output. The decoder adheres to the definition for uniform decoding specified in ITU-T Recommendation G.701.

To decode an integer input into a floating-point output:

- 1 Define and set up your uniform decoder. See “Construction” on page 4-1771.
- 2 Call `step` to decode the input according to the properties of `dsp.UniformDecoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`ud = dsp.UniformDecoder` returns a uniform decoder, `ud`, that performs the inverse operation of the `dsp.UniformEncoder` object, reconstructing quantized floating-point values from encoded integer input.

`ud = dsp.UniformDecoder('PropertyName',PropertyValue,...)` returns a uniform decoder, `ud`, with each specified property set to the specified value.

`ud = dsp.UniformDecoder(peakvalue,numbits,'PropertyName',PropertyValue,...)` returns a uniform decoder, `ud`, with the `PeakValue` property set to `peakvalue`, the `NumBits` property set to `numbits`, and other specified properties set to the specified values.

## Properties

### **PeakValue**

Largest amplitude represented in encoded input

Specify the largest amplitude represented in the encoded input as a nonnegative numeric scalar. To correctly decode values encoded with the `dsp.UniformEncoder` object, set the `PeakValue` property in both objects to the same value. For more information on setting this property, see the `PeakValue` property description on the `dsp.UniformEncoder` reference page. The default is 1.

### **NumBits**

Number of input bits used to encode data

Specify the number of bits used to encode the input data as an integer value between 2 and 32. The value of this property can be less than the total number of bits supplied by the input data type. To correctly decode values encoded with the `dsp.UniformEncoder` object, set the `NumBits` property in both objects to the same value. For more information on setting this property, see the `NumBits` property description on the `dsp.UniformEncoder` reference page. The default is 3.

### **OverflowAction**

Action to take when integer input is out of range

Specify the behavior of the uniform decoder when the integer input is out of range as `Saturate` or `Wrap`. The value of the `NumBits` property specifies the representable range of the input. The default is `Saturate`.

### **OutputDataType**

Output data type as single or double

Specify the data type of the output as `single` or `double`. The default is `double`.

## Methods

step Decode integer input into quantized floating-point output

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Decode An Encoded Sequence

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
ue = dsp.UniformEncoder;
ue.PeakValue = 2;
ue.NumBits = 4;
ue.OutputDataType = 'Signed integer';
x = (0:0.25:2)'; % Create an input sequence
ud = dsp.UniformDecoder;
ud.PeakValue = 2;
ud.NumBits = 4;
x_encoded = ue(x);
```

Check that the last element has been saturated.

```
x_decoded = ud(x_encoded);
```

## dsp.UniformEncoder System object

**Package:** dsp

Quantize and encode floating-point input into integer output

### Description

The `UniformEncoder` object quantizes floating-point input, using the precision you specify in the `NumBits` property, and encodes the quantized input into integer output. The operations of the uniform encoder adhere to the definition for uniform encoding specified in ITU-T Recommendation G.701.

To quantize and encode a floating-point input into an integer output:

- 1 Define and set up your uniform encoder. See “Construction” on page 4-1776.
- 2 Call `step` to encode the input according to the properties of `dsp.UniformEncoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`ue = dsp.UniformEncoder` returns a uniform encoder, `ue`, that quantizes floating-point input samples and encodes them as integers using  $2N$ -level quantization, where  $N$  is an integer.

`ue = dsp.UniformEncoder('PropertyName',PropertyValue,...)` returns an uniform encoder, `ue`, with each specified property set to the specified value.

`ue = dsp.UniformEncoder(peakvalue,numbits,`

'*PropertyName*',*PropertyValue*,...) returns a uniform encoder, *ue*, with the *PeakValue* property set to *peakvalue*, the *NumBits* property set to *numbits*, and other specified properties set to the specified values.

## Properties

### PeakValue

Largest input amplitude to be encoded

Specify the largest input amplitude to be encoded, as a nonnegative numeric scalar. If the real or imaginary input are outside of the interval  $[-P, (1 - 2^{(1-B)})P]$ , where  $P$  is the peak value and  $B$  is the value of the *NumBits* property, the uniform encoder saturates (independently for complex inputs) at those limits. The default is 1.

### NumBits

Number of bits needed to represent output

Specify the number of bits needed to represent the integer output as an integer value between 2 and 32. The number of levels at which the uniform encoder quantizes the floating-point input is  $2^B$ , where  $B$  is the number of bits. The default is 8.

### OutputDataType

Data type of output

Specify the data type of the output as *Unsigned integer* or *Signed integer*. Unsigned outputs are *uint8*, *uint16*, or *uint32*, and signed outputs are *int8*, *int16*, or *int32*. The quantized inputs are linearly (uniformly) mapped to the intermediate integers in the interval  $[0, 2^{(B-1)}]$  when you set this property to *Unsigned integer*, and in the interval  $[-2^{(B-1)}, 2^{(B-1)} - 1]$  when you set this property to *Signed integer*. The variable  $B$  in both expressions corresponds to the value of the *NumBits* property.

## Methods

Quantize and encode input

## Syntax

$Y = \text{step}(ue, X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(ue, X)$  quantizes and encodes the input  $X$  to  $Y$ . Input  $X$  can be real or complex, double-, or single-precision values. The uniform encoder chooses the output data type according to the following table.

Number of Bits	Unsigned Integer	Signed Integer
2 to 8	uint8	int8
9 to 16	uint16	int16
17 to 32	uint32	int32

The row corresponds to the value of the `NumBits` property, and the column corresponds to the value of the `OutputDataType` property.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

# dsp.UpperTriangularSolver System object

**Package:** dsp

Solve upper-triangular matrix equation

## Description

The `UpperTriangularSolver` object solves  $UX = B$  for  $X$  when  $U$  is a square, upper-triangular matrix with the same number of rows as  $B$ .

To solve  $UX = B$ :

- 1 Define and set up your linear system solver. See “Construction” on page 4-1783.
- 2 Call `step` to solve the equation according to the properties of `dsp.UpperTriangularSolver`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

## Construction

$H = \text{dsp.UpperTriangularSolver}$  returns a linear system solver,  $H$ , used to solve  $UX = B$  where  $U$  is an upper (or unit-upper) triangular matrix.

$H = \text{dsp.UpperTriangularSolver}('PropertyName', PropertyValue, \dots)$  returns a linear system solver,  $H$ , with each specified property set to the specified value.

# Properties

## **OverwriteDiagonal**

Replace diagonal elements of input with ones

When you set this property to `true`, the linear system solver replaces the elements on the diagonal of the input,  $U$ , with ones. Set this property to either `true` or `false`. The default is `false`.

## **RealDiagonalElements**

Indicate that diagonal of complex input is real

When you set this property to `true`, the linear system solver optimizes computation speed if the diagonal elements of complex input,  $U$ , are real. This property applies only when you set the `OverwriteDiagonal` property to `false`. Set this property to either `true` or `false`. The default is `false`.

## **Fixed-Point Properties**

### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

### **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

### **ProductDataType**

Data type of product

Specify the product data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

**CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

**AccumulatorDataType**

Data type of accumulator

Specify the accumulator data type as `Full precision`, `Same as first input`, `Same as product`, or `Custom`. The default is `Full precision`.

**CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

**OutputDataType**

Data type of output

Specify the output data type as `Same as first input` or `Custom`. The default is `Same as first input`.

**CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numericType([], 16, 15)`.

## Methods

# dsp.VariableBandwidthFIRFilter System object

**Package:** dsp

Variable bandwidth FIR filter

## Description

The `VariableBandwidthFIRFilter` object filters each channel of the input using FIR filter implementations. It does so while having the capability of tuning the bandwidth. This filter supports double and single precision inputs.

To filter each channel of the input:

- 1 Define and set up your variable bandwidth FIR filter. See “Construction” on page 4-1789.
- 2 Call `step` to filter each channel of the input according to the properties of `dsp.VariableBandwidthFIRFilter`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`vbw = dsp.VariableBandwidthFIRFilter` returns a System object, `vbw`, which independently filters each channel of the input over successive calls to the `step` method. This System object uses a specified FIR filter implementation. The filter’s cutoff frequency may be tuned during the filtering operation. The variable bandwidth FIR filter is designed using the window method.

`vbw =`  
`dsp.VariableBandwidthFIRFilter('PropertyName',PropertyValue, ...)`

returns a variable bandwidth FIR filter System object, `vbw`, with each property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

### Properties

#### **SampleRate**

Input sample rate

Specify the sampling rate of the input in Hertz as a finite numeric scalar. The default is 44.1 kHz. This property is non-tunable.

#### **FilterType**

Filter type

Specify the type of the filter as one of `'Lowpass'` | `'Highpass'` | `'Bandpass'` | `'Bandstop'`. The default is `'Lowpass'`. This property is non-tunable.

#### **FilterOrder**

FIR filter order

Specify the order of the FIR filter as a positive integer scalar. The default is 30. This property is non-tunable.

#### **Window**

Window function

Specify the window function used to design the FIR filter as one of `'Hann'` | `'Hamming'` | `'Chebyshev'` | `'Kaiser'`. The default is `'Hann'`. This property is non-tunable.

#### **KaiserWindowParameter**

Kaiser window parameter

Specify the Kaiser window parameter as a real scalar. This property applies when you set the window property to `'Kaiser'`. The default is 0.5. This property is non-tunable.

### **CutoffFrequency**

Filter cutoff frequency

Specify the filter cutoff frequency in Hz as a real, positive scalar, smaller than the `SampleRate/2`. This property applies if you set the `FilterType` property to 'Lowpass' or 'Highpass'. The default is 512 Hz. This property is tunable.

### **CenterFrequency**

Filter center frequency

Specify the filter center frequency in Hz as a real, positive scalar, smaller than `SampleRate/2`. This property applies when you set the `FilterType` property to 'Bandpass' or 'Bandstop'. The default is 11025 Hz. This property is tunable.

### **Bandwidth**

Filter bandwidth

Specify the filter bandwidth in Hertz as a real, positive scalar, smaller than `SampleRate/2`. This property applies if you set the `FilterType` property to 'Bandpass' or 'Bandstop'. The default is 7680 Hz. This property is tunable.

### **SidelobeAttenuation**

Chebyshev window sidelobe attenuation

Specify the Chebyshev window attenuation as a real, positive scalar in decibels (dB). This property applies if you set the `Window` property to 'Chebyshev'. The default is 60 dB. This property is non-tunable.

## **Methods**

`reset`    Reset internal states of variable bandwidth FIR filter  
`step`     Filter signal using variable bandwidth algorithm

More “Analysis Methods for Filter System Objects” on page 3-2.

**Common to All System Objects**

release	Allow System object property value changes

## Examples

### Filtering through a variable bandwidth bandpass FIR filter

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent step syntax. For example, myObject(x) becomes step(myObject,x).

This example shows you how to tune the center frequency and the bandwidth of the FIR filter.

```
Fs = 44100; % Input sample rate
% Define a bandpass variable bandwidth FIR filter:
vbw = dsp.VariableBandwidthFIRFilter('FilterType','Bandpass',...
    'FilterOrder',100,...
    'SampleRate',Fs,...
    'CenterFrequency',1e4,...
    'Bandwidth',4e3);
tfe = dsp.TransferFunctionEstimator('FrequencyRange','onesided');
aplot = dsp.ArrayPlot('PlotType','Line',...
    'XOffset',0,...
    'YLimits',[-120 5], ...
    'SampleIncrement', 44100/1024,...
    'YLabel','Frequency Response (dB)',...
    'XLabel','Frequency (Hz)',...
    'Title','System Transfer Function');
FrameLength = 1024;
sine = dsp.SineWave('SamplesPerFrame',FrameLength);
for i=1:500
    % Generate input
    x = sine() + randn(FrameLength,1);
    % Pass input through the filter
    y = vbw(x);
    % Transfer function estimation
    h = tfe(x,y);
    % Plot transfer function
    aplot(20*log10(abs(h)))
```

```
% Tune bandwidth and center frequency of the FIR filter
if (i==250)
    vbw.CenterFrequency = 5000;
    vbw.Bandwidth = 2000;
end
end
```

## Algorithms

### FIR Transformations

All transformations assume a lowpass filter of length  $2N+1$ .

Consider an ideal lowpass brickwall filter with normalized cutoff frequency  $\omega_{c1}$ . By taking the inverse Discrete Fourier Transform of the ideal frequency response, and clipping the resulting sequence to length  $2N+1$ , the impulse response is:

$$\begin{aligned} & \text{for } n = 0 \\ & h_{LP}(n) = \frac{\omega_c}{\pi} \cdot w(0) \\ & \text{for } 1 \leq |n| \leq N \\ & h_{LP}(n) = \frac{\sin(\omega_c n)}{\pi n} \cdot w(n) \end{aligned}$$

where  $w(n)$  is the window vector. The lowpass filter coefficients are tuned to a new cutoff frequency  $\omega_{c2}$  as follows:

$$\begin{aligned} & \text{for } n = 0 \\ & h_{LP}(n) = \frac{\omega_{c2}}{\pi} \cdot w(0) \\ & \text{for } 1 \leq |n| \leq N \\ & h_{LP}(n) = \frac{\sin(\omega_{c2} n)}{\pi n} \cdot w(n) \end{aligned}$$

There is no need to recompute the window every time you tune the cutoff frequency.

Assuming a lowpass filter with normalized 6-dB cutoff frequency  $\omega_c$ , a highpass filter with the same cutoff frequency can be obtained by taking the complementary of the lowpass frequency response:  $H_{HP}(e^{j\omega}) = 1 - H_{LP}(e^{j\omega})$

Taking the inverse discrete Fourier transform of the above response, we get the following highpass filter coefficients:

$$\begin{aligned} & \text{for } n = 0 \\ & h_{hp}(n) = 1 - h_{LP}(n) \\ & \text{for } 1 \leq |n| \leq N \\ & h_{hp}(n) = -h_{LP}(n) \end{aligned}$$

A bandpass filtered centered at frequency  $\omega_0$  can be obtained by shifting the lowpass response:

$$H_{BP}(e^{j\omega}) = H_{LP}(e^{j(\omega-\omega_0)}) + H_{LP}(e^{j(\omega+\omega_0)})$$

The bandwidth of the resulting bandpass filter is  $2\omega_c$ , as measured between the two cutoff frequencies of the bandpass filter. The equivalent bandpass filter coefficients are then:

$$h_{BP}(n) = (e^{j\omega_0 n} + e^{-j\omega_0 n})h_{LP}(n)$$

which can be written as:

$$h_{BP}(n) = 2\cos(\omega_0 n)h_{LP}(n)$$

We can transform a lowpass filter to a bandstop filter by combining the highpass and bandpass transformations. That is, first make the filter bandpass by shifting the lowpass response, and then invert in to get a bandstop response centered at  $\omega_0$ .

$$H_{BS}(e^{j\omega}) = 1 - (H_{LP}(e^{j(\omega-\omega_0)}) + H_{LP}(e^{j(\omega+\omega_0)}))$$

This yields the following coefficients:

*for*  $n = 0$

$$h_{BS}(n) = 1 - 2\cos(\omega_0 n)h_{LP}(n)$$

*for*  $1 \leq |n| \leq N$

$$h_{BS}(n) = -2\cos(\omega_0 n)h_{LP}(n)$$

The transformations highlighted above can be combined to transform a lowpass filter to a lowpass, highpass, bandpass or bandstop filter with arbitrary cutoffs.

For example, to transform a lowpass filter with cutoff  $\omega_{c1}$  to a highpass with cutoff  $\omega_{c2}$ , you first apply the lowpass-to-lowpass transformation to get a lowpass filter with cutoff  $\omega_{c2}$ , and then apply the lowpass-to-highpass transformation to get the highpass with cutoff  $\omega_{c2}$ .

To get a bandpass filter with center frequency  $\omega_0$  and bandwidth  $\beta$ , we first apply the lowpass-to-lowpass transformation to go from a lowpass with cutoff  $\omega_c$  to a lowpass with cutoff  $\beta/2$ , and then apply the lowpass-to-bandpass transformation to get the desired bandpass filter. The same approach can be applied to a bandstop filter.

## reset

**System object:** dsp.VariableBandwidthFIRFilter

**Package:** dsp

Reset internal states of variable bandwidth FIR filter

## Syntax

reset(vbw)

## Description

reset(vbw) resets the filter states of the variable bandwidth FIR filter object, vbw, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the step method applies the variable bandwidth FIR filter object to nonzero input data, the states may be nonzero. Invoking the step method again without first invoking the reset method may produce different outputs for an identical input.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(\text{vbw}, x)$  filters the real or complex input signal  $X$  using the variable bandwidth FIR filter, `vbw`, to produce the output  $Y$ . The variable bandwidth FIR filter object operates on each channel, which means every column of the input signal independently over successive calls to `step` method.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.VariableBandwidthIIRFilter System object

**Package:** dsp

Variable bandwidth IIR filter

## Description

The `VariableBandwidthIIRFilter` object filters each channel of the input using IIR filter implementations. It does so while having the capability of tuning the bandwidth. This filter supports double and single precision inputs.

To filter each channel of the input:

- 1 Define and set up your variable bandwidth IIR filter. See “Construction” on page 4-1799.
- 2 Call `step` to filter each channel of the input according to the properties of `dsp.VariableBandwidthIIRFilter`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`vbwIIR = dsp.VariableBandwidthIIRFilter` returns a System object, `vbwIIR`, which independently filters each channel of the input over successive calls to the `step` method. This System object uses a specified IIR filter implementation. The filter’s passband frequency may be tuned during the filtering operation. The variable bandwidth IIR filter is designed using the elliptical method. The filter is tuned using IIR spectral transformations based on allpass filters.

`vbwIIR = dsp.VariableBandwidthIIRFilter('PropertyName',PropertyValue, ...)`  
returns a variable bandwidth IIR filter System object, `vbwIIR`, with each property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### SampleRate

Input sample rate

Specify the sampling rate of the input in Hertz as a finite numeric scalar. The default is 44.1 kHz. This property is non-tunable.

### FilterType

Filter type

Specify the type of the filter as one of 'Lowpass' | 'Highpass' | 'Bandpass' | 'Bandstop'. The default is 'Lowpass'. This property is non-tunable.

### FilterOrder

IIR filter order

Specify the order of the IIR filter as a positive integer scalar. The default is 8. This property is non-tunable.

### PassbandFrequency

Filter passband frequency

Specify the filter passband frequency in Hz as a real, positive scalar, smaller than the `SampleRate/2`. This property applies when you set the `FilterType` property to 'Lowpass' or 'Highpass'. The default is 512 Hz. This property is tunable.

### CenterFrequency

Filter center frequency

Specify the filter center frequency in Hz as a real, positive scalar, smaller than  $\text{SampleRate}/2$ . This property applies when you set the `FilterType` property to 'Bandpass' or 'Bandstop'. The default is 11025 Hz. This property is tunable.

### **Bandwidth**

Filter bandwidth

Specify the filter bandwidth in Hertz as a real, positive scalar, smaller than  $\text{SampleRate}/2$ . This property applies when you set the `FilterType` property to 'Bandpass' or 'Bandstop'. The default is 7680 Hz. This property is tunable.

### **PassbandRipple**

Filter passband ripple

Specify the filter passband ripple as a real, positive scalar in decibels (dB). The default is 1 dB. This property is non-tunable.

### **StopbandAttenuation**

Filter Stopband attenuation

Specify the filter stopband attenuation as a real, positive scalar in decibels (dB). The default is 60 dB. This property is non-tunable.

## **Methods**

`reset`    Reset internal states of variable bandwidth IIR filter

`step`    Filter signal using variable bandwidth algorithm

More “Analysis Methods for Filter System Objects” on page 3-2.

<b>Common to All System Objects</b>	
<code>release</code>	Allow System object property value changes

## **Examples**

### Filtering Through a Variable Bandwidth Bandpass IIR Filter

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent step syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

This examples shows you how to tune the center frequency and bandwidth of the IIR filter.

```
Fs = 44100; % Input sample rate
% Define a bandpass variable bandwidth IIR filter:
vbwiir = dsp.VariableBandwidthIIRFilter('FilterType','Bandpass',...
                                       'FilterOrder',8,...
                                       'SampleRate',Fs,...
                                       'CenterFrequency',1e4,...
                                       'Bandwidth',4e3);

tfe = dsp.TransferFunctionEstimator('FrequencyRange','onesided');
aplot = dsp.ArrayPlot('PlotType','Line',...
                     'XOffset',0,...
                     'YLimits',[-120 5], ...
                     'SampleIncrement', 44100/1024,...
                     'YLabel','Frequency Response (dB)',...
                     'XLabel','Frequency (Hz)',...
                     'Title','System Transfer Function');

FrameLength = 1024;
sine = dsp.SineWave('SamplesPerFrame',FrameLength);
for i = 1:500
    % Generate input
    x = sine() + randn(FrameLength,1);
    % Pass input through the filter
    y = vbwiir(x);
    % Transfer function estimation
    h = tfe(x,y);
    % plot transfer function
    aplot(20*log10(abs(h)))
    % Tune bandwidth and center frequency of the IIR filter
    if (i==250)
        vbwiir.CenterFrequency = 5000;
        vbwiir.Bandwidth = 2000;
    end
end
end
```

## Algorithms

This filter covers frequency transformations. A lowpass IIR prototype is designed, using the elliptical method by specifying its order, passband frequency, passband ripple and stopband attenuation. The passband ripple and stopband attenuation are equal to the values of the `PassbandRipple` and `StopbandAttenuation` properties. The prototype passband frequency is set to 0.5. If the `FilterType` property is 'Lowpass' or 'Highpass', the prototype's order is equal to the value of `FilterOrder`. If the `FilterType` property is 'Bandpass' or 'Bandstop', the prototype filter order is equal to `FilterOrder/2`. The prototype is a Direct Form II Transposed cascade of second-order sections (Biquad filter). The prototype is transformed into the desired filter using

the algorithms used in “Digital Frequency Transformations”. Each prototype SOS section is transformed separately. When `FilterType` is 'Lowpass' or 'Highpass', the resulting filter remains a Direct Form II Transposed cascade of second order sections. If the `FilterType` is 'Bandpass' or 'Bandstop', the resulting filter is a cascade of Direct Form II Transposed cascade of fourth order sections.

**Introduced in R2014a**

## reset

**System object:** dsp.VariableBandwidthIIRFilter

**Package:** dsp

Reset internal states of variable bandwidth IIR filter

## Syntax

`reset(vbwIIR)`

## Description

`reset(vbwIIR)` resets the filter states of the variable bandwidth IIR filter object, `vbwIIR`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the variable bandwidth IIR filter object to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

# step

**System object:** dsp.VariableBandwidthIIRFilter

**Package:** dsp

Filter signal using variable bandwidth algorithm

## Syntax

$Y = \text{step}(\text{vbwIIR}, x)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(\text{vbwIIR}, x)$  filters the real or complex input signal  $X$  using the variable bandwidth IIR filter, `vbwIIR`, to produce the output  $Y$ . The variable bandwidth IIR filter object operates on each channel, which means every column of the input signal independently over successive calls to `step` method.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# **dsp.VariableFractionalDelay System object**

**Package:** dsp

Delay input by time-varying fractional number of sample periods

## **Description**

The `dsp.VariableFractionalDelay` System object delays the input signal by a specified number of fractional samples along each channel of the input. The object can also concurrently compute multiple delayed versions (taps) of the same signal. For an example, see “Signal Delay Using Multitap Fractional Delay” on page 4-1825.

The object interpolates the input signal to obtain new samples at noninteger sampling intervals. You can set the “InterpolationMethod” on page 4-0 property to 'Linear', 'FIR', or 'Farrow'. The object supports time-varying delay values. That is, the delay value can vary within a frame from sample to sample. You can also specify the maximum value of the delay by using the “MaximumDelay” on page 4-0 property. Delay values greater than the maximum are clipped to the maximum.

To delay the input by a time-varying fractional number of sample periods:

- 1 Create the `dsp.VariableFractionalDelay` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

## **Creation**

### **Syntax**

```
vfd = dsp.VariableFractionalDelay  
vfd = dsp.VariableFractionalDelay(Name,Value)
```

## Description

`vfd = dsp.VariableFractionalDelay` creates a variable fractional delay System object that delays a discrete-time input by a time-varying fractional number of sample periods, as specified by the second input.

`vfd = dsp.VariableFractionalDelay(Name, Value)` creates a variable fractional delay System object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `dsp.VariableFractionalDelay('MaximumDelay',50);`

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects (MATLAB)*.

### InterpolationMethod — Method of interpolation

'Linear' (default) | 'FIR' | 'Farrow'

Method of interpolation, specified as one of the following. Using this method, the object interpolates the signal to obtain new samples at noninteger sampling intervals.

- 'Linear' -- The object uses linear interpolation.
- 'FIR' -- The object implements a polyphase FIR interpolation filter to interpolate values.
- 'Farrow' -- The object uses the LaGrange method to interpolate values.

For more details on these methods, see “Algorithms” on page 4-1833.

### FilterHalfLength — Half-length of FIR interpolation filter

4 (default) | positive integer in the range [1 65535]

Half-length of FIR interpolation filter, specified as a positive integer in the range [1 65535].

For periodic signals, a larger value of this property, which indicates a higher order filter, yields a better estimate of the delayed output sample. A property value of 4 to 6, which corresponds to a 7th-order to 11th-order filter, is usually adequate.

**Dependencies**

This property applies only when you set the “InterpolationMethod” on page 4-0 property to 'FIR'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | fi

**FilterLength — Length of Farrow filter**

4 (default) | integer greater than or equal to 2

Length of the FIR filter implemented using the Farrow structure, specified as an integer greater than or equal to 2. If the length equals 2, the filter performs linear interpolation.

Example: 4

Example: 10

**Dependencies**

This property applies only when you set the “InterpolationMethod” on page 4-0 property to 'Farrow'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**InterpolationPointsPerSample — Number of interpolation points per input sample**

10 (default) | positive integer in the range [2, 65,535]

Number of interpolation points per input sample at which a unique FIR interpolation filter is computed, specified as a positive integer in the range [2 65535].

Example: 20

Example: 5

**Dependencies**

This property applies only when you set the “InterpolationMethod” on page 4-0 property to 'FIR'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Bandwidth — Normalized input bandwidth**

1 (default) | real scalar in the range (0 1]

Normalized input bandwidth at which to constrain the interpolated output samples, specified as a real scalar in the range (0 1]. A value of 1 equals the Nyquist frequency, or half the sampling frequency,  $F_s$ . Use this property to take advantage of the bandlimited frequency content of the input. For example, if the input signal does not have frequency content above  $F_s/4$ , you can specify a value of 0.5.

Example: 0.5

Example: 0.8

### **Dependencies**

This property applies only when you set the “InterpolationMethod” on page 4-0 property to 'FIR'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

### **InitialConditions — Initial values in the memory**

0 (default) | scalar | 1-by- $N$ -by- $D$  array | 1-by- $N$ -by- $(D+L)$  array

Initial values in the memory of the object, specified as a scalar or an array. The dimensions of this property can vary depending on whether you want fixed or time-varying initial conditions. The object treats each of the  $N$  input columns as a frame containing  $M$  sequential time samples from an independent channel.

For an  $M$ -by- $N$  input matrix,  $U$ , you can set the `InitialConditions` property as follows :

- To specify fixed initial conditions, specify `InitialConditions` as a scalar value. The object initializes every sample of every channel in memory using the value you specify.
- The dimensions you specify for time-varying initial conditions depend on the value of the “InterpolationMethod” on page 4-0 property.
  - When `InterpolationMethod` is set to 'Linear', specify `InitialConditions` as a 1-by- $N$ -by- $D$ , where  $D$  is the value of the “MaximumDelay” on page 4-0 property.

- When `InterpolationMethod` is set to 'FIR' or 'Farrow', specify `InitialConditions` as a 1-by- $N$ -by- $(D+L)$  array, where  $D$  is the value of the `MaximumDelay` property. For FIR interpolation,  $L$  is the value of the `FilterHalfLength` property. For Farrow interpolation,  $L$  equals the floor of half the value of the `FilterLength` property: `floor(FilterLength/2)`.

Example: 1

Example: `randn(1,3,104)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **MaximumDelay — Maximum delay**

100 (default) | integer in the range [0 65535]

Maximum delay that the object can produce for any sample, specified as an integer in the range [0 65535]. The object clips input delay values greater than `MaximumDelay` to that maximum value.

Example: 100

Example: 10

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **FIRSmallDelayAction — Action to take for small input delay values when object uses FIR interpolation method**

'Clip to the minimum value necessary for centered kernel' (default) |  
'Switch to linear interpolation if kernel cannot be centered'

Action taken for small input delay values when the object uses the FIR interpolation method.

### **Dependencies**

This property applies only when you set the `InterpolationMethod` property to 'FIR'.

### **FarrowSmallDelayAction — Action to take for small input delay values when object uses Farrow interpolation method**

'Clip to the minimum value necessary for centered kernel' (default) |  
'Use off-centered kernel'

Action taken for small input delay values when the object uses the farrow interpolation method.

### **Dependencies**

This property applies only when you set the InterpolationMethod property to 'Farrow'.

### **Fixed-Point Properties**

#### **RoundingMethod — Rounding method for fixed-point operations**

'Zero' (default) | 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest'

Rounding mode for fixed-point operations, specified as one of the following:

- 'Zero'
- 'Ceiling'
- 'Convergent'
- 'Floor'
- 'Nearest'
- 'Round'
- 'Simplest'

For more details, see rounding mode.

#### **OverflowAction — Overflow action for fixed-point operations**

'Wrap' (default) | 'Saturate'

Overflow action for fixed-point operations, specified as one of the following:

- 'Wrap' -- The object wraps the result of its fixed-point operations.
- 'Saturate' -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

#### **CoefficientsDataType — Data type of the coefficients**

'Same word length as input' (default) | 'Custom'

Data type of the coefficients in this object, specified as one of the following:

- 'Same word length as input' -- The object specifies the coefficients word length to be the same as that of the input. The fraction length is computed to get the best possible precision.
- 'Custom' -- The coefficients data type is specified as a custom numeric type through the "CustomCoefficientsDataType" on page 4-0 property.

For more information on the coefficients data type this object uses, see the "Fixed Point" on page 4-0 section.

### **CustomCoefficientsDataType – Coefficient word and fraction lengths**

numericity([],32) (default)

Coefficient word and fraction lengths, specified as an autosigned numeric type with a word length of 32.

Example: numericity([],16)

#### **Dependencies**

This property applies only when you set "CoefficientsDataType" on page 4-0 to 'Custom'.

### **ProductPolynomialValueDataType – Data type of the product polynomial value**

'Same as first input' (default) | 'Custom'

Data type of the product polynomial value, specified as one of the following:

- 'Same as first input' -- The object specifies the product polynomial value data type to be the same as that of the data input.
- 'Custom' -- The product polynomial value data type is specified as a custom numeric type through the "CustomProductPolynomialValueDataType" on page 4-0 property.

For more information on the product polynomial value data type this object uses, see the "Fixed Point" on page 4-0 section.

#### **Dependencies**

This property applies when you set "InterpolationMethod" on page 4-0 to 'Farrow'.

### **CustomProductPolynomialValueDataType – Word and fraction lengths of product polynomial value**

numericity([],32,10) (default)

Word and fraction lengths of the product polynomial value, specified as an autosigned numeric type with a word length of 32 and a fraction length of 10.

Example: `numericType([],30,5)`

### Dependencies

This property applies only when you set “InterpolationMethod” on page 4-0 to 'Farrow' and “ProductPolynomialValueDataType” on page 4-0 to 'Custom'.

### AccumulatorPolynomialValueDataType — Data type of the accumulator polynomial value

'Same as first input' (default) | 'Custom'

Data type of the accumulator polynomial value, specified as one of the following:

- 'Same as first input' -- The object specifies the accumulator polynomial value data type to be the same as that of the data input.
- 'Custom' -- The accumulator polynomial value data type is specified as a custom numeric type through the “CustomAccumulatorPolynomialValueDataType” on page 4-0 property.

For more information on the accumulator polynomial value data type that this object uses, see the “Fixed Point” on page 4-0 section.

### Dependencies

This property applies when you set “InterpolationMethod” on page 4-0 to 'Farrow'.

### CustomAccumulatorPolynomialValueDataType — Word and fraction lengths of accumulator polynomial value

`numericType([],32,10)` (default)

Word and fraction lengths of the accumulator polynomial value, specified as an autosigned numeric type with a word length of 32 and a fraction length of 10.

Example: `numericType([],30,5)`

### Dependencies

This property applies only when you set “InterpolationMethod” on page 4-0 to 'Farrow' and “AccumulatorPolynomialValueDataType” on page 4-0 to 'Custom'.

### **MultiplicandPolynomialValueDataType — Data type of multiplicand polynomial value**

'Same as first input' (default) | 'Custom'

Data type of multiplicand polynomial value, specified as one of the following:

- 'Same as first input' -- The object specifies the multiplicand polynomial value data type to be the same as that of the data input.
- 'Custom' -- The multiplicand polynomial value data type is specified as a custom numeric type through the “CustomMultiplicandPolynomialValueDataType” on page 4-0 property.

For more information on the multiplicand polynomial value data type that this object uses, see the “Fixed Point” on page 4-0 section.

#### **Dependencies**

This property applies when you set “InterpolationMethod” on page 4-0 to 'Farrow'.

### **CustomMultiplicandPolynomialValueDataType — Word and fraction lengths of multiplicand polynomial value**

numericType([],32,10) (default)

Word and fraction lengths of the multiplicand polynomial value, specified as an autosigned numeric type with a word length of 32 and a fraction length of 10.

Example: numericType([],30,5)

#### **Dependencies**

This property applies only when you set “InterpolationMethod” on page 4-0 to 'Farrow' and “MultiplicandPolynomialValueDataType” on page 4-0 to 'Custom'.

### **ProductDataType — Data type of product output**

'Same as first input' (default) | 'Custom'

Data type of the product output in this object, specified as one of the following:

- 'Same as first input' -- The object specifies the product output data type to be the same as that of the data input.
- 'Custom' -- The product output data type is specified as a custom numeric type through the “CustomProductDataType” on page 4-0 property.

For more information on the product output data type, see “Multiplication Data Types” and the “Fixed Point” on page 4-0 section.

### **CustomProductDataType — Word and fraction lengths of product data type**

`numericType([],32,10)` (default)

Word and fraction lengths of the product data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 10.

Example: `numericType([],30,5)`

#### **Dependencies**

This property applies only when you set “ProductDataType” on page 4-0 to 'Custom'.

### **AccumulatorDataType — Data type of accumulation operation**

'Same as product' (default) | 'Same as first input' | 'Custom'

Data type of an accumulation operation in this object, specified as one of the following:

- 'Same as product' -- The object specifies the accumulator data type to be the same as that of the product output data type.
- 'Same as first input' -- The object specifies the accumulator data type to be the same as that of the data input.
- 'Custom' -- The accumulator data type is specified as a custom numeric type through the “CustomAccumulatorDataType” on page 4-0 property.

For more information on the accumulator data type this object uses, see the “Fixed Point” on page 4-0 .

### **CustomAccumulatorDataType — Word and fraction lengths of accumulator data type**

`numericType([],32,10)` (default)

Word and fraction lengths of the accumulator data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 10.

Example: `numericType([],30,5)`

#### **Dependencies**

This property applies only when you set “AccumulatorDataType” on page 4-0 to 'Custom'.

**OutputDataType — Data type of object output**

'Same as accumulator' (default) | 'Same as first input' | 'Custom'

Data type of the object output, specified as one of the following:

- 'Same as accumulator' -- The object specifies the output data type to be the same as that of the accumulator output data type.
- 'Same as first input' -- The object specifies the output data type to be the same as that of the data input.
- 'Custom' -- The output data type is specified as a custom numeric type through the "CustomOutputDataType" on page 4-0 property.

For more information on the output data type this object uses, see the "Fixed Point" on page 4-0 section.

**CustomOutputDataType — Word and fraction lengths of output data type**

numerictype([],32,10) (default)

Word and fraction lengths of the output data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 10.

Example: numerictype([],30,5)

**Dependencies**

This property applies only when you set "OutputDataType" on page 4-0 to 'Custom'.

## Usage

---

**Note** For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

## Syntax

`vfdOut = vfd(input,d)`

## Description

`vfdOut = vfd(input, d)` delays the input to the variable fractional delay System object by `d` samples. `d` must be less than or equal to the value you specify in the “MaximumDelay” on page 4-0 property of the object.

Delay values greater than the specified maximum delay are clipped appropriately. Each column of the input is treated as an independent channel.

## Input Arguments

### **input** — Data input

vector | matrix

Data input, specified as a vector or matrix. The data input must have the same data type as the delay input.

This object supports variable-size input signal. That is, you can change the input frame size (number of rows) even after calling the algorithm. However, the number of channels must remain constant. For an example, see “Variable-Size Signal Support for Input and Delay Signals” on page 4-1831.

Example: `[1 2 3 4;5 1 4 2;2 6 2 3;1 2 3 2;3 4 5 6;1 2 3 1]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

### **d** — Delay input

scalar | vector | matrix | *N*-D array

Delay input, specified as a scalar, vector, matrix, or *N*-D array. The delay can be an integer or a fractional value. When the delay input is a fractional value, the object interpolates the signal to obtain new samples at noninteger sampling intervals. The delay input must have the same data type as the data input.

This object supports variable-size delay signal. That is, you can change one or both of the dimensions of the delay signal after calling the algorithm. However, the object must make sure that the resulting number of output channels remains constant. For an example, see “Variable-Size Signal Support for Input and Delay Signals” on page 4-1831.

The table shows the effect of the dimension of the delay input on the data input.

<b>Data Input</b>	<b>Delay Input</b>	<b>Output</b>	<b>Effect of Delay Input on Data Input</b>
$N$ -by-1 (one channel with frame size equal to $N$ )	scalar	$N$ -by-1	One delay value applied to the input channel
$N$ -by-1 (one channel with frame size equal to $N$ )	$N$ -by-1	$N$ -by-1	Delay value varies within the frame from sample to sample
$N$ -by-1 (one channel with frame size equal to $N$ )	1-by- $P$	$N$ -by- $P$	$P$ taps per channel. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector.
$N$ -by-1 (one channel with frame size equal to $N$ )	$N$ -by- $P$	$N$ -by- $P$	$P$ taps per channel. In addition, delay varies within each frame from sample to sample.
$N$ -by- $L$ ( $L$ channels with frame size equal to $N$ )	scalar	$N$ -by- $L$	One delay value applied to all input channels
$N$ -by- $L$ ( $L$ channels with frame size equal to $N$ )	1-by- $L$	$N$ -by- $L$	Unique delay value for each input channel
$N$ -by- $L$ ( $L$ channels with frame size equal to $N$ )	$N$ -by-1	$N$ -by- $L$	Delay value varies within the frame from sample to sample. Same set of delay values for all channels.

<b>Data Input</b>	<b>Delay Input</b>	<b>Output</b>	<b>Effect of Delay Input on Data Input</b>
<i>N</i> -by- <i>L</i> ( <i>L</i> channels with frame size equal to <i>N</i> )	<i>N</i> -by- <i>L</i>	<i>N</i> -by- <i>L</i>	Delay value varies within the frame from sample to sample. Different delay values for each input channel.
<i>N</i> -by- <i>L</i> ( <i>L</i> channels with frame size equal to <i>N</i> )	1-by-1-by- <i>P</i>	<i>N</i> -by- <i>L</i> -by- <i>P</i>	<i>L</i> channels. <i>P</i> taps per channel. Same delay for all channels.
<i>N</i> -by- <i>L</i> ( <i>L</i> channels with frame size equal to <i>N</i> )	1-by- <i>L</i> -by- <i>P</i>	<i>N</i> -by- <i>L</i> -by- <i>P</i>	<i>L</i> channels. <i>P</i> taps per channel. Delay varies across channels.
<i>N</i> -by- <i>L</i> ( <i>L</i> channels with frame size equal to <i>N</i> )	<i>N</i> -by-1-by- <i>P</i>	<i>N</i> -by- <i>L</i> -by- <i>P</i>	<i>L</i> channels. <i>P</i> taps per channel. Delay varies within the frame from sample to sample. Same set of delay values for each channel.
<i>N</i> -by- <i>L</i> ( <i>L</i> channels with frame size equal to <i>N</i> )	<i>N</i> -by- <i>L</i> -by- <i>P</i>	<i>N</i> -by- <i>L</i> -by- <i>P</i>	<i>L</i> channels. <i>P</i> taps per channel. Delay varies within the frame from sample to sample. Different set of delay values for each channel.

Example: [2 3 4 5]

Example: [2.5]

Example: [5.6]

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## Output Arguments

### **vfdOut** — Delayed output

vector | matrix

Delayed output, returned as a vector or matrix. The size, data type, and complexity of the output match the size, data type, and complexity of the data input.

The table shows how the data input and delay input dimensions affect the output dimensions:

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
$N$ -by-1 (one channel with frame size equal to $N$ )	scalar	$N$ -by-1	One delay value applied to the input channel
$N$ -by-1 (one channel with frame size equal to $N$ )	$N$ -by-1	$N$ -by-1	Delay value varies within the frame from sample to sample
$N$ -by-1 (one channel with frame size equal to $N$ )	1-by- $P$	$N$ -by- $P$	$P$ taps per channel. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector.
$N$ -by-1 (one channel with frame size equal to $N$ )	$N$ -by- $P$	$N$ -by- $P$	$P$ taps per channel. In addition, delay varies within each frame from sample to sample.

<b>Data Input</b>	<b>Delay Input</b>	<b>Output</b>	<b>Effect of Delay Input on Data Input</b>
<i>N</i> -by- <i>L</i> ( <i>L</i> channels with frame size equal to <i>N</i> )	scalar	<i>N</i> -by- <i>L</i>	One delay value applied to all input channels
<i>N</i> -by- <i>L</i> ( <i>L</i> channels with frame size equal to <i>N</i> )	1-by- <i>L</i>	<i>N</i> -by- <i>L</i>	Unique delay value for each input channel
<i>N</i> -by- <i>L</i> ( <i>L</i> channels with frame size equal to <i>N</i> )	<i>N</i> -by-1	<i>N</i> -by- <i>L</i>	Delay value varies within the frame from sample to sample. Same set of delay values for all channels.
<i>N</i> -by- <i>L</i> ( <i>L</i> channels with frame size equal to <i>N</i> )	<i>N</i> -by- <i>L</i>	<i>N</i> -by- <i>L</i>	Delay value varies within the frame from sample to sample. Different delay values for each input channel.
<i>N</i> -by- <i>L</i> ( <i>L</i> channels with frame size equal to <i>N</i> )	1-by-1-by- <i>P</i>	<i>N</i> -by- <i>L</i> -by- <i>P</i>	<i>L</i> channels. <i>P</i> taps per channel. Same tap for all channels.
<i>N</i> -by- <i>L</i> ( <i>L</i> channels with frame size equal to <i>N</i> )	1-by- <i>L</i> -by- <i>P</i>	<i>N</i> -by- <i>L</i> -by- <i>P</i>	<i>L</i> channels. <i>P</i> taps per channel. Taps vary across channels.
<i>N</i> -by- <i>L</i> ( <i>L</i> channels with frame size equal to <i>N</i> )	<i>N</i> -by-1-by- <i>P</i>	<i>N</i> -by- <i>L</i> -by- <i>P</i>	<i>L</i> channels. <i>P</i> taps per channel. Delay varies within the frame from sample to sample. Same set of delay values for each channel.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
$N$ -by- $L$ ( $L$ channels with frame size equal to $N$ )	$N$ -by- $L$ -by- $P$	$N$ -by- $L$ -by- $P$	$L$ channels. $P$ taps per channel. Delay varies within the frame from sample to sample. Different set of delay values for each channel.

Example: [0 0 0 0;0 0 0 0;1 0 0 0;5 2 0 0;2 1 3 0;1 6 4 4]

Example: [0 0 0 0;0 0 0 0;0.5 1.0 1.5 2.0;3 1.5 3.5 3.0;3.5 3.5 3.0 2.5;1.5 4.0 2.5 2.5]

Example: [0 0 0 0;0 0 0 0;0 0 0 0;0 0 0 0;0 0 0 0;0.4 0.8 1.2 1.6]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to dsp.VariableFractionalDelay

`info` Characteristic information about valid delay range  
`generatehdl` Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

### Common to All System Objects

`step` Run System object algorithm  
`release` Release resources and allow changes to System object property values and input characteristics  
`reset` Reset internal states of System object

## Examples

### Signal Delay using Variable Fractional Delay

**Note:** If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Delay a signal by a varying fractional number of sample periods.

```
sr = dsp.SignalSource;  
vfd = dsp.VariableFractionalDelay;  
sink = dsp.SignalSink;
```

```
for ii = 1:10  
    delayedsig = vfd(sr(), ii/10);  
    sink(delayedsig);  
end
```

```
sigd = sink.Buffer;
```

The output `sigd` corresponds to the values of the delayed signal that are sampled at fixed-time intervals. To plot the time instants at which the amplitudes of signal samples are constant, treat the signals as the sampling instants.

```
stem(sr.Signal, 1:10, 'b')  
hold on;  
stem(sigd.', 1:10, 'r');  
legend('Original signal', ...  
       'Variable fractional delayed signal', ...  
       'Location','best')
```

### Signal Delay Using Multitap Fractional Delay

**Note:** If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Delay the input signal using the `dsp.VariableFractionalDelay` object. Each delay value is unique and can vary from sample to sample within a frame, and can vary across channels. You can compute multiple delayed versions of the same input signal concurrently by passing a delay input with the appropriate dimension.

Consider the input to be a random signal with one channel and a frame size of 10. Apply a delay of 4.8 and 8.2 samples concurrently.

```
vfd = dsp.VariableFractionalDelay
```

```
vfd =  
dsp.VariableFractionalDelay with properties:
```

```
    InterpolationMethod: 'Linear'  
    InitialConditions: 0  
    MaximumDelay: 100
```

```
Show all properties
```

```
in = randn(10,1)
```

```
in = 10×1
```

```

  0.7535  0.4301
```

```
-0.0065    1.5746
```

Each channel in the output is delayed by 4.8 and 8.2 samples, respectively. The object uses the 'Linear' interpolation method to compute the delayed value. For more details, see 'Algorithms' in the `dsp.VariableFractionalDelay` object page.

For the same delay vector, if the input has 2 channels, each element of the delay vector is applied on the corresponding channel in the input.

```
release(vfd);
in = randn(10,2)
```

```
in = 10×2

To compute multiple delayed versions of the two-dimensional input signal, pass the delay vector as a three-dimensional array. The third dimension contains the taps or delays to

apply on the signal. If you pass a non-singleton third dimension (1-by-1-by- $P$ ), where  $P$  represents the number of taps, the same tap is applied across all the channels. Pass the delays [4.8 8.2] in the third dimension.

```
clear delayVec;
delayVec(1,1,1) = 4.8;
delayVec(1,1,2) = 8.2;
whos delayVec
```

Name	Size	Bytes	Class	Attributes
delayVec	1x1x2	16	double	

delayVec is a 1-by-1-by-2 array. Pass the two-dimensional input to the dsp.VariableFractionalDelay object with this delay vector.

```
release(vfd);
outcase3 = vfd(in,delayVec)
```

```
outcase3 =
outcase3(:,:,1) =

     0     0

```

```
2.1580 -0.8317
```

```
whos outcase3
```

Name	Size	Bytes	Class	Attributes
outcase3	10x2x2	320	double	

`outcase3(:, :, 1)` represents the input signal delayed by 4.8 samples. `outcase3(:, :, 2)` represents the input signal delayed by 8.2 samples. The same delay is applied across all the channels.

In addition, if you pass a non-singleton second dimension (1-by- $L$ -by- $P$ ), where  $L$  is the number of input channels, taps vary across channels. Apply the delay vectors [2.3 3.5] and [4.4 5.6] to compute the two delayed versions of the input signal.

```
clear delayVec;
delayVec(1,1,1) = 2.3;
delayVec(1,2,1) = 3.5;
delayVec(1,1,2) = 4.4;
delayVec(1,2,2) = 5.6;
whos delayVec
```

Name	Size	Bytes	Class	Attributes
delayVec	1x2x2	32	double	

```
release(vfd);
outcase4 = vfd(in,delayVec)
```

```
outcase4 =
outcase4(:, :, 1) =

     1.4090  0.2939

```

Delay varies across each element in a channel. Same set of delay values apply across all channels. `delayVec(:, 1, 1)` applies to the first delayed signal and `delayVec(:, 1, 2)` applies to the second delayed signal.

### Variable-Size Signal Support for Input and Delay Signals

`dsp.VariableFractionalDelay` System object supports variable-size input and delay signals. That is, you can change the dimension of the input signal and the delay signal even after calling the algorithm. You can change the dimensions of one or both the signals simultaneously. Together, they must make sure that the number of output channels (number of columns) remains constant.

### Variable-Size Support for Input Signal

The number of samples in each frame of the input signal can change. However, the number of input channels must remain constant.

Create a `dsp.VariableFractionalDelay` object. Pass an input signal of size [256 1] and a delay of 1.4 to the object algorithm. In subsequent calls to the algorithm, change the input frame size to 128, 512, and 64, respectively

```
vfd = dsp.VariableFractionalDelay;  
vfd(randn(256,1),1.4);  
vfd(randn(128,1),1.4);  
vfd(randn(512,1),1.4);  
vfd(randn(64,1),1.4);
```

The output frame size (number of rows) changes according to the input frame size. The number of output channels in each of these cases is 1.

To change the number of input channels, release the object.

```
release(vfd);
```

Call the algorithm with a two-channel input and vary the input frame size in subsequent calls.

```
vfd(randn(256,2),1.4);  
vfd(randn(128,2),1.4);
```

### Variable-Size Support for Delay Signal

In addition to the input, the delay signal can also vary. That is, you can change one or both of the dimensions of the delay signal after calling the algorithm. However, the object must make sure that the resulting number of output channels remains constant. The delay signal can be a scalar, vector, matrix, or an N-D array.

```
release(vfd);  
vfd(randn(512,2),randn(512,2));  
vfd(randn(128,2),[1.4 1.7]);  
vfd(randn(256,2),randn(256,1));  
vfd(randn(128,2),1.4);
```

In each of these cases, the number of output channels is 2. To apply different delays on the input signal, release the object.

```
release(vfd);  
vfd(randn(256,1),randn(256,7));  
vfd(randn(512,1),randn(512,7));  
vfd(randn(100,1),randn(100,7));  
vfd(randn(100,1),randn(1,7));
```

The output in each of these cases is [256 7], [512 7], [100 7], and [100 7], respectively.

- “Fractional Delay Filters Using Farrow Structures”

## Algorithms

When you specify a fractional delay value, the algorithm uses a linear, FIR, or Farrow interpolation method to interpolate signal values at noninteger sample intervals.

### Linear Interpolation Mode

For noninteger delays, at each sample time, the linear interpolation method uses the two samples in memory nearest to the specified delay to compute a value for the sample at that time.

For a vector data input, the output vector,  $y$ , is computed using the following relation:

$$\begin{aligned} v_i &= \text{floor}(v) \\ v_f &= v - v_i \\ y(i) &= U(i - v_i - 1) * v_f + U(i - v_i) * (1 - v_f) \end{aligned}$$

where,

- $i$  -- Index of the current sample
- $v$  -- Fractional delay
- $v_i$  -- Integer part of the delay
- $v_f$  -- Fractional part of the delay
- $U$  -- Input data vector
- $y$  -- Output data vector
- $U(i - v_i)$ ,  $U(i - v_i - 1)$  -- Two samples in memory nearest to the specified delay
- $i - v_i$  -- Distance, in samples, between the current index and the nearest point in the interpolation line.

The variable fractional delay stores the  $D_{max} + 1$  most recent samples received at the input for each channel, where  $D_{max}$  is the maximum delay specified.  $U$  represents the stored samples.

## FIR Interpolation Mode

In the FIR interpolation mode, the variable fractional delay stores the  $D_{max}+P+1$  most recent samples received at the input for each channel, where  $P$  is the specified interpolation filter half-length.

In this mode, the object provides a discrete set of fractional delays:

$$v + \frac{i}{L}, \quad v \geq P - 1, \quad i = 0, 1, \dots, L - 1$$

If  $v$  is less than  $P - 1$ , the behavior depends on the FIR small delay value action setting. You can specify the object's behavior when the input delay value is too small to center the kernel (less than  $P-1$ ), by setting the FIR small delay value action setting:

- **Clip to the minimum value necessary for centered kernel** -- The FIR interpolation method remains in use. The small input delay values are clipped to the smallest value necessary to center the kernel.
- **Switch to linear interpolation if kernel cannot be centered** -- Fractional delays are computed using linear interpolation when the input delay value is less than  $P-1$ .

In the FIR interpolation mode, the algorithm implements a polyphase structure to compute a value for each sample at the specified delay. Each arm of the structure corresponds to a different delay value. The output computed for each sample corresponds to the output of the arm with a delay value nearest to the specified input delay. Therefore, only a discrete set of delays is actually possible. The number of coefficients in each of the  $L$  filter arms of the polyphase structure is  $2P$ . In most cases, using values of  $P$  between 4 and 6 provides you with reasonably accurate interpolation values.

The `designMultirateFIR` function designs the FIR interpolation filter.

For example, when you set the following values:

- Interpolation filter half-length ( $P$ ) to 4
- Interpolation points per input sample to 10
- Normalized input bandwidth to 1
- Stopband attenuation to 80 dB

The filter coefficients are given by:

```
b = designMultirateFIR(10,1,4,80);
```

The algorithm then implements this filter as a polyphase structure.

Increasing the filter half length ( $P$ ) increases the accuracy of the interpolation, but also increases the number of computations performed per input sample. The amount of memory needed to store the filter coefficients increases too. Increasing the interpolation points per sample ( $L$ ) increases the number of representable discrete delay points, but also increases the simulation's memory requirements. The computational load per sample is not affected.

The normalized input bandwidth from 0 to 1 allows you to take advantage of the bandlimited frequency content of the input. For example, if you know that the input signal does not have frequency content above  $F_s/4$ , you can specify 0.5 normalized bandwidth to constrain the frequency content of the output to that range.

---

**Note** You can consider each of the  $L$  interpolation filters to correspond to one output phase of an upsample-by- $L$  FIR filter. Therefore, the normalized input value improves the stopband in critical regions and relaxes the stopband requirements in frequency regions without signal energy.

---

## Farrow Interpolation Mode

In Farrow interpolation mode, the algorithm uses the LaGrange method to interpolate values.

To specify the behavior when the input delay value is too small to center the kernel (less

than  $\frac{N}{2} - 1$ ), use the Farrow small delay action setting.

- `Clip to the minimum value necessary for centered kernel` -- The algorithm clips small input delay values to the smallest value necessary to keep the kernel centered. This option yields more accurate interpolation values.
- `Use off-centered kernel` -- The fractional delays are computed using a Farrow

filter with an off-centered kernel. The results for input delay values less than  $\frac{N}{2} - 1$  are less accurate than the results achieved by keeping the kernel centered.

When the length of the farrow filter is 2, the filter performs linear interpolation.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

### Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

The diagrams in the following sections show the data types used within the `dsp.VariableFractionalDelay` object for fixed-point signals.

Although you can specify most of these data types, the following data types are computed internally by the object and cannot be directly specified on the object interface.

Data Type	Word Length	Fraction Length
vf data type	Same word length as the coefficients	Same as the word length
HoldInteger data type	Same word length as the input delay value	0 bits
Integer data type	32 bits	0 bits

---

**Note** When the input is fixed point, all internal data types are signed fixed point.

---

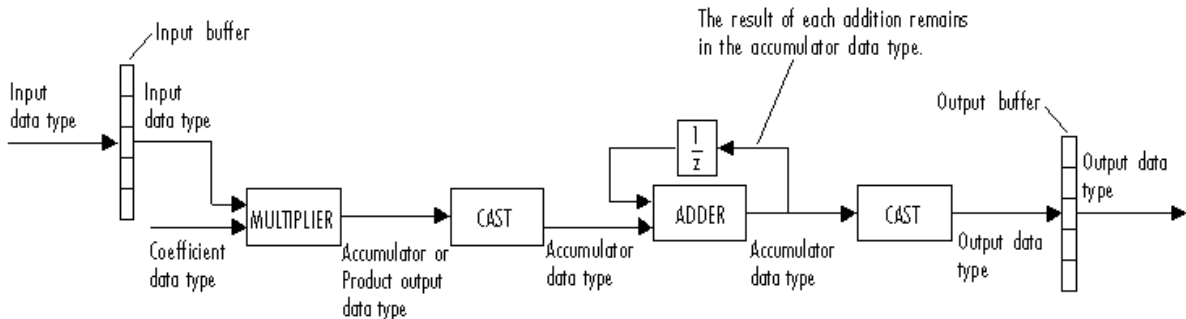

The following diagram shows the fixed-point data types used by the Linear interpolation mode of the variable fractional delay algorithm.

The following diagram illustrates how the variable fractional delay object selects the arm of the polyphase filter structure that most closely matches the fractional delay value ( $v_f$ ).

The following diagram shows the fixed-point data types used by the variable fractional delay algorithm in the FIR interpolation mode.

You can set the coefficient, product output, accumulator, and output data types in the object. This diagram shows that input data is stored in the input buffer with the same data type and scaling as the input. The object stores filtered data and any initial conditions in the output buffer using the output data type and scaling that you set.

When at least one of the inputs to the multiplier is real, the output of the multiplier is in the product output data type. When both inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication, see “Multiplication Data Types”.

The following diagram shows the fixed-point data types used by the Farrow interpolation mode when:

- Farrow filter length is set to 4
- Farrow small delay action is set to 'Clip to the minimum value necessary for centered kernel'

The following diagram shows the fixed-point data types used by the Farrow interpolation mode when:

- Farrow filter length is set to 4
- Farrow small delay action is set to 'Use off-centered kernel'

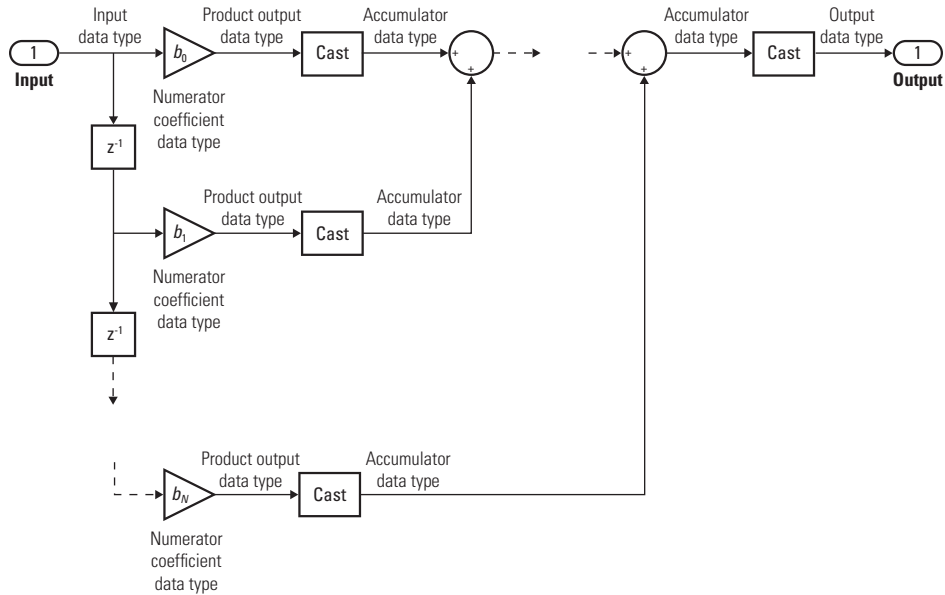

$Diff$  is computed from the integer part of the delay value ( $v_i$ ) and the farrow filter length ( $N$ ) according to the following equation:

$$Diff = v_i - \left( \frac{N - 1}{2} \right)$$

$$Diff \geq 0 \Rightarrow Diff = 0$$

$$Diff < 0 \Rightarrow Diff = -Diff$$

The following diagram shows the fixed-point data types used by the FIR direct form filter.

# dsp.VariableIntegerDelay System object

**Package:** dsp

Delay input by time-varying integer number of sample periods

## Description

---

**Note** Certain functionality of this object will be removed in future releases. For details, see “Functionality being removed or replaced for blocks and System objects” and “Removal of DirectFeedthrough property in dsp.VariableIntegerDelay System object”.

---

The `dsp.VariableIntegerDelay` System object delays input by time-varying integer number of sample periods.

To delay the input by a time-varying integer number of sample periods:

- 1 Create the `dsp.VariableIntegerDelay` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

## Creation

## Syntax

```
vid = dsp.VariableIntegerDelay  
vid = dsp.VariableIntegerDelay(Name,Value)
```

## Description

`vid = dsp.VariableIntegerDelay` returns a variable integer delay System object, `vid`, that delays discrete-time input by a time-varying integer number of sample periods.

`vid = dsp.VariableIntegerDelay(Name, Value)` returns a variable integer delay System object with each specified property set to the specified value.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects (MATLAB)*.

### **MaximumDelay — Maximum delay**

100 (default) | positive integer scalar

Specify the maximum delay the object can produce for any sample. The object clips input delay values greater than the `MaximumDelay` to the `MaximumDelay`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **InitialConditions — Initial values in memory**

0 (default) | scalar | 1-by-*N*-by-*D* array

Specify the values with which the object's memory is initialized. The dimensions of this property can vary depending on whether you want fixed or time-varying initial conditions.

For an *M*-by-*N* frame-based input matrix *U*, you can set the `InitialConditions` property as follows:

- To specify fixed initial conditions, set the `InitialConditions` property to a scalar value. The object initializes every sample of every channel in memory using the value you specify.
- To specify different time-varying initial conditions for each channel, set the `InitialConditions` property to an array of size 1-by-*N*-by-*D*, where *D* is the value of the `MaximumDelay` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**DirectFeedthrough — Allow direct feedthrough**`true (default) | false`

When you set this property to `true`, the object allows direct feedthrough. When you set this property to `false`, the object increases the minimum possible delay by one.

## Usage

---

**Note** For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Syntax

```
vidOut = vid(input,d)
```

## Description

`vidOut = vid(input,d)` delays the input by `d` samples, where `d` should be less than or equal to the value specified in the `MaximumDelay` property and greater than or equal to 0. Delay values outside this range are clipped appropriately and non-integer delays are rounded to the nearest integer values. Each column of the input is treated as an independent channel

## Input Arguments

**input — Data input**`vector | matrix`

Data input, specified as a vector or matrix.

This object supports variable-size input signal. That is, you can change the input frame size (number of rows) even after calling the algorithm. However, the number of channels must remain constant.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

**d — Delay input**

`scalar` | `vector` | `matrix`

Delay input, specified as a scalar, vector, or matrix. The delay is an integer value.

For an  $M$ -by-1 or a 1-by- $N$  data input vector, the delay can be a:

- Scalar
- Vector -- The length and the orientation of the delay vector match the length and the orientation of the data input.

For an  $M$ -by- $N$  matrix data input, the delay can be a:

- Column vector -- The length of the vector is  $M$ .
- Row vector -- The length of the vector is  $N$ .
- Matrix -- Delay must be an  $M$ -by- $N$  matrix.

The dimensions of the delay signal can change according to the supported dimensions listed in the table. The table also shows how delay signal is applied to the input signal.

<b>Data Input</b>	<b>Delay Input</b>	<b>Output</b>	<b>Effect of Delay Input on Data Input</b>
$M$ -by-1 (one channel with frame size equal to $M$ )	scalar	$M$ -by-1	One delay value applied to the input channel
$M$ -by-1 (one channel with frame size equal to $M$ )	$M$ -by-1	$M$ -by-1	Delay value varies within the frame from sample to sample
1-by- $N$ ( $N$ channels with frame size equal to 1)	scalar	1-by- $N$	One delay value applied to all the $N$ channels

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
1-by- $N$ ( $N$ channels with frame size equal to 1)	1-by- $N$	1-by- $N$	Unique delay value for each input channel
$M$ -by- $N$ ( $N$ channels with frame size equal to $M$ )	scalar	$M$ -by- $N$	One delay value applied to all input channels
$M$ -by- $N$ ( $N$ channels with frame size equal to $M$ )	1-by- $N$	$M$ -by- $N$	Unique delay value for each input channel
$M$ -by- $N$ ( $N$ channels with frame size equal to $M$ )	$M$ -by-1	$M$ -by- $N$	Delay value varies within the frame from sample to sample. Same set of delay values for all channels.
$M$ -by- $N$ ( $N$ channels with frame size equal to $M$ )	$M$ -by- $N$	$M$ -by- $N$	Unique delay value for each element in the matrix

Example: [2 3 4 5]

Example: [2;3;4;5]

Example: [5]

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

## Output Arguments

### **vidOut** — Delayed output

vector | matrix

Delayed output, returned as a vector or matrix. The size, data type, and complexity of the output match the size, data type, and complexity of the data input, "input" on page 4-0 .

The table shows how the data input and delay input dimensions affect the output dimensions:

<b>Data Input</b>	<b>Delay Input</b>	<b>Output</b>	<b>Effect of Delay Input on Data Input</b>
$M$ -by-1 (one channel with frame size equal to $M$ )	scalar	$M$ -by-1	One delay value applied to the input channel
$M$ -by-1 (one channel with frame size equal to $M$ )	$M$ -by-1	$M$ -by-1	Delay value varies within the frame from sample to sample
1-by- $N$ ( $N$ channels with frame size equal to 1)	scalar	1-by- $N$	One delay value applied to all the $N$ channels
1-by- $N$ ( $N$ channels with frame size equal to 1)	1-by- $N$	1-by- $N$	Unique delay value for each input channel
$M$ -by- $N$ ( $N$ channels with frame size equal to $M$ )	scalar	$M$ -by- $N$	One delay value applied to all input channels
$M$ -by- $N$ ( $N$ channels with frame size equal to $M$ )	1-by- $N$	$M$ -by- $N$	Unique delay value for each input channel
$M$ -by- $N$ ( $N$ channels with frame size equal to $M$ )	$M$ -by-1	$M$ -by- $N$	Delay value varies within the frame from sample to sample. Same set of delay values for all channels.
$M$ -by- $N$ ( $N$ channels with frame size equal to $M$ )	$M$ -by- $N$	$M$ -by- $N$	Unique delay value for each element in the matrix

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### Delay a Signal with VariableIntegerDelay Object

**Note:** If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

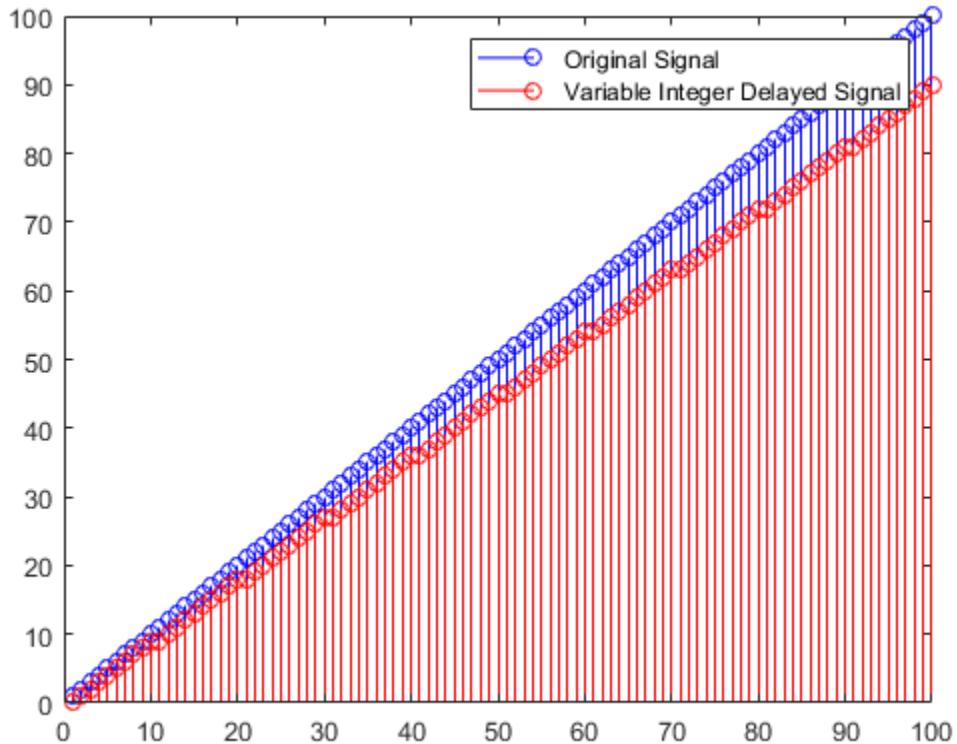

Delay a signal by a varying number of integer sample periods.

```
vid = dsp.VariableIntegerDelay;

yout = zeros(100,1);
x     = (1:100).';

for k=1:10
    range      = (k-1)*10+1:k*10;
    yout(range) = vid(x(range),k);
end

stem(x,'b')
hold on;
stem(yout,'r')
legend('Original Signal', 'Variable Integer Delayed Signal')
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Variable Integer Delay block reference page. The object properties correspond to the block properties, except:

When you set the `DirectFeedthrough` property of the System object to `true`, the object allows direct feedthrough. This behavior is different from the way the block behaves when you select the corresponding **Disable direct feedthrough by increasing minimum possible delay by one** check box on the block dialog. When you enable this block parameter, the block does not allow direct feedthrough.

## dsp.Variance System object

**Package:** dsp

Variance of input or sequence of inputs

### Description

The `Variance` object computes variance for an input or sequence of inputs.

To compute the variance of an input or sequence of inputs:

- 1 Define and set up your variance System object. See “Construction” on page 4-1850.
- 2 Call `step` to compute the variance according to the properties of `dsp.Variance`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

---

**Note** The Running mode in the `dsp.Variance` System object will be removed in a future release. To compute the running variance in MATLAB, use the `dsp.MovingVariance` System object instead.

---

### Construction

`var = dsp.Variance` returns a variance System object, `var`, that computes the variance of an input or a sequence of inputs over the specified `Dimension`.

`var = dsp.Variance('PropertyName',PropertyValue,...)` returns a variance System object, `var`, with each specified property set to the specified value.

## Properties

### RunningVariance

Enable calculation over time

Set this property to `true` to enable variance calculation over successive calls to the `step` method. The default is `false`.

### ResetInputPort

Enable reset input port

Set this property to `true` to enable reset input port. When you set the property to `true`, specify a reset input for the `step` method. The running variance resets anytime the variance object achieves the condition you specify for the `ResetCondition` property. This property applies when you set the `RunningVariance` property to `true`. The default is `false`.

### ResetCondition

Reset condition for running variance mode

Specify which event resets the running variance as one of `Rising edge` | `Falling edge` | `Either edge` | `Non-zero` |. This property applies when you set the “ResetInputPort” on page 4-0 property to `true`.

### Dimension

Dimension to operate along

Specify how the object performs the variance calculation over the data as one of `All` | `Row` | `Column` | `Custom` |. This property applies when you set the `RunningVariance` property to `false`. The default is `Column`.

### CustomDimension

Numerical dimension to operate along

Specify the input signal dimension (one-based value) the object uses to compute variance. The cannot exceed the number of dimensions in the input signal. This property applies when you set the “Dimension” on page 4-0 property to `Custom`. The default is `1`.

## **Fixed-Point Properties**

### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`

### **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`.

### **InputSquaredProductDataType**

Input-squared product word and fraction lengths

Specify the input-squared product fixed-point data type as one of | `Same as input` | `Custom` |. The default is `Same as input`.

### **CustomInputSquaredProductDataType**

Input-squared product word and fraction lengths

Specify the input-squared product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `InputSquaredProductDataType` property to `Custom`. The default is `numericType([], 32, 15)`.

### **InputSumSquaredProductDataType**

Input-sum-squared product word and fraction lengths

Specify the input-sum-squared product fixed-point data type as one of | `Same as input-squared product` | `Custom` |. The default is `Same as input-squared product`.

### **CustomInputSumSquaredProductDataType**

Input-sum-squared product word and fraction lengths

Specify the input-sum-squared product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the

InputSumSquaredProductDataType property to Custom. The default is `numericType([],32,23)`.

### **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of | Same as input-squared product | Same as input | Custom|. The default is Same as input-squared product.

### **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of Auto. This property applies when you set the `AccumulatorDataType` property to Custom. The default is `numericType([],32,0)`.

### **OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as one of | Same as input-squared product | Same as input | Custom|. The default is Same as input-squared product.

### **CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of Auto. This property only applies when the “OutputDataType” on page 4-0 property to Custom. The default is `numericType([],16,0)`.

## **Methods**

<code>reset</code>	Reset variance to zero
<code>step</code>	Variance of input

### Common to All System Objects

release	Allow System object property value changes
---------	--

## Examples

### Running Variance

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Compute the running variance of the signal. That is, compute the variance of each sample in the input signal with respect to all the previous samples.

```
var = dsp.Variance;  
var.RunningVariance = true;  
input = randn(100,1);  
variance = var(input);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Variance block reference page. The object properties correspond to the block parameters, except:

- **Reset port** block parameter corresponds to both the `ResetCondition` and the `ResetInputPort` object properties.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

**Introduced in R2012a**

## **reset**

**System object:** dsp.Variance

**Package:** dsp

Reset variance to zero

## **Syntax**

`reset(var)`

## **Description**

`reset(var)` sets the variance to zero when the `RunningVariance` property is `true`.

---

# step

**System object:** dsp.Variance

**Package:** dsp

Variance of input

## Syntax

$Y = \text{step}(\text{var}, X)$

$Y = \text{step}(\text{var}, X, R)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(\text{var}, X)$  computes the variance,  $Y$ , of input  $X$  over successive calls to the `step` method, when the `RunningVariance` property is `true`.

$Y = \text{step}(\text{var}, X, R)$  resets its state based on the value of reset signal  $R$ , the `ResetInputPort` property and the `ResetCondition` property. This option applies when the `RunningVariance` property is `true` and the `ResetInputPort` property is set to `true`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.VectorQuantizerDecoder System object

**Package:** dsp

Vector quantizer codeword for given index value

## Description

The `VectorQuantizerDecoder` object returns the vector quantizer codeword for a given index value. Each column of the `Codebook` property is a codeword.

To obtain the vector quantizer codeword for a given index value:

- 1 Define and set up your vector quantizer decoder. See “Construction” on page 4-1859.
- 2 Call `step` to get the vector quantizer codeword according to the properties of `dsp.VectorQuantizerDecoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`vqdec = dsp.VectorQuantizerDecoder` creates a vector quantizer decoder System object, `vqdec`, that returns a vector quantizer codeword corresponding to a given, zero-based index value.

`vqdec = dsp.VectorQuantizerDecoder('PropertyName',PropertyValue,...)` returns a vector quantizer decoder, `vqdec`, with each specified property set to the specified value.

## Properties

### CodebookSource

Source of codebook values

Specify the codebook source as `Property` or `Input port`. When you select `Property`, the object reads the codebook from the `Codebook` property. When you select `Input port`, the object reads the codebook from the input of the `step` method.

The default is `Property`.

### Codebook

codebook

Specify quantized output values as a  $k$ -by- $N$  matrix, where  $k \geq 1$  and  $N \geq 1$ . Each column of the codebook matrix is a codeword, and each codeword corresponds to an index value. This property applies when you set the `CodebookSource` property to `Property`. The default is:

$$\begin{bmatrix} 1.5 & 13.3 & 136.4 & 6.8 \\ 2.5 & 14.3 & 137.4 & 7.8 \\ 3.5 & 15.3 & 138.4 & 8.8 \end{bmatrix}$$

This property is tunable.

### OutputDataType

Data type of codebook and quantized output

Specify the data type of the codebook and quantized output values as: `Same as input`, `double`, `single` or `Custom`. This property applies only when you set `CodebookSource` to `Property`. The default is `double`.

### Fixed-Point Properties

#### CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a signed or unsigned `numericType` object. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numericType(true,16)`.

## Methods

`step` Perform vector quantization decoding

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Determine Vector Quantizer Codeword

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Given index values as an input, determine the corresponding vector quantized codewords for a specified codebook.

```
vqdec = dsp.VectorQuantizerDecoder;
vqdec.Codebook = [1 10 100;2 20 200;3 30 300];
indices = uint8([1 0 2 0]);
qout = vqdec(indices)
```

```
qout = 3×4
```

```
10     1    100     1
20     2    200     2
30     3    300     3
```

### Algorithms

This object implements the algorithm, inputs, and outputs described on the Vector Quantizer Decoder block reference page. The object properties correspond to the block parameters, except:

There is no object property that directly corresponds to the **Action for out of range index value** block parameter. The object sets any index values less than 0 to 0 and any index values greater than or equal to  $N$  to  $N-1$ .

### Extended Capabilities

#### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

#### See Also

`dsp.ScalarQuantizerDecoder` | `dsp.VectorQuantizerEncoder`

**Introduced in R2012a**

---

## step

**System object:** dsp.VectorQuantizerDecoder

**Package:** dsp

Perform vector quantization decoding

## Syntax

`Q = step(vqdec,I)`

`Q = step(vqdec,I,C)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Q = step(vqdec,I)` returns the quantized output values `Q` corresponding to the input indices `I`. The data type of `I` can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The `OutputDataType` property determines the data type of `Q`.

`Q = step(vqdec,I,C)` uses input `C` as the codebook values when the `CodebookSource` property is `Input port`. The data type of `C` can be `double`, `single`, or `fixed-point`. The output `Q` has the same data type as the codebook input `C`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.VectorQuantizerEncoder System object

**Package:** dsp

Vector quantization encoding

## Description

The `VectorQuantizerEncoder` object performs vector quantization encoding. The object finds the nearest codeword by computing a distortion based on Euclidean or weighted Euclidean distance.

To perform vector quantization encoding:

- 1 Define and set up your vector quantizer encoder. See “Construction” on page 4-1865.
- 2 Call `step` to perform the quantization encoding according to the properties of `dsp.VectorQuantizerEncoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`vgenc = dsp.VectorQuantizerEncoder` returns a vector quantizer encoder System object, `vgenc`. This object finds a zero-based index of the nearest codeword for each given input column vector.

`vgenc = dsp.VectorQuantizerEncoder('PropertyName',PropertyValue,...)` returns a vector quantizer encoder System object, `vgenc`, with each specified property set to the specified value.

## Properties

### CodebookSource

Source of codebook values

Specify how to determine the codebook values as `Property` or `Input port`. The default is `Property`.

### Codebook

Codebook

Specify the codebook to which the input column vector or matrix is compared, as a  $k$ -by- $N$  matrix. Each column of the codebook matrix is a codeword, and each codeword corresponds to an index value. The codeword vectors must have the same number of rows as the input. The first codeword vector corresponds to an index value of 0, the second codeword vector corresponds to an index value of 1, and so on. This property applies when you set the `CodebookSource` property to `Property`. The default is:

$$\begin{bmatrix} 1.5 & 13.3 & 136.4 & 6.8 \\ 2.5 & 14.3 & 137.4 & 7.8 \\ 3.5 & 15.3 & 138.4 & 8.8 \end{bmatrix}$$

This property is tunable.

### DistortionMeasure

Distortion calculation method

Specify how to calculate the distortion as `Squared error` or `Weighted squared error`. If you set this property to `Squared error`, the object calculates the distortion by evaluating the Euclidean distance between the input column vector and each codeword in the codebook. If you set this property to `Weighted squared error`, the object calculates the distortion by evaluating a weighted Euclidean distance using a weighting factor to emphasize or deemphasize certain input values. The default is `Squared error`.

### WeightsSource

Source of weighting factor

Specify how to determine weighting factor as `Property` or `Input port`. This property applies when you set the `DistortionMeasure` property to `Weighted squared error`. The default is `Property`.

### **Weights**

Weighting factor

Specify the weighting factor as a vector of length equal to the number of rows of the input. This property applies when you set the `DistortionMeasure` property to `Weighted squared error` and `WeightsSource` property is `Property`. The default is `[1 1 1]`. This property is tunable.

### **TiebreakerRule**

Behavior when input column vector is equidistant from two codewords.

Specify whether to represent the input column vector by the lower index valued codeword or higher indexed valued codeword when an input column vector is equidistant from two codewords. You can set this property to `Choose the lower index` or `Choose the higher index`. The default is `Choose the lower index`.

### **CodewordOutputPort**

Enable output of codeword value

Set this property to `true` to output the codeword vectors nearest to the input column vectors. The default is `false`.

### **QuantizationErrorOutputPort**

Enable output of quantization error

Set this property to `true` to output the quantization error value that results when the object represents the input column vector by the nearest codeword. The default is `false`.

### **OutputIndexDataType**

Data type of index output

Specify the data type of the index output as: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`. The default is `int32`.

## **Fixed-Point Properties**

### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest` or `Zero`. The default is `Floor`.

### **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

### **ProductDataType**

Product word and fraction lengths

Specify the product fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

### **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`.

### **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Same as input`, or `Custom`. The default is `Same as product`.

### **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`.

## Methods

step      Perform vector quantization encoding

### Common to All System Objects

release	Allow System object property value changes
---------	--

## Examples

### Find Indices of Nearest Codewords

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Find the indices of nearest codewords based on Euclidean distances.

```

vqenc = dsp.VectorQuantizerEncoder(...
    'Codebook', [-1 -1 1 1;1 -1 -1 1], ...
    'CodewordOutputPort', true, ...
    'QuantizationErrorOutputPort', true, ...
    'OutputIndexDataType', 'uint8');

```

Generate an input signal with some additive noise

```

x = sign(rand(2,40)-0.5) + 0.1*randn(2,40);
[ind, cw, err] = vqenc(x);
plot(cw(1,:), cw(2,:), 'r0', x(1,:), x(2,:), 'g. ');
legend('Quantized', 'Inputs', 'location', 'best');

```

### Algorithms

This object implements the algorithm, inputs, and outputs described on the Vector Quantizer Encoder block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

### See Also

`dsp.ScalarQuantizerEncoder` | `dsp.VectorQuantizerDecoder`

**Introduced in R2012a**

## step

**System object:** dsp.VectorQuantizerEncoder

**Package:** dsp

Perform vector quantization encoding

## Syntax

```
INDEX = step(vqenc, INPUT)
INDEX = step(vqenc, ..., CODEBOOK)
INDEX = step(vqenc, ..., WEIGHTS)
[ ..., CODEWORD] = step(vqenc, ...)
[ ..., QERR] = step(vqenc, ...)
```

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

---

`INDEX = step(vqenc, INPUT)` returns `INDEX`, a scalar or column vector representing the quantization region(s) to which `INPUT` belongs. `INPUT` can be a column vector of size  $k$ -by-1 or an  $M$  multichannel matrix of dimensions  $k$ -by- $M$ , where  $k$  is the length of each codeword in the codebook. All inputs to the object can be real floating-point or fixed-point values and must be of the same data type. The output index values can be signed or unsigned integers.

`INDEX = step(vqenc, ..., CODEBOOK)` uses the codebook given in input `CODEBOOK`, a  $k$ -by- $N$  matrix with  $N$  codewords each of length  $k$ . This option is available when the `CodebookSource` property is `Input port`.

`INDEX = step(vqenc, ..., WEIGHTS)` uses the input vector `WEIGHTS` to emphasize or de-emphasize certain input values when calculating the distortion measure. `WEIGHTS`

must be a vector of length equal to the number of rows of INPUT. This option is available when the `DistortionMeasure` property is `Weighted squared error` and the `WeightsSource` property is `Input port`.

`[..., CODEWORD] = step(vqenc, ...)` outputs the `CODEWORD` values that correspond to each index value when the `CodewordOutputPort` property is `true`.

`[..., QERR] = step(vqenc, ...)` outputs the quantization error `QERR` for each input value when the `QuantizationErrorOutputPort` property is `true`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## dsp.Window System object

**Package:** dsp

Window object

### Description

The Window object applies a window to an input signal.

To apply a window to an input signal:

- 1 Define and set up your window. See “Construction” on page 4-1874.
- 2 Call `step` to apply the window according to the properties of `dsp.Window`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`win = dsp.Window` returns a window object, `win`, that applies a Hamming window with symmetric sampling.

`win = dsp.Window('PropertyName',PropertyValue, ...)` returns a window object, `win`, with each property set to the specified value.

`win = dsp.Window(WINDOW,'PropertyName',PropertyValue, ...)` returns a window object, `win`, with the `WindowFunction` property set to `WINDOW` and other properties set to the specified values.

## Properties

### WindowFunction

Type of window

Specify the type of window to apply as `Bartlett`, `Blackman`, `Boxcar`, `Chebyshev`, `Hamming`, `Hann`, `Hanning`, `Kaiser`, `Taylor`, `Triang`. The default is `Hamming`. If you run this object in simulation, this property is tunable. When you generate code from a function or script that contains this object, and run the generated code, this property is not tunable.

### WeightsOutputPort

Enable the output of window weights

Set this property to `true` to output the window weights. The weights are an  $M$ -by-1 vector with  $M$  equal to the first dimension of the input. The default is `false`.

### StopbandAttenuation

Level of stopband attenuation in decibels

Specify the level of stopband attenuation in decibels. This property only applies when the `WindowFunction` property is `Chebyshev`. The default is 50. This property is tunable.

### Beta

Kaiser window parameter

Specify the Kaiser window parameter as a real number. Increasing the absolute value of `Beta` widens the mainlobe and decreases the amplitude of the window sidelobes in the window's frequency magnitude response. This property only applies when `WindowFunction` property is `Kaiser`. The default is 10. This property is tunable.

### NumConstantSidelobes

Number of constant sidelobes

Specify the number of constant sidelobes as an integer greater than zero. This property only applies when `WindowFunction` property is `Taylor`. The default is 4. This property is tunable.

### **MaximumSidelobeLevel**

Maximum sidelobe level relative to mainlobe

Specify, in decibels, the maximum sidelobe level relative to the mainlobe as a real number less than or equal to zero. The default is -30, which produces sidelobes with peaks 30 dB down from the mainlobe peak. This property only applies when `WindowFunction` property is `Taylor`. This property is tunable.

### **Sampling**

Window sampling for generalized-cosine windows

Specify the window sampling for generalized-cosine windows as `Symmetric` or `Periodic`. This property only applies when `WindowFunction` property is `Blackman`, `Hamming`, `Hann`, or `Hanning`. If you run this object in simulation, this property is tunable. When you generate code from a function or script that contains this object, and run the generated code, this property is not tunable.

### **Fixed-Point Properties**

#### **FullPrecisionOverride**

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

#### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`. This property applies only if the object is not in full precision mode.

**OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

**WindowDataType**

Window word and fraction lengths

Specify the window fixed-point data type as one of `Same word length as input` or `Custom`. The default is `Same word length as input`.

**CustomWindowDataType**

Window word and fraction lengths

Specify the window fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `WindowDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

**ProductDataType**

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

**CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

**OutputDataType**

Output data type

Specify the output fixed-point data type as one of `Same as product`, `Same as input`, or `Custom`. The default is `Same as product`.

### CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numericType([], 16, 15)`.

## Methods

`step`            Multiply input by window

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

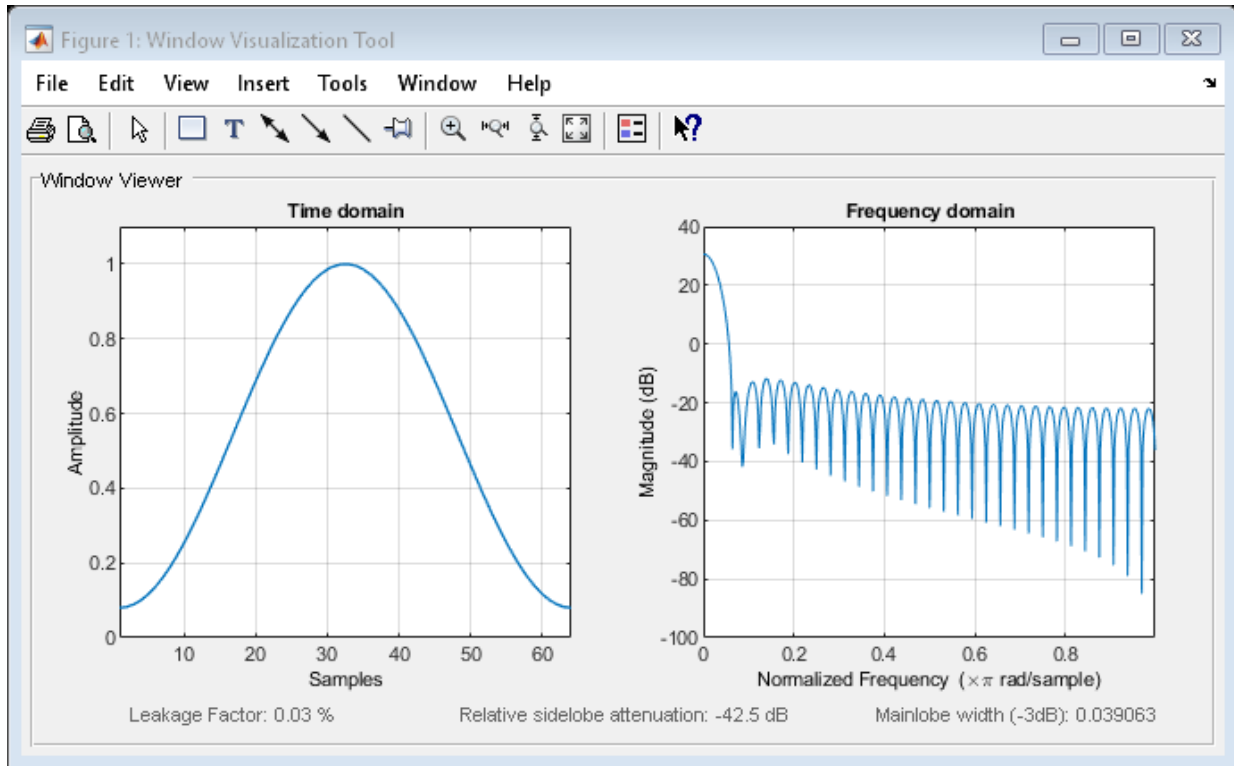

### Apply Hamming Window To the Input

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
win = dsp.Window( ...  
    'WindowFunction', 'Hamming', ...  
    'WeightsOutputPort', true);  
x = rand(64,1);  
[y, w] = win(x);
```

View the window's time and frequency domain responses

```
wvtool(w);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Window Function block reference page. The object properties correspond to the block parameters, except:

- **Operation** — The window object does not support the `Generate` window option.
- **Operation** — The `Generate` and `apply window` option on the block corresponds to the `WeightsOutputPort` property set to `true` on the window object.
- The window object only supports frame-based processing.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- This object has no tunable properties for code generation.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

# step

**System object:** dsp.Window

**Package:** dsp

Multiply input by window

## Syntax

`Y = step(win,X)`

`[Y, W] = step(win,X)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(win,X)` generates the windowed output, `Y`, of the input, `X`, using the specified window.

`[Y, W] = step(win,X)` returns the window values `W` when the `WeightsOutputPort` property is `true`.

This object supports only frame-based processing. To see the effect of the window, the data must have a frame size of at least 2 in each channel.

## **dsp.ZeroCrossingDetector System object**

**Package:** dsp

Detect zero crossings

### **Description**

The `dsp.ZeroCrossingDetector` System object counts the number of times the signal crosses zero, or changes sign. To detect if a signal in a given channel crosses zero, the object looks for the following conditions, where,  $x_{i-l}$  is the current signal value and  $x_{i-1}$  is the previous signal value:

- $x_i < 0$  and  $x_{i-1} > 0$
- $x_i > 0$  and  $x_{i-1} < 0$
- For some positive integer  $L$ ,  $x_i < 0$ ,  $x_{i-l} = 0$ , and  $x_{i-L-1} > 0$ , where  $0 \leq l \leq L$ .
- For some positive integer  $L$ ,  $x_i > 0$ ,  $x_{i-l} = 0$ , and  $x_{i-L-1} < 0$ , where  $0 \leq l \leq L$ .

For the first input value,  $x_{i-1}$  and  $x_{i-2}$  are zero.

To count the number of times a signal crosses zero or changes sign:

- 1** Create the `dsp.ZeroCrossingDetector` object.
- 2** Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#)

### **Creation**

### **Syntax**

```
zcd = dsp.ZeroCrossingDetector
```

## Description

`zcd = dsp.ZeroCrossingDetector` returns a zero crossing detection object that calculates the number of times the signal crosses zero.

## Usage

**Note** For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Syntax

```
zcdOut = zcd(input)
```

## Description

`zcdOut = zcd(input)` calculates the number of zero crossings of the input. Each column of the input is treated as an independent channel.

## Input Arguments

### **input** — Data input

vector | matrix

Data input whose zero crossings are counted by the object, specified as a vector or a matrix.

Example: `rand(20,1)-0.3`

Example: `rand(20,2)-0.3`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

### Output Arguments

#### **zcdOut — Number of zero crossings**

scalar | row vector

Number of zero crossings in the data input, returned as one of the following:

- scalar -- When the data input is a column vector, the scalar output is the number of zero crossings in the data input..
- row vector -- When the data input is a matrix, each element in the row vector output is the number of zero crossings in the corresponding column of the data input.

Example: 10

Example: [9, 6]

Data Types: uint32

### Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

#### **Common to All System Objects**

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

### Examples

#### **Determine Number of Zero Crossings**

**Note:** If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Find the number of zero crossings in electrocardiogram data.

```
EcgData = ecg(500)';  
zcd = dsp.ZeroCrossingDetector;  
numZeroCross = zcd(EcgData)
```

```
numZeroCross = uint32  
4
```

```
plot(1:500, EcgData, 'b', [0 500], [0 0], 'r', 'linewidth', 2)
```

## **Extended Capabilities**

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

#### **System Objects**

`dsp.PeakFinder` | `dsp.PhaseExtractor`

**Introduced in R2012a**

# **dsp.ZoomFFT System object**

**Package:** dsp

High-resolution FFT of a portion of a spectrum

## **Description**

The `dsp.ZoomFFT` System object computes the fast Fourier Transform (FFT) of a signal over a portion of frequencies in the Nyquist interval. By setting an appropriate decimation factor  $D$ , and sampling rate  $F_s$ , you can choose the bandwidth of frequencies to analyze  $BW$ , where  $BW = F_s/D$ . You can also select a specific range of frequencies to analyze in the Nyquist interval by choosing the center frequency of the desired band.

The resolution of a signal is the ratio of  $F_s$  and the FFT length ( $L$ ). Using zoom FFT, you can retain the same resolution you would achieve with a full-size FFT on your original signal by computing a small FFT on a shorter signal. The shorter signal comes from decimating the original signal. The savings come from being able to compute a much shorter FFT while achieving the same resolution. For a decimation factor of  $D$ , the new sampling rate,  $F_{sd}$ , is  $F_s/D$ , and the new frame size (and FFT length) is  $L_d = L/D$ . The resolution of the decimated signal is  $F_{sd}/L_d = F_s/L$ . To achieve a higher resolution of the shorter band, use the original FFT length,  $L$ , instead of the decimated FFT length,  $L_d$ .

To compute the FFT of a portion of the spectrum:

- 1 Create the `dsp.ZoomFFT` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

## **Creation**

## **Syntax**

```
zfft = dsp.ZoomFFT
```

```
zfft = dsp.ZoomFFT(d)
zfft = dsp.ZoomFFT(d,Fc)
zfft = dsp.ZoomFFT(d,Fc,Fs)
zfft = dsp.ZoomFFT(Name,Value)
```

### Description

`zfft = dsp.ZoomFFT` creates a zoom FFT System object, `zfft`, that performs an FFT on a portion of the input signal's frequency range. The object determines the frequency range over which to perform the FFT using the specified center frequency and decimation factor values.

`zfft = dsp.ZoomFFT(d)` creates a zoom FFT object with the “DecimationFactor” on page 4-0 property set to `d`.

`zfft = dsp.ZoomFFT(d,Fc)` creates a zoom FFT object with the “DecimationFactor” on page 4-0 property set to `d`, and the “CenterFrequency” on page 4-0 property set to `Fc`.

`zfft = dsp.ZoomFFT(d,Fc,Fs)` creates a zoom FFT object with the “DecimationFactor” on page 4-0 property set to `d`, the “CenterFrequency” on page 4-0 property set to `Fc`, and the “SampleRate” on page 4-0 property set to `Fs`.

`zfft = dsp.ZoomFFT(Name,Value)` creates a zoom FFT object with each specified property set to the specified value. Enclose each property name in single quotes. You can use this syntax with any previous input argument combinations.

Example: `zfft = dsp.ZoomFFT(2,2e3,48e3,'FFTLength',64);`

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects (MATLAB)*.

**DecimationFactor — Decimation factor**

2 (default) | positive integer

Decimation factor, specified as a positive integer. This value specifies the factor by which the object reduces the bandwidth of the input signal. The number of rows in the input signal must be a multiple of the decimation factor.

Example: 4

Example: 8

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**CenterFrequency — Center frequency**

0 (default) | real scalar

Center frequency of the desired band in Hz, specified as a real scalar in the range ( $-\text{SampleRate}/2$ ,  $\text{SampleRate}/2$ ).

Example: 0.5

Example: 10

**Tunable:** Yes

Data Types: single | double

**FFTLength — FFT length**

[] (default) | positive integer

FFT length, specified as a positive integer. The FFT length must be greater than or equal to the ratio of the frame size (number of input rows) and the decimation factor,  $L/D$ . The default, [], specifies an FFT length that equals the ratio,  $L/D$ .

Example: 24

Example: 52

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**SampleRate — Input sample rate**

44100 (default) | positive real scalar

Input sample rate in Hz, specified as positive real scalar.

Example: 44100

Example: 48000

Data Types: `single` | `double`

## Usage

## Syntax

```
zfftOut = zfft(input)
```

## Description

`zfftOut = zfft(input)` computes the zoom FFT of the input. Each column of the input is treated as an independent channel. The object computes the FFT of each channel of the input signal independently over time.

## Input Arguments

### **input** — Data input

`vector` | `matrix`

Data input whose zoom FFT the object computes, specified as a vector or a matrix. The number of input rows must be a multiple of the decimation factor.

This object supports variable-size input signals, as long as the input frame size is a multiple of the decimation factor. That is, you can change the input frame size (number of rows) even after calling the algorithm. However, the number of channels (number of columns) must remain constant.

Example: `randn(22,2)`

Data Types: `single` | `double`

## Output Arguments

### **zfftOut** — Zoom FFT output

`vector` | `matrix`

Zoom FFT output, returned as a vector or matrix. If the FFT length is set to auto, the output frame size equals the input frame size divided by the decimation factor. If the object specifies the FFT length, the output frame size equals the specified FFT length. The output data type matches the input data type.

Example: `randn(11,2)`

Data Types: `single` | `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### Compute FFT of a Subband Using Zoom FFT

Compute FFT of the [1500 Hz 2500 Hz] subband using zoom FFT for a signal sampled at 48 kHz.

#### Initialization

Set the center frequency to 2 kHz and the bandwidth of interest to 1 kHz. The bandwidth is centered at the center frequency. The decimation factor is the ratio of the input sample rate, 48 kHz, and the bandwidth of interest, 1 kHz. Choose an FFT length of 64. Set the input frame size to be the decimation factor times the FFT length. Create a `dsp.ZoomFFT` object with the specified decimation factor, center frequency, sample rate, and FFT length.

```
Fs = 48e3;  
CF = 2e3;  
BW = 1e3;  
D = Fs/BW;  
fftlen = 64;  
L = D * fftlen;  
zfft = dsp.ZoomFFT(D,CF,Fs, 'FFTLength',fftlen);
```

### Frequencies

The FFT is computed over frequencies starting at 1500 Hz and spaced by

$Fs/(D * \text{fftLen})$  Hz apart, which is the resolution or the minimum frequency that can be discriminated. The number of frequencies at which the zoom FFT is computed equals the FFT length.

```
Fsd = Fs/D;  
F = CF + (Fsd/fftlen)*(0:fftlen-1)-Fsd/2;
```

### Initialize the Scope

Create an array plot to show the frequencies in F.

```
ap = dsp.ArrayPlot('XDataMode','Custom','CustomXData',F,...  
    'YLabel','z .* conj(z)','XLabel','Frequency (Hz)','YLimits',[0 1.1e3],...  
    'Title',sprintf('Decimation Factor = %d. Center Frequency = %d Hz. Resolution = %f
```

### Sine Wave Generator

Create a sine wave with frequencies at 1625 Hz, 2000 Hz, and 2125 Hz.

```
tones = [1625 2000 2125];  
sine = dsp.SineWave('SampleRate',Fs,'Frequency',tones,'SamplesPerFrame',L);
```

### Streaming

Pass a noisy sine wave with a sample rate of 48 kHz. Compute the zoom FFT of this sine wave in the subband [1500 Hz 2500 Hz]. Rearrange the Fourier transform by shifting the zero-frequency component to the center of the array. View the tones at 1625 Hz, 2000 Hz, and 2125 Hz in the array plot.

```
for i = 1:1000  
    x = sum(sine(),2)+1e-1*randn(L,1);  
    z = zfft(x);  
    z = fftshift(z);
```

```

    ap(z.*conj(z));
end

```

### Compute Zoom FFT of Variable-Size Inputs

The `dsp.ZoomFFT` object accepts variable-size inputs as long as the input is a multiple of the decimation factor. The number of input channels cannot change.

Create a `dsp.ZoomFFT` object with a decimation factor of 4, center frequency of 2 kHz, and an input sample rate of 48 kHz. Pass a random input with  $4 \times 64$  rows and 2 columns. Vary the number of rows to  $4 \times 128$  and  $4 \times 32$ . The resulting FFT lengths are 64, 128, and 32, respectively. The size of the outputs is  $[64 \ 2]$ ,  $[128 \ 2]$ , and  $[32 \ 2]$ , respectively.

```
zfft = dsp.ZoomFFT(4,2e3,48e3);  
y1 = zfft(randn(4*64,2));  
y2 = zfft(randn(4*128,2));  
y3 = zfft(randn(4*32,2));
```

Set the FFT length as 256 and pass variable-size inputs. The size of all the outputs is [256 2].

```
release(zfft);  
zfft.FFTLength = 256;  
y4 = zfft(randn(4*64,2));  
y5 = zfft(randn(4*128,2));  
y6 = zfft(randn(4*32,2));
```

## Algorithms

The zoom FFT algorithm leverages bandpass filtering before computing the FFT of the signal. The concept of bandpass filtering is that suppose you are interested in the band  $[F1, F2]$  of the original input signal, sampled at the rate  $F_s$  Hz. If you pass this signal through a complex (one-sided) bandpass filter centered at  $F_c = (F1+F2)/2$ , with the bandwidth  $BW = F2 - F1$ , and then downsample the signal by a factor of  $D = \text{floor}(F_s/BW)$ , the desired band comes down to the baseband.

If  $F_c$  cannot be expressed in the form of  $k \times F_s/D$ , where  $k$  is an integer, then the shifted, decimated spectrum is not centered at DC. In this case, the center frequency gets translated to  $F_d$ .

$$F_d = F_c - (F_s / D) \times \text{floor}((D \times F_c + F_s / 2) / F_s)$$

The complex bandpass filter is obtained by first designing a lowpass filter prototype and then multiplying the lowpass coefficients with a complex exponential. This algorithm uses a multirate, multistage FIR filter as the lowpass filter prototype. To obtain the bandpass filter, the coefficients of each stage are frequency shifted. The decimation factor is the cumulative decimation factor of each stage. The complex bandpass filter followed by the decimator are implemented using an efficient polyphase structure. For more details on the design of the complex bandpass filter from the multirate multistage FIR filter prototype, see “Zoom FFT” and “Complex Bandpass Filter Design”.

# SpectrumAnalyzerConfiguration

Configure Spectrum Analyzer for programmatic access

## Description

The `spbscopes.SpectrumAnalyzerConfiguration` object contains the scope configuration information for the Spectrum Analyzer block.

## Creation

`MyScopeConfiguration = get_param(gcbh, 'ScopeConfiguration')` constructs a new Spectrum Analyzer Configuration object. You must first select the block in the model or give the full path to the block.

## Properties

### Frequently Used

#### **NumInputPorts** — Number of input ports

'1' (default) | character vector

Number of input ports on a scope block, specified by a character vector. Maximum number of input ports is 96.

#### **UI Use**

Select **File > Number of Input Ports**.

#### **InputDomain** — Domain of the input signal

Time (default) | Frequency

The domain of the input signal you want to visualize. If you visualize time-domain signals, the signal is transformed to the frequency spectrum based on the algorithm specified by the `Method` parameter.

### UI Use

Open the **Spectrum Settings**. In the **Main options** section, set **Input Domain**.

### SampleRate — Sample rate of input

'10e3' (default) | character vector

Specify the sample rate of the input signals in hertz as a character vector.

### UI Use

Open the **Spectrum Settings**. In the **Main options** section, set **Sample rate (Hz)**.

### SpectrumType — Type of spectrum to show

'Power' (default) | 'Power density' | 'RMS'

Specify the spectrum type to display.

'Power' — Power spectrum

'Power density' — Power spectral density. The power spectral density is the magnitude squared of the spectrum normalized to a bandwidth of 1 hertz.

'RMS' — Root mean square. The root-mean-square shows the square root of the sum of the squared means. This option is useful when viewing the frequency of voltage or current signals.

**Tunable:** Yes

### UI Use

Open the **Spectrum Settings**. In the **Main options** section, set **Type**.

### ViewType — Viewer type

'Spectrum' (default) | 'Spectrogram' | 'Spectrum and spectrogram'

Specify the spectrum type as one of 'Spectrum', 'Spectrogram', or 'Spectrum and spectrogram'.

- 'Spectrum' — shows the power spectrum.
- 'Spectrogram' — shows frequency content over time. Each line of the spectrogram is one periodogram. Time scrolls from the bottom to the top of the display. The most recent spectrogram update is at the bottom of the display.

- 'Spectrum and Spectrogram' — shows a dual view of a spectrum and spectrogram.

**Tunable:** Yes

**UI Use**

Open the **Spectrum Settings**. In the **Main options** section, set **View**.

**Method — Spectrum estimation method**

'Welch' (default) | 'Filter Bank'

Specify the spectrum estimation method as Welch or Filter bank.

**Dependency**

To enable this property, set InputDomain to 'Time'.

**UI Use**

Open the **Spectrum Settings**. In the **Main options** section, set **Method**.

**NumTapsPerBand — Number of filter taps per frequency band**

'12' (default) | character vector of even integer

Specify the number of filter taps or coefficients for each frequency band as a character vector. This number must be a positive even integer. This value corresponds to the number of filter coefficients per polyphase branch. The total number of filter coefficients is equal to NumTapsPerBand + FFTLength.

**Dependency**

To enable this property, set Method to 'Filter Bank'.

**UI Use**

Open the **Spectrum Settings**. In the **Main options** section, set **Taps per band**.

**SpectralAverages — Number of spectral averages**

'1' (default) | character vector

Specify the number of spectral averages as a character vector. The Spectrum Analyzer computes the current power spectrum estimate by computing a running average of the last  $N$  power spectrum estimates. This property defines  $N$ .

### Dependency

To enable this property, set `ViewType` to `'Spectrum'`.

### UI Use

Open the **Spectrum Settings**. In the **Trace options** section, set **Averages**.

### PlotAsTwoSidedSpectrum — Two-sided spectrum flag

`true` (default) | `false`

- `true` — Compute and plot two-sided spectral estimates. When the input signal is complex-valued, you must set this property to `true`.
- `false` — Compute and plot one-sided spectral estimates. If you set this property to `false`, then the input signal must be real-valued.

When this property is `false`, Spectrum Analyzer uses power-folding. The y-axis values are twice the amplitude that they would be if this property were set to `true`, except at  $\theta$  and the Nyquist frequency. A one-sided power spectral density (PSD) contains the total power of the signal in the frequency interval from DC to half of the Nyquist rate. For more information, see `pwelch`.

### UI Use

Open the **Spectrum Settings**. In the **Trace options** section, select **Two-sided spectrum**.

### FrequencyScale — Frequency scale

`'Linear'` (default) | `'Log'`

- `'Log'` — displays the frequencies on the x-axis on a logarithmic scale. To use the `'Log'` setting, you must also set the `PlotAsTwoSidedSpectrum` property to `false`.
- `'Linear'` — displays the frequencies on the x-axis on a linear scale. To use the `'Linear'` setting, you must also set the `PlotAsTwoSidedSpectrum` property to `true`.

**Tunable:** Yes

### UI Use

Open the **Spectrum Settings**. In the **Trace options** section, set **Scale**.

### AxisScaling — Axes scaling mode

`'Auto'` (default) | `'Manual'` | `'OnceAtStop'` | `'Updates'`

Specify when the scope automatically scales the axes. Valid values are:

- 'Auto' — The scope scales the axes as-needed to fit the data, both during and after simulation.
- 'Manual' — The scope does not scale the axes automatically.
- 'OnceAtStop' — The scope scales the axes when the simulation stops.
- 'Updates' — The scope scales the axes once after 10 updates.

#### UI Use

Select **Tools > Axes Scaling**.

## Advanced

### FrequencyResolutionMethod — Frequency resolution method

'RBW' (default) | 'WindowLength' | 'NumFrequencyBands'

Specify the frequency resolution method of the Spectrum Analyzer.

- 'RBW' - the RBWSource and RBW properties control the frequency resolution (in Hz) of the analyzer. The FFT length is the window length that results from achieving the specified RBW value or 1024, whichever is larger.
- 'WindowLength' - applies only when the Method property is set to 'Welch'. The WindowLength property controls the frequency resolution. You can control the number of FFT points only when the FrequencyResolutionMethod property is 'WindowLength'.
- 'NumFrequencyBands' - applies only when the Method property is set to 'Filter Bank'. The FFTLengthSource and FFTLength properties control the frequency resolution.

**Tunable:** Yes

#### Dependency

To enable this property, set InputDomain to 'Time'.

#### UI Use

Open the **Spectrum Settings**. In the **Main options** section, set the frequency resolution method by selecting the **RBW (Hz)** dropdown.

### **RBWSource — Source of resolution bandwidth value**

'Auto' (default) | 'Property' | 'InputPort'

Specify the source of the resolution bandwidth (RBW) as either 'Auto' or 'Property'.

- 'Auto' — The Spectrum Analyzer adjusts the spectral estimation resolution to ensure that there are 1024 RBW intervals over the defined frequency span.
- 'Property' — Specify the resolution bandwidth directly using the RBW property.
- 'InputPort' — An input port is added to the Spectrum Analyzer block to read the RBW from an input. This option is only applicable to frequency input.

### **Dependencies**

To enable this property, set:

- InputDomain to 'Time' and FrequencyResolutionMethod to 'RBW'.
- InputDomain to 'Frequency'.

### **UI Use**

Open the **Spectrum Settings**. In the **Main options** section, set **RBW (Hz)**.

### **RBW — Resolution bandwidth**

'9.76' (default) | character vector

RBW controls the spectral resolution of the Spectrum Analyzer. Specify the resolution bandwidth in hertz as a character vector. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. Thus, the ratio of the overall span to RBW must be greater than two:

$$\frac{span}{RBW} > 2$$

You can specify the overall span in different ways based on how you set the FrequencySpan property.

### **Dependency**

To enable, set:

- RBWSource to 'Property'

**UI Use**

Open the **Spectrum Settings**. In the **Main options** section, set **RBW (Hz)**.

**FrequencyVectorSource — Source of frequency vector**

'Auto' (default) | 'Property' | 'InputPort'

- **Auto** — The frequency vector is calculated from the length of the input. See “Frequency Vector” on page 2-1602.
- **Property** — Enter a custom vector as the frequency vector.
- **InputPort** — An input port appears on the block for the frequency vector input.

**Dependency**

To enable this property, set InputDomain to 'Frequency'.

**UI Use**

Open the **Spectrum Settings**. In the **Frequency input options** section, set **Frequency (Hz)**.

**FrequencyVector — Custom frequency vector**

[-5000 5000] (default) | monotonically increasing vector

Set the frequency vector which determines the x-axis of the display. The vector must be monotonically increasing and of the same size as the input frame size.

**Dependency**

To enable this property, set FrequencyVectorSource to 'Property'.

**UI Use**

Open the **Spectrum Settings**. In the **Frequency input options** section, set **Frequency (Hz)**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**WindowLength — Window length**

'1024' (default) | character vector of an integer greater than 2

Control the frequency resolution by specifying the window length in samples used to compute the spectral estimates. The window length must be an integer scalar greater than 2, specified as a character vector.

### Dependencies

To enable this property, set:

- FrequencyResolutionMethod to 'WindowLength', which controls the frequency resolution based on your window length setting.
- Method to 'Welch'.

### UI Use

Open the **Spectrum Settings**. Change the **RBW (Hz)** dropdown to Window length.

### FFTLengthSource — Source of the FFT length

'Auto' (default) | 'Property'

- 'Auto' - sets the FFT length to the window length specified in the WindowLength property or 1024, whichever is larger.
- 'Property' - number of FFT points using the FFTLength property. FFTLength must be greater than WindowLength.

**Tunable:** Yes

### Dependency

To enable this property, set FrequencyResolutionMethod to 'WindowLength'.

### UI Use

Open the **Spectrum Settings**. In the **Main options** section, next to the **RBW (Hz)** option, enter a number or select Auto.

### FFTLength — Length of FFT

'1024' (default) | character vector

Specify the length of the FFT that the Spectrum Analyzer uses to compute spectral estimates.

If FrequencyResolutionMethod is 'RBW', the FFT length is set as the window length required to achieve the specified resolution bandwidth value or 1024, whichever is larger.

## Dependencies

To use this property, the following must be true:

- FFTLength value is greater than or equal to the WindowLength.
- FrequencyResolutionMethod is set to 'WindowLength' or 'NumFrequencyBands'
- FFTLengthSource is set to 'Property'.

## UI Use

Open the **Spectrum Settings**. In the **Main options** section, next to the **RBW (Hz)** option, enter a number or select Auto.

## FrequencyOffset — Frequency offset

'0' (default) | scalar character vector | vector character vector

- Scalar — Apply the same frequency offset to all channels, specified in hertz as a character vector.
- Vector — apply a specific frequency offset for each channel, specify a vector of frequencies. The vector length must be equal to number of input channels.

The frequency-axis values are offset by the values specified in this property. The overall span must fall within the “Nyquist frequency interval” on page 4-1631. You can control the overall span in different ways based on how you set the FrequencySpan property.

## UI Use

Open the **Spectrum Settings**. In the **Trace options** section, set **Offset (Hz)**.

## FrequencySpan — Frequency span mode

'Full' (default) | 'Span and center frequency' | 'Start and stop frequencies'

- 'Full' - The Spectrum Analyzer computes and plots the spectrum over the entire “Nyquist frequency interval” on page 4-1631.
- 'Span and center frequency' - The Spectrum Analyzer computes and plots the spectrum over the interval specified by the Span and CenterFrequency properties.
- 'Start and stop frequencies' - The Spectrum Analyzer computes and plots the spectrum over the interval specified by the StartFrequency and StopFrequency properties.

**Tunable:** Yes

### UI Use

Open the **Spectrum Settings**. In the **Main options** section, select **Full frequency span** for 'Full'. Otherwise, clear the **Full frequency span** check box and choose between Span or FStart.

### StartFrequency — Start frequency to compute spectrum

'-5e3' (default) | character vector of a real scalar

Start of the frequency interval over which spectrum is computed, specified in hertz as a character vector of a real scalar. The overall span, which is defined by this property and StopFrequency, must fall within the “Nyquist frequency interval” on page 4-1631.

### Dependency

To enable this property, set FrequencySpan to 'Start and stop frequencies'.

### UI Use

Open the **Spectrum Settings**. In the **Main options** section, clear the **Full frequency span** and change Span to FStart. Set **FStart (Hz)**.

### StopFrequency — Stop frequency to compute spectrum

'5e3' (default) | character vector of a real scalar

End of the frequency interval over which spectrum is computed, specified in hertz as a character vector of a real scalar. The overall span, which is defined by this property and the StartFrequency property, must fall within the Nyquist frequency interval on page 4-1631.

### Dependency

To enable this property, set FrequencySpan to 'Start and stop frequencies'.

### UI Use

Open the **Spectrum Settings**. In the **Main options** section, clear the **Full frequency span** and change Span to FStart. Set **FStop (Hz)**.

### CenterFrequency — Center of frequency span

'0' (default) | character vector of a real scalar

Specify in hertz the center frequency of the span over which the Spectrum Analyzer computes and plots the spectrum. The overall frequency span, defined by the Span and this property, must fall within the “Nyquist frequency interval” on page 4-1631.

**Dependency**

To enable this property, set FrequencySpan to 'Span and center frequency'.

**UI Use**

Open the **Spectrum Settings**. In the **Main options** section, clear **Full frequency span** and set **CF (Hz)**.

**Span — Frequency span to compute spectrum**

'10e3' (default) | character vector of a real positive scalar

Specify the frequency span, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. The overall span, defined by this property and the CenterFrequency property, must fall within the “Nyquist frequency interval” on page 4-1631.

**Dependency**

To enable this property, set FrequencySpan to 'Span and center frequency'.

**UI Use**

Open the **Spectrum Settings**. In the **Main options** section, clear **Full frequency span** and set **Span**.

**TimeResolutionSource — Source of the time resolution value**

'Auto' (default) | 'Property'

Specify the source for the time resolution of each spectrogram line as either 'Auto' or 'Property'. The TimeResolution property shows the time resolution for the different frequency resolution methods and time resolution properties.

**Tunable:** Yes

**Dependency**

To enable this property, set ViewType to 'Spectrogram' or 'Spectrum and spectrogram'.

**UI Use**

Open the **Spectrum Settings**. In the **Spectrogram options** section, set **Time res (s)**.

**TimeResolution — Time resolution**

'1e-3' (default) | character vector of a positive scalar

Specify the time resolution of each spectrogram line as a character vector of a positive scalar, expressed in seconds.

The time resolution value is determined based on frequency resolution method, the RBW setting, and the time resolution setting.

Method	Frequency Resolution Method	Frequency Resolution Setting	Time Resolution Setting	Resulting Time Resolution in Seconds
Welch or Filter Bank	RBW (Hz)	Auto	Auto	1/RBW
Welch or Filter Bank	RBW (Hz)	Auto	Manually entered	Time Resolution
Welch or Filter Bank	RBW (Hz)	Manually entered	Auto	1/RBW
Welch or Filter Bank	RBW (Hz)	Manually entered	Manually entered	Must be equal to or greater than the minimum attainable time resolution, 1/RBW. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW.
Welch	Window length	—	Auto	1/RBW

Method	Frequency Resolution Method	Frequency Resolution Setting	Time Resolution Setting	Resulting Time Resolution in Seconds
Welch	Window length	—	Manually entered	Must be equal to or greater than the minimum attainable time resolution. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW.
Filter Bank	Number of frequency bands	—	Auto	1/RBW
Filter Bank	Number of frequency bands	—	Manually entered	Must be equal to or greater than the minimum attainable time resolution, 1/RBW.

### Dependency

To enable this property, set:

- ViewType to 'Spectrogram' or 'Spectrum and spectrogram'
- TimeResolutionSource to 'Property'.

### UI Use

Open the **Spectrum Settings**. In the **Spectrogram options** section, in the **Time res (s)** box, enter a number.

### TimeSpanSource — Source of time span value

'Auto' (default) | 'Property'

Specify the source for the time span of the spectrogram as either 'Auto' or 'Property'. If you set this property to 'Auto', the spectrogram displays 100 spectrogram lines at any given time. If you set this property to 'Property', the spectrogram uses the time duration you specify in seconds in the TimeSpan property.

**Tunable:** Yes

### **Dependency**

To enable this property, set ViewType to 'Spectrogram' or 'Spectrum and spectrogram'.

### **UI Use**

Open the **Spectrum Settings**. In the **Spectrogram options** section, set **Time span (s)**.

### **TimeSpan — Time span**

'0.1' (default) | character vector of a positive scalar

Specify the time span of the spectrogram display in seconds. You must set the time span to be at least twice as large as the duration of the number of samples required for a spectral update.

### **Dependency**

To enable this property, set:

- ViewType to 'Spectrogram' or 'Spectrum and spectrogram'.
- TimeSpanSource to 'Property'.

### **UI Use**

Open the **Spectrum Settings**. In the **Spectrogram options** section, in the **Time span (s)** box, enter a number.

### **OverlapPercent — Overlap percentage**

'0' (default) | character vector of a real scalar

The percentage overlap between the previous and current buffered data segments, specified as a character vector of a real scalar. The overlap creates a window segment that is used to compute a spectral estimate. The value must be greater than or equal to zero and less than 100.

**UI Use**

Open the **Spectrum Settings**. In the **Window options** section, set **Overlap (%)**.

**Window – Window function**

'Hann' (default) | 'Rectangular' | 'Chebyshev' | 'Flat Top' | 'Hamming' |  
'Kaiser' | 'Blackman-Harris' | 'Custom'

Specify a window function for the spectral estimator. The following table shows preset windows. For more information, follow the link to the corresponding function reference in the Signal Processing Toolbox documentation.

Window Option	Corresponding Signal Processing Toolbox Function
'Rectangular'	rectwin
'Chebyshev'	chebwin
'Flat Top'	flattopwin
'Hamming'	hamming
'Hann'	hann
'Kaiser'	kaiser
'Blackman-Harris'	blackmanharris

To set your own spectral estimation window, set this property to 'Custom' and specify a custom window function in the CustomWindow property.

**Tunable:** Yes

**UI Use**

Open the **Spectrum Settings**. In the **Window options** section, set **Window**.

**CustomWindow – Custom window function**

'hann' (default) | character array | string

Specify a custom window function as a character array or string. The custom window function name must be on the MATLAB path. This property is useful if you want to customize the window using additional properties available with the Signal Processing Toolbox version of the window function.

**Tunable:** Yes

### Example

Define and use a custom window function.

```
function w = my_hann(L)
    w = hann(L, 'periodic')
end

scope.Window = 'Custom';
scope.CustomWindow = 'my_hann'
```

### Dependency

To use this property, set Window to 'Custom'.

### UI Use

Open the **Spectrum Settings**. In the **Window options** section, in the **Window** option box, enter a custom window function name.

### SidelobeAttenuation — Sidelobe attenuation of window

'60' (default) | character vector of real positive scalar

The window sidelobe attenuation, in decibels (dB). The value must be greater than or equal to 45.

### Dependency

To enable this property, set Window to 'Chebyshev' or 'Kaiser'.

### UI Use

Open the **Spectrum Settings**. In the **Window options** section, set **Attenuation (dB)**.

### InputUnits — Units of frequency input

'dBm' (default) | 'dBV' | 'dBW' | 'Vrms' | 'Watts'

Select the units of the frequency-domain input. This property allows the Spectrum Analyzer to scale frequency data if you choose a different display unit with the “Units” on page 2-0 property.

### Dependency

This option is only available for InputDomain set to Frequency.

**UI Use**

Open the **Spectrum Settings**. In the **Frequency input options** section, set **Input units**.

**SpectrumUnits — Units of the spectrum**

'Auto' (default) | 'dBm' | 'dBFS' | 'dBV' | 'dBW' | 'Vrms' | 'Watts'

Specify the units in which the Spectrum Analyzer displays power values.

**Tunable:** Yes

**Dependency**

The available spectrum units depend on the value of SpectrumType.

InputDomain	SpectrumType	Allowed SpectrumUnits
Time	Power or Power density	'dBFS', 'dBm', 'dBW', 'Watts'
	RMS	'Vrms', 'dBV'
Frequency	—	'dBm', 'dBV', 'dBW', 'Vrms', 'Watts',

**UI Use**

Open the **Spectrum Settings**. In the **Trace options** section, set **Units**.

**FullScaleSource — Source of full scale**

'Auto' (default) | 'Property'

Specify the source of the dBFS scaling factor as either 'Auto' or 'Property'.

- 'Auto' - The Spectrum Analyzer adjusts the scaling factor based on the input data.
- 'Property' - Specify the full-scale scaling factor using the FullScale property.

**Dependency**

To enable this property, set SpectrumUnits to 'dBFS'.

**UI Use**

Open the **Spectrum Settings**. In the **Trace options** section, set **Full scale** to Auto or enter a number.

### **FullScale — Full scale**

'1' (default) | character vector of a positive scalar

Specify a character vector of a real positive scalar for the dBFS full scale.

#### **Dependency**

To enable this option set:

- SpectrumUnits to 'dBFS'
- FullScaleSource to 'Property'

#### **UI Use**

Open the **Spectrum Settings**. In the **Trace options** section, set **Full scale** to Auto or enter a number.

### **ReferenceLoad — Reference load**

'1' (default) | character vector of a real positive scalar

The load the scope uses as a reference to compute power levels.

#### **UI Use**

Open the **Spectrum Settings**. In the **Trace options** section, set **Reference load**.

### **PlotNormalTrace — Normal trace flag**

true (default) | false

Set this property to `false` to remove the display of the normal traces. These traces display the free-running spectral estimates. Even when the traces are removed from the display, the Spectrum Analyzer continues its spectral computations.

**Tunable:** Yes

#### **Dependency**

To enable this property, set ViewType to 'Spectrum' or 'Spectrum and spectrogram'.

#### **UI Use**

Open the **Spectrum Settings**. In the **Trace options** section, select **Normal trace**.

**PlotMaxHoldTrace — Max-hold trace flag**

false (default) | true

To compute and plot the maximum-hold spectrum of each input channel, set this property to `true`. The maximum-hold spectrum at each frequency bin is computed by keeping the maximum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its maximum-hold computations.

**Tunable:** Yes**Dependency**

To enable this property, set `ViewType` to 'Spectrum' or 'Spectrum and spectrogram'.

**UI Use**

Open the **Spectrum Settings**. In the **Trace options** section, select **Max-hold trace**.

**PlotMinHoldTrace — Min-hold trace flag**

false (default) | true

To compute and plot the minimum-hold spectrum of each input channel, set this property to `true`. The minimum-hold spectrum at each frequency bin is computed by keeping the minimum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its minimum-hold computations.

**Tunable:** Yes**Dependency**

To enable this property, set `ViewType` to 'Spectrum' or 'Spectrum and spectrogram'.

**UI Use**

Open the **Spectrum Settings**. In the **Trace options** section, select **Min-hold trace**.

**SpectralMask — Spectral mask lines**

SpectralMaskSpecification object

Specify whether to display upper and lower spectral mask lines on a spectrum plot. This property uses `SpectralMaskSpecification` properties to enable and configure the spectral masks. The `SpectralMaskSpecification` properties are:

- **EnabledMasks** — Masks to enable, specified as a character vector or string. Valid values are 'None', 'Upper', 'Lower', or 'Upper and lower'.

Default: 'None'

- **UpperMask** — Upper limit spectral mask, specified as a scalar or two-column matrix. If **UpperMask** is a scalar, the upper limit mask uses the power value of the scalar for all frequency values applicable to the Spectrum Analyzer. If **UpperMask** is a matrix, the first column contains the frequency values (Hz), which correspond to the x-axis values. The second column contains the power values, which correspond to the associated y-axis values. To apply offsets to the power and frequency values, use **ReferenceLevel** and **MaskFrequencyOffset** property values, respectively.

Default: Inf

- **LowerMask** — Lower limit spectral mask, specified as a scalar or two-column matrix. If **LowerMask** is a scalar, the lower limit mask uses the power value of the scalar for all frequency values applicable to the Spectrum Analyzer. If **LowerMask** is a matrix, the first column contains the frequency values (Hz), which correspond to the x-axis values. The second column contains the power values, which correspond to the associated y-axis values. To apply offsets to the power and frequency values, use **ReferenceLevel** and **MaskFrequencyOffset** property values, respectively.

Default: -Inf

- **ReferenceLevel** — Reference level for mask power values, specified as either 'Custom' or 'Spectrum peak'. When **ReferenceLevel** is 'Custom', the **CustomReferenceLevel** property value is used as the reference to the power values, in dBm, in the **UpperMask** and **LowerMask** properties. When **ReferenceLevel** is 'Spectrum peak', the peak value of the current spectrum of the **SelectedChannel** is used.

Default: 'Custom'

- **CustomReferenceLevel** — Custom reference level, specified as a real value, in the same units as the power units. The reference level is the value to which to reference the power values in the **UpperMask** and **LowerMask** properties. This property applies when **ReferenceLevel** is set to 'Custom'. This property uses the same units as the **PowerUnits** property of the Spectrum Analyzer.

Default: 0

- **SelectedChannel** — Input channel with peak spectrum to use as the mask reference level, specified as an integer. This property applies when **ReferenceLevel** is set to 'Spectrum peak'.

Default: 1

- **MaskFrequencyOffset** — Frequency offset, specified as a finite, numeric scalar. Frequency offset is the amount of offset to apply to frequency values in the **UpperMask** and **LowerMask** properties.

Default: 0

All **SpectralMaskSpecification** properties are tunable.

Masks are overlaid on the spectrum. If the mask is green, the signal is passing the mask limitations. If the mask is red, the signal is failing the mask limits.

You can check the status of the spectral mask using one of the following methods:

- To modify the spectral mask and see the spectral mask status, in the scope toolbar, select the spectral mask button, . In the Spectral Mask panel that opens, you can modify the masks and see details about what percentage of the time the mask is succeeding, which mask is failing, how many times the mask failed, and which channels are causing the failure.
- To get the current status of the spectral masks, call the function `getSpectralMaskStatus`.
- To perform an action every time the mask fails, use the `MaskTestFailed` event. To trigger a function when the mask fails, create a listener to the `MaskTestFailed` event and define a callback function to trigger. For more details about using events, see “Events” (MATLAB).

**Tunable:** Yes

### UI Use

Open the **Spectral Mask** panel and modify the **Settings** options.

### **TreatMby1SignalsAsOneChannel** — Treat unoriented sample-based input signal as a column vector

`true` (default) | `false`

Set this property to `true` to treat  $M$ -by-1 and unoriented sample-based inputs as a column vector, or one channel. Set this property to `false` to treat  $M$ -by-1 and unoriented sample-based inputs as a 1-by- $M$  row vector.

### Visualization

#### **Name — Window name**

'Spectrum Analyzer' (default) | character vector | string

Title of the scope window.

**Tunable:** Yes

#### **Position — Window position**

screen center (default) | [left bottom width height]

Spectrum Analyzer window position in pixels, specified by the size and location of the scope window as a four-element double vector of the form [left bottom width height]. You can place the scope window in a specific position on your screen by modifying the values to this property.

By default, the window appears in the center of your screen with a width of 800 pixels and height of 450 pixels. The exact center coordinates depend on your screen resolution.

**Tunable:** Yes

#### **PlotType — Plot type for normal traces**

'Line' (default) | 'Stem'

Specify the type of plot to use for displaying normal traces as either 'Line' or 'Stem'. Normal traces are traces that display free-running spectral estimates.

**Tunable:** Yes

#### **Dependency**

To enable this property, set:

- ViewType to 'Spectrum' or 'Spectrum and spectrogram'
- PlotNormalTrace to true

#### **UI Use**

Open the **Style** properties and set **Plot type**.

#### **ReducePlotRate — Improve performance with reduced plot rate**

true (default) | false

The simulation speed is faster when this property is set to `true`.

- `true` — the scope logs data for later use and updates the display at fixed intervals of time. Data occurring between these fixed intervals might not be plotted.
- `false` — the scope updates every time it computes the power spectrum. Use the `false` setting when you do not want to miss any spectral updates at the expense of slower simulation speed.

#### UI Use

Select **Simulation > Reduce plot rate to improve performance**.

#### Title — Display title

`''` (default) | character vector | string

Specify the display title as a character vector or string. To use the input name as the display title, enter `'%<SignalLabel>'`.

**Tunable:** Yes

#### UI Use

Open the **Configuration Properties**. On the **Display** tab, set **Title**.

#### ShowLegend — Show legend

`false` (default) | `true`

To show a legend with the input names, set this property to `true`.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** dialog box. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name. To show all signals, press **Esc**.

**Tunable:** Yes

#### UI Use

Open the **Configuration Properties**. On the **Display** tab, select **Show legend**.

#### ChannelNames — Channel names

empty cell (default) | cell array of character vectors

Specify the input channel names as a cell array of character vectors. The names appear in the legend, **Style** dialog box, and **Measurements** panels. If you do not specify names, the channels are labeled as Channel 1, Channel 2, etc.

**Tunable:** Yes

### **Dependency**

To see channel names, set `ShowLegend` to `true`.

### **UI Use**

On the legend, double-click the channel name.

### **ShowGrid — Grid visibility**

`false` (default) | `true`

Set this property to `true` to show gridlines on the plot.

**Tunable:** Yes

### **UI Use**

Open the **Configuration Properties**. On the **Display** tab, set **Show grid**.

### **YLimits — Y-axis limits**

`[-80, 20]` (default) | `[ymin ymax]`

Specify the y-axis limits as a two-element numeric vector, `[ymin ymax]`.

Example: `scope.YLimits = [-10,20]`

**Tunable:** Yes

### **Dependencies**

- To enable this property, set the `ViewType` property to `'Spectrum'` or `'Spectrum and spectrogram'`.
- The units directly depend upon the `SpectrumUnits` property.

### **UI Use**

Open the **Configuration Properties**. Set **Y-limits (maximum)** and **Y-limits (minimum)**.

**ColorLimits — Scale spectrogram color limits**

`[-80, 20]` (default) | `[colorMin colorMax]`

Control the color limits of the spectrogram using a two-element numeric vector, `[colorMin colorMax]`.

Example: `scope.ColorLimits = [-10,20]`

**Dependencies**

- To enable this property, set the `ViewType` property to `'Spectrogram'` or `'Spectrum and spectrogram'`.
- The units directly depend upon the `SpectrumUnits` property.

**UI Use**

Open the **Configuration Properties**. Set **Color-limits (minimum)** and **Color-limits (maximum)**.

**YLabel — Y-axis label**

`''` (default) | character vector | string

Specify the text for the scope to display to the left of the y-axis.

Regardless of this property, Spectrum Analyzer always displays power units as one of the `SpectrumUnits` values.

**Tunable:** Yes

**Dependency**

To enable this property, set `ViewType` to `'Spectrum'` or `'Spectrum and spectrogram'`.

**UI Use**

Open the **Configuration Properties**. Set **Y-label**.

**AxesLayout — Orientation of the spectrum and spectrogram**

`'Vertical'` (default) | `'Horizontal'`

Specify the layout type as `'Horizontal'` or `'Vertical'`. A vertical layout stacks the spectrum above the spectrogram. A horizontal layout puts the two views side-by-side.

**Tunable:** Yes

### Dependency

To enable this property, set `ViewType` to `'Spectrum and spectrogram'`.

### UI Use

Open the **Spectrum Settings**. Set **Axes layout**.

### OpenAtSimulationStart — Open scope when starting simulation

`true` (default) | `false`

Set this property to `true` to open the scope when the simulation starts. Set this property to `false` to prevent the scope from opening at the start of simulation.

### UI Use

Select **File > Open at Start of Simulation**.

## Examples

### Construct a Spectrum Analyzer Configuration Object

Create a new Simulink® model with a randomly-generated name.

```
sysname=char(randi(26,1,7)+96);  
new_system(sysname);
```

Add a new Spectrum Analyzer block to the model.

```
add_block('built-in/SpectrumAnalyzer',[sysname,'/SpectrumAnalyzer'])
```

Call the `get_param` function to retrieve the default Spectrum Analyzer block configuration properties.

```
config = get_param([sysname,'/SpectrumAnalyzer'],'ScopeConfiguration')
```

```
config =  
    SpectrumAnalyzerConfiguration with properties:
```

```
    NumInputPorts: '1'  
    SampleRateSource: 'Inherited'  
    SampleRate: '10e3'
```

```
    InputDomain: 'Time'
    SpectrumType: 'Power'
    ViewType: 'Spectrum'
    Method: 'Welch'
    SpectralAverages: '1'
    PlotAsTwoSidedSpectrum: 1
    FrequencyScale: 'Linear'
    AxesScaling: 'Auto'
    FrequencyResolutionMethod: 'RBW'
    RBWSource: 'Auto'
    RBW: '9.76'
    FrequencyOffset: '0'
    FrequencySpan: 'Full'
    Span: '10e3'
    CenterFrequency: '0'
    StartFrequency: '-5e3'
    StopFrequency: '5e3'
    FFTLengthSource: 'Auto'
    FFTLength: '1024'
    FrequencyVectorSource: 'Auto'
    FrequencyVector: '[-5000 5000]'
    WindowLength: '1024'
    OverlapPercent: '0'
    Window: 'Hann'
    CustomWindow: 'hann'
    SidelobeAttenuation: '60'
    NumTapsPerBand: '12'
    TimeResolutionSource: 'Auto'
    TimeResolution: '1e-3'
    TimeSpanSource: 'Auto'
    TimeSpan: '100e-3'
    InputUnits: 'dBm'
    SpectrumUnits: 'dBm'
    FullScaleSource: 'Auto'
    FullScale: '1'

# ArrayPlotConfiguration

Array Plot block appearance and behavior

## Description

Array Plot Configuration properties control the appearance and behavior of an Array Plot block. Create a configuration object with `get_param`, and then change property values using the object with dot notation.

## Creation

`MyScopeConfiguration = get_param(gcbh, 'ScopeConfiguration')` creates a new Array Plot Configuration object. If you do not provide the full path to the block, you must first select the block in the model.

## Properties

### Plot Configuration

#### **Name — Window name**

'Array Plot' (default) | character vector | string

Specify the name of the scope. This name appears as the title of the scope's figure window. To specify a title of a scope plot, use the Title property.

Data Types: char | string

#### **NumInputPorts — Number of input ports**

'1' (default) | character vector

Number of input ports on a scope block, specified as a character vector. The maximum number of input ports is 96.

### UI Use

Select **File > Number of Input Ports**.

### Position — Scope window position and size in pixels

screen center (default) | [left bottom width height]

Specify, in pixels, the size and location of the scope window as a four-element vector of the form [left bottom width height]. By default, the scope window appears in the center of your screen with a width of 800 pixels and height of 450 pixels. The default values for this property may change depending on your screen resolution.

### OpenAtSimulationStart — Open scope when starting simulation

true (default) | false

Set this property to `true` to open the scope when the simulation starts. Set this property to `false` to prevent the scope from opening at the start of simulation.

### UI Use

Select **File > Open at Start of Simulation**.

### XDataMode — Source of x-data spacing

'Sample increment and X-offset' (default) | 'Custom'

Specify whether to use the `SampleIncrement` and `XOffset` property values to determine spacing, or specify your own custom spacing. If you specify 'Custom', you also must specify the `CustomXData` property values.

### UI Use

Open the **Configuration Properties**. On the **Main** tab, set **X-data mode**.

### SampleIncrement — Sample increment of input

'1' (default) | character vector

The spacing between samples along the  $x$ -axis, specified as a finite scalar in a character vector. The input signal is only  $y$ -axis data.  $x$ -axis data is set automatically based on the `XOffset` and `SampleIncrement` properties. For example, when `Xoffset` is 0 and `SampleIncrement` is 1, the  $x$ -data for the input signal is set to 0, 1, 2, 3, 4, and so on. If you set `SampleIncrement` to 0.25, the  $x$ -axis data becomes 0, 0.25, 0.5, 0.75, 1, and so on.

**UI Use**

Open the **Configuration Properties**. On the **Main** tab, set **Sample increment**.

**Dependency**

To use this property, set XDataMode to 'Sample increment and X-offset'.

**XOffset — Display offset of x-axis**

'0' (default) | character vector

Specify the offset to display on the x-axis.

**UI Use**

Open the **Configuration Properties**. On the **Main** tab, set **X-offset**.

**Dependency**

To use this property, set XDataMode to 'Sample increment and X-offset'.

**CustomXData — x-data values**

' []' (default) | character vector

Specify the desired x-data values as a character vector. The row or column vector must be equal to the frame length of the inputs. If you use the default (empty vector) value, the x-data is uniformly spaced and set to (0:L-1), where L is the frame length.

```
Example: scopeConfiguration.XDataMode = 'Custom';  
scopeConfiguration.CustomXData = 'logspace(0,log10(44100/2),1024)'
```

**UI Use**

Open the **Configuration Properties**. On the **Main** tab, set **Custom X-Data**.

**Dependency**

To use this property, set XDataMode to 'Custom'.

**XScale — Scale of x-axis**

'Linear' (default) | 'Log'

Specify whether the scale of the x-axis is 'Linear' or 'Log'. If XOffset is a negative value, you cannot set this property to 'Log'.

### UI Use

Open the **Configuration Properties**. On the **Main** tab, set **X-axis scale**.

### MaximizeAxes — Maximize axes control

'Auto' (default) | 'On' | 'Off'

Specify whether to display the scope in maximized-axes mode. In this mode, the axes are expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- 'Auto' — The axes appear maximized in all displays only if the Title and YLabel properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- 'On' — The axes appear maximized in all displays. Any values entered into the Title and YLabel properties are hidden.
- 'Off' — None of the axes appear maximized.

**Tunable:** Yes

### UI Use

Open the **Configuration Properties**. On the **Main** tab, set **Maximize axes**.

### Title — Display title

' ' (default) | character vector | string

Specify the display title as a character vector or string. To use the input name as the display title, enter '%<SignalLabel>'.

**Tunable:** Yes

### UI Use

Open the **Configuration Properties**. On the **Display** tab, set **Title**.

### ShowLegend — Show legend

false (default) | true

To show a legend with the input names, set this property to `true`.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** dialog box. In the scope legend, click a signal name to

hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name. To show all signals, press **Esc**.

**Tunable:** Yes

#### **UI Use**

Open the **Configuration Properties**. On the **Display** tab, select **Show legend**.

#### **ChannelNames — Channel names**

empty cell (default) | cell array of character vectors

Specify the input channel names as a cell array of character vectors. The names appear in the legend, **Style** dialog box, and **Measurements** panels. If you do not specify names, the channels are labeled as Channel 1, Channel 2, etc.

**Tunable:** Yes

#### **Dependency**

To see channel names, set ShowLegend to true.

#### **UI Use**

On the legend, double-click the channel name.

#### **ShowGrid — Display grid**

true (default) | false

Set this property to true to show grid lines on the plot.

#### **UI Use**

Open the **Configuration Properties**. On the **Display** tab, set **Show grid**.

#### **PlotAsMagnitudePhase — Plot signal as magnitude and phase**

false (default) | true

When you set this property to true, the scope plots the magnitude and phase of the input signal on two separate axes within the same active display. When you set this property to false, the scope plots the real and imaginary parts of the input signal on two separate axes within the same active display.

This property is useful for complex-valued input signals. Turning on this property affects the phase for real-valued input signals. When the amplitude of the input signal is

nonnegative, the phase is 0 degrees. When the amplitude of the input signal is negative, the phase is 180 degrees.

**Tunable:** Yes

### UI Use

Open the **Configuration Properties**. On the **Display** tab, select **Plot signals as magnitude and phase**.

### XLabel — x-axis label

' ' (default) | character vector | string

Specify the text for the scope to display below the x-axis.

### UI Use

Open the **Configuration Properties**. On the **Display** tab, set **X-label**.

### YLabel — y-axis label

'Amplitude' (default) | character vector | string

Specify the text for the scope to display to the left of the y-axis.

**Tunable:** Yes

### Dependencies

This property applies only when `PlotAsMagnitudePhase` is `false`. When `PlotAsMagnitudePhase` is `true`, the two y-axis labels are read-only values. The y-axis labels are set to 'Magnitude' and 'Phase' for the magnitude plot and the phase plot, respectively.

### UI Use

Open the **Configuration Properties**. On the **Display** tab, set **Y-Label**.

Data Types: char | string

### YLimits — y-axis limits

[-10,10] (default) | [ymin, ymax]

Specify the y-axis limits as a two-element numeric vector, [ymin, ymax].

If `PlotAsMagnitudePhase` is `false`, the default is `[-10,10]`. If `PlotAsMagnitudePhase` is `true`, the default is `[0,10]`.

**Tunable:** Yes

#### Dependencies

When `PlotAsMagnitudePhase` is `true`, this property specifies the y-axis limits of only the magnitude plot. The y-axis limits of the phase plot are always `[-180,180]`.

#### UI Use

Open the **Configuration Properties**. On the **Display** tab, set **Y-limits (Minimum)** and **Y-limits (Maximum)**.

#### PlotType — Control type of plot

'Stem' (default) | 'Line' | 'Stairs'

Specify the type of plot to use for all the input signals displayed in the scope window:

- 'Stem' - The scope displays the input signal as circles with vertical lines extending down to the x-axis at each of the sampled values. This option is similar to the `stem` function.
- 'Line' - The scope displays the input signal as lines connecting each of the sampled values. This option is similar to the `line` or `plot` functions.
- 'Stairs' - The scope displays the input signal as a stair-step graph. A stair-step graph is made up of only horizontal lines and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each vertical line represents a change in values occurring at a sample. This option is similar to the `stairs` function. Stair-step graphs are useful for drawing time history graphs of digitally sampled data.

#### UI Use

Open the **Style** dialog box and set **Plot type**.

#### AxesScaling — Axes scaling mode

'OnceAtStop' (default) | 'Auto' | 'Manual' | 'Updates'

Specify when the scope scales the axes. Valid values are:

- 'Auto' — The scope scales the axes as needed to fit the data, both during and after simulation.

- 'Manual' — The scope does not scale the axes automatically.
- 'OnceAtStop' — The scope scales the axes when the simulation stops.
- 'Updates' — The scope scales the axes once and only once after 10 updates.

### UI Use

Select **Tools > Axes Scaling**.

## Examples

### Construct an Array Plot Configuration Object

Create a new Simulink® model with a randomly-generated name.

```
sysname='ArrayPlotExample';  
new_system(sysname);
```

Add a new Array Plot block to the model.

```
add_block('built-in/ArrayPlot',[sysname,'/ArrayPlot'])
```

Call the `get_param` function to retrieve the default Array Plot block configuration properties.

```
scopeConfig = get_param([sysname,'/ArrayPlot'],'ScopeConfiguration')
```

```
scopeConfig =
```

```
ArrayPlotConfiguration with properties:
```

```
                Name: 'ArrayPlot'  
    NumInputPorts: '1'  
OpenAtSimulationStart: 1  
                Visible: 0  
                Position: [240 287 800 450]  
                XDataMode: 'Sample increment and X-offset'  
SampleIncrement: '1'  
                XOffset: '0'  
                CustomXData: '[]'  
                XScale: 'Linear'  
MaximizeAxes: 'Auto'  
                Title: ''  
                ShowLegend: 0
```

```

ChannelNames: {''}
ShowGrid: 1
PlotAsMagnitudePhase: 0
XLabel: ''
YLabel: 'Amplitude'
YLimits: [-10 10]
PlotType: 'Stem'
AxesScaling: 'Manual'
AxesScalingNumUpdates: '10'

```

### Configure Array Plot From the Command-Line

This example shows how to change Array Plot block behavior and appearance from the MATLAB command line.

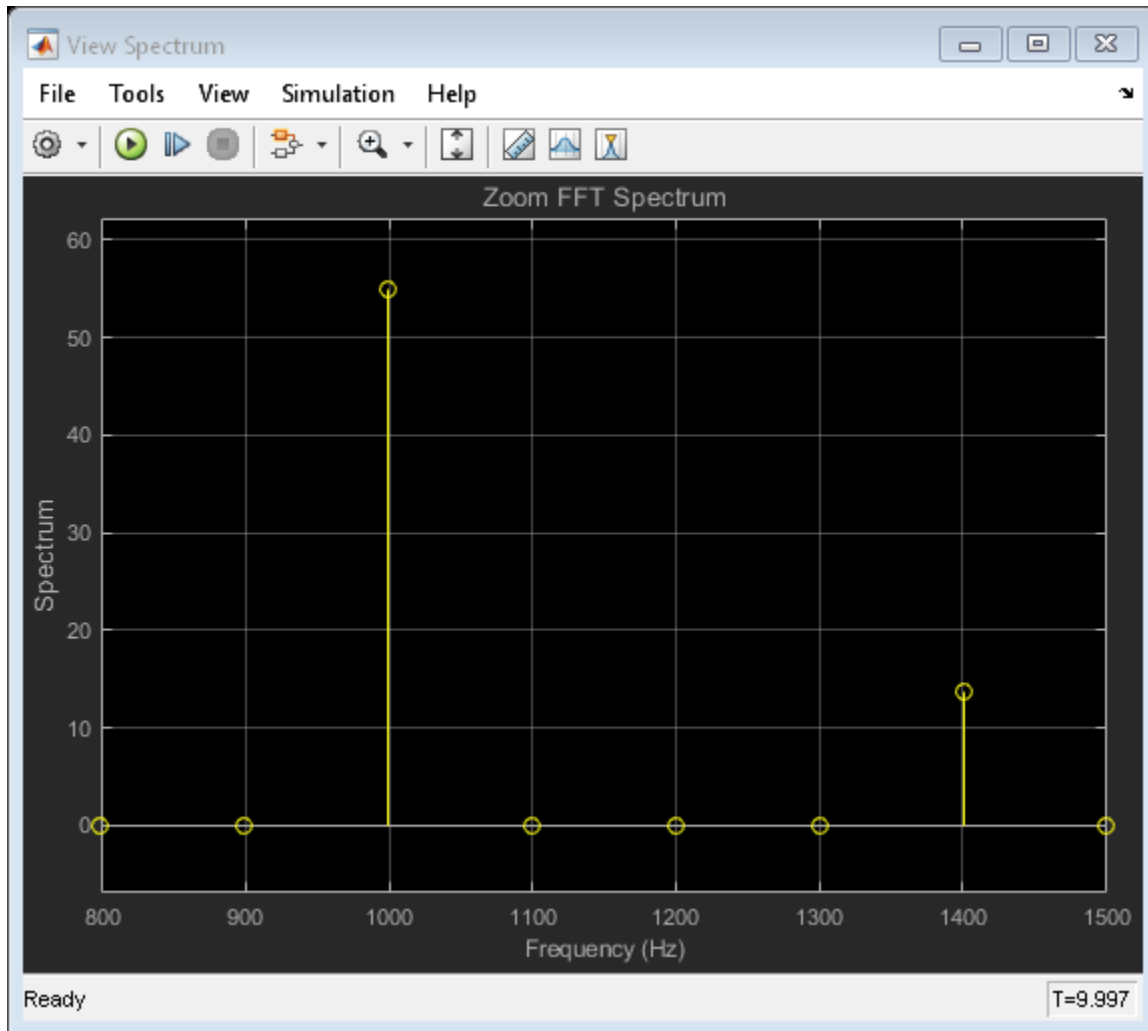

Open the model and create an Array Plot block configuration object.

```

model = 'zoomfftExample';
open_system(model)
sim(model)
open_system([model '/View Spectrum'])
ArrayPlotConfiguration = get_param([model '/View Spectrum'],'ScopeConfiguration');

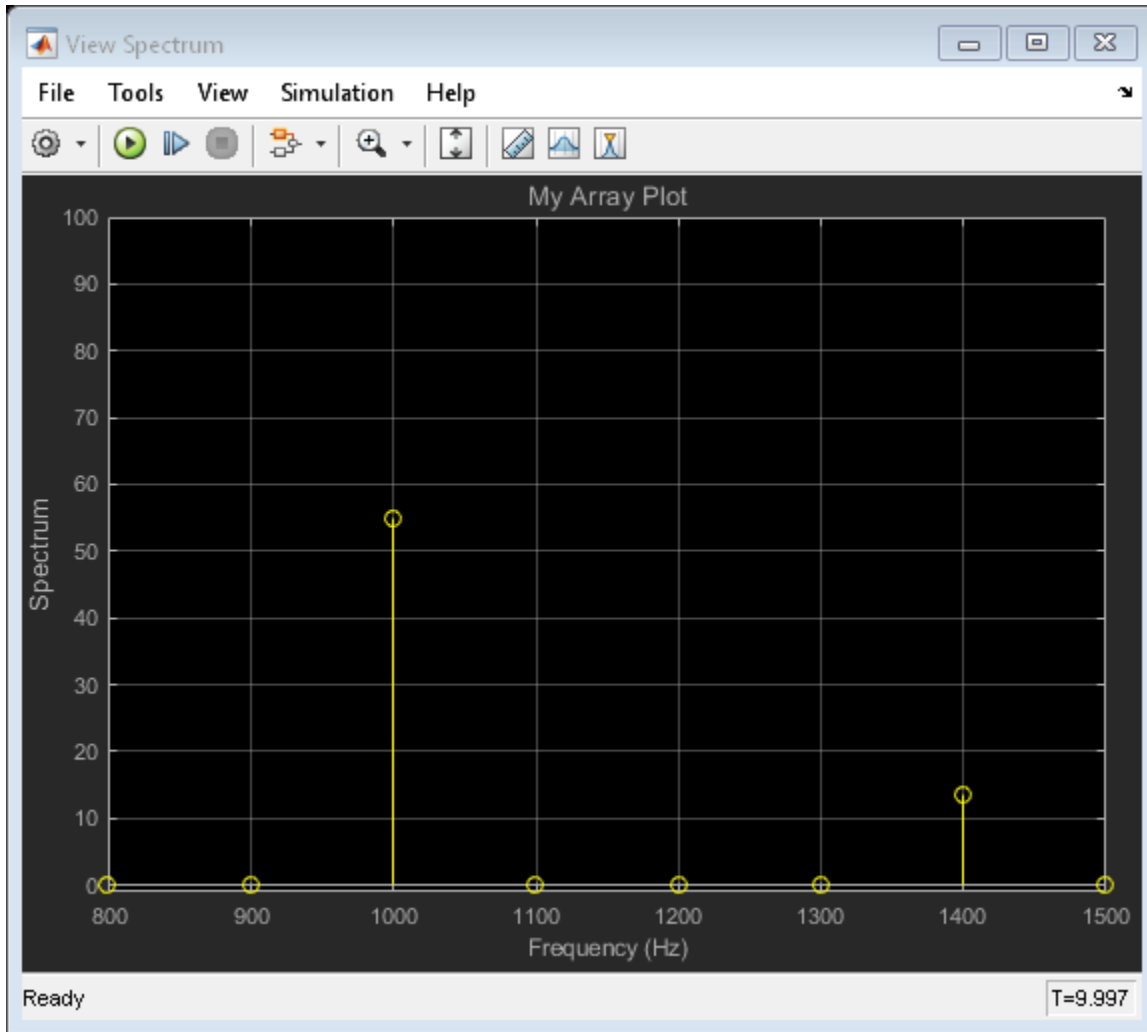

```

Change the title of the Array Plot and the axes scaling.

```
ArrayPlotConfiguration.Title = 'My Array Plot';  
ArrayPlotConfiguration.AxesScaling = 'Manual';  
ArrayPlotConfiguration.YLimits = [-1 100];
```

## addCursor

**Package:** dsp

Add cursor to Logic Analyzer

### Syntax

```
cursorTag = addCursor(scope)
cursorTag = addCursor(scope,Name,Value)
```

### Description

`cursorTag = addCursor(scope)` adds in a cursor to the display. A tag value is returned, which can be used to modify and delete the cursor.

`cursorTag = addCursor(scope,Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

### Examples

#### Modify Logic Analyzer Cursors Programmatically

This example shows how to use functions to create, manipulate, and delete cursors in a `dsp.LogicAnalyzer` object.

#### Create Logic Analyzer and Signals

```
scope = dsp.LogicAnalyzer('NumInputPorts',3);
for ii = 1:20
    scope(ii,10*ii,20*ii);
end
```

## Add Cursor

```
cursor = addCursor(scope, 'Location', 15, 'Color', 'Cyan');
getCursorInfo(scope, cursor)
```

```
ans = struct with fields:
    Location: 15
    Color: [0 1 1]
    Locked: 0
    Tag: 'C2'
```

## Modify Cursor

```
modifyCursor(scope, cursor, 'Color', 'Magenta')
```

## Remove Cursor

```
tags = getCursorTags(scope);
deleteCursor(scope, tags{1});
```

## Input Arguments

**scope** — The Logic Analyzer object to which you want to add a cursor  
 dsp.LogicAnalyzer object

Example: `addCursor(scope)` adds a cursor with the default characteristics.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Location', 2, 'Color', 'Blue'` specifies that a cursor should be moved to the 2-second mark and colored blue.

### **Color** — Color of the cursor

`'Yellow'` (default) | character vector | three element vector

Color of the cursor, specified as an [R G B] value or one of the following:

- `'Black'`
- `'Blue'`
- `'Cyan'`
- `'Green'`
- `'Magenta'`
- `'White'`
- `'Yellow'`

For more information, see `ColorSpec` (Color Specification).

Example: `'Color', 'Blue'`

Example: `'Color', [0,0,1]`

Data Types: `char` | `double`

### **Location** — Location of the cursor

`0` (default) | numeric scalar

Specify as a numeric scalar value, in seconds, the cursor location.

Example: `'Location', 1`

Data Types: `double`

### **Locked** — Locked status of the cursor

`false` (default) | `true`

Locked status of the cursor, specified as `false` or `true`.

- `true` — the cursor's location cannot be changed. Logic Analyzer denotes this by assigning a default color of gray. This color cannot be changed.
- `false` — the cursor's location can be changed. Logic Analyzer denotes this by assigning a default color of yellow.

Example: `'Locked', true`

**Introduced in R2013a**

## addDivider

**Package:** dsp

Add divider to Logic Analyzer

## Syntax

```
dividerTag = addDivider(scope)
dividerTag = addDivider(scope,Name,Value)
```

## Description

`dividerTag = addDivider(scope)` adds a divider to the display. A tag value is returned, which can be used to modify and delete the divider.

`dividerTag = addDivider(scope,Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

## Examples

### Manipulate Logic Analyzer Programmatically

Use functions to construct and manipulate a `dsp.LogicAnalyzer` System object.

### Display Waves on Logic Analyzer scope.

```
scope = dsp.LogicAnalyzer('NumInputPorts',2);

stop = 30;
for count = 1:stop
    sinValVec = sin(count/stop*2*pi);
    cosValVec = cos(count/stop*2*pi);
    cosValVecOffset = cos((count+10)/stop*2*pi);
```

```

scope([count (count-(stop/2))],[sinValVec cosValVec cosValVecOffset])
end

```

### Reorganize Display

```

digitalDividerTag = addDivider(scope,'Name','Digital','Height',20);
analogDividerTag = addDivider(scope,'Name','Analog','Height',40);

tags = getDisplayChannelTags(scope);

modifyDisplayChannel(scope,tags{1},'InputChannel',1,...
    'Name','Ramp Digital','Height',40);
modifyDisplayChannel(scope,tags{2},'InputChannel',2,...
    'Name','Waves Analog','Format','Analog','Height',80);

moveDisplayChannel(scope,digitalDividerTag,'DisplayChannel',1)

```

```
moveDisplayChannel(scope, tags{2}, 'DisplayChannel', length(tags))  
show(scope)
```

### Duplicate Wave and Check Information

```
addWave(scope, 'InputChannel', 2, 'Name', 'Waves Digital', 'Format', 'Digital', ...  
        'Height', 30, 'DisplayChannel', 3);
```

### Remove Dividers

```
deleteDisplayChannel(scope,digitalDividerTag)  
deleteDisplayChannel(scope,analogDividerTag)
```

### Clear variables

```
clear analogDividerTag cosValVec cosValVecOffset count digitalDividerTag duplicateWave
```

## Input Arguments

### scope — Logic Analyzer object

dsp.LogicAnalyzer object

dsp.LogicAnalyzer object to which you want to add a divider.

Example: `addDivider(scope)` adds a divider with the default characteristics.

## Divider Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'DisplayChannel',2,'Name','MyDivider'` specifies that a divider should be added to display channel 2 and named "MyDivider".

### **DisplayChannel** — Channel on the display that shows this divider

`NumInputPorts` (default) | scalar numeric value in the range (1,`NumInputPorts`)

Specify as a scalar numeric value the display channel that shows this divider. By default, the divider is added to the end of the display.

Example: `'DisplayChannel',2`

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

### **Height** — Height of the divider

0 (default) | scalar integer

Specify, in pixels, the height of the divider as a scalar integer in the range 8 to 200. If you choose 0, the value of the `DisplayChannelHeight` property in the Logic Analyzer is used.

Example: `'Height',2`

Data Types: `double`

### **Name** — The name or label for the divider

' ' (default) | character vector

Specify as a character vector the name that you would like to set for the new divider.

Example: `'Name','MyDivider'`

Data Types: `char`

## Output Arguments

### **dividerTag** — tag for new divider

random character vector

A tag for the newly added divider. Use the tag name to modify and delete the divider.

## See Also

`addCursor` | `addDivider` | `addWave` | `dsp.LogicAnalyzer`

**Introduced in R2013a**

# addWave

**Package:** dsp

Add wave to Logic Analyzer

## Syntax

```
waveTag = addWave(scope)
waveTag = addWave(scope,Name,Value)
```

## Description

`waveTag = addWave(scope)` adds a wave to the display. A tag value is returned, which can be used to modify and delete the wave.

`waveTag = addWave(scope,Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

## Examples

### Manipulate Logic Analyzer Programmatically

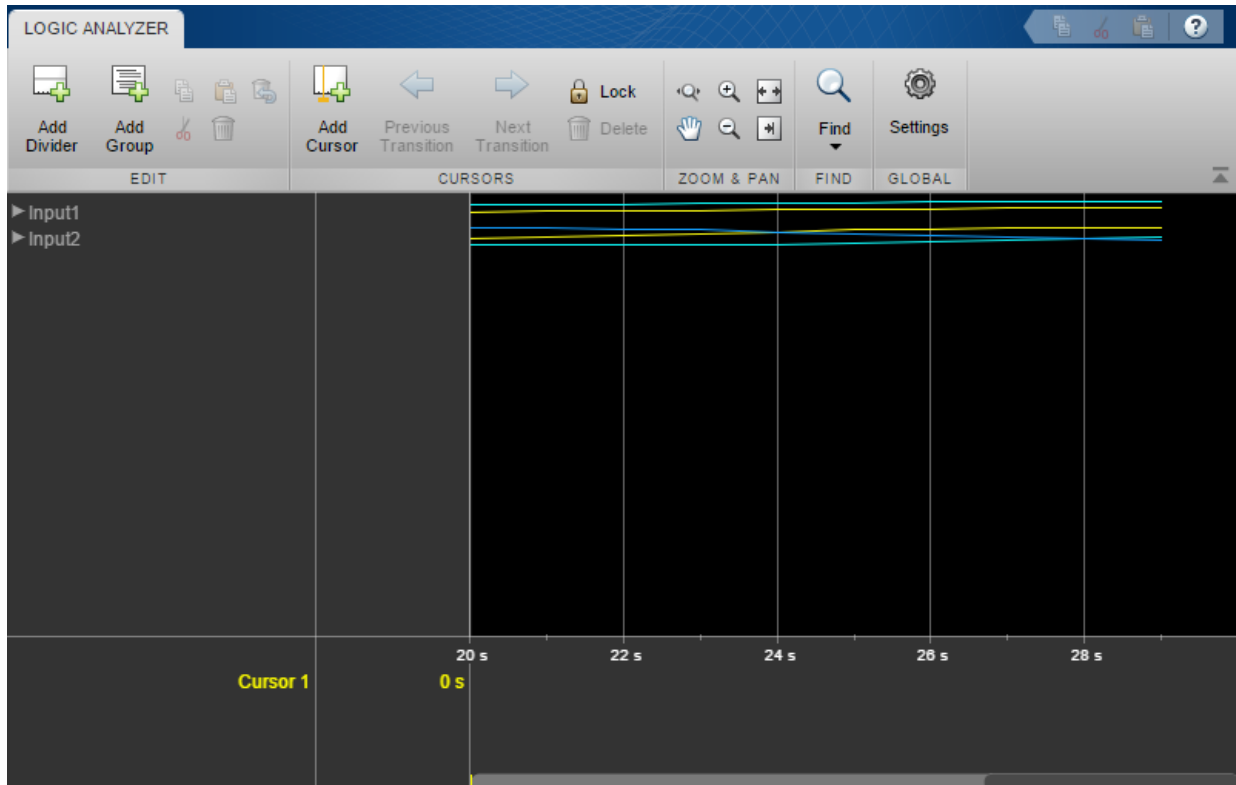

Use functions to construct and manipulate a `dsp.LogicAnalyzer` System object.

### Display Waves on Logic Analyzer scope.

```
scope = dsp.LogicAnalyzer('NumInputPorts',2);

stop = 30;
for count = 1:stop
    sinValVec = sin(count/stop*2*pi);
    cosValVec = cos(count/stop*2*pi);
    cosValVecOffset = cos((count+10)/stop*2*pi);
```

```
scope([count (count-(stop/2))],[sinValVec cosValVec cosValVecOffset])
end
```

### Reorganize Display

```
digitalDividerTag = addDivider(scope,'Name','Digital','Height',20);
analogDividerTag = addDivider(scope,'Name','Analog','Height',40);

tags = getDisplayChannelTags(scope);

modifyDisplayChannel(scope,tags{1},'InputChannel',1,...
    'Name','Ramp Digital','Height',40);
modifyDisplayChannel(scope,tags{2},'InputChannel',2,...
    'Name','Waves Analog','Format','Analog','Height',80);

moveDisplayChannel(scope,digitalDividerTag,'DisplayChannel',1)
```

```

moveDisplayChannel(scope, tags{2}, 'DisplayChannel', length(tags))
show(scope)

```

### Duplicate Wave and Check Information

```

addWave(scope, 'InputChannel', 2, 'Name', 'Waves Digital', 'Format', 'Digital', ...
        'Height', 30, 'DisplayChannel', 3);

```

### Remove Dividers

```
deleteDisplayChannel(scope,digitalDividerTag)  
deleteDisplayChannel(scope,analogDividerTag)
```

### Clear variables

```
clear analogDividerTag cosValVec cosValVecOffset count digitalDividerTag duplicateWave
```

## Input Arguments

**scope** — The Logic Analyzer object to which you want to add a wave  
 dsp.LogicAnalyzer object

Example: 'addWave(scope)' adds a wave with the default characteristics.

## Wave Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'InputChannel', 2, 'Color', 'Blue'` specifies that a wave should be added to input channel 1 and colored blue.

### **Color** — Color of the wave

`'Default'` (default) | character vector

Color of the wave, specified as an [R G B] value or one of the following:

- `'Black'`
- `'Blue'`
- `'Cyan'`
- `'Default'`
- `'Green'`
- `'Magenta'`
- `'Red'`
- `'White'`
- `'Yellow'`

When you choose `'Default'`, the value of the `DisplayChannelColor` property in the Logic Analyzer is used.

Example: `'Color', 'Blue'`

Example: `'Color', [0,0,1]`

Data Types: `char` | `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

### **DisplayChannel** — Channel on the display that shows this wave

`NumInputPorts` (default) | scalar numeric value in the range (1, `NumInputPorts`)

Specify as a scalar numeric value the display channel that shows this wave. By default, the wave is added to the end of the display.

Example: 'DisplayChannel',2

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

### **FontSize — Font size for values in the wave**

0 (default) | scalar nonnegative integer

Specify as a scalar nonnegative integer the font size in points. When you choose 0, the value of the `DisplayChannelFontSize` property in the Logic Analyzer is used.

Example: 'FontSize',8

Data Types: double

### **Format — Display format for the wave**

'Default' (default) | character vector

'Format' must be one of the following.

- 'Analog'
- 'Default'
- 'Digital'

When you choose 'Default', the value of the `DisplayChannelFormat` property in the Logic Analyzer is used.

Example: 'Format','Digital'

Data Types: char

### **Height — Height of the wave**

0 (default) | scalar integer

Specify as a scalar integer the height of the wave in the display in units of 16 pixels. When you choose 0, the value of the `DisplayChannelHeight` property in the Logic Analyzer is used.

Example: 'Height',2

Data Types: double

### **InputChannel — Input channel that corresponds to this wave**

1 (default) | scalar integer in the range (1,NumInputPorts)

This property specifies the input channel whose data is used for this wave. By default, it will connect the first input to this wave.

Example: 'InputChannel',2

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

### **Name — The name or label for the wave**

' ' (default) | character vector

Specify as a character vector the name that you would like to set for the new wave.

Example: 'Name', 'MyWave'

Data Types: char

### **Radix — Radix for the wave**

'Default' (default) | character vector

'Radix' must be one of the following.

- 'Binary'
- 'Default'
- 'Hexadecimal'
- 'Octal'
- 'Signed decimal'
- 'Unsigned decimal'

When the input signals are of class double, single, or logical, you should not set this property. When you choose 'Default', the value of the DisplayChannelRadix property in the Logic Analyzer is used.

Example: 'Radix', 'Hexadecimal'

Data Types: char

## **Output Arguments**

### **waveTag — tag for new wave**

random character vector

A tag for the newly added wave. Use the tag name to modify and delete the wave.

## **See Also**

## allpass2wdf

Allpass to Wave Digital Filter coefficient transformation

### Syntax

```
w = allpass2wdf(a)
W = allpass2wdf(A)
```

### Description

`w = allpass2wdf(a)` accepts a vector of real allpass polynomial filter coefficients `a`, and returns the transformed coefficient `w`. `w` can be used with allpass filter objects such as `dsp.AllpassFilter`, and `dsp.CoupledAllpassFilter`, with Structure set to 'Wave Digital Filter'.

`W = allpass2wdf(A)` accepts the cell array of allpass polynomial coefficient vectors `A`. Each cell of `A` holds the coefficients of a section of a cascade allpass filter. `W` is also a cell array, and each cell of `W` contains the transformed version of the coefficients in the corresponding cell of `A`. `W` can be used with allpass filter objects such as `dsp.AllpassFilter` and `dsp.CoupledAllpassFilter`, with structure set to 'Wave Digital Filter'.

### Examples

#### Convert Allpass coefficients to Wave Digital Filter Coefficients

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent step syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a second order allpass filter with coefficients `a = [0 0.5]`. Convert these coefficients into wave digital filter form using `allpass2wdf`. Assign the transformed coefficients to an allpass filter using the wave digital filter structure. Pass a random input to both these filters and compare the outputs.

```
a = [0 0.5];  
allpass = dsp.AllpassFilter('AllpassCoefficients', a);  
w = allpass2wdf(a);  
allpasswdf = dsp.AllpassFilter('Structure', 'Wave Digital Filter',...  
    'WDFCoefficients', w);  
in = randn(512, 1);  
outputAllpass = allpass(in);  
outputAllpasswdf = allpasswdf(in);  
plot(outputAllpass-outputAllpasswdf)
```

The difference between the two outputs is very small.

## Input Arguments

### **a** — allpass filter coefficients

vector of real numbers

Numeric vector of allpass filter coefficients, specified as real numbers. **a** can have length only equal to 1,2, and 4. When the length is 4, the first and third components must both be zero. **a** can be a row or a column vector.

Example: `0.7`

Data Types: `double` | `single`

### **A** — allpass filter coefficients

vector of cells

Cascade of allpass filter coefficients, specified as a cell vector. Every cell of **A** must contain a real vector of length 1,2, or 4. When the length is 4, the first and third components must both be zero. **A** can be a row or column vector of cells.

Example: `{0.7, [0.1, 0.2]}`

Data Types: `double` | `single`

## Output Arguments

### **w** — transformed version of the coefficients **a**

vector of real numbers

Numeric vector of transformed coefficients, determined as a real number, to use with single-section allpass filter objects having `Structure` set to `'Wave Digital Filter'`. **w** is always returned as a numeric row vector.

Example: `0.7`

Data Types: `double` | `single`

### **W** — transformed version of the coefficients cell array **A**

vector of cell

Cascade of transformed allpass filter coefficients, determined as a cell array, to use with multi-section allpass filter objects having `Structure` set to `'Wave Digital Filter'`. **W** is always returned as a column of cells.

Example: {0.7; [0.2, -0.0833]}

Data Types: double | single

## Algorithms

In the more general case, the input coefficients  $A$  define a cascade or multisection allpass filter. `allpass2wdf` applies separately to each section of the same transformation used in the single-section case. In the single-section case, the numeric coefficients vector  $a$  contains a standard polynomial representation of an allpass filter of order 1, 2, or 4. For example, in the first order case,

$$a = [a_1]$$

represents the first order transfer function:

$$H_1(z) = \frac{z^{-1} + a_1}{1 + a_1 z^{-1}}$$

and in the second order case,

$$a = [a_1, a_2]$$

represents the second order transfer function:

$$H_2(z) = \frac{z^{-2} + a_1 z^{-1} + a_2}{1 + a_1 z^{-1} + a_2 z^{-2}}$$

.

The allpass transfer functions  $H_1$  and  $H_2$  can also have the following alternative representations, using decoupled coefficients in vector  $w_1$  or  $w_2$  respectively.

$$\tilde{H}_1(z) = \frac{z^{-1} + w_1}{1 + w_1 z^{-1}}$$

$$\tilde{H}_2(z) = \frac{z^{-2} + w_2(1 + w_1)z^{-1} + w_1}{1 + w_2(1 + w_1)z^{-1} + w_1z^{-2}}$$

For allpass coefficients,  $w$  is often used to derive adaptor multipliers for Wave Digital Filter structures, and it is required by a number of allpass based filters in DSP System Toolbox when Structure is set to 'Wave Digital Filter' (e.g. `dsp.AllpassFilter`, and `dsp.CoupledAllpassFilter`).

For a given vector of section coefficients  $a$ , `allpass2wdf` computes the corresponding vector  $w$  such that

when  $i = 1, 2$  or  $4$

$$\tilde{H}_i(z) = H_i(z)$$

This results in using the following formulas:

for order 1:

$$w_1 = a_1$$

for order 2:

$$w_1 = a_2$$

$$w_2 = \frac{a_1}{1 + a_2}$$

for order 4:

$$w_1 = a_4$$

$$w_3 = \frac{a_2}{1 + a_4}$$

$$w_2 = w_4 = 0$$

## **allpassbpc2bpc**

Allpass filter for complex bandpass transformation

### **Syntax**

`[AllpassNum,AllpassDen] = allpassbpc2bpc(Wo,Wt)`

### **Description**

`[AllpassNum,AllpassDen] = allpassbpc2bpc(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the first-order allpass mapping filter for performing a complex bandpass to complex bandpass frequency transformation. This transformation effectively places two features of an original filter, located at frequencies  $W_{o1}$  and  $W_{o2}$ , at the required target frequency locations  $W_{t1}$  and  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . In most of the cases the features selected for the transformation are the band edges of the filter passbands. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

This transformation can also be used for transforming other types of filters; e.g., complex notch filters or resonators can be repositioned at two distinct desired frequencies at any place around the unit circle. This is very attractive for adaptive systems.

### **Examples**

### Design of the allpass mapping filter

This example shows how to design allpass mapping filter, changing the complex bandpass filter with the band edges at  $W_{o1} = 0.2$  and  $W_{o2} = 0.4$  to the new band edges of  $W_{n1} = 0.3$  and  $W_{n2} = 0.6$ . Find the frequency response of the allpass mapping filter:

```
Wo = [0.2, 0.4]; Wt = [0.3, 0.6];
[AllpassNum, AllpassDen] = allpassbpc2bpc(Wo, Wt);
[ha, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, -angle(ha)/pi, Wt, Wo, 'ro'); title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

## Arguments

Variable	Description
<i>Wo</i>	Frequency values to be transformed from the prototype filter
<i>Wt</i>	Desired frequency locations in the transformed target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

## allpasslp2bp

Allpass filter for lowpass to bandpass transformation

### Syntax

[AllpassNum,AllpassDen] = allpasslp2bp(Wo,Wt)

### Description

[AllpassNum,AllpassDen] = allpasslp2bp(Wo,Wt) returns the numerator, AllpassNum, and the denominator, AllpassDen, of the second-order allpass mapping filter for performing a real lowpass to real bandpass frequency transformation. This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . This transformation implements the “DC mobility,” which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of  $W_t$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and repositioned at two distinct desired frequencies.

## Examples

Design the allpass mapping filter changing the lowpass filter with cutoff frequency at  $W_o=0.5$  to the real-valued bandpass filter with cutoff frequencies at  $W_{t1}=0.25$  and  $W_{t2}=0.375$ .

Compute the frequency response and plot the phase response normalized to  $\pi$ , which is in effect the mapping function  $W_o(W_t)$ . Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = [0.25, 0.375];
[AllpassNum, AllpassDen] = allpasslp2bp(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

## Arguments

Variable	Description
$W_o$	Frequency value to be transformed from the prototype filter
$W_t$	Desired frequency locations in the transformed target filter
$AllpassNum$	Numerator of the mapping filter
$AllpassDen$	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## allpasslp2bpc

Allpass filter for lowpass to complex bandpass transformation

### Syntax

```
[AllpassNum,AllpassDen] = allpasslp2bpc(Wo,Wt)
```

### Description

`[AllpassNum,AllpassDen] = allpasslp2bpc(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the first-order allpass mapping filter for performing a real lowpass to complex bandpass frequency transformation. This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/resonators. This transformation can be used for designing bandpass filters for radio receivers from the high-quality prototype lowpass filter.

### Examples

Design the allpass mapping filter changing the real lowpass filter with the cutoff frequency of  $W_o=0.5$  into a complex bandpass filter with band edges of  $W_{t1}=0.2$  and

$W_{i2}=0.4$  precisely defined. Calculate the frequency response of the mapping filter in the full range:

```
Wo = 0.5; Wt = [0.2,0.4];
[AllpassNum, AllpassDen] = allpasslp2bpc(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

## Arguments

Variable	Description
<i>Wo</i>	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
<i>Wt</i>	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

## allpasslp2bs

Allpass filter for lowpass to bandstop transformation

### Syntax

```
[AllpassNum,AllpassDen] = allpasslp2bs(Wo,Wt)
```

### Description

`[AllpassNum,AllpassDen] = allpasslp2bs(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the second-order allpass mapping filter for performing a real lowpass to real bandstop frequency transformation. This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . This transformation implements the "Nyquist Mobility," which means that the DC feature stays at DC, but the Nyquist feature moves to a location dependent on the selection of  $W_o$  and  $W_t$ .

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . After the transformation feature  $F_2$  will precede  $F_1$  in the target filter. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

### Examples

Design the allpass filter changing the lowpass filter with cutoff frequency at  $W_o=0.5$  to the real bandstop filter with cutoff frequencies at  $W_{t1}=0.25$  and  $W_{t2}=0.375$ :

```

Wo = 0.5; Wt = [0.25, 0.375];
[AllpassNum, AllpassDen] = allpasslp2bs(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');

```

In the figure, you find the mapping filter function as determined by the example. Note the response is normalized to  $\pi$ :

## Arguments

Variable	Description
$W_o$	Frequency value to be transformed from the prototype filter
$W_t$	Desired frequency locations in the transformed target filter

<b>Variable</b>	<b>Description</b>
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## allpasslp2bsc

Allpass filter for lowpass to complex bandstop transformation

### Syntax

```
[AllpassNum,AllpassDen] = allpasslp2bsc(Wo,Wt)
```

### Description

[AllpassNum,AllpassDen] = allpasslp2bsc(Wo,Wt) returns the numerator, AllpassNum, and the denominator, AllpassDen, of the first-order allpass mapping filter for performing a real lowpass to complex bandstop frequency transformation. This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . Additionally the transformation swaps passbands with stopbands in the target filter.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/resonators. This transformation can be used for designing bandstop filters for band attenuation or frequency equalizers, from the high-quality prototype lowpass filter.

## Examples

Design the allpass filter changing the real lowpass filter with the cutoff frequency of  $W_o=0.5$  into a complex bandstop filter with band edges of  $W_{t1}=0.2$  and  $W_{t2}=0.4$  precisely defined:

```
Wo = 0.5; Wt = [0.2,0.4];  
[AllpassNum, AllpassDen] = allpasslp2bsc(Wo, Wt);  
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

## Arguments

Variable	Description
<i>Wo</i>	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
<i>Wt</i>	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

## allpasslp2hp

Allpass filter for lowpass to highpass transformation

### Syntax

[AllpassNum, AllpassDen] = allpasslp2hp(Wo, Wt)

### Description

[AllpassNum, AllpassDen] = allpasslp2hp(Wo, Wt) returns the numerator, AllpassNum, and the denominator, AllpassDen, of the first-order allpass mapping filter for performing a real lowpass to real highpass frequency transformation. This transformation effectively places one feature of an original filter, located originally at frequency,  $W_o$ , at the required target frequency location,  $W_t$ , at the same time rotating the whole frequency response by half of the sampling frequency. Result is that the DC and Nyquist features swap places.

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . After the transformation feature  $F_2$  will precede  $F_1$  in the target filter. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to highpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband.

Lowpass to highpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way by using the lowpass to highpass transformation.

### Examples

Design the allpass filter changing the lowpass filter to the highpass filter with its cutoff frequency moved from  $W_o = 0.5$  to  $W_t = 0.25$ .

Plot the phase response normalized to  $\pi$ , which is in effect the mapping function  $W_o(W_t)$ . Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpasslp2hp(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt');
ylabel('Old Frequency, Wo');
```

## Arguments

Variable	Description
<i>Wo</i>	Frequency value to be transformed from the prototype filter
<i>Wt</i>	Desired frequency location in the transformed target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## allpasslp2lp

Allpass filter for lowpass to lowpass transformation

### Syntax

```
[AllpassNum,AllpassDen] = allpasslp2lp(Wo,Wt)
```

### Description

`[AllpassNum,AllpassDen] = allpasslp2lp(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the first-order allpass mapping filter for performing a real lowpass to real lowpass frequency transformation. This transformation effectively places one feature of an original filter, located originally at frequency  $W_o$ , at the required target frequency location,  $W_t$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to lowpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband and so on.

Lowpass to lowpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way by applying the lowpass to lowpass transformation.

### Examples

Design the allpass filter changing the lowpass filter cutoff frequency originally at  $W_o=0.5$  to  $W_t=0.25$ . Plot the phase response normalized to  $\pi$ , which is in effect the mapping function  $W_o(W_t)$ . Please note that the transformation works in the same way for both positive and negative frequencies:

```

Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpasslp2lp(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');

```

As shown in the figure, `allpasslp2lp` generates a mapping function that converts your prototype lowpass filter to a target lowpass filter with different passband specifications.

## Arguments

Variable	Description
$W_o$	Frequency value to be transformed from the prototype filter
$W_t$	Desired frequency location in the transformed target filter

<b>Variable</b>	<b>Description</b>
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## allpasslp2mb

Allpass filter for lowpass to M-band transformation

### Syntax

```
[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt)
[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt,Pass)
```

### Description

`[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the  $M$ th-order allpass mapping filter for performing a real lowpass to real multipassband frequency transformation. Parameter  $M$  is the number of times an original feature is replicated in the target filter. This transformation effectively places one feature of an original filter, located at frequency  $W_o$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ . By default the DC feature is kept at its original location.

`[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility." In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is movable.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations

without redesigning them. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

## Examples

Design the allpass filter changing the real lowpass filter with the cutoff frequency of  $W_o=0.5$  into a real multiband filter with band edges of  $W_t=[1:2:9]/10$  precisely defined. Plot the phase response normalized to  $\pi$ , which is in effect the mapping function  $W_o(W_t)$ . Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = [1:2:9]/10;  
[AllpassNum, AllpassDen] = allpasslp2mb(Wo, Wt);  
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');  
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');  
title('Mapping Function Wo(Wt)');  
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

## Arguments

Variable	Description
<i>Wo</i>	Frequency value to be transformed from the prototype filter
<i>Wt</i>	Desired frequency locations in the transformed target filter
<i>Pass</i>	Choice ('pass' / 'stop') of passband/stopband at DC, 'pass' being the default
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## allpasslp2mbc

Allpass filter for lowpass to complex M-band transformation

### Syntax

```
[AllpassNum,AllpassDen] = allpasslp2mbc(Wo,Wt)
```

### Description

`[AllpassNum,AllpassDen] = allpasslp2mbc(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the `M`th-order allpass mapping filter for performing a real lowpass to complex multipassband frequency transformation. Parameter `M` is the number of times an original feature is replicated in the target filter. This transformation effectively places one feature of an original filter, located at frequency  $W_o$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations without the need to design them again. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

### Examples

Design the allpass filter changing the real lowpass filter with the cutoff frequency of  $W_o=0.5$  into a complex multiband filter with band edges of  $W_t=[-3+1:2:9]/10$  precisely defined:

```
Wo = 0.5; Wt = [-3+1:2:9]/10;
[AllpassNum, AllpassDen] = allpasslp2mbc(Wo, Wt);
```

Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Plot the phase response normalized to  $\pi$ , which is in effect the mapping function  $W_o(W_t)$ . Please note that the transformation works in the same way for both positive and negative frequencies:

```
plot(f/pi, angle(h)/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

In this example, the resulting mapping function converts real filters to multiband complex filters.

