The software described in this document is furnished under a license agreement. The software may be used or copied only under the terms of the license agreement. No part of this manual may be photocopied or reproduced in any form without prior written consent from The MathWorks, Inc.

FEDERAL ACQUISITION: This provision applies to all acquisitions of the Program and Documentation by, for, or through the federal government of the United States. By accepting delivery of the Program or Documentation, the government hereby agrees that this software or documentation qualifies as commercial computer software or commercial computer software documentation as such terms are used or defined in FAR 12.212, DFARS Part 227.72, and DFARS 252.227-7014. Accordingly, the terms and conditions of this Agreement and only those rights specified in this Agreement, shall pertain to and govern the use, modification, reproduction, release, performance, display, and disclosure of the Program and Documentation by the federal government (or other entity acquiring for or through the federal government) and shall supersede any conflicting contractual terms or conditions. If this License fails to meet the government's needs or is inconsistent in any respect with federal procurement law, the government agrees to return the Program and Documentation, unused, to The MathWorks, Inc.

Trademarks

MATLAB and Simulink are registered trademarks of The MathWorks, Inc. See www.mathworks.com/trademarks for a list of additional trademarks. Other product or brand names may be trademarks or registered trademarks of their respective holders.

Patents

MathWorks products are protected by one or more U.S. patents. Please see www.mathworks.com/patents for more information.

Revision History

April 2011	Online only	New for Version 6.0 (Release 2011a)
September 2011	Online only	Revised for Version 6.1 (Release 2011b)
March 2012	Online only	Revised for Version 6.2 (Release 2012a)
September 2012	Online only	Revised for Version 6.3 (Release 2012b)
March 2013	Online only	Revised for Version 6.4 (Release 2013a)
September 2013	Online only	Revised for Version 6.5 (Release 2013b)
March 2014	Online only	Revised for Version 6.6 (Release 2014a)
October 2014	Online only	Revised for Version 6.7 (Release 2014b)
March 2015	Online only	Revised for Version 6.8 (Release 2015a)
September 2015	Online only	Revised for Version 6.9 (Release 2015b)
October 2015	Online only	Rereleased for Version 6.8.1 (Release 2015aSP1)
March 2016	Online only	Revised for Version 6.10 (Release 2016a)
September 2016	Online only	Revised for Version 6.11 (Release 2016b)
March 2017	Online only	Revised for Version 6.12 (Release 2017a)
September 2017	Online only	Revised for Version 6.13 (Release 2017b)
March 2018	Online only	Revised for Version 7.0 (Release 2018a)

Check Bug Reports for Issues and Fixes

Software is inherently complex and is not free of errors. The output of a code generator might contain bugs, some of which are not detected by a compiler. MathWorks reports critical known bugs brought to its attention on its Bug Report system at www.mathworks.com/support/bugreports/. Use the Saved Searches and Watched Bugs tool with the search phrase "Incorrect Code Generation" to obtain a report of known bugs that produce code that might compile and execute, but still produce wrong answers.

The bug reports are an integral part of the documentation for each release. Examine periodically all bug reports for a release, as such reports may identify inconsistencies between the actual behavior of a release you are using and the behavior described in this documentation.

In addition to reviewing bug reports, you should implement a verification and validation strategy to identify potential bugs in your design, code, and tools.

Model Architecture and Design

1	Modeling Environment for Embedded Coder	
	Design Models for Generated Embedded Code	
	Deployment	1-2
	Application Algorithms and Run-Time Environments	1-2
	Software Execution Framework for Generated Code	1-3
	Map Embedded System Architecture to Simulink Modeling Environment	1-5
	Model Templates for Code Generation	1-14
	Model Single-Core, Single-Tasking Platform	
	Execution	1-16
	Model Single-Core, Multitasking Platform Execution	1-21
	Model Concurrent Execution for Symmetric Multicore CPU Platforms	1-26
	Model Explicit Function Invocation with Atomic Subsystems	1-34
	Model Explicit Function Invocation with Function-Call Subsystems	1-39
	Modeling Patterns for AUTOSAR Runnables	1-44

Modeling in Simulink Coder

2

Configure a Model for Code Generation	2-2
Blocks and Products Supported for C Code	
Generation	2-4
Related Products	2-4
Simulink Built-In Blocks That Support Code	
Generation	2-7
Simulink Block Data Type Support Table	2-30
Block Set Support for Code Generation	2-30
Modeling Semantic Considerations	2-31
Data Propagation	2-31
Sample Time Propagation	2-33
Latches for Subsystem Blocks	2-34
Block Execution Order	2-35
Algebraic Loops	2-36
Modeling Guidelines for Blocks	2-39
Modeling Guidelines for Subsystems	2-40
Modeling Guidelines for Charts	2-43
Modeling Guidelines for MATLAB Functions	2-45
Modeling Guidelines for Model Configuration	2-46

Subsystems in Simulink Coder

3

Control Generation of Subsystem Functions	3-2
What is a Subsystem Function?	3-2
Options for Controlling Generation of Subsystem Function	
Code	3-2
Subsystem Function Dependence	3-2

Generate Code and Executables for Individual Subsystems	3-4
Subsystem Build Limitations	3-6
Inline Subsystem Code	3-8
Configure Subsystem to Inline Code	3-8
Exceptions to Inlining	3-9
Generate Subsystem Code as Separate Function and Files	3-11
Optimize Code for Identical Nested Subsystems	3-12
Code Generation of Constant Parameters	3-13

Referenced Models in Simulink Coder

4

Code Generation of Referenced Models	4-2
Generate Code for Referenced Models	4-4
About Generating Code for Referenced Models	4-4
Create and Configure the Subsystem	4-4
Convert Model to Use Model Referencing	4-7
Generate Model Reference Code for a GRT Target	4-10
Work with Code Generation Folders	4-12
Configure Referenced Models	4-14
Build Model Reference Targets	4-15
Reduce Change Checking Time	4-15
Simulink Coder Model Referencing Requirements	4-16
Configuration Parameter Requirements	4-16
Configuration Parameters Changed During Code Generation	4-19
Naming Requirements	4-20
Custom Target Requirements	4-20

Storage Classes for Signals Used with Model Blocks . . .	4-21
Storage Classes for Parameters Used with Model Blocks	4-21
Signal Name Mismatches Across Model Reference Boundary	4-22
Inherited Sample Time for Referenced Models	4-25
Customize Library File Suffix and File Type	4-27
Simulink Coder Model Referencing Limitations	4-28
Customization Limitations	4-28
Data Logging Limitations	4-28
State Initialization Limitation	4-29
Reusability Limitations	4-29
S-Function Limitations	4-30
Simulink Tool Limitations	4-30
Subsystem Limitations	4-30
Target Limitations	4-30
Other Limitations	4-31
Configuration Parameters Changed During Accelerated Simulation and Code Generation	4-31

Combined Models in Simulink Coder

5

Combine Code Generated for Multiple Models	5-2
Techniques	5-2
Control Ownership of Data	5-3
Combine Code Generated for Multiple Models or Multiple Instances of a Model	5-3

Code Reuse for Simulink Coder

6

What Is Code Reuse?	6-2
--------------------------------------	------------

What Is Reentrant Code?	6-4
Choose a Componentization Technique for Code Reuse	6-6
Simulink Function Blocks and Code Generation	6-8
Why Generate Code from Simulink Function Blocks and Function Callers?	6-8
Implementation Options	6-8
Choose a Modeling Pattern	6-9
Specify Function Scope	6-11
Decide Whether to Generate Export Function Code ...	6-11
Specify Function Code Interface Customizations	6-11
Requirements	6-12
Limitations	6-12
Generate and Call Reusable Function Code	6-13
Generate Code for a Simulink Function and Function Caller	6-20
Generate Reentrant Code from Top Models	6-24
Generate Reentrant, Multi-Instance Code	6-25
Share Data Between Instances	6-28
Generate Reentrant Code from Simulink Function Blocks	6-30
Identify Requirements	6-30
Create Model	6-31
Configure Model and Model Elements	6-33
Generate and Inspect C Code	6-35
Generate and Inspect C++ Code	6-37
Limitations	6-41
Generate Reentrant Code from Subsystems	6-42
Limitations	6-43
Determine Why Subsystem Code Is Not Reused	6-45
Generate Reusable Code From Referenced Models	6-50
Considerations for Subsystems that Contain Referenced Models	6-50
Code Reuse and Model Blocks with Root Inport or Outport Blocks	6-50

Generate Reusable Code from Library Subsystems Shared	
Across Models	6-53
What Is a Reusable Library Subsystem?	6-53
Reusable Library Subsystem Code Placement and Naming	6-54
Configure Reusable Library Subsystem	6-54
Configure Models That Include Reusable Library Subsystems	6-55
Generate Reusable Code for Subsystems Shared Across Models	6-55
Generate Reusable Code from Stateflow Atomic	
Subcharts	6-64
Generate Reusable Code for Linked Atomic Subcharts .	6-64
Generate Reusable Code for Unlinked Atomic Subcharts	6-65
Generate Reusable Code for Unit Testing	6-65
Generate Shared Utility Code	6-70
When to Generate Shared Utility Code	6-70
Configure Naming of Generated Functions	6-70
Control Placement of Shared Utility Code	6-71
Control Placement of rtwtypes.h for Shared Utility Code	6-72
Avoid Duplicate Header Files for Exported Data	6-73
Reduce Shared Utility Code Generation with Incremental Builds	6-73
Manage the Shared Utility Code Checksum	6-74
Generate Shared Utility Code for Fixed-Point	
Functions	6-80
Generate Shared Utility Code for Custom Data Types . .	6-82
Shared Constant Parameters for Code Reuse	6-84
Suppress Shared Constants in the Generated Code	6-85

Configure Model Parameters for Simulink Coder

7

Configure Run-Time Environment Options	7-2
Configure Production and Test Hardware	7-3
Production Hardware Considerations	7-13
Test Hardware Considerations	7-14
Example Production Hardware Setting That Affects Normal Mode Simulation	7-14

Model Protection in Simulink Coder

8

Protect Models for Third-Party Use	8-2
Requirements for Protecting a Model	8-3
Harness Model	8-4
Protected Model Report	8-5
Code Generation Support in Protected Models	8-6
Protected Model Requirements to Support Code Generation	8-6
Protected Model File	8-9
Create a Protected Model	8-11
Protected Model Creation Settings	8-16
Open Read-Only View of Model	8-17
Simulate	8-17
Use Generated Code	8-17
Create a Protected Model with Multiple Targets	8-19
Use a Protected Model with Multiple Targets	8-21
Test the Protected Model	8-22

Save Base Workspace Definitions	8-24
Package a Protected Model	8-25
Specify Custom Obfuscator for Protected Model	8-26
Define Callbacks for Protected Models	8-28
Creating Callbacks	8-28
Defining Callback Code	8-28
Create a Protected Model with Callbacks	8-29

Component Initialization, Reset, and Termination in Simulink Coder

9

Generate Code That Responds to Initialize, Reset, and Terminate Events	9-2
Generate Code for Initialize and Terminate Events	9-2
Generate Code for Reset Events	9-7
Event Names and Code Aggregation	9-9
Limitation	9-12

Stateflow Blocks in Simulink Coder

10

Code Generation of Stateflow Blocks	10-2
Comparison of Code Generation Methods	10-2
Generate Reusable Code for Atomic Subcharts	10-6
How to Generate Reusable Code for Linked Atomic Subcharts	10-6
How to Generate Reusable Code for Unlinked Atomic Subcharts	10-7
Generate Reusable Code for Unit Testing	10-8
Goal of the Tutorial	10-8
Convert a State to an Atomic Subchart	10-9

Specify Code Generation Parameters	10-10
Generate Code for Only the Atomic Subchart	10-11
Inline State Functions in Generated Code	10-14
Inlined Generated Code for State Functions	10-14
How to Set the State Function Inline Option	10-16
Best Practices for Controlling State Function	
Inlining	10-16
Air-Fuel Ratio Control System with Stateflow Charts ..	10-17

Block Authoring and Code Generation for Simulink Coder

11

S-Functions and Code Generation	11-2
Types of S-Functions	11-3
Files Required for Implementing Noninlined and Inlined S- Functions	11-5
Guidelines for Writing S-Functions that Support Code Generation	11-6
Import Calls to External Code into Generated Code with Legacy Code Tool	11-7
Legacy Code Tool and Code Generation	11-7
Generate Inlined S-Function Files for Code Generation	11-8
Apply Code Style Settings to Legacy Functions	11-9
Address Dependencies on Files in Different Locations	11-9
Deploy S-Functions for Simulation and Code Generation	11-10
Integrate External C++ Object Methods	11-11
Integrate External C++ Objects	11-14
Legacy Code Tool Examples	11-16
External Code Integration Examples	11-51
Insert External C and C++ Code Into Stateflow Charts for Code Generation	11-51

Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters	11-53
Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters	11-56
Insert External C and C++ Code Into Stateflow Charts for Code Generation	11-59
Generate S-Function from Subsystem	11-62
Macro Parameters	11-65
Write S-Function and TLC Files By Hand	11-67
Write Noninlined S-Function and TLC Files	11-67
Write Wrapper S-Function and TLC Files	11-69
Write Fully Inlined S-Functions	11-78
Write Fully Inlined S-Functions with mdlRTW Routine	11-79
Guidelines for Writing Inlined S-Functions	11-87
S-Functions That Support Expression Folding	11-87
S-Functions That Specify Port Scope and Reusability ..	11-99
S-Functions That Specify Sample Time Inheritance Rules	11-103
S-Functions That Support Code Reuse	11-105
S-Functions for Multirate Multitasking Environments	11-106

Guidelines and Standards for Embedded Coder

12

Support for Standards and Guidelines	12-2
MAAB Guidelines	12-5
MISRA C Guidelines	12-6
Secure Coding Standards	12-8

IEC 61508 Standard	12-9
Apply Simulink and Embedded Coder to the IEC 61508 Standard	12-9
Check for IEC 61508 Standard Compliance Using the Model Advisor	12-9
Validate Traceability	12-9
 Develop a Model that Complies with the IEC 61508 Standard	12-11
 IEC 62304 Standard	12-14
Apply Simulink and Embedded Coder to the IEC 62304 Standard	12-14
Check for IEC 62304 Standard Compliance Using the Model Advisor	12-14
 ISO 26262 Standard	12-15
Apply Simulink and Embedded Coder to the ISO 26262 Standard	12-15
Check for ISO 26262 Standard Compliance Using the Model Advisor	12-15
Validate Traceability	12-15
 EN 50128 Standard	12-17
Apply Simulink and Embedded Coder to the EN 50128 Standard	12-17
Check for EN 50128 Standard Compliance Using the Model Advisor	12-17
Validate Traceability	12-17
 DO-178C Standard	12-19
Apply Simulink and Embedded Coder to the DO-178C Standard	12-19
Check for Standard Compliance Using the Model Advisor	12-19
Validate Traceability	12-19

MISRA C:2012 Compliance and Deviations for Code Generated by Using Embedded Coder

13

Using This Documentation When Developing a MISRA C: 2012 Compliance Statement	13-2
MathWorks Process for Identifying Violations of MISRA C: 2012 Guidelines in Generated C Code	13-2
Evaluate Your Generated Code for MISRA C:2012 Compliance	13-4
Compliance Information Summary Tables	13-7
Compliance Summary Tables	13-7
Explanatory Notes	13-17
Modeling Guidelines for MISRA C:2012 Compliance . .	13-21
High-Integrity System Modeling Guidelines for MISRA C: 2012 Compliance	13-21
MISRA C:2012 Rationale for Model Advisor Checks . .	13-23
Deviations Rationale	13-30
MISRA C:2012 Directive 4.7 Deviation Rationale	13-30
MISRA C:2012 Rule 13.5 Deviation Rationale	13-34
MISRA C:2012 Rule 21.1 Deviation Rationale	13-36

Patterns for C Code in Embedded Coder

14

Prepare a Model for Code Generation	14-3
Configure Input Ports, Output Ports, and Arbitrary Signals	14-3
Initialize and Configure States	14-4
Set Up Configuration Parameters for Code Generation	14-4
Set Up an Example Model With a Stateflow Chart	14-5
Set Up an Example Model With a MATLAB Function Block	14-6

Definition, Initialization, and Declaration of Parameter Data	14-7
C Construct	14-7
Procedure	14-7
Results	14-8
Definition and Declaration of Signal Data	14-9
C Construct	14-9
Procedure	14-9
Results	14-9
Data Type Conversion	14-11
C Construct	14-11
Modeling Patterns	14-11
Modeling Pattern for Data Type Conversion — Simulink Block	14-11
Modeling Pattern for Data Type Conversion — Stateflow Chart	14-12
Modeling Pattern for Data Type Conversion — MATLAB Function Block	14-13
Other Type Conversions in Modeling	14-13
Type Qualifiers	14-14
C Construct	14-14
Procedure	14-14
Results	14-15
Relational and Logical Operators	14-16
Modeling Patterns for Relational and Logical Operators	14-16
Modeling Pattern for Relational or Logical Operators — Simulink Blocks	14-16
Modeling Pattern for Relational and Logical Operators — Stateflow Chart	14-17
Modeling Pattern for Relational and Logical Operators — MATLAB Function Block	14-18
Bitwise Operations	14-20
Simulink Bitwise-Operator Block	14-20
Stateflow Chart	14-21

Variant Systems in Embedded Coder

15

Implement Dimension Variants for Array Sizes in Generated Code	15-2
Dimension Variants	15-2
Set Parameter Value Based on Variant Choice	15-11
Code Generation Optimization Considerations	15-12
Backward Compatibility	15-13
Supported Blocks	15-13
Limitations	15-14
Code Generation for Variant Blocks	15-18
Restrictions on Variant Subsystem Code Generation ..	15-18
Generated Code Components Not Compiled Conditionally	15-20
Code Generation for Variant Blocks with One Variant Choice	15-20
Represent Subsystem and Model Variants in Generated Code	15-23
Step 1: Represent Variant Choices in Simulink	15-23
Step 2: Specify Conditions That Control Variant Choice Selection	15-27

Step 3: Configure Model for Generating Preprocessor Conditionals	15-29
Step 4: Review Generated Code	15-30
Limitations	15-33
Generate Preprocessor Conditionals for Variant	
Systems	15-35
Define Variant Controls	15-35
Configure Model for Generating Preprocessor Conditional Directives	15-36
Special Considerations for Generating Preprocessor Conditionals	15-37
Generate Variant Control Macros in Same Header File	15-38
Represent Variant Source and Sink Blocks in Generated	
Code	15-42
Represent Variant Source and Variant Sink blocks in Simulink	15-42
Specify Conditions That Control Variant Choice Selection	15-47
Review the Generated Code	15-47
Generate Code with Zero Active Variant Controls	15-49
Global Data Guarding Limitation	15-50
State Logging Limitation	15-50
Configure Dimension Variants for S-Function Blocks .	
S-Function That Supports Forward Propagation of Symbolic Dimensions	15-54
S-Function That Supports Forward and Backward Propagation of Symbolic Dimensions	15-55
Generate Code for Variant Subsystem with Child	
Subsystems of Different Output Signal	
Dimensions	15-57
Example Model	15-57
Simulate Model	15-58
Generate Code	15-59

16

Absolute and Elapsed Time Computation	16-2
About Timers	16-2
Timers for Periodic and Asynchronous Tasks	16-3
Allocation of Timers	16-3
Integer Timers in Generated Code	16-3
Elapsed Time Counters in Triggered Subsystems	16-4
Access Timers Programmatically	16-5
About Timer APIs	16-5
C API for S-Functions	16-5
TLC API for Code Generation	16-7
Generate Code for an Elapsed Time Counter	16-9
Absolute Time Limitations	16-12

Time-Based Scheduling in Simulink Coder

17

Time-Based Scheduling and Code Generation	17-2
Sample Time Considerations	17-2
Tasking Modes	17-2
Model Execution and Rate Transitions	17-4
Execution During Simulink Model Simulation	17-5
Model Execution in Real Time	17-5
Single-Tasking Versus Multitasking Operation	17-6
Modeling for Single-Tasking Execution	17-8
Single-Tasking Mode	17-8
Build a Program for Single-Tasking Execution	17-8
Single-Tasking Execution	17-8
Modeling for Multitasking Execution	17-12
Multitasking and Pseudomultitasking Modes	17-12
Build a Program for Multitasking Execution	17-14
Execute Multitasking Models	17-14

Multitasking Execution	17-16
Handle Rate Transitions	17-21
Rate Transitions	17-21
Data Transfer Problems	17-22
Data Transfer Assumptions	17-23
Rate Transition Block Options	17-23
Automatic Rate Transition	17-26
Visualize Inserted Rate Transition Blocks	17-27
Periodic Sample Rate Transitions	17-29
Protect Data Integrity with volatile Keyword	17-35
Separate Rate Transition Block Code and Data from Algorithm Code and Data	17-35
Configure Time-Based Scheduling	17-37
Configure Start and Stop Times	17-37
Configure the Solver Type	17-37
Configure the Tasking Mode	17-38
Time-Based Scheduling Example Models	17-39
Optimize Memory Usage for Time Counters	17-39
Single-Rate Modeling (Bare Board, No OS)	17-45
Multirate Modeling in Single-Tasking Mode (Bare Board, no OS)	17-47
Multirate Modeling in Multitasking Mode (Bare Board, no OS)	17-49
Trade Determinism and Data Integrity to Improve System Performance	17-51

Event-Based Scheduling in Simulink Coder

18

Asynchronous Events	18-2
Asynchronous Support	18-2
Block Library for Calls to an Example Real-Time Operating System	18-2
Access the Block Library for RTOS Integration	18-4
Generate Code Using Library Blocks for RTOS Integration	18-4
Examples and Additional Information	18-4

Generate Interrupt Service Routines	18-6
Connecting the Async Interrupt Block	18-6
Requirements and Restrictions	18-7
Performance Considerations	18-7
Using the Async Interrupt Block in Simulation and Code Generation	18-8
Dual-Model Approach: Simulation	18-9
Dual-Model Approach: Code Generation	18-9
Spawn and Synchronize Execution of RTOS Task	18-15
Pass Asynchronous Events in RTOS as Input To a Referenced Model	18-32
Rate Transitions and Asynchronous Blocks	18-40
About Rate Transitions and Asynchronous Blocks	18-40
Handle Rate Transitions for Asynchronous Tasks	18-42
Handle Multiple Asynchronous Interrupts	18-42
Protect Data Integrity with volatile Keyword	18-44
Timers in Asynchronous Tasks	18-46
Create a Customized Asynchronous Library	18-49
About Implementing Asynchronous Blocks	18-49
Async Interrupt Block Implementation	18-50
Task Sync Block Implementation	18-54
asynclib.tlc Support Library	18-56
Import Asynchronous Event Data for Simulation	18-59
Capabilities	18-59
Input Data Format	18-59
Example	18-59
Asynchronous Support Limitations	18-63
Asynchronous Task Priority	18-63
Convert an Asynchronous Subsystem into a Model Reference	18-63

Scheduling Considerations in Embedded Coder

19

Use Discrete and Continuous Time	19-2
Support for Discrete and Continuous Time Blocks	19-2
Support for Continuous Solvers	19-2
Support for Stop Time	19-2
Optimize Multirate Multitasking Execution for RTOS Run-Time Environments	19-4
Use <code>rtmStepTask</code>	19-4
Schedule Code for Real-time Model without an RTOS	19-4
Schedule Code for Multirate Multitasking on an RTOS	19-5
Suppress Redundant Scheduling Calls	19-5

Representing a Software Architecture by Creating Code Generation Definitions

20

Define Storage Classes, Memory Sections, and Function Templates for Software Architecture	20-2
Create Code Definitions for Use as Default Code Generation Settings	20-2
Create Code Definitions to Override Default Settings ..	20-3
Avoid Maintaining Duplicate Definitions in Packages and Dictionaries	20-3
Deploy Code Generation Definitions to Users	20-3
Maintain Code Generation Definitions	20-4
Interact with Code Generation Definitions Programmatically	20-5
Deploy Code Generation Definitions	20-6
Share Code Generation Definitions Between Multiple Models and Users	20-6
Share Embedded Coder Dictionary Definition Between Models	20-6

Migrate Definitions from Model File to Shared Data Dictionary	20-9
Definitions in Shared Dictionary Do Not Appear in Code Mapping Editor	20-12
Make Shared Definitions in a Data Dictionary Available to New Models	20-12
Use Data Dictionary to Store Code Definitions but Not Design Data	20-13
Opening Code Perspective Generates Error	20-13
Limitations for Definitions in a Simulink Data Dictionary	20-13

**Conform to Software Architecture by Sharing and Copying
Default Code Generation Settings Between**

Models	20-15
Tools to Copy and Share Settings	20-16
Techniques to Copy Settings	20-18
Techniques to Share Settings	20-19

**Migrate Memory Section and Shared Utility Settings from
Configuration Parameters to Code**

Mapping Editor	20-21
Effects of Migration	20-21
Considerations Before Migrating	20-22
Considerations After Migrating	20-23

Data, Function, and File Definition

Configuring Data and Functions in the Generated Code

21

**Environment for Configuring Model Data and Functions
for Code Generation**

Software Engineer: Configure Default Settings	21-4
Software Engineer: Override Default Settings	21-4
System Architect: Create Code Generation Definition s	21-5

Configure Default Code Generation for Categories of Model Data and Functions	21-7
Configure Default Data and Function Configurations in Model Editing Environment	21-7
Configure Default Code Generation for Data	21-8
Configure Default Code Generation for Functions	21-15
Configure Default Data and Function Code Generation with Definitions Stored in Shared Data Dictionary	21-20
Configure Default Data and Function Code Generation Programmatically	21-22
Unresolved Storage Classes, Function Customization Templates, and Memory Sections	21-31
Elimination of Parameters and Other Internal Data by Optimizations	21-32
Limitations	21-33

Data Representation in Simulink Coder

22

Configure Data Accessibility for Rapid Prototyping	22-3
Access Signal, State, and Parameter Data During Execution	22-3
Configure Data Accessibility	22-4
Limitations	22-5
Access Signal, State, and Parameter Data During Execution	22-7
Standard Data Structures in the Generated Code	22-26
Control Characteristics of Data Structures (Embedded Coder)	22-27
Use the Real-Time Model Data Structure	22-29
How Generated Code Exchanges Data with an Environment	22-33
Data Interfaces in the Generated Code	22-33
Configure Data Interface	22-41

Control Data and Function Interface in Generated Code	22-42
Control Type Names, Field Names, and Variable Names of Standard I/O Structures (Embedded Coder)	22-42
Control Names of Generated Entry-Point Functions (Embedded Coder)	22-42
Control Data Interface for Nonreentrant Code	22-43
Control Data Interface for Reentrant Code	22-46
Prevent Unintended Changes to the Interface	22-46
Reduce Number of Arguments by Using Structures	22-47
Control Data Types of Arguments	22-48
Promote Data Item to the Interface	22-48
How Generated Code Stores Internal Signal, State, and Parameter Data	22-50
Internal Data in the Generated Code	22-51
Local Variables in the Generated Code	22-61
Appearance of Test Points in the Generated Code	22-61
Appearance of Workspace Variables in the Generated Code	22-62
Promote Internal Data to the Interface	22-63
Control Default Representation of Internal Data (Embedded Coder)	22-65
Choose a Storage Class for Controlling Data Representation in the Generated Code	22-69
Specify File Names and Other Data Attributes With Storage Class (Embedded Coder)	22-76
Specify Default #include Syntax for Header Files That Declare Data (Embedded Coder)	22-77
Storage Class Limitations	22-77
Use Storage Classes in Reentrant, Multi-Instance Models and Components	22-79
Directly Applied Storage Classes	22-79
Storage Classes Applied by Default	22-79
Apply Storage Classes to Individual Signal, State, and Parameter Data Elements	22-81
Apply Storage Classes to Data Items	22-81
Built-In Storage Classes You Can Choose	22-85
Decide Where to Store Storage Class Specification	22-86
Techniques to Apply Storage Classes Interactively	22-87

Techniques to Apply Storage Classes	
Programmatically	22-87
Parameter Object Configuration Quick	
Reference Diagram	22-89
Use Enumerated Data in Generated Code	22-90
Enumerated Data Types	22-90
Specify Integer Data Type for Enumeration	22-90
Customize Enumerated Data Type	22-92
Control Enumerated Type Implementation in Generated	
Code	22-96
Type Casting for Enumerations	22-98
Enumerated Type Limitations	22-99
Data Stores in Generated Code	22-100
About Data Stores	22-100
Generate Code for Data Store Memory Blocks	22-100
Storage Classes for Data Store Memory Blocks	22-101
Data Store Buffering in Generated Code	22-103
Data Stores Shared by Instances of a Reusable	
Model	22-106
Structures in Generated Code Using Data Stores	22-107
Specify Single-Precision Data Type for Embedded	
Application	22-111
Use single Data Type as Default for Underspecified	
Types	22-111
Tune Phase Parameter of Sine Wave Block During Code	
Execution	22-115
Switch Between Output Waveforms During Code	
Execution for Waveform Generator Block	22-117
Create Tunable Calibration Parameter in the Generated	
Code	22-121
Represent Block Parameter as Tunable Global	
Variable	22-121
Apply Storage Class When Block Parameter Refers to	
Numeric MATLAB Variable	22-124
Create Storage Class That Represents Calibration	
Parameters (Embedded Coder)	22-125

Initialize Parameter Value From System Constant or Other Macro (Embedded Coder)	22-129
Code Generation Impact of Storage Location for Parameter Objects	22-130
Configure Accessibility of Signal Data	22-131
Programmatic Interfaces for Tuning Parameters	22-131
Set Tunable Parameter Minimum and Maximum Values	22-132
Considerations for Other Modeling Goals	22-132
Limitations for Block Parameter Tunability in the Generated Code	22-135
Tunable Expression Limitations	22-135
Linear Block Parameter Tunability	22-137
Parameter Structures	22-137
Code Generation of Parameter Objects With Expression Values	22-139
Considerations and Limitations	22-139
Expression Preservation	22-140
Specify Instance-Specific Parameter Values for Reusable Referenced Model	22-142
Pass Parameter Data to Referenced Model Entry-Point Functions as Arguments	22-142
Control Data Types of Model Arguments and Argument Values	22-153
Parameter Data Types in the Generated Code	22-156
Significance of Parameter Data Types	22-156
Typecasts Due to Parameter Data Type Mismatches	22-157
Considerations for Other Modeling Patterns	22-158
Generate Efficient Code by Specifying Data Types for Block Parameters	22-162
Eliminate Unnecessary Typecasts and Shifts by Matching Data Types	22-162
Reduce Memory Consumption by Storing Parameter Value in Small Data Type	22-166
Reuse Parameter Data in Different Data Type Contexts	22-173

Organize Data into Structures in Generated Code . . .	22-177
Techniques to Create Structures	22-181
Default Application of Structured Storage Class	22-182
Direct Application of Structured Storage Class	22-183
Nonvirtual Buses and Parameter Structures	22-183
Combine Techniques to Work Around Limitations . . .	22-194
Arrays of Structures	22-194
Structure Padding	22-194
Limitations	22-195
Switch Between Sets of Parameter Values During Simulation and Code Execution	22-196
Design Data Interface by Configuring Inport and Outport Blocks	22-206
Generate Efficient Code for Bus Signals	22-212
Code Efficiency for Bus Signals	22-212
Set Bus Diagnostics	22-213
Optimize Virtual and Nonvirtual Buses	22-213
Control Signal and State Initialization in the Generated Code	22-216
Signal and State Initialization in the Generated Code	22-216
Generate Tunable Initial Conditions	22-218
Generate Tunable Initial Condition Structure for Bus Signal	22-221
Initialization of Signal, State, and Parameter Data in the Generated Code	22-228
Static Initialization and Dynamic Initialization	22-228
Real-World Ground Initialization Requiring Nonzero Bit Pattern	22-229
Initialization of Signal and State Data	22-229
Initialization of Parameter Data	22-231
Data Initialization in the Generated Code	22-232
Modeling Goals	22-237
Optimize Speed and Size of Signal Processing Algorithm by Using Fixed-Point Data	22-239

Optimize Generated Code Using Fixed-Point Data with Simulink®, Stateflow®, and MATLAB®	22-241
Declare Workspace Variables as Tunable Parameters Using the Model Parameter Configuration Dialog Box ...	22-243
Declare Existing Workspace Variables as Tunable Parameters	22-243
Declare New Tunable Parameters	22-244
Set Tunable Parameter Code Generation Options ...	22-244
Programmatically Declare Workspace Variables as Tunable Parameters	22-245
Share Data Between Code Generated from Simulink, Stateflow, and MATLAB	22-247

Data Definition and Declaration Management in Embedded Coder

23

Control Placement of Global Data Definitions and Declarations in Generated Files	23-2
Organize Data to Support Component-Based, Team-Oriented Model Development	23-9
Specify Default Placement	23-11
Override Default Placement for Individual Data Items	23-12
Prevent Name Clashes by Configuring Data Item as static	23-12
Code Generation Impact of Storage Location for Parameter Objects	23-13
Specify Default #include Syntax for Data Header Files	23-13
Establish Data Ownership in a System of Components	23-15

Control Data Type Names in Generated Code	24-2
Control Names of Primitive Data Types	24-2
Control Names of Structure Types	24-11
Generate Code That Reuses Data Types From External Code	24-11
Create Data Type Alias in the Generated Code	24-12
Create a Named Fixed-Point Data Type in the Generated Code	24-17
Rename Data Type Object	24-21
Display Signal Data Types on Block Diagram	24-21
Limitations	24-21
Control File Placement of Custom Data Types	24-23
Data Scope and Header File	24-23
Macro Guards	24-25
Replace and Rename Data Types to Conform to Coding Standards	24-27
Inspect External C Code	24-27
Explore Example Model and Default Generated Code	24-27
Reuse External Data Type Definitions	24-28
Create Meaningful Data Type Aliases for Individual Data Items	24-29
Create Single Point of Definition for Primitive Types ..	24-31
Permanently Store Data Type Objects	24-32
Create and Maintain Objects Corresponding to Multiple C typedef Statements	24-32
Exchange Structured and Enumerated Data Between Generated and External Code	24-34
Inspect External Code	24-34
Create Simulink Model	24-36
Configure Generated Code to Write Output Data to Existing Structure Variable	24-38
Configure Generated Code to Define Parameter Data	24-39
Generate, Compile, and Inspect Code	24-40
Replace Data Type Names Throughout Model	24-41

Specify Boolean and Data Type Limit Identifiers	24-42
Data Type Limit Identifiers	24-42
Boolean Identifiers	24-43
Boolean and Data Type Limit Identifier Header Files	24-43

Module Packaging Tool (MPT) Data Objects in Embedded Coder

25

MPT Data Object Properties	25-2
Specify Persistence Level for Signals and Parameters	25-16
Register mpt User Object Types	25-19

Custom Storage Classes in Embedded Coder

26

Reuse Parameter Data from External Code in the Generated Code	26-2
Import Parameter Data with Conditionally Compiled Dimension Length	26-7
Access Structured Data Through a Pointer That External Code Defines	26-12
Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements	26-19
Built-In Custom Storage Classes	26-19
Create Your Own Custom Storage Class	26-19
Techniques to Apply Custom Storage Classes Interactively	26-19
Techniques to Apply Custom Storage Classes Programmatically	26-21
Organize Parameter Data into a Structure by Using the Struct Custom Storage Class	26-23
Custom Storage Class Limitations	26-25

Create Custom Storage Classes by Using the Custom Storage Class Designer	26-26
Create and Apply a Custom Storage Class	26-26
Modify a Built-In Custom Storage Class	26-30
Control Data Representation by Configuring Custom Storage Class Properties	26-31
Avoid Errors During Code Generation by Validating Custom Storage Class Configuration	26-35
Make Custom Storage Classes Available Outside the Current Folder	26-35
Share Custom Storage Class Between Packages	26-35
Control Appearance of Storage Class Drop-Down List	26-36
Protect Custom Storage Class Definitions	26-37
Further Customize Generated Code by Writing TLC Code	26-37
Finely Control Data Representation by Writing TLC Code for a Custom Storage Class	26-39
Create Custom Attributes Class for Custom Storage Class	26-39
Write TLC Code for Custom Storage Class	26-39
Create Custom Storage Class by Using Custom Storage Class Designer	26-40
Access Data Through Functions with Custom Storage Class GetSet	26-42
Access Legacy Data Using Get and Set Functions	26-42
Use GetSet with Vector Data	26-46
Use GetSet with Structured Data	26-49
Use GetSet with Matrix Data	26-54
Specify Header File or Function Naming Scheme for All Data Items	26-59
Access Scalar and Array Data Through Macro Instead of Function Call	26-60
GetSet Custom Storage Class Restrictions	26-61
Integrate External Application Code with Code Generated from PID Controller	26-62
Configure Generated Code According to Interface Control Document Interactively	26-73

Configure Generated Code According to Interface Control Document	26-83
Generate Local Variables with Localizable Custom Storage Class	26-94
Example Model	26-94
Generate Code with Localizable Storage Class	26-95
Generate Code Without Localizable Storage Class ...	26-96
Additional Information	26-98

Data Object Wizard in Embedded Coder

27

Create Data Objects for Code Generation with Data Object Wizard	27-2
--	-------------

Entry-Point Functions and Scheduling in Simulink Coder

28

Configure Code Generation for Model Entry-Point Functions	28-2
What Is an Entry-Point Function?	28-2
Categories and Types of Generated Entry-Point Functions	28-2
Configure Whether Entry-Point Functions Are Reusable	28-3
Configure Generated Entry-Point Function Declarations	28-6
Configure Placement of Entry-Point Functions in Memory	28-7
How to Interface with Generated Entry-Point Functions	28-7
Generate C++ Class Interface to Model or Subsystem Code	28-9
Generate C++ Class Interface to Model Code	28-9

Generate C++ Class Interface to Nonvirtual Subsystem Code	28-10
C++ Class Interface Limitations	28-11
Execution of Code Generated from a Model	28-13
Program Execution	28-14
Program Timing	28-14

Identifier Format Control	39-22
Control Case with Token Decorators	39-27
Control Formatting of Identifiers	39-28
Control Name Mangling in Generated Identifiers	39-30
Minimize Name Mangling	39-30

Avoid Identifier Name Collisions with Referenced Models	39-32
Use Model Advisor to Detect Identifier Names Changed During Code Generation	39-32
Maintain Traceability for Generated Identifiers	39-34
Exceptions to Identifier Formatting Conventions	39-35
Identifier Format Control Parameters Limitations	39-36
Control Code Style	39-38
Control Parentheses in Generated Code	39-39
Optimize Code by Reordering Commutable Operands	39-41
Suppress Generation of Default Cases for Unreachable Stateflow Switch Statements	39-42
Replace Multiplication by Powers of Two with Signed Bitwise Shifts	39-45
Generate Code with Right Shifts on Signed Integers ..	39-47
Control Indentation Style in Generated Code	39-48
Control Cast Expressions in Generated Code	39-50
Control Newline Style in Generated Code	39-54
Customize Code Organization and Format	39-56
Custom File Processing Components	39-56
Custom File Processing Configuration	39-57
Specify Templates For Code Generation	39-59
Code Generation Template (CGT) Files	39-60
Default CGT file	39-60
CGT File Structure	39-60
Built-In Tokens and Sections	39-61
Subsections	39-63
Format Generated Code Files Using Templates	39-64
Custom File Processing (CFP) Templates	39-66
Custom File Processing (CFP) Template Structure ...	39-66
Change the Organization of a Generated File	39-68
Customize Generated File Names	39-70

Generate Source and Header Files with a Custom File Processing (CFP) Template	39-73
Generate Code with a CFP Template	39-73
Analysis of the Example CFP Template and Generated Code	39-75
Generate a Custom Section	39-78
Custom Tokens	39-80
Comparison of a Template and Its Generated File	39-81
Template and Generated File	39-82
Code Template API Summary	39-85
Generate Custom File and Function Banners	39-89
Create a Custom File and Function Banner Template	39-90
Customize a Code Generation Template (CGT) File for File and Function Banner Generation	39-91
Template Symbols and Rules	39-97
Introduction	39-97
Template Symbol Groups	39-98
Template Symbols	39-101
Rules for Modifying or Creating a Template	39-104
Annotate Code for Justifying Polyspace Checks	39-106
Enhance Readability of Code for Flow Charts	39-108
Appearance of Generated Code for Flow Charts	39-108
Convert If-Elseif-Else Code to Switch-Case Statements	39-111
Example of Converting Code to Switch-Case Statements	39-113
Generate Inlined Subsystem Code	39-122
Configure Subsystem to Inline Code	39-122
Exceptions to Inlining	39-123

Logging in Simulink Coder

45

Log Program Execution Results	45-2
Log Data for Analysis	45-2
Configure State, Time, and Output Logging	45-9
Log Data with Scope and To Workspace Blocks	45-11
Log Data with To File Blocks	45-11
Data Logging Differences Between Single- and	
Multitasking	45-12

Data Interchange Using the C API in Simulink Coder

46

Exchange Data Between Generated and External Code	
Using C API	46-2
Generated C API Files	46-2

Generate C API Files	46-3
Description of C API Files	46-5
Generate C API Data Definition File for Exchanging Data with a Target System	46-20
C API Limitations	46-22
Use C API to Access Model Signals and States	46-24
Use C API to Access Model Parameters	46-30

ASAP2 Data Measurement and Calibration in Simulink Coder

47

Export ASAP2 File for Data Measurement and Calibration	47-2
What You Should Know	47-3
Targets Supporting ASAP2	47-3
Define ASAP2 Information	47-3
Generate an ASAP2 File	47-9
Structure of the ASAP2 File	47-12
Create a Host-Based ASAM-ASAP2 Data Definition File for Data Measurement and Calibration	47-13

Direct Memory Access to Generated Code for Simulink Coder

48

Access Memory in Generated Code Using Global Data Map	48-2
--	-------------

Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File . . .	49-2
About Rapid Simulation	49-2
Rapid Simulation Advantage	49-2
General Rapid Simulation Workflow	49-3
Identify Rapid Simulation Requirements	49-4
Configure Inports to Provide Simulation Source Data	49-6

Performance

Optimizations for Generated Code in Simulink Coder

56

Increase Code Generation Speed	56-3
Build a Model in Increments	56-3
Build Large Model Reference Hierarchies in Parallel ..	56-3
Minimize Memory Requirements During Code Generation	56-4
Generate Only Code	56-5
No Creation of a Code Generation Report	56-5
Control Compiler Optimizations	56-6
Optimization Tools and Techniques	56-7
Use the Model Advisor to Optimize a Model for Code Generation	56-7
Design Tips for Optimizing Generated Code for Stateflow Objects	56-7
Additional Optimization Techniques	56-8
Control Memory Allocation for Time Counters	56-11
Execution Profiling for Generated Code	56-12

Optimize Generated Code by Combining Multiple for Constructs	56-15
Subnormal Number Performance	56-19
Simulation Time With and Without Subnormal Numbers	56-20
Flush Subnormal Numbers to Zero	56-21
Remove Code From Floating-Point to Integer Conversions That Wraps Out-of-Range Values	56-24
Example Model	56-24
Generate Code Without Optimization	56-25
Generate Code with Optimization	56-26
Remove Code That Maps NaN to Integer Zero	56-27
Example Model	56-27
Generate Code	56-28
Generate Code with Optimization	56-29
Disable Nonfinite Checks or Inlining for Math Functions	56-31
Minimize Computations and Storage for Intermediate Results at Block Outputs	56-37
Expression Folding	56-37
Example Model	56-37
Generate Code	56-38
Enable Optimization	56-38
Generate Code with Optimization	56-39
Inline Invariant Signals	56-40
Optimize Generated Code Using Inline Invariant Signals	56-40
Inline Numeric Values of Block Parameters	56-44
Configure Loop Unrolling Threshold	56-50
Use memcpy Function to Optimize Generated Code for Vector Assignments	56-53
Example Model	56-54
Generate Code	56-55
Generate Code with Optimization	56-55

Generate Target Optimizations Within Algorithm Code	56-57
Remove Code for Blocks That Have No Effect on Computational Results	56-59
Eliminate Dead Code Paths in Generated Code	56-62
Floating-Point Multiplication to Handle a Net Slope Correction	56-65
Use Conditional Input Branch Execution	56-68
Optimize Generated Code for Complex Signals	56-74
Speed Up Linear Algebra in Code Generated from a MATLAB Function Block	56-77
Specify LAPACK Library	56-77
Write LAPACK Callback Class	56-77
Generate LAPACK Calls by Specifying a LAPACK Callback Class	56-78
Locate LAPACK Library in Execution Environment ...	56-79
Speed Up Fast Fourier Transforms in Code Generated from a MATLAB Function Block	56-81
Install an FFTW Library	56-81
Write FFT Callback Class	56-82
Generate FFTW Calls by Specifying an FFT Callback Class	56-83
Synchronize Multithreaded FFTW Planning in Code Generated from a MATLAB Function Block	56-85
Prerequisites	56-85
Create a Model with a MATLAB Function Block That Calls an FFT Function	56-86
Write Supporting C Code	56-86
Create an FFT Library Callback Class	56-87
Configure Code Generation Parameters and Build the Model	56-88
Control Memory Allocation for Variable-Size Arrays in a MATLAB Function Block	56-90
Provide Upper Bounds for Variable-Size Arrays	56-90

Disable Dynamic Memory Allocation for MATLAB Function Blocks	56-91
Modify the Dynamic Memory Allocation Threshold . . .	56-91
Optimize Memory Usage for Time Counters	56-93
Optimize Generated Code Using Boolean Data for Logical Signals	56-100
Reduce Memory Usage for Boolean and State Configuration Variables	56-103
Customize Stack Space Allocation	56-104
Optimize Generated Code Using memset Function . .	56-106
Vector Operation Optimization	56-110
Enable and Reuse Local Block Outputs in Generated Code	56-113
Example Model	56-113

Design Models for Generated Embedded Code Deployment

When using Embedded Coder to generate code for an embedded system architecture, it is important to design your Simulink models with code generation in mind from the very beginning of the design process. Think about relevant design factors and issues such as:

In this section...
“Application Algorithms and Run-Time Environments” on page 1-2
“Software Execution Framework for Generated Code” on page 1-3
“Map Embedded System Architecture to Simulink Modeling Environment” on page 1-5
“Model Templates for Code Generation” on page 1-14

Application Algorithms and Run-Time Environments

Use Simulink to design models that represent application algorithms and run-time environments from which you intend to generate deployable code. Depending on your application, you might deploy code to an execution environment that consists of a combination of:

Execution Environment Components	Choices
Hardware	<ul style="list-style-type: none">• Development computer• Rapid-prototyping board• Microprocessor• Microcontroller• FPGA• ASIC
Cores	<ul style="list-style-type: none">• Single• Multiple
Operating system	<ul style="list-style-type: none">• General-purpose• Real-time• None (bare metal)

Execution Environment Components	Choices
Scheduling	<ul style="list-style-type: none"> • Single-tasking • Multitasking • Interrupt driven • Concurrency • Provided by operating system • Generated from model
Application algorithm code	<ul style="list-style-type: none"> • Generated from model • External code

As you design models to generate C or C++ code for rapid prototyping or production deployment, keep in mind the execution environment. Generate code that meets implementation requirements and avoids potential design rework. As the preceding table reflects, the execution environment for code that you generate can range from relatively simple to complex. For example, a simple case is code that you generate from a single, single-tasking model that runs on a single-core microprocessor. A complex case is code that generate from a model partitioned to run as a distributed system on a multicore microprocessor and an FPGA.

Software Execution Framework for Generated Code

Part of an application execution environment is the software execution framework that is responsible for scheduling and running the generated code. That software can preexist, as in the case of an operating system and its scheduler, or you can code the software manually. The level of complexity varies depending on which of the following modeling and code generation scenarios applies:

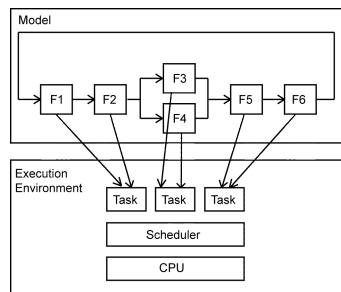

- Generate code from a single top model, which represents the algorithms intended to run in the execution environment.
- Generate code from a model, which represents part of an overall algorithm. You can mix the generated code with code written manually and code generated from other sources or releases of MathWorks® products.

Single Top Model

For a single top model, the software execution framework is responsible for running generated code the same way that Simulink simulates the model. Functions in the

generated code are highly coordinated and optimized because Simulink is aware of dependencies. The framework interfaces with code generated for the top model only. Code generated for a top model handles interfacing with code for referenced Model blocks.

Consider the following example, where a single top model is mapped to tasks that run on a single-core CPU.

For this system, you map model clock rates to tasks that run on the hardware. You can choose for Simulink to map the rates implicitly or you can map them explicitly in your model. You can model latency effects resulting from how you map rates in a model to single-tasking or multitasking execution environments. Simulink schedules the tasks properly based on rates in the model and data dependencies between tasks. The code generator implements the same dependencies in the code that it generates. The software execution framework invokes generated entry-point functions at rates based on system timers and interrupts. The generated code executes in the same manner that Simulink simulates the model, and contains code dedicated to communicating data between functions running at different rates.

Multiple Top-Level Models

When you generate code from multiple top models separately and mix that code with code acquired in other ways, the execution environment of the application takes on more software execution framework responsibility. For this modeling scenario, you generate code for standalone, atomic reusable components.

With this scenario, Simulink is not aware of model dependencies. Functions in code generated from the different models are minimally coordinated and optimized. For example, the models might share generated utility functions. Potential optimizations that cross model boundaries are not possible. You must design the software execution framework taking into account dependencies between units of code, including execution order. For an application that requires concurrent execution across multiple cores, you must consider data latency effects across the cores.

The code generator helps you address software execution framework challenges, such as sharing global data and avoiding identifier conflicts. The code generated for a each model handles the interfacing for referenced Model blocks.

Map Embedded System Architecture to Simulink Modeling Environment

When mapping an embedded system architecture to the Simulink modeling environment, think about the model design.

“Modeling Algorithms” on page 1-6	Given initial state and input, a set of tasks or instructions that efficiently produce the results that you want.
“Modeling Interfaces” on page 1-7	Mechanisms that enable algorithm components to communicate and exchange information across component boundaries.
“Modeling Systems” on page 1-9	Collection of algorithm components that achieve a higher-level, domain-specific goal or result. Components often share resources.

<p>“Modeling Run-Time Environments” on page 1-11</p>	<p>Framework that handles scheduling of system algorithm resources and execution.</p>
--	---

Consider the following questions regarding an embedded system architecture with corresponding modeling capabilities and links to related information. Use the information as a guide for mapping your architecture details to the Simulink modeling environment. Designing a model architecture with your specific embedded system architecture in mind can help you avoid rework and future conversion and maintenance costs.

Model Templates for Code Generation

The code generator provides a set of built-in templates to use as a starting point to create models for common application designs. Use the templates to create models that are preconfigured to generate code for rapid-prototyping or embedded system applications.

Template	Description
Code Generation System	Basic model consisting of an Inport block and Output block.
Exported functions	Model for generating code from function-call subsystems. You can export each function-call subsystem separately by right-clicking a subsystem, selecting C/C++ Code > Export Functions , and clicking Build .
Fixed-step, multirate	Fixed-step model that uses multiple rates and consists of Inport blocks, an Output block, and a Sum block. The model is configured to use a fixed-step discrete solver and to use two rates with Periodic sample time constraint set to Unconstrained and the Treat each discrete rate as a separate task option selected. Simulink inserts a Rate Transition block to handle the two sample rates.
Fixed-step, single rate	Fixed-step model that uses a single rate and consists of Inport blocks, an Output block, and a Sum block. The model is configured to use a fixed-step discrete solver.

To create a model from a template:

- 1 On the MATLAB® home tab, click **Simulink**.
- 2 In the Simulink start page, expand **Embedded Coder**.
- 3 Select a template.
- 4 Click **Create**. A new model that uses the template contents and settings appears in the Simulink Editor window.

For more information, for example to create and use a template as a reference design, see “Create a Template from a Model” (Simulink).

Model Single-Core, Single-Tasking Platform Execution

This example shows a model designed and configured for embedded system code generation intended to execute on a single-core, single-tasking platform. The application algorithm is captured in a single model hierarchy, making it possible to use Simulink® time-based, single-task scheduling to simulate the model and execute the generated code.

Periodic Multirate Model Set Up for Single-Tasking Execution

Open the example model `rtwdemo_multirate_singletasking`. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**.

- Sample times for Inport blocks In1_1s and In2_2s are set to 1 and 2 seconds, respectively.
- To provide clean partitioning of rates, sample times for subsystems SS1 and SS2 are set to 1.

Relevant Model Configuration Parameter Settings

- **Solver > Type** set to Fixed-step.
- **Solver > Solver** set to discrete (no continuous states).
- **Solver > Treat each discrete rate as a separate task** cleared.

Scheduling

Simulink® simulates the model based on the model configuration. Code generated from the model implements the same execution semantics. Simulink propagates and uses the Inport block sample times to order block execution based on a single-core, single-tasking execution platform.

For this model, the sample time legend shows an implicit rate grouping. Red represents the fastest discrete rate. Green represents the second fastest discrete rate.

The generated code schedules subrates in the model. In this example, the rate for Inport block In2_2s, the green rate, is a subrate. The generated code properly transfers data between tasks running at the different rates.

Benefits of implicit rate grouping:

- Simulink does not impose architectural constraints on the model.
- Your execution framework does not require details about underlying function scheduling and data transfers between rates. Therefore, the model interface requirements are simplified. The execution framework uses generated interface code to write input, call the model step function, and read output.
- The code generator optimizes code across rates based on single-tasking execution semantics.

Your execution framework can communicate with external devices for reading and writing model input. For example, model external devices by using Simulink S-Function blocks. Generate code for those blocks with the rest of the algorithm.

Generate Code and Report

Generate code and a code generation report. The example model generates a report.

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code controls model code execution by calling the entry-point function `rtwdemo_multirate_singletasking_step`. Use this file as a starting point for coding your execution framework.
- `rtwdemo_multirate_singletasking.c` contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
- `rtwdemo_multirate_singletasking.h` declares model data structures and a public interface to the model entry points and data structures.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

- 1 Include the generated header file by adding directive `#include rtwdemo_multirate_singletasking.h`.
- 2 Write input data to the generated code for model Inport blocks.
- 3 Call the generated entry-point functions.
- 4 Read data from the generated code for model Outport blocks.

Input ports:

- `rtU.In1_1s` of data type `real_T` with dimension of 1
- `rtU.In2_2s` of data type `real_T` with dimension of 1

Entry-point functions:

- Initialization entry-point function, `void rtwdemo_multirate_singletasking_initialize(void)`. At startup, call this function once.
- Output and update entry-point (step) function, `void rtwdemo_multirate_singletasking_step(void)`. Call this function periodically at the fastest rate in the model. For this model, call the function every second. To achieve real-time execution, attach this function to a timer.

Output ports:

- `rtY.Out1` of data type `real_T` with dimension of 1
- `rtY.Out2` of data type `real_T` with dimension of 1

Model Single-Core, Multitasking Platform Execution

Use Simulink® time-based, multitask scheduling to simulate and generate code for an application algorithm captured in a single model hierarchy. The model is designed and configured for an embedded system intended to execute on a single-core, multitasking platform. The model simulates and the generated code executes based on the model configuration and a rate monotonic scheduling algorithm.

Periodic Multirate Model Set Up for Multitasking Execution

Open the example model `rtwdemo_multirate_multitasking`. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**.

The screenshot displays the Simulink environment for a model named 'rtwdemo_multirate_multitasking'. The main workspace shows a block diagram with the following components and connections:

- In1_1s**: A red input block with a sample time annotation of 1 (D1).
- In2_2s**: A green input block with a sample time annotation of 2 (D2).
- Integrator**: A green block receiving input from In2_2s, with a sample time annotation of 2 (D2).
- RateTransition**: A yellow block receiving input from the Integrator, with a sample time annotation of 1 (D1).
- SS1**: A subsystem block receiving inputs from In1_1s and the RateTransition block, with a sample time annotation of 1 (D1).
- SS2**: A subsystem block receiving inputs from In1_1s and the RateTransition block, with a sample time annotation of 1 (D1).
- Sum**: A red summing junction block receiving inputs from the Out1 ports of both SS1 and SS2, with a sample time annotation of 1 (D1).
- Out1** and **Out2**: Final output blocks of the model, both with a sample time annotation of 1 (D1).

A 'Sample Time Legend' dialog box is open in the foreground, titled 'Sample Times for 'rtwdemo_multirate_multitasking''. It contains the following table:

Color	Annotation	Description	Value
Red	D1	Discrete 1	1
Green	D2	Discrete 2	2
Yellow	H	Hybrid	N/A

- Sample times for Inport blocks In1_1s and In2_2s are set to 1 and 2 seconds, respectively.
- To provide a clear partitioning of rates, sample times for subsystems SS1 and SS2 are set to 1.

- The Rate Transition block models an explicit rate transition. Alternatively, instruct Simulink to insert Rate Transition blocks for you by selecting model configuration parameter **Solver > Automatically handle rate transition for data transfer**.

Relevant Model Configuration Parameter Settings

- **Solver > Type** set to Fixed-step.
- **Solver > Solver** set to discrete (no continuous states).
- **Solver > Treat each discrete rate as a separate task** selected.

Scheduling

Simulink® simulates the model based on the model configuration. Code that this model generates implements the same execution semantics. Simulink propagates and uses the Inport block sample times to order block execution based on a single-core, multitasking execution platform.

For this model, the sample time legend shows an implicit rate grouping. Red represents the fastest discrete rate. Green represents the second fastest discrete rate. Yellow represents the mixture of the two rates.

The generated code schedules subrates in the model. In this example, the rate for Inport block In2_2s, the green rate, is a subrate. The generated code properly transfers data between tasks that run at the different rates.

Benefits of implicit rate grouping:

- Simulink does not impose architectural constraints on the model. Create a model without imposing software architecture constraints within the model.
- Your execution framework does not require details about underlying function scheduling and data transfers between rates. Therefore, the model interface requirements are simplified. The execution framework uses generated interface code to write input, call the model step function, and read output.
- The code generator optimizes code across rates based on multitasking execution semantics.

Simulink enforces data transfer constraints to achieve rate monotonic scheduling:

- Data transfers occur between a single read task and a single write task.
- When data transfers between two tasks, only one task can preempt the other task.

- For periodic tasks, a task with a faster rate has a higher priority than a task with a slower rate. In addition, a task with the faster rate, preempts a task with a slower rate.
- Tasks run on a single processor.
- Time slicing, use of a defined time period during which a task can run in a preemptive multitasking system, is not allowed.
- Processes do not crash or restart, especially during data transfers between tasks.
- Read and write operations on byte-sized variables are atomic.

Your execution framework communicates with external devices for reading and writing model input. For example, model external devices by using Simulink S-Function blocks. Generate code for those blocks with the rest of the algorithm.

Generate Code and Report

Generate code and a code generation report. The example model generates a report.

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code controls model code execution by calling the entry-point functions `rtwdemo_multirate_multitasking_step0` and `rtwdemo_multirate_multitasking_step1`. Use this file as a starting point for coding your execution framework.
- `rtwdemo_multirate_multitasking.c` contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
- `rtwdemo_multirate_multitasking.h` declares model data structures and a public interface to the model entry points and data structures.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

- 1 Include the generated header file by adding directive `#include rtwdemo_multirate_singletasking.h`.

- 2 Write input data to the generated code for model Inport blocks.
- 3 Call the generated entry-point functions.
- 4 Read data from the generated code for model Outport blocks.

Input ports:

- `rtU.In1_1s` of data type `real_T` with dimension of 1
- `rtU.In2_2s` of data type `real_T` with dimension of 1

Entry-point functions:

- Initialization entry-point function, `void rtwdemo_multirate_multitasking_initialize(void)`. At startup, call this function once.
- Output and update entry-point (step) function, `void rtwdemo_multirate_multitasking_step0(void)`. Call this function periodically at the fastest rate in the model. For this model, call the function every second. To achieve real-time execution, attach this function to a timer.
- Output and update entry-point function, `void rtwdemo_multirate_multitasking_step1(void)`. Call this function periodically at the second fastest rate in the model. For this model, call the function every two seconds. To achieve real-time execution, attach this function to a timer.

Output ports:

- `rtY.Out1` of data type `real_T` with dimension of 1
- `rtY.Out2` of data type `real_T` with dimension of 1

Model Concurrent Execution for Symmetric Multicore CPU Platforms

Use Simulink® time-based, multithread scheduling to simulate and generate code for an application algorithm captured in a single model hierarchy. The model is designed and configured for an embedded system intended to execute on a symmetric multicore, multithreading platform.

Periodic Multirate Model Set Up for Multithreading Concurrent Execution

Open the example model `rtwdemo_concurrent_execution`. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**.

Simulink supports simulating concurrent task execution by assigning partitions of a model to tasks that you designate to run concurrently on multicore hardware. Use an implicit or explicit approach to designating partitions.

Simulink implicit partitioning:

- Partitions the model based on sample times specified in the model.
- Assigns a task to each sample rate and designates that the tasks run concurrently.
- Controls the granularity of partitions. For example, you cannot split a sample rate into multiple tasks.

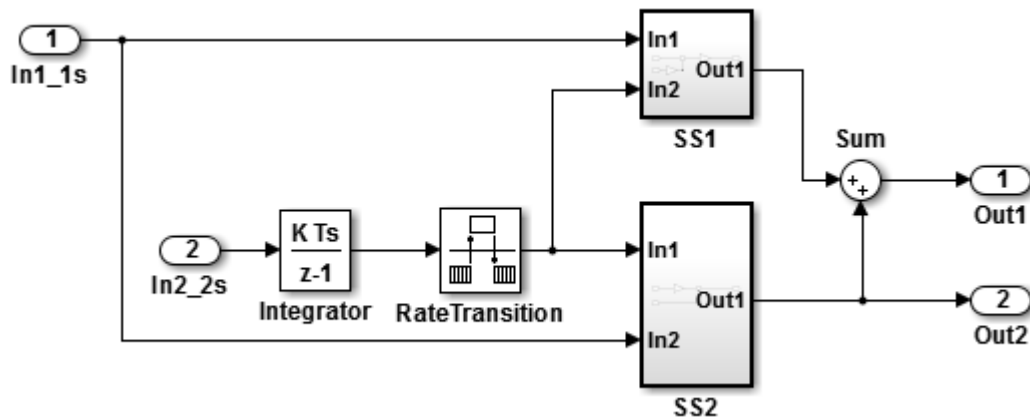

- Does not impose modeling constraints.
- Provides ready-to-use hardware solutions, such as solutions that the Simulink® Real-Time™ product produces.
- Is not relevant to standalone production code generation due to the lack of control over partition granularity.

Explicit partitioning:

- Use Model and Subsystem blocks to partition the model.
- Create an arbitrary number of tasks.
- Simulink assigns each partition to a task.
- Simulink imposes modeling constraints.
- Control the granularity of partitions.
- Split a sample rate into multiple tasks.
- Assign partitions to different processor cores.
- Is for standalone production code generation due to the level of control you have over granularity of partitions.

This example shows explicit partitioning.

Consider the following periodic multirate model that is set up for multitasking execution.

- Sample times for Inport blocks In1_1s and In2_2s are set to 1 and 2 seconds, respectively.
- To provide a clear partitioning of rates, sample times for models SS1 and SS2 are set to 1.
- The Rate Transition block explicitly models a rate transition.

To support concurrent execution of tasks in a multicore run-time environment, the preceding model was modified:

- The Integrator block is in a Model block configured with a fixed-step discrete solver and a step size of two seconds.
- Subsystems SS1 and SS2 were converted to Model blocks configured with a fixed-step discrete solver and a step size of one second.
- The Sum block is in a Model block configured with a fixed-step discrete solver and a step size of one second. Another option for the Sum block is to place it in SS1 or SS2 and compute its value coincident with the Model block. For concurrent execution of tasks, only connection blocks, Model blocks, and Subsystem blocks can be at the root level of a model.
- The Rate Transition block was removed.

Relevant Model Configuration Parameter Settings

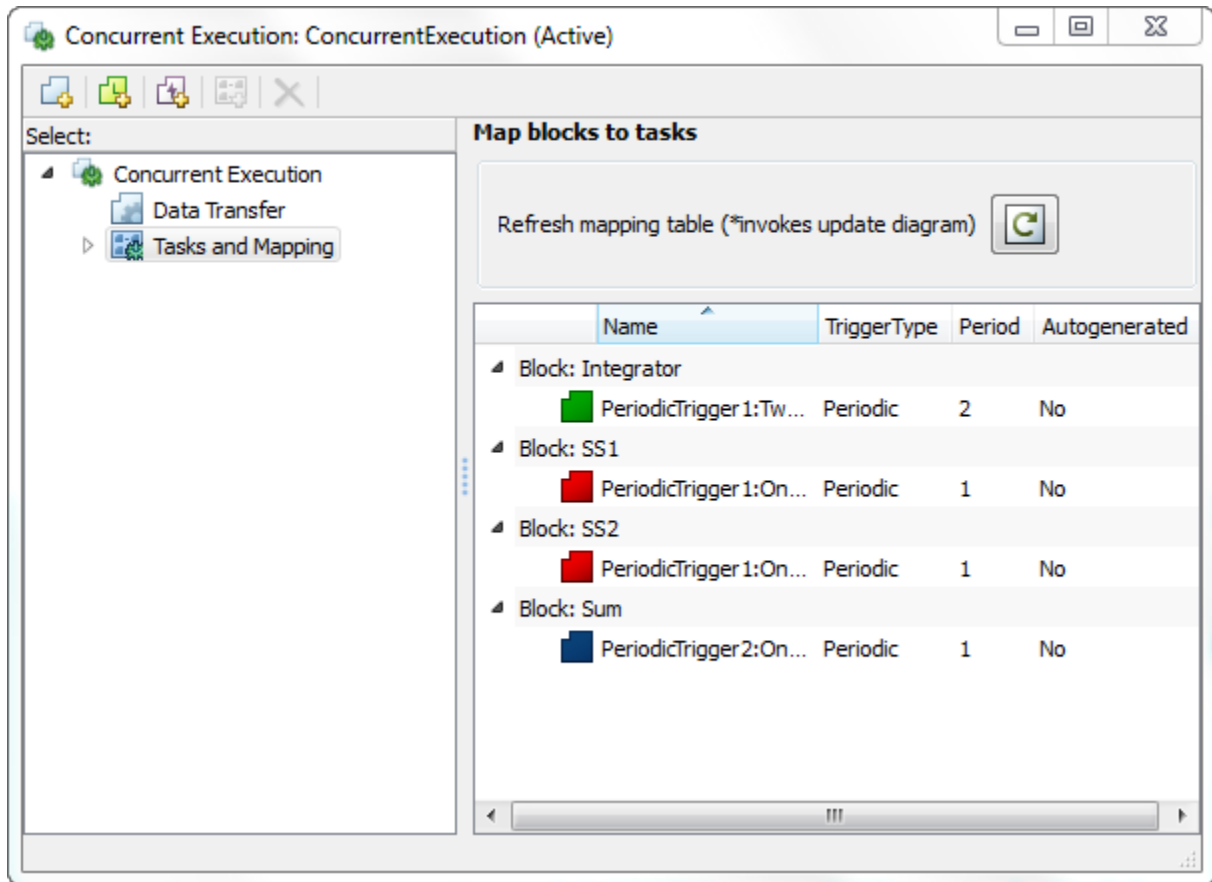

- **Solver > Type** set to Fixed-step.
- **Solver > Solver** set to discrete (no continuous states).
- **Solver > Treat each discrete rate as a separate task** selected.
- **Solver > Automatically handle rate transition for data transfer** selected. Necessary because Rate Transition block was removed.
- **Solver > Allow tasks to execute concurrently on target** selected.

Concurrent Execution Parameter Settings

Open the Concurrent Execution dialog box by clicking **Configure Tasks** on the Configuration Parameters **Solver** pane. Selecting **Allow tasks to execute concurrently on target** enables the **Configure Tasks** button.

When selected, the **Enable explicit model partitioning for concurrent behavior** parameter enables concurrent execution options for the top-level model.

Click **Tasks and Mapping** to review the tasks and mapping.

Simulink creates a default mapping for each partition (Model block) by assigning each partition to a separate task. Simulink designates that each partition executes concurrently and simulates latency effects that data communication between processor cores imposes. This dialog box displays a mapping consisting of partitions spread across two independent periodic triggers: SS1, SS2, and Sum mapped to periodic trigger 1 and Integrator mapped to periodic trigger 2.

Scheduling

Simulink® simulates the model based on the model configuration. Code generated from the model implements the same execution semantics. Simulink propagates and uses the

Inport block sample times to order block execution based on a multicore, multitasking execution platform.

For this model, the sample time legend shows an implicit rate grouping. Red represents the fastest discrete rate. Green represents the second fastest discrete rate.

The generated code schedules subrates in the model. In this example, the rate for Inport block In2_2s, the green rate, is a subrate. The generated code properly transfers data between the rates.

Benefits of implicit Simulink rate grouping:

- Simulink does not impose architectural constraints on the model. Create a model without imposing software architecture constraints within it.
- Your execution framework does not require details about underlying function scheduling and data transfers between rates. Therefore, model interface requirements are simplified. The execution framework uses generated interface code to write input, call the model step function, and read output.
- The code generator optimizes code across rates, based on multitasking execution semantics.

Simulink enforces data transfer constraints:

- Data transfers occur between a single read task and a single write task.
- Tasks run on a single processor.
- Processes do not stop or restart, especially during data transfers between tasks.
- Read and write operations on byte-sized variables are atomic.

Your execution framework can communicate with external devices for reading and writing model input. For example, model external devices by using Simulink S-Function blocks. Generate code for those blocks with the rest of the algorithm.

Generate Code and Report

Generate code and a code generation report. The example model generates a report.

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code controls model code execution by indirectly calling entry-point functions `PeriodicTrigger1_OneSecond_step`, `PeriodicTrigger1_TwoSecond_step`, and `PeriodicTrigger2_OneSecond_step` with the function `rtwdemo_concurrent_execution_step`. Use this file as a starting point for coding your execution framework.
- `rtwdemo_concurrent_execution.c` contains entry points for the code that implements the model algorithm. This file includes the rate and task scheduling code.
- `rtwdemo_concurrent_execution.h` declares model data structures and a public interface to the model entry points and data structures.
- `model_reference_types.h` contains type definitions for timing bridges. These type definitions are generated for a model reference target or a model containing Model blocks.
- `rtw_windows.h` declares mutex and semaphore function prototypes that the generated code uses for concurrent execution on Microsoft® Windows® platforms.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

- 1 Include the generated header file by adding directive `#include rtwdemo_concurrent_execution.h`.
- 2 Write input data to the generated code for model Inport blocks.
- 3 Call the generated entry-point functions.
- 4 Read data from the generated code for model Outport blocks.

Input ports:

- `In1_1s` of data type `real_T` with dimension of 1
- `In2_2s` of data type `real_T` with dimension of 1

Entry-point functions:

- Initialization entry-point function, `void rtwdemo_concurrent_execution_initialize(void)`. At startup, call this function once.

- Output and update entry-point (step) function, `void PeriodicTrigger1_OneSecond_step(void)`. Call this function periodically for one of two tasks that require scheduling at the fastest rate in the model. For this model, call the function every second.
- Output and update entry-point function, `void PeriodicTrigger1_TwoSecond_step(void)`. Call this function periodically at the second fastest rate in the model. For this model, call the function every two seconds.
- Output and update entry-point function, `void PeriodicTrigger2_OneSecond_step(void)`. Call this function periodically for the second task that requires scheduling at the fastest rate in the model. For this model, call the function every second.

To achieve real-time execution, define a task or thread for each entry-point step function. Trigger execution of each function based on a timer that has the same rate as the given function. The operating system schedules the tasks across cores dynamically or based on your mapping of tasks to cores.

Output ports:

- `Out1_1s` of data type `real_T` with dimension 1
- `Out2_1s` of data type `real_T` with dimension 1

Model Explicit Function Invocation with Atomic Subsystems

Deploy embedded system code from Simulink® models by partitioning a model into multiple atomic subsystems that you build separately.

Atomic Subsystem Model

Open the example model `rtwdemo_explicitinvocation_atomicsubsys`. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**.

This model partitions an algorithm into two atomic subsystems: Rate1s and Rate2s. Subsystem Rate1s is configured with a sample time of 1 second. Subsystem Rate2s is configured with a sample time of 2 seconds.

Relevant Model Configuration Parameter Settings

- **Solver > Type** set to Fixed-step.
- **Solver > Solver** set to discrete (no continuous states).

- **Solver > Treat each discrete rate as a separate task** cleared.

Scheduling

Simulink® simulates the model based on the model configuration. Simulink propagates and uses the Inport block sample times to order block execution based on a single-core, single-tasking execution platform.

For this example, the sample time legend shows implicit rate grouping. Red represents the fastest discrete rate. Green represents the second fastest discrete rate.

Based on ratemonotonic scheduling, your application code (execution framework) must transfer data between subsystems `Rate2s` and `Rate1s` at a frequency of 2 seconds with the priority of 1 second. That is, the generated function transfers data in the 1 second task every other time prior to executing code for subsystem `Rate1s`.

Your execution framework must schedule the generated function code and handle the data transfers between them. This is an advantage for multirate models because the generated code assumes no scheduling or data transfer semantics. However, the execution framework must handle data transfers explicitly.

Generate Code and Report

Generate a single callable function for each subsystem without connections between them. Multiple ways are available to generate code for a subsystem, including from the subsystem context menu. For example, right-click a subsystem block and click **C/C++ Code > Build This Subsystem**. In the Build code for Subsystem dialog box, click **Build**.

The example model generates a report.

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the subsystem. This code controls model code execution by calling entry-point function `Rate1s_step` or `Rate2s_step`. Use this file as a starting point for coding your execution framework.
- `Rate1s.c` and `Rate2s.c` contain entry points for the code that implements subsystem `Rate1s` and `Rate2s`, respectively. This file includes the rate and task scheduling code.

- `Rate1s.h` and `Rate2s.h` declare model data structures and a public interface to subsystem entry points and data structures.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

- 1 Include the generated header file by adding directive `#include rtwdemo_explicitinvocation_atomicsusys.h`.
- 2 Write input data to the generated code for model Inport blocks.
- 3 Call the generated entry-point functions.
- 4 Read data from the generated code for model Outport blocks.

Input ports, `Rate1s`:

- `rtU.In1` of type `real_T` with dimension of 1
- `rtU.In2` of type `real_T` with dimension of 1

Entry-point functions, `Rate1s`:

- Initialize entry-point function, `void Rate1s_initialize(void)`. At startup, call this function once.
- Output and update entry-point (step) function, `void Rate1s_step(void)`. Call this function periodically, every second.
- Termination function, `void Rate1s_terminate(void)`. Call this function once from your shutdown code.

Output ports, `Rate1s`:

- `rtY.Out1` of type `real_T` with dimension of 1
- `rtY.Out2` of type `real_T` with dimension of 1

Input ports, `Rate2s`:

- `rtU.In1` of type `real_T` with dimension of 1

Entry-point functions, `Rate2s`:

- Initialize entry-point function, `void Rate2s_initialize(void)`. Call this function once at startup.
- Output and update entry-point (step), `void Rate2s_step(void)`. Call this function periodically, every 2 seconds.
- Termination function, `void Rate2s_terminate(void)`. Call this function once from your shutdown code.

Output ports, `Rate2s`:

- `rtY.Out1` of type `real_T` with dimension of 1

Model Explicit Function Invocation with Function-Call Subsystems

Deploy embedded system code from Simulink® models by partitioning a model into function-call subsystems that you build separately.

Function-Call Subsystem Model

Open the example model `rtwdemo_explicitinvocation_funccallsubsys`. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**.

This model partitions an algorithm into three function-call subsystems: Rate1s, Rate2s, and DataBuffer. Use function-call subsystems to model multirate systems explicitly.

Subsystems Rate1s and DataBuffer use a sample time of 1 second. Subsystem Rate2s use a sample time of 2 seconds.

This model design is referred to as export function modeling. Simulink constrains the model to function-call subsystems at the root level. The driving Inport block specifies the function name.

Relevant Model Configuration Parameter Settings

- **Solver > Type** set to Fixed-step.
- **Solver > Solver** set to discrete (no continuous states).
- **Solver > Treat each discrete rate as a separate task** selected. Simulink applies multitasking execution because the model uses multiple sample rates.

Scheduling

Simulink® simulates the model based on the model configuration. Simulink propagates and uses the Inport block sample times to order block execution based on a single-core, multitasking execution platform.

In the sample time legend, red identifies the fastest discrete rate. Magenta identifies rates inherited from exported functions, indicating their execution is outside the context of Simulink scheduling.

Your execution framework must schedule the generated function code and transfer data between functions.

Your execution framework needs to schedule the generated function code and handle data transfers between functions. The generated code is simple and you control the order of execution.

Generate Code and Report

Generate code and a code generation report. The example model generates a report.

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code shows how to call the exported functions. The code also shows how to initialize, execute, and terminate the generated code.
- `rtwdemo_explicitinvocation_funccallsubsys.c` calls the initialization function and exported functions for subsystems `Rate1s`, `Rate2s`, and `DataBuffer`.
- `rtwdemo_explicitinvocation_funccallsubsys.h` declares model data structures and a public interface to the exported entry point functions and data structures.

- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

- 1 Include the generated header files by adding directives `#include Rate1s.h`, `#include DataBuffer.h`, and `#include Rate2s.h`.
- 2 Write input data to the generated code for model Inport blocks.
- 3 Call the generated entry-point functions.
- 4 Read data from the generated code for model Outport blocks.

Input ports:

- `rtU.In1_1s` of type `real_T` with dimension of 1
- `rtU.In2_2s` of type `real_T` with dimension of 1

Entry-point functions:

- Initialize entry-point function, `void rtwdemo_explicitinvocation_funcallsys_initialize(void)`. At startup, call this function once.
- Exported function, `void CallEvery1s(void)`. Call this function as needed.
- Exported function, `void CallEvery1s(void)`. Call this function as needed.
- Exported function, `void CallEvery2sAt1sPriority(void)`. Call this function as needed.

Output ports:

- `rtY.Out1` of type `real_T` with dimension of 1
- `rtY.Out2` of type `real_T` with dimension of 1

More About

- “Customize Code Organization and Format” on page 39-56

Modeling Patterns for AUTOSAR Runnables

Use Simulink® models, subsystems, and functions to model AUTOSAR atomic software components and their runnable entities (runnables).

Prerequisites

The Embedded Coder Support Package for AUTOSAR Standard is required for generating C code and arxml descriptions for AUTOSAR software components.

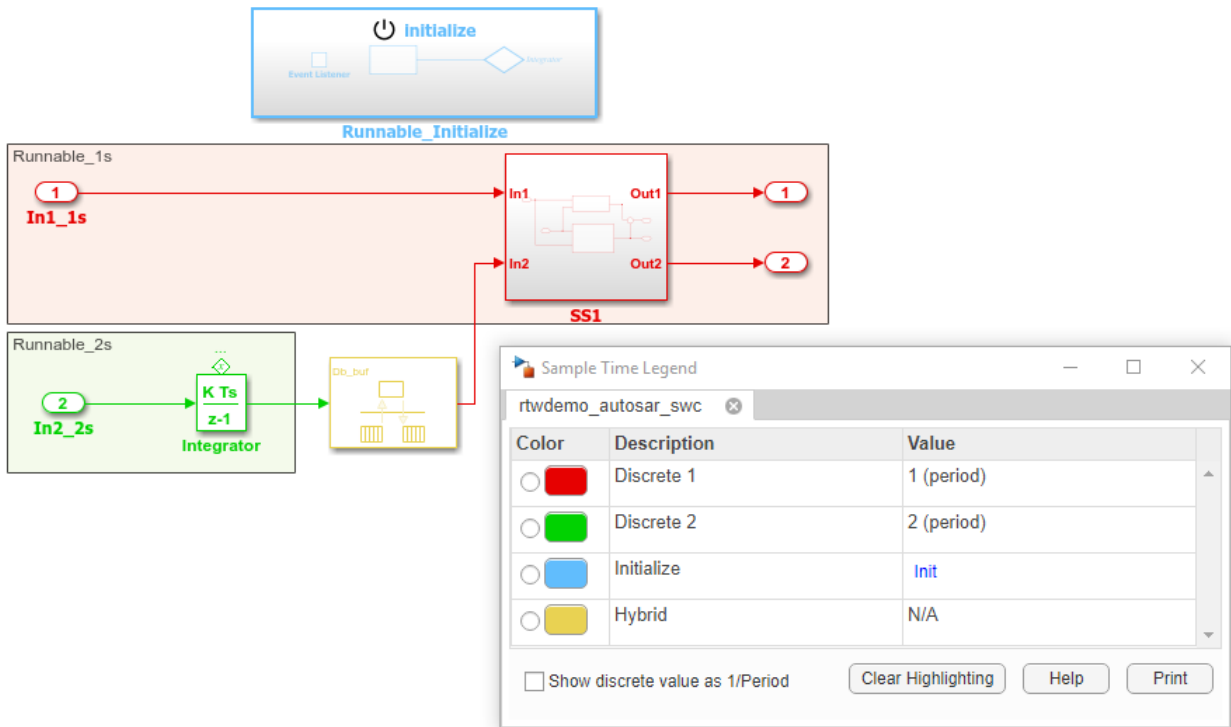

- Install the AUTOSAR Standard Support Package
- “Support Package Installation” (MATLAB)

Multiple Periodic Runnables Configured for Multitasking

Open the example model `rtwdemo_autosar_sw`. The model shows the implementation of an AUTOSAR atomic software component (ASWC). Two periodic runnables, `Runnable_1s` and `Runnable_2s`, are modeled with multiple sample rates: 1 second (`In1_1s`) and 2 seconds (`In2_2s`). To maximize execution efficiency, the model is configured for multitasking.

The model includes an Initialize Function block, which initializes the integrator in `Runnable_2s` to a value of 1.

To display color-coded sample rates with annotations and a legend, select **Display > Sample Time > Colors**.

Relevant Model Configuration Parameter Settings

- **Solver > Type** set to Fixed-step.
- **Solver > Solver** set to discrete (no continuous states).
- **Solver > Fixed-step size (fundamental sample time)** set to auto.
- **Solver > Treat each discrete rate as a separate task** selected.

Scheduling

In the model window, enable sample time color-coding by selecting **Display > Sample Time > Colors**. The sample time legend shows the implicit rate grouping. Red represents the fastest discrete rate. Green represents the second fastest discrete rate. Yellow represents the mixture of the two rates.

Because the model has multiple rates and the **Solver** parameter **Treat each discrete rate as a separate task** is selected, the model simulates in multitasking mode. The model handles the rate transition for In2_2s explicitly with the Rate Transition block.

The Rate Transition block parameter **Ensure deterministic data transfer** is cleared to facilitate integration into an AUTOSAR Runtime Environment (RTE).

The generated code for the model schedules subrates in the model. In this example, the rate for Inport block In2_2s, the green rate, is a subrate. The generated code properly transfers data between tasks that run at the different rates.

Generate Code and Report

Generate code and a code generation report. The example model generates a report.

Generated code complies with AUTOSAR so that you can schedule the code with the AUTOSAR RTE.

Review Generated Code

In the code generation report, review the generated code.

- `rtwdemo_autosar_sw_c.c` contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
- `rtwdemo_autosar_sw_c.h` declares model data structures and a public interface to the model entry points and data structures.
- `rtwdemo_autosar_sw_c_private.h` contains local `define` constants and local data required by the model and subsystems.
- `rtwdemo_autosar_sw_c_types.h` provides forward declarations for the real-time model data structure and the parameters data structure.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.
- `rtwdemo_autosar_sw_c_component.arxml`, `rtwdemo_autosar_sw_c_datatype.arxml`, `rtwdemo_autosar_sw_c_implementation.arxml`, and `rtwdemo_autosar_sw_c_interface.arxml` contain elements and objects that represent AUTOSAR software components, ports, interfaces, data types, and packages. You integrate `arxml` files into an AUTOSAR RTE. You can import `arxml` files into the Simulink environment by using the AUTOSAR `arxml` importer tool.

- `Compiler.h`, `Platform_Types.h`, `Rte_ASWC.h`, `Rte_Type.h`, and `Std_Types.h` contain stub implementations of AUTOSAR RTE functions. Use these files to test the generated code in Simulink, for example, in software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulations of the component under test.

Code Interface

Open and review the Code Interface Report. This information is captured in the `arxml` files. The RTE generator uses the `arxml` descriptions to interface the code into an AUTOSAR RTE.

Input ports:

- Require port, interface: sender-receiver of type `real-T` of 1 dimension
- Require port, interface: sender-receiver of type `real-T` of 1 dimension

Entry-point functions:

- Initialization entry-point function, `void Runnable_Initialize(void)`. At startup, call this function once.
- Output and update entry-point function, `void Runnable_1s(void)`. Call this function periodically at the fastest rate in the model. For this model, call the function every second. To achieve real-time execution, attach this function to a timer.
- Output and update entry-point function, `void Runnable_2s(void)`. Call this function periodically at the second fastest rate in the model. For this model, call the function every 2 seconds. To achieve real-time execution, attach this function to a timer.

Output ports:

- Provide port, interface: sender-receiver of type `real-T` of 1 dimension
- Provide port, interface: sender-receiver of type `real-T` of 1 dimension

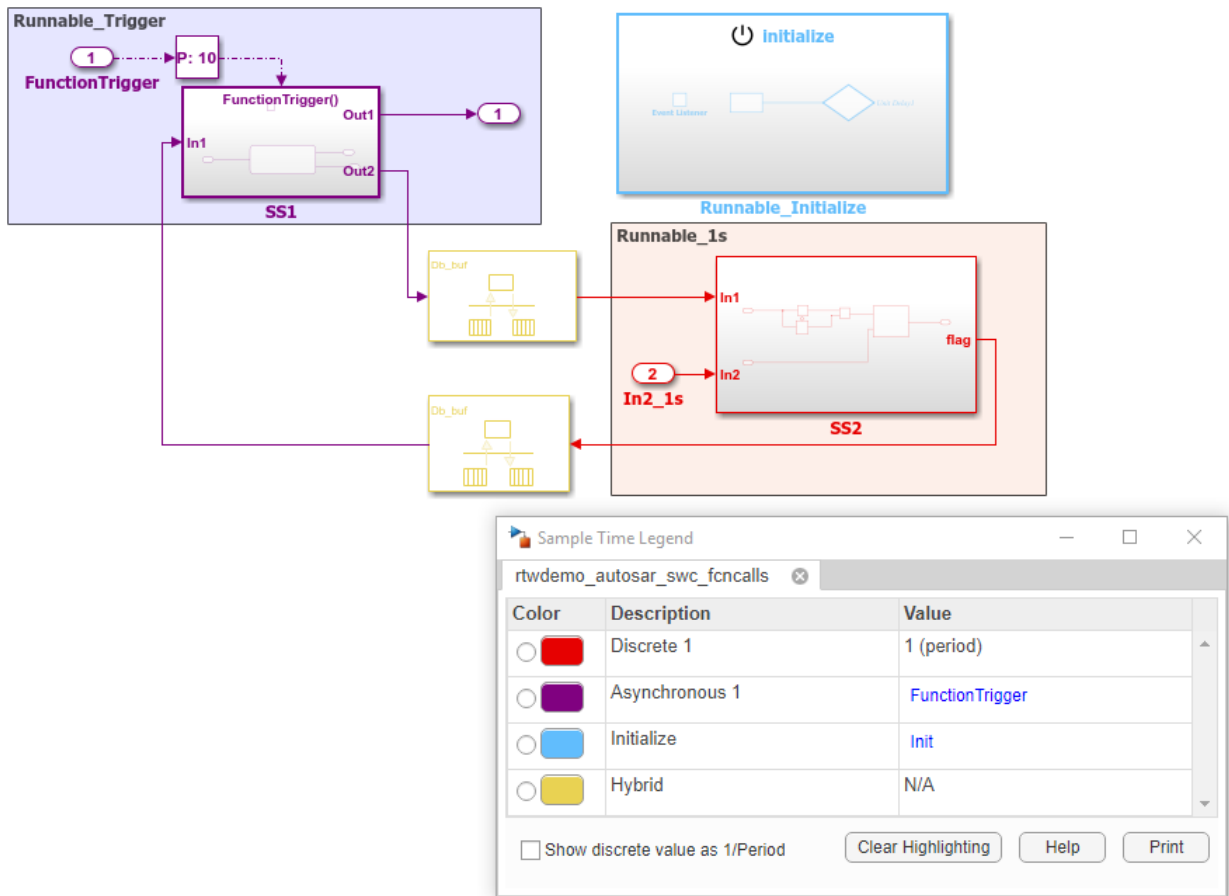

Multiple Runnables Configured as Periodic-Rate Runnable and Asynchronous Function-Call Runnable

Open the example model `rtwdemo_autosar_swc_fcncalls`. The model shows the implementation of an AUTOSAR atomic software component (ASWC). The model uses an asynchronous function-call runnable, `Runnable_Trigger`, which is triggered by an external event. The model also includes a periodic rate-based runnable, `Runnable_1s`. The Rate Transition blocks represent inter-runnable variables (IRVs).

Use this approach to model the JMAAB complex control model type beta architecture. In JMAAB type beta modeling, at the top level of a control model, you place function layers above scheduling layers.

The model includes an Initialize Function block, which initializes the unit delay in Runnable_1s to a value of 0.

To display color-coded sample rates with annotations and a legend, select **Display > Sample Time > Colors**.

Relevant Model Configuration Parameter Settings

- **Solver > Type** set to Fixed-step.
- **Solver > Solver** set to discrete (no continuous states).
- **Solver > Fixed-step size (fundamental sample time)** set to 1.
- **Solver > Treat each discrete rate as a separate task** cleared.

Scheduling

In the model window, enable sample time color-coding by selecting **Display > Sample Time > Colors**. The sample time legend shows the implicit rate grouping. Red represents the discrete rate. Magenta represents the asynchronous function trigger. Yellow represents the mixture of two rates.

The asynchronous trigger runnable runs at asynchronous rates (the **Sample time type** parameter of the function-call subsystem Trigger block is set to |triggered|) while the periodic rate runnable runs at the specified discrete rate. The generated code manages the rates by using single-tasking assumptions. For models with one discrete rate, the code generator does not produce scheduling code because there is only a single rate to execute. Use this technique for a single-rate application when you have one periodic runnable.

The model handles transitions between the asynchronous and discrete rates of the connected runnables with the two Rate Transition blocks. The Rate Transition block parameter **Ensure deterministic data transfer** is cleared to facilitate integration into an AUTOSAR Runtime Environment (RTE).

Generate Code and Report

Generate code and a code generation report. The example model generates a report.

Generated code complies with AUTOSAR so that you can schedule the code with the AUTOSAR RTE.

Review Generated Code

In the code generation report, review the generated code.

- `rtwdemo_autosar_swc_fcncalls.c` contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
- `rtwdemo_autosar_swc_fcncalls.h` declares model data structures and a public interface to the model entry points and data structures.

- `rtwdemo_autosar_swc_fcncalls_private.h` contains local define constants and local data required by the model and subsystems.
- `rtwdemo_autosar_swc_fcncalls_types.h` provides forward declarations for the real-time model data structure and the parameters data structure.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.
- `rtwdemo_autosar_swc_fcncalls_component.arxml`, `rtwdemo_autosar_swc_fcncalls_datatype.arxml`, `rtwdemo_autosar_swc_fcncalls_implementation.arxml`, and `rtwdemo_autosar_swc_fcncalls_interface.arxml` contain elements and objects that represent AUTOSAR software components, ports, interfaces, data types, and packages. You integrate `arxml` files into an AUTOSAR RTE. You can import `arxml` files into the Simulink environment by using the AUTOSAR `arxml` importer tool.
- `Compiler.h`, `Platform_Types.h`, `Rte_ASWC.h`, `Rte_Type.h`, and `Std_Types.h` contain stub implementations of AUTOSAR RTE functions. Use these files to test the generated code in Simulink, for example, in software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulations of the component under test.

Code Interface

Open and review the Code Interface Report. This information is captured in the `arxml` files. The RTE generator uses the `arxml` descriptions to interface the code into an AUTOSAR RTE.

Input port:

- Require port, interface: sender-receiver of type `real-T` of 1 dimension

Entry-point functions:

- Initialization entry-point function, `void Runnable_Initialize(void)`. At startup, call this function once.
- Simulink function, `void Runnable_1s(void)`. Call this function periodically at the fastest rate in the model. For this model, call the function every second. To achieve real-time execution, attach this function to a timer.
- Exported function, `void Runnable_Trigger(void)`. Call this function at any time from an external trigger.

Output port:

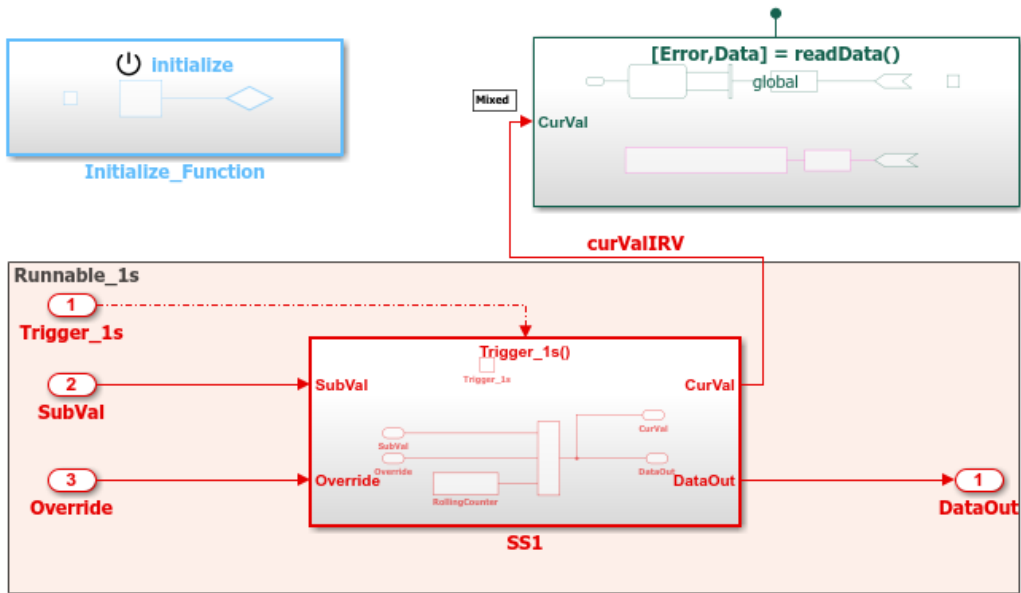

- Provide port, interface: sender-receiver of type `real-T` of 1 dimension

Multiple Runnables Configured As Function-Call Subsystem and Simulink Function

Open the example model `rtwdemo_autosar_swc_slfcns`. The model shows the implementation of an AUTOSAR atomic software component (ASWC). The model includes one periodic rate runnable, `Runnable_1s`, that uses a function-call subsystem, `SS1`. The model also includes a Simulink function, `readData`, to provide a value (`CurVal`) to clients that request it.

The model includes an Initialize Function block, which initializes the unit delay in subsystem `RollingCounter` to a value of 0.

To display color-coded sample rates with annotations and a legend, select **Display > Sample Time > Colors**.

Sample Time Legend

rtwdemo_autosar_swc_slfcn

Color	Description	Value
<input type="radio"/> ■	Exported Discrete	1 (period)
<input type="radio"/> ■	Exported Inherit	readData
<input type="radio"/> ■	Initialize	Init
<input type="radio"/> ■	Constant	Inf

Show discrete value as 1/Period

Clear Highlighting Help Print

Use function-call subsystems:

- When it is difficult or not possible to specify system events in a Simulink model.
- To achieve complex multirate scheduling of runnables. Model each rate as a separate function-call subsystem.

Relevant Model Configuration Parameter Settings

- **Solver > Type** set to Fixed-step.
- **Solver > Solver** set to discrete (no continuous states).
- **Solver > Fixed-step size (fundamental sample time)** set to 1.
- **Solver > Treat each discrete rate as a separate task** selected.

Scheduling

In the model window, enable sample time color-coding by clicking **Display > Sample Time > Colors**. The sample time legend shows the implicit rate grouping. Red identifies the discrete rate. Magenta identifies rates inherited from exported functions, indicating their execution is outside the context of Simulink scheduling.

Your execution framework must schedule the generated function code and handle data transfers between functions.

Generate Code and Report

Generate code and a code generation report. The example model generates a report.

The code generator:

- Produces an AUTOSAR runnable for the function-call subsystem at the root level of the model.
- Implements signal connections between runnables as AUTOSAR inter-runnable variables (IRVs).

Generated code complies with AUTOSAR so that you can schedule the code with the AUTOSAR Runtime Environment (RTE).

Review Generated Code

In the code generation report, review the generated code.

- `rtwdemo_autosar_swc_slfcns.c` contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
- `rtwdemo_autosar_swc_slfcns.h` declares model data structures and a public interface to the model entry points and data structures.
- `rtwdemo_autosar_swc_slfcns_private.h` contains local `define` constants and local data required by the model and subsystems.

- `rtwdemo_autosar_swc_slfcns_types.h` provides forward declarations for the real-time model data structure and the parameters data structure.
- `readData.c` contains code for the Simulink function.
- `readData_private.h` contains local `define` constants and local data required by the function.
- `readData.h` declares data structures and a public interface for calling the function.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.
- `rtwdemo_autosar_swc_slfcns_component.arxml`, `rtwdemo_autosar_swc_slfcns_datatype.arxml`, `rtwdemo_autosar_swc_slfcns_implementation.arxml`, and `rtwdemo_autosar_swc_slfcns_interface.arxml` contain elements and objects that represent AUTOSAR software components, ports, interfaces, data types, and packages. You integrate `arxml` files into an AUTOSAR RTE. You can import `arxml` files into the Simulink environment by using the AUTOSAR `arxml` importer tool.
- `Compiler.h`, `Platform_Types.h`, `Rte_ASWC.h`, `Rte_Type.h`, and `Std_Types.h` contain stub implementations of AUTOSAR RTE functions. Use these files to test the generated code in Simulink, for example, in software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulations of the component under test.

Code Interface

Open and review the Code Interface Report. This information is captured in the `arxml` files. The RTE generator uses the `arxml` descriptions to interface the code into an AUTOSAR RTE.

Input ports:

- Require port, interface: sender-receiver of type `uint16-T` of 1 dimension
- Require port, interface: sender-receiver of type `real-T` of 1 dimension
Entry-point functions:

Entry-point functions:

- Initialization entry-point function, `void Runnable_Init(void)`. At startup, call this function once.
- Exported function, `void Runnable_Is(void)`. Call this function periodically, every second.

- Simulink function, `Std_ReturnType readData(real_T Data[2])`. Call this function at any time.

Output ports:

- Provide port, interface: sender-receiver of type `uint16-T` of 1 dimension

Configure a Model for Code Generation

Model configuration parameters determine the method for generating the code and the resulting format.

- 1 Open `rtwdemo_throttlecntrl` and save a copy as `throttlecntrl` in a writable location on your MATLAB path.

Note This model uses Stateflow® software.

- 2 Open the Configuration Parameters dialog box **Solver** pane. To generate code for a model, you must configure the model to use a fixed-step solver. For this example, set the parameters as noted in the following table.

Parameter	Setting	Effect on Generated Code
Type	Fixed-step	Maintains a constant (fixed) step size, which is required for code generation
Solver	discrete (no continuous states)	Applies a fixed-step integration technique for computing the state derivative of the model
Fixed-step size	.001	Sets the base rate; must be the lowest common multiple of all rates in the system

- 3 Open the **Code Generation** pane and make sure that **System target file** is set to `grt.tlc`.

Note The GRT (Generic Real-Time Target) configuration requires a fixed-step solver. However, the `rsim.tlc` system target file supports variable step code generation.

The system target file (STF) defines a target, which is an environment for generating and building code for execution on a certain hardware or operating system platform. For example, one property of a target is code format. The grt configuration requires a fixed step solver and the `rsim.tlc` supports variable step code generation.

- 4 Open the **Code Generation > Custom Code** pane, and under **Include list of additional**, select **Include directories**. In the **Include directories** text field, enter:

```
"$matlabroot$\toolbox\rtw\rtwdemos\EmbeddedCoderOverview\"
```

This directory includes files that are required to build an executable for the model.

- 5 Apply your changes and close the dialog box.

Blocks and Products Supported for C Code Generation

“Simulink Built-In Blocks That Support Code Generation” on page 2-7

“Simulink Block Data Type Support Table” on page 2-30

“Block Set Support for Code Generation” on page 2-30

As you construct a model, to prevent issues later in the development process, determine whether the Simulink Coder and Embedded Coder code generators support the products and blocks that you want to use.

Related Products

The following table summarizes MathWorks products that extend and complement Simulink Coder software. For information about these products and how code generation supports them, refer to their product documentation at www.mathworks.com.

Product	Extends Code Generation Capabilities for ...
Aerospace Blockset™	Aircraft, spacecraft, rocket, propulsion systems, and unmanned airborne vehicles
Audio System Toolbox™	Audio processing systems
Automated Driving System Toolbox™	Designing, simulating, and testing ADAS and autonomous driving systems
Communications System Toolbox™	Physical layer of communication systems
Computer Vision System Toolbox™	Video processing, image processing, and computer vision systems
Control System Toolbox™	Linear control systems
DSP System Toolbox™	Signal processing systems
Embedded Coder	Embedded systems, rapid prototyping boards, and microprocessors in mass production
Fixed-Point Designer™	Fixed-point systems
Fuzzy Logic Toolbox™	System designs based on fuzzy logic

Product	Extends Code Generation Capabilities for ...
HDL Verifier™	Direct programming interface (DPI) component and transaction-level model (TLM) generation from Simulink
IEC Certification Kit	ISO 26262 and IEC 61508 certification
Model-Based Calibration Toolbox™	Developing processes for systematically identifying optimal balance of engine performance, emissions, and fuel economy, and reusing statistical models for control design, hardware-in-the-loop (HIL) testing, or powertrain simulation
Model Predictive Control Toolbox™	Controllers that optimize performance of multi-input and multi-output systems that are subject to input and output constraints
Neural Network Toolbox™	Neural networks
Parallel Computing Toolbox™	Parallel builds for large Simulink models
Phased Array System Toolbox™	Sensor array systems in radar, sonar, wireless communications, and medical imaging applications
Polyspace® Bug Finder™	MISRA-C compliance and static analysis of generated code
Polyspace Code Prover™	Formal analysis of generated code
Powertrain Blockset™	Real-time testing of powertrain applications
Robotics System Toolbox™	Robot Operating System (ROS) node generation
Simscape™	Systems spanning mechanical, electrical, hydraulic, and other physical domains as physical networks
Simscape Driveline™	Driveline (drivetrain) systems
Simscape Electronics™	Electronic and electromechanical systems
Simscape Fluids™	Hydraulic power and control systems
Simscape Multibody™	Three-dimensional mechanical systems
Simscape Power Systems™	Systems that generate, transmit, distribute, and consume electrical power

Product	Extends Code Generation Capabilities for ...
Simulink 3D Animation™	Systems with 3D visualizations
Simulink Check™	Model standards compliance checking and metrics
Simulink Code Inspector™	Automated reviews of generated code
Simulink Control Design™	Autotuning of PID controllers
Simulink Coverage™	Model and code structural coverage analysis
Simulink Design Optimization™	Systems requiring maximum overall system performance
Simulink Desktop Real-Time™	Rapid prototyping or hardware-in-the-loop (HIL) simulation of control system and signal processing algorithms
Simulink Real-Time™	Rapid control prototyping, hardware-in-the-loop (HIL) simulation, and other real-time testing applications
Simulink Report Generator™	Automatically generating project documentation in a standard format
Simulink Requirements™	Authoring and tracing requirements to design and code
Simulink Test™	Software-in-the-loop (SIL), processor-in-the-loop (PIL), and real-time hardware-in-the-loop (HIL) testing of generated code
Stateflow	State machines and flow charts
System Identification Toolbox™	Systems constructed from measured input-output data
Vehicle Dynamics Blockset™	Modeling and simulation of vehicle dynamics in 3D environment
Vehicle Network Toolbox™	CAN blocks for Accelerator and Rapid Accelerator simulations and code deployment on Windows®

Simulink Built-In Blocks That Support Code Generation

The following tables summarize code generator support for Simulink blocks. There is a table for each block library. For more detail, including data types each block supports, in the MATLAB Command Window, type `showblockdatatypeable`, or consult the block reference pages. For some blocks, the generated code might rely on `memcpy` or `memset` (`string.h`).

Simulink Block Data Type Support Table

The Simulink Block Data Type Support table summarizes characteristics of blocks in the Simulink and Fixed-Point Designer block libraries, including whether or not they are recommended for use in production code generation. To view this table, in the MATLAB Command Window, type `showblockdatatypetable`, or consult the block reference pages.

Block Set Support for Code Generation

Several products that include blocks are available for you to consider for code generation. However, before using the blocks for one of these products, consult the documentation for that product to confirm which blocks support code generation.

Modeling Semantic Considerations

In this section...

“Data Propagation” on page 2-31

“Sample Time Propagation” on page 2-33

“Latches for Subsystem Blocks” on page 2-34

“Block Execution Order” on page 2-35

“Algebraic Loops” on page 2-36

Data Propagation

The first stage of code generation is compilation of the block diagram. This stage is analogous to that of a C or C++ program. The compiler carries out type checking and preprocessing. Similarly, the Simulink engine verifies that input/output data types of block ports are consistent, line widths between blocks are of expected thickness, and the sample times of connecting blocks are consistent.

The Simulink engine propagates data from one block to the next along signal lines. The data propagated consists of

- Data type
- Line widths
- Sample times

You can verify what data types a Simulink block supports by typing

```
showblockdatatypetable
```

at the MATLAB prompt, or (from the Help browser) clicking the command above.

The Simulink engine typically derives signal attributes from a source block. For example, the Inport block's parameters dialog box specifies the signal attributes for the block.

In this example, the Inport block has a port width of 3, a sample time of .01 seconds, the data type is double, and the signal is complex.

This figure shows the propagation of the signal attributes associated with the Inport block through a simple block diagram.

In this example, the Gain and Outport blocks inherit the attributes specified for the Inport block.

Sample Time Propagation

Inherited sample times in source blocks (for example, a root inport) can sometimes lead to unexpected and unintended sample time assignments. Since a block may specify an inherited sample time, information available at the outset is often insufficient to compile a block diagram completely.

In such cases, the Simulink engine propagates the known or assigned sample times to those blocks that have inherited sample times but that have not yet been assigned a sample time. Thus, the engine continues to fill in the blanks (the unknown sample times) until sample times have been assigned to as many blocks as possible. Blocks that still do not have a sample time are assigned a default sample time.

For a completely deterministic model (one where no sample times are set using the above rules), you should explicitly specify the sample times of your source blocks. Source blocks include root inport blocks and blocks without input ports. You do not have to set subsystem input port sample times. You might want to do so, however, when creating modular systems.

An unconnected input implicitly connects to ground. For ground blocks and ground connections, the sample time is always constant (`inf`).

All blocks have an inherited sample time ($T_s = -1$). They are assigned a sample time of $(T_f - T_i)/50$.

Blocks Whose Outputs Have Constant Values

When you display sample time colors, by default, Constant blocks appear magenta in color to indicate that the block outputs have constant values during simulation. Downstream blocks whose output values are also constant during simulation, such as Gain blocks, similarly appear magenta if they use an inherited sample time. The code generated for these blocks depends in part on the tunability of the block parameters.

If you set **Configuration Parameters > Optimization > Default parameter behavior** to `Inlined`, the block parameters are not tunable in the generated code. Because the block outputs are constant, the code generator eliminates the block code due to constant folding. If the code generator cannot fold the code, or if you select settings to disable constant folding, the block code appears in the model initialization function. The

generated code is more efficient because it does not compute the outputs of these blocks during execution.

However, if you configure a block or model so that the block parameters appear in the generated code as tunable variables, the code generator represents the blocks in a different way. Block parameters are tunable if, for example:

- You set **Default parameter behavior** to **Tunable**. By default, numeric block parameters appear as tunable fields of a global parameter structure.
- You use a tunable parameter, such as a `Simulink.Parameter` object that uses a storage class other than `Auto`, as the value of one or more numeric block parameters. These block parameters are tunable regardless of the setting that you choose for **Default parameter behavior**.

If a block parameter is tunable, the generated code must compute the block outputs during execution. Therefore, the block code appears in the model `step` function. If the model uses multiple discrete rates, the block code appears in the output function for the fastest downstream rate that uses the block outputs.

Latches for Subsystem Blocks

When an Inport block is the signal source for a triggered or function-call subsystem, you can use latch options to preserve input values while the subsystem executes. The Inport block latch options include:

For	Use
Triggered subsystems	Latch input by delaying outside signal
Function-call subsystems	Latch input for feedback signals of function-call subsystem outputs

When you use **Latch input for feedback signals of function-call subsystem outputs** for a function-call subsystem, the code generator

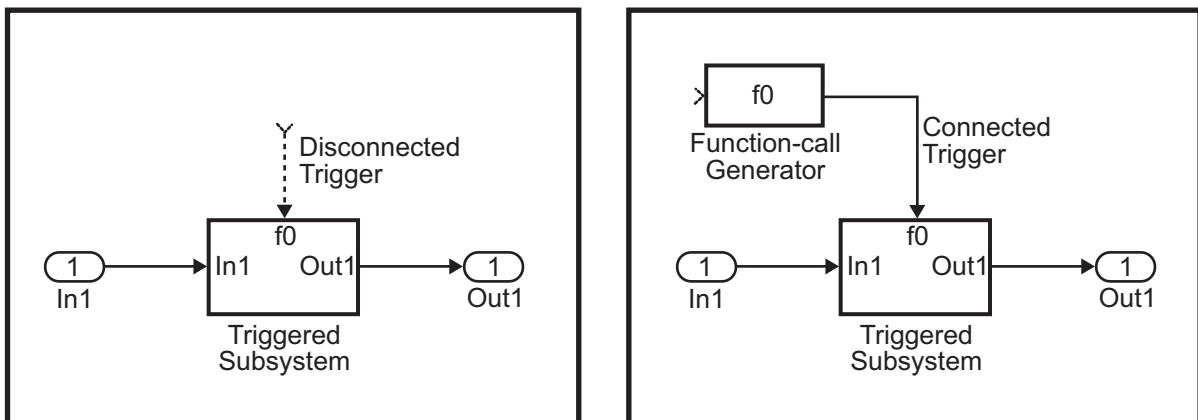

- Preserves latches in generated code regardless of optimizations that might be set
- Places the code for latches at the start of a subsystem's output/update function

For more information on these options, see the block description of Inport.

Block Execution Order

Once the Simulink engine compiles the block diagram, it creates a *model.rtw* file (analogous to an object file generated from a C or C++ file). The *model.rtw* file contains the connection information of the model, as well as the signal attributes. Thus, the timing engine in can determine when blocks with different rates should be executed.

You cannot override this execution order by directly calling a block (in handwritten code) in a model. For example, in the next figure the *disconnected_trigger* model on the left has its trigger port connected to ground, which can lead to the blocks inheriting a constant sample time. Calling the trigger function, $f()$, directly from user code does not work. Instead, you should use a function-call generator to specify the rate at which $f()$ should be executed, as shown in the *connected_trigger* model on the right.

Instead of the function-call generator, you could use another block that can drive the trigger port. Then, you should call the model's main entry point to execute the trigger function.

For multirate models, a common use of the code generator is to generate code for individual models separately and then manually code the I/O between the generated code modules. This approach places the burden of data consistency between models on the developer of the models. Another approach is to let Simulink and the code generator maintain data consistency between rates and generate multirate code for use in a multitasking environment. The Rate Transition block is able to interface periodic and asynchronous signals. For a description of the Simulink Coder block libraries, see

“Asynchronous Events” (Simulink Coder). For more information on multirate code generation, see “Modeling for Multitasking Execution” (Simulink Coder).

Algebraic Loops

Algebraic loops are circular dependencies between variables. This prevents the straightforward direct computation of their values. For example, in the case of a system of equations

- $x = y + 2$
- $y = -x$

the values of x and y cannot be directly computed.

To solve this, either repeatedly try potential solutions for x and y (in an intelligent manner, for example, using gradient based search) or “solve” the system of equations. In the previous example, solving the system into an explicit form leads to

- $2x = 2$
- $y = -x$
- $x = 1$
- $y = -1$

An algebraic loop exists whenever the output of a block having direct feedthrough (such as Gain, Sum, Product, and Transfer Fcn) is fed back as an input to the same block. The Simulink engine is often able to solve models that contain algebraic loops, such as the next diagram.

The code generator does not produce code that solves algebraic loops. This restriction includes models that use Algebraic Constraint blocks in feedback paths. However, the Simulink engine can often eliminate algebraic loops that arise, by grouping equations in certain ways in models that contain them. It does this by separating the update and output functions to avoid circular dependencies. For details, see “Algebraic Loops” (Simulink).

Algebraic Loops in Triggered Subsystems

While the Simulink engine can minimize algebraic loops involving atomic and enabled subsystems, a special consideration applies to some triggered subsystems. An example for which code can be generated is shown in the following model and triggered subsystem.

The default Simulink behavior is to combine output and update methods for the subsystem, which creates an apparent algebraic loop, even though the Unit Delay block in the subsystem has no direct feedthrough.

You can allow the Simulink engine to solve the problem by splitting the output and update methods of triggered and enabled-triggered subsystems when feasible. If you want the code generator to take advantage of this feature, select the **Minimize algebraic loop occurrences** check box in the Subsystem Parameters dialog box. Select this option to avoid algebraic loop warnings in triggered subsystems involved in loops.

Note If you check this box, the generated code for the subsystem might contain split output and update methods, even if the subsystem is not actually involved in a loop. Also, if a direct feedthrough block (such as a Gain block) is connected to the inport in the above

triggered subsystem, the Simulink engine cannot solve the problem, and the code generator is unable to generate code.

A similar **Minimize algebraic loop occurrences** option appears on the **Model Referencing** pane of the Configuration Parameters dialog box. Selecting it enables the Simulink Coder software to generate code for models containing Model blocks that are involved in algebraic loops.

Modeling Guidelines for Blocks

Code generation modeling guidelines include recommended model settings, block usage, and block parameters. When you develop models for code generation, use these guidelines.

For more information, see “Modeling Guidelines” (Simulink).

Control Generation of Subsystem Functions

What is a Subsystem Function?

A subsystem function is function code that the code generator produces for a subsystem in a model. The function interface and how the code generator packages the code depends on whether the subsystem is a virtual or atomic (nonvirtual) subsystem and how you configure the subsystem block parameters. For more information, see [Subsystem](#), [Atomic Subsystem](#), [Nonvirtual Subsystem](#), [CodeReuse Subsystem](#).

Options for Controlling Generation of Subsystem Function Code

You can design and configure a model in a way that controls how the code generator produces code from subsystems.

To	See
Generate inlined code from a selected subsystem.	"Inline Subsystem Code" on page 3-8
Generate code for only a subsystem.	"Generate Code and Executables for Individual Subsystems" on page 3-4
Generate separate functions without arguments, and optionally place the subsystem code in a separate file.	"Generate Subsystem Code as Separate Function and Files" on page 3-11
Generate a single reentrant function for a subsystem that is included in multiple places within a model.	"Generate Reentrant Code from Subsystems" on page 6-42
Generate a single reentrant function for a subsystem that is included in multiple places in a model reference hierarchy.	"Generate Reusable Code from Library Subsystems Shared Across Models" on page 6-53

Subsystem Function Dependence

Code generated from subsystems can be completely independent of code generated for a model. When generating code for a subsystem, the code can reference global data structures of the model, even if the subsystem function code is in a separate file. Each

subsystem code file contains `include` directives and comments describing the dependencies. The code generator checks for cyclic file dependencies and warns about them at build time. For descriptions of how the code generator packages code, see “Manage Build Process File Dependencies” (Simulink Coder).

To generate subsystem function code that is independent of the code generated for the parent model, place the subsystem in a library and configure it as a reusable subsystem, as explained in “Generate Reusable Code from Library Subsystems Shared Across Models” on page 6-53.

Related Examples

- “Modeling Guidelines for Subsystems” on page 2-40

Generate Code and Executables for Individual Subsystems

You can generate code and build an executable for a subsystem within a model. The code generation and build process uses the code generation and build parameters of the root model.

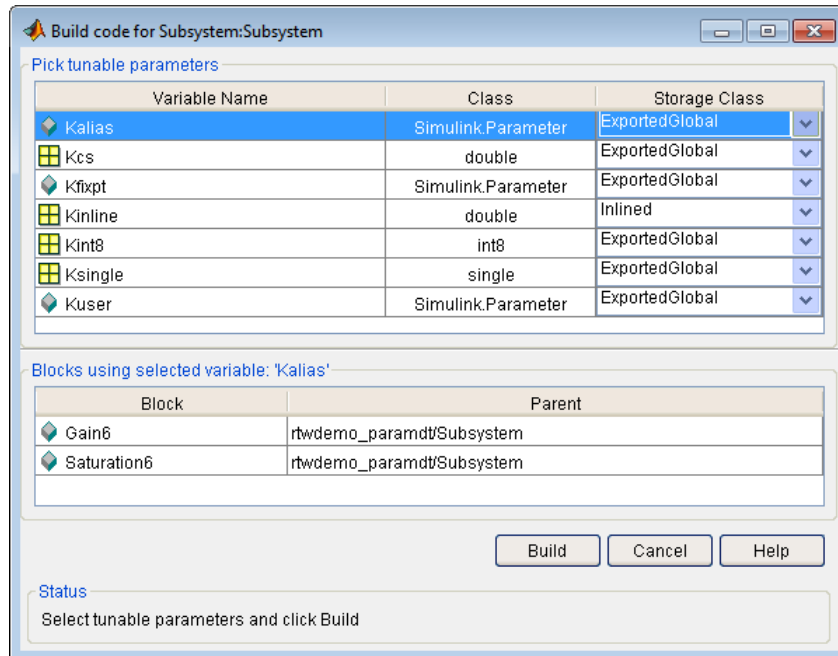

- 1 In the Configuration Parameters dialog box, set up the code generation and build parameters, similar to setting up the code generation for a model.
- 2 Right-click the Subsystem block. From the context menu, select **C/C++ Code > Build This Subsystem** from the context menu.

Alternatively, in the current model, click a subsystem and then from the **Code** menu, select **C/C++ Code > Build Selected Subsystem**.

Note When you select **Build This Subsystem**, if the model is operating in external mode, the build process automatically turns off external mode for the duration of the build. The code generator restores external mode upon completion of the build process.

- 3 The **Build code for Subsystem** window displays a list of the subsystem parameters. The upper pane displays the name, class, and storage class of each variable (or data object) that is referenced as a block parameter in the subsystem. When you select a parameter in the upper pane, the lower pane shows the blocks that reference the parameter and the parent system of each block.

The **Storage Class** column contains a menu for each row. The menu options set the storage class or inline the parameter. To declare a parameter to be tunable, set the **Storage Class** to a value other than **Inlined**.

For more information on tunable and inlined parameters and storage classes, see “Create Tunable Calibration Parameter in the Generated Code” on page 22-121.

- 4 After selecting tunable parameters, **Build** to initiate the code generation and build process.
- 5 The build process displays status messages in the MATLAB Command Window. When the build is complete, the generated executable is in your working folder. The name of the generated executable is *subsystem.exe* (on PC platforms) or *subsystem* (on The Open Group UNIX® platforms). *subsystem* is the name of the source subsystem block.

The generated code is in a build subfolder, named *subsystem_target_rtw*. *subsystem* is the name of the source subsystem block and *target* is the name of the target configuration.

When you generate code for a subsystem, you can generate an S-function by selecting **Code > C/C++ Code > Generate S-Function**, or you right-click the subsystem block and select **C/C++ Code > Build This Subsystem** from the context menu. For more information on S-functions, see “Generate S-Function from Subsystem” (Simulink Coder).

Subsystem Build Limitations

The following limitations apply to building subsystems:

- Subsystem build does not support a subsystem that has a function-call trigger input or a function-call output.
- When you right-click a subsystem block and select **C/C++ Code > Build This Subsystem** from the context menu to build a subsystem that includes an Output block for which the **Data type** parameter specifies a bus object, you must address errors that result from setting signal labels. To configure the software to display these errors, in the Configuration Parameters dialog box for the parent model, on the **Diagnostics > Connectivity** pane, set the **Signal label mismatch** parameter to error.
- When a subsystem is in a triggered or function-call subsystem, the right-click build process might fail if the subsystem code is not sample-time independent. To find out whether a subsystem is sample-time independent:
 - 1 Copy all blocks in the subsystem to an empty model.
 - 2 In the Configuration Parameters dialog box, on the **Solver** pane, set:
 - a **Type** to Fixed-step.
 - b **Periodic sample time constraint** to Ensure sample time independent.
 - c Click **Apply**.
 - 3 Update the model. If the model is sample-time dependent, Simulink generates an error in the process of updating the diagram.
- When you use the right-click build process for a subsystem, the code generator attempts to use the subsystem name for generated code files. In some cases, there can be a conflict with the name that you specify when you set, for example, **File name options** to Use function name or **Function name options** to Use subsystem name. You see an error:

```
The subsystem 'model/subsys'  
is trying to generate code to an reserved file (subsys) for  
the model 'subsys'...
```

To resolve the error, modify one of the conflicting file names so that the names are unique.

- In a subsystem build warning, the subsystem block path hyperlink that is created references a temporary model block path instead of the actual model block path. In the Diagnostic Viewer, clicking the subsystem hyperlink does not take you to the block. In the Command Window, you see a message:

```
...  
No system or file called 'subsystemName' found.  
...
```

Inline Subsystem Code

You can configure a nonvirtual subsystem to inline the subsystem code with the model code. In the Subsystem Parameters dialog box, setting the **Function packaging** parameter to `Auto` or `Inline` inlines the generated code of the subsystem.

The `Auto` option is the default. When there is only one instance of a subsystem in the model, the `Auto` option inlines the subsystem code. When multiple instances of a subsystem exist, the `Auto` option results in a single copy of the function (as a reusable function). For function-call subsystems with multiple callers, the subsystem code is generated as if you specified `Nonreusable function`.

To inline subsystem code, select `Inline`. The `Inline` option explicitly directs the code generator to inline the subsystem unconditionally.

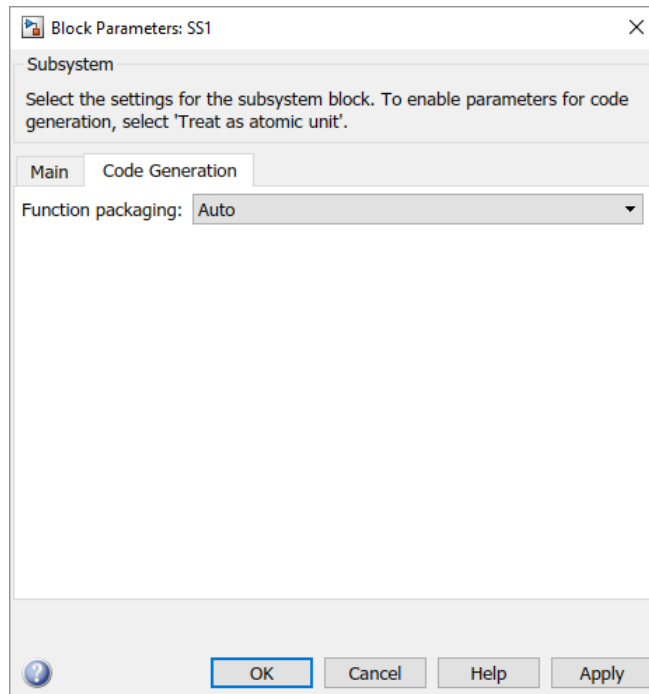

Configure Subsystem to Inline Code

To configure your subsystem for inlining:

- 1 Right-click the Subsystem block. From the context menu, select **Block Parameters (Subsystem)**.
- 2 In the Subsystem Parameters dialog box, if the subsystem is virtual, select **Treat as atomic unit**. This option makes the subsystem nonvirtual. On the **Code Generation** tab, the **Function packaging** option is now available.

If the system is already nonvirtual, the **Function packaging** option is already selected.

- 3 Click the **Code Generation** tab and select `Auto` or `Inline` from the **Function packaging** parameter.

- 4 Click **Apply** and close the dialog box.

The border of the subsystem thickens, indicating that it is nonvirtual.

When you generate code from your model, the code generator inlines subsystem code within `model.c` or `model.cpp` (or in its parent system's source file). You can identify this code by system/block identification tags, such as:

```
/* Atomic SubSystem Block: <Root>/AtomicSubsys1 */
```

Exceptions to Inlining

There are certain cases in which the code generator does not inline a nonvirtual subsystem, even though the **Inline** option is selected.

- If the subsystem is a function-call subsystem that is called by a noninlined S-function, the **Inline** option is ignored. Noninlined S-functions make calls by using function pointers. Therefore, the function-call subsystem must generate a function with all arguments present.

- In a feedback loop involving function-call subsystems, the code generator forces one of the subsystems to be generated as a function instead of inlining it. Based on the order in which the subsystems are sorted internally, the software selects the subsystem to be generated as a function.
- If a subsystem is called from an S-function block that sets the option `SS_OPTION_FORCE_NONINLINED_FCNCALL` to `TRUE`, it is not inlined. When user-defined Async Interrupt blocks or Task Sync blocks are present, this result might occur. Such blocks must be generated as functions. These blocks are located in the `vxlib1` block library and use the `SS_OPTION_FORCE_NONINLINED_FCNCALL` option. This library demonstrates integration with an example RTOS (VxWorks®).¹

Note You can use the blocks in the `vxlib1` (Simulink Coder) library (Async Interrupt and Task Sync) for simulation and code generation. These blocks provide starting point examples to help you develop custom blocks for your target environment.

1. VxWorks is a registered trademark of Wind River® Systems, Inc.

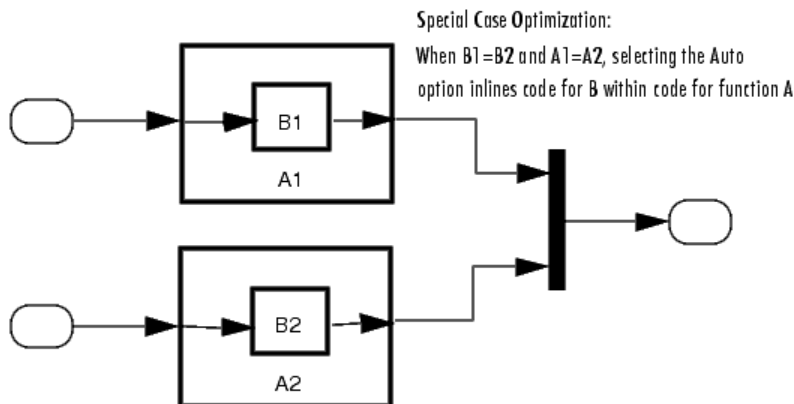

Generate Subsystem Code as Separate Function and Files

To generate a separate subsystem function and a separate file for a subsystem in a model:

- 1 Right-click a Subsystem block. From the context menu, select **Block Parameters (Subsystem)**.
- 2 In the Subsystem Parameters dialog box, if the subsystem is virtual, select **Treat as atomic unit**. On the **Code Generation** tab, the **Function packaging** parameter is now available.
- 3 Click the **Code Generation** tab and select **Nonreusable** function from the **Function packaging** parameter. The **Nonreusable** function option enables two parameters:
 - The “Function name options” (Simulink) parameter controls the naming of the generated function.
 - The “File name options” (Simulink) parameter controls the naming of the generated file.
- 4 Set the **Function name options** parameter.
- 5 Set the **File name options** parameter to a value other than **Auto**. If you are generating a reusable function for your subsystem, see “Generate Reentrant Code from Subsystems” on page 6-42 or “Generate Reusable Code from Library Subsystems Shared Across Models” on page 6-53.
- 6 Click **Apply** and close the dialog box.

Optimize Code for Identical Nested Subsystems

The **Function packaging** parameter Auto option can optimize code in situations in which identical subsystems contain other identical subsystems, by both reusing and inlining generated code. Suppose a model, such as the one shown in “Reuse of Identical Nested Subsystems” on page 3-12, contains identical subsystems A1 and A2. A1 contains subsystem B1, and A2 contains subsystem B2, which are identical. In such cases, the Auto option causes one function to be generated which is called for both A1 and A2. This function contains one piece of inlined code to execute B1 and B2. This optimization generates less code which improves execution speed.

Reuse of Identical Nested Subsystems

Code Generation of Constant Parameters

The code generator attempts to generate constant parameters to the shared utilities folder first. If constant parameters are not generated to the shared utilities folder, they are defined in the top model in a global constant parameter structure. The declaration of the structure, `ConstParam_model`, is in `model.h`:

```
/* Constant parameters (auto storage) */
typedef struct {
    /* Expression: [1 2 3 4 5 6 7]
     * Referenced by: '<Root>/Constant'
     */
    real_T Constant_Value[7];

    /* Expression: [7 6 5 4 3 2 1]
     * Referenced by: '<Root>/Gain'
     */
    real_T Gain_Gain[7];
} ConstParam_model;
```

The definition of the constant parameters, `model_constP`, is in:

```
/* Constant parameters (auto storage) */
const ConstParam_model model_ConstP = {
    /* Expression: [1 2 3 4 5 6 7]
     * Referenced by: '<Root>/Constant'
     */
    { 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0 },

    /* Expression: [7 6 5 4 3 2 1]
     * Referenced by: '<Root>/Gain'
     */
    { 7.0, 6.0, 5.0, 4.0, 3.0, 2.0, 1.0 }
};
```

The `model_constP` is passed as an argument to referenced models.

Code Generation of Referenced Models

This section describes model referencing considerations that apply specifically to code generation by the Simulink Coder. This section assumes that you understand referenced models and related terminology and requirements, as described in “Overview of Model Referencing” (Simulink) and associated topics.

When generating code for a referenced model hierarchy, the code generator produces a stand-alone executable for the top model, and a library module called a model reference target for each referenced model. When the code executes, the top executable invokes the model reference targets to compute the referenced model outputs. Model reference targets are sometimes called *Simulink Coder targets*.

Be careful not to confuse a model reference target (Simulink Coder target) with other types of targets:

- Target hardware — A platform for which the Simulink Coder software generates code
- System target — A file that tells the Simulink Coder software how to generate code for particular purpose
- Rapid Simulation target (RSim) — A system target file supplied with the Simulink Coder product
- Simulation target — A MEX-file that implements a referenced model that executes with Simulink Accelerator™ software

The code generator places the code for the top model of a hierarchy in the code generation folder (Simulink) and places the code for referenced models in an `slprj` folder in the code generation folder (Simulink). Subfolders in `slprj` provide separate places for different types of files. For folder information, see “Manage Build Process Folders” (Simulink Coder).

By default, the product uses *incremental code generation*. When generating code, it compares structural checksums of referenced model files with the generated code files to determine whether to regenerate model reference targets. To control when rebuilds occur, use the configuration parameter **Model Referencing > Rebuild**. For details, see “Rebuild” (Simulink).

In addition to incremental code generation, the Simulink Coder software uses *incremental loading*. The code for a referenced model is not loaded into memory until the code for its parent model executes and needs the outputs of the referenced model. The product then

loads the referenced model target and executes. Once loaded, the target remains in memory until it is no longer used.

Most code generation considerations are the same whether or not a model includes referenced models: the code generator handles the details automatically insofar as possible. This chapter describes topics that you may need to consider when generating code for a model reference hierarchy.

If you have a Embedded Coder license, custom targets must declare themselves to be model reference compliant if they need to support Model blocks. For more information, see “Support Model Referencing” on page 74-84.

Generate Code for Referenced Models

In this section...

“About Generating Code for Referenced Models” on page 4-4

“Create and Configure the Subsystem” on page 4-4

“Convert Model to Use Model Referencing” on page 4-7

“Generate Model Reference Code for a GRT Target” on page 4-10

“Work with Code Generation Folders” on page 4-12

About Generating Code for Referenced Models

To generate code for referenced models, you

- 1 Create a subsystem in an existing model.
- 2 Convert the subsystem to a referenced model (Model block).
- 3 Call the referenced model from the top model.
- 4 Generate code for the top model and referenced model.
- 5 Explore the generated code and the code generation folder.

You can accomplish some of these tasks automatically with a function called `Simulink.Subsystem.convertToModelReference`.

Create and Configure the Subsystem

In the first part of this example, you define a subsystem for the `vdp` example model, set configuration parameters for the model, and use the `Simulink.Subsystem.convertToModelReference` function to convert it into two new models — the top model (`vdptop`) and a referenced model `vdpmultRM` containing a subsystem you created (`vdpmult`).

- 1 In the MATLAB Command Window, create a new working folder wherever you want to work and `cd` into it:

```
mkdir mrexample
cd mrexample
```

- 2 Open the `vdp` example model by typing:

vdp

- 3 Drag a box around the three blocks outlined in blue below:

- 4 Choose **Create Subsystem from Selection** from the **Diagram > Subsystem & Model Reference** menu.

A subsystem block replaces the selected blocks.

- 5 If the new subsystem block is not where you want it, move it to a preferred location.
 6 Rename the block `vdpmult`.
 7 Right-click the `vdpmult` block and select **Block Parameters (Subsystem)**.

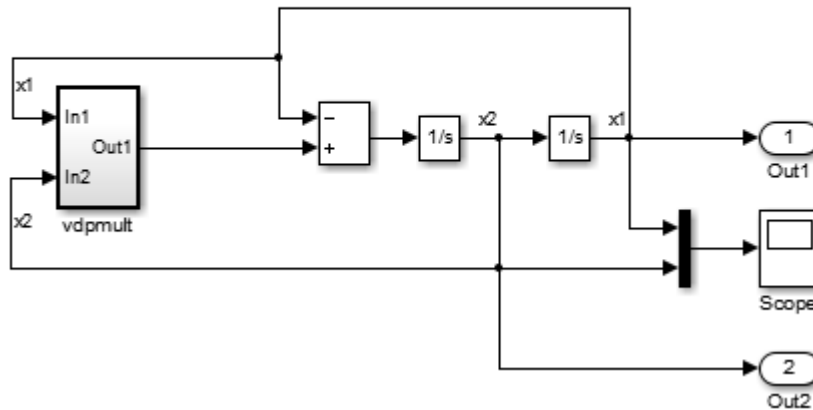

The **Function Block Parameters** dialog box appears.

- 8 In the **Function Block Parameters** dialog box, select **Treat as atomic unit**, then click **OK**.

The border of the `vdpmult` subsystem thickens to indicate that it is now atomic. An atomic subsystem executes as a unit relative to the parent model: subsystem block execution does not interleave with parent block execution. This property makes it possible to extract subsystems for use as stand-alone models and as functions in generated code.

The block diagram should now appear as follows:

van der Pol Equation

You must set several properties before you can extract a subsystem for use as a referenced model. To set the properties,

- 1 Open Model Explorer by selecting **Model Explorer** from the model's **View** menu.
- 2 In the **Model Hierarchy** pane, click the symbol preceding the model name to reveal its components.
- 3 Click **Configuration (Active)** in the left pane.
- 4 In the center pane, select **Solver**.
- 5 In the right pane, under **Solver selection** change the **Type** to **Fixed-step**, then click **Apply**. You must use fixed-step solvers when generating code, although referenced models can use different solvers than top models.
- 6 In the center pane, select **Diagnostics**. In the right pane, select the **Data Validity** tab. In the **Signals** area, set **Signal resolution** to **Explicit only**. Alternatively, if you do not want to use Simulink.Signal objects, set **Signal resolution** to **None**.
- 7 Click **Apply**.

The model now has the properties that model referencing requires.

- 8 In the center pane, click **Model Referencing**. In the right pane, set **Rebuild** to **If any changes in known dependencies detected**. Click **Apply**. This setting prevents code regeneration when it is not required.
- 9 In the vdp model window, choose **File > Save as**. Save the model as vdp_top in your working folder. Leave the model open.

Convert Model to Use Model Referencing

In this portion of the example, you use the conversion function `Simulink.SubSystem.convertToModelReference` to extract the subsystem `vdpmult` from `vdptop` and convert `vdpmult` into a referenced model named `vdpmultRM`. To see the complete syntax of the conversion function, type at the MATLAB prompt:

```
help Simulink.SubSystem.convertToModelReference
```

For additional information, type:

```
doc Simulink.SubSystem.convertToModelReference
```

If you want to see an example of `Simulink.SubSystem.convertToModelReference` before using it yourself, type:

```
sldemo_mdref_conversion
```

Simulink also provides a menu command, **Subsystem & Model Reference > Convert Subsystem to > Referenced Model**, that you can use to convert a subsystem to a referenced model. The command calls `Simulink.SubSystem.convertToModelReference` with default arguments. For more information, see “Convert a Subsystem to a Referenced Model” (Simulink).

Extract the Subsystem to a Referenced Model

To use `Simulink.SubSystem.convertToModelReference` to extract `vdpmult` and convert it to a referenced model, type:

```
Simulink.SubSystem.convertToModelReference...
('vdptop/vdpmult', 'vdpmultRM',...
'ReplaceSubsystem', true, 'BuildTarget', 'Sim')
```

This command:

- 1 Extracts the subsystem `vdpmult` from `vdptop`.

- 2 Converts the extracted subsystem to a separate model named `vdpmultRM` and saves the model to the working folder.
- 3 In `vdptop`, replaces the extracted subsystem with a Model block that references `vdpmultRM`.
- 4 Creates a simulation target for `vdptop` and `vdpmultRM`.

The converter prints progress messages and terminates with

```
ans =
     1
```

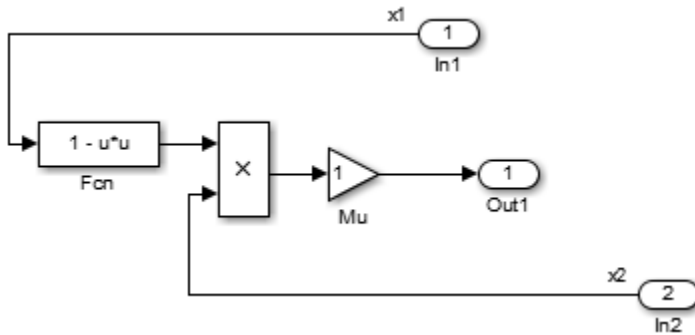

The parent model `vdptop` now looks like this:

Note the changes in the appearance of the block `vdpmult`. These changes indicate that it is now a Model block rather than a subsystem. As a Model block, it does not have contents of its own: the previous contents now exist in the referenced model `vdpmultRM`, whose name appears at the top of the Model block. Widen the Model block to expose the complete name of the referenced model.

If the parent model `vdptop` had been closed at the time of conversion, the converter would have opened it. Extracting a subsystem to a referenced model does *not* automatically create or change a saved copy of the parent model. To preserve the changes to the parent model, save `vdptop`.

Right-click the Model block `vdpmultRM` and choose **Open** to open the referenced model. The model looks like this:

Files Created and Changed by the Converter

The files in your working folder now consist of the following (not in this order).

File	Description
vdptop model file	Top model that contains a Model block where the vdpmult subsystem was
vdpmultRM model file	Referenced model created for the vdpmult subsystem
vdpmultRM_msf.mexw64	Static library file (Microsoft® Windows platforms only). The file extension is system-dependent and may differ. This file executes when the vdptop model calls the Model block vdpmult. When called, vdpmult in turn calls the referenced model vdpmultRM.
/slprj	Folder for generated model reference code

Code for model reference simulation targets is placed in the `slprj/sim` subfolder. Generated code for GRT, ERT, and other Simulink Coder targets is placed in `slprj` subfolders named for those targets. You will inspect some model reference code later in this example. For more information on code generation folders, see “Work with Code Generation Folders” on page 4-12.

Run the Converted Model

Open the Scope block in `vdptop` if it is not visible. In the `vdptop` window, click the **Run** tool or choose **Run** from the **Simulation** menu. The model calls the `vdpmultRM_msf` simulation target to simulate. The output looks like this:

Generate Model Reference Code for a GRT Target

The function `Simulink.SubSystem.convertToModelReference` created the model and the simulation target files for the referenced model `vdpmultRM`. In this part of the example, you generate code for that model and the `vdptop` model, and run the executable you create:

- 1 Verify that you are still working in the `mrexample` folder.
- 2 If the model `vdptop` is not open, open it. Make sure it is the active window.
- 3 Open Model Explorer by selecting **Model Explorer** from the model's **View** menu.
- 4 In the **Model Hierarchy** pane, click the symbol preceding the `vdptop` model to reveal its components.
- 5 Click **Configuration (Active)** in the left pane.
- 6 In the center pane, select **Data Import/Export**.
- 7 In the pane, select **Time** and **Output** and *clear Data stores*. Click **Apply**.

These settings instruct the model `vdptop` (and later its executable) to log time and output data to MAT-files for each time step.

- 8 Generate GRT code (the default) and an executable for the top model and the referenced model. For example, in the model, press **Ctrl+B**.

The Simulink Coder build process generates and compiles code. The current folder now contains a new file and a new folder:

File	Description
vdptop.exe	The executable created by the build process
vdptop_grt_rtw/	The build folder, containing generated code for the top model

The build process also generated GRT code for the referenced model and placed it in the slprj folder.

To view a model's generated code in **Model Explorer**, the model must be open. To use the **Model Explorer** to inspect the newly created build folder, vdptop_grt_rtw:

- 1 Open Model Explorer by selecting **Model Explorer** from the model's **View** menu.
- 2 In the **Model Hierarchy** pane, click the symbol preceding the model name to reveal its components.
- 3 Click the symbol preceding **Code for vdptop** to reveal its components.
- 4 Directly under **Code for vdptop**, click **This Model**.

A list of generated code files for vdptop appears in the **Contents** pane:

```
rtmodel.h
vdptop.c
vdptop.h
vdptop.mk
vdptop_private.h
vdptop_types.h
```

You can browse code by selecting a file of interest in the **Contents** pane.

To open a file in a text editor, click a filename, and then click the hyperlink that appears in the gray area at the top of the **Document** pane. The figure below illustrates viewing code for vdptop.c, in a text editor. Your code may differ.

To view the generated code in the HTML code generation report, see “Generate a Code Generation Report” (Simulink Coder).

Work with Code Generation Folders

Model reference code is generated in your code generation folder (Simulink) and simulation target code is generated in your simulation cache folder (Simulink). Because of this process, there are constraints on:

- When and where model reference targets are built.
- How the model reference targets are accessed.

The models referenced by Model blocks can be stored anywhere on the MATLAB path. A given top model can include models stored on different file systems or in different folders. The same is not true for the simulation targets and generated code derived from these models. Under most circumstances, to allow code reuse, models referenced by a given top model must be set up to simulate and generate model reference target code in a single code generation folder.

This means that, if you reference the same model from several top models, each stored in a different folder, you must choose one of these approaches:

- Always work with the same code generation folder and be sure that the models are on your path.

- Allow separate code generation folders, simulation targets, and Simulink Coder targets to be generated in each folder in which you work.

The second approach requires maintenance of several instances of the model reference code and it is possible for generated code to become redundant. For example, when you make changes to the referenced model. Therefore, to minimize code regeneration of referenced models, choose a specific code generation folder for all sessions.

Configure Referenced Models

Minimize occurrences of algebraic loops by selecting the **Minimize algebraic loop occurrences** parameter on the **Model Reference** pane. The setting of this option affects only generation of code from the model. For information on how this option affects code generation, see “Configure Run-Time Environment Options” (Simulink Coder). For more information about direct feed through, see “Algebraic Loops” (Simulink).

Use the **Integer rounding mode** parameter on your model's blocks to simulate the rounding behavior of the C compiler that you intend to use to compile code generated from the model. This setting appears on the **Signal Attributes** pane of the parameter dialog boxes of blocks that can perform signed integer arithmetic, such as the Product and n-D Lookup Table blocks.

For most blocks, the value of **Integer rounding mode** completely defines rounding behavior. For blocks that support fixed-point data and the Simplest rounding mode, the value of **Signed integer division rounds to** also affects rounding. For details, see “Precision” (Fixed-Point Designer).

When models contain Model blocks, all models that they reference must be configured to use identical hardware settings. For information on the **Model Referencing** pane options, see “Model Configuration Parameters: Model Referencing” (Simulink) and “Set Configuration Parameters for Model Referencing” (Simulink).

Note There are some configuration parameter setting limitations for code generation. See “Simulink Coder Model Referencing Limitations” (Simulink Coder).

Build Model Reference Targets

By default, the Simulink engine rebuilds simulation targets before the Simulink Coder software generates model reference targets. You can change the rebuild criteria or specify when the engine rebuilds targets. For more information, see “Rebuild” (Simulink).

The Simulink Coder software generates a model reference target directly from the Simulink model. The product automatically generates or regenerates model reference targets, for example, when they require an update.

You can command the Simulink and Simulink Coder products to generate a simulation target for an Accelerator mode referenced model, and a model reference target for a referenced model, by executing the `slbuild` command with arguments in the MATLAB Command Window.

The Simulink Coder software generates only one model reference target for all instances of a referenced model. See “Generate Reentrant Code from Subsystems” (Simulink Coder) for details.

Reduce Change Checking Time

You can reduce the time that the Simulink and Simulink Coder products spend checking whether simulation targets and model reference targets need to be rebuilt by setting configuration parameter values as follows:

- In the top model, consider setting the model configuration parameter **Model Referencing > Rebuild** to **If any changes in known dependencies detected**. (See “Rebuild” (Simulink).)
- In all referenced models throughout the hierarchy, set the configuration parameter **Diagnostics > Data Validity > Signal resolution** to **Explicit only** or **None**. (See “Signal resolution” (Simulink).)

These parameter values exist in a referenced model's configuration set, not in the individual Model block. Setting either value for an instance of a referenced model, sets it for all instances of that model.

Simulink Coder Model Referencing Requirements

A model reference hierarchy must satisfy various Simulink Coder requirements, as described in this section. In addition to these requirements, a model referencing hierarchy to be processed by the Simulink Coder software must satisfy:

- The Simulink requirements listed in:
 - “Configuration Requirements for All Referenced Model Simulation” (Simulink)
 - “Define Referenced Model Inputs and Outputs” (Simulink)
- The Simulink limitations listed in “Signal Limitations” (Simulink)
- The Simulink Coder limitations listed in “Simulink Coder Model Referencing Limitations” on page 4-28

Configuration Parameter Requirements

A referenced model uses a configuration set in the same way a top model does, as described in “Manage a Configuration Set” (Simulink). By default, every model in a hierarchy has its own configuration set, which it uses in the same way that it would if the model executed independently.

Because each model can have its own configuration set, configuration parameter values can be different in different models. Furthermore, some parameter values are intrinsically incompatible with model referencing. The response of the Simulink Coder software to an inconsistent or unusable configuration parameter depends on the parameter:

- Where an inconsistency has no significance, the product ignores or resolves the inconsistency without posting a warning.
- Where a nontrivial and possibly acceptable solution exists, the product resolves the conflict silently; resolves it with a warning; or generates an error.
- If an acceptable resolution is not possible, the product generates an error. You must then change parameter values to eliminate the problem.

When a model reference hierarchy contains many referenced models that have incompatible parameter values, or a changed parameter value must propagate to many referenced models, manually eliminating all configuration parameter incompatibilities can be tedious. You can control or eliminate such overhead by using configuration references to assign an externally-stored configuration set to multiple models. See “Manage a Configuration Reference” (Simulink) for details.

The following tables list configuration parameters that can cause problems if set in certain ways, or if set differently in a referenced model than in a parent model. Where possible, the Simulink Coder software resolves violations of these requirements automatically, but most cases require changes to the parameters in some or all models.

Configuration Requirements for Model Referencing with All System Targets

Dialog Box Pane	Option	Requirement
Solver	Start time	Some system targets require the start time of all models to be zero.
Hardware Implementation	All options	Values must be the same for top and referenced models.
Code Generation	System target file	Must be the same for top and referenced models.
	Language	Must be the same for top and referenced models.
	Generate code only	Must be the same for top and referenced models.
Symbols	Maximum identifier length	Cannot be longer for a referenced model than for its parent model.
Interface	Code replacement library	Must be the same for top and referenced models.
	C API options	The C API check boxes must be the same for top and referenced models.
	ASAP2 interface	Can be on or off in a top model, but must be off in a referenced model. If it is not, the Simulink Coder software temporarily sets it to off during code generation.

**Configuration Requirements for Model Referencing with ERT System Targets
(Requires Embedded Coder License)**

Dialog Box Pane	Option	Requirement
Comments > Advanced parameters	Ignore custom storage classes	Must be the same for top and referenced models.
Symbols	Global variables Global types Subsystem methods Local temporary variables Constant macros	\$R token must appear.
	Signal naming	Must be the same for top and referenced models.
	M-function	If specified, must be the same for top and referenced models.
	Parameter naming	Must be the same for top and referenced models.
	#define naming	Must be the same for top and referenced models.
Interface	Support floating- point numbers	Must be the same for both top and referenced models
	Support non- finite numbers	If off for top model, can be on or off for referenced models. If on for top model, must be on for referenced models.
	Support complex numbers	If off for top model, can be on or off for referenced models. If on for top model, must be on for referenced models.

Dialog Box Pane	Option	Requirement
	Suppress error status in real-time model	If on for top model, must be on for referenced models.
Code Placement	Use owner from data object for data definition placement	Must be the same for top and referenced models.
	Signal display level	Must be the same for top and referenced models.
	Parameter tune level	Must be the same for top and referenced models.

Configuration Parameters Changed During Code Generation

For referenced models, if these **Configuration Parameters > Code Generation > Symbols** parameters have settings that do not contain a \$R token (which represents the name of the reference model), code generation prepends the \$R token to the identifier format:

- **Global variables** (CustomSymbolStrGlobalVar)
- **Global types** (CustomSymbolStrType)
- **Subsystem methods** (CustomSymbolStrFcn)
- **Constant macros** (CustomSymbolStrMacro)

You can use the Model Advisor to identify models in a model referencing hierarchy for which code generation changes configuration parameter settings.

- 1 In the Simulink Editor, select **Analysis > Model Advisor**.
- 2 Select **By Task**.
- 3 Run the **Check code generation identifier formats used for model reference** check.

If a script that operates on generated code uses identifier formats that code generation changes, then update the script to use the updated identifier format (which includes an appended \$R token).

For more information about identifiers, see “Identifier Format Control” on page 39-22.

Naming Requirements

Within a model that uses model referencing, names of the constituent models cannot collide. When you generate code from a model that uses model referencing, the **Maximum identifier length** parameter must be large enough to accommodate the root model name and the name-mangling text. A code generation error occurs if **Maximum identifier length** is not large enough.

When a name conflict occurs between a symbol within the scope of a higher-level model and a symbol within the scope of a referenced model, the symbol from the referenced model is preserved. Name mangling is performed on the symbol from the higher-level model.

Embedded Coder Naming Requirements

The Embedded Coder product lets you control the formatting of generated symbols in much greater detail. When generating code with an ERT target from a model that uses model referencing:

- The \$R token must be included in the **Identifier format control** parameter specifications (in addition to the \$M token) except for **Shared utilities identifier format**.
- The **Maximum identifier length** must be large enough to accommodate full expansions of the \$R and \$M tokens.

See “Model Configuration Parameters: Code Generation Symbols” (Simulink Coder) for more information.

Custom Target Requirements

If you have an Embedded Coder license, a custom target must meet various requirements to support model referencing. For details, see “Support Model Referencing” on page 74-84.

Storage Classes for Signals Used with Model Blocks

Models containing Model blocks can use signals of storage class `Auto` without restriction. However, when you declare signals to be global, you must be aware of how the signal data will be handled.

A global signal is a signal with a storage class other than `Auto`:

- `ExportedGlobal`
- `ImportedExtern`
- `ImportedExternPointer`
- `Custom`

The above are distinct from signals that use the storage class `Model default` when you set the default storage class of the corresponding data category to `Default` in the Code Mapping Editor, which are treated as test points with `Auto` storage class.

Global signals are declared, defined, and used as follows:

- An extern declaration is generated by all models that use a given global signal.
As a result, if a signal crosses a Model block boundary, the top model and the referenced model both generate `extern` declarations for the signal.
- For an exported signal, the top model is responsible for defining (allocating memory for) the signal, whether or not the top model itself uses the signal.
- Global signals used by a referenced model are accessed directly (as global memory). They are not passed as arguments to the functions that are generated for the referenced models.

Custom storage classes also follow the above rules. However, certain custom storage classes are not currently supported for use with model reference. For details, see “Storage Class Limitations” (Simulink Coder).

Storage Classes for Parameters Used with Model Blocks

Storage classes are supported for both simulation and code generation, and all except `Auto` are tunable. The supported storage classes thus include

- `Model default`

- `ExportedGlobal`
- `ImportedExtern`
- `ImportedExternPointer`
- `Custom`

Note the following restrictions on parameters in referenced models:

- Tunable parameters are not supported for noninlined S-functions.
- Tunable parameters set using the Model Parameter Configuration dialog box are ignored.

Note the following considerations concerning how global tunable parameters are declared, defined, and used in code generated for targets:

- A global tunable parameter is a parameter in the base workspace with a storage class other than `Auto`.
- An extern declaration is generated by all models that use a given parameter.
- If a parameter is exported, the top model is responsible for defining (allocating memory for) the parameter (whether it uses the parameter or not).
- Global parameters are accessed directly (as global memory). They are not passed as arguments to the functions that are generated for the referenced models.
- In a referenced model that sets the default storage class for a category of parameter data to `Default` in the Code Mapping Editor, symbols for `Model default` parameters are generated using unstructured variables (`rtP_xxx`) instead of being written into the `model_P` structure. This is so that each referenced model can be compiled independently.

Certain custom storage classes for parameters are not currently supported for model reference. For details, see “Storage Class Limitations” (Simulink Coder).

Parameters used as Model block arguments must be defined in the referenced model's workspace. For details, see “Parameterize Instances of a Reusable Referenced Model” (Simulink).

Signal Name Mismatches Across Model Reference Boundary

Within a parent model, the name and storage class for a signal entering or leaving a Model block might not match those of the signal attached to the root inport or outport

within that referenced model. Because referenced models are compiled independently without regard to a parent model, they cannot adapt to the possible variations in how parent models label and store signals.

The Simulink Coder software accepts all cases where input and output signals in a referenced model have `Auto` storage class. When such signals are test pointed or are global, as described above, certain restrictions apply. The following table describes how mismatches in signal labels and storage classes between parent and referenced models are handled:

Relationships of Signals and Storage Classes Across Model Reference Boundary

Referenced Model	Parent Model	Signal Passing Method	Signal Mismatch Checking
Auto	Any storage class	Function argument	None
Model default (when Code Mapping Editor specifies Default storage class) or resolved to Signal Object	Any storage class	Function argument	Signal label mismatch
Global	Auto or Model default (when Code Mapping Editor specifies Default storage class)	Global variable	Signal label mismatch
Global	Global	Global variable	Labels and storage classes must be identical (else error)

To summarize, the following signal resolution rules apply to code generation:

- If the storage class of a root input or output signal in a referenced model is `Auto` (or is `Model default` when you set the storage class of the corresponding data category to `Default` in the Code Mapping Editor), the signal is passed as a function argument.
 - When such a signal is `Model default` or resolves to a `Simulink.Signal` object, the **Signal label mismatch** diagnostic is applied.
- If a root input or output signal in a referenced model is global, it is communicated by using direct memory access (global variable). In addition,

- If the corresponding signal in the parent model is also global, the names and storage classes must match exactly.
- If the corresponding signal in the parent model is not global, the **Signal label mismatch** diagnostic is applied.

You can set the **Signal label mismatch** diagnostic to error, warning, or none in the **Diagnostics > Connectivity** pane of the Configuration Parameters dialog box.

Inherited Sample Time for Referenced Models

For information about Model block sample time inheritance, see “Inherit Sample Times for Model Referencing” (Simulink). In generated code, you can control inheriting sample time by using `ssSetModelReferenceSampleTimeInheritanceRule` in different ways:

- An S-function that precludes inheritance: If the sample time is used in the S-function's run-time algorithm, then the S-function precludes a model from inheriting a sample time. For example, consider the following `mdlOutputs` code:

```
static void mdlOutputs(SimStruct *S, int_T tid)
{
    const real_T *u = (const real_T*)
        ssGetInputPortSignal(S,0);
    real_T *y = ssGetOutputPortSignal(S,0);
    y[0] = ssGetSampleTime(S,tid) * u[0];
}
```

This `mdlOutputs` code uses the sample time in its algorithm, and the S-function therefore should specify

```
ssSetModelReferenceSampleTimeInheritanceRule
(S, DISALLOW_SAMPLE_TIME_INHERITANCE);
```

- An S-function that does not preclude Inheritance: If the sample time is only used for determining whether the S-function has a sample hit, then it does not preclude the model from inheriting a sample time. For example, consider the `mdlOutputs` code from the S-function example `sfun_multirate.c`:

```
static void mdlOutputs(SimStruct *S, int_T tid)
{
    InputRealPtrsType enablePtrs;
    int *enabled = ssGetIWork(S);

    if (ssGetInputPortSampleTime
        (S,ENABLE_IPORT)==CONTINUOUS_SAMPLE_TIME &&
        ssGetInputPortOffsetTime(S,ENABLE_IPORT)==0.0) {
        if (ssIsMajorTimeStep(S) &&
            ssIsContinuousTask(S,tid)) {
            enablePtrs =
                ssGetInputPortRealSignalPtrs(S,ENABLE_IPORT);
            *enabled = (*enablePtrs[0] > 0.0);
        }
    } else {
```

```
int enableTid =
ssGetInputPortSampleTimeIndex(S,ENABLE_IPORT);
if (ssIsSampleHit(S, enableTid, tid)) {
    enablePtrs =
        ssGetInputPortRealSignalPtrs(S,ENABLE_IPORT);
    *enabled = (*enablePtrs[0] > 0.0);
}
}

if (*enabled) {
    InputRealPtrsType uPtrs =
    ssGetInputPortRealSignalPtrs(S,SIGNAL_IPORT);
    real_T          signal = *uPtrs[0];
    int             i;

    for (i = 0; i < NOUTPUTS; i++) {
        if (ssIsSampleHit(S,
            ssGetOutputPortSampleTimeIndex(S,i), tid)) {
            real_T *y = ssGetOutputPortRealSignal(S,i);
            *y = signal;
        }
    }
}
} /* end mdlOutputs */
```

The above code uses the sample times of the block, but only for determining whether there is a hit. Therefore, this S-function should set

```
ssSetModelReferenceSampleTimeInheritanceRule
(S, USE_DEFAULT_FOR_DISCRETE_INHERITANCE);
```

Customize Library File Suffix and File Type

You can control the library file suffix and file type extension that the Simulink Coder code generator uses to name generated model reference libraries. Use the model configuration parameter `TargetLibSuffix` to specify the scheme for the suffix and extension. The scheme must include a period (.). If you do not set this parameter, the Simulink Coder software names the libraries as follows:

- On Windows systems, *model_rtwlib.lib*
- On UNIX or Linux® systems, *model_rtwlib.a*

The `TargetLibSuffix` parameter does not apply for model builds that use the toolchain approach. For more information, see “Identify Library File Type for Toolchain Approach” (Simulink Coder).

Simulink Coder Model Referencing Limitations

The following Simulink Coder limitations apply to model referencing. In addition to these limitations, a model reference hierarchy used for code generation must satisfy:

- The Simulink requirements listed in:
 - “Configuration Requirements for All Referenced Model Simulation” (Simulink)
 - “Define Referenced Model Inputs and Outputs” (Simulink)
- The Simulink limitations listed in “Model Referencing Limitations” (Simulink).
- The Simulink Coder requirements applicable to the code generation target, as listed in “Configuration Parameter Requirements” on page 4-16.

Customization Limitations

- The code generator ignores custom code settings in the Configuration Parameters dialog box and custom code blocks when generating code for a referenced model.
- Data type replacement is not supported for simulation target code generation of referenced models.
- Simulation targets do not include Stateflow target custom code.
- If you have an Embedded Coder license, some restrictions exist on grouped custom storage classes in referenced models. For details, see “Storage Class Limitations” (Simulink Coder).

Data Logging Limitations

- To Workspace blocks, Scope blocks, and all types of runtime display, such as the display of port values and signal values, are ignored when the Simulink Coder software generates code for a referenced model. The resulting code is the same as if the constructs did not exist.
- Code generated for referenced models cannot log data to MAT-files. If data logging is enabled for a referenced model, the Simulink Coder software disables the option before code generation and re-enables it afterwards.
- If you log states for a model that contains referenced models, the ordering of the states in the output is determined by block sorted order, and might not match between simulation output and generated code MAT-file logging output.

State Initialization Limitation

When a top model uses the **Data Import/Export > Initial state** parameter in the Configuration Parameters dialog box to specify initial conditions, the Simulink Coder software does not initialize the discrete states of the referenced models during code generation.

Reusability Limitations

If a referenced model used for code generation has any of the following properties, the model must specify the configuration parameter **Model Referencing > Total number of instances allowed per top model** as **One**, and no other instances of the model can exist in the hierarchy. If you do not set the parameter to **One**, or more than one instance of the model exists in the hierarchy, an error occurs. The properties are:

- The model references another model which has been set to single instance
- The model contains a state or signal with non-auto storage class
- The model uses any of the following Stateflow constructs:
 - Machine-parented data
 - Machine-parented events
 - Stateflow graphical functions
- The model contains a subsystem that is marked as function
- The model contains an S-function that is:
 - Inlined but has not set the option `SS_OPTION_WORKS_WITH_CODE_REUSE`
 - Not inlined
- The model contains a function-call subsystem that:
 - Has been forced by the Simulink engine to be a function
 - Is called by a wide signal

For more information about **Total number of instances allowed per top model**, see “Total number of instances allowed per top model” (Simulink).

S-Function Limitations

- If a referenced model contains an S-function that should be inlined using a Target Language Compiler file, the S-function must use the `ssSetOptions` macro to set the `SS_OPTION_USE_TLC_WITH_ACCELERATOR` option in its `mdlInitializeSizes` method. The simulation target will not inline the S-function unless this flag is set.
- A referenced model cannot use noninlined S-functions generated by the Simulink Coder software.
- The Simulink Coder S-function target does not support model referencing.

For additional information, see “Use S-Functions with Referenced Models” (Simulink).

Simulink Tool Limitations

- Simulink tools that require access to a model's internal data or configuration (including the Model Coverage tool, the Simulink Report Generator product, the Simulink debugger, and the Simulink profiler) have no effect on code generated by the Simulink Coder software for a referenced model, or on the execution of that code. Specifications made and actions taken by such tools are ignored and effectively do not exist.

Subsystem Limitations

- If a subsystem contains Model blocks, you cannot build a subsystem module by right-clicking the subsystem (or by using **Code > C/C++ Code > Build Selected Subsystem**) unless the model is configured to use an ERT target.
- If you generate code for an atomic subsystem as a reusable function, inputs or outputs that connect the subsystem to a referenced model might prevent code reuse, as described in “Generate Reentrant Code from Subsystems” (Simulink Coder).

Target Limitations

- The Simulink Coder S-function target does not support model referencing.

Other Limitations

- Errors or unexpected behavior can occur if a Model block is part of a cycle, the Model block is a direct feedthrough block, and an algebraic loop results. For details, see “Algebraic Loops” (Simulink).
- The **External mode** option is not supported. If it is enabled, it is ignored during code generation.
- When a model contains a trigger or enable port, you cannot generate standalone Simulink Coder code or PIL code.

Configuration Parameters Changed During Accelerated Simulation and Code Generation

During model referencing simulation in accelerator and rapid accelerator mode, Simulink temporarily sets several **Configuration Parameters > Diagnostics > Data Validity** parameter settings to None, if they are set to Warning or Error. You can use the Model Advisor to check for parameters that change. For details, see “Accelerated Simulation and Code Generation Changes Settings” (Simulink).

If the **Configuration Parameters > Code Generation > Symbols** parameters hold identifier information about the name of a referenced model and do not use a \$R token, code generation prepends the \$R token to the name of the model. You can use the Model Advisor to check for changed model names. See “Configuration Parameters Changed During Code Generation” (Simulink Coder).

Combined Models in Simulink Coder

Combine Code Generated for Multiple Models

Techniques

Techniques that you can use to combine code, which the code generator produces for multiple models or multiple instances of a model, into one executable program include:

- Referenced models. See “Overview of Model Referencing” (Simulink) and “Generate Code for Referenced Models” on page 4-4.
- If you have Embedded Coder software, interface the code for multiple models to a common harness program. From the harness program, call the entry-point functions generated for each model. The `ert.tlc` system target file has restrictions, relating to embedded processing, that could be incompatible with your application.
- Generate reusable, multi-instance code that is reentrant. See “Combine Code Generated for Multiple Models or Multiple Instances of a Model” on page 5-3.

The S-function system target (`rtwsfcn.tlc`) does not support combining code generated for multiple models.

Consider using model referencing to combine models for simulation and code generation. Model referencing helps with:

- Symbol naming consistency
- Required scheduling of the overall algorithm
- Model configuration consistency

If you combine code generated for different models (that is, without using referenced models), consider:

- Data is global. Symbol (name) clashes can result.
- Configuration parameter settings for the models must match, including settings such as hardware word sizes.
- Reuse and sharing of code can be suboptimal (for example, duplicate code for shared utility functions, scheduling, and solvers).
- Scheduling can be more complex (for example, models can have periodic sample times that are not multiples of each other, making scheduling from a common timer interrupt more complicated)

- For plant models that use continuous time and state, the continuous time signals connecting models are not handled by a single solver like continuous time signals within a model. This can lead to subtle numeric differences.

Control Ownership of Data

If you have Embedded Coder software, you can specify an owner for individual data items such as signals, parameters, and states. The owner of a data item generates the definition (memory allocation and initialization) for the data item. For example, if you apply a custom storage class to a `Simulink.Signal` object so that it appears as a global variable in the generated code, specify one of the combined models as the owner of the object. The code generated for that model defines the variable.

If you use model referencing, you can modularize the generated code and establish clear ownership of data when you work in a team.

If you do not use model referencing, you can prevent generation of duplicate definitions for a data item. For example, suppose you store a `Simulink.Parameter` object in the base workspace and apply the storage class `ExportedGlobal`. If you generate code from two separate models that use the object, each model generates a definition for the corresponding global variable. Instead, you can specify an owner for the object so that only the owner generates a definition.

To specify an owner for a data item:

- 1 Apply a custom storage class to the data item. See “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19.
- 2 Configure the owner of the data item by specifying the **Owner** custom attribute.
- 3 Select the model configuration parameter **Use owner from data object for data definition placement**.

For more information about controlling ownership and file placement of data definitions and declarations, see “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 23-2.

Combine Code Generated for Multiple Models or Multiple Instances of a Model

For each model for which you are combining code, generate the code.

- 1 Set the system target file to a GRT- or ERT-based system target file. The system target file for the models you combine, must be the same.
- 2 If you intend to have multiple instances of that model in the application, set the model configuration parameter **Code Generation > Interface > Code interface packaging** to `Reusable` function. If you specified an ERT-based system target file, optionally, you can set the model configuration parameter **Use dynamic memory allocation for model initialization**, depending on whether you want to statically or dynamically allocate the memory for each instance of the model.
- 3 Generate source code. The code generator includes an allocation function in the generated file `model.c`. The allocation function dynamically allocates model data for each instance of the model.

After generating source code for each model:

- 1 Compile the code for each model that you are combining.
- 2 Combine the makefiles generated for the models into one makefile.
- 3 Create a combined simulation engine by modifying a main program, such as `rt_malloc_main.c`. The main program initializes and calls the code generated for each model.
- 4 Run the makefile. The makefile links the object files and the main program into an executable program.

Share Data Across Models

Use unidirectional signal connections between models. This affects the order in which models are called. For example, if you use an output signal from `modelA` as input to `modelB`, the `modelA` output computation should be called first.

Timing Issues

When combining code generated for multiple models or multiple instances of a model:

- Configure the models with the same solver mode (single-tasking or multitasking).
- If the models use continuous states, configure the models with the same solver.

If the base rates for the models differ, the main program (such as `rt_malloc_main.c`) must set up the timer interrupt to occur at the greatest common divisor rate of the models. The main program calls each model at a time interval.

Data Logging and External Mode Support

A multiple-model program can log data to separate MAT-files for each model.

Only one of the models in a multiple-model program can use external mode.

Code Reuse for Simulink Coder

What Is Code Reuse?

Code reuse is a programming technique that reduces time and resources to develop software. When you develop code for reuse, the code serves multiple purposes. The technique involves modularization, which enables multiple individuals to develop code for various system components independently and in parallel. The technique also simplifies software distribution.

A software library is an example of code reuse. A library can contain code for several functions, each having specific behavior. To use a library, you need to know only the interface, which is the specification for calling the library functions.

Reusable code can be reentrant. You can invoke, interrupt, and reinvoke reentrant code. Reentrant code resides in shared memory. Instances of data associated with each use of the code are unique and preserved. Multiple calls to a reusable, reentrant function, for example, can access the function code with each call maintaining a unique data set.

Applications of code reuse include:

- Team-based development.
- Switching between implementations of a function.
- Intellectual property protection.
- Overriding library behavior with a custom implementation.
- Implementing a library that is based on standard library functions.
- Unit testing.
- Performance improvement.

The code generator supports code reuse and reentrancy. You can use key Simulink componentization techniques to partition a model into design components that you simulate, generate code for, and verify independently. You can save individual components as subsystems, libraries, referenced models, or combinations of these elements from which you can generate code. For example, the code generator produces reusable function code from library subsystems and export-function models.

More About

- “What Is Reentrant Code?” on page 6-4
- “Choose a Componentization Technique for Code Reuse” on page 6-6

What Is Reentrant Code?

Reentrant (multi-instance) code is a reusable routine that multiple programs can invoke, interrupt, and reinvoke simultaneously. When you want to reuse code, but associate each instance of the shared code with unique, preserved data, use reentrant code. For example, consider this figure that shows four instances of function `sensor_read`. Although the function algorithm is the same in each case, the data associated with each instance varies and is relative to the sensor position.

To make generated code for a model component reentrant, you configure the component such that model entry-point functions receive root-level input and output data as arguments. How you configure the component depends on the modeling style or technique that you apply.

- “What Is Code Reuse?” on page 6-2

- “Choose a Componentization Technique for Code Reuse” on page 6-6

Choose a Componentization Technique for Code Reuse

Key componentization techniques that you can use with Simulink and the code generator to produce reusable code include:

- Reference models
- Subsystems
- Library subsystems
- Combinations of models, subsystems, and library subsystems

Choose componentization techniques based on your code reuse goals.

Goal	Referenced Model	Subsystem in Model	Subsystem in Library
Design for explicit code reuse.	√	√	√
Facilitate parallel team development.	√	√	√
Reuse function within a model or across models.	√		
Improve build performance by generating reusable code incrementally.	√		
Verify reusable code with SIL or PIL simulation.	√		
Optimize generated code by configuring code generator to detect opportunities for code reuse.	√	√	√

Goal	Referenced Model	Subsystem in Model	Subsystem in Library
Maximize reuse with context-dependent behavior.		√	√
Develop a frequently used, and infrequently changed, utility function.			√

Simulink Function Blocks and Code Generation

Why Generate Code from Simulink Function Blocks and Function Callers?

Simulink Function blocks provide a mechanism for generating C or C++ code for modeling components that represent shared resources. You define the logic as a resource in a Simulink Function block, which separates the function interface (name and arguments) from the implementation of the logic. Function callers (Function Caller blocks, MATLAB Function blocks, and Stateflow charts) can then reuse the function logic at different levels of the model hierarchy.

Simulink Function blocks provide an alternative to reusable subsystems. For example, a consideration for using a Simulink Function block instead of a subsystem block is that a Simulink Function block shares states between function callers. The code generator produces one function. If the Simulink Function block contains blocks that have states, such as a delay or memory, the states persistent between function callers. The order of the function calls is an important consideration.

Reusable functions that the code generator produces from subsystems do not share states. The code generator produces one function for multiple instances of the subsystem as an optimization. If that subsystem contains blocks that have states, the code generator produces one function, but passes a different state variable to each instance. The instances do not share states.

Other uses of Simulink Function blocks and callers include:

- Nesting calls to a function.
- Calling a function defined in one modeling component from another modeling component.
- Generating functions that are globally accessible or scoped.
- Producing code for a client and server application.

Implementation Options

Choose how to implement Simulink functions and function callers based on your code generation requirements. Considerations include:

- How you represent a function and function callers in a model
- Scope of a function
- Whether to export a function from a model (requires Embedded Coder)
- Function code interface customizations (requires Embedded Coder)
- Code generation requirements
- Code generation limitations

Choose a Modeling Pattern

This table shows C code for a function that multiplies an input value times two and a Simulink Function block that can represent that function in a Simulink model.

Function Definition	Modeling Element
<pre>codegen-folder/subsystem.c #include "timestwo_sf.h" #include "ex_slfunc_comp_sf.h" #include "ex_slfunc_comp_sf_private.h" void timestwo_sf(real_T rtu_x, real_T *rtty_y) { *rtty_y = 2.0 * rtu_x; }</pre>	<p>Simulink Function block</p> 

A Simulink function caller invokes a function defined with a Simulink Function block. From anywhere in a model or chart hierarchy, you can call a function defined with a Simulink Function block by using one of these modeling elements:

Function Call	Modeling Element
<pre> codegen-folder/model.c void ex_slfunc_comp_sf_step(void) { real_T rtb_FunctionCaller1; timestwo_sf(ex_slfunc_comp_sf_U.In1, &rtb_Func ex_slfunc_comp_sf_Y.Out1 = rtb_FunctionCaller1; . . . </pre>	<p>Function Caller block</p>  <p>The diagram shows a rectangular block labeled 'Function Caller1'. Inside the block, the text reads 'caller timestwo_sf()'. An input port on the left is labeled 'x' and is connected to a signal source block containing the number '1'. An output port on the right is labeled 'y' and is connected to a signal destination block containing the number '1'.</p>
<pre> codegen-folder/model.c void ex_slfunc_comp_gf_step(void) { real_T rtb_y1_l; timestwo_gf(ex_slfunc_comp_gf_U.In4, &rtb_y1 ex_slfunc_comp_gf_Y.Out4 = rtb_y1_l; . . . </pre>	<p>Stateflow chart transition</p>  <p>The diagram shows a yellow rounded rectangular transition block. An input port on the left is labeled 'x1' and is connected to a signal source block containing the number '4'. Inside the block, the text reads '{y1=timestwo_gf(x1);}'. An output port on the right is labeled 'y1' and is connected to a signal destination block containing the number '4'.</p>
<pre> codegen-folder/model.c void ex_slfunc_comp_mf_step(void) { real_T rtb_y; timestwo_mf(ex_slfunc_comp_mf_U.In3, &rtb_y) ex_slfunc_comp_mf_Y.Out3 = rtb_y; . . . </pre>	<p>MATLAB Function block</p>  <p>The diagram shows a rectangular block labeled 'fcn'. Inside the block is the MATLAB logo. An input port on the left is labeled 'x' and is connected to a signal source block containing the number '3'. An output port on the right is labeled 'y' and is connected to a signal destination block containing the number '3'.</p>

For more information about modeling choices, see “Simulink Functions” (Simulink).

Specify Function Scope

A function that you define with a Simulink Function block can be global or scoped.

- Global---The code generator places code for a global function in source and header files that are separate from model code files (for example, *function.c* and *function.h*). The separate files make the function code available for sharing between function callers.
- Scoped---The code generator places code for a scoped function in model code files (*model.c* and *model.h*). To call a scoped function in the context of a model, the function caller must be at the same level as the function in the model hierarchy, or one or more levels below.

To create a library of functions that are accessible from anywhere in the generated model code, set up each function as a scoped Simulink Function block. Place each scoped function within a virtual subsystem at the root level of a model.

For more information, see “Scoped and Global Simulink Function Blocks” (Simulink).

Decide Whether to Generate Export Function Code

Although you can use Simulink Function blocks in a single top-model design, function code is more reusable when you generate it as standalone, atomic components. You do that by designing the functions in the context of export-function models.

For information, see “Generate Component Source Code for Export to External Code Base” on page 42-52 and “Export-Function Models” (Simulink).

Specify Function Code Interface Customizations

With Embedded Coder, simplify integration of generated code with external code by customizing generated function code interfaces for Simulink Function and Function Caller blocks. You can customize the function interfaces for:

- Global Simulink Function blocks
- Scoped Simulink Function blocks that are at the root level of a model

For more information, see “Customize Generated Function Interfaces for Simulink Function and Function Caller Blocks” on page 29-24.

Requirements

- Within a model hierarchy, function names are unique. If the code generator finds multiple functions with the same name, it issues an error. Change the name of one of the functions and delete the `s_lprj` folder.
- The signature (for example, the arguments and argument data types) for a function and function callers must match.
 - If the code generator finds the function first and the signature of a function caller does not match, the code generator issues an error. Change the function caller signature to match the signature of the Simulink Function block or delete the `s_lprj` folder.
 - If the code generator finds a function caller first and the signature of the function does not match, the code generator issues a warning message. Change the signature of the function or function caller so that the signatures match.
- In a Simulink Function block definition, do not define input and output signals for Argument Inport and Argument Outport blocks with a storage class.
- Do not specify Argument Inport and Argument Outport blocks as test points.
- If you specify the data type of input and output signals for Argument Inport and Argument Outport blocks as a `Simulink.IntEnumType`, `Simulink.AliasType`, or `Simulink.Bus`, set the `DataScope` property to `Imported` or `Exported`.
- A function interface and function callers must agree in data type, complexity, dimension, and number of arguments.

Limitations

- To generate code from a model that includes scoped Simulink functions, the model must be an export-function model. The code generator does not support rate-based models that include scoped Simulink functions.
- You can use a Simulink Function block to define a scoped function in a referenced model. However, you cannot generate code for an export-function model that uses a Function Caller block in an atomic subsystem to invoke that function.
- You can invoke a C++ function that the code generator produces from a Simulink Function block with code generated from a Stateflow chart. Due to current scope limitations for generated C++ functions, you must invoke those functions with code generated from a Function Caller block.
- Simulink functions and function callers do not honor the `MaxStackSize` parameter.

- Code generation for a C++ class interface supports scoped Simulink functions only.

Generate and Call Reusable Function Code

This example shows how to use the Simulink Function and Function Caller blocks to generate reusable function code. The code generator produces a global function, which complies with code requirements so that existing external code can call the function and a local function. The code generator also produces calls to global and local functions. The call to the global function shows that the global function is reused (shared).

Code requirements for the global function are:

- Function names start with prefix `func_`.
- Names of input arguments are of the form xn , where n is a unique integer value.
- Names of output arguments are of the form yn , where n is a unique integer value.
- Input and output arguments are integers (`int`) and are passed by reference. The native integer size of the target hardware is 32 bits.

You create a function that calls the generated reusable function code. Then, you construct and configure a model to match the code requirements.

Some of the features used in this example, such as data type aliasing and replacement, require Embedded Coder software.

Inspect External Code That Calls Reusable Function

In your code generation root folder, create the files `call_times2.h` and `call_times2.c`. If you prefer, you can copy the files from `matlabroot\help\toolbox\ecoder\examples`.

```
call_times2.h
typedef int my_int;

call_times2.c
#include "call_times2.h"

void call_times2(void)
{
    int times2result;
```

```

func_times2(x1, &y1);

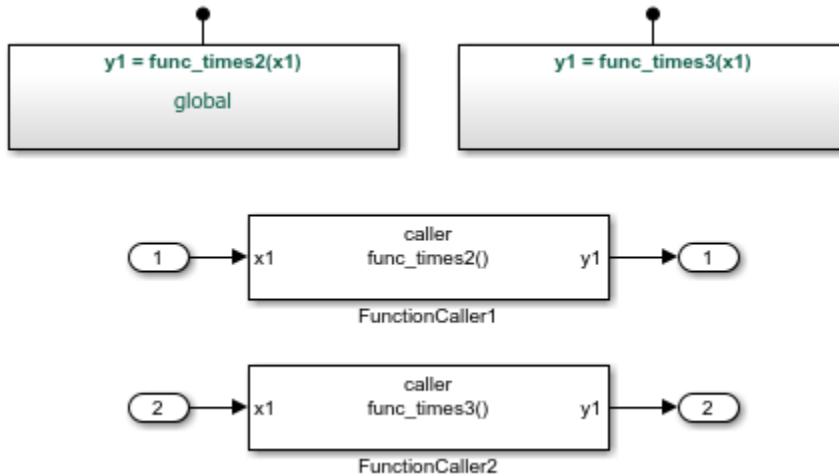

printf('Times 2 Value:', y1);
}

```

This C code calls reusable function `func_times2`. The function multiplies an integer input value `x1` by 2 and returns the result as `y1`.

Create Model

Open the example model `ex_slfunc_comp`, which is available in the folder `matlabroot\help\toolbox\ecoder\examples`. The model includes two Simulink functions modeled as Simulink Function blocks, `func_times2` and `func_times3`, and a call to each function. As indicated in the model, the visibility of the Simulink Function block for `func_times2` is set to `global`. That visibility setting makes the function code accessible to other code, including external code that you want to integrate with the generated code. The visibility for `func_times3` is set to `scoped`.

If you configure the model with the GRT system target file or the ERT system target file with **File packaging format** set to `Modular`, the code generator produces function code for the model.

For more information, see “Generate Code for a Simulink Function and Function Caller” on page 6-20.

Configure Generated Code to Reuse Custom Data Type

The example assumes that the generated code runs on target hardware with a native integer size of 32 bits. The external code represents integers with data type `my_int`, which is an alias of `int`. Configure the code generator to use `my_int` in place of the data type that the code generator uses by default, which is `int32_T`.

- 1 Create a `Simulink.AliasType` object to represent the custom data type `my_int`.

```
my_int = Simulink.AliasType
```

```
my_int =
```

```
AliasType with properties:
```

```
Description: ''
DataScope: 'Auto'
HeaderFile: ''
BaseType: 'double'
```

- 2 Set the alias type properties. Enter a description, set the scope to `Imported`, specify the header file that includes the type definition, and associate the alias type with the Simulink base type `int32`.

```
my_int.Description='Custom 32-bit int representation';
my_int.DataScope='Imported';
my_int.HeaderFile='call_times2.h';
my_int.BaseType='int32';
```

```
my_int
```

```
AliasType with properties:
```

```
Description: 'Custom 32-bit int representation'
DataScope: 'Imported'
HeaderFile: 'call_times2.h'
BaseType: 'int32'
```

- 3 Configure the code generator to replace instances of type `int32_T` with `my_int`. In the Configuration Parameters dialog box, open the **Code Generation Data Type Replacement** pane.
 - Select **Replace data type names in the generated code**.
 - In the **Data type names** table, enter `my_int` for the replacement name for `int32`.

Configure Reusable, Global Function

For external code to call a global function, configure the corresponding Simulink Function block to have global visibility and an interface that matches what is expected by the external callers.

- 1 Open the block that represents the `times2` function.