## Arguments

Variable	Description
<i>Wo</i>	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
<i>Wt</i>	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

## allpasslp2xc

Allpass filter for lowpass to complex N-point transformation

### Syntax

```
[AllpassNum,AllpassDen] = allpasslp2xc(Wo,Wt)
```

### Description

`[AllpassNum,AllpassDen] = allpasslp2xc(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the Nth-order allpass mapping filter, where N is the allpass filter order, for performing a real lowpass to complex multipoint frequency transformation. Parameter N also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places N features of the, original filter located at frequencies  $W_{o1}, \dots, W_{oN}$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation. For DC mobility feature  $F_2$  will precede  $F_1$  after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating N bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

## Examples

Design the allpass filter moving four features of an original complex filter given in  $W_o$  to the new independent frequency locations  $W_t$ . Please note that the transformation creates  $N$  replicas of an original filter around the unit circle, where  $N$  is the order of the allpass mapping filter:

```
Wo = [-0.2, 0.3, -0.7, 0.4]; Wt = [0.3, 0.5, 0.7, 0.9];  
[AllpassNum, AllpassDen] = allpasslp2xc(Wo, Wt);  
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

## Arguments

Variable	Description
<i>Wo</i>	Frequency values to be transformed from the prototype filter
<i>Wt</i>	Desired frequency locations in the transformed target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

## allpasslp2xn

Allpass filter for lowpass to N-point transformation

### Syntax

```
[AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt)
[AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt,Pass)
```

### Description

[AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt) returns the numerator, AllpassNum, and the denominator, AllpassDen, of the Nth-order allpass mapping filter, where N is the allpass filter order, for performing a real lowpass to real multipoint frequency transformation. Parameter N also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places N features of an original filter, located at frequencies  $W_{o1}, \dots, W_{oN}$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ . By default the DC feature is kept at its original location.

[AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt,Pass) allows you to specify an additional parameter, Pass, which chooses between using the “DC Mobility” and the “Nyquist Mobility.” In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is movable.

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation. For DC mobility feature  $F_2$  will precede  $F_1$  after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only

condition is that the features must be selected in such a way that when creating N bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations without the need of designing them again. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

## Arguments

Variable	Description
<i>wo</i>	Frequency values to be transformed from the prototype filter
<i>wt</i>	Desired frequency locations in the transformed target filter
<i>Pass</i>	Choice ( 'pass' / 'stop' ) of passband/stopband at DC, 'pass' being the default
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## allpassrateup

Allpass filter for integer upsample transformation

### Syntax

```
[AllpassNum,AllpassDen] = allpassrateup(N)
```

### Description

[AllpassNum,AllpassDen] = allpassrateup(N) returns the numerator, AllpassNum, and the denominator, AllpassDen, of the Nth-order allpass mapping filter for performing the rateup frequency transformation, which creates N equal replicas of the prototype filter frequency response.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

### Examples

Design the allpass filter creating the effect of upsampling the digital filter four times:

Choose any feature from an original filter, say at  $W_0=0.2$ :

```
N = 4;  
Wo = 0.2; Wt = Wo/N + 2*[0:N-1]/N;  
[AllpassNum, AllpassDen] = allpassrateup(N);
```

Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

## Arguments

Variable	Description
$N$	Frequency replication ratio (upsampling ratio)
$AllpassNum$	Numerator of the mapping filter
$AllpassDen$	Denominator of the mapping filter

## See Also

iirateup | zpkrateup

**Introduced in R2011a**

## allpassshift

Allpass filter for real shift transformation

### Syntax

```
[AllpassNum,AllpassDen] = allpassshift(Wo,Wt)
```

### Description

`[AllpassNum,AllpassDen] = allpassshift(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the second-order allpass mapping filter for performing a real frequency shift transformation. This transformation places one selected feature of an original filter, located at frequency  $W_o$ , at the required target frequency location,  $W_t$ . This transformation implements the “DC mobility,” which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of  $W_o$  and  $W_t$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the real shift transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be moved to a different frequency by applying a shift transformation. In such a way you can avoid designing the filter from the beginning.

### Examples

Design the allpass filter precisely shifting one feature of the lowpass filter originally at  $W_o=0.5$  to the new frequencies of  $W_t=0.25$ :

```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpassshift(Wo, Wt);
```

Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Plot the phase response normalized to  $\pi$ , which is in effect the mapping function  $W_o(W_t)$ . Please note that the transformation works in the same way for both positive and negative frequencies:

```
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

## Arguments

Variable	Description
<i>Wo</i>	Frequency value to be transformed from the prototype filter
<i>Wt</i>	Desired frequency location in the transformed target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

# allpassshiftc

Allpass filter for complex shift transformation

## Syntax

```
[AllpassNum,AllpassDen] = allpassshiftc(Wo,Wt)
[AllpassNum,AllpassDen] = allpassshiftc(0,0.5)
[AllpassNum,AllpassDen] = allpassshiftc(0,-0.5)
```

## Description

[AllpassNum,AllpassDen] = allpassshiftc(Wo,Wt) returns the numerator, AllpassNum, and denominator, AllpassDen, vectors of the allpass mapping filter for performing a complex frequency shift of the frequency response of the digital filter by an arbitrary amount.

[AllpassNum,AllpassDen] = allpassshiftc(0,0.5) calculates the allpass filter for doing the Hilbert transformation, a 90 degree counterclockwise rotation of an original filter in the frequency domain.

[AllpassNum,AllpassDen] = allpassshiftc(0,-0.5) calculates the allpass filter for doing an inverse Hilbert transformation, i.e. a 90 degree clockwise rotation of an original filter in the frequency domain.

## Examples

Design the allpass filter precisely rotating the whole filter by the amount defined by the location of the selected feature from an original filter,  $W_o=0.5$ , and its required position in the target filter,  $W_t=0.25$ :

```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpassshiftc(Wo, Wt);
```

Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

## Arguments

Variable	Description
<i>Wo</i>	Frequency value to be transformed from the prototype filter
<i>Wt</i>	Desired frequency location in the transformed target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

# autoscale

Automatic dynamic range scaling

## Syntax

```
autoscale(hd,x)  
hnew = autoscale(hd,x)
```

## Description

`autoscale(hd,x)` provides dynamic range scaling for each node of the filter `hd`. This method runs signal `x` through `hd` in floating-point to simulate filtering. `autoscale` uses the maximum and minimum data obtained from that simulation at each filter node to set fraction lengths to cover the simulation full range and maximize the precision. Word lengths are not changed during autoscaling.

`hnew = autoscale(hd,x)` If you request an output, `autoscale` returns a new filter with the scaled fraction lengths. The original filter is not changed.

For an introductory example of the automatic scale process, see “Floating-Point to Fixed-Point Conversion of IIR Filters”.

## Examples

### Dynamic Range Scaling in a Lattice ARMA Filter

```
hd = design(fdesign.bandpass,'ellip');  
hd = convert(hd,'latticearma');  
hd.arithmetic = 'fixed';  
rng(4); x = rand(100,10); % Training input data.  
hd(2) = autoscale(hd,x);  
hfv = fvtool(hd,'Analysis','mestimate','ShowReference','off');  
legend(hfv, 'Before Autoscaling', 'After Autoscaling')
```

# bandedgeFrequencies

**Package:** dsp

Compute the bandedge frequencies

## Syntax

```
w = bandedgeFrequencies(obj)
f = bandedgeFrequencies(obj, Fs)
```

## Description

`w = bandedgeFrequencies(obj)` returns a vector of normalized frequencies, `w`, containing the bandedge frequencies between adjacent bandpass filters in the `dsp.Channelizer` System object.

`f = bandedgeFrequencies(obj, Fs)` returns a vector of bandedge frequencies in Hz, using the sample rate `Fs`.

## Examples

### Bandedge Frequencies of Channelizer

Compute the normalized bandedge frequencies of the bandpass filters in a channelizer using the `bandedgeFrequencies` function.

```
channelizer = dsp.Channelizer;
w = bandedgeFrequencies(channelizer)
```

```
w = 1×8
```

```
    -2.7489    -1.9635    -1.1781    -0.3927     0.3927     1.1781     1.9635     2.7489 ...
```

To compute the frequencies in Hz, pass a sampling frequency, `Fs`.

$$f = (\omega/2\pi) \times Fs$$

where:

- $f$  is frequency in Hz.
- $\omega$  is frequency in radians.

Here, the sampling frequency is 44,100 Hz.

```
f = bandedgeFrequencies(channelizer,44100)
```

```
f = 1×8  
104 ×
```

```
-1.9294 -1.3781 -0.8269 -0.2756 0.2756 0.8269 1.3781 1.9294 ...
```

## Input Arguments

### **obj** — Input filter System object

`dsp.Channelizer`

Input filter, specified as a `dsp.Channelizer` System object.

### **Fs** — Sample rate

positive scalar

Sample rate used to compute the bandedge frequencies in Hz, specified as a positive scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Output Arguments

### **w** — Normalized bandedge frequencies

row vector

Normalized frequencies containing the bandedge frequencies between adjacent bandpass filters in the channelizer, returned as a row vector. The length of the vector equals the number of frequency bands.

Data Types: double

### **f — Bandedge frequencies in Hz**

row vector

Bandedge frequencies in Hz, returned as a row vector. The length of the vector equals the number of frequency bands. To return the frequencies in Hz, input the sample rate,  $F_s$ . Frequency in Hz is given by  $[w/(2\pi)] \times F_s$ , where  $w$  is the normalized frequency in rad/sample, and  $F_s$  is the sampling rate in Hz.

Data Types: double

## block

Generate block from a digital filter

### Syntax

```
block(hd)
block(hd, 'propertyname1', propertyvalue1, 'propertyname2', propertyvalu
e2, ...)
```

### Description

`block(hd)` generates a DSP System Toolbox block equivalent to the digital filter, `hd`.

`block(hd, 'propertyname1', propertyvalue1, 'propertyname2', propertyvalu  
e2, ...)` generates a DSP System Toolbox block using the options specified in the property name/property value pairs. The valid properties and their values are

Property Name	Property Values	Description and Values
Destination	'current' (default), 'new', or <i>Subsystemname</i> .	Determine which Simulink model gets the block. Enter 'current', 'new', or specify the name of an existing subsystem with <i>subsystemname</i> . 'current' adds the block to your current Simulink model. Specifying 'new' opens a new model and adds the block. Specifying 'new' opens a new model and adds the block. If you provide the name of a subsystem in <i>subsystemname</i> , block adds the new block to your specified subsystem.
Blockname	'filter' (default)	Specify the name of the generated block. The name appears below the block in the model. When you do not specify a block name, the default is <i>filter</i> .

Property Name	Property Values	Description and Values
OverwriteBlock	'off' (default), or 'on'.	Tell block whether to overwrite an existing block of the same name, or create a new block. 'off' is the default setting—block does not overwrite existing blocks with matching names. Switching from 'off' to 'on' directs block to overwrite existing blocks.
MapStates	'off' (default), or 'on'.	Specify whether to apply the current filter states to the new block. This lets you save states from a filter object you may have used or configured in a specific way. The default setting of 'off' means the states are not transferred to the block. Choosing 'on' preserves the current filter states in the block.
Link2obj	'off' (default), or 'on'.	Specify how to set the <b>Coefficient source</b> in the block mask. The default setting is 'off' and the <b>Coefficient source</b> is set to <b>Dialog parameters</b> . Setting Link2obj to 'on' sets the <b>Coefficient source</b> to <b>Discrete-time filter object (DFILT)</b> . The Link2obj and MapCoeffstoPorts cannot be simultaneously 'on'.
MapCoeffstoPorts	'off' (default) or 'on'	Specify whether to map the coefficients of the filter to the ports of the block. The Link2obj and MapCoeffstoPorts cannot be simultaneously 'on'.

Property Name	Property Values	Description and Values
CoeffNames	{ 'Num' } (default FIR) { 'Num', 'Den' } (default direct form IIR) { 'Num', 'Den', 'g' } (default IIR SOS), { 'K' } (default form lattice)	Specify the coefficient variable names as a cell array of character vectors.  MapCoeffsToPorts must be set to 'on' for this property to apply.
InputProcessing	'columns as channels' (default), 'elements as channels'	Specify sample-based (elements as channels) or frame-based (columns as channels) processing.
RateOption	'enforce single rate' (default) or 'allow multirate'	Specify how the block adjusts the rate at the output to accommodate the reduced number of samples. This parameter applies only when InputProcessing is 'columns as channels'.

## Using block to Realize a Fixed-Point Digital Filter

When the source filter `hd` is fixed-point, the input word and fraction lengths for the block are derived from the block input signal. The realization process issues a warning and ignores the input word and input fraction lengths that are part of the source filter object, choosing to inherit the settings from the input data. Other fixed-point properties map directly to settings for word and fraction length in the realized block.

## Examples

### Create a Block from a Lowpass Filter

Create a lowpass filter specification object. Specify the passband frequency to be  $0.15\pi$  rad/sample and the stopband frequency to be  $0.25\pi$  rad/sample. Specify 1 dB of allowable passband ripple and a stopband attenuation of 60 dB.

In the first example, use block with the default syntax, letting the function determine the block name and configuration.

```
d = fdesign.lowpass('Fp,Fst,Ap,Ast',0.15,0.25,1,60);
hd = design(d);
```

Now use the default syntax to create a block.

```
block(hd);
```

In this second example, define the block name to meet your needs by using the property name/property value pair input arguments.

```
block(hd, 'blockname', 'FIR Filter');
```

The figure shows the blocks in a Simulink model. When you try these examples, you see that the second block writes over the first block location. You can avoid this by moving the first block before you generate the second, always naming your block with the blockname property, or setting the Destination property to new which puts the filter block in a new Simulink model.

# butter

Butterworth IIR filter design using specification object

## Syntax

```
butterFilter = design(d,'butter','SystemObject',true)
butterFilter =
design(d,'butter',designoption,value,'SystemObject',true)
```

## Description

`butterFilter = design(d,'butter','SystemObject',true)` designs a Butterworth IIR digital filter using the specifications supplied in the object `d`.

`butterFilter = design(d,'butter',designoption,value,'SystemObject',true)` returns a Butterworth IIR filter where you specify a design option and value.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `butter`, refer to the command line help system. For example, to get specific information about using `butter` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'butter')
```

## Examples

### Design a Butterworth Filter

Construct a default lowpass filter specification object and design a Butterworth filter.

```
d = fdesign.lowpass;  
Lowpass = design(d, 'butter', 'matchexactly', 'stopband', 'SystemObject', true);  
fvtool(Lowpass);
```

Construct a highpass filter specification object and design a Butterworth filter. Specify the order to be 8 and 3 dB frequency to be  $0.6\pi$  radians/sample.

```
d = fdesign.highpass('N,F3dB',8,.6);  
Highpass = design(d, 'butter', 'SystemObject', true);  
fvtool(Highpass)
```

## ca2tf

Convert coupled allpass filter to transfer function form

### Syntax

```
[b, a]=ca2tf(d1, d2)
[b, a]=ca2tf(d1, d2, beta)
[b, a, bp]=ca2tf(d1, d2)
[b, a, bp]=ca2tf(d1, d2, beta)
```

### Description

`[b, a]=ca2tf(d1, d2)` returns the vector of coefficients `b` and the vector of coefficients `a` corresponding to the numerator and the denominator of the transfer function

$$H(z) = B(z) / A(z) = \frac{1}{2} [H1(z) + H2(z)]$$

`d1` and `d2` are real vectors corresponding to the denominators of the allpass filters  $H1(z)$  and  $H2(z)$ .

`[b, a]=ca2tf(d1, d2, beta)` where `d1`, `d2` and `beta` are complex, returns the vector of coefficients `b` and the vector of coefficients `a` corresponding to the numerator and the denominator of the transfer function

$$H(z) = B(z) / A(z) = \frac{1}{2} [ -\bar{\beta} \cdot H1(z) + \beta \cdot H2(z) ]$$

`[b, a, bp]=ca2tf(d1, d2)`, where `d1` and `d2` are real, returns the vector `bp` of real coefficients corresponding to the numerator of the power complementary filter  $G(z)$

$$G(z) = Bp(z) / A(z) = \frac{1}{2} [H1(z) - H2(z)]$$

`[b,a,bp]=ca2tf(d1,d2,beta)`, where `d1`, `d2` and `beta` are complex, returns the vector of coefficients `bp` of real or complex coefficients that correspond to the numerator of the power complementary filter  $G(z)$

$$G(z) = Bp(z) / A(z) = \frac{1}{2^j} [ -(\bar{\beta}) \cdot H1(z) + \beta \cdot H2(z) ]$$

## Examples

Create a filter, convert the filter to coupled allpass form, and convert the result back to the original structure (create the power complementary filter as well).

```
[b,a]=cheby1(10,.5,.4);
[d1,d2,beta]=tf2ca(b,a);           % tf2ca returns the denominators
                                   % of the allpasses

[num,den,numpc]=ca2tf(d1,         % Reconstruct the original filter
d2,beta);                          % plus the power complementary one

[h,w,s]=freqz(num,den);
hpc = freqz(numpc,den);
s.plot = 'mag';
s.yunits = 'sq';
freqzplot([h hpc],w,s);           % Plot the mag response of the
                                   % original filter and the power
                                   % complementary one
```

## Examples

### Convert Coupled Allpass to Transfer Function Form

Create a filter, convert the filter to coupled allpass form, and convert the result back to the original structure (create the power complementary filter as well).

```
[b,a]=cheby1(10,.5,.4);
[d1,d2,beta]=tf2ca(b,a);
```

tf2ca returns the denominators of the allpass filters

```
[num,den,numpc]=ca2tf(d1, d2,beta);
```

Plot the magnitude response of the original filter and the power complementary one.

```
fvtool(num,den,numpc,den,'Analysis','magnitude','MagnitudeDisplay',...  
       'Magnitude Squared')
```

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

All inputs must be constant. Expressions or variables are allowed if their values do not change.

## cascade

Cascade of filter system objects

### Syntax

```
FC = cascade(obj1,obj2,...objn)
```

### Description

`FC = cascade(obj1,obj2,...objn)` returns an object, `FC`, of type `dsp.FilterCascade`. `FC` is a cascaded version of the input System objects `obj1`, `obj2`, ..., `objn`. You can input multiple System objects to the function. The input System objects must be supported by the cascade method. For the list of supported System objects, see “Input Arguments” on page 5-84.

### Examples

#### Design Two-Stage Decimator

Design a two-stage decimator by cascading `dsp.CICDecimator` and `dsp.CICCompensationDecimator` System objects.

#### Construct the objects

```
CICDecim = dsp.CICDecimator('DecimationFactor', 6, ...  
                           'NumSections', 6);  
fs = 16e3;    % Sampling frequency of input of compensation decimator  
fPass = 4e3;  % Passband frequency  
fStop = 4.5e3; % Stopband frequency  
CICCompDecim = dsp.CICCompensationDecimator(CICDecim, ...  
                                             'DecimationFactor', 2, ...  
                                             'PassbandFrequency', fPass, ...  
                                             'StopbandFrequency', fStop, ...  
                                             'SampleRate', fs);
```

**Create a cascade of the two objects using the cascade method**

```
FC = cascade(CICDecim, CICCompDecim);
```

**Visualize the frequency response of the cascade**

```
f = fvtool(CICDecim, CICCompDecim, FC, 'Fs', [fs*6, fs, fs*6], ...  
          'Arithmetic', 'fixed');  
set(f, 'NormalizeMagnitudetol', 'on');  
legend(f, 'CIC Decimator', 'CIC Compensation Decimator', ...  
       'Overall Response');
```

## Input Arguments

### **obj1** — Filter to be cascaded

filter System object

obj1, obj2, . . . objn are filters to be cascaded. To see the list of System objects you can pass to the cascade method, type

```
dsp.FilterCascade.helpSupportedSystemObjects
```

in the MATLAB command prompt.

## Output Arguments

### **FC — cascaded filter**

`dsp.FilterCascade` System object

Cascaded filter, returned as a System object of type `dsp.FilterCascade`. For information on the properties of the filter in each stage, type `info(FC)` in the MATLAB command prompt.

## See Also

`dsp.FilterCascade`

**Introduced in R2016a**

## centerFrequencies

**Package:** dsp

Compute center frequencies

### Syntax

```
w = centerFrequencies(obj)
f = centerFrequencies(obj,Fs)
```

### Description

`w = centerFrequencies(obj)` returns a vector of normalized frequencies, `w`, containing the center frequencies of all the bandpass filters in the `dsp.Channelizer` System object.

`f = centerFrequencies(obj,Fs)` returns a vector of center frequencies in Hz, using the sample rate `Fs`.

### Examples

#### Center Frequencies of Channelizer

Compute the normalized center frequencies of the bandpass filters in a channelizer using the `centerFrequencies` function.

```
channelizer = dsp.Channelizer;
w = centerFrequencies(channelizer)
```

```
w = 1×8
```

```
    -3.1416    -2.3562    -1.5708    -0.7854         0         0.7854     1.5708     2.3562 ...
```

To compute the frequencies in Hz, pass a sampling frequency. Frequency in Hz,  $f$ , equals  $f = (\omega/2\pi) \times Fs$ , where  $\omega$  is frequency in radians, and  $Fs$  is the sampling rate.

```
f = centerFrequencies(channelizer,44100)
```

```
f = 1×8  
104 ×
```

```
-2.2050 -1.6538 -1.1025 -0.5513 0 0.5513 1.1025 1.6538 ...
```

## Input Arguments

**obj** — Input filter System object

dsp.Channelizer

Input filter, specified as a dsp.Channelizer System object.

**Fs** — Sample rate

positive scalar

Sample rate used to compute the center frequencies in Hz, specified as a positive scalar.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 |  
uint32 | uint64

## Output Arguments

**w** — Normalized center frequencies

row vector

Normalized frequencies containing the center frequencies of all the bandpass filters in the channelizer, returned as a row vector. The length of the vector equals the number of frequency bands.

Data Types: double

**f** — Center frequencies in Hz

row vector

Center frequencies in Hz, returned as a row vector. The length of the vector equals the number of frequency bands. To return the frequencies in Hz, input the sample rate,  $F_s$ . Frequency in Hz is given by  $[w/(2\pi)] \times F_s$ , where  $w$  is the normalized frequency in rad/sample, and  $F_s$  is the sampling rate in Hz.

Data Types: double

# cheby1

Chebyshev Type I filter using specification object

## Syntax

```
chebOneFilter = design(d,'cheby1','SystemObject',true)
chebOneFilter = design(d,'cheby1',designoption,value,designoption,
value,'SystemObject',true)
```

## Description

`chebOneFilter = design(d,'cheby1','SystemObject',true)` designs a type I Chebyshev IIR digital filter using the specifications supplied in the object `d`. Depending on the filter specification object, `cheby1` may or may not be a valid design. Use `designmethods` with the filter specification object to determine if a Chebyshev type I filter design is possible.

`chebOneFilter = design(d,'cheby1',designoption,value,designoption,value,'SystemObject',true)` returns a type I Chebyshev IIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `cheby1`, refer to the command line help system. For example, to get specific information about using `cheby1` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'cheby1')
```

## Examples

### Design a Chebyshev Type I Filter

Construct a default lowpass filter specification object and design a Chebyshev Type I filter.

```
d = fdesign.lowpass; designopts(d, 'cheby1');
```

Use `matchexactly` option to ensure the performance of the filter in the passband.

```
LowpassCheb1 = design(d, 'cheby1', 'matchexactly', 'passband', ...  
    'SystemObject', true);
```

Use `fvtool` to view the resulting filter

```
fvtool(LowpassCheb1)
```

Construct a highpass filter specification object and design a Chebyshev Type I filter. Specify the filter order, passband edge frequency, and the passband ripple to get the filter exactly as required.

```
d = fdesign.highpass('n,fp,ap',7,20,.4,50);  
HighpassCheb1 = design(d,'cheby1','SystemObject',true);
```

Use `fvtool` to view the resulting filter

```
fvtool(HighpassCheb1)
```

By design, `cheby1` returns filters that use second-order sections (SOS). For many applications, and for most fixed-point applications, SOS filters are particularly well-suited.

# cheby2

Chebyshev Type II filter using specification object

## Syntax

```
chebTwoFilter= design(d,'cheby2','SystemObject',true)
chebTwoFilter = design(d,'cheby2',designoption,value,designoption,
value,'SystemObject',true)
```

## Description

`chebTwoFilter= design(d,'cheby2','SystemObject',true)` designs a Chebyshev II IIR digital filter using the specifications supplied in the object `d`.

`chebTwoFilter = design(d,'cheby2',designoption,value,designoption,value,'SystemObject',true)` returns a Chebyshev II IIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `cheby2`, refer to the command line help system. For example, to get specific information about using `cheby2` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'cheby2')
```

## Examples

### Design a Chebyshev Type II Filter

Construct a default lowpass filter specification object and design a Chebyshev Type II filter.

```
d = fdesign.lowpass;
```

Use `matchexactly` option to ensure the performance of the filter in the passband.

```
LowpassCheb2 = design(d,'cheby2','matchexactly','passband',...
    'SystemObject',true);
```

Use `fvtool` to view the resulting filter

```
fvtool(LowpassCheb2)
```

Construct a highpass filter specification object and design a Chebyshev Type II filter. Specify the filter order, stopband edge frequency, and the stopband attenuation to get the filter exactly as required.

```
d = fdesign.highpass('n,fst,ast',5,20,55,50);  
HighpassCheb2 = design(d,'cheby2','SystemObject',true);
```

Use `fvtool` to view the resulting filter

```
fvtool(HighpassCheb2)
```

By design, `cheby2` returns filters that use second-order sections (SOS). For many applications, and for most fixed-point applications, SOS filters are particularly well-suited.

## cl2tf

Convert coupled allpass lattice to transfer function form

### Syntax

```
[b,a] = cl2tf(k1,k2)
[b,a] = cl2tf(k1,k2,beta)
[b,a,bp] = cl2tf(k1,k2)
[b,a,bp] = cl2tf(k1,k2,beta)
```

### Description

`[b,a] = cl2tf(k1,k2)` returns the numerator and denominator vectors of coefficients `b` and `a` corresponding to the transfer function

$$H(z) = B(z) / A(z) = \frac{1}{2}[H1(z) + H2(z)]$$

where  $H1(z)$  and  $H2(z)$  are the transfer functions of the allpass filters determined by `k1` and `k2`, and `k1` and `k2` are real vectors of reflection coefficients corresponding to allpass lattice structures.

`[b,a] = cl2tf(k1,k2,beta)` where `k1`, `k2` and `beta` are complex, returns the numerator and denominator vectors of coefficients `b` and `a` corresponding to the transfer function

$$H(z) = B(z) / A(z) = \frac{1}{2}[ -(\bar{\beta}) \cdot H1(z) + \beta \cdot H2(z) ]$$

`[b,a,bp] = cl2tf(k1,k2)` where `k1` and `k2` are real, returns the vector `bp` of real coefficients corresponding to the numerator of the power complementary filter  $G(z)$

$$G(z) = Bp(z) / A(z) = \frac{1}{2}[H1(z) - H2(z)]$$

`[b,a,bp] = cl2tf(k1,k2,beta)` where `k1`, `k2` and `beta` are complex, returns the vector of coefficients `bp` of possibly complex coefficients corresponding to the numerator of the power complementary filter  $G(z)$

$$G(z) = Bp(z) / A(z) = \frac{1}{2^j} [ -(\bar{\beta}) \cdot H1(z) + \beta \cdot H2(z) ]$$

## Examples

### Convert Coupled Allpass Lattice to Transfer Function

`tf2cl` returns the reflection coeffs

```
[b,a]=cheby1(10,.5,.4);  
[k1,k2,beta]=tf2cl(b,a);
```

Construct the original and the power complementary filter.

```
[num,den,numpc]=cl2tf(k1,k2,beta);  
[h,w]=freqz(num,den); hpc = freqz(numpc,den);
```

Show the frequency response

```
subplot(211);  
plot(w./pi,20*log10(abs(h)),'k'); hold on; grid on;  
plot(w./pi,20*log10(abs(hpc)),'b');  
xlabel('Normalized Frequency (x \pi radians/sample)');  
ylabel('dB');  
legend('Original Filter','Power Complementary Filter',...  
       'Location','best');  
subplot(212);  
plot(w./pi,unwrap(angle(h)),'k'); hold on; grid on;  
xlabel('Normalized Frequency (x \pi radians/sample)');  
ylabel('Phase (radians)');  
plot(w./pi,unwrap(angle(hpc)),'b');
```

## Extended Capabilities

# coeffs

Filter coefficients

## Syntax

```
s = coeffs(obj)
s = coeffs(obj,Name,Value)
```

## Description

`s = coeffs(obj)` returns the coefficients of filter System object, `obj`, in the structure `s`.

`s = coeffs(obj,Name,Value)` returns filter coefficients for the filter System object `obj` with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### `obj`

Filter System object.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **Arithmetic – The types of values:**

```
'double' | 'single' | 'fixed'
```

The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The `coeffs` method returns

the quantized filter coefficients when the arithmetic is set to 'single' or 'fixed'. You can specify 'fixed' only if the System object supports fixed-point arithmetic. When you specify 'fixed', the arithmetic changes depend on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

**Details for Fixed-Point Arithmetic**

<b>System Object State</b>	<b>Coefficient Data Type</b>	<b>Rule</b>
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataProperty property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataProperty property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

## Output Arguments

**s**

Structure with a single field, Numerator, containing filter coefficients.

## Examples

### Coefficients of an FIR Halfband Interpolator

```
FIRHalfbandInterp = dsp.FIRHalfbandInterpolator('Specification',...  
        'Filter order and transition width','FilterOrder',26);
```

```
C = coeffs(FIRHalfbandInterp);  
C.Numerator
```

```
ans = 1×27
```

```
    0.0525         0   -0.0379         0    0.0537         0   -0.0771         0    0.1171         0
```

```
% Impulse response of the filter  
fvtool(FIRHalfbandInterp,'impulse')
```

# coeffs

**Package:** dsp

Coefficients of prototype lowpass filter

## Syntax

```
c = coeffs(obj)
```

## Description

`c = coeffs(obj)` returns the coefficients of the prototype lowpass filter in a `dsp.Channelizer` or `dsp.ChannelSynthesizer` System object.

## Examples

### Coefficients Of Channelizer

Determine the coefficients of the prototype lowpass filter in the `dsp.Channelizer` object using the `coeffs` function.

The `coeffs` function returns a structure, `c`. The structure field `Numerator` contains the coefficients as a row vector. The number of elements in the row vector, given by `c.Numerator`, equals the number of frequency bands times the number of coefficients per band. These values are given by the `NumFrequencyBands` and `NumTapsPerBand` properties of the `dsp.Channelizer` object.

```
channelizer = dsp.Channelizer;  
c = coeffs(channelizer);
```

Visualize the impulse response of the filter using `fvtool`.

```
fvtool(c.Numerator, 'impulse');
```

## Input Arguments

**obj** — Input filter System object

`dsp.Channelizer` | `dsp.ChannelSynthesizer`

Input filter, specified as either a `dsp.Channelizer` or a `dsp.ChannelSynthesizer` System object.

Example: `channelizer = dsp.Channelizer;`

Example: `channelizer = dsp.ChannelSynthesizer;`

## Output Arguments

### **c** — Lowpass filter coefficients

structure

Lowpass filter coefficients, returned as a structure. The structure field `Numerator` contains the coefficients as a row vector.

## See Also

### **Introduced in R2016b**

# coeread

Read Xilinx COE file

## Syntax

```
hd = coeread(filename)
```

## Description

`hd = coeread(filename)` extracts the Distributed Arithmetic FIR filter coefficients defined in the XILINX CORE Generator .COE file specified by `filename`. It returns a `dfilt` object, the fixed-point filter `hd`. If you do not provide the file type extension `.coe` with the `filename`, the function assumes the `.coe` extension.

## See Also

`coewrite` | `dfilt` | `dfilt.dffir`

**Introduced in R2011a**

# coewrite

Write Xilinx COE file

## Syntax

```
coewrite(hd)
coewrite(hd,radix)
coewrite(...,filename)
```

## Description

`coewrite(hd)` writes a XILINX Distributed Arithmetic FIR filter coefficient .COE file which can be loaded into the XILINX CORE Generator. The coefficients are extracted from the fixed-point `dfilt` object `hd`. Your fixed-point filter must be a direct form FIR structure `dfilt` object with one section and whose `Arithmetic` property is set to `fixed`. You cannot export single-precision, double-precision, or floating-point filters as .coe files, nor multiple-section filters. To enable you to provide a name for the file, `coewrite` displays a dialog box where you fill in the file name. If you do not specify the name of the output file, the default file name is `untitled.coe`.

`coewrite(hd, radix)` indicates the radix (number base) used to specify the FIR filter coefficients. Valid `radix` values are 2 for binary, 10 for decimal, and 16 for hexadecimal (default).

`coewrite(..., filename)` writes a XILINX.COE file to `filename`. If you omit the file extension, `coewrite` adds the .coe extension to the name of the file.

The `coewrite` function always generates the XILINX.COE file in your current folder. To use this function, you must have write permission in your current folder.

## Examples

`coewrite` generates an ASCII text file that contains the filter coefficients in a format the XILINX CORE Generator can read and load. In this example, you create a 30th-order

fixed-point filter and generate the `.coe` file that includes the filter coefficients as well as associated information about the filter.

```
b = firceqrip(30,0.4,[0.05 0.03]); hq = dfilt.dffir(b);  
set(hq,'arithmetic','fixed'); coewrite(hq,10,'mycoefile');
```

The `coewrite` function generates the output file, `mycoefile.coe`, in your current folder. The `.coe` file contains the radix, coefficient width, and filter coefficients. The file reports the filter coefficients in column-major order. The radix, coefficient width, and filter coefficients are the minimum set of data needed in a `.coe` file.

# constraincoeffwl

Constrain coefficient wordlength

## Syntax

```
Hq = constraincoeffwl(Hd,wordlength)
Hq = constraincoeffwl(Hd,wordlength,'Ntrials',N)
Hq = constraincoeffwl(Hd,wordlength,...,'NoiseShaping',NSFlag)
Hq = constraincoeffwl(Hd,wordlength,...,'Apassol',Apassol)
Hq = constraincoeffwl(Hd,wordlength,...,'Astoptol',Astoptol)
```

## Description

`Hq = constraincoeffwl(Hd,wordlength)` returns a fixed-point filter `Hq` meeting the design specifications of the single-stage or multistage FIR filter object `Hd` with a wordlength of at most `wordlength` bits. For multistage filters, `wordlength` can either be a scalar or vector. If `wordlength` is a scalar, the same wordlength is used for all stages. If `wordlength` is a vector, each stage uses the corresponding element in the vector. The vector length must equal the number of stages. `Hd` must be generated using `fdesign` and `design`. `constraincoeffwl` uses a stochastic noise-shaping procedure by default to minimize the wordlength. To obtain repeatable results on successive function calls, initialize the uniform random number generator `rand`

`Hq = constraincoeffwl(Hd,wordlength,'Ntrials',N)` specifies the number of Monte Carlo trials to use. `Hq` is first filter among the trials to meet the specifications in `Hd` with a wordlength of at most `wordlength`.

`Hq = constraincoeffwl(Hd,wordlength,...,'NoiseShaping',NSFlag)` enables or disables the stochastic noise-shaping procedure in the constraint of the wordlength. By default `NSFlag` is `true`. Setting `NSFlag` to `false` constrains the wordlength without using noise-shaping.

`Hq = constraincoeffwl(Hd,wordlength,...,'Apassol',Apassol)` specifies the passband ripple tolerance in dB. `'Apassol'` defaults to `1e-4`.

`Hq = constraincoeffwl(Hd,wordlength,...,'Astoptol',Astoptol)` specifies the stopband tolerance in dB. 'Astoptol' defaults to  $1e-2$

You must have the Fixed-Point Designer software installed to use this function.

## Examples

### Design Fixed-Point Filter

Design fixed-point filter with a wordlength of at most 11 bits using `constraincoeffwl`

```
Hf = fdesign.lowpass('Fp,Fst,Ap,Ast',.4,.5,1,60);  
Hd = design(Hf,'equiripple'); % 43 coefficients  
Hq = constraincoeffwl(Hd,11); % 45 11-bit coefficients  
hfvt = fvtool(Hd,Hq);  
legend(hfvt,'Floating-point Filter','Fixed-point Filter');
```

## Topics

"Fixed-Point Data Types"

**Introduced in R2011a**

## convert

Convert filter structure of discrete-time filter

### Syntax

```
hq = convert(hq,newstruct)
```

### Description

#### Discrete-Time Filters

`hq = convert(hq,newstruct)` returns a quantized filter whose structure has been transformed to the filter structure specified by `newstruct`. You can enter any one of the following quantized filter structures:

- `'antisymmetricfir'`: Antisymmetric finite impulse response (FIR)
- `'df1'`: Direct form I
- `'df1t'`: Direct form I transposed
- `'df1sos'`: Direct-Form I, Second-Order Sections
- `'df1tsos'`: Direct-Form I Transposed, Second-Order Sections
- `'df2'`: Direct form II
- `'df2t'`: Direct form II transposed. Default filter structure
- `'df2sos'`: Direct-Form II, Second-Order Sections
- `'df2tsos'`: Direct-Form II Transposed, Second-Order Sections
- `'dffir'`: FIR
- `'dffirt'`: Direct form FIR transposed
- `'latcallpass'`: Lattice allpass
- `'latticeca'`: Lattice coupled-allpass
- `'latticecapc'`: Lattice coupled-allpass power-complementary

- 'latticear': Lattice autoregressive (AR)
- 'laticemamax': Lattice moving average (MA) maximum phase
- 'laticemamin': Lattice moving average (MA) minimum phase
- 'latticearma': Lattice ARMA
- 'statespace': Single-input/single-output state-space
- 'symmetricfir': Symmetric FIR. Even and odd forms

All filters can be converted to the following structures:

- 'df1': Direct form I
- 'df1t': Direct form I transposed
- 'df1sos': Direct-Form I, Second-Order Sections
- 'df1tsos': Direct-Form I Transposed, Second-Order Sections
- 'df2': Direct form II
- 'df2t': Direct form II transposed. Default filter structure
- 'df2sos': Direct-Form II, Second-Order Sections
- 'df2tsos': Direct-Form II Transposed, Second-Order Sections
- 'statespace': Single-input/single-output state-space
- 'symmetricfir': Symmetric FIR. Even and odd forms

For the following filter classes, you can specify other conversions as well:

- Minimum phase FIR filters can be converted to `laticemamin`
- Maximum phase FIR filters can be converted to `laticemamax`
- Allpass filters can be converted to `latcallpass`

`convert` generates an error when you specify a conversion that is not possible.

## Examples

### Convert Direct-Form II Transposed Structure to Direct-Form I

```
[b,a]=ellip(5,3,40,.7); hq = dfilt.df2t(b,a)
```

```
hq =  
    FilterStructure: 'Direct-Form II Transposed'  
    Arithmetic: 'double'  
    Numerator: [1x6 double]  
    Denominator: [1x6 double]  
    PersistentMemory: false  
  
hq2 = convert(hq, 'df1')  
hq2 =  
    FilterStructure: 'Direct-Form I'  
    Arithmetic: 'double'  
    Numerator: [1x6 double]  
    Denominator: [1x6 double]  
    PersistentMemory: false
```

## cost

Estimate cost for implementing filter System objects

### Syntax

```
c = cost(sysobj)
c = cost(sysobj,Name,Value)
```

### Description

`c = cost(sysobj)` returns a cost estimate `c` for the filter System object `sysobj`.

`c = cost(sysobj,Name,Value)` returns a cost estimate `c` for the filter System object `sysobj` with additional options specified by one or more `Name, Value` pair arguments.

### Input Arguments

#### `sysobj`

Filter System object.

All filter system objects support analysis methods. For more information on analysis methods, see “Analysis Methods for Filter System Objects” on page 3-2. For a list of analysis methods supported by a particular filter System object, for example `dsp.FIRHalfbandDecimator`, enter `dsp.FIRHalfbandDecimator.helpFilterAnalysis` at the MATLAB Command prompt.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Arithmetic — Value types:**

'double' | 'single' | 'fixed'

Specify the arithmetic used during analysis. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

**Details for Fixed-Point Arithmetic**

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsData type property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.

System Object State	Coefficient Data Type	Rule
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsData type property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Output Arguments

**c**

Cost estimate, **c** contains the following fields:

Estimated Value	Description
NumCoefficients	Number of filter coefficients (excluding coefficients with values 0, 1 or -1)
NumStates	Number of filter states
MultiplicationsPerInputSample	Number of multiplication operations performed for each input sample
AdditionsPerInputSample	Number of addition operations performed for each input sample

## Examples

### Cost of FIR Filter

This example shows how to compute the cost of implementing an FIR Filter created using `dsp.FIRFilter` object.

```
Fs = 8000; Fcutoff = 2000;  
firFilt = dsp.FIRFilter('Numerator', fir1(130, Fcutoff/(Fs/2)));  
cost(firFilt)
```

```
ans = struct with fields:  
    NumCoefficients: 131  
    NumStates: 130  
    MultiplicationsPerInputSample: 131  
    AdditionsPerInputSample: 130
```

## See Also

# cost

**Package:** dsp

Implementation cost of the filter

## Syntax

```
c = cost(sysobj)
```

## Description

`c = cost(sysobj)` returns a structure, `c`, whose fields contain information about the computation cost of implementing the filter System object.

## Examples

### Compute Cost of Complex Bandpass Decimator

Compute the implementation cost of a complex bandpass decimator using the `cost` function.

Create a `dsp.ComplexBandpassDecimator` object. Set the `DecimationFactor` to 12, the `CenterFrequency` to 5000 Hz, and the `SampleRate` to 44,100 Hz.

```
cbp = dsp.ComplexBandpassDecimator(12,5000,44100)
```

```
cbp =
```

```
  dsp.ComplexBandpassDecimator with properties:
    CenterFrequency: 5000
    Specification: 'Decimation factor'
    DecimationFactor: 12
    StopbandAttenuation: 80
    TransitionWidth: 100
    MinimizeComplexCoefficients: true
```

SampleRate: 44100

Compute the implementation cost of `cbp` using the `cost` function.

```
c = cost(cbp)
```

```
c = struct with fields:
```

```

    NumCoefficients: 201
    NumStates: 384
    RealMultiplicationsPerInputSample: 44.8333
    RealAdditionsPerInputSample: 44.3333
```

## Input Arguments

### **sysobj** — Filter System object

`dsp.ComplexBandpassDecimator` System object

Filter System object, specified as a `dsp.ComplexBandpassDecimator` System object.

## Output Arguments

### **c** — Cost estimate

structure

Cost estimate containing these fields:

Estimated Value	Description
<code>NumCoefficients</code>	Number of filter coefficients (excluding coefficients with values 0, 1 or -1)
<code>NumStates</code>	Number of filter states
<code>RealMultiplicationsPerInputSample</code>	Number of real multiplication operations performed for each input sample
<code>RealAdditionsPerInputSample</code>	Number of real addition operations performed for each input sample

The function assumes that a complex-by-complex multiplication requires 3 real multiplications and 5 real additions.

## See Also

### System Objects

`dsp.ComplexBandpassDecimator`

**Introduced in R2018a**

## cumsec

Cumulative second-order section of `BiquadFilter` System object

### Syntax

```
sect = cumsec(biquad)
sections = cumsec(biquad,indices)
sections = cumsec(biquad,indices,secondary)
cumsec(biquad,...)
sections = cumsec(biquad,Name,Value)
```

### Description

`sect = cumsec(biquad)` returns a cell array, `sect`, which contains cumulative sections of the `dsp.BiquadFilter` filter System object, `biquad`. Each element in `sect` is a filter with the structure of the original filter. The first element is the first filter section of `biquad`. The second element of `sect` is a filter that represents the combination of the first and second sections of `biquad`. The third element of `sections` is a filter which combines sections 1, 2, and 3 of `biquad`. This pattern continues until the final element of `sections` contains all the sections of `biquad` and should be identical to `biquad`.

`sections = cumsec(biquad,indices)` returns the cumulative sections of the `dsp.BiquadFilter` filter System object `biquad` whose indices in the original filter are in the vector `indices`.

`sections = cumsec(biquad,indices,secondary)` uses the secondary scaling points `secondary` in the sections to determine where the sections should be split when `secondary` is true. `secondary` is false by default. This option only applies for `dsp.BiquadFilter` objects with 'Direct form II' and 'Direct form I transposed' structures. For these structures, the secondary scaling points refer to the location between the recursive and the nonrecursive part, that is the 'middle' of the section.

`cumsec(biquad,...)` plots the magnitude response of the cumulative sections using `fvtool`.

`sections = cumsec(biquad,Name,Value)` returns the cumulative sections of the filter System object `biquad` with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **biquad**

`dsp.BiquadFilter` filter System object with one of the following filter structures:

Structure	Description
<code>df1sos</code>	Direct-form I filter object with second-order sections.
<code>df1tsos</code>	Direct-Form I transposed filter with second-order sections.
<code>df2sos</code>	Direct-form II filter object with second-order sections.
<code>df2tsos</code>	Direct-Form II transposed filter with second-order sections.

### **indices**

Filter indices. Use `indices` to specify the filter sections `cumsec` uses to compute the cumulative responses.

### **secondary**

This option applies only when `biquad` has the `df2sos` and `df1tsos` structures. For these second-order section structures, the secondary scaling points refer to the scaling locations between the recursive and the nonrecursive parts of the section (the "middle" of the section). Argument `secondary` accepts either `true` or `false`. By default, `secondary` is `false`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Arithmetic — Value types:**

'double' | 'single' | 'fixed'

Specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

**Details for Fixed-Point Arithmetic**

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsData type property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.

System Object State	Coefficient Data Type	Rule
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsData type property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

## Examples

### Frequency Response of SOS Filter

This example plots the relative responses of the sections of a sixth-order filter with three sections. Each curve adds one more section to form the filter response.

```
Lowpass = fdesign.lowpass('n,fc',6,.4); ButterLowpass = butter(Lowpass,'SystemObject',1);
CumSections = cumsec(ButterLowpass); hfvt = fvtool(CumSections{1},CumSections{2},CumSections{3});
legend(hfvt,'First Section','First Two Sections','Overall Filter');
```

# deleteCursor

**Package:** dsp

Delete Logic Analyzer cursor

## Syntax

```
deleteCursor(scope, tag)
```

## Description

`deleteCursor(scope, tag)` deletes the Logic Analyzer cursor specified by the input tag.

## Examples

### Modify Logic Analyzer Cursors Programmatically

This example shows how to use functions to create, manipulate, and delete cursors in a `dsp.LogicAnalyzer` object.

### Create Logic Analyzer and Signals

```
scope = dsp.LogicAnalyzer('NumInputPorts',3);  
for ii = 1:20  
    scope(ii,10*ii,20*ii);  
end
```

### Add Cursor

```
cursor = addCursor(scope,'Location',15,'Color','Cyan');  
getCursorInfo(scope,cursor)
```

```
ans = struct with fields:  
    Location: 15
```

```
Color: [0 1 1]
Locked: 0
Tag: 'C2'
```

### Modify Cursor

```
modifyCursor(scope,cursor,'Color','Magenta')
```

### Remove Cursor

```
tags = getCursorTags(scope);
deleteCursor(scope,tags{1});
```

## Input Arguments

**scope** — Logic Analyzer object from which you want to delete a cursor  
dsp.LogicAnalyzer object handle

The Logic Analyzer object from which you want to delete a cursor, specified as a handle to the dsp.LogicAnalyzer object.

**tag** — Tag identifying which cursor to delete  
character vector, randomly assigned

The tag identifying which cursor to delete, specified as a randomly assigned character vector.

Example: `deleteCursor(scope, tag)` deletes a cursor from Logic Analyzer.

**Introduced in R2013a**

# deleteDisplayChannel

**Package:** dsp

Delete Logic Analyzer channel

## Syntax

```
deleteDisplayChannel(scope, tag)
```

## Description

`deleteDisplayChannel(scope, tag)` deletes the display channel, either a wave or a divider, specified by the input tag.

## Examples

### Manipulate Logic Analyzer Programatically

Use functions to construct and manipulate a `dsp.LogicAnalyzer` System object.

### Display Waves on Logic Analyzer scope.

```
scope = dsp.LogicAnalyzer('NumInputPorts',2);  
  
stop = 30;  
for count = 1:stop  
    sinValVec = sin(count/stop*2*pi);  
    cosValVec = cos(count/stop*2*pi);  
    cosValVecOffset = cos((count+10)/stop*2*pi);  
  
    scope([count (count-(stop/2))],[sinValVec cosValVec cosValVecOffset])  
end
```

## Reorganize Display

```
digitalDividerTag = addDivider(scope, 'Name', 'Digital', 'Height', 20);
analogDividerTag = addDivider(scope, 'Name', 'Analog', 'Height', 40);

tags = getDisplayChannelTags(scope);

modifyDisplayChannel(scope, tags{1}, 'InputChannel', 1, ...
    'Name', 'Ramp Digital', 'Height', 40);
modifyDisplayChannel(scope, tags{2}, 'InputChannel', 2, ...
    'Name', 'Waves Analog', 'Format', 'Analog', 'Height', 80);

moveDisplayChannel(scope, digitalDividerTag, 'DisplayChannel', 1)
moveDisplayChannel(scope, tags{2}, 'DisplayChannel', length(tags))

show(scope)
```

### Duplicate Wave and Check Information

```
addWave(scope, 'InputChannel', 2, 'Name', 'Waves Digital', 'Format', 'Digital', ...
        'Height', 30, 'DisplayChannel', 3);
```

### Remove Dividers

```
deleteDisplayChannel(scope,digitalDividerTag)  
deleteDisplayChannel(scope,analogDividerTag)
```

### Clear variables

`clear analogDividerTag cosValVec cosValVecOffset count digitalDividerTag duplicateWave`

## Input Arguments

**scope** — Logic Analyzer object

`dsp.LogicAnalyzer` object

The Logic Analyzer object from which you want to delete a display channel, specified as a handle to the `dsp.LogicAnalyzer` object.

**tag** — tag identifier

character vector

The tag identifying which display channel to delete, specified as a character vector.

Example: `'deleteDisplayChannel(scope,tag)'` deletes a display channel from Logic Analyzer.

Data Types: char

**Introduced in R2013a**

## denormalize

Undo filter coefficient and gain changes caused by `normalize`

### Syntax

```
denormalize(hq)
```

### Description

`denormalize(hq)` reverses the coefficient changes you make when you use `normalize` with `hq`. The filter coefficients do not change if you call `denormalize(hq)` before you use `normalize(hq)`. Calling `denormalize` more than once on a filter does not change the coefficients after the first `denormalize` call.

### Examples

#### Denormalize Filter Coefficients

Construct a quantized filter `hd`.

```
d=fdesign.highpass('n,F3dB',14,0.45);  
hd =design(d,'butter');  
hd.arithmetic='fixed';
```

Normalize the filter coefficients

```
normalize(hd)  
NormSOSMatrix = hd.sosMatrix;
```

After normalizing the filter coefficients, restore them to their original values by reversing the effects of the `normalize` function.

```
denormalize(hd)  
eqSOSMatrices = isequal(NormSOSMatrix,hd.sosMatrix)
```

```
eqSOSMatrices = logical  
0
```

## See Also

normalize

**Introduced in R2011a**

## design

Apply design method to filter specification object

### Syntax

```
filt = design(D, 'Systemobject', true)
filt = design(D, METHOD, 'Systemobject', true)
filt =
design(D, METHOD, PARAM1, VALUE1, PARAM2, VALUE2, ..., 'Systemobject', true)
filt = design(D, METHOD, OPTS, 'Systemobject', true)
```

### Description

`filt = design(D, 'Systemobject', true)` uses the filter specifications object `D` to generate a filter System object, `filt`. When you do not provide a design method as an input argument, `design` uses the default design method. Use `designmethods(D, 'default')` to see the default design method for your filter specifications object. For more information on filter design specifications, see “Design a Filter in Fdesign — Process Overview”.

`filt = design(D, METHOD, 'Systemobject', true)` uses the design method specified by `METHOD`. `METHOD` must be one of the options returned by `designmethods`. Use `designmethods(D, 'default')` to determine which algorithm is used by default.

The design method you provide as the `designmethod` input argument must be one of the methods returned by

```
designmethods(D, 'Systemobject', true)
```

To help you design filters more quickly, the input argument `METHOD` accepts a variety of special keywords that force `design` to behave in different ways. The following table presents the keywords you can use for `METHOD` and how `design` responds to the keyword.

Design Method Keyword	Description of the Design Response
'FIR'	Forces <code>design</code> to produce an FIR filter. When no FIR design method exists for object <code>D</code> , <code>design</code> returns an error.
'IIR'	Forces <code>design</code> to produce an IIR filter. When no IIR design method exists for object <code>D</code> , <code>design</code> returns an error.
'ALLFIR'	Produces filters from every applicable FIR design method for the specifications in <code>D</code> , one filter for each design method. As a result, <code>design</code> returns multiple filters in the output object.
'ALLIIR'	Produces filters from every applicable IIR design method for the specifications in <code>D</code> , one filter for each design method. As a result, <code>design</code> returns multiple filters in the output object.
'ALL'	Designs filters using all applicable design methods for the specifications object <code>D</code> . As a result, <code>design</code> returns multiple filters, one for each design method. <code>design</code> uses the design methods in the order that <code>designmethods(D, 'Systemobject', true)</code> returns them.

Keywords are not case sensitive.

When `design` returns multiple filters in the output object, use indexing to see the individual filters. For example, to see the third filter in `filt`, enter:

```
filt(3)
```

```
filt =
```

```
design(D,METHOD,PARAM1,VALUE1,PARAM2,VALUE2,...,'Systemobject',true)
```

specifies design-method options. Use `help(D,METHOD)` for complete information on which design-method-specific options are available. You can also use `designopts(D,METHOD)` for a less-detailed listing of the design-method-specific options.

```
filt = design(D,METHOD,OPTS,'Systemobject',true)
```

specifies design-method options using the structure `OPTS`. `OPTS` is usually obtained from `designopts` and then specified as an input to `design`. Use `help(D,METHOD)` for more information on optional inputs.

If you are specifying design-method-specific options using `OPTS`, you can also set `OPTS.SystemObject` to `true` instead of calling `design` with the `'SystemObject'`, `true` syntax.

## Examples

### Design of Lowpass Filters

Design an FIR equiripple lowpass filter. Specify a passband edge frequency of  $0.2\pi$  rad/sample and a stopband edge frequency of  $0.25\pi$  rad/sample. Set the passband ripple to 0.5 dB and the stopband attenuation to 40 dB. Use the default equiripple method.

```
D = fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.25,0.5,40);  
filt = design(D,'SystemObject',true);
```

Design a minimum-phase FIR equiripple filter. Display pole-zero plots of the default and minimum-phase designs.

```
filtMin = design(D,'equiripple','MinPhase',true,'SystemObject',true);  
  
fvt = fvtool(filt,filtMin,'Analysis','polezero');  
legend(fvt,'Default design','Minimum-phase design')
```

Redesign the filter using the elliptic method. Match the passband exactly.

```
filt = design(D,'ellip','MatchExactly','passband','SystemObject',true);
```

You can specify the P-th norm scaling on the second-order sections. Use L-infinity norm scaling in the time domain.

```
filtL = design(D,'ellip','MatchExactly','passband','SOSScaleNorm','linf', ...
    'SystemObject',true);
```

Display the frequency responses of the Butterworth filters.

```
fvt = fvtool(filt,filtL);
legend(fvt,'Default scaling','L-infinity norm scaling')
```

# designMultirateFIR

Multirate FIR filter design

## Syntax

`B = designMultirateFIR(L,M)`

`B = designMultirateFIR(L,M,P)`

`B = designMultirateFIR(L,M,P,Astop)`

## Description

`B = designMultirateFIR(L,M)` designs a multirate FIR filter with interpolation factor  $L$  and decimation factor  $M$ . The output `B` is the vector of designed FIR coefficients. To design a pure interpolator, set  $M$  to 1. To design a pure decimator, set  $L$  to 1.

`B = designMultirateFIR(L,M,P)` designs a multirate FIR filter with half-polyphase length  $P$ . By default, the half-polyphase length is 12.

`B = designMultirateFIR(L,M,P,Astop)` designs a multirate FIR filter with stopband attenuation  $A_{stop}$ . By default, the stopband attenuation is 80 dB.

## Examples

### Design an FIR Interpolator

To design an FIR Interpolator using the `designMultirateFIR` function, you must specify the interpolation factor of interest (usually greater than 1) and a decimation factor equal to 1. You can use the default half-polyphase length of 12 and the default stopband attenuation of 80 dB. Alternately, you can also specify the half-polyphase length and stopband attenuation values.

Design an FIR interpolator with interpolation factor set to 5. Use the default half-polyphase length of 12 and the default stopband attenuation of 80 dB.

```
b = designMultirateFIR(5,1);  
fvtool(b,'impulse')
```

### Design an FIR Decimator

To design an FIR Decimator using the `designMultirateFIR` function, you must specify the decimation factor of interest (usually greater than 1) and an interpolation factor equal to 1. You can use the default half-polyphase length of 12 and the default stopband

attenuation of 80 dB. Alternately, you can also specify the half-polyphase length and stopband attenuation values. Design an FIR decimator with decimation factor set to 3, and half-polyphase length set to 14. Use the default stopband attenuation of 80 dB.

```
b = designMultirateFIR(1,3,14);  
fvtool(b, 'impulse');
```

### Design an FIR Rate Converter

To design an FIR Rate Converter using the `designMultirateFIR` function, you must specify an interpolation factor and decimation factor of interest (usually greater than 1).

You can use the default half-polyphase length of 12 and the default stopband attenuation of 80 dB. Alternately, you can also specify the half-polyphase length and stopband attenuation values.

Design an FIR rate converter with interpolation factor set to 3, decimation factor set to 4, half-polyphase length set to 14, and stopband attenuation set to 90 dB.

```
b = designMultirateFIR(3,4,14,90);  
fvtool(b,'impulse');
```

## Input Arguments

### **L — Interpolation factor**

positive scalar integer

Interpolation factor, specified as a positive scalar integer. To design a decimator only, set  $L$  to 1.

Example: 2

Data Types: `single` | `double`

### **M — Decimation factor**

positive scalar integer

Decimation factor, specified as a positive scalar integer. To design an interpolator only, set  $M$  to 1.

Example: 2

Data Types: `single` | `double`

### **P — Half-polyphase length**

12 (default) | positive scalar integer

Half-polyphase length, specified as a positive scalar integer.

Example: 12

Example: 20

Data Types: `single` | `double`

### **Astop — Stopband attenuation**

90 (default) | nonnegative scalar

Stopband attenuation in dB, specified as a nonnegative real scalar greater than or equal to 0.

Example: 0.0

Example: 80.5

Data Types: `single` | `double`

## Output Arguments

### B — Coefficients

real-valued vector

Multirate FIR filter coefficients, returned as a real-valued  $N$ -length vector.

If both  $L$  and  $M$  are equal to 1, then  $N$  equals 1.

If  $\max(L, M) > 1$ , then  $N = 2 * P * R$ , where  $P$  is the half-polyphase length and  $R$  is defined by the following equations:

- If  $L > 1$ ,  $R = L$ .
- If  $L = 1$ ,  $R = M$ .

For more details, see the “Algorithms” on page 5-150 section.

## Algorithms

`designMultirateFIR` designs an  $(N - 1)$ th order,  $R$ th band Nyquist FIR filter using the  $N$ -length Kaiser window vector to window the truncated impulse response of the FIR filter.

Filter length,  $N$  is defined as  $N = 2 * P * R$  and  $R$  is defined as explained in “B” on page 5-0 .

The truncated impulse response  $d(n)$  is delayed by  $N/2$  samples to make it causal. The truncated and delayed impulse response is given by:

$$d(n - N / 2) = \frac{\sin(w_c (n - N / 2))}{\pi(n - N / 2)}, \quad n = 0, \dots, \frac{N}{2}, \dots, N$$

where  $w_c = \pi/R$  .

For every  $R$ th band, the impulse response of the Nyquist filters is exactly zero. Because of this property, when Nyquist filters are used for pure interpolation, the input samples remain unaltered after interpolating.

A Kaiser window is used because of its near-optimum performance while providing a robust way of designing a Nyquist filter. The window depends on two parameters: length  $N + 1$  and shape parameter  $\beta$ .

The Kaiser window is defined by:

$$w(n) = \frac{I_0 \left( \beta \sqrt{1 - \left( \frac{n - N/2}{N/2} \right)^2} \right)}{I_0(\beta)}, \quad 0 \leq n \leq N,$$

where  $I_0$  is the zeroth-order modified Bessel function of the first kind.

The shape parameter  $\beta$  is calculated from:

$$\beta = \begin{cases} 0.1102(A_{stop} - 8.7) & \text{if } A_{stop} \geq 50 \\ 0.5842(A_{stop} - 21)^{0.4} + 0.07886(A_{stop} - 21) & \text{if } 21 < A_{stop} < 50 \\ 0 & \text{if } A_{stop} \leq 21, \end{cases}$$

where  $A_{stop}$  is the stopband attenuation in dB.

The windowed impulse response is given by

$$h(n) = w(n)d(n - N/2) = w(n) \frac{\sin(w_c(n - N/2))}{\pi(n - N/2)}, \quad n = 0, \dots, \frac{N}{2}, \dots, N$$

$h(n)$  for  $n = 0, \dots, N/2, \dots, N$  are the coefficients of the multirate filter. These coefficients are defined by the interpolation factor,  $L$ , and decimation factor,  $M$ .

# designmethods

Methods available for designing filter from specification object

## Syntax

```
M = designmethods(D, 'SystemObject', true)
M = designmethods(D, 'default')
M = designmethods(D, TYPE, 'SystemObject', true)
M = designmethods(D, 'full', 'SystemObject', true)
```

## Description

`M = designmethods(D, 'SystemObject', true)` returns the available design methods for designing filter System objects for the filter specification object, D.

`M = designmethods(D, 'default')` returns the default design method for the filter specification object D.

`M = designmethods(D, TYPE, 'SystemObject', true)` returns the TYPE design methods for the filter specification object, D. TYPE can be either 'FIR' or 'IIR'.

`M = designmethods(D, 'full', 'SystemObject', true)` returns the full name for each of the available design methods. For example, `designmethods` with the 'full' argument returns Butterworth for the butter method.

## Examples

### Valid Design Methods for Lowpass Filter

Construct a lowpass filter specification object and determine the valid design methods.

```
D = fdesign.lowpass('Fp,Fst,Ap,Ast', 500, 600, 0.5, 60, 1e4);
M = designmethods(D, 'SystemObject', true)
```

```
M = 8x1 cell array
    {'butter'   }
    {'cheby1'  }
    {'cheby2'  }
    {'ellip'   }
    {'equiripple'}
    {'ifir'    }
    {'kaiserwin'}
    {'multistage'}
```

Obtain detailed command line help on the Chebyshev type I design method.

```
help(D,M{2})
```

DESIGN Design a Chebyshev type I iir filter.

HD = DESIGN(D, 'cheby1') designs a Chebyshev type I filter specified by the FDESIGN object D, and returns the DFILT/MFILT object HD.

HD = DESIGN(D, ..., 'SystemObject', true) implements the filter, HD, using a System object instead of a DFILT/MFILT object.

HD = DESIGN(..., 'FilterStructure', STRUCTURE) returns a filter with the structure STRUCTURE. STRUCTURE is 'df2sos' by default and can be any of the following:

```
'df1sos'
'df2sos'
'df1tsos'
'df2tsos'
'cascadeallpass'
'cascadewdfallpass'
```

Some of the listed structures may not be supported by System object filters. Type validstructures(D, 'cheby1', 'SystemObject', true) to get a list of structures supported by System objects.

HD = DESIGN(..., 'MatchExactly', MATCH) designs a Chebyshev type I filter and matches the frequency and magnitude specification for the band MATCH exactly. The other band will exceed the specification. MATCH can be 'stopband' or 'passband' and is 'passband' by default.

HD = DESIGN(..., 'SOSScaleNorm', NORM) designs an SOS filter and scales the coefficients using the P-Norm NORM. NORM can be either a discrete-time-domain norm or a frequency-domain norm. Valid time-domain

norms are 'l1', 'l2', and 'linf'. Valid frequency-domain norms are 'L1', 'L2', and 'Linf'. Note that L2-norm is equal to l2-norm (Parseval's theorem) but the same is not true for other norms.

The different norms can be ordered in terms of how stringent they are as follows: 'l1' >= 'Linf' >= 'L2' = 'l2' >= 'L1' >= 'linf'. Using the most stringent scaling, 'l1', the filter is the least prone to overflow, but also has the worst signal-to-noise ratio. Linf-scaling is the most commonly used scaling in practice.

Scaling is turned off by default, which is equivalent to setting `SOSScaleNorm = ''`.

`HD = DESIGN(..., 'SOSScaleOpts', OPTS)` designs an SOS filter and scales the coefficients using an `FDOPTS.SOSSCALING` object `OPTS`. Scaling options are:

Property	Default	Description/Valid values
'sosReorder'	'auto'	Reorder section prior to scaling. {'auto', 'none', 'up', 'down', 'lowpass', 'highpass', 'bandpass', 'bandstop'}
'MaxNumerator'	2	Maximum value for numerator coefficients
'NumeratorConstraint'	'none'	{'none', 'unit', 'normalize', 'po2'}
'OverflowMode'	'wrap'	{'wrap', 'saturate'}
'ScaleValueConstraint'	'unit'	{'unit', 'none', 'po2'}
'MaxScaleValue'	'Not used'	Maximum value for scale values

When `sosReorder` is set to 'auto', the sections will be automatically reordered depending on the response type of the design (lowpass, highpass, etc.).

Note that 'MaxScaleValue' will only be used when 'ScaleValueConstraint' is set to something other than 'unit'. If 'MaxScaleValue' is set to a number, the 'ScaleValueConstraint' will be changed to 'none'. Further, if `SOSScaleNorm` is off (as it is by default), then all the `SOSScaleOpts` will be ignored.

For more information about P-Norm and scaling options see help for `DFILT\SCALE`.

```
% Example #1 - Compare passband and stopband MatchExactly.
h      = fdesign.lowpass('Fp,Fst,Ap,Ast', .1, .3, 1, 60);
Hd     = design(h, 'cheby1', 'MatchExactly', 'passband');
Hd(2) = design(h, 'cheby1', 'MatchExactly', 'stopband');
```

```
% Compare the passband edges in FVTool.  
fvtool(Hd);  
axis([.09 .11 -2 0]);
```

### **See Also**

**Introduced in R2009a**

# designopts

Valid input arguments and values for specification object and method

## Syntax

```
OPTS = designopts(D,METHOD)
```

## Description

`OPTS = designopts(D,METHOD)` returns a structure array with the default design parameters used by the design method `METHOD`. `METHOD` must be one of the options returned by `designmethods`.

Use `help(D,METHOD)` to get a description of the design parameters.

If you have DSP System Toolbox software installed, `OPTS` has the `SystemObject` property if at least one of the structures available for that design method is supported by System objects. However, not all structures for that design method are supported by System objects.

## Examples

### Butterworth Filter Design Options

Create a lowpass filter with a numerator and denominator order of 10 and a 3-dB frequency of  $0.2\pi$  rad/sample. Obtain the default design parameters for a Butterworth design. Test whether the filter structure is a direct-form II biquad.

```
D = fdesign.lowpass('Nb,Na,F3dB',10,10,0.2);  
OPTS = designopts(D,'butter')
```

```
OPTS = struct with fields:  
    FilterStructure: 'df2sos'  
    SOSScaleNorm: ''
```

```
SOSScaleOpts: [1x1 fdopts.sosscaling]  
SystemObject: 0
```

```
if isequal(OPTS.FilterStructure,'df2sos')  
    fprintf('The default filter structure is Direct-Form II\n');  
    fprintf('with second-order sections.\n');  
end
```

The default filter structure is Direct-Form II  
with second-order sections.

# dfilt

Discrete-time filter

## Syntax

```
hd = dfilt.structure(input1,...)
hd = [dfilt.structure(input1,...), dfilt.structure(input1,...),...]
hd = design(d,'designmethod')
```

## Description

`hd = dfilt.structure(input1,...)` returns a discrete-time filter, `hd`, of type *structure*. Each structure takes one or more inputs. When you specify a `dfilt.structure` with no inputs, a default filter is created.

---

**Note** You must use a *structure* with `dfilt`.

---

`hd = [dfilt.structure(input1,...), dfilt.structure(input1,...),...]` returns a vector containing `dfilt` filters.

## Structures

Structures for `dfilt.structure` specify the type of filter structure. Available types of structures for `dfilt` are shown below.

<code>dfilt.structure</code>	Description	Coefficient Mapping Support in <code>realizemdl</code>
<code>dfilt.allpass</code>	Allpass filter	Supported
<code>dfilt.cascadeallpass</code>	Cascade of allpass filter sections	Supported

<b>dfilt.structure</b>	<b>Description</b>	<b>Coefficient Mapping Support in realizemdl</b>
dfilt.cascadewdfallpass	Cascade of allpass wave digital filters	Supported
dfilt.delay	Delay	Not supported
dfilt.df1	Direct-form I	Supported
dfilt.df1sos	Direct-form I, second-order sections	Supported
dfilt.df1t	Direct-form I transposed	Supported
dfilt.df1tsos	Direct-form I transposed, second-order sections	Supported
dfilt.df2	Direct-form II	Supported
dfilt.df2sos	Direct-form II, second-order sections	Supported
dfilt.df2t	Direct-form II transposed	Supported
dfilt.df2tsos	Direct-form II transposed, second-order sections	Supported
dfilt.dffir	Direct-form FIR	Supported
dfilt.dffirt	Direct-form FIR transposed	Supported
dfilt.dfsymfir	Direct-form symmetric FIR	Supported
dfilt.dfasymfir	Direct-form antisymmetric FIR	Supported
dfilt.farrowfd	Generic fractional delay Farrow filter	Supported
dfilt.farrowlinearf	Linear fractional delay Farrow filter	Not supported
dfilt.fftfit	Overlap-add FIR	Not supported
dfilt.latticeallpass	Lattice allpass	Supported
dfilt.latticear	Lattice autoregressive (AR)	Supported
dfilt.latticearma	Lattice autoregressive moving-average (ARMA)	Supported

<b>dfilt.structure</b>	<b>Description</b>	<b>Coefficient Mapping Support in realizemdl</b>
<code>dfilt.latticemamax</code>	Lattice moving-average (MA) for maximum phase	Supported
<code>dfilt.latticemamin</code>	Lattice moving-average (MA) for minimum phase	Supported
<code>dfilt.calattice</code>	Coupled, allpass lattice	Supported
<code>dfilt.calatticepc</code>	Coupled, allpass lattice with power complementary output	Supported
<code>dfilt.statespace</code>	State-space	Supported
<code>dfilt.scalar</code>	Scalar gain object	Supported
<code>dfilt.wdfallpass</code>	Allpass wave digital filter object	Supported
<code>dfilt.cascade</code>	Filters arranged in series	Supported
<code>dfilt.parallel</code>	Filters arranged in parallel	Supported

For more information on each structure, refer to its reference page.

`hd = design(d, 'designmethod')` returns the `dfilt` object `hd` resulting from the filter specification object `d` and the design method you specify in *designmethod*. When you omit the `designmethod` argument, `design` uses the default design method to construct a filter from the object `d`.

With this syntax, you design filters by:

- 1 Specifying the filter specifications, such as the response shape (perhaps highpass) and details (passband edges and attenuation).
- 2 Selecting a method (such as `equiripple`) to design the filter.
- 3 Applying the method to the specifications object with `design(d, 'designmethod')`.

Using the specification-based technique can be more effective than the coefficient-based filter design techniques.

## Design Methods for Design Syntax

When you use the `hd = design(d, 'designmethod')` syntax, you have a range of design methods available depending on `d`, the filter specification object. The next table lists all of the design methods in the toolbox.

Design Method String	Filter Design Result
butter	Butterworth IIR
cheby1	Chebyshev Type I IIR
cheby2	Chebyshev Type II IIR
ellip	Elliptic IIR
equiripple	Equiripple with the same ripple in the pass and stopbands
firls	Least-squares FIR
freqsamp	Frequency-Sampled FIR
ifir	Interpolated FIR
iirlpnorm	Least Pth norm IIR
iirls	Least-Squares IIR
kaiserwin	Kaiser-windowed FIR
lagrange	Fractional delay filter
multistage	Multistage FIR
window	Windowed FIR

As the specifications object `d` changes, the available methods for designing filters from `d` also change. For instance, if `d` is a lowpass filter with the default specification `'Fp,Fst,Ap,Ast'`, the applicable methods are:

```
% Create an object to design a lowpass filter.
d=fdesign.lowpass;
designmethods(d) % What design methods apply to object d?
```

If you change the specification string to `'N,F3dB'`, the available design methods change:

```
d=fdesign.lowpass('N,F3dB');
designmethods(d)
```

## Analysis Methods

Methods provide ways of performing functions directly on your `dfilt` object without having to specify the filter parameters again. You can apply these methods directly on the variable you assigned to your `dfilt` object.

For example, if you create a `dfilt` object, `hd`, you can check whether it has linear phase with `islinphase(hd)`, view its frequency response plot with `fvtool(hd)`, or obtain its frequency response values with `h = freqz(hd)`. You can use all of the methods described here in this way.

---

**Note** If your variable `hd` is a 1-D array of `dfilt` filters, the method is applied to each object in the array. Only `freqz`, `grpdelay`, `impz`, `is*`, `order`, and `stepz` methods can be applied to arrays. The `zplane` method can be applied to an array only if `zplane` is used without outputs.

---

Some of the methods listed here have the same name as functions in Signal Processing Toolbox software. They behave similarly.

Method	Description
<code>addstage</code>	Adds a stage to a <code>cascade</code> or <code>parallel</code> object, where a stage is a separate, modular filter. Refer to <code>dfilt.cascade</code> and <code>dfilt.parallel</code> .
<code>block</code>	<p><code>block(hd)</code> creates a block of the <code>dfilt</code> object. The <code>block</code> method can specify these properties and values:</p> <ul style="list-style-type: none"> <li>'Destination' indicates where to place the block.</li> <li>'Current' places the block in the current Simulink model.</li> <li>'New' creates a new model. Default value is 'Current'.</li> </ul> <p>'Blockname' assigns the entered string to the block name. Default name is 'Filter'.</p> <p>'OverwriteBlock' indicates whether to overwrite the block generated by the <code>block</code> method ('on') and defined by <code>Blockname</code>. Default is 'off'.</p> <p>'MapStates' specifies initial conditions in the block ('on'). Default is 'off'. Refer to "Using Filter States" in Signal Processing Toolbox documentation.</p>
<code>cascade</code>	Returns the series combination of two <code>dfilt</code> objects. Refer to <code>dfilt.cascade</code> .

<b>Method</b>	<b>Description</b>
<code>coeffs</code>	Returns the filter coefficients in a structure containing fields that use the same property names as those in the original <code>dfilt</code> .
<code>convert</code>	Converts a <code>dfilt</code> object from one filter structure, to another filter structure.
<code>fcfwrite</code>	Writes a filter coefficient ASCII file. The file can contain a single filter or a vector of objects. The default file name is <code>untitled.fcf</code> .  <code>fcfwrite(hd, filename)</code> writes to a disk file named <code>filename</code> in the current working folder. The <code>.fcf</code> extension is added automatically.  <code>fcfwrite(..., fmt)</code> writes the coefficients in the format <code>fmt</code> , where valid <code>fmt</code> strings are:  'hex' for hexadecimal  'dec' for decimal  'bin' for binary representation
<code>fftcoeffs</code>	Returns the frequency-domain coefficients used when filtering with a <code>dfilt.fftfilter</code>
<code>filter</code>	Performs filtering using the <code>dfilt</code> object.
<code>firtype</code>	Returns the type (1-4) of a linear phase FIR filter.
<code>freqz</code>	Plots the frequency response in <code>fvtool</code> . Unlike the <code>freqz</code> function, this <code>dfilt</code> <code>freqz</code> method has a default length of 8192.
<code>grpdelay</code>	Plots the group delay in <code>fvtool</code> .
<code>impz</code>	Plots the impulse response in <code>fvtool</code> .
<code>impzlength</code>	Returns the length of the impulse response.
<code>info</code>	Displays <code>dfilt</code> information, such as filter structure, length, stability, linear phase, and, when appropriate, lattice and ladder length.

<b>Method</b>	<b>Description</b>
<code>isallpass</code>	Returns a logical 1 (i.e., true) if the <code>dfilt</code> object in an allpass filter or a logical 0 (i.e., false) if it is not.
<code>iscascade</code>	Returns a logical 1 if the <code>dfilt</code> object is cascaded or a logical 0 if it is not.
<code>isfir</code>	Returns a logical 1 if the <code>dfilt</code> object has finite impulse response (FIR) or a logical 0 if it does not.
<code>islinphase</code>	Returns a logical 1 if the <code>dfilt</code> object is linear phase or a logical 0 if it is not.
<code>ismaxphase</code>	Returns a logical 1 if the <code>dfilt</code> object is maximum-phase or a logical 0 if it is not.
<code>isminphase</code>	Returns a logical 1 if the <code>dfilt</code> object is minimum-phase or a logical 0 if it is not.
<code>isparallel</code>	Returns a logical 1 if the <code>dfilt</code> object has parallel stages or a logical 0 if it does not.
<code>isreal</code>	Returns a logical 1 if the <code>dfilt</code> object has real-valued coefficients or a logical 0 if it does not.
<code>isscalar</code>	Returns a logical 1 if the <code>dfilt</code> object is a scalar or a logical 0 if it is not scalar.
<code>issos</code>	Returns a logical 1 if the <code>dfilt</code> object has second-order sections or a logical 0 if it does not.
<code>isstable</code>	Returns a logical 1 if the <code>dfilt</code> object is stable or a logical 0 if it are not.
<code>nsections</code>	Returns the number of sections in a second-order sections filter. If a multistage filter contains stages with multiple sections, using <code>nsections</code> returns the total number of sections in all the stages (a stage with a single section returns 1).
<code>nstages</code>	Returns the number of stages of the filter, where a stage is a separate, modular filter.
<code>nstates</code>	Returns the number of states for an object.

<b>Method</b>	<b>Description</b>
<code>order</code>	Returns the filter order. If <code>hd</code> is a single-stage filter, the order is given by the number of delays needed for a minimum realization of the filter. If <code>hd</code> has multiple stages, the order is given by the number of delays needed for a minimum realization of the overall filter.
<code>parallel</code>	Returns the parallel combination of two <code>dfilt</code> filters. Refer to <code>dfilt.parallel</code> .
<code>phasez</code>	Plots the phase response in <code>fvtool</code> .

Method	Description
realizemdl	<p>(Available only with Simulink.)</p> <p><code>realizemdl(hd)</code> creates a Simulink model containing a subsystem block realization of your <code>dfilt</code>.</p> <p><code>realizemdl(hd,p1,v1,p2,v2,...)</code> creates the block using the properties <code>p1, p2,...</code> and values <code>v1, v2,...</code> specified.</p> <p>The following properties are available:</p> <p>'Blockname' specifies the name of the block. The default value is 'Filter'.</p> <p>'Destination' specifies whether to add the block to a current Simulink model or create a new model. Valid values are 'Current' and 'New'.</p> <p>'OverwriteBlock' specifies whether to overwrite an existing block that was created by <code>realizemdl</code> or create a new block. Valid values are 'on' and 'off'. Only blocks created by <code>realizemdl</code> are overwritten.</p> <p>The following properties optimize the block structure. Specifying 'on' turns the optimization on and 'off' creates the block without optimization. The default for each block is 'off'.</p> <p>'OptimizeZeros' removes zero-gain blocks.</p> <p>'OptimizeOnes' replaces unity-gain blocks with a direct connection.</p> <p>'OptimizeNegOnes' replaces negative unity-gain blocks with a sign change at the nearest summation block.</p> <p>'OptimizeDelayChains' replaces delay chains made up of <math>n</math> unit delays with a single delay by <math>n</math>.</p>

Method	Description
<code>removestage</code>	Removes a stage from a cascade or parallel <code>dfilt</code> . Refer to <code>dfilt.cascade</code> and <code>dfilt.parallel</code> .
<code>setstage</code>	Overwrites a stage of a cascade or parallel <code>dfilt</code> . Refer to <code>dfilt.cascade</code> and <code>dfilt.parallel</code> .
<code>sos</code>	<p>Converts the <code>dfilt</code> to a second-order sections <code>dfilt</code>. If <code>hd</code> has a single section, the returned filter has the same class.</p> <p><code>sos(hd, flag)</code> specifies the ordering of the second-order sections. If <code>flag='UP'</code>, the first row contains the poles closest to the origin, and the last row contains the poles closest to the unit circle. If <code>flag='down'</code>, the sections are ordered in the opposite direction. The zeros are always paired with the poles closest to them.</p> <p><code>sos(hd, flag, scale)</code> specifies the scaling of the gain and the numerator coefficients of all second-order sections. <code>scale</code> can be <code>'none'</code>, <code>'inf'</code> (infinity-norm), or <code>'two'</code> (2-norm). Using infinity-norm scaling with up ordering minimizes the probability of overflow in the realization. Using 2-norm scaling with down ordering minimizes the peak roundoff noise.</p>
<code>ss</code>	Converts the <code>dfilt</code> to state-space. To see the separate <code>A, B, C, D</code> matrices for the state-space model, use <code>[A, B, C, D]=ss(hd)</code> .
<code>stepz</code>	<p>Plots the step response in <code>fvtool</code></p> <p><code>stepz(hd, n)</code> computes the first <code>n</code> samples of the step response.</p> <p><code>stepz(hd, n, Fs)</code> separates the time samples by <math>T = 1/F_s</math>, where <math>F_s</math> is assumed to be in hertz.</p>
<code>sysobj</code>	Converts the <code>dfilt</code> to a filter System object. See the reference page for a list of supported objects.
<code>tf</code>	Converts the <code>dfilt</code> to a transfer function.
<code>zerophase</code>	Plots the zero-phase response in <code>fvtool</code> .
<code>zpk</code>	Converts the <code>dfilt</code> to zeros-pole-gain form.

---

Method	Description
zplane	Plots a pole-zero plot in fvtool.

## Viewing Properties

As with any object, use `get` to view a `dfilt` properties. To see a specific property, use

```
get(hd, 'property')
```

To see all properties for an object, use

```
get(hd)
```

---

**Note** `dfilt` objects include an `arithmetic` property. You can change the internal arithmetic of the filter from double-precision to single-precision using: `hd.arithmetic = 'single'`.

If you have Fixed-Point Designer software, you can change the `arithmetic` property to fixed-point using: `hd.arithmetic = 'fixed'`

---

## Changing Properties

To set specific properties, use

```
set(hd, 'property1', value, 'property2', value, ...)
```

You must use single quotation marks around the property name. Use single quotation marks around the `value` argument when the value is a string, such as `specifyall` or `fixed`.

## Copying an Object

To create a copy of an object, use the `copy` method.

```
h2 = copy(hd)
```

---

**Note** Using the syntax `H2 = hd` copies only the object handle and does not create a new, independent object.

---

## Converting Between Filter Structures

To change the filter structure of a `dfilt` object `hd`, use

```
hd2 = convert(hd,'structure_string');
```

where `structure_string` is any valid structure name in single quotation marks. If `hd` is a cascade or parallel structure, each stage is converted to the new structure.

## Using Filter States

Two properties control the filter states:

- `states` — Stores the current states of the filter. Before the filter is applied, the states correspond to the initial conditions and after the filter is applied, the states correspond to the final conditions. For `dfl`, `dflt`, `dflsos` and `dfltsos` structures, `states` returns a `filtstates` object.
- `PersistentMemory` — Controls whether filter states are saved. The default value is `'false'`, which causes the initial conditions to be reset to zero before filtering and turns off the display of states information. Setting `PersistentMemory` to `'true'` allows the filter to use your initial conditions or to reuse the final conditions from a previous filtering operation as the initial conditions of the next filtering operation. The `true` setting also displays information about the filter states.

---

**Note** If you set the `states` and want to use them for filtering, you must set `PersistentMemory` to `'true'` before you use the filter.

---

## Examples

Create a direct-form I filter, and use a method to see if it is stable.

```
[b,a] = butter(8,0.25);  
hd = dfilt.dfl(b,a);  
isstable(hd)
```

If a `dfilt`'s numerator values do not fit on a single line, a description of the vector is displayed. To see the specific numerator values for this example, use

```
B = get(hd, 'numerator');  
% or  
B1 = hd.numerator;
```

Create an array containing two `dfilt` objects, apply a method and verify that the method acts on both objects. Use a method to test whether the objects are FIR objects.

```
b = fir1(5, .5);  
hd = dfilt.dffir(b);           % Create an FIR filter object  
[b,a] = butter(5, .5);       % Create IIR filter  
hd(2) = dfilt.df2t(b,a);     % Create DF2T object and place  
                             % in the second column of hd.  
  
[h,w] = freqz(hd);  
test_fir = isfir(hd)  
% hd(1) is FIR and hd(2) is not.
```

Refer to the reference pages for each structure for more examples.

## dfilt.allpass

Allpass filter

### Syntax

```
hd = dfilt.allpass(c)
```

### Description

`hd = dfilt.allpass(c)` constructs an allpass filter with the minimum number of multipliers from the elements in vector `c`. To be valid, `c` must contain one, two, three, or four real elements. The number of elements in `c` determines the order of the filter. For example, `c` with two elements creates a second-order filter and `c` with four elements creates a fourth-order filter.

The transfer function for the allpass filter is defined by

$$H(z) = \frac{c(n) + c(n-1)z^{-1} + \dots + z^{-n}}{1 + c(1)z^{-1} + \dots + c(n)z^{-n}}$$

given the coefficients in `c`.

To construct a cascade of allpass filter objects, use `dfilt.cascadeallpass`. For more information about creating cascades of allpass filters, refer to `dfilt.cascadeallpass`.

### Properties

The following table provides a list of all the properties associated with an allpass `dfilt` object.

Property Name	Brief Description
AllpassCoefficients	Contains the coefficients for the allpass filter object

Property Name	Brief Description
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.

## Examples

This example constructs and displays the information about a second-order allpass filter that uses the minimum number of multipliers.

```
c = [1.5, 0.7];
% Create a second-order dfilt object.
hd = dfilt.allpass(c);
```

## **dfilt.calattice**

Coupled-allpass, lattice filter

### **Syntax**

```
hd = dfilt.calattice(k1,k2,beta)
hd = dfilt.calattice
```

### **Description**

`hd = dfilt.calattice(k1,k2,beta)` returns a discrete-time, coupled-allpass, lattice filter object `hd`, which is two allpass, lattice filter structures coupled together. The lattice coefficients for each structure are vectors `k1` and `k2`. Input argument `beta` is shown in the diagram below.

`hd = dfilt.calattice` returns a default, discrete-time coupled-allpass, lattice filter object, `hd`. The default values are `k1 = k2 = []`, which is the default value for `dfilt.latticeallpass`, and `beta = 1`. This filter passes the input through to the output unchanged.

## Examples

Specify a third-order lattice coupled-allpass filter structure for a `dfilt` filter, `hd` with the following code.

```
k1 = [0.9511 + 1j*0.3088; 0.7511 + 1j*0.1158];
k2 = 0.7502 - 1j*0.1218;
beta = 0.1385 + 1j*0.9904;
hd = dfilt.calattice(k1,k2,beta);
```

The `Allpass1` and `Allpass2` properties store vectors of coefficients.

## dfilt.calatticepc

Coupled-allpass, power-complementary lattice filter

### Syntax

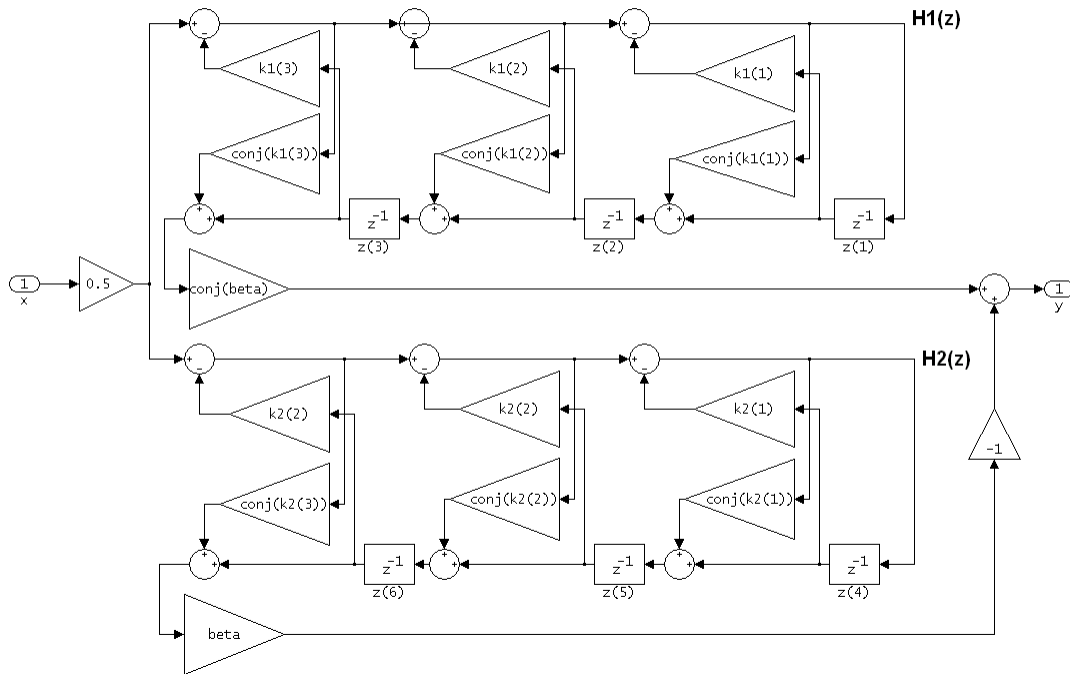

```
hd = dfilt.calatticepc(k1,k2)
hd = dfilt.calatticepc
```

### Description

`hd = dfilt.calatticepc(k1,k2)` returns a discrete-time, coupled-allpass, lattice filter object `hd`, with power-complementary output. This object is two allpass lattice filter structures coupled together to produce complementary output. The lattice coefficients for each structure are vectors, `k1` and `k2`, respectively. `beta` is shown in the following diagram.

`hd = dfilt.calatticepc` returns a default, discrete-time, coupled-allpass, lattice filter object `hd`, with power-complementary output. The default values are `k1 = k2 = []`, which is the default value for the `dfilt.latticeallpass`. The default for `beta = 1`. This filter passes the input through to the output unchanged.

**calatticepc**  
(Coupled Allpass Lattice, Power Complementary output)

## Examples

Specify a third-order lattice coupled-allpass power complementary filter structure for a filter `hd` with the following code. You see from the returned properties that `Allpass1` and `Allpass2` contain vectors of coefficients for the constituent filters.

```
k1 = [0.9511 + 0.3088i; 0.7511 + 0.1158i];
k2 = 0.7502 - 0.1218i;
beta = 0.1385 + 0.9904i;
hd = dfilt.calatticepc(k1,k2,beta);
```

To see the coefficients for `Allpass1`, check the property values.

```
get(hd, 'Allpass1')
```

## dfilt.cascade

Cascade of discrete-time filters

### Syntax

Refer to `dfilt.cascade` in Signal Processing Toolbox documentation for more information.

### Description

`hd = dfilt.cascade(filterobject1,filterobject2,...)` returns a discrete-time filter object `hd` of type `cascade`, which is a serial interconnection of two or more filter objects `filterobject1`, `filterobject2`, and so on. `dfilt.cascade` accepts any combination of `dfilt` objects (discrete time filters) to cascade, as well as Farrow filter objects.

You can use the standard notation to cascade one or more filters:

```
cascade(hd1,hd2,...)
```

where `hd1`, `hd2`, and so on can be mixed types, such as `dfilt` objects and other filtering objects.

`hd1`, `hd2`, and so on can be fixed-point filters. All filters in the cascade must be the same arithmetic format — `double`, `single`, or `fixed`. `hd`, the filter object returned, inherits the format of the cascaded filters.

### Examples

Cascade a lowpass filter and a highpass filter to produce a bandpass filter.

```
[b1,a1]=butter(8,0.6);           % Lowpass
[b2,a2]=butter(8,0.4,'high');   % Highpass
h1=dfilt.df2t(b1,a1);
h2=dfilt.df2t(b2,a2);
hcas=dfilt.cascade(h1,h2);      % Bandpass with passband 0.4-0.6
% View stage 1 with hcas.Stage(1)
```

## See Also

## **dfilt.cascadeallpass**

Cascade of allpass discrete-time filters

### **Syntax**

```
hd = dfilt.cascadeallpass(c1,c2,...)
```

### **Description**

`hd = dfilt.cascadeallpass(c1,c2,...)` constructs a cascade of allpass filters, each of which uses the minimum number of multipliers, given the filter coefficients provided in `c1`, `c2`, and so on.

Each vector `c` represents one section in the cascade filter. `c` vectors must contain one, two, three, or four elements as the filter coefficients for each section. As a result of the design algorithm, each section is a `dfilt.allpass` structure whose coefficients are given in the matching `c` vector, such as the `c1` vector contains the coefficients for the first stage.

States for each section are shared between sections.

Vectors `c` do not have to be the same length. You can combine various length vectors in the input arguments. For example, you can cascade fourth-order sections with second-order sections, or first-order sections.

For more information about the vectors `ci` and about the transfer function of each section, refer to `dfilt.allpass`.

Generally, you do not construct these allpass cascade filters directly. Instead, they result from the design process for an IIR filter. Refer to the first example in Examples for more about using `dfilt.cascadeallpass` to design an IIR filter.

## Properties

In the next table, the row entries are the filter properties and a brief description of each property.

Property Name	Brief Description
AllpassCoefficients	Contains the coefficients for the allpass filter object
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.

## Examples

Two examples show how `dfilt.cascadeallpass` works in very different applications — designing a halfband IIR filter and constructing an allpass cascade of `dfilt` objects.

First, design the IIR halfband filter using cascaded allpass filters. Each branch of the parallel cascade construction is a `cascadeallpass` filter object.

```
tw = 100; % Transition width of filter to be designed, 100 Hz.
ast = 80; % Stopband attenuation of filter to be designed, 80dB.
fs = 2000; % Sampling frequency of signal to be filtered.
% Store halfband design specs in the specifications object d.
d = fdesign.halfband('tw,ast',tw,ast,fs);
```

Now perform the actual filter design. `hd` contains two `dfilt.cascadeallpass` objects.

```
hd = design(d,'ellip','filterstructure','cascadeallpass');  
% Get summary information about one dfilt.cascadeallpass stage.  
StageInfo = hd.Stage(1).Stage(1);
```

This second example constructs a `dfilt.cascadeallpass` filter object directly given allpass coefficients for the input vectors.

```
section1 = 0.8;  
section2 = [1.2,0.7];  
section3 = [1.3,0.9];  
hd = dfilt.cascadeallpass(section1,section2,section3);  
% Get information about the filter  
% return informatio in character array  
S = info(hd);
```

## dfilt.cascadewdfallpass

Cascade allpass WDF filters to construct allpass WDF

### Syntax

```
hd = dfilt.cascadewdfallpass(c1,c2,...)
```

### Description

`hd = dfilt.cascadewdfallpass(c1,c2,...)` constructs a cascade of allpass wave digital filters given the allpass coefficients in the vectors `c1`, `c2`, and so on.

Each `c` vector contains the coefficients for one section of the cascaded filter. `C` vectors must have one, two, or four elements (coefficients). Three element vectors are not supported.

When the `c` vector has four elements, the first and third elements of the vector must be 0. Each section of the cascade is an allpass wave digital filter, from `dfilt.wdfallpass`, with the coefficients given by the corresponding `c` vector. That is, the first section has coefficients from vector `c1`, the second section coefficients come from `c2`, and on until all of the `c` vectors are used.

You can mix the lengths of the `c` vectors. They do not need to be the same length. For example, you can cascade several fourth-order sections (`length(c) = 4`) with first or second-order sections.

Wave digital filters are usually used to create other filters. This toolbox uses them to implement halfband filters, which the first example in Examples demonstrates. They are most often building blocks for filters.

Generally, you do not construct these WDF allpass cascade filters directly. Instead, they result from the design process for an IIR filter. Refer to the first example in Examples for more about using `dfilt.cascadewdfallpass` to design an IIR filter.

For more information about the `c` vectors and the transfer function for the allpass filters, refer to `dfilt.wdfallpass`.

## Properties

In the next table, the row entries are the filter properties and a brief description of each property.

Property Name	Brief Description
AllpassCoefficients	Contains the coefficients for the allpass wave digital filter object
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.

## Examples

To demonstrate two approaches to using `dfilt.cascadewdfallpass` to design a filter, these examples show both direct construction and construction as part of another filter.

The first design shown creates an IIR halfband filter that uses lattice wave digital filters. Each branch of the parallel connection in the lattice is an allpass cascade wave digital filter.

```
tw = 100; % Transition width of filter, 100 Hz.
ast = 80; % Stopband attenuation of filter, 80 dB.
fs = 2000; % Sampling frequency of signal to filter.
% Store halfband specs.
d = fdesign.halfband('tw,ast',tw,ast,fs);
```

Now perform the actual halfband design process. `hd` contains two `dfilt.cascadewdfallpass` filters.

```
hd = design(d,'ellip','filterstructure','cascadewdfallpass');
% Summary info on dfilt.cascadewdfallpass.
StageSummary = hd.stage(1).stage(2);
```

This example demonstrates direct construction of a `dfilt.cascadewdfallpass` filter with allpass coefficients.

```
section1 = 0.8;
section2 = [1.5,0.7];
section3 = [1.8,0.9];
hd = dfilt.cascadewdfallpass(section1,section2,section3);
```

## See Also

`dfilt` | `dfilt.wdfallpass`

**Introduced in R2011a**

# dfilt.delay

Delay filter

## Syntax

```
Hd = dfilt.delay  
Hd = dfilt.delay(latency)
```

## Description

`Hd = dfilt.delay` returns a discrete-time filter, `Hd`, of type `delay`, which adds a single delay to any signal filtered with `Hd`. The filtered signal has its values shifted by one sample.

`Hd = dfilt.delay(latency)` returns a discrete-time filter, `Hd`, of type `delay`, which adds the number of delay units specified in `latency` to any signal filtered with `Hd`. The filtered signal has its values shifted by the `latency` number of samples. The values that appear before the shifted signal are the filter states.

## Examples

Create a delay filter with a latency of 4 and filter a simple signal to view the impact of applying a delay.

```
h = dfilt.delay(4);  
Fs = 1000;  
t = 0:1/Fs:1;  
sig = cos(2*pi*100*t);  
y = filter(h,sig);  
subplot(211);  
stem(sig, 'markerfacecolor', [0 0 1]);  
axis([0 20 -2 2]);  
title('Input Signal');  
subplot(212);  
stem(y, 'markerfacecolor', [0 0 1]);
```

```
axis([0 20 -2 2]);  
title('Delayed Signal');
```

## See Also

`dfilt`

**Introduced in R2011a**

## dfilt.df1

Discrete-time, direct-form I filter

### Syntax

Refer to `dfilt.df1` in Signal Processing Toolbox documentation.

### Description

`hd = dfilt.df1` returns a default discrete-time, direct-form I filter object that uses double-precision arithmetic. By default, the numerator and denominator coefficients `b` and `a` are set to 1. With these coefficients the filter passes the input to the output without changes.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```
- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “Arithmetic” on page 6-18.

---

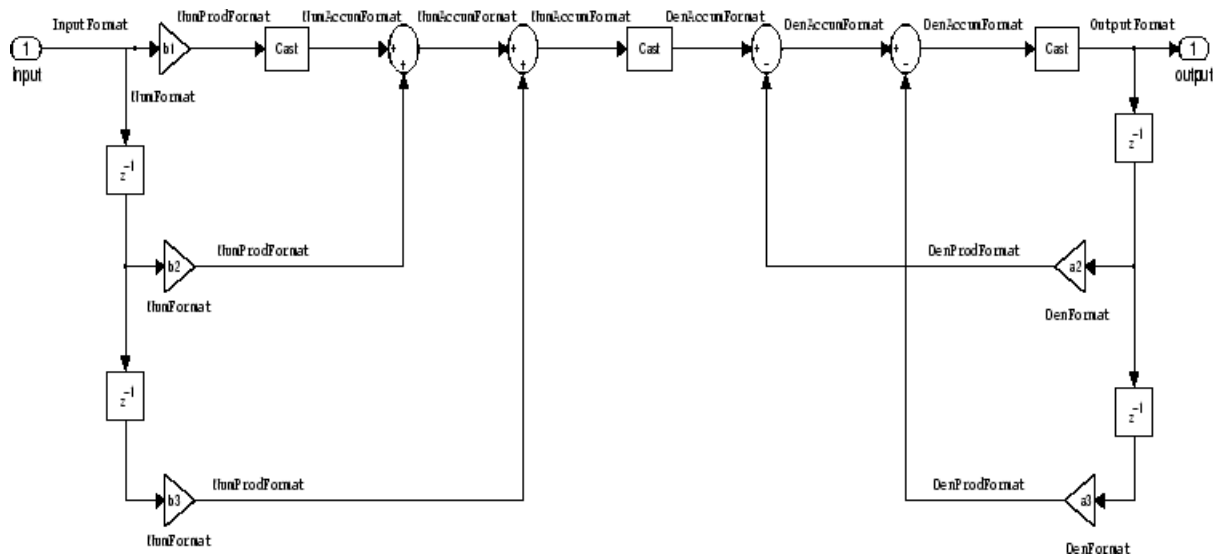

**Note** `a(1)`, the leading denominator coefficient, cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

---

### Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form I filter implemented by `dfilt.df1`. To help you see how the filter processes the coefficients, input, output, and

states of the filter, as well as numerical operations, the figure includes the locations of the arithmetic and data type format elements within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFormat	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFormat	CoeffWordLength	DenFracLength	CoeffAutoScale , SignedDenominator
DenProdFormat	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength
InputFormat	InputWordLength	InputFracLength	None
NumAccumFormat	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFormat	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
NumProdFormat	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
OutputFormat	OutputWordLength	OutputFracLength	OutputMode

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFormat, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFormat refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with df1 implementations of dfilt objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You

might not see all of the listed properties all the time. To view all the properties for a filter at any time, use `get (hd)` where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 6-2.

<b>Property Name</b>	<b>Brief Description</b>
<code>AccumMode</code>	Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
<code>AccumWordLength</code>	Sets the word length used to store data in the accumulator/buffer.
<code>Arithmetic</code>	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
<code>CastBeforeSum</code>	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
<code>CoeffAutoScale</code>	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> and <code>DenFracLength</code> properties to specify the precision used.
<code>CoeffWordLength</code>	Specifies the word length to apply to filter coefficients.
<code>DenAccumFracLength</code>	Specifies the fraction length the filter algorithm uses to interpret the results of product operations involving denominator coefficients. You can change the value for this property when you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .

<b>Property Name</b>	<b>Brief Description</b>
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.
Denominator	Stores the denominator coefficients for the IIR filter.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
Numerator	Holds the numerator coefficient values for the filter.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputWordLength	Determines the word length used for the output data.

Property Name	Brief Description
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.

Property Name	Brief Description
RoundMode	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
Signed	<p>Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.</p>
States	<p>This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.</p>

## Examples

Specify a second-order direct-form I structure for a `dfilt` object, `hd`, with the following code:

```
b = [0.3 0.6 0.3];  
a = [1 0 0.2];  
hd = dfilt.df1(b,a);  
% Convert hd to fixed-point filter  
set(hd,'arithmetic','fixed')
```

**Introduced in R2011a**

## dfilt.df1sos

Discrete-time, SOS direct-form I filter

### Syntax

Refer to `dfilt.df1sos` in Signal Processing Toolbox documentation.

### Description

`hd = dfilt.df1sos(s)` returns a discrete-time, second-order section, direct-form I filter object `hd`, with coefficients given in the `s` matrix.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “Arithmetic” on page 6-18.

`hd = dfilt.df1sos(b1,a1,b2,a2,...)` returns a discrete-time, second-order section, direct-form I filter object `hd`, with coefficients for the first section given in the `b1` and `a1` vectors, for the second section given in the `b2` and `a2` vectors, and so on.

`hd = dfilt.df1sos(...,g)` includes a gain vector `g`. The elements of `g` are the gains for each section. The maximum length of `g` is the number of sections plus one. When you do not specify `g`, all gains default to one.

`hd = dfilt.df1sos` returns a default, discrete-time, second-order section, direct-form I filter object, `hd`. This filter passes the input through to the output unchanged.

---

**Note** The leading coefficient of the denominator  $a(1)$  cannot be 0. To allow you to change the arithmetic setting to fixed or single,  $a(1)$  must be equal to 1.

---

## Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form I filter implemented in `second-order sections` by `dfilt.df1sos`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the `InputFrmt` label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and

InputFracLength (as shown in the table) store the word length and the fraction length in bits. Similarly consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

<b>Signal Flow Label</b>	<b>Corresponding Word Length Property</b>	<b>Corresponding Fraction Length Property</b>	<b>Related Properties</b>
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, Signed, Denominator
DenProdFrmt	ProductWordLength	DenProdFracLength	ProductMode
DenStateFrmt	DenStateWordLength	DenStateFracLength	CastBeforeSum, States
InputFrmt	InputWordLength	InputFracLength	None
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
NumProdFrmt	ProductWordLength	NumProdFracLength	ProductMode
NumStateFrmt	NumStateWordLength	NumStateFracLength	States
OutputFrmt	OutputWordLength	OutputFracLength	OutputMode
ScaleValueFrmt	CoeffWordLength	ScaleValueFracLength	CoeffAutoScale, ScaleValues

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProductWordLength,

DenProdFracLength and ProductMode that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with SOS implementation of direct-form I dfilt objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

get(hd)

where hd is a filter.

---

For further information about the properties of this filter or any dfilt object, refer to “Fixed-Point Filter Properties” on page 6-2.

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.

<b>Property Name</b>	<b>Brief Description</b>
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> and <code>DenFracLength</code> properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. <code>DenFracLength</code> is always available, but it is read-only until you set <code>CoeffAutoScale</code> to <code>false</code> .
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
DenStateFracLength	Specifies the fraction length used to interpret the states associated with denominator coefficients in the filter.
DenStateWordLength	Specifies the word length used to represent the states associated with denominator coefficients in the filter.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.

Property Name	Brief Description
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumStateFracLength	Specifies the fraction length used to interpret the states associated with numerator coefficient operations in the filter.
NumWordFracLength	Specifies the word length used to interpret the states associated with numerator coefficient operations in the filter.
OptimizeScaleValues	When true, the filter skips multiplication-by-one scaling. When false, the filter performs multiplication-by-one scaling.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>OutputMode</code> to <code>SpecifyPrecision</code> .
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: <ul style="list-style-type: none"> <li>• <code>AvoidOverflow</code> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li> <li>• <code>BestPrecision</code> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li> <li>• <code>SpecifyPrecision</code> — lets you set the word and fraction lengths used by the output data from filtering.</li> </ul>
OutputWordLength	Determines the word length applied for the output data.

Property Name	Brief Description
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.

Property Name	Brief Description
RoundMode	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
ScaleValueFracLength	<p>Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Only available when you disable <code>AutoScaleMode</code> by setting it to <code>false</code>.</p>
ScaleValues	<p>Scaling for the filter objects in SOS filters.</p>
Signed	<p>Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.</p>
SosMatrix	<p>Holds the filter coefficients as property values. Displays the matrix in the format [sections x coefficients/section datatype]. A [15x6 <code>double</code>] SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type <code>double</code> to represent the coefficients.</p>

Property Name	Brief Description
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Sets the word length used to represent the filter states.

## Examples

Specify a fixed-point, second-order section, direct-form I `dfilt` object with the following code:

```
b = [0.3 0.6 0.3];  
a = [1 0 0.2];  
hd = dfilt.df1sos(b,a);  
% Convert to fixed-point filter  
hd.arithmetic = 'fixed';
```

## See Also

`dfilt` | `dfilt.df2tsos`

**Introduced in R2011a**

## **dfilt.df1t**

Discrete-time, direct-form I transposed filter

### **Syntax**

Refer to `dfilt.df1t` in Signal Processing Toolbox documentation.

### **Description**

`hd = dfilt.df1t(b,a)` returns a discrete-time, direct-form I transposed filter object `hd`, with numerator coefficients `b` and denominator coefficients `a`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter  

```
set(hd,'arithmetic','single');
```
- To change to fixed-point filtering, enter  

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “`Arithmetic`” on page 6-18.

`hd = dfilt.df1t` returns a default, discrete-time, direct-form I transposed filter object `hd`, with `b=1` and `a=1`. This filter passes the input through to the output unchanged.

---

**Note** The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

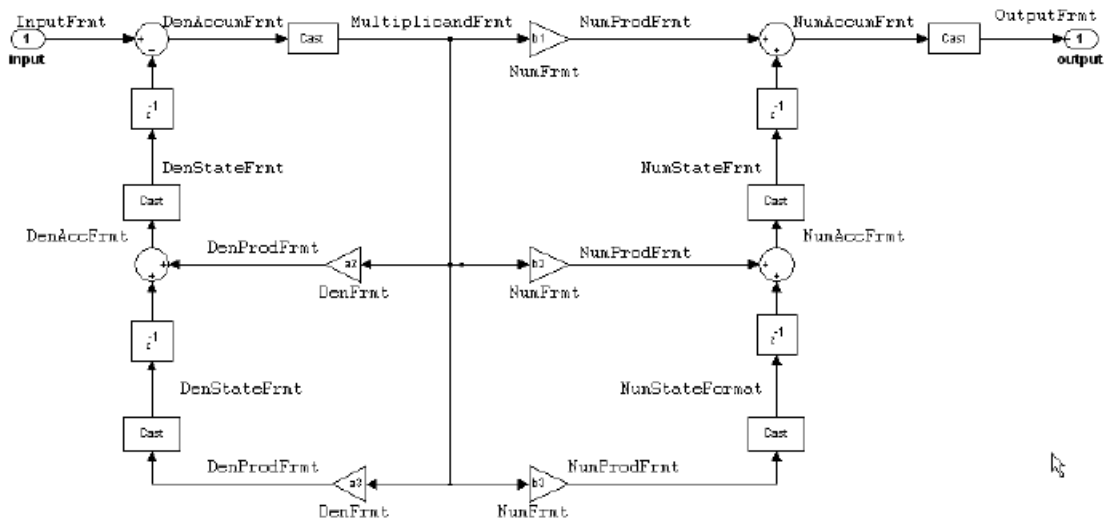

---

### **Fixed-Point Filter Structure**

The following figure shows the signal flow for the transposed direct-form I filter implemented by `dfilt.df1t`. To help you see how the filter processes the coefficients,

input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the `InputFrmt` label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider `NumFrmt`, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, , Signed, Denominator
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength
DenStateFrmt	DenStateWordLength	DenStateFracLength	CastBeforeSum, States
InputFrmt	InputWordLength	InputFracLength	None
Multiplicandfrmt	Multiplicand-WordLength	Multiplicand-FracLength	CastBeforeSum
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
NumStateFrmt	NumStateWordLength	NumStateFracLength	States
OutputFrmt	OutputWordLength	OutputFracLength	OutputMode

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with `df1t` implementation of `dfilt` objects.

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 6-2.

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.

Property Name	Brief Description
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> and <code>DenFracLength</code> properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. <code>DenFracLength</code> is always available, but it is read-only until you set <code>CoeffAutoScale</code> to <code>false</code> .
Denominator	Holds the denominator coefficients for the filter.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
DenStateFracLength	Specifies the fraction length used to interpret the states associated with denominator coefficients in the filter.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.

<b>Property Name</b>	<b>Brief Description</b>
MultiplicandFracLength	Sets the fraction length for values (multiplicands) used in multiply operations in the filter.
MultiplicandWordLength	Sets the word length applied to the values input to a multiply operation (the multiplicands).
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
Numerator	Holds the numerator coefficient values for the filter.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
NumStateFracLength	For IIR filters, this defines the binary point location applied to the numerator states of the filter. Specifies the fraction length used to interpret the states associated with numerator coefficient operations in the filter.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.

Property Name	Brief Description
OutputMode	<p>Sets the mode the filter uses to scale the filtered data for output. You have the following choices:</p> <ul style="list-style-type: none"> <li>• <b>AvoidOverflow</b> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li> <li>• <b>BestPrecision</b> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li> <li>• <b>SpecifyPrecision</b> — lets you set the word and fraction lengths used by the output data from filtering.</li> </ul>
OutputWordLength	<p>Determines the word length used for the output data.</p>
OverflowMode	<p>Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <b>saturate</b> (limit the output to the largest positive or negative representable value) or <b>wrap</b> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.</p>
ProductMode	<p>Determines how the filter handles the output of product operations. Choose from full precision (<b>FullPrecision</b>), or whether to keep the most significant bit (<b>KeepMSB</b>) or least significant bit (<b>KeepLSB</b>) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <b>ProductMode</b> to <b>SpecifyPrecision</b>.</p>

Property Name	Brief Description
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.
RoundMode	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.

Property Name	Brief Description
StateAutoScale	Setting autoscaling for filter states to <code>true</code> reduces the possibility of overflows occurring during fixed-point operations. Set to <code>false</code> , <code>StateAutoScale</code> lets the filter select the fraction length to limit the overflow potential.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

## Examples

Specify a second-order direct-form I transposed filter structure for a `dfilt` object, `hd`, with the following code:

```
b = [0.3 0.6 0.3];  
a = [1 0 0.2];  
hd = dfilt.df1t(b,a);  
% Convert filter to single-precision arithmetic  
set(hd,'arithmetic','single')
```

## See Also

**Introduced in R2011a**

## dfilt.df1tsos

Discrete-time, SOS direct-form I transposed filter

### Syntax

Refer to `dfilt.df1tsos` in Signal Processing Toolbox documentation.

### Description

`hd = dfilt.df1tsos(s)` returns a discrete-time, second-order section, direct-form I, transposed filter object `hd`, with coefficients given in the `s` matrix.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to .

`hd = dfilt.df1tsos(b1,a1,b2,a2,...)` returns a discrete-time, second-order section, direct-form I, transposed filter object `hd`, with coefficients for the first section given in the `b1` and `a1` vectors, for the second section given in the `b2` and `a2` vectors, etc.

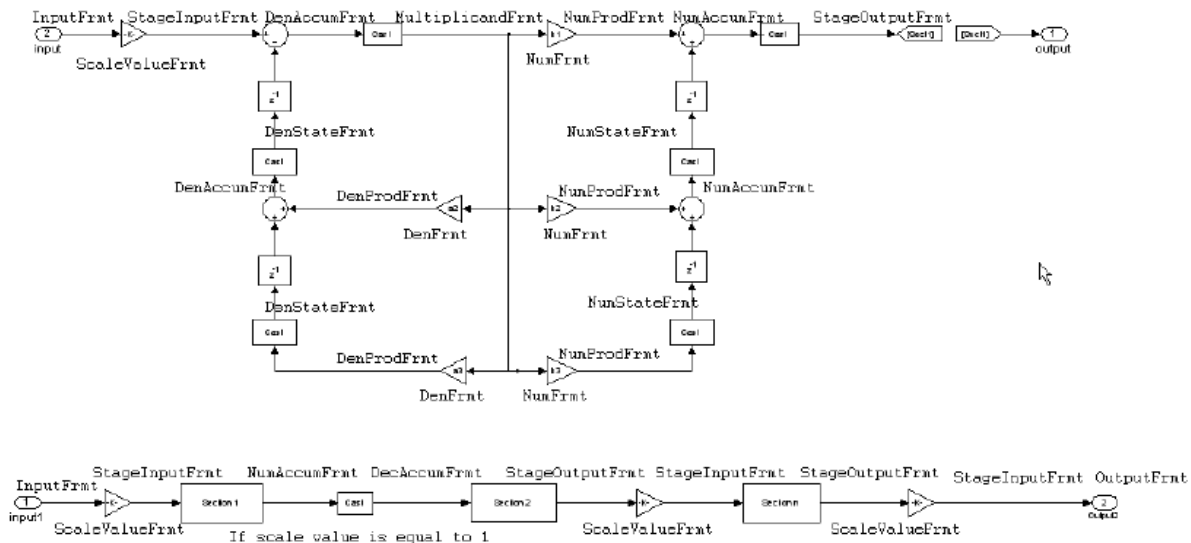

`hd = dfilt.df1tsos(...,g)` includes a gain vector `g`. The elements of `g` are the gains for each section. The maximum length of `g` is the number of sections plus one. If `g` is not specified, all gains default to one.

`hd = dfilt.df1tsos` returns a default, discrete-time, second-order section, direct-form I, transposed filter object, `hd`. This filter passes the input through to the output unchanged.

**Note** The leading coefficient of the denominator  $a(1)$  cannot be 0. To allow you to change the arithmetic setting to fixed or single,  $a(1)$  must be equal to 1.

## Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form I transposed filter implemented using second-order sections by `dfilt.df1tsos`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

<b>Signal Flow Label</b>	<b>Corresponding Word Length Property</b>	<b>Corresponding Fraction Length Property</b>	<b>Related Properties</b>
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, Signed, Denominator
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength
DenStateFrmt	DenStateWordLength	DenStateFracLength	CastBeforeSum, States
InputFrmt	InputWordLength	InputFracLength	None
MultiplicandFrmt	Multiplicand-WordLength	Multiplicand-FracLength	CastBeforeSum
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
NumStateFrmt	NumStateWordLength	NumStateFracLength	States
OutputFrmt	OutputWordLength	OutputFracLength	OutputMode
ScaleValueFrmt	CoeffWordLength	ScaleValue-FracLength	CoeffAutoScale, ScaleValues

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label `DenProdFrmt`, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the `DenProdFrmt` refers to the properties `ProdWordLength`, `ProductMode` and `DenProdFracLength` that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with SOS implementation of transposed direct-form I `dfilt` objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 6-2.

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> and <code>DenFracLength</code> properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .

<b>Property Name</b>	<b>Brief Description</b>
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
DenStateFracLength	Specifies the fraction length used to interpret the states associated with denominator coefficients in the filter.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
MultiplicandFracLength	Sets the fraction length for values (multiplicands) used in multiply operations in the filter.
MultiplicandWordLength	Sets the word length applied to the values input to a multiply operation (the multiplicands)
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
Numerator	Holds the numerator coefficient values for the filter.

Property Name	Brief Description
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
NumStateFracLength	For IIR filters, this defines the binary point location applied to the numerator states of the filter. Specifies the fraction length used to interpret the states associated with numerator coefficient operations in the filter.
NumStateWordLength	For IIR filters, this defines the word length applied to the numerator states of the filter. Specifies the word length used to interpret the states associated with numerator coefficient operations in the filter.
OptimizeScaleValues	When true, the filter skips multiplication-by-one scaling. When false, the filter performs multiplication-by-one scaling.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>OutputMode</code> to <code>SpecifyPrecision</code> .
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: <ul style="list-style-type: none"> <li>• <code>AvoidOverflow</code> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li> <li>• <code>BestPrecision</code> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li> <li>• <code>SpecifyPrecision</code> — lets you set the word and fraction lengths used by the output data from filtering.</li> </ul>

<b>Property Name</b>	<b>Brief Description</b>
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.

Property Name	Brief Description
RoundMode	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
ScaleValueFracLength	<p>Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Only available when you disable <code>AutoScaleMode</code> by setting it to <code>false</code>.</p>
ScaleValues	<p>Scaling for the filter objects in SOS filters.</p>
Signed	<p>Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.</p>

Property Name	Brief Description
SosMatrix	Holds the filter coefficients as property values. Displays the matrix in the format [sections x coefficients/sectiondatatype]. A [15x6 double] SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type <code>double</code> to represent the coefficients.
StateAutoScale	Setting autoscaling for filter states to <code>true</code> reduces the possibility of overflows occurring during fixed-point operations. Set to <code>false</code> , <code>StateAutoScale</code> lets the filter select the fraction length to limit the overflow potential.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

## Examples

With the following code, this example specifies a second-order section, direct-form I transposed `dfilt` object for a filter. Then convert the filter to fixed-point operation.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df1tsos(b,a);
set(hd,'arithmetic','fixed')
```

**Introduced in R2011a**

## dfilt.df2

Discrete-time, direct-form II filter

### Syntax

Refer to `dfilt.df2` in Signal Processing Toolbox documentation.

### Description

`hd = dfilt.df2(b,a)` returns a discrete-time, direct-form II filter object `hd`, with numerator coefficients `b` and denominator coefficients `a`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter  

```
set(hd,'arithmetic','single');
```
- To change to fixed-point filtering, enter  

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “`Arithmetic`” on page 6-18.

`hd = dfilt.df2` returns a default, discrete-time, direct-form II filter object `hd`, with `b = 1` and `a = 1`. This filter passes the input through to the output unchanged.

---

**Note** The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

---

### Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form II filter implemented by `dfilt.df2`. To help you see how the filter processes the coefficients, input, and states of

the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, Signed, Denominator
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength
InputFrmt	InputWordLength	InputFracLength	None
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
OutputFrmt	OutputWordLength	OutputFracLength	OutputMode
StateFrmt	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the df2 implementation of dfilt objects.

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 6-2.

Property Name	Brief Description
<code>AccumMode</code>	Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. ## Examples

Specify a second-order direct-form II filter structure for a `dfilt` object, `hd`, with the following code:

```
b = [0.3 0.6 0.3];  
a = [1 0 0.2];  
hd = dfilt.df2(b,a);  
% Change filter to fixed-point  
set(hd,'arithmetic','fixed')
```

## See Also

**Introduced in R2011a**

## dfilt.df2sos

Discrete-time, SOS, direct-form II filter

### Syntax

Refer to `dfilt.df2sos` in Signal Processing Toolbox documentation.

### Description

`hd = dfilt.df2sos(s)` returns a discrete-time, second-order section, direct-form II filter object `hd`, with coefficients given in the `s` matrix.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “Arithmetic” on page 6-18.

`hd = dfilt.df2sos(b1,a1,b2,a2,...)` returns a discrete-time, second-order section, direct-form II object, `hd`, with coefficients for the first section given in the `b1` and `a1` vectors, for the second section given in the `b2` and `a2` vectors, etc.

`hd = dfilt.df2sos(...,g)` includes a gain vector `g`. The elements of `g` are the gains for each section. The maximum length of `g` is the number of sections plus one. If `g` is not specified, all gains default to one.

`hd = dfilt.df2sos` returns a default, discrete-time, second-order section, direct-form II filter object, `hd`. This filter passes the input through to the output unchanged.

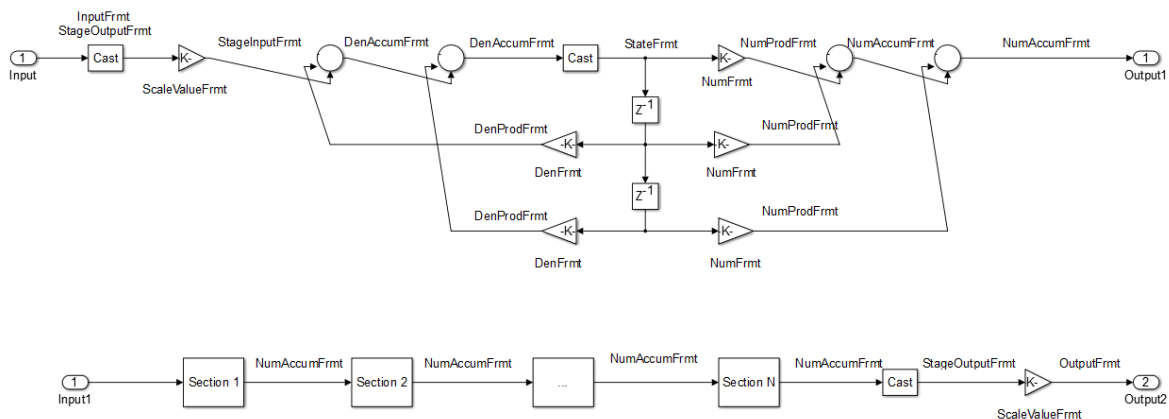

---

**Note** The leading coefficient of the denominator  $a(1)$  cannot be 0. To allow you to change the arithmetic setting to fixed or single,  $a(1)$  must be equal to 1.

---

## Fixed-Point Filter Structure

The figure below shows the signal flow for the direct-form II filter implemented with second-order sections by `dfilt.df2sos`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The frmt properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

<b>Signal Flow Label</b>	<b>Corresponding Word Length Property</b>	<b>Corresponding Fraction Length Property</b>	<b>Related Properties</b>
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, Signed, sosMatrix
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength, sosMatrix
InputFrmt	InputWordLength	InputFracLength	None
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, sosMatrix
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
OutputFrmt	OutputWordLength	OutputFracLength	OutputMode

ScaleValueFracLength	Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Only available when you disable <code>AutoScaleMode</code> by setting it to <code>false</code> .
ScaleValues	Scaling for the filter objects in SOS filters.
SectionInputAutoScale	Tells the filter whether to set the stage input data format to minimize the occurrence of overflow conditions.
SectionInputFracLength	Lets you set the fraction length for section inputs in SOS filters, if you set <code>SectionInputAutoScale</code> to <code>false</code> .

Property Name	Brief Description
SectionInputWordLength	Lets you set the word length for section inputs in SOS filters, if you set SectionInputAutoScale to false.
SectionOutputAutoScale	Tells the filter whether to set the section output data format to minimize the occurrence of overflow conditions.
SectionOutputFracLength	Lets you set the fraction length for section outputs in SOS filters, if you set SectionOutputAutoScale to off.
SectionOutputWordLength	Lets you set the word length for section outputs in SOS filters, if you set SectionOutputAutoScale to false.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
SosMatrix	Holds the filter coefficients as property values. Displays the matrix in the format [sections x coefficients/section datatype]. A [15x6 double] SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type double to represent the coefficients.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

## Examples

Specify a second-order section, direct-form II `dfilt` object for a Butterworth filter converted to second-order sections, with the following code:

```
[z,p,k] = butter(30,0.5);
[s,g] = zp2sos(z,p,k);
hd = dfilt.df2sos(s,g);
% Convert filter to fixed-point
hd.arithmetic='fixed';
```

## **See Also**

**Introduced in R2011a**

## dfilt.df2t

Discrete-time, direct-form II transposed filter

### Syntax

Refer to `dfilt.df2t` in Signal Processing Toolbox documentation.

### Description

`hd = dfilt.df2t(b,a)` returns a discrete-time, direct-form II transposed filter object `hd`, with numerator coefficients `b` and denominator coefficients `a`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```
- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “Arithmetic” on page 6-18.

`hd = dfilt.df2t` returns a default, discrete-time, direct-form II transposed filter object `hd`, with `b = 1` and `a = 1`. This filter passes the input through to the output unchanged.

---

**Note** The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

---

### Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form II transposed filter implemented by `dfilt.df2t`. To help you see how the filter processes the coefficients,

input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt.” In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and

InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

<b>Signal Flow Label</b>	<b>Corresponding Word Length Property</b>	<b>Corresponding Fraction Length Property</b>	<b>Related Properties</b>
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, Signed, Denominator
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength
InputFrmt	InputWordLength	InputFracLength	None
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
OutputFrmt	OutputWordLength	OutputFracLength	None
StateFrmt	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with `df2t` implementation of `dfilt` objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 6-2.

Property Name	Brief Description
<code>AccumMode</code>	Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
<code>AccumWordLength</code>	Sets the word length used to store data in the accumulator/buffer.
<code>Arithmetic</code>	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
<code>CastBeforeSum</code>	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.

<b>Property Name</b>	<b>Brief Description</b>
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> and <code>DenFracLength</code> properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. <code>DenFracLength</code> is always available, but it is read-only until you set <code>CoeffAutoScale</code> to <code>false</code> .
Denominator	Holds the denominator coefficients for IIR filters.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
Numerator	Holds the numerator coefficient values for the filter.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.

<b>Property Name</b>	<b>Brief Description</b>
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
OutputFracLength	Determines how the filter interprets the filter output data.
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.

Property Name	Brief Description
RoundMode	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
Signed	<p>Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.</p>
StateAutoScale	<p>Setting autoscaling for filter states to <code>true</code> reduces the possibility of overflows occurring during fixed-point operations. Set to <code>false</code>, <code>StateAutoScale</code> lets the filter select the fraction length to limit the overflow potential.</p>
StateFracLength	<p>When you set <code>StateAutoScale</code> to <code>false</code>, you enable the <code>StateFracLength</code> property that lets you set the fraction length applied to interpret the filter states.</p>
States	<p>This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.</p>
StateWordLength	<p>Sets the word length used to represent the filter states.</p>

## Examples

Create a fixed-point filter by specifying a second-order direct-form II transposed filter structure for a `dfilt` object, and then converting the double-precision arithmetic setting to fixed-point.

```
b = [0.3 0.6 0.3];  
a = [1 0 0.2];  
hd = dfilt.df2t(b,a);  
% Convert filter to fixed-point  
set(hd,'arithmetic','fixed')
```

## See Also

`dfilt` | `dfilt.df1` | `dfilt.df1t` | `dfilt.df2`

**Introduced in R2011a**

## dfilt.df2tsos

Discrete-time, SOS direct-form II transposed filter

### Syntax

Refer to `dfilt.df2tsos` in Signal Processing Toolbox documentation.

### Description

`hd = dfilt.df2tsos(s)` returns a discrete-time, second-order section, direct-form II, transposed filter object `hd`, with coefficients given in the matrix `s`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “`Arithmetic`” on page 6-18.

`hd = dfilt.df2tsos(b1,a1,b2,a2,...)` returns a discrete-time, second-order section, direct-form II, transposed filter object `hd`, with coefficients for the first section given in the `b1` and `a1` vectors, for the second section given in the `b2` and `a2` vectors, etc.

`hd = dfilt.df2tsos(...,g)` includes a gain vector `g`. The elements of `g` are the gains for each section. The maximum length of `g` is the number of sections plus one. If `g` is not specified, all gains default to one.

`hd = dfilt.df2tsos` returns a default, discrete-time, second-order section, direct-form II, transposed filter object, `hd`. This filter passes the input through to the output unchanged.

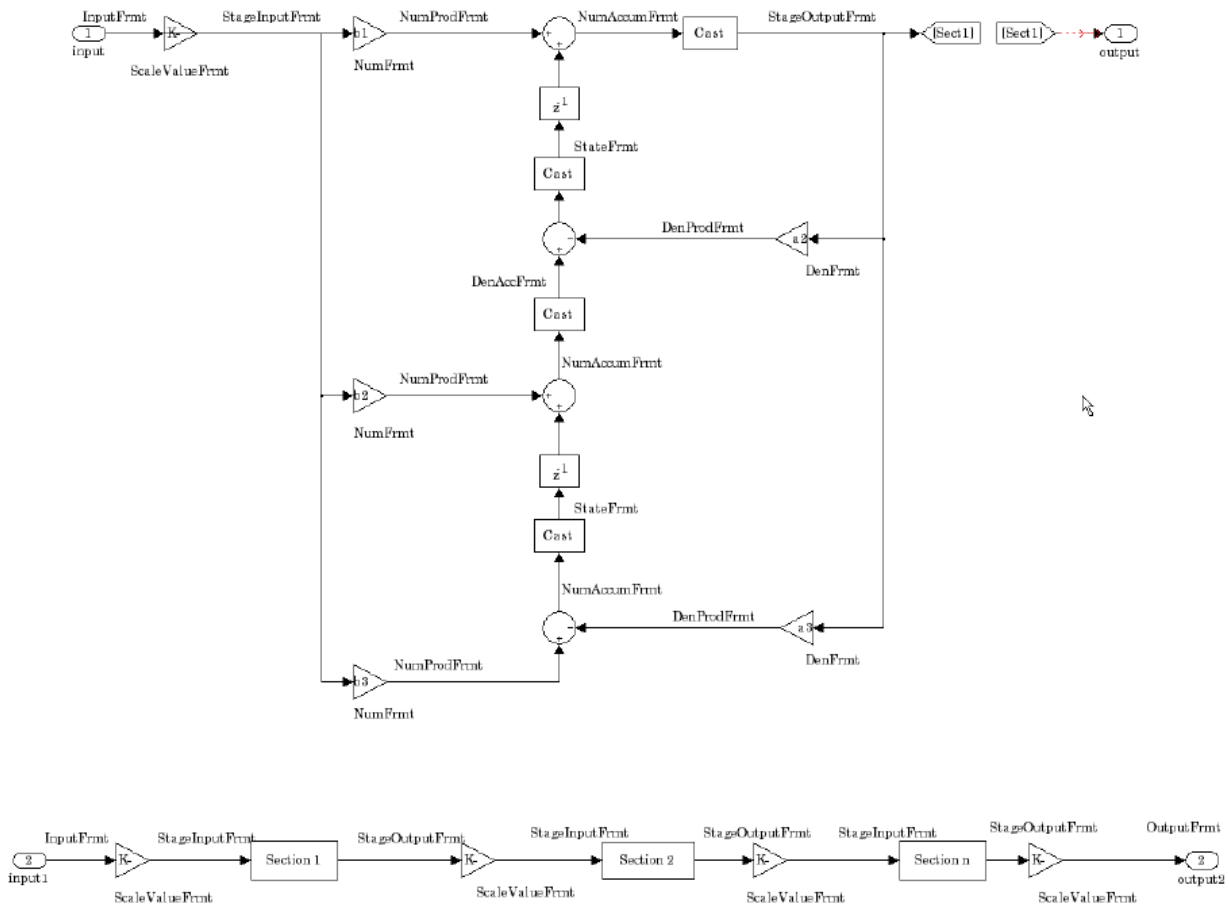

---

**Note** The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

---

## Fixed-Point Filter Structure

The figure below shows the signal flow for the second-order section transposed direct-form II filter implemented by `dfilt.dftsos`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” indicates the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

<b>Signal Flow Label</b>	<b>Corresponding Word Length Property</b>	<b>Corresponding Fraction Length Property</b>	<b>Related Properties</b>
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, Signed, Denominator
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength
InputFrmt	InputWordLength	InputFracLength	None
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, SignedNumerator
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
OutputFrmt	OutputWordLength	OutputFracLength	OutputMode
ScaleValueFrmt	CoeffWordLength	ScaleValueFracLength	CoeffAutoScale, ScaleValues
SectionInputFrmt	SectionInput-WordLength	SectionInput-FracLength	
SectionOutputFrmt	SectionOutput-WordLength	SectionOutput-FracLength	
StateFrmt	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label `DenProdFrmt`, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the `DenProdFrmt` refers to the properties `ProdWordLength`, `ProductMode` and `DenProdFracLength` that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with second-order section implementation of transposed direct-form II `dfilt` objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 6-2.

Property Name	Brief Description
<code>AccumMode</code>	Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> .

<b>Property Name</b>	<b>Brief Description</b>
AccumWordLength	Sets the word length used to store data in the accumulator/ buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> and <code>DenFracLength</code> properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. <code>DenFracLength</code> is always available, but it is read-only until you set <code>CoeffAutoScale</code> to <code>false</code> .
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.

Property Name	Brief Description
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
OptimizeScaleValues	When true, the filter skips multiplication-by-one scaling. When false, the filter performs multiplication-by-one scaling.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	<p>Sets the mode the filter uses to scale the filtered data for output. You have the following choices:</p> <ul style="list-style-type: none"> <li>• <b>AvoidOverflow</b> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li> <li>• <b>BestPrecision</b> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li> <li>• <b>SpecifyPrecision</b> — lets you set the word and fraction lengths used by the output data from filtering.</li> </ul>
OutputWordLength	Determines the word length used for the output data.

<b>Property Name</b>	<b>Brief Description</b>
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.

Property Name	Brief Description
RoundMode	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
ScaleValueFracLength	<p>Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Only available when you disable <code>AutoScaleMode</code> by setting it to <code>false</code>.</p>
ScaleValues	<p>Scaling for the filter objects in SOS filters.</p>
Signed	<p>Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.</p>
SosMatrix	<p>Holds the filter coefficients as property values — you use <code>set</code> and <code>get</code> to modify them. Displays the matrix in the format [sections x coefficients/section data type]. A [15x6 <code>double</code>] SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type <code>double</code> to represent the coefficients.</p>

Property Name	Brief Description
SectionInputFracLength	Lets you set the fraction length for section inputs in SOS filters, if you set SectionInputAutoScale to false.
SectionInputWordLength	Lets you set the word length for section inputs in SOS filters, if you set SectionInputAutoScale to false.
SectionOutputFracLength	Lets you set the fraction length for section outputs in SOS filters, if you set SectionOutputAutoScale to off.
SectionOutputWordLength	Lets you set the word length for section outputs in SOS filters, if you set SectionOutputAutoScale to false.
StateAutoScale	Setting autoscaling for filter states to true reduces the possibility of overflows occurring during fixed-point operations. Set to false, StateAutoScale lets the filter select the fraction length to limit the overflow potential.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

## Examples

Construct a second-order section Butterworth filter for fixed-point filtering. Start by specifying a Butterworth filter, and then convert the filter to second-order sections, with the following code:

```
[z,p,k] = butter(30,0.5);
[s,g] = zp2sos(z,p,k);
hd = dfilt.df2tsos(s,g);
% convert filter to fixed-point
hd.arithmetic='fixed';
```

## See Also

dfilt | dfilt.df1sos | dfilt.df1tsos | dfilt.df2sos

**Introduced in R2011a**

## dfilt.dfasymfir

Discrete-time, direct-form antisymmetric FIR filter

### Syntax

Refer to `dfilt.dfasymfir` in Signal Processing Toolbox documentation.

### Description

`hd = dfilt.dfasymfir(b)` returns a discrete-time, direct-form, antisymmetric FIR filter object `hd`, with numerator coefficients `b`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “Arithmetic” on page 6-18.

`hd = dfilt.dfasymfir` returns a default, discrete-time, direct-form, antisymmetric FIR filter object `hd`, with `b=1`. This filter passes the input through to the output unchanged.

---

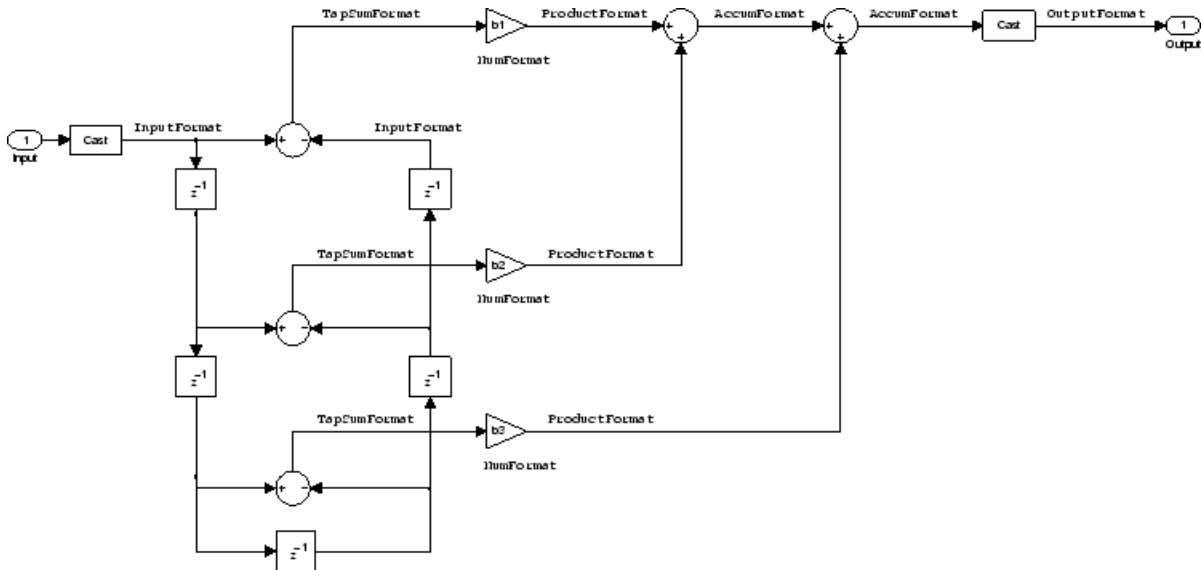

**Note** Only the coefficients in the first half of vector `b` are used because `dfilt.dfasymfir` assumes the coefficients in the second half are antisymmetric to those in the first half. For example, in the figure coefficients,  $b(4) = -b(3)$ ,  $b(5) = -b(2)$ , and  $b(6) = -b(1)$ .

---

## Fixed-Point Filter Structure

The following figure shows the signal flow for the odd-order antisymmetric FIR filter implemented by `dfilt.dfasymfir`. The even-order filter uses similar flow. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the `InputFormat` label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and

InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	AccumWordLength	AccumFracLength	None
InputFormat	InputWordLength	InputFracLength	None
NumFormat	CoeffWordLength	NumFracLength	CoeffAutoScale, , Signed, Numerator
OutputFormat	OutputWordLength	OutputFracLength	None
ProductFormat	ProductWordLength	ProductFracLength	None
TapSumFormat	InputWordLength	InputFracLength	InputFormat

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties ProductFracLength and ProductWordLength that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with an antisymmetric FIR implementation of dfilt objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

`get(hd)`

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 6-2.

Name	Values	Description
<code>AccumFracLength</code>	Any positive or negative integer number of bits [27]	Specifies the fraction length used to interpret data output by the accumulator.
<code>AccumWordLength</code>	Any integer number of bits[33]	Sets the word length used to store data in the accumulator.
<code>Arithmetic</code>	fixed for fixed-point filters	Setting this to <code>fixed</code> allows you to modify other filter properties to customize your fixed-point filter.
<code>CoeffAutoScale</code>	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> property value to specify the precision used.
<code>CoeffWordLength</code>	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
<code>FilterInternals</code>	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, <code>FullPrecision</code> , sets automatic word and fraction length determination by the filter. <code>SpecifyPrecision</code> makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
<code>InputFracLength</code>	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data. Also controls <code>TapSumFracLength</code> .

Name	Values	Description
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data. Also determines TapSumWordLength.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [29]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilterInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [33]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductFracLength	Any positive or negative integer number of bits [27]	Specifies the fraction length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
ProductWordLength	Any integer number of bits [33]	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.

Name	Values	Description
RoundMode	[convergent], ceil, fix, floor, nearest, round	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	fi object to match the filter arithmetic setting	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.

## Examples

### Odd Order

Specify a fifth-order direct-form antisymmetric FIR filter structure for a `dfilt` object, `hd`, with the following code:

```
b = [-0.008 0.06 -0.44 0.44 -0.06 0.008];  
hd = dfilt.dfasymfir(b);
```

### Even Order

Specify a fourth-order direct-form antisymmetric FIR filter structure for `dfilt` object `hd`, with the following code:

```
b = [-0.01 0.1 0.0 -0.1 0.01];  
hd = dfilt.dfasymfir(b);  
hd.arithmetic='fixed';  
FilterCoefs = get(hd,'numerator');  
% or equivalently  
FilterCoefs = hd.numerator;
```

**Introduced in R2011a**

## dfilt.dffir

Discrete-time, direct-form FIR filter

### Syntax

Refer to `dfilt.dffir` in Signal Processing Toolbox documentation.

### Description

`hd = dfilt.dffir(b)` returns a discrete-time, direct-form finite impulse response (FIR) filter object `hd`, with numerator coefficients `b`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

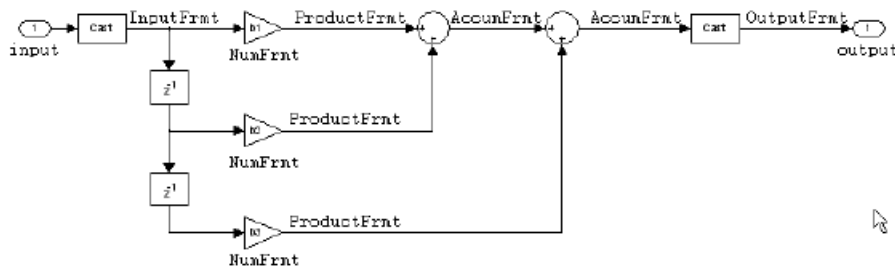

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “Arithmetic” on page 6-18.

`hd = dfilt.dffir` returns a default, discrete-time, direct-form FIR filter object `hd`, with `b=1`. This filter passes the input through to the output unchanged.

### Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form FIR filter implemented by `dfilt.dffir`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” indicates the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFrmt	AccumWordLength	AccumFracLength	None
InputFrmt	InputWordLength	InputFracLength	None
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
OutputFrmt	OutputWordLength	OutputFracLength	None
ProductFrmt	ProductWordLength	ProductFracLength	None

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label `ProductFrmt`, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the `ProductFrmt` refers to the properties `ProductFracLength` and `ProductWordLength` that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with direct-form FIR implementation of `dfilt` objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 6-2.

<b>Name</b>	<b>Values</b>	<b>Description</b>
AccumFracLength	Any positive or negative integer number of bits [30]	Specifies the fraction length used to interpret data output by the accumulator.
AccumWordLength	Any integer number of bits[34]	Sets the word length used to store data in the accumulator.
Arithmetic	fixed for fixed-point filters	Setting this to <code>fixed</code> allows you to modify other filter properties to customize your fixed-point filter.
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, <code>FullPrecision</code> , sets automatic word and fraction length determination by the filter. <code>SpecifyPrecision</code> makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.

Name	Values	Description
OutputFracLength	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>FilterInternals</code> to <code>SpecifyPrecision</code> .
OutputWordLength	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting <code>FilterInternals</code> to <code>SpecifyPrecision</code> .
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductFracLength	Any positive or negative integer number of bits [30]	Specifies the fraction length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
ProductWordLength	Any integer number of bits [32]	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .

Name	Values	Description
RoundMode	[convergent], ceil, fix, floor, nearest, round	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	<code>fi</code> object to match the filter arithmetic setting	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.

## Examples

Specify a second-order direct-form FIR filter structure for a `dfilt` object `hd`, with the following code that constructs the filter in double-precision format and then converts the filter to fixed-point operation:

```
b = [0.05 0.9 0.05];  
hd = dfilt.dffir(b);  
% Create fixed-point filter  
hd.arithmetic='fixed';  
% Change FilterInternals property to  
% SpecifyPrecision enabling other properties  
hd.FilterInternals='SpecifyPrecision';
```

**Introduced in R2011a**

## **dfilt.dffirt**

Discrete-time, direct-form FIR transposed filter

### **Syntax**

Refer to `dfilt.dffirt` in Signal Processing Toolbox documentation.

### **Description**

`hd = dfilt.dffirt(b)` returns a discrete-time, direct-form FIR transposed filter object `hd`, with numerator coefficients `b`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

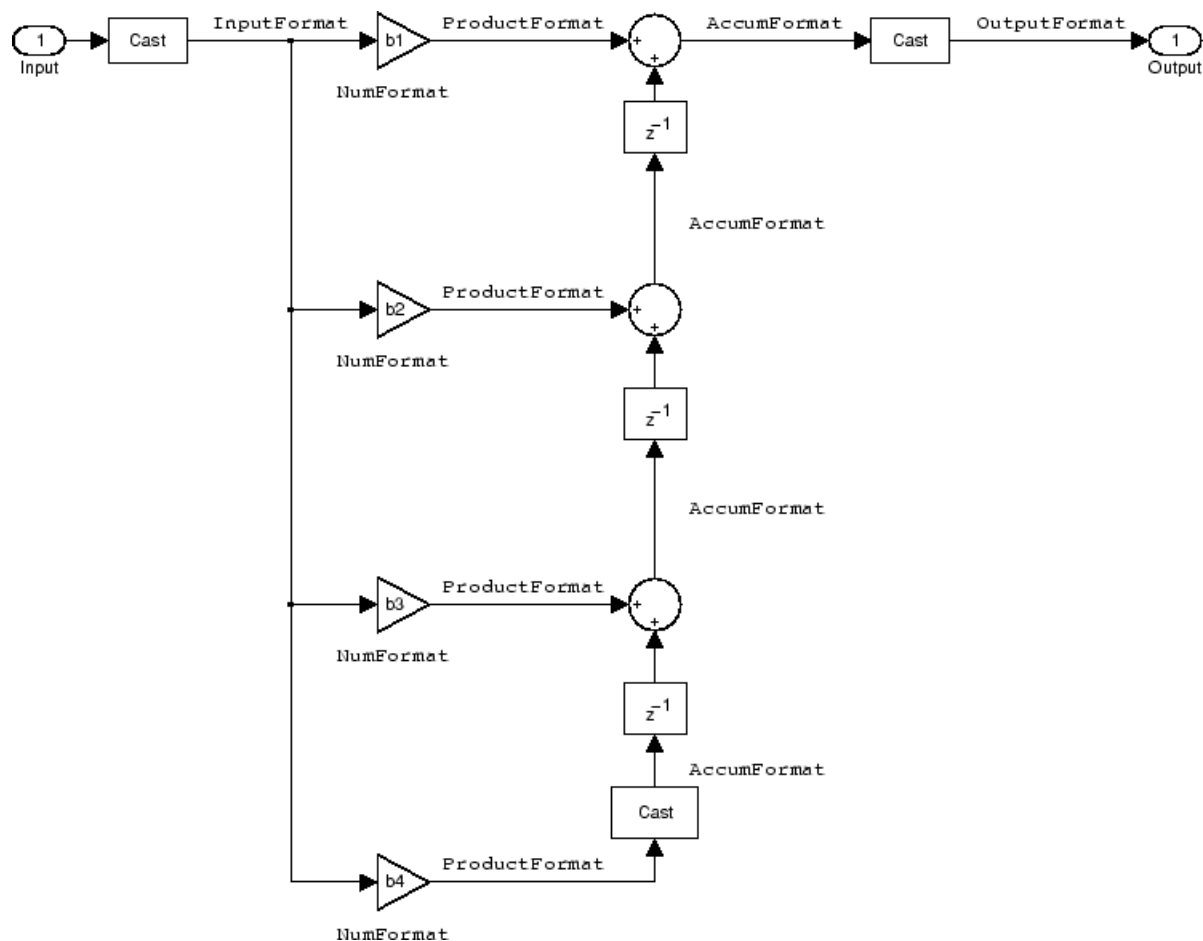

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “Arithmetic” on page 6-18.

`hd = dfilt.dffirt` returns a default, discrete-time, direct-form FIR transposed filter object `hd`, with `b = 1`. This filter passes the input through to the output unchanged.

### **Fixed-Point Filter Structure**

The following figure shows the signal flow for the transposed direct-form FIR filter implemented by `dfilt.dffirt`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the `InputFormat` label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider `NumFormat`, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
<code>AccumFormat</code>	<code>AccumWordLength</code>	<code>AccumFracLength</code>	None
<code>InputFormat</code>	<code>InputWordLength</code>	<code>InputFracLength</code>	None
<code>NumFormat</code>	<code>CoeffWordLength</code>	<code>NumFracLength</code>	<code>CoeffAutoScale</code> , <code>Signed</code> , <code>Numerator</code>
<code>OutputFormat</code>	<code>OutputWordLength</code>	<code>OutputFracLength</code>	None
<code>ProductFormat</code>	<code>ProductWordLength</code>	<code>ProductFracLength</code>	None

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label `ProductFormat`, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the `ProductFormat` refers to the properties `ProductFracLength` and `ProductWordLength` that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the transposed direct-form FIR implementation of `dfilt` objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

get(hd)

where hd is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 6-2.

Name	Values	Description
AccumFracLength	Any positive or negative integer number of bits [30]	Specifies the fraction length used to interpret data output by the accumulator.
AccumWordLength	Any integer number of bits[34]	Sets the word length used to store data in the accumulator.

**Introduced in R2011a**

# dfilt.dfsymfir

Discrete-time, direct-form symmetric FIR filter

## Syntax

Refer to `dfilt.dfsymfir` in Signal Processing Toolbox documentation.

## Description

`hd = dfilt.dfsymfir(b)` returns a discrete-time, direct-form symmetric FIR filter object `hd`, with numerator coefficients `b`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “Arithmetic” on page 6-18.

`hd = dfilt.dfsymfir` returns a default, discrete-time, direct-form symmetric FIR filter object `hd`, with `b=1`. This filter passes the input through to the output unchanged.

---

**Note** Only the coefficients in the first half of vector `b` are used because `dfilt.dfsymfir` assumes the coefficients in the second half are symmetric to those in the first half. In the following figure, for example,  $b(3) = 0$ ,  $b(4) = b(2)$  and  $b(5) = b(1)$ .

---

## Fixed-Point Filter Structure

In the following figure you see the signal flow diagram for the symmetric FIR filter that `dfilt.dfsymfir` implements.

### Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” indicates the word length and fraction length associated with the filter part referred to by the prefix.

For example, the `InputFrmt` label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider `NumFrmt`, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFrmt	AccumWordLength	AccumFracLength	None
InputFrmt	InputWordLength	InputFracLength	None
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
OutputFrmt	OutputWordLength	OutputFracLength	None
ProductFrmt	ProductWordLength	ProductFracLength	None
TapSumFrmt	InputWordLength	InputFracLength	None

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label `ProductFrmt`, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the `ProductFrmt` refers to the properties `ProductFracLength` and `ProductWordLength` that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the symmetric FIR implementation of `dfilt` objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 6-2.

## Examples

### Odd Order

Specify a fifth-order direct-form symmetric FIR filter structure for a `dfilt` object `hd`, with the following code:

```
b = [-0.008 0.06 0.44 0.44 0.06 -0.008];  
hd = dfilt.dfsymfir(b);  
% Create fixed-point filter  
set(hd,'arithmetic','fixed')  
% Change FilterInternals property to  
% SpecifyPrecision  
hd.Filterinternals='SpecifyPrecision';
```

### Even Order

Specify a fourth-order, fixed-point, direct-form symmetric FIR filter structure for a `dfilt` object `hd`, with the following code:

```
b = [-0.01 0.1 0.8 0.1 -0.01];  
hd = dfilt.dfsymfir(b);  
set(hd,'arithmetic','fixed');
```

## **dfilt.farrowfd**

Fractional Delay Farrow filter

### **Syntax**

```
Hd = dfilt.farrowfd(D, COEFFS)
```

### **Description**

`Hd = dfilt.farrowfd(D, COEFFS)` Constructs a discrete-time fractional delay Farrow filter with COEFFS coefficients and D delay.

### **Examples**

#### **Design a Fractional Delay Farrow Filter**

Farrow filters can be designed with the `dfilt.farrowfd` filter designer.

```
coeffs = [-1/6 1/2 -1/3 0;1/2 -1 -1/2 1;  
-1/2 1/2 1 0;1/6 0 -1/6 0];  
farrow = dfilt.farrowfd(0.5, coeffs);
```

Design a cubic fractional delay filter with the Lagrange method.

```
fdelay = .2; % Fractional delay  
d = fdesign.fracdelay(fdelay,'N',3);  
cubicfarrow = design(d, 'lagrange', 'FilterStructure', 'farrowfd');  
fvtool(cubicfarrow, 'Analysis', 'grpdelay');
```

For more information about fractional delay filter implementations, see the "Fractional Delay Filters Using Farrow Structures" example, `farrowdemo`.

## **dfilt.fftfir**

Discrete-time, overlap-add, FIR filter

### **Syntax**

```
Hd = dfilt.fftfir(b,len)
Hd = dfilt.fftfir(b)
Hd = dfilt.fftfir
```

### **Description**

This object uses the overlap-add method of block FIR filtering, which is very efficient for streaming data.

`Hd = dfilt.fftfir(b,len)` returns a discrete-time, FFT, FIR filter, `Hd`, with numerator coefficients, `b` and block length, `len`. The block length is the number of input points to use for each overlap-add computation.

`Hd = dfilt.fftfir(b)` returns a discrete-time, FFT, FIR filter, `Hd`, with numerator coefficients, `b` and block length, `len=100`.

`Hd = dfilt.fftfir` returns a default, discrete-time, FFT, FIR filter, `Hd`, with the numerator `b=1` and block length, `len=100`. This filter passes the input through to the output unchanged.

---

**Note** When you use a `dfilt.fftfir` object to filter, the input signal length must be an integer multiple of the object's block length, `len`. The resulting number of FFT points = (filter length + the block length - 1). The filter is most efficient if the number of FFT points is a power of 2.

---

The `fftfir` uses an overlap-add block processing algorithm, which is represented as follows,

where  $len$  is the block length and  $M$  is the length of the numerator-1,  $(length(b) - 1)$ , which is also the number of states. The output of each convolution is a block that is longer than the input block by a tail of  $(length(b) - 1)$  samples. These tails overlap the next block and are added to it. The states reported by `dfilt.fftfir` are the tails of the final convolution.

## Examples

Create an FFT FIR discrete-time filter with coefficients from a 30<sup>th</sup> order lowpass equiripple design:

```
b = firpm(30,[0 .1 .2 .5]*2,[1 1 0 0]);
Hd = dfilt.fftfir(b);
% To obtain frequency domain coefficients
% used in filtering
Coeffs = fftcoeffs(Hd);
```

**Introduced in R2011a**

# dfilt.latticeallpass

Discrete-time, lattice allpass filter

## Syntax

Refer to `dfilt.latticeallpass` in Signal Processing Toolbox documentation.

## Description

`hd = dfilt.latticeallpass(k)` returns a discrete-time, lattice allpass filter object `hd`, with lattice coefficients, `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter  

```
set(hd,'arithmetic','single');
```
- To change to fixed-point filtering, enter  

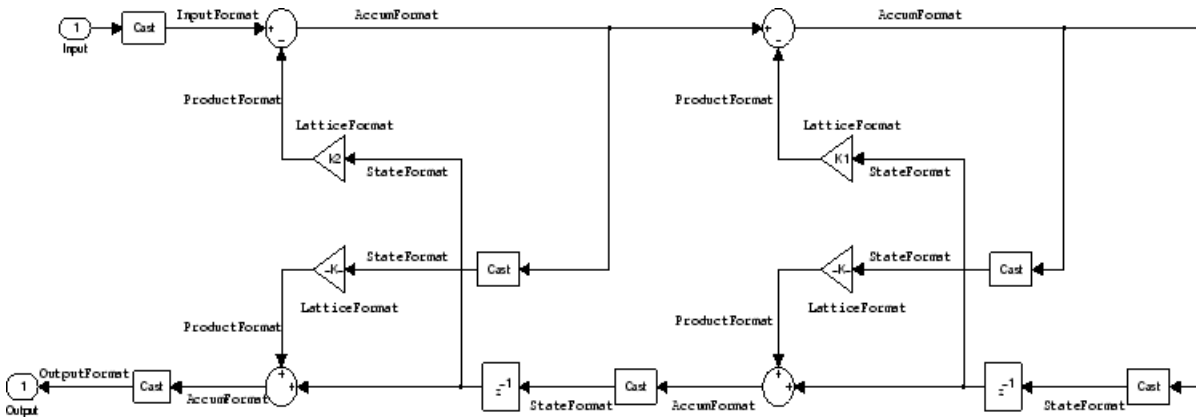

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “Arithmetic” on page 6-18.

`hd = dfilt.latticeallpass` returns a default, discrete-time, lattice allpass filter object `hd`, with `k=[ ]`. This filter passes the input through to the output unchanged.

## Fixed-Point Filter Structure

The following figure shows the signal flow for the allpass lattice filter implemented by `dfilt.latticeallpass`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	AccumWordLength	AccumFracLength	AccumMode
InputFormat	InputWordLength	InputFracLength	None
LatticeFormat	CoeffWordLength	LatticeFracLength	CoeffAutoScale

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
OutputFormat	OutputWordLength	OutputFracLength	OutputMode
ProductFormat	ProductWordLength	ProductFracLength	ProductMode
StateFormat	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label `ProductFormat`, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the `ProductFormat` refers to the properties `ProductFracLength`, `ProductWordLength`, and `ProductMode` that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the allpass lattice implementation of `dfilt` objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 6-2.

<b>Property Name</b>	<b>Brief Description</b>
AccumFracLength	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — <code>DenAccumFracLength</code> and <code>NumAccumFracLength</code> — that let you set the precision for numerator and denominator operations separately.
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>LatticeFracLength</code> property value to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.

Property Name	Brief Description
Lattice	Any lattice structure coefficients. No default value.
LatticeFracLength	Sets the fraction length applied to the lattice coefficients.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>OutputMode</code> to <code>SpecifyPrecision</code> .
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: <ul style="list-style-type: none"> <li>• <code>AvoidOverflow</code> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li> <li>• <code>BestPrecision</code> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li> <li>• <code>SpecifyPrecision</code> — lets you set the word and fraction lengths used by the output data from filtering.</li> </ul>
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductFracLength	For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .

Property Name	Brief Description
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.
RoundMode	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>

Property Name	Brief Description
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Sets the word length used to represent the filter states.

## Examples

Specify a third-order lattice allpass filter structure for a dfilt object hd, with the following code:

```
k = [.66 .7 .44];
hd=dfilt.latticeallpass(k);
% convert to fixed-point arithmetic
hd.arithmetic = 'fixed';
```

dfilt.latticemin

**Introduced in R2011a**

## **dfilt.latticear**

Discrete-time, lattice, autoregressive filter

### **Syntax**

Refer to `dfilt.latticear` in Signal Processing Toolbox documentation.

### **Description**

`hd = dfilt.latticear(k)` returns a discrete-time, lattice autoregressive filter object `hd`, with lattice coefficients, `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

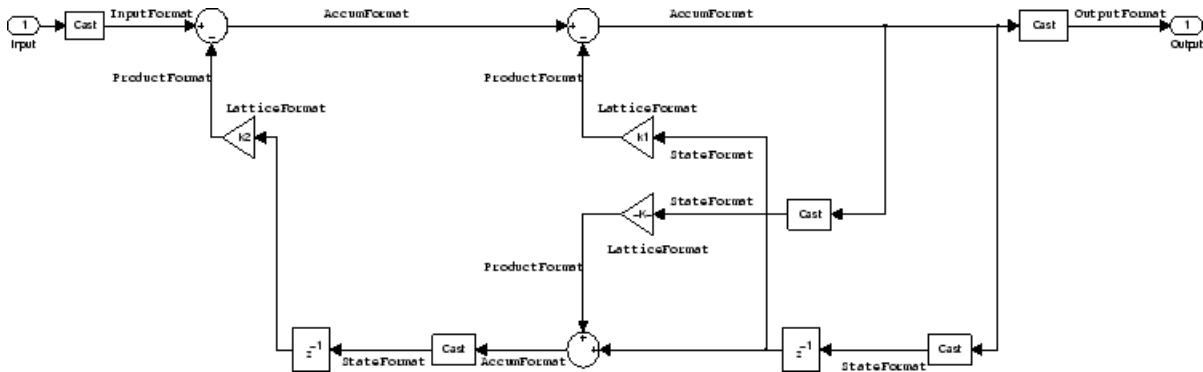

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “Arithmetic” on page 6-18.

`hd = dfilt.latticear` returns a default, discrete-time, lattice autoregressive filter object `hd`, with `k=[ ]`. This filter passes the input through to the output unchanged.

### **Fixed-Point Filter Structure**

The following figure shows the signal flow for the autoregressive lattice filter implemented by `dfilt.latticear`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	AccumWordLength	AccumFracLength	AccumMode
InputFormat	InputWordLength	InputFracLength	None
LatticeFormat	CoeffWordLength	LatticeFracLength	CoeffAutoScale
OutputFormat	OutputWordLength	OutputFracLength	OutputMode

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
ProductFormat	ProductWordLength	ProductFracLength	ProductMode
StateFormat	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label `ProductFormat`, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the `ProductFormat` refers to the properties `ProductFracLength`, `ProductWordLength`, and `ProductMode` that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the autoregressive lattice implementation of `dfilt` objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

**Introduced in R2011a**

# dfilt.latticearma

Discrete-time, lattice, autoregressive, moving-average filter

## Syntax

Refer to `dfilt.latticearma` in Signal Processing Toolbox documentation.

## Description

`hd = dfilt.latticearma(k)` returns a discrete-time, lattice moving-average autoregressive filter object `hd`, with lattice coefficients, `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd, 'arithmetic', 'single');
```

- To change to fixed-point filtering, enter

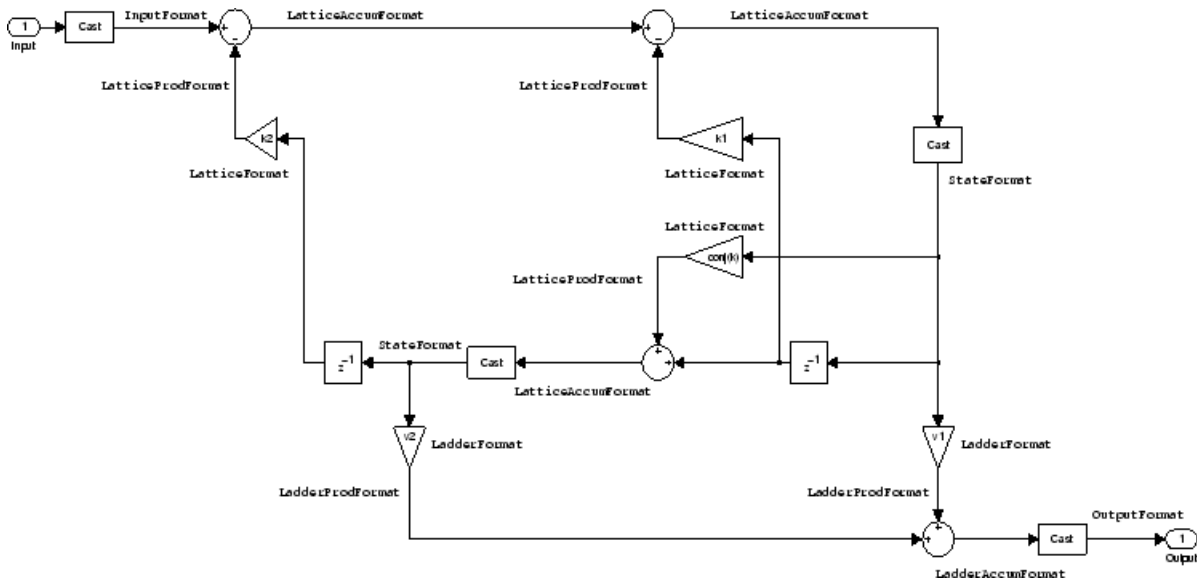

```
set(hd, 'arithmetic', 'fixed');
```

For more information about the property `Arithmetic`, refer to “Arithmetic” on page 6-18.

`hd` `dfilt.latticearma` returns a default, discrete-time, lattice moving-average, autoregressive filter object `hd`, with `k = []`. This filter passes the input through to the output unchanged.

## Fixed-Point Filter Structure

The following figure shows the signal flow for the autoregressive lattice filter implemented by `dfilt.latticearma`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
InputFormat	InputWordLength	InputFracLength	None
LadderAccumFormat	AccumWordLength	LadderAccumFracLength	AccumMode
LadderFormat	CoeffWordLength	LadderFracLength	CoeffAutoScale
LadderProdFormat	ProductWordLength	LadderProdFracLength	ProductMode
LatticeAccumFormat	AccumWordLength	LatticeAccum-FracLength	AccumMode
LatticeFormat	CoeffWordLength	LatticeFracLength	CoeffAutoScale
LatticeProdFormat	ProductWordLength	LatticeProdFracLength	ProductMode
OutputFormat	OutputWordLength	OutputFracLength	OutputMode
StateFormat	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label `LatticeProdFormat`, which always follows a coefficient multiplication element in the signal flow. The label indicates that lattice coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the `LatticeProdFormat` refers to the properties `ProductWordLength`, `LatticeProdFracLength`, and `ProductMode` that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the autoregressive moving-average lattice implementation of `dfilt` objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 6-2.

Property Name	Brief Description
AccumFracLength	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — <code>DenAccumFracLength</code> and <code>NumAccumFracLength</code> — that let you set the precision for numerator and denominator operations separately.
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>LatticeFracLength</code> property to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.

Property Name	Brief Description
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
Ladder	Stores the ladder coefficients for lattice ARMA ( <code>dfilt.latticearma</code> ) filters.
LadderAccumFracLength	Sets the fraction length used to interpret the output from sum operations that include the ladder coefficients. You can change this property value after you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
LadderFracLength	Determines the precision used to represent the ladder coefficients in ARMA lattice filters.
Lattice	Stores the lattice structure coefficients.
LatticeFracLength	Sets the fraction length applied to the lattice coefficients.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>OutputMode</code> to <code>SpecifyPrecision</code> .
OutputMode	<p>Sets the mode the filter uses to scale the filtered data for output. You have the following choices:</p> <ul style="list-style-type: none"> <li>• <code>AvoidOverflow</code> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li> <li>• <code>BestPrecision</code> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li> <li>• <code>SpecifyPrecision</code> — lets you set the word and fraction lengths used by the output data from filtering.</li> </ul>

Property Name	Brief Description
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductFracLength	For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.

Property Name	Brief Description
RoundMode	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <b>ceil</b> - Round toward positive infinity.</li> <li>• <b>convergent</b> - Round to the closest representable integer. ## dfilt.latticemamax

Discrete-time, lattice, moving-average filter with maximum phase

### Syntax

Refer to `dfilt.latticemamax` in Signal Processing Toolbox documentation.

### Description

`hd = dfilt.latticemamax(k)` returns a discrete-time, lattice, moving-average filter object `hd`, with lattice coefficients `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “`Arithmetic`” on page 6-18.

---

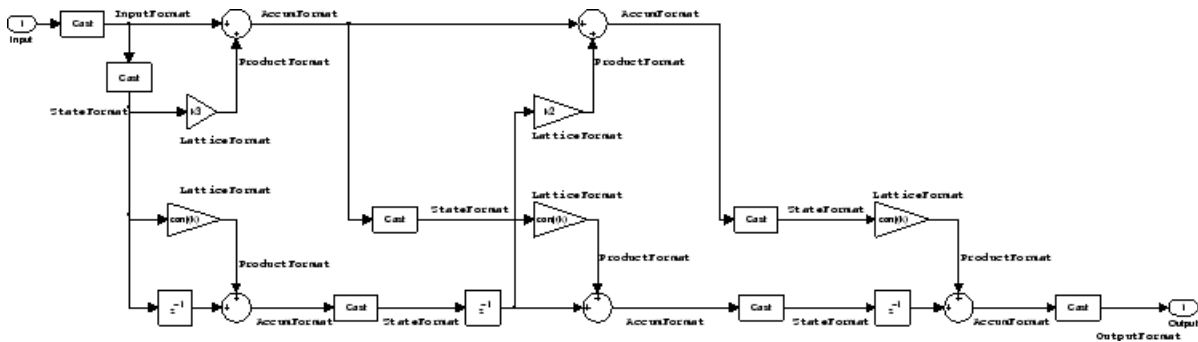

**Note** When the `k` coefficients define a maximum phase filter, the resulting filter in this structure is maximum phase. When your coefficients do not define a maximum phase filter, placing them in this structure does not produce a maximum phase filter.

---

`hd = dfilt.latticemamax` returns a default discrete-time, lattice, moving-average filter object `hd`, with `k = [ ]`. This filter passes the input through to the output unchanged.

## Fixed-Point Filter Structure

The following figure shows the signal flow for the maximum phase implementation of a moving-average lattice filter implemented by `dfilt.latticemamax`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the `InputFormat` label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider `NumFormat`, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	AccumWordLength	AccumFracLength	AccumMode
InputFormat	InputWordLength	InputFracLength	None
LatticeFormat	CoeffWordLength	LatticeFracLength	CoeffAutoScale
OutputFormat	OutputWordLength	OutputFracLength	OutputMode
ProductFormat	ProductWordLength	ProductFracLength	ProductMode
StateFormat	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label `ProductFormat`, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the `ProductFormat` refers to the properties `ProductFracLength`, `ProductWordLength`, and `ProductMode` that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the maximum phase, moving average lattice implementation of `dfilt` objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 6-2.

<b>Property Name</b>	<b>Brief Description</b>
<code>AccumFracLength</code>	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — <code>DenAccumFracLength</code> and <code>NumAccumFracLength</code> — that let you set the precision for numerator and denominator operations separately.
<code>AccumMode</code>	Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> .
<code>AccumWordLength</code>	Sets the word length used to store data in the accumulator/buffer.
<code>Arithmetic</code>	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
<code>CastBeforeSum</code>	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
<code>CoeffAutoScale</code>	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>LatticeFracLength</code> property to specify the precision used.
<code>CoeffWordLength</code>	Specifies the word length to apply to filter coefficients.
<code>FilterStructure</code>	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering —gains, delays, sums, products, and input/output.

Property Name	Brief Description
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
Lattice	Any lattice structure coefficients.
LatticeFracLength	Sets the fraction length applied to the lattice coefficients.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	<p>Sets the mode the filter uses to scale the filtered data for output. You have the following choices:</p> <ul style="list-style-type: none"> <li>• <b>AvoidOverflow</b> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li> <li>• <b>BestPrecision</b> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li> <li>• <b>SpecifyPrecision</b> — lets you set the word and fraction lengths used by the output data from filtering.</li> </ul>
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <b>saturate</b> (limit the output to the largest positive or negative representable value) or <b>wrap</b> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductFracLength	For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.

Property Name	Brief Description
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.
RoundMode	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>

Property Name	Brief Description
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateFracLength	When you set <code>StateAutoScale</code> to <code>false</code> , you enable the <code>StateFracLength</code> property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Sets the word length used to represent the filter states.

## Examples

Specify a fourth-order lattice, moving-average, maximum phase filter structure for a `dfilt` object, `hd`, with the following code:

```
k = [.66 .7 .44 .33];
hd = dfilt.latticemamax(k);
```

## See Also

`dfilt` | `dfilt.latticeallpass` | `dfilt.latticear` | `dfilt.latticearma` | `dfilt.latticemamin`

**Introduced in R2011a**

## dfilt.latticemamin

Discrete-time, lattice, moving-average filter with minimum phase

### Syntax

Refer to `dfilt.latticemamin` in Signal Processing Toolbox documentation.

### Description

`hd = dfilt.latticemamin(k)` returns a discrete-time, lattice, moving-average, minimum phase, filter object `hd`, with lattice coefficients `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “Arithmetic” on page 6-18.

---

**Note** When the `k` coefficients define a minimum phase filter, the resulting filter in this structure is minimum phase. When your coefficients do not define a minimum phase filter, placing them in this structure does not produce a minimum phase filter.

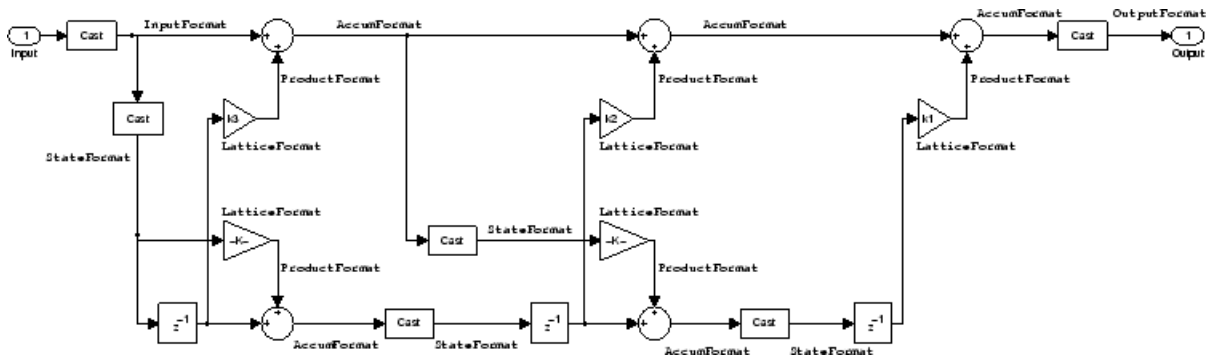

---

`hd = dfilt.latticemamin` returns a default discrete-time, lattice, moving-average, minimum phase, filter object `hd`, with `k=[ ]`. This filter passes the input through to the output unchanged.

## Fixed-Point Filter Structure

The following figure shows the signal flow for the minimum phase implementation of a moving-average lattice filter implemented by `dfilt.latticemamin`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the `InputFormat` label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider `NumFormat`, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	AccumWordLength	AccumFracLength	AccumMode
InputFormat	InputWordLength	InputFracLength	None
LatticeFormat	CoeffWordLength	LatticeFracLength	CoeffAutoScale
OutputFormat	OutputWordLength	OutputFracLength	OutputMode
ProductFormat	ProductWordLength	ProductFracLength	ProductMode
StateFormat	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label `ProductFormat`, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the `ProductFormat` refers to the properties `ProductFracLength`, `ProductWordLength`, and `ProductMode` that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the minimum phase, moving average lattice implementation of `dfilt` objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 6-2.

## Examples

Specify a third-order lattice, moving-average, minimum phase, filter structure for a `dfilt` object, `hd`, with the following code:

```
k = [.66 .7 .44];  
hd = dfilt.latticemamin(k);
```

## See Also

**Introduced in R2011a**

# dfilt.parallel

Discrete-time, parallel structure filter

## Syntax

Refer to `dfilt.parallel` in Signal Processing Toolbox documentation.

## Description

`hd = dfilt.parallel(hd1,hd2,...)` returns a discrete-time filter object `hd`, which is a structure of two or more `dfilt` filter objects, `hd1`, `hd2`, and so on arranged in parallel.

You can also use the standard notation to combine filters into a parallel structure.

`parallel(hd1,hd2,...)`

In this syntax, `hd1`, `hd2`, and so on can be a mix of `dfilt` objects and other filtering objects.

`hd1`, `hd2`, and so on can be fixed-point filters. All filters in the parallel structure must be the same arithmetic format — double, single, or fixed. `hd`, the filter returned, inherits the format of the individual filters.

## **See Also**

`dfilt` | `dfilt.cascade` | `dfilt.cascade` | `dfilt.parallel`

**Introduced in R2011a**

# dfilt.scalar

Discrete-time, scalar filter

## Syntax

Refer to `dfilt.scalar` in Signal Processing Toolbox documentation.

## Description

`dfilt.scalar(g)` returns a discrete-time, scalar filter object with gain `g`, where `g` is a scalar.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to “Arithmetic” on page 6-18.

`dfilt.scalar` returns a default, discrete-time scalar gain filter object `hd`, with gain 1.

## Properties

In this table you see the properties associated with the scalar implementation of `dfilt` objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You

might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 6-2.

Property Name	Brief Description
Arithmetic	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>CoeffFracLength</code> property to specify the precision used.
CoeffFracLength	Set the fraction length the filter uses to interpret coefficients. <code>CoeffFracLength</code> is always available, but it is read-only until you set <code>CoeffAutoScale</code> to <code>false</code> .
CoeffWordLength	Specifies the word length to apply to filter coefficients.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
Gain	Returns the gain for the scalar filter. Scalar filters do not alter the input data except by adding gain.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.

Property Name	Brief Description
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: <ul style="list-style-type: none"> <li>• <b>AvoidOverflow</b> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li> <li>• <b>BestPrecision</b> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li> <li>• <b>SpecifyPrecision</b> — lets you set the word and fraction lengths used by the output data from filtering.</li> </ul>
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <b>saturate</b> (limit the output to the largest positive or negative representable value) or <b>wrap</b> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <b>False</b> is the default setting.

Property Name	Brief Description
RoundMode	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.

## Examples

Create a direct-form I filter object `hd_filt` and a scalar object with a gain of 3 `hd_gain` and cascade them together.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
```

```

hd_filt = dfilt.df1(b,a);
hd_gain = dfilt.scalar(3);
hd_cascade=cascade(hd_gain,hd_filt);
fvtool_handle = fvtool(hd_filt,hd_gain,hd_cascade);
legend(fvtool_handle,'IIR Filter (direct form I)',...
'Gain','Cascaded Filter');

```

To view the stages of the cascaded filter, use

```
hd.Stage(1)
```

and

```
hd.Stage(2)
```

**Introduced in R2011a**

# dfilt.wdfallpass

Wave digital allpass filter

## Syntax

```
hd = dfilt.wdfallpass(c)
```

## Description

`hd = dfilt.wdfallpass(c)` constructs an allpass wave digital filter structure given the allpass coefficients in vector `c`.

Vector `c` must have, one, two, or four elements (filter coefficients). Filters with three coefficients are not supported. When you use `c` with four coefficients, the first and third coefficients must be 0.

Given the coefficients in `c`, the transfer function for the wave digital allpass filter is defined by

$$H(z) = \frac{c(n) + c(n-1)z^{-1} + \dots + z^{-n}}{1 + c(1)z^{-1} + \dots + c(n)z^{-n}}$$

Internally, the allpass coefficients are converted to wave digital filters for filtering. Note that `dfilt.wdfallpass` allows only stable filters. Also note that the leading coefficient in the denominator, a 1, does not need to be included in vector `c`.

Use the constructor `dfilt.cascadewdfallpass` to cascade `wdfallpass` filters.

To compare these filters to other similar filters, `dfilt.wdfallpass` and `dfilt.cascadewdfallpass` filters have the same number of multipliers as the non-wave digital filters `dfilt.allpass` and `dfilt.cascadeallpass`. However, the wave digital filters use fewer states and they may require more adders in the filter structure.