- 2 Configure the function name and visibility by setting Trigger Port block parameters. For example, the code requirements specify that the function name start with the prefix `func_`.
 - Set **Function name** to `func_times2`.
 - Set **Function visibility** to `global`.
- 3 Configure the function input and output arguments by setting Argument Inport and Argument Outport block parameters. For example, the code requirements specify that argument names be of the form `xn` and `yn`. The requirements also specify that arguments be type `my_int`.
 - On the **Main** tab, set **Argument name** to `x1` (input) and `y1` (output).
 - On the **Signal Attributes** tab, set **Data type** to `int32`. With the data type replacement that you specified previously, `int32` appears in the generated code as `myint`.
- 4 Configure the Simulink Function block code interface. At the top level of the model, right-click the global function `func_times2`. From the menu, select **C/C++ CodeConfigure C/C++ Function Interface**.
 - Set **C/C++ function name** to `func_times2`.
 - Set **C/C++ return argument** to `void`.
 - Set **C/C++ Identifier Name** for argument `x1` to `x1`.

- Set **C/C++ Identifier Name** for argument `y1` to `y1`.

If the dialog box lists output argument `y1` before input argument `x1`, reorder the arguments by dragging the row for `x1` above the row for `y1`.

Configure Local Function

Configure a Simulink Function block that represents a local function with scoped visibility. Based on code requirements, you might also have to configure the function name, input and output argument names and types, and the function interface.

- 1 Open the block that represents the `times3` function.
- 2 Configure the function name and visibility by setting Trigger Port block parameters. For example, the code requirements specify that the function name start with the prefix `func_`.
 - Set **Function name** to `func_times3`.
 - Set **Function visibility** to `scoped`.
- 3 Configure the function input and output arguments by setting Argument Inport and Argument Outport block parameters. For example, the code requirements specify that argument names be of the form `xn` and `yn`. The requirements also specify that arguments be type `my_int`.
 - On the **Main** tab, set **Argument name** to `x1` (input) and `y1` (output).
 - On the **Signal Attributes** tab, set **Data type** to `int32`. With the data type replacement that you specified previously, `int32` appears in the generated code as `my_int`.
- 4 Configure the Simulink Function block code interface. At the top level of the model, right-click the scoped function `func_times3`. From the menu, select **C/C++ CodeConfigure C/C++ Function Interface**. In this case, the code generator controls naming the function and arguments. The function name combines the name of the root model and the function name that you specify for the trigger port of the Simulink Function block. In this example, the name is `ex_slfunc_comp_func_times3`.

You can set **C/C++ return argument** to the argument name that you specify for the Argument Outport block or `void`. For this example, set it to `void`.

For arguments, the code generator prepends `rtu_` (input) or `rtty_` (output) to the argument name that you specify for the Argument Inport block.

If the dialog box lists output argument `y1` before input argument `x1`, reorder the arguments by dragging the row for `x1` above the row for `y1`.

Configure Function Callers

For each function caller, configure Function Caller block parameters:

- Set **Function prototype** to `y1 = func_times2(x1)`.
- Set **Input argument specifications** to `int32(1)`.
- Set **Output argument specifications** to `int32(1)`.

Generate and Inspect Code

Generate code for the model.

- Global function code

Source code for the global, reusable function `func_times2` is in the build folder in subsystem file, `func_times2.c`.

```
#include "func_times2.h"

/* Include model header file for global data */
#include "ex_slfunc_comp.h"
#include "ex_slfunc_comp_private.h"

void func_times2(my_int x1, my_int *y1)
{
    *y1 = x1 << 1;
}
```

- Local function code

The code generator places the definition for the local (scoped) function `func_times3` in file build folder in file `ex_slfunc_comp.c`.

```
void ex_slfunc_comp_func_times3(my_int rtu_x1, my_int *rty_y1)
{
    *rty_y1 = 3 * rtu_x1;
}
```

- Calls to generated functions

The model execution (step) function, in model file `ex_slfunc_comp.c`, calls the two Simulink functions: global function `func_times2` and local function

`ex_slfunc_comp_func_times3`. The name `ex_slfunc_comp_func_times3` reflects the scope of the local function by combining the name of the model and the name of the function.

```
void ex_slfunc_comp_step(void)
{
    my_int rtb_FunctionCaller2;

    func_times2(ex_slfunc_comp_U.In1, &rtb_FunctionCaller2);

    ex_slfunc_comp_Y.Out1 = rtb_FunctionCaller2;

    ex_slfunc_comp_func_times3(ex_slfunc_comp_U.In2, &rtb_FunctionCaller2);

    ex_slfunc_comp_Y.Out2 = rtb_functionCaller2;
    .
    .
    .
}
```

- Entry-point declaration for local function

The model header file `ex_slfunc_comp.h` includes an extern declaration for function `ex_slfunc_comp_func_times3`. That statement declares the function entry point.

```
extern void ex_slfunc_comp_func_times3(my_int rtu_x1, my_int *rty_y1);
```

- Include statements for global function

The model header file `ex_slfunc_comp.h` lists include statements for the global function `func_times2`.

```
#include "func_times2_private.h"
#include "func_times2.h"
```

- Local macros and data for global function

The subsystem header file `func_times2_private.h` defines macros and includes header files that declare data and functions for the global function, `func_times2`.

```
#ifndef RTW_HEADER_func_times2_private_h_
#define RTW_HEADER_func_times2_private_h_
#ifndef ex_slfunc_comp_COMMON_INCLUDES_
#define ex_slfunc_comp_COMMON_INCLUDES_
#include "rtwtypes.h"
#endif
#endif
```

- Entry-point declaration for global function

The shared header file `func_times2.h`, in the shared utilities folder `s\prj\stf_sharedutils`, lists shared type includes for `rtwtypes.h`. The file also includes an extern declaration for the global function, `func_times2`. That statement declares the function entry point.

```
#ifndef RTW_HEADER_func_times2_
#define RTW_HEADER_func_times2_

#include "rtwtypes.h"

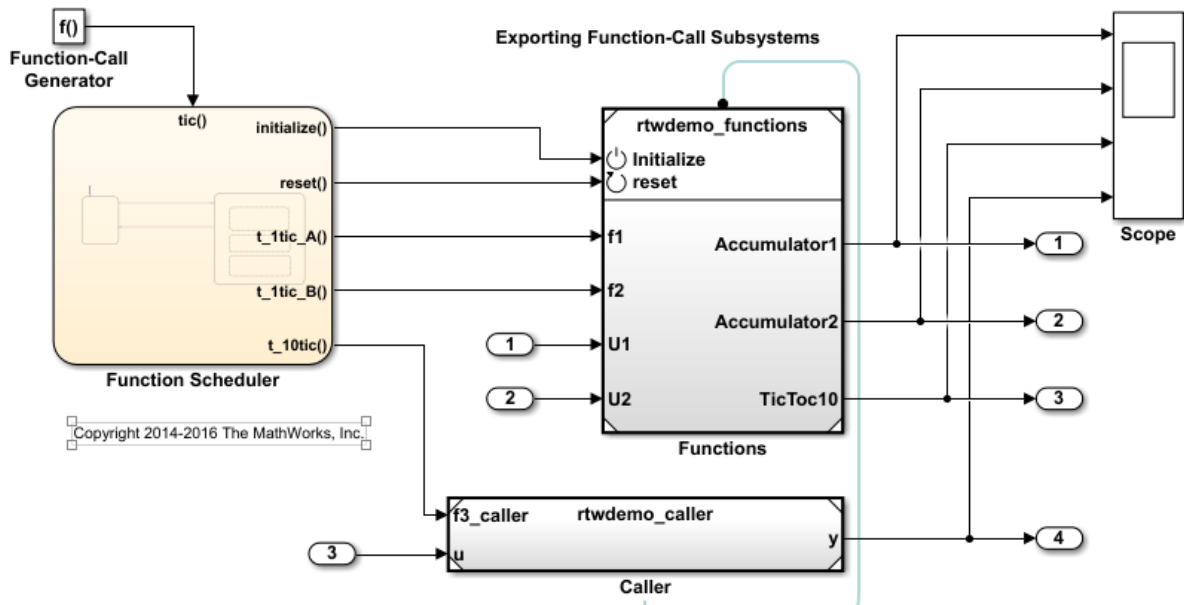

extern void func_times2(my_int rtu_x1, my_int *rty_y1);

#endif
```

Generate Code for a Simulink Function and Function Caller

This example shows how to generate C code for Simulink Function and Function Caller blocks and displays the relevant generated code.

Open the example model `rtwdemo_export_functions`. The model uses Stateflow software, but this example reviews only the code generated from the referenced models.

Generate Code for Function Definition

- To view the contents of the subsystem, double-click `rtwdemo_functions`. The Simulink Function block is the `f3` subsystem defined as $y = f3(u)$.

Copyright 2014-2016 The MathWorks, Inc.

- Generate code.

The code generator creates `rtwdemo_functions.c`. This file contains the function definition and function initialization code.

- Initialization code for function `f3`:

```
void f3_Init(void)
{
    rtDWork.Delay_DSTATE = 1;
}
```

- Code for function `f3`:

```
void f3(real_T rtu_u, real_T *rty_y)
{
```

```
rtY.TicToc10 = rtDWork.Delay_DSTATE;

rtDWork.Delay_DSTATE = (int8_T)(int32_T)-(int32_T)rtY.TicToc10;

adder_h(rtB.Subtract, rtU.U2, rtu_u, rtB.FunctionCaller);

*rty_y = rtB.FunctionCaller;
}

void adder_h(real_T rtu_u1,
            real_T rtu_u2,
            real_T rtu_u3,
            real_T *rty_y)
{
    *rty_y = (rtu_u1 + rtu_u2) + rtu_u3;
}
```

- The shared header file `f3.h` contains the entry point declaration for function `f3`.

```
#include "rtwtypes.h"

extern void f3(real_T rtu_u, real_T *rty_y);
```

Generate Code for Function Caller

- 1 In the `rtwdemo_export_functions` model, double-click `rtwdemo_caller` to view the contents of the caller subsystem.
- 2 Generate code.

The code generator creates the files `rtwdemo_caller.h` and `rtwdemo_caller.c` in the folder `rtwdemo_caller_ert_rtw`.

`rtwdemo_caller.h` includes the shared header file, `f3.h`, which contains the function entry-point declaration.

`rtwdemo_caller.c` calls function `f3`.

```
void rtwdemo_caller_t_10tic(const real_T *rtu_u,
                          real_T *rty_y)
{
    f3(*rtu_u, rty_y);
}
```

Generate Reentrant Code from Top Models

By default, for top models, the code generator produces code that is not reentrant. Entry-point functions have a void-void interface. Code communicates with other code by sharing access to global data structures that reside in shared memory.

For applications that can benefit from reuse and require that each use or instance of the code maintains its own unique data, configure a model such that the code generator produces reentrant code. To generate reentrant code, set the model configuration parameter “Code interface packaging” (Simulink Coder) to `Reusable function`. If you are using Embedded Coder and generating C++ code, alternatively, you can set the parameter to `C++ class`. In both cases, the code generator:

- Packages model data, such as block I/O, DWork vectors, and parameters, in the real-time model data structure (`rtModel`).
- Passes the real-time model data structure as an input argument, by reference, to generated model entry-point functions.
- Passes root-level input and output arguments to generated model entry-point functions as individual arguments.
- Allocates memory for model data structures statically.
- Exports the real-time model data structure in the generated header file `model.h`.

Apply additional diagnostic and code generation control by setting these model configuration parameters:

- To select the severity level for diagnostic messages that the code generator displays when a model does not meet requirements for multi-instance code, set parameter “Multi-instance code error diagnostic” (Simulink Coder) to `None`, `Warning`, or `Error`.
- To control how the generated code passes root-level model input and output to the reusable execution (step) function (requires Embedded Coder), set parameter “Pass root-level I/O as” (Simulink Coder) to `Individual arguments`, `Structure reference`, or `Part of model data structure`.
- To reduce memory usage by omitting the error status field from the real-time model data structure (requires Embedded Coder), set parameter **Remove error status field in real-time model data structure** to `0n`.
- To include a function in the generated file `model.c` that uses `malloc` to dynamically allocate memory for model data structures (requires Embedded Coder), set parameter **Use dynamic memory allocation for model initialization** to `0n`.

Generate Reentrant, Multi-Instance Code

This example shows you how to configure a model for reentrant, multi-instance code generation. Multiple programs can use reentrant code simultaneously. When you configure a model for reentrancy, the execution (step) entry-point function uses root-level input and output arguments instead of global data structures. After examining the configuration settings, generate and review the generated code.

Open the Model

Open the model `rtwdemo_reusable`. The model contains two root Inport blocks and a root Output block.

```
model='rtwdemo_reusable';
open_system(model);
```

Copyright 1994-2016 The MathWorks, Inc.

In your working folder, create a temporary folder for generating and reviewing the code.

```
currentDir=pwd;
[~,cgDir] = rtwdemodir();
```

Examine Relevant Model Configuration Settings

1. Open the Model Configuration Parameters dialog box.
2. **System target file** is set to `ert.tlc`. Although you can generate reentrant code for a model configured with the **System target file** set to `grt.tlc`, ERT and ERT-based system target files provide more control over how the code passes root-level I/O.
3. Open the **Code Generation > Interface** pane and explore relevant parameter settings.

- **Code interface packaging** is set to `Reusable` function. This parameter setting instructs the code generator to produce reusable, multi-instance code.
- The `Reusable` function parameter setting also displays the **Multi-instance code error diagnostic** parameter. That parameter is set to `Error`, indicating that the code generator abort if the model violates requirements for generating multi-instance code.
- **Pass root-level I/O as** is set to `Part of model data structure`. This setting packages root-level model input and output into the real-time model data structure (`rtModel`), which is an optimized data structure that replaces `SimStruct` as the top-level data structure for a model.
- **Remove error status field in real-time model data structure** is selected. This parameter setting reduces memory usage by omitting the error status field from the generated real-time model data structure.

Generate and Review Code

```
rtwbuild(model);  
  
### Starting build procedure for model: rtwdemo_reusable  
### Successful completion of build procedure for model: rtwdemo_reusable
```

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code controls model code execution by calling the entry-point function `rtwdemo_reusable_step`. Use this file as a starting point for coding your execution framework.
- `rtwdemo_reusable.c` contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
- `rtwdemo_reusable.h` declare model data structures and a public interface to the model entry points and data structures.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework.

1. Include the generated header file by adding directive `#include rtwdemo_reusable.h`.
2. Write input data to the generated code for model Inport blocks.

3. Call the generated entry-point functions.
4. Read data from the generated code for the model Outport block.

Input ports:

- <Root>/In1 of data `real_T` with dimension of 1
- <Root>/In2 of data `real_T` with dimension of 1

Entry-point functions:

- Initialization entry-point function, `void`
`rtwdemo_reusable_initialize(RT_MODEL *const rtM)`. At startup, call this function once.
- Output and update (step) entry-point function, `void`
`rtwdemo_reusable_step(RT_MODEL *const rtM)`. Call this function periodically at the fastest rate in the model. For this model, call the function every second. To achieve real-time execution, attach this function to a timer.

Output port:

- <Root>/Out1 of data type `real_T` with dimension of 1

Examine the `|rtwdemo_reusable_step|` function code in `|rtwdemo_reusable.c|`.

```
cfile = fullfile(cgDir, 'rtwdemo_reusable_ert_rtw', 'rtwdemo_reusable.c');
rtwdemodbtype(cfile, /* Model step function', /* Model initialize function ', 1, 0);
```

```
/* Model step function */
void rtwdemo_reusable_step(RT_MODEL *const rtM)
{
    Parameters *rtP = ((Parameters *) rtM->defaultParam);
    D_Work *rtDWork = ((D_Work *) rtM->dwork);
    ExternalInputs *rtU = (ExternalInputs *) rtM->inputs;
    ExternalOutputs *rtY = (ExternalOutputs *) rtM->outputs;

    /* Outport: '<Root>/Out1' incorporates:
     * UnitDelay: '<Root>/Delay'
     */
    rtY->Out1 = rtDWork->Delay_DSTATE;

    /* Gain: '<Root>/Gain' incorporates:
     * Inport: '<Root>/In1'
```

```
* Inport: '<Root>/In2'  
* Sum: '<Root>/Sum'  
* UnitDelay: '<Root>/Delay'  
*/  
rtDWork->Delay_DSTATE = (rtU->In1 + rtU->In2) * rtP->k1;  
}
```

The code generator passes model data to the `rtwdemo_reusable_step` function as part of the real-time model data structure. Try different settings for the **Code interface packaging** and **Pass root-level I/O** parameters and regenerate code. Observe how the function signature for the `rtwdemo_reusable_step` function changes.

Close the model and the code generation report.

```
bdclose(model)  
rtwdemoclean;  
cd(currentDir)
```

Share Data Between Instances

When your code calls a reentrant model entry-point function multiple times, each call represents an instance of the model. By default, the code generator generates code that assumes each instance reads from and writes to a separate copy of the signals, block states, and parameters in the model.

- To share a piece of parameter data between the instances (for example, to share a setpoint for a reusable PID control algorithm), use a parameter object, such as `Simulink.Parameter`, and apply a storage class other than `Auto` or, if you set the default storage class for the corresponding category of parameter data to `Default` (the default setting) in the Code Mapping Editor, `Model default`. The parameter object appears in the code as a global symbol, such as a global variable, that the function accesses directly. For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).
- To share a piece of nonparameter data between the instances, for example, to share a fault indication or an accumulator, use a data store. You can configure the data store to appear in the code as a global symbol, such as a global variable, that the function accesses directly. Create a global data store by using a `Simulink.Signal` object or use a Data Store Memory block and select the **Share across model instances** parameter. For more information, see “Model Global Data by Creating Data Stores” (Simulink) and Data Store Memory.

Generate Reentrant Code from Simulink Function Blocks

If you are using Embedded Coder, you can generate reusable, reentrant code by representing an algorithm as a scoped Simulink Function block. Examples of when to generate reentrant code from Simulink Function blocks are when a function shares state between function callers within a model or for client/server applications. You can generate code that is highly modularized by using multiple instances of a shared Simulink Function block in an export-function model. The code generator produces function code and associates each use or call to the function with instance-specific data. The scope of the function depends on whether you place the function at the root level of model or in a subsystem.

The code generator produces reentrant function code when you configure a:

- Top model with model configuration parameter “Code interface packaging” (Simulink Coder) set to `Reusable function` or `C++ class` (C++ only).
- Referenced model with “Total number of instances allowed per top model” (Simulink) set to `Multiple`.

Call a function represented by a scoped Simulink Function block from one level above, at the same level, or from a level below the level of the function definition. You can scope a function in an atomic or nonvirtual subsystem, but function call accessibility is limited to the same level or below of the hierarchy. The function name does not have to be unique.

Identify Requirements

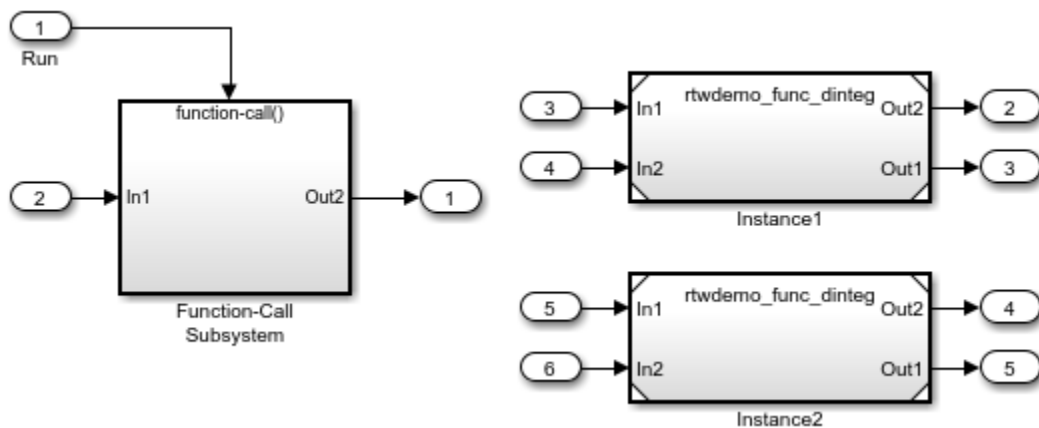

Before and while you design your model, consider:

- How many instances of each function are required?
- Do you need to restrict call sites for a function to the model containing the function definition?
- Do you need for a function to interface with signals in the local environment, but keep those signals hidden from callers?
- Do functions need to communicate directly with each other?
- Do functions need to connect to external I/O?
- Do you need to log function output?

Create Model

Use the example model component `rtwdemo_comp` to see how to use Simulink Function blocks to generate reentrant C code. Use example model `rtwdemo_comp_cpp` if you prefer to generate C++ code. Open the model and examine the model hierarchy.

The top level of the model includes a function-call subsystem and two instances of a referenced model.

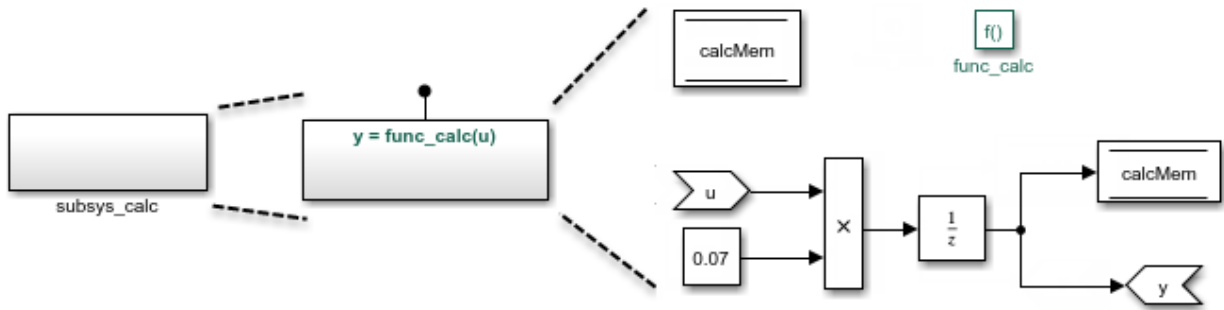

The referenced model, `rtwdemo_func_dinteg`, consists of a Simulink Function block that defines function `multiinstfunc` and subsystem `subsys_calc`.

The subsystem consists of a Simulink Function block. This use of a Simulink Function block shows how you can limit the scope of the function that the block defines to the model that contains the subsystem. The code generator produces function code for

func_calc and associates each call to the function with instance-specific data. The data includes states, such as data stored in memory.

The Simulink Function block that defines function multiinstfunc uses a Function Caller block to invoke function func_calc. That Simulink Function block also shows that it can interface to signals in the local environment of the block through Inport and Outport blocks (see “Simulink Functions in a Simulink Model” (Simulink)).

At the top level of model rtwdemo_comp, the function-call subsystem uses Function Caller blocks to invoke the two instances of function multiinstfunc. The code generator produces function code and associates each call with instance-specific data.

Configure Model and Model Elements

Configure Simulink Function Blocks

Configure the Simulink Function blocks by setting parameters for the function Trigger Port block. For the code generator to produce reentrant code from Simulink Function blocks:

- Configure block instances with the same function name.
- Set **Function visibility** to scoped.

In the example, the function name for the Simulink Function blocks in the two instances of the referenced model `rtwdemo_func_dinteg` is specified as `multiinstfunc`.

Configure Function Caller Blocks

Configure the Function Caller blocks. For each of the blocks, set the **Function prototype** block parameter. Start typing a prototype. For example, type `y`. Prototype options, based on function definitions in the model, appear in a selection list. Select the prototype that is appropriate for each function call.

For this example, the prototypes are configured as follows:

- In the function-call subsystem, the prototypes for the function callers are configured as `y = Instance1.multiinstfunc(u)` and `y = Instance2.multiinstfunc(u)`. The `Instancen` prefix identifies each function invocation uniquely and associates the invocation with its own data set.
- The function caller in function `multiinstfunc` is configured with the prototype `y = subsystem_calc.func_calc(u)`. The prefix `subsystem_calc` identifies the subsystem that contains the function definition.

For the example, the input and output argument specifications and sample time retain default settings.

Subsystem Configuration

No configuration changes are required for the subsystem in the example model. When you include a Simulink Function block in a subsystem, the code generator

- Scopes the function to the model that includes the subsystem.
- Treats the subsystem as an atomic unit.

Configure Referenced Model

Configure the referenced model that includes a Simulink Function block:

- In the Block Parameters dialog box, set **Model name** to the referenced model file name. For this example, the model name is `rtwdemo_func_dinteg.slx`.
- Set **Number of model instances allowed** to `Multiple`.
- To generate a C++ class interface for the reference model, set **Language** to `C++` and **Code interface packaging** to `C++ class`.

Optionally, you can configure custom prototypes for the initialize and execution (step) model-entry point functions. Custom prototypes can minimize changes to existing external code that you integrate with the generated code. The example uses the default function prototypes. See “Customize Generated Function Interfaces for Simulink Function and Function Caller Blocks” on page 29-24.

Configure Top Model

Configure the top model for a model component. If you want the model component (that is, the top model) to be reusable, set **Code interface packaging** to `Reusable`

function. If you are generating C++ code, you can set this parameter to C++ class. In either case, also:

- Set **Multi-instance code error diagnostic** to Error.
- Set **Pass root-level I/O as** to Part of model data structure.

Optionally, you can configure custom prototypes for the initialize and execution (step) model-entry point functions. Custom prototypes can minimize changes to existing external code that you integrate with the generated code. Also see “Customize Generated Function Interfaces for Simulink Function and Function Caller Blocks” on page 29-24.

Generate and Inspect C Code

Generate C code for the model.

- Function code for multi-instance Simulink Function block

When you place a scoped Simulink Function block in a referenced model that you use multiple times in another model, the code generator places the function code in the *model.c* file for the referenced model. For this example, the code generator places function code for *multiinstfunc* in *slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg.c*.

```
real_T rtwdemo_func_dinteg_multiinstfunc(RT_MODEL_rtwdemo_func_dinteg_T * const
rtwdemo_func_dinteg_M, const real_T rtu_u)
{
    real_T rtb_TmpLatchAtInOutput1;
    real_T rtb_TmpLatchAtIn2Output1;
    real_T rty_y_0;

    rtb_TmpLatchAtInOutput1 =
        *rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtxtInport.rtu_In1;

    rtb_TmpLatchAtIn2Output1 =
        *rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtxtInport.rtu_In2;

    *rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtxtOutputport.rty_Out2 = 2.0 *
        rtb_TmpLatchAtInOutput1;

    rtwdemo_func_dinteg_func_calc(rtwdemo_func_dinteg_M, rtb_TmpLatchAtIn2Output1,
        rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtxtOutputport.rty_Out1);

    rty_y_0 = rtwdemo_func_dinteg_M->dwork.DiscreteIntegrator_DSTATE;

    rtwdemo_func_dinteg_M->dwork.DiscreteIntegrator_DSTATE += 0.1 * rtu_u;
    return rty_y_0;
}
```

- Function code for a Simulink Function block defined in a subsystem

The code generator places the function code for a Simulink Function block that you define in a subsystem in the `model.c` file for the model that contains the subsystem. For this example, the code generator places the function code for `func_calc` in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg.c`.

```
void rtwdemo_func_dinteg_func_calc(RT_MODEL_rtwdemo_func_dinteg_T * const
rtwdemo_func_dinteg_M, real_T rtu_u, real_T *rty_y)
{
    rtwdemo_func_dinteg_M->dwork.calcMem =
        rtwdemo_func_dinteg_M->dwork.UnitDelay_DSTATE;

    *rty_y = rtwdemo_func_dinteg_M->dwork.UnitDelay_DSTATE;

    rtwdemo_func_dinteg_M->dwork.UnitDelay_DSTATE = rtu_u * 0.07;
}
```

- Self-referential structure that stores multi-instance data for reusable functions

The code generator uses the real-time model (RT_MODEL) data structure as a self-referential structure to store the multi-instance data associated with a reusable function. The code generator defines the structure in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg.h`.

```
typedef struct rtwdemo_func_dinteg_tag_RTM RT_MODEL_rtwdemo_func_dinteg_T;
```

- Initialization code for multi-instance referenced model

For each instance of a referenced model that includes the same scoped Simulink Function block, the code generator produces initialization and startup function code. A single copy of the initialization code is defined in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg.c`.

```
void rtwdemo_func_dinteg_Start(RT_MODEL_rtwdemo_func_dinteg_T *const
rtwdemo_func_dinteg_M, const real_T *rtu_In1, const real_T *rtu_In2, real_T
*rty_Out2, real_T *rty_Out1)
{
    rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextInport.rtu_In1 = rtu_In1;
    rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextInport.rtu_In2 = rtu_In2;
    rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextOutputport.rty_Out2 = rty_Out2;
    rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextOutputport.rty_Out1 = rty_Out1;
}

void rtwdemo_func_dinteg_initialize(const char_T **rt_errorStatus,
RT_MODEL_rtwdemo_func_dinteg_T *const rtwdemo_func_dinteg_M)
{
    {
        rtmSetErrorStatusPointer(rtwdemo_func_dinteg_M, rt_errorStatus);
    }
}
```

The initialization code is called for each instance of a referenced model that contains the same Simulink Function block. That code is in file `rtwdemo_comp.c` in the build folder.

```

:
:
:
rtwdemo_func_dinteg_initialize(rtmGetErrorStatusPointer(rtwdemo_comp_M),
    (&(rtwdemo_comp_M->Instance1)));

rtwdemo_func_dinteg_initialize(rtmGetErrorStatusPointer(rtwdemo_comp_M),
    (&(rtwdemo_comp_M->Instance2)));

rtwdemo_func_dinteg_Start((&(rtwdemo_comp_M->Instance1)), &rtU->In2, &rtU->In3,
    &rtY->Out2, &rtY->Out3);

rtwdemo_func_dinteg_Start((&(rtwdemo_comp_M->Instance2)), &rtU->In4, &rtU->In5,
    &rtY->Out4, &rtY->Out5);
}

```

- Top model entry-point function declarations

The model header file `rtwdemo_comp.h` includes extern declarations for top model initialize, terminate, and execution (run) entry-point functions.

```
extern void rtwdemo_comp_initialize(RT_MODEL_rtwdemo_comp_T *const
    rtwdemo_comp_M);
```

```
extern void Run(RT_MODEL_rtwdemo_comp_T *const rtwdemo_comp_M);
```

- Reference model entry-point function declarations

Header file `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg.h` includes extern declarations for reference model entry-point functions.

```
extern void rtwdemo_func_dinteg_initialize(const char_T **rt_errorStatus,
    RT_MODEL_rtwdemo_func_dinteg_T *const rtwdemo_func_dinteg_M);
extern real_T rtwdemo_func_dinteg_multiinstfunc(RT_MODEL_rtwdemo_func_dinteg_T *
    const rtwdemo_func_dinteg_M, const real_T rtu_u);
extern void rtwdemo_func_dinteg_Start(RT_MODEL_rtwdemo_func_dinteg_T *const
    rtwdemo_func_dinteg_M, const real_T *rtu_In1, const real_T *rtu_In2, real_T
    *rty_Out2, real_T *rty_Out1);
```

Generate and Inspect C++ Code

Generate C++ code for the model.

- Function code for multi-instance Simulink Function block

When you place a scoped Simulink Function block in a referenced model that you use multiple times in another model, the code generator places the function code in the

`model.cpp` file for the referenced model. For this example, the code generator places function code for `multiinstfunc` in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg_cpp.cpp`.

```
real_T rtwdemo_func_dintegModelClass::multiinstfunc(const real_T rtu_u)
{
    real_T rtb_TmpLatchAtInOutput1;
    real_T rtb_TmpLatchAtIn2Output1;
    real_T rty_y_0;

    rtb_TmpLatchAtInOutput1 = *rtwdemo_func_dinteg_cprrtu_In1;
    rtb_TmpLatchAtIn2Output1 = *rtwdemo_func_dinteg_cprrtu_In2;
    *rtwdemo_func_dinteg_crtrty_Out2 = 2.0 * rtb_TmpLatchAtInOutput1;
    rtwdemo_func_dinteg_c_func_calc(rtb_TmpLatchAtIn2Output1,
        rtwdemo_func_dinteg_crtrty_Out1);
    rty_y_0 = rtwdemo_func_dinteg_cprrtDW.DiscreteIntegrator_DSTATE;
    rtwdemo_func_dinteg_cprrtDW.DiscreteIntegrator_DSTATE += 0.1 * rtu_u;
    return rty_y_0;
}
```

- Function code for a Simulink Function block defined in a subsystem

The code generator places the function code for a Simulink Function block that you define in a subsystem in `model.cpp` for the model that contains the subsystem. For this example, the code generator places the function code for `func_calc` in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg_cpp.cpp`.

```
void rtwdemo_func_dintegModelClass::rtwdemo_func_dinteg_c_func_calc(real_T rtu_u,
    real_T *rty_y)
{
    rtwdemo_func_dinteg_cprrtDW.calcMem =
        rtwdemo_func_dinteg_cprrtDW.UnitDelay_DSTATE;

    *rty_y = rtwdemo_func_dinteg_cprrtDW.UnitDelay_DSTATE;

    rtwdemo_func_dinteg_cprrtDW.UnitDelay_DSTATE = rtu_u * 0.07;
}
```

- Self-referential structure that stores multi-instance data for reusable functions

The code generator uses the real-time model (`RT_MODEL`) data structure as a self-referential structure to store the multi-instance data associated with a `Reusable` function. The code generator defines the structure in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg_cpp.h`.

```
typedef struct rtwdemo_func_dinteg_cpp_tag_RTM rtwdemo_func_dinteg_cp_RTM_MODEL;
```

- Initialization code for multi-instance referenced model

For each instance of a referenced model that includes the same scoped Simulink Function block, the code generator produces initialization and startup function code. A single copy of the initialization code is defined in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg_cpp.cpp`.

```
void rtwdemo_func_dintegModelClass::start(real_T *rtu_In1, real_T *rtu_In2,
    real_T *rty_Out2, real_T *rty_Out1)
{
    rtwdemo_func_dinteg_cprrtu_In1 = rtu_In1;
    rtwdemo_func_dinteg_cprrtu_In2 = rtu_In2;
    rtwdemo_func_dinteg_crtrty_Out2 = rty_Out2;
    rtwdemo_func_dinteg_crtrty_Out1 = rty_Out1;
}
.
.
.
void rtwdemo_func_dintegModelClass::initializeRTM()
{
    (void) memset((void *)(&rtwdemo_func_dinteg_cprrtm), 0,
        sizeof(rtwdemo_func_dinteg_cp_RT_MODEL));
}
}
```

The initialization code is called for each instance of a referenced model that contains the same Simulink Function block. That code is in file `rtwdemo_comp_cpp.cpp` in the build folder.

```
.
.
.
Instance1MDL0BJ0.initializeRTM();

Instance1MDL0BJ0.setErrorStatusPointer(rtmGetErrorStatusPointer((&rtm)));
Instance1MDL0BJ0.initialize();

Instance2MDL0BJ1.initializeRTM();

Instance2MDL0BJ1.setErrorStatusPointer(rtmGetErrorStatusPointer((&rtm)));

Instance1MDL0BJ0.start(&rtU.In2, &rtU.In3, &rtY.Out2, &rtY.Out3);

Instance2MDL0BJ1.start(&rtwU.In4, &rtwU.In5, &rtY.Out4, &rtY.Out5);
}
```

- Top model class declaration

The model header file `rtwdemo_comp_cpp.h` includes the class declaration for the top model.

```
class rtwdemo_compModelClass {
public:
```

```
ExtU rtU;
ExtY rtY;
void initialize();
void Run();
rtwdemo_compModelClass();
~rtwdemo_compModelClass();
RT_MODEL * getRTM();
private:
RT_MODEL rtM;
rtwdemo_func_dintegModelClass Instance1MDLOBJ0;
rtwdemo_func_dintegModelClass Instance2MDLOBJ1;
};
```

- Reference model class declaration

Header file `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg_cpp.h` includes the class declaration for the reference model.

```
class rtwdemo_func_dintegModelClass {
public:
    real_T multiinstfunc(const real_T rtu_u);

    void start(real_T *rtu_In1, real_T *rtu_In2, real_T *rty_Out2, real_T
               *rty_Out1);

    rtwdemo_func_dintegModelClass();
    ~rtwdemo_func_dintegModelClass();

    rtwdemo_func_dinteg_cp_RT_MODEL * getRTM();

    void initializeRTM();

    void setErrorStatusPointer(const char_T **rt_errorStatus);

private:
    rtwdemo_func_dinteg_cpp_DW rtwdemo_func_dinteg_cpprtDW;

    const real_T *rtwdemo_func_dinteg_cprrtu_In1;
    const real_T *rtwdemo_func_dinteg_cprrtu_In2;
    real_T *rtwdemo_func_dinteg_crtrty_Out2;
    real_T *rtwdemo_func_dinteg_crtrty_Out1;

    rtwdemo_func_dinteg_cp_RT_MODEL rtwdemo_func_dinteg_cpprtM;
```

```
void rtwdemo_func_dinteg_c_func_calc(real_T rtu_u, real_T *rty_y);  
};
```

Limitations

These code generation limitations apply to export-function models that include multiple instances of a Simulink Function block.

- You must set the model configuration parameter **Pass root-level I/O as** to `Part` of `model data structure`.
- Generated code is compatible with single-threaded execution only. To avoid race conditions for shared signal data, invoke instances of the function code from the same execution thread.
- You cannot:
 - Generate code if the export-function model includes model variants.
 - Call the generated code from a Stateflow chart.
 - Enable the external mode data exchange interface.

- “Use Storage Classes in Reentrant, Multi-Instance Models and Components” (Simulink Coder)

Generate Reentrant Code from Subsystems

You can reduce the amount of code that the code generator produces for identical atomic subsystems by configuring the subsystems as reusable functions that pass data as arguments (for example, `rtB_*` for block input and output, `rtDW_*` for continuous states, and `rtP_*` for parameters). By default, the code generator produces subsystem code that communicates with other code by sharing access to global data structures that reside in shared memory. By passing data as arguments, the code can be reentrant. Each instance of the code maintains its own unique data.

To configure subsystems for reusability and reentrancy, configure mask and block parameters of the identical subsystems the same way. The code generator performs a checksum to determine whether subsystems are identical and whether the code is reusable. If the code is reusable, the code generator produces a single instance of reusable, reentrant function code.

To configure the subsystem block parameters:

- 1 If a subsystem is virtual, select “Treat as atomic unit” (Simulink) to enable function packaging parameters.
- 2 On the **Code Generation** tab, set “Function packaging” (Simulink) to **Reusable function**. The code generator produces a separate function with arguments for each subsystem. Selecting **Reusable function** also enables additional parameters that you can use to control the names of the function and file that the code generator produces for the subsystem code.
- 3 Set “Function name options” (Simulink). To generate reusable, reentrant code, specify the same setting for identical subsystems.
 - To let the code generator determine the function name, select **Auto**.
 - To use the subsystem name or, for a library block, the name of the library block, select **Use subsystem name**.
 - To display the “Function name” (Simulink) parameter and enter a unique, valid C/C++ function name, select **User specified**.

If there are multiple instances of an identical subsystem within a model reference hierarchy, select **Auto**.

If you are using Embedded Coder, you can use identifier format controls. See “Identifier Format Control” on page 39-22.

- 4 Set “File name options” (Simulink). To generate reusable, reentrant code, specify the same setting for identical subsystems.
- To let the code generator determine file naming select **Auto**.
 - To use the subsystem name or, for a library block, the name of the library block select **Use subsystem name**.
 - To use the function name, as specified by **Function name options** select **Use function name**.
 - To display the “File name (no extension)” (Simulink) parameter and enter a file name, excluding the extension (for example, .c or .cpp) select **User specified**.

Other considerations:

- If there are multiple instances of an identical subsystem within a model reference hierarchy, select **Auto**.
- If the code generator does not generate a separate file for a subsystem, the function code is placed in the file generated from the subsystem's parent system. If the parent is the model itself, the code generator places the function code in *model.c* or *model.cpp*.
- If your generated code is under source control, specify a value other than **Auto**. This specification prevents the generated file name from changing when you modify and rebuild the model.
- If you select **Use subsystem name**, the code generator mangles the subsystem file name if the model contains Model blocks, or if a model reference target is being generated for the model. In these situations, the code generator uses the file name *modelsubsystem.c*.

If subsystem A has mask parameter b and K and subsystem B has mask parameters c and K, code reuse is not possible. The code generator produces separate functions for subsystems A and B. If you set block parameters for subsystems A and B differently, code reuse is not possible.

Limitations

- The code generator uses a checksum to determine whether subsystems are identical and reusable. Subsystem code is not reused if:

- In blocks and data objects, you use symbols to specify dimensions.
- A port has different sample times, data types, complexity, frame status, or dimensions across subsystems.
- The output of a subsystem is marked as a global signal.
- Subsystems contain identical blocks with different names or parameter settings.
- The output of a subsystem is connected to a Merge block, and the output of the Merge block is configured with a custom storage class that is implemented in the C code as nonaddressable memory (for example, `BitField`).
- The input of a subsystem is nonscalar and is configured with a custom storage class that is implemented in the C code as nonaddressable memory.
- A masked subsystem has a parameter that is nonscalar and is configured with a custom storage class that is implemented in the C code as nonaddressable memory.
- A function-call subsystem uses mask parameters when you set the model configuration parameter “Default parameter behavior” (Simulink Coder) to `Tunable`. To reuse the masked function-call subsystem, place it inside a new atomic subsystem without a mask. Then move the Trigger block from the masked subsystem into the atomic subsystem.
- A block in a subsystem uses a partially tunable expression. Some partially tunable expressions disable code reuse.

Partially tunable expressions are expressions that contain one or more tunable variables and an expression that is not tunable. For example, suppose that you create the tunable variable `K` with value `15.23` and the tunable variable `P` with value `[5;7;9]`. The expression `K+P'` is a partially tunable expression because the expression `P'` is not tunable. For more information about tunable expression limitations, see “Tunable Expression Limitations” (Simulink Coder).

- For subsystems that contain S-function blocks that are reusable, the blocks must meet the requirements listed in “S-Functions That Support Code Reuse” on page 11-105.
- If you select `Reusable function`, and the code generator determines that you cannot reuse the code for a subsystem, it generates a separate function that is not reused. The code generation report might show that the separate function is reusable, even if only one subsystem uses it. If you prefer that the code generator inline subsystem code in such cases (rather than deployed as functions), set “Function packaging” (Simulink) to `Auto`.
- If a reusable subsystem uses a shared local data store and you configure default mapping for model data elements, leave the default storage class mapping for category **Shared local data stores** set to **Default**.

Determine Why Subsystem Code Is Not Reused

Due to the limitations described in “Generate Reentrant Code from Subsystems” (Simulink Coder), the code generator might not reuse generated code as you expect. To determine why code generated for a subsystem is not reused:

- 1 Review the Subsystems section of the code generation report.
- 2 Compare subsystem checksum data.

Review Subsystems Section of HTML Code Generation Report

If the code generator does not generate code for a subsystem as reusable code, and you configured the subsystem as reusable, examine the Subsystems section of the code generation report (see “Generate a Code Generation Report” (Simulink Coder)). The Subsystems section contains:

- A table that summarizes how nonvirtual subsystems were converted to generated code.
- Diagnostic information that describes why subsystems were not generated as reusable code.

The Subsystems section also maps noninlined subsystems in the model to functions or reused functions in the generated code. For an example, open and build the `rtwdemo_atomic` model.

Compare Subsystem Checksum Data

You can determine why subsystem code is not reused by comparing subsystem checksum data. The code generator determines whether subsystems are identical by comparing subsystem checksums, as noted in “Limitations” (Simulink Coder). For subsystem reuse across referenced models, this procedure might not flag every difference.

Consider the model, `rtwdemo_ssreuse`. SS1 and SS2 are instances of the same subsystem. In both instances the subsystem parameter **Function packaging** is set to Reusable function.

Use the method `Simulink.SubSystem.getChecksum` to get the checksum for a subsystem. Review the results to determine why code is not reused.

- 1 Open the model `rtwdemo_ssreuse`. Save a copy of the model in a folder where you have write access.
- 2 Associate the subsystems `SS1` and `SS2` with `gcb`. For each of the subsystems, in the model window, select the subsystem. While the subsystem is selected, in the Command Window, enter:

```
SS1 = gcb;
```

```
SS2 = gcb;
```

- 3 Use the method `Simulink.SubSystem.getChecksum` to get the checksum for each subsystem. This method returns two output values: the checksum value and details on the input used to compute the checksum.

```
[chksum1, chksum1_details] = ...
Simulink.SubSystem.getChecksum(SS1);
[chksum2, chksum2_details] = ...
Simulink.SubSystem.getChecksum(SS2);
```

- 4 Compare the two checksum values. The values should be equal based on the subsystem configurations.

```
isequal(chksum1, chksum2)
ans =
    1
```

- 5 To use `Simulink.SubSystem.getChecksum` to determine why the checksums of two subsystems differ, change the data type mode of the output port of `SS1` so that it differs from that of `SS2`.

- a Look under the mask of SS1. Right-click the subsystem. In the context menu, select **MaskLook Under Mask**.
 - b In the block diagram of the subsystem, double-click the Lookup Table block to open the Subsystem Parameters dialog box.
 - c Click **Data Types**.
 - d Select **Saturate on integer overflow** and click **OK**.
- 6 Get the checksum for SS1. Compare the checksums for the two subsystems. This time, the checksums are not equal.

```
[chksum1, chksum1_details] = ...
Simulink.SubSystem.getChecksum(SS1);
isequal(chksum1, chksum2)
ans =
    0
```

- 7 After you determine that the checksums are different, find out why. The Simulink engine uses information, such as signal data types, some block parameter values, and block connectivity information, to compute the checksums. To determine why checksums are different, compare the data that computes the checksum values. You can get this information from the second value returned by `Simulink.SubSystem.getChecksum`, which is a structure array with four fields.

Look at the structure `chksum1_details`.

```
chksum1_details

chksum1_details =
    ContentsChecksum: [1x1 struct]
    InterfaceChecksum: [1x1 struct]
    ContentsChecksumItems: [287x1 struct]
    InterfaceChecksumItems: [53x1 struct]
```

`ContentsChecksum` and `InterfaceChecksum` are component checksums of the subsystem checksum. The remaining two fields, `ContentsChecksumItems` and `InterfaceChecksumItems`, contain the checksum details.

- 8 Determine whether a difference exists in the subsystem contents, interface, or both. For example:

```
isequal(chksum1_details.ContentsChecksum.Value, ...
        chksum2_details.ContentsChecksum.Value)
ans =
    0
```

```

isequal(chksum1_details.InterfaceChecksum.Value,...
        chksum2_details.InterfaceChecksum.Value)
ans =
     1

```

In this case, differences exist in the content.

- 9 Write a script like this script to find the differences.

```

idxForCDiffs=[];
for idx = 1:length(chksum1_details.ContentsChecksumItems)
    if (~strcmp(chksum1_details.ContentsChecksumItems(idx).Identifier, ...
               chksum2_details.ContentsChecksumItems(idx).Identifier))
        disp(['Identifiers different for contents item ', num2str(idx)]);
        idxForCDiffs=[idxForCDiffs, idx];
    end
    if (ischar(chksum1_details.ContentsChecksumItems(idx).Value))
        if (~strcmp(chksum1_details.ContentsChecksumItems(idx).Value, ...
                   chksum2_details.ContentsChecksumItems(idx).Value))
            disp(['Character vector values different for contents item ', num2str(idx)]);
            idxForCDiffs=[idxForCDiffs, idx];
        end
    end
    if (isnumeric(chksum1_details.ContentsChecksumItems(idx).Value))
        if (chksum1_details.ContentsChecksumItems(idx).Value ~= ...
           chksum2_details.ContentsChecksumItems(idx).Value)
            disp(['Numeric values different for contents item ', num2str(idx)]);
            idxForCDiffs=[idxForCDiffs, idx];
        end
    end
end
end

```

- 10 Run the script. The example assumes that you named the script `check_details`.

```

check_details
Character vector values different for contents item 202

```

The results indicate that differences exist for index item 202 in the subsystem contents.

- 11 Use the returned index values to get the handle, identifier, and value details for each difference found.

```

chksum1_details.ContentsChecksumItems(202)

ans =

    Handle: 'rtwdemo_ssreuse/SS1/Lookup Table'
  Identifier: 'SaturateOnIntegerOverflow'
     Value: 'on'

```

The details identify the Lookup Table block parameter **Saturate on integer overflow** as the focus for debugging a subsystem reuse issue.

Generate Reusable Code From Referenced Models

Considerations for Subsystems that Contain Referenced Models

You can generate reusable code for subsystems that contain referenced models by using the same procedures and options described in “Control Generation of Subsystem Functions” on page 3-2. However, consider these restrictions:

- A top model that uses single-tasking mode and includes a referenced model that uses multi-tasking mode executes for blocks with different rates that are not connected. however, you get an error if the blocks with different rates are connected by a Rate Transition block (inserted manually or by Simulink).
- S-functions that you generate with the Embedded Coder **Code > C/C++ Code > Generate S-function** menu option do not support subsystems that contain a continuous sample time.
- The S-function system target file is not supported.
- The code generator ignores tunable parameters settings that you configure from the Model Parameter Configuration dialog box. To configure parameters to be tunable, define them as Simulink parameter objects in the base workspace.
- The code generator inlines parameters that are not tunable in the generated code and S-function.

Note If you select the S-function system target file, the subsystem block menu options **C/C++ Code > Build This System** and **Code > C/C++ Code > Build Selected Subsystem** behave like **Code > C/C++ Code > Generate S-Function** (see “Generate S-Function from Subsystem” on page 11-62).

Code Reuse and Model Blocks with Root Inport or Output Blocks

A reusable subsystem function with input or output connected to the root Inport or Output block of a referenced model can affect code reuse. This can prevent you from reusing atomic subsystems in a reference model context the same way you might reuse the subsystems in a standalone model.

For example, consider this subsystem:

Suppose that you make the following changes to the subsystem block parameters:

- Select “Treat as atomic unit” (Simulink).
- On the **Code Generation** tab, set “Function packaging” (Simulink) to Reusable function.

Then, suppose you create this model, which includes three instances of the preceding subsystem.

With the model configuration parameter “Default parameter behavior” (Simulink Coder) set to Inlined, the code generator optimizes the code by generating one copy of the function for the reused subsystem.

```
void reuse_subsys1_Subsystem(real_T rtu_In1, B_Subsystem_reuse_subsys1_T *localB)
{
    localB->Gain = 3.0 * rtu_In1;
}
```

If you move the three subsystems into a Model block, you must modify your model and model configuration.

- 1 Add a Signal Conversion block or a Bias block between Subsystem3 and the Output block. If the subsystem has a Merge block with initial conditions, do not add a Signal Conversion block. Instead, add a Bias block to obtain a reusable function.
- 2 Select the model configuration parameter “Pass fixed-size scalar root inputs by value for code generation” (Simulink).

The result is a single reusable function:

```
void reuse_subsys1_Subsystem(real_T rtu_In1, B_Subsystem_reuse_subsys1_T *localB)
{
    localB->Gain = 3.0 * rtu_In1;
}
```

Generate Reusable Code from Library Subsystems Shared Across Models

What Is a Reusable Library Subsystem?

A reusable library subsystem is a subsystem included in a library that is configured for reuse. You must define a subsystem in a library and configure it for reuse to reuse the subsystem across models.

To reuse common functionality, you can include multiple instances of a subsystem:

- Within a single model, which is a top model or part of model reference hierarchy
- Across multiple referenced models in a model reference hierarchy
- Across multiple top models that contain Model blocks
- Across multiple top models that do not include Model blocks

The code generator uses checksums to determine reusability. There are cases when the code generator cannot reuse subsystem code.

For incremental code generation, if the reusable library subsystem changes, a rebuild of itself and its parents occurs. During the build, if a matching function is not found, a new instance of the reusable function is generated into the shared utilities folder. If a different matching function is found from previous builds, that function is used, and a new reusable function is not emitted.

For subsequent builds, unused files are not replaced or deleted from your folder. During development of a model, when many obsolete shared functions exist in the shared utilities folder, you can delete the folder and regenerate the code. If all instances of a reusable library subsystem are removed from a model reference hierarchy and you regenerate the code, the obsolete shared functions remain in the shared utilities folder until you delete them.

If a model changes such that the change might cause different generated code for the subsystem, a new reusable function is generated. For example, model configuration parameters that modify code comments might cause different generated code for the subsystem even if the reusable library subsystem did not change.

Reusable Library Subsystem Code Placement and Naming

The generated code of a reusable library subsystem is independent of the generated code of the model. Code for the reusable library subsystem is generated to the shared utility folder, `slprj/target/_sharedutils`, instead of the model reference hierarchy folders. The generated code for the supporting types, which are generated to the `.h` file, are also in the shared utilities folder.

For unique naming, reusable function names have a checksum appended to the reusable library subsystem name. For example, the code and files for a subsystem, `SS1`, which links to a reusable library subsystem, `RLS`, might be:

- Function name: `RLS_mgdj_lngd`
- File name: `RLS_mgdj_lnd.c` and `RLS_mgdj_lnd.h`

Configure Reusable Library Subsystem

Set the Subsystem parameters as listed here:

- Select **Treat as an atomic unit**.
- On the **Code Generation** tab:
 - Set **Function packaging** to `Reusable function`.
 - Set **Function name options**

and **File name options** to `Auto, Use subsystem name, or User specified`.

In a model reference hierarchy, if an instance of the reusable library subsystem is in the top model, then on the **Model Referencing** pane of the Configuration Parameters dialog box, you must select the **Pass fixed-size scalar root input by value for code generation** parameter. If you do not select the parameter, a separate shared function is generated for the reusable library subsystem instance in the top model, and a reusable function is generated for instances in the referenced models.

If a reusable library subsystem is connected to the root output, reuse does not happen with identical subsystems that are not connected to the root output. However, you can set **Pass reusable system outputs as** to `Individual` arguments on the **Optimizations** pane to make sure that reuse occurs between these subsystems. This parameter requires an Embedded Coder license.

For more information on creating a library, see “Libraries” (Simulink). For an example of creating a reusable library subsystem, see “Generate Reusable Code for Subsystems Shared Across Models” (Simulink Coder).

Configure Models That Include Reusable Library Subsystems

For a model to use a reusable library subsystem, you must configure the model differently depending on whether the model is a reference model or top model. If the subsystem is in a referenced model hierarchy, set the configuration parameter, “Shared code placement” (Simulink Coder) to **Auto**. Otherwise, for each model that uses the subsystem, set the model configuration parameter **Shared code placement** to **Shared location**.

If a reusable library subsystem uses a shared local data store and you configure default mapping for model data elements, leave the default storage class mapping for category **Shared local data stores** set to **Default**.

Generate Reusable Code for Subsystems Shared Across Models

This example shows how to configure a reusable library subsystem and generate a reusable function for a subsystem shared across referenced models. The result is reusable code for the subsystem, which is generated to the shared utility folder (`slprj/target/_sharedutils`).

- “Create a reusable library subsystem.” on page 6-55
- “Create the example model.” on page 6-58
- “Set configuration parameters of the top model.” on page 6-60
- “Create and propagate a configuration reference.” on page 6-60
- “Generate and view the code.” on page 6-61

Create a reusable library subsystem.

- 1 In the Simulink Editor, select **File > New > Library**. Open `rtwdemo_ssreuse` to copy and paste subsystem `SS1` into the Library Editor. This action loads the variables for `SS1` into the base workspace. Rename the subsystem block to `RLS`.

- 2 Click the Subsystem block and press **Ctrl+U** to view the contents of subsystem RLS.

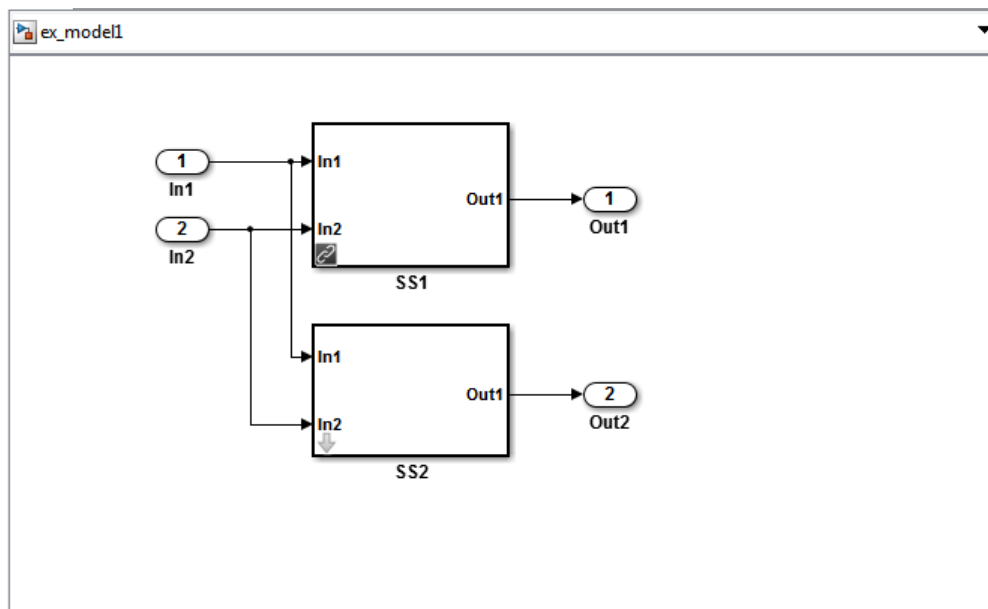

- 3 To configure the subsystem, in the Library editor, right-click RLS. In the context menu, select **Block Parameters(Subsystem)**. In the Subsystem Parameters dialog box, choose the following options:
 - Select **Treat as an atomic unit**.
 - On the **Code Generation** tab:
 - Set **Function packaging** to Reusable function.
 - Set **Function name options** to User specified and verify that the **Function name** is set to myfun.
 - Set **File name options** to Auto.
- 4 Click **Apply** and **OK**.

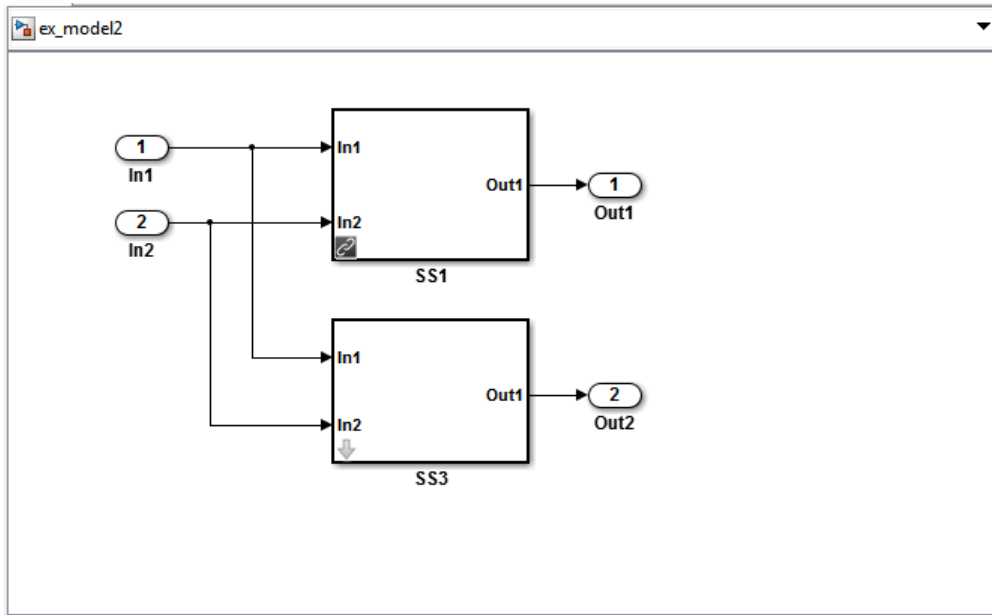

- 5 Save the reusable library subsystem as `ssreuselib`, which creates a file, `ssreuselib.slx`.

Create the example model.

- 1 Create a model which includes one instance of RLS from `ssreuselib`. Name this subsystem `SS1`. Add another subsystem and name it `SS2`. Name the model `ex_model1`.

- 2 Create another model which includes one instance of RLS from `ssreuselib`. Name this subsystem `SS1`. Add another subsystem and name it `SS3`. Name the model `ex_model2`.

- 3 Create a top model with two model blocks that reference `ex_model1` and `ex_model2`. Save the top model as `ex_md1ref_ssreuse`.

Set configuration parameters of the top model.

- 1 With model `ex_md1ref_ssreuse` open in the Simulink Editor, select **Simulation > Model Configuration Parameters** to open the Configuration Parameters dialog box.
- 2 On the **Solver** pane, specify the **Type** as Fixed-step.
- 3 On the **Model Referencing** pane, select **Pass fixed-size scalar root inputs by value for code generation**.
- 4 On the **Code Generation > Report** pane, select **Create code generation report** and **Open report automatically**.
- 5 On the **Code Generation > Interface** pane, set the “Shared code placement” (Simulink Coder) to Shared location.
- 6 On the **Code Generation > Symbols** pane, set the **Maximum identifier length** to 256. This step is optional.
- 7 Click **Apply** and **OK**.

Create and propagate a configuration reference.

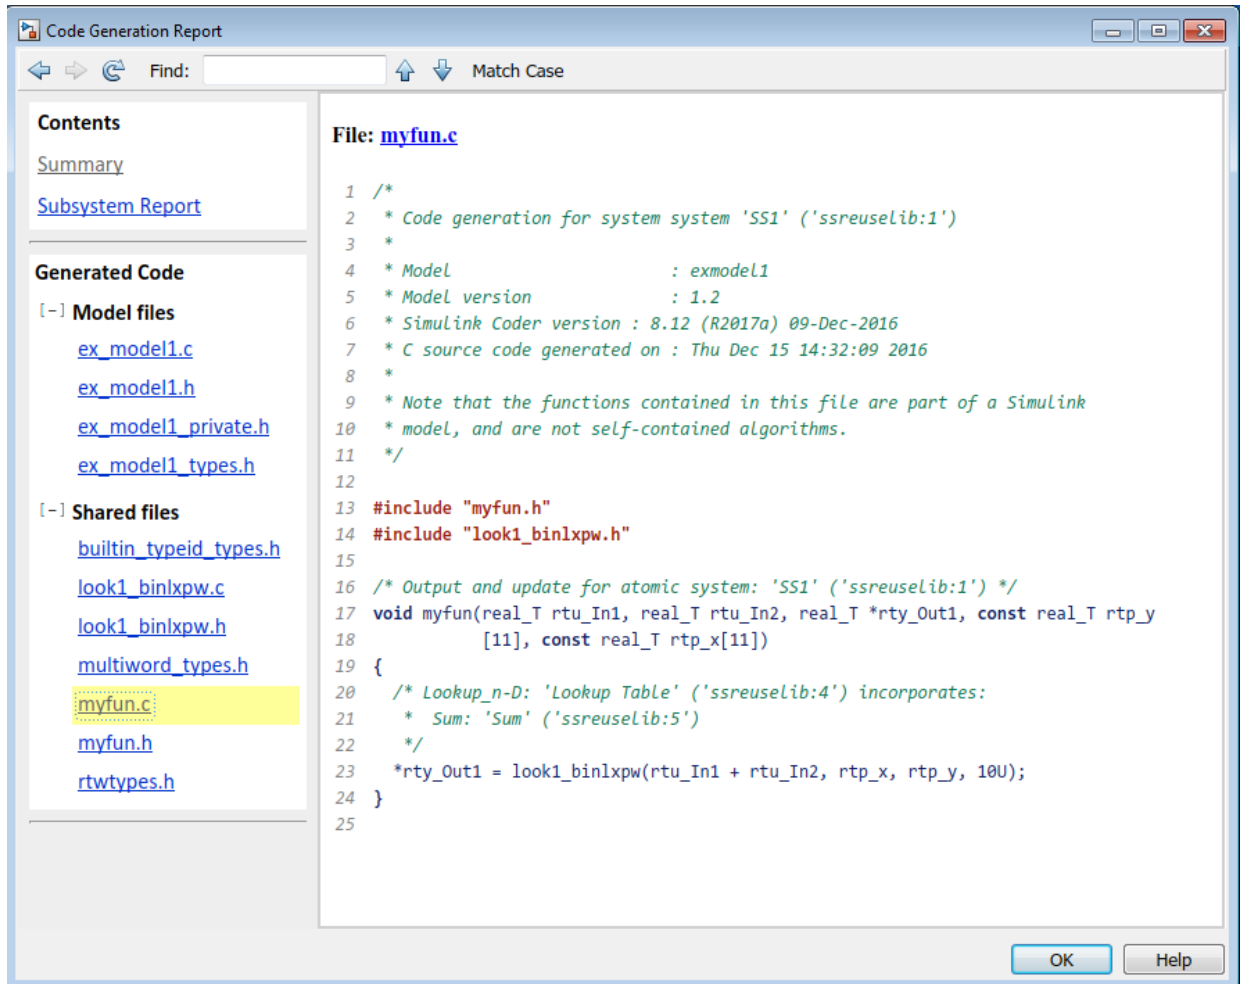

- 1 In the Simulink Editor, select **View > Model Explorer** to open the Model Explorer. In the left navigation column of the Model Explorer, expand the `ex_md1ref_ssreuse` node.

- 2 Right-click **Configuration** and select **Convert to Configuration Reference**.
- 3 In the **Convert Active Configuration to Reference** dialog box, click **OK**. This action converts the model configuration set to a configuration reference, `Simulink.ConfigSetRef`, and creates the configuration reference object, `configSetObj`, in the base workspace.
- 4 In the left navigation column, right-click **Reference (Active)** and select **Propagate to Referenced Models**.
- 5 In the **Configuration Reference Propagation to Referenced Models** dialog box, select the referenced models in the list. Click **Propagate**.

Now, the top model and referenced models use the same configuration reference, **Reference (Active)**, which points to a model configuration reference object, `configSetObj`, in the base workspace. When you save your model, you also need to export the `configSetObj` to a MAT-file.

Generate and view the code.

- 1 To generate code, in the Simulink Editor, press **Ctrl+B**. After the code is generated, the code generation report opens.
- 2 To view the code generation report for a referenced model, in the left navigation pane, in the **Referenced Models** section, select `ex_model1`. The code generation report displays the generated files for `ex_model1`.
- 3 In the left navigation pane, expand the **Shared files**. The code generator uses the reusable library subsystem name. The code for subsystem `SS1` is in `myfun.c` and `myfun.h`.

- 4 Click **Back** and navigate to the ex_model2 code generation report. ex_model2 uses the same source code, myfun.c and myfun.h, as the code for ex_model1. Your subsystem function and file names will be different.

Generate Reusable Code from Stateflow Atomic Subcharts

Generate Reusable Code for Linked Atomic Subcharts

To specify code generation parameters for linked atomic subcharts from the same library:

- 1 Open the library model that contains your atomic subchart.
- 2 Unlock the library.
- 3 Right-click the library chart and select **Block Parameters**.
- 4 In the dialog box, specify the following parameters:
 - a On the **Main** tab, select **Treat as atomic unit**.
 - b On the **Code Generation** tab, set **Function packaging** to Reusable function.
 - c Set **File name options** to User specified.
 - d For **File name**, enter the name of the file with no extension.
 - e Click **OK** to apply the changes.
- 5 (OPTIONAL) Customize the generated function names for atomic subcharts:
 - a Open the Model Configuration Parameters dialog box.
 - b On the **Code Generation** pane, set **System target file** to `ert.tlc`.
 - c Navigate to the **Code Generation > Symbols** pane.
 - d For **Subsystem methods**, specify the format of the function names using a combination of the following tokens:
 - `$R` — root model name
 - `$F` — type of interface function for the atomic subchart
 - `$N` — block name
 - `$H` — subsystem index
 - `$M` — name-mangling text
 - e Click **OK** to apply the changes.

When you generate code for your model, a separate file stores the code for linked atomic subcharts from the same library.

Generate Reusable Code for Unlinked Atomic Subcharts

To specify code generation parameters for an unlinked atomic subchart:

- 1 In your chart, right-click the atomic subchart and select **Properties**.
- 2 In the dialog box, specify the following parameters:
 - a Set **Code generation function packaging** to Reusable function.
 - b Set **Code generation file name options** to User specified.
 - c For **Code generation file name**, enter the name of the file with no extension.
 - d Click **OK** to apply the changes.
- 3 (OPTIONAL) Customize the generated function names for atomic subcharts:
 - a Open the Model Configuration Parameters dialog box.
 - b On the **Code Generation** pane, set **System target file** to `ert.tlc`.
 - c Navigate to the **Code Generation > Symbols** pane.
 - d For **Subsystem methods**, specify the format of the function names using a combination of the following tokens:
 - \$R — root model name
 - \$F — type of interface function for the atomic subchart
 - \$N — block name
 - \$H — subsystem index
 - \$M — name-mangling text
 - e Click **OK** to apply the changes.

When you generate code for your model, a separate file stores the code for the atomic subchart. For more information, see “Generate Reusable Code for Unit Testing” on page 10-8.

Generate Reusable Code for Unit Testing

Convert a State to an Atomic Subchart

To convert state A to an atomic subchart, right-click the state and select **Group & Subchart > Atomic Subchart**. State A changes to an atomic subchart:

Set Up a Standalone C File for the Atomic Subchart

- 1 Open the properties dialog box for A.
- 2 Set **Code generation function packaging** to Reusable function.
- 3 Set **Code generation file name options** to User specified.
- 4 For **Code generation file name**, enter saturator as the name of the file.
- 5 Click **OK**.

Set Up the Code Generation Report

- 1 Open the Model Configuration Parameters dialog box.
- 2 In the **Code Generation** pane, set **System target file** to `ert.tlc`.
- 3 In the **Code Generation > Report** pane, select **Create code generation report**.
This step automatically selects **Open report automatically** and **Code-to-model**.
- 4 Select **Model-to-code**.
- 5 Click **Apply**.

Customize the Generated Function Names

- 1 In the Model Configuration Parameters dialog box, go to the **Code Generation > Symbols** pane.
- 2 Set **Subsystem methods** to the format scheme $\$R\$N\$M\F , where:
 - $\$R$ is the root model name.
 - $\$N$ is the block name.
 - $\$M$ is the mangle token.
 - $\$F$ is the type of interface function for the atomic subchart.

For more information, see “Subsystem methods” (Simulink Coder).

- 3 Click **Apply**.

Generate Code for Only the Atomic Subchart

To generate code for your model, press **Ctrl+B**. In the code generation report that appears, you see a separate file that contains the generated code for the atomic subchart.

To inspect the code for `saturation.c`, click the hyperlink in the report to see the following code:

The screenshot shows a window titled "Code Generation Report" with a navigation pane on the left and a code editor on the right. The navigation pane includes "Contents" (Summary, Subsystem Report, Code Interface Report, Traceability Report) and "Generated Files" (Main file: ert_main.c; Model files: ex_reuse_states.c, ex_reuse_states.h, ex_reuse_states_private.h, ex_reuse_states_types.h; Subsystem files: saturator.c, saturator.h; Data files: ex_reuse_states_data.c; Utility files (1)). The code editor displays the following C code:

```

27  /* Function for Stateflow: '<S1>/A' */
28  void ex_reuse_states_A_during(real_T rtu_u1, real_T *rty_y1,
29  rtDW_u ex_reuse_states *localDW)
30  {
31  /* During: Chart/A */
32  localDW->isStable = TRUE;
33  switch (localDW->is_c2_ex_reuse_states) {
34  case ex_reuse_states_IN_Neg:
35  /* During 'Neg': '<S2>:7' */
36  if (rtu_u1 > 0.0) {
37  /* Transition: '<S2>:5' */
38  localDW->isStable = FALSE;
39  localDW->is_c2_ex_reuse_states = ex_reuse_states_IN_Pos;
40
41  /* Entry 'Pos': '<S2>:6' */
42  (*rty_y1) = 1.0;
43  }
44  break;
45
46  case ex_reuse_states_IN_Pos:
47  /* During 'Pos': '<S2>:6' */
48  if (rtu_u1 < 0.0) {
49  /* Transition: '<S2>:4' */
50  localDW->isStable = FALSE;
51  localDW->is_c2_ex_reuse_states = ex_reuse_states_IN_Neg;
52
53  /* Entry 'Neg': '<S2>:7' */
54  (*rty_y1) = -1.0;
55  }
56  break;
57
58  default:
59  if (rtu_u1 > 0.0) {
60  /* Transition: '<S2>:2' */
61  localDW->isStable = FALSE;
62  localDW->is_c2_ex_reuse_states = ex_reuse_states_IN_Pos;
63
64  /* Entry 'Pos': '<S2>:6' */
65  (*rty_y1) = 1.0;
66  } else {
67  /* Transition: '<S2>:3' */
68  localDW->isStable = FALSE;
69  localDW->is_c2_ex_reuse_states = ex_reuse_states_IN_Neg;
70
71  /* Entry 'Neg': '<S2>:7' */
72  (*rty_y1) = -1.0;
73  }
74  break;
75  }
76  }
77

```

At the bottom right of the window, there are "OK" and "Help" buttons.

Line 28 shows that the `during` function generated for the atomic subchart has the name `ex_reuse_states_A_during`. This name follows the format scheme `RNMF` specified for **Subsystem methods**:

- `$R` is the root model name, `ex_reuse_states`.
- `$N` is the block name, `A`.
- `$M` is the mangle token, which is empty.
- `$F` is the type of interface function for the atomic subchart, `during`.

Note The line numbers shown can differ from the numbers that appear in your code generation report.

Generate Shared Utility Code

When to Generate Shared Utility Code

Blocks in a model can require common functionality to implement their algorithms. Consider modularizing this functionality into standalone support or helper functions. This approach can be more efficient than inlining the code for the functionality for each block instance. To decide about using a library or a shared utility, consider:

- Packaging functions that can have multiple callers into a library when the functions are defined statically. That is, before you use the code generator to produce code for your model, the function source code exists in a file.
- Packaging functions that can have multiple callers as shared utilities (produced during code generation) when the functions cannot be defined statically. For example, several model- and block-specific properties specify which functions are used and their behavior. Also, these properties determine type definitions (for example, `typedef`) in shared utility header files. The number of possible combinations of properties that determine unique behavior make it impractical to define statically the possible function files before code generation.

Configure Naming of Generated Functions

Configure a default naming rule for generated shared utility functions by using one of these methods.

Configuration	Action
A new model or an existing model for which you have mapped default customization settings by using the Code Mapping Editor or code default mapping programming interface	In the Embedded Coder Dictionary , define a function customization template that specifies a custom function naming rule. Then, in the Code Mapping Editor or by using the code default mapping programming interface, map the Shared utility function category to that template. For more information, see “Configure Default Code Generation for Categories of Model Data and Functions” on page 21-7.

Configuration	Action
A model created in a release earlier than R2018a and that has not been configured with the Code Mapping Editor or default mapping programming interface	Set the model configuration parameter Shared utilities identifier format (CustomSymbolsStrUtil) to a custom function naming rule. For more information, see “Identifier Format Control” on page 39-22.

Once you use the **Code Mapping Editor** or default mapping programming interface to configure a model, setting the **Shared utilities identifier format** parameter has no effect.

The naming rule for shared utility functions must include the conditional checksum token \$C. To customize the length of the checksum that the code generator produces, use the **Shared checksum length** (SharedChecksumLength) parameter. Increasing the length of the checksum reduces the probability of clashes.

This example shows the customization of shared utility function names.

- 1 Open the example model `rtwdemo_crlmath`.
- 2 Set model configuration parameter **Shared code placement** to Shared location.
- 3 Set parameter **Shared utilities identifier format** as `mymodel_$$C`. You can customize this format with any string. However, you must include token \$C.
- 4 Set parameter **Shared checksum length** to 5.
- 5 Generate code and a code generation report.
- 6 In the left navigation pane of the report, review the list generated files for shared utilities under **Shared files**.

Control Placement of Shared Utility Code

Control placement of shared utility code with the model configuration parameter **Shared code placement**. The default option value is `Auto`. For this setting, the code generator places required code for fixed-point and other utilities in the `model.c` file, the `model.cpp` file, or a separate file in the build folder (for example, `vdp_grt_rtw`) if a model does not contain existing shared utility code or one of these blocks:

- Model blocks

- Simulink Function blocks
- Function Caller blocks
- Calls to Simulink Functions from Stateflow or MATLAB Function blocks
- Stateflow graphical functions when you select the **Export Chart Level Functions** parameter

If a model contains one or more of the preceding blocks, the code generator creates and uses a shared utilities folder within `slprj`. The naming convention for shared utility folders is `slprj/target/_sharedutils`. *target* is `sim` for simulations with Model blocks or the name of the system target file for code generation.

```
slprj/sim/_sharedutils      % folder used with simulation
slprj/grt/_sharedutils     % folder used with grt.tlc STF
slprj/ert/_sharedutils     % folder used with ert.tlc STF
slprj/mytarget/_sharedutils % folder used with mytarget.tlc STF
```

To force a model build to use the `slprj` folder for shared utility generation, even when the current model does not contain existing shared utility code or one of the preceding blocks, set parameter **Shared code placement** to `Shared location`. The code generator places utilities under the `slprj` folder rather than in the normal build folder. This setting is useful when you are manually combining code from several models, because it prevents symbol collisions between the models.

Control Placement of `rtwtypes.h` for Shared Utility Code

The generated `rtwtypes.h` header file provides fundamental type definitions, `#define` statements, and enumerations. For more information, see “`rtwtypes.h`” on page 36-50.

Control placement of `rtwtypes.h` file by selecting whether the build process uses the shared utilities folder. If the model build uses a shared utilities folder, the build process places `rtwtypes.h` in `slprj/target/_sharedutils`. Otherwise, the software places `rtwtypes.h` in `model_target_rtw`.

Adding a model to a model hierarchy or changing an existing model in the hierarchy can result in updates to the shared `rtwtypes.h` file during code generation. If updates occur, recompile and, depending on your development process, reverify previously generated code. To minimize updates to the `rtwtypes.h` file, make the following changes in the Configuration Parameters dialog box:

- Select **Support: complex numbers** even if the model does not currently use complex data types. Selecting this parameter protects against a future requirement to add support for complex data types when integrating code.

- Clear the **Support non-inlined S-functions** parameter. If you use noninlined S-functions in the model, this option generates an error.
- Clear the **Classic call interface** parameter. This parameter setting disables use of the GRT system target file.

Avoid Duplicate Header Files for Exported Data

Exported header files appear in the shared utility folder when:

- You control the file placement of declarations for signals, parameters, and states by defining and applying storage classes.
- The code generator places utility code in a shared location.

For example, you can specify a header file for a piece of data through:

- A storage class that you define in the **Embedded Coder Dictionary** and map to categories of model data in the **Code Mapping Editor**.
- The **Code Generation** tab in a Signal Properties dialog box.
- The `HeaderFile` property of a data object. Data objects are objects of the classes `Simulink.Signal` and `Simulink.Parameter`.

If you want the declaration to appear in the file `model.h`, it is a best practice to leave the header file name unspecified. By default, the code generator places data declarations in `model.h`.

If you specify `model.h` as the header file name, and if the code generator places utility code in a shared location, you cannot generate code from the model. The code generator cannot create the file `model.h` in both the model build folder and the shared utility folder.

Reduce Shared Utility Code Generation with Incremental Builds

You can specify that the model build generates C source files in a shared utilities folder. See “Generate Shared Utility Code” (Simulink Coder). These files include C source files that contain function definitions and header files that contain macro definitions. For this discussion, the term functions means functions and macros.

Blocks within the same model and blocks in different models can use a shared function when you use model reference or when you build multiple standalone models from the

same start build folder. The code generator produces the code for a given function only once for the block that first triggers code generation. As the product determines the requirement to generate function code for subsequent blocks, it performs a file existence check. If the file exists, the model build does not regenerate the function. The shared utility code mechanism requires that a given function and file name represent the same functional behavior regardless of which block or model generates the function. To satisfy this requirement:

- Model properties that determine function behavior contribute to the shared utility checksum or determine the function and file name.
- Block properties that determine the function behavior also determine the function and file name.

During compilation, makefile rules for the shared utilities folder select compilation of only new C files and incrementally archive the object file into the shared utility library, `rtwshared.lib`, or `rtwshared.a`. Incremental compilation also occurs.

Manage the Shared Utility Code Checksum

When you set the model configuration parameter **Shared code placement** to **Shared location** or when the model contains Model blocks, the code generator places shared code in the shared utilities folder. The build process generates a shared utilities checksum of the code generation configuration for the shared code.

During subsequent code generation, if the checksum file `s\prj\target_sharedutils/checksummap.mat` exists relative to the current folder, the code generator reads that file. The code generator verifies that the current model that you are building has configuration properties that match the checksum of properties from the shared utility model. If mismatches occur between the properties defined in `checksummap.mat` and the current model properties, you see an error. Use the error message to manage the checksum (for example, diagnose and resolve the configuration issues with the current model).

For more information, see “Reduce Shared Utility Code Generation with Incremental Builds” (Simulink Coder).

- “View the Shared Utility Checksum Hash Table” on page 6-75
- “Relate the Shared Utility Checksum to Configuration Parameters” on page 6-76

View the Shared Utility Checksum Hash Table

It is helpful to view the property values that contribute to the checksum. This example uses the `rtwdemo_lct_start_term.slx` model. To load the `checksum.mat` file into MATLAB and view the `targetInfoStruct` that defines the checksum-related properties:

- 1 Open the `rtwdemo_lct_start_term.slx` model. In the Command Window, type:

```
rtwdemo_lct_start_term
```

- 2 Create and move to a new working folder.

```
mkdir C:\Temp\demo
cd C:\Temp\demo
```

- 3 Save a copy of the model in the folder.

- 4 Build the model. This model is already set up to produce shared utilities.

- 5 Move to the `_sharedutils` folder created by the build process.

```
cd C:\Temp\demo\slprj\grt\_sharedutils
```

- 6 Load the `checksummap.mat` file into MATLAB.

```
load checksummap
```

- 7 Display the contents of `hashTbl.targetInfoStruct` and examine the checksum-related property values.

```
hashTbl.targetInfoStruct
```

For this example, the Command Window displays `hashTbl.targetInfoStruct` for the shared utilities that you generated from the model:

```

    ShiftRightIntArith: 'on'
    ProdShiftRightIntArith: 'on'

Relate the Shared Utility Checksum to Configuration Parameters

Examine the `targetInfoStruct` hash table from the shared utility model. Some key-value pairs relate directly to a model property. Other pairs relate to groups of properties.

The following table describes the key-value pairs.

Key Names	Model Properties
ShiftRightIntArith	TargetShiftRightIntArith
ProdShiftRightIntArith	ProdShiftRightIntArith
Endianess	TargetEndianess
ProdEndianess	ProdEndianess

Key Names	Model Properties
wordlengths	TargetBitPerChar, TargetBitPerShort, TargetBitPerInt, TargetBitPerLong, TargetBitPerLongLong, TargetBitPerFloat, TargetBitPerDouble, TargetBitPerPointer
Prodwordlengths	ProdBitPerChar, ProdBitPerShort, ProdBitPerInt, ProdBitPerLong, ProdBitPerLongLong, ProdBitPerFloat, ProdBitPerDouble, ProdBitPerPointer
TargetWordSize	TargetWordSize
ProdWordSize	ProdWordSize
TargetHWDeviceType	TargetHWDeviceType
ProdHWDeviceType	ProdHWDeviceType
TargetIntDivRoundTo	TargetIntDivRoundTo
ProdIntDivRoundTo	ProdIntDivRoundTo
tmfName	TemplateMakefile
toolchainName	Toolchain
computer	return value of the computer command
UseDivisionForNetSlopeComputation	UseDivisionForNetSlopeComputation
PurelyIntegerCode	PurelyIntegerCode
PortableWordSizes	PortableWordSizes
SupportNonInlinedSFcns	SupportNonInlinedSFcns
RTWReplacementTypes	EnableUserReplacementTypes, ReplacementTypes
MaxIdInt8	MaxIdInt8
MinIdInt8	MinIdInt8
MaxIdUInt8	MaxIdUInt8
MaxIdInt16	MaxIdInt16

Key Names	Model Properties
MinIdInt16	MinIdInt16
MaxIdUInt16	MaxIdUInt16
MaxIdInt32	MaxIdInt32
MinIdInt32	MinIdInt32
MaxIdUInt32	MaxIdUInt32
BooleanTrueId	BooleanTrueId
BooleanFalseId	BooleanFalseId
TypeLimitIdReplacementHeaderFile	TypeLimitIdReplacementHeaderFile
SharedCodeRepository	reserved (internal use only)
TargetLang	TargetLang

Generate Shared Utility Code for Fixed-Point Functions

An important set of generated functions that the model build places in the shared utility folder are the fixed-point support functions. Based on model and block properties, there are many possible versions of fixed-point utilities functions that make it impractical to provide a complete set as static files. Generating only the required fixed-point utility functions during the code generation process is an efficient alternative.

The shared utility checksum mechanism makes sure that several critical properties are identical for models that use the shared utilities. For the fixed-point functions, there are additional properties that determine function behavior. The mechanism codes these properties into the functions and file names to maintain requirements. The additional properties include:

Category	Function/Property
Block properties	<ul style="list-style-type: none"> Fixed-point operation that the block performs Fixed-point data type and scaling (Slope, Bias) of function inputs and outputs Overflow handling mode (Saturation, Wrap) Rounding Mode (Floor, Ceil, Zero)
Model properties	<code>get_param(bdroot, 'NoFixptDivByZeroProtection')</code>

The property-based naming convention for the fixed-point utilities is as follows:

```
operation + [zero protection] + output data type + output bits +
[input1 data] + input1 bits + [input2 data type + input2 bits] +
[shift direction] + [saturate mode] + [round mode]
```

The file names shown are examples of generated fixed-point utility files. The function or macro names in the file are identical to the file name without the extension.

```
FIX2FIX_U12_U16.c
FIX2FIX_S9_S9_SR99.c
ACCUM_POS_S30_S30.h
MUL_S30_S30_S16.h
div_nzp_s16s32_floor.c
div_s32_sat_floor.c
```

For these examples, the table shows how the respective fields correspond.

The `ACCUM_POS` example uses the output variable as one of the input variables. So, the file and macro name only contain the output and second input.

The second `div` example has identical data type and bits for both inputs and the output. So, the file and function name only include the output.

Operation	FIX2FIX	FIX2FIX	ACCUM_POS	MUL	div	div
Zero protection	NULL	NULL	NULL	NULL	<code>_nzp</code>	NULL
Output data type	<code>_U</code>	<code>_S</code>	<code>_S</code>	<code>_S</code>	<code>_s</code>	<code>_s</code>
Output bits	12	9	30	30	16	32
Input data type	<code>_U</code>	<code>_S</code>	<code>_S</code>	<code>_S [and _S]</code>	<code>s</code>	NULL
Input bits	16	9	30	<code>30 [and 16]</code>	32	NULL
Shift direction	NULL	SR99	NULL	NULL	NULL	NULL
Saturate mode	NULL	NULL	NULL	NULL	NULL	<code>_sat</code>
Round mode	NULL	NULL	NULL	NULL	<code>_floor</code>	<code>_floor</code>

- “Generate Shared Utility Code for Custom Data Types” (Simulink Coder)
- “Cross-Release Shared Utility Code Reuse” (Simulink Coder)

Generate Shared Utility Code for Custom Data Types

By default, if a model employs a custom data type (such as a `Simulink.AliasType` object or an enumeration class), the code generator places the corresponding type definition (`typedef`) in the `model_types.h` file. When you generate code from multiple models, each model duplicates the type definition. These duplicate definitions can prevent you from compiling the bodies of generated code together.

However, you can configure the code generator to place a single type definition in a header file in the `_sharedutils` folder. Then, when you generate code from a model, if the type definition already exists in the `_sharedutils` folder, the code generator does not duplicate the definition, but instead reuses it through inclusion (`#include`).

Through this mechanism, you can share:

- Simulink data type objects that you instantiate from the classes `Simulink.AliasType`, `Simulink.Bus`, and `Simulink.NumericType`. For basic information about creating and using these objects, see “Control Data Type Names in Generated Code” on page 24-2 and `Simulink.Bus`.
- Enumerations that you define, for example, by authoring an enum class in a script file or by using the function `Simulink.defineIntEnumType`. For basic information about defining enumerations in Simulink, see “Use Enumerated Data in Simulink Models” (Simulink).

To share a custom data type across multiple models:

- 1 Define the data type. For example, create the `Simulink.AliasType` object.
- 2 Set data scope and header file properties to specific values that enable sharing.

For a data type object, set the `DataScope` property to 'Exported' and, optionally, specify the header file name through the `HeaderFile` property.

For an enumeration that you define as an enum class in a script file, implement the `getDataScope` method (with return value 'Exported') and, optionally, implement the `getHeaderFile` method.

For an enumeration that you define by using the `Simulink.defineIntEnumType` function, set the 'DataScope' pair argument to 'Exported' and, optionally, specify the 'HeaderFile' pair argument

- 3 Use the data type in the models.

- 4 Before generating code from each model, set the model configuration parameter **Shared code placement** to `Shared location`.
- 5 Generate code from the models.

Note You can configure the definition of the custom data type to appear in a header file in the `_sharedutils` folder. The shared utility functions that the model build generates into the `_sharedutils` folder do not use the custom data type name. Only model code located in code folders for each model uses the custom data type name.

Shared Constant Parameters for Code Reuse

You can share the generated code for constant parameters across models if either of the following conditions applies:

- Constant parameters are shared in a model reference hierarchy.
- The model configuration parameter “Shared code placement” (Simulink Coder) is set to `Shared location`.

If you do not want to generate shared constants, and **Shared code placement** is set to `Shared location`, set the parameter `GenerateSharedConstants` to `off`. For example, to turn off shared constants for the current model, in the Command Window, type the following.

```
set_param(gcs, 'GenerateSharedConstants', 'off');
```

The code generator produces shared constant parameters individually and places them in the file `const_params.c`. The code generator places that file in the shared utilities folder `slprj/target/_sharedutils`.

For example, if a constant has multiple uses within a model reference hierarchy where the top model is named `topmod`, the code for the shared constant is as follows:

- In the shared utility folder, `slprj/grt/_sharedutils`, the constant parameters are defined in `const_params.c` and named `rtCP_pooled_` appended to a unique checksum:

```
extern const real_T rtCP_pooled_lfcjjmohiecj[7];
const real_T rtCP_pooled_lfcjjmohiecj[7] = { 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0 };
```

```
extern const real_T rtCP_pooled_ppphohdbfcba[7];
const real_T rtCP_pooled_ppphohdbfcba[7] = { 7.0, 6.0, 5.0, 4.0, 3.0, 2.0, 1.0 };
```

- In `top_model_private.h` or in a referenced model, `ref_model_private.h`, for better readability, the constants are renamed as follows:

```
extern const real_T rtCP_pooled_lfcjjmohiecj[7];
extern const real_T rtCP_pooled_ppphohdbfcba[7];

#define rtCP_Constant_Value    rtCP_pooled_lfcjjmohiecj /* Expression: [1 2 3 4 5 6 7]
                          * Referenced by: '<Root>/Constant' */
#define rtCP_Gain_Gain        rtCP_pooled_ppphohdbfcba /* Expression: [7 6 5 4 3 2 1]
                          * Referenced by: '<Root>/Gain' */
```

- In `topmod.c` or `refmod.c`, the call site might be:

```
for (i = 0; i < 7; i++) {
    topmod_Y.Out1[i] = (topmod_U.In1 + rtCP_Constant_Value[i]) * rtCP_Gain_Gain[i];
}
```

The code generator attempts to generate constants as individual constants to the `const_params.c` file in the shared utilities folder. Otherwise, constants are generated as described in “Code Generation of Constant Parameters” on page 3-13.

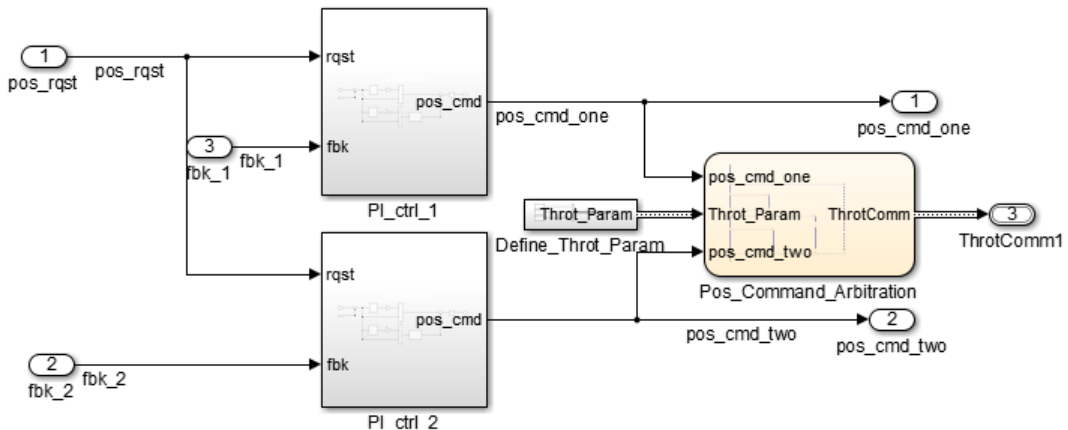

Suppress Shared Constants in the Generated Code

You can choose whether the code generator produces shared constants and shared functions. You might want to be able to keep the code and data separate between subsystems, or you might find that sharing constants results in a memory shortage during code generation.

You can change this setting programmatically by using the parameter `GenerateSharedConstants` with `set_param` and `get_param`.

In the following example, when `GenerateSharedConstants` is set to on, the code generator defines the constant values in the `_sharedutils` folder in the `const_params.c` file. When `GenerateSharedConstants` is set to off, the code generator defines the constant values in a nonshared area, in the `model_ert_rtw` file in the `model_data.c` file.

Open the model `rtwdemo_throttlecntrl`:

In the Configuration parameters dialog box, on the **Code Generation > Interface** pane, verify that “Shared code placement” (Simulink Coder) is set to Shared location. If

Shared code placement is set to Auto, the `GenerateSharedConstants` setting is ignored. If you try to set the parameter value, an error message appears. The default value of `GenerateSharedConstants` is on.

In the Command Window, set `GenerateSharedConstants` to on:

```
>> set_param('rtwdemo_throttlecntrl','GenerateSharedConstants','on')
```

You see the shared constant definitions in the folder `s\prj\grt_sharedutils`, in the file `const_params.c`:

```
extern const real_T rtCP_pooled_H4eTKtECwveN[9];
const real_T rtCP_pooled_H4eTKtECwveN[9] = { 1.0, 0.75, 0.6, 0.0, 0.0, 0.0, 0.6,
    0.75, 1.0 };

extern const real_T rtCP_pooled_SghuHxKVKGHD[9];
const real_T rtCP_pooled_SghuHxKVKGHD[9] = { -1.0, -0.5, -0.25, -0.05, 0.0, 0.05,
    0.25, 0.5, 1.0 };

extern const real_T rtCP_pooled_WqWb2t17NA2R[7];
const real_T rtCP_pooled_WqWb2t17NA2R[7] = { -1.0, -0.25, -0.01, 0.0, 0.01, 0.25,
    1.0 };

extern const real_T rtCP_pooled_Ygna10wM3c14[7];
const real_T rtCP_pooled_Ygna10wM3c14[7] = { 1.0, 0.25, 0.0, 0.0, 0.0, 0.25, 1.0
    } ;
```

In the Command Window, set `GenerateSharedConstants` to off:

```
>> set_param('rtwdemo_throttlecntrl','GenerateSharedConstants','off')
```

You can see the unshared constants in the folder `rtwdemo_throttlecntrl_grt_rtw`, in the file `rtwdemo_throttlecntrl_data.c`:

```
/* Constant parameters (auto storage) */
const ConstP_rtwdemo_throttlecntrl_T rtwdemo_throttlecntrl_ConstP = {
    /* Pooled Parameter (Expression: P_OutMap)
     * Referenced by:
     *   '<S2>/Proportional Gain Shape'
     *   '<S3>/Proportional Gain Shape'
     */
    { 1.0, 0.25, 0.0, 0.0, 0.0, 0.25, 1.0 },

    /* Pooled Parameter (Expression: P_InErrMap)
     * Referenced by:
     *   '<S2>/Proportional Gain Shape'
     *   '<S3>/Proportional Gain Shape'
     */
    { -1.0, -0.25, -0.01, 0.0, 0.01, 0.25, 1.0 },

    /* Pooled Parameter (Expression: I_OutMap)
     * Referenced by:
```

```

* '<S2>/Integral Gain Shape'
* '<S3>/Integral Gain Shape'
*/

```

Shared constant Parameters Limitations

No shared constants or shared functions are generated for a model when:

- The model has a code replacement library (CRL) that is specified for data alignment.
- The model is specified to replace data type names in the generated code.
- The **Memory Section** for constants is `MemVolatile` or `MemConstVolatile`.
- The parameter `GenerateSharedConstants` is set to `off`.

Individual constants are not shared, if:

- A constant is referenced by a non-inlined S-function.
- A constant has a user-defined type where **Data Scope** is not set to `Exported`.

Configure Model Parameters for Simulink Coder

Configure Run-Time Environment Options

When you use Simulink software to create and execute a model and use the code generator to produce C or C++ code, consider your configuration for up to three run-time environments:

- The MATLAB development computer run-time environment that runs MathWorks software during application development.
- The production hardware run-time environment in which you deploy an application when it is put into production.
- The test hardware run-time environment in which you test an application under development before deployment.

One run-time environment can serve in multiple capacities, but the run-time environments remain conceptually distinct. Often, the MATLAB development computer is the test hardware. Typically, the production hardware is different from, and less powerful than, the MATLAB development or the test hardware. Many types of production hardware can do little more than run a downloaded executable file.

Provide information about the production hardware board and the compiler that you use with it when:

- You use Simulink software to simulate a model for which you later generate code
- You use the code generator to produce code for deployment on *production* hardware

The software uses the board and compiler information to get bit-true agreement for the results of integer and fixed-point operations performed in simulation and in code generated for the production hardware. The code generator uses the information to create code that executes with maximum efficiency.

When you generate code for testing on *test* hardware, provide information about the test hardware board and the compiler that you use. The code generator uses this information to create code that provides bit-true agreement between results from:

- Integer and fixed-point operations performed in simulation
- Generated code run on the production hardware
- Generated code run on the test hardware

You can achieve bit-true agreement for results even if the production and test hardware are different. Where the C standard does not completely define behavior, the compilers for the two types of hardware can use different defaults.

Configure Production and Test Hardware

You can specify model simulation or code generation for a specific hardware board and its device type. For example, you can set the data size, byte ordering, and compiler behavior, such as integer rounding. You can configure:

- The production hardware and the compiler that you use with it. This information affects simulation and code generation. See “Example Production Hardware Setting That Affects Normal Mode Simulation” on page 7-14.
- The test hardware and the compiler that you use with it. This information affects only code generation.

Configure production hardware by selecting **Configuration Parameters > Hardware Implementation**. By default, the Hardware Implementation pane lists **Hardware board**, **Device vendor**, and **Device type** parameter fields only. Unless you have installed hardware support packages, **Hardware board** lists values None or Determine by Code Generation system target file, and Get Hardware Support Packages. After installing a hardware support package, the list also includes the corresponding hardware board name. If you select a hardware board name, parameters for that board appear. To set device details, such as data size and byte ordering, click **Device details**.

Configure test hardware on the **Configuration Parameters > Hardware Implementation > Advanced parameters** pane. To enable parameters for configuring test hardware details, disable the **Configuration Parameters > Hardware Implementation > Advanced parameters > Test hardware is the same as production hardware** parameter. Code generated for test hardware executes in the environment specified by the test hardware parameters. The code behaves as if it were executing in the environment specified for the production hardware. For more information, see “Test Hardware Considerations” on page 7-14.

Default values and properties appear as initial values in the **Hardware Implementation** pane when:

- You specify a **System target file** in the **Code Generation** pane.
- The system target file specifies a default microprocessor and its hardware properties.

You cannot change parameters that have only one possible value. Parameters that have more than one possible value provide a list of valid values. If you specify hardware properties manually in **Hardware Implementation** pane, verify that these values are consistent with the system target file. Otherwise, the generated code can fail to compile or execute, or can execute but produce incorrect results.

Hardware implementation parameters describe hardware and compiler properties to MATLAB software. The code generator uses the information to produce code for the run-time environment that runs as efficiently as possible. The generated code gives bit-true agreement for the results of integer and fixed-point operations in simulation, production code, and test code.

For details about specific parameters, see “Hardware Implementation Pane” (Simulink). To see an example of **Hardware Implementation** pane capabilities, see the `rtwdemo_targetsettings` example model. For details related to configuring a hardware implementation, see:

Specify Hardware Board

Specify the hardware board that runs the code generated from your model. Select a value for **Configuration Parameters > Hardware Implementation > Hardware board**.

The Hardware Implementation pane identifies the system target file selected on **Configuration Parameters > Code Generation**.

To configure test hardware, use the **Configuration Parameters > Hardware Implementation > Advanced parameters** pane.

To enable parameters for configuring test hardware details, set `ProdEqTarget` to `off`.

Ways to Specify the Hardware Board

If	Select
The menu <i>includes</i> the name of the hardware board that you want to use.	The name of that hardware board. If you select a hardware board name, parameters for that board appear.
The menu <i>does not include</i> the name of the hardware board that you want to use.	Get Hardware Support Packages. That value opens the Support Package Installer. Install the support package that you want. After you install the support package, the menu includes relevant hardware board names.
The model configuration <i>uses</i> system target file <code>ert.tlc</code> , <code>realtime.tlc</code> , or <code>autosar.tlc</code> .	None. No hardware board is specified for the hardware implementation.
The model configuration <i>does not use</i> system target file <code>ert.tlc</code> , <code>realtime.tlc</code> , or <code>autosar.tlc</code> .	Determine by Code Generation system target file. The code generator uses the specified system target file to determine the hardware implementation.

Specify Device Vendor

To specify the vendor of the microprocessor of the hardware device, use the **Device vendor** parameter. Your selection determines the available microprocessors in the **Device type** menu. If the vendor name does not appear, select Custom Processor. Then, use the **Device type** parameter to specify the microprocessor.

- For complete lists of **Device vendor** and **Device type** values, see “Device vendor” (Simulink) and “Device type” (Simulink).
- To add **Device vendor** and **Device type** values to the default set that is displayed on the **Hardware Implementation** pane, see “Register More Device Vendor and Device Type Values” on page 7-6.

Specify the Device Type

To specify the microprocessor name from the supported devices listed for your **Device vendor** selection, use the **Device type** parameter. If the microprocessor does not appear

in the menu, change **Device vendor** to Custom Processor. Then, specify device details for your custom device.

If you select a device type for which the system target file specifies default hardware properties, the properties appear as initial values. You cannot change the value of parameters with only one possible selection. Parameters that have more than one possible value provide a menu. Select values for your hardware.

Register More Device Vendor and Device Type Values

To add **Device vendor** and **Device type** values to the default set that is displayed on the **Hardware Implementation** pane, you can use a hardware device registration API provided by the code generator.

To use this API, you create an `sl_customization.m` file, on your MATLAB path, that invokes the `registerTargetInfo` function and fills in a hardware device registry entry with device information. The device information is registered with Simulink software for each subsequent Simulink session. (To register your device information without restarting MATLAB, issue the MATLAB command `sl_refresh_customizations`.)

For example, the following `sl_customization.m` file adds device vendor `MyDevVendor` and device type `MyDevType` to the Simulink device lists.

```
function sl_customization(cm)
    cm.registerTargetInfo(@loc_register_device);
end

function thisDev = loc_register_device
    thisDev = RTW.HWDeviceRegistry;
    thisDev.Vendor = 'MyDevVendor';
    thisDev.Type = 'MyDevType';
    thisDev.Alias = {};
    thisDev.Platform = {'Prod', 'Target'};
    thisDev.setWordSizes([8 16 32 32 32]);
    thisDev.LargestAtomicInteger = 'Char';
    thisDev.LargestAtomicFloat = 'None';
    thisDev.Endianess = 'Unspecified';
    thisDev.IntDivRoundTo = 'Undefined';
    thisDev.ShiftRightIntArith = true;
    thisDev.setEnabled({'IntDivRoundTo'});
end
```

After device registration, you can select the device in the **Hardware Implementation** pane.

To register multiple devices, specify an array of `RTW.HWDeviceRegistry` objects in your `sl_customization.m` file. For example:

```
function sl_customization(cm)
    cm.registerTargetInfo(@loc_register_device);
end

function thisDev = loc_register_device

    thisDev(1) = RTW.HWDeviceRegistry;
    thisDev(1).Vendor = 'MyDevVendor';
    thisDev(1).Type = 'MyDevType1';
    ...

    thisDev(4) = RTW.HWDeviceRegistry;
    thisDev(4).Vendor = 'MyDevVendor';
    thisDev(4).Type = 'MyDevType4';
    ...

end
```

You can specify various `RTW.HWDeviceRegistry` properties in the `registerTargetInfo` function call in your `sl_customization.m` file.

Properties for registerTargetInfo Function Call

Property	Description
Vendor	Character vector specifying the Device vendor value for your hardware device.
Type	Character vector specifying the Device type value for your hardware device.
Alias	<p>Cell array of character vectors specifying aliases or legacy names that can resolve to this device. Specify each alias or legacy name in the format 'Vendor->Type'.</p> <p>Embedded Coder software provides the utility functions <code>RTW.isHWDeviceTypeEq</code> and <code>RTW.resolveHWDeviceType</code>. These functions detect and resolve alias values or legacy values when testing user-specified values for the hardware device type.</p>
Platform	Cell array of enumerated character vector values specifying whether this device can be listed in the Production hardware subpane ({'Prod'}), the Test hardware subpane ({'Target'}), or both ({'Prod', 'Target'}).
setWordSizes	Array of integer sizes to associate with the Number of bits parameters char , short , int , long , and native word size , respectively.
LargestAtomicInteger	Character vector specifying an enumerated value for the Largest atomic size: integer parameter: 'Char', 'Short', 'Int', or 'Long'.
LargestAtomicFloat	Character vector specifying an enumerated value for the Largest atomic size: floating-point parameter: 'Float', 'Double', or 'None'.
Endianness	Character vector specifying an enumerated value for the Byte ordering parameter: 'Unspecified', 'Little' for little Endian, or 'Big' for big Endian.
IntDivRoundTo	Character vector specifying an enumerated value for the Signed integer division rounds to parameter: 'Zero', 'Floor', or 'Undefined'.

Property	Description
ShiftRightIntArith	Boolean value specifying whether your compiler implements a signed integer right shift as an arithmetic right shift (true) or not (false).
setEnabled	Cell array of character vectors specifying which device properties you can modify in the Hardware Implementation pane when you select this device type. This property applies for the 'Endianness', 'IntDivRoundTo', and 'ShiftRightIntArith' properties. You can apply this property to individual Number of bits parameters by using the property names 'BitPerChar', 'BitPerShort', 'BitPerInt', 'BitPerLong', and 'NativeWordSize'.

Set Bit Lengths for Device Data Types

The **Number of bits** parameters describe the **native word size** of the microprocessor and the bit lengths of **char**, **short**, **int**, and **long** data. For code generation to succeed:

- The bit lengths must be such that **char** <= **short** <= **int** <= **long**.
- Bit lengths must be multiples of 8, with a maximum of 32.
- The bit length for **long** data must not be less than 32.

The `rtwtypes.h` file defines integer type names. The values that you provide must be consistent with the word sizes as defined in the compiler `limits.h` header file. The code generator maps its integer type names to the corresponding Simulink integer type names.

If no ANSI® C type with a matching word size is available, but a larger ANSI C type is available, the code generator uses the larger type for `int8_T`, `uint8_T`, `int16_T`, `uint16_T`, `int32_T`, and `uint32_T`. When the code generator uses a larger type, the resulting logged values (for example, MAT-file logging) can have different data types than logged values for simulation.

An application can use an integer data of length from 1 (unsigned) or 2 (signed) bits up to 32 bits. If the integer length matches the length of an available type, the code generator uses that type. If a matching type is not available, the code generator uses the smallest available type that can hold the data, generating code that does not use unnecessary higher-order bits. For example, on hardware that supports 8-bit, 16-bit, and 32-bit

integers, for a signal specified as 24 bits, the code generator implements the data as an `int32_T` or `uint32_T`.

Code that uses emulated integer data is not maximally efficient. This code can be useful during application development for emulating integer lengths that are available only on production hardware. Emulation does not affect the results of execution.

During code generation, the software checks the compatibility of model data types with the data types that you specify for production hardware.

- If none of the lengths that you specify for production hardware integers is 32 bits, the software generates an error.
- If the lengths of data types that the model uses are smaller than the available production hardware integer lengths, the software generates a warning.

Mapping of Integer Types from Code Generator to Simulink

Code Generator Integer Type	Simulink Integer Type
<code>boolean_T</code>	<code>boolean</code>
<code>int8_T</code>	<code>int8</code>
<code>uint8_T</code>	<code>uint8</code>
<code>int16_T</code>	<code>int16</code>
<code>uint16_T</code>	<code>uint16</code>
<code>int32_T</code>	<code>int32</code>
<code>uint32_T</code>	<code>uint32</code>

Set Byte Ordering for Device

The **Byte ordering** parameter specifies whether the hardware uses **Big Endian** (most significant byte first) or **Little Endian** (least significant byte first) byte ordering. If left as **Unspecified**, the code generator produces code that determines the endianness of the hardware. This setting is the least efficient.

Set Quotient Rounding Behavior for Signed Integer Division

ANSI C does not completely define the quotient rounding technique for compilers to use when dividing one signed integer by another. So, the behavior is implementation-dependent. If both integers are positive, or both are negative, the quotient must round

down. If either integer is positive and the other is negative, the quotient can round up or down.

The **Signed integer division rounds to** parameter instructs the code generator about how the compiler rounds the result of signed integer division. Providing this information does not change the operation of the compiler. It only describes that behavior to the code generator, which uses the information to optimize code generated for signed integer division. The parameter values are:

- **Zero** — If the quotient is between two integers, the compiler chooses the integer that is closer to zero as the result.
- **Floor** — If the quotient is between two integers, the compiler chooses the integer that is closer to negative infinity.
- **Undefined** — If **Zero** or **Floor** do not describe the compiler behavior or if that behavior is unknown, choose this value.

Avoid selecting **Undefined**. When the code generator does not know the signed integer division rounding behavior of the compiler, the model build generates extra code.

The compiler quotient rounding behavior varies according to these values.

You can obtain the compiler implementation for signed integer division rounding from the compiler documentation. If documentation is not available, you can determine this behavior by experiment.

Example Quotient Rounding for Zero, Floor, and Undefined

N	D	Ideal N/D	Zero	Floor	Undefined
33	4	8.25	8	8	8
-33	4	-8.25	-8	-9	-8 or -9
33	-4	-8.25	-8	-9	-8 or -9
-33	-4	8.25	8	8	8 or 9

Set Arithmetic Right Shift Behavior for Signed Integers

ANSI C does not define the behavior of right shifts on negative integers for compilers. So, the behavior is implementation-dependent. The **Shift right on a signed integer as arithmetic shift** option instructs the code generator about how the compiler implements right shifts on negative integers. Providing this information does not change the operation

of the compiler. It only describes that behavior to the code generator, which uses the information to optimize the code generated for arithmetic right shifts.

If the C compiler implements a signed integer right shift as an arithmetic right shift, select the option. Otherwise, clear the option. An arithmetic right shift fills bits vacated by the right shift with the value of the most significant bit, which indicates the sign of the number in two's-complement notation. The option is selected by default. If your compiler handles right shifts as arithmetic shifts, this setting is preferred.

- When you select the option, the code generator produces efficient code whenever the Simulink model performs arithmetic shifts on signed integers.
- When the option is cleared, the code generator produces fully portable but less efficient code to implement right arithmetic shifts.

You can obtain the compiler implementation for arithmetic right shifts from the compiler documentation. If documentation is not available, you can determine this behavior by experiment.

Update Release 14 Hardware Configuration

If your model was created before Release 14 and you have not updated the model, the **Configure current execution hardware device** parameter (TargetUnknown) value is 'on' by default.

To update your model, clear the box for **Configuration Parameters > Hardware Implementation > Advanced parameters > Test hardware > Configure test hardware**. Or in the Command Window, type:

```
cs = getActiveConfigSet('your_model_name');  
set_param(cs, 'TargetUnknown', 'off');
```

This update to your model:

- Enables the **Test Hardware is the same as production hardware** parameter (ProdEqTarget), setting the parameter to 'on'.
- Copies the **Production device vendor and type** parameter (ProdHWDeviceType) value to the **Test device vendor and type** parameter (TargetHWDeviceType).

To complete the update:

- 1 Clear the box for **Configuration Parameters > Hardware Implementation > Advanced parameters > Test hardware > Test Hardware is the same as**

- production hardware.** Apply this step only if your production and test hardware are different.
- 2 Set the parameters in **Configuration Parameters > Hardware implementation > Advanced parameters** to match your production and test systems.
 - 3 Save the model.

Production Hardware Considerations

When you configure production hardware, consider these points:

- Production hardware can have word sizes and other hardware characteristics that differ from the MATLAB development computer. You can prototype code on hardware that is different from the production hardware or the MATLAB development computer. When producing code, the code generator accounts for these differences.
- The Simulink product uses some of the information in the production hardware configuration. That information enables simulations without code generation to give the same results as executing generated code. For example, the results can detect error conditions that arise on the production hardware, such as hardware overflow.
- The code generator produces code that provides bit-true agreement with Simulink results for integer and fixed-point operations. Generated code that emulates unavailable data lengths runs less efficiently than without emulation. The emulation does not affect bit-true agreement with Simulink for integer and fixed-point results.
- If you change run-time environments during application development, before generating or regenerating code, reconfigure the hardware implementation parameters for the new run-time environment. When code executes on hardware for which it was not generated, bit-true agreement is not always achieved for results of integer and fixed-point operations in simulation, production code, and test code.
- To compile code generated from the model, use the **Integer rounding mode** parameter on model blocks to simulate the rounding behavior of the C compiler that you intend. This setting appears on the **Signal Attributes** pane in the parameter dialog boxes of blocks that can perform signed integer arithmetic, such as the Product and n-D Lookup Table blocks.
- For most blocks, the value of **Integer rounding mode** completely defines rounding behavior. For blocks that support fixed-point data and the simplest rounding mode, the value of **Signed integer division rounds to** also affects rounding. For details, see “Precision” (Fixed-Point Designer).
- When models contain Model blocks, configure models that they reference to use identical hardware settings.

Test Hardware Considerations

By default, the test hardware configuration is the same as the configuration for the production hardware. You can use the generated code for testing in an environment that is identical to the production environment.

If the test and production environments differ, you can generate code that runs on test hardware as if it were running on production hardware:

- 1 To enable test hardware parameters, clear the box for **Configuration Parameters > Hardware Implementation > Advanced parameters > Test hardware > Test hardware is the same as production hardware**. Or, in the Command Window type:

```
cs = getActiveConfigSet('your_model_name');  
set_param(cs, 'ProdEqTarget', 'off');
```

- 2 Specify device type details through the test hardware (Target*) parameters.

If you select a system target file that specifies a default microprocessor and its hardware properties, these default values and properties appear as initial values.

Parameters with only one possible value cannot be changed. If you modify hardware properties, check that their values are consistent with the system target file. Otherwise, the generated code can fail to compile or execute, or can execute but produce incorrect results.

Example Production Hardware Setting That Affects Normal Mode Simulation

Changing some production hardware settings, for example, `ProdLongLongMode` and `ProdIntDivRoundTo`, can affect normal mode simulation results. The following example simulates an adder with four inputs. In the first simulation, `ProdLongLongMode` is disabled. In the second simulation, `ProdLongLongMode` is enabled. In the plot of simulation outputs, you observe small differences between output values in the time step range 125-175.

```
model = 'hwSettingEffect';  
new_system(model)  
open_system(model)  
  
% Create adder  
pos = [140 140 200 340];  
add_block('simulink/Math Operations/Add', ...  
         [model '/sum_int32'], ...
```

```

        'Inputs','++++', ...
        'SaturateOnIntegerOverflow', ...
        'on', ...
        'Position', ...
    pos)

pos = [75 155 105 175];
add_block('built-in/Inport',[model '/In1'],'Position',pos)
set_param([model '/In1'], 'OutDataTypeStr', ...
    'int32','PortDimensions','1','SampleTime','1');
add_line(model, 'In1/1','sum_int32/1')

pos = [75 205 105 225];
add_block('built-in/Inport',[model '/In2'],'Position',pos)
set_param([model '/In2'], 'OutDataTypeStr', ...
    'int32','PortDimensions','1','SampleTime','1');
add_line(model, 'In2/1','sum_int32/2')

pos = [75 255 105 275];
add_block('built-in/Inport',[model '/In3'],'Position',pos)
set_param([model '/In3'], 'OutDataTypeStr', ...
    'int32','PortDimensions','1','SampleTime','1');
add_line(model, 'In3/1','sum_int32/3')

pos = [75 305 105 325];
add_block('built-in/Inport',[model '/In4'],'Position',pos)
set_param([model '/In4'], 'OutDataTypeStr', ...
    'int32','PortDimensions','1','SampleTime','1');
add_line(model, 'In4/1','sum_int32/4')

pos = [275 230 305 250];
add_block('built-in/Outport',[model '/Out1'],'Position',pos)
add_line(model, 'sum_int32/1','Out1/1')

% Specify input data
t = 0:200;
peakValue = 1.5e9;
in1 = peakValue * sin(t*2*pi/100);
in2 = peakValue * cos(t*2*pi/70);
in3 = -peakValue * sin(t*2*pi/40);
in4 = -peakValue * cos(t*2*pi/30);
set = Simulink.SimulationData.Dataset;
set = set.addElement(1, timeseries(int32(in1),t,'Name','sig1'));
set = set.addElement(2, timeseries(int32(in2),t,'Name','sig2'));
set = set.addElement(3, timeseries(int32(in3),t,'Name','sig3'));
set = set.addElement(4, timeseries(int32(in4),t,'Name','sig4'));

set_param(model, 'LoadExternalInput', 'on');
set_param(model, 'ExternalInput', 'set');

set_param(model, 'StopTime', '50');

% Disable production hardware setting and run first simulation
set_param(model, 'ProdLongLongMode', 'off');
[~,~, y1] = sim(model, 200);

```

```
% Enable production hardware setting and run second simulation
set_param(model, 'ProdLongLongMode', 'on');
[~, ~, y2] = sim(model, 200);

plot([y1 y2]);
figure(gcf);
```

The difference in behavior is due to the accumulator data type in the Sum block. The **Accumulator data type** block parameter is set to **Inherit: Inherit via internal rule**. For this example, the resulting accumulator data type is 64 bits wide if the use of the C long long data type is enabled. Otherwise, it is 32 bits wide. Depending on the input values for the sum block, the 32-bit accumulator can saturate when the 64-bit accumulator does not. Therefore, normal mode behavior can depend on the `ProdLongLongMode` setting. In both cases, the normal mode behavior and production hardware behavior matches bitwise.

Protect Models for Third-Party Use

Protect a model when you want to share a model with a third party without revealing intellectual property. Protecting a model does not use encryption technology unless you use the optional password protection available for read-only view, simulation, and code generation. If you choose password protection for one of these options, the software protects the supporting files by using AES-256 encryption.

When you create a protected model (Simulink):

- By default, Simulink creates and stores a protected version of the model in the current working folder. The protected model has the same name as the source model, with an `.slxp` extension.
- To share a protected model, share only the protected model file.
- The original Model block does not change. If the Model block parameter **Model name** does not specify an extension, a protected model, `.slxp`, takes precedence over a model file, `.slx`.
- You can optionally create a harness model which includes the protected model. A badge icon appears in the lower-left corner of the protected model block in the harness model. For more information, see “Harness Model” on page 8-4.
- You can optionally include generated code with the protected model so that a third party can generate code for a model that contains the protected model. For more information, see “Code Generation Support in Protected Models” on page 8-6.
- If the Model block uses variants, only the active variant is protected. For more information, see “Set up Model Variants Using a Model Block” (Simulink).
- If the model defines callbacks, the model protection process does not preserve these callbacks. For more information on creating callbacks for use with a protected model, see “Define Callbacks for Protected Models” (Simulink Coder).
- If you rename a protected model, or change its suffix, the model is unusable until you restore its original name and suffix. You cannot change a protected model file internally because such changes make the file unusable.

Create a protected model by using one of these options:

- The Model block context menu. For more information, see “Create a Protected Model” on page 8-11.
- The `Simulink.ModelReference.protect` function.

- The Simulink Editor menu bar. To create a protected model from the current model, select **File > Export Model To > Protected Model**.

Requirements for Protecting a Model

To protect a model, the model must meet all requirements listed in “Model Referencing Limitations” (Simulink) and these requirements:

- You must have a Simulink Coder license to create a protected model.
- The model must be available on the MATLAB path.
- The model cannot have unsaved changes.
- The model cannot use a noninlined S-function directly or indirectly.
- All protected referenced models must support simulation in Accelerator mode. The protected referenced model creator must select **Simulate** in the Create Protected Model dialog box or set the 'Mode' to 'Accelerator' or 'CodeGeneration' by using the `Simulink.ModelReference.protect` function.
- All protected referenced models must use the default 'CodeInterface' setting: 'Model reference'.
- Protected referenced models cannot have password protection on simulation.
- Protected referenced models cannot have callbacks.
- The model cannot support operations that a protected referenced model does not support or supports with password protection. For example, a protected model can support code generation only if all protected referenced models support code generation without password protection.
- When protecting a model for code generation, the model must use a **Content type** that is compatible with the **Content type** of each protected referenced model. See “Code Generation Support in Protected Models” (Simulink Coder).

To use a protected model that requires passwords across platforms, before you create the protected model, set the MATLAB character set encoding to 'US-ASCII'. For more information, see `slCharacterEncoding`.

Harness Model

You can create a harness model for the generated protected model. The harness model opens as a new, untitled model that contains only a Model block that references the protected model. This Model block:

- Specifies the Model block parameter, **Model name**, as the name of the protected model.
- Has a badge icon in the lower-left corner.
- Has the same number of input and output ports as the protected model.
- Defines model reference arguments that the protected model uses, but does not provide values.

To create a harness model, see “Create a Protected Model” on page 8-11. You can use a harness model to test your protected model. For more information, see “Test the Protected Model” on page 8-22. You can also copy the Model block in your harness model to another model, where it is an interface to the protected model.

Protected Model Report

You can generate a protected model report when you create the protected model. The report is included as part of the protected model. The report has:

- A **Summary**, including the following tables:
 - **Environment**, providing the Simulink version and platform used to create the protected model.
 - **Supported functionality**, reporting On, Off, or On with password protection for each possible functionality that the protected model supports.
 - **Licenses**, listing licenses required to run the protected model.
- An **Interface Report**, including model interface information such as input and output specifications, exported function information, interface parameters, and data stores.

When you create the protected model from the Simulink Editor, the protected model report is generated. To generate a report when using the `Simulink.ModelReference.protect` function, set the 'Report' option to `true`.

If you configure your protected model for multiple targets, the **Summary** includes a list of supported targets in the **Supported functionality** table. When you build a model that references a protected model with multiple targets, the protected model code generation report represents the currently configured target.

To view the protected model report, right-click the protected-model badge icon and select **Display Report**. Or, call the `Simulink.ProtectedModel.open` function with the `report` option.

Code Generation Support in Protected Models

You can create a protected model that supports code generation. When a protected model includes generated code, a third party can generate code for a model that includes the protected model. If you choose to obfuscate the code, the code is obfuscated before compilation. The protected model file contains only headers and binaries. Source code, such as .c and .cpp, is not present in the protected model file, although the headers are documented in the protected model report. For more information, see “Protected Model File” on page 8-9 and “Protected Model Report” on page 8-5.

In the Create Protected Model dialog box, select the **Use generated code** check box. The **Content type** determines the appearance of the generated code. If you select **Readable source code** or **Obfuscated source code**, the header files match the appearance of the generated code. If you select **Binaries**, the header files can appear readable or obfuscated based on the 'ObfuscateCode' argument. By default, the header files appear obfuscated.

When you create a protected model that supports code generation:

- Simulink ignores source code comments in the **Code Generation > Comments** pane. Obfuscation of the generated code removes comments because comments can reveal intellectual property.
- Simulink obfuscates custom code specified in the **Code Generation > Custom Code** pane, but does not obfuscate identifiers.

For an example on including code generation support, see “Create a Protected Model” on page 8-11.

Protected Model Requirements to Support Code Generation

Contents and configuration of a model can prevent code generation support of the protected model. Interaction between the parent model and the protected referenced model can also prevent code generation.

To create a protected model that supports code generation, your model must meet all requirements as described in “Requirements for Protecting a Model” (Simulink Coder) and these requirements:

- The protected model must use normal, accelerator, software-in-the-loop (SIL), or processor-in-the-loop (PIL) mode and a single target.

- To avoid an error during code generation of a model that includes a protected model:
 - The protected model name must be unique from other model names in the same model reference hierarchy.
 - The interfaces must match.
 - The parameters must be compatible.
- You must not select the **Code Generation > Verification > Measure function execution time** check box. If you have this option selected when you protect your model, the software turns off the parameter and displays a warning.
- The protected model **Existing shared code** (ExistingSharedCode) parameter must not specify a value.
- All protected referenced models must support code generation without password protection.
- The protected model must be compatible with the **Content type** of each protected referenced model. This table provides compatibility information.

Code Generation Content Type Compatibility

Protected Parent Model Content Type	Compatible Protected Referenced Model Content Types
Binaries	<ul style="list-style-type: none"> • Binaries • Obfuscated source code
Binaries with 'ObfuscateCode' set to 'false'	<ul style="list-style-type: none"> • Binaries • Binaries with 'ObfuscateCode' set to 'false' • Obfuscated source code • Readable source code
Obfuscated source code	<ul style="list-style-type: none"> • Obfuscated source code
Readable source code	<ul style="list-style-type: none"> • Obfuscated source code • Readable source code

When the **Content type** of the protected parent model and protected referenced models do not match, code generation applies the more secure **Content type**. For example, a protected parent model set for **Binaries** generates **Binaries** for protected referenced models that are set to **Obfuscated source code**. A protected

parent model set for Readable source code generates Obfuscated source code for protected referenced models that are set to Obfuscated source code.

Protected Model File

A protected model file (.slxp) consists of the model itself and supporting files, depending on the options that you selected when you created the protected model.

If you created a protected model for simulation only and the referencing model is in Normal mode, after simulation, the *model.mexext* file is placed in the build folder.

If you created a protected model for simulation only and the referencing model is in Accelerator or Rapid Accelerator mode, after simulation, the following files are unpacked:

- slprj/sim/model/*.h
- slprj/sim/model/modellib.a (or *modellib.lib*)
- slprj/sim/model/tmwinternal/*
- slprj/sim/_sharedutils/*

For the protected model report, these additional files are unpacked (but not in the build folder):

- slprj/sim/model/html/*
- slprj/sim/model/buildinfo.mat

If you included code generation support when you created the protected model, after building your model the following files are unpacked (in addition to the preceding files):

- slprj/sim/model/*.h
- slprj/sim/model/modellib.a (or *modellib.lib*)
- slprj/sim/model/tmwinternal/*
- slprj/sim/_sharedutils/*
- slprj/target/model/*.h
- slprj/target/model/model_rtwlib.a (or *model_rtwlib.lib*)
- slprj/target/model/buildinfo.mat
- slprj/target/model/codeinfo.mat
- slprj/target/_sharedutils/*
- slprj/target/model/tmwinternal/*

With an Embedded Coder license, you can specify a Top model code interface. In this case, if you opted to include code generation support when you created the protected model, after building your model the following files are unpacked:

- `slprj/sim/model/*.h`
- `slprj/sim/model/modellib.a` (or `modellib.lib`)
- `slprj/sim/model/tmwinternal/*`
- `slprj/sim/_sharedutils/*`
- `model_target_rtw/*.h`
- `model_target_rtw/*.objExt`
- `model_target_rtw/buildinfo.mat`
- `model_target_rtw/codeinfo.mat`
- `slprj/target/_sharedutils/*`
- `slprj/target/model/tmwinternal/*`

For the protected model report, after building your model these files are unpacked (in addition to the preceding files):

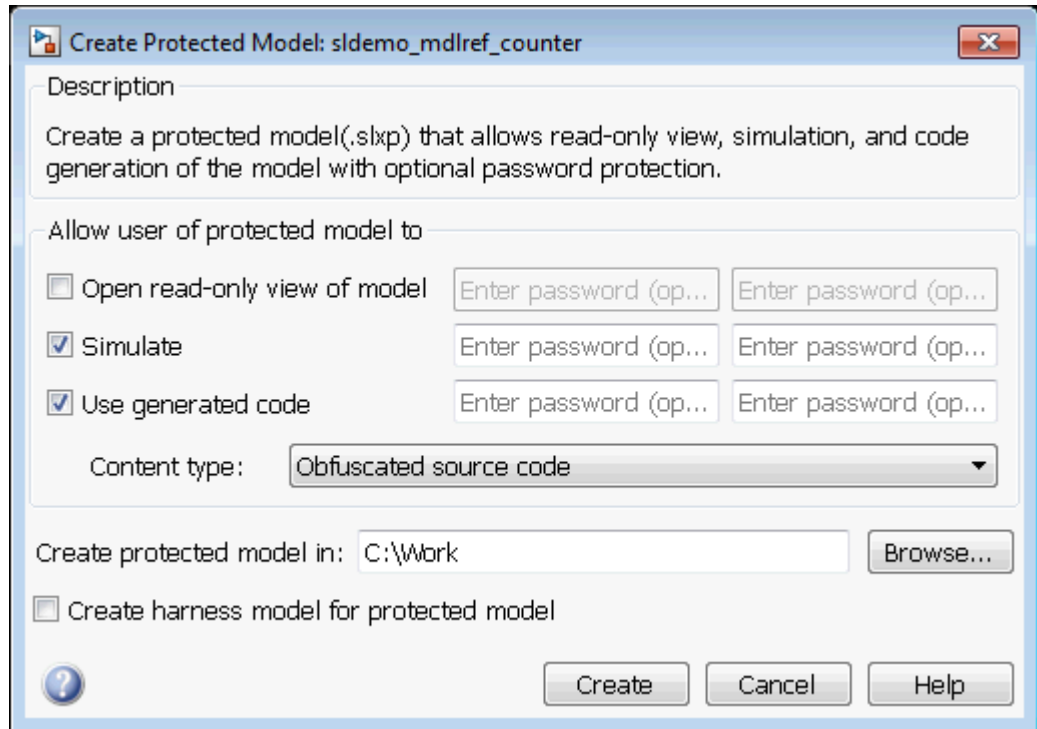

- `slprj/target/model/html/*`
- `slprj/target/model/buildinfo.mat`
- `slprj/target/_sharedutils/html/*`

Note The `slprj/sim/model/*` files are deleted after they are used.

Create a Protected Model

This example shows how to create a protected model for read-only viewing, simulation, or code generation.

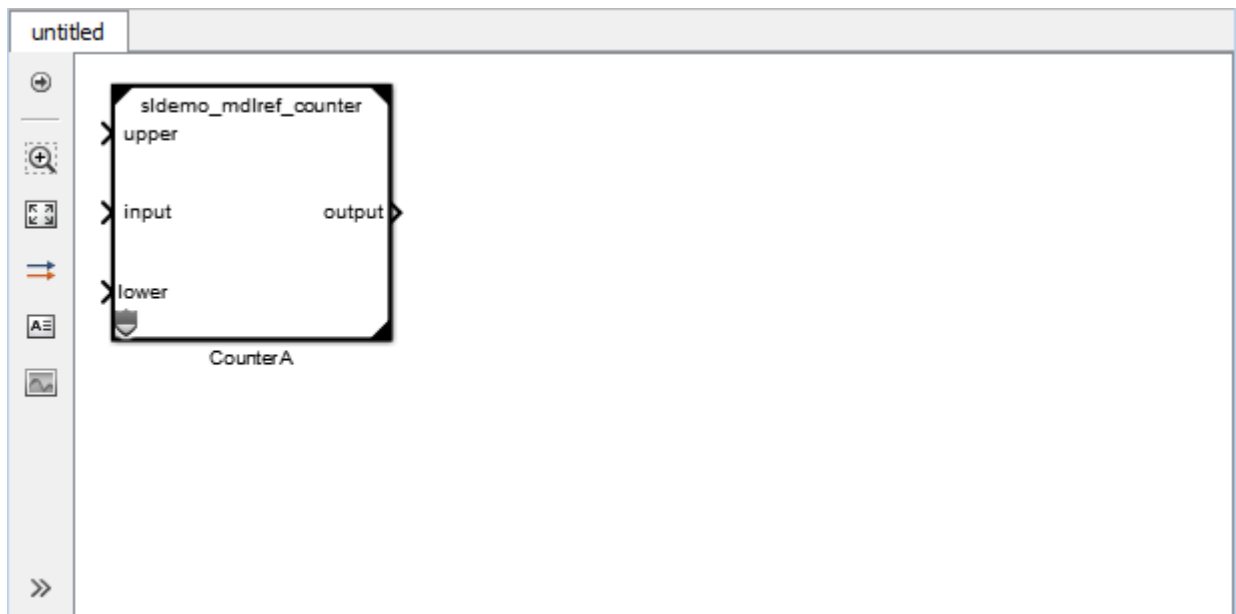

- 1 Open your model. For this example, `sldemo_mdhref_basic` is used as a demonstration.
- 2 In the Simulink Editor, right-click the model block that references the model for which you want to generate protected model code. In this example, right-click CounterA.
- 3 From the context menu, select **Block Parameters (ModelReference)**.
- 4 In the Block Parameters dialog box, in the **Model name** field, specify the extension for the model, `.slx`. When both the model and the protected model exist in the same folder, `.slxp` takes precedence over `.slx`. In the **Model name** field, if you do not specify an extension, then the original model block in the model becomes protected.
- 5 Click **OK**.
- 6 Right-click the model block. From the context menu, select **Subsystem & Model Reference > Create Protected Model for Selected Model Block**.

- 7 In the Create Protected Model dialog box, select the **Simulate** and **Use generated code** check boxes. If you want to password-protect the functionality of the protected model, enter a password with a minimum of four characters. Each functionality can have a unique password.
- 8 If you have an Embedded Coder license and specify an ERT-based system target file (for example, `ert.tlc`) for the model, the **Code interface** field is visible. From the **Code interface** drop-down list, select one of the following options:
 - **Model reference** — Specifies code access through the model reference code interface, which allows use of the protected model within a model reference hierarchy. Users of the protected model can generate code from a parent model that contains the protected model. In addition, users can run Model block SIL/PIL simulations with the protected model.
 - **Top model** — Specifies code access through the standalone interface. Users of the protected model can run Model block SIL/PIL simulations with the protected model.

Note In this example, `sldemo_mdhref_basic` does not specify an ERT-based system target file, therefore the Code interface options are not available on the Create Protected Model dialog box.

- 9 From the **Content type** list, select **Obfuscated source code** to conceal the source code purpose and logic of the protected model.
- 10 In the **Create protected model in** field, specify the folder path for the protected model. The default value is the current working folder.
- 11 To create a harness model for the protected model, select the **Create harness model for protected model** check box.
- 12 Click **Create**. An untitled harness model opens. It contains a model block, which refers to the protected model `sldemo_mdhref_counter.slxp`. The **Simulation mode** for the Model block is set to **Accelerator**. You cannot change the mode.

- 13 To view the protected model report, right-click the protected-model badge icon on the CounterA block and select **Display Report**.

More About

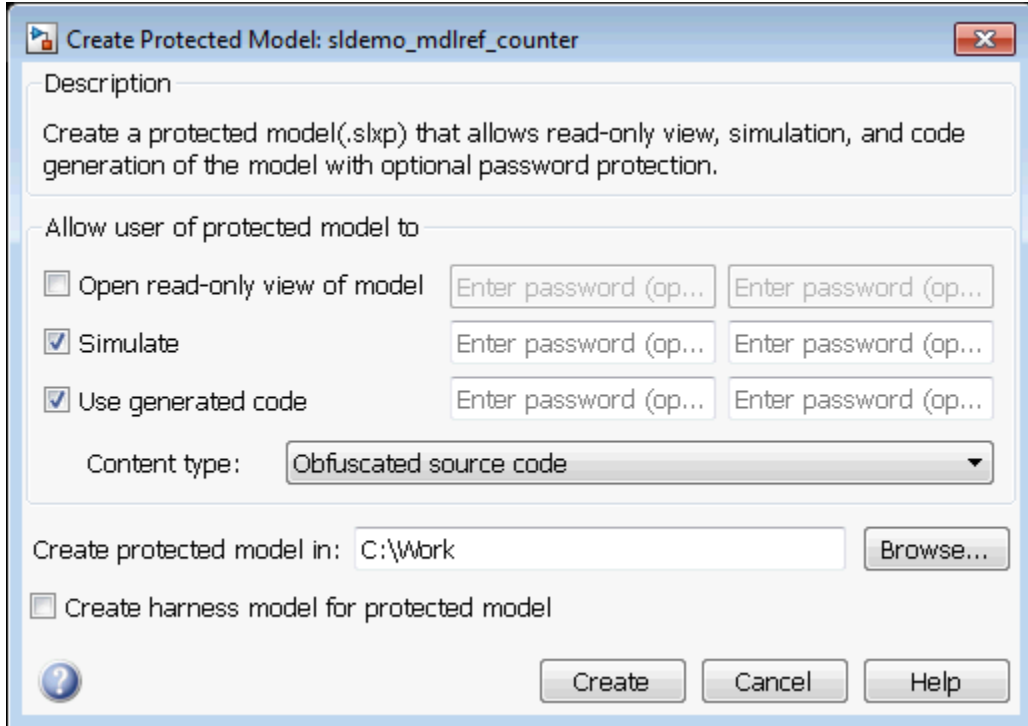

- “Code Generation Support in Protected Models” on page 8-6
- “Protected Model Creation Settings” on page 8-16
- “Code Interfaces for SIL and PIL” on page 67-6

Protected Model Creation Settings

When you create a protected model, in the Create Protected Model dialog box, you can select which settings you want configured. The settings provide certain functionality permissions when using a protected model. The functionality choices are:

- Read-only viewing
- Simulation
- Code Generation

Password-protection is optional. You must have a minimum of four characters.

Open Read-Only View of Model

If you want to share a view-only version of your model, this option allows someone using the protected model to open a Web view of the model. The contents and block parameters are viewable in the model Web view.

Simulate

The **Simulate** check box allows someone to simulate a protected model. When you select this check box, the Web view is not inherited. To enable the Web view with simulation functionality, select the **Open Read-Only View of Model** check box. The **Simulate** functionality:

- Enables protected model Simulation Report.
- Sets Mode to Accelerator. You can run Normal Mode and Accelerator simulations.
- Displays only binaries and headers.
- Enables code obfuscation.

Use Generated Code

The **Use generated code** check box allows simulation and code generation for a protected model. To generate code, the **Simulate** check box must also be selected. This functionality:

- Enables protected model Simulation Report and Code Generation Report.
- Sets Mode to enable code generation.
- Enables support for simulation.
- Supports the Model block if you have an Embedded Coder license and specify an ERT system target file (`ert.tlc`) for the model. From the **Code interface** drop-down list, select one of the following options:
 - **Model reference** — Specifies the model reference code interface, which allows use of the protected model within a model reference hierarchy. Users of the protected model can generate code from a parent model that contains the protected model. In addition, users can run Model block SIL/PIL simulations with the protected model.

- **Top model** — Specifies code access through the standalone interface. Users of the protected model can run Model block SIL/PIL simulations with the protected model.
- Determines the appearance of the generated code by the **Content type** list. The options are:
 - **Binaries**
 - **Obfuscated source code** (default)
 - **Readable source code**, which also includes readable code comments

Create a Protected Model with Multiple Targets

You can create a protected model that supports multiple code generation targets. This example shows how to use command-line functions to create a protected model that supports code generation for GRT and ERT targets.

- 1 Load a model and save a local copy. This model is configured for a GRT target.

```
sldemo_mdhref_counter
save_system('sldemo_mdhref_counter','mdhref_counter.slx');
```

- 2 Add a required password for modifying a protected model. If you do not add a password, you are prompted to set a password when you create a modifiable, protected model.

```
Simulink.ModelReference.ProtectedModel.setPasswordForModify(...
'mdhref_counter','password');
```

- 3 Create a modifiable, protected model with support for code generation.

```
Simulink.ModelReference.protect('mdhref_counter','Mode',...
'CodeGeneration','Modifiable',true,'Report',true);
```

- 4 Get a list of targets that the protected model supports.

```
st = Simulink.ProtectedModel.getSupportedTargets('mdhref_counter')

st =

    'grt'    'sim'
```

- 5 Configure the unprotected model to support an ERT target.

```
set_param('mdhref_counter','SystemTargetFile','ert.tlc');
save_system('mdhref_counter');
```

- 6 Add support to the protected model for the ERT target. You are prompted for the modification password.

```
Simulink.ProtectedModel.addTarget('mdhref_counter');
```

- 7 Verify that the list of supported targets now includes the ERT target.

```
st = Simulink.ProtectedModel.getSupportedTargets('mdhref_counter')
```

```
st =  
    'ert'    'grt'    'sim'
```

Use a Protected Model with Multiple Targets

When using a protected model with multiple targets, prepare your model for code generation.

- 1 Get a list of the targets that the protected model supports using the `Simulink.ProtectedModel.getSupportedTargets` function.

You can also get this information from the protected model report. To view the report, on the protected model block, right-click the badge icon. Select **Display Report**. The **Summary** lists the supported targets.

- 2 Get the configuration set for your chosen target using the `Simulink.ProtectedModel.getConfigSet` function. You can use the configuration set to verify that the protected model interface is compatible with the parent model.
- 3 Generate code. The build process selects the corresponding target.

Test the Protected Model

To test a protected model that you created, you use the generated harness model and the procedure described in “Simulate a Protected Model” (Simulink).

You can also compare the output of the protected model to the output of the original model. Because you are the supplier, both the original and the protected model might exist on the MATLAB path. In the original model, if the Model block **Model name** parameter names the model without providing a suffix, the protected model takes precedence over the unprotected model. To override this default when testing the output, in the Model block **Model name** parameter, specify the file name with the extension of the unprotected model, `.slx`.

To compare the unprotected and protected versions of a Model block, use the Simulation Data Inspector. This example uses `sldemo_mdhref_basic` and the protected model, `sldemo_mdhref_counter.slxp`, which is created in “Create a Protected Model” on page 8-11.

- 1 If it is not already open, open `sldemo_mdhref_basic`.
- 2 Enable logging for the output signal of the Model block, CounterA. In the Configuration Parameters dialog box, in the **Data Import/Export** pane, select the **Signal logging** parameter. Click **Apply** and **OK**.
- 3 Right-click the output signal. From the context menu, select **Properties**. In the Signal Properties dialog box, select **Log signal data**. Click **Apply** and **OK**. For more information, see “Export Signal Data Using Signal Logging” (Simulink).
- 4 Right-click the CounterA block. From the context menu, select **Block Parameters (ModelReference)**. In the Block Parameters dialog box, specify the **Model name** parameter with the name of the unprotected model and the extension, `sldemo_mdhref_counter.slx`. Click **Apply** and **OK**. Repeat this step for CounterB block and CounterC block.
- 5 In the Simulink Editor, click the **Simulation Data Inspector** button arrow and select **Send Logged Workspace Data to Data Inspector** from the menu.
- 6 Simulate the model. When the simulation is complete, click the **Simulation Data Inspector** button to open the Simulation Data Inspector.
- 7 In the Simulation Data Inspector, rename the run to indicate that it is for the unprotected model.
- 8 In the Simulink Editor, right-click the CounterA block. From the context menu, select **Block Parameters (ModelReference)**. In the Block Parameters dialog

box, specify the **Model name** parameter with the name of the protected model, `sldemo_mdref_counter.slxp`. A badge icon appears on the Model block. Repeat this step for CounterB block and CounterC block.

- 9** Simulate the model, which now refers to the protected model. When the simulation is complete, a new run appears in the Simulation Data Inspector.
- 10** In the Simulation Data Inspector, rename the new run to indicate that it is for the protected model.
- 11** In the Simulation Data Inspector, click the **Compare** tab. From the **Baseline** and **Compare To** lists, select the runs from the unprotected and protected model, respectively. To compare the runs, click **Compare Runs**. For more information about comparing runs, see “Compare Simulation Data” (Simulink).

Save Base Workspace Definitions

Referenced models can use object definitions or tunable parameters that are defined in the MATLAB base workspace. These variables are not saved with the model. When you protect a model, you must obtain the definitions of required base workspace entities and ship them with the model.

The following base workspace variables must be saved to a MAT-file:

- Global tunable parameter
- Global data store
- The following objects used by a signal that connects to a root-level model Inport or Outport:
 - `Simulink.Signal`
 - `Simulink.Bus`
 - `Simulink.Alias`
 - `Simulink.NumericType` that is an alias

For more information, see “Edit and Manage Workspace Variables by Using Model Explorer” (Simulink).

Before executing the protected model as a part of a third-party model, the receiver of the protected model must load the MAT-file.

Package a Protected Model

In addition to the protected model file (.slxp), you can include additional files in the protected model package:

- Harness model file.
- Any required definitions saved in a MAT-file. For more information, see “Save Base Workspace Definitions” on page 8-24.
- Instructions on how to retrieve the files.

Some ways to deliver the protected model package are:

- Provide the .slxp file and other supporting files as separate files.
- Combine the files into a ZIP or other container file.
- Combine the files using a manifest. For more information, see “Export Files in a Manifest” (Simulink).
- Provide the files in some other standard or proprietary format specified by the receiver.

Whichever approach you use to deliver a protected model, include information on how to retrieve the original files. One approach to consider is to use the Simulink Manifest Tools, as described in “Analyze Model Dependencies” (Simulink).

Specify Custom Obfuscator for Protected Model

When creating a protected model, you can specify your own postprocessing function for files that the protected model creation process generates. Before packaging the protected model files, this function is called by the `Simulink.ModelReference.protect` function. You can use this functionality to run your own custom obfuscator on the generated files by following these steps:

- 1 Create your postprocessing function. Use this function to call your custom obfuscator. The function must be on the MATLAB path and accept a `Simulink.ModelReference.ProtectedModel.HookInfo` object as an input variable.
- 2 In your function, get the files and exported symbol information that your custom obfuscator requires to process the protected model files. To get the files and information, access the properties of your function input variable. The variable is a `Simulink.ModelReference.ProtectedModel.HookInfo` object with the following properties:
 - `SourceFiles`
 - `NonSourceFiles`
 - `ExportedSymbols`
- 3 Pass the protected model file information to your custom obfuscator. The following is an example of a postprocessing function for custom obfuscation:

```
function myHook(protectedModelInfo)

    % Get source file list information.
    srcFileList = protectedModelInfo.SourceFiles;
    disp('### Obfuscating...');
    for i=1:length(srcFileList)
        disp(['### Obfuscator: Processing ' srcFileList{i} '...']);
        % call to custom obfuscator
        customObfuscator(srcFileList{i});
    end
end
```

- 4 Specify your postprocessing function when creating the protected model:

```
Simulink.ModelReference.protect('myModel, ...
    'Mode', ...
    'CodeGeneration', ...
```

```
'CustomPostProcessingHook', ...  
@(protectedModelInfo)myHook(protectedModelInfo))
```

The protected model creator can also enable obfuscation of simulation target code and generated code through the 'ObfuscateCode' option of the `Simulink.ModelReference.protect` function. Your custom obfuscator runs only on the generated code and not on the simulation target code. If both obfuscators are in use, the custom obfuscator is the last to run on the generated code before the files are packaged.

Define Callbacks for Protected Models

When you create a protected model, you can customize its behavior by defining callbacks. Callbacks specify code that executes when you view, simulate, or generate code for the protected model. A protected model user cannot view or modify a callback. If a model references a protected model with callbacks, you cannot protect the model.

To create a protected model with callbacks:

- 1 Define `Simulink.ProtectedModel.Callback` objects for each callback.
- 2 To create your protected model, call the `Simulink.ModelReference.protect` function. Use the 'Callbacks' option to specify a cell array of callbacks to include in the protected model.

Creating Callbacks

To create and define a protected model callback, create a `Simulink.ProtectedModel.Callback` object. Callback objects specify:

- The code to execute for the callback. The code can be a character vector of MATLAB commands or a script on the MATLAB path.
- The event that triggers the callback. The event can be 'PreAccess' or 'Build'.
- The protected model functionality that the event applies to. The functionality can be 'CODEGEN', 'SIM', 'VIEW', or 'AUTO'. If you select 'AUTO', and the event is 'PreAccess', the callback applies to each functionality. If you select 'AUTO', and the event is 'Build', the callback applies only to 'CODEGEN' functionality. If you do not select any functionality, the default behavior is 'AUTO'.
- The option to override the protected model build process. This option applies only to 'CODEGEN' functionality.

You can create only one callback per event and per functionality.

Defining Callback Code

You can define the code for a callback by using either a character vector of MATLAB commands or a script on the MATLAB path. When you write callback code, follow these guidelines:

- Callbacks must use MATLAB code (.m or .p).
- The code can include protected model functions or any MATLAB command that does not require loading the model.
- Callback code must not call out to external utilities unless those utilities are available in the environment where the protected model is used.
- Callback code cannot reference the source protected model unless you are using protected model functions.

You can use the `Simulink.ProtectedModel.getCallbackInfo` function in callback code to get information on the protected model. The function returns a `Simulink.ProtectedModel.CallbackInfo` object that provides the protected model name and the names of submodels. If the callback is specified for 'CODEGEN' functionality and 'Build' event, the object provides the target identifier and model code interface type ('Top model' or 'Model reference').

Create a Protected Model with Callbacks

This example creates a protected model with a callback for code generation.

- 1 On the MATLAB path, create a callback script, `pm_callback.m`, containing:

```
s1 = 'Code interface is: ';
cbinfoobj = Simulink.ProtectedModel.getCallbackInfo(...
    'sldemo_mdref_counter', 'Build', 'CODEGEN');
disp([s1 cbinfoobj.CodeInterface]);
```

- 2 Create a callback that uses the script. If the callback code replaces the protected model build process, set the override option.

```
pmCallback = Simulink.ProtectedModel.Callback('Build',...
    'CODEGEN', 'pm_callback.m');
pmCallback.setOverrideBuild(true);
```

- 3 Create the protected model and specify the code generation callback.

```
Simulink.ModelReference.protect('sldemo_mdref_counter',...
    'Mode', 'CodeGeneration', 'Callbacks', {pmCallback})
```

- 4 Build the protected model. In place of the build, the callback displays the code interface.

```
rtwbuild('sldemo_mdref_basic')
```

Component Initialization, Reset, and Termination in Simulink Coder

Generate Code That Responds to Initialize, Reset, and Terminate Events

To generate code from a modeling component that responds to initialize, reset, and terminate events during execution, use the blocks Initialize Function and Terminate Function. For information on how to use these blocks, see “Customize Initialize, Reset, and Terminate Functions” (Simulink). You can use the blocks anywhere in a model hierarchy.

Examples of when to generate code that responds to initialize, reset, or terminate events include:

- Starting and stopping a component.
- Calculating initial conditions.
- Saving and restoring state from nonvolatile memory.
- Generating reset entry-point functions that respond to external events.

Each nonvirtual subsystem and referenced model can have its own set of initialize, reset, and terminate functions.

The code generator produces initialization and termination code differently than reset code. For initialization and termination code, the code generator includes your component initialization and termination code in the default entry-point functions, *model_initialize* and *model_terminate*. The code generator produces reset code only if you model reset behavior.

Generate Code for Initialize and Terminate Events

When you generate code for a component that includes Initialize Function and Terminate Function blocks, the code generator:

- Includes initialize event code with default initialize code in entry-point function *model_initialize*.
- Includes terminate event code with default terminate code in entry-point function *model_terminate*.

Consider the model *rtwdemo_irt_base*.

For this model, the code generator produces initialize and terminate entry-point functions that other code can interface with.

```
void rtwdemo_irt_base_initialize(void)
void rtwdemo_irt_base_terminate(void)
```

This code appears in the generated file `rtwdemo_irt_base.c`. The initialize function, `rtwdemo_irt_base_initialize`:

- Initializes an error status.
- Allocates memory for block I/O and state parameters.
- Sets the output value
- Sets the initial condition for the discrete integrator.

The terminate function, `rtwdemo_irt_base_terminate`, requires no code.

This code assumes that support for nonfinite numbers and MAT-file logging is disabled.

```
void rtwdemo_irt_base_initialize(void)
{
    rtmSetErrorStatus(rtwdemo_irt_base_M, (NULL));

    (void) memset((void *)&rtwdemo_irt_base_DW, 0,
                 sizeof(DW_rtwdemo_irt_base_T));

    rtwdemo_irt_base_Y.Out1 = 0.0;

    rtwdemo_irt_base_DW.DiscreteIntegrator_DSTATE = 0.0;
}

void rtwdemo_irt_base_terminate(void)
{
    /* (no terminate code required) */
}
```

Add Initialize Function and Terminate Function blocks to the model (see `rtwdemo_irt_initterm`). The Initialize Function block uses the State Writer block to set the initial condition of a Discrete Integrator block. The Terminate Function block includes a State Reader block, which reads the state of the Discrete Integrator block.

The **Event type** parameter of the Event Listener block for the initialize and terminate functions is set to `Initialize` and `Terminate`, respectively. The initialize function uses the State Writer block to initialize the input value for the Discrete Integrator block to 10. The terminate function uses the State Reader block to read the state of the Discrete Integrator block.

The code generator includes the event code that it produces for the Initialize Function and Terminate Function blocks with standard initialize and terminate code in entry-point functions `rtwdemo_irt_initterm_initialize` and `rtwdemo_irt_initterm_terminate`. This code assumes that support for nonfinite numbers and MAT-file logging is disabled.

```
void rtwdemo_irt_initterm_initialize(void)
{
    rtmSetErrorStatus(rtwdemo_irt_initterm_M, (NULL));

    (void) memset((void *)&rtwdemo_irt_initterm_DW, 0,
        sizeof(DW_rtwdemo_irt_initterm_T));

    rtwdemo_irt_initterm_Y.Out1 = 0.0;
}
```

```
    rtwdemo_irt_initterm_DW.DiscreteIntegrator_DSTATE = 10.0;
}

void rtwdemo_irt__initterm_terminate(void)
{
    /* (no terminate code required) */
}
```

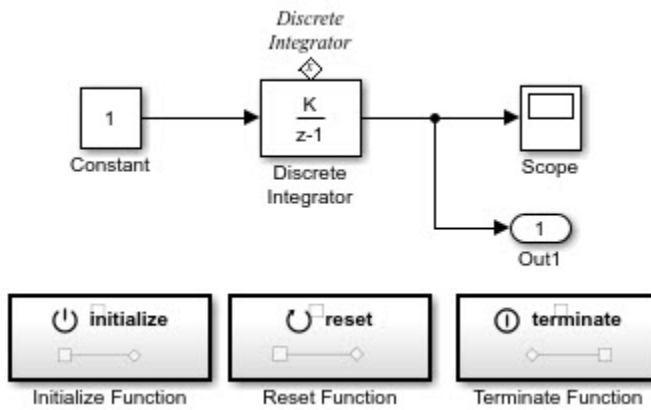

Generate Code for Reset Events

Generate code that responds to a reset event by including an Initialize Function or Terminate Function block in a modeling component. Configure the block for a reset by setting the **Event type** parameter of its Event Listener block to **Reset**. Also set the **Event name** parameter. The default name is **reset**.

The code generator produces a reset entry-point function *only* if you model reset behavior. If a component contains multiple reset specifications, the code that the code generator produces depends on whether reset functions share an event name. For a given component hierarchy:

- For reset functions with unique event names, the code generator produces a separate entry-point function for each named event. The name of each function is the name of the corresponding event.
- For reset functions that share an event name, the code generator aggregates the reset code into one entry-point function. The code for the reset functions appears in order, starting with the lowest level (innermost) of the component hierarchy and ending with the root (outermost). The name of the function is *model_reset*. For more information, see “Event Names and Code Aggregation” (Simulink Coder).

Consider the model `rtwdemo_irt_reset`, which includes a Reset Function block derived from an Initialize Function block.

The **Event type** and **Event name** parameters of the Event Listener block are set to Reset and reset, respectively. The function uses the State Writer block to reset the input value for the Discrete Integrator block to 5.

The code generator produces reset function `rtwdemo_irt_reset_reset`.

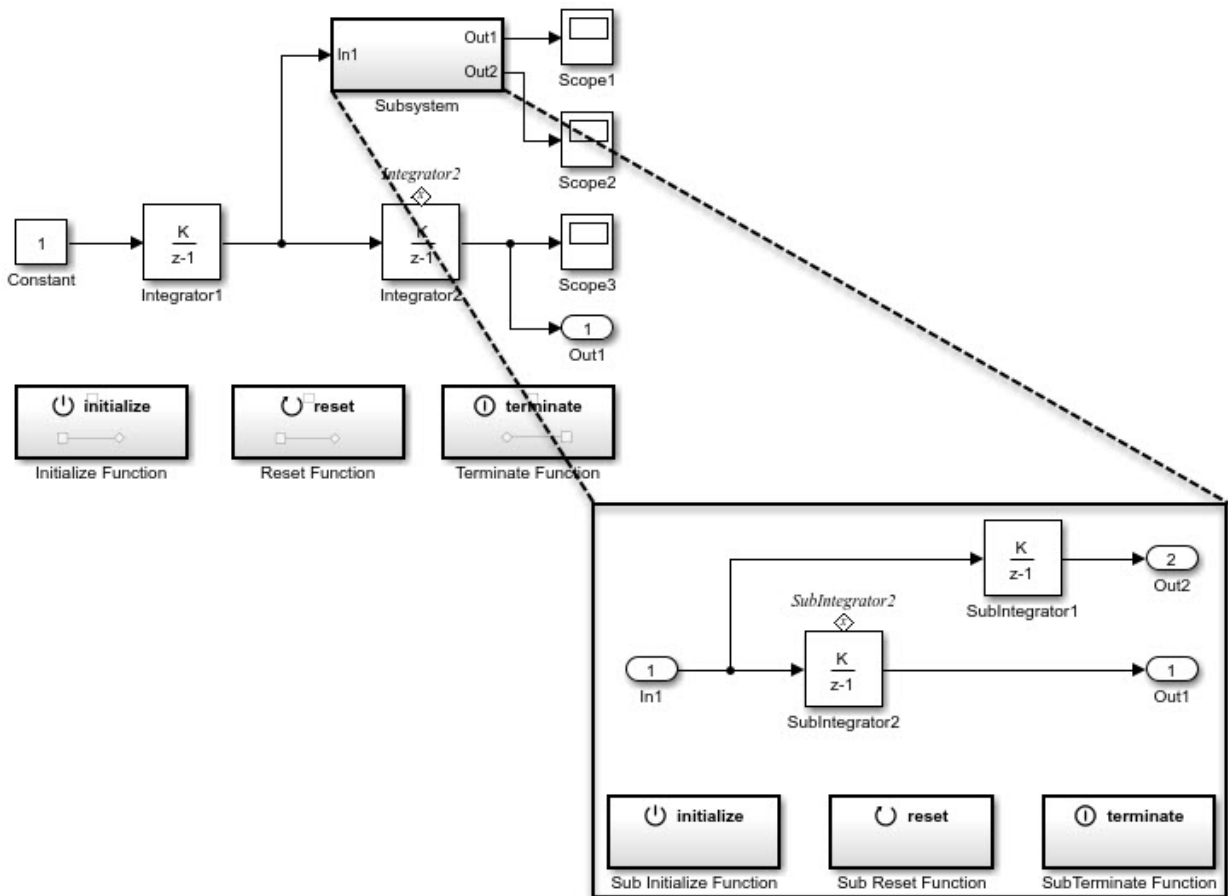

```
void rtwdemo_irt_reset_reset(void)
{
    rtwdemo_irt_reset_DW.DiscreteIntegrator_DSTATE = 5.0;
}
```

Event Names and Code Aggregation

Use the Initialize Function and Terminate Function blocks to define multiple initialize, reset, and terminate functions for a component hierarchy. Define only one initialize function and one terminate function per hierarchy level. You can define multiple reset functions for a hierarchy level. The event names that you configure for the functions at a given level must be unique.

When producing code, the code generator aggregates code for functions that have a given event name across the entire component hierarchy into one entry-point function. The code for reset functions appears in order, starting with the lowest level (innermost) of the component hierarchy and ending with the root (outermost). The code generator uses the event name to name the function.

For example, the model `rtwdemo_irt_shared` includes a subsystem that replicates the initialize, reset, and terminate functions that are in the parent model.

Although the model includes multiple copies of the initialize, reset, and terminate functions, the code generator produces one entry-point function for reset

(`rtwdemo_irt_shared_reset`), one for initialize (`rtwdemo_irt_shared_initialize`), and one for terminate (`rtwdemo_irt_shared_terminate`). Within each entry-point function, after listing code for blocks configured with an initial condition (*model_P.block_IC*), the code generator orders code for components, starting with the lowest level of the hierarchy and ending with the root.

```
.
.
.
void rtwdemo_irt_shared_reset(void)
{
    rtwdemo_irt_shared_DW.SubIntegrator2_DSTATE = 5.0;

    rtwdemo_irt_shared_DW.Integrator2_DSTATE = 5.0;
}
.
.
.
void rtwdemo_irt_shared_initialize(void)
{
    rtmSetErrorStatus(rtwdemo_irt_shared_M, (NULL));

    (void) memset(((void *)&rtwdemo_irt_shared_DW), 0,
                 sizeof(DW_rtwdemo_irt_shared_T));

    rtwdemo_irt_shared_Y.Out1 = 0.0;

    rtwdemo_irt_shared_DW.Integrator1_DSTATE = 0.0;
    rtwdemo_irt_shared_DW.SubIntegrator2_DSTATE = 2.0;
    rtwdemo_irt_shared_DW.Integrator2_DSTATE = 10.0;
.
.
.
void rtwdemo_irt_shared_terminate(void)
{
    /* (no terminate code required) */
}
```

If you rename the event configured for the subsystem reset function to `reset_02`, the code generator produces two reset entry-point functions, `rtwdemo_irt_shared_reset` and `rtwdemo_irt_shared_reset_02`.

```
void rtwdemo_irt_shared_reset(void)
{
    rtwdemo_irt_shared_DW.SubIntegrator2_DSTATE = 5.0;
}

void rtwdemo_irt_shared_reset_02(void)
{
    rtwdemo_irt_shared_DW.Integrator2_DSTATE = 5.0;
}
```

Limitation

You cannot generate code from a harness model—a root model that contains a Model block, which exposes initialize, reset, or terminate function ports.

Code Generation of Stateflow Blocks

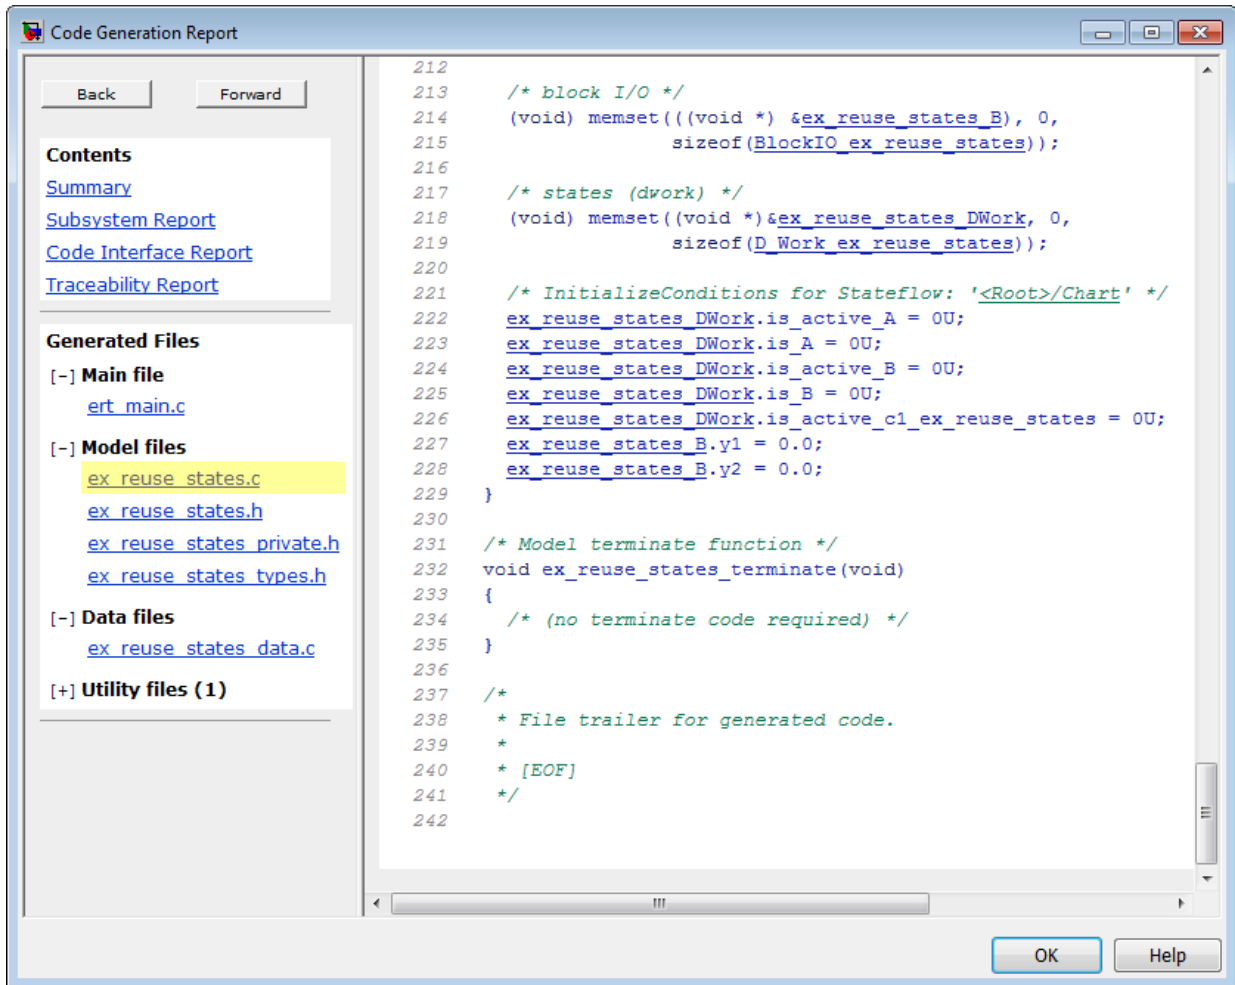

The code generator produces code for Stateflow blocks for rapid prototyping. If you have an Embedded Coder license, you can generate production code for Stateflow blocks.

Comparison of Code Generation Methods

The following sections compare two ways of generating code.

Code Generation Without Atomic Subcharts

You generate code for the entire model in one file and look through that entire file to find code for a specific part of the chart.

Code Generation With Atomic Subcharts

You specify code generation parameters so that code for an atomic subchart appears in a separate file. This method of code generation enables unit testing for a specific part of a chart. You can avoid searching through unrelated code and focus only on the part that interests you.

Note Unreachable Stateflow states are optimized out and are not included in the generated code.

For more information, see “Generate Reusable Code for Unit Testing” on page 10-8.

Generate Reusable Code for Atomic Subcharts

In this section...
“How to Generate Reusable Code for Linked Atomic Subcharts” on page 10-6
“How to Generate Reusable Code for Unlinked Atomic Subcharts” on page 10-7

How to Generate Reusable Code for Linked Atomic Subcharts

To specify code generation parameters for linked atomic subcharts from the same library:

- 1 Open the library model that contains your atomic subchart.
- 2 Unlock the library.
- 3 Right-click the library chart and select **Block Parameters**.
- 4 In the dialog box, specify the following parameters:
 - a On the **Main** tab, select **Treat as atomic unit**.
 - b On the **Code Generation** tab, set **Function packaging** to Reusable function.
 - c Set **File name options** to User specified.
 - d For **File name**, enter the name of the file with no extension.
 - e Click **OK** to apply the changes.
- 5 (OPTIONAL) Customize the generated function names for atomic subcharts:
 - a Open the Model Configuration Parameters dialog box.
 - b On the **Code Generation** pane, set **System target file** to `ert.tlc`.
 - c Navigate to the **Code Generation > Symbols** pane.
 - d For **Subsystem methods**, specify the format of the function names using a combination of the following tokens:
 - \$R — root model name
 - \$F — type of interface function for the atomic subchart
 - \$N — block name
 - \$H — subsystem index
 - \$M — name-mangling text

- e Click **OK** to apply the changes.

When you generate code for your model, a separate file stores the code for linked atomic subcharts from the same library.

How to Generate Reusable Code for Unlinked Atomic Subcharts

To specify code generation parameters for an unlinked atomic subchart:

- 1 In your chart, right-click the atomic subchart and select **Properties**.
- 2 In the dialog box, specify the following parameters:
 - a Set **Code generation function packaging** to `Reusable function`.
 - b Set **Code generation file name options** to `User specified`.
 - c For **Code generation file name**, enter the name of the file with no extension.
 - d Click **OK** to apply the changes.
- 3 (OPTIONAL) Customize the generated function names for atomic subcharts:
 - a Open the Model Configuration Parameters dialog box.
 - b On the **Code Generation** pane, set **System target file** to `ert.tlc`.
 - c Navigate to the **Code Generation > Symbols** pane.
 - d For **Subsystem methods**, specify the format of the function names using a combination of the following tokens:
 - `$R` — root model name
 - `$F` — type of interface function for the atomic subchart
 - `$N` — block name
 - `$H` — subsystem index
 - `$M` — name-mangling text
 - e Click **OK** to apply the changes.

When you generate code for your model, a separate file stores the code for the atomic subchart. For more information, see “Generate Reusable Code for Unit Testing” on page 10-8.

Generate Reusable Code for Unit Testing

In this section...

“Goal of the Tutorial” on page 10-8

“Convert a State to an Atomic Subchart” on page 10-9

“Specify Code Generation Parameters” on page 10-10

“Generate Code for Only the Atomic Subchart” on page 10-11

Goal of the Tutorial

Assume that you have the following model, and the chart has two states:

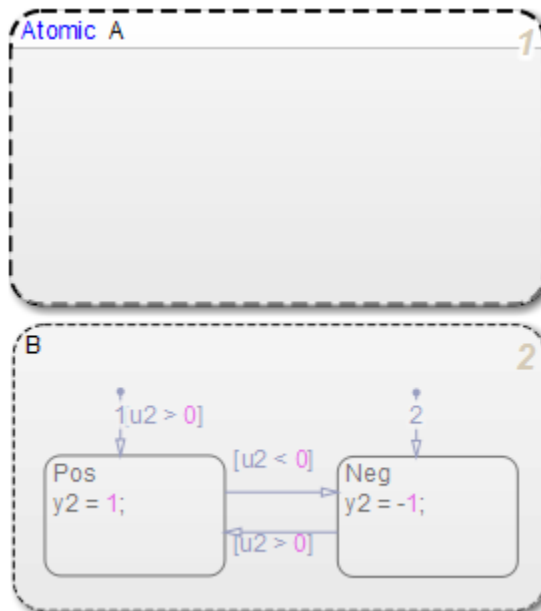

Suppose that you want to generate reusable code so that you can perform unit testing on state A. You can convert that part of the chart to an atomic subchart and then specify a separate file to store the generated code.

Convert a State to an Atomic Subchart

To convert state A to an atomic subchart, right-click the state and select **Group & Subchart > Atomic Subchart**. State A changes to an atomic subchart:

Specify Code Generation Parameters

Set Up a Standalone C File for the Atomic Subchart

- 1 Open the properties dialog box for A.
- 2 Set **Code generation function packaging** to Reusable function.
- 3 Set **Code generation file name options** to User specified.
- 4 For **Code generation file name**, enter saturator as the name of the file.
- 5 Click **OK**.

Set Up the Code Generation Report

- 1 Open the Model Configuration Parameters dialog box.
- 2 In the **Code Generation** pane, set **System target file** to `ert.tlc`.
- 3 In the **Code Generation > Report** pane, select **Create code generation report**.

This step automatically selects **Open report automatically** and **Code-to-model**.

- 4 Select **Model-to-code**.
- 5 Click **Apply**.

Customize the Generated Function Names

- 1 In the Model Configuration Parameters dialog box, go to the **Code Generation > Symbols** pane.
- 2 Set **Subsystem methods** to the format scheme $\$R\$N\$M\F , where:
 - $\$R$ is the root model name.
 - $\$N$ is the block name.
 - $\$M$ is the mangle token.
 - $\$F$ is the type of interface function for the atomic subchart.

For more information, see “Subsystem methods” (Simulink Coder).

- 3 Click **Apply**.

Generate Code for Only the Atomic Subchart

To generate code for your model, press **Ctrl+B**. In the code generation report that appears, you see a separate file that contains the generated code for the atomic subchart.

To inspect the code for `saturation.c`, click the hyperlink in the report to see the following code:

Line 28 shows that the `during` function generated for the atomic subchart has the name `ex_reuse_states_A_during`. This name follows the format scheme `RNMF` specified for **Subsystem methods**:

- `$R` is the root model name, `ex_reuse_states`.
- `$N` is the block name, `A`.
- `$M` is the mangle token, which is empty.
- `$F` is the type of interface function for the atomic subchart, `during`.

Note The line numbers shown can differ from the numbers that appear in your code generation report.

Inline State Functions in Generated Code

In this section...

“Inlined Generated Code for State Functions” on page 10-14

“How to Set the State Function Inline Option” on page 10-16

“Best Practices for Controlling State Function Inlining” on page 10-16

Inlined Generated Code for State Functions

By default, the code generator uses an internal heuristic to determine whether to inline generated code for state functions. The heuristic takes into consideration an inlining threshold. As code grows and shrinks in size, generated code for state functions can be unpredictable.

If your model includes Stateflow objects and you have rigorous requirements for traceability between generated code and the corresponding state functions, you can override the default behavior. Use the state property `Function Inline Option` to explicitly force or prevent inlining of state functions.

What Happens When You Force Inlining

If you force inlining for a state, the code generator inlines code for state actions into the parent function. The parent function contains code for executing the state actions, outer transitions, and flow charts. It does not include code for empty state actions.

What Happens When You Prevent Inlining

If you prevent inlining for a state, the code generator produces these static functions for state *foo*.

Function	Description
<code>enter_atomic_foo</code>	Marks <i>foo</i> active and performs entry actions.
<code>enter_internal_foo</code>	Calls default paths.

Function	Description
<code>inner_default_foo</code>	<p>Executes flow charts that originate when an inner transition and default transition reach the same junction inside a state.</p> <p>The code generator produces this function only when the flow chart is complex enough to exceed the inlining threshold.</p> <p>In generated code, Stateflow software calls this function from both the <code>enter_internal_foo</code> and <code>foo</code> functions.</p>
<code>foo</code>	Checks for valid outer transitions and if none, performs during actions.
<code>exit_atomic_foo</code>	Performs exit actions and marks <code>foo</code> inactive.
<code>exit_internal_foo</code>	Performs exit actions of the child substates and then exits <code>foo</code> .

Suppose the following chart is in model M.

If you prevent inlining for state A, the code generator produces this code.

```
static void M_inner_default_A(void);
static void M_exit_atomic_A(void);
static void M_A(void);
static void M_enter_atomic_A(void);
static void M_enter_internal_A(void);
```

How to Set the State Function Inline Option

To set the function inlining property for a state:

- 1 Right-click inside the state and, from the context menu, select **Properties**.

The State properties dialog box opens.

- 2 In the **Function Inline Option** field, select one of these options.

Option	Behavior
Inline	Forces inlining of state functions into the parent function, as long as the function is not part of a recursion. See “What Happens When You Force Inlining” on page 10-14.
Function	Prevents inlining of state functions. Generates up to six static functions for the state. See “What Happens When You Prevent Inlining” on page 10-14.
Auto	Uses internal heuristics to determine whether or not to inline the state functions.

- 3 Click **Apply**.

Best Practices for Controlling State Function Inlining

To	Set Function Inline Option Property To
Generate a separate function for each action of a state and a separate function for each action of its substates	Function for the state and each substate
Generate a separate function for each action of a state, but include code for the associated action of its substates	Function for the state and Inline for each substate

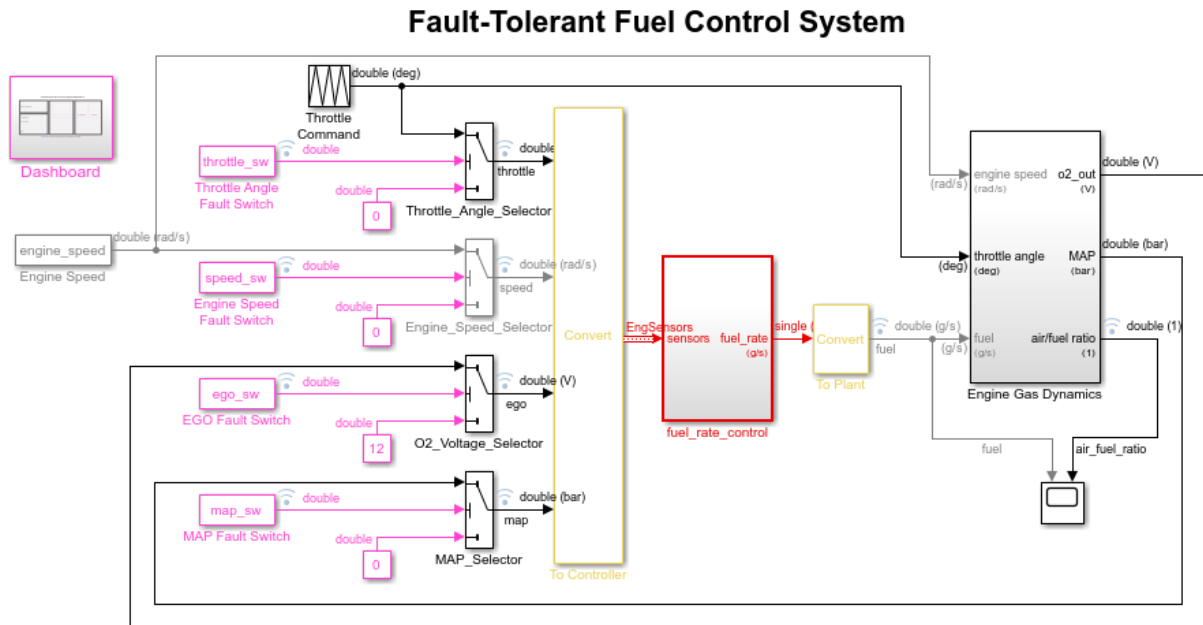

Air-Fuel Ratio Control System with Stateflow Charts

Generate code for an air-fuel ratio control system designed with Simulink® and Stateflow®.

Figures 1, 2, and 3 show relevant portions of the `sldemo_fuelsys` model, a closed-loop system containing a plant and controller. The plant validates the controller in simulation early in the design cycle. In this example, you generate code for the relevant controller subsystem, "fuel_rate_control". Figure 1 shows the top-level simulation model.

Open `sldemo_fuelsys` via `rtwdemo_fuelsys` and compile the diagram to see the signal data types.

```
rtwdemo_fuelsys
sldemo_fuelsys([],[],[],[],'compile');
sldemo_fuelsys([],[],[],[],'term');
```

[Open the Dashboard](#) subsystem to simulate any combination of sensor failures.

Copyright 1990-2017 The MathWorks, Inc.

Figure 1: Top-level model of the plant and controller

The air-fuel ratio control system is comprised of Simulink® and Stateflow®. The control system is the portion of the model for which you generate code.

```
open_system('sldemo_fuelsys/fuel_rate_control');
```

Figure 2: The air-fuel ratio controller subsystem

The control logic is a Stateflow® chart that specifies the different modes of operation.

```
open_system('sldemo_fuelsys/fuel_rate_control/control_logic');
```

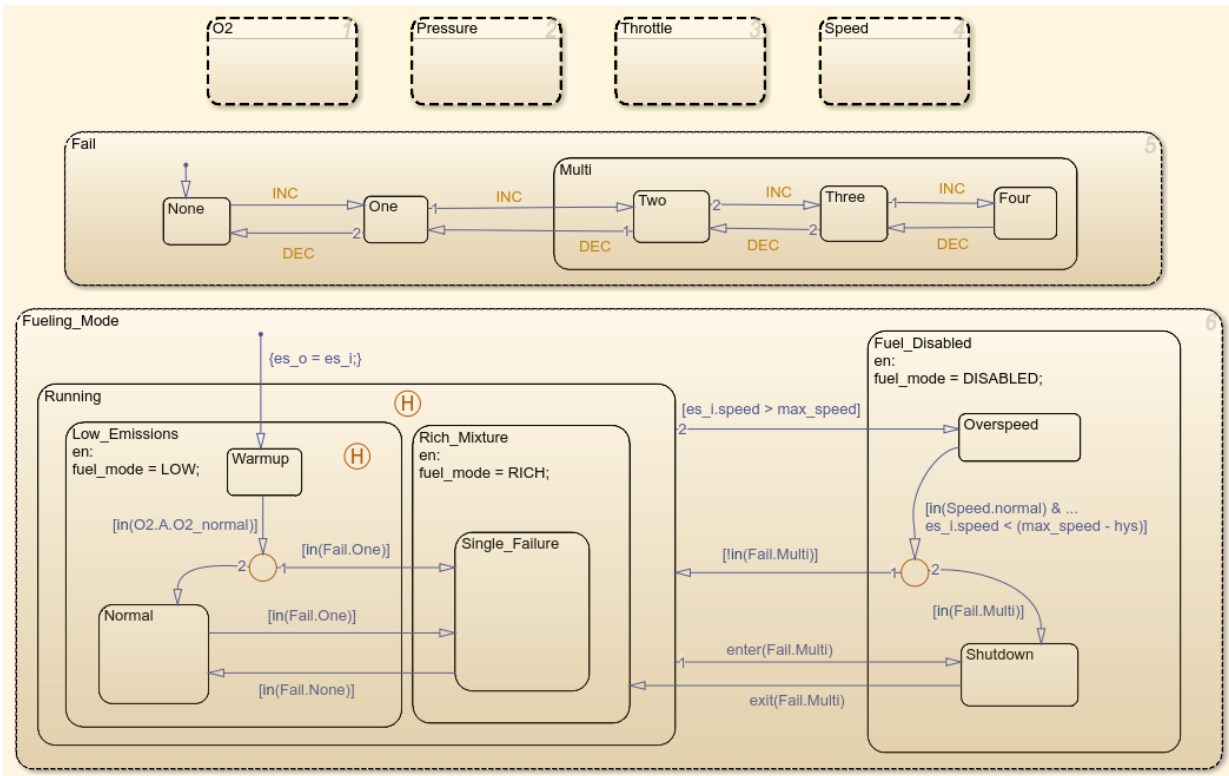

Figure 3: Air-fuel rate controller logic

Close these windows.