Wave digital filters are usually used to create other filters. This toolbox uses them to implement halfband filters, which the first example in Examples demonstrates. They are most often building blocks for filters.

## Properties

In the next table, the row entries are the filter properties and a brief description of each property.

Property Name	Brief Description
AllpassCoefficients	Contains the coefficients for the allpass wave digital filter object
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.

## Filter Structure

When you change the order of the wave digital filters in the cascade, the filter structure changes as well.

As shown in this example, `realizemdl` lets you see the filter structure used for your filter, if you have Simulink installed.

```
section11=0.8;
section12=[1.5,0.7];
section13=[1.8,0.9];
hdl=dfilt.cascadewdfallpass(section11,section12,section13);
```

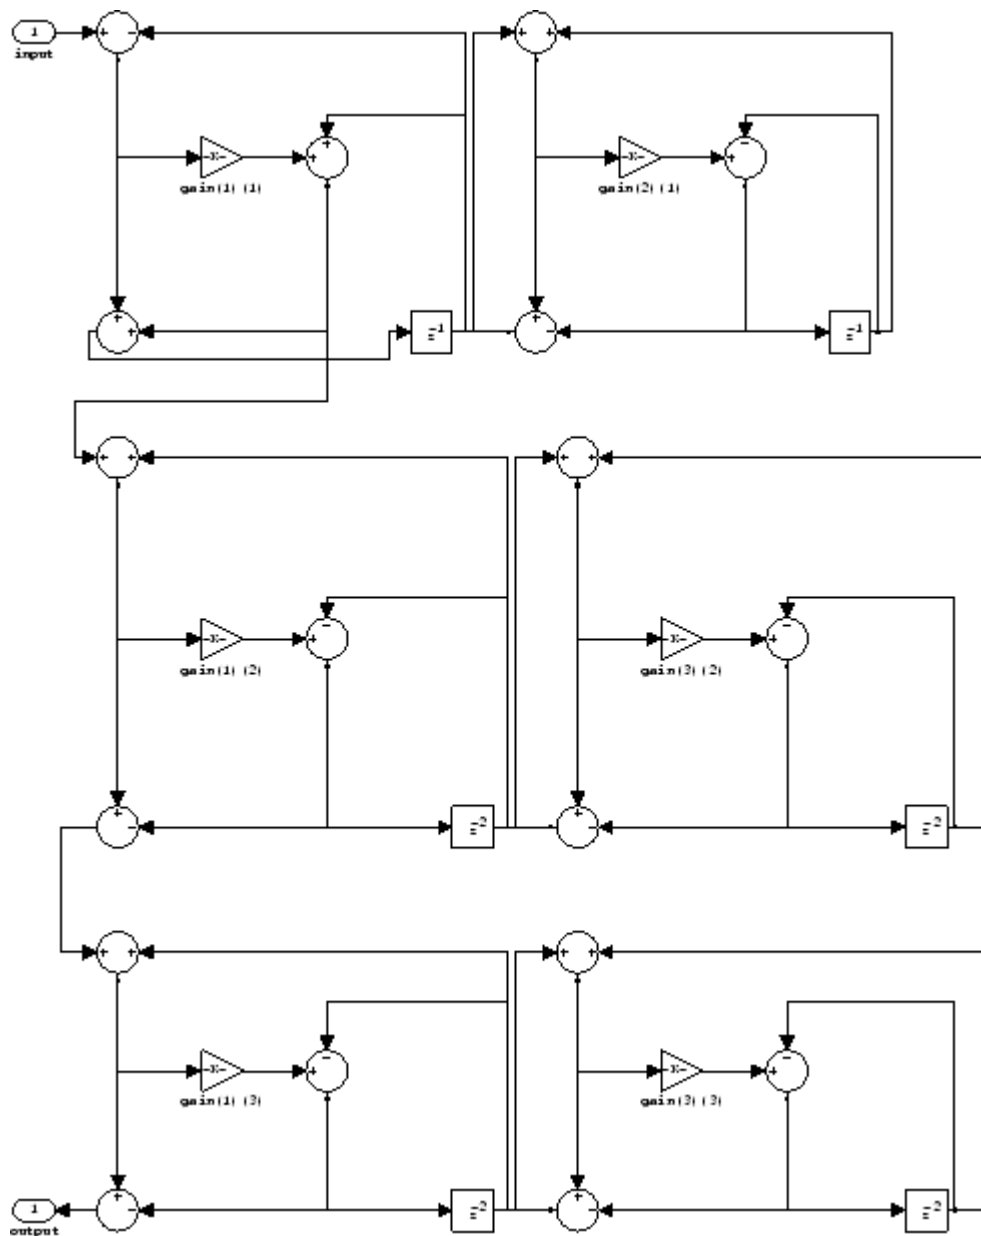

```
section21=[0.8,0.4];  
section22=[0,1.5,0,0.7];  
section23=[0,1.8,0,0.9];  
hd2=dfilt.cascadewdfallpass(section21,section22,section23);  
% If you have Simulink  
realizemdl(hd2)
```

hd1 has this filter structure with three sections.

The filter structure for hd2 is somewhat different, with the different orders and interconnections between the three sections.

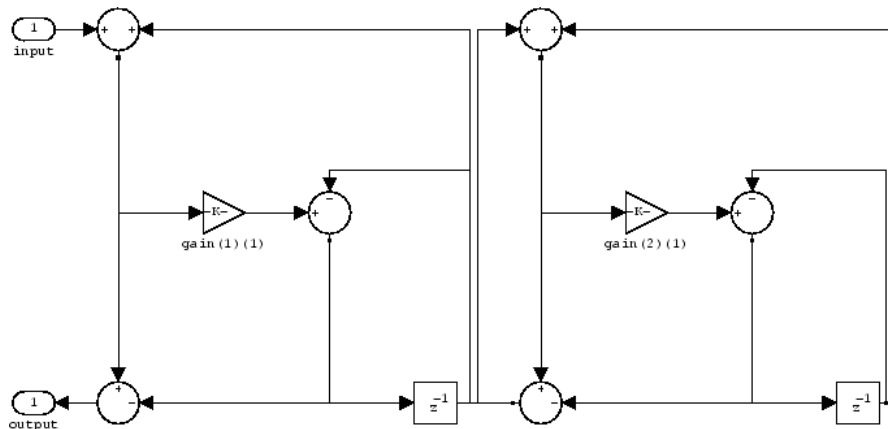

## Examples

Construct a second-order wave digital allpass filter with two coefficients. Note that to use `realizemdl`, you must have Simulink.

```
c = [1.5,0.7];
hd = dfilt.wdfallpass(c);
```

With Simulink installed, `realizemdl` returns this structure for `hd`.

## disp

Filter properties and values

### Syntax

```
disp(h)
```

### Description

`disp(h)` lists the property names and property values of a filter object. In all ways, it is the same as leaving the semicolon off an on the command line, except that `disp` does not display the variable name.

### Examples

#### Display the Properties of a Filter Object

```
FIRfilt = dsp.FIRFilter;  
disp(FIRfilt);
```

```
    dsp.FIRFilter with properties:
```

```
        Structure: 'Direct form'  
    NumeratorSource: 'Property'  
        Numerator: [0.5000 0.5000]  
    InitialConditions: 0
```

```
Use get to show all properties
```

### See Also

set

**Introduced in R2011a**

## double

Cast fixed-point filter to use double-precision arithmetic

### Syntax

```
hd = double(h)
```

### Description

`hd = double(h)` returns a new filter `hd` that has the same structure and coefficients as `h`, but whose arithmetic property is set to `double` to use double-precision arithmetic for filtering. `double(h)` is not the same as the `reffilter(h)` function:

- `hd`, the filter returned by `double` has the quantized coefficients of `h` represented in double-precision floating-point format
- The reference filter returned by `reffilter` has double-precision, floating-point coefficients that have not been quantized.

You might find `double(h)` useful to isolate the effects of quantizing the coefficients of a filter by using `double` to create a filter `hd` that operates in double-precision but uses the quantized filter coefficients.

### Examples

#### Compare Fixed-point Output with Floating-Point Output

Construct a Lowpass Filter

```
h = dfilt.dffir(firgr(27,[0 .4 .6 1],...  
[1 1 0 0]));
```

Set `h` to use fixed-point arithmetic to filter. Quantize the coeffs.

```
h.arithmetic = 'fixed';
```

Cast h to double-precision

```
hd = double(h);
```

Set up an input signal.

```
n = 0:99; x = sin(0.7*pi*n(:));
```

Fixed-point output.

```
y = filter(h,x);
```

Floating-point output.

```
yd = filter(hd,x);
```

Compare the Fixed-point output with Floating-point output

```
FixedFloatNormDiff=norm(yd-double(y),inf)
```

```
FixedFloatNormDiff = 2.1234e-05
```

**Introduced in R2011a**

## **dsp.util.getLogArray**

**Package:** dsp.util

Return logged signal as MATLAB array

### **Syntax**

```
Array = dsp.util.getLogArray(LogObject,Format2D,'SignalPath',PATH)
Array = dsp.util.getLogArray(LogObject,Format2D,'SignalName',NAME)
```

### **Description**

`Array = dsp.util.getLogArray(LogObject,Format2D,'SignalPath',PATH)` returns a MATLAB array that contains a signal in `LogObject`. You must specify the `PATH` to the signal in `LogObject` using the `Name, Value` pair argument.

`Array = dsp.util.getLogArray(LogObject,Format2D,'SignalName',NAME)` returns a MATLAB array that contains a signal in `LogObject`. You must specify the `NAME` of the signal in `LogObject` using the `Name, Value` pair argument.

### **Input Arguments**

#### **LogObject**

Specify the name of the object that contains your logged signals. Valid classes for `LogObject` depend on the syntax you use:

- When you specify `PATH` as a `dsp.util.getSignalPath` object, `LogObject` can be either a `Simulink.SimulationData.Dataset` or `Simulink.SimulationData.Signal` object.
- When you specify `PATH` as the full path to a block in a Simulink model, `LogObject` must be a `Simulink.SimulationData.Dataset` object.

- When you specify the `NAME` of a signal in `LogObject`, `LogObject` can be an object of class `timeseries`, `Simulink.SimulationData.Dataset`, or `Simulink.SimulationData.Signal`.

### **Format2D**

Specify a logical value to determine whether the function formats 3-D logged signals as a 2-D or 3-D MATLAB array. When you set this property to `true`, the function uses the following formula to format the 3-D logged signal into a 2-D MATLAB array:

```
dim = size(signal);  
ntimes = dim(1)*dim(3);  
Array = reshape(permute(signal,[1 3 2]),[ntimes dim(2)]);
```

When you set this property to `false`, the function returns the logged signal without any reformatting.

### **PATH**

Specify the path to the logged signal in `LogObject`. You can specify the path using a `dsp.util.getSignalPath` object, or you can provide the full path to a block in your Simulink model. To get the full path to a block in your Simulink model, use the `gcb` command.

### **NAME**

Specify the name of the signal in `LogObject`.

## **Output Arguments**

### **Array**

The output `Array` is a MATLAB array that contains the specified logged signal. When the input is a 3-D logged signal, the dimensions of `Array` depend on the value you specify for `Format2D`:

- When `Format2D` is `true`, `Array` is a 2-D MATLAB array.
- When `Format2D` is `false`, `Array` is a 3-D MATLAB array.

When the input is not a 3-D signal, the dimensions of the output `Array` match those of the input.

## Examples

---

**Note** To run the following examples, you must first load `ex_logout.mat` which contains a `Simulink.SimulationData.Dataset` object. Alternatively, you can open and simulate the `ex_log_utils` Simulink model. Doing so will log signals and generate the necessary `ex_logout` object.

---

**Example 5.1. Extract a unique signal named `Signal3x4` from `ex_logout`.**

```
dsp.util.getLogArray(ex_logout, true, 'SignalName','Signal3x4')
```

**Example 5.2. Extract a unique signal named `Signal3x4` from `ex_logout` as a 3-D array.**

```
dsp.util.getLogArray(ex_logout, false, 'SignalName','Signal3x4')
```

**Example 5.3. Find and extract a specific signal from multiple signals that have the same name.**

Because `ex_logout` contains multiple signals named `Signal2x4`, you must use the `dsp.util.getSignalPath` function to find the paths to each of those signals.

```
paths = dsp.util.getSignalPath(ex_logout, 'Signal2x4')
% paths is a 2x1 array of dsp.util.SignalPath objects. Next, examine
% the BlockPath property of each paths object.
paths.BlockPath
% Find the signal path that corresponds to the logged signal you are
% interested in. For example paths(2). You can then use the
% dsp.util.getLogArray function and provide the 'SignalPath' name-value
% pair argument.
dsp.util.getLogArray(ex_logout, true, 'SignalPath', paths(2))
```

**Example 5.4. Find and extract a signal from a bus.**

Use the `dsp.util.getSignalPath` function to get paths to all the signals in the bus named `Bus1`.

```
buspaths = dsp.util.getSignalPath(ex_logout, 'Bus1')
% buspaths is a 2x1 array of dsp.util.SignalPath objects. Examine the
% BusElement property of each buspaths object.
buspaths.BusElement
% Select a signal path. For example buspaths(1). This is the path to the
```

```
% signal named 'Signal3x4' in bus 'Bus' that is contained in bus 'Bus1'.  
% Now that you have the path to the signal, call dsp.util.getLogsArray  
% using the 'SignalPath' name-value pair argument.  
dsp.util.getLogsArray(ex_logout, true, 'SignalPath', buspaths(1))
```

## Introduced in R2011b

## **dsp.util.getSignalPath**

**Package:** dsp.util

Paths to logged signals

### **Syntax**

```
Path = dsp.util.getSignalPath(LogObject, SignalName)
```

### **Description**

`Path = dsp.util.getSignalPath(LogObject, SignalName)` returns all paths to signals in `LogObject` with name `SignalName`. The output `Path` is a `dsp.util.SignalPath` object or an array of `dsp.util.SignalPath` objects.

### **Input Arguments**

#### **LogObject**

Specify the name of the object that contains your logged signals. `LogObject` must be a `Simulink.SimulationData.Dataset` or `Simulink.SimulationData.Signal` object.

#### **SignalName**

Specify the name of a logged signal in `LogObject`.

### **Output Arguments**

#### **Path**

The output `Path` contains the path to all signals named `SignalName` in `LogObject`.

- If LogObject contains a unique signal with name SignalName, the function returns a single dsp.util.SignalPath object.
- If LogObject contains more than one signal with the specified name, the function returns an array of dsp.util.SignalPath objects.

## Examples

---

**Note** To run the following examples, you must first load `ex_logout.mat` which contains a `Simulink.SimulationData.Dataset` object. Alternatively, you can open and simulate the `ex_log_utils` Simulink model. Doing so will log signals and generate the necessary `ex_logout` object.

---

### Example 5.5. Find and extract a specific signal from multiple signals that have the same name.

Because `ex_logout` contains multiple signals named `Signal2x4`, you must use the `dsp.util.getSignalPath` function to find the paths to each of those signals.

```
paths = dsp.util.getSignalPath(ex_logout, 'Signal2x4')
% paths is a 2x1 array of dsp.util.SignalPath objects. Next, examine
% the BlockPath property of each paths object.
paths.BlockPath
% Find the signal path that corresponds to the logged signal you are
% interested in. For example paths(2). You can then use the
% dsp.util.getLogsArray function and provide the 'SignalPath' name-value
% pair argument.
dsp.util.getLogsArray(ex_logout, true, 'SignalPath', paths(2))
```

### Example 5.6. Find and extract a signal from a bus.

Use the `dsp.util.getSignalPath` function to get paths to all the signals in the bus named `Bus1`.

```
buspaths = dsp.util.getSignalPath(ex_logout, 'Bus1')
% buspaths is a 2x1 array of dsp.util.SignalPath objects. Examine the
% BusElement property of each buspaths object.
buspaths.BusElement
% Select a signal path. For example buspaths(1). This is the path to the
% signal named 'Signal3x4' in bus 'Bus' that is contained in bus 'Bus1'.
% Now that you have the path to the signal, call dsp.util.getLogsArray
```

```
% using the 'SignalPath' name-value pair argument.  
dsp.util.getLogsArray(ex_logout, true, 'SignalPath', buspaths(1))
```

### Tips

- To return the path to an unnamed signal in `LogObject`, set `SignalName` to the empty string ('').

# dsp.util.SignalPath

**Package:** dsp.util

Properties of paths to signals

## Description

`dsp.util.SignalPath` objects contain path information for signals in `Simulink.SimulationData.Dataset` objects. You get `Simulink.SimulationData.Dataset` objects when you use `Dataset` logging to log signals from a Simulink model.

## Construction

`dsp.util.SignalPath` objects are returned by the `dsp.util.getSignalPath` function and can be used as input to the `dsp.util.getLogArray` function.

## Properties

### SignalName

Contains the name of the signal output by the block at the specified `BlockPath`.

### BlockPath

Provides the `Simulink.SimulationData.BlockPath` to the block in the Simulink model from which the signal originates.

### PortIndex

Provides the output port index of the block from which the logged signal `SignalName` originates.

### **BusElement**

Provides a string description of a signal in a logged bus. When `SignalPath` is not a logged bus, this property will be an empty string.

If the `SignalPath` object is a logged bus signal, the `BusElement` string will be formatted as follows:

- When the bus contains a nonbus signal, `BusElement` is the name of that signal.
- When the bus contains a nested bus that contains a nonbus signal, `BusElement` will be a dot-separated string consisting of the name of the nested bus followed by the name of the non-bus signal. For example: `nestbus.signal1`
- When the bus contains nested busses within nested busses to any depth, `BusElement` will be a dot-separated string. This string contains each of the nested bus names, and ends with the nonbus signal name. For example:  
`outernestedbus.innernestedbus.signal1`

## dsp\_links

Identify whether blocks in model are current, deprecated, or obsolete

### Syntax

```
dsp_links
dsp_links('modelName')
```

### Description

`dsp_links` returns a structure with three elements that identify whether the DSP System Toolbox blocks in the current model are current, deprecated, or obsolete. Each element is one of the three block categories and contains a cell array of character vectors. Each character vector is the name of a library block in the current model.

`dsp_links('modelName')` returns the three-element structure for the specified model.

### Examples

#### Name of the First Current Block

Display block support information for the specified model, and then find the name of the first current block.

```
sys = 'dspcochlear';
```

Load the dspcochlear model

```
load_system(sys)
```

Run `dsp_links` on the model

```
links = dsp_links(sys)
```

```
links = struct with fields:
    obsolete: {}
```

```
deprecated: {}  
current: {1x23 cell}
```

Find the name of the first current block

```
links.current{1}
```

```
ans =  
'dspcochlear/Filter bank signal processing/Subsystem3/IIR Filter Bank/Digital Filter10
```

## Definitions

### Obsolete Blocks

*Obsolete blocks* are blocks that the toolbox no longer supports. In some cases, these blocks no longer function properly.

### Deprecated Blocks

*Deprecated blocks* are blocks that the toolbox still supports but are likely to become obsolete in a future release. Refer to the block reference page for suggested replacements.

### Current Blocks

*Current blocks* are blocks that the toolbox supports and that represent the latest block functionality.

# dsplib

Open top-level DSP System Toolbox library

## Syntax

```
dsplib
```

## Description

dsplib opens the top-level DSP System Toolbox block library model.

## Examples

View and gain access to the DSP System Toolbox blocks:

```
dsplib
```

## Alternatives

To view and gain access to the DSP System Toolbox blocks using the Simulink library browser:

- Type `simulink` at the MATLAB command line, and then expand the DSP System Toolbox node in the library browser.

- 

Click the Simulink icon from the MATLAB Toolstrip.

**Introduced before R2006a**

## dspstartup

Configure Simulink environment for signal processing systems

---

**Note** `dspstartup` will be removed in a future release. Use DSP Simulink model templates instead. For more information on DSP Simulink model templates, see [Configure the Simulink Environment for Signal Processing Models](#).

---

### Syntax

`dspstartup`

### Description

`dspstartup` configures Simulink environment parameters with settings appropriate for a typical signal processing project. You can use the `dspstartup` function in the following ways:

- At the MATLAB command line. Doing so configures the Simulink environment in your current session for signal processing projects.
- By adding a call to the `dspstartup` function from your `startup.m` file. When you do so, MATLAB configures your Simulink environment for typical signal processing projects each time you launch MATLAB.

When the function successfully configures your Simulink environment, MATLAB displays the following message in the command window.

```
Changed default Simulink settings for signal processing
systems (dspstartup.m).
```

The `dspstartup.m` file executes the following commands.

```
set_param(0, ...
    'SingleTaskRateTransMsg', 'error', ...
    'multiTaskRateTransMsg', 'error', ...
```

```

'Solver',                'fixedstepdiscrete', ...
'EnableMultiTasking',   'Off', ...
'StartTime',            '0.0', ...
'StopTime',             'inf', ...
'FixedStep',            'auto', ...
'SaveTime',             'off', ...
'SaveOutput',           'off', ...
'AlgebraicLoopMsg',     'error', ...
'SignalLogging',        'off');

```

## Examples

Add a call to the `dspstartup` function from your `startup.m` file:

- 1 To find out if there is a `startup.m` file on your MATLAB path, run the following code at the MATLAB command line:

```
which startup.m
```

- 2 If MATLAB returns '`startup.m`' not found, see “Specify Startup Options” (MATLAB) to learn more about the `startup.m` file.

If MATLAB returns a path to your `startup.m` file, open that file for editing.

```
edit startup.m
```

- 3 Add a call to the `dspstartup` function. Your `startup.m` file now resembles the following code sample:

```

%STARTUP  Startup file
%  This file is executed when MATLAB starts up, if it exists
%  anywhere on the path.  In this case, the startup.m file
%  runs the dspstartup.m file to configure the Simulink
%  environment with settings appropriate for typical
%  signal processing projects.

```

```
dspstartup;
```

# **dspunfold**

Generates a multi-threaded MEX file from a MATLAB function

## **Syntax**

```
dspunfold file  
dspunfold options file
```

## **Description**

`dspunfold file` generates a multi-threaded MEX file from the entry-point MATLAB function specified by `file`, using the DSP unfolding technology. DSP unfolding is a technique to improve throughput through parallelization. The multi-threaded MEX file leverages the multicore CPU architecture of the host computer and can improve speed significantly. In addition to the multi-threaded MEX file, the function generates a single-threaded MEX file, a self-diagnostic analyzer function, and the corresponding help files.

`dspunfold options file` generates a multi-threaded MEX file from the entry-point MATLAB function specified by `file`, using the function arguments specified by `options`.

---

**Note** This function requires a MATLAB Coder license.

---

## **Input Arguments**

### **options — Function parameters**

option value pairs

Option	Values	Description	Examples
-args arguments	Cell array	<p>Argument types for the entry-point MATLAB function, specified as a cell array.</p> <p>The cell array accepts numeric elements, the <code>coder.typeof</code> function, and the <code>coder.Constant</code> function.</p> <p>The generated multi-threaded MEX file is specialized to the size, class, and complexity of arguments.</p>	<p>The number of elements in the cell array must be the same as the number of arguments that the entry-point MATLAB function expects.</p> <ul style="list-style-type: none"> <li>• <code>dspunfold fcn -args {ones(10,1), 5}</code>  <code>dspunfold</code> extracts the type (size, class, and complexity) information from the elements in the arguments cell array.  <code>fcn</code> is the entry-point MATLAB function.</li> <li>• <code>dspunfold fcn -args {coder.typeof(ones(10,1)), coder.typeof(5)}</code>  <code>coder.typeof</code> is used to specify the types of the <code>fcn</code> arguments.</li> <li>• <code>dspunfold fcn -args {coder.Constant(ones(10,1)), coder.Constant(5)}</code></li> <li>• <code>dspunfold fcn -args {}</code></li> </ul> <p>By default, <code>arguments</code> is <code>{}</code>. An empty cell array <code>{}</code> indicates that <code>fcn</code> accepts no input arguments.</p>

Option	Values	Description	Examples
-o output	Character vector	Name of the output multi-threaded MEX file, specified as a character vector. If no output name is specified, the name of the generated multi-threaded MEX file is inherited from the input MATLAB function with an '_mt' suffix. dspunfold also adds a platform-specific extension to this name. In addition, dspunfold generates a single-threaded MEX file with an '_st' suffix, and a test bench file with an '_analyzer' suffix.	<ul style="list-style-type: none"> <li>• No output name specified <code>dspunfold fcn</code>  Files generated: <code>fcn_mt.mexw64,</code> <code>fcn_st.mexw64,</code> <code>fcn_analyzer.p</code></li> <li>• output name specified  <code>dspunfold fcn -o foo</code>  Files generated: <code>foo.mexw64,</code> <code>foo_st.mexw64,</code> <code>foo_analyzer.p</code></li> </ul>

Option	Value s	Description	Examples
-s statelength	<p>Scalar integer greater than or equal to zero</p> <p>auto</p>	<p>State length of the algorithm in the entry-point MATLAB function, specified as a scalar integer greater than or equal to zero, or auto. By default, the <code>statelength</code> is zero frames, indicating that the algorithm is stateless.</p> <p>If at least one entry of <code>frameinputs</code> is true, <code>statelength</code> is considered in samples.</p> <p>For information on frames and samples, see “Sample- and Frame-Based Concepts”</p> <p>-s auto triggers automatic state length detection. In this mode, you must provide numeric inputs to the arguments cell array. These inputs detect the</p>	<ul style="list-style-type: none"> <li>• <code>dspunfold fcn -args {randn(10,1), randn(10,1), randn(10,1)} -s 3 -f [false, false, false]</code>  State length is three frames.</li> <li>• <code>dspunfold fcn -args {randn(10,1), randn(10,1), randn(10,1)} -s 3 -f [true, false, false]</code>  State length is three samples. State length is considered in samples, because at least one entry of the -f option is true.</li> <li>• <code>dspunfold fcn -args {randn(10,1), randn(10,1), randn(10,1)} -s auto</code>  Automatic state length detection is invoked.</li> <li>• <code>dspunfold fcn -args {coder.typeof(randn(10,1)), coder.typeof(randn(10,1))}, coder.typeof(randn(10,1))} -s auto</code> generates this error message: The input argument 1 is of type <code>coder.PrimitiveType</code> which is not supported when using -s auto</li> </ul>

Option	Value s	Description	Examples
		state length of the algorithm. You can input <code>coder.Constant</code> but not <code>coder.typeof</code> . When automatic state length detection is invoked, it is recommended that you provide random inputs to the arguments array. See "Automatic State Length Detection" on page 5-384	

Option	Value s	Description	Examples
-f frameinputs	scalar logical vector of logical values	<p>Frame status of input arguments for the entry-point MATLAB function, specified as one of true or false.</p> <ul style="list-style-type: none"> <li>• true — Input is in frames and can be subdivided into samples without changing the system behavior.</li> <li>• false — Input cannot be subdivided into samples without changing the system behavior. For example, you cannot subdivide the coefficients of a filter without changing the characteristics of the filter.</li> </ul> <p>By default, frameinputs is false.</p> <p>frameinputs set to a scalar logical value sets the</p>	<ul style="list-style-type: none"> <li>• dspunfold fcn -args {randn(10,1), randn(10,1), randn(10,1)} -s 3 -f true</li> </ul> <p>All the inputs are marked as frames. State length is three samples.</p> <ul style="list-style-type: none"> <li>• dspunfold fcn -args {randn(10,1), randn(10,1), randn(10,1)} -s 3 -f [true, false, false]</li> </ul> <p>State length is three samples.</p> <ul style="list-style-type: none"> <li>• dspunfold fcn -args {randn(10,1), randn(10,1), randn(10,1)} -s 3</li> </ul> <p>The default value of frameinputs is false. State length is three frames.</p>

Option	Values	Description	Examples
		<p>frame status of all the inputs simultaneously.</p> <p>To specify <code>statelength</code> in samples, set at least one entry of <code>frameinputs</code> to <code>true</code>.</p> <p>If <code>frameinputs</code> is not specified, the unit of <code>statelength</code> is frames.</p>	
-r repetition	Positive integer	<p>Repetition factor used to generate the multi-threaded MEX file, specified as a positive integer. The default value of repetition is 1. See "Repetition Factor" on page 5-384.</p>	<pre>dspunfold fcn -args {randn(10,2), randn(20,2), randn(30,3)} -r 2</pre>

Option	Value s	Description	Examples
-t threads	Positive integer	Number of threads used by the multi-threaded MEX file, specified as a positive integer. The default value of threads is the number of physical CPU cores present on your machine. See “Threads” on page 5-384.	<code>dspunfold fcn -args {randn(10,1), randn(20,2), randn(30,3)} -t 4</code>
-v verbose	Scalar logical	Option to show verbose output during code generation, specified as true or false. The default is true.	<ul style="list-style-type: none"> <li>• <code>dspunfold fcn -args {randn(10,1), randn(20,2), randn(30,3)} -v true</code></li> <li>• <code>dspunfold fcn -args {randn(10,1), randn(20,2), randn(30,3)} -v false</code></li> </ul>

**file — entry-point MATLAB function**

character vector

Entry-point MATLAB function from which `dspunfold` generates the multi-threaded MEX file. The function must support code generation.

Example: `dspunfold fcn -args {randn(10,1), randn(10,2), randn(20,1)}`

`fcn` is the entry-point MATLAB function and `{randn(10,1), randn(10,2), randn(20,1)}` are its input arguments.

## Output Files

When you invoke `dspunfold` on an entry-point MATLAB function, `dspunfold` generates the following files.

File	Value	Description	Examples
Multi-threaded MEX file	MEX file	Multi-threaded MEX file generated from the entry-point MATLAB function. The MEX file inherits the output name. If no output name is specified, the name of this file is inherited from the MATLAB function with an '_mt' suffix. A platform-specific extension is also added to the name.	<ul style="list-style-type: none"> <li>• <code>dspunfold fcn -o foo</code> generates <code>foo.mexw64</code></li> <li>• <code>dspunfold fcn</code> generates <code>fcn_mt.mexw64</code></li> </ul>
Help file for the multi-threaded MEX file	MATLAB file	<p>MATLAB help file for the multi-threaded MEX file. The help file has the same name as the MEX file, but with an '.m' extension. To invoke the help file, type <code>help &lt;MEX filename&gt;</code> at the MATLAB command prompt.</p> <p>This help file displays information on how to invoke the MEX file, its syntax, latency, and types (size, class, and complexity) of the inputs to the MEX file. In addition, the help file documents the parameters used by <code>dspunfold</code> — <code>Threads</code>, <code>Repetition</code>, and <code>State length</code>. This information is useful when you are invoking the MEX file. The syntax to invoke the MEX file should be the same as the syntax shown in the help file.</p>	<ul style="list-style-type: none"> <li>• <code>help foo</code></li> <li>• <code>help fcn_mt</code></li> </ul>

File	Value	Description	Examples
Single-threaded MEX file	MEX file	Single-threaded MEX file generated from the entry-point MATLAB function. The MEX file inherits the output name with an '_st' suffix. If no output name is specified, the name of this file is inherited from the MATLAB function with an '_st' suffix. A platform-specific extension is also added to the name. Use this file as a benchmark to compare against the speed of the multi-threaded MEX file.	<ul style="list-style-type: none"> <li>• <code>dspunfold fcn -o foo</code> generates <code>foo_st.mexw64</code></li> <li>• <code>dspunfold fcn</code> generates <code>fcn_st.mexw64</code></li> </ul>
Help file for the single-threaded MEX file	MATLAB file	<p>MATLAB help file for the single-threaded MEX file. The help file has the same name as the MEX file, but with an '.m' extension. To invoke the help file, type <code>help &lt;MEX filename&gt;</code> at the MATLAB command prompt.</p> <p>The help file displays information on how to invoke the MEX file, its syntax, and types (size, class, and complexity) of the inputs to the MEX file. The syntax to invoke the MEX file should be the same as the syntax shown in the help file.</p>	<ul style="list-style-type: none"> <li>• <code>help foo_st</code></li> <li>• <code>help fcn_st</code></li> </ul>

File	Value	Description	Examples
Self-diagnostic analyzer function	P-coded file	<p>report = function_analyzer (input 1, input 2, ...input n) measures the difference in speed between the multi-threaded MEX file and the single-threaded MEX file. This file verifies that the output values match.</p> <p>report = function_analyzer('latency') reports the latency of the multi-threaded MEX file introduced by DSP unfolding.</p> <p>report contains the following fields:</p> <ul style="list-style-type: none"> <li>• Latency — The value of the latency (in frames)</li> <li>• Speedup — The speedup difference between the multi-threaded MEX file and single-threaded MEX file. If you specified latency option, the value of this field is empty [ ].</li> <li>• Pass — Logical value that shows if the outputs match between the generated multi-threaded MEX file and the single-threaded MEX file. If you specified latency option, the value of this field is empty [ ].</li> </ul>	<ul style="list-style-type: none"> <li>• Multiple frames with different values are specified along the first dimension</li> </ul> <p>Example 1: report = foo_analyzer(randn(10*2,1), randn(20*2,2), randn(30*3,3))</p> <p>Example 2: report = foo_analyzer([randn(10,1);randn(10,1)], [randn(20,1);randn(20,1)], [randn(30,1);randn(30,1);randn(30,1)])</p> <ul style="list-style-type: none"> <li>• report = foo_analyzer('latency')</li> </ul>

File	Value	Description	Examples
		<p>The first dimension of the analyzer inputs must be a multiple of the first dimension of the corresponding inputs, given to the <code>-args</code> option. The other dimensions must match exactly.</p> <p>The analyzer inherits the output name with an <code>'_analyzer'</code> suffix. If no output name is specified, the name of this file is inherited from the MATLAB function with an <code>'_analyzer'</code> suffix.</p>	
<p>Help file for the self-diagnostic analyzer function</p>	<p>MATLAB file</p>	<p>Help file for the self-diagnostic analyzer function. The help file has the same name as the MEX file, but with an <code>'.m'</code> extension. To invoke the help file, type <code>help &lt;function_analyzer&gt;</code> in MATLAB.</p> <p>The help file for the self-diagnostic analyzer function displays information on how to invoke the analyzer function, its syntax, and types (size, class, and complexity) of the inputs to the analyzer function. The syntax to invoke the analyzer function should be the same as the syntax shown in the help file.</p>	<p><code>help foo_analyzer</code></p>

## Limitations

### General Limitations:

- On Windows and Linux, you must use a compiler that supports the Open Multiprocessing (OpenMP) application interface. See [https://www.mathworks.com/support/compilers/current\\_release/](https://www.mathworks.com/support/compilers/current_release/).
- If the input MATLAB function has runtime errors, the errors are not caught when you run the multi-threaded MEX file. Before you use the `dspunfold` function, call `codegen` on the MATLAB function and make sure that the MEX file is generated successfully.
- If the generated code uses a large amount of memory to store the local variables, around 4 MB on Windows platform, the generated multi-threaded MEX file can have unexpected behavior. This limit varies with each platform. As a workaround, reduce the size of the input signals or restructure the MATLAB function to use less local memory.
- `dspunfold` does not support:
  - `varargin` and `varargout` inside the MATLAB function
  - variable-size inputs and outputs
  - P-coded entry-point MATLAB functions
  - cell arrays as inputs and outputs

### Analyzer Limitations:

The following limitations apply to the analyzer function generated by the `dspunfold` function. For more information on the analyzer function, see 'Self-Diagnostic Analyzer' in the 'More About' section of `dspunfold`.

- If multiple frames of the analyzer input are identical, the analyzer might throw false positive pass results. It is recommended that you provide at least two different frames for each input of the analyzer.
- If the algorithm in the entry-point MATLAB function chooses its state length based on the input values, the analyzer might provide different *pass* results for different input values. For an example, see the `FIR_Mean` function in "Why Does the Analyzer Choose the Wrong State Length?".
- If the input to the entry-point MATLAB function does affect the output immediately, the analyzer might throw false positive *pass* results. For an example, see the `Input_Output` function in "Why Does the Analyzer Choose a Zero State Length?".

- If the output results of the multi-threaded MEX file and single-threaded MEX file match statistically but do not match numerically, the analyzer does not pass. Consider the `FilterNoise` function that follows, which filters a random noise signal with an FIR filter. The function calls `randn` from within itself to generate random noise. Hence, the output results of the `FilterNoise` function match statistically but not match numerically.

```
function Output = FilterNoise(x)

persistent FIRFilter
if isempty(FIRFilter)
    FIRFilter = dsp.FIRFilter('Numerator',fir1(12,0.4));
end
Output = FIRFilter(x+randn(1000,1));

end
```

When you run the automatic state length detection tool run on `FilterNoise`, the tool detects an infinite state length. Because the tool cannot find a numerical match for a finite state length, it chooses an infinite state length.

```
dspunfold FilterNoise -args {randn(1000,1)} -s auto
```

```
Analyzing input MATLAB function FilterNoise
Creating single-threaded MEX file FilterNoise_st.mexw64
Searching for minimal state length (this might take a while)
Checking stateless ... Insufficient
Checking 1 ... Insufficient
Checking Infinite ... Sufficient
Checking 2 ... Insufficient
Minimal state length is Inf
Creating multi-threaded MEX file FilterNoise_mt.mexw64
Warning: The multi-threading was disabled due to performance considerations.
This happens when the state length is greater than or
equal to (Threads-1)*Repetition frames (3 frames in this case).
> In coder.internal.warning (line 8)
   In unfoldingEngine/BuildParallelSolution (line 25)
   In unfoldingEngine/generate (line 207)
   In dspunfold (line 234)
Creating analyzer file FilterNoise_analyzer
```

The algorithm does not need an infinite state. The state length of the FIR filter, hence the algorithm is 12.

Call `dspunfold` with state length set to 12.

```
dspunfold FilterNoise -args {randn(1000,1)} -s 12 -f true
```

```
Analyzing input MATLAB function FilterNoise
Creating single-threaded MEX file FilterNoise_st.mexw64
```

```
Creating multi-threaded MEX file FilterNoise_mt.mexw64
Creating analyzer file FilterNoise_analyzer
```

Run the analyzer function.

```
FilterNoise_analyzer(randn(1000*4,1))
```

```
Analyzing multi-threaded MEX file FilterNoise_mt.mexw64 ...
Latency = 8 frames
Speedup = 0.5x
Warning: The output results of the multi-threaded MEX file FilterNoise_mt.mexw64 do not
match the output results of the single-threaded MEX file FilterNoise_st.mexw64. Check that
you provided the correct state length value to the dspunfold function when you generated the
multi-threaded MEX file FilterNoise_mt.mexw64. For best practices and possible solutions to
this problem, see the 'Tips' section in the dspunfold function reference page.
> In coder.internal.warning (line 8)
   In FilterNoise_analyzer
   ans =
       Latency: 8
       Speedup: 0.4970
           Pass: 0
```

The analyzer looks for a numerical match and fails the verification, even though the generated multi-threaded MEX file is valid.

### Speedup Limitations:

- If the entry-point MATLAB function contains code with low complexity, MATLAB overhead or multi-threaded MEX overhead overshadow any performance gains. In such cases, do not use `dspunfold`.
- If the number of operations in the input MATLAB function is small compared to the size of the input or output data, the multi-threaded MEX file does not provide any speedup gain. Sometimes, it can result in a speedup loss, even if the repetition value is increased. In such cases, do not use `dspunfold`.

## More About

### State Length

State length of the algorithm.

Most of the time, the state length used by `dspunfold` matches the state length of the algorithm in the entry-point MATLAB function. If the algorithm is simple, state length is easy to determine. For example, the state length of an FIR filter is the number of taps in the filter - 1. In some scenarios, to optimize speedup, `dspunfold` chooses a state length

that is different from the algorithm state length or the state length specified using the `-s` option. For example, when the state length is greater than  $(threads - 1) \times repetition$  frames, `dspunfold` considers the state length to be infinite. Also, multi-threading gets disabled due to performance considerations.

## Automatic State Length Detection

You can automatically detect the minimum state length for which the outputs of the multi-threaded MEX and single-threaded MEX match.

In complex algorithms, it is not easy to determine the state length analytically. In such scenarios, use the analyzer to compute the state length. When you set `-s` to `auto`, `dspunfold` invokes the analyzer. The analyzer computes the outputs for different state lengths and detects the minimum state length for which the outputs of the multi-threaded MEX file and single-threaded MEX file match. The analyzer uses the numeric value of the inputs given to `-args`. To detect the most efficient state length, provide random inputs to `-args`. In this mode, you cannot input `coder.typeof` to `arguments`. Due to the extra analysis this tool requires, the time to generate the MEX file increases.

When you use automatic state length detection on an algorithm with code paths that depend on the input values, use inputs that choose the code path with the longest state length. Also, the inputs must have an immediate effect on the output. If inputs choose a code path that triggers runtime errors, automatic state length detection stops, and so does the analyzer. Make sure that the MATLAB function supports code generation and does not have run-time errors for the inputs under test. Before invoking `dspunfold`, call `codegen` on the entry-point MATLAB function. In addition, simulate the entry-point MATLAB function to make sure it has no run-time errors.

## Threads

The `-t` option specifies the number of threads used by the multi-threaded MEX file.

Increasing this value can improve the multi-threaded MEX speedup, at the cost of a larger latency. Decreasing this value reduces the latency and potentially decreases the multi-threaded MEX speedup.

## Repetition Factor

*Repetition factor* is the number of consecutive frames processed by each thread in one processing step.

Increasing this value reduces the overhead per frame of data, potentially improving the speedup at the cost of larger latency. Decreasing this value reduces the latency, and potentially decreases the multi-threaded MEX speedup.

## Self-Diagnostic Analyzer

The self-diagnostic analyzer function is a help tool that is generated with the MEX file. This function measures the speedup gain of the multi-threaded MEX file compared to the single-threaded MEX file. The analyzer function also verifies that the outputs of the multi-threaded MEX file and single-threaded MEX file match.

If you specify an incorrect state length value, the outputs usually do not match. To check for the numerical match between the multi-threaded MEX file and the single-threaded MEX file, provide at least two different frames for each input argument of the analyzer. The frames are appended along the first dimension. The analyzer alternates between these frames while verifying that the outputs match. Failure to provide multiple frames for each input can decrease the effectiveness of the analyzer and can lead to false positive verification results. In other words, the analyzer might produce *pass = 1* results even when an incorrect state length value is specified. The analyzer alternates through a maximum of  $3 \times (2 \times \text{threads} \times \text{repetition})$  frames. If your algorithm requires more than  $3 \times (2 \times \text{threads} \times \text{repetition})$  frames to verify the results, then the analyzer cannot verify accurately.

## Tips

### General

- Do not display plots, scopes, or execute other user interface operations from within the multi-threaded MEX file. The generated MEX file can have unexpected behavior.
- Do not use `coder.extrinsic` inside the input MATLAB function. The generated MEX file can have unexpected behavior.

When the state length is less than or equal to  $(\text{threads} - 1) \times \text{repetition}$  frames:

- Do not use a random number inside the MATLAB function. The outputs of the single-threaded MEX file and the multi-threaded MEX file might not match. Also, the outputs of the consecutive executions of the multi-threaded MEX file might not match. The analyzer might not pass the numerical match verification.

It is recommended that you generate the random number outside the entry-point MATLAB function and pass it as an argument to the function.

- Do not use global or persistent variables anywhere other than in the entry-point MATLAB function. For example, avoid using persistent variables in subfunctions. The generated MEX file can produce inaccurate results. In general, global variables are not recommended.
- Do not access I/O resources from within the multi-threaded MEX file. The generated MEX file can have unexpected behavior. These resources include file writers and readers, UDP sockets, and audio players and recorders.
- Do not use functions with interactive inputs (for example, the keyboard) inside the multi-threaded MEX file. The generated MEX file can have unexpected behavior.

### Workflow

- To generate a valid multi-threaded MEX file with the required speedup and latency, follow the “Workflow for Generating a Multi-Threaded MEX File using `dspunfold`”.
- Before using `dspunfold`, call `codegen` on the entry-point MATLAB function and make sure that the function generates a MEX file successfully.
- After generating the multi-threaded MEX file using `dspunfold`, run the analyzer function. Make sure that the analyzer function passes. The exception to this rule is when the algorithm produces results that match statistically, but not numerically. In this exception, the analyzer function does not pass, even though the `dspunfold` function generates a valid multi-threaded MEX file. See 'Analyzer Limitations' for an example.
- For help on using the MEX file and analyzer, at the MATLAB command prompt, enter `help <mexfile name>` and `help <analyzer name>`.

### State Length

- If you choose a state length that is greater than or equal to the value of the exact state length, the analyzer passes. If the analyzer fails, increase the state length, regenerate the MEX file, and verify again.
- If the state length is greater than 0, the inputs marked as frames (through `-f` option) must all have the same dimensions.
- When generating the MEX file and running the analyzer, use inputs that invoke the same state length.

### Automatic State Length Detection

When you set `-s` to `auto`:

- If the algorithm in the entry-point MATLAB function chooses a code path based on the input values, use inputs that choose the code path with the longest state length.
- Provide random inputs to `-args`.
- Choose inputs that have an immediate effect on the output. See “Why Does the Analyzer Choose a Zero State Length?”.

### Analyzer

- Make sure the outputs of the multi-threaded MEX file and the single-threaded MEX file do not contain NaN or an Inf. The analyzer cannot do numeric checks and returns `pass` as `false`. The automatic state length detection tool detects infinite state length and displays a warning

---

**Warning** The output results of the multi-threaded MEX file do not match the output results of the single-threaded MEX file even for Infinite state length. A possible reason is that input MATLAB function generates different output results between consecutive runs even for the same input values.

---

- Provide multiple frames with different values for each input of the analyzer. To improve the analyzer effectiveness, append successive frames along the first dimension.
- Provide inputs to the analyzer that lead to efficient code coverage.

### Speedup

- To improve the speedup of the multi-threaded MEX file, specify the exact state length in samples. You can specify the state length in samples by setting at least one entry of `frameinputs` to `true`. The use of samples reduces the overhead and increases the speedup.
- To increase the speedup at the cost of larger latency, you can:
  - Increase the repetition factor. Use the `-r` option.
  - Increase the number of threads. Use the `-t` option.
- For each input that can be divided into samples without altering the algorithm behavior, set frame status to `true` using the `-f` option. The input is then considered in samples, which can increase the speedup of the generated multi-threaded MEX file.

## Algorithms

The multi-threaded MEX file buffers multiple-input signal frames into a buffer of  $2 \times \textit{threads} \times \textit{repetition}$  frames, where *threads* is the number of threads, and *repetition* is the repetition factor. The MEX file processes these frames simultaneously, using multiple cores. This process introduces some deterministic latency, where  $\textit{latency} = 2 \times \textit{threads} \times \textit{repetition}$ . Latency is traded off with the speedup you might gain by increasing the number of threads or the repetition factor.

### Introduced in R2015b

# ellip

Elliptic filter using specification object

## Syntax

```
ellipFilter = design(d,'ellip','SystemObject',true)
ellipFilter = design(d,'ellip',designoption,value,designoption,...
value,...,'SystemObject',true)
```

## Description

`ellipFilter = design(d,'ellip','SystemObject',true)` designs an elliptical IIR digital filter using the specifications supplied in the object `d`.

`ellipFilter = design(d,'ellip',designoption,value,designoption,... value,...,'SystemObject',true)` returns an elliptical or Causer FIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `ellip`, refer to the command line help system. For example, to get specific information about using `ellip` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'ellip')
```

## Examples

These examples demonstrate how to use `ellip` to design filters based on filter specification objects.

## Design a Bandpass Filter

Construct the default bandpass filter specification object and design an elliptic filter.

```
d = fdesign.bandpass;  
bandpass = design(d, 'ellip', 'matchexactly', 'both', 'SystemObject', true);  
fvtool(bandpass);
```

## Design Lowpass Filter

Construct a lowpass object with order, passband-edge frequency, stopband-edge frequency, and passband ripple specifications, and then design an elliptic filter.

```
d = fdesign.lowpass('n,fp,fst,ap',6,20,25,.8,80);  
design(d,'ellip','SystemObject',true); % Starts fvtool to display the filter.
```

Construct a lowpass object with filter order, passband edge frequency, passband ripple, and stopband attenuation specifications, and then design an elliptic filter.

```
d = fdesign.lowpass('n,fp,ap,ast',6,20,.8,60,80);  
design(d,'ellip','SystemObject',true); % Starts fvtool to display the filter.
```

**Introduced in R2011a**

# euclidfactors

Euclid factors for multirate filter

## Compatibility

`mfilt` will be removed in a future release. See `dsp.CICDecimator`, `dsp.CICInterpolator`, `dsp.FIRDecimator`, `dsp.FIRInterpolator`, `dsp.FilterCascade`, `dsp.FarrowRateConverter`, `dsp.FIRRateConverter`, `dsp.IIRHalfbandDecimator`, or `dsp.IIRHalfbandInterpolator` instead.

## Syntax

```
[lo,mo] = euclidfactors(hm)
```

## Description

`[lo,mo] = euclidfactors(hm)` returns integer factors `lo` and `mo` such that  $(lo*L)-(mo*M) = -1$ . `L` and `M` are relatively prime and represent the interpolation and decimation factors of the multirate filter `hm`.

`euclidfactors` works with the multirate filter `mfilt.firsc`. You cannot return `lo` and `mo` for decimators or interpolators.

## Examples

Use an FIR fractional decimator, with `L = 5` and `M = 7`, to show what `euclidfactors` does.

Indeed,  $(lo*L)-(mo*M) = (4*5)-(3*7) = -1$ .

# equiripple

Equiripple single-rate FIR filter from specification object

## Syntax

```
equiFilt = design(d,'equiripple','SystemObject',true)
equiFilt =
design(d,'equiripple',designoption,value,...,'SystemObject',true)
```

## Description

`equiFilt = design(d,'equiripple','SystemObject',true)` designs an equiripple FIR digital filter using the specifications supplied in the object `d`. Equiripple filter designs minimize the maximum ripple in the passbands and stopbands.

When you use `equiripple` with Nyquist filter specification objects, you might encounter design cases where the filter design does not converge. Convergence errors occur mostly at large filter orders, or small transition widths, or large stopband attenuations. These specifications, alone or combined, can cause design failures. For more information, refer to `fdesign.nyquist` in the online Help system.

```
equiFilt =
design(d,'equiripple',designoption,value,...,'SystemObject',true)
returns an equiripple FIR filter where you specify design options as input arguments.
```

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `equiripple`, refer to the command line help system. For example, to get specific information about using `equiripple` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'equiripple')
```

## Examples

### Design a Single-Rate Equiripple Filter

```
d = fdesign.halfband('tw,ast',0.1,80);  
designmethods(d,'Systemobject',true)
```

Design Methods that support System objects for class `fdesign.halfband (TW,Ast)`:

```
butter  
ellip  
iirlinphase  
equiripple  
kaiserwin
```

```
help(d,'equiripple')
```

DESIGN Design a Equiripple FIR filter.

HD = DESIGN(D, 'equiripple') designs a Equiripple filter specified by the FDESIGN object D, and returns the DFILT/MFILT object HD.

HD = DESIGN(D, ..., 'SystemObject', true) implements the filter, HD, using a System object instead of a DFILT/MFILT object.

HD = DESIGN(..., 'FilterStructure', STRUCTURE) returns a filter with the structure STRUCTURE. STRUCTURE is 'dffir' by default and can be any of the following:

```
'dffir'  
'dffirt'  
'dfsymfir'  
'fftfir'
```

Some of the listed structures may not be supported by System object filters. Type `validstructures(D, 'equiripple', 'SystemObject', true)` to get a list of structures supported by System objects.

HD = DESIGN(..., 'MinPhase', MPHASE) designs a minimum-phase filter when MPHASE is TRUE. MPHASE is FALSE by default.

HD = DESIGN(..., 'StopbandShape', SHAPE) designs a filter whose stopband has the shape defined by SHAPE. SHAPE can be 'flat', '1/f', or 'linear'.

SHAPE is 'flat' by default.

HD = DESIGN(..., 'StopbandDecay', DECAY) specifies the decay to use when 'StopbandShape' is not set to 'flat'. When the shape is '1/f' this specifies the power that 1/f is raised. When shaped is 'linear' this specifies the slope of the stopband in dB/rad/s.

```
% Example #1 - Design a halfband lowpass equiripple filter with increased stopband
TW = 0.1; % Transition Width
Ast = 80; % Stopband Attenuation (dB)
h = fdesign.halfband('Type','Lowpass','TW,Ast',TW,Ast);
Hd = design(h, 'equiripple', 'StopbandShape','linear','StopbandDecay',50);
fvtool(Hd)
```

```
designopts(d,'equiripple')
```

```
ans = struct with fields:
  FilterStructure: 'dffir'
  MinPhase: 0
  StopbandShape: 'flat'
  StopbandDecay: 0
  SystemObject: 0
```

```
equiFilt = design(d,'equiripple','stopbandshape','flat','SystemObject',true);
fvtool(equiFilt);
```

The `fvtool` shows the equiripple nature of the filter.

### Design an Equiripple FIR Filter with a Direct-Form Transposed Structure

This example designs an equiripple filter with a direct-form transposed structure by specifying the 'FilterStructure' argument. To set the design options for the filter, use the `designopts` method and options object `opts`.

```
d = fdesign.lowpass('fp,fst,ap,ast');
opts = designopts(d,'equiripple');
opts.FilterStructure='dffirt';
opts.DensityFactor=20
```

```
opts = struct with fields:
  FilterStructure: 'dffirt'
  DensityFactor: 20
  MinPhase: 0
  MaxPhase: 0
  MinOrder: 'any'
  StopbandShape: 'flat'
  StopbandDecay: 0
  UniformGrid: 1
  SystemObject: 0

firFilt = design(d,'equiripple','SystemObject',true,opts)

firFilt =
  dsp.FIRFilter with properties:

      Structure: 'Direct form transposed'
      NumeratorSource: 'Property'
      Numerator: [1x43 double]
      InitialConditions: 0

  Show all properties

fvtool(firFilt);
```

The MaxPhase design option for equiripple FIR filters is currently only available for lowpass, highpass, bandpass, and bandstop filters.

**Introduced in R2011a**

# fcfwrite

Write file containing filter coefficients

## Syntax

```
fcfwrite(h)
fcfwrite(h,filename)
fcfwrite(...,'fmt')
```

## Description

`fcfwrite(h)` writes a filter coefficient ASCII file in a folder you choose, or your current MATLAB working folder. `h` can be a single filter object or a vector of filter objects. On execution, `fcfwrite` opens the **Export Filter Coefficients to .FCF File** dialog box to let you assign a file name for the output file. You can choose the destination folder within this dialog as well.

The default file name is `untitled.fcf`. When you have DSP System Toolbox software, you can use `fcfwrite(h)` to write filter coefficient files for multirate filters, adaptive filters, and discrete-time filters.

`fcfwrite(h,filename)` writes the filter coefficients and general information to a text file called `filename` in your present MATLAB working folder and opens the file in the MATLAB editor for you to review or modify.

If you do not include a file extension in `filename`, `fcfwrite` adds the extension `fcf` to `filename`.

`fcfwrite(...,'fmt')` writes the filter coefficients in the format specified by the input argument `fmt`. Valid `fmt` values are `hex` for hexadecimal, `dec` for decimal, or `bin` for binary representation of the filter coefficients.

## Examples

To demonstrate `fcfwrite`, create a fixed-point IIR filter at the command line, and then write the filter coefficients to a file named `iirfilter.fcf`.

```
d=fdesign.lowpass;
hd=design(d,'butter');
set(hd,'arithmetic','fixed');
fcfwrite(hd,'iirfilter.fcf');
```

Here is the output from `fcfwrite` as it appears in the MATLAB editor. Not shown here is the filename — `iirfilter.fcf` as specified and some comments at the top of the file.

```

**Introduced in R2011a**

## **filterDesigner**

Open Filter Designer app

### **Syntax**

`filterDesigner`

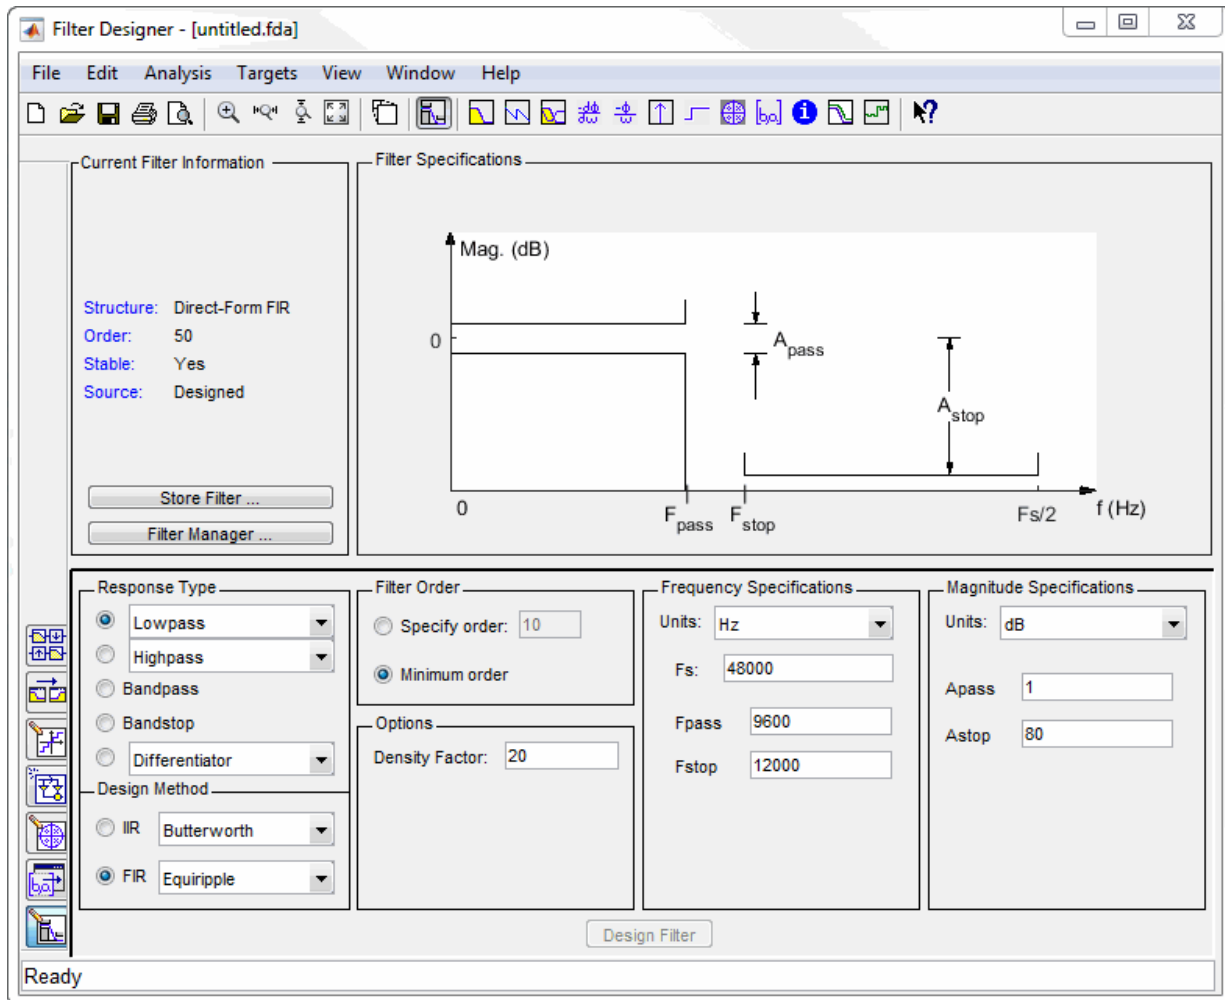

### **Description**

`filterDesigner` opens the Filter Designer app. Use this tool to:

- Design filters
- Quantize filters (with DSP System Toolbox software installed)
- Analyze filters
- Modify existing filter designs
- Create multirate filters (with DSP System Toolbox software installed)
- Realize Simulink models of quantized, direct-form, FIR filters (with DSP System Toolbox software installed)
- Perform digital frequency transformations of filters (with DSP System Toolbox software installed)

Refer to “Use Filter Designer with DSP System Toolbox Software” for more information about using the analysis, design, and quantization features of filter designer. For general information about using filter designer, refer to “Using Filter Designer”.

When you open the filter designer app and you have DSP System Toolbox software installed, filter designer incorporates features that are added by DSP System Toolbox software. With DSP System Toolbox software installed, filter designer lets you design and analyze quantized filters, as well as convert quantized filters to various filter structures, transform filters, design multirate filters, and realize models of filters.

Use the buttons on the sidebar to configure the design area to use various tools in the filter designer app.

**Set Quantization Parameters** — provides access to the properties of the quantizers that compose a quantized filter. When you click **Set Quantization Parameters**, you see filter designer displaying the quantization options at the bottom of the dialog box (the design area), as shown in the figure.

**Transform Filter** — clicking this button opens the *Frequency Transformations* pane so you can use digital frequency transformations to change the magnitude response of your filter.

**Create a multirate filter** — clicking this button switches filter designer to multirate filter design mode so you can design interpolators, decimators, and fractional rate change filters.

**Realize Model** — starting from your quantized, direct-form, FIR filter, clicking this button creates a Simulink model of your filter structure in new model window.

Other options in the menu bar let you convert the filter structure to a new structure, change the order of second-order sections in a filter, or change the scaling applied to the filter, among many possibilities.

## fdesign

Filter specification object

### Syntax

```
filtSpecs = fdesign.response  
filtSpecs = fdesign.response(spec)  
filtSpecs = fdesign.response(...,Fs)  
filtSpecs = fdesign.response(...,magunits)
```

### Description

#### Filter Specification Objects

`filtSpecs = fdesign.response` returns a filter specification object, `filtSpecs`, of filter response *response*. To create filters from `filtSpecs`, use one of the design methods listed in “Using Filter Design Methods with Specification Objects” on page 5-415.

---

**Note** Several of the filter response types described below are only available if your installation includes the DSP System Toolbox. The DSP System Toolbox significantly expands the functionality available for the specification, design, and analysis of filters.

---

Here is how you design filters using `fdesign`.

- 1 Use `fdesign.response` to construct a filter specification object.
- 2 Use `designmethods` to determine which filter design methods work for your new filter specification object.
- 3 Use `design` to apply your filter design method from step 2 to your filter specification object to construct a filter object.
- 4 Use `FVTool` to inspect and analyze your filter object.

---

**Note** `fdesign` does not create filters. `fdesign` returns a filter specification object that contains the specifications for a filter, such as the passband cutoff or attenuation in the stopband. To design a filter from a filter specification object `filtSpecs`, use `filtSpecs` with a filter design method such as `butter` — `IIRbutter = design(filtSpecs, 'butter', 'SystemObject', true)`.

---

*response* can be one of the entries in the following table that specify the filter response desired, such as a bandstop filter or an interpolator.

<b>fdesign Response Method</b>	<b>Description</b>
<code>arbgrpdelay</code>	<code>fdesign.arbgrpdelay</code> creates an object to specify allpass arbitrary group delay filters. Requires the DSP System Toolbox
<code>arbmag</code>	<code>fdesign.arbmag</code> creates an object to specify IIR filters that have arbitrary magnitude responses defined by the input arguments.
<code>arbmagnphase</code>	<code>fdesign.arbmagnphase</code> creates an object to specify IIR filters that have arbitrary magnitude and phase responses defined by the input arguments. Requires the DSP System Toolbox.
<code>audioweighting</code>	<code>fdesign.audioweighting</code> creates a filter specification object for audio weighting filters. The supported audio weighting types are: A, C, C-message, ITU-T 0.41, and ITU-R 468-4 weighting. Requires the DSP System Toolbox
<code>bandpass</code>	<code>fdesign.bandpass</code> creates an object to specify bandpass filters.
<code>bandstop</code>	<code>fdesign.bandstop</code> creates an object to specify bandstop filters.
<code>ciccomp</code>	<code>fdesign.ciccomp</code> creates an object to specify filters that compensate for the CIC decimator or interpolator response curves. Requires the DSP System Toolbox.
<code>comb</code>	<code>fdesign.comb</code> creates an object to specify a notching or peaking comb filter. Requires the DSP System Toolbox.
<code>decimator</code>	<code>fdesign.decimator</code> creates an object to specify decimators. Requires the DSP System Toolbox

<b>fdesign Response Method</b>	<b>Description</b>
<code>differentiator</code>	<code>fdesign.differentiator</code> creates an object to specify an FIR differentiator filter.
<code>fracdelay</code>	<code>fdesign.fracdelay</code> creates an object to specify fractional delay filters. Requires the DSP System Toolbox.
<code>halfband</code>	<code>fdesign.halfband</code> creates an object to specify halfband filters. Requires the DSP System Toolbox.
<code>highpass</code>	<code>fdesign.highpass</code> creates an object to specify highpass filters.
<code>hilbert</code>	<code>fdesign.hilbert</code> creates an object to specify an FIR Hilbert transformer.
<code>interpolator</code>	<code>fdesign.interpolator</code> creates an object to specify interpolators. Requires the DSP System Toolbox.
<code>isinchp</code>	<code>fdesign.isinchp</code> creates an object to specify an inverse sinc highpass filter. Requires the DSP System Toolbox.
<code>isinclp</code>	<code>fdesign.isinclp</code> creates an object to specify an inverse sinc lowpass filters. Requires the DSP System Toolbox.
<code>lowpass</code>	<code>fdesign.lowpass</code> creates an object to specify lowpass filters.
<code>notch</code>	<code>fdesign.notch</code> creates an object to specify notch filters. Requires the DSP System Toolbox.
<code>nyquist</code>	<code>fdesign.nyquist</code> creates an object to specify Nyquist filters. Requires the DSP System Toolbox.
<code>octave</code>	<code>fdesign.octave</code> creates an object to specify octave and fractional octave filters. Requires the DSP System Toolbox.
<code>parameq</code>	<code>fdesign.parameq</code> creates an object to specify parametric equalizer filters. Requires the DSP System Toolbox.
<code>peak</code>	<code>fdesign.peak</code> creates an object to specify peak filters. Requires the DSP System Toolbox.
<code>polysrc</code>	<code>fdesign.polysrc</code> creates an object to specify polynomial sample-rate converter filters. Requires the DSP System Toolbox.

fdesign Response Method	Description
rsrc	fdesign.rsrc creates an object to specify rational-factor sample-rate convertors. Requires the DSP System Toolbox.

Use the doc `fdesign.response` syntax at the MATLAB prompt to get help on a specific structure. Using doc in a syntax like

```
doc fdesign.lowpass
doc fdesign.bandstop
```

gets more information about the lowpass or bandstop structure objects.

Each response has a property `Specification` that defines the specifications to use to design your filter. You can use defaults or specify the `Specification` property when you construct the specifications object.

Using the `Specification` property, you can provide filter constraints such as the filter order or the passband attenuation to use when you construct your filter from the specification object.

## Properties

fdesign returns a filter specification object. Every filter specification object has the following properties.

Property Name	Default Value	Description
Response	Depends on the chosen type	Defines the type of filter to design, such as an interpolator or bandpass filter. This is a read-only value.
Specification	Depends on the chosen type	Defines the filter characteristics used to define the desired filter performance, such as the cutoff frequency $F_c$ or the filter order $N$ .

Property Name	Default Value	Description
Description	Depends on the filter type you choose	Contains descriptions of the filter specifications used to define the object, and the filter specifications you use when you create a filter from the object. This is a read-only value.
NormalizedFrequency	Logical true	Determines whether the filter calculation uses normalized frequency from 0 to 1, or the frequency band from 0 to $F_s/2$ , the sampling frequency. Accepts either <code>true</code> or <code>false</code> without single quotation marks. Audio weighting filters do not support normalized frequency.

In addition to these properties, filter specification objects may have other properties as well, depending on whether they design single-rate filters or multirate filters.

Added Properties for Multirate Filters	Description
DecimationFactor	Specifies the amount to decrease the sampling rate. Always a positive integer.
InterpolationFactor	Specifies the amount to increase the sampling rate. Always a positive integer.
PolyphaseLength	Polyphase length is the length of each polyphase subfilter that composes the decimator or interpolator or rate-change factor filters. Total filter length is the product of <code>p<sub>l</sub></code> and the rate change factors. <code>p<sub>l</sub></code> must be an even integer.

`filtSpecs = fdesign.response(spec)`. In `spec`, you specify the variables to use that define your filter design, such as the passband frequency or the stopband attenuation. The specifications are applied to the filter design method you choose to design your filter.

For example, when you create a default lowpass filter specification object, `fdesign.lowpass` sets the passband frequency `Fp`, the stopband frequency `Fst`, the stopband attenuation `Ast`, and the passband ripple `Ap`:

```
filtSpecs = fdesign.lowpass
```

Use without a terminating semicolon to display the filter specifications.

The default specification '`Fp,Fst,Ap,Ast`' is only one of the possible specifications for `fdesign.lowpass`. To see all available specifications:

```
filtSpecs = fdesign.lowpass;  
set(filtSpecs,'Specification')
```

The DSP System Toolbox software supports all available specification options. The Signal Processing Toolbox supports a subset of the specification options. See the reference pages for the filter specification object to determine which specification option your installation supports.

One important note is that the specification option you choose determines which design methods apply to the filter specifications object.

Specifications that do not contain the filter order result in minimum order designs when you invoke the `design` method:

```
filtSpecs = fdesign.lowpass;           % Specification is 'Fp,Fst,Ap,Ast'  
FIRReq = design(filtSpecs,'equiripple','SystemObject',true);  
length(FIRReq.Numerator)             % Returns 43. The filter order is 42  
fvtool(FIRReq)                       % View magnitude
```

`filtSpecs = fdesign.response(...,Fs)` specifies the sampling frequency in Hz to use in the filter specifications. The sampling frequency is a scalar trailing all other input arguments. If you specify a sampling frequency, all frequency specifications are in Hz.

`filtSpecs = fdesign.response(...,magunits)` specifies the units for any magnitude specification you provide in the input arguments. `magunits` can be one of the following options:

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in decibels
- `'squared'` — specify the magnitude in power units

When you omit the `magunits` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Using Filter Design Methods with Specification Objects

After you create a filter specification object, you use a filter design method to implement your filter with a selected algorithm. Use `designmethods` to determine valid design methods for your filter specification object.

```
filtSpecs = fdesign.lowpass('N,Fc,Ap,Ast',10,0.2,0.5,40);
designmethods(filtSpecs)
% Design FIR equiripple filter
FIRReq = design(filtSpecs,'equiripple','SystemObject',true);
```

When you use any of the design methods without providing an output argument, the resulting filter design appears in FVTool by default.

Along with filter design methods, `fdesign` works with supporting methods that help you create filter specification objects or determine which design methods work for a given specifications object.

Supporting Function	Description
<code>setspecs</code>	Set all of the specifications simultaneously.
<code>designmethods</code>	Return the design methods.
<code>designopts</code>	Return the input arguments and default values that apply to a specifications object and method

You can set filter specification values by passing them after the `Specification` argument, or by passing the values without the `Specification`.

Filter object constructors take the input arguments in the same order as `setspecs` and `Specification`. Enter `doc setspecs` at the prompt for more information about using `setspecs`.

When the first input to `fdesign` is not a valid `Specification` option like `'N,Fc'`, `fdesign` assumes that the input argument is a filter specification and applies it using the default `Specification` option — `'Fp,Fst,Ap,Ast'` for a lowpass object, for example.

## Examples

## Design of Lowpass Filter

This example requires the DSP System Toolbox product.

Design a lowpass filter to be used on a signal sampled at 96 kHz. The passband of the filter extends up to 20 kHz. The stopband of the filter starts at 24 kHz. Specify a passband ripple of 0.01 dB and a stopband attenuation of 80 dB. Determine automatically the order required to meet the specifications.

Set up the filter design specifications and determine the available design algorithms.

```
Fs = 96e3;  
Fpass = 20e3;  
Fstop = 24e3;  
Apass = 0.01;  
Astop = 80;
```

```
filtSpecs = fdesign.lowpass(Fpass,Fstop,Apass,Astop,Fs);  
designmethods(filtSpecs)
```

```
Design Methods for class fdesign.lowpass (Fp,Fst,Ap,Ast):
```

```
butter  
cheby1  
cheby2  
ellip  
equiripple  
ifir  
kaiserwin  
multistage
```

Design an equiripple FIR filter and an elliptic IIR filter that meet the specifications. Measure the designs to verify that the filters satisfy the constraints.

```
lpFIR = design(filtSpecs, 'equiripple', 'SystemObject', true);  
lpIIR = design(filtSpecs, 'ellip', 'SystemObject', true);
```

```
FIRmeas = measure(lpFIR)
```

```
FIRmeas =  
Sample Rate      : 96 kHz  
Passband Edge    : 20 kHz  
3-dB Point       : 21.4297 kHz  
6-dB Point       : 21.8447 kHz
```

```

Stopband Edge      : 24 kHz
Passband Ripple   : 0.0092309 dB
Stopband Atten.   : 80.6014 dB
Transition Width   : 4 kHz

```

```
IIRmeas = measure(lpIIR)
```

```

IIRmeas =
Sample Rate       : 96 kHz
Passband Edge     : 20 kHz
3-dB Point        : 20.5524 kHz
6-dB Point        : 20.7138 kHz
Stopband Edge     : 24 kHz
Passband Ripple   : 0.01 dB
Stopband Atten.   : 80 dB
Transition Width   : 4 kHz

```

Estimate and display the computational cost of each filter. The equiripple FIR filter requires many more coefficients than the elliptic IIR filter.

```
FIRcost = cost(lpFIR)
```

```

FIRcost = struct with fields:
    NumCoefficients: 101
    NumStates: 100
    MultiplicationsPerInputSample: 101
    AdditionsPerInputSample: 100

```

```
IIRcost = cost(lpIIR)
```

```

IIRcost = struct with fields:
    NumCoefficients: 20
    NumStates: 10
    MultiplicationsPerInputSample: 20
    AdditionsPerInputSample: 20

```

Visualize the resulting designs with FVTool to compare their properties.

```

fvtool(lpFIR,lpIIR,'Fs',Fs);
legend('FIR Equiripple','Elliptic IIR')

```

### Design of Lowpass Decimator

This example requires the DSP System Toolbox product.

Design a 100-tap FIR lowpass decimator filter that reduces the sample rate of a signal from 60 kHz to 20 kHz. The passband of the filter extends up to 6 kHz. Specify a passband ripple of 0.01 dB and a stopband attenuation of 100 dB.

```
Fs = 60e3;  
N = 99;  
Fpass = 6e3;
```

```
Apass = 0.01;  
Astop = 100;  
M = Fs/20e3;  
  
filtSpecs = fdesign.decimator(M, 'lowpass', 'N,Fp,Ap,Ast',N,Fpass,Apass,Astop,Fs);
```

Design the filter and display information about it.

```
decimFIR = design(filtSpecs, 'equiripple', 'SystemObject', true);  
info(decimFIR)
```

```
ans = 10x56 char array  
'Discrete-Time FIR Multirate Filter (real)'  
'-----'  
'Filter Structure : Direct-Form FIR Polyphase Decimator'  
'Decimation Factor : 3'  
'Polyphase Length : 34'  
'Filter Length : 100'  
'Stable : Yes'  
'Linear Phase : Yes (Type 2)'  
'  
'Arithmetic : double'
```

Visualize the magnitude response of the filter.

```
fvtool(decimFIR, 'Fs', Fs)
```

### Lowpass Butterworth Filter Specification and Design

Use a filter specification object to construct a lowpass Butterworth filter with the default specification, 'Fp,Fst,Ap,Ast'. Specify a passband edge frequency of  $0.4\pi$  rad/sample, a stopband frequency of  $0.5\pi$  rad/sample, a passband ripple of 1 dB, and a stopband attenuation of 80 dB.

```
filtSpecs = fdesign.lowpass(0.4,0.5,1,80);
```

Determine which design methods apply to `filtSpecs`.

```
designmethods(filtSpecs)
```

```
Design Methods for class fdesign.lowpass (Fp,Fst,Ap,Ast):
```

```
butter
cheby1
cheby2
ellip
equiripple
ifir
kaiserwin
multistage
```

You can use `filtSpecs` and the `butter` design method to design a Butterworth filter. Determine the available design options.

```
designoptions(filtSpecs, 'butter')
```

```
ans = struct with fields:
    FilterStructure: {1x6 cell}
    SOSScaleNorm: 'ustring'
    SOSScaleOpts: 'fdopts.sosscaling'
    MatchExactly: {'passband' 'stopband'}
    SystemObject: 'bool'
    DefaultFilterStructure: 'df2sos'
    DefaultMatchExactly: 'stopband'
    DefaultSOSScaleNorm: ''
    DefaultSOSScaleOpts: [1x1 fdopts.sosscaling]
    DefaultSystemObject: 0
```

The filter order necessary to meet a set of design constraints must also be rounded up to an integer value. This loosens some of the constraints, and, as a consequence, some design specifications are met while others are exceeded. The `'MatchExactly'` option allows you to match the passband or stopband exactly while exceeding the specification for the other band. Design the filter so that it matches the passband exactly.

```
IIRbutter = design(filtSpecs, 'butter', 'MatchExactly', 'passband', ...
    'SystemObject', true);
```

Use `FVTool` to visualize the magnitude response of the filter.

```
fvtool(IIRbutter)
```

If you have the DSP System Toolbox software installed, the preceding figure appears with the filter specification mask.

designmethods | designopts | filterBuilder | fvtool

**Introduced in R2009a**

## **fdesign.arbgrpdelay**

Arbitrary group delay filter specification object

### **Syntax**

`D = fdesign.arbgrpdelay(SPEC)`  
`D = fdesign.arbgrpdelay(SPEC, SPEC1, SPEC2, ...)`  
`D = fdesign.arbgrpdelay(N, F, Gd)`  
`D = fdesign.arbgrpdelay(..., Fs)`

### **Description**

Arbitrary group delay filters are allpass filters you can use for correcting phase distortion introduced by other filters. `fdesign.arbgrpdelay` uses an iterative least  $p$ -th norm optimization procedure to minimize the phase response error [1] on page 5-433.

`D = fdesign.arbgrpdelay(SPEC)` specifies an allpass arbitrary group delay filter with the `Specification` property set to `SPEC`. See “Input Arguments” on page 5-425 for a description of supported specifications.

`D = fdesign.arbgrpdelay(SPEC, SPEC1, SPEC2, ...)` initializes the allpass arbitrary group delay filter specification object with specifications `SPEC1`, `SPEC2`, ... See `SPEC` on page 5-0 for a description of supported specifications.

`D = fdesign.arbgrpdelay(N, F, Gd)` specifies an allpass arbitrary group delay filter. The filter order is equal to `N`, frequency vector equal to `F`, and group delay vector equal to `Gd`. See `SPEC` on page 5-0 for a description of the filter order, frequency vector, and group delay vector inputs. See the example “Design an Allpass Filter With an Arbitrary Group Delay” on page 5-429 for an example using this syntax.

`D = fdesign.arbgrpdelay(..., Fs)` specifies the sampling frequency in hertz as a trailing scalar. If you do not specify a sampling frequency, all frequencies are normalized frequencies and group delay values are in samples. If you specify a sampling frequency, group delay values are in seconds.

## Tips

If your arbitrary group delay design produces the error `Poorly conditioned Hessian matrix`, attempt one or more of the following:

- Set the `MaxPoleRadius` IIR lp norm design option to some number less than 1. Set this option when you design your filter with the syntax:

```
design(d,'iirlpnorm','MaxPoleRadius',0.95)
```

See the “Design an Arbitrary Group Delay Filter” on page 5-427 and “Multiband Delay Equalization” on page 5-430 examples for the use of the `MaxPoleRadius` design option.

- Reduce the order of your filter design.

## Input Arguments

### SPEC

Filter specification. SPEC is one of the following two options. The entries are not case sensitive.

- 'N,F,Gd'
- 'N,B,F,Gd'

The filter specifications are defined as follows:

- N — Filter order. This value must be an even positive integer. The numerator and denominator orders are both equal to N. “Allpass Systems” on page 5-432 explains why the numerator and denominator filter orders are equal and the order must be even in `fdesign.arbgrpdelay`.
- F — Frequency vector for the group delay specifications. The elements of the frequency vector must increase monotonically. If you do not specify a sampling frequency, `Fs`, in hertz, the frequencies are normalized frequencies. For a single-band design, the first element of the normalized frequency vector must be zero and the last element must be 1. These correspond to 0 and  $\pi$  radians/sample respectively. For multiband designs, the union of the frequency vectors must range from [0,1].

If you specify a sampling frequency,  $F_s$ , the first element of the frequency vector in a single-band design must be 0. The last element must be the Nyquist frequency,  $F_s/2$ . For multiband designs, the union of the frequency vectors must range from  $[0, F_s/2]$ .

- **Gd** — Group delay vector. A vector with nonnegative elements equal in length to the frequency vector,  $F$ . The elements of **Gd** specify the nonnegative group delay at the corresponding element of the frequency vector,  $F$ .

If you do not specify a sampling frequency,  $F_s$ , in Hertz, the group delays are in samples. If you specify a sampling frequency, the group delays are in seconds.

- **B** — Number of frequency bands. If you use this specification, you must specify a frequency and group delay vector for each band. The union of the frequency vectors must range from  $[0,1]$  in normalized frequency, or  $[0, F_s/2]$  when a sampling frequency is specified. The elements in the union of the frequency bands must be monotonically increasing.

For example:

```
filterorder = 14;
freqband1 = [0 0.1 0.4]; grpdelay1 = [1 2 3];
freqband2 = [0.5 0.8 1]; grpdelay2 = [3 2 1];
D = fdesign.arbgrpdelay('N,B,F,Gd', filterorder, 2, freqband1, grpdelay1, freqband2, grpdelay2);
```

**Default:** 'N, F, Gd'

## **F<sub>s</sub>**

Sampling frequency. Specify the sampling frequency as a trailing positive scalar after all other input arguments. Specifying a sampling frequency forces the group delay units to be in seconds. If you specify a sampling frequency, the first element of the frequency vector must be 0. The last element must be the Nyquist frequency,  $F_s/2$ .

## **Output Arguments**

### **D**

Filter specification object. An allpass arbitrary group delay filter specification object containing the following modifiable properties: **Specification**, **NormalizedFrequency**, **FilterOrder**, **Frequencies**, and **GroupDelay**.

Use the `normalizefreq` method to change the **NormalizedFrequency** property after construction.

## Examples

### Design an Arbitrary Group Delay Filter

Construct a signal consisting of two discrete-time windowed sinusoids (wave packets) with disjoint time support to illustrate frequency dispersion. One discrete-time sinusoid has a frequency of  $\pi/2$  radians/sample and the other has a frequency of  $\pi/4$  radians/sample. There are 9 periods of the higher-frequency sinusoid that precede 5 periods of the lower-frequency signal.

Create the signal.

```
x = zeros(300,1);
x(1:36) = cos(pi/2*(0:35)).*hamming(36)';
x(40:40+39) = cos(pi/4*(0:39)).*hamming(40)';
```

Create an arbitrary group delay filter that delays the higher-frequency wave packet by approximately 100 samples.

```
N = 18;
f = 0:.1:1;
gd = ones(size(f));
```

Delay  $\pi/2$  radians/sample by 100 samples

```
gd(6) = 100;
d = fdesign.arbgrpdelay(N,f,gd);
Hd = design(d,'iirlpnorm','MaxPoleRadius',0.9,'SystemObject',true);
```

Visualize the group delay

```
fvtool(Hd,'analysis','grpdelay');
```

Filter the input signal with the arbitrary group delay filter and illustrate the frequency dispersion. The high-frequency wave packet, which initially preceded the low-frequency wave packet, now occurs later because of the nonconstant group delay.

```
y = Hd(x);
subplot(211)
plot(x); title('Input Signal');
grid on; ylabel('Amplitude');
subplot(212);
plot(y); title('Output Signal'); grid on;
xlabel('Samples'); ylabel('Amplitude');
```

### Design an Allpass Filter With an Arbitrary Group Delay

```

N = 10;
f = [0 0.02 0.04 0.06 0.08 0.1 0.25 0.5 0.75 1];
g = [5 5 5 5 5 5 4 3 2 1];
w = [2 2 2 2 2 2 1 1 1 1];
hgd = fdesign.arbgrpdelay(N,f,g);
Hgd = design(hgd,'iirlpnorm','Weights',w,'MaxPoleRadius',0.95,...
    'SystemObject',true);
fvtool(Hgd,'Analysis','grpdelay') ;

```

### Multiband Delay Equalization

Perform multiband delay equalization outside the stopband.

```

Fs = 1e3;
Hcheby2 = design(fdesign.bandstop('N,Fst1,Fst2,Ast',10,150,400,60,Fs),'cheby2',...
    'SystemObject',true);
f1 = 0.0:0.5:150; % Hz

## Definitions

### Group Delay in Discrete-Time Filter Design

The frequency response of a rational discrete-time filter is:

$$H(e^{j\omega}) = \frac{B(e^{j\omega})}{A(e^{j\omega})}$$

The argument of the frequency response as a function of the angle,  $\omega$ , is referred to as the *phase response*.

The negative of the first derivative of the argument with respect to  $\omega$  is the group delay.

$$\tau(\omega) = -\frac{d}{d\omega} \text{Arg}(H(e^{j\omega}))$$

Systems with nonlinear phase responses have nonconstant group delay, which causes dispersion of the frequency components of the signal. You may not want this phase distortion even if the magnitude distortion introduced by the filter produces the desired effect. See “Design an Arbitrary Group Delay Filter” on page 5-427 for an illustration of frequency dispersion resulting from nonconstant group delay.

In these cases, you can cascade the frequency-selective filter with an allpass filter that compensates for the group delay. This process is often referred to as *delay equalization*.

### Allpass Systems

The general form of an allpass system function with a real-valued impulse response is:

$$H_{ap}(z) = \prod_{k=1}^M \frac{z^{-1} - d_k}{1 - d_k z^{-1}} \prod_{k=1}^N \frac{(z^{-1} - c_k)(z^{-1} - c_k^*)}{(1 - c_k z^{-1})(1 - c_k^* z^{-1})}$$

where the  $d_k$  denote the real-valued poles and the  $c_k$  denote the complex-valued poles, which occur in conjugate pairs.

The preceding equation demonstrates that allpass systems with real-valued impulse responses have  $2N+M$  zeros and poles. The poles and zeros occur in pairs with reciprocal magnitudes. The filter order is always the same for the numerator and denominator.

Because `fdesign.arbgrpdelay` uses robust second-order section (biquad) filter structures to implement the allpass arbitrary group delay filter, the filter order must be even.

## Algorithms

`fdesign.arbgrpdelay` uses a least  $p$ -th norm iterative optimization described in [1] on page 5-433.

## Alternatives

`iirgrpdelay` — Returns an allpass arbitrary group delay filter. The `iirgrpdelay` function returns the numerator and denominator coefficients. This behavior differs from that of `fdesign.arbgrpdelay`, which returns the filter in second-order sections. `iirgrpdelay` accepts only normalized frequencies.

## Topics

“Design a Filter in Fdesign — Process Overview”

**Introduced in R2011b**

## **fdesign.arbmag**

Arbitrary response magnitude filter specification object

### **Syntax**

```
D= fdesign.arbmag
D= fdesign.arbmag(SPEC)
D = fdesign.arbmag(SPEC,specvalue1,specvalue2,...)
D = fdesign.arbmag(specvalue1,specvalue2,specvalue3)
D = fdesign.arbmag(...,Fs)
```

### **Description**

D= fdesign.arbmag constructs an arbitrary magnitude filter specification object D.

D= fdesign.arbmag(SPEC) initializes the `Specification` property to SPEC. The input argument SPEC must be one of the entries shown in the following table. Specification entries are not case sensitive.

---

**Note** Specification entries marked with an asterisk require the DSP System Toolbox software.

---

- 'N,F,A' — Single band design (default)
- 'F,A,R' — Single band minimum order design \*
- 'N,B,F,A' — Multiband design
- 'N,B,F,A,C' — Constrained multiband design \*
- 'B,F,A,R' — Multiband minimum order design \*
- 'Nb,Na,F,A' — Single band design \*
- 'Nb,Na,B,F,A' — Multiband design \*

The SPEC entries are defined as follows:

- **A** — Amplitude vector. Values in **A** define the filter amplitude at frequency points you specify in **f**, the frequency vector. If you use **A**, you must use **F** as well. Amplitude values must be real. For complex values designs, use `fdesign.arbmagnphase`.
- **B** — Number of bands in the multiband filter
- **C** — Constrained band flag. This enables you to constrain the passband ripple in your multiband design. You cannot constrain the passband ripple in all bands simultaneously.
- **F** — Frequency vector. Frequency values in specified in **F** indicate locations where you provide specific filter response amplitudes. When you provide **F**, you must also provide **A**.
- **N** — Filter order for FIR filters and the numerator and denominator orders for IIR filters.
- **Nb** — Numerator order for IIR filters
- **Na** — Denominator order for IIR filter designs
- **R** — Ripple

By default, this method assumes that all frequency specifications are supplied in normalized frequency.

## Specifying Frequency and Amplitude Vectors

**F** and **A** are the input arguments you use to define the filter response desired. Each frequency value you specify in **F** must have a corresponding response value in **A**. The following table shows how **F** and **A** are related.

Define the frequency vector **F** as `[0 0.25 0.3 0.4 0.5 0.6 0.7 0.75 1.0]`

Define the response vector **A** as `[1 1 0 0 0 0 0 1 1]`

These specifications connect **F** and **A** as shown here:

<b>F (Normalized Frequency)</b>	<b>A (Response Desired at F)</b>
0	1
0.25	1
0.3	0

F (Normalized Frequency)	A (Response Desired at F)
0.4	0
0.5	0
0.6	0
0.7	0
0.75	1
1.0	1

Different specifications can have different design methods available. Use `designmethods` to get a list of design methods available for a given specification and filter specification object.

Use `designopts` to get a list of design options available for a filter specification object and a given design method. Enter `help(D,METHOD)` to get detailed help on the available design options for a given design method.

`D = fdesign.arbmag(SPEC,specvalue1,specvalue2,...)` initializes the specifications with `specvalue1`, `specvalue2`. Use `get(D,'Description')` for descriptions of the various specifications `specvalue1`, `specvalue2`, ... `specvalueN`.

`D = fdesign.arbmag(specvalue1,specvalue2,specvalue3)` uses the default specification 'N,F,A', setting the filter order, filter frequency vector, and the amplitude vector to the values `specvalue1`, `specvalue2`, and `specvalue3`.

`D = fdesign.arbmag(...,Fs)` specifies the sampling frequency in Hz. All other frequency specifications are also assumed to be in Hz when you specify `Fs`.

## Examples

### Design Multiband Arbitrary-Magnitude Filter

Use `fdesign.arbmag` to design a three-band filter.

- Define the frequency vector `F = [0 0.25 0.3 0.4 0.5 0.6 0.7 0.75 1.0]`.
- Define the response vector `A = [1 1 0 0 0 0 0 1 1]`.

```
N = 150;  
B = 3;  
F = [0 .25 .3 .4 .5 .6 .7 .75 1];  
A = [1 1 0 0 0 0 0 1 1];  
A1 = A(1:2);  
A2 = A(3:7);  
A3 = A(8:end);  
F1 = F(1:2);  
F2 = F(3:7);  
F3 = F(8:end);  
d = fdesign.arbmag('N,B,F,A',N,B,F1,A1,F2,A2,F3,A3);  
Hd = design(d);  
fvtool(Hd)
```

A response with two passbands -- one roughly between 0 and 0.25 and the second between 0.75 and 1 -- results from the mapping between F and A.

### **Design Single-Band Arbitrary-Magnitude Filter**

Use `fdesign.arbmag` to design a single band equiripple filter.

Specify 100 frequency points.

```
n = 120;
f = linspace(0,1,100);

as = ones(1,100)-f*0.2;
absorb = [ones(1,30),1-0.6*bohmanwin(10)',ones(1,5), ...
          1-0.5*bohmanwin(8)',ones(1,47)];
a = as.*absorb;

d = fdesign.arbmag('N,F,A',n,f,a);
hd1 = design(d,'equiripple');
```

Design a minimum-phase equiripple filter. Visualize the poles and zeros of the two filters.

```
hd2 = design(d,'equiripple','MinPhase',true);

hfvtool(hd1,hd2,'Analysis','polezero');
legend(hfvtool,'Equiripple Filter','Minimum-phase Equiripple Filter')
```

### Design Multiband Minimum-Order Arbitrary-Magnitude Filter

Use `fdesign.arbmag` to design a multiband minimum order filter.

Place the notches at  $0.25\pi$  and  $0.55\pi$  rad/sample.

```
d = fdesign.arbmag('B,F,A,R');
d.NBands = 5;
d.B1Frequencies = [0 0.2];
d.B1Amplitudes = [1 1];
d.B1Ripple = 0.25;
```

```
d.B2Frequencies = 0.25;  
d.B2Amplitudes = 0;  
d.B3Frequencies = [0.3 0.5];  
d.B3Amplitudes = [1 1];  
d.B3Ripple = 0.25;  
d.B4Frequencies = 0.55;  
d.B4Amplitudes = 0;  
d.B5Frequencies = [0.6 1];  
d.B5Amplitudes = [1 1];  
d.B5Ripple = 0.25;  
Hd = design(d, 'equiripple');
```

Visualize the frequency response of the resulting filter.

```
fvtool(Hd)
```

### Design Multiband Constrained Arbitrary-Magnitude Filter

Use `fdesign.arbmag` to design a multiband constrained FIR filter.

Force the frequency response at  $0.15\pi$  rad/sample to 0 dB.

```
d = fdesign.arbmag('N,B,F,A,C',82,2);
d.B1Frequencies = [0 0.06 0.1];
d.B1Amplitudes = [0 0 0];
d.B2Frequencies = [0.15 1];
d.B2Amplitudes = [1 1];
```

Design a filter with no constraints.

```
Hd1 = design(d, 'equiripple', 'B2ForcedFrequencyPoints', 0.15);
```

Add a constraint to the first band to increase attenuation.

```
d.B1Constrained = true;  
d.B1Ripple = 0.001;  
Hd2 = design(d, 'equiripple', 'B2ForcedFrequencyPoints', 0.15);
```

Visualize the frequency response.

```
hfvt = fvtool(Hd1, Hd2);  
legend(hfvt, 'Original Design', 'Design with Constrained Stopband Ripple')
```

## fdesign.arbmagnphase

Arbitrary response magnitude and phase filter specification object

### Syntax

```
d = fdesign.arbmagnphase
d = fdesign.arbmagnphase(specification)
d = fdesign.arbmagnphase(specification,specvalue1,specvalue2,...)
d = fdesign.arbmagnphase(specvalue1,specvalue2,specvalue3)
d = fdesign.arbmagnphase(...,fs)
```

### Description

`d = fdesign.arbmagnphase` constructs an arbitrary magnitude filter specification object `d`.

`d = fdesign.arbmagnphase(specification)` initializes the `Specification` property for specifications object `d` to `specification`. The input argument `specification` must be one of the choices shown in the following table. Specification options are not case sensitive.

Specification	Description of Resulting Filter
<code>n, f, h</code>	Single band design (default). FIR and IIR ( <code>n</code> is the order for both numerator and denominator).
<code>n, b, f, h</code>	FIR multiband design where <code>b</code> defines the number of bands.
<code>nb, na, f, h</code>	IIR single band design.

The following table describes the specification arguments.

Argument	Description
<code>b</code>	Number of bands in the multiband filter.

Argument	Description
f	Frequency vector. Frequency values specified in f indicate locations where you provide specific filter response amplitudes. When you provide f you must also provide h which contains the response values.
h	Complex frequency response values.
n	Filter order for FIR filters and the numerator and denominator orders for IIR filters (when not specified by nb and na).
nb	Numerator order for IIR filters.
na	Denominator order for IIR filter designs.

By default, this method assumes that all frequency specifications are supplied in normalized frequency.

## Specifying f and h

f and h are the input arguments you use to define the filter response desired. Each frequency value you specify in f must have a corresponding response value in h. This example creates a filter with two passbands (b = 4) and shows how f and h are related. This example is for illustration only. It is not an actual filter.

Define the frequency vector f as [0 0.1 0.2 0.4 0.5 0.6 0.9 1.0]

Define the response vector h as [0 0.5 0.5 0.1 0.1 0.8 0.8 0]

These specifications connect f and h as shown in the following table.

f (Normalized Frequency)	h (Response Desired at f)
0	0
0.1	0.5
0.2	0.5
0.4	0.1
0.5	0.1
0.6	0.8
0.9	0.8

<b>f (Normalized Frequency)</b>	<b>h (Response Desired at f)</b>
1.0	0.0

A response with two passbands—one roughly between 0.1 and 0.2 and the second between 0.6 and 0.9—results from the mapping between  $f$  and  $h$ . Plotting  $f$  and  $h$  yields the following figure that resembles a filter with two passbands.

The second example in Examples shows this plot in more detail with a complex filter response for  $h$ . In the example,  $h$  uses complex values for the response.

Different specification types often have different design methods available. Use `designmethods(d)` to get a list of design methods available for a given specification option and specifications object.

```
d = fdesign.arbmagnphase(specification,specvalue1,specvalue2,...)
```

initializes the filter specification object with `specvalue1`, `specvalue2`, and so on. Use `get(d, 'description')` for descriptions of the various specifications `specvalue1`, `specvalue2`, ...`specn`.

`d = fdesign.arbmagnphase(specvalue1,specvalue2,specvalue3)` uses the default specification option `n, f, h`, setting the filter order, filter frequency vector, and the complex frequency response vector to the values `specvalue1`, `specvalue2`, and `specvalue3`.

`d = fdesign.arbmagnphase(...,fs)` specifies the sampling frequency in Hz. All other frequency specifications are also assumed to be in Hz when you specify `fs`.

## Examples

### Construct a Complex Analog Filter

Use `fdesign.arbmagnphase` to model a complex analog filter.

```
d = fdesign.arbmagnphase('n,f,h',100); % N=100, f and h set to defaults.  
design(d,'freqsamp','SystemObject',true);
```

For a more complex example, design a bandpass filter with low group delay by specifying the desired delay and using `f` and `h` to define the filter bands.

```
n = 50;      % Group delay of a linear phase filter would be 25.
gd = 12;    % Set the desired group delay for the filter.
f1=linspace(0,.25,30); % Define the first stopband frequencies.
f2=linspace(.3,.56,40); % Define the passband frequencies.
f3=linspace(.62,1,30); % Define the second stopband frequencies.
h1 = zeros(size(f1)); % Specify the filter response at the freqs in f1.
h2 = exp(-1j*pi*gd*f2); % Specify the filter response at the freqs in f2.
h3 = zeros(size(f3)); % Specify the response at the freqs in f3.
d=fdesign.arbmagnphase('n,b,f,h',50,3,f1,h1,f2,h2,f3,h3);
D = design(d,'equiripple','SystemObject',true);
fvtool(D,'Analysis','freq');
```

## fdesign.audioweighting

Audio weighting filter specification object

### Syntax

```
HAwf = fdesign.audioweighting  
HAwf = fdesign.audioweighting(spec)  
HAwf = fdesign.audioweighting(spec,specvalue1,specvalue2)  
HAwf = fdesign.audioweighting(specvalue1,specvalue2)  
HAwf = fdesign.audioweighting(...,Fs)
```

### Description

Supported audio weighting filter types are: A weighting, C weighting, C-message, ITU-T 0.41, and ITU-R 468-4 weighting.

*HAwf* = fdesign.audioweighting constructs an audio weighting filter specification object *HAwf* with a weighting type of A and a filter class of 1. Use the `design` method and set the 'SystemObject' flag to true, to instantiate a System object based on the specifications in *HAwf*. Use `designmethods` to find valid filter design methods. Because the standards for audio weighting filters are in Hz, normalized frequency specifications are not supported for `fdesign.audioweighting` objects. The default sampling frequency for A weighting, C weighting, C-message, and ITU-T 0.41 filters is 48 kHz. The default sampling frequency for the ITU-R 468-4 filter is 80 kHz. If you invoke the `normalizefreq` method, a warning is issued when you instantiate the System object and the default sampling frequencies in Hz are used.

*HAwf* = fdesign.audioweighting(*spec*) returns an audio weighting filter specification object using default values for the specification string in *spec*. The following are valid entries for *spec*. The entries are not case sensitive.

- 'WT,Class' (default *spec*)

The 'WT,Class' specification is valid for A weighting and C weighting filters of class 1 or 2.

The weighting type is specified by the string: 'A' or 'C'. The class is the scalar 1 or 2.

The default values for 'WT,Class' are 'A',1.

- 'WT'

The 'WT' specification is valid for C-message (default), ITU-T 0.41, and ITU-R 468-4 weighting filters.

The weighting type is specified by the string: 'Cmessage', 'ITUT041', or 'ITUR4684'.

*HAwf* = fdesign.audioweighting(*spec,specvalue1,specvalue2*) constructs an audio weighting filter specification object *HAwf* and sets its specifications at construction time.

*HAwf* = fdesign.audioweighting(*specvalue1,specvalue2*) constructs an audio weighting filter specification object *HAwf* with the specification 'WT,Class' using the values you provide. The valid weighting types are 'A' or 'C'.

*HAwf* = fdesign.audioweighting(...,Fs) specifies the sampling frequency in Hz. The sampling frequency is a scalar trailing all other input arguments.

## Input Arguments

### Parameter Name/Value Pairs

#### WT

Weighting type

The weighting type defines the frequency response of the filter. The valid weighting types are: A weighting, C weighting, C-message, ITU-T 0.41, and ITU-R 468-4 weighting. The weighting types are described in “Definitions” on page 5-455.

#### Class

Filter Class

Filter class is only applicable for A weighting and C weighting filters. The filter class describes the frequency-dependent tolerances specified in the relevant standards [1], [2].

There are two possible class values: 1 and 2. Class 1 weighting filters have stricter tolerances than class 2 filters. The filter class value does not affect the design. The class value is only used to provide a specification mask in `fvtool` for the analysis of the filter design.

**Default:** 1

## Examples

### Compare Class 1 A and ITU-R 468-4 Weighting Filters

Compare class 1 A weighting and ITU-R 468-4 filters between 0.1 and 12 kHz. %  
Sampling frequency is 44.1 kHz

```
HawfA = fdesign.audioweighting('WT,Class','A',1,44.1e3);  
HawfITUR = fdesign.audioweighting('WT','ITUR4684',44.1e3);  
Afilter = design(HawfA,'SystemObject',true);  
ITURfilter = design(HawfITUR,'SystemObject',true);  
hfvt = fvtool(Afilter,ITURfilter);  
axis([0.1 12 -80 20]);  
legend(hfvt,'A-weighting','ITU-R 468-4');
```

### Compare C-message and ITU-T 0.41 Weighting Filters

```
hCmessage = fdesign.audioweighting('WT','Cmessage',24e3);
hITUT = fdesign.audioweighting('WT','ITUT041',24e3);
dCmessage = design(hCmessage,'SystemObject',true);
dITUT = design(hITUT,'SystemObject',true);
hfvt = fvtool(dCmessage,dITUT);
legend(hfvt,'C-Message Weighting','ITU-T 0.41 Weighting');
axis([0.1 10 -50 5]);
```

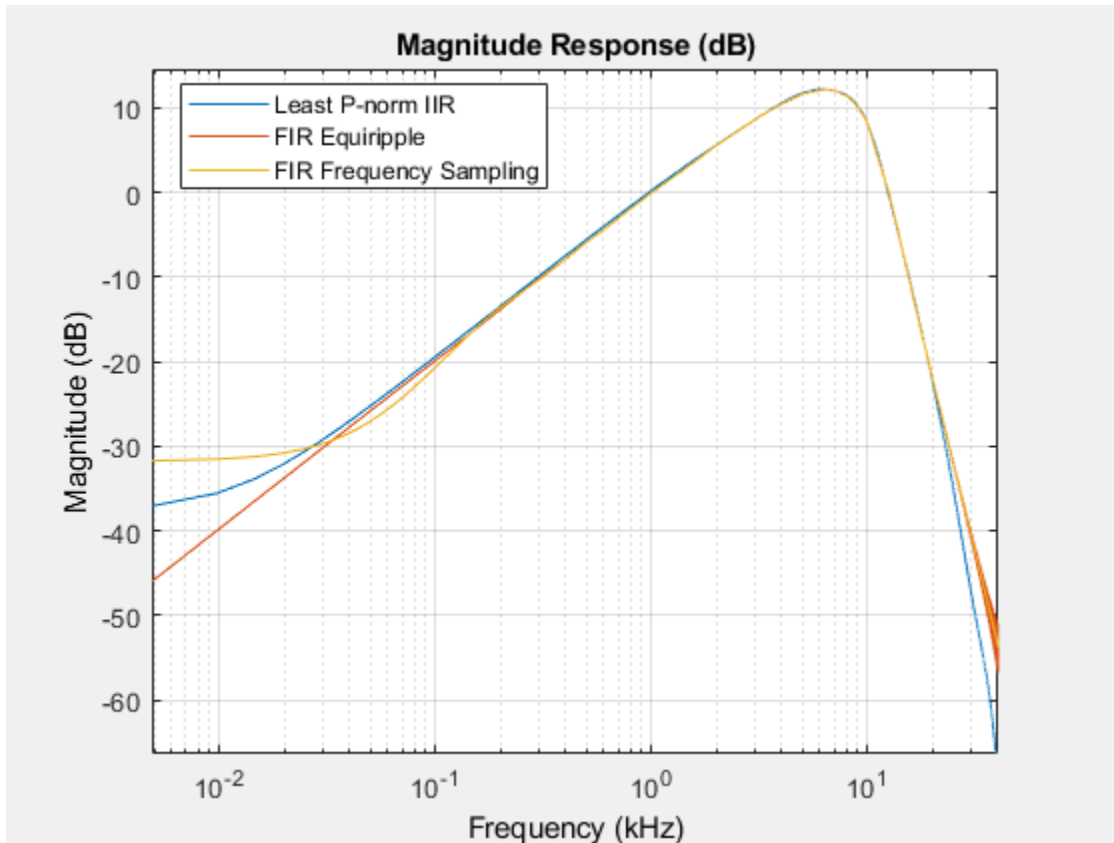

### Construct an ITU-R 468-4 Weighting Filter

Construct an ITU-R 468-4 filter using all available design methods.

```

HAwf = fdesign.audioweighting('WT','ITUR4684');
ValidDesigns = designmethods(HAwf);
% returns iirlpnorm,equiripple,freqsamp in cell array
D = design(HAwf,'all','SystemObject',true); % returns all designs
hfvt = fvtool(D{1},D{2},D{3});
legend(hfvt,'Least P-norm IIR','FIR Equiripple',...,
'FIR Frequency Sampling')

```

## Definitions

### A weighting

The specifications for the A weighting filter are found in ANSI standard S1.42-2001. The A weighting filter is based on the 40-phon Fletcher-Munson equal loudness contour [3]. One phon is equal to one dB sound pressure level (SPL) at one kHz. The Fletcher-Munson equal loudness contours are designed to account for frequency and level dependent differences in the perceived loudness of tonal stimuli. The 40-phon contour reflects the fact that the human auditory system is more sensitive to frequencies around 1-2 kHz than

lower and higher frequencies. The filter roll off is more pronounced at lower frequencies and more modest at higher frequencies. While A weighting is based on the equal loudness contour for low-level (40-phon) tonal stimuli, it is commonly used in the United States for assessing potential health risks associated with noise exposure to narrowband and broadband stimuli at high levels.

### **C weighting**

The specifications for the C weighting filter are found in ANSI standard S1.42-2001. The C weighting filter approximates the 100-phon Fletcher-Munson equal loudness contour for tonal stimuli. The C weighting magnitude response is essentially flat with 3-dB frequencies at 31.5 Hz and 8000 Hz. While C weighting is not as common as A weighting, sound level meters frequently have a C weighting filter option.

### **C-message**

The specifications for the C-message weighting filter are found in Bell System Technical Reference, PUB 41009. C-message weighting filters are designed for measuring the impact of noise on telecommunications circuits used in speech transmission [6]. C-message weighting filters are commonly used in North America, while the ITU-T 0.41 filter is more commonly used outside of North America.

### **ITU-R 468-4**

The specifications for the ITU-R 468-4 weighting filter are found in the International Telecommunication Union Recommendation ITU-R BS.468-4. ITU-R 468-4 is an equal loudness contour weighting filter. Unlike the A weighting filter, the ITU-R 468-4 filter describes subjective loudness judgements for broadband stimuli [4]. A common criticism of the A weighting filter is that it underestimates the loudness judgement of real-world stimuli particularly in the frequency band from about 1–9 kHz. A comparison of A weighting and ITU-R 468-4 weighting curves shows that the ITU-R 468-4 curve applies more gain between 1 and 10 kHz with a peak difference of approximately 12 dB around 6–7 kHz.

### **ITU-T 0.41**

The specifications for the ITU-T 0.41 filter are found in the ITU-T Recommendation 0.41. ITU-T 0.41 weighting filters are designed for measuring the impact of noise on

telecommunications circuits used in speech transmission [5]. ITU-T 0.41 weighting filters are commonly used outside of North America, while the C-message weighting filter is more common in North America.

Audio Weighting Filters Example  
"Design a Filter in Fdesign — Process Overview"

**Introduced in R2011a**

## **fdesign.bandpass**

Bandpass filter specification object

### **Syntax**

```
D = fdesign.bandpass
D = fdesign.bandpass(SPEC)
D = fdesign.bandpass(spec,specvalue1,specvalue2,...)
D = fdesign.bandpass(specvalue1,specvalue2,specvalue3,
specvalue4,...specvalue4,specvalue5,specvalue6)
D = fdesign.bandpass(...,Fs)
D = fdesign.bandpass(...,MAGUNITS)
```

### **Description**

`D = fdesign.bandpass` constructs a bandpass filter specification object `D`, applying default values for the properties `Fstop1`, `Fpass1`, `Fpass2`, `Fstop2`, `Astop1`, `Apass`, and `Astop2` — one possible set of values you use to specify a bandpass filter.

`D = fdesign.bandpass(SPEC)` constructs object `D` and sets its `Specification` property to `SPEC`. Entries in the `SPEC` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` are shown below and used to define the bandpass filter. These entries are not case sensitive.

---

**Note** Specifications marked with an asterisk require the DSP System Toolbox software.

---

- 'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2' (default spec)
- 'N,F3dB1,F3dB2'
- "N,F3dB1,F3dB2,Ap" \*
- 'N,F3dB1,F3dB2,Ast' \*
- 'N,F3dB1,F3dB2,Ast1,Ap,Ast2' \*
- 'N,F3dB1,F3dB2,Bwp' \*

- 'N,F3dB1,F3dB2,BWst' \*
- 'N,Fc1,Fc2'
- 'N,Fc1,Fc2,Ast1,Ap,Ast2'
- 'N,Fp1,Fp2,Ap'
- 'N,Fp1,Fp2,Ast1,Ap,Ast2'
- 'N,Fst1,Fp1,Fp2,Fst2'
- 'N,Fst1,Fp1,Fp2,Fst2,C' \*
- 'N,Fst1,Fp1,Fp2,Fst2,Ap' \*
- 'N,Fst1,Fst2,Ast'
- 'Nb,Na,Fst1,Fp1,Fp2,Fst2' \*

The filter specifications are defined as follows:

- **Ap** — amount of ripple allowed in the pass band. Also called **Apass**.
- **Ast1** — attenuation in the first stop band in decibels (the default units). Also called **Astop1**.
- **Ast2** — attenuation in the second stop band in decibels (the default units). Also called **Astop2**.
- **BWp** — bandwidth of the filter passband. Specified in normalized frequency units.
- **BWst** — bandwidth of the filter stopband. Specified in normalized frequency units.
- **C** — Constrained band flag. This enables you to specify passband ripple or stopband attenuation for fixed-order designs in one or two of the three bands.

In the specification 'N,Fst1,Fp1,Fp2,Fst2,C', you cannot specify constraints in both stopbands and the passband simultaneously. You can specify constraints in any one or two bands.

- **F3dB1** — cutoff frequency for the point 3 dB point below the passband value for the first cutoff. Specified in normalized frequency units. (IIR filters)
- **F3dB2** — cutoff frequency for the point 3 dB point below the passband value for the second cutoff. Specified in normalized frequency units. (IIR filters)
- **Fc1** — cutoff frequency for the point 6 dB point below the passband value for the first cutoff. Specified in normalized frequency units. (FIR filters)
- **Fc2** — cutoff frequency for the point 6 dB point below the passband value for the second cutoff. Specified in normalized frequency units. (FIR filters)

- $F_{p1}$  — frequency at the edge of the start of the pass band. Specified in normalized frequency units. Also called  $F_{pass1}$ .
- $F_{p2}$  — frequency at the edge of the end of the pass band. Specified in normalized frequency units. Also called  $F_{pass2}$ .
- $F_{st1}$  — frequency at the edge of the start of the first stop band. Specified in normalized frequency units. Also called  $F_{stop1}$ .
- $F_{st2}$  — frequency at the edge of the start of the second stop band. Specified in normalized frequency units. Also called  $F_{stop2}$ .
- $N$  — filter order for FIR filters. Or both the numerator and denominator orders for IIR filters when  $n_a$  and  $n_b$  are not provided.
- $N_a$  — denominator order for IIR filters
- $N_b$  — numerator order for IIR filters

Graphically, the filter specifications look similar to those shown in the following figure.

Regions between specification values like  $F_{st1}$  and  $F_{p1}$  are transition regions where the filter response is not explicitly defined.

The filter design methods that apply to a bandpass filter specification object change depending on the `Specification`. Use `designmethods` to determine which design methods apply to an object and the `Specification` property value.

Use `designopts` to determine the design options for a given design method. Enter `help(D,METHOD)` at the MATLAB command line to obtain detailed help on the design options for a given design method, `METHOD`.

`D = fdesign.bandpass(spec,specvalue1,specvalue2,...)` constructs an object `D` and sets its specifications at construction time.

`D = fdesign.bandpass(specvalue1,specvalue2,specvalue3,specvalue4,...specvalue4,specvalue5,specvalue6)` constructs `D` with the default `Specification` property, using the values you provide as input arguments for `specvalue1`, `specvalue2`, `specvalue3`, `specvalue4`, `specvalue4`, `specvalue5`, `specvalue6` and `specvalue7`.

`D = fdesign.bandpass(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`D = fdesign.bandpass(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- 'linear' — specify the magnitude in linear units
- 'dB' — specify the magnitude in dB (decibels)
- 'squared' — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

### Bandpass Filtering of Sinusoids

Filter a discrete-time signal with a bandpass filter. The signal is a sum of three discrete-time sinusoids,  $\pi/8$ ,  $\pi/2$ , and  $3\pi/4$  rad/sample.

```
n = 0:159;
x = cos(pi/8*n)+cos(pi/2*n)+sin(3*pi/4*n);
```

Design an FIR equiripple bandpass filter to remove the lowest and highest discrete-time sinusoids. View the frequency response of the filter.

```
d = fdesign.bandpass('Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2', ...
    1/4,3/8,5/8,6/8,60,1,60);
```

```
Hd = design(d,'equiripple');
freqz(Hd)
```

Apply the filter to the discrete-time signal. Plot the original and filtered signals in the frequency domain.

```
y = filter(Hd,x);
freq = 0:(2*pi)/length(x):pi;
xdft = fft(x);
ydft = fft(y);

plot(freq/pi,abs(xdft(1:length(x)/2+1)))
hold on
```

```

plot(freq/pi,abs(ydft(1:length(x)/2+1)))
hold off
xlabel('Normalized Frequency (\times\pi rad/sample)')
legend('Original Signal','Bandpass Signal')

```

### Butterworth Bandpass Filter

Design an IIR Butterworth filter of order 10 with 3-dB frequencies of 1 and 1.2 kHz. The sample rate is 10 kHz. Visualize the frequency response of the filter.

```

d = fdesign.bandpass('N,F3dB1,F3dB2',10,1e3,1.2e3,1e4);
Hd = design(d,'butter');

```

```
fvtool(Hd)
```

### Equiripple FIR Passband Filter

Design a constrained-band FIR equiripple filter of order 100 with a passband of [1, 1.4] kHz. Both stopband attenuation values are constrained to 60 dB. The sample rate is 10 kHz.

```
d = fdesign.bandpass('N,Fst1,Fp1,Fp2,Fst2,C',100,800,1e3,1.4e3,1.6e3,1e4);  
d.Stopband1Constrained = true;
```

```
d.Astop1 = 60;  
d.Stopband2Constrained = true;  
d.Astop2 = 60;
```

```
Hd = design(d,'equiripple');
```

Visualize and measure the magnitude response of the filter.

```
fvtool(Hd)
```

```
measure(Hd)
```

```
ans =  
Sample Rate           : 10 kHz  
First Stopband Edge   : 800 Hz
```

```
First 6-dB Point      : 946.7621 Hz
First 3-dB Point     : 975.1807 Hz
First Passband Edge  : 1 kHz
Second Passband Edge : 1.4 kHz
Second 3-dB Point    : 1.4248 kHz
Second 6-dB Point    : 1.4533 kHz
Second Stopband Edge : 1.6 kHz
First Stopband Atten. : 60.0614 dB
Passband Ripple      : 2.1443 dB
Second Stopband Atten. : 60.0399 dB
First Transition Width : 200 Hz
Second Transition Width : 200 Hz
```

The passband ripple is slightly over 2 dB. Because the design constrains both stopbands, you cannot constrain the passband ripple.

# fdesign.bandstop

Bandstop filter specification object

## Syntax

`D = fdesign.bandstop`

`D = fdesign.bandstop(SPEC)`

`D = fdesign.bandstop(SPEC,specvalue1,specvalue2,...)`

`D = fdesign.bandstop(specvalue1,specvalue2,specvalue3,specvalue4,...,specvalue5,specvalue6,specvalue7)`

`D = fdesign.bandstop(...,Fs)`

`D = fdesign.bandstop(...,MAGUNITS)`

## Description

`D = fdesign.bandstop` constructs a bandstop filter specification object `D`, applying default values for the properties `Fpass1`, `Fstop1`, `Fstop2`, `Fpass2`, `Apass1`, `Astop1` and `Apass2`.

`D = fdesign.bandstop(SPEC)` constructs object `D` and sets the `Specification` property to `SPEC`. Entries in `SPEC` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` are shown below. These entries are not case sensitive.

---

**Note** Specification options marked with an asterisk require the DSP System Toolbox software.

---

- 'Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2' (default spec)
- 'N,F3dB1,F3dB2'
- 'N,F3dB1,F3dB2,Ap' \*
- 'N,F3dB1,F3dB2,Ap,Ast' \*
- 'N,F3dB1,F3dB2,Ast' \*

- 'N,F3dB1,F3dB2,Bwp' \*
- 'N,F3dB1,F3dB2,BWst' \*
- 'N,Fc1,Fc2'
- 'N,Fc1,Fc2,Ap1,Ast,Ap2'
- 'N,Fp1,Fp2,Ap'
- 'N,Fp1,Fp2,Ap,Ast'
- 'N,Fp1,Fst1,Fst2,Fp2'
- 'N,Fp1,Fst1,Fst2,Fp2,C' \*
- 'N,Fp1,Fst1,Fst2,Fp2,Ap' \*
- 'N,Fst1,Fst2,Ast'
- 'Nb,Na,Fp1,Fst1,Fst2,Fp2' \*

The filter specifications are defined as follows:

- **Ap** — amount of ripple allowed in the passband in decibels (the default units). Also called **Apass**.
- **Ap1** — amount of ripple allowed in the pass band in decibels (the default units). Also called **Apass1**.
- **Ap2** — amount of ripple allowed in the pass band in decibels (the default units). Also called **Apass2**.
- **Ast** — attenuation in the first stopband in decibels (the default units). Also called **Astop1**.
- **Bwp** — bandwidth of the filter passband. Specified in normalized frequency units.
- **BWst** — bandwidth of the filter stopband. Specified in normalized frequency units.
- **C** — Constrained band flag. This enables you to specify passband ripple or stopband attenuation for fixed-order designs in one or two of the three bands.

In the specification 'N,Fp1,Fst1,Fst2,Fp2,C', you cannot specify constraints simultaneously in both passbands and the stopband. You can specify constraints in any one or two bands.

- **F3dB1** — cutoff frequency for the point 3 dB point below the passband value for the first cutoff.
- **F3dB2** — cutoff frequency for the point 3 dB point below the passband value for the second cutoff.

- $F_{c1}$  — cutoff frequency for the point 6 dB below the passband value for the first cutoff. (FIR filters)
- $F_{c2}$  — cutoff frequency for the point 6 dB below the passband value for the second cutoff. (FIR filters)
- $F_{p1}$  — frequency at the start of the pass band. Also called  $F_{pass1}$ .
- $F_{p2}$  — frequency at the end of the pass band. Also called  $F_{pass2}$ .
- $F_{st1}$  — frequency at the end of the first stop band. Also called  $F_{stop1}$ .
- $F_{st2}$  — frequency at the start of the second stop band. Also called  $F_{stop2}$ .
- $N$  — filter order.
- $N_a$  — denominator order for IIR filters.
- $N_b$  — numerator order for IIR filters.

Graphically, the filter specifications look similar to those shown in the following figure.

Regions between specification values like  $F_{p1}$  and  $F_{st1}$  are transition regions where the filter response is not explicitly defined.

The filter design methods that apply to a bandstop filter specification object change depending on the `Specification`. Use `designmethods` to determine which design methods apply to an object and the `Specification` property value.

Use `designopts` to determine the design options for a given design method. Enter `help(D,METHOD)` at the MATLAB command line to obtain detailed help on the design options for a given design method, `METHOD`.

`D = fdesign.bandstop(SPEC,specvalue1,specvalue2,...)` constructs an object `D` and sets its specifications at construction time.

`D = fdesign.bandstop(specvalue1,specvalue2,specvalue3,specvalue4,...specvalue5,specvalue6,specvalue7)` constructs an object `D` with the default `Specification` property, using the values you provide in `specvalue1,specvalue2,specvalue3,specvalue4,specvalue5,specvalue6` and `specvalue7`.

`D = fdesign.bandstop(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency. If you specify the sampling frequency as a trailing scalar, all frequencies in the specifications are in Hz as well.

`D = fdesign.bandstop(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in dB (decibels)
- `'squared'` — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

### Bandstop Filtering of Sinusoids

Construct a bandstop filter to reject the discrete frequency band between  $3\pi/8$  and  $5\pi/8$  rad/sample. Apply the filter to a discrete-time signal consisting of the superposition of three discrete-time sinusoids.

Design an FIR equiripple filter and view its magnitude response.

```
d = fdesign.bandstop('Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2', ...  
    2/8,3/8,5/8,6/8,1,60,1);  
Hd = design(d,'equiripple');  
  
fvtool(Hd)
```

Construct the discrete-time signal and filter it.

```
n = 0:99;
x = cos(pi/5*n)+sin(pi/2*n)+cos(4*pi/5*n);
y = filter(Hd,x);
```

Plot the original and filtered signals in the frequency domain.

```
xdft = fft(x);
ydft = fft(y);
freq = 0:(2*pi)/length(x):pi;

plot(freq/pi,abs(xdft(1:length(x)/2+1)))
hold on
```

```
plot(freq/pi,abs(ydft(1:length(y)/2+1)),'r','linewidth',2)
hold off
xlabel('Normalized Frequency (\times\pi rad/sample)')
ylabel('Magnitude')
legend('Original Signal','Bandstop Signal')
```

### Butterworth Bandstop Filter

Create a Butterworth bandstop filter for data sampled at 10 kHz. The stopband is [1,1.5] kHz. The order of the filter is 20. Visualize the frequency response.

```
d = fdesign.bandstop('N,F3dB1,F3dB2',20,1e3,1.5e3,1e4);  
Hd = design(d,'butter');  
  
fvtool(Hd)
```

Zoom in on the magnitude response plot to verify that the 3-dB down points are located at 1 and 1.5 kHz.

```
axis([0.5 2 -5 2])
```

### Equiripple FIR Bandstop Filter

Design a constrained-band FIR equiripple filter of order 100 for data sampled at 10 kHz. You can specify constraints on at most two of the three bands: two passbands and one stopband. In this example, constrain the passband ripple to be 0.5 dB in each passband.

```
d = fdesign.bandstop('N,Fp1,Fst1,Fst2,Fp2,C',100,800,1e3,1.5e3,1.7e3,1e4);
d.Passband1Constrained = true; d.Apass1 = 0.5;
d.Passband2Constrained = true; d.Apass2 = 0.5;
Hd = design(d,'equiripple');
```

Visualize the magnitude response and measure the design.

```
fvtool(Hd)
```

```
measure(Hd)
```

```
ans =  
Sample Rate           : 10 kHz  
First Passband Edge   : 800 Hz  
First 3-dB Point      : 852.4565 Hz  
First 6-dB Point      : 881.7834 Hz  
First Stopband Edge   : 1 kHz  
Second Stopband Edge  : 1.5 kHz  
Second 6-dB Point     : 1.6185 kHz  
Second 3-dB Point     : 1.6478 kHz  
Second Passband Edge  : 1.7 kHz
```

```
First Passband Ripple : 0.49642 dB
Stopband Atten.      : 48.8466 dB
Second Passband Ripple : 0.49634 dB
First Transition Width : 200 Hz
Second Transition Width : 200 Hz
```

With this order filter and passband ripple constraints, you achieve approximately 50 dB of stopband attenuation.

**Introduced in R2009a**

# fdesign.ciccomp

CIC compensator filter specification object

## Syntax

```
d= fdesign.ciccomp
d= fdesign.ciccomp(d,nsections,rcic)
d= fdesign.ciccomp(...,spec)
h = fdesign.ciccomp(...,spec,specvalue1,specvalue2,...)
```

## Description

`d= fdesign.ciccomp` constructs a CIC compensator specifications object `d`, applying default values for the properties `Fpass`, `Fstop`, `Apass`, and `Astop`. In this syntax, the filter has two sections and the differential delay is 1.

Using `fdesign.ciccomp` with `design` method creates a System object, if the 'SystemObject' flag is set to `true`.

`d= fdesign.ciccomp(d,nsections,rcic)` constructs a CIC compensator specifications object with the filter differential delay set to `d`, the number of sections in the filter set to `nsections`, and the CIC rate change factor set to `rcic`. The default values of these parameters are: the differential delay equal to 1, the number of sections equal to 2, and the CIC rate change factor equal to 1.

If the CIC rate change factor is equal to 1, the filter passband response is an inverse sinc that is an approximation to the true inverse passband response of the CIC filter.

If you specify a CIC rate change factor not equal to 1, the filter passband response is an inverse Dirichlet sinc that matches exactly the true inverse passband response of the CIC filter.

`d= fdesign.ciccomp(...,spec)` constructs a CIC Compensator specifications object and sets its `Specification` property to `spec`. Entries in the `spec` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `spec` are shown in the list below. The entries are not case sensitive.

- 'fp,fst,ap,ast' (default spec)
- 'n,fc,ap,ast'
- 'n,fp,ap,ast'
- 'n,fp,fst'
- 'n,fst,ap,ast'

The filter specifications are defined as follows:

- **ap** — amount of ripple allowed in the pass band in decibels (the default units). Also called  $A_{pass}$ .
- **ast** — attenuation in the stop band in decibels (the default units). Also called  $A_{stop}$ .
- **fc** — cutoff frequency for the point 6 dB point below the passband value. Specified in normalized frequency units.
- **fp** — frequency at the end of the pass band. Specified in normalized frequency units. Also called  $F_{pass}$ .
- **fst** — frequency at the start of the stop band. Specified in normalized frequency units. Also called  $F_{stop}$ .
- **n** — filter order.

In graphic form, the filter specifications look like this:

Regions between specification values like **fp** and **fst** are transition regions where the filter response is not explicitly defined.

The filter design methods that apply to a CIC compensator specifications object change depending on the `Specification`. Use `designmethods` to determine which design method applies to an object and its specification.

`h = fdesign.ciccomp(...,spec,specvalue1,specvalue2,...)` constructs an object and sets the specifications in the order they are specified in the `spec` input when you construct the object.

## Designing CIC Compensators

Typically, when they develop filters, designers want flat passbands and transition regions that are as narrow as possible. CIC filters present a  $(\sin x/x)$  profile in the passband and relatively wide transitions.

To compensate for this fall off in the passband, and to try to reduce the width of the transition region, you can use a CIC compensator filter that demonstrates an  $(x/\sin x)$  profile in the passband. `fdesign.ciccomp` is specifically tailored to designing CIC compensators.

You can design a compensator for CIC filter using differential delay, `d`, number of sections, `numberofsections`, and the usable passband frequency, `Fpass`.

By taking the number of sections, passband, and differential delay from your CIC filter and using them in the definition of the CIC compensator, the resulting compensator filter effectively corrects for the passband droop of the CIC filter, and narrows the transition region.

As a demonstration of this concept, this example creates a CIC decimator and its compensator.

```
fs = 96e3; % Input sampling frequency.
fpass = 4e3; % Frequency band of interest.
m = 6; % Decimation factor.
hcic = design(fdesign.decimator(m,'cic',1,fpass,60,fs),'SystemObject',true);
hd = design(fdesign.ciccomp(hcic.DifferentialDelay, ...
    hcic.NumSections,fpass,4.5e3,.1,60,fs/m),'SystemObject',true);
fvtool(hcic,hd,...
    cascade(hcic,hd),'ShowReference','off','Fs',[96e3 96e3/m 96e3])
legend('CIC Decimator','CIC Compensator','Resulting Cascade Filter');
```

Here is a plot of a CIC filter and a compensator for that filter.

## Examples

### Design a CIC Compensator Using `fdesign` Object

Designed to compensate for the rolloff inherent in CIC filters, CIC compensators can improve the performance of your CIC design. This example designs a compensator `d` with five sections and a differential delay equal to one. The plot displayed after the code shows the increasing gain in the passband that is characteristic of CIC compensators, to

overcome the droop in the CIC filter passband. Ideally, cascading the CIC compensator with the CIC filter results in a lowpass filter with flat passband response and narrow transition region.

```
h = fdesign.ciccomp;
set(h, 'NumberOfSections', 5, 'DifferentialDelay', 1);
cicComp = design(h, 'equiripple', 'SystemObject', true);
fvtool(cicComp);
```

This compensator would work for a decimator or interpolator that had differential delay of 1 and 5 sections.

**Introduced in R2011a**

# fdesign.comb

IIR comb filter specification object

## Syntax

```
d=fdesign.comb
d=fdesign.comb(combtype)
d=fdesign(combtype,specstring)
d=fdesign(combtype,specstring,specvalue1,specvalue2,...)
d=fdesign.comb(...,Fs)
```

## Description

`fdesign.comb` specifies a peaking or notching comb filter. Comb filters amplify or attenuate a set of harmonically related frequencies.

`d=fdesign.comb` creates a notching comb filter specification object and applies default values for the filter order ( $N=10$ ) and quality factor ( $Q=16$ ).

`d=fdesign.comb(combtype)` creates a comb filter specification object of the specified type and applies default values for the filter order and quality factor. The valid entries for `combtype` are shown in the following table. The entries are not case-sensitive.

Argument	Description
notch	creates a comb filter that attenuates a set of harmonically related frequencies.
peak	creates a comb filter that amplifies a set of harmonically related frequencies.

`d=fdesign(combtype,specstring)` creates a comb filter specification object of type `combtype` and sets its `Specification` property to `specstring` with default values. The entries in `specstring` determine the number of peaks or notches in the comb filter as well as their bandwidth and slope. Valid entries for `specstring` are shown below. The entries are not case-sensitive.

- 'N,Q' (default)
- ''N,BW'
- 'L,BW,GWB,Nsh'

The following table describes the arguments in *specstring*.

Argument	Description
BW	Bandwidth of the notch or peak. By default the bandwidth is calculated at the point -3 dB down from the center frequency of the peak or notch. For example, setting <code>BW=0.01</code> specifies that the -3 dB point will be +/- 0.005 (in normalized frequency) from the center of the notch or peak.
GWB	Gain at which the bandwidth is measured. This allows the user to specify the bandwidth of the notch or peak at a gain different from the -3 dB default.
L	Upsampling factor for a shelving filter of order Nsh. L determines the number of peaks or notches, which are equally spaced over the normalized frequency interval [-1,1].
N	Filter order. Specifies a filter with N+1 numerator and denominator coefficients. The filter will have N peaks or notches equally spaced over the interval [-1,1].
Nsh	Shelving filter order. Nsh represents a positive integer that determines the sharpness of the peaks or notches. The greater the value of the shelving filter order, the steeper the slope of the peak or notch. This results in a filter of order $L*Nsh$ .

Argument	Description
Q	Peak or notch quality factor. Q represents the ratio of the lowest center frequency peak or notch (not including DC) to the bandwidth calculated at the -3 dB point.

`d=fdesign(combtype,specstring,specvalue1,specvalue2,...)` creates an IIR comb filter specification object of type `combtype` and sets its `Specification` property to the values in `specvalue1,specvalue2,...`

`d=fdesign.comb(...,Fs)` creates an IIR comb filter specification object using the sampling frequency, `Fs`, of the signal to be filtered. The function assumes that `Fs` is in Hertz and must be specified as a scalar trailing all other provided values.

## Examples

### Construct a Peaking and Notching Combing Filter

These examples demonstrate how to create IIR comb filter specification objects.

First, create a default specification object.

```
d = fdesign.comb; %#ok
```

In the next example, create a notching filter of order 8 with a bandwidth of 0.02 (normalized frequency) referenced to the -3 dB point.

```
d = fdesign.comb('notch','N,BW',8,0.02);
Hd = design(d,'SystemObject',true);
fvtool(Hd);
```

Next, create a peaking comb filter with 5 peaks and a quality factor of 25.

```
d = fdesign.comb('peak','N,Q',5,25);  
Hd = design(d,'SystemObject',true);  
fvtool(Hd);
```

In the next example, create a notching filter to remove interference at 60 Hz and its harmonics. The following code creates a filter with 10 notches and a notch bandwidth of 5 Hz referenced to the -4dB level. The filter has a shelving filter order of 4 and a sampling frequency of 600 Hz. Because the notches are equidistantly spaced in the interval [-300, 300] Hz, they occur at multiples of 60 Hz.

```
d = fdesign.comb('notch', 'L,BW,GBW,Nsh', 10, 5, -4, 4, 600);
Hd=design(d, 'SystemObject', true);
fvtool(Hd);
```

**Introduced in R2011a**

# fdesign.decimator

Decimator filter specification object

## Syntax

```
D = fdesign.decimator(M)
D = fdesign.decimator(M, RESPONSE)
D = fdesign.decimator(M, CICRESPONSE, D)
D = fdesign.decimator(M, RESPONSE, SPEC)
D = fdesign.decimator(..., SPEC, specvalue1, specvalue2, ...)
D = fdesign.decimator(..., Fs)
D = fdesign.decimator(..., MAGUNITS)
```

## Description

`D = fdesign.decimator(M)` constructs a decimator filter specification object `D` with the `DecimationFactor` property equal to the positive integer `M` and the `Response` property set to `'Nyquist'`. The default values for the transition width and stopband attenuation in the Nyquist design are  $0.1\pi$  radians/sample and 80 dB. If `M` is unspecified, `M` defaults to 2.

`D = fdesign.decimator(M, RESPONSE)` constructs a decimator specification object with the decimation factor `M` and the `'Response'` property.

`D = fdesign.decimator(M, CICRESPONSE, D)` constructs a CIC or CIC compensator decimator specification object with the decimation factor, `M`, `'Response'` property equal to `'CIC'` or `'CICCOMP'`, and `D` equal to the differential delay. The differential delay, `D`, must precede any specification option.

Because you are designing multirate filters, the specification options available are not the same as the specifications for designing single-rate filters. The decimation factor `M` is not included in the specification options. Different filter responses support different specifications. The following table lists the supported response types and specification options. The options are not case sensitive.

Design Method	Valid Specification Options
'Arbitrary Magnitude'	<p>See <code>fdesign.arbmag</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'N,F,A' (default option)</li> <li>• 'N,B,F,A'</li> </ul>
'Arbitrary Magnitude and Phase'	<p>See <code>fdesign.arbmagnphase</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'N,F,H' (default option)</li> <li>• 'N,B,F,H'</li> </ul>
'Bandpass'	<p>See <code>fdesign.bandpass</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2' (default option)</li> <li>• 'N,Fc1,Fc2'</li> <li>• 'N,Fst1,Fp1,Fp2,Fst2'</li> </ul>
'Bandstop'	<p>See <code>fdesign.bandstop</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'N,Fc1,Fc2'</li> <li>• 'N,Fp1,Fst1,Fst2,Fp2'</li> <li>• 'Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2' (default option)</li> </ul>
'CIC'	<p>'Fp,Ast' — Only valid specification. Fp is the passband frequency and Ast is the stopband attenuation in decibels.</p> <p>To specify a CIC decimator, include the differential delay after 'CIC' and before the filter specification option: 'Fp,Ast'.</p> <p>For example:</p> <pre>d = fdesign.decimator(2,'cic',4,'Fp,Ast',0.4,40);</pre>

Design Method	Valid Specification Options
'CIC Compensator'	<p>See <code>fdesign.ciccomp</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'Fp,Fst,Ap,Ast' (default option)</li> <li>• 'N,Fc,Ap,Ast'</li> <li>• 'N,Fp,Ap,Ast'</li> <li>• 'N,Fp,Fst'</li> <li>• 'N,Fst,Ap,Ast'</li> </ul> <p>To specify a CIC compensator decimator, include the differential delay after 'CICCOMP' and before the filter specification. For example:  <code>d = fdesign.decimator(2,'ciccomp',4);</code></p>
'Differentiator'	'N' — filter order
'Gaussian'	<p>'Nsym,BT — Nsym is the filter order in symbols and BT is the bandwidth-symbol time product.</p> <p>The specification must be preceded by an integer-valued <code>SamplesPerSymbol</code>.</p>
'Halfband'	<p>See <code>fdesign.halfband</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'TW,Ast' (default option)</li> <li>• 'N,TW'</li> <li>• 'N'</li> <li>• 'N,Ast'</li> </ul> <p>If you use the quasi-linear IIR design method, <code>iirlinphase</code>, with a halfband specification, the interpolation factor must be 2.</p>

<b>Design Method</b>	<b>Valid Specification Options</b>
'Highpass'	<p>See <code>fdesign.highpass</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'Fst,Fp,Ast,Ap' (default option)</li> <li>• 'N,F3db'</li> <li>• 'N,Fc'</li> <li>• 'N,Fc,Ast,Ap'</li> <li>• 'N,Fp,Ast,Ap'</li> <li>• 'N,Fst,Ast,Ap'</li> <li>• 'N,Fst,Fp'</li> <li>• 'N,Fst,Ast,Ap'</li> <li>• 'N,Fst,Fp,Ast'</li> </ul>
'Hilbert'	<p>See <code>fdesign.hilbert</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'N,TW' (default option)</li> <li>• 'TW,Ap'</li> </ul>
'Inverse-sinc Lowpass'	<p>See <code>fdesign.isinclp</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'Fp,Fst,Ap,Ast' (default option)</li> <li>• 'N,Fc,Ap,Ast'</li> <li>• 'N,Fp,Fst'</li> <li>• 'N,Fst,Ap,Ast'</li> </ul>
'Inverse-sinc Highpass'	<p>See <code>fdesign.isinchp</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'Fst,Fp,Ast,Ap' (default option)</li> <li>• 'N,Fc,Ast,Ap'</li> <li>• 'N,Fst,Fp'</li> <li>• 'N,Fst,Ast,Ap'</li> </ul>

Design Method	Valid Specification Options
'Lowpass'	<p>See <code>fdesign.lowpass</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'Fp,Fst,Ap,Ast' (default option)</li> <li>• 'N,F3dB'</li> <li>• 'N,Fc'</li> <li>• 'N,Fc,Ap,Ast'</li> <li>• 'N,Fp,Ap,Ast'</li> <li>• 'N,Fp,Fst'</li> <li>• 'N,Fp,Fst,Ap'</li> <li>• 'N,Fp,Fst,Ast'</li> <li>• 'N,Fst,Ap,Ast'</li> </ul>
'Nyquist'	<p>See <code>fdesign.nyquist</code> for a description of the specification entries. For all Nyquist specifications, you must specify the Lth band. This typically corresponds to the DecimationFactor.</p> <ul style="list-style-type: none"> <li>• 'TW,Ast' (default option)</li> <li>• 'N'</li> <li>• 'N,Ast'</li> <li>• 'N,Ast'</li> </ul>

`D = fdesign.decimator(M, RESPONSE, SPEC)` constructs object `D` and sets the Specification property to `SPEC` for the response type, `RESPONSE`. Entries in the `SPEC` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` depend on the `RESPONSE` type.

Because you are designing multirate filters, the specification options available are not the same as the specifications for designing single-rate filters with such response types as `fdesign.lowpass`. The options are not case sensitive.

The decimation factor `M` is not in the specification options.

`D = fdesign.decimator(...,SPEC,specvalue1,specvalue2,...)` constructs an object `D` and sets its specifications at construction time.

`D = fdesign.decimator(...,Fs)` provides the sampling frequency of the signal to be filtered. `Fs` must be specified as a scalar trailing the other numerical values provided. `Fs` is assumed to be in Hz as are all other frequency values provided.

`D = fdesign.decimator(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units.
- `'dB'` — specify the magnitude in dB (decibels).
- `'squared'` — specify the magnitude in power units.

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

### Construct a Decimator Using `fdesign` Object

These examples show how to construct decimating filter specification objects.

First, create a default specifications object without using input arguments except for the decimation factor `m`.

```
d = fdesign.decimator(2,'Nyquist',2,0.1,80) %#ok % Set tw=0.1, and ast=80.
```

```
d =  
  decimator with properties:  
  
      MultirateType: 'Decimator'  
        Response: 'Nyquist'  
  DecimationFactor: 2  
    Specification: 'TW,Ast'  
      Description: {2x1 cell}  
          Band: 2  
NormalizedFrequency: 1  
  TransitionWidth: 0.1000  
        Astop: 80
```

Now create an object by passing a specification type option 'fst1,fp1,fp2,fst2,ast1,ap,ast2' and a design - the resulting object uses default values for the filter specifications. You must provide the design input argument, bandpass in this example, when you include a specification.

```
d = fdesign.decimator(8, 'bandpass', ...  
'fst1,fp1,fp2,fst2,ast1,ap,ast2'); %#ok
```

Create another decimating filter specification object, passing the specification values to the object rather than accepting the default values for fp,fst,ap,ast.

```
d = fdesign.decimator(3, 'lowpass', .45,0.55,.1,60); %#ok
```

Now pass the filter specifications that correspond to the specifications - n,fc,ap,ast.

```
d = fdesign.decimator(3, 'ciccomp',1,2, 'n,fc,ap,ast', ...  
20,0.45,.05,50);
```

Now design a decimator using the equiripple design method.

```
equiDecimator = design(d, 'equiripple', 'SystemObject', true);
```

Pass a new specification type for the filter, specifying the filter order. Note that the inputs must include the differential delay dd with the CIC input argument to design a CIC specification object.

```
m = 5;  
dd = 2;  
d = fdesign.decimator(m, 'cic', dd, 'fp,ast', 0.55,55); %#ok
```

In this example, you specify a sampling frequency as the last input argument. Here is it 1000 Hz. Design an equiripple filter and plot the magnitude response:

```
d = fdesign.decimator(8, 'bandpass', 'fst1,fp1,fp2,fst2,ast1,ap,ast2', ...  
100,150,250,300,50,.05,50,1000);  
fvtool(design(d, 'equiripple', 'SystemObject', true))
```

**Introduced in R2011a**

# fdesign.differentiator

Differentiator filter specification object

## Syntax

```
D = fdesign.differentiator
D = fdesign.differentiator(SPEC)
D = fdesign.differentiator(SPEC,specvalue1,specvalue2, ...)
D = fdesign.differentiator(specvalue1)
D = fdesign.differentiator(...,Fs)
D = fdesign.differentiator(...,MAGUNITS)
```

## Description

`D = fdesign.differentiator` constructs a default differentiator filter designer `D` with the filter order set to 31.

`D = fdesign.differentiator(SPEC)` initializes the filter designer `Specification` property to `SPEC`. You provide one of the following filter entries as input to replace `SPEC`. These entries are not case sensitive.

---

**Note** Specifications marked with an asterisk require the DSP System Toolbox software.

---

- 'N' — Full band differentiator (default)
- 'N,Fp,Fst' — Partial band differentiator
- 'N,Fp,Fst,Ap' — Partial band differentiator \*
- 'N,Fp,Fst,Ast' — Partial band differentiator \*
- 'Ap' — Minimum order full band differentiator \*
- 'Fp,Fst,Ap,Ast' — Minimum order partial band differentiator \*

The filter specifications are defined as follows:

- **Ap** — amount of ripple allowed in the pass band in decibels (the default units). Also called **Apass**.
- **Ast** — attenuation in the stop band in decibels (the default units). Also called **Astop**.
- **Fp** — frequency at the start of the pass band. Specified in normalized frequency units. Also called **Fpass**.
- **Fst** — frequency at the end of the stop band. Specified in normalized frequency units. Also called **Fstop**.
- **N** — filter order.

By default, `fdesign.differentiator` assumes that all frequency specifications are provided in normalized frequency units. Also, decibels is the default for all magnitude specifications.

Use `designopts` to determine the design options for a given design method. Enter `help(D,METHOD)` at the MATLAB command line to obtain detailed help on the design options for a given design method, `METHOD`.

`D = fdesign.differentiator(SPEC,specvalue1,specvalue2, ...)` initializes the filter designer specifications in `SPEC` with `specvalue1`, `specvalue2`, and so on. To get a description of the specifications `specvalue1`, `specvalue2`, and more, enter

```
get(d, 'description')
```

at the Command prompt.

`D = fdesign.differentiator(specvalue1)` assumes the default specification `N`, setting the filter order to the value you provide.

`D = fdesign.differentiator(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`D = fdesign.differentiator(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in dB (decibels)
- `'squared'` — specify the magnitude in power units

When you omit the `MAGUNITES` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

### FIR Differentiator Filters

Design a 33rd-order FIR differentiator using least squares. Plot the zero-phase response of the filter.

```
d = fdesign.differentiator(33);  
hd = design(d, 'firls', 'SystemObject', true);  
  
zerophase(hd)
```

Design a 54th-order narrowband equiripple differentiator. Differentiate the lowest 25% of the frequencies in the Nyquist range and filter the higher frequencies. Specify a sample rate of 20 kHz, a passband frequency of 2.5 kHz, and a stopband frequency of 3 kHz.

```
Fs = 20000;
```

```
d = fdesign.differentiator('N,Fp,Fst',54,2500,3000,Fs);
Hd = design(d,'equiripple','SystemObject',true);
```

Redesign the filter, but this time weight the stopband to increase the attenuation.

```
Hd1 = design(d,'equiripple','Wstop',4,'SystemObject',true);
```

```
hfvt = fvtool(Hd,Hd1,'MagnitudeDisplay','zero-phase', ...
```

```
'FrequencyRange',[0, Fs/2)');  
legend(hfvt,'No stopband weighting','Stopband weighting');
```

## **fdesign.fracdelay**

Fractional delay filter specification object

### **Syntax**

```
d = fdesign.fracdelay(delta)
d = fdesign.fracdelay(delta, 'N')
d = fdesign.fracdelay(delta, 'N', n)
d = fdesign.fracdelay(delta, n)
d = fdesign.fracdelay(..., fs)
```

### **Description**

`d = fdesign.fracdelay(delta)` constructs a default fractional delay filter designer `d` with the filter order set to 3 and the delay value set to `delta`. The fractional delay `delta` must be between 0 and 1 samples.

`d = fdesign.fracdelay(delta, 'N')` initializes the filter designer specification to `N`, where `N` specifies the fractional delay filter order and defaults to filter order of 3.

Use `designmethods(d)` to get a list of the design methods available for a specification.

`d = fdesign.fracdelay(delta, 'N', n)` initializes the filter designer to `N` and sets the filter order to `n`.

`d = fdesign.fracdelay(delta, n)` assumes the default specification `N`, filter order, and sets the filter order to the value you provide in input `n`.

`d = fdesign.fracdelay(..., fs)` adds the argument `fs`, specified in units of Hertz (Hz) to define the sampling frequency. In this case, specify the fractional delay `delta` to be between 0 and  $1/fs$ .

### **Examples**

### Create a Fractional Delay Filter Using fdesign Object

Design a second-order fractional delay filter of 0.2 samples using the Lagrange method. Implement the filter using a Farrow fractional delay (fd) structure.

```
d = fdesign.fracdelay(0.2, 'N', 2);
secondOrderFrac = design(d, 'lagrange', 'filterstructure', 'farrowfd');
fvtool(secondOrderFrac, 'analysis', 'grpdelay')
```

Design a cubic fractional delay filter with a sampling frequency of 8 kHz and fractional delay of 50 microseconds using the Lagrange method.

```
d = fdesign.fracdelay(50e-6, 'N', 3, 8000);
cubicFrac = design(d, 'lagrange', 'FilterStructure', 'farrowfd');
```

**Introduced in R2011a**

# fdesign.halfband

Halfband filter specification object

## Syntax

```
d = fdesign.halfband
d = fdesign.halfband('type',type)
d = fdesign.halfband(spec)
d = fdesign.halfband(spec,specvalue1,specvalue2,...)
d = fdesign.halfband(specvalue1,specvalue2)
d = fdesign.halfband(...,fs)
d = fdesign.halfband(...,magunits)
```

## Description

`d = fdesign.halfband` constructs a halfband filter specification object `d`, applying default values for the properties `tw` and `ast`.

Using `fdesign.halfband` along with `design` method generates a System object, if the 'SystemObject' flag in the `design` method is set to `true`.

`d = fdesign.halfband('type',type)` initializes the filter designer 'Type' property with `type`. 'type' must be either `lowpass` or `highpass` and is not case sensitive.

`d = fdesign.halfband(spec)` constructs object `d` and sets its 'Specification' to `spec`. Entries in `spec` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `spec` are shown below. These options are not case sensitive.

- `tw,ast` (default `spec`)
- `n,tw`
- `n`
- `n,ast`

where,

- `ast` — attenuation in the stop band in decibels (the default units).
- `n` — filter order.
- `tw` — width of the transition region between the pass and stop bands. Specified in normalized frequency units.

By default, all frequency specifications are assumed to be in normalized frequency units. Moreover, all magnitude specifications are assumed to be in dB. Different specification types may have different design methods available.

The filter design methods that apply to a halfband filter specification object change depending on the `Specification` choice. Use `designmethods` to determine which design method applies to an object and its specification choice. Different filter design methods also have options that you can specify. Use `designopts` with the design method to see the available options. For example:

```
f=fdesign.halfband('N,TW');  
designmethods(f)
```

`d = fdesign.halfband(spec,specvalue1,specvalue2,...)` constructs an object `d` and sets its specifications at construction time.

`d = fdesign.halfband(specvalue1,specvalue2)` constructs an object `d` assuming the default `Specification` property `tw`, `ast`, using the values you provide for the input arguments `specvalue1` and `specvalue2` for `tw` and `ast`.

`d = fdesign.halfband(...,fs)` adds the argument `fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.halfband(...,magunits)` specifies the units for any magnitude specification you provide in the input arguments. `magunits` can be one of

- `linear` — specify the magnitude in linear units
- `dB` — specify the magnitude in dB (decibels)
- `squared` — specify the magnitude in power units

When you omit the `magunits` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

### Create Halfband Filters Using fdesign Object

Create a default halfband filter specifications object.

```
d=fdesign.halfband;
```

Create another halfband filter object, passing the specification values to the object rather than accepting the default values for n and ast.

```
d2 = fdesign.halfband('n,ast', 42, 80);
```

For another example, pass the filter values that correspond to the default Specification - n,ast.

```
d3 = fdesign.halfband(.01, 80);
```

This example designs an equiripple FIR filter, starting by passing a new specification type and specification values to fdesign.halfband.

```
hs = fdesign.halfband('n,ast',80,70);
hd =design(hs,'equiripple','SystemObject',true);
```

In this example, pass the specifications for the filter, and then design a least-squares FIR filter from the object, using firls as the design method.

```
hs = fdesign.halfband('n,tw', 42, .04);
hd2 = design(hs,'firls','SystemObject',true);
```

Create two equiripple halfband filters with and without a nonnegative zero phase response:

```
f=fdesign.halfband('N,TW',12,0.2);
```

Equiripple halfband filter with nonnegative zero phase response

```
Hd1 = design(f,'equiripple','ZeroPhase',true,'SystemObject',true);
```

Equiripple halfband filter with zero phase false 'zerophase',false is the default

```
Hd2=design(f,'equiripple','ZeroPhase',false,'SystemObject',true);
```

Obtain real-valued amplitudes (not magnitudes)

```
[Hr_zerophase,~]=zerophase(Hd1);
[Hr,W]=zerophase(Hd2);
```

Plot and compare response

```
plot(W,Hr_zerophase,'k','linewidth',2);
xlabel('Radians/sample'); ylabel('Amplitude');
hold on;
plot(W,Hr,'r');
axis tight; grid on;
legend('with ''ZeroPhase'', true','with ''ZeroPhase'' false');
```

Note that the amplitude of the zero phase response (black line) is nonnegative for all frequencies. The 'ZeroPhase' option is valid only for equiripple halfband designs with the

'N,TW' specification. You cannot specify 'MinPhase' and 'ZeroPhase' to be simultaneously 'true'.

## **fdesign.highpass**

Highpass filter specification object

### **Syntax**

```
D = fdesign.highpass
D = fdesign.highpass(SPEC)
D = fdesign.highpass(SPEC,specvalue1,specvalue2,...)
D = fdesign.highpass(specvalue1,specvalue2,specvalue3,
specvalue4)
D = fdesign.highpass(...,Fs)
D = fdesign.highpass(...,MAGUNITS)
```

### **Description**

`D = fdesign.highpass` constructs a highpass filter specification object `D`, applying default values for the specification, `'Fst,Fp,Ast,Ap'`.

`D = fdesign.highpass(SPEC)` constructs object `D` and sets the `Specification` property to `SPEC`. Entries in the `SPEC` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` are shown below. These entries are not case sensitive.

---

**Note** Specification entries marked with an asterisk require the DSP System Toolbox software.

---

- `'Fst,Fp,Ast,Ap'` (default spec)
- `'N,F3db'`
- `'N,F3db,Ap' *`
- `'N,F3db,Ast' *`
- `'N,F3db,Ast,Ap' *`
- `'N,F3db,Fp' *`

- 'N, Fc'
- 'N, Fc, Ast, Ap'
- 'N, Fp, Ap'
- 'N, Fp, Ast, Ap'
- 'N, Fst, Ast'
- 'N, Fst, Ast, Ap'
- 'N, Fst, F3db' \*
- 'N, Fst, Fp'
- 'N, Fst, Fp, Ap' \*
- 'N, Fst, Fp, Ast' \*
- 'Nb, Na, Fst, Fp' \*

The filter specifications are defined as follows:

- **Ap** — amount of ripple allowed in the pass band in decibels (the default units). Also called **Apass**.
- **Ast** — attenuation in the stop band in decibels (the default units). Also called **Astop**.
- **F3db** — cutoff frequency for the point 3 dB point below the passband value. Specified in normalized frequency units.
- **Fc** — cutoff frequency for the point 6 dB point below the passband value. Specified in normalized frequency units.
- **Fp** — frequency at the start of the pass band. Specified in normalized frequency units. Also called **Fpass**.
- **Fst** — frequency at the end of the stop band. Specified in normalized frequency units. Also called **Fstop**.
- **N** — filter order.
- **Na** and **Nb** are the order of the denominator and numerator.

Graphically, the filter specifications look similar to those shown in the following figure.

Regions between specification values like  $F_{st}$  and  $F_p$  are transition regions where the filter response is not explicitly defined.

The filter design methods that apply to a highpass filter specification object change depending on the `Specification`. Use `designmethods` to determine which design method applies to an object and its specification.

Use `designopts` to determine which design options are valid for a given design method. For detailed information on design options for a given design method, `METHOD`, enter `help(D,METHOD)` at the MATLAB command line.

`D = fdesign.highpass(SPEC,specvalue1,specvalue2,...)` constructs an object `D` and sets its specification values at construction time.

`D = fdesign.highpass(specvalue1,specvalue2,specvalue3,specvalue4)` constructs an object `D` with the default `Specification` property and the values you enter for `specvalue1,specvalue2,...`

`D = fdesign.highpass(...,Fs)` provides the sampling frequency for the filter specification object. `Fs` is in Hz and must be specified as a scalar trailing the other numerical values provided. If you specify a sampling frequency, all other frequency specifications are in Hz.

`D = fdesign.highpass(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- 'linear' — specify the magnitude in linear units
- 'dB' — specify the magnitude in dB (decibels)
- 'squared' — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

### Highpass Filtering of Sinusoids

Highpass filter a discrete-time signal consisting of two sine waves.

Create a highpass filter specification object. Specify the passband frequency to be  $0.25\pi$  rad/sample and the stopband frequency to be  $0.15\pi$  rad/sample. Specify 1 dB of allowable passband ripple and a stopband attenuation of 60 dB.

```
d = fdesign.highpass('Fst,Fp,Ast,Ap',0.15,0.25,60,1);
```

Query the valid design methods for your filter specification object.

```
designmethods(d)
```

```
Design Methods for class fdesign.highpass (Fst,Fp,Ast,Ap):
```

```
butter  
cheby1  
cheby2  
ellip  
equiripple  
ifir  
kaiserwin
```

Create an FIR equiripple filter and view the filter magnitude response with `FVTool`.

```
Hd = design(d,'equiripple');  
fvtool(Hd)
```

Create a signal consisting of the sum of two discrete-time sinusoids with frequencies of  $\pi/8$  and  $\pi/4$  rad/sample and amplitudes of 1 and 0.25 respectively. Filter the discrete-time signal with the FIR equiripple filter object.

```
n = 0:159;
x = cos(pi/8*n)+0.25*sin(pi/4*n);
y = filter(Hd,x);
```

Plot the original and filtered signals in the frequency domain.

```
freq = 0:(2*pi)/160:pi;
xdft = fft(x);
ydft = fft(y);
```

```
plot(freq/pi,abs(xdft(1:length(x)/2+1)))  
hold on  
plot(freq/pi,abs(ydft(1:length(y)/2+1)),'r','linewidth',2)  
hold off  
legend('Original Signal','Lowpass Signal','Location','NorthEast')  
ylabel('Magnitude')  
xlabel('Normalized Frequency (\times\pi rad/sample)')
```

### Window Method Highpass Design

Create a filter of order 10 with a 6-dB frequency of 9.6 kHz and a sample rate of 48 kHz. Look at the available design methods.

```
d=fdesign.highpass('N,Fc',10,9600,48000);  
designmethods(d)
```

```
Design Methods for class fdesign.highpass (N,Fc):
```

```
window
```

The only available method is the FIR window method. Design the filter and display its magnitude response.

```
Hd = design(d);
```

```
fvtool(Hd)
```

### Stopband Constraints

You can specify the shape of the stopband and the rate at which the stopband decays.

Create two FIR equiripple filters with different linear stopband slopes. Specify the passband frequency to be  $0.3\pi$  rad/sample and the stopband frequency to be  $0.35\pi$  rad/sample. Specify 1 dB of allowable passband ripple and a stopband attenuation of 60 dB. Design one filter with a 20 dB/(rad/sample) stopband slope and another filter with a slope of 40 dB/(rad/sample).

```
D = fdesign.highpass('Fst,Fp,Ast,Ap',0.3,0.35,60,1);  
Hd1 = design(D,'equiripple','StopBandShape','linear','StopBandDecay',20);  
Hd2 = design(D,'equiripple','StopBandShape','linear','StopBandDecay',40);
```

Visualize the magnitude responses of the filters.

```
hfvt = fvtool([Hd1 Hd2]);  
legend(hfvt,'20 dB/rad/sample','40 dB/rad/sample')
```

## fdesign.hilbert

Hilbert filter specification object

### Syntax

```
d = fdesign.hilbert
d = fdesign.hilbert(specvalue1,specvalue2)
d = fdesign.hilbert(spec)
d = fdesign.hilbert(spec,specvalue1,specvalue2)
d = fdesign.hilbert(...,Fs)
d = fdesign.hilbert(...,MAGUNITS)
```

### Description

`d = fdesign.hilbert` constructs a default Hilbert filter designer `d` with `N`, the filter order, set to 30 and `TW`, the transition width set to  $0.1\pi$  radians/sample.

`d = fdesign.hilbert(specvalue1,specvalue2)` constructs a Hilbert filter designer `d` assuming the default specification '`N, TW`'. You input `specvalue1` and `specvalue2` for `N` and `TW`.

`d = fdesign.hilbert(spec)` initializes the filter designer `Specification` property to `spec`. You provide one of the following as input to replace `spec`. The specification options are not case sensitive.

---

**Note** Specifications marked with an asterisk require the DSP System Toolbox software.

---

- '`N, TW`' default specification option.
- '`TW, Ap`' \*

The filter specifications are defined as follows:

- `Ap` — amount of ripple allowed in the pass band in decibels (the default units). Also called `Apass`.

- $N$  — filter order.
- $TW$  — width of the transition region between the passband and the stopband.

By default, `fdesign.hilbert` assumes that all frequency specifications are provided in normalized frequency units. Also, decibels is the default for all magnitude specifications.

Different specifications may have different design methods available. Use `designmethods(d)` to get a list of the design methods available for a given specification.

`d = fdesign.hilbert(spec,specvalue1,specvalue2)` initializes the filter designer specifications in `spec` with `specvalue1`, `specvalue2`, and so on. To get a description of the specifications `specvalue1` and `specvalue2`, enter

```
get(d,'description')
```

at the Command prompt.

`d = fdesign.hilbert(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.hilbert(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- 'linear' — specify the magnitude in linear units
- 'dB' — specify the magnitude in dB (decibels)
- 'squared' — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

### Hilbert Transformers

Design a Hilbert transformer of order 30 with a transition width of  $0.2\pi$  rad/sample. Use least-squares minimization to obtain an equiripple linear-phase FIR filter. Plot the zero-phase response in the interval  $[-\pi,\pi)$ .

```
d = fdesign.hilbert('N,TW',30,0.2);  
Hd = design(d,'equiripple','SystemObject',true);  
zerophase(Hd,'whole')
```

The impulse response of this even-order type-3 filter is antisymmetric.

```
impz(Hd)
```

```
ftype = firtype(Hd)
```

```
ftype = 3
```

Design a minimum-order Hilbert transformer that has a sample rate of 1 kHz. Specify the width of the transition region as 10 Hz and the passband ripple as 1 dB. Display the zero-phase response of the filter.

```
fs = 1e3;
d = fdesign.hilbert('TW,Ap',10,1,fs);
hd = design(d,'equiripple','SystemObject',true);
zerophase(hd,-fs/2:0.1:fs/2,fs)
```

# fdesign.interpolator

Interpolator filter specification

## Syntax

```
D = fdesign.interpolator(L)
D = fdesign.interpolator(L,RESPONSE)
D = fdesign.interpolator(L,CICRESPONSE,D)
D = fdesign.interpolator(L,RESPONSE,spec)
D = fdesign.interpolator(...,spec,specvalue1,specvalue2,...)
D = fdesign.interpolator(...,Fs)
d = fdesign.interpolator(...,MAGUNITS)
```

## Description

`D = fdesign.interpolator(L)` constructs an interpolator filter specification object `D` with the `InterpolationFactor` property equal to the positive integer `L` and the `Response` property set to `'Nyquist'`. The default values for the transition width and stopband attenuation in the Nyquist design are  $0.1\pi$  radians/sample and 80 dB. If `L` is unspecified, `L` defaults to 2.

`D = fdesign.interpolator(L,RESPONSE)` constructs a interpolator specification object with the interpolation factor `L` and the `'Response'` property set to one of the supported types.

`D = fdesign.interpolator(L,CICRESPONSE,D)` constructs a CIC or CIC compensator interpolator specification object with the interpolation factor, `L`, and `'Response'` property equal to `'CIC'` or `'CICCOMP'`. `D` is the differential delay. The differential delay, `D`, must precede any specification option.

`D = fdesign.interpolator(L,RESPONSE,spec)` constructs object `D` and sets its `Specification` property to `spec`. Entries in the `spec` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `spec` depend on the design type of the specifications object.

When you add the `spec` input argument, you must also add the `RESPONSE` input argument.

Because you are designing multirate filters, the specification options available are not the same as the specifications for designing single-rate filters with design methods such as `fdesign.lowpass`. The options are not case sensitive.

The interpolation factor `L` is not in the specification options. The different filter responses support different specifications. The following table lists the supported response types and specification options.

<b>Design Method</b>	<b>Valid Specification Options</b>
'Arbitrary Magnitude'	See <code>fdesign.arbmag</code> for a description of the specification entries. <ul style="list-style-type: none"> <li>'N,F,A' (default option)</li> <li>'N,B,F,A'</li> </ul>

'Highpass'	<p>See <code>fdesign.highpass</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'Fst,Fp,Ast,Ap' (default option)</li> <li>• 'N,F3db'</li> <li>• 'N,Fc'</li> <li>• 'N,Fc,Ast,Ap'</li> <li>• 'N,Fp,Ast,Ap'</li> <li>• 'N,Fst,Ast,Ap'</li> <li>• 'N,Fst,Fp'</li> <li>• 'N,Fst,Ast,Ap'</li> <li>• 'N,Fst,Fp,Ast'</li> </ul>
'Hilbert'	<p>See <code>fdesign.hilbert</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'N,TW' (default option)</li> <li>• 'TW,Ap'</li> </ul>

Design Method	Valid Specification Options
'Inverse-sinc Lowpass'	See <code>fdesign.isinc1p</code> for a description of the specification entries. <ul style="list-style-type: none"> <li>• 'Fp,Fst,Ap,Ast' (default option)</li> <li>• 'N,Fc,Ap,Ast'</li> <li>• 'N,Fp,Fst'</li> <li>• 'N,Fst,Ap,Ast'</li> </ul>
'Inverse-sinc Highpass'	See <code>fdesign.isinchp</code> for a description of the specification entries. <ul style="list-style-type: none"> <li>• 'Fst,Fp,Ast,Ap' (default option)</li> <li>• 'N,Fc,Ast,Ap'</li> <li>• 'N,Fst,Fp'</li> <li>• 'N,Fst,Ast,Ap'</li> </ul>
'Lowpass'	See <code>fdesign.lowpass</code> for a description of the specification entries. <ul style="list-style-type: none"> <li>• 'Fp,Fst,Ap,Ast' (default option)</li> <li>• 'N,F3dB'</li> <li>• 'N,Fc'</li> <li>• 'N,Fc,Ap,Ast'</li> <li>• 'N,Fp,Ap,Ast'</li> <li>• 'N,Fp,Fst'</li> <li>• 'N,Fp,Fst,Ap'</li> <li>• 'N,Fp,Fst,Ast'</li> <li>• 'N,Fst,Ap,Ast'</li> </ul>

Design Method	Valid Specification Options
'Nyquist'	<p>See <code>fdesign.nyquist</code> for a description of the specification entries. For all Nyquist specifications, you must specify the <i>L</i>th band. This typically corresponds to the interpolation factor so that the nonzero samples of the upsampler output are preserved.</p> <ul style="list-style-type: none"> <li>• 'TW,Ast' (default option)</li> <li>• 'N'</li> <li>• 'N,Ast'</li> <li>• 'N,Ast'</li> </ul>

`D = fdesign.interpolator(...,spec,specvalue1,specvalue2,...)` constructs an object `D` and sets its specifications at construction time.

`D = fdesign.interpolator(...,Fs)` adds the argument `Fs`, specified in Hz, to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.interpolator(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- 'linear' — specify the magnitude in linear units.
- 'dB' — specify the magnitude in dB (decibels).
- 'squared' — specify the magnitude in power units.

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

### Create an Interpolator Using `fdesign` Object

These examples show how to construct interpolating filter specification objects.

First, create a default specifications object without using input arguments except for the interpolation factor `l`.

```
l = 2;
d = fdesign.interpolator(l); %#ok
```

Now create an object by passing a specification option `'fst1,fp1,fp2,fst2,ast1,ap,ast2'` and a design - the resulting object uses default values for all of the filter specifications. You must provide the design input argument when you include a specification.

```
d = fdesign.interpolator(8, 'bandpass', 'fst1,fp1,fp2,fst2,ast1,ap,ast2'); %#ok
```

Create another interpolating filter object, passing the specification values to the object rather than accepting the default values for, in this case, `fp,fst,ap,ast`.

```
d = fdesign.interpolator(3, 'lowpass', .45,0.55,.1,60); %#ok
```

Now pass the filter specifications that correspond to the specifications - `n,fc,ap,ast`.

```
d = fdesign.interpolator(3, 'ciccomp', 1,2, 'n,fc,ap,ast', ...
20,0.45, .05,50);
```

With the specifications object in your workspace, design an interpolator using the equiripple design method.

```
hm = design(d, 'equiripple', 'SystemObject', true); %#ok
```

Pass a new specification type for the filter, specifying the filter order.

```
d = fdesign.interpolator(5, 'CIC', 1, 'fp,ast', 0.05,55);
```

With the specifications object in your workspace, design an interpolator using the multisection design method.

```
hm = design(d, 'multisection', 'SystemObject', true); %#ok
```

In this example, you specify a sampling frequency as the right most input argument. Here, it is set to 1000 Hz.

```
d = fdesign.interpolator(8, 'bandpass', 'fst1,fp1,fp2,fst2,ast1,ap,ast2', ...
0.25,0.35, .55, .65,50, .05,1e3); %#ok
```

In this, the last example, use the linear option for the filter specification object and specify the stopband ripple attenuation in linear form.

```
d = fdesign.interpolator(4, 'lowpass', 'n,fst,ap,ast', 15, 0.55, .05, 0.001, ...
    'linear'); %#ok
```

Now design a CIC interpolator for a signal sampled at 19200 Hz. Specify the differential delay of 2 and set the attenuation of information beyond 50 Hz to be at least 80 dB.

% The filter object sampling frequency is (l x fs) where fs is the sampling frequency of the input signal.

```
dd = 2;      % Differential delay.
fp = 50;     % Passband of interest.
ast = 80;    % Minimum attenuation of alias components in passband.
fs = 600;    % Sampling frequency for input signal.
l = 32;      % Interpolation factor.
d = fdesign.interpolator(l, 'cic', dd, 'fp,ast', fp, ast, l*fs);
hm = design(d, 'SystemObject', true); %Use the default design method.
```

This next example results in a minimum-order CIC compensator that interpolates by 4 and compensates for the droop in the passband for the CIC filter hm from the previous example.

```
nsecs = hm.NumSections;
d = fdesign.interpolator(4, 'ciccomp', dd, nsecs, ...
    50, 100, 0.1, 80, fs);
hmc = design(d, 'equiripple', 'SystemObject', true);
```

hmc is designed to compensate for hm. To see the effect of the compensating CIC filter, use fvtool to analyze both filters individually and include the compound filter response by cascading hm and hmc.

```
hfvtool = fvtool(hmc, hm, cascade(hmc, hm), 'fs', [fs, l*fs, l*fs], 'ShowReference', 'off');
legend(hfvtool, 'CIC Compensator', 'CIC Interpolator', ...
    'Overall Response');
```

fvtool returns with this plot.

For the third example, use `fdesign.interpolator` to design a minimum-order Nyquist interpolator that uses a Kaiser window. For comparison, design a multistage interpolator as well and compare the responses.

```

l = 15; % Set the interpolation factor and the Nyquist band.
tw = 0.05; % Specify the normalized transition width.
ast = 40; % Set the minimum stopband attenuation in dB.
d = fdesign.interpolator(l,'nyquist',l,tw,ast);
hm = design(d,'kaiserwin','SystemObject',true);
hm2 = design(d,'multistage','SystemObject',true); % Design the multistage interpolator
hfvt = fvtool(hm,hm2);
legend(hfvt,'Kaiser Window','Multistage')

```

fvtool shows both responses.

Design a lowpass interpolator for an interpolation factor of 8. Compare the single-stage equiripple design to a multistage design with the same interpolation factor.

```
l = 8; % Interpolation factor.
d = fdesign.interpolator(l,'lowpass');
hm1 = design(d,'equiripple','SystemObject',true);
% Use halfband filters whenever possible.
hm2 = design(d,'multistage','usehalfbands',true,'SystemObject',true);
hfvt = fvtool(hm1,hm2);
legend(hfvt,'Single-Stage Equiripple','Multistage')
```

## fdesign.isinchnp

Inverse sinc highpass filter specification

### Syntax

```
D = fdesign.isinchnp
D = fdesign.isinchnp(SPEC)
D = fdesign.isinchnp(SPEC,specvalue1,specvalue2,...)
D = fdesign.isinchnp(specvalue1,specvalue2,specvalue3,specvalue4)
D = fdesign.isinchnp(...,Fs)
D = fdesign.isinchnp(...,MAGUNITS)
```

### Description

`D = fdesign.isinchnp` constructs an inverse sinc highpass filter specification object `D`, applying default values for the default specification `'Fst,Fp,Ast,Ap'`.

`D = fdesign.isinchnp(SPEC)` constructs object `D` and sets the `Specification` property to `SPEC`. Entries in the `SPEC` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` are shown below. The entries are not case sensitive.

- `'Fst,Fp,Ast,Ap'` (default spec)
- `'N,Fc,Ast,Ap'`
- `'N,Fst,Fp'`
- `'N,Fp,Ast,Ap'`
- `'N,Fst,Ast,Ap'`

The filter specifications are defined as follows:

- `Ast` — attenuation in the stopband in decibels (the default units). Also called `Astop`.
- `Ap` — amount of ripple allowed in the passband in decibels (the default units). Also called `Apass`.

- $F_p$  — frequency at the start of the passband. Specified in normalized frequency units. Also called  $F_{pass}$ .
- $F_{st}$  — frequency at the end of the stopband. Specified in normalized frequency units. Also called  $F_{stop}$ .
- $N$  — filter order.

The filter design methods that apply to an inverse sinc highpass filter specification object change depending on the value of the `Specification` property. Use `designmethods` to determine which design method applies to a specific `Specification`.

Use `designopts` to see the available design options for a specific design method. Enter `help(D,METHOD)` at the MATLAB command line to obtain detailed information on the design options for a given design method, `METHOD`.

`D = fdesign.isinchnp(SPEC,specvalue1,specvalue2,...)` constructs an object `D` and sets the specifications at construction time.

`D = fdesign.isinchnp(specvalue1,specvalue2,specvalue3,specvalue4)` constructs an object `D` assuming the default `Specification` property `'Fst,Fp,Ast,Ap'`, using the values you provide in `specvalue1`, `specvalue2`, `specvalue3`, and `specvalue4`.

`D = fdesign.isinchnp(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`D = fdesign.isinchnp(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in dB (decibels)
- `'squared'` — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

The design method of `fdesign.isinchnp` implements a filter with a passband magnitude response equal to:

$$H(\omega) = \text{sinc}(C(1 - \omega))^{-P}$$

You can control the values of the sinc frequency factor,  $C$ , and the sinc power,  $P$ , using the 'SincFrequencyFactor' and 'SincPower' options in the `design` method. 'SincFrequencyFactor' and 'SincPower' default to 0.5 and 1 respectively.

## Examples

### Construct an Inverse Sinc Highpass Filter Using `fdesign` Object

Design a minimum order inverse sinc highpass filter and shape the stopband to have a slope of 20 dB/radian/sample.

```
d = fdesign.isinchnp('Fst,Fp,Ast,Ap',.4,.5,40,0.01);  
Hd = design(d,'SystemObject',true);
```

Shape the stopband to have a linear slope of 20 dB/rad/sample

```
Hd1 = design(d,'StopbandShape','linear','StopbandDecay',20,'SystemObject',...  
            true);  
fvtool(Hd,Hd1);
```

Design a 50th order inverse sinc highpass filter. Set the sinc frequency factor to 0.25, and the sinc power to 16 to achieve a magnitude response in the passband of the form  $H(?) = \text{sinc}(0.25*(1-?))^{-16}$ .

```
d = fdesign.isinchnp('N,Fst,Fp',50,.4,.5);
Hd = design(d,'SincFrequencyFactor',0.25,'SincPower',16,...
'SystemObject',true);
fvtool(Hd);
```

**Introduced in R2011b**

# fdesign.isinclp

Inverse sinc lowpass filter specification

## Syntax

```
d = fdesign.isinclp
d = fdesign.isinclp(spec)
d = fdesign.isinclp(spec,specvalue1,specvalue2,...)
d = fdesign.isinclp(specvalue1,specvalue2,specvalue3,specvalue4)
d = fdesign.isinclp(...,Fs)
d = fdesign.isinclp(...,MAGUNITS)
```

## Description

`d = fdesign.isinclp` constructs an inverse sinc lowpass filter specification object `d`, applying default values for the default specification, '`Fp,Fst,Ap,Ast`'.

`d = fdesign.isinclp(spec)` constructs object `d` and sets its 'Specification' to `spec`. Entries in the `spec` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `spec` are shown below. The options are not case sensitive.

- '`Fp,Fst,Ap,Ast`' (default option)
- '`N,Fc,Ap,Ast`'
- '`N,Fp,Ap,Ast`'
- '`N,Fp,Fst`'
- '`N,Fst,Ap,Ast`'

The filter specifications are defined as follows:

- `Ast` — attenuation in the stopband in decibels (the default units). Also called `Astop`.
- `Ap` — amount of ripple allowed in the passband in decibels (the default units). Also called `Apass`.

- `Fp` — frequency at the start of the passband. Specified in normalized frequency units. Also called `Fpass`.
- `Fst` — frequency at the end of the stopband. Specified in normalized frequency units. Also called `Fstop`.
- `N` — filter order.

The filter design methods that apply to an inverse sinc lowpass filter specification object change depending on the `Specification`. Use `designmethods` to determine which design method applies to an object and its specification.

`d = fdesign.isinclp(spec,specvalue1,specvalue2,...)` constructs an object `d` and sets its specifications at construction time.

`d = fdesign.isinclp(specvalue1,specvalue2,specvalue3,specvalue4)` constructs an object `d` assuming the default `Specification` property `'Fp,Fst,Ap,Ast'`, using the values you provide in `specvalue1,specvalue2,specvalue3,` and `specvalue4`.

`d = fdesign.isinclp(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.isinclp(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in dB (decibels)
- `'squared'` — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

The design method of `fdesign.isinclp` implements a filter with a passband magnitude response equal to:

$$H(\omega) = \text{sinc}(C\omega)^{-P}$$

You can control the values of the sinc frequency factor,  $C$ , and the sinc power,  $P$ , using the `'SincFrequencyFactor'` and `'SincPower'` options in the `design` method. `'SincFrequencyFactor'` and `'SincPower'` default to 0.5 and 1 respectively.

## Examples

### Construct an Inverse Sinc Lowpass Filter Using fdesign Object

Pass the specifications for the default specification - 'Fp,Fst,Ap,Ast', as input arguments to the specifications object.

```
d = fdesign.isinclp(.4,.5,.01,40);  
hd = design(d,'equiripple','SystemObject',true);  
fvtool(hd);
```

Design a 50th order inverse sinc lowpass filter. Set the sinc frequency factor to 0.25 and the sinc power to 16 to achieve a magnitude response in the passband of the form  $H(\omega) = \text{sinc}(0.25*\omega)^{-16}$ .

```
d = fdesign.isinclp('N,Fp,Fst',50,.4,.5);  
Hd = design(d,'SincFrequencyFactor',0.25,'SincPower',16,'SystemObject',...  
    true);  
fvtool(Hd, 'MagnitudeDisplay', 'Magnitude');
```

## **fdesign.lowpass**

Lowpass filter specification

### **Syntax**

```
D = fdesign.lowpass
D = fdesign.lowpass(SPEC)
D = fdesign.lowpass(SPEC,specvalue1,specvalue2,...)
D = fdesign.lowpass(specvalue1,specvalue2,specvalue3,specvalue4)
D = fdesign.lowpass(...,Fs)
D = fdesign.lowpass(...,MAGUNITS)
```

### **Description**

`D = fdesign.lowpass` constructs a lowpass filter specification object `D`, applying default values for the default specification option `'Fp,Fst,Ap,Ast'`.

`D = fdesign.lowpass(SPEC)` constructs object `D` and sets the `Specification` property to the entry in `SPEC`. Entries in `SPEC` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` are shown below. The options are not case sensitive.

---

**Note** Specifications options marked with an asterisk require the DSP System Toolbox software.

---

- `'Fp,Fst,Ap,Ast'` (default option)
- `'N,F3db'`
- `'N,F3db,Ap' *`
- `'N,F3db,Ap,Ast' *`
- `'N,F3db,Ast' *`
- `'N,F3db,Fst' *`

- 'N, Fc'
- 'N, Fc, Ap, Ast'
- 'N, Fp, Ap'
- 'N, Fp, Ap, Ast'
- 'N, Fp, Fst, Ap' \*
- 'N, Fp, F3db' \*
- 'N, Fp, Fst'
- 'N, Fp, Fst, Ast' \*
- 'N, Fst, Ap, Ast' \*
- 'N, Fst, Ast'
- 'Nb, Na, Fp, Fst' \*

The filter specifications are defined as follows:

- **Ap** — amount of ripple allowed in the pass band in decibels (the default units). Also called **Apass**.
- **Ast** — attenuation in the stop band in decibels (the default units). Also called **Astop**.
- **F3db** — cutoff frequency for the point 3 dB point below the passband value. Specified in normalized frequency units.
- **Fc** — cutoff frequency for the point 6 dB point below the passband value. Specified in normalized frequency units.
- **Fp** — frequency at the start of the pass band. Specified in normalized frequency units. Also called **Fpass**.
- **Fst** — frequency at the end of the stop band. Specified in normalized frequency units. Also called **Fstop**.
- **N** — filter order.
- **Na** and **Nb** are the order of the denominator and numerator.

Graphically, the filter specifications look similar to those shown in the following figure.

Regions between specification values like  $F_p$  and  $F_{st}$  are transition regions where the filter response is not explicitly defined.

`D = fdesign.lowpass(SPEC,specvalue1,specvalue2,...)` constructs an object `D` and sets the specification values at construction time using `specvalue1`, `specvalue2`, and so on for all of the specification variables in `SPEC`.

`D = fdesign.lowpass(specvalue1,specvalue2,specvalue3,specvalue4)` constructs an object `D` with values for the default `Specification` property '`Fp,Fst,Ap,Ast`' using the specifications you provide as input arguments `specvalue1,specvalue2,specvalue3,specvalue4`.

`D = fdesign.lowpass(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`D = fdesign.lowpass(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- 'linear' — specify the magnitude in linear units
- 'dB' — specify the magnitude in dB (decibels)
- 'squared' — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

### Lowpass Filtering of Sinusoids

Lowpass filter a discrete-time signal consisting of two sine waves.