```
close_system('sldemo_fuelsys/fuel_rate_control/airflow_calc');
close_system('sldemo_fuelsys/fuel_rate_control/fuel_calc');
close_system('sldemo_fuelsys/fuel_rate_control/control_logic');
hDemo.rt=sfroot;hDemo.m=hDemo.rt.find('-isa','Simulink.BlockDiagram');
hDemo.c=hDemo.m.find('-isa','Stateflow.Chart','-and','Name','control_logic');
hDemo.c.visible=false;
close_system('sldemo_fuelsys/fuel_rate_control');
```

Configure and Build the Model with Simulink® Coder™

Simulink® Coder™ generates generic ANSI® C code for Simulink® and Stateflow® models via the Generic Real-Time (GRT) target. You can configure a model for code generation programmatically.

```
rtwconfiguredemo('sldemo_fuelsys','GRT');
```

For this example, build only the air-fuel ratio control system. Once the code generation process is complete, an HTML report detailing the generated code is displayed. The main body of the code is located in `fuel_rate_control.c`.

```
rtwbuild('sldemo_fuelsys/fuel_rate_control');

### Starting build procedure for model: fuel_rate_control
### Successful completion of build procedure for model: fuel_rate_control
```

Configure and Build the Model with Embedded Coder®

Embedded Coder® generates production ANSI® C/C++ code via the Embedded Real-Time (ERT) target. You can configure a model for code generation programmatically.

```
rtwconfiguredemo('sldemo_fuelsys','ERT');
```

Repeat the build process and inspect the generated code. In the Simulink® Coder™ Report, you can navigate to the relevant code segments interactively by using the **Previous** and **Next** buttons. From the chart context menu (right-click the Stateflow® block), select **Code Generation > Navigate to Code**. Programmatically, use the `rtwtrace` utility.

```
rtwbuild('sldemo_fuelsys/fuel_rate_control');
rtwtrace('sldemo_fuelsys/fuel_rate_control/control_logic')

### Starting build procedure for model: fuel_rate_control
### Successful completion of build procedure for model: fuel_rate_control
```

View the air-fuel ratio control logic in the generated code.

```
rtwdemodbtype('fuel_rate_control_ert_rtw/fuel_rate_control.c','/* Function for Chart: '

/* Function for Chart: '<S1>/control_logic' */
static void Fueling_Mode(const int32_T *sfEvent)
{
    /* This state interprets the other states in the chart to directly control the fueling
```

```

switch (rtDW.bitsForTID0.is_Fueling_Mode) {
case IN_Fuel_Disabled:
    rtDW.fuel_mode = DISABLED;

    /* The fuel is completely shut off while in this state. */
    switch (rtDW.bitsForTID0.is_Fuel_Disabled) {
    case IN_Overspeed:
        /* Inport: '<Root>/sensors' */
        /* The speed is dangerously high, so shut off the fuel. */
        if ((rtDW.bitsForTID0.is_Speed == IN_normal) && (rtU.sensors.speed <
            603.0F)) {
            if (!(rtDW.bitsForTID0.is_Fail == IN_Multi)) {
                rtDW.bitsForTID0.is_Fuel_Disabled = IN_NO_ACTIVE_CHILD;
                rtDW.bitsForTID0.is_Fueling_Mode = IN_Running;
                switch (rtDW.bitsForTID0.was_Running) {
                case IN_Low_Emissions:
                    if (rtDW.bitsForTID0.is_Running != IN_Low_Emissions) {
                        rtDW.bitsForTID0.is_Running = IN_Low_Emissions;
                        rtDW.bitsForTID0.was_Running = IN_Low_Emissions;
                        rtDW.fuel_mode = LOW;
                    }

                    switch (rtDW.bitsForTID0.was_Low_Emissions) {
                    case IN_Normal:
                        rtDW.bitsForTID0.is_Low_Emissions = IN_Normal;
                        rtDW.bitsForTID0.was_Low_Emissions = IN_Normal;
                        break;

```

Close the model and code generation report.

```

clear hDemo;
rtwdemoclean;
close_system('sldemo_fuelsys',0);

```

S-Functions and Code Generation

In this section...
“Types of S-Functions” on page 11-3
“Files Required for Implementing Noninlined and Inlined S-Functions” on page 11-5
“Guidelines for Writing S-Functions that Support Code Generation” on page 11-6

You use S-functions to extend Simulink support for simulation and code generation. For example, you can use them to:

- Represent custom algorithms
- Interface existing external code with Simulink and the code generator
- Represent device drivers for interfacing with hardware
- Generate highly optimized code for embedded systems
- Verify code generated for a subsystem as part of a Simulink simulation

The application program interface (API) for writing S-functions allows you to implement generic algorithms in the Simulink environment with a great deal of flexibility. If you intend to use S-functions in a model for code generation, the level of flexibility can vary. For example, it is not possible to access the MATLAB workspace from an S-function that you use with the code generator. This topic explains conditions to be aware of for using S-functions. However, using the techniques presented in this topic, you can create S-functions for most applications that work with the generated code.

Although S-functions provide a generic and flexible solution for implementing complex algorithms in a model, the underlying API incurs overhead in terms of memory and computation resources. Most often the additional resources are acceptable for real-time rapid prototyping systems. In many cases, though, additional resources are unavailable in real-time embedded applications. You can minimize memory and computational requirements by using the Target Language Compiler technology provided with the code generator to inline your S-functions. If you are producing an S-function for existing external code, consider using the Legacy Code Tool to generate your S-function and relevant TLC file.

This content assumes that you understand the following concepts:

- Level 2 S-functions

- Target Language Compiler (TLC) scripting
- How the code generator produces and builds C/C++ code

Notes This information is for code generator users. Even if you do not currently use the code generator, follow these practices when writing S-functions, especially if you are creating general-purpose S-functions.

Types of S-Functions

Examples for which you might choose to implement an S-function for simulation and code generation include:

- 1 “I’m not concerned with efficiency. I just want to write one version of my algorithm and have it work in the Simulink and code generator products automatically.”
- 2 “I want to implement a highly optimized algorithm in the Simulink and code generator products that looks like a built-in block and generates very efficient code.”
- 3 “I have a lot of hand-written code that I need to interface. I want to call my function from the Simulink and code generator products in an efficient manner.”

Respectively, the preceding situations map to the following MathWorks terminology:

- 1 Noninlined S-function
- 2 Inlined S-function
- 3 Autogenerated S-function for external code

Noninlined S-Functions

A noninlined S-function is a C or C++ MEX S-function that is treated identically by the Simulink engine and generated code. In general, you implement your algorithm once according to the S-function API. The Simulink engine and generated code call the S-function routines (for example, `mdlOutputs`) during model execution.

Additional memory and computation resources are required for each instance of a noninlined S-Function block. However, this routine of incorporating algorithms into models and code generation applications is typical during the prototyping phase of a project where efficiency is not important. The advantage gained by forgoing efficiency is the ability to change model parameters and structures rapidly.

Writing a noninlined S-function does not involve TLC coding. Noninlined S-functions are the default case for the build process in the sense that once you build a MEX S-function in your model, there is no additional preparation prior to pressing **Ctrl+B** to build your model.

Some restrictions exist concerning the names and locations of noninlined S-function files when generating makefiles. See “Write Noninlined S-Function and TLC Files” on page 11-67.

Inlined S-Functions

For S-functions to work in the Simulink environment, some overhead code is generated. When the code generator produces code from models that contain S-functions (without *sfunction.tlc* files), it embeds some of this overhead code in the generated code. If you want to optimize your real-time code and eliminate some of the overhead code, you must *inline* (or embed) your S-functions. This involves writing a TLC (*sfunction.tlc*) file that eliminates overhead code from the generated code. The Target Language Compiler processes *sfunction.tlc* files to define how to inline your S-function algorithm in the generated code.

Note The term *inline* should not be confused with the C++ *inline* keyword. Inline means to specify text in place of the call to the general S-function API routines (for example, `mdlOutputs`). For example, when a TLC file is used to inline an S-function, the generated code contains the C/C++ code that would normally appear within the S-function routines and the S-function itself has been removed from the build process.

A fully inlined S-function builds your algorithm (block) into generated code in a manner that is indistinguishable from a built-in block. Typically, a fully inlined S-function requires you to implement your algorithm twice: once for the Simulink model (C/C++ MEX S-function) and once for code generation (TLC file). The complexity of the TLC file depends on the complexity of your algorithm and the level of efficiency you're trying to achieve in the generated code. TLC files vary from simple to complex in structure. See “Inlining S-Functions” (Simulink Coder)

Autogenerated S-Functions for Legacy or Custom Code

If you need to invoke hand-written C/C++ code in your model, consider using the Simulink Legacy Code Tool. The Legacy Code Tool can automate the generation of a fully inlined S-function and a corresponding TLC file based on information that you register in a Legacy Code Tool data structure.

For more information, see “Integrate C Functions Using Legacy Code Tool” (Simulink) and see “Import Calls to External Code into Generated Code with Legacy Code Tool” on page 11-7.

Files Required for Implementing Noninlined and Inlined S-Functions

This topic briefly describes what files and functions you need to create noninlined and inlined S-functions.

- Noninlined S-functions require the C or C++ MEX S-function source code (*sfunction.c* or *sfunction.cpp*).
- Fully inlined S-functions require an *sfunction.tlc* file. Fully inlined S-functions produce the optimal code for a parameterized S-function. This is an S-function that operates in a specific mode dependent upon fixed S-function parameters that do not change during model execution. For a given operating mode, the *sfunction.tlc* file specifies the exact code that is generated to implement the algorithm for that mode. For example, the direct-index lookup table S-function in “Write Fully Inlined S-Functions with mdlRTW Routine” on page 11-79 contains two operating modes — one for evenly spaced *x-data* and one for unevenly spaced *x-data*.

Note Fully-inlined S-functions that are generated to invoke legacy or custom C/C++ code also require an *sfunction.tlc* file, which is generated by Legacy Code Tool.

Fully inlined S-functions might require the placement of the mdlRTW routine in your S-function MEX-file *sfunction.c* or *sfunction.cpp*. The mdlRTW routine lets you place information in *model.rtw*, the record file that specifies a model, and which the code generator invokes the Target Language Compiler to process prior to executing *sfunction.tlc* when generating code.

Including a mdlRTW routine is useful when you want to introduce nontunable parameters into your TLC file. Such parameters are generally used to determine which operating mode is active in a given instance of the S-function. Based on this information, the TLC file for the S-function can generate highly efficient, optimal code for that operating mode.

Guidelines for Writing S-Functions that Support Code Generation

- You can use C/C++ MEX, MATLAB language, and Fortran MEX S-functions with code generation.
- You can inline S-functions for code generation by providing an inlining TLC file. See S-Function Inlining in “Target Language Compiler” (Simulink Coder). MATLAB and Fortran MEX S-functions must be inlined. C/C++ MEX S-functions can be inlined for code efficiency, or noninlined.
- To automatically generate a fully inlined C MEX S-function for invoking legacy or custom code, use the Legacy Code Tool. For more information, see “Integrate C Functions Using Legacy Code Tool” (Simulink) and see “Import Calls to External Code into Generated Code with Legacy Code Tool” (Simulink Coder).
- If code efficiency is not an overriding consideration, for example, if you are rapid prototyping, you can choose not to inline a C/C++ MEX S-function. For more information, see “Write Noninlined S-Function and TLC Files” on page 11-67.

Legacy Code Tool and Code Generation

You can use the Simulink Legacy Code Tool to generate fully inlined C MEX S-functions for legacy or custom code. The S-functions are optimized for embedded components, such as device drivers and lookup tables, and they call existing C or C++ functions.

Note The Legacy Code Tool can interface with C++ functions, but not C++ objects. To work around this issue so that the tool can interface with C++ objects, see “Legacy Code Tool Limitations” (Simulink).

You can use the tool to:

- Compile and build the generated S-function for simulation.
- Generate a masked S-Function block that is configured to call the existing external code.

If you want to include these types of S-functions in models for which you intend to generate code, use the tool to generate a TLC block file. The TLC block file specifies how the generated code for a model calls the existing C or C++ function.

If the S-function depends on files in folders other than the folder containing the S-function dynamically loadable executable file, use the tool to generate an

sFunction_makecfg.m or *rtwmakecfg.m* file for the S-function. Generating the file maintains those dependencies when you build a model that includes the S-function. For example, for some applications, such as custom targets, you might want to locate files in a target-specific location. The build process looks for *sFunction_makecfg.m* or *rtwmakecfg.m* in the same folder as the S-function dynamically loadable executable and calls the function in the file.

For more information, see “Integrate C Functions Using Legacy Code Tool” (Simulink).

Generate Inlined S-Function Files for Code Generation

Depending on the code generation requirements of your application, to generate code for a model that uses the S-function, do either of the following:

- Generate one `.cpp` file for the inlined S-function. In the Legacy Code Tool data structure, set the value of the `Options.singleCPPMexFile` field to `true` before generating the S-function source file from your existing C function. For example:

```
def.Options.singleCPPMexFile = true;
legacy_code('sfcn_cmex_generate', def);
```

- Generate a source file and a TLC block file for the inlined S-function. For example:

```
def.Options.singleCPPMexFile = false;
legacy_code('sfcn_cmex_generate', def);
legacy_code('sfcn_tlc_generate', def);
```

singleCPPMexFile Limitations

You cannot set the `singleCPPMexFile` field to `true` if

- `Options.language='C++'`
- You use one of the following Simulink objects with the `IsAlias` property set to `true`:
 - `Simulink.Bus`
 - `Simulink.AliasType`
 - `Simulink.NumericType`
- The Legacy Code Tool function specification includes a `void*` or `void**` to represent scalar work data for a state argument
- `HeaderFiles` field of the Legacy Code Tool structure specifies multiple header files

Apply Code Style Settings to Legacy Functions

To apply the model configuration parameters for code style to a legacy function:

- 1 Initialize the Legacy Code Tool data structure. For example:

```
def = legacy_code('initialize');
```

- 2 In the data structure, set the value of the `Options.singleCPPMexFile` field to `true`. For example:

```
def.Options.singleCPPMexFile = true;
```

To check the setting, enter:

```
def.Options.singleCPPMexFile
```

singleCPPMexFile Limitations

You cannot set the `singleCPPMexFile` field to `true` if

- `Options.language='C++'`
- You use one of the following Simulink objects with the `IsAlias` property set to `true`:
 - `Simulink.Bus`
 - `Simulink.AliasType`
 - `Simulink.NumericType`
- The Legacy Code Tool function specification includes a `void*` or `void**` to represent scalar work data for a state argument
- `HeaderFiles` field of the Legacy Code Tool structure specifies multiple header files

Address Dependencies on Files in Different Locations

By default, the Legacy Code Tool assumes that files on which an S-function depends reside in the same folder as the dynamically loadable executable file for the S-function. If your S-function depends on files that reside elsewhere and you are using the template makefile build process, generate an `sFunction_makecfg.m` or `rtwmakecfg.m` file for the S-function. For example, you might generate this file if your Legacy Code Tool data structure defines compilation resources as path names.

To generate the `sFunction_makecfg.m` or `rtwmakecfg.m` file, call the `legacy_code` function with `'sfcn_makecfg_generate'` or `'rtwmakecfg_generate'` as the first

argument, and the name of the Legacy Code Tool data structure as the second argument. For example:

```
legacy_code('sfcn_makecfg_generate', lct_spec);
```

If you use multiple registration files in the same folder and generate an S-function for each file with a single call to `legacy_code`, the call to `legacy_code` that specifies `'sfcn_makecfg_generate'` or `'rtwmakecfg_generate'` must be common to all registration files. For more information, see “Handling Multiple Registration Files” (Simulink).

For example, if you define `defs` as an array of Legacy Code Tool structures, you call `legacy_code` with `'sfcn_makecfg_generate'` once.

```
defs = [defs1(:);defs2(:);defs3(:)];  
legacy_code('sfcn_makecfg_generate', defs);
```

For more information, see “Build Support for S-Functions” (Simulink Coder).

Deploy S-Functions for Simulation and Code Generation

You can deploy the S-functions that you generate with the Legacy Code Tool so that other people can use them. To deploy an S-function for simulation and code generation, share the following files:

- Registration file
- Compiled dynamically loadable executable
- TLC block file
- `sFunction_makecfg.m` or `rtwmakecfg.m` file
- Header, source, and include files on which the generated S-function depends

When you use these deployed files:

- Before using the deployed files in a Simulink model, add the folder that contains the S-function files to the MATLAB path.
- If the Legacy Code Tool data structure registers required files as absolute paths and the location of the files changes, regenerate the `sFunction_makecfg.m` or `rtwmakecfg.m` file.

Integrate External C++ Object Methods

Integrate legacy C++ object methods by using the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C++ MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a block TLC file and optional rtwmakecfg.m file that calls the legacy code during code generation.

Provide the Legacy Function Specification

Functions provided with the Legacy Code Tool take a specific data structure or array of structures as the argument. The data structure is initialized by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call `legacy_code('help')`. The definition of the legacy C++ class in this example is:

```
class adder {
private:
    int int_state;
public:
    adder();
    int add_one(int increment);
    int get_val();
};
```

The legacy source code is in the files `adder_cpp.h` and `adder_cpp.cpp`.

```
% rtwdemo_sfun_adder_cpp
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_adder_cpp';
def.StartFcnSpec = 'createAdder()';
def.OutputFcnSpec = 'int32 y1 = adderOutput(int32 u1)';
def.TerminateFcnSpec = 'deleteAdder()';
def.HeaderFiles = {'adder_cpp.h'};
def.SourceFiles = {'adder_cpp.cpp'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
```

```
def.Options.language = 'C++';  
def.Options.useTlcWithAccel = false;
```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function `legacy_code()` again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file `rtwdemo_sfun_adder_cpp.cpp`.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
### Start Compiling rtwdemo_sfun_adder_cpp  
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc18a_815039_1...  
Building with 'Microsoft Visual C++ 2015'.  
MEX completed successfully.  
    mex('rtwdemo_sfun_adder_cpp.cpp', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src...  
Building with 'Microsoft Visual C++ 2015'.  
MEX completed successfully.  
### Finish Compiling rtwdemo_sfun_adder_cpp  
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again. Set the first input to 'sfcn_tlc_generate' to generate a TLC block file that supports code generation through Simulink® Coder™. If the TLC block file is not created and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfun_adder_cpp.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again. Set the first input to 'rtwmakecfg_generate' to generate an `rtwmakecfg.m` file that supports code

generation through Simulink® Coder™. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again. Set the first input to `'slblock_generate'` to generate a masked S-function block that is configured to call that S-function. The software places the block in a new model. You can copy the block to an existing model.

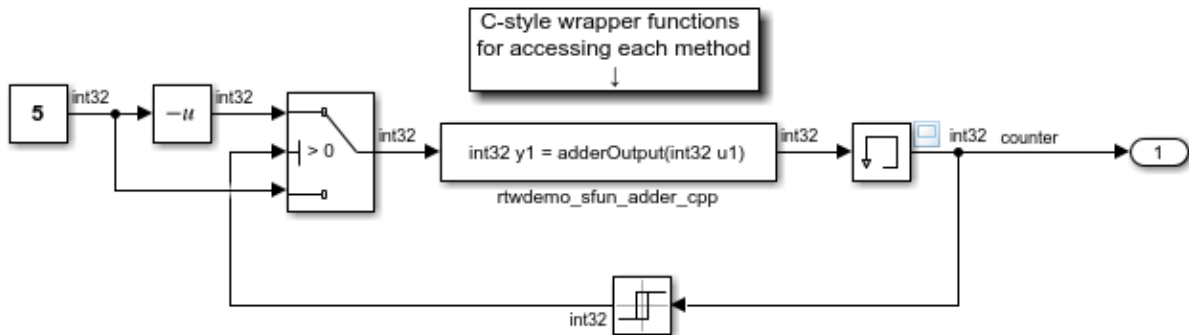

```
% legacy_code('slblock_generate', def);
```

Show the Generated Integration with Legacy Code

The model `rtwdemo_lct_cpp` shows integration with the legacy code.

```
open_system('rtwdemo_lct_cpp')  
sim('rtwdemo_lct_cpp')
```

This example illustrates how the Legacy Code Tool is used to call C++ object member functions

For this example to run you must go to the MATLAB command prompt and enter: `>> mex -setup` then select a C++ compiler.

To view the sources for this example click the links below.

- open legacy files [adder_cpp.h](#) and [adder_cpp.cpp](#)
- open registration script [rtwdemo_lct_cpp_script.m](#)
- open generated S-Function [rtwdemo_sfund_adder_cpp.cpp](#)
- open generated TLC file [rtwdemo_sfund_adder_cpp.tlc](#)

Generate Code Using Embedded Coder (double-click)

Copyright 1990-2012 The MathWorks, Inc.

Integrate External C++ Objects

The Legacy Code Tool can interface with C++ functions, but not C++ objects. Using the previous example as a starting point, here is an example of how you can work around this limitation.

- Modify the class definition for `adder` in a new file `adder_cpp.hpp`. Add three new macros that dynamically allocate a new `adder` object, invoke the method `add_one()`, and free the memory allocated. Each macro takes a pointer to an `adder` object. Because each function called by the Legacy Code Tool must have a C-like signature,

the pointer is cached and passed as a `void*`. Then you must explicitly cast to `adder*` in the macro. The new class definition for `adder`:

```
#ifndef _ADDER_CPP_
#define _ADDER_CPP_

class adder {
private:
    int int_state;
public:
    adder(): int_state(0) {};
    int add_one(int increment);
    int get_val() {return int_state;};
};

// Method wrappers implemented as macros
#define createAdder(work1) \
    *(work1) = new adder

#define deleteAdder(work1) \
    delete(static_cast<adder*>(*(work1)))

#define adderOutput(work1, u1) \
    (static_cast<adder*> ((work1)))->add_one(u1)

#endif /* _ADDER_CPP_ */
```

- Update `adder_cpp.cpp`. With the class modification, instead of one global instance, each generated S-function manages its own `adder` object.

```
#include "adder_cpp.hpp"

int adder::add_one(int increment)
{
    int_state += increment;
    return int_state;
}
```

- Update `rtwdemo_sfun_adder_cpp.cpp` with the following changes:
 - `StartFcnSpec` calls the macro that allocates a new `adder` object and caches the pointer.

```
def.StartFcnSpec = 'createAdder(void **work1)';
```
 - `OutputFcnSpec` calls the macro that invokes the method `add_one()` and provides the S-function specific `adder` pointer object.

```
def.OutputFcnSpec = 'int32 y1 = adderOutput(void *work1, int32 u1)';
```

- TerminateFcnSpec calls the macro that frees the memory.

```
def.TerminateFcnSpec = 'deleteAdder(void **work1)';
```

Legacy Code Tool Examples

Integrate External C Functions That Pass Input Arguments By Value Versus Address

This example shows how to use the Legacy Code Tool to integrate legacy C functions that pass their input arguments by value versus address.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call `legacy_code('help')`. The prototypes of the legacy functions being called in this example are:

- FLT filterV1(const FLT signal, const FLT prevSignal, const FLT gain)
- FLT filterV2(const FLT* signal, const FLT prevSignal, const FLT gain)

FLT is a typedef to float. The legacy source code is in the files `your_types.h`, `myfilter.h`, `filterV1.c`, and `filterV2.c`.

Note the difference in the `OutputFcnSpec` defined in the two structures; the first case specifies that the first input argument is passed by value, while the second case specifies pass by pointer.

```

defs = [];

% rtwdemo_sfun_filterV1
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_filterV1';
def.OutputFcnSpec = 'single y1 = filterV1(single u1, single u2, single p1)';
def.HeaderFiles = {'myfilter.h'};
def.SourceFiles = {'filterV1.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
defs = [defs; def];

% rtwdemo_sfun_filterV2
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_filterV2';
def.OutputFcnSpec = 'single y1 = filterV2(single u1[1], single u2, single p1)';
def.HeaderFiles = {'myfilter.h'};
def.SourceFiles = {'filterV2.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
defs = [defs; def];
    
```

Generate S-Functions for Simulation

To generate C-MEX S-functions according to the description provided by the input argument 'defs', call the function `legacy_code()` again with the first input set to 'sfcn_cmex_generate'. The S-functions call the legacy functions in simulation. The source code for the S-functions is in the files `rtwdemo_sfun_filterV1.c` and `rtwdemo_sfun_filterV2.c`.

```
legacy_code('sfcn_cmex_generate', defs);
```

Compile the Generated S-Functions for Simulation

After you generate the C-MEX S-function source files, to compile the S-functions for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', defs);
```

```

### Start Compiling rtwdemo_sfun_filterV1
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc18a_815039_1');
Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.
    
```

```
mex('rtwdemo_sfun_filterV1.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src',
Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_filterV1
### Exit

### Start Compiling rtwdemo_sfun_filterV2
mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc18a_815039_
Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.
mex('rtwdemo_sfun_filterV2.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src',
Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_filterV2
### Exit
```

Generate TLC Block Files for Code Generation

After you compile the S-functions and use them in simulation, you can call the function `legacy_code()` again with the first input set to `'sfcn_tlc_generate'` to generate TLC block files. Block files specify how the generated code for a model calls the legacy code. If you do not generate TLC block files and you try to generate code for a model that includes the S-functions, code generation fails. The TLC block files for the S-functions are `rtwdemo_sfun_filterV1.tlc` and `rtwdemo_sfun_filterV2.tlc`.

```
legacy_code('sfcn_tlc_generate', defs);
```

Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block files, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-functions are not in the same folder as the S-functions, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', defs);
```

Generate Masked S-Function Blocks for Calling the Generated S-Functions

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate masked S-function blocks that call the S-functions. The software places the blocks in a new model. From there you can copy them to an existing model.

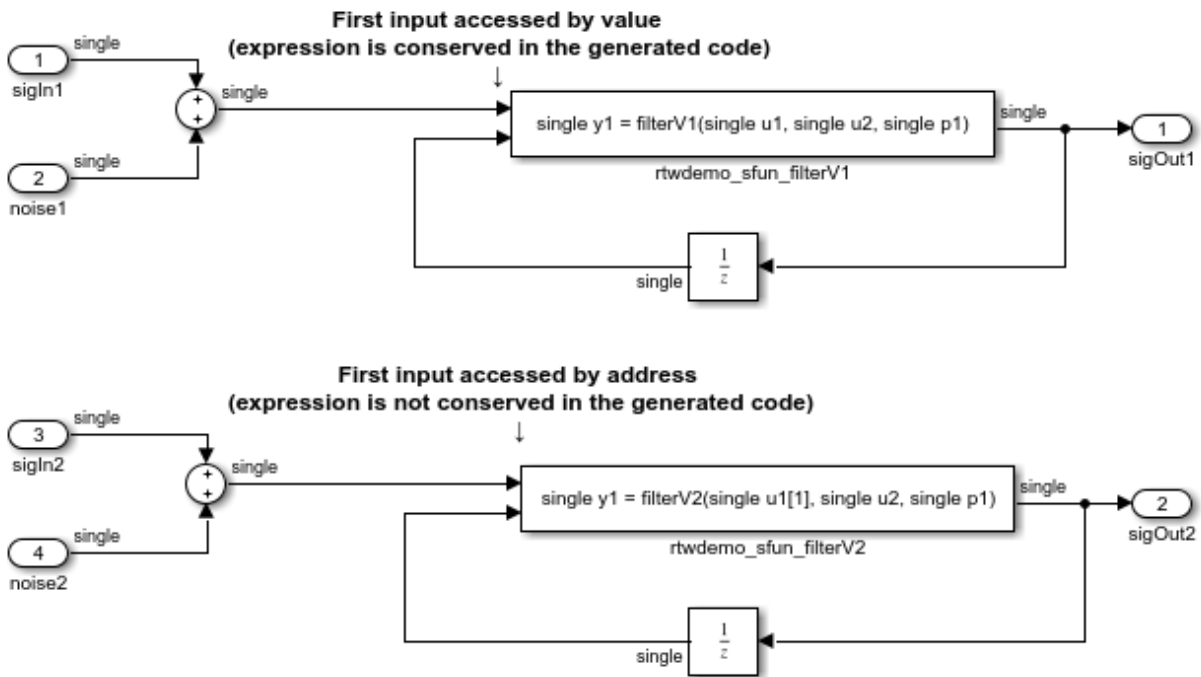

```
legacy_code('slblock_generate', defs);
```

Show the Generated Integration with Legacy Code

The model `rtwdemo_lct_filter` shows integration of the model with the legacy code. The subsystem `TestFilter` serves as a harness for the calls to the legacy C functions via the generate S-functions, with unit delays serving to store the previous output values.

```
open_system('rtwdemo_lct_filter')  
open_system('rtwdemo_lct_filter/TestFilter')  
sim('rtwdemo_lct_filter')
```

Integrate External C Functions That Pass the Output Argument As a Return Argument

This example shows how to use the Legacy Code Tool to integrate legacy C functions that pass their output as a return argument.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call `legacy_code('help')`. The prototype of the legacy functions being called in this example is:

```
FLT gainScalar(const FLT in, const FLT gain)
```

FLT is a typedef to float. The legacy source code is in the files `your_types.h`, `gain.h`, and `gainScalar.c`.

```
% rtwdemo_sfun_gain_scalar
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_gain_scalar';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles = {'gain.h'};
def.SourceFiles = {'gainScalar.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function `legacy_code()` again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file `rtwdemo_sfun_gain_scalar.c`.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
### Start Compiling rtwdemo_sfun_gain_scalar
mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc18a_815039_
Building with 'Microsoft Visual C++ 2015 (C)'.
```

```
MEX completed successfully.  
    mex('rtwdemo_sfund_gain_scalar.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_s  
Building with 'Microsoft Visual C++ 2015 (C)'.  
MEX completed successfully.  
### Finish Compiling rtwdemo_sfund_gain_scalar  
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again with the first input set to `'sfcn_tlc_generate'` to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfund_gain_scalar.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

```
legacy_code('slblock_generate', def);
```

Show the Generated Integration with Legacy Code

The model `rtwdemo_lct_gain` shows integration of the model with the legacy code. The subsystem `TestGain` serves as a harness for the call to the legacy C function via the generate S-function.

```
open_system('rtwdemo_lct_gain')
open_system('rtwdemo_lct_gain/TestGain')
sim('rtwdemo_lct_gain')
```

Integrate External C Functions That Pass Input and Output Arguments as Signals with a Fixed-Point Data Type

This example shows how to use the Legacy Code Tool to integrate legacy C functions that pass their inputs and outputs by using parameters of fixed-point data type.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call `legacy_code('help')`. The prototype of the legacy functions being called in this example is:

```
myFixpt timesS16(const myFixpt in1, const myFixpt in2, const uint8_T fracLength)
```

myFixpt is logically a fixed-point data type, which is physically a typedef to a 16-bit integer:

```
myFixpt = Simulink.NumericType;
myFixpt.DataTypeMode = 'Fixed-point: binary point scaling';
myFixpt.Signed = true;
myFixpt.WordLength = 16;
myFixpt.FractionLength = 10;
myFixpt.IsAlias = true;
myFixpt.HeaderFile = 'timesFixpt.h';
```

The legacy source code is in the files timesFixpt.h, and timesS16.c.

```
% rtwdemo_sfun_times_s16
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_times_s16';
def.OutputFcnSpec = 'myFixpt y1 = timesS16(myFixpt u1, myFixpt u2, uint8 p1)';
def.HeaderFiles = {'timesFixpt.h'};
def.SourceFiles = {'timesS16.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_times_s16.c.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
### Start Compiling rtwdemo_sfun_times_s16
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc18a_815039_...
Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_times_s16.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src'
```

```
Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_times_s16
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again with the first input set to `'sfcn_tlc_generate'` to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfun_times_s16.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

```
legacy_code('slblock_generate', def);
```

Show the Integration of the Model with Legacy Code

The model `rtwdemo_lct_fixpt_signals` shows integration of the model with the legacy code. The subsystem `TestFixpt` serves as a harness for the call to the legacy C function via the generated S-function.

```
open_system('rtwdemo_lct_fixpt_signals')
open_system('rtwdemo_lct_fixpt_signals/TestFixpt')
sim('rtwdemo_lct_fixpt_signals')
```

Integrate External C Functions with Instance-Specific Persistent Memory

Integrate legacy C functions that use instance-specific persistent memory by using the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call `legacy_code('help')`. The prototypes of the legacy functions being called in this example are:

```
void memory_bus_init(COUNTERBUS *mem, int32_T upper_sat, int32_T lower_sat);

void memory_bus_step(COUNTERBUS *input, COUNTERBUS *mem, COUNTERBUS
*output);
```

mem is an instance-specific persistent memory for applying a one integration step delay. COUNTERBUS is a struct typedef defined in counterbus.h and implemented with a Simulink.Bus object in the base workspace. The legacy source code is in the files memory_bus.h, and memory_bus.c.

```
evalin('base','load rtwdemo_lct_data.mat')

% rtwdemo_sfun_work
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_work';
def.InitializeConditionsFcnSpec = ...
    'void memory_bus_init(COUNTERBUS work1[1], int32 p1, int32 p2)';
def.OutputFcnSpec = ...
    'void memory_bus_step(COUNTERBUS u1[1], COUNTERBUS work1[1], COUNTERBUS y1[1])';
def.HeaderFiles = {'memory_bus.h'};
def.SourceFiles = {'memory_bus.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_work.c.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
### Start Compiling rtwdemo_sfun_work
mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc18a_815039_1
```

```
Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.
    mex('rtwdemo_sfundemo.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-I
Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfundemo
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again with the first input set to `'sfcn_tlc_generate'` to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfundemo.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

```
legacy_code('slblock_generate', def);
```

The image shows a Simulink block definition for a function named `memory_bus_step`. The block is represented by a rectangular box with a right-pointing arrow on its right side. Inside the box, the function signature is: `void memory_bus_step(COUNTERBUS u1[1], COUNTERBUS work1[1], COUNTERBUS y1[1])`. Below the box, the name of the S-function source file is indicated as `rtwdemo_sfundemo`.

Show the Integration of the Model with Legacy Code

The model `rtwdemo_lct_work` shows integration of the model with the legacy code. The subsystem `memory_bus` serves as a harness for the call to the legacy C function.

```
open_system('rtwdemo_lct_work')
open_system('rtwdemo_lct_work/memory_bus')
sim('rtwdemo_lct_work')
```

This legacy function apply a one integration step delay. The output is the previous input value. The parameters P1 and P2 set the initial values of the sub structure fields "upper_saturation_limit" and "lower_saturation_limit"

Integrate External C Functions That Use Structure Arguments

Integrate legacy C functions with structure arguments that use Simulink® buses with the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call `legacy_code('help')`. The prototype of the legacy functions being called in this example is:

```
counterbusFcn(COUNTERBUS *u1, int32_T u2, COUNTERBUS *y1, int32_T *y2)
```

COUNTERBUS is a struct typedef defined in counterbus.h and implemented with a Simulink.Bus object in the base workspace. The legacy source code is in the files counterbus.h, and counterbus.c.

```
evalin('base','load rtwdemo_lct_data.mat')

% rtwdemo_sfun_counterbus
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_counterbus';
def.OutputFcnSpec = ...
    'void counterbusFcn(COUNTERBUS u1[1], int32 u2, COUNTERBUS y1[1], int32 y2[1])';
def.HeaderFiles = {'counterbus.h'};
def.SourceFiles = {'counterbus.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_counterbus.c.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
### Start Compiling rtwdemo_sfun_counterbus
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc18a_815039_1');
Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_counterbus.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src');
Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_counterbus
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again with the first input set to `'sfcn_tlc_generate'` to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfund_counterbus.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

```
legacy_code('slblock_generate', def);
```

Show the Integration of the Model with Legacy Code

The model `rtwdemo_lct_bus` shows integration of the model with the legacy code. The subsystem `TestCounter` serves as a harness for the call to the legacy C function.

```
open_system('rtwdemo_lct_bus')
open_system('rtwdemo_lct_bus/TestCounter')
sim('rtwdemo_lct_bus')
```

Integrate External C Functions That Pass Input and Output Arguments as Signals with Complex Data

Integrate legacy C functions using complex signals with the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using `'initialize'` as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call `legacy_code('help')`. The prototype of the legacy functions being called in this example is:

```
void cplx_gain(creal_T *input, creal_T *gain, creal_T *output);
```

`creal_T` is the complex representation of a double. The legacy source code is in the files `cplxgain.h`, and `cplxgain.c`.

```
% rtwdemo_sfun_gain_scalar
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_cplx_gain';
def.OutputFcnSpec = ...
    ['void cplx_gain(complex<double> u1[1], '...
```

```

    'complex<double> p1[1], complex<double> y1[1]');
def.HeaderFiles = {'cplxgain.h'};
def.SourceFiles = {'cplxgain.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};

```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function `legacy_code()` again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file `rtwdemo_sfun_cplx_gain.c`.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```

### Start Compiling rtwdemo_sfun_cplx_gain
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc18a_815039_');
Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_cplx_gain.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src');
Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_cplx_gain
### Exit

```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again with the first input set to 'sfcn_tlc_generate' to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfun_cplx_gain.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

```
legacy_code('slblock_generate', def);
```

Show the Integration of the Model with Legacy Code

The model `rtwdemo_lct_cplxgain` shows integration of the model with the legacy code. The subsystem `complex_gain` serves as a harness for the call to the legacy C function via the generate S-function.

```
if isempty(find_system('SearchDepth',0,'Name','rtwdemo_lct_cplxgain'))
    open_system('rtwdemo_lct_cplxgain')
    open_system('rtwdemo_lct_cplxgain/complex_gain')
    sim('rtwdemo_lct_cplxgain')
end
```

Integrate External C Functions That Pass Arguments That Have Inherited Dimensions

This example shows how to use the Legacy Code Tool to integrate legacy C functions whose arguments have inherited dimensions.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call `legacy_code('help')`. The prototypes of the legacy functions being called in this example are:

- `void mat_add(real_T *u1, real_T *u2, int32_T nbRows, int32_T nbCols, real_T *y1)`
- `void mat_mult(real_T *u1, real_T *u2, int32_T nbRows1, int32_T nbCols1, int32_T nbCols2, real_T *y1)`

`real_T` is a typedef to `double`, and `int32_T` is a typedef to a 32-bit integer. The legacy source code is in the files `mat_ops.h`, and `mat_ops.c`.

```
defs = [];
```

```
% rtwdemo_sfun_mat_add
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_mat_add';
```

```

def.OutputFcnSpec = ['void mat_add(double u1[[[[], double u2[[[[], ' ...
                    'int32 u3, int32 u4, double y1[size(u1,1)][size(u1,2)])'];
def.HeaderFiles   = {'mat_ops.h'};
def.SourceFiles   = {'mat_ops.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
defs = [defs; def];

% rtwdemo_sfun_mat_mult
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_mat_mult';
def.OutputFcnSpec = ['void mat_mult(double u1[p1][p2], double u2[p2][p3], '...
                    'int32 p1, int32 p2, int32 p3, double y1[p1][p3)'];
def.HeaderFiles   = {'mat_ops.h'};
def.SourceFiles   = {'mat_ops.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
defs = [defs; def];

```

Generate S-Functions for Simulation

To generate C-MEX S-functions according to the description provided by the input argument 'defs', call the function `legacy_code()` again with the first input set to 'sfcn_cmex_generate'. The S-functions call the legacy functions during simulation. The source code for the S-function is in the files `rtwdemo_sfun_mat_add.c` and `rtwdemo_sfun_mat_mult.c`.

```
legacy_code('sfcn_cmex_generate', defs);
```

Compile the Generated S-Functions for Simulation

After you generate the C-MEX S-function source files, to compile the S-functions for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', defs);
```

```

### Start Compiling rtwdemo_sfun_mat_add
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc18a_815039_
Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_mat_add.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src',
Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.

```

```
### Finish Compiling rtwdemo_sfun_mat_add
### Exit

### Start Compiling rtwdemo_sfun_mat_mult
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc18a_815039_...
Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_mat_mult.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src',

MEX completed successfully.
### Finish Compiling rtwdemo_sfun_mat_mult
### Exit
```

Generate TLC Block Files for Code Generation

After you compile the S-functions and use them in simulation, you can call the function `legacy_code()` again with the first input set to `'sfcn_tlc_generate'` to generate TLC block files. Block files specify how the generated code for a model calls the legacy code. If you do not generate TLC block files and you try to generate code for a model that includes the S-functions, code generation fails. The TLC block files for the S-functions are `rtwdemo_sfun_mat_add.tlc` and `rtwdemo_sfun_mat_mult.tlc`.

```
legacy_code('sfcn_tlc_generate', defs);
```

Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block files, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-functions are not in the same folder as the S-functions, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', defs);
```

Generate Masked S-Function Blocks for Calling the Generated S-Functions

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate masked S-function blocks that call the S-functions. The software places the blocks in a new model. From there you can copy them to an existing model

```
legacy_code('slblock_generate', defs);
```

```
void mat_add(double u1[], double u2[], int32 u3, int32 u4, double y1[size(u1,1)][size(u1,2)])
```

rtwdemo_sfun_mat_add

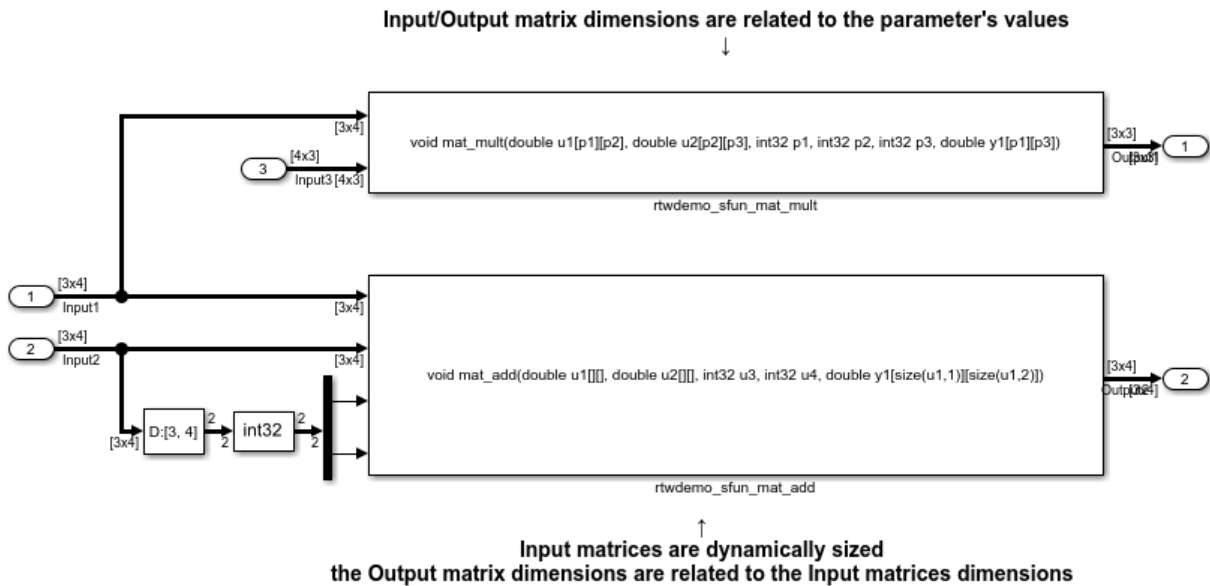

```
void mat_mult(double u1[p1][p2], double u2[p2][p3], int32 p1, int32 p2, int32 p3, double y1[p1][p3])
```

rtwdemo_sfun_mat_mult

Show the Generated Integration with Legacy Code

The model `rtwdemo_lct_inherit_dims` shows integration of the model with the legacy code. The subsystem `TestMatOps` serves as a harness for the calls to the legacy C functions, with unit delays serving to store the previous output values.

```
open_system('rtwdemo_lct_inherit_dims')
open_system('rtwdemo_lct_inherit_dims/TestMatOps')
sim('rtwdemo_lct_inherit_dims')
```

Integrate External C Functions That Implement Start and Terminate Actions

Integrate legacy C functions that have start and terminate actions by using the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties,

call `legacy_code('help')`. The prototypes of the legacy functions being called in this example are:

- `void initFaultCounter(unsigned int *counter)`
- `void openLogFile(void **fid)`
- `void incAndLogFaultCounter(void *fid, unsigned int *counter, double time)`
- `void closeLogFile(void **fid)`

The legacy source code is in the files `your_types.h`, `fault.h`, and `fault.c`.

```
% rtwdemo_sfun_fault
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_fault';
def.InitializeConditionsFcnSpec = 'initFaultCounter(uint32 work2[1])';
def.StartFcnSpec = 'openLogFile(void **work1)';
def.OutputFcnSpec = ...
    'incAndLogFaultCounter(void *work1, uint32 work2[1], double u1)';
def.TerminateFcnSpec = 'closeLogFile(void **work1)';
def.HeaderFiles = {'fault.h'};
def.SourceFiles = {'fault.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
def.Options.useTlcWithAccel = false;
```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument `def`, call the function `legacy_code()` again with the first input set to `'sfcn_cmex_generate'`. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file `rtwdemo_sfun_fault.c`.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function `legacy_code()` again with the first input set to `'compile'`.

```
legacy_code('compile', def);
```

```
### Start Compiling rtwdemo_sfun_fault
```

```

        mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc18a_815039_
Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.
        mex('rtwdemo_sfun_fault.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-
Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_fault
### Exit
    
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again with the first input set to `'sfcn_tlc_generate'` to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfun_fault.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

```
legacy_code('slblock_generate', def);
```

```

    > incAndLogFaultCounter(void *work1, uint32 work2[1], double u1)
    rtwdemo_sfun_fault
    
```

Showing the Generated Integration with Legacy Code

The model `rtwdemo_lct_start_term` shows integration of the model with the legacy code. The subsystem `TestFixpt` serves as a harness for the call to the legacy C function, and the scope compares the output of the function with the output of the built-in Simulink® product block; the results should be identical.

```
open_system('rtwdemo_lct_start_term')
open_system('rtwdemo_lct_start_term/TestFault')
sim('rtwdemo_lct_start_term')
```

Integrate External C Functions That Pass Arguments as Multi-Dimensional Signals

This example shows how to use the Legacy Code Tool to integrate legacy C functions with multi-dimensional Signals.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call `legacy_code('help')`. The prototype of the legacy functions being called in this example is:

```
void array3d_add(real_T *y1, real_T *u1, real_T *u2, int32_T nbRows, int32_T nbCols,
int32_T nbPages);
```

real_T is a typedef to double, and int32_T is a typedef to a 32-bit integer. The legacy source code is in the files ndarray_ops.h, and ndarray_ops.c.

```
% rtwdemo_sfun_ndarray_add
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_ndarray_add';
def.OutputFcnSpec = ...
    ['void array3d_add(double y1[size(u1,1)][size(u1,2)][size(u1,3)], ', ...
    'double u1[][][], double u2[][][], ' ...
    'int32 size(u1,1), int32 size(u1,2), int32 size(u1,3))'];
def.HeaderFiles = {'ndarray_ops.h'};
def.SourceFiles = {'ndarray_ops.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
```

y1 is a 3-D output signal of same dimensions as the 3-D input signal u1. Note that the last 3 arguments passed to the legacy function correspond to the number of element in each dimension of the 3-D input signal u1.

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_ndarray_add.c.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
### Start Compiling rtwdemo_sfun_ndarray_add
mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc18a_815039_
Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.
```

```
mex('rtwdemo_sfun_ndarray_add.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_sro
Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_ndarray_add
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again with the first input set to `'sfcn_tlc_generate'` to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfun_ndarray_add.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

```
legacy_code('slblock_generate', def);
```

Showing the Generated Integration with Legacy Code

The model `rtwdemo_lct_ndarray` shows integration of the model with the legacy code. The subsystem `ndarray_add` serves as a harness for the call to the legacy C function.

```
open_system('rtwdemo_lct_ndarray')
open_system('rtwdemo_lct_ndarray/ndarray_add')
sim('rtwdemo_lct_ndarray')
```

This legacy function computes the addition of the 2 input signals:

- Input1 and Input2 are dynamically sized 3D arrays
- Output1 is a dynamically sized 3D array of same size as Input1
- the last 3 function's arguments allow to pass the Input1's dimensions to the legacy function

Integrate External C Functions with a Block Sample Time Specified, Inherited, and Parameterized

This example shows how to use the Legacy Code Tool to integrate legacy C functions with the block's sample time specified, inherited and parameterized.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values

corresponding to the legacy code being integrated. For detailed help on the properties, call `legacy_code('help')`. The prototype of the legacy functions being called in this example is:

```
FLT gainScalar(const FLT in, const FLT gain)
```

FLT is a typedef to float. The legacy source code is in the files `your_types.h`, `gain.h`, and `gainScalar.c`.

```
defs = [];  
  
% rtwdemo_sfun_st_inherited  
def = legacy_code('initialize');  
def.SFunctionName = 'rtwdemo_sfun_st_inherited';  
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';  
def.HeaderFiles = {'gain.h'};  
def.SourceFiles = {'gainScalar.c'};  
def.IncPaths = {'rtwdemo_lct_src'};  
def.SrcPaths = {'rtwdemo_lct_src'};  
defs = [defs; def];  
  
% rtwdemo_sfun_st_fixed  
def = legacy_code('initialize');  
def.SFunctionName = 'rtwdemo_sfun_st_fixed';  
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';  
def.HeaderFiles = {'gain.h'};  
def.SourceFiles = {'gainScalar.c'};  
def.IncPaths = {'rtwdemo_lct_src'};  
def.SrcPaths = {'rtwdemo_lct_src'};  
def.SampleTime = [2 1];  
defs = [defs; def];  
  
% rtwdemo_sfun_st_parameterized  
def = legacy_code('initialize');  
def.SFunctionName = 'rtwdemo_sfun_st_parameterized';  
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';  
def.HeaderFiles = {'gain.h'};  
def.SourceFiles = {'gainScalar.c'};  
def.IncPaths = {'rtwdemo_lct_src'};  
def.SrcPaths = {'rtwdemo_lct_src'};  
def.SampleTime = 'parameterized';  
defs = [defs; def];
```

Generate S-Functions for Simulation

To generate C-MEX S-functions according to the description provided by the input argument 'defs', call the function `legacy_code()` again with the first input set to 'sfcn_cmex_generate'. The S-functions call the legacy functions during simulation. The source code for the S-functions is in the files `rtwdemo_sfun_st_inherited.c` and `rtwdemo_sfun_st_fixed.c`. `rtwdemo_sfun_st_parameterized.c`.

```
legacy_code('sfcn_cmex_generate', defs);
```

Compile the Generated S-Functions for Simulation

After you generate the C-MEX S-function source files, to compile the S-functions for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', defs);
```

```
### Start Compiling rtwdemo_sfun_st_inherited

```

Generate TLC Block Files for Code Generation

After you compile the S-functions and use them in simulation, you can call the function `legacy_code()` again with the first input set to `'sfcn_tlc_generate'` to generate TLC block files. Block files specify how the generated code for a model calls the legacy code. If you do not generate TLC block files and you try to generate code for a model that includes the S-functions, code generation fails. The TLC block files for the S-functions are `rtwdemo_sfun_st_inherited.tlc` and `rtwdemo_sfun_st_fixed.tlc`. `rtwdemo_sfun_st_parameterized.tlc`.

```
legacy_code('sfcn_tlc_generate', defs);
```

Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block files, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-functions are not in the same folder as the S-functions, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', defs);
```

Generate Masked S-Function Blocks for Calling the Generated S-Functions

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate masked S-function blocks that call the S-functions. The software places the blocks in a new model. From there you can copy them to an existing model.

```
legacy_code('slblock_generate', defs);
```

Show the Generated Integration with Legacy Code

The model `rtwdemo_lct_sampletime` shows integration of the model with the legacy code. The subsystem `sample_time` serves as a harness for the calls to the legacy C functions, with unit delays serving to store the previous output values.

```
open_system('rtwdemo_lct_sampletime')
open_system('rtwdemo_lct_sampletime/sample_time')
sim('rtwdemo_lct_sampletime')
```

External Code Integration Examples

This topic shows various scenarios of external code integration.

Insert External C and C++ Code Into Stateflow Charts for Code Generation

This example shows how to use Stateflow® to integrate external code into a model.

Open Model

```
model='rtwdemo_sfcustom';
open_system(model);
```

Integrating c-code into model

Custom written c-files can be easily integrated into Stateflow models. This code can be used to augment Stateflow's capabilities or to take advantage of legacy code.

To add custom c-files open the simulation target and enter the following:

Include Code - Header that defines functions, structures, and data to be accessible by Stateflow.

Include Path - Path to this include file.

Source Files - c-files that define the functions and data accessible by Stateflow.

- ▶ [Open simulation custom code settings](#)

If generating code via Simulink Coder, these same settings must also be added to the Model's configuration parameters custom code settings.

- ▶ [Open Code Generation custom code settings](#)
- ▶ [Build model using Simulink Coder](#)

Calling c-code from Stateflow

Functions

Custom c-code functions can be called from Stateflow using the same syntax as graphical function calls. The statement takes the form:

```
result = my_custom_function(in_args);
```

Structures

Variables of structure type can be accessed in Stateflow via the "dot" notation. The expression takes the form:

```
result = my_var.my_field;
```

To view the custom source for this examplenstration double click the links below.

Integrate Code

1. The example includes the custom header file `my_header.c` and the custom source file `my_function.c`.

```
%Open files my_header.h and my_function.c
eval('edit my_header.h')
eval('edit my_function.c')
```

2. On the Configuration Parameters dialog box **Simulation Target** pane, enter the custom source file and header file. Also enter additional include directories and source files.

In this example, the custom header file `my_header.c` and source file `my_function.c` are entered on the **Simulation Target** pane.

```
%Open Configuration Parameters dialog box
slCfgPrmDlg(model, 'Open');
slCfgPrmDlg(bdroot, 'TurnToPage', 'Simulation Target');
```

3. If you generate code with Simulink Coder®, on the Configuration Parameters dialog box **Code Generation > Custom Code** pane, enter the same custom source file and header file. Also enter the same additional include directories and source files.

In this example, the custom header file `my_header.c` and source file `my_function.c` are entered on the **Code Generation > Custom Code** pane.

```
%Open Configuration Parameters dialog box
slCfgPrmDlg(model, 'Open');
slCfgPrmDlg(bdroot, 'TurnToPage', 'Code Generation/Custom Code');
```

Generate Code

```
rtwbuild('rtwdemo_sfcustom')
```

```
### Starting build procedure for model: rtwdemo_sfcustom
### Successful completion of build procedure for model: rtwdemo_sfcustom
```

Call C Code from Stateflow

To call custom C code functions from Stateflow, use the same syntax as graphical function calls: `result = my_custom_function(in_args);`

To call variables of structure type, use the dot notation: `result = my_var.my_field;`

Close Model

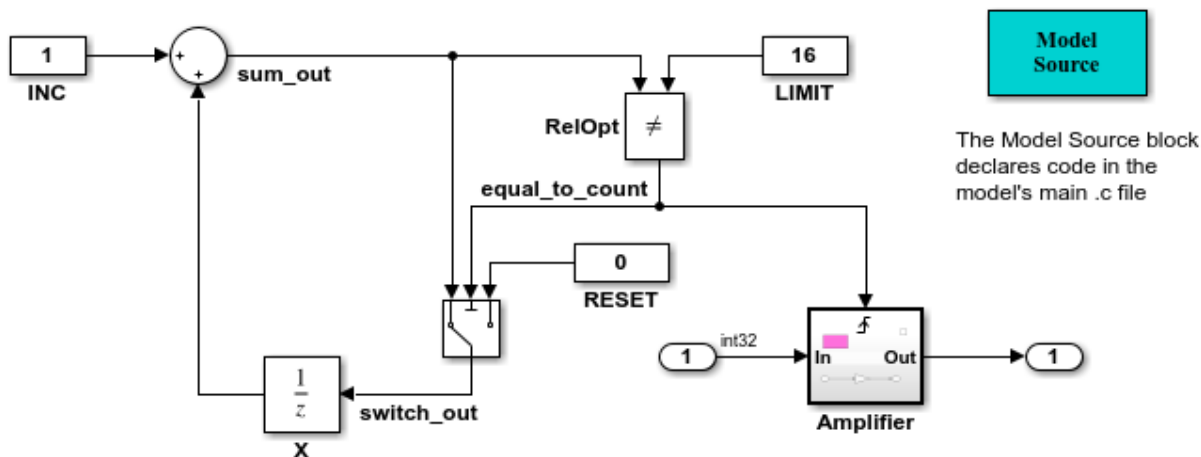

```
rtwdemoclean;  
close_system('rtwdemo_sfcustom',0);
```

Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters

This example shows how to place external code in generated code by using custom code blocks and model configuration parameters.

1. Open the model `rtwdemo_slcustcode`.

```
open_system('rtwdemo_slcustcode')
```

Several techniques exist for incorporating custom code into Simulink Coder. This model shows the use of the Simulink Coder custom code blocks and the Configuration Parameters Code Generation Custom Code page:

1. The Model Source custom code block declares an integer GLOBAL_INT1 in <model>.c.
2. The Subsystem Outputs custom code block (inside subsystem Amplifier) uses GLOBAL_INT1.
3. The variable GLOBAL_INT2 is declared and set from the Configuration Parameters Code Generation Custom Code page, from the "Source file" and "Initialize function," respectively.

Some overlap exists between custom code blocks and custom code specified using configuration parameters, but custom code blocks provide much finer granularity of code placement, and have the advantage of being graphical.

Generate Code Using Simulink Coder (double-click)	Generate Code Using Embedded Coder (double-click)	View Custom Code Configuration (double-click)	View Custom Code Library (double-click)
--	--	--	--

Copyright 1994-2012 The MathWorks, Inc.

2. Open the Model Configuration Parameters dialog box and navigate to the **Custom Code** pane.
3. Examine the settings for parameters **Source file** and **Initialize function**.

- **Source file** specifies a comment and sets the variable GLOBAL_INT2 to -1.
 - **Initialize function** initializes the variable GLOBAL_INT2 to 1.
4. Close the dialog box.
 5. Double-click the Model Source block. The **Top of Model Source** field specifies that the code generator declare the variable GLOBAL_INT1 and set it to 0 at the top of the generated file `rtwdemo_slcustcode.c`.
 6. Open the triggered subsystem **Amplifier**. The subsystem includes the System Outputs block. The code generator places code that you specify in that block in the generated code for the nearest parent atomic subsystem. In this case, the code generator places the external code in the generated code for the **Amplifier** subsystem. The external code:
 - Declares the pointer variable `*intPtr` and initializes it with the value of variable GLOBAL_INT1.
 - Sets the pointer variable to -1 during execution.
 - Resets the pointer variable to 0 before exiting.
 7. Generate code and a code generation report.
 8. Examine the code in the generated source file `rtwdemo_slcustcode.c`. At the top of the file, after the `#include` statements, you find the following declaration code. The example specifies the first declaration with the **Source file** configuration parameter and the second declaration with the Model Source block.

```
int_T GLOBAL_INT2 = -1;
```

```
int_T GLOBAL_INT1 = 0;
```

The Output function for the **Amplifier** subsystem includes the following code, which shows the external code integrated with generated code that applies the gain. The example specifies the three lines of code for the pointer variable with the System Outputs block in the **Amplifier** subsystem.

```
int_T *intPtr = &GLOBAL_INT1;
```

```
*intPtr = -1;
```

```
rtwdemo_slcustcode_Y.Output = rtwdemo_slcustcode_U.Input << 1;
```

```
*intPtr = 0;
```

The following assignment appears in the model initialize entry-point function. The example specifies this assignment with the **Initialize function** configuration parameter.

```
GLOBAL_INT2 = 1;
```

Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters

This example shows how to place external code in generated code by using custom code blocks and model configuration parameters.

1. Open the model `rtwdemo_slcustcode`.

```
open_system('rtwdemo_slcustcode')
```

Several techniques exist for incorporating custom code into Simulink Coder. This model shows the use of the Simulink Coder custom code blocks and the Configuration Parameters Code Generation Custom Code page:

1. The Model Source custom code block declares an integer GLOBAL_INT1 in <model>.c.
2. The Subsystem Outputs custom code block (inside subsystem Amplifier) uses GLOBAL_INT1.
3. The variable GLOBAL_INT2 is declared and set from the Configuration Parameters Code Generation Custom Code page, from the "Source file" and "Initialize function," respectively.

Some overlap exists between custom code blocks and custom code specified using configuration parameters, but custom code blocks provide much finer granularity of code placement, and have the advantage of being graphical.

2. Open the Model Configuration Parameters dialog box and navigate to the **Custom Code** pane.
3. Examine the settings for parameters **Source file** and **Initialize function**.

- **Source file** specifies a comment and sets the variable GLOBAL_INT2 to -1.
 - **Initialize function** initializes the variable GLOBAL_INT2 to 1.
4. Close the dialog box.
 5. Double-click the Model Source block. The **Top of Model Source** field specifies that the code generator declare the variable GLOBAL_INT1 and set it to 0 at the top of the generated file `rtwdemo_slcustcode.c`.
 6. Open the triggered subsystem **Amplifier**. The subsystem includes the System Outputs block. The code generator places code that you specify in that block in the generated code for the nearest parent atomic subsystem. In this case, the code generator places the external code in the generated code for the **Amplifier** subsystem. The external code:
 - Declares the pointer variable `*intPtr` and initializes it with the value of variable GLOBAL_INT1.
 - Sets the pointer variable to -1 during execution.
 - Resets the pointer variable to 0 before exiting.
 7. Generate code and a code generation report.
 8. Examine the code in the generated source file `rtwdemo_slcustcode.c`. At the top of the file, after the `#include` statements, you find the following declaration code. The example specifies the first declaration with the **Source file** configuration parameter and the second declaration with the Model Source block.

```
int_T GLOBAL_INT2 = -1;
```

```
int_T GLOBAL_INT1 = 0;
```

The Output function for the **Amplifier** subsystem includes the following code, which shows the external code integrated with generated code that applies the gain. The example specifies the three lines of code for the pointer variable with the System Outputs block in the **Amplifier** subsystem.

```
int_T *intPtr = &GLOBAL_INT1;
```

```
*intPtr = -1;
```

```
rtwdemo_slcustcode_Y.Output = rtwdemo_slcustcode_U.Input << 1;
```

```
*intPtr = 0;
```

The following assignment appears in the model initialize entry-point function. The example specifies this assignment with the **Initialize function** configuration parameter.

```
GLOBAL_INT2 = 1;
```

```

Generate S-Function from Subsystem

The **Generate S-function** feature automates the process of generating an S-function from a subsystem. In addition, the **Generate S-function** feature presents a display of parameters used within the subsystem, and lets you declare selected parameters tunable.

As an example, consider `SourceSubsys`, the same subsystem illustrated in the example “Create S-Function Blocks from a Subsystem” on page 49-63. The objective is to automatically extract `SourceSubsys` from the model and build an S-Function block from it, as in the previous example. In addition, the workspace variable `K`, which is the gain factor of the Gain block within `SourceSubsys` (as shown in the Gain block parameter dialog box below), is declared and generated as a tunable variable.

To auto-generate an S-function from `SourceSubsys` with tunable parameter `K`,

- 1 With the `SourceSubsys` model open, click the subsystem to select it.
- 2 From the **Code** menu, select **C/C++ Code > Generate S-Function**. This menu item is enabled when a subsystem is selected in the current model.

Alternatively, you can right-click the subsystem and select **C/C++ Code > Generate S-Function** from the subsystem block's context menu.

- 3 The **Generate S-Function** window is displayed (see the next figure). This window shows variables (or data objects) that are referenced as block parameters in the subsystem, and lets you declare them as tunable.

The upper pane of the window displays three columns:

- **Variable Name:** name of the parameter.
- **Class:** If the parameter is a workspace variable, its data type is shown. If the parameter is a data object, its name and class is shown
- **Tunable:** Lets you select tunable parameters. To declare a parameter tunable, select the check box. In the next figure, the parameter K is declared tunable.

When you select a parameter in the upper pane, the lower pane shows the blocks that reference the parameter, and the parent system of each such block.

Generate S-Function Window

- 4 After selecting tunable parameters, click the **Build** button. This initiates code generation and compilation of the S-function, using the S-function target. The **Create New Model** option is automatically enabled.
- 5 The build process displays status messages in the MATLAB Command Window. When the build completes, the tunable parameters window closes, and a new untitled model window opens.

- 6 The model window contains an S-Function block with the same name as the subsystem from which the block was generated (in this example, `SourceSubsys`). Optionally, you can save the generated model containing the generated block.
- 7 The generated code for the S-Function block is stored in the current working folder. The following files are written to the top level folder:
 - `subsys_sf.c` or `.cpp`, where *subsys* is the subsystem name (for example, `SourceSubsys_sf.c`)
 - `subsys_sf.h`
 - `subsys_sf.mexext`, where *mexext* is a platform-dependent MEX-file extension (for example, `SourceSubsys_sf.mexw64`)

The source code for the S-function is written to the subfolder `subsys_sfcn_rtw`. The top-level `.c` or `.cpp` file is a stub file that simply contains an include directive that you can use to interface other C/C++ code to the generated code.

Note For a list of files required to deploy your S-Function block for simulation or code generation, see “Required Files for S-Function Deployment” on page 49-60.

- 8 The generated S-Function block has inports and outports whose widths and sample times correspond to those of the original model.

The following code, from the `mdlOutputs` routine of the generated S-function code (in `SourceSubsys_sf.c`), shows how the tunable variable `K` is referenced by using calls to the MEX API.

```
static void mdlOutputs(SimStruct *S, int_T tid)
...
```

```

/* Gain: '<S1>/Gain' incorporates:
 * Sum: '<S1>/Sum'
 */
rtb_Gain_n[0] = (rtb_Product_p + (((const
real_T**)ssGetInputPortSignalPtrs(S, 2))[0]))) * ((real_T
*)(mxGetData(K(S))));
rtb_Gain_n[1] = (rtb_Product_p + (((const
real_T**)ssGetInputPortSignalPtrs(S, 2))[1]))) * ((real_T
*)(mxGetData(K(S))));

```

- In automatic S-function generation, the **Use Value for Tunable Parameters** option is cleared or at the command line is set to 'off'.
- Use a MEX S-function wrapper only in the MATLAB version in which the wrapper is created.

If you specify paths and files with absolute

Macro Parameters

Suppose that you apply a custom storage class such as `Define` to a `Simulink.Parameter` object so that the parameter appears as a macro in the generated code. If you use the parameter object inside a subsystem from which you generate an ERT S-function, you cannot select the parameter object as a tunable parameter. Instead, the S-function code generator applies the custom storage class to the parameter object. This generation of macros in the S-function code allows you to generate S-functions from subsystems that contain variant elements, such as Variant Subsystem blocks, that you configure to produce preprocessor conditionals in the generated code. However, you cannot change the value of the parameter during simulation of the S-function.

To select the parameter object as a tunable parameter, apply a different storage class or custom storage class. Custom storage classes that treat parameters as macros include `Define`, `ImportedDefine`, `CompilerFlag`, and custom storage classes that you create by setting **Data initialization** to **Macro** in the Custom Storage Class Designer. If you use a non-macro storage class or custom storage class, you cannot use the parameter object as a variant control variable and generate preprocessor conditionals.

If you apply a custom storage class that treats the parameter object as an imported macro, provide the macro definition before you generate the ERT S-function. For example, suppose you apply the custom storage class `ImportedDefine` to a `Simulink.Parameter` object, and use the parameter object as a variant control variable in the subsystem. If you set the custom attribute `HeaderFile` to 'myHdr.h', when you generate the S-function, place the custom header file `myHdr.h` in the current folder. The

generated S-function uses the macro value from your header file instead of the value from the Value property of the parameter object.

To use a macro that you define through a compiler option, for example by applying the custom storage class `CompilerFlag`, use the model configuration parameter **Configuration Parameters > Code Generation > Custom Code > Additional build information > Defines** to specify the compiler option. For more information, see Code Generation Pane: Custom Code: Additional Build Information: Defines (Simulink Coder).

Write S-Function and TLC Files By Hand

You can choose from several approaches for writing S-function and TLC files by hand.

Write Noninlined S-Function and TLC Files

- “About Noninlined S-Functions” on page 11-67
- “Guidelines for Writing Noninlined S-Functions” on page 11-67
- “Noninlined S-Function Parameter Type Limitations” on page 11-68

About Noninlined S-Functions

Noninlined S-functions are identified by the *absence* of an *sfunction.tlc* file for your S-function. The filename varies depending on your platform. For example, on a 64-bit Microsoft Windows system, the file name would be *sfunction.mexw64*. Type *mexext* in the MATLAB Command Window to see which extension your system uses.

Guidelines for Writing Noninlined S-Functions

- The MEX-file cannot call MATLAB functions.
- If the MEX-file uses functions in the MATLAB External Interface libraries, include the header file *cg_sfun.h* instead of *mex.h* or *simulink.c*. To handle this case, include the following lines at the end of your S-function:

```
#ifdef MATLAB_MEX_FILE /* Is this file being compiled as a MEX-file? */
#include "simulink.c" /* MEX-file interface mechanism */
#else
#include "cg_sfun.h" /* Code generation registration function */
#endif
```

- Use only MATLAB API function that the code generator supports, which include:

```
mxGetEps
mxGetInf
mxGetM
mxGetN
mxGetNaN
mxGetPr
mxGetScalar
mxGetString
mxIsEmpty
mxIsFinite
```

mxIsInf

- MEX library calls are not supported in generated code. To use such calls in MEX-file and not in the generated code, conditionalize the code as follows:

```
#ifndef MATLAB_MEX_FILE
#endif
```

- Use only full matrices that contain only real data.
- Do not specify a return value for calls to `mxGetString`. If you do specify a return value, the MEX-file will not compile. Instead, use the function's second input argument, which returns a pointer to a character vector.
- Make sure that the `#define s-function_name` statement is correct. The S-function name that you specify must match the S-function's filename.
- Use the data types `real_T` and `int_T` instead of `double` and `int`, if possible. The data types `real_T` and `int_T` are more generic and can be used in multiple environments.
- Provide the build process with the names of the modules used to build the S-function. You can do this by using a template make file, the `set_param` function, or the S-function `modules` field of the S-Function block parameters dialog box. For example, suppose you build your S-function with the following command:

```
mex sfun_main.c sfun_module1.c sfun_module2.c
```

You can then use the following call to `set_param` to include the required modules:

```
set_param(sfun_block, "SFunctionModules", "sfun_module1 sfun_module2")
```

When you are ready to generate code, force the code generator to rebuild the top model, as explained in “Control Regeneration of Top Model Code” (Simulink Coder).

Noninlined S-Function Parameter Type Limitations

Parameters to noninlined S-functions can be of the following types only:

- Double precision
- Characters in scalars, vectors, or 2-D matrices

For more flexibility in the type of parameters you can supply to S-functions or the operations in the S-function, inline your S-function and consider using an `mdlRTW` S-function routine.

Use of other functions from the MATLAB `matrix.h` API or other MATLAB APIs, such as `mex.h` and `mat.h`, is not supported. If you call unsupported APIs from an S-function

source file, compiler errors occur. See the files `matlabroot/rtw/c/src/rt_matrix.h` and `matlabroot/rtw/c/src/rt_matrix.c` for details on supported MATLAB API functions.

If you use `mxGetPr` on an empty matrix, the function does not return `NULL`; rather, it returns a random value. Therefore, you should protect calls to `mxGetPr` with `mxIsEmpty`.

Write Wrapper S-Function and TLC Files

This topic describes how to create S-functions that work seamlessly with the Simulink and code generator products using the *wrapper* concept. This topic begins by describing how to interface your algorithms in Simulink models by writing MEX S-function wrappers (`sfunction.mex`). It finishes with a description of how to direct the code generator to insert your algorithm into the generated code by creating a TLC S-function wrapper (`sfunction.tlc`).

- “MEX S-Function Wrapper” on page 11-69
- “TLC S-Function Wrapper” on page 11-74
- “Code Overhead for Noninlined S-Functions” on page 11-74
- “How to Inline” on page 11-75
- “The Inlined Code” on page 11-77

MEX S-Function Wrapper

Creating S-functions using an S-function wrapper allows you to insert C/C++ code algorithms in Simulink models and the generated code with little or no change to your original C/C++ function. A *MEX S-function wrapper* is an S-function that calls code that resides in another module. A *TLC S-function wrapper* is a TLC file that specifies how the code generator should call your code (the same code that was called from the C MEX S-function wrapper).

Note A MEX S-function wrapper must only be used in the MATLAB version in which the wrapper is created.

Suppose you have an algorithm (that is, a C function) called `my_alg` that resides in the file `my_alg.c`. You can integrate `my_alg` into a Simulink model by creating a MEX S-function wrapper (for example, `wrapsfcn.c`). Once this is done, a Simulink model can call `my_alg` from an S-Function block. However, the Simulink S-function contains a set of

empty functions that the Simulink engine requires for various API-related purposes. For example, although only `mdlOutputs` calls `my_alg`, the engine calls `mdlTerminate` as well, even though this S-function routine performs no action.

You can integrate `my_alg` into generated code (that is, embed the call to `my_alg` in the generated code) by creating a TLC S-function wrapper (for example, `wrapsfcn.tlc`). The advantage of creating a TLC S-function wrapper is that the empty function calls can be eliminated and the overhead of executing the `mdlOutputs` function and then the `my_alg` function can be eliminated.

Wrapper S-functions are useful when you are creating new algorithms that are procedural in nature or when you are integrating legacy code into a Simulink model. However, if you want to create code that is

- Interpretive in nature (that is, highly parameterized by operating modes)
- Heavily optimized (that is, no extra tests to decide what mode the code is operating in)

then you must create a *fully inlined TLC file* for your S-function.

The next figure shows the wrapper S-function concept.

Simulink

Place the name of your S-function in the S-Function block dialog box.

In Simulink, the S-function calls `mdlOutputs`, which in turn calls `my_alg`.

`mdlOutputs` in `wrapsfcn.mex` calls external function `my_alg`.

**Simulink Coder**

`wrapper.c`, the generated code, calls `mdlOutputs`, which then calls `my_alg`.

*See note below

In the TLC wrapper version of the S-function, `mdlOutputs` in `wrapper.exe` calls `my_alg`.

*The dotted line is the path taken if the S-function does not have a TLC wrapper file. If there is no TLC wrapper file, the generated code calls `mdlOutputs`.

Using an S-function wrapper to import algorithms in your Simulink model means that the S-function serves as an interface that calls your C/C++ algorithms from `mdlOutputs`. S-function wrappers have the advantage that you can quickly integrate large standalone C/C++ programs into your model without having to make changes to the code.

The following sample model includes an S-function wrapper.

There are two files associated with the `wrapsfcn` block, the S-function wrapper and the C/C++ code that contains the algorithm. The S-function wrapper code for `wrapsfcn.c` appears below. The first three statements do the following:

- 1 Defines the name of the S-function (what you enter in the Simulink S-Function block dialog).
- 2 Specifies that the S-function is using the level 2 format.
- 3 Provides access to the `SimStruct` data structure, which contains pointers to data used during simulation and code generation and defines macros that store data in and retrieve data from the `SimStruct`.

For more information, see “Templates for C S-Functions” (Simulink).

```
#define S_FUNCTION_NAME wrapsfcn
#define S_FUNCTION_LEVEL 2
#include "simstruc.h"

extern real_T my_alg(real_T u); /* Declare my_alg as extern */

/*
 * mdlInitializeSizes - initialize the sizes array
 */
static void mdlInitializeSizes(SimStruct *S)
{
    ssSetNumSFcnParams( S, 0); /*number of input arguments*/

    if (!ssSetNumInputPorts(S, 1)) return;
    ssSetInputPortWidth(S, 0, 1);
    ssSetInputPortDirectFeedThrough(S, 0, 1);

    if (!ssSetNumOutputPorts(S,1)) return;
    ssSetOutputPortWidth(S, 0, 1);

    ssSetNumSampleTimes( S, 1);
}

/*
```

```

* mdlInitializeSampleTimes - indicate that this S-function runs
* at the rate of the source (driving block)
*/
static void mdlInitializeSampleTimes(SimStruct *S)
{
    ssSetSampleTime(S, 0, INHERITED_SAMPLE_TIME);
    ssSetOffsetTime(S, 0, 0.0);
}

/*
* mdlOutputs - compute the outputs by calling my_alg, which
* resides in another module, my_alg.c
*/
static void mdlOutputs(SimStruct *S, int_T tid)
{
    InputRealPtrsType uPtrs = ssGetInputPortRealSignalPtrs(S,0);
    real_T *y = ssGetOutputPortRealSignal(S,0);
    *y = my_alg(*uPtrs[0]); /* Call my_alg in mdlOutputs */
}
/*
* mdlTerminate - called when the simulation is terminated.
*/
static void mdlTerminate(SimStruct *S)
{
}

#ifdef MATLAB_MEX_FILE /* Is this file being compiled as a MEX-file? */
#include "simulink.c" /* MEX-file interface mechanism */
#else
#include "cg_sfun.h" /* Code generation registration function */
#endif

```

The S-function routine `mdlOutputs` contains a function call to `my_alg`, which is the C function containing the algorithm that the S-function performs. This is the code for `my_alg.c`:

```

#ifdef MATLAB_MEX_FILE
#include "tmwtypes.h"
#else
#include "rtwtypes.h"
#endif
real_T my_alg(real_T u)
{
    return(u * 2.0);
}

```

For more information, see “Manage Build Process File Dependencies” (Simulink Coder).

The wrapper S-function `wrapsfcn` calls `my_alg`, which computes $u * 2.0$. To build `wrapsfcn.mex`, use the following command:

```
mex wrapsfcn.c my_alg.c
```

TLC S-Function Wrapper

This topic describes how to inline the call to `my_alg` in the `mdlOutputs` section of the generated code. In the above example, the call to `my_alg` is embedded in the `mdlOutputs` section as

```
*y = my_alg(*uPtrs[0]);
```

When you are creating a TLC S-function wrapper, the goal is to embed the same type of call in the generated code.

It is instructive to look at how the code generator executes S-functions that are not inlined. A noninlined S-function is identified by the absence of the file `sfunction.tlc` and the existence of `sfunction.mex`. When generating code for a noninlined S-function, the code generator produces a call to `mdlOutputs` through a function pointer that, in this example, then calls `my_alg`.

The wrapper example contains one S-function, `wrapsfcn.mex`. You must compile and link an additional module, `my_alg`, with the generated code. To do this, specify

```
set_param('wrapper/S-Function','SFunctionModules','my_alg')
```

Code Overhead for Noninlined S-Functions

The code generated when using `grt.tlc` as the system target file *without* `wrapsfcn.tlc` is

<Generated code comments for wrapper model with **noninlined** `wrapsfcn` S-function>

```
#include <math.h>
#include <string.h>
#include "wrapper.h"
#include "wrapper.prm"

/* Start the model */
void mdlStart(void)
{
    /* (start code not required) */
}

/* Compute block outputs */
void mdlOutputs(int_T tid)
{
    /* Sin Block: <Root>/Sin */
    rtB.Sin = rtP.Sin.Amplitude *
        sin(rtP.Sin.Frequency * ssGetT(rtS) + rtP.Sin.Phase);

    /* Level2 S-Function Block: <Root>/S-Function (wrapsfcn) */
    {
```

```

    /* Noninlined S-functions create a SimStruct object and
     * generate a call to S-function routine mdlOutputs
     */
    SimStruct *rts = ssGetSFunction(rtS, 0);
    sfcnOutputs(rts, tid);
}

/* Outport Block: <Root>/Out */
rtY.Out = rtB.S_Function;
}

/* Perform model update */
void mdlUpdate(int_T tid)
{
    /* (update code not required) */
}

/* Terminate function */
void mdlTerminate(void)
{
    /* Level2 S-Function Block: <Root>/S-Function (wrapsfcn) */
    {
        /* Noninlined S-functions require a SimStruct object and
         * the call to S-function routine mdlTerminate
         */
        SimStruct *rts = ssGetSFunction(rtS, 0);
        sfcnTerminate(rts);
    }
}

#include "wrapper.reg"

/* [EOF] wrapper.c */

```

In addition to the overhead outlined above, the `wrapper.reg` generated file contains the initialization of the `SimStruct` for the wrapper S-Function block. There is one child `SimStruct` for each S-Function block in your model. You can significantly reduce this overhead by creating a TLC wrapper for the S-function.

How to Inline

The generated code makes the call to your S-function, `wrapsfcn.c`, in `mdlOutputs` by using this code:

```

SimStruct *rts = ssGetSFunction(rtS, 0);
sfcnOutputs(rts, tid);

```

This call has computational overhead associated with it. First, the Simulink engine creates a `SimStruct` data structure for the S-Function block. Second, the code generator constructs a call through a function pointer to execute `mdlOutputs`, then `mdlOutputs` calls `my_alg`. By inlining the call to your C/C++ algorithm, `my_alg`, you can eliminate

both the `SimStruct` and the extra function call, thereby improving the efficiency and reducing the size of the generated code.

Inlining a wrapper S-function requires an `sfunction.tlc` file for the S-function (see the “Target Language Compiler” (Simulink Coder) for details). The TLC file must contain the function call to `my_alg`. The following figure shows the relationships between the algorithm, the wrapper S-function, and the `sfunction.tlc` file.

The `wrapsfcn.tlc` file tells Simulink Coder how to inline the call to `my_alg` using this statement.

To inline this call, you have to place your function call in an `sfunction.tlc` file with the same name as the S-function (in this example, `wrapsfcn.tlc`). This causes the Target Language Compiler to override the default method of placing calls to your S-function in the generated code.

This is the `wrapsfcn.tlc` file that inlines `wrapsfcn.c`.

```

%% File      : wrapsfcn.tlc
%% Abstract:
%%      Example inlined tlc file for S-function wrapsfcn.c
%%

%implements "wrapsfcn" "C"

%% Function: BlockTypeSetup =====
%% Abstract:
%%      Create function prototype in model.h as:
%%      "extern real_T my_alg(real_T u);"
%%
%%function BlockTypeSetup(block, system) void
%openfile buffer
    extern real_T my_alg(real_T u); /* This line is placed in wrapper.h */
%closefile buffer
%<LibCacheFunctionPrototype(buffer)>
%endfunction %% BlockTypeSetup
    
```

```

%% Function: Outputs =====
%% Abstract:
%%     y = my_alg( u );
%%
%function Outputs(block, system) Output
/* %<Type> Block: %<Name> */
%assign u = LibBlockInputSignal(0, "", "", 0)
%assign y = LibBlockOutputSignal(0, "", "", 0)
%% PROVIDE THE CALLING STATEMENT FOR "algorithm"
%% The following line is expanded and placed in mdlOutputs within wrapper.c
%<y> = my_alg(%<u>);

%endfunction %% Outputs

```

The first section of this code inlines the wrapsfcn S-Function block and generates the code in C:

```
%implements "wrapsfcn" "C"
```

The next task is to tell the code generator that the routine `my_alg` needs to be declared external in the generated `wrapper.h` file for any `wrapsfcn` S-Function blocks in the model. You only need to do this once for all `wrapsfcn` S-Function blocks, so use the `BlockTypeSetup` function. In this function, you tell the Target Language Compiler to create a buffer and cache the `my_alg` as `extern` in the `wrapper.h` generated header file.

The final step is the inlining of the call to the function `my_alg`. This is done by the `Outputs` function. In this function, you access the block's input and output and place a direct call to `my_alg`. The call is embedded in `wrapper.c`.

The Inlined Code

The code generated when you inline your wrapper S-function is similar to the default generated code. The `mdlTerminate` function does not contain a call to an empty function and the `mdlOutputs` function now directly calls `my_alg`.

```

void mdlOutputs(int_T tid)
{
    /* Sin Block: <Root>/Sin */
    rtB.Sin = rtP.Sin.Amplitude *
        sin(rtP.Sin.Frequency * ssGetT(rtS) + rtP.Sin.Phase);

    /* S-Function Block: <Root>/S-Function */
    rtB.S_Function = my_alg(rtB.Sin); /* Inlined call to my_alg */

    /* Output Block: <Root>/Out */
    rtY.Out = rtB.S_Function;
}

```

In addition, `wrapper.reg` does not create a child `SimStruct` for the S-function because the generated code is calling `my_alg` directly. This eliminates over 1 KB of memory usage.

Write Fully Inlined S-Functions

Using the example from “Write Wrapper S-Function and TLC Files” (Simulink Coder), you could eliminate the call to `my_alg` entirely by specifying the explicit code (that is, `2.0 * u`) in `wrapsfcn.tlc`. This is referred to as a *fully inlined S-function*. While this can improve performance, if you are working with a large amount of C/C++ code, this can be a lengthy task. In addition, you now have to maintain your algorithm in two places, the C/C++ S-function itself and the corresponding TLC file. However, the performance gains might outweigh the disadvantages. To inline the algorithm used in this example, in the Outputs section of your `wrapsfcn.tlc` file, instead of writing

```
%<y> = my_alg(%<u>);
```

```
use
```

```
%<y> = 2.0 * %<u>;
```

This is the code produced in `mdlOutputs`:

```
void mdlOutputs(int_T tid)
{
    /* Sin Block: <Root>/Sin */
    rtB.Sin = rtP.Sin.Amplitude *
        sin(rtP.Sin.Frequency * ssGetT(rtS) + rtP.Sin.Phase);

    /* S-Function Block: <Root>/S-Function */
    rtB.S_Function = 2.0 * rtB.Sin; /* Explicit embedding of algorithm */

    /* Output Block: <Root>/Out */
    rtY.Out = rtB.S_Function;
}
```

The Target Language Compiler has replaced the call to `my_alg` with the algorithm itself.

Multiport S-Function

A more advanced multiport inlined S-function example is `sfun_multiport.c` and `sfun_multiport.tlc`. This S-function illustrates how to create a fully inlined TLC file for an S-function that contains multiple ports. You might find that looking at this example helps you to understand fully inlined TLC files.

Write Fully Inlined S-Functions with mdlRTW Routine

You can inline more complex S-functions that use the S-function mdlRTW routine. The purpose of the mdlRTW routine is to provide the code generation process with more information about how the S-function is to be inlined, by creating a parameter record of a nontunable parameter for use with a TLC file. The mdlRTW routine does this by placing information in the *model.rtw* file. The mdlRTW function is described in the text file *matlabroot/simulink/src/sfuntmpl_doc.c*.

As an example of how to use the mdlRTW function, this topic discusses the steps you must take to create a direct-index lookup S-function. Lookup tables are collections of ordered data points of a function. Typically, these tables use some interpolation scheme to approximate values of the associated function between known data points. To incorporate the example lookup table algorithm into a Simulink model, the first step is to write an S-function that executes the algorithm in mdlOutputs. To produce the most efficient code, the next step is to create a corresponding TLC file to eliminate computational overhead and improve the speed of the lookup computations.

For your convenience, the Simulink product provides support for two general-purpose lookup 1-D and 2-D algorithms. You can use these algorithms as they are or create a custom lookup table S-function to fit your requirements. This topic illustrates how to create a 1-D lookup S-function, *sfun_directlook.c*, and its corresponding inlined *sfun_directlook.tlc* file (see “Target Language Compiler” (Simulink Coder) for more details). This 1-D direct-index lookup table example illustrates the following concepts that you need to know to create your own custom lookup tables:

- Error checking of S-function parameters
- Caching of information for the S-function that doesn't change during model execution
- How to use the mdlRTW function to customize the code generator to produce the optimal code for a given set of block parameters
- How to generate an inlined TLC file for an S-function in a combination of the fully inlined form and/or the wrapper form
- “S-Function RTWdata” on page 11-80
- “Direct-Index Lookup Table Algorithm” on page 11-80
- “Direct-Index Lookup Table Example” on page 11-82
- “Error Handling” on page 11-83
- “User Data Caching” on page 11-83

- “mdlRTW Usage” on page 11-84

S-Function RTWdata

There is a property of blocks called `RTWdata`, which can be used by the Target Language Compiler when inlining an S-function. `RTWdata` is a structure of character vectors that you can attach to a block. It is saved with the model and placed in the `model.rtw` file when generating code. For example, this set of MATLAB commands,

```
mydata.field1 = 'information for field1';  
mydata.field2 = 'information for field2';  
set_param(gcf,'RTWdata',mydata)  
get_param(gcf,'RTWdata')
```

produces this result:

```
ans =  
  
    field1: 'information for field1'  
    field2: 'information for field2'
```

Inside the `model.rtw` file for the associated S-Function block is this information.

```
Block {  
    Type                "S-Function"  
    RTWdata {  
        field1          "information for field1"  
        field2          "information for field2"  
    }  
}
```

Note `RTWdata` is saved in the model file for S-functions that are not linked to a library. However, `RTWdata` is **not persistent** for S-Function blocks that are linked to a library.

Direct-Index Lookup Table Algorithm

The 1-D lookup table block provided in the Simulink library uses interpolation or extrapolation when computing outputs. This extra accuracy might not be required. In this example, you create a lookup table that directly indexes the output vector (y -data vector) based on the current input (x -data) point.

This direct 1-D lookup example computes an approximate solution $p(x)$ to a partially known function $f(x)$ at $x=x_0$, given data point pairs (x,y) in the form of an x -data vector and a y -data vector. For a given data pair (for example, the i 'th pair), $y_i = f(x_i)$. It is assumed that the x -data values are monotonically increasing. If x_0 is outside the range of the x -data vector, the first or last point is returned.

The parameters to the S-function are

`XData`, `YData`, `XEvenlySpaced`

`XData` and `YData` are double vectors of equal length representing the values of the unknown function. `XDataEvenlySpaced` is a scalar, `0.0` for false and `1.0` for true. If the `XData` vector is evenly spaced, `XDataEvenlySpaced` is `1.0` and more efficient code is generated.

The following graph shows how the parameters `XData=[1:6]` and `YData=[1,2,7,4,5,9]` are handled. For example, if the input (x-value) to the S-Function block is 3, the output (y-value) is 7.

Direct-Index Lookup Table Example

This topic shows how to improve the lookup table by inlining a direct-index S-function with a TLC file. This direct-index lookup table S-function does not require a TLC file. Here the example uses a TLC file for the direct-index lookup table S-function to reduce the code size and increase efficiency of the generated code.

Implementation of the direct-index algorithm with inlined TLC file requires the S-function main module, `sfun_directlook.c`, and a corresponding `lookup_index.c` module. The `lookup_index.c` module contains the `GetDirectLookupIndex` function that is used to locate the index in the `XData` for the current `x` input value when the `XData` is unevenly

spaced. The `GetDirectLookupIndex` routine is called from both the S-function and the generated code. Here the example uses the wrapper concept for sharing C/C++ code between Simulink MEX-files and the generated code.

If the `XData` is evenly spaced, then both the S-function main module and the generated code contain the lookup algorithm (not a call to the algorithm) to compute the `y`-value of a given `x`-value, because the algorithm is short. This illustrates the use of a fully inlined S-function for generating optimal code.

The inlined TLC file is `sfun_directlook.tlc`, which is used to either perform a wrapper call or embed the optimal C/C++ code for the S-function. (See the example in “mdlRTW Usage” (Simulink Coder)).

Error Handling

In `sfun_directlook.tlc`, the `mdlCheckParameters` routine verifies that:

- The new parameter settings are valid.
- `XData` and `YData` are vectors of the same length containing real finite numbers.
- `XDataEvenlySpaced` is a scalar.
- The `XData` vector is a monotonically increasing vector and evenly spaced.

The `mdlInitializeSizes` function explicitly calls `mdlCheckParameters` after it verifies the number of parameters passed to the S-function. After the Simulink engine calls `mdlInitializeSizes`, it then calls `mdlCheckParameters` whenever you change the parameters or there is a need to reevaluate them.

User Data Caching

In `sfun_directlook.tlc`, the `mdlStart` routine shows how to cache information that does not change during the simulation (or while the generated code is executing). The example caches the value of the `XDataEvenlySpaced` parameter in `UserData`, a field of the `SimStruct`. The following line in `mdlInitializeSizes` tells the Simulink engine to disallow changes to `XDataEvenlySpaced`.

```
ssSetSFcnParamTunable(S, iParam, SS_PRM_NOT_TUNABLE);
```

During execution, `mdlOutputs` accesses the value of `XDataEvenlySpaced` from `UserData` rather than calling the `mxGetPr` MATLAB API function.

mdlRTW Usage

The code generator calls the mdlRTW routine while generating the *model*.rtw file. To produce optimal code for your Simulink model, you can add information to the *model*.rtw file about the mode in which your S-Function block is operating.

The following example adds parameter settings to the *model*.rtw file. The parameter settings do not change during execution. In this case, the XDataEvenlySpaced S-function parameter cannot change during execution (ssSetSFcnParamTunable was specified as false (0) for it in mdlInitializeSizes). The example writes it out as a parameter setting (XSpacing) using the function ssWriteRTWParamSettings.

Because xData and yData are registered as run-time parameters in mdlSetWorkWidths, the code generator handles writing to the *model*.rtw file automatically.

Before examining the S-function and the inlined TLC file, consider the generated code for the following model.

The model uses evenly spaced XData in the top S-Function block and unevenly spaced XData in the bottom S-Function block. When creating this model, you need to specify the following for each S-Function block.

```
set_param('sfun_directlook_ex/S-Function','SFunctionModules','lookup_index')
set_param('sfun_directlook_ex/S-Function1','SFunctionModules','lookup_index')
```

This informs the build process to use the module `lookup_index.c` when creating the executable.

When generating code for this model, the code generator uses the S-function `mdlRTW` method to generate a `model.rtw` file with the value `EvenlySpaced` for the `XSpacing` parameter for the top S-Function block, and the value `UnEvenlySpaced` for the `XSpacing` parameter for the bottom S-Function block. The TLC-file uses the value of `XSpacing` to determine what algorithm to include in the generated code. The generated code contains the lookup algorithm when the `XData` is evenly spaced, but calls the `GetDirectLookupIndex` routine when the `XData` is unevenly spaced. The generated `model.c` or `model.cpp` code for the lookup table example model is similar to the following:

```

/*
 * sfun_directlook_ex.c
 *
 * Code generation for Simulink model
 * "sfun_directlook_ex.slx".
 *
 * ...
 */

#include "sfun_directlook_ex.h"
#include "sfun_directlook_ex_private.h"

/* External outputs (root outputs fed by signals with auto storage) */
ExtY_sfun_directlook_ex_T sfun_directlook_ex_Y;

/* Real-time model */
RT_MODEL_sfun_directlook_ex_T sfun_directlook_ex_M;
RT_MODEL_sfun_directlook_ex_T *const sfun_directlook_ex_M =
    &sfun_directlook_ex_M;

/* Model output function */
void sfun_directlook_ex_output(void)
{
    /* local block i/o variables */
    real_T rtb_SFunction;
    real_T rtb_SFunction1;

    /* Sin: '<Root>/Sine Wave' */
    rtb_SFunction1 = sin(sfun_directlook_ex_M->Timing.t[0]);

    /* Code that is inlined for the top S-function block in the
     * sfun_directlook_ex model
     */
    /* S-Function (sfun_directlook): '<Root>/S-Function' */
    {
        const real_T *xData = sfun_directlook_ex_ConstP.SFunction_XData;
        const real_T *yData = sfun_directlook_ex_ConstP.SFunction_YData;
        real_T spacing = xData[1] - xData[0];
    }
}

```

```

    if (rtb_SFunction1 <= xData[0] ) {
        rtb_SFunction = yData[0];
    } else if (rtb_SFunction1 >= yData[20] ) {
        rtb_SFunction = yData[20];
    } else {
        int_T idx = (int_T)( ( rtb_SFunction1 - xData[0] ) / spacing );
        rtb_SFunction = yData[idx];
    }
}

/* Output: '<Root>/Out1' */
sfun_directlook_ex_Y.Out1 = rtb_SFunction;

/* Code that is inlined for the bottom S-function block in the
 * sfun_directlook_ex model
 */
/* S-Function (sfun_directlook): '<Root>/S-Function1' */
{
    const real_T *xData = sfun_directlook_ex_ConstP.SFunction1_XData;
    const real_T *yData = sfun_directlook_ex_ConstP.SFunction1_YData;
    int_T idx;
    idx = GetDirectLookupIndex(xData, 5, rtb_SFunction1);
    rtb_SFunction1 = yData[idx];
}

/* Output: '<Root>/Out2' */
sfun_directlook_ex_Y.Out2 = rtb_SFunction1;
}

/* Model update function */
void sfun_directlook_ex_update(void)
{
    /* signal main to stop simulation */

            !((rtmGetTFinal(sfun_directlook_ex_M)-sfun_directlook_ex_M->Timing.t[0])
              > sfun_directlook_ex_M->Timing.t[0] * (DBL_EPSILON))) {
            rtmSetErrorStatus(sfun_directlook_ex_M, "Simulation finished");
        }
    }

    /* Update absolute time for base rate */
    /* The "clockTick0" counts the number of times the code of this task has
     * been executed. The absolute time is the multiplication of "clockTick0"
     * and "Timing.stepSize0". Size of "clockTick0" ensures timer will not
     * overflow during the application lifespan selected.
     * Timer of this task consists of two 32 bit unsigned integers.
     * The two integers represent the low bits Timing.clockTick0 and the high bits
     * Timing.clockTickH0. When the low bit overflows to 0, the high bits increment.
     */
    if (!(++sfun_directlook_ex_M->Timing.clockTick0)) {
        ++sfun_directlook_ex_M->Timing.clockTickH0;
    }

    sfun_directlook_ex_M->Timing.t[0] = sfun_directlook_ex_M->Timing.clockTick0 *

```

```

sfun_directlook_ex_M->Timing.stepSize0 +
sfun_directlook_ex_M->Timing.clockTickH0 *
sfun_directlook_ex_M->Timing.stepSize0 * 4294967296.0;
}
...

```

Guidelines for Writing Inlined S-Functions

- Consider using the block property `RTWdata` (see “S-Function RTWdata” (Simulink Coder)). This property is a structure of character vectors that you can associate with a block. The code generator saves the structure with the model in the `model.rtw` file and makes the `.rtw` file more readable. For example, suppose you enter the following commands in the MATLAB Command Window:

```

mydata.field1 = 'information for field1';
mydata.field2 = 'information for field2';
set_param(sfun_block, 'RTWdata', mydata);

```

The `.rtw` file that the code generator produces for the block includes the comments specified in the structure `mydata`.

- Consider using the `mdlRTW` function to inline your C MEX S-function in the generated code. This is useful when you want to
 - Rename tunable parameters in the generated code
 - Introduce nontunable parameters into a TLC file

S-Functions That Support Expression Folding

- “About S-Functions that Support Expression Folding” on page 11-87
- “Categories of Output Expressions” on page 11-88
- “Acceptance or Denial of Requests for Input Expressions” on page 11-93
- “Expression Folding in a TLC Block Implementation” on page 11-95

About S-Functions that Support Expression Folding

This topic describes how you can take advantage of expression folding to increase the efficiency of code generated by your own inlined S-Function blocks, by calling macros provided in the S-Function API. This topic assumes that you are familiar with:

- Writing inlined S-functions (see “S-Function Basics” (Simulink)).
- “Target Language Compiler” (Simulink Coder)

The S-Function API lets you specify whether a given S-Function block should nominally accept expressions at a given input port. A block should not always accept expressions. For example, if the address of the signal at the input is used, expressions should not be accepted at that input, because it is not possible to take the address of an expression.

The S-Function API also lets you specify whether an expression can represent the computations associated with a given output port. When you request an expression at a block's input or output port, the Simulink engine determines whether or not it can honor that request, given the block's context. For example, the engine might deny a block's request to output an expression if the destination block does not accept expressions at its input, if the destination block has an update function, or if multiple output destinations exist.

The decision to honor or deny a request to output an expression can also depend on the category of output expression the block uses (see “Categories of Output Expressions” on page 11-88).

The topics that follow explain

- When and how you can request that a block accept expressions at an input port
- When and how you can request that a block generate expressions at an output port
- The conditions under which the Simulink engine will honor or deny such requests

To take advantage of expression folding in your S-functions, you should understand when to request acceptance and generation of expressions for specific blocks. You do not have to understand the algorithm by which the Simulink engine chooses to accept or deny these requests. However, if you want to trace between the model and the generated code, it is helpful to understand some of the more common situations that lead to denial of a request.

Categories of Output Expressions

When you implement a C MEX S-function, you can specify whether the code corresponding to a block's output is to be generated as an expression. If the block generates an expression, you must specify that the expression is *constant*, *trivial*, or *generic*.

A *constant* output expression is a direct access to one of the block's parameters. For example, the output of a Constant block is defined as a constant expression because the output expression is simply a direct access to the block's `Value` parameter.

A *trivial* output expression is an expression that can be repeated, without a performance penalty, when the output port has multiple output destinations. For example, the output of a Unit Delay block is defined as a trivial expression because the output expression is simply a direct access to the block's state. Because the output expression does not have computations, it can be repeated more than once without degrading the performance of the generated code.

A *generic* output expression is an expression that should be assumed to have a performance penalty if repeated. As such, a generic output expression is not suitable for repeating when the output port has multiple output destinations. For instance, the output of a Sum block is a generic rather than a trivial expression because it is costly to recompute a Sum block output expression as an input to multiple blocks.

Examples of Trivial and Generic Output Expressions

Consider the following block diagram. The Delay block has multiple destinations, yet its output is designated as a trivial output expression, so that it can be used more than once without degrading the efficiency of the code.

The following code excerpt shows code generated from the Unit Delay block in this block diagram. The three root outputs are directly assigned from the state of the Unit Delay block, which is stored in a field of the global data structure `rtDWork`. Since the assignment is direct, without expressions, there is no performance penalty associated with using the trivial expression for multiple destinations.

```
void MdlOutputs(int_T tid)
{
    ...
    /* Outport: <Root>/Out1 incorporates:
     *   UnitDelay: <Root>/Unit Delay */
    rtY.Out1 = rtDWork.Unit_Delay_DSTATE;
```

```

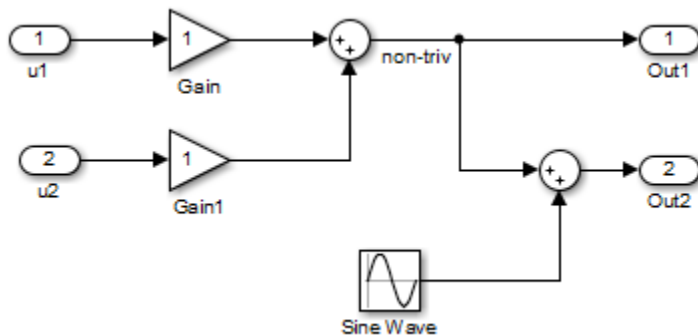

/* Outport: <Root>/Out2 incorporates:
 *   UnitDelay: <Root>/Unit Delay */
rtY.Out2 = rtDWork.Unit_Delay_DSTATE;

/* Outport: <Root>/Out3 incorporates:
 *   UnitDelay: <Root>/Unit Delay */
rtY.Out3 = rtDWork.Unit_Delay_DSTATE;

...
}

```

On the other hand, consider the Sum blocks in the following model:

The upper Sum block in the preceding model generates the signal labeled `non_triv`. Computation of this output signal involves two multiplications and an addition. If the Sum block's output were permitted to generate an expression even when the block had multiple destinations, the block's operations would be duplicated in the generated code. In the case illustrated, the generated expressions would proliferate to four multiplications and two additions. This would degrade the efficiency of the program. Accordingly the output of the Sum block is not allowed to be an expression because it has multiple destinations

The code generated for the previous block diagram shows how code is generated for Sum blocks with single and multiple destinations.

The Simulink engine does not permit the output of the upper Sum block to be an expression because the signal `non_triv` is routed to two output destinations. Instead, the result of the multiplication and addition operations is stored in a temporary variable (`rtb_non_triv`) that is referenced twice in the statements that follow, as seen in the code excerpt below.

In contrast, the lower Sum block, which has only a single output destination (Out2), does generate an expression.

```
void MdlOutputs(int_T tid)
{
    /* local block i/o variables */
    real_T rtb_non_triv;
    real_T rtb_Sine_Wave;

    /* Sum: <Root>/Sum incorporates:
    *   Gain: <Root>/Gain
    *   Inport: <Root>/u1
    *   Gain: <Root>/Gain1
    *   Inport: <Root>/u2
    *
    * Regarding <Root>/Gain:
    *   Gain value: rtP.Gain_Gain
    *
    * Regarding <Root>/Gain1:
    *   Gain value: rtP.Gain1_Gain
    */
    rtb_non_triv = (rtP.Gain_Gain * rtU.u1) + (rtP.Gain1_Gain *
rtU.u2);

    /* Outport: <Root>/Out1 */
    rtY.Out1 = rtb_non_triv;

    /* Sin Block: <Root>/Sine Wave */

    rtb_Sine_Wave = rtP.Sine_Wave_Amp *
        sin(rtP.Sine_Wave_Freq * rtmGetT(rtm_model) +
            rtP.Sine_Wave_Phase) + rtP.Sine_Wave_Bias;

    /* Outport: <Root>/Out2 incorporates:
    *   Sum: <Root>/Sum1
    */
    rtY.Out2 = (rtb_non_triv + rtb_Sine_Wave);
}
```

Specify the Category of an Output Expression

The S-Function API provides macros that let you declare whether an output of a block should be an expression, and if so, to specify the category of the expression. The following table specifies when to declare a block output to be a constant, trivial, or generic output expression.

Types of Output Expressions

Category of Expression	When to Use
Constant	Use only if block output is a direct memory access to a block parameter.
Trivial	Use only if block output is an expression that can appear multiple times in the code without reducing efficiency (for example, a direct memory access to a field of the <code>DWork</code> vector, or a literal).
Generic	Use if output is an expression, but not constant or trivial.

You must declare outputs as expressions in the `mdlSetWorkWidths` function using macros defined in the S-Function API. The macros have the following arguments:

- `SimStruct *S`: pointer to the block's `SimStruct`.
- `int idx`: zero-based index of the output port.
- `bool value`: pass in `TRUE` if the port generates output expressions.

The following macros are available for setting an output to be a constant, trivial, or generic expression:

- `void ssSetOutputPortConstOutputExprInRTW(SimStruct *S, int idx, bool value)`
- `void ssSetOutputPortTrivialOutputExprInRTW(SimStruct *S, int idx, bool value)`
- `void ssSetOutputPortOutputExprInRTW(SimStruct *S, int idx, bool value)`

The following macros are available for querying the status set by prior calls to the macros above:

- `bool ssGetOutputPortConstOutputExprInRTW(SimStruct *S, int idx)`
- `bool ssGetOutputPortTrivialOutputExprInRTW(SimStruct *S, int idx)`
- `bool ssGetOutputPortOutputExprInRTW(SimStruct *S, int idx)`

The set of generic expressions is a superset of the set of trivial expressions, and the set of trivial expressions is a superset of the set of constant expressions.

Therefore, when you query an output that has been set to be a constant expression with `ssGetOutputPortTrivialOutputExprInRTW`, it returns `True`. A constant expression

is considered a trivial expression, because it is a direct memory access that can be repeated without degrading the efficiency of the generated code.

Similarly, an output that has been configured to be a constant or trivial expression returns True when queried for its status as a generic expression.

Acceptance or Denial of Requests for Input Expressions

A block can request that its output be represented in code as an expression. Such a request can be denied if the destination block cannot accept expressions at its input port. Furthermore, conditions independent of the requesting block and its destination blocks can prevent acceptance of expressions.

This topic discusses block-specific conditions under which requests for input expressions are denied. For information on other conditions that prevent acceptance of expressions, see “Denial of Block Requests to Output Expressions” on page 11-94.

A block should not be configured to accept expressions at its input port under the following conditions:

- The block must take the address of its input data. It is not possible to take the address of most types of input expressions.
- The code generated for the block references the input more than once (for example, the Abs or Max blocks). This would lead to duplication of a potentially complex expression and a subsequent degradation of code efficiency.

If a block refuses to accept expressions at an input port, then a block that is connected to that input port is not permitted to output a generic or trivial expression.

A request to output a constant expression is not denied, because there is no performance penalty for a constant expression, and the software can take the parameter’s address.

S-Function API to Specify Input Expression Acceptance

The S-Function API provides macros that let you:

- Specify whether a block input should accept nonconstant expressions (that is, trivial or generic expressions)
- Query whether a block input accepts nonconstant expressions

By default, block inputs do not accept nonconstant expressions.

You should call the macros in your `mdlSetWorkWidths` function. The macros have the following arguments:

- `SimStruct *S`: pointer to the block's `SimStruct`.
- `int idx`: zero-based index of the input port.
- `bool value`: pass in `TRUE` if the port accepts input expressions; otherwise pass in `FALSE`.

The macro available for specifying whether or not a block input should accept a nonconstant expression is as follows:

```
void ssSetInputPortAcceptExprInRTW(SimStruct *S, int portIdx, bool value)
```

The corresponding macro available for querying the status set by any prior calls to `ssSetInputPortAcceptExprInRTW` is as follows:

```
bool ssGetInputPortAcceptExprInRTW(SimStruct *S, int portIdx)
```

Denial of Block Requests to Output Expressions

Even after a specific block requests that it be allowed to generate an output expression, that request can be denied for generic reasons. These reasons include, but are not limited to

- The output expression is nontrivial, and the output has multiple destinations.
- The output expression is nonconstant, and the output is connected to at least one destination that does not accept expressions at its input port.
- The output is a test point.
- The output has been assigned an external storage class.
- The output must be stored using global data (for example is an input to a merge block or a block with states).
- The output signal is complex.

You do not need to consider these generic factors when deciding whether or not to utilize expression folding for a particular block. However, these rules can be helpful when you are examining generated code and analyzing cases where the expression folding optimization is suppressed.

Expression Folding in a TLC Block Implementation

To take advantage of expression folding, you must modify the TLC block implementation of an inlined S-Function such that it informs the Simulink engine whether it generates or accepts expressions at its

- Input ports, as explained in “S-Function API to Specify Input Expression Acceptance” on page 11-93.
- Output ports, as explained in “Categories of Output Expressions” on page 11-88.

This topic discusses required modifications to the TLC implementation.

Expression Folding Compliance

In the `BlockInstanceSetup` function of your S-function, register your block to be compliant with expression folding. Otherwise, expression folding requested or allowed at the block's outputs or inputs will be disabled, and temporary variables will be used.

To register expression folding compliance, call the TLC library function `LibBlockSetIsExpressionCompliant(block)`, which is defined in `matlabroot/rtw/c/tlc/lib/utllib.tlc`. For example:

```
%% Function: BlockInstanceSetup =====
%%
%function BlockInstanceSetup(block, system) void
    %%
    %<LibBlockSetIsExpressionCompliant(block)>
    %%
%endfunction
```

You can conditionally disable expression folding at the inputs and outputs of a block by making the call to this function conditionally.

If you override one of the TLC block implementations provided by the code generator with your own implementation, you should not make the preceding call until you have updated your implementation, as described by the guidelines for expression folding in the following topics.

Output Expressions

The `BlockOutputSignal` function is used to generate code for a scalar output expression or one element of a nonscalar output expression. If your block outputs an expression, you should add a `BlockOutputSignal` function. The prototype of the `BlockOutputSignal` is

```
%function BlockOutputSignal(block,system,portIdx,ucv,lcu,idx,retType) void
```

The arguments to `BlockOutputSignal` are as follows:

- `block`: the record for the block for which an output expression is being generated
- `system`: the record for the system containing the block
- `portIdx`: zero-based index of the output port for which an expression is being generated
- `ucv`: user control variable defining the output element for which code is being generated
- `lcv`: loop control variable defining the output element for which code is being generated
- `idx`: signal index defining the output element for which code is being generated
- `retType`: character vector defining the type of signal access desired:

"Signal" specifies the contents or address of the output signal.

"SignalAddr" specifies the address of the output signal

The `BlockOutputSignal` function returns a character vector for the output signal or address. The character vector should enforce the precedence of the expression by using opening and terminating parentheses, unless the expression consists of a function call. The address of an expression can only be returned for a constant expression; it is the address of the parameter whose memory is being accessed. The code implementing the `BlockOutputSignal` function for the Constant block is shown below.

```
%% Function: BlockOutputSignal =====
%% Abstract:
%%     Return the reference to the parameter. This function *may*
%%     be used by Simulink when optimizing the Block IO data structure.
%%
%function BlockOutputSignal(block,system,portIdx,ucv,lcv,idx,retType) void
    %switch retType
        %case "Signal"
            %return LibBlockParameter(Value,ucv,lcv,idx)
        %case "SignalAddr"
            %return LibBlockParameterAddr(Value,ucv,lcv,idx)
        %default
            %assign errTxt = "Unsupported return type: %<retType>"
            %<LibBlockReportError(block,errTxt)>
    %endswitch
%endfunction
```

The code implementing the `BlockOutputSignal` function for the Relational Operator block is shown below.

```
%% Function: BlockOutputSignal =====
%% Abstract:
```

```

%%      Return an output expression. This function *may*
%%      be used by Simulink when optimizing the Block IO data structure.
%%
%function BlockOutputSignal(block,system,portIdx,ucv,lcx,idx,retType) void
%switch retType
%case "Signal"
%assign logicOperator = ParamSettings.Operator
  %if ISEQUAL(logicOperator, "~=")
    %assign op = "!="
  elseif ISEQUAL(logicOperator, "==") %assign op = "=="
    %else
      %assign op = logicOperator
    %endif
  %assign u0 = LibBlockInputSignal(0, ucv, lcv, idx)
  %assign u1 = LibBlockInputSignal(1, ucv, lcv, idx)
  %return "(%<u0> %<op> %<u1>)"
%default
%assign errTxt = "Unsupported return type: %<retType>"
%<LibBlockReportError(block,errTxt)>
%endswitch
%endfunction

```

Expression Folding for Blocks with Multiple Outputs

When a block has a single output, the `Outputs` function in the block's TLC file is called only if the output port is not an expression. Otherwise, the `BlockOutputSignal` function is called.

If a block has multiple outputs, the `Outputs` function is called if any output port is not an expression. The `Outputs` function should guard against generating code for output ports that are expressions. This is achieved by guarding sections of code corresponding to individual output ports with calls to `LibBlockOutputSignalIsExpr()`.

For example, consider an S-Function with two inputs and two outputs, where

- The first output, `y0`, is equal to two times the first input.
- The second output, `y1`, is equal to four times the second input.

The `Outputs` and `BlockOutputSignal` functions for the S-function are shown in the following code excerpt.

```

%% Function: BlockOutputSignal =====
%% Abstract:
%%      Return an output expression. This function *may*
%%      be used by Simulink when optimizing the Block IO data structure.
%%
%function BlockOutputSignal(block,system,portIdx,ucv,lcx,idx,retType) void
%switch retType
%case "Signal"
  %assign u = LibBlockInputSignal(portIdx, ucv, lcv, idx)

```

```

%case "Signal"
%if portIdx == 0
%return "(2 * %<u>)"
%elseif portIdx == 1
%return "(4 * %<u>)"
%endif
%default
%assign errTxt = "Unsupported return type: %<retType>"
%<LibBlockReportError(block,errTxt)>
%endswitch
%endfunction
%%
%% Function: Outputs =====
%% Abstract:
%%     Compute output signals of block
%%
%function Outputs(block,system) Output
%assign rollVars = ["U", "Y"]
%roll sigIdx = RollRegions, lcv = RollThreshold, block, "Roller", rollVars
%assign u0 = LibBlockInputSignal(0, "", lcv, sigIdx)
%assign u1 = LibBlockInputSignal(1, "", lcv, sigIdx)
%assign y0 = LibBlockOutputSignal(0, "", lcv, sigIdx)
%assign y1 = LibBlockOutputSignal(1, "", lcv, sigIdx)
%if !LibBlockOutputSignalIsExpr(0)
%<y0> = 2 * %<u0>;
%endif
%if !LibBlockOutputSignalIsExpr(1)
%<y1> = 4 * %<u1>;
%endif
%endroll
%endfunction

```

Comments for Blocks That Are Expression-Folding-Compliant

In the past, blocks preceded their outputs code with comments of the form

```
/* %<Type> Block: %<Name> */
```

When a block is expression-folding-compliant, the initial line shown above is generated automatically. You should not include the comment as part of the block's TLC implementation. Additional information should be registered using the `LibCacheBlockComment` function.

The `LibCacheBlockComment` function takes a character vector as an input, defining the body of the comment, except for the opening header, the final newline of a single or multiline comment, and the closing trailer.

The following TLC code illustrates registering a block comment. Note the use of the function `LibBlockParameterForComment`, which returns a character vector, suitable for a block comment, specifying the value of the block parameter.

```
%openfile commentBuf
$c(*) Gain value: %<LibBlockParameterForComment(Gain)>
%closefile commentBuf
%<LibCacheBlockComment(block, commentBuf)>
```

S-Functions That Specify Port Scope and Reusability

You can use the following `SimStruct` macros in the `mdlInitializeSizes` method to specify the scope and reusability of the memory used for your S-function's input and output ports:

- `ssSetInputPortOptimOpts`: Specify the scope and reusability of the memory allocated to an S-function input port
- `ssSetOutputPortOptimOpts`: Specify the scope and reusability of the memory allocated to an S-function output port
- `ssSetInputPortOverWritable`: Specify whether one of your S-function's input ports can be overwritten by one of its output ports
- `ssSetOutputPortOverwritesInputPort`: Specify whether an output port can share its memory buffer with an input port

You declare an input or output as local or global, and indicate its reusability, by passing one of the following four options to the `ssSetInputPortOptimOpts` and `ssSetOutputPortOptimOpts` macros:

- `SS_NOT_REUSABLE_AND_GLOBAL`: Indicates that the input and output ports are stored in separate memory locations in the global block input and output structure
- `SS_NOT_REUSABLE_AND_LOCAL`: Indicates that the code generator can declare individual local variables for the input and output ports
- `SS_REUSABLE_AND_LOCAL`: Indicates that the code generator can reuse a single local variable for these input and output ports
- `SS_REUSABLE_AND_GLOBAL`: Indicates that these input and output ports are stored in a single element in the global block input and output structure

Note Marking an input or output port as a local variable does not imply that the code generator uses a local variable in the generated code. If your S-function accesses the inputs and outputs only in its `mdlOutputs` routine, the code generator declares the inputs and outputs as local variables. However, if the inputs and outputs are used elsewhere in the S-function, the code generator includes them in the global block input and output structure.

The reusability setting indicates if the memory associated with an input or output port can be overwritten. To reuse input and output port memory:

- 1 Indicate the ports are reusable using either the `SS_REUSABLE_AND_LOCAL` or `SS_REUSABLE_AND_GLOBAL` option in the `ssSetInputPortOptimOpts` and `ssSetOutputPortOptimOpts` macros
- 2 Indicate the input port memory is overwritable using `ssSetInputPortOverWritable`
- 3 If your S-function has multiple input and output ports, use `ssSetOutputPortOverwritesInputPort` to indicate which output and input ports share memory

The following example shows how different scope and reusability settings affect the generated code. The following model contains an S-function block pointing to the C MEX S-function `matlabroot/toolbox/simulink/simdemos/simfeatures/src/sfun_directlook.c`, which models a direct 1-D lookup table.

The S-function's `mdlInitializeSizes` method declares the input port as reusable, local, and overwritable and the output port as reusable and local, as follows:

```
static void mdlInitializeSizes(SimStruct *S)
{
/* snip */
    ssSetInputPortOptimOpts(S, 0, SS_REUSABLE_AND_LOCAL);
    ssSetInputPortOverWritable(S, 0, TRUE);

/* snip */
    ssSetOutputPortOptimOpts(S, 0, SS_REUSABLE_AND_LOCAL);

/* snip */
}
```

The generated code for this model stores the input and output signals in a single local variable `rtb_SFunction`, as shown in the following output function:

```
static void sl_directlook_output(int_T tid)
{
/* local block i/o variables */
    real_T rtb_SFunction[2];
```

```

/* Sin: '<Root>/Sine Wave' */
rtb_SFunction[0] = sin(((real_T)sl_directlook_DWork.counter[0] +
  sl_directlook_P.SineWave_Offset) * 2.0 * 3.1415926535897931E+000 /
  sl_directlook_P.SineWave_NumSamp) * sl_directlook_P.SineWave_Amp[0] +
  sl_directlook_P.SineWave_Bias;
rtb_SFunction[1] = sin(((real_T)sl_directlook_DWork.counter[1] +
  sl_directlook_P.SineWave_Offset) * 2.0 * 3.1415926535897931E+000 /
  sl_directlook_P.SineWave_NumSamp) * sl_directlook_P.SineWave_Amp[1] +
  sl_directlook_P.SineWave_Bias;

/* S-Function Block: '<Root>/S-Function' */
{
  const real_T *xData = &sl_directlook_P.SFunction_XData[0];
  const real_T *yData = &sl_directlook_P.SFunction_YData [0];
  real_T spacing = xData[1] - xData[0];
  if (rtb_SFunction[0] <= xData[0] ) {
    rtb_SFunction[0] = yData[0];
  } else if (rtb_SFunction[0] >= yData[20] ) {
    rtb_SFunction[0] = yData[20];
  } else {
    int_T idx = (int_T)( ( rtb_SFunction[0] - xData[0] ) / spacing );
    rtb_SFunction[0] = yData[idx];
  }

  if (rtb_SFunction[1] <= xData[0] ) {
    rtb_SFunction[1] = yData[0];
  } else if (rtb_SFunction[1] >= yData[20] ) {
    rtb_SFunction[1] = yData[20];
  } else {
    int_T idx = (int_T)( ( rtb_SFunction[1] - xData[0] ) / spacing );
    rtb_SFunction[1] = yData[idx];
  }
}

/* Output: '<Root>/Out1' */
sl_directlook_Y.Out1[0] = rtb_SFunction[0];
sl_directlook_Y.Out1[1] = rtb_SFunction[1];
UNUSED_PARAMETER(tid);
}

```

The following table shows variations of the code generated for this model when using the generic real-time target (GRT). Each row explains a different setting for the scope and reusability of the S-function's input and output ports.

Scope and reusability	S-function mdlInitializeSizes code	Generated code
<p>Inputs: Local, reusable, overwritable</p> <p>Outputs: Local, reusable</p>	<pre>ssSetInputPortOptimOpts(S, 0, SS_REUSABLE_AND_LOCAL); ssSetInputPortOverWritable(S, 0, TRUE); ssSetOutputPortOptimOpts(S, 0, SS_REUSABLE_AND_LOCAL);</pre>	<p>The <i>model.c</i> file declares a local variable in the output function.</p> <pre>/* local block i/o variables */ real_T rtb_SFunction[2];</pre>

<p>Inputs: Local, not reusable</p> <p>Outputs: Local, not reusable</p>	<pre>ssSetInputPortOptimOpts(S, 0, SS_NOT_REUSABLE_AND_LOCAL); ssSetInputPortOverWritable(S, 0, FALSE); ssSetOutputPortOptimOpts(S, 0, SS_NOT_REUSABLE_AND_LOCAL);</pre>	<p>The <i>model.c</i> file declares local variables for the S-function's input and output in the output function</p> <pre>/* local block i/o variables */ real_T rtb_SineWave[2]; real_T rtb_SFunction[2];</pre>

Scope and reusability	S-function mdlInitializeSizes code	Generated code
<p>Inputs: Global, not reusable</p> <p>Outputs: Global, not reusable</p>	<pre>ssSetInputPortOptimOpts(S, 0, SS_NOT_REUSABLE_AND_GLOBAL); ssSetInputPortOverWritable(S, 0, FALSE); ssSetOutputPortOptimOpts(S, 0, SS_NOT_REUSABLE_AND_GLOBAL);</pre>	<p>The <i>model.h</i> file defines a block signal structure with individual elements to store the S-function's input and output.</p> <pre>/* Block signals (auto storage) */ typedef struct { real_T SineWave[2]; real_T SFunction[2]; } BlockIO_sl_directlook;</pre> <p>The <i>model.c</i> file uses the different elements in this structure when calculating the S-function's input and output.</p> <pre>/* Sin: '<Root>/Sine Wave' */ sl_directlook_B.SineWave[0] = sin ... /* snip */ /*S-Function Block:<Root>/S-Function*/ { const real_T *xData = &sl_directlook_P.SFunction_XData[0]</pre>

S-Functions That Specify Sample Time Inheritance Rules

For the Simulink engine to determine whether a model can inherit a sample time, the S-functions in the model need to specify how they use sample times. You can specify this information by calling the macro `ssSetModelReferenceSampleTimeInheritanceRule` from `mdlInitializeSizes` or `mdlSetWorkWidths`. To use this macro:

- 1 Check whether the S-function calls any of the following macros:
 - `ssGetSampleTime`
 - `ssGetInputPortSampleTime`
 - `ssGetOutputPortSampleTime`
 - `ssGetInputPortOffsetTime`
 - `ssGetOutputPortOffsetTime`
 - `ssGetSampleTimePtr`

- `ssGetInputPortSampleTimeIndex`
 - `ssGetOutputPortSampleTimeIndex`
 - `ssGetSampleTimeTaskID`
 - `ssGetSampleTimeTaskIDPtr`
- 2 Check for the following in your S-function TLC code:
- `LibBlockSampleTime`
 - `CompiledModel.SampleTime`
 - `LibBlockInputSignalSampleTime`
 - `LibBlockInputSignalOffsetTime`
 - `LibBlockOutputSignalSampleTime`
 - `LibBlockOutputSignalOffsetTime`
- 3 Depending on your search results, use `ssSetModelReferenceSampleTimeInheritanceRule` as indicated in the following table.

If...	Use...
None of the macros or functions are present, the S-function does not preclude the model from inheriting a sample time.	<code>ssSetModelReferenceSampleTimeInheritanceRule(S, USE_DEFAULT_FOR_DISCRETE_INHERITANCE)</code>
Any of the macros or functions are used for <ul style="list-style-type: none"> • Throwing errors if sample time is inherited, continuous, or constant • Checking <code>ssIsSampleHit</code> • Checking whether sample time is inherited in either <code>mdlSetInputPortSampleTime</code> or <code>mdlSetOutputPortSampleTime</code> before setting 	<code>ssSetModelReferenceSampleTimeInheritanceRule... (S,USE_DEFAULT_FOR_DISCRETE_INHERITANCE)</code>

If...	Use...
The S-function uses its sample time for computing parameters, outputs, and so on	<code>ssSetModelReferenceSampleTimeInheritanceRule(S, DISALLOW_SAMPLE_TIME_INHERITANCE)</code>

Note If an S-function does not set the `ssSetModelReferenceSampleTimeInheritanceRule` macro, by default the Simulink engine assumes that the S-function does not preclude the model containing that S-function from inheriting a sample time. However, the engine issues a warning indicating that the model includes S-functions for which this macro is not set.

You can use settings on **Configuration Parameters > Diagnostics > Advanced parameters** to control how the Simulink engine responds when it encounters S-functions that have unspecified sample time inheritance rules. Toggle the **Configuration Parameters > Diagnostics > Sample Time > Unspecified inheritability of sample time** diagnostic to none, warning, or error. The default is warning.

S-Functions That Support Code Reuse

You can reuse the generated code for identical subsystems that occur in multiple instances within a model and across referenced models. For more information about code generation of subsystems for code reuse, see “Control Generation of Subsystem Functions” (Simulink Coder). If you want your S-function to support code reuse for a subsystem, the S-function must meet the following requirements:

- The S-function must be inlined.
- Code generated from the S-function must not use static variables.
- The S-function must initialize its pointer work vector in `mdlStart` and not before.
- The S-function must not be a sink that logs data to the workspace.
- The S-function must register its parameters as run-time parameters in `mdlSetWorkWidths`. (It must not use `ssWriteRTWParameters` in its `mdlRTW` function for this purpose.)
- The S-function must not be a device driver.

In addition to meeting the preceding requirements, your S-function must set the `SS_OPTION_WORKS_WITH_CODE_REUSE` flag (see the description of `ssSetOptions` in

the Simulink Writing S-Function documentation). This flag indicates that your S-function meets the requirements for subsystem code reuse.

S-Functions for Multirate Multitasking Environments

- “About S-Functions for Multirate Multitasking Environments” on page 11-106
- “Rate Grouping Support in S-Functions” on page 11-106
- “Create Multitasking, Multirate, Port-Based Sample Time S-Functions” on page 11-107

About S-Functions for Multirate Multitasking Environments

S-functions can be used in models with multiple sample rates and deployed in multitasking target environments. Likewise, S-functions themselves can have multiple rates at which they operate. The code generator produces code for multirate multitasking models using an approach called *rate grouping*. In code generated for ERT-based targets, rate grouping generates separate *model_step* functions for the base rate task and each subrate task in the model. Although rate grouping is a code generation feature found in ERT targets only, your S-functions can use it in other contexts when you code them as explained below.

Rate Grouping Support in S-Functions

To take advantage of rate grouping, you must inline your multirate S-functions if you have not done so. You need to follow certain Target Language Compiler protocols to exploit rate grouping. Coding TLC to exploit rate grouping does not prevent your inlined S-functions from functioning properly in GRT. Likewise, your inlined S-functions will still generate valid ERT code even if you do not make them rate-grouping-compliant. If you do so, however, they will generate more efficient code for multirate models.

For instructions and examples of Target Language Compiler code illustrating how to create and upgrade S-functions to generate rate-grouping-compliant code, see “Rate Grouping Compliance and Compatibility Issues” on page 52-17.

For each multirate S-function that is not rate grouping-compliant, the code generator issues the following warning when you build:

```
Warning: Simulink Coder: Code of output function for multirate block
'<Root>/S-Function' is guarded by sample hit checks rather than being rate
grouped. This will generate the same code for all rates used by the block,
possibly generating dead code. To avoid dead code, you must update the TLC
file for the block.
```

You will also find a comment such as the following in code generated for each noncompliant S-function:

```
/* Because the output function of multirate block
   <Root>/S-Function is not rate grouped,
   the following code might contain unreachable blocks of code.
   To avoid this, you must update your block TLC file. */
```

The words “update function” are substituted for “output function” in these warnings.

Create Multitasking, Multirate, Port-Based Sample Time S-Functions

The following instructions show how to support both data determinism and data integrity in multirate S-functions. They do not cover cases where there is no determinism nor integrity. Support for frame-based processing does not affect the requirements.

Note The slow rates must be multiples of the fastest rate. The instructions do not apply when two rates being interfaced are not multiples or when the rates are not periodic.

Rules for Properly Handling Fast-to-Slow Transitions

The rules that multirate S-functions should observe for inputs are

- The input should only be read at the rate that is associated with the input port sample time.
- Generally, the input data is written to DWork, and the DWork can then be accessed at the slower (downstream) rate.

The input can be read at every sample hit of the input rate and written into DWork memory, but this DWork memory cannot then be directly accessed by the slower rate. DWork memory that will be read by the slow rate must only be written by the fast rate when there is a *special sample hit*. A special sample hit occurs when both this input port rate and rate to which it is interfacing have a hit. Depending on their requirements and design, algorithms can process the data in several locations.

The rules that multirate S-functions should observe for outputs are

- The output should not be written by a rate other than the rate assigned to the output port, except in the optimized case described below.
- The output should always be written when the sample rate of the output port has a hit.

If these conditions are met, the S-Function block can specify that the input port and output port can both be made local and reusable.

You can include an optimization when little or no processing needs to be done on the data. In such cases, the input rate code can directly write to the output (instead of by using DWork) when there is a special sample hit. If you do this, however, you must declare the output port to be *global* and *not reusable*. This optimization results in one less memcopy but does introduce nonuniform processing requirements on the faster rate.

Whether you use this optimization or not, the most recent input data, as seen by the slower rate, is the value when both the faster and slower rate had their hits (and possible earlier input data as well, depending on the algorithm). Subsequent steps by the faster rate and the associated input data updates are not seen by the slower rate until the next hit for the slow rate occurs.

Pseudocode Examples of Fast-to-Slow Rate Transition

The pseudocode below abstracts how you should write your C MEX code to handle fast-to-slow transitions, illustrating with an input rate of 0.1 second driving an output rate of one second. A similar approach can be taken when inlining the code. The block has following characteristics:

- File: `sfun_multirate_zoh.c`, Equation: $y = u(\text{tslow})$
- Input: local and reusable
- Output: local and reusable
- DirectFeedthrough: yes

```
OutputFcn
if (ssIsSampleHit(".1")) {
    if (ssIsSpecialSampleHit("1")) {
        DWork = u;
    }
}
if (ssIsSampleHit("1")) {
    y = DWork;
}
```

An alternative, slightly optimized approach for simple algorithms:

- Input: local and reusable
- Output: global and not reusable because it needs to persist between special sample hits
- DirectFeedthrough: yes

```

OutputFcn
if (ssIsSampleHit(".1")) {
    if (ssIsSpecialSampleHit("1")) {
        y = u;
    }
}

```

Example adding a simple algorithm:

- File: `sfun_multirate_avg.c`; Equation: $y = \text{average}(u)$
- Input: local and reusable
- Output: local and reusable
- DirectFeedthrough: yes

(Assume `DWork[0:10]` and `DWork[mycounter]` are initialized to zero)

```

OutputFcn
if (ssIsSampleHit(".1")) {
    /* In general, processing on 'u' could be done here,
       it runs on every hit of the fast rate. */
    DWork[DWork[mycounter]++] = u;
    if (ssIsSpecialSampleHit("1")) {
        /* In general, processing on DWork[0:10] can be done
           here, but it does cause the faster rate to have
           nonuniform processing requirements (every 10th hit,
           more code needs to be run).*/
        DWork[10] = sum(DWork[0:9])/10;
        DWork[mycounter] = 0;
    }
}
if (ssIsSampleHit("1")) {
    /* Processing on DWork[10] can be done here before
       outputting. This code runs on every hit of the
       slower task. */
    y = DWork[10];
}

```

Rules for Properly Handling Slow-to-Fast Transitions

When output rates are faster than input rates, input should only be read at the rate that is associated with the input port sample time, observing the following rules:

- Always read input from the update function.
- Use no special sample hit checks when reading input.
- Write the input to a `DWork`.
- When there is a special sample hit between the rates, copy the `DWork` into a second `DWork` in the output function.

- Write the second DWork to the output at every hit of the output sample rate.

The block can request that the input port be made local but it cannot be set to reusable. The output port can be set to local and reusable.

As in the fast-to-slow transition case, the input should not be read by a rate other than the one assigned to the input port. Similarly, the output should not be written to at a rate other than the rate assigned to the output port.

An optimization can be made when the algorithm being implemented is only required to run at the slow rate. In such cases, you use only one DWork. The input still writes to the DWork in the update function. When there is a special sample hit between the rates, the output function copies the same DWork directly to the output. You must set the output port to be global and not reusable in this case. This optimization results in one less memcopy operation per special sample hit.

In either case, the data that the fast rate computations operate on is always delayed, that is, the data is from the previous step of the slow rate code.

Pseudocode Examples of Slow-to-Fast Rate Transition

The pseudocode below abstracts what your S-function needs to do to handle slow-to-fast transitions, illustrating with an input rate of one second driving an output rate of 0.1 second. The block has following characteristics:

- File: `sfun_multirate_delay.c`, Equation: $y = u(t_{\text{slow}} - 1)$
- Input: Set to local, will be local if output/update are combined (ERT) otherwise will be global. Set to not reusable because input needs to be preserved until the update function runs.
- Output: local and reusable
- DirectFeedthrough: no

```
OutputFcn
if (ssIsSampleHit(".1")) {
    if (ssIsSpecialSampleHit("1")) {
        DWork[1] = DWork[0];
    }
    y = DWork[1];
}
UpdateFcn
if (ssIsSampleHit("1")) {
    DWork[0] = u;
}
```

An alternative, optimized approach can be used by some algorithms:

- Input: Set to local, will be local if output/update are combined (ERT) otherwise will be global. Set to not reusable because input needs to be preserved until the update function runs.
- Output: global and not reusable because it needs to persist between special sample hits.
- DirectFeedthrough: no

```

OutputFcn
if (ssIsSampleHit(".1")) {
    if (ssIsSpecialSampleHit("1")) {
        y = DWork;
    }
}
UpdateFcn
if (ssIsSampleHit("1")) {
    DWork = u;
}

```

Example adding a simple algorithm:

- File: `sfun_multirate_modulate.c`, Equation: $y = \sin(t_{\text{fast}}) + u(t_{\text{slow}}-1)$
- Input: Set to local, will be local if output/update are combined (an ERT feature) otherwise will be global. Set to not reusable because input needs to be preserved until the update function runs.
- Output: local and reusable
- DirectFeedthrough: no

```

OutputFcn
if (ssIsSampleHit(".1")) {
    if (ssIsSpecialSampleHit("1")) {
        /* Processing not likely to be done here. It causes
        * the faster rate to have nonuniform processing
        * requirements (every 10th hit, more code needs to
        * be run).*/
        DWork[1] = DWork[0];
    }
    /* Processing done at fast rate */
    y = sin(ssGetTaskTime(".1")) + DWork[1];
}
UpdateFcn
if (ssIsSampleHit("1")) {
    /* Processing on 'u' can be done here. There is a delay of
    one slow rate period before the fast rate sees it.*/
    DWork[0] = u;}

```

MAAB Guidelines

The MathWorks Automotive Advisory Board (MAAB) involves major automotive OEMs and suppliers in the process of evolving MathWorks controls, simulation, and code generation products, including Simulink, Stateflow, and Simulink Coder. An important result of the MAAB has been the “MAAB Control Algorithm Modeling” (Simulink) guidelines.

If you have a Simulink Check product license, you can check that your Simulink model or subsystem, and the code that you generate from it, complies with MAAB guidelines. To check your model or subsystem, open the Simulink Model Advisor (Simulink). Navigate to **By Product > Simulink Check > Modeling Standards > MathWorks Automotive Advisory Board Checks** and run the MathWorks Automotive Advisory Board checks (Simulink Check).

For more information on using the Model Advisor, see “Run Model Checks” (Simulink).

MISRA C Guidelines

The Motor Industry Software Reliability Association (MISRA²) has established “Guidelines for the Use of the C Language in Critical Systems” (MISRA C).

For information about MISRA C, see www.misra.org.uk.

In 1998, MIRA Ltd. published MISRA C (MISRA C:1998) to provide a restricted subset of a standardized, structured language that met Safety Integrity Level (SIL) 2 and higher. A major update based on feedback was published in 2004 (MISRA C:2004), followed by a minor update in 2007 known as Technical Corrigendum (TC1).

In 2007, MIRA Ltd. published the MISRA AC AGC standard, “MISRA AC AGC: Guidelines for the Application of MISRA-C:2004 in the Context of Automatic Code Generation.” MISRA AC AGC does not change MISRA C:2004 rules, rather it modifies the adherence recommendation.

In 2013, MIRA Ltd. published the MISRA C:2012 standard, “Guidelines for the use of the C language in critical systems.” MISRA C:2012 provides improvements based on user feedback and includes guidance on automatic code generation.

Embedded Coder and Simulink offer capabilities to minimize the potential for MISRA C rule violations.

To configure a model or subsystem so that the code generator is most likely to produce MISRA C:2012 compliant code, use the Code Generation Advisor. For more information, see “Configure Model for Code Generation Objectives by Using Code Generation Advisor” on page 32-2.

The Model Advisor (Simulink) also checks that you developed your model or subsystem to increase the likelihood of generating MISRA C:2012 compliant code. To check your model or subsystem:

- 1 Open the Model Advisor.
- 2 Navigate to **By Task > Modeling Guidelines for MISRA C:2012**.
- 3 Run the checks in the folder.

For more information about using the Model Advisor, see “Run Model Checks” (Simulink).

2. MISRA and MISRA C are registered trademarks of MIRA Ltd., held on behalf of the MISRA Consortium.

For information about using Embedded Coder software within MISRA C guidelines, see Technical Solution 1-1IFP0W on the MathWorks website.

Secure Coding Standards

These coding standards are for software developers to use in the development of code in the C language:

- **CERT® C** — Published by the CERT Division of the Software Engineering Institute (SEI), these guidelines help eliminate constructs with undefined behavior that can lead to unexpected results at runtime and expose security weaknesses.
- **Common Weakness Enumeration (CWE™)** — Published by The MITRE Corporation, this list identifies common software weakness types that can occur in software architecture, design, code, or implementation. These weaknesses can lead to security vulnerabilities.
- **ISO/IEC TS 19761:2013** — Published by International Organization for Standardization and International Electrotechnical Commission, these rules are designed so that they can be enforced by static analysis tools without excessive false positives.

If you have an Embedded Coder or Simulink Check product license, you can check that your Simulink model or subsystem, and the code that you generate from it, conforms to these secure coding standards. To check your model or subsystem:

- 1** Open the Model Advisor.
- 2** Navigate to **By Task > Modeling Guidelines for secure coding standards (CERT C, CWE, ISO/IEC TS 17961)** .
- 3** Run the checks in the folder.

For more information about using the Model Advisor, see “Run Model Checks” (Simulink).

If you have a Polyspace Bug Finder product license, you can evaluate your code against these secure coding standards. For more information, see “Check C/C++ Code for Security Standards” (Polyspace Bug Finder)

IEC 61508 Standard

In this section...

“Apply Simulink and Embedded Coder to the IEC 61508 Standard” on page 12-9

“Check for IEC 61508 Standard Compliance Using the Model Advisor” on page 12-9

“Validate Traceability” on page 12-9

Apply Simulink and Embedded Coder to the IEC 61508 Standard

Applying Model-Based Design to a safety-critical system requires extra consideration and rigor so that the system adheres to defined safety standards. IEC 61508, Functional safety of electrical/electronic/programmable electronic safety related systems, is such a standard. Because the standard was published when most software was coded by hand, the standard needs to be mapped to Model-Based Design technologies. For further information about MathWorks support for IEC 61508, see IEC 61508 Support in MATLAB and Simulink.

MathWorks provides an IEC Certification Kit product that you can use to certify MathWorks code generation and verification tools for projects based on the IEC 61508 standard. For more information, see <https://www.mathworks.com/products/iec-61508/>.

Check for IEC 61508 Standard Compliance Using the Model Advisor

If you have a Simulink Check product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the IEC 61508 standard by running the Simulink Model Advisor (Simulink). Navigate to **By Task > Modeling Standards for IEC 61508** and run the “IEC 61508, IEC 62304, ISO 26262, and EN 50128 Checks” (Simulink Check).

For more information on using the Model Advisor, see “Run Model Checks” (Simulink).

Validate Traceability

Typically, applications that require certification require some level of traceability between requirements, models, and corresponding code.

To...	Use...
Associate requirements documents with objects in Simulink models	The “Requirements Management Interface Setup” (Simulink Requirements) that is available if you have a Simulink Requirements license.
Trace model blocks and subsystems to generated code	The “Model-to-Code Traceability” on page 64-10 option when generating an HTML report during the code generation or build process.
Trace generated code to model blocks and subsystems	The “Code-to-Model Traceability” on page 64-8 option when generating an HTML report during the code generation or build process.

Develop a Model that Complies with the IEC 61508 Standard

This example shows how to use Model Advisor checks for the IEC 61508 standard to develop a model and code that comply with the standard.

The IEC 61508 checks identify issues with a model that impede deployment in safety-related applications or limit traceability.

Understanding the Model

According to the functional requirements, a model shall be created that checks whether the 1-norm distance between points $(x1, x2)$ and $(y1, y2)$ is less than or equal to a given threshold thr . For two points $(x1, x2)$ and $(y1, y2)$, the 1-norm distance is given as:

$$\sum_{i=1}^2 |x_i - y_i|$$

The `rtwdemo_iec61508` model implements the preceding requirement. Open and get familiar with the model.

```
model='rtwdemo_iec61508';  
open_system(model)
```

Using the IEC 61508 Modeling Standard Checks

Description
 This example uses Model Advisor checks for the IEC 61508 standard to facilitate developing a model and code that comply with that standard. The IEC 61508 checks identify issues with a model that might impede deployment in safety-related applications or limit traceability.

Instructions

1. Start the Model Advisor by selecting Analysis > Model Advisor.
2. Expand the By Task > Modeling Standards for IEC 61508 group of checks.
3. Select all checks within the group and the "Show report after run" option.
4. Click the Run Selected Checks button.
5. Inspect the check results and the generated Model Advisor report.
6. Fix reported issues.
7. Rerun the checks.

Double-click the Launch Model Advisor button to automate step 1.
 Double-click the Generate Code Using Embedded Coder button to generate source code and open the code generation HTML report.

Copyright 2008-2017 The MathWorks, Inc.

This example requires a Simulink Check license.

Apply the IEC 61508 Modeling Standard Checks

To deploy the model in a safety-related software component that must comply with the IEC 61508 safety standard, check the model for issues that might impede deployment in such an environment or limit traceability between the model and generated source code.

To identify possible compliance issues with the model:

- 1 Start the Model Advisor by selecting **Analysis > Model Advisor** or by entering `modeladvisor('rtwdemo_IEC61508')` at the MATLAB command line.
- 2 In the **Task Hierarchy**, expand **By Task > Modeling Standards for IEC 61508**.
- 3 Select the checks within the group.
- 4 Select **Show report after run** to generate an HTML report that shows the check results.
- 5 Click **Run Selected Checks**. Model Advisor processes the IEC 61508 checks and displays the results.

To review the check results and make changes:

- 1 Review the **Summary** in the **Report** section of the right pane.
- 2 In the **Task Hierarchy**, select a check that did not pass. Review the results that appear in the right pane for that check. For more information on the check and on how to resolve reported issues, with the check selected, click **Help**.
- 3 Click the **Generate Code Using Embedded Coder** button in the model to inspect the generated code and the traceability report.
- 4 Resolve the reported issues and rerun the checks.
- 5 Review the generated HTML report of the check results by clicking the link in the **Report** box.
- 6 Print the generated HTML report. You can use the report as evidence in the IEC 61508 compliance example process.

IEC 62304 Standard

Apply Simulink and Embedded Coder to the IEC 62304 Standard

Applying Model-Based Design to a safety-critical system requires extra consideration and rigor so that the system adheres to defined safety standards. Standard: IEC 62304, Medical device software - Software life cycle processes, is such a standard.

MathWorks provides an IEC Certification Kit product that you can use to certify MathWorks code generation and verification tools for projects based on the IEC 62304 standard. For more information, see <https://www.mathworks.com/products/iec-61508/>.

Check for IEC 62304 Standard Compliance Using the Model Advisor

If you have a Simulink Check product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the IEC 62304 standard by running the Simulink Model Advisor (Simulink). Navigate to **By Task > Modeling Standards for IEC 62304** and run the “IEC 61508, IEC 62304, ISO 26262, and EN 50128 Checks” (Simulink Check).

For more information on using the Model Advisor, see “Run Model Checks” (Simulink).

ISO 26262 Standard

In this section...
“Apply Simulink and Embedded Coder to the ISO 26262 Standard” on page 12-15
“Check for ISO 26262 Standard Compliance Using the Model Advisor” on page 12-15
“Validate Traceability” on page 12-15

Apply Simulink and Embedded Coder to the ISO 26262 Standard

Applying Model-Based Design to a safety-critical system requires extra consideration and rigor so that the system adheres to defined functional safety standards. ISO 26262, Road Vehicles - Functional Safety, is such a standard. For further information about MathWorks support for ISO 26262, see ISO 26262 Support in MATLAB and Simulink.

MathWorks provides an IEC Certification Kit product that you can use to qualify MathWorks code generation and verification tools for projects based on the ISO 26262 standard. For more information, see <https://www.mathworks.com/products/iso-26262/>.

Check for ISO 26262 Standard Compliance Using the Model Advisor

If you have a Simulink Check product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the ISO 26262 standard by running the Simulink Model Advisor (Simulink). Navigate to **By Task > Modeling Standards for ISO 26262** and run the “IEC 61508, IEC 62304, ISO 26262, and EN 50128 Checks” (Simulink Check).

For more information on using the Model Advisor, see “Run Model Checks” (Simulink).

Validate Traceability

Typically, applications that require certification require some level of traceability between requirements, models, and corresponding code.

To...	Use...
Associate requirements documents with objects in Simulink models	The “Requirements Management Interface Setup” (Simulink Requirements) that is available if you have a Simulink Requirements license.
Trace model blocks and subsystems to generated code	The “Model-to-Code Traceability” on page 64-10 option when generating an HTML report during the code generation or build process.
Trace generated code to model blocks and subsystems	The “Code-to-Model Traceability” on page 64-8 option when generating an HTML report during the code generation or build process.

EN 50128 Standard

“Apply Simulink and Embedded Coder to the EN 50128 Standard” on page 12-17

“Check for EN 50128 Standard Compliance Using the Model Advisor” on page 12-17

“Validate Traceability” on page 12-17

Apply Simulink and Embedded Coder to the EN 50128 Standard

Applying Model-Based Design to a safety-critical system requires extra consideration and rigor so that the system adheres to defined safety standards. EN 50128, Railway applications — Software for railway control and protection systems, is such a standard.

MathWorks provides an IEC Certification Kit product that you can use to certify MathWorks code generation and verification tools for projects based on the EN 50128 standard. For more information, see <https://www.mathworks.com/products/iec-61508/>.

Check for EN 50128 Standard Compliance Using the Model Advisor

If you have a Simulink Check product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the EN 50128 standard by running the Simulink Model Advisor (Simulink). Navigate to **By Task > Modeling Standards for EN 50128** and run the “IEC 61508, IEC 62304, ISO 26262, and EN 50128 Checks” (Simulink Check).

For more information on using the Model Advisor, see “Run Model Checks” (Simulink).

Validate Traceability

Typically, applications that require certification require some level of traceability between requirements, models, and corresponding code.

To...	Use...
Associate requirements documents with objects in Simulink models	The “Requirements Management Interface Setup” (Simulink Requirements) that is available if you have a Simulink Requirements license.
Trace model blocks and subsystems to generated code	The “Model-to-Code Traceability” on page 64-10 option when generating an HTML report during the code generation or build process.
Trace generated code to model blocks and subsystems	The “Code-to-Model Traceability” on page 64-8 option when generating an HTML report during the code generation or build process.

DO-178C Standard

In this section...

“Apply Simulink and Embedded Coder to the DO-178C Standard” on page 12-19

“Check for Standard Compliance Using the Model Advisor” on page 12-19

“Validate Traceability” on page 12-19

Apply Simulink and Embedded Coder to the DO-178C Standard

Applying Model-Based Design to a high-integrity system requires extra consideration and rigor so that the system adheres to defined safety standards. DO-178C Software Considerations in Airborne Systems and Equipment Certification is such a standard. A supplement to DO-178C, DO-331, provides guidance on the use of Model-Based Design technologies. MathWorks provides a DO Qualification Kit product that you can use to qualify MathWorks verification tools for projects based on the DO-178C, DO-331, and related standards. For more information, see <https://www.mathworks.com/products/do-178/>.

For information about Model-Based Design and MathWorks support of aerospace and defense industry standards, see <https://www.mathworks.com/aerospace-defense/>.

Check for Standard Compliance Using the Model Advisor

If you have a Simulink Check product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the DO-178C standard by running the Simulink Model Advisor (Simulink). Navigate to **By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks** or **By Task > Modeling Standards for DO-178C/DO-331** and run the DO-178C/DO-331 checks (Simulink Check).

For more information on using the Model Advisor, see “Run Model Checks” (Simulink).

Validate Traceability

Typically, applications that require certification require some level of traceability between requirements, models, and corresponding code.

To...	Use...
Associate requirements documents with objects in Simulink models	The “Requirements Management Interface Setup” (Simulink Requirements) that is available if you have a Simulink Requirements license.
Trace model blocks and subsystems to generated code	The “Model-to-Code Traceability” on page 64-10 option when generating an HTML report during the code generation or build process.
Trace generated code to model blocks and subsystems	The “Code-to-Model Traceability” on page 64-8 option when generating an HTML report during the code generation or build process.

MISRA C:2012 Compliance and Deviations for Code Generated by Using Embedded Coder

- “Using This Documentation When Developing a MISRA C:2012 Compliance Statement” on page 13-2
- “Evaluate Your Generated Code for MISRA C:2012 Compliance” on page 13-4
- “Compliance Information Summary Tables” on page 13-7
- “Modeling Guidelines for MISRA C:2012 Compliance” on page 13-21
- “Deviations Rationale” on page 13-30

Using This Documentation When Developing a MISRA C:2012 Compliance Statement

As part of the model development process, it is important that C code generated by Embedded Coder from Simulink and Stateflow complies with industry coding standards.

When using MISRA C:2012 coding guidelines to evaluate the quality of your generated C code, you are required per section 5.3 of the *MISRA C:2012 Guidelines for the Use of C Language in Critical Systems* document to prepare a compliance statement for the project being evaluated. To assist you in the development of this compliance statement, MathWorks evaluates the MISRA C:2012 guidelines against C code generated by using Embedded Coder and provides the following information:

- Compliance Summary Tables on page 13-7, which identify the method used to obtain compliance for each rule and directive.
- Deviations on page 13-30, which identify rules or directives that are not compliant.

For information about the process MathWorks uses to evaluate generated C code against MISRA C:2012 guidelines, see “MathWorks Process for Identifying Violations of MISRA C:2012 Guidelines in Generated C Code” on page 13-2.

For additional information about the MISRA organization, their coding guidelines, and the MISRA publication timeline, see www.misra.org.uk.

Disclaimer While adhering to the recommendations in the MISRA C:2012 Compliance and Deviations for Code Generated using Embedded Coder documentation will reduce the risk that an error is introduced during development and not be detected, it is not a guarantee that the system being developed will be safe. Conversely, if some of the recommendations are not followed, it does not mean that the system being developed will be unsafe.

MathWorks Process for Identifying Violations of MISRA C:2012 Guidelines in Generated C Code

To determine any potential violations in the generated code, MathWorks maintains an extensive set of test models that cover the standard usage of compliant blocks. For each release, MathWorks uses these test models with the following products to evaluate the modeling, code generation, and analysis of generated code.

Product	Purpose
Simulink	Create/maintain models.
Stateflow	Create/maintain models.
Fixed-Point Designer	Create/maintain models.
Embedded Coder	Generate C code.
Simulink Check	Execute MISRA C:2012 Model Advisor checks. ^a
Polyspace Bug Finder	Identify bug/coding defects. Use the Polyspace Bug Finder MISRA C: 2012 Checker (Polyspace Bug Finder) to analyze the generated code against the MISRA C:2012 Directives and Rules (Polyspace Bug Finder) and provide information about violations.
Polyspace Code Prover	Prove absence of run-time errors. Use the Polyspace Code Prover MISRA C: 2012 checker (Polyspace Code Prover) to analyze the generated code against the MISRA C:2012 Directives and Rules (Polyspace Code Prover) and provide information about violations.

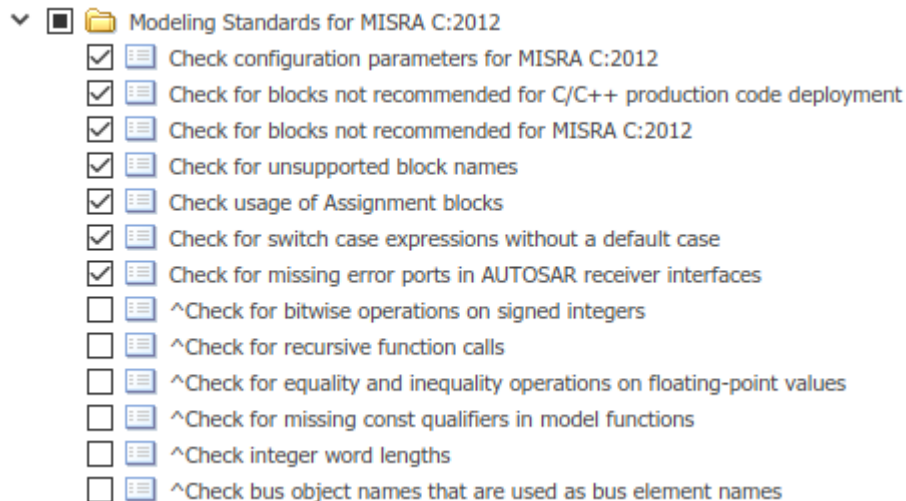

a. MISRA C:2012 checks are available only when you have an Simulink Check or Embedded Coder license.

Note The compliance analysis performed by the Polyspace MISRA C:2012 Checker assesses C code generated by Embedded Coder. No assessment is made of the Embedded Coder tool chain. Handwritten C code and third-party libraries that are used with code generated by Embedded Coder are not considered. Other MISRA C code analysis tools can yield different results.

Evaluate Your Generated Code for MISRA C:2012 Compliance

It is important to check that C code generated by Embedded Coder from Simulink and Stateflow complies with MISRA C:2012 coding standards. This workflow illustrates the process of evaluating your generated code for compliance to MISRA C:2012 guidelines.

- 1 Design the model in Simulink (Simulink) or Stateflow (Stateflow)
- 2 Open the Model Advisor (Simulink) and run the MISRA C:2012 checks (Simulink Check), which are available in **By Task > Modeling Standards for MISRA C:2012**.

- 3 If necessary, modify the model to adhere to the “Modeling Guidelines for MISRA C: 2012 Compliance” on page 13-21.
- 4 After all MISRA C:2012 checks pass successfully, generate code by using Embedded Coder.

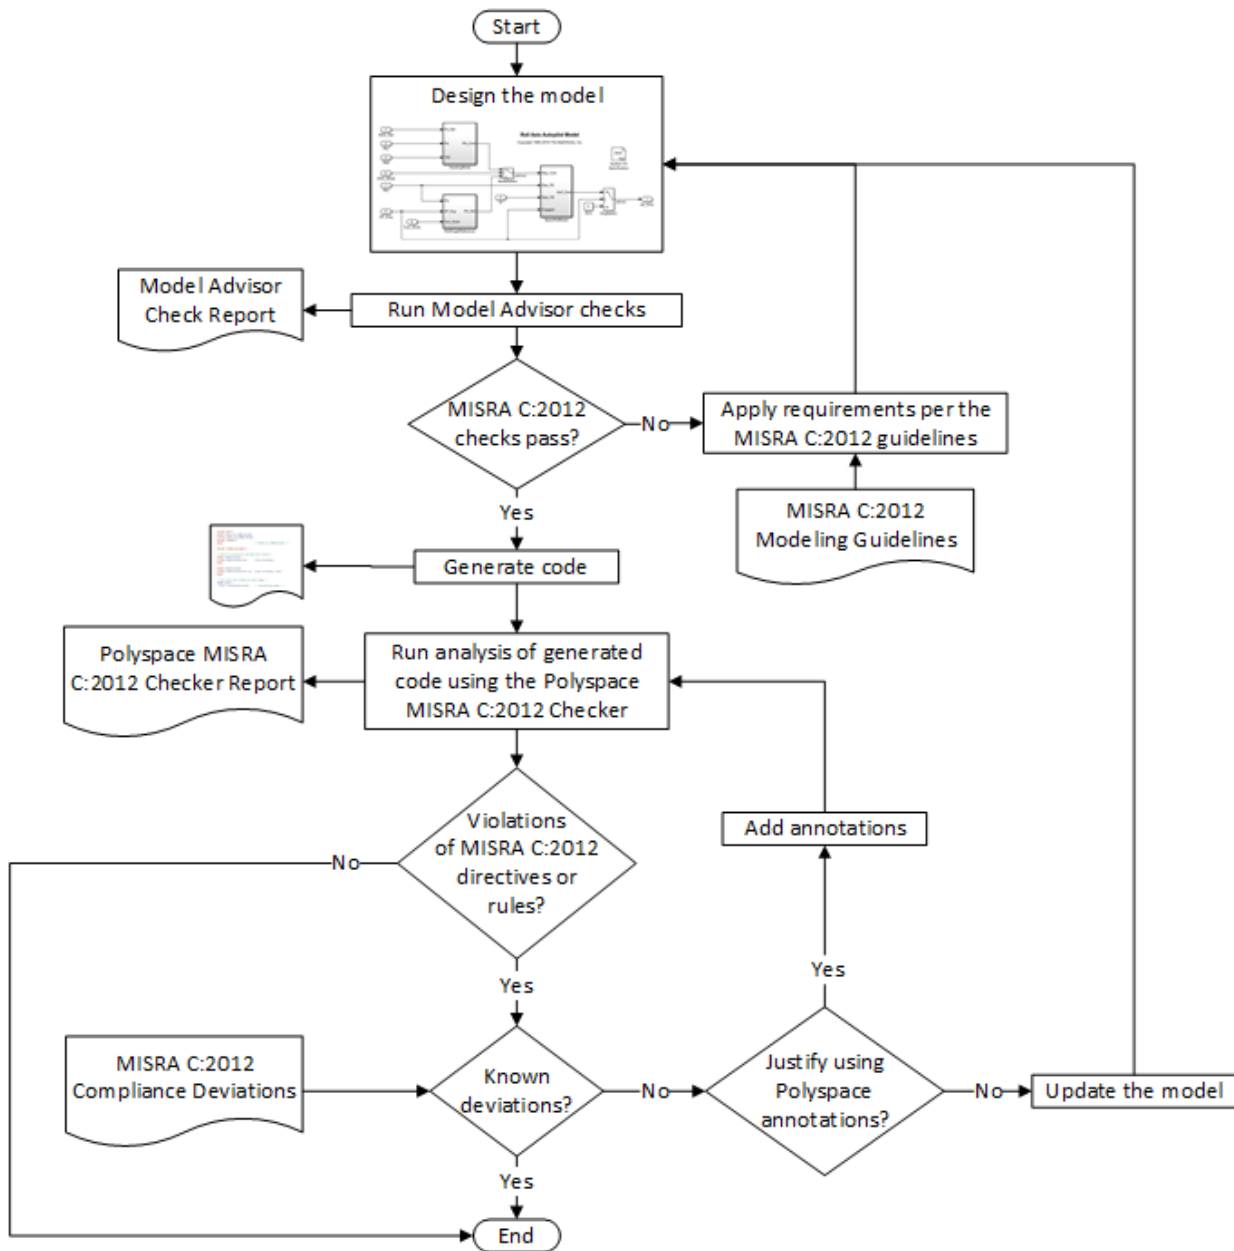

To avoid possible name clashes, multiple functions definitions, and multiple data definitions, use one of these code generation approaches:

- Single model: Generate code from a single model, including submodels, by using Model blocks.
- Multiple models: Generate code from multiple models, including:

- A shared utility folder to synchronize functions
 - Data ownership to control data definitions
 - Hand integration to manage code generated from various models
- 5** Execute the Polyspace Bug Finder MISRA C:2012 Checker (Polyspace Bug Finder).

For more information about running a Polyspace analysis on your generated code, including analysis options and results, see:

- Analysis of Generated Code using Polyspace Bug Finder (Polyspace Bug Finder)
 - Analysis of Generated Code using Polyspace Code Prover (Polyspace Code Prover)
- 6** Justify violations to the MISRA C:2012 coding standards using Polyspace annotations (Polyspace Bug Finder).

Compliance Information Summary Tables

In this section...

“Compliance Summary Tables” on page 13-7

“Explanatory Notes” on page 13-17

Compliance Summary Tables

MathWorks evaluates C code generated by Embedded Coder from Simulink and Stateflow against the MISRA C:2012 coding standards. The results from this effort are available in these compliance summary tables. These tables identify:

- Methods used to obtain compliance:
 - Compliant: Compliance to the rule/directive is achieved through adherence to the code generation process, modeling guidelines, or Model Advisor checks. When applicable, there are explanatory notes that provide information relevant to compliance methods or actions that you can perform to satisfy the directive or rule.
 - Deviation: The rule or directive is not compliant.
- Whether the Polyspace MISRA C:2012 Checker supports the rule or directive.

You can use these tables when preparing the MISRA C:2012 compliance statement for your project as required per section 5.3 of the *MISRA C:2012 Guidelines for the Use of C Language in Critical Systems* document. These tables align with the published MISRA C: 2012 rule and directives tables.

"Implementation" MISRA C:2012 Directives

Explanatory Notes

These explanatory notes are referenced from the "Compliance Information Summary Tables" on page 13-7.

Explanatory Note for Directive 1.1

Information about the implementation-defined behavior for Embedded Coder is available in "Configure Run-Time Environment Options" on page 7-2 . Compiler documentation is out of scope.

Character set encoding is managed by using the `SavedCharacterEncoding` model parameter. For additional information, including a list of supported character encodings, see `slCharacterEncoding`.

Configure the integer division method in the Model Configuration Parameters dialog box, on the **Hardware Implementation** pane. For additional information, see "Configure Run-Time Environment Options" on page 7-2

Embedded Coder generates `#pragma` when the user:

- Selects the use of memory sections (Simulink Coder)
- Creates a custom storage class with memory sections on page 26-26

In both instances, you are responsible for documenting the intended use of the `#pragma`. For more information, see "Control Data and Function Placement in Memory by Inserting Pragmas" on page 30-2.

To enable the generation of bitfields:

- 1** Select at least one of these model configuration parameters:
 - Pack Boolean data into bitfields. This parameter is available only for ERT-based system target files on page 33-2.
 - Use bitsets for storing state configuration.
 - Use bitsets for storing Boolean data.
- 2** Create a custom storage class with defined bitfields. See “Create Custom Storage Classes by Using the Custom Storage Class Designer” on page 26-26 for more information.

Explanatory Note for MISRA Directive 3.1

You can link requirements model elements. These links are included in the generated C code to provide traceability from a requirements document, to the model elements, and to the generated code. For additional information, see “View Linked Requirements in Models and Blocks” (Simulink) and “Link Blocks and Requirements” (Simulink Requirements).

Explanatory Note for Directive 4.1

You can use Polyspace Bug Finder to identify run-time errors and Polyspace Code Prover to prove the absence of run-time errors.

For information about running an analysis, see:

- “Configure and Run Analysis” (Polyspace Code Prover)
- “Configure and Run Analysis” (Polyspace Bug Finder)

Explanatory Note for Directive 4.3

Embedded Coder does not directly call assembly language code. You can add calls to assembly language functions through S-functions, code replacement libraries, Stateflow, and in MATLAB blocks. These calls are documented as calls to “External C Functions” on page 14-65. In these cases, you are responsible for encapsulation.

For additional information, see:

- “External C Functions” on page 14-65
- “Code Replacement Customization”

- “Control Data and Function Placement in Memory by Inserting Pragmas” on page 30-2

Explanatory Note for Directive 4.6

Embedded Coder replaces basic data types with typedefs types, which are compatible with Directive 4.6. A guideline is not required because this behavior is default behavior in Embedded Coder. For additional information, see “Replace and Rename Data Types to Conform to Coding Standards” on page 24-27 and Typedefs on page 14-75.

Explanatory Note for Directive 4.11

The requirements of this directive are satisfied by:

“Demonstrate statically that the input parameters can never take invalid values”.

You can use Polyspace Code Prover to analyze parameter ranges and prove the absence of run-time errors caused by out-of-range values. For additional information, see “Run Polyspace Analysis on Code Generated with Embedded Coder” (Polyspace Code Prover).

Explanatory Note for Rules 5.1, 5.2, 5.4, 5.5, 5.6, 5.7, and 5.8

Embedded Coder is configurable to limit the number of characters imposed by the implementation. For additional information, see Maximum identifier length.

To ensure unique names for different types of variables (local scope variables, global scope variables, macros, and so on), implement a naming convention. For additional information, see Model Configuration Parameters: Code Generation Symbols.

Explanatory Note for Rule 8.12

Embedded Coder supports the use of enumerated data. The file used to define the enumeration can be either manually or automatically generated. Files defining enumerations generated by Embedded Coder are compliant with MISRA C:2012 Rule 8.12 by design. If you manually create the definition file, you are responsible for ensuring compliance. For additional information, see “Use Enumerated Data in Simulink Models” (Simulink).

Explanatory Note for Rules 10.1 and 10.2

Embedded Coder does not directly create data of type char. Data of char type can be introduced by user-defined S-functions, code replacement libraries, and custom storage classes. In this case, limit the usage of plain char to:

- Plain char type for character values
- Signed and unsigned char type for numeric values

Modeling Guidelines for MISRA C:2012 Compliance

The “Compliance Information Summary Tables” on page 13-7 identifies modeling guidelines that are relevant to the compliance of generated C code with MISRA C:2012 coding standards. For a list of these guidelines and their corresponding Model Advisor check, see “High-Integrity System Modeling Guidelines for MISRA C:2012 Compliance” on page 13-21. For information about the MISRA rationale for Model Advisor checks, see “MISRA C:2012 Rationale for Model Advisor Checks” on page 13-23.

High-Integrity System Modeling Guidelines for MISRA C:2012 Compliance

To augment the modeling guidelines developed by the MathWorks Automotive Advisory Board (MAAB), MathWorks has published a set of modeling guidelines that focus on high-integrity applications.

Many high-integrity modeling guidelines have Model Advisor checks that you can use to verify adherence of your model to the guideline. This table identifies the high-integrity modeling guidelines for Simulink and provides the corresponding Model Advisor check. Not all modeling guidelines have a corresponding Model Advisor check.

High-Integrity Guideline	Model Advisor Check
hisl_0001: Usage of Abs block	Check usage of Math Operations blocks
hisl_0002: Usage of Math Function blocks (rem and reciprocal)	Check usage of Math Operations blocks
hisl_0005: Usage of Product blocks	Check safety-related diagnostic settings for signal data
hisl_0006: Usage of While Iterator blocks	Check usage of Ports and Subsystem blocks
hisl_0008: Usage of For Iterator Blocks	Check usage of Ports and Subsystem blocks
hisl_0010: Usage of If blocks and If Action Subsystem blocks	Check usage of Ports and Subsystem blocks
hisl_0011: Usage of Switch Case blocks and Action Subsystem blocks	Check usage of Ports and Subsystem blocks

High-Integrity Guideline	Model Advisor Check
hisl_0016: Usage of blocks that compute relational operators	Check usage of Logic and Bit Operations blocks
hisl_0017: Usage of blocks that compute relational operators (2)	Check usage of Logic and Bit Operations blocks
hisl_0018: Usage of Logical Operator block	Check usage of Logic and Bit Operations blocks
hisl_0019: Usage of Bitwise Operator block	Not applicable
hisl_0020: Blocks not recommended for MISRA C:2012 compliance	<p>Check for blocks not recommended for MISRA C:2012</p> <p>Check for blocks not recommended for C/C++ production code deployment.</p>
hisl_0029: Usage of Assignment blocks	Check usage of Math Operations blocks
hisl_0045: Configuration Parameters > Code Generation > Optimization > Implement logic signals as Boolean data (vs. double)	Check safety-related optimization settings
hisl_0053: Configuration Parameters > Code Generation > Optimization > Remove code from floating-point to integer conversions that wraps out-of-range values	Check safety-related optimization settings
hisl_0054: Configuration Parameters > Code Generation > Optimization > Remove code that protects against division arithmetic exceptions	Check safety-related optimization settings
hisl_0060: Configuration parameters that improve MISRA C:2012 compliance	<p>Check configuration parameters for MISRA C:2012.</p> <p>Check for bitwise operations on signed integers</p>
hisl_0061: Unique identifiers for clarity	<p>Check Stateflow charts for uniquely defined data objects</p> <p>Check usage of Stateflow constructs</p>

High-Integrity Guideline	Model Advisor Check
hisl_0062: Global variables in graphical functions	Not applicable
hisl_0063: Length of user-defined object names to improve MISRA C:2012 compliance	Not applicable
hisf_0064: Shift operations for Stateflow data to improve code compliance	Check usage of shift operations for Stateflow data
hisf_0065: Type cast operations in Stateflow to improve code compliance	Check assignment operations in Stateflow charts
hisl_0101: Avoid invariant comparison operations to improve MISRA C:2012 compliance	Not applicable
hisl_0102: Data type of loop control variables to improve MISRA C:2012 compliance	Not applicable
hisl_0201: Define reserved keywords to improve MISRA C:2012 compliance	Not applicable

This table identifies the high-integrity modeling guidelines for Stateflow and indicates whether the guideline has a corresponding Model Advisor check.

High-Integrity Guideline	Model Advisor Check
hisf_0003: Usage of bitwise operations	Check for bitwise operations in Stateflow charts
hisf_0004: Usage of recursive behavior	Not applicable
hisf_0064: Shift operations for Stateflow data to improve code compliance	Check usage of shift operations for Stateflow data
hisf_0065: Type cast operations in Stateflow to improve code compliance	Check assignment operations in Stateflow charts
hisf_0211: Protect against use of unary operators in Stateflow Charts to improve code compliance	Check Stateflow charts for unary operators

MISRA C:2012 Rationale for Model Advisor Checks

This table provides MISRA C:2012 rationale for the Model Advisor checks.

Model Advisor Check	MISRA C:2012 Rule or Directive
Check configuration parameters for MISRA C:2012	
Set Model Verification block enabling to Disable all	General recommendation for embedded systems
Set System target file to and ERT-based target	General recommendation for embedded systems
Set Code replacement library to None or AUTOSAR 4.0	General recommendation for embedded systems
Set Shared code placement to Shared location	Prerequisite of configuration parameter Generate shared constants
Clear Generate shared constants	MISRA Rule 8.5: An external object or function shall be declared once in one and only one file
Clear Support non-finite numbers	MISRA C:2012 Directive 4.1: Run-time failures shall be minimized
Clear Support continuous time	General recommendation for embedded systems
Clear Support non-inlined S-functions	General recommendation for embedded systems
Clear Mat-file logging	General recommendation for embedded systems
Set Parentheses level to Maximum (Specify precedence with parentheses)	MISRA C:2012 Rule 12.1: The precedence of operators within expressions should be made explicit
Set Casting modes to Standards Compliant	MISRA C:2012 Rules 10.x: The essential type model

Model Advisor Check	MISRA C:2012 Rule or Directive
Set System-generated identifiers to Shortened	<p>MISRA C:2012 5.1: External identifiers shall be distinct</p> <p>MISRA C:2012 5.2: Identifiers declared in the same scope and name space shall be distinct</p> <p>MISRA C:2012 5.4: Macro identifiers shall be distinct</p> <p>MISRA C:2012 5.5: Identifiers shall be distinct from macro names</p>
Set Bitfield declarator type specifier to uint_T	<p>MISRA C:2012 Rule 6.1: Bit-fields shall only be declared with an appropriate type</p> <p>MISRA C:2012 Rule 6.2: Single-bit named bit fields shall not be of a signed type</p>
Set Signed integer division rounds to to Zero or Floor	MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type.
Set Use division for fixed-point net slope computation to on or Use division for reciprocals of integers only	MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type.
EnableSignedLeftShifts - off	MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type
Clear Allow right shifts on signed integers	MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type.
Clear Use dynamic memory allocation for model initialization	<p>MISRA C:2012 Directive 4.12: Dynamic memory allocation shall not be used.</p> <p>MISRA C:2012 Rule 21.3: The memory allocation and deallocation functions of <stdlib.h> shall not be used.</p>
Set Wrap on overflow to warning or error	MISRA C:2012 Directive 4.1: Run-time failures shall be minimized

Model Advisor Check		MISRA C:2012 Rule or Directive
	Set Inf or NaN block output to warning or error	MISRA C:2012 Directive 4.1: Run-time failures shall be minimized
	Clear Dynamic memory allocation in MATLAB functions	MISRA C:2012 Directive 4.12: Dynamic memory allocation shall not be used. MISRA C:2012 Rule 21.3: The memory allocation and deallocation functions of <stdlib.h> shall not be used.
	Select Preserve static keyword in function declarations	MISRA Rule 8.7: Functions and objects should not be defined with external linkage if they are referenced in only one translation unit MISRA Rule 8.8: The static storage class specifier shall be used in all declarations of objects and functions that have internal linkage
	Check for blocks not recommended for C/C++ production code deployment	General recommendation for embedded systems
Check for blocks not recommended for MISRA C:2012		

Model Advisor Check	MISRA C:2012 Rule or Directive
Lookup Table blocks using cubic spline interpolation or extrapolation methods	<p>MISRA C:2012 Rule 11.3: A cast shall not be performed between a pointer to object type and a pointer to a different object type.</p> <p>MISRA C:2012 Rule 11.5: A conversion should not be performed from pointer to void into pointer to object.</p> <p>MISRA C:2012 Rule 11.8: A cast shall not remove any const or volatile qualification from the type pointed to by a pointer.</p> <p>MISRA C:2012 Rule 11.9: The macro NULL shall be the only permitted form of integer null pointer constant.</p> <p>MISRA C:2012 Rule 12.1: The precedence of operators within expressions should be made explicit.</p>

Model Advisor Check		MISRA C:2012 Rule or Directive
	Deprecated Lookup Table blocks	<p>MISRA C:2012 Rule 11.3: A cast shall not be performed between a pointer to object type and a pointer to a different object type.</p> <p>MISRA C:2012 Rule 11.5: A conversion should not be performed from pointer to void into pointer to object.</p> <p>MISRA C:2012 Rule 11.8: A cast shall not remove any const or volatile qualification from the type pointed to by a pointer.</p> <p>MISRA C:2012 Rule 11.9: The macro NULL shall be the only permitted form of integer null pointer constant.</p> <p>MISRA C:2012 Rule 12.1: The precedence of operators within expressions should be made explicit.</p> <p>MISRA C:2012 Rule 12.2: The right hand operand of a shift operator shall lie in the range zero to one less than the width in bits of the essential type of the left hand operand.</p>
	S-Function Builder blocks	<p>MISRA C:2012 Rule 8.4: A compatible declaration shall be visible when an object or function with external linkage is defined.</p> <p>MISRA C:2012 Rule 8.5: An external object or function shall be declared once in one and only one file.</p>
	From Workspace blocks	<p>MISRA C:2012 Rule 18.4: The +, -, += and -= operators should not be applied to an expression of pointer type.</p>
Check for unsupported block names		<p>MISRA C:2012 Rule 3.1: The character sequences /* and // shall not be used within a comment.</p>

Model Advisor Check	MISRA C:2012 Rule or Directive
Check usage of Assignment blocks	MISRA C:2012 Rule 9.1: The value of an object with automatic storage duration shall not be read before it has been set.
Check for switch case expressions without a default case	MISRA C:2012 Rule 16.4: Every switch statement shall have a default label.
Check for missing error ports in AUTOSAR receiver interfaces	MISRA C:2012 Directive 4.7 If a function returns error information, then that error information shall be tested. MISRA C:2012 Rule 17.7: The value returned by a function having non-void return type shall be used.
Check for bitwise operations on signed integers	MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type.
Check for recursive function calls	MISRA C:2012 Rule 17.2: Functions shall not call themselves, either directly or indirectly.
Check for equality and inequality operations on floating-point values	MISRA C:2012 Directive 1.1: Any implementation-defined behaviour on which the output of the program depends shall be documented and understood.
Check for missing const qualifiers in model functions	MISRA C:2012 Rule 8.13: A pointer should point to a const-qualified type whenever possible.
Check integer word lengths	MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type.
Check for bus object names that are used as bus element names	MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type. MISRA C:2012 Rule 5.6: A typedef name shall be a unique identifier.

Deviations Rationale

Instances in which the generated code does not comply with the MISRA C:2012 guidelines are marked as deviations in the “Compliance Information Summary Tables” on page 13-7. In accordance with Section 5.4 of the MISRA C:2012 guidelines, information about the deviations includes:

- The guideline being deviated
- The circumstances in which the deviation is permitted
- Justification for the deviation, including a risk assessment
- Demonstration of how safety is assured
- Potential consequences of non-conformance

Deviations to the MISRA C:2012 directives and rules include:

- “MISRA C:2012 Directive 4.7 Deviation Rationale” on page 13-30
- “MISRA C:2012 Rule 13.5 Deviation Rationale” on page 13-34
- “MISRA C:2012 Rule 21.1 Deviation Rationale” on page 13-36

MISRA C:2012 Directive 4.7 Deviation Rationale

Directive Definition

If a function returns error information, then that error information shall be tested.

Rationale

Note This directive is violated only when an AUTOSAR-based code generation target is used.

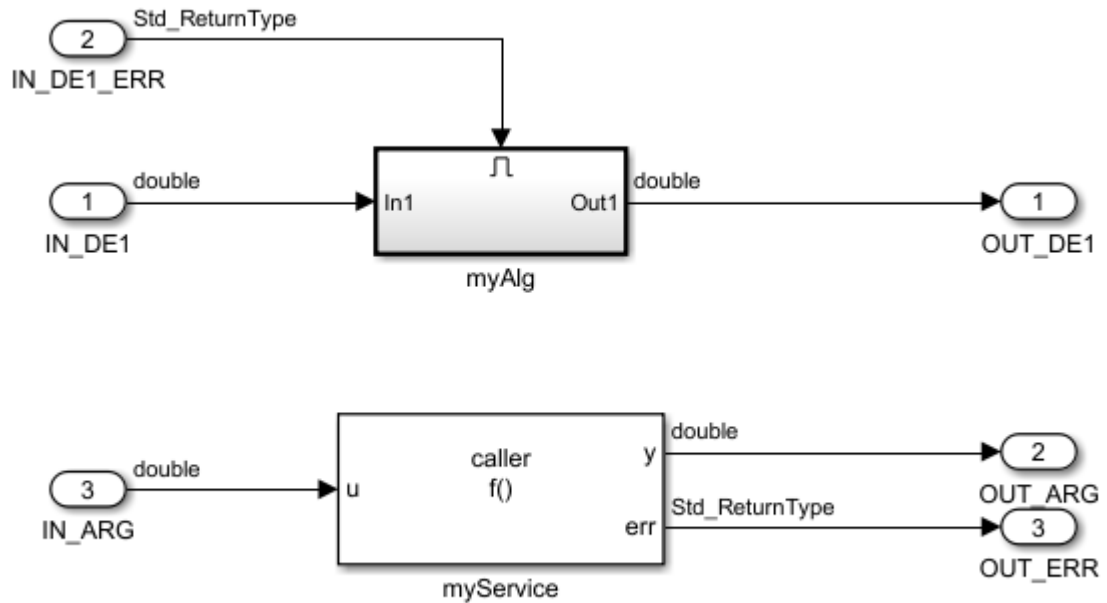

When a function call provides information that indicates an unsuccessful operation, the calling program has to check for the indication of an error when the function is returned. The function calls are not limited to calls in the standard library.

Description

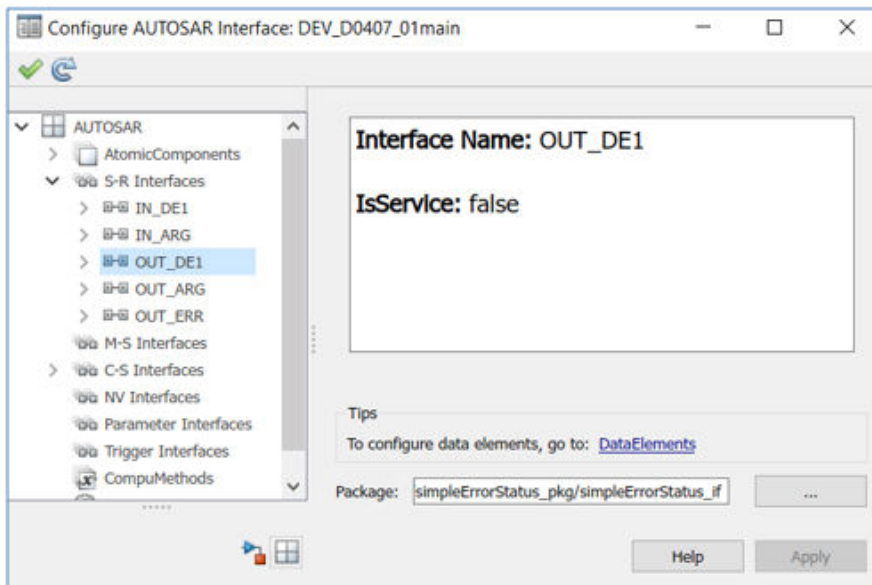

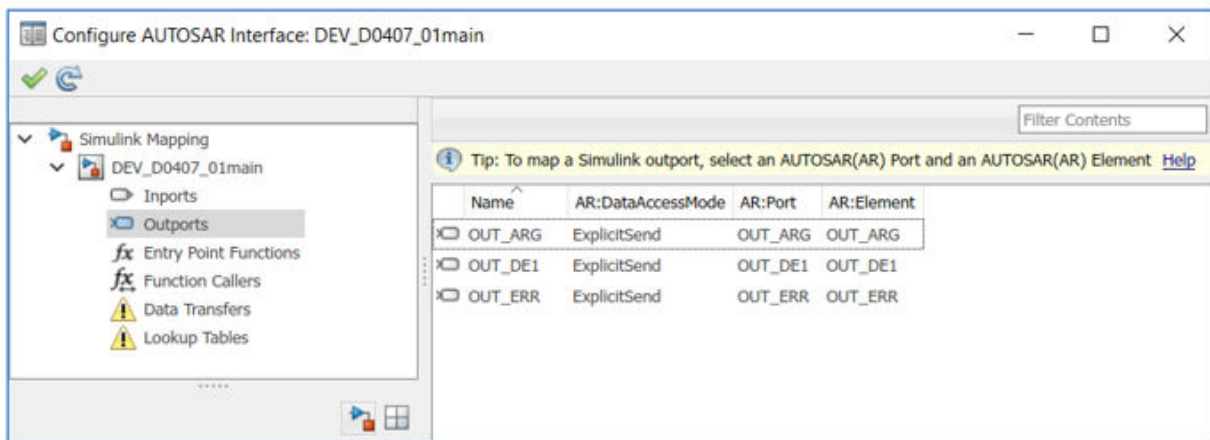

AUTOSAR sender interface function calls, such as `Rte_Write_...`, have return type `Std_ReturnType` that indicates if writing the value was successful. The matching

Simulink pattern is a top-level output port that is configured as an AUTOSAR Sender Interface.