Create a lowpass filter specification object. Specify the passband frequency to be  $0.15\pi$  rad/sample and the stopband frequency to be  $0.25\pi$  rad/sample. Specify 1 dB of allowable passband ripple and a stopband attenuation of 60 dB.

```
d = fdesign.lowpass('Fp,Fst,Ap,Ast',0.15,0.25,1,60);
```

Query the valid design methods for your filter specification object, d.

```
designmethods(d)
```

```
Design Methods for class fdesign.lowpass (Fp,Fst,Ap,Ast):
```

```
butter  
cheby1  
cheby2  
ellip  
equiripple  
ifir  
kaiserwin  
multistage
```

Create an FIR equiripple filter and view the filter magnitude response with fvtool.

```
Hd = design(d,'equiripple');  
fvtool(Hd)
```

Create a signal consisting of the sum of two discrete-time sinusoids with frequencies of  $\pi/8$  and  $\pi/4$  rad/sample and amplitudes of 1 and 0.25, respectively. Filter the discrete-time signal with the FIR equiripple filter object, Hd.

```
n = 0:159;
x = (0.25*cos((pi/8)*n)+sin((pi/4)*n));
y = filter(Hd,x);
```

Compute the Fourier transform of the original signal and the filtered signal. Verify that the high-frequency component has been filtered out.

```
freq = 0:(2*pi)/160:pi;
xdft = fft(x);
```

```
ydfc = fft(y);  
  
figure  
plot(freq/pi,abs(xdfc(1:length(x)/2+1)))  
hold on  
plot(freq/pi,abs(ydfc(1:length(y)/2+1)))  
hold off  
  
legend('Original Signal','Filtered Signal')  
ylabel('Magnitude')  
xlabel('Normalized Frequency (\times\pi rad/sample)')
```

### Window Method Lowpass Design

Create a filter of order 10 with a 6-dB frequency of 9.6 kHz and a sampling frequency of 48 kHz. Look at the available design methods.

```
d = fdesign.lowpass('N,Fc',10,9600,48000);  
designmethods(d)
```

```
Design Methods for class fdesign.lowpass (N,Fc):
```

```
window
```

The only valid design method is the FIR window method. Design the filter.

```
Hd = design(d);
```

Display the filter magnitude response. The -6 dB point is at 9.6 kHz, as expected.

```
fvtool(Hd)
```

### Stopband Shape and Decay

Create an FIR equiripple filter with a passband frequency of  $0.2\pi$  rad/sample, a stopband frequency of  $0.25\pi$  rad/sample, a passband ripple of 1 dB, and a stopband attenuation of 60 dB. Design the filter with a 20 dB/rad/sample linear stopband.

```
D = fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.25,1,60);
Hd = design(D,'equiripple','StopbandShape','linear','StopbandDecay',20);
```

Visualize the frequency response of the filter.

fvtool(Hd)

**Introduced in R2009a**

# fdesign.notch

Notch filter specification

## Syntax

```
d = fdesign.notch(specstring, value1, value2, ...)  
d = fdesign.notch(n, f0, q)  
d = fdesign.notch(..., Fs)  
d = fdesign.notch(..., MAGUNITS)
```

## Description

`d = fdesign.notch(specstring, value1, value2, ...)` constructs a notch filter specification object `d`, with the specification set to `specstring` and values provided for all members of the `specstring`. The possible specification entries, which are not case sensitive, are listed as follows:

- 'N,F0,Q' (default)
- 'N,F0,Q,Ap'
- 'N,F0,Q,Ast'
- 'N,F0,Q,Ap,Ast'
- 'N,F0,BW'
- 'N,F0,BW,Ap'
- 'N,F0,BW,Ast'
- 'N,F0,BW,Ap,Ast'

where the variables are defined as follows:

- N - Filter Order (must be even)
- F0 - Center Frequency
- Q - Quality Factor
- BW - 3-dB Bandwidth

- $A_p$  - Passband Ripple (decibels)
- $A_s$  - Stopband Attenuation (decibels)

Different specification entries, resulting in different specification objects, may have different design methods available. Use the function `designmethods` to get a list of design methods available for a given specification. For example:

```
d = fdesign.notch('N,F0,Q,Ap',6,0.5,10,1);  
designmethods(d);
```

`d = fdesign.notch(n,f0,q)` constructs a notch filter specification object using the default `specstring` ('N,F0,Q') and setting the corresponding values to  $n$ ,  $f_0$ , and  $q$ .

By default, all frequency specifications are assumed to be in normalized frequency units. All magnitude specifications are assumed to be in decibels.

`d = fdesign.notch(...,Fs)` constructs a notch filter specification object while providing the sampling frequency of the signal to be filtered.  $F_s$  must be specified as a scalar trailing the other values provided. If you specify an  $F_s$ , it is assumed to be in Hz, as are all the other frequency values provided.

`d = fdesign.notch(...,MAGUNITS)` constructs a notch filter specification while providing the units for any magnitude specification given. `MAGUNITS` can be one of the following: 'linear', 'dB', or 'squared'. If this argument is omitted, 'dB' is assumed. The magnitude specifications are always converted and stored in decibels regardless of how they were specified. If  $F_s$  is provided, `MAGUNITS` must follow  $F_s$  in the input argument list.

## Examples

### Design a Notch Filter

Design a notching filter with a passband ripple of 1 dB.

```
d = fdesign.notch('N,F0,Q,Ap',6,0.5,10,1);  
Hd = design(d,'SystemObject',true);  
fvtool(Hd)
```

## fdesign.nyquist

Nyquist filter specification

### Syntax

```
d = fdesign.nyquist
d = fdesign.nyquist(l, spec)
d = fdesign.nyquist(l,spec,specvalue1,specvalue2,...)
d = fdesign.nyquist(l,specvalue1,specvalue2)
d = fdesign.nyquist(...,fs)
d = fdesign.nyquist(...,magunits)
```

### Description

`d = fdesign.nyquist` constructs a Nyquist or L-band filter specification object `d`, applying default values for the properties `tw` and `ast`. By default, the filter object designs a minimum-order half-band ( $L=2$ ) Nyquist filter.

Using `fdesign.nyquist` along with `design` method generates a System object, if the 'SystemObject' flag in the `design` method is set to `true`.

`d = fdesign.nyquist(l, spec)` constructs object `d` and sets its `Specification` property to `spec`. Use `l` to specify the desired value for `L`.  $L = 2$  designs a half-band FIR filter,  $L = 3$  a third-band FIR filter, and so on. When you use a Nyquist filter as an interpolator, `l` or `L` is the interpolation factor. The first input argument must be `l` when you are not using the default syntax `d = fdesign.nyquist`.

Entries in the `spec` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `spec` are shown below. The entries are not case sensitive.

- `tw,ast` (default option)
- `n,tw`
- `n`

- `n,ast`

where,

- `ast` — attenuation in the stop band in decibels (the default units).
- `n` — filter order.
- `tw` — width of the transition region between the pass and stop bands. Specified in normalized frequency units.

The filter design methods that apply to a Nyquist filter specification object change depending on the `Specification` option. Use `designmethods` to determine which design method applies to an object and its specification option. Different filter design methods also have options that you can specify. Use `designopts` with the design method to see the available options. For example:

```
f=fdesign.nyquist(4,'N,TW');
designmethods(f)
```

`d = fdesign.nyquist(l,spec,specvalue1,specvalue2,...)` constructs an object `d` and sets its specification to `spec`, and the specification values to `specvalue1`, `specvalue2`, and so on at construction time.

`d = fdesign.nyquist(l,specvalue1,specvalue2)` constructs an object `d` with the values you provide in `l`, `specvalue1`, `specvalue2` as the values for `l`, `tw` and `ast`.

`d = fdesign.nyquist(...,fs)` adds the argument `fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.nyquist(...,magunits)` specifies the units for any magnitude specification you provide in the input arguments. `magunits` can be one of

- `linear` — specify the magnitude in linear units
- `dB` — specify the magnitude in dB (decibels)
- `squared` — specify the magnitude in power units

When you omit the `magunits` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Limitations of the Nyquist fdesign Object

Using Nyquist filter specification objects with the `equiripple` design method imposes a few limitations on the resulting filter, caused by the `equiripple` design algorithm.

- When you request a minimum-order design from `equiripple` with your Nyquist object, the design algorithm might not converge and can fail with a filter convergence error.
- When you specify the order of your desired filter, and use the `equiripple` design method, the design might not converge.
- Generally, the following specifications, alone or in combination with one another, can cause filter convergence problems with Nyquist objects and the `equiripple` design method.
  - very high order
  - small transition width
  - very large stopband attenuation

Note that halfband filters (filters where `band = 2`) do not exhibit convergence problems.

When convergence issues arise, either in the cases mentioned or in others, you might be able to design your filter with the `kaiserwin` method.

In addition, if you use Nyquist objects to design decimators or interpolators (where the interpolation or decimation factor is not a prime number), using multistage filter designs might be your best approach.

## Examples

### Construct a Nyquist Filter Using fdesign Object

These examples show how to construct a Nyquist filter specification object.

First, create a default specifications object without using input arguments.

```
d = fdesign.nyquist; %#ok
```

Now create an object by passing a specification type 'n,ast' - the resulting object uses default values for `n` and `ast`.

```
d = fdesign.nyquist(2, 'n,ast'); %#ok
```

Create another Nyquist filter object, passing the specification values to the object rather than accepting the default values for n and ast.

```
d = fdesign.nyquist(3, 'n,ast',42,80) %#ok
```

```
d =
  nyquist with properties:
      Response: 'Nyquist'
  Specification: 'N,Ast'
  Description: {2x1 cell}
NormalizedFrequency: 1
  FilterOrder: 42
      Astop: 80
      Band: 3
```

Finally, pass the filter specifications that correspond to the default Specification - tw,ast. When you pass only the values, fdesign.nyquist assumes the default Specification option.

```
d = fdesign.nyquist(4, .01,80)
```

```
d =
  nyquist with properties:
      Response: 'Nyquist'
  Specification: 'TW,Ast'
  Description: {2x1 cell}
NormalizedFrequency: 1
  TransitionWidth: 0.0100
      Astop: 80
      Band: 4
```

Now design a Nyquist filter using the kaiserwin design method.

```
hd = design(d, 'kaiserwin', 'SystemObject', true);
```

Create two equiripple Nyquist 4th-band filters with and without a nonnegative zero phase response:

```
f = fdesign.nyquist(4, 'N,TW',12,0.2);
```

Equiripple Nyquist 4th-band filter with nonnegative zero phase response

```
Hd1 = design(f, 'equiripple', 'zerophase', true, 'SystemObject', true);
```

Equiripple Nyquist 4th-band filter with 'ZeroPhase' set to false 'zerophase', false is the default

```
Hd2 = design(f, 'equiripple', 'zerophase', false, 'SystemObject', true);
```

Obtain real-valued amplitudes (not magnitudes)

```
[Hr_zerophase, ~] = zerophase(Hd1);  
[Hr, W] = zerophase(Hd2);
```

Plot and compare response

```
plot(W, Hr_zerophase, 'k', 'linewidth', 2);  
xlabel('Radians/sample'); ylabel('Amplitude');  
hold on;  
plot(W, Hr, 'r');  
axis tight; grid on;  
legend('with ''ZeroPhase'', true', 'with ''ZeroPhase'' false');
```

Note that the amplitude of the zero phase response (black line) is nonnegative for all frequencies.

The 'ZeroPhase' option is valid only for equiripple Nyquist designs with the 'N,TW' specification. You cannot specify 'MinPhase' and 'ZeroPhase' to be simultaneously 'true'.

**Introduced in R2011a**

# fdesign.octave

Octave filter specification

## Syntax

```
d = fdesign.octave(l)
d = fdesign.octave(l, MASK)
d = fdesign.octave(l, MASK, spec)
d = fdesign.octave(..., Fs)
```

## Description

`d = fdesign.octave(l)` constructs an octave filter specification object `d`, with `l` bands per octave. The default value for `l` is one.

---

**Note** The filters created by `fdesign.octave` comply with the ANSI® S1.11-2004 and IEC 61260:1995 standards.

---

`d = fdesign.octave(l, MASK)` constructs an octave filter specification object `d` with `l` bands per octave and `MASK` specification for the FVTool. The available values for `mask` are:

- 'class 0'
- 'class 1'
- 'class 2'

`d = fdesign.octave(l, MASK, spec)` constructs an octave filter specification object `d` with `l` bands per octave, `MASK` specification for the FVTool, and the `spec` specification string. The specification strings available are:

- 'N, F0'

(not case sensitive), where:

- `N` is the filter order
- `F0` is the center frequency. The center frequency is specified in normalized frequency units assuming a sampling frequency of 48 kHz, unless a sampling frequency in Hz is included in the specification: `d = fdesign.octave(..., Fs)`. If you specify an invalid center frequency, a warning is issued and the center frequency is rounded to the nearest valid value. You can determine the valid center frequencies for your design by using `validfrequencies` with your octave filter specification object. For example:

```
d = fdesign.octave(1, 'Class 1', 'N,F0', 6, 1000, 44.1e3);  
validcenterfreq = validfrequencies(d);
```

Valid center frequencies:

- Must be greater than 20 Hz and less than 20 kHz if you specify a sampling frequency. The range 20 Hz to 20 kHz is the standard range of human hearing.
- Are calculated according to the following algorithm if the number of bands per octave, `L`, is even:

```
G = 10^(3/10);  
x = -1000:1350;  
validcenterfreq = 1000*(G.^((2*x-59)/(2*L)));  
validcenterfreq = validcenterfreq(validcenterfreq>20 & validcenterfreq<2e4);
```

- Are calculated according to the following algorithm if the number of bands per octave, `L`, is odd:

```
G = 10^(3/10);  
x = -1000:1350;  
validcenterfreq = 1000*(G.^(x-30)/L);  
validcenterfreq = validcenterfreq(validcenterfreq>20 & validcenterfreq<2e4);
```

Only center frequencies greater than 20 and less than 20,000 are retained. The center frequencies and the corresponding upper band frequencies must be less than the Nyquist frequency, which is half the sampling rate (`samplingfreq`). The vector of upper band frequencies (`upperbandfreq`) corresponding to the center frequencies (`validcenterfreq`) is computed using the following algorithm:

```
upperbandfreq = validcenterfreq.*(G^(1/(2*L)));
```

The algorithm removes the center frequencies whose corresponding upper band frequencies do not obey the Nyquist rule.

```
validcenterfreq = validcenterfreq(upperbandfreq < samplingfreq/2);
```

If you do not specify a sampling frequency, `fdesign.octave` assumes a `samplingfreq` of 48 kHz. To obtain valid normalized center frequencies, the remaining center frequencies are divided by 24,000.

```
validcenterfreq = validcenterfreq/24000;
```

## Examples

### Design an Octave Band Filter

Design a sixth order, octave-band class 0 filter with a center frequency of 1000 Hz and, a sampling frequency of 44.1 kHz.

```
d = fdesign.octave(1, 'Class 0', 'N,F0', 6, 1000, 44100)
```

```
d =
  octave with properties:
      Response: 'Octave and Fractional Octave'
  BandsPerOctave: 1
      Mask: 'Class 0'
  Specification: 'N,F0'
  Description: {2x1 cell}
  NormalizedFrequency: 0
      Fs: 44100
  FilterOrder: 6
      F0: 1000
```

```
Hd = design(d, 'SystemObject', true)
```

```
Hd =
  dsp.BiquadFilter with properties:
      Structure: 'Direct form II'
  SOSMatrixSource: 'Property'
      SOSMatrix: [3x6 double]
  ScaleValues: [4x1 double]
  InitialConditions: 0
  OptimizeUnityScaleValues: true
```

```
Show all properties
```

```
fvtool(Hd)
```

The figure shows the magnitude response plot of the filter. The logarithmic scale for frequency is automatically set by FVTool for the octave filters.

## See Also

`fdesign`

**Introduced in R2011a**

# fdesign.parmeq

Parametric equalizer filter specification

---

**Note** The `fdesign.parmeq` function will be removed from DSP System Toolbox in a future release. Existing instances of the function continue to run. For new code, use the `fdesign.parmeq` function from Audio System Toolbox instead.

---

## Syntax

```
d = fdesign.parmeq(spec, specvalue1, specvalue2, ...)
d = fdesign.parmeq(... fs)
```

## Description

`d = fdesign.parmeq(spec, specvalue1, specvalue2, ...)` constructs a parametric equalizer filter design object, where `spec` is a non-case sensitive specification string. The choices for `spec` are as follows:

- 'F0, BW, BWp, Gref, G0, GBW, Gp' (minimum order default)
- 'F0, BW, BWst, Gref, G0, GBW, Gst'
- 'F0, BW, BWp, Gref, G0, GBW, Gp, Gst'
- 'N, F0, BW, Gref, G0, GBW'
- 'N, F0, BW, Gref, G0, GBW, Gp'
- 'N, F0, Fc, Qa, G0'
- 'N, F0, Fc, S, G0'
- 'N, F0, BW, Gref, G0, GBW, Gst'
- 'N, F0, BW, Gref, G0, GBW, Gp, Gst'
- 'N, Flow, Fhigh, Gref, G0, GBW'
- 'N, Flow, Fhigh, Gref, G0, GBW, Gp'

- 'N, Flow, Fhigh, Gref, G0, GBW, Gst'
- 'N, Flow, Fhigh, Gref, G0, GBW, Gp, Gst'

where the parameters are defined as follows:

- BW — Bandwidth
- BWp — Passband Bandwidth
- BWst — Stopband Bandwidth
- Gref — Reference Gain (decibels)
- G0 — Center Frequency Gain (decibels)
- GBW — Gain at which Bandwidth (BW) is measured (decibels)
- Gp — Passband Gain (decibels)
- Gst — Stopband Gain (decibels)
- N — Filter Order
- F0 — Center Frequency
- Fc— Cutoff frequency
- Fhigh - Higher Frequency at Gain GBW
- Flow - Lower Frequency at Gain GBW
- Qa-Quality Factor
- S-Slope Parameter for Shelving Filters

Regardless of the specification string chosen, there are some conditions that apply to the specification parameters. These are as follows:

- Specifications for parametric equalizers must be given in decibels
- To boost the input signal, set  $G0 > Gref$ ; to cut, set  $Gref > G0$
- For boost:  $G0 > Gp > GBW > Gst > Gref$ ; For cut:  $G0 < Gp < GBW < Gst < Gref$
- Bandwidth must satisfy:  $BWst > BW > BWp$

`d = fdesign.paremeq(... fs)` adds the input sampling frequency. Fs must be specified as a scalar trailing the other numerical values provided, and is assumed to be in Hz.

## Examples

Design a Chebyshev Type II parametric equalizer filter that cuts by 12 dB:

```
d = fdesign.parmeq('N,Flow,Fhigh,Gref,G0,GBW,Gst',...
    4,.3,.5,0,-12,-10,-1);
Hd = design(d,'cheby2');
fvtool(Hd)
```

Design a 4th order audio lowpass ( $F_0 = 0$ ) shelving filter with cutoff frequency of  $F_c = 0.25$ , quality factor  $Q_a = 10$ , and boost gain of  $G_0 = 8$  dB:

```
d = fdesign.parmeq('N,F0,Fc,Qa,G0',4,0,0.25,10,8);
Hd = design(d);
fvtool(Hd)
```

Design 4th-order highpass shelving filters with  $S=1.5$  and  $S=3$ :

```

N=4;
F0 = 1;
Fc = .4; % Cutoff Frequency
G0 = 10;
S = 1.5;
S2=3;
f = fdesign.parmeq('N,F0,Fc,S,G0',N,F0,Fc,S,G0);
h1 = design(f);
f.S=3;
h2=design(f);
hfvf=fvtool([h1 h2]);
set(hfvf,'Filters',[h1 h2]);
legend(hfvf,'S=1.5','S=3');
    
```

## See Also

fdesign

Introduced in R2011a

## **fdesign.peak**

Peak filter specification

### **Syntax**

```
d = fdesign.peak(specstring, value1, value2, ...)  
d = fdesign.peak(n, f0, q)  
d = fdesign.peak(..., Fs)  
d = fdesign.peak(..., MAGUNITS)
```

### **Description**

`d = fdesign.peak(specstring, value1, value2, ...)` constructs a peaking filter specification object `d`, with specification set to `specstring` and values provided for all members of the `specstring`. The possible specification options, which are not case sensitive, are listed as follows:

- 'N,F0,Q' (default)
- 'N,F0,Q,Ap'
- 'N,F0,Q,Ast'
- 'N,F0,Q,Ap,Ast'
- 'N,F0,BW'
- 'N,F0,BW,Ap'
- 'N,F0,BW,Ast'
- 'N,F0,BW,Ap,Ast'

where the variables are defined as follows:

- N - Filter Order (must be even)
- F0 - Center Frequency
- Q - Quality Factor
- BW - 3-dB Bandwidth

- $A_p$  - Passband Ripple (decibels)
- $A_{st}$  - Stopband Attenuation (decibels)

Different specification options, resulting in different specification objects, may have different design methods available. Use the function `designmethods` to get a list of design methods available for a given specification. For example:

```
>> d = fdesign.peak('N,F0,Q,Ap',6,0.5,10,1);
>> designmethods(d)
```

Design Methods for class `fdesign.peak (N,F0,Q,Ap)`:

`cheby1`

`d = fdesign.peak(n,f0,q)` constructs a peaking filter specification object using the default `specstring ('N,F0,Q')` and setting the corresponding values to `n`, `f0`, and `q`.

By default, all frequency specifications are assumed to be in normalized frequency units. All magnitude specifications are assumed to be in decibels.

`d = fdesign.peak(...,Fs)` constructs a peak filter specification object while providing the sampling frequency of the signal to be filtered. `Fs` must be specified as a scalar trailing the other values provided. If you specify an `Fs`, it is assumed to be in Hz, as all the other frequency values provided.

`d = fdesign.peak(...,MAGUNITS)` constructs a notch filter specification while providing the units for any magnitude specification given. `MAGUNITS` can be one of the following: `'linear'`, `'dB'`, or `'squared'`. If this argument is omitted, `'dB'` is assumed. The magnitude specifications are always converted and stored in decibels regardless of how they were specified. If `Fs` is provided, `MAGUNITS` must follow `Fs` in the input argument list.

## Examples

### Design a Chebyshev Type II Peaking Filter

Design a Chebyshev Type II peaking filter with a stopband attenuation of 80 dB.

```
d = fdesign.peak('N,F0,BW,Ast',8,.65,.02,80);  
Hd = design(d,'cheby2','SystemObject',true);  
fvtool(Hd)
```

# fdesign.polysrc

Construct polynomial sample-rate converter (POLYSRC) filter designer

## Syntax

```
d = fdesign.polysrc(l,m)
d = fdesign.polysrc(l,m,'Fractional Delay','Np',Np)
d = fdesign.polysrc(...,Fs)
```

## Description

`d = fdesign.polysrc(l,m)` constructs a polynomial sample-rate converter filter designer `D` with an interpolation factor `L` and a decimation factor `M`. `L` defaults to 3. `M` defaults to 2. `L` and `M` can be arbitrary positive numbers.

`d = fdesign.polysrc(l,m,'Fractional Delay','Np',Np)` initializes the filter designer specification with `Np` and sets the polynomial order to the value `Np`. If omitted `Np` defaults to 3.

`d = fdesign.polysrc(...,Fs)` specifies the sampling frequency (in Hz).

## Examples

### Design a Sample-Rate Converter

This example shows how to design sample-rate converter that uses a 3rd order Lagrange interpolation filter to convert from 44.1kHz to 48kHz.

```
[L,M] = rat(48/44.1);
f = fdesign.polysrc(L,M,'Fractional Delay','Np',3);
Hm = design(f,'lagrange');
```

Original sampling frequency

```
Fs = 44.1e3;
```

9408 samples, 0.213 seconds long

```
n = 0:9407;
```

Original signal, sinusoid at 1kHz

```
x = sin(2*pi*1e3/Fs*n);
```

10241 samples, still 0.213 seconds

```
y = filter(Hm,x);
```

Plot original sampled at 44.1kHz

```
stem(n(1:45)/Fs,x(1:45))
```

```
hold on
```

Plot fractionally interpolated signal (48kHz) in red

```
stem((n(3:51)-2)/(Fs*L/M),y(3:51),'r','filled')  
xlabel('Time (sec)');ylabel('Signal value')  
legend('44.1 kHz sample rate','48 kHz sample rate')
```

For more information about Farrow SRCs, see the "Efficient Sample Rate Conversion between Arbitrary Factors" example, `efficientsrcdemo`.

# fdesign.pulseshaping

Pulse-shaping filter specification object

## Syntax

```
D = fdesign.pulseshaping
D = fdesign.pulseshaping(sps)
D = fdesign.pulseshaping(sps,shape)
d = fdesign.pulseshaping(sps,shape,spec,value1,value2,...)
d = fdesign.pulseshaping(...,fs)
d = fdesign.pulseshaping(...,magunits)
```

## Description

---

**Note** The use of `fdesign.pulseshaping` is not recommended. Use `rcosdesign` or `gaussdesign` instead.

---

`D = fdesign.pulseshaping` constructs a specification object `D`, which can be used to design a minimum-order raised cosine filter object with a default stop band attenuation of 60dB and a rolloff factor of 0.25.

`D = fdesign.pulseshaping(sps)` constructs a minimum-order raised cosine filter specification object `d` with a positive integer-valued oversampling factor, `SamplesPerSymbol`.

`D = fdesign.pulseshaping(sps,shape)` constructs `d` where `shape` specifies the `PulseShape` property. Valid entries for `shape` are:

- 'Raised Cosine'
- 'Square Root Raised Cosine'
- 'Gaussian'

`d = fdesign.pulseshaping(sps,shape,spec,value1,value2,...)` constructs `d` where `spec` defines the `Specification` properties. The entries for `spec` specify various

properties of the filter, including the order and frequency response. Valid entries for `spec` depend upon the `shape` property. For 'Raised Cosine' and 'Square Root Raised Cosine' filters, the valid entries for `spec` are:

- 'Ast,Beta' (minimum order; default)
- 'Nsym,Beta'
- 'N,Beta'

The filter specifications are defined as follows:

- **Ast** —stopband attenuation (in dB). The default stopband attenuation for a raised cosine filter is 60 dB. The default stopband attenuation for a square root raised cosine filter is 30 dB. If **Ast** is specified, the minimum-order filter is returned.
- **Beta** —rolloff factor expressed as a real-valued scalar ranging from 0 to 1. Smaller rolloff factors result in steeper transitions between the passband and stopband of the filter.
- **Nsym** —filter order in symbols. The length of the impulse response is given by  $Nsym * SamplesPerSymbol + 1$ . The product  $Nsym * SamplesPerSymbol$  must be even.
- **N** —filter order (must be even). The length of the impulse response is  $N + 1$ .

If the `shape` property is specified as 'Gaussian', the valid entries for `spec` are:

- 'Nsym,BT' (default)

The filter specifications are defined as follows:

- **Nsym**—filter order in symbols. **Nsym** defaults to 6. The length of the filter impulse response is  $Nsym * SamplesPerSymbol + 1$ . The product  $Nsym * SamplesPerSymbol$  must be even.
- **BT** —the 3-dB bandwidth-symbol time product. **BT** is a positive real-valued scalar, which defaults to 0.3. Larger values of **BT** produce a narrower pulse width in time with poorer concentration of energy in the frequency domain.

`d = fdesign.pulseshaping(...,fs)` specifies the sampling frequency of the signal to be filtered. `fs` must be specified as a scalar trailing the other numerical values provided. For this case, `fs` is assumed to be in Hz and is used for analysis and visualization.

`d = fdesign.pulseshaping(...,magunits)` specifies the units for any magnitude specification you provide in the input arguments. Valid entries for `magunits` are:

- `linear` — specify the magnitude in linear units
- `dB` — specify the magnitude in dB (decibels)
- `squared` — specify the magnitude in power units

When you omit the `magunits` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

After creating the specification object `d`, you can use the `design` function to create a filter object such as `h` in the following example:

```
d = fdesign.pulseshaping(8,'Raised Cosine','Nsym,Beta',6,0.25);  
h = design(d);
```

Normally, the `Specification` property of the specification object also determines which design methods you can use when you create the filter object. Currently, regardless of the `Specification` property, the `design` function uses the `window` design method with all `fdesign.pulseshaping` specification objects. The `window` method creates an FIR filter with a windowed impulse response.

## Examples

Pulse-shaping can be used to change the waveform of transmitted pulses so the signal bandwidth matches that of the communication channel. This helps to reduce distortion and intersymbol interference (ISI).

This example shows how to design a minimum-order raised cosine filter that provides a stop band attenuation of 60 dB, rolloff factor of 0.50, and 8 samples per symbol.

```
h = fdesign.pulseshaping(8,'Raised Cosine','Ast,Beta',60,0.50);  
Hd = design(h);  
fvtool(Hd)
```

This code generates the following figure.

This example shows how to design a raised cosine filter that spans 8 symbol durations (i.e., of order 8 symbols), has a rolloff factor of 0.50, and oversampling factor of 10.

```
h = fdesign.pulseshaping(10,'Raised Cosine','Nsym,Beta',8,0.50);
Hd = design(h);
fvtool(Hd, 'impulse')
```

This example shows how to design a square root raised cosine filter of order 42, rolloff factor of 0.25, and 10 samples per symbol.

```
h = fdesign.pulseshaping(10,'Square Root Raised Cosine','N,Beta',42);  
Hd = design(h);  
fvtool(Hd, 'impulse')
```

The following example demonstrates how to create a Gaussian pulse-shaping filter with an oversampling factor (sps) of 10, a bandwidth-time symbol product of 0.2, and 8 symbol periods. The sampling frequency is specified as 10 kHz.

**Introduced in R2011a**

# fdesign.rsrc

Rational-factor sample-rate converter specification

## Syntax

```
D = fdesign.rsrc(L,M)
D = fdesign.rsrc(L,M,RESPONSE)
D = fdesign.rsrc(L,M,CICRESPONSE,D)
D = fdesign.rsrc(L,M,RESPONSE,SPEC)
D = fdesign.rsrc(L,M,SPEC,specvalue1,specvalue2,...)
D = fdesign.rsrc(...,Fs)
D = fdesign.rsrc(...,MAGUNITS)
```

## Description

`D = fdesign.rsrc(L,M)` constructs a rational-factor sample-rate filter specification object `D` with the `InterpolationFactor` property equal to the positive integer `L`, the `DecimationFactor` property equal to the positive integer `M` and the `Response` property set to `'Nyquist'`. The default values for the transition width and stopband attenuation in the Nyquist design are  $0.1\pi$  radians/sample and 80 dB. If `L` is unspecified, `L` defaults to 3. If `M` is unspecified, `M` defaults to 2.

`D = fdesign.rsrc(L,M,RESPONSE)` constructs an rational-factor sample-rate converter with the interpolation factor `L`, decimation factor `M`, and the response you specify in `RESPONSE`.

`D = fdesign.rsrc(L,M,CICRESPONSE,D)` constructs a CIC or CIC compensator rational-factor sample-rate convertor filter specification object with the `'RESPONSE'` property equal to `'CIC'` or `'CICCOMP'`. `D` is the differential delay. The differential delay, `D`, must precede the filter specification.

Because you are designing multirate filters, the specification options available are not the same as the specification options for designing single-rate filters. The interpolation and decimation factors are not included in the specification. Different filter responses support different specifications. The following table lists the supported response types and specification options. These options are not case sensitive.

Design Method	Valid Specification Options
'Arbitrary Magnitude'	<p>See <code>fdesign.arbmag</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'N,F,A' (default option)</li> <li>• 'N,B,F,A'</li> </ul>
'Arbitrary Magnitude and Phase'	<p>See <code>fdesign.arbmagnphase</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'N,F,H' (default option)</li> <li>• 'N,B,F,H'</li> </ul>
'Bandpass'	<p>See <code>fdesign.bandpass</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2' (default option)</li> <li>• 'N,Fc1,Fc2'</li> <li>• 'N,Fst1,Fp1,Fp2,Fst2'</li> </ul>
'Bandstop'	<p>See <code>fdesign.bandstop</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'N,Fc1,Fc2'</li> <li>• 'N,Fp1,Fst1,Fst2,Fp2'</li> <li>• 'Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2' (default option)</li> </ul>
'CIC'	<p>'Fp,Fst,Ap,Ast' — Only valid specification. Fp is the passband frequency, Fst is the stopband frequency, Ap is the passband ripple, and Ast is the stopband attenuation in decibels.</p> <p>To specify a CIC rational-factor sample-rate convertor, include the differential delay after 'CIC' and before the filter specification: 'Fp,Ast'. For example:  <code>d = fdesign.rsrc(2,2,'cic',4);</code></p>

Design Method	Valid Specification Options
'CIC Compensator'	<p>See <code>fdesign.ciccomp</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'Fp,Fst,Ap,Ast' (default option)</li> <li>• 'N,Fc,Ap,Ast'</li> <li>• 'N,Fp,Ap,Ast'</li> <li>• 'N,Fp,Fst'</li> <li>• 'N,Fst,Ap,Ast'</li> </ul> <p>To specify a CIC compensator rational-factor sample-rate convertor, include the differential delay after 'CICCOMP' and before the filter specification. For example:  <code>d = fdesign.rsrc(2,2,'ciccomp',4);</code></p>
'Differentiator'	'N' — filter order
'Gaussian'	<p>'Nsym,BT — Nsym is the filter order in symbols and BT is the bandwidth-symbol time product.</p> <p>The filter specification must be preceded by an integer-valued <code>SamplesPerSymbol</code>.</p>
'Halfband'	<p>See <code>fdesign.halfband</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'TW,Ast' (default option)</li> <li>• 'N,TW'</li> <li>• 'N'</li> <li>• 'N,Ast'</li> </ul> <p>If you use the quasi-linear IIR design method, <code>iirlinphase</code>, with a halfband specification, the interpolation factor must be 2.</p>

<b>Design Method</b>	<b>Valid Specification Options</b>
'Highpass'	<p>See <code>fdesign.highpass</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'Fst,Fp,Ast,Ap' (default option)</li> <li>• 'N,F3db'</li> <li>• 'N,Fc'</li> <li>• 'N,Fc,Ast,Ap'</li> <li>• 'N,Fp,Ast,Ap'</li> <li>• 'N,Fst,Ast,Ap'</li> <li>• 'N,Fst,Fp'</li> <li>• 'N,Fst,Ast,Ap'</li> <li>• 'N,Fst,Fp,Ast'</li> </ul>
'Hilbert'	<p>See <code>fdesign.hilbert</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'N,TW' (default option)</li> <li>• 'TW,Ap'</li> </ul>
'Inverse-sinc Lowpass'	<p>See <code>fdesign.isinclp</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'Fp,Fst,Ap,Ast' (default option)</li> <li>• 'N,Fc,Ap,Ast'</li> <li>• 'N,Fp,Fst'</li> <li>• 'N,Fst,Ap,Ast'</li> </ul>
'Inverse-sinc Highpass'	<p>See <code>fdesign.isinchp</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'Fst,Fp,Ast,Ap' (default option)</li> <li>• 'N,Fc,Ast,Ap'</li> <li>• 'N,Fst,Fp'</li> <li>• 'N,Fst,Ast,Ap'</li> </ul>

Design Method	Valid Specification Options
'Lowpass'	<p>See <code>fdesign.lowpass</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'Fp,Fst,Ap,Ast' (default option)</li> <li>• 'N,F3dB'</li> <li>• 'N,Fc'</li> <li>• 'N,Fc,Ap,Ast'</li> <li>• 'N,Fp,Ap,Ast'</li> <li>• 'N,Fp,Fst'</li> <li>• 'N,Fp,Fst,Ap'</li> <li>• 'N,Fp,Fst,Ast'</li> <li>• 'N,Fst,Ap,Ast'</li> </ul>
'Nyquist'	<p>See <code>fdesign.nyquist</code> for a description of the specification entries. For all Nyquist specifications, you must specify the <i>L</i>th band. This typically corresponds to the interpolation factor so that the nonzero samples of the upsampler output are preserved.</p> <ul style="list-style-type: none"> <li>• 'TW,Ast' (default option)</li> <li>• 'N'</li> <li>• 'N,Ast'</li> <li>• 'N,Ast'</li> </ul>

`D = fdesign.rsrc(L,M,RESPONSE,SPEC)` constructs object `D` and sets its `Specification` property to `SPEC`. Entries in the `SPEC` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` depend on the design type of the specifications object.

When you add the `SPEC` input argument, you must also add the `RESPONSE` input argument.

`D = fdesign.rsrc(L,M,SPEC,specvalue1,specvalue2,...)` constructs an object `D` and sets its specifications at construction time.

`D = fdesign.rsrc(...,Fs)` provides the sampling frequency of the signal to be filtered. `Fs` must be specified as a scalar trailing the other numerical values provided. `Fs` is assumed to be in Hz as are all other frequency values provided.

`D = fdesign.rsrc(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units.
- `'dB'` — specify the magnitude in dB (decibels).
- `'squared'` — specify the magnitude in power units.

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

### Construct a Sample-Rate Converter Using `fdesign` Object

Design a rational-factor sample-rate converter. Set the rational sample-rate change to  $5/3$ . Use the default Nyquist design with a transition width of  $0.05\pi$  radians/sample and stopband attenuation of 40 dB. The `Lth` band factor in the Nyquist design is equal to the interpolation factor.

```
d = fdesign.rsrc(5,3,'nyquist',5,.05,40);  
hm = design(d,'kaiserwin','SystemObject',true); %design with Kaiser window
```

Design a rational-factor sample-rate converter. Set the rational sample-rate change to  $5/3$ . Use a Nyquist design with the filter specification set to `'N,TW'`. Set the order equal to 12 and the transition width to  $0.1\pi$  radians/sample. The `Lth` band factor in the Nyquist design is equal to the interpolation factor.

```
d = fdesign.rsrc(5,3,'nyquist',5,'N,TW',12,0.1); %#ok
```

Design a rational-factor sample-rate converter. Assume the data are sampled at 10 kHz. Set the rational sample-rate change to  $3/2$ . Use a Nyquist design with the filter specification set to `'N,TW'`. Set the order equal to 12 and the transition width to 100 Hz. The `Lth` band factor in the Nyquist design is equal to the interpolation factor.

```
d = fdesign.rsrc(3,2,'nyquist',3,'N,TW',12,100,1e4);  
hd = design(d,'equiripple','SystemObject',true);
```

## fftcoeffs

Frequency-domain coefficients

### Syntax

```
c = fftcoeffs(hd)
```

### Description

`c = fftcoeffs(hd)` return the frequency-domain coefficients used when filtering with the `dfilt.fftfir` object. `c` contains the coefficients

### Examples

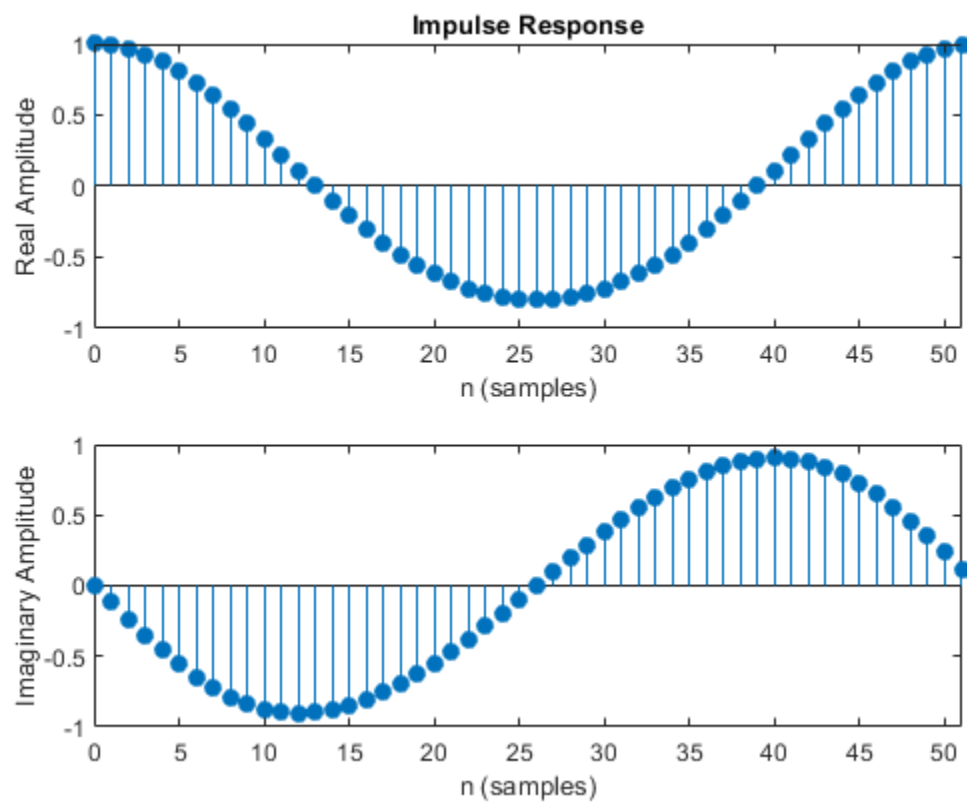

#### Frequency Domain Coefficients of FIR Filter

This example demonstrates returning the FFT coefficients from the discrete-time filter `hd`.

```
b = [0.05 0.9 0.05];  
len = 50;  
hd = dfilt.fftfir(b,len);  
c=fftcoeffs(hd);
```

Plot the impulse response of the coefficients.

```
impz(c);
```

**Introduced in R2011a**

## filter

Filter data with filter object

### Syntax

```
y = filter(hd,x)
y = filter(hd,x,dim)
```

### Description

#### Fixed-Point Filter Syntaxes

`y = filter(hd,x)` filters a vector of real or complex input data `x` through a fixed-point filter `hd`, producing filtered output data `y`. The vectors `x` and `y` have the same length. `filter` stores the final conditions for the filter in the `States` property of `hd` — `hd.states`.

When you set the property `PersistentMemory` to `false` (the default setting), the initial conditions for the filter are set to zero before filtering starts. To use nonzero initial conditions for `hd`, set `PersistentMemory` to `true`. Then set `hd.states` to a vector of `nstates(hd)` elements, one element for each state to set. If you specify a scalar for `hd.states`, `filter` expands the scalar to a vector of the proper length for the states. All elements of the expanded vector have the value of the scalar.

If `x` is a matrix, `y = filter(hd,x)` filters along each column of `x` to produce a matrix `y` of independent channels. If `x` is a multidimensional array, `y = filter(hd,x)` filters `x` along the first nonsingleton dimension of `x`.

To use nonzero initial conditions when you are filtering a matrix `x`, set the filter states to a matrix of initial condition values. Set the initial conditions by setting the `States` property for the filter (`hd.states`) to a matrix of `nstates(hd)` rows and `size(x,2)` columns.

`y = filter(hd,x,dim)` applies the filter `hd` to the input data located along the specific dimension of `x` specified by `dim`.

When you are filtering multichannel data, `dim` lets you specify which dimension of the input matrix to filter along — whether a row represents a channel or a column represents

a channel. When you provide the `dim` input argument, the filter operates along the dimension specified by `dim`. When your input data `x` is a vector or matrix and `dim` is 1, each column of `x` is treated as a one input channel. When `dim` is 2, the filter treats each row of the input `x` as a channel.

To filter multichannel data in a loop environment, you must use the `dim` input argument to set the proper processing dimension.

You specify the initial conditions for each channel individually, when needed, by setting `hm.states` to a matrix of `nstates` (`hd`) rows (one row containing the states for one channel of input data) and `size(x,2)` columns (one column containing the filter states for each channel).

## Examples

### Filter a Signal Using the `filter` function

Filter a signal using a filter with various initial conditions (IC) or no initial conditions.

```
x = randn(100,1);    % Original signal.
b = fir1(50,.4);    % 50th-order linear-phase FIR filter.
hd = dfilt.dffir(b); % Direct-form FIR implementation.
```

Do not set specific initial conditions.

```
y1 = filter(hd,x);    % 'PersistentMemory'='false'(default).
zf = hd.states;      % Final conditions.
```

Now use nonzero initial conditions by setting ICs after before you filter.

```
hd.persistentmemory = true;
hd.states = 1;       % Uses scalar expansion.
y2 = filter(hd,x);
stem([y1 y2])       % Different sequences at beginning.
legend('y1','y2');
```

Looking at the stem plot shows that the sequences are different at the beginning of the filter process.

Here is one way to use filter with streaming data.

```
reset(hd);           % Clear filter history.
y3 = filter(hd,x);  % Filter entire signal in one block.
```

As an experiment, repeat the process, filtering the data as sections, rather than in streaming form.

```
reset(hd);           % Clear filter history.
yloop = zeros(20,5); % Preallocate output array.
xblock = reshape(x,[20 5]);
```

```
for i=1:5
    yloop(:,i) = filter(hd,xblock(:,i));
end
```

Use a stem plot to see the comparison between streaming and block-by-block filtering.

```
stem([y3 yloop(:)]);
legend('y3','yloop')
```

Filtering the signal section-by-section is equivalent to filtering the entire signal at once.

## Algorithms

### Quantized Filters

The `filter` command implements fixed- or floating-point arithmetic on the quantized filter structure you specify.

The algorithm applied by `filter` when you use a discrete-time filter object on an input signal depends on the response you chose for the filter, such as lowpass or Nyquist or bandstop. To learn more about each filter algorithm, refer to the literature reference provided on the appropriate discrete-time filter reference page.

---

**Note** `dfilt/filter` does not normalize the filter coefficients automatically. Function `filter` supplied by MATLAB does normalize the coefficients.

---

### Adaptive Filters

The algorithm used by `filter` when you apply an adaptive filter object to a signal depends on the algorithm you chose for your adaptive filter. To learn more about each adaptive filter algorithm, refer to the literature reference provided on the appropriate adaptive filter object reference page.

**Introduced in R2011a**

# filterBuilder

Interactive filter design

## Syntax

```
filterBuilder(h)  
filterBuilder('response')
```

## Description

`filterBuilder` starts a interactive tool for building filters. It relies on the `fdesign` object-object oriented filter design paradigm, and is intended to reduce development time during the filter design process. `filterBuilder` uses a specification-centered approach to find the best algorithm for the desired response.

---

**Note** You must have the Signal Processing Toolbox installed to use `fdesign` and `filterBuilder`. Some of the features described below may be unavailable if your installation does not additionally include the DSP System Toolbox. You can verify the presence of both toolboxes by typing `ver` at the command prompt.

---

For more information on how to use `filterBuilder`, see “Filter Builder Design Process”.

To use `filterBuilder`, enter `filterBuilder` at the MATLAB command line using one of three approaches:

- Simply enter `filterBuilder`. MATLAB opens a dialog for you to select a filter response type. After you select a filter response type, `filterBuilder` launches the appropriate filter design dialog box.
- Enter `filterBuilder(h)`, where `h` is an existing filter object. For example, if `h` is a bandpass filter, `filterBuilder(h)` opens the bandpass filter design dialog box. The `h` object must have been created using `filterBuilder` or using `fdesign`.

**Note** You must have the DSP System Toolbox software to create and import filter System objects.

- Enter `filterBuilder('response')` to replace *response* with a response method from the following table. MATLAB opens a filter design dialog that corresponds to the specified response.

**Note** You must have the DSP System Toolbox software to implement a number of the filter designs listed in the following table. If you only have the Signal Processing Toolbox software, you can design a limited set of the following filter-response types.

peak on page 5-683	Peak filter	fdesign.peak

---

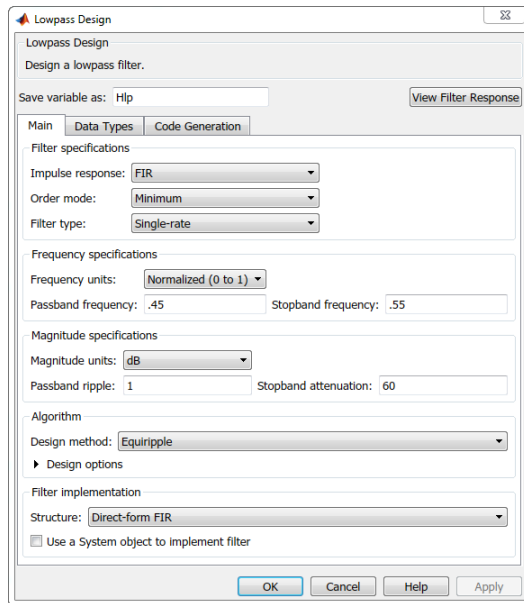

**Note** Because they do not change the filter structure, the magnitude specifications and design method are tunable when using `filterBuilder`.

---

## Filter Builder Design Panes

### Main Design Pane

The main pane of Filter Builder varies depending on the filter response type, but the basic structure is the same. The following figure shows the basic layout of the dialog box.

As you choose the response for the filter, the available options and design parameters displayed in the dialog box change. This display allows you to focus only on parameters that make sense in the context of your filter design.

Every filter design dialog box includes the options displayed at the top of the dialog box, shown in the following figure.

- **Save variable as** — When you click **Apply** to apply your changes or **OK** to close this dialog box, `filterBuilder` saves the current filter to your MATLAB workspace as a filter object with the name you enter.
- **View Filter Response** — Displays the magnitude response for the current filter specifications and design method by opening the Filter Visualization Tool (`fvtool`).

---

**Note** The `filterBuilder` dialog box includes an **Apply** option. Each time you click **Apply**, `filterBuilder` writes the modified filter to your MATLAB workspace. This modified filter has the variable name you assign in **Save variable as**. To apply changes

without overwriting the variable in your workspace, change the variable name in **Save variable as** before you click **Apply**.

---

There are three tabs in the Filter Builder dialog box, containing three panes: **Main**, **Data Types**, and **Code Generation**. The first pane changes according to the filter being designed. The last two panes are the same for all filters. These panes are discussed in the following sections.

## Data Types Pane

The second tab in the Filter Builder dialog box is shown in the following figure.

The **Arithmetic** drop down box allows the choice of **Double precision**, **Single precision**, or **Fixed point**. Some of these options may be unavailable depending on the filter parameters. The following table describes these options.

Arithmetic List Entry	Effect on the Filter
Double precision	All filtering operations and coefficients use double-precision, floating-point representations and math. When you use <code>filterBuilder</code> to create a filter, <code>double precision</code> is the default value for the Arithmetic property.
Single precision	All filtering operations and coefficients use single-precision floating-point representations and math.
Fixed point	This entry applies selected default values, typically used on many digital processors, for the properties in the fixed-point filter. These properties include coefficient word lengths, fraction lengths, and various operating modes. This setting allows signed fixed data types only. Fixed-point filter design with <code>filterBuilder</code> is available only when you install Fixed-Point Designer software along with DSP System Toolbox software.

The following figure shows the **Data Types** pane after you select `Fixed point` for **Arithmetic** and set **Filter internals** to `Specify precision`. This figure shows the **Data Types** pane for the case where the **Use a System object to implement filter** check box is not selected in the **Main** pane.

Lowpass Design

Design a lowpass filter.

Filter output variable name:  View Filter Response

Main Data Types Code Generation

Arithmetic: Fixed point

Fixed-point data types

	Mode	Signed	Word length	Fraction length
Input signal	Binary point scaling	yes	<input type="text" value="16"/>	<input type="text" value="15"/>
Coefficients	<input type="text" value="Specify word length"/>	<input checked="" type="checkbox"/>	<input type="text" value="16"/>	
Filter internals	<input type="text" value="Specify precision"/>			
Product	Binary point scaling	yes	<input type="text" value="32"/>	<input type="text" value="29"/>
Accum	Binary point scaling	yes	<input type="text" value="40"/>	<input type="text" value="29"/>
Output	Binary point scaling	yes	<input type="text" value="16"/>	<input type="text" value="15"/>

Fixed-point operational parameters

Rounding mode:  Overflow mode:

OK Cancel Help Apply

When you select **Use a System object to implement filter** check box in the **Main** pane, the **Data Types** pane appears as below:

Not all parameters described in the following section apply to all filters. For example, FIR filters do not have the **Section input** and **Section output** parameters.

### **Input signal**

Specify the format the filter applies to data to be filtered. For all cases, `filterBuilder` implements filters that use binary point scaling and signed input. You set the word length and fraction length as needed.

### **Coefficients**

Choose how you specify the word length and the fraction length of the filter numerator and denominator coefficients:

- `Specify word length` enables you to enter the word length of the coefficients in bits. In this mode, `filterBuilder` automatically sets the fraction length of the coefficients to the binary-point only scaling that provides the best possible precision for the value and word length of the coefficients.
- `Binary point scaling` enables you to enter the word length and the fraction length of the coefficients in bits. If applicable, enter separate fraction lengths for the numerator and denominator coefficients.
- The filter coefficients do not obey the **Rounding mode** and **Overflow mode** parameters that are available when you select `Specify precision` from the Filter internals list. Coefficients are always saturated and rounded to `Nearest`.

### **Section Input**

Choose how you specify the word length and the fraction length of the fixed-point data type going into each section of an SOS filter. This parameter is visible only when the selected filter structure is IIR and SOS.

- `Binary point scaling` enables you to enter the word and fraction lengths of the section input in bits.
- `Specify word length` enables you to enter the word lengths in bits.

### **Section Output**

Choose how you specify the word length and the fraction length of the fixed-point data type coming out of each section of an SOS filter. This parameter is visible only when the selected filter structure is IIR and SOS.

- `Binary point scaling` enables you to enter the word and fraction lengths of the section output in bits.

- `Specify word length` enables you to enter the output word lengths in bits.

### State

Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. Use this parameter to specify how to designate the state word and fraction lengths. This parameter is not visible for direct form and direct form I filter structures because `filterBuilder` deduces the state directly from the input format. States always use signed representation:

- `Binary point scaling` enables you to enter the word length and the fraction length of the accumulator in bits.
- `Specify precision` enables you to enter the word length and fraction length in bits (if available).

### Product

Determines how the filter handles the output of product operations. Choose from the following options:

- `Full precision` — Maintain full precision in the result.
- `Keep LSB` — Keep the least significant bit in the result when you need to shorten the data words.
- `Specify Precision` — Enables you to set the precision (the fraction length) used by the output from the multiplies.

### Filter internals

Specify how the fixed-point filter performs arithmetic operations within the filter. The affected filter portions are filter products, sums, states, and output. Select one of these options:

- `Full precision` — Specifies that the filter maintains full precision in all calculations for products, output, and in the accumulator.
- `Specify precision` — Set the word and fraction lengths applied to the results of product operations, the filter output, and the accumulator. Selecting this option enables the word and fraction length controls.

### Signed

Selecting this option directs the filter to use signed representations for the filter coefficients.

**Word length**

Sets the word length for the associated filter parameter in bits.

**Fraction length**

Sets the fraction length for the associate filter parameter in bits.

**Accum**

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths.

Determines how the accumulator outputs stored values. Choose from the following options:

- **Full precision** — Maintain full precision in the accumulator.
- **Keep MSB** — Keep the most significant bit in the accumulator.
- **Keep LSB** — Keep the least significant bit in the accumulator when you need to shorten the data words.
- **Specify Precision** — Enables you to set the precision (the fraction length) used by the accumulator.

**Output**

Sets the mode the filter uses to scale the output data after filtering. You have the following choices:

- **Avoid Overflow** — Set the output data fraction length to avoid causing the data to overflow. **Avoid overflow** is considered the conservative setting because it is independent of the input data values and range.
- **Best Precision** — Set the output data fraction length to maximize the precision in the output data.
- **Specify Precision** — Set the fraction length used by the filtered data.

**Fixed-point operational parameters**

Parameters in this group control how the filter rounds fixed-point values and how it treats values that overflow.

**Rounding mode**

Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).

- `ceil` — Round toward positive infinity.
- `convergent` — Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.
- `zero/fix` — Round toward zero.
- `floor` — Round toward negative infinity.
- `nearest` — Round toward nearest. Ties round toward positive infinity.
- `round` — Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.

The choice you make affects everything except coefficient values and input data which always round. In most cases, products do not overflow—they maintain full precision.

### **Overflow mode**

Sets the mode the filter uses to respond to overflow conditions in fixed-point arithmetic. Choose from the following options:

- `Saturate` — Limit the output to the largest positive or negative representable value.
- `Wrap` — Set overflowing values to the nearest representable value using modular arithmetic.

The choice you make affects everything except coefficient values and input data which always round. In most cases, products do not overflow—they maintain full precision.

### **Cast before sum**

Specifies whether to cast numeric data to the appropriate accumulator format before performing sum operations. Selecting **Cast before sum** ensures that the results of the affected sum operations match most closely the results found on most digital signal processors. Performing the cast operation before the summation adds one or two additional quantization operations that can add error sources to your filter results.

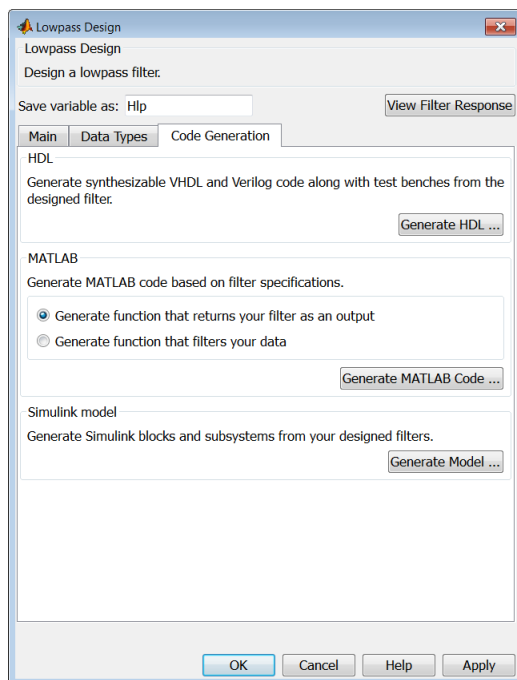

If you clear **Cast before sum**, the filter prevents the addends from being cast to the sum format before the addition operation. Choose this setting to get the most accurate results from summations without considering the hardware your filter might use. The input format referenced by **Cast before sum** depends on the filter structure you are using.

The effect of clearing or selecting **Cast before sum** is as follows:

- Cleared — Configures filter summation operations to retain the addends in the format carried from the previous operation.
- Selected — Configures filter summation operations to convert the input format of the addends to match the summation output format before performing the summation operation. Usually, selecting **Cast before sum** generates results from the summation that more closely match those found from digital signal processors.

## Code Generation Pane

The code generation pane contains options for various implementations of the completed filter design. Depending on your installation, you can generate MATLAB, VHDL, and Verilog code from the designed filter. You can also choose to create or update a Simulink model from the designed filter. The following section explains these options.

## HDL

For more information on this option, see “Opening the Filter Design HDL Coder UI from the Filter Builder” (Filter Design HDL Coder).

## MATLAB

### Generate MATLAB code based on filter specifications

- **Generate function that returns your filter as an output**

Selecting this option generates a function that designs a filter object using `fdesign`.

- **Generate function that filters your data**

Selecting this option generates a function that takes data as input, and outputs data filtered with the designed filter. The data type of the filter output is set according to the data type settings in the **Data Types** pane.

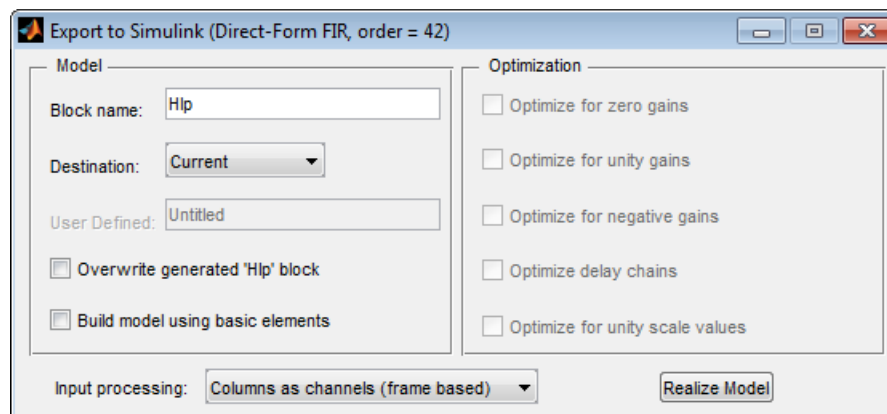

Clicking on the **Generate MATLAB code** button, brings up a Save File dialog. Specify the file name and location, and save. The filter is now contained in an editable file.

## Simulink Model

### Generate Simulink blocks and subsystems from your designed filters

When you click **Generate Model**, the filter builder generates Simulink blocks and subsystems from your designed filters.

Clicking on the **Generate Model** button opens the Export to Simulink dialog box.

- **Block Name** — The name for the new subsystem block, set to **Filter** by default.
- **Destination** — **Current** saves the generated model to the current Simulink model. **New** creates a new model to contain the generated block. **User Defined** creates a new model or subsystem at the location specified in **User Defined**.
- **Overwrite generated 'Filter' block** — Overwrites an existing block with the name specified in **Block Name**. Clear this check box to create a new block with the same name.
- **Build model using basic elements** — Builds the model using only basic blocks.
- **Optimize for zero gains** — Removes all zero-gain blocks from the model.
- **Optimize for unity gains** — Replaces all unity gains with direct connections.
- **Optimize for negative gains** — Removes all negative unity gain blocks, and changes sign at the nearest summation block.
- **Optimize delay chains** — Replaces delay chains made up of  $n$  unit delays with a single delay by  $n$ .
- **Optimize for unity scale values** — Removes all scale value multiplications by 1 from the filter structure.
- **Input processing** — Specify how the generated filter block or subsystem block processes the input. Depending on the type of filter you are designing, one or both of the following options may be available:
  - **Columns as channels (frame based)** — The block treats each column of the input as a separate channel.
  - **Elements as channels (sample based)** — The block treats each element of the input as a separate channel.

For more information about sample-based and frame-based processing, see “Sample- and Frame-Based Concepts”.

- **Realize Model** — Builds the model with the set parameters.

When the **Use a System object to implement filter** check box is selected in the **Main** pane, the **Generate Model** button in the **Simulink model** panel is disabled under the following conditions:

- Select **Filter response** as **Comb** and **Arithmetic** on the **Data Types** pane as **Fixed point**.
- Select **Filter response** as **Arbitrary Response**, **Impulse response** as **IIR**, set **Specify response as** to either **Magnitudes and phases** or **Frequency response**, and **Arithmetic** on the **Data Types** pane as **Fixed point**.

These settings design a `dsp.IIRFilter` System object with fixed point arithmetic. Generating a Simulink model for fixed point `dsp.IIRFilter` object is not supported.

## Filter Responses

Select your filter response from the `filterBuilder` **Response Selection** main menu.

If you have the DSP System Toolbox software, the following **Response Selection** menu appears.

Select your desired filter response from the menu and design your filter.

The following sections describe the options available for each response type.

## Arbitrary Response Filter Design — Main Pane

### Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

### Impulse response

This dialog only applies if you have the DSP System Toolbox software. Select either FIR or IIR from the drop down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly. Arbitrary group delay designs are only available if **Impulse response** is IIR. Without the DSP System Toolbox, the only available arbitrary response filter design is FIR.

### Order mode

This dialog only applies if you have the DSP System Toolbox software. Choose Minimum or Specify. Choosing Specify enables the **Order** dialog.

### Order

This dialog only applies when **Order mode** is Specify. For an FIR design, specify the filter order. For an IIR design, you can specify an equal order for the numerator and denominator, or you can specify different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box. Because the Signal Processing Toolbox only supports FIR arbitrary-magnitude filters, you do not have the option to specify a denominator order.

### Denominator order

Select the check box and enter the denominator order. This option is enabled only if IIR is selected for **Impulse response**.

### Filter type

This dialog only applies if you have the DSP System Toolbox software and is only available for FIR filters. Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterBuilder specifies single-rate filters.

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting Sample-rate converter activates both factors.

When you design either a decimator or interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

### **Decimation Factor**

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Decimator or Sample-rate converter. The default factor value is 2 for Decimator and 3 for Sample-rate converter.

### **Interpolation Factor**

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Interpolator or Sample-rate converter. The default factor value is 2.

### **Response Specification**

#### **Number of Bands**

Select the number of bands in the filter. Multiband design is available for both FIR and IIR filters.

#### **Specify response as:**

Specify the response as Amplitudes, Magnitudes and phase, Frequency response, or Group delay. Amplitudes is the only option if you do not have the DSP System Toolbox software. Group delay is only available for IIR designs.

#### **Frequency units**

Specify frequency units as either Normalized, Hz, kHz, MHz, or GHz.

#### **Input sample rate**

Enter the input sampling frequency in the units specified in the **Frequency units** drop-down box. This option is enabled when **Frequency units** is set to an option in hertz.

### **Band Properties**

These properties are modified automatically depending on the response chosen in the **Specify response as** drop-down box. Two or three columns are presented for input. The first column is always Frequencies. The other columns are either Amplitudes, Magnitudes, Phases, or Frequency Response. Enter the corresponding vectors of values for each column.

- **Frequencies** and **Amplitudes** — These columns are presented for input if you select Amplitudes in the **Specify response as** drop-down box.

- **Frequencies, Magnitudes, and Phases** — These columns are presented for input if the response chosen in the **Specify response as** drop-down box is Magnitudes and phases.
- **Frequencies and Frequency response** — These columns are presented for input if the response chosen in the **Specify response as** drop-down box is Frequency response.

### Algorithm

The options for each design are specific for each design method. In the arbitrary response design, the available options also depend on the **Response specifications**. This section does not present all of the available options for all designs and design methods.

### Design Method

Select the design method for the filter. Different methods are enabled depending on the defining parameters entered in the previous sections.

### Design Options

- **Window** — Valid when the **Design method** is Frequency Sampling. Replace the square brackets with the name of a window function or function handle. For example, 'hamming' or @hamming. If the window function takes parameters other than the length, use a cell array. For example, {'kaiser', 3.5} or {@chebwin, 60}.
- **Density factor** — Valid when the **Design method** is equiripple. Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

The default changes to 20 for an IIR arbitrary group delay design.

- **Phase constraint** — Valid when the **Design method** is equiripple, you have the DSP System Toolbox installed, and **Specify response as** is set to Amplitudes. Choose one of Linear, Minimum, or Maximum.
- **Weights** — Uses the weights in **Weights** to weight the error for a single-band design. If you have multiple frequency bands, the **Weights** design option changes

to **B1 Weights**, **B2 Weights** to designate the separate bands. Use **Bi Weights** to specify weights for the *i*-th band. The **Bi Weights** design option is only available when you specify the *i*-th band as an unconstrained.

- **Bi forced frequency point** — This option is only available in a multi-band constrained equiripple design when **Specify response as** is **Amplitudes**. **Bi forced frequency point** is the frequency point in the *i*-th band at which the response is forced to be zero. The index *i* corresponds to the frequency bands in **Band properties**. For example, if you specify two bands in **Band properties**, you have **B1 forced frequency point** and **B2 forced frequency point**.
- **Norm** — Valid only for IIR arbitrary group delay designs. **Norm** is the norm used in the optimization. The default value is 128, which essentially equals the L-infinity norm. The norm must be even.
- **Max pole radius** — Valid only for IIR arbitrary group delay designs. Constrains the maximum pole radius. The default is 0.999999. Reducing the **Max pole radius** can produce a transfer function more resistant to quantization.
- **Init norm** — Valid only for IIR arbitrary group delay designs. The initial norm used in the optimization. The default initial norm is 2.
- **Init numerator** — Specifies an initial estimate of the filter numerator coefficients.
- **Init denominator** — Specifies an initial estimate of the filter denominator coefficients. This may be useful in difficult optimization problems. In allpass filters, you only have to specify either the denominator or numerator coefficients. If you specify the denominator coefficients, you can obtain the numerator coefficients.

## Filter implementation

### Structure

Select the structure for the filter. The available filter structures depend on the parameters you select for your filter.

### Use a System object to implement filter

This check box appears when you set **Filter type** to **Single-rate**. Selecting this check box gives you the choice of using a System object to implement the filter. By default, this check box is cleared.

This check box no longer appears when you set **Filter type** to **Interpolator**, **Decimator**, or **Sample-rate converter**. The filter builder always implements the filter as a System object.

## Audio Weighting Filter Design — Main Pane

### Filter specifications

- **Weighting type** — The weighting type defines the frequency response of the filter. The valid weighting types are: A, C, C-message, ITU-T 0.41, and ITU-R 468-4 weighting. See `fdesign.audioweighting` for definitions of the weighting types.
- **Class** — Filter class is only applicable for A weighting and C weighting filters. The filter class describes the frequency-dependent tolerances specified in the relevant standards. There are two possible class values: 1 and 2. Class 1 weighting filters have stricter tolerances than class 2 filters. The filter class value does not affect the design. The class value is only used to provide a specification mask in `fvtool` for the analysis of the filter design.
- **Impulse response** — Impulse response type as one of IIR or FIR. For A, C, C-message, and ITU-R 468-4 filter, IIR is the only option. For a ITU-T 0.41 weighting filter, FIR is the only option.
- **Frequency units** — Choose Hz, kHz, MHz, or GHz. Normalized frequency designs are not supported for audio weighting filters.
- **Input sample rate** — The sampling frequency in **Frequency units**. For example, if **Frequency units** is set to kHz, setting **Input sample rate** to 40 is equivalent to a 40 kHz sampling frequency.

### Algorithm

- **Design method** — Valid design methods depend on the weighting type. For type A and C weighting filters, the only valid design type is ANSI S1.42. This is an IIR design method that follows ANSI standard S1.42-2001. For a C message filter, the only valid design method is Bell 41009, which is an IIR design method following the Bell System Technical Reference PUB 41009. For a ITU-R 468-4 weighting filter, you can design an IIR or FIR filter. If you choose an IIR design, the design method is IIR least p-norm. If you choose an FIR design, the design method choices are: Equiripple or Frequency Sampling. For an ITU-T 0.41 weighting filter, the available FIR design methods are Equiripple or Frequency Sampling.
- **Scale SOS filter coefficients to reduce chance of overflow** — Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

### Filter implementation

- **Structure** — For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. For audio weighting IIR filter designs, you can choose direct form I or II biquad (SOS). You can also choose to implement these structures in transposed form.

For FIR designs, you can choose direct form, direct-form transposed, direct-form symmetric, direct-form asymmetric structures, or an overlap and add structure.

- **Use a System object to implement filter** — Selecting this check box gives you the choice of using a System object to implement the filter. By default, this check box is cleared. When the current design method or structure is not supported by a System object filter, then this check box is disabled.

### Bandpass Filter Design — Main Pane

#### Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

#### Impulse response

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

#### Order mode

Select **Minimum** (the default) or **Specify** from the drop-down box. Selecting **Specify** enables the **Order** option so you can enter the filter order.

If you have the DSP System Toolbox software installed, you can specify IIR filters with different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

**Filter type** — This dialog only applies if you have the DSP System Toolbox software.

Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures

that are available to implement your filter. By default, filterBuilder specifies single-rate filters.

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting Sample-rate converter activates both factors.

### Order

Enter the filter order. This option is enabled only if you select Specify for **Order mode**.

### Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Decimator or Sample-rate converter. The default factor value is 2.

### Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Interpolator or Sample-rate converter. The default factor value is 2.

### Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

In the figure, regions between specification values such as Stopband frequency 1 ( $F_{stop1}$ ) and Passband frequency 1 ( $F_{pass1}$ ) represent transition regions where the filter response is not explicitly defined.

### Frequency constraints

Select the filter features to use to define the frequency response characteristics. This dialog applies only when **Order mode** is **Specify**.

- **Passband and stopband frequencies** — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- **Passband frequency** — Define the filter by specifying frequencies for the edges of the passband.
- **Stopband frequency** — Define the filter by specifying frequencies for the edges of the stopbands.
- **Half power (3dB) frequency** — Define the filter response by specifying the locations of the 3 dB points (IIR filters). The 3-dB point is the frequency for the point 3 dB below the passband value.
- **Half power (3dB) frequencies and passband width** — Define the filter by specifying frequencies for the 3-dB points in the filter response and the width of the passband. (IIR filters)
- **Half power (3dB) frequencies and stopband width** — Define the filter by specifying frequencies for the 3-dB points in the filter response and the width of the stopband. (IIR filters)
- **Cutoff (6dB) frequency** — Define the filter response by specifying the locations of the 6-dB points. The 6-dB point is the frequency for the point 6 dB below the passband value. (FIR filters)

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in hertz, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

### Input sample rate

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

### Stopband frequency 1

Enter the frequency at the edge of the end of the first stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

### Passband frequency 1

Enter the frequency at the edge of the start of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### Passband frequency 2

Enter the frequency at the edge of the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### Stopband frequency 2

Enter the frequency at the edge of the start of the second stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

## Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

### Magnitude constraints

Specify as **Unconstrained** or **Constrained** bands. You must have the DSP System Toolbox software to select **Constrained** bands. Selecting **Constrained** bands enables dialogs for both stopbands and the passband: **Stopband attenuation 1**, **Stopband attenuation 2**, and **Passband ripple**. You cannot specify constraints for all three bands simultaneously.

Setting **Magnitude constraints** to **Constrained** bands enables the **Wstop** and **Wpass** options under **Design options**.

### Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- **Linear** — Specify the magnitude in linear units.
- **dB** — Specify the magnitude in dB (decibels). This is the default setting.
- **Squared** — Specify the magnitude in squared units.

### **Stopband attenuation 1**

Enter the filter attenuation in the first stopband in the units you choose for **Magnitude units**, either linear or decibels.

### **Passband ripple**

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

### **Stopband attenuation 2**

Enter the filter attenuation in the second stopband in the units you choose for **Magnitude units**, either linear or decibels.

### **Algorithm**

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

### **Design Method**

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

### **Scale SOS filter coefficients to reduce chance of overflow**

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

### **Design Options**

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

### **Density factor**

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

**Phase constraint**

Valid when the **Design method** is `equiripple` and you have the DSP System Toolbox installed. Choose one of `Linear`, `Minimum`, or `Maximum`.

**Minimum order**

This option only applies when you have the DSP System Toolbox software and **Order mode** is `Minimum`.

Select Any (default), Even, or Odd. Selecting Even or Odd forces the minimum-order design to be an even or odd order.

**Wstop1**

Weight for the first stopband.

**Wpass**

Passband weight.

**Wstop2**

Weight for the second stopband.

**Max pole radius**

Valid only for IIR designs. Constrains the maximum pole radius. The default is 1. Reducing the max pole radius can produce a transfer function more resistant to quantization.

**Init norm**

Valid only for IIR designs. The initial norm used in the optimization. The default initial norm is 2.

**Init numerator**

Specifies an initial estimate of the filter numerator coefficients. This may be useful in difficult optimization problems.

**Init denominator**

Specifies an initial estimate of the filter denominator coefficients. This may be useful in difficult optimization problems.

### Filter implementation

#### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

#### Use a System object to implement filter

This check box appears when you set **Filter type** to `Single-rate`. Selecting this check box gives you the choice of using a System object to implement the filter. By default, this check box is cleared.

This check box no longer appears when you set **Filter type** to `Interpolator`, `Decimator`, or `Sample-rate converter`. The filter builder always implements the filter as a System object.

## Bandstop Filter Design — Main Pane

### Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

#### Impulse response

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

#### Order mode

Select `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option so you can enter the filter order.

If you have the DSP System Toolbox software installed, you can specify IIR filters with different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

## Filter type

Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterBuilder specifies single-rate filters.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

## Order

Enter the filter order. This option is enabled only if **Specify** was selected for **Order mode**.

## Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default factor value is 2.

## Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default factor value is 2.

## Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

### Frequency constraints

Select the filter features to use to define the frequency response characteristics. This dialog applies only when **Order mode** is **Specify**.

- **Passband and stopband frequencies** — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- **Passband frequency** — Define the filter by specifying frequencies for the edges of the passband.
- **Stopband frequency** — Define the filter by specifying frequencies for the edges of the stopbands.
- **Half power (3dB) frequency** — Define the filter response by specifying the locations of the 3 dB points (IIR filters). The 3 dB point is the frequency for the point 3 dB point below the passband value.
- **Half power (3dB) frequencies and passband width** — Define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the passband (IIR filters).
- **Half power (3dB) frequencies and stopband width** — Define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the stopband (IIR filters).
- **Cutoff (6dB) frequency** — Define the filter response by specifying the locations of the 6-dB points (FIR filters). The 6-dB point is the frequency for the point 6 dB point below the passband value.

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

### Input sample rate

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

### Output sample rate

When you design an interpolator,  $F_s$  represents the sampling frequency at the filter output rather than the filter input. This option is available only when you set **Filter type** is interpolator.

### Passband frequency 1

Enter the frequency at the edge of the end of the first passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

### Stopband frequency 1

Enter the frequency at the edge of the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### Stopband frequency 2

Enter the frequency at the edge of the end of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### Passband frequency 2

Enter the frequency at the edge of the start of the second passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

## Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

### Magnitude constraints

Specify as Unconstrained or Constrained bands. You must have the DSP System Toolbox software to select Constrained bands. Selecting Constrained bands enables dialogs for both passbands and the stopband: **Passband ripple 1**, **Passband ripple 2**, and **Stopband attenuation**. You cannot specify constraints for all three bands simultaneously.

Setting **Magnitude constraints** to Constrained bands enables the **Wstop** and **Wpass** options under **Design options**.

### Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- **Linear** — Specify the magnitude in linear units.
- **dB** — Specify the magnitude in decibels (default).
- **Squared** — Specify the magnitude in squared units.

### **Passband ripple 1**

Enter the filter ripple allowed in the first passband in the units you choose for **Magnitude units**, either linear or decibels.

### **Stopband attenuation**

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels

### **Passband ripple 2**

Enter the filter ripple allowed in the second passband in the units you choose for **Magnitude units**, either linear or decibels

### **Algorithm**

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

### **Design Method**

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

### **Scale SOS filter coefficients to reduce chance of overflow**

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

### **Design Options**

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

**Density factor**

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

**Phase constraint**

Valid when the **Design method** is equiripple and you have the DSP System Toolbox installed. Choose one of Linear, Minimum, or Maximum.

**Minimum order**

This option only applies when you have the DSP System Toolbox software and **Order mode** is Minimum.

Select Any (default), Even, or Odd. Selecting Even or Odd forces the minimum-order design to be an even or odd order.

**Wpass1**

Weight for the first passband.

**Wstop**

Stopband weight.

**Wpass2**

Weight for the second passband.

**Match exactly**

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select passband or stopband .

**Max pole radius**

Valid only for IIR designs. Constrains the maximum pole radius. The default is 1. Reducing the max pole radius can produce a transfer function more resistant to quantization.

**Init norm**

Valid only for IIR designs. The initial norm used in the optimization. The default initial norm is 2.

### **Init numerator**

Specifies an initial estimate of the filter numerator coefficients. This may be useful in difficult optimization problems.

### **Init denominator**

Specifies an initial estimate of the filter denominator coefficients. This may be useful in difficult optimization problems.

### **Filter implementation**

#### **Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

#### **Use a System object to implement filter**

This check box appears when you set **Filter type** to `Single-rate`. Selecting this check box gives you the choice of using a System object to implement the filter. By default, this check box is cleared.

This check box no longer appears when you set **Filter type** to `Interpolator`, `Decimator`, or `Sample-rate converter`. The filter builder always implements the filter as a System object.

## **CIC Filter Design — Main Pane**

### **Filter specifications**

Parameters in this group enable you to specify your CIC filter format, such as the filter type and the differential delay.

#### **Filter type**

Select whether your filter will be a `decimator` or an `interpolator`. Your choice determines the type of filter and the design methods and structures that are available to implement your filter. Selecting `decimator` or `interpolator` activates the **Factor** option. When you design an interpolator, you enable the **Output sample rate** parameter.

When you design either a decimator or interpolator, the resulting filter is a CIC filter that decimates or interpolates your input signal.

### **Differential Delay**

Specify the differential delay of your CIC filter as an integer value greater than or equal to 1. The default value is 1. The differential delay changes the shape, number, and location of nulls in the filter response. Increasing the differential delay increases the sharpness of the nulls and the response between the nulls. In practice, differential delay values of 1 or 2 are the most common.

### **Factor**

Specify the decimation or interpolation factor for your filter as an integer value greater than or equal to 1. The default value is 2.

### **Frequency specifications**

#### **Frequency units**

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

#### **Input sample rate**

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

#### **Output sample rate**

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter output. When you provide an output sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available only when you design interpolators.

#### **Passband frequency**

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### **Magnitude specifications**

#### **Magnitude units**

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- **Linear** — Specify the magnitude in linear units.
- **dB** — Specify the magnitude in decibels (default).
- **Squared** — Specify the magnitude in squared units.

### Stopband attenuation

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

## CIC Compensator Design — Main Pane

### Filter specifications

Parameters in this group enable you to specify your filter format, such as the filter order mode and the filter type.

#### Order mode

Select **Minimum** (the default) or **Specify** from the drop-down list. Selecting **Specify** enables the **Order** option (see the following sections) so you can enter the filter order.

#### Filter type

Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterBuilder` specifies single-rate filters.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

#### Order

Enter the filter order. This option is enabled only if **Specify** was selected for **Order mode**.

#### Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default factor value is 2.

### Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Interpolator or Sample-rate converter. The default factor value is 2.

### Number of CIC sections

Specify the number of sections in the CIC filter for which you are designing this compensator. Select the number of sections from the drop-down list or enter the number.

### Differential Delay

Specify the differential delay of your target CIC filter. The default value is 1. Most CIC filters use 1 or 2.

### Frequency specifications

The parameters in this group allow you to specify your filter response curve.

#### Frequency specifications

##### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

##### Input sample rate

F<sub>s</sub>, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

##### Output sample rate

F<sub>s</sub>, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter output. When you provide an output sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available only when you design interpolators.

##### Passband frequency

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### Stopband frequency

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

### Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

### Passband ripple

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels

### Algorithm

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

### Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

### Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

### Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally

spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

### **Minimum phase**

To design a filter that is minimum phase, select **Minimum phase**. Clearing the **Minimum phase** option removes the phase constraint—the resulting design is not minimum phase.

### **Minimum order**

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select Any, Even, or Odd from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

---

**Note** Generally, **Minimum order** designs are not available for IIR filters.

---

### **Match exactly**

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select passband or stopband or both from the drop-down list.

### **Stopband Shape**

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where  $f$  is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

### Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to Flat, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to Linear, enter the slope of the stopband in units of dB/rad/s. `filterBuilder` applies that slope to the stopband.
- When you set **Stopband shape** to 1/f, enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. `filterBuilder` applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

### Filter implementation

#### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

#### Use a System object to implement filter

This check box appears when you set **Filter type** to Single-rate. Selecting this check box gives you the choice of using a System object to implement the filter. By default, this check box is cleared.

This check box no longer appears when you set **Filter type** to Interpolator, Decimator, or Sample-rate converter. The filter builder always implements the filter as a System object.

## Comb Filter Design —Main Pane

### Filter specifications

Parameters in this group enable you to specify the type of comb filter and the number of peaks or notches.

**Comb Type**

Select **Notch** or **Peak** from the drop-down list. **Notch** creates a comb filter that attenuates a set of harmonically related frequencies. **Peak** creates a comb filter that amplifies a set of harmonically related frequencies.

**Order mode**

Select **Order** or **Number of Peaks/Notches** from the drop-down menu.

Select **Order** to enter the desired filter order in the dialog box. The comb filter has notches or peaks at increments of  $2/Order$  in normalized frequency units.

Select **Number of Peaks** or **Number of Notches** to specify the number of peaks or notches and the **Shelving filter order**

**Shelving filter order**

The **Shelving filter order** is a positive integer that determines the sharpness of the peaks or notches. Larger values result in sharper peaks or notches.

**Frequency specifications**

Parameters in this group enable you to specify the frequency constraints and frequency units.

**Frequency specifications**

Select **Quality factor** or **Bandwidth**.

**Quality factor** is the ratio of the center frequency of the peak or notch to the bandwidth calculated at the -3 dB point.

Bandwidth specifies the bandwidth of the peak or notch. By default the bandwidth is measured at the -3 dB point. For example, setting the bandwidth equal to 0.1 results in 3 dB frequencies at normalized frequencies 0.05 above and below the center frequency of the peak or notch.

### Frequency Units

Specify the frequency units. The default is normalized frequency. Choosing an option in Hz enables the **Input sample rate** dialog box.

### Magnitude specifications

Specify the units for the magnitude specification and the gain at which the bandwidth is measured. This menu is disabled if you specify a filter order. Select one of the following magnitude units from the drop down list:

- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

**Bandwidth gain** — Specify the gain at which the bandwidth is measured. The default is -3 dB.

### Algorithm

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

### Design Method

The IIR Butterworth design is the only option for peaking or notching comb filters.

### Filter implementation

#### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

#### Use a System object to implement filter

Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

## Differentiator Filter Design – Main Pane

### Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order. Graphically, the filter specifications look similar to those shown in the following figure.

In the figure, regions between specification values such as **Passband frequency** ( $f_1$ ) and **Stopband frequency** ( $f_3$ ) represent transition regions where the filter response is not explicitly defined.

### Order mode

Select **Minimum** (the default) or **Specify** from the drop-down list. Selecting **Specify** enables the **Order** option (see the following sections) so you can enter the filter order.

### Filter type

Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterBuilder specifies single-rate filters.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.

- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

### **Order**

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

### **Decimation Factor**

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

### **Interpolation Factor**

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

## **Frequency specifications**

The parameters in this group allow you to specify your filter response curve.

### **Frequency constraints**

This option is only available when you specify the order of the filter design. Supported options are `Unconstrained` and `Passband edge and stopband edge`.

### **Frequency units**

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0 to 1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input sample rate** parameter.

### **Input sample rate**

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

### **Passband frequency**

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

**Stopband frequency**

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

**Magnitude specifications**

The parameters in this group let you specify the filter response in the passbands and stopbands.

**Magnitude constraints**

This option is only available when you specify the order of your filter design. The options for **Magnitude constraints** depend on the value of the **Frequency constraints**. If the value of **Frequency constraints** is Unconstrained, **Magnitude constraints** must be Unconstrained. If the value of **Frequency constraints** is Passband edge and stopband edge, **Magnitude constraints** can be Unconstrained, Passband ripple, or Stopband attenuation.

**Magnitude units**

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

**Passband ripple**

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

**Stopband attenuation 2**

Enter the filter attenuation in the second stopband in the units you choose for **Magnitude units**, either linear or decibels.

**Algorithm**

The parameters in this group allow you to specify the design method and structure that filterBuilder uses to implement your filter.

**Design Method**

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse

response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

### **Scale SOS filter coefficients to reduce chance of overflow**

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

### **Design Options**

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications.

### **Density factor**

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

### **Wpass**

Passband weight. This option is only available for a specified-order design when **Frequency constraints** is equal to Passband edge and stopband edge and the **Design method** is Equiripple.

### **Wstop**

Stopband weight. This option is only available for a specified-order design when **Frequency constraints** is equal to Passband edge and stopband edge and the **Design method** is Equiripple.

### **Filter implementation**

#### **Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

### Use a System object to implement filter

This check box appears when you set **Filter type** to **Single-rate**. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to **Interpolator**, **Decimator**, or **Sample-rate converter**. The filter builder always implements the filter as a System object.

## Fractional Delay Design — Main Pane

### Frequency specifications

Parameters in this group enable you to specify your filter format, such as the fractional delay and the filter order.

#### Order

If you choose **Specify** for **Order mode**, enter your filter order in this field, or select the order from the drop-down list. `filterBuilder` designs a filter with the order you specify.

#### Fractional delay

Specify a value between 0 and 1 samples for the filter fractional delay. The default value is 0.5 samples.

#### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized** (0 to 1) to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

#### Input sample rate

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

## Halfband Filter Design — Main Pane

### Filter specifications

Parameters in this group enable you to specify your filter type and order.

### Impulse response

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

### Order mode

Select Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option (see the following sections) so you can enter the filter order.

### Filter type

Select Single-rate, Decimator, or Interpolator. By default, `filterBuilder` specifies single-rate filters.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that decimates or interpolates your input by a factor of two.

### Order

Enter the filter order. This option is enabled only if Specify was selected for **Order mode**.

### Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications for a halfband lowpass filter look similar to those shown in the following figure.

In the figure, the transition region lies between the end of the passband and the start of the stopband. The width is defined explicitly by the value of **Transition width**.

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

### Input sample rate

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

### Transition width

Specify the width of the transition between the end of the passband and the edge of the stopband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

### Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

### Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default).

### Stopband attenuation

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

### Algorithm

The parameters in this group allow you to specify the design method and structure that filterBuilder uses to implement your filter.

### Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. For FIR halfband filters, the available design options are Equiripple and Kaiser window. For IIR halfband filters, the available design options are Butterworth, Elliptic, and IIR quasi-linear phase.

### Design Options

The following design options are available for FIR halfband filters when the user specifies an equiripple design:

### Minimum phase

To design a filter that is minimum phase, select **Minimum phase**. Clearing the **Minimum phase** option removes the phase constraint—the resulting design is not minimum phase.

### Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where  $f$  is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

### Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. The following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to **Flat**, **Stopband decay** has no effect on the stopband.
- When you set **Stopband shape** to **Linear**, enter the slope of the stopband in units of dB/rad/s. `filterBuilder` applies that slope to the stopband.
- When you set **Stopband shape** to **1/f**, enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. `filterBuilder` applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

### Filter implementation

#### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

#### Use a System object to implement filter

This check box appears when you set **Filter type** to **Single-rate**. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to either **Interpolator** or **Decimator**. The filter builder always implements the filter as a System object.

## Highpass Filter Design — Main Pane

### Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

#### Impulse response

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

#### Order mode

Select **Minimum** (the default) or **Specify** from the drop-down list. Selecting **Specify** enables the **Order** option so you can enter the filter order.

If your **Impulse response** is IIR, you can specify an equal order for the numerator and denominator, or different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

#### Filter type

This option is only available if you have the DSP System Toolbox software. Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterBuilder` specifies single-rate filters.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a highpass filter that either decimates or interpolates your input signal.

#### Order

Enter the filter order. This option is enabled only if **Specify** was selected for **Order mode**.

### Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Decimator or Sample-rate converter. The default factor value is 2.

### Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to Interpolator or Sample-rate converter. The default factor value is 2.

### Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

In the figure, the region between specification values Stopband frequency ( $F_{stop}$ ) and Passband frequency ( $F_{pass}$ ) represents the transition region where the filter response is not explicitly defined.

### Frequency constraints

Select the filter features to use to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- Stopband edge and passband edge — Define the filter by specifying the frequencies for the edges for the stopband and passband.
- Passband frequency — Define the filter by specifying the frequency for the edge of the passband.
- Stopband frequency — Define the filter by specifying the frequency for the edges of the stopband.

- **Stopband and half power (3dB) frequencies** — Define the filter by specifying the stopband edge frequency and the 3-dB down point (IIR designs).
- **Half power (3dB) and passband frequencies** — Define the filter by specifying the 3-dB down point and passband edge frequency (IIR designs).
- **Half power (3dB) frequency** — Define the filter by specifying the frequency for the 3-dB point (IIR designs or maxflat FIR).
- **Cutoff (6dB) frequency** — Define the filter by specifying the frequency for the 6-dB point in the filter response (FIR designs).

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

### Input sample rate

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

### Passband frequency

Enter the frequency at the of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### Stopband frequency

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

### Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

### **Stopband attenuation**

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

### **Passband ripple**

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

### **Algorithm**

The parameters in this group allow you to specify the design method and structure that filterBuilder uses to implement your filter.

### **Design Method**

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

### **Scale SOS filter coefficients to reduce chance of overflow**

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

### **Design Options**

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

### **Density factor**

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

### Phase constraint

This option only applies when you have the DSP System Toolbox software and when the **Design method** is equiripple. Select one of Linear, Minimum, or Maximum.

**Minimum order** — This option only applies when you have the DSP System Toolbox software and the **Order mode** is Minimum.

Select Any (default), Even, or Odd. Selecting Even or Odd forces the minimum-order design to be an even or odd order.

### Match Exactly

Specifies that the resulting filter design matches either the passband or stopband when you select Passband or Stopband.

### Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where  $f$  is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

### Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to Flat, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to Linear, enter the slope of the stopband in units of dB/rad/s. `filterBuilder` applies that slope to the stopband.

- When you set **Stopband shape** to  $1/f$ , enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. filterBuilder applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

**Wpass**

Passband weight. This option only applies when **Impulse response** is FIR and **Order mode** is Specify.

**Wstop**

Stopband weight. This option only applies when **Impulse response** is FIR and **Order mode** is Specify.

**Filter implementation****Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

**Use a System object to implement filter**

This check box appears when you set **Filter type** to Single-rate. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to Interpolator, Decimator, or Sample-rate converter. The filter builder always implements the filter as a System object.

**Hilbert Filter Design — Main Pane****Filter specifications**

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

**Impulse response**

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

### Order mode

This option is only available if you have the DSP System Toolbox software. Select either `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

### Filter type

This option is only available if you have the DSP System Toolbox software. Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterBuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

### Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

### Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

### Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

### Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

In the figure, the regions between 0 and  $f_1$  and between  $f_2$  and 1 represent the transition regions where the filter response is explicitly defined by the transition width.

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized** (0 to 1) to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

### Input sample rate

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

### Transition width

Specify the width of the transitions at the ends of the passband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

### Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

### Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default)
- Squared — Specify the magnitude in squared units.

### Passband ripple

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

### Algorithm

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

### Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

### Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

### Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

### Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

### **FIR Type**

This option is only available in a minimum-order design. Specify whether to design a type 3 or a type 4 FIR filter. The filter type is defined as follows:

- Type 3 — FIR filter with even order antisymmetric coefficients
- Type 4 — FIR filter with odd order antisymmetric coefficients

Select 3 or 4 from the drop-down list.

### **Filter implementation**

#### **Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

#### **Use a System object to implement filter**

This check box appears when you set **Filter type** to **Single-rate**. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to **Interpolator**, **Decimator**, or **Sample-rate converter**. The filter builder always implements the filter as a System object.

## **Inverse Sinc Filter Design — Main Pane**

### **Filter specifications**

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

#### **Order mode**

Select **Minimum** (the default) or **Specify** from the drop-down list. Selecting **Specify** enables the **Order** option (see the following sections) so you can enter the filter order.

### Response type

Select `Lowpass` or `Highpass` to design an inverse sinc lowpass or highpass filter.

### Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterBuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

### Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

### Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

### Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

### Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

Regions between specification values such as Passband frequency ( $F_{\text{pass}}$ ) and Stopband frequency ( $F_{\text{stop}}$ ) represent transition regions where the filter response is not explicitly defined.

### Frequency constraints

This option is only available when you specify the filter order. The following options are available:

- **Passband and stopband frequencies** — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- **Passband frequency** — Define the filter by specifying frequencies for the edges of the passband.
- **Stopband frequency** — Define the filter by specifying frequencies for the edges of the stopbands.
- **Cutoff (6dB) frequency** — The 6-dB point is the frequency for the point 6 dB point below the passband value.

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

### Input sample rate

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

### Passband frequency

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### Stopband frequency

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

### Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default)
- Squared — Specify the magnitude in squared units.

### Passband ripple

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

### Stopband attenuation

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

### Algorithm

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

## Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

## Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

### Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

### Phase constraint

Available options are Linear, Minimum, and Maximum.

### Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options;

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where  $f$  is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

### Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to Flat, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to Linear, enter the slope of the stopband in units of dB/rad/s. `filterBuilder` applies that slope to the stopband.
- When you set **Stopband shape** to 1/f, enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. `filterBuilder` applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

### Sinc frequency factor

A frequency dilation factor. The sinc frequency factor,  $C$ , parameterizes the passband magnitude response for a lowpass design through  $H(\omega) = \text{sinc}(C\omega)^{-P}$  and for a highpass design through  $H(\omega) = \text{sinc}(C(1-\omega))^{-P}$ .

### Sinc power

Negative power of passband magnitude response. The sinc power,  $P$ , parameterizes the passband magnitude response for a lowpass design through  $H(\omega) = \text{sinc}(C\omega)^{-P}$  and for a highpass design through  $H(\omega) = \text{sinc}(C(1-\omega))^{-P}$ .

### Filter implementation

#### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure.

#### Use a System object to implement filter

This check box appears when you set **Filter type** to Single-rate. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to Interpolator, Decimator, or Sample-rate converter. The filter builder always implements the filter as a System object.

## Lowpass Filter Design — Main Pane

### Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

#### Impulse response

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

#### Order mode

Select **Minimum** (the default) or **Specify** from the drop-down list. Selecting **Specify** enables the **Order** option (see the following sections) so you can enter the filter order.

If your **Impulse response** is IIR, you can specify an equal order for the numerator and denominator, or different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

#### Filter type

This option is only available if you have the DSP System Toolbox. Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterBuilder` specifies single-rate filters.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

#### Order

Enter the filter order. This option is enabled only if **Specify** was selected for **Order mode**.

### Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Decimator or Sample-rate converter. The default factor value is 2.

### Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Interpolator or Sample-rate converter. The default factor value is 2.

### Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to the one shown in the following figure.

In the figure, regions between specification values such as Passband frequency ( $F_{\text{pass}}$ ) and Stopband frequency ( $F_{\text{stop}}$ ) represent transition regions where the filter response is not explicitly defined.

### Frequency constraints

Select the filter features to use to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- Passband and stopband frequencies — Define the filter by specifying the frequencies for the edge of the stopband and passband.
- Passband frequency — Define the filter by specifying the frequency for the edge of the passband.
- Stopband frequency — Define the filter by specifying the frequency for the edges of the stopband.

- **Passband edge and 3dB point** — Define the filter by specifying the passband edge frequency and the 3-dB down point (IIR designs).
- **Half power (3dB) and stopband frequencies** — Define the filter by specifying the 3-dB down point and stopband edge frequency (IIR designs).
- **Half power (3dB) frequency** — Define the filter by specifying the frequency for the 3-dB point (IIR designs or maxflat FIR).
- **Cutoff (6dB) frequency** — Define the filter by specifying the frequency for the 6-dB point in the filter response (FIR designs).

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

### Input sample rate

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

### Passband frequency

Enter the frequency at the of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### Stopband frequency

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

### Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default)
- Squared — Specify the magnitude in squared units.

### Passband ripple

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

### Stopband attenuation

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

### Algorithm

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

### Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

### Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

### Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

### Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

### Phase constraint

This option only applies when you have the DSP System Toolbox software and when the **Design method** is equiripple. Select one of Linear, Minimum, or Maximum.

**Minimum order** — This option only applies when you have the DSP System Toolbox software and the **Order mode** is Minimum.

Select Any (default), Even, or Odd. Selecting Even or Odd forces the minimum-order design to be an even or odd order.

### Match Exactly

Specifies that the resulting filter design matches either the passband or stopband when you select Passband or Stopband.

### Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where  $f$  is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

### Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. The following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to Flat, **Stopband decay** has no effect on the stopband.
- When you set **Stopband shape** to Linear, enter the slope of the stopband in units of dB/rad/s. filterBuilder applies that slope to the stopband.

- When you set **Stopband shape** to  $1/f$ , enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. `filterBuilder` applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

### **Wpass**

Passband weight. This option only applies when **Impulse response** is FIR and **Order mode** is `Specify`.

### **Wstop**

Stopband weight. This option only applies when **Impulse response** is FIR and **Order mode** is `Specify`.

## **Filter implementation**

### **Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

### **Use a System object to implement filter**

This check box appears when you set **Filter type** to `Single-rate`. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to `Interpolator`, `Decimator`, or `Sample-rate converter`. The filter builder always implements the filter as a System object.

## **Notch**

See “Peak/Notch Filter Design — Main Pane” on page 5-683.

## **Nyquist Filter Design — Main Pane**

### **Filter specifications**

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

## Band

Specifies the location of the center of the transition region between the passband and the stopband. The center of the transition region,  $bw$ , is calculated using the value for Band:

$$bw = Fs/(2 \times \text{Band}).$$

## Impulse response

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

## Order mode

Select Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option (see the following sections) so you can enter the filter order.

## Filter type

Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterBuilder specifies single-rate filters.

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting Sample-rate converter activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

## Order

Enter the filter order. This option is enabled only if Specify was selected for **Order mode**.

## Decimation Factor

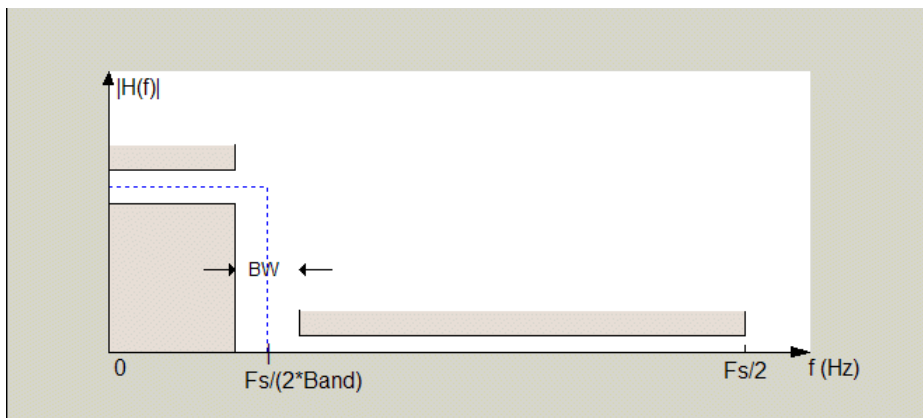

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Decimator or Sample-rate converter. The default factor value is 2.

### Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Interpolator or Sample-rate converter. The default factor value is 2.

### Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

In the figure,  $BW$  is the width of the transition region and **Band** determines the location of the center of the region.

### Frequency constraints

Select the filter features to use to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- **Transition width** — Define the filter using transition width and stopband attenuation or transition width and order.
- **Unconstrained** — Define the filter by specifying the filter order and having no constraints on the transition width and stopband attenuation. You can add constraints on the magnitude by specifying the stopband attenuation.

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values,

select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

### **Input sample rate**

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

### **Transition width**

Specify the width of the transition between the end of the passband and the edge of the stopband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

### **Magnitude specifications**

The parameters in this group let you specify the filter response in the passbands and stopbands.

#### **Magnitude units**

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default)
- Squared — Specify the magnitude in squared units.

#### **Stopband attenuation**

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

### **Algorithm**

The parameters in this group allow you to specify the design method and structure that filterBuilder uses to implement your filter.

#### **Design Method**

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse

response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

### **Scale SOS filter coefficients to reduce chance of overflow**

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

### **Design Options**

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

### **Density factor**

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

### **Minimum phase**

To design a filter that is minimum phase, select **Minimum phase**. Clearing the **Minimum phase** option removes the phase constraint—the resulting design is not minimum phase.

### **Minimum order**

When you select this parameter, the design method determines and designs the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select **Any**, **Even**, or **Odd** from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

---

**Note** Generally, **Minimum order** designs are not available for IIR filters.

---

### Match Exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select `passband` or `stopband` or `both` from the drop-down list.

### Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where  $f$  is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

### Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to **Flat**, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to **Linear**, enter the slope of the stopband in units of dB/rad/s. `filterBuilder` applies that slope to the stopband.
- When you set **Stopband shape** to **1/f**, enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. `filterBuilder` applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

### Filter implementation

#### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

### **Use a System object to implement filter**

This check box appears when you set **Filter type** to **Single-rate**. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to **Interpolator**, **Decimator**, or **Sample-rate converter**. The filter builder always implements the filter as a System object.

## **Octave Filter Design — Main Pane**

### **Filter specifications**

#### **Order**

Specify filter order. Possible values are: 4, 6, 8, 10.

#### **Bands per octave**

Specify the number of bands per octave. Possible values are: 1, 3, 6, 12, 24.

#### **Frequency units**

Specify frequency units as Hz or kHz.

#### **Input sample rate**

Specify the input sampling frequency in the frequency units specified previously.

#### **Center Frequency**

Select from the drop-down list of available center frequency values.

### **Algorithm**

#### **Design Method**

Butterworth is the design method used for this type of filter.

#### **Scale SOS filter coefficients to reduce chance of overflow**

Select the check box to scale the filter coefficients.

### **Filter implementation**

#### **Structure**

Specify filter structure. Choose from:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

### Use a System object to implement filter

Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

## Parametric Equalizer Filter Design — Main Pane

### Filter specifications

#### Order mode

Select **Minimum** to design a minimum order filter that meets the design specifications, or **Specify** to enter a specific filter order. The order mode also affects the possible frequency constraints, which in turn limit the gain specifications. For example, if you specify a **Minimum** order filter, the available frequency constraints are:

- Center frequency, bandwidth, passband width
- Center frequency, bandwidth, stopband width

If you select **Specify**, the available frequency constraints are:

- Center frequency, bandwidth
- Center frequency, quality factor
- Shelf type, cutoff frequency, quality factor
- Shelf type, cutoff frequency, shelf slope parameter
- Low frequency, high frequency

#### Order

This parameter is enabled only if the **Order mode** is set to **Specify**. Enter the filter order in this text box.

### Frequency specifications

Depending on the filter order, the possible frequency constraints change. Once you choose the frequency constraints, the input boxes in this area change to reflect the selection.

### Frequency constraints

Select the specification to represent the frequency constraints. The following options are available:

- Center frequency, bandwidth, passband width (available for minimum order only)
- Center frequency, bandwidth, stopband width (available for minimum order only)
- Center frequency, bandwidth (available for a specified order only)
- Center frequency, quality factor (available for a specified order only)
- Shelf type, cutoff frequency, quality factor (available for a specified order only)
- Shelf type, cutoff frequency, shelf slope parameter (available for a specified order only)
- Low frequency, high frequency (available for a specified order only)

### Frequency units

Select the frequency units from the available drop down list (Normalized, Hz, kHz, MHz, GHz). If Normalized is selected, then the **Input sample rate** box is disabled for input.

### Input sample rate

Enter the input sampling frequency. This input box is disabled for input if Normalized is selected in the **Frequency units** input box.

### Center frequency

Enter the center frequency in the units specified by the value in **Frequency units**.

### Bandwidth

The bandwidth determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Bandwidth gain** in the **Gain specifications** section. By default, the **Bandwidth gain** defaults to  $\text{db}(\text{sqrt}(.5))$ , or -3 dB relative to the center frequency. The **Bandwidth** property only applies when the **Frequency**

**constraints** are: Center frequency, bandwidth, passband width, Center frequency, bandwidth, stopband width, or Center frequency, bandwidth.

### **Passband width**

The passband width determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Passband gain** in the **Gain specifications** section. This option is enabled only if the filter is of minimum order, and the frequency constraint selected is Center frequency, bandwidth, passband width.

### **Stopband width**

The stopband width determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Stopband gain** in the **Gain specifications** section. This option is enabled only if the filter is of minimum order, and the frequency constraint selected is Center frequency, bandwidth, stopband width.

### **Low frequency**

Enter the low frequency cutoff. This option is enabled only if the filter order is user specified and the frequency constraint selected is Low frequency, high frequency. The filter magnitude is attenuated by the amount specified in **Bandwidth gain**.

### **High frequency**

Enter the high frequency cutoff. This option is enabled only if the filter order is user specified and the frequency constraint selected is Low frequency, high frequency. The filter magnitude is attenuated by the amount specified in **Bandwidth gain**.

## **Gain specifications**

Depending on the filter order and frequency constraints, the possible gain constraints change. Also, once you choose the gain constraints the input boxes in this area change to reflect the selection.

### **Gain constraints**

Select the specification array to represent gain constraints, and remember that not all of these options are available for all configurations. The following is a list of all available options:

- Reference, center frequency, bandwidth, passband
- Reference, center frequency, bandwidth, stopband

- Reference, center frequency, bandwidth, passband, stopband
- Reference, center frequency, bandwidth

### **Gain units**

Specify the gain units either dB or squared. These units are used for all gain specifications in the dialog box.

### **Reference gain**

The reference gain determines the level to which the filter magnitude attenuates in **Gain units**. The reference gain is a *floor* gain for the filter magnitude response. For example, you may use the reference gain together with the **Center frequency gain** to leave certain frequencies unattenuated (reference gain of 0 dB) while boosting other frequencies.

### **Bandwidth gain**

Specifies the gain in **Gain units** at which the bandwidth is defined. This property applies only when the **Frequency constraints** specification contains a bandwidth parameter, or is Low frequency, high frequency.

### **Center frequency gain**

Specify the center frequency in **Gain units**

### **Passband gain**

The passband gain determines the level in **Gain units** at which the passband is defined. The passband is determined either by the **Passband width** value, or the **Low frequency** and **High frequency** values in the **Frequency specifications** section.

### **Stopband gain**

The stopband gain is the level in **Gain units** at which the stopband is defined. This property applies only when the **Order mode** is minimum and the **Frequency constraints** are Center frequency, bandwidth, stopband width.

### **Boost/cut gain**

The boost/cut gain applies only when the designing a shelving filter. Shelving filters include the *Shelf* type parameter in the **Frequency constraints** specification. The gain in the passband of the shelving filter is increased by **Boost/cut gain** dB from a *floor* gain of 0 dB.

## **Algorithm**

### **Design method**

Select the design method from the drop-down list. Different IIR design methods are available depending on the filter constraints you specify.

### **Scale SOS filter coefficients to reduce chance of overflow**

Select the check box to scale the filter coefficients.

## **Filter implementation**

### **Structure**

Select filter structure. The possible choices are:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

### **Use a System object to implement filter**

Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared. When the current design method or structure is not supported by a System object filter, then this check box is disabled.

## **Peak/Notch Filter Design — Main Pane**

### **Filter specifications**

In this area you can specify whether you want to design a peaking filter or a notching filter, as well as the order of the filter.

### **Response**

Select Peak or Notch from the drop-down box.

### **Order**

Enter the filter order. The order must be even.

### **Frequency specifications**

This group of parameters allows you to specify frequency constraints and units.

### Frequency Constraints

Select the frequency constraints for filter specification. There are two choices as follows:

- Center frequency and quality factor
- Center frequency and bandwidth

### Frequency units

The frequency units are normalized by default. If you specify units other than normalized, `filterBuilder` assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: Normalized (0 to 1), Hz, kHz, MHz, GHz.

### Input sample rate

This input box is enabled if **Frequency units** other than Normalized (0 to 1) are specified. Enter the input sampling frequency.

### Center frequency

Enter the center frequency in the units you specified in **Frequency units**.

### Quality Factor

This input box is enabled only when Center frequency and quality factor is chosen for the **Frequency Constraints**. Enter the quality factor.

### Bandwidth

This input box is enabled only when Center frequency and bandwidth is chosen for the **Frequency Constraints**. Enter the bandwidth.

### Magnitude specifications

This group of parameters allows you to specify the magnitude constraints, as well as their values and units.

### Magnitude Constraints

Depending on the choice of constraints, the other input boxes are enabled or disabled. Select from four magnitude constraints available:

- Unconstrained
- Passband ripple
- Stopband attenuation

- Passband ripple and stopband attenuation

**Magnitude units**

Select the magnitude units: either dB or squared.

**Passband ripple**

This input box is enabled if the magnitude constraints selected are Passband ripple or Passband ripple and stopband attenuation. Enter the passband ripple.

**Stopband attenuation**

This input box is enabled if the magnitude constraints selected are Stopband attenuation or Passband ripple and stopband attenuation. Enter the stopband attenuation.

**Algorithm**

The parameters in this group allow you to specify the design method and structure that filterBuilder uses to implement your filter.

**Design Method**

Lists all design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter the methods available to design filters changes as well.

**Scale SOS filter coefficients to reduce chance of overflow**

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

**Filter implementation****Structure**

Lists all available filter structures for the filter specifications and design method you select. The typical options are:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS

- Direct-form II transposed SOS

### Use a System object to implement filter

Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared. When the current design method or structure is not supported by a System object filter, then this check box is disabled.

## Pulse-shaping Filter Design —Main Pane

### Filter specifications

Parameters in this group enable you to specify the shape and length of the filter.

#### Pulse shape

Select the shape of the impulse response from the following options:

- Raised Cosine
- Square Root Raised Cosine
- Gaussian

#### Order mode

This specification is only available for raised cosine and square root raised cosine filters. For these filters, select one of the following options:

- **Minimum**— This option will result in the minimum-length filter satisfying the user-specified **Frequency specifications**.
- **Specify order**—This option allows the user to construct a raised cosine or square root cosine filter of a specified order by entering an even number in the **Order** input box. The length of the impulse response will be **Order+1**.
- **Specify symbols**—This option enables the user to specify the length of the impulse response in an alternative manner. If **Specify symbols** is chosen, the **Order** input box changes to the **Number of symbols** input box.

#### Samples per symbol

Specify the oversampling factor. Increasing the oversampling factor guards against aliasing and improves the FIR filter approximation to the ideal frequency response. If **Order** is specified in **Number of symbols**, the filter length will be **Number of symbols\*Samples per symbol+1**. The product **Number of symbols\*Samples per symbol** must be an even number.

If a Gaussian filter is specified, the filter length must be specified in **Number of symbols** and **Samples per symbol**. The product **Number of symbols\*Samples per symbol** must be an even number. The filter length will be **Number of symbols\*Samples per symbol+1**.

### Filter Type

This option is only available if you have the DSP System Toolbox software. Choose **Single rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. If you select **Decimator** or **Interpolator**, the decimation and interpolation factors default to the value of the **Samples per symbol**. If you select **Sample-rate converter**, the interpolation factor defaults to **Samples per symbol** and the decimation factor defaults to 3.

### Frequency specifications

Parameters in this group enable you to specify the frequency response of the filter. For raised cosine and square root raised cosine filters, the frequency specifications include:

#### Rolloff factor

The rolloff factor takes values in the range [0,1]. The smaller the rolloff factor, the steeper the transition in the stopband.

#### Frequency units

The frequency units are normalized by default. If you specify units other than normalized, **filterBuilder** assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: **Normalized (0 to 1)**, **Hz**, **kHz**, **MHz**, **GHz**

For a Gaussian pulse shape, the available frequency specifications are:

#### Bandwidth-time product

This option allows the user to specify the width of the Gaussian filter. Note that this is independent of the length of the filter. The bandwidth-time product (BT) must be a positive real number. Smaller values of the bandwidth-time product result in larger pulse widths in time and steeper stopband transitions in the frequency response.

#### Frequency units

The frequency units are normalized by default. If you specify units other than normalized, **filterBuilder** assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: **Normalized (0 to 1)**, **Hz**, **kHz**, **MHz**, **GHz**

### Magnitude specifications

If the **Order mode** is specified as Minimum, the **Magnitude units** may be selected from:

- dB— Specify the magnitude in decibels (default).
- Linear— Specify the magnitude in linear units.

### Algorithm

The only **Design method** available for FIR pulse-shaping filters is the Window method.

### Filter implementation

#### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure.

#### Use a System object to implement filter

This check box appears when you set **Filter type** to Single-rate. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to Interpolator, Decimator, or Sample-rate converter. The filter builder always implements the filter as a System object.

### Introduced in R2009a

# filtstates.cic

Store CIC filter states

## Description

`filtstates.cic` objects hold the states information for CIC filters. Once you create a CIC filter, the states for the filter are stored in `filtstates.cic` objects, and you can access them and change them as you would any property of the filter. This arrangement parallels that of the `filtstates` object that IIR direct-form I filters use (refer to `filtstates` for more information).

Each `States` property in the CIC filter comprises two properties — `Numerator` and `Comb` — that hold `filtstates.cic` objects. Within the `filtstates.cic` objects are the numerator-related and comb-related filter states. The states are column vectors, where each column represents the states for one section of the filter. For example, a CIC filter with four decimator sections and four interpolator sections has `filtstates.cic` objects that contain four columns of states each.

## Examples

### Integrator and Comb States of a CIC Filter

Construct an object with integrator and comb states as vectors of zeros.

```
h = filtstates.cic(zeros(4,1),zeros(4,1));
```

`h` has zero states now. You can use `int` to see the states as 32-bit integers.

```
intStates = int(h.Integrator)
```

```
intStates = 4x1 int32 column vector
```

```
0  
0  
0  
0
```

```
combStates = int(h.Comb)
```

```
combStates = 4x1 int32 column vector
```

```

**Introduced in R2011a**

# firband

Constrained-band equiripple FIR filter

## Syntax

```
b = firband(n,f,a,w,c)
b = firband(n,f,a,s)
b = firband(...,'l')
b = firband(...,'minphase')
b = firband(...,'check')
b = firband(...,{lgrid})
[b,err] = firband(...)
[b,err,res] = firband(...)
```

## Description

`firband` is a minimax filter design algorithm that you use to design the following types of real FIR filters:

- Types 1-4 linear phase
  - Type 1 is even order, symmetric
  - Type 2 is odd order, symmetric
  - Type 3 is even order, antisymmetric
  - Type 4 is odd order, antisymmetric
- Minimum phase
- Maximum phase
- Minimum order (even or odd), extra ripple
- Maximal ripple
- Constrained ripple
- Single-point band (notching and peaking)
- Forced gain

- Arbitrary shape frequency response curve filters

`b = fircband(n, f, a, w, c)` designs filters having constrained error magnitudes (ripples). `c` is a cell array of character vectors of the same length as `w`. The entries of `c` must be either 'c' to indicate that the corresponding element in `w` is a constraint (the ripple for that band cannot exceed that value) or 'w' indicating that the corresponding entry in `w` is a weight. There must be at least one unconstrained band — `c` must contain at least one `w` entry. For instance, the example 'Design a Constrained Lowpass Filter' uses a weight of one in the passband, and constrains the stopband ripple not to exceed 0.2 (about 14 dB).

A hint about using constrained values: if your constrained filter does not touch the constraints, increase the error weighting you apply to the unconstrained bands.

Notice that, when you work with constrained stopbands, you enter the stopband constraint according to the standard conversion formula for power — the resulting filter attenuation or constraint equals  $20 \cdot \log(\text{constraint})$  where *constraint* is the value you enter in the function. For example, to set 20 dB of attenuation, use a value for the constraint equal to 0.1. This applies to constrained stopbands only.

`b = fircband(n, f, a, s)` is used to design filters with special properties at certain frequency points. `s` is a cell array of character vectors and must be the same length as `f` and `a`. Entries of `s` must be one of:

- 'n' — normal frequency point.
- 's' — single-point band. The frequency band is given by a single point. You must specify the corresponding gain at this frequency point in `a`.
- 'f' — forced frequency point. Forces the gain at the specified frequency band to be the value specified.
- 'i' — indeterminate frequency point. Use this argument when bands abut one another (no transition region).

`b = fircband(..., '1')` designs a type 1 filter (even-order symmetric). You could also specify type 2 (odd-order symmetric), type 3 (even-order antisymmetric), or type 4 (odd-order antisymmetric) filters. Note there are restrictions on `a` at `f = 0` or `f = 1` for types 2, 3, and 4.

`b = fircband(..., 'minphase')` designs a minimum-phase FIR filter. There is also '**maxphase**'.

`b = fircband(..., 'check')` produces a warning when there are potential transition-region anomalies in the filter response.

`b = fircband(..., {lgrid})`, where `{lgrid}` is a scalar cell array containing an integer, controls the density of the frequency grid.

`[b,err] = fircband(...)` returns the unweighted approximation error magnitudes. `err` has one element for each independent approximation error.

`[b,err,res] = fircband(...)` returns a structure `res` of optional results computed by `fircband`, and contains the following fields:

Structure Field	Contents
<code>res.fgrid</code>	Vector containing the frequency grid used in the filter design optimization
<code>res.des</code>	Desired response on <code>fgrid</code>
<code>res.wt</code>	Weights on <code>fgrid</code>
<code>res.h</code>	Actual frequency response on the frequency grid
<code>res.error</code>	Error at each point (desired response - actual response) on the frequency grid
<code>res.iextr</code>	Vector of indices into <code>fgrid</code> of external frequencies
<code>res.fextr</code>	Vector of extremely frequencies
<code>res.order</code>	Filter order
<code>res.edgecheck</code>	Transition-region anomaly check. One element per band edge. Element values have the following meanings: 1 = OK, 0 = probable transition-region anomaly, -1 = edge not checked. Computed when you specify the 'check' input option in the function syntax.
<code>res.iterations</code>	Number of Remez iterations for the optimization
<code>res.ivals</code>	Number of function evaluations for the optimization

## Examples

### Design a Constrained Lowpass Filter

Design a 12th-order lowpass filter with a constraint on the filter response.

```
b = firband(12,[0 0.4 0.5 1], [1 1 0 0], ...  
[1 0.2], {'w' 'c'});
```

Using `fvtool` to display the result `b` shows you the response of the filter you designed.

```
fvtool(b)
```

Design two filters of different order with the stopband constrained to 60 dB. Use excess order (80) in the second filter to improve the passband ripple.

```
b1 = firband(60,[0 .2 .25 1],[1 1 0 0],...  
[1 .001],{'w','c'});  
b2 = firband(80,[0 .2 .25 1],[1 1 0 0],...  
[1 .001],{'w','c'});  
hfvt = fvtool(b1,1,b2,1);  
legend(hfvt,'Filter Order 60','Filter Order 80');
```

# fireqint

Equiripple FIR interpolators

## Syntax

```
b = fireqint(n,l,alpha)
b = fireqint(n,l,alpha,w)
b = fireqint('minorder',l,alpha,r)
b = fireqint({'minorder',initord},l,alpha,r)
```

## Description

`b = fireqint(n,l,alpha)` designs an FIR equiripple filter useful for interpolating input signals. `n` is the filter order and it must be an integer. `l`, also an integer, is the interpolation factor. `alpha` is the bandlimitedness factor, identical to the same feature in `intfilt`.

`alpha` is inversely proportional to the transition bandwidth of the filter. It also affects the bandwidth of the don't-care regions in the stopband. Specifying `alpha` allows you to control how much of the Nyquist interval your input signal occupies. This can be beneficial for signals to be interpolated because it allows you to increase the transition bandwidth without affecting the interpolation, resulting in better stopband attenuation for a given `l`. If you set `alpha` to 1, `fireqint` assumes that your signal occupies the entire Nyquist interval. Setting `alpha` to a value less than one allows for don't-care regions in the stopband. For example, if your input occupies half the Nyquist interval, you could set `alpha` to 0.5.

The signal to be interpolated is assumed to have zero (or negligible) power in the frequency band between  $(\alpha*\pi)$  and  $\pi$ . `alpha` must therefore be a positive scalar between 0 and 1. `fireqint` treat such bands as don't-care regions for assessing filter design.

`b = fireqint(n,l,alpha,w)` allows you to specify a vector of weights in `w`. The number of weights required in `w` is given by  $1 + \text{floor}(l/2)$ . The weights in `w` are applied to the passband ripple and stopband attenuations. Using weights (values between 0 and

1) enables you to specify different attenuations in different parts of the stopband, as well as providing the ability to adjust the compromise between passband ripple and stopband attenuation.

`b = fireqint('minorder',l,alpha,r)` allows you to design a minimum-order filter that meets the design specifications. `r` is a vector of maximum deviations or ripples from the ideal filter magnitude response. When you use the input argument **minorder**, you must provide the vector `r`. The number of elements required in `r` is given by  $1 + \text{floor}(l/2)$ .

`b = fireqint({'minorder',initord},l,alpha,r)` adds the argument `initord` so you can provide an initial estimate of the filter order. Any positive integer is valid here. Again, you must provide `r`, the vector of maximum deviations or ripples, from the ideal filter magnitude response.

## Examples

### Design an FIR Equiripple Filter

Design a minimum order interpolation filter with `l` set to 6, and `alpha` set to 0.8. A vector of ripples must be supplied with the input argument `minorder`.

```
b = fireqint('minorder',6,.8,[0.01 .1 .05 .02]);
```

Create a polyphase interpolation filter.

```
hm = dsp.FIRInterpolator(6,'Numerator',b)
```

```
hm =  
dsp.FIRInterpolator with properties:
```

```
    NumeratorSource: 'Property'  
      Numerator: [1x70 double]  
InterpolationFactor: 6
```

```
Show all properties
```

Here is the zero phase response of the interpolator.

```
zerophase(hm);
```

# firceqrip

Constrained equiripple FIR filter

## Syntax

```
B = firceqrip(n,Fo,DEV)
B = firceqrip(...,'slope',r)
B = firceqrip(...,'passedge')
B = firceqrip(...,'stopedge')
B = firceqrip(...,'high')
B = firceqrip(...,'min')
B = firceqrip(...,'invsinc',C)
B = firceqrip(...,'invdiric',C)
```

## Description

`B = firceqrip(n,Fo,DEV)` designs an order  $n$  filter (filter length equal  $n + 1$ ) lowpass FIR filter with linear phase.

`firceqrip` produces the same equiripple lowpass filters that `firpm` produces using the Parks-McClellan algorithm. The difference is how you specify the filter characteristics for the function.

The input argument `Fo` specifies the frequency at the upper edge of the passband in normalized frequency ( $0 < Fo < 1$ ). The two-element vector `dev` specifies the peak or maximum error allowed in the passband and stopbands. Enter `[d1 d2]` for `dev` where `d1` sets the passband error and `d2` sets the stopband error.

`B = firceqrip(...,'slope',r)` uses the input keyword `'slope'` and input argument `r` to design a filter with a nonequiripple stopband. `r` is specified as a positive constant and determines the slope of the stopband attenuation in dB/normalized frequency. Greater values of `r` result in increased stopband attenuation in dB/normalized frequency.

`B = firceqrip(...,'passedge')` designs a filter where `Fo` specifies the frequency at which the passband starts to rolloff.

`B = firceqrip(..., 'stopedge')` designs a filter where `Fo` specifies the frequency at which the stopband begins.

`B = firceqrip(..., 'high')` designs a high pass FIR filter instead of a lowpass filter.

`B = firceqrip(..., 'min')` designs a minimum-phase filter.

`B = firceqrip(..., 'invsinc', C)` designs a lowpass filter whose magnitude response has the shape of an inverse sinc function. This may be used to compensate for sinc-like responses in the frequency domain such as the effect of the zero-order hold in a D/A converter. The amount of compensation in the passband is controlled by `C`, which is specified as a scalar or two-element vector. The elements of `C` are specified as follows:

- If `C` is supplied as a real-valued scalar or the first element of a two-element vector, `firceqrip` constructs a filter with a magnitude response of  $1/\text{sinc}(C*\pi*F)$  where `F` is the normalized frequency.
- If `C` is supplied as a two-element vector, the inverse-sinc shaped magnitude response is raised to the positive power `C(2)`. If we set `P=C(2)`, `firceqrip` constructs a filter with a magnitude response  $1/\text{sinc}(C*\pi*F)^P$ .

If this FIR filter is used with a cascaded integrator-comb (CIC) filter, setting `C(2)` equal to the number of stages compensates for the multiplicative effect of the successive sinc-like responses of the CIC filters.

---

**Note** Since the value of the inverse sinc function becomes unbounded at  $C=1/F$ , the value of `C` should be greater the reciprocal of the passband edge frequency. This can be expressed as  $F_0 < 1/C$ . For users familiar with CIC decimators, `C` is equal to 1/2 the product of the differential delay and decimation factor.

---

`B = firceqrip(..., 'invdiric', C)` designs a lowpass filter with a passband that has the shape of an inverse Dirichlet sinc function. The frequency response of the inverse Dirichlet sinc function is given by

$$\{rC \left( \frac{\sin(f/2r)}{\sin(Cf/2)} \right)\}^p$$

where `C`, `r`, and `p` are scalars. The input `C` can be a scalar or vector containing 2 or 3 elements. If `C` is a scalar, `p` and `r` equal 1. If `C` is a two-element vector, the first element is

C and the second element is  $p$ ,  $[C \ p]$ . If  $C$  is a three-element vector, the third element is  $r$ ,  $[C \ p \ r]$ .

## Examples

To introduce a few of the variations on FIR filters that you design with `firceqrip`, these five examples cover both the default syntax `b = firceqrip(n,wo,del)` and some of the optional input arguments. For each example, the input arguments  $n$ ,  $wo$ , and  $del$  remain the same.

### Filter design using `firceqrip`

Design a 30th order FIR filter using `firceqrip`.

```
b = firceqrip(30,0.4,[0.05 0.03]); fvtool(b)
```

Design a 30th order FIR filter with the `stopedge` keyword to define the response at the edge of the filter stopband.

```
b = firceqrip(30,0.4,[0.05 0.03],'stopedge'); fvtool(b)
```

Design a 30th order FIR filter with the `slope` keyword and `r = 20`.

```
b = firceqip(30,0.4,[0.05 0.03],'slope',20,'stopedge'); fvtool(b)
```

Design a 30th order FIR filter defining the stopband and specifying that the resulting filter is minimum phase with the `min` keyword.

```
b = firceqrip(30,0.4,[0.05 0.03],'stopedge','min'); fvtool(b)
```

Comparing this filter to the filter in Figure 1. The cutoff frequency  $\omega_0 = 0.4$  now applies to the edge of the stopband rather than the point at which the frequency response magnitude is 0.5.

Viewing the zero-pole plot shown here reveals this is a minimum phase FIR filter - the zeros lie on or inside the unit circle,  $z = 1$

```
fvtool(b, 'polezero')
```

Design a 30th order FIR filter with the `invsinc` keyword to shape the filter passband with an inverse sinc function.

```
b = firceqrip(30,0.4,[0.05 0.03],'invsinc',[2 1.5]); fvtool(b)
```

The inverse sinc function being applied is defined as  $1/\text{sinc}(2*w)^{1.5}$ .

### Inverse-Dirichlet-Sinc-Shaped Passband

Design two order 30 constrained equiripple FIR filters with inverse-Dirichlet-sinc-shaped passbands. The cutoff frequency in both designs is  $\pi/4$  radians/sample. Set  $C=1$  in one design  $C=2$  in the second design. The maximum passband and stopband ripple is 0.05. Set  $p=1$  in one design and  $p=2$  in the second design.

Design the filters.

```
b1 = firceqrip(30,0.25,[0.05 0.05], 'invdiric', [1 1]);
b2 = firceqrip(30,0.25,[0.05 0.05], 'invdiric', [2 2]);
```

Obtain the filter frequency responses using `freqz`. Plot the magnitude responses.

```
[h1,~] = freqz(b1,1);
[h2,w] = freqz(b2,1);
plot(w,abs(h1)); hold on;
plot(w,abs(h2),'r');
axis([0 pi 0 1.5]);
xlabel('Radians/sample');
ylabel('Magnitude');
legend('C=1 p=1','C=2 p=2');
```

Inspect the stopband ripple in the design with  $C=1$  and  $p=1$ . The constrained design sets the maximum ripple to be 0.05. Zoom in on the stopband from the cutoff frequency of  $\pi/4$  radians/sample to  $3\pi/4$  radians/sample.

```
figure;  
plot(w,abs(h1));  
set(gca,'xlim',[pi/4 3*pi/4]);  
grid on;
```

# fircls

FIR Constrained Least Squares filter

## Syntax

```
clsFilter = design(d,'fircls','SystemObject',true)
clsFilter =
design(d,'fircls','FilterStructure',value,'SystemObject',true)
clsFilter =
design(d,'fircls','PassbandOffset',value,'SystemObject',true)
clsFilter = design(d,'fircls','zerophase',value,'SystemObject',true)
```

## Description

`clsFilter = design(d,'fircls','SystemObject',true)` designs a FIR Constrained Least Squares (CLS) filter, `clsFilter`, from a filter specifications object, `d`.

`clsFilter = design(d,'fircls','FilterStructure',value,'SystemObject',true)` where `value` is one of the following filter structures:

- `'dffir'`, a discrete-time, direct-form FIR filter (the default value)
- `'dffirt'`, a discrete-time, direct-form FIR transposed filter
- `'dfsymfir'`, a discrete-time, direct-form symmetric FIR filter

`clsFilter = design(d,'fircls','PassbandOffset',value,'SystemObject',true)` where `value` sets the passband band gain in dB. The `PassbandOffset` and `Ap` values affect the upper and lower approximation bound in the passband as follows:

- Lower bound =  $(\text{PassbandOffset} - A_p/2)$
- Upper bound =  $(\text{PassbandOffset} + A_p/2)$

For bandstop filters, the `PassbandOffset` is a vector of length two that specifies the first and second passband gains. The `PassbandOffset` value defaults to 0 for lowpass,

highpass and bandpass filters. The `PassbandOffset` value defaults to [0 0] for bandstop filters.

```
clsFilter = design(d,'fircls','zerophase',value,'SystemObject',true)
```

where `value` is either 'true' ('1') or 'false' ('0'). If `zerophase` is true, the lower approximation bound in the stopband is forced to zero (i.e., the filter has a zero phase response). `Zerophase` is false (0) by default.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'fircls')
```

For complete help about using `fircls`, refer to the command line help system. For example, to get specific information about using `fircls` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'fircls')
```

## Examples

### Create an FIR Constrained Least Squares (CLS) Filter

The following example designs a constrained least-squares FIR lowpass filter.

```
h = fdesign.lowpass('n,fc,ap,ast', 50, 0.3, 2, 30);  
firLPFilter = design(h, 'fircls','SystemObject',true);  
fvtool(firLPFilter)
```

The following example constructs a constrained least-squares FIR bandpass filter.

```
d = fdesign.bandpass('N,Fc1,Fc2,Ast1,Ap,Ast2',...  
30,0.4,0.6,60,1,60);  
firBPFfilter = design(d,'fircls','SystemObject',true);  
fvtool(firBPFfilter)
```

# firgr

Parks-McClellan FIR filter

## Syntax

```
b = firgr(n,f,a,w)
b = firgr(n,f,a,'hilbert')
b = firgr(m,f,a,r),
b = firgr({m,ni},f,a,r)
b = firgr(n,f,a,w,e)
b = firgr(n,f,a,s)
b = firgr(n,f,a,s,w,e)
b = firgr(...,'l')
b = firgr(...,'minphase')
b = firgr(...,'check')
b = firgr(...,{lgrid}),
[b,err] = firgr(...)
[b,err,res] = firgr(...)
b = firgr(n,f,fresp,w)
b = firgr(n,f,{fresp,p1,p2,...},w)
b = firgr(n,f,a,w)
```

## Description

`firgr` is a minimax filter design algorithm you use to design the following types of real FIR filters:

- Types 1-4 linear phase:
  - Type 1 is even order, symmetric
  - Type 2 is odd order, symmetric
  - Type 3 is even order, antisymmetric
  - Type 4 is odd order, antisymmetric
- Minimum phase

- Maximum phase
- Minimum order (even or odd)
- Extra ripple
- Maximal ripple
- Constrained ripple
- Single-point band (notching and peaking)
- Forced gain
- Arbitrary shape frequency response curve filters

`b = firgr(n, f, a, w)` returns a length  $n+1$  linear phase FIR filter which has the best approximation to the desired frequency response described by `f` and `a` in the minimax sense. `w` is a vector of weights, one per band. When you omit `w`, all bands are weighted equally. For more information on the input arguments, refer to `firpm` in *Signal Processing Toolbox User's Guide*.

`b = firgr(n, f, a, 'hilbert')` and `b = firgr(n, f, a, 'differentiator')` design FIR Hilbert transformers and differentiators. For more information on designing these filters, refer to `firpm` in *Signal Processing Toolbox User's Guide*.

`b = firgr(m, f, a, r)`, where `m` is one of 'minorder', 'mineven' or 'minodd', designs filters repeatedly until the minimum order filter, as specified in `m`, that meets the specifications is found. `r` is a vector containing the peak ripple per frequency band. You must specify `r`. When you specify 'mineven' or 'minodd', the minimum even or odd order filter is found.

`b = firgr({m, ni}, f, a, r)` where `m` is one of 'minorder', 'mineven' or 'minodd', uses `ni` as the initial estimate of the filter order. `ni` is optional for common filter designs, but it must be specified for designs in which `firpmord` cannot be used, such as while designing differentiators or Hilbert transformers.

`b = firgr(n, f, a, w, e)` specifies independent approximation errors for different bands. Use this syntax to design extra ripple or maximal ripple filters. These filters have interesting properties such as having the minimum transition width. `e` is a cell array of character vectors specifying the approximation errors to use. Its length must equal the number of bands. Entries of `e` must be in the form 'e#' where # indicates which approximation error to use for the corresponding band. For example, when `e = {'e1', 'e2', 'e1'}`, the first and third bands use the same approximation error 'e1' and the second band uses a different one 'e2'. Note that when all bands use the same

approximation error, such as {'e1', 'e1', 'e1', ...}, it is equivalent to omitting e, as in `b = firgr(n,f,a,w)`.

`b = firgr(n,f,a,s)` is used to design filters with special properties at certain frequency points. `s` is a cell array of character vectors and must be the same length as `f` and `a`. Entries of `s` must be one of:

- 'n' — normal frequency point.
- 's' — single-point band. The frequency “band” is given by a single point. The corresponding gain at this frequency point must be specified in `a`.
- 'f' — forced frequency point. Forces the gain at the specified frequency band to be the value specified.
- 'i' — indeterminate frequency point. Use this argument when adjacent bands abut one another (no transition region).

For example, the following command designs a bandstop filter with zero-valued single-point stop bands (notches) at 0.25 and 0.55.

```
b = firgr(42,[0 0.2 0.25 0.3 0.5 0.55 0.6 1],...
[1 1 0 1 1 0 1 1],{'n' 'n' 's' 'n' 'n' 's' 'n' 'n'})
```

`b = firgr(82,[0 0.055 0.06 0.1 0.15 1],[0 0 0 0 1 1],...{'n' 'i' 'f' 'n' 'n' 'n'})` designs a highpass filter with the gain at 0.06 forced to be zero. The band edge at 0.055 is indeterminate since the first two bands actually touch. The other band edges are normal.

`b = firgr(n,f,a,s,w,e)` specifies weights and independent approximation errors for filters with special properties. The weights and properties are included in vectors `w` and `e`. Sometimes, you may need to use independent approximation errors to get designs with forced values to converge. For example,

```
b = firgr(82,[0 0.055 0.06 0.1 0.15 1], [0 0 0 0 1 1],...
{'n' 'i' 'f' 'n' 'n' 'n'}, [10 1 1] ,{'e1' 'e2' 'e3'});
```

`b = firgr(...,'1')` designs a type 1 filter (even-order symmetric). You can specify type 2 (odd-order symmetric), type 3 (even-order antisymmetric), and type 4 (odd-order antisymmetric) filters as well. Note that restrictions apply to `a` at `f = 0` or `f = 1` for FIR filter types 2, 3, and 4.

`b = firgr(...,'minphase')` designs a minimum-phase FIR filter. You can use the argument 'maxphase' to design a maximum phase FIR filter.

`b = firgr(..., 'check')` returns a warning when there are potential transition-region anomalies.

`b = firgr(..., {lgrid})`, where `{lgrid}` is a scalar cell array. The value of the scalar controls the density of the frequency grid by setting the number of samples used along the frequency axis.

`[b,err] = firgr(...)` returns the unweighted approximation error magnitudes. `err` contains one element for each independent approximation error returned by the function.

`[b,err,res] = firgr(...)` returns the structure `res` comprising optional results computed by `firgr`. `res` contains the following fields.

Structure Field	Contents
<code>res.fgrid</code>	Vector containing the frequency grid used in the filter design optimization
<code>res.des</code>	Desired response on <code>fgrid</code>
<code>res.wt</code>	Weights on <code>fgrid</code>
<code>res.h</code>	Actual frequency response on the frequency grid
<code>res.error</code>	Error at each point (desired response - actual response) on the frequency grid
<code>res.iextr</code>	Vector of indices into <code>fgrid</code> of external frequencies
<code>res.fextr</code>	Vector of external frequencies
<code>res.order</code>	Filter order
<code>res.edgecheck</code>	Transition-region anomaly check. One element per band edge. Element values have the following meanings: 1 = OK, 0 = probable transition-region anomaly, -1 = edge not checked. Computed when you specify the 'check' input option in the function syntax.
<code>res.iterations</code>	Number of <code>s</code> iterations for the optimization
<code>res.evals</code>	Number of function evaluations for the optimization

`firgr` is also a “function function,” allowing you to write a function that defines the desired frequency response.

`b = firgr(n, f, fresp, w)` returns a length  $N + 1$  FIR filter which has the best approximation to the desired frequency response as returned by the user-defined function `fresp`. Use the following `firgr` syntax to call `fresp`:

```
[dh, dw] = fresp(n, f, gf, w)
```

where:

- `fresp` identifies the function that you use to define your desired filter frequency response.
- `n` is the filter order.
- `f` is the vector of frequency band edges which must appear monotonically between 0 and 1, where 1 is one-half of the sampling frequency. The frequency bands span  $f(k)$  to  $f(k+1)$  for  $k$  odd. The intervals  $f(k+1)$  to  $f(k+2)$  for  $k$  odd are “transition bands” or “don't care” regions during optimization.
- `gf` is a vector of grid points that have been chosen over each specified frequency band by `firgr`, and determines the frequencies at which `firgr` evaluates the response function.
- `w` is a vector of real, positive weights, one per band, for use during optimization. `w` is optional in the call to `firgr`. If you do not specify `w`, it is set to unity weighting before being passed to `fresp`.
- `dh` and `dw` are the desired frequency response and optimization weight vectors, evaluated at each frequency in grid `gf`.

`firgr` includes a predefined frequency response function named `'firpmfrf2'`. You can write your own based on the simpler `'firpmfrf'`. See the help for `private/firpmfrf` for more information.

`b = firgr(n, f, {fresp, p1, p2, ...}, w)` specifies optional arguments `p1`, `p2`, ..., `pn` to be passed to the response function `fresp`.

`b = firgr(n, f, a, w)` is a synonym for `b = firgr(n, f, {'firpmfrf2', a}, w)`, where `a` is a vector containing your specified response amplitudes at each band edge in `f`. By default, `firgr` designs symmetric (even) FIR filters. `'firpmfrf2'` is the predefined frequency response function. If you do not specify your own frequency response function (the `fresp` variable), `firgr` uses `'firpmfrf2'`.

`b = firgr(..., 'h')` and `b = firgr(..., 'd')` design antisymmetric (odd) filters. When you omit the `'h'` or `'d'` arguments from the `firgr` command syntax, each

frequency response function `fresp` can tell `firgr` to design either an even or odd filter. Use the command syntax `sym = fresp('defaults',{n,f,[],w,p1,p2,...})`.

`firgr` expects `fresp` to return `sym = 'even'` or `sym = 'odd'`. If `fresp` does not support this call, `firgr` assumes even symmetry.

For more information about the input arguments to `firgr`, refer to `firpm`.

## Examples

### Design a Filter Using `firgr`

Design an FIR filter with two single-band notches at 0.25 and 0.55.

```
b1 = firgr(42,[0 0.2 0.25 0.3 0.5 0.55 0.6 1],[1 1 0 1 1 0 1 1],...  
{'n' 'n' 's' 'n' 'n' 's' 'n' 'n'});
```

Design a highpass filter whose gain at 0.06 is forced to be zero. The gain at 0.055 is indeterminate since it should about the band.

```
b2 = firgr(82,[0 0.055 0.06 0.1 0.15 1],[0 0 0 0 1 1],...  
{'n' 'i' 'f' 'n' 'n' 'n'});
```

Design a second highpass filter with forced values and independent approximation errors.

```
b3 = firgr(82,[0 0.055 0.06 0.1 0.15 1], [0 0 0 0 1 1], ...  
{'n' 'i' 'f' 'n' 'n' 'n'}, [10 1 1] ,{'e1' 'e2' 'e3'});
```

Use the filter visualization tool to view the results of the filters.

```
fvtool(b1,1,b2,1,b3,1)  
legend('Filter b1','Filter b2','Filter b3');
```

# firhalfband

Halfband FIR filter design

## Syntax

```
b = firhalfband(n,fp)
b = firhalfband(n,win)
b = firhalfband(n,dev,'dev')
b = firhalfband('minorder',fp,dev)
b = firhalfband('minorder',fp,dev,'kaiser')
b = firhalfband(...,'high')
b = firhalfband(...,'minphase')
```

## Description

`b = firhalfband(n,fp)` designs a lowpass halfband FIR filter of order  $n$  with an equiripple characteristic.  $n$  must be an even integer.  $fp$  determines the passband edge frequency, and it must satisfy  $0 < fp < 1/2$ , where  $1/2$  corresponds to  $\pi/2$  rad/sample.

`b = firhalfband(n,win)` designs a lowpass  $N$ th-order filter using the truncated, windowed-impulse response method instead of the equiripple method. `win` is an  $n+1$  length vector. The ideal impulse response is truncated to length  $n + 1$ , and then multiplied point-by-point with the window specified in `win`.

`b = firhalfband(n,dev,'dev')` designs an  $N$ th-order lowpass halfband filter with an equiripple characteristic. Input argument `dev` sets the value for the maximum passband and stopband ripple allowed.

`b = firhalfband('minorder',fp,dev)` designs a lowpass minimum-order filter, with passband edge  $fp$ . The peak ripple is constrained by the scalar `dev`. This design uses the equiripple method.

`b = firhalfband('minorder',fp,dev,'kaiser')` designs a lowpass minimum-order filter, with passband edge  $fp$ . The peak ripple is constrained by the scalar `dev`. This design uses the Kaiser window method.

`b = firhalfband(..., 'high')` returns a highpass halfband FIR filter.

`b = firhalfband(..., 'minphase')` designs a minimum-phase FIR filter such that the filter is a spectral factor of a halfband filter (recall that `h = conv(b, flipplr(b))` is a halfband filter). This can be useful for designing perfect reconstruction, two-channel FIR filter banks. The **minphase** option for `firhalfband` is not available for the window-based halfband filter designs — `b = firhalfband(n, win)` and `b = firhalfband('minorder', fp, dev, 'kaiser')`.

In the minimum phase cases, the filter order must be odd.

## Examples

### Design a Halfband Filter using `halfband`

This example designs a minimum order halfband filter with a specified maximum ripple.

```
b = firhalfband('minorder', .45, 0.0001);  
impz(b)
```

You can see that the impulse response is zero for every alternate sample.

## **fir2lp**

Convert FIR Type I lowpass to FIR Type 1 lowpass with inverse bandwidth

### **Syntax**

```
g = fir2lp(b)
```

### **Description**

`g = fir2lp(b)` transforms the Type I lowpass FIR filter `b` with zero-phase response  $H_r(w)$  to a Type I lowpass FIR filter `g` with zero-phase response  $[1 - H_r(\pi-w)]$ .

When `b` is a narrowband filter, `g` will be a wideband filter and vice versa. The passband and stopband ripples of `g` will be equal to the stopband and passband ripples of `b`.

### **Examples**

#### **Convert Narrowband Lowpass Filter to Wideband Lowpass Filter**

Create a narrowband lowpass filter to use as prototype. Display its zero-phase response.

```
b = firgr(36,[0 0.2 0.25 1],[1 1 0 0],[1 5]);
```

```
zerophase(b)
```

Convert the prototype filter to a wideband lowpass filter. Add to the plot the zero-phase response of the new filter.

```
h = fir1p2lp(b);
```

```
hold on  
zerophase(h)
```

Convert the previous filter back to a narrowband lowpass filter. Add to the plot the zero-phase response of the new filter.

```
g = firp2lp(h);
[gr,w] = zerophase(g);
plot(w/pi,gr,'--')
hold off
```

## firlp2hp

Convert FIR lowpass filter to Type I FIR highpass filter

### Syntax

```
g = firlp2hp(b)
g = firlp2hp(b,'narrow')
g = firlp2hp(b,'wide')
```

### Description

`g = firlp2hp(b)` transforms the lowpass FIR filter `b` into a Type I highpass FIR filter `g` with zero-phase response  $H_r(\pi-w)$ . Filter `b` can be any FIR filter, including a nonlinear-phase filter.

The passband and stopband ripples of `g` will be equal to the passband and stopband ripples of `b`.

`g = firlp2hp(b,'narrow')` transforms the lowpass FIR filter `b` into a Type I narrow band highpass FIR filter `g` with zero-phase response  $H_r(\pi-w)$ . `b` can be any FIR filter, including a nonlinear-phase filter.

`g = firlp2hp(b,'wide')` transforms the Type I lowpass FIR filter `b` with zero-phase response  $H_r(w)$  into a Type I wide band highpass FIR filter `g` with zero-phase response  $1 - H_r(w)$ . Note the restriction that `b` must be a Type I linear-phase filter.

For this case, the passband and stopband ripples of `g` will be equal to the stopband and passband ripples of `b`.

### Examples

#### Convert Narrowband Lowpass Filter to Highpass Filter

Create a narrowband lowpass filter to use as prototype. Display its zero-phase response.

```
b = firgr(36,[0 0.2 0.25 1],[1 1 0 0],[1 3]);  
zerophase(b)
```

Convert the prototype filter to a narrowband highpass filter. Add to the plot the zero-phase response of the new filter.

```
h = fir1p2hp(b);  
  
hold on  
zerophase(h)
```

Convert the prototype filter to a wideband highpass filter. Add to the plot the zero-phase response of the new filter.

```
g = fir1p2hp(b, 'wide');
```

```
zerophase(g)  
hold off
```

# firlpnorm

Least P-norm optimal FIR filter

## Syntax

```
b = firlpnorm(n,f,edges,a)
b = firlpnorm(n,f,edges,a,w)
b = firlpnorm(n,f,edges,a,w,p)
b = firlpnorm(n,f,edges,a,w,p,dens)
b = firlpnorm(n,f,edges,a,w,p,dens,initnum)
b = firlpnorm(...,'minphase')
[b,err] = firlpnorm(...)
```

## Description

`b = firlpnorm(n,f,edges,a)` returns a filter of numerator order `n` which represents the best approximation to the frequency response described by `f` and `a` in the least-Pth norm sense. `P` is set to 128 by default, which is essentially equivalent to the infinity norm. Vector `edges` specifies the band-edge frequencies for multiband designs. `firlpnorm` uses an unconstrained quasi-Newton algorithm to design the specified filter.

`f` and `a` must have the same number of elements, which can exceed the number of elements in `edges`. This lets you specify filters with any gain contour within each band. However, the frequencies in `edges` must also be in vector `f`. Always use `freqz` to check the resulting filter.

---

**Note** `firlpnorm` uses a nonlinear optimization routine that may not converge in some filter design cases. Furthermore the algorithm is not well-suited for certain large-order (order > 100) filter designs.

---

`b = firlpnorm(n,f,edges,a,w)` uses the weights in `w` to weight the error. `w` has one entry per frequency point (the same length as `f` and `a`) which tells `firlpnorm` how much emphasis to put on minimizing the error in the vicinity of each frequency point relative to the other points. For example,

```
b = firlnorm(20,[0 .15 .4 .5 1],[0 .4 .5 1],...  
[1 1.6 1 0 0],[1 1 1 10 10])
```

designs a lowpass filter with a peak of 1.6 within the passband, and with emphasis placed on minimizing the error in the stopband.

`b = firlnorm(n,f,edges,a,w,p)` where `p` is a two-element vector [`pmin pmax`] lets you specify the minimum and maximum values of `p` used in the least-`p`th algorithm. Default is [2 128] which essentially yields the L-infinity, or Chebyshev, norm. `pmin` and `pmax` should be even numbers. The design algorithm starts optimizing the filter with `pmin` and moves toward an optimal filter in the `pmax` sense. When `p` is set to '**inspect**', `firlnorm` does not optimize the resulting filter. You might use this feature to inspect the initial zero placement.

`b = firlnorm(n,f,edges,a,w,p,dens)` specifies the grid density `dens` used in the optimization. The number of grid points is [`dens*(n+1)`]. The default is 20. You can specify `dens` as a single-element cell array. The grid is equally spaced.

`b = firlnorm(n,f,edges,a,w,p,dens,initnum)` lets you determine the initial estimate of the filter numerator coefficients in vector `initnum`. This can prove helpful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating `initnum`.

`b = firlnorm(...,'minphase')` where '`minphase`' is the last argument in the argument list generates a minimum-phase FIR filter. By default, `firlnorm` design mixed-phase filters. Specifying input option '`minphase`' causes `firlnorm` to use a different optimization method to design the minimum-phase filter. As a result of the different optimization used, the minimum-phase filter can yield slightly different results.

`[b,err] = firlnorm(...)` returns the least-`p`th approximation error `err`.

## Examples

### Design a Lowpass and Highpass Filter Using `firlnorm`

Lowpass filter with a peak of 1.4 in the passband.

```
b = firlnorm(22,[0 .15 .4 .5 1],[0 .4 .5 1],[1 1.4 1 0 0],...  
[1 1 1 2 2]);  
fvtool(b)
```

The resulting filter is lowpass, with the desired 1.4 peak in the passband (notice the 1.4 specified in vector a).

Highpass minimum-phase filter optimized for the 4-norm.

```
b = firlpnorm(44,[0 .4 .45 1],[0 .4 .45 1],[0 0 1 1],[5 1 1 1],...
[2 4], 'minphase');
fvtool(b)
```

This is a minimum-phase, highpass filter.

The zero-pole plot shows the minimum phase nature more clearly.

```
fvtool(b, 'polezero')
```

## firls

Least-square linear-phase FIR filter design

### Syntax

```
b = firls(n,f,a)
b = firls(n,f,a,w)
b = firls(n,f,a,ftype)
b = firls(n,f,a,w,ftype)
```

### Description

`b = firls(n,f,a)` returns row vector `b` containing the `n+1` coefficients of the order `n` FIR filter. This filter has frequency-amplitude characteristics approximately matching those given by vectors, `f` and `a`.

`b = firls(n,f,a,w)` uses the weights in vector `w`, to weigh the error.

`b = firls(n,f,a,ftype)` specifies a filter type where `ftype` is:

- 'hilbert'
- 'differentiator'

`b = firls(n,f,a,w,ftype)` uses the weights in vector `w` to weigh the error. It also specifies a filter type where `ftype` is:

- 'hilbert'
- 'differentiator'

### Examples

#### Design a Lowpass Filter with Transition Band

The following illustrates how to design a lowpass filter of order 225 with transition band.

Create the frequency and amplitude vectors, `f` and `a`.

```
f = [0 0.25 0.3 1]
```

```
f = 1×4
```

```
0    0.2500    0.3000    1.0000
```

```
a = [1 1 0 0]
```

```
a = 1×4
```

```
1    1    0    0
```

Use `firls` to obtain the `n+1` coefficients of the order `n` lowpass FIR filter.

```
b = firls(255,f,a);
```

Show the impulse response of the filter

```
fvtool(b,'impulse')
```

### Design an Antisymmetric Filter with Piecewise Linear Passbands

The following shows how to design a 24th-order anti-symmetric filter with piecewise linear passbands, and plot the desired and actual amplitude responses.

Create the frequency and amplitude vectors,  $f$  and  $a$ .

```
f = [0 0.3 0.4 0.6 0.7 0.9];
a = [0 1 0 0 0.5 0.5];
```

Use `firls` to obtain the 25 coefficients of the filter.

```
b = firls(24,f,a,'hilbert');
```

Plot the ideal amplitude response along with the transition regions.

```
plot(f.*pi,a,'o','markerfacecolor',[1 0 0]);  
hold on;  
plot(f.*pi,a,'r--','linewidth',2);
```

Use `freqz` to obtain the frequency response of the designed filter and plot the magnitude response of the filter.

```
[H,F] = freqz(b,1);  
plot(F,abs(H));  
set(gca,'xlim',[0 pi])  
legend('Filter Specification','Transition Regions','Magnitude Response')
```

## Input Arguments

### **n** — Filter order

integer scalar

Order of the filter, specified as an integer scalar. For odd orders, the frequency response at the Nyquist frequency is necessarily 0. For this reason, `firls` always uses an even filter order for configurations with a passband at the Nyquist frequency. If you specify an odd-valued `n`, `firls` increments it by 1.

Example: 8

Data Types: `int8` | `int16` | `int32` | `int64`

**f — Pairs of frequency points**

vector of numeric values

Pairs of frequency points, specified as a vector of values ranging between 0 and 1, where 1 corresponds to the Nyquist frequency. The frequencies must be in increasing order, and duplicate frequency points are allowed. You can use duplicate frequency points to design filters exactly like those returned by the `fir1` and `fir2` functions with a rectangular (`rectwin`) window.

`f` and `a` are the same length. This length must be an even number.

Example: `[0 0.3 0.4 1]`

Data Types: `double` | `single`

**a — Amplitude values**

vector of numeric values

Amplitude values of the function at each frequency point, specified as a vector of the same length as `f`. This length must be an even number.

The desired amplitude at frequencies between pairs of points ( $f(k)$ ,  $f(k+1)$ ) for  $k$  odd, is the line segment connecting the points ( $f(k)$ ,  $a(k)$ ) and ( $f(k+1)$ ,  $a(k+1)$ ).

The desired amplitude at frequencies between pairs of points ( $f(k)$ ,  $f(k+1)$ ) for  $k$  even is unspecified. These are transition or “don't care” regions.

Example: `[1 1 0 0]`

Data Types: `double` | `single`

**w — Weights**

vector of numeric values

Weights to weigh the fit for each frequency band, specified as a vector of length half the length of `f` and `a`, so there is exactly one weight per band. `w` indicates how much emphasis to put on minimizing the integral squared error in each band, relative to the other bands.

Example: `[0.5 1]`

Data Types: `double` | `single`

**ftype — Filter type**

'hilbert' and 'differentiator'

Filter type, specified as either 'hilbert' or 'differentiator'.

Example: 'hilbert'

Data Types: char

## Output Arguments

**b — Filter coefficients**

vector of numeric values

Filter coefficients, returned as a numeric vector of  $n+1$  values, where  $n$  is the filter order.

$b = \text{firls}(n, f, a)$  designs a linear-phase filter of type I ( $n$  odd) and type II ( $n$ ). The output coefficients, or “taps,” in  $b$  obey the relation:

$$b(k) = b(n+2-k), k = 1, \dots, n + 1$$

$b = \text{firls}(n, f, a, 'hilbert')$  designs a linear-phase filter with odd symmetry (type III and type IV). The output coefficients, or “taps,” in  $b$  obey the relation:

$$b(k) = -b(n+2-k), k = 1, \dots, n + 1$$

$b = \text{firls}(n, f, a, 'differentiator')$  designs type III and type IV filters, using a special weighting technique. For nonzero amplitude bands, the integrated squared error has a weight of  $(1/f)^2$ . This weighting causes the error at low frequencies to be much smaller than at high frequencies. For FIR differentiators, which have an amplitude characteristic proportional to frequency, the filters minimize the relative integrated squared error. This value is the integral of the square of the ratio of the error to the desired amplitude.

## Definitions

### Diagnostics

Error and warning messages

One of the following diagnostic messages is displayed when an incorrect argument is used:

```
F must be even length.
F and A must be equal lengths.
Requires symmetry to be 'hilbert' or 'differentiator'.
Requires one weight per band.
Frequencies in F must be nondecreasing.
Frequencies in F must be in range [0,1].
```

A more serious warning message is

```
Warning: Matrix is close to singular or badly scaled.
```

This tends to happen when the product of the filter length and transition width grows large. In this case, the filter coefficients `b` might not represent the desired filter. You can check the filter by looking at its frequency response.

## Algorithms

`firls` designs a linear-phase FIR filter. This filter minimizes the weighted, integrated squared error between an ideal piecewise linear function and the magnitude response of the filter over a set of desired frequency bands.

Reference [1] describes the theoretical approach behind `firls`. The function solves a system of linear equations involving an inner product matrix of size roughly  $n/2$  using the MATLAB `\` operator.

This function designs type I, II, III, and IV linear-phase filters. Type I and II are the defaults for  $n$  even and odd respectively. The `'hilbert'` and `'differentiator'` flags produce type III ( $n$  even) and IV ( $n$  odd) filters. The various filter types have different symmetries and constraints on their frequency responses (see [2] for details).

Linear Phase Filter Type	Filter Order	Symmetry of Coefficients	Response $H(f)$ , $f = 0$	Response $H(f)$ , $f = 1$ (Nyquist)
Type I	Even	$b(k) = b(n+2-k)$ , $k=1, \dots, n+1$	No restriction	No restriction
Type II	Even	$b(k) = b(n+2-k)$ , $k=1, \dots, n+1$	No restriction	$H(1) = 0$
Type III	Odd	$b(k) = -b(n+2-k)$ , $k=1, \dots, n+1$	$H(0) = 0$	$H(1) = 0$

Linear Phase Filter Type	Filter Order	Symmetry of Coefficients	Response $H(f)$ , $f = 0$	Response $H(f)$ , $f = 1$ (Nyquist)
Type IV	Odd	$b(k) = -b(n+2-k)$ , $k=1, \dots, n+1$	$H(0) = 0$	No restriction

## firminphase

Minimum-phase FIR spectral factor

### Syntax

```
h = firminphase(b)
h = firminphase(b,nz)
```

### Description

`h = firminphase(b)` computes the minimum-phase FIR spectral factor `h` of a linear-phase FIR filter `b`. Filter `b` must be real, have even order, and have nonnegative zero-phase response.

`h = firminphase(b,nz)` specifies the number of zeros, `nz`, of `b` that lie on the unit circle. You must specify `nz` as an even number to compute the minimum-phase spectral factor because every root on the unit circle must have even multiplicity. Including `nz` can help `firminphase` calculate the required FIR spectral factor. Zeros with multiplicity greater than two on the unit circle cause problems in the spectral factor determination.

---

**Note** You can find the maximum-phase spectral factor, `g`, by reversing `h`, such that  $g = \text{fliplr}(h)$ , and  $b = \text{conv}(h, g)$ .

---

### Examples

#### Design a Constrained Least Squares Filter using firminphase

This example designs a constrained least squares filter with a nonnegative zero-phase response, and then uses `firminphase` to compute the minimum-phase spectral factor.

```
f = [0 0.4 0.8 1];
a = [0 1 0];
up = [0.02 1.02 0.01];
```

```
lo = [0 0.98 0]; % The zeros insure nonnegative zero-phase resp.  
n = 32;  
b = fircls(n,f,a,up,lo);  
h = firminphase(b)
```

```
h = 1×17
```

```
0.2397 -0.1556 -0.2834 0.3866 0.0415 -0.2529 0.0584 -0.0028 0.0
```

## firnyquist

Lowpass Nyquist (Lth-band) FIR filter

### Syntax

```
b = firnyquist(n,l,r)
b = firnyquist('minorder',l,r,dev)
b = firnyquist(n,l,r,decay)
b = firnyquist(n,l,r,'nonnegative')
b = firnyquist(n,l,r,'minphase')
```

### Description

`b = firnyquist(n,l,r)` designs an Nth order, Lth band, Nyquist FIR filter with a rolloff factor  $r$  and an equiripple characteristic.

The rolloff factor  $r$  is related to the normalized transition width  $tw$  by  $tw = 2\pi(r/l)$  (rad/sample). The order,  $n$ , must be even.  $l$  must be an integer greater than one. If  $l$  is not specified, it defaults to 4.  $r$  must satisfy  $0 < r < 1$ . If  $r$  is not specified, it defaults to 0.5.

`b = firnyquist('minorder',l,r,dev)` designs a minimum-order, Lth band Nyquist FIR filter with a rolloff factor  $r$  using the Kaiser window. The peak ripple is constrained by the scalar `dev`.

`b = firnyquist(n,l,r,decay)` designs an Nth order ( $n$ ), Lth band ( $l$ ), Nyquist FIR filter where the scalar `decay`, specifies the rate of decay in the stopband. `decay` must be nonnegative. If you omit or leave it empty, `decay` defaults to 0 which yields an equiripple stopband. A nonequiripple stopband (`decay`  $\neq 0$ ) may be desirable for decimation purposes.

`b = firnyquist(n,l,r,'nonnegative')` returns an FIR filter with nonnegative zero-phase response. This filter can be spectrally factored into minimum-phase and maximum-phase “square-root” filters. This allows you to use the spectral factors in applications such as matched-filtering.

`b = firnyquist(n,l,r,'minphase')` returns the minimum-phase spectral factor `bmin` of order `n`. `bmin` meets the condition `b=conv(bmin,bmax)` so that `b` is an `L`th band FIR Nyquist filter of order `2n` with filter rolloff factor `r`. Obtain `bmax`, the maximum phase spectral factor by reversing the coefficients of `bmin`. For example, `bmax = bmin(end:-1:1)`.

## Examples

### Design a Nyquist Filter Using `firnyquist`

This example designs a minimum phase factor of a Nyquist filter.

```
bmin = firnyquist(47,10,.45,'minphase');  
b = firnyquist(2*47,10,.45,'nonnegative');  
[h,w,s] = freqz(b); hmin = freqz(bmin);  
fvtool(b,1,bmin,1);
```

This example compares filters with different decay rates.

```
b1 = firnyquist(72,8,.3,0); % Equiripple  
b2 = firnyquist(72,8,.3,15);  
b3 = firnyquist(72,8,.3,25);  
fvtool(b1,1,b2,1,b3,1);
```

Two-channel FIR filter bank for perfect reconstruction

## Syntax

```
[h0,h1,g0,g1] = firpr2chfb(n,fp)
[h0,h1,g0,g1] = firpr2chfb(n,dev,'dev')
[h0,h1,g0,g1] = firpr2chfb('minorder',fp,dev)
```

## Description

`[h0,h1,g0,g1] = firpr2chfb(n,fp)` designs four FIR filters for the analysis sections (`h0` and `h1`) and synthesis section is (`g0` and `g1`) of a two-channel perfect reconstruction filter bank. The design corresponds to the orthogonal filter banks also known as power-symmetric filter banks.

`n` is the order of all four filters. It must be an odd integer. `fp` is the passband-edge for the lowpass filters `h0` and `g0`. The passband-edge argument `fp` must be less than 0.5. `h1` and `g1` are highpass filters with the passband-edge given by  $(1-fp)$ .

`[h0,h1,g0,g1] = firpr2chfb(n,dev,'dev')` designs the four filters such that the maximum stopband ripple of `h0` is given by the scalar `dev`. Specify `dev` in linear units, not decibels. The stopband-ripple of `h1` is also be given by `dev`, while the maximum stopband-ripple for both `g0` and `g1` is  $(2*dev)$ .

`[h0,h1,g0,g1] = firpr2chfb('minorder',fp,dev)` designs the four filters such that `h0` meets the passband-edge specification `fp` and the stopband-ripple `dev` using minimum order filters to meet the specification.

## Examples

### Design a Filter Bank Using firpr2chfb

Design a filter bank with filters of order  $n$  equal to 99 and passband edges of 0.45 and 0.55.

```
n = 99;  
[h0,h1,g0,g1] = firpr2chfb(n,.45);  
fvtool(h0,1,h1,1,g0,1,g1,1);
```

Here are the filters, showing clearly the passband edges.

Use the following stem plots to verify perfect reconstruction using the filter bank created by firpr2chfb.

```
stem(1/2*conv(g0,h0)+1/2*conv(g1,h1))
n=0:n;
stem(1/2*conv((-1).^n.*h0,g0)+1/2*conv((-1).^n.*h1,g1))
stem(1/2*conv((-1).^n.*g0,h0)+1/2*conv((-1).^n.*g1,h1))
stem(1/2*conv((-1).^n.*g0,(-1).^n.*h0)+...
1/2*conv((-1).^n.*g1,(-1).^n.*h1))
stem(conv((-1).^n.*h1,h0)-conv((-1).^n.*h0,h1))
```

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

All inputs must be constant. Expressions or variables are allowed if their values do not change.

## firtype

Type of linear phase FIR filter

### Syntax

```
t = firtype(b)
t = firtype(d)
```

### Description

`t = firtype(b)` determines the type, `t`, of an FIR filter with coefficients `b`. `t` can be 1, 2, 3, or 4. The filter must be real and have linear phase.

`t = firtype(d)` determines the type, `t`, of an FIR filter, `d`. `t` can be 1, 2, 3, or 4. The filter must be real and have linear phase.

### Examples

#### Types of Linear Phase Filters

Design two FIR filters using the window method, one of even order and the other of odd order. Determine their types and plot their impulse responses.

```
subplot(2,1,1)
b = fir1(8,0.5);
impz(b), title(['Type ' int2str(firtype(b))])
```

```
subplot(2,1,2)
b = fir1(9,0.5);
impz(b), title(['Type ' int2str(firtype(b))])
```

Design two equiripple Hilbert transformers, one of even order and the other of odd order. Determine their types and plot their impulse responses.

```
subplot(2,1,1)
b = firpm(8,[0.2 0.8],[1 1],'hilbert');
impz(b), title(['Type ' int2str(firtype(b))])
```

```
subplot(2,1,2)
b = firpm(9,[0.2 0.8],[1 1],'hilbert');
impz(b), title(['Type ' int2str(firtype(b))])
```

### Types of FIR digitalFilter Objects

Use `designfilt` to design the filters from the previous example. Display their types.

```
d1 = designfilt('lowpassfir','DesignMethod','window', ...
               'FilterOrder',8,'CutoffFrequency',0.5);
disp(['d1 is of type ' int2str(firtype(d1))])

d1 is of type 1
```

```

d2 = designfilt('lowpassfir','DesignMethod','window', ...
               'FilterOrder',9,'CutoffFrequency',0.5);
disp(['d2 is of type ' int2str(firtype(d2))])

d2 is of type 2

d3 = designfilt('hilbertfir','DesignMethod','equiripple', ...
               'FilterOrder',8,'TransitionWidth',0.4);
disp(['d3 is of type ' int2str(firtype(d3))])

d3 is of type 3

d4 = designfilt('hilbertfir','DesignMethod','equiripple', ...
               'FilterOrder',9,'TransitionWidth',0.4);
disp(['d4 is of type ' int2str(firtype(d4))])

d4 is of type 4

```

## Input Arguments

### **b** — Filter coefficients

vector

Filter coefficients of the FIR filter, specified as a double- or single-precision real-valued row or column vector.

Data Types: double | single

### **d** — FIR filter

digitalFilter object | filter System object

FIR filter, specified as any of the following:

- A `digitalFilter` object. Use `designfilt` to generate a digital filter based on frequency-response specifications.
- A Filter System object. You can use this input if you have a license for DSP System Toolbox software. `firtype` supports the following Filter System objects:

<code>dsp.LowpassFilter</code>
<code>dsp.HighpassFilter</code>

<code>dsp.FIRFilter</code>
<code>dsp.FIRRateConverter</code>
<code>dsp.FIRDecimator</code>
<code>dsp.FIRInterpolator</code>
<code>dsp.FIRHalfbandDecimator</code>
<code>dsp.FIRHalfbandInterpolator</code>
<code>dsp.CICDecimator</code>
<code>dsp.CICInterpolator</code>
<code>dsp.CICCompensationDecimator</code>
<code>dsp.CICCompensationInterpolator</code>
<code>dsp.VariableBandwidthFIRFilter</code>

## Output Arguments

### **t** — Filter type

1 | 2 | 3 | 4

Filter type, returned as either 1, 2, 3, or 4. Filter types are defined as follows:

- Type 1 — Even-order symmetric coefficients
- Type 2 — Odd-order symmetric coefficients
- Type 3 — Even-order antisymmetric coefficients
- Type 4 — Odd-order antisymmetric coefficients

# freqrespest

Frequency response estimate via filtering

## Syntax

```
[h,w] = freqrespest(sysobj,L)
[h,w] = freqrespest(sysobj,L,param1,value1,param2,value2,...)
[h,w] = freqrespest(sysobj,L,opts)
freqrespest(sysobj,...)
```

## Description

`[h,w] = freqrespest(sysobj,L)` estimates the frequency response of a filter System object, `sysobj`. A set of input data is filtered and then forming the ratio between output data and input data. The test input data comprises sinusoids with uniformly distributed random frequencies.

Use this technique for comparing the performance of fixed-point filters to that of another filter type. You can, for example, compare fixed—point frequency response estimate to that of a similar filter that uses quantized coefficients, but applies floating-point arithmetic internally. Such comparison determines whether the fixed-point filter performance closely matches the floating-point, quantized coefficients version of the filter.

`L` is the number of trials to use to compute the estimate. If you do not specify this value, `L` defaults to 10. More trials generates a more accurate estimate of the response, but require more time to compute the estimate.

`h` is the estimate of the complex frequency response. `w` contains the vector of frequencies at which `h` is estimated.

`[h,w] = freqrespest(sysobj,L,param1,value1,param2,value2,...)` uses parameter value (PV) pairs as input arguments to specify optional parameters for the test. These parameters are the valid PV pairs. Enter the parameter names as input arguments in single quotation marks. The following table provides valid parameters for `[h, w]`.

Parameter Name	Default Value	Description
NFFT	512	Number of FFT points to use.
NormalizedFrequency	true	Indicate whether to use normalized frequency or linear frequency. Values are true (use normalized frequency), or false (use linear frequency). When you specify false, you must supply the sampling frequency Fs.
Fs	normalized	Specify the sampling frequency when NormalizedFrequency is false. No default value. You must set NormalizedFrequency to false before setting a value for Fs.
SpectrumRange	half	Specify the spectrum range to be used as whole or half (default).
CenterDC	false	Specify whether to set the center of the spectrum to the DC value in the output plot. If you select true, both the negative and positive values appear in the plot. If you select false, DC appears at the origin of the axes.
Arithmetic	ARITH	Analyze the filter System object, based on the arithmetic specified in the ARITH input. ARITH can be set to double, single, or fixed. The analysis tool assumes a double-precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state.

`freqrespest` requires knowledge of the input data type. Analysis cannot be performed if the input data type is not available. If you do not specify the `Arithmetic` parameter, i.e., use the syntax `[h,w] = freqrespest(sysobj)`, then the following rules apply for this method:

- The System object state is `UnLocked` — `freqrespest` performs double precision analysis.

- The System object state is Locked — freqrespest performs analysis based on the locked input data type.

When you do specify the Arithmetic parameter, i.e., use the syntax `[h,w] = freqrespest(sysobj, 'Arithmetic', ARITH)`, review the following rules for this method. Which rule applies depends on the value you set for the Arithmetic parameter.

Value	System Object State	Rule
ARITH = 'double'	Unlocked	freqrespest performs double-precision analysis.
	Locked	freqrespest performs double-precision analysis.
ARITH = 'single'	Unlocked	freqrespest performs single-precision analysis.
	Locked	freqrespest performs single-precision analysis.
ARITH = 'fixed'	Unlocked	freqrespest produces an error because the fixed-point input data type is unknown.
	Locked	If the input data type is double or single, then freqrespest produces an error because the fixed-point input data type is unknown.
		When the input data is of fixed-point type, freqrespest performs analysis based on the locked input data type.

The following Filter System objects are supported by this analysis function:

Filter System objects
<code>dsp.AllpoleFilter</code>

Filter System objects
<code>dsp.AllpassFilter</code>
<code>dsp.BiquadFilter</code>
<code>dsp.CoupledAllpassFilter</code>
<code>dsp.FIRFilter</code>
<code>dsp.HighpassFilter</code>
<code>dsp.IIRFilter</code>
<code>dsp.LowpassFilter</code>
<code>dsp.NotchPeakFilter</code>
<code>dsp.VariableBandwidthFIRFilter</code>
<code>dsp.VariableBandwidthIIRFilter</code>

`[h,w] = freqrespest(sysobj,L,opts)` uses an object, `opts`, to specify the optional input parameters. This specification is not done directly by specifying PV pairs as input arguments. Create `opts` with

```
opts = freqrespopts(sysobj);
```

Because `opts` is an object, you use `set` to change the parameter values in `opts` before you use it with `freqrespest`. For example, you could specify a new sample rate with

```
set(opts,'fs',48e3); % Same as opts.fs=48e3
```

`freqrespest(sysobj,...)` with no output argument launches FVTool.

`freqrespest` can also compute the frequency response of double-precision floating filters. Such filters cannot be converted to transfer-function form without introducing significant round off errors which affect the `freqz` frequency response computation. Examples of these kinds of filters include state-space or lattice filters, especially if they are high-order filters.

## Examples

### Estimate the Frequency Response of Fixed-Point FIR Filter

This example shows to how to estimate the frequency response of a fixed-point FIR filter.

```

firFilt = design(fdesign.lowpass(.4,.5,1,60), 'equiripple', 'Systemobject', true);
dataIn = fi(randn(16,15),1,16,15);
dataOut = firFilt(dataIn); %#ok
[h,w] = freqrespest(firFilt); %#ok % This should be about the same as freqz.
release(firFilt);

```

Continuing with filter `firFilt`, change `FullPrecisionOverride` to `false` and then specify the word lengths and precision (the fraction lengths) applied to the output from internal addition and multiplication operations. After you set the word and fraction lengths, use `freqrespest` to compute the frequency response estimate for the fixed-point filter.

```

firFilt.FullPrecisionOverride = false;
firFilt.ProductDataType = 'Custom';
firFilt.CustomProductDataType = numerictype(1,16,15);
firFilt.AccumulatorDataType = 'Custom';
firFilt.CustomAccumulatorDataType = numerictype(1,16,15);
firFilt.OutputDataType = 'Same as accumulator';
dataOut = firFilt(dataIn);
[h,w] = freqrespest(firFilt,2);
[h2,w2] = freqz(firFilt,512);
plot(w/pi,20*log10(abs([h,h2])))
legend('Frequency response estimated by filtering',...
'Freq. response computed by quantizing coefficients only');
xlabel('Normalized Frequency (\times\pi rad/sample)')
ylabel('Magnitude (dB)')

```

freqrespopts | freqz | limitcycle | noisepsd | scale

Introduced in R2011a

# freqrespopts

Options for filter frequency response analysis

## Syntax

```
opts = freqrespopts(H)
```

## Description

`opts = freqrespopts(H)` uses the settings in the filter System object, `H`, to create an object, `opts`. This object contains parameters and values for estimating the filter frequency response. You pass `opts` as an input argument to `freqrespest` to specify values for the input parameters.

`freqrespopts` allows you to use the same settings for `freqrespest` with multiple filters without specifying all of the parameters as input arguments to `freqrespest`.

The following Filter System objects are supported by this analysis function:

Filter System objects
<code>dsp.AllpoleFilter</code>
<code>dsp.AllpassFilter</code>
<code>dsp.BiquadFilter</code>
<code>dsp.CoupledAllpassFilter</code>
<code>dsp.FIRFilter</code>
<code>dsp.HighpassFilter</code>
<code>dsp.IIRFilter</code>
<code>dsp.LowpassFilter</code>
<code>dsp.NotchPeakFilter</code>
<code>dsp.VariableBandwidthFIRFilter</code>
<code>dsp.VariableBandwidthIIRFilter</code>

In addition, `dsp.FarrowRateConverter` and `dsp.FilterCascade` support this analysis method.

## Examples

### Set the Frequency Response Options

This example shows `freqrespest` in use for setting options for `freqrespest`. `hd` and `hd2` are bandpass filters that use different design methods. The `opts` object makes it easier to set the same conditions for the frequency response estimate in `freqrespest`.

```
d = fdesign.bandpass('fst1,fp1,fp2,fst2,ast1,ap,ast2',...  
0.25,0.3,0.45,0.5,60,0.1,60);  
hd = design(d,'butter','SystemObject',true)
```

```
hd =  
  dsp.BiquadFilter with properties:  
  
          Structure: 'Direct form II'  
    SOSMatrixSource: 'Property'  
          SOSMatrix: [18x6 double]  
        ScaleValues: [19x1 double]  
    InitialConditions: 0  
  OptimizeUnityScaleValues: true
```

Show all properties

```
hd2 = design(d,'cheby2','SystemObject',true)
```

```
hd2 =  
  dsp.BiquadFilter with properties:  
  
          Structure: 'Direct form II'  
    SOSMatrixSource: 'Property'  
          SOSMatrix: [9x6 double]  
        ScaleValues: [10x1 double]  
    InitialConditions: 0  
  OptimizeUnityScaleValues: true
```

Show all properties

```
opts = freqrespopts(hd)
opts =
    struct with fields:
        FreqPoints: 'All'
        NFFT: 512
        NormalizedFrequency: true
        Fs: 'Normalized'
        SpectrumRange: 'Half'
        CenterDC: false

opts.NFFT=256; % Same as set(opts,'nfft',256).
opts.NormalizedFrequency=false;
opts.fs=1.5e3;
opts.CenterDC=true

opts =
    struct with fields:
        FreqPoints: 'All'
        NFFT: 256
        NormalizedFrequency: false
        Fs: 1500
        SpectrumRange: 'Whole'
        CenterDC: true
```

With `opts` configured as needed, use it as an input argument for `freqrespest`.

```
[h2,w2]=freqrespest(hd2,20,opts);
[h1,w1]=freqrespest(hd,20,opts);
```

**Introduced in R2011a**

## freqsamp

Real or complex frequency-sampled FIR filter from specification object

### Syntax

```
hd = design(d,'freqsamp','SystemObject',true)
hd = design(...,'filterstructure',structure,'SystemObject',true)
hd = design(...,'window',window,'SystemObject',true)
```

### Description

`hd = design(d,'freqsamp','SystemObject',true)` designs a frequency-sampled filter specified by the filter specifications object `d`.

`hd = design(...,'filterstructure',structure,'SystemObject',true)` returns a filter with the filter structure you specify by the `structure` input argument. `structure` is `dffir` by default and can be any one of the following filter structures.

Structure	Description of Resulting Filter Structure
<code>dffir</code>	Direct-form FIR filter
<code>dffirt</code>	Transposed direct-form FIR filter
<code>dfsymfir</code>	Symmetrical direct-form FIR filter
<code>dfasymfir</code>	Asymmetrical direct-form FIR filter

`hd = design(...,'window',window,'SystemObject',true)` designs filters using the window specified by `window`. Provide the input argument `window` as

- A character vector for the window type. For example, use `'bartlett'`, or `'hamming'`. See `window` for the full list of windows available or refer to `window` in the *Signal Processing Toolbox User's Guide*.
- A function handle that references the window function. When the window function requires more than one input, use a cell array to hold the required arguments. The first example shows a cell array input argument.

- The window vector itself.

## Examples

### Design a Frequency Sampled FIR Filter

These examples design FIR filters that have arbitrary magnitude responses. In the first filter, the response has three distinct sections and the resulting filter is real.

The second example creates a complex filter.

```
b1 = 0:0.01:0.18;
b2 = [.2 .38 .4 .55 .562 .585 .6 .78];
b3 = 0.79:0.01:1;
a1 = .5+sin(2*pi*7.5*b1)/4; % Sinusoidal response section.
a2 = [.5 2.3 1 1 -.2 -.2 1 1]; % Piecewise linear response section.
a3 = .2+18*(1-b3).^2; % Quadratic response section.
f = [b1 b2 b3];
a = [a1 a2 a3];
n = 300;
d = fdesign.arbmag('n,f,a',n,f,a); % First specifications object.
hd = design(d,'freqsamp','window',{@kaiser,.5},...
    'SystemObject',true); % Filter.
fvtool(hd)
```

Now design the arbitrary-magnitude complex FIR filter. Recall that vector `f` contains frequency locations and vector `a` contains the desired filter response values at the locations specified in `f`.

```
f = [-1 -.93443 -.86885 -.80328 -.7377 -.67213 -.60656 -.54098 ...
-.47541,-.40984 -.34426 -.27869 -.21311 -.14754 -.081967 ...
-.016393 .04918 .11475,.18033 .2459 .31148 .37705 .44262 ...
.5082 .57377 .63934 .70492 .77049,.83607 .90164 1];
a = [.0095848 .021972 .047249 .099869 .23119 .57569 .94032 ...
.98084 .99707,.99565 .9958 .99899 .99402 .99978 .99995 .99733 ...
.99731 .96979 .94936,.8196 .28502 .065469 .0044517 .018164 ...
.023305 .02397 .023141 .021341,.019364 .017379 .016061];
n = 48;
d = fdesign.arbmag('n,f,a',n,f,a); % Second spec. object.
```

```
hdc = design(d, 'freqsamp', 'window', 'rectwin', 'SystemObject', true); % Filter.  
fvtool(hdc)
```

fvtool shows you the response for hdc from -1 to 1 in normalized frequency. design(d,...) returns a complex filter for hdc because the frequency vector includes negative frequency values.

**Introduced in R2011a**

## freqz

Frequency response of filter

### Syntax

```
[h,w] = freqz(sysobj)
[h,w] = freqz(sysobj,n)
[h,w] = freqz(sysobj,Name,Value)
freqz(sysobj)
```

### Description

`[h,w] = freqz(sysobj)` returns the complex frequency response `h` of the filter System object, `sysobj`. The vector `w` contains the frequencies (in radians) at which the function evaluates the frequency response. The frequency response is evaluated at 8192 points equally spaced around the upper half of the unit circle.

`[h,w] = freqz(sysobj,n)` returns the complex frequency response of the filter System object and the corresponding frequencies at `n` points equally spaced around the upper half of the unit circle.

`freqz` uses the transfer function associated with the filter to calculate the frequency response of the filter with the current coefficient values.

`[h,w] = freqz(sysobj,Name,Value)` returns a frequency response with additional options specified by one or more `Name,Value` pair arguments.

`freqz(sysobj)` uses `fvtool` to plot the magnitude and unwrapped phase of the frequency response of the filter System object `sysobj`.

For more information about optional input arguments for `freqz`, refer to `freqz` in Signal Processing Toolbox documentation.

## Input Arguments

### sysobj

Filter System object.

The following Filter System objects are supported by this analysis function:

<b>Filter System objects</b>
dsp.AllpassFilter
dsp.AllpoleFilter
dsp.BiquadFilter
dsp.Channelizer
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.CICDecimator
dsp.CICInterpolator
dsp.CoupledAllpassFilter
dsp.FarrowRateConverter
dsp.FilterCascade
dsp.FIRDecimator
dsp.FIRFilter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.FIRInterpolator
dsp.FIRRateConverter
dsp.HighpassFilter
dsp.IIRFilter
dsp.IIRHalfbandDecimator
dsp.IIRHalfbandInterpolator
dsp.LowpassFilter

Filter System objects
dsp.NotchPeakFilter
dsp.VariableBandwidthFIRFilter
dsp.VariableBandwidthIIRFilter

dsp.SampleRateConverter is also supported by freqz.

### **n**

Number of samples. For an FIR filter where *n* is a power of two, the computation is done faster using FFTs.

**Default:** 8192

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of *Name*, *Value* arguments. *Name* is the argument name and *Value* is the corresponding value. *Name* must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as *Name1*, *Value1*, ..., *NameN*, *ValueN*.

### **Arithmetic — Value types:**

'double' | 'single' | 'fixed'

Specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the *CoefficientDataType* property and whether the System object is locked or unlocked.

**Details for Fixed-Point Arithmetic**

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsData type property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsData type property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Output Arguments

**h**

Complex  $n$ -element frequency response vector. If  $n$  is not specified, the function uses a default value of 8192.

**w**

Frequency vector of length  $n$ , in radians/sample.  $w$  consists of  $n$  points equally spaced around the upper half of the unit circle (from 0 to  $\pi$  radians/sample). If  $n$  is not specified, the function uses a default value of 8192.

## Examples

### Frequency Response of the Filter

This examples plot the frequency response of the lowpass FIR filter using `freqz`.

```
b = fir1(80,0.5,kaiser(81,8));  
firFilt = dsp.FIRFilter('Numerator',b);  
freqz(firFilt);
```

## Tips

There are several ways of analyzing the frequency response of filters. `freqz` accounts for quantization effects in the filter coefficients, but does not account for quantization effects in filtering arithmetic. To account for the quantization effects in filtering arithmetic, refer to function `noisepd`.

## Algorithms

`freqz` calculates the frequency response for a filter from the filter transfer function  $Hq(z)$ . The complex-valued frequency response is calculated by evaluating  $Hq(e^{j\omega})$  at discrete values of  $\omega$  specified by the syntax you use. The integer input argument `n` determines the number of equally-spaced points around the upper half of the unit circle at which `freqz` evaluates the frequency response. The frequency ranges from 0 to  $\pi$  radians per sample when you do not supply a sampling frequency as an input argument. When you supply the scalar sampling frequency `fs` as an input argument to `freqz`, the frequency ranges from 0 to `fs/2` Hz.

## freqz

**Package:** dsp

Frequency response of filters in channelizer

## Syntax

```
[H,w] = freqz(obj)
[H,w] = freqz(obj,ind)
[H,f] = freqz(obj,ind,Name,Value)
```

## Description

`[H,w] = freqz(obj)` computes a matrix of complex frequency responses for each filter in the `dsp.Channelizer` System object. Each column of `H` corresponds to the frequency response for one of the filters in the channelizer. `w` is a vector of normalized frequencies at which the rows of `H` are computed.

`[H,w] = freqz(obj,ind)` computes the frequency response of the filters with indices corresponding to the elements in the vector `ind`. `ind` is a row vector of indices between 1 and `obj.NumFrequencyBands`. By default, this vector is `[1:N]`, where `N` is the number of frequency bands.

For example, to compute the frequency response of the first 4 filters, set `ind` to `[1:4]`.

```
channelizer = dsp.Channelizer;
[H,w] = freqz(channelizer,[1:4]);
```

`[H,f] = freqz(obj,ind,Name,Value)` computes the frequency response of the filters with additional options specified by one or more `Name,Value` pair arguments.

For example, to specify a sampling rate of 44100 Hz, set `'Fs'` to 44100. To compute the frequency response using 1024 frequency points, set `'NFFT'` to 1024. In addition, to compute the sum of the frequency response of the filters, set `'overall'` to `true`.

```
channelizer = dsp.Channelizer;
[H,f] = freqz(channelizer,[1:4],'Fs',44100,'NFFT',1024,'overall',true);
```

## Examples

### Frequency Response of Channelizer Filter Bank

Compute the frequency response of the filters in the channelizer using the `freqz` function.

Design a channelizer with the number of frequency bands or polyphase branches set to 8, the number of taps or coefficients per band set to 12, and stopband attenuation set to 80 dB. Compute the frequency response matrix,  $H$ , and the corresponding vector of frequency points,  $w$ .

```
channelizer = dsp.Channelizer;
[H,w] = freqz(channelizer); %#ok
whos H
```

Name	Size	Bytes	Class	Attributes
H	8192x8	1048576	double	complex

The number of rows in  $H$  corresponds to the number of frequency points, and the number of columns in  $H$  corresponds to the number of frequency bands. To view only a portion of the filter bank, specify the indices.

```
[H,w] = freqz(channelizer,(1:4)); %#ok
```

Specifying the filter indices as `[1:4]` computes the individual frequency response of the first 4 filters. You can alternatively view the sum of the filter responses by setting the `'overall'` to `true`.

```
[H,w] = freqz(channelizer,1:4,'overall',true);
plot(w/pi,20*log10(abs(H)))
xlabel('Normalized Frequency (\times \pi rad/sample)')
ylabel('Magnitude (dB)')
```

You can also compute the frequencies in Hz by passing a sampling frequency. Frequency in Hz,  $f$ , equals  $(w/2 * pi) * Fs$ , where  $w$  is frequency in radians, and  $Fs$  is the sampling rate.

```
[H,f] = freqz(channelizer,'Fs',44100); %#ok
```

Specify the number of frequency points using the 'NFFT' argument.

```
[H,f] = freqz(channelizer,'Fs',44100,'NFFT',1024);
```

## Input Arguments

### **obj** — Input filter System object

`dsp.Channelizer`

Input filter, specified as a `dsp.Channelizer` System object.

Example: `[H,w] = freqz(channelizer);`

### **ind** — Filter indices

row vector

Filter indices, specified as a row vector in the range `[1 obj.NumFrequencyBands]`. By default, `ind` is set to `1:N`, where  $N$  is the number of frequency bands specified through the `obj.NumFrequencyBands` property.

Example: `freqz(channelizer,[1:4]);`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `[H,f] = freqz(channelizer,[1:4],'Fs',44100,'NFFT',1024,'overall',true);`

### **Fs** — Sampling rate

scalar

Sampling rate, specified as a scalar. This value determines the frequencies in Hz at which `freqz` computes the frequency response.

Example: `44100`

Example: `22050`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **NFFT — Number of frequency points used to compute frequency response**

8192 (default) | positive scalar

Number of frequency points used to compute the frequency response, specified as a positive scalar.

Example: 8192

Example: 1024

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **overall — Type of filter response**

false (default) | true

The type of filter response, specified as either:

- `true` -- `freqz` computes the sum of the filter responses.
- `false` -- `freqz` computes the individual filter responses.

Data Types: `logical`

## Output Arguments

### **H — Frequency response of filter**

matrix (default) | vector

Complex frequency response of the filters in the channelizer. The dimensions of the output depend on the value of the 'overall' argument:

- When the 'overall' argument is `true`, the frequency response vector contains the sum of the frequency responses of all the filters. The vector is of size `[nfft 1]`, where `nfft` is the number of frequency points. For example, if `nfft` is 8192, `H` is a matrix of size `[8192 1]`.
- When the 'overall' argument is `false`, the frequency response is a matrix of size `[nfft nFilters]`, where `nfft` is the number of frequency points and `nFilters` is the number of filters whose frequency response is computed. Suppose `nfft` is 8192 and `ind` is `[2:5]`, `H` is a matrix of size `[8192 4]`.

Data Types: `double`

**w — Normalized frequencies**

vector

Normalized frequencies, specified in rad/sample, at which the frequency response is computed. The vector is of size `[nfft 1]`.

Data Types: double

**f — Frequencies**

vector

Frequencies, specified in Hz, at which the frequency response is computed. The vector is of size `[nfft 1]`.

Data Types: double

## freqz

**Package:** dsp

Frequency response of the filter

### Syntax

```
[h,f] = freqz(sysobj,n,range)
[h,f] = freqz(sysobj,f)
```

### Description

`[h,f] = freqz(sysobj,n,range)` returns the complex frequency response, `h`, of the filter System object and the frequency vector `f` at which `h` is computed. `n` is the number of frequency points and `range` is the frequency range over which the response is computed.

`[h,f] = freqz(sysobj,f)` returns the complex frequency response `h` computed at the frequency points specified by vector `f`. The vector `f` is assumed to be in Hz.

### Examples

#### Frequency Response of Default Converter

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz. Compute and display the frequency response.

```
src = dsp.SampleRateConverter;
[H,f] = freqz(src);
plot(f,20*log10(abs(H)))
```

Compute and display the frequency response over the range between 20 Hz and 44.1 kHz.

```
f = 20:10:44.1e3;  
[H,f] = freqz(src,f);  
plot(f,20*log10(abs(H)))
```

### Compute Frequency Response of Complex Bandpass Decimator

Compute the complex frequency response of a complex bandpass decimator using the `freqz` function.

Create a `dsp.ComplexBandpassDecimator` object. Set the `DecimationFactor` to 12, the `CenterFrequency` to 5000 Hz, and the `SampleRate` to 44100 Hz. Compute and display the frequency response.

```
cbp = dsp.ComplexBandpassDecimator(12,5000,44100);  
[h,f] = freqz(cbp);
```

```

plot(f,20*log10(abs(h)))
grid on
xlabel('Frequency (Hz)')
ylabel('h (dB)')

```

## Input Arguments

**sysobj** — Filter System object

`dsp.ComplexBandpassDecimator` | `dsp.SampleRateConverter`

Filter System object, specified as a `dsp.ComplexBandpassDecimator` or a `dsp.SampleRateConverter` System object.

### **n — Number of evaluation points**

8192 (default) | positive integer

Number of frequency points for response evaluation, specified as a positive integer scalar. If *n* is not specified, the default is 8192.

Data Types: single | double

### **range — Range of frequencies**

'half' (default) | 'whole'

Range considered when computing the frequency response, specified as either 'half' (from 0 to  $\pi$ ) or 'whole' (from 0 to  $2\pi$ ). If *range* is not specified, the default is 'half'.

### **f — Frequencies in Hz at which response is computed**

vector

Frequencies in Hz at which the response is computed, specified as a vector.

Data Types: double

## Output Arguments

### **h — Complex frequency response**

vector

Complex frequency response, returned as a vector.

Data Types: double

### **f — Frequencies at which response is computed**

vector

Frequencies at which the response is computed, returned as a vector.

Data Types: double

## fvtool

Visualize frequency response of DSP filters

### Syntax

```
fvtool(sysobj)
fvtool(sysobj,options)
fvtool(____,'Arithmetic',arith)
```

### Description

`fvtool(sysobj)` displays the magnitude response of the filter System object.

`fvtool(sysobj,options)` displays the response that is specified by the options.

For example, to visualize the impulse response of an FIR filter System object, set options to 'impulse'.

```
Fs = 96e3; filtSpecs = fdesign.lowpass(20e3,22.05e3,1,80,Fs);
    firlp2 = design(filtSpecs,'equiripple','SystemObject',true);
fvtool(firlp2,'impulse');
```

`fvtool(____,'Arithmetic',arith)` analyzes the filter System object, based on the arithmetic specified in `arith`, using either of the previous syntaxes. You can set `arith` to 'double', 'single', or 'fixed'. The analysis tool assumes a double-precision filter when the arithmetic input is not specified and the filter System object is unlocked. The 'Arithmetic' property applies only to filter System objects.

For example, to analyze an FIR filter with fixed-point arithmetic, set `arith` to 'fixed'.

```
Fs = 96e3; filtSpecs = fdesign.lowpass(20e3,22.05e3,1,80,Fs);
    firlp2 = design(filtSpecs,'equiripple','SystemObject',true);
firlp2.CoefficientsDataType = 'Custom';
firlp2.CustomCoefficientsDataType = numericType(1,32,30);
fvtool(firlp2,'Arithmetic','fixed');
```

For more information on `fvtool`, see `fvtool`.

## Examples

### Impulse and Frequency Response of Halfband Decimation Filter

Create a lowpass halfband decimation filter for data sampled at 44.1 kHz. The output data rate is 1/2 the input sampling rate, or 22.05 kHz. Specify the filter order to be 52 with a transition width of 4.1 kHz.

```
Fs = 44.1e3;
filterspec = 'Filter order and transition width';
Order = 52;
TW = 4.1e3;
firhalfbanddecim = dsp.FIRHalfbandDecimator('Specification',filterspec, ...
                                             'FilterOrder',Order, ...
                                             'TransitionWidth',TW, ...
                                             'SampleRate',Fs);
```

Plot the impulse response. The zeroth-order coefficient is delayed 26 samples, which is equal to the group delay of the filter. This yields a causal halfband filter.

```
fvtool(firhalfbanddecim,'Analysis','impulse')
```

Plot the magnitude and phase response.

```
fvtool(firhalfbanddecim,'Analysis','freq')
```

### Impulse and Frequency Response of FIR and IIR Lowpass Filters

Create a minimum-order FIR lowpass filter for data sampled at 44.1 kHz. Specify a passband frequency of 8 kHz, a stopband frequency of 12 kHz, a passband ripple of 0.1 dB, and a stopband attenuation of 80 dB.

```
Fs = 44.1e3;
filtertype = 'FIR';
Fpass = 8e3;
Fstop = 12e3;
Rp = 0.1;
```

```
Astop = 80;
FIRLPF = dsp.LowpassFilter('SampleRate',Fs, ...
    'FilterType',filtertype, ...
    'PassbandFrequency',Fpass, ...
    'StopbandFrequency',Fstop, ...
    'PassbandRipple',Rp, ...
    'StopbandAttenuation',Astop);
```

Design a minimum-order IIR lowpass filter with the same properties as the FIR lowpass filter. Change the `FilterType` property of the cloned filter to IIR.

```
IIRLPF = clone(FIRLPF);
IIRLPF.FilterType = 'IIR';
```

Plot the impulse response of the FIR lowpass filter. The zeroth-order coefficient is delayed by 19 samples, which is equal to the group delay of the filter. The FIR lowpass filter is a causal FIR filter.

```
fvtool(FIRLPF,'Analysis','impulse')
```

Plot the impulse response of the IIR lowpass filter.

```
fvtool(IIRLPF, 'Analysis', 'impulse')
```

Plot the magnitude and phase response of the FIR lowpass filter.

```
fvtool(FIRLPF,'Analysis','freq')
```

Plot the magnitude and phase response of the IIR lowpass filter.

```
fvtool(IIRLPF, 'Analysis', 'freq')
```

Calculate the cost of implementing the FIR lowpass filter.

```
cost(FIRLPF)
```

```
ans = struct with fields:
    NumCoefficients: 39
    NumStates: 38
    MultiplicationsPerInputSample: 39
    AdditionsPerInputSample: 38
```

Calculate the cost of implementing the IIR lowpass filter. The IIR filter is more efficient to implement than the FIR filter.

```
cost(IIRLPF)
```

```
ans = struct with fields:
    NumCoefficients: 18
    NumStates: 14
    MultiplicationsPerInputSample: 18
    AdditionsPerInputSample: 14
```

Calculate the group delay of the FIR lowpass filter.

```
grpdelay(FIRLPF)
```

Calculate the group delay of the IIR lowpass filter. The FIR filter has a constant group delay (linear phase), while its IIR counterpart does not.

```
grpdelay(IIRLPF)
```

## Input Arguments

### **sysobj** — Input filter

System object

Input filter, specified as a System object.

Example: `firFilt = dsp.FIRFilter('Numerator', fir1(130, 2000/(8000/2)));`

**options — Filter analysis options**

```
'magnitude' (default) | 'phase' | 'freq' | 'grpdelay' | 'phasedelay' |
'impulse' | 'step' | 'polezero' | 'coefficients' | 'info' | 'magestimate' |
'noisepower'
```

Filter analysis options, specified as one of the following:

- 'magnitude' -- Magnitude response
- 'phase' -- Phase response
- 'freq' -- Frequency response
- 'grpdelay' -- Group delay
- 'phasedelay' -- Phase delay
- 'impulse' -- Impulse response
- 'step' -- Step response
- 'polezero' -- Pole zero plot
- 'coefficients' -- Coefficients vector
- 'info' -- Filter information
- 'magestimate' -- Magnitude response estimate
- 'noisepower' -- Round-off noise power spectrum

Example: `fvtool(firFilt,'freq');`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `fvtool(sysobj,'Arithmetic','single');`

**Arithmetic — Analysis arithmetic**

```
'double' (default) | 'single' | 'fixed'
```

Analysis arithmetic used on the filter System object, specified as 'double', 'single', or 'fixed'.

The analysis tool assumes a double-precision filter when the 'Arithmetic' input is not specified and the filter System object is unlocked. This property applies to all filter System objects that you input to `fvtool`.

```
Example: firFilt = dsp.FIRFilter('Numerator', fir1(130, 2000/(8000/2)));  
fvtool(firFilt, 'Arithmetic', 'single');
```

# fvtool

**Package:** dsp

Visualize the filters in the channelizer

## Syntax

```
fvtool(obj)
fvtool(obj,ind)
fvtool(obj,ind,Name,Value)
```

## Description

`fvtool(obj)` visualizes the filters in the `dsp.Channelizer` System object using the Filter Visualization Tool (FVTool).

`fvtool(obj,ind)` visualizes the filters corresponding to the indices in the vector `ind`. `ind` is a row vector of indices between 1 and `obj.NumFrequencyBands`. By default, this vector is `[1:N]`, where  $N$  is the smallest of `obj.NumFrequencyBands` and 64.

For example, to visualize the first 4 filters, set `ind` to `[1:4]`.

```
channelizer = dsp.Channelizer;
fvtool(channelizer,[1:4]);
```

`fvtool(obj,ind,Name,Value)` visualizes the filters with additional options specified by one or more `Name,Value` pair arguments.

For example, to visualize the first 4 filters in the channelizer over the Nyquist interval  $[-44100/2, 44100/2]$  Hz, set `'Fs'` to 44100. To compute the frequency response using 1024 frequency points, set `'NFFT'` to 1024. In addition, to visualize sum of the filter responses, set `'overall'` to true.

```
channelizer = dsp.Channelizer;
fvtool(channelizer,[1:4], 'Fs',44100, 'NFFT',1024, 'overall',true);
```

## Examples

### Visualize Filters in Channelizer

Using the `fvtool` function, you can visualize the individual filter responses or sum of all the filter responses in the channelizer filter bank.

Design a channelizer with the number of frequency bands or polyphase branches set to 8, the number of taps or coefficients per band set to 12, and stopband attenuation set to 80 dB. View the response of the filter bank.

```
channelizer = dsp.Channelizer;  
fvtool(channelizer)
```

```
ans =
```

```
Figure (filtervisualizationtool) with properties:
```

```
    Number: 1  
    Name: 'Filter Visualization Tool - Magnitude Response (dB)'  
    Color: [0.9400 0.9400 0.9400]  
    Position: [361 292 560 420]  
    Units: 'pixels'
```

```
Use get to show all properties
```

The `fvtool` shows the response of the lowpass prototype filter and all the modulated filters. To view only a portion of the filter bank, specify the indices in `ind`. To view the response of the first 4 filters, set `ind` to `[1:4]`.

```
fvtool(channelizer,(1:4));
```

You can change the Nyquist interval to `[-22,050 22,050]` Hz and the number of frequency points to 1024.

```
fvtool(channelizer,(1:4),'Fs',44100,'NFFT',1024);
```

To see the sum of the responses of all 4 filters, set the 'overall' argument to true.

```
fvtool(channelizer,(1:4),'Fs',44100,'NFFT',1024,'overall',true);
```

## Input Arguments

**obj** — Input filter System object

`dsp.Channelizer`

Input filter, specified as a `dsp.Channelizer` System object.

Example: `channelizer = dsp.Channelizer; fvtool(channelizer);`

**ind** — Filter indices

row vector

Filter indices, specified as a row vector in the range [1 `obj.NumFrequencyBands`]. By default, `ind` is set to  $1:N$ , where  $N$  is the smallest of `obj.NumFrequencyBands` and 64.

Example: `fvtool(channelizer,[1:4]);`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `fvtool(channelizer,'Fs',44100,'NFFT',1024,'overall',true);`

### **Fs** — Sampling rate

scalar

Sampling rate, specified as a scalar. This value determines the Nyquist interval  $[-Fs/2, Fs/2]$  in which the `fvtool` shows the frequency response of the filters in the channelizer.

Example: 44100

Example: 22050

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **NFFT** — Number of frequency points used to compute the frequency response

8192 (default) | positive scalar

Number of frequency points used to compute the frequency response, specified as a positive scalar.

Example: 8192

Example: 1024

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **overall** — Type of filter response

false (default) | true

Type of filter response, specified as either:

- `true` -- `fvtool` shows the sum of the filter responses.
- `false` -- `fvtool` shows the individual filter responses.

Data Types: `logical`

### System Objects

`dsp.Channelizer`

**Introduced in R2017b**

# gain

**Package:** dsp

CIC filter gain

## Syntax

```
gain(sysobj)  
gain(sysobj,j)
```

## Description

`gain(sysobj)` returns the gain of the filter System object `sysobj`. The function supports the `dsp.CICDecimator` and `dsp.CICInterpolator` filter structures.

When `sysobj` is a decimator, `gain` returns the gain for the overall CIC decimator.

When `sysobj` is an interpolator, the CIC interpolator inserts zeros into the input data stream, reducing the filter overall gain by  $1/R$ , where  $R$  is the interpolation factor, to account for the added zero valued samples. Therefore, the gain of a CIC interpolator is  $(RM)^N/R$ , where  $N$  is the number of filter sections and  $M$  is the filter differential delay. `gain(sysobj)` returns this value. The next example presents this case.

`gain(sysobj,j)` returns the gain of the  $j$ th section of a CIC interpolation filter. When you omit  $j$ , `gain` assumes that  $j$  is  $2*N$ , where  $N$  is the number of sections, and returns the gain of the last section of the filter. This syntax does not apply when `sysobj` is a decimator.

## Examples

### Compare the Performance of Interpolation Filters

To compare the performance of two interpolators, one a CIC filter and the other an FIR filter, use gain to adjust the CIC filter output amplitude to match the FIR filter output amplitude. Start by creating an input data set, a sinusoidal signal  $x$ .

```
fs = 1000;           % Input sampling frequency.
t = 0:1/fs:1.5;     % Signal length = 1501 samples.
x = sin(2*pi*10*t); % Amplitude = 1 sinusoid.
x = x';

l = 4; % Interpolation factor for FIR filter.
d = fdesign.interpolator(l);
firInterp = design(d, 'multistage', 'SystemObject', true);
yfir = firInterp(x);

r = 4; % Interpolation factor for the CIC filter.
d = fdesign.interpolator(r, 'cic');
cicInterp = design(d, 'multisection', 'SystemObject', true);
ycic = cicInterp(x);
gaincic = gain(cicInterp);
subplot(211);
plot([yfir; double(ycic)]);
subplot(212)
plot([yfir; double(ycic)/gain(cicInterp)]);
```

After correcting for the gain induced by the CIC interpolator, the second subplot shows that the FIR filter and the CIC filter provide nearly identical interpolation.

This gain equals the gain of the last section of the CIC filter. To confirm, correct the FIR filter amplitude using `gain(cicInterp, 2 * N)`. If  $N$  is the number of integrator and comb sections of the CIC filter, then  $2 * N$  is the last section of the CIC filter.

$N$  is given by `cicInterp.NumSections`.

The second subplot shows that the FIR filter and CIC filter provide nearly identical interpolation, when the correction gain equals the gain of the last section of the CIC filter.

```
subplot(212);  
plot([yfir; double(ycic)/gain(cicInterp,2*cicInterp.NumSections)]);
```

### Functions

[freqz](#) | [fvtool](#) | [generatehdl](#) | [getFixedPointInfo](#) | [impz](#) | [phasez](#)

**Introduced in R2011a**

# generatehdl

**Package:** dsp

Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

## Syntax

```
generatehdl(filtS0, 'InputDataType', nt)  
generatehdl(filtS0, 'InputDataType', nt, 'FractionalDelayDataType', fd)  
generatehdl(filterObj)
```

```
generatehdl( ____, Name, Value)
```

## Description

`generatehdl(filtS0, 'InputDataType', nt)` generates HDL code for the specified filter System object and the input data type, `nt`.

The generated file is a single source file that includes the entity declaration and architecture code. You can find this file in your current working folder, inside the `hdlsrc` subfolder.

`generatehdl(filtS0, 'InputDataType', nt, 'FractionalDelayDataType', fd)` generates HDL code for a `dsp.VariableFractionalDelay` filter System object. Specify the input data type, `nt`, and the fractional delay data type, `fd`.

`generatehdl(filterObj)` generates HDL code for the specified `dfilt` filter object using default settings.

`generatehdl( ____, Name, Value)` uses optional name-value pair arguments, in addition to the input arguments in previous syntaxes. Use these properties to override default HDL code generation settings.

For more details, see the corresponding properties in the Filter Design HDL Coder™ documentation:

- To customize filter name, destination folder, and to specify target language, see Fundamental HDL Code Generation Properties.
- To configure coefficients, complex input ports, and optional ports for specific filter types, see HDL Filter Configuration Properties.
- To optimize the speed or area of generated HDL code, see HDL Optimization Properties.
- To customize ports, identifiers, and comments, see HDL Ports and Identifiers Properties.
- To customize HDL constructs, see HDL Constructs Properties.
- To generate and customize test bench, see HDL Test Bench Properties.
- To integrate third-party EDA tools into the filter design workflow, see Synthesis and Workflow Automation Properties.

## Examples

### Generate HDL Code for FIR Equiripple Filter

Design a direct form symmetric equiripple filter with these specifications:

- Normalized passband frequency of 0.2
- Normalized stopband frequency of 0.22
- Passband ripple of 1 dB
- Stopband attenuation of 60 dB

The design function returns a `dsp.FIRFilter System` object™ that implements the specification.

```
filtSpecs = fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.22,1,60);  
FIRe = design(filtSpecs,'equiripple','FilterStructure','dfsymfir','SystemObject',true)
```

```
FIRe =  
  dsp.FIRFilter with properties:  
  
      Structure: 'Direct form symmetric'  
  NumeratorSource: 'Property'  
      Numerator: [1x202 double]  
  InitialConditions: 0
```

Show all properties

To generate HDL code, call the `generatehdl` function. When the filter is a System object, you must specify a fixed-point data type for the input using the “InputDataType” (Filter Design HDL Coder) property. The coder generates the file `MyFilter.vhd` in the default target folder, `hdlsrc`.

```
generatehdl(FIRe, 'InputDataType', numerictype(1,16,15), 'Name', 'MyFilter');

### Starting VHDL code generation process for filter: MyFilter

### Starting generation of MyFilter VHDL entity
### Starting generation of MyFilter VHDL architecture
### Successful completion of VHDL code generation process for filter: MyFilter
### HDL latency is 2 samples
```

## Generate HDL Code and Test Bench for FIR Equiripple Filter

Design a direct form symmetric equiripple filter with these specifications:

- Normalized passband frequency of 0.2
- Normalized stopband frequency of 0.22
- Passband ripple of 1 dB
- Stopband attenuation of 60 dB

The design function returns a `dsp.FIRFilter` System object™ that implements the specification.

```
filtSpecs = fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.22,1,60);
FIRe = design(filtSpecs, 'equiripple', 'FilterStructure', 'dfsymfir', 'SystemObject', true)

FIRe =
    dsp.FIRFilter with properties:

        Structure: 'Direct form symmetric'
    NumeratorSource: 'Property'
        Numerator: [1x202 double]
    InitialConditions: 0
```

Show all properties

Generate VHDL code and a VHDL test bench for the FIR equiripple filter. When the filter is a System object, you must specify a fixed-point data type for the input data type. The coder generates the files `MyFilter.vhd` and `MyFilterTB.vhd` in the default target folder, `hdlsrc`.

```
generatehdl(FIR,'InputDataType',numerictype(1,16,15),'Name','MyFilter',...
            'GenerateHDLTestbench','on','TestBenchName','MyFilterTB')

### Starting VHDL code generation process for filter: MyFilter

### Generate HDL Code for Fully Parallel FIR Filter with Programmable Coefficients

Design a direct form symmetric equiripple filter with fully parallel (default) architecture and programmable coefficients. The design function returns a `dsp.FIRFilter` System object™ with default lowpass filter specification.

```
firfilt = design(fdesign.lowpass,'equiripple','FilterStructure','dfsymfir','SystemObjec
```

```
firfilt =
```

```
    dsp.FIRFilter with properties:
```

```
        Structure: 'Direct form symmetric'
    NumeratorSource: 'Property'
        Numerator: [1x43 double]
    InitialConditions: 0
```

Use `get` to show all properties

To generate HDL code, call the `generatehdl` function. When the filter is a System object, you must specify a fixed-point data type for the input data. To generate a processor interface for the coefficients, you must specify an additional name-value pair argument.

```
generatehdl(firfilt, 'InputDataType', numerictype(1,16,15), 'CoefficientSource', 'Processor')

### Starting VHDL code generation process for filter: firfilt
### Generating: <a href="matlab:edit('C:\TEMP\Bdoc18a_815039_17936\ib0BF173\10\tp01ee1...
### Starting generation of firfilt VHDL entity
### Starting generation of firfilt VHDL architecture
### Successful completion of VHDL code generation process for filter: firfilt
### HDL latency is 2 samples
```

The coder generates this VHDL entity for the filter object.

```
ENTITY firfilt IS
  PORT ( clk          : IN      std_logic;
         clk_enable   : IN      std_logic;
         reset        : IN      std_logic;
         filter_in    : IN      std_logic_vector(15 DOWNTO 0); -- sfix16_En15
         write_enable : IN      std_logic;
         write_done   : IN      std_logic;
         write_address : IN      std_logic_vector(4 DOWNTO 0); -- ufix5
         coeffs_in    : IN      std_logic_vector(15 DOWNTO 0); -- sfix16_En16
         filter_out   : OUT     std_logic_vector(36 DOWNTO 0) -- sfix37_En31
        );
END firfilt;
```

## Generate Partly Serial FIR Filter with Programmable Coefficients

Create a direct form antisymmetric filter.

```
coeffs = fir1(22,0.45);
firfilt = dsp.FIRFilter('Numerator',coeffs,'Structure','Direct form antisymmetric')

firfilt =
  dsp.FIRFilter with properties:
```

```

        Structure: 'Direct form antisymmetric'
    NumeratorSource: 'Property'
        Numerator: [1x23 double]
    InitialConditions: 0

```

Show all properties

To generate HDL code, call the `generatehdl` function. When the filter is a System object, you must specify a fixed-point data type for the input data. To generate a partly serial architecture, specify a serial partition. To enable `CoefficientMemory` property, you must set `CoefficientSource` to `ProcessorInterface`.

```

generatehdl(firfilt, 'InputDataType', numerictype(1,16,15), ...
    'SerialPartition', [7 4], 'CoefficientMemory', 'DualPortRAMs', ...
    'CoefficientSource', 'ProcessorInterface')

### Starting VHDL code generation process for filter: firfilt
### Generating: C:\TEMP\Bdoc18a_815039_17936\ib0BF173\27\tpb68d4edc\hdlfilter-ex214657
### Starting generation of firfilt VHDL entity
### Starting generation of firfilt VHDL architecture
### Clock rate is 7 times the input sample rate for this architecture.
### Successful completion of VHDL code generation process for filter: firfilt
### HDL latency is 3 samples

```

The generated code includes a dual-port RAM interface for the programmable coefficients.

```

ENTITY firfilt IS
    PORT ( clk           : IN      std_logic;
           clk_enable   : IN      std_logic;
           reset        : IN      std_logic;
           filter_in    : IN      std_logic_vector(15 DOWNTO 0); -- sfix16_En15
           write_enable  : IN      std_logic;
           write_done    : IN      std_logic;
           write_address : IN      std_logic_vector(3 DOWNTO 0); -- ufix4
           coeffs_in     : IN      std_logic_vector(15 DOWNTO 0); -- sfix16_En16
           filter_out    : OUT     std_logic_vector(35 DOWNTO 0) -- sfix36_En31
        );
END firfilt;

```

## Generate Serial Partitions for FIR Filter

Explore clock rate and latency for different serial implementations of the same filter. Using a symmetric structure also allows the filter logic to share multipliers for symmetric coefficients.

Create a direct form symmetric FIR filter with these specifications:

- Filter order 13
- Normalized cutt-off frequency of 0.4 for the 6-dB point

The `design` function returns a `dsp.FIRFilter` System object™ that implements the specification.

```
FIR = design(fdesign.lowpass('N,Fc',13,.4),'FilterStructure','dfsymfir','SystemObject')
```

```
FIR =
```

```
    dsp.FIRFilter with properties:
```

```
        Structure: 'Direct form symmetric'
    NumeratorSource: 'Property'
        Numerator: [1x14 double]
    InitialConditions: 0
```

```
Use get to show all properties
```

To generate HDL code, call the `generatehdl` function. When the filter is a System object, you must specify a fixed-point data type for the input data.

For a baseline comparison, first generate a default fully parallel architecture.

```
generatehdl(FIR,'Name','FullyParallel',...
    'InputDataType',numerictype(1,16,15))
```

```
### Starting VHDL code generation process for filter: FullyParallel
### Generating: <a href="matlab:edit('C:\TEMP\Bdoc18a_815039_17936\ib0BF173\10\tp01ee1
### Starting generation of FullyParallel VHDL entity
### Starting generation of FullyParallel VHDL architecture
### Successful completion of VHDL code generation process for filter: FullyParallel
### HDL latency is 2 samples
```

Generate a fully serial architecture by setting the partition size to the effective filter length. The system clock rate is six times the input sample rate. The reported HDL latency is one sample greater than the default parallel implementation.

```
generatehdl(FIR, 'SerialPartition', 6, 'Name', 'FullySerial', ...
    'InputDataType', numerictype(1,16,15))

### Starting VHDL code generation process for filter: FullySerial
### Generating: <a href="matlab:edit('C:\TEMP\Bdoc18a_815039_17936\ib0BF173\10\tp01ee1
### Starting generation of FullySerial VHDL entity
### Starting generation of FullySerial VHDL architecture
### Clock rate is 6 times the input sample rate for this architecture.
### Successful completion of VHDL code generation process for filter: FullySerial
### HDL latency is 3 samples
```

Generate a partly serial architecture with three equal partitions. This architecture uses three multipliers. The clock rate is two times the input rate, and the latency is the same as the default parallel implementation.

```
generatehdl(FIR, 'SerialPartition', [2 2 2], 'Name', 'PartlySerial', ...
    'InputDataType', numerictype(1,16,15))

### Starting VHDL code generation process for filter: PartlySerial
### Generating: <a href="matlab:edit('C:\TEMP\Bdoc18a_815039_17936\ib0BF173\10\tp01ee1
### Starting generation of PartlySerial VHDL entity
### Starting generation of PartlySerial VHDL architecture
### Clock rate is 2 times the input sample rate for this architecture.
### Successful completion of VHDL code generation process for filter: PartlySerial
### HDL latency is 3 samples
```

Generate a cascade-serial architecture by enabling accumulator reuse. Specify the three partitions in descending order of size. Notice that the clock rate is higher than the rate in the partly serial (without accumulator reuse) example.

```
generatehdl(FIR, 'SerialPartition', [3 2 1], 'ReuseAccum', 'on', 'Name', 'CascadeSerial', ...
    'InputDataType', numerictype(1,16,15))

### Starting VHDL code generation process for filter: CascadeSerial
### Generating: <a href="matlab:edit('C:\TEMP\Bdoc18a_815039_17936\ib0BF173\10\tp01ee1
### Starting generation of CascadeSerial VHDL entity
### Starting generation of CascadeSerial VHDL architecture
### Clock rate is 4 times the input sample rate for this architecture.
### Successful completion of VHDL code generation process for filter: CascadeSerial
### HDL latency is 3 samples
```

You can also generate a cascade-serial architecture without specifying the partitions explicitly. The coder automatically selects partition sizes.

```
generatehdl(FIR, 'ReuseAccum', 'on', 'Name', 'CascadeSerial', ...
    'InputDataType', numerictype(1,16,15))

### Starting VHDL code generation process for filter: CascadeSerial
### Generating: <a href="matlab:edit('C:\TEMP\Bdoc18a_815039_17936\ib0BF173\10\tp01ee1
### Starting generation of CascadeSerial VHDL entity
### Starting generation of CascadeSerial VHDL architecture
### Clock rate is 4 times the input sample rate for this architecture.
### Serial partition # 1 has 3 inputs.
### Serial partition # 2 has 3 inputs.
### Successful completion of VHDL code generation process for filter: CascadeSerial
### HDL latency is 3 samples
```

## Generate Serial Partitions of Cascaded Filter

Create a two-stage cascaded filter with these specifications for each filter stage:

- Direct form symmetric FIR filter
- Filter order 8
- Normalized cutt-off frequency of 0.4 for the 6-dB point

Each call of the `design` function returns a `dsp.FIRFilter` System object™ that implements the specification. The `cascade` function returns a two-stage cascaded filter.

```
lp = design(fdesign.lowpass('N,Fc',8,.4), 'FilterStructure', 'dfsymfir', 'SystemObject', t
hp = design(fdesign.highpass('N,Fc',8,.4), 'FilterStructure', 'dfsymfir', 'SystemObject', t
casc = cascade(lp, hp)
```

```
lp =
```

```
  dsp.FIRFilter with properties:
```

```
      Structure: 'Direct form symmetric'
      NumeratorSource: 'Property'
      Numerator: [1x9 double]
      InitialConditions: 0
```

```
Use get to show all properties
```

```
hp =  
  
dsp.FIRFilter with properties:  
  
    Structure: 'Direct form symmetric'  
    NumeratorSource: 'Property'  
    Numerator: [1x9 double]  
    InitialConditions: 0  
  
Use get to show all properties
```

```
casc =  
  
dsp.FilterCascade with properties:  
  
    Stage1: [1x1 dsp.FIRFilter]  
    Stage2: [1x1 dsp.FIRFilter]
```

To generate HDL code, call the `generatehdl` function for the cascaded filter. When the filter is a System object, you must specify a fixed-point data type for the input data.

Specify different partitions for each cascade stage as a cell array.

```
generatehdl(casc, 'InputDataType', numerictype(1,16,15), 'SerialPartition', {[3 2],[4 1]})  
  
### Starting VHDL code generation process for filter: casfilt  
### Cascade stage # 1  
### Starting VHDL code generation process for filter: casfilt_stage1  
### Generating: <a href="matlab:edit('C:\TEMP\Bdoc18a_815039_17936\ib0BF173\10\tp01ee1...  
### Starting generation of casfilt_stage1 VHDL entity  
### Starting generation of casfilt_stage1 VHDL architecture  
### Clock rate is 3 times the input sample rate for this architecture.

```

```

### Starting generation of casfilt VHDL entity
### Starting generation of casfilt VHDL architecture
### Successful completion of VHDL code generation process for filter: casfilt
### HDL latency is 2 samples

```

To explore the effective filter length and partitioning options for each filter stage of a cascade, call the `hdlfilterserialinfo` function. The function returns a partition vector corresponding to a desired number of multipliers. Request serial partition possibilities for the first stage, and choose a number of multipliers.

```
hdlfilterserialinfo(casc.Stage1, 'InputDataType', numerictype(1,16,15))
```

Total Coefficients	Zeros	A/Symm	Effective
9	0	4	5

Effective filter length for SerialPartition value is 5.

Table of 'SerialPartition' values with corresponding values of folding factor and number of multipliers for the given filter.

Folding Factor	Multipliers	SerialPartition
1	5	[1 1 1 1 1]
2	3	[2 2 1]
3	2	[3 2]
4	2	[4 1]
5	1	[5]

Select a serial partition vector for a target of two multipliers, and pass the vectors to the `generatehdl` function. Calling the function this way returns the first possible partition vector, but there are multiple partition vectors that achieve a two-multiplier architecture. Each stage uses a different clock rate based on the number of multipliers. The coder generates a timing controller to derive these clocks.

```

sp1 = hdlfilterserialinfo(casc.Stage1, 'InputDataType', numerictype(1,16,15), 'Multiplier
sp2 = hdlfilterserialinfo(casc.Stage2, 'InputDataType', numerictype(1,16,15), 'Multiplier
generatehdl(casc, 'InputDataType', numerictype(1,16,15), 'SerialPartition', {sp1,sp2})

```

```
sp1 =
```

```
3 2
```

```

sp2 =

    2    2    1

### Starting VHDL code generation process for filter: casfilt
### Cascade stage # 1
### Starting VHDL code generation process for filter: casfilt_stage1

### Starting generation of casfilt VHDL entity
### Starting generation of casfilt VHDL architecture
### Successful completion of VHDL code generation process for filter: casfilt
### HDL latency is 2 samples

```

### Generate Serial Architectures for IIR Filter

Create a direct form I SOS filter with these specifications:

- Sampling frequency of 48 kHz
- Filter order 5
- Cutt-off frequency of 10.8 kHz for the 3 dB point

The `design` function returns a `dsp.BiquadFilter` System object™ that implements the specification. The custom accumulator data type avoids quantization error.

```

Fs = 48e3;
Fc = 10.8e3;
N = 5;
lp = design(fdesign.lowpass('n,f3db',N,Fc,Fs),'butter', ...
    'FilterStructure','df1sos','SystemObject',true)

```

```

nt_accum = numerictype('Signedness','auto','WordLength',20, ...
    'FractionLength',15);
nt_input = numerictype(1,16,15);
lp.NumeratorAccumulatorDataType = 'Custom';
lp.CustomNumeratorAccumulatorDataType = nt_accum;
lp.DenominatorAccumulatorDataType = 'Custom';
lp.CustomDenominatorAccumulatorDataType = nt_accum;

```

```
lp =
```

```
dsp.BiquadFilter with properties:
```

```

                Structure: 'Direct form I'
        SOSMatrixSource: 'Property'
                SOSMatrix: [3x6 double]
                ScaleValues: [4x1 double]
    NumeratorInitialConditions: 0
    DenominatorInitialConditions: 0
    OptimizeUnityScaleValues: true

```

```
Use get to show all properties
```

To list all possible serial architecture specifications for this filter, call the `hdlfilterserialinfo` function. When the filter is a System object, you must specify a fixed-point data type for the input data.

```
hdlfilterserialinfo(lp,'InputDataType',nt_input)
```

```
Table of folding factors with corresponding number of multipliers for the given filter
```

Folding factor	Multipliers
6	3
9	2
18	1

To generate HDL code, call the `generatehdl` function with one of the serial architectures. Specify either the `NumMultipliers` or `FoldingFactor` property, but not both. For instance, using the `NumMultipliers` property:

```
generatehdl(lp,'NumMultipliers',2,'InputDataType',nt_input)
```

```
### Starting VHDL code generation process for filter: lp
### Generating: <a href="matlab:edit('C:\TEMP\Bdoc18a_815039_17936\ib0BF173\10\tp01ee1
### Starting generation of lp VHDL entity
### Starting generation of lp VHDL architecture
### Successful completion of VHDL code generation process for filter: lp
### HDL latency is 2 samples
```

Alternatively, specify the same architecture with the `FoldingFactor` property.

```
generatehdl(lp, 'FoldingFactor',9, 'InputDataType',nt_input)
```

```
### Starting VHDL code generation process for filter: lp
### Generating: <a href="matlab:edit('C:\TEMP\Bdoc18a_815039_17936\ib0BF173\10\tp01ee1
### Starting generation of lp VHDL entity
### Starting generation of lp VHDL architecture
### Successful completion of VHDL code generation process for filter: lp
### HDL latency is 2 samples
```

Both these commands generate a filter that uses a total of two multipliers, with a latency of nine clock cycles. This architecture uses less area than the parallel implementation, at the expense of latency.

### Distributed Arithmetic for Single Rate Filters

Use distributed arithmetic options to reduce the number of multipliers in the filter implementation.

Create a direct-form FIR filter and calculate the filter length, FL.

```
filtdes = fdesign.lowpass('N,Fc,Ap,Ast',30,0.4,0.05,0.03,'linear');
firfilt = design(filtdes,'FilterStructure','dffir','SystemObject',true);
FL = length(find(firfilt.Numerator ~= 0))
```

```
FL = 31
```

Specify a set of partitions such that the partition sizes add up to the filter length. This is just one partition option, you can specify other combinations of sizes.

```
generatehdl(firfilt,'InputDataType',numeric(1,16,15), ...
'DALUTPartition',[8 8 8 7])
```

```
Warning: Structure fir has symmetric coefficients, consider converting to structure sym
```

```
Warning: Structure fir has symmetric coefficients, consider converting to structure sym
```

```

### Starting VHDL code generation process for filter: firfilt
### Generating: C:\TEMP\Bdoc18a_815039_17936\ib0BF173\27\tpb68d4edc\hdlfilter-ex001985
### Starting generation of firfilt VHDL entity
### Starting generation of firfilt VHDL architecture
### Clock rate is 16 times the input sample rate for this architecture.
### Successful completion of VHDL code generation process for filter: firfilt
### HDL latency is 3 samples

```

For comparison, create a direct-form symmetric FIR filter. The filter length is smaller in the symmetric case.

```

filtDES = fdesign.lowpass('N,Fc,Ap,Ast',30,0.4,0.05,0.03,'linear');
firfilt = design(filtDES,'FilterStructure','dfsymfir','SystemObject',true);
FL = ceil(length(find(firfilt.Numerator ~= 0))/2)

```

```
FL = 16
```

Specify a set of partitions such that the partition sizes add up to the filter length. This is just one partition option, you can specify other combinations of sizes. **Tip:** Use the `hdlfilterdainfo` function to display the effective filter length, LUT partitioning options, and possible `DARadix` values for a filter.

```

generatehdl(firfilt,'InputDataType',numerictype(1,16,15), ...
'DALUTPartition',[8 8])

```

```

### Starting VHDL code generation process for filter: firfilt
### Generating: C:\TEMP\Bdoc18a_815039_17936\ib0BF173\27\tpb68d4edc\hdlfilter-ex001985
### Starting generation of firfilt VHDL entity
### Starting generation of firfilt VHDL architecture
### Clock rate is 17 times the input sample rate for this architecture.
### Successful completion of VHDL code generation process for filter: firfilt
### HDL latency is 3 samples

```

## Distributed Arithmetic for Multirate Filters

Use distributed arithmetic options to reduce the number of multipliers in the filter implementation.

Create a direct-form FIR polyphase decimator, and calculate the filter length.

```
d = fdesign.decimator(4);
filt = design(d,'SystemObject',true);
FL = size(polyphase(filt),2)
```

```
FL = 27
```

Specify distributed arithmetic LUT partitions that add up to the filter size. When you specify partitions as a vector for a polyphase filter, each subfilter uses the same partitions.

```
generatehdl(filt,'InputDataType',numeric(1,16,15), ...
    'DALUTPartition',[8 8 8 3])
```

```
### Starting VHDL code generation process for filter: firdecim
### Generating: C:\TEMP\Bdoc18a_815039_17936\ib0BF173\27\tpb68d4edc\hdlfilter-ex516701
### Starting generation of firdecim VHDL entity
### Starting generation of firdecim VHDL architecture
### Clock rate is 4 times the input and 16 times the output sample rate for this archi
### Successful completion of VHDL code generation process for filter: firdecim
### HDL latency is 16 samples
```

You can also specify unique partitions for each subfilter. For the same filter, specify subfilter partitioning as a matrix. The length of the first subfilter is 1, and the other subfilters have length 26. **Tip:** Use the `hdlfilterdainfo` function to display the effective filter length, LUT partitioning options, and possible DARadix values for a filter.

```
d = fdesign.decimator(4);
filt = design(d,'SystemObject',true);
generatehdl(filt,'InputDataType',numeric(1,16,15), ...
    'DALUTPartition',[1 0 0 0; 8 8 8 2; 8 8 6 4; 8 8 8 2])
```

```
### Starting VHDL code generation process for filter: firdecim

### Starting generation of firdecim VHDL architecture
### Clock rate is 4 times the input and 16 times the output sample rate for this archi
### Successful completion of VHDL code generation process for filter: firdecim
### HDL latency is 16 samples
```

### Distributed Arithmetic for Cascaded Filters

Use distributed arithmetic options to reduce the number of multipliers in the filter implementation.

## Create Cascaded Filter

Create a two-stage cascaded filter. Define different LUT partitions for each stage, and specify the partition vectors in a cell array.

```
lp = design(fdesign.lowpass('N,Fc',8,.4),'filterstructure','dfsymfir', ...
    'SystemObject',true);
hp = design(fdesign.highpass('N,Fc',8,.4),'filterstructure','dfsymfir', ...
    'SystemObject',true);
casc = cascade(lp,hp);
nt1 = numerictype(1,12,10);
generatehdl(casc,'InputDataType',nt1,'DALUTPartition',{[3 2],[2 2 1]})

### Starting VHDL code generation process for filter: casfilt

### Starting generation of casfilt VHDL entity
### Starting generation of casfilt VHDL architecture
### Successful completion of VHDL code generation process for filter: casfilt
### HDL latency is 4 samples
```

## Distributed Arithmetic Options

Use the `hdlfilterdainfo` function to display the effective filter length, LUT partitioning options, and possible DARadix values for each filter stage of a cascade. The function returns a LUT partition vector corresponding to a desired number of address bits.

Request LUT partition possibilities for the first stage.

```
hdlfilterdainfo(casc.Stage1,'InputDataType',nt1);
| Total Coefficients | Zeros | A/Symm | Effective |
-----
```

```
|          9          | 0 | 4 | 5 |
```

Effective filter length for SerialPartition value is 5.

Table of 'DARadix' values with corresponding values of folding factor and multiple for LUT sets for the given filter.

Folding Factor	LUT-Sets Multiple	DARadix
1	12	2 <sup>12</sup>
3	6	2 <sup>6</sup>
4	4	2 <sup>4</sup>
5	3	2 <sup>3</sup>
7	2	2 <sup>2</sup>
13	1	2 <sup>1</sup>

Details of LUTs with corresponding 'DALUTPartition' values.

Max Address Width	Size(bits)	LUT Details	DALUTPartition
5	416	1x32x13	[5]
4	216	1x16x12, 1x2x12	[4 1]
3	124	1x4x13, 1x8x9	[3 2]
2	104	1x2x12, 1x4x12, 1x4x8	[2 2 1]

Notes:

1. LUT Details indicates number of LUTs with their sizes. e.g. 1x1024x18 implies 1 LUT of 1024 18-bit wide locations.

To request LUT partition possibilities for the second stage, you must first determine the input data type of the second stage.

```
y = casc.Stage1(fi(0,nt1));
nt2 = y.numericType;
hdlfilterdainfo(casc.Stage2, 'InputDataType', nt2);
```

```
| Total Coefficients | Zeros | A/Symm | Effective |
```

---

```
|          9          | 0 | 4 | 5 |
```

Effective filter length for SerialPartition value is 5.

Table of 'DARadix' values with corresponding values of folding factor and multiple for LUT sets for the given filter.

Folding Factor	LUT-Sets Multiple	DARadix
1	27	2 <sup>27</sup>
4	9	2 <sup>9</sup>
10	3	2 <sup>3</sup>
28	1	2 <sup>1</sup>

Details of LUTs with corresponding 'DALUTPartition' values.

Max Address Width	Size(bits)	LUT Details	DALUTPartition
5	864	1x32x27	[5]
4	470	1x16x26, 1x2x27	[4 1]
3	292	1x4x27, 1x8x23	[3 2]
2	246	1x2x27, 1x4x22, 1x4x26	[2 2 1]

Notes:

1. LUT Details indicates number of LUTs with their sizes. e.g. 1x1024x18 implies 1 LUT of 1024 18-bit wide locations.

### Different LUT Partitions for Each Stage

Select address widths and folding factors to obtain LUT partition for each stage. The first stage uses LUTs with a maximum address size of five bits. The second stage uses LUTs with a maximum address size of three bits. They run at the same clock rate, and have different LUT partitions.

```

dp1 = hdlfilterdainfo(casc.Stage1, 'InputDataType', nt1, ...
    'LUTInputs', 5, 'FoldingFactor', 3);
dp2 = hdlfilterdainfo(casc.Stage2, 'InputDataType', nt1, ...
    'LUTInputs', 3, 'FoldingFactor', 5);
generatehdl(casc, 'InputDataType', nt1, 'DALUTPartition', {dp1, dp2});

### Different DARadix Values for Each Stage

You can also specify different DARadix values for each filter in a cascade. You can only specify different cascade partitions on the command-line. When you specify partitions in the **Generate HDL** dialog box, all cascade stages use the same partitions. Inspect the results of `hdlfilterdainfo` to set DARadix values for each stage.

```
generatehdl(casc, 'InputDataType', nt1, ...
'DALUTPartition', {[3 2],[2 2 1]}, 'DARadix', {2^3, 2^9})

```

## Cascaded Filter with Multiple Architectures

Specify different filter architectures for the different stages of a cascaded filter. You can specify a mix of serial, distributed arithmetic (DA), and parallel architectures depending upon your hardware constraints.

### Create Cascaded Filter

Create a three-stage filter. Each stage is a different type.

```
h1 = dsp.FIRFilter('Numerator',[0.05 -.25 .88 0.9 .88 -.25 0.05]);
h2 = dsp.FIRFilter('Numerator',[-0.008 0.06 -0.44 0.44 -0.06 0.008], ...
    'Structure','Direct form antisymmetric');
h3 = dsp.FIRFilter('Numerator',[-0.008 0.06 0.44 0.44 0.06 -0.008], ...
    'Structure','Direct form symmetric');
casc = cascade(h1,h2,h3);
```

### Specify Architecture for Each Stage

Specify a DA architecture for the first stage, a serial architecture for the second stage, and a fully parallel (default) architecture for the third stage.

To obtain DARadix values for the first architecture, use `hdlfilterdainfo`, then pick a value from `dr`.

```
nt = numerictype(1,12,10);
[dp,dr,lutsizes,ff] = hdlfilterdainfo(casc.Stage1, ...
    'InputDataType',numerictype(1,12,10));
dr
dr = 6x1 cell array
    {'2^12'}
    {'2^6' }
    {'2^4' }
    {'2^3' }
    {'2^2' }
    {'2^1' }
```

Set the property values as cell arrays, where each cell applies to a stage. To disable a property for a particular stage, use default values (-1 for the partitions and 2 for DARadix).

```
generatehdl(casc,'InputDataType',nt, ...
    'SerialPartition',{-1,3,-1}, ...
```

```
'DALUTPartition',[4 3],-1,-1}, ...  
'DARadix',{2^6,2,2});
```

### **Test Bench for FIR Filter with Programmable Coefficients**

You can specify input coefficients to test a filter with programmable coefficients.

Create a direct-form symmetric FIR filter with a fully parallel (default) architecture.

Define the coefficients for the filter object in the vector **b**. The coder generates test bench code to test the coefficient interface using a second set of coefficients, **c**. The coder trims **c** to the effective length of the filter.

```

b = [-0.01 0.1 0.8 0.1 -0.01];
c = [-0.03 0.5 0.7 0.5 -0.03];
c = c(1:ceil(length(c)/2));
filt = dsp.FIRFilter('Numerator',b,'Structure','Direct form symmetric');
generatehdl(filt,'InputDataType',numeric(1,16,15), ...
    'GenerateHDLTestbench','on', ...
    'CoefficientSource','ProcessorInterface','TestbenchCoeffStimulus',c)

```

## IIR Filter with Programmable Coefficients

Create a filter specification. When you generate HDL code, specify a programmable interface for the coefficients.

```

Fs = 48e3;
Fc = 10.8e3;
N = 5;
f_lp = fdesign.lowpass('n,f3db',N,Fc,Fs);
filtiir = design(f_lp,'butter','FilterStructure','df2sos','SystemObject',true);
filtiir.OptimizeUnityScaleValues = 0;
generatehdl(filtiir,'InputDataType',numeric(1,16,15), ...
    'CoefficientSource','ProcessorInterface')

### Starting VHDL code generation process for filter: filtiiir
### Generating: C:\TEMP\Bdoc18a_815039_17936\ib0BF173\27\tpb68d4edc\hdlfilter-ex923895
### Starting generation of filtiiir VHDL entity
### Starting generation of filtiiir VHDL architecture
### Second-order section, # 1
### Second-order section, # 2
### First-order section, # 3

```

```
### Successful completion of VHDL code generation process for filter: filtiir
### HDL latency is 2 samples
```

The coder generates this VHDL entity for the filter object.

```
ENTITY filtiir IS
  PORT ( clk           : IN      std_logic;
         clk_enable    : IN      std_logic;
         reset         : IN      std_logic;
         filter_in     : IN      std_logic_vector(15 DOWNTO 0); -- sfix16_En15
         write_enable  : IN      std_logic;
         write_done    : IN      std_logic;
         write_address : IN      std_logic_vector(4 DOWNTO 0); -- ufix5
         coeffs_in     : IN      std_logic_vector(15 DOWNTO 0); -- sfix16
         filter_out    : OUT     std_logic_vector(15 DOWNTO 0) -- sfix16_En15
        );
END filtiir;
```

### Clock Ports for Multirate Filters

Explore various ways to specify clock ports for multirate filters.

#### Default Setting

Create a polyphase sample rate converter. By default, the coder generates a single input clock (`clk`), an input clock enable (`clk_enable`), and a clock enable output signal named `ce_out`. The `ce_out` signal indicates when an output sample is ready. The `ce_in` output signal indicates when an input sample was accepted. You can use this signal to control the upstream data flow.

```
firrc = dsp.FIRRateConverter('InterpolationFactor',5,'DecimationFactor',3);
generatehdl(firrc,'InputDataType',numerictype(1,16,15))
```

```
### Starting VHDL code generation process for filter: firrc
### Generating: C:\TEMP\Bdoc18a_815039_17936\ib0BF173\27\tpb68d4edc\hdlfilter-ex090491
### Starting generation of firrc VHDL entity
### Starting generation of firrc VHDL architecture
### Successful completion of VHDL code generation process for filter: firrc
### HDL latency is 2 samples
```

The generated entity has the following signals:

```
ENTITY firrc IS
  PORT( clk           : IN    std_logic;
        clk_enable    : IN    std_logic;
        reset         : IN    std_logic;
        filter_in     : IN    std_logic_vector(15 DOWNTO 0); -- sfix16_En15
        filter_out    : OUT   std_logic_vector(35 DOWNTO 0); -- sfix36_En31
        ce_in         : OUT   std_logic;
        ce_out        : OUT   std_logic
  );

END firrc;
```

### Custom Clock Names

You can provide custom names for the input clock enable and the output clock enable signals. You cannot rename the `ce_in` signal.

```
firrc = dsp.FIRRateConverter('InterpolationFactor',5,'DecimationFactor',3)
```

```
firrc =
  dsp.FIRRateConverter with properties:
```

```
  InterpolationFactor: 5
  DecimationFactor: 3
  Numerator: [1x71 double]
```

```
Show all properties
```

```
generatehdl(firrc,'InputDataType',numerictype(1,16,15),...
  'ClockEnableInputPort','clk_en1', ...
  'ClockEnableOutputPort','clk_en2')
```

```
### Starting VHDL code generation process for filter: firrc
### Generating: C:\TEMP\Bdoc18a_815039_17936\ib0BF173\27\tpb68d4edc\hdlfilter-ex090491
### Starting generation of firrc VHDL entity
### Starting generation of firrc VHDL architecture
### Successful completion of VHDL code generation process for filter: firrc
### HDL latency is 2 samples
```

The generated entity has the following signals:

```

ENTITY firrc IS
  PORT( clk           : IN    std_logic;
        clk_en1      : IN    std_logic;
        reset        : IN    std_logic;
        filter_in    : IN    std_logic_vector(15 DOWNTO 0); -- sfix16_En15
        filter_out   : OUT   std_logic_vector(35 DOWNTO 0); -- sfix36_En31
        ce_in        : OUT   std_logic;
        clk_en2      : OUT   std_logic
        );

END firrc;

```

### Multiple Clock Inputs

To generate multiple clock input signals for a supported multirate filter, set the `ClockInputs` property to `'Multiple'`. In this case, the coder does not generate any output clock enable ports.

```

decim = dsp.CICDecimator(7,1,4);
generatehdl(decim, 'InputDataType', numerictype(1,16,15), ...
            'ClockInputs', 'Multiple')

### Starting VHDL code generation process for filter: cicDec0rIntFilt

        );
END cicdecimfilt;

```

## Generate Default Altera Quartus II Synthesis Script

Create a filter object. Then call `generatehdl`, and specify a synthesis tool.

```

lpf = fdesign.lowpass('fp,fst,ap,ast',0.45,0.55,1,60);
firfilt = design(lpf,'equiripple','FilterStructure','dfsymfir', ...
  'SystemObject',true);
generatehdl(firfilt,'InputDataType',numerictype(1,14,13), ...
  'HDLSynthTool','Quartus');

### Starting VHDL code generation process for filter: firfilt
### Generating: C:\TEMP\Bdoc18a_815039_17936\ib0BF173\27\tpb68d4edc\hdlfilter-ex922190
### Starting generation of firfilt VHDL entity
### Starting generation of firfilt VHDL architecture
### Successful completion of VHDL code generation process for filter: firfilt
### HDL latency is 2 samples

```

The coder generates a script file named `firfilt_quartus.tcl`, using the default script properties for the Altera® Quartus II synthesis tool.

```
type hdlsrc/firfilt_quartus.tcl
```

```

load_package flow
set top_level firfilt
set src_dir "./hdlsrc"
set prj_dir "q2dir"
file mkdir ../$prj_dir
cd ../$prj_dir

```

```
project_new $top_level -revision $top_level -overwrite
set_global_assignment -name FAMILY "Stratix II"
set_global_assignment -name DEVICE EP2S60F484C3
set_global_assignment -name TOP_LEVEL_ENTITY $top_level
set_global_assignment -name vhdl_FILE "$src_dir/firfilt.vhd"
execute_flow -compile
project_close
```

### Construct Customized Synthesis Script

You can set the script automation properties to dummy values to illustrate how the coder constructs the synthesis script from the properties.

Design a filter and generate HDL. Specify a synthesis tool and custom text to include in the synthesis script.

```
lpf = fdesign.lowpass('fp,fst,ap,ast',0.45,0.55,1,60);
firfilt = design(lpf,'equiripple','FilterStructure','dfsymfir', ...
    'Systemobject',true);
generatehdl(firfilt,'InputDataType',numericity(1,14,13), ...
    'HDLSynthTool','ISE', ...
    'HDLSynthInit','init line 1 : module name is %s\ninit line 2\n', ...
    'HDLSynthCmd','command : HDL filename is %s\n', ...
    'HDLSynthTerm','term line 1\nterm line 2\n');

### Starting VHDL code generation process for filter: firfilt

### Starting generation of firfilt VHDL entity
### Starting generation of firfilt VHDL architecture
### Successful completion of VHDL code generation process for filter: firfilt
### HDL latency is 2 samples
```

The coder generates a script file named `firfilt_ise.tcl`. Note the locations of the custom text you specified. You can use this feature to add synthesis instructions to the generated script.

```
type hdlsrc/firfilt_ise.tcl

init line 1 : module name is firfilt
init line 2
command : HDL filename is firfilt.vhd
```

term line 1  
term line 2

## Input Arguments

### **filtS0** – Filter

filter System object

Filter from which to generate HDL code, specified as a filter System object. To create a filter System object, use the `design` function or see the reference page of the object. You can use the following System objects from DSP System Toolbox:

#### **Single Rate Filters**

- `dsp.FIRFilter`
- `dsp.BiquadFilter`
- `dsp.HighpassFilter`
- `dsp.LowpassFilter`
- `dsp.FilterCascade`
- `dsp.VariableFractionalDelay`

#### **Multirate Filters**

- `dsp.FIRDecimator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FarrowRateConverter`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.FilterCascade`
- `dsp.DigitalDownConverter`
- `dsp.DigitalUpConverter`

**nt — Input data type**`numericType` object

Input data type, specified as a `numericType` object. This argument applies only when the input filter is a System object. Call `numericType(s,w,f)`, where `s` is 1 for signed and 0 for unsigned, `w` is the word length in bits, and `f` is the number of fractional bits.

**fd — Fractional delay data type**`numericType` object

Fractional delay data type, specified as a `numericType` object. This argument applies only when the input filter is a `dsp.VariableFractionalDelay` System object. Call `numericType(s,w,f)`, where `s` is 1 for signed and 0 for unsigned, `w` is the word length in bits, and `f` is the number of fractional bits.

**filterObj — Filter**`dfilt` object

Filter from which to generate HDL code, specified as a `dfilt` object. You can create this object by using the `design` function. For an overview of supported filter features, see “Filter Configuration Options” (Filter Design HDL Coder).

## Alternatives

You can use the `fdhdltool` function to generate HDL code instead (requires Filter Design HDL Coder). Specify the input and fractional delay data types as arguments, and then set additional properties in the Generate HDL dialog box.

# getCursorInfo

**Package:** dsp

Return settings for Logic Analyzer cursor

## Syntax

```
cursorInfo = getCursorInfo(scope, 'CursorTag', tag)
```

## Description

`cursorInfo = getCursorInfo(scope, 'CursorTag', tag)` returns the settings for the cursor or cursors specified by the input tag.

## Examples

### Modify Logic Analyzer Cursors Programmatically

This example shows how to use functions to create, manipulate, and delete cursors in a `dsp.LogicAnalyzer` object.

### Create Logic Analyzer and Signals

```
scope = dsp.LogicAnalyzer('NumInputPorts',3);  
for ii = 1:20  
    scope(ii,10*ii,20*ii);  
end
```

### Add Cursor

```
cursor = addCursor(scope, 'Location', 15, 'Color', 'Cyan');  
getCursorInfo(scope, cursor)
```

```
ans = struct with fields:  
    Location: 15
```

```
Color: [0 1 1]
Locked: 0
Tag: 'C2'
```

### Modify Cursor

```
modifyCursor(scope,cursor,'Color','Magenta')
```

### Remove Cursor

```
tags = getCursorTags(scope);
deleteCursor(scope,tags{1});
```

## Input Arguments

**scope** — The Logic Analyzer object from which you want to return cursor settings  
dsp.LogicAnalyzer object

The Logic Analyzer object from which you want to return cursor settings, specified as a handle to the dsp.LogicAnalyzer object.

**tag** — identifying tag or tags

character vector | cell array of character vectors

The tag or tags identifying the cursor or cursors about which to get information, specified as a character vector or cell array of character vectors.

Example: 'C5'

Example: {'C4', 'C5'}

Data Types: char | cell

## Output Arguments

**cursorInfo** — Information about settings for the cursor or cursors

struct

The `cursorInfo` struct contains the following fields:

- **Location** — Location of the cursors
- **Color** — Color of the cursors
- **Locked** — Locked status of the cursors
- **Tag** — Tag identifying cursors

## getCursorTags

**Package:** dsp

Return all Logic Analyzer cursor tags

### Syntax

```
cursorTags = getCursorTags(scope)
```

### Description

`cursorTags = getCursorTags(scope)` returns all the cursor tags for the Logic Analyzer. You can use these tags to get information about a cursor using the `dsp.LogicAnalyzer.getCursorInfo` method, to modify a cursor using the `dsp.LogicAnalyzer.modifyCursor` method, or to delete a cursor using the `dsp.LogicAnalyzer.deleteCursor` method.

### Examples

#### Modify Logic Analyzer Cursors Programmatically

This example shows how to use functions to create, manipulate, and delete cursors in a `dsp.LogicAnalyzer` object.

#### Create Logic Analyzer and Signals

```
scope = dsp.LogicAnalyzer('NumInputPorts',3);  
for ii = 1:20  
    scope(ii,10*ii,20*ii);  
end
```

#### Add Cursor

```
cursor = addCursor(scope,'Location',15,'Color','Cyan');  
getCursorInfo(scope,cursor)
```

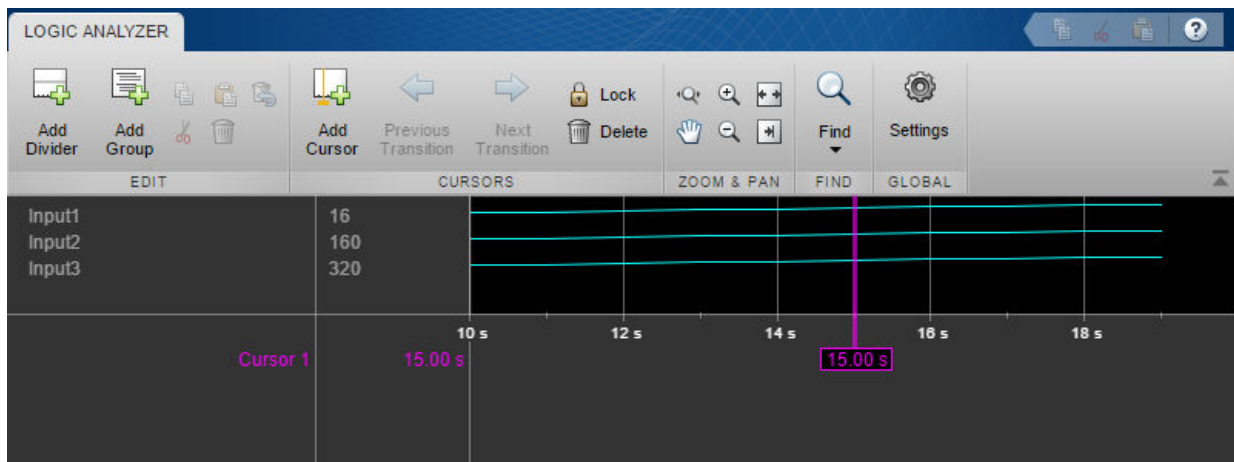

```
ans = struct with fields:
  Location: 15
  Color: [0 1 1]
  Locked: 0
  Tag: 'C2'
```

## Modify Cursor

```
modifyCursor(scope,cursor,'Color','Magenta')
```

## Remove Cursor

```
tags = getCursorTags(scope);
deleteCursor(scope,tags{1});
```

## Input Arguments

### scope — Logic analyzer object

dsp.LogicAnalyzer object

The Logic Analyzer object from which you want to return all cursor tags, specified as a handle to the dsp.LogicAnalyzer object.

## Output Arguments

### **cursorTags** — All cursor tags

cell array of character vectors

The cursor tags, specified as a cell array of character vectors.

Example: { 'C1' }

Example: { 'C1', 'C2', 'C3' }

Data Types: cell

# getDisplayChannelInfo

**Package:** dsp

Return settings for Logic Analyzer display channel

## Syntax

```
channelInfo = getDisplayChannelInfo(scope, 'DisplayChannelTag', tag)
```

## Description

`channelInfo = getDisplayChannelInfo(scope, 'DisplayChannelTag', tag)` returns the settings for the display channel or channels, specified by the input tag.

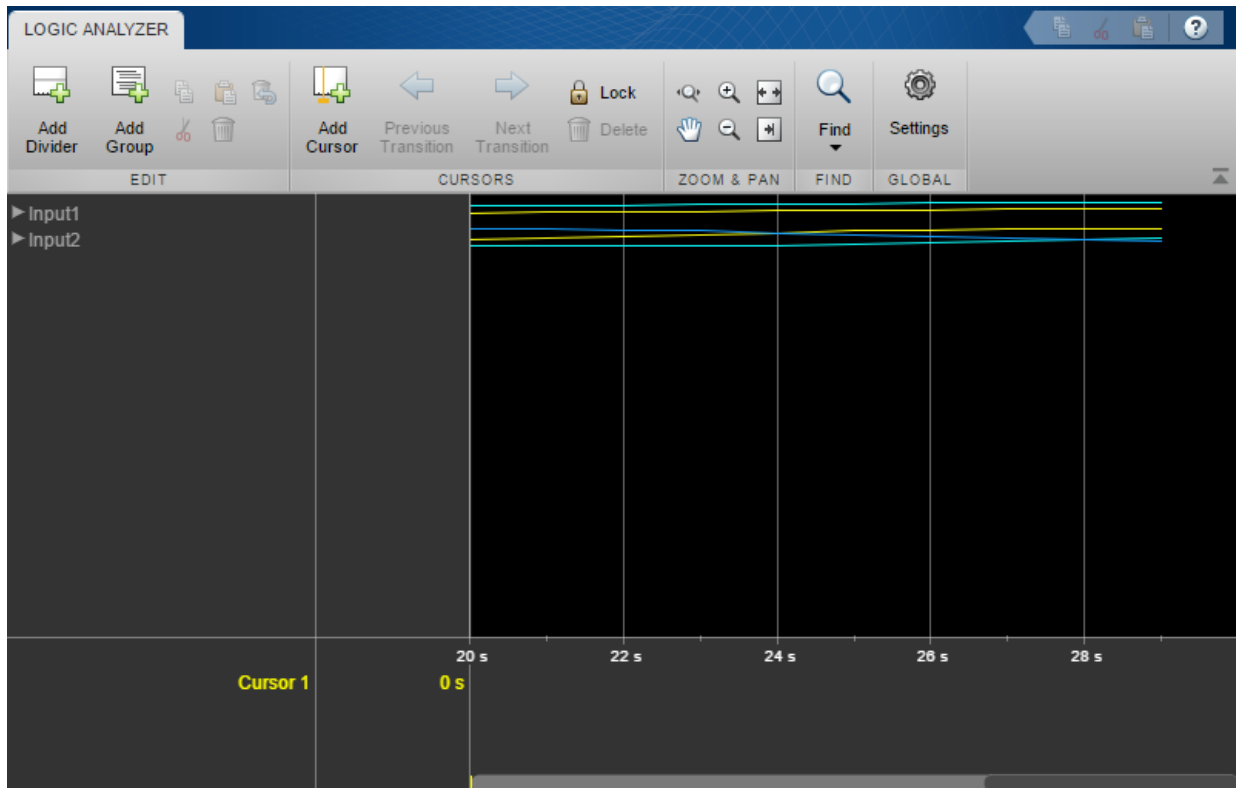

## Examples

### Manipulate Logic Analyzer Programatically

Use functions to construct and manipulate a `dsp.LogicAnalyzer` System object.

#### Display Waves on Logic Analyzer scope.

```
scope = dsp.LogicAnalyzer('NumInputPorts',2);  
  
stop = 30;  
for count = 1:stop  
    sinValVec = sin(count/stop*2*pi);  
    cosValVec = cos(count/stop*2*pi);  
    cosValVecOffset = cos((count+10)/stop*2*pi);  
  
    scope([count (count-(stop/2))],[sinValVec cosValVec cosValVecOffset])  
end
```

### Reorganize Display

```
digitalDividerTag = addDivider(scope, 'Name', 'Digital', 'Height', 20);
analogDividerTag = addDivider(scope, 'Name', 'Analog', 'Height', 40);

tags = getDisplayChannelTags(scope);

modifyDisplayChannel(scope, tags{1}, 'InputChannel', 1, ...
    'Name', 'Ramp Digital', 'Height', 40);
modifyDisplayChannel(scope, tags{2}, 'InputChannel', 2, ...
    'Name', 'Waves Analog', 'Format', 'Analog', 'Height', 80);

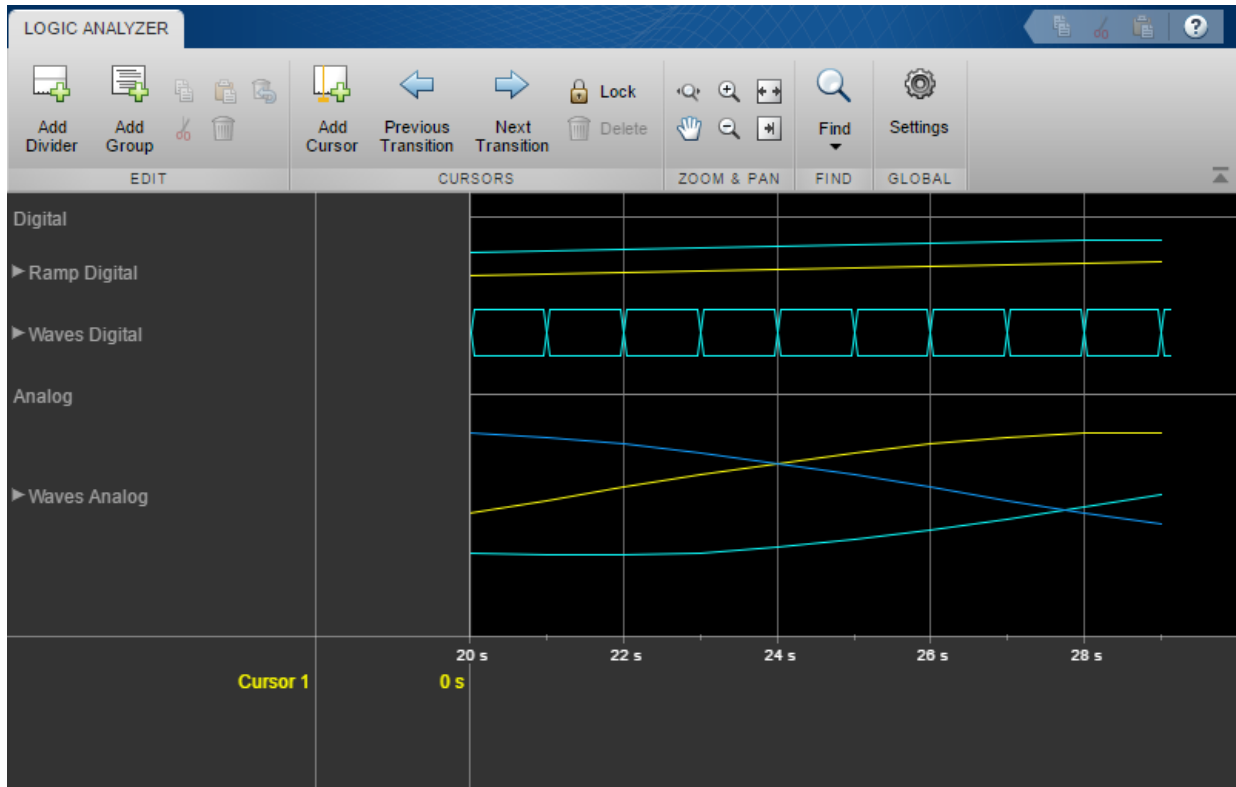

moveDisplayChannel(scope, digitalDividerTag, 'DisplayChannel', 1)
moveDisplayChannel(scope, tags{2}, 'DisplayChannel', length(tags))

show(scope)
```

### Duplicate Wave and Check Information

```
addWave(scope, 'InputChannel', 2, 'Name', 'Waves Digital', 'Format', 'Digital', ...
        'Height', 30, 'DisplayChannel', 3);
```

### Remove Dividers

```
deleteDisplayChannel(scope,digitalDividerTag)  
deleteDisplayChannel(scope,analogDividerTag)
```

### Clear variables

```
clear analogDividerTag cosValVec cosValVecOffset count digitalDividerTag duplicateWave
```

## Input Arguments

**scope** — Logic Analyzer object

dsp.LogicAnalyzer object

The Logic Analyzer object from which you want to return display channel settings, specified as a handle to the dsp.LogicAnalyzer object.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'DisplayChannelTag', 'W5'` specifies to return display channel settings about the wave with tag `'W5'`.

### **DisplayChannelTag** — The tag or tags identifying the display channel or channels about which to get information

character vector or cell array of character vectors

The tag or tags identifying the display channel or channels about which to get information, specified as a character vector or cell array of character vectors.

Example: `'DisplayChannelTag', 'W5'`

Example: `'DisplayChannelTag', {'W4', 'W5'}`

Data Types: `char` | `cell`

## Output Arguments

### **channelInfo** — Information about settings for the display channel or channels

struct

The `channelInfo` struct contains the following fields:

- `Color` — Color of the waves.
- `InputChannel` — Channel on the display that corresponds to the specified waves.
- `Radix` — Radix for the waves.
- `FontSize` — Font size for values in the waves. A value of `0` indicates that the waves inherit `FontSize` from the global `DisplayChannelColor` property.
- `Name` — The name or label for the waves.
- `Height` — Height of the wave. A value of `0` indicates that the waves inherit `Height` from the global `DisplayChannelHeight` property.
- `Tag` — Tag for the channel.

## See Also

`getDisplayChannelTags` | `modifyDisplayChannel`

**Introduced in R2013a**

## getDisplayChannelTags

**Package:** dsp

Return all Logic Analyzer display channel tags

### Syntax

```
displayChannelTags = getDisplayChannelTags(scope)
```

### Description

`displayChannelTags = getDisplayChannelTags(scope)` returns all the tags for waves or dividers in a Logic Analyzer. You use these tags to

- Get information about a wave or divider using `getDisplayChannelInfo`
- Modify a wave or divider using `modifyDisplayChannel`
- Delete a wave or divider using `deleteDisplayChannel`

### Examples

#### Manipulate Logic Analyzer Programmatically

Use functions to construct and manipulate a `dsp.LogicAnalyzer` System object.

#### Display Waves on Logic Analyzer scope.

```
scope = dsp.LogicAnalyzer('NumInputPorts',2);

stop = 30;
for count = 1:stop
    sinValVec = sin(count/stop*2*pi);
    cosValVec = cos(count/stop*2*pi);
    cosValVecOffset = cos((count+10)/stop*2*pi);
```

```

scope([count (count-(stop/2))],[sinValVec cosValVec cosValVecOffset])
end

```

### Reorganize Display

```

digitalDividerTag = addDivider(scope,'Name','Digital','Height',20);
analogDividerTag = addDivider(scope,'Name','Analog','Height',40);

tags = getDisplayChannelTags(scope);

modifyDisplayChannel(scope,tags{1},'InputChannel',1,...
    'Name','Ramp Digital','Height',40);
modifyDisplayChannel(scope,tags{2},'InputChannel',2,...
    'Name','Waves Analog','Format','Analog','Height',80);

moveDisplayChannel(scope,digitalDividerTag,'DisplayChannel',1)

```

```
moveDisplayChannel(scope, tags{2}, 'DisplayChannel', length(tags))  
show(scope)
```

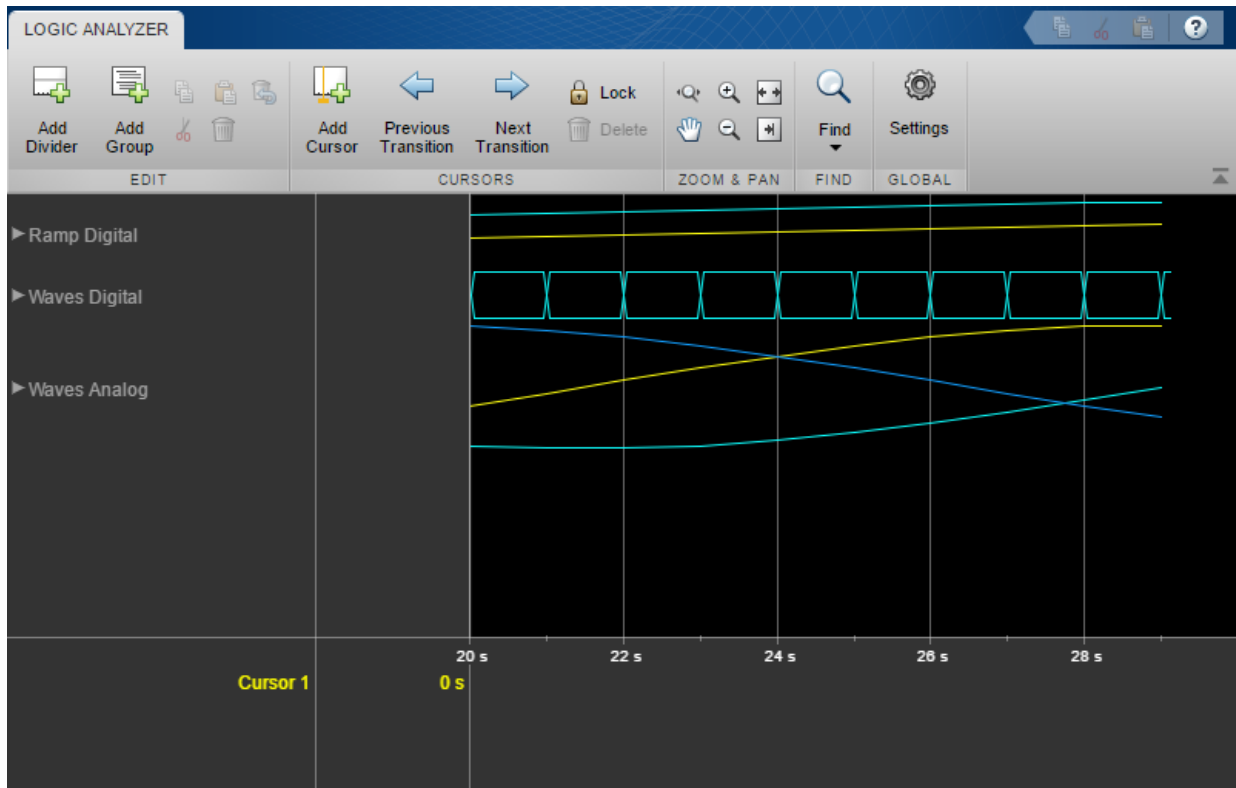

### Duplicate Wave and Check Information

```
addWave(scope, 'InputChannel', 2, 'Name', 'Waves Digital', 'Format', 'Digital', ...  
        'Height', 30, 'DisplayChannel', 3);
```

### Remove Dividers

```
deleteDisplayChannel(scope,digitalDividerTag)  
deleteDisplayChannel(scope,analogDividerTag)
```

### Clear variables

```
clear analogDividerTag cosValVec cosValVecOffset count digitalDividerTag duplicateWave
```

## Input Arguments

**scope** — The Logic Analyzer object from which you want to return all display channel tags

`dsp.LogicAnalyzer` object

The Logic Analyzer object from which you want to return all display channel tags, specified as a handle to the `dsp.LogicAnalyzer` object.

## Output Arguments

### **displayChannelTags** — The display channel tags

cell array of character vectors

The display channel tags, returned as a cell array of character vectors.

Example: {'W1'}

Example: {'W1', 'W2', 'W3'}

Data Types: cell

**Introduced in R2013a**

## getFixedPointInfo

**Package:** dsp

Get fixed-point word and fraction lengths

### Syntax

```
[WLs, FLs] = getFixedPointInfo(cicObj,nt)
```

### Description

[WLs, FLs] = `getFixedPointInfo(cicObj,nt)` returns all the word lengths and fraction lengths of the fixed-point sections and the output of the CIC filter System objects, `dsp.CICDecimator` and `dsp.CICInterpolator`, based on the input numeric type, `nt`. For locked objects or when the `FixedPointDataType` property of the unlocked CIC filter object is set to 'Specify word and fraction lengths', the input numeric type argument, `nt`, is optional.

### Examples

#### Determine the Section and Output Word Lengths and Fraction Lengths

Using the `getFixedPointInfo` function, you can determine the word lengths and fraction lengths of the fixed-point sections and the output of the `dsp.CICDecimator` and `dsp.CICInterpolator` System objects. The data types of the filter sections and the output depend on the `FixedPointDataType` property of the filter System object™.

#### Full precision

Create a `dsp.CICDecimator` object. The default value of the `NumSections` property is 2. This value indicates that there are two integrator and comb sections. The WLs and FLs vectors returned by the `getFixedPointInfo` function contain five elements each. The first two elements represent the two integrator sections. The third and fourth elements represent the two comb sections. The last element represents the filter output.

```

cicD = dsp.CICDecimator

cicD =
    dsp.CICDecimator with properties:

        DecimationFactor: 2
        DifferentialDelay: 1
        NumSections: 2
        FixedPointDataType: 'Full precision'

```

By default, the `FixedPointDataType` property of the object is set to `'Full precision'`. Calling the `getFixedPointInfo` function on this object with the input numeric type, `nt`, yields the following word length and fraction length vectors.

```

nt = numerictype(1,16,15)

nt =

        DataTypeMode: Fixed-point: binary point scaling
        Signedness: Signed
        WordLength: 16
        FractionLength: 15

```

```

[WLs,FLs] = getFixedPointInfo(cicD,nt) %#ok

```

```

WLs = 1x5

    18    18    18    18    18

FLs = 1x5

    15    15    15    15    15

```

For details on how the word lengths and fraction lengths are computed, see the description for *Output Arguments*.

If you lock the `cicD` object by passing an input to its algorithm, you do not need to pass the `nt` argument to the `getFixedPointInfo` function.

```

input = int64(randn(8,1))

```

```

input = 8x1 int64 column vector

     1
     2
    -2
     1
     0
    -1
     0
     0

output = cicD(input)

output =
     0
     1
     3
     0

        DataTypeMode: Fixed-point: binary point scaling
        Signedness: Signed
        WordLength: 66
        FractionLength: 0

[WLs,FLs] = getFixedPointInfo(cicD) %#ok

WLs = 1x5

    66    66    66    66    66

FLs = 1x5

     0     0     0     0     0

```

The output and section word lengths are the sum of input word length, 64 in this case, and the number of sections, 2. The output and section fraction lengths are 0 since the input is a built-in integer.

### Minimum section word lengths

Release the object and change the `FixedPointDataType` property to 'Minimum section word lengths'. Determine the section and output fixed-point information when the input is fixed-point data, `fi(randn(8,2),1,24,15)`.

```

release(cicD);
cicD.FixedPointDataType = 'Minimum section word lengths'

cicD =
    dsp.CICDecimator with properties:

        DecimationFactor: 2
        DifferentialDelay: 1
        NumSections: 2
        FixedPointDataType: 'Minimum section word lengths'
        OutputWordLength: 32

inputF = fi(randn(8,2),1,24,15)

inputF =
    3.5784    -0.1241
    2.7694     1.4897
   -1.3499     1.4090
    3.0349     1.4172
    0.7254     0.6715
   -0.0630    -1.2075
    0.7148     0.7172
   -0.2050     1.6302

        DataTypeMode: Fixed-point: binary point scaling
        Signedness: Signed
        WordLength: 24
        FractionLength: 15

[WLs, FLs] = getFixedPointInfo(cicD,numericType(inputF)) %#ok

WLs = 1x5

    26    26    26    26    32

FLs = 1x5

    15    15    15    15    21

```

### Specify word and fraction lengths

Change the `FixedPointDataType` property to 'Specify word and fraction lengths'. Determine the fixed-point information using the `getFixedPointInfo` function.

```
cicD.FixedPointDataType = 'Specify word and fraction lengths'

cicD =
  dsp.CICDecimator with properties:

    DecimationFactor: 2
    DifferentialDelay: 1
    NumSections: 2
    FixedPointDataType: 'Specify word and fraction lengths'
    SectionWordLengths: [16 16 16 16]
    SectionFractionLengths: 0
    OutputWordLength: 32
    OutputFractionLength: 0
```

```
[WLs, FLs] = getFixedPointInfo(cicD, numerictype(inputF)) %#ok
```

```
WLs = 1x5
     16     16     16     16     32
```

```
FLs = 1x5
     0     0     0     0     0
```

The section and output word lengths and fraction lengths are assigned as per the respective fixed-point properties of the `cicD` object. These values are not determined by the input numeric type. To confirm, call the `getFixedPointInfo` function without passing the `numerictype` input argument.

```
[WLs, FLs] = getFixedPointInfo(cicD) %#ok
```

```
WLs = 1x5
     16     16     16     16     32
```

```
FLs = 1x5
      0      0      0      0      0
```

### Specify word lengths

To specify the word lengths of the filter section and output, set the `FixedPointDataType` property to 'Specify word lengths'.

```
cicD.FixedPointDataType = 'Specify word lengths'
```

```
cicD =
  dsp.CICDecimator with properties:
    DecimationFactor: 2
    DifferentialDelay: 1
    NumSections: 2
    FixedPointDataType: 'Specify word lengths'
    SectionWordLengths: [16 16 16 16]
    OutputWordLength: 32
```

The `getFixedPointInfo` function requires the input numeric type because that information is used to compute the section and word fraction lengths.

```
[WLs, FLs] = getFixedPointInfo(cicD, numerictype(inputF))
```

```
WLs = 1x5
      16      16      16      16      32
```

```
FLs = 1x5
      5       5       5       5      21
```

For more details on how the function computes the word and fraction lengths, see the description for *Output Arguments*.

## Input Arguments

### **cicObj** — CIC filter System object

`dsp.CICDecimator` | `dsp.CICInterpolator`

CIC filter System object, specified as either a `dsp.CICDecimator` or `dsp.CICInterpolator` System object.

Example: `cicObj = dsp.CICDecimator`

Example: `cicObj = dsp.CICInterpolator`

### **nt** — Input numeric type

`numericType`

Input data numeric type, specified as a `numericType` object. Specify this input when the System object is unlocked and the `FixedPointDataType` property of the CIC filter is set to 'Full precision', 'Minimum section word lengths', or 'Specify word lengths'. If the `FixedPointDataType` property is set to 'Specify word and fraction lengths', the word and fraction lengths of the filter sections and the output are specified through the object parameters. In this case, the `nt` input is optional. Alternatively, if the object is locked, the fixed-point data input to the object specifies the input word length and fraction length. The `nt` argument in this case is also optional.

Example: `numericType(1,16,15)`

Example: `input = fi(randn(16,1),1,32,30); numericType(input)`

## Output Arguments

### **WLs** — Section and output word lengths

row vector

Section and output word lengths, returned as a row vector. The first  $2 \times \text{NumSections}$  elements in the row vector correspond to the word lengths of the integrator and comb sections of the CIC filter. The value of the `NumSections` property specifies the number of sections in either the integrator part or the comb part of the filter. The last element in the vector corresponds to the word length of the object output.

The word length of the CIC filter sections and the object output depend on the `FixedPointDataType` property of the CIC filter object.

### Full precision

When the `FixedPointDataType` property of the CIC filter object is set to 'Full precision', the section and output word lengths are computed using the following equation:

$$WL_{\text{section}} = WL_{\text{input}} + NumSect$$

$$WL_{\text{output}} = WL_{\text{input}} + NumSect$$

where,

- $WL_{\text{section}}$  -- Word length of the CIC filter section.
- $WL_{\text{output}}$  -- Word length of the output data.
- $WL_{\text{input}}$  -- Word length of the input data.
- $NumSect$  -- Number of CIC filter sections specified through the `NumSections` property.

For locked objects,  $WL_{\text{input}}$  is inherited from the data input you pass to the object algorithm. For unlocked objects, the  $WL_{\text{input}}$  is inherited from the `nt` argument.

### Minimum section word lengths

When the `FixedPointDataType` property is set to 'Minimum section word lengths', the section word length is given by the following equation:

$$WL_{\text{section}} = WL_{\text{input}} + NumSect$$

The output word length is the value you specify in `OutputWordLength` property of the CIC filter object.

### Specify word and fraction lengths

When the `FixedPointDataType` property is set to 'Specify word and fraction lengths', the section word lengths and output word length are the values you specify in the `SectionWordLengths` and `OutputWordLength` properties of the CIC filter object.

### Specify word lengths

When the `FixedPointDataType` property is set to 'Specify word lengths', the section word lengths and the output word length are the values you specify in the `SectionWordLengths` and `OutputWordLength` properties of the CIC filter object.

Example: [20 20 20 20 20]

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### FLs — Section and output fraction lengths

row vector

Section and output fraction lengths, returned as a row vector. The first  $2 \times \text{NumSections}$  elements in the row vector correspond to the fraction lengths of the integrator and comb sections of the CIC filter. The value of `NumSections` property specifies the number of sections in either the integrator part or the comb part of the filter. The last element in the vector corresponds to the fraction length of the object output.

The fraction length of the CIC filter sections and the object output depend on the `FixedPointDataType` property of the CIC filter object.

#### Full precision

When the `FixedPointDataType` property of the CIC filter object is set to 'Full precision', the section and output fraction lengths are computed using the following equation:

$$FL_{\text{section}} = WL_{\text{section}} - (WL_{\text{input}} - FL_{\text{input}} + \text{NumSect})$$

$$FL_{\text{output}} = WL_{\text{output}} - (WL_{\text{input}} - FL_{\text{input}} + \text{NumSect})$$

For inputs of built-in integer data types, the section and output fraction lengths are 0.

#### Minimum section word lengths

When the `FixedPointDataType` property of the CIC filter object is set to 'Minimum section word lengths', the section and output fraction lengths,  $FL_{\text{section}}$  and  $FL_{\text{output}}$  are given by the following equation:

$$FL_{\text{section}} = WL_{\text{section}} - (WL_{\text{input}} - FL_{\text{input}} + \text{NumSect})$$

$$FL_{\text{output}} = WL_{\text{output}} - (WL_{\text{input}} - FL_{\text{input}} + \text{NumSect})$$

For inputs of built-in integer data types, the section and output fraction lengths are 0.

### Specify word and fraction lengths

When the `FixedPointDataType` property of the CIC filter object is set to 'Specify word and fraction lengths', the section and output fraction lengths are the values you specify in the `SectionFractionLengths` and `OutputFractionLength` properties.

### Specify word lengths

When the `FixedPointDataType` property of the CIC filter object is set to 'Specify word lengths', the section and output fraction lengths,  $FL_{\text{section}}$  and  $FL_{\text{output}}$  are given by the following equation:

$$FL_{\text{section}} = WL_{\text{section}} - (WL_{\text{input}} - FL_{\text{input}} + NumSect)$$

$$FL_{\text{output}} = WL_{\text{output}} - (WL_{\text{input}} - FL_{\text{input}} + NumSect)$$

Example: [12 12 12 12 12]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**System Objects**

`dsp.CICDecimator` | `dsp.CICInterpolator`

**Introduced in R2018a**

# getFilters

**Package:** dsp

Return matrix of channelizer FIR filters

## Syntax

```
B = getFilters(obj)
B = getFilters(obj,ind)
```

## Description

`B = getFilters(obj)` returns a matrix **B** of filter coefficients corresponding to each filter in the `dsp.Channelizer` System object filter bank. Each row contains the coefficients for the corresponding bandpass filter. The channelizer does not actually use all these filters in the implementation. It only uses the prototype lowpass filter (the first row of matrix **B**) and an FFT to implement the filter bank. The combination of polyphase implementation of the prototype lowpass and the FFT effectively implements all the filters in **B**, but does so in a very efficient manner.

`B = getFilters(obj,ind)` returns the filters with indices corresponding to the elements in the vector `ind`. `ind` is a row vector of indices between 1 and `obj.NumFrequencyBands`. By default, this vector is `[1:N]`, where *N* is the number of frequency bands specified in the `obj.NumFrequencyBands` property.

## Examples

### Coefficients of Channelizer Filters

Using the `getFilters` function, you can access the coefficients of the lowpass prototype filter and the modulated bandpass filters of the channelizer.

```
channelizer = dsp.Channelizer;
B = getFilters(channelizer);
```

The first row corresponds to the coefficients of the prototype filter. The subsequent rows correspond to the coefficients of the respective modulated filters. Compare the first row with the coefficients returned by the `tf` function.

```
b = tf(channelizer);  
isequal(b,B(1,:))
```

```
ans = logical  
     1
```

The output of the `tf` function and the first row of the `B` matrix are equal.

Visualize the frequency response of the first 4 filters of the channelizer.

```
fvtool(B(1,:),1, B(2,:),1, B(3,:),1, B(4,:),1);
```

## Input Arguments

**obj** — Input filter System object

`dsp.Channelizer`

Input filter, specified as `dsp.Channelizer` System object. The `getFilters` function returns a matrix of filter coefficients corresponding to each filter in the channelizer filter bank.

**ind** — Filter indices

row vector

Filter indices, specified as a row vector in the range [1 obj.NumFrequencyBands]. If not specified, ind is 1:N, where  $N$  is the number of frequency bands specified through the obj.NumFrequencyBands property.

Example: getFilters(channelizer,[1:4]);

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

## Output Arguments

### **B — Matrix of channelizer FIR filter coefficients**

matrix

Matrix of channelizer finite impulse response (FIR) filter coefficients, returned as a matrix. Each row in the matrix corresponds to a filter in the filter bank. The first row corresponds to the prototype filter as returned by  $b = \text{tf}(\text{obj})$ . The remaining rows in  $B$  are given by:

$$b_k = b \times e^{j\omega_k n/N}$$

$N$  is the number of frequency bands, and  $k$  is the row index - 1.

# getLatency

**Package:** dsp

Latency of FFT or channelizer calculation

## Syntax

```
Y = getLatency(hdlfft)
Y = getLatency(hdlfft,N)
Y = getLatency(hdlfft,N,V)
```

## Description

`Y = getLatency(hdlfft)` returns the number of cycles, `Y`, that the object takes to calculate the FFT of an input frame. The latency depends on the input vector size and the FFT length. The channelizer filter coefficients do not affect the latency.

`Y = getLatency(hdlfft,N)` returns the number of cycles that an object would take to calculate the FFT of an input frame, if it had FFT length `N`, and scalar input. This function does not change the properties of the `hdlfft`.

`Y = getLatency(hdlfft,N,V)` returns the number of cycles that an object would take to calculate the FFT of an input frame, if it had FFT length `N`, and vector input of size `V`. This function does not change the properties of `hdlfft`.

## Examples

### Explore Latency of HDL FFT Object

The latency of the object varies with the FFT length and the vector size. Use the `getLatency` function to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming that the input is contiguous.

Create a new `dsp.HDLFFT` object and request the latency.

```
hdlfft = dsp.HDLFFT('FFTLength',512);  
L512 = getLatency(hdlfft)
```

```
L512 = 599
```

Request hypothetical latency information about a similar object with a different FFT length. The properties of the original object do not change.

```
L256 = getLatency(hdlfft,256)
```

```
L256 = 329
```

```
N = hdlfft.FFTLength
```

```
N = 512
```

Request hypothetical latency information of a similar object that accepts eight-sample vector input.

```
L256v8 = getLatency(hdlfft,256,8)
```

```
L256v8 = 93
```

Enable scaling at each stage of the FFT. The latency does not change.

```
hdlfft.Normalize = true;  
L512n = getLatency(hdlfft)
```

```
L512n = 599
```

Request the same output order as the input order. The latency increases because the object must collect the output before reordering.

```
hdlfft.BitReversedOutput = false;  
L512r = getLatency(hdlfft)
```

```
L512r = 1078
```

## Input Arguments

**hdlfft** — HDL-optimized FFT or channelizer System object

dsp.HDLFFT | dsp.HDLIFFT | dsp.HDLChannelizer

HDL-optimized FFT or channelizer System object that you created and configured. See `dsp.HDLChannelizer`, `dsp.HDLIFFT`, or `dsp.HDLFFT`.

**N — FFT length**

integer power of 2 from  $2^3$  to  $2^{16}$

FFT length, specified as an integer power of 2 from  $2^3$  to  $2^{16}$ . Use this argument to request the latency of an object similar to `hdlfft`, but with FFT length N.

**V — Vector size**

power of 2 from 1 to 64

Vector size, specified as a power of 2 from 1 to 64. The vector size cannot be greater than the FFT length. Use this argument to request the latency of an object similar to `hdlfft`, but with V-sample vector input. When you do not specify this argument, the function assumes scalar input.

## Output Arguments

**Y — Cycles of latency**

integer

Cycles of latency that the object takes to calculate the FFT of an input frame, returned as an integer. The latency is the number of cycles between the first valid input and the first valid output, assuming the input is contiguous. Each call to the object simulates one cycle.

# getSpectralMaskStatus

**Package:** dsp

Get test results of current spectral mask

## Syntax

```
results = getSpectralMaskStatus(scope)
```

## Description

`results = getSpectralMaskStatus(scope)` returns the current status of the spectral mask on the spectrum analyzer, `scope`, in a structure, `results`.

## Examples

### Get Spectral Mask Status

This example shows how to add a spectral mask to an existing `dsp.SpectrumAnalyzer` System object `scope` and get the status with `getSpectralMaskStatus`.

```
sine = dsp.SineWave('Frequency',[98 100],'SampleRate',1000);
sine.SamplesPerFrame = 1024;
scope = dsp.SpectrumAnalyzer('SampleRate',sine.SampleRate, ...
    'PlotAsTwoSidedSpectrum',false,'ShowLegend',true);
hide(scope);

scope.SpectralMask.EnabledMasks = 'Upper and lower';
upperMask = [0 -10; 90 -10; 90 30; 110 30; 110 -10; 500 -10];
set(scope.SpectralMask,'UpperMask',upperMask,'LowerMask',-55);

for i=1:100
    scope(sine() + 0.05*randn(1024,2));
end
```

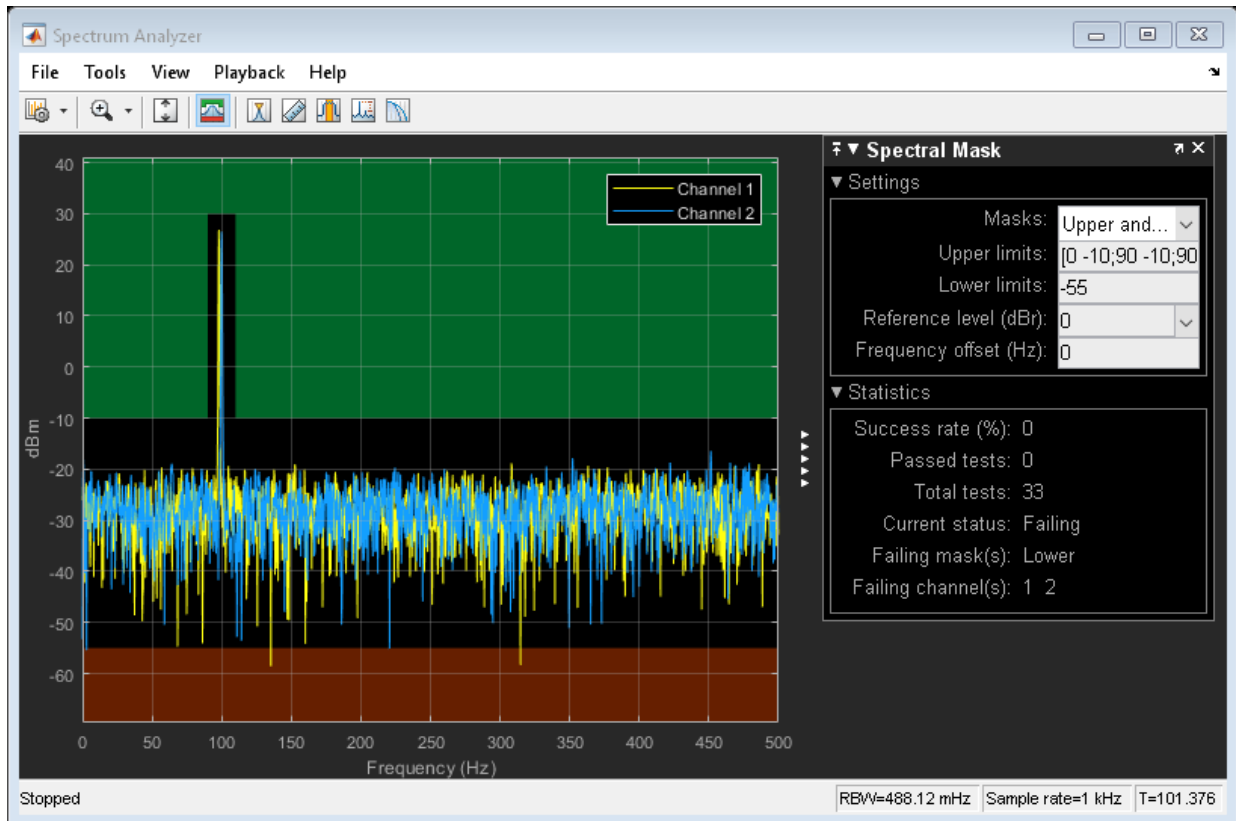

```
res = getSpectralMaskStatus(scope)

res = struct with fields:
    IsCurrentlyPassing: 0
    NumPassedTests: 0
    NumTotalTests: 33
    SuccessRate: 0
    FailingMasks: 'Lower'
    FailingChannels: [1 2]
    SimulationTime: 101.3760
```

In the Spectrum Analyzer, you can see the same information in the Spectral Mask panel.

```
show(scope);
release(scope);
```

## Input Arguments

### scope — Spectrum Analyzer

spectrum analyzer name

Spectrum Analyzer with spectral masks whose status you want to check. Specified by the name of the `dsp.SpectrumAnalyzer` object.

## Output Arguments

### results — Current status of the spectral mask

structure

The results return the current status of the spectral mask with these properties:

Field	Description
IsCurrentlyPassing	Indicator of whether one or more masks are currently passing  1 — All masks are passing  0 — One or more masks are failing
NumPassedTests	Number of mask tests that have passed
NumTotalTests	Total number of mask tests
SuccessRate	Percentage of tests that have passed
FailingChannels	Array of channel numbers that are currently failing the mask test
FailingMasks	Character array of which masks are currently failing: 'None', 'Upper', 'Lower', or 'Upper and lower'
SimulationTime	Simulation time

## getSpectrumData

**Package:** dsp

Save spectrum data shown in spectrum analyzer

### Syntax

```
spectrumTable = getSpectrumData(scope)
```

### Description

`spectrumTable = getSpectrumData(scope)` returns the spectrum and spectrogram displayed on the spectrum analyzer along with additional statistics about the spectrum.

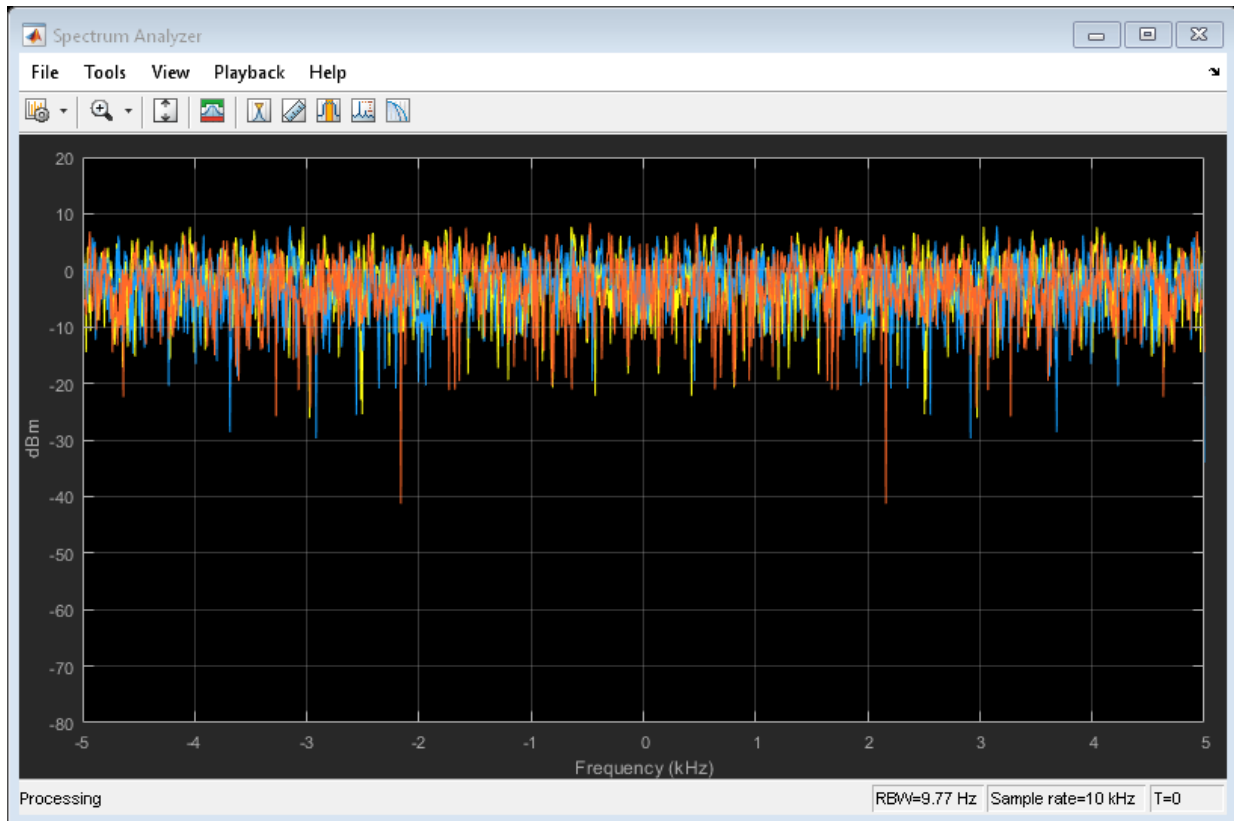

### Examples

#### Save Spectrum Data

Save the spectrum estimation displayed on a spectrum analyzer.

Create a Spectrum Analyzer System object, `scope`, and generate data.

```
scope = dsp.SpectrumAnalyzer;  
scope(randn(5000,3))
```

Save data from the last spectrum shown on the spectrum analyzer to a table.

```
specTable = getSpectrumData(scope)
```

```
specTable =
```

```
1x6 table
```

```
SimulationTime
```

```
Spectrum
```

```
Spectrogram
```

```
MinHoldTrace
```

```
MaxHoldTrace
```

[0]

[1536x3 double]

[]

[]

[]

## Input Arguments

### scope — Spectrum analyzer

system object name | block configuration

Spectrum analyzer you want to query. Specify a `dsp.SpectrumAnalyzer` System object or a `Spectrum Analyzer Configuration` object for a spectrum analyzer block.

## Output Arguments

### spectrumTable — Data about current spectrum estimation

table

A spectrum table is returned containing the following fields:

Field	Description
SimulationTime	Simulation time
Spectrum	Power, power density, or RMS spectrum data
Spectrogram	Spectrogram data
MinHoldTrace	Minimum hold trace data
MaxHoldTrace	Maximum hold trace data
FrequencyVector	Frequency vector

# grpdelay

Group delay response of discrete-time filter System object

## Syntax

```
[gd,w] = grpdelay(sysobj)
[gd,w] = grpdelay(sysobj,n)
[gd,w] = grpdelay(sysobj,Name,Value)
grpdelay(sysobj)
```

## Description

`[gd,w] = grpdelay(sysobj)` returns the group delay `gd` of the filter System object, `sysobj`, based on the current filter coefficients. The vector `w` contains the frequencies (in radians) at which the group delay is evaluated. The group delay is defined as:

$$-\frac{d}{dw}(\text{angle}(w))$$

The group delay is evaluated at 8192 points equally spaced around the upper half of the unit circle.

`[gd,w] = grpdelay(sysobj,n)` returns the group delay of the filter System object and the corresponding frequencies at `n` points equally spaced around the upper half of the unit circle.

`[gd,w] = grpdelay(sysobj,Name,Value)` returns the group delay with additional options specified by one or more `Name,Value` pair arguments.

`grpdelay(sysobj)` plots the group delay of the filter System object `sysobj` in the `fvtool`.

For information on more input options, refer to `grpdelay` in Signal Processing Toolbox documentation.

## Examples

### Group Delay of a Discrete-Time Multirate Filter

```
CICComp = dsp.CICCompensationDecimator;
```

`grpdelay` computes the group delay of the filter and displays it using `fvtool`

```
grpdelay(CICComp);
```

## Input Arguments

### sysobj

Filter System object.

The following Filter System objects are supported by this analysis function:

<b>Filter System objects</b>
dsp.AllpassFilter
dsp.AllpoleFilter
dsp.BiquadFilter
dsp.Channelizer
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.CICDecimator
dsp.CICInterpolator
dsp.CoupledAllpassFilter
dsp.FarrowRateConverter
dsp.FilterCascade
dsp.FIRDecimator
dsp.FIRFilter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.FIRInterpolator
dsp.FIRRateConverter
dsp.HighpassFilter
dsp.IIRFilter
dsp.IIRHalfbandDecimator
dsp.IIRHalfbandInterpolator
dsp.LowpassFilter

Filter System objects
dsp.NotchPeakFilter
dsp.VariableBandwidthFIRFilter
dsp.VariableBandwidthIIRFilter

**n**

Number of samples. For an FIR filter where n is a power of two, the computation is done faster using FFTs.

**Default:** 8192

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### Arithmetic — Value types:

'double' | 'single' | 'fixed'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depend on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

### Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.

System Object State	Coefficient Data Type	Rule
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataProperty property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataProperty property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Output Arguments

### gd

Group delay vector of length  $n$ . If  $n$  is not specified, the function uses a default value of 8192.

### w

Frequency vector of length  $n$ , in radians/sample.  $w$  consists of  $n$  points equally spaced around the upper half of the unit circle (from 0 to  $\pi$  radians/sample). If  $n$  is not specified, the function uses a default value of 8192.

# help

Help for design method with filter specification

## Syntax

```
help(d, 'designmethod')
```

## Description

`help(d, 'designmethod')` displays help in the command window for the design algorithm `designmethod` for the current specifications of the filter specification object `d`. `designmethod` must be one of the design algorithms returned by `designmethods` for `d`, the design object.

## Examples

### Get Help for Designing Butterworth Filters

Get specific help for designing lowpass Butterworth filters.

The first lowpass filter uses the default specification 'Fp,Fst,Ap,Ast' and returns help text specific to the specification.

```
d = fdesign.lowpass;  
designmethods(d, 'Systemobject', true)
```

Design Methods that support System objects for class `fdesign.lowpass (Fp,Fst,Ap,Ast)`:

```
butter  
cheby1  
cheby2  
ellip  
equiripple  
ifir
```

kaiserwin  
multistage

`help(d, 'butter')`

DESIGN Design a Butterworth IIR filter.

HD = DESIGN(D, 'butter') designs a Butterworth filter specified by the FDESIGN object D, and returns the DFILT/MFILT object HD.

HD = DESIGN(D, ..., 'SystemObject', true) implements the filter, HD, using a System object instead of a DFILT/MFILT object.

HD = DESIGN(..., 'FilterStructure', STRUCTURE) returns a filter with the structure STRUCTURE. STRUCTURE is 'df2sos' by default and can be any of the following:

```
'df1sos'  
'df2sos'  
'df1tsos'  
'df2tsos'  
'cascadeallpass'  
'cascadewdfallpass'
```

Some of the listed structures may not be supported by System object filters. Type `validstructures(D, 'butter', 'SystemObject', true)` to get a list of structures supported by System objects.

HD = DESIGN(..., 'MatchExactly', MATCH) designs a Butterworth filter and matches the frequency and magnitude specification for the band MATCH exactly. The other band will exceed the specification. MATCH can be 'stopband' or 'passband' and is 'stopband' by default.

HD = DESIGN(..., 'SOSScaleNorm', NORM) designs an SOS filter and scales the coefficients using the P-Norm NORM. NORM can be either a discrete-time-domain norm or a frequency-domain norm. Valid time-domain norms are 'l1', 'l2', and 'linf'. Valid frequency-domain norms are 'L1', 'L2', and 'Linf'. Note that L2-norm is equal to l2-norm (Parseval's theorem) but the same is not true for other norms.

The different norms can be ordered in terms of how stringent they are as follows: 'l1' >= 'Linf' >= 'L2' = 'l2' >= 'L1' >= 'linf'. Using the most stringent scaling, 'l1', the filter is the least prone to overflow, but also has the worst signal-to-noise ratio. Linf-scaling is the most commonly used scaling in practice.

Scaling is turned off by default, which is equivalent to setting `SOSScaleNorm = ''`.

`HD = DESIGN(..., 'SOSScaleOpts', OPTS)` designs an SOS filter and scales the coefficients using an `FDOPTS.SOSSCALING` object `OPTS`. Scaling options are:

Property	Default	Description/Valid values
'sosReorder'	'auto'	Reorder section prior to scaling. {'auto', 'none', 'up', 'down', 'lowpass', 'highpass', 'bandpass', 'bandstop'}
'MaxNumerator'	2	Maximum value for numerator coefficients
'NumeratorConstraint'	'none'	{'none', 'unit', 'normalize', 'po2'}
'OverflowMode'	'wrap'	{'wrap', 'saturate'}
'ScaleValueConstraint'	'unit'	{'unit', 'none', 'po2'}
'MaxScaleValue'	'Not used'	Maximum value for scale values

When `sosReorder` is set to 'auto', the sections will be automatically reordered depending on the response type of the design (lowpass, highpass, etc.).

Note that 'MaxScaleValue' will only be used when 'ScaleValueConstraint' is set to something other than 'unit'. If 'MaxScaleValue' is set to a number, the 'ScaleValueConstraint' will be changed to 'none'. Further, if `SOSScaleNorm` is off (as it is by default), then all the `SOSScaleOpts` will be ignored.

For more information about P-Norm and scaling options see help for `DFILT\SCALE`.

```
% Example #1 - Compare passband and stopband MatchExactly.
h      = fdesign.lowpass('Fp,Fst,Ap,Ast', .1, .3, 1, 60);
Hd     = design(h, 'butter', 'MatchExactly', 'passband');
Hd(2) = design(h, 'butter', 'MatchExactly', 'stopband');

% Compare the passband edges in FVTool.
fvtool(Hd);
axis([.09 .11 -2 0]);
```

Note the discussion of the `MatchExactly` input option. When you use a design object that uses a different specification, such as 'N,F3dB', the help content for the butter design method changes.

In this case, the `MatchExactly` option does not appear in the help because it is not an available input argument for the specification 'N,F3dB'.

```
d = fdesign.lowpass('N,F3dB')
```

```
d =  
  lowpass with properties:  
  
      Response: 'Lowpass'  
  Specification: 'N,F3dB'  
    Description: {2x1 cell}  
  NormalizedFrequency: 1  
      FilterOrder: 10  
          F3dB: 0.5000
```

```
designmethods(d,'Systemobject',true)
```

Design Methods that support System objects for class `fdesign.lowpass (N,F3dB)`:

```
butter  
maxflat
```

```
help(d,'butter')
```

DESIGN Design a Butterworth IIR filter.

HD = DESIGN(D, 'butter') designs a Butterworth filter specified by the FDESIGN object D, and returns the DFILT/MFILT object HD.

HD = DESIGN(D, ..., 'SystemObject', true) implements the filter, HD, using a System object instead of a DFILT/MFILT object.

HD = DESIGN(..., 'FilterStructure', STRUCTURE) returns a filter with the structure STRUCTURE. STRUCTURE is 'df2sos' by default and can be any of the following:

```
'df1sos'  
'df2sos'  
'df1tsos'  
'df2tsos'  
'cascadeallpass'  
'cascadewdfallpass'
```

Some of the listed structures may not be supported by System object

filters. Type `validstructures(D, 'butter', 'SystemObject', true)` to get a list of structures supported by System objects.

`HD = DESIGN(..., 'SOSScaleNorm', NORM)` designs an SOS filter and scales the coefficients using the P-Norm `NORM`. `NORM` can be either a discrete-time-domain norm or a frequency-domain norm. Valid time-domain norms are `'l1'`, `'l2'`, and `'linf'`. Valid frequency-domain norms are `'L1'`, `'L2'`, and `'Linf'`. Note that L2-norm is equal to l2-norm (Parseval's theorem) but the same is not true for other norms.

The different norms can be ordered in terms of how stringent they are as follows: `'l1' >= 'Linf' >= 'L2' = 'l2' >= 'L1' >= 'linf'`. Using the most stringent scaling, `'l1'`, the filter is the least prone to overflow, but also has the worst signal-to-noise ratio. `Linf`-scaling is the most commonly used scaling in practice.

Scaling is turned off by default, which is equivalent to setting `SOSScaleNorm = ''`.

`HD = DESIGN(..., 'SOSScaleOpts', OPTS)` designs an SOS filter and scales the coefficients using an `FDOPTS.SOSSCALING` object `OPTS`. Scaling options are:

Property	Default	Description/Valid values
-----	-----	-----
'sosReorder'	'auto'	Reorder section prior to scaling. {'auto', 'none', 'up', 'down', 'lowpass', 'highpass', 'bandpass', 'bandstop'}
'MaxNumerator'	2	Maximum value for numerator coefficients
'NumeratorConstraint'	'none'	{'none', 'unit', 'normalize', 'po2'}
'OverflowMode'	'wrap'	{'wrap', 'saturate'}
'ScaleValueConstraint'	'unit'	{'unit', 'none', 'po2'}
'MaxScaleValue'	'Not used'	Maximum value for scale values

When `sosReorder` is set to `'auto'`, the sections will be automatically reordered depending on the response type of the design (lowpass, highpass, etc.).

Note that `'MaxScaleValue'` will only be used when `'ScaleValueConstraint'` is set to something other than `'unit'`. If `'MaxScaleValue'` is set to a number, the `'ScaleValueConstraint'` will be changed to `'none'`. Further, if `SOSScaleNorm` is off (as it is by default), then all the `SOSScaleOpts` will be ignored.

For more information about P-Norm and scaling options see help for `DFILT\SCALE`.

```
% Example #1 - Design a lowpass Butterworth filter in the DF2TSOS structure.  
h = fdesign.lowpass('N,F3dB');  
Hd = design(h, 'butter', 'FilterStructure', 'df2tsos');
```

# hide

**Package:** dsp

Hide scope window

## Syntax

```
hide(scope)
```

## Description

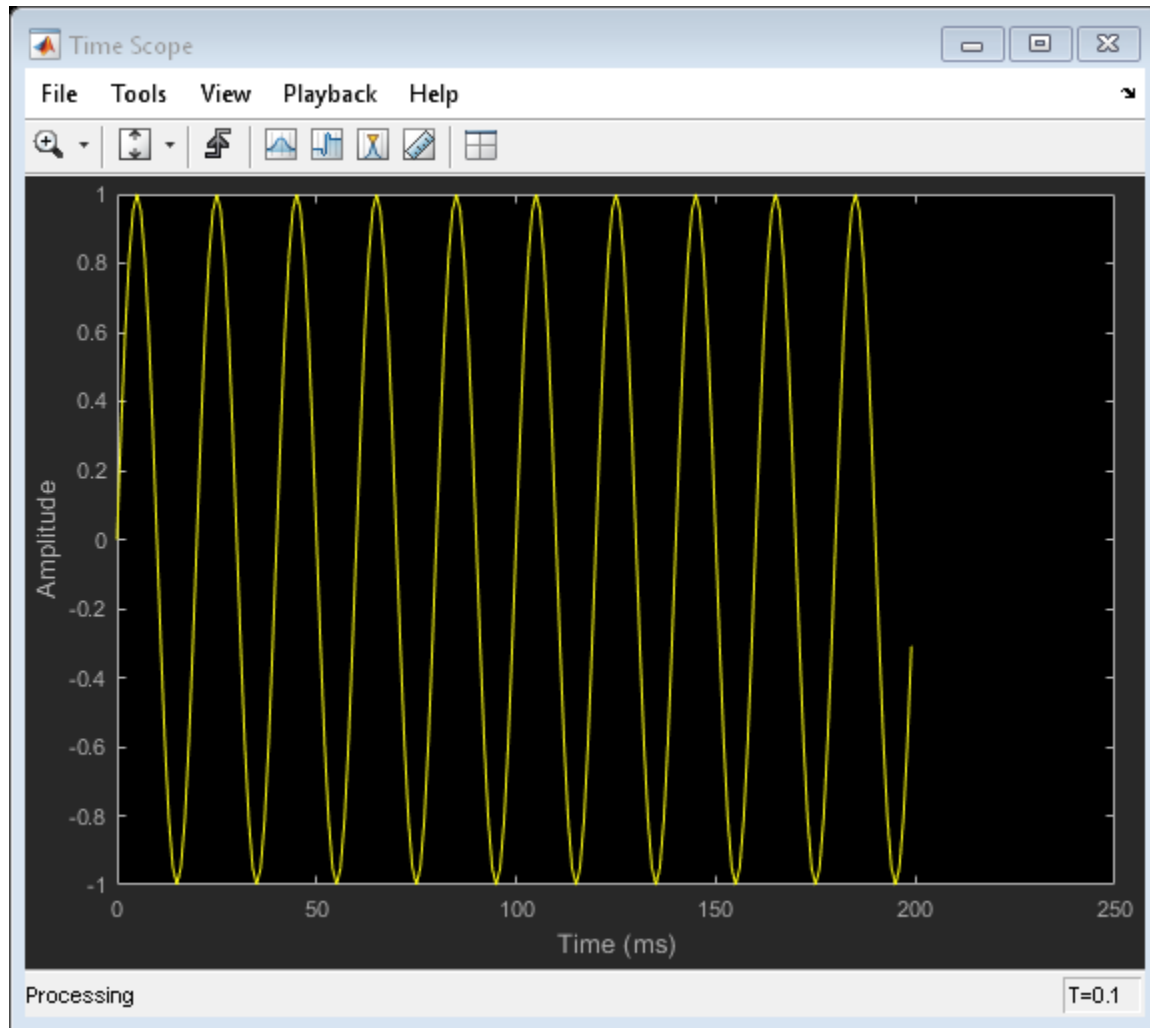

hide(scope) hides the window of the System object scope.

## Examples

### Hide and Show Time Scope

Create a sine wave signal and view it in the scope.

```
Fs = 1000; % Sampling frequency
signal = dsp.SineWave('Frequency',50,'SampleRate',Fs,'SamplesPerFrame',100);
scope = dsp.TimeScope(1,Fs,'TimeSpan',0.25,'YLimits',[-1 1]);
for ii = 1:2
    xsine = signal();
    scope(xsine)
end
```

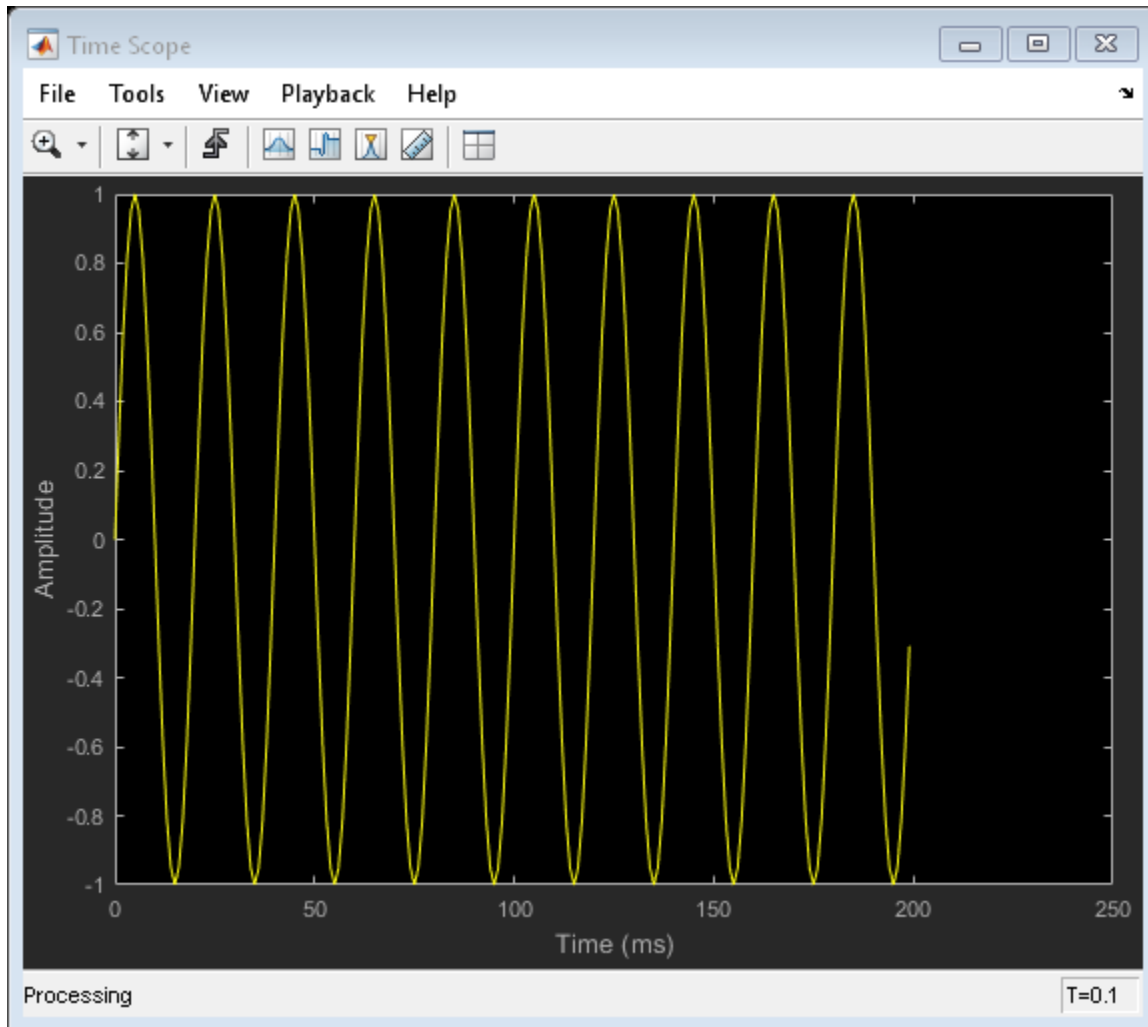

Hide the scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the scope window.

```
if(~isVisible(scope))
    show(scope)
end
```

Clean up workspace variables.

```
clear scope Fs sine ii xsine
```

## Input Arguments

**scope** — Scope System object

System object

Scope System object whose window you want to hide.

Example: `myScope = dsp.TimeScope; hide(myScope)`

# ifir

Interpolated FIR filter design

## Syntax

```
[h,g] = ifir(l,type,f,dev)
[h,g,d] = ifir(l,type,f,dev)
[...] = ifir(...,str)
```

## Description

`[h,g] = ifir(l,type,f,dev)` designs a periodic filter  $h(z^l)$ , where  $l$  is the interpolation factor. It also finds an image-suppressor filter  $g(z)$ , such that the cascade of the two filters represents the optimal minimax FIR approximation of the desired response. This response is specified by `type`, with band edge frequencies contained in vector `f`. This is done while not exceeding the maximum deviations or ripples (linear) specified in vector `dev`.

When `type` is set to 'low', the filter design is a lowpass design. When `type` is set to 'high', the filter design is a highpass design. `f` is a two-element vector with passband and stopband edge frequency values. For narrowband lowpass filters and wideband highpass filters,  $l \times f(2)$  is less than 1. For wideband lowpass filters and narrowband highpass filters, specify `f` so that  $l \times (1 - f(1))$  is less than 1.

`dev` is a two-element vector that contains the peak ripple or deviation (in linear units) allowed for both the passband and the stopband.

The `ifir` design algorithm achieves an efficient design in the sense that it reduces the total number of multipliers required. To do this, the design problem is broken into two stages. In the first stage, the filter is upsampled to achieve the stringent specifications without using many multipliers. In the second stage, the filter removes the images created when upsampling the previous filter.

`[h,g,d] = ifir(l,type,f,dev)` returns a delay `d` that is connected in parallel with the cascade of  $h(z^l)$  and  $g(z)$  for both wideband lowpass and highpass filters. This is necessary to obtain the desired response.

[...] = `ifir(...,str)` uses `str` to choose the algorithm level of optimization used. Possible values for `str` are 'simple', 'intermediate' (default) or 'advanced'. `str` provides for a tradeoff between design speed and filter order optimization. The 'advanced' option can result in substantial filter order reduction, especially for  $g(z)$ .

## Examples

### Narrowband lowpass design using an interpolation factor of 6

This example shows how to use the function `ifir` to design a narrowband lowpass filter.

```
[h,g]=ifir(6,'low',[.12 .14],[.01 .001]);  
H = dsp.FIRFilter('Numerator',h);  
G = dsp.FIRFilter('Numerator',g);  
hfv = fvtool(H,G);  
legend(hfv,'Periodic Filter','Image Suppressor Filter');
```

```
Hcas = cascade(H,G);  
hfv2 = fvtool(Hcas);  
legend(hfv2,'Overall Filter');
```

### Wideband highpass design using an interpolation factor of 6

This example shows how to use `ifir` to design a wideband highpass filter.

```
[h,g,d]=ifir(6,'high',[.12 .14],[.001 .01]);
H = dsp.FIRFilter('Numerator',h); G = dsp.FIRFilter('Numerator',g);
b1 = cascade(H,G); % Branch 1
b2 = dsp.FIRFilter('Numerator',d); % Branch 2
Hoverall = freqz(b1) + freqz(b2); % Overall wideband highpass
plot(linspace(0,1,length(Hoverall)),20*log10(abs(Hoverall)))
xlabel('Normalized frequency (\times \pi) rad/s')
```

```
ylabel('Magnitude (dB)')  
title('Overall Filter');  
grid on
```

### Design a cascade of lowpass filters

This example shows how to use `fdesign.lowpass` to design a cascade of lowpass filters. After designing the filter, use `fvtool` to plot the response curve.

```
fpass = 0.2;  
fstop = 0.24;
```

```
d1 = fdesign.lowpass(fpass, fstop);  
lowpassCascade = design(d1, 'ifir', 'Systemobject', true);  
fvtool(lowpassCascade)
```

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

All inputs must be constant. Expressions or variables are allowed if their values do not change.

## iirbpc2bpc

Transform IIR complex bandpass filter to IIR complex bandpass filter with different characteristics

### Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirbpc2bpc(B,A,Wo,Wt)
```

### Description

`[Num,Den,AllpassNum,AllpassDen] = iirbpc2bpc(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the complex bandpass prototype by applying a first-order complex bandpass to complex bandpass frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with the numerator specified by `B` and the denominator specified by `A`.

This transformation effectively places two features of an original filter, located at frequencies  $W_{o1}$  and  $W_{o2}$ , at the required target frequency locations,  $W_{t1}$ , and  $W_{t2}$  respectively. It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . In most of the cases the features selected for the transformation are the band edges of the filter passbands. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

This transformation can also be used for transforming other types of filters; e.g., complex notch filters or resonators can be repositioned at two distinct desired frequencies at any place around the unit circle; e.g., in the adaptive system.

## Examples

### Shift Complex Bandpass

Design a prototype real IIR lowpass elliptic filter with a gain of about -3 dB at  $0.5\pi$  rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);
```

Create a complex passband from  $0.25\pi$  to  $0.75\pi$ .

```
[bc,ac] = iirlp2bpc(b,a,0.5,[0.25 0.75]);
```

Move the bandpass to between  $-0.3\pi$  and  $0.1\pi$ .

```
[num,den] = iirbpc2bpc(bc,ac,[0.25 0.75],[-0.3 0.1]);
```

Compare the three filters in FVTool.

```
hvft = fvtool(b,a,bc,ac,num,den);  
legend(hvft, 'Prototype', 'Positive complex band', 'Target')
```

## Arguments

Variable	Description
$B$	Numerator of the prototype lowpass filter
$A$	Denominator of the prototype lowpass filter
$w_0$	Frequency values to be transformed from the prototype filter
$w_t$	Desired frequency locations in the transformed target filter
$Num$	Numerator of the target filter

<b>Variable</b>	<b>Description</b>
<i>Den</i>	Denominator of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

**Introduced in R2011a**

## iircomb

IIR comb notch or peak filter

### Syntax

```
[num,den] = iircomb(n,bw)
[num,den] = iircomb(n,bw,ab)
[num,den] = iircomb(...,'type')
```

### Description

[num,den] = iircomb(n,bw) returns a digital notching filter with order  $n$  and with the width of the filter notch at -3 dB set to  $bw$ , the filter bandwidth. The filter order must be a positive integer.  $n$  also defines the number of notches in the filter across the frequency range from 0 to  $2\pi$  — the number of notches equals  $n+1$ .

For the notching filter, the transfer function takes the form

$$H(z) = b \frac{1 - z^{-n}}{1 - \alpha z^{-n}}$$

where  $\alpha$  and  $b$  are the positive scalars and  $n$  is the filter order or the number of notches in the filter minus 1.

The quality factor (Q factor)  $q$  for the filter is related to the filter bandwidth by  $q = \omega_0/bw$  where  $\omega_0$  is the frequency to remove from the signal.

[num,den] = iircomb(n,bw,ab) returns a digital notching filter whose bandwidth,  $bw$ , is specified at a level of  $-ab$  decibels. Including the optional input argument  $ab$  lets you specify the magnitude response bandwidth at a level that is not the default -3 dB point, such as -6 dB or 0 dB.

[num,den] = iircomb(...,'type') returns a digital filter of the specified type. The input argument `type` can be either

- 'notch' to design an IIR notch filter. Notch filters attenuate the response at the specified frequencies. This is the default type. When you omit the type input argument, `iircomb` returns a notch filter.
- 'peak' to design an IIR peaking filter. Peaking filters boost the signal at the specified frequencies.

The transfer function for peaking filters is

$$H(z) = b \frac{1 - z^{-n}}{1 + az^{-n}}$$

## Examples

### Design an IIR Notch Filter Using `iircomb`

Design and plot an IIR notch filter with 11 notches (equal to filter order plus 1) that removes a 60 Hz tone ( $f_0$ ) from a signal at 600 Hz ( $f_s$ ). For this example, set the Q factor for the filter to 35 and use it to specify the filter bandwidth.

```
fs = 600; fo = 60; q = 35; bw = (fo/(fs/2))/q;  
[b,a] = iircomb(fs/fo,bw,'notch'); % Note type flag 'notch'  
fvtool(b,a);
```

Using the Filter Visualization Tool (FVTool) generates the following plot showing the filter notches. Note the notches are evenly spaced and one falls at exactly 60 Hz.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

All inputs must be constant. Expressions or variables are allowed if their values do not change.

## iirftransf

IIR frequency transformation of filter

### Syntax

```
[OutNum,OutDen] = iirftransf(OrigNum,OrigDen,FTFNum,FTFDen)
```

### Description

`[OutNum,OutDen] = iirftransf(OrigNum,OrigDen,FTFNum,FTFDen)` returns the numerator and denominator vectors, `OutNum` and `OutDen`, of the target filter, which is the result of transforming the prototype filter specified by the numerator, `OrigNum`, and denominator, `OrigDen`, with the mapping filter given by the numerator, `FTFNum`, and the denominator, `FTFDen`. If the allpass mapping filter is not specified, then the function returns an original filter.

### Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);  
[AlpNum, AlpDen] = allpasslp2lp(0.5, 0.25);  
[num, den] = iirftransf(b, a, AlpNum, AlpDen);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

Here's the comparison between the filters.

## Arguments

Variable	Description
<i>OrigNum</i>	Numerator of the prototype lowpass filter
<i>OrigDen</i>	Denominator of the prototype lowpass filter
<i>FTFNum</i>	Numerator of the mapping filter
<i>FTFDen</i>	Denominator of the mapping filter
<i>OutNum</i>	Numerator of the target filter
<i>OutDen</i>	Denominator of the target filter

# iirgrpdelay

Optimal IIR filter with prescribed group-delay

## Syntax

```
[num,den] = iirgrpdelay(n,f,edges,a)
[num,den] = iirgrpdelay(n,f,edges,a,w)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden,tau)
[num,den,tau] = iirgrpdelay(n,f,edges,a,w)
```

## Description

`[num,den] = iirgrpdelay(n,f,edges,a)` returns an allpass IIR filter of order  $n$  ( $n$  must be even) which is the best approximation to the relative group-delay response described by  $f$  and  $a$  in the least- $p$ th sense.  $f$  is a vector of frequencies between 0 and 1 and  $a$  is specified in samples. The vector  $edges$  specifies the band-edge frequencies for multi-band designs. `iirgrpdelay` uses a constrained Newton-type algorithm. Always check your resulting filter using `grpdelay` or `freqz`.

`[num,den] = iirgrpdelay(n,f,edges,a,w)` uses the weights in  $w$  to weight the error.  $w$  has one entry per frequency point and must be the same length as  $f$  and  $a$ ). Entries in  $w$  tell `iirgrpdelay` how much emphasis to put on minimizing the error in the vicinity of each specified frequency point relative to the other points.

$f$  and  $a$  must have the same number of elements.  $f$  and  $a$  can contain more elements than the vector  $edges$  contains. This lets you use  $f$  and  $a$  to specify a filter that has any group-delay contour within each band.

`[num,den] = iirgrpdelay(n,f,edges,a,w,radius)` returns a filter having a maximum pole radius equal to `radius`, where  $0 < \text{radius} < 1$ . `radius` defaults to 0.999999. Filters whose pole radius you constrain to be less than 1.0 can better retain transfer function accuracy after quantization.

`[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p)`, where `p` is a two-element vector `[pmin pmax]`, lets you determine the minimum and maximum values of `p` used in the least-pth algorithm. `p` defaults to `[2 128]` which yields filters very similar to the L-infinity, or Chebyshev, norm. `pmin` and `pmax` should be even. If `p` is 'inspect', no optimization occurs. You might use this feature to inspect the initial pole/zero placement.

`[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens)` specifies the grid density `dens` used in the optimization process. The number of grid points is `(dens*(n+1))`. The default is 20. `dens` can be specified as a single-element cell array. The grid is not equally spaced.

`[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden)` allows you to specify the initial estimate of the denominator coefficients in vector `initden`. This can be useful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating `initden`.

`[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden,tau)` allows the initial estimate of the group delay offset to be specified by the value of `tau`, in samples.

`[num,den,tau] = iirgrpdelay(n,f,edges,a,w)` returns the resulting group delay offset. In all cases, the resulting filter has a group delay that approximates `[a + tau]`. Allpass filters can have only positive group delay and a non-zero value of `tau` accounts for any additional group delay that is needed to meet the shape of the contour specified by `(f,a)`. The default for `tau` is `max(a)`.

Hint: If the zeros or poles cluster together, your filter order may be too low or the pole radius may be too small (overly constrained). Try increasing `n` or `radius`.

For group-delay equalization of an IIR filter, compute `a` by subtracting the filter's group delay from its maximum group delay. For example,

```
[be,ae] = ellip(4,1,40,0.2);
f = 0:0.001:0.2;
g = grpdelay(be,ae,f,2); % Equalize only the passband.
a = max(g)-g;
[num,den]=iirgrpdelay(8, f, [0 0.2], a);
```

## iirlinphase

Quasi-linear phase IIR filter from halfband filter specification

### Syntax

```
iirlinFilter= design(d,'iirlinphase','SystemObject',true)
hd = design(...,'filterstructure',structure,'SystemObject',true)
```

### Description

`iirlinFilter= design(d,'iirlinphase','SystemObject',true)` designs a quasi-linear phase filter `iirlinFilter` specified by the filter specification object `d`.

`hd = design(...,'filterstructure',structure,'SystemObject',true)` returns a filter with the structure specified by `structure`. By default, the filter structure is a cascade structure. The following table lists all the structures `design` supports for the IIR linear phase response.

Structure	Filter Structure
<code>cascadeallpass</code>	Cascade of allpass filters
<code>cascadewdfallpass</code>	Cascade of allpass wave digital filters
<code>iirdecim</code>	IIR polyphase decimator
<code>iirwdfdecim</code>	IIR wave digital filter polyphase decimator
<code>iirinterp</code>	IIR polyphase interpolator
<code>iirwdfinterp</code>	IIR wave digital filter polyphase interpolator

To get a list of all the structures the specific `fdesign` method supports, type the following in the MATLAB command prompt.

```
d = fdesign.halfband;
strucs = validstructures(d,'SystemObject',true);
```

To get a list of structures `iirlinphase` supports, type the following in the MATLAB command prompt.

```
iirlinphaseStrucs = strucs.iirlinphase;
```

## Examples

### Design a Minimum-order Halfband IIR Filter

Design a quasi-linear phase, minimum-order halfband IIR filter with transition width of 0.36 and stopband attenuation of at least 80 dB.

```
tw = 0.36;  
ast = 80;  
d = fdesign.halfband('tw,ast',tw,ast); % Transition width,  
                                     % stopband attenuation.  
halfbandIIR = design(d,'iirlinphase','SystemObject',true);  
fvtool(halfbandIIR)
```

Notice the characteristic halfband nature of the ripple in the stopband. If you measure the resulting filter, you see it meets the specifications.

```
measure(halfbandIIR)
```

```
ans =
Sample Rate      : N/A (normalized frequency)
Passband Edge    : 0.32
3-dB Point       : 0.5
6-dB Point       : 0.51911
Stopband Edge    : 0.68
Passband Ripple  : 4.0866e-08 dB
Stopband Atten.  : 80.2642 dB
```

Transition Width : 0.36

## iirlp2bp

Transform IIR lowpass filter to IIR bandpass filter

### Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2bp(B,A,Wo,Wt)
```

### Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2bp(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a second-order real lowpass to real bandpass frequency mapping.

It also returns the numerator, `AllpassNum`, and the denominator `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . This transformation implements the “DC Mobility,” meaning that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of  $W_t$ s.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature: the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Real lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies.

## Examples

### Transform Lowpass Filter to Bandpass Filter

Design a prototype real IIR lowpass elliptic filter with a gain of about -3 dB at  $0.5\pi$  rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);
```

Create a real bandpass filter by placing the cutoff frequencies of the prototype filter at  $0.25\pi$  and  $0.75\pi$ .

```
[num,den] = iirlp2bp(b,a,0.5,[0.25 0.75]);
```

Compare the magnitude responses of the filters using FVTool.

```
hvft = fvtool(b,a,num,den);  
legend(hvft, 'Prototype', 'Target')
```

## Arguments

Variable	Description
$B$	Numerator of the prototype lowpass filter
$A$	Denominator of the prototype lowpass filter
$w_0$	Frequency value to be transformed from the prototype filter
$w_t$	Desired frequency locations in the transformed target filter
$Num$	Numerator of the target filter

Variable	Description
<i>Den</i>	Denominator of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## iirlp2bpc

IIR lowpass to complex bandpass transformation

### Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2bpc(B,A,Wo,Wt)
```

### Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2bpc(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to complex bandpass frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; for example real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex

notches/resonators. This transformation can be used for designing bandpass filters for radio receivers from the high-quality prototype lowpass filter.

## Examples

### Transform Lowpass Filter to Complex Bandpass Filter

Design a prototype real IIR lowpass elliptic filter with a gain of about -3 dB at  $0.5\pi$  rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);
```

Create a complex bandpass filter by placing the cutoff frequencies of the prototype filter at  $0.25\pi$  and  $0.75\pi$ .

```
[num,den] = iirlp2bpc(b,a,0.5,[0.25 0.75]);
```

Compare the magnitude responses of the filters using FVTool.

```
hvft = fvtool(b,a,num,den);  
legend(hvft, 'Prototype', 'Target')
```

## Arguments

Variable	Description
$B$	Numerator of the prototype lowpass filter
$A$	Denominator of the prototype lowpass filter
$\omega_0$	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

<b>Variable</b>	<b>Description</b>
<i>Wt</i>	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
<i>Num</i>	Numerator of the target filter
<i>Den</i>	Denominator of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

## iirlp2bs

Transform IIR lowpass filter to IIR bandstop filter

### Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2bs(B,A,Wo,Wt)
```

### Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2bs(B,A,Wo,Wt)` returns the numerator and denominator vectors, Num and Den of the bandstop digital filter. AllpassNum and AllpassDen are the vectors of numerator and denominator coefficients of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by B and a denominator specified by A.

This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

This transformation implements the "Nyquist Mobility," which means that the DC feature stays at DC, but the Nyquist feature moves to a location dependent on the selection of  $W_o$  and  $W_t$ s.

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . After the transformation feature  $F_2$  will precede  $F_1$  in the target filter. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

For more details on the lowpass to bandstop frequency transformation, see "Digital Frequency Transformations".

## Examples

### Transform Lowpass Filter to Bandstop Filter

Design a prototype real IIR lowpass elliptic filter with a gain of about -3 dB at  $0.5\pi$  rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);
```

Create a bandstop filter by placing the cutoff frequencies of the prototype filter at  $0.25\pi$  and  $0.75\pi$ .

```
[num,den] = iirlp2bs(b,a,0.5,[0.25 0.75]);
```

Compare the magnitude responses of the filters using FVTool.

```
fvt = fvtool(b,a,num,den);  
legend(fvt, 'Prototype', 'Target')
```

## Arguments

Variable	Description
$B$	Numerator of the prototype lowpass filter
$A$	Denominator of the prototype lowpass filter
$w_0$	Frequency value to be transformed from the prototype filter
$w_t$	Desired frequency locations in the transformed target filter
$Num$	Numerator of the target filter

Variable	Description
<i>Den</i>	Denominator of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## iirlp2bsc

Transform IIR lowpass filter to IIR complex bandstop filter

### Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2bsc(B,A,Wo,Wt)
```

### Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2bsc(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to complex bandstop frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and the denominator specified by `A`.

This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . Additionally the transformation swaps passbands with stopbands in the target filter.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/

resonators. This transformation can be used for designing bandstop filters for band attenuation or frequency equalizers, from the high-quality prototype lowpass filter.

## Examples

### Transform Lowpass Filter to Complex Bandstop Filter

Design a prototype real IIR lowpass elliptic filter with a gain of about -3 dB at  $0.5\pi$  rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);
```

Create a complex bandstop filter by placing the cutoff frequencies of the prototype filter at  $-0.25\pi$  and  $0.75\pi$ .

```
[num,den] = iirlp2bsc(b,a,0.5,[-0.25 0.75]);
```

Compare the magnitude responses of the filters using FVTool.

```
fvt = fvtool(b,a,num,den);  
legend(fvt, 'Prototype', 'Target')
```

## Arguments

Variable	Description
$B$	Numerator of the prototype lowpass filter
$A$	Denominator of the prototype lowpass filter
$W_0$	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

<b>Variable</b>	<b>Description</b>
<i>Wt</i>	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
<i>Num</i>	Numerator of the target filter
<i>Den</i>	Denominator of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

## iirlp2hp

Transform lowpass IIR filter to highpass filter

### Syntax

```
[num,den] = iirlp2hp(b,a,wc,wd)
```

### Description

`[num,den] = iirlp2hp(b,a,wc,wd)` with input arguments `b` and `a`, the numerator and denominator coefficients (zeros and poles) for a lowpass IIR filter, `iirlp2hp` transforms the magnitude response from lowpass to highpass. `num` and `den` return the coefficients for the transformed highpass filter. For `wc`, enter a selected frequency from your lowpass filter. You use the chosen frequency to define the magnitude response value you want in the highpass filter. Enter one frequency for the highpass filter — the value that defines the location of the transformed point — in `wd`. Note that all frequencies are normalized between zero and one. Notice also that the filter order does not change when you transform to a highpass filter.

When you select `wc` and designate `wd`, the transformation algorithm sets the magnitude response at the `wd` values of your bandstop filter to be the same as the magnitude response of your lowpass filter at `wc`. Filter performance between the values in `wd` is not specified, except that the stopband retains the ripple nature of your original lowpass filter and the magnitude response in the stopband is equal to the peak response of your lowpass filter. To accurately specify the filter magnitude response across the stopband of your bandpass filter, use a frequency value from within the stopband of your lowpass filter as `wc`. Then your bandstop filter response is the same magnitude and ripple as your lowpass filter stopband magnitude and ripple.

The fact that the transformation retains the shape of the original filter is what makes this function useful. If you have a lowpass filter whose characteristics, such as rolloff or passband ripple, particularly meet your needs, the transformation function lets you create a new filter with the same characteristic performance features, but in a highpass version. Without designing the highpass filter from the beginning.

In some cases transforming your filter may cause numerical problems, resulting in incorrect conversion to the highpass filter. Use `fvtool` to verify the response of your converted filter.

## Examples

### Transform Lowpass Filter to Highpass Filter

This example transforms an IIR filter from lowpass to highpass by moving the magnitude response at one frequency in the source filter to a new location in the transformed filter.

Generate a least P-norm optimal IIR lowpass filter with varying attenuation levels in the stopband. Specify a numerator order of 10 and a denominator order of 6. Visualize the magnitude response of the filter.

```
[b,a] = iirlpnorm(10,6,[0 0.0175 0.02 0.0215 0.025 1], ...  
    [0 0.0175 0.02 0.0215 0.025 1],[1 1 0 0 0 0], ...  
    [1 1 1 1 20 20]);  
fvtool(b,a)
```

To generate a highpass filter whose passband flattens out at  $0.4\pi$  rad/sample, select the frequency in the lowpass filter at  $0.0175\pi$ , the frequency where the passband starts to roll off, and move it to the new location. Compare the magnitude responses of the filters using FVTool.

```

wc = 0.0175;
wd = 0.4;
[num,den] = iirlp2hp(b,a,wc,wd);

hvft = fvtool(b,a,num,den);
legend(hvft, 'Prototype', 'Target')

```

The transition band for the highpass filter is essentially the mirror image of the transition for the lowpass filter from  $0.0175\pi$  to  $0.025\pi$ , stretched out over a wider frequency range. In the passbands, the filter share common ripple characteristics and magnitude.

# iirlp2lp

Transform lowpass IIR filter to different lowpass filter

## Syntax

```
[num,den] = iirlp2lp(b,a,wc,wd)
```

## Description

`[num,den] = iirlp2lp(b,a,wc,wd)` with input arguments `b` and `a`, the numerator and denominator coefficients (zeros and poles) for a lowpass IIR filter, `iirlp2lp` transforms the magnitude response from lowpass to highpass. `num` and `den` return the coefficients for the transformed highpass filter. For `wc`, enter a selected frequency from your lowpass filter. You use the chosen frequency to define the magnitude response value you want in the highpass filter. Enter one frequency for the highpass filter — the value that defines the location of the transformed point — in `wd`. Note that all frequencies are normalized between zero and one. Notice also that the filter order does not change when you transform to a highpass filter.

When you select `wc` and designate `wd`, the transformation algorithm sets the magnitude response at the `wd` values of your bandstop filter to be the same as the magnitude response of your lowpass filter at `wc`. Filter performance between the values in `wd` is not specified, except that the stopband retains the ripple nature of your original lowpass filter and the magnitude response in the stopband is equal to the peak response of your lowpass filter. To accurately specify the filter magnitude response across the stopband of your bandpass filter, use a frequency value from within the stopband of your lowpass filter as `wc`. Then your bandstop filter response is the same magnitude and ripple as your lowpass filter stopband magnitude and ripple.

The fact that the transformation retains the shape of the original filter is what makes this function useful. If you have a lowpass filter whose characteristics, such as rolloff or passband ripple, particularly meet your needs, the transformation function lets you create a new filter with the same characteristic performance features, but in a highpass version. Without designing the highpass filter from the beginning.

In some cases transforming your filter may cause numerical problems, resulting in incorrect conversion to the highpass filter. Use `fvtool` to verify the response of your converted filter.

## Examples

### Extend Passband of Lowpass Filter

This example transforms the passband of a lowpass IIR filter by moving the magnitude response at one frequency in the source filter to a new location in the transformed filter.

Generate a least P-norm optimal IIR lowpass filter with varying attenuation levels in the stopband. Specify a numerator order of 10 and a denominator order of 6. Visualize the magnitude response of the filter.

```
[b,a] = iirlpnorm(10,6,[0 0.0175 0.02 0.0215 0.025 1], ...  
    [0 0.0175 0.02 0.0215 0.025 1],[1 1 0 0 0 0], ...  
    [1 1 1 1 10 10]);  
fvtool(b,a)
```

To generate a lowpass filter whose passband extends out to  $0.2\pi$  rad/sample, select the frequency in the lowpass filter at  $0.0175\pi$ , the frequency where the passband starts to roll off, and move it to the new location. Compare the magnitude responses of the filters using FVTool.

```

wc = 0.0175;
wd = 0.2;
[num,den] = iirlp2lp(b,a,wc,wd);

hvft = fvtool(b,a,num,den);
legend(hvft, 'Prototype', 'Target')

```

Moving the edge of the passband from  $\pi$  to  $0.2\pi$  results in a new lowpass filter whose peak response in-band is the same as in the original filter, with the same ripple and the same absolute magnitude. The rolloff is slightly less steep and the stopband profiles are the same for both filters. The new filter stopband is a "stretched" version of the original, as is the passband of the new filter.

### Functions

firlp2hp | firlp2lp | iirlp2bp | iirlp2bs | iirlp2hp

**Introduced in R2011a**

## iirlp2mb

Transform IIR lowpass filter to IIR M-band filter

### Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2mb(B,A,Wo,Wt)
[Num,Den,AllpassNum,AllpassDen]=iirlp2mb(B,A,Wo,Wt,Pass)
```

### Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2mb(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying an `M`th-order real lowpass to real multiple bandpass frequency mapping. By default the DC feature is kept at its original location.

`[Num,Den,AllpassNum,AllpassDen]=iirlp2mb(B,A,Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the “DC Mobility” and the “Nyquist Mobility.” In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is movable.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

This transformation effectively places one feature of an original filter, located at frequency  $W_o$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Relative positions of other features of an original filter do not change in the target filter. It is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

## Examples

### Transform Lowpass Filter to Multiband Filters

Design a prototype real IIR lowpass elliptic filter with a gain of about -3 dB at  $0.5\pi$  rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);
```

Create a real multiband filter with two passbands.

```
[num1,den1] = iirlp2mb(b,a,0.5,[2 4 6 8]/10);
```

Create a real multiband filter with two stopbands.

```
[num2,den2] = iirlp2mb(b,a,0.5,[2 4 6 8]/10, 'stop');
```

Compare the magnitude responses of the filters using FVTool.

```
hvft = fvtool(b,a,num1,den1,num2,den2);  
legend(hvft, 'Prototype', 'Two passbands', 'Two stopbands')
```

## Arguments

Variable	Description
$B$	Numerator of the prototype lowpass filter
$A$	Denominator of the prototype lowpass filter
$w_0$	Frequency value to be transformed from the prototype filter
$w/t$	Desired frequency locations in the transformed target filter

Variable	Description
<i>Pass</i>	Choice ('pass' / 'stop') of passband/stopband at DC, 'pass' being the default
<i>Num</i>	Numerator of the target filter
<i>Den</i>	Denominator of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## iirlp2mbc

Transform IIR lowpass filter to IIR complex M-band filter

### Syntax

`[Num,Den,AllpassNum,AllpassDen] = iirlp2mbc(B,A,Wo,Wc)`

### Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2mbc(B,A,Wo,Wc)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying an `M`th-order real lowpass to complex multibandpass frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

This transformation effectively places one feature of an original filter, located at frequency  $W_o$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

## Examples

### Transform Lowpass Filter to Complex Multiband Filter

Design a prototype real IIR lowpass elliptic filter with a gain of about -3 dB at  $0.5\pi$  rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);
```

Create a complex multiband filter with two passbands.

```
[num,den] = iirlp2mbc(b,a,0.5,[-7 -5 6 8]/10);
```

Compare the magnitude responses of the filters using FVTool. `iirlp2mbc` replicates the desired feature at 0.5 in the lowpass filter at four locations in the multiband filter.

```
hvft = fvtool(b,a,num,den);  
legend(hvft, 'Prototype', 'Target')
```

## Arguments

Variable	Description
$B$	Numerator of the prototype lowpass filter.
$A$	Denominator of the prototype lowpass filter.
$\omega_0$	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

<b>Variable</b>	<b>Description</b>
<i>Wc</i>	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
<i>Num</i>	Numerator of the target filter.
<i>Den</i>	Denominator of the target filter.
<i>AllpassNum</i>	Numerator of the mapping filter.
<i>AllpassDen</i>	Denominator of the mapping filter.

## iirlp2xc

Transform IIR lowpass filter to IIR complex N-point filter

### Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2xc(B,A,Wo,Wt)
```

### Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2xc(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying an Nth-order real lowpass to complex multipoint frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

Parameter `N` also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places `N` features of an original filter, located at frequencies  $W_{o1}, \dots, W_{oN}$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation. For DC mobility feature  $F_2$  will precede  $F_1$  after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., a stopband edge, DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating `N` bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

## Examples

### Transform Lowpass Filter to IIR Complex N-Point Filter

Design a prototype real IIR lowpass elliptic filter with a gain of about -3 dB at  $0.5\pi$  rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);
```

Transform the lowpass filter to an IIR complex N-point filter. Compare the magnitude responses of the filters using FVTool.

```
[num,den] = iirlp2xc(b,a,[-0.5 0.5],[-0.25 0.25])
```

```
num = 1x4 complex
```

```
0.0643 - 0.0000i    0.0464 + 0.0000i    0.0464 + 0.0000i    0.0643 + 0.0000i ...
```

```
den = 1x4 complex
```

```
1.0000 + 0.0000i   -1.6918 - 0.0000i    1.2340 + 0.0000i   -0.3207 - 0.0000i ...
```

```
fvt = fvtool(b,a,num,den);
legend(fvt,'Prototype','Target')
```

The target filter has complex coefficients and is indeed a bandpass filter.

## Arguments

Variable	Description
$B$	Numerator of the prototype lowpass filter.
$A$	Denominator of the prototype lowpass filter.

<b>Variable</b>	<b>Description</b>
<i>Wo</i>	Frequency values to be transformed from the prototype filter. They should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
<i>Wt</i>	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
<i>Num</i>	Numerator of the target filter.
<i>Den</i>	Denominator of the target filter.
<i>AllpassNum</i>	Numerator of the mapping filter.
<i>AllpassDen</i>	Denominator of the mapping filter.

## iirlp2xn

Transform IIR lowpass filter to IIR real N-point filter

### Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2xn(B,A,Wo,Wt)
[Num,Den,AllpassNum,AllpassDen]= iirlp2xn(B,A,Wo,Wt,Pass)
```

### Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2xn(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying an Nth-order real lowpass to real multipoint frequency transformation, where `N` is the number of features being mapped. By default the DC feature is kept at its original location.

`[Num,Den,AllpassNum,AllpassDen]= iirlp2xn(B,A,Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility." In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is allowed to move.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with the numerator specified by `B` and the denominator specified by `A`.

Parameter `N` also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places `N` features of an original filter, located at frequencies  $W_{01}, \dots, W_{0N}$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the

distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation. For DC mobility feature  $F_2$  will precede  $F_1$  after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating  $N$  bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

## Examples

### Transform Lowpass Filter to IIR Real N-Point Filter

Design a prototype real IIR lowpass elliptic filter with a gain of about -3 dB at  $0.5\pi$  rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);
```

Transform the lowpass filter to an IIR real  $N$ -point filter. Compare the magnitude responses of the filters using FVTool.

```
[num,den] = iirlp2xn(b,a,[-0.5 0.5],[0.25 0.75]);
```

```
hvft = fvtool(b,a,num,den);  
legend(hvft, 'Prototype', 'Target')
```

## Arguments

Variable	Description
$B$	Numerator of the prototype lowpass filter
$A$	Denominator of the prototype lowpass filter
$w_0$	Frequency values to be transformed from the prototype filter
$w_t$	Desired frequency locations in the transformed target filter

Variable	Description
<i>Pass</i>	Choice ('pass' / 'stop') of passband/stopband at DC, 'pass' being the default
<i>Num</i>	Numerator of the target filter
<i>Den</i>	Denominator of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

[num,den,err] = iirlpnorm(...)
[num,den,err,sos,g] = iirlpnorm(...)
```

### Description

`[num,den] = iirlpnorm(n,d,f,edges,a)` returns a filter having a numerator order `n` and denominator order `d` which is the best approximation to the desired frequency response described by `f` and `a` in the least- $p$ th sense. The vector `edges` specifies the band-edge frequencies for multi-band designs. An unconstrained quasi-Newton algorithm is employed and any poles or zeros that lie outside of the unit circle are reflected back inside. `n` and `d` should be chosen so that the zeros and poles are used effectively. See the “Hints” on page 5-988 section. Always use `freqz` to check the resulting filter.

`[num,den] = iirlpnorm(n,d,f,edges,a,w)` uses the weights in `w` to weight the error. `w` has one entry per frequency point (the same length as `f` and `a`) which tells `iirlpnorm` how much emphasis to put on minimizing the error in the vicinity of each frequency point relative to the other points. `f` and `a` must have the same number of elements, which may exceed the number of elements in `edges`. This allows for the specification of filters having any gain contour within each band. The frequencies specified in `edges` must also appear in the vector `f`. For example,

```
[num,den] = iirlpnorm(5,12,[0 .15 .4 .5 1],[0 .4 .5 1],...
[1 1.6 1 0 0],[1 1 1 10 10])
```

is a lowpass filter with a peak of 1.6 within the passband.

`[num,den] = iirlpnorm(n,d,f,edges,a,w,p)` where `p` is a two-element vector `[pmin pmax]` allows for the specification of the minimum and maximum values of `p` used in the least-pth algorithm. Default is `[2 128]` which essentially yields the L-infinity, or Chebyshev, norm. `pmin` and `pmax` should be even. If `p` is `'inspect'`, no optimization will occur. This can be used to inspect the initial pole/zero placement.

`[num,den] = iirlpnorm(n,d,f,edges,a,w,p,dens)` specifies the grid density `dens` used in the optimization. The number of grid points is `(dens*(n+d+1))`. The default is 20. `dens` can be specified as a single-element cell array. The grid is not equally spaced.

`[num,den] = iirlpnorm(n,d,f,edges,a,w,p,dens,initnum,initden)` allows for the specification of the initial estimate of the filter numerator and denominator coefficients in vectors `initnum` and `initden`. `initnum` should be of length `n+1`, and `initden` should be of length `d+1`. This may be useful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating `initnum` and `initden`.

`[num,den,err] = iirlpnorm(...)` returns the least-p<sup>th</sup> approximation error, `err`.

`[num,den,err,sos,g] = iirlpnorm(...)` returns the second-order section representation in the matrix `sos` and gain `g`. For numerical reasons it may be beneficial to use `sos` and `g` in some cases.

```
fvtool(num,den)
```

## Hints

- This is a weighted least-p<sup>th</sup> optimization.

- Check the radii and locations of the poles and zeros for your filter. If the zeros are on the unit circle and the poles are well inside the unit circle, try increasing the order of the numerator or reducing the error weighting in the stopband.
- Similarly, if several poles have a large radii and the zeros are well inside of the unit circle, try increasing the order of the denominator or reducing the error weighting in the passband.

## iirlpnormc

Constrained least Pth-norm optimal IIR filter

### Syntax

```
[num,den] = iirlpnormc(n,d,f,edges,a)
[num,den] = iirlpnormc(n,d,f,edges,a,w)
[num,den] = iirlpnormc(n,d,f,edges,a,w,radius)
[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p)
[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p,dens)
[num,den] =
iirlpnormc(n,d,f,edges,a,w,radius,p,dens,initnum,initden)
[num,den,err] = iirlpnormc(...)
[num,den,err,sos,g] = iirlpnormc(...)
```

### Description

`[num,den] = iirlpnormc(n,d,f,edges,a)` returns a filter having numerator order `n` and denominator order `d` which is the best approximation to the desired frequency response described by `f` and `a` in the least-`p`th sense. The vector `edges` specifies the band-edge frequencies for multi-band designs. A constrained Newton-type algorithm is employed. `n` and `d` should be chosen so that the zeros and poles are used effectively. See the Hints on page 5-991 section. Always check the resulting filter using `fvtool`.

`[num,den] = iirlpnormc(n,d,f,edges,a,w)` uses the weights in `w` to weight the error. `w` has one entry per frequency point (the same length as `f` and `a`) which tells `iirlpnormc` how much emphasis to put on minimizing the error in the vicinity of each frequency point relative to the other points. `f` and `a` must have the same number of elements, which can exceed the number of elements in `edges`. This allows for the specification of filters having any gain contour within each band. The frequencies specified in `edges` must also appear in the vector `f`. For example,

```
[num,den] = iirlpnormc(5,5,[0 .15 .4 .5 1],[0 .4 .5 1],...
[1 1.6 1 0 0],[1 1 1 10 10])
```

designs a lowpass filter with a peak of 1.6 within the passband.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius)` returns a filter having a maximum pole radius of `radius` where  $0 < \text{radius} < 1$ . `radius` defaults to 0.999999. Filters that have a reduced pole radius may retain better transfer function accuracy after you quantize them.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p)` where `p` is a two-element vector `[pmin pmax]` allows for the specification of the minimum and maximum values of `p` used in the least-pth algorithm. Default is `[2 128]` which essentially yields the L-infinity, or Chebyshev, norm. `pmin` and `pmax` should be even. If `p` is `'inspect'`, no optimization will occur. This can be used to inspect the initial pole/zero placement.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p,dens)` specifies the grid density `dens` used in the optimization. The number of grid points is  $(\text{dens} * (n+d+1))$ . The default is 20. `dens` can be specified as a single-element cell array. The grid is not equally spaced.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p,dens,initnum,initden)` allows for the specification of the initial estimate of the filter numerator and denominator coefficients in vectors `initnum` and `initden`. This may be useful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating `initnum` and `initden`.

`[num,den,err] = iirlpnormc(...)` returns the least-Pth approximation error `err`.

`[num,den,err,sos,g] = iirlpnormc(...)` returns the second-order section representation in the matrix `SOS` and gain `G`. For numerical reasons you may find `SOS` and `G` beneficial in some cases.

## Hints

- This is a weighted least-pth optimization.
- Check the radii and location of the resulting poles and zeros.
- If the zeros are all on the unit circle and the poles are well inside of the unit circle, try increasing the order of the numerator or reducing the error weighting in the stopband.
- Similarly, if several poles have a large radius and the zeros are well inside of the unit circle, try increasing the order of the denominator or reducing the error weight in the passband.

- If you reduce the pole radius, you might need to increase the order of the denominator.

The message

Poorly conditioned matrix. See the "help" file.

indicates that `iirlpnormc` cannot accurately compute the optimization because either:

- a** The approximation error is extremely small (try reducing the number of poles or zeros — refer to the hints above).
- b** The filter specifications have huge variation, such as `a=[1 1e9 0 0]`.

## Examples

### Magnitude Response of Constrained Least Pth-norm Optimal IIR Filter

This example returns a lowpass filter whose pole radius is constrained to 0.8.

```
[b,a,err,s,g] = iirlpnormc(6,6,[0 .4 .5 1],[0 .4 .5 1],...  
[1 1 0 0],[1 1 1 1],.8);  
fvtool(b,a);
```

The magnitude response shows the lowpass nature of the filter. The pole/zero plot following shows that the poles are constrained to 0.8 as specified in the command.

```
fvtool(b,a,'polezero');
```

## iirls

Least-squares IIR filter from specification object

### Syntax

```
hd = design(d,'iirls','SystemObject',true)
hd =
design(d,'iirls',designoption,value,designoption,value,...,'SystemObject',true)
```

### Description

`hd = design(d,'iirls','SystemObject',true)` designs a least-squares filter specified by the filter specification object `d`.

---

**Note** The `iirls` algorithm might not be well behaved in all cases. Experience is your best guide to determining if the resulting filter meets your needs. When you use `iirls` to design a filter, review the filter carefully to ensure that it is appropriate for your use.

---

`hd = design(d,'iirls',designoption,value,designoption,value,...,'SystemObject',true)` returns a least-squares IIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `iirls`, refer to the command line help system. For example, to get specific information about using `iirls` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'iirls')
```

## Examples

### Design a Complex Bandpass Filter

Starting from an arbitrary magnitude and phase design object `d`, generate a complex bandpass filter of order = 5. To make the example a little easier to do, use the default values for `F`, and `H`, the frequency vector and the complex desired frequency response.

```
d = fdesign.arbmagnphase('N,F,H',5)

d =
  arbmagnphase with properties:
    Response: 'Arbitrary Magnitude and Phase'
    Specification: 'N,F,H'
    Description: {3x1 cell}
    NormalizedFrequency: 1
    FilterOrder: 5
    Frequencies: [1x655 double]
    FreqResponse: [1x655 double]

fvt = design(d,'iirls','SystemObject',true);
fvtool(fvt,'freq');
legend('Magnitude','phase');
```

# iirnotch

Second-order IIR notch filter

## Syntax

```
[num,den] = iirnotch(w0,bw)
[num,den] = iirnotch(w0,bw,ab)
```

## Description

`[num,den] = iirnotch(w0,bw)` turns a digital notching filter with the notch located at  $w_0$ , and with the bandwidth at the -3 dB point set to  $bw$ . To design the filter,  $w_0$  must meet the condition  $0.0 < w_0 < 1.0$ , where 1.0 corresponds to  $\pi$  radians per sample in the frequency range.

The quality factor (Q factor)  $q$  for the filter is related to the filter bandwidth by  $q = w_0/bw$  where  $w_0$  is  $w_0$ , the frequency to remove from the signal.

`[num,den] = iirnotch(w0,bw,ab)` returns a digital notching filter whose bandwidth,  $bw$ , is specified at a level of  $-ab$  decibels. Including the optional input argument  $ab$  lets you specify the magnitude response bandwidth at a level that is not the default -3 dB point, such as -6 dB or 0 dB.

## Examples

### Design an IIR Notch Filter Using iirnotch

Design and plot an IIR notch filter that removes a 60 Hz tone ( $f_0$ ) from a signal at 300 Hz ( $f_s$ ). For this example, set the Q factor for the filter to 35 and use it to specify the filter bandwidth:

```
w0 = 60/(300/2);  bw = w0/35;
[b,a] = iirnotch(w0,bw);
fvtool(b,a);
```

The notch filter has the desired bandwidth with the notch located at 60 Hz, or  $0.4\pi$  radians per sample. Compare this plot to the comb filter plot shown on the reference page for `iircomb`.

## Extended Capabilities

## iirparameq

IIR biquad digital parametric equalizer filter

---

**Note** `iirparameq` function will be removed in a future release. Existing code using the function continues to run. For new code, use the `designParamEQ` function from Audio System Toolbox™ instead.

---

### Syntax

```
[SOS,SV] = iirparameq(N,G,Wo,BW)
```

```
[SOS,SV,B,A] = iirparameq(N,G,Wo,BW)
```

### Description

`[SOS,SV] = iirparameq(N,G,Wo,BW)` returns the coefficients of an Nth order IIR biquad digital parametric equalizer with gain `G`, center frequency `Wo`, and bandwidth `BW`. The coefficients are returned in a second-order section matrix, `SOS`, and a vector of scale values between each biquad stage, `SV`.

`[SOS,SV,B,A] = iirparameq(N,G,Wo,BW)` additionally returns a matrix of numerator fourth-order sections, `B`, and a matrix `A` of denominator fourth-order sections, `A`. These can be used in lieu of a biquad implementation and are useful for the case `Wo = 0.5`.

### Examples

#### Second-order section matrices of the parametric equalizer

Compute the second-order section matrix and scale values of a parametric equalizer.

```
[SOS,SV] = iirparameq(6,5,0.0042,0.0028)
```

```
SOS =
```

1.0000	-3.9908	5.9729	-3.9733	0.9912

### Two Equalizers Centered at Different Frequencies

Design two equalizers centered at 100 Hz and 1000 Hz respectively, both with a gain of 5 dB and a Q-factor of 1.5, for a system running at 48 kHz.

```
Fs = 48e3;  
N = 6;  
G = 5;  
Q = 1.5;  
Wo1 = 100/(Fs/2);  
Wo2 = 1000/(Fs/2);  
% Obtain the bandwidth of the equalizers from the center frequencies and  
% Q-factors.  
BW1 = Wo1/Q;  
BW2 = Wo2/Q;  
% Design the equalizers and obtain their SOS and SV values.  
[SOS1,SV1] = iirparameq(N,G,Wo1,BW1);  
[SOS2,SV2] = iirparameq(N,G,Wo2,BW2);
```

Design biquad filters using the obtained SOS and SV values.

```
BQ1 = dsp.BiquadFilter('SOSMatrix',SOS1,'ScaleValues',SV1);  
BQ2 = dsp.BiquadFilter('SOSMatrix',SOS2,'ScaleValues',SV2);
```

Plot the magnitude response of both filters using a log scale.

```
fvtool(BQ1,BQ2,'Fs',Fs,'FrequencyScale','Log');  
legend('Equalizer centered at 100 Hz','Equalizer centered at 1000 Hz');
```

### Compare Notch Filters Designed with Different Orders

Design an eighth-order notch filter and compare it to a traditional second-order notch filter designed with IIRNOTCH.

```

Fs = 44.1e3;
N = 8;
G = -inf;
Q = 1.8;
Wo = 60/(Fs/2); % Notch at 60 Hz
BW = Wo/Q; % Bandwidth occurs at -3 dB for this special case

```

```
[SOS1,SV1] = iirparameq(N,G,Wo,BW);  
[NUM,DEN] = iirnotch(Wo,BW);  
SOS2 = [NUM,DEN];
```

Design the notch filters using the SOS and SV values.

```
BQ1 = dsp.BiquadFilter('SOSMatrix',SOS1,'ScaleValues',SV1);  
BQ2 = dsp.BiquadFilter('SOSMatrix',SOS2);
```

Plot the magnitude response of both filters. The filters intersect at -3 dB point.

```
FVT = fvtool(BQ1,BQ2,'Fs',Fs,'FrequencyScale','Log');  
legend(FVT,'8th order notch filter','2nd order notch filter');
```

## Input Arguments

### **N — Order of the parametric equalizer**

even positive integer

Order of the parametric equalizer, specified as an even positive integer.

Example: 6

Example: 10

Data Types: `single` | `double`

### **G — Gain of the parametric equalizer**

real scalar

Gain of the parametric equalizer in dB, specified as a real scalar.