Model Example

AUTOSAR Configuration

Generated Code Sample

In the sample code, note the use of AUTOSAR function call `Rte_Write_...` in `Rte_Write_OUT_DE1_OUT_DE1(rtb_TmpSignalConversionAtIN_DE1);`.

```
void Runnable_Step(void)
{
    /* local block i/o variables */
    real_T rtb_TmpSignalConversionAtIN_DE1;
    ...
    rtb_TmpSignalConversionAtIN_D_l = Rte_Read_IN_DE1_IN_DE1
        (&rtb_TmpSignalConversionAtIN_DE1);
    ...
    if (rtb_TmpSignalConversionAtIN_D_l > 0) {
        ...
        Rte_Write_OUT_DE1_OUT_DE1(rtb_TmpSignalConversionAtIN_DE1);
    }
    ...
}
```

Justification

Failures of `Rte_Write_...` function calls are typically handled on the receiver side because function call returns do not always include all potential errors.

Conditions Under Which the Deviation is Requested

The deviation is requested for all instances of AUTOSAR sender ports.

Consequences of Noncompliance

The calling program cannot react when the sender operation is unsuccessful.

Actions to Control Reporting

When a Polyspace analysis of your code finds known or acceptable coding rule violations, you can suppress the violations in subsequent analyses by adding code annotations (Polyspace Bug Finder) to the Outport block. In future analyses, Polyspace hides results justified through annotations in the **Results List** pane. To review the coding rule violations, see “Filter and Group Results” (Polyspace Bug Finder).

If you have already provided annotations for MISRA C:2004 violations, Polyspace imports these justifications when you check your code for MISRA C:2012 violations. For additional information, see “Import Existing MISRA C: 2004 Justifications to MISRA C: 2012 Results” (Polyspace Bug Finder).

For additional information, see:

- “Modeling Patterns for AUTOSAR Runnables” on page 1-44
- “Getting Started with AUTOSAR Code Generation”
- “Compliance Information Summary Tables” on page 13-7

MISRA C:2012 Rule 13.5 Deviation Rationale

Rule Definition

The right hand operand of a logical && or || operator shall not contain persistent side effects.

Rationale

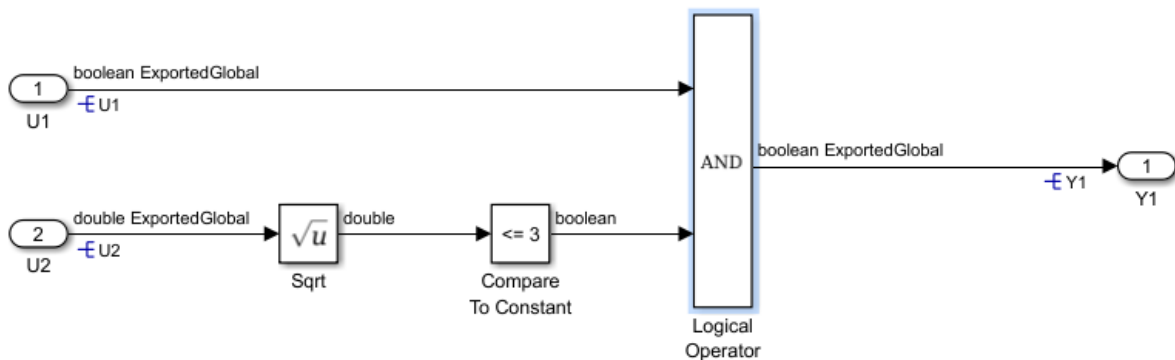

Persistent side effects of the right hand side operand of the && and || operators can occur depending on the left hand side operand, which is contrary to the expectations of the programmer.

Note The term *persistent side effect* is defined in "Appendix J: Glossary" of the *MISRA C: 2012 Guidelines for the Use of C Language in Critical Systems* document.

Description

Using math operations as second input to Logical Operator blocks configured as AND or OR operation.

Model Example

Generated Code Sample

In the sample code, note the use of operand `&&` in `Y1 = (U1 && (sqrt(U2) <= 3.0));`.

```

/* Exported block signals */
boolean_T U1;          /* '<Root>/U1' */
real_T U2;            /* '<Root>/U2' */
boolean_T Y1;         /* '<Root>/Logical Operator' */

/* Model step function */
void DEV_R1305_01main_step(void)
{
    /* Logic: '<Root>/Logical Operator' incorporates:
     * Constant: '<S1>/Constant'
     * Inport: '<Root>/U1'
     * Inport: '<Root>/U2'
     * RelationalOperator: '<S1>/Compare'
     * Sqrt: '<Root>/Sqrt'
     */
    Y1 = (U1 && (sqrt(U2) <= 3.0));
}

```

Justification

Some standard math functions have at least one persistent side effect of modifying the global `errno` variable, as defined in the C90 or C99 standard. Since the `errno` variable is not used by Embedded Coder, the second operand can be treated as not having persistent side effects.

Note Polyspace Bug Finder treats every function with no available source code as potentially having side effects.

Conditions Under Which the Deviation is Requested

This deviation is requested for all calls to standard math functions used as right hand side argument of `&&` and `||` operators.

Consequences of Noncompliance

There are no consequences associated with noncompliance with MISRA C:2012 Rule 13.5 in the circumstances described in this deviation record. There are no additional verification and validation requirements resulting from this deviation.

Actions to Control Reporting

When a Polyspace analysis of your code finds known or acceptable coding rule violations, you can suppress the violations in subsequent analyses by adding code annotations (Polyspace Bug Finder) to the Logical Operator block. In future analyses, Polyspace hides results justified through annotations in the **Results List** pane. To review the coding rule violations, see “Filter and Group Results” (Polyspace Bug Finder).

If you have already provided annotations for MISRA C:2004 violations, Polyspace imports these justifications when you check your code for MISRA C:2012 violations. For additional information, see “Import Existing MISRA C: 2004 Justifications to MISRA C: 2012 Results” (Polyspace Bug Finder).

For additional information, see “Compliance Information Summary Tables” on page 13-7.

MISRA C:2012 Rule 21.1 Deviation Rationale

Rule Definition

`#define` and `#undef` shall not be used on a reserved identifier or reserved macro name.

Rationale

Identifiers that begin with an underscore (`_`) are treated as reserved identifiers and apply to MISRA C:2012 Rule 21.1. Reserved identifiers are intended to be used for implementation only.

Description

Depending on modeling patterns and used features, identifiers with leading underscores might be present in generated and static code files. For example, the generated `rtwtypes.h` file might redefine the following macros with leading underscores:

- `__RTWTYPES_H__`
- `__TMWTYPES_H__`
- `__ZERO_CROSSING_TYPES__`

Justification

A symbol with a leading underscore is not defined by the compiler implementation: Code behaves as expected because the compiler-provided headers are included before headers provided by Embedded Coder.

A symbol is a variable or function name and is already defined: Flagged by compiler warnings/errors for symbol redefinition.

A symbol is a macro name and is already defined: Flagged by compiler warnings/errors for macro redefinition.

Conditions Under Which the Deviation is Requested

The deviation is requested for all instances of identifiers starting with an underscore in the generated code.

Consequences of Noncompliance

A reserved identifier that is redefined in the generated code can result in undefined or unexpected behavior.

Actions to Control Reporting

Review violations caused by leading underscores to check whether there is a conflict with compiler implementation.

Prepare a Model for Code Generation

In this section...

“Configure Input Ports, Output Ports, and Arbitrary Signals” on page 14-3

“Initialize and Configure States” on page 14-4

“Set Up Configuration Parameters for Code Generation” on page 14-4

“Set Up an Example Model With a Stateflow Chart” on page 14-5

“Set Up an Example Model With a MATLAB Function Block” on page 14-6

Several standard methods are available for setting up a model to generate specific C constructs in your code. For preparing your model for code generation, some of these methods include: configuring signals and ports, initializing states, and setting up configuration parameters for code generation. Depending on the components of your model, some of these methods are optional. Methods for configuring a model to generate specific C constructs are organized by category, for example, the Control Flow category includes constructs `if-else`, `switch`, `for`, and `while`. Refer to the name of a construct to see how you should configure blocks and parameters in your model. Different modeling methodologies are available, such as Simulink blocks, Stateflow charts, and MATLAB Function blocks, to implement a C construct.

Model examples in “Modeling Patterns for C Code” have the following naming conventions:

Model Components	Naming Convention
Inputs	u1, u2, u3, and so on
Outputs	y1, y2, y3, and so on
Parameters	p1, p2, p3, and so on
States	x1, x2, x3, and so on

Input ports are named to reflect the signal names that they propagate.

Configure Input Ports, Output Ports, and Arbitrary Signals

- 1 Create a model in Simulink. For more information, see “Model Editing Fundamentals” (Simulink).

- 2 In the model, select **View > Model Data Editor**.
- 3 In the Model Data Editor, on the **Inports/Outports** tab or the **Signals** tab, use the **Signal Name** column or the **Name** column to give the target signal a name.
- 4 Set the **Change view** drop-down list to Code.
- 5 Use the **Storage Class** column to apply a storage class to the signal.

For example, apply the storage class `ExportedGlobal`, which makes the signal appear in the generated code as a separate global variable. The variable has the same name as the signal in the model.

Initialize and Configure States

- 1 In the Model Data Editor, on the **States** tab, use the **Initial Value** column to specify initial values for a block state (such as the state of a Unit Delay block).
- 2 Set the **Change view** drop-down list to Code.
- 3 Use the **Name** column to give the state a name.
- 4 Use the **Storage Class** column to apply a storage class to the state.

Set Up Configuration Parameters for Code Generation

- 1 Open the Configuration Parameter dialog box by selecting **Simulation > Model Configuration parameters**. You can also use the keyboard shortcut `Ctrl+E`.
- 2 Open the **Solver** pane and select
 - **Solver type**: Fixed-Step
 - **Solver**: discrete (no continuous states)
- 3 Open the **Optimization** pane, and set **Default parameter behavior** to `Inlined`.
- 4 Open the **Code Generation** pane, and specify `ert.tlc` as the **System Target File**.
- 5 Clear **Generate makefile**.
- 6 Select **Generate code only**.
- 7 Enable the HTML report generation by opening the **Code Generation > Report** pane and selecting **Create code generation report** and **Open report automatically**. Click the horizontal ellipsis and, under **Advanced parameters**, select **Code-to-model**. Enabling the HTML report generation is optional.
- 8 Click **Apply** and then **OK** to exit.

Set Up an Example Model With a Stateflow Chart

Follow this general procedure to create a simple model containing a Stateflow chart.

- 1 From the **Stateflow > Chart** library, add a Stateflow chart to your model .
- 2 Add Inport blocks and Output blocks according to the example model.
- 3 Open the **Stateflow Editor** by performing one of the following:
 - Double-click the Stateflow chart.
 - Press **Ctrl+R**.
- 4 Select **Chart > Add Inputs & Outputs > Data Input from Simulink** to add the inputs to the chart. A Data dialog box opens for each input.
- 5 Specify the **Name** (u1, u2, ...) and the **Type** (Inherit: Same as Simulink) for each input, unless specified differently in the example. Click **OK**.

Click **Apply** and close each dialog box.

- 6 Select **Chart > Add Inputs & Outputs > Data Output from Simulink** to add the outputs to the chart. A Data dialog opens for each output.
- 7 Specify the **Name** (y1, y2, ...) and **Type** (Inherit: Same as Simulink) for each output, unless specified differently in the example. Click **OK**.
- 8 Click **Apply** and close each dialog box.
- 9 In the **Stateflow Editor**, create the Stateflow diagram specific to the example.
- 10 The inputs and outputs appear on the chart in your model.
- 11 Connect the Inport and Output blocks to the Stateflow Chart.
- 12 Configure the input and output signals; see “Configure Input Ports, Output Ports, and Arbitrary Signals” on page 14-3.

Set Up an Example Model With a MATLAB Function Block

- 1 Add the number of Inport and Outport blocks according to a C construct example included in this chapter.
- 2 From the Simulink User-defined Functions library drag a MATLAB Function block into the model.
- 3 Double-click the block. The MATLAB Function Block Editor opens. Edit the function to implement your application.
- 4 Click **File** > **Save** and close the MATLAB Function Block Editor.
- 5 Connect the Inport and Outport blocks to the MATLAB Function block. See “Configure Input Ports, Output Ports, and Arbitrary Signals” on page 14-3.
- 6 Save your model.

Definition, Initialization, and Declaration of Parameter Data

This example shows how to export the definition, initialization, and declaration of a global variable that the generated code uses as a parameter.

C Construct

```
int32 myParam = 3;
extern int32 myParam;
```

Procedure

- 1 Create the `ex_defn_decl` model by using a Gain block.

- 2 In the model, select **View > Property Inspector**.
- 3 In the model, select the Gain block.
- 4 In the Property Inspector, set the value of the **Gain** parameter to `myParam`.
- 5 Next to the parameter value, click the action button  and select **Create**.
- 6 In the Create New Data dialog box, set **Value** to `Simulink.Parameter(3)`. Click **Create**.

A `Simulink.Parameter` object, `myParam`, appears in the base workspace. The Gain block uses the object to set the value of the **Gain** parameter, in this case, 3.

- 7 In the `Simulink.Parameter` property dialog box, set **Data type** to `int32`.
- 8 Set **Storage class** to `ExportToFile`.
- 9 Set **HeaderFile** to `myDecls.h`.
- 10 Set **DefinitionFile** to `myDefns.c`. Click **OK**.
- 11 Generate code from the model.

Results

The generated header file `myDecls.h` declares the global variable `myParam` by using the `extern` keyword.

```
/* Declaration for custom storage class: ExportToFile */  
extern int32_T myParam;
```

The generated source file `myDefns.c` defines and initializes `myParam`.

```
/* Definition for custom storage class: ExportToFile */  
int32_T myParam = 3;
```

Definition and Declaration of Signal Data

This example shows how to export the definition and declaration of a global variable that the generated code uses as a signal.

C Construct

```
float mySig;
extern float mySig;
```

Procedure

- 1 Create the `ex_defn_decl` model by using a Gain block.

- 2 In the model, select **View > Model Data Editor**.
- 3 In the Model Data Editor, view the **Inports/Outports** tab.
- 4 From the **Change view** drop-down list, select Design.
- 5 In the model, select the Inport block.
- 6 In the Model Data Editor, for the Inport block, set **Signal Name** to `mySig`.
- 7 Set **Data Type** to single.
- 8 From the **Change View** drop-down list, select Code.
- 9 For the Inport block, set **Storage Class** to `ExportToFile`.
- 10 Set **Header File** to `myDecls.h`.
- 11 Set **Definition File** to `myDefns.c`.
- 12 Generate code from the model.

Results

The generated header file `myDecls.h` declares the global variable `mySig` by using the `extern` keyword.

```
/* Declaration for custom storage class: ExportToFile */  
extern real32_T mySig;
```

The generated source file `myDefns.c` defines the variable `mySig`.

```
/* Definition for custom storage class: ExportToFile */  
real32_T mySig;
```

Data Type Conversion

C Construct

```
y1 = (double)u1;
```

Modeling Patterns

- “Modeling Pattern for Data Type Conversion — Simulink Block” on page 14-11
- “Modeling Pattern for Data Type Conversion — Stateflow Chart” on page 14-12
- “Modeling Pattern for Data Type Conversion — MATLAB Function Block” on page 14-13

Modeling Pattern for Data Type Conversion — Simulink Block

One method to create a data type conversion is to use a Data Type Conversion block from the **Simulink > Commonly Used Blocks** library.

ex_data_type_SL

- 1 From the **Commonly Used Blocks** library, drag a Data Type Conversion block into your model and connect to the Inport and Outport blocks.
- 2 Double-click on the Data Type Conversion block to open the Block Parameters dialog box.
- 3 Select the **Output data type** parameter as `double`.
- 4 Press **Ctrl+B** to build the model and generate code.

The generated code appears in `ex_data_type_SL.c`, as follows:

```
int32_T u1;
real_T y1;
```

```
void ex_data_type_SL_step(void)
{
    y1 = (real_T)u1;
}
```

The code generator type definition for double is `real_T`.

Modeling Pattern for Data Type Conversion — Stateflow Chart

Stateflow Chart Type Conversion

Procedure

- 1 Follow the steps for “Set Up an Example Model With a Stateflow Chart” on page 14-5 . This example contains one Inport block and one Outport block.
- 2 Name the example model `ex_data_type_SF`.
- 3 Double-click the Inport block and select the **Signal Attributes** tab. Specify the **Data Type** as `int32` from the drop down menu.
- 4 Double-click the Outport block and select the **Signal Attributes** tab. Specify the **Data Type** as `Inherit: auto` from the drop down menu.
- 5 Press **Ctrl+B** to build the model and generate code.

Results

The generated code appears in `ex_data_type_SF.c`, as follows:

```
int32_T u1;
real_T y1;
RT_MODEL_ex_data_type_SF ex_data_type_SF_M_;
RT_MODEL_ex_data_type_SF *const ex_data_type_SF_M = &ex_data_type_SF_M_;
void ex_data_type_SF_step(void)
{
    y1 = u1;
}
```

Modeling Pattern for Data Type Conversion — MATLAB Function Block

Procedure

- 1 Follow the steps for “Set Up an Example Model With a MATLAB Function Block” on page 14-6 . This example model contains one Inport block and one Outport block.
- 2 Name the model `ex_data_type_ML_Func`.
- 3 In the MATLAB Function Block Editor enter the function, as follows:

```
function y1 = typeconv(u1)
y1 = double(u1);
end
```

- 4 Press **Ctrl+B** to build the model and generate code.

Results

The generated code appears in `ex_data_type_ML_func.c`, where `real32_T` is a float and `real_T` is a double. Type conversion occurs across assignments.

```
real32_T u1;
real_T y1;

void ex_data_type_ML_func_step(void)
{
    y1 = u1;
}
```

Other Type Conversions in Modeling

Type conversions can also occur on the output of blocks where the output variable is specified as a different data type. For example, in the Gain block, you can select the **Inherit via internal rule** parameter to control the output signal data type. Another example of type conversion can occur at the boundary of a Stateflow chart. You can specify the output variable as a different data type.

See Also

Data Type Conversion

Type Qualifiers

This example shows how to apply the `const` and `volatile` keywords to a global variable that represents parameter data.

C Construct

```
const volatile double myParam = 9.8;
```

Procedure

- 1 Create the `ex_const_volatile` model by using a Gain block.

- 2 In the model, select **View > Model Data Editor**.
- 3 In the Model Data Editor, on the **Parameters** tab, set the value of the **Gain** parameter to `myParam`.
- 4 Next to `myParam`, click the action button  and select **Create**.
- 5 In the Create New Data dialog box, set **Value** to `Simulink.Parameter(9.8)` and click **Create**.

A `Simulink.Parameter` object, `myParam`, appears in the base workspace. The Gain block uses the object to set the value of the **Gain** parameter, in this case, 9.8.

- 6 In the `Simulink.Parameter` property dialog box, set **Storage class** to `ConstVolatile`.

Alternatively, to apply only one of the keywords, you can use the storage classes `Const` or `Volatile`.

- 7 Generate code from the model.

Results

The generated source file `ex_const_volatile.c` defines `myParam` by using the `const` and `volatile` keywords.

```
/* Definition for custom storage class: ConstVolatile */  
const volatile real_T myParam = 9.8;
```

Relational and Logical Operators

Modeling Patterns for Relational and Logical Operators

- “Modeling Pattern for Relational or Logical Operators — Simulink Blocks” on page 14-16
- “Modeling Pattern for Relational and Logical Operators - Stateflow Chart” on page 14-17
- “Modeling Pattern for Relational and Logical Operators — MATLAB Function Block” on page 14-18

Modeling Pattern for Relational or Logical Operators — Simulink Blocks

ex_logical_SL

Procedure

- 1 From the **Logic and Bit Operations** library, drag a Logical Operator block into your model.
- 2 Double-click the block to configure the logical operation. Set the **Operator** field to OR.
- 3 Name the blocks, as shown in the model ex_logical_SL.
- 4 Connect the blocks and name the signals, as shown in the model ex_logical_SL.
- 5 Press **Ctrl+B** to build the model and generate code.

Note You can use the above procedure to implement relational operators by replacing the Logical Operator block with a Relational Operator block.

Results

Code implementing the logical operator OR is in the `ex_logical_SL_step` function in `ex_logical_SL.c`:

```
/* Exported block signals */
boolean_T u1;           /* '<Root>/u1' */
boolean_T u2;           /* '<Root>/u2' */
boolean_T y1;           /* '<Root>/Logical Operator' */

/* Logic: '<Root>/Logical Operator' incorporates:
 * Inport: '<Root>/u1'
 * Inport: '<Root>/u2'
 */
y1 = (u1 || u2);
```

Modeling Pattern for Relational and Logical Operators - Stateflow Chart

ex_logical_SF/Logical Operator Stateflow Chart

Procedure

- 1 Follow the steps for “Set Up an Example Model With a Stateflow Chart” on page 14-5. This example model contains two Inport blocks and one Outport block.
- 2 Name the example model `ex_logical_SF`.
- 3 In the **Stateflow Editor**, specify the **Data Type** for `y1` as Boolean.
- 4 In the **Stateflow Editor**, create the Stateflow diagram as shown. The relational or logical operation actions are on the transition from one junction to another. Relational statements specify conditions to conditionally allow a transition. In that case, the statement would be within square brackets.

- 5 Press **Ctrl+B** to build the model and generate code.

Results

Code implementing the logical operator OR is in the `ex_logical_SF_step` function in `ex_logical_SF.c`:

```
boolean_T u1;          /* '<Root>/u1' */
boolean_T u2;          /* '<Root>/u2' */
boolean_T y1;          /* '<Root>/Chart' */

void ex_logical_SF_step(void)
{
    y1 = (u1 || u2);
}
```

Modeling Pattern for Relational and Logical Operators – MATLAB Function Block

This example demonstrates the MATLAB Function block method for incorporating operators into the generated code using a relational operator.

Procedure

- 1 Follow the steps for “Set Up an Example Model With a MATLAB Function Block” on page 14-6 . This example model contains two Inport blocks and one Outport block.
- 2 Name the example model `ex_rel_operator_ML`.
- 3 In the MATLAB Function Block Editor enter the function, as follows:

```
function y1 = fcn(u1, u2)
y1 = u1 > u2;
end
```

- 4 Press **Ctrl+B** to build the model and generate code.

Results

Code implementing the relational operator '>' is in the `ex_rel_operator_ML_step` function in `ex_rel_operator_ML.c`:

```
real_T u1;          /* '<Root>/u1' */
real_T u2;          /* '<Root>/u2' */
boolean_T y;        /* '<Root>/MATLAB Function' */
```

```
void ex_rel_operator_ML_step(void)
{
    y = (u1 > u2);
}
```

Bitwise Operations

Simulink Bitwise-Operator Block

ex_bit_logic_SL

Procedure

- 1 Drag a Bitwise Operator block from the **Logic and Bit Operations** library into your model.
- 2 Double-click the block to open the Block Parameters dialog.
- 3 Select the type of **Operator**. In this example, select AND.
- 4 In order to perform Bitwise operations with a bit-mask, select **Use bit mask**.

Note If another input uses Bitwise operations, clear the **Use bit mask** parameter and enter the number of input ports.

- 5 In the **Bit Mask** field, enter a decimal number. Use `bin2dec` or `hex2dec` to convert from binary or hexadecimal. In this example, enter `hex2dec('D9')`.
- 6 Name the blocks, as shown in, model `ex_bit_logic_SL`.
- 7 Connect the blocks and name the signals, as shown in, model `ex_bit_logic_SL`.
- 8 Press **Ctrl+B** to build the model and generate code.

Results

Code implementing the logical operator OR is in the `ex_bit_logic_SL_step` function in `ex_bit_logic_SL.c`:

```

uint8_T u1;
uint8_T y1;

void ex_bit_logic_SL_step(void)
{
    y1 = (uint8_T)(u1 & 217);
}

```

Stateflow Chart

ex_bit_logic_SF/Bit_Logic Stateflow Chart

Procedure

- 1 Follow the steps for “Set Up an Example Model With a Stateflow Chart” on page 14-5. This example contains one Inport block and one Outport block.
- 2 Name the example model ex_bit_logic_SF.
- 3 From the **Stateflow Editor**, select **Tools > Explore** to open the Model Explorer.
- 4 In the Model Explorer, on the right pane, select **Enable C-bit operations**.
- 5 In the **Stateflow Editor**, create the Stateflow diagram, ex_bit_logic_SF/Bit_Logic.
- 6 Press **Ctrl+B** to build the model and generate code.

Results

Code implementing the logical operator OR is in the ex_bit_logic_SF_step function in ex_bit_logic_SF.c:

```

uint8_T u1;
uint8_T y1;

void bit_logic_SF_step(void)

```

```
{  
    y1 = (uint8_T)(u1 & 0xD9);  
}
```

MATLAB Function Block

In this example, to demonstrate the MATLAB Function block method for implementing bitwise logic into the generated code, use the bitwise OR, '|'.

Procedure

- 1 Follow the steps for “Set Up an Example Model With a MATLAB Function Block” on page 14-6. This example model contains two Inport blocks and one Outport block.
- 2 Name your model `ex_bit_logic_ML`.
- 3 In the MATLAB Function Block Editor enter the function, as follows:

```
function y1 = fcn(u1, u2)  
  
    y1 = bitor(u1, u2);  
end
```

- 4 Press **Ctrl+B** to build the model and generate code.

Results

Code implementing the bitwise operator OR is in the `ex_bit_logic_ML_step` function in `ex_bit_logic_ML.c`:

```
uint8_T u1;  
uint8_T u2;  
uint8_T y1;  
  
void ex_bit_logic_ML_step(void)  
{  
    y1 = (uint8_T)(u1 | u2);  
}
```

Enumeration

To generate an enumerated data type, define an enumeration class in a MATLAB file. Then, use the enumeration class as the data type of signals, block parameters, and states in a model.

C Construct

```
typedef enum {  
    Choice1 = 0,  
    Choice2  
} myEnumType;
```

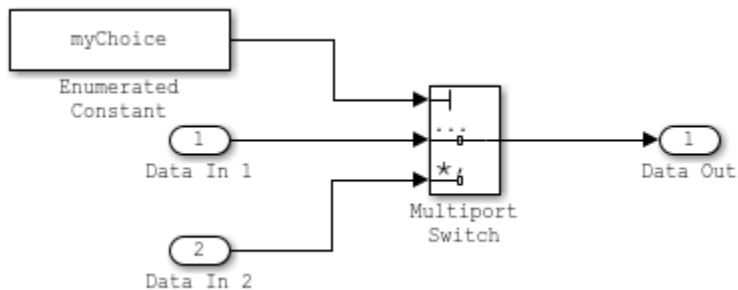

Procedure

In your current folder, create the MATLAB file `ex_myEnumType.m`. The file defines an enumeration class `ex_myEnumType`.

```
classdef ex_myEnumType < Simulink.IntEnumType  
  
    enumeration  
        Choice1(0)  
        Choice2(1)  
    end %enumeration  
  
    methods (Static)  
        function retVal = getHeaderFile()  
            retVal = 'myEnumHdr.h';  
        end %function  
  
        function retVal = getDataScope()  
            retVal = 'Exported';  
        end %function  
    end %methods  
  
end %classdef
```

Create the model `ex_pattern_enum` by using an Enumerated Constant block and a Multiport Switch block.

```
open_system('ex_pattern_enum')
```

In the model, select **View > Model Data Editor**.

In the Model Data Editor, select the **Parameters** tab.

In the model, click the Enumerated Constant block.

In the Model Data Editor, use the **Value** column to set the constant value to myChoice.

Next to myChoice, click the action button (with three vertical dots) and select **Create**.

In the Create New Data dialog box, set **Value** to `Simulink.Parameter(ex_myEnumType.Choice1)` and click **Create**. A `Simulink.Parameter` object named myChoice appears in the base workspace. The object stores the enumerated value Choice1 of the type ex_myEnumType.

In the property dialog box for myChoice, set **Storage Class** to `ExportedGlobal`. With this setting, the object appears in the generated code as a global variable.

Alternatively, at the command prompt, use these commands to create the object:

```
myChoice = Simulink.Parameter(ex_myEnumType.Choice1);
myChoice.CoderInfo.StorageClass = 'ExportedGlobal';
```

In the Model Data Editor, select the **Signals** tab.

In the model, select the output signal of the Enumerated Constant block.

In the Model Data Editor, use the **Data Type** column to set the signal data type to `Enum: ex_myEnumType`.

In the model, select **View > Property Inspector**.

In the model, select the Multiport Switch block.

In the Property Inspector, set:

- **Data port order** to Specify indices.
- **Data port indices** to enumeration('ex_myEnumType'). This expression returns all of the enumeration members of ex_myEnumType.

Set **Configuration Parameters > File packaging format** to Modular. With this setting, in the generated code, the definition of ex_myEnumType can appear in the specified header file, myEnumHdr.h.

Generate code from the model.

```
rtwbuild('ex_pattern_enum');

### Starting build procedure for model: ex_pattern_enum
### Successful completion of build procedure for model: ex_pattern_enum
```

Results

View the generated header file myEnumHdr.h. The file defines the enumerated data type.

```
file = fullfile('ex_pattern_enum_ert_rtw','myEnumHdr.h');
rtwdemodbtype(file,'typedef enum {'','} ex_myEnumType;',1,1)
```

```
typedef enum {
    Choice1 = 0,                /* Default value */
    Choice2
} ex_myEnumType;
```

View the source file ex_pattern_enum.c. The file defines the variable myChoice. The algorithm in the step function uses myChoice to route one of the input signals to the output signal.

```
file = fullfile('ex_pattern_enum_ert_rtw','ex_pattern_enum.c');
rtwdemodbtype(file,'ex_myEnumType myChoice = Choice1;', /* Variable: myChoice */1,1)
rtwdemodbtype(file,'/* Model step function */', /* Model initialize function */1,0)

ex_myEnumType myChoice = Choice1;    /* Variable: myChoice

/* Model step function */
```

```
void ex_pattern_enum_step(void)
{
  /* MultiPortSwitch: '<Root>/Multiport Switch' incorporates:
   * Constant: '<S1>/Constant'
   */
  if (myChoice == Choice1) {
    /* Output: '<Root>/Data Out' incorporates:
     * Inport: '<Root>/Data In 1'
     */
    rtY.DataOut = rtU.DataIn1;
  } else {
    /* Output: '<Root>/Data Out' incorporates:
     * Inport: '<Root>/Data In 2'
     */
    rtY.DataOut = rtU.DataIn2;
  }

  /* End of MultiPortSwitch: '<Root>/Multiport Switch' */
}
```

Modeling Pattern for If-Else: Switch block

One method to create an `if-else` statement is to use a Switch block from the **Simulink** > **Signal Routing** library.

Model ex_if_else_SL

Procedure

- 1 Drag the Switch block from the **Simulink>Signal Routing** library into your model.
- 2 Connect the data inputs and outputs to the block.
- 3 Drag a Relational Operator block from the Logic & Bit Operations library into your model.
- 4 Connect the signals that are used in the if-expression to the Relational Operator block. The order of connection determines the placement of each signal in the if-expression.
- 5 Configure the Relational Operator block to be a greater than operator.
- 6 Connect the controlling input to the middle input port of the Switch block.
- 7 Double-click the Switch block and set **Criteria for passing first input** to $u2 \neq 0$. The software selects $u1$ if $u2$ is TRUE; otherwise $u2$ passes.
- 8 Enter **Ctrl+B** to build the model and generate code.

Results

The generated code includes the following `ex_if_else_SL_step` function in the file `ex_if_else_SL.c`:

```
/* External inputs (root inport signals with auto storage) */
ExternalInputs U;
```

```

/* External outputs (root outputs fed by signals with auto storage) */
ExternalOutputs Y;

/* Model step function */
void ex_if_else_SF_step(void)
{
  /* Switch: '<Root>/Switch' incorporates:
   * Inport: '<Root>/u1'
   * Inport: '<Root>/u2'
   * Outport: '<Root>/y1'
   * RelationalOperator: '<Root>/Relational Operator'
   */
  if (U.u1 > U.u2) {
    Y.y1 = U.u1;
  } else {
    Y.y1 = U.u2;
  }
}

```

Modeling Pattern for If-Else: Stateflow Chart

ex_if_else_SF/Chart

Procedure

- 1 Follow the steps for “Set Up an Example Model With a Stateflow Chart” on page 14-5. This example model contains two Inport blocks and one Outport block.
- 2 Name your model `ex_if_else_SF`.
- 3 When configuring your Stateflow chart, select **Chart > Add Patterns > Decision > If-Else**. The Stateflow Pattern dialog opens. Fill in the fields as follows:

Description

If-Else (optional)

If condition	<code>u1 > u2</code>
If action	<code>y1 = u1</code>
Else action	<code>y1 = u2</code>

4 Press **Ctrl+B** to build the model and generate code.

Results

The generated code includes the following `ex_if_else_SF_step` function in the file `If_Else_SF.c`:

```
/* External inputs (root inport signals with auto storage) */
ExternalInputs U;

/* External outputs (root outports fed by signals with auto storage) */
ExternalOutputs Y;

/* Model step function */
void ex>If_Else_SF_step(void)
{
    /* Chart: '<Root>/Chart' incorporates:
     * Inport: '<Root>/u1'
     * Inport: '<Root>/u2'
     */
    /* Gateway: Chart */
    /* During: Chart */
    /* Entry Internal: Chart */
    /* Transition: '<S1>:15' */
    /* If-Else */
    if (U.u1 > U.u2) {
        /* Output: '<Root>/y1' */
        /* Transition: '<S1>:16' */
        /* Transition: '<S1>:18' */
        Y.y1 = U.u1;

        /* Transition: '<S1>:19' */
    } else {
        /* Outport: '<Root>/y1' */
        /* Transition: '<S1>:17' */
        Y.y1 = U.u2;
    }

    /* End of Chart: '<Root>/Chart' */
    /* Transition: '<S1>:20' */
}
}
```

Modeling Pattern for If-Else: MATLAB Function Block

Procedure

- 1 Follow the steps for “Set Up an Example Model With a MATLAB Function Block” on page 14-6. This example model contains two Inport blocks and one Outport block.

- 2 Name your model `ex_if_else_ML`.
- 3 In the MATLAB Function Block Editor enter the function, as follows:

```
function y1 = fcn(u1, u2)
if u1 > u2;
    y1 = u1;
else y1 = u2;
end
```

- 4 Press **Ctrl+B** to build the model and generate code.

Results

The generated code includes the following `ex_if_else_ML_step` function in the file `ex_if_else_ML.c`:

```
/* External inputs (root inport signals with auto storage) */
ExternalInputs U;

/* External outputs (root outports fed by signals with auto storage) */
ExternalOutputs Y;

/* Model step function */
void ex_if_else_ML_step(void)
{
    /* MATLAB Function Block: '<Root>/MATLAB Function' incorporates:
    * Inport: '<Root>/u1'
    * Inport: '<Root>/u2'
    * Outport: '<Root>/y1'
    */
    /* MATLAB Function 'MATLAB Function': '<S1>:1' */
    if (U.u1 > U.u2) {
        /* '<S1>:1:4' */
        /* '<S1>:1:5' */
        Y.y1 = U.u1;
    } else {
        /* '<S1>:1:6' */
        Y.y1 = U.u2;
    }
}
```

Switch

C Construct

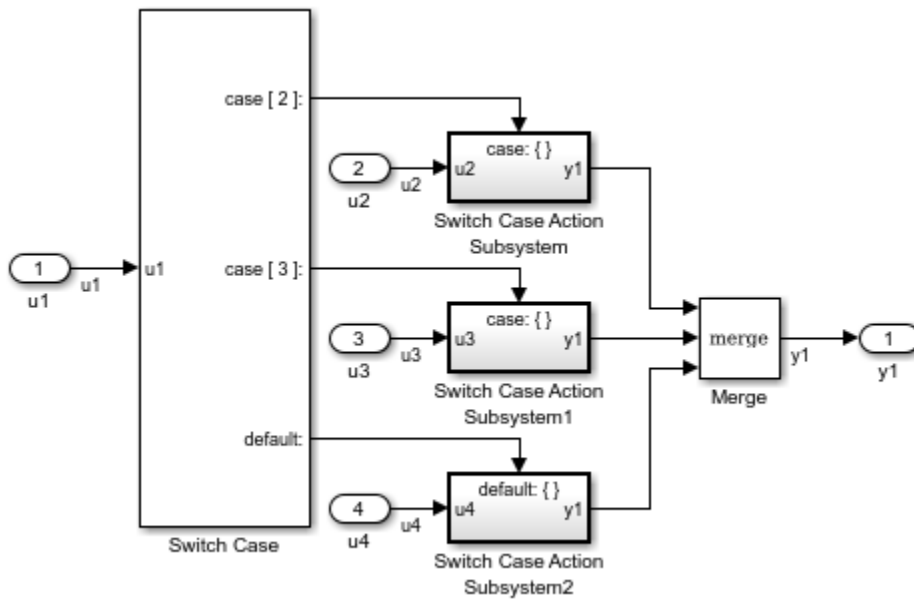

```
switch (u1)
{
  case 2:
    y1 = u2;
    break;
  case 3:
    u3;
    break;
  default:
    y1 = u4;
    break;
}
```

Modeling Pattern for Switch: Switch Case block

One method for creating a `switch` statement is to use a Switch Case block from the **Simulink > Ports and Subsystems** library.

Model ex_switch_SL

Procedure

- 1 Drag a Switch Case block from the **Simulink > Ports and Subsystems** library into your model.
- 2 Double-click the block. In the Block Parameters dialog box, fill in the **Case Conditions** parameter. In this example, the two cases are: {2, 3}.
- 3 Select the **Show default case** parameter. The default case is optional in a switch statement.
- 4 Connect the condition input u1 to the input port of the Switch block.
- 5 Drag Switch Case Action Subsystem blocks from the **Simulink>Ports and Subsystems** library to correspond with the number of cases.
- 6 Configure the Switch Case Action Subsystem subsystems.
- 7 Drag a Merge block from the **Simulink > Signal Routing** library to merge the outputs.
- 8 The Switch Case block takes an integer input, therefore, the input signal u1 is type cast to an int32.

9 Enter Ctrl+B to build the model and generate code.

Results

The generated code includes the following `ex_switch_SL_step` function in the file `ex_switch_SL.c`:

```

/* Exported block signals */
int32_T u1;                                /* '<Root>/u1' */

/* External inputs (root inport signals with auto storage) */
ExternalInputs U;

/* External outputs (root outports fed by signals with auto storage) */
ExternalOutputs Y;

/* Model step function */
void ex_switch_SL_step(void)
{
    /* SwitchCase: '<Root>/Switch Case' incorporates:
     * ActionPort: '<S1>/Action Port'
     * ActionPort: '<S2>/Action Port'
     * ActionPort: '<S3>/Action Port'
     * Inport: '<Root>/u1'
     * SubSystem: '<Root>/Switch Case Action Subsystem'
     * SubSystem: '<Root>/Switch Case Action Subsystem1'
     * SubSystem: '<Root>/Switch Case Action Subsystem2'
     */
    switch (u1) {
        case 2:
            /* Inport: '<S1>/u2' incorporates:
             * Inport: '<Root>/u2'
             * Output: '<Root>/y1'
             */
            Y.y1 = U.u2;
            break;

        case 3:
            /* Inport: '<S2>/u3' incorporates:
             * Inport: '<Root>/u3'
             * Output: '<Root>/y1'
             */
            Y.y1 = U.u3;
            break;

        default:
            /* Inport: '<S3>/u4' incorporates:
             * Inport: '<Root>/u4'
             * Output: '<Root>/y1'
             */
            Y.y1 = U.u4;
            break;
    }
}

```

Modeling Pattern for Switch: MATLAB Function block

Procedure

- 1 Follow the steps for “Set Up an Example Model With a MATLAB Function Block” on page 14-6. This example model contains four Inport blocks and one Outport block.
- 2 Name your model `ex_switch_ML`.
- 3 In the MATLAB Function Block Editor enter the function, as follows:

```
function y1 = fcn(u1, u2, u3, u4)

switch u1
    case 2
        y1 = u2;
    case 3
        y1 = u3;
    otherwise
        y1 = u4;
end
```

- 4 Press **Ctrl+B** to build the model and generate code.

Results

The generated code includes the following `ex_switch_ML_step` function in the file `ex_switch_ML.c`:

```
/* External inputs (root inport signals with auto storage) */
ExternalInputs U;

/* External outputs (root outports fed by signals with auto storage) */
ExternalOutputs Y;

/* Model step function */
void ex_switch_ML_step(void)
{
    /* MATLAB Function Block: '<Root>/MATLAB Function' incorporates:
    * Inport: '<Root>/u1'
    * Inport: '<Root>/u2'
    * Inport: '<Root>/u3'
    * Inport: '<Root>/u4'
    * Outport: '<Root>/y1'
    */
    /* MATLAB Function 'MATLAB Function': '<S1>:1' */
    /* '<S1>:1:4' */
    switch (U.u1) {
        case 2:
            /* '<S1>:1:6' */
            Y.y1 = U.u2;
            break;
    }
```

```
case 3:
    /* '<S1>:1:8' */
    Y.y1 = U.u3;
    break;

default:
    /* '<S1>:1:10' */
    Y.y1 = U.u4;
    break;
}
}
```

Convert If-Elseif-Else to Switch statement

If a MATLAB Function block or a Stateflow chart uses `if-elseif-else` decision logic, you can convert it to a `switch` statement by using a configuration parameter. In the Configuration Parameters dialog box, on the **Code Generation > Code Style** pane, select the “Convert if-elseif-else patterns to switch-case statements” parameter. For more information, see “Converting If-Elseif-Else Code to Switch-Case Statements” (Simulink). For more information on this conversion using a Stateflow chart, see “Enhance Readability of Code for Flow Charts” on page 39-108.

Modeling Pattern for For Loop: For-Iterator Subsystem block

One method for creating a `for` loop is to use a For Iterator Subsystem block from the **Simulink > Ports and Subsystems** library.

Model ex_for_loop_SL

For Iterator Subsystem

Procedure

- 1 Drag a For Iterator Subsystem block from the **Simulink > Ports and Subsystems** library into your model.
- 2 Connect the data inputs and outputs to the For Iterator Subsystem block.
- 3 Open the Inport block.
- 4 In the Block Parameters dialog box, select the **Signal Attributes** pane and set the **Port dimensions** parameter to 10.
- 5 Double-click the For Iterator Subsystem block to open the subsystem.
- 6 Drag an Index Vector block from the Signal-Routing library into the subsystem.
- 7 Open the For Iterator block. In the Block Parameters dialog box set the **Index-mode** parameter to Zero-based and the **Iteration limit** parameter to 10.
- 8 Connect the controlling input to the topmost input port of the Index Vector block, and the other input to the second port.
- 9 Drag an Add block from the **Math Operations** library into the subsystem.
- 10 Drag a Unit Delay block from **Commonly Used Blocks** library into the subsystem.
- 11 Double-click the Unit Delay block and set the **Initial Conditions** parameter to 0. This parameter initializes the state to zero.
- 12 Connect the blocks as shown in the model diagram.

- 13 Save the subsystem and the model.
- 14 Enter Ctrl+B to build the model and generate code.

Results

The generated code includes the following `ex_for_loop_SL_step` function in the file `ex_for_loop_SL.c`:

```

    /* External inputs (root inport signals with auto storage) */
    ExternalInputs U;

    /* External outputs (root outports fed by signals with auto storage) */
    ExternalOutputs Y;

    /* Model step function */
    void ex_for_loop_SL_step(void)
    {
        int32_T sl_iter;
        int32_T rtb_y1;

        /* Outputs for iterator SubSystem: '<Root>/For Iterator Subsystem' incorporates:
        * ForIterator: '<S1>/For Iterator'
        */
        for (sl_iter = 0; sl_iter < 10; sl_iter++) {
            /* Sum: '<S1>/Add' incorporates:
            * Inport: '<Root>/u1'
            * MultiPortSwitch: '<S1>/Index Vector'
            * UnitDelay: '<S1>/Unit Delay'
            */
            rtb_y1 = U.ul[sl_iter] + DWork.UnitDelay_DSTATE;

            /* Update for UnitDelay: '<S1>/Unit Delay' */
            DWork.UnitDelay_DSTATE = rtb_y1;
        }

        /* end of Outputs for SubSystem: '<Root>/For Iterator Subsystem' */

        /* Outport: '<Root>/y1' */
        Y.y1 = rtb_y1;
    }

```

Modeling Pattern for For Loop: Stateflow Chart

Model ex_for_loop_SF

Procedure

- 1 Follow the steps for “Set Up an Example Model With a Stateflow Chart” on page 14-5. This example model contains one Inport block and one Output block.
- 2 Name the model ex_for_loop_SF.
- 3 Enter Ctrl+R to open the Model Explorer.
- 4 In the Model Explorer, select the output variable, u1, and in the right pane, select the **General** tab and set the **Initial Value** to 0.
- 5 In the **Stateflow Editor**, select **Chart > Add Patterns > Loop > For**. The Stateflow Pattern dialog opens.
- 6 Fill in the fields in the Stateflow Pattern dialog box as follows:

Description	For Loop (optional)
Initializer expression	inx = 0
Loop test expression	inx < 10
Counting expression	inx++
For loop body	y1 = u1[inx] + y1

The Stateflow diagram is shown.

7 Press **Ctrl+B** to build the model and generate code.

Results

The generated code includes the following `ex_for_loop_SF_step` function in the file `ex_for_loop_SF.c`:

```

/* External inputs (root inport signals with auto storage) */
ExternalInputs U;

/* External outputs (root outports fed by signals with auto storage) */
ExternalOutputs Y;

/* Model step function */
void ex_for_loop_SF_step(void)
{
    int32_T inx;

    /* Chart: '<Root>/Chart' */
    /* Gateway: Chart */
    /* During: Chart */
    /* Entry Internal: Chart */
    /* Transition: '<S1>:13' */
    /* Transition: '<S1>:14' */
    for (inx = 0; inx < 10; inx++) {
        /* Outport: '<Root>/y1' incorporates:
         * Inport: '<Root>/u1'
         */
        /* Transition: '<S1>:11' */
        /* Transition: '<S1>:12' */
        Y.y1 += U.u1[inx];

        /* Transition: '<S1>:10' */
    }

    /* End of Chart: '<Root>/Chart' */
    /* Transition: '<S1>:9' */
}

```

Modeling Pattern for For Loop: MATLAB Function block

Procedure

- 1 Follow the directions for “Set Up an Example Model With a MATLAB Function Block” on page 14-6. This example model contains one Inport block and one Outport block.
- 2 Name your model `ex_for_loop_ML`.
- 3 In the MATLAB Function Block Editor enter the function, as follows:

```
function y1 = fcn(u1)
```

```
y1 = 0;
```

```
for inx=1:10
    y1 = u1(inx) + y1 ;
end
```

- 4 Press **Ctrl+B** to build the model and generate code.

Results

The generated code includes the following `ex_for_loop_ML_step` function in the file `ex_for_loop_ML.c`:

```
/* Exported block signals */
real_T u1[10];                /* '<Root>/u1' */
real_T y1;                    /* '<Root>/MATLAB Function' */

/* Model step function */
void ex_for_loop_ML_step(void)
{
    int32_T inx;

    /* MATLAB Function Block: '<Root>/MATLAB Function' incorporates:
     * Inport: '<Root>/u1'
     */
    /* MATLAB Function 'MATLAB Function': '<S1>:1' */
    /* '<S1>:1:3' */
    y1 = 0.0;
    for (inx = 0; inx < 10; inx++) {
        /* '<S1>:1:5' */
        /* '<S1>:1:6' */
        y1 = u1[inx] + y1;
    }
}
```

Modeling Pattern for While Loop: While Iterator Subsystem block

One method for creating a while loop is to use a While Iterator Subsystem block from the **Simulink > Ports and Subsystems** library.

Model `ex_while_loop_SL`

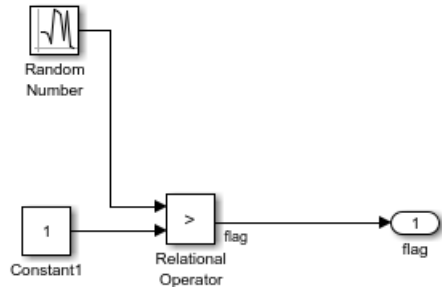

ex_while_loop_SL/While Iterator Subsystem

Procedure

- 1 Drag a While Iterator Subsystem block from the **Simulink > Ports and Subsystems** library into the model.
- 2 Drag a Constant block from the **Simulink > Commonly Used Blocks** library into the model. In this case, set the **Initial Condition** to 1 and the **Data Type** to **Boolean**. You do not have to set the initial condition to FALSE. The initial condition can be dependent on the input to the block.
- 3 Connect the Constant block to the While Iterator Subsystem block.
- 4 Double-click the While Iterator Subsystem block to open the subsystem.
- 5 Place a Subsystem block next to the While Iterator block.
- 6 Right-click the subsystem and select **Block Parameters (Subsystem)**. The Block Parameters dialog box opens.
- 7 Select the **Treat as atomic unit** parameter to configure the subsystem to generate a function. This enables parameters on the **Code Generation** tab.
- 8 Select the **Code Generation** tab. From the **Function packaging** list, select the option, **Nonreusable function**.
- 9 From the **Function name options** list, select the option, **User specified**. The **Function name** parameter is displayed.
- 10 Specify the name as **func**.
- 11 Click **Apply**.

- 12 Double-click the func subsystem block. In this example, function func () has an output flag set to 0 or 1 depending on the result of the algorithm in func (). Create the func() algorithm as shown in the following diagram:

func

- 13 Double-click the While Iterator block to set the **Maximum number of iterations** to 100.
- 14 Connect blocks as shown in the model and subsystem diagrams.

Results

The generated code includes the following ex_while_loop_SL_step function in the file ex_while_loop_SL.c:

```

/* Model step function */
void ex_while_loop_SL_step(void)
{
    int32_T sl_iter;
    boolean_T loopCond;

    /* Constant: '<Root>/Initial Condition SET to TRUE' */
    IC = P.InitialConditionSETtoTRUE_Value;

    /* Outputs for Iterator SubSystem:
     * '<Root>/While Iterator Subsystem' incorporates:
     * WhileIterator: '<S1>/While Iterator'
     */
    sl_iter = 1;

    /* InitializeConditions for Atomic SubSystem: '<S1>/func' */
    func_Init();
  
```

```

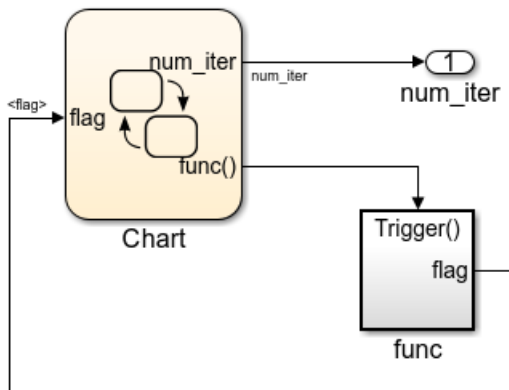

/* End of InitializeConditions for SubSystem: '<S1>/func' */
loopCond = IC;
while (loopCond && (s1_iter <= 100)) {
  /* Outputs for Atomic SubSystem: '<S1>/func' */
  func();

  /* End of Outputs for SubSystem: '<S1>/func' */
  loopCond = flag;
  s1_iter++;
}

/* End of Outputs for SubSystem: '<Root>/While Iterator Subsystem' */
}

```

Modeling Pattern for While Loop: Stateflow Chart

Model ex_while_loop_SF

ex_while_loop_SF/Chart Executes the desired while-loop

Procedure

- 1 Add a Stateflow Chart to your model from the **Stateflow > Chart** library.
- 2 Double-click the chart.
- 3 Add the input, `flag`, and output, `func`, to the chart and specify their data type.
- 4 Connect the data input and output to the Stateflow chart as shown in the model diagram.
- 5 In the Model Explorer, select the output variable, then, in the right pane, select the **General** tab and set the **Initial Value** to 0.
- 6 Select **Chart > Add Patterns > Loop > While**. The Stateflow Pattern dialog opens.
- 7 Fill in the fields for the Stateflow Pattern dialog box as follows:

Description	While Loop (optional)
While condition	<code>(flag) && (num_iter <= 100)</code>
Do action	<code>func; num_iter++;</code>

- 8 Place a Subsystem block in your model.
- 9 Right-click the subsystem and select **Block Parameters (Subsystem)**. The Block Parameters dialog box opens.
- 10 Select the **Treat as atomic unit** parameter to configure the subsystem to generate a function. This enables parameters on the **Code Generation** tab.
- 11 Select the **Code Generation** tab. From the **Function packaging** list, select the option, Nonreusable function.

- 12 From the **Function name options** list, select the option, User specified. The **Function name** parameter is displayed.
- 13 Specify the name as func.
- 14 Click **Apply** to apply the changes.
- 15 Double-click the func subsystem block. In this example, function func has an output flag set to 0 or 1 depending on the result of the algorithm in func(). The Trigger block parameter **Trigger type** is function-call. Create the func() algorithm, as shown in the following diagram:

ex_while_loop_SF/func A function that updates the flag

- 16 Save and close the subsystem.
- 17 Connect blocks to the Stateflow chart as shown in the model diagram for ex_while_loop_SF.
- 18 Save your model.

Results

The generated code includes the following ex_while_loop_SF_step function in the file ex_while_loop_SF.c:

```

/* Exported block signals */
int32_T num_iter;
boolean_T flag;

/* Block states (auto storage) */
D_Work DWork;

/* Model step function */
void ex_while_loop_SF_step(void)
{
    /* '<Root>/Chart' */
    /* '<S2>/Relational Operator' */

```

```

/* Chart: '<Root>/Chart' */
/* Gateway: Chart */
/* During: Chart */
/* Entry Internal: Chart */
/* Transition: '<S1>:2' */
num_iter = 1;
while (flag && (num_iter <= 100)) {
  /* Outputs for Function Call SubSystem: '<Root>/func' */

  /* Transition: '<S1>:3' */
  /* Transition: '<S1>:4' */
  /* Event: '<S1>:12' */
  func();

  /* End of Outputs for SubSystem: '<Root>/func' */
  num_iter++;

  /* Transition: '<S1>:5' */
}

/* End of Chart: '<Root>/Chart' */
/* Transition: '<S1>:1' */
}

```

Model ex_while_loop_ML

Procedure

- 1 In the Simulink Library Browser, click **Simulink > User Defined Functions**, and drag a MATLAB Function block into your model.
- 2 Double-click the MATLAB Function block. The MATLAB Function Block Editor opens.
- 3 In the MATLAB Function Block Editor enter the function, as follows:

```
function fcn(func_flag)

flag = true;
num_iter = 1;

while(flag && (num_iter<=100))
    func;
    flag = func_flag;
    num_iter = num_iter + 1;
end
```

- 4 Select **Edit Data** on the Editor tab. The Ports and Data Manager opens.
- 5 Select **Add > Function Call Output**. Change the name of the function call output to func.
- 6 Click **Save** and close the MATLAB Function Block Editor.
- 7 Place a Subsystem block in your model, right-click the subsystem and select **Block Parameters (Subsystem)**. The Block Parameters dialog box opens.
- 8 Select the **Treat as atomic unit** parameter to configure the subsystem to generate a function. This enables parameters on the **Code Generation** tab.
- 9 Select the **Code Generation** tab. From the **Function packaging** list, select the option, Nonreusable function.
- 10 From the **Function name options** list, select the option, User specified. The **Function name** parameter is displayed.
- 11 Specify the name as func.
- 12 Click **Apply**.
- 13 Double-click the func() subsystem block. In this example, function func() has an output flag set to 0 or 1 depending on the result of the algorithm in func(). The Trigger block parameter **Trigger type** is function-call. Create the func() algorithm, as shown in the following diagram:

Model ex_while_loop_ML_func

- 14 Save and close the subsystem.
- 15 Connect the MATLAB Function block to the func() subsystem.
- 16 Save your model.

Results

The generated code includes the following while_loop_ML_step function in the file while_loop_ML.c. In some cases an equivalent for loop might be generated instead of a while loop.

```

/* Model step function */
void ex_while_loop_ML_step(void)
{
    boolean_T func_flag_0;
    boolean_T flag;
    int32_T num_iter;

    /* MATLAB Function: '<Root>/MATLAB Function' */
    func_flag_0 = func_flag;

    /* MATLAB Function 'MATLAB Function': '<S1>:1' */
    /* '<S1>:1:3' */
    flag = true;

    /* '<S1>:1:4' */
    num_iter = 1;
    while (flag && (num_iter <= 100)) {
        /* Outputs for Function Call SubSystem: '<Root>/func' */

        /* '<S1>:1:6' */
        /* '<S1>:1:7' */

```

```
func();

/* End of Outputs for SubSystem: '<Root>/func' */

/* '<S1>:1:8' */
flag = func_flag_0;

/* '<S1>:1:9' */
num_iter++;
}

/* End of MATLAB Function: '<Root>/MATLAB Function' */
}
```

Modeling Pattern for Do While Loop: While Iterator Subsystem block

One method for creating a while loop is to use a While Iterator Subsystem block from the **Simulink > Ports and Subsystems** library.

While Iterator
Subsystem

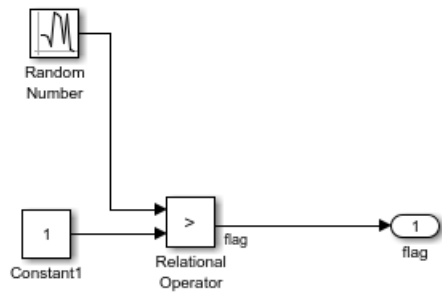

ex_do_while_loop_SL

ex_do_while_loop_SL/While Iterator Subsystem

Procedure

- 1 Drag a While Iterator Subsystem block from the **Simulink > Ports and Subsystems** library into the model.
- 2 Double-click the While Iterator Subsystem block to open the subsystem.
- 3 Place a Subsystem block next to the While Iterator block.
- 4 Right-click the subsystem and select **Block Parameters (Subsystem)**. The Block Parameters dialog box opens.
- 5 Select the **Treat as atomic unit** parameter to configure the subsystem to generate a function. This enables parameters on the **Code Generation** tab.
- 6 Select the **Code Generation** tab. From the **Function packaging** list, select the option, Nonreusable function.
- 7 From the **Function name options** list, select the option, User specified. The **Function name** parameter is displayed.
- 8 Specify the name as func.
- 9 Click **Apply**.
- 10 Double-click the func subsystem block. In this example, function func has an output flag set to 0 or 1 depending on the result of the algorithm in func. Create the func algorithm as shown in the following diagram:

ex_do_while_loop_SL/While Iterator Subsystem/func

- 11 Double-click the While Iterator block. This opens the Block Parameters dialog.
- 12 Set the **Maximum number of iterations** to 100.
- 13 Specify the **While loop type** as do-while.
- 14 Connect blocks as shown in the model and subsystem diagrams.
- 15 Enter Ctrl+B to generate code.

Results

```

void func(void)
{
    flag = (DWork.NextOutput > (real_T)P.Constant1_Value);
    DWork.NextOutput =
        rt_NormalRand(&DWork.RandSeed) * P.RandomNumber_StdDev +
        P.RandomNumber_Mean;
}

void ex_do_while_loop_SL_step(void)
{
    int32_T s1_iter;

    s1_iter = 1;
    do {
        func();
        s1_iter++;
    } while (flag && (s1_iter <= 100));
}
  
```

Modeling Pattern for Do While Loop: Stateflow Chart

ex_do_while_loop_SF

ex_do_while_loop_SF/Chart

- 1 Add a Stateflow Chart to your model from the **Stateflow > Chart** library.
- 2 Double-click the chart to open it.
- 3 Add the inputs and outputs to the chart and specify their data type.
- 4 Connect the data input and output to the Stateflow chart.
- 5 In the Model Explorer, select the output variable, then, in the right pane, select the **General** tab and set the **Initial Value** to 0.

- 6 Select **Chart > Add Patterns > Loop > While**. The Stateflow Pattern dialog opens.
- 7 Fill in the fields for the Stateflow Pattern dialog box as follows:

Description	While Loop (optional)
While condition	(flag) && (num_iter<=100)
Do action	func; num_iter++;

- 8 Place a Subsystem block in your model.
- 9 Right-click the subsystem and select **Block Parameters (Subsystem)**. The Block Parameters dialog box opens.
- 10 Select the **Treat as atomic unit** parameter to configure the subsystem to generate a function. This enables parameters on the **Code Generation** tab.
- 11 Select the **Code Generation** tab. From the **Function packaging** list, select the option, Nonreusable function.
- 12 From the **Function name options** list, select the option, User specified. The **Function name** parameter is displayed.
- 13 Specify the name as func.
- 14 Click **Apply** to apply the changes.
- 15 Double-click the func subsystem block. In this example, function func has an output flag set to 0 or 1 depending on the result of the algorithm in func. The Trigger block parameter **Trigger type** is function-call. Create the func algorithm, as shown in the following diagram:

ex_do_while_loop_SF/func Updates the flag

- 16 Save and close the subsystem.
- 17 Connect blocks to the Stateflow chart as shown in the model diagram for ex_do_while_loop_SF.

18 Save your model.

Results

```
void ex_do_while_loop_SF_step(void)
{
    int32_T sf_num_iter;
    num_iter = 1;
    do {
        func();
        num_iter++;
    } while (flag && (sf_num_iter <= 100));
}
```

Function Call

To generate a function call, add a subsystem, which implements the operations that you want.

C Construct

```
void add_function(void)
{
    y1 = u1 + u2;
}
```

ex_function_call

Procedure

- 1 Create a model containing a subsystem. In this example, the subsystem has two inputs and returns one output.
- 2 Double-click the subsystem. Create `Add_Subsystem`, as shown.

ex_function_call/Add_Subsystem

- 3 Right-click the subsystem and select **Block Parameters (Subsystem)** to open the Subsystem Parameters dialog box.
- 4 Select the **Treat as atomic unit** parameter. This enables parameters on the **Code Generation** tab.

Select the **Code Generation** tab. For the **Function packaging** parameter, from the drop-down list, select **Nonreusable function**.

- 5 For the **Function name options** parameter, from the drop-down list, select **User specified**.
- 6 In the **Function name** field, enter the subsystem name, `add_function`.
- 7 In the **File name options** field, select **Use function name**.
- 8 Click **Apply** and **OK**.
- 9 Press **Ctrl+B** to build and generate code.

Results

In `ex_function_call.c`, the function is called from `ex_function_call_step`:

```
void ex_function_call_step(void)
{
    add_function();
}
```

The function prototype is externed through the subsystem file, `add_function.h`.

```
extern void add_function(void);
```

The function definition is in the subsystem file `add_function.c`:

```
void add_function(void)
{
    function_call_Y.y1 = u1 + u2;
}
```

Function Prototyping

C Construct

```
double add_function(double u1, double u2)
{
    return u1 + u2;
}
```

Modeling Patterns

- “Function Call Using Graphical Functions” on page 14-61
- “Control Function Prototype of the model_step Function” on page 14-63

Function Call Using Graphical Functions

Procedure

- 1 Follow the steps in “Set Up an Example Model With a Stateflow Chart” on page 14-5. This example model contains two Inport blocks and one Outport block.
- 2 Name the example model `ex_func_SF`.
- 3 In the **Stateflow Editor**, create a graphical function by clicking the **fx** button and placing a graphical function into the Stateflow chart.
- 4 Edit the graphical function signature to: `output = add_function(u1, u2)`.
- 5 Add the transition action.

ex_func_SF/Chart

In the Stateflow chart, there is an example of a simple transition that calls `add_function`.

- 6 Open the Model Explorer. From the Model Hierarchy tree, select **ex_func_SF > Chart > f()add_function**. On the right pane, specify the **Function Inline Option** as **Function**.
- 7 From the Model Hierarchy tree, click **Chart** and on the right pane select the **Export Chart Level Functions (Make Global)** parameter. The function is now available globally to the entire model.
- 8 Press **Ctrl+B** to build the model and generate code.

Results

`ex_func_SF.c` contains the generated code:

```
real_T add_function(real_T in1, real_T in2)
{
    return in1 + in2;
}
.
.
.
void ex_func_SF_step(void)
{
    y1 = add_function(u1, u2);
}
```

Control Function Prototype of the model_step Function

ex_control_step_function

Procedure

- 1 Create the model `ex_control_step_function`. See “Configure Input Ports, Output Ports, and Arbitrary Signals” on page 14-3.
- 2 Open the Configuration Parameters dialog box by pressing **Ctrl+E**.
- 3 Open the Configure C/C++ Function Interface dialog box. In the **Code Generation > Interface** pane, click **Configure Model Functions**. The dialog box opens showing a preview of an execution function prototype with no arguments (`void-void`). If arguments have been configured for the model previously, the dialog box displays the current settings.
- 4 Configure step function arguments. If an application requires a `void-void` interface, clear **Configure arguments for function prototype**. For this example, select **Configure arguments for function prototype**.
- 5 Display current default settings for the entry-point function arguments by clicking **Get default**. An updated diagram appears and a table that lists external I/O ports with property settings.
- 6 Configure the step function return argument by setting **C return argument** to `void` or `Output`. For this example, select `void`.
- 7 Configure the function input and output arguments:
 - Switch the order of the two inports. Move the row for `Inport` below the row for `Inport1`.
 - For `Inport1`, set **C Type Qualifier** to `Auto` (pass by value) and **C Identifier Name** to `argIn1`.
 - For `Inport`, set **C Type Qualifier** to `Pointer to const` and **C Identifier Name** to `argIn2`.

- For the output, set **C Identifier Name** to `argOut`.

The function prototype preview is updated as you make these changes.

- 8 Validate your changes by clicking **Validate**.
- 9 Close the Configure C/C++ Function Interface dialog box. Click **Apply**. Then, click **OK**.
- 10 Generate code and a report. Use the report to verify that the generated step function in `ex_control_step_function.c` reflects the argument changes that you made.

For more information about controlling function prototypes, see “Customize Generated C Function Interfaces” on page 29-2.

Results

`ex_control_step_function.c` contains the generated code:

```
void ex_control_step_function_step(real_T argIn1, const real_T *argIn2,...
    real_T *argOut)
{
    y1 = *argIn2 + argIn1;
}
```

External C Functions

C Construct

```
extern double add(double, double);

#include "add.h"
double add(double u1, double u2)
{
    double y1;
    y1 = u1 + u2;
    return (y1);
}
```

Modeling Patterns

There are several methods for integrating legacy C functions into the generated code. These methods either create an S-function or make a call to an external C function. For more information on S-functions, see “S-Functions and Code Generation” (Simulink Coder).

- “Use the Legacy Code Tool to Create S-functions” on page 14-65
- “Use a Stateflow Chart to Make Calls to C Functions” on page 14-67
- “Using a MATLAB Function Block to Make Calls to C Functions” on page 14-69

Use the Legacy Code Tool to Create S-functions

This method uses the Legacy Code Tool to create an S-function and generate a TLC file. The code generation software uses the TLC file to generate code from this S-function. The advantage of using the Legacy Code Tool is that the generated code is fully inlined and does not need wrapper functions to access the custom code.

Procedure

- 1 Create a C header file named `add.h` that contains the function signature:

```
extern double add(double, double);
```

- 2 Create a C source file named `add.c` that contains the function body:

```
double add(double u1, double u2)
{
    double y1;
    y1 = u1 + u2;
    return (y1);
}
```

- 3 To build an S-function for use in both simulation and code generation, run the following script or execute each of these commands at the MATLAB command line:

```
%% Initialize legacy code tool data structure
def = legacy_code('initialize');

%% Specify Source File
def.SourceFiles = {'add.c'};

%% Specify Header File
def.HeaderFiles = {'add.h'};

%% Specify the Name of the generated S-function
def.SFunctionName = 'add_function';

%% Create a c-mex file for S-function
legacy_code('sfcn_cmex_generate', def);

%% Define function signature and target the Output method
def.OutputFcnSpec = ['double y1 = add(double u1, double u2)'];

%% Compile/Mex and generate a block that can be used in simulation
legacy_code('generate_for_sim', def);

%% Create a TLC file for Code Generation
legacy_code('sfcn_tlc_generate', def);

%% Create a Masked S-function Block
legacy_code('slblock_generate', def);
```

The output of this script produces:

- A new model containing the S-function block
- A TLC file named `add_function.tlc`.
- A C source file named `add_function.c`.

- A mexw32 dll file named `add_function.mexw32`
- 4 Add inport blocks and an output block and make the connections, as shown in the model.

ex_function_call_lct

- 5 Name and save your model. In this example, the model is named `ex_function_call_lct`.
- 6 Press **Ctrl+B** to build the model and generate code.

Results

The following code is generated in `ex_function_call_lct.c`:

```
real_T u1;
real_T u2;
real_T y1;
void ex_function_call_lct_step(void)
{
    y1 = add(u1, u2);
}
```

The user-specified header file, `add.h`, is included in `ex_function_call_lct.h`:

```
#include "add.h"
```

Use a Stateflow Chart to Make Calls to C Functions

Procedure

- 1 Create a C header file named `add.h` that contains the example function signature.
- 2 Create a C source file named `add.c` that contains the function body.
- 3 Follow the steps for “Set Up an Example Model With a Stateflow Chart” on page 14-5. This example model contains two Inport blocks and one Outport block.
- 4 Name the example model `ex_exfunction_call_SF`.

- 5 Double-click the Stateflow chart and edit the chart as shown. Place the call to the add function within a transition action.

ex_exfunction_call_SF/Chart

- 6 On the **Stateflow Editor**, select **Simulation > Model Configuration Parameters**.
- 7 On the Configuration Parameters dialog box, select **Simulation Target > Custom Code**. In the **Include custom C code in generated** section, on the left pane, select **Header file** and in the **Header file** field, enter the #include statement:

```
#include "add.h"
```
- 8 In the **Include list of additional** section, select **Source files** and in the **Source files** field, enter add.c.
- 9 On the Configuration Parameters dialog box, select **Code Generation > Custom Code**.
- 10 Select **Use the same custom code settings as Simulation Target**.
- 11 Press **Ctrl+B** to build the model and generate code.

Results

ex_exfunction_call_SF.c contains the following code in the step function:

```
real_T u1;
real_T u2;
real_T y1;

void exfunction_call_SF_step(void)
{
    y1 = (real_T)add(u1, u2);
}
```

ex_exfunction_call_SF.h contains the include statement for add.h:

```
#include "add.h"
```

Using a MATLAB Function Block to Make Calls to C Functions

Procedure

- 1 Create a C header file named `add.h` that contains the example function signature.
- 2 Create a C source file named `add.c` that contains the function body.
- 3 In the Simulink Library Browser, click **Simulink > User Defined Functions**, and drag a MATLAB Function block into your model.
- 4 Double-click the MATLAB Function block. The MATLAB Function Block Editor opens.
- 5 Edit the function to include the statement:

```
function y1 = add_function(u1, u2)

% Set the class and size of output
y1 = u1;

% Call external C function
y1 = coder.ceval('add',u1,u2);

end
```

- 6 Open the Configuration Parameters dialog box, and select **Simulation Target > Custom Code**.
- 7 In the **Include custom C code in generated** section, on the left pane, select **Header file** and in the **Header file** field, enter the statement, :

```
#include "add.h"
```
- 8 In the **Include list of additional** section, select **Source files** and in the **Source files** field, enter `add.c`.
- 9 Add two Inport blocks and one Outport block to the model and connect to the MATLAB Function block.
- 10 Configure the signals: `u1`, `u2`, and `y1`, as described in “Configure Input Ports, Output Ports, and Arbitrary Signals” on page 14-3.
- 11 Save the model as `ex_exfunction_call_ML`.
- 12 Press **Ctrl+B** to build the model and generate code.

Results

`ex_exfunction_call_ML.c` contains the following code:

```
real_T u1;
real_T u2;
real_T y1;

void ex_exfunction_call_ML_step(void)
{
    y1 = add(u1, u2);
}
```

`ex_exfunction_call_ML.h` contains the `#include` statement for `add.h`:

```
#include "add.h"
```

Macro Definitions (#define)

C Construct

```
#define myParam 9.8;
```

Export Generated Macro Definition

Procedure

- 1 Create the `ex_param_macro` model by using a Gain block.

- 2 Create the `ex_defn_decl` model by using a Gain block.

- 3 In the model, select **View > Model Data Editor**.
- 4 In the Model Data Editor, on the **Parameters** tab, set the value of the **Gain** parameter to `myParam`.
- 5 Next to `myParam`, click the action button  and select **Create**.
- 6 In the Create New Data dialog box, set **Value** to `Simulink.Parameter(9.8)` and click **Create**.

A `Simulink.Parameter` object, `myParam`, appears in the base workspace. The Gain block uses the object to set the value of the **Gain** parameter, in this case, 9.8.

- 7 In the `Simulink.Parameter` property dialog box, set **Storage class** to **Define**. Click **OK**.
- 8 Generate code from the model.

Results

The generated header file `ex_param_macro.h` defines `myParam` as a macro.

```
/* Definition for custom storage class: Define */  
#define myParam 9.8
```

Reuse Macro from Handwritten Code

Procedure

- 1 Follow the steps in “Export Generated Macro Definition” on page 14-71.
- 2 In the Model Data Editor, on the **Parameters** tab, click the **Show/refresh additional information** button.
- 3 Set the **Change view** drop-down list to **Code**.
- 4 Use the **Storage Class** column to change the storage class of `myParam` from **Define** to **ImportedDefine**.
- 5 For `myParam`, set **Header File** to `external_params.h`. With this setting, the generated code imports the macro definition from a custom header file named `external_params.h`.
- 6 In your current folder, create the C header file `external_params.h`, which contains the `#define` statement.

```
#ifndef _EXTERNAL_PARAMS  
#define _EXTERNAL_PARAMS  
  
#define myParam 9.8  
  
#endif  
  
/* EOF */
```

- 7 Generate code from the model.

Results

The generated header file `ex_param_macro.h` does not define the macro. Instead, the file includes (`#include`) the custom header file `external_params.h`.

```
/* Includes for objects with custom storage classes. */  
#include "external_params.h"
```

The source file `ex_param_macro.c` contains a guard to check that a definition for `myParam` exists.

```
/*  
 * Check that imported macros with storage  
 * class "ImportedDefine" are defined  
 */  
#ifndef myParam  
#error The variable for the parameter "myParam" is not defined  
#endif
```

Conditional Inclusions (**#if / #endif**)

You can generate preprocessor conditional directives in your code by implementing variant blocks (Model Variants block or Variant Subsystem block) in your model. In the generated code, preprocessor conditional directives select a section of code to execute at compile time. To implement variants in your model, see “Create a Simple Variant Model” (Simulink). To generate code for variants, see “Generate Preprocessor Conditionals for Variant Systems” on page 15-35.

Typedef

C Construct

```
typedef float float_32;
```

Procedure

To create a data type alias in Simulink, use a `Simulink.AliasType`. The code generator creates a `typedef` statement.

The built-in Simulink data type `single` corresponds to the C data type `float`.

- 1 At the command prompt, create a `Simulink.AliasType` object named `float_32` that represents an alias of `single`.

```
float_32 = Simulink.AliasType('single')
```

- 2 Create the `ex_typedef` model by using a Gain block.

- 3 In the model, select **View > Model Data Editor**.
- 4 In the Model Data Editor, view the **Inports/Outports** tab.
- 5 From the **Change View** drop-down list, select **Design**.
- 6 In the model, select the Inport block.
- 7 In the Model Data Editor, for the Inport block, set **Data Type** to `float_32`.
- 8 From the **Change view** drop-down list, select **Code**.
- 9 For the Inport block, set **Signal Name** to `mySig`.
- 10 Set **Storage Class** to `ExportedGlobal`.

With this setting, the Inport block appears in the generated code as a separate global variable.

- 11 Generate code from the model.

Results

The generated header file `ex_typedef.h` defines the data type alias `float_32`.

```
#ifndef DEFINED_TYPEDEF_FOR_float_32_
#define DEFINED_TYPEDEF_FOR_float_32_

typedef real32_T float_32;

#endif
```

By default, the code generator also creates the alias `real32_T`, which corresponds to the C data type `float`. You can see the `typedef` statement in the generated header file `rtwtypes.h`.

```
typedef float real32_T;
```

The generated source file `ex_typedef.c` uses `float_32` to define the global variable `mySig`.

```
/* Exported block signals */
float_32 mySig;                               /* '<Root>/In1' */
```

`Simulink.AliasType`

Related Examples

- “Control Data Type Names in Generated Code” on page 24-2
- “Structures of Signals” on page 14-81

Structures of Parameters

Create a structure in the generated code. The structure stores parameter data.

C Construct

```
typedef struct {
    double G1;
    double G2;
} myStructType;

myStructType myStruct = {
    2.0,
    -2.0
};
```

Procedure

Open the example model `rtwdemo_paraminline`.

`rtwdemo_paraminline`

Select **View > Model Data Editor**.

In the Model Data Editor, select the **Parameters** tab.

In the model, click the Gain block labeled G1.

In the Model Data Editor, use the **Value** column to set the value of the **Gain** parameter to `myStruct.G1`.

Use the Model Data Editor to set the value of the **Gain** parameter in the G2 block to `myStruct.G2`.

Next to `myStruct.G2`, click the action button (with three vertical dots) and select **Create**.

In the Create New Data dialog box, set **Value** to `Simulink.Parameter(struct)` and click **Create**. A `Simulink.Parameter` object named `myStruct` appears in the base workspace.

In the `Simulink.Parameter` property dialog box, next to the **Value** property, click the action button and select **Open Variable Editor**.

In the Variable Editor, right-click the white space under the **Field** column and select **New**. Name the new structure field G1. Use the **Value** column to set the value of the field to 2.

Use the Variable Editor to add a field G2 whose value is -2 and then close the Variable Editor.

In the `Simulink.Parameter` property dialog box, set **Storage class** to `ExportedGlobal`. With this setting, the structure `myStruct` appears in the generated code as a global variable.

Alternatively, use these commands to configure the blocks and create `myStruct`.

```
rtwdemo_paraminline
set_param('rtwdemo_paraminline/G1','Gain','myStruct.G1')
set_param('rtwdemo_paraminline/G2','Gain','myStruct.G2')

myStruct.G1 = 2;
myStruct.G2 = -2;
myStruct = Simulink.Parameter(myStruct);
myStruct.CoderInfo.StorageClass = 'ExportedGlobal';
```

Results

Generate code from the model.

```
rtwbuild('rtwdemo_paraminline')

### Starting build procedure for model: rtwdemo_paraminline
### Successful completion of build procedure for model: rtwdemo_paraminline
```

The generated header file `rtwdemo_paraminline_types.h` defines a structure type with a random name.

```
file = fullfile('rtwdemo_paraminline_grt_rtw',...
    'rtwdemo_paraminline_types.h');
rtwdemodbtype(file,'typedef struct {' ,'} struct_6h72eH5WFuEIyQr5YrdGuB;',...
    1,1)
```

```
typedef struct {
    real_T G1;
    real_T G2;
} struct_6h72eH5WFuEIyQr5YrdGuB;
```

The source file `rtwdemo_paraminline.c` defines and initializes the structure variable `myStruct`.

```
file = fullfile('rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline.c');
rtwdemodbtype(file,'struct_6h72eH5WFuEIyQr5YrdGuB myStruct',...
    '/* Variable: myStruct',1,1)
```

```
struct_6h72eH5WFuEIyQr5YrdGuB myStruct = {
    2.0,
    -2.0
} ; /* Variable: myStruct
```

Specify Name of Structure Type

Optionally, specify a name to use for the structure type definition (`struct`).

At the command prompt, use the function `Simulink.Bus.createObject` to create a `Simulink.Bus` object that represents the structure type.

```
Simulink.Bus.createObject(myStruct.Value);
```

The default name of the object is `slBus1`. Change the name by copying the object into a new MATLAB variable.

```
myStructType = copy(slBus1);
```

In the Model Data Editor, click the **Show/refresh additional information** button.

In the data table, find the row that corresponds to `myStruct`. Use the **Data Type** column to set the data type of `myStruct` to `Bus: myStructType`.

Alternatively, at the command prompt, use this command to set the data type of `myStruct`.

```
myStruct.DataType = 'Bus: myStructType';
```

Generate code from the model.

```
rtwbuild('rtwdemo_paraminline')  
  
### Starting build procedure for model: rtwdemo_paraminline  
### Successful completion of build procedure for model: rtwdemo_paraminline
```

The code generates the definition of the structure type `myStructType` and uses this type to define the global variable `myStruct`.

```
rtwdemodbtype(file, 'myStructType myStruct = {' /* Variable: myStruct', ...  
1,1)
```

```
myStructType myStruct = {  
    2.0,  
    -2.0  
}; /* Variable: myStruct
```

Structures of Signals

This example shows how to create a structure of signal data in the generated code.

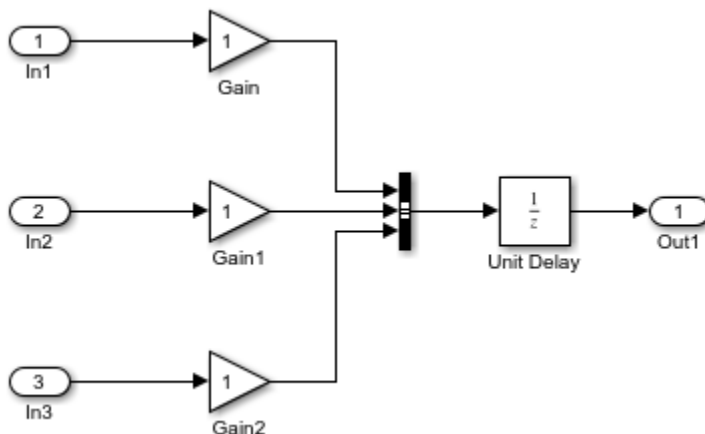

C Construct

```
typedef struct {
    double signal1;
    double signal2;
    double signal3;
} my_signals_type;
```

Procedure

To represent a structure type in a model, create a `Simulink.Bus` object. Use the object as the data type of bus signals in your model.

Create the `ex_signal_struct` model with Gain blocks, a Bus Creator block, and a Unit Delay block. The Gain and Unit Delay blocks make the structure more identifiable in the generated code.

To configure the Bus Creator block to accept three inputs, in the block dialog box, set **Number of inputs** to 3.

In the model, select **Edit > Bus Editor**.

Use the Bus Editor to create a `Simulink.Bus` object named `my_signals_type` that contains three signal elements: `signal1`, `signal2`, and `signal3`. To create bus objects with the Bus Editor, see “Create Bus Objects with the Bus Editor” (Simulink).

This bus object represents the structure type that you want the generated code to use.

In the Bus Creator block dialog box, set **Output data type** to `Bus: my_signals_type`.

Select **Output as nonvirtual bus**. Click **OK**. A nonvirtual bus appears in the generated code as a structure.

In the model, select **View > Model Data Editor**.

In the Model Data Editor, on the **Signals** tab, from the **Change view** drop-down list, select `Code`.

In the model, click the output signal of the Bus Creator block.

In the Model Data Editor, for the output of the Bus Creator block, set **Name** to `sig_struct_var`.

Set **Storage Class** to `ExportedGlobal`. With this setting, the output of the Bus Creator block appears in the generated code as a separate global structure variable named `sig_struct_var`.

Generate code from the model.

Results

The generated header file `ex_signal_struct_types.h` defines the structure type `my_signals_type`.

```
typedef struct {
    real_T signal1;
    real_T signal2;
```

```
    real_T signal3;  
} my_signals_type;
```

The source file `ex_signal_struct.c` allocates memory for the global variable `sig_struct_var`, which represents the output of the Bus Creator block.

```
/* Exported block signals */  
my_signals_type sig_struct_var;          /* '<Root>/Bus Creator' */
```

In the same file, in the model `step` function, the algorithm accesses `sig_struct_var` and the fields of `sig_struct_var`.

Nested Structures of Signals

You can create nested structures of signal data in the generated code.

C Construct

```
typedef struct {
    double signal1;
    double signal2;
    double signal3;
} B_struct_type;

typedef struct {
    double signal1;
    double signal2;
} C_struct_type;

typedef struct {
    B_struct_type subStruct_B;
    C_struct_type subStruct_C;
} A_struct_type;
```

Procedure

To represent a structure type in a model, create a `Simulink.Bus` object. Use the object as the data type of bus signals in your model.

To nest a structure inside another structure, use a bus object as the data type of a signal element in another bus object.

Create the `ex_signal_nested_struct` model with Gain blocks, Bus Creator blocks, and a Unit Delay block. The Gain and Unit Delay blocks make the structure more identifiable in the generated code.

To configure a Bus Creator block to accept three inputs, in the block dialog box, set **Number of inputs** to 3.

In the model, select **Edit > Bus Editor**.

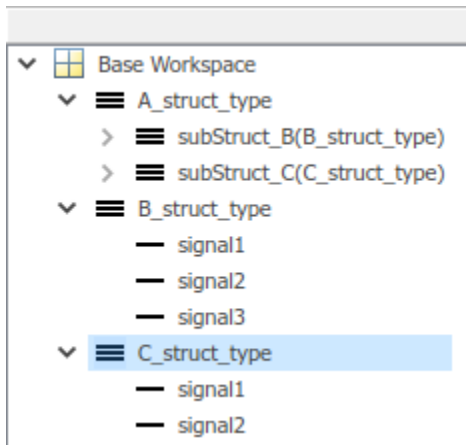

Use the Bus Editor to create a `Simulink.Bus` object named `A_struct_type` that contains two signal elements: `subStruct_B` and `subStruct_C`. To create bus objects with the Bus Editor, see “Create Bus Objects with the Bus Editor” (Simulink). This bus object represents the top-level structure type that you want the generated code to use.

For the `subStruct_B` element, set **DataType** to `Bus: B_struct_type`. Use a similar type name for `subStruct_C`.

Each signal element in `A_struct_type` uses another bus object as a data type. Now, these elements represent substructures.

Use the Bus Editor to create the `Simulink.Bus` objects `B_struct_type` (with three signal elements) and `C_struct_type` (with two signal elements).

In the dialog box of the Bus Creator block that collects the three Gain signals, set **Output data type** to Bus: `B_struct_type`. Click **Apply**.

Select **Output as nonvirtual bus** and click **OK**.

In the dialog box of the other subordinate Bus Creator block, set **Output data type** to Bus: `C_struct_type` and select **Output as nonvirtual bus**. Click **OK**.

In the last Bus Creator block dialog box, set **Output data type** to Bus: `A_struct_type` and select **Output as nonvirtual bus**. Click **OK**.

In the model, select **View > Model Data Editor**.

In the Model Data Editor, on the **Signals** tab, from the **Change view** drop-down list, select **Code**.

In the model, click the output signal of the `A_struct_type` Bus Creator block, which feeds the Unit Delay block.

In the Model Data Editor, for the output of the Bus Creator block, set **Name** to `sig_struct_var`.

Set **Storage Class** to `ExportedGlobal`. With this setting, the output of the Bus Creator block appears in the generated code as a separate global structure variable named `sig_struct_var`.

Generate code from the model.

Results

The generated header file `ex_signal_nested_struct_types.h` defines the structure types. Each structure type corresponds to a `Simulink.Bus` object.

```
typedef struct {
    real_T signal1;
    real_T signal2;
    real_T signal3;
} B_struct_type;

typedef struct {
    real_T signal1;
    real_T signal2;
} C_struct_type;

typedef struct {
    B_struct_type subStruct_B;
    C_struct_type subStruct_C;
} A_struct_type;
```

The generated source file `ex_signal_nested_struct.c` allocates memory for the global structure variable `sig_struct_var`. By default, the name of the `A_struct_type` Bus Creator block is `Bus Creator2`.

```
/* Exported block signals */
A_struct_type sig_struct_var;          /* '<Root>/Bus Creator2' */
```

In the same file, in the model `step` function, the algorithm accesses `sig_struct_var` and the fields of `sig_struct_var`.

Bitfields

C Construct

```
typedef struct {
    unsigned int p1 : 1;
    unsigned int p2 : 1;
    unsigned int p3 : 1;
} my_struct_type
```

Procedure

- 1 Create the `ex_struct_bitfield_CSC` model with three Constant blocks and three Output blocks.

- 2 In the model, select **View > Model Data Editor**.
- 3 In the Model Data Editor, on the **Parameters** tab, use the **Value** column to set value of the first Constant block to `p1`.
- 4 Next to `p1`, click the action button  and select **Create**.
- 5 In the Create New Data dialog box, set **Value** to `Simulink.Parameter(false)` and click **Create**.

A `Simulink.Parameter` object named `p1` appears in the base workspace. The object stores a Boolean value, `false`, and uses the data type `boolean`.

- 6 In the `Simulink.Parameter` property dialog box, click **OK**.
- 7 Use the Model Data Editor to configure the other Constant blocks to refer to new parameter objects named `p2` and `p3`.

- 8** In the Model Data Editor, click the **Show/refresh additional information** button.
- 9** Set the **Change view** drop-down list to Code.
- 10** Use the **Storage Class** column to apply the custom storage class `BitField` to the parameter objects.
- 11** Use the **Struct Name** column to configure each object to use the same structure type, `my_struct`.
- 12** Generate code from the model.

Results

The generated header file `ex_struct_bitfield_CSC.h` defines the structure type `my_struct_type`.

```
/* Type definition for custom storage class: BitField */
typedef struct my_struct_tag {
    uint_T p1 : 1;
    uint_T p2 : 1;
    uint_T p3 : 1;
} my_struct_type;
```

The generated source file `ex_struct_bitfield_CSC.c` defines and initializes the structure variable `my_struct`.

```
/* Definition for custom storage class: BitField */
my_struct_type my_struct = {
    /* p1 */
    0,

    /* p2 */
    1,

    /* p3 */
    0
};
```

Arrays for Parameters

C Construct

```
float myParams[5]= {1.0F,2.0F,3.0F,4.0F,5.0F};
```

Procedure

- 1 Create the `ex_param_array` model by using a Gain block.

- 2 In the model, select **View > Property Inspector**. The Property Inspector opens.
- 3 In the model, select the Gain block.
- 4 In the Property Inspector, set the value of the **Gain** parameter to `myParams`.
- 5 Next to the parameter value, click the action button  and select **Create**.
- 6 In the Create New Data dialog box, set **Value** to `Simulink.Parameter([1 2 3 4 5])`. Click **Create**.

A `Simulink.Parameter` object, `myParams`, appears in the base workspace. The Gain block uses the object to set the value of the **Gain** parameter.

- 7 In the `Simulink.Parameter` property dialog box, set **Storage class** to `ExportedGlobal`.

With this setting, `myParams` appears in the generated code as a separate global variable.

- 8 Set **Data type** to `single`. Click **OK**.
- 9 Generate code from the model.

Results

The generated source file `ex_param_array.c` defines and initializes the global variable `myParams`.

```
/* Exported block parameters */  
real32_T myParams[5] = { 1.0F, 2.0F, 3.0F, 4.0F, 5.0F } ;  
/* Variable: myParams  
 * Referenced by: '<Root>/Gain'  
*/
```

Arrays for Signals

C Construct

```
double myIn[5];  
double myOut[5];
```

Procedure

- 1 Create the `ex_signal_array` model by using a Gain block.

- 2 In the model, select **View > Model Data Editor**.
- 3 In the Model Data Editor, view the **Inports/Outports** tab.
- 4 From the **Change View** drop-down list, select **Design**.
- 5 In the model, select the Inport block.
- 6 In the Model Data Editor, for the Inport block, set **Signal Name** to `myIn`.
- 7 Set **Dimensions** to `[5 1]`.
- 8 For the Output block, set **Signal Name** to `myOut`.
- 9 From the **Change View** drop-down list, select **Code**.
- 10 For the Inport block and the Output block, set **Storage Class** to `ExportedGlobal`.

With this setting, the blocks appear in the generated code as separate global variables.

- 11 Generate code from the model.

Results

The generated source file `ex_signal_array.c` defines the global variables `myIn` and `myOut` as arrays with 5 elements each.

```
/* Exported block signals */  
real_T myIn[5];  
real_T myOut[5];  
  
/* '<Root>/In1' */  
/* '<Root>/Out1' */
```

Pointers

When your handwritten code allocates memory for signal, state, or parameter data, you can generate code that accesses that data through a pointer. Apply a storage class such as `ImportedExternPointer` to a data item in the model. Your handwritten code provides the pointer definition.

C Construct

```
extern double *myIn;
```

Procedure

- 1 Create the `ex_pointer` model by using a Gain block.

- 2 In the model, select **View > Model Data Editor**.
- 3 In the Model Data Editor, view the **Inports/Outports** tab.
- 4 From the **Change view** drop-down list, select Code.
- 5 In the model, select the Inport block.
- 6 In the Model Data Editor, for the Inport block, set **Signal Name** to `myIn`.
- 7 Set **Storage Class** to `ImportedExternPointer`.
- 8 Generate code from the model.

Results

The generated header file `ex_pointer.h` declares the pointer.

```
/* Imported (extern) pointer block signals */
extern real_T *myIn; /* '<Root>/In1' */
```

In the generated source file `ex_pointer.c`, in the model step function, the algorithm dereferences the pointer, `myIn`.

```
/* Model step function */  
void ex_pointer_step(void)  
{  
    /* Output: '<Root>/Out1' incorporates:  
     * Inport: '<Root>/In1'  
     */  
    rtY.Out1 = *myIn;  
}
```

Implement Dimension Variants for Array Sizes in Generated Code

Dimension Variants

Use symbolic dimensions to simulate various sets of dimension choices without regenerating code for every set. Set up your model with dimensions that you specify as symbols in blocks and data objects. These symbols propagate throughout the model during simulation, and then go into the generated code. Modeling constraints for symbols during simulation (for example, $C=A+B$) are output as preprocessor conditionals in either the `model.h` or the `model_types.h` file.

You can directly specify dimension information as a symbol or a numeric constant for these blocks and data objects:

- Inport
- Output
- Signal Specification
- Data Store Memory
- Interpreted MATLAB Function
- `Simulink.Signal`
- `Simulink.Parameter`
- `Simulink.BusElement`
- `AUTOSAR.Parameter`

The Data Store Memory and Interpreted MATLAB Function blocks also support variable dimension signals. For these blocks, the symbolic dimensions control the maximum allowed size.

You must provide the code for `Simulink.Parameter` objects that contain symbolic dimensions. You can provide this code by using the `ImportedExtern` or `ImportedExternPointer` built-in storage classes.

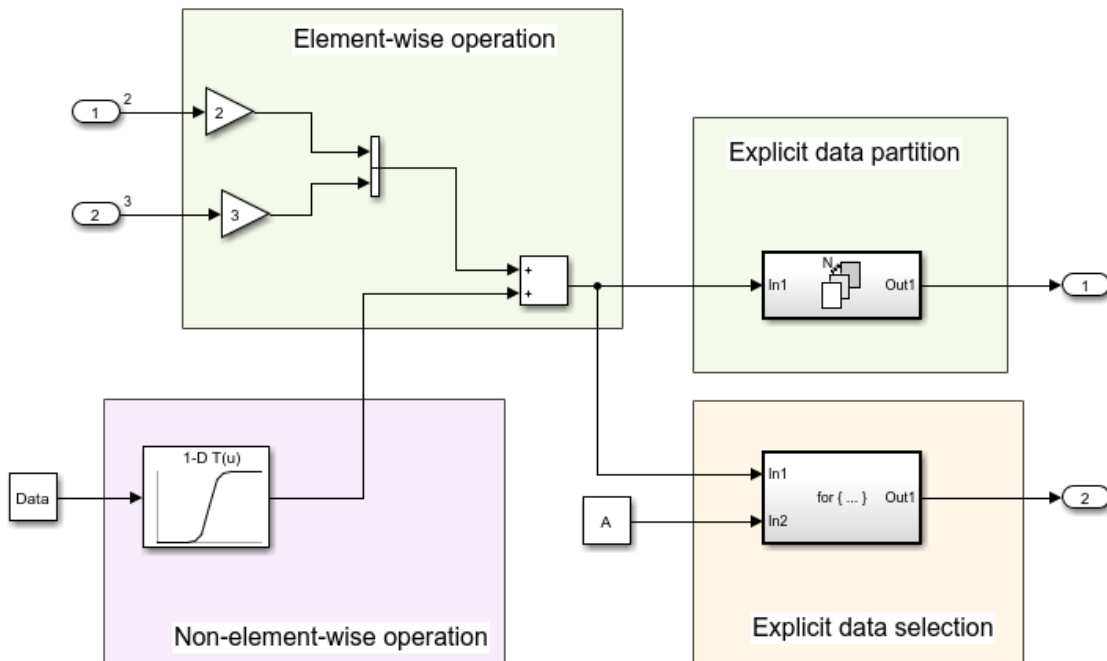

You use `Simulink.Parameter` objects to specify dimension information as symbols. For more information on signal dimensions, see “Signal Dimensions” (Simulink).

You must fix symbolic dimension values at compile-time. You can not resolve a symbolic dimension to another variable and then vary it during run-time because you define the behavior during simulation.

Note: The dimension variants feature is on by default. You can turn off this feature by clearing the “Allow symbolic dimension specification” (Simulink) parameter in the Configuration Parameters dialog box.

Define Symbolic Dimensions

This example uses the model `rtwdemo_dimension_variants` to show how to implement symbolic dimensions. This model has four modeling patterns involving vectors and matrices.

- 1 To show block names, on the **Display** menu, deselect **Hide Automatic Names**.
- 2 Open the Model Explorer. Select the base workspace pane.

- 3 In the base workspace, there are four `Simulink.Parameter` objects for specifying symbolic dimensions. These `Simulink.Parameter` objects have the names A, B, C, and D.
- 4 Select the `Simulink.Parameter` object A. Review the information in the `Simulink.Parameter` dialog box. A has a storage class of `CompilerFlag`.
- 5 Repeat Step 4 for each of the `Simulink.Parameter` objects B, C, and D.
- 6 For `Simulink.Parameter` objects with an `ImportedDefine` custom storage class, provide a header file on the MATLAB path. Insert the name of the header file in the **HeaderFile** field in the `Simulink.Parameter` dialog box.

To use a `Simulink.Parameter` object for dimension specification, it must be defined in the base workspace and have one of these storage classes:

- `Define` or `ImportedDefine` with header file specified
- `CompilerFlag`
- User-defined custom storage class that defines data as a macro in a specified header file

You can use MATLAB expressions to specify symbolic dimensions. For a list of supported MATLAB expressions, see the section `Operators and Operands in Variant Condition Expressions` in “Introduction to Variant Controls” (Simulink).

Specify Symbolic Dimensions for Blocks and Data Objects

- 1 Open the Source Block Parameters dialog box of Inport Block In2. In the **Signal Attributes** tab, the **Port Dimensions** field contains the `Simulink.Parameter` object A. For Inport blocks, you specify symbolic dimensions in the **Port Dimensions** field.
- 2 Open the Source Block Parameters dialog box of Inport block In3. In the **Signal Attributes** tab, the **Port Dimensions** field contains the `Simulink.Parameter` object B.
- 3 In the base workspace, select the `Simulink.Parameter` object Data. In the `Simulink.Parameter` dialog box for Data, the Dimension field has the character vector `'[1,C]'`, which is equivalent to `'[1,5]'` because C has a value of 5. The **Value** field contains an array with 5 values, so the dimensions of C are consistent with the dimension of the Data object. The dimensions of the Data object must always be consistent with the value of the `Simulink.Parameter` object that is in the Data object **Dimensions** field. Data has a **Storage class** of `ImportedExtern`. A `Simulink.Parameter` object that uses a `Simulink.Parameter` for symbolic

dimension specification must have a storage class of either `ImportedExtern` or `ImportedExternPointer`.

- 4 Open the Block Parameters dialog box of the 1-D Lookup Table1 block. The **Table data** field contains the `Simulink.Parameter`, PT. The **Breakpoints 1** field contains the `Simulink.Parameter`, PB.
- 5 In the base workspace, view the information in the `Simulink.Parameter` dialog boxes for PB and PT. These parameters contain the character vector '`[1,D]`' in their **Dimensions** field and are arrays consisting of 15 values. The dimension of D are consistent with the dimension of the PB and PT parameters because D has a value of 15 .
- 6 Simulate the model. Simulink propagates the dimensions symbolically in the diagram. During propagation, Simulink establishes modeling constraints among symbols. Simulink then checks for consistency with these constraints based on current numerical assignments. One modeling constraint for `rtwdemo_dimension_variants` is that $C=A+B$. The **Diagnostic Viewer** produces a warning for any violations of constraints.
- 7 Change the dimension specification to a different configuration and simulate the model again.

Though not shown in this example, you can specify an n-D dimension expression with one or more of the dimensions being a symbol (for example, ' [A,B,C] ' or ' [1,A,3] ').

Generate Code for a Model with Dimension Variants

Once you have verified dimension specifications through model simulation, generate code for `rtwdemo_dimension_variants`.

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
model='rtwdemo_dimension_variants';
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_dimension_variants
### Successful completion of build procedure for model: rtwdemo_dimension_variants
```

View the generated code. In the `rtwdemo_dimension_variants.h` file, symbolic dimensions are in data declarations.

```
hfile = fullfile(cgDir,'rtwdemo_dimension_variants_ert_rtw',...
    'rtwdemo_dimension_variants.h');
rtwdemodbtype(hfile,'/* External inputs', '/* Real-time', 1, 0);

/* External inputs (root inport signals with default storage) */
typedef struct {
    real_T In2[A];                /* '<Root>/In2' */
    real_T In3[B];                /* '<Root>/In3' */
} ExtU;

/* External outputs (root outputs fed by signals with default storage) */
typedef struct {
    real_T Out1[A + B];           /* '<Root>/Out1' */
    real_T Out2[A + B];           /* '<Root>/Out2' */
} ExtY;
```

The `rtwdemo_dimension_variants.h` file contains data definitions and preprocessor conditionals that define constraints established among the symbols during simulation. One of these constraints is that the value of a symbolic dimension must be greater than 1. This file also includes the user-provided header file for any Simulink.Parameter objects with an ImportedDefine custom storage class.

```
hfile = fullfile(cgDir,'rtwdemo_dimension_variants_ert_rtw',...
    'rtwdemo_dimension_variants.h');
rtwdemodbtype(hfile,'#ifndef A', '/* Macros for accessing', 1, 0);

#ifndef A
#error The variable for the parameter "A" is not defined
#endif

#ifndef B
#error The variable for the parameter "B" is not defined
#endif

#ifndef C
#error The variable for the parameter "C" is not defined
#endif

#ifndef D
```

```
#error The variable for the parameter "D" is not defined
#endif

/*
 * Constraints for division operations in dimension variants
 */
#if (1 == 0) || ((A+B) % 1) != 0
# error "The preprocessor definition '1' must not be equal to zero and the division of
#endif

/*
 * Registered constraints for dimension variants
 */
/* Constraint 'C == (A+B)' registered by:
 * '<Root>/1-D Lookup Table1'
 */
#if C != (A+B)
# error "The preprocessor definition 'C' must be equal to '(A+B)'"
#endif

#if A <= 1
# error "The preprocessor definition 'A' must be greater than '1'"
#endif

#if B <= 1
# error "The preprocessor definition 'B' must be greater than '1'"
#endif

/* Constraint 'D > 1' registered by:
 * '<Root>/1-D Lookup Table1'
 */
#if D <= 1
# error "The preprocessor definition 'D' must be greater than '1'"
#endif

/* Constraint 'C > 1' registered by:
 * '<S2>/Assignment'
 */
#if C <= 1
# error "The preprocessor definition 'C' must be greater than '1'"
#endif
```

In the `rtwdemo_dimension_variants.c` file, symbolic dimensions participate in loop bound calculations, array size and index offset calculations, and a parameterized utility function (for example, Lookup Table block) calculation.

```

cfile = fullfile(cgDir,'rtwdemo_dimension_variants_ert_rtw',...
    'rtwdemo_dimension_variants.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_dimension_variants_step(void)
{
    real_T rtb_VectorConcatenate[A + B];
    int32_T s2_iter;
    int32_T ForEach_itr;
    real_T rtb_VectorConcatenate_m;

    /* Gain: '<Root>/Gain' incorporates:
     * Inport: '<Root>/In2'
     */
    for (ForEach_itr = 0; ForEach_itr <= (int32_T)(A - 1); ForEach_itr++) {
        rtb_VectorConcatenate[ForEach_itr] = 2.0 * rtU.In2[ForEach_itr];
    }

    /* End of Gain: '<Root>/Gain' */

    /* Gain: '<Root>/Gain1' incorporates:
     * Inport: '<Root>/In3'
     */
    for (ForEach_itr = 0; ForEach_itr <= (int32_T)(B - 1); ForEach_itr++) {
        rtb_VectorConcatenate[(int32_T)(A + ForEach_itr)] = 3.0 *
            rtU.In3[ForEach_itr];
    }

    /* End of Gain: '<Root>/Gain1' */

    /* Outputs for Iterator SubSystem: '<Root>/For Each Subsystem' incorporates:
     * ForEach: '<S1>/For Each'
     */
    for (ForEach_itr = 0; ForEach_itr <= (int32_T)((int32_T)(A + B) - 1);
        ForEach_itr++) {
        /* Sum: '<Root>/Add' incorporates:
         * Constant: '<Root>/Constant'
         * Lookup_n-D: '<Root>/1-D Lookup Table1'
         */
        rtb_VectorConcatenate_m = rtb_VectorConcatenate[ForEach_itr] + look1_binlx

```

```
(Data[ForEach_itr], PB, PT, (uint32_T)((uint32_T)D - 1U));

Close the model and code generation report.

```

bdclose(model)
rtwdemoclean;
cd(currentDir)

```

Set Parameter Value Based on Variant Choice

When you specify the dimensions of a parameter in a model by using a symbol, you must make sure that the parameter value is consistent with the dimension value. To simulate different choices for the dimension value, you must manually correct the parameter value.

For example, in the `rtwdemo_dimension_variants` model, the `Simulink.Parameter` object `Data` stores a vector value, `[1 2 3 4 5]`, and uses a symbolic dimension `C` with initial value 5. If you change the value of `C`, to simulate the model, you must make sure the number of elements in the vector value matches the new value of `C`.

To reduce the effort of maintenance when you change the value of `C`, you can set the value of `Data` to an expression involving `C`.

- 1 Open the model.

```
rtwdemo_dimension_variants
```

- 2 At the command prompt, inspect the initial values of `Data` and `C`. The value of `Data` is a vector of integers from 1 to `C`.

```
Data.Value
```

```
ans =
```

```
1 2 3 4 5
```

```
C.Value
```

```
ans =
```

```
5
```

- 3 In MATLAB code syntax, the value of `Data` is `1:C`. To preserve this relationship between the parameter objects, set the value of `Data` by using the `slexpr` function.

```
Data.Value = slexpr('1:C');
```

- 4 To prevent data type propagation errors, set the data type of `Data` explicitly to `double`, which is the data type that the parameter acquired before you set the parameter value to an expression.

- ```
Data.DataType = 'double';
```
- 5 Set the value of `C` to a different number, such as 6. Due to dimension constraints in the model, you must set the value of another dimension symbol, `A`, to 3.  

```
C.Value = 6;
A.Value = 3;
```
  - 6 Simulate the model. The block diagram shows that the value of `Data` now has six elements.

For more complicated applications, you can write your own MATLAB function that returns parameter values based on dimension symbols. Set the value of the parameter data to an expression that calls your function.

For general information about using an expression to set the value of a `Simulink.Parameter` object, see “Set Variable Value by Using a Mathematical Expression” (Simulink).

## Code Generation Optimization Considerations

When you create a model with symbolic dimensions, be aware of the following optimization considerations:

- The code generator reuses buffers only if dimension propagation establishes equivalence among buffers.
- Two loops with symbolic loop bound calculations are fused together only if they share equivalent symbolic expression.

- Optimizations do not eliminate a symbolic expression or condition check based on the current value of a symbolic dimension.

## Backward Compatibility

If an existing model uses `Simulink.Parameter` objects to specify dimensions, it can be incompatible with dimension variants. Here are two common scenarios:

- Only a subset of blocks accepts symbolic dimension specifications. If a block is not compatible with symbolic dimensions, it causes an update diagram error.
- `Simulink.Parameter` objects that you use to define symbolic dimensions or have symbolic dimensions must have one of the storage classes described in this example. If these specifications are not met, the build procedure for the model fails during code generation.

You can address these backward compatibility issues by doing the following:

- Turn off dimension variants feature by clearing the **Allow symbolic dimension specification** parameter in the Configuration Parameters dialog box.
- Update `Simulink.Parameter` objects that define symbolic dimensions or have symbolic dimension specifications.
- Update the model so that only supported blocks have symbolic dimensions or propagate symbolic dimensions.

## Supported Blocks

For a list of supported blocks, see the Block Support Table. To access the information in this table, enter `showblockdatatypetable` at the MATLAB command prompt. Unsupported blocks (for example, MATLAB Function) can still work in a model containing symbolic dimensions as long as these blocks do not directly interact with symbolic dimensions.

In the following cases, supported blocks do not propagate symbolic dimensions.

- For `Unit Delay` blocks, you specify a `Simulink.Signal` object that has symbolic dimensions for the **Block Parameters > State Attributes > State name** parameter.
- For Assignment and Selector blocks, you set the **Block Parameters > Index Option** parameter to `Index vector (dialog)`. For Selector and Assignment blocks, if you specify a symbolic dimension for the Index parameter, the code generator does not honor the symbolic dimension in the generated code.

- For the Sum block, you specify |+ for the **Block Parameters > List of signs** parameter, and you set the **Block Parameters > Sum over** parameter to Specified dimension.
- For the Product block, you specify a value of 1 for the **Block Parameters > Number of inputs** parameter, and you set the **Multiply over** parameter to Specified dimensions.
- For the ForEach block, you specify a symbolic dimension for the **Partition Width** parameter.

Note that the following modeling patterns are among those modeling patterns that can cause Simulink to error out:

- For Switch blocks, an input signal or the **Threshold** parameter has symbolic dimensions, and you select **Allow different data input sizes (Results in variable-size output signal)**.
- A Data Store Read block selects elements of a `Simulink.Bus` signal that has symbolic dimensions.
- For Lookup Table blocks, on the **Block Parameters > Algorithm** tab, you select the parameter **Use one input port for all input data**.

## Limitations

The following products and software capabilities support dimension variants in that they act on the numeric value of a symbolic dimension. These features do not support the propagation of symbolic dimensions during model simulation and the preservation of symbolic dimensions in the generated code.

- Code Replacement for Lookup Tables
- Software-in-the-Loop (SIL) and Processor-in-the-Loop (PIL) simulations
- Accelerator and rapid accelerator simulation modes
- Scope and simulation observation (for example, logging, SDI, and so on)
- Model coverage
- Simulink Design Verifier
- Fixed-Point Designer
- Data Dictionary
- Simulink PLC Coder

- HDL Coder

The following do not support dimension variants:

- System Object
- Stateflow
- Physical modeling
- Discrete-event simulation
- Frame data
- MATLAB functions

The following limitations also apply to models that utilize symbolic dimensions.

- For simulation, the size of a symbolic dimension can equal 1. For code generation, the size of a symbolic dimension must be greater than 1.
- If a symbolic dimension is a MATLAB expression that contains an arithmetic expression and either a relational or logical expression, you must add `+0` after the relational or logical part of the MATLAB expression. If you do not add `+0`, the model errors out during simulation because you cannot mix a `boolean` data type with integer or `double` data types. Adding `+0` converts the data type of the relational or logical part of the expression from a `boolean` to a `double`.

For example, suppose in the Inport block parameters dialog box, the **Port dimensions** parameter has the expression `[(C==8)*D+E, 3]`. The **Data type** parameter is set to `double`. Since `C==8` is a relational expression, you must change the expression to `[((C==8)+0)*D+E, 3]` to prevent the model from producing an error during simulation.

- Simulink propagates symbolic dimensions for an entire structure or matrix, but not for a part of a structure or matrix. For example, the `Simulink.Parameter` P is a 2x3 matrix with symbolic dimensions `[Dim,Dim1]`.

```
p=Simulink.Parameter(struct('A',[1 2 3;4 5 6]))
p.DataType='Bus:bo'
bo=Simulink.Bus
bo.Elements(1).Name='A'
bo.Elements(1).Dimensions='[Dim,Dim1]'
Dim=Simulink.Parameter(2)
Dim1=Simulink.Parameter(3)
p.CoderInfo.StorageClass='Custom'
p.CoderInfo.CustomStorageClass='Define'
```

```
Dim.CoderInfo.StorageClass='Custom'
Dim.CoderInfo.CustomStorageClass='Define'
Dim1.CoderInfo.StorageClass='Custom'
Dim1.CoderInfo.CustomStorageClass='Define'
```

If you specify `p.A` for a dimensions parameter, Simulink propagates the symbolic dimensions `[Dim,Dim1]`. If you specify `p.A(1, :)`, Simulink propagates the numeric dimension 3 but not the symbolic dimension, `Dim1`.

- The MATLAB expression `A(:)` does not maintain symbolic dimension information. Use `A` instead.
- The MATLAB expression `P(2:A)` does not maintain symbolic dimension information. Use the Selector block instead.
- The MATLAB expression `P(2, :)` is not a tunable expression, so it does not maintain symbolic dimension information.
- Suppose that you set the value of a mask parameter, `myMaskParam`, by using a field of a structure or by using a subset of the structures in an array of structures. You store the structure or array of structures in a `Simulink.Parameter` object so that you can use a `Simulink.Bus` object to apply symbolic dimensions to the structure fields. Under the mask, you configure a block parameter to use one of the fields that have symbolic dimensions. The table shows some example cases.

| Description                                                                                                                                              | Value of mask parameter ( <code>myMaskParam</code> ) | Value of block parameter       |
|----------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|--------------------------------|
| <code>myStruct</code> is a structure with field <code>gains</code> , which uses symbolic dimensions.                                                     | <code>myStruct.gains</code>                          | <code>myMaskParam</code>       |
| <code>myStruct</code> is a structure with field hierarchy <code>myStruct.subStruct.gains</code> . The field <code>gains</code> uses symbolic dimensions. | <code>myStruct.subStruct</code>                      | <code>myMaskParam.gains</code> |
| <code>myStructs</code> is an array of structures. Each structure has a field <code>gains</code> , which uses symbolic dimensions.                        | <code>myStructs(2)</code>                            | <code>myMaskParam.gains</code> |

In these cases, you cannot generate code from the model. As a workaround, choose one of these techniques:

- Use the entire structure (`myStruct`) or array of structures (`myStructs`) as the value of the mask parameter. Under the mask, configure the block parameter to dereference the target field from the mask parameter by using an expression such as `myMaskParam.subStruct.gains`.
- Use literal dimensions instead of symbolic dimensions for the target field (`gains`).

This limitation also applies when you use a field of a structure or a subset of the structures in an array of structures as the value of a model argument in a Model block.

## Code Generation for Variant Blocks

The code generator produces code from a Simulink model containing one or more Variant Subsystem, Variant Source, and Variant Sink blocks. To learn how to create a model containing variant blocks, see “Create a Simple Variant Model” (Simulink).

Code is generated for different variant choices, the active variant, and the default variant. To generate code for variants, set the following conditions in the Variant Subsystem, Variant Source, or Variant Sink block:

- Clear the option **Override variant conditions and use the following variant**.
- Select the option **Analyze all choices during update diagram and generate preprocessor conditionals**.

Code generated for Variant Subsystem blocks is surrounded by C preprocessor conditionals `#if`, `#else`, `#elif`, and `#endif`. Code generated for Variant Source and Variant Sink blocks is surrounded by C preprocessor conditionals `#if` and `#endif`. Therefore, the active variant is selected at compile time and the preprocessor conditionals determine which sections of the code to execute.

To construct model reference variants and generate preprocessor directives in the generated code, see the example “Use Model Variants to Generate Code That Uses C Preprocessor Conditionals”.

To construct variant subsystems and generate preprocessor directives in the generated code, see the example “Use Subsystem Variants To Generate Code That Uses C Preprocessor Conditionals”.

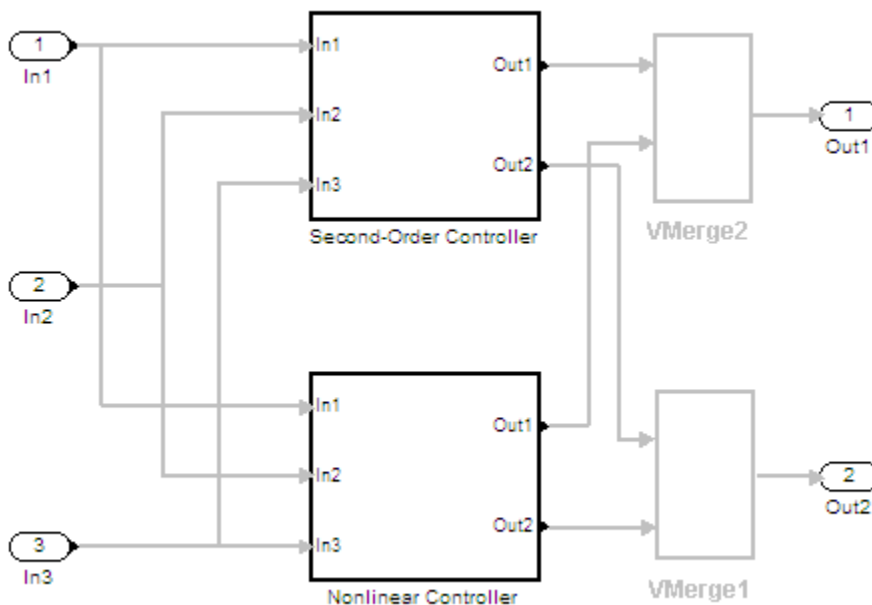

To construct models with variant sources and sinks and generate preprocessor directives in the generated code, see the example “Represent Variant Source and Sink Blocks in Generated Code” on page 15-42.

### Restrictions on Variant Subsystem Code Generation

To generate preprocessor conditionals, the types of blocks that you can place within the child subsystems of a Variant Subsystem block are limited. Connections are not allowed in the Variant Subsystem block diagram. However, during the code generation process, one `VariantMerge` block is placed at the input of each `Outport` block within the Variant Subsystem block diagram. All of the child subsystems connect to each of the `VariantMerge` blocks.

In the figure below, the code generation process makes the following connections and adds `VariantMerge` blocks to the `sldemo_variant_subsystems` model.

When compared to a generic `Merge` block the `VariantMerge` block can have only one parameter which is the number of Inputs. The `VariantMerge` block is used for code generation in variant subsystems internally, and is not available externally to be used in models. The number of inputs for `VariantMerge` is determined and wired as shown in the figure below.

The child subsystems of the Variant Subsystem block must be atomic subsystems. Select **Treat as atomic unit** parameter in the Subsystem block parameters dialog, to make the subsystems atomic. The `VariantMerge` blocks are inserted at the output of the subsystems if more than one child subsystems are present. If the source block of a `VariantMerge` block input is nonvirtual, an error message will be displayed during code generation. You must make the source block contiguous, by inserting Signal Conversion blocks inside the variant choices. The signals that enter a Variant Subsystem block must have the same signal properties (for example, signal dimensions, port width, and storage class). The `VariantMerge` block does not support different signal properties because the

input ports and output ports share the same memory. You can use symbolic dimensions to generate code for a variant subsystem with child subsystems of different output signal dimensions.

## Generated Code Components Not Compiled Conditionally

The following components are not conditionally compiled even if only code for variant subsystems or models that are conditionally compiled reference them.

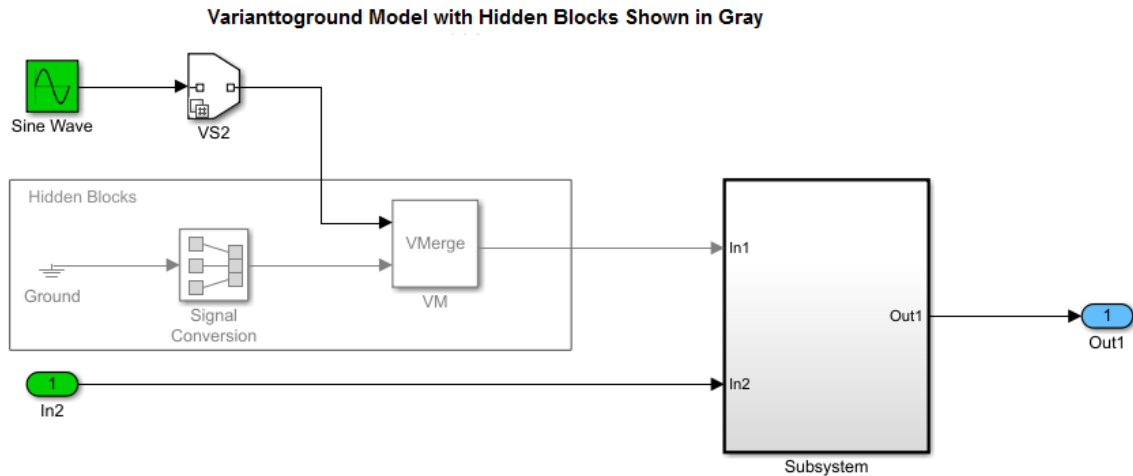

- `rtModel` data structure fields
- `#include`'s of utility files
- Global non-constant parameter structure fields; when the configuration parameter **Optimization > Parameter structure** is set to `NonHierarchical`
- Global constant parameter structure fields that are referenced by multiple subsystems activated by different variants
- Parameters that are configured to use an imported, exported, or custom code generation storage class, and are referenced by multiple subsystems that are activated by different variants
- Parameters that are configured to use an imported, exported, or custom code generation storage class, and are used by variant model blocks

## Code Generation for Variant Blocks with One Variant Choice

For modeling patterns in which a Root Inport block connects to a Variant block with one variant choice, Simulink inserts a hidden block combination of a Ground block, Signal Conversion block, and a Variant Merge block. If the variant choice evaluates to false, this block combination produces an output of `0.0`.

For example, the model `Varianttground` contains a Variant Source block with one variant choice. When the Variant Control `SYSCONST_A==6` evaluates to true, the input to Subsystem is a sine wave. When `SYSCONST_A==6` evaluates to false, the input to Subsystem is `0.0`.

The `varianttground.c` file contains this code:

```

/* Sin: '<Root>/Sine Wave' */
#if SYSCONST_A == 6

 varianttground_B.VM_Conditional_Signal_Subsystem_0_r64 = sin
 (varianttground_M->Timing.t[0]);

#endif

/* End of Sin: '<Root>/Sine Wave' */

/* SignalConversion: '<Root>/VM_SignalConversion_Subsystem_0' */
#if SYSCONST_A != 6

 varianttground_B.VM_Conditional_Signal_Subsystem_0_r64 = 0.0;

#endif

/* End of SignalConversion: '<Root>/VM_SignalConversion_Subsystem_0' */

```

The comments in the generated code indicate the presence of the hidden signal conversion block. The code does not contain a comment for the Variant Merge block

because this block does not have associated generated code. The Variant Merge block is used internally and is not in the Simulink library.

# Represent Subsystem and Model Variants in Generated Code

**In this section...**

“Step 1: Represent Variant Choices in Simulink” on page 15-23

“Step 2: Specify Conditions That Control Variant Choice Selection” on page 15-27

“Step 3: Configure Model for Generating Preprocessor Conditionals” on page 15-29

“Step 4: Review Generated Code” on page 15-30

“Limitations” on page 15-33

**Required products:** Simulink, Embedded Coder, Simulink Coder

Using Simulink, you can create models that are based on a modular design platform that comprises a fixed common structure with a finite set of variable components. The variability helps you develop a single, fixed master design with variable components. For more information, see “What Are Variants and When to Use Them” (Simulink) (Simulink). When you implement variants in the generated code, you can:

- Reuse generated code from a set of application models that share functionality with minor variations.
- Share generated code with a third party that activates one of the variants in the code.
- Validate the supported variants for a model and then choose to activate one variant for a particular application, without regenerating and re-validating the code.
- Generate code for the default variant that is selected when an active variant does not exist.

Using Embedded Coder, you can generate code from Simulink models containing one or more variant choices. The generated code contains preprocessor conditionals that control the activation of each variant choice.

This example shows how to represent variant choices in a Simulink model and then prepare the model so that those variant choices are represented in generated code.

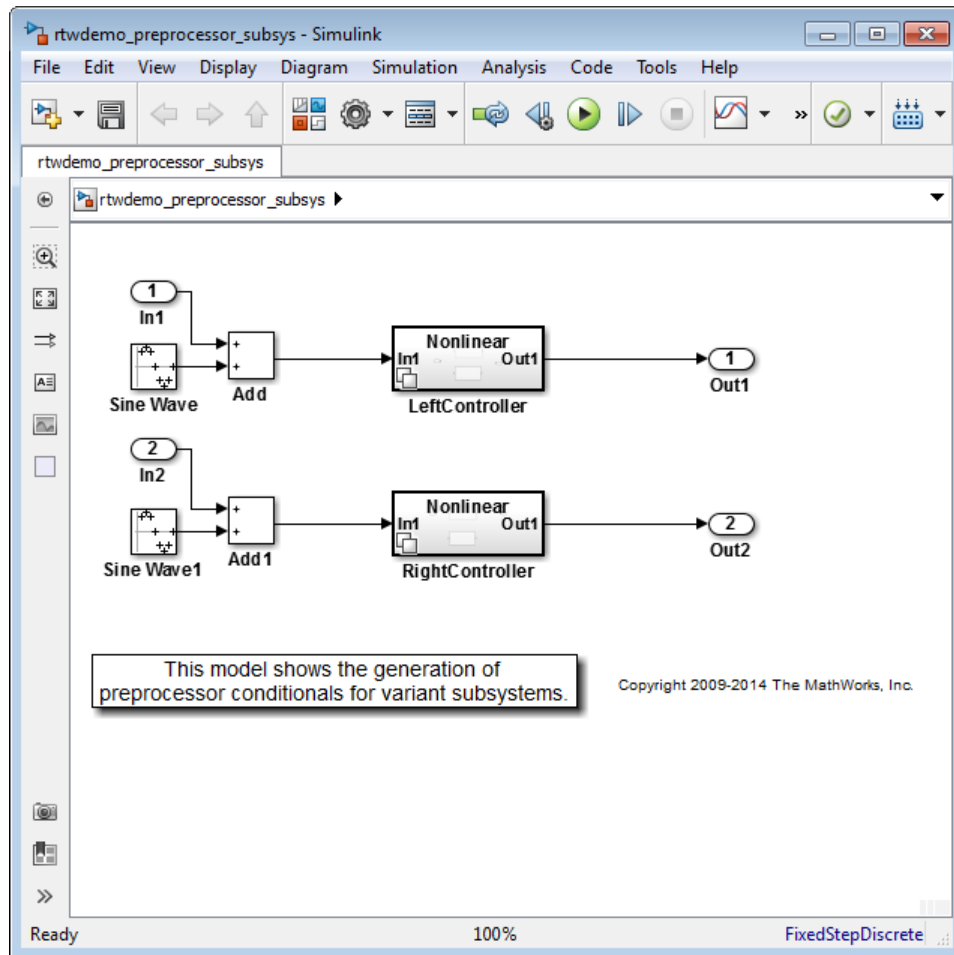

## Step 1: Represent Variant Choices in Simulink

Variant choices are two or more configurations of a component in your model. This example uses the model `rtwdemo_preprocessor_subsys` to illustrate how to represent

variant choices inside Variant Subsystem blocks. For other ways to represent variant choices, see “Options for Representing Variants in Simulink” (Simulink) (Simulink).

- 1 Open the model `rtwdemo_preprocessor_subsys`.

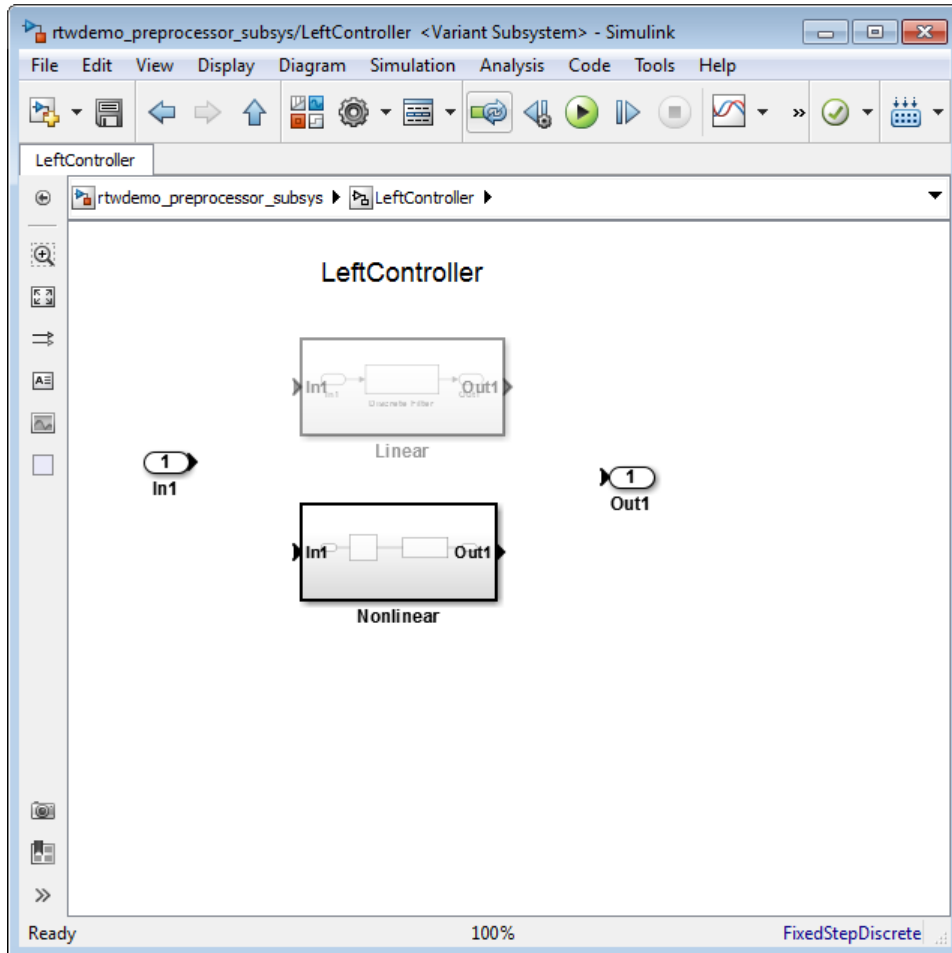

```
open_system('rtwdemo_preprocessor_subsys')
```

The model contains two Variant Subsystem blocks: **LeftController** and **RightController**.

**Note** You can only add Inport, Outport, Subsystem, and Model blocks inside a Variant Subsystem block.

- 2 Open the **LeftController** block.

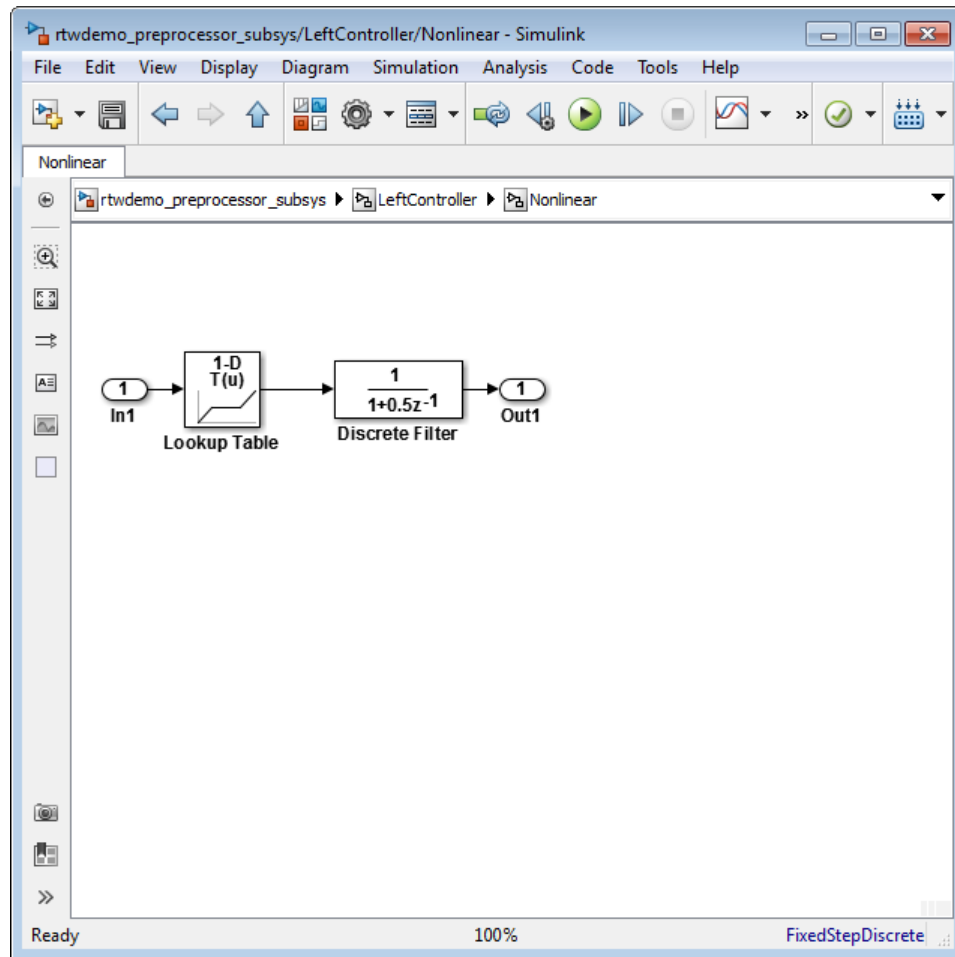

The **LeftController** block serves as the container for the variant choices. It contains two variant choices represented using Subsystem blocks **Nonlinear** and **Linear**. The nonlinear controller subsystems implement hysteresis, whereas the linear controller subsystems act as simple low-pass filters.

The Subsystem blocks have the same number of inports and outputs as the containing Variant Subsystem block.

Variant choices can have different numbers of inports and outputs. See “Mapping Inports and Outputs of Variant Choices” (Simulink) (Simulink).

- 3 Open the **Nonlinear** block.

The **Nonlinear** block represents one variant choice that Simulink activates when a condition is satisfied. The **Linear** block represents another variant choice.

---

**Tip** When you are prototyping variant choices, you can create empty Subsystem blocks with no inputs or outputs inside a Variant Subsystem block. The empty subsystem recreates the situation in which that subsystem is inactive without the need for completely modeling the variant choice.

---

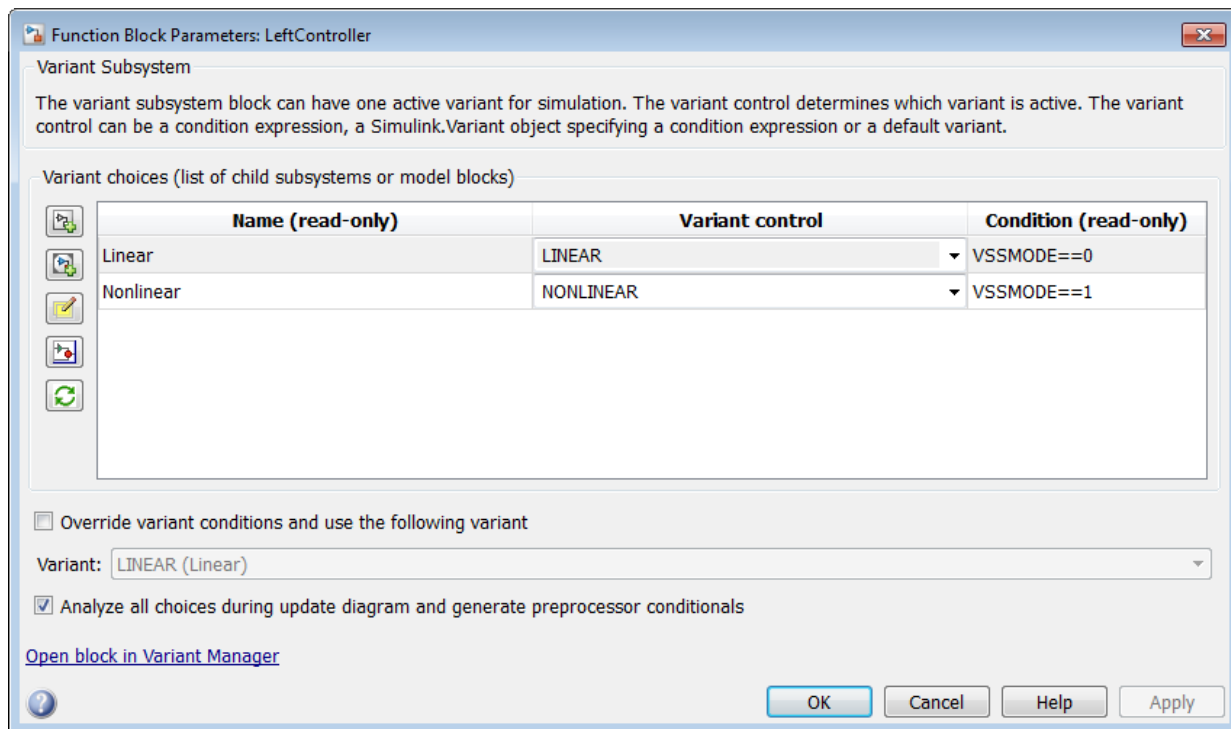

## Step 2: Specify Conditions That Control Variant Choice Selection

You can switch between variant choices by constructing conditional expressions called variant controls for each variant choice represented in a Variant Subsystem block. Variant controls determine which variant choice is active, and changing the value of a variant control causes the active variant choice to switch.

A variant control is a Boolean expression that activates a specific variant choice when it evaluates to `true`.

For more information, see “Introduction to Variant Controls” (Simulink) (Simulink).

- 1 Right-click the **LeftController** block and select **Block Parameters (Subsystem)**.

The **Condition** column displays the Boolean expression that when true activates each variant choice. In this example, these conditions are specified using Simulink.Variant objects LINEAR and NONLINEAR.

- 2 Use these commands to specify a variant control using a Simulink.Variant object.

```
LINEAR = Simulink.Variant;
LINEAR.Condition = 'VSSMODE==0';
NONLINEAR = Simulink.Variant;
NONLINEAR.Condition = 'VSSMODE==1';
```

Here, VSSMODE is called a variant control variable that can be specified in one of the ways listed in “Approaches for Specifying Variant Controls” (Simulink) (Simulink).

- 3 Define the variant control variable VSSMODE.

You can define VSSMODE as a scalar variable or as a Simulink.Parameter object. In addition to enabling the specification of parameter value, Simulink.Parameter

objects allow you to specify other attributes such as data type that are required for generating code.

```
VSSMODE = Simulink.Parameter;
VSSMODE.Value = 1;
VSSMODE.DataType = 'int32';
VSSMODE.CoderInfo.StorageClass = 'Custom';
VSSMODE.CoderInfo.CustomStorageClass = 'ImportedDefine';
VSSMODE.CoderInfo.CustomAttributes.HeaderFile = 'rtwdemo_importedmacros.h';
```

Variant control variables defined as `Simulink.Parameter` objects can have one of these storage classes.

- Define or ImportedDefine with header file specified
- CompilerFlag
- SystemConstant (AUTOSAR)
- Your own custom storage class that defines data as a macro

You can also convert a scalar variant control variable into a `Simulink.Parameter` object. See “Convert Variant Control Variables into `Simulink.Parameter` Objects” (`Simulink`) (`Simulink`).

### Step 3: Configure Model for Generating Preprocessor Conditionals

Code generated for each variant choice is enclosed within C preprocessor conditionals `#if`, `#else`, `#elif`, and `#endif`. Therefore, the active variant is selected at compile time and the preprocessor conditionals determine which sections of the code to execute.

- 1 In the Simulink editor, select **Simulation > Model Configuration Parameters**.
- 2 Select the **Code Generation** pane, and set **System target file** to `ert.tlc`.
- 3 In the **Report** pane, select **Create code generation report**.
- 4 In the Configuration Parameters dialog box, clear **Ignore custom storage classes** and click **Apply**.
- 5 In your model, right-click the **LeftController** block and select **Block Parameters (Subsystem)**.
- 6 Select the option **Analyze all choices during update diagram and generate preprocessor conditionals**.

When you select this option, Simulink analyzes all variant choices during an update diagram or simulation. This analysis provides early validation of the code generation readiness of all variant choices.

- 7 Clear the option **Override variant conditions and use following variant**.
- 8 Build the model.

## Step 4: Review Generated Code

The code generation report contains a section dedicated to the subsystems that have variants controlled by preprocessor conditionals.

- 1 To open the Code Generation Report click **Code > C/C++ Code > Code Generation Report > Open Model Report**.

- 2 Select the **Code Variant Report** from the left.

**Code Variants Report for rtwdemo\_preprocessor\_subsys**

**Table of Contents**

- [Variant Control](#)
- [Model Reference Blocks that have Variants](#)
- [Subsystem Blocks that have Variants](#)

**Variant Control** [[hide](#)]

| Variant   | Condition    | Used in Blocks                                                                              |
|-----------|--------------|---------------------------------------------------------------------------------------------|
| LINEAR    | VSSMODE == 0 | <a href="#">&lt;Root&gt;/LeftController</a><br><a href="#">&lt;Root&gt;/RightController</a> |
| NONLINEAR | VSSMODE == 1 | <a href="#">&lt;Root&gt;/LeftController</a><br><a href="#">&lt;Root&gt;/RightController</a> |

**Model Reference Blocks that have Variants** [[hide](#)]

(No ModelReference blocks that have Variants)

**Subsystem Blocks that have Variants** [[hide](#)]

| Subsystem Block                              | Variant   | Block                                |
|----------------------------------------------|-----------|--------------------------------------|
| <a href="#">&lt;Root&gt;/LeftController</a>  | LINEAR    | <a href="#">&lt;S1&gt;/Linear</a>    |
|                                              | NONLINEAR | <a href="#">&lt;S1&gt;/Nonlinear</a> |
| <a href="#">&lt;Root&gt;/RightController</a> | LINEAR    | <a href="#">&lt;S2&gt;/Linear</a>    |
|                                              | NONLINEAR | <a href="#">&lt;S2&gt;/Nonlinear</a> |

In this example, the generated code includes references to the Simulink.Variant objects LINEAR and NONLINEAR. The code also includes the definitions of macros corresponding to those variants. The definitions depend on the value of VSSMODE, which is supplied in an external header file rtwdemo\_importedmacros.h. The

active variant is determined by using preprocessor conditionals (`#if`) on the macros (`#define`) `LINEAR` and `NONLINEAR`.

- 3 Select the `rtwdemo_preprocessor_subsys_types.h` file from the left.

This file contains the definitions of macros `LINEAR` and `NONLINEAR`.

```
#ifndef LINEAR
 #define LINEAR (VSSMODE == 0)
#endif

#ifndef NONLINEAR
 #define NONLINEAR (VSSMODE == 1)
#endif
```

- 4 Select the `rtwdemo_preprocessor_subsys.c` file from the left.

In this file, calls to the step and initialization functions of each variant are conditionally compiled.

```
 /* Outputs for Atomic SubSystem: '<Root>/LeftController' */
 #if LINEAR
 /* Output and update for atomic system: '<S1>/Linear' */
 ...
 #elif NONLINEAR
 /* Output and update for atomic system: '<S1>/Nonlinear' */
 ...
 #endif
```

## Limitations

- When you are generating code for Model Variants blocks and Variant Subsystem blocks, the blocks cannot have:
  - Mass matrices
  - Function call ports
  - Outports with constant sample time
  - Simscape blocks
- The Model Variants block and its referenced models must have the same number of inports and outports.
- The port numbers and names for each active child subsystem must belong to a subset of the port numbers and names of the parent Variant Subsystem block.

# Generate Preprocessor Conditionals for Variant Systems

## In this section...

“Define Variant Controls” on page 15-35

“Configure Model for Generating Preprocessor Conditional Directives” on page 15-36

“Special Considerations for Generating Preprocessor Conditionals” on page 15-37

“Generate Variant Control Macros in Same Header File” on page 15-38

## Define Variant Controls

For variant systems, conditional expressions called variant controls determine which variant choice is active. You can specify a variant control as a condition expression, a `Simulink.Variant` object specifying a condition expression, a MATLAB variable, or a `Simulink.Parameter` object. This example shows how to define variant controls as `Simulink.Parameter` objects.

- 1 Open the Model Explorer. Select the **base workspace**.
- 2 In the Model Explorer, select **Add > Simulink Parameter**. Specify a name for the new parameter.
- 3 Use the function `Simulink.VariantManager.findVariantControlVars` to find and convert MATLAB variables used in variant control expressions into `Simulink.Parameter` objects. For an example, see “Convert Variant Control Variables into Simulink.Parameter Objects” (Simulink).
- 4 On the `Simulink.Parameter` property dialog box, specify the **Value** and **Data type**.
- 5 Select one of these **Storage class** values.
  - Define
  - `ImportedDefine(Custom)`
  - `CompilerFlag(Custom)`
  - A storage class created using the Custom Storage Class Designer. Your storage class must have the **Data initialization** parameter set to **Macro** and the **Data scope** parameter set to **Imported**. See “Control Data Representation by Configuring Custom Storage Class Properties” on page 26-31 for more information.
- 6 Specify the value of the variant control. If the storage class is `ImportedDefine(Custom)`, do the following:

- a Specify the **Header File** parameter as an external header file in the Custom Attributes section of the `Simulink.Parameter` property dialog box.
- b Enter the values of the variant controls in the external header file.

---

**Note** The generated code refers to a variant control as a user-defined macro. The generated code does not contain the value of the macro. The value of the variant control determines the active variant in the compiled code.

If the variant control is a `CompilerFlag` custom storage class, the value of the variant control is set at compile time. Use the **Configuration Parameters > Code Generation > Custom Code > Additional build information > Defines** parameter to add a list of variant controls (macro definitions) to the compiler command line. For example, for variant control `VSSMODE`, in the text field for the **Defines** parameter, enter:

```
-DVSSMODE=1
```

If you want to modify the value of the variant control after generating a makefile, use a makefile option when compiling your code. For example, at a command line outside of MATLAB, enter:

```
makecommand -f model.mk DEFINES_CUSTOM="-DVSSMODE=1"
```

---

---

**Note** You can define the variant controls using `Simulink.Parameter` object of enumerated type. This approach provides meaningful names and improves the readability of the conditions. The generated code includes preprocessor conditionals to check that the variant condition contains valid values of the enumerated type.

---

## Configure Model for Generating Preprocessor Conditional Directives

- 1 Open the Configuration Parameters dialog box.
- 2 Select the **Code Generation** pane, and set **System target file** as `ert.tlc`.
- 3 In the **Report** pane, select **Create code generation report**.
- 4 In the Configuration Parameters dialog box, clear the "Ignore custom storage classes" (Simulink Coder) parameter. In order to generate preprocessor conditionals, you must use custom storage classes.

- 5 In the Model Variants block parameter dialog box, select the **Generate preprocessor conditionals** parameter option. In the Variant Subsystem, Variant Source, or Variant Sink block parameter dialog boxes, select the **Analyze all choices during update diagram and generate preprocessor conditionals** option.
- 6 In both cases, clear the option to **Override variant conditions and use following variant**.
- 7 Generate code.

## Special Considerations for Generating Preprocessor Conditionals

- The code generation process checks that the inports and outports of a Model Variants block are identical (same port numbers and names) to the corresponding inports and outports of its variants. The build process for simulation does not make this check. Therefore, if your variant block contains mismatched inports or outports, the code generation process issues an error.
- The port numbers and names for each child variant subsystem must belong to a subset of the port numbers and names of the parent Variant Subsystem block.
- The code generation process checks that there is at least one active variant by using the variant control values stored in the base workspace. The variant control that evaluates to `true` becomes the active variant. If none of the variant controls evaluates to `true`, the default variant, if specified, becomes the active variant. The code generation process issues an error if an active variant does not exist.
- Implement the condition expressions of the variant objects such that only one evaluates to `true`. The generated code includes a test of the variant objects to determine that there is only one active variant. If this test fails, your code will not compile.
- If you comment out child subsystems listed in the **Variant Choices** table in the Variant Subsystem block parameter dialog box, the code generator does not generate code for the commented out subsystems.
- If the sample time for a default variant differs from that of the other variant choices, the `#else` preprocessor conditional is not generated for the default variant. Instead, an `#if !(<variant conditions>)` is generated.
- For Variant Subsystems, the `model_private.h` file contains conditional parameter definitions. For example, if the value of a Constant block is a `Simulink.Parameter` with an `ImportedDefine` custom storage class, and the Constant block is in a Variant

Subsystem, the conditional definition of the Simulink.Parameter is in the `model_private.h` file.

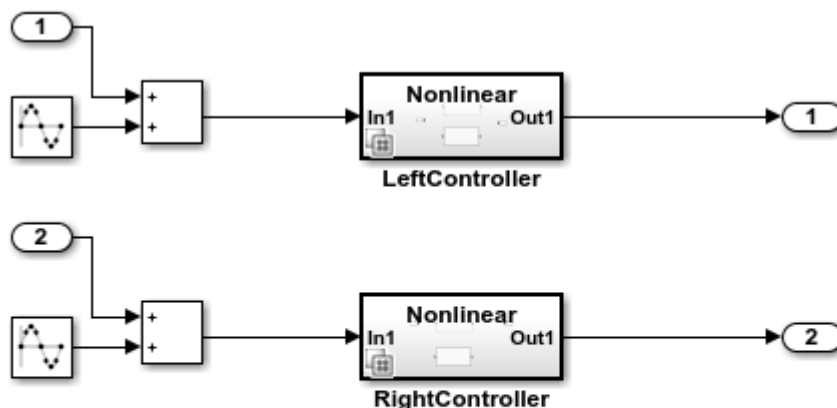

## Generate Variant Control Macros in Same Header File

This example shows how to aggregate multiple variant control macros (`#define`) into the same generated header file. This aggregation makes it easier for you to manage the complexities inherent in a system with multiple interacting variant conditions.

### Explore Example Model

Run the script `prepare_rtwdemo_preproc_subsys`, which opens the model `rtwdemo_preprocessor_subsys` and prepares it for this example.

```
run(fullfile(matlabroot, 'examples', 'ecoder', 'main', 'prepare_rtwdemo_preproc_subsys'));
```

This model shows the generation of preprocessor conditionals for variant subsystems.

Copyright 2009-2014 The MathWorks, Inc.

The model contains two Variant Subsystem blocks.

Navigate inside the variant subsystems. The subsystems each have a linear and a nonlinear algorithm variant.

At the root level of the model, open the block dialog box of the variant subsystem labeled `LeftController`. The algorithm variants in the subsystem activate based on the states of two Simulink.Variant objects, `LINEAR` and `NONLINEAR`, in the base workspace.

The state of each object depends on the values of two variant control variables, `MODE_A` and `MODE_B`, which are Simulink.Parameter objects in the base workspace. The parameter objects use the custom storage class `Define` and are configured to appear in the generated code as C-code macros in `macros.h`.

### **Change Name of Generated Header File Through Model Data Editor**

In this example, change the name of the generated header file from `macros.h` to `variant_controls.h`. You must change the file name in each parameter object.

In the model, select **View > Model Data Editor**.

In the Model Data Editor, select the **Parameters** tab.

Click the **Show/refresh additional information** button.

Set the **Change view** drop-down list to `Code`.

In the **Filter contents** box, enter `MODE`. The Model Data Editor shows two rows that correspond to the parameter objects.

Select both rows. Then, for one of the rows, use the **Header File** column to change the header file name from `macros.h` to `variant_controls.h`. The Model Data Editor applies the change to both rows.

### **Reduce Maintenance Effort by Creating Custom Storage Class**

To change the name of the header file, you must change the configuration of each parameter object. You can use the Model Data Editor to perform batch editing, but when you add a new variant control variable (parameter object), you must remember to specify the name of the header file for that object. Also, the Model Data Editor can show the parameter objects used by only one model at a time.

Instead, you can create a custom storage class and specify the name of the header file only once: In the definition of the custom storage class.

Set your current folder to a writable location.

At the command prompt, copy the built-in SimulinkDemos package into your current folder as myPackage.

```
copyfile(fullfile(matlabroot,...
 'toolbox','simulink','simdemos','dataclasses','+SimulinkDemos'),...
 '+myPackage','f')
```

Navigate inside the +myPackage folder to the file Parameter.m and open the file.

Uncomment the methods section that defines the method setupCoderInfo. In the call to the function useLocalCustomStorageClasses, replace 'packageName' with 'myPackage'. When you finish, the section appears as follows:

```
methods
function setupCoderInfo(h)
 % Use custom storage classes from this package
 useLocalCustomStorageClasses(h, 'myPackage');
end
end % methods
```

Save and close the file.

Set your current folder to the folder that contains the package myPackage.

Open the Custom Storage Class Designer.

```
cscdesigner('myPackage')
```

Select the custom storage class Define.

Click **Copy**. A new custom storage class, Define\_1, appears. Select this new custom storage class.

Set **Name** to VariantControlVar.

Set **Header file** to Specify. In the text box, enter variant\_controls.h.

Click **Apply**, **Save**, and **OK**.

At the command prompt, replace the Simulink.Parameter objects MODE\_A and MODE\_B with myPackage.Parameter objects. Apply the new custom storage class VariantControlVar.

```
MODE_A = myPackage.Parameter;
MODE_A.Value = 1;
MODE_A.DataType = 'int32';
MODE_A.CoderInfo.StorageClass = 'Custom';
MODE_A.CoderInfo.CustomStorageClass = 'VariantControlVar';

MODE_B = myPackage.Parameter;
MODE_B.Value = 1;
MODE_B.DataType = 'int32';
MODE_B.CoderInfo.StorageClass = 'Custom';
MODE_B.CoderInfo.CustomStorageClass = 'VariantControlVar';
```

Now, to indicate that a parameter object represents a variant control variable, you can apply the custom storage class `VariantControlVar`. To change the name of the header file, use the Custom Storage Class Designer.

## Represent Variant Source and Sink Blocks in Generated Code

| In this section...                                                           |
|------------------------------------------------------------------------------|
| “Represent Variant Source and Variant Sink blocks in Simulink” on page 15-42 |
| “Specify Conditions That Control Variant Choice Selection” on page 15-47     |
| “Review the Generated Code” on page 15-47                                    |
| “Generate Code with Zero Active Variant Controls” on page 15-49              |
| “Global Data Guarding Limitation” on page 15-50                              |
| “State Logging Limitation” on page 15-50                                     |

You can use Variant Source and Variant Sink blocks to perceive multiple implementations of a model in a single, unified block diagram. Each implementation depends on conditions that you set for Variant Source and Variant Sink blocks. Simulink propagates these conditions to upstream and downstream blocks including root input and root output ports.

You can generate:

- Code from a Simulink model containing Variant Sink and Variant Source blocks.
- Code that contains preprocessor conditionals that control the activation of each variant choice.
- Preprocessor conditionals that allow for no active variant choice.

### Represent Variant Source and Variant Sink blocks in Simulink

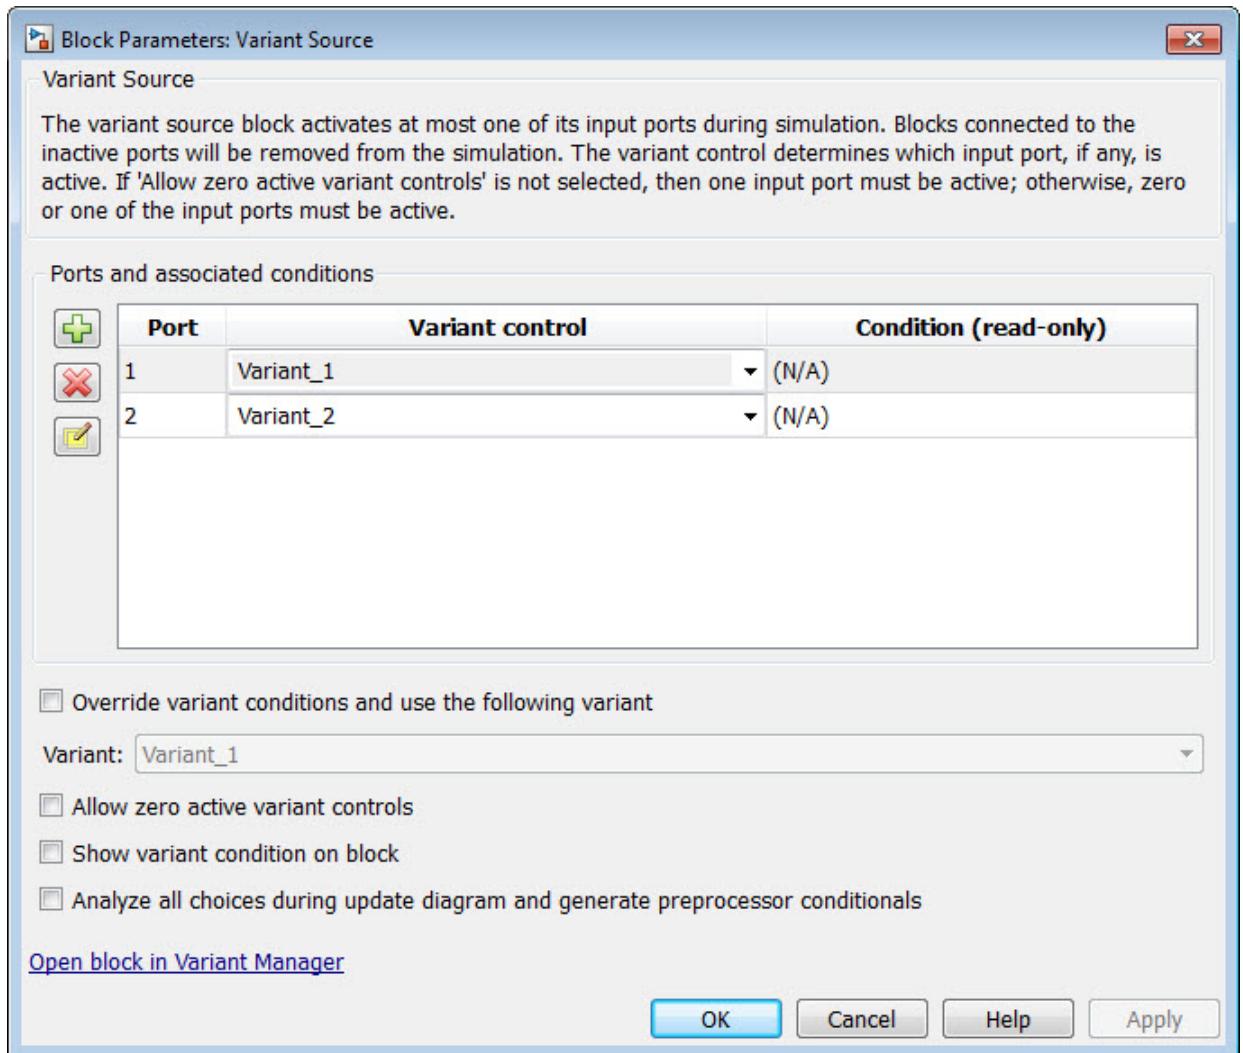

This example shows how Variant Source blocks make model elements conditional.

- 1 From the Simulink Block Library, add 1 Sine Wave Function block, two Add blocks, three Gain blocks, two Outports, and two Variant Source blocks into a new model.
- 2 Open the Sine Wave Function block. For the **Sine type** parameter, select **Sample based**. For the **Time (t)** parameter, select **Use simulation time**. For the **Sample time** parameter, insert a value of **0.2**.
- 3 Make four copies of the Sine Wave Function block.
- 4 Connect and name the blocks as shown.

Copyright 2015 The MathWorks Inc.  
MathWorks Confidential

- 5 Insert values of 2, 3, and 4 in the Gain2, Gain3, and Gain4 blocks, respectively.
- 6 Give the model the name `inline_variants_example`.
- 7 Open the Block Parameters dialog box for Variant Source.

- 8 In the **Variant control** column, for Port 1, replace Variant\_1 with V==1. For Port 2, replace Variant\_2 with V==2.
- 9 Open the Block Parameters dialog box for Variant Source1.
- 10 In the **Variant control** column, replace Variant\_1 with W==1. For Port 2, replace Variant\_2 with W==2.

- 11** In the MATLAB Command Window, use these commands to define V and W as Simulink.Parameter objects.

```
V = Simulink.Parameter;
V.Value = 1;
V.DataType='int32';
V.CoderInfo.StorageClass = 'custom';
V.CoderInfo.CustomStorageClass = 'Define';
V.CoderInfo.CustomAttributes.HeaderFile='inline_importedmacro.h'
```

```
W = Simulink.Parameter;
W.Value = 2;
W.DataType='int32';
W.CoderInfo.StorageClass = 'custom';
W.CoderInfo.CustomStorageClass = 'Define';
W.CoderInfo.CustomAttributes.HeaderFile='inline_importedmacro.h'
```

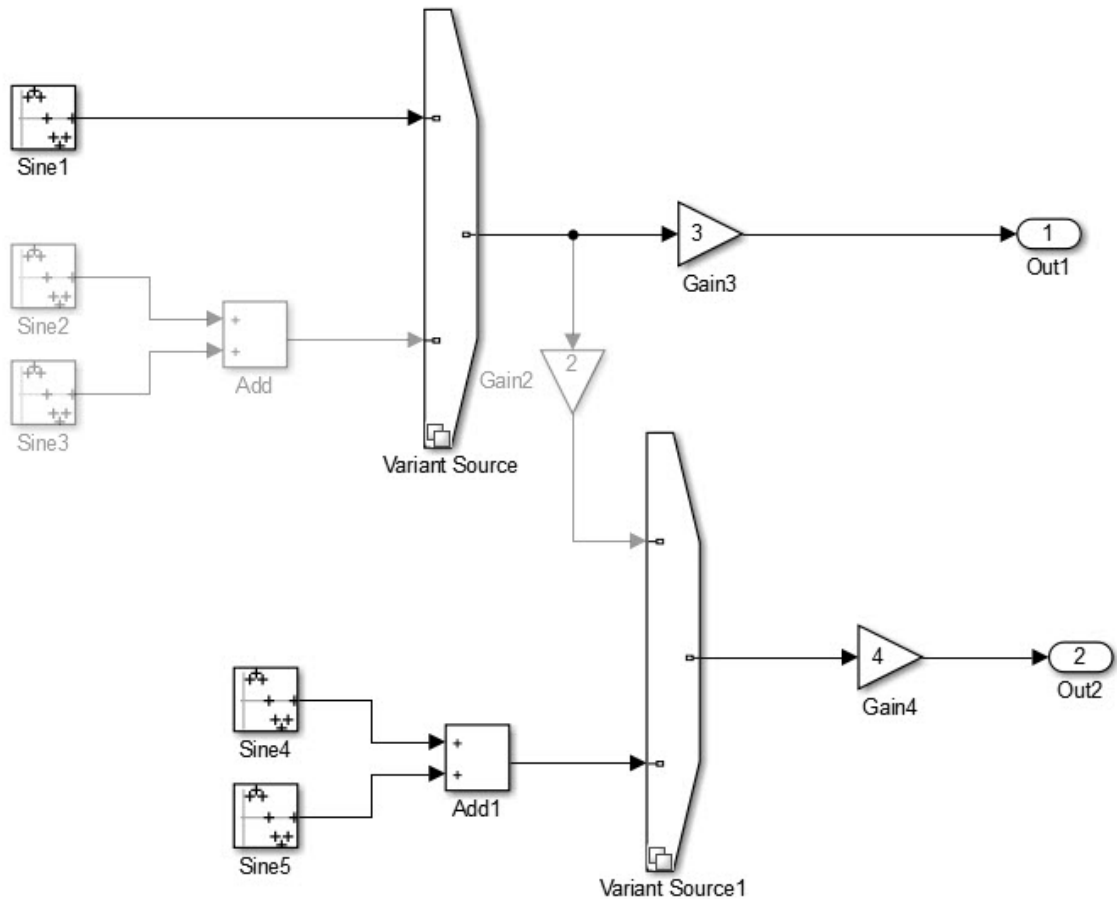

In this example, the variant control variables are Simulink.Parameter objects. For code generation, if you use Simulink.Variant objects to specify variant controls, use Simulink.Parameter objects or MATLAB variables to specify their conditions. .

Variant control variables defined as Simulink.Parameter objects can have one of these storage classes:

- Define with header file specified
- ImportedDefine with header file specified
- CompilerFlag
- SystemConstant (AUTOSAR)
- User-defined custom storage class that defines data as a macro in a specified header file

If you use scalar variant control variables to simulate the model, you can convert those variables into Simulink.Parameter objects. See “Convert Variant Control Variables into Simulink.Parameter Objects” (Simulink).

- 12** Simulate the model.

Copyright 2015 The MathWorks Inc.  
MathWorks Confidential

Input port 1 is the active choice for `Variant Source` because the value of variant control variable `V` is 1. Input port 2 is the active choice for `Variant Source1` because the value of variant control variable `W` is 2. The inactive choices are removed from execution, and their paths are grayed-out in the diagram.

## Specify Conditions That Control Variant Choice Selection

You can generate code in which each variant choice is enclosed within C preprocessor conditionals `#if` and `#endif`. The compiler chooses the active variant at compile time and the preprocessor conditionals determine which sections of the code to execute.

- 1 In the Simulink editor, select **Simulation > Model Configuration Parameters**.
- 2 Select the **Code Generation** pane, and set **System target file** to `ert.tlc`.
- 3 In the **Report** pane, select **Create code generation report**.
- 4 In your model, open the block parameters dialog box for **Variant Source**.
- 5 Select the **Analyze all choices during update diagram and generate preprocessor conditionals** parameter. During an update diagram or simulation, when you select this parameter, Simulink analyzes all variant choices. This analysis provides early validation of the code generation readiness of variant choices. During code generation, when you select this parameter, the code generator generates preprocessor conditionals that control the activation of each variant choice.
- 6 Clear the **Override variant conditions and use the following variant** parameter.
- 7 Clear the **Allow zero active variant controls** parameter.
- 8 Open the Block Parameters dialog box for **Variant Source** 1. Repeat steps 5 through 7.
- 9 Build the model. When code generation is complete, the Code Generation Report is displayed.

## Review the Generated Code

- 1 In the code generation report, select the `inline_variants_example.c` file.
- 2 In the `inline_variants_example.c` file, calls to the `inline_variants_example_step` function and the `inline_variants_example_initialize` functions are conditionally compiled as shown:

```
/* Model step function */
void inline_variants_example_step(void)
{
 real_T rtb_Sine4;
 real_T rtb_VariantMerge_For_Variant_So;

 /* Sin: '<Root>/Sine1' */
```

```
#if V == 1

 rtb_Sine4 = sin((real_T)inline_variants_example_DW.counter * 2.0 *
 3.1415926535897931 / 10.0);

#endif /* V == 1 */

/* End of Sin: '<Root>/Sine1' */

/* Sin: '<Root>/Sine2' incorporates:
 * Sin: '<Root>/Sine3'
 * Sum: '<Root>/Add'
 */
#if V == 2

 rtb_Sine4 = sin((real_T)inline_variants_example_DW.counter_i * 2.0 *
 3.1415926535897931 / 10.0) + sin((real_T)
 inline_variants_example_DW.counter_f * 2.0 * 3.1415926535897931 / 10.0);

#endif /* V == 2 */

/* End of Sin: '<Root>/Sine2' */

/* Outport: '<Root>/Out1' incorporates:
 * Gain: '<Root>/Gain3'
 */
inline_variants_example_Y.Out1 = 3.0 * rtb_Sine4;

/* Gain: '<Root>/Gain2' */
#if W == 1

 rtb_VariantMerge_For_Variant_So = 2.0 * rtb_Sine4;

#endif /* W == 1 */

/* End of Gain: '<Root>/Gain2' */

/* Sin: '<Root>/Sine4' incorporates:
 * Sin: '<Root>/Sine5'
 * Sum: '<Root>/Add1'
 */
#if W == 2

 rtb_VariantMerge_For_Variant_So = sin((real_T)
```

```

 inline_variants_example_DW.counter_fe * 2.0 * 3.1415926535897931 / 10.0) *
 2.0 + sin((real_T)inline_variants_example_DW.counter_e * 2.0 *
 3.1415926535897931 / 10.0);

#ifdef W == 2
 /* End of Sin: '<Root>/Sine4' */

 /* Output: '<Root>/Out2' incorporates:
 * Gain: '<Root>/Gain4'
 */
 inline_variants_example_Y.Out2 = inline_variants_example_P.Gain4_Gain *
 rtb_VariantMerge_For_Variant_So;
 ...
}

```

The variables `rtb_Sine4` and `rtb_VariantMerge_For_Variant_So` hold the input values to the Variant Source blocks. Notice that the code for these variables is conditional. The variables `inline_variants_example_Y.Out1` and `inline_variants_example_Y.Out2` hold the output values of the Variant Source blocks. Notice that the code for these variables is not conditional.

## Generate Code with Zero Active Variant Controls

You can generate code in which blocks connected to the input and the output of a Variant Source block are conditional.

- 1 For Variant Source, open the Block Parameters dialog box. Select the parameter **Allow zero active variant controls**.
- 2 For Variant Source 1, open the Block Parameters dialog box. Select the parameter **Allow zero active variant controls**.

When you select **Allow zero active variant controls** parameter, you can generate code for a model containing Variant Source and Variant Sink blocks even when you specify a value for a variant control variable that does not allow for an active variant. Choosing a value for a variant control variable that does not allow for an active variant and not selecting the **Allow zero active variant controls** parameter, produces an error.

Generate code for `inline_variants_example`. Notice in the `inline_variants_example.c` file, that the code for the variables `inline_variants_example_Y.Out1` and `inline_variants_example_Y.Out2` is conditional.

```
/* Model step function */
void inline_variants_example_step(void)
{
 ...
 #if V == 1 || V == 2

 inline_variants_example_Y.Out1 = 3.0 * rtb_Sine4;

 #endif /* V == 1 || V == 2 */

 ...
 #if (V == 1 && W == 1) || (V == 2 && W == 1) || W == 2
 inline_variants_example_Y.Out2 = 4.0 * rtb_VariantMerge_For_Variant_So;
 #endif /* (V == 1 && W == 1) || (V == 2 && W == 1) || W == 2 */
 ...
}
```

## Global Data Guarding Limitation

For external ports and most DWork vectors, signals, and states, preprocessor conditionals (`#if` and `#endif`) surround global data variable declarations. For models in which you enable C API code for global block output signals, global block parameters, and discrete and continuous states, preprocessor conditionals do not surround global data variable declarations. For information on the C API, see “Exchange Data Between Generated and External Code Using C API” (Simulink Coder).

## State Logging Limitation

There are some rare cases in which preprocessor conditionals do not surround global data structures that contain state variable declarations. For models that contain Variant Source blocks or Variant Sink blocks and also contain blocks that maintain state information, such as Unit Delay blocks, the exclusion of preprocessor conditionals surrounding state variable declarations can lead to a mismatch between simulation and code generation results.

For example, suppose that a model has a Variant Source block with four variant choices. One of these choices contains blocks with state information. If you simulate the model with the active variant that is other than the variant choice that contains state information, there is no logged state data. In the `model.h` file, the generated code still

initializes these global state variables to 0 because `#if` and `#endif` guards do not surround the state variable declarations. If you create a `model.mat` file from a `model.exe` file, and compare it to the simulation output, the results do not match. For this example, the simulation output is empty because there is no logged state data. The `model.mat` file contains multiple values of 0.

If the active variant is the variant choice containing state information, the results do match.

## Configure Dimension Variants for S-Function Blocks

To configure symbolic dimensions for S-function blocks, you can use the following C/C++ functions. You can configure S-functions to support forward propagation, backward propagation, or forward and backward propagation of symbolic dimensions during simulation.

Many of these functions return the variable `SymbDimsId`. A `SymbDimsId` is a unique integer value. This value corresponds to each symbolic dimension specification that you create or is the result of a mathematical operation that you perform with symbolic dimensions.

---

**Note** If you are writing an S-function with symbolic dimensions, you cannot use the `%roll` directive. You must write an explicit loop.

---

| C/C++ S-Functions                               | Purpose                                                                                                                                 |
|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>ssSetSymbolicDimsSupport</code>           | Specify whether or not an S-function supports symbolic dimensions.                                                                      |
| <code>mdlSetInputPortSymbolicDimensions</code>  | Specify the symbolic dimensions of an input port and how those dimensions propagate forward.                                            |
| <code>mdlSetOutputPortSymbolicDimensions</code> | Specify the symbolic dimensions of an output port and how those dimensions propagate backward.                                          |
| <code>ssRegisterSymbolicDimsExpr</code>         | Create a <code>SymbDimsId</code> from an expression string ( <code>aExpr</code> ). The expression string must form a valid syntax in C. |
| <code>ssRegisterSymbolicDims</code>             | Create a <code>SymbDimsId</code> from a vector of <code>SymbDimsIds</code> .                                                            |
| <code>ssRegisterSymbolicDimsString</code>       | Create a <code>SymbDimsId</code> from an identifier string ( <code>aString</code> ).                                                    |
| <code>ssRegisterSymbolicDimsIntValue</code>     | Create a <code>SymbDimsId</code> from an integer value ( <code>aIntValue</code> )                                                       |

| <code>ssGetCompInputPortSymbolicDimsId</code>  | Get the compiled <code>SymbDimsId</code> of an input port.                                                                                          |
| <code>ssSetCompInputPortSymbolicDimsId</code>  | Set the compiled <code>SymbDimsId</code> of an input port.                                                                                          |
| <code>ssSetOutputPortSymbolicDimsId</code>     | Set the precompiled <code>SymbDimsId</code> of an output port. You can call this function from inside the <code>mdlInitializeSizes</code> function. |
| <code>ssGetCompOutputPortSymbolicDimsId</code> | Get the compiled <code>SymbDimsId</code> of an output port.                                                                                         |
| <code>ssSetCompOutputPortSymbolicDimsId</code> | Set the compiled <code>SymbDimsId</code> of an output port.                                                                                         |
| <code>ssSetCompDWorkSymbolicDimsId</code>      | Set the compiled <code>SymbDimsId</code> of an index of a block's data type work ( <code>DWork</code> ) vector.                                     |

## S-Function That Supports Forward Propagation of Symbolic Dimensions

This S-function subtracts the symbolic dimension B from a symbolic input dimension. It does not support backward propagation of symbolic dimensions because the compiled symbolic dimensions of the input port are not set. Symbolic dimensions are set for the output port, so forward propagation occurs.

```
static void mdlInitializeSizes(SimStruct *S)
{
 // Enable symbolic dimensions for the s-function.
 ssSetSymbolicDimsSupport(S, true);
}

#if defined(MATLAB_MEX_FILE)
#define MDL_SET_INPUT_PORT_SYMBOLIC_DIMENSIONS
static void mdlSetInputPortSymbolicDimensions(SimStruct* S,
 int_T portIndex, SymbDimsId symbDimsId)
{
 assert(0 == portIndex);
 // Set the compiled input symbolic dimension.
 ssSetCompInputPortSymbolicDimsId(S, portIndex, symbDimsId);
 // Register "B" and get its symbolic dimensions id.
 const SymbDimsId symbolIdForB = ssRegisterSymbolicDimsString(S, "B");
 // Subtract "B" from the input symbolic dimension.
 const SymbDimsId outputDimsId =
 ssRegisterSymbolicDimsMinus(S, symbDimsId, symbolIdForB);
 //Set the resulting symbolic dimensions id as the output.
 ssSetCompOutputPortSymbolicDimsId(S, portIndex, outputDimsId);
}
#endif

#if defined(MATLAB_MEX_FILE)
#define MDL_SET_OUTPUT_PORT_SYMBOLIC_DIMENSIONS
static void mdlSetOutputPortSymbolicDimensions(SimStruct *S,
 int_T portIndex, SymbDimsId symbDimsId)
{
 assert(0 == portIndex);
 // The input dimensions are not set, so this S-function only
 // supports forward propagation.
 ssSetCompOutputPortSymbolicDimsId(S, portIndex, symbDimsId);
}
#endif
```

## S-Function That Supports Forward and Backward Propagation of Symbolic Dimensions

This S-function transposes two symbolic dimensions. It supports forward and backward propagation of symbolic dimensions because the compiled symbolic dimension of both the input and output ports are set.

```
static void mdlInitializeSizes(SimStruct *S)
{
 // Enable symbolic dimensions for the s-function.
 ssSetSymbolicDimsSupport(S, true);
}

#if defined(MATLAB_MEX_FILE)
#define MDL_SET_INPUT_PORT_SYMBOLIC_DIMENSIONS
static void mdlSetInputPortSymbolicDimensions(SimStruct* S,
 int_T portIndex, SymbDimsId symbDimsId)
{
 assert(0 == portIndex);

 ssSetCompInputPortSymbolicDimsId(S, portIndex, symbDimsId);

 assert(2U == ssGetNumSymbolicDims(S, symbDimsId));

 if (SL_INHERIT ==
 ssGetCompOutputPortSymbolicDimsId(S, portIndex)) {

 const SymbDimsId idVec[] = {
 ssGetSymbolicDim(S, symbDimsId, 1),
 ssGetSymbolicDim(S, symbDimsId, 0)};
 // Register the transposed dimensions.
 // Set the output symbolic dimension to the resulting id.
 const SymbDimsId outputDimsId =
 ssRegisterSymbolicDims(S, idVec, 2U);

 ssSetCompOutputPortSymbolicDimsId(S, portIndex,
 outputDimsId);
 }
}
#endif

#if defined(MATLAB_MEX_FILE)
#define MDL_SET_OUTPUT_PORT_SYMBOLIC_DIMENSIONS
static void mdlSetOutputPortSymbolicDimensions(SimStruct *S,
```

```
int_T portIndex, SymbDimsId symbDimsId)
{
 assert(0 == portIndex);
 ssSetCompOutputPortSymbolicDimsId(S, portIndex, symbDimsId);

 assert(2U == ssGetNumSymbolicDims(S, symbDimsId));

 if (SL_INHERIT ==
 ssGetCompInputPortSymbolicDimsId(S, portIndex)) {

 const SymbDimsId idVec[] = {
 ssGetSymbolicDim(S, symbDimsId, 1),
 ssGetSymbolicDim(S, symbDimsId, 0)};
 const SymbDimsId inputDimsId =
 ssRegisterSymbolicDims(S, idVec, 2U);
 // Register the transposed dimensions.
 // Set the input symbolic dimension to the resulting id.
 ssSetCompInputPortSymbolicDimsId(S, portIndex, inputDimsId);
 }
}
#endif
```

## Generate Code for Variant Subsystem with Child Subsystems of Different Output Signal Dimensions

| In this section...             |
|--------------------------------|
| “Example Model” on page 15-57  |
| “Simulate Model” on page 15-58 |
| “Generate Code” on page 15-59  |

This example shows how to use symbolic dimensions to generate code with preprocessor conditionals for a variant subsystem consisting of child subsystems of different output signal dimensions. The value of the variant control variable determines the active variant choice and the output signal dimensions. By changing the value of the variant control variable, you change the active variant and the output signal dimensions in the generated code.

### Example Model

The model `slexVariantSymbolicDims` contains a Variant Subsystem consisting of the child subsystems `Subsystem` and `Subsystem1`. When the variant control variable `Var` has a value of 1, `Subsystem` is the active variant. When `Var` has a value of 2, `Subsystem1` is the active variant.

## Simulate Model

To generate code with preprocessor conditionals, the output signal dimensions of the child subsystems must be the same during simulation. In this example, double-clicking the subsystem **Activate Variant Choice** changes the active variant and the output signal dimension. When **Var** equals 1, the output signal dimension of each child subsystem is 5. When **Var** equals 2, the output signal dimension of each child subsystem is 6.

- 1 Open the example model `slexVariantSymbolicDims`.
- 2 From the **Display > Signals & Ports** menu, select **Signal Dimensions**.
- 3 Open the Variant Subsystem Block Parameters dialog box. The **Analyze all choices during update diagram and generate preprocessor conditionals** parameter is selected.
- 4 Open **Subsystem**. In the Constant Block Parameters dialog box, the **Constant value** parameter is P1.
- 5 Open **Subsystem1**. In the Constant Block Parameters dialog box, the **Constant value** parameter is P2.

- 6 Open the base workspace. The Simulink.Parameters P1 and P2 are arrays with dimensions ' [1,A] '. The Simulink.Parameter A has a value of 5. Var has a value of 1.
- 7 Simulate the model. Subsystem is the active variant with an output signal dimension of 5.
- 8 Double-click the masked subsystem ActivateVariant.
- 9 In the base workspace, Var has a value of 2. P1 and P2 have a dimension of 6. A has a value of 6.
- 10 Simulate the model. Subsystem1 is the active variant with an output signal dimension of 6.

In the base workspace, A has a **Storage class** of ImportedDefine(Custom). To use a Simulink.Parameter object for dimension specification, it must have one of these storage classes:

- Define or ImportedDefine with header file specified
- CompilerFlag
- User-defined custom storage class that defines data as a macro in a specified header file

In the base workspace, P1 and P2 have a storage class of ImportedExtern. A Simulink.Parameter object that uses a Simulink.Parameter for symbolic dimension specification must have a storage class of either ImportedExtern or ImportedExternPointer.

## Generate Code

- 1 Open the header file slxVariantSymbolicDims\_variant\_defines.h. The definition of A is conditional upon the value of Var.

```

/* Copyright 2016 The MathWorks, Inc. */
// To select variant choice during compile, define Var at compile time,

#ifndef Var
#define Var 1
#endif

#if Var == 1
#define A 5
#elif Var == 2

```

```
#define A 6
#else
#error "Variant control variable, Var, must be defined as 1 or 2"
#endif
```

2 Generate code.

3 Open the `slexVariantSymbolicDims.h` file. The output dimension size is A.

```
/* External outputs (root outputs fed by signals with auto storage) */
typedef struct {
 int32_T Out1[A]; /* '<Root>/Out1' */
} ExternalOutputs_slexVariantSymb;
```

4 Open the `slexVariantSymbolicDims.c` file. If `Var` equals 1, P1 has five values. If `Var` equals 2, P2 has six values. In the Configuration Parameters dialog box, on the **Code Generation > Custom Code** pane, the **Source file** parameter contains this code.

```
/* user code (top of source file) */
#if Var == 1

int32_T P1[] = { 5, 5, 5, 5, 5 };

#elif Var == 2

int32_T P2[] = { 6, 6, 6, 6, 6, 6 };

#endif
```

Preprocessor conditionals control the size of A and which array, P1 or P2, is active in the generated code. By changing the value of `Var`, you can change the size of A and the active array.

“Allocation of Timers” on page 16-3

“Integer Timers in Generated Code” on page 16-3

“Elapsed Time Counters in Triggered Subsystems” on page 16-4

### About Timers

Certain blocks require the value of either *absolute* time (that is, the time from the start of program execution to the present time) or *elapsed* time (for example, the time elapsed between two trigger events). Targets that support the real-time model (`rtModel`) data structure provide efficient time computation services to blocks that request absolute or elapsed time. Absolute and elapsed timer features include

- Timers are implemented as unsigned integers in generated code.
- In multirate models, at most one timer is allocated per rate. If no blocks executing at a given rate require a timer, a timer is not allocated to that rate. This minimizes memory allocated for timers and significantly reduces overhead involved in maintaining timers.
- Allocation of elapsed time counters for use of blocks within triggered subsystems is minimized, further reducing memory usage and overhead.
- S-function and TLC APIs let your S-functions access timers, in simulation and code generation.
- The word size of the timers is determined by a user-specified maximum counter value, **Application lifespan (days)** (Simulink). If you specify this value, timers will not overflow. For more information, see “Control Memory Allocation for Time Counters” (Simulink Coder).

See “Absolute Time Limitations” (Simulink Coder) for more information about absolute time and the restrictions that it imposes.

## Timers for Periodic and Asynchronous Tasks

Timing services provided for blocks execute within *periodic* tasks (that is, tasks running at the model base rate or subrates).

The code generator also provides timer support for blocks whose execution is *asynchronous* with respect to the periodic timing source of the model. See the following topics:

- “Timers in Asynchronous Tasks” on page 18-46
- “Create a Customized Asynchronous Library” on page 18-49

## Allocation of Timers

If you create or maintain an S-Function block that requires absolute or elapsed time data, it must register the requirement (see “Access Timers Programmatically” on page 16-5). In multirate models, timers are allocated on a per-rate basis. For example, consider a model structured as follows:

- There are three rates, A, B, and C, in the model.
- No blocks running at rate B require absolute or elapsed time.
- Two blocks running at rate C register a requirement for absolute time.
- One block running at rate A registers a requirement for absolute time.

In this case, two timers are generated, running at rates A and C respectively. The timing engine updates the timers as the tasks associated with rates A and C execute. Blocks executing at rates A and C obtain time data from the timers associated with rates A and C.

## Integer Timers in Generated Code

In the generated code, timers for absolute and elapsed time are implemented as unsigned integers. The default size is 64 bits. This is the amount of memory allocated for a timer if you specify a value of `inf` for the **Application lifespan (days)** (Simulink) parameter. For an application with a sample rate of 1000 MHz, a 64-bit counter will not overflow for more than 500 years. See “Timers in Asynchronous Tasks” on page 18-46 and “Control Memory Allocation for Time Counters” on page 56-11 for more information.

## Elapsed Time Counters in Triggered Subsystems

Some blocks, such as the Discrete-Time Integrator block, perform computations requiring the elapsed time (delta T) since the previous block execution. Blocks requiring elapsed time data must register the requirement (see “Access Timers Programmatically” on page 16-5). A triggered subsystem then allocates and maintains a single elapsed time counter if required. This timer functions at the subsystem level, not at the individual block level. The timer is generated if the triggered subsystem (or a unconditionally executed subsystem within the triggered subsystem) contains one or more blocks requiring elapsed time data.

---

**Note** If you are using simplified initialization mode, elapsed time is reset on first execution after becoming enabled, whether or not the subsystem is configured to reset on enable. For more information, see “Underspecified initialization detection” (Simulink).

## Access Timers Programmatically

### In this section...

“About Timer APIs” on page 16-5

“C API for S-Functions” on page 16-5

“TLC API for Code Generation” on page 16-7

### About Timer APIs

This topic describes APIs that let your S-functions take advantage of the efficiencies offered by absolute and elapsed timers. SimStruct macros are provided for use in simulation, and TLC functions are provided for inlined code generation. Note that

- To generate and use the new timers as described above, your S-functions must register the need to use an absolute or elapsed timer by calling `ssSetNeedAbsoluteTime` or `ssSetNeedElapseTime` in `mdlInitializeSampleTime`.
- Existing S-functions that read absolute time but do not register by using these macros continue to operate as expected, but generate less efficient code.

### C API for S-Functions

The SimStruct macros described in this topic provide access to absolute and elapsed timers for S-functions during simulation.

In the functions below, the SimStruct `*S` argument is a pointer to the `simstruct` of the calling S-function.

- `void ssSetNeedAbsoluteTime(SimStruct *S, boolean b)`: if `b` is `TRUE`, registers that the calling S-function requires absolute time data, and allocates an absolute time counter for the rate at which the S-function executes (if such a counter has not already been allocated).
- `int ssGetNeedAbsoluteTime(SimStruct *S)`: returns 1 if the S-function has registered that it requires absolute time.
- `double ssGetTaskTime(SimStruct *S, tid)`: read absolute time for a given task with task identifier `tid`. `ssGetTaskTime` operates transparently, regardless of whether or not you use the new timer features. `ssGetTaskTime` is documented in the SimStruct Functions chapter of the Simulink documentation.

- `void ssSetNeedElapseTime(SimStruct *S, boolean b)`: if `b` is `TRUE`, registers that the calling S-function requires elapsed time data, and allocates an elapsed time counter for the triggered subsystem in which the S-function executes (if such a counter has not already been allocated). See also “Elapsed Time Counters in Triggered Subsystems” on page 16-4.
- `int ssGetNeedElapseTime(SimStruct *S)`: returns 1 if the S-function has registered that it requires elapsed time.
- `void ssGetElapseTime(SimStruct *S, (double *)elapseTime)`: returns, to the location pointed to by `elapseTime`, the value (as a double) of the elapsed time counter associated with the S-function.
- `void ssGetElapseTimeCounterDtype(SimStruct *S, (int *)dtype)`: returns the data type of the elapsed time counter associated with the S-function to the location pointed to by `dtype`. This function is intended for use with the `ssGetElapseTimeCounter` function (see below).
- `void ssGetElapseResolution(SimStruct *S, (double *)resolution)`: returns the resolution (that is, the sample time) of the elapsed time counter associated with the S-function to the location pointed to by `resolution`. This function is intended for use with the `ssGetElapseTimeCounter` function (see below).
- `void ssGetElapseTimeCounter(SimStruct *S, (void *)elapseTime)`: This function is provided for the use of blocks that require the elapsed time values for fixed-point computations. `ssGetElapseTimeCounter` returns, to the location pointed to by `elapseTime`, the integer value of the elapsed time counter associated with the S-function. If the counter size is 64 bits, the value is returned as an array of two 32-bit words, with the low-order word stored at the lower address.

To determine how to access the returned counter value, obtain the data type of the counter by calling `ssGetElapseTimeCounterDtype`, as in the following code:

```
int *y_dtype;
ssGetElapseTimeCounterDtype(S, y_dtype);

switch(*y_dtype) {
 case SS_DOUBLE_UINT32:
 {
 uint32_T dataPtr[2];
 ssGetElapseTimeCounter(S, dataPtr);
 }
 break;
 case SS_UINT32:
 {
```

```

 uint32_T dataPtr[1];
 ssGetElapseTimeCounter(S, dataPtr);
 }
 break;
case SS_UINT16:
 {
 uint16_T dataPtr[1];
 ssGetElapseTimeCounter(S, dataPtr);
 }
 break;
case SS_UINT8:
 {
 uint8_T dataPtr[1];
 ssGetElapseTimeCounter(S, dataPtr);
 }
 break;
case SS_DOUBLE:
 {
 real_T dataPtr[1];
 ssGetElapseTimeCounter(S, dataPtr);
 }
 break;
default:
 ssSetErrorStatus(S, "Invalid data type for elapse time
 counter");
 break;
}

```

If you want to use the actual elapsed time, issue a call to the `ssGetElapseTime` function to access the elapsed time directly. You do not need to get the counter value and then calculate the elapsed time.

```

double *y_elapseTime;
.
.
.
ssGetElapseTime(S, elapseTime)

```

## TLC API for Code Generation

The following TLC functions support elapsed time counters in generated code when you inline S-functions by writing TLC scripts for them.

- `LibGetTaskTimeFromTID(block)`: Generates code to read the absolute time for the task in which `block` executes.

`LibGetTaskTimeFromTID` is documented with other sample time functions in the TLC Function Library Reference pages of the Target Language Compiler documentation.

---

**Note** Do not use `LibGetT` for this purpose. `LibGetT` always reads the base rate (`tid 0`) timer. If `LibGetT` is called for a block executing at a subrate, the wrong timer is read, causing serious errors.

---

- `LibGetElapseTime(system)`: Generates code to read the elapsed time counter for `system`. (`system` is the parent system of the calling block.) See “Generate Code for an Elapsed Time Counter” on page 16-9 for an example of code generated by this function.
- `LibGetElapseTimeCounter(system)`: Generates code to read the integer value of the elapsed time counter for `system`. (`system` is the parent system of the calling block.) This function should be used in conjunction with `LibGetElapseTimeCounterDtypeId` and `LibGetElapseTimeResolution`. (See the discussion of `ssGetElapseTimeCounter` above.)
- `LibGetElapseTimeCounterDtypeId(system)`: Generates code that returns the data type of the elapsed time counter for `system`. (`system` is the parent system of the calling block.)
- `LibGetElapseTimeResolution(system)`: Generates code that returns the resolution of the elapsed time counter for `system`. (`system` is the parent system of the calling block.)

## Generate Code for an Elapsed Time Counter

This example shows a model that includes a triggered subsystem, `Amplifier`, consisting of a Discrete-Time Integrator block that uses an elapsed time counter. The model `ex_elapseTime` is in the folder `matlab/help/toolbox/rtw/examples`.

### `ex_elapseTime` Model

### Amplifier Subsystem

Code in the generated header file `ex_elapseTime.h` for the model uses 64 bits to implement the timer for the base rate (`clockTick0` and `clockTick0H0`).

```

/*
 * Timing:
 * The following substructure contains information regarding
 * the timing information for the model.
 */
struct {
 time_T taskTime0;
 uint32_T clockTick0;

```

```

uint32_T clockTickH0;
time_T stepSize0;
time_T tFinal;
boolean_T stopRequestedFlag;
} Timing;

```

The code generator allocates storage for the previous-time value and elapsed-time value of the Amplifier subsystem (Amplifier\_PREV\_T) in the D\_Work(states) structure in ex\_elapsedTime.h.

```

/* Block states (auto storage) for system '<Root>' */
typedef struct {
 real_T DiscreteTimeIntegrator_DSTATE;
 /* '<S1>/Discrete-Time Integrator' */
 int32_T clockTickCounter;
 /* '<Root>/Pulse Generator' */
 uint32_T Amplifier_ELAPS_T[2];
 /* '<Root>/Amplifier' */
 uint32_T Amplifier_PREV_T[2];
 /* '<Root>/Amplifier' */
} DW_ex_elapseTime_T;

```

The elapsed time computation is performed as follows within the ex\_elapseTime\_step function:

```

/* ---
 Outputs for Triggered SubSystem:
 '<Root>/Amplifier' incorporates:
 TriggerPort: '<S1>/Trigger'
--- */
zcEvent = rt_ZCFcn(RISING_ZERO_CROSSING,
 &ex_elapseTime_PrevZCX.Amplifier_Trig_ZCE,
 ((real_T)rtb_PulseGenerator));
if (zcEvent != NO_ZCEVENT) {
 elapseT_H = ex_elapseTime_M->Timing.clockTickH0 -
 ex_elapseTime_DW.Amplifier_PREV_T[1];
 if (ex_elapseTime_DW.Amplifier_PREV_T[0] >
 ex_elapseTime_M->Timing.clockTick0) {
 elapseT_H--;
 }

 ex_elapseTime_DW.Amplifier_ELAPS_T[0] =
 ex_elapseTime_M->Timing.clockTick0
 - ex_elapseTime_DW.Amplifier_PREV_T[0];
 ex_elapseTime_DW.Amplifier_PREV_T[0] =

```

```

 ex_elapsedTime_M->Timing.clockTick0;
 ex_elapsedTime_DW.Amplifier_ELAPS_T[1] =
 elapseT_H;
 ex_elapsedTime_DW.Amplifier_PREV_T[1] =
 ex_elapsedTime_M->Timing.clockTickH0;

```

As shown above, the elapsed time is maintained as a state of the triggered subsystem. The Discrete-Time Integrator block finally performs its output and update computations using the elapsed time.

```

/* ---
DiscreteIntegrator: '<S1>/Discrete-Time Integrator'
--- */
OUTPUT = ex_elapsedTime_DW.DiscreteTimeIntegrator_DSTATE;

/* ---
Update for DiscreteIntegrator:
'<S1>/Discrete-Time Integrator' incorporates:
 Constant: '<Root>/Constant'
--- */
 ex_elapsedTime_DW.DiscreteTimeIntegrator_DSTATE += 0.3 * (real_T)
 ex_elapsedTime_DW.Amplifier_ELAPS_T[0] * 1.5;

```

### More About

- “Absolute and Elapsed Time Computation” (Simulink Coder)
- “Absolute Time Limitations” (Simulink Coder)

## Absolute Time Limitations

*Absolute time* is the time that has elapsed from the beginning of program execution to the present time, as distinct from *elapsed time*, the interval between two events. See “Absolute and Elapsed Time Computation” on page 16-2 for more information.

When you design an application that is intended to run indefinitely, you must take care when logging time values, or using charts or blocks that depend on absolute time. If the value of time reaches the largest value that can be represented by the data type used by the timer to store time, the timer overflows and the logged time or block output is incorrect.

If your target uses `rtModel`, you can avoid timer overflow by specifying a value for the **Application life span** parameter. See “Integer Timers in Generated Code” on page 16-3 for more information.

The following limitations apply to absolute time:

- If you log time values by opening the Configuration Parameters dialog box and enabling **Data Import/Export > Time** parameter, your model uses absolute time.
- Every Stateflow chart that uses time is dependent on absolute time. The only way to eliminate the dependency is to change the Stateflow chart to not use time.
- The following Simulink blocks depend on absolute time:
  - Backlash
  - Chirp Signal
  - Clock
  - Derivative
  - Digital Clock
  - Discrete-Time Integrator (only when used in triggered subsystems)
  - From File
  - From Workspace
  - Pulse Generator
  - Ramp
  - Rate Limiter
  - Repeating Sequence

- Signal Generator
- Sine Wave (only when the **Sine type** parameter is set to Time-based)
- Step
- To File
- To Workspace (only when logging to StructureWithTime format)
- Transport Delay
- Variable Time Delay
- Variable Transport Delay

In addition to the Simulink blocks above, blocks in other blocksets may depend on absolute time. See the documentation for the blocksets that you use.

“Execution During Simulink Model Simulation” on page 17-5

“Model Execution in Real Time” on page 17-5

“Single-Tasking Versus Multitasking Operation” on page 17-6

### Sample Time Considerations

Simulink models run at one or more sample times. The Simulink product provides considerable flexibility in building multirate systems, that is, systems with more than one sample time. However, this same flexibility also allows you to construct models for which the code generator cannot generate real-time code for execution in a multitasking environment. To make multirate models operate as expected in real time (that is, to give the right answers), you sometimes must modify your model or instruct the Simulink engine to modify the model for you. In general, the modifications involve placing Rate Transition blocks between blocks that have unequal sample times. The following sections discuss issues you must address to use a multirate model in a multitasking environment. For a comprehensive discussion of sample times, including rate transitions, see “What Is Sample Time?” (Simulink), “Sample Times in Subsystems” (Simulink), “Sample Times in Systems” (Simulink), “Resolve Rate Transitions” (Simulink), and associated topics.

### Tasking Modes

There are two execution modes for a fixed-step Simulink model: single-tasking and multitasking. These modes are available only for fixed-step solvers. To select an execution mode, use the **Treat each discrete rate as a separate task** checkbox on the **Solver** pane of the Configuration Parameters dialog box. When this parameter is selected, multitasking execution is applied for a multirate model. When this option is cleared, single-tasking execution is applied.

---

**Note** A model that is multirate and uses multitasking cannot reference a multirate model that uses single-tasking.

---

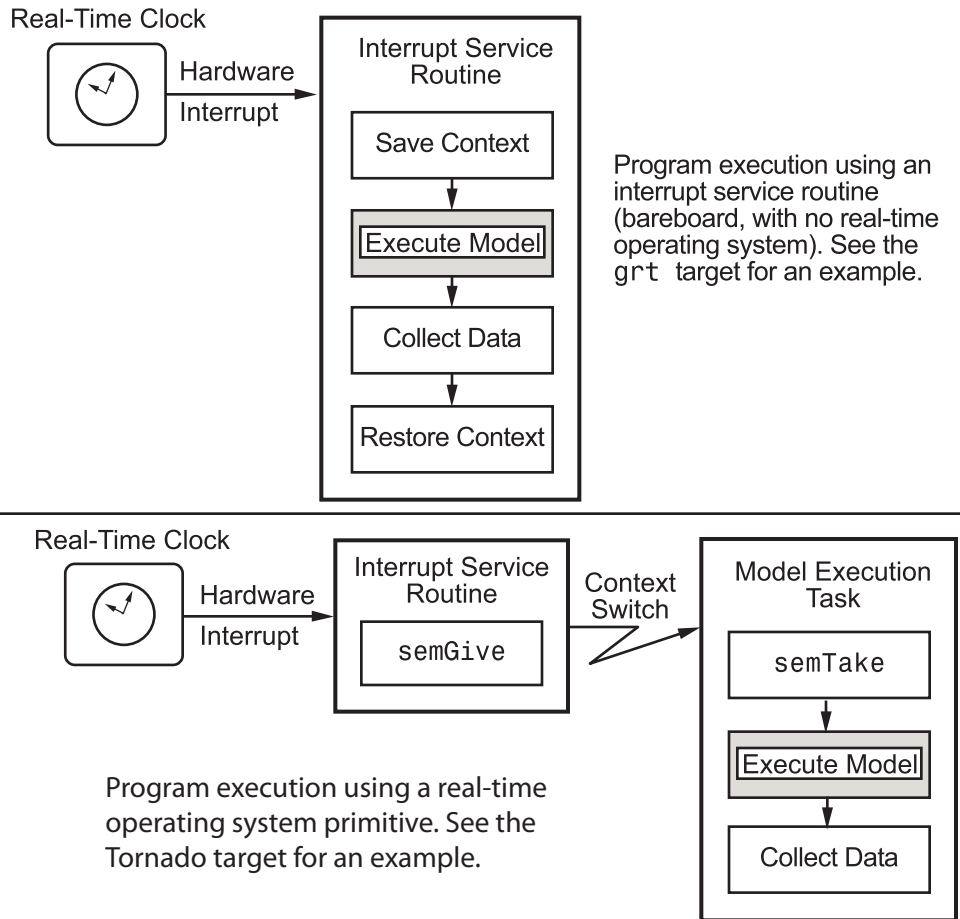

Execution of models in a real-time system can be done with the aid of a real-time operating system, or it can be done on *bare-metal* target hardware, where the model runs in the context of an interrupt service routine (ISR).

The fact that a system (such as The Open Group UNIX or Microsoft Windows systems) is multitasking does not imply that your program can execute in real time. This is because the program might not preempt other processes when required.

In operating systems (such as PC-DOS) where only one process can exist at a given time, an interrupt service routine (ISR) must perform the steps of saving the processor context, executing the model code, collecting data, and restoring the processor context.

Other operating systems, such as POSIX-compliant ones, provide automatic context switching and task scheduling. This simplifies the operations performed by the ISR. In this case, the ISR simply enables the model execution task, which is normally blocked. The next figure illustrates this difference.

## Model Execution and Rate Transitions

To generate code that executes as expected in real time, you (or the Simulink engine) might need to identify and handle sample rate transitions within the model. In multitasking mode, by default the Simulink engine flags errors during simulation if the model contains invalid rate transitions, although you can use the **Multitask rate transition** diagnostic to alter this behavior. A similar diagnostic, called **Single task rate transition**, exists for single-tasking mode.

To avoid raising rate transition errors, insert Rate Transition blocks between tasks. You can request that the Simulink engine handle rate transitions automatically by inserting hidden Rate Transition blocks. See “Automatic Rate Transition” on page 17-26 for an explanation of this option.

To understand such problems, first consider how Simulink simulations differ from real-time programs.

## **Execution During Simulink Model Simulation**

Before the Simulink engine simulates a model, it orders the blocks based upon their topological dependencies. This includes expanding virtual subsystems into the individual blocks they contain and flattening the entire model into a single list. Once this step is complete, each block is executed in order.

The key to this process is the ordering of blocks. A block whose output is directly dependent on its input (that is, a block with direct feedthrough) cannot execute until the block driving its input executes.

Some blocks set their outputs based on values acquired in a previous time step or from initial conditions specified as a block parameter. The output of such a block is determined by a value stored in memory, which can be updated independently of its input. During simulation, computations are performed prior to advancing the variable corresponding to time. This results in computations occurring instantaneously (that is, no computational delay).

## **Model Execution in Real Time**

A real-time program differs from a Simulink simulation in that the program must execute the model code synchronously with real time. Every calculation results in some computational delay. This means the sample intervals cannot be shortened or lengthened (as they can be in a Simulink simulation), which leads to less efficient execution.

Consider the following timing figure.

Note the processing inefficiency in the sample interval  $t_1$ . That interval cannot be compressed to increase execution speed because, by definition, sample times are clocked in real time.

You can circumvent this potential inefficiency by using the multitasking mode. The multitasking mode defines tasks with different priorities to execute parts of the model code that have different sample rates.

See “Multitasking and Pseudomultitasking Modes” on page 17-12 for a description of how this works. It is important to understand that section before proceeding here.

## Single-Tasking Versus Multitasking Operation

Single-tasking programs require longer sample intervals, because all computations must be executed within each clock period. This can result in inefficient use of available CPU time, as shown in the previous figure.

Multitasking mode can improve the efficiency of your program if the model is large and has many blocks executing at each rate.

However, if your model is dominated by a single rate, and only a few blocks execute at a slower rate, multitasking can actually degrade performance. In such a model, the overhead incurred in task switching can be greater than the time required to execute the slower blocks. In this case, it is more efficient to execute all blocks at the dominant rate.

If you have a model that can benefit from multitasking execution, you might need to modify your model by adding Rate Transition blocks (or instruct the Simulink engine to do so) to generate expected results.

For more information about the two modes of execution and examples, see “Modeling for Single-Tasking Execution” on page 17-8 and “Modeling for Multitasking Execution” on page 17-12.

## Modeling for Single-Tasking Execution

### Single-Tasking Mode

You can execute model code in a strictly single-tasking manner. While this mode is less efficient with regard to execution speed, in certain situations, it can simplify your model.

In single-tasking mode, the base sample rate must define a time interval that is long enough to allow the execution of all blocks within that interval.

The next figure illustrates the inefficiency inherent in single-tasking execution.

Single-tasking system execution requires a base sample rate that is long enough to execute one step through the entire model.

### Build a Program for Single-Tasking Execution

To use single-tasking execution, clear the **Treat each discrete rate as a separate task** checkbox on the **Solver** pane of the Configuration Parameters dialog box. If you select the checkbox, single-tasking mode is used in the following cases:

- If your model contains one sample time
- If your model contains a continuous and a discrete sample time and the fixed step size is equal to the discrete sample time

### Single-Tasking Execution

This example examines how a simple multirate model executes in both real time and simulation, using a fixed-step solver. It considers operation in both single-tasking and multitasking modes, as determined by setting of the **Treat each discrete rate as a separate task** parameter on the **Solver** pane.

The example model is shown in the next figure. The discussion refers to the six blocks of the model as A through F, as labeled in the block diagram.

The execution order of the blocks (indicated in the upper right of each block) has been forced into the order shown by assigning higher priorities to blocks F, E, and D. The ordering shown is one possible valid execution ordering for this model. For more information, see “Simulation Phases in Dynamic Systems” (Simulink).

The execution order is determined by data dependencies between blocks. In a real-time system, the execution order determines the order in which blocks execute within a given time interval or task. This discussion treats the model's execution order as a given, because it is concerned with the allocation of block computations to tasks, and the scheduling of task execution.

---

**Note** The discussion and timing diagrams in this section are based on the assumption that the Rate Transition blocks are used in the default (protected/deterministic) mode, with the **Ensure data integrity during data transfer** and **Ensure deterministic data transfer (maximum delay)** options on.

---

This example considers the execution of the above model when the **Treat each discrete rate as a separate task** checkbox is cleared, which indicates the single-tasking mode.

In a single-tasking system, if the **Configuration Parameters > Optimization > Advanced parameters > Block reduction** option is selected, fast-to-slow Rate Transition blocks are optimized out of the model. The default case is shown (**Block reduction** selected), so block B does not appear in the timing diagrams in this section. For more information, see “Block reduction” (Simulink).

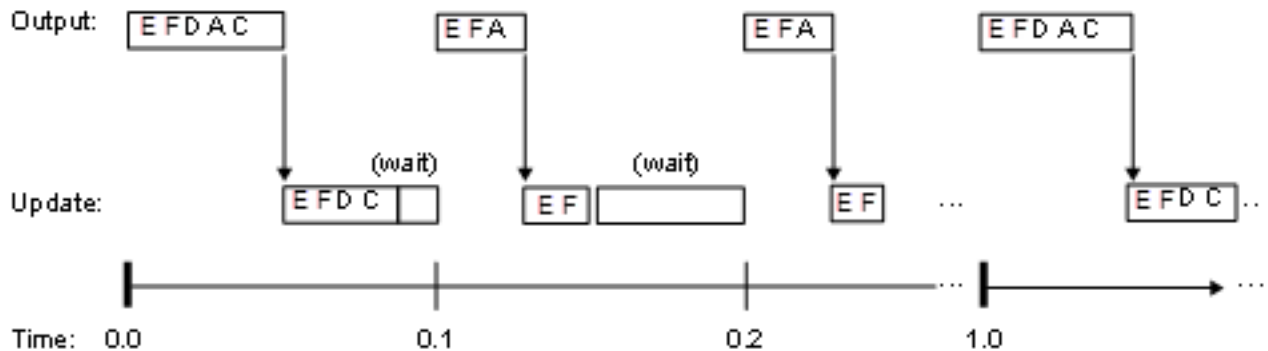

The following table shows, for each block in the model, the execution order, sample time, and whether the block has an output or update computation. Block A does not have discrete states, and accordingly does not have an update computation.

**Execution Order and Sample Times (Single-Tasking)**

| Blocks<br>(in Execution Order) | Sample Time<br>(in Seconds) | Output | Update |
|--------------------------------|-----------------------------|--------|--------|
| E                              | 0.1                         | Y      | Y      |
| F                              | 0.1                         | Y      | Y      |
| D                              | 1                           | Y      | Y      |
| A                              | 0.1                         | Y      | N      |
| C                              | 1                           | Y      | Y      |

**Real-Time Single-Tasking Execution**

The next figure shows the scheduling of computations when the generated code is deployed in a real-time system. The generated program is shown running in real time, under control of interrupts from a 10 Hz timer.

At time 0.0, 1.0, and every second thereafter, both the slow and fast blocks execute their output computations; this is followed by update computations for blocks that have states. Within a given time interval, output and update computations are sequenced in block execution order.

The fast blocks execute on every tick, at intervals of 0.1 second. Output computations are followed by update computations.

The system spends some portion of each time interval (labeled “wait”) idling. During the intervals when only the fast blocks execute, a larger portion of the interval is spent idling. This illustrates an inherent inefficiency of single-tasking mode.

## Simulated Single-Tasking Execution

The next figure shows the execution of the model during the Simulink simulation loop.

Because time is simulated, the placement of ticks represents the iterations of the simulation loop. Blocks execute in exactly the same order as in the previous figure, but without the constraint of a real-time clock. Therefore there is no idle time between simulated sample periods.

## Modeling for Multitasking Execution

### Multitasking and Pseudomultitasking Modes

When periodic tasks execute in a multitasking mode, by default the blocks with the fastest sample rates are executed by the task with the highest priority, the next fastest blocks are executed by a task with the next higher priority, and so on. Time available in between the processing of high-priority tasks is used for processing lower priority tasks. This results in efficient program execution.

Where tasks are asynchronous rather than periodic, there may not necessarily be a relationship between sample rates and task priorities; the task with the highest priority need not have the fastest sample rate. You specify asynchronous task priorities using Async Interrupt and Task Sync blocks. You can switch the sense of what priority numbers mean by selecting or deselecting the Solver option **Higher priority value indicates higher task priority**.

In multitasking environments (that is, under a real-time operating system), you can define separate tasks and assign them priorities. For bare-metal target hardware (that is, no real-time operating system present), you cannot create separate tasks. However, generated application modules implement what is effectively a multitasking execution scheme using overlapped interrupts, accompanied by programmatic context switching.

This means an interrupt can occur while another interrupt is currently in progress. When this happens, the current interrupt is preempted, the floating-point unit (FPU) context is saved, and the higher priority interrupt executes its higher priority (that is, faster sample rate) code. Once complete, control is returned to the preempted ISR.

The next figures illustrate how timing of tasks in multirate systems are handled by the code generator in multitasking, pseudomultitasking, and single-tasking environments.

- ↑ Vertical arrows indicate sample time hits.
- ⋮ Dotted lines with downward pointing arrows indicate the release of control to a lower priority task.
- ⋮ Dotted lines with upward pointing arrows indicate preemption by a higher priority task.
- Dark gray areas indicate task execution.
- ▨ Hashed areas indicate task preemption by a higher priority task.
- Light gray areas indicate task execution is pending.

The next figure shows how overlapped interrupts are used to implement pseudomultitasking. In this case, Interrupt 0 does not return until after Interrupts 1, 2, and 3.

## Build a Program for Multitasking Execution

To use multitasking execution, select the **Treat each discrete rate as a separate task** check box on the **Solver** pane of the Configuration Parameters dialog box. This menu is active only if you select **Fixed-step** as the solver type. Auto mode results in a multitasking environment if your model has two or more different sample times. A model with a continuous and a discrete sample time runs in single-tasking mode if the fixed-step size is equal to the discrete sample time.

## Execute Multitasking Models

In cases where the continuous part of a model executes at a rate that is different from the discrete part, or a model has blocks with different sample rates, the Simulink engine assigns each block a *task identifier* (*tid*) to associate the block with the task that executes at the block's sample rate.

You set sample rates and their constraints on the **Solver** pane of the Configuration Parameters dialog box. To generate code, select **Fixed-step** for the solver type. Certain restrictions apply to the sample rates that you can use:

- The sample rate of a block must be an integer multiple of the base (that is, the fastest) sample period.
- When **Periodic sample time constraint** is unconstrained, the base sample period is determined by the **Fixed step size** specified on the **Solvers** pane of the Configuration parameters dialog box.
- When **Periodic sample time constraint** is Specified, the base rate fixed-step size is the first element of the sample time matrix that you specify in the companion option **Sample time properties**. The **Solver** pane from the example model `rtwdemo_mrmtbb` shows an example.

Higher priority value indicates higher task priority

- Continuous blocks execute by using an integration algorithm that runs at the base sample rate. The base sample period is the greatest common denominator of all rates in the model only when **Periodic sample time constraint** is set to Unconstrained and **Fixed step size** is Auto.
- The continuous and discrete parts of the model can execute at different rates only if the discrete part is executed at the same or a slower rate than the continuous part and is an integer multiple of the base sample rate.

## Multitasking Execution

This example examines how a simple multirate model executes in both real time and simulation, using a fixed-step solver. It considers operation in both single-tasking and multitasking modes, as determined by setting of the **Treat each discrete rate as a separate task** parameter on the **Solver** pane.

The example model is shown in the next figure. The discussion refers to the six blocks of the model as A through F, as labeled in the block diagram.

The execution order of the blocks (indicated in the upper right of each block) has been forced into the order shown by assigning higher priorities to blocks F, E, and D. The ordering shown is one possible valid execution ordering for this model. For more information, see “Simulation Phases in Dynamic Systems” (Simulink).

The execution order is determined by data dependencies between blocks. In a real-time system, the execution order determines the order in which blocks execute within a given time interval or task. This discussion treats the model's execution order as a given, because it is concerned with the allocation of block computations to tasks, and the scheduling of task execution.

**Note** The discussion and timing diagrams in this section are based on the assumption that the Rate Transition blocks are used in the default (protected/deterministic) mode,

with the **Ensure data integrity during data transfer** and **Ensure deterministic data transfer (maximum delay)** options on.

---

This example considers the execution of the above model when the solver **Tasking mode** is `MultiTasking`. Block computations are executed under two tasks, prioritized by rate:

- The slower task, which gets the lower priority, is scheduled to run every second. This is called the *1 second task*.
- The faster task, which gets higher priority, is scheduled to run 10 times per second. This is called the *0.1 second task*. The 0.1 second task can preempt the 1 second task.

The following table shows, for each block in the model, the execution order, the task under which the block runs, and whether the block has an output or update computation. Blocks A and B do not have discrete states, and accordingly do not have an update computation.

### Task Allocation of Blocks in Multitasking Execution

| Blocks<br>(in Execution Order) | Task                                                                                                                                                                                                                                                                                                        | Output | Update |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|--------|
| E                              | 0.1 second task                                                                                                                                                                                                                                                                                             | Y      | Y      |
| F                              | 0.1 second task                                                                                                                                                                                                                                                                                             | Y      | Y      |

| C                              | 1 second task                                                                                                                                                                                                                                                                                               | Y      | Y      |

### Real-Time Multitasking Execution

The next figure shows the scheduling of computations in `MultiTasking` solver mode when the generated code is deployed in a real-time system. The generated program is shown running in real time, as two tasks under control of interrupts from a 10 Hz timer.

**Simulated Multitasking Execution**

The next figure shows the Simulink execution of the same model, in MultiTasking solver mode. In this case, the Simulink engine runs the blocks in one thread of execution, simulating multitasking. No preemption occurs.

# Handle Rate Transitions

## Rate Transitions

Two periodic sample rate transitions can exist within a model:

- A faster block driving a slower block
- A slower block driving a faster block

The following sections concern models with periodic sample times with zero offset only. Other considerations apply to multirate models that involve asynchronous tasks. For details on how to generate code for asynchronous multitasking, see “Asynchronous Support” (Simulink Coder).

In multitasking and pseudomultitasking systems, differing sample rates can cause blocks to be executed in the wrong order. To prevent possible errors in calculated data, you must control model execution at these transitions. When connecting faster and slower blocks, you or the Simulink engine must add Rate Transition blocks between them. Fast-to-slow transitions are illustrated in the next figure.

becomes

Slow-to-fast transitions are illustrated in the next figure.

becomes

---

**Note** Although the Rate Transition block offers a superset of the capabilities of the Unit Delay block (for slow-to-fast transitions) and the Zero-Order Hold block (for fast-to-slow transitions), you should use the Rate Transition block instead of these blocks.

---

## Data Transfer Problems

Rate Transition blocks deal with issues of data integrity and determinism associated with data transfer between blocks running at different rates.

- *Data integrity*: A problem of data integrity exists when the input to a block changes during the execution of that block. Data integrity problems can be caused by preemption.

Consider the following scenario:

- A faster block supplies the input to a slower block.
- The slower block reads an input value  $V_1$  from the faster block and begins computations using that value.
- The computations are preempted by another execution of the faster block, which computes a new output value  $V_2$ .
- A data integrity problem now arises: when the slower block resumes execution, it continues its computations, now using the “new” input value  $V_2$ .

Such a data transfer is called *unprotected*. “Faster to Slower Transitions in Real Time” on page 17-30 shows an unprotected data transfer.

In a *protected* data transfer, the output  $V_1$  of the faster block is held until the slower block finishes executing.

- *Deterministic* versus *nondeterministic* data transfer: In a *deterministic* data transfer, the timing of the data transfer is completely predictable, as determined by the sample rates of the blocks.

The timing of a *nondeterministic* data transfer depends on the availability of data, the sample rates of the blocks, and the time at which the receiving block begins to execute relative to the driving block.

You can use the Rate Transition block to protect data transfers in your application and make them deterministic. These characteristics are considered desirable in most applications. However, the Rate Transition block supports flexible options that allow you to compromise data integrity and determinism in favor of lower latency. The next section summarizes these options.

## Data Transfer Assumptions

When processing data transfers between tasks, the code generator makes these assumptions:

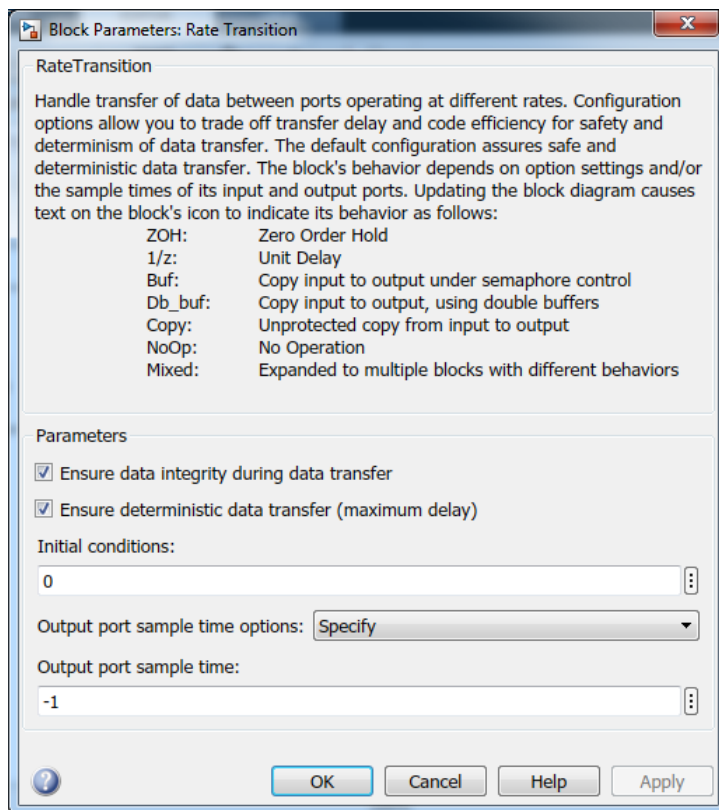

- Data transitions occur between a single reading task and a single writing task.
- A read or write of a byte-sized variable is atomic.
- When two tasks interact through a data transition, only one of them can preempt the other.
- For periodic tasks, the faster rate task has higher priority than the slower rate task; the faster rate task preempts the slower rate task.
- All tasks run on a single processor. Time slicing is not allowed.
- Processes do not crash or restart (especially while data is transferred between tasks).

## Rate Transition Block Options

Several parameters of the Rate Transition block are relevant to its use in code generation for real-time execution, as discussed below. For a complete block description, see Rate Transition.

The Rate Transition block handles periodic (fast to slow and slow to fast) and asynchronous transitions. When inserted between two blocks of differing sample rates, the Rate Transition block automatically configures its input and output sample rates for the type of transition; you do not need to specify whether a transition is slow-to-fast or fast-to-slow (low-to-high or high-to-low priorities for asynchronous tasks).

The critical decision you must make in configuring a Rate Transition block is the choice of data transfer mechanism to be used between the two rates. Your choice is dictated by considerations of safety, memory usage, and performance. As the Rate Transition block parameter dialog box in the next figure shows, the data transfer mechanism is controlled by two options.

- **Ensure data integrity during data transfer**: When this option is on, data transferred between rates maintains its integrity (the data transfer is protected).

When this option is off, the data might not maintain its integrity (the data transfer is unprotected). By default, **Ensure data integrity during data transfer** is on.

- **Ensure deterministic data transfer (maximum delay)**: This option is supported for periodic tasks with an offset of zero and fast and slow rates that are multiples of each other. Enable this option for protected data transfers (when **Ensure data integrity during data transfer** is on). When this option is on, the Rate Transition block behaves like a Zero-Order Hold block (for fast to slow transitions) or a Unit Delay block (for slow to fast transitions). The Rate Transition block controls the timing of data transfer in a completely predictable way. When this option is off, the data transfer is nondeterministic. By default, **Ensure deterministic data transfer (maximum delay)** is on for transitions between periodic rates with an offset of zero; for asynchronous transitions, it cannot be selected.

Thus the Rate Transition block offers three modes of operation with respect to data transfer. In order of level of safety:

- **Protected/Deterministic (default)**: This is the safest mode. The drawback of this mode is that it introduces deterministic latency into the system for the case of slow-to-fast periodic rate transitions. For that case, the latency introduced by the Rate Transition block is one sample period of the slower task. For the case of fast-to-slow periodic rate transitions, the Rate Transition block introduces no additional latency.
- **Protected/NonDeterministic**: In this mode, for slow-to-fast periodic rate transitions, data integrity is protected by double-buffering data transferred between rates. For fast-to-slow periodic rate transitions, a semaphore flag is used. The blocks downstream from the Rate Transition block use the latest available data from the block that drives the Rate Transition block. Maximum latency is less than or equal to one sample period of the faster task.

The drawbacks of this mode are its nondeterministic timing. The advantage of this mode is its low latency.

- **Unprotected/NonDeterministic**: This mode is not recommended for mission-critical applications. The latency of this mode is the same as for Protected/NonDeterministic mode, but memory requirements are reduced since neither double-buffering nor semaphores are required. That is, the Rate Transition block does nothing in this mode other than to pass signals through; it simply exists to notify you that a rate transition exists (and can cause generated code to compute incorrect answers). Selecting this mode, however, generates the least amount of code.

**Note** In unprotected mode (**Ensure data integrity during data transfer** option off), the Rate Transition block does nothing other than allow the rate transition to exist in the model.

---

## Rate Transition Blocks and Continuous Time

The sample time at the output port of a Rate Transition block can only be discrete or fixed in minor time step. This means that when a Rate Transition block inherits continuous sample time from its destination block, it treats the inherited sample time as Fixed in Minor Time Step. Therefore, the output function of the Rate Transition block runs only at major time steps. If the destination block sample time is continuous, Rate Transition block output sample time is the base rate sample time (if solver is fixed-step), or zero-order-hold-continuous sample time (if solver is variable-step).

## Automatic Rate Transition

The Simulink engine can detect mismatched rate transitions in a multitasking model during an update diagram and automatically insert Rate Transition blocks to handle them. To enable this, in the **Solver** pane of model configuration parameters, select **Automatically handle rate transition for data transfer**. The default setting for this option is off. When you select this option:

- Simulink handles transitions between periodic sample times and asynchronous tasks.
- Simulink inserts hidden Rate Transition blocks in the block diagram.
- The code generator produces code for the Rate Transition blocks that were automatically inserted. This code is identical to the code generated for Rate Transition blocks that were inserted manually.
- Automatically inserted Rate Transition blocks operate in protected mode for periodic tasks and asynchronous tasks. You cannot alter this behavior. For periodic tasks, automatically inserted Rate Transition blocks operate with the level of determinism specified by the **Deterministic data transfer** parameter in the **Solver** pane. The default setting is **Whenever possible**, which enables determinism for data transfers between periodic sample-times that are related by an integer multiple. For more information, see “Deterministic data transfer” (Simulink). To use other modes, you must insert Rate Transition blocks and set their modes manually.

For example, in this model, SineWave2 has a sample time of 2, and SineWave3 has a sample time of 3.

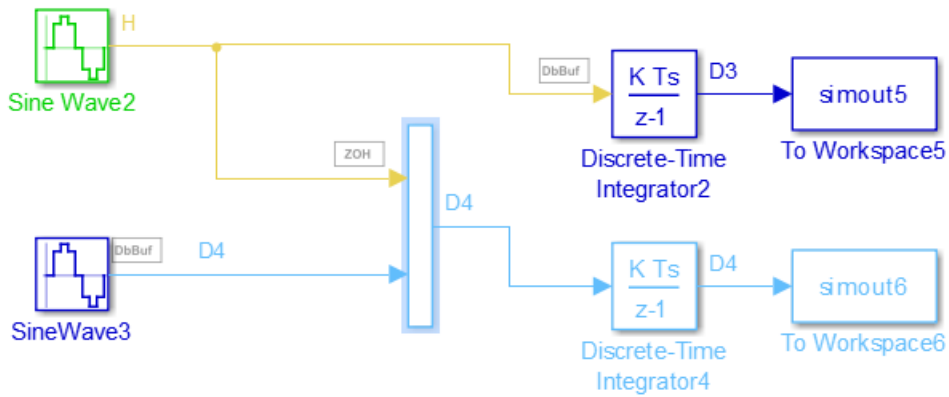

When you select **Automatically handle rate transition for data transfer**, Simulink inserts a Rate Transition block between each Sine Wave block and the Product block. The inserted blocks have the parameter values to reconcile the Sine Wave block sample times.

If the input port and output port data sample rates in a model are not multiples of each other, Simulink inserts a Rate Transition block whose sample rate is the greatest common divisor (GCD) of the two rates. If no other block in the model contains this new rate, an error occurs during simulation. In this case, you must insert a Rate Transition block manually.

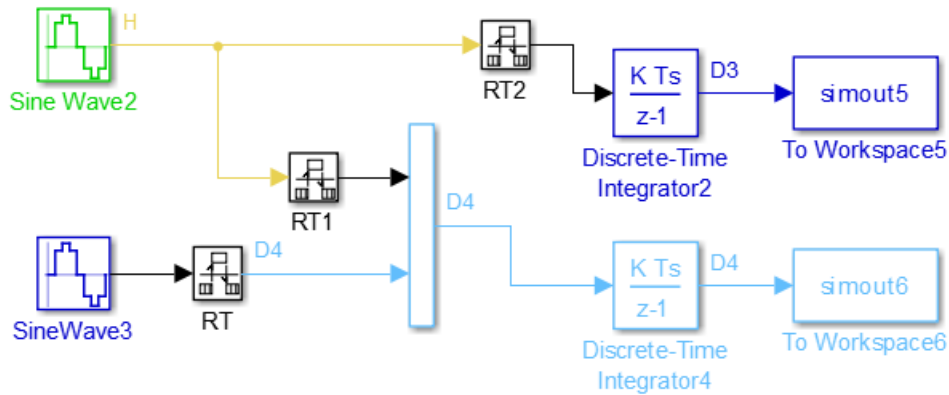

## Visualize Inserted Rate Transition Blocks

When you select the **Automatically handle rate transition for data transfer** option, Simulink inserts Rate Transition blocks in the paths that have mismatched transition rates. These blocks are hidden by default. To visualize the inserted blocks, update the diagram. Badge labels appear in the model and indicate where Simulink inserted Rate Transition blocks during the compilation phase. For example, in this model, three Rate Transition blocks were inserted between the two Sine Wave blocks and the Multiplexer and Integrator when the model compiled. The ZOH and DbBuf badge labels indicate these blocks.

You can show or hide badge labels using the **Display > Signals and Ports > Hidden Rate Transition Block Indicators** setting.

To configure the hidden Rate Transition blocks, right click on a badge label and click on **Insert rate transition block** to make the block visible.

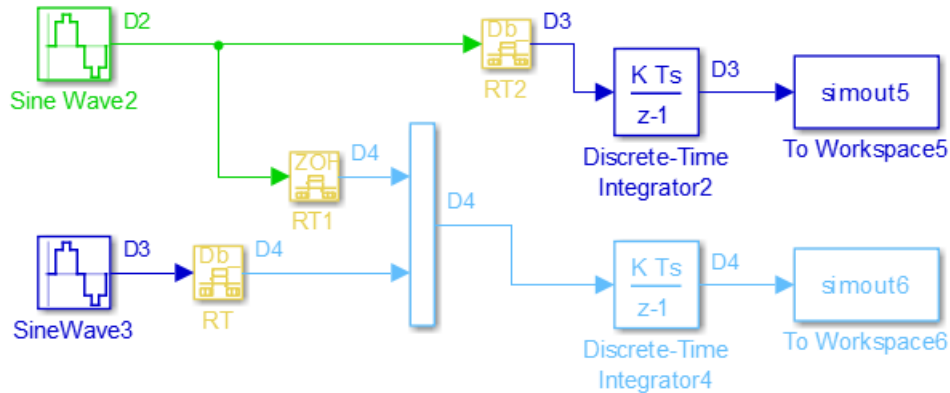

When you make hidden Rate Transition blocks visible:

- You can see the type of Rate Transition block inserted as well as the location in the model.

- You can set the **Initial Conditions** of these blocks.
- You can change block parameters for rate transfer.

Validate the changes to your model by updating your diagram.

Displaying inserted Rate Transition blocks is not compatible with:

- Concurrent execution environment
- Export-function models

To learn more about the types of Rate Transition blocks, see [Rate Transition](#).

## Periodic Sample Rate Transitions

These sections describe cases in which Rate Transition blocks are required for periodic sample rate transitions. The discussion and timing diagrams in these sections are based on the assumption that the Rate Transition block is used in its default (protected/deterministic) mode; that is, the **Ensure data integrity during data transfer** and **Ensure deterministic data transfer (maximum delay)** options are both on. These are the settings used for automatically inserted Rate Transition blocks.

### Faster to Slower Transitions in a Simulink Model

In a model where a faster block drives a slower block having direct feedthrough, the outputs of the faster block are computed first. In simulation intervals where the slower

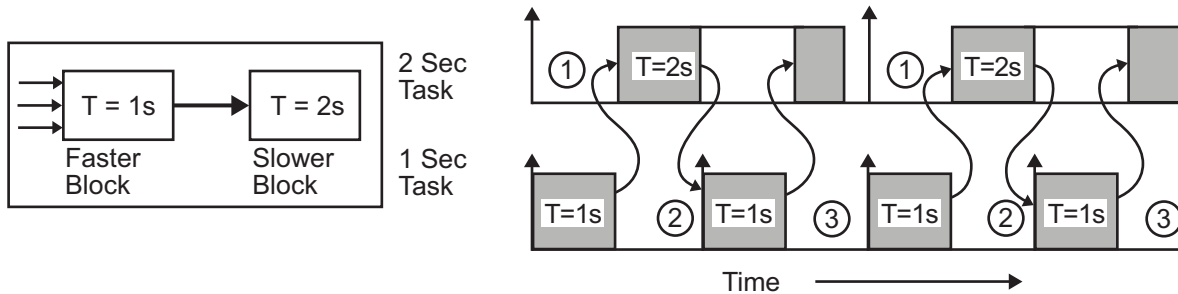

block does not execute, the simulation progresses more rapidly because there are fewer blocks to execute. The next figure illustrates this situation.

A Simulink simulation does not execute in real time, which means that it is not bound by real-time constraints. The simulation waits for, or moves ahead to, whatever tasks are required to complete simulation flow. The actual time interval between sample time steps can vary.

### Faster to Slower Transitions in Real Time

In models where a faster block drives a slower block, you must compensate for the fact that execution of the slower block might span more than one execution period of the faster block. This means that the outputs of the faster block can change before the slower block has finished computing its outputs. The next figure shows a situation in which this problem arises ( $T = \text{sample time}$ ). Note that lower priority tasks are preempted by higher priority tasks before completion.

- ① The faster task ( $T=1s$ ) completes.
- ② Higher priority preemption occurs.
- ③ The slower task ( $T=2s$ ) resumes and its inputs have changed. This leads to unpredictable results.

In the above figure, the faster block executes a second time before the slower block has completed execution. This can cause unpredictable results because the input data to the slow task is changing. Data might not maintain its integrity in this situation.

To avoid this situation, the Simulink engine must hold the outputs of the 1 second (faster) block until the 2 second (slower) block finishes executing. The way to accomplish this is by inserting a Rate Transition block between the 1 second and 2 second blocks. The input to the slower block does not change during its execution, maintaining data integrity.

It is assumed that the Rate Transition block is used in its default (protected/deterministic) mode.

The Rate Transition block executes at the sample rate of the slower block, but with the priority of the faster block.

When you add a Rate Transition block, the block executes before the 2 second block (its priority is higher) and its output value is held constant while the 2 second block executes (it executes at the slower sample rate).

### Slower to Faster Transitions in a Simulink Model

In a model where a slower block drives a faster block, the Simulink engine again computes the output of the driving block first. During sample intervals where only the faster block executes, the simulation progresses more rapidly.

The next figure shows the execution sequence.

As you can see from the preceding figures, the Simulink engine can simulate models with multiple sample rates in an efficient manner. However, a Simulink simulation does not operate in real time.

### Slower to Faster Transitions in Real Time

In models where a slower block drives a faster block, the generated code assigns the faster block a higher priority than the slower block. This means the faster block is executed before the slower block, which requires special care to avoid incorrect results.

- ① The faster block executes a second time prior to the completion of the slower block.
- ② The faster block executes before the slower block.

This timing diagram illustrates two problems:

- Execution of the slower block is split over more than one faster block interval. In this case the faster task executes a second time before the slower task has completed execution. This means the inputs to the faster task can have incorrect values some of the time.
- The faster block executes before the slower block (which is backward from the way a Simulink simulation operates). In this case, the 1 second block executes first; but the inputs to the faster task have not been computed. This can cause unpredictable results.

To eliminate these problems, you must insert a Rate Transition block between the slower and faster blocks.

It is assumed that the Rate Transition block is used in its default (protected/deterministic) mode.

The next figure shows the timing sequence that results with the added Rate Transition block.

Three key points about transitions in this diagram (refer to circled numbers):

- 1 The Rate Transition block output runs in the 1 second task, but at a slower rate (2 seconds). The output of the Rate Transition block feeds the 1 second task blocks.
- 2 The Rate Transition update uses the output of the 2 second task to update its internal state.
- 3 The Rate Transition output in the 1 second task uses the state of the Rate Transition that was updated in the 2 second task.

The first problem is alleviated because the Rate Transition block is updating at a slower rate and at the priority of the slower block. The input to the Rate Transition block (which is the output of the slower block) is read after the slower block completes executing.

The second problem is alleviated because the Rate Transition block executes at a slower rate and its output does not change during the computation of the faster block it is driving. The output portion of a Rate Transition block is executed at the sample rate of the slower block, but with the priority of the faster block. Since the Rate Transition block drives the faster block and has effectively the same priority, it is executed before the faster block.

**Note** This use of the Rate Transition block changes the model. The output of the slower block is now delayed by one time step compared to the output without a Rate Transition block.

---

## Protect Data Integrity with volatile Keyword

When you select **Ensure data integrity during data transfer**, the code generated for a Rate Transition block defines global buffers and semaphores and uses them to protect the integrity of the transferred data.

Particularly for a multitasking application, the tasks (rates) involved in a data transfer can write to the transferred data, buffers, and semaphores at times that your compiler cannot anticipate. To prevent your compiler from optimizing the assembly code in a manner that compromises the integrity of the transferred data, the code generator applies the keyword `volatile` to the buffers and semaphores. The code generator does not apply `volatile` to the global variable that represents the transferred data because the `volatile` buffers and semaphores typically offer enough protection.

If necessary, with Embedded Coder, you can explicitly apply `volatile` to the transferred data by applying the built-in custom storage class `Volatile` to the input of the Rate Transition block. For example, you can use this technique to help protect the integrity of data that your external code shares with the generated code.

Alternatively, to protect data that your external code shares with the generated code, you can write your own C functions that read and write the data in a protected manner. Then, you can apply the custom storage class `GetSet` to the data in the model, which causes the generated code to call your functions instead of directly accessing the data.

For more information about applying `volatile`, see “Protect Global Data with `const` and `volatile` Keywords” on page 30-17. For more information about `GetSet`, see “Access Data Through Functions with Custom Storage Class `GetSet`” on page 26-42.

## Separate Rate Transition Block Code and Data from Algorithm Code and Data

By default, Rate Transition block code is set inline with algorithm code and data. If you have Embedded Coder, you can separate the code and data, so that the generated code contains separate `get` and `set` functions that the `model_step` functions call and a dedicated structure for state data. The generated code also contains separate `start` and

initialize functions that the *model\_initialize* function calls. To separate Rate Transition block code and data from algorithm code and data, in the Configuration Parameters dialog box, set the Rate Transition block code parameter to **Function**.

Separating Rate Transition block code and data from algorithm code and data enables you to analyze, optimize, and test Rate Transition block and algorithm code independently from each other.

## Configure Time-Based Scheduling

For details about solver options, see “Solver Pane” (Simulink).

### Configure Start and Stop Times

The **Stop time** (Simulink) must be greater than or equal to the **Start time** (Simulink). If the stop time is zero, or if the total simulation time (**Stop** minus **Start**) is less than zero, the generated program runs for one step. If the stop time is set to `inf`, the generated program runs indefinitely.

When using the GRT or ERT targets, you can override the stop time when running a generated program from the Microsoft Windows command prompt or UNIX<sup>3</sup> command line. To override the stop time that was set during code generation, use the `-tf` switch.

```
model -tf n
```

The program runs for `n` seconds. If `n = inf`, the program runs indefinitely.

Certain blocks have a dependency on absolute time. If you are designing a program that is intended to run indefinitely (**Stop time** = `inf`), and your generated code does not use the `rtModel` data structure (that is, it uses `simstructs` instead), you must not use these blocks. See “Absolute Time Limitations” on page 16-12 for a list of blocks that can potentially overflow timers.

If you know how long an application that depends on absolute time needs to run, you can prevent the timers from overflowing and force the use of optimal word sizes by specifying the **Application lifespan (days)** (Simulink) parameter on the **Math and Data Types** pane. See “Control Memory Allocation for Time Counters” on page 56-11 for details.

### Configure the Solver Type

For code generation, you must configure a model to use a fixed-step solver for all targets except the S-function and RSim targets. You can configure the S-function and RSim targets with a fixed-step or variable-step solver.

## Time-Based Scheduling Example Models

### Optimize Memory Usage for Time Counters

This example shows how to optimize the amount of memory that the code generator allocates for time counters. The example optimizes the memory that stores elapsed time, the interval of time between two events.

The code generator represents time counters as unsigned integers. The word size of time counters is based on the setting of the model configuration parameter **Application lifespan (days)**, which specifies the expected maximum duration of time the application runs. You can use this parameter to prevent time counter overflows. The default size is 64 bits.

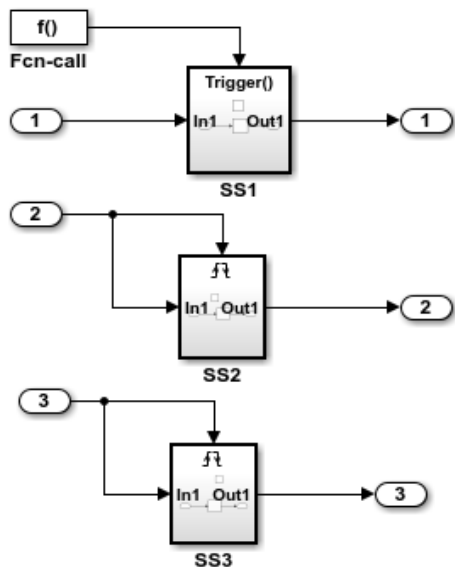

The number of bits that a time counter uses depends on the setting of the **Application lifespan (days)** parameter. For example, if a time counter increments at a rate of 1 kHz, to avoid an overflow, the counter has the following number of bits:

- Lifespan < 0.25 sec: 8 bits
- Lifespan < 1 min: 16 bits
- Lifespan < 49 days: 32 bits
- Lifespan > 50 days: 64 bits

A 64-bit time counter does not overflow for 590 million years.

### Open Example Model

Open the example model `rtwdemo_abstime`.

SS1 is clocked at 1 kHz, and contains a discrete-time integrator that requires elapsed time to compute its output. However, a counter is not required to compute elapsed time since the trigger port 'Sample time type' is set to 'periodic.' Instead, time is inlined as 1 kHz.

SS2 is clocked at 100 Hz, and contains a discrete-time integrator that requires elapsed time to compute its output. Since the application life span of the model is 1 day, a 32-bit counter is required to compute elapsed time for SS2.

SS3 is clocked at 0.5 Hz, and contains a discrete-time integrator that requires elapsed time to compute its output. Since the application life span of the model is 1 day, a 16-bit counter is required to compute elapsed time for SS3.

Simulink Coder optimizes how counters are employed to measure absolute and elapsed time:

- o Time is computed from unsigned integer counters.
- o Only tasks that require time are allocated a counter.
- o Elapsed time is computed by a subsystem if and only if a block in its hierarchy requires elapsed time.
- o Time is shared by all blocks within a triggered hierarchy.

Simulink Coder further optimizes counters based on the option "Application life span," whereby the number of bits used for a particular counter is optimized based on how long the application will run.

Display Sample Time Colors (double-click)

Generate Code Using Simulink Coder (double-click)

Generate Code Using Embedded Coder (double-click)

Copyright 1994-2012 The MathWorks, Inc.

The model consists of three subsystems SS1, SS2, and SS3. On the **Math and Data Types** pane, the **Application lifespan (days)** parameter is set to the default, which is inf.

The three subsystems contain a discrete-time integrator that requires elapsed time as input to compute its output value. The subsystems vary as follows:

- SS1 - Clocked at 1 kHz. Does not require a time counter. **Sample time type** parameter for trigger port is set to **periodic**. Elapsed time is inlined as 0.001.
- SS2 - Clocked at 100 Hz. Requires a time counter. Based on a lifespan of 1 day, a 32-bit counter stores the elapsed time.
- SS3 - Clocked at 0.5 Hz. Requires a time counter. Based on a lifespan of 1 day, a 16-bit counter stores the elapsed time.

### Simulate the Model

Simulate the model. By default, the model is configured to show sample times in different colors. Discrete sample times for the three subsystems appear red, green, and blue. Triggered subsystems are blue-green.

### Generate Code and Report

1. Create a temporary folder for the build and inspection process.
2. Configure the model for the code generator to use the GRT system target file and a lifespan of `inf` days.
3. Build the model.

```
Starting build procedure for model: rtwdemo_abstime
Successful completion of build procedure for model: rtwdemo_abstime
```

### Review Generated Code

Open the generated source file `rtwdemo_abstime.c`.

```
struct tag_RTM_rtwdemo_abstime_T {
 const char_T *errorStatus;

 /*
 * Timing:
 * The following substructure contains information regarding
 * the timing information for the model.
 */
 struct {
 uint32_T clockTick1;
```

```

 uint32_T clockTickH1;
 uint32_T clockTick2;
 uint32_T clockTickH2;
 struct {
 uint16_T TID[3];
 uint16_T cLimit[3];
 } TaskCounters;
} Timing;
};

/* Block states (default storage) */
extern DW_rtwdemo_abstime_T rtwdemo_abstime_DW;

/* External inputs (root inport signals with default storage) */
extern ExtU_rtwdemo_abstime_T rtwdemo_abstime_U;

/* External outputs (root outports fed by signals with default storage) */
extern ExtY_rtwdemo_abstime_T rtwdemo_abstime_Y;

/* Model entry point functions */
extern void rtwdemo_abstime_initialize(void);
extern void rtwdemo_abstime_step(int_T tid);
extern void rtwdemo_abstime_terminate(void);

/* Real-time Model object */
extern RT_MODEL_rtwdemo_abstime_T *const rtwdemo_abstime_M;

/*-
 * The generated code includes comments that allow you to trace directly
 * back to the appropriate location in the model. The basic format
 * is <system>/block_name, where system is the system number (uniquely
 * assigned by Simulink) and block_name is the name of the block.
 *
 * Use the MATLAB hilite_system command to trace the generated code back
 * to the model. For example,
 *
 * hilite_system('<S3>') - opens system 3
 * hilite_system('<S3>/Kp') - opens and selects block Kp which resides in S3
 *
 * Here is the system hierarchy for this model
 *
 * '<Root>' : 'rtwdemo_abstime'
 * '<S1>' : 'rtwdemo_abstime/SS1'
 * '<S2>' : 'rtwdemo_abstime/SS2'

```

```

* '<S3>' : 'rtwdemo_abstime/SS3'
*/
#endif /* RTW_HEADER_rtwdemo_abstime_h_ */

```

Four 32-bit unsigned integers, `clockTick1`, `clockTickH1`, `clockTick2`, and `clockTickH2` are counters for storing the elapsed time of subsystems SS2 and SS3.

### Enable Optimization and Regenerate Code

1. Reconfigure the model to set the lifespan to 1 day.
2. Build the model.

```

Starting build procedure for model: rtwdemo_abstime
Successful completion of build procedure for model: rtwdemo_abstime

```

### Review the Regenerated Code

```

struct tag_RTM_rtwdemo_abstime_T {
 const char_T *errorStatus;

 /*
 * Timing:
 * The following substructure contains information regarding
 * the timing information for the model.
 */
 struct {
 uint32_T clockTick1;
 uint16_T clockTick2;
 struct {
 uint16_T TID[3];
 uint16_T cLimit[3];
 } TaskCounters;
 } Timing;
};

/* Block states (default storage) */
extern DW_rtwdemo_abstime_T rtwdemo_abstime_DW;

/* External inputs (root inport signals with default storage) */
extern ExtU_rtwdemo_abstime_T rtwdemo_abstime_U;

/* External outputs (root outports fed by signals with default storage) */
extern ExtY_rtwdemo_abstime_T rtwdemo_abstime_Y;

```

```
/* Model entry point functions */
extern void rtwdemo_abstime_initialize(void);
extern void rtwdemo_abstime_step(int_T tid);
extern void rtwdemo_abstime_terminate(void);

/* Real-time Model object */
extern RT_MODEL_rtwdemo_abstime_T *const rtwdemo_abstime_M;

/*-
 * The generated code includes comments that allow you to trace directly
 * back to the appropriate location in the model. The basic format
 * is <system>/block_name, where system is the system number (uniquely
 * assigned by Simulink) and block_name is the name of the block.
 *
 * Use the MATLAB hilite_system command to trace the generated code back
 * to the model. For example,
 *
 * hilite_system('<S3>') - opens system 3
 * hilite_system('<S3>/Kp') - opens and selects block Kp which resides in S3
 *
 * Here is the system hierarchy for this model
 *
 * '<Root>' : 'rtwdemo_abstime'
 * '<S1>' : 'rtwdemo_abstime/SS1'
 * '<S2>' : 'rtwdemo_abstime/SS2'
 * '<S3>' : 'rtwdemo_abstime/SS3'
 */
#endif /* RTW_HEADER_rtwdemo_abstime_h_ */
```

The new setting for the **Application lifespan (days)** parameter instructs the code generator to set aside less memory for the time counters. The regenerated code includes:

- 32-bit unsigned integer, `clockTick1`, for storing the elapsed time of the task for SS2
- 16-bit unsigned integer, `clockTick2`, for storing the elapsed time of the task for SS3

## Explore Example Model

The model contains two sample times. Inport block 1 and Inport block 2 specify 1-second and 2-second sample times, respectively, which are enforced by the **Periodic sample time constraint** option on the **Solver** configuration page. The solver is set for multitasking operation, which means a rate transition block is required to ensure that data integrity is enforced when the 1-second task preempts the 2-second task. Proper rate transitions are always enforced by Simulink and Simulink Coder. This model specifies an explicit rate transition block. Alternatively, this block could be automatically inserted by Simulink using the model configuration parameter **Automatically handle rate transition for data transfer**.

The model is configured to display sample-time colors upon diagram update. Red represents the fastest discrete sample time in the model, green represents the second fastest, and yellow represents mixed sample times. Click the yellow button to the right to update the diagram and show sample-time colors.

## Data Transfer Assumptions

Basis of operation for data transfers between tasks:

- 1 Data transitions occur between a single reading task and a single writing task.
- 2 A read or write of a byte sized variable is atomic.
- 3 When two tasks interact through a data transition, only one of them can preempt the other.
- 4 For periodic tasks, the faster rate task has higher priority than the slower rate task; the faster rate task always preempts the slower rate task.
- 5 All tasks run on a single processor. Time slicing is not allowed.
- 6 Processes do not crash/restart (especially while data is being transferred between tasks)

## Trade Determinism and Data Integrity to Improve System Performance

This model shows the differences in the operation modes of the Rate Transition block when used in a multirate, multitasking model. The flexible options for the Rate Transition block allow you to select the mode that is best suited for your application. You can trade levels of determinism and data integrity to improve system performance.

## Rate Transition Block Modes of Operation

**Ensure data integrity and determinism (DetAndInteg)** : Data is transferred such that all data bytes for the signal (including all elements of a wide signal) are from the same time step. Additionally, it is ensured that the relative sample time (delay) from which the data is transferred from one rate to another is always the same. Only ANSI-C code is used, no target specific 'critical section' protection is needed.

**Ensure integrity (IntegOnly)** : Data is transferred such that all data bytes for the signal (including all elements of a wide signal) are from the same time step. However, from one transfer of data to the next, the relative sample time (delay) for which the data is transferred can vary. In this mode, the code to read/write the data is run more often than in the DetandInt mode. In the worst case, the delay is equivalent to the DetandInt mode, but the delay can be less which is important in some applications. Also, this mode supports data transfers to/from asynchronous rates which the DetandInt mode cannot support. Only ANSI-C code is used, no target specific 'critical section' protection is needed.

**No data consistency operations are performed (None)** : For this case, the Rate Transition block does not generate code. This mode is acceptable in some applications where atomic access of scalar data types is guaranteed and when the relative temporal values of the data is not important. This mode does not introduce any delay.

## Data Transfer Assumptions

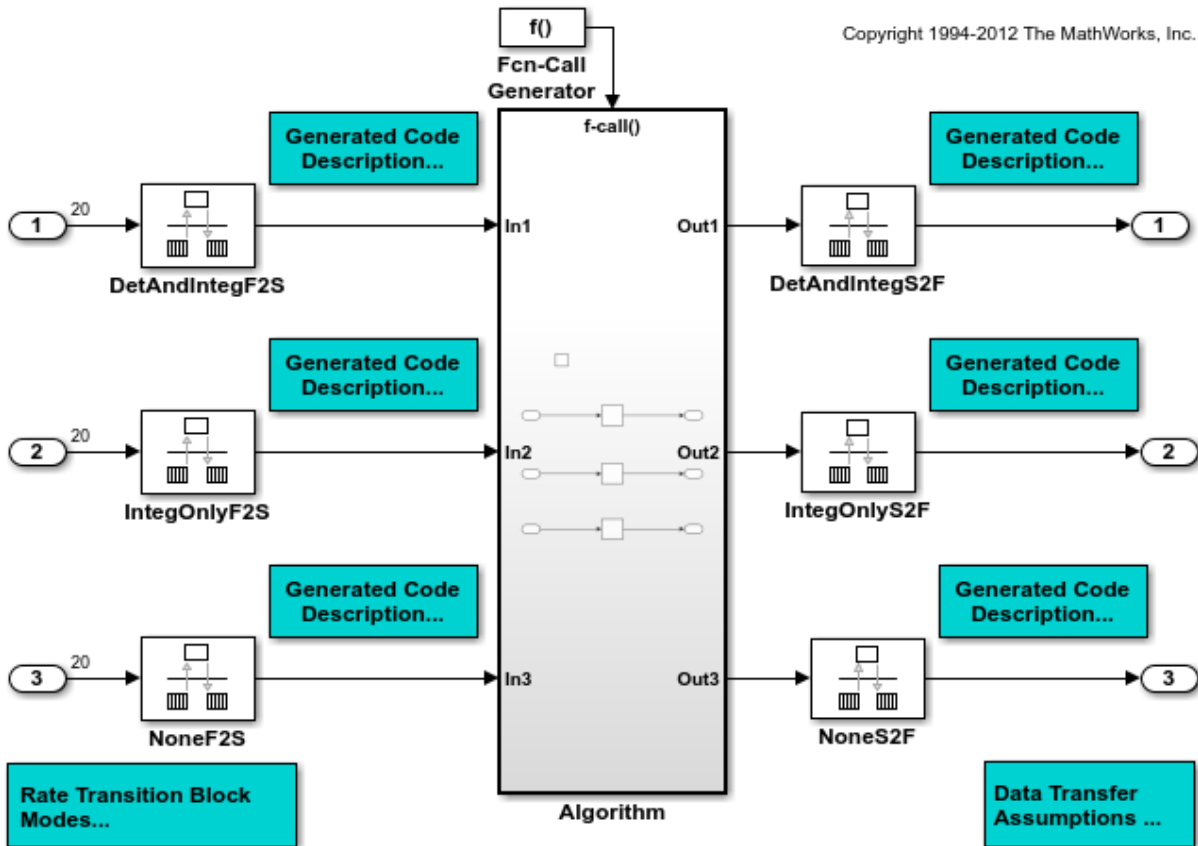

Basis of operation for data transfers between tasks:

- Data transitions occur between a single reading task and a single writing task.
- A read or write of a byte sized variable is atomic.
- When two tasks interact through a data transition, only one of them can preempt the other.
- For periodic tasks, the faster rate task has higher priority than the slower rate task; the faster rate task always preempts the slower rate task.
- All tasks run on a single processor. Time slicing is not allowed.
- Processes do not crash/restart (especially while data is being transferred between tasks)

## Model `rtwdemo_ratetrans`

```
open_system('rtwdemo_ratetrans')
```

Copyright 1994-2012 The MathWorks, Inc.

This model shows the differences in the operation modes of the Rate Transition block when used in a multirate, multitasking model. The flexible options for the Rate Transition block allow you to select the mode that is best suited for your application. You can trade levels of determinism and data integrity to improve system performance.

Generate Code Using Simulink Coder (double-click)

Generate Code Using Embedded Coder (double-click)

Display Sample Time Colors (double-click)

Model `rtwdemo_ratetrans` shows the differences in the operation modes of the following Rate Transition blocks.

### **Rate Transition block DetAndIntegF2S**

Determinism and data integrity (fast to slow transition):

- The block output is used as a persistent data buffer.
- Data is written to output at slower rate but done during the faster rate context
- Data as seen by the slower rate is always the value when both the faster and slower rate last executed. Any subsequent steps by the faster rate (and associated data updates) while the slower rate is running are not seen by the slower rate.

### **Rate Transition block DetAndIntegS2F**

Determinism and data integrity (slow to fast transition):

- Uses two persistent data buffers, an internal buffer and the blocks output.
- The internal buffer is copied to the output at the slower rate but done during the faster rate context.
- The internal buffer is written at the slower rate and during the slower rate context.
- The data that Fast rate sees is always delayed, i.e. data is from the previous step of the slow rate code.

### **Rate Transition block IntegOnlyF2S**

Data integrity only (fast to slow transition):

- The block output is used as a persistent data buffer.
- Data is written to buffer during the faster rate context if a flag indicates it not in the process of being read.
- The flag is set and data is copied from the buffer to output at the slow rate, the flag is then cleared. This is an additional copy as compared to the deterministic case.
- Data as seen by the slower rate can be from a more recent step of the faster rate than from when the slower rate and faster rate both executed.

### **Rate Transition block IntegOnlyS2F**

Data integrity only (slow to fast transition):

- Uses two persistent data buffers, both are internal buffers.
- One of the 2 buffers is always copied to the output at faster rate.
- One of the 2 buffers is written at the slower rate and during the slower rate context, then the active buffer is switched.
- The data as seen by the faster rate can be more recent than for the deterministic case. Specifically, when both the slower and faster rate have their hits, the faster rate will see a previous value from the slower rate. But, subsequent steps for the faster rate may see an updated value (when the slower rate updates the non-active buffer and switches the active buffer flag).

### **Rate Transition block NoneF2S**

No code is generated for the Rate Transition block when determinism and data integrity is waived.

### **Rate Transition block NoneS2F**

No code is generated for the Rate Transition block when determinism and data integrity is waived.

```
bdclose('rtwdemo_ratetrans');
```

## Asynchronous Events

### Asynchronous Support

Normally, you time models from which you plan to generate code from a *periodic* interrupt source (for example, a hardware timer). Blocks in a periodically clocked single-rate model run at a timer interrupt rate (the base rate of the model). Blocks in a periodically clocked multirate model run at the base rate or at multiples of that rate.

Many systems must also support execution of blocks in response to events that are *asynchronous* with respect to the periodic timing source of the system. For example, a peripheral device might signal completion of an input operation by generating an interrupt. The system must service such interrupts, for example, by acquiring data from the interrupting device.

This chapter explains how to use blocks to model and generate code for asynchronous event handling, including servicing of hardware-generated interrupts, maintenance of timers, asynchronous read and write operations, and spawning of asynchronous tasks under a real-time operating system (RTOS). This block library demonstrates integration with an example RTOS (VxWorks). Although the blocks target an example RTOS, this chapter provides source code analysis and other information you can use to develop blocks that support asynchronous event handling for an alternative target RTOS.<sup>4</sup>

### Block Library for Calls to an Example Real-Time Operating System

The next figure shows the blocks in the `vxlib1` block library.

---

4. VxWorks is a registered trademark of Wind River Systems, Inc.

The key blocks in the library are the Async Interrupt and Task Sync blocks. These blocks are targeted for an example RTOS (VxWorks). You can use them, with modification, to support your RTOS applications.

---

**Note** You can use the blocks in the `vxlib1` (Simulink Coder) library (Async Interrupt and Task Sync) for simulation and code generation. These blocks provide starting point examples to help you develop custom blocks for your target environment.

---

To implement asynchronous support for an RTOS other than the example RTOS, use the guidelines and example code are provided to help you adapt the `vxlib1` library blocks to target your RTOS. This topic is discussed in “Create a Customized Asynchronous Library” on page 18-49.

The `vxlib1` library includes blocks you can use to

- Generate interrupt-level code — Async Interrupt block
- Spawn an RTOS task that calls a function call subsystem — Task Sync block
- Enable data integrity when transferring data between blocks running as different tasks — Protected RT block
- Use an unprotected/nondeterministic mode when transferring data between blocks running as different tasks — Unprotected RT block

The use of protected and unprotected Rate Transition blocks in asynchronous contexts is discussed in “Rate Transitions and Asynchronous Blocks” on page 18-40. For general information on rate transitions, see “Time-Based Scheduling and Code Generation” on page 17-2.

## Access the Block Library for RTOS Integration

To access the example RTOS (VxWorks) block library, enter the MATLAB command `vxlabel`.

## Generate Code Using Library Blocks for RTOS Integration

To generate an example RTOS compatible application from a model containing `vxlabel` library blocks, use the following configuration parameter values for your model.

- Select system target file `ert.tlc` (requires an Embedded Coder license) from the browse menu for the **Code Generation > System target file** parameter (`SystemTargetFile`).
- Enable the **Configuration Parameters > Code Generation > Generate code only** parameter (`GenCodeOnly`).
- Enable the **Configuration Parameters > Code Generation > Templates > Custom templates > Generate an example main program** parameter (`GenerateSampleERTMain`).
- Select `VxWorksExample` from the menu for the **Configuration Parameters > Code Generation > Templates > Custom templates > Target operating system** parameter (`TargetOS`).

## Examples and Additional Information

Additional information relevant to the topics in this chapter can be found in

- The `rtwdemo_async` model, which uses the `tornado.tlc` system target file and `vxlabel` block library. To open this example, type `rtwdemo_async` at the MATLAB command prompt.
- The `rtwdemo_async_mdltreftop` model, which uses the `tornado.tlc` system target file and `vxlabel` block library. To open this example, type `rtwdemo_async_mdltreftop` at the MATLAB command prompt.
- “Time-Based Scheduling and Code Generation” (Simulink Coder), discusses general multitasking and rate transition issues for periodic models.
- The Embedded Coder documentation discusses the `ert.tlc` system target file, including task execution and scheduling.

- For detailed information about the system calls to the example RTOS (VxWorks) mentioned in this chapter, see VxWorks system documentation on the Wind River website.

## Generate Interrupt Service Routines

To generate an interrupt service routine (ISR) associated with a specific VME interrupt level for the example RTOS (VxWorks), use the Async Interrupt block. The Async Interrupt block enables the specified interrupt level and installs an ISR that calls a connected function call subsystem.

You can also use the Async Interrupt block in a simulation. It provides an input port that can be enabled and connected to a simulated interrupt source.

---

**Note** The operating system integration techniques that are demonstrated in this section use one or more blocks the blocks in the `vxl1b1` (Simulink Coder) library. These blocks provide starting point examples to help you develop custom blocks for your target environment.

---

### Connecting the Async Interrupt Block

To generate an ISR, connect an output of the Async Interrupt block to the control input of

- A function call subsystem
- The input of a Task Sync block
- The input to a Stateflow chart configured for a function call input event

The next figure shows an Async Interrupt block configured to service two interrupt sources. The outputs (signal width 2) are connected to two function call subsystems.

## Requirements and Restrictions

Note the following requirements and restrictions:

- The Async Interrupt block supports VME interrupts 1 through 7.
- The Async Interrupt block uses the following system calls to the example RTOS (VxWorks):
  - `sysIntEnable`
  - `sysIntDisable`
  - `intConnect`
  - `intLock`
  - `intUnlock`
  - `tickGet`

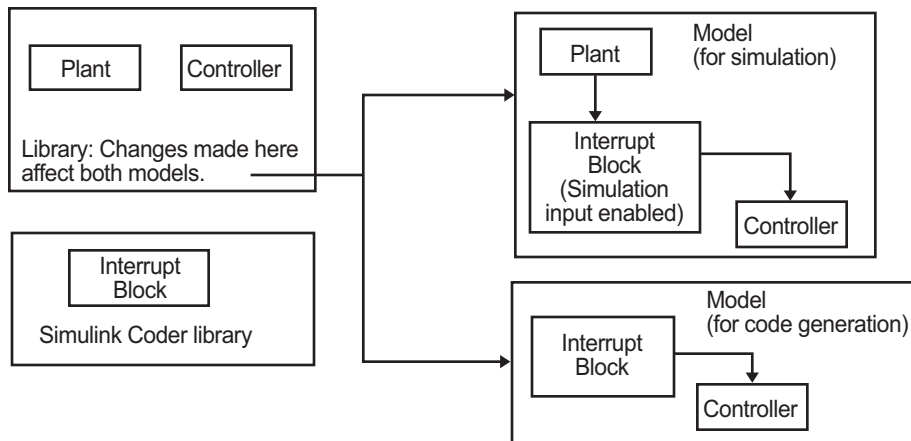

## Performance Considerations

Execution of large subsystems at interrupt level can have a significant impact on interrupt response time for interrupts of equal and lower priority in the system. As a general rule, it is best to keep ISRs as short as possible. Connect only function call subsystems that contain a small number of blocks to an Async Interrupt block.

A better solution for large subsystems is to use the Task Sync block to synchronize the execution of the function call subsystem to a RTOS task. The Task Sync block is placed between the Async Interrupt block and the function call subsystem. The Async Interrupt block then installs the Task Sync block as the ISR. The ISR releases a synchronization semaphore (performs a `semGive`) to the task, and returns immediately from interrupt level. The task is then scheduled and run by the example RTOS (VxWorks). See “Spawn and Synchronize Execution of RTOS Task” on page 18-15 for more information.

## Using the Async Interrupt Block in Simulation and Code Generation

This section describes a *dual-model* approach to the development and implementation of real-time systems that include ISRs. In this approach, you develop one model that includes a plant and a controller for simulation, and another model that only includes the controller for code generation. Using a Simulink library, you can implement changes to both models simultaneously. The next figure shows how changes made to the plant or controller, both of which are in a library, are propagated to the models.

### Dual-Model Use of Async Interrupt Block for Simulation and Code Generation

A *single-model* approach is also possible. In this approach, the Plant component of the model is active only in simulation. During code generation, the Plant components are effectively switched out of the system and code is generated only for the interrupt block and controller parts of the model. For an example of this approach, see the `rtwdemo_async` model.

## Dual-Model Approach: Simulation

The following block diagram shows a simple model that illustrates the dual-model approach to modeling. During simulation, the Pulse Generator blocks provide simulated interrupt signals.

The simulated interrupt signals are routed through the Async Interrupt block's input port. Upon receiving a simulated interrupt, the block calls the connected subsystem.

During simulation, subsystems connected to Async Interrupt block outputs are executed in order of their priority in the example RTOS (VxWorks). In the event that two or more interrupt signals occur simultaneously, the Async Interrupt block executes the downstream systems in the order specified by their interrupt levels (level 7 gets the highest priority). The first input element maps to the first output element.

You can also use the Async Interrupt block in a simulation without enabling the simulation input. In such a case, the Async Interrupt block inherits the base rate of the model and calls the connected subsystems in order of their priorities in the RTOS. (In this case, the Async Interrupt block behaves as if all inputs received a 1 simultaneously.)

## Dual-Model Approach: Code Generation

In the generated code for the sample model,

- Ground blocks provide input signals to the Environment Controller block
- The Async Interrupt block does not use its simulation input

The Ground blocks drive control input of the Environment Controller block, so code is not generated for that signal path. The code generator does not produce code for blocks that drive the simulation control input to the Environment Controller block because that path is not selected during code generation. However, the sample times of driving blocks for the simulation input to the Environment Controller block contribute to the sample times supported in the generated code. To avoid including unnecessary sample times in the generated code, use the sample times of the blocks driving the simulation input in the model where generated code is intended.

Standalone functions are installed as ISRs and the interrupt vector table is as follows:

| Offset |                                     |
|--------|-------------------------------------|
| 192    | <code>&amp;isr_num1_vec192()</code> |
| 193    | <code>&amp;isr_num2_vec193()</code> |

Consider the code generated from this model, assuming that the Async Interrupt block parameters are configured as shown in the next figure.

## Initialization Code

In the generated code, the Async Interrupt block installs the code in the Subsystem blocks as interrupt service routines. The interrupt vectors for IRQ1 and IRQ2 are stored at locations 192 and 193 relative to the base of the interrupt vector table, as specified by the **VME interrupt vector offset(s)** parameter.

Installing an ISR requires two RTOS (VxWorks) calls, `int_connect` and `sysInt_Enable`. The Async Interrupt block inserts these calls in the `model_initialize` function, as shown in the following code excerpt.

```
/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
/* Connect and enable ISR function: isr_num1_vec192 */
if(intConnect(INUM_TO_IVEC(192), isr_num1_vec192, 0) != OK) {
 printf("intConnect failed for ISR 1.\n");
}
sysIntEnable(1);
```

```
/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
/* Connect and enable ISR function: isr_num2_vec193 */
if(intConnect(INUM_TO_IVEC(193), isr_num2_vec193, 0) != OK)
{
 printf("intConnect failed for ISR 2.\n");
}
sysIntEnable(2);
```

The hardware that generates the interrupt is not configured by the Async Interrupt block. Typically, the interrupt source is a VME I/O board, which generates interrupts for specific events (for example, end of A/D conversion). The VME interrupt level and vector are set up in registers or by using jumpers on the board. You can use the `mdlStart` routine of a user-written device driver (S-function) to set up the registers and enable interrupt generation on the board. You must match the interrupt level and vector specified in the Async Interrupt block dialog to the level and vector set up on the I/O board.

### Generated ISR Code

The actual ISR generated for IRQ1 in the RTOS (VxWorks) is listed below.

```
/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */

void isr_num1_vec192(void)
{
 int_T lock;
 FP_CONTEXT context;

 /* Use tickGet() as a portable tick counter example.
 A much higher resolution can be achieved with a
 hardware counter */
 Async_Code_M->Timing.clockTick2 = tickGet();

 /* disable interrupts (system is configured as non-ive) */
 lock = intLock();

 /* save floating point context */
 fppSave(&context);

 /* Call the system: <Root>/Subsystem A */
 Count(0, 0);

 /* restore floating point context */
 fppRestore(&context);

 /* re-enable interrupts */
```

```

 intUnlock(lock);
}

```

There are several features of the ISR that should be noted:

- Because of the setting of the **Preemption Flag(s)** parameter, this ISR is locked; that is, it cannot be preempted by a higher priority interrupt. The ISR is locked and unlocked in the example RTOS (VxWorks) by the `int_lock` and `int_unlock` functions.
- The connected subsystem, `Count`, is called from within the ISR.
- The `Count` function executes algorithmic (model) code. Therefore, the floating-point context is saved and restored across the call to `Count`.
- The ISR maintains its own absolute time counter, which is distinct from other periodic base rate or subrate counters in the system. Timing data is maintained for the use of any blocks executed within the ISR that require absolute or elapsed time.

See “Timers in Asynchronous Tasks” on page 18-46 for details.

### Model Termination Code

The model's termination function disables the interrupts in the RTOS (VxWorks):

```

/* Model terminate function */
void Async_Code_terminate(void)
{
 /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
 /* Disable interrupt for ISR system: isr_num1_vec192 */
 sysIntDisable(1);

 /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
 /* Disable interrupt for ISR system: isr_num2_vec193 */
 sysIntDisable(2);
}

```

## Spawn and Synchronize Execution of RTOS Task

This example shows how to simulate and generate code for asynchronous events on a multitasking real-time operating system (VxWorks®). The model shows different techniques for handling asynchronous events depending on the size of the triggered subsystems.

### **About the Example Model**

Open the example model `rtwdemo_async`.

This model shows how to simulate and generate code for asynchronous events on a real-time multitasking system. This model contains two asynchronously executed subsystems, "Count" and "Algorithm." "Count" is executed at interrupt level, whereas "Algorithm" is executed in an asynchronous task. The code generated for these blocks is specifically tailored for the VxWorks operating system. However, you can modify the Async Interrupt and Task Sync blocks to generated code specific to your environment whether you are using an operating system or not.

The model simulates an interrupt source and includes an Async Interrupt block, a Task Sync block, function-call subsystems Count and Algorithm, and Rate Transition blocks. The Async Interrupt block creates two Versa Module Eurocard (VME) interrupt service routines (ISRs) that pass interrupt signals to subsystem Count and the Task Sync block. You can place an Async Interrupt block between a simulated interrupt source and one of the following:

- Function call subsystem
- Task Sync block
- A Stateflow® chart configured for a function call input event
- A referenced model with an Inport block that connects to one of the preceding model elements

The Async Interrupt and Task Sync blocks enable the subsystems to execute asynchronously.

Count represents a simple interrupt service routine (ISR) that executes at interrupt level. It is best to keep ISRs as simple as possible. This subsystem includes only a Discrete-Time Integrator block.

Algorithm includes more substance. It includes multiple blocks and produces two output values. Execution of larger subsystems at interrupt level can significantly impact response time for interrupts of equal and lower priority in the system. A better solution for larger subsystems is to use the Task Sync block to represent the ISR for the function-call subsystem.

The Async Interrupt block generates calls to ISRs. Place the block between a simulated interrupt source and one of the following:

- Function call subsystem
- Task Sync block
- A Stateflow® chart configured for a function call input event

For each specified interrupt level, the block generates a Versa Module Eurocard (VME) ISR that executes the connected subsystem, Task Sync block, or chart.

In the example model, the Async Interrupt block is configured for VME interrupts 1 and 2, by using interrupt vector offsets 192 and 193. Interrupt 1 connects directly to subsystem Count. Interrupt 2 connects to a Task Sync block, which serves as the ISR for Algorithm. Place a Task Sync block in one of the following locations:

- Between an Async Interrupt block and a function-call subsystem or Stateflow® chart.
- At the output port of a Stateflow® chart that has an event, `Output to Simulink`, that you configure as a function call.

In the example model, the Task Sync block is between the Async Interrupt block and function-call subsystem Algorithm. The Task Sync block is configured with the task

name `Task()`, a priority of 50, a stack size of 8192, and data transfers of the task synchronized with the caller task. The spawned task uses a semaphore to synchronize task execution. The Async Interrupt block triggers a release of the task semaphore.

Four Rate Transition blocks handle data transfers between ports that operate at different rates. In two instances, Protected Rate Transition blocks protect data transfers (prevent them from being preempted and corrupted). In the other two instances, Unprotected Rate Transition blocks introduce no special behavior. Their presence informs Simulink® of a rate transition.

The code generated for the Async Interrupt and Task Sync blocks is tailored for the example RTOS (VxWorks®). However, you can modify the blocks to generate code specific to your run-time environment.

### **Data Transfer Assumptions**

- Data transfers occur between one reading task and one writing task.
- A read or write operation on a byte-size variable is atomic.
- When two tasks interact, only one can preempt the other.
- For periodic tasks, the task with the faster rate has higher priority than the task with the slower rate. The task with the faster rate preempts the tasks with slower rates.
- Tasks run on a single processor. Time slicing is not allowed.
- Processes do not stop and restart, especially while data is being transferred between tasks.

### **Simulate the Model**

Simulate the model. By default, the model is configured to show sample times in different colors. Discrete sample times for input and output appear red and green, respectively. Constants are reddish-blue. Asynchronous interrupts and tasks are purple. The Rate Transition Blocks, which are a hybrid rate (their input and output sample times can differ), are yellow.

### **Generate Code and Report**

Generate code and a code generation report for the model. Generated code for the Async Interrupt and Task Sync blocks is for the example RTOS (VxWorks®). However, you can modify the blocks to generate code for another run-time environment.

1. Create a temporary folder for the build and inspection process.

## 2. Build the model.

```
Starting build procedure for model: rtwdemo_async
Warning: Simulink Coder: The tornado.tlc target will be removed in a future
release.
```

```
Wrapping unrecognized make command (angle brackets added)
<make>
in default batch file
Successful completion of code generation for model: rtwdemo_async
```

### Review Initialization Code

Open the generated source file `rtwdemo_async.c`. The initialization code:

#### 1. Creates and initializes the synchronization semaphore `Task0_semaphore`.

```
*(SEM_ID *)rtwdemo_async_DW.SFunction_PWORK.SemID = semBCreate(SEM_Q_PRIORITY,
SEM_EMPTY);
if (rtwdemo_async_DW.SFunction_PWORK.SemID == NULL) {
 printf("semBCreate call failed for block Task0.\n");
}
```

#### 2. Spawns task `task0` and assigns the task priority 50.

```
rtwdemo_async_DW.SFunction_IWORK.TaskID = taskSpawn("Task0",
50.0,
VX_FP_TASK,
8192.0,
(FUNCPTR)Task0,
0, 0, 0, 0, 0, 0, 0, 0, 0, 0);
if (rtwdemo_async_DW.SFunction_IWORK.TaskID == ERROR) {
 printf("taskSpawn call failed for block Task0.\n");
}

/* End of Start for S-Function (vxtask1): '<S5>/S-Function' */

/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
/* Connect and enable ISR function: isr_num1_vec192 */
if (intConnect(INUM_T0_IVEC(192), isr_num1_vec192, 0) != OK) {
 printf("intConnect failed for ISR 1.\n");
}
```

```
sysIntEnable(1);

/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
/* Connect and enable ISR function: isr_num2_vec193 */
if (intConnect(INUM_TO_IVEC(193), isr_num2_vec193, 0) != OK) {
 printf("intConnect failed for ISR 2.\n");
}

sysIntEnable(2);
```

3. Connects and enables ISR `isr_num1_vec192` for interrupt 1 and ISR `isr_num2_vec193` for interrupt 2.

```
{
 int32_T i;

 /* InitializeConditions for RateTransition: '<Root>/Protected RT1' */

return rtwdemo_async_M;

```

```

}

/*=====
 * End of Classic call interface
 =====/

```

The order of these operations is important. Before the code generator enables the interrupt that activates the task, it must spawn the task.

### Review Task and Task Synchronization Code

In the generated source file `rtwdemo_async.c`, review the task and task synchronization code.

The code generator produces the code for function `Task0` from the Task Sync block. That function includes a small amount of interrupt-level code and runs as an RTOS task.

The task waits in an infinite `for` loop until the system releases a synchronization semaphore. If the system releases the semaphore, the function updates its task timer and calls the code generated for the `Algorithm` subsystem.

In the example model, the **Synchronize the data transfer of this task with the caller task** parameter for the Task Sync block is set. This parameter setting updates the timer associated with the Task Sync block (`rtM->Timing.clockTick2`) with the value of the timer that the Async Interrupt block (`rtM->Timing.clockTick3`) maintains. As a result, code for blocks within the `Algorithm` subsystem use timer values that are based on the time of the most recent interrupt, rather than the most recent activation of `Task0`.

```

{
 /* Wait for semaphore to be released by system: rtwdemo_async/Task Sync */
 for (;;) {
 if (semTake(*(SEM_ID *)rtwdemo_async_DW.SFunction_PWORK.SemID,NO_WAIT) !=
 ERROR) {
 logMsg("Rate for Task Task0() too fast.\n",0,0,0,0,0,0);

#ifdef STOPONOVERRUN

 logMsg("Aborting real-time simulation.\n",0,0,0,0,0,0);
 semGive(stopSem);
 return(ERROR);

#endif

 }
 }
}

```

```

} else {
 semTake(*(SEM_ID *)rtwdemo_async_DW.SFunction_PWORK.SemID, WAIT_FOREVER);
}

/* Use the upstream clock tick counter for this Task. */
rtwdemo_async_M->Timing.clockTick4 = rtwdemo_async_M->Timing.clockTick3;

/* Call the system: '<Root>/Algorithm' */
{
 {
 int32_T tmp;
 int32_T i;

 /* RateTransition: '<Root>/Protected RT1' */
 tmp = rtwdemo_async_DW.ProtectedRT1_ActiveBufIdx * 60;
 for (i = 0; i < 60; i++) {
 rtwdemo_async_B.ProtectedRT1[i] =
 rtwdemo_async_DW.ProtectedRT1_Buffer[i + tmp];
 }

 /* End of RateTransition: '<Root>/Protected RT1' */

 /* S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

 /* S-Function (vxtask1): '<S5>/S-Function' */

 /* Output and update for function-call system: '<Root>/Algorithm' */
 {
 real_T tmp;
 int32_T i;
 uint32_T Algorithm_ELAPS_T_tmp;
 rtwdemo_async_M->Timing.clockTick4 =
 rtwdemo_async_M->Timing.clockTick3;
 Algorithm_ELAPS_T_tmp = rtwdemo_async_M->Timing.clockTick4;
 rtwdemo_async_DW.Algorithm_ELAPS_T = Algorithm_ELAPS_T_tmp -
 rtwdemo_async_DW.Algorithm_PREV_T;
 rtwdemo_async_DW.Algorithm_PREV_T = Algorithm_ELAPS_T_tmp;

 /* Outport: '<Root>/Out3' incorporates:

 (rtwdemo_async_DW.ProtectedRT2_ActiveBufIdx == 0) * 60] =
 rtwdemo_async_B.Sum[i];
 }

 rtwdemo_async_DW.ProtectedRT2_ActiveBufIdx = (int8_T)
 (rtwdemo_async_DW.ProtectedRT2_ActiveBufIdx == 0);

 /* End of Update for RateTransition: '<Root>/Protected RT2' */
}
}
}
}

```

```
}

```

The code generator produces code for ISRs `isr_num1_vec192` and `isr_num2_vec293`.  
ISR `isr_num2_vec192`:

- Disables interrupts.
- Saves floating-point context.
- Calls the code generated for the subsystem that connects to the referenced model Inport block, which receives the interrupt.
- Restores floating-point context.
- Reenables interrupts.

```
void isr_num1_vec192(void)
{
 int_T lock;
 FP_CONTEXT context;

 /* Use tickGet() as a portable tick
 counter example. A much higher resolution can
 be achieved with a hardware counter */
 rtwdemo_async_M->Timing.clockTick2 = tickGet();

 /* disable interrupts (system is configured as non-preemptive) */
 lock = intLock();

 /* save floating point context */
 fppSave(&context);

 /* Call the system: '<Root>/Count' */
 {
 /* S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

 /* Output and update for function-call system: '<Root>/Count' */
 {
 uint32_T Count_ELAPS_T_tmp;
 Count_ELAPS_T_tmp = rtwdemo_async_M->Timing.clockTick2;
 rtwdemo_async_DW.Count_ELAPS_T = Count_ELAPS_T_tmp -
 rtwdemo_async_DW.Count_PREV_T;
 rtwdemo_async_DW.Count_PREV_T = Count_ELAPS_T_tmp;

 /* Output: '<Root>/Out1' incorporates:

```

```

 * DiscreteIntegrator: '<S2>/Integrator'
 */
 rtwdemo_async_Y.Out1 = rtwdemo_async_DW.Integrator_DSTATE_l;

 /* Update for DiscreteIntegrator: '<S2>/Integrator' */
 rtwdemo_async_DW.Integrator_DSTATE_l += 0.01666666666666666 * (real_T)
 rtwdemo_async_DW.Count_ELAPS_T;
}

/* End of Outputs for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
}

/* restore floating point context */
fppRestore(&context);

/* re-enable interrupts */
intUnlock(lock);
}

/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */

```

ISR `isr_num2_vec293` maintains a timer that stores the tick count at the time that the interrupt occurs. After updating the timer, the ISR releases the semaphore that activates `Task0`.

```

void isr_num2_vec193(void)
{
 /* Use tickGet() as a portable tick
 counter example. A much higher resolution can
 be achieved with a hardware counter */
 rtwdemo_async_M->Timing.clockTick3 = tickGet();

 /* Call the system: '<S4>/Subsystem' */
 {
 /* S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

 /* Output and update for function-call system: '<S4>/Subsystem' */

 /* S-Function (vxtask1): '<S5>/S-Function' */

 /* VxWorks Task Block: '<S5>/S-Function' (vxtask1) */
 /* Release semaphore for system task: Task0 */
 semGive(*(SEM_ID *)rtwdemo_async_DW.SFunction_PWORK.SemID);
 }
}

```

```
 /* End of Outputs for S-Function (vxtask1): '<S5>/S-Function' */
 /* End of Outputs for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
 }
}
/* VxWorks Task Block: '<S5>/S-Function' (vxtask1) */
```

### **Review Task Termination Code**

The Task Sync block generates the following termination code.

```
static void rtwdemo_async_terminate(void)
{
 /* Terminate for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

 /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
 /* Disable interrupt for ISR system: isr_num1_vec192 */
 sysIntDisable(1);

 /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
 /* Disable interrupt for ISR system: isr_num2_vec193 */
 sysIntDisable(2);

 /* End of Terminate for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

 /* Terminate for S-Function (vxinterrupt1): '<Root>/Async Interrupt' incorporates:
 * SubSystem: '<S4>/Subsystem'
 */

 /* Termination for function-call system: '<S4>/Subsystem' */

 /* Terminate for S-Function (vxtask1): '<S5>/S-Function' */

 /* VxWorks Task Block: '<S5>/S-Function' (vxtask1) */
 /* Destroy task: Task0 */
 taskDelete(rtwdemo_async_DW.SFunction_IWORK.TaskID);

 /* End of Terminate for S-Function (vxtask1): '<S5>/S-Function' */

 /* End of Terminate for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
}
}
```

## Pass Asynchronous Events in RTOS as Input To a Referenced Model

This example shows how to simulate and generate code for a model that triggers asynchronous events in an example RTOS (VxWorks®) that get passed as input to a referenced model.

### Open Example Model

Open the example model `rtwdemo_async_md\ref_top`.

Warning: Undefined function 'LibraryBrowserCustomizer' for input arguments of type 'DASstudio.CustomizationManager'.

This model shows how to simulate and generate code for asynchronous events on a real-time multitasking system. The two asynchronous events, "Interrupt1" and "Interrupt2", are executed in the referenced model via two different function-call input ports. The code generated for these blocks is specifically tailored for the VxWorks operating system. However, you can modify the Async Interrupt block to generate code specific to your environment whether or not you are using an operating system.

Copyright 2010-2012 The MathWorks, Inc.

The model simulates an interrupt source and includes an Async Interrupt block and referenced model. The Async Interrupt block creates two Versa Module Eurocard (VME) interrupt service routines (ISRs) that pass interrupt signals to Inport blocks 1 and 2 of the referenced model. You can place an Async Interrupt block between a simulated interrupt source and one of the following:

- Function call subsystem
- Task Sync block
- A Stateflow® chart configured for a function call input event
- A referenced model with a Inport block that connects to one of the preceding model elements

In this example model, the Async Interrupt block passes asynchronous events (function-call trigger signals), `Interrupt1` and `Interrupt2`, to the referenced model through Inport blocks 1 and 2.

The code generated for the Async Interrupt block is tailored for the example real-time operating system (VxWorks). However, you can modify the block to generate code specific to your run-time environment.

Open the referenced model.

The referenced model includes the two Inport blocks that receive the interrupts, each connected to an Asynchronous Task Specification block, function-call subsystems `Count` and `Algorithm`, and Rate Transition blocks. The Asynchronous Task Specification block, in combination with a root-level Inport block, allows a reference model to receive asynchronous function-call input. To use the block:

- 1** Connect the Asynchronous Task Specification block to the output port of a root-level Inport block that outputs a function-call trigger.
- 2** Select the **Output function call** parameter of the Inport block to specify that it accepts function-call signals.
- 3** On the Asynchronous Task Specification parameters dialog box, set the task priority for the asynchronous task associated with an Inport block. Specify an integer or []. If you specify an integer, it must match the priority of the interrupt initiated by the Async Interrupt block in the parent model. If you specify [], the priorities do not have to match.

The Asynchronous Task Specification block for the higher priority interrupt, `interrupt1`, connects to function-call subsystem `Count`. `Count` represents a simple interrupt service routine (ISR). The second Asynchronous Task Specification block connects to the subsystem `Algorithm`, which includes more substance. It includes multiple blocks and produces two output values. Both subsystems execute at interrupt level.

For each interrupt level specified for the Async Interrupt block in the parent model, the block generates a VME ISR that executes the connected subsystem, Task Sync block, or chart.

In the example top model, the Async Interrupt block is configured for VME interrupts 1 and 2, using interrupt vector offsets 192 and 193. Interrupt 1 is wired to trigger subsystem `Count`. Interrupt 2 is wired to trigger subsystem `Algorithm`.

The Rate Transition blocks handle data transfers between ports that operate at different rates. In two instances, the blocks protect data transfers (prevent them from being preempted and corrupted). In the other instance, no special behavior occurs.

### **Data Transfer Assumptions**

- Data transfers occur between one reading task and one writing task.
- A read or write operation on a byte-sized variable is atomic.
- When two tasks interact, only one can preempt the other.
- For periodic tasks, the task with the faster rate has higher priority than the task with the slower rate. The task with the faster rate preempts the tasks slower rates.
- Tasks run on a single processor. Time slicing is not allowed.
- Processes do not crash and restart, especially while data is being transferred between tasks.

### **Simulate the Model**

Simulate the model. By default, the model is configured to show sample times in different colors. Discrete sample times for input and output appear red and green, respectively. Constants are magenta. Asynchronous interrupts are purple. The Rate Transition Blocks, which are hybrid (input and output sample times can differ), appear yellow.

### **Generate Code and Report**

Generate code and a code generation report for the model. Async Interrupt block and Task Sync block generated code is for the example RTOS (VxWorks). However, you can modify the blocks to generate code for another run-time environment.

1. Create a temporary folder for the build and inspection process.
2. Build the model.

```
Warning: Simulink Coder: The tornado.tlc target will be removed in a future release.
```

```
Wrapping unrecognized make command (angle brackets added)
```

```
<make>
```

```
in default batch file
```

```
Successfully updated the model reference RTW target for model: rtwdemo_async_mdltre
```

```
Starting build procedure for model: rtwdemo_async_mdltre
```

```
Warning: Simulink Coder: The tornado.tlc target will be removed in a future release.
```

```

Wrapping unrecognized make command (angle brackets added)
<make>
in default batch file
Successful completion of code generation for model: rtwdemo_async_mdltreftop

```

### Review Initialization Code

Open the generated source file `rtwdemo_async_mdltreftop.c`. The initialization code connects and enables ISR `isr_num1_vec192` for interrupt 1 and ISR `isr_num2_vec193` for interrupt 2.

```

static void rtwdemo_async_mdltreftop_initialize(void)
{
 /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
 /* Connect and enable ISR function: isr_num1_vec192 */
 if (intConnect(INUM_T0_IVEC(192), isr_num1_vec192, 0) != OK) {
 printf("intConnect failed for ISR 1.\n");
 }

 sysIntEnable(1);

 /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
 /* Connect and enable ISR function: isr_num2_vec193 */
 if (intConnect(INUM_T0_IVEC(193), isr_num2_vec193, 0) != OK) {
 printf("intConnect failed for ISR 2.\n");
 }

 sysIntEnable(2);

 /* SystemInitialize for ModelReference: '<Root>/Model' */
 rtwdemo_async_mdltreftop_Init(&rtwdemo_async_mdltreftop_Y.Out1);

 /* Enable for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

 /* Enable for ModelReference: '<Root>/Model' incorporates:
 * Enable for Inport: '<Root>/In1_60hz'
 * Enable for Inport: '<Root>/In2_60_hz'
 * Enable for Inport: '<Root>/In3_60hz'
 */
 rtwdemo_async_mdltreftop_Interrupt1_Enable();
 rtwdemo_async_mdltreftop_Interrupt2_Enable();

 /* End of Enable for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
}

```

## Review ISR Code

In the generated source file `rtwdemo_async_mdltreftop.c`, review the code for ISRs `isr_num1_vec192` and `isr_num2_vec293`. Each ISR:

- Disables interrupts.
- Saves floating-point context.
- Calls the code generated for the subsystem connected to the referenced model Inport block that receives the interrupt.
- Restores floating-point context.
- Reenables interrupts.

```
void isr_num1_vec192(void)
{
 int_T lock;
 FP_CONTEXT context;

 /* disable interrupts (system is configured as non-preemptive) */
 lock = intLock();

 /* save floating point context */
 fppSave(&context);

 /* Call the system: '<Root>/Model' */
 {
 /* S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

 /* ModelReference: '<Root>/Model' incorporates:
 * Inport: '<Root>/In1_60hz'
 * Inport: '<Root>/In2_60_hz'
 * Inport: '<Root>/In3_60hz'
 */
 rtwdemo_async_mdltreftop_Interrupt1(&rtwdemo_async_mdltreftop_Y.Out1);

 /* End of Outputs for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
 }

 /* restore floating point context */
 fppRestore(&context);

 /* re-enable interrupts */
 intUnlock(lock);
}
```

```
}

/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
void isr_num2_vec193(void)
{
 FP_CONTEXT context;

 /* save floating point context */
 fppSave(&context);

 /* Call the system: '<Root>/Model' */
 {
 /* S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

 /* ModelReference: '<Root>/Model' incorporates:
 * Inport: '<Root>/In1_60hz'
 * Inport: '<Root>/In2_60_hz'
 * Inport: '<Root>/In3_60hz'
 */
 rtwdemo_async_mdrefbot_Interrupt2();

 /* End of Outputs for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
 }

 /* restore floating point context */
 fppRestore(&context);
}

```

### Review Task Termination Code

The Task Sync block generates the following termination code.

```
static void rtwdemo_async_mdleftop_terminate(void)
{
 /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
 /* Disable interrupt for ISR system: isr_num1_vec192 */
 sysIntDisable(1);

 /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
 /* Disable interrupt for ISR system: isr_num2_vec193 */
 sysIntDisable(2);
}

```

## Rate Transitions and Asynchronous Blocks

Because an asynchronous function call subsystem can preempt or be preempted by other model code, an inconsistency arises when more than one signal element is connected to an asynchronous block. The issue is that signals passed to and from the function call subsystem can be in the process of being written to or read from when the preemption occurs. Thus, some old and some new data is used. This situation can also occur with scalar signals in some cases. For example, if a signal is a double (8 bytes), the read or write operation might require two machine instructions. The following sections describe these issues.

**Note** The operating system integration techniques that are demonstrated in this section use one or more blocks the blocks in the `vxlib1` (Simulink Coder) library. These blocks provide starting point examples to help you develop custom blocks for your target environment.

---

### About Rate Transitions and Asynchronous Blocks

The Simulink Rate Transition block is designed to deal with preemption problems that occur in data transfer between blocks running at different rates. These issues are discussed in “Time-Based Scheduling and Code Generation” (Simulink Coder).

You can handle rate transition issues automatically by selecting the **Automatically handle rate transition for data transfer** parameter on the **Solver** pane of the Configuration Parameters dialog box. This saves you from having to manually insert Rate Transition blocks to avoid invalid rate transitions, including invalid *asynchronous-to-periodic* and *asynchronous-to-asynchronous* rate transitions, in multirate models. For asynchronous tasks, the Simulink engine configures inserted blocks for data integrity but not determinism during data transfers.

For asynchronous rate transitions, the Rate Transition block provides data integrity, but cannot provide determinism. Therefore, when you insert Rate Transition blocks explicitly,

you must clear the **Ensure data determinism** check box in the Block Parameters dialog box.

When you insert a Rate Transition block between two blocks to maintain data integrity and priorities are assigned to the tasks associated with the blocks, the code generator assumes that the higher priority task can preempt the lower priority task and the lower priority task cannot preempt the higher priority task. If the priority associated with task for either block is not assigned or the priorities of the tasks for both blocks are the same, the code generator assumes that either task can preempt the other task.

Priorities of periodic tasks are assigned by the Simulink engine, in accordance with the options specified in the **Solver selection** section of the **Solver** pane of the Configuration Parameters dialog box. When the **Periodic sample time constraint** option field of **Solver selection** is set to **Unconstrained**, the model base rate priority is set to 40. Priorities for subrates then increment or decrement by 1 from the base rate priority, depending on the setting of the **Higher priority value indicates higher task priority option**.

You can assign priorities manually by using the **Periodic sample time properties** field. The Simulink engine does not assign a priority to asynchronous blocks. For example, the priority of a function call subsystem that connects back to an Async Interrupt block is assigned by the Async Interrupt block.

The **Simulink task priority** field of the Async Interrupt block specifies a priority level (required) for every interrupt number entered in the **VME interrupt number(s)** field. The priority array sets the priorities of the subsystems connected to each interrupt.

For the Task Sync block, if the example RTOS (VxWorks) is the target, the **Higher priority value indicates higher task priority** option should be deselected. The **Simulink task priority** field specifies the block priority relative to connected blocks (in addition to assigning an RTOS priority to the generated task code).

The `vxlib1` library provides two types of rate transition blocks as a convenience. These are simply preconfigured instances of the built-in Simulink Rate Transition block:

- Protected Rate Transition block: Rate Transition block that is configured with the **Ensure data integrity during data transfers** on and **Ensure deterministic data transfer** off.
- Unprotected Rate Transition block: Rate Transition block that is configured with the **Ensure data integrity during data transfers** option off.

## Handle Rate Transitions for Asynchronous Tasks

For rate transitions that involve asynchronous tasks, you can maintain data integrity. However, you cannot achieve determinism. You have the option of using the Rate Transition block or target-specific rate transition blocks.

Consider the following model, which includes a Rate Transition block.

You can use the Rate Transition block in either of the following modes:

- Maintain data integrity, no determinism
- Unprotected

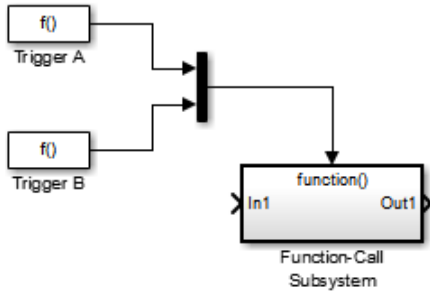

Alternatively, you can use target-specific rate transition blocks. The following blocks are available for the example RTOS (VxWorks):

- Protected Rate Transition block (reader)
- Protected Rate Transition block (writer)
- Unprotected Rate Transition block

## Handle Multiple Asynchronous Interrupts

Consider the following model, in which two functions trigger the same subsystem.

The two tasks must have equal priorities. When priorities are the same, the outcome depends on whether they are firing periodically or asynchronously, and also on a diagnostic setting. The following table and notes describe these outcomes:

**Supported Sample Time and Priority for Function Call Subsystem with Multiple Triggers**

|                            | Async Priority = 1 | Async Priority = 2 | Async Priority Unspecified | Periodic Priority = 1 | Periodic Priority = 2 |
|----------------------------|--------------------|--------------------|----------------------------|-----------------------|-----------------------|
| Async Priority = 1         | Supported (1)      |                    |                            |                       |                       |
| Async Priority = 2         |                    | Supported (1)      |                            |                       |                       |
| Async Priority Unspecified |                    |                    | Supported (2)              |                       |                       |
| Periodic Priority = 1      |                    |                    |                            | Supported             |                       |
| Periodic Priority = 2      |                    |                    |                            |                       | Supported             |

- 1 Control these outcomes using the **Tasks with equal priority** option in the **Diagnostics** pane of the Configuration Parameters dialog box; set this diagnostic to none if tasks of equal priority cannot preempt each other in the target system.
- 2 For this case, the following warning message is issued unconditionally:

The function call subsystem <name> has multiple asynchronous triggers that do not specify priority. Data integrity will not be maintained if these triggers can preempt one another.

Empty cells in the above table represent multiple triggers with differing priorities, which are unsupported.

The code generator provides absolute time management for a function call subsystem connected to multiple interrupts in the case where timer settings for `TriggerA` and `TriggerB` (time source, resolution) are the same.

Assume that all of the following conditions are true for the model shown above:

- A function call subsystem is triggered by two asynchronous triggers (`TriggerA` and `TriggerB`) having identical priority settings.
- Each trigger sets the source of time and timer attributes by calling the functions `ssSetTimeSource` and `ssSetAsyncTimerAttributes`.
- The triggered subsystem contains a block that needs elapsed or absolute time (for example, a Discrete Time Integrator).

The asynchronous function call subsystem has one global variable, `clockTick#` (where `#` is the task ID associated with the subsystem). This variable stores absolute time for the asynchronous task. There are two ways timing can be handled:

- If the time source is set to `SS_TIMESOURCE_BASERATE`, the code generator produces timer code in the function call subsystem, updating the clock tick variable from the base rate clock tick. Data integrity is maintained if the same priority is assigned to `TriggerA` and `TriggerB`.
- If the time source is `SS_TIMESOURCE_SELF`, generated code for both `TriggerA` and `TriggerB` updates the same clock tick variable from the hardware clock.

The word size of the clock tick variable can be set directly or be established according to the **Application lifespan (days)** (Simulink) setting and the timer resolution set by the `TriggerA` and `TriggerB` S-functions (which must be the same). See “Timers in Asynchronous Tasks” on page 18-46 and “Control Memory Allocation for Time Counters” on page 56-11 for more information.

## Protect Data Integrity with `volatile` Keyword

When you select **Ensure data integrity during data transfer**, the code generated for a Rate Transition block defines `volatile` global buffers and semaphores and uses them to protect the integrity of the transferred data. If necessary, for additional protection, or for protection without a Rate Transition block, you can explicitly apply `volatile` to the

transferred data. For more information, see “Protect Global Data with const and volatile Keywords” on page 30-17.

- “Asynchronous Support Limitations” (Simulink Coder)

## Timers in Asynchronous Tasks

An ISR can set a source for absolute time. This is done with the function `ssSetTimeSource`. The function `ssSetTimeSource` cannot be called before `ssSetOutputPortWidth` is called. If this occurs, the program will come to a halt and generate an error message. `ssSetTimeSource` has the following three options:

- `SS_TIMESOURCE_SELF`: Each generated ISR maintains its own absolute time counter, which is distinct from a periodic base rate or subrate counters in the system. The counter value and the timer resolution value (specified in the **Timer resolution (seconds)** parameter of the Async Interrupt block) are used by downstream blocks to determine absolute time values required by block computations.
- `SS_TIMESOURCE_CALLER`: The ISR reads time from a counter maintained by its caller. Time resolution is thus the same as its caller's resolution.
- `SS_TIMESOURCE_BASERATE`: The ISR can read absolute time from the model's periodic base rate. Time resolution is thus the same as its base rate resolution.

---

**Note** The operating system integration techniques that are demonstrated in this section use one or more blocks the blocks in the `vxlib1` (Simulink Coder) library. These blocks provide starting point examples to help you develop custom blocks for your target environment.

---

By default, the counter is implemented as a 32-bit unsigned integer member of the Timing substructure of the real-time model structure. For a target that supports the `rtModel` data structure, when the time data type is not set by using `ssSetAsyncTimeDataType`, the counter word size is determined by the **Application lifespan (days)** (Simulink) model parameter. As an example (from ERT target code),

```
/* Real-time Model Data Structure */
struct _RT_MODEL_elapseTime_exp_Tag {
 const char *errorStatus;

 /*
 * Timing:
 * The following substructure contains information regarding
 * the timing information for the model.
 */
 struct {
 uint32_T clockTick1;
```

```

 uint32_T clockTick2;
} Timing;
};

```

The example omits unused fields in the `Timing` data structure (a feature of ERT target code not found in GRT). For a target that supports the `rtModel` data structure, the counter word size is determined by the **Application lifespan (days)** (Simulink) model parameter.

By default, the `vxlib1` library blocks for the example RTOS (VxWorks) set the timer source to `SS_TIMESOURCE_SELF` and update their counters by using the system call `tickGet`. `tickGet` returns a timer value maintained by the RTOS kernel. The maximum word size for the timer is `UINT32`. The following example shows a generated call to `tickGet`.

```

/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
void isr_num2_vec193(void)
{
 /* Use tickGet() as a portable tick counter example. A much
 higher resolution can be achieved with a hardware counter */
 rtM->Timing.clockTick2 = tickGet();
 . . .
}

```

The `tickGet` call is supplied only as an example. It can (and in many instances should) be replaced by a timing source that has better resolution. If you are implementing a custom asynchronous block for an RTOS other than the example RTOS (VxWorks), you should either generate an equivalent call to the target RTOS, or generate code to read a timer register on the target hardware.

The default **Timer resolution (seconds)** parameter of your Async Interrupt block implementation should be changed to match the resolution of your target's timing source.

The counter is updated at interrupt level. Its value represents the tick value of the timing source at the most recent execution of the ISR. The rate of this timing source is unrelated to sample rates in the model. In fact, typically it is faster than the model's base rate. Select the timer source and set its rate and resolution based on the expected rate of interrupts to be serviced by the Async Interrupt block.

For an example of timer code generation, see “Async Interrupt Block Implementation” on page 18-50.

## Create a Customized Asynchronous Library

This topic describes how to implement asynchronous blocks for use with your target RTOS, using the Async Interrupt and Task Sync blocks as a starting point. Rate Transition blocks are target-independent, so you do not need to develop customized rate transition blocks. The following sections provide implementation details.

### In this section...

“About Implementing Asynchronous Blocks” on page 18-49

“Async Interrupt Block Implementation” on page 18-50

“Task Sync Block Implementation” on page 18-54

“asynclib.tlc Support Library” on page 18-56

---

**Note** The operating system integration techniques that are demonstrated in this section use one or more blocks the blocks in the `vxlib1` (Simulink Coder) library. These blocks provide starting point examples to help you develop custom blocks for your target environment.

---

### About Implementing Asynchronous Blocks

You can customize the asynchronous library blocks by modifying the block implementation. These files are

- The block's underlying S-function MEX-file
- The TLC files that control code generation of the block

In addition, you need to modify the block masks to remove references specific to the example RTOS (VxWorks) and to incorporate parameters required by your target RTOS.

Custom block implementation is an advanced topic, requiring familiarity with the Simulink MEX S-function format and API, and with the Target Language Compiler (TLC). These topics are covered in the following documents:

- Simulink topics “What Is an S-Function?” (Simulink), “Use S-Functions in Models” (Simulink), “How S-Functions Work” (Simulink), and “Implementing S-Functions” (Simulink) describe MEX S-functions and the S-function API in general.

- The “Inlining S-Functions” (Simulink Coder), “Inline C MEX S-Functions” (Simulink Coder), and “S-Functions and Code Generation” (Simulink Coder) describe how to create a TLC block implementation for use in code generation.

The following sections discuss the C/C++ and TLC implementations of the asynchronous library blocks, including required `SimStruct` macros and functions in the TLC asynchronous support library (`asynclib.tlc`).

## Async Interrupt Block Implementation

The source files for the Async Interrupt block are located in `matlabroot/rtw/c/tornado/devices` (open):

- `vxinterrupt1.c`: C MEX-file source code, for use in configuration and simulation
- `vxinterrupt1.tlc`: TLC implementation, for use in code generation
- `asynclib.tlc`: library of TLC support functions, called by the TLC implementation of the block. The library calls are summarized in “`asynclib.tlc` Support Library” on page 18-56.

## C MEX Block Implementation

Most of the code in `vxinterrupt1.c` performs ordinary functions that are not related to asynchronous support (for example, obtaining and validating parameters from the block mask, marking parameters nontunable, and passing parameter data to the `model.rtw` file).

The `mdlInitializeSizes` function uses special `SimStruct` macros and `SS_OPTIONS` settings that are required for asynchronous blocks, as described below.

Note that the following macros cannot be called before `ssSetOutputPortWidth` is called:

- `ssSetTimeSource`
- `ssSetAsyncTimerAttributes`
- `ssSetAsyncTimerResolutionEl`
- `ssSetAsyncTimerDataType`
- `ssSetAsyncTimerDataTypeEl`
- `ssSetAsyncTaskPriorities`

- `ssSetAsyncTaskPrioritiesEl`

If one of the above macros is called before `ssSetOutputPortWidth`, the following error message appears:

```
SL_SfcnMustSpecifyPortWidthBfCallSomeMacro {
S-function '%s' in '%<BLOCKFULLPATH>'
must set output port %d width using
ssSetOutputPortWidth before calling macro %s
}
```

### **ssSetAsyncTimerAttributes**

`ssSetAsyncTimerAttributes` declares that the block requires a timer, and sets the resolution of the timer as specified in the **Timer resolution (seconds)** parameter.

The function prototype is

```
ssSetAsyncTimerAttributes(SimStruct *S, double res)
```

where

- `S` is a `SimStruct` pointer.
- `res` is the **Timer resolution (seconds)** parameter value.

The following code excerpt shows the call to `ssSetAsyncTimerAttributes`.

```
/* Setup Async Timer attributes */
ssSetAsyncTimerAttributes(S,mxGetPr(TICK_RES)[0]);
```

### **ssSetAsyncTaskPriorities**

`ssSetAsyncTaskPriorities` sets the Simulink task priority for blocks executing at each interrupt level, as specified in the block's **Simulink task priority** field.

The function prototype is

```
ssSetAsyncTaskPriorities(SimStruct *S, int numISRs,
 int *priorityArray)
```

where

- `S` is a `SimStruct` pointer.
- `numISRs` is the number of interrupts specified in the **VME interrupt number(s)** parameter.

- `priorityarray` is an integer array containing the interrupt numbers specified in the **VME interrupt number(s)** parameter.

The following code excerpt shows the call to `ssSetAsyncTaskPriorities`:

```
/* Setup Async Task Priorities */
priorityArray = malloc(numISRs*sizeof(int_T));
for (i=0; i<numISRs; i++) {
 priorityArray[i] = (int_T)(mxGetPr(ISR_PRIORITIES)[i]);
}
ssSetAsyncTaskPriorities(S, numISRs, priorityArray);
free(priorityArray);
priorityArray = NULL;
}
```

### SS\_OPTION Settings

The code excerpt below shows the `SS_OPTION` settings for `vxinterrupt1.c`. `SS_OPTION_ASYNCHRONOUS_INTERRUPT` should be used when a function call subsystem is attached to an interrupt. For more information, see the documentation for `SS_OPTION` and `SS_OPTION_ASYNCHRONOUS` in `matlabroot/simulink/include/simstruc.h`.

```
ssSetOptions(S, (SS_OPTION_EXCEPTION_FREE_CODE |
 SS_OPTION_DISALLOW_CONSTANT_SAMPLE_TIME |
 SS_OPTION_ASYNCHRONOUS_INTERRUPT |
```

If an S-function specifies the `SS_OPTION_DISALLOW_CONSTANT_SAMPLE_TIME` option and inherits a sample time of `Inf`, the code generator determines how to produce code for the block based on whether the block is invariant. A block is invariant if its port signals are invariant. A signal is invariant if it has a constant value during the entire simulation. A Constant block sample time does not guarantee that the port signals are invariant. For more information, see “Inline Invariant Signals” (Simulink Coder). If the block is not invariant, the code generator produces code only in the initialize entry-point function. If the block is invariant, the code generator does not produce code for the block.

### TLC Implementation

This section discusses each function of `vxinterrupt1.tlc`, with an emphasis on target-specific features that you will need to change to generate code for your target RTOS.

#### Generate #include Directives

`vxinterrupt1.tlc` begins with the statement

```
%include "vxlib.tlc"
```

`vxlib.tlc` is a target-specific file that generates directives to include header files for the example RTOS (VxWorks). You should replace this with a file that generates includes for your target RTOS.

### **BlockInstanceSetup Function**

For each connected output of the Async Interrupt block, `BlockInstanceSetup` defines a function name for the corresponding ISR in the generated code. The functions names are of the form

```
isr_num_vec_offset
```

where *num* is the ISR number defined in the **VME interrupt number(s)** block parameter, and *offset* is an interrupt table offset defined in the **VME interrupt vector offset(s)** block parameter.

In a custom implementation, this naming convention is optional.

The function names are cached for use by the `Outputs` function, which generates the actual ISR code.

### **Outputs Function**

`Outputs` iterates over the connected outputs of the Async Interrupt block. An ISR is generated for each such output.

The ISR code is cached in the "Functions" section of the generated code. Before generating the ISR, `Outputs` does the following:

- Generates a call to the downstream block (cached in a temporary buffer).
- Determines whether the ISR should be locked or not (as specified in the **Preemption Flag(s)** block parameter).
- Determines whether the block connected to the Async Interrupt block is a Task Sync block. (This information is obtained by using the `asynclib` calls `LibGetFcnCallBlock` and `LibGetBlockAttribute`.) If so,
  - The preemption flag for the ISR must be set to 1. An error results otherwise.
  - The RTOS (VxWorks) calls to save and restore floating-point context are generated, unless the user has configured the model for integer-only code generation.

When generating the ISR code, `Outputs` calls the `asynclib` function `LibNeedAsyncCounter` to determine whether a timer is required by the connected subsystem. If so, and if the time source is set to be `SS_TIMESOURCE_SELF` by `ssSetTimeSource`, `LibSetAsyncCounter` is called to generate an RTOS (VxWorks) `tickGet` function call and update the counter. In your implementation, you should generate either an equivalent call to the target RTOS, or generate code to read the a timer register on the target hardware.

### Start Function

The `Start` function generates the required RTOS (VxWorks) calls (`int_connect` and `sysInt_Enable`) to connect and enable each ISR. You should replace this with calls to your target RTOS.

### Terminate Function

The `Terminate` function generates the call `sysIntDisable` to disable each ISR. You should replace this with calls to your target RTOS.

## Task Sync Block Implementation

The source files for the Task Sync block are located in `matlabroot/rtw/c/tornado/devices` (open). They are

- `vxtask1.cpp`: MEX-file source code, for use in configuration and simulation.
- `vxtask1.tlc`: TLC implementation, for use in code generation.
- `asynclib.tlc`: library of TLC support functions, called by the TLC implementation of the block. The library calls are summarized in “`asynclib.tlc` Support Library” on page 18-56.

### C MEX Block Implementation

Like the Async Interrupt block, the Task Sync block sets up a timer, in this case with a fixed resolution. The priority of the task associated with the block is obtained from the **Simulink task priority** parameter. The `SS_OPTION` settings are the same as those used for the Async Interrupt block.

```
ssSetAsyncTimerAttributes(S, 0.01);

priority = (int_T) (*(mxGetPr(PRIORITY)));
ssSetAsyncTaskPriorities(S, 1, &priority);
```

```

ssSetOptions(S, (SS_OPTION_EXCEPTION_FREE_CODE |
 SS_OPTION_ASYNCHRONOUS |
 SS_OPTION_DISALLOW_CONSTANT_SAMPLE_TIME |
)
}

```

## TLC Implementation

### Generate #include Directives

`vxtask1.tlc` begins with the statement

```
%include "vxlib.tlc"
```

`vxlib.tlc` is a target-specific file that generates directives to include header files for the example RTOS (VxWorks). You should replace this with a file that generates includes for your target RTOS.

### BlockInstanceSetup Function

The `BlockInstanceSetup` function derives the task name, block name, and other identifiers used later in code generation. It also checks for and warns about unconnected block conditions, and generates a storage declaration for a semaphore (`stopSem`) that is used in case of interrupt overflow conditions.

### Start Function

The `Start` function generates the required RTOS (VxWorks) calls to define storage for the semaphore that is used in management of the task spawned by the Task Sync block. Depending on the value of the `CodeFormat` TLC variable of the target, either a static storage declaration or a dynamic memory allocation call is generated. This function also creates a semaphore (`semBCreate`) and spawns an RTOS task (`taskSpawn`). You should replace these with calls to your target RTOS.

### Outputs Function

The `Outputs` function generates an example RTOS (VxWorks) task that waits for a semaphore. When it obtains the semaphore, it updates the block's tick timer and calls the downstream subsystem code, as described in "Spawn and Synchronize Execution of RTOS Task" on page 18-15. `Outputs` also generates code (called from interrupt level) that grants the semaphore.

### **Terminate Function**

The `Terminate` function generates the example RTOS (VxWorks) call `taskDelete` to end execution of the task spawned by the block. You should replace this with calls to your target RTOS.

Note also that if the target RTOS has dynamically allocated memory associated with the task, the `Terminate` function should deallocate the memory.

### **asynclib.tlc Support Library**

`asynclib.tlc` is a library of TLC functions that support the implementation of asynchronous blocks. Some functions are specifically designed for use in asynchronous blocks. For example, `LibSetAsyncCounter` generates a call to update a timer for an asynchronous block. Other functions are utilities that return information required by asynchronous blocks (for example, information about connected function call subsystems).

The following table summarizes the public calls in the library. For details, see the library source code and the `vxinterrupt1.tlc` and `vxtask1.tlc` files, which call the library functions.

## Summary of asyncLib.tlc Library Functions

| Function                             | Description                                                                                                          |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| LibBlockExecuteFcnCall               | For use by inlined S-functions with function call outputs. Generates code to execute a function call subsystem.      |
| LibGetBlockAttribute                 | Returns a field value from a block record.                                                                           |
| LibGetFcnCallBlock                   | Given an S-Function block and call index, returns the block record for the downstream function call subsystem block. |
| LibGetCallerClockTickCounter         | Provides access to the time counter of an upstream asynchronous task.                                                |
| LibGetCallerClockTickCounterHighWord | Provides access to the high word of the time counter of an upstream asynchronous task.                               |
| LibManageAsyncCounter                | Determines whether an asynchronous task needs a counter and manages its own timer.                                   |
| LibNeedAsyncCounter                  | If the calling block requires an asynchronous counter, returns TLC_TRUE, otherwise returns TLC_FALSE.                |
| LibSetAsyncClockTicks                | Returns code that sets clockTick counters that are to be maintained by the asynchronous task.                        |
| LibSetAsyncCounter                   | Generates code to set the tick value of the block's asynchronous counter.                                            |
| LibSetAsyncCounterHighWord           | Generates code to set the tick value of the high word of the block's asynchronous counter                            |

# Import Asynchronous Event Data for Simulation

## Capabilities

You can import asynchronous event data into a function-call subsystem via an Inport block. For standalone fixed-step simulations, you can specify:

- The time points at which each asynchronous event occurs
- The number of asynchronous events at each time point

## Input Data Format

You can enter your asynchronous data at the MATLAB command line or on the **Data Import/Export** pane of the Configuration Parameters dialog box. In either case, a number of restrictions apply to the data format.

- The expression for the parameter **Data Import/Export > Input** must be a comma-separated list of tables.
- The table corresponding to the input port outputting asynchronous events must be a column vector containing time values for the asynchronous events.
  - The time vector of the asynchronous events must be of double data type and monotonically increasing.
  - All time data must be integer multiples of the model step size.
  - To specify multiple function calls at a given time step, you must repeat the time value accordingly. In other words, if you wish to specify three asynchronous events at  $t = 1$  and two events at  $t = 9$ , then you must list 1 three times and 9 twice in your time vector: (`t = [1 1 1 9 9]'`)
- The table corresponding to normal data input port can be of any other supported format.

See “Load Data to Root-Level Input Ports” (Simulink) for more information.

## Example

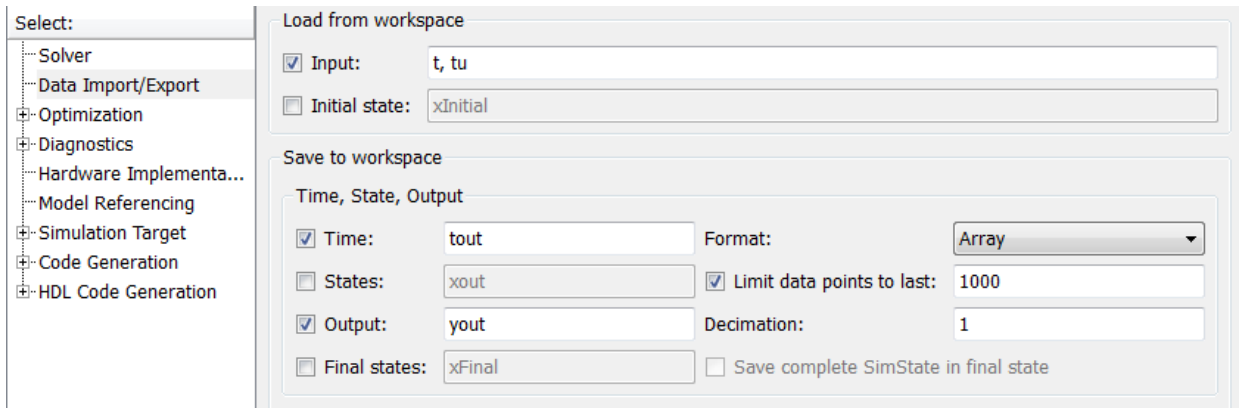

In this model, a function-call subsystem is used to track the total number of asynchronous events and to multiply a set of inputs by 2.

- 1 To input data via the Configuration Parameters dialog box,
  - a Select **Simulation > Configuration Parameters > Data Import/Export**.
  - b Select the **Input** parameter.
  - c For this example, enter the following command in the MATLAB window:

```
>> t = [1 1 5 9 9 9]', u = [[0:10]' [0:10]']
```

Alternatively, you can enter the data as  $t$ ,  $tu$  in the Data Import/Export pane:

Here,  $t$  is a column vector containing the times of asynchronous events for Inport block In1 while  $tu$  is a table of input values versus time for Inport block In2.

- 2 By default, the **Time** and **Output** options are selected and the output variables are named  $tout$  and  $yout$ .
- 3 Simulate the model.
- 4 Display the output by entering `[tout yout]` at the MATLAB command line and obtain:

ans =

```

0 0 -1
1 2 2
2 2 2
3 2 2
4 2 2
5 3 10
6 3 10
7 3 10
8 3 10
9 6 18
10 6 18

```

Here the first column contains the simulation times.

The second column represents the output of Out1 — the total number of asynchronous events. Since the function-call subsystem is triggered twice at  $t = 1$ , the output is 2. It is not called again until  $t = 5$ , and so does not increase to 3 until then. Finally, it is called three times at 9, so it increases to 6.

The third column contains the output of Out2 obtained by multiplying the input value at each asynchronous event time by 2. At any other time, the output is held at its previous value

## Asynchronous Support Limitations

### In this section...

“Asynchronous Task Priority” on page 18-63

“Convert an Asynchronous Subsystem into a Model Reference” on page 18-63

### Asynchronous Task Priority

The Simulink product does not simulate asynchronous task behavior. Although you can specify a task priority for an asynchronous task represented in a model with the Task Sync block, the priority setting is for code generation purposes only and is not honored during simulation.

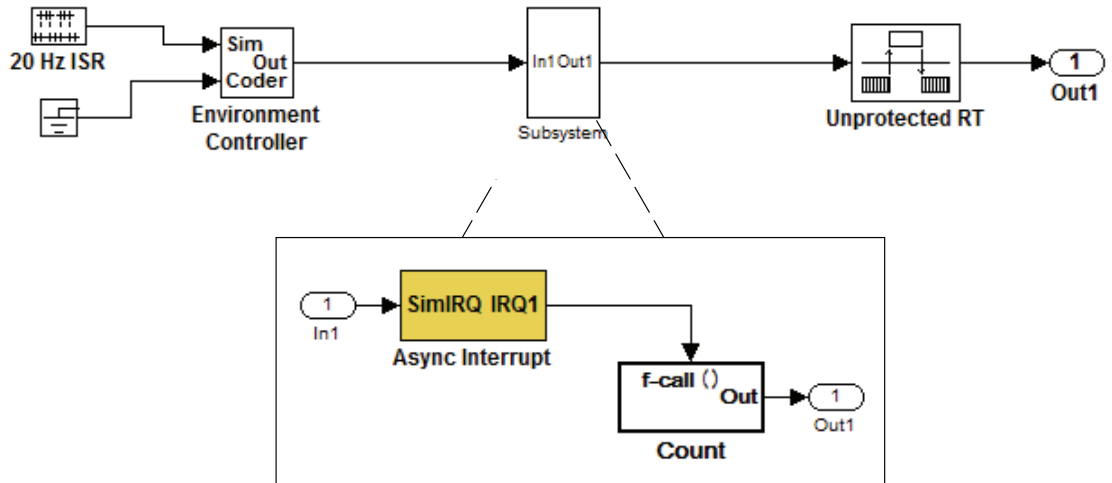

### Convert an Asynchronous Subsystem into a Model Reference

You can use the Asynchronous Task Specification block to specify an asynchronous function-call input to a model reference. However, you must convert the Async Interrupt and Function-Call blocks into a subsystem and then convert the subsystem into a model reference.

Following is an example with step-by-step instructions for conversion.

- 1 Convert the Async Interrupt and Count blocks into a subsystem. Select both blocks and right-click Count. From the menu, select **Subsystem & Model Reference > Create Subsystem from Selection**.

- 2 To prepare for converting the new subsystem to a Model block, set the following configuration parameters in the top model. Open the Configuration Parameters dialog box.
  - Under Diagnostics, navigate to the Sample Time pane. Then set **Multitask rate transition** to error and **Multitask conditionally executed subsystem** to error.
  - Under Diagnostics, navigate to the Connectivity pane. Set **Bus signal treated as vector**, and **Invalid function-call connection** to error. Also set **Context-dependent inputs** to Enable All.
  - Under Diagnostics, navigate to the Data Validity pane and set the **Multitask data store** option to error.
  - Set the **Configuration Parameters > Diagnostics > Data Validity > Advanced parameters > Underspecified initialization detection** parameter to Simplified.
  - If your model is large or complex, run the Model Advisor checks in the folder “Migrating to Simplified Initialization Mode Overview” (Simulink) and make the suggested changes.
- 3 Convert the subsystem to an atomic subsystem. Select **Edit > Subsystem Parameters > Treat as atomic unit**.

- 4 Convert the subsystem to a Model block. Right-click the subsystem and select **Subsystem & Model Reference > Convert Subsystem to > Referenced Model**. A window opens with a model reference block inside of it.
- 5 Replace the subsystem in the top model with the new model reference block.

- 6 Move the Async Interrupt block from the model reference to the top model, before the model reference block.

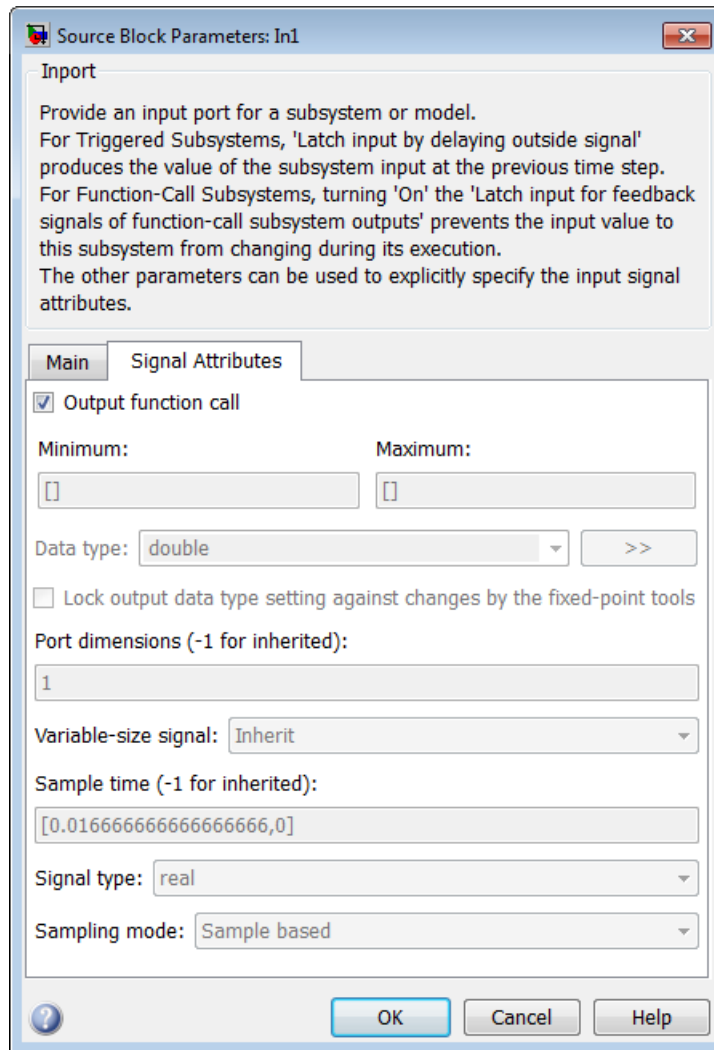

- 7 Insert an Asynchronous Task Specification block in the model reference. Set the priority of the Asynchronous Task Specification block. (For more information on setting the priority, see Asynchronous Task Specification.)

- 8 In the model reference, double-click the input port to open its Source Block Parameters dialog box. Click the **Signal Attributes** tab and select the **Output function call** option. Click **OK**.

- 9 Save your model and then perform **Simulation > Update Diagram** to verify your settings.

## Use Discrete and Continuous Time

### In this section...

“Support for Discrete and Continuous Time Blocks” on page 19-2

“Support for Continuous Solvers” on page 19-2

“Support for Stop Time” on page 19-2

### Support for Discrete and Continuous Time Blocks

The ERT target supports code generation for discrete and continuous time blocks. If the **Support: continuous time** option is selected on the **Code Generation > Interface** pane, you can use these blocks in your models, without restriction.

Note that use of certain blocks is not recommended for production code generation for embedded systems. The Simulink Block Data Type Support table summarizes characteristics of blocks in the Simulink and Fixed-Point Designer block libraries, including whether or not they are recommended for use in production code generation. To view this table, execute the following command and see the “Code Generation Support” column of the table that appears:

```
showblockdatatypetable
```

### Support for Continuous Solvers

The ERT target supports continuous solvers. In the **Solver** options dialog, you can select an available solver in the **Solver** menu. (Note that the solver **Type** must be **fixed-step** for use with the ERT target.)

---

**Note** Custom targets must be modified to support continuous time. The required modifications are described in “Customize System Target Files” (Simulink Coder).

---

### Support for Stop Time

The ERT target supports the stop time for a model. When generating host-based executables, the stop time value is honored if one of the following is true:

- **External mode** is selected on the **Code Generation > Interface** pane
- **MAT-file logging** is selected
- **Classic call interface** is selected

Otherwise, the executable runs indefinitely.

---

**Note** The ERT target provides both generated and static examples of the `ert_main.c` file. The `ert_main.c` file controls the overall model code execution by calling the `model_step` function and optionally checking the `ErrorStatus/StopRequested` flags to terminate execution. For a custom target, if you provide your own custom static `main.c`, you should consider including support for checking these flags.

## Optimize Multirate Multitasking Execution for RTOS Run-Time Environments

Using the `rtmStepTask` macro, run-time environments that employ task management mechanisms of a real-time operating system (RTOS)—for example, VxWorks—can improve performance of generated code by eliminating redundant scheduling calls during the execution of tasks in a multirate, multitasking model. The following sections describe implementation details.

### Use `rtmStepTask`

The `rtmStepTask` macro is defined in `model.h` and its syntax is as follows:

```
boolean task_ready = rtmStepTask(rtm, idx);
```

The arguments are:

- `rtm`: pointer to the real-time model structure (`rtM`)
- `idx`: task identifier (`tid`) of the task whose scheduling counter is to be tested

`rtmStepTask` returns `TRUE` if the task's scheduling counter equals zero, indicating that the task should be scheduled for execution on the current time step. Otherwise, it returns `FALSE`.

If your target supports the **Generate an example main program** parameter, you can generate calls to `rtmStepTask` using the TLC function `RTMTaskRunsThisBaseStep`.

### Schedule Code for Real-time Model without an RTOS

To understand the optimization that is available for an RTOS target, consider how the ERT target schedules tasks for bareboard targets (where RTOS is not present). The ERT target maintains scheduling counters and event flags for each subrate task. The scheduling counters are implemented within the real-time model (`rtM`) data structure as arrays, indexed on task identifier (`tid`).

The scheduling counters are updated by the base-rate task. The counters are clock rate dividers that count up the sample period associated with each subrate task. When a given subrate counter reaches a value that indicates it has a hit, the sample period for that rate has elapsed and the counter is reset to zero. When this occurs, the subrate task must be scheduled for execution.

The event flags indicate whether or not a given task is scheduled for execution. For a multirate, multitasking model, the event flags are maintained by code in the main program for the model. For each task, the code maintains a task counter. When the counter reaches 0, indicating that the task's sample period has elapsed, the event flag for that task is set.

On each time step, the counters and event flags are updated and the base-rate task executes. Then, the scheduling flags are checked in `tid` order, and tasks whose event flag is set is executed. Therefore, tasks are executed in order of priority.

For bareboard targets that cannot rely on an external RTOS, the event flags are mandatory to allow overlapping task preemption. However, an RTOS target uses the operating system itself to manage overlapping task preemption, making the maintenance of the event flags redundant.

## Schedule Code for Multirate Multitasking on an RTOS

The following task scheduling code, from `ertmainlib.tlc`, is designed for multirate multitasking operation on an example RTOS (VxWorks) target. The example uses the TLC function `RTMTaskRunsThisBaseStep` to generate calls to the `rtmStepTask` macro. A loop iterates over each subrate task, and `rtmStepTask` is called for each task. If `rtmStepTask` returns `TRUE`, the RTOS `semGive` function is called, and the RTOS schedules the task to run.

```
%assign ifarg = RTMTaskRunsThisBaseStep("i")
for (i = 1; i < %<FcnNumST>; i++) {
 if (%<ifarg>) {
 semGive(taskSemList[i]);
 if (semTake(taskSemList[i],NO_WAIT) != ERROR) {
 logMsg("Rate for SubRate task %d is too fast.\n",i,0,0,0,0);
 semGive(taskSemList[i]);
 }
 }
}
```

## Suppress Redundant Scheduling Calls

Redundant scheduling calls are still generated by default for backward compatibility. To change this setting and suppress them, add the following TLC variable definition to your system target file before the `%include "codegenentry.tlc"` statement:

```
%assign SuppressSetEventsForThisBaseRateFcn = 1
```

# Representing a Software Architecture by Creating Code Generation Definitions

---

- “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 20-2
- “Deploy Code Generation Definitions” on page 20-6
- “Conform to Software Architecture by Sharing and Copying Default Code Generation Settings Between Models” on page 20-15
- “Migrate Memory Section and Shared Utility Settings from Configuration Parameters to Code Mapping Editor” on page 20-21

## Define Storage Classes, Memory Sections, and Function Templates for Software Architecture

In a team or large organization, to enable multiple users to generate code that conforms to a standard architecture, you can create and share code generation definitions, such as storage classes, with those users. When configuring code generation settings for different models, the users can apply the definitions to data and function elements in the models, generating standardized code.

### Create Code Definitions for Use as Default Code Generation Settings

To control the default appearance of model elements in the generated code, you apply settings to categories of elements, such as data and functions, by using the Code Mapping Editor. For more information, see “Configure Default Code Generation for Categories of Model Data and Functions” on page 21-7.

To create definitions that you and other users can use in the Code Mapping Editor, use an Embedded Coder Dictionary.

When you create definitions in an Embedded Coder Dictionary, you must decide where to store the definitions.

- If you need to use the definitions only in one model, create the definitions in the Embedded Coder Dictionary of the model. If the model is not linked to a Simulink data dictionary (see “What Is a Data Dictionary?” (Simulink)), open the Embedded Coder Dictionary for the model as described in Embedded Coder Dictionary.

If you link the model to a data dictionary, you must store the definitions in the Embedded Coder Dictionary of that data dictionary, or of a referenced data dictionary, as described in “Share Embedded Coder Dictionary Definition Between Models” on page 20-6.

- If you need to use the definitions in multiple models, including the models in a model reference hierarchy, store the definitions in the Embedded Coder Dictionary of a Simulink data dictionary. For general information about data dictionaries, see “What Is a Data Dictionary?” (Simulink).

To use an Embedded Coder Dictionary, and for limitations with respect to code generation definitions in an Embedded Coder Dictionary, see Embedded Coder Dictionary.

## Create Code Definitions to Override Default Settings

To override the default settings that you specify in the Code Mapping Editor, you apply code generation settings to individual model elements by using other tools such as the Model Data Editor and the Property Inspector. For general information, see “Environment for Configuring Model Data and Functions for Code Generation” on page 21-2.

To create code definitions that you can apply through these other tools, use the Custom Storage Class Designer. You can define storage classes and memory sections, which you can apply only to data elements. For more information, see “Create Custom Storage Classes by Using the Custom Storage Class Designer” on page 26-26 and “Control Data and Function Placement in Memory by Inserting Pragmas” on page 30-2.

## Avoid Maintaining Duplicate Definitions in Packages and Dictionaries

If you want to use the same code generation definition as a default setting and for direct application to individual model elements, you do not need to store one copy of the definition in an Embedded Coder Dictionary and another copy in a package. Instead, store the definition in a package (by using the Custom Storage Class Designer). Then, configure one or more Embedded Coder Dictionaries to refer to the definition in the package. With this technique, when you want to make changes to the definition, you make the changes in only one place, the package.

However, if you create a custom storage class by using the Custom Storage Class Designer and set **Type** to `FlatStructure`, as described in “Generate Structured Data” on page 26-33, or to `Other`, as described in “Finely Control Data Representation by Writing TLC Code for a Custom Storage Class” on page 26-39, you cannot configure an Embedded Coder Dictionary to refer to the package. Therefore, you cannot use the storage class in the Code Mapping Editor.

To create a code generation definition in a package by using the Custom Storage Class Designer, see “Create Custom Storage Classes by Using the Custom Storage Class Designer” on page 26-26. Then, to configure an Embedded Coder Dictionary to refer to the package, see “Refer to Code Generation Definitions in a Package”.

## Deploy Code Generation Definitions to Users

In a large organization with multiple models and users, you can share code generation definitions by storing them in a mutually accessible location. The process of sharing code

definitions is called deployment. For more information, see “Deploy Code Generation Definitions” on page 20-6.

## Maintain Code Generation Definitions

In a model, you apply a code definition to a model element by selecting the name of the definition in a drop-down list, for example, in the Model Data Editor or in the Code Mapping Editor. Also, you can associate a memory section with a storage class or function template by using a drop-down list in the Custom Storage Class Designer or in an Embedded Coder Dictionary.

Depending on the storage location of the code definition, changing or deleting the definition can break these usage points, requiring you to take action.

### Package Definitions

If you created the code definition in a package, changing the name or deleting the definition can break usage points, which you must fix manually.

- To fix usage points for individual data elements in a model, you can optionally write a script. See the interactive and programmatic examples in “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19.
- To fix usage points in a package (for example, when you change the name of a memory section that a storage class uses), you must use the Custom Storage Class Designer. You cannot write a script.

If you loaded the package into one or more Embedded Coder Dictionaries (see “Refer to Code Generation Definitions in a Package”), when you make any changes to the code definition (including to properties other than the name) or delete the definition, you must:

- 1 Reload the package. In each dictionary, use the **Manage Package** button to unload, and then reload the package.

Reloading the package breaks usage points in the Code Mapping Editor for affected models, which you must fix manually.

- 2 Fix usage points in the Code Mapping Editor for affected models. To write a script that fixes Code Mapping Editor usage points, see “Configure Default Data and Function Code Generation Programmatically” on page 21-22.

## Embedded Coder Dictionary Definitions

If you created the code definition in an Embedded Coder Dictionary:

- Changing the name of the code definition does not break usage points. Simulink propagates the new name to the usage points.
- Deleting the code definition breaks usage points in the Code Mapping Editor for affected models. In the Editor, drop-down lists display `Unresolved`. You must fix these usage points manually. To fix them by writing a script, see “Configure Default Data and Function Code Generation Programmatically” on page 21-22.

## Interact with Code Generation Definitions Programmatically

You cannot create code generation definitions programmatically. However, for Embedded Coder Dictionary definitions, you can delete, copy, and move code definitions between models and data dictionaries by using these functions:

- `coder.dictionary.copy`
- `coder.dictionary.move`
- `coder.dictionary.remove`

- “Configure Default Code Generation for Categories of Model Data and Functions” on page 21-7

## Deploy Code Generation Definitions

As described in “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 20-2, you can create code generation definitions that you and other users can apply to model elements such as data and functions. The code definitions control the appearance of those elements in the generated code.

In a large organization with multiple models and users, you can share code generation definitions by storing them in a mutually accessible location. The process of sharing code definitions is called deployment.

### Share Code Generation Definitions Between Multiple Models and Users

When you create custom code generation definitions, to share the definitions between models and other users:

- When you create definitions in a package by using the Custom Storage Class Designer, for each user, place the folder containing the package folder on the MATLAB path. For more information, see “What Is the MATLAB Search Path?” (MATLAB).
- When you create definitions in an Embedded Coder Dictionary, store the definitions in a Simulink data dictionary. Then, link each model to a separate data dictionary. Configure each separate dictionary to refer to the dictionary that contains the code generation definitions. For an example, see “Share Embedded Coder Dictionary Definition Between Models” on page 20-6.

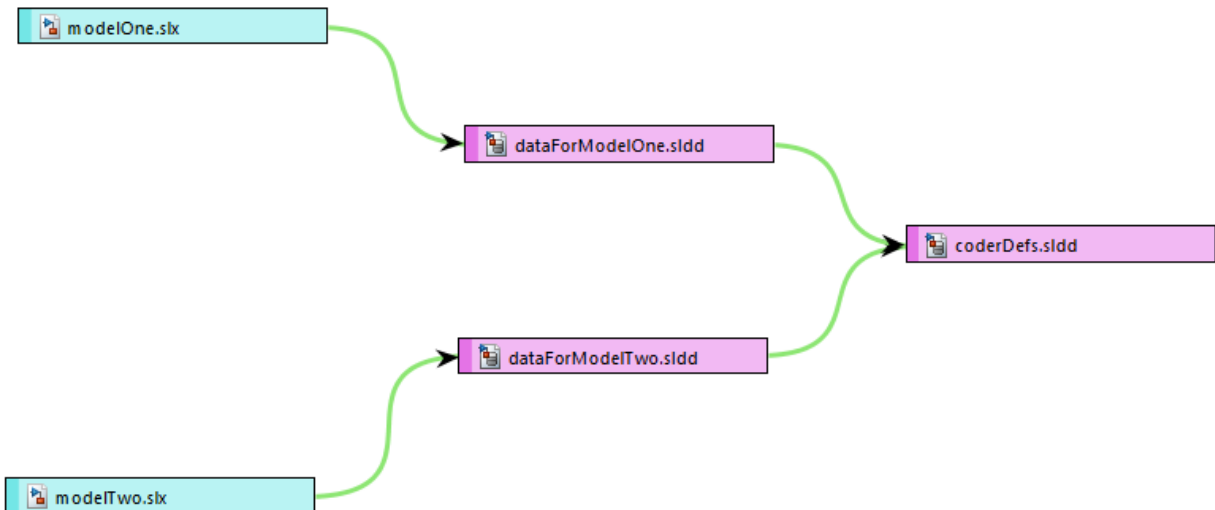

### Share Embedded Coder Dictionary Definition Between Models

This example shows how to create a storage class that yields separate global variables in the generated code and share the storage class between two models, `rtwdemo_roll` and `rtwdemo_advsc`. Then, you configure each model to use the storage class as the default code generation setting for internal data, which includes block states.

It is a best practice to store shared code generation definitions in a standalone data dictionary, which means that no models are linked directly to the dictionary. Then, you can link the target models to one or more additional, intermediate dictionaries, which you configure to refer to the standalone dictionary. With this modular dictionary hierarchy, each model can store other data, such as design data, separately from the code generation definitions.

The figure shows an example dictionary hierarchy. In the figure:

- `modelOne.slx` and `modelTwo.slx` are different model files.
- `dataForModelOne.sldd` and `dataForModelTwo.sldd` are data dictionaries. Each dictionary stores design data, such as numeric MATLAB variables, for one of the models.
- `coderDefs.sldd` is a shared data dictionary that stores code generation definitions for both models. The other dictionaries reference `coderDefs.sldd`.

### Create Code Generation Definition in Standalone Data Dictionary

Create a data dictionary. Then, create the storage class in the dictionary.

- 1 At the command prompt, open the Model Explorer.  

```
daexplr
```
- 2 In the Model Explorer, select **File > New > Data Dictionary**.
- 3 Name the dictionary `coderDefs.sldd`.
- 4 In the Model Explorer **Model Hierarchy** pane, right-click `coderDefs` and select **Show Empty Sections**.
- 5 In the **Model Hierarchy** pane, select the **Embedded Coder Dictionary** node.

- 6 In the Dialog pane (the right pane), click **Open Embedded Coder Dictionary**.
- 7 In the Embedded Coder Dictionary dialog box, click **Add**.
- 8 For the new storage class, set these property values:
  - **Name** to `internalsInFile`.
  - **Header File** to `$R_internal.h`.
  - **Definition File** to `$R_internal.c`.
- 9 In the Model Explorer **Model Hierarchy** pane, right-click `coderDefs` and select **Save Changes**.

### Link Models to Data Dictionaries

Link each model to a separate data dictionary. Then, configure each dictionary to refer to the standalone dictionary (`coderDefs.sldd`).

- 1 Open the models.

```
rtwdemo_advsc
rtwdemo_roll
```

- 2 In `rtwdemo_roll`, select **File > Model Properties > Link to Data Dictionary**.
- 3 In the Model Properties dialog box, select **Data Dictionary** and click **New**.
- 4 Use the Create a new Data Dictionary dialog box to create a dictionary named `rtwdemo_roll_data.sldd`.
- 5 In the Model Properties dialog box, click **OK**.
- 6 In the Link Model to Data Dictionary dialog box, click **OK**.

Simulink links the model to the new dictionary and attempts to migrate design data from the base workspace to the dictionary. However, the model does not use data in the base workspace, so the dictionary does not contain any data.

- 7 In the lower-left corner of the model, click the data dictionary badge, which opens the dictionary in the Model Explorer.
- 8 In the Dialog pane, under **Referenced Dictionaries**, click **Add**.
- 9 In the Open Data Dictionary dialog box, double-click `coderDefs.sldd`.
- 10 Use the **Model Hierarchy** pane to save the changes you made to `rtwdemo_roll_data.sldd`.
- 11 Link `rtwdemo_advsc` to a dictionary named `rtwdemo_advsc_data.sldd` and configure the new dictionary to refer to `coderDefs.sldd`.

`rtwdemo_advsc` uses a variable in the base workspace, so Simulink migrates the variable into the dictionary.

## Apply Code Generation Definition in Models

Confirm that the shared definition is available for use in the models by applying it as a default setting for internal data and inspecting the generated code.

- 1 In `rtwdemo_roll`, select **Code > C/C++ Code > Configure Model in Code Perspective**.
- 2 Under **Code Mappings > Data Defaults**, for the **Internal data** row, set **Storage Class** to `internalsInFile`.
- 3 In `rtwdemo_advsc`, use the Code Perspective to set **Storage Class** to `internalsInFile` for the **Internal data** row.
- 4 Generate code from `rtwdemo_roll`.
- 5 In the code generation report, inspect the generated file `rtwdemo_roll_internal.c`. The file defines global variables that correspond to state data in the model, such as the state of the Integrator block in the `BasicRollMode` subsystem.

```
/* Storage class 'internalsInFile' */
real32_T rtwdemo__FixPtUnitDelay1_DSTATE;
real32_T rtwdemo_roll_Integrator_DSTATE;
int8_T rtwde_Integrator_PrevResetState;
```

- 6 Optionally, generate code from `rtwdemo_advsc` and confirm that the code appears as expected.

## Migrate Definitions from Model File to Shared Data Dictionary

If you create code generation definitions in the Embedded Coder Dictionary of a model, the definitions are stored in the model file. If you want to share the definitions between models:

- 1 Create a shared data dictionary as shown in “Share Embedded Coder Dictionary Definition Between Models” on page 20-6. Before you proceed to the next step, make sure all of the target models have access to the shared dictionary.
- 2 Use the `coder.dictionary.move` function to migrate the definitions from the source model file to the shared data dictionary.
- 3 Optionally, copy Code Mapping Editor settings from the source model to other models by using the programmatic interface of the Code Mapping Editor (see “Configure Default Data and Function Code Generation Programmatically” on page 21-22).

In this example, you create a storage class in the Embedded Coder Dictionary of a model and use the storage class in the Code Mapping Editor. Then, you convert a subsystem to a

referenced model. To use the same Code Mapping Editor settings for the first model and for the referenced model, you must extract the storage class into a shared data dictionary (.sldd).

### Create and Apply Storage Class

- 1 Open the example model `rtwdemo_roll`.  
`rtwdemo_roll`
- 2 In the model, select **Code > C/C++ Code > Configure Model in Code Perspective**.
- 3 Underneath the block diagram, in the Code Mapping Editor, click the **Embedded Coder Dictionary** button .
- 4 In the Embedded Coder Dictionary dialog box, on the **Storage Classes** tab, click **Add**.
- 5 For the new storage class, set these property values:
  - **Name** to `internalsInFile`.
  - **Header File** to `$R_internal.h`.
  - **Definition File** to `$R_internal.c`.
- 6 In the model, in the Code Mapping Editor, for the **Data Defaults > Internal data** row, set **Storage Class** to `internalsInFile`.

### Create Referenced Model

- 1 In the model, right-click the `BasicRollMode` subsystem and select **Subsystem & Model Reference > Convert to > Referenced Model**.
- 2 In the Model Reference Conversion Advisor, click **Convert**.

The new referenced model, `BasicRollMode`, opens. The model file is in your current folder.

By default, the referenced model cannot access the code generation definitions in the Embedded Coder Dictionary of the parent model. Now, move the storage class out of the parent model and into a shared data dictionary.

### Move Storage Class to Shared Data Dictionary

As a best practice, link each model to a separate data dictionary (.sldd), create a shared, standalone data dictionary to store the code generation definition (the storage class), and

configure dictionary referencing so that all of the models can use the code generation definition.

To link the models to separate dictionaries:

- 1 In the `rtwdemo_roll` model, select **File > Model Properties > Link to Data Dictionary**.
- 2 In the Model Properties dialog box, select the **Data Dictionary** option and click **New**.
- 3 Use the Create a new Data Dictionary dialog box to create a dictionary named `rtwdemo_roll_data.sldd`.
- 4 In the Model Properties dialog box, click **OK**.
- 5 In the Link Model to Data Dictionary dialog box, click **OK**.
- 6 Click **OK** in response to the message about importing data from the base workspace.
- 7 In the `BasicRollMode` model, use the Model Properties dialog box to link the model to a new data dictionary named `basicRollMode_data.sldd`. In response to the message about changing dictionaries or moving data, click **Move Data**.

Selecting **Move Data** causes Simulink to configure the dictionary of the parent model, `rtwdemo_roll_data.sldd`, to refer to `basicRollMode_data.sldd`. To simulate and generate code from the model reference hierarchy, this reference must be in place.

To create the shared, standalone dictionary and store the code generation definition in it:

- 1 In both models, at the lower-left corner of the block diagram, click the data dictionary badge to open each dictionary in the Model Explorer.
- 2 In the Model Explorer, select **File > New > Data Dictionary**.
- 3 Create a data dictionary named `coderDefs.sldd`.
- 4 In the Model Explorer **Model Hierarchy** pane, select the `rtwdemo_roll_data` node.
- 5 In the Dialog pane (the right pane), under **Referenced Dictionaries**, click **Add**.
- 6 Add a reference to `coderDefs.sldd`.
- 7 Configure `basicRollMode_data.sldd` to refer to `coderDefs.sldd`.
- 8 In the **Model Hierarchy** pane, right-click the `rtwdemo_roll_data` node and select **Save Changes**.
- 9 At the command prompt, move the code generation definitions from the `rtwdemo_roll` model file to the `coderDefs.sldd` data dictionary.

```
coder.dictionary.move('rtwdemo_roll', 'coderDefs.sldd')
```

Now, both models have access to the storage class `internalsInFile`.

### **Copy Code Mapping Editor Settings from Parent Model to Referenced Model**

By default, the new referenced model does not use the Code Mapping Editor settings that the parent model uses. To copy the settings from the parent model to the referenced model, use the programmatic interface of the Code Mapping Editor.

At the command prompt, copy the storage class setting for **Internal data** from `rtwdemo_roll` to `BasicRollMode`.

```
roll_sc = coder.mapping.defaults.get('rtwdemo_roll','InternalData','StorageClass');
coder.mapping.create('BasicRollMode');
coder.mapping.defaults.set('BasicRollMode','InternalData','StorageClass',roll_sc);
```

Now, both models use the same Code Mapping Editor settings. For more information about the programmatic interface of the Code Mapping Editor, see “Configure Default Data and Function Code Generation Programmatically” on page 21-22.

### **Definitions in Shared Dictionary Do Not Appear in Code Mapping Editor**

If a model file contains Embedded Coder Dictionary definitions, and the model is linked to a data dictionary that also contains Embedded Coder Dictionary definitions, the Code Mapping Editor uses the definitions in the model file. To resolve this issue so that you can use the definitions in the data dictionary, remove the definitions from the model file. Use one or more of these functions:

- `coder.dictionary.remove`, which deletes all of the code generation definitions in a model file or data dictionary.
- `coder.dictionary.move`, which moves all of the code generation definitions from a model or data dictionary to a different model or data dictionary.

### **Make Shared Definitions in a Data Dictionary Available to New Models**

A model that you create from the Simulink Start Page or by using the `new_system` function is not linked to a Simulink data dictionary. The new model cannot access code generation definitions that you store in a data dictionary.

To make code definitions available to a new model out of the box, write callbacks and other code that immediately links the model to a data dictionary.

- For a simple example that shows how to link a model to a data dictionary programmatically and for information about configuring dictionary referencing programmatically, see “Store Data in Dictionary Programmatically” (Simulink).
- If you use Simulink projects, consider creating a project shortcut that creates a model and immediately links the new model to a data dictionary. For information about projects and project shortcuts, see “What Are Simulink Projects?” (Simulink).

## Use Data Dictionary to Store Code Definitions but Not Design Data

A Simulink data dictionary can store design data such as MATLAB variables and `Simulink.AliasType` objects (see “Global and Shared Data: Data Dictionary” (Simulink)). However, migrating the design data of a large model or of multiple models from the base workspace to a data dictionary can take time and careful planning.

If you want to store shared code generation definitions in a data dictionary but do not want to migrate the design data of a model, in the data dictionary to which the model is linked, select the **Allow access to base workspace** property. The model can use design data from the base workspace and code generation definitions from the dictionary or from a referenced dictionary. For more information about **Allow access to base workspace**, see “Continue to Use Shared Data in the Base Workspace” (Simulink).

## Opening Code Perspective Generates Error

In a hierarchy of referenced data dictionaries (see “Dictionary Referencing” (Simulink)), only one dictionary can store code generation definitions in an Embedded Coder Dictionary. When you open the Code Perspective in a model that has access to multiple Embedded Coder Dictionaries through referenced data dictionaries, Simulink generates an error. To resolve the error, use `coder.dictionary.move` and `coder.dictionary.remove` to transfer and delete Embedded Coder Dictionaries until only one exists in the dictionary hierarchy. If necessary, store the Embedded Coder Dictionary in a standalone, shared data dictionary as described in “Share Embedded Coder Dictionary Definition Between Models” on page 20-6.

## Limitations for Definitions in a Simulink Data Dictionary

When you store code generation definitions in a data dictionary, these limitations apply:

- In a hierarchy of referenced data dictionaries (see “Dictionary Referencing” (Simulink)), only one dictionary can store code generation definitions in an Embedded Coder Dictionary. You cannot partition the definitions by storing them in multiple referenced dictionaries.
- When you link a model to a data dictionary, if the model file contains code generation definitions in an Embedded Coder Dictionary, you cannot use code generation definitions that the data dictionary provides. To use code generation definitions from the data dictionary, use `coder.dictionary.move` or `coder.dictionary.remove` to remove the Embedded Coder Dictionary from the model file.

- “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 20-2
- “Conform to Software Architecture by Sharing and Copying Default Code Generation Settings Between Models” on page 20-15
- “Partition Data for Model Reference Hierarchy Using Data Dictionaries” (Simulink)
- “Create Custom Storage Classes by Using the Custom Storage Class Designer” on page 26-26

## **Conform to Software Architecture by Sharing and Copying Default Code Generation Settings Between Models**

You and other users can configure default code generation settings for categories of model data and functions by using the Code Mapping Editor (see “Configure Default Code Generation for Categories of Model Data and Functions” on page 21-7). You can also configure other model-wide code generation settings through configuration parameters. With these broad, general settings, you can make models generate code that conforms to a general software architecture by default.

As projects expand and you and other users create more models, manually configuring the default settings for each new model takes time. To reduce this manual data entry, you can write scripts and create templates that apply these default settings to new models.

You can copy settings between models, enabling each model to later change the settings independently of each other. Alternatively, you can share settings, enabling you to change the settings for multiple models at once with minimal effort.

## Tools to Copy and Share Settings

| Tool              | Description and Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                | Reference                                   |

| Template projects | <p>You can create a template Simulink project that contains models, data dictionaries, and other artifacts. You can also write project shortcuts that execute custom code to create models, copy settings, and share settings.</p>                                                                                                                                                                                                                            | “What Are Simulink Projects?” (Simulink)    |

| Tool                      | Description and Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Reference                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Programmatic interfaces   | To copy settings between models, you can write scripts, callbacks, and shortcuts. Each kind of setting has a programmatic interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | "Techniques to Copy Settings" on page 20-18                                                                                                                                                                                                                                                                                                               |
| Configuration set objects | To share configuration parameter settings between models, you can create a configuration set object that each model can refer to.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | "About Configuration References" (Simulink)                                                                                                                                                                                                                                                                                                               |
| Data dictionaries         | <p>A Simulink data dictionary stores variables, objects, and other data for one or more models. You can create hierarchies of referenced dictionaries to share configuration parameter settings and to partition and organize the settings.</p> <p>It is a best practice to store shared settings in a standalone dictionary, which means that no models are linked to the dictionary. Then, you can link models to one or more additional, intermediate dictionaries, which you configure to refer to the standalone dictionary. With this modular dictionary hierarchy, each model can store other data, such as design data, separately from the shared settings.</p> | <p>For general information about data dictionaries, including how to access them programmatically, see "What Is a Data Dictionary?" (Simulink). For an example that shows how to store shared data for a model reference hierarchy in a standalone dictionary, see "Partition Data for Model Reference Hierarchy Using Data Dictionaries" (Simulink).</p> |

## Techniques to Copy Settings

To copy settings, use one or more of the techniques described in the table.

| <b>Technique</b>           | <b>Description</b>                                                                                                                                                                                                 |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Create a template model.   | To create a model, you and other users can instantiate the template. Each new model can later change the settings independently of other models.                                                                   |
| Create a template project. | The template project can contain models and associated data dictionaries. Also, through custom project shortcuts and referenced projects, you can make shared data stored in a dictionary available to new models. |

| Technique                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>Write code by using programmatic interfaces.</p> | <p>You can execute this code in:</p> <ul style="list-style-type: none"> <li>• A script.</li> <li>• A model callback. For example, you can use the <code>PreLoadFcn</code> callback, which executes whenever you open a model. For information about model callbacks, see “Model Callbacks” (Simulink).</li> <li>• A Simulink Project shortcut. The shortcut can create a model and copy settings into the model. For information about project shortcuts, see “What Can You Do With Project Shortcuts?” (Simulink).</li> </ul> <p>To copy settings programmatically, use the appropriate programmatic interface.</p> <ul style="list-style-type: none"> <li>• For configuration parameter settings, use the <code>set_param</code> and <code>get_param</code> functions.</li> <li>• For Code Mapping Editor settings, see “Configure Default Data and Function Code Generation Programmatically” on page 21-22.</li> </ul> |

## Techniques to Share Settings

- To share configuration parameter settings, create a configuration set object. Create a template model that refers to the object through a configuration reference.

Consider storing the object in a data dictionary. Because you cannot create a template model that is linked to a data dictionary, you must configure dictionary linking and referencing for each new model.

- You cannot share default data and function settings that you specify in the Code Mapping Editor.

## Migrate Memory Section and Shared Utility Settings from Configuration Parameters to Code Mapping Editor

Starting in R2018a, for new models:

- To apply model-wide memory section settings, you do not use the model configuration parameters under **Code Generation > Advanced parameters > Memory Sections**. Instead, you use the Code Mapping Editor in the Code Perspective. To define the memory sections, you can continue to use packages or you can use the new Embedded Coder Dictionary.
- To set a naming rule for shared utility functions, you do not use the model configuration parameter **Code Generation > Symbols > Advanced parameters > Shared utilities identifier format**. Instead, you use the Embedded Coder Dictionary to create a function customization template that specifies the naming rule, then apply the template by using the Code Mapping Editor.

For general information about the Code Perspective, the Code Mapping Editor, and the Embedded Coder Dictionary, see “Environment for Configuring Model Data and Functions for Code Generation” on page 21-2.

In a model that you created in a release before R2018a, when you or another user opens the Code Perspective, Simulink migrates memory section and shared utility settings from the configuration parameters to the Code Mapping Editor of the model. If necessary, as part of this migration, Simulink configures the Embedded Coder Dictionary that the model uses:

- To refer to the package that defines the memory sections, as described in “Refer to Code Generation Definitions in a Package”.
- To contain a function customization template that specifies the naming rule and, if applicable, memory section settings that you specified for shared utilities.

Also, if you use the `coder.mapping.create` function on such a model, Simulink migrates memory section and shared utility settings in this manner.

### Effects of Migration

- The migration process makes changes to the model file, which you must save. The changes include:

- Translating the configuration parameter settings into Code Mapping Editor settings.
- If the model is not linked to a data dictionary, configuring the Embedded Coder Dictionary in the model file to refer to the memory section package and to contain a function customization template.
- If the model is linked to a data dictionary, the migration process makes changes to the dictionary, which you must save. The changes include:
  - If the configuration parameters are stored in the model file (the model does not refer to a `Simulink.ConfigSet` object), configuring the Embedded Coder Dictionary of the data dictionary to refer to the memory section package and to contain a function customization template.

If the data dictionary references other dictionaries, the migration process configures the dictionary at the bottom of the reference hierarchy so other models and dictionaries in the hierarchy can use the memory section and function template definitions.

- If the model refers to a `Simulink.ConfigSet` object, configuring the Embedded Coder Dictionary of the data dictionary that stores the object.

## Considerations Before Migrating

- Typically, when you open the Code Perspective, it executes the migration process without prompting you. Do not open the Code Perspective unless you are ready to migrate memory section and shared utility naming settings.

The Code Perspective prompts you to accept the migration if your model meets either of these conditions:

- The model has multiple configuration sets (one active and one or more inactive).
- The model refers to a `Simulink.ConfigSet` object.

If you do not accept, you cannot use the Code Perspective.

- If you use Simulink data dictionaries, before you or other users open the Code Perspective in any models, consider creating and configuring the dictionaries first.

In a hierarchy of referenced data dictionaries (for example, a dictionary hierarchy that parallels a model hierarchy), only one dictionary can contain an Embedded Coder Dictionary. Setting up data dictionaries before migrating associated models enables

you to control where the Embedded Coder Dictionary resides in the dictionary hierarchy. Create or identify a data dictionary at the bottom of the hierarchy so that all of the models can access the memory section and function template definitions. Then, when you initiate migration by opening the Code Perspective in a model, Simulink configures that data dictionary.

For information about sharing an Embedded Coder Dictionary between models by using referenced dictionaries, see “Share Embedded Coder Dictionary Definition Between Models” on page 20-6.

- The migration process makes changes based on the active configuration set of the model (see “Manage a Configuration Set” (Simulink)) at the time that you open the Code Perspective. Before you open the Code Perspective, activate the configuration set whose settings you want the migration process to use.

The process ignores settings in inactive configuration sets. If different configuration sets of the model specify different settings, you must choose one set to migrate.

## Considerations After Migrating

- In a branching hierarchy of referenced models and referenced data dictionaries, after you or other users migrate referenced models in different branches, opening the Code Perspective in a parent model can generate an error due to the presence of multiple Embedded Coder Dictionaries in the data dictionary hierarchy. To resolve these errors, use `coder.dictionary.move` and `coder.dictionary.remove` to transfer and delete Embedded Coder Dictionaries until only one dictionary remains. Place the remaining Embedded Coder Dictionary in a data dictionary at the bottom of the hierarchy so that all of the models can access the memory section and function template definitions.

For information about sharing an Embedded Coder Dictionary between models by using referenced dictionaries, see “Share Embedded Coder Dictionary Definition Between Models” on page 20-6.

- After you migrate a model, Embedded Coder ignores memory section and shared utility settings in the configuration parameters. If you use `set_param` or `get_param` to access these configuration parameter settings programmatically, the functions generate warnings. To change or set these settings, use the Code Mapping Editor or the equivalent programmatic interface as described in “Configure Default Code Generation for Categories of Model Data and Functions” on page 21-7.

However, if a model contains atomic subsystems that have nondefault memory section settings, the model continues to depend on the **Package** setting in the configuration parameters. See “Override Default Memory Placement for Subsystem Functions and Data” on page 30-12.

- If a model refers to a `Simulink.ConfigSet` object, after migration, the model no longer uses the memory section and shared utility settings in the object. If you used the object to set the configuration parameters of multiple models:
  - Changing memory section and shared utility settings in the object affects only models that you have not migrated.
  - Migrated models no longer acquire memory section and shared utility settings from a single location (the `Simulink.ConfigSet` object). To change these settings for these models, you must use the Code Mapping Editor of each individual model.

# Environment for Configuring Model Data and Functions for Code Generation

When you generate code from a model, the code includes:

- Entry-point functions such as *model\_step*, which your application code calls to execute the model algorithm.
- Data such as signals, states, and parameters, which your application code can read and write to.

To control the names and representation of the data and functions in the code, follow the iterative paradigm shown in the diagram.

In this paradigm:

- A software engineer directly interacts with and generates code from production models.
- A system architect helps multiple engineers and multiple projects generate code that conforms to the standards of a department or organization. The architect achieves this

standardization by customizing the Simulink development environment that engineers use.

To access tools such as the **Code Mapping Editor**, consider placing your model in the Code Perspective. In the model, select **Code > C/C++ Code > Configure Model in Code Perspective**.