Example: 2

Example: -2.2

Data Types: `single` | `double`

### **Wo — Center frequency of the parametric equalizer**

real scalar

Center frequency of the parametric equalizer, specified as a real scalar in the range  $[0.0 \ 1.0]$ . A value of 1.0 corresponds to  $\pi$  radians/sample.

Example: 0.0

Example: 1.0

Data Types: `single` | `double`

### **BW — Bandwidth of the parametric equalizer**

real scalar

Bandwidth of the parametric equalizer, specified as a real scalar in the range  $[0.0 \ 1.0]$ . A value of 1.0 corresponds to  $\pi$  radians/sample.

Example: 0.0

Example: 1.0

Data Types: `single` | `double`

## Output Arguments

### **SOS — Second-order section matrix**

real-valued matrix

Second-order section matrix, returned as a real-valued  $L$ -by-6 matrix, where  $L$  is the number of second-order sections of the filter.

### **SV — Scale values between each biquad stage**

real-valued vector

Scale values between each biquad stage, returned as a real-valued vector of length  $L + 1$ .

### **B — Numerator coefficients of the fourth-order sections of the parametric equalizer**

real-valued matrix

Numerator coefficients of the fourth-order sections of the parametric equalizer, returned as a real-valued  $M$ -by-5 matrix.  $M$  is the number of fourth-order sections of the filter.

### **A — Denominator coefficients of the fourth-order sections of the parametric equalizer**

real-valued matrix

Denominator coefficients of the fourth-order sections of the parametric equalizer, returned as a real-valued  $M$ -by-5 matrix.  $M$  is the number of fourth-order sections of the filter.

## Algorithms

### High-order Parametric Equalizer

Parametric equalizers are digital filters used in audio processing for adjusting the frequency content of a sound signal. Parametric equalizers provide capabilities beyond those of graphic equalizers by allowing the adjustment of gain, center frequency, and bandwidth of each filter. In contrast, graphic equalizers allow for the adjustment of the gain of each filter only. Digital parametric audio equalizers are commonly implemented as biquadratic (second-order IIR) filters. Due to low order, biquadratic filters can present relatively large ripple or transition regions. When several filters are connected in

cascade, they can overlap with each other. In such circumstances, high-order filters are preferred. High-order filters provide flatter passbands, sharper band edges, and more control over the shape of each filter. In addition, if the order of the filter is set to two, the design changes to a special case: a traditional second-order parametric equalizer.

The figure shows the magnitude response of a second-order parametric equalizer compared with a high-order parametric equalizer.

$W_0 = 0.3 \times \pi$  radians/sample is the center frequency of the equalizer,  $BW = 0.2$  radians/sample is the bandwidth of the equalizer,  $G = 10$  is the peak gain of the equalizer,  $G_0 = 1$ , and  $G_B = (G_0^2 + G^2) / 2$ .

## Algorithm

The first step in the filter design is to design a high-order analog lowpass shelving filter that meets the specified gain and bandwidth. A high-order Butterworth filter is used for this purpose. The analog Butterworth filter is then transformed into a digital lowpass

shelving filter, and finally into a peaking equalizer that is centered at the specified peak frequency.

The design specifications for the digital equalizer are the order of the equalizer,  $N$ , the gain of the equalizer,  $G$ , the center frequency of the equalizer,  $W_0$ , and the bandwidth of the equalizer,  $BW$ .

The transfer function of the high-order parametric equalizer is given by:

$$H(z) = \left[ \frac{b_{00} + b_{01}z^{-1} + b_{02}z^{-2}}{1 + a_{01}z^{-1} + a_{02}z^{-2}} \right]^r \times \prod_{i=1}^L \left[ \frac{b_{i0} + b_{i1}z^{-1} + b_{i2}z^{-2} + b_{i3}z^{-3} + b_{i4}z^{-4}}{1 + a_{i1}z^{-1} + a_{i2}z^{-2} + a_{i3}z^{-3} + a_{i4}z^{-4}} \right]$$

where  $b_{00}$ ,  $b_{01}$ ,  $b_{02}$ ,  $a_{01}$ , and  $a_{02}$  are coefficients of the second-order section of the equalizer.  $b_{i0}$ ,  $b_{i1}$ ,  $b_{i2}$ ,  $b_{i3}$ ,  $b_{i4}$ ,  $a_{i1}$ ,  $a_{i2}$ , and  $a_{i3}$  are coefficients of the fourth-order sections of the equalizer.  $L = (N - r) / 2$ , where  $r = 1$  when  $N$  is odd, and  $r = 0$  when  $N$  is even. The fourth-order sections are factored into second-order sections so that you can implement them using biquad filters.

For more information on how coefficients are computed in terms of the design specifications, see the "Butterworth Designs" section in [1].

`dsp.ParametricEQFilter` | `iircomb` | `iirnotch` | `iirpeak`

**Introduced in R2015a**

# iirpeak

Second-order IIR peak or resonator filter

## Syntax

```
[num,den] = iirpeak(w0,bw)  
[num,den] = iirpeak(w0,bw,ab)
```

## Description

`[num,den] = iirpeak(w0,bw)` turns a second-order digital peaking filter with the peak located at  $w_0$ , and with the bandwidth at the +3 dB point set to `bw`. To design the filter,  $w_0$  must meet the condition  $0.0 < w_0 < 1.0$ , where 1.0 corresponds to  $\pi$  radians per sample in the frequency range.

The quality factor (Q factor)  $q$  for the filter is related to the filter bandwidth by  $q = w_0/bw$  where  $w_0$  is  $w_0$  the signal frequency to boost.

`[num,den] = iirpeak(w0,bw,ab)` returns a digital peaking filter whose bandwidth, `bw`, is specified at a level of `+ab` decibels. Including the optional input argument `ab` lets you specify the magnitude response bandwidth at a level that is not the default +3 dB point, such as +6 dB or 0 dB.

## Examples

### Design an IIR Peaking Filter Using `iirpeak`

Design and plot an IIR peaking filter that boosts the frequency at 1.75 KHz in a signal and has bandwidth of 500 Hz at the -3 dB point:

```
fs = 10000; wo = 1750/(fs/2); bw = 500/(fs/2);  
[b,a] = iirpeak(wo,bw);  
fvtool(b,a);
```

The peak filter has the desired gain and bandwidth at 1.75 KHz.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

All inputs must be constant. Expressions or variables are allowed if their values do not change.

[bp,ap] = iirpowcomp(b,a,c)
```

### Description

`[bp,ap] = iirpowcomp(b,a)` returns the coefficients of the power complementary IIR filter  $g(z) = bp(z)/ap(z)$  in vectors `bp` and `ap`, given the coefficients of the IIR filter  $h(z) = b(z)/a(z)$  in vectors `b` and `a`. `b` must be symmetric (Hermitian) or antisymmetric (antihermitian) and of the same length as `a`. The two power complementary filters satisfy the relation

$$|H(w)|^2 + |G(w)|^2 = 1.$$

`[bp,ap] = iirpowcomp(b,a,c)` where `c` is a complex scalar of unity magnitude, forces `bp` to satisfy the generalized hermitian property:

$$\text{conj}(bp(\text{end}:-1:1)) = c*bp.$$

When `c` is omitted, the function chooses `c` as follows:

- When `b` is real, the function chooses `c` as 1 or -1, whichever yields `bp` as real.
- When `b` is complex, `c` defaults to 1.

`ap` is always equal to `a`.

### Examples

## Power Complementary IIR Filter

```
[b,a]=cheby1(10,.5,.4);  
[bp,ap]=iirpowcomp(b,a);  
fvtool(b,a,bp,ap,'MagnitudeDisplay','Magnitude squared');  
legend('Original Filter','Power Complementary Version');
```

# iirrateup

Upsample IIR filter by integer factor

## Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirrateup(B,A,N)
```

## Description

`[Num,Den,AllpassNum,AllpassDen] = iirrateup(B,A,N)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter being transformed from any prototype by applying an `N`th-order rateup frequency transformation, where `N` is the upsample ratio. Transformation creates `N` equal replicas of the prototype filter frequency response.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

The relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);  
[num, den] = iirrateup(b, a, 4);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

As shown in the figure produced by FVTool, the transformed filter appears as expected.

## Arguments

Variable	Description
<i>B</i>	Numerator of the prototype lowpass filter
<i>A</i>	Denominator of the prototype lowpass filter
<i>N</i>	Frequency multiplication ratio
<i>Num</i>	Numerator of the target filter
<i>Den</i>	Denominator of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

## iirshift

Shift frequency response of IIR filter

### Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirshift(B,A,Wo,Wt)
```

### Description

`[Num,Den,AllpassNum,AllpassDen] = iirshift(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a second-order real shift frequency mapping.

It also returns the numerator, `AllpassNum`, and the denominator of the allpass mapping filter, `AllpassDen`. The prototype lowpass filter is given with the numerator specified by `B` and the denominator specified by `A`.

This transformation places one selected feature of an original filter located at frequency  $W_o$  to the required target frequency location,  $W_t$ . This transformation implements the "DC Mobility," which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of  $W_o$  and  $W_t$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the real shift transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way without designing them from the beginning.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Perform the real frequency shift by defining where the selected feature of the prototype filter, originally at  $W_0=0.5$ , should be placed in the target filter,  $W_t=0.75$ :

```
Wo = 0.5; Wt = 0.75;
[num, den] = iirshift(b, a, Wo, Wt);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

Shifting the specified feature from the prototype to the target generates the response shown in the figure.

## Arguments

Variable	Description
<i>B</i>	Numerator of the prototype lowpass filter
<i>A</i>	Denominator of the prototype lowpass filter
<i>wo</i>	Frequency value to be transformed from the prototype filter
<i>wt</i>	Desired frequency location in the transformed target filter
<i>Num</i>	Numerator of the target filter
<i>Den</i>	Denominator of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

# iirshiftc

Shift frequency response of IIR complex filter

## Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,Wo,Wc)
[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,0.5)
[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,-0.5)
```

## Description

`[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,Wo,Wc)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a first-order complex frequency shift transformation. This transformation rotates all the features of an original filter by the same amount specified by the location of the selected feature of the prototype filter, originally at  $W_o$ , placed at  $W_t$  in the target filter.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with the numerator specified by `B` and the denominator specified by `A`.

`[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,0.5)` calculates the allpass filter for doing the Hilbert transformation, i.e. a 90 degree counterclockwise rotation of an original filter in the frequency domain.

`[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,-0.5)` calculates the allpass filter for doing an inverse Hilbert transformation, i.e. a 90 degree clockwise rotation of an original filter in the frequency domain.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Rotate all features of the prototype filter in the frequency domain by the same amount by specifying where the selected feature of an original filter,  $W_0 = 0.5$ , should appear in the target filter,  $W_t = 0.25$ :

```
[num, den] = iirshiftc(b, a, 0.5, 0.25);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

After applying the shift, the selected feature from the original filter is just where it should be, at  $W_t = 0.25$ .

## Arguments

Variable	Description
$B$	Numerator of the prototype lowpass filter
$A$	Denominator of the prototype lowpass filter
$\omega_0$	Frequency value to be transformed from the prototype filter
$\omega_t$	Desired frequency location in the transformed target filter
$Num$	Numerator of the target filter
$Den$	Denominator of the target filter
$AllpassNum$	Numerator of the mapping filter
$AllpassDen$	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

## impz

**Package:** dsp

Impulse response of discrete-time filter System object

### Syntax

```
[impResp,t] = impz(sysobj)
[impResp,t] = impz(sysobj,n)
[impResp,t] = impz(sysobj,n,fs)
[impResp,t] = impz(sysobj,[],fs)
[impResp,t] = impz(sysobj,Name,Value)
impz(sysobj)
```

### Description

`[impResp,t] = impz(sysobj)` computes the impulse response of the filter System object, `sysobj`, and returns the response in column vector `impResp`, and a vector of times (or sample intervals) in `t`, where `t = [0 1 2 ... k-1]'`. `k` is the number of filter coefficients.

`[impResp,t] = impz(sysobj,n)` computes the impulse response at `floor(n)` 1-second intervals. The time vector `t` equals `(0:floor(n)-1)'`.

`[impResp,t] = impz(sysobj,n,fs)` computes the impulse response at `floor(n)` `1/fs`-second intervals. The time vector `t` equals `(0:floor(n)-1)'/fs`.

`[impResp,t] = impz(sysobj,[],fs)` computes the impulse response at `k 1/fs`-second intervals. `k` is the number of filter coefficients. The time vector `t` equals `(0:k-1)'/fs`.

`[impResp,t] = impz(sysobj,Name,Value)` returns an impulse response with additional options specified by one or more `Name,Value` pair arguments.

`impz(sysobj)` uses `fvtool` to plot the impulse response of the filter System object `sysobj`.

For more input options, refer to `impz` in Signal Processing Toolbox documentation.

---

**Note** You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

---

## Input Arguments

### `sysobj`

Filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
<code>dsp.AllpassFilter</code>
<code>dsp.AllpoleFilter</code>
<code>dsp.BiquadFilter</code>
<code>dsp.CICCompensationDecimator</code>
<code>dsp.CICCompensationInterpolator</code>
<code>dsp.CICDecimator</code>
<code>dsp.CICInterpolator</code>
<code>dsp.CoupledAllpassFilter</code>
<code>dsp.FarrowRateConverter</code>
<code>dsp.FilterCascade</code>
<code>dsp.FIRDecimator</code>
<code>dsp.FIRFilter</code>
<code>dsp.FIRHalfbandDecimator</code>
<code>dsp.FIRHalfbandInterpolator</code>
<code>dsp.FIRInterpolator</code>
<code>dsp.FIRRateConverter</code>
<code>dsp.HighpassFilter</code>

<b>Filter System objects</b>
<code>dsp.IIRFilter</code>
<code>dsp.IIRHalfbandDecimator</code>
<code>dsp.IIRHalfbandInterpolator</code>
<code>dsp.LowpassFilter</code>
<code>dsp.NotchPeakFilter</code>
<code>dsp.VariableBandwidthFIRFilter</code>
<code>dsp.VariableBandwidthIIRFilter</code>

**n**

Length of the impulse response vector.

**Default:** Number of filter coefficients

**fs**

Sampling frequency.

**Default:** 1

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Arithmetic — Value types:**

`'double' | 'single' | 'fixed'`

Specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'`, the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

### Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsData type property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsData type property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Output Arguments

### **impResp**

n-element impulse response vector. If n is not specified, the length of the impulse response vector equals the number of coefficients in the filter.

### **t**

Time vector of length n, in seconds. **t** consists of n equally spaced points in the range  $(0:\text{floor}(n)-1)/fs$ . If n is not specified, the function uses the number of coefficients of the filter.

## Examples

### **Plot the Impulse Response of a Lowpass Elliptic Filter**

Create a discrete-time filter for a fourth-order, lowpass elliptic filter with a cutoff frequency of 0.4 times the Nyquist frequency. Use a second-order sections structure to resist quantization errors. Plot the first 50 samples of the impulse response, along with the reference impulse response.

```
d = fdesign.lowpass(.4, .5, 1, 80);
```

Create a design object for the prototype filter. Use `ellip` to design a minimum order discrete-time biquad filter.

```
biquad = design(d, 'ellip', 'Systemobject', true);
```

Plot the impulse response.

```
impz(biquad);  
axis([1 75 -0.2 0.35])
```

## See Also

`filter` | `stepz`

Introduced in R2011a

## impzlength

Impulse response length

### Syntax

```
len = impzlength(b,a)
len = impzlength(sos)
len = impzlength(d)

len = impzlength(hs)

len = impzlength( ____,tol)
```

### Description

`len = impzlength(b,a)` returns the impulse response length for the causal discrete-time filter with the rational system function specified by the numerator, `b`, and denominator, `a`, polynomials in  $z^{-1}$ . For stable IIR filters, `len` is the effective impulse response sequence length. Terms in the IIR filter's impulse response after the `len`-th term are essentially zero.

`len = impzlength(sos)` returns the effective impulse response length for the IIR filter specified by the second order sections matrix, `sos`. `sos` is a  $K$ -by-6 matrix, where the number of sections,  $K$ , must be greater than or equal to 2. If the number of sections is less than 2, `impzlength` considers the input to be the numerator vector, `b`. Each row of `sos` corresponds to the coefficients of a second order (biquad) filter. The  $i$ th row of the `sos` matrix corresponds to `[bi(1) bi(2) bi(3) ai(1) ai(2) ai(3)]`.

`len = impzlength(d)` returns the impulse response length for the digital filter, `d`. Use `designfilt` to generate `d` based on frequency-response specifications.

`len = impzlength(hs)` returns the impulse response length for the filter System object, `hs`. You must have the DSP System Toolbox software to use `impzlength` with a filter System object.

`len = impzlength( ____,tol)` specifies a tolerance for estimating the effective length of an IIR filter's impulse response. By default, `tol` is  $5e-5$ . Increasing the value of `tol`

estimates a shorter effective length for an IIR filter's impulse response. Decreasing the value of `tol` produces a longer effective length for an IIR filter's impulse response.

## Examples

### IIR Filter Effective Impulse Response Length — Coefficients

Create a lowpass allpole IIR filter with a pole at 0.9. Calculate the effective impulse response length. Obtain the impulse response. Plot the result.

```
b = 1;  
a = [1 -0.9];  
len = impzlength(b,a)
```

```
len = 93
```

```
[h,t] = impz(b,a);  
stem(t,h)
```

`h(len)`

`ans = 6.1704e-05`

### IIR Filter Effective Impulse Response Length — Second-Order Sections

Design a 4th-order lowpass elliptic filter with a cutoff frequency of  $0.4\pi$  rad/sample. Specify 1 dB of passband ripple and 60 dB of stopband attenuation. Design the filter in pole-zero-gain form and obtain the second-order section matrix using `zp2sos`. Determine the effective impulse response sequence length from the second-order section matrix.

```
[z,p,k] = ellip(4,1,60,.4);  
[sos,g] = zp2sos(z,p,k);  
len = impzlength(sos)  
  
len = 80
```

### **IIR Filter Effective Impulse Response Length — Digital Filter**

Use `designfilt` to design a 4th-order lowpass elliptic filter with normalized passband frequency  $0.4\pi$  rad/sample. Specify 1 dB of passband ripple and 60 dB of stopband attenuation. Determine the effective impulse response sequence length and visualize it.

```
d = designfilt('lowpassiir','FilterOrder',4,'PassbandFrequency',0.4, ...  
              'PassbandRipple',1,'StopbandAttenuation',60, ...  
              'DesignMethod','ellip');  
len = impzlength(d)  
  
len = 80  
  
impz(d)
```

### Impulse Response Length of Filter System object

This example requires DSP System Toolbox™ software.

Design a 4th-order lowpass elliptic filter with a cutoff frequency of  $0.4\pi$  rad/sample. Specify 1 dB of passband ripple and 60 dB of stopband attenuation. Design the filter in pole-zero-gain form and obtain the second order section matrix using `zp2sos`. Create a biquad filter System object™ and input the System object to `impzlength`.

```
[z,p,k] = ellip(4,1,60,.4);  
[sos,g] = zp2sos(z,p,k);
```

```

hBqdFilt = dsp.BiquadFilter('Structure','Direct form I',...
                            'SOSMatrix', sos,...
                            'ScaleValues',g);
len = impzlength(hBqdFilt)
len = 80

```

### Impulse Response Length — Filter System Objects

Design IIR Butterworth and FIR equiripple filters for data sampled at 1 kHz. The passband frequency is 100 Hz and the stopband frequency is 150 Hz. The passband ripple is 0.5 dB and there is 60 dB of stopband attenuation. Obtain System objects for the filters and compare the filter impulse response sequence lengths.

```

d = fdesign.lowpass('Fp,Fst,Ap,Ast',100,150,0.5,60,1000);
Hd1 = design(d,'butter','SystemObject',true);
Hd2 = design(d,'equiripple','SystemObject',true);
len = [impzlength(Hd1) impzlength(Hd2)]

len = 1×2
    183    49

```

## Input Arguments

### **b** — Numerator coefficients

vector | scalar

Numerator coefficients, specified as a scalar (allpole filter) or a vector.

Example: `b = fir1(20,0.25)`

Data Types: `single` | `double`

Complex Number Support: Yes

### **a** — Denominator coefficients

vector | scalar

Denominator coefficients, specified as a scalar (FIR filter) or vector.

Data Types: `single` | `double`  
Complex Number Support: Yes

### **sos** — Matrix of second order sections

matrix

Matrix of second order sections, specified as a  $K$ -by-6 matrix. The system function of the  $K$ -th biquad filter has the rational Z-transform

$$H_k(z) = \frac{B_k(1) + B_k(2)z^{-1} + B_k(3)z^{-2}}{A_k(1) + A_k(2)z^{-1} + A_k(3)z^{-2}}.$$

The coefficients in the  $K$ th row of the matrix, `sos`, are ordered as follows.

$$[B_k(1) \ B_k(2) \ B_k(3) \ A_k(1) \ A_k(2) \ A_k(3)]$$

The frequency response of the filter is the system function evaluated on the unit circle with

$$z = e^{j2\pi f}.$$

### **d** — Digital filter

`digitalFilter` object

Digital filter, specified as a `digitalFilter` object. Use `designfilt` to generate a digital filter based on frequency-response specifications.

Example: `d = designfilt('lowpassiir','FilterOrder',3,'HalfPowerFrequency',0.5)` specifies a third-order Butterworth filter with normalized 3-dB frequency  $0.5\pi$  rad/sample.

### **hs** — Filter System object

filter System object

Filter System object, specified as one of the following:

The following Filter System objects are supported by this analysis function:

<b>Filter System objects</b>
dsp.AllpassFilter
dsp.AllpoleFilter
dsp.BiquadFilter
dsp.Channelizer
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.CICDecimator
dsp.CICInterpolator
dsp.CoupledAllpassFilter
dsp.FarrowRateConverter
dsp.FilterCascade
dsp.FIRDecimator
dsp.FIRFilter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.FIRInterpolator
dsp.FIRRateConverter
dsp.HighpassFilter
dsp.IIRFilter
dsp.IIRHalfbandDecimator
dsp.IIRHalfbandInterpolator
dsp.LowpassFilter
dsp.NotchPeakFilter
dsp.VariableBandwidthFIRFilter
dsp.VariableBandwidthIIRFilter

Using `impzlength` with a filter System object requires the DSP System Toolbox software.

**tol — Tolerance for IIR filter effective impulse response length**

5e-5 (default) | positive scalar

Tolerance for IIR filter effective impulse response length, specified as a positive number. The tolerance determines the term in the absolutely summable sequence after which subsequent terms are considered to be 0. The default tolerance is  $5e-5$ . Increasing the tolerance returns a shorter effective impulse response sequence length. Decreasing the tolerance returns a longer effective impulse response sequence length.

## Output Arguments

### **len** — Length of impulse response

positive integer

Length of the impulse response, specified as a positive integer. For stable IIR filters with absolutely summable impulse responses, `impzlength` returns an effective length for the impulse response beyond which the coefficients are essentially zero. You can control this cutoff point by specifying the optional `tol` input argument.

# info

Information about filter

## Syntax

```
info(obj)  
info(obj, 'short')  
info(obj, 'long')  
s = info(obj)
```

## Description

`info(obj)` returns very basic information about the filter System object, `obj`. The particulars depend on the filter type and structure.

`info(obj, 'short')` returns the same information as `info(obj)`.

`info(obj, 'long')` returns the following information about the filter:

- Specifications such as the filter structure and filter order
- Information about the design method and options
- Performance measurements for the filter response, such as the passband cutoff or stopband attenuation, included in the `measure` method
- Cost of implementing the filter in terms of operations required to apply the filter to data, included in the `cost` method

When the filter uses fixed-point arithmetic, the function returns additional information about the filter, including the arithmetic setting and details about the filter internals.

`s = info(obj)` returns filter information in the variable `s`. You can also provide the optional arguments `'short'` and `'long'` with this syntax.

## Input Arguments

### obj

One of the following types of filter System objects:

The following Filter System objects are supported by this analysis function:

<b>Filter System objects</b>
dsp.AllpassFilter
dsp.AllpoleFilter
dsp.BiquadFilter
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.CICDecimator
dsp.CICInterpolator
dsp.ComplexBandpassDecimator
dsp.CoupledAllpassFilter
dsp.FarrowRateConverter
dsp.FilterCascade
dsp.FIRDecimator
dsp.FIRFilter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.FIRInterpolator

dsp.HighpassFilter
dsp.IIRFilter
dsp.IIRHalfbandDecimator
dsp.IIRHalfbandInterpolator
dsp.LowpassFilter

Filter System objects
<code>dsp.VariableBandwidthFIRFilter</code>
<code>dsp.VariableBandwidthIIRFilter</code>

**'short'**

Input argument that instructs the function to return basic information about the filter.

**'long'**

Input argument that instructs the function to return in-depth information about the filter.

## Output Arguments

**s**

Variable for storing filter information.

## Examples

### Obtain Filter Information

Obtain short-format and long-format information about a filter.

```

## Decimate a Signal Using a CICDecimator Object

**Note:** If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a `dsp.CICDecimator` System object™ with `DecimationFactor` set to 4. Decimate a signal from 44.1 kHz to 11.025 kHz.

```
cicdec = dsp.CICDecimator(4);
cicdec.FixedPointDataType = 'Minimum section word lengths';
cicdec.OutputWordLength = 16;
```

Create a fixed-point sinusoidal input signal of 1024 samples, with a sampling frequency of 44.1e3 Hz.

```
Fs = 44.1e3;
n = (0:1023)'; % 0.0232 sec signal
x = fi(sin(2*pi*1e3/Fs*n),true,16,15);
```

Create a `dsp.SignalSource` object.

```
src = dsp.SignalSource(x,64);
```

Decimate the output with 16 samples per frame.

```
y = zeros(16,16);
for ii = 1:16
    y(ii,:) = cicdec(src());
end
```

Plot the first frame of the original and decimated signals. Output latency is 2 samples.

```
gainCIC = ...
    (cicdec.DecimationFactor*cicdec.DifferentialDelay)^cicdec.NumSections;
stem(n(1:56)/Fs,double(x(4:59)))
hold on;
stem(n(1:14)/(Fs/cicdec.DecimationFactor),double(y(1,3:end))/gainCIC,'r','filled')
xlabel('Time (sec)')
```

```
ylabel('Signal Amplitude')
legend('Original signal','Decimated signal','Location','north')
hold off;
```

Using the `info` method in 'long' format, obtain the word lengths and fraction lengths of the fixed-point filter sections and the filter output.

```
info(cicdec, 'long')
```

```
ans =
'Discrete-Time FIR Multirate Filter (real)
-----
Filter Structure      : Cascaded Integrator-Comb Decimator
Decimation Factor    : 4
```

```

Differential Delay : 1
Number of Sections : 2
Stable : Yes

Output fraction length : 11

```

## Interpolate a Signal Using CICInterpolator Object

**Note:** If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a `dsp.CICInterpolator System` object™ with `InterpolationFactor` set to 2. Interpolate signal by a factor of 2 from 22.05 kHz to 44.1 kHz.

```
cicint = dsp.CICInterpolator(2);
```

Create fixed-point sinusoidal input signal of 512 samples, with a sampling frequency 22.05 kHz.

```

Fs = 22.05e3;
n = (0:511)'; % 0.0113 sec signal
x = fi(sin(2*pi*1e3/Fs*n),true,16,15);

```

Create `dsp.SignalSource` System object.

```
src = dsp.SignalSource(x,32);
```

Interpolate the output with 64 samples per frame.

```
y = zeros(16,64);
for ii = 1:16
    y(ii,:) = cicint(src());
end
```

Plot the first frame of the original and interpolated signals. Output latency is 2 samples.

```
gainCIC = ...
    (cicint.InterpolationFactor*cicint.DifferentialDelay)...
    ^cicint.NumSections/cicint.InterpolationFactor;
stem(n(1:31)/Fs, double(x(1:31)), 'r', 'filled')
hold on;
stem(n(1:61)/(Fs*cicint.InterpolationFactor), ...
    double(y(1,4:end))/gainCIC, 'b')
xlabel('Time (sec)')
ylabel('Signal Amplitude')
legend('Original signal', 'Interpolated signal', ...
    'location', 'north')
hold off;
```

Using the `info` method in 'long' format, obtain the word lengths and fraction lengths of the fixed-point filter sections and the filter output.

```
info(cicint, 'long')
```

```
ans =
'Discrete-Time FIR Multirate Filter (real)
-----
Filter Structure      : Cascaded Integrator-Comb Interpolator

**Introduced in R2011a**

## info

**Package:** dsp

Characteristic information about valid delay range

## Syntax

```
S = info(obj)
```

## Description

`S = info(obj)` returns a structure that contains the valid delay range values of the `dsp.VariableFractionalDelay` object.

## Examples

### Obtain the Valid Delay Range

Create a `dsp.VariableFractionalDelay` object. Set the interpolation method to 'Farrow', and the maximum delay to 9. Obtain the valid delay range for these settings using the `info` method.

```
vfd = dsp.VariableFractionalDelay('InterpolationMethod','Farrow','MaximumDelay',9);  
info(vfd)
```

```
ans = struct with fields:  
    ValidDelayRange: '[1, 9]'
```

Specify the delay vector to have two taps - [0.95 10]. These values are out of the valid range. The object clips these values to [1 9] and concurrently applies the delay values to the input channel.

```
in = randn(10,1)
```

```
in = 10x1

    0.5377
    1.8339
   -2.2588
    0.8622
    0.3188
   -1.3077
   -0.4336
    0.3426
    3.5784
    2.7694

delayVec = [0.95 10]

delayVec = 1x2

    0.9500    10.0000

vfdout = vfd(in,delayVec)

vfdout = 10x2

         0         0
    0.5377         0
    1.8339         0
   -2.2588         0
    0.8622         0
    0.3188         0
   -1.3077         0
   -0.4336         0
    0.3426         0
    3.5784    0.5377
```

The output contains two channels, each being a delayed version of the input channel. The first channel is delayed by 1 sample and the second channel is delayed by 9 samples.

---

## Input Arguments

### **obj** — Input System object

`dsp.VariableFractionalDelay`

Input object, specified as a `dsp.VariableFractionalDelay` System object.

Example: `vfd = dsp.VariableFractionalDelay; info(vfd);`

## Output Arguments

### **S** — Valid delay range information

structure

Valid delay range information of the input `dsp.VariableFractionalDelay` object, returned as the `ValidDelayRange` field in the output structure `S`. `ValidDelayRange` contains the possible range of delay values based on the current property values of the object. The `ValidDelayRange` is in the format `[MinValidDelay, MaxValidDelay]`. The object clips all input delay values to be within this `ValidDelayRange`.

`dsp.VariableFractionalDelay`

**Introduced in R2012a**

# int

States from CIC filter

## Compatibility

`mfilt` will be removed in a future release. Refer to the reference page for a specific `mfilt` object to see its recommended replacement.

## Syntax

```
integerstates = int(hm.states)
```

## Description

`integerstates = int(hm.states)` returns the states of a CIC filter in matrix form, rather than as the native `filtstates` object. An important point about `int` is that it quantizes the state values to the smallest number of bits possible while maintaining the values accurately.

## Examples

For many users, the states of multirate filters are most useful as a matrix, but the CIC filters store the states as objects. Here is how you get the states from you CIC filter as a matrix.

```
hm = mfilt.cicinterp;  
hs = hm.states; % Returns a FILTSTATES.CIC object hs.  
states = int(hs); % Convert object hs to a signed integer matrix.
```

After using `int` to convert the states object to a matrix, here is what you get.

Before converting:

```
hm.states
```

```
ans =
```

```
    Integrator: [2x1 States]  
    Comb: [2x1 States]
```

After the conversion and assigning the states to `states`:

```
states
```

```
states =
```

```
    0    0  
    0    0
```

## isallpass

Determine whether filter is allpass

### Syntax

```
flag = isallpass(b,a)
flag = isallpass(sos)
flag = isallpass(d)
flag = isallpass(...,tol)
flag = isallpass(hs,...)
flag = isallpass(hs,'Arithmetic',arithtype)
```

### Description

`flag = isallpass(b,a)` returns a logical output, `flag`, equal to `true` if the filter specified by numerator coefficients, `b`, and denominator coefficients, `a`, is an allpass filter. If the filter is not an allpass filter, `flag` is equal to `false`.

`flag = isallpass(sos)` returns `true` if the filter specified by second order sections matrix, `sos`, is an allpass filter. `sos` is a  $K$ -by-6 matrix, where the number of sections,  $K$ , must be greater than or equal to 2. Each row of `sos` corresponds to the coefficients of a second order (biquad) filter. The  $i$ th row of the `sos` matrix corresponds to `[bi(1) bi(2) bi(3) ai(1) ai(2) ai(3)]`.

`flag = isallpass(d)` returns `true` if the digital filter, `d`, is an allpass filter. Use `designfilt` to generate `d` based on frequency-response specifications.

`flag = isallpass(...,tol)` uses the tolerance, `tol`, to determine when two numbers are close enough to be considered equal. If not specified, `tol`, defaults to  $\text{eps}^{(2/3)}$ . Specifying a tolerance may be most helpful in fixed-point allpass filters.

`flag = isallpass(hs,...)` returns `true` if the filter System object, `hs`, is an allpass filter. You must have the DSP System Toolbox software to use this syntax.

`flag = isallpass(hs,'Arithmetic',arithtype)` analyzes the filter System object `hs` based on the specified `arithtype`. `arithtype` can be `'double'`, `'single'`, or

'fixed'. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked. You must have the DSP System Toolbox software to use this syntax.

### Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the <code>CustomCoefficientsDataType</code> property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the <code>CustomCoefficientsDataType</code> property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Examples

### Allpass Filters

Create an allpass filter and verify that the frequency response is allpass.

```
b = [1/3 1/4 1/5 1];  
a = fliplr(b);  
flag = isallpass(b,a)
```

```
flag = logical  
      1
```

```
fvtool(b,a)
```

Create a lattice allpass filter and verify that the filter is allpass.

```
k = [1/2 1/3 1/4 1/5];  
[b,a] = latc2tf(k,'allpass');  
flag_isallpass = isallpass(b,a)
```

```
flag_isallpass = logical  
1
```

```
fvtool(b,a)
```

**Introduced in R2013a**

## isfir

Determine whether filter System object is FIR

## Syntax

```
isfir(sysobj)
```

## Description

`isfir(sysobj)` determines whether the filter System object `sysobj` is an FIR filter. If the filter is FIR, `isfir` returns 1.

To determine whether `sysobj` is an FIR filter, `isfir(sysobj)` inspects if the filter in the transfer function form has a scalar denominator. If it does, it is an FIR filter.

## Examples

### Determine Whether an FIR Filter

Design a Lowpass FIR Filter.

```
d = fdesign.lowpass;  
h = design(d, 'Systemobject', true)  
  
h =  
    dsp.FIRFilter with properties:  
        Structure: 'Direct form'  
        NumeratorSource: 'Property'  
        Numerator: [1x43 double]  
        InitialConditions: 0  
  
Show all properties
```

Determine if the filter is an FIR filter using `isfir`.

```
isfir(h)
```

```
ans = logical  
     1
```

`isfir` returns 1 to indicate that the filter is an FIR filter.

# islinphase

Determine whether filter has linear phase

## Syntax

```
flag = islinphase(b,a)
flag = islinphase(sos)
flag = islinphase(d)
flag = islinphase(...,tol)
flag = islinphase(hs,...)
flag = islinphase(hs,'Arithmetic',arithtype)
```

## Description

`flag = islinphase(b,a)` returns a logical output, `flag`, equal to `true` if the filter coefficients in `b` and `a` define a linear phase filter. `flag` is equal to `false` if the filter does not have linear phase.

`flag = islinphase(sos)` returns `true` if the filter specified by second order sections matrix, `sos`, has linear phase. `sos` is a  $K$ -by-6 matrix, where the number of sections,  $K$ , must be greater than or equal to 2. Each row of `sos` corresponds to the coefficients of a second order (biquad) filter. The  $i$ th row of the `sos` matrix corresponds to `[bi(1) bi(2) bi(3) ai(1) ai(2) ai(3)]`.

`flag = islinphase(d)` returns `true` if the digital filter, `d`, has linear phase. Use `designfilt` to generate `d` based on frequency-response specifications.

`flag = islinphase(...,tol)` uses the tolerance, `tol`, to determine when two numbers are close enough to be considered equal. If not specified, `tol`, defaults to  $\text{eps}^{(2/3)}$ .

`flag = islinphase(hs,...)` determines whether the filter System object, `hs`, has linear phase. You must have the DSP System Toolbox to use `islinphase` with a System object.

`flag = islinphase(hs,'Arithmetic',arithtype)` analyzes the filter System object `hs` based on the specified `arithtype`. `arithtype` can be one of 'double',

'single', or 'fixed'. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked. You must have the DSP System Toolbox to use `islinphase` with a System object.

**Details for Fixed-Point Arithmetic**

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the <code>CustomCoefficientsData</code> property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the <code>CustomCoefficientsData</code> property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object

is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Examples

### Linear and Nonlinear Phase

Use the window method to design a tenth-order lowpass FIR filter with normalized cutoff frequency 0.55. Verify that the filter has linear phase.

```
firSpecs = fdesign.lowpass('N,Fc',10,0.55);
lpFIR = design(firSpecs,'window','SystemObject',true);

flag = islinphase(lpFIR)

flag = logical
     1

[phs,w] = phasez(lpFIR);

plot(w/pi,phs)
xlabel('Frequency \omega/\pi')
ylabel('Phase')
```

IIR filters in general do not have linear phase. Verify the statement by constructing eighth-order Butterworth, Chebyshev, and elliptic filters with similar specifications.

```
ord = 4;
```

```
Wp = 0.35;  
Wst = 0.4;  
atten = 20;  
rippl = 1;
```

```
buttSpecs = fdesign.lowpass('Fp,Fst,Ap,Ast',Wp,Wst,rippl,atten);  
buttIIR = design(buttSpecs,'butter','SystemObject',true);
```

```
chb1Specs = fdesign.lowpass('Fp,Fst,Ap,Ast',Wp,Wst,rippl,atten);
```

```

chb1IIR = design(chb1Specs, 'cheby1', 'SystemObject', true);

chb2Specs = fdesign.lowpass('Fp,Fst,Ap,Ast', Wp, Wst, rippl, atten);
chb2IIR = design(chb2Specs, 'cheby2', 'SystemObject', true);

ellpSpecs = fdesign.lowpass('Fp,Fst,Ap,Ast', Wp, Wst, rippl, atten);
ellpIIR = design(ellpSpecs, 'ellip', 'SystemObject', true);

```

Plot the phase responses of the filters. Determine whether they have linear phase.

```

fv = fvtool(buttIIR, chb1IIR, chb2IIR, ellpIIR, 'Analysis', 'phase');
legend(fv, 'Butterworth', 'Chebyshev I', 'Chebyshev II', 'Elliptic')

```

```
phs = [islinphase(buttIIR) islinphase(chb1IIR) ...  
       islinphase(chb2IIR) islinphase(ellpIIR)]
```

```
phs = 1x4 logical array
```

```
  0   0   0   0
```

## Examples

### Maximum- and Minimum-Phase Filters

Design maximum-phase and minimum-phase lattice filters and verify their phase type.

```
k = [1/6 1/1.4];  
bmax = latc2tf(k, 'max');  
bmin = latc2tf(k, 'min');  
max_flag = ismaxphase(bmax)
```

```
max_flag = logical  
1
```

```
min_flag = isminphase(bmin)
```

```
min_flag = logical  
1
```

Given a filter defined with a set of single precision numerator and denominator coefficients, check if it is maximum phase for different values of the tolerance.

```
b = single([1 -0.9999]);  
a = single([1 0.45]);  
max_flag1 = ismaxphase(b,a)
```

```
max_flag1 = logical  
0
```

```
max_flag2 = ismaxphase(b,a,1e-3)
```

```
max_flag2 = logical  
1
```

# isminphase

Determine whether filter is minimum phase

## Syntax

```
flag = isminphase(b,a)
flag = isminphase(sos)
flag = isminphase(d)
flag = isminphase(...,tol)
flag = isminphase(hs,...)
isminphase(hs,'Arithmetic',arithtype)
```

## Description

A filter is *minimum phase* when all the zeros of its transfer function are on or inside the unit circle, or the numerator is a scalar. An equivalent definition for a minimum phase filter is a causal and stable system with a causal and stable inverse.

`flag = isminphase(b,a)` returns a logical output, `flag`, equal to `true` if the filter specified by numerator coefficients, `b`, and denominator coefficients, `a`, is a minimum phase filter.

`flag = isminphase(sos)` returns `true` if the filter specified by second order sections matrix, `sos`, is minimum phase. `sos` is a  $K$ -by-6 matrix, where the number of sections,  $K$ , must be greater than or equal to 2. Each row of `sos` corresponds to the coefficients of a second order (biquad) filter. The  $i$ th row of the `sos` matrix corresponds to `[bi(1) bi(2) bi(3) ai(1) ai(2) ai(3)]`.

`flag = isminphase(d)` returns `true` if the digital filter, `d`, has minimum phase. Use `designfilt` to generate `d` based on frequency-response specifications.

`flag = isminphase(...,tol)` uses the tolerance, `tol`, to determine when two numbers are close enough to be considered equal. If not specified, `tol`, defaults to  $\text{eps}^{(2/3)}$ .

`flag = isminphase(hs,...)` determines whether the filter System object `hs` is minimum phase, returning 1 if true and 0 if false. You must have the DSP System Toolbox software to use this syntax.

`isminphase(hs,'Arithmetic',arithtype)` analyzes the filter System object `hs` based on the specified *arithtype*. *arithtype* can be 'double', 'single', or 'fixed'. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked. You must have the DSP System Toolbox software to use this syntax.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Examples

### Minimum Phase Filters

Design a sixth-order lowpass Butterworth IIR filter using second order sections. Specify a normalized 3-dB frequency of 0.15. Check if the filter has minimum phase.

```
[z,p,k] = butter(6,0.15);
SOS = zp2sos(z,p,k);
min_flag = isminphase(SOS)
```

```
min_flag = logical
    1
```

Redesign the filter using `designfilt`. Check that the zeros and poles of the transfer function are on or within the unit circle.

```
d = designfilt('lowpassiir','DesignMethod','butter','FilterOrder',6, ...
              'HalfPowerFrequency',0.25);
d_flag = isminphase(d)
```

```
d_flag = logical
    1
```

```
zplane(d)
```

Given a filter defined with a set of single-precision numerator and denominator coefficients, check if it has minimum phase for different tolerance values.

```
b = single([1 1.00001]);  
a = single([1 0.45]);  
min_flag1 = isminphase(b,a)
```

```
min_flag1 = logical  
0
```

```
min_flag2 = isminphase(b,a,1e-3)
```

```
min_flag2 = logical  
1
```

**Introduced in R2013a**

# isNewDataReady

**Package:** dsp

Check spectrum analyzer for new data

## Syntax

```
flag = isNewDataReady(scope)
```

## Description

`flag = isNewDataReady(scope)` indicates whether or not the spectrum analyzer scope displays new spectrum estimates. When you are logging spectrum analyzer data from the `dsp.SpectrumAnalyzer` scope, use this function to ignore duplicate spectrums from the `getSpectrumData` function.

## Examples

### Log Spectrum Data

While a spectrum analyzer is running, save the spectrum data to a table. The spectrum analyzer does not update at every time step. To avoid saving that redundant spectrum data, use the `isNewDataReady` function.

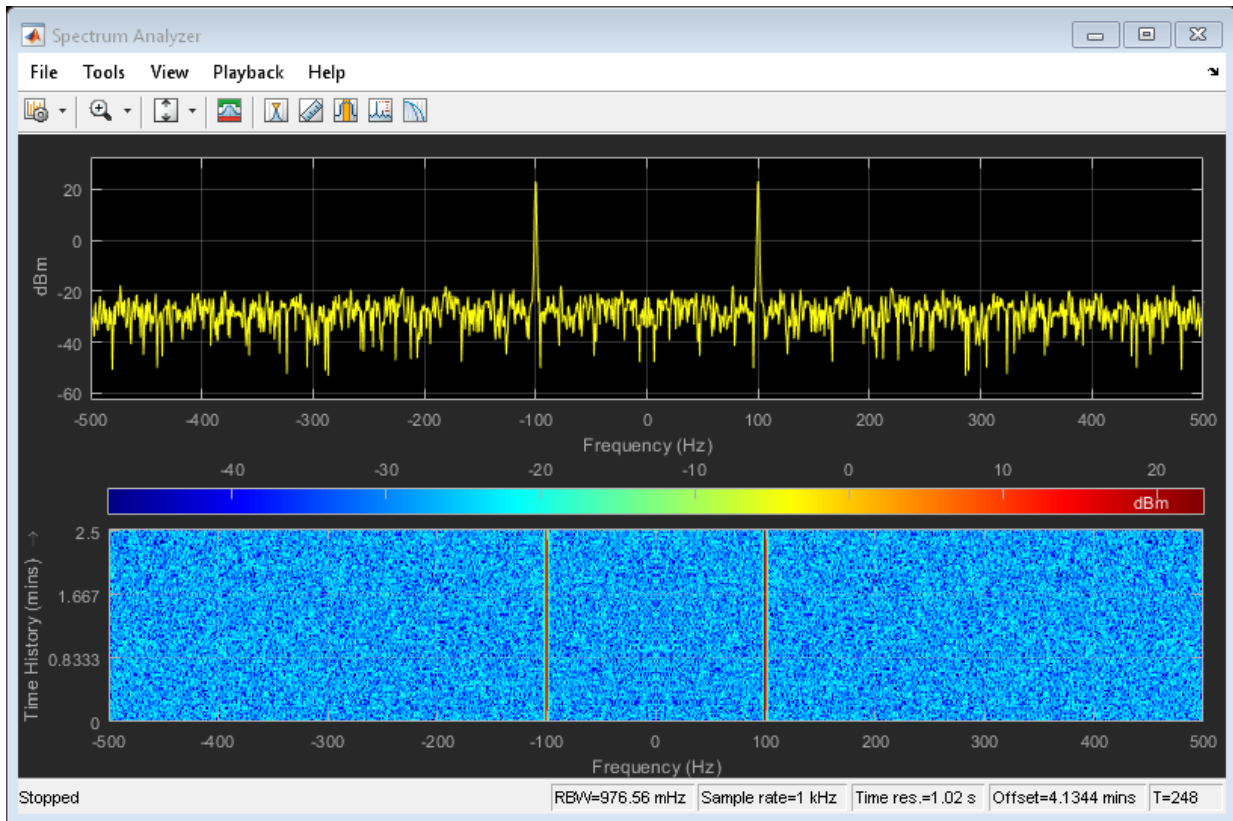

```
wave = dsp.SineWave('Frequency',100,'SampleRate',1000);  
wave.SamplesPerFrame = 1000;  
scope = dsp.SpectrumAnalyzer('SampleRate',wave.SampleRate,...  
    'ReducePlotRate',false,...  
    'ViewType','Spectrum and spectrogram');  
data = [];  
  
for ii = 1:250  
    x = wave() + 0.05*randn(1000,1);  
    scope(x);  
end
```

```

if scope.isNewDataReady
    data = [data;getSpectrumData(scope)];
end
end

release(scope);

```

In the data table, you can see gaps in the simulation time. These missing rows indicate times where the spectrum analyzer was waiting for additional samples to update the spectrum. The `isNewDataReady` function prevented the script from saving that redundant data.

```
data(1:5,:)
```

ans =

5x6 table

<u>SimulationTime</u>	<u>Spectrum</u>	<u>Spectrogram</u>	<u>MinHoldTrace</u>	<u>MaxHoldT</u>
[1]	[1536x1 double]	[100x1536 double]	[]	[]
[3]	[1536x1 double]	[100x1536 double]	[]	[]
[4]	[1536x1 double]	[100x1536 double]	[]	[]
[6]	[1536x1 double]	[100x1536 double]	[]	[]
[7]	[1536x1 double]	[100x1536 double]	[]	[]

## Input Arguments

### scope — Spectrum analyzer

System object name

Spectrum analyzer that you want to save data from.

## Output Arguments

### flag — New data flag

true | false

true

The spectrum analyzer shows new data.

false

The spectrum analyzer shows the same spectrum as the last time the scope was called.

## See Also

dsp.SpectrumAnalyzer | getSpectrumData

**Introduced in R2017b**

## isreal

Determine whether filter uses real coefficients

### Syntax

```
isreal(hd)  
isreal(hs)
```

### Description

`isreal(hd)` returns 1 (or true) if all filter coefficients for the filter `hd` are real, and returns 0 (or false) otherwise. Complex filters have one or more coefficients with nonzero imaginary parts.

`isreal(hs)` determines whether the filter coefficients of the filter System object `hs` are real, returning 1 if true and 0 if false.

---

**Note** Quantizing a filter cannot make a real filter into a complex filter.

---

## Examples

### Check If the Filter Coefficients are Real

Create a `dsp.BiquadFilter` System object™. Pass a fixed-point input to the object. Test the coefficients of the fixed-point filter to see if they are strictly real.

```
d = fdesign.lowpass('n,fp,ap,ast',5,0.4,0.5,20);  
biquadFilter = design(d,'ellip','SystemObject',true);  
IsRealBefore = isreal(biquadFilter)
```

```
IsRealBefore = logical  
1
```

Pass a fixed-point input to the object.

```
fiInput = fi(randn(1000,2),1,32,16);  
fiOutput = biquadFilter(fiInput);  
IsRealAfter = isreal(biquadFilter)
```

```
IsRealAfter = logical  
             1
```

`isreal` returns a 1, indicating that the filter coefficients are real.

**Introduced in R2011a**

## issos

Determine whether filter is SOS form

## Syntax

```
issos(hd)  
issoss(hs)
```

## Description

`issos(hd)` determines whether quantized filter `hq` consists of second-order sections. Returns 1 if all sections of quantized filter `hq` have order less than or equal to two, and 0 otherwise.

`issoss(hs)` determines whether the filter System object `hs` consists of second-order sections, returning 1 if true and 0 if false.

## Examples

### Design a Lowpass SOS Filter

By default, `fdesign` and `design` return SOS filters when possible. This example designs a lowpass SOS filter that uses fixed-point arithmetic.

```
d = fdesign.lowpass('n,fp,ap,ast',40,0.55,0.1,60);  
hd = design(d,'ellip','SystemObject',true);  
IsSOS=issos(hd)
```

```
IsSOS = logical  
       1
```

The filter is in second-order section form.

## isVisible

**Package:** dsp

Determine visibility of scope

## Syntax

```
visibility = isVisible(scope)
```

## Description

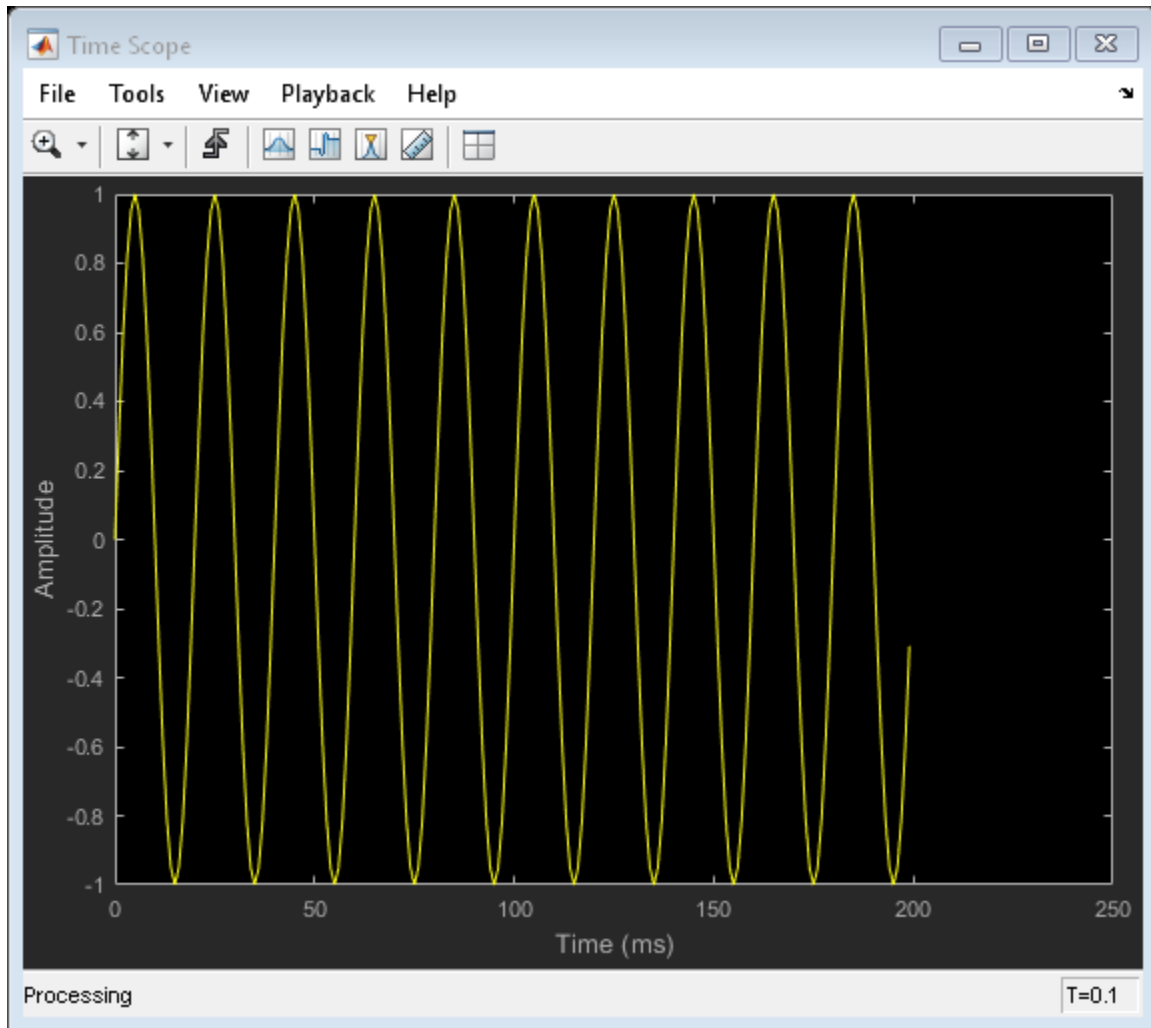

`visibility = isVisible(scope)` returns the visibility of the System object scope.

## Examples

### Hide and Show Time Scope

Create a sine wave signal and view it in the scope.

```
Fs = 1000; % Sampling frequency
signal = dsp.SineWave('Frequency',50,'SampleRate',Fs,'SamplesPerFrame',100);
scope = dsp.TimeScope(1,Fs,'TimeSpan',0.25,'YLimits',[-1 1]);
for ii = 1:2
    xsine = signal();
    scope(xsine)
end
```

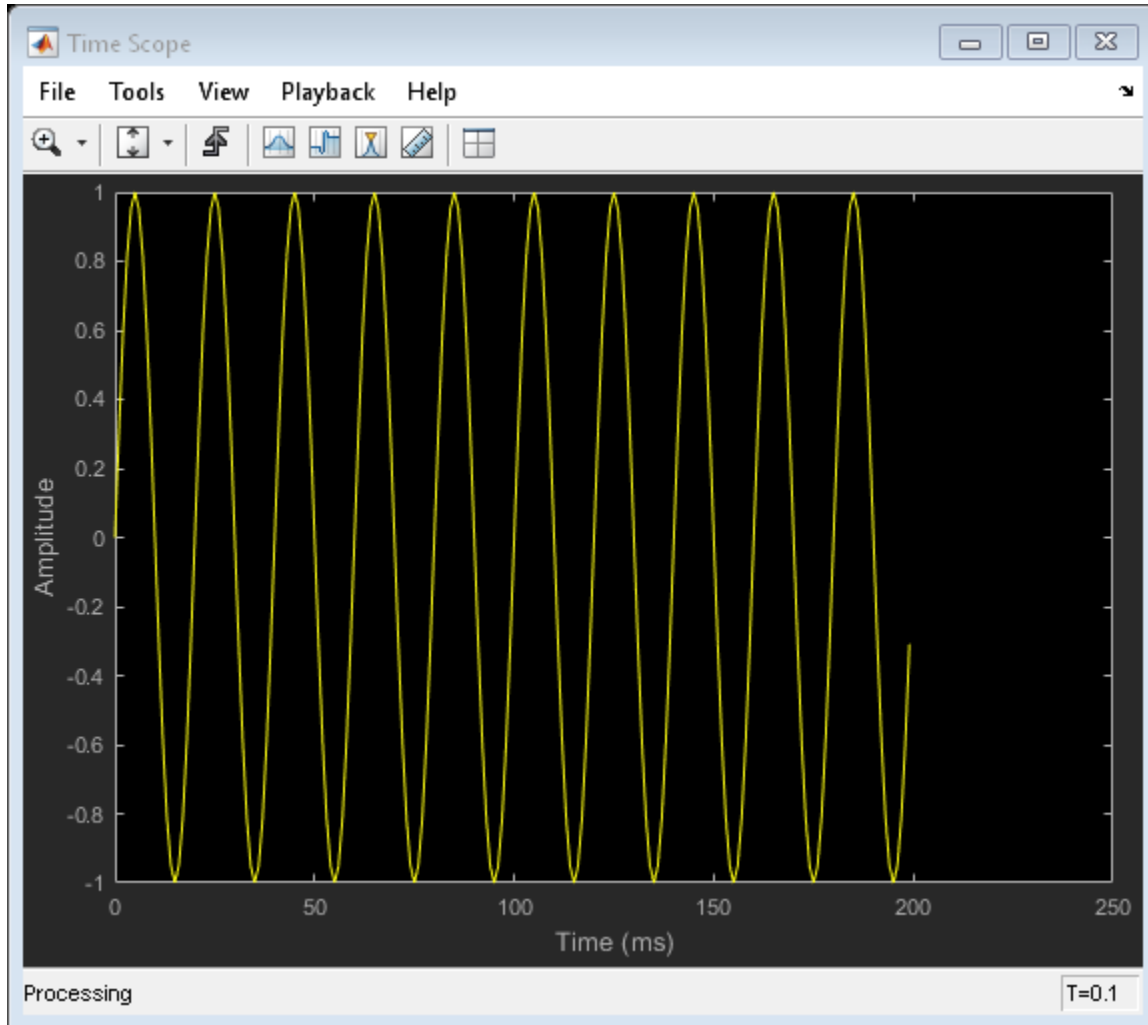

Hide the scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the scope window.

```
if(~isVisible(scope))  
    show(scope)  
end
```

Clean up workspace variables.

```
clear scope Fs sine ii xsine
```

## Input Arguments

### **scope** — Scope System object

System object

Scope System object whose visibility you want to query.

```
Example: myScope = dsp.SpectrumAnalyzer; visibility = isVisible(myScope)
```

```
Example: myTS = dsp.TimeScope; visibility = isVisible(myTS)
```

## Output Arguments

### **visibility** — Scope visibility

'true' | 'false'

If the scope display is showing, the `isVisible` function returns true. Otherwise, the function returns false.

## See Also

### **Functions**

hide | show

### **System Objects**

### **Introduced in R2016b**

## isstable

Determine whether filter is stable

### Syntax

```
flag = isstable(b,a)
flag = isstable(sos)
flag = isstable(d)
flag = isstable(hs)
flag = isstable(hs,'Arithmetic',arithtype)
```

### Description

`flag = isstable(b,a)` returns a logical output, `flag`, equal to `true` if the filter specified by numerator coefficients, `b`, and denominator coefficients, `a`, is a stable filter. If the poles lie on or outside the circle, `isstable` returns `false`. If the poles are inside the circle, `isstable` returns `true`.

`flag = isstable(sos)` returns `true` if the filter specified by second order sections matrix, `sos`, is stable. `sos` is a  $K$ -by-6 matrix, where the number of sections,  $K$ , must be greater than or equal to 2. Each row of `sos` corresponds to the coefficients of a second order (biquad) filter. The  $i$ th row of the `sos` matrix corresponds to `[bi(1) bi(2) bi(3) ai(1) ai(2) ai(3)]`.

`flag = isstable(d)` returns `true` if the digital filter, `d`, is stable. Use `designfilt` to generate `d` based on frequency-response specifications.

`flag = isstable(hs)` returns `true` if the filter System object `hs` is stable. You must have the DSP System Toolbox software to use this syntax.

`flag = isstable(hs,'Arithmetic',arithtype)` analyzes the filter System object `hs` based on the specified `arithtype`. `arithtype` can be `'double'`, `'single'`, or `'fixed'`. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'`, the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked. You must have the DSP System Toolbox software to use this syntax.

### Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataProperty property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataProperty property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Examples

### Filter Stability

Design a sixth-order Butterworth highpass IIR filter using second order sections. Specify a normalized 3-dB frequency of 0.7. Determine if the filter is stable.

```
[z,p,k] = butter(6,0.7,'high');  
SOS = zp2sos(z,p,k);  
flag = isstable(SOS)
```

```
flag = logical  
      1
```

```
zplane(z,p)
```

Redesign the filter using `designfilt` and check it for stability.

```
d = designfilt('highpassiir','DesignMethod','butter','FilterOrder',6, ...  
              'HalfPowerFrequency',0.7);  
dflg = isstable(d)
```

```
dflg = logical  
      1
```

```
zplane(d)
```

Create a filter and determine its stability at double and single precision.

```
b = [1 -0.5];  
a = [1 -0.999999999];  
act_flag1 = isstable(b,a)
```

```
act_flag1 = logical  
1
```

```
act_flag2 = isstable(single(b),single(a))
```

```
act_flag2 = logical  
0
```

# kaiserwin

Kaiser window filter from specification object

## Syntax

```
kFilter = design(d,'kaiserwin','SystemObject',true)
kFilter = design(d,'kaiserwin',designoption,value,designoption,...
value,'SystemObject',true)
```

## Description

`kFilter = design(d,'kaiserwin','SystemObject',true)` designs a digital filter `kFilter` that uses a Kaiser window. For `kaiserwin` to work properly, the filter order in the specifications object must be even. In addition, higher order filters (filter order greater than 120) tend to be more accurate for smaller transition widths. `kaiserwin` returns a warning when your filter order may be too low to design your filter accurately.

`kFilter = design(d,'kaiserwin',designoption,value,designoption,... value,'SystemObject',true)` returns a filter where you specify design options as input arguments and the design process uses the Kaiser window technique.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `kaiserwin`, refer to the command line help system. For example, to get specific information about using `kaiserwin` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'kaiserwin')
```

## Examples

### Design a Direct Form FIR Filter

This example designs a direct form FIR filter from a halfband filter specification object.

```
d = fdesign.halfband('n,tw',200,0.01);  
hbFilter = design(d,'kaiserwin','filterstructure','dffir',...  
    'SystemObject',true)
```

```
hbFilter =  
    dsp.FIRFilter with properties:  
  
        Structure: 'Direct form'  
        NumeratorSource: 'Property'  
        Numerator: [1x201 double]  
        InitialConditions: 0
```

```
Show all properties
```

```
fvtool(hbFilter);
```

In this example, kaiserwin uses an interpolating filter specification object.

```
d = fdesign.interpolator(4,'lowpass');
interpFilter= design(d,'kaiserwin','SystemObject',true)
```

```
interpFilter =
  dsp.FIRInterpolator with properties:
    NumeratorSource: 'Property'
    Numerator: [1x147 double]
    InterpolationFactor: 4
```

Show all properties

```
fvtool(interpFilter);
```

# lagrange

Fractional delay filter from `fdesign.fracdelay` specification object

## Syntax

```
Hd = design(d,'lagrange')  
hd = design(d,'lagrange',FilterStructure,structure)
```

## Description

`Hd = design(d,'lagrange')` designs a fractional delay filter using the Lagrange method based on the specifications in `d`.

`hd = design(d,'lagrange',FilterStructure,structure)` specifies the Lagrange design method and the *structure* filter structure for `hd`. The sole valid filter structure string for `structure` is `fd`, describing the fractional delay structure.

## Examples

This example uses a fractional delay of 0.30 samples. The `help` and `designopts` commands provide the details about designing fractional delay filters.

```
d=fdesign.fracdelay(.30)  
d =  
    Response: 'Fractional Delay'  
    Specification: 'N'  
    Description: {'Filter Order'}  
    FracDelay: 0.3  
    NormalizedFrequency: true  
    FilterOrder: 3  
  
designmethods(d)  
Design Methods for class fdesign.fracdelay (N):  
lagrange  
help(d,'lagrange')
```

```
DESIGN Design a Lagrange fractional delay filter.
HD = DESIGN(D, 'lagrange') designs a Lagrange filter specified by the
    FDESIGN object D, and returns the DFILT object HD.

HD = DESIGN(..., 'FilterStructure', STRUCTURE) returns a filter with the
    structure STRUCTURE. STRUCTURE is 'farrowfd' by default and can be any of
    the following:

'farrowfd'
'fd'

% Example #1 - Design a linear Lagrange fractional delay filter of 0.2 samples.
h = fdesign.fracdelay(0.2,'N',2);
Hd = design(h, 'lagrange', 'FilterStructure', 'farrowfd')

% Example #2 - Design a cubic Lagrange fractional delay filter
Fs = 8000; % Sampling frequency of 8kHz
fdelay = 50e-6; % Fractional delay of 50 microseconds.
h = fdesign.fracdelay(fdelay,'N',3,Fs);
Hd = design(h, 'lagrange', 'FilterStructure', 'farrowfd');
```

This example designs a linear Lagrange fractional delay filter where you set the delay to 0.2 seconds and the filter order N to 2.

```
h = fdesign.fracdelay(0.2,'N',2);
hd = design(h,'lagrange','FilterStructure','farrowfd')
```

Design a cubic Lagrange fractional delay filter with filter order equal to 3.

```
Fs = 8000; % Sampling frequency of 8 kHz.
fdelay = 50e-6; % Fractional delay of 50 microseconds.
h = fdesign.fracdelay(fdelay,'N',3,Fs);
hd = design(h,'lagrange','FilterStructure','farrowfd');
```

# liblinks

Check model for blocks from specific DSP System Toolbox libraries

## Syntax

```
liblinks(lib)  
liblinks(lib,sys)  
liblinks(lib,sys,c)
```

## Description

`liblinks(lib)` returns a cell array of character vectors that lists the blocks in the current model that are linked to the specified libraries. The input `lib` provides a cell array of character vectors with the library names. Use the library name visible in the title bar when you open a library model.

`liblinks(lib,sys)` acts on the named model `sys`.

`liblinks(lib,sys,c)` changes the foreground color of the returned blocks to the color `c`. Possible values of `c` are 'blue', 'green', 'red', 'cyan', 'magenta', 'yellow', or 'black'.

## Examples

Check for blocks from the Sources library in the specified model:

```
rlsdemo  
liblinks('dspsrcs4',gcs)
```

## See Also

`dsp_links`

# limitcycle

Response of single-rate, fixed-point IIR filter

## Syntax

```
report = limitcycle(hd)
report = limitcycle(hd,ntrials,inputlengthfactor,stopcriterion)
```

## Description

`report = limitcycle(hd)` returns the structure `report` that contains information about how filter `hd` responds to a zero-valued input vector. By default, the input vector has length equal to twice the impulse response length of the filter.

`limitcycle` returns a structure whose elements contain the details about the limit cycle testing. As shown in this table, the `report` includes the following details.

Output Object Property	Description
LimitCycleType	Contains one of the following results: <ul style="list-style-type: none"> <li>• <b>Granular</b> — indicates that a granular overflow occurred.</li> <li>• <b>Overflow</b> — indicates that an overflow limit cycle occurred.</li> <li>• <b>None</b> — indicates that the test did not find any limit cycles.</li> </ul>
Zi	Contains the initial condition value(s) that caused the detected limit cycle to occur.
Output	Contains the output of the filter in the steady state.
Trial	Returns the number of the Monte Carlo trial on which the limit cycle testing stopped. For example, <code>Trial = 10</code> indicates that testing stopped on the tenth Monte Carlo trial.

Using an input vector longer than the filter impulse response ensures that the filter is in steady-state operation during the limit cycle testing. `limitcycle` ignores output that occurs before the filter reaches the steady state. For example, if the filter impulse length is 500 samples, `limitcycle` ignores the filter output from the first 500 input samples.

To perform limit cycle testing on your IIR filter, you must set the filter `Arithmetic` property to `fixed` and `hd` must be a fixed-point IIR filter of one of the following forms:

- `df1` — direct-form I
- `df1t` — direct-form I transposed
- `df1sos` — direct-form I with second-order sections
- `df1tsos` — direct-form I transposed with second-order sections
- `df2` — direct-form II
- `df2t` — direct-form II transposed
- `df2sos` — direct-form II with second-order sections
- `df2tsos` — direct-form II transposed with second-order sections

When you use `limitcycle` without optional input arguments, the default settings are

- Run 20 Monte Carlo trials
- Use an input vector twice the length of the filter impulse response
- Stop testing if the simulation process encounters either a granular or overflow limit cycle

To determine the length of the filter impulse response, use `impzlength`:

```
impzlength(hd)
```

During limit cycle testing, if the simulation runs reveal both overflow and granular limit cycles, the overflow limit cycle takes precedence and is the limit cycle that appears in the report.

Each time you run `limitcycle`, it uses a different sequence of random initial conditions, so the results can differ from run to run.

Each Monte Carlo trial uses a new set of randomly determined initial states for the filter. Test processing stops when `limitcycle` detects a zero-input limit cycle in filter `hd`.

`report = limitcycle(hd,ntrials,inputlengthfactor,stopcriterion)`  
 returns a report of how filter `hd` responds to a zero-valued input vector, using the following optional input arguments:

- `ntrials` — Number of Monte Carlo trials (default is 20).
- `inputlengthfactor` — integer factor used to calculate the length of the input vector. The length of the input vector comes from `(impzlength(hd) * inputlengthfactor)`, where `inputlengthfactor = 2` is the default value.
- `stopcriterion` — the criterion for stopping the Monte Carlo trial processing. `stopcriterion` can be set to **either** (the default), **granular**, **overflow**. This table describes the results of each stop criterion.

stopcriterion Setting	Description
<b>either</b>	Stop the Monte Carlo trials when <code>limitcycle</code> detects either a granular or overflow limit cycle.
<b>granular</b>	Stop the Monte Carlo trials when <code>limitcycle</code> detects a granular limit cycle.
<b>overflow</b>	Stop the Monte Carlo trials when <code>limitcycle</code> detects an overflow limit cycle.

---

**Note** An important feature is that if you specify a specific limit cycle stop criterion, such as `overflow`, the Monte Carlo trials do not stop when testing encounters a granular limit cycle. You receive a warning that no `overflow` limit cycle occurred, but consider that a granular limit cycle might have occurred.

---

## Examples

In this example, there is a region of initial conditions in which no limit cycles occur and a region where they do. If no limit cycles are detected before the Monte Carlo trials are over, the state sequence converges to zero. When a limit cycle is found, the states do not end at zero. Each time you run this example, it uses a different sequence of random initial conditions, so the plot you get can differ from the one displayed in the following figure.

```
s = [1 0 0 1 0.9606 0.9849];
hd = dfilt.df2sos(s);
hd.arithmetic = 'fixed';
greport = limitcycle(hd,20,2,'granular')
oreport = limitcycle(hd,20,2,'overflow')
figure,
```

```
subplot(211),plot(greport.Output(1:20)), title('Granular Limit Cycle');
subplot(212),plot(oreport.Output(1:20)), title('Overflow Limit Cycle');

greport =
  LimitCycle: 'granular'
            Zi: [2x1 double]
            Output: [1303x1 embedded.fi]
            Trial: 1

oreport =
  LimitCycle: 'overflow'
            Zi: [2x1 double]
            Output: [1303x1 embedded.fi]
            Trial: 2
```

The plots shown in this figure present both limit cycle types — the first displays the small amplitude granular limit cycle, the second the larger amplitude overflow limit cycle.

As you see from the plots, and as is generally true, overflow limit cycles are much greater magnitude than granular limit cycles. This is why `limitcycle` favors overflow limit cycle detection and reporting.

## maxflat

Maxflat FIR filter

### Syntax

```
maxflatFilter = design(d,'maxflat','SystemObject',true)
maxflatFilter =
design(d,'maxflat','FilterStructure',structure,'SystemObject',true)
```

### Description

`maxflatFilter = design(d,'maxflat','SystemObject',true)` designs a maximally flat filter, `maxflatFilter`, from a filter specification object, `d`.

`maxflatFilter = design(d,'maxflat','FilterStructure',structure,'SystemObject',true)` designs a maximally flat filter where `structure` is one of the following:

- `'dffir'`, a discrete-time, direct-form FIR filter (the default value)
- `'dffirt'`, a discrete-time, direct-form FIR transposed filter
- `'dfsymfir'`, a discrete-time, direct-form symmetric FIR filter

### Examples

#### Design a Lowpass Filter with a Maximally Flat FIR Structure

```
d = fdesign.lowpass('N,F3dB', 50, 0.3);
flatLowpass = design(d, 'maxflat','SystemObject',true);
fvtool(flatLowpass);
```

### Design a Highpass Filter With a Maximally Flat Symmetric FIR Structure

```
d = fdesign.highpass('N,F3dB', 50, 0.7);  
flatHighpass = design(d,'maxflat','FilterStructure','dfsymfir',...  
    'SystemObject',true);  
fvtool(flatHighpass)
```

**Introduced in R2011a**

# maxstep

**Package:** dsp

Maximum step size for LMS adaptive filter convergence

## Syntax

```
mumax = maxstep(lmsFilt,x)
[mumax,mumaxmse] = maxstep(lmsFilt,x)
```

## Description

`mumax = maxstep(lmsFilt,x)` predicts a bound on the step size to provide convergence of the mean values of the coefficients of the adaptive filter, `lmsFilt`.

`[mumax,mumaxmse] = maxstep(lmsFilt,x)` predicts a bound, in mean squared sense, on the adaptive filter step size to provide convergence of the adaptive filter coefficients.

## Examples

### Compute Maximum Step of LMS Adaptive Filter

The `maxstep` function computes the maximum step size of the adaptive filter. This step size keeps the filter stable at the maximum possible speed of convergence. Create the primary input signal, `x`, by passing a signed random signal to an IIR filter. Signal `x` contains 50 frames of 2000 samples each frame. Create an LMS filter with 32 taps and a step size of 0.1.

```
x = zeros(2000,50);
IIRFilter = dsp.IIRFilter('Numerator',sqrt(0.75),'Denominator',[1 -0.5]);
for k = 1:size(x,2)
    x(:,k) = IIRFilter(sign(randn(size(x,1),1)));
end
```

```
mu = 0.1;  
LMSFilter = dsp.LMSFilter('Length',32,'StepSize',mu);
```

Compute the maximum adaptation step size and the maximum step size in mean-squared sense using the `maxstep` function.

```
[mumax,mumaxmse] = maxstep(LMSFilter,x)
```

```
mumax = 0.0625
```

```
mumaxmse = 0.0536
```

## Input Arguments

### **lmsFilt** — LMS adaptive filter System object

`dsp.LMSFilter` | `dsp.BlockLMSFilter`

LMS adaptive filter, specified as either a `dsp.LMSFilter` System object or a `dsp.BlockLMSFilter` System object.

### **x** — Input signal

scalar | column vector | matrix

Columns of the matrix `x` contain individual input signal sequences. The signal set is assumed to have zero mean or close to zero mean.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

Complex Number Support: Yes

## Output Arguments

### **mumax** — Maximum step size

scalar

Maximum step size value, returned as a scalar. This is the step size you can specify for the adaptive filter without causing the filter to become unstable. For details on how this parameter is calculated, see “Algorithms” on page 5-1113.

Data Types: `double`

**mumaxmse — Maximum step size in mean squared sense**

scalar

Maximum adaptive filter step size to provide convergence of the LMS adaptive filter coefficients in the mean squared sense, returned as a scalar. For details on how this parameter is calculated, see “Algorithms” on page 5-1113.

Data Types: double

## Algorithms

The step size of the adaptive filter must satisfy the following equation in order for the adaptive filter to be stable:

$$0 < \mu < \mu_{\max}$$

where,  $\mu_{\max}$  is the maximum step size.

The value of  $\mu_{\max}$  depends on the LMS filter System object and the adaptive filter algorithm the object uses.

### **dsp.LMSFilter**

#### **LMS**

When the Method property of the `dsp.LMSFilter` object is set to 'LMS', maximum step size  $\mu_{\max}$  is calculated using the following equation:

$$\mu_{\max} = \frac{2}{\text{mean}(xt \circ xt)L}$$

where,

- $xt$  -- Concatenated columns of the input matrix,  $x(\cdot)$ .
- $xt \circ xt$  -- Hadamard or entrywise product of the two vectors.
- $L$  -- Length of the filter coefficients.

The maximum step size in mean-square sense,  $\mu_{\max\text{MSE}}$  is computed using the following equation:

$$\mu_{\max\text{MSE}} = \frac{2}{\lambda_{\max} (\text{Kurt} + 2) + \text{sum}(\lambda)}$$

where,

- $\text{sum}(\lambda)$  -- Sum of the eigenvalues of the input auto correlation matrix.
- $\lambda_{\max}$  -- Maximum eigenvalue of the input auto correlation matrix.
- $\text{Kurt}$  -- Average kurtosis value of eigenvector-filtered signals.

### Normalized LMS

When the Method property of the `dsp.LMSFilter` System object is set to 'Normalized LMS':

- Maximum step size,  $\mu_{\max} = 2$ .
- Maximum step size in mean-square sense,  $\mu_{\max\text{MSE}} = 2$ .

### For Other Methods

For all other methods such as Sign-Data LMS, Sign-Error LMS, and Sign-Sign LMS:

- $\mu_{\max} = \infty$ .
- $\mu_{\max\text{MSE}} = \infty$ .

### `dsp.BlockLMSFilter`

The maximum step size for `dsp.BlockLMSFilter` is computed using the following equation:

$$\mu_{\max} = \frac{2}{\text{mean}(xt \circ xt)L}$$

where,

- $xt$  -- Concatenated columns of the input matrix,  $x(:)$ .
- $xt \circ xt$  -- Hadamard or entrywise product of the two vectors.
- $L$  -- Length of the filter coefficients.

The maximum step size in mean-square sense,  $\mu_{\max\text{MSE}}$  is computed using the following equation:

$$\mu_{\max\text{MSE}} = \frac{\mu_{\max}}{3}$$

## maximizestopband

Maximize stopband attenuation of fixed-point filter

### Syntax

```
Hq = maximizestopband(Hd,Wordlength)
Hq = maximizestopband(Hd,Wordlength,'Ntrials',N)
```

### Description

`Hq = maximizestopband(Hd,Wordlength)` quantizes the single-stage or multistage FIR filter `Hd` and returns the fixed-point filter `Hq` with wordlength `wordlength` that maximizes the stopband attenuation. `Hd` must be generated using `fdesign` and `design`. For multistage filters, `wordlength` can either be a scalar or vector. If `wordlength` is a scalar, the same `wordlength` is used for all stages. If `wordlength` is a vector, each stage uses the corresponding element in the vector. The vector length must equal the number of stages. `maximizestopband` uses a stochastic noise-shaping procedure by default to minimize the wordlength. To obtain repeatable results on successive function calls, initialize the uniform random number generator `rand`

`Hq = maximizestopband(Hd,Wordlength,'Ntrials',N)` specifies the number of Monte Carlo trials to use in the maximization. `Hq` is the fixed-point filter with the largest stopband attenuation among the trials. The number of Monte Carlo trials `N` defaults to 1.

You must have the Fixed-Point Designer software installed to use this function.

### Examples

#### Maximize Stopband Attenuation

Maximize stopband attenuation for 16-bit fixed-point filter.

```
Hf = fdesign.lowpass('Fp,Fst,Ap,Ast',0.4,0.45,0.5,60);
Hd = design(Hf,'equiripple');
```

Use 16 bits to represent coefficients.

```
WL = 16;  
Hq = maximizestopband(Hd,WL);
```

Compare stopband attenuation

```
md = measure(Hd)
```

```
md =  
Sample Rate      : N/A (normalized frequency)  
Passband Edge    : 0.4  
3-dB Point       : 0.41178  
6-dB Point       : 0.41845  
Stopband Edge    : 0.45  
Passband Ripple  : 0.49369 dB  
Stopband Atten.  : 60.0697 dB  
Transition Width : 0.05
```

```
mq = measure(Hq)
```

```
mq =  
Sample Rate      : N/A (normalized frequency)  
Passband Edge    : 0.4  
3-dB Point       : 0.41178  
6-dB Point       : 0.41845  
Stopband Edge    : 0.45  
Passband Ripple  : 0.49773 dB  
Stopband Atten.  : 59.9728 dB  
Transition Width : 0.05
```

```
hfvf=fvtool(Hd,Hq,'ShowReference','off');  
legend(hfvf,'Floating-point Filter','Fixed-point Filter');
```

# measure

Measure frequency response characteristics of filter System object

## Syntax

```
measure(sysobj)
M = measure(sysobj)
M = measure(sysobj, 'Arithmetic', ARITH, ...)
M = measure(sysobj, 'freqspec', freqspecvalue, ...)
```

## Description

`measure(sysobj)` displays measurements of various quantities from the frequency response of the filter System object, `sysobj`. Measurements include the actual passband ripple, the minimum stopband attenuation, the frequency point at which the filter's gain is 3 dB below the nominal passband gain, etc. You must construct `sysobj` using `fdesign` and `design` with the name-value pair argument `'SystemObject', true`. You can optionally specify additional options by one or more `Name, Value` pair arguments.

`M = measure(sysobj)` returns the measurements, `M`, such that the measurements can be queried programmatically. For example, to query the 3 dB point, type `M.F3dB`. Type `get(M)` to see the full list of properties that can be queried. Note that different filter responses generate different measurements.

`M = measure(sysobj, 'Arithmetic', ARITH, ...)` analyzes the filter System object, `sysobj`, based on the arithmetic specified in the `ARITH` input. `ARITH` can be set to one of `'double'`, `'single'`, or `'fixed'`. When the arithmetic input is not specified and the filter System object is in an unlocked state, the analysis tool assumes a double precision filter.

`M = measure(sysobj, 'freqspec', freqspecvalue, ...)` passes the frequency value as an input to `measure` in order to determine the corresponding magnitude measurements. For designs that do not specify some of the frequency constraints, you can determine the corresponding magnitude measurements using this option.

In the following example, the passband edge, passband ripple, and the transition width of the IIR filter are unknown.

```
designLowpass = fdesign.lowpass('N,F3dB,Ast',8,0.5,80);
chebFilter = design(designLowpass,'cheby2');
measure(chebFilter)
```

```
Sample Rate      : N/A (normalized frequency)
Passband Edge    : Unknown
3-dB Point       : 0.5
6-dB Point       : 0.51823
Stopband Edge    : 0.68727
Passband Ripple  : Unknown
Stopband Atten. : 79.9994 dB
Transition Width : Unknown
```

Specify the passband edge to be 0.4, and measure the passband ripple and the transition width of this filter.

```
measure(chebFilter,'Fpass',0.4)
```

```
Sample Rate      : N/A (normalized frequency)
Passband Edge    : 0.4
3-dB Point       : 0.5
6-dB Point       : 0.51823
Stopband Edge    : 0.68727
Passband Ripple  : 0.013644 dB
Stopband Atten. : 79.9994 dB
Transition Width : 0.28727
```

When `sysobj` is a generic discrete-time filter, for example, a single-rate lowpass filter, `measure(sysobj)` returns the following filter specifications.

Lowpass Filter Specification	Description
Sample Rate	Filter sampling frequency.
Passband Edge	Location of the edge of the passband as it enters transition.
3-dB Point	Location of the -3 dB point on the response curve.
6-dB Point	Location of the -6 dB point on the response curve.

Lowpass Filter Specification	Description
Stopband Edge	Location of the edge of the transition band as it enters the stopband.
Passband Ripple	Ripple in the passband.
Stopband Atten	Attenuation in the stopband.
Transition Width	Width of the transition between the passband and stopband, in normalized frequency or absolute frequency. Measured between $F_{pass}$ and $F_{stop}$ .

When `sysobj` is a bandstop filter, `measure(sysobj)` returns these specifications for the resulting bandstop filter.

Bandstop Filter Specification	Description
Sample Rate	Filter sampling frequency.
First Passband Edge	Location of the edge of the first passband.
First 3-dB Point	Location of the edge of the -3 dB point in the first transition band.
First 6-dB Point	Location of the edge of the -6 dB point in the first transition band.
First Stopband Edge	Location of the start of the stopband.
Second Stopband Edge	Location of the end of the stopband.
Second 6-dB Point	Location of the edge of the -6 dB point in the second transition band.
Second 3-dB Point	Location of the edge of the -3 dB point in the second transition band.
Second Passband Edge	Location of the start of the second passband.
First Passband Ripple	Ripple in the first passband.
Stopband Atten	Attenuation in the stopband.
Second Passband Ripple	Ripple in the second passband.
First Transition Width	Width of the first transition region. Measured between the -3 and -6 dB points.

Bandstop Filter Specification	Description
Second Transition Width	Width of the second transition region. Measured between the -6 and -3 dB points.

When `sysobj` is an interpolator, decimator, or a rate converter, `measure(sysobj)` returns these specifications for the resulting filter.

Interpolator Filter Specification	Description
Sample Rate	Filter sampling frequency.
First Passband Edge	Location of the edge of the passband as it enters transition.
3-dB Point	Location of the -3 dB point on the response curve.
6-dB Point	Location of the -6 dB point on the response curve.
Stopband Edge	Location of the edge of the transition band as it enters the stopband.
Passband Ripple	Ripple in the passband.
Stopband Atten	Attenuation in the stopband.
Transition Width	Width of the transition between the passband and stopband, in normalized frequency or absolute frequency. Measured between $F_{pass}$ and $F_{stop}$ .

## Input Arguments

### `sysobj`

Filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
<code>dsp.AllpassFilter</code>
<code>dsp.AllpoleFilter</code>

<b>Filter System objects</b>
dsp.BiquadFilter
dsp.Channelizer
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.CICDecimator
dsp.CICInterpolator
dsp.CoupledAllpassFilter
dsp.FarrowRateConverter
dsp.FilterCascade
dsp.FIRDecimator
dsp.FIRFilter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.FIRInterpolator
dsp.FIRRateConverter
dsp.HighpassFilter
dsp.IIRFilter
dsp.IIRHalfbandDecimator
dsp.IIRHalfbandInterpolator
dsp.LowpassFilter
dsp.NotchPeakFilter
dsp.VariableBandwidthFIRFilter
dsp.VariableBandwidthIIRFilter

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Arithmetic — Value types:**

'double' | 'single' | 'fixed'

Specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

**Details for Fixed-Point Arithmetic**

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the <code>CustomCoefficientsData</code> property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the <code>CustomCoefficientsData</code> property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Examples

### Measure the Filter Specifications

Create a lowpass filter and check whether the actual filter meets the specifications. For this case, use normalized frequency for  $F_s$ , the default setting.

```
desigLowpass = fdesign.lowpass('Fp,Fst,Ap,Ast',0.45,0.55,0.1,80)
```

```
desigLowpass =
  lowpass with properties:
      Response: 'Lowpass'
      Specification: 'Fp,Fst,Ap,Ast'
      Description: {4x1 cell}
      NormalizedFrequency: 1
      Fpass: 0.4500
      Fstop: 0.5500
      Apass: 0.1000
      Astop: 80
```

```
designmethods(desigLowpass,'SystemObject',true)
```

Design Methods that support System objects for class `fdesign.lowpass (Fp,Fst,Ap,Ast)`:

```
butter
cheby1
cheby2
ellip
equiripple
ifir
kaiserwin
multistage
```

Use the default equiripple design method.

```
equiFilter = design(desigLowpass, 'SystemObject', true)
```

```
equiFilter =  
  dsp.FIRFilter with properties:  
  
      Structure: 'Direct form'  
      NumeratorSource: 'Property'  
      Numerator: [1x70 double]  
      InitialConditions: 0
```

```
Show all properties
```

Measure the specifications of the designed lowpass filter.

```
measure(equiFilter)
```

```
ans =  
Sample Rate      : N/A (normalized frequency)  
Passband Edge    : 0.45  
3-dB Point       : 0.47798  
6-dB Point       : 0.48913  
Stopband Edge    : 0.55  
Passband Ripple  : 0.095021 dB  
Stopband Atten.  : 80.1164 dB  
Transition Width : 0.1
```

Stopband Edge, Passband Edge, Passband Ripple, and Stopband Atten. all meet the specifications.

Now, using  $F_s$  in linear frequency, create a bandpass filter, and measure the magnitude response characteristics.

```
designBandpass = fdesign.bandpass
```

```
designBandpass =  
  bandpass with properties:  
  
      Response: 'Bandpass'  
      Specification: 'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2'  
      Description: {7x1 cell}  
      NormalizedFrequency: 1  
          Fstop1: 0.3500  
          Fpass1: 0.4500
```

```

Fpass2: 0.5500
Fstop2: 0.6500
Astop1: 60
Apass: 1
Astop2: 60

```

Convert to Linear Frequency.

```
normalizefreq(designBandpass,false,1.5e3)
```

```
bpFilter = design(designBandpass,'cheby2','SystemObject',true);
```

Measure the specifications of the designed bandpass filter.

```
measure(bpFilter)
```

```

ans =
Sample Rate           : 1.5 kHz
First Stopband Edge   : 262.5 Hz
First 6-dB Point      : 319.9585 Hz
First 3-dB Point      : 324.9744 Hz
First Passband Edge   : 337.5 Hz
Second Passband Edge  : 412.5 Hz
Second 3-dB Point     : 425.0256 Hz
Second 6-dB Point     : 430.0415 Hz
Second Stopband Edge  : 487.5 Hz
First Stopband Atten. : 60 dB
Passband Ripple       : 0.17985 dB
Second Stopband Atten.: 60 dB
First Transition Width: 75 Hz
Second Transition Width: 75 Hz

```

## Tips

For designs that do not specify some of the frequency constraints, the function may not be able to determine corresponding magnitude measurements. In these cases, a constraint can be passed in to `measure` to determine such measurements. For example:

```

f = fdesign.lowpass('N,F3dB,Ast',8,0.5,80);
H = design(f,'cheby2','SystemObject',true);
measure(H)

```

returns values of Unknown for the passband edge, passband ripple, and transition width measurements, but

```
f = fdesign.lowpass('N,F3dB,Ast',8,0.5,80);  
H = design(f,'cheby2','SystemObject',true);  
measure(H,'Fpass',0.4)
```

provides measurements for all returned values.

**Introduced in R2011a**

# mfilt

Multirate filter

## Compatibility

`mfilt` will be removed in a future release. See `dsp.CICDecimator`, `dsp.CICInterpolator`, `dsp.FIRDecimator`, `dsp.FIRInterpolator`, `dsp.FilterCascade`, `dsp.FarrowRateConverter`, `dsp.FIRRateConverter`, `dsp.IIRHalfbandDecimator`, or `dsp.IIRHalfbandInterpolator` instead.

## Syntax

```
hm = mfilt.structure(input1,input2,...)
```

## Description

`hm = mfilt.structure(input1,input2,...)` returns the object `hm` of type *structure*. As with `dfilt` objects, you must include the *structure* string to construct a multirate filter object. You can, however, construct a default multirate filter object of a given structure by not including input arguments in your calling syntax.

Multirate filters include decimators and interpolators, and fractional decimators and fractional interpolators where the resulting interpolation or decimation factor is not an integer.

## Structures

Each of the following multirate filter structures has a reference page of its own.

Filter Structure String	Description of Resulting Multirate Filter	Coefficient Mapping Support in <code>realizemdl</code> and <code>block</code>
<code>mfilt.cascade</code>	Cascade multirate filters to form another filter	Supported
<code>mfilt.cicdecim</code>	Cascaded integrator-comb decimator	Not supported
<code>mfilt.cicinterp</code>	Cascaded integrator-comb interpolator	Not supported
<code>mfilt.farrowsrc</code>	Multirate Farrow filter	Supported.
<code>mfilt.fftfirinterp</code>	Overlap-add FIR polyphase interpolator	Not supported
<code>mfilt.firdecim</code>	Direct-form FIR polyphase decimator	Supported
<code>mfilt.firinterp</code>	Direct-form FIR polyphase interpolator	Supported
<code>mfilt.firsrc</code>	Direct-form FIR polyphase sample rate converter	Supported
<code>mfilt.firtdecim</code>	Direct-form transposed FIR polyphase decimator	Supported
<code>mfilt.holdinterp</code>	FIR hold interpolator	Not supported
<code>mfilt.iirdecim</code>	IIR decimator	Supported
<code>mfilt.iirinterp</code>	IIR interpolator	Supported
<code>mfilt.linearinterp</code>	FIR Linear interpolator	Supported
<code>mfilt.iirwdfdecim</code>	IIR wave digital filter decimator	Supported
<code>mfilt.iirwdfinterp</code>	IIR wave digital filter interpolator	Supported

## Copying `mfilt` Objects

To create a copy of an `mfilt` object, use the `copy` method.

```
h2 = copy(hd)
```

---

**Note** The syntax `hd2 = hd` copies only the object handle. It does not create a new object. `hd2` and `hd` are not independent. If you change the property value for one of the two, such as `hd2`, you are changing the property for both.

---

## Examples

Decimation by a factor of two. Convert input sampled at 48 kHz to 24 kHz:

```
Fs = 4.8e4;
t = 0:1/Fs:1-(1/Fs);
x = cos(2*pi*4000*t);
Hm=mfilt.firdecim(2);
% Note cutoff frequency of 1/2 normalized frequency
fvtool(Hm);
% Note the group delay of 34 samples
fvtool(Hm,'analysis','grpdelay');
y = filter(Hm,x);
% Note delay in output is consistent with 36/2
stem(y(1:48),'markerfacecolor',[0 0 1]);
```

Using existing coefficients to decimate a signal by a factor of two:

```
M = 2; % Decimation factor
b = firhalfband('minorder',.45,0.0001);
Hm = mfilt.firdecim(M,b);
% Decimate a signal which consists of the sum of 2 sinusoids.
N = 160;
x = sin(2*pi*.05*[0:N-1]+pi/3)+cos(2*pi*.03*[0:N-1]+pi/3);
y = filter(Hm,x);
```

---

**Note** Multirate filters can also have complex coefficients. For example, you can specify complex coefficients in the argument `num` passed to the filter structure. This works for all multirate filter structures.

```
m = 2;
num = [0.5 0.5+1j*0.2];
Hm = mfilt.firdecim(m, num);
y = filter(Hm, [1:10]);
```

---

## See Also

**Introduced in R2011a**

# mfilt.cascade

Cascade filter objects

---

**Note** `mfilt.cascade` will be removed in a future release. Use `dsp.FilterCascade` instead.

---

## Syntax

```
hm = cascade(hm1, hm2, ..., hmn)
```

## Description

`hm = cascade(hm1, hm2, ..., hmn)` creates filter object `hm` by cascading (connecting in series) the individual filter objects `hm1`, `hm2`, and so on to `hmn`.

In block diagram form, the cascade looks like this, with `x` as the input to the filter `hm` and `y` the output from the cascade filter `hm`:

`mfilt.cascade` accepts any combination of `mfilt` and `dfilt` objects (discrete time filters) to cascade, as well as Farrow filter objects.

## Examples

Create a variety of `mfilt` objects and cascade them together.

```

hm(1) = mfilt.firdecim(12);
hm(2) = mfilt.firdecim(4);
h1 = mfilt.cascade(hm(1), hm(2));
hm(3) = mfilt.firinterp(4);
  
```

```
hm(4) = mfilt.firinterp(12);  
h2 = mfilt.cascade(hm(3),hm(4));  
% Cascade h1 and h2 together  
h3 = mfilt.cascade(h1,h2,9600);
```

## See Also

dfilt.cascade

**Introduced in R2011a**

# mfilt.cicdecim

Fixed-point CIC decimator

---

**Note** `mfilt.cicdecim` will be removed in a future release. Use `dsp.CICDecimator` instead.

---

## Syntax

```
hm = mfilt.cicdecim(r,m,n,iwl,owl,wlps)
```

## Description

`hm = mfilt.cicdecim(r,m,n,iwl,owl,wlps)` returns a cascaded integrator-comb (CIC) decimation filter object.

All of the input arguments are optional. To enter any optional value, you must include all optional values to the left of your desired value.

When you omit one or more input options, the omitted option applies the default values shown in the table below.

The following table describes the input arguments for creating `hm`.

Input Arguments	Description
<code>r</code>	Decimation factor applied to the input signal. Sharpens the response curve to let you change the shape of the response. <code>r</code> must be an integer value greater than or equal to 1. The default value is 2.

Input Arguments	Description
m	Differential delay. Changes the shape, number, and location of nulls in the filter response. Increasing m increases the sharpness of the nulls and the response between nulls. In practice, differential delay values of 1 or 2 are the most common. m must be an integer value greater than or equal to 1. The default value is 1.
n	Number of sections. Deepens the nulls in the response curve. Note that this is the number of either comb or integrator sections, not the total section count. 2 is the default value.
iwl	Word length of the input signal. Use any integer number of bits. The default value is 16 bits.
owl	Word length of the output signal. It can be any positive integer number of bits. By default, owl is 16 bits.
wlps	<p>Defines the number of bits per word in each filter section while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter wlps as a scalar or vector of length 2*n, where n is the number of sections. When wlps is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the decimator.</p> <p>When you elect to specify wlps as an input argument, the FilterInternals property automatically switches from the default value of 'FullPrecision' to 'SpecifyWordLengths'.</p>

## Constraints and Word Length Considerations

CIC decimators have the following constraint — the word lengths of the filter section must be monotonically decreasing. The word length of each filter section must be the same size as, or smaller than, the word length of the previous filter section.

The formula for  $B_{max}$ , the most significant bit at the filter output, is given in the Hogenauer paper in the References on page 5-1151 below.

$$B_{max} = (N \log_2 RM + B_{in} - 1)$$

where  $B_{in}$  is the number of bits of the input.

The cast operations shown in the diagram in “Algorithms” on page 5-1150 perform the changes between the word lengths of each section. When you specify word lengths that do not follow the constraints above, the constructor returns an error.

When you specify the word lengths correctly, the most significant bit  $B_{max}$  stays the same throughout the filter, while the word length of each section either decreases or stays the same. This can cause the fraction length to change throughout the filter as least significant bits are truncated to decrease the word length, as shown in “Algorithms” on page 5-1150.

## Properties of the Object

Objects have properties that control the way the object behaves. This table lists all the properties for the filter, with a description of each.

Name	Values	Default	Description
Arithmetic	fixed	fixed	Reports the kind of arithmetic the filter uses. CIC decimators are always fixed-point filters.
DecimationFactor	Any positive integer	2	Amount to reduce the input sampling rate.
DifferentialDelay	Any positive integer	1	Sets the differential delay for the filter. Usually a value of one or two is appropriate.
FilterStructure	mfilt structure string	None	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of mfilt objects.

Name	Values	Default	Description
FilterInternals	FullPrecision, MinWordLengths, SpecifyPrecision, SpecifyWordLengths	FullPrecision	Set the usage mode for the filter. Refer to “Usage Modes” on page 5-1142 below for details.
InputFracLength	Any positive integer	15	The number of bits applied to the fraction length to interpret the input data to the filter.
InputOffset	Integers in the range $0 \leq \text{InputOffset} \leq r - 1$	0	<p>Contains a value derived from the number of input samples and the decimation factor —</p> $\text{InputOffset} = \text{mod}(\text{length}(nx), m)$ <p>where <math>nx</math> is the number of input samples that have been processed so far and <math>m</math> is the decimation factor.</p> <p>The <code>InputOffset</code> property applies only when you set the <code>PersistentMemory</code> property to <code>true</code>. See “<code>InputOffset</code>” on page 6-103 for more information.</p>
InputWordLength	Any positive integer	16	The number of bits applied to the word length to interpret the input data to the filter.

<b>Name</b>	<b>Values</b>	<b>Default</b>	<b>Description</b>
NumberOfSections	Any positive integer	2	Number of sections used in the decimator. Generally called $n$ . Reflects either the number of decimator or comb sections, not the total number of sections in the filter.
OutputFracLength	Any positive integer	15	The number of bits applied to the fraction length to interpret the output data from the filter. Read-only.
OutputWordLength	Any positive integer	16	The number of bits applied to the word length to interpret the output data from the filter.

<b>Name</b>	<b>Values</b>	<b>Default</b>	<b>Description</b>
PersistentMemory	false or true	false	<p>Determines whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. <b>PersistentMemory</b> returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.</p> <p>When <b>PersistentMemory</b> is <b>false</b>, you cannot access the filter states. Setting <b>PersistentMemory</b> to <b>true</b> reveals the <b>States</b> property so you can modify the filter states.</p>

Name	Values	Default	Description
SectionWordLengths	Any integer or a vector of length 2*n.	16	Defines the bits per section used while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter SectionWordLengths as a scalar or vector of length 2*n, where n is the number of sections. When SectionWordLengths is a scalar, the scalar value is applied to each filter section. When SectionWordLengths is a vector of values, the values apply to the sections in order. The default is 16 for each section in the decimator. Available when FilterInternals is 'SpecifyWordLengths'.

Name	Values	Default	Description
States	filtstates.cic object	m+1-by-n matrix of zeros, after you call function int.	Stored conditions for the filter, including values for the integrator and comb sections before and after filtering. m is the differential delay of the comb section and n is the number of sections in the filter. The integrator states are stored in the first matrix row. States for the comb section fill the remaining rows in the matrix. Available for modification when PersistentMemory is true. Refer to the filtstates object in Signal Processing Toolbox documentation for more general information about the filtstates object.

## Usage Modes

There are four modes of usage for this which are set using the `FilterInternals` property

- `FullPrecision` — All word and fraction lengths set to  $B_{max} + 1$ , called  $B_{accum}$  by Fred Harris in [3]. Full Precision is the default setting.
- `MinWordLengths` — Automatically set the sections for minimum word lengths.
- `SpecifyWordLengths` — Specify the word lengths for each section.
- `SpecifyPrecision` — Specify precision by providing values for the word and fraction lengths for each section.

Full Precision

In full precision mode, the word lengths of all sections and the output are set to  $B_{accum}$  as defined by

$$B_{accum} = \text{ceil}(N_{secs}(\text{Log}_2(D \times M)) + \text{InputWordLength})$$

where  $N_{secs}$  is the number of filter sections.

Section fraction lengths and the fraction length of the output are set to the input fraction length.

Here is the display for this mode:

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false
```

```
InputWordLength: 16
InputFracLength: 15
```

```
FilterInternals: 'FullPrecision'
```

### Minimum Wordlengths

In minimum word length mode, you control the output word length explicitly. When the output word length is less than  $B_{accum}$ , roundoff noise is introduced at the output of the filter. Hogenauer's bit pruning theory (refer to [1]) states that one valid design criterion is to make the word lengths of the different sections of the filter smaller than  $B_{accum}$  as well, so that the roundoff noise introduced by all sections does not exceed the roundoff noise introduced at the output.

In this mode, the design calculates the word lengths of each section to meet the Hogenauer criterion. The algorithm subtracts the number of bits computed using eq. 21 in Hogenauer's paper from  $B_{accum}$  to determine the word length each section.

To compute the fraction lengths of the different sections, the algorithm notes that the bits thrown out for this word length criterion are least significant bits (LSB), therefore each bit thrown out at a particular section decrements the fraction length of that section by one bit compared to the input fraction length. Setting the output wordlength for the filter automatically sets the output fraction length as well.

Here is the display for this mode:

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'  
Arithmetic: 'fixed'  
DifferentialDelay: 1  
NumberOfSections: 2  
DecimationFactor: 4  
PersistentMemory: false
```

```
InputWordLength: 16  
InputFracLength: 15
```

```
FilterInternals: 'MinWordLengths'
```

```
OutputWordLength: 16
```

Specify word lengths

In this mode, the design algorithm discards the LSBs, adjusting the fraction length so that unrecoverable overflow does not occur, always producing a reasonable output.

You can specify the word lengths for all sections and the output, but you cannot control the fraction lengths for those quantities.

To specify the word lengths, you enter a vector of length  $2*(\text{NumberOfSections})$ , where each vector element represents the word length for a section. If you specify a scalar, such as  $B_{accum}$ , the full-precision output word length, the algorithm expands that scalar to a vector of the appropriate size, applying the scalar value to each section.

The CIC design does not check that the specified word lengths are monotonically decreasing. There are some cases where the word lengths are not necessarily monotonically decreasing, for example

```
hcic=mfilt.cicdecim;  
hcic.FilterInternals='minwordlengths';  
hcic.Outputwordlength=14;
```

which are valid CIC filters but the word lengths do not decrease monotonically across the sections.

Here is the display for the SpecifyWordLengths mode.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'  
Arithmetic: 'fixed'
```

```
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false
```

```
InputWordLength: 16
InputFracLength: 15
```

```
FilterInternals: 'SpecifyWordLengths'
```

```
SectionWordLengths: [19 18 18 17]
```

```
OutputWordLength: 16
```

Specify precision

In this mode, you have full control over the word length and fraction lengths of all sections and the filter output.

When you elect the SpecifyPrecision mode, you must enter a vector of length  $2*(NumberOfSections)$  with elements that represent the word length for each section. When you enter a scalar such as  $B_{accum}$ , `mfilt.cicdecim` expands that scalar to a vector of the appropriate size and applies the scalar value to each section and the output. The design does not check that this vector is monotonically decreasing.

Also, you must enter a vector of length  $2*(NumberOfSections)$  with elements that represent the fraction length for each section as well. When you enter a scalar such as  $B_{accum}$ , `mfilt.cicdecim` applies scalar expansion as done for the word lengths.

Here is the SpecifyPrecision display.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false
```

```
InputWordLength: 16
InputFracLength: 15
```

```
FilterInternals: 'SpecifyPrecision'
```

```
SectionWordLengths: [19 18 18 17]
```

```
SectionFracLengths: [14 13 13 12]
```

```
OutputWordLength: 16
```

```
OutputFracLength: 11
```

## About the States of the Filter

In the `states` property you find the states for both the integrator and comb portions of the filter. `states` is a matrix of dimensions  $m + 1$ -by- $n$ , with the states apportioned as follows:

- States for the integrator portion of the filter are stored in the first row of the state matrix.
- States for the comb portion fill the remaining rows in the state matrix.

To review the states of a CIC filter, use `int` to assign the states to a variable in MATLAB. As an example, here are the states for a CIC decimator `hm` before and after filtering a data set.

```
x = fi(ones(1,10),true,16,0); % Fixed-point input data.
hm = mfilt.cicdecim(2,1,2,16,16,16);
sts=int(hm.states)
set(hm,'InputFracLength',0); % Integer input specified.
y=filter(hm,x);
sts=int(hm.states)
```

STS is an integer matrix that `int` returns from the contents of the `filtstates.cic` object in `hm`.

## Design Considerations

When you design your CIC decimation filter, remember the following general points:

- The filter output spectrum has nulls at  $\omega = k * 2\pi/rm$  radians,  $k = 1,2,3,\dots$
- Aliasing and imaging occur in the vicinity of the nulls.
- $n$ , the number of sections in the filter, determines the passband attenuation. Increasing  $n$  improves the filter ability to reject aliasing and imaging, but it also increases the droop (or rolloff) in the filter passband. Using an appropriate FIR filter in series after the CIC decimation filter can help you compensate for the induced droop.
- The DC gain for the filter is a function of the decimation factor. Raising the decimation factor increases the DC gain.

## Examples

This example applies a decimation factor  $r$  equal to 8 to a 160-point impulse signal. The signal output from the filter has  $160/r$ , or 20, points or samples. Choosing 10 bits for the word length represents a fairly common setting for analog to digital converters. The plot shown after the code presents the stem plot of the decimated signal, with 20 samples remaining after decimation:

```
m = 2; % Differential delays in the filter.
n = 4; % Filter sections
r = 8; % Decimation factor
x = int16(zeros(160,1)); x(1) = 1; % Create a 160-point
                                % impulse signal.
hm = mfilt.cicdecim(r,m,n); % Expects 16-bit input
                                % by default.
y = filter(hm,x);
stem(double(y)); % Plot output as a stem plot.
xlabel('Samples'); ylabel('Amplitude');
title('Decimated Signal');
```

The next example demonstrates one way to compute the filter frequency response, using a 4-section decimation filter with the decimation factor set to 7:

```
hm = mfilt.cicdecim(7,1,4);
fvtool(hm)
```

FVTool provides ways for you to change the title and x labels to match the figure shown. Here's the frequency response plot for the filter. For details about the transfer function used to produce the frequency response, refer to [1] in the References on page 5-1151 section.

This final example demonstrates the decimator for converting from 44.1 kHz audio to 22.05 kHz — decimation by two. To overlay the before and after signals, scale the output and plot the signals on a stem plot.

```

r = 2; % Decimation factor.
hm = mfilter.cicdecim(r); % Use default NumberOfSections &
% DifferentialDelay property values.
fs = 44.1e3; % Original sampling frequency: 44.1kHz.
n = 0:10239; % 10240 samples, 0.232 second long signal.
x = sin(2*pi*1e3*n); % Original signal, sinusoid at 1kHz.

y_fi = filter(hm,x); % 5120 samples, still 0.232 seconds.

% Scale the output to overlay the stem plots.
x = double(x);
y = double(y_fi);
y = y/max(abs(y));
stem(n(1:44)/fs,x(2:45)); hold on; % Plot original signal
% sampled at 44.1kHz.
stem(n(1:22)/(fs/r),y(3:24),'r','filled'); % Plot decimated
% signal (22.05kHz)
% in red.
xlabel('Time (seconds)');ylabel('Signal Value');

```

## Algorithms

To show how the CIC decimation filter is constructed, the following figure presents a block diagram of the filter structure for a two-section CIC decimation filter ( $n = 2$ ).  $f_s$  is the high sampling rate, the input to the decimation process.

For details about the bits that are removed in the Comb portion, refer to [1] in References.

`mfilt.cicdecim` calculates the fraction length at each section of the decimator to avoid overflows at the output of the filter.

## mfilt.cicinterp

Fixed-point CIC interpolator

---

**Note** `mfilt.cicinterp` will be removed in a future release. Use `dsp.CICInterpolator` instead.

---

### Syntax

```
hm = mfilt.cicinterp(R,M,N,ILW,OWL,WLPS)
hm = mfilt.cicinterp
hm = mfilt.cicinterp(R,...)
```

### Description

`hm = mfilt.cicinterp(R,M,N,ILW,OWL,WLPS)` constructs a cascaded integrator-comb (CIC) interpolation filter object that uses fixed-point arithmetic.

All of the input arguments are optional. To enter any optional value, you must include all optional values to the left of your desired value.

When you omit one or more input options, the omitted option applies the default values shown in the table below.

The following table describes the input arguments for creating `hm`.

Input Arguments	Description
R	Interpolation factor applied to the input signal. Sharpens the response curve to let you change the shape of the response. R must be an integer value greater than or equal to 1. The default value is 2.

Input Arguments	Description
M	Differential delay. Changes the shape, number, and location of nulls in the filter response. Increasing M increases the sharpness of the nulls and the response between nulls. In practice, differential delay values of 1 or 2 are the most common. M must be an integer value greater than or equal to 1. The default value is 1.
N	Number of sections. Deepens the nulls in the response curve. Note that this is the number of either comb or integrator sections, not the total section count. By default, the filter has two sections.
IWL	Word length of the input signal. Use any integer number of bits. The default value is 16 bits.
OWL	Word length of the output signal. It can be any positive integer number of bits. By default, OWL is 16 bits.
WLPS	<p>Defines the number of bits per word in each filter section while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter WLPS as a scalar or vector of length <math>2*N</math>, where N is the number of sections. When WLPS is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the integrator.</p> <p>When you elect to specify <code>wlps</code> as an input argument, the <code>FilterInternals</code> property automatically switches from the default value of 'FullPrecision' to 'SpecifyWordLengths'.</p>

`hm = mfilt.cicinterp` constructs the CIC interpolator using the default values for the optional input arguments.

`hm = mfilt.cicinterp(R, ...)` constructs the CIC interpolator applying the values you provide for R and any other values you specify as input arguments.

## Constraints and Conversions

In Hogenauer [1], the author describes the constraints on CIC interpolator filters. `mfilt.cicinterp` enforces a constraint—the word lengths of the filter sections must be non-decreasing. That is, the word length of each filter section must be the same size as, or greater than, the word length of the previous filter section.

The formula for  $W_j$ , the minimum register width, is derived in [1]. The formula for  $W_j$  is given by

$$W_j = \text{ceil}(B_{in} + \log_2 G_j)$$

where  $G_j$ , the maximum register growth up to the  $j$ th section, is given by

$$G_j = \begin{cases} 2^j, & j = 1, 2, \dots, N \\ \frac{2^{2N-j}(RM)^{j-N}}{R}, & j = N + 1, \dots, 2N \end{cases}$$

When the differential delay,  $M$ , is 1, there is also a special condition for the register width of the last comb,  $W_N$ , that is given by

$$W_N = B_{in} + N - 1 \text{ if } M = 1$$

The conversions denoted by the cast blocks in the integrator diagrams in “Algorithms” on page 5-1161 perform the changes between the word lengths of each section. When you specify word lengths that do not follow the constraints described in this section, `mfilt.cicinterp` returns an error.

The fraction lengths and scalings of the filter sections do not change. At each section the word length is either staying the same or increasing. The signal scaling can change at the output after the final filter section if you choose the output word length to be less than the word length of the final filter section.

## Properties of the Object

The following table lists the properties for the filter with a description of each.

Name	Values	Default	Description
Arithmetic	fixed	fixed	Reports the kind of arithmetic the filter uses. CIC interpolators are always fixed-point filters.
InterpolationFactor	Any positive integer	2	Amount to increase the input sampling rate.

<b>Name</b>	<b>Values</b>	<b>Default</b>	<b>Description</b>
DifferentialDelay	Any positive integer	1	Sets the differential delay for the filter. Usually a value of one or two is appropriate.
FilterStructure	mfilt structure string	None	Reports the type of filter object, such as a interpolator or fractional integrator. You cannot set this property – it is always read only and results from your choice of mfilter objects.
FilterInternals	FullPrecision, MinWordLengths, SpecifyWordLengths , SpecifyPrecision	FullPrecision	Set the usage mode for the filter. Refer to “Usage Modes” on page 5-1158 below for details.
InputFracLength	Any positive integer	16	The number of bits applied as the fraction length to interpret the input data to the filter.
InputWordLength	Any positive integer	16	The number of bits applied to the word length to interpret the input data to the filter.
NumberOfSections	Any positive integer	2	Number of sections used in the interpolator. Generally called n. Reflects either the number of interpolator or comb sections, not the total number of sections in the filter.
OutputFracLength	Any positive integer	15	The number of bits applied to the fraction length to interpret the output data from the filter. Read-only.

<b>Name</b>	<b>Values</b>	<b>Default</b>	<b>Description</b>
OutputWordLength	Any positive integer	16	The number of bits applied to the word length to interpret the output data from the filter.
PersistentMemory	false or true	false	Determines whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. When PersistentMemory is false, you cannot access the filter states. Setting PersistentMemory to true reveals the States property so you can modify the filter states.

Name	Values	Default	Description
SectionWordLengths	<p>Any integer or a vector of length <math>2^N</math>, where <math>N</math> is a positive integer.</p> <p>This property only applies when the <code>FilterInternals</code> is <code>SpecifyWordLengths</code>.</p>	16	<p>Defines the bits per section used while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter <code>SectionWordLengths</code> as a scalar or vector of length <math>2*n</math>, where <math>n</math> is the number of sections. When <code>SectionWordLengths</code> is a scalar, the scalar value is applied to each filter section. When <code>SectionWordLengths</code> is a vector of values, the values apply to the sections in order. The default is 16 for each section in the interpolator. Available when <code>FilterInternals</code> is <code>'SpecifyWordLengths'</code>.</p>

Name	Values	Default	Description
States	<code>filtstates.cic</code> object	$m+1$ -by- $n$ matrix of zeros, after you call function <code>int</code> .	Stored conditions for the filter, including values for the integrator and comb sections before and after filtering. $m$ is the differential delay of the comb section and $n$ is the number of sections in the filter. The integrator states are stored in the first matrix row. States for the comb section fill the remaining rows in the matrix. Available for modification when <code>PersistentMemory</code> is true. Refer to the <code>filtstates</code> object in Signal Processing Toolbox documentation for more general information about the <code>filtstates</code> object.

## Usage Modes

There are usage modes which are set using the `FilterInternals` property:

- **FullPrecision** — In this mode, the word and fraction lengths of the filter sections and outputs are automatically selected for you. The output and last section word lengths are set to:

$$\text{wordlength} = \text{ceil}(\log_2((RM)^N / R)) + I,$$

where  $R$  is the interpolation factor,  $M$  is the differential delay,  $N$  is the number of filter sections, and  $I$  denotes the input word length.

- **MinWordLengths** — In this mode, you specify the word length of the filter output in the `OutputWordLength` property. The word lengths of the filter sections are automatically set in the same way as in the `FullPrecision` mode. The section fraction lengths are set to the input fraction length. The output fraction length is set to

the input fraction length minus the difference between the last section and output word lengths.

- **SpecifyWordLengths** — In this mode, you specify the word lengths of the filter sections and output in the `SectionWordLengths` and `OutputWordLength` properties. The fraction lengths of the filter sections are set such that the spread between word length and fraction length is the same as in full-precision mode. The output fraction length is set to the input fraction length minus the difference between the last section and output word lengths.
- **SpecifyPrecision** — In this mode, you specify the word and fraction lengths of the filter sections and output in the `SectionWordLengths`, `SectionFracLengths`, `OutputWordLength`, and `OutputFracLength` properties.

## About the States of the Filter

In the `states` property you find the states for both the integrator and comb portions of the filter. `states` is a matrix of dimensions  $m+1$ -by- $n$ , with the states apportioned as follows:

- States for the integrator portion of the filter are stored in the first row of the state matrix.
- States for the comb portion fill the remaining rows in the state matrix.

To review the states of a CIC filter, use the `int` method to assign the states. As an example, here are the states for a CIC interpolator `hm` before and after filtering data:

```
x = fi(cos(pi/4*[0:99]),true,16,0); % Fixed-point input data
hm = mfilt.cicinterp(2,1,2,16,16,16);
% get initial states-all zero
sts=int(hm.states)
set(hm,'InputFracLength',0); % Integer input specified
y=filter(hm,x);
sts=int(hm.states)
%sts =
%
%      -1      -1
%      -1      -1
```

## Design Considerations

When you design your CIC interpolation filter, remember the following general points:

- The filter output spectrum has nulls at  $\omega = k * 2\pi/rm$  radians,  $k = 1,2,3,\dots$
- Aliasing and imaging occur in the vicinity of the nulls.
- $n$ , the number of sections in the filter, determines the passband attenuation. Increasing  $n$  improves the filter ability to reject aliasing and imaging, but it also increases the droop or rolloff in the filter passband. Using an appropriate FIR filter in series after the CIC interpolation filter can help you compensate for the induced droop.
- The DC gain for the filter is a function of the interpolation factor. Raising the interpolation factor increases the DC gain.

## Examples

Demonstrate interpolation by a factor of two, in this case from 22.05 kHz to 44.1 kHz. Note the scaling required to see the results in the stem plot and to use the full range of the `int16` data type.

```
R = 2; % Interpolation factor.
hm = mfilt.cicinterp(R); % Use default NumberOfSections and
% DifferentialDelay property values.
fs = 22.05e3; % Original sample frequency:22.05 kHz.
n = 0:5119; % 5120 samples, .232 second long signal.
x = sin(2*pi*1e3/fs*n); % Original signal, sinusoid at 1 kHz.

y_fi = filter(hm,x); % 5120 samples, still 0.232 seconds.

% Scale the output to overlay stem plots correctly.
x = double(x);
y = double(y_fi);
y = y/max(abs(y));
stem(n(1:22)/fs,x(1:22),'filled'); % Plot original signal sampled
% at 22.05 kHz.

hold on;
stem(n(1:44)/(fs*R),y(4:47),'r'); % Plot interpolated signal
% (44.1 kHz) in red.
xlabel('Time (sec)');ylabel('Signal Value');
```

As you expect, the plot shows that the interpolated signal matches the input sine shape, with additional samples between each original sample.

Use the filter visualization tool (FVTool) to plot the response of the interpolator object. For example, to plot the response of an interpolator with an interpolation factor of 7, 4 sections, and 1 differential delay, do something like the following:

```
hm = mfilt.cicinterp(7,1,4)
fvtool(hm)
```

## Algorithms

To show how the CIC interpolation filter is constructed, the following figure presents a block diagram of the filter structure for a two-section CIC interpolation filter ( $n = 2$ ).  $fs$  is the high sampling rate, the output from the interpolation process.

For details about the bits that are removed in the integrator section, refer to [1] in References.

When you select `MinWordLengths`, the filter section word lengths are automatically set to the minimum number of bits possible in a valid CIC interpolator. `mfilt.cicinterp` computes the wordlength for each section so the roundoff noise introduced by all sections is less than the roundoff noise introduced by the quantization at the output.

**Introduced in R2011a**

# mfilt.farrowsrc

Sample rate converter with arbitrary conversion factor

## Compatibility

mfilt.farrowsrc will be removed in a future release. Use dsp.FarrowRateConverter instead.

## Syntax

```
hm = mfilt.farrowsrc(L,M,C)
hm = mfilt.farrowsrc
hm = mfilt.farrowsrc(l,...)
```

## Description

hm = mfilt.farrowsrc(L,M,C) returns a filter object that is a natural extension of dfilt.farrowfd with a time-varying fractional delay. It provides a economical implementation of a sample rate converter with an arbitrary conversion factor. This filter works well in the interpolation case, but may exhibit poor anti-aliasing properties in the decimation case.

---

**Note** You can use the realizemdl method to create a Simulink block of a filter created using mfilt.farrowsrc.

---

## Input Arguments

The following table describes the input arguments for creating hm.

Input Argument	Description
<code>l</code>	Interpolation factor for the filter. <code>l</code> specifies the amount to increase the input sampling rate. The default value of <code>l</code> is 3.
<code>m</code>	Decimation factor for the filter. <code>m</code> specifies the amount to decrease the input sampling rate. The default value for <code>m</code> is 2.
<code>c</code>	Coefficients for the filter. When no input arguments are specified, the default coefficients are <code>[-1 1; 1, 0]</code>

`hm = mfilt.farrowsrc` constructs the filter using the default values for `l`, `m`, and `c`.

`hm = mfilt.farrowsrc(l, ...)` constructs the filter using the input arguments you provide and defaults for the argument you omit.

### **mfilt.farrowsrc Object Properties**

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.farrowsrc` objects. The next table describes each property for an `mfilt.farrowsrc` filter object.

Name	Values	Description
<code>FilterStructure</code>	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object.
<code>Arithmetic</code>	String	Reports the arithmetic precision used by the filter.
<code>Coefficients</code>	Vector	Vector containing the coefficients of the FIR lowpass filter
<code>InterpolationFactor</code>	Integer	Interpolation factor for the filter. It specifies the amount to increase the input sampling rate.
<code>DecimationFactor</code>	Integer	Decimation factor for the filter. It specifies the amount to increase the input sampling rate.

Name	Values	Description
PersistentMemory	false or true	Determines whether the filter states are restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.

## Examples

Interpolation by a factor of 8. This object removes the spectral replicas in the signal after interpolation.

```
[L,M] = rat(48/44.1);
Hm = mfilt.farrowsrc(L,M);           % We use the default filter
Fs = 44.1e3;                         % Original sampling frequency
n = 0:9407;                          % 9408 samples, 0.213 seconds long
x = sin(2*pi*1e3/Fs*n);              % Original signal, sinusoid at 1kHz
y = filter(Hm,x);                   % 10241 samples, still 0.213 seconds
stem(n(1:45)/Fs,x(1:45))            % Plot original sampled at 44.1kHz
hold on
% Plot fractionally interpolated signal (48kHz) in red
stem((n(2:50)-1)/(Fs*L/M),y(2:50),'r','filled')
xlabel('Time (sec)');ylabel('Signal value')
legend('44.1 kHz sample rate','48kHz sample rate')
```

The results of the example are shown in the following figure:

## See Also

`dsp.FarrowRateConverter`

**Introduced in R2011a**

# mfilt.fftfirinterp

Overlap-add FIR polyphase interpolator

---

**Note** `mfilt.fftfirinterp` will be removed in a future release. Use `dsp.FIRInterpolator` instead.

---

## Syntax

```
hm = mfilt.fftfirinterp(l,num,bl)
hm = mfilt.fftfirinterp
hm = mfilt.fftfirinterp(l,...)
```

## Description

`hm = mfilt.fftfirinterp(l,num,bl)` returns a discrete-time FIR filter object that uses the overlap-add method for filtering input data.

The input arguments are optional. To enter any optional value, you must include all optional values to the left of your desired value.

When you omit one or more input options, the omitted option applies the default values shown in the table below.

The number of FFT points is given by  $[bl + \text{ceil}(\text{length}(\text{num})/l) - 1]$ . It is to your advantage to choose `bl` such that the number of FFT points is a power of two—using powers of two can improve the efficiency of the FFT and the associated interpolation process.

## Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
<code>l</code>	Interpolation factor for the filter. <code>l</code> specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for <code>l</code> it defaults to 2.
<code>num</code>	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When <code>num</code> is not provided as an input, <code>fftfirinterp</code> uses a lowpass Nyquist filter with gain equal to <code>l</code> and cutoff frequency equal to $\pi/l$ by default.
<code>bl</code>	Length of each block of input data used in the filtering. <code>bl</code> must be an integer. When you omit input <code>bl</code> , it defaults to 100

`hm = mfilt.fftfirinterp` constructs the filter using the default values for `l`, `num`, and `bl`.

`hm = mfilt.fftfirinterp(l, ...)` constructs the filter using the input arguments you provide and defaults for the argument you omit.

## **mfilt.fftfirinterp Object Properties**

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.fftfirinterp` objects. The next table describes each property for an `mfilt.fftfirinterp` filter object.

Name	Values	Description
<code>FilterStructure</code>		Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object.
<code>Numerator</code>		Vector containing the coefficients of the FIR lowpass filter used for interpolation.
<code>InterpolationFactor</code>		Interpolation factor for the filter. It specifies the amount to increase the input sampling rate. It must be an integer.
<code>BlockLength</code>		Length of each block of input data used in the filtering.

Name	Values	Description
PersistentMemory	false or true	Determines whether the filter states are restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.
States		Stored conditions for the filter, including values for the interpolator states.

## Examples

Interpolation by a factor of 8. This object removes the spectral replicas in the signal after interpolation.

```

l = 8; % Interpolation factor
hm = mfilt.fftfirinterp(l); % We use the default filter
n = 8192; % Number of points
hm.blocklength = n; % Set block length to number of points
fs = 44.1e3; % Original sample freq: 44.1 kHz.
n = 0:n-1; % 0.1858 secs of data
x = sin(2*pi*n*22e3/fs); % Original signal, sinusoid at 22 kHz
y = filter(hm,x); % Interpolated sinusoid
xu = l*upsample(x,8); % Upsample to compare--the spectrum
% does not change
[px,f]=periodogram(xu,[],65536,l*fs); % Power spectrum of original
% signal
[py,f]=periodogram(y,[],65536,l*fs); % Power spectrum of
% interpolated signal
plot(f,10*log10([fs*px,l*fs*py]))
legend('22 kHz sinusoid sampled at 44.1 kHz',...
'22 kHz sinusoid sampled at 352.8 kHz')
xlabel('Frequency (Hz)'); ylabel('Power Spectrum');

```

To see the results of the example, look at this figure.

`mfilt.linearinterp`

**Introduced in R2011a**

# mfilt.firdecim

Direct-form FIR polyphase decimator

---

**Note** `mfilt.firdecim` will be removed in a future release. Use `dsp.FIRDecimator` instead.

---

## Syntax

```
hm = mfilt.firdecim(m)
hm = mfilt.firdecim(m,num)
```

## Description

`hm = mfilt.firdecim(m)` returns a direct-form FIR polyphase decimator object `hm` with a decimation factor of  $m$ . A lowpass Nyquist filter of gain 1 and cutoff frequency of  $\pi/m$  is designed by default. This filter allows some aliasing in the transition band but it very efficient because the first polyphase component is a pure delay.

`hm = mfilt.firdecim(m,num)` uses the coefficients specified by `num` for the decimation filter. This lets you specify more completely the FIR filter to use for the decimator.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hm` as follows:

- To change to single-precision filtering, enter

```
set(hm,'arithmetic','single');
```
- To change to fixed-point filtering, enter

```
set(hm,'arithmetic','fixed');
```

## Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
<code>m</code>	Decimation factor for the filter. <code>m</code> specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for <code>m</code> it defaults to 2.
<code>num</code>	Vector containing the coefficients of the FIR lowpass filter used for decimation. When <code>num</code> is not provided as an input, <code>mfilt.firdecim</code> constructs a lowpass Nyquist filter with gain of 1 and cutoff frequency equal to $\pi/m$ by default. The default length for the Nyquist filter is $24*m$ . Therefore, each polyphase filter component has length 24.

## Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

### Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.firdecim` objects. The next table describes each property for an `mfilt.firdecim` filter object.

Name	Values	Description
<code>Arithmetic</code>	Double, single, fixed	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operation mode for your filter.
<code>DecimationFactor</code>	Integer	Decimation factor for the filter. <code>m</code> specifies the amount to reduce the sampling rate of the input signal. It must be an integer.

Name	Values	Description
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object. Describes the signal flow for the filter object.
InputOffset	Integers	Contains a value derived from the number of input samples and the decimation factor — $\text{InputOffset} = \text{mod}(\text{length}(nx), m)$ where $nx$ is the number of input samples that have been processed so far and $m$ is the decimation factor.
Numerator	Vector	Vector containing the coefficients of the FIR lowpass filter used for decimation.
PersistentMemory	false, true	Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. <code>PersistentMemory</code> set to <code>false</code> returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to <code>true</code> allows you to modify the <code>States</code> , <code>InputOffset</code> , and <code>PolyphaseAccum</code> properties.
PolyphaseAccum	0 in <code>double</code> , <code>single</code> , or <code>fixed</code> for the different filter arithmetic settings.	Differentiates between the adders in the filter that work in full precision at all times ( <code>PolyphaseAccum</code> ) and the adders in the filter that the user controls and that may introduce quantization effects when <code>FilterInternals</code> is set to <code>SpecifyPrecision</code> .

Name	Values	Description
States	Double, single, or fi matching the filter arithmetic setting.	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. Double is the default setting for floating-point filters in double arithmetic.

## Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the filter. You see one or more of these properties when you set Arithmetic to fixed. Some of the properties have different default values when they refer fixed point filters. One example is the property PolyphaseAccum which stores data as doubles when you use your filter in double-precision mode, but stores a fi object in fixed-point mode.

---

**Note** The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use `info(hm)` where `hm` is a filter.

---

For further information about the properties of this filter or any `mfilt` object, refer to “Multirate Filter Properties” on page 6-94.

Name	Values	Description
AccumFracLength	Any positive or negative integer number of bits [32]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters.
AccumWordLength	Any integer number of bits [39]	Sets the word length used to store data in the accumulator.
Arithmetic	fixed for fixed-point filters	Setting this to <code>fixed</code> allows you to modify other filter properties to customize your fixed-point filter.

Name	Values	Description
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, <code>FullPrecision</code> , sets automatic word and fraction length determination by the filter. <code>SpecifyPrecision</code> makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits[16]	Specifies the word length applied to interpret input data.
OutputFracLength	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>FilterInternals</code> to <code>SpecifyPrecision</code> .
OutputWordLength	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting <code>FilterInternals</code> to <code>SpecifyPrecision</code> .

Name	Values	Description
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
RoundMode	[convergent], ceil, fix, floor, nearest, round	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.

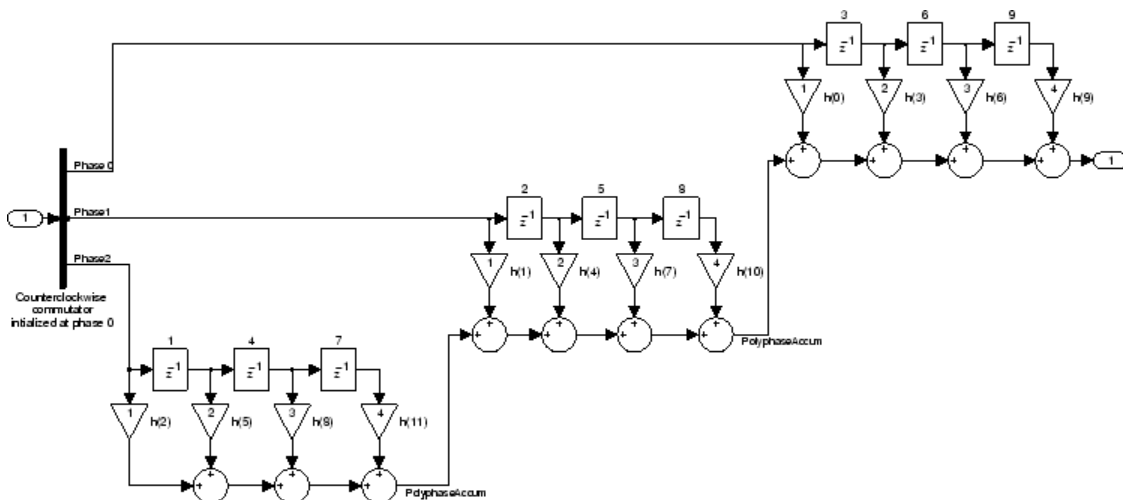

Name	Values	Description
States	fi object	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation. For information about the ordering of the states, refer to the filter structure section.

## Filter Structure

To provide decimation, `mfilt.firdecim` uses the following structure. At the input you see a commutator that operates counterclockwise, moving from position 0 to position 2, position 1, and back to position 0 as input samples enter the filter.

The following figure details the signal flow for the direct form FIR filter implemented by `mfilt.firdecim`.

Notice the order of the states in the filter flow diagram. States 1 through 9 appear in the diagram above each delay element. State 1 applies to the first delay element in phase 2. State 2 applies to the first delay

element in phase 0. State 4 applies to the second delay in phase 2, and so on. When you provide the states for the filter as a vector to the `States` property, the above description explains how the filter assigns the states you specify.

In property value form, the states for a filter `hm` are

```
hm.states=[1:9];
```

## Examples

Convert an input signal from 44.1 kHz to 22.05 kHz using decimation by a factor of 2. In the figure that appears after the example code, you see the results of the decimation.

```
m = 2; % Decimation factor.
hm = mfilt.firdecim(m); % Use the default filter.
fs = 44.1e3; % Original sample freq: 44.1kHz.
n = 0:10239; % 10240 samples, 0.232 second long
% signal.
x = sin(2*pi*1e3/fs*n); % Original signal--sinusoid at 1kHz.
y = filter(hm,x); % 5120 samples, 0.232 seconds.
stem(n(1:44)/fs,x(1:44)) % Plot original sampled at 44.1 kHz.
hold on % Plot decimated signal (22.05 kHz)
% in red.
stem(n(1:22)/(fs/m),y(13:34),'r','filled')
xlabel('Time (sec)');ylabel('Signal Value')
```

`mfilt.cicdecim` | `mfilt.firsrc` | `mfilt.firtdecim`

**Introduced in R2011a**

## **mfilt.firinterp**

FIR filter-based interpolator

### **Compatibility**

`mfilt.firinterp` will be removed in a future release. Use `dsp.FIRInterpolator` instead.

### **Syntax**

```
Hm = mfilt.firinterp(L)
Hm = mfilt.firinterp(L,num)
```

### **Description**

`Hm = mfilt.firinterp(L)` returns a FIR polyphase interpolator object `Hm` with an interpolation factor of `L` and gain equal to `L`. `L` defaults to 2 if unspecified.

`Hm = mfilt.firinterp(L,num)` uses the values in the vector `num` as the coefficients of the interpolation filter.

Make this filter a fixed-point or single-precision filter by changing the value of the Arithmetic property for the filter `Hm` as follows:

- To change to single-precision filtering, enter

```
set(hm,'arithmetic','single');
```
- To change to fixed-point filtering, enter

```
set(hm,'arithmetic','fixed');
```

### **Input Arguments**

The following table describes the input arguments for creating `hm`.

Input Argument	Description
<code>l</code>	Interpolation factor for the filter. <code>l</code> specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for <code>l</code> it defaults to 2.
<code>num</code>	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When <code>num</code> is not provided as an input, <code>firinterp</code> uses a lowpass Nyquist filter with gain equal to <code>l</code> and cutoff frequency equal to $\pi/l$ by default. The default length for the Nyquist filter is $24 * l$ . Therefore, each polyphase filter component has length 24.

## Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

### Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.firinterp` objects. The next table describes each property for an `mfilt.firinterp` filter object.

Name	Values	Description
Arithmetic	Double, single, fixed	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operation mode for your filter.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object. Describes the signal flow for the filter object.
InterpolationFactor	Integer	Interpolation factor for the filter. <code>l</code> specifies the amount to increase the sampling rate of the input signal. It must be an integer.

Name	Values	Description
Numerator	Vector	Vector containing the coefficients of the FIR lowpass filter used for decimation.
PersistentMemory	[false], true	Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory set to false returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to true allows you to modify the States property.
States	Double, single, matching the filter arithmetic setting.	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.

## Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the `mfilt.firinterp` filter.

---

**Note** The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

`info(hm)`

where `hm` is a filter.

---

For further information about the properties of this filter or any `mfilt` object, refer to “Multirate Filter Properties” on page 6-94.

Name	Values	Description
AccumFracLength	Any positive or negative integer number of bits. [32]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — DenAccumFracLength and NumAccumFracLength — that let you set the precision for numerator and denominator operations separately.
AccumWordLength	Any integer number of bits [39]	Sets the word length used to store data in the accumulator.
Arithmetic	fixed for fixed-point filters	Setting this to fixed allows you to modify other filter properties to customize your fixed-point filter.
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.

Name	Values	Description
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of <b>OutputFracLength</b> when you set <b>FilterInternals</b> to <b>SpecifyPrecision</b> .
OutputWordLength	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting <b>FilterInternals</b> to <b>SpecifyPrecision</b> .
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <b>saturate</b> (limit the output to the largest positive or negative representable value) or <b>wrap</b> (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.

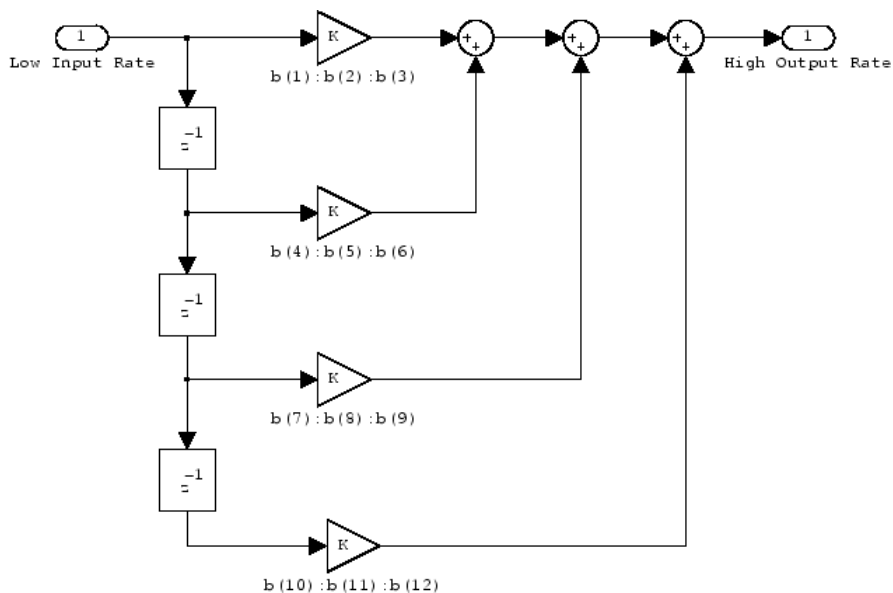

Name	Values	Description
RoundMode	[convergent], ceil, fix, floor, nearest, round	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	fi object to match the filter arithmetic setting.	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.

## Filter Structure

To provide interpolation, `mfilt.firinterp` uses the following structure.

The following figure details the signal flow for the direct form FIR filter implemented by `mfilt.firinterp`. In the figure, the delay line updates happen at the lower input rate. The remainder of the filter — the sums and coefficients — operate at the higher output rate.

## Examples

This example uses `mfilt.firinterp` to double the sample rate of a 22.05 kHz input signal. The output signal ends up at 44.1 kHz. Although `l` is set explicitly to 2, this represents the default interpolation value for `mfilt.firinterp` objects.

```
L = 2; % Interpolation factor.
Hm = mfilt.firinterp(L); % Use the default filter.
fs = 22.05e3; % Original sample freq: 22.05 kHz.
n = 0:5119; % 5120 samples, 0.232s long signal.
x = sin(2*pi*1e3/fs*n); % Original signal, sinusoid at 1 kHz.
y = filter(Hm,x); % 10240 samples, still 0.232s.
stem(n(1:22)/fs,x(1:22),'filled') % Plot original sampled at
```

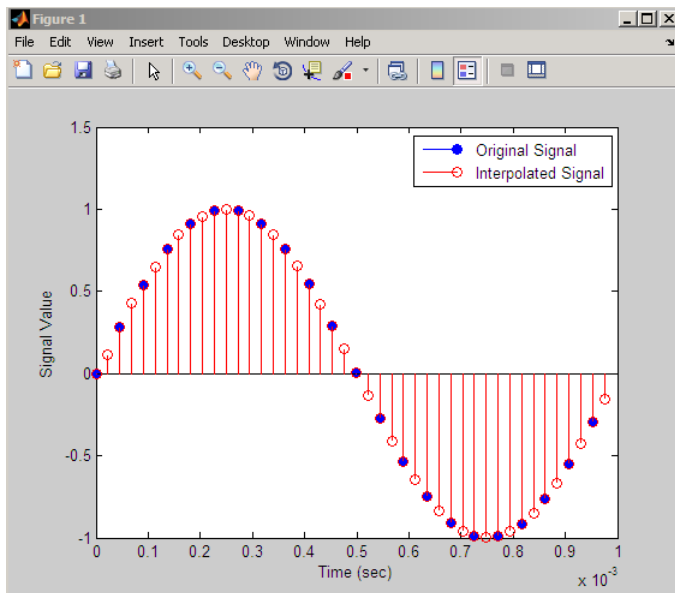

```

                                % 22.05 kHz.
hold on;

% Plot interpolated signal (44.1 kHz) in red
stem(n(1:44)/(fs*L),y(25:68),'r')
xlabel('Time (sec)');ylabel('Signal Value')
legend('Original Signal','Interpolated Signal');

```

With interpolation by 2, the resulting signal perfectly matches the original, but with twice as many samples — one between each original sample, as shown in the following figure.

## See Also

mfilt.linearinterp

**Introduced in R2011a**

## **mfilt.firsrc**

Direct-form FIR polyphase sample rate converter

---

**Note** `mfilt.firsrc` will be removed in a future release. Use `dsp.FIRRateConverter` instead.

---

### **Syntax**

```
hm = mfilt.firsrc(l,m,num)
```

### **Description**

`hm = mfilt.firsrc(l,m,num)` returns a direct-form FIR polyphase sample rate converter. `l` specifies the interpolation factor. It must be an integer and when omitted in the calling syntax, it defaults to 2.

`m` is the decimation factor. It must be an integer. If not specified, `m` defaults to 1. If `l` is also not specified, `m` defaults to 3 and the overall rate change factor is 2/3.

You specify the coefficients of the FIR lowpass filter used for sample rate conversion in `num`. If omitted, a lowpass Nyquist filter with gain `l` and cutoff frequency of  $\pi/\max(l,m)$  is the default.

Combining an interpolation factor and a decimation factor lets you use `mfilt.firsrc` to perform fractional interpolation or decimation on an input signal. Using an `mfilt.firsrc` object applies a rate change factor defined by  $l/m$  to the input signal. For proper rate changing to occur, `l` and `m` must be relatively prime — meaning the ratio  $l/m$  cannot be reduced to a ratio of smaller integers.

When you are doing sample-rate conversion with large values of `l` or `m`, such as `l` or `m` greater than 20, using the `mfilt.firsrc` structure is the most effective approach.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hm` as follows:

- To change to single-precision filtering, enter

```
set(hm,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hm,'arithmetic','fixed');
```

---

**Note** You can use the `realizemdl` method to create a Simulink block of a filter created using `mfilt.firsrc`.

---

## Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
<code>l</code>	Interpolation factor for the filter. <code>l</code> specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for <code>l</code> , it defaults to 2.
<code>num</code>	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When <code>num</code> is not provided as an input, <code>mfilt.firsrc</code> uses a lowpass Nyquist filter with gain equal to <code>l</code> and cutoff frequency equal to $\pi/\max(l, m)$ by default. The default length for the Nyquist filter is $24*\max(1, m)$ . Therefore, each polyphase filter component has length 24.
<code>m</code>	Decimation factor for the filter. <code>m</code> specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for <code>m</code> , it defaults to 1. When <code>l</code> is unspecified as well, <code>m</code> defaults to 3.

## Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

## Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.firsrc` objects. The next table describes each property for an `mfilt.firsrc` filter object.

Name	Values	Description
Arithmetic	[Double], single, fixed	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operation mode for your filter.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object. Describes the signal flow for the filter object.
InputOffset	Integers	Contains a value derived from the number of input samples and the decimation factor — $\text{InputOffset} = \text{mod}(\text{length}(nx), m)$ where $nx$ is the number of input samples and $m$ is the decimation factor.
Numerator	Vector	Vector containing the coefficients of the FIR lowpass filter used for decimation.
PersistentMemory	false, true	Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. <code>PersistentMemory</code> set to <code>false</code> returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to <code>true</code> allows you to modify the <code>States</code> , <code>InputOffset</code> , and <code>PolyphaseAccum</code> properties.
RateChangeFactors	Positive integers. [2 3]	Specifies the interpolation and decimation factors [l m] (the rate change factors) for changing the input sample rate by nonintegral amounts.

Name	Values	Description
States	Double, single, matching the filter arithmetic setting.	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.

## Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the `mfilt.firsrc` filter.

**Note** The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

```
info(hm)
```

where `hm` is a filter.

For further information about the properties of this filter or any `mfilt` object, refer to “Multirate Filter Properties” on page 6-94.

Name	Values	Description
AccumFracLength	Any positive or negative integer number of bits. [32]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters.
AccumWordLength	Any integer number of bits [39]	Sets the word length used to store data in the accumulator.
Arithmetic	fixed for fixed-point filters	Setting this to <code>fixed</code> allows you to modify other filter properties to customize your fixed-point filter.
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> property value to specify the precision used.

<b>Name</b>	<b>Values</b>	<b>Description</b>
<code>CoeffWordLength</code>	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
<code>FilterInternals</code>	[ <code>FullPrecision</code> ], <code>SpecifyPrecision</code>	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, <code>FullPrecision</code> , sets automatic word and fraction length determination by the filter. <code>SpecifyPrecision</code> makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
<code>InputFracLength</code>	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
<code>InputWordLength</code>	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
<code>NumFracLength</code>	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
<code>OutputFracLength</code>	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>FilterInternals</code> to <code>SpecifyPrecision</code> .
<code>OutputWordLength</code>	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting <code>FilterInternals</code> to <code>SpecifyPrecision</code> .

Name	Values	Description
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
RateChangeFactors	Positive integers [2 3]	Specifies the interpolation and decimation factors [l m] (the rate change factors) for changing the input sample rate by nonintegral amounts.

Name	Values	Description
RoundMode	[convergent], ceil, fix, floor, nearest, round	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
Signed	[true], false	<p>Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.</p>
States	fi object	<p>Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation. For information about the ordering of the states, refer to the filter structure section.</p>

## Examples

This is an example of a common audio rate change process — changing the sample rate of a high end audio (48 kHz) signal to the compact disc sample rate (44.1 kHz). This conversion requires a rate change factor of 0.91875, or  $l = 147$  and  $m = 160$ .

```

l = 147; m = 160;           % Interpolation/decimation factors.
hm = mfilt.firsrc(l,m);    % Use the default FIR filter.
fs = 48e3;                 % Original sample freq: 48 kHz.
n = 0:10239;               % 10240 samples, 0.213 seconds long.
x = sin(2*pi*1e3/fs*n);    % Original signal, sinusoid at 1 kHz.
y = filter(hm,x);          % 9408 samples, still 0.213 seconds.
stem(n(1:49)/fs,x(1:49))  % Plot original sampled at 48 kHz.
hold on

% Plot fractionally decimated signal (44.1 kHz) in red
stem(n(1:45)/(fs*l/m),y(13:57),'r','filled')
xlabel('Time (sec)');ylabel('Signal Value')

```

Fractional decimation provides you the flexibility to pick and choose the sample rates you want by carefully selecting  $l$  and  $m$ , the interpolation and decimation factors, that result in the final fractional decimation. The following figure shows the signal after applying the rate change filter  $hm$  to the original signal.

**Introduced in R2011a**

# mfilt.firtdecim

Direct-form transposed FIR filter

---

**Note** `mfilt.firtdecim` will be removed in a future release. Use `dsp.FIRDecimator` instead.

---

## Syntax

```
hm = mfilt.firtdecim(m)
hm = mfilt.firtdecim(m,num)
```

## Description

`hm = mfilt.firtdecim(m)` returns a polyphase decimator `mfilt` object `hm` based on a direct-form transposed FIR structure with a decimation factor of  $m$ . A lowpass Nyquist filter of gain 1 and cutoff frequency of  $\pi/m$  is the default.

`hm = mfilt.firtdecim(m,num)` uses the coefficients specified by `num` for the decimation filter. `num` is a vector containing the coefficients of the transposed FIR lowpass filter used for decimation. If omitted, a lowpass Nyquist filter with gain of 1 and cutoff frequency of  $\pi/m$  is the default.

Make this filter a fixed-point or single-precision filter by changing the value of the Arithmetic property for the filter `hm` as follows:

- To change to single-precision filtering, enter

```
set(hm,'arithmetic','single');
```
- To change to fixed-point filtering, enter

```
set(hm,'arithmetic','fixed');
```

## Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
num	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When num is not provided as an input, <code>firtdecim</code> uses a lowpass Nyquist filter with gain equal to 1 and cutoff frequency equal to $\pi/m$ by default. The default length for the Nyquist filter is $24*m$ . Therefore, each polyphase filter component has length 24.
m	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for m it defaults to 2.

## Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

### Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.firtdecim` objects. The next table describes each property for an `mfilt.firtdecim` filter object.

Name	Values	Description
Arithmetic	Double, single, fixed	Specifies the arithmetic the filter uses to process data while filtering.
DecimationFactor	Integer	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object. Also describes the signal flow for the filter object.

Name	Values	Description
InputOffset	Integers	Contains a value derived from the number of input samples and the decimation factor — $\text{InputOffset} = \text{mod}(\text{length}(\text{nx}), m)$ where $\text{nx}$ is the number of input samples that have been processed so far and $m$ is the decimation factor.
Numerator	Vector	Vector containing the coefficients of the FIR lowpass filter used for decimation.
PersistentMemory	[false], true	Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. <code>PersistentMemory</code> set to <code>false</code> returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to <code>true</code> allows you to modify the <code>States</code> , <code>InputOffset</code> , and <code>PolyphaseAccum</code> properties.
PolyphaseAccum	Double, single [0]	The idea behind having both <code>PolyphaseAccum</code> and <code>Accum</code> is to differentiate between the adders in the filter that work in full precision at all times ( <code>PolyphaseAccum</code> ) from the adders in the filter that the user controls and that may introduce quantization effects when <code>FilterInternals</code> is set to <code>SpecifyPrecision</code> .
States	Double, single matching the filter arithmetic setting.	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.

## Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the `mfilt.firtdecim` filter.

**Note** The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

`info(hm)`

where `hm` is a filter.

---

For further information about the properties of this filter or any `mfilt` object, refer to “Multirate Filter Properties” on page 6-94.

<b>Name</b>	<b>Values</b>	<b>Description</b>
<code>AccumFracLength</code>	Any positive or negative integer number of bits. [32]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — <code>DenAccumFracLength</code> and <code>NumAccumFracLength</code> — that let you set the precision for numerator and denominator operations separately.
<code>AccumWordLength</code>	Any integer number of bits [39]	Sets the word length used to store data in the accumulator.
<code>Arithmetic</code>	fixed for fixed-point filters	Setting this to <code>fixed</code> allows you to modify other filter properties to customize your fixed-point filter.
<code>CoeffAutoScale</code>	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> property value to specify the precision used.
<code>CoeffWordLength</code>	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.

Name	Values	Description
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilterInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.

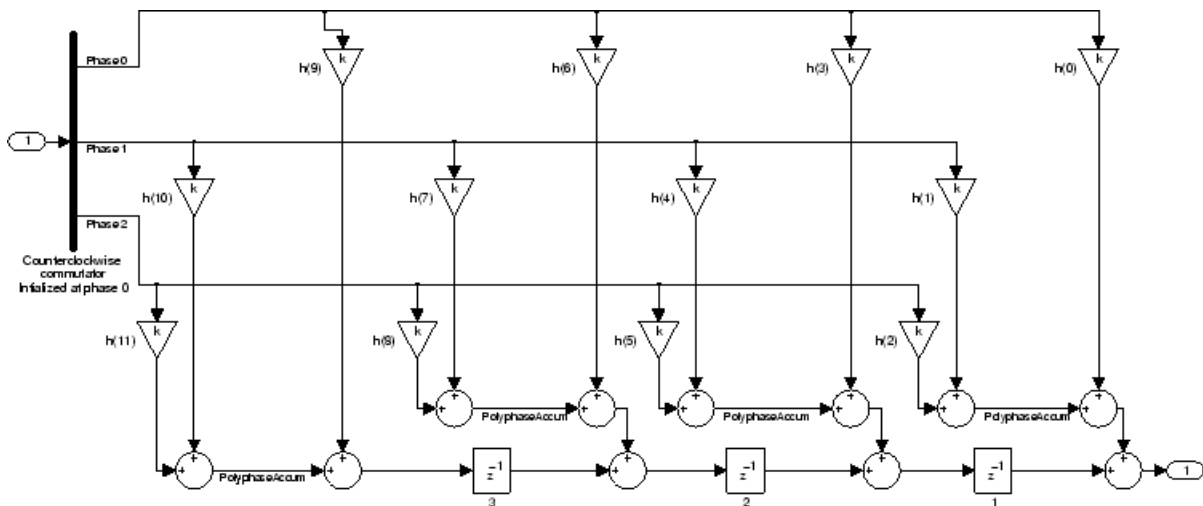

Name	Values	Description
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
PolyphaseAccum	<code>fi</code> object with zeros to start	Differentiates between the adders in the filter that work in full precision at all times ( <code>PolyphaseAccum</code> ) and the adders in the filter that the user controls and that may introduce quantization effects when <code>FilterInternals</code> is set to <code>SpecifyPrecision</code> .

Name	Values	Description
RoundMode	[convergent], ceil, fix, floor, nearest, round	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	fi object	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation. For information about the ordering of the states, refer to the filter structure section.

## Filter Structure

To provide sample rate changes, `mfilt.firtddecim` uses the following structure. At the input you see a commutator that operates counterclockwise, moving from position 0 to position 2, position 1, and back to position 0 as input samples enter the filter. To keep track of the position of the commutator, the `mfilt` object uses the property `InputOffset` which reports the current position of the commutator in the filter.

The following figure details the signal flow for the direct form FIR filter implemented by `mfilt.firtddecim`.

Notice the order of the states in the filter flow diagram. States 1 through 3 appear in the following diagram at each delay element. State 1 applies to the third delay element in phase 2. State 2 applies to the second delay element in phase 2. State 3 applies to the first delay element in phase 2. When you provide the states for the filter as a vector to the `States` property, the above description explains how the filter assigns the states you specify.

In property value form, the states for a filter `hm` are

```
hm.states=[1:3];
```

## Examples

Demonstrate decimating an input signal by a factor of 2, in this case converting from 44.1 kHz down to 22.05 kHz. In the figure shown following the code, you see the results of decimating the signal.

```
m = 2; % Decimation factor.
hm = mfilt.firtdecim(m); % Use the default filter coeffs.
fs = 44.1e3; % Original sample freq: 44.1 kHz.
n = 0:10239; % 10240 samples, 0.232 second long signal
x = sin(2*pi*1e3/fs*n); % Original signal--sinusoid at 1 kHz.
y = filter(hm,x); % 5120 samples, 0.232 seconds.
stem(n(1:44)/fs,x(1:44)) % Plot original sampled at 44.1 kHz.
axis([0 0.001 -1.2 1.2]);
hold on % Plot decimated signal (22.05 kHz) in red
stem(n(1:22)/(fs/m),y(1:34),'r','filled')
xlabel('Time (sec)');ylabel('Signal Value');
legend('Original signal','Decimated signal','location','best');
```

## See Also

[mfilt.cicdecim](#) | [mfilt.firdecim](#) | [mfilt.firsrc](#)

Introduced in R2011a

## **mfilt.holdinterp**

FIR hold interpolator

---

**Note** `mfilt.holdinterp` will be removed in a future release. Use `dsp.CICInterpolator` (with `NumSections = 1`) instead.

---

### **Syntax**

```
hm = mfilt.holdinterp(l)
```

### **Description**

`hm = mfilt.holdinterp(l)` returns the object `hm` that represents a hold interpolator with the interpolation factor `l`. To work, `l` must be an integer. When you do not include `l` in the calling syntax, it defaults to 2. To perform interpolation by noninteger amounts, use one of the fractional interpolator objects, such as `mfilt.firsrc`.

When you use this hold interpolator, each sample added to the input signal between existing samples has the value of the most recent sample from the original signal. Thus you see something like a staircase profile where the interpolated samples form a plateau between the previous and next original samples. The example demonstrates this profile clearly. Compare this to the interpolation process for other interpolators in the toolbox, such as `mfilt.linearinterp`.

Make this filter a fixed-point or single-precision filter by changing the value of the Arithmetic property for the filter `hm` as follows:

- To change to single-precision filtering, enter

```
set(hm,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hm,'arithmetic','fixed');
```

## Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
<code>l</code>	Interpolation factor for the filter. <code>l</code> specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for <code>l</code> it defaults to 2.

## Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

### Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.holdinterp` objects. The next table describes each property for an `mfilt.interp` filter object.

Name	Values	Description
<code>Arithmetic</code>	Double, single, fixed	Specifies the arithmetic the filter uses to process data while filtering.
<code>FilterStructure</code>	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object.
<code>InterpolationFactor</code>	Integer	Interpolation factor for the filter. <code>l</code> specifies the amount to increase the input sampling rate. It must be an integer.
<code>PersistentMemory</code>	'false' or 'true'	Determines whether the filter states are restored to zero for each filtering operation.

Name	Values	Description
States	Double or single array	Filter states. <code>states</code> defaults to a vector of zeros that has length equal to <code>nstates</code> ( <code>hm</code> ). Always available, but visible in the display only when <code>PersistentMemory</code> is true.

## Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the `mfilt.holdinterp` filter.

---

**Note** The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

`info(hm)`

where `hm` is a filter.

---

For further information about the properties of this filter or any `mfilt` object, refer to “Multirate Filter Properties” on page 6-94.

Name	Values	Description
Arithmetic	Double, single, fixed	Specifies the arithmetic the filter uses to process data while filtering.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.

Name	Values	Description
InterpolationFactor	Integer	Interpolation factor for the filter. <code>l</code> specifies the amount to increase the input sampling rate. It must be an integer.
PersistentMemory	'false' or 'true'	Determine whether the filter states get restored to zero for each filtering operation
States	fi object	Contains the filter states before, during, and after filter operations. For hold interpolators, the states are always empty — hold interpolators do not have states. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.

## Filter Structure

Hold interpolators do not have filter coefficients and their filter structure is trivial.

## Examples

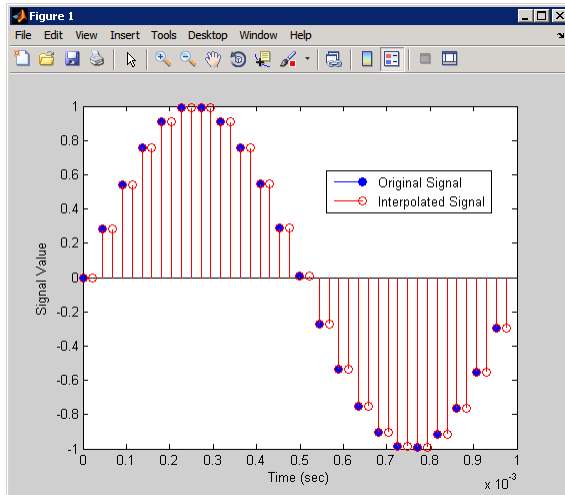

To see the effects of hold-based interpolation, interpolate an input sine wave from 22.05 to 44.1 kHz. Note that each added sample retains the value of the most recent original sample.

```

l = 2; % Interpolation factor
hm = mfilt.holdinterp(l);
fs = 22.05e3; % Original sample freq: 22.05 kHz.
n = 0:5119; % 5120 samples, 0.232 second long signal
x = sin(2*pi*1e3/fs*n); % Original signal, sinusoid at 1 kHz
y = filter(hm,x); % 10240 samples, still 0.232 seconds
stem(n(1:22)/fs,x(1:22),'filled') % Plot original sampled at
% 22.05 kHz
hold on % Plot interpolated signal (44.1 kHz)
stem(n(1:44)/(fs*l),y(1:44),'r')
legend('Original Signal','Interpolated Signal','Location','best');
xlabel('Time (sec)');ylabel('Signal Value')

```

The following figure shows clearly the step nature of the signal that comes from interpolating the signal using the hold algorithm approach. Compare the output to the linear interpolation used in `mfilt.linearinterp`.

**Introduced in R2011a**

# mfilt.iirdecim

IIR decimator

---

**Note** `mfilt.iirdecim` will be removed in a future release. Use `dsp.IIRHalfbandDecimator` instead.

---

## Syntax

```
hm = mfilt.iirdecim(c1,c2,...)
```

## Description

`hm = mfilt.iirdecim(c1,c2,...)` constructs an IIR decimator filter given the coefficients specified in the cell arrays `c1`, `c2`, and so on. The resulting IIR decimator is a polyphase IIR filter where each phase is a cascade allpass IIR filter.

Each cell array `ci` contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to `dfilt.cascadeallpass`. The contents of the cell arrays are the same for both filter constructors and `mfilt.iirdecim` interprets them same way as `mfilt.cascadeallpass`.

The following exception applies to interpreting the contents of a cell array — if one of the cell arrays `ci` contains only one vector, and that vector comprises a series of 0s and one element equal to 1, that cell array represents a `dfilt.delay` section with latency equal to the number of zeros, rather than a `dfilt.cascadeallpass` section. This exception case occurs with quasi-linear phase IIR decimators.

Although the first example shows how to construct an IIR decimators explicitly, one usually constructs an IIR decimators filter as a result of designing an decimators, as shown in the subsequent examples.

## Examples

When the coefficients are known, you can construct the IIR decimator directly using `mfilt.iirdecim`. For example, if the filter's coefficients are [0.6 0.5] for the first phase in the first stage, 0.7 for the second phase in the first stage and 0.8 for the third phase in the first stage; as well as 0.5 for the first phase in the second stage and 0.4 for the second phase in the second stage, construct the filter as shown here.

```
Hm = mfilt.iirdecim([0.6 0.5] 0.7 0.8),{0.5 0.4})
```

Also refer to the “Quasi-Linear Phase Halfband and Dyadic Halfband Designs” section of the “IIR Polyphase Filter Design” example, `iirallpassdemo` example.

When the coefficients are not known, use the approach given by the following set of examples. Start by designing an elliptic halfband decimator with a decimation factor of 2. The example specifies the optional sampling frequency argument.

```
tw = 100; % Transition width of filter.
ast = 80; % Stopband attenuation of filter.
fs = 2000; % Sampling frequency of signal to filter.
m = 2; % Decimation factor.
hm = fdesign.decimator(m,'halfband','tw,ast',tw,ast,fs);
```

`hm` contains the specifications for a decimator defined by `tw`, `ast`, `m`, and `fs`.

Use the specification object `hm` to design a `mfilt.iirdecim` filter object.

```
d = design(hm,'ellip','filterstructure','iirdecim');
% Note that realizemdl requires Simulink
realizemdl(d) % Build model of the filter.
```

Designing a linear phase decimator is similar to the previous example. In this case, design a halfband linear phase decimator with decimation factor of 2.

```
tw = 100; % Transition width of filter.
ast = 60; % Stopband attenuation of filter.
fs = 2000; % Sampling frequency of signal to filter.
m = 2; % Decimation factor.
```

Create a specification object for the decimator.

```
hm = fdesign.decimator(m,'halfband','tw,ast',tw,ast,fs);
```

Finally, design the filter `d`.

```
d = design(hm,'iirlinphase','filterstructure','iirdecim');  
% Note that realizemdl requires Simulink  
realizemdl(d) % Build model of the filter.
```

The filter implementation appears in this model, generated by `realizemdl` and Simulink.

Given the design specifications shown here

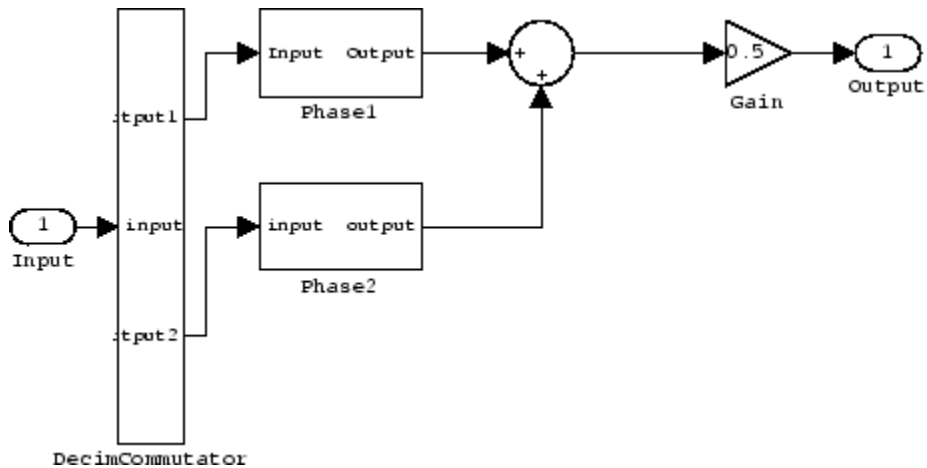

the first phase is a delay section with 0s and a 1 for coefficients and the second phase is a linear phase decimator, shown in the next models.

**Phase 1 model**

**Phase 2 model**

### Overall model

```

### **Description**

`hm = mfilt.iirinterp(c1,c2,...)` constructs an IIR interpolator filter given the coefficients specified in the cell arrays `C1`, `C2`, etc.

The IIR interpolator is a polyphase IIR filter where each phase is a cascade allpass IIR filter.

Each cell array `ci` contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to `dfilt.cascadeallpass`. The contents of the cell arrays are the same for both filter constructors and `mfilt.iirdecim` interprets them same way as `mfilt.cascadeallpass`.

The following exception applies to interpreting the contents of a cell array—if one of the cell arrays `ci` contains only one vector, and that vector comprises a series of 0s and a unique element equal to 1, that cell array represents a `dfilt.delay` section with latency equal to the number of zeros, rather than a `dfilt.cascadeallpass` section. This exception case occurs with quasi-linear phase IIR interpolators.

Although the first example shows how to construct an IIR interpolator explicitly, one usually constructs an IIR interpolator filter as a result of designing an interpolator, as shown in the subsequent examples.

## Examples

When the coefficients are known, you can construct the IIR interpolator directly using `mfilt.iirinterp`. In the following example, a cascaded polyphase IIR interpolator filter is constructed using 2 phases for each of three stages. The coefficients are given below:

```
Phase1Sect1=0.0603;Phase1Sect2=0.4126; Phase1Sect3=0.7727;
Phase2Sect1=0.2160; Phase2Sect2=0.6044; Phase2Sect3=0.9239;
```

Next the filter is implemented by passing the above coefficients to `mfilt.iirinterp` as cell arrays, where each cell array represents a different phase.

```
Hm = mfilt.iirinterp({Phase1Sect1,Phase1Sect2,Phase1Sect3},...
{Phase2Sect1,Phase2Sect2,Phase2Sect3})
```

Hm =

```
FilterStructure: 'IIR Polyphase Interpolator'
Polyphase: Phase1: Section1: 0.0603
             Section2: 0.4126
             Section3: 0.7727
           Phase2: Section1: 0.216
             Section2: 0.6044
             Section3: 0.9239
InterpolationFactor: 2
PersistentMemory: false
```

Also refer to the “Quasi-Linear Phase Halfband and Dyadic Halfband Designs” section of the “IIR Polyphase Filter Design” example, `iirallpassdemo` example.

When the coefficients are not known, use the approach given by the following set of examples. Start by designing an elliptic halfband interpolator with a interpolation factor of 2.

```
tw = 100; % Transition width of filter.
ast = 80; % Stopband attenuation of filter.
fs = 2000; % Sampling frequency of filter.
l = 2; % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);
```

Specification object `d` stores the interpolator design specifics. With the details in `d`, design the filter, returning `hm`, an `mfilt.iirinterp` object. Use `hm` to realize the filter if you have Simulink installed.

```
hm = design(d,'ellip','filterstructure','iirinterp');
% Note that realizemdl requires Simulink
realizemdl(hm) % Build model of the filter.
```

Designing a linear phase halfband interpolator follows the same pattern.

```
tw = 100; % Transition width of filter.
ast= 60; % Stopband attenuation of filter.
fs = 2000; % Sampling frequency of filter.
l = 2; % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);
```

`fdesign.interpolator` returns a specification object that stores the design features for an interpolator.

Now perform the actual design that results in an `mfilt.iirinterp` filter, `hm`.

```
hm = design(d,'iirlinphase','filterstructure','iirinterp');
% Note that realizemdl requires Simulink
realizemdl(hm) % Build model of the filter.
```

The toolbox creates a Simulink model for `hm`, shown here. `Phase1`, `Phase2`, and `InterpCommutator` are all subsystem blocks.

For more information about Multirate Filter Constructors see the “Getting Started with Multirate Filter (MFILT) Objects” example, `mfiltgettingstarteddemo`.

# mfilt.iirwdfdecim

IIR wave digital filter decimator

---

**Note** `mfilt.iirwdfdecim` will be removed in a future release. Use `dsp.IIRHalfbandDecimator` instead.

---

## Syntax

```
hm = mfilt.iirwdfdecim(c1,c2,...)
```

## Description

`hm = mfilt.iirwdfdecim(c1,c2,...)` constructs an IIR wave digital decimator given the coefficients specified in the cell arrays `c1`, `c2`, and so on. The IIR decimator `hm` is a polyphase IIR filter where each phase is a cascade wave digital allpass IIR filter.

Each cell array `ci` contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to `dfilt.cascadewdfallpass`. The contents of the cell arrays are the same for both filter constructors and `mfilt.iirwdfdecim` interprets them same way as `mfilt.cascadewdfallpass`.

The following exception applies to interpreting the contents of a cell array — if one of the cell arrays `ci` contains only one vector, and that vector comprises a series of 0s and one element equal to 1, that cell array represents a `dfilt.delay` section with latency equal to the number of zeros, rather than a `dfilt.cascadewdfallpass` section. This exception occurs with quasi-linear phase IIR decimators.

Usually you do not construct IIR wave digital filter decimators explicitly. Instead, you obtain an IIR wave digital filter decimator as a result of designing a halfband decimator. The first example in the following section illustrates this case.

## Examples

Design an elliptic halfband decimator with a decimation factor equal to 2. Both examples use the `iirwdfdecim` filter structure (an input argument to the design method) to design the final decimator.

The first portion of this example generates a filter specification object `d` that stores the specifications for the decimator.

```
tw = 100; % Transition width of filter to design, 100 Hz.
ast = 80; % Stopband attenuation of filter 80 dB.
fs = 2000; % Sampling frequency of the input signal.
m = 2; % Decimation factor.
d = fdesign.decimator(m,'halfband','tw,ast',tw,ast,fs);
```

Now perform the actual design using `d`. Filter object `hm` is an `mfilt.iirwdfdecim` filter.

```
Hm = design(d,'ellip','FilterStructure','iirwdfdecim');
% Note that realizemdl requires Simulink
realizemdl(hm) % Build model of the filter.
```

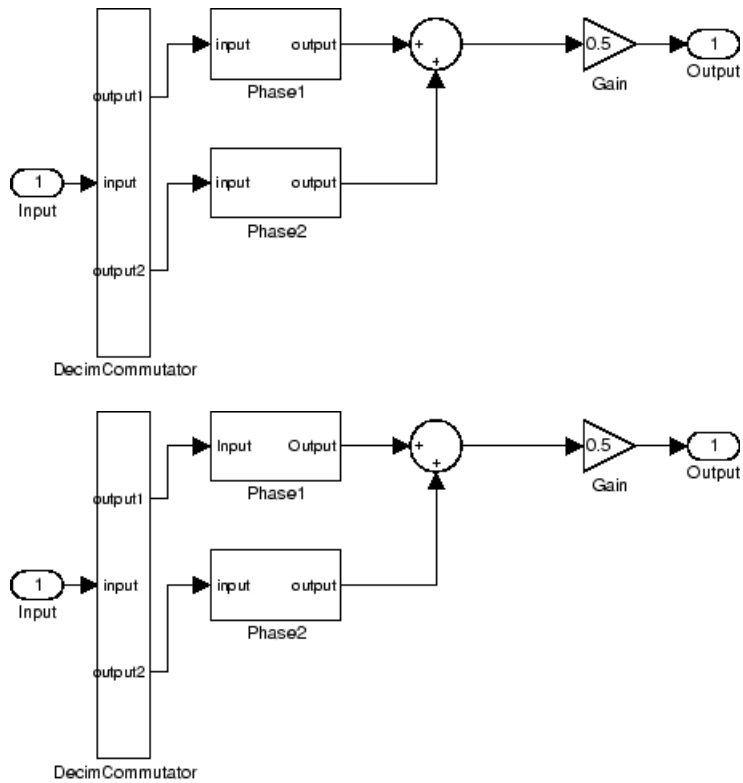

Design a linear phase halfband decimator for decimating a signal by a factor of 2.

```
tw = 100; % Transition width of filter, 100 Hz.
ast = 60; % Filter stopband attenuation = 80 dB
fs = 2000; % Input signal sampling frequency.
m = 2; % Decimation factor.
d = fdesign.decimator(m,'halfband','tw,ast',tw,ast,fs);
```

Use `d` to design the final filter `hm`, an `mfilt.iirwdfdecim` object.

```
hm = design(d,'iirlinphase','filterstructure',...
'iirwdfdecim');
% Note that realizemdl requires Simulink
realizemdl(hm) % Build model of the filter.
```

The models that `realizemdl` returns for each example appear below. At this level, the realizations of the filters are identical. The differences appear in the subsystem blocks Phase1 and Phase2.

This is the Phase1 subsystem from the halfband model.

Phase1 subsystem from the linear phase model is less revealing—an allpass filter.

## **mfilt.iirwdfinterp**

IIR wave digital filter interpolator

---

**Note** `mfilt.iirwdfinterp` will be removed in a future release. Use `dsp.IIRHalfbandInterpolator` instead.

---

### **Syntax**

```
hm = mfilt.iirwdfinterp(c1,c2,...)
```

### **Description**

`hm = mfilt.iirwdfinterp(c1,c2,...)` constructs an IIR wave digital interpolator given the coefficients specified in the cell arrays `c1`, `c2`, and so on. The IIR interpolator `hm` is a polyphase IIR filter where each phase is a cascade wave digital allpass IIR filter.

Each cell array `ci` contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to `dfilt.cascadewdfallpass`. The contents of the cell arrays are the same for both filter constructors and `mfilt.iirwdfinterp` interprets them same way as `mfilt.cascadewdfallpass`.

The following exception applies to interpreting the contents of a cell array — if one of the cell arrays `ci` contains only one vector, and that vector comprises a series of 0s and one element equal to 1, that cell array represents a `dfilt.delay` section with latency equal to the number of zeros, rather than a `dfilt.cascadewdfallpass` section. This exception occurs with quasi-linear phase IIR interpolators.

Usually you do not construct IIR wave digital filter interpolators explicitly. Rather, you obtain an IIR wave digital interpolator as a result of designing a halfband interpolator. The first example in the following section illustrates this case.

## Examples

Design an elliptic halfband interpolator with interpolation factor equal to 2. At the end of the design process, `hm` is an IIR wave digital filter interpolator.

```
tw = 100; % Transition width of filter, 100 Hz.
ast = 80; % Stopband attenuation of filter, 80 dB.
fs = 2000; % Sampling frequency after interpolation.
l = 2; % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);
```

The specification object `d` stores the interpolator design requirements. Now use `d` to design the actual filter `hm`.

```
hm = design(d,'ellip','filterstructure','iirwdfinterp');
```

If you have Simulink installed, you can realize your filter as a model built from DSP System Toolbox blocks.

```
% Note that realizemdl requires Simulink
realizemdl(hm) % Build model of the filter.
```

For variety, design a linear phase halfband interpolator with an interpolation factor of 2.

```
tw = 100; % Transition width of filter, 100 Hz.
ast = 80; % Stopband attenuation of filter, 80 dB.
fs = 2000; % Sampling frequency after interpolation.
l = 2; % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);
```

Now perform the actual design process with `d`. Filter `hm` is an IIR wave digital filter interpolator. As in the previous example, `realizemdl` returns a Simulink model of the filter if you have Simulink installed.

```
hm = design(d,'iirlinphase','filterstructure',...
'iirwdfinterp');
% Note that realizemdl requires Simulink
realizemdl(hm) % Build model of the filter.
```

**Introduced in R2011a**

# mfilt.linearinterp

Linear interpolator

---

**Note** `mfilt.linearinterp` will be removed in a future release. Use `idsp.CICInterpolator` (with `NumSections = 2`) instead.

---

## Syntax

```
hm = mfilt.linearinterp(l)
```

## Description

`hm = mfilt.linearinterp(l)` returns an FIR linear interpolator `hm` with an integer interpolation factor `l`. Provide `l` as a positive integer. The default value for the interpolation factor is 2 when you do not include the input argument `l`.

When you use this linear interpolator, the samples added to the input signal have values between the values of adjacent samples in the original signal. Thus you see something like a smooth profile where the interpolated samples continue a line between the previous and next original samples. The example demonstrates this smooth profile clearly. Compare this to the interpolation process for `mfilt.holdinterp`, which creates a staircase profile.

Make this filter a fixed-point or single-precision filter by changing the value of the Arithmetic property for the filter `hm` as follows:

- To change to single-precision filtering, enter

```
set(hm,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hm,'arithmetic','fixed');
```

## Input Arguments

The following table describes the input argument for `mfilt.linearinterp`.

Input Argument	Description
<code>l</code>	Interpolation factor for the filter. <code>l</code> specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for <code>l</code> it defaults to 2.

## Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

### Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.linearinterp` objects. The next table describes each property for an `mfilt.linearinterp` filter object.

Name	Values	Description
Arithmetic	Double, single, fixed	Specifies the arithmetic the filter uses to process data while filtering.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object.
InterpolationFactor	Integer	Interpolation factor for the filter. <code>l</code> specifies the amount to increase the input sampling rate. It must be an integer.
PersistentMemory	'false' or 'true'	Determine whether the filter states get restored to zero for each filtering operation

Name	Values	Description
States	Double or single array	Filter states. <code>states</code> defaults to a vector of zeros that has length equal to <code>nstates(hm)</code> . Always available, but visible in the display only when <code>PersistentMemory</code> is <code>true</code> .

## Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the `mfilt.holdinterp` filter.

**Note** The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

`info(hm)`

where `hm` is a filter.

For further information about the properties of this filter or any `mfilt` object, refer to "Multirate Filter Properties" on page 6-94.

Name	Values	Description
AccumFracLength	Any positive or negative integer number of bits. Depends on L. [29 when L=2]	Specifies the fraction length used to interpret data output by the accumulator.
AccumWordLength	Any integer number of bits [33]	Sets the word length used to store data in the accumulator.
Arithmetic	fixed for fixed-point filters	Setting this to <code>fixed</code> allows you to modify other filter properties to customize your fixed-point filter.

Name	Values	Description
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, <code>FullPrecision</code> , sets automatic word and fraction length determination by the filter. <code>SpecifyPrecision</code> makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [29]	Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>FilterInternals</code> to <code>SpecifyPrecision</code> .

Name	Values	Description
OutputWordLength	Any integer number of bits [33]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.

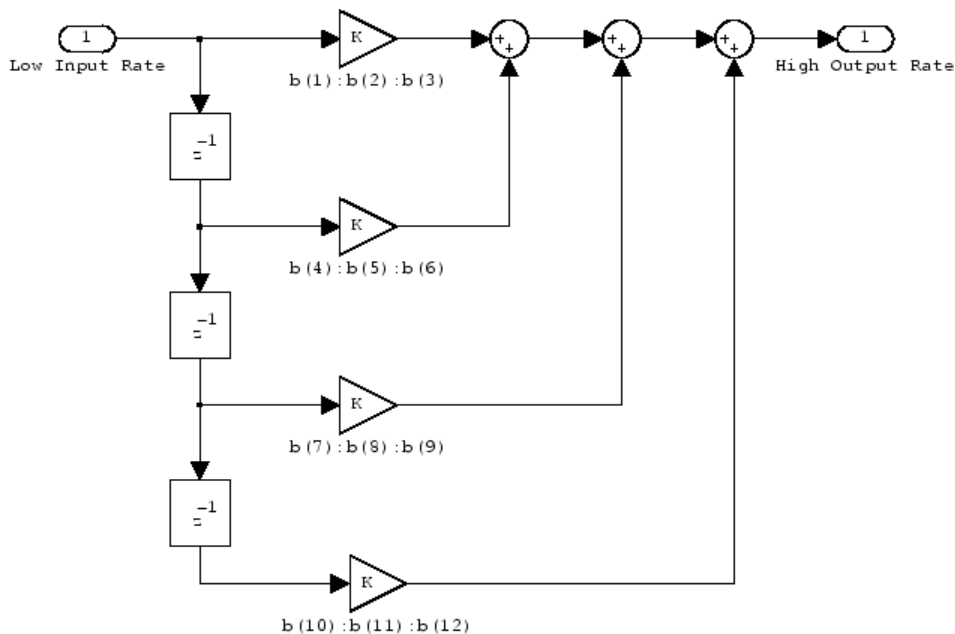

Name	Values	Description
RoundMode	[convergent], ceil, fix, floor, nearest, round	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p>
Signed	[true], false	<p>Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.</p>

Name	Values	Description
States	fi object	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation. For information about the ordering of the states, refer to the filter structure in the following section.