### Software Engineer: Configure Default Settings

For each category of data and functions in a model, such as root-level inputs, parameters, and execution functions, you can specify default code generation settings. For example, you can configure the generated code to conform to these objectives by default:

- Read root-level input data from global variables defined by your external code.
- Store state data in structures whose placement in memory you can control.
- Name functions according to a rule that you specify.

The default settings can help you to reduce manual data entry.

- As you add blocks and signals to a model, the new data elements and functions inherit the default settings.
- To change code generation settings for many data elements or functions at once, you make the changes in one place—the default settings.
- You can use naming rules and other parameterized, abstract schemes to avoid additional duplication of effort as you make changes elsewhere in the model.

For some categories of data, code generation optimizations can eliminate the data from the code. For your default settings to apply, you must identify individual data elements that you want to preserve against the optimizations. For more information, see “Elimination of Parameters and Other Internal Data by Optimizations” on page 21-32.

To configure default settings, use the **Code Mapping Editor**.

### Software Engineer: Override Default Settings

After using the **Code Mapping Editor** to configure model-wide default settings, you can override the defaults for individual data elements and functions.

| Override Defaults For                                                        | Action                                                                                                                                                                                                          |
|------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data                                                                         | Use the Model Data Editor Code view. Apply a setting in the <b>Storage Class</b> column. See “Configure Data Properties by Using the Model Data Editor” (Simulink).                                             |
| Model entry-point functions<br><i>model_step</i> and <i>model_initialize</i> | Use the Model Interface dialog box. Open it from the <b>Code Generation &gt; Interface</b> pane in the Model Configuration Parameters dialog box. See “Customize Generated C Function Interfaces” on page 29-2. |

## System Architect: Create Code Generation Definitions

Using the Code Mapping Editor and the Model Data Editor, application developers apply code generation definitions, such as the built-in storage class `ExportedGlobal`, to model data elements and functions. To standardize the code that you and your users generate from multiple models, you can create and share custom definitions with meaningful names. Creating custom definitions also enables you to achieve code generation objectives that the built-in definitions cannot satisfy.

- To create definitions that you want to appear in the **Code Mapping Editor**, use the **Embedded Coder Dictionary**. See Embedded Coder Dictionary.

If you plan to use your Embedded Coder Dictionary definitions in one model, you can store the definitions in the model file. Alternatively, to share the definitions between models and projects, store the definitions in a Simulink data dictionary. With a data dictionary, to modify a shared definition, you change a definition in one place—the dictionary.

- To create definitions that you want to appear in other tools, such as the Model Data Editor, use the Custom Storage Class Designer. See “Create Custom Storage Classes by Using the Custom Storage Class Designer” on page 26-26.

For some definitions that you create by using the Custom Storage Class Designer, you can make the definitions appear in the Code Mapping Editor by configuring an Embedded Coder Dictionary to refer to them.

- “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 20-2

## Configure Default Code Generation for Categories of Model Data and Functions

Reduce the effort of preparing a model for code generation by specifying default configurations for categories of data elements and functions across a model. Applying default configurations can save time and reduce the risk of introducing errors in code, especially for larger models and models from which you generate multi-instance code.

You can set a default code generation configuration for:

- Categories of model data. When producing code for the data, the code generator uses a storage class that you specify to determine properties, such as whether the data is structured, naming rules for definition and header files, and whether the data is stored in a memory section.
- Categories of functions. When producing code for the functions, the code generator uses a function customization template that you specify to determine properties, such as a function naming rule and whether the function code is stored in a memory section.

You can specify the default configurations interactively in the Simulink model editing environment from the **Code Mapping Editor** or programmatically by using an API.

### Configure Default Data and Function Configurations in Model Editing Environment

To specify default code generation configurations for model data and functions interactively in Simulink model editing environment, use the **Code Mapping Editor** and Property Inspector. When a model is in Code Perspective mode, the editor and inspector are accessible. After preparing the model for code generation, the Embedded Coder Quick Start tool places a model in Code Perspective mode. Alternatively, you can enable Code Perspective mode from the Simulink Editor by doing one of the following:

- Click the perspective control in the lower-right corner and select **Code**.
- Select **Code > C/C++ Code > Configure Model in Code Perspective**.

The Code Mapping Editor appears below the model diagram. The editor display consists of two tabbed tables: **Data Defaults** and **Function Defaults**. Use the tables to associate categories of model data elements with storage classes and functions with function customization templates. When you select a row in one of the tables, the **Code** section of

the Property Inspector shows the property settings for that data element category or function category.

If you close the Code Mapping Editor, the Model Editor window remains in Code Perspective mode. To reopen the Code Mapping Editor, select **View > Code Mappings**.

After you open the Code Perspective or use the default mapping programmatic interface to configure one or more categories of data and functions for a model, setting memory section and **Shared utilities identifier format** model configuration parameters has no effect. Also, when you open the Perspective, Simulink migrates the model configuration parameter settings to the Code Mapping Editor. If necessary, as part of the migration, Simulink configures the Embedded Coder Dictionary that the model uses as described in “Migrate Memory Section and Shared Utility Settings from Configuration Parameters to Code Mapping Editor” on page 20-21.

### Configure Default Code Generation for Data

You configure default code generation for categories of data elements in a model by associating the categories with storage classes and memory sections. Data elements are grouped into these categories.

| Model Element Category | Description                                                                                                                                                 |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Inports                | Root-level input ports of a model.                                                                                                                          |
| Outports               | Root-level output ports of a model.                                                                                                                         |
| Global parameters      | Parameters that are defined in the base workspace or in a data dictionary. Multiple models in an application can use these parameters.                      |
| Local parameters       | Parameters that are defined within a model, such as parameters in the model workspace. Excludes model arguments.                                            |
| Global data stores     | Data stores that are defined by a signal object in the base workspace or in a data dictionary. Multiple models in an application can use these data stores. |

| Model Element Category   | Description                                                                                                                                                                                                                         |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Shared local data stores | Data Store Memory blocks with the block parameter <b>Share across model instances</b> set. These data stores are accessible only in the model where they are defined. The data store value is shared across instances of the model. |
| Internal data            | Local data, such as data stores, discrete block states, block output signals, and zero-crossing signals.                                                                                                                            |
| Constants                | Constant-value block output and constant parameters in a model.                                                                                                                                                                     |

The **Code Mapping Editor** presents valid storage class options for a given category. The options can include:

- Unspecified storage class (**Default**). The code generator places the code for the category of data elements in standard structures, such as `B_`, `ExtY_`, `ExtU_`, `DW_`, and `P_`. See “Standard Data Structures in the Generated Code” on page 22-26.
- Relevant built-in storage class, such as `ExportedGlobal`.
- Relevant storage class in an available package, such as `ImportFromFile`.
- Storage class defined in an Embedded Coder Dictionary.

Before configuring default code generation settings for data, consider:

| Consideration                                                                                                                                                                                                                                                    | See                                                                                                                                                                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| What categories are relevant to your model?                                                                                                                                                                                                                      | The model element categories in the preceding table                                                                                                                                                                                                                              |
| Does the model use several instances of data that are in a category? If the answer is yes, applying default mappings is beneficial. If the answer is no, consider configuring code generation for each data element individually by using the Model Data Editor. | “Configure Data Properties by Using the Model Data Editor” (Simulink), “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81, and “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19 |
| Which storage class aligns with your code generation requirements for each category?                                                                                                                                                                             | “Choose a Storage Class for Controlling Data Representation in the Generated Code” on page 22-69                                                                                                                                                                                 |

| Consideration                                                                                                                                                                                                       | See                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Do you want the model data be structured? For example, if you configured the model for multi-instance code generation, structures can improve code efficiency and readability.                                      | "Organize Data into Structures in Generated Code" on page 22-177                                                                                                                                      |
| Do categories require the code generator to store data in specific areas of memory? For example, consider whether to store initialization data in slow memory and algorithmic or computational data in fast memory. | "Define Storage Classes, Memory Sections, and Function Templates for Software Architecture" on page 20-2 and "Control Data and Function Placement in Memory by Inserting Pragmas" on page 30-2        |
| Do you want to prevent optimizations from eliminating specific data from the code?                                                                                                                                  | "Elimination of Parameters and Other Internal Data by Optimizations" on page 21-32                                                                                                                    |
| Are there data elements for which you must override the default configuration settings?                                                                                                                             | Example below.                                                                                                                                                                                        |
| Do you need to define new storage classes that you can select in the Code Mapping Editor?                                                                                                                           | "Define Storage Classes, Memory Sections, and Function Templates for Software Architecture" on page 20-2 and "Create Custom Storage Classes by Using the Custom Storage Class Designer" on page 26-26 |

This example shows how to use the **Code Mapping Editor** to specify code generation requirements for model data. The model uses multiple execution rates and is configured for single-instance usage.

In this example, the code generation requirements for data:

- Use project type definition `DBL_FLOAT` defined in header file `exDbFloat.h`.
- Get data element `ex_input1` from header file `exInDataMem.h`. The data is used for computing a value stored in memory, and then used in an if-else condition of a Switch block.
- Get data elements `ex_input2`, `ex_input3`, and `ex_input4` from header file `exInDataLut.h`. The data is used in lookup tables `Table1` and `Table2`.
- Data imported into the model from header files `exInDataMem.h` and `exInDataLut.h` is of type `DBL_FLOAT`, a project standard.

- Parameter `K1` must be tunable to enable calibration.
- Data store `mode` defines data that is shared within the model. The Logical Operator block writes to the data store and a Rate Transition block reads from the data store.
- Data element `X` represents the delay for the Unit Delay block.
- Store data that is internal to the model, such as delay `X`, in a section of memory labeled `internalDataMem`.
- Export output data declarations to header file `exSysOut.h` and definitions to `exSysOut.c`.

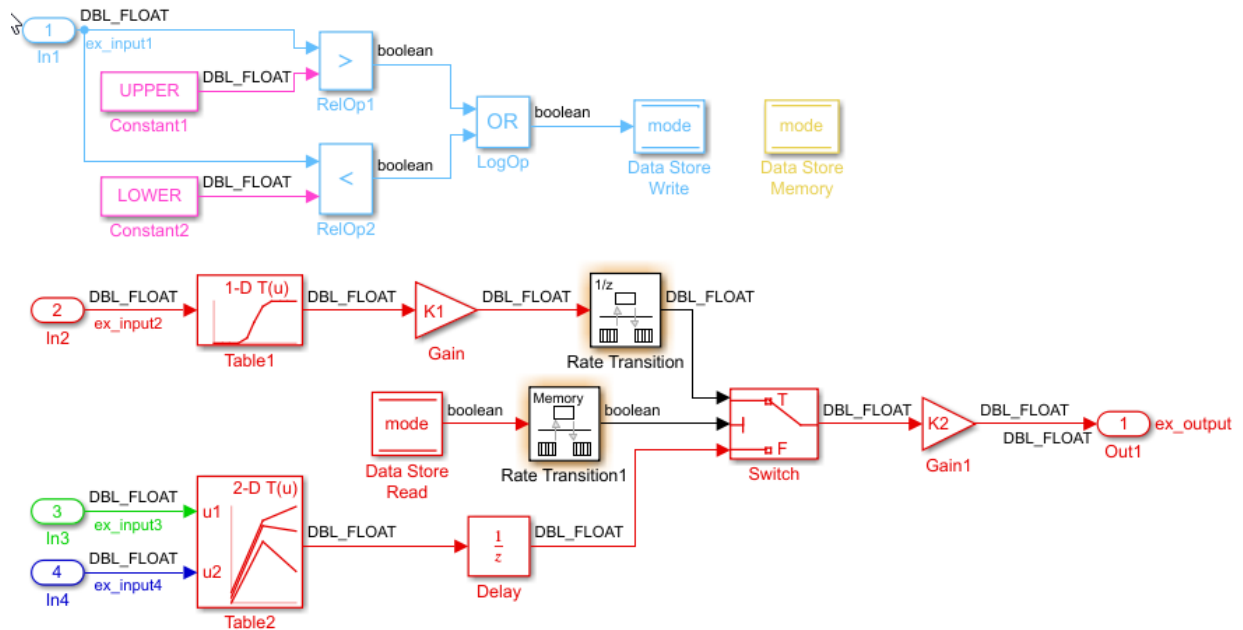

To configure default code generation mappings for the model data, use the **Code Mapping Editor**. Although the model uses single instances of some data, the example configures default settings to demonstrate different types of mappings. As you add blocks to the model, new data elements acquire the default code generation mappings.

### Set Up Example Environment

- 1 Copy these external source and header files from `matlabroot/toolbox/rtw/rtwdemos` to a writable working folder. These files define and declare the external data type and data that the generated code uses.

| File                                    | Description                                                                                                                                                                                                                                                    |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>exDbFloat.h</code>                | Defines the project data type alias for <code>double</code> , <code>DBL_FLOAT</code> . Simulink uses the <code>PreLoadFcn</code> callback specified for the model to parse this header file and create a corresponding <code>Simulink.AliasType</code> object. |
| <code>exInDataMem.c</code>              | Includes <code>exInDataMem.h</code> and defines variable <code>ex_input1</code> .                                                                                                                                                                              |
| <code>exInDataMem.h</code>              | Includes <code>exDbFloat.h</code> and declares variable <code>ex_input1</code> .                                                                                                                                                                               |
| <code>exInDataLut.c</code>              | <code>exInDataLut.c</code> includes <code>exInDataLut.h</code> and defines variables <code>ex_input2</code> , <code>ex_input3</code> , and <code>ex_input4</code> .                                                                                            |
| <code>exInDataLut.h</code>              | Includes <code>exDbFloat.h</code> and declares variables <code>ex_input2</code> , <code>ex_input3</code> , and <code>ex_input4</code> .                                                                                                                        |
| <code>rtwdemo_configdefaults.slx</code> | Example model.                                                                                                                                                                                                                                                 |

2 Open your copy of example model `rtwdemo_configdefaults`.

3 To gain access to the Code Mapping Editor, open the Code Perspective. Click **Code** > **C/C++ Code** > **Configure Model in Code Perspective**.

### Configure Default Settings for Inport Data

Specify an external header file that declares input data. Three of the four root inports read input from variables declared in header file `exInDataLut.h`. Set that header file as the default.

- 1 Under **Code Mappings - C**, in the **Data Defaults** tab, select category **Inports** and set the storage class to `ImportFromFile`.
- 2 In the Property Inspector, set **Header File** to `exInDataLut.h`.

The default mappings for a model are stored as part of the model.

### Override Default Settings for Inport In1

Override the default external header file setting for `In1`. That inport reads data from a variable declared in header file `exInDataMem.h`.

- 1 Open the Model Data Editor.
- 2 In the **Source** column, select **In1**.
- 3 Set the storage class for **In1** to `ImportFromFile`.
- 4 Set **Header File** to `inDataMem.h`.
- 5 Return to the Code Mappings Editor by clicking the **Code Mappings - C** tab.

### Configure Default Settings for Local Parameters

Configure parameters UPPER, LOWER, K1, and K2. Those parameters are local parameters for which parameter objects are stored in the model workspace. Map category **Local parameters** to storage class `ExportedGlobal`, which makes the parameter objects appear in the generated code as tunable global variables.

### Prevent Optimizations From Eliminating Parameter From Generated Code

Prevent code generator optimizations from eliminating K1 from the generated code. The data requirements indicate that K1 must be tunable. To prevent potential elimination of the variable from the generated code, in the **Code** view of the Model Data Editor, find the model workspace parameter for K1. Set the storage class to `Model default`. For more information, see “Elimination of Parameters and Other Internal Data by Optimizations” on page 21-32.

### Define Memory Section for Internal Data

Define a memory section for storing the unit delay X, data that is internal to the model.

- 1 Return to the Code Mappings Editor.
- 2 Open the Embedded Coder Dictionary by clicking .
- 3 Click the **Memory Sections** tab.
- 4 Click **Add**.
- 5 In the new row at the bottom of the table, name the new memory section `internalDataMem`. Also set:
  - **Pre Statement** to `#pragma start INTERNALDATA`
  - **Post Statement** to `#pragma end INTERNALDATA`
  - **Statements Surround** to `Group of variables`
- 6 Close the dictionary.

### Configure Default Memory Section for Internal Data

In the Code Mapping Editor, configure the code generator to place internal data in memory section `internalDataMem`.

- 1 Select category **Internal data**.
- 2 In the Property Inspector, set **Memory Section** to `internalDataMem`.

### Configure Default Settings for Output Data

Specify the default external header and definition files for variables to which the generated code writes output. Map category **Outputs** to storage class `ExportToFile`. In the Property Inspector, set **Header File** to `exSysOut.h` and **Definition File** to `exSysOut.c`. Save the model.

### Generate and Verify Code

- Use the code generation report to verify the following code: `rtwdemo_configdefaults_private.h` includes header files that declare external input data:

```
#include "exInDataMem.h"
#include "exInDataLut.h"
```

- `rtwdemo_configdefaults.c` initializes the gain variable `K1` and uses the variable in the model step function `exFast_step1`.

```
DBL_FLOAT K1 = 2.0;
.
.
.
void exFast_step1(void)
{
 DBL_FLOAT rtb_Gain;

 rtb_Gain = K1 * look1_binlc(ex_input2, rtCP_Table1_bp01Data,
 rtCP_Table1_tableData, 10U);
 .
 .
 .
}
```

- `rtwdemo_configdefaults.c` includes pragma control lines that define memory sections for the local data store, unit delay, and constants.

```
#pragma start INTERNALDATA
BlockIO_rtwdemo_configdefaults B;
#pragma end INTERNALDATA
```

```
#pragma start INTERNALDATA
D_Work_rtwdemo_configdefaults DWork;
#pragma end INTERNALDATA

#pragma start INTERNALDATA
RT_MODEL_rtwdemo_configdefaults M_;
#pragma end INTERNALDATA

#pragma start INTERNALDATA
RT_MODEL_rtwdemo_configdefaults *const M = &M_;
#pragma end INTERNALDATA
```

```
#include "rtwtypes.h"
#include "rtwdemo_dataconfig_types.h"
```

```
DBL_FLOAT Out1;
```

- Shared file `exSysOut.h` declares `Out1`. To gain access to `Out1`, external code can include this header file.

```
extern DBL_FLOAT Out1;
```

## Configure Default Code Generation for Functions

Configure default code generation for a category of functions by using the **Code Mapping Editor** to associate the category with a function customization template.

| Model Function Category | Description                                                                                                |
|-------------------------|------------------------------------------------------------------------------------------------------------|
| Initialize/Terminate    | Initialization and termination function code, such as <i>model_initialize</i> and <i>model_terminate</i> . |
| Execution               | Execution code for a model, such as <i>model_step</i> and <i>model_reset</i> .                             |
| Shared utility          | Code for shared utility functions.                                                                         |

A function customization template defines how the code generator produces code for a category of functions. For a function category, you can define:

- A rule for naming functions
- A location in memory for function definitions (memory section)

By default, the code generator uses the identifier naming rule `$R$N` to name entry-point functions. `$R` is the name of the root model. `$N` is the default code generator name of the

function, for example, `initialize`, `step`, and `terminate`. To integrate generated code with existing external code or to comply with naming standards or guidelines, you can adjust the default naming rule. Adjusting the default naming rule can save time, especially for multirate models for which the code generator produces a unique `step` function for each rate.

Unless someone has defined function customization templates for a model, the Code Mapping Editor presents `Default` as the only template option. To define a template, use the Embedded Coder Dictionary. You can open the dictionary by clicking .

Before configuring default code generation settings for functions, consider these questions.

| Consideration                                                                                                                                                                                                                                                                                                 | See                                                                                                                                                                                            |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| What categories are relevant to your model?                                                                                                                                                                                                                                                                   | "Configure Code Generation for Model Entry-Point Functions" on page 28-2                                                                                                                       |
| Do you have function naming requirements? If the answer is yes, what are they? To which categories do the requirements apply?                                                                                                                                                                                 | "Configure Code Generation for Model Entry-Point Functions" on page 28-2 and "Identifier Format Control" on page 39-22                                                                         |
| Does the model use several instances of functions that are in a category? If the answer is yes, applying default mappings is beneficial. If the answer is no, consider configuring code generation for each function separately by using function-prototype control options as described in the cited topics. | "Customize Generated C Function Interfaces" on page 29-2 and "Customize Generated Function Interfaces for Simulink Function and Function Caller Blocks" on page 29-24                          |
| Does your application require the code generator to store function code in a specific area of memory?                                                                                                                                                                                                         | "Define Storage Classes, Memory Sections, and Function Templates for Software Architecture" on page 20-2 and "Control Data and Function Placement in Memory by Inserting Pragmas" on page 30-2 |
| Do you need to define new function customization templates to include as options in the Code Mapping Editor?                                                                                                                                                                                                  | "Define Storage Classes, Memory Sections, and Function Templates for Software Architecture" on page 20-2                                                                                       |

| Consideration                                                                                    | See                                                                                          |
|--------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| What function customization template aligns with code generation requirements for each category? | "Define Function Customization Templates" on page 21-18 and <b>Embedded Coder Dictionary</b> |

This example shows how to use the **Code Mapping Editor** to specify code generation requirements for model functions. The model uses multiple execution rates and is configured for single-instance usage. The code generator produces initialize, execution, and terminate entry-point functions. Because the model uses multiple rates, the code generator produces an execution function for each rate.

In this example, code generation requirements for entry-point functions:

- Store generated initialize and terminate functions in memory section `functionSlowMem` and execution functions in memory section `functionFastMem`.
- Use the naming rule `exSlow_ $N` to name initialize and terminate entry-point functions. Use the naming rule `exFast_ $N` to name execution functions.

To configure default code generation settings for the functions, use the **Embedded Coder Dictionary** and **Code Mapping Editor**.

## Open Model

Open the copy of example model `rtwdemo_configdefaults` that you previously created.

## Define Memory Sections

Define the two memory sections: `functionSlowMem` for initialize and terminate functions and `functionFastMem` for execution functions.

- 1 Open the Embedded Coder Dictionary by clicking **Code > C/C++ Code > Embedded Coder Dictionary**.
- 2 Click the **Memory Sections** tab.
- 3 Click **Add**.
- 4 In the new row at the bottom of the table, name the new memory section `functionFastMem`. Then, set:
  - **Pre Statement** to `#pragma start FASTMEM`

- **Post Statement** to `#pragma end FASTMEM`
- 5 Click **Add** again. Name the memory section `functionSlowMem`. Then, set:
- **Pre Statement** to `#pragma start SLOWMEM`
  - **Post Statement** to `#pragma end SLOWMEM`

### Define Function Customization Templates

To configure categories of functions, define function customization templates. Unless you define templates in the Embedded Coder Dictionary that are associated with a model, the only available template is `Default`. Based on the requirements, in the dictionary, define two function customization templates: one to specify the naming rule and memory section for initialize and terminate functions and one to specify the naming rule and memory section for execution functions.

- 1 In the Embedded Coder Dictionary, click the **Function Customization Templates** tab.
- 2 Click **Add**.
- 3 In the new row of the table, name the new template `exFastFunction`. Then, set:
  - **Function Name** to `exFast_$N`. This naming rule applies the prefix `exFast_` to the name that identifies the default code generator name of the function (for example, `initialize` or `step`).
  - **Memory Section** to `functionFastMem`. This mapping associates the memory section that you defined in step 2 with the new template.
- 4 Click **Add** again. Name the template `exSlowFunction`. Then, set:
  - **Function Name** to `exSlow_$N`.
  - **Memory Section** to `functionSlowMem`.

### Configure Default Settings for Functions

- 1 To access the Code Mapping Editor, open the Code Perspective.
- 2 In the Code Mapping Editor, click the **Function Defaults** tab.
- 3 Configure the initialize and terminate entry-point functions. For category **Initialize/Terminate**, from the template menu, `exSlowFunction`.
- 4 Configure the execution entry-point functions. For category **Execution**, select template `exFastFunction`.

The default mappings for a model are stored as part of the model.

## Generate and Verify Code

Use the code generation report to verify the following code:

- The Code Interface Report section documents the generated entry-point functions:
  - `exSlow_initialize`
  - `exFast_step` (called periodically, every 0.5 seconds)
  - `exFast_step1` (called periodically, every 1 second)
  - `exFast_step2` (called periodically, every 1.5 seconds)
  - `exSlow_terminate`
- To gain access to the entry-point function code in `rtwdemo_configdefaults.c`, use the function name file links in the Code Interface Report. Verify that the correct `pragma` control statements surround the function code. For example:

```

:
:
:
#pragma start FASTMEM

void exFast_step2(void) /* Sample time: [1.5s, 0.0s] */
{
 DWork.RateTransition1_Buffer0 = ((ex_input1 > 10.0) || (ex_input1 < -10.0));
}

#pragma end FASTMEM

#pragma start SLOWMEM

void exSlow_initialize(void)
{
 /* (no initialization code required) */
}

#pragma end SLOWMEM
:
:
:

```

- To gain access to the entry-point function declarations in `rtwdemo_configdefaults.h`, use the header file links in the report. Verify that the correct `pragma` control statements surround the declarations. For example:

```

:
:
:

```

```
#pragma start SLOWMEM
extern void exSlow_initialize(void);
#pragma end SLOWMEM

#pragma start FASTMEM
extern void exFast_step0(void);
#pragma end SLOWMEM
.
.
.
```

### Configure Default Data and Function Code Generation with Definitions Stored in Shared Data Dictionary

You have the option of configuring default data and function code generation with definitions that are set up in a Simulink data dictionary. A data dictionary enables sharing of code definitions between models. Using definitions in a data dictionary, configure default mappings:

- 1 If not already defined, define code definitions (storage classes, function customization templates, and memory sections) in a data dictionary. For this example, use definitions defined in the existing data dictionary `exSharedCodeDefs.slidd`. See “Share Code Generation Definitions Between Multiple Models and Users” on page 20-6.
- 2 Link the model to the data dictionary.
- 3 Map data and function default categories to code definitions in the dictionary.

This example shows how to link model `model_rtwdemo_configdefaults` to data dictionary `exSharedCodeDefs.slidd`. That data dictionary includes Embedded Coder Dictionary definitions for:

- Memory section `internalDataMem` with **Pre Statement** set to `#pragma start INTERNALDATA` and **Post Statement** set to `#pragma end INTERNALDATA`.
- Memory section `functionFastMem` with **Pre Statement** set to `#pragma start FASTMEM` and **Post Statement** set to `#pragma end FASTMEM`.
- Memory section `functionSlowMem` with **Pre Statement** set to `#pragma start SLOWMEM` and **Post Statement** set to `#pragma end SLOWMEM`.
- Function customization template `exFastFunction` with function naming rule `exFast_$N` and memory section `functionFastMem`
- Function customization template `exSlowFunction` with function naming rule `exSlow_$N` and memory section `functionSlowMem`

Then, use the Code Mapping Editor to map data and function categories to code definitions in the data dictionary.

### Link Model to Data Dictionary

- 1 Open model `rtwdemo_configdefaults`.
- 2 In the model window, select **File > Model Properties > Link to Data Dictionary**.
- 3 In the Model Properties dialog box, select **Data Dictionary** and click **Browse**.
- 4 Open the dictionary `exSharedCodeDefs.sldd` through the Open Data Dictionary dialog box.
- 5 In the Model Properties dialog box, click **OK**. The Link Model to Data Dictionary dialog box appears. Leave the option **Migrate reference variables from base workspace to dictionary 'sharedCodeDefs.sldd'** selected. Click **OK**. Simulink links the model to the dictionary and migrates design data from the base workspace to the dictionary.
- 6 In the lower-left corner of the model, click the data dictionary badge. The dictionary opens in Model Explorer.
- 7 In the **Model Hierarchy** pane, under `exSharedCodeDefs`, select **Embedded Coder Dictionary**.
- 8 In the **Dialog** pane, click **Open Embedded Coder Dictionary**.
- 9 Verify that the dictionary includes the required code definitions.

### Configure Default Categories for Code Generation

- 1 In the model window for `rtwdemo_config_defaults`, select **Code > C/C++ Code > Configure Model in Code Perspective**.
- 2 In the Code Mapping Editor, in the **Data Defaults** tab, select category **Internal data**.
- 3 In the Property Inspector, set **Memory Section** to `internalDataMem`.
- 4 In the **Function Defaults** tab, for the **Initialize/Terminate** category, select the function customization template `exSlowFunction`. For the **Execution** category, select template `exFastFunction`.
- 5 Save the model.
- 6 Generate and review code.

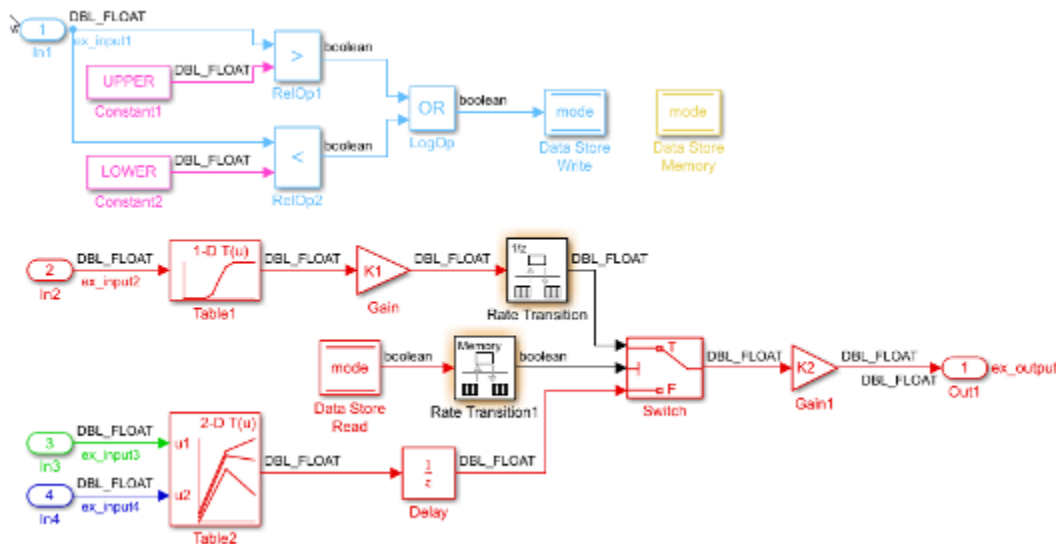

For more information about setting up an Embedded Coder Dictionary, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 20-2.

## Configure Default Data and Function Code Generation Programmatically

This example shows how to configure default data and function code generation for example model `rtwdemo_configdefaults`. The example uses the default mapping programming interface to specify code generation requirements for model data and functions. Use that interface to automate the configuration, or if you prefer to configure models programmatically. For information about configuring the default data and function code generation by using the Code Mapping Editor, see “Configure Default Code Generation for Categories of Model Data and Functions” on page 21-7.

### Open the Model

The model `rtwdemo_configdefaults` uses multiple execution rates and is configured for single-instance usage.

```
open_system('rtwdemo_configdefaults')
```

## Code Generation Requirements

For this example, the code generation requirements:

- Import project type definition for data of type `double`, `DBL_FLOAT`, from header file `exDbFloat.h`.
- Import signal `ex_input1` for computing a value stored in memory and used in an if-else condition in the Switch block. Import the signal data from header file `exInDataMem.h`.
- Import signals `ex_input2`, `ex_input3`, and `ex_input4` for lookup tables `Table1` and `Table2`. Import the signal data from header file `exInDataLut.h`.
- Data imported into the model from header files `exInDataMem.h` and `exInDataLut.h` is of type `DBL_FLOAT`, a project standard.
- Parameters `UPPER`, `LOWER`, `K1`, and `K2` are parameter objects stored in the model workspace. `K1` must be tunable to enable calibration.
- Data store mode defines data that is shared within the model.
- Data element `X` represents the delay for the Unit Delay block.
- Store data that is internal to the model in memory section `internalDataMem`.
- Store generated initialize and terminate functions in memory section `functionSlowMem` and execution functions in memory section `functionFastMem`.
- Use the identifier naming rule `exSlow_$N` to name `initialize` and `terminate` entry-point functions. Use the naming rule `exFast_$N` to name execution functions.
- Export output data declarations to header file `exSysOut.h` and definitions to `exSysOut.c`.

For this example someone, such as a system architect, has previously created these code definitions in an Embedded Coder Dictionary that is part of Simulink data dictionary `ex_configdefault.sldd`:

- Memory sections `internalDataMem`, `functionFastMem`, and `functionSlowMem`.
- Function customization templates `exFastFunction` and `exSlowFunction`.

## Create Environment for Configuring Code Generation for Data and Functions

Create an environment for configuring code generation for data and functions associated with model `rtwdemo_configdefaults` by calling the function `coder.mapping.create`. You can skip this step if you previously opened the model in Code Perspective mode.

```
coder.mapping.create('rtwdemo_condigdefaults');
```

### Identify Category, Property, and Value Combinations To Set As Data Defaults

Align the code generation requirements for data with available data categories. Each category has a set of properties that you can configure. Each property has a set of possible values. Use calls to `coder.mapping.defaults.dataCategories`, `coder.mapping.defaults.allowedProperties`, and `coder.mapping.defaults.allowedValues` to review the list of names for categories, properties, and values of interest.

For this example, you need to configure default settings for inports, outports, and parameter objects stored in the model workspace. Get a list of the available data categories by calling `coder.mapping.defaults.dataCategories`.

```
coder.mapping.defaults.dataCategories()

ans = 1x8 cell array
 Columns 1 through 4

 {'Inports'} {'Outports'} {'GlobalParameters'} {'LocalParameters'}

 Columns 5 through 7

 {'SharedLocalDat...'} {'GlobalDataStores'} {'InternalData'}

 Column 8

 {'Constants'}
```

For data categories `Inports`, `Outports`, `LocalParameters`, and `InternalData` identify the properties that you can set with calls to `coder.mapping.defaults.allowedProperties`.

```
coder.mapping.defaults.allowedProperties('rtwdemo_configdefaults', 'Inports')

ans = 2x1 cell array
 {'StorageClass'}
 {'HeaderFile' }

coder.mapping.defaults.allowedProperties('rtwdemo_configdefaults', 'Outports')

ans = 4x1 cell array
 {'StorageClass' }
```

```

 {'HeaderFile' }
 {'DefinitionFile'}
 {'Owner' }

```

```

coder.mapping.defaults.allowedProperties('rtwdemo_configdefaults', 'LocalParameters')

```

```

ans = 1x1 cell array
 {'StorageClass'}

```

```

coder.mapping.defaults.allowedProperties('rtwdemo_configdefaults', 'InternalData')

```

```

ans = 2x1 cell array
 {'StorageClass' }
 {'MemorySection'}

```

For data category and property combinations that you want to set, identify possible values with calls to `coder.mapping.defaults.allowedValues`. Based on requirements and the results of step b, specify:

- StorageClass with categories Inports, Outports, LocalParameters, and InternalData
- MemorySection with InternalData

You do not need to determine values for properties HeaderFile (for Inports and Outports) and DefinitionFile (Outports). The values that you set for those properties are known strings.

```

coder.mapping.defaults.allowedValues('rtwdemo_configdefaults', 'Inports', 'StorageClass')

```

```

ans = 9x1 cell array
 {'Default' }
 {'ExportedGlobal' }
 {'ImportedExtern' }
 {'ImportedExternPointer'}
 {'Volatile' }
 {'ExportToFile' }
 {'ImportFromFile' }
 {'AutoScope' }
 {'GetSet' }

```

```

coder.mapping.defaults.allowedValues('rtwdemo_configdefaults', 'Outports', 'StorageClass')

```

```
ans = 9x1 cell array
 {'Default' }
 {'ExportedGlobal' }
 {'ImportedExtern' }
 {'ImportedExternPointer'}
 {'Volatile' }
 {'ExportToFile' }
 {'ImportFromFile' }
 {'AutoScope' }
 {'GetSet' }
```

```
coder.mapping.defaults.allowedValues('rtwdemo_configdefaults', 'LocalParameters', 'Storage')
```

```
ans = 14x1 cell array
 {'Default' }
 {'ExportedGlobal' }
 {'ImportedExtern' }
 {'ImportedExternPointer'}
 {'Const' }
 {'Volatile' }
 {'ConstVolatile' }
 {'Define' }
 {'ImportedDefine' }
 {'ExportToFile' }
 {'ImportFromFile' }
 {'FileScope' }
 {'GetSet' }
 {'CompilerFlag' }
```

```
coder.mapping.defaults.allowedValues('rtwdemo_configdefaults', 'InternalData', 'Storage')
```

```
ans = 10x1 cell array
 {'Default' }
 {'ExportedGlobal' }
 {'ImportedExtern' }
 {'ImportedExternPointer'}
 {'Volatile' }
 {'ExportToFile' }
 {'ImportFromFile' }
 {'FileScope' }
 {'AutoScope' }
 {'GetSet' }
```

```

coder.mapping.defaults.allowedValues('rtwdemo_configdefaults', 'InternalData', 'Memory')
ans = 5x1 cell array
 {'None' }
 {'MemVolatile' }
 {'functionFastMem'}
 {'functionSlowMem'}
 {'internalDataMem'}

```

### Identify Category, Property, and Value Combinations To Set As Function Defaults

Align the code generation requirements for functions with available function categories. For this example, you need to configure default settings for initialize, execution, and terminate functions. Get a list of the available function categories by calling `coder.mapping.defaults.functionCategories`.

```

coder.mapping.defaults.functionCategories()
ans = 1x3 cell array
 {'InitializeTermi...'} {'Execution'} {'SharedUtility'}

```

The categories that apply are `InitializeTerminate` and `Execution`.

For function categories `InitializeTerminate` and `Execution`, identify the properties that you can set with calls to `coder.mapping.defaults.allowedProperties`.

```

coder.mapping.defaults.allowedProperties('rtwdemo_configdefaults', 'InitializeTerminate')
ans = 1x1 cell array
 {'FunctionCustomizationTemplate'}

```

You get the same output for category `Execution`.

For function category and property combinations that you want to set, identify possible values with calls to `coder.mapping.defaults.allowedValues`. Based on requirements and the results of calling `coder.mapping.defaults.allowedProperties`, specify `FunctionCustomizationTemplate` with categories `InitializeTerminate` and `Execution`.

```

coder.mapping.defaults.allowedValues('rtwdemo_configdefaults', 'InitializeTerminate',
'FunctionCustomizationTemplate')

```

```
ans = 3x1 cell array
 {'Default' }
 {'exSlowFunction'}
 {'exFastFunction'}
```

The list of templates is the same for InitializeTerminate and Execution.

### Set Relevant Category, Property, and Value Combinations

Set relevant category, property, and value combinations with calls to `coder.mapping.defaults.set`.

```
coder.mapping.defaults.set('rtwdemo_configdefaults', 'Inports',...
 'Storageclass', 'ImportFromFile',...
 'HeaderFile', 'exInDataLut.h');

coder.mapping.defaults.set('rtwdemo_configdefaults', 'Outports',...
 'Storageclass', 'ExportToFile',...
 'HeaderFile', 'exSysOut.h',...
 'DefinitionFile', 'exSysOut.c');

coder.mapping.defaults.set('rtwdemo_configdefaults', 'LocalParameters',...
 'Storageclass', 'ExportedGlobal');

coder.mapping.defaults.set('rtwdemo_configdefaults', 'InternalData',...
 'MemorySection', 'internalDataMem');

coder.mapping.defaults.set('rtwdemo_configdefaults', 'InitializeTerminate',...
 'FunctionCustomizationTemplate', 'exSlowFunction');

coder.mapping.defaults.set('rtwdemo_configdefaults', 'Execution',...
 'FunctionCustomizationTemplate', 'exFastFunction');
```

### Verify Default Mappings

Verify default mappings with calls to `coder.mapping.defaults.get`.

```
coder.mapping.defaults.get('rtwdemo_configdefaults', 'Inports', 'StorageClass')

ans =
'ImportFromFile'

coder.mapping.defaults.get('rtwdemo_configdefaults', 'Inports', 'HeaderFile')
```

```
ans =
'exInDataLut.h'

coder.mapping.defaults.get('rtwdemo_configdefaults', 'Outports', 'StorageClass')

ans =
'ExportToFile'

coder.mapping.defaults.get('rtwdemo_configdefaults', 'Outports', 'HeaderFile')

ans =
'exSysOut.h'

coder.mapping.defaults.get('rtwdemo_configdefaults', 'Outports', 'DefinitionFile')

ans =
'exSysOut.c'

coder.mapping.defaults.get('rtwdemo_configdefaults', 'LocalParameters',...
 'StorageClass')

ans =
'ExportedGlobal'

coder.mapping.defaults.get('rtwdemo_configdefaults', 'InternalData',...
 'MemorySection')

ans =
'internalDataMem'

coder.mapping.defaults.get('rtwdemo_configdefaults', 'InitializeTerminate',...
 'FunctionCustomizationTemplate')

ans =
'exSlowFunction'

coder.mapping.defaults.get('rtwdemo_configdefaults', 'Execution',...
 'FunctionCustomizationTemplate')

ans =
'exFastFunction'
```

### Override Header File Setting

Override the header file setting for input signal `ex_input1`. Previously, you set the default header file for data in the `Inports` category to `exInDataLut.h`. The

requirements specify that you import data for that signal from header file `exInDataMem.h`.

Create a handle to the output port of block In1.

```
portHandles = get_param('rtwdemo_configdefaults/In1', 'PortHandles');
outH = portHandles.Outport;
```

In the base workspace, create a temporary signal object.

```
temp_Obj = Simulink.Signal
temp_Obj =
 Signal with properties:

 CoderInfo: [1x1 Simulink.CoderInfo]
 Description: ''
 DataType: 'auto'
 Min: []
 Max: []
 Unit: ''
 Dimensions: -1
DimensionsMode: 'auto'
 Complexity: 'auto'
 SampleTime: -1
 InitialValue: ''
```

In the nested `Simulink.CoderInfo` object, set the `StorageClass` property to `CIn` in step 3, `youustom`. Then, use the `CustomStorageClass` property to specify the storage class `ImportFromFile`.

```
temp_Obj.CoderInfo.StorageClass = 'Custom';
temp_Obj.CoderInfo.CustomStorageClass = 'ImportFromFile';
```

Define the instance-specific header file, `exDataInMem.h`, in the nested `Simulink.CoderInfo` object by using the `CustomAttributes` property.

```
temp_Obj.CoderInfo.CustomAttributes.HeaderFile='exInDataMem.h';
```

Embed the signal object in the target signal line by attaching a copy of the temporary workspace object.

```
set_param(outH, 'SignalObject', temp_Obj);
```

Clear the object from the base workspace. The signal now uses an embedded copy of the object.

```
clear tempObj
```

## Unresolved Storage Classes, Function Customization Templates, and Memory Sections

If someone removes the definition for a storage class, function customization template, or memory section from the Embedded Coder Dictionary associated with a model, the **Code Mapping Editor** identifies the definition as **Unresolved**. For example, this figure shows that the function customization template for execution entry-point functions was removed from the dictionary associated with the model.

|           | Model Function Category | Function Customization Template |
|-----------|-------------------------|---------------------------------|
| <i>fx</i> | Initialize/Terminate    | exSlowFunction                  |
| <i>fx</i> | Execution               | ! Unresolved                    |
| <i>fx</i> | Shared utility          | Default                         |

To fix the unresolved code definition, do one of the following:

- In the second column of the Code Mapping Editor, select a different definition from the **Storage Classes, Function Customization Templates, or Memory Sections** list.
- Replace or add an appropriate definition to the Embedded Coder Dictionary. Then, update the mapping.

- Consult with someone else, such as the system architect for your project, about adding an appropriate definition to the Embedded Coder Dictionary. Then, update the mapping.

### Elimination of Parameters and Other Internal Data by Optimizations

Code generation optimizations can eliminate data from the code, which means your application code cannot interact with the data. For general information about data elimination by optimizations, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50.

The optimizations can eliminate data in these categories:

- **Global parameters**
- **Local parameters**
- **Internal data**

The optimizations cannot eliminate:

- Data in other categories.
- Data that the code needs for numeric accuracy, including most block states, which are in the **Internal data** category.

After eliminating data with optimizations, the code generator applies the default code generation settings in the Code Mapping Editor to the remaining data. For parameters and signal lines, optimizations can eliminate data for an entire category. If this happens, default settings that you specify for that category do not apply to data.

To prevent optimizations from eliminating individual data elements, explicitly apply a storage class to the element by using the Model Data Editor. The storage class controls the appearance of the data in the generated code. To force a data element to use the default storage class that you specify in the Code Mapping Editor, explicitly apply the storage class `Model default`. See “Choose a Storage Class for Controlling Data Representation in the Generated Code” on page 22-69.

## Limitations

- For a referenced model, map data element categories **Inports** and **Outports** to **Default**, a built-in storage class other than **ParamStruct** or **SignalStruct**, or a package storage class.
- For these categories, use the built-in storage class **SignalStruct** or create your own structured storage class in an Embedded Coder Dictionary.
  - **Inport**
  - **Output**
  - **Internal data**
- For these categories, set up default mappings to a storage class defined with property **Const** selected or property **Data Initialization** set to **Dynamic** or **None**:
  - **Inports**
  - **Outports**
  - Data store categories
  - **Internal data**
- Map parameter categories to storage classes defined with the **Data Initialization** property set to **Static** or **None**.
- Map categories **Inport**, **Output**, and **Internal data**, where at least one data element in the category is specified with symbolic dimensions (see “Define Variable-Size Data for Code Generation” (Simulink)), to a storage class defined with the **Data Scope** property set to **Imported**.
- Map data element categories **Global parameters** and **Global data stores** to **Default**, a built-in storage class other than **ParamStruct** or **SignalStruct**, or a package storage class.
- If a model includes a reusable subsystem (subsystem with block parameter **Function packaging** set to **Reusable function**) that contains a shared local data store, map the category **Shared local data stores** to a storage class that is defined in the Embedded Coder Dictionary for that model. For more information, see “Generate Reentrant Code from Subsystems” on page 6-42.
- For top and referenced models configured for multi-instance usage (see “Generate Reentrant Code from Top Models” on page 6-24 and “Generate Reentrant Code from Simulink Function Blocks” on page 6-30), map data element categories to storage classes that have the **Storage Type** property set to **Structured**.

- If a model uses data object alignment, do not configure default data mappings for the model. For more information, see `Simulink.CoderInfo`.
- If you configure a model with a code replacement library that includes a data alignment specification, you cannot configure default code mappings that involve storage classes defined in an Embedded Coder Dictionary. For more information, see “Data Alignment for Code Replacement” on page 54-136.
- When evaluating storage class settings for variant control variables, the code generator ignores default mappings. For more information, see “Represent Subsystem and Model Variants in Generated Code” on page 15-23.
- Default mappings for global data categories must be the same across model reference hierarchies.
- You cannot set up default mappings to:
  - Structure-based built-in storage classes, `Struct` and `BitField`
  - Package storage classes of type `FlatStructure` or `Other` (requires you to write TLC code) , which you create with the Custom Storage Class Designer
- .
- When a model is configured for compact file packaging, you cannot map a data element category to a storage class defined with the **Data Scope** property set to `Exported` and the **Header File** property set to a naming rule other than `$N.h`.
- Storage classes defined in an Embedded Coder Dictionary are not compatible with models that contain nonreusable subsystems with separate data or are configured to generate a C++ class interface.
- If a model contains a tunable, nonfinite parameter (for example, with a value of `inf`):
  - If you specify the nonfinite value directly in the model, without using a MATLAB variable or parameter object (such as `Simulink.Parameter`), in the generated code, the parameter appears as a field of the default parameter data structure (see “Standard Data Structures in the Generated Code” on page 22-26). The parameter does not use the storage class that you specify for the corresponding category of parameter data in the Code Mapping Editor.
  - If you store the nonfinite value in a variable or parameter object, for the corresponding category of parameter data in the Code Mapping Editor, you cannot use a storage class that you create in an Embedded Coder Dictionary. When you try to generate code, the model generates an error. Choose one of these workarounds:

- Apply a storage class other than `Auto` or `Model default` directly to the nonfinite parameter as described in “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81.
- If only one block uses the variable or object, instead of using the variable or object, specify the nonfinite value directly in the model, in the block parameter.

## Configure Data Accessibility for Rapid Prototyping

As you iteratively develop a model, you capture the values of signals and states that model execution generates. You also tune parameter values during execution to observe the effect on the signals and states. You can then base your design decisions upon analysis of these outputs. To access signal, state, and parameter data in a rapid prototyping environment, you can configure the generated code to store the data in addressable memory.

Depending on the system target file that you use (such as `grt.tlc`), by default, optimization settings can make the generated code more efficient by:

- Eliminating unnecessary global and local storage for signals and some states.

However, the optimizations do not eliminate storage for root-level Inport and Outport blocks, which represent the primary inputs and outputs of a system. To access this data, you do not need to take optimizations into consideration.

- Inlining the numeric values of block parameters. The code does not store the parameters in memory, so you cannot interact with the parameters during code execution.

To generate code that instead allocates addressable memory for this data, you can disable the optimizations, or override the optimizations by specifying code generation settings for individual data items.

### Access Signal, State, and Parameter Data During Execution

For an example that shows how to configure data accessibility for rapid prototyping, see “Access Signal, State, and Parameter Data During Execution” on page 22-7.

## Configure Data Accessibility

| Goal                                                                                | Considerations and More Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Configure signals as accessible and parameters as tunable by default                | <p>Clear the model configuration parameter <b>Signal storage reuse</b> and set the configuration parameter <b>Default parameter behavior</b> to <b>Tunable</b>. These settings prevent the elimination of storage for signals and prevent parameter inlining. Each block parameter and signal line appears in the generated code as a field of a structure. For more information about these data structures, see “How Generated Code Exchanges Data with an Environment” on page 22-33 and “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50.</p> <p>For more information about <b>Default parameter behavior</b>, see “Default parameter behavior” (Simulink Coder). For more information about optimizations that eliminate storage for signals, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50 and “Minimize Computations and Storage for Intermediate Results at Block Outputs” (Simulink Coder).</p>                                                                                                                                         |
| Preserve accessibility and tunability of a data item after you select optimizations | <p>You can generate more efficient code by selecting optimizations such as <b>Signal storage reuse</b>, but the code generator eliminates storage for as many data items as possible. To exclude individual data items from the optimizations:</p> <ul style="list-style-type: none"> <li>• Configure a signal as a test point (see “Configure Signals as Test Points” (Simulink)) or apply a storage class such as <code>ExportedGlobal</code> to the signal (see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81). If you use test points, when you later configure the model for efficient production code, you can subject all of the test-point signals to optimizations by selecting the model configuration parameter <b>Ignore test point signals</b>. Apply a storage class only when you need to control the representation of the signal in the code.</li> <li>• Apply a storage class, such as <code>ExportedGlobal</code>, to states and parameters. See “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81.</li> </ul> |

| Goal                                                                      | Considerations and More Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Represent a data item as a separate global variable in the generated code | When you disable optimizations, signal lines, block states, and parameters appear in the generated code as fields of structures. You cannot control the names of the structures without Embedded Coder. To instead store a data item in a separate global variable whose name, file placement, and other characteristics you can control, apply a storage class to a signal, state, or Simulink.Parameter object. See “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81.                                                                                                                  |
| Generate a standardized C-code interface for accessing data               | You can configure the generated code to contain extra code and files so that you can access model data through standardized interfaces. For more information, see “Exchange Data Between Generated and External Code Using C API” on page 46-2.                                                                                                                                                                                                                                                                                                                                                                                        |
| Tune parameters and monitor signals during external mode simulation       | <p>When you generate code and an external executable from a model, you can simulate the model in external mode to communicate with the running executable. You can tune parameters and monitor signals during the simulation. However, in this simulation mode, parameter tunability limitations that apply to code generation also apply to the simulation. For information about the code generation limitations, see “Limitations for Block Parameter Tunability in the Generated Code” on page 22-135.</p> <p>For information about external mode, see “Host-Target Communication with External Mode Simulation” on page 44-2.</p> |
| Tune parameters and monitor signals with Simulink Real-Time               | If you have Simulink Real-Time, you can tune parameters and monitor signals during execution of your real-time application. Make signals accessible and parameters tunable by clearing optimizations and applying test points and storage classes. See “Parameter Tuning with Simulink Real-Time Explorer” (Simulink Real-Time).                                                                                                                                                                                                                                                                                                       |

## Limitations

For information about limitations that apply to the tunability of parameters in the generated code, see “Limitations for Block Parameter Tunability in the Generated Code” on page 22-135.

## Access Signal, State, and Parameter Data During Execution

As you iteratively develop a model, you capture output signal and state data that model execution generates. You also tune parameter values during execution to observe the effect on the outputs. You can then base your design decisions upon analysis of these outputs. To access this signal, state, and parameter data in a rapid prototyping environment, you can configure the generated code to store the data in addressable memory.

By default, optimization settings make the generated code more efficient by eliminating unnecessary signal storage and inlining the numeric values of block parameters. To generate code that instead allocates addressable memory for this data, you can disable the optimizations or specify code generation settings for individual data items.

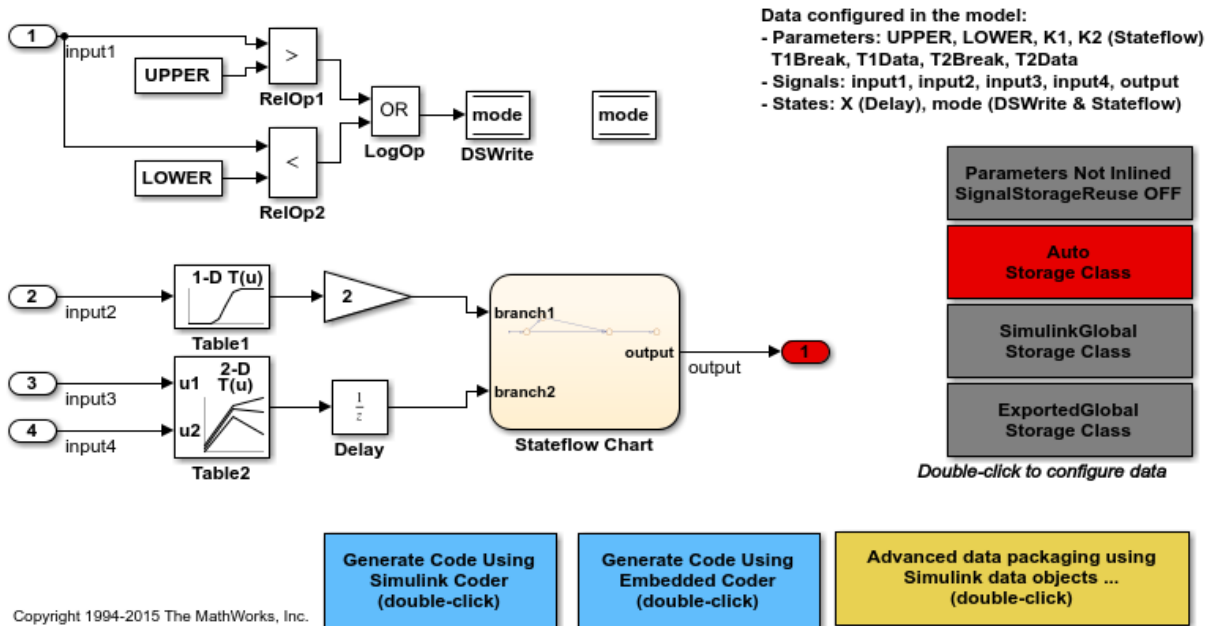

### Explore Example Model

Run a script that prepares the model `rtwdemo_basicsc` for this example.

```
run(fullfile(matlabroot, 'examples', 'simulinkcoder', 'main', 'prepare_rtwdemo_basicsc'));
```

Open the example model, `rtwdemo_basicsc`.

```
rtwdemo_basicsc
```

Copyright 1994-2015 The MathWorks, Inc.

The model loads numeric MATLAB variables into the base workspace. The workspace variables set some block parameters in the model. However, The Gain block in the model uses the literal value 2.

### Disable Optimizations

In the model, clear the model configuration parameter **Signal storage reuse**. When you clear this optimization and other optimizations such as **Eliminate superfluous local variables (expression folding)**, the generated code allocates memory for signal lines. Clearing **Signal storage reuse** disables most of the other optimizations.

```
set_param('rtwdemo_basicsc', 'OptimizeBlockIOStorage', 'off')
```

Set the optimization **Configuration Parameters > Optimization > Default parameter behavior** to Tunable. When set to Tunable, this configuration parameter causes the generated code to allocate memory for block parameters and workspace variables.

```
set_param('rtwdemo_basicsc', 'DefaultParameterBehavior', 'Tunable')
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')

Starting build procedure for model: rtwdemo_basicsc
Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generation report, view the file `rtwdemo_basicsc.h`. This header file defines a structure type that contains signal data. The structure contains fields that each represent a signal line in the model. For example, the output signal of the Gain block, whose name is Gain, appears as the field Gain.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.h');
rtwdemodbtype(file,'/* Block signals (default storage) */',...
 'B_rtwdemo_basicsc_T;',1,1)
```

```
/* Block signals (default storage) */
typedef struct {
 real32_T Table1; /* '<Root>/Table1' */
 real32_T Gain; /* '<Root>/Gain' */
 real32_T Delay; /* '<Root>/Delay' */
 real32_T Table2; /* '<Root>/Table2' */
 boolean_T RelOp1; /* '<Root>/RelOp1' */
 boolean_T RelOp2; /* '<Root>/RelOp2' */
 boolean_T LogOp; /* '<Root>/LogOp' */
} B_rtwdemo_basicsc_T;
```

The file defines a structure type that contains block parameter data. For example, the **Gain** parameter of the Gain block appears as the field `Gain_Gain`. The other fields of the structure represent other block parameters and workspace variables from the model, including initial conditions for signals and states.

```
rtwdemodbtype(file,'/* Parameters (default storage) */',...
 '/* Real-time Model Data Structure */',1,0)
```

```
/* Parameters (default storage) */
struct P_rtwdemo_basicsc_T_ {
 real_T K2; /* Variable: K2
 * Referenced by: '<Root>/Stateflow Chart'
 */
 real32_T LOWER; /* Variable: LOWER
 * Referenced by: '<Root>/Constant2'
 */
 real32_T T1Break[11]; /* Variable: T1Break
 * Referenced by: '<Root>/Table1'
 */
};
```

```

real32_T T1Data[11]; /* Variable: T1Data
 * Referenced by: '<Root>/Table1'
 */
real32_T T2Break[3]; /* Variable: T2Break
 * Referenced by: '<Root>/Table2'
 */
real32_T T2Data[9]; /* Variable: T2Data
 * Referenced by: '<Root>/Table2'
 */
real32_T UPPER; /* Variable: UPPER
 * Referenced by: '<Root>/Constant1'
 */
real32_T Gain_Gain; /* Computed Parameter: Gain_Gain
 * Referenced by: '<Root>/Gain'
 */
real32_T Delay_InitialCondition; /* Computed Parameter: Delay_InitialCondition
 * Referenced by: '<Root>/Delay'
 */
uint32_T Table2_maxIndex[2]; /* Computed Parameter: Table2_maxIndex
 * Referenced by: '<Root>/Table2'
 */
boolean_T DataStoreMemory_InitialValue; /* Computed Parameter: DataStoreMemory_InitialValue
 * Referenced by: '<Root>/Data Store Memory'
 */
};

```

View the file `rtwdemo_basicsc_data.c`. This source file allocates global memory for a parameter structure and initializes the field values based on the parameter values in the model.

View the source file `rtwdemo_basicsc.c`. The code allocates global memory for a structure variable that contains signal data.

```

file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file, /* Block signals (default storage) */',...
 'B_rtwdemo_basicsc_T rtwdemo_basicsc_B;',1,1)

```

```

/* Block signals (default storage) */
B_rtwdemo_basicsc_T rtwdemo_basicsc_B;

```

The code algorithm in the model `step` function calculates the signal values. It then assigns these values to the fields of the signal structure. To perform the calculations, the algorithm uses the parameter values from the fields of the parameter structure.

## Exclude Data Items from Optimizations

When you want to select code generation optimizations such as **Signal storage reuse**, you can preserve individual data items from the optimizations. The generated code then allocates addressable memory for the items.

Select the optimizations that you previously cleared.

```
set_param('rtwdemo_basicsc','OptimizeBlockIOStorage','on')
set_param('rtwdemo_basicsc','LocalBlockOutputs','on')
set_param('rtwdemo_basicsc','DefaultParameterBehavior','Inlined')
```

In the model, select **View > Model Data Editor**.

In the Model Data Editor, inspect the **Signals** tab.

Set the **Change view** drop-down list to Instrumentation.

In the model, select the output signal of the Gain block.

In the Model Data Editor, select the check box in the **Test Point** column.

```
portHandle = get_param('rtwdemo_basicsc/Gain','PortHandles');
portHandle = portHandle.Outputport;
set_param(portHandle,'TestPoint','on')
```

Inspect the **Parameters** tab.

In the model, select the Gain block.

In the Model Data Editor, use the **Value** column to set the gain value to K1.

Next to K1, click the action button (with three vertical dots) and select **Create**.

In the Create New Data dialog box, set **Value** to `Simulink.Parameter(2)` and click **Create**. A `Simulink.Parameter` object named K1, with value 2, appears in the base workspace.

In the property dialog box for K1, apply a storage class other than `Auto` by using **Storage class**. For example, use the storage class `Model default` to represent the parameter object as a field of the global parameters structure.

```
set_param('rtwdemo_basicsc/Gain','Gain','K1');
K1 = Simulink.Parameter(2);
K1.StorageClass = 'Model default';
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')

Starting build procedure for model: rtwdemo_basicsc
Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generation report, view the file `rtwdemo_basicsc.h`. The structure that contains signal data now defines only one field, `Gain`, which represents the test-pointed output of the `Gain` block.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.h');
rtwdemodbtype(file,'/* Block signals (default storage) */',...
 'B_rtwdemo_basicsc_T;',1,1)
```

```
/* Block signals (default storage) */
typedef struct {
 real32_T Gain; /* '<Root>/Gain' */
} B_rtwdemo_basicsc_T;
```

The structure that contains block parameter data defines one field, `K1`, which represents the parameter object `K1`.

```
rtwdemodbtype(file,'/* Parameters (default storage) */',...
 '/* Real-time Model Data Structure */',1,0)

/* Parameters (default storage) */
struct P_rtwdemo_basicsc_T_ {
 real32_T K1; /* Variable: K1
 * Referenced by: '<Root>/Gain'
 */
};
```

### Access Data Through Generated Interfaces

You can configure the generated code to contain extra code and files so that you can access model data through standardized interfaces. For example, use the C API to log signal data and tune parameters during execution.

Copy this custom source code into a file named `ex_myHandCode.c` in your current folder.

```

#include "ex_myHandHdr.h"

#define paramIdx 0 /* Index of the target parameter,
determined by inspecting the array of structures generated by the C API. */
#define sigIdx 0 /* Index of the target signal,
determined by inspecting the array of structures generated by the C API. */

void tuneFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr)
{
 /* Take action with the parameter value only at
 the beginning of simulation and at the 5-second mark. */
 if (*tPtr == 0 || *tPtr == 5) {

 /* Local variables to store information extracted from
 the model mapping information (mmi). */
 void** dataAddrMap;
 const rtwCAPI_DataTypeMap *dataTypeMap;
 const rtwCAPI_ModelParameters *params;
 int_T addrIdx;
 uint16_T dTypeIdx;
 uint8_T slDataType;

 /* Use built-in C API macros to extract information. */
 dataAddrMap = rtwCAPI_GetDataAddressMap(mmi);
 dataTypeMap = rtwCAPI_GetDataTypeMap(mmi);
 params = rtwCAPI_GetModelParameters(mmi);
 addrIdx = rtwCAPI_GetModelParameterAddrIdx(params,paramIdx);
 dTypeIdx = rtwCAPI_GetModelParameterDataTypeIdx(params,paramIdx);
 slDataType = rtwCAPI_GetDataTypeSLId(dataTypeMap, dTypeIdx);

 /* Handle data types 'double' and 'int8'. */
 switch (slDataType) {

 case SS_DOUBLE: {
 real_T* dataAddress;
 dataAddress = dataAddrMap[addrIdx];
 /* At the 5-second mark, increment the parameter value by 1. */
 if (*tPtr == 5) {
 (*dataAddress)++;
 }
 printf("Parameter value is %f\n", *dataAddress);
 break;
 }
 }
 }
}

```

```

 case SS_INT8: {
 int8_T* dataAddress;
 dataAddress = dataAddrMap[addrIdx];
 if (*tPtr == 5) {
 (*dataAddress)++;
 }
 printf("Parameter value is %i\n", *dataAddress);
 break;
 }
 }
}

void logFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr)
{
 /* Take action with the signal value only when
 the simulation time is an integer value. */
 if (*tPtr-(int_T)*tPtr == 0) {

 /* Local variables to store information extracted from
 the model mapping information (mmi). */
 void** dataAddrMap;
 const rtwCAPI_DataTypeMap *dataTypeMap;
 const rtwCAPI_Signals *sigs;
 int_T addrIdx;
 uint16_T dTypeIdx;
 uint8_T slDataType;

 /* Use built-in C API macros to extract information. */
 dataAddrMap = rtwCAPI_GetDataAddressMap(mmi);
 dataTypeMap = rtwCAPI_GetDataTypeMap(mmi);
 sigs = rtwCAPI_GetSignals(mmi);
 addrIdx = rtwCAPI_GetSignalAddrIdx(sigs, sigIdx);
 dTypeIdx = rtwCAPI_GetSignalDataTypeIdx(sigs, sigIdx);
 slDataType = rtwCAPI_GetDataTypeSLId(dataTypeMap, dTypeIdx);

 /* Handle data types 'double' and 'single'. */
 switch (slDataType) {

 case SS_DOUBLE: {
 real_T* dataAddress;
 dataAddress = dataAddrMap[addrIdx];
 printf("Signal value is %f\n", *dataAddress);
 }
 }
 }
}

```

```

 break;
 }

 case SS_SINGLE: {
 real32_T* dataAddress;
 dataAddress = dataAddrMap[addrIdx];
 printf("Signal value is %f\n", *dataAddress);
 break;
 }
}
}
}
}
}

```

Copy this custom header code into a file named `ex_myHandHdr.h` in your current folder.

```

#include <stdio.h>
#include <string.h>
#include <math.h>
/* Include rtw_modelmap.h for definitions of C API macros. */
#include "rtw_modelmap.h"
#include "builtin_typeid_types.h"
#include "rtwtypes.h"
void tuneFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr);
void logFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr);

```

These files use the C API to access signal and parameter data in the code that you generate from the example model.

In the model, set **Configuration Parameters > Code Generation > Custom Code > Insert custom C code in generated > Header file** to `#include "ex_myHandHdr.h"`. In the same pane in the Configuration Parameters dialog box, set **Additional Build Information > Source files** to `ex_myHandCode.c`.

```

set_param('rtwdemo_basicsc', 'CustomHeaderCode', '#include "ex_myHandHdr.h"')
set_param('rtwdemo_basicsc', 'CustomSource', 'ex_myHandCode.c')

```

Select **Configuration Parameters > MAT-file Logging**. The generated executable runs only until the simulation stop time (which you set in the model configuration parameters).

```

set_param('rtwdemo_basicsc', 'MatFileLogging', 'on')

```

Select all of the options under **Configuration Parameters > Code Generation > Interface > Generate C API for**.

```
set_param('rtwdemo_basicsc','RTWCAPIParams','on')
set_param('rtwdemo_basicsc','RTWCAPISignals','on')
set_param('rtwdemo_basicsc','RTWCAPIStates','on')
set_param('rtwdemo_basicsc','RTWCAPIRootIO','on')
```

Load the Custom Code block library.

custcode

These blocks allow you to insert custom code into specific files and functions.

Add a System Outputs block to the model.

```
add_block('custcode/System Outputs','rtwdemo_basicsc/System Outputs')
```

In the System Outputs block dialog box, set **System Outputs Function Execution Code** to this code:

```
{
rtwdemo_basicsc_U.input2++;
rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);
tuneFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));
}
```

In the block dialog box, set **System Outputs Function Exit Code** to this code:

```
{
rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);
logFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));
}
```

Alternatively, to configure the System Outputs block, at the command prompt, use these commands:

```
temp.TLCFile = 'custcode';
temp.Location = 'System Outputs Function';
temp.Middle = sprintf(['\nrtwdemo_basicsc_U.input2++;'...
 '\nrtwCAPI_ModelMappingInfo *MMI = '...
 '&(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);'...
 '\ntuneFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));\n']);
temp.Bottom = sprintf(['\nrtwCAPI_ModelMappingInfo *MMI = '...
 '&(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);'...
 '\nlogFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));\n']);
set_param('rtwdemo_basicsc/System Outputs', 'RTWdata', temp)
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')

Starting build procedure for model: rtwdemo_basicsc
Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generation report, view the interface file `rtwdemo_basicsc_capi.c`. This file initializes the arrays of structures that you can use to interact with data items through the C API. For example, in the array of structures `rtBlockSignals`, the first structure (index 0) describes the test-pointed output signal of the Gain block in the model.

```
file = fullfile('rtwdemo_basicsc_grt_rtw', 'rtwdemo_basicsc_capi.c');
rtwdemodbtype(file, '/* Block output signal information */', ...
 '/* Individual block tuning', 1, 0)
```

```
/* Block output signal information */
static const rtwCAPI_Signals rtBlockSignals[] = {
 /* addrMapIndex, sysNum, blockPath,
 * signalName, portNumber, dataTypeIndex, dimIndex, fxpIndex, sTimeIndex
 */
 { 0, 0, TARGET_STRING("rtwdemo_basicsc/Gain"),
 TARGET_STRING(""), 0, 0, 0, 0, 0, 0 },

 {
```

```

 0, 0, (NULL), (NULL), 0, 0, 0, 0, 0
}
};

```

The fields of the structure, such as `addrMapIndex`, indicate indices into other arrays of structures, such as `rtDataAddrMap`, that describe the characteristics of the signal. These characteristics include the address of the signal data (a pointer to the data), the numeric data type, and the dimensions of the signal.

In the file `rtwdemo_basicsc.c`, view the code algorithm in the model step function. The algorithm first executes the code that you specified in the System Outputs block.

```

file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file, /* user code (Output function Body) */',...
 /* Logic: '<Root>/LogOp' incorporates:',1,0)

/* user code (Output function Body) */

/* System '<Root>' */
{
 rtwdemo_basicsc_U.input2++;
 rtwC_API_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);
 tuneFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));
}

/* DataStoreWrite: '<Root>/DSWrite' incorporates:
 * Constant: '<Root>/Constant1'
 * Constant: '<Root>/Constant2'
 * Inport: '<Root>/In1'

```

```

 /* InitializeConditions for UnitDelay: '<Root>/Delay' */
 rtwdemo_basicsc_DW.X = 0.0F;
}

/* Model terminate function */
void rtwdemo_basicsc_terminate(void)
{
 /* (no terminate code required) */
}

```

This code first perturbs the input signal `input2` by incrementing the value of the signal each time the `step` function executes. The code then uses the built-in macro `rtmGetDataMapInfo` to extract model mapping information from the model data structure `rtwdemo_basicsc_M`. The pointer `MMI` points to the extracted mapping information, which allows the functions `tuneFcn` and `logFcn` to access the information contained in the arrays of structures that the C API file `rtwdemo_basicsc_capi.c` defines.

View the function `tuneFcn` in the file `ex_myHandCode.c`. This function uses the C API (through the model mapping information `mmi`) and a pointer to the simulation time to print the value of the parameter `K1` at specific times during code execution. When the simulation time reaches 5 seconds, the function changes the parameter value in memory. By using a `switch case` block, the function can access the parameter data whether the data type is `int8` or `double`.

View the code algorithm in the model `step` function again. Near the end of the function, the algorithm executes the code that you specified in the System Outputs block. This code calls the function `logFcn`.

```

rtwdemodbtype(file, /* user code (Output function Trailer) */',...
 /* Matfile logging */',1,0)

/* user code (Output function Trailer) */

/* System '<Root>' */
{
 rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);
 logFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));
}

```

View the function `logFcn` in the file `ex_myHandCode.c`. The function uses the C API to print the value of the test-pointed signal. The function can access the signal data whether the data type is `single` or `double`.

At the command prompt, run the generated executable `rtwdemo_bascisc.exe`.

```
system('rtwdemo_bascisc')
```

The parameter and signal values appear in the Command Window output.

For more information about data interfaces, including the C API, see “Data Exchange Interfaces” (Simulink Coder).

## Standard Data Structures in the Generated Code

By default, signal lines, block parameters, states, and other model data appear in the generated code as fields of standard structures. For general information, see “How Generated Code Stores Internal Signal, State, and Parameter Data” (Simulink Coder).

The table shows some common data structures in the generated code. The name of the structure type and, if applicable, structure variable in the code that you generate from a model depends on the model settings. Regardless of the settings, the name of the structure type in the code contains the short name from the **Short Name of Structure Type** column in the table.

### Data Structures Generated for a Model

| Short Name of Structure Type | Data Represented in the Structure       |
|------------------------------|-----------------------------------------|
| ExtU                         | Data from root Inport blocks            |
| ExtY                         | Data from root Outport blocks           |
| B                            | Block output signals                    |
| ConstB                       | Block outputs that have constant values |
| P                            | Block parameters                        |
| ConstP                       | Constant parameters                     |
| DW                           | Discrete block states                   |
| XDis                         | Status of enabled subsystems            |

For additional structures, see “System-generated identifiers” (Simulink Coder).

You can exclude data from appearing in these structures by using:

- Direct application of storage classes. For example, you can use storage classes to represent signals, tunable parameters, and states as individual global variables. For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81.
- Configuration parameters, such as those on the **Optimization** pane in the Configuration Parameters dialog box. You can adjust these configuration parameters to control the default representation of data. For more information, see “Optimization Pane” (Simulink Coder).

## Control Characteristics of Data Structures (Embedded Coder)

To control the characteristics of the standard data structures, use the information in the table.

| Name                           | How to Change Name                                                                                                                                                                                                                                                                                        |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Structure types                | Specify a naming rule to use for all of the types. Set a value for <b>Configuration Parameters &gt; Global types</b> .                                                                                                                                                                                    |
| Global structure variables     | Specify a naming rule with <b>Configuration Parameters &gt; Global variables</b> .                                                                                                                                                                                                                        |
| Names of structure fields      | By default, the name of each structure field derives from the name of the data item in the model (for example, the name of a block state, which you specify by using the <b>State name</b> block parameter). Specify a naming rule with <b>Configuration Parameters &gt; Field name of global types</b> . |
| Data types of structure fields | Use <code>Simulink.AliasType</code> objects and data type replacement to rename primitive types for the corresponding data items in the model. See “Control Data Type Names in Generated Code” on page 24-2.                                                                                              |

For more information about configuration parameters that control names and other identifiers in the generated code, see “Customize Generated Identifiers” on page 78-21.

## Use the Real-Time Model Data Structure

The code generator uses the real-time model (RT\_MODEL) data structure. This structure is also referred to as the `rtModel` data structure. You can access `rtModel` data by using a set of macros analogous to the `ssSetxxx` and `ssGetxxx` macros that S-functions use to access `SimStruct` data, including noninlined S-functions compiled by the code generator.

You need to use the set of macros `rtmGetxxx` and `rtmSetxxx` to access the real-time model data structure. The `rtModel` is an optimized data structure that replaces `SimStruct` as the top level data structure for a model. The `rtmGetxxx` and `rtmSetxxx` macros are used in the generated code as well as from the `main.c` or `main.cpp` module. If you are customizing `main.c` or `main.cpp` (either a static file or a generated file), you need to use `rtmGetxxx` and `rtmSetxxx` instead of the `ssSetxxx` and `ssGetxxx` macros.

Usage of `rtmGetxxx` and `rtmSetxxx` macros is the same as for the `ssSetxxx` and `ssGetxxx` versions, except that you replace `SimStruct` S by real-time model data structure `rtM`. The following table lists `rtmGetxxx` and `rtmSetxxx` macros that are used in `grt_main.c` and `grt_main.cpp`.

**Macros for Accessing the Real-Time Model Data Structure**

| <b>rtm Macro Syntax</b>                            | <b>Description</b>                                                                                  |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>rtmGetX(rtm)</code>                          | Get the derivatives of block continuous states                                                      |
| <code>rtmGetOffsetTimePtr(RT_MDL rtm)</code>       | Return the pointer to vector that stores sample time offsets of the model associated with rtm       |
| <code>rtmGetNumSampleTimes(RT_MDL rtm)</code>      | Get the number of sample times that a block has                                                     |
| <code>rtmGetPerTaskSampleHitsPtr(RT_MDL)</code>    | Return a pointer to NumSampleTime × NumSampleTime matrix                                            |
| <code>rtmGetRTWExtModeInfo(RT_MDL rtm)</code>      | Return an external mode information data structure of the model (used internally for external mode) |
| <code>rtmGetRTWLogInfo(RT_MDL)</code>              | Return a data structure used by code generator logging (internal use only)                          |
| <code>rtmGetRTWRTModelMethodsInfo(RT_MDL)</code>   | Return a data structure of real-time model methods information (internal use only)                  |
| <code>rtmGetRTWSolverInfo(RT_MDL)</code>           | Return data structure containing solver information of the model (internal use only)                |
| <code>rtmGetSampleHitPtr(RT_MDL)</code>            | Return a pointer to Sample Hit flag vector                                                          |
| <code>rtmGetSampleTime(RT_MDL rtm, int TID)</code> | Get task sample time                                                                                |
| <code>rtmGetSampleTimePtr(RT_MDL rtm)</code>       | Get pointer to a task sample time                                                                   |
| <code>rtmGetSampleTimeTaskIDPtr(RT_MDL rtm)</code> | Get pointer to a task ID                                                                            |
| <code>rtmGetSimTimeStep(RT_MDL)</code>             | Return simulation step type ID (MINOR_TIME_STEP, MAJOR_TIME_STEP)                                   |
| <code>rtmGetStepSize(RT_MDL)</code>                | Return the fundamental step size of the model                                                       |
| <code>rtmGetT(RT_MDL, t)</code>                    | Get the current simulation time                                                                     |
| <code>rtmSetT(RT_MDL, t)</code>                    | Set the time of the next sample hit                                                                 |
| <code>rtmGetTaskTime(RT_MDL, tid)</code>           | Get the current time for the current task                                                           |
| <code>rtmGetTFinal(RT_MDL)</code>                  | Get the simulation stop time                                                                        |
| <code>rtmSetTFinal(RT_MDL, finalT)</code>          | Set the simulation stop time                                                                        |
| <code>rtmGetTimingData(RT_MDL)</code>              | Return a data structure used by timing engine of the model (internal use only)                      |

| <b>rtm Macro Syntax</b>                     | <b>Description</b>                                                                                   |
|---------------------------------------------|------------------------------------------------------------------------------------------------------|
| <code>rtmGetTPtr(RT_MDL)</code>             | Return a pointer to the current time                                                                 |
| <code>rtmGetTStart(RT_MDL)</code>           | Get the simulation start time                                                                        |
| <code>rtmIsContinuousTask(rtm)</code>       | Determine whether a task is continuous                                                               |
| <code>rtmIsMajorTimeStep(rtm)</code>        | Determine whether the simulation is in a major step                                                  |
| <code>rtmIsSampleHit(RT_MDL, tid)</code>    | Determine whether the sample time is hit                                                             |
| <code>rtmGetErrorStatus(rtm)</code>         | Get the current error status                                                                         |
| <code>rtmSetErrorStatus(rtm, val)</code>    | Set the current error status                                                                         |
| <code>rtmGetErrorStatusPointer(rtm)</code>  | Return a pointer to the current error status                                                         |
| <code>rtmGetStopRequested(rtm)</code>       | Return whether a stop is requested                                                                   |
| <code>rtmGetBlockIO(rtm)</code>             | Get the block I/O data structure                                                                     |
| <code>rtmSetBlockIO(rtm, val)</code>        | Set the block I/O data structure                                                                     |
| <code>rtmGetContStates(rtm)</code>          | Get the continuous states data structure                                                             |
| <code>rtmSetContStates(rtm, val)</code>     | Set the continuous states data structure                                                             |
| <code>rtmGetDefaultParam(rtm)</code>        | Get the default parameters data structure                                                            |
| <code>rtmSetDefaultParam(rtm, val)</code>   | Set the default parameters data structure                                                            |
| <code>rtmGetPrevZCSigState(rtm)</code>      | Get the previous zero-crossing signal state data structure                                           |
| <code>rtmSetPrevZCSigState(rtm, val)</code> | Set the previous zero-crossing signal state data structure                                           |
| <code>rtmGetRootDWork(rtm)</code>           | Get the DWork data structure                                                                         |
| <code>rtmSetRootDWork(rtm, val)</code>      | Set the DWork data structure                                                                         |
| <code>rtmGetU(rtm)</code>                   | Get the root inputs data structure (when root inputs are passed as part of the model data structure) |
| <code>rtmSetU(rtm, val)</code>              | Set the root inputs data structure (when root inputs are passed as part of the model data structure) |

| <b>rtm Macro Syntax</b>        | <b>Description</b>                                                                                     |
|--------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>rtmGetY(rtm)</code>      | Get the root outputs data structure (when root outputs are passed as part of the model data structure) |
| <code>rtmSetY(rtm, val)</code> | Set the root outputs data structure (when root outputs are passed as part of the model data structure) |

For additional details on usage, see “SimStruct Macros and Functions Listed by Usage” (Simulink).

## How Generated Code Exchanges Data with an Environment

To use the code that you generate from a model, you call the generated entry-point functions such as `step` and `initialize`. The environment in which you call these functions must provide input signal data and, depending on your application, scheduling information. The generated algorithm then calculates output data that the calling environment can use. The environment and the algorithm can exchange this data through global variables or through formal parameters (arguments).

The set of input and output data and the exchange mechanisms constitute the interfaces of the entry-point functions. When you understand the default interfaces and how to control them, you can:

- Write code that calls the generated code.
- Generate reusable (reentrant) code that you can call multiple times in a single application.
- Integrate the generated code with other, external code in your application.

In a model, root-level Inport and Outport blocks represent the primary inputs and outputs of the block algorithm. By default, the code generator aggregates these blocks into standard structures that store input and output data.

For information about how the generated code stores internal data, which does not participate in the model interface, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50.

### Data Interfaces in the Generated Code

This example shows how the generated code exchanges data with an environment.

#### Explore Example Model

Open the example model `rtwdemo_roll`.

```
open_system('rtwdemo_roll')
```

At the root level, the model has a number of Inport blocks and one Outport block.

In the model, set **Configuration Parameters > Code Generation > System target file** to `grt.tlc`.

```
set_param('rtwdemo_roll', 'SystemTargetFile', 'grt.tlc')
```

Inspect the setting for **Configuration Parameters > Code Generation > Interface > Code interface packaging**. The setting `Nonreusable` function means that the generated code is not reusable (not reentrant).

For this example, to generate simpler code, clear the **Configuration Parameters > Code Generation > Interface > Advanced parameters > Mat-file logging**.

```
set_param('rtwdemo_roll', 'MatFileLogging', 'off')
```

### Generate Nonreusable Code

Generate code from the model.

```
rtwbuild('rtwdemo_roll')
```

```
Starting build procedure for model: rtwdemo_roll
Successful completion of build procedure for model: rtwdemo_roll
```

Inspect the file `rtwdemo_roll.h`. The file defines a structure type that represents input data and a type that represents output data.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.h');
rtwdemodbtype(file,...
 /* External inputs (root inport signals with default storage) */,...
 '} ExtY_rtwdemo_roll_T;',1,1)

/* External inputs (root inport signals with default storage) */
typedef struct {
 real32_T Phi; /* '<Root>/Phi' */
 real32_T Psi; /* '<Root>/Psi' */
 real32_T Rate_FB; /* '<Root>/Rate_FB' */
 real32_T TAS; /* '<Root>/TAS' */
 boolean_T AP_Eng; /* '<Root>/AP_Eng' */
 boolean_T HDG_Mode; /* '<Root>/HDG_Mode' */
 real32_T HDG_Ref; /* '<Root>/HDG_Ref' */
 real32_T Turn_Knob; /* '<Root>/Turn_Knob' */
} ExtU_rtwdemo_roll_T;

/* External outputs (root outports fed by signals with default storage) */
typedef struct {
 real32_T Ail_Cmd; /* '<Root>/Ail_Cmd' */
} ExtY_rtwdemo_roll_T;
```

Each field corresponds to an Inport or Outport block at the root level of the model. The name of each field derives from the name of the block.

The file also defines a structure type, the *real-time model data structure*, whose single field stores a run-time indication of whether the generated code has encountered an error during execution.

```
rtwdemodbtype(file,'/* Real-time Model Data Structure */',...
 /* Block states (default storage) */',1,0)

/* Real-time Model Data Structure */
struct tag_RTM_rtwdemo_roll_T {
 const char_T *errorStatus;
};
```

When you modify model configuration parameters to suit your application, this structure can also contain other data that pertain to the entire model, such as scheduling information.

For the structure type that represents the real-time model data structure, the file `rtwdemo_roll_types.h` creates an alias (typedef) that the generated code later uses to allocate memory for the structure.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll_types.h');
rtwdemodbtype(file, /* Forward declaration for rtModel */,...
 'RT_MODEL_rtwdemo_roll_T;',1,1)
```

```
/* Forward declaration for rtModel */
typedef struct tag_RTM_rtwdemo_roll_T RT_MODEL_rtwdemo_roll_T;
```

Using these structure types, the file `rtwdemo_roll.c` defines (allocates memory for) global structure variables that store input and output data for the generated algorithm. The file also defines variables that represent the real-time model data structure and a pointer to the structure.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,...
 /* External inputs (root inport signals with default storage) */,...
 '= &rtwdemo_roll_M;',1,1)
```

```
/* External inputs (root inport signals with default storage) */
ExtU_rtwdemo_roll_T rtwdemo_roll_U;
```

```
/* External outputs (root outputs fed by signals with default storage) */
ExtY_rtwdemo_roll_T rtwdemo_roll_Y;
```

```
/* Real-time model */
RT_MODEL_rtwdemo_roll_T rtwdemo_roll_M;
RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M = &rtwdemo_roll_M;
```

The file `rtwdemo_roll.h` declares these structure variables. Your external code can include (`#include`) this file, whose general name is `model.h` where `model` is the name of the model, to access data that participate in the model interface.

In `rtwdemo_roll.c`, the model step function, which represents the primary model algorithm, uses a void void interface (with no arguments).

```
rtwdemodbtype(file,...
 /* Model step function */,'void rtwdemo_roll_step(void)',1,1)
```

```
/* Model step function */
void rtwdemo_roll_step(void)
```

In the function definition, the algorithm reads input data and writes output data by directly accessing the global structure variables. For example, near the end of the algorithm, the code for the EngSwitch block reads the value of the AP\_Eng field (which represents an input) and, based on that value, conditionally writes a constant value to the Ail\_Cmd field (which represents an output).

```
rtwdemodbtype(file,'if (rtwdemo_roll_U.AP_Eng) {' , ' }',1,1)
```

```
if (rtwdemo_roll_U.AP_Eng) {
 /* Outputs for Atomic SubSystem: '<Root>/BasicRollMode' */
 /* Saturate: '<S1>/CmdLimit' */
 if (rtwdemo_roll_Y.Ail_Cmd > 15.0F) {
 /* Sum: '<S1>/Sum2' incorporates:
 * Output: '<Root>/Ail_Cmd'
 */
 rtwdemo_roll_Y.Ail_Cmd = 15.0F;
 } else {
 if (rtwdemo_roll_Y.Ail_Cmd < -15.0F) {
 /* Sum: '<S1>/Sum2' incorporates:
 * Output: '<Root>/Ail_Cmd'
 */
 rtwdemo_roll_Y.Ail_Cmd = -15.0F;
 }
 }
}
```

Due to the `void void` interface and the direct data access, the function is not reentrant. If you call the function multiple times in an application, each call reads and writes input and output data to the same global structure variables, resulting in data corruption and unintentional interaction between the calls.

The model initialization function, `rtwdemo_roll_initialize`, initializes all of the input and output data to zero. The function also initializes the error status. The function directly accesses the global variables, which means the function is not reentrant.

```
rtwdemodbtype(file,'/* Model initialize function */',...
 'rtmSetErrorStatus(rtwdemo_roll_M, (NULL));',1,1)
```

```
/* Model initialize function */
void rtwdemo_roll_initialize(void)
```

```

{
 /* Registration code */

 /* initialize error status */
 rtmSetErrorStatus(rtwdemo_roll_M, (NULL));

 rtwdemodbtype(file, ' /* external inputs */', ...
 ' /* SystemInitialize for Atomic SubSystem:', 1, 0)

 /* external inputs */
 (void)memset((void *)&rtwdemo_roll_U, 0, sizeof(ExtU_rtwdemo_roll_T));

 /* external outputs */
 rtwdemo_roll_Y.Ail_Cmd = 0.0F;

```

### Generate Reusable Code

You can configure the generated code as reentrant, which means that you can call the entry-point functions multiple times in an application. With this configuration, instead of directly accessing global variables, the entry-point functions exchange input, output, and other model data through formal parameters (pointer arguments). With these pointer arguments, each call can read inputs and write outputs to a set of separate global variables, preventing unintentional interaction between the calls.

In the model, set **Configuration Parameters > Code Generation > Interface > Code interface packaging** to Reusable function.

```
set_param('rtwdemo_roll', 'CodeInterfacePackaging', 'Reusable function')
```

Generate code from the model.

```
rtwbuild('rtwdemo_roll')

Starting build procedure for model: rtwdemo_roll
Successful completion of build procedure for model: rtwdemo_roll
```

Now, in `rtwdemo_roll.h`, the real-time model data structure contains pointers to the error indication, the input data, the output data, and additional data in the form of a `DWork` substructure (which stores, for example, block states such as the state of a Discrete-Time Integrator block).

```
file = fullfile('rtwdemo_roll_grt_rtw', 'rtwdemo_roll.h');
rtwdemodbtype(file, ' /* Real-time Model Data Structure */', ...
 ' /* External data declarations for dependent source files */', 1, 0)
```

```

/* Real-time Model Data Structure */
struct tag_RTM_rtwdemo_roll_T {
 const char_T *errorStatus;
 ExtU_rtwdemo_roll_T *inputs;
 ExtY_rtwdemo_roll_T *outputs;
 DW_rtwdemo_roll_T *dwork;
};

```

To call the generated code multiple times in an application, your code must allocate memory for a real-time model data structure per call. The file `rtwdemo_roll.c` defines a specialized function that allocates memory for a new real-time model data structure and returns a pointer to the structure. The function also allocates memory for the substructures that the fields in the model data structure point to, such as the input and output structures.

```

file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,'/* Model data allocation function */',...
 'RT_MODEL_rtwdemo_roll_T *rtwdemo_roll(void)',1,1)

```

```

/* Model data allocation function */
RT_MODEL_rtwdemo_roll_T *rtwdemo_roll(void)

```

In `rtwdemo_roll.c`, the model step function accepts an argument that represents the real-time model data structure.

```

file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,...
 '/* Model step function */','void rtwdemo_roll_step',1,1)

```

```

/* Model step function */
void rtwdemo_roll_step(RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M)

```

In the function definition, the algorithm first extracts each pointer from the real-time model data structure into a local variable.

```

rtwdemodbtype(file,...
 '*rtwdemo_roll_DW =','rtwdemo_roll_M->outputs;',1,1)

 DW_rtwdemo_roll_T *rtwdemo_roll_DW = ((DW_rtwdemo_roll_T *)
 rtwdemo_roll_M->dwork);
 ExtU_rtwdemo_roll_T *rtwdemo_roll_U = (ExtU_rtwdemo_roll_T *)

```

```

 rtwdemo_roll_M->inputs;
 ExtY_rtwdemo_roll_T *rtwdemo_roll_Y = (ExtY_rtwdemo_roll_T *)
 rtwdemo_roll_M->outputs;

```

Then, to access the input and output data stored in global memory, the algorithm interacts with these local variables.

```

rtwdemodbtype(file, ' if (rtwdemo_roll_U->AP_Eng) {' ,...
 ' /* End of Switch: '<Root>/EngSwitch' */',1,1)

if (rtwdemo_roll_U->AP_Eng) {
 /* Outputs for Atomic SubSystem: '<Root>/BasicRollMode' */
 /* Saturate: '<S1>/CmdLimit' */
 if (rtwdemo_roll_Y->Ail_Cmd > 15.0F) {
 /* Sum: '<S1>/Sum2' incorporates:
 * Output: '<Root>/Ail_Cmd'
 */
 rtwdemo_roll_Y->Ail_Cmd = 15.0F;
 } else {
 if (rtwdemo_roll_Y->Ail_Cmd < -15.0F) {
 /* Sum: '<S1>/Sum2' incorporates:
 * Output: '<Root>/Ail_Cmd'
 */
 rtwdemo_roll_Y->Ail_Cmd = -15.0F;
 }
 }

 /* End of Saturate: '<S1>/CmdLimit' */
 /* End of Outputs for SubSystem: '<Root>/BasicRollMode' */
} else {
 /* Sum: '<S1>/Sum2' incorporates:
 * Constant: '<Root>/Zero'
 * Output: '<Root>/Ail_Cmd'
 */
 rtwdemo_roll_Y->Ail_Cmd = 0.0F;
}

```

Similarly, the model initialization function accepts the real-time model data structure as an argument.

```

rtwdemodbtype(file,...
 '/* Model initialize function */','void rtwdemo_roll_initialize',1,1)

```

```
/* Model initialize function */
void rtwdemo_roll_initialize(RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M)
```

Because each call that you make to an entry-point function interacts with a separate real-time model data structure, you avoid unintentional interaction between the calls.

## Configure Data Interface

To control the characteristics of the data interface in the generated code, see “Control Data and Function Interface in Generated Code” on page 22-42.

## Control Data and Function Interface in Generated Code

To use the code that you generate from a model, you call the generated entry-point functions such as `step` and `initialize`. The calling environment and the generated functions can exchange input and output data through global variables or through formal parameters (arguments). This data and the exchange mechanisms constitute the interfaces of the entry-point functions. For information about the default interfaces for reentrant and nonreentrant models in the generated code, see “How Generated Code Exchanges Data with an Environment” on page 22-33.

By controlling the interfaces that appear in the generated code, you can:

- Minimize the modifications that you must make to your existing code.
- Generate stable interfaces that do not change or minimally change when you make changes to the model.
- Generate code that exchanges data more efficiently (for example, by using pointers and pass-by-reference arguments for nonscalar data).

### Control Type Names, Field Names, and Variable Names of Standard I/O Structures (Embedded Coder)

By default, for nonreentrant code, Inport blocks at the root level of the model appear in the generated code as fields of a global structure variable. Similarly, Outport blocks appear in a different structure. For reentrant code, depending on your setting for **Configuration Parameters > Code Generation > Interface > Pass root-level I/O as**, the code can also package input and output data into standard structures.

With Embedded Coder, you can control these names. See “Control Characteristics of Data Structures (Embedded Coder)” (Simulink Coder).

### Control Names of Generated Entry-Point Functions (Embedded Coder)

To use the generated code, you write code that calls generated entry-point functions. For example, entry-point functions include `model_step`, `model_initialize`, and top-level functions generated from an export-function model. To control the names of the model entry-point functions, choose one or both of these techniques, which require Embedded Coder:

- Specify a default naming rule for categories of entry-point functions by applying function customization templates in the Code Mapping Tool. With this technique, the naming rule applies to all of the functions in each category. For more information, see “Configure Default Code Generation for Functions” on page 21-15.
- Apply function prototype control to individual functions. With this technique:
  - You can specify a literal name for a function, which overrides the default naming rule that you specify with a function customization template in the Code Mapping Editor.
  - You can control the names of only step functions, initialization functions, and Simulink functions.

You use different tools and dialog boxes to apply function prototype control based on the kind of target function. For more information, see “Control Generation of Function Interfaces” on page 53-2.

## Control Data Interface for Nonreentrant Code

When you set **Configuration Parameters > Code Generation > Interface > Code interface packaging** to **Nonreusable function** (the default), the generated entry-point functions are not reentrant. Typically, the functions exchange data with the calling environment through direct access to global variables.

### Configure Inport or Outport Block as Separate Global Variable

To remove the block from the standard I/O structures by creating a separate global variable, apply a storage class, such as `ExportedGlobal` or `ExportToFile`, to the signal that the block represents.

- To specify a default storage class for Inport blocks and a different default for Outport blocks, use the Code Mapping Tool. As you add such blocks to the model, they acquire the storage class that you specify. You do not need to configure each individual block.

For this technique, you must have Embedded Coder.

- To override the default for an individual block, apply a different storage class by using other tools such as the Model Data Editor or the Property Inspector. See “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

For an example, see “Design Data Interface by Configuring Inport and Outport Blocks” (Simulink Coder). For general information about storage classes, see “Choose a Storage Class for Controlling Data Representation in the Generated Code” (Simulink Coder).

### **Configure Generated Code to Read or Write to Global Variables Defined by External Code**

If your calling code already defines a global variable that you want the generated code to use as input data or use to store output data, you can reuse the variable by preventing the code generator from duplicating the definition. Apply a storage class to the corresponding Inport or Outport block in the model. Choose a storage class that specifies an imported data scope, such as `ImportedExtern` or `ImportFromFile`. For information about applying storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder) and “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19.

### **Package Multiple Inputs or Outputs into Custom Structure**

You can configure a single Inport or Outport block to appear in the generated code as a custom structure that contains multiple input or output signals. You can also configure the block to appear as a substructure of the default I/O structures or as a separate structure variable.

Configure the block as a nonvirtual bus by using a `Simulink.Bus` object as the data type of the block. If your external code defines the structure type, consider using the `Simulink.importExternalCTypes` function to generate the bus object.

- To generate the bus signal as a substructure in the standard I/O structures, leave the block storage class at the default setting, `Auto`. If you have Embedded Coder, in the Code Mapping Editor, leave **Data Defaults > Inports** and **Data Defaults > Outports** at the default setting, `Default`.
- To generate the bus signal as a separate global structure variable, apply a storage class such as `ExportedGlobal` or `ExportToFile`.

For more information about grouping signals into custom structures in the generated code, see “Organize Data into Structures in Generated Code” on page 22-177.

### **Configure Inport or Outport Block as Function Call (Embedded Coder)**

If your external code defines a function that returns input data for the generated code or accepts output data that the generated code produces, you can configure an Inport or

Outport block so that the generated code calls the function instead of accessing a global variable. Apply the Embedded Coder storage class `GetSet`. For more information, see “Access Data Through Functions with Custom Storage Class `GetSet`” on page 26-42.

### **Pass Inputs and Outputs Through Function Arguments (Embedded Coder)**

With Embedded Coder, you can optionally configure the model execution function to access inputs and outputs through arguments instead of directly reading and writing to global variables. Completely control the argument characteristics such as name, order, and passing mechanism (by reference or by value). This configuration can help to integrate the generated code with your external code.

To pass inputs and outputs through arguments, apply function prototype control to the model. Then, each Inport and Outport block at the root level of the model appears in the code as an argument of the execution function. For more information, see “Customize Generated C Function Interfaces” on page 29-2.

### **Configure Referenced Model Inputs and Outputs as Global Variables (void-void)**

By default, for a nonreentrant referenced model, the generated code passes root-level inputs and outputs through function arguments. A nonreentrant referenced model is one in which you set Configuration Parameter **Total number of instances allowed per top model** to One.

To pass this data through global variables instead (for a `void-void` interface), in the referenced model, apply storage classes such as `ExportedGlobal` and `ExportToFile` to root-level Inport and Outport blocks.

- To apply a default storage class to all such blocks, use the Code Mapping Editor, which requires Embedded Coder. With this technique, as you add such blocks to the model, the blocks acquire the default storage class, preserving the `void-void` interface. For more information, see “Configure Default Code Generation for Data” on page 21-8.
- To override the default storage class, apply storage classes directly to individual blocks by using the Model Data Editor. See “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81.
- For an example that requires Embedded Coder, see “Establish Data Ownership in a System of Components” on page 23-15.

## Control Data Interface for Reentrant Code

When you set **Configuration Parameters > Code Generation > Interface > Code interface packaging** to Reusable function, the generated entry-point functions are reentrant. The functions exchange data with the calling environment through formal parameters (arguments). By default, each root-level Inport and Outport block appears in the generated code as a separate argument instead of a field of the standard I/O structures.

- To reduce the number of arguments, see “Reduce Number of Arguments by Using Structures” (Simulink Coder).
- To control the data types of the arguments, see “Control Data Types of Arguments” (Simulink Coder).

## Prevent Unintended Changes to the Interface

Some changes that you make to a model change the signatures of the entry-point functions in the generated code. For example, if you change the name of the model, the names of the functions can change. If you configure the model code to exchange data through arguments, when you add or remove Inport or Outport blocks or change the names of the blocks, the corresponding arguments can change.

For easier maintenance of your calling code, prevent changes to the interfaces of the entry-point functions.

- If you exchange input and output data through arguments, configure the generated code to package Inport and Outport blocks into structures instead of allowing each block to appear as a separate argument (the default). Then, when you add or remove Inport or Outport blocks, or change their properties such as name and data type, the fields of the structures change, but the signatures of the entry-point functions do not change. See “Reduce Number of Arguments by Using Structures” on page 22-47.
- Set the data types of Inport and Outport blocks explicitly instead of using an inherited data type setting (which these blocks use by default). Inherited data type settings can cause the blocks to use different data types depending on the data types of upstream and downstream signals. For more information about configuring data types, see “Control Signal Data Types” (Simulink).
- With Embedded Coder, specify function names that do not depend on the model name. If you specify a naming rule with a function customization template, do not use the token \$R in the rule. See “Control Names of Generated Entry-Point Functions (Embedded Coder)” (Simulink Coder).

## Reduce Number of Arguments by Using Structures

Reducing the number of arguments of a function can improve the readability of the code and reduce consumption of stack memory. To create a structure argument that can pass multiple pieces of data at one time, use any of these techniques:

- Manually combine multiple Inport or Outport blocks so that they appear in the generated code as fields of a structure or substructure of a standard data structure. The generated entry-point function or functions accept the address of the structure either as a separate argument or as a substructure (field) of the standard I/O structures.

Replace the Inport or Outport blocks with a single block, and configure the new block as a nonvirtual bus by using a `Simulink.Bus` object as the data type of the block. If your external code defines the structure type, consider using the `Simulink.importExternalCTypes` function to generate the bus object. See “Organize Data into Structures in Generated Code” on page 22-177 and `Simulink.importExternalCTypes`.

- When you generate reentrant code with Embedded Coder, configure Inport and Outport blocks to appear in aggregated structures by default. Set **Configuration Parameters > Code Generation > Interface > Pass root-level I/O as** to a setting other than `Individual arguments`.
  - To package all of the Inport and Outport blocks into the real-time model data structure, select `Part of model data structure`. The code generator aggregates the blocks into the default I/O structures, which the real-time model data structure points to. The generated entry-point function or functions accept the real-time model data structure as a single argument. If you choose this setting, the function has the smallest number of arguments.
  - To aggregate all Inport blocks into a structure and all Outport blocks into a different structure, select `Structure reference`. The generated entry-point function or functions accept the address of each structure as an argument. Another argument accepts the real-time model data structure. If you choose this setting, the inputs and outputs are more identifiable in the function signatures.

With this setting, if you remove all root-level Inport blocks or all root-level Outport blocks, the function signature can change. Similarly, the signature can change if you add a root-level Inport or Outport block to a model that does not have any such blocks.

- For additional control over the characteristics of the structures, set **Pass root-level I/O as** to `Part of model data structure`. Then, set the default storage class for Inport and Outport blocks to a structured storage class that you create. With this technique:
  - You can create a single structure for all of the blocks or create two separate structures.
  - You can control the names of the structure types.
  - The structures appear as substructures of the real-time model data structure. You must set **Pass root-level I/O as** to `Part of model data structure`.

Create the storage class by using the Embedded Coder Dictionary (see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 20-2). Apply the storage class by using the Code Mapping Editor (see “Configure Default Code Generation for Data” on page 21-8).

For more information about **Pass root-level I/O as**, see “Pass root-level I/O as” (Simulink Coder).

## Control Data Types of Arguments

You can configure the generated entry-point functions to exchange data through arguments. For a scalar or array argument, to control the name of the primitive data type, use a `Simulink.AliasType` object to either set the data type of the corresponding block or to configure data type replacements for the entire model. These techniques require Embedded Coder. For more information, see “Control Data Type Names in Generated Code” on page 24-2.

## Promote Data Item to the Interface

By default, the code generator assumes that Inport and Outport blocks at the root level of the model constitute the data interface of the model. You can promote an arbitrary signal, block parameter, or block state to the interface so that other systems and components can access it. See “Promote Internal Data to the Interface” on page 22-63.

## How Generated Code Stores Internal Signal, State, and Parameter Data

To calculate outputs from inputs, the generated code stores some internal data in global memory. A signal that does not connect to a root-level input or output (Inport or Outport block) is internal data.

Internal data can also include:

- A block state such as the state of a Unit Delay block. The algorithm must retain the state value between execution cycles, so the generated code typically stores states in global memory (for example, as a global variable or a field of a global structure variable).
- A block parameter, such as the **Gain** parameter of a Gain block, whose value the code generator cannot inline in the code. For example, the code generator cannot inline the value of a nonscalar parameter.
- The status indicator of a conditionally executed subsystem such as an enabled subsystem.

For more efficient code, you can configure optimizations such as **Configuration Parameters > Default parameter behavior** and **Configuration Parameters > Signal storage reuse** that attempt to eliminate storage for internal data. However, the optimizations cannot eliminate storage for some data, which consume memory in the generated code.

When you understand the default format in which the generated code stores internal data, you can:

- Make signals accessible and parameters tunable by default. You can then interact with and monitor the code during execution.
- Generate efficient production code by eliminating storage for internal data and, depending on your hardware and build toolchain, controlling the placement in memory of data that the optimizations cannot eliminate.
- Promote pieces of internal data to the model interface so that other components and systems can access that data.

For information about how the generated code exchanges data with a calling environment through interfaces, see “How Generated Code Exchanges Data with an Environment” on page 22-33.

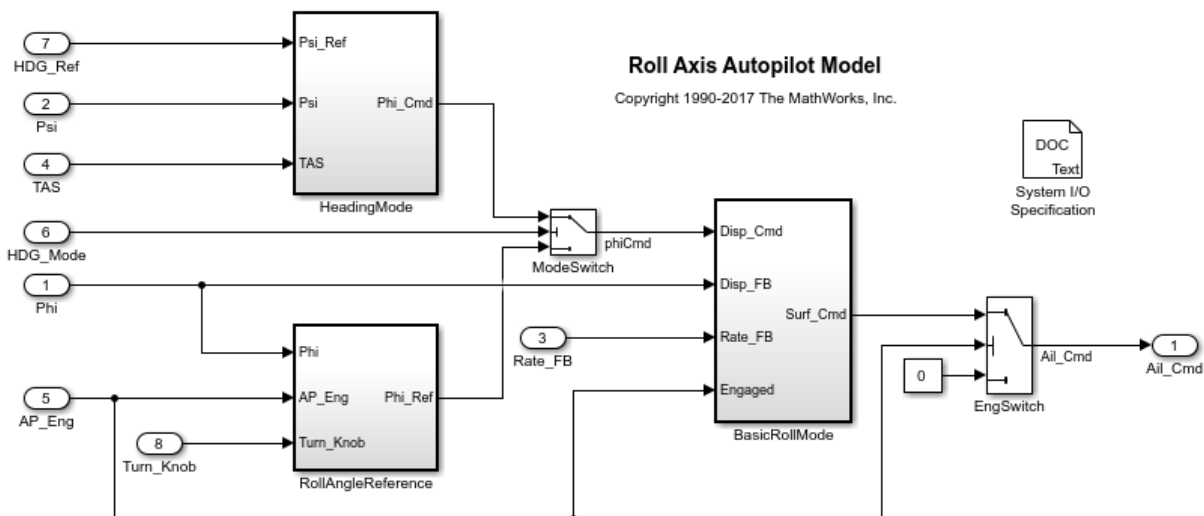

## Internal Data in the Generated Code

This example shows how the generated code stores internal data such as block states.

### Explore Example Model

Open the example model `rtwdemo_roll`.

```
open_system('rtwdemo_roll')
```

The model contains internal signals that do not connect to root-level Inport or Outport blocks. Some of the signals have a name, such as the `phiCmd` signal.

The model also contains some blocks that maintain state data. For example, in the `BasicRollMode` subsystem, a Discrete-Time Integrator block labeled `Integrator` maintains a state.

In the model, set **Configuration Parameters > Code Generation > System target file** to `grt.tlc`.

```
set_param('rtwdemo_roll','SystemTargetFile','grt.tlc')
```

Inspect the setting for **Configuration Parameters > Code Generation > Interface > Code interface packaging**. The setting `Nonreusable function` means that the generated code is not reusable (reentrant).

For this example, generate simpler code by clearing **Configuration Parameters > Code Generation > Interface > Advanced parameters > Mat-file logging**.

```
set_param('rtwdemo_roll','MatFileLogging','off')
```

### Generate Nonreusable Code

Set these configuration parameters:

- Set **Default parameter behavior** to Tunable.
- Clear **Signal storage reuse**.

```
set_param('rtwdemo_roll','DefaultParameterBehavior','Tunable',...
 'OptimizeBlockIOStorage','off')
```

Generate code from the model.

```
rtwbuild('rtwdemo_roll')
```

```
Starting build procedure for model: rtwdemo_roll
Successful completion of build procedure for model: rtwdemo_roll
```

The file `rtwdemo_roll.h` defines several structure types that represent internal data. For example, the `block input and output structure` defines one field for each internal signal in the model. Each field name derives from the name of the block that generates the signal or, if you specify a name for the signal, from the name of the signal.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.h');
rtwdemodbtype(file,...
 '/* Block signals (default storage) */',{' B_rtwdemo_roll_T;',1,1)
```

```
/* Block signals (default storage) */
typedef struct {
 real32_T phiCmd; /* '<Root>/ModeSwitch' */
 real32_T Abs; /* '<S3>/Abs' */
 real32_T FixPtUnitDelay1; /* '<S7>/FixPt Unit Delay1' */
 real32_T Xnew; /* '<S7>/Enable' */
 real32_T TKSwitch; /* '<S3>/TKSwitch' */
 real32_T RefSwitch; /* '<S3>/RefSwitch' */
}
```

```

real32_T Integrator; /* '<S1>/Integrator' */
real32_T DispLimit; /* '<S1>/DispLimit' */
real32_T Sum; /* '<S1>/Sum' */
real32_T DispGain; /* '<S1>/DispGain' */
real32_T RateLimit; /* '<S1>/RateLimit' */
real32_T Sum1; /* '<S1>/Sum1' */
real32_T RateGain; /* '<S1>/RateGain' */
real32_T Sum2; /* '<S1>/Sum2' */
real32_T CmdLimit; /* '<S1>/CmdLimit' */
real32_T IntGain; /* '<S1>/IntGain' */
real32_T hdgError; /* '<S2>/Sum' */
real32_T DispGain_a; /* '<S2>/DispGain' */
real32_T Product; /* '<S2>/Product' */
boolean_T NotEngaged; /* '<S3>/NotEngaged' */
boolean_T TKThreshold; /* '<S3>/TKThreshold' */
boolean_T RefThreshold2; /* '<S3>/RefThreshold2' */
boolean_T RefThreshold1; /* '<S3>/RefThreshold1' */
boolean_T Or; /* '<S3>/Or' */
boolean_T NotEngaged_e; /* '<S1>/NotEngaged' */
} B_rtwdemo_roll_T;

```

The file defines a structure type, the `DWork` structure, to represent block states such as the state of the Discrete-Time Integrator block.

```

rtwdemodbtype(file,...
 /* Block states (default storage) for system','} DW_rtwdemo_roll_T;',1,1)

/* Block states (default storage) for system '<Root>' */
typedef struct {
 real32_T FixPtUnitDelay1_DSTATE; /* '<S7>/FixPt Unit Delay1' */
 real32_T Integrator_DSTATE; /* '<S1>/Integrator' */
 int8_T Integrator_PrevResetState; /* '<S1>/Integrator' */
} DW_rtwdemo_roll_T;

```

The file defines a structure type to represent parameter data. Each tunable block parameter in the model, such as the **Gain** parameter of a Gain block, appears as a field of this structure. If a block parameter acquires its value from a MATLAB variable or a Simulink.Parameter object, the variable or object appears as a field, not the block parameter.

The file also defines a structure type, the *real-time model data structure*, whose single field represents a run-time indication of whether the generated code has encountered an error during execution.

```
rtwdemodbtype(file, /* Real-time Model Data Structure */ , ...
 /* Block parameters (default storage) */ , 1, 0)
```

```
/* Real-time Model Data Structure */
struct tag_RTM_rtwdemo_roll_T {
 const char_T *errorStatus;
};
```

For the structure type that represents the real-time model data structure, the file `rtwdemo_roll_types.h` creates an alias that the generated code later uses to allocate memory for the structure.

```
file = fullfile('rtwdemo_roll_grt_rtw', 'rtwdemo_roll_types.h');
rtwdemodbtype(file, /* Forward declaration for rtModel */ , ...
 'RT_MODEL_rtwdemo_roll_T', 1, 1)
```

```
/* Forward declaration for rtModel */
typedef struct tag_RTM_rtwdemo_roll_T RT_MODEL_rtwdemo_roll_T;
```

Using these structure types, the file `rtwdemo_roll.c` defines (allocates memory for) global structure variables that store internal data for the generated algorithm. The file also defines variables that represent the real-time model data structure and a pointer to the structure.

```
file = fullfile('rtwdemo_roll_grt_rtw', 'rtwdemo_roll.c');
rtwdemodbtype(file, /* Block signals (default storage) */ , ...
 '= &rtwdemo_roll_M;', 1, 1)
```

```
/* Block signals (default storage) */
B_rtwdemo_roll_T rtwdemo_roll_B;
```

```
/* Block states (default storage) */
DW_rtwdemo_roll_T rtwdemo_roll_DW;
```

```
/* External inputs (root inport signals with default storage) */
ExtU_rtwdemo_roll_T rtwdemo_roll_U;
```

```
/* External outputs (root outports fed by signals with default storage) */
ExtY_rtwdemo_roll_T rtwdemo_roll_Y;
```

```
/* Real-time model */
```

```
RT_MODEL_rtwdemo_roll_T rtwdemo_roll_M;
RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M = &rtwdemo_roll_M;
```

The model step function, which represents the primary model algorithm, uses a void void interface (with no arguments).

```
rtwdemodbtype(file,...
 /* Model step function */, 'void rtwdemo_roll_step(void)', 1, 1)
```

```
/* Model step function */
void rtwdemo_roll_step(void)
```

In the function definition, the algorithm performs calculations and stores intermediate results in the signal and state structures by directly accessing the global variables. The algorithm also reads parameter data from the corresponding global variable. For example, in the BasicRollMode subsystem, the code generated for the Integrator block reads and writes signal, state, and parameter data from the structures.

```
rtwdemodbtype(file, /* DiscreteIntegrator: '<S1>/Integrator' */, ...
 /* End of DiscreteIntegrator: '<S1>/Integrator' */, 1, 1)

/* DiscreteIntegrator: '<S1>/Integrator' */
if (rtwdemo_roll_B.NotEngaged_e || (rtwdemo_roll_DW.Integrator_PrevResetState
 != 0)) {
 rtwdemo_roll_DW.Integrator_DSTATE = rtwdemo_roll_P.Integrator_IC;
}

if (rtwdemo_roll_DW.Integrator_DSTATE >= rtwdemo_roll_P.intLim) {
 rtwdemo_roll_DW.Integrator_DSTATE = rtwdemo_roll_P.intLim;
} else {
 if (rtwdemo_roll_DW.Integrator_DSTATE <= rtwdemo_roll_P.Integrator_LowerSat)
 {
 rtwdemo_roll_DW.Integrator_DSTATE = rtwdemo_roll_P.Integrator_LowerSat;
 }
}

rtwdemo_roll_B.Integrator = rtwdemo_roll_DW.Integrator_DSTATE;
```

Due to the void void interface and the direct data access, the function is not reentrant. If you call the function multiple times in an application, each call writes data to the global structure variables and the subsequent call can read that data, resulting in unintentional interference between the calls.

The model initialization function `rtwdemo_roll_initialize` initializes all of the internal data to zero. The function also initializes the error status by calling a specialized macro function. The initialization function directly accesses the global variables, which means that the function is not reentrant.

```
rtwdemodbtype(file, /* Model initialize function */ , ...
 'sizeof(DW_rtwdemo_roll_T));', 1, 1)
```

```
/* Model initialize function */
void rtwdemo_roll_initialize(void)
{
 /* Registration code */

 /* initialize error status */
 rtmSetErrorStatus(rtwdemo_roll_M, (NULL));

 /* block I/O */
 (void) memset((void *) &rtwdemo_roll_B, 0,
 sizeof(B_rtwdemo_roll_T));

 /* states (dwork) */
 (void) memset((void *)&rtwdemo_roll_DW, 0,
 sizeof(DW_rtwdemo_roll_T));
```

The function then initializes the block states in the `DWork` structure to the initial values that the block parameters in the model specify. Two of the three states in the model have tunable initial values, so the code initializes them by reading data from the parameters structure.

```
rtwdemodbtype(file, ...
 /* SystemInitialize for Atomic SubSystem: '<Root>/RollAngleReference' */ , ...
 /* Model terminate function */ , 1, 0)

/* SystemInitialize for Atomic SubSystem: '<Root>/RollAngleReference' */
/* InitializeConditions for UnitDelay: '<S7>/FixPt Unit Delay1' */
rtwdemo_roll_DW.FixPtUnitDelay1_DSTATE = rtwdemo_roll_P.LatchPhi_vinit;

/* End of SystemInitialize for SubSystem: '<Root>/RollAngleReference' */

/* SystemInitialize for Atomic SubSystem: '<Root>/BasicRollMode' */
/* InitializeConditions for DiscreteIntegrator: '<S1>/Integrator' */
rtwdemo_roll_DW.Integrator_DSTATE = rtwdemo_roll_P.Integrator_IC;
rtwdemo_roll_DW.Integrator_PrevResetState = 0;
```

```

 /* End of SystemInitialize for SubSystem: '<Root>/BasicRollMode' */
}

```

## Generate Reusable Code

You can configure the generated code as reentrant, which means you can call the entry-point functions multiple times in an application. With this configuration, instead of directly accessing global variables, the entry-point functions accept internal data through formal parameters (pointer arguments). With these pointer arguments, each call can maintain internal data in a set of separate global variables, preventing unintentional interaction between the calls.

In the model, set **Configuration Parameters > Code Generation > Interface > Code interface packaging** to Reusable function.

```
set_param('rtwdemo_roll','CodeInterfacePackaging','Reusable function')
```

Generate code from the model.

```

rtwbuild('rtwdemo_roll')

Starting build procedure for model: rtwdemo_roll
Successful completion of build procedure for model: rtwdemo_roll

```

Now, in `rtwdemo_roll.h`, the real-time model data structure contains pointers to the error indication, the internal data, and primary input and output data in the form of `ExtU` and `ExtY` substructures (the fields of which represent Inport and Outport blocks at the root level of the model).

```

file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.h');
rtwdemodbtype(file,'/* Real-time Model Data Structure */',...
 '/* External data declarations for dependent source files */',1,0)

```

```

/* Real-time Model Data Structure */
struct tag_RTM_rtwdemo_roll_T {
 const char_T *errorStatus;
 B_rtwdemo_roll_T *blockIO;
 P_rtwdemo_roll_T *defaultParam;
 ExtU_rtwdemo_roll_T *inputs;
 ExtY_rtwdemo_roll_T *outputs;
 boolean_T paramIsMallocated;
 DW_rtwdemo_roll_T *dwork;
};

```

To call the generated code multiple times in an application, your code must allocate memory for a real-time model data structure per call. The file `rtwdemo_roll.c` defines a specialized function that allocates memory for a new real-time model data structure and returns a pointer to the structure. The function also allocates memory for the substructures that the fields in the model data structure point to, such as the `DWork` structure.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,'/* Model data allocation function */',...
 'RT_MODEL_rtwdemo_roll_T *rtwdemo_roll(void)',1,1)
```

```
/* Model data allocation function */
RT_MODEL_rtwdemo_roll_T *rtwdemo_roll(void)
```

The model `step` function accepts an argument that represents the real-time model data structure.

```
rtwdemodbtype(file,'/* Model step function */','void rtwdemo_roll_step',1,1)
```

```
/* Model step function */
void rtwdemo_roll_step(RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M)
```

In the function definition, the algorithm first extracts each pointer from the real-time model data structure into a local variable.

```
rtwdemodbtype(file,'*rtwdemo_roll_P_e =','rtwdemo_roll_M->outputs;',1,1)
```

```
P_rtwdemo_roll_T *rtwdemo_roll_P_e = ((P_rtwdemo_roll_T *)
 rtwdemo_roll_M->defaultParam);
B_rtwdemo_roll_T *rtwdemo_roll_B = ((B_rtwdemo_roll_T *)
 rtwdemo_roll_M->blockIO);
DW_rtwdemo_roll_T *rtwdemo_roll_DW = ((DW_rtwdemo_roll_T *)
 rtwdemo_roll_M->dwork);
ExtU_rtwdemo_roll_T *rtwdemo_roll_U = (ExtU_rtwdemo_roll_T *)
 rtwdemo_roll_M->inputs;
ExtY_rtwdemo_roll_T *rtwdemo_roll_Y = (ExtY_rtwdemo_roll_T *)
 rtwdemo_roll_M->outputs;
```

Then, to access the internal data stored in global memory, the algorithm interacts with these local variables.

```

rtwdemodbtype(file, /* DiscreteIntegrator: '<S1>/Integrator' */ , ...
 /* End of DiscreteIntegrator: '<S1>/Integrator' */ , 1, 1)

/* DiscreteIntegrator: '<S1>/Integrator' */
if (rtwdemo_roll_B->NotEngaged_e ||
 (rtwdemo_roll_DW->Integrator_PrevResetState != 0)) {
 rtwdemo_roll_DW->Integrator_DSTATE = rtwdemo_roll_P_e->Integrator_IC;
}

if (rtwdemo_roll_DW->Integrator_DSTATE >= rtwdemo_roll_P_e->intLim) {
 rtwdemo_roll_DW->Integrator_DSTATE = rtwdemo_roll_P_e->intLim;
} else {
 if (rtwdemo_roll_DW->Integrator_DSTATE <=
 rtwdemo_roll_P_e->Integrator_LowerSat) {
 rtwdemo_roll_DW->Integrator_DSTATE = rtwdemo_roll_P_e->Integrator_LowerSat;
 }
}

rtwdemo_roll_B->Integrator = rtwdemo_roll_DW->Integrator_DSTATE;

```

Similarly, the model initialization function accepts the real-time model data structure as an argument.

```

rtwdemodbtype(file, ...
 /* Model initialize function */ , 'void rtwdemo_roll_initialize' , 1, 1)

/* Model initialize function */
void rtwdemo_roll_initialize(RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M)

```

Because each call that you make to an entry-point function interacts with a separate real-time model data structure, you avoid unintentional interaction between the calls.

### Eliminate Internal Data with Code Generation Optimizations

For more efficient code that consumes less memory, select the optimizations, such as **Default parameter behavior**, that you cleared earlier.

```

set_param('rtwdemo_roll', 'DefaultParameterBehavior', 'Inlined' , ...
 'OptimizeBlockIOStorage', 'on' , ...
 'LocalBlockOutputs', 'on')

```

In this example, for simpler code, set **Code interface packaging** to Nonreusable function.

```
set_param('rtwdemo_roll','CodeInterfacePackaging','Nonreusable function')
```

Generate code from the model.

```
rtwbuild('rtwdemo_roll')
```

```
Starting build procedure for model: rtwdemo_roll
Successful completion of build procedure for model: rtwdemo_roll
```

Now, `rtwdemo_roll.h` does not define a structure for block inputs and outputs. For all of the internal signals in the model, the optimizations either eliminated storage or created local function variables instead of global structure fields.

The optimizations were not able to eliminate storage for the three block states, so the file continues to define the `DWork` structure type.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.h');
rtwdemodbtype(file,...
 /* Block states (default storage) for system','} DW_rtwdemo_roll_T;',1,1)

/* Block states (default storage) for system '<Root>' */
typedef struct {
 real32_T FixPtUnitDelay1_DSTATE; /* '<S7>/FixPt Unit Delay1' */
 real32_T Integrator_DSTATE; /* '<S1>/Integrator' */
 int8_T Integrator_PrevResetState; /* '<S1>/Integrator' */
} DW_rtwdemo_roll_T;
```

The code generated for the Discrete-Time Integrator block now stores state and output data only in the `DWork` structure.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,'/* Update for DiscreteIntegrator: '<S1>/Integrator''',...
 /* End of Update for DiscreteIntegrator: '<S1>/Integrator' */',1,1)

/* Update for DiscreteIntegrator: '<S1>/Integrator' incorporates:
 * Gain: '<S1>/IntGain'
 */
rtwdemo_roll_DW.Integrator_DSTATE += 0.5F * rtb_TKSwitch * 0.025F;
if (rtwdemo_roll_DW.Integrator_DSTATE >= 5.0F) {
 rtwdemo_roll_DW.Integrator_DSTATE = 5.0F;
```

```

} else {
 if (rtwdemo_roll_DW.Integrator_DSTATE <= -5.0F) {
 rtwdemo_roll_DW.Integrator_DSTATE = -5.0F;
 }
}

rtwdemo_roll_DW.Integrator_PrevResetState = (int8_T)rtb_NotEngaged_f;

```

The optimizations also eliminated storage for the block parameters in the model. For example, in the Discrete-Time Integrator block, the **Upper saturation limit** and **Lower saturation limit** parameters are set to `intLim` and `-intLim`. `intLim` is a Simulink.Parameter object that stores the value 5. In the code generated for the Discrete-Time Integrator, these block parameters and `intLim` appear as inlined literal numbers `5.0F` and `-5.0F`.

If a model contains a parameter that the code generator cannot inline directly (for example, an array parameter), the code defines a structure type that represents the data. This *constant parameters* structure uses the `const` storage type qualifier, so some build toolchains can optimize the assembly code further.

## Local Variables in the Generated Code

When you select the optimization **Configuration Parameters > Enable local block outputs**, the code generator attempts to yield more efficient code by representing internal signals as local variables instead of fields of a global structure. If the memory consumed by local variables risks exceeding the stack space available on your target hardware, consider indicating the maximum stack size by setting **Configuration Parameters > Maximum stack size (bytes)**. For more information, see “Maximum stack size (bytes)” (Simulink Coder).

## Appearance of Test Points in the Generated Code

A *test point* is a signal that is stored in a unique memory location. For information about including test points in your model, see “Test Points” (Simulink).

When you generate code for models that include test points, the build process allocates a separate memory buffer for each test point. By default, test points are stored as members of an appropriate standard data structure such as `model_B`.

If you have Embedded Coder:

- You can control the default representation of test points by specifying code generation settings for the **Internal data** category of data in the Code Mapping Editor (see “Configure Default Code Generation for Data” on page 21-8).
- You can specify that the build process ignore test points in the model, allowing optimal buffer allocation, by using the “Ignore test point signals” (Simulink Coder) parameter. Ignoring test points facilitates transitioning from prototyping to deployment and avoids accidental degradation of generated code due to workflow artifacts. See “Ignore test point signals” (Simulink Coder).

Virtual buses do not appear in generated code, even when associated with a test point. To display a bus in generated code, use a nonvirtual bus or a virtual bus converted to a nonvirtual bus by a Signal Conversion block.

## Appearance of Workspace Variables in the Generated Code

Workspace variables are variables that you use to specify block parameter values in a model. Workspace variables include numeric MATLAB variables and `Simulink.Parameter` objects that you store in a workspace, such as the base workspace, or in a data dictionary.

When you set **Default parameter behavior** to `Tunable`, by default, workspace variables appear in the generated code as tunable fields of the global parameters structure. If you use such a variable to specify multiple block parameter values, the variable appears as a single field of the global parameters structure. The code does not create multiple fields to represent the block parameters. Therefore, tuning the field value during code execution changes the mathematical behavior of the model in the same way as tuning the value of the MATLAB variable or parameter object during simulation.

If you have Embedded Coder, you can control the default representation of workspace variables by specifying code generation settings for categories of parameter data in the Code Mapping Editor (see “Configure Default Code Generation for Data” on page 21-8).

- The **Local parameters** category applies to variables that you store in a model workspace.
- The **Global parameters** category applies to variables that you store in the base workspace or a data dictionary.

## Promote Internal Data to the Interface

By default, the code generator assumes that other systems and components in your application do not need to access internal data. For example, internal data are subject to optimizations that can eliminate them from the generated code. For prototyping and testing purposes, you can access internal data by clearing the optimizations or by configuring test points and applying storage classes (see “Configure Data Accessibility for Rapid Prototyping” on page 22-3). For optimized production code, configure individual data items to appear in the generated code as part of the model interface.

### Data That You Can Promote

Depending on the reentrancy of the generated code, that is, the setting that you choose for **Code interface packaging**, you can configure each data item in a model to participate in the interface by appearing in the code as one of these entities:

- A global symbol, such as a global variable or a call to a specialized function
- A formal parameter (argument) of the generated entry-point functions

The table shows the mechanisms that each category of data can use to participate in the interface.

| Category of Data                   | Appear as Global Symbol        | Appear as Argument of Entry-Point Function                                                                                             |
|------------------------------------|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| Root-level Inport or Outport block | Only for a nonreentrant model. | Yes.                                                                                                                                   |
| Signal connecting two blocks       | Only for a nonreentrant model. | Only for a reentrant model and only as a field of a structure.<br><br>Alternatively, connect the signal to a root-level Outport block. |
| Block state                        | Only for a nonreentrant model. | Only for a reentrant model and only as a field of a structure.                                                                         |

| Category of Data                                                            | Appear as Global Symbol | Appear as Argument of Entry-Point Function                     |
|-----------------------------------------------------------------------------|-------------------------|----------------------------------------------------------------|
| Data store such as a Data Store Memory block                                | Yes.                    | Only for a reentrant model and only as a field of a structure. |
| Block parameter or parameter object such as <code>Simulink.Parameter</code> | Yes.                    | Only as a field of a structure.                                |

### Single-Instance Algorithm

For a single-instance algorithm (you set **Code interface packaging** to **Nonreusable function**), apply storage classes directly to individual data items by using the Model Data Editor or the Property Inspector. With a directly applied storage class, a data item appears in the code as a global symbol such as a global variable. The storage class also prevents optimizations from eliminating storage for the data item.

You can apply storage classes to signals, block states, and block parameters. (For block parameters, you apply storage classes indirectly through parameter objects such as `Simulink.Parameter`). However, for a signal, consider connecting the signal to an Outputport block at the root level of the model. Then, optionally, you can apply a storage class to the block. In the block diagram, the Outputport block shows that the signal represents a system output.

For more information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81.

### Reentrant Algorithm

For a reentrant algorithm (you set **Code interface packaging** to **Reusable function**), use different techniques to configure data items to appear in the code as formal parameters (arguments) of the generated entry-point functions.

- For an internal signal, directly apply the storage class `Model default` (see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81). If you have Embedded Coder, in the Code Mapping Editor, for the **Internal data** category, set the default storage class to `Default` or to a structured storage class that you define in an Embedded Coder Dictionary (see “Create Code Definitions for Use as Default Code Generation Settings” on page 20-2). Alternatively, configure the signal as a test point (see “Appearance of Test Points in the Generated Code” on

page 22-61). By default, the signal appears as a field of one of the standard data structures (see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50). If you do not want the signal to appear in production code, use a test point so that you can later select the model configuration parameter **Ignore test point signals**.

Alternatively, connect the signal to an Outport block at the root level of the model. Connecting the signal to a root-level Outport block prevents optimizations from eliminating the signal from the code. To help with signal routing in a large model, use Goto and From blocks.

- For a block parameter, create a parameter object such as `Simulink.Parameter` and directly apply a storage class other than `Auto` to the object. The storage class prevents optimizations from inlining the parameter value in the code.

With the storage class, the parameter is shared between all instances of the model, which are calls to the entry-point functions. The functions access the parameter data directly, as a global symbol, not an argument. You cannot configure a parameter to appear in the code as an argument, so you cannot enable each instance of the model to use a different value for the parameter.

For information about applying storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

## Control Default Representation of Internal Data (Embedded Coder)

By default, the code generator aggregates internal data that optimizations cannot eliminate, such as most state data, into standard structures such as the `DWork` structure. With Embedded Coder, you can control how the generated code stores this data.

### Control Placement of Data in Memory by Inserting Pragmas

Use the Code Mapping Editor to specify a default memory section for each category of data such as states and signals (**Internal data**). In the generated code, your custom pragmas or other decorations surround the data definitions and declarations.

You can also partition the structures according to atomic subsystems in your model so that you can specify different default memory sections for the data of subroutines and other algorithmic subcomponents.

For more information, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 30-2.

### **Control Names of Types, Fields, and Global Variables for Standard Data Structures**

You can control some characteristics of the standard data structures. For more information, see “Control Characteristics of Data Structures (Embedded Coder)” (Simulink Coder).

For additional control over structure characteristics, such as placement in generated code files, create your own structured storage class by using the Embedded Coder Dictionary. Then, apply the storage class to categories of data by using the Code Mapping Editor. The storage class removes the data from the standard structures, creating other structures that you can more finely control. For more information about applying default storage classes to categories of data, see “Configure Default Code Generation for Data” on page 21-8. For more information about creating a storage class, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 20-2.

### **Organize Data into Structures According to Subcomponents**

- In the standard data structures, to create substructures that contain the data for a single-instance (nonreentrant) subroutine or subcomponent, use an atomic subsystem to encapsulate the corresponding blocks. In the subsystem parameters, set **Function packaging** to `Reusable` function. For more information, see “Generate Modular Function Code” on page 29-65.

Alternatively, encapsulate the blocks in a model and use a Model block. In the referenced model, set **Configuration Parameters > Model Referencing > Total number of instances allowed per top model** to `Multiple`. For more information, see “Code Generation of Referenced Models” on page 4-2.

- To create separate, standalone structures that contain the data for a multi-instance (reentrant) subroutine or subcomponent, in the model, use an atomic subsystem to encapsulate the corresponding blocks. In the subsystem parameters, set **Function packaging** to `Nonreusable` function and select **Function with separate data**. For more information, see “Generate Modular Function Code” on page 29-65.

Alternatively, encapsulate the blocks in a model and use a Model block. In the referenced model, choose one of these techniques:

- Set **Configuration Parameters > Model Referencing > Total number of instances allowed per top model** to One. For more information, see “Code Generation of Referenced Models” on page 4-2.
- Set **Total number of instances allowed per top model** to Multiple and create a structured storage class by using an Embedded Coder Dictionary. Then, apply the storage class to categories of data by using the Code Mapping Editor. To create a storage class, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 20-2. To apply the storage class to categories of data, see “Configure Default Code Generation for Data” on page 21-8.

### **Organize Signal and Parameter Data into Meaningful, Custom Structures and Substructures**

To organize arbitrary signals and parameters into custom structures and substructures, create nonvirtual bus signals and parameter structures. Optionally, to prevent optimizations from eliminating the data from the code, set the storage class of a bus signal or parameter structure to a value other than Auto (the default setting).

As you add blocks to the model, you must explicitly place each new signal and parameter into a bus or a structure.

For more information, see “Organize Data into Structures in Generated Code” on page 22-177.

### **Create Separate Global Variables Instead of Structure Fields**

To make a category of internal data appear in the generated code as separate, unstructured global variables instead of fields of a standard data structure, apply an unstructured storage class to the data category by using the Code Mapping Editor. For example, apply the storage class `ExportedGlobal`. However, if you generate multi-instance, reentrant code by setting the configuration parameter **Code interface packaging** to a value other than `Nonreusable function`, you cannot use this technique for some categories of data (see “Use Storage Classes in Reentrant, Multi-Instance Models and Components” (Simulink Coder)).

To apply default storage classes to categories of data by using the Code Mapping Editor, see “Configure Default Code Generation for Data” on page 21-8. To choose a storage class, see “Choose a Storage Class for Controlling Data Representation in the Generated Code” (Simulink Coder).

## **Choose a Storage Class for Controlling Data Representation in the Generated Code**

A storage class is a code generation setting that you apply to model data, such as signals, block parameters, and states. Use storage classes to control the appearance of data elements in the generated code.

The table shows built-in storage classes that you can choose. These storage classes come with Simulink Coder.

| Storage Class Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Auto               | <p>Auto is the default storage class setting for each data element in a model. The data element is subject to code generation optimizations, which can eliminate the element from the code or change the representation of the element. For information about these optimizations, such as those on the <b>Configuration Parameters &gt; Code Generation &gt; Optimization</b> pane, see “How Generated Code Stores Internal Signal, State, and Parameter Data” (Simulink Coder).</p> <p>Optimizations cannot eliminate some data, such as most block states, from the code. This remaining data acquire the appropriate default storage class that you specify with the Code Mapping Editor (see “Configure Default Code Generation for Data” on page 21-8—requires Embedded Coder). If you leave the storage class setting in the Code Mapping Editor at the default value, <b>Default</b>, the data element appears as a field of the appropriate standard data structure (see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50).</p> <p>If optimizations cannot eliminate the data element, the name of the element in the code is based on naming rules that you specify with model configuration parameters (see “Identifier Format Control” on page 39-22—requires Embedded Coder).</p> <p>Use this storage class to enable optimizations to operate on the data</p> |

| Storage Class Name    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <p>element, potentially generating more efficient code.</p>                                                                                                                                                                                                                                                                                                                                                                                                              |
| <p>Model default</p>  | <p>The data element acquires the corresponding default storage class that you specify with the Code Mapping Editor. The name of the data element in the code is the same as the name in the model.</p> <p>Use this storage class to prevent optimizations from eliminating storage for a data element (see “How Generated Code Stores Internal Signal, State, and Parameter Data” (Simulink Coder)).</p>                                                                 |
| <p>ExportedGlobal</p> | <p>Generate a global variable definition and declaration. The name of the variable is the name of the data element. The code declares the variable in the generated file <i>model.h</i>, which you can include (<code>#include</code>) in your external code.</p>                                                                                                                                                                                                        |
| <p>ImportedExtern</p> | <p>Generate code that reads from and writes to a global variable defined by your external code. The generated code declares the variable in the generated file <i>model_private.h</i> so that the model entry-point functions can read and write to the variable.</p> <p>Use this storage class to make a data element in a model represent a global variable that your external code defines. The generated algorithmic code uses the variable without defining it.</p> |

| Storage Class Name    | Description                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ImportedExternPointer | <p>Generate code that reads from and writes to a global pointer variable defined by your external code. The generated code declares the variable in the generated file <i>model_private.h</i> and reads and writes to the data by dereferencing the pointer.</p> <p>Use this storage class when your external code defines a data element and provides a pointer for accessing that data.</p> |

If you have Embedded Coder, you can choose additional built-in storage classes, shown in the next table.

| Storage Class Name | Description                                                                                                                                                                                   | Use for Signal or State Data | Use for Parameter Data |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|------------------------|
| BitField           | <p>Generate a structure that stores Boolean data in named bit fields. For an example, see “Bitfields” on page 14-89.</p> <p>You cannot use this storage class in the Code Mapping Editor.</p> | Yes                          | Yes                    |

| Storage Class Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Use for Signal or State Data | Use for Parameter Data |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|------------------------|
| CompilerFlag       | <p>Supports preprocessor conditionals defined via compiler flag or option. See “Generate Preprocessor Conditionals for Variant Systems” on page 15-35.</p> <p>If you build the generated code by using Embedded Coder (you clear <b>Configuration Parameters &gt; Generate code only</b>), to specify the compiler option, you can use the model configuration parameter <b>Configuration Parameters &gt; Code Generation &gt; Custom Code &gt; Additional build information &gt; Defines</b>. See Code Generation Pane: Custom Code: Additional Build Information: Defines (Simulink Coder).</p> | No                           | Yes                    |
| Const              | Generate a global variable definition and declaration with the <code>const</code> type qualifier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | No                           | Yes                    |
| ConstVolatile      | Generate a global variable definition and declaration with the <code>const</code> and <code>volatile</code> type qualifiers. For an example, see “Type Qualifiers” on page 14-14.                                                                                                                                                                                                                                                                                                                                                                                                                 | No                           | Yes                    |
| Define             | Generate a macro ( <code>#define</code> directive) such as <code>#define myParam 5</code> . For an example, see “Macro Definitions ( <code>#define</code> )” on page 14-71.                                                                                                                                                                                                                                                                                                                                                                                                                       | No                           | Yes                    |
| ExportToFile       | Generate a global variable definition and declaration. You can specify the names of the files that define and declare the variable.                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Yes                          | Yes                    |

| Storage Class Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Use for Signal or State Data | Use for Parameter Data |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|------------------------|
| FileScope          | <p>Generate a global variable definition and declaration with the <code>static</code> type qualifier. In the generated code, the scope of the variable is limited to the current file, which is typically <code>model.c</code>.</p> <p>In a model reference hierarchy, if a referenced model uses a parameter object (such as <code>Simulink.Parameter</code>) that you create in the base workspace or a data dictionary, you cannot apply <code>FileScope</code> to the object. As a workaround, move the parameter object into the model workspace of the referenced model. Then, you can use <code>FileScope</code>.</p> | Yes                          | Yes                    |
| GetSet             | Generate code that interacts with data by calling your custom accessor functions. Your external code defines the data and provides the function definitions. For examples, see “Access Data Through Functions with Custom Storage Class <code>GetSet</code> ” on page 26-42.                                                                                                                                                                                                                                                                                                                                                 | Yes                          | Yes                    |
| ImportedDefine     | Generate code that uses a macro ( <code>#define</code> directive) defined in a header file in your external code. For an example, see “Macro Definitions ( <code>#define</code> )” on page 14-71.                                                                                                                                                                                                                                                                                                                                                                                                                            | No                           | Yes                    |
| ImportFromFile     | Generate code that reads from and writes to a global variable defined by your external code. Similar to <code>ExportToFile</code> , but the generated code does not define the variable.                                                                                                                                                                                                                                                                                                                                                                                                                                     | Yes                          | Yes                    |

| Storage Class Name | Description                                                                                                                                                                                                                                                                                                                                                                                     | Use for Signal or State Data | Use for Parameter Data |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|------------------------|
| Reusable           | <p>Generate more efficient code that stores intermediate calculations of a data path (a series of connected blocks) in a single, reused global variable. For an example, see “Specify Buffer Reuse by Using Simulink.Signal Objects” on page 58-19.</p> <p>You can apply this storage class only to a <code>Simulink.Signal</code> object that represents multiple signal lines in a model.</p> | Yes                          | No                     |
| Struct             | <p>Generate a global structure whose name you can specify. For examples, see “Organize Parameter Data into a Structure by Using the Struct Custom Storage Class” on page 26-23 and “Structures of Signals” on page 14-81.</p> <p>You cannot use this storage class in the Code Mapping Editor.</p>                                                                                              | Yes                          | Yes                    |
| Volatile           | Generate a global variable definition and declaration with the <code>volatile</code> type qualifier.                                                                                                                                                                                                                                                                                            | Yes                          | Yes                    |
| ParamStruct        | Generate global structures that contain parameter data. In a hierarchy of components (referenced models or atomic subsystems), you can use this storage class to create a corresponding hierarchy of parameter structures. This storage class appears only in the Code Mapping Editor for the data category called <b>Local parameters</b> .                                                    | No                           | Yes                    |

| Storage Class Name | Description                                                                                                                                                                                                                                                                                                                                           | Use for Signal or State Data | Use for Parameter Data |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|------------------------|
| SignalStruct       | Generate global structures that contain signal or state data. In a hierarchy of components (referenced models or atomic subsystems), you can use this storage class to create a corresponding hierarchy of signal and state structures. This storage class appears only in the Code Mapping Editor.                                                   | Yes                          | No                     |
| Localizable        | For signals, if possible, generate variables that are local to functions rather than in global storage. Generating local variables prevents the code generator from implementing optimizations that remove the variables from the generated code. For an example, see “Generate Local Variables with Localizable Custom Storage Class” on page 26-94. | Yes (signals not states)     | No                     |

When you generate reentrant, multi-instance code, limitations and restrictions apply if you want to use storage classes. See “Use Storage Classes in Reentrant, Multi-Instance Models and Components” (Simulink Coder).

### Specify File Names and Other Data Attributes With Storage Class (Embedded Coder)

After you apply some storage classes, such as `ExportToFile`, you can specify additional settings such as declaration (header) and definition file names. In the Code Mapping Editor, to access these additional settings, you use the Property Inspector.

With other storage classes, you cannot specify additional settings.

- These built-in Simulink Coder storage classes do not allow you to specify additional settings:

- ExportedGlobal
- ImportedExtern
- ImportedExternPointer
- The built-in Embedded Coder storage classes typically allow you to specify declaration and definition file names.
- When you create a storage class with the Custom Storage Class Designer, you can choose whether the user of the storage class can specify additional settings. See “Allow Users of Custom Storage Class to Specify Property Value” on page 26-32.

## Specify Default #include Syntax for Header Files That Declare Data (Embedded Coder)

To control the file placement of a data item, such as a signal line or block state, in the generated code, you can apply a storage class to the data item (see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19). You then use the **Header file** custom attribute to specify the generated or external header file that contains the declaration of the data.

To reduce maintenance effort and data entry, when you specify **Header file**, you can omit delimiters (" or <>) and use only the file name. You can then control the default delimiters that the generated code uses for the corresponding #include directives. To use angle brackets by default, set **Configuration Parameters > Code Generation > Code Placement > #include file delimiters** to #include <header.h>.

## Storage Class Limitations

- When you use storage classes in the Code Mapping Editor (Embedded Coder), some limitations apply. See “Limitations” on page 21-33.
- Data objects cannot use an Embedded Coder storage class and a multiword data type.
- The Fcn block does not support parameters with an Embedded Coder storage class in code generation.
- For Embedded Coder storage classes in models that use referenced models:
  - If you apply a grouped storage class to multiple data items, the storage class **Data scope** property must be set to **Imported** and you must provide the data declaration in an external header file. Grouped storage classes use a single variable in the generated code to represent multiple data objects. For example, the storage classes **BitField** and **Struct** are grouped storage classes.

- If a parameter object exists in the base workspace or a data dictionary, and a referenced model uses the object, you cannot apply the storage class `FileScope`. As a workaround, move the object into the model workspace of the referenced model. Then, you can use `FileScope`.
- You cannot apply the storage class `FileScope` to data items used by a data exchange interface (C API, external mode, or ASAP2) or MAT-file logging. File-scoped data is not externally accessible.

## Use Storage Classes in Reentrant, Multi-Instance Models and Components

The code that you generate from a model or component (referenced model or subsystem) is multi-instance code if it allows your application to maintain multiple independent instances of the component during execution. For example, you can generate reentrant, multi-instance code from an entire model by setting the model configuration parameter **Code interface packaging** to `Reusable function`. For general information about multi-instance models and components, see “Code Reuse” (Simulink Coder).

Under some circumstances, applying storage classes can:

- Prevent you from generating multi-instance code.
- Cause some data elements to appear in the generated code as singletons, which means that each instance of the model or component directly accesses the same shared, global data, creating dependencies between the instances.

To avoid errors and unexpected generation of single-instance code and singleton data, observe the guidelines and limitations below.

### Directly Applied Storage Classes

When you apply a storage class directly to a data element (see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder)):

- To generate multi-instance code, you must apply the storage class only to parameter objects, global data stores, and shared local data stores.
- The storage class yields only singleton data.

### Storage Classes Applied by Default

When you apply a default storage class by using the Code Mapping Editor (see “Configure Default Code Generation for Data” on page 21-8—requires Embedded Coder):

- For these data categories, you can generate only singleton data:
  - **Local parameters**
  - **Global parameters**

- **Global data stores**
- **Shared local data stores**
- For these data categories, you can generate only instance-specific data, which means each instance of the model or component operates on a separate copy of the data:
  - **Inports**
  - **Outports**
  - **Internal data**

For these categories, you must use the built-in storage class `SignalStruct` or create your own structured storage class by using an Embedded Coder Dictionary.

## Apply Storage Classes to Individual Signal, State, and Parameter Data Elements

A storage class is a code generation setting that you apply to a data item (signal, block parameter, or state) in a model. When you directly apply it to a data item, a storage class:

- Causes the data item to appear in the generated code as a global symbol, typically a global variable.
- Prevents optimizations such as **Default parameter behavior** and **Signal storage reuse** from eliminating the data item from the generated code.
- With Embedded Coder, you can configure the format in which the generated code stores or otherwise defines the data item. For example, you can apply the storage type qualifiers `const` or `volatile` or configure a parameter data item to appear as a macro (`#define`).

Directly apply storage classes to individual data items to:

- Tune parameters and monitor signals and states during execution.
- Configure data placement in memory through memory sections.
- Generate code that exchanges data (for example, global variables) with your external code.

For information about applying storage classes to categories of data by default, by using the Code Mapping Editor, see “Configure Default Code Generation for Data” on page 21-8.

### Apply Storage Classes to Data Items

This example shows how to apply storage classes to a signal, a block state, and a block parameter in a model.

#### Explore Example Model

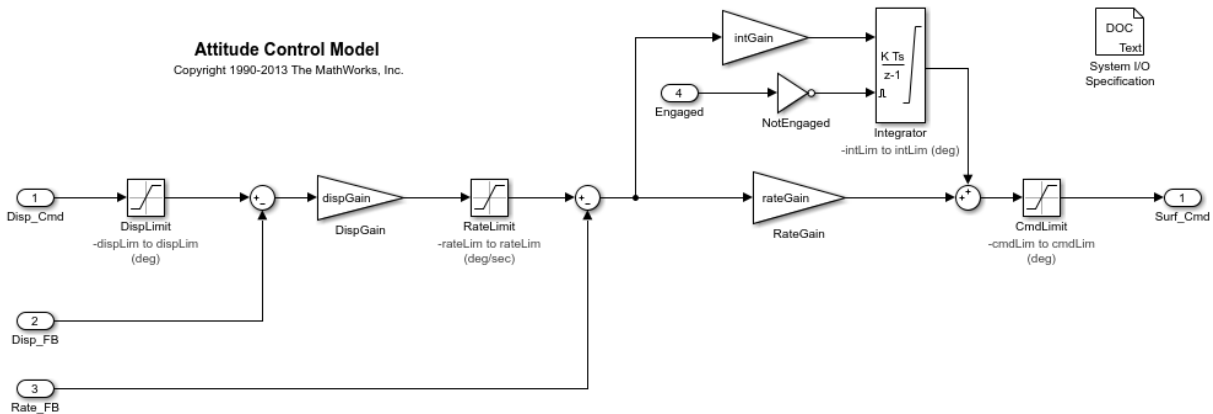

Open the example model `rtwdemo_roll`.

```
open_system('rtwdemo_roll')
```

Navigate into the BasicRollMode subsystem.

```
open_system('rtwdemo_roll/BasicRollMode')
```

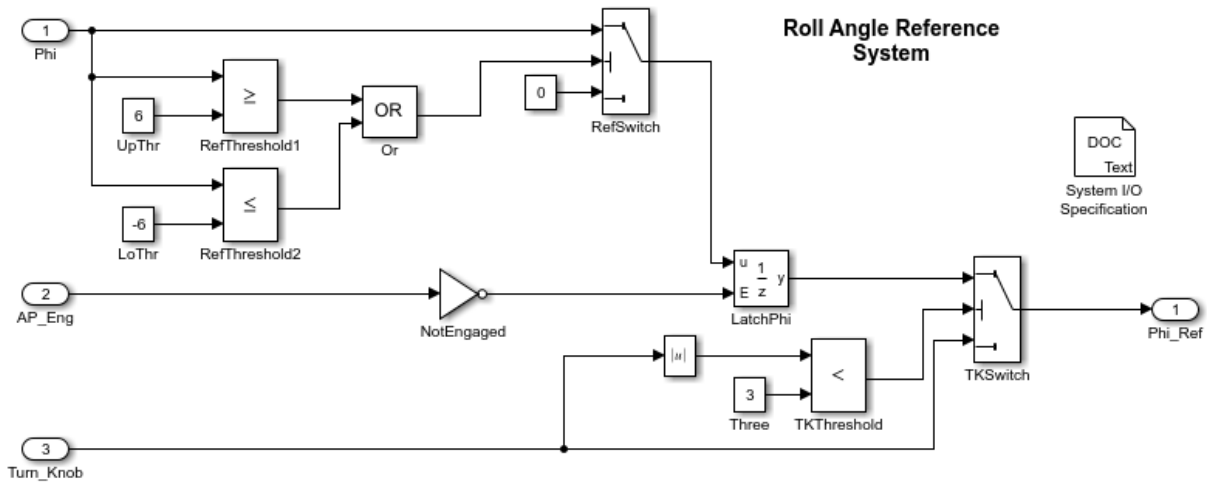

The subsystem contains an Integrator block, which maintains a piece of state data.

From the root level of the model, navigate into the RollAngleReference subsystem.

```
open_system('rtwdemo_roll/RollAngleReference')
```

The subsystem contains a Constant block labeled UpThr.

In this example, you configure the state and output signal of the Integrator block and the **Constant value** parameter of the Constant block to appear in the generated code as separate global variables.

### Apply Storage Classes

Navigate to the root level of the model.

Select **View > Model Data Editor**.

To see the data items in the subsystems, activate the **Change scope** button.

Select the **Signals** tab.

Set the **Change view** drop-down list to Code.

In the **Filter contents** box, enter `integrator`.

Optionally, use the **Name** column to specify a name for the output signal of the Integrator block, such as `mySignal`.

Use the **Storage Class** column to apply the storage class `ExportedGlobal`.

Select the **States** tab.

Optionally, use the **Name** column to specify a name for the state, such as `myState`.

Use the **Storage Class** column to apply the storage class `ExportedGlobal`.

Select the **Parameters** tab. You cannot apply a storage class directly to a block parameter. Instead, you must create a parameter object, such as `Simulink.Parameter`, use the object to set the value of the block parameter, and apply the storage class to the object.

Set the **Change view** drop-down list to **Design**.

In the **Filter contents** box, enter `UpThr`.

Use the **Value** column to change the parameter value from 6 to `UpThr`.

While editing the parameter value, next to `UpThr`, click the action button (with three vertical dots) and select **Create**.

In the **Create New Data** dialog box, set **Value** to `Simulink.Parameter` and click **OK**. A `Simulink.Parameter` object named `UpThr` appears in the base workspace.

In the `UpThr` property dialog box, set **Value** to 6 and **Storage class** to `ExportedGlobal`. Click **OK**.

Alternatively, you can use these commands at the command prompt to configure the signal, state, and parameter data.

```
% Configure signal
portHandles = get_param('rtwdemo_roll/BasicRollMode/Integrator',...
 'PortHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle, 'Name', 'mySignal')
set_param(outportHandle, 'StorageClass', 'ExportedGlobal')

% Configure state
set_param('rtwdemo_roll/BasicRollMode/Integrator',...
 'StateName', 'myState')
set_param('rtwdemo_roll/BasicRollMode/Integrator',...
 'StateStorageClass', 'ExportedGlobal')

% Configure parameter
set_param('rtwdemo_roll/RollAngleReference/UpThr', 'Value', 'UpThr')
```

```
UpThr = Simulink.Parameter(6);
UpThr.StorageClass = 'ExportedGlobal';
```

## Generate and Inspect Code

Generate code from the model.

```
set_param('rtwdemo_roll', 'SystemTargetFile', 'grt.tlc')
rtwbuild('rtwdemo_roll')

Starting build procedure for model: rtwdemo_roll
Successful completion of build procedure for model: rtwdemo_roll
```

Inspect the file `rtwdemo_roll.c`. The file defines the global variables.

```
file = fullfile('rtwdemo_roll_grt_rtw', 'rtwdemo_roll.c');
rtwdemodbtype(file, '/* Exported block signals */', 'real32_T myState;', 1, 1)
```

```
/* Exported block signals */
real32_T mySignal; /* '<S1>/Integrator' */

/* Exported block parameters */
real32_T UpThr = 6.0F; /* Variable: UpThr
* Referenced by: '<S3>/UpThr'
*/

/* Exported block states */
real32_T myState; /* '<S1>/Integrator' */
```

The file `rtwdemo_roll.h` declares the variables. To access these variables, your external code can include (`#include`) this header file.

In `rtwdemo_roll.c`, search the file for the names of the variables, such as `UpThr`. The model algorithm in the `rtwdemo_roll_step` function reads and writes to the variables.

## Built-In Storage Classes You Can Choose

The default storage class setting for a data item is `Auto`, which means the code generator determines how the item appears in the code. For a list of built-in storage classes that you can choose, see “Choose a Storage Class for Controlling Data Representation in the Generated Code” (Simulink Coder).

## Decide Where to Store Storage Class Specification

For each individual signal or state data item (including Data Store Memory blocks) to which you directly apply a storage class, Simulink stores your storage class specification either in the model file or in the properties of a signal data object (`Simulink.Signal`), which you create in the base workspace, a model workspace, or a data dictionary. To apply a storage class to a block parameter, you must create a parameter data object (such as `Simulink.Parameter`) and specify the storage class in the object.

- When you apply a storage class to a signal or state in a model, for example, by using the Model Data Editor or the Property Inspector, you store the storage class specification in the model file.

If you use this technique, you cannot control other characteristics of the data item, such as data type, by using an external signal data object.

- When you create a signal or parameter data object, you apply the storage class by using the `CoderInfo` property of the object. The value of the property is a `Simulink.CoderInfo` object, whose `StorageClass` property you use to specify the storage class. After you associate the data item in the model with the object, the data item acquires the storage class from the object.

For signals, states, and Data Store Memory blocks, to decide whether to store the storage class specification in the model or in a data object, see “Store Design Attributes of Signals and States” (Simulink).

### Apply Storage Classes to Output Blocks by Using the Model Data Editor

You can use the Model Data Editor to apply a storage class directly to a root-level Output block or to the input signal that drives the block.

- To store the storage class specification in the Output block, use the **Inports/Outputs** tab in the Model Data Editor. When you use this technique, the specification remains after you delete the input signal that drives the block. Use this technique to configure the model interface before you develop the internal algorithm.
- To store the specification in the input signal that drives the block, use the **Signals** tab in the Model Data Editor.

## Techniques to Apply Storage Classes Interactively

To apply storage classes to multiple data items in a list that you can search, sort, and filter, use the Model Data Editor (**View > Model Data Editor**) as shown in “Apply Storage Classes to Data Items” on page 22-81.

To apply a storage class while focusing on a single signal, block state, or parameter, use the Property Inspector (**View > Property Inspector**), the Signal Properties dialog box (for a signal), or the block dialog box (for a state or parameter). Under **Code Generation**, apply the storage class.

- For a parameter, first set the value of the parameter to the name that you want to use for the required parameter object. Then, create and configure the parameter object as shown in “Create Tunable Calibration Parameter in the Generated Code” on page 22-121.
- For a signal, state, or Data Store Memory block, first give the signal or state a name, which the code generator uses as the name of the corresponding global symbol. Then, either specify a storage class using **Storage class** (in which case the model file stores the specification) or create a signal data object as shown in “Use Data Objects in Simulink Models” (Simulink) and apply a storage class to the object.

## Techniques to Apply Storage Classes Programmatically

- For a block parameter, use `set_param` to set the value of the parameter. Use other commands to create and configure the properties of the required parameter object. For an example, see “Create Tunable Calibration Parameter in the Generated Code” on page 22-121.
- For a signal, use `get_param` or `find_system` to return a handle to the block port that generates the signal. Use the parameters of the handle to name the signal, then apply the storage class directly (see “Apply Storage Class Directly to Signal Line” (Simulink Coder)) or configure the signal to acquire settings, including the storage class, from a signal object (see “Use Data Objects in Simulink Models” (Simulink)).
- For an Inport block, configure the signal line that exits the block. For an Output block, configure the block or the signal line that enters the block. For an example, see “Design Data Interface by Configuring Inport and Output Blocks” on page 22-206.
- For a block state, use `set_param` to interact with the block. Name the state, then apply the storage class directly (see “Apply Storage Class Directly to Block State” (Simulink Coder)) or configure the state to acquire the storage class from a signal object (see “Use Data Objects in Simulink Models” (Simulink)).

- For a Data Store Memory block, use `set_param` to interact with the block. Because the data store already has a name, you do not need to specify a name. Apply the storage class directly by using the `StateStorageClass` parameter or configure the data store to acquire the storage class from a signal object.

To interact with a signal or parameter data object that you store in a model workspace or data dictionary, use the programmatic interface of the workspace or dictionary. See “Interact With Variables Programmatically” (Simulink).

### Apply Storage Class Directly to Signal Line

This example shows how to programmatically apply a storage class directly to a signal line.

- 1 Open the example model `rtwdemo_secondOrderSystem`.

```
rtwdemo_secondOrderSystem
```

- 2 Get a handle to the output of the block named Force: `f(t)`.

```
portHandles = ...
 get_param('rtwdemo_secondOrderSystem/Force: f(t)', 'PortHandles');
outportHandle = portHandles.Output;
```

- 3 Set the name of the corresponding signal to `ForceSignal`.

```
set_param(outportHandle, 'Name', 'ForceSignal')
```

- 4 Set the storage class of the signal to `ExportedGlobal`.

```
set_param(outportHandle, 'StorageClass', 'ExportedGlobal')
```

- 5 Generate code from the model. The code declares and defines a global variable `ForceSignal` to represent the signal.

### Apply Storage Class Directly to Block State

This example shows how to programmatically apply a storage class to a block state.

- 1 Open the example model `rtwdemo_basicsc`.

```
rtwdemo_basicsc
```

- 2 Name the state of the Delay block as `myState`.

```
set_param('rtwdemo_basicsc/Delay', 'StateName', 'myState')
```

- 3 Set the storage class of the state to ExportedGlobal.

```
set_param('rtwdemo_basicsc/Delay',...
 'StateStorageClass','ExportedGlobal')
```

- 4 Generate code from the model. The code declares and defines a global variable myState to represent the state.

## Parameter Object Configuration Quick Reference Diagram

This diagram shows the code generation and storage class options that control the representation of parameter objects in the generated code.

### Enumerated Data Types

*Enumerated data* is data that is restricted to a finite set of values. An *enumerated data type* is a MATLAB class that defines a set of *enumerated values*. Each enumerated value consists of an *enumerated name* and an *underlying integer* which the software uses internally and in generated code. The following is a MATLAB class definition for an enumerated data type named `BasicColors`, which is used in the examples in this section.

```
classdef BasicColors < Simulink.IntEnumType
 enumeration
 Red(0)
 Yellow(1)
 Blue(2)
 end
end
```

For basic information about enumerated data types and their use in Simulink models, see “Use Enumerated Data in Simulink Models” (Simulink). For information about enumerated data types in Stateflow charts, see “Define Enumerated Data Types” (Stateflow).

### Specify Integer Data Type for Enumeration

When you specify a data type for your enumeration, you can:

- Control the size of enumerated data types in the generated code by specifying a superclass.

- Reduce RAM/ROM usage.
- Improve code portability.
- Improve integration with legacy code.

You can specify any of these integer data types:

- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `Simulink.IntEnumType`. Specify values in the range of the signed integer for your hardware platform.

### Use a Class Definition in a MATLAB File

To specify an integer data type size, derive your enumeration class from the integer data type.

```
classdef Colors < int8
 enumeration
 Red(0)
 Green(1)
 Blue(2)
 end
end
```

The code generator generates this code:

```
typedef int8_T Colors;

#define Red ((Colors)0)
#define Green ((Colors)1)
#define Blue ((Colors)2)
```

### Use the Function `Simulink.defineIntEnumType`

To specify an integer data type size, specify the name-value pair `StorageType` as the integer data type.

```
Simulink.defineIntEnumType('Colors',{ 'Red', 'Green', 'Blue'},...
[0;1;2], 'StorageType', 'int8')
```

The code generator generates this code:

```
typedef int8_T Colors;

#define Red ((Colors)0)
#define Green ((Colors)1)
#define Blue ((Colors)2)
```

## Customize Enumerated Data Type

When you generate code from a model that uses enumerated data, you can implement these static methods to customize the behavior of the type during simulation and in generated code:

- `getDefaultValue` — Specifies the default value of the enumerated data type.
- `getDescription` — Specifies a description of the enumerated data type.
- `getHeaderFile` — Specifies a header file where the type is defined for generated code.
- `getDataScope` — Specifies whether generated code exports or imports the enumerated data type definition to or from a separate header file.
- `addClassNameToEnumNames` — Specifies whether the class name becomes a prefix in generated code.

The first of these methods, `getDefaultValue`, is relevant to both simulation and code generation, and is described in “Specify a Default Enumerated Value” (Simulink). The other methods are relevant only to code generation. To customize the behavior of an enumerated type, include a version of the method in the `methods(Static)` section of the enumeration class definition. If you do not want to customize the type, omit the `methods(Static)` section. The table summarizes the methods and the data to supply for each one.

| Static Method   | Purpose                                                                                                            | Default Value Without Implementing Method            | Custom Return Value                                                                                                                                                                                                                                                                                                                                           |
|-----------------|--------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| getDefaultValue | Specifies the default enumeration member for the class.                                                            | First member specified in the enumeration definition | A character vector containing the name of an enumeration member in the class (see "Instantiate Enumerations" (Simulink)).                                                                                                                                                                                                                                     |
| getDescription  | Specifies a description of the enumeration class.                                                                  | ' '                                                  | A character vector containing the description of the type.                                                                                                                                                                                                                                                                                                    |
| getHeaderFile   | Specifies the name of a header file. The method <code>getDataScope</code> determines the significance of the file. | ' '                                                  | A character vector containing the name of the header file that defines the enumerated type.<br><br>By default, the generated <code>#include</code> directive uses the preprocessor delimiter " instead of < and >. To generate the directive <code>#include &lt;myTypes.h&gt;</code> , specify the custom return value as ' <code>&lt;myTypes.h&gt;</code> '. |

| Static Method            | Purpose                                                                                                                                                                                                           | Default Value Without Implementing Method | Custom Return Value                        |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|--------------------------------------------|
| getDataScope             | Specifies whether generated code exports or imports the definition of the enumerated data type. Use the method <code>getHeaderFile</code> to specify the generated or included header file that defines the type. | 'Auto'                                    | One of: 'Auto', 'Exported', or 'Imported'. |
| addClassNameToEnum Names | Specifies whether to prefix the class name in generated code.                                                                                                                                                     | false                                     | true or false.                             |

### Specify a Description

To specify a description for an enumerated data type, include this method in the `methods(Static)` section of the enumeration class:

```
function retVal = getDescription()
% GETDESCRIPTION Optional description of the data type.
 retVal = 'description';
end
```

Substitute a MATLAB character vector for *description*. The generated code that defines the enumerated type includes the specified description.

### Import Type Definition in Generated Code

To prevent generated code from defining an enumerated data type, which allows you to provide the definition in an external file, include these methods in the `methods(Static)` section of the enumeration class:

```
function retVal = getHeaderFile()
% GETHEADERFILE Specifies the file that defines this type in generated code.
% The method getDataScope determines the significance of the specified file.
 retVal = 'imported_enum_type.h';
end
```

```

function retVal = getDataScope()
% GETDATASCOPE Specifies whether generated code imports or exports this type.
% Return one of:
% 'Auto': define type in model_types.h, or import if header file specified
% 'Exported': define type in a generated header file
% 'Imported': import type definition from specified header file
% If you do not define this method, DataScope is 'Auto' by default.
retVal = 'Imported';
end

```

Instead of defining the type in `model_types.h`, which is the default behavior, generated code imports the definition from the specified header file using a `#include` statement like:

```
#include "imported_enum_type.h"
```

Generating code does not create the imported header file. You must provide the header file, using the file name specified by the method `getHeaderFile`, that defines the enumerated data type.

To create a Simulink enumeration that corresponds to your existing C-code enumeration, use the `Simulink.importExternalCTypes` function.

### Export Type Definition in Generated Code

To generate a separate header file that defines an enumerated data type, include these methods in the `methods(Static)` section of the enumeration class:

```

function retVal = getDataScope()
% GETDATASCOPE Specifies whether generated code imports or exports this type.
% Return one of:
% 'Auto': define type in model_types.h, or import if header file specified
% 'Exported': define type in a generated header file
% 'Imported': import type definition from specified header file
% If you do not define this method, DataScope is 'Auto' by default.
retVal = 'Exported';
end

function retVal = getHeaderFile()
% GETHEADERFILE Specifies the file that defines this type in generated code.
% The method getDataScope determines the significance of the specified file.
retVal = 'exported_enum_type.h';
end

```

Generated code exports the enumerated type definition to the generated header file `exported_enum_type.h`.

## Add Prefixes To Class Names

By default, enumerated values in generated code have the same names that they have in the enumeration class definition. Alternatively, your code can prefix every enumerated value in an enumeration class with the name of the class. You can use this technique to prevent identifier conflicts or to improve the readability of the code. To specify class name prefixing, include this method in the `methods(Static)` section of an enumeration class:

```
function retVal = addClassNameToEnumNames()
 % ADDCLASSNAMETOENUMNAMES Specifies whether to add the class name
 % as a prefix to enumeration member names in generated code.
 % Return true or false.
 % If you do not define this method, no prefix is added.
 retVal = true;
end
```

Specify the return value as `true` to enable class name prefixing or as `false` to suppress prefixing. If you specify `true`, each enumerated value in the class appears in generated code as `EnumTypeName_EnumName`. For the example enumeration class `BasicColors` in “Enumerated Data Types” on page 22-90, the data type definition in generated code might look like this:

```
#ifndef _DEFINED_TYPEDEF_FOR_BasicColors_
#define _DEFINED_TYPEDEF_FOR_BasicColors_

typedef enum {
 BasicColors_Red = 0, /* Default value */
 BasicColors_Yellow = 1,
 BasicColors_Blue = 2,
} BasicColors;

#endif
```

The enumeration class name `BasicColors` appears as a prefix for each of the enumerated names.

## Control Enumerated Type Implementation in Generated Code

Suppose that you define an enumerated type `BasicColors`. You can specify that the generated code implement the type definition using:

- An `enum` block. The native integer type of your hardware is the underlying integer type for the enumeration members.
- A `typedef` statement and a series of `#define` macros. The `typedef` statement bases the enumerated type name on a specific integer data type, such as `int8`. The macros associate the enumeration members with the underlying integer values.

## Implement Enumerated Type Using enum Block

To implement the type definition using an enum block:

- In Simulink, define the enumerated type using a `classdef` block in a script file. Derive the enumeration from the type `Simulink.IntEnumType`.
- Alternatively, use the function `Simulink.defineIntEnumType`. Do not specify the property `StorageType`.

When you generate code, the type definition appears in an enum block.

```
#ifndef _DEFINED_TYPEDEF_FOR_BasicColors_
#define _DEFINED_TYPEDEF_FOR_BasicColors_

typedef enum {
 Red = 0, /* Default value */
 Yellow,
 Blue,
} BasicColors;

#endif
```

## Implement Enumerated Type Using a Specific Integer Type

To implement the type definition using a typedef statement and #define macros:

- In Simulink, define the enumerated type using a `classdef` block in a script file. Derive the enumeration from a specific integer type such as `int8`.
- Alternatively, use the function `Simulink.defineIntEnumType`. Specify the property `StorageType` using a specific integer type such as `int8`.

When you generate code, the type definition appears as a typedef statement and a series of #define macros.

```
#ifndef _DEFINED_TYPEDEF_FOR_BasicColors_
#define _DEFINED_TYPEDEF_FOR_BasicColors_

typedef int8_T BasicColors;

#define Red ((BasicColors)0) /* Default value */
#define Yellow ((BasicColors)1)
#define Blue ((BasicColors)2)
```

```
#endif
```

By default, the generated file `model_types.h` contains enumerated type definitions.

## Type Casting for Enumerations

### Safe Casting

A Simulink Data Type Conversion block accepts a signal of integer type. The block converts the input to one of the underlying values of an enumerated type.

If the input value does not match any of the underlying values of the enumerated type values, Simulink inserts a safe cast to replace the input value with the enumerated type default value.

### Enable and Disable Safe Casting

You can enable or disable safe casting for enumerations during code generation for a Simulink Data Type Conversion block or a Stateflow block.

To control safe casting, enable or disable the **Saturate on integer overflow** block parameter. The parameter works as follows:

- **Enabled:** Simulink replaces a nonmatching input value with the default value of the enumerated values during simulation. The software generates a safe cast function during code generation.
- **Disabled:** For a nonmatching input value, Simulink generates an error during simulation. The software omits the safe cast function during code generation. In this case, the code is more efficient. However, the code may be more vulnerable to run-time errors.

### Safe Cast Function in Generated Code

This example shows how the safe cast function `int32_T ET08_safe_cast_to_BasicColors` for the enumeration `BasicColors` appears in generated code when generated for 32-bit hardware.

```
static int32_T ET08_safe_cast_to_BasicColors(int32_T input)
{
 int32_T output;
 /* Initialize output value to default value for BasicColors (Red) */
```

```
output = 0;
if ((input >= 0) && (input <= 2)) {
/* Set output value to input value if it is a member of BasicColors */
 output = input;
}
return output;
}
```

Through this function, the enumerated type's default value is used if the input value does not match one of underlying values of the enumerated type's values.

If the block's **Saturate on integer overflow** parameter is disabled, this function does not appear in generated code.

## Enumerated Type Limitations

- Generated code does not support logging enumerated data.

## Data Stores in Generated Code

### In this section...

“About Data Stores” on page 22-100

“Generate Code for Data Store Memory Blocks” on page 22-100

“Storage Classes for Data Store Memory Blocks” on page 22-101

“Data Store Buffering in Generated Code” on page 22-103

“Data Stores Shared by Instances of a Reusable Model” on page 22-106

“Structures in Generated Code Using Data Stores” on page 22-107

### About Data Stores

A data store contains data that is accessible in a model hierarchy at or below the level in which the data store is defined. Data stores can allow subsystems and referenced models to share data without having to use I/O ports to pass the data from level to level. See “Data Stores with Data Store Memory Blocks” (Simulink) for information about data stores in Simulink. This section provides additional information about data store code generation.

### Generate Code for Data Store Memory Blocks

To control the code generated for a Data Store Memory block, apply a storage class to the data store. You can associate a Data Store Memory block with a signal object that you store in a workspace or data dictionary, and control code generation for the block by applying the storage class to the object:

- 1 In the model, select **View > Model Data Editor**.
- 2 In the Model Data Editor, select the **Data Stores** tab.
- 3 Begin editing the name of the target Data Store Memory block by clicking the corresponding row in the **Name** column.
- 4 Next to the name, click the button  and select **Create and Resolve**.
- 5 In the Create New Data dialog box, set **Value** to `Simulink.Signal`. Optionally, use the **Location** drop-down list to choose a workspace for storing the resulting `Simulink.Signal` object.

- 6 Click **Create**. The `Simulink.Signal` object, which has the same name as the data store, appears in the target workspace. Simulink selects the block parameter **Data store name must resolve to Simulink signal object**.

The property dialog box for the object opens.

- 7 Use the **Storage class** drop-down list to apply the target storage class.

---

**Note** When a Data Store Memory block is associated with a signal object, the mapping between the **Data store name** and the signal object name must be one-to-one. If two or more identically named entities map to the same signal object, the name conflict is flagged as an error at code generation time. See “Resolve Conflicts in Configuration of Signal Objects for Code Generation” (Simulink) for more information.

---

## Storage Classes for Data Store Memory Blocks

You can control how Data Store Memory blocks in your model are stored and represented in the generated code by assigning storage classes and type qualifiers. You do this in almost exactly the same way you assign storage classes and type qualifiers for block states.

Data Store Memory blocks, like block states, have `Auto` storage class by default, and their memory is stored within the `DWork` vector. The symbolic name of the storage location is based on the data store name.

You can generate code from multiple Data Store Memory blocks that have the same data store name, subject to the following restriction: *at most one* of the identically named blocks can have a storage class other than `Auto`. An error is reported if this condition is not met.

For blocks with `Auto` storage class, the code generator produces a unique symbolic name for each block to avoid name clashes. For Data Store Memory blocks with storage classes other than `Auto`, the generated code uses the data store name as the symbol.

In the following model, a Data Store Write block writes to memory declared by the Data Store Memory block `myData`:

To control the storage declaration for a Data Store Memory block, use the **Code Generation > Signal object class** and **Code Generation > Storage class** drop-down lists of the Data Store Memory block dialog box. Set **Signal object class** to **Simulink.Signal** (the default), and choose a storage class from the **Storage class** drop-down list. The next figure shows the Data Store Memory block dialog box for the preceding model.

To apply storage classes to data stores, you can alternatively use the **Data Stores** tab in the Model Data Editor (in the model, **View > Model Data Editor**).

Data Store Memory blocks are nonvirtual because code is generated for their initialization in .c and .cpp files and their declarations in header files. The following table shows how the code generated for the Data Store Memory block in the preceding model differs for different storage classes. The table gives the variable declarations and MdlOutputs code generated for the myData block.

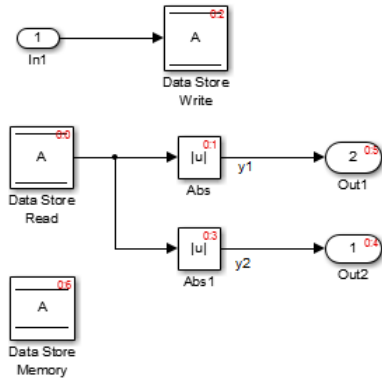

| Storage Class                                                                             | Declaration                                                                                                                                                                                                   | Code                                          |

| ImportedExternPointer                                                                     | In <i>model_private.h</i><br><br><pre>extern real_T *myData;</pre>                                                                                                                                            | (*myData) = rtb_SineWave;                     |

For information about applying storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81.

## Data Store Buffering in Generated Code

A Data Store Read block is a nonvirtual block that copies the value of the data store to its output buffer when it executes. Since the value is buffered, downstream blocks connected to the output of the data store read utilize the same value, even if a Data Store Write block updates the data store in between execution of two of the downstream blocks.

The next figure shows a model that uses blocks whose priorities have been modified to achieve a particular order of execution:

```

/* local block i/o variables */
real_T rtb_DataStoreRead;

/* DataStoreRead: '<Root>/Data Store Read' */
rtb_DataStoreRead = A; Buffer the value of A

/* Abs: '<Root>/Abs1' incorporates:
 * DataStoreRead: '<Root>/Data Store Read'
 */
y1 = fabs(A); Use A (whose value equals
the buffered value at this point

/* DataStoreWrite: '<Root>/Data Store Write' incorporates:
 * Inport: '<Root>/In1'
 */
A = u1; Update the value of A

/* Abs: '<Root>/Abs' */
y2 = fabs(rtb_DataStoreRead); Consistently use the same buffered
value as before the update to A

```

The following execution order applies:

- 1 The block Data Store Read buffers the current value of the data store A at its output.
- 2 The block Abs1 uses the buffered output of Data Store Read.
- 3 The block Data Store Write updates the data store.
- 4 The block Abs uses the buffered output of Data Store Read.

Because the output of Data Store Read is a buffer, both Abs and Abs1 use the same value: the value of the data store at the time that Data Store Read executes.

The next figure shows another example:

```

real_T rtb_DataStoreRead;

/* DataStoreWrite: '<Root>/Data Store Write' incorporates:
 * Constant: '<Root>/Constant'
 */
A = DoBufferDSMRead2_P.Constant_Value;

/* DataStoreRead: '<Root>/Data Store Read' */
rtb_DataStoreRead = A; Buffer the value of A

/* Outputs for atomic SubSystem: '<Root>/Atomic Subsystem' */
DoBufferDSMRead_AtomicSubsystem(); We don't do a global analysis to
detect if this function writes to A

/* end of Outputs for SubSystem: '<Root>/Atomic Subsystem' */

/* Outport: '<Root>/Out1' incorporates:
 * Sum: '<Root>/Sum'
 */
Use the buffered value of A
DoBufferDSMRead2_Y.Out1 = rtb_DataStoreRead + DoBufferDSMRead2_B.Abs;

```

In this example, the following execution order applies:

- 1 The block Data Store Read buffers the current value of the data store A at its output.
- 2 Atomic Subsystem executes.
- 3 The Sum block adds the output of Atomic Subsystem to the output of Data Store Read.

Simulink assumes that Atomic Subsystem might update the data store, so Simulink buffers the data store. Atomic Subsystem executes after Data Store Read buffers its output, and the buffer provides a way for the Sum block to use the value of the data store as it was when Data Store Read executed.

In some cases, the code generator determines that it can optimize away the output buffer for a Data Store Read block, and the generated code refers to the data store directly, rather than a buffered value of it. The next figure shows an example:

```

/* Model step function */
void DONTbufferDSMRead_step(void)
{
 /* DataStoreWrite: '<Root>/Data Store Write' incorporates:
 * Inport: '<Root>/In1'
 */
 A = u1;

 /* Abs: '<Root>/Abs' incorporates:
 * DataStoreRead: '<Root>/Data Store Read'
 */
 y2 = fabs(A);
}

```

In the generated code, the argument of the `fabs()` function is the data store `A` rather than a buffered value.

## Data Stores Shared by Instances of a Reusable Model

You can use a data store to share a piece of data between the instances of a reusable referenced model (see “Specify Reusability of Referenced Models” (Simulink)) or a model that you configure to generate reentrant code (by setting the configuration parameter

**Code interface packaging** to Reusable function). If you implement the data store as a Data Store Memory block and select the **Share across model instances** parameter:

- By default, the data store appears in the generated code as a separate global symbol.
- If you have Embedded Coder, to restrict access such that only the code generated from the model can use the data store, configure the data store to appear as `static` by applying the custom storage class `FileScope`. For more information about `FileScope` and other custom storage classes, see “Choose a Storage Class for Controlling Data Representation in the Generated Code” on page 22-69.

## Structures in Generated Code Using Data Stores

If you use more than one data store to provide global access to multiple signals in generated code, you can combine the signals into a single structure variable by using one data store. This combination of signal data can help you integrate the code generated from a model with other existing code that requires the data in a structure format.

This example shows how to store several model signals in a structure in generated code using a single data store. To store multiple signals in a data store, you configure the data store to accept a composite signal, such as a nonvirtual bus signal or an array of nonvirtual bus signals.

### Explore Example Model

- 1 Open the example model `ex_bus_struct_in_code`.

The model contains three subsystems that perform calculations on the inputs from the top level of the model. In each subsystem, a Data Store Memory block stores an intermediate calculated signal.

- 2 Generate code with the model. In the code generation report, view the file `ex_bus_struct_in_code.c`. The code defines a global variable for each data store.

```
real_T BioBTURate;
real_T CoalBTURate;
real_T GasBTURate;
```

Suppose that you want to integrate code generated from the example model with other existing code. Suppose also that the existing code requires access to all of the data from the three data stores in a single structure variable. You can use a data store to assemble all of the target data in a structure in generated code.

## Configure Data Store

Configure a data store to contain multiple signals by creating a bus type to use as the data type of the data store. Define the bus type using the same hierarchy of elements as the structure that you want to appear in generated code.

- 1 Open the Bus Editor tool.

buseditor

- 2 Define a new bus type `Raw_BTU_Rate` with one element for each of the three target signals. Name the elements `BioBTU`, `GasBTU`, and `CoalBTU`.

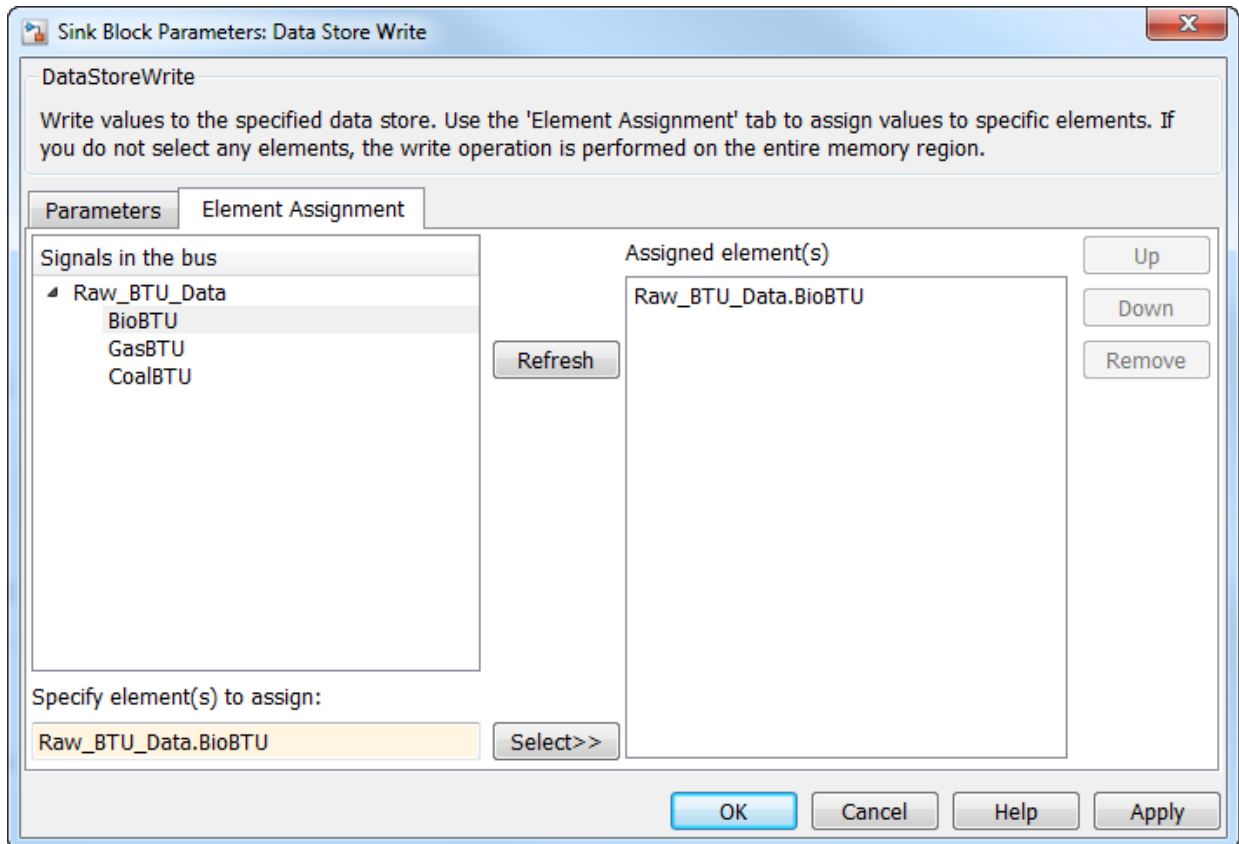

- 3 At the top level of the example model, add a Data Store Memory block.
- 4 In the Simulink Editor, select **View > Model Data Editor**.
- 5 In the Model Data Editor, inspect the **Data Stores** tab.
- 6 For the new Data Store Memory block, use the **Name** column to set the data store name to `Raw_BTU_Data`.
- 7 Use the **Data Type** column to set the data type of the data store to **Bus : Raw\_BTU\_Rate**.
- 8 Set the **Change view** drop-down list to **Code**.
- 9 Use the **Storage Class** column to apply the storage class `ExportedGlobal`.

## Write to Data Store Elements

To write to a specific element of a data store, use a Data Store Write block. On the **Element Assignment** tab in the dialog box, you can specify to write to a single element, a collection of elements, or the entire contents of a data store.

- 1 Open the **Biomass Calc** subsystem.
- 2 Delete the Data Store Memory block `BioBTURate`.
- 3 In the block dialog box for the Data Store Write block, set **Data store name** to `Raw_BTU_Data`.

- 4 On the **Element Assignment** tab, under **Signals in the bus**, expand the contents of the data store `Raw_BTU_Data`. Click the element `BioBTU`, and then click **Select**. Click **OK**.

- 5 Modify the **Gas Calc** and **Coal Calc** subsystems similarly.
  - Delete the Data Store Memory block in each subsystem.
  - In each Data Store Write block dialog box, set **Data store name** to `Raw_BTU_Data`.
  - In the **Gas Calc** subsystem, use the Data Store Write block to write to the data store element `GasBTU`. In the **Coal Calc** subsystem, write to the element `CoalBTU`.

### **Generate Code with Data Store Structure**

- 1 Generate code for the example model.
- 2 In the code generation report, view the file `ex_bus_struct_in_code_types.h`. The code defines a structure that corresponds to the bus type `Raw_BTU_Rate`.

```
typedef struct {
 real_T BioBTU;
 real_T GasBTU;
 real_T CoalBTU;
} Raw_BTU_Rate;
```

- 3 View the file `ex_bus_struct_in_code.c`. The code represents the data store with a global variable `Raw_BTU_Data` of the structure type `Raw_BTU_Rate`. In the model step function, the code assigns the data from the calculated signals to the fields of the global variable `Raw_BTU_Data`.

## Specify Single-Precision Data Type for Embedded Application

When you want code that uses only single precision, such as when you are targeting a single-precision processor, you can use model configuration parameters and block parameters to prevent the introduction of `double` in the model.

To design and validate a single-precision model, see “Validate a Floating-Point Embedded Model” (Simulink). If you have Fixed-Point Designer, you can use the Single Precision Converter app (see “Single-Precision Design for Simulink” (Fixed-Point Designer)).

### Use single Data Type as Default for Underspecified Types

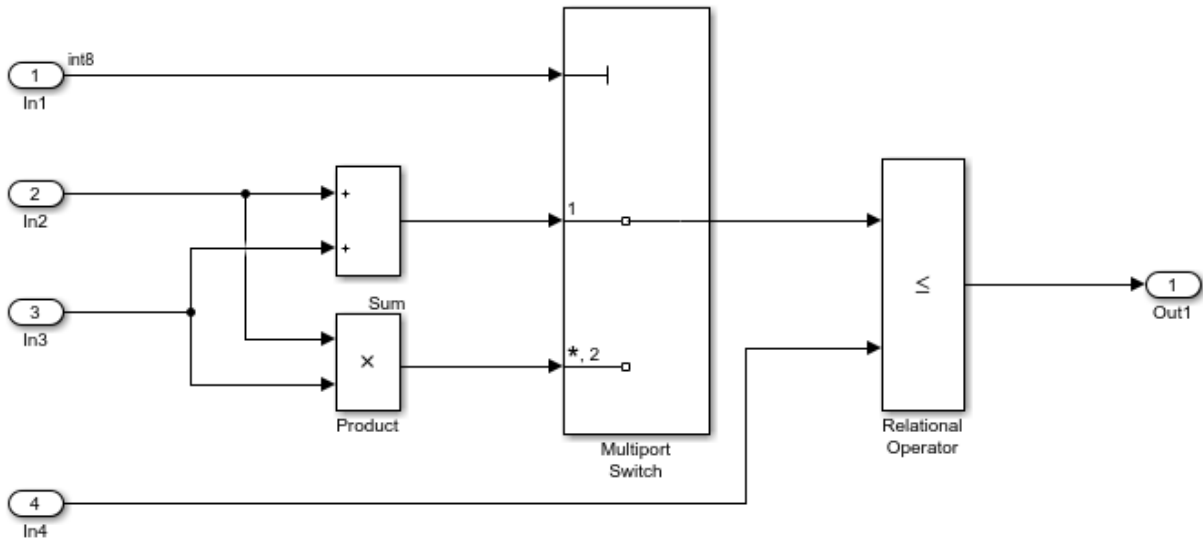

This example shows how to avoid introducing a double-precision data type in code generated for a single-precision hardware target.

If you specify an inherited data type for signals, but data type propagation rules cannot determine data types for the signals, the signal data types default to `double`. You can use a model configuration parameter to specify the default data type as `single`.

#### Explore Example Model

Open the example model `rtwdemo_underspecified_datatype` and configure it to show the generated names of blocks.

```
model = 'rtwdemo_underspecified_datatype';
load_system(model)
set_param(model, 'HideAutomaticNames', 'off')
open_system(model);
```

Copyright 2014 The MathWorks, Inc.

The root inports In2, In3, and In4 specify `Inherit: Auto` for the **Data type** block parameter. The downstream blocks also use inherited data types.

### Generate Code with `double` as Default Data Type

The model starts with the configuration parameter **System target file** set to `ert.tlc`, which requires Embedded Coder. Set **System target file** to `grt.tlc` instead.

```
set_param(model, 'SystemTargetFile', 'grt.tlc')
```

Generate code from the model.

```
rtwbuild(model)
```

```
Starting build procedure for model: rtwdemo_underspecified_datatype
Successful completion of build procedure for model: rtwdemo_underspecified_datatype
```

In the code generation report, view the file `rtwdemo_underspecified_datatype.h`. The code uses the double data type to define the variables In2, In3, and In4 because the Inport data types are underspecified in the model.

```
cfile = fullfile('rtwdemo_underspecified_datatype_grt_rtw',...
 'rtwdemo_underspecified_datatype.h');
rtwdemodbtype(cfile,...
 /* External inputs (root inport signals with default storage) */',...
 /* External outputs (root outports fed by signals with default storage) */',...
 1, 0);

/* External inputs (root inport signals with default storage) */
typedef struct {
 int8_T In1; /* '<Root>/In1' */
 real_T In2; /* '<Root>/In2' */
 real_T In3; /* '<Root>/In3' */
 real_T In4; /* '<Root>/In4' */
} ExtU_rtwdemo_underspecified_d_T;
```

### Generate Code with single as Default Data Type

Open the Configuration Parameters dialog box. On the **Math and Data Types** pane, select `single` in the **Default for underspecified data type** drop-down list.

Alternatively, enable the optimization at the command prompt.

```
set_param(model, 'DefaultUnderspecifiedDataType', 'single');
```

Generate code from the model.

```
rtwbuild(model)

Starting build procedure for model: rtwdemo_underspecified_datatype
Successful completion of build procedure for model: rtwdemo_underspecified_datatype
```

In the code generation report, view the file `rtwdemo_underspecified_datatype.h`. The code uses the single data type to define the variables In2, In3, and In4.

```
rtwdemodbtype(cfile,...
 /* External inputs (root inport signals with default storage) */',...
 /* External outputs (root outports fed by signals with default storage) */',...
 1, 0);

/* External inputs (root inport signals with default storage) */
```

```
typedef struct {
 int8_T In1; /* '<Root>/In1' */
 real32_T In2; /* '<Root>/In2' */
 real32_T In3; /* '<Root>/In3' */
 real32_T In4; /* '<Root>/In4' */
} ExtU_rtwdemo_underspecified_d_T;
```

## Tune Phase Parameter of Sine Wave Block During Code Execution

Under certain conditions, you cannot configure the **Phase** parameter of a Sine Wave block to appear in the generated code as a tunable global variable (for more information, see the block reference page). This example shows how to generate code so that you can tune the phase during execution.

Create the model `ex_phase_tunable` by using a Digital Clock block.

```
open_system('ex_phase_tunable')
```

Set **Default parameter behavior** to `Tunable` so that the parameters of the Sine Wave block appear in the generated code as tunable fields of the global parameter structure.

```
set_param('ex_phase_tunable', 'DefaultParameterBehavior', 'Tunable')
```

Generate code from the model.

```
rtwbuild('ex_phase_tunable')
```

```
Starting build procedure for model: ex_phase_tunable
Successful completion of code generation for model: ex_phase_tunable
```

In the code generation report, view the file `ex_phase_tunable.c`. The code algorithm in the model `step` function calculates the Sine Wave block output. The parameters of the block, including **Phase**, appear in the code as tunable structure fields.

```
file = fullfile('ex_phase_tunable_grt_rtw', 'ex_phase_tunable.c');
rtwdemodbtype(file, '/* Outport: '<Root>/Out1' incorporates:', ...
 'ex_phase_tunable_P.SineWave_Bias;', 1, 1)

/* Outport: '<Root>/Out1' incorporates:
 * DigitalClock: '<Root>/Digital Clock'
 * Sin: '<Root>/Sine Wave'
 */
```

```
ex_phase_tunable_Y.Out1 = sin(ex_phase_tunable_P.SineWave_Freq *
 ((ex_phase_tunable_M->Timing.clockTick1+
 ex_phase_tunable_M->Timing.clockTickH1* 4294967296.0)) * 1.0) +
 ex_phase_tunable_P.SineWave_Phase) * ex_phase_tunable_P.SineWave_Amp +
 ex_phase_tunable_P.SineWave_Bias;
```

During code execution, you can assign new values to the structure field that corresponds to the **Phase** parameter.

## Switch Between Output Waveforms During Code Execution for Waveform Generator Block

This example shows how to generate code that enables you to switch between stimulus waveforms during code execution.

For a Waveform Generator block, you cannot make the parameters of a waveform, such as amplitude and phase shift, tunable in the generated code. Instead, you can generate code that enables you to choose an active waveform from a set of waveform variants that you specify in the block. During execution of the code, you activate a variant by adjusting the value of a global structure field.

You must set the model configuration parameter **Default parameter behavior** to **Tunable**. Then, by default, block parameters in the model appear tunable in the generated code. These parameters can consume large amounts of memory for a large model.

Create the model `ex_switch_waveform`.

```
open_system('ex_switch_waveform')
```

In the Waveform Generator block, configure this waveform:

```
square(amp,10,0,dutyCycle)
```

In the base workspace, create the variables `amp` and `dutyCycle`.

```
amp = 2.71;
dutyCycle = 50;
```

This waveform represents the baseline stimulus that you want the application to use at the start of execution.

Suppose that, during execution, you want to observe the effects of changing the waveform frequency from 10 to 15 and the phase shift from 0 to 0.5. In the Waveform Generator block, add these waveform variants:

```
square(amp,10,0.5,dutyCycle)
square(amp,15,0,dutyCycle)
square(amp,15,0.5,dutyCycle)
```

Set the model configuration parameter **Default parameter behavior** to Tunable.

```
set_param('ex_switch_waveform','DefaultParameterBehavior','Tunable')
```

Generate code from the model.

```
rtwbuild('ex_switch_waveform')
```

```
Starting build procedure for model: ex_switch_waveform
Successful completion of code generation for model: ex_switch_waveform
```

The generated file `ex_switch_waveform.h` defines the standard structure type that stores tunable parameter data for the model. The structure contains a field whose value represents the active waveform.

```
file = fullfile('ex_switch_waveform_grt_rtw','ex_switch_waveform.h');
rtwdemodbtype(file,'/* Parameters (default storage) */',...
 '/* Real-time Model Data Structure */',1,0)
```

```
/* Parameters (default storage) */
struct P_ex_switch_waveform_T_ {
 real_T WaveformGeneratorStimulus_Select; /* Mask Parameter: WaveformGeneratorStimulus_Select
 * Referenced by: '<S1>/Switch'
 */
 real_T GainControlSystem_Gain; /* Expression: 3.5
 * Referenced by: '<Root>/Gain (Control System)'
 */
};
```

The file `ex_switch_waveform_data.c` defines a global structure variable and initializes the field value to 1. This value represents the baseline waveform.

```
file = fullfile('ex_switch_waveform_grt_rtw','ex_switch_waveform_data.c');
rtwdemodbtype(file,'/* Block parameters (default storage) */',';',1,1)
```

```
/* Block parameters (default storage) */
```

```

P_ex_switch_waveform_T ex_switch_waveform_P = {
 /* Mask Parameter: WaveformGeneratorStimulus_Select
 * Referenced by: '<S1>/Switch'
 */
 1.0,

 /* Expression: 3.5
 * Referenced by: '<Root>/Gain (Control System)'
 */
 3.5
};

```

The file `ex_switch_waveform.c` defines the model execution function. The function uses a `switch` statement to determine the value of the active waveform, and then calculates the value of the root-level Outport block, `Out1`.

```

file = fullfile('ex_switch_waveform_grt_rtw', 'ex_switch_waveform.c');
rtwdemoddbtype(file, 'switch ((int32_T)', ...
 'ex_switch_waveform_Y.Out1 =', 1, 1)

switch ((int32_T)ex_switch_waveform_P.WaveformGeneratorStimulus_Select) {
case 1:
 temp = temp - floor(temp) <= 0.5 ? 2.71 : -2.71;
 break;

case 2:
 temp = (temp - 0.79577471545947676) - floor(temp - 0.79577471545947676) <=
 0.5 ? 2.71 : -2.71;
 break;

case 3:
 temp = temp_tmp_tmp - floor(temp_tmp_tmp) <= 0.5 ? 2.71 : -2.71;
 break;

default:
 temp = (temp_tmp_tmp - 1.1936620731892151) - floor(temp_tmp_tmp -
 1.1936620731892151) <= 0.5 ? 2.71 : -2.71;
 break;
}

/* End of MultiPortSwitch: '<S1>/MultiportSwitch' */

/* Outport: '<Root>/Out1' incorporates:
 * Gain: '<Root>/Gain (Control System)'

```

```
*/
ex_switch_waveform_Y.Out1 = ex_switch_waveform_P.GainControlSystem_Gain * temp;
```

During code execution, to change the active waveform, adjust the value of the structure field in the global parameters structure.

# Create Tunable Calibration Parameter in the Generated Code

A calibration parameter is a value stored in global memory that an algorithm reads for use in calculations but does not write to. Calibration parameters are tunable because you can change the stored value during algorithm execution. You create calibration parameters so that you can:

- Determine an optimal parameter value by tuning the parameter and monitoring signal values during execution.
- Efficiently adapt an algorithm to different execution conditions by overwriting the parameter value stored in memory. For example, you can use the same control algorithm for multiple vehicles of different masses by storing different parameter values in each vehicle's engine control unit.

In Simulink, create a `Simulink.Parameter` object to represent a calibration parameter. You use the parameter object to set block parameter values, such as the **Gain** parameter of a Gain block. To control the representation of the parameter object in the generated code, you apply a storage class to the object.

To make block parameters accessible in the generated code by default, for example for rapid prototyping, set **Default parameter behavior** (see “Default parameter behavior” (Simulink Coder)) to **Tunable**. For more information, see “Configure Data Accessibility for Rapid Prototyping” on page 22-3.

## Represent Block Parameter as Tunable Global Variable

This example shows how to create tunable parameter data by representing block parameters as global variables in the generated code.

### Configure Block Parameter by Using Parameter Object

Open the example model `rtwdemo_paraminline` and configure it to show the generated names of blocks.

```
load_system('rtwdemo_paraminline')
set_param('rtwdemo_paraminline','HideAutomaticNames','off')
open_system('rtwdemo_paraminline')
```

|                                                                  |                                                                  |                                                               |                                                          |
|------------------------------------------------------------------|------------------------------------------------------------------|---------------------------------------------------------------|----------------------------------------------------------|
| <b>Generate Code Using<br/>Simulink Coder<br/>(double-click)</b> | <b>Generate Code Using<br/>Embedded Coder<br/>(double-click)</b> | <b>View Optimization<br/>Configuration<br/>(double-click)</b> | <b>Display Sample<br/>Time Colors<br/>(double-click)</b> |
|------------------------------------------------------------------|------------------------------------------------------------------|---------------------------------------------------------------|----------------------------------------------------------|

Copyright 1994-2015 The MathWorks, Inc.

In the model, select **View > Model Data Editor**.

In the Model Data Editor, inspect the **Parameters** tab.

In the model, click the G1 Gain block. The Model Data Editor highlights the row that corresponds to the **Gain** parameter of the block.

In the Model Data Editor **Value** column, change the gain value from 2 to myGainParam.

Next to myGainParam, click the action button (with three vertical dots) and select **Create**.

In the Create New Data block dialog box, set **Value** to `Simulink.Parameter(2)`. Click **Create**. A `Simulink.Parameter` object myGainParam stores the parameter value, 2, in the base workspace.

In the myGainParam dialog box, set **Storage class** to `ExportedGlobal` and click **OK**. This storage class causes the parameter object to appear in the generated code as a tunable global variable.

Alternatively, to create the parameter object and configure the model, use these commands at the command prompt:

```
set_param('rtwdemo_paraminline/G1','Gain','myGainParam')
myGainParam = Simulink.Parameter(2);
myGainParam.CoderInfo.StorageClass = 'ExportedGlobal';
```

Use the Model Data Editor to create a parameter object, myOtherGain, for the G2 Gain block. Apply the storage class ExportedGlobal.

Alternatively, use these commands at the command prompt:

```
set_param('rtwdemo_paraminline/G2','Gain','myOtherGain')
myOtherGain = Simulink.Parameter(-2);
myOtherGain.CoderInfo.StorageClass = 'ExportedGlobal';
```

### Generate and Inspect Code

Generate code from the model.

```
rtwbuild('rtwdemo_paraminline')

Starting build procedure for model: rtwdemo_paraminline
Successful completion of build procedure for model: rtwdemo_paraminline
```

The generated file `rtwdemo_paraminline.h` contains extern declarations of the global variables `myGainParam` and `myOtherGain`. You can include (`#include`) this header file so that your code can read and write the value of the variable during execution.

```
file = fullfile('rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline.h');
rtwdemodbtype(file,...
 'extern real_T myGainParam;', 'Referenced by: ''<Root>/G2''',1,1)
```

```
extern real_T myGainParam; /* Variable: myGainParam
 * Referenced by: '<Root>/G1'
 */
extern real_T myOtherGain; /* Variable: myOtherGain
 * Referenced by: '<Root>/G2'
 */
```

The file `rtwdemo_paraminline.c` allocates memory for and initializes `myGainParam` and `myOtherGain`.

```
file = fullfile('rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline.c');
rtwdemodbtype(file,...
 '/* Exported block parameters */', 'Referenced by: ''<Root>/G2''',1,1)

/* Exported block parameters */
```

```

real_T myGainParam = 2.0; /* Variable: myGainParam
 * Referenced by: '<Root>/G1'
 */
real_T myOtherGain = -2.0; /* Variable: myOtherGain
 * Referenced by: '<Root>/G2'

```

The generated code algorithm in the model `step` function uses `myGainParam` and `myOtherGain` for calculations.

```

rtwdemodbtype(file,...
 /* Model step function */, /* Model initialize function */,1,0)

/* Model step function */
void rtwdemo_paraminline_step(void)
{
 /* Output: '<Root>/Out1' incorporates:
 * Gain: '<Root>/G1'
 * Gain: '<Root>/G2'
 * Inport: '<Root>/In1'
 * Sum: '<Root>/Sum'
 */
 rtwdemo_paraminline_Y.Out1 = myGainParam * rtwdemo_paraminline_U.In1 +
 myOtherGain * -75.0;
}

```

## Apply Storage Class When Block Parameter Refers to Numeric MATLAB Variable

If you use a numeric variable to set the value of a block parameter, you cannot apply a storage class to the variable. As a workaround, you can convert the variable to a parameter object, and then apply a storage class to the object. To convert the variable to a parameter object, choose one of these techniques:

- On the Model Data Editor **Parameters** tab, with **Change view** set to Code, find the row that corresponds to the variable. In the **Storage Class** column, from the drop-down list, select **Convert to parameter object**. The Model Data Editor converts the variable to a parameter object. Then, use the **Storage Class** column to apply a storage class to the object.

You can also use this technique in the Model Explorer.

- Use the Data Object Wizard (see “Create Data Objects for a Model Using Data Object Wizard” (Simulink)). In the Wizard, select the **Parameters** check box. The Wizard

converts variables to objects. Then, apply storage classes to the objects, for example, by using the Model Data Editor or the Model Explorer.

## Create Storage Class That Represents Calibration Parameters (Embedded Coder)

This example shows how to create a storage class that yields a calibration parameter in the generated code. The storage class causes each parameter object (`Simulink.Parameter`) to appear as a global variable with special decorations such as keywords and pragmas.

In the generated code, the calibration parameters must appear as global variables defined in a file named `calPrms.c` and declared in `calPrms.h`. The variable definitions must look like these definitions:

```
#pragma SEC(CALPRM)

const volatile float param1 = 3.0F;
const volatile float param2 = 5.0F;
const volatile float param3 = 7.0F;

#pragma SEC()
```

The variables use the keywords `const` and `volatile`. The pragma `#pragma SEC(CALPRM)` controls the placement of the variables in memory. To implement the pragma, all of the variable definitions must appear in a contiguous block of code.

Also, the generated code must include an ASAP2 (a2l) description of each parameter.

### Create Package for Storing Storage Class and Memory Section Definitions

Now, create a package in your current folder by copying the example package `+SimulinkDemos`. The package stores the definitions of `Parameter` and `Signal` classes that you later use to apply the storage class to data elements in models. Later, the package also stores the definitions of the storage class and an associated memory section.

- 1 Set your current MATLAB folder to a writable location.
- 2 Copy the `+SimulinkDemos` package folder into your current folder. Name the copy `+myPackage`.

```
copyfile(fullfile(matlabroot,...
 'toolbox','simulink','simdemos','dataclasses','+SimulinkDemos'),...
 '+myPackage','f')
```

- 3 Navigate inside the +myPackage folder to the file Signal.m to edit the definition of the Signal class.
- 4 Uncomment the methods section that defines the method setupCoderInfo. In the call to the function useLocalCustomStorageClasses, replace 'packageName' with 'myPackage'. When you finish, the section looks like this:

```
methods
function setupCoderInfo(h)
 % Use custom storage classes from this package
 useLocalCustomStorageClasses(h, 'myPackage');
end
end % methods
```

- 5 Save and close the file.
- 6 Navigate inside the +myPackage folder to the file Parameter.m to edit the definition of the Parameter class. Uncomment the methods section that defines the method setupCoderInfo and replace 'packageName' with 'myPackage'.
- 7 Save and close the file.

### Create Storage Class and Memory Section

- 1 Set your current folder to the folder that contains the package folder +myPackage.
- 2 Open the Custom Storage Class Designer.

```
cscdesigner('myPackage')
```

- 3 In the Custom Storage Class Designer, on the **Memory Sections** tab, click **New**.
- 4 For the new memory section, set properties according to the table.

| Property                   | Value               |
|----------------------------|---------------------|
| <b>Name</b>                | CaMem               |
| <b>Statements Surround</b> | Group of variables  |
| <b>Pre Statement</b>       | #pragma SEC(CALPRM) |
| <b>Post Statement</b>      | #pragma SEC()       |
| <b>Is const</b>            | Select              |
| <b>Is volatile</b>         | Select              |

- 5 Click **Apply**.
- 6 On the **Custom Storage Class** tab, click **New**.

- 7 For the new storage class, set properties according to the table.

| Property               | Value     |
|------------------------|-----------|
| <b>Name</b>            | CalParam  |
| <b>For signals</b>     | Clear     |
| <b>Data scope</b>      | Exported  |
| <b>Header File</b>     | calPrms.h |
| <b>Definition File</b> | calPrms.c |
| <b>Memory Section</b>  | CalMem    |

- 8 Click **OK**. In response to the message about saving changes, click **Yes**.

### Set Default Parameter Object to myPackage.Parameter

To make applying the storage class easier, use the Model Explorer to change the default parameter object from Simulink.Parameter to myPackage.Parameter.

- 1 At the command prompt, open the Model Explorer.
 

```
daexplr
```
- 2 In the Model Explorer **Model Hierarchy** pane, select **Base Workspace**.
- 3 In the Model Explorer toolbar, click the arrow next to the **Add Simulink Parameter** button. In the drop-down list, select **Customize class lists**.
- 4 In the **Customize class lists** dialog box, under **Parameter classes**, select the check box next to **myPackage.Parameter**. Click **OK**.
- 5 In the Model Explorer toolbar, click the arrow next to the **Add Simulink Parameter** button. In the drop-down list, select **myPackage Parameter**.

A myPackage.Parameter object appears in the base workspace. You can delete this object.

Now, when you use tools such as the Model Data Editor to create parameter objects, Simulink creates myPackage.Parameter objects instead of Simulink.Parameter objects.

### Apply Storage Class

In the example model rtwdemo\_roll, the BasicRollMode subsystem represents a PID controller. Configure the P, I, and D parameters as calibration parameters.

- 1 Open the model.

```
rtwdemo_roll
```

- 2 In the model, navigate into the BasicRollMode subsystem.
- 3 Select **Code > C/C++ Code > Configure Model in Code Perspective**.
- 4 Underneath the block diagram, open the Model Data Editor by selecting the **Model Data Editor** tab.
- 5 In the Model Data Editor, select the **Parameters** tab and update the block diagram.

Now, the data table contains rows that correspond to workspace variables used by the Gain blocks (which represent the P, I, and D parameters of the controller).

- 6 In the Model Data Editor, next to the **Filter contents** box, activate the **Filter using selection** button.
- 7 In the model, select the three Gain blocks.
- 8 In the **Filter contents** box, enter model workspace.

The variables that the Gain blocks use are in the model workspace.

- 9 In the data table, select the three rows and, in the **Storage Class** column for any of the rows, select Convert to parameter object.

The Model Data Editor converts the workspace variables to myPackage.Parameter objects. Now, you can apply a storage class to the objects.

- 10 In the **Storage Class** column for any of the rows, select CalParam.

### Configure Generation of ASAP2 Interface

Configure the model to generate a2l files. Select **Configuration Parameters > Code Generation > Interface > ASAP2 interface**.

### Generate and Inspect Code

- 1 Generate code from the model.
- 2 In the code generation report, inspect the calPrms.c file. The file defines the calibration parameters.

```
/* Exported data definition */
#pragma SEC(CALPRM)
```

```
/* Definition for custom storage class: CalParam */
const volatile real32_T dispGain = 0.75F;
const volatile real32_T intGain = 0.5F;
const volatile real32_T rateGain = 2.0F;
```

```
#pragma SEC()
```

The file `calPrms.h` declares the parameters.

- 3 Inspect the interface file `rtwdemo_roll.a2l`. The file contains information about each parameter, for example, for `dispGain`.

```
/begin CHARACTERISTIC
/* Name */ dispGain
/* Long Identifier */ ""
/* Type */ VALUE
/* ECU Address */ 0x0000 /* @ECU_Address@dispGain@ */
/* Record Layout */ Scalar_FLOAT32_IEEE
/* Maximum Difference */ 0
/* Conversion Method */ rtwdemo_roll_CM_single
/* Lower Limit */ -3.4E+38
/* Upper Limit */ 3.4E+38
/end CHARACTERISTIC
```

## Initialize Parameter Value From System Constant or Other Macro (Embedded Coder)

You can generate code that initializes a tunable parameter with a value calculated from some system constants (macros). For example, you can generate this code, which initializes a tunable parameter `totalVol` with a value calculated from macros `numVessels` and `vesInitVol`:

```
#define numVessels 16
#define vesInitVol 18.2

double totalVol = numVessels * vesInitVol;
```

This initialization technique preserves the mathematical relationship between the tunable parameter and the system constants, which can make the generated code more readable and easier to maintain. To generate this code:

- 1 Create parameter objects that represent the system constants.

```
numVessels = Simulink.Parameter(16);
vesInitVol = Simulink.Parameter(18.2);
```

- 2 Configure the objects to use the storage class `Define`, which yields a macro in the generated code.

```
numVessels.CoderInfo.StorageClass = 'Custom';
numVessels.CoderInfo.CustomStorageClass = 'Define';
```

```
vesInitVol.CoderInfo.StorageClass = 'Custom';
vesInitVol.CoderInfo.CustomStorageClass = 'Define';
```

- 3 Create another parameter object that represents the tunable parameter. Configure the object to use the storage class `ExportedGlobal`, which yields a global variable in the generated code.

```
totalVol = Simulink.Parameter;
totalVol.CoderInfo.StorageClass = 'ExportedGlobal';
```

- 4 Set the value of `totalVol` by using the expression `numVessels * vesInitVol`. To specify that the generated code preserve the expression, use the `slexpr` function.

```
totalVol.Value = slexpr('numVessels * vesInitVol');
```

- 5 Use `totalVol` to set block parameter values in your model. The code that you generate from the model initializes the tunable parameter with a value based on the system constants.

For more information and limitations about using an expression to set the value of a `Simulink.Parameter` object, see “Set Variable Value by Using a Mathematical Expression” (Simulink).

## Code Generation Impact of Storage Location for Parameter Objects

You can create a parameter object in the base workspace, a model workspace, or a data dictionary. However, when you end your MATLAB session, variables in the base workspace are deleted. To determine where to store parameter objects and other variables that a model uses, see “Determine Where to Store Variables and Objects for Simulink Models” (Simulink).

The location of a parameter object can impact the file placement of the corresponding data definition in the generated code.

- If you place a parameter object in the base workspace or a data dictionary, the code generator assumes that the corresponding parameter data (for example, a global variable) belongs to the system from which you generate code, not to any specific component in the system. For example, if a model in a model reference hierarchy uses a parameter object with a storage class other than `Auto`, the data definition appears in

the code generated for the top model in the hierarchy, not in the code generated for the model that uses the object.

However, if you have Embedded Coder, some custom storage classes enable you to specify the name of the model that owns a piece of data. When you specify an owner model, the code generated for that model defines the data. For more information about data ownership, see “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 23-2.

- If you place a parameter object in a model workspace, the code generator assumes that the model owns the data. If you generate code from a reference hierarchy that includes the containing model, the data definition appears in the code generated for the containing model.

For more information about data ownership, see “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 23-2.

- If you apply a storage class other than `Auto` to a parameter object, the object appears in the generated code as a global symbol. Therefore, in a model reference hierarchy, two such objects in different model workspaces or dictionaries cannot have the same name. The name of each object must be unique throughout the model hierarchy.

However, if you have Embedded Coder, you can use the storage class `FileScope` to prevent name clashes between parameter objects in different model workspaces. See “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19.

If you store an `AUTOSAR.Parameter` object in a model workspace, the code generator ignores the storage class that you specify for the object.

## Configure Accessibility of Signal Data

When you tune the value of a parameter during algorithm execution, you monitor or capture output signal values to analyze the effect of the tuning. To represent signals in the generated code as accessible data, you can use techniques such as test points and storage classes. See “Configure Data Accessibility for Rapid Prototyping” on page 22-3.

## Programmatic Interfaces for Tuning Parameters

You can configure the generated code to include:

- A C application programming interface (API) for tuning parameters independent of external mode. The generated code includes extra code so that you can write your own code to access parameter values. See “Exchange Data Between Generated and External Code Using C API” on page 46-2.
- A Target Language Compiler API for tuning parameters independently of external mode. See “Parameter Functions” (Simulink Coder).

## Set Tunable Parameter Minimum and Maximum Values

It is a best practice to specify minimum and maximum values for tunable parameters.

You can specify these minimum and maximum values:

- In the block dialog box that uses the parameter object. Use this technique to store the minimum and maximum information in the model.
- By using the properties of a `Simulink.Parameter` object that you use to set the parameter value. Use this technique to store the minimum and maximum information outside the model.

For more information, see “Specify Minimum and Maximum Values for Block Parameters” (Simulink).

## Considerations for Other Modeling Goals

| Goal                                                                                                        | Considerations and More Information                                                                                                                                                                                        |
|-------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Apply storage type qualifiers <code>const</code> and <code>volatile</code>                                  | If you have Embedded Coder, to generate the storage type qualifiers, see “Protect Global Data with <code>const</code> and <code>volatile</code> Keywords” on page 30-17.                                                   |
| Prevent name clashes between parameters in different components by applying the keyword <code>static</code> | If you have Embedded Coder, use the storage class <code>FileScope</code> or a similar storage class that you create. See “Choose a Storage Class for Controlling Data Representation in the Generated Code” on page 22-69. |
| Generate ASAP2 ( <code>a2l</code> ) description                                                             | You can generate an <code>a2l</code> file that uses the ASAP2 standard to describe your calibration parameters. For more information, see “Define ASAP2 Information for Parameters and Signals” on page 47-4.              |

| Goal                                                             | Considerations and More Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Generate AUTOSAR (arxml) description                             | If you have Embedded Coder, you can generate an arxml file that describes calibration parameters used by models that you configure for the AUTOSAR standard. See “Model AUTOSAR Calibration Parameters and Lookup Tables”.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Store lookup table data for calibration                          | <p>To store lookup table data for calibration according to the ASAP2 or AUTOSAR standards (for example, STD_AXIS, COM_AXIS, or CURVE), you can use <code>Simulink.LookupTable</code> and <code>Simulink.Breakpoint</code> objects in lookup table blocks. However, some limitations apply. See <code>Simulink.LookupTable</code>.</p> <p>To work around the limitations of <code>Simulink.LookupTable</code> and <code>Simulink.Breakpoint</code> objects, use <code>Simulink.Parameter</code> and <code>AUTOSAR.Parameter</code> objects instead. See “Define ASAP2 Information for Parameters and Signals” on page 47-4 and “Configure STD_AXIS and COM_AXIS Lookup Tables for AUTOSAR Measurement and Calibration”.</p> |
| Use pragmas to store parameter data in specific memory locations | If you have an Embedded Coder license, to generate code that includes custom pragmas, use custom storage classes and memory sections. See “Control Data and Function Placement in Memory by Inserting Pragmas” on page 30-2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Limitations for Block Parameter Tunability in the Generated Code

A block parameter, MATLAB variable, or `Simulink.Parameter` object is tunable if it appears in the generated code as data stored in memory, such as a global variable. For example, when you apply the storage class `ExportedGlobal` to a parameter object, the parameter object appears tunable in the generated code. When you set **Default parameter behavior** to `Tunable`, MATLAB variables and parameter objects appear tunable in the generated code. By definition, model arguments also appear tunable.

Under certain conditions, the code generator cannot maintain tunability of a parameter, variable, object, or expression. In this case, the code generator inlines the numeric value, preventing you from changing the value during code execution.

To detect these conditions in your model, set the model configuration parameter **Detect loss of tunability** (see “Detect loss of tunability” (Simulink)) to `warning` or `error`.

### Tunable Expression Limitations

You can specify block parameter values as expressions that use `Simulink.Parameter` objects or workspace variables. For example, you can use the expression `5 * gainParam`. For general information about using expressions to set block parameter values, see “Use Mathematical Expressions, MATLAB Functions, and Custom Functions” (Simulink). For limitations with respect to expressions that you use to set the values of `Simulink.Parameter` objects, see “Code Generation of Parameter Objects With Expression Values” (Simulink Coder).

A tunable workspace variable is a `Simulink.Parameter` object or workspace variable that appears tunable in the generated code. For example, an object or variable is tunable if you apply a storage class other than `Auto` or if you set **Default parameter behavior** to `Tunable`.

An expression that contains one or more tunable workspace variables, model arguments, or tunable mask parameters is called a tunable expression. The expression is tunable because the code generator attempts to preserve the expression in the code. Because the code generator preserves the expression, you can change the values of the parameter data during code execution.

The code generator reduces certain expressions to an inlined numeric value in the generated code. The inlining renders workspace variables in the expression nontunable. To avoid loss of tunability due to unsupported expressions, observe these guidelines:

- Expressions involving complex (i) workspace variables or parameter objects are not supported.
- Certain operators and functions cause the code generator to reduce expressions and remove tunability. To determine whether an operator or function causes loss of tunability, use the information in this table.

| Category | Operators or Functions                                                                                                                                              |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1        | + - .* ./ < > <= >= == ~= &                                                                                                                                         |
| 2        | * /                                                                                                                                                                 |
| 3        | abs, acos, asin, atan, atan2, boolean, ceil, cos, cosh, exp, floor, log, log10, sign, sin, sinh, sqrt, tan, tanh, single, int8, int16, int32, uint8, uint16, uint32 |
| 4        | : .^ ^ [] {} . \ .\ ' .' , ;                                                                                                                                        |

- Use operators from category 1 without loss of tunability.
- Use operators from category 2 in expressions as long as at least one operand is a scalar. For example, scalar/scalar and scalar/matrix operand combinations are supported, but matrix/matrix combinations are not supported.
- You can use tunable workspace variables as arguments for the functions in category 3. If you use other functions, the code generator removes the tunability of the arguments.
- The operators in category 4 are not supported.
- The Fcn and If blocks do not support tunable expressions for code generation or in referenced models.
- You can write mask initialization code that creates and modifies variables. If you use those variables in an expression, the expression is not tunable.
- You can specify any data type for the Simulink.Parameter objects or workspace variables that makeup expressions. As long as the data type of these variables and objects and the data type of the corresponding block parameters are the same or double, the code generator can preserve tunability.

## Linear Block Parameter Tunability

These blocks have a `Realization` parameter that affects the tunability of their numeric parameters:

- Transfer Fcn
- State-Space
- Discrete State-Space

To set the `Realization` parameter, you must use the command prompt:

```
set_param(gcb, 'Realization', 'auto')
```

For the `Realization` parameter, you can choose these options:

- `general`: The block's numeric parameters appear tunable in the generated code.
- `sparse`: The generated code represents the block's parameters as transformed values that increase efficiency. The parameters are not tunable.
- `auto`: The default. If one or more of the block's parameters are tunable (for example, because you use a tunable parameter object to set a parameter value), then the block uses the `general` realization. Otherwise, the block uses the `sparse` realization.

To tune the parameter values of one of these blocks during an external mode simulation, the block must use the `general` realization.

## Parameter Structures

As described in “Organize Data into Structures in Generated Code” on page 22-177, you can create structures of parameter data in the generated code.

- If a parameter structure is tunable, the numeric fields of the structure are tunable in the generated code. However, if any field contains a nontunable entity, such as a multidimensional array, none of the structure fields are tunable.
- You cannot declare individual substructures or fields within a parameter structure as tunable. You cannot use a `Simulink.Parameter` object as the value of a structure field. Instead, you must store the entire structure in the parameter object.

## Code Generation of Parameter Objects With Expression Values

As described in “Set Variable Value by Using a Mathematical Expression” (Simulink), you can set the value of a `Simulink.Parameter` object to an expression involving other MATLAB variables or parameter objects. When you generate code from a model that uses such a parameter object, to achieve your goal, use the information in the table.

| Goal                                                                                                                                                          | Technique and More Information                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Generate code without Embedded Coder.                                                                                                                         | <p>For the parameter object that uses the expression, apply any available storage class (see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder)).</p> <p>For the parameter objects used in the expression, apply only the storage class <code>Auto</code>.</p>                                                                                                                                  |
| Generate code that defines a global variable and initializes it by using an expression involving system constants and other macros (requires Embedded Coder). | See “Initialize Parameter Value From System Constant or Other Macro (Embedded Coder)” on page 22-129.                                                                                                                                                                                                                                                                                                                                          |
| Generate code that defines a macro whose value is an expression involving other macros (requires Embedded Coder).                                             | <p>For the parameter object that uses the expression, apply a storage class that yields a macro in the generated code, such as <code>Define</code> (see “Macro Definitions (<code>#define</code>)” on page 14-71).</p> <p>For the parameter objects used in the expression, apply storage classes that yield imported macros. For example, use the storage class <code>ImportedDefine</code>. Your external code must define these macros.</p> |

### Considerations and Limitations

- To avoid errors that prevent code generation, if you apply a storage class other than `Auto` to the dependent parameter object (which uses the expression as its value), the

parameter objects used in the expression must use either `Auto` or a storage class that yields a macro in the generated code.

- You cannot set the value of a parameter object that represents a symbolic dimension (see “Implement Dimension Variants for Array Sizes in Generated Code” on page 15-2) to an expression.
- With Embedded Coder, you can generate code that preserves the expression, but only for the purpose of statically initializing the value of a global variable or macro that corresponds to the dependent parameter object. Follow the guidelines in “Expression Preservation” (Simulink Coder).

## Expression Preservation

If you want Embedded Coder to preserve expressions in the generated code, adhere to these restrictions and guidelines.

- The dependent parameter object must use a storage class other than `Auto`. For example, to generate a global variable and initialize it by using the expression, use `ExportedGlobal` or `ExportToFile`.
- The parameter objects used in the expression must:
  - Use a storage class that yields a macro in the generated code, such as `Define`.
  - Have scalar, real values if the expression uses operators.
- The expression can use only these operators (in MATLAB syntax):
  - Mathematical: `+`, `-`, `*`
  - Relational: `==`, `~=`, `<`, `>`, `<=`, `>=`
- These data typing guidelines apply:
  - If possible, for a parameter object used in an expression, leave the `DataType` property at the default value, `auto`.

To use a value other than `auto`, you must set the `DataType` property of the object that uses the expression to the same value. Otherwise, the code generator does not preserve the expression.

- If you want to use a parameter object in multiple different expressions, and the dependent parameter objects have different data types, leave the `DataType` property of the independent object at the default value, `auto`. In the generated code, the value of the macro is expressed as a floating-point number (with effective

data type `double`), and the code initializes the dependent parameters by typecasting the result of each expression.

## Specify Instance-Specific Parameter Values for Reusable Referenced Model

When you use model referencing to break a large system into components, each component is a separate model. You can reuse a component by referring to it with multiple Model blocks. Each Model block is an instance of the component. You can then configure a block parameter (such as the **Gain** parameter of a Gain block) to use either the same value or a different value for each instance of the component. To use different values, create and use a model argument to set the value of the block parameter.

When you generate code from a model hierarchy that uses model arguments, the arguments appear in the code as formal parameters of the referenced model entry-point functions, such as the `output(step)` function. The generated code then passes the instance-specific parameter values, which you specify in each Model block, to the corresponding function calls.

Whether you use or do not use model arguments, you can use storage classes to configure block parameters to appear in the generated code as tunable global variables. You can also use storage classes to generate tunable model argument values, which the generated code stores in memory and passes to the function calls. You can then change the values during execution.

### Pass Parameter Data to Referenced Model Entry-Point Functions as Arguments

Configure a referenced model to accept parameter data through formal parameters of the generated model entry-point function. This technique enables you to specify a different parameter value for each instance (Model block) of the referenced model.

#### Configure Referenced Model to Use Model Arguments

Create the model `ex_arg_code_ref`. This model represents a reusable algorithm.

```
open_system('ex_arg_code_ref')
```

In the model, select **View > Model Data Editor**.

In the Model Data Editor, in the data table, use the **Data Type** column to set the data type of the Inport block to **single**. Due to data type inheritance, the other signals in the model use the same data type.

Select the **Parameters** tab.

In the model, select the Gain block.

In the Model Data Editor, use the **Value** column to set the value of the **Gain** parameter to **gainArg**.

Next to **gainArg**, click the action button  and select **Create**.

In the Create New Data dialog box, set **Value** to **Simulink.Parameter** and **Location** to **Model Workspace**. Click **Create**.

In the property dialog box, set **Value** to a number, for example, **3.17**. Click **OK**.

Use the Model Data Editor to set the **Numerator** parameter by using a **Simulink.Parameter** object named **coeffArg** whose value is **1.05**. As with **gainArg**, store the parameter object in the model workspace.

In the Model Data Editor, click the **Show/refresh additional information** button.

Use the **Filter contents** box to find each parameter object (**gainArg** and **coeffArg**). For each object, select the check box in the **Argument** column.

The screenshot shows the 'Model Data' window with the 'Parameters' tab selected. The 'model workspace' is active. A table lists two parameters: 'coeffArg' with a value of 1.05 and 'gainArg' with a value of 3.17. Both parameters are of type 'auto' and have dimensions of [1 1]. The 'Argument' column shows checkboxes for both parameters.

| Source          | Name     | Value | Data Type | Min | Max | Dimensions | Unit | Argument                            |
|-----------------|----------|-------|-----------|-----|-----|------------|------|-------------------------------------|
| Model Workspace | coeffArg | 1.05  | auto      | []  | []  | [1 1]      |      | <input checked="" type="checkbox"/> |
| Model Workspace | gainArg  | 3.17  | auto      | []  | []  | [1 1]      |      | <input checked="" type="checkbox"/> |

Save the `ex_arg_code_ref` model.

Alternatively, at the command prompt, you can use these commands to configure the blocks and the parameter objects:

```
set_param('ex_arg_code_ref/In1', 'OutDataTypeStr', 'single')

set_param('ex_arg_code_ref/Gain', 'Gain', 'gainArg')
modelWorkspace = get_param('ex_arg_code_ref', 'ModelWorkspace');
assignin(modelWorkspace, 'gainArg', Simulink.Parameter(3.17));

set_param('ex_arg_code_ref/Discrete Filter', 'Numerator', 'coeffArg')
assignin(modelWorkspace, 'coeffArg', Simulink.Parameter(1.05));

set_param('ex_arg_code_ref', 'ParameterArgumentNames', 'coeffArg,gainArg')

save_system('ex_arg_code_ref')
```

### Specify Instance-Specific Parameter Values in Model Blocks

Create the model `ex_arg_code_ref`. This model uses multiple instances (Model blocks) of the reusable algorithm.

```
open_system('ex_arg_code')
```

In the model, open the Model Data Editor **Parameters** tab (**View > Model Data Editor**). The Model Data Editor shows four rows that correspond to the model arguments, `coeffArg` and `gainArg`, that you can specify for the two Model blocks.

Use the Model Data Editor to set values for the model arguments. For example, use the values in the figure.

| Model Data                                                         |        |                       |       |           |     |     |            |      |          |
|--------------------------------------------------------------------|--------|-----------------------|-------|-----------|-----|-----|------------|------|----------|
| Inports/Outports    Signals    Data Stores    States    Parameters |        |                       |       |           |     |     |            |      |          |
| Design <input type="text" value="Filter contents"/>                |        |                       |       |           |     |     |            |      |          |
|                                                                    | Source | Name                  | Value | Data Type | Min | Max | Dimensions | Unit | Argument |
|                                                                    | Model  | <code>coeffArg</code> | 0.98  | —         | —   | —   | —          | —    | —        |
|                                                                    | Model  | <code>gainArg</code>  | 2.98  | —         | —   | —   | —          | —    | —        |
|                                                                    | Model1 | <code>coeffArg</code> | 1.11  | —         | —   | —   | —          | —    | —        |
|                                                                    | Model1 | <code>gainArg</code>  | 3.34  | —         | —   | —   | —          | —    | —        |

Alternatively, at the command prompt, you can use these commands to set the values:

```
set_param('ex_arg_code/Model', 'ParameterArgumentValues', ...
 struct('coeffArg', '0.98', 'gainArg', '2.98'))
```

```
set_param('ex_arg_code/Model1', 'ParameterArgumentValues', ...
 struct('coeffArg', '1.11', 'gainArg', '3.34'))
```

Generate code from the top model.

```
rtwbuild('ex_arg_code')
```

The file `ex_arg_code_ref.c` defines the referenced model entry-point function, `ex_arg_code_ref`. The function has two formal parameters, `rtp_coeffArg` and `rtp_gainArg`, that correspond to the model arguments, `coeffArg` and `gainArg`. The formal parameters use the data type `real32_T`, which corresponds to the data type `single` in Simulink.

```
/* Output and update for referenced model:
 'ex_arg_code_ref' */
void ex_arg_code_ref(const real32_T *rtu_In1,
 real32_T *rty_Out1,
 DW_ex_arg_code_ref_f_T *localDW,
 real32_T rtp_coeffArg,
 real32_T rtp_gainArg)
```

The file `ex_arg_code.c` contains the definition of the top model entry-point function `ex_arg_code`. This function calls the referenced model entry-point function `ex_arg_code_ref` and uses the model argument values that you specified (such as 1.11 and 3.34) as the values of `rtp_coeffArg` and `rtp_gainArg`.

```
/* ModelReference: '<Root>/Model' incorporates:
 * Inport: '<Root>/In1'
 * Outport: '<Root>/Out1'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out1,
 &(ex_arg_code_DW.Model_InstanceData.rtdw), 0.98F, 2.98F);

/* ModelReference: '<Root>/Model1' incorporates:
 * Inport: '<Root>/In1'
 * Outport: '<Root>/Out2'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out2,
 &(ex_arg_code_DW.Model1_InstanceData.rtdw), 1.11F, 3.34F);
```

The formal parameters use the data type `real32_T` (`single`).

- The block parameters in `ex_arg_code_ref` determine their data types through internal rules. For example, in the Gain block dialog box, on the **Parameter Attributes** tab, **Parameter data type** is set to `Inherit: Inherit via internal rule` (the default). In this case, the internal rule chooses the same data type as the input and output signals, `single`.
- The model arguments in the model workspace use context-sensitive data typing because the value of the `DataType` property is set to `auto` (the default). With this setting, the model arguments use the same data type as the block parameters, `single`.
- The formal parameters in the generated code use the same data type as the model arguments, `single`.

## Generate Tunable Argument Values

You can configure the instance-specific values in the Model blocks to appear in the generated code as tunable global variables. This technique enables you to store the parameter values for each instance in memory and tune the values during code execution.

In the top model `ex_arg_code`, select the Model Data Editor **Parameters** tab.

Use the Model Data Editor to set the values of the model arguments according to this figure.

|                                                                                   | Source ^ | Name     | Value         |
|-----------------------------------------------------------------------------------|----------|----------|---------------|
|  | Model    | coeffArg | coeffForInst1 |
|  | Model    | gainArg  | gainForInst1  |
|  | Model1   | coeffArg | coeffForInst2 |
|  | Model1   | gainArg  | gainForInst2  |

```
set_param('ex_arg_code/Model', 'ParameterArgumentValues', ...
 struct('coeffArg', 'coeffForInst1', 'gainArg', 'gainForInst1'))
set_param('ex_arg_code/Model1', 'ParameterArgumentValues', ...
 struct('coeffArg', 'coeffForInst2', 'gainArg', 'gainForInst2'))
```

View the contents of the `ex_arg_code_ref` model workspace in Model Explorer by selecting **View > Model Explorer > Model Explorer**.

Copy `gainArg` and `coeffArg` from the `ex_arg_code_ref` model workspace to the base workspace.

Rename `gainArg` as `gainForInst1`. Rename `coeffArg` as `coeffForInst1`.

```
gainForInst1 = getVariable(modelWorkspace, 'gainArg');
gainForInst1 = copy(gainForInst1);
coeffForInst1 = getVariable(modelWorkspace, 'coeffArg');
coeffForInst1 = copy(coeffForInst1);
```

Copy `gainForInst1` and `coeffForInst1` as `gainForInst2` and `coeffForInst2`.

```
gainForInst2 = copy(gainForInst1);
coeffForInst2 = copy(coeffForInst1);
```

Set the instance-specific parameter values by using the `Value` property of the parameter objects in the base workspace.

```
gainForInst1.Value = 2.98;
coeffForInst1.Value = 0.98;
```

```
gainForInst2.Value = 3.34;
coeffForInst2.Value = 1.11;
```

In the Model Data Editor for the top model `ex_arg_code`, click the **Show/refresh additional information** button.

Set the **Change view** drop-down list to Code.

For the new parameter objects, set the value in the **Storage Class** column to `ExportedGlobal`. This setting causes the parameter objects to appear in the generated code as tunable global variables.

```
gainForInst1.StorageClass = 'ExportedGlobal';
coeffForInst1.StorageClass = 'ExportedGlobal';
gainForInst2.StorageClass = 'ExportedGlobal';
coeffForInst2.StorageClass = 'ExportedGlobal';
```

Generate code from the top model.

```
rtwbuild('ex_arg_code')
```

The file `ex_arg_code.c` defines the global variables that correspond to the parameter objects in the base workspace.

```
/* Exported block parameters */
real32_T coeffForInst1 = 0.98F; /* Variable: coeffForInst1
 * Referenced by: '<Root>/Model'
 */
real32_T coeffForInst2 = 1.11F; /* Variable: coeffForInst2
 * Referenced by: '<Root>/Model1'
 */
real32_T gainForInst1 = 2.98F; /* Variable: gainForInst1
 * Referenced by: '<Root>/Model'
 */
real32_T gainForInst2 = 3.34F; /* Variable: gainForInst2
 * Referenced by: '<Root>/Model1'
 */
```

In each call to `ex_arg_code_ref`, the top model algorithm uses the global variables to set the values of the formal parameters.

```
/* ModelReference: '<Root>/Model' incorporates:
 * Inport: '<Root>/In1'
 * Outport: '<Root>/Out1'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out1,
 &(ex_arg_code_DW.Model_InstanceData.rtdw), coeffForInst1,
 gainForInst1);

/* ModelReference: '<Root>/Model1' incorporates:
 * Inport: '<Root>/In1'
 * Outport: '<Root>/Out2'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out2,
 &(ex_arg_code_DW.Model1_InstanceData.rtdw), coeffForInst2,
 gainForInst2);
```

The global variables in the generated code use the data type `real32_T` (single).

- The parameter objects in the base workspace use context-sensitive data typing because the `DataType` property is set to `auto` (the default). With this setting, the parameter objects in the base workspace use the same data type as the model arguments, `single`.
- The global variables in the generated code use the same data type as the parameter objects in the base workspace.

### Group Multiple Model Arguments into Single Structure

Use the Model Explorer to copy `gainArg` and `coeffArg` from the `ex_arg_code_ref` model workspace into the base workspace.

```
temp = getVariable(modelWorkspace, 'gainArg');
gainArg = copy(temp);
temp = getVariable(modelWorkspace, 'coeffArg');
coeffArg = copy(temp);
```

At the command prompt, combine these two parameter objects into a structure, `structArg`.

```
structArg = Simulink.Parameter(struct('gain', gainArg.Value, ...
 'coeff', coeffArg.Value));
```

Use the Model Explorer to move `structArg` into the model workspace.

```
assignin(modelWorkspace, 'structArg', copy(structArg));
clear structArg gainArg coeffArg
```

In the **Contents** pane, configure `structArg` as the only model argument.

```
set_param('ex_arg_code_ref', 'ParameterArgumentNames', 'structArg')
```

|                                                                                   | Name      | Value        | Argument                            | DataType | Dimension |
|-----------------------------------------------------------------------------------|-----------|--------------|-------------------------------------|----------|-----------|
|  | coeffArg  | 1.05         | <input type="checkbox"/>            | auto     | [1 1]     |
|  | gainArg   | 3.17         | <input type="checkbox"/>            | auto     | [1 1]     |
|  | structArg | <1x1 struct> | <input checked="" type="checkbox"/> | struct   | [1 1]     |

In the `ex_arg_code_ref` model, select the Model Data Editor **Parameters** tab.

Use the Model Data Editor to set the value of the **Gain** parameter to `structArg.gain` and the value of the **Numerator** parameter to `structArg.coeff`. Save the model.

```
set_param('ex_arg_code_ref/Gain', 'Gain', 'structArg.gain')
set_param('ex_arg_code_ref/Discrete Filter', ...
 'Numerator', 'structArg.coeff')
```

```
save_system('ex_arg_code_ref')
```

At the command prompt, combine the four parameter objects in the base workspace into two structures. Each structure stores the parameter values for one instance of `ex_arg_code_ref`.

```
structForInst1 = Simulink.Parameter(struct('gain', gainForInst1.Value, ...
 'coeff', coeffForInst1.Value));

structForInst2 = Simulink.Parameter(struct('gain', gainForInst2.Value, ...
 'coeff', coeffForInst2.Value));
```

In the top model `ex_arg_code`, set the **Change view** drop-down list to **Design**. Use the Model Data Editor to set the argument values according to this figure.

| Model Data       |           |                |             |        |            |
|------------------|-----------|----------------|-------------|--------|------------|
| Inports/Outports |           | Signals        | Data Stores | States | Parameters |
| Design           |           |                |             |        |            |
| Source           | Name      | Value          |             |        |            |
| Model            | structArg | structForInst1 |             |        |            |
| Model1           | structArg | structForInst2 |             |        |            |

```
set_param('ex_arg_code/Model', 'ParameterArgumentValues', ...
 struct('structArg', 'structForInst1'))
set_param('ex_arg_code/Model1', 'ParameterArgumentValues', ...
 struct('structArg', 'structForInst2'))
```

Click the **Show/refresh additional information** button.

For the new parameter objects `structForInst1` and `structForInst2`, use the Model Data Editor to apply the storage class `ExportedGlobal`.

```
structForInst1.StorageClass = 'ExportedGlobal';
structForInst2.StorageClass = 'ExportedGlobal';
```

At the command prompt, use the function `Simulink.Bus.createObject` to create a `Simulink.Bus` object. The hierarchy of elements in the object matches the hierarchy of the structure fields. The default name of the object is `slBus1`.

```
Simulink.Bus.createObject(structForInst1.Value);
```

Rename the bus object as `myParamStructType` by copying it.

```
myParamStructType = copy(slBus1);
```

In the Model Data Editor for `ex_arg_code`, set **Change view** to **Design**. Use the **Data Type** column to set the data type of `structForInst1` and `structForInst2` to `Bus: myParamStructType`.

```
structForInst1.DataType = 'Bus: myParamStructType';
structForInst2.DataType = 'Bus: myParamStructType';
```

In the Model Data Editor for `ex_arg_code_ref`, use the Model Data Editor to set the data type of `structArg` to `Bus: myParamStructType`.

| Source          | Name      | Value        | Data Type              | Min | Max | Dimensions | Unit | Argument                            |
|-----------------|-----------|--------------|------------------------|-----|-----|------------|------|-------------------------------------|
| Model Workspace | structArg | <1x1 struct> | Bus: myParamStructType | [ ] | [ ] | [1 1]      |      | <input checked="" type="checkbox"/> |

```
temp = getVariable(modelWorkspace, 'structArg');
temp = copy(temp);
temp.DataType = 'Bus: myParamStructType';
assignin(modelWorkspace, 'structArg', copy(temp));
```

Save the `ex_arg_code_ref` model.

```
save_system('ex_arg_code_ref')
```

When you use structures to group parameter values, you cannot take advantage of context-sensitive data typing to control the data types of the fields of the structures (for example, the fields of `structForInst1`). However, you can use the properties of the bus object to control the field data types.

At the command prompt, set the data type of the elements in the bus object to `single`. The corresponding fields in the structures (such as `structForInst1` and `structArg`) use the same data type.

```
myParamStructType.Elements(1).DataType = 'single';
myParamStructType.Elements(2).DataType = 'single';
```

Generate code from the top model `ex_arg_code`.

```
rtwbuild('ex_arg_code')
```

The file `ex_arg_code_types.h` defines the structure type `myParamStructType`, which corresponds to the `Simulink.Bus` object.

```
typedef struct {
 real32_T gain;
 real32_T coeff;
} myParamStructType;
```

In the file `ex_arg_code_ref.c`, the referenced model entry-point function has a formal parameter, `rtp_structArg`, that corresponds to the model argument `structArg`.

```
/* Output and update for referenced model:
 'ex_arg_code_ref' */
void ex_arg_code_ref(const real32_T *rtu_In1,
```

```

real32_T *rty_Out1,
DW_ex_arg_code_ref_f_T *localDW,
const myParamStructType *rtp_structArg)

```

The file `ex_arg_code.c` defines the global structure variables that correspond to the parameter objects in the base workspace.

```

/* Exported block parameters */
myParamStructType structForInst1 = {
 2.98F,
 0.98F
} ;
/* Variable: structForInst1
 * Referenced by: '<Root>/Model'
 */

myParamStructType structForInst2 = {
 3.34F,
 1.11F
} ;
/* Variable: structForInst2
 * Referenced by: '<Root>/Model1'
 */

```

The top model algorithm in the file `ex_arg_code.c` passes the addresses of the structure variables to the referenced model entry-point function.

```

/* ModelReference: '<Root>/Model' incorporates:
 * Inport: '<Root>/In1'
 * Output: '<Root>/Out1'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out1,
 &(ex_arg_code_DW.Model_InstanceData.rtdw), &structForInst1);

/* ModelReference: '<Root>/Model1' incorporates:
 * Inport: '<Root>/In1'
 * Output: '<Root>/Out2'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out2,
 &(ex_arg_code_DW.Model1_InstanceData.rtdw), &structForInst2);

```

## Control Data Types of Model Arguments and Argument Values

When you use model arguments, you can apply a data type to:

- The block parameters that use the arguments (for certain blocks, such as those in the Discrete library).
- The arguments in the referenced model workspace.

- The argument values that you specify in Model blocks.

To generate efficient code by eliminating unnecessary typecasts and C shifts, consider using inherited and context-sensitive data typing to match the data types.

- In the model workspace, use a MATLAB variable whose data type is `double` or a parameter object whose `DataType` property is set to `auto`. In this case, the variable or object uses the same data type as the block parameter.
- When you set the argument values in Model blocks, take advantage of context-sensitive data typing. To set an argument value, use an untyped value.
  - A literal number such as `15.23`. Do not use a typed expression such as `single(15.23)`.
  - A MATLAB variable whose data type is `double`.
  - A `Simulink.Parameter` object whose `DataType` property is set to `auto`.

In these cases, the number, variable, or object uses the same data type as the model argument in the referenced model workspace. If you also configure the model argument to use context-sensitive data typing, you can control the data types of the block parameter, the argument, and the argument value by specifying the type only for the block parameter.

For basic information about controlling parameter data types, see “Parameter Data Types in the Generated Code” on page 22-156.

### **Use Model Argument in Different Data Type Contexts**

If you use a model argument to set multiple block parameter values, and the data types of the block parameters differ, you cannot use context-sensitive data typing (`double` or `auto`) for the argument in the model workspace. You must explicitly specify a data type for the argument. For example, if the argument in the model workspace is a parameter object (such as `Simulink.Parameter`), set the `DataType` property to a value other than `auto`. For more information about this situation, see “Reuse Parameter Data in Different Data Type Contexts” on page 22-173.

In this case, you can continue to take advantage of context-sensitive data typing to control the data type of the argument values that you specify in Model blocks. Each argument value uses the data type that you specify for the corresponding argument in the model workspace.

## Parameter Data Types in the Generated Code

The data type of a block parameter (such as the **Gain** parameter of a Gain block), numeric MATLAB variable, or `Simulink.Parameter` object determines the data type that the corresponding entity in the generated code uses (for example, a global variable or an argument of a function). To generate more efficient code, you can match parameter data types with signal data types or store parameters in smaller data types.

For basic information about setting block parameter data types in a model, see “Control Block Parameter Data Types” (Simulink).

### Significance of Parameter Data Types

The data type that a block parameter, MATLAB variable, or parameter object uses determines the data type that the generated code uses to store the parameter value in memory. For example:

- If you set the model configuration parameter **Default parameter behavior** (see “Default parameter behavior” (Simulink Coder)) to `Tunable`, the **Gain** parameter of a Gain block appears in the generated code as a field of a global structure that stores parameter data. If you apply the data type `single` to the block parameter in the model, the structure field in the code uses the corresponding data type, `real32_T`.
- If you apply the storage class `ExportedGlobal` to a `Simulink.Parameter` object, the object appears in the generated code as a separate global variable. If you set the `DataType` property of the object to `int8`, the global variable in the code uses the corresponding data type, `int8_T`.
- If you configure a `Simulink.Parameter` object in a model workspace as a model argument, the object appears in the generated code as a formal parameter (argument) of a model entry-point function, such as the `step` function. The `DataType` property of the object determines the data type of the formal parameter.

Other than determining the data type that the generated code uses to store parameter values in memory, the data type of a parameter, variable, or object can also:

- Cause the block to cast the value of the parameter prior to code generation. The cast can result in overflow, underflow, or quantization.
- Cause the generated code to include extra code, for example saturation code.

## Typecasts Due to Parameter Data Type Mismatches

When the data types of block parameters, workspace variables, and signals differ, blocks can use typecasts to reconcile the data type mismatches. These typecasts can cause the generated code algorithm, including the `model step` function, to include explicit casts to reconcile mismatches in storage data type and C bit shifts to reconcile mismatches in fixed-point scaling.

Parameter data type mismatches can occur when:

- The data type that you specify for a MATLAB variable or parameter object (`Simulink.Parameter`) differs from the data type of a block parameter. The block parameter typecasts the value of the variable or object.
- The data type that you specify for an initial value differs from the data type of the initialized signal or state.
- The data type that you specify for a block parameter differs from the data type of the signal or signals that the parameter operates on. Some blocks typecast the parameter to perform the operation. For example, the Gain block performs this typecast.

If you configure a variable or object to use bias or fractional fixed-point slope, the block parameter cannot perform the typecast. In this case, you must match the data type of the variable or parameter object with the data type of the block parameter. Use one of these techniques:

- Use context-sensitive data typing for the variable or parameter object. For a MATLAB variable, use a `double` number to set the value of the variable. For a parameter object, set the `DataType` property to `auto`.
- Use a `Simulink.AliasType` or `Simulink.NumericType` object to set the data type of the block parameter and the data type of a parameter object.

Use this technique when you cannot rely on context-sensitive data typing, for example, when you use the field of a structure to set the value of the block parameter.

- Manually specify the same data type for the block parameter and the variable or parameter object.

Use this technique to reduce the dependence of the model on inherited and context-sensitive data types and on external variables and objects.

For blocks that access parameter data through pointer or reference in the generated code, if you specify different data types for the workspace variable and the block

parameter, the generated code implicitly casts the data type of the variable to the data type of the block parameter. Note, that an implicit cast requires a data copy which could significantly increase RAM consumption and slow down code execution speed for large data sets. For example, Lookup Table blocks often access large vectors or matrices through pointer or reference in the generated code.

For information about matching parameter data types when you use model arguments, see “Control Data Types of Model Arguments and Argument Values” on page 22-153.

### **Detect Downcast and Loss of Precision due to Data Type Mismatches**

You can configure diagnostic configuration parameters to detect unintentional data type mismatches that result in quantization and loss of parameter precision. See “Model Configuration Parameters: Data Validity Diagnostics” (Simulink).

## **Considerations for Other Modeling Patterns**

When you use specific modeling patterns and constructs such as fixed-point data types, parameter structures, and lookup table objects, use different techniques to control parameter data types.

- “Tunable Parameters and Best-Precision Fixed-Point Scaling” on page 22-158
- “Control Data Types of Structure Fields” on page 22-159
- “Control Data Types of Lookup Table Objects” on page 22-159
- “Data Typing for Expressions in Parameter Objects” on page 22-160

### **Tunable Parameters and Best-Precision Fixed-Point Scaling**

To apply best-precision fixed-point scaling to a tunable block parameter or parameter object, you can use the Fixed-Point Tool to autoscale an entire system or use the Data Type Assistant to configure individual parameters or objects. See “Calculate Best-Precision Fixed-Point Scaling for Tunable Block Parameters” (Simulink).

If a tunable parameter uses best-precision fixed-point scaling, Simulink chooses a data type based on the minimum and maximum values that you specify for the parameter (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink)). You can specify these values in the block dialog box that uses the parameter or in the properties of a `Simulink.Parameter` object.

If you do not specify a minimum or maximum, Simulink chooses a data type based on the value of the parameter. The chosen scaling might restrict the range of possible tuning

values. Therefore, it is a best practice to specify minimum and maximum values for each tunable parameter.

A tunable parameter can use best-precision scaling even if you do not specify it in the parameter data type. For example, the Gain block can choose a best-precision scaling if the **Parameter data type** in the block dialog box is set to `Inherit: Inherit via internal rule`. This setting is the default for the block.

### **Control Data Types of Structure Fields**

When you use a structure as the value of a block parameter (for example to initialize a bus signal), or when you organize multiple block parameter values into a single structure, you can create a `Simulink.Bus` object to use as the data type of a `Simulink.Parameter` object. You can then control the data types of individual fields in the structure. See “Control Field Data Types and Characteristics by Creating Parameter Object” (Simulink) and “Control Data Types of Initial Condition Structure Fields” (Simulink).

### **Control Data Types of Lookup Table Objects**

When you use `Simulink.LookupTable` and `Simulink.Breakpoint` objects to store table and breakpoint data for a lookup table block, to control the data types of the table and breakpoint data, use one of these techniques:

- Set the `Value` property of the embedded `Simulink.lookuptable.Table` and `Simulink.lookuptable.Breakpoint` objects by using untyped expressions such as `[1 2 3]`, which returns a `double` vector. To control the data type, set the `DataType` property to a value other than `auto`.

Use this technique to separate the value of the table or breakpoint data from the data type, which can improve readability and understanding of your design. You can then use a `Simulink.NumericType` or `Simulink.AliasType` object to:

- Customize the name of the data type in the generated code.
- Match the data type of the table or breakpoint data with the data type of a signal in the model.
- Set the `Value` property of the embedded objects by using typed expressions such as `single([1 2 3])`. To use a fixed-point data type, set the `Value` property with an `fi` object.

Set the `DataType` property of the embedded objects to the default value, `auto`. The table and breakpoint data then acquire the data type that you use to set the `Value` property.

Use this technique to store the data type information in the `Value` property, which can simplify the way you interact with the `Simulink.LookupTable` and `Simulink.Breakpoint` objects. You can leave the `DataType` property at the default value.

When you later change the breakpoint or table data in the `Value` property, preserve the data type information by using a typed expression. Alternatively, if you use a command at the command prompt or a script to change the data, to avoid using a typed expression, use subscripted assignment, `(:)`.

```
myLUTObject.Table.Value(:) = [4 5 6];
```

When you change the data stored in the `Value` property, if you do not use a typed expression or subscripted assignment, you lose the data type information.

When blocks in a subsystem use `Simulink.LookupTable` or `Simulink.Breakpoint` objects, you cannot set data type override (see “Control Fixed-Point Instrumentation and Data Type Override” (Simulink)) only on the subsystem. Instead, set data type override on the entire model.

### **Data Typing for Expressions in Parameter Objects**

You can use an expression to set the value of a parameter object (such as `Simulink.Parameter`). The expression encodes mathematical relationships between different objects. When you use this technique, different data typing rules apply. See “Set Variable Value by Using a Mathematical Expression” (Simulink).

- “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50

## Generate Efficient Code by Specifying Data Types for Block Parameters

To generate more efficient code, match the data types of block parameters (such as the **Gain** parameter of a Gain block) with signal data types. Alternatively, you can store parameters in smaller data types.

### Eliminate Unnecessary Typecasts and Shifts by Matching Data Types

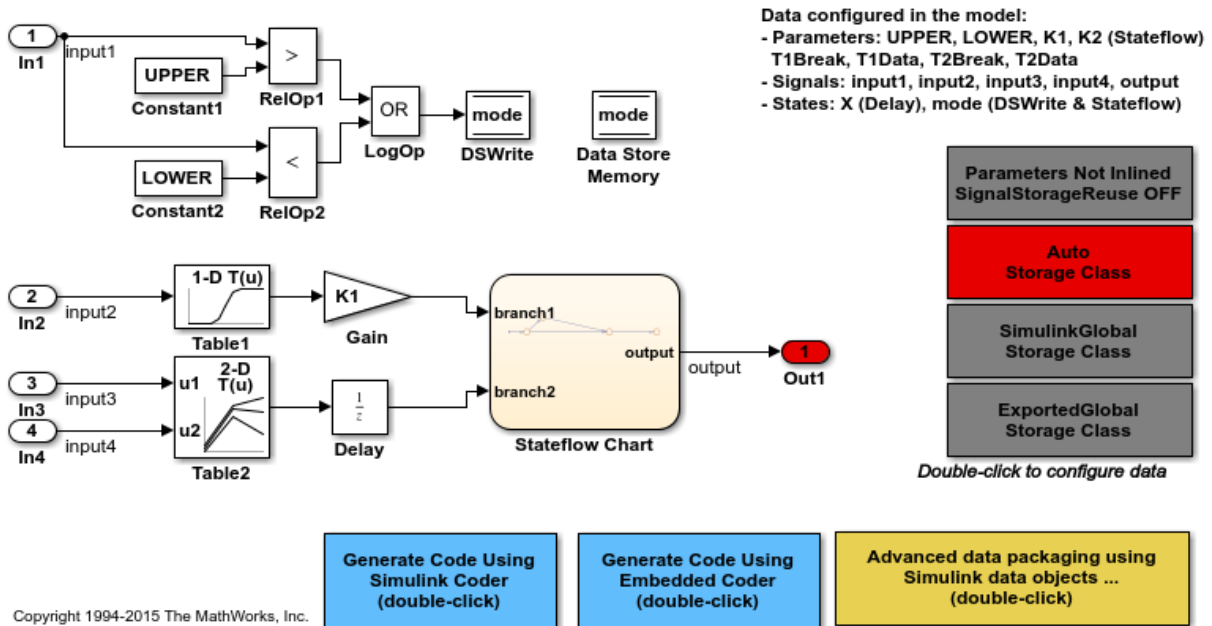

These examples show how to generate efficient code by configuring a block parameter to use the same data type as a signal that the block operates on.

#### Store Data Type Information in Model

Open the example model `rtwdemo_basicsc` and configure it to show the generated names of blocks.

```
load_system('rtwdemo_basicsc')
set_param('rtwdemo_basicsc','HideAutomaticNames','off')
open_system('rtwdemo_basicsc')
```

Copyright 1994-2015 The MathWorks, Inc.

Identify the Gain block in the model, which uses the base workspace variable K1 to set the value of the **Gain** parameter. The input signal of this block uses the data type single.

In the model, select **View > Model Data Editor**.

In the Model Data Editor, select the **Parameters** tab.

In the model, select the Gain block. In the Model Data Editor, the **Data Type** column shows that the data type of the **Gain** parameter of the block is set to **Inherit: Same as input**. With this setting, the **Gain** parameter of this block uses the same data type as the input signal.

In the Model Data Editor, set the **Change view** drop-down list to Code.

Update the block diagram. Now, in the Model Data Editor, the data table shows rows that correspond to workspace variables that the model uses, including K1.

In the Model Data Editor, find the row that corresponds to K1. For that row, in the **Storage Class** column, select **Convert to parameter object**. Simulink converts K1 to a **Simulink.Parameter** object.

Use the **Storage Class** column to apply the storage class `ExportedGlobal`. With this setting, the object appears in the generated code as a global variable.

In the Model Data Editor, set **Change view** to **Design**.

In the data table, for the row that represents `K1`, in the **Data Type** column, select `auto`. With this setting, the parameter object acquires its data type from the block parameters that use the object (in this case, the **Gain** block parameter).

Alternatively, to create and configure the object, use these commands at the command prompt:

```
K1 = Simulink.Parameter(2);
K1.CoderInfo.StorageClass = 'ExportedGlobal';
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
Starting build procedure for model: rtwdemo_basicsc
Successful completion of build procedure for model: rtwdemo_basicsc
```

The generated file `rtwdemo_basicsc.c` defines the global variable `K1` by using the data type `real32_T`, which corresponds to the data type `single` in Simulink.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file, /* Exported block parameters */,'real32_T K1 = 2.0F;',1,1)
```

```
/* Exported block parameters */
real32_T K1 = 2.0F; /* Variable: K1
```

The generated code algorithm in the model `step` function uses `K1` directly without typecasting.

```
rtwdemodbtype(file, 'rtwdemo_basicsc_DW.X = K1',...
'rtCP_Table1_bp01Data, rtCP_Table1_tableData',1,1)

rtwdemo_basicsc_DW.X = K1 * look1_iflf_binlx(rtwdemo_basicsc_U.input2,
rtCP_Table1_bp01Data, rtCP_Table1_tableData, 10U);
```

On the Model Data Editor **Parameters** tab, you can optionally set the data type of the **Gain** block parameter to **Inherit: Inherit via internal rule** (the default). In this case, the block parameter chooses the same data type as the input signal, `single`.

However, when you use `Inherit: Inherit` via internal rule, under other circumstances (for example, when you use fixed-point data types), the block parameter might choose a different data type.

### Store Data Type Information in Parameter Object

When you use a `Simulink.Parameter` object to export or import parameter data from the generated code to your external code, for example by applying the storage class `ImportedExtern`, you can specify data type information in the parameter object. To match the data type of the parameter object with a signal data type, create a `Simulink.NumericType` or `Simulink.AliasType` object. You can strictly control the data type that the parameter object uses in the generated code, eliminating the risk that Simulink chooses a different data type when you make changes to the model.

At the command prompt, create a `Simulink.NumericType` object that represents the data type `single`.

```
myType = Simulink.NumericType;
myType.DataTypeMode = 'Single';
```

Use the Model Data Editor **Data Type** column to set these data types to `myType`:

- The parameter object. Use the **Parameters** tab.
- The Inport block named `In2`. Use the **Inports/Outports** tab. Due to data type propagation, the input signal of the Gain block also uses `myType`.

Use the Model Data Editor **Parameters** tab to set the data type of the **Gain** block parameter to `Inherit: Inherit` from `'Gain'`. Use this data type object as the data type of the parameter object.

Alternatively, to configure the object and the blocks, use these commands at the command prompt:

```
K1.DataType = 'myType';
set_param('rtwdemo_basicsc/In2', 'OutDataTypeStr', 'myType')
set_param('rtwdemo_basicsc/Gain', 'ParamDataTypeStr', 'Inherit: Inherit from ''Gain''')
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')

Starting build procedure for model: rtwdemo_basicsc
Successful completion of build procedure for model: rtwdemo_basicsc
```

The global variable K1 continues to use the data type `real32_T`.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'/* Exported block parameters */','real32_T K1 = 2.0F;',1,1)

/* Exported block parameters */
real32_T K1 = 2.0F; /* Variable: K1
```

## Reduce Memory Consumption by Storing Parameter Value in Small Data Type

When you use a parameter object (for example, `Simulink.Parameter`) to set block parameter values, you can configure the object to appear in the generated code as a tunable global variable. By default, the parameter object and the corresponding global variable typically uses the same data type as the signal or signals on which the block operates. For example, if the input signal of a Gain block uses the data type `int16`, the parameter object typically use the same data type. To reduce the amount of memory that this variable consumes, specify that the variable use a smaller integer data type such as `int8`.

### Store Parameter Value in Integer Data Type

Run the script `prepare_rtwdemo_basicsc_2`, which prepares the model `rtwdemo_basicsc` for this example.

```
run(fullfile(matlabroot,'examples','simulinkcoder',...
 'main','prepare_rtwdemo_basicsc_2'))
```

Copyright 1994-2015 The MathWorks, Inc.

Many of the signals in the model use the data type `single`.

In the model, select **View > Model Data Editor**.

In the Model Data Editor, inspect the **Parameters** tab.

Click the **Show/refresh additional information** button.

Next to the **Filter contents** box, activate the **Filter using selection** button.

In the model, click the Gain block. The Model Data Editor shows one row that corresponds to the **Gain** parameter of the block and one row that corresponds to the MATLAB variable `K1`, which sets the parameter value to 2. `K1` resides in the base workspace.

In the Model Data Editor, set the **Change view** drop-down list to **Code**.

In the data table, for the row that corresponds to `K1`, in the **Storage Class** column, from the drop-down list, select **Convert to parameter object**. Simulink converts `K1` to a `Simulink.Parameter` object.

```
K1 = Simulink.Parameter(K1);
```

Use the **Storage Class** column to apply the storage class `ExportedGlobal` to K1. With this setting, K1 appears in the generated code as a global variable.

```
K1.CoderInfo.StorageClass = 'ExportedGlobal';
```

In the Model Data Editor, set **Change view** to `Design` and use the **Data Type** column to apply the data type `int8` to K1.

```
K1.DataType = 'int8';
```

For the row that represents the **Gain** block parameter, in the **Data Type** column, set the drop-down list to `Inherit: Inherit from 'Gain'`. With this setting, the **Gain** parameter of the block inherits the `int8` data type from the parameter object.

```
set_param('rtwdemo_basicsc/Gain','ParamDataTypeStr',...
 'Inherit: Inherit from ''Gain''')
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
Starting build procedure for model: rtwdemo_basicsc
Successful completion of build procedure for model: rtwdemo_basicsc
```

The generated file `rtwdemo_basicsc.c` defines the global variable K1 by using the data type `int8_T`, which corresponds to the data type `int8` in Simulink.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'/* Exported block parameters */','int8_T K1 = 2;',1,1)
```

```
/* Exported block parameters */
int8_T K1 = 2; /* Variable: K1
```

The code algorithm in the model `step` function uses K1 to calculate the output of the Gain block. The algorithm casts K1 to the data type `real32_T` (single) because the signals involved in the calculation use the data type `real32_T`.

```
rtwdemodbtype(file,' rtwdemo_basicsc_DW.X = ','10U;',1,1)
```

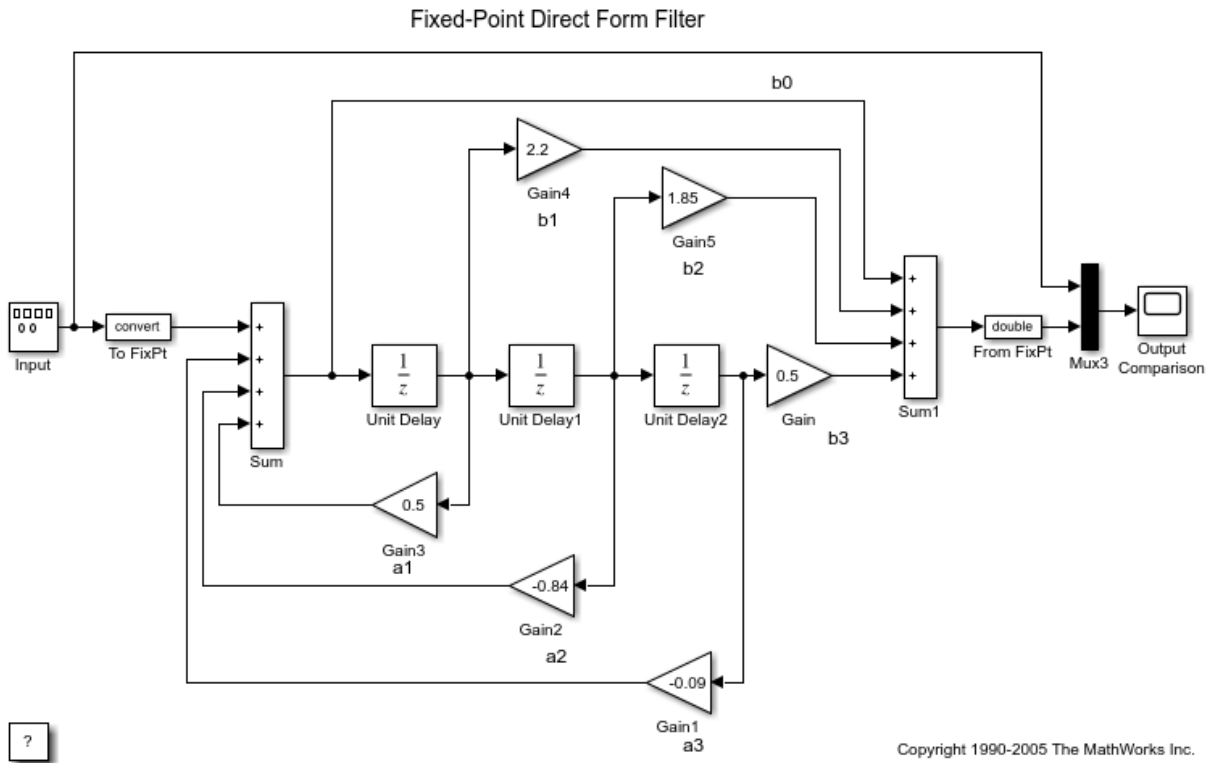

```
rtwdemo_basicsc_DW.X = (real32_T)K1 * look1_iflf_binlx
 (rtwdemo_basicsc_U.input2, rtCP_Table1_bp01Data, rtCP_Table1_tableData,
 10U);
```

## Store Fixed-Point Parameter Value in Smaller Integer Data Type

Suppose you configure the signals in your model to use fixed-point data types. You want a gain parameter to appear in the generated code as a tunable global variable. You know the range of real-world values that you expect the parameter to assume (for example, between 0 and 4). If you can meet your application requirements despite reduced precision, you can reduce memory consumption by configuring the parameter to use a different data type than the input and output signals of the block.

Open the example model `fxpdemo_direct_form2` and configure it to show the generated names of blocks.

```
load_system('fxpdemo_direct_form2')
set_param('fxpdemo_direct_form2','HideAutomaticNames','off')
open_system('fxpdemo_direct_form2')
```

Update the block diagram. Signals in this model use signed fixed-point data types with a word length of 16 and binary-point-only scaling.

Open the Gain5 block dialog box. The **Gain** parameter is set to 1.85. Suppose you want to configure this parameter.

Set **Gain** to myGainParam and click **Apply**.

Click the action button (with three vertical dots) next to the parameter value. Select **Create**.

In the Create New Data dialog box, set **Value** to `Simulink.Parameter(1.85)` and click **Create**. The `Simulink.Parameter` object myGainParam appears in the base workspace.

In the myGainParam property dialog box, set **Storage class** to `ExportedGlobal` and click **OK**. With this setting, myGainParam appears in the generated code as a global variable.

In the block dialog box, on the **Parameter Attributes** tab, set **Parameter minimum** to 0 and **Parameter maximum** to 4.

Set **Parameter data type** to `fixdt(0,8)` and click **Apply**.

Click the **Show Data Type Assistant** button. The Data Type Assistant shows that the expression `fixdt(0,8)` specifies an unsigned fixed-point data type with a word length of 8 and best-precision scaling. When you simulate or generate code, the block parameter chooses a fraction length (scaling) that enables the data type to represent values between the parameter minimum and maximum (0 and 4) with the best possible precision.

In the Data Type Assistant, set **Scaling** to `Binary point`. Click **Calculate Best-Precision Scaling**, **Fixed-point details**, and **Refresh Details**. The information under **Fixed-point details** shows that a fraction length of 5 can represent the parameter values with a precision of 0.03125.

Set **Scaling** back to `Best precision` and click **OK**. In this example, when you simulate or generate code, the block parameter chooses a fraction length of 5.

Alternatively, you can use these commands at the command prompt to create the object and configure the block:

```
myGainParam = Simulink.Parameter(1.85);
myGainParam.CoderInfo.StorageClass = 'ExportedGlobal';
```

```
set_param('fxpdemo_direct_form2/Gain5','Gain','myGainParam')
set_param('fxpdemo_direct_form2/Gain5','ParamMin','0','ParamMax','4')
set_param('fxpdemo_direct_form2/Gain5','ParamDataTypeStr','fixdt(0,8)')
```

Configure the model to produce a code generation report. To reduce clutter in the Command Window, clear the configuration parameter **Verbose build**.

```
set_param('fxpdemo_direct_form2','GenerateReport','on',...
 'LaunchReport','on','RTWVerbose','off')
```

Generate code from the model.

```
evalc('rtwbuild(''fxpdemo_direct_form2'')');
```

The generated file `fxpdemo_direct_form2.c` defines the global variable `myGainParam` by using the data type `uint8_T`, which corresponds to the specified word length, 8. The code initializes the variable by using an integer value that, given the fraction length of 5, represents the real-world parameter value 1.85.

```
file = fullfile('fxpdemo_direct_form2_grt_rtw','fxpdemo_direct_form2.c');
rtwdemodbtype(file,'/* Exported block parameters */','uint8_T myGainParam = 59U;',1,1)
```

```
/* Exported block parameters */
uint8_T myGainParam = 59U; /* Variable: myGainParam
```

The code algorithm uses `myGainParam` to calculate the output of the Gain5 block. The algorithm uses a C shift to scale the result of the calculation.

```
rtwdemodbtype(file,'/* Gain: '<Root>/Gain5' */',...
 '/* Gain: '<Root>/Gain' incorporates:',1,0)
```

```
/* Gain: '<Root>/Gain5' */
fxpdemo_direct_form2_B.Gain5 = (int16_T)((myGainParam *
 fxpdemo_direct_form2_B.UnitDelay1) >> 5);
```

## Reuse Parameter Data in Different Data Type Contexts

When you use a `Simulink.Parameter` object or a numeric MATLAB variable to set two or more block parameter values, if the block parameters have different data types, you must explicitly specify the data type of the object or variable. For example, you cannot leave the data type of the parameter object at the default value, `auto`.

### Create and Configure Example Model

Create the model `ex_paramdt_contexts`.

`ex_paramdt_contexts`

In the model, select **View > Model Data Editor**.

In the Model Data Editor, on the **Inports/Outports** tab, use the **Data Type** column to set the data type of the In1 Inport block to `single` and the data type of the In2 block to `int8`.

On the **Signals** tab, set the data types of the Gain block outputs to `Inherit: Same as input`.

On the **Parameters** tab, for the **Gain** parameters of the Gain blocks, set **Data Type** to `Inherit: Same as input`.

For the **Gain** parameters, set **Value** to `myGainParam`.

Alternatively, to configure the blocks, use these commands at the command prompt:

```
set_param('ex_paramdt_contexts/In1', 'OutDataTypeStr', 'single')
set_param('ex_paramdt_contexts/In2', 'OutDataTypeStr', 'int8')
set_param('ex_paramdt_contexts/Gain - single', 'Gain', 'myGainParam', ...
 'OutDataTypeStr', 'Inherit: Same as input', ...
 'ParamDataTypeStr', 'Inherit: Same as input')
set_param('ex_paramdt_contexts/Gain - int8', 'Gain', 'myGainParam', ...
 'OutDataTypeStr', 'Inherit: Same as input', ...
 'ParamDataTypeStr', 'Inherit: Same as input')
```

In the Model Data Editor, for either **Gain** block parameter, click the cell in the **Value** column. Next to myGainParam, click the action button (with three vertical dots) and select **Create**.

In the **Create New Data** dialog box, set **Value** to Simulink.Parameter(3) and click **Create**. A Simulink.Parameter object with value 3 appears in the base workspace.

In the **myGainParam** property dialog box, set **Data type** to int8 and **Storage class** to ExportedGlobal. With the storage class ExportedGlobal, the object appears in the generated code as a global variable.

Alternatively, to create and configure the parameter object, use these commands at the command prompt:

```
myGainParam = Simulink.Parameter(3);
myGainParam.CoderInfo.StorageClass = 'ExportedGlobal';
myGainParam.DataType = 'int8';
```

In this model, you use the parameter object myGainParam to set two block parameter values. The block parameters inherit different data types from the block input signals (single or int8). To use myGainParam in these different data type contexts, you explicitly specify the data type of the parameter object by setting the DataType property to int8.

### Match Parameter Object Data Type with Signal Data Type

Optionally, use a Simulink.NumericType or Simulink.AliasType object to set the parameter object data type and one of the signal data types. This technique eliminates unnecessary typecasts and shifts in the generated code due to a mismatch between the parameter object data type and the signal data type.

At the command prompt, create a Simulink.NumericType object to represent the data type int8.

```
sharedType_int8 = fixdt('int8');
```

In the Model Data Editor, on the **Inports/Outports** tab, set the data type of the In2 Inport block to `sharedType_int8`.

On the **Parameters** tab, update the block diagram. The data table now contains a row that represents the parameter object, `myGainParam`.

Use the **Data Type** column to set the data type of the parameter object to `sharedType_int8`.

Alternatively, to configure the block and the object, use these commands at the command prompt:

```
myGainParam.DataType = 'sharedType_int8';
set_param('ex_paramdt_contexts/In2', 'OutDataTypeStr', 'sharedType_int8')
```

The parameter object and the signal use the data type `int8`. To change this data type, adjust the properties of the data type object `sharedType_int8`.

### Generate and Inspect Code

Generate code from the model.

```
rtwbuild('ex_paramdt_contexts')

Starting build procedure for model: ex_paramdt_contexts
Successful completion of build procedure for model: ex_paramdt_contexts
```

The generated file `ex_paramdt_contexts.c` defines the global variable `myGainParam` by using the data type `int8_T`, which corresponds to the data type `int8` in Simulink.

```
file = fullfile('ex_paramdt_contexts_grt_rtw', 'ex_paramdt_contexts.c');
rtwdemodbtype(file, '/* Exported block parameters */', 'int8_T myGainParam = 3;', 1, 1)

/* Exported block parameters */
int8_T myGainParam = 3; /* Variable: myGainParam
```

The generated code algorithm in the model `step` function uses `myGainParam` to calculate the outputs of the two Gain blocks. In the case of the Gain block whose input signal uses the data type `single`, the code algorithm casts `myGainParam` to the data type `real32_T`, which corresponds to the data type `single` in Simulink.

```
rtwdemodbtype(file, '/* Model step function */', ...
 '/* Model initialize function */', 1, 0)
```

```
/* Model step function */
void ex_paramdt_contexts_step(void)
{
 /* Outport: '<Root>/Out1' incorporates:
 * Gain: '<Root>/Gain - single'
 * Inport: '<Root>/In1'
 */
 ex_paramdt_contexts_Y.Out1 = (real32_T)myGainParam * ex_paramdt_contexts_U.In1;

 /* Outport: '<Root>/Out2' incorporates:
 * Gain: '<Root>/Gain - int8'
 * Inport: '<Root>/In2'
 */
 ex_paramdt_contexts_Y.Out2 = (int8_T)(myGainParam * ex_paramdt_contexts_U.In2);
}
```

## Organize Data into Structures in Generated Code

In C code, you use structures (`struct`) to store data in contiguous locations in memory. You can organize data, such as signals and states, by using meaningful names. Each structure acts as a namespace, so you can reuse a name to designate multiple data items. Like arrays, with structures, you can write code that efficiently transfers and operates on large amounts of data by using pointers.

By default, the code generator aggregates data into standard structures (see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50). To control the characteristics of these structures or to override this default behavior by creating different structures, use the information in the table.

| Goal                                                                                                                                                      | Technique                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| Control the characteristics of the standard data structures. For example, specify the names of the structure types, structure variables, and field names. | With Embedded Coder, see “Control Characteristics of Data Structures (Embedded Coder)” on page 22-27.       |
| Control the placement of the structures in memory, for example, by inserting pragmas or other code decorations.                                           | With Embedded Coder, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 30-2. |

| Goal                                                                                                                                                                                                          | Technique                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <p>Reduce the number of arguments (formal parameters) for generated functions.</p> | <ul style="list-style-type: none"> <li>• To reduce the number of arguments for the entry-point functions of the model from which you generate code, such as <i>model_step</i>, see “Reduce Number of Arguments by Using Structures” on page 22-47.</li> <li>• To reduce the number of arguments for the entry-point functions of a referenced model, in the referenced model:               <ul style="list-style-type: none"> <li>• Configure root-level Inport and Outport blocks to appear in the code as structure fields. Replace multiple such blocks with a single block that you configure as a nonvirtual bus signal. With this technique, you have the greatest control over the structure characteristics. As you add blocks to the model, you must manually modify the bus definitions. See “Nonvirtual Buses and Parameter Structures” on page 22-183.</li> <li>• Organize model arguments into a custom structure (see “Specify Instance-Specific Parameter Values for Reusable Referenced Model” on page 22-142).</li> </ul> </li> <li>• To reduce the number of arguments for the entry-point functions of a masked, reentrant subsystem, aggregate mask parameters into a custom structure.</li> </ul> |
| <p>Organize lookup table data into a structure.</p>                                | <p>Use <code>Simulink.LookupTable</code> and <code>Simulink.Breakpoint</code> objects. See <code>Simulink.LookupTable</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Techniques to Create Structures

To create structures in the generated code, you can use any of these techniques:

- Apply a structured storage class to categories of data by using the Code Mapping Editor. As you add blocks and signals to a model, new data elements acquire this storage class by default.
- Apply a structured storage class, such as the built-in custom storage class `Struct`, directly to individual data items by using the Model Data Editor.
- Create custom nonvirtual buses and parameter structures.

To decide which techniques to use, use the information in the table.

| Capability                                                                                                   | Default Application of Structured Storage Class | Direct Application of Structured Storage Class | Nonvirtual Buses and Parameter Structures                                                              |
|--------------------------------------------------------------------------------------------------------------|-------------------------------------------------|------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| Aggregate new data items into a structure by default                                                         | Yes                                             | No                                             | No                                                                                                     |
| Prevent elimination of the target data by optimizations (specify that the data appear in the generated code) | No                                              | Yes                                            | Only if you directly apply a storage class such as <code>ExportedGlobal</code> to the bus or structure |
| Aggregate data into a structure without changing the appearance of the block diagram                         | Yes                                             | Yes                                            | No                                                                                                     |

| <b>Capability</b>                                                            | <b>Default Application of Structured Storage Class</b>                                | <b>Direct Application of Structured Storage Class</b>                    | <b>Nonvirtual Buses and Parameter Structures</b> |
|------------------------------------------------------------------------------|---------------------------------------------------------------------------------------|--------------------------------------------------------------------------|--------------------------------------------------|
| Place signal, state, and parameter data in the same structure                | No                                                                                    | Yes                                                                      | No                                               |
| Include state data in a structure                                            | Yes                                                                                   | Yes                                                                      | No                                               |
| Organize structures into nested structures                                   | No                                                                                    | No                                                                       | Yes                                              |
| Organize structures into an array of structures                              | No                                                                                    | No                                                                       | Yes                                              |
| Control name of structure type                                               | Yes                                                                                   | Yes, but the type name derives from the variable name, which you specify | Yes                                              |
| Create a structure to reduce the number of arguments in a generated function | Yes, but you must create your own storage class by using an Embedded Coder Dictionary | No                                                                       | Yes                                              |
| Requires Embedded Coder                                                      | Yes                                                                                   | Yes                                                                      | No                                               |

## **Default Application of Structured Storage Class**

You can apply a default storage class to a category of model data. As you add blocks and signals to the model, the associated data acquire the default storage class that you specify. To aggregate new data into structures by default, you can apply structured storage classes. You must use the built-in storage classes `ParamStruct` and `SignalStruct` or create your own storage class by using an Embedded Coder Dictionary.

You cannot use default application to aggregate global data stores or global parameters (parameter objects that you store in the base workspace or a data dictionary).

To apply default storage classes, use the Code Mapping Editor. In a model window, select **Code > C/C++ Code > Configure Model in Code Perspective**. Then, under **Code Mappings > Data Defaults**, apply storage classes by using the **Storage Class** column.

For more information about the Code Mapping Editor, see “Configure Default Code Generation for Categories of Model Data and Functions” on page 21-7. To create your own storage class by using an Embedded Coder Dictionary, see “Create Code Definitions for Use as Default Code Generation Settings” on page 20-2.

## Direct Application of Structured Storage Class

You can apply a structured storage class to individual data items. The direct application prevents code generation optimizations, such as **Default parameter behavior** and **Signal storage reuse**, from eliminating each data item from the generated code. The direct application also overrides the default storage classes that you specify with **Code Mappings > Data Defaults**.

To directly apply a storage class, use the Model Data Editor (**View > Model Data Editor**). Set **Change view** to Code and apply the storage class by using the **Storage Class** column.

For an example that shows how to use `Struct`, see “Organize Parameter Data into a Structure by Using the Struct Custom Storage Class” on page 26-23. For more information about applying storage classes, see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19.

## Nonvirtual Buses and Parameter Structures

- To create a nonvirtual bus signal, use a Bus Creator block to organize multiple signal lines into a single bus, or configure an Inport block or Outport block as a nonvirtual bus. You must create a `Simulink.Bus` object that represents the structure type. For an example, see “Structures of Signals” on page 22-187. For general information about nonvirtual buses, see “Getting Started with Buses” (Simulink).
- To create a parameter structure, use MATLAB commands or the Variable Editor to organize the values of multiple block parameters into a MATLAB structure. Optionally, create a `Simulink.Bus` object so that you can control the name of the structure type and other characteristics such as the data type and dimensions of each field. For an example, see “Structures of Parameters” on page 22-184. For general information about parameter structures, see “Organize Related Block Parameter Definitions in Structures” (Simulink).

## Structures of Parameters

Create a structure in the generated code. The structure stores parameter data.

### C Construct

```
typedef struct {
 double G1;
 double G2;
} myStructType;

myStructType myStruct = {
 2.0,
 -2.0
};
```

### Procedure

Open the example model `rtwdemo_paraminline`.

`rtwdemo_paraminline`

Select **View > Model Data Editor**.

In the Model Data Editor, select the **Parameters** tab.

In the model, click the Gain block labeled G1.

In the Model Data Editor, use the **Value** column to set the value of the **Gain** parameter to `myStruct.G1`.

Use the Model Data Editor to set the value of the **Gain** parameter in the G2 block to `myStruct.G2`.

Next to `myStruct.G2`, click the action button (with three vertical dots) and select **Create**.

In the Create New Data dialog box, set **Value** to `Simulink.Parameter(struct)` and click **Create**. A `Simulink.Parameter` object named `myStruct` appears in the base workspace.

In the `Simulink.Parameter` property dialog box, next to the **Value** property, click the action button and select **Open Variable Editor**.

In the Variable Editor, right-click the white space under the **Field** column and select **New**. Name the new structure field G1. Use the **Value** column to set the value of the field to 2.

Use the Variable Editor to add a field G2 whose value is -2 and then close the Variable Editor.

In the `Simulink.Parameter` property dialog box, set **Storage class** to `ExportedGlobal`. With this setting, the structure `myStruct` appears in the generated code as a global variable.

Alternatively, use these commands to configure the blocks and create `myStruct`.

```
rtwdemo_paraminline
set_param('rtwdemo_paraminline/G1','Gain','myStruct.G1')
set_param('rtwdemo_paraminline/G2','Gain','myStruct.G2')

myStruct.G1 = 2;
myStruct.G2 = -2;
myStruct = Simulink.Parameter(myStruct);
myStruct.CoderInfo.StorageClass = 'ExportedGlobal';
```

## Results

Generate code from the model.

```
rtwbuild('rtwdemo_paraminline')

Starting build procedure for model: rtwdemo_paraminline
Successful completion of build procedure for model: rtwdemo_paraminline
```

The generated header file `rtwdemo_paraminline_types.h` defines a structure type with a random name.

```
file = fullfile('rtwdemo_paraminline_grt_rtw',...
 'rtwdemo_paraminline_types.h');
rtwdemodbtype(file,'typedef struct {','} struct_6h72eH5WFuEIyQr5YrdGuB;',...
 1,1)
```

```
typedef struct {
 real_T G1;
 real_T G2;
} struct_6h72eH5WFuEIyQr5YrdGuB;
```

The source file `rtwdemo_paraminline.c` defines and initializes the structure variable `myStruct`.

```
file = fullfile('rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline.c');
rtwdemodbtype(file,'struct_6h72eH5WFuEIyQr5YrdGuB myStruct',...
 '/* Variable: myStruct',1,1)
```

```
struct_6h72eH5WFuEIyQr5YrdGuB myStruct = {
 2.0,
 -2.0
}; /* Variable: myStruct
```

## Specify Name of Structure Type

Optionally, specify a name to use for the structure type definition (`struct`).

At the command prompt, use the function `Simulink.Bus.createObject` to create a `Simulink.Bus` object that represents the structure type.

```
Simulink.Bus.createObject(myStruct.Value);
```

The default name of the object is `slBus1`. Change the name by copying the object into a new MATLAB variable.

```
myStructType = copy(slBus1);
```

In the Model Data Editor, click the **Show/refresh additional information** button.

In the data table, find the row that corresponds to `myStruct`. Use the **Data Type** column to set the data type of `myStruct` to `Bus: myStructType`.

Alternatively, at the command prompt, use this command to set the data type of `myStruct`.

```
myStruct.DataType = 'Bus: myStructType';
```

Generate code from the model.

```
rtwbuild('rtwdemo_paraminline')
```

```
Starting build procedure for model: rtwdemo_paraminline
Successful completion of build procedure for model: rtwdemo_paraminline
```

The code generates the definition of the structure type `myStructType` and uses this type to define the global variable `myStruct`.

```
rtwdemodbtype(file, 'myStructType myStruct = {' , /* Variable: myStruct' , ...
1,1)
```

```
myStructType myStruct = {
 2.0,
 -2.0
} ; /* Variable: myStruct
```

### Structures of Signals

This example shows how to create a structure of signal data in the generated code.

#### C Construct

```
typedef struct {
 double signal1;
 double signal2;
 double signal3;
} my_signals_type;
```

## Procedure

To represent a structure type in a model, create a `Simulink.Bus` object. Use the object as the data type of bus signals in your model.

Create the `ex_signal_struct` model with Gain blocks, a Bus Creator block, and a Unit Delay block. The Gain and Unit Delay blocks make the structure more identifiable in the generated code.

To configure the Bus Creator block to accept three inputs, in the block dialog box, set **Number of inputs** to 3.

In the model, select **Edit > Bus Editor**.

Use the Bus Editor to create a `Simulink.Bus` object named `my_signals_type` that contains three signal elements: `signal1`, `signal2`, and `signal3`. To create bus objects with the Bus Editor, see “Create Bus Objects with the Bus Editor” (Simulink).

The screenshot shows the Simulink Bus Editor interface. On the left, a tree view shows the workspace structure with 'Base Workspace' and 'my\_signals\_type' (containing 'signal1', 'signal2', and 'signal3'). The main area displays a table of the bus elements:

| Name      | Data Type | Complexity | Dimensions |
|-----------|-----------|------------|------------|
| — signal1 | double    | real       | 1          |
| — signal2 | double    | real       | 1          |
| — signal3 | double    | real       | 1          |

On the right, the 'Properties' section shows the 'Name' field set to 'my\_signals\_type'.

This bus object represents the structure type that you want the generated code to use.

In the Bus Creator block dialog box, set **Output data type** to `Bus: my_signals_type`.

Select **Output as nonvirtual bus**. Click **OK**. A nonvirtual bus appears in the generated code as a structure.

In the model, select **View > Model Data Editor**.

In the Model Data Editor, on the **Signals** tab, from the **Change view** drop-down list, select `Code`.

In the model, click the output signal of the Bus Creator block.

In the Model Data Editor, for the output of the Bus Creator block, set **Name** to `sig_struct_var`.

Set **Storage Class** to `ExportedGlobal`. With this setting, the output of the Bus Creator block appears in the generated code as a separate global structure variable named `sig_struct_var`.

Generate code from the model.

## Results

The generated header file `ex_signal_struct_types.h` defines the structure type `my_signals_type`.

```
typedef struct {
 real_T signal1;
 real_T signal2;
 real_T signal3;
} my_signals_type;
```

The source file `ex_signal_struct.c` allocates memory for the global variable `sig_struct_var`, which represents the output of the Bus Creator block.

```
/* Exported block signals */
my_signals_type sig_struct_var; /* '<Root>/Bus Creator' */
```

In the same file, in the model `step` function, the algorithm accesses `sig_struct_var` and the fields of `sig_struct_var`.

### **Nested Structures of Signals**

You can create nested structures of signal data in the generated code.

#### **C Construct**

```
typedef struct {
 double signal1;
 double signal2;
 double signal3;
} B_struct_type;

typedef struct {
 double signal1;
 double signal2;
} C_struct_type;

typedef struct {
 B_struct_type subStruct_B;
 C_struct_type subStruct_C;
} A_struct_type;
```

#### **Procedure**

To represent a structure type in a model, create a `Simulink.Bus` object. Use the object as the data type of bus signals in your model.

To nest a structure inside another structure, use a bus object as the data type of a signal element in another bus object.

Create the `ex_signal_nested_struct` model with Gain blocks, Bus Creator blocks, and a Unit Delay block. The Gain and Unit Delay blocks make the structure more identifiable in the generated code.

To configure a Bus Creator block to accept three inputs, in the block dialog box, set **Number of inputs** to 3.

In the model, select **Edit > Bus Editor**.

Use the Bus Editor to create a `Simulink.Bus` object named `A_struct_type` that contains two signal elements: `subStruct_B` and `subStruct_C`. To create bus objects with the Bus Editor, see “Create Bus Objects with the Bus Editor” (Simulink). This bus object represents the top-level structure type that you want the generated code to use.

For the `subStruct_B` element, set **Data Type** to `Bus: B_struct_type`. Use a similar type name for `subStruct_C`.

Each signal element in `A_struct_type` uses another bus object as a data type. Now, these elements represent substructures.

Use the Bus Editor to create the `Simulink.Bus` objects `B_struct_type` (with three signal elements) and `C_struct_type` (with two signal elements).

In the dialog box of the Bus Creator block that collects the three Gain signals, set **Output data type** to Bus: `B_struct_type`. Click **Apply**.

Select **Output as nonvirtual bus** and click **OK**.

In the dialog box of the other subordinate Bus Creator block, set **Output data type** to Bus: `C_struct_type` and select **Output as nonvirtual bus**. Click **OK**.

In the last Bus Creator block dialog box, set **Output data type** to Bus: `A_struct_type` and select **Output as nonvirtual bus**. Click **OK**.

In the model, select **View > Model Data Editor**.

In the Model Data Editor, on the **Signals** tab, from the **Change view** drop-down list, select **Code**.

In the model, click the output signal of the `A_struct_type` Bus Creator block, which feeds the Unit Delay block.

In the Model Data Editor, for the output of the Bus Creator block, set **Name** to `sig_struct_var`.

Set **Storage Class** to `ExportedGlobal`. With this setting, the output of the Bus Creator block appears in the generated code as a separate global structure variable named `sig_struct_var`.

Generate code from the model.

## Results

The generated header file `ex_signal_nested_struct_types.h` defines the structure types. Each structure type corresponds to a `Simulink.Bus` object.

```
typedef struct {
 real_T signal1;
 real_T signal2;
 real_T signal3;
} B_struct_type;

typedef struct {
 real_T signal1;
 real_T signal2;
} C_struct_type;

typedef struct {
 B_struct_type subStruct_B;
 C_struct_type subStruct_C;
} A_struct_type;
```

The generated source file `ex_signal_nested_struct.c` allocates memory for the global structure variable `sig_struct_var`. By default, the name of the `A_struct_type` Bus Creator block is `Bus Creator2`.

```
/* Exported block signals */
A_struct_type sig_struct_var; /* '<Root>/Bus Creator2' */
```

In the same file, in the model `step` function, the algorithm accesses `sig_struct_var` and the fields of `sig_struct_var`.

## Combine Techniques to Work Around Limitations

To work around some of the limitations of each technique, you can combine structured custom storage classes with nonvirtual buses and parameter structures. For example, you can:

- Include a structure of signal data and a structure of parameter data in the same parent structure.
- Nest structures while aggregating new data by default.

In the generated code, a flat parent structure, which corresponds to the structured custom storage class, contains substructures, which correspond to each bus and parameter structure. Choose one of these combined techniques:

- Apply the structured custom storage class directly to each bus and parameter structure. For example, set the storage class of two nonvirtual bus signals to `Struct`. Each bus appears in the generated code as a field (substructure) of a single structure.
- Leave the storage class of each bus and parameter structure at the default setting, `Auto`, or at `Model default`, which prevents code generation optimizations from eliminating the bus or parameter structure. Then, configure default storage classes such that signal data and parameter data use the structured custom storage class by default.

## Arrays of Structures

You can further package multiple consistent bus signals or parameter structures into an array. The array of buses or parameter structures appears in the generated code as an array of structures. To create arrays of buses, see “Combine Buses into an Array of Buses” (Simulink). To create arrays of parameter structures, see “Group Multiple Parameter Structures into an Array” (Simulink).

## Structure Padding

By default, the code generator does not explicitly add padding fields to structure types. Structure types can appear in the generated code through, for example, the standard data

structures (see “Standard Data Structures in the Generated Code” (Simulink Coder)), `Simulink.Bus` objects, and parameter structures that you use in a model.

However, when you use a code replacement library with Embedded Coder, you can specify data alignment (including structure padding) as part of the replacement library. For more information, see “Provide Data Alignment Specifications for Compilers” on page 54-138.

## Limitations

- With built-in Simulink Coder and Embedded Coder features, you cannot generate or use a custom structure that contains a field whose value is a pointer. You can do so manually by creating an advanced custom storage class and writing accompanying TLC code (see “Finely Control Data Representation by Writing TLC Code for a Custom Storage Class” on page 26-39).
- You cannot use the built-in storage class `Struct`, or any structured storage class that you create with the Custom Storage Class Designer (you set the storage class property **Type** to `FlatStructure`), to set data defaults in the Code Mapping Editor.

## Switch Between Sets of Parameter Values During Simulation and Code Execution

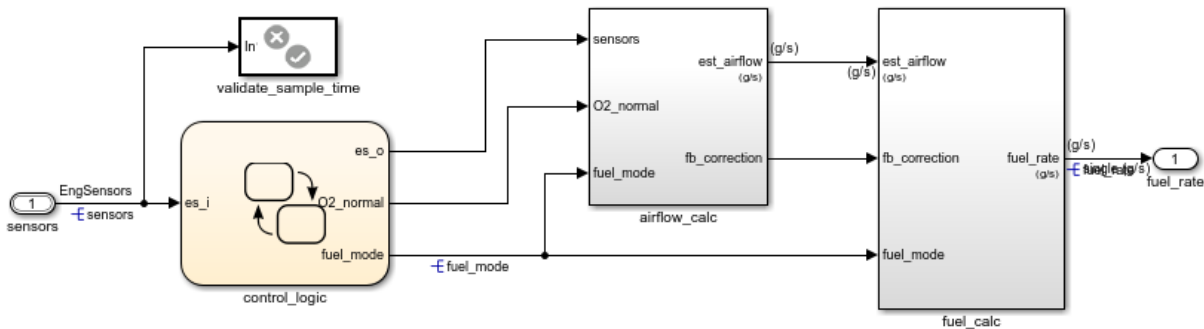

To store multiple independent sets of values for the same block parameters, you can use an array of structures. To switch between the parameter sets, create a variable that acts as an index into the array, and change the value of the variable. You can change the value of the variable during simulation and, if the variable is tunable, during execution of the generated code.

### Explore Example Model

Open this example model:

```
open_system('sldemo_fuelsys_dd_controller')
```

### Fuel Rate Controller

Copyright 1990-2017 The MathWorks, Inc.

This model represents the fueling system of a gasoline engine. The output of the model is the rate of fuel flow to the engine.

Navigate to the `switchable_compensation` nested subsystem.

```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/', ...
 'switchable_compensation'])
```

## Loop Compensation and Filtering

This subsystem corrects and filters noise out of the fuel rate signal. The subsystem uses different filter coefficients based on the fueling mode, which the control logic changes based on sensor failures in the engine. For example, the control algorithm activates the `low_mode` subsystem during normal operation. It activates the `rich_mode` subsystem in response to sensor failure.

Open the `low_mode` subsystem.

```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/',...
 'switchable_compensation/low_mode'])
```

The Discrete Filter block filters the fuel rate signal. In the block dialog box, the **Numerator** parameter sets the numerator coefficients of the filter.

The sibling subsystem `rich_mode` also contains a Discrete Filter block, which uses different coefficients.

Update the model diagram to display the signal data types. The input and output signals of the block use the single-precision, floating-point data type `single`.

In the lower-left corner of the model, click the data dictionary badge. The data dictionary for this model, `sldemo_fuelsys_dd_controller.sldd`, opens in the Model Explorer.

In the Model Explorer **Model Hierarchy** pane, select the **Design Data** node.

In the **Contents** pane, view the properties of the `Simulink.NumericType` objects, such as `s16En15`. All of these objects currently represent the single-precision, floating-point data type `single`. The model uses these objects to set signal data types, including the input and output signals of the Discrete Filter blocks.

Suppose that during simulation and execution of the generated code, you want each of these subsystems to switch between different numerator coefficients based on a variable whose value you control.

### Store Parameter Values in Array of Structures

Store the existing set of numerator coefficients in a `Simulink.Parameter` object whose value is a structure. Each field of the structure stores the coefficients for one of the Discrete Filter blocks.

```

lowBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/'...
 'switchable_compensation/low_mode/Discrete Filter'];
richBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/'...
 'switchable_compensation/rich_mode/Discrete Filter'];
params.lowNumerator = eval(get_param(lowBlock, 'Numerator'));
params.richNumerator = eval(get_param(richBlock, 'Numerator'));
params = Simulink.Parameter(params);

```

Copy the value of `params` into a temporary variable. Modify the field values in this temporary structure, and assign the modified structure as the second element of `params`.

```

temp = params.Value;
temp.lowNumerator = params.Value.lowNumerator * 2;
temp.richNumerator = params.Value.richNumerator * 2;
params.Value(2) = temp;
clear temp

```

The value of `params` is an array of two structures. Each structure stores one set of filter coefficients.

### Create Variable to Switch Between Parameter Sets

Create a `Simulink.Parameter` object named `Ctrl`.

```

Ctrl = Simulink.Parameter(2);
Ctrl.DataType = 'uint8';

```

In the `low_mode` subsystem, in the Discrete Filter block dialog box, set the **Numerator** parameter to the expression `params(Ctrl).lowNumerator`.

```

set_param(lowBlock, 'Numerator', 'params(Ctrl).lowNumerator');

```

In the Discrete Filter block in the `rich_mode` subsystem, set the value of the **Numerator** parameter to `params(Ctrl).richNumerator`.

```

set_param(richBlock, 'Numerator', 'params(Ctrl).richNumerator');

```

The expressions select one of the structures in `params` by using the variable `Ctrl`. The expressions then dereference one of the fields in the structure. The field value sets the values of the numerator coefficients.

To switch between the sets of coefficients, you change the value of `Ctrl` to the corresponding index in the array of structures.

### Use Bus Object as Data Type of Array of Structures

Optionally, create a `Simulink.Bus` object to use as the data type of the array of structures. You can:

- Control the shape of the structures.
- For each field, control characteristics such as data type and physical units.
- Control the name of the `struct` type in the generated code.

Use the function `Simulink.Bus.createObject` to create the object and rename the object as `paramsType`.

```
Simulink.Bus.createObject(params.Value)
paramsType = slBus1;
clear slBus1
```

You can use the `Simulink.NumericType` objects from the data dictionary to control the data types of the structure fields. In the bus object, use the name of a data type object to set the `DataType` property of each element.

```
paramsType.Elements(1).DataType = 's16En15';
paramsType.Elements(2).DataType = 's16En7';
```

Use the bus object as the data type of the array of structures.

```
params.DataType = 'Bus: paramsType';
```

### Use Enumerated Type for Switching Variable

Optionally, use an enumerated type as the data type of the switching variable. You can associate each of the parameter sets with a meaningful name and restrict the allowed values of the switching variable.

Create an enumerated type named `FilterCoeffs`. Create an enumeration member for each of the structures in `params`. Set the underlying integer value of each enumeration member to the corresponding index in `params`.

```
Simulink.defineIntEnumType('FilterCoeffs', {'Weak', 'Aggressive'}, [1 2])
```

Use the enumerated type as the data type of the switching variable. Set the value of the variable to `Aggressive`, which corresponds to the index 2.

```
Ctrl.Value = FilterCoeffs.Aggressive;
```

## Add New Objects to Data Dictionary

Add the objects that you created to the data dictionary  
`sldemo_fuelsys_dd_controller.sldd`.

```
dictObj = Simulink.data.dictionary.open('sldemo_fuelsys_dd_controller.sldd');
sectObj = getSection(dictObj, 'Design Data');
addEntry(sectObj, 'Ctrl', Ctrl)
addEntry(sectObj, 'params', params)
addEntry(sectObj, 'paramsType', paramsType)
```

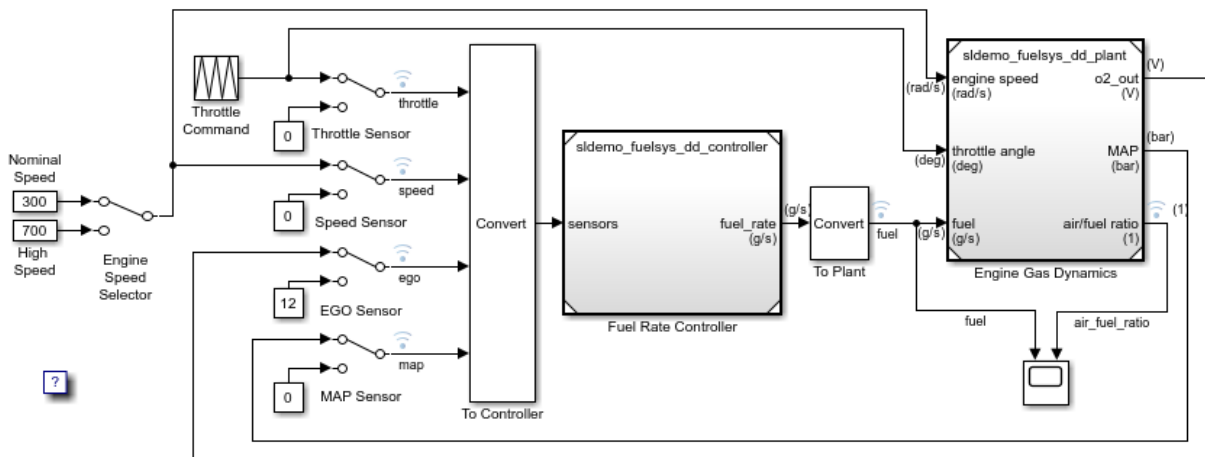

You can also store enumerated types in data dictionaries. However, you cannot import the enumerated type in this case because you cannot save changes to `sldemo_fuelsys_dd_controller.sldd`. For more information about storing enumerated types in data dictionaries, see “Enumerations in Data Dictionary” (Simulink).

## Switch Between Parameter Sets During Simulation

Open the example model `sldemo_fuelsys_dd`, which references the controller model `sldemo_fuelsys_dd_controller`.

```
open_system('sldemo_fuelsys_dd')
```

## Fault-Tolerant Fuel Control System

The sensor switches simulate any combination of sensor failures.  
 The Engine Speed Selector switch simulates different engine speeds (rad/s).

Copyright 1990-2017 The MathWorks, Inc.

Set the simulation stop time to `Inf` so that you can interact with the model during simulation.

Begin a simulation run and open the Scope block dialog box. The scope shows that the fuel flow rate (the `fuel` signal) oscillates with significant amplitude during normal operation of the engine.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. Set the value of `Ctrl` to `FilterCoeffs.Weak`.

Update the `sldemo_fuelsys_dd` model diagram. The scope shows that the amplitude of the fuel rate oscillations decreases due to the less aggressive filter coefficients.

Stop the simulation.

### Generate and Inspect Code

If you have Simulink Coder software, you can generate code that enables you to switch between the parameter sets during code execution.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. In the **Contents** pane, set **Column View** to **Storage Class**.

Use the **StorageClass** column to apply the storage class `ExportedGlobal` to `params` so that the array of structures appears as a tunable global variable in the generated code. Apply the same storage class to `Ctrl` so that you can change the value of the switching variable during code execution.

Alternatively, to configure the objects, use these commands:

```
tempEntryObj = getEntry(sectObj, 'params');
params = getValue(tempEntryObj);
params.StorageClass = 'ExportedGlobal';
setValue(tempEntryObj, params);
```

```
tempEntryObj = getEntry(sectObj, 'Ctrl');
Ctrl = getValue(tempEntryObj);
Ctrl.StorageClass = 'ExportedGlobal';
setValue(tempEntryObj, Ctrl);
```

Generate code from the controller model.

```
rtwbuild('sldemo_fuelsys_dd_controller')

Starting build procedure for model: sldemo_fuelsys_dd_controller
Successful completion of code generation for model: sldemo_fuelsys_dd_controller
```

In the code generation report, view the header file `sldemo_fuelsys_dd_controller_types.h`. The code defines the enumerated data type `FilterCoeffs`.

```
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw',...
 'sldemo_fuelsys_dd_controller_types.h');
rtwdemodbtype(file, '#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_',...
 '/* Forward declaration for rtModel */',1,0)
```

```
#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_
#define DEFINED_TYPEDEF_FOR_FilterCoeffs_

typedef enum {
 Weak = 1, /* Default value */
 Aggressive
} FilterCoeffs;

#endif
```

The code also defines the structure type `paramsType`, which corresponds to the `Simulink.Bus` object. The fields use the single-precision, floating-point data type from the model.

```
rtwdemodbtype(file, '#ifndef DEFINED_TYPEDEF_FOR_paramsType_',...
 '#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_',1,0)
```

```
#ifndef DEFINED_TYPEDEF_FOR_paramsType_
#define DEFINED_TYPEDEF_FOR_paramsType_

typedef struct {
 real32_T lowNumerator[2];
 real32_T richNumerator[2];
} paramsType;

#endif
```

View the source file `sldemo_fuelsys_dd_controller.c`. The code uses the enumerated type to define the switching variable `Ctrl`.

```
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw',...
 'sldemo_fuelsys_dd_controller.c');
rtwdemodbtype(file,'FilterCoeffs Ctrl = Aggressive;',...
 '/* Block signals (default storage) */',1,0)

FilterCoeffs Ctrl = Aggressive; /* Variable: Ctrl
 * Referenced by:
 * '<S12>/Discrete Filter'
 * '<S13>/Discrete Filter'
 */
```

The code also defines the array of structures `params`.

```
rtwdemodbtype(file,'/* Exported block parameters */',...
 '/* Variable: params',1,1)

/* Exported block parameters */
paramsType params[2] = { {
 { 8.7696F, -8.5104F },

 { 0.0F, 0.2592F }
}, { { 17.5392F, -17.0208F },

 { 0.0F, 0.5184F }
} } ; /* Variable: params
```

The code algorithm in the model `step` function uses the switching variable to index into the array of structures.

To switch between the parameter sets stored in the array of structures, change the value of `Ctrl` during code execution.

## Design Data Interface by Configuring Inport and Output Blocks

The data interface of a model is the means by which the model exchanges data (for example, signal values) with other, external models or systems. Customize the data interface of a model to:

- Enable integration of the generated code with your own code.
- Improve traceability and readability of the code.

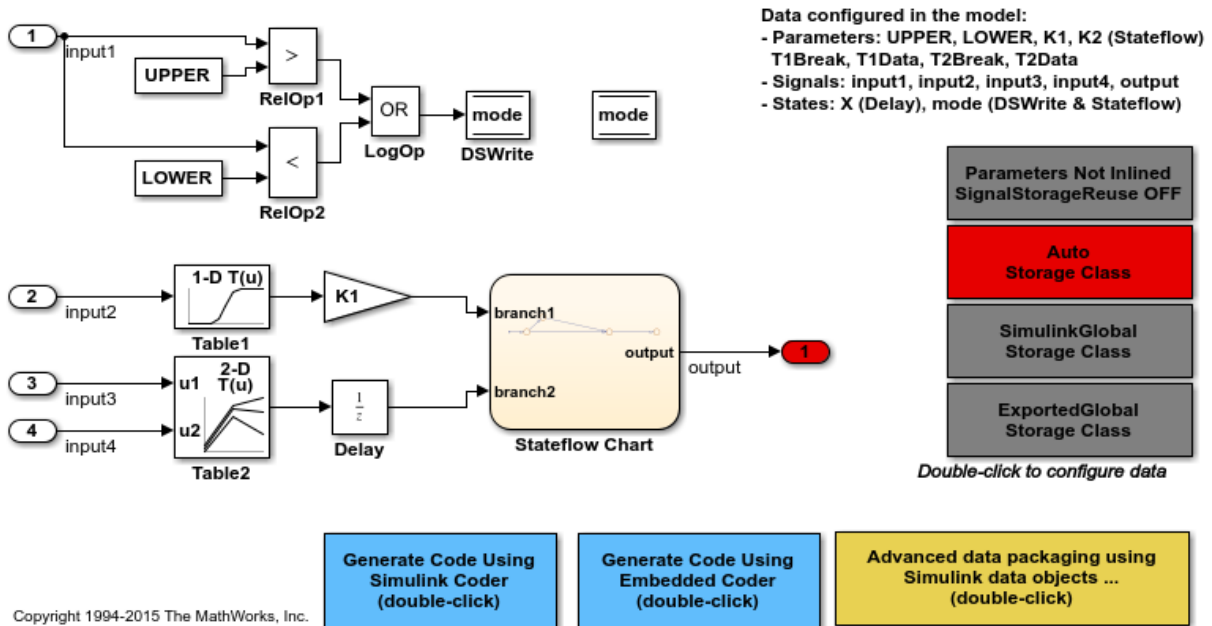

At the top level of a model, Inport and Output blocks represent the input and output signals of the model. To customize the data interface in the generated code, configure these blocks. Early in the design process, when a model can contain unconnected Inport and Output blocks, use this technique to specify the interface before developing the internal algorithm.

When you apply storage classes to Inport and Output blocks, each block appears in the generated code as a field of a global structure or as a separate global variable that the generated algorithm references directly. If you have Embedded Coder, you can use function prototype control instead of storage classes to pass data into and out of the model `step` function as formal parameters. See “Customize Generated C Function Interfaces” on page 29-2.

### Design Data Interface

Open the example model `rtwdemo_basicsc`.

```
open_system('rtwdemo_basicsc')
```

Copyright 1994-2015 The MathWorks, Inc.

Configure the model to show the generated names of blocks.

```
set_param('rtwdemo_basicsc', 'HideAutomaticNames', 'off')
```

In the model, select **View > Model Data Editor**.

In the Model Data Editor, select the **Inports/Outports** tab. Each row in the table represents an Outport block or a signal that exits an Inport block.

Name the signal data that the Outport block Out1 represents. Set **Signal Name** to `output_sig`.

For each of the signals that exit the Inport blocks, set **Data Type** to `single` or to a different data type. Due to the data type inheritance settings that the other blocks in the model use by default, downstream signals in the rest of the model use the same or a similar data type.

Optionally, configure other design attributes such as **Min** and **Max** (minimum and maximum values).

Set the **Change View** drop-down list to Code.

For the Outport block and all of the Inport blocks, set **Storage Class** to ExportedGlobal. To configure all of the blocks at once, select all of the rows in the table.

To configure the blocks and signals, you can use these commands at the command prompt.

```
portHandles = get_param('rtwdemo_basicsc/In1','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','ExportedGlobal');

portHandles = get_param('rtwdemo_basicsc/In2','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','ExportedGlobal');

portHandles = get_param('rtwdemo_basicsc/In3','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','ExportedGlobal');

portHandles = get_param('rtwdemo_basicsc/In4','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','ExportedGlobal');

set_param('rtwdemo_basicsc/Out1','SignalName','output_sig',...
 'StorageClass','ExportedGlobal')
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc');

Starting build procedure for model: rtwdemo_basicsc
Successful completion of build procedure for model: rtwdemo_basicsc
```

View the generated file `rtwdemo_basicsc.c`. Because you applied the storage class `ExportedGlobal` to the Inport and Outport blocks, the code creates separate global variables that represent the inputs and the output.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'/* Exported block signals */','real32_T output_sig;',1,1)

/* Exported block signals */
real32_T input1; /* '<Root>/In1' */
```

```

real32_T input2; /* '<Root>/In2' */
real32_T input3; /* '<Root>/In3' */
real32_T input4; /* '<Root>/In4' */
real32_T output_sig; /* '<Root>/Out1' */

```

The generated algorithm in the model `step` function directly references these global variables to calculate and store the output signal value, `output_sig`.

While you use the Model Data Editor to configure the interface of a system, consider using the interface display to view the system inputs and outputs (Inport and Output blocks) at a high level. See “Configure Data Interface for Component” (Simulink).

### Reduce Manual Data Entry by Configuring Default Storage Class (Embedded Coder)

If you have Embedded Coder, you can configure a default storage class for Inport blocks and Output blocks. As you add such blocks to the model, they acquire the storage class that you specify.

In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`.

In the model, select **Code > C/C++ Code > Configure Model in Code Perspective**.

Underneath the block diagram, under **Code Mappings > Data Defaults**, for the **Inports** and **Outports** rows, set **Storage Class** to `ExportedGlobal`.

Underneath the block diagram, open the Model Data Editor by clicking the **Model Data Editor** tab.

Use the Model Data Editor to set the storage class of the Inport and Output blocks to `Auto`. With this setting, the blocks acquire the default storage classes that you specified in **Code Mappings > Data Defaults**.

With `Auto`, the global variables that correspond to the Inport and Output blocks are subject to a naming rule that you specify in the model configuration parameters. By default, the naming rule adds the name of the model to the name of each variable. To remove the model name, change the value of **Configuration Parameters > Code Generation > Symbols > Global variables** from `$R$N$M` to `$N$M`. The token `$R` represents the model name.

Alternatively, to configure the data defaults and the configuration parameter, at the command prompt, use these commands:

```
set_param('rtwdemo_basicsc','SystemTargetFile','ert.tlc')

coder.mapping.create('rtwdemo_basicsc')
coder.mapping.defaults.set('rtwdemo_basicsc','Inports',...
 'StorageClass','ExportedGlobal')
coder.mapping.defaults.set('rtwdemo_basicsc','Outports',...
 'StorageClass','ExportedGlobal')

portHandles = get_param('rtwdemo_basicsc/In1','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','Auto');

portHandles = get_param('rtwdemo_basicsc/In2','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','Auto');

portHandles = get_param('rtwdemo_basicsc/In3','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','Auto');

portHandles = get_param('rtwdemo_basicsc/In4','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','Auto');

set_param('rtwdemo_basicsc/Out1','SignalName','output_sig',...
 'StorageClass','Auto')

set_param('rtwdemo_basicsc','CustomSymbolStrGlobalVar','NM')
```

### Route Signal Data to Multiple Outputs

You can route a single signal to multiple Outport blocks and apply a different storage class to each Outport. For example, use this technique to send signal data to a custom function (such as a device driver) and to a global variable that your custom algorithmic code can use:

- 1 Branch the target signal line to each Outport block.
- 2 For more efficient code, set the storage class of the target signal line to Auto (the default). Optimizations can then eliminate the signal line from the generated code.
- 3 Use the Model Data Editor to apply the custom storage class GetSet to one Outport block and ExportToFile to the other Outport block. Apply a signal name to each block.

```
open_system('ex_route_sig')
```

## Limitations

You cannot apply a storage class to an Outport block if the input to the block has a variable size. Instead, apply the storage class to the signal line.

## Generate Efficient Code for Bus Signals

| In this section...                                     |
|--------------------------------------------------------|
| “Code Efficiency for Bus Signals” on page 22-212       |
| “Set Bus Diagnostics” on page 22-213                   |
| “Optimize Virtual and Nonvirtual Buses” on page 22-213 |

In a model, you use bus signals to package multiple signals together into a single signal line. You can create virtual or nonvirtual bus signals. The representation in the generated code depends on:

- For a virtual bus, the generated code appears as if the bus did not exist.
- Generated code for a nonvirtual bus represents the bus data with a structure. When you want to trace the correspondence between the model and the code, the use of a structure in the generated code can be helpful. To generate structures using nonvirtual bus signals, see “Organize Data into Structures in Generated Code” on page 22-177.

For general information about buses, see and “Virtual and Nonvirtual Buses” (Simulink).

To generate efficient code from models that contain bus signals, eliminate unnecessary data copies by following best practices as you construct the model.

### Code Efficiency for Bus Signals

When you use buses in a model for which you intend to generate code:

- Setting bus diagnostic configuration parameters can make model development easier.
- The bus implementation techniques, and the choice of a nonvirtual or virtual bus, can influence the speed, size, and clarity of the generated code.
- Some useful bus implementation techniques are not immediately obvious.

When you work with buses, these guidelines help you to improve the results. The guidelines describe techniques to:

- Simplify the layout of the model.
- Increase the efficiency of generated code.

- Define data structures for function (subsystem) interfaces.
- Define data structures that match existing data structures in external C code.

There are some trade-offs among speed, size, and clarity. For example, the code for nonvirtual buses is easier to read because the buses appear in the code as structures, but the code for virtual buses is faster because virtual buses do not require copying signal data. Apply some of the guidelines based on where you are in the application development process.

## Set Bus Diagnostics

Simulink provides diagnostics that you can use to optimize bus usage. Set the following values on the **Configuration Parameters > Diagnostics > Connectivity** pane.

| Buses                                        |                 |
|----------------------------------------------|-----------------|
| Unspecified bus object at root Output block: | warning         |
| Element name mismatch:                       | warning         |
| Mux blocks used to create bus signals:       | error           |
| Bus signal treated as vector:                | warning         |
| Non-bus signals treated as bus signals:      | none            |
| Repair bus selections:                       | Warn and repair |

## Optimize Virtual and Nonvirtual Buses

Virtual buses are graphical conveniences that do not affect generated code. As a result, the code generation engine is able to fully optimize the signals in the bus. Use virtual buses rather than nonvirtual buses wherever possible. You can convert between virtual and nonvirtual buses by using Signal Conversion blocks. In some cases, Simulink automatically converts a virtual bus to a nonvirtual bus when required. For example, a Stateflow chart converts an input virtual bus to a nonvirtual bus.

To bundle function-call signals, you must use a virtual bus.

You must use nonvirtual buses for:

- Nonauto storage classes

- Generating a specific structure from the bus
- Root-level Inport or Outport blocks when the bus has mixed data types

### Avoid Nonlocal Nested Buses in Nonvirtual Buses

Buses can contain subordinate buses. To generate efficient code, set the storage classes of subordinate buses to **Auto**. Setting the storage class to **Auto** eliminates:

- Allocation of redundant memory for the subordinate bus signal and for the parent bus signal
- Additional copy operations (copying data to the subordinate bus, and then copying from the subordinate bus to the final bus)

This model contains nonvirtual bus signals. The subordinate bus signals `Sub_Bus_1` and `Sub_Bus_2` use the storage class `Auto`.

The generated code algorithm efficiently assigns the input signal data to the bus signals.

```
void ex_nonvirtual_buses_step(void)
{
 Nonvirtual_In_One.SimpleBus_1.A1 = A1;
 Nonvirtual_In_One.SimpleBus_1.A2 = A2;
 Nonvirtual_In_One.SimpleBus_2.A3 = A3;
 Nonvirtual_In_One.SimpleBus_2.A4 = A4;
 Nonvirtual_In_One.A5 = A5;
}
```

## Control Signal and State Initialization in the Generated Code

To initialize signals and discrete states with custom values for simulation and code generation, you can use signal objects and block parameters. Data initialization increases application reliability and is a requirement of safety critical applications. Initializing signals for both simulation and code generation can expedite transitions between phases of Model-Based Design.

For basic information about specifying initial values for signals and discrete states in a model, see “Initialize Signals and Discrete States” (Simulink).

### Signal and State Initialization in the Generated Code

The initialization behavior for code generation is the same as that for model simulation with the following exceptions:

- RSim executables can use the **Data Import/Export** pane of the Configuration Parameters dialog box to load input values from MAT-files. GRT and ERT executables cannot load input values from MAT-files.
- The initial value for a block output signal or root level input or output signal can be overwritten by an external (calling) program.
- Setting the initial value for persistent signals is relevant if the value is used or viewed by an external application.

When you generate code, initialization statements are placed in *model.c* or *model.cpp* in the model's initialize code.

For example, consider the model `rtwdemo_sigobj_iv`.

If you create and initialize signal objects in the base workspace, the code generator places initialization code for the signals in the file `rtwdemo_sigobj_iv.c` under the `rtwdemo_sigobj_iv_initialize` function, as shown below.

```

/* Model initialize function */
void rtwdemo_sigobj_iv_initialize(void)
{
 .
 .
 .
 /* exported global signals */
 S3 = -3.0;
 S2 = -2.0;
 .
 .
 /* exported global states */
 X1 = 0.0;
 X2 = 0.0;
 .
 .
 /* external inputs */
 S1 = -4.5;
 .
 .
}

```

The following code shows the initialization code for the enabled subsystem's Unit Delay block state X1 and output signal S2.

```

void MdlStart(void) {
 .
 .
 .
 /* InitializeConditions for UnitDelay: '<S2>/Unit Delay' */
 X1 = aal;
}

```

```
/* Start for enable system: '<Root>/Enabled Subsystem (state X1 inside)' */
/* virtual outputs code */
/* (Virtual) Outport Block: '<S2>/Out1' */
S2 = aa2;
}
```

For an enabled subsystem, the initial value is also used as a reset value if the subsystem's Outport block parameter **Output when disabled** is set to **reset**. The following code from `rtwdemo_sigobj_iv.c` shows the assignment statement for `S3` as it appears in the model output function `rtwdemo_sigobj_iv_output`.

```
/* Model output function */
static void rtwdemo_sigobj_iv_output(void)
{
 .
 .
 .
/* Disable for enable system: '<Root>/Enabled Subsystem (state X1 inside)' */
/* (Virtual) Outport Block: '<S2>/Out1' */
S2 = aa2;
```

## Generate Tunable Initial Conditions

You can represent initial conditions for signals and states by creating tunable global variables in the generated code. These variables allow you to restart an application by using initial conditions that are stored in memory.

If you set **Configuration Parameters > Optimization > Default parameter behavior** to **Tunable**, initial conditions appear as tunable fields of the global parameters structure.

Whether you set **Default parameter behavior** to **Tunable** or **Inlined**, you can use a tunable parameter to specify the `InitialValue` property of a signal object or the **Initial condition** parameter of a block. For basic information about tunable parameters, see “Create Tunable Calibration Parameter in the Generated Code” (Simulink Coder).

This example shows how to use tunable parameters to specify initial conditions for signals and states.

### Explore Example Model

Open the example model `rtwdemo_sigobj_iv` and configure it to show the generated names of blocks. The signal `S2` uses a `Simulink.Signal` object in the base workspace.

Copyright 1994-2015 The MathWorks, Inc.

Double-click the Simulink.Signal object S2 to view its properties. The **Initial value** property is set to aa2. The object uses the variable aa2 to specify an initial condition for the signal S2. The **Storage class** property is set to ExportedGlobal. To use a Simulink.Signal object to initialize a signal, the signal object must use a storage class other than Auto or, if the corresponding data category in the Code Mapping Editor uses a storage class setting other than Default, Model default.

On the **Optimization** pane, in the Configuration Parameters dialog box, click **Configure**. The variable aa2 is a tunable parameter that uses the storage class ExportedGlobal.

In the model, open the Enabled Subsystem. In the Outport block dialog box, the parameter **Output when disabled** is set to reset. When the subsystem becomes disabled, the output signal S2 resets to the initial value aa2.

Open the Unit Delay block dialog box. On the **State Attributes** tab, the **State name** box is set to X1.

Open the Enable block dialog box. The parameter **States when enabling** is set to reset. When the subsystem transitions from a disabled state to an enabled state, it resets internal block states, such as X1, to their initial values.

In the base workspace, double-click the `Simulink.Signal` object `X1` to view its properties. The **Initial value** property is set to `aa1`.

Double-click the `Simulink.Parameter` object `aa1` to view its properties. The **Storage class** property is set to `ExportedGlobal`. You can generate tunable initial conditions for block states by using tunable parameters such as `aa1` and `Simulink.Signal` objects such as `X1`.

### Generate and Inspect Code

Generate code with the example model.

```
Starting build procedure for model: rtwdemo_sigobj_iv
Successful completion of build procedure for model: rtwdemo_sigobj_iv
```

In the code generation report, view the file `rtwdemo_sigobj_iv.c`. The code uses global variables to represent the block state `X1` and the signal `S2`.

```
/* Exported block states */
real_T X1; /* '<S2>/Unit Delay' */

/* Exported block signals */
real_T S1; /* '<Root>/In1' */
real_T S3; /* '<Root>/Signal Conversion' */
real_T S2; /* '<S2>/Unit Delay' */
```

The code uses global variables to represent the tunable parameters `aa1` and `aa2`.

```
/* Exported block parameters */
real_T aa1 = -2.5; /* Variable: aa1 */

real_T aa2 = -2.0; /* Variable: aa2 */
```

The model initialization function uses the tunable parameter `aa1` to initialize the state `X1`. The function also uses the tunable parameter `aa2` to initialize the signal `S2`.

```
/* SystemInitialize for Enabled SubSystem: '<Root>/Enabled Subsystem (state X1 inside
/* InitializeConditions for UnitDelay: '<S2>/Unit Delay' */
X1 = aa1;

/* SystemInitialize for Output: '<S2>/Out1' */
```

```
S2 = aa2;
```

In the model step function, when the Enabled Subsystem transitions from a disabled state to an enabled state, the Unit Delay block state X1 resets to its initial value.

```
if (rtb_PulseGenerator > 0) {
 if (!rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M) {
 /* InitializeConditions for UnitDelay: '<S2>/Unit Delay' */
 X1 = aa1;
 rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M = true;
 }
}
```

If the Enabled Subsystem becomes disabled during code execution, the algorithm uses the tunable initial condition aa2 to set the value of the signal S2.

```
} else {

 if (rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M) {
 /* Disable for Outport: '<S2>/Out1' */
 S2 = aa2;
 rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M = false;
 }
}
```

## Generate Tunable Initial Condition Structure for Bus Signal

When you use a MATLAB® structure to specify initialization values for the signal elements in a bus, you can create a tunable global structure in the generated code.

If you set **Configuration Parameters > Optimization > Default parameter behavior** to **Tunable**, the initial condition appears as a tunable substructure of the global parameters structure.

Whether you set **Default parameter behavior** to **Tunable** or **Inlined**, you can specify the initial condition by using a tunable `Simulink.Parameter` object whose value is a structure. If you apply a storage class other than `Auto` to the parameter object, the structure is tunable in the generated code.

To generate efficient code by avoiding data type mismatches between the structure and the bus signal, use either:

- Typed expressions to specify the values of the structure fields. Match the data type of each field with the data type of the corresponding signal element.
- A `Simulink.Bus` object to control the data types of the structure fields and the signal elements.

For basic information about using structures to initialize bus signals, and to decide how to control field data types, see “Specify Initial Conditions for Bus Signals” (Simulink).

### Generate Tunable Initial Condition Structure

This example shows how to use a tunable structure parameter to initialize a virtual bus signal.

Open the example model `rtwdemo_tunable_init_struct` and configure it to show the generated names of blocks.

Copyright 2015 The Mathworks, Inc.

In the model, select **View > Model Data Editor**.

On the **Inports/Outports** tab, the **Data Types** column shows that each Inport block in the model uses a different output data type.

Open the Bus Creator block dialog box. The block output is a virtual bus.

In the Configuration Parameters dialog box, open the **Optimization** pane. The configuration parameter **Default parameter behavior** is set to Tunable. By default, block parameters, including initial conditions, appear in the generated code as tunable fields of the global parameters structure.

In the Model Data Editor, inspect the **States** tab.

For the Unit Delay block, set **Initial Value** to a structure that specifies an initial condition for each of the three signal elements. To generate efficient code, match the data types of the structure fields with the data types of the corresponding signal elements. For example, set **Initial Value** to the expression `struct('thermocpl', 15.23, 'magFlow', uint32(79), 'posSwitch', false)`.

```
set_param('rtwdemo_tunable_init_struct/Unit Delay','InitialCondition',...
'struct('thermocpl',15.23,'magFlow',uint32(79),'posSwitch',false)')
```

Generate code from the example model.

```
Starting build procedure for model: rtwdemo_tunable_init_struct
Successful completion of build procedure for model: rtwdemo_tunable_init_struct
```

In the code generation report, view the file `rtwdemo_tunable_init_struct_types.h`. The code defines a structure type whose fields use the data types that you specified in the `struct` expression.

```
#ifndef DEFINED_TYPEDEF_FOR_struct_mqGiljsItE0G7cf1bNqMu_
#define DEFINED_TYPEDEF_FOR_struct_mqGiljsItE0G7cf1bNqMu_

typedef struct {
 real_T thermocpl;
 uint32_T magFlow;
 boolean_T posSwitch;
} struct_mqGiljsItE0G7cf1bNqMu;
```

View the file `rtwdemo_tunable_init_struct.h`. The `struct` type definition of the global parameters structure contains a substructure, `UnitDelay_InitialCondition`, which represents the **Initial condition** parameter of the Unit Delay block.

```
struct P_rtwdemo_tunable_init_struct_T_ {
 struct_mqGiljsItE0G7cf1bNqMu UnitDelay_InitialCondition; /* Mask Parameter: UnitDelay_InitialCondition */
```

View the file `rtwdemo_tunable_init_struct_data.c`. This source file allocates memory for the global parameters structure. The substructure `UnitDelay_InitialCondition` appears.

```
/* Block parameters (default storage) */
```

```
P_rtwdemo_tunable_init_struct_T rtwdemo_tunable_init_struct_P = {
 /* Mask Parameter: UnitDelay_InitialCondition
 * Referenced by:
 * '<Root>/Unit Delay'
 * '<Root>/Unit Delay'
 * '<Root>/Unit Delay'
 */
 {
 15.23,
 79U,
 0
 },

```

View the file `rtwdemo_tunable_init_struct.c`. The model initialization function uses the fields of the substructure to initialize the block states.

```
/* InitializeConditions for UnitDelay: '<Root>/Unit Delay' */
rtwdemo_tunable_init_struct_DW.UnitDelay_1_DSTATE =
 rtwdemo_tunable_init_struct_P.UnitDelay_InitialCondition.thermocpl;
rtwdemo_tunable_init_struct_DW.UnitDelay_2_DSTATE =
 rtwdemo_tunable_init_struct_P.UnitDelay_InitialCondition.magFlow;
rtwdemo_tunable_init_struct_DW.UnitDelay_3_DSTATE =
 rtwdemo_tunable_init_struct_P.UnitDelay_InitialCondition.posSwitch;
```

### Use Bus Object to Specify Data Types

If you create a bus object, you can use it to specify the data type of the bus signal and the tunable initial condition structure. Before code generation, the `Simulink.Parameter` object casts the values of the structure fields to the data types of the signal elements. For basic information about creating bus objects and using them in models, see “When to Use Bus Objects” (Simulink).

Open the example model `rtwdemo_init_struct_busobj` and configure it to show the generated names of blocks.

In the base workspace, double-click the Simulink.Bus object ComponentData. The object defines three signal elements: thermocpl, magFlow, and posSwitch. The elements each use a different data type.

In the model, open the Model Data Editor (**View > Model Data Editor**). The **Inports/Outputs** tab shows that for the Inport block DataIn, the output data type (**Data Type** column) is set to Bus: ComponentData.

At the command prompt, create the structure parameter initStruct. You can specify the field values by using untyped expressions. To improve readability, specify the field posSwitch with a Boolean value.

```
initStruct = struct(...
 'thermocpl',15.23,...
 'magFlow',79,...
 'posSwitch',false ...
);
```

```
initStruct = Simulink.Parameter(initStruct);
```

In the Model Data Editor, inspect the **Parameters** tab.

In the model, click the Unit Delay block. The Model Data Editor highlights the row that corresponds to the **Initial condition** parameter of the block.

In the Model Data Editor, set the parameter value (**Value** column) to initStruct.

Click the **Show/refresh additional information** button. The parameter object, `initStruct`, appears in the data table as a row.

Use the **Data Type** column to set the data type of `initStruct` to `Bus: ComponentData`.

```
initStruct.DataType = 'Bus: ComponentData';
```

Set the **Change View** drop-down list to `Code`.

Use the **Storage Class** column to apply the storage class `ExportedGlobal` to `initStruct`.

```
initStruct.StorageClass = 'ExportedGlobal';
```

Generate code from the example model.

```
Starting build procedure for model: rtwdemo_init_struct_busobj
Successful completion of build procedure for model: rtwdemo_init_struct_busobj
```

In the code generation report, view the file `rtwdemo_init_struct_busobj_types.h`. The code creates a structure type `ComponentData` whose fields use the data types in the bus object.

```
#ifndef DEFINED_TYPEDEF_FOR_ComponentData_
#define DEFINED_TYPEDEF_FOR_ComponentData_

typedef struct {
 real_T thermocpl;
 uint32_T magFlow;
 boolean_T posSwitch;
} ComponentData;
```

View the file `rtwdemo_init_struct_busobj.c`. The code creates a global variable to represent the tunable parameter object `initStruct`.

```
/* Exported block parameters */
ComponentData initStruct = {
 15.23,
 79U,
 0
};
/* Variable: initStruct
```

The model initialization function uses the structure fields to initialize the block states.

```
/* InitializeConditions for UnitDelay: '<Root>/Unit Delay' */
rtwdemo_init_struct_busobj_DW.UnitDelay_1_DSTATE = initStruct.thermocpl;
rtwdemo_init_struct_busobj_DW.UnitDelay_2_DSTATE = initStruct.magFlow;
rtwdemo_init_struct_busobj_DW.UnitDelay_3_DSTATE = initStruct.posSwitch;
```

To change the data type of any of the three signal elements, specify the new type in the bus object. The signal element in the model uses the new type. Before simulation and code generation, the parameter object `initStruct` casts the corresponding structure field to the new type.

## Initialization of Signal, State, and Parameter Data in the Generated Code

Signal lines, block parameters, and block states in a model can appear in the generated code as data, for example, as global variables. By default, the code initializes this data before execution of the primary algorithm. To match the numerics of simulation in Simulink, the code generator chooses the initial values based on specifications that you make in the model.

By understanding how the generated code initializes data, you can:

- Model a system that reinitializes states during execution, which means that the application can restart the entire system.
- Store initial values in memory as variables, which can persist between execution runs. You can then overwrite these values before starting or restarting a system.
- Generate efficient code by eliminating storage for invariant initial values and by preventing the generation of code that unnecessarily or redundantly initializes data.

For basic information about initializing signals and states in a model, see “Initialize Signals and Discrete States” (Simulink) and “Load State Information” (Simulink).

### Static Initialization and Dynamic Initialization

To initialize a data item such as a global variable, an application can use either static or dynamic initialization.

- Static initialization occurs in the same statement that defines (allocates memory for) the variable. The initialization does not occur inside a function definition.

The code can be more efficient because none of the generated model functions execute initialization statements.

- Dynamic initialization occurs inside a function. For each model or nonvirtual subsystem, the code generator typically creates one or more functions that are dedicated to initialization.

The generated code or your code can restart a system by calling the initialization function or functions at any time during execution.

## Real-World Ground Initialization Requiring Nonzero Bit Pattern

Each data item has a real-world ground value. This value can depend on the data type of the item. For example, for a signal whose data type is `double` or `int8`, the real-world ground value is zero. For an enumeration, the ground value is the default enumeration member.

For some kinds of data, to represent a real-world ground value, a computer stores zero in memory (all bits zero). However, for some other data, a computer stores a nonzero value in memory. This data includes, for example:

- Fixed-point data with bias. The code initializes such a data item to the stored integer value that, given the scaling and bias, represents real-world zero.
- An enumeration whose default member maps to an integer value other than zero. For example, if the default member is `High` with an underlying integer value of 3, the code initializes such a data item to `High`.

## Initialization of Signal and State Data

In a model, you can control signal and state initial values through block parameters. For example, to set the initial value of a Unit Delay block, you use the **Initial condition** parameter. In some cases, you can also use the `InitialValue` property of a `Simulink.Signal` object. For most of these block parameters, the default value is 0.

You can also initialize states by using State Writer blocks in Initialize Function subsystems and the **Initial states** model configuration parameter.

By default, the generated code dynamically initializes signal and state data (and other data, such as the model error status) in the generated initialization function. The function, named `model_initialize` by default, performs signal and state initialization operations in this order:

- 1 Initializes all of the signal and state data in the default generated structures, such as the `DWork` structure, to a stored value of zero.
- 2 Initializes additional signal and state data that are not in the default generated structures to the relevant real-world ground value.

This initialization applies only to data that meet both of these criteria:

- The generated code defines (allocates memory for) the data.
- The data use a storage class other than `Auto` (the default storage class) or `Model default` (when the Code Mapping Editor specifies the `Default` storage class, the default setting).

For example, the code applies this operation to data items that use the storage class `ExportedGlobal`.

- 3 Initializes each signal and state to the real-world value that the model specifies, for example, through the **Initial condition** parameter of a Unit Delay block.
- 4 Initializes each state to the real-world value that you assign by using a State Writer block. The function performs this initialization only if you use an Initialize Function subsystem in the model.
- 5 Initializes each state to the real-world value that you specify with the configuration parameter **Initial states**.

After this initialization function executes, each data item has the last real-world value that the function assigned. For example, if you use a State Writer block to initialize a block state to 5 while also using the **Initial states** configuration parameter to initialize the same state to 10, the state ultimately uses 10 as an initial value.

### memset for Bulk Initialization

To initialize signal or state data items that have contiguous storage to a stored value of zero, the generated code can call `memset` in an initialization function. Data items that have contiguous storage include the `DWork` structure, arrays, or data items that use a multiword data type.

If your application requires it, you can prevent the generated code from using `memset` for initializing floating-point data to stored zero. See “Use `memset` to initialize floats and doubles to 0.0” (Simulink Coder).

### Tunable Initial Values

You can configure the way that tunable block parameters, such as the **Gain** parameter of a Gain block, appear in the generated code. Most block parameters that set initial values (for example, **Initial condition**) are tunable. For example, the configuration parameter **Default parameter behavior** can determine whether the initial values appear in the generated code as inlined constants or as tunable global data. You can also use parameter objects and storage classes to control the representation of these initial values.

For tunable initial values, in the model initialization function, the right-hand side of the assignment statement is a global variable, structure field, or other data whose value you can change in memory.

To make initial values tunable in the generated code, see “Control Signal and State Initialization in the Generated Code” on page 22-216.

## Initialization of Parameter Data

The generated code statically initializes parameter data to the values that you specify in Simulink.

To express the initial value of a tunable parameter (a global variable) as a mathematical expression involving system constants or other macros, which requires Embedded Coder, see “Initialization by Mathematical Expression (Embedded Coder)” (Simulink Coder).

### Kinds of Parameter Data

These model elements appear in the generated code as parameter data:

- Tunable block parameters, such as the **Gain** parameter of a Gain block, when you set **Default parameter behavior** to **Tunable**. Each parameter appears as a field of a dedicated global structure.
- Some tunable block parameters when you set **Default parameter behavior** to **Inlined**. When the code generator cannot inline the value of a parameter as a literal number, the parameter appears as a field of a dedicated global `const` structure.
- `Simulink.Parameter` objects to which you apply a storage class or custom storage class that has an exported data scope. For example, the built-in storage class `ExportedGlobal` has an exported data scope, but the storage class `ImportedExtern` does not.

### Initialization by Mathematical Expression (Embedded Coder)

You can set the value of a parameter object (such as `Simulink.Parameter`) to a mathematical expression involving numbers, MATLAB variables, and other parameter objects. See “Set Variable Value by Using a Mathematical Expression” (Simulink).

If you use this technique with Embedded Coder, you can generate code that initializes the corresponding parameter data (global variable) by using the specified expression. For an example, see “Initialize Parameter Value From System Constant or Other Macro

(Embedded Coder)” on page 22-129. For general information, including limitations, see “Code Generation of Parameter Objects With Expression Values” (Simulink Coder).

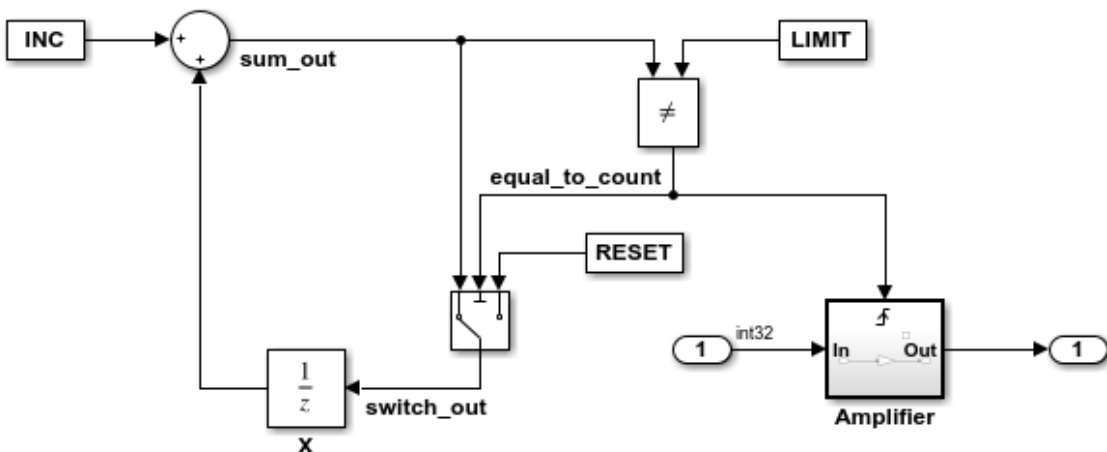

## Data Initialization in the Generated Code

This example shows how the generated code initializes signal, state, and parameter data.

### Explore Example Model

Open the example model, `rtwdemo_rtwintro`.

```
open_system('rtwdemo_rtwintro')
```

#### Algorithm Description

An 8-bit counter feeds a triggered subsystem parameterized by constants INC, LIMIT, and RESET. The I/O for the model is Input and Output. The Amplifier subsystem amplifies the input signal by gain factor K, which is updated whenever signal equal\_to\_count is true.

Copyright 1994-2012 The MathWorks, Inc.

In the model, select **View > Model Data Editor**.

In the Model Data Editor, inspect the **States** tab. For the Unit Delay block state, the **Initial Value** is set to 0, the default, which means the initial value of the state is zero. The state is named X.

Set **Initial Value** to a nonzero number, for example, 5.

```
set_param('rtwdemo_rtwintr/X', 'InitialCondition', '5')
```

Set the **Change view** drop-down list to Code.

In the data table, set **Storage Class** to ExportedGlobal. With this setting, the block state appears in the generated code as a separate global variable.

```
set_param('rtwdemo_rtwintr/X', 'StateStorageClass', 'ExportedGlobal')
```

In the model, open the Amplifier subsystem, which is a triggered subsystem.

In the Model Data Editor, inspect the **Parameters** tab and set the **Change view** drop-down list to Design. To set and inspect initial values of signals and states, you can use the **Parameters** tab instead of the **States** tab.

The Model Data Editor shows that for the Outport block, the **Initial output** (InitialOutput) parameter is set to 0, the default. This subsystem output requires an initial value because the subsystem executes conditionally. Leave the initial value at the default.

In the model, clear **Configuration Parameters > Signal storage reuse**. When you clear this setting, signal lines appear in the generated code as fields of a generated structure whose purpose is to store signal data. This representation of the signals makes it easier to see how the code generator initializes data.

```
set_param('rtwdemo_rtwintr', 'OptimizeBlockIOStorage', 'off')
```

In the model, inspect the configuration parameter **Configuration Parameters > Optimization > Default parameter behavior**. The configuration parameter is set to Inlined, which means block parameters, including initial values, appear in the generated code as inlined literals or as const data.

Navigate to the root level of the model.

In the Model Data Editor, click the **Show/refresh additional information** button.

Near the **Filter contents** box, click the **Filter using selection** button.

In the model, click the Constant block labeled INC. The Model Data Editor shows that the **Constant value** (Value) parameter of the block is set to INC. INC is a MATLAB variable in the base workspace.

For INC, set the value in the **Value** column to `Simulink.Parameter(uint8(1))`. MATLAB converts INC to a `Simulink.Parameter` object.

Use the **Storage Class** column to apply the storage class `ExportedGlobal` to INC. With this setting, the generated code defines INC as a global variable. Concerning initialization, INC is an item of parameter data.

```
INC = Simulink.Parameter(INC);
INC.StorageClass = 'ExportedGlobal';
```

### Generate and Inspect Code

Generate code from the model.

```
rtwbuild('rtwdemo_rtwintr0');
```

```
Starting build procedure for model: rtwdemo_rtwintr0
Successful completion of build procedure for model: rtwdemo_rtwintr0
```

In the generated file `rtwdemo_rtwintr0.c`, outside the definition of any function, the code statically initializes the parameter data INC. The value of INC is 1.

```
file = fullfile('rtwdemo_rtwintr0_grt_rtw','rtwdemo_rtwintr0.c');
rtwdemodbtype(file,'/* Exported block parameters */','uint8_T INC = 1U;',1,1)
```

```
/* Exported block parameters */
uint8_T INC = 1U; /* Variable: INC
```

In the same file, inspect the definition of the `rtwdemo_rtwintr0_initialize` function. First, the function uses `memset` to initialize all of the internal signals in the model to a stored value of 0.

```
rtwdemodbtype(file,'/* block I/O */','sizeof(B_rtwdemo_rtwintr0_T);',1,1)
```

```
/* block I/O */
(void) memset(((void *) &rtwdemo_rtwintr0_B), 0,
 sizeof(B_rtwdemo_rtwintr0_T));
```

The function then initializes the Unit Delay state, X, to the appropriate ground value. In this case, the ground value is zero.

```
rtwdemodbtype(file, '/* exported global states */', 'X = 0U;', 1, 1)
```

```
/* exported global states */
X = 0U;
```

The function also initializes other data, including the root-level inputs and outputs (Inport and Outport blocks), to the appropriate ground values.

```
rtwdemodbtype(file, '/* external inputs */', 'Amplifier_Trig_ZCE = POS_ZCSIG;', 1, 1)
```

```
/* external inputs */
rtwdemo_rtwintro_U.Input = 0;

/* external outputs */
rtwdemo_rtwintro_Y.Output = 0;
rtwdemo_rtwintro_PrevZCX.Amplifier_Trig_ZCE = POS_ZCSIG;
```

The function then initializes X to the value that you specified in the **Initial condition** block parameter.

```
rtwdemodbtype(file, '/* InitializeConditions for UnitDelay: '<Root>/X' */', ...
 'X = 5U;', 1, 1)
```

```
/* InitializeConditions for UnitDelay: '<Root>/X' */
X = 5U;
```

Finally, the function initializes the output of the Amplifier subsystem.

```
rtwdemodbtype(file, 'SystemInitialize for Triggered SubSystem', ...
 'End of SystemInitialize for SubSystem', 1, 1)
```

```
/* SystemInitialize for Triggered SubSystem: '<Root>/Amplifier' */
/* SystemInitialize for Outport: '<Root>/Output' incorporates:
 * Outport: '<S1>/Out'
 */
rtwdemo_rtwintro_Y.Output = 0;
```

## Inspect Difference Between Stored Value and Real-World Value

For some data, even if the real-world initial value is zero, a computer stores a nonzero value in memory. To observe this difference, apply a slope-bias fixed-point data type to the block state,  $X$ . To run this example, you must have Fixed-Point Designer™.

In the Model Data Editor, inspect the **Signals** tab.

In the model, click the output signal of the Switch block, `switch_out`.

Use the **Data Type** column of the Model Data Editor to set the signal data type to `fixdt(1,16,1,3)`. This expression represents a fixed-point data type with a slope of 1 and a bias of 3.

```
set_param('rtwdemo_rtwinintro/Switch','OutDataTypeStr',...
 'fixdt(1,16,1,3)')
```

In the model, select **View > Property Inspector** and click the Sum block.

In the Property Inspector, under **Signal Attributes**, clear **Require all inputs to have the same data type**.

```
set_param('rtwdemo_rtwinintro/Sum','InputSameDT','off')
```

To prevent compilation errors on different platforms, select the model configuration parameter **Generate code only**. This setting causes the model to generate only code.

```
set_param('rtwdemo_rtwinintro','GenCodeOnly','on')
```

Generate code from the model.

```
rtwbuild('rtwdemo_rtwinintro')
```

```
Starting build procedure for model: rtwdemo_rtwinintro
Successful completion of code generation for model: rtwdemo_rtwinintro
```

The model initialization function first initializes  $X$  to the appropriate real-world ground value, 0. Due to the slope-bias data type, which has bias 3, this real-world value corresponds to a stored value of -3.

```
rtwdemodbtype(file,'/* exported global states */','X = -3;',1,1)
```

```
/* exported global states */
X = -3;
```

The function then initializes X to the real-world initial value that you specified in the **Initial condition** block parameter, 5. This real-world value corresponds to a stored value of 2.

```
rtwdemodbtype(file, /* InitializeConditions for UnitDelay: '<Root>/X' */ , ...
 'X = 2;', 1, 1)

/* InitializeConditions for UnitDelay: '<Root>/X' */
X = 2;
```

## Modeling Goals

| Goal                                                                | More Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Explicitly model initialization behavior by using blocks            | <p>You can explicitly model initialization and reset behavior by using Initialize Function and Reset Function subsystems. In the subsystems, use State Writer blocks to calculate and assign an initial value for a state dynamically. The corresponding code appears in the model initialization function.</p> <p>For more information, see “Generate Code That Responds to Initialize, Reset, and Terminate Events” on page 9-2.</p>                                                                                                                                                                                                                                                                                                                                                                                                   |
| Prevent generation of code that explicitly initializes data to zero | <p>If your application environment already initializes global variables to zero, for more efficient code, you can prevent the generation of statements that explicitly initialize global variables to zero. This optimization applies only to signals and states whose initial values are stored in memory as zero. For example, the code generator does not apply the optimization to:</p> <ul style="list-style-type: none"> <li>• Data for which you specify a nonzero initial value by using a block parameter.</li> <li>• Data whose real-world initial value is zero but whose corresponding stored value is not zero.</li> <li>• Enumerated data whose default member maps to a nonzero integer.</li> </ul> <p>The optimization requires Embedded Coder. For more information, see “Remove Initialization Code” on page 59-4.</p> |

| Goal                                                    | More Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Generate code that imports data from your external code | <p>You can generate code that reuses (imports) data that your external code defines. For example, you can apply the storage class <code>ImportedExtern</code> to a signal line, block state, or parameter object. For imported data:</p> <ul style="list-style-type: none"><li>• The generated code does not initialize parameter data. Your code must initialize imported parameter data.</li><li>• The generated initialization functions dynamically initialize some signal and state data. Unlike data that the generated code allocates, the code does not initialize imported signal or state data to a stored value of zero. Instead, the code immediately initializes the data to the real-world value that you specify in Simulink.</li></ul> <p>For more information, including how to prevent the generated code from initializing imported data, see “Exchange Data Between External Calling Code and Generated Code” (Simulink Coder).</p> |

## Declare Workspace Variables as Tunable Parameters Using the Model Parameter Configuration Dialog Box

You can use the Model Parameter Configuration dialog box to declare numeric MATLAB variables in the base workspace as tunable parameters. You can select code generation options, such as storage class, for each tunable parameter.

However, it is a best practice to instead use parameter objects to declare tunable parameters. Do not use the Model Parameter Configuration dialog box to select parameter objects in the base workspace. To use parameter objects, instead of the Model Parameter Configuration dialog box, to declare tunable parameters, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81.

---

**Note** You cannot use the Model Parameter Configuration dialog box to declare tunable parameters for a referenced model. Use `Simulink.Parameter` objects instead.

---

### Declare Existing Workspace Variables as Tunable Parameters

Use the Model Parameter Configuration dialog box to declare existing workspace variables as tunable parameters for a model.

- 1 In the Configuration Parameters dialog box, on the **Optimization** pane, click **Configure**.
- 2 In the Model Parameter Configuration dialog box, under **Source list**, select a method to populate the list of available workspace variables.
  - Select **MATLAB workspace** to view all of the numeric variables that are defined in the base workspace.
  - Select **Referenced workspace variables** to view only the numeric variables in the base workspace that the model uses. Selecting this option begins a diagram update and a search for used variables, which can take time for a large model.
- 3 In the Model Parameter Configuration dialog box, under **Source list**, select one or more workspace variables.
- 4 Click **Add to table**. The variables appear as tunable parameters under **Global (tunable) parameters**, and appear in italic font under **Source list**.
- 5 Optionally, select a parameter under **Global (tunable) parameters**, and adjust the code generation settings for the parameter. For more information about adjusting the

code generation options for tunable parameters, see “Set Tunable Parameter Code Generation Options” on page 22-244

- 6 Click **OK** to apply your selection of tunable parameters and close the dialog box.

### Declare New Tunable Parameters

Use the Model Parameter Configuration dialog box to declare new tunable parameters. You can use this technique to declare the names of tunable parameters, and to adjust their code generation settings, before you create the corresponding workspace variables.

- 1 In the Configuration Parameters dialog box, on the **Optimization > Signals and Parameters** pane, click **Configure**.
- 2 In the Model Parameter Configuration dialog box, under **Global (tunable) parameters**, click **New**.
- 3 Under the **Name** column, specify a name for the new tunable parameter.
- 4 Optionally, adjust the code generation settings for the new parameter. For more information about adjusting the code generation options for tunable parameters, see “Set Tunable Parameter Code Generation Options” on page 22-244
- 5 Click **OK** to apply your changes and close the dialog box.

### Set Tunable Parameter Code Generation Options

To set the properties of tunable parameters listed under **Global (tunable) parameters** in the Model Parameter Configuration dialog box, select a parameter and specify a storage class and, optionally, a storage type qualifier.

| Property                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Storage class</b>          | Select one of the following to use for code generation: <ul style="list-style-type: none"> <li>• Model default</li> <li>• ExportedGlobal</li> <li>• ImportedExtern</li> <li>• ImportedExternPointer</li> </ul> For more information about tunable parameter storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81.                                                                        |
| <b>Storage type qualifier</b> | For variables with a storage class other than Auto, you can add a qualifier (such as <code>const</code> or <code>volatile</code> ) to the generated storage declaration. To do so, you can select a predefined qualifier from the list, or add qualifiers not in the list by typing them in. The code generator does not check the storage type qualifier for validity, and includes the qualifier text in the generated code without checking syntax . |

## Programmatically Declare Workspace Variables as Tunable Parameters

### Tune Parameters from the Command Line

When parameters are MATLAB workspace variables, the Model Parameter Configuration dialog box is the recommended way to see or set the properties of tunable parameters. In addition to that dialog box, you can also use MATLAB `get_param` and `set_param` commands.

---

**Note** You can also use `Simulink.Parameter` objects for tunable parameters. See “Create Tunable Calibration Parameter in the Generated Code” on page 22-121 for details.

---

The following commands return the tunable parameters and corresponding properties:

- `get_param(gcs, 'TunableVars')`
- `get_param(gcs, 'TunableVarsStorageClass')`
- `get_param(gcs, 'TunableVarsTypeQualifier')`

The following commands declare tunable parameters or set corresponding properties:

- `set_param(gcs, 'TunableVars', str)`

The argument `str` (character vector) is a comma-separated list of variable names.

- `set_param(gcs, 'TunableVarsStorageClass', str)`

The argument `str` (character vector) is a comma-separated list of storage class settings.

The valid storage class settings are

- `Auto`
- `ExportedGlobal`
- `ImportedExtern`
- `ImportedExternPointer`
- `set_param(gcs, 'TunableVarsTypeQualifier', str)`

The argument `str` (character vector) is a comma-separated list of storage type qualifiers.

The following example declares the variable `k1` to be tunable, with storage class `ExportedGlobal` and type qualifier `const`. The number of variables and number of specified storage class settings must match. If you specify multiple variables and storage class settings, separate them with a comma.

```
set_param(gcs, 'TunableVars', 'k1')
set_param(gcs, 'TunableVarsStorageClass', 'ExportedGlobal')
set_param(gcs, 'TunableVarsTypeQualifier', 'const')
```

## Share Data Between Code Generated from Simulink, Stateflow, and MATLAB

Stateflow and MATLAB Coder can fully define their data definitions, or they can inherit them from Simulink. Data definition capabilities include:

- Inheriting input/output data types and sizes from Simulink.
- Parameterized data types and sizes. That is, data type and size may be specified as a function of another data's type and size, e.g.,  $\text{type}(y)=\text{type}(u)$  and  $\text{size}(y)=\text{size}(u)$ .
- Inferred output size and type from Simulink via signal attribute back propagation.
- Parameter scoped data, which allows referencing Simulink parameters in Stateflow and MATLAB.

### Open Example Model

Open the example model `rtwdemo_dynamicio`.

```
open_system('rtwdemo_dynamicio')
```

### Instructions

- 1 Compile the model (**Simulation > Update Diagram**) and note the displayed signal types and sizes.
- 2 Change the data type and/or size of the Constant block and recompile the model. Note that the attributes of the signals automatically adapt to the Constant block specification.
- 3 Generate and inspect code using the blue buttons in the model. Note that K is shared by the Gain and sfVerticalSum block.

### Notes

- The data type and size of all Stateflow and MATLAB data is inherited from Simulink.
- The Gain block and the Stateflow chart sfVerticalSum share the Simulink parameter K, which is defined in the MATLAB workspace as a Simulink.Parameter with Model default storage class (i.e., rtP.K in the generated code).

# Data Definition and Declaration Management in Embedded Coder

- “Establish Data Ownership in a System of Components” on page 23-15

## **Control Placement of Global Data Definitions and Declarations in Generated Files**

The generated code can create standard, global structure variables whose fields represent the signal, state, and parameter data in a model. With storage classes, you can configure data to appear in the code as separate global variables or custom global structures. For information about the standard data structures, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50 and “How Generated Code Exchanges Data with an Environment” on page 22-33. For information about storage classes, see “Choose a Storage Class for Controlling Data Representation in the Generated Code” on page 22-69.

You can control the file placement of the variable definitions and declarations. Use the information in the table.

| Goal                                           | Details and Techniques                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Generate a variable that external code can use | <p>Apply a storage class with exported data scope, such as <code>ExportToFile</code>. The generated code declares the variable in a file that your code can include (<code>#include</code>).</p> <p>To generate an <code>extern</code> declaration in <code>model.h</code>, consider using the storage class <code>ExportedGlobal</code>.</p> <p>Alternatively, to place the declaration in a file whose name you can specify, choose one of these techniques:</p> <ul style="list-style-type: none"><li>• To aggregate multiple variable declarations into one or more specific header files by default, apply a storage class such as <code>ExportToFile</code> to a category of data by using the Code Mapping Editor. As you add blocks and signals to the model, new data items are declared in the files that you specify.</li><li>• To explicitly specify the placement for an individual data item, directly apply a storage class such as <code>ExportToFile</code> and specify a header file name by using the <b>Header file</b> custom attribute. To configure multiple data items in a list that you can search, sort, and filter, use the Model Data Editor (see “Configure Data Properties by Using the Model Data Editor” (Simulink)).</li></ul> <p>See “Exchange Data Between External Calling Code and Generated Code” on page 42-102.</p> |

| <b>Goal</b>                                                 | <b>Details and Techniques</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Generate code that uses a variable defined by external code | <p>Apply a storage class with imported data scope, such as <code>ImportFromFile</code>, to a data element in a model that represents the variable. Then, the generated code does not define the variable, but instead includes (<code>#include</code>) an external header file whose name you can specify. The generated algorithm (for example, the model <code>step</code> function) reads and writes to the variable.</p> <p>Alternatively, if you do not have an external declaration header file or do not want the generated code to include a header file, apply the storage class <code>ImportedExtern</code>. Then, the generated code declares the variable in <code>model_private.h</code>.</p> <p>See “Exchange Data Between External Calling Code and Generated Code” on page 42-102.</p> |

| Goal                                                                                                                                                                                                                 | Details and Techniques                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Combine multiple files into a single file | <ul style="list-style-type: none"><li data-bbox="798 305 1314 557">• Consider setting the model configuration parameter <b>File packaging format</b> to <b>Compact</b>. Then, the code generator does not create the <i>model_data.c</i> file. Instead, the definitions of the standard structures that store tunable and constant parameter data appear in <i>model.c</i>.</li><li data-bbox="798 569 1314 885">• When you apply a custom storage class such as <code>ExportToFile</code> to data elements, leave the custom attributes <b>Definition file</b> and <b>Header file</b> blank, the default value. Also, set the model configuration parameter <b>Data definition</b> to <b>Data defined in source file</b>. Then, the data definitions appear in <i>model.c</i> with the definitions of other global data.</li></ul> |

| Goal                                                                                            | Details and Techniques                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Separate data definitions from function definitions                                             | <p>By default, the generated file that defines the entry-point functions for a model or subsystem also defines the data for that model or subsystem. When you frequently make changes to data, especially initial values for tunable parameters, the changing source code files can impede verification and make change management more difficult. To separate the data from the functions:</p> <ul style="list-style-type: none"> <li>• Consider setting the model configuration parameter <b>File packaging format</b> to a value that results in the generation of the separate data file <i>model_data.c</i>. Then, the definitions of the standard structures that store tunable and constant parameter data appear in this file instead of in <i>model.c</i>.</li> <li>• Apply storage classes such as <code>ExportToFile</code> to data elements by using the Code Mapping Editor and the Model Data Editor. Use the custom attributes of the custom storage class, such as <b>Definition file</b> and <b>Header file</b>, to specify file placement. For more information, see “Configure Default Code Generation for Data” on page 21-8 and “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19.</li> </ul> |
| Isolate data definitions in separate files for component-based, team-oriented model development | See “Organize Data to Support Component-Based, Team-Oriented Model Development” on page 23-9.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Goal                                                                                                         | Details and Techniques                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Aggregate definitions of variant control parameters ( <code>#define</code> macros) into a single header file | <p>As described in “Generate Preprocessor Conditionals for Variant Systems” on page 15-35, a variant control parameter is a parameter object such as <code>Simulink.Parameter</code>. You apply a storage class that makes the object appear in the generated code as a macro. To control the file placement, choose one of these techniques:</p> <ul style="list-style-type: none"><li>• For each variant control parameter that uses the storage class <code>Define</code>, set the <b>Header file</b> property to the same value. To configure these objects in a list that you can search, sort, and filter, you can use the Model Data Editor <b>Parameters</b> tab. For an example, see “Generate Variant Control Macros in Same Header File” on page 15-38.</li><li>• Create one or more storage classes that represent variant control parameters. In the Custom Storage Class Designer, you can set <b>Header file</b> to a value that applies to all of the variant control parameters that use the storage class. With this technique, you do not need to manually specify a header file for each variant control parameter. For more information, see “Create Custom Storage Classes by Using the Custom Storage Class Designer” on page 26-26.</li></ul> |

## **Organize Data to Support Component-Based, Team-Oriented Model Development**

Depending on your model configuration, data definitions can appear aggregated in large generated files. In a system of components (subsystems or referenced models), you can separate and organize the data definitions into manageable, meaningful files based on the component hierarchy.

| Goal                                                                                                                      | Technique                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <p>For an atomic subsystem, place the standard data structures for the subsystem with the subsystem code</p> | <p>By default, the standard data structures for an atomic subsystem appear as substructures of the data structures for the entire model.</p> <p>To generate separate data structures for a subsystem, select the <b>Function with separate data</b> parameter in the subsystem block. Then, the subsystem data appear in separate structure variables that the subsystem code defines. See “Generate Modular Function Code” on page 29-65.</p>                                                                                                     |

## Specify Default Placement

When you create data in a model by adding blocks and signal lines, by default, the data definitions appear in `model.c`. To specify a different default placement, use these tools and parameters:

- The model configuration parameter **File packaging format**. The setting that you choose determines whether the code generator places the standard structures that store tunable and constant parameter data in `model_data.c` instead of `model.c`. See “File packaging format”.
- The Code Mapping Editor. For each category of model data, you can specify a default storage class, which controls file placement. For example, apply the storage class

`ExportToFile` to a data category and, in the Property Inspector, use the **DefinitionFile**, **HeaderFile**, and **Owner** custom attributes to control file placement.