## Filter Structure

Linear interpolator structures depend on the FIR filter you use to implement the filter. By default, the structure is direct-form FIR.

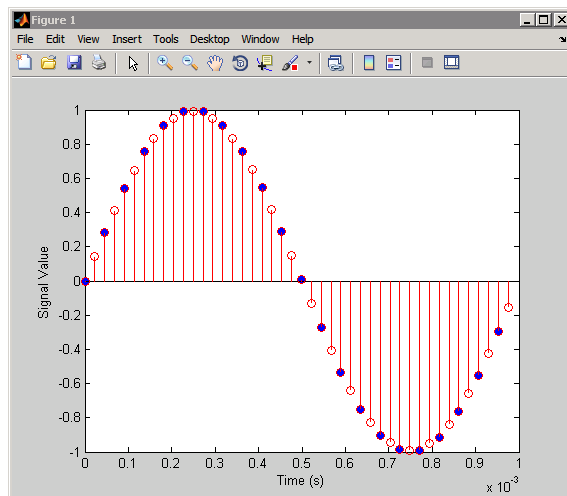

## Examples

Interpolation by a factor of 2 (used to convert the input signal sampling rate from 22.05 kHz to 44.1 kHz).

```
l = 2; % Interpolation factor
hm = mfilt.linearinterp(l);
fs = 22.05e3; % Original sample freq: 22.05 kHz.
n = 0:5119; % 5120 samples, 0.232 second long signal
x = sin(2*pi*1e3/fs*n); % Original signal, sinusoid at 1 kHz
y = filter(hm,x); % 10240 samples, still 0.232 seconds
stem(n(1:22)/fs,x(1:22),'filled') % Plot original sampled at
% 22.05 kHz
hold on % Plot interpolated signal (44.1
% kHz) in red
stem(n(1:44)/(fs*l),y(2:45),'r')
xlabel('Time (s)');ylabel('Signal Value')
```

Using linear interpolation, as compared to the hold approach of `mfilt.holdinterp`, provides greater fidelity to the original signal.

# midicallback

Call function handle when MIDI controls change value

---

**Note** The `midicallback` function will be removed from DSP System Toolbox™ in a future release. Existing instances of the function continue to run. For new code, use the `midicallback` function from Audio System Toolbox™ instead.

---

## Syntax

```
oldfh = midicallback(h,newfh)
oldfh = midicallback(h,[])
fh= midicallback(h)
```

## Description

`oldfh = midicallback(h,newfh)` sets `newfh` as the function handle to be called when `h` changes value, and returns the previous function handle, `oldfh`.

`oldfh = midicallback(h,[])` clears the function handle.

`fh= midicallback(h)` returns the current function handle.

## Examples

### Interactively Read MIDI Controls

Use the `midicallback` command with an anonymous function to interactively read MIDI controls.

```
h = midicontrols;
midicallback(h,@(h)disp(midiread(h)));
% Now move any control on the default MIDI device.
0.6587
```

```
0.6429
0.6349
0.6270
0.6190
0.6111
0.6032
0.5952
clear h
```

## Input Arguments

### **h** — Object that listens to the controls on a MIDI device

object

h is an object that listens to the controls on a MIDI device.

### **newfh** — new function handle

function handle

The new function handle, which is set as the function handle to be called when h changes value. For information on what function handles are, see “Function Handles” (MATLAB).

Example: @myFunction

## Output Arguments

### **oldfh** — Old function handle

function handle

The function handle set by the previous call to midicallback.

Example: @myFunction

### **fh** — Current function handle

function handle

The function handle set by the current call to midicallback.

Example: @myFunction

## **See Also**

`midicontrols` | `midiid` | `midiread` | `midisync` | `setpref`

**Introduced in R2013b**

## midicontrols

Open a group of MIDI controls for reading

---

**Note** The `midicontrols` function will be removed from DSP System Toolbox™ in a future release. Existing instances of the function continue to run. For new code, use the `midicontrols` function from Audio System Toolbox™ instead.

---

### Syntax

```
h = midicontrols
h = midicontrols(ControlNumbers)
h = midicontrols(ControlNumbers,InitialValues)
h = midicontrols( ____, 'MIDIDevice',devicename)
h = midicontrols( ____, 'OutputMode',mode)
```

### Description

`h = midicontrols` returns an object that responds to any control on the default MIDI device. Calling `midiread` with the object, returns the double scalar value of the MIDI control that recently moved after the object was created. The value is normally in the range [0 1]. See `OutputMode` for an alternative. This object can only determine a control's value if the control is moved after the `midicontrols` object is created. If `midiread` is called before the control is moved, `midiread` returns a default initial value of 0.

`h = midicontrols(ControlNumbers)` returns an object that responds to the MIDI controls specified by `ControlNumbers`. Calling `midiread` with the object, returns a double array of the same shape as `ControlNumbers`. Use `midiid` to interactively identify the control number of individual MIDI controls.

`h = midicontrols(ControlNumbers,InitialValues)` returns an object that uses the specified `InitialValues` when controls are not moved after the object is created. Because initial values are quantized for the underlying MIDI protocol, sometimes `midiread` returns an initial value that is slightly different from `InitialValues`.

`h = midicontrols( ____, 'MIDIDevice', devicename)` specifies the MIDI device to which the object responds. Use `midiiid` to interactively identify the name of a specific MIDI device. If you do not specify the 'MIDIDevice' name-value pair, the default MIDI device is used. The MATLAB preference 'midi' 'DefaultDevice' determines the default device.

`h = midicontrols( ____, 'OutputMode', mode)` specifies the range of values returned by `midiread` and accepted as `InitialValues`. This name-value pair is optional, and you can insert it only at the end of the argument list.

## Examples

### Respond to any Control on the Default Device

Create the object, and read from it:

```
h =midicontrols
midiread(h)
```

Move one of the controls, and read the data:

```
midiread(h)
```

### Respond to a Specific Control

Make the object respond to a specific control:

```
h = midicontrols(1081);
```

### Use Control Numbers and an Initial Value

Return a square array, with initial value of 0.5:

```
h = midicontrols([1081 1083; 1082 1084], 0.5);
```

### **Set Mode to raw, and Set an Initial Value**

Return a square array, with the raw initial value of 63:

```
h = midicontrols([1081 1083; 1082 1084], 63, 'OutputMode', 'rawmidi');
```

### **Set the Default MIDI Device**

Assume your MIDI device is a Behringer BCF2000. Set the default device this way:

```
setpref midi DefaultDevice BCF2000
```

This preference persists across MATLAB sessions, so you do not need to set it again unless you want to change devices.

### **Use Both ControlNumbers and DeviceName**

Respond to control 1001 on a Behringer BCF2000:

```
h = midicontrols(1001, 'MIDIDevice', 'BCF2000');
```

## **Input Arguments**

### **ControlNumbers — Identifying MIDI controls**

integer values

**ControlNumbers** are integer-valued double-precision numbers. Each control on the MIDI device has a specific integer assigned to it by the device manufacturer. If **ControlNumbers** is `[]`, then the `midicontrols` object responds to any control on the MIDI device. As a result, `midiread` returns a double scalar.

Example: 1081

Data Types: double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **InitialValues — Initial value of MIDI control**

any numeric value within range

`InitialValues` must either be an array of the same size as `ControlNumbers` or a scalar. If you do not specify `InitialValues`, the default initial value is 0. Typically, initial values must be in the range [0 1]. However, if you specify 'rawmidi' as `OutputMode`, the `InitialValues` range is between 0 and 127. Because the initial values are quantized for the underlying MIDI protocol, sometimes `midiread` returns an initial value that is slightly different from `InitialValues`.

Example: 0.3 or [0 0.3 0.6]

Data Types: double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **devicename — Name of device**

character string

`devicename` is a character string assigned by the device manufacturer or the host operating system. The specified `devicename` can be a substring of the device's exact name. If you do not specify the 'MIDIdevice' name-value pair, the default MIDI device is used. The MATLAB preference 'midi', 'DefaultDevice' determines the default device.

If you do not set the MATLAB preference, the host operating system chooses the default device in an unspecified way. Some systems have virtual (ie, software) MIDI devices installed. Even if you have only one hardware MIDI device attached to your system, the system may not choose it, which can cause confusion. As a best practice, use `mididid` to identify the name of the device you want. Then use `setpref` to set it as the default device.

Example: 'BCF2000 MIDI 1'

Data Types: char

### **mode — Mode of output**

character string

`mode` is a string and must be one of 'normalized' or 'rawmidi'. In normalized mode, values are in the range [0 1]. Also, initial values are quantized for the underlying MIDI protocol. In the raw MIDI mode, values are integers in the range [0 127], and the quantization of the initial values is not performed. The default of this name-value pair is 'normalized'.

Example: 'rawmidi'

Data Types: char

## Output Arguments

**h** — Object that listens to the controls on a MIDI device

object

h is an object that listens to the controls on a MIDI device.

## See Also

`midicallback` | `midiid` | `midiread` | `midisync` | `setpref`

**Introduced in R2013b**

# midiid

Interactively identify MIDI control

---

**Note** The `midiid` function will be removed from DSP System Toolbox™ in a future release. Existing instances of the function continue to run. For new code, use the `midiid` function from Audio System Toolbox™ instead.

---

## Syntax

```
[ctl device] = midiid
```

## Description

`[ctl device] = midiid` returns the control number and device name of the MIDI control moved by the user. Call the function at the MATLAB command prompt and then move the control you want to identify on the MIDI control surface. The function detects which control you move and returns the corresponding control number and device name that specify that control.

## Examples

### Retrieve Control Number and Device Name

Call `midiid`.

```
[ctl,dev] = midiid;  
Move the control you wish to identify; type ^C to abort.  
Waiting for control message...
```

```
ctl =  
1002
```

dev =  
nanoKONTROL

## Output Arguments

### **ctl** — Number associated with control being moved

integer values

ctl is an integer-valued double-precision number. Each control on the MIDI device has a specific integer assigned to it by the device manufacturer.

Example: 1003

Data Types: double

### **device** — Name of device

character string

device is a character string assigned by the device manufacturer or the host operating system.

Example: 'nanoKontrol'

Data Types: char

## See Also

[midicallback](#) | [midicontrols](#) | [midiread](#) | [midisync](#) | [setpref](#)

**Introduced in R2013b**

# midiread

Return most recent value of MIDI controls

---

**Note** The `midiread` function will be removed from DSP System Toolbox™ in a future release. Existing instances of the function continue to run. For new code, use the `midiread` function from Audio System Toolbox™ instead.

---

## Syntax

```
v = midiread(h)
```

## Description

`v = midiread(h)` returns the most recent value of the MIDI controls associated with `midicontrols` object, `h`. You must create `h` first before it can determine the values of its MIDI controls if they are moved. Calling `midiread` before the controls are moved, returns the initial values specified to `midicontrols`. In this case, when `h` is created. (or 0 if no initial values are specified).

## Examples

### Read Control Values

```
h = midicontrols;  
v = midiread(h);
```

## Input Arguments

**h** — Object that listens to the controls on a MIDI device  
object

`h` is an object that listens to the controls on a MIDI device.

## Output Arguments

### **v** — Most recent value of MIDI controls

any numeric value

The output value depends on the `OutputMode` specified by `midicontrols` when `h` is created. If you specify that the `OutputMode` is normalized, then the `midiread` returns output values in the range `[0 1]`. Also, initial values are quantized and may be slightly different from those specified by `midicontrols`.

If you specify the mode as `rawmidi`, then `midiread` returns integer values in the range `[0 127]`, and no quantization is required. If you do not specify the `OutputMode`, the default is normalized.

Example: `0.3` or `[0 0.3 0.6]`

Data Types: `double` | `uint8`

## See Also

**Introduced in R2013b**

# midisync

Send values to MIDI controls to synchronize

---

**Note** The `midisync` function will be removed from DSP System Toolbox™ in a future release. Existing instances of the function continue to run. For new code, use the `midisync` function from Audio System Toolbox™ instead.

---

## Syntax

```
midisync(h)  
midisync(h,Values)
```

## Description

`midisync(h)` sends the initial values specified by `midicontrols`. `h` is created by the MIDI controls associated with the `midicontrols` object, `h`. You can use `midisync` with bidirectional MIDI devices that can both send and receive messages, and move a control in response to a received message. For example, when a `midicontrols` object is first created, it is often helpful to move the MIDI control to match the initial value of the object. Many MIDI devices are not bidirectional, and calling `midisync` with a unidirectional device has no effect. `midisync` cannot tell whether a value is successfully sent to a device or even whether the device is bidirectional. Therefore, no errors or warnings are generated if sending a value fails.

`midisync(h,Values)` sends `Values` to the MIDI controls associated with the `midicontrols` object, `h`. `Values` must follow the same rules as `InitialValue` arguments of `midicontrols`.

## Examples

### Send a Slider Change to MIDI Control

```
midisync(h, get(slider, 'Value'))
```

### Create a GUI with a Single Slider, and Synchronize it with a MIDI Control

When you move either control, the other control tracks it. The resulting value appears on the command prompt.

```
function trivialmidigui(controlnum,DEVICENAME)
    slider = uicontrol('Style','slider');
    mc = midicontrols(controlnum,'MIDIDevice',DEVICENAME);
    midisync(mc);
    set(slider,'Callback',@slidercb);
    midicallback(mc, @mccb);

    function slidercb(slider,~)
        val = get(slider,'Value');
        midisync(mc, val);
        disp(val);
    end

    function mccb(mc)
        val = midiread(mc);
        set(slider,'Value',val);
        disp(val);
    end
end
```

## Input Arguments

### **h** — Object that listens to the controls on a MIDI device

object

h is an object that listens to the controls on a MIDI device.

### **Values** — Values sent to select MIDI control

any numeric value in range

Values must either be an array the same size as ControlNumbers from midicontrols or a scalar. If you do not specify Values, the default value is whatever the

`InitialValues` is from `midicontrols`. Typically, values must normally be in the range `[0 1]`. However, if you specify `'rawmidi'` as `OutputMode` of `midicontrols`, the `Values` range is between 0 and 127.

Example: `0.3` or `[0 0.3 0.6]`

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## See Also

## minimizecoeffwl

Minimum wordlength fixed-point filter

### Syntax

```
Hq = minimizecoeffwl(Hd)
Hq = minimizecoeffwl(Hd,...,'NoiseShaping',NSFlag)
Hq = minimizecoeffwl(Hd,...,'NTrials',N)
Hq = minimizecoeffwl(Hd,...,'Apasstol',Apasstol)
Hq = minimizecoeffwl(Hd,...,'Astoptol',Astoptol)
Hq = minimizecoeffwl(Hd,...,'MatchrefFilter',RefFiltFlag)
```

### Description

`Hq = minimizecoeffwl(Hd)` returns the minimum wordlength fixed-point filter object `Hq` that meets the design specifications of the single-stage or multistage FIR filter object `Hd`. `Hd` must be generated using `fdesign` and `design`. If `Hd` is a multistage filter object, the procedure minimizes the wordlength for each stage separately. `minimizecoeffwl` uses a stochastic noise-shaping procedure by default to minimize the wordlength. To obtain repeatable results on successive function calls, initialize the uniform random number generator `rand`.

`Hq = minimizecoeffwl(Hd,...,'NoiseShaping',NSFlag)` enables or disables the stochastic noise-shaping procedure in the minimization of the wordlength. By default `NSFlag` is `true`. Setting `NSFlag` to `false` minimizes the wordlength without using noise-shaping.

`Hq = minimizecoeffwl(Hd,...,'NTrials',N)` specifies the number of Monte Carlo trials to use in the minimization. `Hq` is the filter with the minimum wordlength among the `N` trials that meets the specifications in `Hd`. `'NTrials'` defaults to one.

`Hq = minimizecoeffwl(Hd,...,'Apasstol',Apasstol)` specifies the passband ripple tolerance in dB. `'Apasstol'` defaults to `1e-4`.

`Hq = minimizecoeffwl(Hd,...,'Astoptol',Astoptol)` specifies the stopband tolerance in dB. `'Astoptol'` defaults to `1e-2`.

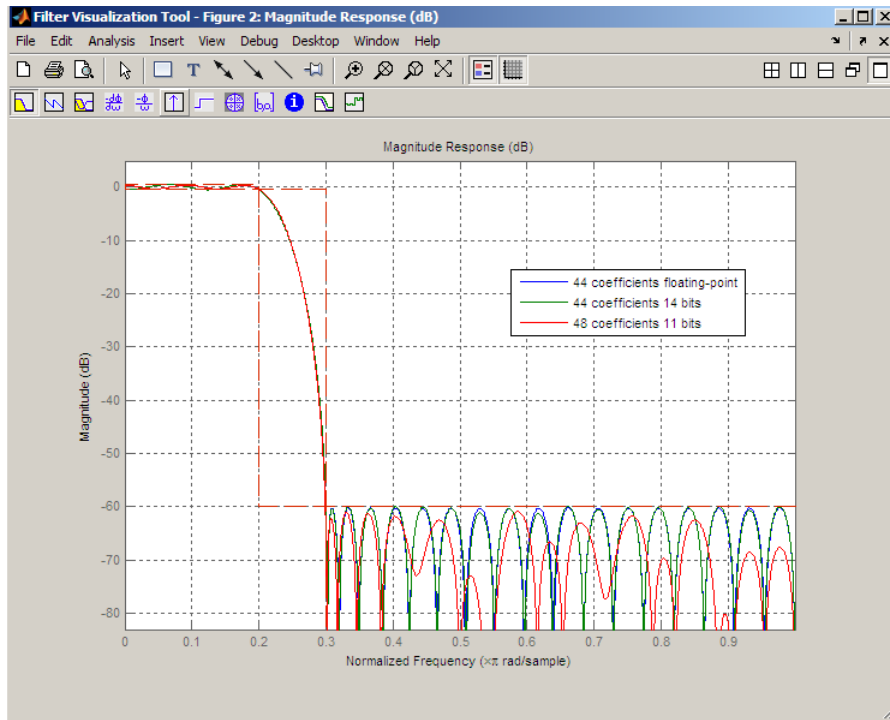

Hq = minimizecoeffwl(Hd,...,'MatchRefFilter',RefFiltFlag) determines whether the fixed-point filter matches the filter order and transition width of the floating-point design. Setting 'MatchRefFilter' to true returns a fixed-point filter with the same order and transition width as Hd. The 'MatchRefFilter' property defaults to false and the resulting fixed-point filter may have a different order and transition width than the floating-point design Hd.

You must have the Fixed-Point Designer software installed to use this function.

## Examples

Minimize wordlength for lowpass FIR equiripple filter:

```
f=fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.3,1,60);
% Design filter with double-precision floating point
Hd=design(f,'equiripple');
% Find minimum wordlength fixed-point filter
% with 0.15 dB stopband tolerance
Hq=minimizecoeffwl(Hd,'MatchRefFilter',true,'Astoptol',0.15);
Hq1=minimizecoeffwl(Hd,'Astoptol',0.15);
% Hq.coeffwordlength is 14 bits.
% Hq1.coeffwordlength is 11 bits
hfvt=fvtool(Hd,Hq,Hq1,'showreference','off');
legend(hfvt,'44 coefficients floating-point',...
'44 coefficients 14 bits','48 coefficients 11 bits');
```

# modifyCursor

**Package:** dsp

Modify properties of Logic Analyzer cursor

## Syntax

```
modifyCursor(scope,tag)  
modifyCursor(scope,tag,Name,Value)
```

## Description

`modifyCursor(scope,tag)` modifies the properties of the Logic Analyzer cursor specified by the input tag.

`modifyCursor(scope,tag,Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

## Examples

### Modify Logic Analyzer Cursors Programmatically

This example shows how to use functions to create, manipulate, and delete cursors in a `dsp.LogicAnalyzer` object.

#### Create Logic Analyzer and Signals

```
scope = dsp.LogicAnalyzer('NumInputPorts',3);  
for ii = 1:20  
    scope(ii,10*ii,20*ii);  
end
```

### Add Cursor

```
cursor = addCursor(scope, 'Location', 15, 'Color', 'Cyan');  
getCursorInfo(scope, cursor)
```

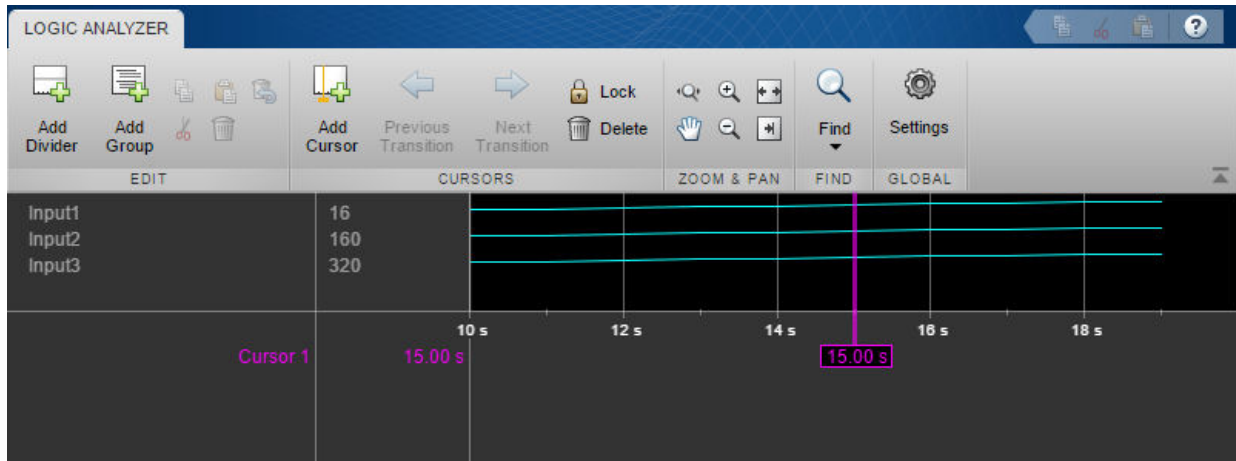

```
ans = struct with fields:  
    Location: 15  
    Color: [0 1 1]  
    Locked: 0  
    Tag: 'C2'
```

### Modify Cursor

```
modifyCursor(scope, cursor, 'Color', 'Magenta')
```

### Remove Cursor

```
tags = getCursorTags(scope);  
deleteCursor(scope, tags{1});
```

## Input Arguments

**scope** — The Logic Analyzer object for which you want to modify a cursor  
dsp.LogicAnalyzer object

The Logic Analyzer object for which you want to modify a cursor specified, as a handle to the `dsp.LogicAnalyzer` object.

**tag — The tag identifying which cursor to modify**

character vector, randomly assigned

The tag identifying which cursor to modify specified, as a randomly assigned character vector.

Example: `modifyCursor(scope,tag)` modifies a cursor in Logic Analyzer.

Example: `scope.modifyCursor(tag)` modifies a cursor in Logic Analyzer.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Location',2,'Color','Blue'` specifies that a cursor should be moved to the 2-second mark and colored blue.

**Color — Color of the cursor**

'Yellow' (default) | character vector | three element vector

Color of the cursor, specified as an [R G B] value or one of the following:

- 'Black'
- 'Blue'
- 'Cyan'
- 'Green'
- 'Magenta'
- 'White'
- 'Yellow'

For more information, see `ColorSpec` (Color Specification).

Example: `'Color','Blue'`

Example: `'Color',[0,0,1]`

Data Types: char | double

### **Location — Location of the cursor**

0 (default) | numeric scalar

Specify as a numeric scalar value, in seconds, the cursor location.

Example: 'Location',1

Data Types: double

### **Locked — Locked status of the cursor**

false (default) | true

Locked status of the cursor, specified as `false` or `true`.

- `true` — the cursor's location cannot be changed. Logic Analyzer denotes this by assigning a default color of gray. This color cannot be changed.
- `false` — the cursor's location can be changed. Logic Analyzer denotes this by assigning a default color of yellow.

Example: 'Locked',true

# modifyDisplayChannel

**Package:** dsp

Modify properties of Logic Analyzer display channel

## Syntax

```
modifyDisplayChannel(scope,tag,Name,Value)
```

## Description

`modifyDisplayChannel(scope,tag,Name,Value)` modifies the properties of `tag` using properties specified by one or more name-value pairs. Enclose each property name in single quotes.

## Examples

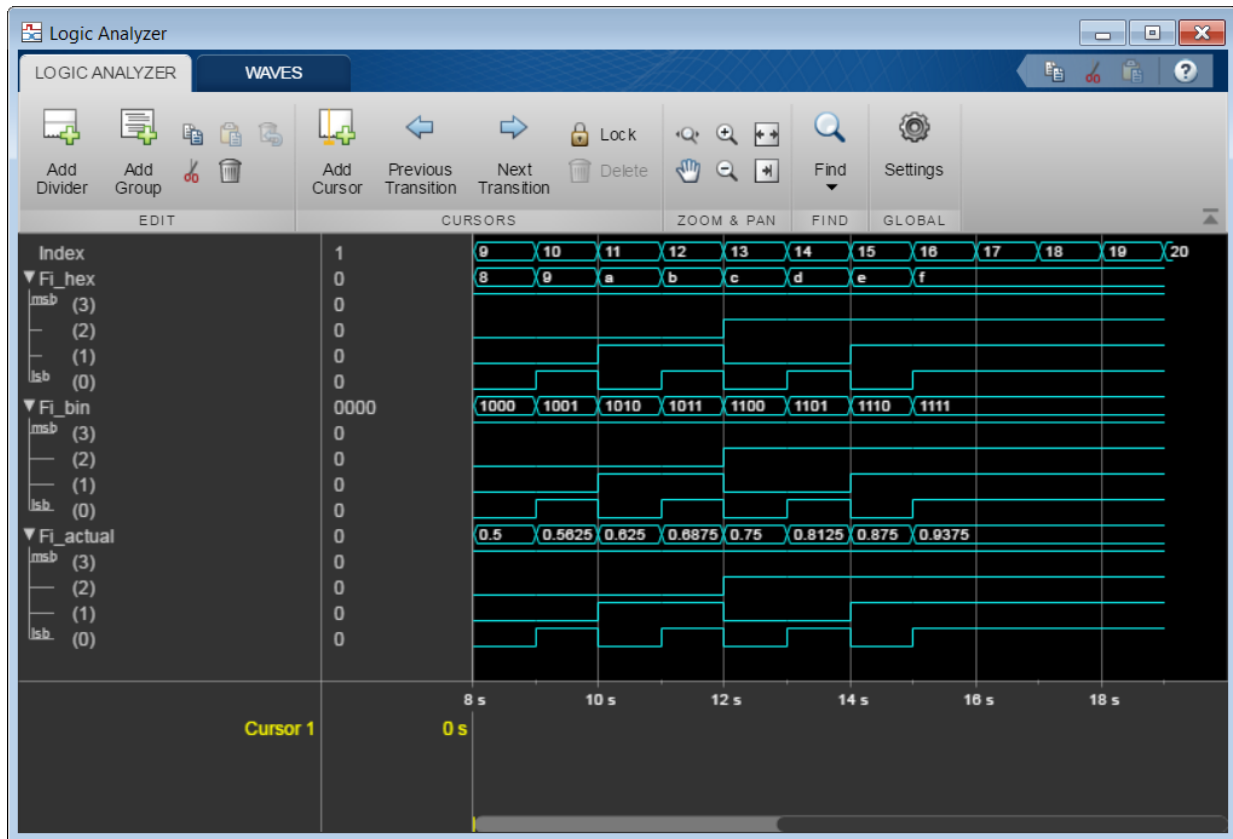

### Display Fixed-Point Signals

Create a `dsp.LogicAnalyzer` object with four channels. Call `modifyDisplayChannel` to set the radix of each of the channels. Run the scope in a loop to display the waves.

```
scope = dsp.LogicAnalyzer('NumInputPorts',4,'DisplayChannelFormat','Digital');
scope.TimeSpan = 12;

modifyDisplayChannel(scope,1,'Name','Index','Radix','Unsigned decimal');
modifyDisplayChannel(scope,2,'Name','Fi_hex','Radix','Hexadecimal');
modifyDisplayChannel(scope,3,'Name','Fi_bin','Radix','Binary');
modifyDisplayChannel(scope,4,'Name','Fi_actual','Radix','Signed decimal');

for ii = 1:20
    fival = fi((ii-1)/16,0,4,4);
    scope(ii,fival,fival,fival);
end
```

### Manipulate Logic Analyzer Programmatically

Use functions to construct and manipulate a `dsp.LogicAnalyzer` System object.

#### Display Waves on Logic Analyzer scope.

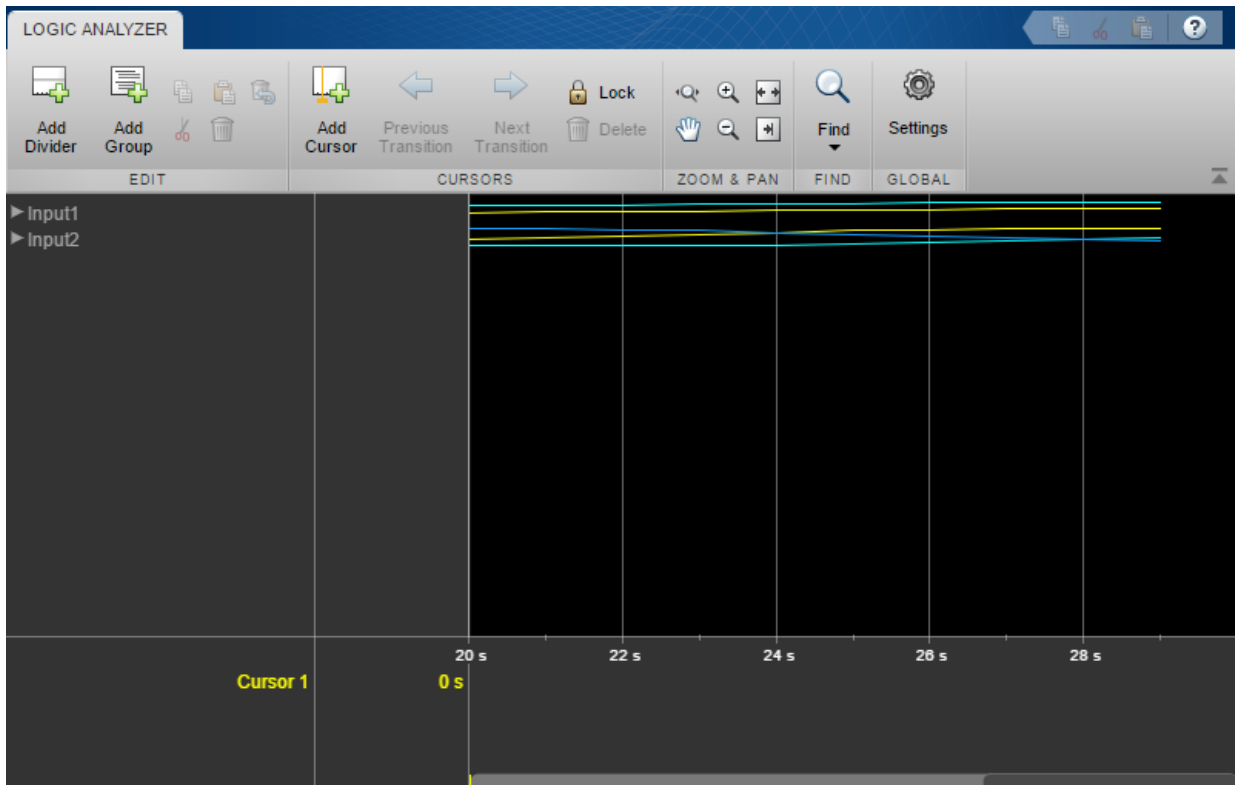

```
scope = dsp.LogicAnalyzer('NumInputPorts',2);

stop = 30;
for count = 1:stop
    sinValVec = sin(count/stop*2*pi);
    cosValVec = cos(count/stop*2*pi);
```

```

cosValVecOffset = cos((count+10)/stop*2*pi);
scope([count (count-(stop/2))],[sinValVec cosValVec cosValVecOffset])
end

```

### Reorganize Display

```

digitalDividerTag = addDivider(scope,'Name','Digital','Height',20);
analogDividerTag = addDivider(scope,'Name','Analog','Height',40);

tags = getDisplayChannelTags(scope);

modifyDisplayChannel(scope,tags{1},'InputChannel',1,...
    'Name','Ramp Digital','Height',40);
modifyDisplayChannel(scope,tags{2},'InputChannel',2,...
    'Name','Waves Analog','Format','Analog','Height',80);

```

```
moveDisplayChannel(scope,digitalDividerTag,'DisplayChannel',1)
moveDisplayChannel(scope,tags{2},'DisplayChannel',length(tags))

show(scope)
```

### Duplicate Wave and Check Information

```
addWave(scope,'InputChannel',2,'Name','Waves Digital','Format','Digital',...
        'Height',30,'DisplayChannel',3);
```

### Remove Dividers

```
deleteDisplayChannel(scope,digitalDividerTag)  
deleteDisplayChannel(scope,analogDividerTag)
```

### Clear variables

```
clear analogDividerTag cosValVec cosValVecOffset count digitalDividerTag duplicateWave
```

## Input Arguments

**scope** — Logic Analyzer object for which you want to modify a display channel  
 dsp.LogicAnalyzer object

The Logic Analyzer object for which you want to modify a display channel, specified as a handle to the dsp.LogicAnalyzer object.

**tag** — which display channel to modify  
 character vector, randomly assigned

The tag identifying which display channel to modify, specified as a randomly assigned character vector.

Example: `modifyDisplayChannel(scope, tag)` modifies a display channel in Logic Analyzer.

The first section on Name-Value Pair Arguments shows the properties you can set if the display channel contains a wave. The second section on Name-Value Pair Arguments shows the properties you can set if the display channel contains a divider.

## Wave Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'InputChannel', 2, 'Color', 'Blue'` specifies that a wave should be added to input channel 1 and colored blue.

### Color — Color of the wave

'Default' (default) | character vector

Color of the wave, specified as an [R G B] value or one of the following:

- 'Black'
- 'Blue'
- 'Cyan'
- 'Default'
- 'Green'
- 'Magenta'
- 'Red'
- 'White'
- 'Yellow'

When you choose 'Default', the value of the `DisplayChannelColor` property in the Logic Analyzer is used.

Example: `'Color', 'Blue'`

Example: 'Color', [0,0,1]

Data Types: char | double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

### **DisplayChannel — Channel on the display that shows this wave**

NumInputPorts (default) | scalar numeric value in the range (1,NumInputPorts)

Specify as a scalar numeric value the display channel that shows this wave. By default, the wave is added to the end of the display.

Example: 'DisplayChannel', 2

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

### **FontSize — Font size for values in the wave**

0 (default) | scalar nonnegative integer

Specify as a scalar nonnegative integer the font size in points. When you choose 0, the value of the DisplayChannelFontSize property in the Logic Analyzer is used.

Example: 'FontSize', 8

Data Types: double

### **Format — Display format for the wave**

'Default' (default) | character vector

'Format' must be one of the following.

- 'Analog'
- 'Default'
- 'Digital'

When you choose 'Default', the value of the DisplayChannelFormat property in the Logic Analyzer is used.

Example: 'Format', 'Digital'

Data Types: char

### **Height — Height of the wave**

0 (default) | scalar integer

Specify as a scalar integer the height of the wave in the display in units of 16 pixels. When you choose 0, the value of the `DisplayChannelHeight` property in the Logic Analyzer is used.

Example: `'Height',2`

Data Types: double

### **InputChannel — Input channel that corresponds to this wave**

1 (default) | scalar integer in the range (1,NumInputPorts)

This property specifies the input channel whose data is used for this wave. By default, it will connect the first input to this wave.

Example: `'InputChannel',2`

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

### **Name — The name or label for the wave**

' ' (default) | character vector

Specify as a character vector the name that you would like to set for the new wave.

Example: `'Name','MyWave'`

Data Types: char

### **Radix — Radix for the wave**

'Default' (default) | character vector

'Radix' must be one of the following.

- `'Binary'`
- `'Default'`
- `'Hexadecimal'`
- `'Octal'`
- `'Signed decimal'`
- `'Unsigned decimal'`

When the input signals are of class double, single, or logical, you should not set this property. When you choose `'Default'`, the value of the `DisplayChannelRadix` property in the Logic Analyzer is used.

Example: `'Radix', 'Hexadecimal'`

Data Types: `char`

### Divider Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'DisplayChannel', 2, 'Name', 'MyDivider'` specifies that a divider should be added to display channel 2 and named “MyDivider”.

#### **DisplayChannel** — Channel on the display that shows this divider

`NumInputPorts` (default) | scalar numeric value in the range (1, `NumInputPorts`)

Specify as a scalar numeric value the display channel that shows this divider. By default, the divider is added to the end of the display.

Example: `'DisplayChannel', 2`

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

#### **Height** — Height of the divider

`0` (default) | scalar integer

Specify, in pixels, the height of the divider as a scalar integer in the range 8 to 200. If you choose 0, the value of the `DisplayChannelHeight` property in the Logic Analyzer is used.

Example: `'Height', 2`

Data Types: `double`

#### **Name** — The name or label for the divider

`' '` (default) | character vector

Specify as a character vector the name that you would like to set for the new divider.

Example: `'Name', 'MyDivider'`

Data Types: `char`

## See Also

# moveDisplayChannel

**Package:** dsp

Move position of Logic Analyzer display channel

## Syntax

```
moveDisplayChannel(scope,tag,'DisplayChannel',displayChannelValue)
```

## Description

`moveDisplayChannel(scope,tag,'DisplayChannel',displayChannelValue)` moves the display channel, either a wave or a divider, specified by the input `tag`, to the new location specified by the input `displayChannelValue`.

## Examples

### Manipulate Logic Analyzer Programmatically

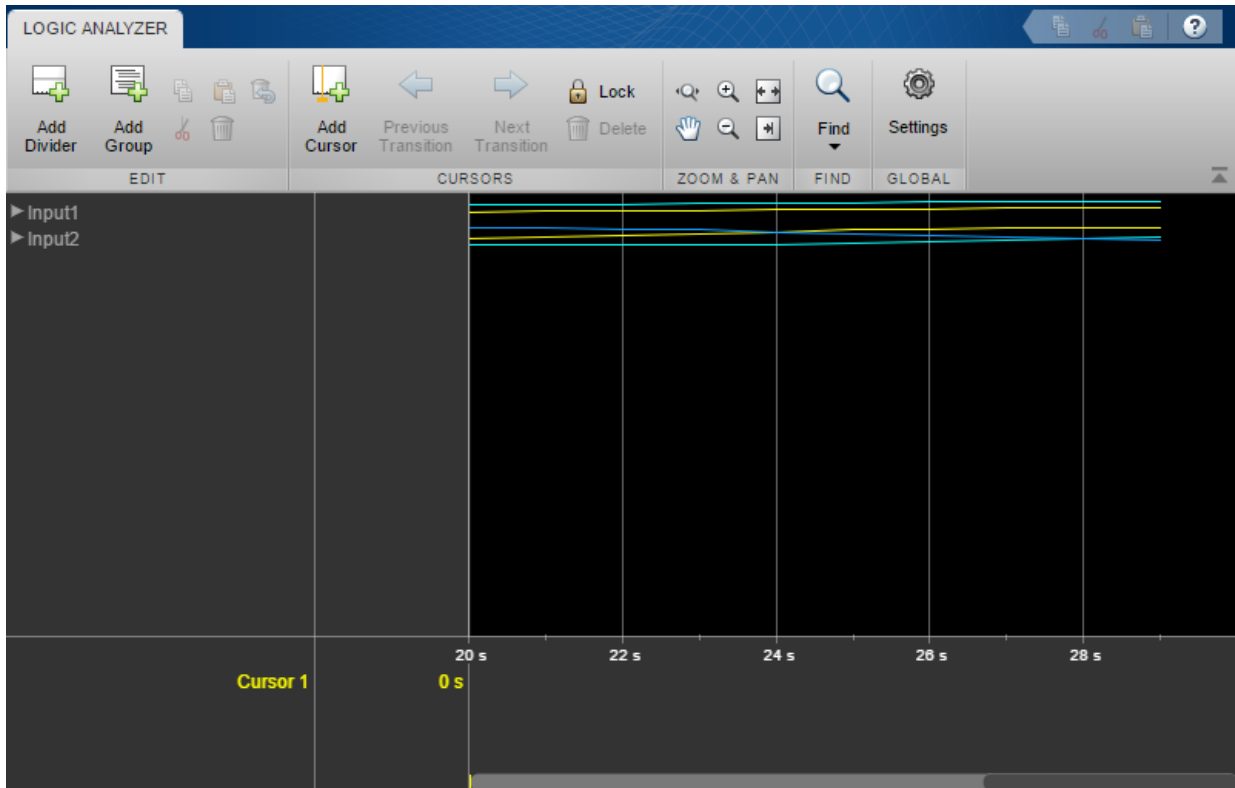

Use functions to construct and manipulate a `dsp.LogicAnalyzer` System object.

### Display Waves on Logic Analyzer scope.

```
scope = dsp.LogicAnalyzer('NumInputPorts',2);

stop = 30;
for count = 1:stop
    sinValVec = sin(count/stop*2*pi);
    cosValVec = cos(count/stop*2*pi);
    cosValVecOffset = cos((count+10)/stop*2*pi);

    scope([count (count-(stop/2))],[sinValVec cosValVec cosValVecOffset])
end
```

## Reorganize Display

```
digitalDividerTag = addDivider(scope, 'Name', 'Digital', 'Height', 20);
analogDividerTag = addDivider(scope, 'Name', 'Analog', 'Height', 40);

tags = getDisplayChannelTags(scope);

modifyDisplayChannel(scope, tags{1}, 'InputChannel', 1, ...
    'Name', 'Ramp Digital', 'Height', 40);
modifyDisplayChannel(scope, tags{2}, 'InputChannel', 2, ...
    'Name', 'Waves Analog', 'Format', 'Analog', 'Height', 80);

moveDisplayChannel(scope, digitalDividerTag, 'DisplayChannel', 1)
moveDisplayChannel(scope, tags{2}, 'DisplayChannel', length(tags))

show(scope)
```

### Duplicate Wave and Check Information

```
addWave(scope, 'InputChannel', 2, 'Name', 'Waves Digital', 'Format', 'Digital', ...  
        'Height', 30, 'DisplayChannel', 3);
```

### Remove Dividers

```
deleteDisplayChannel(scope,digitalDividerTag)  
deleteDisplayChannel(scope,analogDividerTag)
```

### Clear variables

```
clear analogDividerTag cosValVec cosValVecOffset count digitalDividerTag duplicateWave
```

## Input Arguments

### scope — Logic Analyzer object

dsp.LogicAnalyzer object

The Logic Analyzer object in which you want to move a display channel, specified as a handle to the dsp.LogicAnalyzer object.

### tag — The tag identifying which display channel to move

character vector

The tag identifying which display channel to move, specified as a character vector.

Example: 'W1'

Data Types: char

**displayChannelValue** — The location identifying where the display channel should be moved

scalar integer

The location identifying where the display channel should be moved, specified as a scalar integer.

Example: 'DisplayChannel',2

Data Types: double

## See Also

`deleteDisplayChannel` | `dsp.LogicAnalyzer` | `getDisplayChannelInfo` | `getDisplayChannelTags` | `modifyDisplayChannel`

**Introduced in R2013a**

## msepred

**Package:** dsp

Predicted mean squared error for LMS adaptive filter

### Syntax

```
[mmseemse] = msepred(lmsFilt,x,d)
[mmseemse,meanw,mse,tracek] = msepred(lmsFilt,x,d)
[mmseemse,meanw,mse,tracek] = msepred(lmsFilt,x,d,m)
```

### Description

[mmseemse] = msepred(lmsFilt,x,d) predicts the steady-state values at convergence of the minimum mean squared error, mmse, and the excess mean squared error, emse, given the input and the desired response signal sequences in x and d and the quantities in the dsp.LMSFilter System object, lmsFilt.

[mmseemse,meanw,mse,tracek] = msepred(lmsFilt,x,d) also computes meanw, the sequence of means of the coefficient vectors, mse, sequence of mean-squared errors, and tracek, the sequence of total coefficient error powers.

[mmseemse,meanw,mse,tracek] = msepred(lmsFilt,x,d,m) specifies an optional decimation factor for computing meanw, mse, and tracek. If m > 1, every m<sup>th</sup> predicted value of each of these sequences is saved. If omitted, the value of m is the default, which is one.

### Examples

#### Predict Mean Squared Error for LMS Filter

The mean squared error (MSE) measures the average of the squares of the errors between the desired signal and the primary signal input to the adaptive filter. Reducing

this error converges the primary input to the desired signal. Determine the predicted value of MSE and the simulated value of MSE with each time instant using the `msepred` and `msesim` functions. Compare these MSE values with each other and with respect to the minimum MSE and steady-state MSE values. In addition, compute the sum of the squares of the coefficient errors given by the trace of the coefficient covariance matrix.

**Note:** If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

### Initialization

Create a `dsp.FIRFilter` System object™ that represents the unknown system. Pass the signal, `x`, to the FIR filter. The output of the unknown system is the desired signal, `d`, which is the sum of the output of the unknown system (FIR filter) and an additive noise signal, `n`.

```
num = fir1(31,0.5);
fir = dsp.FIRFilter('Numerator',num);
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
n = 0.1*randn(size(x));
d = fir(x) + n;
```

### LMS Filter

Create a `dsp.LMSFilter` System object to create a filter that adapts to output the desired signal. Set the length of the adaptive filter to 32 taps, step size to 0.008 and the decimation factor for analysis and simulation to 5. The variable `simmse` represents the simulated MSE between the output of the unknown system, `d`, and the output of the adaptive filter. The variable `mse` gives the corresponding predicted value.

```
l = 32;
mu = 0.008;
m = 5;

lms = dsp.LMSFilter('Length',l,'StepSize',mu);
[mmse,emse,meanW,mse,traceK] = msepred(lms,x,d,m);
[simmse,meanWsim,Wsim,traceKsim] = msesim(lms,x,d,m);
```

### Plot the MSE Results

Compare the values of simulated MSE, predicted MSE, minimum MSE, and the final MSE. The final MSE value is given by the sum of minimum MSE and excess MSE.

```

nn = m:m:size(x,1);
semilogy(nn,simmse,[0 size(x,1)],[(emse+mmse)...
(emse+mmse)],nn,mse,[0 size(x,1)],[mmse mmse])
title('Mean Squared Error Performance')
axis([0 size(x,1) 0.001 10])
legend('MSE (Sim.)','Final MSE','MSE','Min. MSE')
xlabel('Time Index')
ylabel('Squared Error Value')

```

The predicted MSE follows the same trajectory as the simulated MSE. Both these trajectories converge with the steady-state (final) MSE.

## Plot the Coefficient Trajectories

meanWsim is the mean value of the simulated coefficients given by msesim. meanW is the mean value of the predicted coefficients given by msepred.

Compare the simulated and predicted mean values of LMS filter coefficients 12,13,14, and 15.

```
plot(nn,meanWsim(:,12),'b',nn,meanW(:,12),'r',nn,...
meanWsim(:,13:15),'b',nn,meanW(:,13:15),'r')
PlotTitle ={'Average Coefficient Trajectories for';...
            'W(12), W(13), W(14), and W(15)'}

PlotTitle = 2x1 cell array
            {'Average Coefficient Trajectories for'}
            {'W(12), W(13), W(14), and W(15)'}

title(PlotTitle)
legend('Simulation','Theory')
xlabel('Time Index')
ylabel('Coefficient Value')
```

In steady state, both the trajectories converge.

### Sum of Squared Coefficient Errors

Compare the sum of the squared coefficient errors given by `msepred` and `msesim`. These values are given by the trace of the coefficient covariance matrix.

```
semilogy(nn,traceKsim,nn,traceK,'r')
title('Sum-of-Squared Coefficient Errors')
axis([0 size(x,1) 0.0001 1])
legend('Simulation','Theory')
xlabel('Time Index')
ylabel('Squared Error Value')
```

## Input Arguments

**lmsFilt** — LMS adaptive filter System object

`dsp.LMSFilter`

LMS adaptive filter, specified as a `dsp.LMSFilter` System object.

**x** — Input signal

scalar | column vector | matrix

Input signal, specified as a scalar, column vector, or matrix. Columns of the matrix  $x$  contain individual input signal sequences. The input,  $x$ , and the desired signal,  $d$ , must have the same size, data type, and complexity.

Data Types: `single` | `double`

### **d — Desired signal**

`scalar` | `column vector` | `matrix`

Desired response signal, specified as a scalar, column vector, or matrix. Columns of the matrix  $d$  contain individual desired signal sequences. The input,  $x$ , and the desired signal,  $d$ , must have the same size, data type, and complexity.

Data Types: `single` | `double`

### **m — Decimation factor**

`1` (default) | `positive scalar`

Decimation factor, specified as a positive scalar. Every  $m$ th predicted value of the 3rd, 4th, and 5th predicted sequences output is saved into the corresponding output arguments, `meanw`, `mse`, and `tracek`. If  $m$  equals 1, every value of these sequences is saved.

$m$  must be a factor of the input frame size.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

## Output Arguments

### **mmse — Minimum mean squared error**

`scalar`

Minimum mean squared error (mmse), returned as a scalar. This parameter is estimated using a Wiener filter. The Wiener filter minimizes the mean squared error between the desired signal and the input signal filtered by the Wiener filter. A large value of the mean squared error indicates that the adaptive filter cannot accurately track the desired signal. The minimal value of the mean squared error ensures that the adaptive filter is optimal. The minimum mean squared error between a particular frame of the desired signal and the filtered signal is computed as the variance between the two frames of signals. The `msepred` function outputs the average of the mmse values for all the frames. For more details on how this parameter is calculated, see “Algorithms” on page 5-1282.

Data Types: `single` | `double`

### **emse — Steady state excess mean squared error**

scalar

Excess mean squared error, returned as a scalar. This error is the difference between the mean squared error introduced by adaptive filters and the minimum mean squared error produced by corresponding Wiener filter. For details on how this parameter is calculated, see “Algorithms” on page 5-1282.

Data Types: `single` | `double`

### **meanw — Sequence of coefficient vector means**

matrix

Sequence of coefficient vector means of the adaptive filter at each time instant, returned as a matrix. The columns of this matrix contain predictions of the mean values of the LMS adaptive filter coefficients at each time instant. If the decimation factor,  $m$  equals 1, the dimensions of `meanw` is  $M$ -by- $N$ .  $M$  is the frame size (number of rows) of the input signal,  $x$ .  $N$  is the length of the FIR filter weights vector, specified by the `Length` property of the `lmsfilt` System object. If  $m > 1$ , the dimensions of `meanw` is  $M/m$ -by- $N$ .

For details on how this parameter is calculated, see “Algorithms” on page 5-1282.

Data Types: `double`

### **mse — Sequence of mean squared errors**

column vector

Predictions of the mean squared error of the LMS adaptive filter at each time instant, returned as a column vector. If the decimation factor,  $m$  equals 1, the length of `mse` equals the frame size (number of rows) of the input signal,  $M$ . If  $m > 1$ , the length of `mse` equals  $M/m$ .

For details on how this parameter is calculated, see “Algorithms” on page 5-1282.

Data Types: `double`

### **tracek — Sequence of total coefficient error powers**

column vector

Predictions of the total coefficient error power of the LMS adaptive filter at each time instant, returned as a column vector. If the decimation factor,  $m$  equals 1, the length of

`t tracek` equals the frame size (number of rows) of the input signal, given by `size(x,1)`. If `m > 1`, the length of `t tracek` equals the ratio of input frame size and the decimation factor, `m`.

For details on how this parameter is calculated, see “Algorithms” on page 5-1282.

Data Types: `double`

## Algorithms

### Minimum Mean Squared Error (mmse)

The `msepred` function computes the minimum mean-squared error (mmse) using the following equation:

$$mmse = \frac{\sum_{i=1}^N \text{var}(d_i - W(x_i))}{N}$$

where,

- $N$  -- Number of frames in the input signal,  $x$ .
- $d_i$  --  $i$ th frame (column) of the desired signal.
- $x_i$  --  $i$ th frame (column) of the input signal.
- $W(x_i)$  -- Output of the Wiener filter.
- `var` -- Variance

### Excess Mean Squared Error (emse)

The `msepred` function computes the steady-state excess mean squared error using the following equations:

$$emse = K\lambda,$$

$$K = \frac{B}{I(L) - A},$$

$$B = \mu^2 \cdot mmse \cdot \lambda',$$

$$A = I(L) - 2\mu Lam + \mu^2 (Lam^2 (kurt + 2) + \lambda\lambda').$$

where,

- $K$  -- Final values of transformed coefficient variances.
- $\lambda$  -- Column vector containing the eigenvalues of the input autocorrelation matrix.
- $\lambda'$  -- Transpose of  $\lambda$ .
- $B$  -- MSE analysis driving term.
- $L$  -- Length of the FIR adaptive filter, given by `lmsFilt.Length`.
- $I(L)$  --  $L$ -by- $L$  identity matrix.
- $A$  -- MSE analysis transition matrix.
- $\mu$  -- Step size given by `lmsFilt.StepSize`.
- $Lam$  -- Diagonal matrix containing the eigenvalues.
- $kurt$  -- Average kurtosis value of eigenvector-filtered signals.

## Coefficient Vector Means (meanw)

The `msepred` function computes each element of the sequence of coefficient vector means using the following equations:

$$meanw = meanw.T.D,$$

$$T = I(L) - \mu R,$$

$$D = \mu P.$$

where,

- $meanw$  -- The initial value of  $meanw$  is given by `lmsFilt.InitialConditions`.
- $T$  -- Transition matrix for mean coefficient analysis.

- $I(L)$  --  $L$ -by- $L$  identity matrix.
- $\mu$  -- Step size given by `lmsFilt.StepSize`.
- $R$  -- Input autocorrelation matrix of size  $L$ -by- $L$ .
- $D$  -- Driving term for mean coefficient analysis.
- $P$  -- Cross correlation vector of size 1-by- $L$ .
- $kurt$  -- Average kurtosis value of eigenvector-filtered signals.

## Mean Squared Errors (mse)

The `msepred` function computes each element of the sequence of the mean squared errors using the following equations:

$$\begin{aligned}mse &= mmse + dk \cdot \lambda, \\ dk &= dk \circ diagA + mse \cdot D, \\ diagA &= (1 - 2\mu\lambda + \mu^2(kurt + 2)\lambda^2)', \\ D &= \mu^2\lambda' .\end{aligned}$$

where,

- $mmse$  -- Minimum mean squared error.
- $dk$  -- Diagonal entries of coefficient covariance matrix. The initial value of  $dk$  is given by  $dk = ((meanw - Wopt)Q)^2$ .
- $meanw$  -- Coefficient vector means given by `lmsFilt.InitialConditions`.
- $Wopt$  -- Optimal Wiener filter coefficients.
- $Q$  --  $L$ -by- $L$  matrix whose columns are the eigenvectors of the input autocorrelation matrix,  $R$ , so that  $RQ = QLam$ .  $Lam$  is the diagonal matrix containing the corresponding eigen values.
- $diagA$  -- Portion of MSE analysis transition matrix.
- $dk \circ diagA$  -- Hadamard or entrywise product of  $dk$  and  $diagA$ .
- $\lambda$  -- Column vector containing the eigenvalues of the input autocorrelation matrix,  $R$ .
- $\mu$  -- Step size given by `lmsFilt.StepSize`.
- $kurt$  -- Average kurtosis value of eigenvector filtered signals.

- $\lambda^2$  -- Hadamard or entrywise power of the column vector containing the eigenvalues.
- $D$  -- Driving term for MSE analysis.

## Total Coefficient Error Powers (tracek)

The `msepred` function computes each element of the sequence of the total coefficient error powers. These values are given by the trace of the coefficient covariance matrix. The diagonal entries of the coefficient covariance matrix are given by  $dk$  in the following equations:

$$\begin{aligned}mse &= mmse + dk \cdot \lambda, \\ dk &= dk \circ \text{diag}A + mse \cdot D, \\ \text{diag}A &= (1 - 2\mu\lambda + \mu^2(\text{kurt} + 2)\lambda^2); \\ D &= \mu^2 \lambda' .\end{aligned}$$

The trace of the coefficient covariance matrix is given by the following equation:

$$\text{tracek} = \text{sum}(dk).$$

# msesim

**Package:** dsp

Estimated mean-squared error for adaptive filters

## Syntax

```
mse = msesim(adaptFilt,x,d)
[mse,meanw,w,tracek] = msesim(adaptFilt,x,d)
[___] = msesim(adaptFilt,x,m)
```

## Description

`mse = msesim(adaptFilt,x,d)` estimates the mean squared error of the adaptive filter at each time instant given the input and the desired response signal sequences in `x` and `d`.

`[mse,meanw,w,tracek] = msesim(adaptFilt,x,d)` also calculates the sequences of coefficient vector means, `meanw`, adaptive filter coefficients, `w`, and the total coefficient error powers, `tracek`, corresponding to the simulated behavior of the adaptive filter.

`[___] = msesim(adaptFilt,x,m)` specifies an optional decimation factor for computing `mse`, `meanw`, and `tracek`. If `m > 1`, every `m`th value of each of these sequences is saved. If omitted, the value of `m` defaults to 1.

## Examples

### Predict Mean Squared Error for LMS Filter

The mean squared error (MSE) measures the average of the squares of the errors between the desired signal and the primary signal input to the adaptive filter. Reducing this error converges the primary input to the desired signal. Determine the predicted value of MSE and the simulated value of MSE with each time instant using the `msepred`

and `mseSim` functions. Compare these MSE values with each other and with respect to the minimum MSE and steady-state MSE values. In addition, compute the sum of the squares of the coefficient errors given by the trace of the coefficient covariance matrix.

**Note:** If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

### Initialization

Create a `dsp.FIRFilter` System object™ that represents the unknown system. Pass the signal, `x`, to the FIR filter. The output of the unknown system is the desired signal, `d`, which is the sum of the output of the unknown system (FIR filter) and an additive noise signal, `n`.

```
num = fir1(31,0.5);
fir = dsp.FIRFilter('Numerator',num);
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
n = 0.1*randn(size(x));
d = fir(x) + n;
```

### LMS Filter

Create a `dsp.LMSFilter` System object to create a filter that adapts to output the desired signal. Set the length of the adaptive filter to 32 taps, step size to 0.008 and the decimation factor for analysis and simulation to 5. The variable `simmse` represents the simulated MSE between the output of the unknown system, `d`, and the output of the adaptive filter. The variable `mse` gives the corresponding predicted value.

```
l = 32;
mu = 0.008;
m = 5;

lms = dsp.LMSFilter('Length',l,'StepSize',mu);
[mmse,emse,meanW,mse,traceK] = msepred(lms,x,d,m);
[simmse,meanWsim,Wsim,traceKsim] = mseSim(lms,x,d,m);
```

### Plot the MSE Results

Compare the values of simulated MSE, predicted MSE, minimum MSE, and the final MSE. The final MSE value is given by the sum of minimum MSE and excess MSE.

```
nn = m:m:size(x,1);
semilogy(nn,simmse,[0 size(x,1)],[(emse+mmse)...
```

```
(emse+mmse)],nn,mse,[0 size(x,1)],[mmse mmse])
title('Mean Squared Error Performance')
axis([0 size(x,1) 0.001 10])
legend('MSE (Sim.)','Final MSE','MSE','Min. MSE')
xlabel('Time Index')
ylabel('Squared Error Value')
```

The predicted MSE follows the same trajectory as the simulated MSE. Both these trajectories converge with the steady-state (final) MSE.

### Plot the Coefficient Trajectories

`meanWsim` is the mean value of the simulated coefficients given by `msesim`. `meanW` is the mean value of the predicted coefficients given by `msepred`.

Compare the simulated and predicted mean values of LMS filter coefficients 12,13,14, and 15.

```
plot(nn,meanWsim(:,12),'b',nn,meanW(:,12),'r',nn,...
meanWsim(:,13:15),'b',nn,meanW(:,13:15),'r')
PlotTitle ={'Average Coefficient Trajectories for';...
            'W(12), W(13), W(14), and W(15)'}

PlotTitle = 2x1 cell array
            {'Average Coefficient Trajectories for'}
            {'W(12), W(13), W(14), and W(15)'}

title(PlotTitle)
legend('Simulation','Theory')
xlabel('Time Index')
ylabel('Coefficient Value')
```

In steady state, both the trajectories converge.

### Sum of Squared Coefficient Errors

Compare the sum of the squared coefficient errors given by `msepred` and `msesim`. These values are given by the trace of the coefficient covariance matrix.

```
semilogy(nn,traceKsim,nn,traceK,'r')
title('Sum-of-Squared Coefficient Errors')
axis([0 size(x,1) 0.0001 1])
legend('Simulation','Theory')
xlabel('Time Index')
ylabel('Squared Error Value')
```

### System Identification of an FIR Filter Using Filtered XLMS Filter

Identify an unknown system by performing active noise control using a filtered-X LMS algorithm. The objective of the adaptive filter is to minimize the error signal between the output of the adaptive filter and the output of the unknown system (or the system to be identified). Once the error signal is minimal, the unknown system converges to the adaptive filter.

**Note:** If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

## Initialization

Create a `dsp.FIRFilter` object that represents the system to be identified. Pass the signal, `x`, to the FIR filter. The output of the unknown system is the desired signal, `d`, which is the sum of the output of the unknown system (FIR filter) and an additive noise signal, `n`.

```
num = fir1(31,0.5);
fir = dsp.FIRFilter('Numerator',num);
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
n = 0.1*randn(size(x));
d = fir(x) + n;
```

## Adaptive Filter

Create a `dsp.FilteredXLMSFilter` object to create an adaptive filter that uses the filtered-X LMS algorithm. Set the length of the adaptive filter to 32 taps, step size to 0.008, and the decimation factor for analysis and simulation to 5. The variable `simmse` represents the error between the output of the unknown system, `d`, and the output of the adaptive filter.

```
l = 32;
mu = 0.008;
m = 5;
fxlms = dsp.FilteredXLMSFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(fxlms,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse))
xlabel('Iteration')
ylabel('MSE (dB)')
title('Learning curve for Filtered-X LMS filter used in system identification')
```

With each iteration of adaptation, the value of `simmse` decreases to a minimal value, indicating that the unknown system has converged to the adaptive filter.

## Input Arguments

### **adaptFilt** — Adaptive filter System object

`dsp.LMSFilter` | `dsp.BlockLMSFilter` | `dsp.AdaptiveLatticeFilter` |  
`dsp.AffineProjectionFilter` | `dsp.FastTransversalFilter` |  
`dsp.FilteredXLMSFilter` | `dsp.RLSFilter`

Adaptive filter, specified as one of the following System objects:

- `dsp.LMSFilter`
- `dsp.BlockLMSFilter`
- `dsp.AdaptiveLatticeFilter`
- `dsp.AffineProjectionFilter`
- `dsp.FastTransversalFilter`
- `dsp.FilteredXLMSFilter`
- `dsp.RLSFilter`

**x — Input signal**

scalar | column vector | matrix

Input signal, specified as a scalar, column vector, or matrix. Columns of the matrix `x` contain individual input signal sequences. The input, `x`, and the desired signal, `d`, must have the same size, data type, and complexity.

If `adaptFilt` is a `dsp.BlockLMSFilter` object, the input signal frame size must be greater than or equal to the value you specify in the `BlockSize` property of the object.

Data Types: `single` | `double`

**d — Desired signal**

scalar | column vector | matrix

Desired response signal, specified as a scalar, column vector, or matrix. Columns of the matrix `d` contain individual desired signal sequences. The input, `x`, and the desired signal, `d`, must have the same size, data type, and complexity.

If `adaptFilt` is a `dsp.BlockLMSFilter System` object, the desired signal frame size must be greater than or equal to the value you specify in the `BlockSize` property of the object.

Data Types: `single` | `double`

**m — Decimation factor**

1 (default) | positive scalar

Decimation factor, specified as a positive scalar. Every `m`th value of the estimated sequences is saved into the corresponding output arguments, `mse`, `meanw`, `w`, and `tracek`. If `m` equals 1, every value of these sequences is saved.

If `adaptFilt` is a `dsp.BlockLMSFilter` System object, the decimation factor must be a multiple of the value you specify in the `BlockSize` property of the object.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

## Output Arguments

### **mse** — Sequence of mean squared errors

column vector

Estimates of the mean squared error of the adaptive filter at each time instant, returned as a column vector.

If the adaptive filter is `dsp.BlockLMSFilter` and the decimation factor `m` is specified, length of `mse` equals  $\text{floor}(M/m)$ .  $M$  is the frame size (number of rows) of the input signal, `x`. If `m` is not specified, the length of `mse` equals  $\text{floor}(M/B)$ , where  $B$  is the value you specify in the `BlockSize` property of the object. The input signal frame size must be greater than or equal to the value you specify in the `BlockSize` property of the object. The decimation factor, if specified, must be a multiple of the `BlockSize` property.

For the other adaptive filters, if the decimation factor,  $m = 1$ , the length of `mse` equals the frame size of the input signal. If  $m > 1$ , the length of `mse` equals  $\text{floor}(M/m)$ .

Data Types: `double`

### **meanw** — Sequence of coefficient vector means

matrix

Sequence of coefficient vector means of the adaptive filter at each time instant, estimated as a matrix. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant.

If the adaptive filter is `dsp.BlockLMSFilter` and the decimation factor `m` is specified, the dimensions of `meanw` is  $\text{floor}(M/m)$ -by- $N$ .  $M$  is the frame size (number of rows) of the input signal, `x`.  $N$  is the length of the filter weights vector, specified by the `Length` property of the adaptive filter. If `m` is not specified, the dimensions of `meanw` is  $\text{floor}(M/B)$ -by- $N$ , where  $B$  is the value you specify in the `BlockSize` property of the object. The input signal frame size must be greater than or equal to the value you specify in the `BlockSize` property of the object. The decimation factor, if specified, must be a multiple of the `BlockSize` property.

For the other adaptive filters, if the decimation factor,  $m = 1$ , the dimensions of `meanw` is  $M$ -by- $N$ . If  $m > 1$ , the dimensions of `meanw` is  $\text{floor}(M/m)$ -by- $N$ .

Data Types: `double`

### **w** — Final values of adaptive filter coefficients

row vector

Final values of the adaptive filter coefficients for the algorithm corresponding to `adaptFilt`, returned as a row vector. The length of the row vector equals the value you specify in the `Length` property of the object.

Data Types: `single` | `double`

### **tracek** — Sequence of total coefficient error powers

column vector

Sequence of total coefficient error powers, estimated as a column vector. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant.

If the adaptive filter is `dsp.BlockLMSFilter` and the decimation factor  $m$  is specified, length of `tracek` equals  $\text{floor}(M/m)$ .  $M$  is the frame size (number of rows) of the input signal,  $x$ . If  $m$  is not specified, the length of `tracek` equals  $\text{floor}(M/B)$ , where  $B$  is the value you specify in the `BlockSize` property of the object. The input signal frame size must be greater than or equal to the value you specify in the `BlockSize` property of the object. The decimation factor, if specified, must be a multiple of the `BlockSize` property.

For the other adaptive filters, if the decimation factor,  $m = 1$ , the length of `tracek` equals the frame size of the input signal. If  $m > 1$ , the length of `tracek` equals  $\text{floor}(M/m)$ .

Data Types: `double`

# multistage

Multistage filter from specification object

## Syntax

```
msFilter = design(d,'multistage','SystemObject',true)
msFilter =
design(...,'filterstructure',structure,'SystemObject',true)
msFilter = design(...,'nstages',nstages,'SystemObject',true)
msFilter = design(...,'usehalfbands',hb,'SystemObject',true)
```

## Description

`msFilter = design(d,'multistage','SystemObject',true)` designs a multistage filter whose response you specified by the filter specification object `d`.

`msFilter = design(...,'filterstructure',structure,'SystemObject',true)` returns a filter with the structure specified by `structure`. Input argument `structure` is `dffir` by default and can also be one of the following options.

structure	Valid with These Responses
<code>firdecim</code>	Lowpass or Nyquist response
<code>firtdecim</code>	Lowpass or Nyquist response
<code>firinterp</code>	Lowpass or Nyquist response
<code>lowpass</code>	Default lowpass only

Multistage design applies to the default lowpass filter specification object and to decimators and interpolators that use either lowpass or Nyquist responses.

`msFilter = design(...,'nstages',nstages,'SystemObject',true)` specifies `nstages`, the number of stages to be used in the design. `nstages` must be an integer or `auto`. To allow the design algorithm to use the optimal number of stages while minimizing the cost of using the resulting filter, `nstages` is `auto` by default. When you specify an

integer for `nstages`, the design algorithm minimizes the cost for the number of stages you specify.

`msFilter = design(...,'usehalfbands',hb,'SystemObject',true)` uses halfband filters when you set `hb` to `true`. The default value for `hb` is `false`.

---

**Note** To see a list of the design methods available for your filter, use `designmethods(hd)`.

---

## Examples

### Design a Multistage Interpolator

This example designs a minimum-order, multistage Nyquist interpolator.

```
l = 15; % Interpolation factor. Also the Nyquist band.
tw = 0.05; % Normalized transition width
ast = 40; % Minimum stopband attenuation in dB
d = fdesign.interpolator(l,'nyquist',l,'tw,ast',tw,ast);
msMinInterp = design(d,'multistage','SystemObject',true);
fvtool(msMinInterp);
```

Design a multistage lowpass interpolator with an interpolation factor of 8.

```
m = 8;
d = fdesign.interpolator(m, 'lowpass');
% Use halfband filters if possible.
msInterp = design(d, 'multistage', 'Usehalfbands', true, 'SystemObject', true);
fvtool(msInterp);
```

## See Also

`design` | `designopts`

Introduced in R2011a

# noisepsd

Power spectral density of filter output due to roundoff noise

## Syntax

```
hpsd = noisepsd(sysobj,L)
hpsd = noisepsd(sysobj,L,param1,value1,param2,value2,...)
hpsd = noisepsd(sysobj,L,opts)
noisepsd(sysobj,...)
```

## Description

`hpsd = noisepsd(sysobj,L)` computes the power spectral density (PSD) at the output of filter System object, `sysobj`, occurring because of roundoff noise. This noise is produced by quantization errors within the filter. `L` is the number of trials used to compute the average. The PSD is computed from the average over the `L` trials. The more trials you specify, the better the estimate, but at the expense of longer computation time. When you do not explicitly specify `L`, the default is 10 trials.

`hpsd` is a psd data object. To extract the PSD vector (the data from the PSD) from `hpsd`, enter

```
get(hpsd,'data')
```

at the prompt. Plot the PSD data with `plot(hpsd)`. The average power of the output noise (the integral of the PSD) can be computed with `avgpwr`, a method of `pspdata` objects:

```
avgpwr = avgpower(hpsd).
```

`hpsd = noisepsd(sysobj,L,param1,value1,param2,value2,...)` where `sysobj` is a filter System object, specifies optional parameters via `propertyname/propertyvalue` pairs. Valid psd object property values are:

Property Name	Default Value	Description and Valid Entries
Nfft	512	Specify the number of FFT points to use to calculate the PSD.
NormalizedFrequency	true	Determine whether to use normalized frequency. Enter a logical value of <code>true</code> or <code>false</code> . Because this property is a logical value, do not enclose the single quotation marks.
Fs	normalized	Specify the sampling frequency to use when you set <code>NormalizedFrequency</code> to <code>false</code> . Use any integer value greater than 1. Enter the value in Hz.
SpectrumType	onesided	Specify how <code>noisepsd</code> should generate the PSD. Options are <code>onesided</code> or <code>twosided</code> . If you choose a two-sided computation, you can also choose <code>CenterDC = true</code> . Otherwise, <code>CenterDC</code> must be <code>false</code> . <ul style="list-style-type: none"> <li>• <code>onesided</code> converts the type to a spectrum that is calculated over half the Nyquist interval. All properties affected by the new frequency range are adjusted automatically.</li> <li>• <code>twosided</code> converts the type to a spectrum that is calculated over the whole Nyquist interval. All properties affected by the new frequency range are adjusted automatically.</li> </ul>
CenterDC	false	Shift the zero-frequency component to the center of a two-sided spectrum. <ul style="list-style-type: none"> <li>• When you set <code>SpectrumType</code> to <code>onesided</code>, it is changed to <code>twosided</code> and the data is converted to a two-sided spectrum.</li> <li>• Setting <code>CenterDC</code> to <code>false</code> shifts the data and the frequency values in the object so that DC is in the left edge of the spectrum. This operation does not affect the <code>SpectrumType</code> property setting.</li> </ul>

Property Name	Default Value	Description and Valid Entries
Arithmetic	ARITH	Analyze the filter System object, based on the arithmetic specified in the ARITH input. ARITH can be set to <code>double</code> , <code>single</code> , or <code>fixed</code> . The analysis tool assumes a double-precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state.

**Note** If the spectrum data you specify is calculated over half the Nyquist interval and you do not specify a corresponding frequency vector, the default frequency vector assumes that the number of points in the whole FFT was even. Also, the plot option to convert to a whole or two-sided spectrum assumes the original whole FFT length is even.

`noisepsd` requires knowledge of the input data type. Analysis cannot be performed if the input data type is not available. If you do not specify the `Arithmetic` parameter, i.e., use the syntax `[h,w] = noisepsd(sysobj)`, then the following rules apply to this method:

- The System object state is `Unlocked` — `noisepsd` performs double-precision analysis.
- The System object state is `Locked` — `noisepsd` performs analysis based on the locked input data type.

If you do specify the `Arithmetic` parameter, i.e., use the syntax `[h,w] = noisepsd(sysobj, 'Arithmetic', ARITH)`, review the following rules for this method. Which rule applies depends on the value you set for the `Arithmetic` parameter.

Value	System Object State	Rule
ARITH = 'double'	Unlocked	<code>noisepsd</code> performs double-precision analysis.
	Locked	<code>noisepsd</code> performs double-precision analysis.
ARITH = 'single'	Unlocked	<code>noisepsd</code> performs single-precision analysis.
	Locked	<code>noisepsd</code> performs single-precision analysis.

Value	System Object State	Rule
ARITH = 'fixed'	Unlocked	noisepsd produces an error because the fixed-point input data type is unknown.
	Locked	When the input data type is double or single, then noisepsd produces an error because since the fixed-point input data type is unknown.
		When the input data is of fixed-point type, noisepsd performs analysis based on the locked input data type.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.AllpoleFilter
dsp.AllpassFilter
dsp.BiquadFilter
dsp.CoupledAllpassFilter
dsp.FIRFilter
dsp.HighpassFilter
dsp.IIRFilter
dsp.LowpassFilter
dsp.NotchPeakFilter
dsp.VariableBandwidthFIRFilter
dsp.VariableBandwidthIIRFilter

hpsd = noisepsd(sysobj,L,opts) uses an options object, opts, to specify the optional input arguments. This specification is not made using property-value pairs in the command. Use opts = noisepsdopts(sysobj) to create the object. opts then has

the `noisepsd` settings from `sysobj`. After creating `opts`, you change the property values before calling `noisepsd`:

```
set(opts,'fs',48e3); % Set Fs to 48 kHz.
```

`noisepsd(sysobj,...)` with no output argument launches `fvtool`.

## Examples

### Compute the PSD of Output Noise

Compute the PSD of the output noise caused by the quantization processes in a fixed-point, direct form FIR filter. The input is of fixed-point type. `noisepsd` performs analysis based on the locked input data type.

```
b = firgr(27,[0 .4 .6 1],[1 1 0 0]);  
firfilt = dsp.FIRFilter('Numerator',b); % Create the filter object.  
data = fi(randn(15,16),1,16,3);  
output = firfilt(data);
```

Quantize the filter to fixed-point.

```
hpsd = noisepsd(firfilt,'Arithmetic','fixed');  
plot(hpsd)
```

hpsd looks similar to the following figure - the data resulting from the noise PSD calculation. You can review the data in hpsd.data.

## noisepsdopts

Options for running filter output noise PSD

### Syntax

```
opts = noisepsdopts(sysobj)
```

### Description

`opts = noisepsdopts(sysobj)` uses the current settings in the filter System object, `sysobj`, to create an options object, `opts`, that contains specified options for computing the output noise PSD. You can pass `opts` to the `noisepsd` method as an input argument.

Using `opts`, you can set the following properties for `noisepsd`:

Property Name	Default Value	Description and Valid Entries
<code>Nfft</code>	512	Specify the number of FFT points to use to calculate the PSD.
<code>NormalizedFrequency</code>	<code>true</code>	Determine whether to use normalized frequency. Enter a logical value of the logical <code>true</code> or <code>false</code> . Because this property is a logical value, do not enclose with single quotation marks.
<code>Fs</code>	<code>normalized</code>	Specify the sampling frequency to use when you set <code>NormalizedFrequency</code> to <code>false</code> . Use any integer value greater than 1. Enter the value in Hz.

Property Name	Default Value	Description and Valid Entries
SpectrumType	onesided	<p>Specify how noisepsd should generate the PSD. Options are onesided or twosided. If you choose a two-sided computation, you can also choose centerdc = true. Otherwise, centerdc must be false.</p> <ul style="list-style-type: none"><li>• onesided converts the type to a spectrum that is calculated over half the Nyquist interval. All properties affected by the new frequency range are adjusted automatically.</li><li>• twosided converts the type to a spectrum that is calculated over the whole Nyquist interval. All properties affected by the new frequency range are adjusted automatically.</li></ul>
CenterDC	false	<p>Shift the zero-frequency component to the center of a two-sided spectrum.</p> <ul style="list-style-type: none"><li>• When you set SpectrumType to onesided, it is changed to twosided and the data is converted to a two-sided spectrum.</li><li>• Setting CenterDC to false shifts the data and the frequency values in the object so that DC is in the left edge of the spectrum. This operation does not effect the SpectrumType property setting.</li></ul>

<b>Property Name</b>	<b>Default Value</b>	<b>Description and Valid Entries</b>
Arithmetic	ARITH	Analyze the filter System object, based on the arithmetic specified in the ARITH input. ARITH can be set to double, single, or fixed. The analysis tool assumes a double-precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state.

## norm

P-norm of filter

### Syntax

```
l = norm(hd)
l = norm(hd, pnorm)
```

### Description

All of the variants of `norm` return the filter p-norm for the object in the syntax, a digital filter. When you omit the `pnorm` argument, `norm` returns the L2-norm for the object.

Note that by Parseval's theorem, the L2-norm of a filter is equal to the `l2` norm. This equality is not true for the other norm variants.

### For dfilt Objects

`l = norm(hd)` returns the L2-norm of a discrete-time filter.

`l = norm(hd, pnorm)` includes input argument `pnorm` that lets you specify the norm returned. `pnorm` can be either

- Frequency-domain norms specified by one of `L1`, `L2`, or `Linf`
- Discrete-time domain norms specified by one of `l1`, `l2`, or `linf`

By Parseval's theorem, the L2-norm of a filter is equal to the `l2` norm. This equality is not true for the other norm variants.

IIR filters respond slightly differently to `norm`. When you compute the `l2`, `linf`, `L1`, and `L2` norms for an IIR filter, `norm(..., L2, tol)` lets you specify the tolerance for the accuracy in the computation. For `l1`, `l2`, `L2`, and `linf`, `norm` uses the tolerance to truncate the infinite impulse response that it uses to calculate the norm. For `L1`, `norm` passes the tolerance to the numerical integration algorithm. Refer to Examples on page 5-0 to see this in use. You cannot specify `Linf` for the norm and include the `tol` option.

## Examples

### Norm of an IIR Filter

This example shows how to compute the L2 norm of an IIR filter. A tolerance of 1e-10 is used.

```
spec = fdesign.lowpass('n,fc',5,0.4);  
filter = butter(spec);  
filternorm = norm(filter,'l2',1e-10)  
  
filternorm = 0.6336
```

# normalize

Normalize filter numerator or feed-forward coefficients

## Syntax

```
normalize(hq)  
g = normalize(hd)
```

## Description

`normalize(hq)` normalizes the filter numerator coefficients for a quantized filter to have values between -1 and 1. The coefficients of `hq` change — `normalize` does not copy `hq` and return the copy. To restore the coefficients of `hq` to the original values, use `denormalize`.

Note that for lattice filters, the feed-forward coefficients stored in the property `lattice` are normalized.

`g = normalize(hd)` normalizes the numerator coefficients for the filter `hq` to between -1 and 1 and returns the gain `g` due to the normalization operation. Calling `normalize` again does not change the coefficients. `g` always returns the gain returned by the first call to `normalize` the filter.

## Examples

### Normalize the Coefficients of a Direct Form II Filter

Create a direct form II quantized filter that uses second-order sections. Then use `normalize` to maximize the use of the range of representable coefficients.

```
d = fdesign.lowpass('n,fp,ap,ast',8,.5,2,40);  
hd = design(d,'ellip');  
hd.arithmetic = 'fixed';
```

Check the filter coefficients. Note that `InitialSOSMatrix(3,2)>1`

```
InitialSOSMatrix = hd.sosMatrix;
```

Use `normalize` to modify the coefficients into the range between -1 and 1. The output `g` contains the gains applied to each section of the SOS filter.

```
g = normalize(hd);
```

None of the numerator coefficients exceed -1 or 1.

# normalizefreq

Switch filter specification between normalized frequency and absolute frequency

## Syntax

```
normalizefreq(d)  
normalizefreq(d, flag)  
normalizefreq(d, false, fs)
```

## Description

`normalizefreq(d)` normalizes the frequency specifications in filter specifications object `d`. By default, the `NormalizedFrequency` property is set to `true` when you create a design object. You provide the design specifications in normalized frequency units. `normalizefreq` does not affect filters that already use normalized frequency.

If you use this syntax when `d` does not use normalized frequency specifications, all of the frequency specifications are normalized by  $fs/2$  so they lie between 0 and 1, where `fs` is specified in the object. Included in the normalization are the filter properties that define the filter pass and stopband edge locations by frequency:

- `F3 dB` — Used by IIR filter specifications objects to describe the passband cutoff frequency
- `Fcutoff` — Used by FIR filter specifications objects to describe the passband cutoff frequency
- `Fpass` — Describes the passband edges
- `Fstop` — Describes the stopband edges

In this syntax, `normalizefreq(d)` assumes you specified `fs` when you created `d` or changed `d` to use absolute frequency specifications.

`normalizefreq(d, flag)` where `flag` is either **true** or **false**, specifies whether the `NormalizedFrequency` property value is `true` or `false` and therefore whether the filter normalizes the sampling frequency `fs` and other related frequency specifications. `fs` defaults to 1 for this syntax.

When you do not provide the input argument `flag`, it defaults to `true`. If you set `flag` to `false`, affected frequency specifications are multiplied by `fs/2` to remove the normalization. Use this syntax to switch your filter between using normalized frequency specifications and not using normalized frequency specifications.

`normalizefreq(d, false, fs)` lets you specify a new sampling frequency `fs` when you set the `NormalizedFrequency` property to `false`.

## Examples

### Normalize the Frequency Specifications of a Filter

These examples demonstrate using `normalizefreq` in both of the major syntax applications—setting the design object frequency specifications to use absolute frequency (`normalizefreq(hd,false,fs)`) and resetting a design object to using normalized frequencies (`normalizefreq(d)`).

Construct a highpass filter specifications object by specifying the passband and stopband edges and the desired attenuations in the bands. By default, provide the frequency specifications in normalized values between 0 and 1.

```
d = fdesign.highpass(0.35, 0.45, 60, 40);
```

`Fstop` and `Fpass` are in normalized form, and the property `NormalizedFrequency` is `true`.

Now use `normalizedfreq` to convert to absolute frequency specifications, with a sampling frequency of 1000 Hz.

```
normalizefreq(d, false, 1e3);
```

Both of the attenuation specifications remain the same. The passband and stopband edge definitions now appear in Hz, where the new value represents the normalized values multiplied by `Fs/2`, or 500 Hz.

Converting to using normalized frequencies consists of using `normalizefreq` with the design object `d`.

```
normalizefreq(d)
```

For `bandstop`, `bandpass`, and multiple band filter specifications objects, `normalizefreq` works the same way for all band edge definitions. When you do not provide the sampling frequency `Fs` as an input argument and you are converting to absolute frequency specifications, `normalizefreq` sets `Fs` to 1, as shown in this example.

```
d=fdesign.bandstop(0.25,0.35,0.55,0.65,50,60);  
normalizefreq(d,false)
```

## nstates

Number of filter states

## Syntax

```
n = nstates(hd)
```

## Description

### Discrete-Time Filters

`n = nstates(hd)` returns the number of states `n` in the discrete-time filter `hd`. The number of states depends on the filter structure and the coefficients.

## Examples

### Number of States of a Filter

Determine the number of states of a direct form FIR filter.

```
FIRFilter = firls(30,[0 .1 .2 .5]*2,[1 1 0 0]);  
DiscFilter = dfilt.dffir(FIRFilter);  
NstateDF = nstates(DiscFilter)
```

```
NstateDF = 30
```

**Introduced in R2011a**

## order

Order of discrete-time filter System object

## Syntax

```
n = order(sysobj)
```

## Description

`n = order(sysobj)` returns the order `n` of the filter System object `sysobj`. The order depends on the filter structure and the reference double-precision floating-point coefficients.

The following Filter System objects are supported by this analysis function:

<b>Filter System objects</b>
<code>dsp.AllpassFilter</code>
<code>dsp.AllpoleFilter</code>
<code>dsp.BiquadFilter</code>
<code>dsp.Channelizer</code>
<code>dsp.CICCompensationDecimator</code>
<code>dsp.CICCompensationInterpolator</code>
<code>dsp.CICDecimator</code>
<code>dsp.CICInterpolator</code>
<code>dsp.CoupledAllpassFilter</code>
<code>dsp.FarrowRateConverter</code>
<code>dsp.FilterCascade</code>
<code>dsp.FIRDecimator</code>
<code>dsp.FIRFilter</code>

<b>Filter System objects</b>
<code>dsp.FIRHalfbandDecimator</code>
<code>dsp.FIRHalfbandInterpolator</code>
<code>dsp.FIRInterpolator</code>
<code>dsp.FIRRateConverter</code>
<code>dsp.HighpassFilter</code>
<code>dsp.IIRFilter</code>
<code>dsp.IIRHalfbandDecimator</code>
<code>dsp.IIRHalfbandInterpolator</code>
<code>dsp.LowpassFilter</code>
<code>dsp.NotchPeakFilter</code>
<code>dsp.VariableBandwidthFIRFilter</code>
<code>dsp.VariableBandwidthIIRFilter</code>

## Examples

### Determine the Order of a Filter

Design a compensation decimator for a CIC decimator using the `dsp.FilterCascade` object. Determine the order of the overall filter.

```
cicdecim = dsp.CICDecimator('DecimationFactor', 6, ...  
    'NumSections', 6);  
  
fs = 16e3;    % Sampling frequency of input of compensation decimator  
fPass = 4e3; % Passband frequency  
fStop = 4.5e3; % Stopband frequency  
ciccomp = dsp.CICCompensationDecimator(cicdecim, ...  
    'DecimationFactor', 2, ...  
    'PassbandFrequency', fPass, ...  
    'StopbandFrequency', fStop, ...  
    'SampleRate', fs);  
  
filtchain = dsp.FilterCascade(cicdecim, ciccomp);
```

```
order(filtchain)
```

```
ans = 648
```

**Introduced in R2011a**

## phasedelay

Phase delay response of discrete-time filter System object

### Syntax

```
[phi,w] = phasedelay(sysobj)
[phi,w] = phasedelay(sysobj,n)
[phi,w] = phasedelay(sysobj,Name,Value)
phasedelay(sysobj)
```

### Description

`[phi,w] = phasedelay(sysobj)` returns the phase delay `phi` of the filter System object, `sysobj`, based on the current filter coefficients. The vector `w` contains the frequencies (in radians) at which the phase delay is evaluated.

The phase delay is evaluated at 8192 points equally spaced around the upper half of the unit circle.

`[phi,w] = phasedelay(sysobj,n)` returns the phase delay of the filter System object at `n` points equally spaced around the upper half of the unit circle.

`[phi,w] = phasedelay(sysobj,Name,Value)` returns the phase delay with additional options specified by one or more `Name,Value` pair arguments.

`phasedelay(sysobj)` plots the phase delay of the filter System object `sysobj` in the `fvtool`.

For information on more input options, refer to `phasedelay` in Signal Processing Toolbox documentation.

### Examples

### Phase Delay of a Discrete-Time Filter

```
Fs = 8000; Fcutoff = 2000;  
FIRfilt = dsp.FIRFilter('Numerator', fir1(130, Fcutoff/(Fs/2)));
```

phasedelay computes the phase delay of the filter and displays it using fvtool

```
phasedelay(FIRfilt);
```

## Input Arguments

### sysobj

Filter System object.

The following Filter System objects are supported by this analysis function:

<b>Filter System objects</b>
dsp.AllpassFilter
dsp.AllpoleFilter
dsp.BiquadFilter
dsp.Channelizer
dsp.CICCompensationDecimator

dsp.FilterCascade
dsp.FIRDecimator
dsp.FIRFilter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.FIRInterpolator
dsp.FIRRateConverter
dsp.HighpassFilter
dsp.IIRFilter
dsp.IIRHalfbandDecimator
dsp.IIRHalfbandInterpolator
dsp.LowpassFilter

Filter System objects
dsp.NotchPeakFilter
dsp.VariableBandwidthFIRFilter
dsp.VariableBandwidthIIRFilter

**n**

Number of samples. For an FIR filter where *n* is a power of two, the computation is done faster using FFTs.

**Default:** 8192

## Name-Value Pair Arguments

Specify optional comma-separated pairs of *Name*, *Value* arguments. *Name* is the argument name and *Value* is the corresponding value. *Name* must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as *Name1*, *Value1*, ..., *NameN*, *ValueN*.

### Arithmetic – Value types:

'double' | 'single' | 'fixed'

Specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the *CoefficientDataType* property and whether the System object is locked or unlocked.

### Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.

System Object State	Coefficient Data Type	Rule
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataProperty property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataProperty property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Output Arguments

### phi

Phase delay vector of length  $n$ . If  $n$  is not specified, the function uses a default value of 8192.

### w

Frequency vector of length  $n$ , in radians/sample.  $w$  consists of  $n$  points equally spaced around the upper half of the unit circle (from 0 to  $\pi$  radians/sample). If  $n$  is not specified, the function uses a default value of 8192.

## Algorithms

You can provide `fs`, the sampling frequency, as an input as well. `phasedelay` uses `fs` to calculate the delay response and plots the response to `fs/2`.

## phasez

Unwrapped phase response for filter

### Syntax

```
[phi,w] = phasez(sysobj)
[phi,w] = phasez(sysobj,n)
[phi,w] = phasez(sysobj,Name,Value)
phasez(sysobj)
```

### Description

`[phi,w] = phasez(sysobj)` returns the unwrapped phase response `phi` of the filter System object, `sysobj`, based on the current filter coefficients. The vector `w` contains the frequencies (in radians) at which the function evaluates the phase response. The phase response is evaluated at 8192 points equally spaced around the upper half of the unit circle.

`[phi,w] = phasez(sysobj,n)` returns the phase response of the filter System object and the corresponding frequencies at `n` points equally spaced around the upper half of the unit circle.

`[phi,w] = phasez(sysobj,Name,Value)` returns the phase response with additional options specified by one or more `Name,Value` pair arguments.

`phasez(sysobj)` displays the phase response of the filter System object `sysobj` in the `fvtool`.

For more information about optional input arguments for `phasez`, refer to `phasez` in Signal Processing Toolbox documentation.

### Examples

### Unwrapped Phase Response of a Discrete-Time Filter

```
Fs = 8000; Fcutoff = 2000;  
FIRfilt = dsp.FIRFilter('Numerator', fir1(130, Fcutoff/(Fs/2)));
```

phasez computes the unwrapped phase response of the filter and displays it using fvtool

```
phasez(FIRfilt);
```

## polyphase

Polyphase decomposition of multirate filter

### Syntax

```
p = polyphase(obj)
p = polyphase(obj,Name,Value)
polyphase(obj)
```

### Description

`p = polyphase(obj)` returns the polyphase matrix `p` of the multirate filter System object `obj`. Each row in the matrix corresponds to a polyphase branch. The number of columns in `p` corresponds to the number of filter taps per polyphase branch.

`p = polyphase(obj,Name,Value)` returns the polyphase matrix `p` of the multirate filter System object `obj`.

`polyphase(obj)` launches the Filter Visualization Tool (`fvtool`) with all the polyphase subfilters to allow you to analyze each component subfilter individually.

### Input Arguments

#### **obj**

Filter System object.

#### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Arithmetic – Value types:**`'double' | 'single' | 'fixed'`

When you specify 'double' or 'single', the function performs double- or single-precision analysis. You can specify 'fixed' only if the System object supports fixed-point arithmetic. When you specify 'fixed', the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

**Details for Fixed-Point Arithmetic**

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the <code>CustomCoefficientsDataType</code> property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the <code>CustomCoefficientsDataType</code> property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Output Arguments

### **p**

Polyphase matrix **p** of the multirate filter. Each row in the matrix corresponds to a polyphase branch. The first row of matrix **p** represents the first polyphase branch, the second row the second polyphase branch, and so on to the last polyphase branch. The number of columns in **p** corresponds to the number of filter taps per polyphase branch.

## Examples

### **Polyphase Matrix of an FIR Interpolator**

When you create a multirate filter that uses polyphase decomposition, `polyphase` lets you analyze the component filters individually by returning the components as rows in a matrix. First, create an `interpolate-by-three` filter.

```
hs = dsp.FIRInterpolator
hs =
  dsp.FIRInterpolator with properties:
      NumeratorSource: 'Property'
      Numerator: [1x16 double]
      InterpolationFactor: 3

Show all properties
```

In this syntax, the matrix **p** contains all of the subfilters for **hm**, one filter per matrix row.

```
p = polyphase(hs)
```

```
p = 3×6
```

```

# polyphase

**Package:** dsp

Return polyphase matrix

## Syntax

`p = polyphase(obj)`

## Description

`p = polyphase(obj)` returns the polyphase matrix used by the filter bank. Each row in the matrix corresponds to a polyphase branch. The number of columns in `p` corresponds to the number of filter taps per branch.

## Examples

### Polyphase Matrix of Filter Bank

Compute the polyphase matrix of the filter bank used by the channelizer.

Design a channelizer with the number of frequency bands or polyphase branches set to 8, the number of taps or coefficients per band set to 12, and stopband attenuation set to 80 dB.

```
channelizer = dsp.Channelizer;
p = polyphase(channelizer)
```

`p = 8×12`

0	0	0	0	0	0	0.1250	0

```

Each row in the matrix corresponds to a polyphase branch. The number of columns in the matrix corresponds to the number of filter taps per branch.

## Input Arguments

### **obj** — Input filter System object

`dsp.Channelizer` | `dsp.ChannelSynthesizer`

Input filter, specified as either a `dsp.Channelizer` or `dsp.ChannelSynthesizer` System object.

Example: `channelizer = dsp.Channelizer;`

Example: `channelizer = dsp.ChannelSynthesizer;`

## Output Arguments

### **p** — Polyphase matrix

matrix

Polyphase matrix of the filter bank, returned as a matrix of size  $[NFBands, NTPerBand]$ . The dimensions of the matrix depend on the type of System object in the `obj` argument:

- `dsp.Channelizer` -- *NFBands* is the value you specify in the `NumFrequencyBands` property, and *NTPerBand* is the value you specify in the `NumTapsPerBand` property.
- `dsp.ChannelSynthesizer` -- *NFBands* is the number of narrowband signals or the number of columns in the input signal, and *NTPerBand* is the value you specify in the `NumTapsPerBand` property.

## qreport

Most recent fixed-point filtering operation report

### Syntax

```
rlog = qreport(h)
```

### Description

`rlog = qreport(h)` returns the logging report stored in the filter object `h` in the object `rlog`. The ability to log features of the filtering operation is integrated in the fixed-point filter object and the `filter` method.

Each time you filter a signal with `h`, new log data overwrites the results in the filter from the previous filtering operation. To save the log from a filtering simulation, change the name of the output argument for the operation before subsequent filtering runs.

---

**Note** `qreport` requires Fixed-Point Designer software and that filter `h` is a fixed-point filter. Data logging for `fi` operations is a preference you set for each MATLAB session. To learn more about logging, `LoggingMode`, and `fi` object preferences, refer to `fi`pref in the Fixed-Point Designer documentation.

Also, you cannot use `qreport` to log the filtering operations from a fixed-point Farrow filter.

---

Enable logging during filtering by setting `LoggingMode` to `on` for `fi` objects for your MATLAB session. Trigger logging by setting the `Arithmetic` property for `h` to `fixed`, making `h` a fixed-point filter and filtering an input signal.

### Using Fixed-Point Filtering Logging

Filter operation logging with `qreport` requires some preparation in MATLAB. Complete these steps before you use `qreport`.

- 1 Set the fixed-point object preference for `LoggingMode` to `on` for your MATLAB session. This setting enables data logging.

```
fipref('LoggingMode','on')
```

- 2 Create your fixed-point filter.
- 3 Filter a signal with the filter.
- 4 Use `qreport` to return the filtering information stored in the filter object.

`qreport` provides a way to instrument your fixed-point filters and the resulting data log offers insight into how the filter responds to a particular input data signal.

Report object `rlog` contains a filter-structure-specific list of internal signals for the filter. Each signal contains

- Minimum and maximum values that were recorded during the last simulation. Minimum and maximum values correspond to values before quantization.
- Representable numerical range of the word length and fraction length format
- Number of overflows during filtering for that signal.

## Examples

### View the Logging Report

This example shows how to use `qreport` to log the results of filtering a sinusoidal signal with a fixed-point direct-form FIR filter, `firfilt`. To use the `qreport`, set the `LoggingMode` of fixed-point objects to `'on'`.

```
fipref('loggingmode','on');
hd = design(fdesign.lowpass,'equiripple');
hd.arithmetic = 'fixed';
hd.InputWordLength = 32;
fs = 1000;           % Input sampling frequency.
t = 0:1/fs:1.5;     % Signal length = 1501 samples.
x = sin(2*pi*10*t); % Amplitude = 1 sinusoid.
y = filter(hd,x);
rlog = qreport(hd)
```

```
rlog =
```

	Fixed-Point Report			
	Min	Max	Range	
Input:	-1	1	-65536	65536
Output:	-1.02325	1.02325	-131072	131072
Product:	-0.48538208	0.48538208	-32768	32768
Accumulator:	-1.0852075	1.0852075	-131072	131072

Restore the default logging mode preference.

```
fipref('loggingmode','off');
```

# realizemdl

Simulink subsystem block for filter

## Syntax

```
realizemdl(hq)  
realizemdl(hq,Name,Value)
```

## Description

`realizemdl(hq)` generates a model of filter `hq` in a Simulink subsystem block using `sum`, `gain`, and `delay` blocks from Simulink. The properties and values of `hq` define the resulting subsystem block parameters.

`realizemdl` requires Simulink. To accurately realize models of quantized filters, use Fixed-Point Designer.

`realizemdl(hq,Name,Value)` generates the model for `hq` with additional options specified by one or more `Name,Value` pair arguments. Using name-value pair arguments lets you control more fully the way the block subsystem model gets built. You can specify such details as where the block goes, what the name is, or how to optimize the block structure.

## Input Arguments

### **hq** — Filter System object

filter System object

List of filter system objects that the function supports:

Filter System objects
<code>dsp.AllpassFilter</code>
<code>dsp.AllpoleFilter</code>

<b>Filter System objects</b>
dsp.BiquadFilter
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.CoupledAllpassFilter
dsp.FarrowRateConverter
dsp.FilterCascade
dsp.FIRFilter
dsp.FIRInterpolator
dsp.FIRDecimator
dsp.FIRRateConverter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.HighpassFilter
dsp.IIRFilter
dsp.IIRHalfbandDecimator
dsp.IIRHalfbandInterpolator
dsp.LowpassFilter
dsp.NotchPeakFilter

## Name-Value Pair Arguments

### Destination — Destination choices:

'current' (default) | 'new' | *subsystemname*

Specify whether to add the block to your current Simulink model or create a new model to contain the block. If you provide the name of a current subsystem in *subsystemname*, `realizemdl` adds the new block to the specified subsystem.

### Blockname — The name of the block (not the default) :

'filter' (default)

Provide the name for the new subsystem block. By default the block is named Filter.

**MapCoeffstoPorts — Value options:**

'off' (default) | 'on'

Specify whether to map the coefficients of the filter to the ports of the block.

**MapStates — Value options:**

'off' (default) | 'on'

Specify whether to apply the current filter states to the realized model. Such specification allows you to save states from a filter object you may have used or configured in a specific way. The default setting of 'off' means the states are not transferred to the model. Setting the property to 'on' preserves the current filter states in the realized model.

**OverwriteBlock — Value options:**

'off' (default) | 'on'

Specify whether to overwrite an existing block with the same name or create a new block.

**OptimizeZeros — Value options:**

'off' (default) | 'on'

Specify whether to remove zero-gain blocks.

**OptimizeOnes — Value options:**

'off' (default) | 'on'

Specify whether to replace unity-gain blocks with direct connections.

**OptimizeNegOnes — Value options:**

'off' (default) | 'on'

Specify whether to replace negative unity-gain blocks with a sign change at the nearest sum block.

**OptimizeDelayChains — Value options:**

'off' (default) | 'on'

Specify whether to replace delay chains made up of  $n$  unit delays with a single delay by  $n$ .

**CoeffNames — Names of coefficients:**

{ 'Num' } (default FIR) | { 'Num', 'Den' } (default direct form IIR) |  
 { 'Num', 'Den', 'g' } (default IIR SOS) | { 'Num\_1', 'Num\_2', 'Num\_3' . . . } (default multistage) | { 'K' } (default form lattice)

Specify the coefficient variable name as a cell array of character vectors. MapCoeffsToPorts must be set to 'on' for this property to apply.

### **InputProcessing — Possible input processing options:**

'columns as channels' (default) | 'elements as channels'

Specify sample-based ('elements as channels') or frame-based ('columns as channels') processing.

### **RateOption — Rate options:**

'enforce single rate' (default) | 'allow multirate'

Specify how the block adjusts the rate at the output to accommodate the reduced number of samples. This parameter applies only when InputProcessing is 'columns as channels'.

### **Arithmetic — Value types:**

'double' | 'single'

The arithmetic for System object inputs must be 'double' or 'single'.

## Examples

### **Realize Simulink Model of a Lowpass Butterworth Filter**

```
d = fdesign.lowpass('N,F3dB',4,0.25);  
filterobject = design(d,'butter','systemobject',true);
```

Create a new model, LPFilter.slx, and realize the subsystem block in this model.

```
new_system('LPFilter');  
realizemdl(filterobject);
```

View the block diagram by clicking on the subsystem block.

Create a new model, `LPFilterMapping.slx`, and realize the subsystem block, with coefficients mapped to ports, in this model.

```
new_system('LPFilterMapping');
realizemdl(filterobject, 'MapCoeffsToPorts', 'on');
```

View the block diagram by clicking on the subsystem block.

In this case, the filter is an IIR filter with a direct form II second-order sections structure. Setting `MapCoeffstoPorts` to `'on'` exports the numerator coefficients, the denominator coefficients, and the gains to the MATLAB® workspace using the default variable names

Num, Den, and  $g$ . Each column of Num and Den represents one second-order section. You can modify the filter coefficients directly in the MATLAB workspace providing tunability to the realized Simulink model.

# rebuffer\_delay

Number of samples of delay introduced by buffering and unbuffering operations

## Syntax

```
d = rebuffer_delay(f,n,v)
d = rebuffer_delay(f,n,v,'mode')
```

## Description

`d = rebuffer_delay(f,n,v)` returns the delay, in samples, introduced by the Buffer or Unbuffer block in multitasking operations.

`d = rebuffer_delay(f,n,v,'mode')` returns the delay, in samples, introduced by the Buffer or Unbuffer block in the specified tasking mode.

## Input Arguments

**f**

Frame size of the input to the Buffer or Unbuffer block.

**n**

Size of the output buffer. Specify one of the following:

- The value of the **Output buffer size** parameter, if you are computing the delay introduced by a Buffer block.
- 1, if you are computing the delay introduced by an Unbuffer block.

**v**

Amount of buffer overlap. Specify one of the following:

- The value of the **Buffer overlap** parameter, if you are computing the delay introduced by a Buffer block.
- 0, if you are computing the delay introduced by an Unbuffer block.

### 'mode'

The tasking mode of the model. Specify one of the following options:

- 'singletasking'
- 'multitasking'

**Default:** 'multitasking'

## Examples

Compute the delay introduced by a Buffer block in a multitasking model:

- 1 Open a model containing a Buffer block. For this example, open the `ex_buffer_tut4` model by typing `ex_buffer_tut4` at the MATLAB command line.
- 2 Double-click the Buffer block to open the block mask. Verify that you have the following settings:
  - **Output buffer size** = 3
  - **Buffer overlap** = 1
  - **Initial conditions** = 0

Based on these settings, two of the required inputs to the `rebuffer_delay` function are as follows:

- `n` = 3
  - `v` = 1
- 3 To determine the frame size of the input signal to the Buffer block, open the Signal From Workspace block mask. Verify that you have the following settings:
    - **Signal** = `sp_examples_src`
    - **Sample time** = 1
    - **Samples per frame** = 4

Because **Samples per frame** = 4, you know the *f* input to the `rebuffer_delay` function is 4.

- 4 After you verify the values of all the inputs to the `rebuffer_delay` function, determine the delay that the Buffer block introduces in this multitasking model. To do so, type the following at the MATLAB command line:

```
d = rebuffer_delay(4,3,1)
```

```
d =  
    8
```

Compute the delay introduced by an Unbuffer block in a multitasking model:

- 1 Open a model containing an Unbuffer block. For this example, open the `ex_unbuffer_ref1` model by typing `ex_unbuffer_ref1` at the MATLAB command line.
- 2 To determine the frame size of the input to the Buffer block, open the Signal From Workspace block mask by double-clicking the block in your model. Verify that you have the following settings:
  - **Signal** = `sp_examples_src`
  - **Sample time** = 1
  - **Samples per frame** = 3

Because **Samples per frame** = 3, you know the *f* input to the `rebuffer_delay` function is 3.

- 3 Use the `rebuffer_delay` function to determine the amount of delay that the Unbuffer block introduces in this multitasking model. To compute the delay introduced by the Unbuffer block, use *f* = 3, *n* = 1 and *v* = 0.

```
d = rebuffer_delay(3,1,0)
```

```
d =  
    3
```

# Definitions

## Multitasking

When you run a model in `MultiTasking` mode, Simulink processes groups of blocks with the same execution priority through each stage of simulation based on task priority. Multitasking mode helps to create valid models of real-world multitasking systems, where sections of your model represent concurrent tasks. The **Treat each discrete rate as a separate task** parameter on the Solver (Simulink) pane of the Configuration Parameters dialog box controls this setting.

## Singletasking

When you run a model in `SingleTasking` mode, Simulink processes all blocks through each stage of simulation together. The **Treat each discrete rate as a separate task** parameter on the Solver (Simulink) pane of the Configuration Parameters dialog box controls this setting.

**Introduced before R2006a**

# refilter

Reference filter for fixed-point or single-precision filter

## Syntax

```
href = refilter(hd)
```

## Description

`href = refilter(hd)` returns a new filter `href` that has the same structure as `hd`, but uses the reference coefficients and has its arithmetic property set to `double`. Note that `hd` can be either a fixed-point filter (arithmetic property set to `'fixed'`, or a single-precision floating-point filter whose arithmetic property is `'single'`).

`refilter(hd)` differs from `double(hd)` in that

- the filter `href` returned by `refilter` has the reference coefficients of `hd`.
- `double(hd)` returns the quantized coefficients of `hd` represented in double-precision.

To check the performance of your fixed-point filter, use `href = refilter(hd)` to quickly have the floating-point, double-precision version of `hd` available for comparison.

## Examples

### Compare Fixed-point Quantizations of a Filter

Compare several fixed-point quantizations of a filter with the same double-precision floating-point version of the filter.

```
h = dfilt.dffir(firceqrip(87,.5,[1e-3,1e-6])); % Lowpass filter.
h1 = copy(h); h2 = copy(h); % Create copies of h.
h.arithmetic = 'fixed'; % Set h to filter using fixed-point...
% arithmetic.
h1.arithmetic = 'fixed'; % Same for h1.
```

```
h2.arithmetic = 'fixed'; % Same for h2.
h.CoeffWordLength = 16; % Use 16 bits to represent the...
                        % coefficients.
h1.CoeffWordLength = 12; % Use 12 bits to represent the...
                        % coefficients.
h2.CoeffWordLength = 8; % Use 8 bits to represent the...
                        % coefficients.

href = reffilter(h);
hfvt = fvtool(href,h,h1,h2);
set(hfvt,'ShowReference','off'); % Reference displayed once
                                % already.
legend(hfvt,'Reference filter','16-bits','12-bits','8-bits');
```

The fvtool shows href, the reference filter, and the effects of using three different word lengths to represent the coefficients.

## reorder

Rearrange sections in SOS filter

### Syntax

```
reorder(hs,order)
reorder(hs,numorder,denorder)
reorder(hs,numorder,denorder,svorder)
reorder(hs,filter_type)
reorder(hs,dir_flag)
reorder(hs,dir_flag,sv)
reorder(hs,...)
reorder(hs,...,Name,Value)
```

### Description

`reorder(hs,order)` rearranges the sections of filter `hd` using the vector of indices provided in `order`.

`reorder(hs,numorder,denorder)` reorders the numerator and denominator separately using the vectors of indices in `numorder` and `denorder`.

`reorder(hs,numorder,denorder,svorder)` specifies that the scale values can be independently reordered.

`reorder(hs,filter_type)` reorders `hd` in a way suitable for the specified filter type. This reordering mode can be especially helpful for fixed-point implementations where the order of the filter sections can significantly affect your filter performance.

`reorder(hs,dir_flag)` specifies rearranges the sections according to proximity to the origin of the poles of the sections.

`reorder(hs,dir_flag,sv)` reorders scale values in addition to rearranging sections according to pole-origin proximity.

`reorder(hs, ...)` rearranges the sections of the filter System object `hs` according to any of the preceding input arguments.

`reorder(hs, ..., Name, Value)` rearranges the sections of the filter System object `hs` with additional options specified by one or more `Name, Value` pair arguments.

## Input Arguments

**hs** —

`dsp.BiquadFilter` filter System object with one of the following filter structures:

Structure	Description
<code>df1sos</code>	Direct-form I filter object with second-order sections.
<code>df1tsos</code>	Direct-Form I transposed filter with second-order sections.
<code>df2sos</code>	Direct-form II filter object with second-order sections.
<code>df2tsos</code>	Direct-Form II transposed filter with second-order sections.

**order** —

Vector of indices used to reorder the filter sections. `order` does not need to contain all of the indices of the filter. Omitting one or more filter section indices removes the omitted sections from the filter. You can use a logical array to remove sections from the filter, but not to reorder it.

**numorder** —

Vector of indices used to reorder the numerator. `numorder` and `denorder` must be the same length.

**denorder** —

Vector of indices used to reorder the denominator. `numorder` and `denorder` must be the same length.

**svorder** —

Independent reordering of scale values. When `svorder` is not specified, the scale values are reordered with the numerator. The output scale value always remains on the end when you use the argument `numorder` to reorder the scale values.

**filter\_type** — Different types of filters:

'auto' | 'bandpass' | 'bandstop' | 'highpass' | 'lowpass'

Filter type. The 'auto' option and automatic ordering only apply to filters that you used `fdesign` to create. With the 'auto' option as an input argument, `reorder` automatically rearranges the filter sections depending on the specification response type of the design.

**dir\_flag** — Direction options:

'down' | 'up'

Pole direction flag. When `dir_flag` is 'up', the first filter section contains the poles closest to the origin, and the last section contains the poles closest to the unit circle. When `dir_flag` is 'down', the sections are ordered in the opposite direction. `reorder` always pairs zeros with the poles closest to them.

**sv** — Scale value options:

'poles' | 'zeros'

Reorder scale values according to poles or zeros. By default the scale values are not reordered when you use the `dir_flag` input argument.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Arithmetic** — Value types:

'double' | 'single' | 'fixed'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of

the `CoefficientDataType` property and whether the System object is locked or unlocked.

### Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the <code>CustomCoefficientsDataType</code> property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the <code>CustomCoefficientsDataType</code> property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

## Examples

### Reorder a Biquad Filter

Being able to rearrange the order of the sections in a filter can be a powerful tool for controlling the filter process. This example uses `reorder` to change the sections of a `df2sos` filter. Let `reorder` do the reordering automatically in the first example. In the second, use `reorder` to specify the new order for the sections.

First use the automatic reordering option on a lowpass filter.

```
d = fdesign.lowpass('n,f3db',15,0.75);
biquad = design(d,'butter','SystemObject',true);
biquadreorder = reorder(biquad,'auto');
```

For another example of using `reorder`, create an SOS filter in the direct form II implementation.

```
biquad2sos = design(d,'butter','FilterStructure','df2sos',...
    'SystemObject',true);
biquad2sosreorder = reorder(biquad2sos,[1 3:7 2 8]);
fvt = fvtool(biquad2sos,biquad2sosreorder,'analysis','coefficients');
```

```
% Filter #1
% -----
%
% -----
Section #1

## reset

Reset the internal states of a System object

### Syntax

```
reset(sysobj)
```

### Description

`reset(sysobj)` resets the internal states of System object, `sysobj` to their initial values. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the filter to nonzero input data, the states might be nonzero. Invoking the `step` method again without first invoking the `reset` method might produce different outputs for an identical input. System objects with no states are unaffected by `reset`.

### Examples

#### Reset a Lowpass Filter

Create a lowpass filter with default properties.

```
LPF = dsp.LowpassFilter;
```

Create a two-channel random signal. Apply the `step` method twice on the signal.

```
x = randn(10,2);
```

```
y1 = step(LPf,x);
```

```
y2 = step(LPf,x);
```

```
no = all(y2==y1)
```

```
no = 1x2 logical array
```

```
0 0
```

The output is different because the internal states of LPF have changed. Use `reset` to reset the lowpass filter and apply `step` again. Verify that the output is unchanged.

```
reset(LPF)
```

```
y3 = step(LPF,x);
```

```
yes = all(y3==y1)
```

```
yes = 1x2 logical array
```

```
1 1
```

## scale

Scale second-order sections of `dsp.BiquadFilter` System object

### Syntax

```
scale(biquad)
biquadnew = scale(biquad)
scale(biquad,pnorm)
scale(biquad,pnorm,Name,Value)
scale(biquad,pnorm,opts)
scale(biquad,'Arithmetic',ARITH)
```

### Description

`scale(biquad)` scales the `dsp.BiquadFilter` System object, `biquad`, using peak magnitude response scaling (L-infinity, 'Linf'). This scaling reduces the possibility of overflows when your filter `biquad` operates in fixed-point arithmetic mode.

`biquadnew = scale(biquad)` generates a new filter System object, `biquadnew`, with scaled second-order sections. The original filter System object, `biquad`, is not changed.

`scale(biquad,pnorm)` specifies the norm used to scale the filter. Pnorm can be either a discrete-time-domain norm or a frequency-domain norm. Valid time-domain norms are 'l1', 'l2', and 'linf'. Valid frequency-domain norms are 'L1', 'L2', and 'Linf'. Note that L2-norm is equal to l2-norm (Parseval's theorem) but the same is not true for other norms.

The different norms can be ordered in terms of how stringent they are as follows: 'l1' >= 'Linf' >= 'L2' = 'l2' >= 'L1' >= 'linf'.

Using the most stringent scaling, 'l1', the filter is the least prone to overflow, but also has the worst signal-to-noise ratio. Linf-scaling is the most commonly used scaling in practice.

`scale(biquad,pnorm,Name,Value)` specifies optional scaling parameters via by one or more Name,Value pair arguments.

`scale(biquad, pnorm, opts)` uses an options object to specify the optional scaling parameters in lieu of specifying parameter-value pairs. The `opts` object can be created using the `scalexts` method: `opts = scalexts(biquad)`.

`scale(biquad, 'Arithmetic', ARITH)` assumes that the filter arithmetic is equal to `ARITH`. `ARITH` can be set to one of `'double'`, `'single'`, or `'fixed'`. The `scale` method assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. If `'Arithmetic'` is `'double'` or `'single'`, the default values are used for all scaling options that are not specified as an input to the `scale` method. If `'Arithmetic'` is `'fixed'`, the values used for the scaling options are set according to the settings in the filter System object, `biquad`. However, if a scaling option is specified that differs from the settings in `biquad`, this option is used for scaling purposes but does not change the setting in `biquad`. For example, if you do not specify the `'OverflowMode'` scaling option, the `scale` method assumes that the `'OverflowMode'` is equal to the value in the `OverflowAction` property of the System object, `biquad`. If you do specify an `'OverflowMode'` scaling option, then the `scale` method uses this overflow mode value regardless of the value in the `OverflowAction` property of the System object.

## Input Arguments

### **biquad**

`dsp.BiquadFilter` filter System object.

### **pnorm**

Discrete-time-domain norm or a frequency-domain norm.

Valid time-domain norm values for `pnorm` are `'l1'`, `'l2'`, and `'linf'`. Valid frequency-domain norm values are `'L1'`, `'L2'`, and `'Linf'`. The `'L2'` norm is equal to the `'l2'` norm (by Parseval's theorem), but this equivalency does not hold for other norms — `'l1'` is not the same as `'L1'` and `'Linf'` is not the same as `'linf'`.

Filter norms can be ordered in terms of how stringent they are, as follows from most stringent to least: `'l1'`, `'Linf'`, `'l2'` (`'L2'`), `'linf'`. Using `'l1'`, the most stringent scaling, produces a filter that is least likely to overflow, but has the worst signal-to-noise ratio performance. The default scaling `'Linf'` (default) is the most commonly used scaling norm.

**opts**

Scale options object. You can create the `opts` object using the `scalesopts` function.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

**Arithmetic**

Specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the `System` object is locked or unlocked.

**Details for Fixed-Point Arithmetic**

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the <code>CustomCoefficientsDataType</code> property.

System Object State	Coefficient Data Type	Rule
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsData type property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

### MaxNumerator

Maximum allowed value for numerator coefficients.

**Default:** 2

### MaxScaleValue

Maximum allowed scale values. The filter applies the MaxScaleValue limit only when you set ScaleValueConstraint to a value other than unit (the default setting). Setting MaxScaleValue to any numerical value automatically changes the ScaleValueConstraint setting to none.

**Default:** 'Not Used'

### NumeratorConstraint

Specifies whether and how to constrain numerator coefficient values. Possible options:

- 'none' (default)

- 'normalized'
- 'po2'
- 'unit'

### **OverflowMode**

Sets the way the filter handles arithmetic overflow situations during scaling. If your device does not have guard bits available, and you are using saturation arithmetic for filtering, use 'satall' instead of 'saturate'. The default is 'wrap'.

### **ScaleValueConstraint**

Specify whether to constrain the filter scale values, and how to constrain them. Choosing 'unit' for the constraint disables the `MaxScaleValue` property setting. 'po2' constrains the scale values to be powers of 2, while 'none' removes any constraint on the scale values. 'unit' is the default value.

### **sosReorder**

Reorder filter sections prior to applying scaling. Possible options:

- 'auto' (default)
- 'none'
- 'up'
- 'down'
- 'lowpass'
- 'highpass'
- 'bandpass'
- 'bandstop'

## **Examples**

### **Lin<sup>∞</sup>-norm Scaling of a Biquad Filter**

Demonstrate the Lin<sup>∞</sup>-norm scaling of a biquad filter using the `scale` function.

```
Fs = 8000; Fcutoff = 2000;  
[z,p,k] = butter(10, Fcutoff/(Fs/2)); [s,g] = zp2sos(z,p,k);
```

```
biquad = dsp.BiquadFilter('Structure', 'Direct form I', ...  
    'SOSMatrix', s, 'ScaleValues', g);  
scale(biquad, 'linf', 'scalevalueconstraint', 'none', 'maxscalevalue', 2)
```

### Functions

cumsec | norm | reorder | scalecheck | scaleopts

**Introduced in R2011a**

## scalecheck

Check scaling of SOS filter

### Syntax

```
s = scalecheck(biquad,pnorm)
s = scalecheck(biquad,pnorm,Name,Value)
```

### Description

`s = scalecheck(biquad,pnorm)` checks the scaling of the filter System object `biquad`.

`s = scalecheck(biquad,pnorm,Name,Value)` checks the scaling of the filter System object `biquad` with additional options specified by one or more `Name,Value` pair arguments.

### Input Arguments

**biquad** —

`dsp.BiquadFilter` filter System object with one of the following filter structures:

Structure	Description
<code>df1sos</code>	Direct-form I filter object with second-order sections.
<code>df1tsos</code>	Direct-Form I transposed filter with second-order sections.
<code>df2sos</code>	Direct-form II filter object with second-order sections.
<code>df2tsos</code>	Direct-Form II transposed filter with second-order sections.

**pnorm — Different types of norm:**

'l1' | 'l2' | 'linf' | 'L1' | 'L2' | 'Linf'

Discrete-time-domain norm or a frequency-domain norm.

Valid time-domain norm values for `pnorm` are 'l1', 'l2', and 'linf'. Valid frequency-domain norm values are 'L1', 'L2', and 'Linf'. The 'L2' norm is equal to the 'l2' norm (by Parseval's theorem), but this equivalency does not hold for other norms — 'l1' is not the same as 'L1' and 'Linf' is not the same as 'linf'.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Arithmetic — Value type:**

'double' | 'single' | 'fixed'

For filter `System` object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the `System` object is locked or unlocked.

**Details for Fixed-Point Arithmetic**

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.

System Object State	Coefficient Data Type	Rule
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the <code>CustomCoefficientsData</code> property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the <code>CustomCoefficientsData</code> property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

## Output Arguments

### s

Filter scaling for a given p-norm. An optimally scaled filter has partial norms equal to one. In such cases, `s` contains all ones.

For direct-form I (`df1sos`) and direct-form II transposed (`df2tsos`) filters, the function returns the p-norm of the filter computed from the filter input to the output of each second-order section. Therefore, the number of elements in `s` is one less than the number of sections in the filter. This p-norm computation does not include the trailing scale value of the filter, which you can find by entering `hd.scalevalue(end)` at the MATLAB prompt.

For direct-form II (`df2sos`) and direct-form I transposed (`df1tsos`) filters, the function returns a row vector whose elements contain the p-norm from the filter input to the input of the recursive part of each second-order section. This computation of the p-norm corresponds to the input to the multipliers in these filter structures. These inputs correspond to the locations in the signal flow where overflow should be avoided.

When `hd` has nontrivial scale values, that is, if any scale values are not equal to one, `s` is a two-row matrix, rather than a vector. The first row elements of `s` report the p-norm of the filter computed from the filter input to the output of each second-order section. The elements of the second row of `s` contain the p-norm computed from the input of the filter to the input of each scale value between the sections. For `df2sos` and `df1tsos` filter structures, the last numerator and the trailing scale value for the filter are not included when `scalecheck` checks the scaling.

## Examples

### Lin<sup>∞</sup>-norm scaling of a filter

This example shows how to check the Lin<sup>∞</sup>-norm scaling of a filter.

Design an elliptic sos filter in the direct form II structure with default specifications.

```
EllipII = design(fdesign.lowpass, 'ellip', 'FilterStructure', 'df2sos', ...
    'SystemObject', true);
```

Check the scaling.

```
scalecheck(EllipII, 'Linf')
```

```
ans = 2×3
```

```
    3.1678    15.0757    1.4974
    4.7360    52.6026    1.0000
```

Design an elliptic sos filter in the direct form I structure with default specifications.

```
EllipI = design(fdesign.lowpass('N,Fp,Ap,Ast',10,0.5,0.5,20), 'ellip', ...
    'FilterStructure', 'df1sos', 'SystemObject', true);
```

Check the scaling.

```
scalecheck(EllipI, 'Linf')
```

```
ans = 1×5
```

```
1.7078    2.0807    2.6084    7.1467    1.0000
```

## scaleopts

Create an options object for second-order section scaling

### Syntax

```
opts = scaleopts(biquad)
opts = scaleopts(biquad,Name,Value)
```

### Description

`opts = scaleopts(biquad)` uses the current settings in the `dsp.BiquadFilter` System object, `biquad`, to create an options object `opts` that contains specified scaling options for second-order section scaling. You can pass `opts` as an input to `scale` to apply scaling settings to a second-order filter.

`opts = scaleopts(biquad,Name,Value)` creates an options object with additional options specified by one or more `Name,Value` pair arguments.

### Input Arguments

#### **biquad**

`dsp.BiquadFilter` filter System object.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

#### **Arithmetic — Value types:**

'double' | 'single' | 'fixed'

Specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

**Details for Fixed-Point Arithmetic**

<b>System Object State</b>	<b>Coefficient Data Type</b>	<b>Rule</b>
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataProperty property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataProperty property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

## Output Arguments

### opts

Scaling object. The following table lists the properties of `opts`.

Parameter	Default	Description and Valid Value
<code>sosReorder</code>	<code>'auto'</code>	Reorder section prior to scaling.  Valid options are <code>'auto'</code> (default), <code>'none'</code> , <code>'up'</code> , <code>'down'</code> , <code>'lowpass'</code> , <code>'highpass'</code> , <code>'bandpass'</code> , and <code>'bandstop'</code> .
<code>MaxNumerator</code>	2	Maximum allowed value for numerator coefficients.
<code>NumeratorConstraint</code>	<code>'none'</code>	Specifies whether and how to constrain numerator coefficient values. Options are <code>'none'</code> (default), <code>'unit'</code> , <code>'normalize'</code> , and <code>'po2'</code> .
<code>OverflowMode</code>	<code>'wrap'</code>	Sets the way the filter handles arithmetic overflow situations during scaling. Valid options are <code>'wrap'</code> (default), <code>'saturate'</code> , and <code>'satall'</code> .
<code>ScaleValueConstraint</code>	<code>'unit'</code>	Specify whether to constrain the filter scale values, and how to constrain them. Valid options are <code>'unit'</code> (default), <code>'none'</code> , and <code>'po2'</code> .

Parameter	Default	Description and Valid Value
MaxScaleValue	'Not used'	Maximum allowed scale values. The filter applies the MaxScaleValue limit only when you set ScaleValueConstraint to a value other than unit. Setting MaxScaleValue to a numerical value automatically changes the ScaleValueConstraint setting to none.

## Examples

### Options for scaling SOS filter

Create an options scaling object that contains the scaling options settings you require.

```
EllipI = design(fdesign.lowpass('N,Fp,Ap,Ast',10,0.5,0.5,20), 'ellip', 'FilterStructure')
```

```
EllipI =  
    dsp.BiquadFilter with properties:
```

```
        Structure: 'Direct form I'  
        SOSMatrixSource: 'Property'  
        SOSMatrix: [5x6 double]  
        ScaleValues: [6x1 double]  
        NumeratorInitialConditions: 0  
        DenominatorInitialConditions: 0  
        OptimizeUnityScaleValues: true
```

```
Show all properties
```

```
opts = scaleopts(EllipI)
```

```
opts =
```

```
        sosReorder: 'auto'  
        MaxNumerator: 2
```

```
NumeratorConstraint: 'none'  
  OverflowMode: 'wrap'  
ScaleValueConstraint: 'unit'  
  MaxScaleValue: 'Not used'
```

## set2int

Configure filter for integer filtering

### Syntax

```
set2int(h)
set2int(h,coeffwl)
set2int(...,inwl)
g = set2int(...)
```

### Description

This section applies to discrete-time (`dfilt`) filters.

`set2int(h)` scales the filter coefficients to integer values and sets the filter coefficient and input fraction lengths to zero.

`set2int(h,coeffwl)` uses the number of bits specified by `coeffwl` as the word length it uses to represent the filter coefficients.

`set2int(...,inwl)` uses the number of bits specified by `coeffwl` as the word length it uses to represent the filter coefficients and the number of bits specified by `inwl` as the word length to represent the input data.

`g = set2int(...)` returns the gain `g` introduced into the filter by scaling the filter coefficients to integers. `g` is always calculated to be a power of 2.

---

**Note** `set2int` does not work with CIC decimators or interpolators because they do not have coefficients.

---

### Examples

## Configure an FIR Filter for Integer Filtering

Two parts comprise this example. Part 1 compares the step response of an FIR filter in both the fractional and integer filter modes. Fractional mode filtering is essentially the opposite of integer mode. Integer mode uses a filter which has coefficients represented by integers. Fractional mode filters have coefficients represented in fractional form (nonzero fraction length).

The second part of the example depends on the following - after you filter a set of data, the input data and output data cover the same range of values, unless the filter process introduces gain in the output. Converting your filter object to integer form, and then filtering a set of data, does introduce gain into the system. When the examples refer to resetting the output to the same range as the input, the examples are accounting for this added gain feature.

```
b = rcosdesign(.25,4,25,'sqrt');
hd = dfilt.dffir(b);
hd.Arithmetic = 'fixed';
hd.InputFracLength = 0; % Integer inputs.
x = ones(100,1);
yfrac = filter(hd,x); % Fractional mode output.
g = set2int(hd); % Convert to integer coefficients.
yint = filter(hd,x); % Integer mode output.
```

Note that `yint` and `yfrac` are `fi` objects. Later in this example, use the `fi` object properties `WordLength` and `FractionLength` to work with the output data. Now use the gain `g` to rescale the output from the integer mode filter operation. Verify that the scaled integer output is equal to the fractional output.

```
yints = double(yint)/g;
```

Verify that the scaled integer output is equal to the fractional output.

```
max(abs(yints-double(yfrac)))
```

```
ans = 0
```

In part two, the example reinterprets the output binary data, putting the input and the output on the same scale by weighting the most significant bits in the input and output data equally.

```
WL = yint.WordLength;
FL = yint.FractionLength + log2(g);
yints2 = fi(zeros(size(yint)),true,WL,FL);
```

```
yints2.bin = yint.bin;  
max(abs(double(yints2)-double(yfrac)))  
  
ans = 0
```

**Introduced in R2011a**

## setspecs

Specifications for filter specification object

### Syntax

```
setspecs(D,specvalue1,specvalue2,...)
setspecs(D,Specification,specvalue1,specvalue2,...)
setspecs(...Fs)
setspecs(...,MAGUNITS)
```

### Description

`setspecs(D,specvalue1,specvalue2,...)` sets the specifications in filter specification object, `D`, in the same order they appear in the `Specification` property.

`setspecs(D,Specification,specvalue1,specvalue2,...)` changes the specifications for an existing filter specification object and sets values for the new `Specification` property.

`setspecs(...Fs)` specifies the sampling frequency, `Fs`, in Hz. The sampling frequency must be a scalar trailing all other specifications. Entering a sampling frequency causes all other frequency specifications to be in Hz.

`setspecs(...,MAGUNITS)` specifies the units for any magnitude specifications. `MAGUNITS` can be one of the following: 'linear', 'dB', or 'squared'. The default is 'dB'. The magnitude specifications are always converted and stored in dB regardless of how the units are specified.

Use `SET(D,'SPECIFICATION')` to get the list of all available specification types for the filter specification object, `D`.

### Examples

### Set the Filter Order and Cutoff Frequency Using `setspecs`

Construct a lowpass filter with specifications for the filter order and cutoff frequency (-6 dB). Use `setspecs` after construction to set the values of the filter order and cutoff frequency. Display the values in the MATLAB® command window.

```
D = fdesign.lowpass('N,Fc');  
setspecs(D,10,0.2);
```

```
D.FilterOrder
```

```
ans = 10
```

```
D.Fcutoff
```

```
ans = 0.2000
```

### Set the Specifications of a Highpass Filter Using `setspecs`

Construct a highpass filter with specifications for the numerator order, denominator order, and 3-dB frequency. Assume the sampling frequency is 1 kHz. Use `setspecs` to set the numerator and denominator orders to 6. Set the 3-dB frequency to 250 Hz. In order to use frequency specifications in Hz, specify the sampling frequency as a trailing scalar.

```
D = fdesign.highpass('Nb,Na,F3dB');  
setspecs(D,6,6,250,1000);
```

# show

**Package:** dsp

Display scope window

## Syntax

show(scope)

## Description

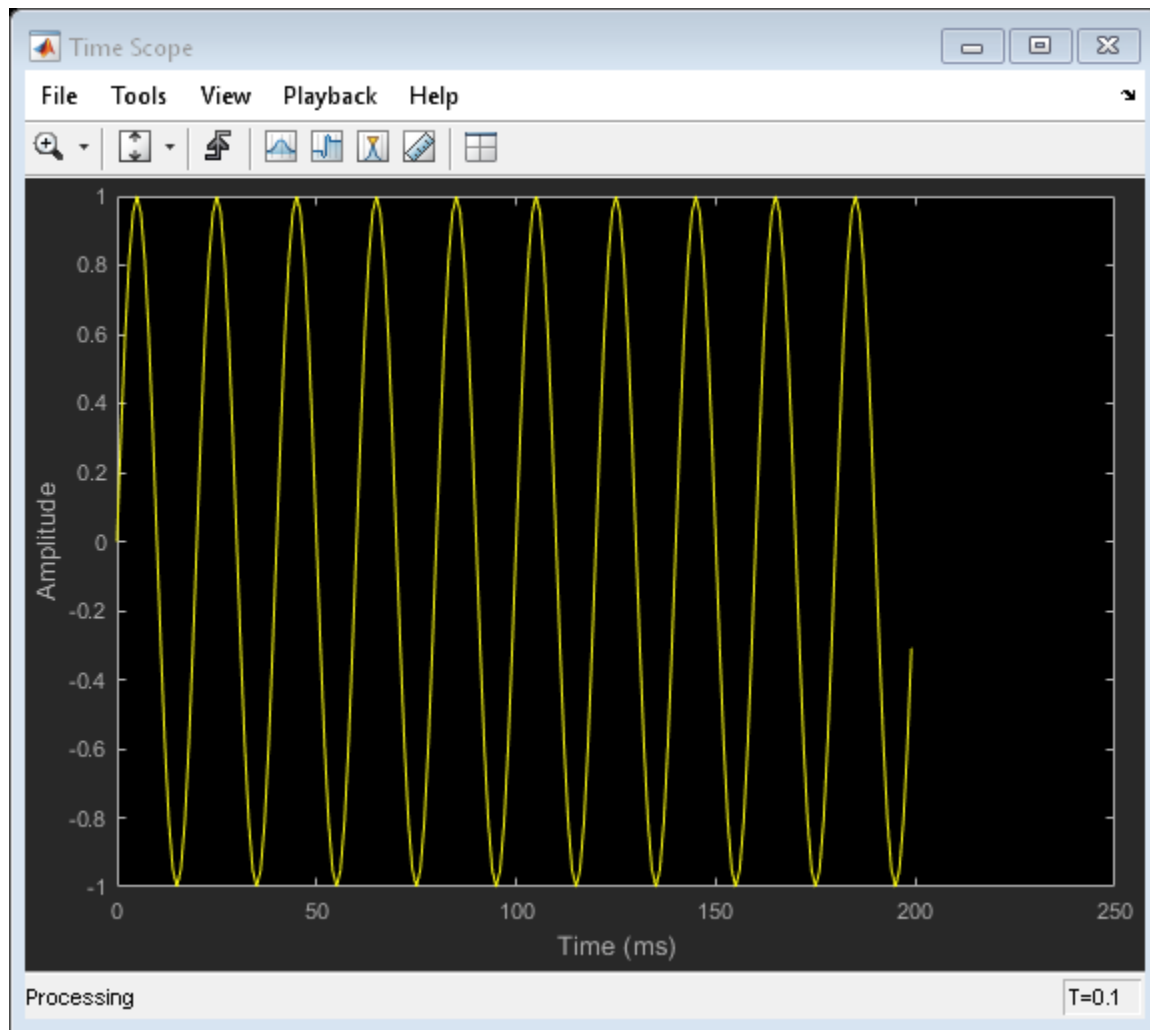

show(scope) shows the window of the System object scope.

## Examples

### Hide and Show Time Scope

Create a sine wave signal and view it in the scope.

```
Fs = 1000; % Sampling frequency
signal = dsp.SineWave('Frequency',50,'SampleRate',Fs,'SamplesPerFrame',100);
scope = dsp.TimeScope(1,Fs,'TimeSpan',0.25,'YLimits',[-1 1]);
for ii = 1:2
    xsine = signal();
    scope(xsine)
end
```

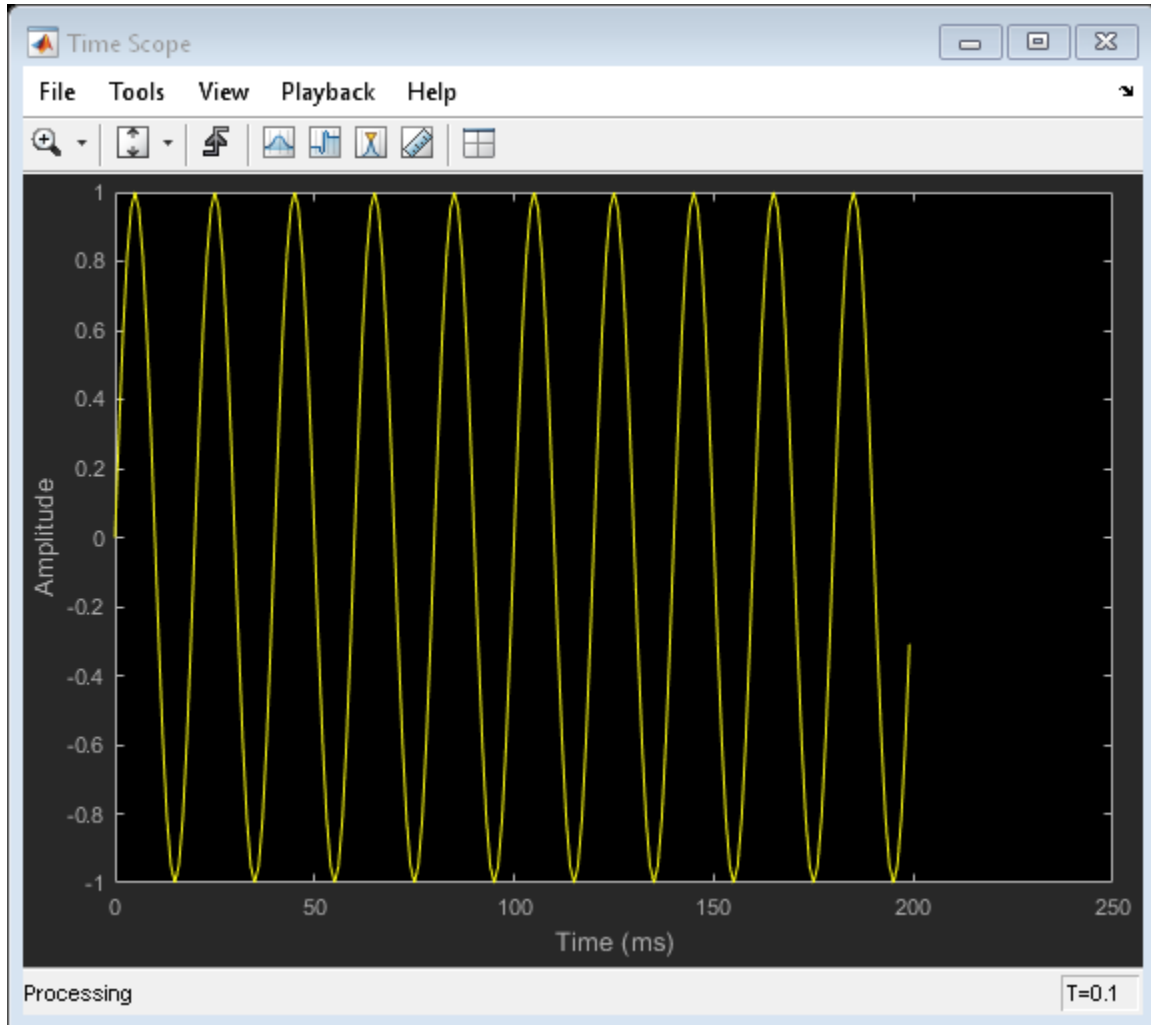

Hide the scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the scope window.

```
if(~isVisible(scope))  
    show(scope)  
end
```

Clean up workspace variables.

```
clear scope Fs sine ii xsine
```

## Input Arguments

**scope** — Scope System object

System object

Scope System object whose window you want to show.

Example: `myScope = dsp.SpectrumAnalyzer; show(myScope)`

## See Also

`hide` | `isVisible`

## SOS

Convert quantized filter to second-order sections (SOS) form

## Syntax

```
Hq2 = sos(Hq)
Hq2 = sos(Hq, order)
Hq2 = sos(Hq, order, scale)
```

## Description

`Hq2 = sos(Hq)` returns a quantized filter `Hq2` that has second-order sections and the `dft2` structure. Use the same optional arguments used in `tf2sos`.

`Hq2 = sos(Hq, order)` specifies the order of the sections in `Hq2`, where `order` is one of the following options:

- 'down' — to order the sections so the first section of `Hq2` contains the poles closest to the unit circle ( $L_\infty$  norm scaling)
- 'up' — to order the sections so the first section of `Hq2` contains the poles farthest from the unit circle ( $L_2$  norm scaling and the default)

`Hq2 = sos(Hq, order, scale)` also specifies the desired scaling of the gain and numerator coefficients of all second-order sections, where `scale` is one of the following options:

- 'none' — to apply no scaling (default)
- 'inf' — to apply infinity-norm scaling
- 'two' — to apply 2-norm scaling

`Hq2` is a `dsp.BiquadFilter` filter System object.

Use infinity-norm scaling in conjunction with up-ordering to minimize the probability of overflow in the filter realization. Consider using 2-norm scaling in conjunction with down-ordering to minimize the peak round-off noise.

When `Hq` is a fixed-point filter, the filter coefficients are normalized so that the magnitude of the maximum coefficient in each section is 1. The gain of the filter is applied to the first scale value of `Hq2`.

`sos` uses the direct form II transposed (`df2t`) structure to implement second-order section filters.

### Examples

```
[b,a]=butter(8,.5);  
Hq = dfilt.df2t(b,a);  
Hq.arithmetic = 'fixed';  
Hq1 = sos(Hq)
```

Hq1 =

```
    FilterStructure: 'Direct-Form II Transposed, Second-Order Sections'  
        Arithmetic: 'double'  
        sosMatrix: [4x6 double]  
        ScaleValues: [0.00927734375;1;1;1;1]  
    OptimizeScaleValues: true  
    PersistentMemory: false
```

# specifyall

Fully specify fixed-point filter System object settings

## Syntax

```
specifyall(sysobj)  
specifyall(sysobj,false)  
specifyall(sysobj,true)
```

## Description

`specifyall(sysobj)` sets all the data type fixed-point properties of the filter System object `sysobj` to 'Custom' so that you can easily specify all the fixed-point settings. If the object has a `FullPrecisionOverride` property, its value is set to `false`.

`specifyall` is intended as a shortcut to changing all the fixed-point properties one by one.

`specifyall(sysobj, false)` sets all fixed-point properties of the filter System object `sysobj` to their default values and sets the filter to full-precision mode, if one is available.

`specifyall(sysobj, true)` is equivalent to `specifyall(sysobj)`.

## Examples

### Specify all Fixed-point Settings of an FIRFilter

This example demonstrates using `specifyall` to provide access to all of the fixed-point settings of an FIR filter implemented with the direct-form structure. Using `specifyall` disables all of the automatic filter scaling and reset the mode values.

```
b = fircband(12,[0 0.4 0.5 1],[1 1 0 0],[1 0.2],{'w' 'c'});  
firFilter = dsp.FIRFilter('Numerator',b);  
get(firFilter)
```

```
ans = struct with fields:
    Numerator: [1x13 double]
    ReflectionCoefficients: [0.5000 0.5000]
    InitialConditions: 0
    NumeratorSource: 'Property'
    ReflectionCoefficientsSource: 'Property'
    Structure: 'Direct form'
    FullPrecisionOverride: 1
    RoundingMethod: 'Floor'
    OverflowAction: 'Wrap'
    CoefficientsDataType: 'Same word length as input'
    ReflectionCoefficientsDataType: 'Same word length as input'
    CustomCoefficientsDataType: [1x1 embedded.numerictype]
    CustomReflectionCoefficientsDataType: [1x1 embedded.numerictype]
    ProductDataType: 'Full precision'
    CustomProductDataType: [1x1 embedded.numerictype]
    AccumulatorDataType: 'Full precision'
    CustomAccumulatorDataType: [1x1 embedded.numerictype]
    StateDataType: 'Same as accumulator'
    CustomStateDataType: [1x1 embedded.numerictype]
    OutputDataType: 'Same as accumulator'
    CustomOutputDataType: [1x1 embedded.numerictype]
```

`specifyall` sets all the data type fixed-point properties of the FIR filter to 'Custom'.

```
specifyall(firFilter)
get(firFilter)
```

```
ans = struct with fields:
    Numerator: [1x13 double]
    ReflectionCoefficients: [0.5000 0.5000]
    InitialConditions: 0
    NumeratorSource: 'Property'
    ReflectionCoefficientsSource: 'Property'
    Structure: 'Direct form'
    FullPrecisionOverride: 0
    RoundingMethod: 'Floor'
    OverflowAction: 'Wrap'
    CoefficientsDataType: 'Custom'
    ReflectionCoefficientsDataType: 'Custom'
    CustomCoefficientsDataType: [1x1 embedded.numerictype]
    CustomReflectionCoefficientsDataType: [1x1 embedded.numerictype]
    ProductDataType: 'Custom'
    CustomProductDataType: [1x1 embedded.numerictype]
```

```
AccumulatorDataType: 'Custom'  
CustomAccumulatorDataType: [1x1 embedded.numerictype]  
StateDataType: 'Custom'  
CustomStateDataType: [1x1 embedded.numerictype]  
OutputDataType: 'Custom'  
CustomOutputDataType: [1x1 embedded.numerictype]
```

### Functions

double | reffilter

**Introduced in R2011a**

## stepz

Step response of discrete-time filter System object

### Syntax

```
[stepResp,t] = stepz(sysobj)
[stepResp,t] = stepz(sysobj,n)
[stepResp,t] = stepz(sysobj,n,fs)
[stepResp,t] = stepz(sysobj,[],fs)
[stepResp,t] = stepz(sysobj,Name,Value)
stepz(sysobj)
```

### Description

`[stepResp,t] = stepz(sysobj)` computes the step response of the filter System object, `sysobj`, and returns the response in column vector `stepResp`, and a vector of times (or sample intervals) in `t`, where `t = [0 1 2 ...k-1]'`. `k` is the number of filter coefficients.

`[stepResp,t] = stepz(sysobj,n)` computes the step response at `floor(n)` 1-second intervals. The time vector `t` equals `(0:floor(n)-1)'`.

`[stepResp,t] = stepz(sysobj,n,fs)` computes the step response at `floor(n)` `1/fs`-second intervals. The time vector `t` equals `(0:floor(n)-1)'/fs`.

`[stepResp,t] = stepz(sysobj,[],fs)` computes the step response at `k` `1/fs`-second intervals. `k` is the number of filter coefficients. The time vector `t` equals `(0:k-1)'/fs`.

`[stepResp,t] = stepz(sysobj,Name,Value)` returns a step response with additional options specified by one or more `Name,Value` pair arguments.

`stepz(sysobj)` uses `fvtool` to plot the step response of the filter System object `sysobj`.

For more input options, refer to `stepz` in Signal Processing Toolbox documentation.

---

**Note** stepz works for both real and complex filters. When you omit the output arguments, stepz plots only the real part of the step response.

---

## Input Arguments

### sysobj

Filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.AllpassFilter
dsp.AllpoleFilter
dsp.BiquadFilter
dsp.Channelizer
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.CICDecimator
dsp.CICInterpolator
dsp.CoupledAllpassFilter
dsp.FarrowRateConverter
dsp.FilterCascade
dsp.FIRDecimator
dsp.FIRFilter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.FIRInterpolator
dsp.FIRRateConverter
dsp.HighpassFilter
dsp.IIRFilter

<b>Filter System objects</b>
<code>dsp.IIRHalfbandDecimator</code>
<code>dsp.IIRHalfbandInterpolator</code>
<code>dsp.LowpassFilter</code>
<code>dsp.NotchPeakFilter</code>
<code>dsp.VariableBandwidthFIRFilter</code>
<code>dsp.VariableBandwidthIIRFilter</code>

**n**

Length of the step response vector.

**Default:** Number of filter coefficients

**fs**

Sampling frequency.

**Default:** 1

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Arithmetic — Value types:**

`'double' | 'single' | 'fixed'`

Specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'`, the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

### Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataProperty property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataProperty property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Output Arguments

### **stepResp**

n-element step response vector. If n is not specified, the length of the step response vector equals the number of coefficients in the filter.

### **t**

Time vector of length n, in seconds. **t** consists of n equally spaced points in the range  $(0:\text{floor}(n)-1)/fs$ . If n is not specified, the function uses the number of coefficients of the filter.

## sysobj

Create filter System object from discrete-time filter

### Syntax

```
hs = sysobj(hfilt)
```

### Description

`hs = sysobj(hfilt)` creates a new filter System object `hs` from the `dfilt` object, `hfilt`.

The function supports a subset of `dfilt` objects. The following table lists supported filter structures for `hfilt` and the filter System object that the function creates.

Single-rate	Filter System object
Lattice AR( <code>dfilt.latticear</code> )	<code>dsp.AllpoleFilter</code>
Coupled-allpass, power-complementary lattice filter ( <code>dfilt.calatticepc</code> )	<code>dsp.CoupledAllpassFilter</code>
Coupled-allpass, lattice filter ( <code>dfilt.calattice</code> )	<code>dsp.CoupledAllpassFilter</code>
Cascade of discrete time filters ( <code>dfilt.cascade</code> )	<code>dsp.CoupledAllpassFilter</code>
Direct Form I ( <code>dfilt.df1</code> )	<code>dsp.IIRFilter</code>
Direct Form I transposed ( <code>dfilt.df1t</code> )	<code>dsp.IIRFilter</code>
Direct Form II ( <code>dfilt.df2</code> )	<code>dsp.IIRFilter</code>
Direct Form II transposed ( <code>dfilt.df2t</code> )	<code>dsp.IIRFilter</code>
Direct-form FIR ( <code>dfilt.dffir</code> )	<code>dsp.FIRFilter</code>
Direct-form FIR transposed ( <code>dfilt.dffirt</code> )	<code>dsp.FIRFilter</code>

Single-rate	Filter System object
Direct-form symmetric FIR ( <code>dfilt.dfsymfir</code> )	<code>dsp.FIRFilter</code>
Direct-form antisymmetric FIR ( <code>dfilt.dfasymfir</code> )	<code>dsp.FIRFilter</code>
Discrete-time, lattice, moving-average ( <code>dfilt.latticemamin</code> )	<code>dsp.FIRFilter</code>
Discrete-time, second-order section, direct-form I ( <code>dfilt.dflsos</code> )	<code>dsp.BiquadFilter</code>
Discrete-time, second-order section, direct-form I transposed ( <code>dfilt.dfltsos</code> )	<code>dsp.BiquadFilter</code>
Discrete-time, second-order section, direct-form II ( <code>dfilt.df2sos</code> )	<code>dsp.BiquadFilter</code>
Discrete-time, second-order section, direct-form II transposed ( <code>dfilt.df2tsos</code> )	<code>dsp.BiquadFilter</code>

## Input Arguments

### `hfilt`

Discrete-time filter (`dfilt`) object. The preceding table lists supported filter structures.

If `hfilt` is a discrete-time filter with the `PersistentMemory` property set to `true`, then the filter states are copied into the initial conditions properties of `hs`. Otherwise, initial conditions are ignored.

The function does not support some properties for SOS filter structures:

- If the `CastBeforeSum` property is set to `false`, the function issues a warning. `dsp.BiquadFilter` System objects always have a cast before a sum.
- If the `Signed` property is `false`, the function issues an error. `dsp.BiquadFilter` System objects do not support unsigned arithmetic.

## Output Arguments

**hs**

Filter System object. The function maps almost all properties of `hfilt` into the filter System object. However, some properties are not mapped exactly:

- Filter System objects do not have a `CoeffAutoScale` property. The function specifies a word length and a fraction length regardless of whether the `CoeffAutoScale` property of `hfilt` is `true` or `false`.
- `dsp.BiquadFilter` System objects do not have a `FullPrecisionOverride` property. Full-precision values in `hfilt` are mapped to word and fraction lengths in `hs`. These settings correspond to the full-precision setting of the input data type.

## Examples

### Convert a discrete-time filter object to a System object

```

hfilt = dfilt.df1sos; %Direct-form I SOS
hs = sysobj(hfilt) %Biquadratic IIR filter

hs =
    dsp.BiquadFilter with properties:
        Structure: 'Direct form I'
        SOSMatrixSource: 'Property'
        SOSMatrix: [1 0 0 1 0 0]
        ScaleValues: [2x1 double]
        NumeratorInitialConditions: 0
        DenominatorInitialConditions: 0
        OptimizeUnityScaleValues: true

    Show all properties

```

## See Also

`block`

**Introduced in R2012a**

# tf

**Package:** dsp

Return transfer function of overall prototype lowpass filter

## Syntax

```
[num,den] = tf(obj)
```

## Description

`[num,den] = tf(obj)` returns the vector of numerator coefficients, `num`, and the vector of denominator coefficients, `den`, for the overall prototype lowpass filter used for the filter bank in a `dsp.Channelizer` or a `dsp.ChannelSynthesizer` System object.

## Examples

### Transfer Function of Prototype Lowpass Filter

Determine the transfer function of the overall prototype lowpass filter used for the filter bank in the `dsp.Channelizer` System object.

Design a channelizer with the number of frequency bands or polyphase branches set to 8, the number of taps or coefficients per band set to 12, and stopband attenuation set to 80 dB. The function `tf` returns the transfer function of the prototype lowpass filter.

```
channelizer = dsp.Channelizer;  
[num,den] = tf(channelizer);
```

View the magnitude response of the prototype lowpass filter using `fvtool`.

```
fvtool(num,den);
```

## Input Arguments

**obj** — Input filter System object

`dsp.Channelizer` | `dsp.ChannelSynthesizer`

Input filter, specified as either a `dsp.Channelizer` or a `dsp.ChannelSynthesizer` System object.

Example: `channelizer = dsp.Channelizer;`

Example: `channelizer = dsp.ChannelSynthesizer;`

## Output Arguments

### **num — Numerator coefficients**

row vector

Numerator coefficients, returned as a row vector.

### **den — Denominator coefficients**

row vector

Denominator coefficients, returned as a row vector. For a finite Impulse response (FIR) filter, this value is 1.

## tf2ca

Transfer function to coupled allpass

### Syntax

```
[d1,d2] = tf2ca(b,a)
[d1,d2] = tf2ca(b,a)
[d1,d2,beta] = tf2ca(b,a)
```

### Description

`[d1,d2] = tf2ca(b,a)` where **b** is a real, symmetric vector of numerator coefficients and **a** is a real vector of denominator coefficients, corresponding to a stable digital filter, returns real vectors **d1** and **d2** containing the denominator coefficients of the allpass filters  $H1(z)$  and  $H2(z)$  such that

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)[H1(z) + H2(z)]$$

representing a coupled allpass decomposition.

`[d1,d2] = tf2ca(b,a)` where **b** is a real, antisymmetric vector of numerator coefficients and **a** is a real vector of denominator coefficients, corresponding to a stable digital filter, returns real vectors **d1** and **d2** containing the denominator coefficients of the allpass filters  $H1(z)$  and  $H2(z)$  such that

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)[H1(z) - H2(z)]$$

In some cases, the decomposition is not possible with real  $H1(z)$  and  $H2(z)$ . In those cases a generalized coupled allpass decomposition may be possible, as described in the following syntax.

`[d1,d2,beta] = tf2ca(b,a)` returns complex vectors `d1` and `d2` containing the denominator coefficients of the allpass filters  $H1(z)$  and  $H2(z)$ , and a complex scalar `beta`, satisfying  $|\text{beta}| = 1$ , such that

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right) \left[ \bar{\beta} \cdot H1(z) + \beta \cdot H2(z) \right]$$

representing the generalized allpass decomposition.

In the above equations,  $H1(z)$  and  $H2(z)$  are real or complex allpass IIR filters given by

$$H1(z) = \frac{\text{fliplr}(\overline{D1(z)})}{D1(z)}, H2(z) = \frac{\text{fliplr}(\overline{D2(1/z)})}{D2(1/z)}$$

where  $D1(z)$  and  $D2(z)$  are polynomials whose coefficients are given by `d1` and `d2`.

---

**Note** A coupled allpass decomposition is not always possible. Nevertheless, Butterworth, Chebyshev, and Elliptic IIR filters, among others, can be factored in this manner. For details, refer to Signal Processing Toolbox User's Guide.

---

## Examples

```
[b,a]=cheby1(9,.5,.4);
[d1,d2]=tf2ca(b,a); % TF2CA returns denominators of the allpass.
num = 0.5*conv(fliplr(d1),d2)+0.5*conv(fliplr(d2),d1);
den = conv(d1,d2); % Reconstruct numerator and denominator.
MaxDiff=max([max(b-num),max(a-den)]); % Compare original and reconstructed
% numerator and denominators.
```

## Extended Capabilities

## tf2cl

Transfer function to coupled allpass lattice

### Syntax

```
[k1,k2] = tf2cl(b,a)
[k1,k2] = tf2cl(b,a)
[k1,k2,beta] = tf2cl(b,a)
```

### Description

[k1,k2] = tf2cl(b,a) where b is a real, symmetric vector of numerator coefficients and a is a real vector of denominator coefficients, corresponding to a stable digital filter, will perform the coupled allpass decomposition

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right) [H1(z) + H2(z)]$$

of a stable IIR filter  $H(z)$  and convert the allpass transfer functions  $H1(z)$  and  $H2(z)$  to a coupled lattice allpass structure with coefficients given in vectors k1 and k2.

[k1,k2] = tf2cl(b,a) where b is a real, antisymmetric vector of numerator coefficients and a is a real vector of denominator coefficients, corresponding to a stable digital filter, performs the coupled allpass decomposition

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right) [H1(z) - H2(z)]$$

of a stable IIR filter  $H(z)$  and converts the allpass transfer functions  $H1(z)$  and  $H2(z)$  to a coupled lattice allpass structure with coefficients given in vectors k1 and k2.

In some cases, the decomposition is not possible with real  $H1(z)$  and  $H2(z)$ . In those cases, a generalized coupled allpass decomposition may be possible, using the syntax described below.

`[k1,k2,beta] = tf2cl(b,a)` performs the generalized allpass decomposition of a stable IIR filter  $H(z)$  and converts the complex allpass transfer functions  $H1(z)$  and  $H2(z)$  to corresponding lattice allpass filters

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right) \left[ \bar{\beta} \cdot H1(z) + \beta \cdot H2(z) \right]$$

where `beta` is a complex scalar of magnitude equal to 1.

---

**Note** Coupled allpass decomposition is not always possible. Nevertheless, Butterworth, Chebyshev, and Elliptic IIR filters, among others, can be factored in this manner. For details, refer to Signal Processing Toolbox User's Guide.

---

## Examples

```
[b,a]=cheby1(9,.5,.4);
[k1,k2]=tf2cl(b,a); % Get the reflection coeffs. for the lattices.
[num1,den1]=latc2tf(k1,'allpass'); % Convert each allpass lattice
[num2,den2]=latc2tf(k2,'allpass'); % back to transfer function.
num = 0.5*conv(num1,den2)+0.5*conv(num2,den1);
den = conv(den1,den2); % Reconstruct numerator and denominator.
MaxDiff=max([max(b-num),max(a-den)]); % Compare original and reconstructed
% numerator and denominators.
```

## validstructures

Structures for specification object with design method

### Syntax

```
filtstruct = validstructures(D,'Systemobject',true)
filtstruct = validstructures(D,METHOD,'Systemobject',true)
```

### Description

`filtstruct = validstructures(D,'Systemobject',true)` returns a structure of cell arrays, `filtstruct`, which contains a set of valid filter structures for the filter specification object, `D`. When you set `'Systemobject'` to `true`, `validstructures` returns a list of structures that support filter System objects. Each field in `filtstruct` lists a set of filter structures for the design method specified.

`filtstruct = validstructures(D,METHOD,'Systemobject',true)` returns the valid structures for the filter specification object, `D`, and the design method, `METHOD`, in a cell array of character vectors.

### Examples

#### Valid Filter Structures

Design a default lowpass filter specification object. Return all valid design methods and structures in a structure array. Display the fieldnames to see all valid design methods. Display the valid filter structures for the `equiripple` field.

```
D = fdesign.lowpass;
filtstruct = validstructures(D,'SystemObject',true);

fn = fieldnames(filtstruct)

fn = 8x1 cell array
    {'butter' }
```

```

{'cheby1'   }
{'cheby2'   }
{'ellip'    }
{'equiripple'}
{'ifir'     }
{'multistage'}
{'kaiserwin' }

```

```

strs = eval(['filtstruct.' fn{5}])

strs = 1x3 cell array
    {'dffir'}    {'dffirt'}    {'dfsymfir'}

```

Create a highpass filter of order 50 with a 3-dB frequency of 0.2. Obtain the available structures for a Butterworth design.

```

## visualizeFilterStages

**Package:** dsp

Visualize filter stages

### Syntax

```
visualizeFilterStages(sysobj)
```

### Description

`visualizeFilterStages(sysobj)` shows the response of each individual filter stage of the filter System object using FVTool.

### Examples

#### Filter Signal Through Complex Bandpass Decimator

Filter an input signal through a complex bandpass decimator and visualize the filtered spectrum in a spectrum analyzer.

#### Initialization

Create a `dsp.ComplexBandpassDecimator System` object™ with center frequency set to 2000 Hz, bandwidth of interest set to 1000 Hz, and sample rate set to 48 kHz. The decimation factor is computed as the ratio of the sample rate to the bandwidth of interest. The input to the decimator is a sine wave with a frame length of 1200 samples with tones at 1625 Hz, 2000 Hz, and 2125 Hz. Create a `dsp.SpectrumAnalyzer` scope to visualize the signal spectrum.

```
Fs = 48e3;  
CF = 2000;  
BW = 1000;  
D = Fs/BW;
```

```
FrameLength = 1200;
bpdecim = dsp.ComplexBandpassDecimator(D,CF,Fs);

sa = dsp.SpectrumAnalyzer('SampleRate',Fs/D,...
    'YLimits',[-120 40],...
    'FrequencyOffset',CF);

tones = [1625 2000 2125];
sin = dsp.SinWave('SampleRate',Fs,'Frequency',tones,...
    'SamplesPerFrame',FrameLength);
```

### **Visualize Filter Stages**

Using the `visualizeFilterStages` function, you can visualize the response of each individual filter stage using FVTool.

```
visualizeFilterStages(bpdecim)
```

### Display Filter info

The `info` function displays information about the bandpass decimator.

```
fprintf('%s',info(bpdecim))
```

```
Overall Decimation Factor      : 48
Bandwidth                     : 1000 Hz
Number of Filters             : 3
Real multiplications per Input Sample: 16.125000
Real additions per Input Sample  : 15.958333
Number of Coefficients       : 155
Filters:
  Filter 1:
```

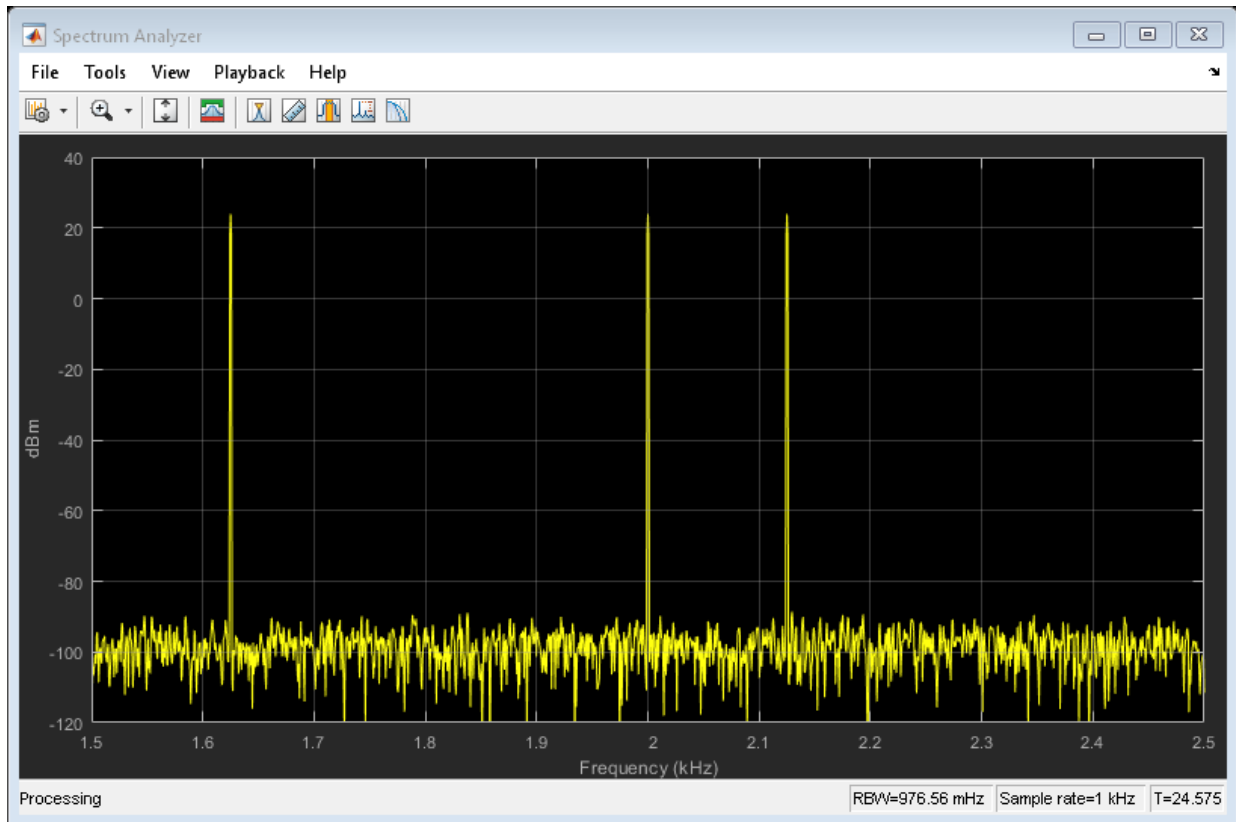

```
dsp.FIRDecimator    - Decimation Factor    : 8
Filter 2:
dsp.FIRDecimator    - Decimation Factor    : 2
Filter 3:
dsp.FIRDecimator    - Decimation Factor    : 3
```

### **Stream In and Filter Signal**

Construct a for-loop to run for 1000 iterations. In each iteration, stream in 1200 samples (one frame) of the noisy sine wave and apply the complex bandpass decimator on each frame of the input signal. Visualize the input and output spectrum in the spectrum analyzer, `sa`.

```
for index = 1:1000
    x = sum(sin(),2) + 1e-4 * randn(FrameLength,1);
    z = bpdecim(x);
    sa(z);
end
```

The bandpass decimator with center frequency at 2000 Hz and a bandwidth of 1000 Hz passes the three sine wave tones at 1625 Hz, 2000 Hz, and 2125 Hz.

Change the center frequency of the decimator to 2400 Hz and filter the signal.

```
release(bpdecim);
bpdecim.CenterFrequency = 2400

bpdecim =
    dsp.ComplexBandpassDecimator with properties:
        CenterFrequency: 2400
        Specification: 'Decimation factor'
        DecimationFactor: 48
        StopbandAttenuation: 80
```

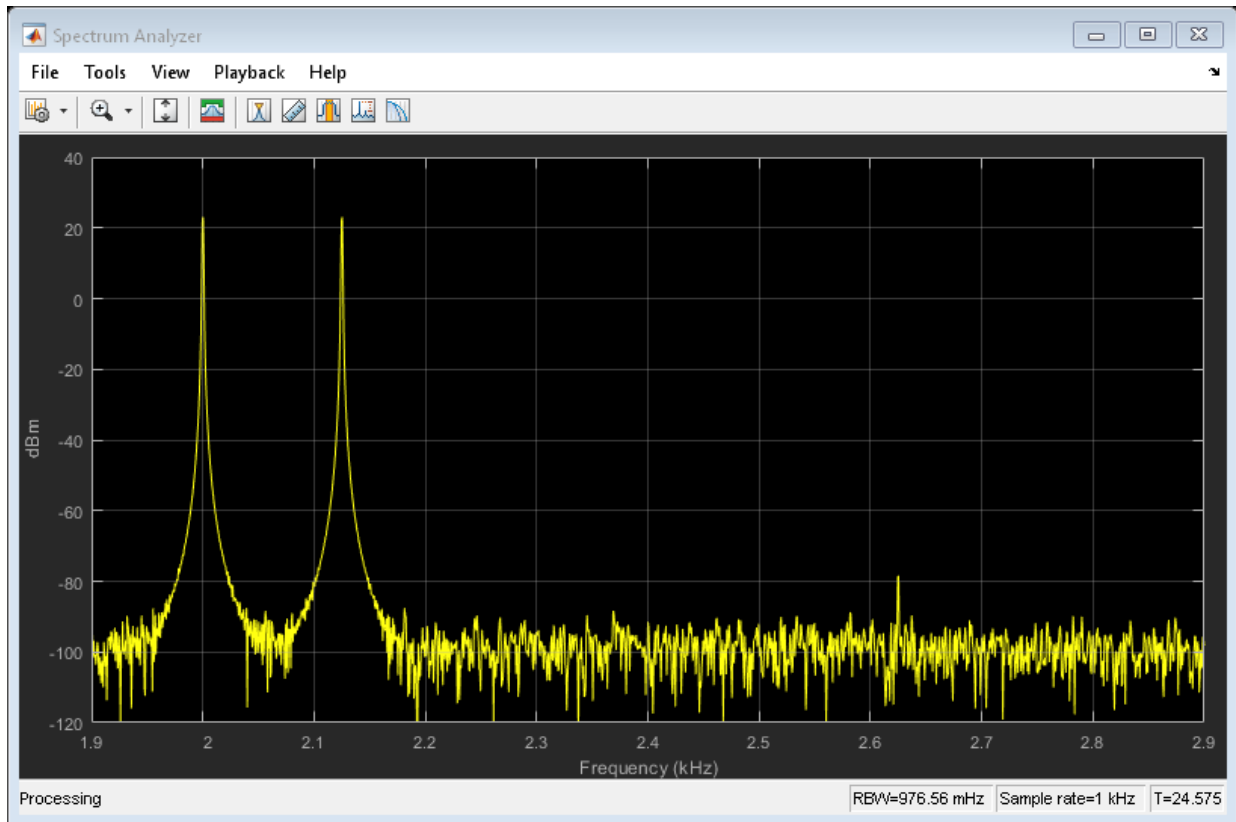

```
        TransitionWidth: 100
MinimizeComplexCoefficients: true
        SampleRate: 48000
```

Configure the spectrum analyzer to show the bandwidth of interest, [-1900 2900] Hz.

```
release(sa)
sa.FrequencyOffset = 2400;
```

Stream in the data and filter the signal.

```
for index = 1:1000
    x = sum(sin(),2) + 1e-4 * randn(FrameLength,1);
    z = bpdecim(x);
    sa(z);
end
```

The tones at 2000 Hz and 2125 Hz are passed through the decimator, while the tone at 1625 Hz is filtered out.

## wdf2allpass

Wave Digital Filter to allpass coefficient transformation

### Syntax

```
a = wdf2allpass(w)
A = wdf2allpass(W)
```

### Description

`a = wdf2allpass(w)` accepts a vector of transformed real allpass coefficients, `w`, and returns the conventional allpass polynomial version `a`. `w` is used by allpass filter objects such as `dsp.AllpassFilter`, and `dsp.CoupledAllpassFilter`, with `Structure` set to 'Wave Digital Filter'.

`A = wdf2allpass(W)` accepts the cell array of transformed allpass coefficient vectors `W`. Each cell of `W` contains the transformed real coefficients of a section of a cascade allpass filter. The output `A` is also a cell array, and each cell of `A` contains the conventional polynomial version of the corresponding cell of `W`. `W` is used by allpass filter objects such as `dsp.AllpassFilter` and `dsp.CoupledAllpassFilter`, with `Structure` set to 'Wave Digital Filter'. Every cell of `W` must contain a real vector of length 1, 2, or 4. When the length is 4, the second and fourth components must both be zero. `W` can be a row or column vector of cells while `A` is always returned as column.

### Examples

#### Convert Wave Digital Filter Coefficients to Allpass Polynomial Coefficients

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a second order allpass filter with wave digital filter coefficients `w = [0.5 0]`. Convert these coefficients into polynomial form using `wdf2allpass`. Assign the

polynomial coefficients to an allpass filter using the 'Minimum multiplier' structure. Pass a random input to both these filters and compare the outputs.

```
w = [0.5 0];  
allpasswdf = dsp.AllpassFilter('Structure', 'Wave Digital Filter',...  
    'WDFCoefficients', w);  
a = wdf2allpass(w);  
allpass = dsp.AllpassFilter('AllpassCoefficients', a);  
in = randn(512, 1);  
outputallpasswdf = allpasswdf(in);  
outputallpass = allpass(in);  
plot(outputallpasswdf-outputallpass);
```

The difference between the two outputs is very small.

## Input Arguments

### **w** — Transformed Wave Digital Filter allpass coefficients

scalar | vector of real numbers

Numeric vector of transformed Wave Digital Filter allpass coefficients, specified as a real number. *w* can have only length equal to 1, 2, and 4. When the length is 4, the second and fourth components must both be zero. *w* can be a row or a column vector.

Example: `[0.3, -0.2]`

Data Types: `double` | `single`

### **W** — Transformed Wave Digital Filter allpass coefficients

scalar cell | vector of cells

Cascade of allpass filter coefficients in transformed Wave Digital Filter form, specified as a cell vector. Every cell of *W* must contain a real vector of length 1, 2, or 4. When the length is 4, the second and fourth components must both be zero. *W* can be a row or a column vector of cells.

Example: `{[0.3, -0.2];0.5}`

## Output Arguments

### **a** — allpass filter coefficients

vector of real numbers

Numeric vector of polynomial allpass coefficients, determined as a numeric row vector.

Data Types: `double` | `single`

### **A** — allpass filter coefficients

vector cell array

Cascade of allpass filter coefficient, determined as a column of cells, each containing a vector of length 1, 2, or 4.

Example: `{0.3 5.0 0.2}`

Data Types: `double` | `single`

## Algorithms

wdf2allpass provides the inverse operation of allpass2wdf, by transforming the transformed cascade of allpass coefficients  $W$  into their conventional polynomial representation  $A$ . Please refer to the reference page for allpass2wdf for more details about the two representations.

$W$  defines a multisection allpass filter, and wdf2allpass applies separately to each section, with the same transformation used in the single-section case. In this case, the numeric coefficients vector  $w$  can have order 1, 2, or 4.

The relations between the vector of section coefficients  $a$  and  $w$  respectively depend on the order, as follows:

*for order 1:*

$$a_1 = w_1$$

*for order 2:*

$$a_1 = w_2(1 + w_1)$$

$$a_2 = w_1$$

*for order 4:*

$$a_2 = w_3(1 + w_1)$$

$$a_4 = w_1$$

$$a_1 = a_3 = 0$$

## window

FIR filter using windowed impulse response

### Syntax

```
h = window(d,fcnhdl,fcncarg,'SystemObject',true)
h = window(d,win,'SystemObject',true)
```

### Description

`h = window(d,fcnhdl,fcncarg,'SystemObject',true)` designs a single-rate digital filter System object using the specifications in filter specification object `d`.

`fcnhdl` is a handle to a filter design function that returns a window vector, such as the `hamming` or `blackman` functions. `fcncarg` is an optional argument that returns a window. You pass the function to `window`.

`h = window(d,win,'SystemObject',true)` designs a filter using the vector you supply in `win`. The length of vector `win` must be the same as the impulse response of the filter, which is equal to the filter order plus one.

### Examples

#### Design a Nyquist Filter Using Kaiser Window

This example designs a filter using the two design techniques of specifying a function handle and passing a window vector as an input argument.

Use a window vector provided by the `kaiser` window function to design a Nyquist filter. The window length must be the filter order plus one.

```
d = fdesign.nyquist(5,'n',150);
% Kaiser window with beta parameter 2.5
```

```
nyqFilter = window(d, 'window', kaiser(151, 2.5), 'SystemObject', true);  
fvtool(nyqFilter)
```

## zerophase

Zero-phase response of discrete-time filter System object

### Syntax

```
[zphase,w] = zerophase(sysobj)
[zphase,w] = zerophase(sysobj,n)
[zphase,w] = zerophase(sysobj,Name,Value)
zerophase(sysobj)
```

### Description

[zphase,w] = zerophase(sysobj) returns the instantaneous zero-phase response zphase of the filter System object, sysobj, based on the current filter coefficients. The vector w contains the frequencies (in radians) at which the function evaluates the zero-phase response.

The zero-phase response is evaluated at 8192 points equally spaced around the upper half of the unit circle.

[zphase,w] = zerophase(sysobj,n) returns the instantaneous zero-phase response of the filter System object and the corresponding frequencies at n points equally spaced around the upper half of the unit circle.

[zphase,w] = zerophase(sysobj,Name,Value) returns the zero-phase response with additional options specified by one or more Name,Value pair arguments.

zerophase(sysobj) displays the zero-phase response of the filter System object sysobj in the fvtool.

For information on more input options, refer to zerophase in Signal Processing Toolbox documentation.

## Input Arguments

### sysobj

Filter System object.

The following Filter System objects are supported by this analysis function:

<b>Filter System objects</b>
dsp.AllpassFilter
dsp.AllpoleFilter
dsp.BiquadFilter
dsp.Channelizer
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.CICDecimator
dsp.CICInterpolator
dsp.CoupledAllpassFilter
dsp.FarrowRateConverter
dsp.FilterCascade
dsp.FIRDecimator
dsp.FIRFilter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.FIRInterpolator
dsp.FIRRateConverter
dsp.HighpassFilter
dsp.IIRFilter
dsp.IIRHalfbandDecimator
dsp.IIRHalfbandInterpolator
dsp.LowpassFilter

Filter System objects
dsp.NotchPeakFilter
dsp.VariableBandwidthFIRFilter
dsp.VariableBandwidthIIRFilter

**n**

Number of samples. For an FIR filter where n is a power of two, the computation is done faster using FFTs.

**Default:** 8192

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### Arithmetic — Value type:

'double' | 'single' | 'fixed'

Specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

### Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.

System Object State	Coefficient Data Type	Rule
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataProperty property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataProperty property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Output Arguments

### zphase

Zero phase response vector of length  $n$ . If  $n$  is not specified, the function uses a default value of 8192.

### w

Frequency vector of length  $n$ , in radians/sample.  $w$  consists of  $n$  points equally spaced around the upper half of the unit circle (from 0 to  $\pi$  radians/sample). If  $n$  is not specified, the function uses a default value of 8192.

# zpkbpc2bpc

Zero-pole-gain complex bandpass frequency transformation

## Syntax

$[Z2, P2, K2, AllpassNum, AllpassDen] = zpkbpc2bpc(Z, P, K, Wo, Wt)$

## Description

$[Z2, P2, K2, AllpassNum, AllpassDen] = zpkbpc2bpc(Z, P, K, Wo, Wt)$  returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the complex bandpass prototype by applying a first-order complex bandpass to complex bandpass frequency transformation.

It also returns the numerator,  $AllpassNum$ , and the denominator,  $AllpassDen$ , of the allpass mapping filter. The original lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

This transformation effectively places two features of an original filter, located at frequencies  $W_{o1}$  and  $W_{o2}$ , at the required target frequency locations,  $W_{t1}$ , and  $W_{t2}$  respectively. It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . In most of the cases the features selected for the transformation are the band edges of the filter passbands. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

This transformation can also be used for transforming other types of filters; e.g., complex notch filters or resonators can be repositioned at two distinct desired frequencies at any place around the unit circle; e.g., in the adaptive system.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
```

Create a complex passband from 0.25 to 0.75:

```
[b, a] = iirlp2bpc(b,a,0.5,[0.25,0.75]);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpkbpc2bpc(z,p,k,[0.25, 0.75],[-0.75, -0.25]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Comparing the filters in FVTool shows the example results. Use the features in FVTool to check the filter coefficients, or other filter analyses.

## Arguments

Variable	Description
$Z$	Zeros of the prototype lowpass filter
$P$	Poles of the prototype lowpass filter
$K$	Gain factor of the prototype lowpass filter
$W_0$	Frequency value to be transformed from the prototype filter
$W_t$	Desired frequency location in the transformed target filter
$Z_2$	Zeros of the target filter
$P_2$	Poles of the target filter
$K_2$	Gain factor of the target filter
$AllpassNum$	Numerator of the mapping filter
$AllpassDen$	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

## See Also

`allpassbpc2bpc` | `iirbpc2bpc` | `zpkftransf`

**Introduced in R2011a**

## zpkfttransf

Zero-pole-gain frequency transformation

### Syntax

```
[Z2,P2,K2] = zpkfttransf(Z,P,K,AllpassNum,AllpassDen)
```

### Description

`[Z2,P2,K2] = zpkfttransf(Z,P,K,AllpassNum,AllpassDen)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the transformed lowpass digital filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ . If `AllpassDen` is not specified it will default to 1. If neither `AllpassNum` nor `AllpassDen` is specified, then the function returns the input filter.

### Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);  
[AlpNum, AlpDen] = allpasslp2lp(0.5, 0.25);  
[z2, p2, k2] = zpkfttransf(roots(b),roots(a),b(1),AlpNum,AlpDen);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

After transforming the filter, you get the response shown in the figure, where the passband has been shifted towards zero.

## Arguments

Variable	Description
$Z$	Zeros of the prototype lowpass filter
$P$	Poles of the prototype lowpass filter
$K$	Gain factor of the prototype lowpass filter
$FTFNum$	Numerator of the mapping filter
$FTFDen$	Denominator of the mapping filter
$Z2$	Zeros of the target filter
$P2$	Poles of the target filter
$K2$	Gain factor of the target filter

## zpklp2bp

Zero-pole-gain lowpass to bandpass frequency transformation

### Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bp(Z,P,K,Wo,Wt)
```

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bp(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying a second-order real lowpass to real bandpass frequency mapping.

It also returns the numerator, `AllpassNum`, and the denominator `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . This transformation implements the "DC Mobility," which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of  $W_t$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Real lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be easily doubled and positioned at two distinct, desired frequencies.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[B,A] = ellip(3,0.1,30,0.409);
Z = roots(B);
P = roots(A);
K = B(1);
[Z2,P2,K2] = zpklp2bp(Z,P,K, 0.5, [0.2 0.3]);
hfvtool(B,A,K2*poly(Z2),poly(P2));
legend(hfvtool,'Prototype Lowpass Filter', 'Bandpass Filter');
```

## Arguments

Variable	Description
$Z$	Zeros of the prototype lowpass filter
$P$	Poles of the prototype lowpass filter

Variable	Description
$K$	Gain factor of the prototype lowpass filter
$W_o$	Frequency value to be transformed from the prototype filter
$W_t$	Desired frequency location in the transformed target filter
$Z_2$	Zeros of the target filter
$P_2$	Poles of the target filter
$K_2$	Gain factor of the target filter
$AllpassNum$	Numerator of the mapping filter
$AllpassDen$	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## zpklp2bpc

Zero-pole-gain lowpass to complex bandpass frequency transformation

### Syntax

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bpc(Z,P,K,Wo,Wt)`

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bpc(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to complex bandpass frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/

resonators. This transformation can be used for designing bandpass filters for radio receivers from the high-quality prototype lowpass filter.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2bpc(z, p, k, 0.5, [0.2 0.3]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

## Arguments

Variable	Description
<i>Z</i>	Zeros of the prototype lowpass filter
<i>P</i>	Poles of the prototype lowpass filter
<i>K</i>	Gain factor of the prototype lowpass filter
<i>Wo</i>	Frequency value to be transformed from the prototype filter. It should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
<i>Wt</i>	Desired frequency locations in the transformed target filter. They should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
<i>Z2</i>	Zeros of the target filter
<i>P2</i>	Poles of the target filter
<i>K2</i>	Gain factor of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

## zpklp2bs

Zero-pole-gain lowpass to bandstop frequency transformation

### Syntax

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bs(Z,P,K,Wo,Wt)`

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bs(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying a second-order real lowpass to real bandstop frequency mapping.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . This transformation implements the "Nyquist Mobility," which means that the DC feature stays at DC, but the Nyquist feature moves to a location dependent on the selection of  $W_o$  and  $W_t$ s.

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . After the transformation feature  $F_2$  will precede  $F_1$  in the target filter. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);  
z = roots(b);  
p = roots(a);  
k = b(1);  
[z2,p2,k2] = zpklp2bs(z, p, k, 0.5, [0.2 0.3]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

## Arguments

Variable	Description
<i>Z</i>	Zeros of the prototype lowpass filter
<i>P</i>	Poles of the prototype lowpass filter
<i>K</i>	Gain factor of the prototype lowpass filter
<i>Wo</i>	Frequency value to be transformed from the prototype filter
<i>Wt</i>	Desired frequency location in the transformed target filter
<i>Z2</i>	Zeros of the target filter
<i>P2</i>	Poles of the target filter
<i>K2</i>	Gain factor of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## zpklp2bsc

Zero-pole-gain lowpass to complex bandstop frequency transformation

### Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bsc(Z,P,K,Wo,Wt)
```

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bsc(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to complex bandstop frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . Additionally the transformation swaps passbands with stopbands in the target filter.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct

desired frequencies at any place around the unit circle forming a pair of complex notches/resonators.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2bsc(z, p, k, 0.5, [0.2, 0.3]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

## Arguments

Variable	Description
<i>Z</i>	Zeros of the prototype lowpass filter
<i>P</i>	Poles of the prototype lowpass filter
<i>K</i>	Gain factor of the prototype lowpass filter
<i>Wo</i>	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
<i>Wt</i>	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
<i>Z2</i>	Zeros of the target filter
<i>P2</i>	Poles of the target filter
<i>K2</i>	Gain factor of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

## zpklp2hp

Zero-pole-gain lowpass to highpass frequency transformation

### Syntax

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2hp(Z,P,K,Wo,Wt)`

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2hp(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to real highpass frequency mapping. This transformation effectively places one feature of an original filter, located at frequency  $W_o$ , at the required target frequency location,  $W_t$ , at the same time rotating the whole frequency response by half of the sampling frequency. Result is that the DC and Nyquist features swap places.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and the gain factor,  $K$ .

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . After the transformation feature  $F_2$  will precede  $F_1$  in the target filter. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to highpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, or the deep minimum in the stopband, or other ones.

Lowpass to highpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way without designing them again.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);  
z = roots(b);  
p = roots(a);  
k = b(1);  
[z2,p2,k2] = zpklp2hp(z, p, k, 0.5, 0.25);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

## Arguments

Variable	Description
<i>Z</i>	Zeros of the prototype lowpass filter
<i>P</i>	Poles of the prototype lowpass filter
<i>K</i>	Gain factor of the prototype lowpass filter
<i>W0</i>	Frequency value to be transformed from the prototype filter
<i>Wt</i>	Desired frequency location in the transformed target filter
<i>Z2</i>	Zeros of the target filter
<i>P2</i>	Poles of the target filter
<i>K2</i>	Gain factor of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## zpklp2lp

Zero-pole-gain lowpass to lowpass frequency transformation

### Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2lp(Z,P,K,Wo,Wt)
```

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2lp(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to real lowpass frequency mapping. This transformation effectively places one feature of an original filter, located at frequency  $W_o$ , at the required target frequency location,  $W_t$ .

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to lowpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to lowpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way without designing them again.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2lp(z, p, k, 0.5, 0.25);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Using `zpklp2lp` creates the desired half band IIR filter with the transformed features that you specify in the transformation function. This figure shows the results.

## Arguments

Variable	Description
$Z$	Zeros of the prototype lowpass filter
$P$	Poles of the prototype lowpass filter
$K$	Gain factor of the prototype lowpass filter
$\omega_0$	Frequency value to be transformed from the prototype filter
$\omega_t$	Desired frequency location in the transformed target filter
$Z_2$	Zeros of the target filter
$P_2$	Poles of the target filter
$K_2$	Gain factor of the target filter
$AllpassNum$	Numerator of the mapping filter
$AllpassDen$	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## zpklp2mb

Zero-pole-gain lowpass to M-band frequency transformation

### Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2mb(Z,P,K,Wo,Wt)
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2mb(Z,P,K,Wo,Wt,Pass)
```

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2mb(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying an Mth-order real lowpass to real multibandpass frequency mapping. By default the DC feature is kept at its original location.

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2mb(Z,P,K,Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility". In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is allowed to move.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

This transformation effectively places one feature of an original filter, located at frequency  $W_o$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);  
z = roots(b);  
p = roots(a);  
k = b(1);  
[z1,p1,k1] = zpklp2mb(z, p, k, 0.5, [2 4 6 8]/10, 'pass');  
[z2,p2,k2] = zpklp2mb(z, p, k, 0.5, [2 4 6 8]/10, 'stop');
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k1*poly(z1), poly(p1), k2*poly(z2), poly(p2));
```

The resulting multiband filter that replicates features from the prototype appears in the figure shown. Note the accuracy of the replication process.

## Arguments

Variable	Description
$Z$	Zeros of the prototype lowpass filter
$P$	Poles of the prototype lowpass filter
$K$	Gain factor of the prototype lowpass filter
$\omega_0$	Frequency value to be transformed from the prototype filter
$\omega_t$	Desired frequency location in the transformed target filter
$Pass$	Choice ( ' pass ' / ' stop ' ) of passband/stopband at DC, ' pass ' being the default
$Z_2$	Zeros of the target filter
$P_2$	Poles of the target filter
$K_2$	Gain factor of the target filter

Variable	Description
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## zpklp2mbc

Zero-pole-gain lowpass to complex M-band frequency transformation

### Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklpmbc(Z,P,K,Wo,Wt)
```

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklpmbc(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying an Mth-order real lowpass to complex multibandpass frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

This transformation effectively places one feature of an original filter, located at frequency  $W_o$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature, for example, the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

This transformation can also be used for transforming other types of filters; e.g., to replicate notch filters and resonators at any required location.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z1,p1,k1] = zpklp2mbc(z, p, k, 0.5, [2 4 6 8]/10);
[z2,p2,k2] = zpklp2mbc(z, p, k, 0.5, [2 4 6 8]/10);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k1*poly(z1), poly(p1), k2*poly(z2), poly(p2));
```

You could review the coefficients to compare the filters, but the graphical comparison shown here is quicker and easier.

However, looking at the coefficients in FVTool shows the complex nature desired.

## Arguments

Variable	Description
<i>Z</i>	Zeros of the prototype lowpass filter
<i>P</i>	Poles of the prototype lowpass filter
<i>K</i>	Gain factor of the prototype lowpass filter
<i>Wo</i>	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
<i>Wt</i>	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
<i>Z2</i>	Zeros of the target filter
<i>P2</i>	Poles of the target filter
<i>K2</i>	Gain factor of the target filter
<i>AllpassNum</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

## See Also

## zpklp2xc

Zero-pole-gain lowpass to complex N-point frequency transformation

### Syntax

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xc(Z,P,K,Wo,Wt)`

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xc(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying an Nth-order real lowpass to complex multipoint frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

Parameter  $N$  also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places  $N$  features of an original filter, located at frequencies  $W_{o1}, \dots, W_{oN}$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation. For DC mobility feature  $F_2$  will precede  $F_1$  after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating  $N$  bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2xc(z, p, k, [-0.5 0.5], [-0.25 0.25]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Plotting the filters on the same axes lets you compare the results graphically, shown here.

## Arguments

Variable	Description
$Z$	Zeros of the prototype lowpass filter
$P$	Poles of the prototype lowpass filter
$K$	Gain factor of the prototype lowpass filter
$wo$	Frequency values to be transformed from the prototype filter. They should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
$Wt$	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
$Z2$	Zeros of the target filter
$P2$	Poles of the target filter
$K2$	Gain factor of the target filter
$AllpassNum$	Numerator of the mapping filter
$AllpassDen$	Denominator of the mapping filter

## zpklp2xn

Zero-pole-gain lowpass to N-point frequency transformation

### Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xn(Z,P,K,Wo,Wt)
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xn(Z,P,K,Wo,Wt,Pass)
```

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xn(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying an Nth-order real lowpass to real multipoint frequency transformation, where N is the number of features being mapped. By default the DC feature is kept at its original location.

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xn(Z,P,K,Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility". In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is allowed to move.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

Parameter N also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places N features of an original filter, located at frequencies  $W_{01}, \dots, W_{0N}$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the

distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation. For DC mobility feature  $F_2$  will precede  $F_1$  after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating  $N$  bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2xn(z, p, k, [-0.5 0.5], [0 0.25], 'pass');
hfvt = fvtool(b, a, k2*poly(z2), poly(p2));
legend(hfvt, 'Original Filter', 'Half-band Filter');
```

As demonstrated by the figure, the target filter has the desired response shape and values replicated from the prototype.

## Arguments

Variable	Description
$Z$	Zeros of the prototype lowpass filter
$P$	Poles of the prototype lowpass filter
$K$	Gain factor of the prototype lowpass filter
$\omega_0$	Frequency value to be transformed from the prototype filter
$\omega_t$	Desired frequency location in the transformed target filter

<b>Variable</b>	<b>Description</b>
<i>Pass</i>	Choice ('pass' / 'stop') of passband/stopband at DC, 'pass' being the default
<i>Z2</i>	Zeros of the target filter
<i>P2</i>	Poles of the target filter
<i>K2</i>	Gain factor of the target filter
<i>AllpassDen</i>	Numerator of the mapping filter
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

# zpkrateup

Zero-pole-gain complex bandpass frequency transformation

## Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpkrateup(Z,P,K,N)
```

## Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpkrateup(Z,P,K,N)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter being transformed from any prototype by applying an  $N$ th-order rateup frequency transformation, where  $N$  is the upsample ratio. Transformation creates  $N$  equal replicas of the prototype filter frequency response.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The original lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
% Upsample the prototype filter 4 times
[z2,p2,k2] = zpkrateup(z, p, k, 4);
% Compare prototype filter with target filter
fvtool(b, a, k2*poly(z2), poly(p2));
```

## Arguments

Variable	Description
$Z$	Zeros of the prototype lowpass filter
$P$	Poles of the prototype lowpass filter
$K$	Gain factor of the prototype lowpass filter
$N$	Integer upsampling ratio
$Z2$	Zeros of the target filter
$P2$	Poles of the target filter
$K2$	Gain factor of the target filter
$AllpassNum$	Numerator of the mapping filter
$AllpassDen$	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

# zpkshift

Zero-pole-gain real shift frequency transformation

## Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpkshift(Z,P,K,Wo,Wt)
```

## Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpkshift(Z,P,K,Wo,Wt)` returns the zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the zeros, poles, and gain factor of real lowpass prototype by applying a second-order real shift frequency mapping. It also returns the numerator,  $AllpassNum$ , and the denominator,  $AllpassDen$  of the allpass mapping filter.

This transformation places one selected feature of an original filter, located at frequency  $W_o$ , at the required target frequency location,  $W_t$ . This transformation implements the "DC Mobility," which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of  $W_o$  and  $W_t$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

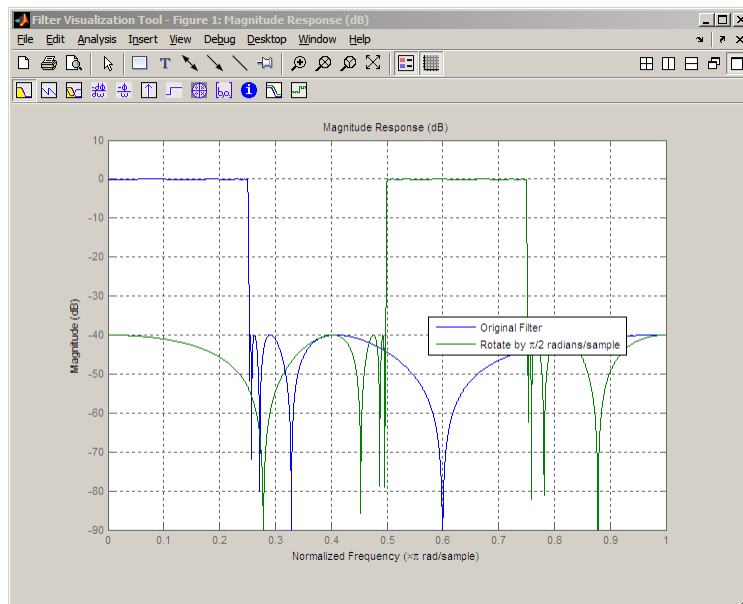

Choice of the feature subject to the real shift transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way without the need to design them again.

## Examples

Rotate frequency response by  $\pi/2$  radians/sample:

```
[B,A] = ellip(10,0.1,40,0.25);
% Elliptic lowpass filter with passband frequency 0.25*pi rad/sample
Z = roots(B); % get roots of numerator polynomial- filter zeros
P = roots(A); % get roots of denominator polynomial- filter poles
K = B(1);
[Z2,P2,K2] = zpkshtft(Z,P,K,0.25,0.75); % shift by 0.25*pi rad/sample
Num = poly(Z2);
Den = poly(P2);
hfvf = fvtool(B,A,K2*Num,Den);
legend(hfvf, 'Original Filter', 'Rotate by \pi/2 radians/sample');
axis([0 1 -90 10]);
```

## zpkshifc

Zero-pole-gain complex shift frequency transformation

### Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpkshifc(Z,P,K,Wo,Wt)
[Num,Den,AllpassNum,AllpassDen] = zpkshifc(Z,P,K,0,0.5)
[Num,Den,AllpassNum,AllpassDen] = zpkshifc(Z,P,K,0,-0.5)
```

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpkshifc(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying a first-order complex frequency shift transformation. This transformation rotates all the features of an original filter by the same amount specified by the location of the selected feature of the prototype filter, originally at  $W_o$ , placed at  $W_t$  in the target filter.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and the gain factor,  $K$ .

`[Num,Den,AllpassNum,AllpassDen] = zpkshifc(Z,P,K,0,0.5)` performs the Hilbert transformation, i.e. a 90 degree counterclockwise rotation of an original filter in the frequency domain.

`[Num,Den,AllpassNum,AllpassDen] = zpkshifc(Z,P,K,0,-0.5)` performs the inverse Hilbert transformation, i.e. a 90 degree clockwise rotation of an original filter in the frequency domain.

### Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);  
z = roots(b);  
p = roots(a);  
k = b(1);
```

## Rotation by $\pi/4$ Radians/Sample

Rotation by -0.25:

```
[z2,p2,k2] = zpkshftc(z, p, k, 0.5, 0.25);  
hfvt = fvtool(b,a,k2*poly(z2),poly(p2));
```

## Rotation by $\pi/2$ Radians/Sample

```
[z3,p3,k3] = zpkshftc(z, p, k, 0, 0.5);  
addfilter(hfvt,k3*poly(z3),poly(p3));  
legend(hfvt,'Original Filter','Rotation by  $-\pi/4$  radians/sample',...  
        'Rotation by  $\pi/2$  radians/sample');
```

## Rotation by $-\pi/2$ Radians/Sample

```
[z2,p2,k2] = zpkshftc(z, p, k, 0.5, -0.5);  
fvtool(b, a, k2*poly(z2), poly(p2));
```

## Result of Example 1

After performing the rotation, the resulting filter shows the features desired.

## Result of Example 2

Similar to the first example, performing the Hilbert transformation generates the desired target filter, shown here.

### Result of Example 3

Finally, using the inverse Hilbert transformation creates yet a third filter, as the figure shows.

## Arguments

Variable	Description
$Z$	Zeros of the prototype lowpass filter
$P$	Poles of the prototype lowpass filter
$K$	Gain factor of the prototype lowpass filter
$w_0$	Frequency value to be transformed from the prototype filter
$w_t$	Desired frequency location in the transformed target filter
$Z_2$	Zeros of the target filter
$P_2$	Poles of the target filter
$K_2$	Gain factor of the target filter
$AllpassDen$	Numerator of the mapping filter

Variable	Description
<i>AllpassDen</i>	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

## zplane

Z-plane zero-pole plot for discrete-time filter System object

### Syntax

```
zplane(filt)
zplane(filt,Name,Value)
[zLoc,pLoc,tLoc] = zplane(filt)
```

### Description

`zplane(filt)` plots the zeros and poles of the filter System object, `filt`, with the unit circle for reference in the filter visualization tool (`fvtool`). Each zero is represented with a 'o' and each pole with a 'x' on the plot. Multiple zeros and poles are indicated by the multiplicity number shown to the upper right of the zero or pole.

When you call the `step` method on the filter System object with a fixed-point input, the filter becomes a quantized fixed-point filter, `filtQuant`. When `filtQuant` is a quantized filter, `zplane(filtQuant)` plots the poles and zeros of the quantized and unquantized filters. The symbols `o` and `+` represent the zeros and poles of the quantized filter `filtQuant`. The plot includes the unit circle for reference.

`zplane(filt,Name,Value)` returns the pole zero plot with additional options specified by one or more `Name,Value` pair arguments.

`[zLoc,pLoc,tLoc] = zplane(filt)` returns the vector of locations for zeros, poles, and text objects. `zLoc` is the vector of locations of zeros, `pLoc` is the vector of locations of poles, and `tLoc` is the vector of locations of the axes/unit circle line and text objects which are present when there are multiple zeros or poles. In case there are no zeros or poles, `zLoc` or `pLoc` is set to the empty matrix `[]`.

## Input Arguments

### **filt**

A filter System object.

The following Filter System objects are supported by this analysis function:

<b>Filter System objects</b>
dsp.AllpassFilter
dsp.AllpoleFilter
dsp.BiquadFilter
dsp.Channelizer
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.CICDecimator
dsp.CICInterpolator
dsp.CoupledAllpassFilter
dsp.FarrowRateConverter
dsp.FilterCascade
dsp.FIRDecimator
dsp.FIRFilter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.FIRInterpolator
dsp.FIRRateConverter
dsp.HighpassFilter
dsp.IIRFilter
dsp.IIRHalfbandDecimator
dsp.IIRHalfbandInterpolator
dsp.LowpassFilter

Filter System objects
dsp.NotchPeakFilter
dsp.VariableBandwidthFIRFilter
dsp.VariableBandwidthIIRFilter

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Arithmetic — Value types:

'double' | 'single' | 'fixed'

When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

### Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the <code>CustomCoefficientsDataType</code> property.

System Object State	Coefficient Data Type	Rule
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsData property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## Output Arguments

### **zLoc**

Vector of locations of zeros.

### **pLoc**

Vector of locations of poles.

### **tLoc**

Vector of locations of axes/unit circle line and text objects.

## Examples

### Plot the Poles and Zeros of a Fourth-Order Filter

Create a Fourth-order IIR digital filter with a cutoff frequency of 0.6. Plot the poles and zeros of this filter.

```
[b,a] = ellip(4,.5,20,.6);  
zplane(b,a);
```

Quantize the filter by passing a fixed-point input through the filter algorithm. Plot the quantized and unquantized poles and zeros associated with this filter.

```
iirFilt = dsp.IIRFilter('Numerator',b,'Denominator',a);  
in = fi(randn(15,6),1,15,3);
```

```
out = iirFilt(in);  
zplane(iirFilt);
```

## Fixed-Point Filter Properties

### In this section...

“Overview of Fixed-Point Filters” on page 6-2

“Fixed-Point Objects and Filters” on page 6-2

“Summary — Fixed-Point Filter Properties” on page 6-4

“Property Details for Fixed-Point Filters” on page 6-17

### Overview of Fixed-Point Filters

There is a distinction between fixed-point filters and quantized filters — quantized filters represent a superset that includes fixed-point filters.

When `dfilt` objects have their `Arithmetic` property set to `single` or `fixed`, they are quantized filters. However, after you set the `Arithmetic` property to `fixed`, the resulting filter is both quantized and fixed-point. Fixed-point filters perform arithmetic operations without allowing the binary point to move in response to the calculation — hence the name fixed-point. You can find out more about fixed-point arithmetic in your Fixed-Point Designer documentation or from the Help system.

With the `Arithmetic` property set to `single`, meaning the filter uses single-precision floating-point arithmetic, the filter allows the binary point to move during mathematical operations, such as sums or products. Therefore these filters cannot be considered fixed-point filters. But they are quantized filters.

The following sections present the properties for fixed-point filters, which includes all the properties for double-precision and single-precision floating-point filters as well.

### Fixed-Point Objects and Filters

Fixed-point filters depend in part on fixed-point objects from Fixed-Point Designer software. You can see this when you display a fixed-point filter at the command prompt.

```
hd=dfilt.df2t
```

```
hd =
```

```
    FilterStructure: 'Direct-Form II Transposed'
```

```

        Arithmetic: 'double'
        Numerator: 1
        Denominator: 1
    PersistentMemory: false
        States: [0x1 double]

set(hd,'arithmetic','fixed')
hd

hd =

    FilterStructure: 'Direct-Form II Transposed'
        Arithmetic: 'fixed'
        Numerator: 1
        Denominator: 1
    PersistentMemory: false
        States: [1x1 embedded.fi]

    CoeffWordLength: 16
        CoeffAutoScale: true
        Signed: true

    InputWordLength: 16
    InputFracLength: 15

    OutputWordLength: 16
    OutputFracLength: 15

    StateWordLength: 16
        StateAutoScale: true

        ProductMode: 'FullPrecision'

    AccumWordLength: 40
        CastBeforeSum: true

        RoundMode: 'convergent'
        OverflowMode: 'wrap'

```

Look at the States property, shown here

```
States: [1x1 embedded.fi]
```

The notation embedded `.fi` indicates that the states are being represented by fixed-point objects, usually called `fi` objects. If you take a closer look at the property `States`, you see how the properties of the `fi` object represent the values for the filter states.

```
hd.states
```

```
ans =
```

```
[]
```

```
        DataType: Fixed
        Scaling: BinaryPoint
        Signed: true
        WordLength: 16
        FractionLength: 15

        RoundMode: round
        OverflowMode: saturate
        ProductMode: FullPrecision
MaxProductWordLength: 128
        SumMode: FullPrecision
MaxSumWordLength: 128
        CastBeforeSum: true
```

To learn more about `fi` objects (fixed-point objects) in general, refer to your Fixed-Point Designer documentation.

As inputs (data to be filtered), fixed-point filters accept both regular double-precision values and `fi` objects. Which you use depends on your needs. How your filter responds to the input data is determined by the settings of the filter properties, discussed in the next few sections.

### Summary — Fixed-Point Filter Properties

Discrete-time filters in this toolbox use objects that perform the filtering and configuration of the filter. As objects, they include properties and methods that are often referred to as functions — not strictly the same as MATLAB functions but mostly so) to provide filtering capability. In discrete-time filters, or `dfilt` objects, many of the properties are dynamic, meaning they become available depending on the settings of other properties in the `dfilt` object or filter.

## Dynamic Properties

When you use a `dfilt.structure` function to create a filter, MATLAB displays the filter properties in the command window in return (unless you end the command with a semicolon which suppresses the output display). Generally you see six or seven properties, ranging from the property `FilterStructure` to `PersistentMemory`. These first properties are always present in the filter. One of the most important properties is `Arithmetic`. The `Arithmetic` property controls all of the dynamic properties for a filter.

Dynamic properties become available when you change another property in the filter. For example, when you change the `Arithmetic` property value to `fixed`, the display now shows many more properties for the filter, all of them considered dynamic. Here is an example that uses a direct form II filter. First create the default filter:

```
hd=dfilt.df2
```

```
hd =
```

```

    FilterStructure: 'Direct-Form II'
      Arithmetic: 'double'
        Numerator: 1
        Denominator: 1
  PersistentMemory: false
           States: [0x1 double]
```

With the filter `hd` in the workspace, convert the arithmetic to fixed-point. Do this by setting the property `Arithmetic` to `fixed`. Notice the display. Instead of a few properties, the filter now has many more, each one related to a particular part of the filter and its operation. Each of the now-visible properties is dynamic.

```
hd.arithmetic='fixed'
```

```
hd =
```

```

    FilterStructure: 'Direct-Form II'
      Arithmetic: 'fixed'
        Numerator: 1
        Denominator: 1
  PersistentMemory: false
           States: [1x1 embedded.fi]

    CoeffWordLength: 16
      CoeffAutoScale: true
           Signed: true
```

```
InputWordLength: 16
InputFracLength: 15

OutputWordLength: 16
OutputMode: 'AvoidOverflow'

StateWordLength: 16
StateFracLength: 15

ProductMode: 'FullPrecision'

AccumWordLength: 40
CastBeforeSum: true

RoundMode: 'convergent'
OverflowMode: 'wrap'
```

Even this list of properties is not yet complete. Changing the value of other properties such as the `ProductMode` or `CoeffAutoScale` properties may reveal even more properties that control how the filter works. Remember this feature about `dfilt` objects and dynamic properties as you review the rest of this section about properties of fixed-point filters.

An important distinction is you cannot change the value of a property unless you see the property listed in the default display for the filter. Entering the filter name at the MATLAB prompt generates the default property display for the named filter. Using `get(filtername)` does not generate the default display — it lists all of the filter properties, both those that you can change and those that are not available yet.

The following table summarizes the properties, static and dynamic, of fixed-point filters and provides a brief description of each. Full descriptions of each property, in alphabetical order, follow the table.

Property Name	Valid Values [Default Value]	Brief Description
AccumFracLength	Any positive or negative integer number of bits [29]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — <code>DenAccumFracLength</code> and <code>NumAccumFracLength</code> — that let you set the precision for numerator and denominator operations separately.
AccumWordLength	Any positive integer number of bits [40]	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	[Double], single, fixed	Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.
CastBeforeSum	[True] or false	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	[True] or false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> and <code>DenFracLength</code> properties to specify the precision used.
CoeffFracLength	Any positive or negative integer number of bits [14]	Set the fraction length the filter uses to interpret coefficients. <code>CoeffFracLength</code> is not available until you set <code>CoeffAutoScale</code> to <code>false</code> . Scalar filters include this property.
CoeffWordLength	Any positive integer number of bits [16]	Specifies the word length to apply to filter coefficients.

<b>Property Name</b>	<b>Valid Values [Default Value]</b>	<b>Brief Description</b>
DenAccumFracLength	Any positive or negative integer number of bits [29]	Specifies how the filter algorithm interprets the results of addition operations involving denominator coefficients.
DenFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length the filter uses to interpret denominator coefficients. <b>DenFracLength</b> is always available, but it is read-only until you set <b>CoeffAutoScale</b> to <code>false</code> .
Denominator	Any filter coefficient value [1]	Holds the denominator coefficients for IIR filters.
DenProdFracLength	Any positive or negative integer number of bits [29]	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value after you set <b>ProductMode</b> to <code>SpecifyPrecision</code> .
DenStateFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length used to interpret the states associated with denominator coefficients in the filter.
FracDelay	Any decimal value between 0 and 1 samples	Specifies the fractional delay provided by the filter, in decimal fractions of a sample.
FDAutoScale	[True] or false	Specifies whether the filter automatically chooses the proper scaling to represent the fractional delay value without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <b>FDWordLength</b> and <b>FDfracLength</b> properties to specify the data format applied.
FDfracLength	Any positive or negative integer number of bits [5]	Specifies the fraction length to represent the fractional delay.

Property Name	Valid Values [Default Value]	Brief Description
FDProdFracLength	Any positive or negative integer number of bits [34]	Specifies the fraction length to represent the result of multiplying the coefficients with the fractional delay.
FDProdWordLength	Any positive or negative integer number of bits [39]	Specifies the word length to represent result of multiplying the coefficients with the fractional delay.
FDWordLength	Any positive or negative integer number of bits [6]	Specifies the word length to represent the fractional delay.
DenStateWordLength	Any positive integer number of bits [16]	Specifies the word length used to represent the states associated with denominator coefficients in the filter.
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter sets the output word and fraction lengths, and the accumulator word and fraction lengths automatically to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision exposes the output and accumulator related properties so you can set your own word and fraction lengths for them.
FilterStructure	Not applicable.	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret data to be processed by the filter.
InputWordLength	Any positive integer number of bits [16]	Specifies the word length applied to represent input data.

<b>Property Name</b>	<b>Valid Values [Default Value]</b>	<b>Brief Description</b>
Ladder	Any ladder coefficients in double-precision data type [1]	latticearma filters include this property to store the ladder coefficients.
LadderAccumFracLength	Any positive or negative integer number of bits [29]	latticearma filters use this to define the fraction length applied to values output by the accumulator that stores the results of ladder computations.
LadderFracLength	Any positive or negative integer number of bits [14]	latticearma filters use ladder coefficients in the signal flow. This property determines the fraction length used to interpret the coefficients.
Lattice	Any lattice structure coefficients. No default value.	Stores the lattice coefficients for lattice-based filters.
LatticeAccumFracLength	Any positive or negative integer number of bits [29]	Specifies how the accumulator outputs the results of operations on the lattice coefficients.
LatticeFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length applied to the lattice coefficients.
MultiplicandFracLength	Any positive or negative integer number of bits [15]	Sets the fraction length for values used in product operations in the filter. Direct-form I transposed (df1t) filter structures include this property.
MultiplicandWordLength	Any positive integer number of bits [16]	Sets the word length applied to the values input to a multiply operation (the multiplicands). The filter structure df1t includes this property.
NumAccumFracLength	Any positive or negative integer number of bits [29]	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients.
Numerator	Any double-precision filter coefficients [1]	Holds the numerator coefficient values for the filter.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.

Property Name	Valid Values [Default Value]	Brief Description
NumProdFracLength	Any positive or negative integer number of bits [29]	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. You can change the property value after you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .
NumStateFracLength	Any positive or negative integer number of bits [15]	For IIR filters, this defines the fraction length applied to the numerator states of the filter. Specifies the fraction length used to interpret the states associated with numerator coefficients in the filter.
NumStateWordLength	Any positive integer number of bits [16]	For IIR filters, this defines the word length applied to the numerator states of the filter. Specifies the word length used to interpret the states associated with numerator coefficients in the filter.
OutputFracLength	Any positive or negative integer number of bits — [15] or [12] bits depending on the filter structure	Determines how the filter interprets the filtered data. You can change the value of <code>OutputFracLength</code> after you set <code>OutputMode</code> to <code>SpecifyPrecision</code> .
OutputMode	[ <code>AvoidOverflow</code> ], <code>BestPrecision</code> , <code>SpecifyPrecision</code>	Sets the mode the filter uses to scale the filtered input data. You have the following choices: <ul style="list-style-type: none"> <li>• <code>AvoidOverflow</code> — directs the filter to set the output data fraction length to avoid causing the data to overflow.</li> <li>• <code>BestPrecision</code> — directs the filter to set the output data fraction length to maximize the precision in the output data.</li> <li>• <code>SpecifyPrecision</code> — lets you set the fraction length used by the filtered data.</li> </ul>

Property Name	Valid Values [Default Value]	Brief Description
OutputWordLength	Any positive integer number of bits [16]	Determines the word length used for the filtered data.
OverflowMode	Saturate or [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <b>saturate</b> (limit the output to the largest positive or negative representable value) or <b>wrap</b> (set overflowing values to the nearest representable value using modular arithmetic. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductFracLength	Any positive or negative integer number of bits [29]	For the output from a product operation, this sets the fraction length used to interpret the numeric data. This property becomes writable (you can change the value) after you set <b>ProductMode</b> to <b>SpecifyPrecision</b> .
ProductMode	[FullPrecision], KeepLSB, KeepMSB, SpecifyPrecision	Determines how the filter handles the output of product operations. Choose from full precision ( <b>FullPrecision</b> ), or whether to keep the most significant bit ( <b>KeepMSB</b> ) or least significant bit ( <b>KeepLSB</b> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <b>ProductMode</b> to <b>SpecifyPrecision</b> .

<b>Property Name</b>	<b>Valid Values [Default Value]</b>	<b>Brief Description</b>
ProductWordLength	Any positive number of bits. Default is 16 or 32 depending on the filter structure	Specifies the word length to use for the results of multiplication operations. This property becomes writable (you can change the value) after you set ProductMode to SpecifyPrecision.
PersistentMemory	True or [false]	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. True is the default setting.

Property Name	Valid Values [Default Value]	Brief Description
RoundMode	[Convergent], ceil, fix, floor, nearest, round	<p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow – they maintain full precision.</p>
ScaleValueFracLength	Any positive or negative integer number of bits [29]	<p>Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Available only when you disable <code>CoeffAutoScale</code> by setting it to <code>false</code>.</p>
ScaleValues	[2 x 1 double] array with values of 1	<p>Stores the scaling values for sections in SOS filters.</p>

Property Name	Valid Values [Default Value]	Brief Description
Signed	[True] or false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
sosMatrix	[1 0 0 1 0 0]	Holds the filter coefficients as property values. Displays the matrix in the format [sections x coefficients/section datatype]. A [15x6 double] SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type double to represent the coefficients.
SectionInputAuto Scale	[True] or false	Specifies whether the filter automatically chooses the proper fraction length to prevent overflow by data entering a section of an SOS filter. Setting this property to false enables you to change the SectionInputFracLength property to specify the precision used. Available only for SOS filters.
SectionInputFrac Length	Any positive or negative integer number of bits [29]	Section values work with SOS filters. Setting this property controls how your filter interprets the section values between sections of the filter by setting the fraction length. This applies to data entering a section. Compare to SectionOutputFracLength. Available only when you disable SectionInputAutoScale by setting it to false.
SectionInputWord Length	Any positive or negative integer number of bits [29]	Sets the word length used to represent the data moving into a section of an SOS filter.

Property Name	Valid Values [Default Value]	Brief Description
SectionOutputAutoScale	[True] or false	Specifies whether the filter automatically chooses the proper fraction length to prevent overflow by data leaving a section of an SOS filter. Setting this property to <code>false</code> enables you to change the SectionOutputFracLength property to specify the precision used.
SectionOutputFracLength	Any positive or negative integer number of bits [29]	Section values work with SOS filters. Setting this property controls how your filter interprets the section values between sections of the filter by setting the fraction length. This applies to data leaving a section. Compare to SectionInputFracLength. Available after you disable SectionOutputAutoScale by setting it to <code>false</code> .
SectionOutputWordLength	Any positive or negative integer number of bits [32]	Sets the word length used to represent the data moving out of one section of an SOS filter.
StateFracLength	Any positive or negative integer number of bits [15]	Lets you set the fraction length applied to interpret the filter states.
States	[1x1 embedded <code>fi</code> ]	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. Notice that the states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to <code>filtstates</code> in your Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Any positive integer number of bits [16]	Sets the word length used to represent the filter states.

Property Name	Valid Values [Default Value]	Brief Description
TapSumFracLength	Any positive or negative integer number of bits [15]	Sets the fraction length used to represent the filter tap values in addition operations. This is available after you set TapSumMode to false. Symmetric and antisymmetric FIR filters include this property.
TapSumMode	FullPrecision, KeepLSB, [KeepMSB], SpecifyPrecision	Determines how the accumulator outputs stored that involve filter tap weights. Choose from full precision (FullPrecision) to prevent overflows, or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when outputting results from the accumulator. To let you set the precision (the fraction length) used by the output from the accumulator, set FilterInternals to SpecifyPrecision.  Symmetric and antisymmetric FIR filters include this property.
TapSumWordLength	Any positive number of bits [17]	Sets the word length used to represent the filter tap weights during addition. Symmetric and antisymmetric FIR filters include this property.

## Property Details for Fixed-Point Filters

When you create a fixed-point filter, you are creating a filter object (a `dfilt` object). In this manual, the terms filter, `dfilt` object, and filter object are used interchangeably. To filter data, you apply the filter object to your data set. The output of the operation is the data filtered by the filter and the filter property values.

Filter objects have properties to which you assign property values. You use these property values to assign various characteristics to the filters you create, including

- The type of arithmetic to use in filtering operations
- The structure of the filter used to implement the filter (not a property you can set or change — you select it by the `dfilt.structure` function you choose)
- The locations of quantizations and cast operations in the filter
- The data formats used in quantizing, casting, and filtering operations

Details of the properties associated with fixed-point filters are described in alphabetical order on the following pages.

### **AccumFracLength**

Except for state-space filters, all `dfilt` objects that use fixed arithmetic have this property that defines the fraction length applied to data in the accumulator. Combined with `AccumWordLength`, `AccumFracLength` helps fully specify how the accumulator outputs data after processing addition operations. As with all fraction length properties, `AccumFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers.

### **AccumWordLength**

You use `AccumWordLength` to define the data word length used in the accumulator. Set this property to a value that matches your intended hardware. For example, many digital signal processors use 40-bit accumulators, so set `AccumWordLength` to 40 in your fixed-point filter:

```
set(hq,'arithmetic','fixed');  
set(hq,'AccumWordLength',40);
```

Note that `AccumWordLength` only applies to filters whose `Arithmetic` property value is `fixed`.

### **Arithmetic**

Perhaps the most important property when you are working with `dfilt` objects, `Arithmetic` determines the type of arithmetic the filter uses, and the properties or quantizers that compose the fixed-point or quantized filter. You use strings to set the `Arithmetic` property value.

The next table shows the valid strings for the `Arithmetic` property. Following the table, each property string appears with more detailed information about what happens when you select the string as the value for `Arithmetic` in your `dfilt`.

Arithmetic Property String	Brief Description of Effect on the Filter
double	All filtering operations and coefficients use double-precision floating-point representations and math. When you use <code>dfilt.structure</code> to create a filter object, <code>double</code> is the default value for the <code>Arithmetic</code> property.
single	All filtering operations and coefficients use single-precision floating-point representations and math.
fixed	This string applies selected default values for the properties in the fixed-point filter object, including such properties as coefficient word lengths, fraction lengths, and various operating modes. Generally, the default values match those you use on many digital signal processors. Allows signed fixed data types only. Fixed-point arithmetic filters are available only when you install Fixed-Point Designer software with this toolbox.

### double

When you use one of the `dfilt.structure` methods to create a filter, the `Arithmetic` property value is `double` by default. Your filter is identical to the same filter without the `Arithmetic` property, as you would create if you used Signal Processing Toolbox software.

Double means that the filter uses double-precision floating-point arithmetic in all operations while filtering:

- All input to the filter must be double data type. Any other data type returns an error.
- The states and output are doubles as well.
- All internal calculations are done in double math.

When you use `double` data type filter coefficients, the reference and quantized (fixed-point) filter coefficients are identical. The filter stores the reference coefficients as double data type.

### single

When your filter should use single-precision floating-point arithmetic, set the `Arithmetic` property to `single` so all arithmetic in the filter processing gets restricted to single-precision data type.

- Input data must be single data type. Other data types return errors.
- The filter states and filter output use single data type.

When you choose `single`, you can provide the filter coefficients in either of two ways:

- Double data type coefficients. With `Arithmetic` set to `single`, the filter casts the double data type coefficients to single data type representation.
- Single data type. These remain unchanged by the filter.

Depending on whether you specified single or double data type coefficients, the reference coefficients for the filter are stored in the data type you provided. If you provide coefficients in double data type, the reference coefficients are double as well. Providing single data type coefficients generates single data type reference coefficients. Note that the arithmetic used by the reference filter is always double.

When you use `reffilter` to create a reference filter from the reference coefficients, the resulting filter uses double-precision versions of the reference filter coefficients.

To set the `Arithmetic` property value, create your filter, then use `set` to change the `Arithmetic` setting, as shown in this example using a direct form FIR filter.

```
b=fir1(7,0.45);

hd=dfilt.dffir(b)

hd =

    FilterStructure: 'Direct-Form FIR'
      Arithmetic: 'double'
    Numerator: [1x8 double]
 PersistentMemory: false
       States: [7x1 double]

set(hd,'arithmetic','single')
hd

hd =

    FilterStructure: 'Direct-Form FIR'
      Arithmetic: 'single'
    Numerator: [1x8 double]
 PersistentMemory: false
       States: [7x1 single]
```

**fixed**

Converting your `dfilt` object to use fixed arithmetic results in a filter structure that uses properties and property values to match how the filter would behave on digital signal processing hardware.

---

**Note** The `fixed` option for the property `Arithmetic` is available only when you install Fixed-Point Designer software as well as DSP System Toolbox software.

---

After you set `Arithmetic` to `fixed`, you are free to change any property value from the default value to a value that more closely matches your needs. You cannot, however, mix floating-point and fixed-point arithmetic in your filter when you select `fixed` as the `Arithmetic` property value. Choosing `fixed` restricts you to using either fixed-point or floating point throughout the filter (the data type must be homogenous). Also, all data types must be signed. `fixed` does not support unsigned data types except for unsigned coefficients when you set the property `Signed` to `false`. Mixing word and fraction lengths within the fixed object is acceptable. In short, using fixed arithmetic assumes

- fixed word length.
- fixed size and dedicated accumulator and product registers.
- the ability to do either saturation or wrap arithmetic.
- that multiple rounding modes are available.

Making these assumptions simplifies your job of creating fixed-point filters by reducing repetition in the filter construction process, such as only requiring you to enter the accumulator word size once, rather than for each step that uses the accumulator.

Default property values are a starting point in tailoring your filter to common hardware, such as choosing 40-bit word length for the accumulator, or 16-bit words for data and coefficients.

In this `dfilt` object example, `get` returns the default values for `dfilt.dflt` structures.

```
[b,a]=butter(6,0.45);
hd=dfilt.dfl(b,a)
```

```
hd =
```

```
    FilterStructure: 'Direct-Form I'
           Arithmetic: 'double'
```

```
        Numerator: [1x7 double]
        Denominator: [1x7 double]
PersistentMemory: false
        States: Numerator: [6x1 double]
               Denominator: [6x1 double]
```

```
set(hd,'arithmetic','fixed')
get(hd)
    PersistentMemory: false
    FilterStructure: 'Direct-Form I'
        States: [1x1 filtstates.dfiir]
        Numerator: [1x7 double]
        Denominator: [1x7 double]
        Arithmetic: 'fixed'
    CoeffWordLength: 16
    CoeffAutoScale: 1
    Signed: 1
    RoundMode: 'convergent'
    OverflowMode: 'wrap'
    InputWordLength: 16
    InputFracLength: 15
    ProductMode: 'FullPrecision'
    OutputWordLength: 16
    OutputFracLength: 15
    NumFracLength: 16
    DenFracLength: 14
    ProductWordLength: 32
    NumProdFracLength: 31
    DenProdFracLength: 29
    AccumWordLength: 40
    NumAccumFracLength: 31
    DenAccumFracLength: 29
    CastBeforeSum: 1
```

Here is the default display for `hd`.

```
hd
```

```
hd =
```

```
    FilterStructure: 'Direct-Form I'
        Arithmetic: 'fixed'
        Numerator: [1x7 double]
        Denominator: [1x7 double]
```

```

PersistentMemory: false
    States: Numerator: [6x1 fi]
           Denominator:[6x1 fi]

CoeffWordLength: 16
    CoeffAutoScale: true
    Signed: true

InputWordLength: 16
InputFracLength: 15

OutputWordLength: 16
OutputFracLength: 15

    ProductMode: 'FullPrecision'

AccumWordLength: 40
    CastBeforeSum: true

    RoundMode: 'convergent'
    OverflowMode: 'wrap'

```

This second example shows the default property values for `dfilt.latticemamax` filter objects, using the coefficients from an `fir1` filter.

```

b=fir1(7,0.45)

hdlat=dfilt.latticemamax(b)

hdlat =

    FilterStructure: [1x45 char]
    Arithmetic: 'double'
    Lattice: [1x8 double]
    PersistentMemory: false
    States: [8x1 double]

hdlat.arithmetic='fixed'

hdlat =

    FilterStructure: [1x45 char]
    Arithmetic: 'fixed'

```

```
Lattice: [1x8 double]
PersistentMemory: false
States: [1x1 embedded.fi]

CoeffWordLength: 16
CoeffAutoScale: true
Signed: true

InputWordLength: 16
InputFracLength: 15

OutputWordLength: 16
OutputMode: 'AvoidOverflow'

StateWordLength: 16
StateFracLength: 15

ProductMode: 'FullPrecision'

AccumWordLength: 40
CastBeforeSum: true

RoundMode: 'convergent'
OverflowMode: 'wrap'
```

Unlike the `single` or `double` options for `Arithmetic`, `fixed` uses properties to define the word and fraction lengths for each portion of your filter. By changing the property value of any of the properties, you control your filter performance. Every word length and fraction length property is independent — set the one you need and the others remain unchanged, such as setting the input word length with `InputWordLength`, while leaving the fraction length the same.

```
d=fdesign.lowpass('n,fc',6,0.45)
```

```
d =
```

```
Response: 'Lowpass with cutoff'

    Section OutputAutoScale: true
```

```
    OutputWordLength: 16
      OutputMode: 'AvoidOverflow'

    StateWordLength: 16
    StateFracLength: 15

      ProductMode: 'FullPrecision'

    AccumWordLength: 40
      CastBeforeSum: true

      RoundMode: 'convergent'
      OverflowMode: 'wrap'

hd.inputWordLength=12

hd =

  FilterStructure: 'Direct-Form II, Second-Order Sections'
    Arithmetic: 'fixed'
    sosMatrix: [3x6 double]
    ScaleValues: [4x1 double]
  PersistentMemory: false
    States: [1x1 embedded.fi]

  CoeffWordLength: 16
    CoeffAutoScale: true
    Signed: true

  InputWordLength: 12
  InputFracLength: 15

  SectionInputWordLength: 16
  SectionInputAutoScale: true

  SectionOutputWordLength: 16
  SectionOutputAutoScale: true

    OutputWordLength: 16
      OutputMode: 'AvoidOverflow'

    StateWordLength: 16
    StateFracLength: 15
```

```
ProductMode: 'FullPrecision'  
  
AccumWordLength: 40  
CastBeforeSum: true  
  
RoundMode: 'convergent'  
OverflowMode: 'wrap'
```

Notice that the properties for the lattice filter `hdlat` and direct-form II filter `hd` are different, as befits their differing filter structures. Also, some properties are common to both objects, such as `RoundMode` and `PersistentMemory` and behave the same way in both objects.

### Notes About Fraction Length, Word Length, and Precision

Word length and fraction length combine to make the format for a fixed-point number, where word length is the number of bits used to represent the value and fraction length specifies, in bits, the location of the binary point in the fixed-point representation. Therein lies a problem — fraction length, which you specify in bits, can be larger than the word length, or a negative number of bits. This section explains how that idea works and how you might use it.

Unfortunately fraction length is somewhat misnamed (although it continues to be used in this User's Guide and elsewhere for historical reasons).

Fraction length defined as the number of fractional bits (bits to the right of the binary point) is true only when the fraction length is positive and less than or equal to the word length. In MATLAB format notation you can use [word length fraction length]. For example, for the format [16 16], the second 16 (the fraction length) is the number of fractional bits or bits to the right of the binary point. In this example, all 16 bits are to the right of the binary point.

But it is also possible to have fixed-point formats of [16 18] or [16 -45]. In these cases the fraction length can no longer be the number of bits to the right of the binary point since the format says the word length is 16 — there cannot be 18 fraction length bits on the right. And how can there be a negative number of bits for the fraction length, such as [16 -45]?

A better way to think about fixed-point format [word length fraction length] and what it means is that the representation of a fixed-point number is a weighted sum of powers of two driven by the fraction length, or the two's complement representation of the fixed-point number.

Consider the format [B L], where the fraction length L can be positive, negative, 0, greater than B (the word length) or less than B. (B and L are always integers and B is always positive.)

Given a binary string  $b(1) b(2) b(3) \dots b(B)$ , to determine the two's-complement value of the string in the format described by [B L], use the value of the individual bits in the binary string in the following formula, where  $b(1)$  is the first binary bit (and most significant bit, MSB),  $b(2)$  is the second, and on up to  $b(B)$ .

The decimal numeric value that those bits represent is given by

$$\text{value} = -b(1)*2^{(B-L-1)} + b(2)*2^{(B-L-2)} + b(3)*2^{(B-L-3)} + \dots + b(B)*2^{(-L)}$$

L, the fraction length, represents the negative of the weight of the last, or least significant bit (LSB). L is also the step size or the precision provided by a given fraction length.

### **Precision**

Here is how precision works.

When all of the bits of a binary string are zero except for the LSB (which is therefore equal to one), the value represented by the bit string is given by  $2^{(-L)}$ . If L is negative, for example  $L=-16$ , the value is  $2^{16}$ . The smallest step between numbers that can be represented in a format where  $L=-16$  is given by  $1 \times 2^{16}$  (the rightmost term in the formula above), which is 65536. Note the precision does not depend on the word length.

Take a look at another example. When the word length set to 8 bits, the decimal value 12 is represented in binary by 00001100. That 12 is the decimal equivalent of 00001100 tells you that you are using [8 0] data format representation — the word length is 8 bits and fraction length 0 bits, and the step size or precision (the smallest difference between two adjacent values in the format [8,0], is  $2^0=1$ .

Suppose you plan to keep only the upper 5 bits and discard the other three. The resulting precision after removing the right-most three bits comes from the weight of the lowest remaining bit, the fifth bit from the left, which is  $2^3=8$ , so the format would be [5,-3].

Note that in this format the step size is 8, I cannot represent numbers that are between multiples of 8.

In MATLAB, with Fixed-Point Designer software installed:

```
x=8;  
q=quantizer([8,0]); % Word length = 8, fraction length = 0
```

```

xq=quantize(q,x);
binxq=num2bin(q,xq);
q1=quantizer([5 -3]); % Word length = 5, fraction length = -3
xq1 = quantize(q1,xq);
binxq1=num2bin(q1,xq1);
binxq

```

```
binxq =
```

```
00001000
```

```
binxq1
```

```
binxq1 =
```

```
00001
```

But notice that in [5,-3] format, 00001 is the two's complement representation for 8, not for 1;  $q = \text{quantizer}([8 \ 0])$  and  $q1 = \text{quantizer}([5 \ -3])$  are not the same. They cover the about the same range —  $\text{range}(q) > \text{range}(q1)$  — but their quantization step is different —  $\text{eps}(q) = 8$ , and  $\text{eps}(q1) = 1$ .

Look at one more example. When you construct a quantizer  $q$

```
q = quantizer([a,b])
```

the first element in  $[a, b]$  is  $a$ , the word length used for quantization. The second element in the expression,  $b$ , is related to the quantization step — the numerical difference between the two closest values that the quantizer can represent. This is also related to the weight given to the LSB. Note that  $2^{(-b)} = \text{eps}(q)$ .

Now construct two quantizers,  $q1$  and  $q2$ . Let  $q1$  use the format [32,0] and let  $q2$  use the format [16, -16].

```
q1 = quantizer([32,0])
q2 = quantizer([16,-16])
```

Quantizers  $q1$  and  $q2$  cover the same range, but  $q2$  has less precision. It covers the range in steps of  $2^{16}$ , while  $q$  covers the range in steps of 1.

This lost precision is due to (or can be used to model) throwing out 16 least-significant bits.

An important point to understand is that in `dfilt` objects and filtering you control which bits are carried from the sum and product operations in the filter to the filter output by setting the format for the output from the sum or product operation.

For instance, if you use `[16 0]` as the output format for a 32-bit result from a sum operation when the original format is `[32 0]`, you take the lower 16 bits from the result. If you use `[16 -16]`, you take the higher 16 bits of the original 32 bits. You could even take 16 bits somewhere in between the 32 bits by choosing something like `[16 -8]`, but you probably do not want to do that.

Filter scaling is directly implicated in the format and precision for a filter. When you know the filter input and output formats, as well as the filter internal formats, you can scale the inputs or outputs to stay within the format ranges.

Notice that overflows or saturation might occur at the filter input, filter output, or within the filter itself, such as during add or multiply or accumulate operations. Improper scaling at any point in the filter can result in numerical errors that dramatically change the performance of your fixed-point filter implementation.

### **CastBeforeSum**

Setting the `CastBeforeSum` property determines how the filter handles the input values to sum operations in the filter. After you set your filter `Arithmetic` property value to `fixed`, you have the option of using `CastBeforeSum` to control the data type of some inputs (addends) to summations in your filter. To determine which addends reflect the `CastBeforeSum` property setting, refer to the reference page for the signal flow diagram for the filter structure.

`CastBeforeSum` specifies whether to cast selected addends to summations in the filter to the output format from the addition operation before performing the addition. When you specify `true` for the property value, the results of the affected sum operations match most closely the results found on most digital signal processors. Performing the cast operation before the summation adds one or two additional quantization operations that can add error sources to your filter results.

Specifying `CastBeforeSum` to be `false` prevents the addends from being cast to the output format before the addition operation. Choose this setting to get the most accurate results from summations without considering the hardware your filter might use.

Notice that the output format for every sum operation reflects the value of the output property specified in the filter structure diagram. Which input property is referenced by `CastBeforeSum` depends on the structure.

Property Value	Description
false	Configures filter summation operations to retain the addends in the format carried from the previous operation.
true	Configures filter summation operations to convert the input format of the addends to match the summation output format before performing the summation operation. Usually this generates results from the summation that more closely match those found from digital signal processors

Another point — with `CastBeforeSum` set to `false`, the filter realization process inserts an intermediate data type format to hold temporarily the full precision sum of the inputs. A separate Convert block performs the process of casting the addition result to the accumulator format. This intermediate data format occurs because the Sum block in Simulink always casts input (addends) to the output data type.

#### Diagrams of `CastBeforeSum` Settings

When `CastBeforeSum` is `false`, sum elements in filter signal flow diagrams look like this:

showing that the input data to the sum operations (the addends) retain their format word length and fraction length from previous operations. The addition process uses the existing input formats and then casts the output to the format defined by `AccumFormat`. Thus the output data has the word length and fraction length defined by `AccumWordLength` and `AccumFracLength`.

When `CastBeforeSum` is `true`, sum elements in filter signal flow diagrams look like this:

showing that the input data gets recast to the accumulator format word length and fraction length (`AccumFormat`) before the sum operation occurs. The data output by the addition operation has the word length and fraction length defined by `AccumWordLength` and `AccumFracLength`.

### **CoeffAutoScale**

How the filter represents the filter coefficients depends on the property value of `CoeffAutoScale`. When you create a `dfilt` object, you use coefficients in double-precision format. Converting the `dfilt` object to fixed-point arithmetic forces the coefficients into a fixed-point representation. The representation the filter uses depends on whether the value of `CoeffAutoScale` is `true` or `false`.

- `CoeffAutoScale = true` means the filter chooses the fraction length to maintain the value of the coefficients as close to the double-precision values as possible. When you change the word length applied to the coefficients, the filter object changes the fraction length to try to accommodate the change. `true` is the default setting.
- `CoeffAutoScale = false` removes the automatic scaling of the fraction length for the coefficients and exposes the property that controls the coefficient fraction length so you can change it. For example, if the filter is a direct form FIR filter, setting `CoeffAutoScale = false` exposes the `NumFracLength` property that specifies the fraction length applied to numerator coefficients. If the filter is an IIR filter, setting `CoeffAutoScale = false` exposes both the `NumFracLength` and `DenFracLength` properties.

Here is an example of using `CoeffAutoScale` with a direct form filter.

```
hd2=dfilt.dffir([0.3 0.6 0.3])
```

```
hd2 =
```

```
FilterStructure: 'Direct-Form FIR'  
Arithmetic: 'double'  
Numerator: [0.3000 0.6000 0.3000]  
PersistentMemory: false  
States: [2x1 double]
```

```
hd2.arithmetic='fixed'
```

```
hd2 =
```

```
FilterStructure: 'Direct-Form FIR'  
Arithmetic: 'fixed'  
Numerator: [0.3000 0.6000 0.3000]  
PersistentMemory: false  
States: [1x1 embedded.fi]
```

```
CoeffWordLength: 16  
CoeffAutoScale: true  
Signed: true
```

```
InputWordLength: 16  
InputFracLength: 15
```

```
OutputWordLength: 16  
OutputMode: 'AvoidOverflow'
```

```
ProductMode: 'FullPrecision'
```

```
AccumWordLength: 40  
CastBeforeSum: true
```

```
RoundMode: 'convergent'  
OverflowMode: 'wrap'
```

To this point, the filter coefficients retain the original values from when you created the filter as shown in the `Numerator` property. Now change the `CoeffAutoScale` property value from `true` to `false`.

```
hd2.coeffautoScale=false
```

```
hd2 =
```

```
FilterStructure: 'Direct-Form FIR'
```

```
    Arithmetic: 'fixed'
    Numerator: [0.3000 0.6000 0.3000]
PersistentMemory: false
    States: [1x1 embedded.fi]

    CoeffWordLength: 16
    CoeffAutoScale: false
    NumFracLength: 15
    Signed: true

    InputWordLength: 16
    InputFracLength: 15

    OutputWordLength: 16
    OutputMode: 'AvoidOverflow'

    ProductMode: 'FullPrecision'

    AccumWordLength: 40
    CastBeforeSum: true

    RoundMode: 'convergent'
    OverflowMode: 'wrap'
```

With the NumFracLength property now available, change the word length to 5 bits.

Notice the coefficient values. Setting CoeffAutoScale to false removes the automatic fraction length adjustment and the filter coefficients cannot be represented by the current format of [5 15] — a word length of 5 bits, fraction length of 15 bits.

```
hd2.coeffwordlength=5
```

```
hd2 =
```

```
    FilterStructure: 'Direct-Form FIR'
    Arithmetic: 'fixed'
    Numerator: [4.5776e-004 4.5776e-004 4.5776e-004]
PersistentMemory: false
    States: [1x1 embedded.fi]

    CoeffWordLength: 5
    CoeffAutoScale: false
    NumFracLength: 15
    Signed: true
```

```

InputWordLength: 16
InputFracLength: 15

OutputWordLength: 16
  OutputMode: 'AvoidOverflow'

  ProductMode: 'FullPrecision'

AccumWordLength: 40
  CastBeforeSum: true

  RoundMode: 'convergent'
  OverflowMode: 'wrap'

```

Restoring `CoeffAutoScale` to `true` goes some way to fixing the coefficient values. Automatically scaling the coefficient fraction length results in setting the fraction length to 4 bits. You can check this with `get(hd2)` as shown below.

```
hd2.coeffautoScale=true
```

```
hd2 =
```

```

FilterStructure: 'Direct-Form FIR'
  Arithmetic: 'fixed'
  Numerator: [0.3125 0.6250 0.3125]
PersistentMemory: false
  States: [1x1 embedded.fi]

CoeffWordLength: 5
  CoeffAutoScale: true
  Signed: true

InputWordLength: 16
InputFracLength: 15

OutputWordLength: 16
  OutputMode: 'AvoidOverflow'

  ProductMode: 'FullPrecision'

AccumWordLength: 40
  CastBeforeSum: true

  RoundMode: 'convergent'

```

```
        OverflowMode: 'wrap'

get(hd2)
    PersistentMemory: false
FilterStructure: 'Direct-Form FIR'
    States: [1x1 embedded.fi]
    Numerator: [0.3125 0.6250 0.3125]
    Arithmetic: 'fixed'
    CoeffWordLength: 5
    CoeffAutoScale: 1
    Signed: 1
    RoundMode: 'convergent'
    OverflowMode: 'wrap'
    InputWordLength: 16
    InputFracLength: 15
    OutputWordLength: 16
    OutputMode: 'AvoidOverflow'
    ProductMode: 'FullPrecision'
    NumFracLength: 4
    OutputFracLength: 12
    ProductWordLength: 21
    ProductFracLength: 19
    AccumWordLength: 40
    AccumFracLength: 19
    CastBeforeSum: 1
```

Clearly five bits is not enough to represent the coefficients accurately.

### **CoeffFracLength**

Fixed-point scalar filters that you create using `dfilt.scalar` use this property to define the fraction length applied to the scalar filter coefficients. Like the coefficient-fraction-length-related properties for the FIR, lattice, and IIR filters, `CoeffFracLength` is not displayed for scalar filters until you set `CoeffAutoScale` to `false`. Once you change the automatic scaling you can set the fraction length for the coefficients to any value you require.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 14 bits, with the `CoeffWordLength` of 16 bits.

## CoeffWordLength

One primary consideration in developing filters for hardware is the length of a data word. `CoeffWordLength` defines the word length for these data storage and arithmetic locations:

- Numerator and denominator filter coefficients
- Tap sum in `dfilt.dfsymfir` and `dfilt.dfasymfir` filter objects
- Section input, multiplicand, and state values in direct-form SOS filter objects such as `dfilt.df1t` and `dfilt.df2`
- Scale values in second-order filters
- Lattice and ladder coefficients in lattice filter objects, such as `dfilt.latticearma` and `dfilt.latticemamax`
- Gain in `dfilt.scalar`

Setting this property value controls the word length for the data listed. In most cases, the data words in this list have separate fraction length properties to define the associated fraction lengths.

Any positive, integer word length works here, limited by the machine you use to develop your filter and the hardware you use to deploy your filter.

## DenAccumFracLength

Filter structures `df1`, `df1t`, `df2`, and `df2t` that use fixed arithmetic have this property that defines the fraction length applied to denominator coefficients in the accumulator. In combination with `AccumWordLength`, the properties fully specify how the accumulator outputs data stored there.

As with all fraction length properties, `DenAccumFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers. To be able to change the property value for this property, you set `FilterInternals` to `SpecifyPrecision`.

## DenFracLength

Property `DenFracLength` contains the value that specifies the fraction length for the denominator coefficients for your filter. `DenFracLength` specifies the fraction length used to interpret the data stored in `C`. Used in combination with `CoeffWordLength`, these two properties define the interpretation of the coefficients stored in the vector that contains the denominator coefficients.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 15 bits, with the `CoeffWordLength` of 16 bits.

### **Denominator**

The denominator coefficients for your IIR filter, taken from the prototype you start with, are stored in this property. Generally this is a 1-by-N array of data in double format, where N is the length of the filter.

All IIR filter objects include `Denominator`, except the lattice-based filters which store their coefficients in the `Lattice` property, and second-order section filters, such as `dfilt.df1tsos`, which use the `SosMatrix` property to hold the coefficients for the sections.

### **DenProdFracLength**

A property of all of the direct form IIR `dfilt` objects, except the ones that implement second-order sections, `DenProdFracLength` specifies the fraction length applied to data output from product operations that the filter performs on denominator coefficients.

Looking at the signal flow diagram for the `dfilt.df1t` filter, for example, you see that denominators and numerators are handled separately. When you set `ProductMode` to `SpecifyPrecision`, you can change the `DenProdFracLength` setting manually. Otherwise, for multiplication operations that use the denominator coefficients, the filter sets the fraction length as defined by the `ProductMode` setting.

### **DenStateFracLength**

When you look at the flow diagram for the `dfilt.df1sos` filter object, the states associated with denominator coefficient operations take the fraction length from this property. In combination with the `DenStateWordLength` property, these properties fully specify how the filter interprets the states.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 15 bits, with the `DenStateWordLength` of 16 bits.

### **DenStateWordLength**

When you look at the flow diagram for the `dfilt.df1sos` filter object, the states associated with the denominator coefficient operations take the data format from this

property and the `DenStateFracLength` property. In combination, these properties fully specify how the filter interprets the state it uses.

By default, the value is 16 bits, with the `DenStateFracLength` of 15 bits.

### FilterInternals

Similar to the `FilterInternals` pane in `FDATool`, this property controls whether the filter sets the output word and fraction lengths automatically, and the accumulator word and fraction lengths automatically as well, to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. Setting `FilterInternals` to `SpecifyPrecision` exposes the output and accumulator related properties so you can set your own word and fraction lengths for them. Note that

### FilterStructure

Every `dfilt` object has a `FilterStructure` property. This is a read-only property containing a string that declares the structure of the filter object you created.

When you construct filter objects, the `FilterStructure` property value is returned containing one of the strings shown in the following table. Property `FilterStructure` indicates the filter architecture and comes from the constructor you use to create the filter.

After you create a filter object, you cannot change the `FilterStructure` property value. To make filters that use different structures, you construct new filters using the appropriate methods, or use `convert` to switch to a new structure.

#### Default value

Since this depends on the constructor you use and the constructor includes the filter structure definition, there is no default value. When you try to create a filter without specifying a structure, MATLAB returns an error.

Filter Constructor Name	FilterStructure Property String and Filter Type
' <code>dfilt.dfl</code> '	Direct form I
' <code>dfilt.dflsos</code> '	Direct form I filter implemented using second-order sections
' <code>dfilt.dflt</code> '	Direct form I transposed

Filter Constructor Name	FilterStructure Property String and Filter Type
'dfilt.df2'	Direct form II
'dfilt.df2sos'	Direct form II filter implemented using second order sections
'dfilt.df2t'	Direct form II transposed
'dfilt.dfasymfir'	Antisymmetric finite impulse response (FIR). Even and odd forms.
'dfilt.dffir'	Direct form FIR
'dfilt.dffirt'	Direct form FIR transposed
'dfilt.latticeallpass'	Lattice allpass
'dfilt.latticear'	Lattice autoregressive (AR)
'dfilt.latticemamin'	Lattice moving average (MA) minimum phase
'dfilt.latticemamax'	Lattice moving average (MA) maximum phase
'dfilt.latticearma'	Lattice ARMA
'dfilt.dfsymfir'	Symmetric FIR. Even and odd forms
'dfilt.scalar'	Scalar

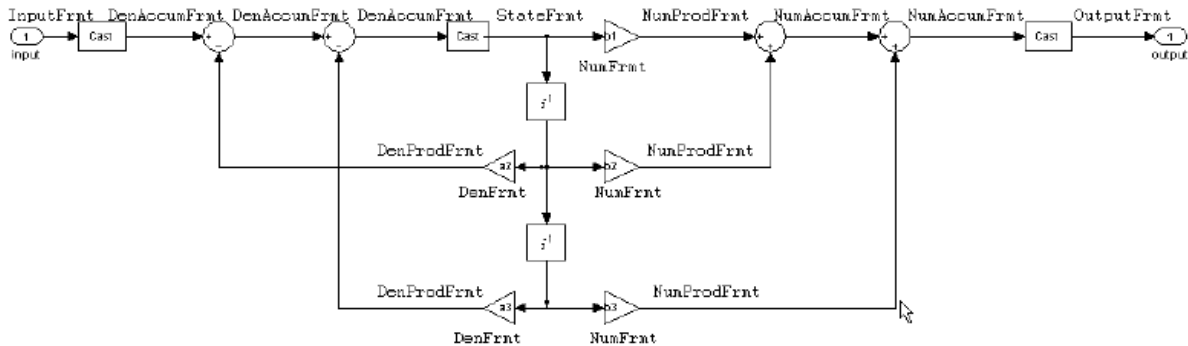

### Filter Structures with Quantizations Shown in Place

To help you understand how and where the quantizations occur in filter structures in this toolbox, the figure below shows the structure for a Direct Form II filter, including the quantizations (fixed-point formats) that compose part of the fixed-point filter. You see that one or more quantization processes, specified by the `*format` label, accompany each filter element, such as a delay, product, or summation element. The input to or output from each element reflects the result of applying the associated quantization as defined by the word length and fraction length format. Wherever a particular filter element appears in a filter structure, recall the quantization process that accompanies the element as it appears in this figure. Each filter reference page, such as the `dfilt.df2` reference page, includes the signal flow diagram showing the formatting elements that define the quantizations that occur throughout the filter flow.

For example, a product quantization, either numerator or denominator, follows every product (gain) element and a sum quantization, also either numerator or denominator, follows each sum element. The figure shows the `Arithmetic` property value set to `fixed`.

## df2 IIR Filter Structure Including the Formatting Objects, with Arithmetic Property Value fixed

When your df2 filter uses the Arithmetic property set to fixed, the filter structure contains the formatting features shown in the diagram. The formats included in the structure are fixed-point objects that include properties to set various word and fraction length formats. For example, the NumFormat or DenFormat in the fixed-point arithmetic filter set the properties for quantizing numerator or denominator coefficients according to word and fraction length settings.

When the leading denominator coefficient  $a(1)$  in your filter is not 1, choose it to be a power of two so that a shift replaces the multiply that would otherwise be used.

### Fixed-Point Arithmetic Filter Structures

You choose among several filter structures when you create fixed-point filters. You can also specify filters with single or multiple cascaded sections of the same type. Because quantization is a nonlinear process, different fixed-point filter structures produce different results.

To specify the filter structure, you select the appropriate `dfilt.structure` method to construct your filter. Refer to the function reference information for `dfilt` and `set` for details on setting property values for quantized filters.

The figures in the following subsections of this section serve as aids to help you determine how to enter your filter coefficients for each filter structure. Each subsection contains an example for constructing a filter of the given structure.

Scale factors for the input and output for the filters do not appear in the block diagrams. The default filter structures do not include, nor assume, the scale factors. For filter scaling information, refer to `scale` in the Help system.

### About the Filter Structure Diagrams

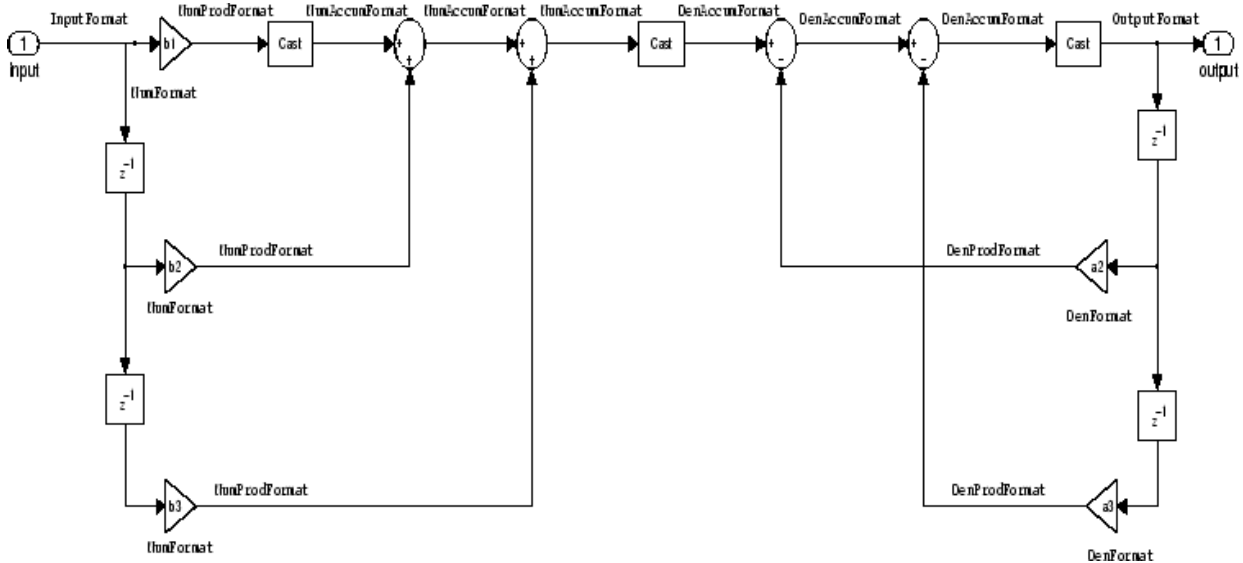

In the diagrams that accompany the following filter structure descriptions, you see the active operators that define the filter, such as sums and gains, and the formatting features that control the processing in the filter. Notice also that the coefficients are labeled in the figure. This tells you the order in which the filter processes the coefficients.

While the meaning of the block elements is straightforward, the labels for the formats that form part of the filter are less clear. Each figure includes text in the form *labelFormat* that represents the existence of a formatting feature at that point in the structure. The *Format* stands for formatting object and the *label* specifies the data that the formatting object affects.

For example, in the `dfilt.df2` filter shown above, the entries `InputFormat` and `OutputFormat` are the formats applied, that is the word length and fraction length, to the filter input and output data. For example, filter properties like `OutputWordLength` and `InputWordLength` specify values that control filter operations at the input and output points in the structure and are represented by the formatting objects `InputFormat` and `OutputFormat` shown in the filter structure diagrams.

### Direct Form I Filter Structure

The following figure depicts the *direct form I* filter structure that directly realizes a transfer function with a second-order numerator and denominator. The numerator coefficients are numbered  $b(i)$ ,  $i = 1, 2, 3$ ; the denominator coefficients are numbered  $a(i)$ ,  $i = 1, 2, 3$ ; and the states (used for initial and final state values in filtering) are labeled  $z(i)$ . In the figure, the `Arithmetic` property is set to `fixed`.

### Example — Specifying a Direct Form I Filter

You can specify a second-order direct form I structure for a quantized filter `hq` with the following code.

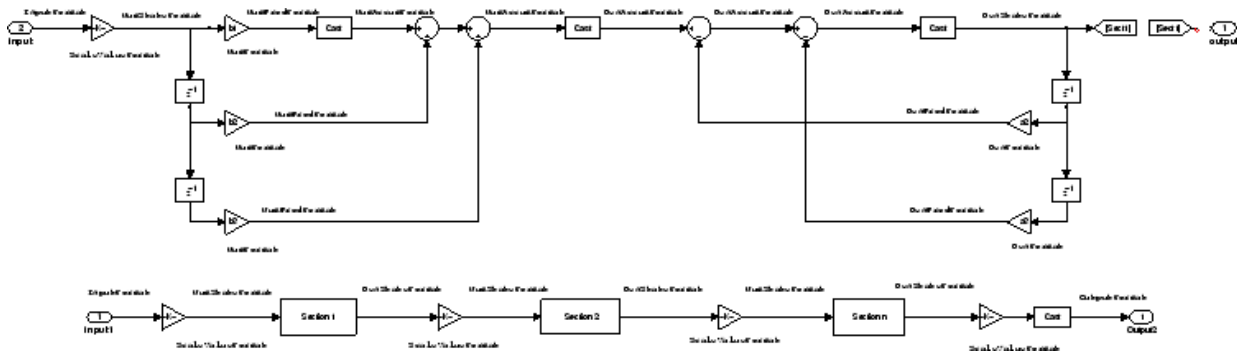

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.df1(b,a);
```

To create the fixed-point filter, set the Arithmetic property to fixed as shown here.

```
set(hq,'arithmetic','fixed');
```

### Direct Form I Filter Structure With Second-Order Sections

The following figure depicts a *direct form I* filter structure that directly realizes a transfer function with a second-order numerator and denominator and second-order sections. The numerator coefficients are numbered  $b(i)$ ,  $i = 1, 2, 3$ ; the denominator coefficients are numbered  $a(i)$ ,  $i = 1, 2, 3$ ; and the states (used for initial and final state values in filtering) are labeled  $z(i)$ . In the figure, the Arithmetic property is set to fixed to place the filter in fixed-point mode.

### Example — Specifying a Direct Form I Filter with Second-Order Sections

You can specify an eighth-order direct form I structure for a quantized filter `hq` with the following code.

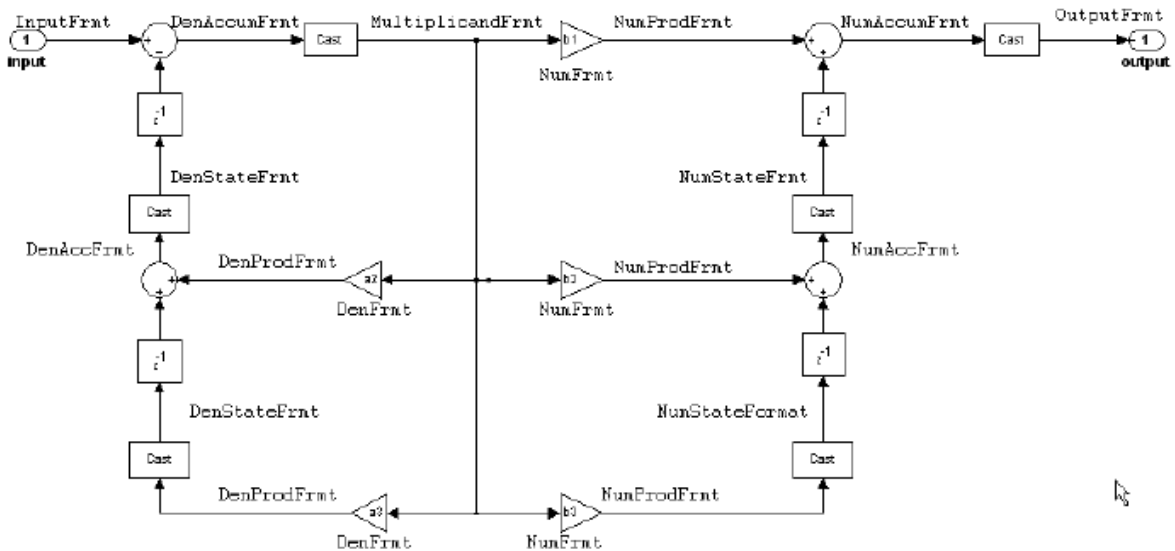

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.df1sos(b,a);
```

To create the fixed-point filter, set the Arithmetic property to `fixed`, as shown here.

```
set(hq,'arithmetic','fixed');
```

### Direct Form I Transposed Filter Structure

The next signal flow diagram depicts a *direct form I transposed* filter structure that directly realizes a transfer function with a second-order numerator and denominator. The numerator coefficients are  $b(i)$ ,  $i = 1, 2, 3$ ; the denominator coefficients are  $a(i)$ ,  $i = 1, 2, 3$ ; and the states (used for initial and final state values in filtering) are labeled  $z(i)$ . With the Arithmetic property value set to `fixed`, the figure shows the filter with the properties indicated.

### Example — Specifying a Direct Form I Transposed Filter

You can specify a second-order direct form I transposed filter structure for a quantized filter `hq` with the following code.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.dflt(b,a);
set(hq,'arithmetic','fixed');
```

### Direct Form II Filter Structure

The following graphic depicts a *direct form II* filter structure that directly realizes a transfer function with a second-order numerator and denominator. In the figure, the Arithmetic property value is `fixed`. Numerator coefficients are named  $b(i)$ ; denominator coefficients are named  $a(i)$ ,  $i = 1, 2, 3$ ; and the states (used for initial and final state values in filtering) are named  $z(i)$ .

Use the method `dfilt.df2` to construct a quantized filter whose `FilterStructure` property is `Direct-Form II`.

#### Example — Specifying a Direct Form II Filter

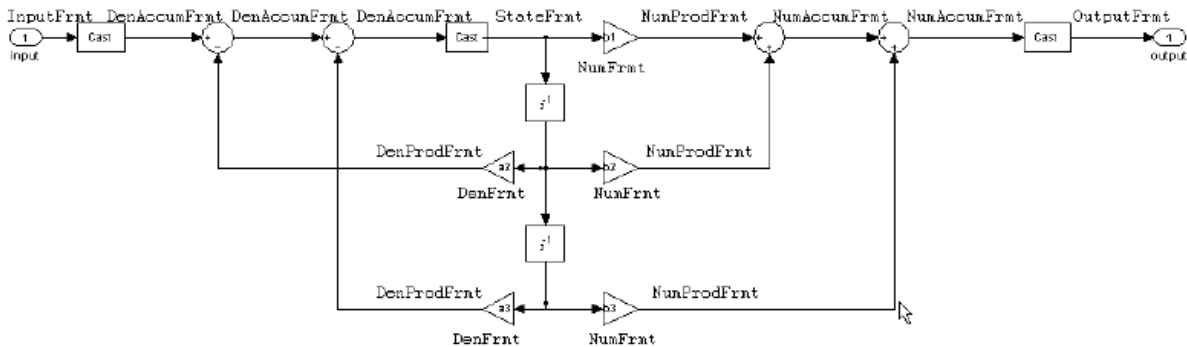

You can specify a second-order direct form II filter structure for a quantized filter `hq` with the following code.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.df2(b,a);
hq.arithmetic = 'fixed'
```

To convert your initial double-precision filter `hq` to a quantized or fixed-point filter, set the `Arithmetic` property to `fixed`, as shown.

#### Direct Form II Filter Structure With Second-Order Sections

The following figure depicts *direct form II* filter structure using second-order sections that directly realizes a transfer function with a second-order numerator and denominator sections. In the figure, the `Arithmetic` property value is `fixed`. Numerator coefficients are labeled  $b(i)$ ; denominator coefficients are labeled  $a(i)$ ,  $i = 1, 2, 3$ ; and the states (used for initial and final state values in filtering) are labeled  $z(i)$ .

Use the method `dfilt.df2sos` to construct a quantized filter whose `FilterStructure` property is `Direct-Form II`.

#### Example — Specifying a Direct Form II Filter with Second-Order Sections

You can specify a tenth-order direct form II filter structure that uses second-order sections for a quantized filter `hq` with the following code.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.df2sos(b,a);
hq.arithmetic = 'fixed'
```

To convert your prototype double-precision filter `hq` to a fixed-point filter, set the `Arithmetic` property to `fixed`, as shown.

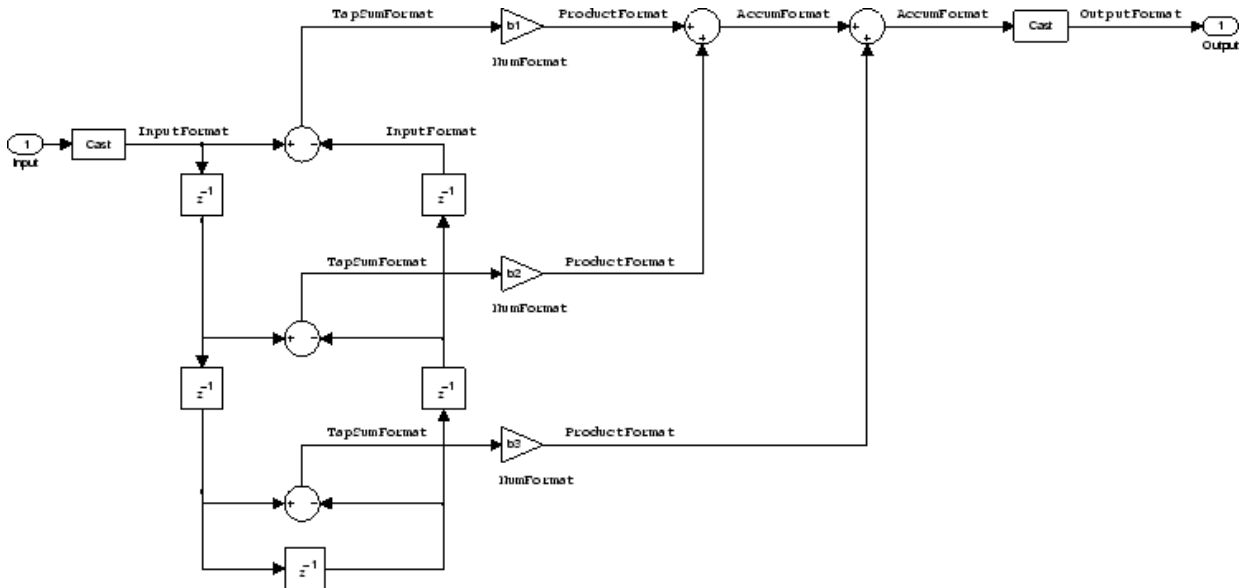

#### Direct Form II Transposed Filter Structure

The following figure depicts the *direct form II transposed* filter structure that directly realizes transfer functions with a second-order numerator and denominator. The numerator coefficients are labeled  $b(i)$ , the denominator coefficients are labeled  $a(i)$ ,  $i = 1, 2, 3$ , and the states (used for initial and final state values in filtering) are labeled  $z(i)$ . In the first figure, the `Arithmetic` property value is `fixed`.

and the initial and final state values in filtering are labeled  $z(i)$ . This structure reflects the Arithmetic property set to fixed.

Use the method `dfilt.dfasymfir` to construct the filter, and then set the Arithmetic property to fixed to convert to a fixed-point filter with this structure.

#### Example — Specifying an Odd-Order Direct Form Antisymmetric FIR Filter

Specify a fifth-order direct form antisymmetric FIR filter structure for a fixed-point filter `hq` with the following code.

```
b = [-0.008 0.06 -0.44 0.44 -0.06 0.008];
hq = dfilt.dfasymfir(b);
set(hq,'arithmetic','fixed')

hq

hq =

    FilterStructure: 'Direct-Form Antisymmetric FIR'
    Arithmetic: 'fixed'
    Numerator: [-0.0080 0.0600 -0.4400 0.4400 -0.0600 0.0080]
    PersistentMemory: false
    States: [1x1 fi object]

    CoeffWordLength: 16
    CoeffAutoScale: true
    Signed: true
```

```
InputWordLength: 16
InputFracLength: 15

OutputWordLength: 16
  OutputMode: 'AvoidOverflow'

  TapSumMode: 'KeepMSB'
TapSumWordLength: 17

  ProductMode: 'FullPrecision'

AccumWordLength: 40

CastBeforeSum: true
  RoundMode: 'convergent'
  OverflowMode: 'wrap'

InheritSettings: false
```

### Example — Specifying an Even-Order Direct Form Antisymmetric FIR Filter

You can specify a fourth-order direct form antisymmetric FIR filter structure for a fixed-point filter `hq` with the following code.

```
b = [-0.01 0.1 0.0 -0.1 0.01];
hq = dfilt.dfasymfir(b);
hq.arithmetic='fixed'
```

```
hq =
```

```
FilterStructure: 'Direct-Form Antisymmetric FIR'
  Arithmetic: 'fixed'
    Numerator: [-0.0100 0.1000 0 -0.1000 0.0100]
PersistentMemory: false
  States: [1x1 fi object]

CoeffWordLength: 16
  CoeffAutoScale: true
    Signed: true

InputWordLength: 16
InputFracLength: 15

### Direct Form Finite Impulse Response (FIR) Filter Structure

In the next figure, you see the signal flow graph for a *direct form finite impulse response (FIR)* filter structure that directly realizes a second-order FIR filter. The filter coefficients are  $b(i)$ ,  $i = 1, 2, 3$ , and the states (used for initial and final state values in filtering) are  $z(i)$ . To generate the figure, set the Arithmetic property to fixed after you create your prototype filter in double-precision arithmetic.

Use the `dfilt.dffir` method to generate a filter that uses this structure.

#### Example — Specifying a Direct Form FIR Filter

You can specify a second-order direct form FIR filter structure for a fixed-point filter `hq` with the following code.

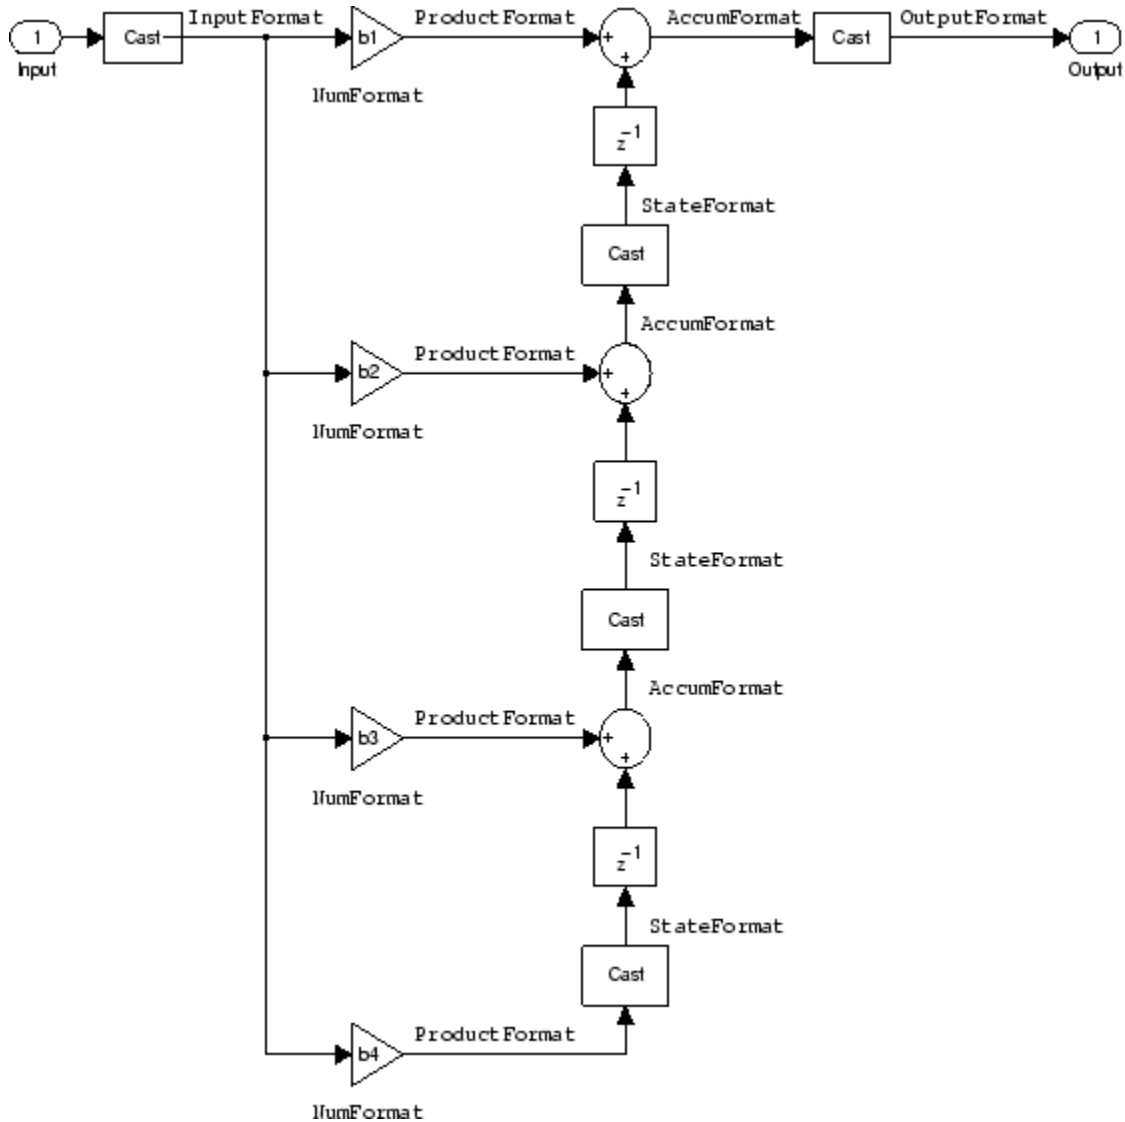

```

b = [0.05 0.9 0.05];
hd = dfilt.dffir(b);
hq = set(hd,'arithmetic','fixed');

```

**Direct Form FIR Transposed Filter Structure**

This figure uses the filter coefficients labeled  $b(i)$ ,  $i = 1, 2, 3$ , and states (used for initial and final state values in filtering) are labeled  $z(i)$ . These depict a *direct form finite impulse response (FIR) transposed* filter structure that directly realizes a second-order FIR filter.

With the Arithmetic property set to fixed, your filter matches the figure. Using the method `dfilt.dffirt` returns a double-precision filter that you convert to a fixed-point filter.

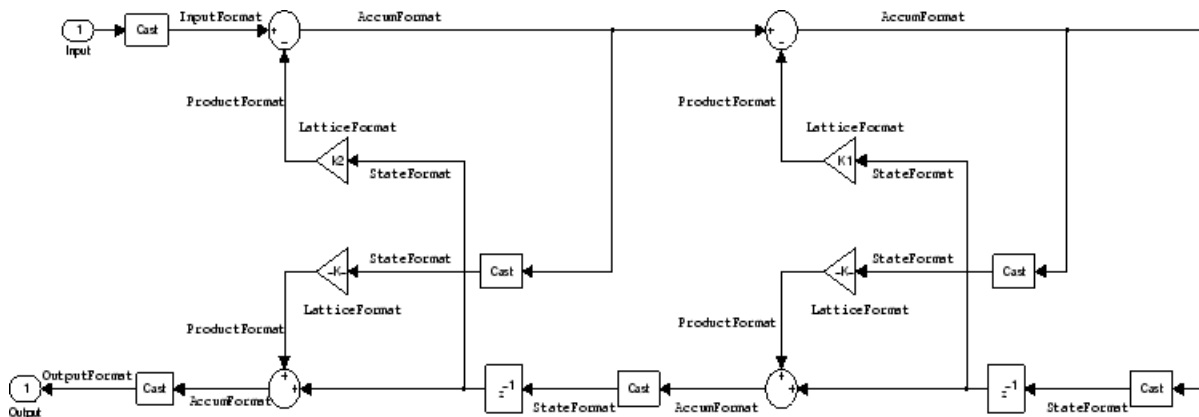

### Example — Specifying a Direct Form FIR Transposed Filter

You can specify a second-order direct form FIR transposed filter structure for a fixed-point filter `hq` with the following code.

```
b = [0.05 0.9 0.05];
hd=dfilt.dffirt(b);
hq = copy(hd);
hq.arithmetic = 'fixed';
```

### Lattice Allpass Filter Structure

The following figure depicts the *lattice allpass* filter structure. The pictured structure directly realizes third-order lattice allpass filters using fixed-point arithmetic. The filter reflection coefficients are labeled  $k1(i)$ ,  $i = 1, 2, 3$ . The states (used for initial and final state values in filtering) are labeled  $z(i)$ .

To create a quantized filter that uses the lattice allpass structure shown in the figure, use the `dfilt.latticeallpass` method and set the `Arithmetic` property to `fixed`.

### Example — Specifying a Lattice Allpass Filter

You can create a third-order lattice allpass filter structure for a quantized filter `hq` with the following code.

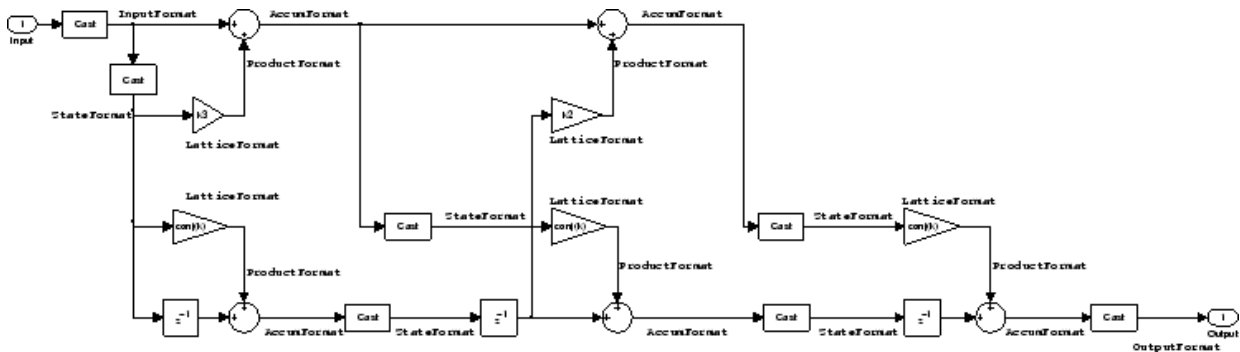

```
k = [.66 .7 .44];
hd=dfilt.latticeallpass(k);
set(hq,'arithmetic','fixed');
```

### Lattice Moving Average Maximum Phase Filter Structure

In the next figure you see a *lattice moving average maximum phase* filter structure. This signal flow diagram directly realizes a third-order lattice moving average (MA) filter with the following phase form depending on the initial transfer function:

- When you start with a minimum phase transfer function, the upper branch of the resulting lattice structure returns a minimum phase filter. The lower branch returns a maximum phase filter.
- When your transfer function is neither minimum phase nor maximum phase, the lattice moving average maximum phase structure will not be maximum phase.
- When you start with a maximum phase filter, the resulting lattice filter is maximum phase also.

The filter reflection coefficients are labeled  $k(i)$ ,  $i = 1, 2, 3$ . The states (used for initial and final state values in filtering) are labeled  $z(i)$ . In the figure, we set the Arithmetic property to fixed to reveal the fixed-point arithmetic format features that control such options as word length and fraction length.

### Example — Constructing a Lattice Moving Average Maximum Phase Filter

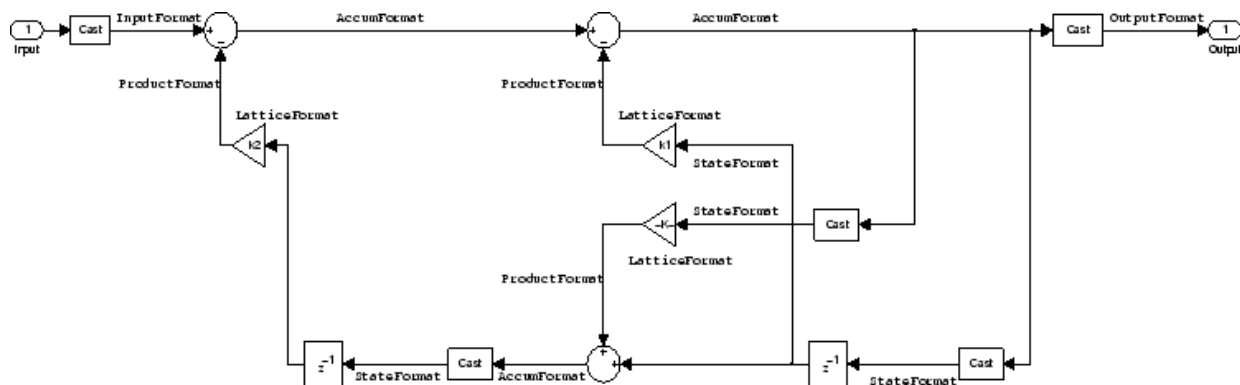

Constructing a fourth-order lattice MA maximum phase filter structure for a quantized filter  $h_q$  begins with the following code.

```
k = [.66 .7 .44 .33];
hd=dfilt.latticemamax(k);
```

### Lattice Autoregressive (AR) Filter Structure

The method `dfilt.latticear` directly realizes lattice autoregressive filters in the toolbox. The following figure depicts the third-order *lattice autoregressive (AR)* filter

structure — with the Arithmetic property equal to fixed. The filter reflection coefficients are labeled  $k(i)$ ,  $i = 1, 2, 3$ , and the states (used for initial and final state values in filtering) are labeled  $z(i)$ .

### Example — Specifying a Lattice AR Filter

You can specify a third-order lattice AR filter structure for a quantized filter `hq` with the following code.

```
k = [.66 .7 .44];
hd=dfilt.latticear(k);
hq.arithmetic = 'custom';
```

### Lattice Moving Average (MA) Filter Structure for Minimum Phase

The following figures depict *lattice moving average (MA)* filter structures that directly realize third-order lattice MA filters for minimum phase. The filter reflection coefficients are labeled  $k(i)$ ,  $(i) = 1, 2, 3$ , and the states (used for initial and final state values in filtering) are labeled  $z(i)$ . Setting the Arithmetic property of the filter to fixed results in a fixed-point filter that matches the figure.

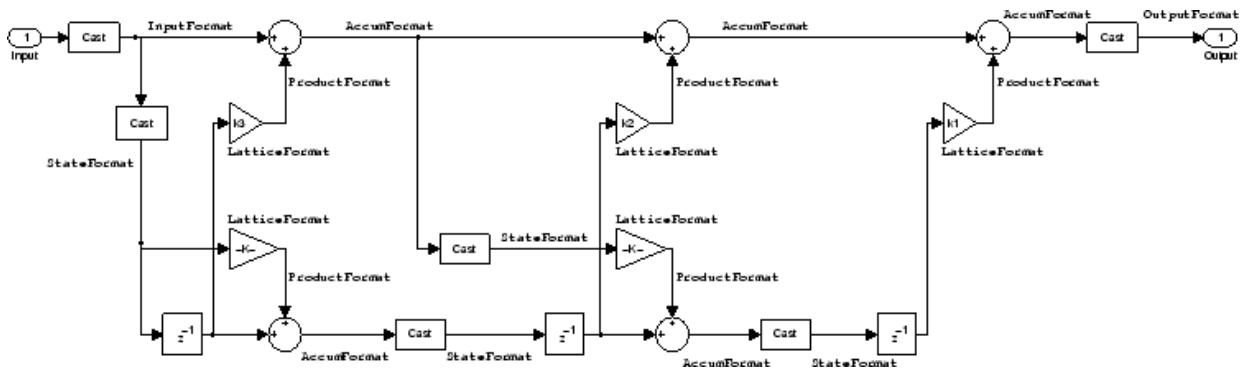

This signal flow diagram directly realizes a third-order lattice moving average (MA) filter with the following phase form depending on the initial transfer function:

- When you start with a minimum phase transfer function, the upper branch of the resulting lattice structure returns a minimum phase filter. The lower branch returns a minimum phase filter.
- When your transfer function is neither minimum phase nor maximum phase, the lattice moving average minimum phase structure will not be minimum phase.

- When you start with a minimum phase filter, the resulting lattice filter is minimum phase also.

The filter reflection coefficients are labeled  $k(i)$ ,  $i = 1, 2, 3$ . The states (used for initial and final state values in filtering) are labeled  $z(i)$ . This figure shows the filter structure when the `Arithmetic` property is set to `fixed` to reveal the fixed-point arithmetic format features that control such options as word length and fraction length.

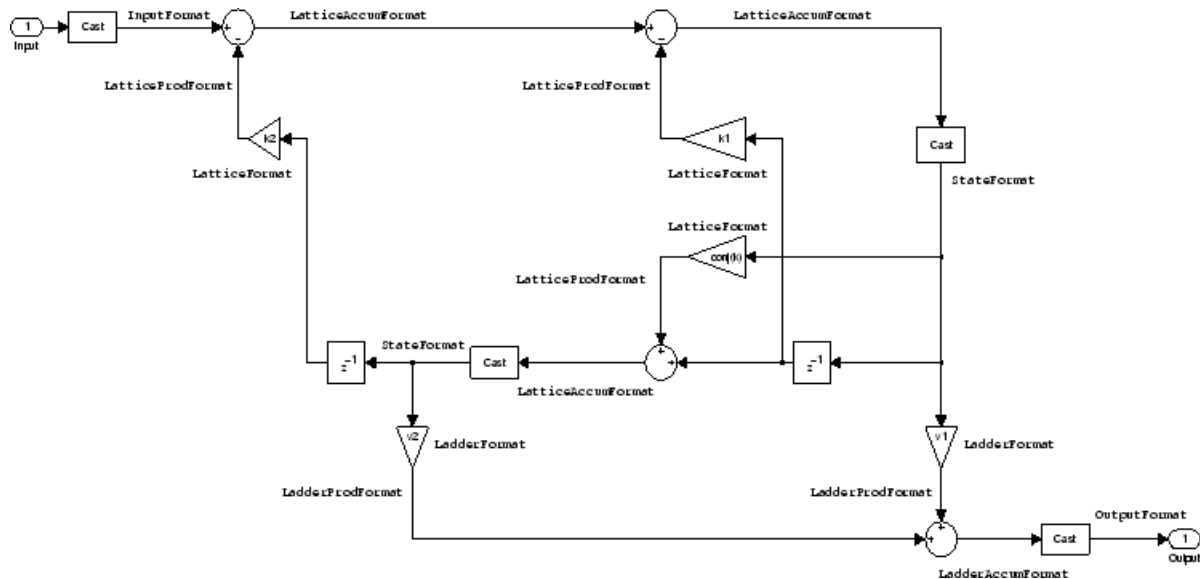

### Example — Specifying a Minimum Phase Lattice MA Filter

You can specify a third-order lattice MA filter structure for minimum phase applications using variations of the following code.

```
k = [.66 .7 .44];
hd=dfilt.latticemamin(k);
set(hq,'arithmetic','fixed');
```

### Lattice Autoregressive Moving Average (ARMA) Filter Structure

The figure below depicts a *lattice autoregressive moving average (ARMA)* filter structure that directly realizes a fourth-order lattice ARMA filter. The filter reflection coefficients are labeled  $k(i)$ ,  $(i) = 1, \dots, 4$ ; the ladder coefficients are labeled  $v(i)$ ,  $(i) = 1, 2, 3$ ; and the states (used for initial and final state values in filtering) are labeled  $z(i)$ .

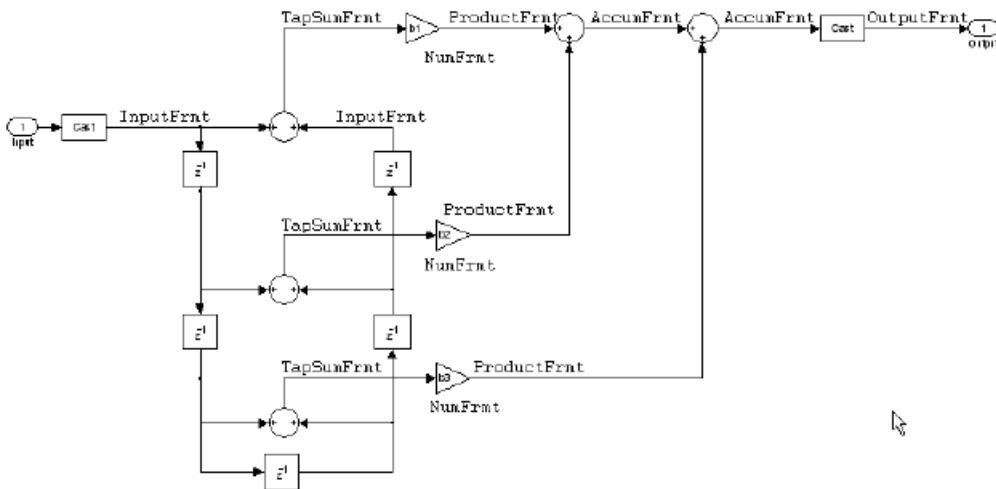

### Example — Specifying an Lattice ARMA Filter

The following code specifies a fourth-order lattice ARMA filter structure for a quantized filter `hq`, starting from `hd`, a floating-point version of the filter.

```
k = [.66 .7 .44 .66];
v = [1 0 0];
hd=dfilt.latticearma(k,v);
hq.arithmetic = 'fixed';
```

### Direct Form Symmetric FIR Filter Structure (Any Order)

Shown in the next figure, you see signal flow that depicts a *direct form symmetric FIR* filter structure that directly realizes a fifth-order direct form symmetric FIR filter. Filter coefficients are labeled  $b(i)$ ,  $i = 1, \dots, n$ , and states (used for initial and final state values in filtering) are labeled  $z(i)$ . Showing the filter structure used when you select `fixed` for the Arithmetic property value, the first figure details the properties in the filter object.

### Example — Specifying an Odd-Order Direct Form Symmetric FIR Filter

By using the following code in MATLAB, you can specify a fifth-order direct form symmetric FIR filter for a fixed-point filter `hq`:

```
b = [-0.008 0.06 0.44 0.44 0.06 -0.008];
hd=dfilt.dfsymfir(b);
set(hq,'arithmetic','fixed');
```

### Assigning Filter Coefficients

The syntax you use to assign filter coefficients for your floating-point or fixed-point filter depends on the structure you select for your filter.

### Converting Filters Between Representations

Filter conversion functions in this toolbox and in Signal Processing Toolbox software let you convert filter transfer functions to other filter forms, and from other filter forms to transfer function form. Relevant conversion functions include the following functions.

Conversion Function	Description
<code>ca2tf</code>	Converts from a coupled allpass filter to a transfer function.

Conversion Function	Description
<code>cl2tf</code>	Converts from a lattice coupled allpass filter to a transfer function.
<code>convert</code>	Convert a discrete-time filter from one filter structure to another.
<code>sos</code>	Converts quantized filters to create second-order sections. We recommend this method for converting quantized filters to second-order sections.
<code>tf2ca</code>	Converts from a transfer function to a coupled allpass filter.
<code>tf2cl</code>	Converts from a transfer function to a lattice coupled allpass filter.
<code>tf2latc</code>	Converts from a transfer function to a lattice filter.
<code>tf2sos</code>	Converts from a transfer function to a second-order section form.
<code>tf2ss</code>	Converts from a transfer function to state-space form.
<code>tf2zp</code>	Converts from a rational transfer function to its factored (single section) form (zero-pole-gain form).
<code>zp2sos</code>	Converts a zero-pole-gain form to a second-order section form.
<code>zp2ss</code>	Conversion of zero-pole-gain form to a state-space form.
<code>zp2tf</code>	Conversion of zero-pole-gain form to transfer functions of multiple order sections.

Note that these conversion routines do not apply to `dfilt` objects.

The function `convert` is a special case — when you use `convert` to change the filter structure of a fixed-point filter, you lose all of the filter states and settings. Your new filter has default values for all properties, and it is not fixed-point.

To demonstrate the changes that occur, convert a fixed-point direct form I transposed filter to direct form II structure.

```
hd=dfilt.dflt
```

```
hd =
```

```
    FilterStructure: 'Direct-Form I Transposed'
           Arithmetic: 'double'
```

```

        Numerator: 1
        Denominator: 1
    PersistentMemory: false
        States: Numerator: [0x0 double]
               Denominator:[0x0 double]

hd.arithmetic='fixed'
hd =

    FilterStructure: 'Direct-Form I Transposed'
    Arithmetic: 'fixed'
    Numerator: 1
    Denominator: 1
    PersistentMemory: false
        States: Numerator: [0x0 fi]
               Denominator:[0x0 fi]

convert(hd,'df2')

Warning: Using reference filter for structure conversion.
Fixed-point attributes will not be converted.

ans =

    FilterStructure: 'Direct-Form II'
    Arithmetic: 'double'
    Numerator: 1
    Denominator: 1
    PersistentMemory: false
        States: [0x1 double]

```

You can specify a filter with  $L$  sections of arbitrary order by

- 1 Factoring your entire transfer function with `tf2zp`. This converts your transfer function to zero-pole-gain form.
- 2 Using `zp2tf` to compose the transfer function for each section from the selected first-order factors obtained in step 1.

---

**Note** You are not required to normalize the leading coefficients of each section's denominator polynomial when you specify second-order sections, though `tf2sos` does.

---

**Gain**

`dfilt.scalar` filters have a gain value stored in the `gain` property. By default the gain value is one — the filter acts as a wire.

**InputFracLength**

`InputFracLength` defines the fraction length assigned to the input data for your filter. Used in tandem with `InputWordLength`, the pair defines the data format for input data you provide for filtering.

As with all fraction length properties in `dfilt` objects, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, in this case `InputWordLength`, as well.

**InputWordLength**

Specifies the number of bits your filter uses to represent your input data. Your word length option is limited by the arithmetic you choose — up to 32 bits for `double`, `float`, and `fixed`. Setting `Arithmetic` to `single` (single-precision floating-point) limits word length to 16 bits. The default value is 16 bits.

**Ladder**

Included as a property in `dfilt.latticearma` filter objects, `Ladder` contains the denominator coefficients that form an IIR lattice filter object. For instance, the following code creates a high pass filter object that uses the lattice ARMA structure.

```
[b,a]=cheby1(5,.5,.5,'high')  
b =  
    0.0282   -0.1409    0.2817   -0.2817    0.1409   -0.0282  
  
a =  
    1.0000    0.9437    1.4400    0.9629    0.5301    0.1620  
  
hd=dfilt.latticearma(b,a)  
hd =
```

```

FilterStructure: [1x44 char]
  Arithmetic: 'double'
  Lattice: [1x6 double]
  Ladder: [1 0.9437 1.4400 0.9629 0.5301 0.1620]
PersistentMemory: false
  States: [6x1 double]

```

```
hd.arithmetic='fixed'
```

```
hd =
```

```

FilterStructure: [1x44 char]
  Arithmetic: 'fixed'
  Lattice: [1x6 double]
  Ladder: [1 0.9437 1.4400 0.9629 0.5301 0.1620]
PersistentMemory: false
  States: [1x1 embedded.fi]

```

```

CoeffWordLength: 16
  CoeffAutoScale: true
  Signed: true

```

```

InputWordLength: 16
InputFracLength: 15

```

```

  OutputMode: 'AvoidOverflow'

```

```

StateWordLength: 16
StateFracLength: 15

```

```
  ProductMode: 'FullPrecision'
```

```

AccumWordLength: 40
  CastBeforeSum: true

```

```

  RoundMode: 'convergent'
  OverflowMode: 'wrap'

```

### **LadderAccumFracLength**

Autoregressive, moving average lattice filter objects (`latticearma`) use ladder coefficients to define the filter. In combination with `LadderFracLength` and `CoeffWordLength`, these three properties specify or reflect how the accumulator

outputs data stored there. As with all fraction length properties, `LadderAccumFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers. The default value is 29 bits.

### **LadderFracLength**

To let you control the way your `latticearma` filter interprets the denominator coefficients, `LadderFracLength` sets the fraction length applied to the ladder coefficients for your filter. The default value is 14 bits.

As with all fraction length properties, `LadderFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers.

### **Lattice**

When you create a lattice-based IIR filter, your numerator coefficients (from your IIR prototype filter or the default `dfilt` lattice filter function) get stored in the `Lattice` property of the `dfilt` object. The properties `CoeffWordLength` and `LatticeFracLength` define the data format the object uses to represent the lattice coefficients. By default, lattice coefficients are in double-precision format.

### **LatticeAccumFracLength**

Lattice filter objects (`latticeallpass`, `latticearma`, `latticeamax`, and `latticeamin`) use lattice coefficients to define the filter. In combination with `LatticeFracLength` and `CoeffWordLength`, these three properties specify how the accumulator outputs lattice coefficient-related data stored there. As with all fraction length properties, `LatticeAccumFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers. By default, the property is set to 31 bits.

### **LatticeFracLength**

To let you control the way your filter interprets the denominator coefficients, `LatticeFracLength` sets the fraction length applied to the lattice coefficients for your lattice filter. When you create the default lattice filter, `LatticeFracLength` is 16 bits.

As with all fraction length properties, `LatticeFracLength` can be any integer, including integers larger than `CoeffWordLength`, and positive or negative integers.

### **MultiplicandFracLength**

Each input data element for a multiply operation has both word length and fraction length to define its representation. `MultiplicandFracLength` sets the fraction length to use

when the filter object performs any multiply operation during filtering. For default filters, this is set to 15 bits.

As with all word and fraction length properties, `MultiplicandFracLength` can be any integer, including integers larger than `CoeffWordLength`, and positive or negative integers.

### **MultiplicandWordLength**

Each input data element for a multiply operation has both word length and fraction length to define its representation. `MultiplicandWordLength` sets the word length to use when the filter performs any multiply operation during filtering. For default filters, this is set to 16 bits. Only the `df1t` and `df1tsos` filter objects include the `MultiplicandFracLength` property.

Only the `df1t` and `df1tsos` filter objects include the `MultiplicandWordLength` property.

### **NumAccumFracLength**

Filter structures `df1`, `df1t`, `df2`, and `df2t` that use fixed arithmetic have this property that defines the fraction length applied to numerator coefficients in output from the accumulator. In combination with `AccumWordLength`, the `NumAccumFracLength` property fully specifies how the accumulator outputs numerator-related data stored there.

As with all fraction length properties, `NumAccumFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers. 30 bits is the default value when you create the filter object. To be able to change the value for this property, set `FilterInternals` for the filter to `SpecifyPrecision`.

### **Numerator**

The numerator coefficients for your filter, taken from the prototype you start with or from the default filter, are stored in this property. Generally this is a 1-by-N array of data in double format, where N is the length of the filter.

All of the filter objects include `Numerator`, except the lattice-based and second-order section filters, such as `dfilt.latticema` and `dfilt.df1tsos`.

### **NumFracLength**

Property `NumFracLength` contains the value that specifies the fraction length for the numerator coefficients for your filter. `NumFracLength` specifies the fraction length used

to interpret the numerator coefficients. Used in combination with `CoeffWordLength`, these two properties define the interpretation of the coefficients stored in the vector that contains the numerator coefficients.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 15 bits, with the `CoeffWordLength` of 16 bits.

### **NumProdFracLength**

A property of all of the direct form IIR `dfilt` objects, except the ones that implement second-order sections, `NumProdFracLength` specifies the fraction length applied to data output from product operations the filter performs on numerator coefficients.

Looking at the signal flow diagram for the `dfilt.dflt` filter, for example, you see that denominators and numerators are handled separately. When you set `ProductMode` to `SpecifyPrecision`, you can change the `NumProdFracLength` setting manually. Otherwise, for multiplication operations that use the numerator coefficients, the filter sets the word length as defined by the `ProductMode` setting.

### **NumStateFracLength**

All the variants of the direct form I structure include the property `NumStateFracLength` to store the fraction length applied to the numerator states for your filter object. By default, this property has the value 15 bits, with the `CoeffWordLength` of 16 bits, which you can change after you create the filter object.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well.

### **NumStateWordLength**

When you look at the flow diagram for the `df1sos` filter object, the states associated with the numerator coefficient operations take the data format from this property and the `NumStateFracLength` property. In combination, these properties fully specify how the filter interprets the state it uses.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 16 bits, with the `NumStateFracLength` of 11 bits.

## OutputFracLength

To define the output from your filter object, you need both the word and fraction lengths. `OutputFracLength` determines the fraction length applied to interpret the output data. Combining this with `OutputWordLength` fully specifies the format of the output.

Your fraction length can be any negative or positive integer, or zero. In addition, the fraction length you specify can be larger than the associated word length. Generally, the default value is 11 bits.

## OutputMode

Sets the mode the filter uses to scale the filtered (output) data. You have the following choices:

- `AvoidOverflow` — directs the filter to set the property that controls the output data fraction length to avoid causing the data to overflow. In a `df2` filter, this would be the `OutputFracLength` property.
- `BestPrecision` — directs the filter to set the property that controls the output data fraction length to maximize the precision in the output data. For `df1t` filters, this is the `OutputFracLength` property. When you change the word length (`OutputWordLength`), the filter adjusts the fraction length to maintain the best precision for the new word size.
- `SpecifyPrecision` — lets you set the fraction length used by the filtered data. When you select this choice, you can set the output fraction length using the `OutputFracLength` property to define the output precision.

All filters include this property except the direct form I filter which takes the output format from the filter states.

Here is an example that changes the mode setting to `bestprecision`, and then adjusts the word length for the output.

```

Changing the `OutputWordLength` to 8 bits caused the filter to change the `OutputFracLength` to 5 bits to keep the best precision for the output data.

## OutputWordLength

Use the property `OutputWordLength` to set the word length used by the output from your filter. Set this property to a value that matches your intended hardware. For example, some digital signal processors use 32-bit output so you would set `OutputWordLength` to 32.

```
[b,a] = butter(6,.5);
hd=dfilt.dflt(b,a);

set(hd,'arithmetic','fixed')

hd

hd =

        Arithmetic: 'fixed'
        Numerator: [1x7 double]
        Denominator: [1 0 0.7777 0 0.1142 0 0.0018]
    PersistentMemory: false
        States: Numerator: [6x1 fi]
              Denominator: [6x1 fi]

    CoeffWordLength: 16
        CoeffAutoScale: true
        Signed: true

    InputWordLength: 16
    InputFracLength: 15

    OutputWordLength: 32
        OutputMode: 'AvoidOverflow'

    MultiplicandWordLength: 16
    MultiplicandFracLength: 15

    StateWordLength: 16
        StateAutoScale: true

        ProductMode: 'FullPrecision'

    AccumWordLength: 40
        CastBeforeSum: true

        RoundMode: 'convergent'
        OverflowMode: 'wrap'
```

When you create a filter object, this property starts with the value 16.

## OverflowMode

The `OverflowMode` property is specified as one of the following two strings indicating how to respond to overflows in fixed-point arithmetic:

- `'saturate'` — saturate overflows.

When the values of data to be quantized lie outside of the range of the largest and smallest representable numbers (as specified by the applicable word length and fraction length properties), these values are quantized to the value of either the largest or smallest representable value, depending on which is closest. `saturate` is the default value for `OverflowMode`.

- `'wrap'` — wrap all overflows to the range of representable values.

When the values of data to be quantized lie outside of the range of the largest and smallest representable numbers (as specified by the data format properties), these values are wrapped back into that range using modular arithmetic relative to the smallest representable number. You can learn more about modular arithmetic in Fixed-Point Designer documentation.

These rules apply to the `OverflowMode` property.

- Applies to the accumulator and output data only.
- Does not apply to coefficients or input data. These always saturate the results.
- Does not apply to products. Products maintain full precision at all times. Your filters do not lose precision in the products.

---

**Note** Numbers in floating-point filters that extend beyond the dynamic range overflow to  $\pm\text{inf}$ .

---

## ProductFracLength

After you set `ProductMode` for a fixed-point filter to `SpecifyPrecision`, this property becomes available for you to change. `ProductFracLength` sets the fraction length the filter uses for the results of multiplication operations. Only the FIR filters such as asymmetric FIRs or lattice autoregressive filters include this dynamic property.

Your fraction length can be any negative or positive integer, or zero. In addition, the fraction length you specify can be larger than the associated word length. Generally, the default value is 11 bits.

### **ProductMode**

This property, available when your filter is in fixed-point arithmetic mode, specifies how the filter outputs the results of multiplication operations. All `dfilt` objects include this property when they use fixed-point arithmetic.

When available, you select from one of the following values for `ProductMode`:

- `FullPrecision` — means the filter automatically chooses the word length and fraction length it uses to represent the results of multiplication operations. The setting allow the product to retain the precision provided by the inputs (multiplicands) to the operation.
- `KeepMSB` — means you specify the word length for representing product operation results. The filter sets the fraction length to discard the LSBs, keep the higher order bits in the data, and maintain the precision.
- `KeepLSB` — means you specify the word length for representing the product operation results. The filter sets the fraction length to discard the MSBs, keep the lower order bits, and maintain the precision. Compare to the `KeepMSB` option.
- `SpecifyPrecision` — means you specify the word length and the fraction length to apply to data output from product operations.

When you switch to fixed-point filtering from floating-point, you are most likely going to throw away some data bits after product operations in your filter, perhaps because you have limited resources. When you have to discard some bits, you might choose to discard the least significant bits (LSB) from a result since the resulting quantization error would be small as the LSBs carry less weight. Or you might choose to keep the LSBs because the results have MSBs that are mostly zero, such as when your values are small relative to the range of the format in which they are represented. So the options for `ProductMode` let you choose how to maintain the information you need from the accumulator.

For more information about data formats, word length, and fraction length in fixed-point arithmetic, refer to “Notes About Fraction Length, Word Length, and Precision” on page 6-27.

### **ProductWordLength**

You use `ProductWordLength` to define the data word length used by the output from multiplication operations. Set this property to a value that matches your intended application. For example, the default value is 32 bits, but you can set any word length.

```
set(hq,'arithmetic','fixed');
set(hq,'ProductWordLength',64);
```

Note that `ProductWordLength` applies only to filters whose `Arithmetic` property value is `fixed`.

### PersistentMemory

Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter object. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false` — the filter does not retain memory about filtering operations from one to the next. Maintaining memory (setting `PersistentMemory` to `true`) lets you filter large data sets as collections of smaller subsets and get the same result.

In this example, filter `hd` first filters data `xtot` in one pass. Then you can use `hd` to filter `x` as two separate data sets. The results `ytot` and `ysec` are the same in both cases.

```
xtot=[x,x];
ytot=filter(hd,xtot)
ytot =
    0    -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
reset(hm1); % Clear history of the filter
hm1.PersistentMemory='true';
ysec=[filter(hd,x) filter(hd,x)]
ysec =
    0    -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
```

This test verifies that `ysec` (the signal filtered by sections) is equal to `ytot` (the entire signal filtered at once).

### RoundMode

The `RoundMode` property value specifies the rounding method used for quantizing numerical values. Specify the `RoundMode` property values as one of the following five strings.

RoundMode String	Description of Rounding Algorithm
Ceiling	Round toward positive infinity.
Floor	Round toward negative infinity.

RoundMode String	Description of Rounding Algorithm
Nearest	Round toward nearest. Ties round toward positive infinity.
Nearest (Convergent)	Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.
Round	Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.
Zero	Round toward zero.

The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.

### ScaleValueFracLength

Filter structures `df1sos`, `df1tsos`, `df2sos`, and `df2tsos` that use fixed arithmetic have this property that defines the fraction length applied to the scale values the filter uses between sections. In combination with `CoeffWordLength`, these two properties fully specify how the filter interprets and uses the scale values stored in the property `ScaleValues`. As with fraction length properties, `ScaleValueFracLength` can be any integer, including integers larger than `CoeffWordLength`, and positive or negative integers. 15 bits is the default value when you create the filter.

### ScaleValues

The `ScaleValues` property values are specified as a scalar (or vector) that introduces scaling for inputs (and the outputs from cascaded sections in the vector case) during filtering:

- When you only have a single section in your filter:
  - Specify the `ScaleValues` property value as a scalar if you only want to scale the input to your filter.
  - Specify the `ScaleValues` property as a vector of length 2 if you want to specify scaling to the input (scaled with the first entry in the vector) and the output (scaled with the last entry in the vector).

- When you have  $L$  cascaded sections in your filter:
  - Specify the `ScaleValues` property value as a scalar if you only want to scale the input to your filter.
  - Specify the value for the `ScaleValues` property as a vector of length  $L+1$  if you want to scale the inputs to every section in your filter, along with the output:

The first entry of your vector specifies the input scaling

Each successive entry specifies the scaling at the output of the next section

The final entry specifies the scaling for the filter output.

The default value for `ScaleValues` is 0.

The interpretation of this property is described as follows with diagrams in “Interpreting the `ScaleValues` Property” on page 6-77.

---

**Note** The value of the `ScaleValues` property is not quantized. Data affected by the presence of a scaling factor in the filter is quantized according to the appropriate data format.

---

When you apply `normalize` to a fixed-point filter, the value for the `ScaleValues` property is changed accordingly.

It is good practice to choose values for this property that are either positive or negative powers of two.

### Interpreting the `ScaleValues` Property

When you specify the values of the `ScaleValues` property of a quantized filter, the values are entered as a vector, the length of which is determined by the number of cascaded sections in your filter:

- When you have only one section, the value of the `ScaleValues` property can be a scalar or a two-element vector.
- When you have  $L$  cascaded sections in your filter, the value of the `ScaleValues` property can be a scalar or an  $L+1$ -element vector.

The following diagram shows how the `ScaleValues` property values are applied to a quantized filter with only one section.

### Application of ScaleValues to a Single Section

The following diagram shows how the ScaleValues property values are applied to a quantized filter with two sections.

### Application of ScaleValues to Multiple Sections

### Signed

When you create a `dfilt` object for fixed-point filtering (you set the property `Arithmetic` to `fixed`, the property `Signed` specifies whether the filter interprets coefficients as signed or unsigned. This setting applies only to the coefficients. While the default setting is `true`, meaning that all coefficients are assumed to be signed, you can change the setting to `false` after you create the fixed-point filter.

For example, create a fixed-point direct-form II transposed filter with both negative and positive coefficients, and then change the property value for `Signed` from `true` to `false` to see what happens to the negative coefficient values.

```
hd=dfilt.df2t(-5:5)
```

```
hd =
```

```
FilterStructure: 'Direct-Form II Transposed'
Arithmetic: 'double'
Numerator: [-5 -4 -3 -2 -1 0 1 2 3 4 5]
```

```

        Denominator: 1
    PersistentMemory: false
        States: [10x1 double]

set(hd,'arithmetic','fixed')
hd.numerator

ans =

    -5    -4    -3    -2    -1     0
     1     2     3     4     5

set(hd,'signed',false)
hd.numerator

ans =

     0     0     0     0     0     0
     1     2     3     4     5

```

Using unsigned coefficients limits you to using only positive coefficients in your filter. Signed is a dynamic property — you cannot set or change it until you switch the setting for the Arithmetic property to fixed.

### SosMatrix

When you convert a `dfilt` object to second-order section form, or create a second-order section filter, `sosMatrix` holds the filter coefficients as property values. Using the double data type by default, the matrix is in [sections coefficients per section] form, displayed as [15-x-6] for filters with 6 coefficients per section and 15 sections, [15 6].

To demonstrate, the following code creates an order 30 filter using second-order sections in the direct-form II transposed configuration. Notice the `sosMatrix` property contains the coefficients for all the sections.

```

d = fdesign.lowpass('n,fc',30,0.5);
hd = butter(d);

hd =

    FilterStructure: 'Direct-Form II, Second-Order Sections'
        Arithmetic: 'double'
        sosMatrix: [15x6 double]
        ScaleValues: [16x1 double]

```

```
PersistentMemory: false
    States: [2x15 double]

hd.arithmetic='fixed'

hd =

    FilterStructure: 'Direct-Form II, Second-Order Sections'
        Arithmetic: 'fixed'
        sosMatrix: [15x6 double]
        ScaleValues: [16x1 double]
    PersistentMemory: false
        States: [1x1 embedded.fi]

    CoeffWordLength: 16
        CoeffAutoScale: true
        Signed: true

    InputWordLength: 16
    InputFracLength: 15

    SectionInputWordLength: 16
    SectionInputAutoScale: true

    SectionOutputWordLength: 16
    SectionOutputAutoScale: true

        OutputWordLength: 16
        OutputMode: 'AvoidOverflow'

        StateWordLength: 16
        StateFracLength: 15

            ProductMode: 'FullPrecision'

        AccumWordLength: 40
        CastBeforeSum: true

            RoundMode: 'convergent'
            OverflowMode: 'wrap'

hd.sosMatrix

ans =
```

1.0000	2.0000	1.0000	1.0000	0	0.9005
1.0000	2.0000	1.0000	1.0000	0	0.7294
1.0000	2.0000	1.0000	1.0000	0	0.5888
1.0000	2.0000	1.0000	1.0000	0	0.4724

1.0000	2.0000	1.0000	1.0000	0	0.2948
1.0000	2.0000	1.0000	1.0000	0	0.2275
1.0000	2.0000	1.0000	1.0000	0	0.1716
1.0000	2.0000	1.0000	1.0000	0	0.1254
1.0000	2.0000	1.0000	1.0000	0	0.0878
1.0000	2.0000	1.0000	1.0000	0	0.0576
1.0000	2.0000	1.0000	1.0000	0	0.0344
1.0000	2.0000	1.0000	1.0000	0	0.0173
1.0000	2.0000	1.0000	1.0000	0	0.0062
1.0000	2.0000	1.0000	1.0000	0	0.0007

The SOS matrix is an M-by-6 matrix, where M is the number of sections in the second-order section filter. Filter `hd` has M equal to 15 as shown above (15 rows). Each row of the SOS matrix contains the numerator and denominator coefficients (b's and a's) and the scale factors of the corresponding section in the filter.

### SectionInputAutoScale

Second-order section filters include this property that determines who the filter handles data in the transitions from one section to the next in the filter.

How the filter represents the data passing from one section to the next depends on the property value of `SectionInputAutoScale`. The representation the filter uses between the filter sections depends on whether the value of `SectionInputAutoScale` is `true` or `false`.

- `SectionInputAutoScale = true` means the filter chooses the fraction length to maintain the value of the data between sections as close to the output values from the previous section as possible. `true` is the default setting.
- `SectionInputAutoScale = false` removes the automatic scaling of the fraction length for the intersection data and exposes the property that controls the coefficient fraction length (`SectionInputFracLength`) so you can change it. For example, if the filter is a second-order, direct form FIR filter, setting `SectionInputAutoScale` to `false` exposes the `SectionInputFracLength` property that specifies the fraction length applied to data between the sections.

### **SectionInputFracLength**

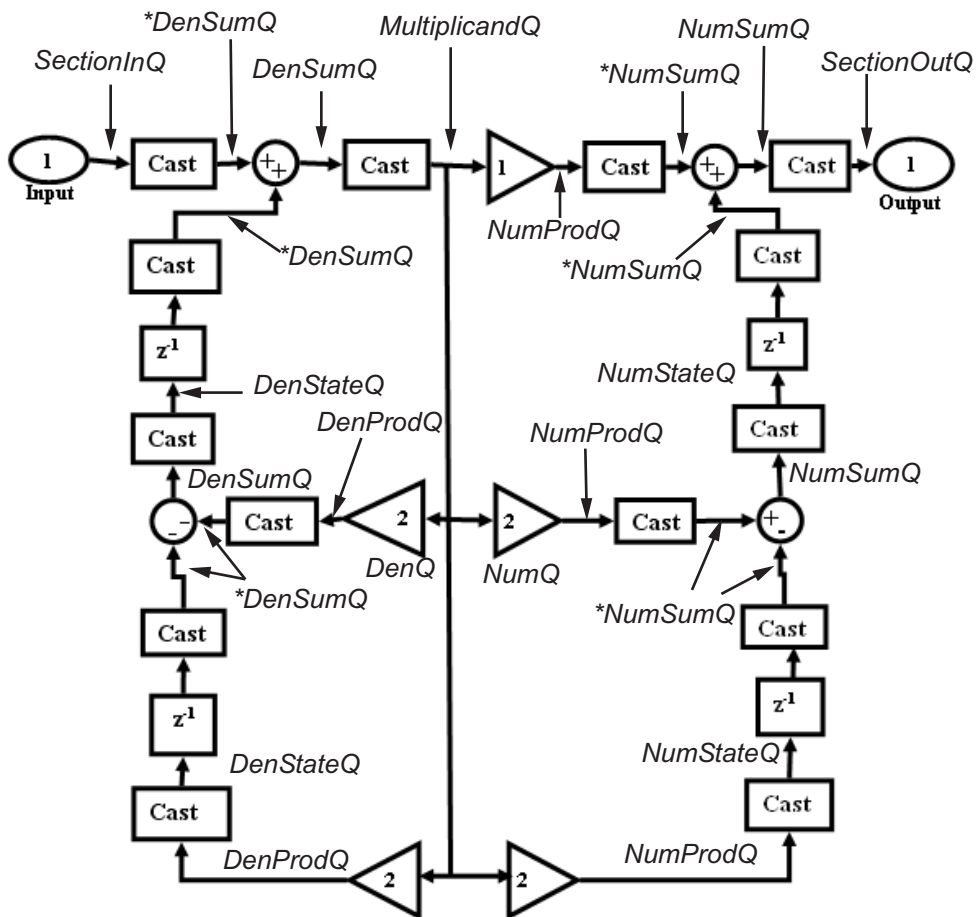

Second-order section filters use quantizers at the input to each section of the filter. The quantizers apply to the input data entering each filter section. Note that the quantizers for each section are the same. To set the fraction length for interpreting the input values, use the property value in `SectionInputFracLength`.

In combination with `CoeffWordLength`, `SectionInputFracLength` fully determines how the filter interprets and uses the state values stored in the property `States`. As with all word and fraction length properties, `SectionInputFracLength` can be any integer, including integers larger than `CoeffWordLength`, and positive or negative integers. 15 bits is the default value when you create the filter object.

### **SectionInputWordLength**

SOS filters are composed of sections, each one a second-order filter. Filtering data input to the filter involves passing the data through each filter section. `SectionInputWordLength` specifies the word length applied to data as it enters one filter section from the previous section. Only second-order implementations of direct-form I transposed and direct-form II transposed filters include this property.

The following diagram shows an SOS filter composed of sections (the bottom part of the diagram) and a possible internal structure of each Section (the top portion of the diagram), in this case — a direct form I transposed second order sections filter structure. Note that the output of each section is fed through a multiplier. If the gain of the multiplier =1, then the last Cast block of the Section is ignored, and the format of the output is NumSumQ.

\* : only if CastBeforeSum is True

`SectionInputWordLength` defaults to 16 bits.

### **SectionOutputAutoScale**

Second-order section filters include this property that determines who the filter handles data in the transitions from one section to the next in the filter.

How the filter represents the data passing from one section to the next depends on the property value of `SectionOutputAutoScale`. The representation the filter uses between the filter sections depends on whether the value of `SectionOutputAutoScale` is `true` or `false`.

- `SectionOutputAutoScale = true` means the filter chooses the fraction length to maintain the value of the data between sections as close to the output values from the previous section as possible. `true` is the default setting.
- `SectionOutputAutoScale = false` removes the automatic scaling of the fraction length for the intersection data and exposes the property that controls the coefficient fraction length (`SectionOutputFracLength`) so you can change it. For example, if the filter is a second-order, direct form FIR filter, setting `SectionOutputAutoScale = false` exposes the `SectionOutputFracLength` property that specifies the fraction length applied to data between the sections.

### **SectionOutputFracLength**

Second-order section filters use quantizers at the output from each section of the filter. The quantizers apply to the output data leaving each filter section. Note that the quantizers for each section are the same. To set the fraction length for interpreting the output values, use the property value in `SectionOutputFracLength`.

In combination with `CoeffWordLength`, `SectionOutputFracLength` determines how the filter interprets and uses the state values stored in the property `States`. As with all fraction length properties, `SectionOutputFracLength` can be any integer, including integers larger than `CoeffWordLength`, and positive or negative integers. 15 bits is the default value when you create the filter object.

### **SectionOutputWordLength**

SOS filters are composed of sections, each one a second-order filter. Filtering data input to the filter involves passing the data through each filter section. `SectionOutputWordLength` specifies the word length applied to data as it leaves one filter section to go to the next. Only second-order implementations direct-form I transposed and direct-form II transposed filters include this property.

The following diagram shows an SOS filter composed of sections (the bottom part of the diagram) and a possible internal structure of each Section (the top portion of the diagram), in this case — a direct form I transposed second order sections filter structure. Note that the output of each section is fed through a multiplier. If the gain of the multiplier =1, then the last Cast block of the Section is ignored, and the format of the output is NumSumQ.

`SectionOutputWordLength` defaults to 16 bits.

### **StateAutoScale**

Although all filters use states, some do not allow you to choose whether the filter automatically scales the state values to prevent overruns or bad arithmetic errors. You select either of the following settings:

- `StateAutoScale = true` means the filter chooses the fraction length to maintain the value of the states as close to the double-precision values as possible. When you change the word length applied to the states (where allowed by the filter structure), the filter object changes the fraction length to try to accommodate the change. `true` is the default setting.
- `StateAutoScale = false` removes the automatic scaling of the fraction length for the states and exposes the property that controls the coefficient fraction length so you can change it. For example, in a direct form I transposed SOS FIR filter, setting `StateAutoScale = false` exposes the `NumStateFracLength` and `DenStateFracLength` properties that specify the fraction length applied to states.

Each of the following filter structures provides the `StateAutoScale` property:

- `df1t`
- `df1tsos`
- `df2t`
- `df2tsos`
- `dffirt`

Other filter structures do not include this property.

### **StateFracLength**

Filter states stored in the property `States` have both word length and fraction length. To set the fraction length for interpreting the stored filter object state values, use the property value in `StateFracLength`.

In combination with `CoeffWordLength`, `StateFracLength` fully determines how the filter interprets and uses the state values stored in the property `States`.

As with all fraction length properties, `StateFracLength` can be any integer, including integers larger than `CoeffWordLength`, and positive or negative integers. 15 bits is the default value when you create the filter object.

## States

Digital filters are dynamic systems. The behavior of dynamic systems (their response) depends on the input (stimulus) to the system and the current or previous *state* of the system. You can say the system has memory or inertia. All fixed- or floating-point digital filters (as well as analog filters) have states.

Filters use the states to compute the filter output for each input sample, as well using them while filtering in loops to maintain the filter state between loop iterations. This toolbox assumes zero-valued initial conditions (the dynamic system is at rest) by default when you filter the first input sample. Assuming the states are zero initially does not mean the states are not used; they are, but arithmetically they do not have any effect.

Filter objects store the state values in the property `States`. The number of stored states depends on the filter implementation, since the states represent the delays in the filter implementation.

When you review the display for a filter object with fixed arithmetic, notice that the states return an embedded `fi` object, as you see here.

```
b = ellip(6,3,50,300/500);
hd=dfilt.dffir(b)
```

```
hd =
```

```
    FilterStructure: 'Direct-Form FIR'
           Arithmetic: 'double'
           Numerator: [0.0773 0.2938 0.5858 0.7239 0.5858 0.2938 0.0773]
 PersistentMemory: false
           States: [6x1 double]
```

```
hd.arithmetic='fixed'
```

```
hd =
```

```
    FilterStructure: 'Direct-Form FIR'
           Arithmetic: 'fixed'
           Numerator: [0.0773 0.2938 0.5858 0.7239 0.5858 0.2938 0.0773]
 PersistentMemory: false
           States: [1x1 embedded.fi]
```

```
    CoeffWordLength: 16
    CoeffAutoScale: 'on'
           Signed: 'on'
```

```
    InputWordLength: 16
    InputFracLength: 15
```

```
    OutputWordLength: 16
           OutputMode: 'AvoidOverflow'
```

```
           ProductMode: 'FullPrecision'
```

```

AccumWordLength: 40
CastBeforeSum: 'on'

    RoundMode: 'convergent'
    OverflowMode: 'wrap'

InheritSettings: 'off'

```

`fi` objects provide fixed-point support for the filters. To learn more about the details about `fi` objects, refer to your Fixed-Point Designer documentation.

The property `States` lets you use a `fi` object to define how the filter interprets the filter states. For example, you can create a `fi` object in MATLAB, then assign the object to `States`, as follows:

```
statefi=fi([],16,12)
```

```
statefi =
```

```

[]
  DataTypeMode = Fixed-point: binary point scaling
      Signed = true
  Wordlength = 16
  Fractionlength = 12

```

This `fi` object does not have a value associated (notice the `[]` input argument to `fi` for the value), and it has word length of 16 bits and fraction length of 12 bit. Now you can apply `statefi` to the `States` property of the filter `hd`.

```
set(hd,'States',statefi);
```

```
Warning: The 'States' property will be reset to the value
specified at construction before filtering.
```

```
Set the 'PersistentMemory' flag to 'True'
to avoid changing this property value.
```

```
hd
```

```
hd =
```

```

  FilterStructure: 'Direct-Form FIR'
    Arithmetic: 'fixed'
      Numerator: [0.0773 0.2938 0.5858 0.7239 0.5858
                 0.2938 0.0773]
  PersistentMemory: false
      States: [1x1 embedded.fi]

  CoeffWordLength: 16

```

```
CoeffAutoScale: 'on'

    CastBeforeSum: 'on'  
  
    RoundMode: 'convergent'  
    OverflowMode: 'wrap'
```

### StateWordLength

While all filters use states, some do not allow you to directly change the state representation — the word length and fraction lengths — independently. For the others, `StateWordLength` specifies the word length, in bits, the filter uses to represent the states. Filters that do not provide direct state word length control include:

- `df1`
- `dfasymfir`
- `dffir`
- `dfsymfir`

For these structures, the filter derives the state format from the input format you choose for the filter — except for the `df1` IIR filter. In this case, the numerator state format comes from the input format and the denominator state format comes from the output format. All other filter structures provide control of the state format directly.

### TapSumFracLength

Direct-form FIR filter objects, both symmetric and antisymmetric, use this property. To set the fraction length for output from the sum operations that involve the filter tap weights, use the property value in `TapSumFracLength`. To enable this property, set the `TapSumMode` to `SpecifyPrecision` in your filter.

As you can see in this code example that creates a fixed-point asymmetric FIR filter, the TapSumFracLength property becomes available after you change the TapSumMode property value.

```
hd=dfilt.dfasymfir
```

```
hd =
```

```
    FilterStructure: 'Direct-Form Antisymmetric FIR'
      Arithmetic: 'double'
      Numerator: 1
 PersistentMemory: false
      States: [0x1 double]
```

```
set(hd,'arithmetic','fixed');
```

```
hd
```

```
hd =
```

```
    FilterStructure: 'Direct-Form Antisymmetric FIR'
      Arithmetic: 'fixed'
      Numerator: 1
 PersistentMemory: false
      States: [1x1 embedded.fi]
```

```
    CoeffWordLength: 16
      CoeffAutoScale: true
      Signed: true
```

```
    InputWordLength: 16
      InputFracLength: 15
```

```
    OutputWordLength: 16
      OutputMode: 'AvoidOverflow'
```

```
      TapSumMode: 'KeepMSB'
    TapSumWordLength: 17
```

```
      ProductMode: 'FullPrecision'
```

```
    AccumWordLength: 40
```

```
      CastBeforeSum: true
```

```
    RoundMode: 'convergent'  
    OverflowMode: 'wrap'
```

With the filter now in fixed-point mode, you can change the `TapSumMode` property value to `SpecifyPrecision`, which gives you access to the `TapSumFracLength` property.

```
set(hd, 'TapSumMode', 'SpecifyPrecision');  
hd
```

```
hd =
```

```
    FilterStructure: 'Direct-Form Antisymmetric FIR'  
        Arithmetic: 'fixed'  
        Numerator: 1  
    PersistentMemory: false  
        States: [1x1 embedded.fi]  
  
    CoeffWordLength: 16  
        CoeffAutoScale: true  
        Signed: true  
  
    InputWordLength: 16  
    InputFracLength: 15  
  
    OutputWordLength: 16  
        OutputMode: 'AvoidOverflow'  
  
        TapSumMode: 'SpecifyPrecision'  
    TapSumWordLength: 17  
    TapSumFracLength: 15  
  
        ProductMode: 'FullPrecision'  
  
    AccumWordLength: 40  
  
    CastBeforeSum: true  
        RoundMode: 'convergent'  
        OverflowMode: 'wrap'
```

In combination with `TapSumWordLength`, `TapSumFracLength` fully determines how the filter interprets and uses the state values stored in the property `States`.

As with all fraction length properties, `TapSumFracLength` can be any integer, including integers larger than `TapSumWordLength`, and positive or negative integers. 15 bits is the default value when you create the filter object.

### **TapSumMode**

This property, available only after your filter is in fixed-point mode, specifies how the filter outputs the results of summation operations that involve the filter tap weights. Only symmetric (`dfilt.dfsymfir`) and antisymmetric (`dfilt.dfasymfir`) FIR filters use this property.

When available, you select from one of the following values:

- **FullPrecision** — means the filter automatically chooses the word length and fraction length to represent the results of the sum operation so they retain all of the precision provided by the inputs (addends).
- **KeepMSB** — means you specify the word length for representing tap sum summation results to keep the higher order bits in the data. The filter sets the fraction length to discard the LSBs from the sum operation. This is the default property value.
- **KeepLSB** — means you specify the word length for representing tap sum summation results to keep the lower order bits in the data. The filter sets the fraction length to discard the MSBs from the sum operation. Compare to the **KeepMSB** option.
- **SpecifyPrecision** — means you specify the word and fraction lengths to apply to data output from the tap sum operations.

### **TapSumWordLength**

Specifies the word length the filter uses to represent the output from tap sum operations. The default value is 17 bits. Only `dasympfir` and `dfsymfir` filters include this property.

## Multirate Filter Properties

### In this section...

“Compatibility” on page 6-94

“Property Summaries” on page 6-94

“Property Details for Multirate Filter Properties” on page 6-98

“References for Multirate Filters” on page 6-108

### Compatibility

`mfilt` objects will be removed in a future release. Refer to the reference page for a specific `mfilt` object to see its recommended replacement.

### Property Summaries

The following table summarizes the multirate filter properties and provides a brief description of each. Full descriptions of each property are given in the subsequent section.

Name	Values	Default	Description
BlockLength	Positive integers	100	Length of each block of data input to the FFT used in the filtering. <code>fftfirinterp</code> multirate filters include this property.
DecimationFactor	Any positive integer	2	Amount to reduce the input sampling rate.
DifferentialDelay	Any integer	1	Sets the differential delay for the filter. Usually a value of one or two is appropriate.

Name	Values	Default	Description
FilterInternals	FullPrecision, MinWordlengths, SpecifyWordLengths, SpecifyPrecision	FullPrecision	Controls whether the filter sets the output word and fraction lengths, and the accumulator word and fraction lengths automatically to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision exposes the output and accumulator related properties so you can set your own word and fraction lengths for them.
FilterStructure	mfilt structure string	None	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output. You cannot set this property — it is always read only and results from your choice of mfilt object.
InputOffset	Integers	0	Contains the number of input data samples processed without generating an output sample. $\text{InputOffset} = \text{mod}(\text{length}(nx), m)$ where $nx$ is the number of input samples that have been processed so far and $m$ is the decimation factor.

Name	Values	Default	Description
InterpolationFactor	Positive integers	2	Interpolation factor for the filter. 1 specifies the amount to increase the input sampling rate.
NumberOfSections	Any positive integer	2	Number of sections used in the decimator, or in the comb and integrator portions of CIC filters.
Numerator	Array of double values	No default values	Vector containing the coefficients of the FIR lowpass filter used for interpolation.
OverflowMode	saturate, [wrap]	wrap	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.

Name	Values	Default	Description
PolyphaseAccum	Values depend on filter type. Either double, single, or fixed-point object	0	Stores the value remaining in the accumulator after the filter processes the last input sample. The stored value for PolyphaseAccum affects the next output when PersistentMemory is true and InputOffset is not equal to 0. Always provides full precision values. Compare the AccumWordLength and AccumFracLength.
PersistentMemory	false or true	false	Determines whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.
RateChangeFactors	[l,m]	[2,3] or [3,2]	Reports the decimation (m) and interpolation (l) factors for the filter object. Combining these factors results in the final rate change for the signal. The default changes depending on whether the filter decimates or interpolates.

Name	Values	Default	Description
States	Any $m+1$ -by- $n$ matrix of double values	2-by-2 matrix, int32	Stored conditions for the filter, including values for the integrator and comb sections. $n$ is the number of filter sections and $m$ is the differential delay. Stored in a <code>filtstates</code> object.
SpecifyWordLengths	Vector of integers	[16 16 16 16] bits	
WordLengthPerSection	Any integer or a vector of length $2*n$	16	Defines the word length used in each section while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter <code>WordLengthPerSection</code> as a scalar or vector of length $2*n$ , where $n$ is the number of sections. When <code>WordLengthPerSection</code> is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the decimator.

The following sections provide details about the properties that govern the way multirate filter work. Creating any multirate filter object puts in place a number of these properties. The following pages list the `mfilt` object properties in alphabetical order.

## Property Details for Multirate Filter Properties

### BitsPerSection

Any integer or a vector of length  $2*n$ .

Defines the bits per section used while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using wrap arithmetic). Enter `bps`

as a scalar or vector of length  $2*n$ , where  $n$  is the number of sections. When `bps` is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the decimator.

### **BlockLength**

Length of each block of input data used in the filtering.

`mfilt.fftfirinterp` objects process data in blocks whose length is determined by the value you set for the `BlockLength` property. By default the property value is 100. When you set the `BlockLength` value, try choosing a value so that `[BlockLength + length(filter order)]` is a power of two.

Larger block lengths generally reduce the computation time.

### **DecimationFactor**

Decimation factor for the filter. `m` specifies the amount to reduce the sampling rate of the input signal. It must be an integer. You can enter any integer value. The default value is 2.

### **DifferentialDelay**

Sets the differential delay for the filter. Usually a value of one or two is appropriate. While you can set any value, the default is one and the maximum is usually two.

### **FilterInternals**

Similar to the `FilterInternals` pane in `FDATool`, this property controls whether the filter sets the output word and fraction lengths automatically, and the accumulator word and fraction lengths automatically as well, to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. Setting `FilterInternals` to `SpecifyPrecision` exposes the output and accumulator related properties so you can set your own word and fraction lengths for them.

#### **About FilterInternals Mode**

There are four usage modes for this that you set using the `FilterInternals` property in multirate filters.

- `FullPrecision` — All word and fraction lengths set to  $B_{max} + 1$ , called  $B_{accum}$  by Fred Harris in [2]. Full precision is the default setting.

- `MinWordLengths` — Minimum Word Lengths
- `SpecifyWordLengths` — Specify Word Lengths
- `SpecifyPrecision` — Specify Precision

### Full Precision

In full precision mode, the word lengths of all sections and the output are set to  $B_{accum}$  as defined by

$$B_{accum} = \text{ceil}(N_{secs}(\text{Log}_2(D \times M)) + \text{InputWordLength})$$

where  $N_{secs}$  is the number of filter sections.

Section fraction lengths and the fraction length of the output are set to the input fraction length.

Here is the display looks for this mode.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'  
Arithmetic: 'fixed'  
DifferentialDelay: 1  
NumberOfSections: 2  
DecimationFactor: 4  
PersistentMemory: false
```

```
InputWordLength: 16  
InputFracLength: 15
```

```
FilterInternals: 'FullPrecision'
```

### Minimum Word Lengths

In minimum word length mode, you control the output word length explicitly. When the output word length is less than  $B_{accum}$ , roundoff noise is introduced at the output of the filter. Hogenauer's bit pruning theory (refer to [3] in the following References section) states that one valid design criterion is to make the word lengths of the different sections of the filter smaller than  $B_{accum}$  as well, so that the roundoff noise introduced by all sections does not exceed the roundoff noise introduced at the output.

In this mode, the design calculates the word lengths of each section to meet the Hogenauer criterion. The algorithm subtracts the number of bits computed using eq. 21 in Hogenauer's paper from  $B_{accum}$  to determine the word length each section.

To compute the fraction lengths of the different sections, the algorithm notes that the bits thrown out for this word length criterion are least significant bits (LSB), therefore each bit thrown out at a particular section decrements the fraction length of that section by one bit compared to the input fraction length. Setting the output word length for the filter automatically sets the output fraction length as well.

Here is the display for this mode:

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false
```

```
InputWordLength: 16
InputFracLength: 15
```

```
FilterInternals: 'MinWordLengths'
```

```
OutputWordLength: 16
```

### Specify Word Lengths

In this mode, the design algorithm discards the LSBs, adjusting the fraction length so that unrecoverable overflow does not occur, always producing a reasonable output.

You can specify the word lengths for all sections and the output, but you cannot control the fraction lengths for those quantities.

To specify the word lengths, you enter a vector of length  $2*(\text{NumberOfSections})$ , where each vector element represents the word length for a section. If you specify a scalar, such as  $B_{accum}$ , the full-precision output word length, the algorithm expands that scalar to a vector of the appropriate size, applying the scalar value to each section.

The CIC design does not check that the specified word lengths are monotonically decreasing. There are some cases where the word lengths are not necessarily monotonically decreasing, for example

```
hcic=mfilt.cicdecim;
hcic.FilterInternals='minwordlengths';
hcic.Outputwordlength=14;
```

which are valid CIC filters but the word lengths do not decrease monotonically across the sections.

Here is the display looks like for the `SpecifyWordLengths` mode.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'  
Arithmetic: 'fixed'  
DifferentialDelay: 1  
NumberOfSections: 2  
DecimationFactor: 4  
PersistentMemory: false
```

```
InputWordLength: 16  
InputFracLength: 15
```

```
FilterInternals: 'SpecifyWordLengths'
```

```
SectionWordLengths: [19 18 18 17]
```

```
OutputWordLength: 16
```

### **Specify Precision**

In this mode, you have full control over the word length and fraction lengths of all sections and the filter output.

When you elect the `SpecifyPrecision` mode, you must enter a vector of length  $2*(\text{NumberOfSections})$  with elements that represent the word length for each section. When you enter a scalar such as  $B_{accum}$ , the CIC algorithm expands that scalar to a vector of the appropriate size and applies the scalar value to each section and the output. The design does not check that this vector is monotonically decreasing.

Also, you must enter a vector of length  $2*(\text{NumberOfSections})$  with elements that represent the fraction length for each section as well. When you enter a scalar such as  $B_{accum}$ , the design applies scalar expansion as done for the word lengths.

Here is the `SpecifyPrecision` display.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'  
Arithmetic: 'fixed'  
DifferentialDelay: 1  
NumberOfSections: 2  
DecimationFactor: 4  
PersistentMemory: false
```

```
InputWordLength: 16
InputFracLength: 15
```

```
FilterInternals: 'SpecifyPrecision'
```

```
SectionWordLengths: [19 18 18 17]
SectionFracLengths: [14 13 13 12]
```

```
OutputWordLength: 16
OutputFracLength: 11
```

### FilterStructure

Reports the type of filter object, such as a decimator or fractional integrator. You cannot set this property — it is always read only and results from your choice of `mfilt` object.

```
hm = mfilt.firdecim
```

```
hm =
```

```
    FilterStructure: 'Direct-Form FIR Polyphase Decimator'
           Arithmetic: 'double'
           Numerator: [1x48 double]
    DecimationFactor: 2
    PersistentMemory: false
```

### InputOffset

When you decimate signals whose length is not a multiple of the decimation factor  $M$ , the last samples —  $(nM + 1)$  to  $[(n+1)M - 1]$ , where  $n$  is an integer — are processed and used to track where the filter stopped processing input data and when to expect the next output sample. If you think of the filtering process as generating an output for a block of input data, `InputOffset` contains a count of the number of samples in the last incomplete block of input data.

---

**Note** `InputOffset` applies only when you set `PersistentMemory` to `true`. Otherwise, `InputOffset` is not available for you to use.

---

Two different cases can arise when you decimate a signal:

- 1 The input signal is a multiple of the filter decimation factor. In this case, the filter processes the input samples and generates output samples for all inputs as determined by the decimation factor. For example, processing 99 input samples with a filter that decimates by three returns 33 output samples.
- 2 The input signal is not a multiple of the decimation factor. When this occurs, the filter processes all of the input samples, generates output samples as determined by the decimation factor, and has one or more input samples that were processed but did not generate an output sample.

For example, when you filter 100 input samples with a filter which has decimation factor of 3, you get 33 output samples, and 1 sample that did not generate an output. In this case, `InputOffset` stores the value 1 after the filter run.

`InputOffset` equal to 1 indicates that, if you divide your input signal into blocks of data with length equal to your filter decimation factor, the filter processed one sample from a new (incomplete) block of data. Subsequent inputs to the filter are concatenated with this single sample to form the next block of length  $m$ .

One way to define the value stored in `InputOffset` is

```
InputOffset = mod(length(nx),m)
```

where  $nx$  is the number of input samples in the data set and  $m$  is the decimation factor.

Storing `InputOffset` in the filter allows you to stop filtering a signal at any point and start over from there, provided that the `PersistentMemory` property is set to `true`. Being able to resume filtering after stopping a signal lets you break large data sets in to smaller pieces for filtering. With `PersistentMemory` set to `true` and the `InputOffset` property in the filter, breaking a signal into sections of arbitrary length and filtering the sections is equivalent to filtering the entire signal at once.

```
xtot=[x,x];
ytot=filter(hm1,xtot)
ytot =

    0    -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
reset(hm1); % Clear history of the filter
hm1.PersistentMemory='true';
ysec=[filter(hm1,x) filter(hm1,x)]

ysec =

    0    -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
```

This test verifies that `ysec` (the signal filtered by sections) is equal to `ytot` (the entire signal filtered at once).

### **InterpolationFactor**

Amount to increase the sampling rate. Interpolation factor for the filter. It specifies the amount to increase the input sampling rate. It must be an integer. Two is the default value. You may use any positive value.

### **NumberOfSections**

Number of sections used in the multirate filter. By default multirate filters use two sections, but any positive integer works.

### **OverflowMode**

The `OverflowMode` property is specified as one of the following two strings indicating how to respond to overflows in fixed-point arithmetic:

- `'saturate'` — saturate overflows.

When the values of data to be quantized lie outside of the range of the largest and smallest representable numbers (as specified by the applicable word length and fraction length properties), these values are quantized to the value of either the largest or smallest representable value, depending on which is closest.

- `'wrap'` — wrap all overflows to the range of representable values.

When the values of data to be quantized lie outside of the range of the largest and smallest representable numbers (as specified by the data format properties), these values are wrapped back into that range using modular arithmetic relative to the smallest representable number. You can learn more about modular arithmetic in Fixed-Point Designer documentation.

These rules apply to the `OverflowMode` property.

- Applies to the accumulator and output data only.
- Does not apply to coefficients or input data. These always saturate the results.
- Does not apply to products. Products maintain full precision at all times. Your filters do not lose precision in the products.

### **Default value**

: 'saturate'

---

**Note** Numbers in floating-point filters that extend beyond the dynamic range overflow to  $\pm\text{inf}$ .

---

### **PolyphaseAccum**

The idea behind `PolyphaseAccum` and `AccumWordLength/AccumFracLength` is to distinguish between the adders that always work in full precision (`PolyphaseAccum`) from the others [the adders that are controlled by the user (through `AccumWordLength` and `AccumFracLength`) and that may introduce quantization effects when you set property `FilterInternals` to `SpecifyPrecision`].

Given a product format determined by the input word and fraction lengths, and the coefficients word and fraction lengths, doing full precision accumulation means allowing enough guard bits to avoid overflows and underflows.

Property `PolyphaseAccum` stores the value that was in the accumulator the last time your filter ran out of input samples to process. The default value for `PolyphaseAccum` affects the next output only if `PersistentMemory` is `true` and `InputOffset` is not equal to 0.

`PolyphaseAccum` stores data in the format for the filter arithmetic. Double-precision filters store doubles in `PolyphaseAccum`. Single-precision filter store singles in `PolyphaseAccum`. Fixed-point filters store `fi` objects in `PolyphaseAccum`.

### **PersistentMemory**

Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.

Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter object. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `true` — the filter retains memory about filtering operations from one to the next. Maintaining memory lets you filter large data sets as collections of smaller subsets and get the same result.

```

xtot=[x,x];
ytot=filter(hm1,xtot)
ytot =

    0   -0.0003   0.0005  -0.0014   0.0028  -0.0054   0.0092
reset(hm1); % Clear history of the filter
hm1.PersistentMemory='true';
ysec=[filter(hm1,x) filter(hm1,x)]

ysec =

    0   -0.0003   0.0005  -0.0014   0.0028  -0.0054   0.0092

```

This test verifies that `ysec` (the signal filtered by sections) is equal to `ytot` (the entire signal filtered at once).

### RateChangeFactors

Reports the decimation (`m`) and interpolation (`l`) factors for the filter object when you create fractional integrators and decimators, although `m` and `l` are used as arguments to both decimators and integrators, applying the same meaning. Combining these factors as input arguments to the fractional decimator or integrator results in the final rate change for the signal.

For decimating filters, the default is [2,3]. For integrators, [3,2].

### States

Stored conditions for the filter, including values for the integrator and comb sections. `m` is the differential delay and `n` is the number of sections in the filter.

#### About the States of Multirate Filters

In the `states` property you find the states for both the integrator and comb portions of the filter, stored in a `filtstates` object. `states` is a matrix of dimensions `m+1`-by-`n`, with the states in CIC filters apportioned as follows:

- States for the integrator portion of the filter are stored in the first row of the state matrix.
- States for the comb portion fill the remaining rows in the state matrix.

In the state matrix, state values are specified and stored in `double` format.

`States` stores conditions for the delays between each interpolator phase, the filter states, and the states at the output of each phase in the filter, including values for the interpolator and comb states.

The number of states is  $(l_h-1)*m+(l-1)*(l_o+m_o)$  where  $l_h$  is the length of each subfilter, and  $l$  and  $m$  are the interpolation and decimation factors.  $l_o$  and  $m_o$ , the input and output delays between each interpolation phase, are integers from Euclid's theorem such that  $l_o*l-m_o*m = -1$  (refer to the reference for more details). Use `euclidfactors` to get  $l_o$  and  $m_o$  for an `mfilt.firfracdecim` object.

`States` defaults to a vector of zeros that has length equal to `nstates(hm)`

## Glossary

This glossary defines terms related to fixed-point data types and numbers. These terms may appear in some or all of the documents that describe MathWorks® products that have fixed-point support.

**arithmetic shift** Shift of the bits of a binary word for which the sign bit is recycled for each bit shift to the right. A zero is incorporated into the least significant bit of the word for each bit shift to the left. In the absence of overflows, each arithmetic shift to the right is equivalent to a division by 2, and each arithmetic shift to the left is equivalent to a multiplication by 2.

*See also* binary point, binary word, bit, logical shift, most significant bit

**bias** Part of the numerical representation used to interpret a fixed-point number. Along with the slope, the bias forms the scaling of the number. Fixed-point numbers can be represented as

$$\text{real-world value} = (\text{slope} \times \text{stored integer}) + \text{bias}$$

where the slope can be expressed as

$$\text{slope} = \text{fractional slope} \times 2^{\text{exponent}}$$

*See also* fixed-point representation, fractional slope, integer, scaling, slope, [Slope Bias]

**binary number** Value represented in a system of numbers that has two as its base and that uses 1's and 0's (bits) for its notation.

*See also* bit

**binary point** Symbol in the shape of a period that separates the integer and fractional parts of a binary number. Bits to the left of the binary point are integer bits and/or sign bits, and bits to the right of the binary point are fractional bits.

	<p><i>See also</i> binary number, bit, fraction, integer, radix point</p>
<b>binary point-only scaling</b>	<p>Scaling of a binary number that results from shifting the binary point of the number right or left, and which therefore can only occur by powers of two.</p> <p><i>See also</i> binary number, binary point, scaling</p>
<b>binary word</b>	<p>Fixed-length sequence of bits (1's and 0's). In digital hardware, numbers are stored in binary words. The way in which hardware components or software functions interpret this sequence of 1's and 0's is described by a data type.</p> <p><i>See also</i> bit, data type, word</p>
<b>bit</b>	<p>Smallest unit of information in computer software or hardware. A bit can have the value 0 or 1.</p>
<b>ceiling (round toward)</b>	<p>Rounding mode that rounds to the closest representable number in the direction of positive infinity. This is equivalent to the <code>ceil</code> mode in Fixed-Point Designer software.</p> <p><i>See also</i> convergent rounding, floor (round toward), nearest (round toward), rounding, truncation, zero (round toward)</p>
<b>contiguous binary point</b>	<p>Binary point that occurs within the word length of a data type. For example, if a data type has four bits, its contiguous binary point must be understood to occur at one of the following five positions:</p> <p>.0000 0.000 00.00 000.0 0000.</p> <p><i>See also</i> data type, noncontiguous binary point, word length</p>

**convergent rounding**

Rounding mode that rounds to the nearest allowable quantized value. Numbers that are exactly halfway between the two nearest allowable quantized values are rounded up only if the least significant bit (after rounding) would be set to 0.

*See also* ceiling (round toward), floor (round toward), nearest (round toward), rounding, truncation, zero (round toward)

**data type**

Set of characteristics that define a group of values. A fixed-point data type is defined by its word length, its fraction length, and whether it is signed or unsigned. A floating-point data type is defined by its word length and whether it is signed or unsigned.

*See also* fixed-point representation, floating-point representation, fraction length, signedness, word length

**data type override**

Parameter in the Fixed-Point Tool that allows you to set the output data type and scaling of fixed-point blocks on a system or subsystem level.

*See also* data type, scaling

**exponent**

Part of the numerical representation used to express a floating-point or fixed-point number.

1. Floating-point numbers are typically represented as

$$\text{real-world value} = \text{mantissa} \times 2^{\text{exponent}}$$

2. Fixed-point numbers can be represented as

$$\text{real-world value} = (\text{slope} \times \text{stored integer}) + \text{bias}$$

where the slope can be expressed as

$$\text{slope} = \text{fractional slope} \times 2^{\text{exponent}}$$

The exponent of a fixed-point number is equal to the negative of the fraction length:

$$\text{exponent} = -1 \times \text{fraction length}$$

*See also* bias, fixed-point representation, floating-point representation, fraction length, fractional slope, integer, mantissa, slope

**fixed-point representation**

Method for representing numerical values and data types that have a set range and precision.

1. Fixed-point numbers can be represented as

$$\text{real-world value} = (\text{slope} \times \text{stored integer}) + \text{bias}$$

where the slope can be expressed as

$$\text{slope} = \text{fractional slope} \times 2^{\text{exponent}}$$

The slope and the bias together represent the scaling of the fixed-point number.

2. Fixed-point data types can be defined by their word length, their fraction length, and whether they are signed or unsigned.

*See also* bias, data type, exponent, fraction length, fractional slope, integer, precision, range, scaling, slope, word length

**floating-point representation**

Method for representing numerical values and data types that can have changing range and precision.

1. Floating-point numbers can be represented as

$$\text{real-world value} = \text{mantissa} \times 2^{\text{exponent}}$$

2. Floating-point data types are defined by their word length.

---

	<i>See also</i> data type, exponent, mantissa, precision, range, word length
<b>floor (round toward)</b>	<p>Rounding mode that rounds to the closest representable number in the direction of negative infinity.</p> <p><i>See also</i> ceiling (round toward), convergent rounding, nearest (round toward), rounding, truncation, zero (round toward)</p>
<b>fraction</b>	<p>Part of a fixed-point number represented by the bits to the right of the binary point. The fraction represents numbers that are less than one.</p> <p><i>See also</i> binary point, bit, fixed-point representation</p>
<b>fraction length</b>	<p>Number of bits to the right of the binary point in a fixed-point representation of a number.</p> <p><i>See also</i> binary point, bit, fixed-point representation, fraction</p>
<b>fractional slope</b>	<p>Part of the numerical representation used to express a fixed-point number. Fixed-point numbers can be represented as</p> $real\text{-}world\ value = (slope \times stored\ integer) + bias$ <p>where the slope can be expressed as</p> $slope = fractional\ slope \times 2^{exponent}$ <p>The term <i>slope adjustment</i> is sometimes used as a synonym for fractional slope.</p> <p><i>See also</i> bias, exponent, fixed-point representation, integer, slope</p>
<b>full range</b>	<p>The broadest range available for a data type. From <math>-\infty</math> to <math>\infty</math> for floating-point types. For integer types, the representable range is the range from the smallest to</p>

largest integer value (finite) the type can represent. For example, from -128 to 127 for a signed 8-bit integer. Also known as representable range.

**guard bits**

Extra bits in either a hardware register or software simulation that are added to the high end of a binary word to ensure that no information is lost in case of overflow.

*See also* binary word, bit, overflow

**incorrect range**

A range that is too restrictive and does not include values that can actually occur in the model element. A range that is too broad is not considered incorrect because it will not lead to overflow.

*See also* range analysis

**integer**

1. Part of a fixed-point number represented by the bits to the left of the binary point. The integer represents numbers that are greater than or equal to one.

2. Also called the "stored integer." The raw binary number, in which the binary point is assumed to be at the far right of the word. The integer is part of the numerical representation used to express a fixed-point number. Fixed-point numbers can be represented as

$$\text{real-world value} = 2^{-\text{fraction length}} \times \text{stored integer}$$

or

$$\text{real-world value} = (\text{slope} \times \text{stored integer}) + \text{bias}$$

where the slope can be expressed as

$$\text{slope} = \text{fractional slope} \times 2^{\text{exponent}}$$

*See also* bias, fixed-point representation, fractional slope, integer, real-world value, slope

---

<b>integer length</b>	<p>Number of bits to the left of the binary point in a fixed-point representation of a number.</p> <p><i>See also</i> binary point, bit, fixed-point representation, fraction length, integer</p>
<b>least significant bit (LSB)</b>	<p>Bit in a binary word that can represent the smallest value. The LSB is the rightmost bit in a big-endian-ordered binary word. The weight of the LSB is related to the fraction length according to</p> $\text{weight of LSB} = 2^{-\text{fraction length}}$ <p><i>See also</i> big-endian, binary word, bit, most significant bit</p>
<b>logical shift</b>	<p>Shift of the bits of a binary word, for which a zero is incorporated into the most significant bit for each bit shift to the right and into the least significant bit for each bit shift to the left.</p> <p><i>See also</i> arithmetic shift, binary point, binary word, bit, most significant bit</p>
<b>mantissa</b>	<p>Part of the numerical representation used to express a floating-point number. Floating-point numbers are typically represented as</p> $\text{real-world value} = \text{mantissa} \times 2^{\text{exponent}}$ <p><i>See also</i> exponent, floating-point representation</p>
<b>model element</b>	<p>Entities in a model that range analysis software tracks, for example, blocks, signals, parameters, block internal data (such as accumulators, products).</p> <p><i>See also</i> range analysis</p>
<b>most significant bit (MSB)</b>	<p>Bit in a binary word that can represent the largest value. The MSB is the leftmost bit in a big-endian-ordered binary word.</p>

	<i>See also</i> binary word, bit, least significant bit
<b>nearest (round toward)</b>	Rounding mode that rounds to the closest representable number, with the exact midpoint rounded to the closest representable number in the direction of positive infinity. This is equivalent to the <b>nearest</b> mode in Fixed-Point Designer software.  <i>See also</i> ceiling (round toward), convergent rounding, floor (round toward), rounding, truncation, zero (round toward)
<b>noncontiguous binary point</b>	Binary point that is understood to fall outside the word length of a data type. For example, the binary point for the following 4-bit word is understood to occur two bits to the right of the word length,  0000__.  thereby giving the bits of the word the following potential values:  $2^5 2^4 2^3 2^2$ __.  <i>See also</i> binary point, data type, word length
<b>one's complement representation</b>	Representation of signed fixed-point numbers. Negating a binary number in one's complement requires a bitwise complement. That is, all 0's are flipped to 1's and all 1's are flipped to 0's. In one's complement notation there are two ways to represent zero. A binary word of all 0's represents "positive" zero, while a binary word of all 1's represents "negative" zero.  <i>See also</i> binary number, binary word, sign/magnitude representation, signed fixed-point, two's complement representation
<b>overflow</b>	Situation that occurs when the magnitude of a calculation result is too large for the range of the data type being

used. In many cases you can choose to either saturate or wrap overflows.

*See also* saturation, wrapping

**padding**

Extending the least significant bit of a binary word with one or more zeros.

*See also* least significant bit

**precision**

1. Measure of the smallest numerical interval that a fixed-point data type and scaling can represent, determined by the value of the number's least significant bit. The precision is given by the slope, or the number of fractional bits. The term *resolution* is sometimes used as a synonym for this definition.

2. Measure of the difference between a real-world numerical value and the value of its quantized representation. This is sometimes called quantization error or quantization noise.

*See also* data type, fraction, least significant bit, quantization, quantization error, range, slope

**Q format**

Representation used by Texas Instruments™ to encode signed two's complement fixed-point data types. This fixed-point notation takes the form

$Q_{m.n}$

where

- $Q$  indicates that the number is in Q format.
- $m$  is the number of bits used to designate the two's complement integer part of the number.
- $n$  is the number of bits used to designate the two's complement fractional part of the number, or the number of bits to the right of the binary point.

	<p>In Q format notation, the most significant bit is assumed to be the sign bit.</p> <p><i>See also</i> binary point, bit, data type, fixed-point representation, fraction, integer, two's complement</p>
<b>quantization</b>	<p>Representation of a value by a data type that has too few bits to represent it exactly.</p> <p><i>See also</i> bit, data type, quantization error</p>
<b>quantization error</b>	<p>Error introduced when a value is represented by a data type that has too few bits to represent it exactly, or when a value is converted from one data type to a shorter data type. Quantization error is also called quantization noise.</p> <p><i>See also</i> bit, data type, quantization</p>
<b>radix point</b>	<p>Symbol in the shape of a period that separates the integer and fractional parts of a number in any base system. Bits to the left of the radix point are integer and/or sign bits, and bits to the right of the radix point are fraction bits.</p> <p><i>See also</i> binary point, bit, fraction, integer, sign bit</p>
<b>range</b>	<p>Span of numbers that a certain data type can represent.</p> <p><i>See also</i> data type, full range, precision, representable range</p>
<b>range analysis</b>	<p>Static analysis of model to derive minimum and maximum range values for elements in the model. The software statically analyzes the ranges of the individual computations in the model based on specified design ranges, inputs, and the semantics of the calculation.</p>
<b>real-world value</b>	<p>Stored integer value with fixed-point scaling applied. Fixed-point numbers can be represented as</p>

$$real - world\ value = 2^{-fraction\ length} \times stored\ integer$$

or

$$\text{real-world value} = (\text{slope} \times \text{stored integer}) + \text{bias}$$

where the slope can be expressed as

$$\text{slope} = \text{fractional slope} \times 2^{\text{exponent}}$$

*See also* integer

**representable range**

The broadest range available for a data type. From  $-\infty$  to  $\infty$  for floating-point types. For integer types, the representable range is the range from the smallest to largest integer value (finite) the type can represent. For example, from -128 to 127 for a signed 8-bit integer. Also known as full range.

**resolution**

*See* **precision**

**rounding**

Limiting the number of bits required to express a number. One or more least significant bits are dropped, resulting in a loss of precision. Rounding is necessary when a value cannot be expressed exactly by the number of bits designated to represent it.

*See also* bit, ceiling (round toward), convergent rounding, floor (round toward), least significant bit, nearest (round toward), precision, truncation, zero (round toward)

**saturation**

Method of handling numeric overflow that represents positive overflows as the largest positive number in the range of the data type being used, and negative overflows as the largest negative number in the range.

*See also* overflow, wrapping

**scaled double**

A double data type that retains fixed-point scaling information. For example, in Simulink and Fixed-Point Designer software you can use data type override to convert your fixed-point data types to scaled doubles. You can then simulate to determine the ideal floating-point behavior of your system. After you gather that information

you can turn data type override off to return to fixed-point data types, and your quantities still have their original scaling information because it was held in the scaled double data types.

**scaling**

1. Format used for a fixed-point number of a given word length and signedness. The slope and bias together form the scaling of a fixed-point number.

2. Changing the slope and/or bias of a fixed-point number without changing the stored integer.

*See also* bias, fixed-point representation, integer, slope

**shift**

Movement of the bits of a binary word either toward the most significant bit ("to the left") or toward the least significant bit ("to the right"). Shifts to the right can be either logical, where the spaces emptied at the front of the word with each shift are filled in with zeros, or arithmetic, where the word is sign extended as it is shifted to the right.

*See also* arithmetic shift, logical shift, sign extension

**sign bit**

Bit (or bits) in a signed binary number that indicates whether the number is positive or negative.

*See also* binary number, bit

**sign extension**

Addition of bits that have the value of the most significant bit to the high end of a two's complement number. Sign extension does not change the value of the binary number.

*See also* binary number, guard bits, most significant bit, two's complement representation, word

**sign/magnitude representation**

Representation of signed fixed-point or floating-point numbers. In sign/magnitude representation, one bit of a binary word is always the dedicated sign bit, while the remaining bits of the word encode the magnitude of the number. Negation using sign/magnitude representation

---

	<p>consists of flipping the sign bit from 0 (positive) to 1 (negative), or from 1 to 0.</p> <p><i>See also</i> binary word, bit, fixed-point representation, floating-point representation, one's complement representation, sign bit, signed fixed-point, signedness, two's complement representation</p>
<b>signed fixed-point</b>	<p>Fixed-point number or data type that can represent both positive and negative numbers.</p> <p><i>See also</i> data type, fixed-point representation, signedness, unsigned fixed-point</p>
<b>signedness</b>	<p>The signedness of a number or data type can be signed or unsigned. Signed numbers and data types can represent both positive and negative values, whereas unsigned numbers and data types can only represent values that are greater than or equal to zero.</p> <p><i>See also</i> data type, sign bit, sign/magnitude representation, signed fixed-point, unsigned fixed-point</p>
<b>slope</b>	<p>Part of the numerical representation used to express a fixed-point number. Along with the bias, the slope forms the scaling of a fixed-point number. Fixed-point numbers can be represented as</p> $\text{real-world value} = (\text{slope} \times \text{stored integer}) + \text{bias}$ <p>where the slope can be expressed as</p> $\text{slope} = \text{fractional slope} \times 2^{\text{exponent}}$ <p><i>See also</i> bias, fixed-point representation, fractional slope, integer, scaling, [Slope Bias]</p>
<b>slope adjustment</b>	<i>See</i> <b>fractional slope</b>
<b>[Slope Bias]</b>	Representation used to define the scaling of a fixed-point number.

*See also* bias, scaling, slope

**stored integer**

*See* **integer**

**trivial scaling**

Scaling that results in the real-world value of a number being simply equal to its stored integer value:

$$\text{real-world value} = \text{stored integer}$$

In [Slope Bias] representation, fixed-point numbers can be represented as

$$\text{real-world value} = (\text{slope} \times \text{stored integer}) + \text{bias}$$

In the trivial case, slope = 1 and bias = 0.

In terms of binary point-only scaling, the binary point is to the right of the least significant bit for trivial scaling, meaning that the fraction length is zero:

$$\text{real-world value} = \text{stored integer} \times 2^{-\text{fraction length}} = \text{stored integer} \times 2^0$$

Scaling is always trivial for pure integers, such as `int8`, and also for the true floating-point types `single` and `double`.

*See also* bias, binary point, binary point-only scaling, fixed-point representation, fraction length, integer, least significant bit, scaling, slope, [Slope Bias]

**truncation**

Rounding mode that drops one or more least significant bits from a number.

*See also* ceiling (round toward), convergent rounding, floor (round toward), nearest (round toward), rounding, zero (round toward)

**two's complement representation**

Common representation of signed fixed-point numbers. Negation using signed two's complement representation consists of a translation into one's complement followed by the binary addition of a one.

	<p><i>See also</i> binary word, one's complement representation, sign/magnitude representation, signed fixed-point</p>
<b>unsigned fixed-point</b>	<p>Fixed-point number or data type that can only represent numbers greater than or equal to zero.</p> <p><i>See also</i> data type, fixed-point representation, signed fixed-point, signedness</p>
<b>word</b>	<p>Fixed-length sequence of binary digits (1's and 0's). In digital hardware, numbers are stored in words. The way hardware components or software functions interpret this sequence of 1's and 0's is described by a data type.</p> <p><i>See also</i> binary word, data type</p>
<b>word length</b>	<p>Number of bits in a binary word or data type.</p> <p><i>See also</i> binary word, bit, data type</p>
<b>wrapping</b>	<p>Method of handling overflow. Wrapping uses modulo arithmetic to cast a number that falls outside of the representable range the data type being used back into the representable range.</p> <p><i>See also</i> data type, overflow, range, saturation</p>
<b>zero (round toward)</b>	<p>Rounding mode that rounds to the closest representable number in the direction of zero. This is equivalent to the <code>fix</code> mode in Fixed-Point Designer software.</p> <p><i>See also</i> ceiling (round toward), convergent rounding, floor (round toward), nearest (round toward), rounding, truncation</p>