- The model configuration parameters **Data definition** and **Data declaration**. These configuration parameters specify the default file placement for data items to which you apply storage classes.
  - These configuration parameters do not affect data items to which you apply the storage classes `ExportedGlobal`, `ImportedExtern`, and `ImportedExternPointer`.
  - If you apply a storage class that explicitly specifies definition and declaration files for a data element, those specifications override the **Data definition** and **Data declaration** configuration parameters.

For more information, see “Data definition” and “Data declaration”.

- The subsystem block parameter **Function with separate data**. When you select this parameter, the standard structures that store the subsystem data, such as the `DWork` structure, appear as separate structure variables. By default, the variable definitions appear in the source file that defines the subsystem execution function. See “Generate Modular Function Code” on page 29-65.

## Override Default Placement for Individual Data Items

For an individual data item, to override the default file placement, use the Model Data Editor to apply a storage class directly. For example, to make a data item appear in the generated code as a global variable, apply the custom storage class `ExportToFile`. Then, use the **Definition file**, **Header file** custom attributes to control file placement. To apply storage classes directly, see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19.

## Prevent Name Clashes by Configuring Data Item as static

To apply the C keyword `static` to a global variable, which can help you avoid name clashes by limiting the scope of the variable name to the file that defines the variable, choose one of these techniques:

- Apply the built-in storage class `FileScope`. For more information, see “Choose a Storage Class for Controlling Data Representation in the Generated Code” on page 22-69.

- If FileScope does not satisfy your requirements, create your own custom storage class by using the Custom Storage Class Designer. In the Designer, set **Data scope** to File or Auto.
  - With File, the data element appears in the code as a `static` global variable.
  - With Auto, the code generator first attempts to represent the data element with a local variable in a function. If this attempt fails, the code generator uses a `static` global variable.

For an example that shows how to create your own custom storage class by using the Designer, see “Create and Apply a Custom Storage Class” on page 26-26.

You cannot apply `static` to the standard data structures such as the DWork structure.

To access `static` data, you can configure the generated code to include an interface such as an a2l (ASAP2) file. For more information, see “Export ASAP2 File for Data Measurement and Calibration” on page 47-2. To place the data in a specific memory location by including pragmas or other decorations in the generated code, create your own memory section and custom storage class. See “Control Data and Function Placement in Memory by Inserting Pragmas” on page 30-2.

## Code Generation Impact of Storage Location for Parameter Objects

You can create a parameter object (such as `Simulink.Parameter`) in the base workspace, a model workspace, or a data dictionary. However, when you apply a storage class or custom storage class to the object, the location of the object can impact the file placement of the corresponding data definition in the generated code. See “Code Generation Impact of Storage Location for Parameter Objects” on page 22-130.

## Specify Default #include Syntax for Data Header Files

To control the file placement of a data item, such as a signal line or block state, in the generated code, you can apply a storage class to the data item (see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19). You then use the **Header file** custom attribute to specify the generated or external header file that contains the declaration of the data.

To reduce maintenance effort and data entry, when you specify **Header file**, you can omit delimiters (“ or <>) and use only the file name. You can then control the default delimiters

that the generated code uses for the corresponding `#include` directives. To use angle brackets by default, set **Configuration Parameters > Code Generation > Code Placement > #include file delimiters** to `#include <header.h>`.

## Establish Data Ownership in a System of Components

This example shows how to establish ownership of global data in the code generated from a system of components (referenced models).

When you create a global variable in the generated code by applying a storage class to a data element in a referenced model (see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81), under certain conditions, the code generator places the variable definition with the code generated from the top model in the hierarchy. This default placement can make it more difficult to determine which component is responsible for the data and to manage code changes in a team-based development environment.

To establish ownership of a global variable by placing the definition with the code generated from the relevant component, apply a storage class such as `ExportToFile` and specify the **Owner** custom attribute. Alternatively, for parameter objects such as `Simulink.Parameter` that you use in only one component, you can establish ownership by storing the object in a model workspace instead of the base workspace or a data dictionary.

### Explore Example Model

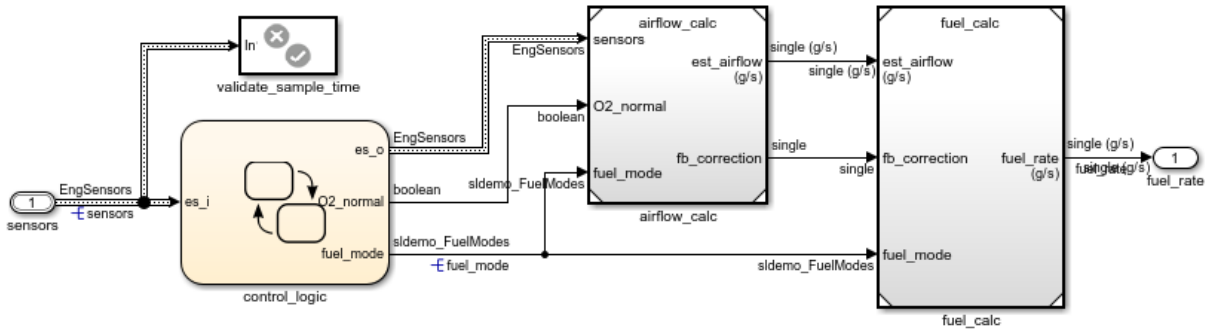

Copy the script file `prepare_sl-demo_fuelsys_dd_ctrl.m` to your current folder.

```
[~, ~] = copyfile(fullfile(matlabroot, 'examples', 'ecoder', 'main', 'prepare_sl-demo_fuelsys',
 'prepare_sl-demo_fuelsys_dd_ctrl.m', 'f'));
```

Run the copy of the script in your current folder. The script opens the model `sl-demo_fuelsys_dd_controller` and prepares it for this example.

```
prepare_sl-demo_fuelsys_dd_ctrl
open_system('sl-demo_fuelsys_dd_controller')
```

## Fuel Rate Controller

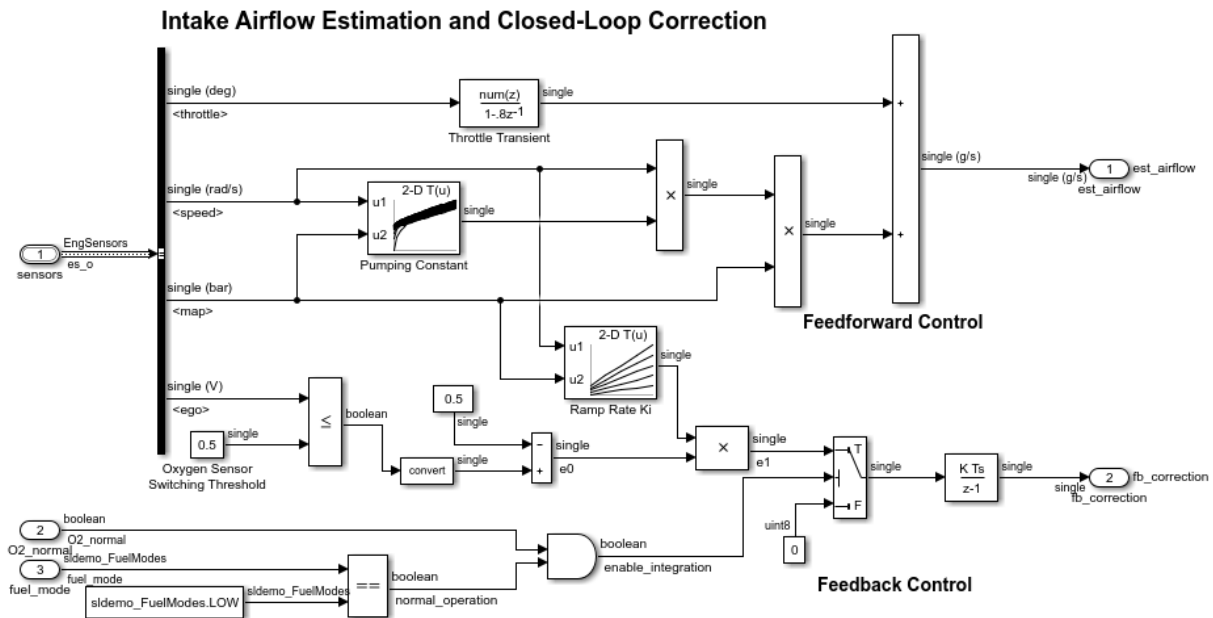

Copyright 1990-2017 The MathWorks, Inc.

This controller model contains two component models, `airflow_calc` and `fuel_calc`. The two outputs of `airflow_calc`, `est_airflow` and `fb_correction`, are inputs of `fuel_calc`.

Open the `airflow_calc` model.

```
open_system('airflow_calc')
```

In this model, select **View > Model Data Editor**.

In the Model Data Editor, set the **Change view** drop-down list to Code.

In the model, select the upper Outport block.

In the Model Data Editor, inspect the value in the **Storage Class** column. The signal that this block represents, `est_airflow`, uses the storage class `ExportToFile`. With this setting, the signal appears in the generated code as a global variable. The Outport block labeled `fb_correction` also uses this setting.

In the Model Data Editor, select the **Parameters** tab and click the **Show/refresh additional information** button. The Model Data Editor now shows information about workspace variables and objects, such as `Simulink.Parameter` objects, that the model uses to set block parameter values.

In the **Filter contents** box, enter `numerator`. The `Simulink.Parameter` object `numerator_param`, which is in the base workspace, sets the value of the **Numerator** parameter in the Discrete Filter block labeled `Throttle Transient`. The object uses the storage class `ExportToFile`.

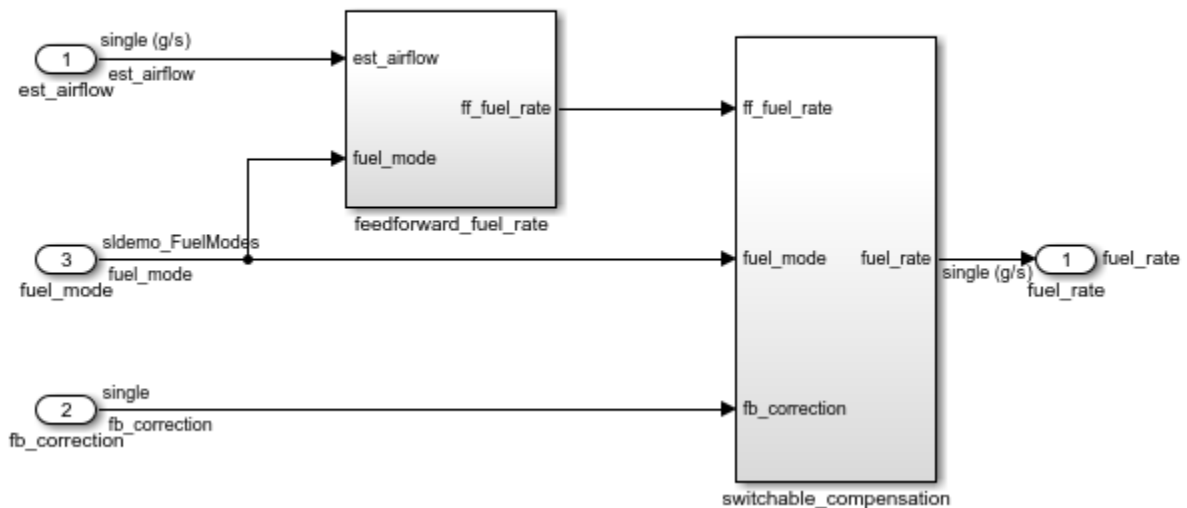

Select the **Signals** tab.

In the **Filter contents** box, enter `e0`. The signal `e0`, which is internal to the `airflow_calc` component, also uses `ExportToFile`. The signal is internal because it is not a root-level input or output of the model.

Open the `fuel_calc` model.

```
open_system('fuel_calc')
```

## Fuel Rate Calculation

In the Model Data Editor for this model, on the **Inports/Outports** tab, set **Change view** to **Code**. The Inport blocks `est_airflow` and `fb_correction` use the same storage class, `ExportToFile`, as the corresponding Outport blocks in `airflow_calc`. The Outport block labeled `fuel_rate` also uses `ExportToFile`.

### Generate and Inspect Code

Generate code from the controller model, `sldemo_fuelsys_dd_controller`.

```
rtwbuild('sldemo_fuelsys_dd_controller')
```

```

Starting build procedure for model: airflow_calc
Successful completion of build procedure for model: airflow_calc
Starting build procedure for model: fuel_calc
Successful completion of build procedure for model: fuel_calc
Starting build procedure for model: sldemo_fuelsys_dd_controller
Successful completion of build procedure for model: sldemo_fuelsys_dd_controller

```

In the code generation report, under **Referenced Models**, click the hyperlink to inspect the code generated for `airflow_calc`.

The file `airflow_calc.c` defines the global variable that represents the signal `e0`. Because the blocks that write to and read from `e0` exist only in `airflow_calc`, the code generator assumes that this component owns the signal.

```

file = fullfile('slprj','ert','airflow_calc','airflow_calc.c');
rtwdemodbtype(file,'/* Definition for custom storage class: ExportToFile */',...
 'real32_T e0;',1,1)

```

```

/* Definition for custom storage class: ExportToFile */
real32_T e0;

```

In the code generation report, return to the code generated for `sldemo_fuelsys_dd_controller`.

The file `sldemo_fuelsys_dd_controller.c` defines the other global variables.

```

file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw',...
 'sldemo_fuelsys_dd_controller.c');
rtwdemodbtype(file,...
 '/* Definition for custom storage class: ExportToFile */',...
 'real32_T numerator_param[2] = { 0.01F, -0.01F } ;',1,1);

```

```

/* Definition for custom storage class: ExportToFile */
real32_T est_airflow;
real32_T fb_correction;
real32_T fuel_rate;
real32_T numerator_param[2] = { 0.01F, -0.01F } ;

```

Because the signals `est_airflow` and `fb_correction` pass between the two components and through the top-level controller model, the code generator assumes that `sldemo_fuelsys_dd_controller` owns the signals. The code generator makes a similar assumption about `fuel_rate`. Because the parameter object `numerator_param`

exists in the base workspace, any model in the hierarchy can use the object. Therefore, the code generator assumes that `sldemo_fuelsys_dd_controller` owns the parameter.

You can configure each shared signal and the parameter object so that the corresponding variable definition appears in the code generated for the relevant component.

### Configure Data Ownership

In this example, you configure code generation settings so that:

- The code generated for the `airflow_calc` model defines the signals that pass between the two components, `est_airflow` and `fb_correction`.
- The code generated for `airflow_calc` defines the parameter data, `numerator_param`.
- The code generated for `fuel_calc` defines the output signal that it calculates, `fuel_rate`.

In the `airflow_calc` model, select **View > Property Inspector**.

In the Model Data Editor, select the **Inports/Outports** tab.

Find the row that corresponds to the Outport block `est_airflow`.

In the row, click the icon in the left column. The Property Inspector shows the properties of the Outport block.

In the Property Inspector, under **Code**, set **CoderInfo.CustomAttributes.Owner** to `airflow_calc`. The code generator places the definition of the global variable with the code generated for `airflow_calc`.

For `fb_correction`, use the Model Data Editor and the Property Inspector to set **Owner** to `airflow_calc`.

Select the **Parameters** tab.

Find the row that corresponds to the parameter object, `numerator_param`.

In the row, double-click the icon in the left column. The Model Explorer opens and displays the properties of `numerator_param`.

In the **Model Hierarchy** pane, expand the `airflow_calc` node so that you can see the subordinate **Model Workspace** node.

Use the Model Explorer to move `numerator_param` from the base workspace to the `airflow_calc` model workspace. For example, in the **Model Hierarchy** pane, select **Base Workspace**. Then, drag `numerator_param` from the **Contents** pane to the **Model Workspace** node in the **Model Hierarchy** pane. With this change, the code generator assumes that `airflow_calc` owns `numerator_param`, and places the variable definition in the code generated for `airflow_calc`.

In the `fuel_calc` model, select **View > Property Inspector**.

For the Inport blocks `est_airflow` and `fb_correction`, use the Model Data Editor and the Property Inspector to set **Owner** to `airflow_calc`. With this configuration, the `fuel_calc` code does not define the variables.

For the Outport block, use the Model Data Editor and the Property Inspector to set **Owner** to `fuel_calc`.

Alternatively, to configure the data in the models, use these commands at the command prompt:

```
temp = Simulink.Signal;
temp.CoderInfo.StorageClass = 'Custom';
temp.CoderInfo.CustomStorageClass = 'ExportToFile';
temp.CoderInfo.CustomAttributes.Owner = 'airflow_calc';

set_param('airflow_calc/est_airflow', 'SignalName', 'est_airflow')
set_param('airflow_calc/est_airflow', 'SignalObject', copy(temp))

set_param('airflow_calc/fb_correction', 'SignalName', 'fb_correction')
set_param('airflow_calc/fb_correction', 'SignalObject', copy(temp))

mdlwks = get_param('airflow_calc', 'ModelWorkspace');
assignin(mdlwks, 'numerator_param', copy(numerator_param));

portHandles = get_param('fuel_calc/est_airflow', 'portHandles');
outportHandle = portHandles.Output;
set_param(outportHandle, 'Name', 'est_airflow')
set_param(outportHandle, 'SignalObject', copy(temp))

portHandles = get_param('fuel_calc/fb_correction', 'portHandles');
outportHandle = portHandles.Output;
set_param(outportHandle, 'Name', 'fb_correction')
set_param(outportHandle, 'SignalObject', copy(temp))

temp.CoderInfo.CustomAttributes.Owner = 'fuel_calc';
```

```
set_param('fuel_calc/fuel_rate','SignalName','fuel_rate')
set_param('fuel_calc/fuel_rate','SignalObject',copy(temp))
```

```
clear temp portHandles outportHandle numerator_param
```

In each of the three models, select **Configuration Parameters > Use owner from data object for data definition placement**. With this setting cleared (the default), the code generator ignores the values that you specify for **Owner**.

```
set_param('fuel_calc','EnableDataOwnership','on')
set_param('airflow_calc','EnableDataOwnership','on')
set_param('sldemo_fuelsys_dd_controller','EnableDataOwnership','on')
```

Save the component models.

```
save_system('fuel_calc')
save_system('airflow_calc')
```

### Generate Improved Code

Generate code from the controller model, `sldemo_fuelsys_dd_controller`.

```
rtwbuild('sldemo_fuelsys_dd_controller')

Starting build procedure for model: airflow_calc
Successful completion of build procedure for model: airflow_calc
Starting build procedure for model: fuel_calc
Successful completion of build procedure for model: fuel_calc
Starting build procedure for model: sldemo_fuelsys_dd_controller
Successful completion of build procedure for model: sldemo_fuelsys_dd_controller
```

Now, the file `sldemo_fuelsys_dd_controller.c` does not define any of the global variables.

In the code generation report, inspect the code generated for `airflow_calc`.

The file `airflow_calc.c` now defines the global variables that belong to `airflow_calc`.

```
file = fullfile('slprj','ert','airflow_calc','airflow_calc.c');
rtwmodbtype(file,'/* Definition for custom storage class: ExportToFile */',...
 'real32_T numerator_param[2] = { 0.01F, -0.01F } ;',1,1)

/* Definition for custom storage class: ExportToFile */
```

```
real32_T e0;
real32_T est_airflow;
real32_T fb_correction;
real32_T numerator_param[2] = { 0.01F, -0.01F } ;
```

Inspect the code generated for `fuel_calc`. The file `fuel_calc.c` defines the global variable `fuel_rate`.

```
file = fullfile('slprj','ert','fuel_calc','fuel_calc.c');
rtwdemodbtype(file,'/* Definition for custom storage class: ExportToFile */',...
 'real32_T fuel_rate;',1,1)

/* Definition for custom storage class: ExportToFile */
real32_T fuel_rate;
```

### Create Single Point of Specification for Signals That Pass Between Components

The signal data elements `est_airflow` and `fb_correction` are represented by Output blocks in `airflow_calc` and by Inport blocks in `fuel_calc`. If you want to change the configuration of one of these signals, you must make the change in both models. For example, if you want to change the storage class of `est_airflow` from `ExportToFile` to `Volatile`, you must change the storage class twice: once for the Output block in `airflow_calc` and again for the Inport block in `fuel_calc`.

To make maintenance of each signal easier, store the code generation settings in a `Simulink.Signal` object, which can exist in the base workspace or a data dictionary.

In the Model Data Editor for `airflow_calc`, on the **Inports/Outputs** tab, find the row that corresponds to `est_airflow`.

For that row, in the **Signal Name** column, click the cell.

In the cell, next to the `est_airflow` text, click the action button (with three vertical dots). Select **Create and Resolve**.

In the **Create New Data** dialog box, set **Value** to `Simulink.Signal` and click **Create**. A `Simulink.Signal` object named `est_airflow` appears in the base workspace. In the Model Data Editor, for `est_airflow`, the check box in the **Resolve** check box is selected, which means the Output block acquires code generation settings from the signal object in the base workspace.

In the `est_airflow` property dialog box, set **Storage class** to `ExportToFile`.

Set **Owner** to `airflow_calc`.

Use the Model Data Editor to create a similar signal object for `fb_correction`.

In the Model Data Editor for `fuel_calc`, on the **Inports/Outports** tab, in the **Resolve** column, select the check boxes for `est_airflow` and `fb_correction`. Now, each Inport block acquires code generation settings from the corresponding signal object.

Alternatively, to create the signal object and configure the blocks and lines in the model, at the command prompt, use these commands:

```
est_airflow = Simulink.Signal;
est_airflow.CoderInfo.StorageClass = 'Custom';
est_airflow.CoderInfo.CustomStorageClass = 'ExportToFile';
est_airflow.CoderInfo.CustomAttributes.Owner = 'airflow_calc';

fb_correction = Simulink.Signal;
fb_correction.CoderInfo.StorageClass = 'Custom';
fb_correction.CoderInfo.CustomStorageClass = 'ExportToFile';
fb_correction.CoderInfo.CustomAttributes.Owner = 'airflow_calc';

set_param('airflow_calc/est_airflow', 'MustResolveToSignalObject', 'on')

set_param('airflow_calc/fb_correction', 'MustResolveToSignalObject', 'on')

portHandles = get_param('fuel_calc/est_airflow', 'portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle, 'MustResolveToSignalObject', 'on')

portHandles = get_param('fuel_calc/fb_correction', 'portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle, 'MustResolveToSignalObject', 'on')

clear portHandles outportHandle
```

Save the component models and generate code from `sldemo_fuelsys_dd_controller`. The code is the same as it was before you created the `Simulink.Signal` objects. Now, you can make changes to the signal objects instead of the corresponding blocks and lines in the models.

```
save_system('airflow_calc')
save_system('fuel_calc')
rtwbuild('sldemo_fuelsys_dd_controller')
```

```
Starting build procedure for model: airflow_calc
Successful completion of build procedure for model: airflow_calc
Starting build procedure for model: fuel_calc
Successful completion of build procedure for model: fuel_calc
Starting build procedure for model: sldemo_fuelsys_dd_controller
Successful completion of build procedure for model: sldemo_fuelsys_dd_controller
```

## Control Data Type Names in Generated Code

By default, the generated code uses Simulink Coder data type aliases to define scalar and array variables. For example, the Simulink Coder type `real32_T` corresponds to the Simulink type `single`. The code defines these types through `typedef` statements that build on C primitive types such as `float` and `short`. You can configure the code to use custom type names instead.

The code also aggregates signal, block parameter, and state data into structures (see “How Generated Code Exchanges Data with an Environment” on page 22-33 and “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50) by default. You can specify a naming rule for these structure types. You can also place data items into separate custom structures whose type names you can control.

Control these type names to help you to:

- Conform to coding standards. For an example, see “Replace and Rename Data Types to Conform to Coding Standards” on page 24-27.
- Integrate the generated code with your external code. For an example, see “Exchange Structured and Enumerated Data Between Generated and External Code” on page 24-34.
- Make the generated code more readable and meaningful.

For custom types, you can also specify that the generated code reuse type definitions, for example, `typedef` statements, from your external code.

For information about data type names that you cannot control and about custom data types that the generated code does not support, see “Limitations” on page 24-21.

To inform the code generator about the bit length of generic C types such as `int` and `short` for your target hardware, use **Hardware Implementation** configuration parameters. See “Configure Run-Time Environment Options” on page 7-2.

### Control Names of Primitive Data Types

To rename a Simulink Coder primitive data type such as `int8_T`, first create a `Simulink.AliasType` object whose name matches the type name that you want the generated code to use. For example, to create a type named `myType`, at the command prompt, enter:

```
myType = Simulink.AliasType;
```

Set the `BaseType` property to the name of the Simulink data type that corresponds to the target Simulink Coder data type. For example, if the target type is `int8_T`, specify `int8`. To identify the Simulink data type, use the information in the table.

| Simulink Coder Type Name | Corresponding Simulink Type Name                                                                                                                                                                                                                                                                                                                                       |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>real_T</code>      | <code>double</code>                                                                                                                                                                                                                                                                                                                                                    |
| <code>real32_T</code>    | <code>single</code>                                                                                                                                                                                                                                                                                                                                                    |
| <code>int32_T</code>     | <code>int32</code>                                                                                                                                                                                                                                                                                                                                                     |
| <code>int16_T</code>     | <code>int16</code>                                                                                                                                                                                                                                                                                                                                                     |
| <code>int8_T</code>      | <code>int8</code>                                                                                                                                                                                                                                                                                                                                                      |
| <code>uint32_T</code>    | <code>uint32</code>                                                                                                                                                                                                                                                                                                                                                    |
| <code>uint16_T</code>    | <code>uint16</code>                                                                                                                                                                                                                                                                                                                                                    |
| <code>uint8_T</code>     | <code>uint8</code>                                                                                                                                                                                                                                                                                                                                                     |
| <code>boolean_T</code>   | <p><code>boolean</code></p> <p>For configuring data type replacement throughout an entire model (<b>Configuration Parameters &gt; Code Generation &gt; Data Type Replacement</b>), you can alternatively use one of these types:</p> <ul style="list-style-type: none"> <li>• <code>uint8</code></li> <li>• <code>int8</code></li> <li>• <code>intn*</code></li> </ul> |
| <code>int_T</code>       | <code>intn*</code>                                                                                                                                                                                                                                                                                                                                                     |
| <code>uint_T</code>      | <code>uintn*</code>                                                                                                                                                                                                                                                                                                                                                    |
| <code>char_T</code>      | <code>intn*</code>                                                                                                                                                                                                                                                                                                                                                     |

\* Replace *n* with the number of bits displayed in **Configuration Parameters > Hardware Implementation** for either **Number of bits: int** or **Number of bits: char**. Use the appropriate number of bits for the data type that you want to rename.

---

**Note** The `boolean_T` `BaseType` must promote to a signed `int`.

---

For example, to replace the type name `uint8_T` with `myType`, set the `BaseType` property of the `Simulink.AliasType` object to `'int8'`.

```
myType.BaseType = 'int8';
```

Then, use one or both of these techniques to apply the type to data items in a model:

- Configure data type replacements. Throughout the code that you generate from a model, you can replace a Simulink Coder data type name with the name of the `Simulink.AliasType` object. You configure data type replacements through model configuration parameters (**Configuration Parameters > Code Generation > Data Type Replacement**).

For an example that shows how to use data type replacement, see “Replace and Rename Data Types to Conform to Coding Standards” on page 24-27.

- Use the name of the `Simulink.AliasType` object to specify the data type of an individual signal, that is, a block output, or block parameter. By default, due to data type propagation and inheritance (see “Data Type Inheritance Rules” (Simulink)), the signals, states, and parameters of other downstream blocks typically inherit the same data type. Optionally, you can configure data items in upstream blocks to inherit the type (**Inherit: Inherit via back propagation**) or stop the propagation at an arbitrary block by specifying a noninherited data type setting.

To specify a data type for an individual data item, use the Model Data Editor (**View > Model Data Editor**). You can use the name of the same `Simulink.AliasType` object to specify the data types of multiple data items.

For an example that shows how to use a `Simulink.AliasType` object directly in a model, see “Create Data Type Alias in the Generated Code” on page 24-12.

| Control Names of Primitive Types                                                                                                           | Technique                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <p>Use the same type name for multiple signals and other data items in a data path, which is a series of connected blocks.</p>                                                                                              | <p>In the model, use the name of a <code>Simulink.AliasType</code> object to set the data type of one of the signals in the path, for example, a root-level Inport block or a Constant block. For example, if the path begins with an Inport block at the root level of the model, you can specify the type in that block. By default, due to data type propagation, the data items in the other blocks typically inherit the same type.</p> <p>In most cases, no matter where on the data path you specify the type, downstream data items inherit the type. You can configure upstream data items to inherit the type, too. Consider specifying the type in a block that you do not expect to remove or change frequently.</p> |
| <p>Configure the generated code to replace an implementation-dependent type, such as <code>char_T</code> or <code>boolean_T</code>, and another type of equivalent bit length with a single type name that you specify.</p> | <p>Use the name of the <code>Simulink.AliasType</code> object to configure multiple data type replacements simultaneously. See “Replace Implementation-Dependent Types with the Same Type Name” on page 24-8.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Use Simulink Data Type Names Instead of Simulink Coder Data Type Names**

For consistency between the data type names that you see in a model and in the generated code, you can configure data type replacements so the code uses Simulink type names instead of Simulink Coder names. For each Simulink Coder type that you want to rename, use the Simulink data type name to specify the replacement name. You do not need to create `Simulink.AliasType` objects.

## Data type names

| Simulink Name | Code Generation Name | Replacement Name |
|---------------|----------------------|------------------|
| double        | real_T               | <empty>          |
| single        | real32_T             | <empty>          |
| int32         | int32_T              | <empty>          |
| int16         | int16_T              | <empty>          |
| int8          | int8_T               | int8             |
| uint32        | uint32_T             | <empty>          |
| uint16        | uint16_T             | <empty>          |
| uint8         | uint8_T              | <empty>          |
| boolean       | boolean_T            | <empty>          |
| int           | int_T                | <empty>          |
| uint          | uint_T               | <empty>          |
| char          | char_T               | <empty>          |

To replace `boolean_T`, `int_T`, or `uint_T`, use the information in the table.

| Simulink Coder Type Name | Replacement Names to Use                                                                                                                                                              |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>boolean_T</code>   | One of these names: <ul style="list-style-type: none"> <li>• <code>boolean</code></li> <li>• <code>uint8</code></li> <li>• <code>int8</code></li> <li>• <code>intn*</code></li> </ul> |
| <code>int_T</code>       | <code>intn*</code>                                                                                                                                                                    |
| <code>uint_T</code>      | <code>uintn*</code>                                                                                                                                                                   |
| <code>char_T</code>      | <code>intn*</code>                                                                                                                                                                    |

\* Replace *n* with the number of bits displayed in **Configuration Parameters > Hardware Implementation** for either **Number of bits: int** or **Number of bits: char**. Use the appropriate number of bits for the data type that you want to replace.

You cannot use this technique to replace `real_T` with `double` or `real32_T` with `single`.

### **Replace Implementation-Dependent Types with the Same Type Name**

Some Simulink Coder type names map to C primitives that are implementation-dependent. For example, the Simulink Coder type `int_T` maps to the C type `int`, whose bit length depends on the native integer size of your target hardware. Other implementation-dependent types include `boolean_T`, `char_T`, and `uint_T`.

For more readable, simpler code, you can use the same type name to replace multiple Simulink Coder types of the same size. For example, if the native integer size of your hardware is 32 bits, you can replace `int_T` and `int32_T` with the same type name, say, `myInt`.

- 1 Configure your target hardware settings in **Configuration Parameters > Hardware Implementation**.
- 2 Create a `Simulink.AliasType` object named `myInt`. In this case, because `int_T` and `int32_T` represent a 32-bit signed integer, set `BaseType` to `int32`.

```
myInt = Simulink.AliasType('int32')
```

- 3 Configure the same data type replacement for `int32_T` and `int_T`.

| Data type names |                      |                  |
|-----------------|----------------------|------------------|
| Simulink Name   | Code Generation Name | Replacement Name |
| double          | real_T               | <empty>          |
| single          | real32_T             | <empty>          |
| int32           | int32_T              | myInt            |
| int16           | int16_T              | <empty>          |
| int8            | int8_T               | <empty>          |
| uint32          | uint32_T             | <empty>          |
| uint16          | uint16_T             | <empty>          |
| uint8           | uint8_T              | <empty>          |
| boolean         | boolean_T            | <empty>          |
| int             | int_T                | myInt            |
| uint            | uint_T               | <empty>          |
| char            | char_T               | <empty>          |

**Note** Many-to-one data type replacement does not support the char (char\_T) built-in data type. Use char only in one-to-one data type replacements.

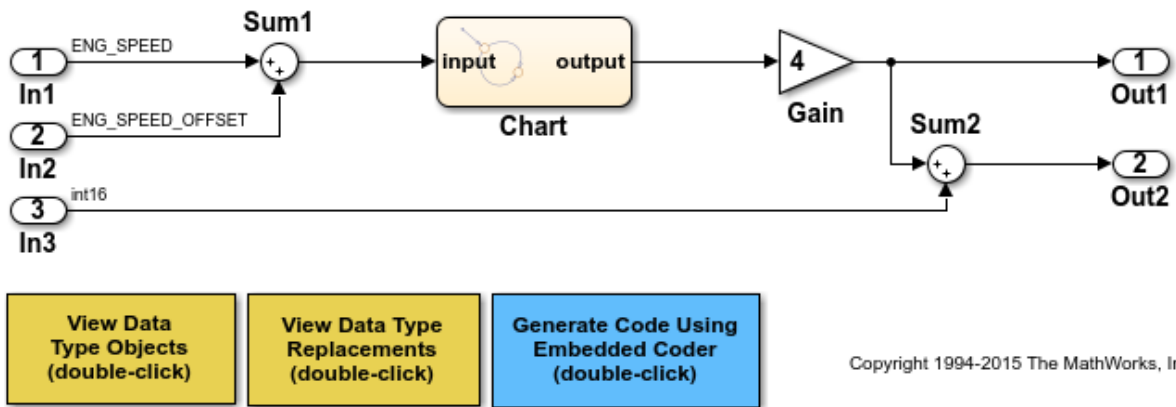

## Define Abstract Numeric Types and Rename Types

This model shows user-defined types, consisting of numeric and alias types. Numeric types allow you to define abstract numeric types, which is particularly useful for fixed-point types. Alias types allow you to rename types, which allows you create a relationship for types.

### Explore Example Model

Open the example model and configure it to show the generated names of blocks.

```
load_system('rtwdemo_udt')
set_param('rtwdemo_udt', 'HideAutomaticNames', 'off')
open_system('rtwdemo_udt')
```

### Key Features of User-Defined Types

- Displayed and propagated on signal lines
- Used to parameterize a model by type (e.g., In1 specifies its **Output data type** as ENG\_SPEED)
- Types with a common ancestor can be mixed, whereby the common ancestor is propagated (e.g., output of Sum1)
- Intrinsically supported by the Simulink Model Explorer
- Include an optional header file attribute that is ideal for importing legacy types (ignored for GRT targets)
- Types used in the generated code (ignored for GRT targets)

### Instructions

- 1 Inspect the user-defined types in the Model Explorer by double-clicking the first yellow button below.
- 2 Inspect the replacement data type mapping by double-clicking the second yellow button below.
- 3 Compile the diagram to display the types in this model (Simulation > Update Diagram or **Ctrl+D**).
- 4 Generate code with the blue button below and inspect model files to see how user-defined types appear in the generated code.
- 5 Modify the attributes of ENG\_SPEED and ENG\_SPEED\_OFFSET and repeat steps 1-4.

## Notes

- User-defined types are a feature of Simulink that facilitate parameterization of the data types in a model. Embedded Coder preserves alias data type names (e.g., `ENG_SPEED`) in the generated code, whereas Simulink Coder implements user-defined types as their base type (e.g., `real32_T`).
- Embedded Coder also enables you to replace the built-in data types with user-defined data types in the generated code.

## Control Names of Structure Types

To control the names of the standard structures that Simulink Coder creates by default to store data (`model_P` for parameter data, for example), use **Configuration Parameters > Code Generation > Symbols > Global types** to specify a naming rule. For more information, see “Customize Generated Identifiers” on page 78-21.

When you use nonvirtual buses and parameter structures to aggregate signals and block parameters into a custom structure in the generated code, control the name of the structure type by creating a `Simulink.Bus` object. For more information, see “Organize Data into Structures in Generated Code” on page 22-177.

## Generate Code That Reuses Data Types From External Code

To generate code that reuses a data type definition from your external C code, specify the data scope of the corresponding data type object or enumeration in Simulink as `Imported`. With this setting, the generated code includes (`#include`) the definition from your code. For more information about controlling the file placement of a custom data type, see “Control File Placement of Custom Data Types” on page 24-23.

Instead of creating individual data type objects and enumerated types, and then configuring them, consider creating the objects and types by using the `Simulink.importExternalCTypes` function. By default, the function configures the new objects and types so that the generated code imports (reuses) the type definitions from your code. You can then use the objects and types to set data types in a model and to configure data type replacements. For more information, see `Simulink.importExternalCTypes` and “Exchange Structured and Enumerated Data Between Generated and External Code” on page 24-34.

## Create Data Type Alias in the Generated Code

This example shows how to configure the generated code to use a data type name (typedef) that you specify.

### Export Type Definition

When you integrate code generated from a model with code from other sources, your model code can create an exported typedef statement. Therefore, all of the integrated code can use the type. This example shows how to export the definition of a data type to a generated header file.

Create a `Simulink.AliasType` object named `mySingleAlias` that acts as an alias for the built-in data type `single`.

```
mySingleAlias = Simulink.AliasType('single')
```

```
mySingleAlias =
```

```
 AliasType with properties:
```

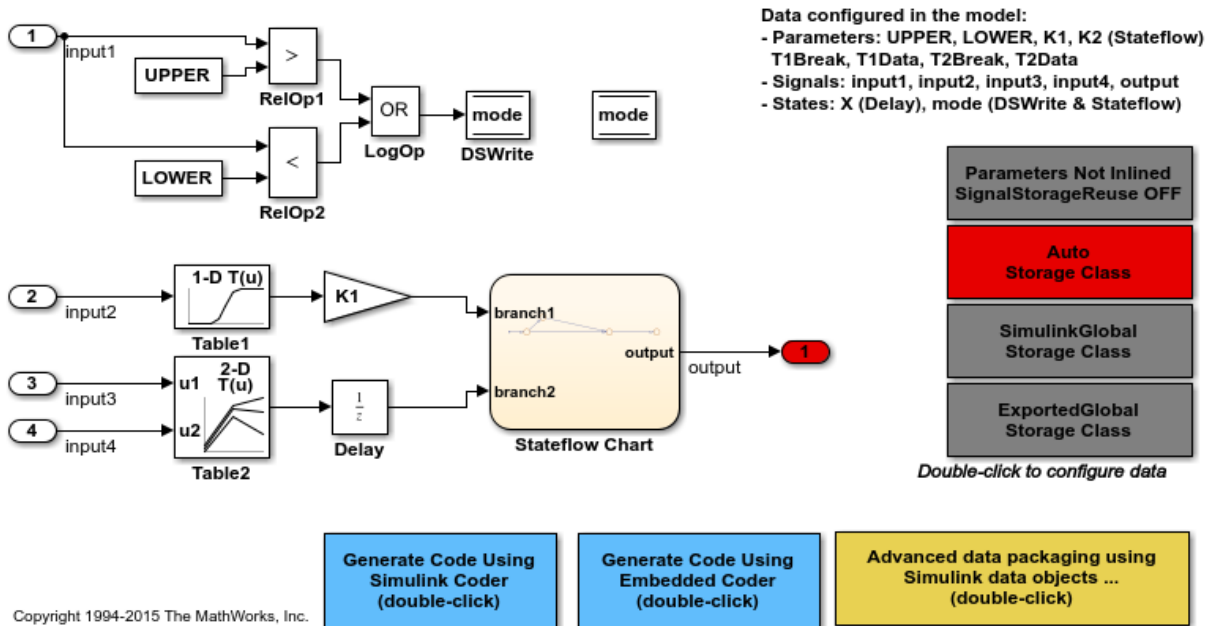

```
 Description: ''
 DataScope: 'Auto'
 HeaderFile: ''
 BaseType: 'single'
```

Configure the object to export its definition to a header file called `myHdrFile.h`.

```
mySingleAlias.DataScope = 'Exported';
mySingleAlias.HeaderFile = 'myHdrFile.h';
```

Open the model `rtwdemo_basicsc`.

```
open_system('rtwdemo_basicsc')
```

Copyright 1994-2015 The MathWorks, Inc.

Configure the model to show the generated names of blocks.

```
set_param('rtwdemo_basicsc', 'HideAutomaticNames', 'off')
```

In the model, select **View > Model Data Editor**.

In the model, select the Inport block labeled In1.

Use the **Data Type** column to set the data type to mySingleAlias.

```
set_param('rtwdemo_basicsc/In1', 'OutDataTypeStr', 'mySingleAlias')
```

In the model, set **Configuration Parameters > Code Generation > System target file** to ert.tlc. The code generator honors data type aliases such as mySingleAlias only if you select an ERT-based system target file.

```
set_param('rtwdemo_basicsc', 'SystemTargetFile', 'ert.tlc')
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
Starting build procedure for model: rtwdemo_basicsc
Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generation report, view the file `rtwdemo_basicsc_types.h`. The code creates a `#include` directive for the generated file `myHdrFile.h`.

```
file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc_types.h');
rtwdemodbtype(file,'#include "myHdrFile.h"',...
 '#include "myHdrFile.h"',1,1)
```

```
#include "myHdrFile.h"
```

View the file `myHdrFile.h`. The code uses the identifier `mySingleAlias` as an alias for the data type `real32_T`. By default, generated code represents the Simulink data type `single` by using the identifier `real32_T`.

The code also provides a macro guard of the form `RTW_HEADER_filename_h_`. When you export a data type definition to integrate generated code with code from other sources, you can use macro guards of this form to prevent unintentional identifier clashes.

```
file = fullfile('rtwdemo_basicsc_ert_rtw','myHdrFile.h');
rtwdemodbtype(file,'#ifndef RTW_HEADER_myHdrFile_h_',...
 ' * File trailer for generated code.',1,0)
```

```
#ifndef RTW_HEADER_myHdrFile_h_
#define RTW_HEADER_myHdrFile_h_
#include "rtwtypes.h"
```

```
typedef real32_T mySingleAlias;
typedef creal32_T cmySingleAlias;
```

```
#endif /* RTW_HEADER_myHdrFile_h_ */

/*
```

View the file `rtwdemo_basicsc.h`. The code uses the data type alias `mySingleAlias` to define the structure field `input1`, which corresponds to the Inport block labeled `In1`.

```
file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc.h');
rtwdemodbtype(file,...
 '/* External inputs (root inport signals with default storage) */',...
 '} ExtU_rtwdemo_basicsc_T;',1,1)
```

```

/* External inputs (root inport signals with default storage) */
typedef struct {
 mySingleAlias input1; /* '<Root>/In1' */
 real32_T input2; /* '<Root>/In2' */
 real32_T input3; /* '<Root>/In3' */
 real32_T input4; /* '<Root>/In4' */
} ExtU_rtwdemo_basicsc_T;

```

### Import Type Definition

When you integrate code generated from a model with code from other sources, to avoid redundant `typedef` statements, you can import a data type definition from the external code. This example shows how to import your own definition of a data type from a header file that you create.

Use a text editor to create a header file to import. Name the file `ex_myImportedHdrFile.h`. Place it in your working folder. Copy the following code into the file.

```

#ifndef HEADER_myImportedHdrFile_h_
#define HEADER_myImportedHdrFile_h_

typedef float myTypeAlias;

#endif

```

The code uses the identifier `myTypeAlias` to create an alias for the data type `float`. The code also uses a macro guard of the form `HEADER_filename_h`. When you import a data type definition to integrate generated code with code from other sources, you can use macro guards of this form to prevent unintentional identifier clashes.

At the command prompt, create a `Simulink.AliasType` object named `myTypeAlias` that creates an alias for the built-in type `single`. The Simulink data type `single` corresponds to the C data type `float`.

```
myTypeAlias = Simulink.AliasType('single')
```

```
myTypeAlias =
```

```
 AliasType with properties:
```

```
Description: ''
 DataScope: 'Auto'
 HeaderFile: ''
 BaseType: 'single'
```

Configure the object so that generated code imports the type definition from the header file `ex_myImportedHdrFile.h`.

```
myTypeAlias.DataScope = 'Imported';
myTypeAlias.HeaderFile = 'ex_myImportedHdrFile.h';
```

Open the model `rtwdemo_basicsc`.

```
open_system('rtwdemo_basicsc')
```

In the model, select **View > Model Data Editor**.

In the model, select the Inport block labeled In1.

Use the **Data Type** column to set the data type to `myTypeAlias`.

```
set_param('rtwdemo_basicsc/In1','OutDataTypeStr','myTypeAlias')
```

In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`. The code generator honors data type aliases such as `mySingleAlias` only if you select an ERT-based system target file.

```
set_param('rtwdemo_basicsc','SystemTargetFile','ert.tlc')
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
Starting build procedure for model: rtwdemo_basicsc
Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generation report, view the file `rtwdemo_basicsc_types.h`. The code creates a `#include` directive for your header file `ex_myImportedHdrFile.h`.

```
file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc_types.h');
rtwmodbtype(file,'#include "ex_myImportedHdrFile.h",...
 /* Forward declaration for RtModel */',1,0)

#include "ex_myImportedHdrFile.h"
```

View the file `rtwdemo_basicsc.h`. The code uses the data type alias `myTypeAlias` to define the structure field `input1`, which corresponds to the Inport block labeled In1.

```
file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc.h');
rtwdemodbtype(file,...
 /* External inputs (root inport signals with default storage) */,...
 /* ExtU_rtwdemo_basicsc_T; ',1,1)

/* External inputs (root inport signals with default storage) */
typedef struct {
 myTypeAlias input1; /* '<Root>/In1' */
 real32_T input2; /* '<Root>/In2' */
 real32_T input3; /* '<Root>/In3' */
 real32_T input4; /* '<Root>/In4' */
} ExtU_rtwdemo_basicsc_T;
```

### Display Base Data Types and Aliases on Model Diagram

When you display signal data types on the model diagram by selecting **Display > Signals and Ports > Port Data Types**, by default, the diagram displays aliases (such as `myTypeAlias`) instead of base data types (such as `int16`). To display the base types, choose an option for **Display > Signals and Ports > Port Data Type Display Format**. For more information, see “Port Data Types” (Simulink).

### Create a Named Fixed-Point Data Type in the Generated Code

This example shows how to create and name a fixed-point data type in generated code. You can use the name of the type to specify parameter and signal data types throughout a model and in generated code.

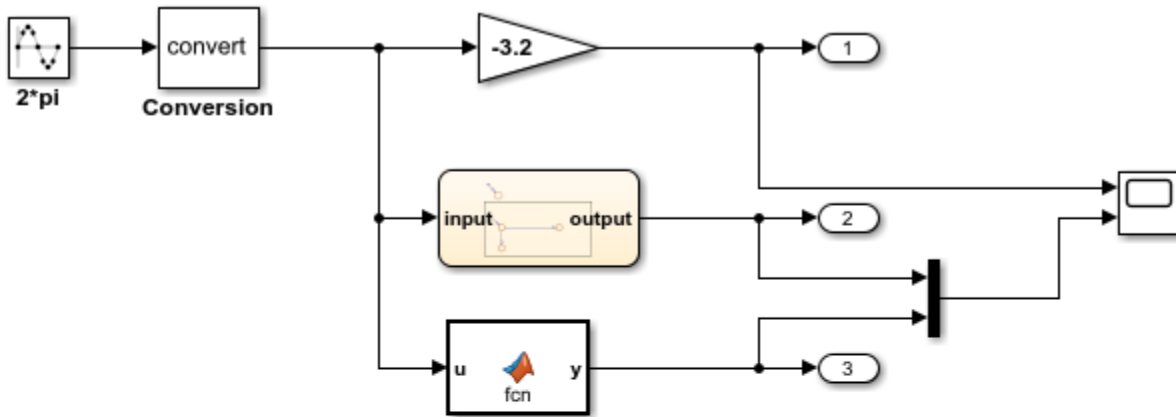

The example model `rtwdemo_fixpt1` uses fixed-point data types. So that you can more easily see the fixed-point data type in the generated code, in this example, you create a Simulink.Parameter object that appears in the code as a global variable.

Create a `Simulink.AliasType` object that defines a fixed-point data type. Name the object `myFixType`. The generated code uses the name of the object as a data type.

```
myFixType = Simulink.AliasType('fixdt(1,16,4)');
```

Open the model `rtwdemo_fixpt1`.

```
open_system('rtwdemo_fixpt1')
```

This introductory model shows fixed-point code generation in Simulink, Stateflow, and MATLAB. To generate and inspect the code, double-click the blue buttons below. An HTML report detailing the code is displayed automatically.

**Generate Code Using Simulink Coder (double-click)**

**Generate Code Using Embedded Coder (double-click)**

Copyright 1994-2012 The MathWorks, Inc.

Configure the model to show the generated names of the blocks.

```
set_param('rtwdemo_fixpt1', 'HideAutomaticNames', 'off')
```

In the model, select **View > Model Data Editor**.

In the Model Data Editor, select the **Parameters** tab.

In the model, select the Gain block.

In the Model Data Editor, for the row that represents the **Gain** parameter of the Gain block, in the **Value** column, specify myParam.

Click the action button (with three vertical dots) next to the parameter value. Select **Create**.

In the **Create New Data** dialog box, set **Value** to `Simulink.Parameter(8)`. In this example, for more easily readable code, you set the parameter value to 8 instead of -3.2. Click **Create**. A `Simulink.Parameter` object named `myParam` appears in the base workspace. The object stores the real-world value 8, which the Gain block uses for the value of the **Gain** parameter.

In the **Simulink.Parameter** property dialog box, set **Storage class** to `ExportedGlobal`. Click **OK**. With this setting, `myParam` appears in the generated code as a separate global variable.

In the Model Data Editor, use the **Data Type** column to set the data type of the **Gain** parameter of the Gain block to `myFixType`.

On the **Signals** tab, use the **Data Type** column to set the data type of the Gain block output to `myFixType`.

Use the **Data Type** column to set the data type of the Conversion block output to `myFixType`.

Alternatively, you can use these commands at the command prompt to configure the blocks and create the object:

```
set_param('rtwdemo_fixpt1/Gain', 'Gain', 'myParam', 'OutDataTypeStr', 'myFixType', ...
 'ParamDataTypeStr', 'myFixType')
myParam = Simulink.Parameter(8);
myParam.StorageClass = 'ExportedGlobal';
set_param('rtwdemo_fixpt1/Conversion', 'OutDataTypeStr', 'myFixType')
```

In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`. With this setting, the code generator honors data type aliases such as `myFixType`.

```
set_param('rtwdemo_fixpt1', 'SystemTargetFile', 'ert.tlc')
```

Select the configuration parameter **Generate code only**.

```
set_param('rtwdemo_fixpt1', 'GenCodeOnly', 'on')
```

Generate code from the model.

```
rtwbuild('rtwdemo_fixpt1')
```

```
Starting build procedure for model: rtwdemo_fixpt1
Successful completion of code generation for model: rtwdemo_fixpt1
```

In the code generation report, view the file `rtwdemo_fixpt1_types.h`. The code defines the type `myFixType` based on an integer type of the specified word length (16).

```
file = fullfile('rtwdemo_fixpt1_ert_rtw','rtwdemo_fixpt1_types.h');
rtwdemodbtype(file,'#ifndef DEFINED_TYPEDEF_FOR_myFixType_',...
 '/* Forward declaration for rtModel */',1,0)
```

```
#ifndef DEFINED_TYPEDEF_FOR_myFixType_
#define DEFINED_TYPEDEF_FOR_myFixType_

typedef int16_T myFixType;
typedef cint16_T cmyFixType;

#endif
```

View the file `rtwdemo_fixpt1.c`. The code uses the type `myFixType`, which is an alias of the integer type `int16`, to define the variable `myParam`.

```
file = fullfile('rtwdemo_fixpt1_ert_rtw','rtwdemo_fixpt1.c');
rtwdemodbtype(file,'myFixType myParam = 128;', 'myFixType myParam = 128;',1,1)

myFixType myParam = 128; /* Variable: myParam
```

The stored integer value 128 of `myParam` is not the same as the real-world value 8 because of the scaling that the fixed-point data type `myFixType` specifies. For more information, see “Scaling” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

The line of code that represents the Gain block applies a right bit shift corresponding to the fraction length specified by `myFixType`.

```
rtwdemodbtype(file,...
 'rtwdemo_fixpt1_Y.Out1 = (myFixType)((myParam * rtb_Conversion) >> 4);',...
 'rtwdemo_fixpt1_Y.Out1 = (myFixType)((myParam * rtb_Conversion) >> 4);',1,1)
```

```
rtwdemo_fixpt1_Y.Out1 = (myFixType)((myParam * rtb_Conversion) >> 4);
```

## Rename Data Type Object

To rename a data type object such as `Simulink.AliasType` or `Simulink.Bus` after you create it (for example, to rename an alias when coding standards change or when you encounter a naming conflict), you can allow Simulink to rename the object and correct all of the references to the object that appear in a model or models. In the Model Explorer, right-click the variable and select **Rename All**. For more information, see “Rename Variables” (Simulink).

## Display Signal Data Types on Block Diagram

For readability, you can display signal data types directly on a block diagram. When you use custom names for primitive data types, you can choose to display the custom name (the alias), the underlying primitive, or both. See “Port Data Types” (Simulink).

## Limitations

- You cannot configure the generated code to use these custom C data types:
  - Array types
  - Pointer types
  - `const` or `volatile` types
- You cannot configure the generated code to use generic C primitive types such as `int` and `short`.

## Data Type Replacement Limitations

When you select the model configuration parameter **Replace data type names in the generated code** on the **Code Generation > Data Type Replacement** pane of the Configuration Parameters dialog box, these limitations apply:

- Data type replacement does not support multiple levels of mapping. Each replacement data type name maps directly to one or more built-in data types.
- Data type replacement is not supported for simulation target code generation for referenced models.

- If you select the **Classic call interface** configuration parameter for your model, data type replacement is not supported.
- Code generation performs data type replacements while generating `.c`, `.cpp`, and `.h` files. Code generation places these files in build folders (including top and referenced model build folders) and in the `_sharedutils` folder. *Exceptions* are as follows:
  - `rtwtypes.h`
  - `multiword_types.h`
  - `model_reference_types.h`
  - `builtin_typeid_types.h`
  - `model_sf.c` or `.cpp` (ERT S-function wrapper)
  - `model_dt.h` (C header file supporting external mode)
  - `model_capi.c` or `.cpp`
  - `model_capi.h`
- Data type replacement is not supported for complex data types.
- Many-to-one data type replacement is not supported for the `char` data type. Attempting to use `char` as part of a many-to-one mapping to a custom data type represents a violation of the MISRA C specification. For example, if you map `char` (`char_T`) and either `int8` (`int8_T`) or `uint8` (`uint8_T`) to the same replacement type, the result is a MISRA C violation. If you try to generate C++ code, the code generator makes invalid implicit type casts, resulting in compile-time errors. Use `char` only in one-to-one data type replacements.
- For ERT S-functions, replace the `boolean` data type with only an 8-bit integer, `int8`, or `uint8`.
- Set the `DataScope` property of a `Simulink.AliasType` object to `Auto` (default) or `Imported`.

## Control File Placement of Custom Data Types

By default, when you use data type objects, such as `Simulink.AliasType` and `Simulink.Bus`, and custom enumerations to specify data types for signals and block parameters, the code generated from the model defines the types (for example, with `typedef` statements). To ease integration of the generated code with other existing code and to modularize the generated code, you can control the file placement of the type definitions by adjusting the properties of the objects and the enumerations.

### Data Scope and Header File

To control the file placement of a custom type definition in generated code, set the `DataScope` and `HeaderFile` properties of the data type object according to the table. Similarly, for an enumeration that you define in a MATLAB file, set the return arguments of the `getDataScope` and `getHeaderFile` methods.

- *typename* is the name of the custom data type.
- *filename* is the name of a header file.
- *model* is the name of the model.

| Goal                                                                       | Specify DataScope as | Specify HeaderFile as                                  |
|----------------------------------------------------------------------------|----------------------|--------------------------------------------------------|
| Export type definition to <i>model_types.h</i>                             | Auto                 | Empty                                                  |
| Import type definition from a header file that you create, <i>filename</i> | Auto or Imported     | <i>filename</i> (if necessary, include a .h extension) |
| Export type definition to a generated header file, <i>filename.h</i>       | Exported             | <i>filename</i> or <i>filename.h</i>                   |
| Export type definition to a generated header file, <i>typename.h</i>       | Exported             | Empty                                                  |

When you import a data type definition (for example, by setting `DataScope` to `Imported`), the generated model code creates an `#include` directive for your header file in place of a type definition. You supply the header file that contains the definition.

### Considerations for Data Type Replacement

- If you use data type replacement to replace a built-in Simulink data type with your own data type in generated code (see “Model Configuration Parameters: Code Generation Data Type Replacement”), `typedef` statements and `#include` directives appear in `rtwtypes.h` instead of `model_types.h`.
- When a `Simulink.AliasType` or `Simulink.NumericType` object participates in data type replacements, you cannot set the `DataScope` property of the object to `Exported`. Therefore, if you want the code generator to generate the corresponding `typedef` statement, you cannot control the file placement of the statement. However, you can set `DataScope` to `Imported`, which means that you can configure the code to reuse the `typedef` statement that your external code provides.

As a workaround, instead of using the data type object as a data type replacement, use the object to set the data types of individual data items in a model. To configure many data items, you can use the Model Data Editor and take advantage of data type propagation and inheritance. For more information, see “Control Names of Primitive Data Types” on page 24-2.

### Import Definition of Numerically Complex Data Type

You can use a `Simulink.AliasType` object with numerically complex data (i). In this case, if you configure the generated code to import the type definition from your external code (for example, by setting the `DataScope` property to `Imported`), your code must provide two complementary `typedef` statements.

Suppose your external header file `myAliasTypes.h` defines the data type `IAT_int32` as an alias of a 32-bit integer. The file must define two types: `IAT_int32` and `cIAT_int32`:

```
#ifndef myAliasTypes_H_
#define myAliasTypes_H_

#include "rtwtypes.h"

typedef int32_T IAT_int32;
typedef cint32_T cIAT_int32;

#endif
```

You do not need to create two `Simulink.AliasType` objects. In this example, you create one object, `IAT_int32`. The generated code then creates complex data (variables) by using both `IAT_int32` and `cIAT_int32`.

## Macro Guards

When you export one or more data type definitions to a generated header file, the file contains a file-level macro guard of the form `RTW_HEADER_<filename>.h`.

Suppose you use several `Simulink.AliasType` objects: `mySingleAlias`, `myDoubleAlias`, and `myIntAlias` with these properties:

- `DataScope` set to `Exported`
- `HeaderFile` set to `myTypes.h`

When you generate code, the guarded file `myTypes.h` contains the `typedef` statements:

```
#ifndef RTW_HEADER_myTypes_h_
#define RTW_HEADER_myTypes_h_
#include "rtwtypes.h"

typedef real_T myDoubleAlias;
typedef real32_T mySingleAlias;
typedef int16_T myIntAlias;

#endif
```

When you export data type definitions to `model_types.h`, the file contains a macro guard of the form `_DEFINED_TYPEDEF_FOR_<typename>` for each `typedef` statement. Suppose you use a `Simulink.AliasType` object `mySingleAlias` with these properties:

- `DataScope` set to `Auto`
- `HeaderFile` not specified

When you generate code, the file `model_types.h` contains the guarded `typedef` statement:

```
#ifndef _DEFINED_TYPEDEF_FOR_mySingleAlias_
#define _DEFINED_TYPEDEF_FOR_mySingleAlias_

typedef real32_T mySingleAlias;

#endif
```

## **Related Examples**

- “Control Data Type Names in Generated Code” on page 24-2

## Replace and Rename Data Types to Conform to Coding Standards

By default, the generated code uses data type aliases such as `real_T` and `int32_T`. The code uses these aliases to define global and local variables. If your coding standards require that you use other data type aliases, including aliases that your existing code defines, you can:

- Configure data type replacement for the entire model.
- Configure individual data items (such as signals, parameters, and states) to use specific data type aliases.

For information about controlling data types in a model, see “Control Signal Data Types” (Simulink).

### Inspect External C Code

Save this C code into a file named `my_types.h` in your current folder. This file represents a header file in your existing code that defines custom data type aliases by using `typedef` statements.

```
#include <stdbool.h>

typedef double my_dblPrecision;
typedef short my_int16;
typedef bool my_bool;
```

### Explore Example Model and Default Generated Code

- 1 Open the example model `ex_data_type_replacement`.
 

```
open_system(fullfile(docroot, 'toolbox', 'ecoder', 'examples', ...
 'ex_data_type_replacement'))
```
- 2 In the model, select **View > Model Data Editor**.
- 3 In the Model Data Editor, inspect the **Signals** tab.
- 4 Set the **Change view** drop-down list to **Code**. In the data table, the **Storage Class** column shows that named signal lines such as `temp` use the storage class `ExportedGlobal`. With this setting, the signal lines appear in the generated code as separate global variables.

- 5 Set the **Change view** drop-down list to **Design**.
- 6 Update the block diagram.

Simulink assigns a specific data type to each signal that uses an inherited data type setting such as `Inherit: Inherit via internal rule`.

- 7 In the data table, expand the width of the **Data Type** column. The column shows that the signals in the model use a mix of the data types `int16`, `double`, and `boolean`. You can also see these data types in the model.
- 8 Generate code from the model.
- 9 In the code generation report, inspect the shared utility file `rtwtypes.h`. The code uses `typedef` statements to rename the primitive C data types by using standard Simulink Coder aliases. For example, the code renames the primitive type `double` by using the alias `real_T`.

```
typedef double real_T;
```

- 10 Inspect the file `ex_data_type_replacement.c`. The code uses the default data type aliases to declare and define variables. For example, the code uses the data types `real_T`, `int16_T`, and `boolean_T` to define the global variables `flowIn`, `temp`, and `intlk`.

```
real_T flowIn; /* '<Root>/In3' */
int16_T temp; /* '<Root>/Add2' */
boolean_T intlk; /* '<S1>/Compare' */
```

The model `step` function defines local variables by using the same data type aliases.

```
real_T rtb_Add;
real_T rtb_FilterCoefficient;
```

## Reuse External Data Type Definitions

Configure the generated code to define variables by using the custom data types defined in `my_types.h` instead of the default type names.

- 1 At the command prompt, create a `Simulink.AliasType` object for each data type alias that your external code defines.

```
Simulink.importExternalCTypes('my_types.h');
```

In the base workspace, the `Simulink.importExternalCTypes` function creates the objects `my_dblPrecision`, `my_int16`, and `my_bool`.

For each object, the function sets the `DataScope` property to 'Imported' and the `HeaderFile` property to 'my\_types.h'. With these settings, the code generator does not create a `typedef` statement for each object, but instead the generated code reuses the statements from `my_types.h` by including (`#include`) the file.

- 2 In the model, in the Configuration Parameters dialog box, on the **Code Generation > Data Type Replacement** pane, select **Replace data type names in the generated code**.
- 3 Specify the options in the **Replacement Name** column according to the table.

| Simulink Name | Replacement Name |
|---------------|------------------|
| double        | my_dblPrecision  |
| int16         | my_int16         |
| boolean       | my_bool          |

- 4 Generate code from the model.
- 5 In the code generation report, inspect the file `rtwtypes.h`. Now, the code uses an `#include` directive to import the contents of the external header file `my_types.h`, which contains the custom data type aliases.

```
#include "my_types.h" /* User defined replacement datatype for int16_T real_T boolean_T */
```

- 6 Inspect the file `ex_data_type_replacement.c`. The code uses the custom data type aliases `my_dblPrecision`, `my_int16`, and `my_bool` to define the global variables such as `flowIn`, `temp`, and `intlk`.

```
my_dblPrecision flowIn; /* '<Root>/In3' */
my_int16 temp; /* '<Root>/Add2' */
my_bool intlk; /* '<S1>/Compare' */
```

The model `step` function defines local variables by using the custom data type aliases.

```
my_dblPrecision rtb_Add;
my_dblPrecision rtb_FilterCoefficient;
```

## Create Meaningful Data Type Aliases for Individual Data Items

Suppose your coding standards require that important data items use a data type whose name indicates the real-world significance. You can create more `Simulink.AliasType` objects to represent these custom data type aliases. Use the objects to set the data types of data items in the model.

- 1 In the Model Data Editor **Data Type** column, use the `Simulink.AliasType` objects to set the data types of these block outputs. You can select a signal line in the model, which highlights the corresponding row in the Model Data Editor, or search for the signals in the Model Data Editor by using the **Filter contents** box.

| Block                                | Output Data Type |
|--------------------------------------|------------------|
| Flow Setpoint                        | flow_T           |
| Add2 (which feeds the Compare block) | diffTemp_T       |

- 2 Use the Model Data Editor **Inports/Outports** tab to set the data type of the third Inport block to `flow_T`.
- 3 In the model, select **View > Property Inspector**.
- 4 Select the block labeled Flow Controller. In the Property Inspector, click **Open** to open the block dialog box.
- 5 On the **Data Types** tab, set **Sum output** to `ctrl_T`. Click **OK**.

With these data type settings, some of the named signals, such as `temp` and `flowIn`, use data types that evoke real-world quantities, such as liquid flow rate and temperature.

- 6 At the command prompt, create `Simulink.AliasType` objects to represent these new custom data type aliases.

```
flow_T = Simulink.AliasType('double');
diffTemp_T = Simulink.AliasType('int16');
ctrl_T = Simulink.AliasType('double');
```

In the model, the signals `flowIn` and `flowSetPt` use the primitive data type `double`, so the data type alias `flow_T` maps to `double`.

- 7 Update the block diagram.

Due to data type inheritance, other signals also use the custom data type aliases. For example, the output data type of the Add block fed by the third Inport block is set to `Inherit: Inherit via internal rule`. The internal rule chooses the same data type that the block inputs use, `flow_T`.

- 8 Generate code from the model.
- 9 The file `ex_data_type_replacement_types.h` defines the new data types `flow_T`, `diffTemp_T`, and `ctrl_T` as aliases of `my_dblPrecision` and `my_int16`.

```
typedef my_dblPrecision flow_T;
typedef my_int16 diffTemp_T;
typedef my_dblPrecision ctrl_T;
```

- 10** In the file `ex_data_type_replacement.c`, the code defines global variables by using the new type names.

```
flow_T flowIn; /* '<Root>/In3' */
flow_T flowSetPt; /* '<Root>/Flow Setpoint' */
ctrl_T flowCtrl; /* '<Root>/Interlock' */
diffTemp_T temp; /* '<Root>/Add2' */
```

- 11** For blocks that do not use the new data types, the corresponding generated code continues to use the replacement types that you specified earlier. For example, in the file `ex_data_type_replacement.h`, the outputs of the blocks `In1` and `In2` appear as structure fields that use the replacement type `my_int16`.

```
/* External inputs (root inport signals with auto storage) */
typedef struct {
 my_int16 In1; /* '<Root>/In1' */
 my_int16 In2; /* '<Root>/In2' */
} ExtU_ex_data_type_replacement_T;
```

## Create Single Point of Definition for Primitive Types

The custom data type aliases `flow_T` and `ctrl_T` map to the primitive data type `double`. If you want to change this underlying data type from `double` to `single` (`float`), you must remember to modify the `BaseType` property of both `Simulink.AliasType` objects.

To more easily make this change, you can create a `Simulink.NumericType` object and configure both `Simulink.AliasType` objects to refer to it. Then, you need to modify only the `Simulink.NumericType` object. A `Simulink.NumericType` object enables you to share a data type without creating a data type alias.

- 1** At the command prompt, create a `Simulink.NumericType` object to represent the primitive data type `single`.

```
sharedType = Simulink.NumericType;
sharedType.DataTypeMode = 'Single';
```

- 2** Configure the `Simulink.AliasType` objects `flow_T` and `ctrl_T` to acquire an underlying data type from this new object.

```
flow_T.BaseType = 'sharedType';
ctrl_T.BaseType = 'sharedType';
```

- 3 In the model, select **Display > Signals and Ports > Port Data Type Display Format > Base and Alias Types** (see “Port Data Types” (Simulink)). Update the block diagram.

The data type indicators in the model show that the aliases `flow_T` and `ctrl_T` map to the primitive type `single`. To change this underlying primitive type, you can modify the `DataTypeMode` property of the `Simulink.NumericType` object, `sharedType`.

By default, the `Simulink.NumericType` object does not cause another `typedef` statement to appear in the generated code.

If you generate code from the model while the `Simulink.NumericType` object represents the data type `single`, the generated code maps `flow_T` and `ctrl_T` to the default Simulink Coder data type alias `real32_T`, which maps to the C data type `float`. You can replace `real32_T` in the same way that you replaced `real_T`, `int16_T`, and `boolean_T` (**Configuration Parameters > Code Generation > Data Type Replacement**).

## Permanently Store Data Type Objects

The `Simulink.NumericType` and `Simulink.AliasType` objects in the base workspace do not persist if you end your current MATLAB session. To permanently store these objects, consider migrating your model to a data dictionary. See “Migrate Models to Use Simulink Data Dictionary” (Simulink).

## Create and Maintain Objects Corresponding to Multiple C typedef Statements

To create `Simulink.AliasType` objects for a large number of `typedef` statements in your external C code, consider using the `Simulink.importExternalCTypes` function.

## Exchange Structured and Enumerated Data Between Generated and External Code

This example shows how to generate code that exchanges data with external, existing code. Construct and configure a model to match data types with the external code and to avoid duplicating type definitions and memory allocation (definition of global variables). Then, compile the generated code together with the external code into a single application.

### Inspect External Code

Create the file `ex_cc_algorithm.c` in your current folder.

```
#include "ex_cc_algorithm.h"

inSigs_T inSigs;

float_32 my_alg(void)
{
 if (inSigs.err == TMP_HI) {
 return 27.5;
 }
 else if (inSigs.err == TMP_LO) {
 return inSigs.sig1 * calPrms.cal3;
 }
 else {
 return inSigs.sig2 * calPrms.cal3;
 }
}
```

The C code defines a global structure variable named `inSigs`. The code also defines a function, `my_alg`, that uses `inSigs` and another structure variable named `calPrms`.

Create the file `ex_cc_algorithm.h` in your current folder.

```
#ifndef ex_cc_algorithm_h
#define ex_cc_algorithm_h

typedef float float_32;

typedef enum {
```

```
 TMP_HI = 0,
 TMP_LO,
 NORM,
} err_T;

typedef struct inSigs_tag {
 err_T err;
 float_32 sig1;
 float_32 sig2;
} inSigs_T;

typedef struct calPrms_tag {
 float_32 cal1;
 float_32 cal2;
 float_32 cal3;
} calPrms_T;

extern calPrms_T calPrms;
extern inSigs_T inSigs;

float_32 my_alg(void);

#endif
```

The file defines `float_32` as an alias of the C data type `float`. The file also defines an enumerated data type, `err_T`, and two structure types, `inSigs_T` and `calPrms_T`.

The function `my_alg` is designed to calculate a return value by using the fields of `inSigs` and `calPrms`, which are global structure variables of the types `inSigs_T` and `calPrms_T`. The function requires another algorithm to supply the signal data that `inSigs` stores.

This code allocates memory for `inSigs`, but not for `calPrms`. Create a model whose generated code:

- Defines and initializes `calPrms`.
- Calculates values for the fields of `inSigs`.
- Reuses the type definitions (such as `err_T` and `float_32`) that the external code defines.

## Create Simulink Model

- 1 So that you can create enumerated and structured data in the Simulink model, first create Simulink representations of the data types that the external code defines. Store the Simulink types in a new data dictionary named `ex_cc_integ.sldd`.

```
Simulink.importExternalCTypes('ex_cc_algorithm.h', ...
 'DataDictionary', 'ex_cc_integ.sldd');
```

The data dictionary appears in your current folder.

- 2 To inspect the dictionary contents in the Model Explorer, in your current folder, double-click the file, `ex_cc_integ.sldd`.

The `Simulink.importExternalCTypes` function creates `Simulink.Bus`, `Simulink.AliasType`, and `Simulink.data.dictionary.EnumTypeDefinition` objects that correspond to the custom C data types from `ex_cc_algorithm.h`.

- 3 Create a new model and save it in your current folder as `ex_struct_enum_integ`.
- 4 Link the model to the data dictionary. In the model, select **File > Model Properties > Link to Data Dictionary**.
- 5 Add algorithmic blocks that calculate the fields of `inSigs`.

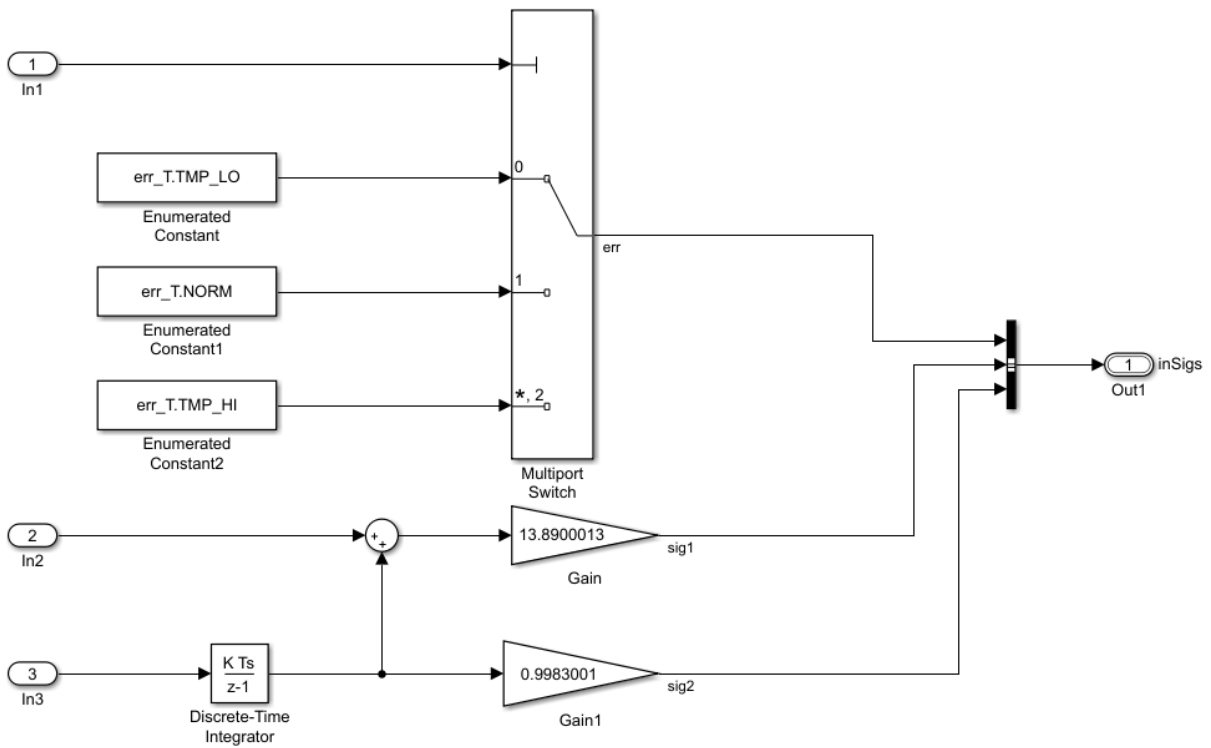

Now that you have the algorithm model, you must:

- Organize the output signals into a structure variable named `inSigs`.
- Create the structure variable `calPrms`.
- Include `ex_cc_algorithm.c` in the build process that compiles the code after code generation.

## Configure Generated Code to Write Output Data to Existing Structure Variable

- 1 Add a Bus Creator block near the existing Output blocks. The output of a Bus Creator block is a bus signal, which you can configure to appear in the generated code as a structure.
- 2 In the Bus Creator block, set these parameters:
  - **Number of inputs** to 3
  - **Output data type** to Bus: `inSigs_T`
  - **Output as nonvirtual bus** to selected
- 3 Delete the three existing Output blocks (but not the signals that enter the blocks).
- 4 Connect the three remaining signal lines to the inputs of the Bus Creator block.
- 5 Add an Output block after the Bus Creator block. Connect the output of the Bus Creator to the Output.
- 6 In the Output block, set the **Data type** parameter to Bus: `inSigs_T`.
- 7 In the model, select **View > Model Data Editor**.
- 8 On the **Inports/Outports** tab, for the Inport blocks labeled In2 and In3, change **Data Type** from Inherit: auto to `float_32`.
- 9 Change the **Change View** drop-down list from Design to Code.
- 10 For the Output block, set **Signal Name** to `inSigs`.
- 11 Set **Storage Class** to `ImportFromFile`.
- 12 Set **Header File** to `ex_cc_algorithm.h`.
- 13 Inspect the **Signals** tab.
- 14 In the model, select the output signal of the Multiport Switch block.
- 15 In the Model Data Editor, for the selected signal, set **Name** to `err`.
- 16 Set the name of the output signal of the Gain block to `sig1`.
- 17 Set the name of the output signal of the Gain1 block to `sig2`.

When you finish, the model stores output signal data (such as the signals `err` and `sig1`) in the fields of a structure variable named `inSigs`.

Because you set **Storage Class** to `ImportFromFile`, the generated code does not allocate memory for `inSigs`.

## Configure Generated Code to Define Parameter Data

Configure the generated code to define the global structure variable, `calPrms`, that the external code needs.

- 1 In the Model Explorer **Model Hierarchy** pane, under the dictionary node **ex\_cc\_integ**, select the **Design Data** node.
- 2 In the **Contents** pane, select the `Simulink.Bus` object `calPrms_T`.
- 3 In the Dialog pane (the right pane), click **Launch Bus Editor**.
- 4 In the Bus Editor, in the left pane, select `calPrms_T`.

- 5 On the Bus Editor toolbar, click the **Create/Edit a Simulink.Parameter Object from a Bus Object** button.
- 6 In the MATLAB Editor, copy the generated MATLAB code and run the code at the command prompt. The code creates a `Simulink.Parameter` object in the base workspace.
- 7 In the Model Explorer **Model Hierarchy** pane, select **Base Workspace**.
- 8 Use the Model Explorer to move the parameter object, `calPrms_T_Param`, from the base workspace to the Design Data section of the data dictionary.
- 9 With the data dictionary selected, in the **Contents** pane, rename the parameter object as `calPrms`.
- 10 In the Model Data Editor, select the **Parameters** tab.
- 11 Set the **Change view** drop-down list to **Design**.
- 12 For the Gain block, replace the value `13.8900013` with `calPrms.cal1`.
- 13 In the other Gain block, use `calPrms.cal2`.
- 14 While editing the value of the other Gain block, next to `calPrms.cal2`, click the action button  and select **calPrms > Open**.
- 15 In the `calPrms` property dialog box, next to the **Value** box, click the action button  and select **Open Variable Editor**.
- 16 Use the Variable Editor to set the field values in the parameter object.
  - For the fields `cal1` and `cal2`, use the numeric values that the Gain blocks in the model previously used.
  - For `cal3`, use a nonzero number such as `15.2299995`.

When you finish, close the Variable Editor.

- 17 In the property dialog box, set **Storage class** to `ExportedGlobal`. Click **OK**.
- 18 Use the Model Explorer to save the changes that you made to the dictionary.

## Generate, Compile, and Inspect Code

- 1 Configure the model to include `ex_cc_algorithm.c` in the build process. Set **Configuration Parameters > Code Generation > Custom Code > Additional build information > Source files** to `ex_cc_algorithm.c`.
- 2 Generate code from the model.

- 3 Inspect the generated file `ex_struct_enum_integ.c`. The file defines and initializes `calPrms`.

```
/* Exported block parameters */
calPrms_T calPrms = {
 13.8900013F,
 0.998300076F,
 15.23F
}; /* Variable: calPrms
```

The generated algorithm in the model `step` function defines a local variable for buffering the value of the signal `err`.

```
err_T rtb_err;
```

The algorithm then calculates and stores data in the fields of `inSig`.

```
inSigs.err = rtb_err;
inSigs.sig1 = (rtU.In2 + rtDW.DiscreteTimeIntegrator_DSTATE) * calPrms.cal1;
inSigs.sig2 = (real32_T)(calPrms.cal2 * rtDW.DiscreteTimeIntegrator_DSTATE);
```

## Replace Data Type Names Throughout Model

To generate code that uses `float_32` instead of the default, `real32_T`, instead of manually specifying the data types of block output signals and bus elements, you can use data type replacement (**Configuration Parameters > Code Generation > Data Type Replacement**). For more information, see “Replace and Rename Data Types to Conform to Coding Standards” on page 24-27.

## Specify Boolean and Data Type Limit Identifiers

You can use command-line parameters to replace the default Boolean and data type limit identifiers. If you want to associate the data type limit identifiers with the data type names, consider replacing the default identifiers. You can also use command-line parameters to import a header file with the Boolean and data type limit identifier definitions.

### Data Type Limit Identifiers

You can control the data type limit identifiers in the generated code by using the command-line parameters in this table.

| Data Type Limit                 | Default Identifier | Command-Line Parameter |
|---------------------------------|--------------------|------------------------|
| 8-bit integer maximum           | MAX_int8_T         | MaxIdInt8              |
| 16-bit integer maximum          | MAX_int16_T        | MaxIdInt16             |
| 32-bit integer maximum          | MAX_int32_T        | MaxIdInt32             |
| 8-bit unsigned integer maximum  | MAX_uint8_T        | MaxIdUInt8             |
| 16-bit unsigned integer maximum | MAX_uint16_T       | MaxIdUInt16            |
| 32-bit unsigned integer maximum | MAX_uint32_T       | MaxIdUInt32            |
| 8-bit integer minimum           | MIN_int8_T         | MinIdInt8              |
| 16-bit integer minimum          | MIN_int16_T        | MinIdInt16             |
| 32-bit integer minimum          | MIN_int32_T        | MinIdInt32             |

For example, to change the default identifiers for the 8-bit integer data limit minimum and maximum to `s4g_S4MIN` and `s4g_S4MAX`, respectively:

```
set_param(gcs, 'MinIdInt8', 's4g_S4MIN');
set_param(gcs, 'MaxIdInt8', 's4g_S4MAX');
```

If you do not import a header file, the generated file `rtwtypes.h` defines the 8-bit integer data minimum and maximum identifiers:

```
#define s4g_S4MAX ((int8_T)(127))
#define s4g_S4MIN ((int8_T)(-128))
```

If you do import a header file defining the data type limit identifiers, the header file is included in `rtwtypes.h`.

## Boolean Identifiers

You can control the Boolean identifiers in the generated code by using the command-line parameters in this table. When changing boolean identifiers, you must define `false` to be numerically equivalent to 0, and `true` to be numerically equivalent to 1.

| Boolean | Default Identifier | Command-Line Parameter      |
|---------|--------------------|-----------------------------|
| True    | <code>true</code>  | <code>BooleanTrueId</code>  |
| False   | <code>false</code> | <code>BooleanFalseId</code> |

For example, to change the default Boolean `true` and `false` identifiers:

```
set_param(gcs, 'BooleanTrueId', 'bTrue');
set_param(gcs, 'BooleanFalseId', 'bFalse')
```

If you do not import a header file, the generated file `rtwtypes.h` defines the Boolean identifiers:

```
#define bFalse (0U)
#define bTrue (1U)
```

If you do import a header file defining the Boolean identifiers, the header file is included in `rtwtypes.h`.

---

**Note** When changing boolean identifiers, you must define `false` to be numerically equivalent to 0, and `true` to be numerically equivalent to 1.

---

## Boolean and Data Type Limit Identifier Header Files

You can import a header file that defines Boolean and data type limit identifiers using the command-line parameter `TypeLimitIdReplacementHeaderFile`. The header file is included in `rtwtypes.h`. You must use the command-line parameters to specify the Boolean and data type limit identifiers that are included in the imported header file.

For example, if you have a header file `myfile.h` with data type limit definitions, use `TypeLimitIdReplacementHeaderFile` to include the definitions in the generated code:

```
set_param(gcs, 'TypeLimitIdReplacementHeaderFile', 'myfile.h');
```

The generated file `rtwtypes.h` includes `myfile.h`.

```
/* Import type limit identifier replacement definitions. */
#include "myfile.h"
```

# Module Packaging Tool (MPT) Data Objects in Embedded Coder

---

## MPT Data Object Properties

| In this section...                                                   |
|----------------------------------------------------------------------|
| “Specify Persistence Level for Signals and Parameters” on page 25-16 |
| “Register mpt User Object Types” on page 25-19                       |

The following table describes the properties and property values for `mpt.Parameter` and `mpt.Signal` data objects that appear in the Model Explorer.

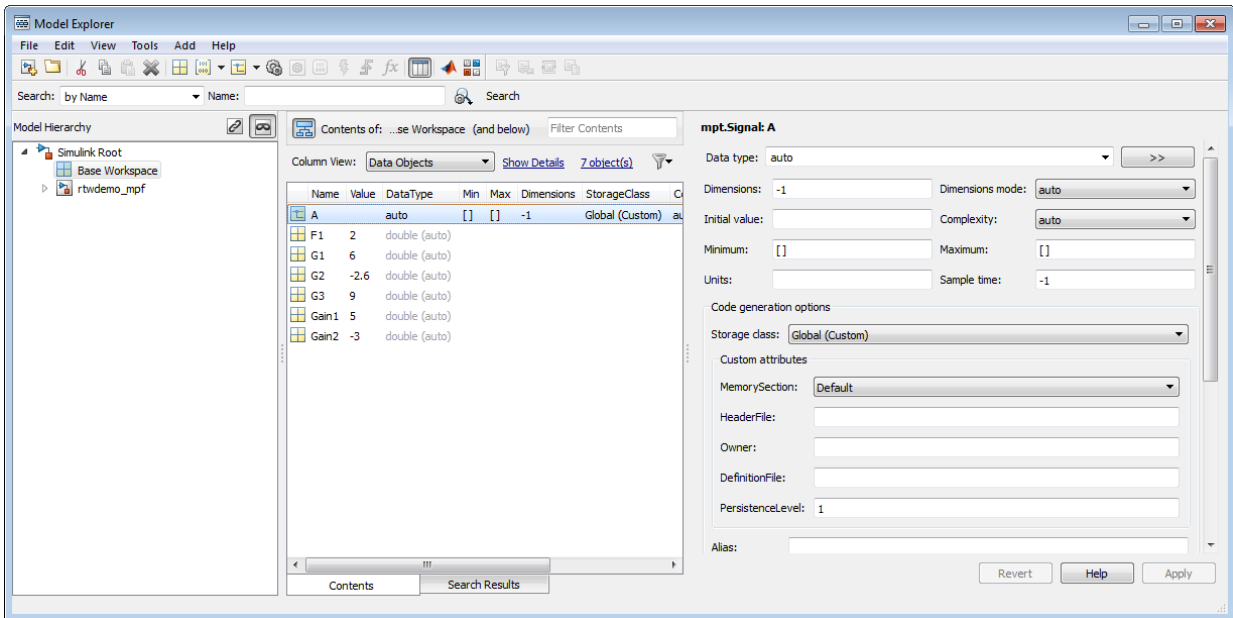

---

**Note** You can create `mpt.Signal` and `mpt.Parameter` objects in the base MATLAB or model workspace. However, if you create a signal object in a model workspace, the object's storage class must be set to `Auto`.

---

The figure below shows an example of the Model Explorer. When you select an `mpt.Parameter` or `mpt.Signal` data object in the middle pane, its properties and property values display in the rightmost pane.

In the Properties column, the table lists the properties in the order in which they appear on the Model Explorer.

**Parameter and Signal Property Values**

| Class:<br>Parameter,<br>Signal, or<br>Both | Property         | Available Property<br>Values<br>(* Indicates<br>Default) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------------|------------------|----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Both                                       | User object type | *auto                                                    | <p>Prenamed and predefined property sets that are registered in the <code>sl_customization.m</code> file. The fields on the Model Explorer are populated with default values.</p> |
|                                            |                  | Listed user object type name                             | <p>Select a user object type name to apply the properties and values that you associated with this name in the <code>sl_customization.m</code> file. The fields on the Model Explorer are automatically populated with those values.</p>                                                                                                                                                                                                                    |
| Parameter                                  | Value            | *0                                                       | <p>The data type and numeric value of the data object. For example, <code>int8(5)</code>. The numeric value is used as an initial parameter value in the generated code.</p>                                                                                                                                                                                                                                                                                |
| Both                                       | Data type        |                                                          | <p>Used to specify the data type for an <code>mpt.Signal</code> data object, but not for an <code>mpt.Parameter</code> data object. The data type for an <code>mpt.Parameter</code> data object is specified in the <b>Value</b> field above. See “About Data Types in Simulink” (Simulink).</p>                                                                                                                                                            |
| Both                                       | Unit             | *null                                                    | <p>Units of measurement of the signal or parameter. (Enter text in this field.)</p>                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Class:<br/>Parameter,<br/>Signal, or<br/>Both</b> | <b>Property</b>         | <b>Available Property<br/>Values<br/>(* Indicates<br/>Default)</b>                                                              | <b>Description</b>                                                                                                                                                                         |
|------------------------------------------------------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Both                                                 | Dimensions              | * - 1                                                                                                                           | The dimension of the signal or parameter. For a parameter, the dimension is derived from its value.                                                                                        |
| Both                                                 | Complexity              | *auto<br>real<br>complex                                                                                                        | Complexity specifies whether the signal or parameter is a real or complex number. Select auto for the code generator to decide. For a parameter, the complexity is derived from its value. |
| Signal                                               | Sample time             | * - 1                                                                                                                           | Model or block execution rate.                                                                                                                                                             |
| Signal                                               | Sample mode             | *auto                                                                                                                           | Determines how the signal propagates through the model. Select auto for the code generator to decide.                                                                                      |
|                                                      |                         | Sample based                                                                                                                    | The signal propagates through the model one sample at a time.                                                                                                                              |
|                                                      |                         | Frame based                                                                                                                     | The signal propagates through the model in batches of samples.                                                                                                                             |
| Both                                                 | Minimum                 | *0.0                                                                                                                            | The minimum value to which the parameter or signal is expected to be bound.                                                                                                                |
|                                                      |                         | Number within the minimum range of the parameter or signal. (Based on the data type and resolution of the parameter or signal.) |                                                                                                                                                                                            |
| Both                                                 | Maximum                 | *0.0                                                                                                                            | Maximum value to which the parameter or signal is expected to be bound. (Enter information using a dialog box.)                                                                            |
|                                                      | Code generation options |                                                                                                                                 |                                                                                                                                                                                            |

| Class:<br>Parameter,<br>Signal, or<br>Both | Property        | Available Property<br>Values<br>(* Indicates<br>Default)           | Description                                                                                                                                                                                                                           |
|--------------------------------------------|-----------------|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                            | Storage class   |                                                                    | Note that an <code>auto</code> selection for a storage class tells the build process to decide how to declare and store the selected parameter or signal.                                                                             |
| Both                                       | Global (Custom) | Global (Custom) is the default storage class for mpt data objects. | Specifies that a code generator not place a qualifier in the data object's declaration.                                                                                                                                               |
| Both                                       | Memory section  | *Default                                                           | <b>Memory section</b> allows you to specify storage directives for the data object. <b>Default</b> specifies that the code generator not place a type qualifier and <code>pragma</code> statement with the data object's declaration. |
| Parameter                                  |                 | MemConst                                                           | Places the <code>const</code> type qualifier in the declaration.                                                                                                                                                                      |
| Both                                       |                 | MemVolatile                                                        | Places the <code>volatile</code> type qualifier in the declaration.                                                                                                                                                                   |
| Parameter                                  |                 | MemConstVolatile                                                   | Places the <code>const volatile</code> type qualifier in the declaration.                                                                                                                                                             |

| Both                                       | Persistence level |                                                          | The number you specify is relative to <b>Signal display level</b> or <b>Parameter tune level</b> on the <b>Code Placement</b> pane of the Configuration Parameters dialog box. For a signal, allows you to specify whether or not the code generator declares the data object as global data. For a parameter, allows you to specify whether or not the code generator declares the data object as tunable global data. See <b>Signal display level</b> and <b>Parameter tune level</b> in “Model Configuration Parameters: Code Generation Code Placement”. |

|--------------------------------------------|-----------------|----------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Both                                       |                 | Pointer                                                  | If you select <b>Pointer</b> , the code generator places * before the identifier in the generated code.                                                                                                                                                                  |
|                                            | Header file     |                                                          | See above.                                                                                                                                                                                                                                                               |
| Both                                       | Struct (Custom) |                                                          | Embeds data in a named <b>struct</b> to encapsulate sets of data.                                                                                                                                                                                                        |
| Both                                       | Struct name     |                                                          | See above.                                                                                                                                                                                                                                                               |
| Signal                                     | GetSet (Custom) |                                                          | Reads (gets) and writes (sets) data using functions.                                                                                                                                                                                                                     |
| Signal                                     | Header file     |                                                          | See above.                                                                                                                                                                                                                                                               |
| Signal                                     | Get function    |                                                          | Specify the Get function.                                                                                                                                                                                                                                                |
| Signal                                     | Set function    |                                                          | Specify the Set function.                                                                                                                                                                                                                                                |
| Both                                       | Alias           | *null                                                    | As explained in detail in “Override Data Object Naming Rules” on page 39-18, for a Simulink or mpt data object (identifier), specifying a name in the <b>Alias</b> field overrides the global naming rule selection you make on the Configuration Parameters dialog box. |
|                                            |                 | Valid ANSI <sup>a</sup> C/C++ variable name              |                                                                                                                                                                                                                                                                          |
| Both                                       | Description     | *null                                                    | Text description of the parameter or signal. Appears as a comment beside the signal or parameter's identifier in the generated code.                                                                                                                                     |
|                                            |                 | Character vector                                         |                                                                                                                                                                                                                                                                          |

| Class:<br>Parameter,<br>Signal, or<br>Both | Property             | Available Property<br>Values<br>(* Indicates<br>Default) | Description                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------------|----------------------|----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Signal                                     | Reusable<br>(Custom) |                                                          | Allows the code generator to reuse a pair of root I/O signals when you specify the same name and the same custom storage class for both. The custom storage class is either <code>Reusable (Custom)</code> or derived from <code>Reusable (Custom)</code> .                                                                                                 |
| Signal                                     | Data Scope           | *Auto                                                    | You can specify the scope of symbols code generation generates for a data object of this class by selecting a value for <b>DataScope</b> . When you take the default of <code>Auto</code> , code generation determines the symbol scope internally. If possible, symbols have <code>File</code> scope. Otherwise, symbols have <code>Exported</code> scope. |
|                                            |                      | File                                                     | Code generation defines the scope of each symbol as the file that defines it. <code>File</code> scope requires each symbol to be used in a single file. If the same symbol is referenced in multiple files, code generation reports an error.                                                                                                               |
|                                            |                      | Exported                                                 | Code generation exports symbols to external code in the header file specified by the <b>HeaderFile</b> field. If a <b>HeaderFile</b> is not specified, symbols are exported to external code in <code>model.h</code> .                                                                                                                                      |
|                                            |                      | Imported                                                 | Code generation imports symbols from external code in the header file specified by the <b>HeaderFile</b> field. If you do not specify a header file, code generation generates an <code>extern</code> directive in <code>model_private.h</code> .                                                                                                           |
| Signal                                     | Header file          |                                                          | See above.                                                                                                                                                                                                                                                                                                                                                  |
| Signal                                     | Owner                |                                                          | See above.                                                                                                                                                                                                                                                                                                                                                  |

| <b>Class:<br/>Parameter,<br/>Signal, or<br/>Both</b> | <b>Property</b> | <b>Available Property<br/>Values<br/>(* Indicates<br/>Default)</b> | <b>Description</b> |
|------------------------------------------------------|-----------------|--------------------------------------------------------------------|--------------------|
| Signal                                               | Definition file |                                                                    | See above.         |

**mpt Package Custom Storage Classes**

| <b>CSC Name</b> | <b>Purpose</b>                                                                                                                                                                                  | <b>Signals?</b> | <b>Parameters?</b> |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|--------------------|
| BitField        | Generate a struct declaration that embeds Boolean data in named bit fields.                                                                                                                     | Y               | Y                  |
| CompilerFlag    | Supports preprocessor conditionals defined via compiler flag. See “Generate Preprocessor Conditionals for Variant Systems” on page 15-35.                                                       | N               | Y                  |
| Const           | Generate a constant declaration with the <code>const</code> type qualifier.                                                                                                                     | N               | Y                  |
| ConstVolatile   | Generate declaration of volatile constant with the <code>const volatile</code> type qualifier.                                                                                                  | N               | Y                  |
| Define          | Generate <code>#define</code> directive.                                                                                                                                                        | Y               | Y                  |
| ExportToFile    | Generate header (.h) file, with user-specified name, containing global variable declarations.                                                                                                   | Y               | Y                  |
| FileScope       | Generate a static qualifier suffix for a variable declaration so that the scope of the variable is limited to the current file.                                                                 | Y               | Y                  |
| GetSet          | Supports specialized function calls to read and write the memory associated with a Data Store Memory block. See “Access Data Through Functions with Custom Storage Class GetSet” on page 26-42. | Y               | Y                  |
| Global          | The default custom storage class for the mpt package. Generate the declaration and definition of a data object in specified files, and use the specified memory section.                        | Y               | Y                  |

| <b>CSC Name</b> | <b>Purpose</b>                                                                                                                                                                                                                   | <b>Signals?</b> | <b>Parameters?</b> |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|--------------------|
| ImportedDefine  | Supports preprocessor conditionals defined via legacy header file. See “Generate Preprocessor Conditionals for Variant Systems” on page 15-35.                                                                                   | N               | Y                  |
| ImportFromFile  | Generate directives to include predefined header files containing global variable declarations.                                                                                                                                  | Y               | Y                  |
| Reusable        | Allows the code generator to reuse a pair of root I/O signals when you specify the same name and the same custom storage class for both. The custom storage class is either Reusable (Custom) or derived from Reusable (Custom). | Y               | N                  |
| Struct          | Generate a struct declaration encapsulating parameter or signal object data.                                                                                                                                                     | Y               | Y                  |
| StructConst     | Generate a struct declaration, with a const type qualifier, encapsulating parameter object data.                                                                                                                                 | N               | Y                  |
| StructVolatile  | Generate a struct declaration, with a volatile type qualifier, encapsulating parameter or signal object data.                                                                                                                    | Y               | Y                  |
| Volatile        | Use volatile type qualifier in declaration.                                                                                                                                                                                      | Y               | Y                  |

## Examples of Property Value Changes on Generated Code

| What I noticed when inspecting the .c/.cpp file                                                                                                                                                                                                                                                                                                                                  | Change I made to property value settings                                                                                                                                                                                                                                                                                                                                                                                                 | What I noticed after regenerating and reinspecting the file                                                                                                                                                                                                  |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>Example 1:<br/>Parameter data objects can be declared or defined as constants. I know that the data object GAIN is a parameter. I want this to be declared or defined in the .c file as a variable. But I notice that GAIN is declared as a constant by the statement <code>const real_T GAIN = 5.0;</code>. Also, this statement is in the constant section of the file.</p> | <p>In the Model Explorer, I clicked the data object GAIN. I noticed that the property value for its <b>Memory section</b> property is set at MemConst. I changed this to Default.</p>                                                                                                                                                                                                                                                    | <p>I notice two differences. One is that now GAIN is declared as a variable with the statement <code>real_T GAIN = 5.0;</code>. The second difference is that the declaration now is located in the MemConst memory section in the .c or .cpp file.</p>      |
| <p>Example 2:<br/>I notice again the declaration of GAIN in the .c file mentioned in Example 1. It appears as <code>real_T GAIN = 5.0;</code>. But I have changed my mind. I want data object GAIN to be <code>#define</code>.</p>                                                                                                                                               | <p>I changed the <b>Storage class</b> selection to Define (Custom).</p>                                                                                                                                                                                                                                                                                                                                                                  | <p>GAIN is not declared in the .c file as a MemConst parameter. Rather, it is defined as a <code>#define</code> macro by the code <code>#define GAIN 5.0</code>, and this is located near the top of the .c file with the other preprocessor directives.</p> |
| <p>Example 3:<br/>I changed my mind again after doing Example 2. I do want GAIN defined using the <code>#define</code> preprocessor directive. But I do not want to include the <code>#define</code> in this file. I know it exists in another file and I want to reference that file.</p>                                                                                       | <p>On the Model Explorer, I notice that the property value for the <b>Header file</b> property is blank. I changed this to <code>filename.h</code>. (I chose the ANSI C/C++ double quote mechanism for the <code>#include</code>, but could have chosen the angle bracket mechanism.) Also, I must make the user-defined <code>filename.h</code> available to the compiler, placing it either in the system path or local directory.</p> | <p><code>#define GAIN 5.0</code> is not present in this .c file. Instead, the <code>#include filename.h</code> code appears as a preprocessor directive at the top of the file.</p>                                                                          |

| What I noticed when inspecting the .c/.cpp file                                                                                                                                                                                                                                                                              | Change I made to property value settings                                                                                                                                                                                       | What I noticed after regenerating and reinspecting the file                                                                        |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <p>Example 4:<br/>I have one more change I want to make. Let us say that we have declared the data object <code>data_in</code>, and that its declaration statement in the <code>.c</code> file reads<br/><code>real_T data_in = 0.0;</code>. I want to replace this statement with an alias in the <code>.c</code> file.</p> | <p>In the Model Explorer, I selected the data object <code>data_in</code>. I noticed that the <b>Alias</b> field is blank. I changed this to <code>data_in_alias</code>, which I know is a valid ANSI C/C++ variable name.</p> | <p>The identifier <code>data_in_alias</code> now appears in the <code>.c</code> file everywhere <code>data_in</code> appeared.</p> |

## Specify Persistence Level for Signals and Parameters

With this procedure, you can control the persistence level of signal and parameter objects associated with a model. Persistence level allows you to make intermediate variables or parameters global during initial development. At the later stages of development, you can use this procedure to remove these signals and parameters for efficiency. Use the **Persistence Level** property of `mpt.Signal` and `mpt.Parameter` data objects. For descriptions of the properties on the Model Explorer, see “MPT Data Object Properties” on page 25-2.

Notice also the **Signal display level** and **Parameter tune level** fields on the **Code Placement** pane of the Configuration Parameters dialog box, as illustrated in the next figure.

The **Signal display level** field allows you to specify whether or not the code generator defines a signal data object as global data in the generated code. The number you specify in this field is relative to the number you specify in the **Persistence level** field. The **Signal display level** number is for mpt (module packaging tool) signal data objects in the model. The **Persistence level** number is for a *particular* mpt signal data object. If the data object's **Persistence level** is equal to or less than the **Signal display level**, the signal appears in the generated code as global data with the custom attributes that you specified. For example, this would occur if **Persistence level** is 2 and **Signal display level** is 5.

Otherwise, the code generator automatically determines how the particular signal data object appears in the generated code. Depending on the settings on the **Optimization**

pane of the Configuration Parameters dialog box, the signal data object could appear in the code as local data without the custom attributes you specified for that data object. Or, based on expression folding, the code generator could remove the data object so that it does not appear in the code.

The **Parameter tune level** field allows you to specify whether or not the code generator declares a parameter data object as tunable global data in the generated code.

The number you specify in this field is relative to the number you specify in the **Persistence level** field. The **Parameter tune level** number is for `mpt` parameter data objects in the model. The **Persistence level** number is for a *particular* `mpt` parameter data object. If the data object's **Persistence level** is equal to or less than the **Parameter tune level**, the parameter appears tunable in the generated code with the custom attributes that you specified. For example, this would occur if **Persistence level** is 2 and **Parameter tune level** is 5.

Otherwise, the parameter is inlined in the generated code, and the code generation settings determine its exact form.

Note that, in the initial stages of development, you might be more concerned about debugging than code size. Or, you might want one or more particular data objects to appear in the code so that you can analyze intermediate calculations of an equation. In this case, you might want to specify the **Parameter tune level (Signal display level** for signals) to be higher than **Persistence level** for some `mpt` parameter (or signal) data objects. This results in larger code size, because the code generator defines the parameter (or signal) data objects as global data, which have the custom properties you specified. As you approach production code generation, however, you might have more concern about reducing the size of the code and less need for debugging or intermediate analyses. In this stage of the tradeoff, you could make the **Parameter tune level (Signal display level** for signals) greater than **Persistence level** for one or more data objects, generate code and observe the results. Repeat until satisfied.

- 1 With the model open, in the Configuration Parameters dialog box, select **Code Generation > Code Placement**.
- 2 Type the desired number in the **Signal display level** or **Parameter tune level** field, and click **Apply**.
- 3 In the Model Explorer, type the desired number in the **Persistence** field for the selected signal or parameter, and click **Apply**.
- 4 Save the model and generate code.

## Register mpt User Object Types

- “Introduction” on page 25-19
- “Register mpt User Object Types Using `sl_customization.m`” on page 25-19
- “mpt User Object Type Customization Using `sl_customization.m`” on page 25-20

### Introduction

Embedded Coder allows you to create custom `mpt` object types and specify properties and property values to be associated with them. Once created, a user object type can be applied to data objects displayed in Model Explorer. When you apply a user object type to a data object, by selecting a type name in the **User object type** pull-down list in Model Explorer, the data object is automatically populated with the properties and property values that you specified for the user object type.

To register `mpt` user object type customizations, use the Simulink customization file `sl_customization.m`. This file is a mechanism that allows you to use MATLAB code to perform customizations of the standard Simulink user interface. The Simulink software reads the `sl_customization.m` file, if present on the MATLAB path, when it starts and the customizations specified in the file are applied to the Simulink session. For more information on the `sl_customization.m` customization file, see “Registering Customizations” (Simulink).

### Register mpt User Object Types Using `sl_customization.m`

To register `mpt` user object type customizations, you create an instance of `sl_customization.m` and include it on the MATLAB path of the Simulink installation that you want to customize. The `sl_customization` function accepts one argument: a handle to a customization manager object. For example,

```
function sl_customization(cm)
```

As a starting point for your customizations, the `sl_customization` function must first get the default (factory) customizations, using the following assignment statement:

```
hObj = cm.slDataObjectCustomizer;
```

You then invoke methods to register your customizations. The customization manager object includes the following methods for registering `mpt` user object type customizations:

- `addMPTObjectType(hObj, objectTypeName, classtype, propName1, propValue1, propName2, propValue2, ...)`

```
addMPTObjectType(hObj, objectTypeName, classtype, {propName1,
propName2, ...}, {propValue1, propValue2, ...})
```

Registers the specified user object type, along with specified values for object properties, and adds the object type to the top of the user object type list, as displayed in the **User object type** pull-down list in the Model Explorer.

- `objectTypeName` — Name of the user object type
  - `classType` — Class to which the user object type applies: 'Signal', 'Parameter', or 'Both'
  - `propName` — Name of a property of an mpt or mpt-derived data object to be populated with a corresponding `propValue` when the registered user object type is selected
  - `propValue` — Specifies the value for a corresponding `propName`
- `moveMPTObjectTypeToTop(hObj, objectTypeName)`

Moves the specified user object type to the top of the user object type list, as displayed in the **User object type** pull-down list in the Model Explorer.

- `moveMPTObjectTypeToEnd(hObj, objectTypeName)`

Moves the specified user object type to the end of the user object type list, as displayed in the **User object type** pull-down list in the Model Explorer.

- `removeMPTObjectType(hObj, objectTypeName)`

Removes the specified user object type from the user object type list.

Your instance of the `sl_customization` function should use these methods to register mpt object type customizations for your Simulink installation.

The Simulink software reads the `sl_customization.m` file when it starts. If you subsequently change the file, to use the changes, you must restart your MATLAB session.

### **mpt User Object Type Customization Using `sl_customization.m`**

The `sl_customization.m` file shown in “mpt User Object Type Customization Using `sl_customization.m`” on page 25-20 uses the `addMPTObjectType` method to register the user signal types `EngineType` and `FuelType` for mpt objects.

#### **Example 25.1. `sl_customization.m` for mpt Object Type Customizations**

```
function sl_customization(cm)
% Register user customizations
```

```
% Get default (factory) customizations
hObj = cm.slDataObjectCustomizer;

% Add commonly used signal types
hObj.addMPTObjectType(...
 'EngineType','Signal',...
 'DataType', 'uint8',...
 'Min', 0,...
 'Max', 255,...
 'Unit','m/s');

hObj.addMPTObjectType(...
 'FuelType','Signal',...
 'DataType', 'int16',...
 'Min', -12,...
 'Max', 3000,...
 'Unit','mg/hr');

end
```

If you include the above file on the MATLAB path of the Simulink installation that you want to customize, the specified customizations will appear in Model Explorer. For example, you could view the customizations as follows:

- 1 Start a MATLAB session.
- 2 Open Model Explorer, for example, by entering the MATLAB command `daexplr`.
- 3 Select **Base Workspace**.
- 4 Add an `mpt` signal, for example, by selecting **Add > Add Custom**.
- 5 In the right-hand pane display for the added `mpt` signal, examine the **User object type** drop-down list, noting the impact of the changes specified in “`mpt User Object Type Customization Using sl_customization.m”` on page 25-20.
- 6 From the **User object type** drop-down list, select one of the registered user signal types, for example, `FuelType`, and verify that the displayed settings are consistent with the arguments specified to the `addMPTObjectType` method in `sl_customization.m`.

## Reuse Parameter Data from External Code in the Generated Code

This example shows how to generate code that imports a parameter value from your external code.

### Create External Code Files

Suppose your external code defines a vector parameter `myGains` with three elements. Save the definition in your current folder in a file called `ex_vector_import_src.c`.

```
#include "ex_vector_import_decs.h"

my_int8 myGains[3] = {
 2,
 4,
 6
};
```

Save the declaration in your current folder in a file called `ex_vector_import_decs.h`.

```
#include "ex_vector_import_cust_types.h"

extern my_int8 myGains[3];
```

Save the data type definition `my_int8` in your current folder in a file called `ex_vector_import_cust_types.h`.

```
typedef signed char my_int8;
```

### Import Parameter Value for Simulation

In your current folder, right-click the file `ex_vector_import_src.c` and select **Import Data**.

In the Import dialog box, set **Output Type** to `Numeric Matrix`.

Set the name of the generated MATLAB variable to `tempVar`.

Select only the parameter values (2, 4, and 6) to import.

```

A
tempVar
NUMBER
1 #include "ex_vector_import_decs....
2 my_int8 myGains[3] = {
3 2
4 4
5 6
6 };

```

Import the data by clicking the green check mark. The MATLAB variable `tempVar` appears in the base workspace.

Alternatively, use the command prompt to manually create `tempVar`.

```
tempVar = [2;4;6];
```

At the command prompt, create a `Simulink.Parameter` object that represents `myGains`.

```
myGains = Simulink.Parameter(tempVar);
```

### Create and Configure Model

Create the model `ex_vector_import`.

```
open_system('ex_vector_import')
```

In the model, select **View > Model Data Editor**.

In the Model Data Editor, inspect the **Parameters** tab.

Use the **Value** column to set the value of the **Gain** parameter in the Gain block to `myGains`.

Click the **Show/refresh additional information** button. The data table now contains a row that represents the parameter object, myGains.

Use the **Data Type** column to set the data type of myGains to my\_int8.

For the other row (which represents the **Gain** parameter of the Gain block), set **Data Type** to **Inherit: Inherit from 'Gain'**. With this setting, the **Gain** parameter inherits the data type my\_int8 from myGains.

Set the **Change view** drop-down list to Code.

Set these properties for myGains:

- **Storage Class** to ImportFromFile
- **Header File** to ex\_vector\_import\_decs.h

Alternatively, use these commands at the command prompt to configure the object and the block:

```
set_param('ex_vector_import/Gain','Gain','myGains',...
 'ParamDataTypeStr','Inherit: Inherit from ''Gain''')
myGains.DataType = 'my_int8';
myGains.CoderInfo.StorageClass = 'Custom';
myGains.CoderInfo.CustomStorageClass = 'ImportFromFile';
myGains.CoderInfo.CustomAttributes.HeaderFile = 'ex_vector_import_decs.h';
```

At the command prompt, create a Simulink.AliasType object to represent your custom data type my\_int8. Set the DataScope and HeaderFile properties to import the type definition from your external code.

```
my_int8 = Simulink.AliasType('int8');
my_int8.DataScope = 'Imported';
my_int8.HeaderFile = 'ex_vector_import_cust_types.h';
```

Set **Configuration Parameters > Code Generation > Custom Code > Additional build information > Source files** to ex\_vector\_import\_src.c.

```
set_param('ex_vector_import','CustomSource','ex_vector_import_src.c')
```

### Generate and Inspect Code

Generate code from the model.

```
rtwbuild('ex_vector_import')
```

```
Starting build procedure for model: ex_vector_import
Successful completion of build procedure for model: ex_vector_import
```

The generated file `ex_vector_import.h` includes the external header files `ex_vector_import_decs.h` and `ex_vector_import_cust_types.h`, which contain the parameter variable declaration (`myGains`) and custom type definition (`my_int8`).

```
file = fullfile('ex_vector_import_ert_rtw','ex_vector_import.h');
rtwdemodbtype(file,'#include "ex_vector_import_cust_types.h"',...
 '#include "ex_vector_import_cust_types.h"',1,1)
rtwdemodbtype(file,'/* Includes for objects with custom storage classes. */',...
 '#include "ex_vector_import_decs.h"',1,1)
```

```
#include "ex_vector_import_cust_types.h"
```

```
/* Includes for objects with custom storage classes. */
#include "ex_vector_import_decs.h"
```

The generated code algorithm in the model `step` function in the generated file `ex_vector_import.c` uses `myGains` for calculations.

```
file = fullfile('ex_vector_import_ert_rtw','ex_vector_import.c');
rtwdemodbtype(file,'/* Model step function */','/* Model initialize function */',1,0)

/* Model step function */
void ex_vector_import_step(void)
{
 /* Output: '<Root>/Out1' incorporates:
 * Gain: '<Root>/Gain'
 * Inport: '<Root>/In1'
 */
 rtY.Out1[0] = (real_T)myGains[0] * rtU.In1;
 rtY.Out1[1] = (real_T)myGains[1] * rtU.In1;
 rtY.Out1[2] = (real_T)myGains[2] * rtU.In1;
}
```

The generated code does not define (allocate memory for) or initialize the global variable `myGains` because the data scope of the corresponding parameter object is imported.

When you simulate the model in Simulink, the model uses the value stored in the `Value` property of the parameter object. However, if you use external mode simulation, the

external executable begins the simulation by using the value from your code. See “Considerations for Other Modeling Goals” on page 42-100.

- “Import Parameter Data with Conditionally Compiled Dimension Length” on page 26-7

## Import Parameter Data with Conditionally Compiled Dimension Length

Suppose your external code conditionally allocates memory for and initializes lookup table and breakpoint set data based on a dimension length that you specify as a `#define` macro. This example shows how to generate code that imports this external global data.

### Create External Code Files

Save the definition of the breakpoint set data `T1Break` and lookup table data `T1Data` in your current folder in a file called `ex_vec_syndim_src.c`. These global variables have either 9 or 11 elements depending on the value of the macro `bpLen`.

```
#include "ex_vec_syndim_decs.h"
```

```
#if bpLen == 11
double T1Break[bpLen] = {
 -5.0,
 -4.0,
 -3.0,
 -2.0,
 -1.0,
 0.0,
 1.0,
 2.0,
 3.0,
 4.0,
 5.0
};
```

```
double T1Data[bpLen] = {
 -1.0,
 -0.99,
 -0.98,
 -0.96,
 -0.76,
 0.0,
 0.76,
 0.96,
 0.98,
 0.99,
 1.0
};
```

```
};
#endif

#if bpLen == 9
double T1Break[bpLen] = {
 -4.0,
 -3.0,
 -2.0,
 -1.0,
 0.0,
 1.0,
 2.0,
 3.0,
 4.0
};

double T1Data[bpLen] = {
 -0.99,
 -0.98,
 -0.96,
 -0.76,
 0.0,
 0.76,
 0.96,
 0.98,
 0.99
};
#endif
```

Save the declarations of the variables and the definition of the macro in your current folder in a file called `ex_vec_syndim_decs.h`.

```
#define bpLen 11

extern double T1Break[bpLen];
extern double T1Data[bpLen];
```

### **Explore and Configure Example Model**

Open the example model `rtwdemo_basicsc`.

```
open_system('rtwdemo_basicsc')
```

Copyright 1994-2015 The MathWorks, Inc.

Open the Table1 block dialog box. The block refers to variables, T1Data and T1Break, in the base workspace. These variables store the lookup table and breakpoint set data with 11 elements.

At the command prompt, convert the variables to Simulink.Parameter objects.

```
T1Data = Simulink.Parameter(T1Data);
T1Break = Simulink.Parameter(T1Break);
```

Configure the objects to import the data definitions from your external code.

```
T1Data.CoderInfo.StorageClass = 'Custom';
T1Data.CoderInfo.CustomStorageClass = 'ImportFromFile';
T1Data.CoderInfo.CustomAttributes.HeaderFile = 'ex_vec_syndim_decs.h';
```

```
T1Break.CoderInfo.StorageClass = 'Custom';
T1Break.CoderInfo.CustomStorageClass = 'ImportFromFile';
T1Break.CoderInfo.CustomAttributes.HeaderFile = 'ex_vec_syndim_decs.h';
```

At the command prompt, create a Simulink.Parameter object to represent the custom macro bpLen.

```
bpLen = Simulink.Parameter(11);
bpLen.Min = 9;
bpLen.Max = 11;
bpLen.DataType = 'int32';
bpLen.CoderInfo.StorageClass = 'Custom';
bpLen.CoderInfo.CustomStorageClass = 'ImportedDefine';
bpLen.CoderInfo.CustomAttributes.HeaderFile = 'ex_vec_syndim_decs.h';
```

Use `bpLen` to set the dimensions of the lookup table and breakpoint set data. Configure the model to enable symbolic dimensions by selecting the configuration parameter **Allow symbolic dimension specification**.

```
T1Data.Dimensions = '[1 bpLen]';
T1Break.Dimensions = '[1 bpLen]';
set_param('rtwdemo_basicsc', 'AllowSymbolicDim', 'on')
```

Set **Configuration Parameters > Code Generation > Custom Code > Additional build information > Source files** to `ex_vec_syndim_src.c`.

```
set_param('rtwdemo_basicsc', 'CustomSource', 'ex_vec_syndim_src.c')
```

To generate code with custom storage classes such as `ImportFromFile`, you must use an ERT-based system target file. Set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`.

```
set_param('rtwdemo_basicsc', 'SystemTargetFile', 'ert.tlc')
```

### Generate and Inspect Code

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
Starting build procedure for model: rtwdemo_basicsc
Successful completion of build procedure for model: rtwdemo_basicsc
```

The generated code algorithm is in the model `step` function in the generated file `rtwdemo_basicsc.c`. The algorithm passes `T1Break`, `T1Data`, and `bpLen` as argument values to the function that performs the table lookup. In this case, `bpLen` controls the upper bound of the binary search that the function uses.

```
file = fullfile('rtwdemo_basicsc_ert_rtw', 'rtwdemo_basicsc.c');
rtwdemodbtype(file, '.X = look1_iflf_binlx', 'bpLen - 1U', 1, 1)
```

```
rtwdemo_basicsc_DW.X = look1_iflf_binlx(rtwdemo_basicsc_U.input2,
 (&(T1Break[0])), (&(T1Data[0])), bpLen - 1U) * 2.0F;
```

For more information about symbolic dimensions, see “Implement Dimension Variants for Array Sizes in Generated Code” on page 15-2.

### Related Examples

- “Exchange Data Between External C/C++ Code and Simulink Model or Generated Code” on page 42-90
- “Reuse Parameter Data from External Code in the Generated Code” on page 26-2

## Access Structured Data Through a Pointer That External Code Defines

This example shows how to generate code that uses global data that some handwritten code defines. In the handwritten code, a pointer variable points to one of two structure variables that contain parameter data. A handwritten function switches the pointer between the two structures. The generated code accesses the parameter data by dereferencing the pointer variable.

### Explore External Code

Open the example source file `rtwdemo_importstruct_user.c`. The code defines a structure variable `ReferenceStruct` as constant (`const`) data and statically initializes each field.

```
/* Constant default data struct: ReferenceStruct */
const DataStruct_type ReferenceStruct =
{
 11, /* OFFSET */
 2 /* GAIN */
};
```

The code defines another structure variable, `WorkingStruct`, as volatile (`volatile`) data.

```
/* Volatile data struct: WorkingStruct */
volatile DataStruct_type WorkingStruct;
```

The code defines a function that copies the field values from `ReferenceStruct` to `WorkingStruct`.

```
/* Function to initialize WorkingStruct with data from ReferenceStruct */
void Init_WorkingStruct(void)
{
 memcpy((void*)&WorkingStruct, &ReferenceStruct, sizeof(ReferenceStruct));
}
```

The code defines `StructPointer`, which is a `const volatile` pointer to a structure. The code initializes the pointer to the address of `ReferenceStruct`.

```
/* Create pointer to the default data struct, e.g. ReferenceStruct */
const volatile DataStruct_type *StructPointer = &ReferenceStruct;
```

Finally, the code defines a function that can dynamically set `StructPointer` to point to either `ReferenceStruct` or `WorkingStruct`.

```
/* Function to switch between structures */
void SwitchStructPointer(Dataset_T Dataset)
{
 switch (Dataset)
 {
 case Working:
 StructPointer = &WorkingStruct;
 break;
 default:
 StructPointer = &ReferenceStruct;
 }
}
```

The example header file `rtwdemo_importstruct_user.h` defines the enumeration `Dataset_T` and the structure type `Datastruct_type`. The file includes (`#include`) the built-in Simulink® Coder™ header file `rtwtypes.h`, which defines (`typedef`) Simulink Coder data types such as `int16_T`.

```
#include "rtwtypes.h"

typedef enum {
 Reference=0,
 Working
} Dataset_T;

typedef struct DataStruct_tag {
 int16_T OFFSET; /* OFFSET */
 int16_T GAIN; /* GAIN */
} DataStruct_type;
```

The file also declares the global variables and the functions.

### Purpose of External Code

The code is designed so that the source code of a control algorithm (whether generated or handwritten) can read data from either `ReferenceStruct` or `WorkingStruct` by

dereferencing (->) `StructPointer`. A software engineer can write code that dynamically switches `StructPointer` between the address of `WorkingStruct` and `ReferenceStruct` by passing the corresponding enumeration member as the input argument in calls to the `SwitchStructPointer` function.

Later, in preparation for calibration while the algorithm executes, a calibration tool can make `StructPointer` point to `WorkingStruct`. The tool can then modify the fields of `WorkingStruct`.

If necessary for safety or in preparation for shutting down the application, the calibration tool can point `StructPointer` to `ReferenceStruct` instead. `ReferenceStruct` stores default parameter values that do not change during execution.

### **Explore Example Model**

Open the example model, `rtwdemo_importstruct`.

**View User C-files  
Containing Imported Struct  
(double-click)**

**View Custom Code  
Configuration  
(double-click)**

**Custom Storage Class  
Definition  
(double-click)**

**View MATLAB program For  
Creating Variables  
(double-click)**

**View Workspace  
Variables  
(double-click)**

**Generate Code Using  
Embedded Coder  
(double-click)**

Copyright 2006-2015 The MathWorks, Inc.

The model creates variables and objects in the base workspace. The Constant block and the Gain block use the ECoderDemos.Parameter objects GAIN and OFFSET to set the **Constant value** and **Gain** block parameters. ECoderDemos is an example custom package that defines two classes, Parameter and Signal, and some custom storage classes.

In the model, select **View > Model Data Editor**.

In the Model Data Editor, inspect the **Parameters** tab.

Set the **Change view** drop-down list to Code.

Click the **Show/refresh additional information** button.

The Model Data Editor shows rows that correspond to the **Constant value** and **Gain** parameters of the blocks and rows that corresponds to **OFFSET** and **GAIN**, which set the parameter values. In the **Storage Class** column, **OFFSET** and **GAIN** use the custom storage class `StructPointer`, which the `ECoderDemos` package defines.

Open the Custom Storage Class Designer and inspect the custom storage classes in the `ECoderDemos` package. At the command prompt, use this command:

```
cscdesigner('ECoderDemos')
```

This example package defines multiple custom storage classes, including `StructPointer`. You cannot edit the definitions. However, you can create your own packages and custom storage classes later. For an example that shows how to create a package and a custom storage class, see “Create and Apply a Custom Storage Class” on page 26-26.

Under **Custom storage class definitions**, click `StructPointer`. The settings for this custom storage class enable the generated code to interact with the pointer variable, `StructPointer`, from the external code. For example, the custom storage class uses these settings:

- **Data scope** is set to `Imported` because the example external code defines (allocates memory for) `StructPointer`. With this setting, the code generator avoids generating unnecessary, duplicate definitions for the data items, such as the `ECoderDemos.Parameter` objects, that use the custom storage class.
- **Data access** is set to `Pointer` because in the example external code, `StructPointer` is a pointer.
- **Memory section** is set to `ConstVolatile` because the example external code defines `StructPointer` as constant, volatile data (`const volatile`).
- **Type** is set to `FlatStructure` because in the example external code, `StructPointer` points to a structure. With this setting, the generated code treats each data item (`ECoderDemos.Parameter` object) as a field of a flat structure whose variable name and type name you can specify.
- On the **Structure Attributes** tab, **Struct name** is set to `StructPointer`. For a `FlatStructure` custom storage class, **Struct name** specifies the name of the

structure variable in the generated code. In this example, `StructPointer` is the name of the variable that the external code defines.

- **Type name** is set to `DataStruct_type`, which is the name of the structure type that the example external code defines.

In the model, in the **Configuration Parameters** dialog box, inspect the **Code Generation > Custom Code** pane.

Under **Insert custom C code in generated**, select **Initialize function**. In this model, this configuration parameter is set so that the generated code calls the `Init_WorkingStruct` function before execution of the primary algorithm. `Init_WorkingStruct` initializes the fields of `WorkingStruct` with the values from `ReferenceStruct`.

Under **Additional build information**, select **Source files**. This configuration parameter identifies the example external code file `rtwdemo_importstruct_user.c` for inclusion in the build process after code generation.

### Generate and Inspect Code

Generate code from the model.

In the generated file `rtwdemo_importstruct.c`, the model initialization function calls `Init_WorkingStruct`.

```
/* Model initialize function */
void rtwdemo_importstruct_initialize(void)
{
 /* user code (Initialize function Body) */

 /* Initialize the volatile memory data set before switching to it */
 Init_WorkingStruct();
}

/*
```

The algorithm in the model execution (`step`) function dereferences the pointer variable `StructPointer`.

```
/* Model step function */
void rtwdemo_importstruct_step(void)
```

```
{
 /* Gain: '<Root>/Gain' incorporates:
 * Constant: '<Root>/Offset'
 * Inport: '<Root>/In'
 * Sum: '<Root>/Sum'
 */
 Sensor_Out = (int16_T)((int16_T)(Sensor_In - StructPointer->OFFSET) *
 StructPointer->GAIN);
}
```

## Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements

In “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81, you control the declaration and definition of global variables in the generated code by applying storage classes directly to individual data elements. With Embedded Coder and an ERT-based system target file, you can use custom storage classes for more precise control over the way that data appear in the generated code.

To achieve C code patterns such as grouping variables into flat structures and to control declaration and definition file placement, you can use the custom storage classes from the built-in package `Simulink`.

For information about applying storage classes to categories of data by default, by using the Code Mapping Editor, see “Configure Default Code Generation for Data” on page 21-8.

### Built-In Custom Storage Classes

For a list of built-in custom storage classes that you can choose, see “Choose a Storage Class for Controlling Data Representation in the Generated Code” on page 22-69.

### Create Your Own Custom Storage Class

If the custom storage classes from the `Simulink` package do not satisfy your requirements, you can define your own custom storage classes. For information about defining your own custom storage class, see “Create Code Definitions to Override Default Settings” on page 20-3.

### Techniques to Apply Custom Storage Classes Interactively

To directly apply a custom storage class from the built-in package `Simulink` interactively, use the same techniques that you use to directly apply standard storage classes, described in “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81.

To apply a custom storage class from a package other than `Simulink` (such as a package that you create):

- To apply the custom storage class to a signal, state, or Data Store Memory block (without creating a data object), configure the data item to use custom storage classes from the target package instead of the Simulink package. For example, if the name of the target package is `myPackage`, in a Signal Properties dialog box or the Property Inspector, set **Signal object class** to `myPackage.Signal`. If the target class does not appear in the list, see “Target Class Does Not Appear in List of Signal Object Classes” on page 26-20.

If you use the Model Data Editor, to identify the target package, you must use a different technique. See “Apply Custom Storage Class from Specific Package to Signal, State, or Data Store Memory Block Using the Model Data Editor” on page 26-20.

- To apply the custom storage class by using a data object (required for block parameters), instead of creating a `Simulink.Signal` or `Simulink.Parameter` object, create a `myPackage.Signal` or `myPackage.Parameter` object. To create data objects from your package, see “Create Data Objects from Another Data Class Package” (Simulink). For an example that shows how to create and apply your own custom storage class, see “Create and Apply a Custom Storage Class” on page 26-26.

### Target Class Does Not Appear in List of Signal Object Classes

When you use the **Signal object class** drop-down list in a dialog box or in the Property Inspector, if the class that you want does not appear in the list:

- 1 From the list, select `Customize class lists`.
- 2 In the dialog box, under **Signal classes**, select the check box next to the class that you want. For example, to use custom storage classes from the built-in package `mpt`, select the check box next to `mpt.Signal`. Click **OK**.

If you created your own package, the classes that the package defines appear in the dialog box only if you put the package folder in your current folder or put the parent folder of the package folder on the MATLAB path.

- 3 From the drop-down list, select the option that corresponds to what you selected. For example, select `mpt.Signal`.

### Apply Custom Storage Class from Specific Package to Signal, State, or Data Store Memory Block Using the Model Data Editor

When you use the Model Data Editor, to apply custom storage classes from a specific package, use the Model Explorer to create a signal object from the target package. Then, when you open the Model Data Editor, the **Storage class** column displays custom storage classes from the target package.

- 1 In the Model Explorer **Model Hierarchy** pane, select **Base Workspace**.
- 2 In the toolbar, click the arrow next to the **Add Signal**  button.
- 3 In the drop-down list, select `Customize class lists`.
- 4 In the **Customize class lists** dialog box, select a signal class from the target package. Click **OK**.
- 5 In the Model Explorer toolbar, click the arrow next to the **Add Signal** button.
- 6 In the drop-down list, select the target signal class.

An object of the target signal class appears in the base workspace. Optionally, delete this unnecessary object.

- 7 Use the Model Data Editor to apply custom storage classes from the target package to other data items. In the Model Data Editor, in the **Storage class** column, the drop-down list allows you to select custom storage classes from the target package.

To learn how to use the Model Data Editor to configure a data interface, see “Design Data Interface by Configuring Inport and Outport Blocks” (Simulink Coder).

## Techniques to Apply Custom Storage Classes Programmatically

To apply a custom storage class to an individual data item programmatically:

- 1 Create a signal or parameter data object from the target package. For example, create a `Simulink.Signal` object or a `myPackage.Parameter` object.

```
myParam = Simulink.Parameter(5.2);
```

- 2 In the nested `Simulink.CoderInfo` object, set the `StorageClass` property to `'Custom'`. Then, use the `CustomStorageClass` property to specify the custom storage class.

```
myParam.CoderInfo.StorageClass = 'Custom';
myParam.CoderInfo.CustomStorageClass = 'ExportToFile';
```

- 3 If the custom storage class allows you to specify additional settings such as **Header file** (see “Specify File Names and Other Data Attributes With Storage Class (Embedded Coder)” on page 22-76), in the nested `Simulink.CoderInfo` object, use the `CustomAttributes` property to specify values for the additional settings.

```
myParam.CoderInfo.CustomAttributes.HeaderFile = 'myHeader.h';
```

- 4 Choose one of these techniques to apply the custom storage class to a data item in a model:
  - To apply the custom storage class directly to a signal, state, or Data Store Memory block, name the signal or state. Then, use the data object you created to set the `SignalObject` signal property, the `SignalObject` block parameter (for an Output block), or the `StateSignalObject` block parameter. Clear the data object you created. For an example, see “Apply Custom Storage Class Directly to Signal Line Programmatically” on page 26-22.
  - To apply the custom storage class by keeping the data object you created (required for parameters), associate the data object with the data item in the model. To make this association, see “Use Data Objects in Simulink Models” (Simulink).

### Apply Custom Storage Class Directly to Signal Line Programmatically

This example shows how to apply a custom storage class directly to a signal line in a model, without an external data object.

- 1 Open the example model `rtwdemo_secondOrderSystem`.

```
rtwdemo_secondOrderSystem
```

- 2 Create a handle to the output of the block named Force: `f(t)`.

```
portHandles = get_param('rtwdemo_secondOrderSystem/Force: f(t)', 'PortHandles');
outportHandle = portHandles.Outport;
```

- 3 Set the name of the corresponding signal to `ForceSignal`.

```
set_param(outportHandle, 'Name', 'ForceSignal')
```

- 4 In the base workspace, create a signal object and specify a custom storage class and relevant additional settings such as `HeaderFile`.

```
tempObj = Simulink.Signal;
tempObj.CoderInfo.StorageClass = 'Custom';
tempObj.CoderInfo.CustomStorageClass = 'ExportToFile';
tempObj.CoderInfo.CustomAttributes.HeaderFile = 'myHdrFile.h';
```

You can create the object from the data class package `Simulink`, or from any other package, such as a package that you create.

- 5 Embed the signal object in the target signal line by attaching a copy of the temporary workspace object.

```
set_param(outportHandle, 'SignalObject', tempObj);
```

- 6 Clear the object from the base workspace. The signal now uses an embedded copy of the object.

```
clear tempObj
```

### Modify Custom Storage Class Applied Directly to Signal Line

To modify an existing embedded signal object, copy the object into the base workspace, modify the copy, and reattach the copy to the signal or state. For example, to change the custom storage class of the embedded signal object that you attached to the signal ForceSignal in “Apply Custom Storage Class Directly to Signal Line Programmatically” on page 26-22:

- 1 Copy the existing embedded signal object into the base workspace.

```
tempObj = get_param(outportHandle, 'SignalObject');
```

- 2 Modify the properties of the object in the workspace.

```
tempObj.CoderInfo.CustomStorageClass='ImportFromFile';
tempObj.CoderInfo.CustomAttributes.HeaderFile = 'myOtherHdrFile.h';
```

- 3 Reattach a copy of the signal object.

```
set_param(outportHandle, 'SignalObject', tempObj);
clear tempObj
```

### Organize Parameter Data into a Structure by Using the Struct Custom Storage Class

This example shows how to use the Struct custom storage class to organize block parameter values into a structure in the generated code. You apply the storage class directly to individual data items in a model.

To create a custom structure of parameter data in the generated code, consider creating a corresponding structure in Simulink. See “Organize Data into Structures in Generated Code” on page 22-177.

- 1 Create the ex\_struct\_param model with three Constant blocks and three Outport blocks.

- 2 In the model, select **View > Model Data Editor**.
- 3 In the Model Data Editor, select the **Parameters** tab.
- 4 In the model, select the upper Constant block.
- 5 In the Model Data Editor, use the **Value** column to set the constant value to p1.
- 6 Next to p1, click the action button  and select **Create**.
- 7 In the Create New Data dialog box, set **Value** to `Simulink.Parameter(1.0)` and click **Create**.

A `Simulink.Parameter` object named p1 appears in the base workspace.

- 8 In the property dialog box for p1, click **OK**.
- 9 Use the Model Data Editor to set the other constant values by using parameter objects named p2 (value 2.0) and p3 (value 3.0).
- 10 In the Model Data Editor, set the **Change view** drop-down list to Code.
- 11 Click the **Show/refresh additional information** button.

The data table now contains rows that correspond to the new parameter objects.

- 12 Use the **Storage Class** column to apply the custom storage class `Struct` to all three parameter objects.
- 13 Use the **Struct Name** column to set the structure name to `my_struct`.
- 14 Press **Ctrl+B** to generate code.

The file `ex_struct_param.h` defines a structure type, `my_struct_type`.

```
/* Type definition for custom storage class: Struct */
typedef struct my_struct_tag {
 real_T p1;
 real_T p2;
```

```
 real_T p3;
} my_struct_type;
```

The file `ex_struct_param.c` defines the global variable `my_struct`.

```
/* Definition for custom storage class: Struct */
my_struct_type my_struct = {
 /* p1 */
 1.0,

 /* p2 */
 2.0,

 /* p3 */
 3.0
};
```

## Custom Storage Class Limitations

For information about limitations, see “Storage Class Limitations” on page 22-77.

## Create Custom Storage Classes by Using the Custom Storage Class Designer

You can use built-in custom storage classes such as `ExportToFile` to control the appearance of data in the generated code (see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19). If the built-in custom storage classes do not satisfy your requirements, you can create your own custom storage classes. As described in “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 20-2, to create a custom storage class that you can apply to individual data elements (for example, in the Model Data Editor), you must create the storage class in a package by using the Custom Storage Class Designer.

A package also defines `Signal` and `Parameter` data classes (see “Data Objects” (Simulink)). A data object from a package such as `Simulink` can use custom storage classes defined in that package but not custom storage classes that are defined in packages.

For information about using the Custom Storage Class Designer to create memory sections, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 30-2.

### Create and Apply a Custom Storage Class

This example shows how to control code generated from a model by creating and applying your own custom storage class.

#### Explore Example Model

Open the model `rtwdemo_cscpredef`. You can control code generated from this model by defining your own data classes and creating your own custom storage classes.

In this example, you export the declarations and definitions of multiple signals and parameters in the model to one declaration header file and one definition file.

#### Create Data Class Package

To create custom storage classes, you first create a data class package to contain the custom storage class definitions. Data objects that you create from your package can use all of the custom storage classes that the package defines.

- 1 Create your own data class package by copying the example package folder +SimulinkDemos. Navigate to the example package folder.

```
% Remember the current folder path
currentPath = pwd;

% Navigate to the example package folder
demoPath = '\toolbox\simulink\simdemos\dataclasses';
cd([matlabroot,demoPath])
```

- 2 Copy the +SimulinkDemos folder to your clipboard.
- 3 Return to your working folder.

```
cd(currentPath)
```

- 4 Paste the +SimulinkDemos folder from your clipboard into your working folder. Rename the copied folder to +myPackage.
- 5 Navigate inside the +myPackage folder to the file Signal.m to edit the definition of the Signal class.
- 6 Uncomment the methods section that defines the method setupCoderInfo. In the call to the function useLocalCustomStorageClasses, replace 'packageName' with 'myPackage'. When you finish, the section appears as follows:

```
methods
 function setupCoderInfo(h)
 % Use custom storage classes from this package
 useLocalCustomStorageClasses(h, 'myPackage');
 end
end % methods
```

The function useLocalCustomStorageClasses allows you to apply the custom storage classes that myPackage defines to data objects that you create from myPackage.

- 7 Save and close the file.
- 8 Navigate inside the +myPackage folder to the file Parameter.m to edit the definition of the Parameter class. Uncomment the methods section that defines the method setupCoderInfo and replace 'packageName' with 'myPackage'.
- 9 Save and close the file.

### Create Custom Storage Class

You can use the Custom Storage Class Designer to create or to edit the custom storage classes that a data class package defines.

- 1 Set your current folder to the folder that contains the package `myPackage`.
- 2 Open the Custom Storage Class Designer.  

```
cscdesigner('myPackage')
```
- 3 Select the custom storage class `ExportToFile`.
- 4 In the **Name** field, rename the custom storage class to `ExportToGlobal`.
- 5 In the **Header file** drop-down list, change the selection from `Instance specific` to `Specify`. In the new field, provide the header file name `global.h`.
- 6 In the **Definition file** drop-down list, change the selection from `Instance specific` to `Specify`. In the new field, provide the definition file name `global.c`.
- 7 Click **OK**. Click **Yes** to save changes to the data class package `myPackage`.

### Apply Custom Storage Class

To apply your own custom storage class, you create data objects from your package and configure the objects to use your custom storage class.

- 1 Create data objects to represent some of the parameters and signals in the example model. Create the objects using the data class package `myPackage`.

```
% Parameters
templimit = myPackage.Parameter(202);
pressurelimit = myPackage.Parameter(45.2);
O2limit = myPackage.Parameter(0.96);
rpmlimit = myPackage.Parameter(7400);
```

```
% Signals
tempalarm = myPackage.Signal;
pressurealarm = myPackage.Signal;
O2alarm = myPackage.Signal;
rpmalarm = myPackage.Signal;
```

- 2 Set the custom storage class of each object to `ExportToGlobal`.

```
% Parameters
templimit.CoderInfo.StorageClass = 'Custom';
templimit.CoderInfo.CustomStorageClass = 'ExportToGlobal';
```

```

pressurelimit.CoderInfo.StorageClass = 'Custom';
pressurelimit.CoderInfo.CustomStorageClass = 'ExportToGlobal';
O2limit.CoderInfo.StorageClass = 'Custom';
O2limit.CoderInfo.CustomStorageClass = 'ExportToGlobal';
rpmlimit.CoderInfo.StorageClass = 'Custom';
rpmlimit.CoderInfo.CustomStorageClass = 'ExportToGlobal';

% Signals
tempalarm.CoderInfo.StorageClass = 'Custom';
tempalarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';
pressurealarm.CoderInfo.StorageClass = 'Custom';
pressurealarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';
O2alarm.CoderInfo.StorageClass = 'Custom';
O2alarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';
rpmalarm.CoderInfo.StorageClass = 'Custom';
rpmalarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';

```

- 3 Select the **Signal name must resolve to Simulink signal object** option for each of the target signals in the model. You can select the option by using the Signal Properties dialog box, the **Resolve** column in the Model Data Editor, or by using the command prompt.

```

% Signal tempalarm
portHandles = get_param('rtwdemo_cscpredef/Rel0p1', 'PortHandles');
outputPortHandle = portHandles.Outputport;
set_param(outputPortHandle, 'MustResolveToSignalObject', 'on')

% Signal pressurealarm
portHandles = get_param('rtwdemo_cscpredef/Rel0p2', 'PortHandles');
outputPortHandle = portHandles.Outputport;
set_param(outputPortHandle, 'MustResolveToSignalObject', 'on')

% Signal O2alarm
portHandles = get_param('rtwdemo_cscpredef/Rel0p3', 'PortHandles');
outputPortHandle = portHandles.Outputport;
set_param(outputPortHandle, 'MustResolveToSignalObject', 'on')

% Signal rpmalarm
portHandles = get_param('rtwdemo_cscpredef/Rel0p4', 'PortHandles');
outputPortHandle = portHandles.Outputport;
set_param(outputPortHandle, 'MustResolveToSignalObject', 'on')

```

## Generate Code

- 1 Generate code for the example model.

```
rtwbuild('rtwdemo_cscpredef')
```

- 2 In the code generation report, view the generated header file `global.h`. The file contains the `extern` declarations of all of the model signals and parameters that use the custom storage class `ExportToGlobal`.

```
/* Declaration for custom storage class: ExportToGlobal */
extern boolean_T O2alarm;
extern real_T O2limit;
extern boolean_T pressurealarm;
extern real_T pressurelimit;
extern boolean_T rpmalarm;
extern real_T rpmlimit;
extern boolean_T tempalarm;
extern real_T templimit;
```

- 3 View the generated file `global.c`. The file contains the definitions of the model signals and parameters that use the custom storage class `ExportToGlobal`.

```
/* Definition for custom storage class: ExportToGlobal */
boolean_T O2alarm;
real_T O2limit = 0.96;
boolean_T pressurealarm;
real_T pressurelimit = 45.2;
boolean_T rpmalarm;
real_T rpmlimit = 7400.0;
boolean_T tempalarm;
real_T templimit = 202.0;
```

## Modify a Built-In Custom Storage Class

You cannot directly modify a built-in custom storage class, such as `ExportToFile` from the `Simulink` package, but you can create a copy, and then modify the copy. When you create a new package with no `csc_registration.m` file, and then open the Custom Storage Class Designer for the first time in that package, Simulink copies the definitions of the built-in custom storage classes into the package. Then, in the Custom Storage Class Designer, you can modify the copied definitions. Alternatively, to keep the built-in custom storage classes available in your package, copy one of them by clicking **Copy**, then modify the resulting copy.

## Control Data Representation by Configuring Custom Storage Class Properties

The Custom Storage Class Designer is a tool for creating and managing custom storage classes and memory sections. To open the Custom Storage Class Designer for a specific package, for example, `+mypkg`, at the command prompt, use the `cscdesigner` function:

```
cscdesigner('mypkg')
```

The name of the folder that represents a package begins with a `+`. When you use `cscdesigner`, omit the `+` from the name of the target package.

To control the effect that a custom storage class has on data in a model, you specify properties of the storage class in the Custom Storage Class Designer. To determine how to generate a particular kind of code, use the information in the table.

| Kind of Data in Generated Code                   | Technique                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Structure                                        | Set <b>Type</b> to <code>FlatStructure</code> . See “Generate Structured Data” on page 26-33.                                                                                                                                                                                                                                                                                            |
| Macro                                            | Set <b>Data initialization</b> to <code>Macro</code> and clear <b>For signals</b> . See “Generate a Macro” on page 26-32.                                                                                                                                                                                                                                                                |
| Pointer                                          | Set <b>Data access</b> to <code>Pointer</code> and <b>Data scope</b> to <code>Auto</code> , <code>Imported</code> , or <code>Instance specific</code> . Your external code must define the pointer variable.                                                                                                                                                                             |
| <code>static</code> data (file-scoped data)      | Set <b>Data scope</b> to <code>File</code> .                                                                                                                                                                                                                                                                                                                                             |
| <code>const</code> or <code>volatile</code> data | Set <b>Memory section</b> to a memory section that specifies <code>const</code> , <code>volatile</code> , or both. For example, use one of the built-in memory sections <code>MemConst</code> , <code>MemVolatile</code> , and <code>MemConstVolatile</code> . To create your own memory section, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 30-2. |

| Kind of Data in Generated Code                        | Technique                                                                                                 |
|-------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|
| Calls to external functions to read and write to data | See “Call Custom Accessor Functions or Macros Instead of Reading and Writing to Variables” on page 26-34. |

### Allow Users of Custom Storage Class to Specify Property Value

For some properties of a custom storage class, such as **Data scope**, instead of specifying a value in the Custom Storage Class Designer, you can allow users of the storage class to specify the value. You can create a single, flexible custom storage class instead of multiple custom storage classes that vary only by a few property values.

For example, suppose you create a custom storage class that yields a global variable in the generated code. You can configure the storage class so that a user can set the **Data scope** property to **Exported** for a signal in a model and set the property to **Imported** for a different signal.

In the Custom Storage Class Designer, for each property that you want to configure in this way, set the property value to **Instance specific**. Then, when a user applies the custom storage class to a data item, the property appears to the user as a custom attribute for that data item. For information about instance-specific custom attributes, see “Specify File Names and Other Data Attributes With Storage Class (Embedded Coder)” on page 22-76.

### Generate a Macro

To create a custom storage class that yields a macro in the generate code, set **Data initialization** to **Macro** and clear **For signals**.

When you set **Data initialization** to **Macro**, **Definition file** has no meaning. To prevent users of the custom storage class from specifying a meaningless definition file, in the Custom Storage Class Designer, set **Definition file** to **Specify** and leave the text box empty.

- To define the macro in a header file (**#define**), specify the name of the header file with the **Header file** property.
- To provide the macro definition as a compiler option or compiler flag, set **Data access** to **Imported** and **Header file** to **Specify**. Leave the **Header file** text box empty. Then, the generated code does not define the macro and does not include (**#include**) a header file.

To specify the compiler option or flag, use the model configuration parameter **Configuration Parameters > Code Generation > Custom Code > Additional build information > Defines**. See Code Generation Pane: Custom Code: Additional Build Information: Defines (Simulink Coder).

## Generate Structured Data

To create a custom storage class that aggregates data items into a flat structure (similar to the built-in custom storage class `Struct`), set **Type** to `FlatStructure`. The **Structure Attributes** tab appears.

- To control the name of the global structure variable that appears in the generated code, use the **Struct name** property and text box.
- If you set **Struct name** to `Instance specific`, users of the custom storage class specify the name of the structure variable. In this case, the code generator derives the name of the structure type from the name of the variable.

To more precisely control the name and other characteristics of the structure type, set **Struct name** to `Specify`. Control the type characteristics by using the additional properties that appear.

- To generate a structure with bit fields (similar to the built-in custom storage class `BitField`), select **Bit-pack booleans**. Data items that use the data type `boolean` appear in the generated code as bit fields of the structure.

## Control Assignment of Initial Value in Generated Code

- To use the default Simulink Coder initialization strategy, set **Data initialization** to the default value, `Auto`.
  - The generated code statically initializes parameter data with an assignment statement at the top of a `.c` or `.cpp` source file, outside of any function.
  - The generated code dynamically initializes signal and state data as part of the initialization function of the model (named `model_initialize` by default).
- To statically initialize the data, set **Data initialization** to `Static`.
- To dynamically initialize the data, set **Data initialization** to `Dynamic`.
- To prevent the generated code from initializing the data, set **Data initialization** to `None`. When your external code initializes the data, use this setting to prevent the generated code from overwriting your initialization.

## Call Custom Accessor Functions or Macros Instead of Reading and Writing to Variables

Using the built-in custom storage class `GetSet`, you can generate code that calls your external, custom functions instead of directly interacting with variables. For general information about `GetSet`, see “Access Data Through Functions with Custom Storage Class `GetSet`” on page 26-42.

To create a similar custom storage class, set **Type** to `AccessFunction`.

- Specify the names of the external functions.
  - To apply the same `get` or `set` function naming scheme to all data items that use the custom storage class, set **Get function** and **Set function** to `Specify`. Then, in the text boxes, specify the function naming scheme, for example, `get_myData_$N`. Use the token `$N` in a naming scheme to represent the name of each data item. If you do not use the token, each data item uses the same specified `get` or `set` function name, so the model generates an error when you generate code.
  - To specify a different `get` or `set` function name for each data item, set **Get function** or **Set function** to `Instance specific`. Later, when you create a data item and apply the custom storage class, specify the function name by configuring the custom attributes of the data item.
- Specify the name of the header file that declares the `get` and `set` functions with the **Header file** property. In this case, **Definition file** has no meaning. To prevent users of the custom storage class from specifying a meaningless definition file, set **Definition file** to `Specify` and leave the text box empty.
- If you implement the `get` mechanism for scalar or array data as a macro instead of a function, you can generate code that omits parentheses when reading that data. On the **Access Function Attributes** tab, select **Get data through macro (omit parentheses)**.

## Generate Code That Uses Data From External Code

When your external code defines data, to avoid generating a duplicate definition, you must configure the generated code to read and write to the existing data. In the Custom Storage Class Designer, set **Data scope** to `Imported`. The code generator does not generate a definition for the global variable or macro.

- If your code defines a pointer variable, to generate code that interacts with the pointer, set **Data access** to `Pointer`.

- If you generate structured data by setting **Type** to FlatStructure, your code must define the structure type and the global structure variable.
- If your code initializes state or signal data, you can prevent the generated code from overwriting your initialization by setting **Data initialization** to None. See “Prevent Duplicate Initialization Code for Global Variables” on page 42-103

### **Generate Code Comments with Data Definitions and Declarations**

To customize the comments that appear in the generated code, on the **Comments** tab, set **Comment rules** to Specify. To specify a comment that appears with the declaration of each data item, use the **Declaration comment** box. To specify a comment that appears with the definition, use the **Definition comment** box.

For structured data (you set **Type** to FlatStructure), to specify a comment that appears with the structure type definition, use the **Type comment** box.

### **Avoid Errors During Code Generation by Validating Custom Storage Class Configuration**

As you configure a custom storage class in the Custom Storage Class Designer, to check for possible errors in the configuration, click **Validate**.

For example, validating the custom storage class warns you if you accidentally set **Data initialization** to Macro with **For signals** selected. A signal cannot appear in the generated code as a macro.

### **Make Custom Storage Classes Available Outside the Current Folder**

To use a custom storage class that you create, you must make the defining package available. Either set your current folder to the folder that contains the package or add the folder containing the package folder to the MATLAB path (see “What Is the MATLAB Search Path?” (MATLAB)). Adding the package to the MATLAB path enables you to use the custom storage classes no matter where you set your current folder.

### **Share Custom Storage Class Between Packages**

When you create a package, you can refer to a custom storage class defined in another package such as the built-in package Simulink or a different package that you created.

Then, the defining package and any referencing packages can use the custom storage class. When you want to make a change to the custom storage class, you make the change only once, in the defining package.

To configure a package to refer to a custom storage class that another package defines:

- 1 In the Custom Storage Class Designer, select the **Custom Storage Class** tab.
- 2 Use **Select Package** to select the referencing package. The package must be writable.
- 3 In the **Custom storage class definitions** pane, select the existing definition below which you want to insert the reference.
- 4 Click **New Reference**.

A new reference with a default name and properties appears below the previously selected definition. The new reference is selected and a **Reference** tab appears that shows the initial properties.

- 5 Use **Name** to specify a name for the new reference. The name must be unique in the importing package, but can duplicate the name in the source package. The name cannot be a TLC keyword.
- 6 Set **Refer to custom storage class in package** to specify the package that contains the custom storage class that you want to reference.
- 7 Set **Custom storage class to reference** to specify the custom storage class to be referenced.
- 8 Click **OK** or **Apply**. To save the changes permanently, click **Save**.

## Control Appearance of Storage Class Drop-Down List

When you apply a custom storage class to a data item, you select the custom storage class from a drop-down list.

- To control the order of the custom storage classes in the list, in the Custom Storage Class Designer, use the **Up** and **Down** buttons. The order of the custom storage classes in drop-down lists matches the order that you specify in the Custom Storage Class Designer.
- To prevent a user of a custom storage class from applying the storage class to parameter data or to signal and state data, use the **For parameters** and **For signals** check boxes. When you clear one of these properties, for the corresponding kind of data, the custom storage class does not appear in the drop-down list.

For example, if your custom storage class yields a macro in the generated code because you set **Data initialization** to **Macro**, to prevent users from applying the custom storage class to signal data, clear **For signals**.

## Protect Custom Storage Class Definitions

When you click **Save** in the Custom Storage Class Designer, the Designer saves memory section and custom storage class definitions into the `csc_registration.m` file in the package folder. To determine the location of this file, in the Custom Storage Class Designer, inspect the value of **Filename**.

You can prevent changes to the custom storage class definitions of an entire package by converting the `csc_registration.m` file from a MATLAB file to a P-file. Use the `pcode` function.

A best practice is to keep both `csc_registration.m` and `csc_registration.p` in your package folder. That way, if you need to modify the custom storage classes by using the Designer, you can delete `csc_registration.p` and later regenerate it after you finish the modifications. Because the P-coded version of the file takes precedence, when both files exist in the package, the custom storage classes are protected and cannot be modified in the Custom Storage Class Designer.

## Further Customize Generated Code by Writing TLC Code

If creating your own custom storage class by manipulating the properties in the Custom Storage Class Designer does not satisfy your requirements, you can finely control the generated code by writing TLC code for your custom storage class. Use an advanced mode of the Custom Storage Class Designer and, for the custom storage class, set **Type** to **Other**. See “Finely Control Data Representation by Writing TLC Code for a Custom Storage Class” on page 26-39.

## Finely Control Data Representation by Writing TLC Code for a Custom Storage Class

If creating your own custom storage class by using the properties in an Embedded Coder Dictionary or the Custom Storage Class Designer does not meet your requirements for controlling data representation in the generated code, you can write TLC code that explicitly controls the effect that a custom storage class has on the code. For example, to create a custom storage class that yields arbitrarily nested structures, you must write TLC code. In the Custom Storage Class Designer, these advanced custom storage classes have **Type** set to **Other**. You cannot create such a storage class in an Embedded Coder Dictionary, so you cannot use the storage class as a default code generation setting in the Code Mapping Editor.

For an example, see “Generate Code That Dereferences Data from a Literal Memory Address” on page 52-21. For general information about TLC code, see “Why Use the Target Language Compiler?” (Simulink Coder).

### Create Custom Attributes Class for Custom Storage Class

As described in “Allow Users of Custom Storage Class to Specify Property Value” on page 26-32, instance-specific properties enable users of a custom storage class to control the effect that the storage class has on each data item. For example, the built-in custom storage class `ExportToFile` has several instance-specific properties such as **Header file** and **Definition file**.

When you create a custom storage class with **Type** set to **Other**, to add your own instance-specific properties that are not built into the Custom Storage Class Designer, create a custom attributes class for your package. A custom attributes class is a MATLAB class that you create as a subclass of `Simulink.CustomStorageClassAttributes`. Each property that you add to your custom attributes class appears to the user of the custom storage class as an instance-specific property.

To create your custom attributes class, see “Define Data Classes” (Simulink).

### Write TLC Code for Custom Storage Class

To control the effect of your custom storage class, write TLC code that specifies the code to generate for each data item.

- 1 In your package folder (for example, `+myPackage`), create a `tlc` folder.
- 2 Copy a TLC template such as `TEMPLATE_v1.tlc` from the folder `matlabroot/toolbox/rtw/targets/ecoder/csc_templates` (open) into your `tlc` folder.
- 3 Write your TLC code, following the comments in the template file. The comments describe how to specify, for example, how the generated code declares, defines, and accesses (by value or by reference) each data item.

## Create Custom Storage Class by Using Custom Storage Class Designer

To create your custom storage class in your package, you open the Custom Storage Class Designer in an advanced mode.

- 1 At the command prompt, enter:  

```
cscdesigner -advanced
```
- 2 Select your package and create a custom storage class.
- 3 For the custom storage class, set **Type** to **Other**. In the **Other Attributes** pane, specify the name of your TLC file and the name of your custom attributes class.
- 4 Set the properties on the **Other Attributes** pane.
  - **Is grouped**: Select this option if you intend to combine multiple data items into a single entity in the generated code. For example, the built-in custom storage classes `BitField` and `Struct` are grouped because they can aggregate multiple data items into a single structure variable.
  - **TLC file name**: Enter the name of your TLC file. The Custom Storage Class Designer assumes that the file exists in the package `tlc` folder, so specify only the name of the file, not the file path.
  - **CSC attributes class name**: (optional) If you created a custom attributes class, enter the full name of the class, including the package name. For example, specify `myPackage.myCustomAttsClass`. For more information, see “Create Custom Attributes Class for Custom Storage Class” on page 26-39.
- 5 On the **General** and **Comments** panes, specify values for the remaining properties.

## Access Data Through Functions with Custom Storage Class GetSet

To integrate the generated code with legacy code that uses specialized functions to read from and write to data, you can use the custom storage class `GetSet`. Signals, block parameters, and states that use `GetSet` appear in the generated code as calls to accessor functions. You provide the function definitions.

To generate code that conforms to the AUTOSAR standard by accessing data through `Rte` function calls, use the Configure AUTOSAR Interface dialog box. See “AUTOSAR Component Configuration”.

### Access Legacy Data Using Get and Set Functions

This example shows how to generate code that interfaces with legacy code by using specialized `get` and `set` functions to access data.

View the example legacy header file `ComponentDataHdr.h`. The file defines a large structure type `ComponentData`.

```
rtwdemodbtype('ComponentDataHdr.h', '/* ComponentData */', '} ComponentData;', 1, 1)
```

```
/* ComponentData */

typedef struct {
 ScalarData scalars;
 VectorData vectors;
 StructData structs;
 MatricesData matrices;
} ComponentData;
```

The field `scalars` is a substructure that uses the structure type `ScalarData`. The structure type `ScalarData` defines three scalar fields: `inSig`, `scalarParam`, and `outSig`.

```
rtwdemodbtype('ComponentDataHdr.h', '/* ScalarData */', '} ScalarData;', 1, 1)
```

```
/* ScalarData */

typedef struct {
```

```

 double inSig;
 double scalarParam;
 double outSig;
} ScalarData;

```

View the example legacy source file `getsetSrc.c`. The file defines and initializes a global variable `ex_getset_data` that uses the structure type `ComponentData`. The initialization includes values for the substructure `scalars`.

```

rtwdemodbtype('getsetSrc.c', '/* Field "scalars" */', '/* End of "scalars" */', 1, 1)

```

```

 /* Field "scalars" */
 {
 3.9,

 12.3,

 0.0
 },
 /* End of "scalars" */

```

The file also defines functions that read from and write to the fields of the substructure `scalars`. The functions simplify data access by dereferencing the leaf fields of the global structure variable `ex_getset_data`.

```

rtwdemodbtype('getsetSrc.c', ...
 '/* Scalar get() and set() functions */', '/* End of scalar functions */', 1, 1)

```

```

/* Scalar get() and set() functions */

double get_inSig(void)
{
 return ex_getset_data.scalars.inSig;
}

void set_inSig(double value)
{
 ex_getset_data.scalars.inSig = value;
}

double get_scalarParam(void)
{
 return ex_getset_data.scalars.scalarParam;
}

```

```

}

void set_scalarParam(double value)
{
 ex_getset_data.scalars.scalarParam = value;
}

double get_outSig(void)
{
 return ex_getset_data.scalars.outSig;
}

void set_outSig(double value)
{
 ex_getset_data.scalars.outSig = value;
}

```

View the example legacy header file `getsetHdrScalar.h`. The file contains the extern prototypes for the get and set functions defined in `getsetSrc.c`.

Open the example model `rtwdemo_getset_scalar`. The model creates the data objects `inSig`, `outSig`, and `scalarParam` in the base workspace. The objects correspond to the signals and parameter in the model.

```
open_system('rtwdemo_getset_scalar')
```

Copyright 2015 The Mathworks, Inc.

In the base workspace, double-click the object `inSig` to view its properties. The object uses the custom storage class `GetSet`. The `GetFunction` and `SetFunction` properties are set to the defaults, `get_$N` and `set_$N`. The generated code uses the function names that you specify in `GetFunction` and `SetFunction` to read from and write to the data. The code replaces the token `$N` with the name of the data object. For example, for the data object `inSig`, the generated code uses calls to the legacy functions `get_inSig` and `set_inSig`.

For the data object `inSig`, the `HeaderFile` property is set to `getsetHdrScalar.h`. This legacy header file contains the `get` and `set` function prototypes. The data objects `outSig` and `scalarParam` also use the custom storage class `GetSet` and the header file `getsetHdrScalar.h`.

In the model Configuration Parameters dialog box, on the **Code Generation > Custom Code** pane, under **Include list of additional**, select **Source files**. The **Source files** box identifies the source file `getsetSrc.c` for inclusion during the build process. This legacy source file contains the `get` and `set` function definitions and the definition of the global structure variable `ex_getset_data`.

Generate code with the example model.

```
rtwbuild('rtwdemo_getset_scalar');

Starting build procedure for model: rtwdemo_getset_scalar
Successful completion of build procedure for model: rtwdemo_getset_scalar
```

In the code generation report, view the file `rtwdemo_getset_scalar.c`. The model step function uses the legacy `get` and `set` functions to execute the algorithm. The generated code accesses the legacy signal and parameter data by calling the custom, handwritten `get` and `set` functions.

```
rtwdemodbtype(fullfile('rtwdemo_getset_scalar_ert_rtw','rtwdemo_getset_scalar.c'),...
 /* Model step function */,'}',1,1)

/* Model step function */
void rtwdemo_getset_scalar_step(void)
{
 /* Gain: '<Root>/Gain' incorporates:
 * Inport: '<Root>/In1'
 */
 set_outSig(get_scalarParam() * get_inSig());
}
```

You can generate code that calls your custom `get` and `set` functions as long as the functions that you write accept and return the expected values. For scalar data, the functions must have these characteristics:

- The `get` function must return a single scalar numeric value of the appropriate data type, and must not accept any arguments (`void`).

- The `set` function must not return anything (`void`), and must accept a single scalar numeric value of the appropriate data type.

## Use GetSet with Vector Data

This example shows how to apply the custom storage class `GetSet` to signals and parameters that are vectors.

View the example legacy header file `ComponentDataHdr.h`. The file defines a large structure type `ComponentData`.

```
rtwdemodbtype('ComponentDataHdr.h', '/* ComponentData */', '} ComponentData;', 1, 1)

/* ComponentData */

typedef struct {
 ScalarData scalars;
 VectorData vectors;
 StructData structs;
 MatricesData matrices;
} ComponentData;
```

The field `vectors` is a substructure that uses the structure type `VectorData`. The structure type `VectorData` defines three vector fields: `inVector`, `vectorParam`, and `outVector`. The vectors each have five elements.

```
rtwdemodbtype('ComponentDataHdr.h', '/* VectorData */', '} VectorData;', 1, 1)

/* VectorData */

typedef struct {
 double inVector[5];
 double vectorParam[5];
 double outVector[5];
} VectorData;
```

View the example legacy source file `getsetSrc.c`. The file defines and initializes a global variable `ex_getset_data` that uses the structure type `ComponentData`. The initialization includes values for the substructure `vectors`.

```
rtwdemodbtype('getsetSrc.c', '/* Field "vectors" */', '/* End of "vectors" */', 1, 1)
```

```

/* Field "vectors" */
{
 {5.7, 6.8, 1.2, 3.5, 10.1},
 {12.3, 18.7, 21.2, 28, 32.9},
 {0.0, 0.0, 0.0, 0.0, 0.0}
},
/* End of "vectors" */

```

The file also defines functions that read from and write to the fields of the substructure `vectors`. The functions simplify data access by dereferencing the leaf fields of the global structure variable `ex_getset_data`. To access the vector data, all of the functions accept an integer index argument. The `get` function returns the vector value at the input index. The `set` function assigns the input value to the input index.

```

rtwdemodbtype('getsetSrc.c',...
 /* Vector get() and set() functions */,'/* End of vector functions */',1,1)

/* Vector get() and set() functions */

double get_inVector(int index)
{
 return ex_getset_data.vectors.inVector[index];
}

void set_inVector(int index, double value)
{
 ex_getset_data.vectors.inVector[index] = value;
}

double get_vectorParam(int index)
{
 return ex_getset_data.vectors.vectorParam[index];
}

void set_vectorParam(int index, double value)
{
 ex_getset_data.vectors.vectorParam[index] = value;
}

double get_outVector(int index)
{

```

```

 return ex_getset_data.vectors.outVector[index];
}

void set_outVector(int index, double value)
{
 ex_getset_data.vectors.outVector[index] = value;
}

```

View the example legacy header file `getsetHdrVector.h`. The file contains the extern prototypes for the `get` and `set` functions defined in `getsetSrc.c`.

Open the example model `rtwdemo_getset_vector`. The model creates the data objects `inVector`, `outVector`, and `vectorParam` in the base workspace. The objects correspond to the signals and parameter in the model.

```
open_system('rtwdemo_getset_vector')
```

Copyright 2015 The Mathworks, Inc.

In the base workspace, double-click the object `inVector` to view its properties. The object uses the custom storage class `GetSet`. The property `HeaderFile` is specified as `getsetHdrVector.h`. This legacy header file contains the `get` and `set` function prototypes.

In the model Configuration Parameters dialog box, on the **Code Generation > Custom Code** pane, the example legacy source file `getsetSrc.c` is identified for inclusion during the build process. This legacy source file contains the `get` and `set` function definitions and the definition of the global structure variable `ex_getset_data`.

Generate code with the example model.

```

rtwbuild('rtwdemo_getset_vector');

Starting build procedure for model: rtwdemo_getset_vector
Successful completion of build procedure for model: rtwdemo_getset_vector

```

In the code generation report, view the file `rtwdemo_getset_vector.c`. The model step function uses the legacy `get` and `set` functions to execute the algorithm.

```
rtwdemodbtype(fullfile('rtwdemo_getset_vector_ert_rtw','rtwdemo_getset_vector.c'),...
 /* Model step function */,'}',1,1)

/* Model step function */
void rtwdemo_getset_vector_step(void)
{
 int32_T i;

 /* Gain: '<Root>/Gain' incorporates:
 * Inport: '<Root>/In1'
 */
 for (i = 0; i < 5; i++) {
 set_outVector(i, get_vectorParam(i) * get_inVector(i));
 }
}
```

When you use the custom storage class `GetSet` with vector data, the `get` and `set` functions that you provide must accept an index input. The `get` function must return a single element of the vector. The `set` function must write to a single element of the vector.

## Use GetSet with Structured Data

This example shows how to apply the custom storage class `GetSet` to nonvirtual bus signals and structure parameters in a model.

View the example legacy header file `ComponentDataHdr.h`. The file defines a large structure type `ComponentData`.

```
rtwdemodbtype('ComponentDataHdr.h',...
 /* ComponentData */,'}' ComponentData;',1,1)

/* ComponentData */

typedef struct {
 ScalarData scalars;
 VectorData vectors;
 StructData structs;
 MatricesData matrices;
} ComponentData;
```

The field `structs` is a substructure that uses the structure type `StructData`. The structure type `StructData` defines three fields: `inStruct`, `structParam`, and `outStruct`.

```
rtwdemodbtype('ComponentDataHdr.h', /* StructData */,'} StructData;',1,1)

/* StructData */

typedef struct {
 SigBus inStruct;
 ParamBus structParam;
 SigBus outStruct;
} StructData;
```

The fields `inStruct`, `structParam`, and `outStruct` are also substructures that use the structure types `SigBus` and `ParamBus`. Each of these two structure types define three scalar fields.

```
rtwdemodbtype('ComponentDataHdr.h', /* SigBus */,'} ParamBus',1,1)

/* SigBus */

typedef struct {
 double cmd;
 double sensor1;
 double sensor2;
} SigBus;

/* ParamBus */

typedef struct {
 double offset;
 double gain1;
 double gain2;
} ParamBus;
```

View the example legacy source file `getsetSrc.c`. The file defines and initializes a global variable `ex_getset_data` that uses the structure type `ComponentData`. The initialization includes values for the substructure `structs`.

```
rtwdemodbtype('getsetSrc.c',...
 /* Field "structs" */,'/* End of "structs" */',1,1)
```

```

/* Field "structs" */
{
 {1.3, 5.7, 9.2},
 {12.3, 9.6, 1.76},
 {0.0, 0.0, 0.0}
},
/* End of "structs" */

```

The file also defines functions that read from and write to the fields of the substructure `structs`. The functions simplify data access by dereferencing the fields of the global structure variable `ex_getset_data`. The functions access the data in the fields `inStruct`, `structParam`, and `outStruct` by accepting and returning complete structures of the types `SigBus` and `ParamBus`.

```

rtwdemodbtype('getsetSrc.c',...
 /* Structure get() and set() functions */,...
 /* End of structure functions */',1,1)

/* Structure get() and set() functions */

SigBus get_inStruct(void)
{
 return ex_getset_data.structs.inStruct;
}

void set_inStruct(SigBus value)
{
 ex_getset_data.structs.inStruct = value;
}

ParamBus get_structParam(void)
{
 return ex_getset_data.structs.structParam;
}

void set_structParam(ParamBus value)
{
 ex_getset_data.structs.structParam = value;
}

SigBus get_outStruct(void)

```

```

{
 return ex_getset_data.structs.outStruct;
}

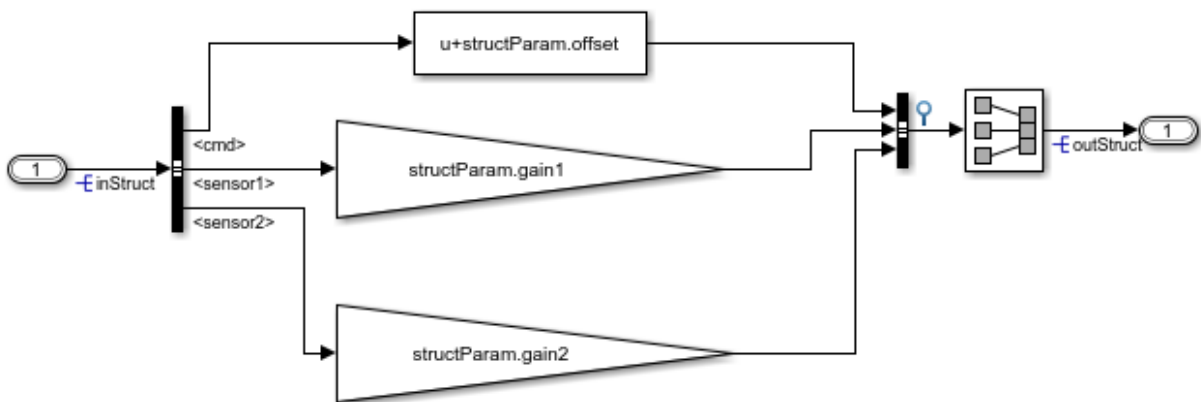

void set_outStruct(SigBus value)
{
 ex_getset_data.structs.outStruct = value;
}

```

View the example legacy header file `getsetHdrStruct.h`. The file contains the extern prototypes for the get and set functions defined in `getsetSrc.c`.

Open the example model `rtwdemo_getset_struct`. The model creates the data objects `inStruct`, `structParam`, and `outStruct` in the base workspace. The objects correspond to the signals and parameter in the model.

```
open_system('rtwdemo_getset_struct')
```

Copyright 2015 The Mathworks, Inc.

In the base workspace, double-click the object `inStruct` to view its properties. The object uses the custom storage class `GetSet`. The property `HeaderFile` is specified as `getsetHdrStruct.h`. This legacy header file contains the get and set function prototypes.

The model also creates the bus objects ParamBus and SigBus in the base workspace. The signals and parameter in the model use the bus types that these objects define. The property DataScope of each bus object is set to Imported. The property HeaderFile is set to ComponentDataHdr.h. The generated code imports these structure types from the legacy header file ComponentDataHdr.h.

In the model Configuration Parameters dialog box, on the **Code Generation > Custom Code** pane, the example legacy source file getsetSrc.c is identified for inclusion during the build process. This legacy source file contains the get and set function definitions and the definition of the global structure variable ex\_getset\_data.

Generate code with the example model.

```
rtwbuild('rtwdemo_getset_struct');

Starting build procedure for model: rtwdemo_getset_struct
Successful completion of build procedure for model: rtwdemo_getset_struct
```

In the code generation report, view the file rtwdemo\_getset\_struct.c. The model step function uses the legacy get and set functions to execute the algorithm.

```
rtwdemodbtype(fullfile('rtwdemo_getset_struct_ert_rtw',...
 'rtwdemo_getset_struct.c'),...
 /* Model step function */,'}',1,1)

/* Model step function */
void rtwdemo_getset_struct_step(void)
{
 /* Bias: '<Root>/Bias' incorporates:
 * Inport: '<Root>/In1'
 */
 rtDW.BusCreator.cmd = (get_inStruct()).cmd + (get_structParam()).offset;

 /* Gain: '<Root>/Gain' incorporates:
 * Inport: '<Root>/In1'
 */
 rtDW.BusCreator.sensor1 = (get_structParam()).gain1 * (get_inStruct()).sensor1;

 /* Gain: '<Root>/Gain1' incorporates:
 * Inport: '<Root>/In1'
 */
 rtDW.BusCreator.sensor2 = (get_structParam()).gain2 * (get_inStruct()).sensor2;
```

```
/* SignalConversion: '<Root>/Signal Conversion' */
set_outStruct(rtDW.BusCreator);
}
```

When you use the custom storage class `GetSet` with structured data, the `get` and `set` functions that you provide must return and accept complete structures. The generated code dereferences individual fields of the structure that the `get` function returns.

The output signal of the Bus Creator block is a test point. This signal is the input for a Signal Conversion block. The test point and the Signal Conversion block exist so that the generated code defines a variable for the output of the Bus Creator block. To provide a complete structure argument for the function `set_outStruct`, you must configure the model to create this variable.

## Use GetSet with Matrix Data

This example shows how to apply the custom storage class `GetSet` to signals and parameters that are matrices.

View the example legacy header file `ComponentDataHdr.h`. The file defines a large structure type `ComponentData`.

```
rtwdemodbtype('ComponentDataHdr.h',...
 '/* ComponentData */','} ComponentData;',1,1)
```

```
/* ComponentData */

typedef struct {
 ScalarData scalars;
 VectorData vectors;
 StructData structs;
 MatricesData matrices;
} ComponentData;
```

The field `matrices` is a substructure that uses the structure type `MatricesData`. The structure type `MatricesData` defines three fields: `matrixInput`, `matrixParam`, and `matrixOutput`. The fields store matrix data as serial arrays. In this case, the input and parameter fields each have 15 elements. The output field has nine elements.

```
rtwdemodbtype('ComponentDataHdr.h'...
 , '/* MatricesData */','} MatricesData;',1,1)
```

```

/* MatricesData */

typedef struct {
 double matrixInput[15];
 double matrixParam[15];
 double matrixOutput[9];
} MatricesData;

```

View the example legacy source file `getsetSrc.c`. The file defines and initializes a global variable `ex_getset_data` that uses the structure type `ComponentData`. The initialization includes values for the substructure matrices.

```

rtwdemodbtype('getsetSrc.c',...
 /* Field "matrices" */,'/* End of "matrices" */',1,1)

 /* Field "matrices" */
 {
 {12.0, 13.9, 7.4,
 0.5, 11.8, 6.4,
 4.7, 5.3, 13.0,
 0.7, 16.1, 13.5,
 1.6, 0.5, 3.1},

 {8.3, 12.0, 11.5, 2.0, 5.7,
 7.5, 12.8, 11.1, 8.4, 9.9,
 10.9, 4.6, 2.7, 16.3, 3.8},

 {0.0, 0.0, 0.0,
 0.0, 0.0, 0.0,
 0.0, 0.0, 0.0}
 }
 /* End of "matrices" */

```

The input matrix has five rows and three columns. The matrix parameter has three rows and five columns. The matrix output has three rows and three columns. The file defines macros that indicate these dimensions.

```

rtwdemodbtype('getsetSrc.c',...
 /* Matrix dimensions */,'/* End of matrix dimensions */',1,1)

 /* Matrix dimensions */

```

```
#define MATRIXINPUT_NROWS 5
#define MATRIXINPUT_NCOLS 3

#define MATRIXPARAM_NROWS 3
#define MATRIXPARAM_NCOLS 5

#define MATRIXOUTPUT_NROWS MATRIXPARAM_NROWS
#define MATRIXOUTPUT_NCOLS MATRIXINPUT_NCOLS
```

The file also defines functions that read from and write to the fields of the substructure matrices.

```
rtwdemodbtype('getsetSrc.c',...
 /* Matrix get() and set() functions */,'/* End of matrix functions */',1,1)

/* Matrix get() and set() functions */

double get_matrixInput(int colIndex)
{
 int rowIndexGetInput = MATRIXINPUT_NCOLS * (colIndex % MATRIXINPUT_NROWS) + colIndex;
 return ex_getset_data.matrices.matrixInput[rowIndexGetInput];
}

void set_matrixInput(int colIndex, double value)
{
 int rowIndexSetInput = MATRIXINPUT_NCOLS * (colIndex % MATRIXINPUT_NROWS) + colIndex;
 ex_getset_data.matrices.matrixInput[rowIndexSetInput] = value;
}

double get_matrixParam(int colIndex)
{
 int rowIndexGetParam = MATRIXPARAM_NCOLS * (colIndex % MATRIXPARAM_NROWS) + colIndex;
 return ex_getset_data.matrices.matrixParam[rowIndexGetParam];
}

void set_matrixParam(int colIndex, double value)
{
 int rowIndexSetParam = MATRIXPARAM_NCOLS * (colIndex % MATRIXPARAM_NROWS) + colIndex;
 ex_getset_data.matrices.matrixParam[rowIndexSetParam] = value;
}

double get_matrixOutput(int colIndex)
{
```

```
int rowIndexGetOut = MATRIXOUTPUT_NCOLS * (colIndex % MATRIXOUTPUT_NROWS) + colIndex;
return ex_getset_data.matrices.matrixOutput[rowIndexGetOut];
}

void set_matrixOutput(int colIndex, double value)
{
 int rowIndexSetOut = MATRIXOUTPUT_NCOLS * (colIndex % MATRIXOUTPUT_NROWS) + colIndex;
 ex_getset_data.matrices.matrixOutput[rowIndexSetOut] = value;
}
```

The code that you generate from a model represents matrices as serial arrays. Therefore, each of the `get` and `set` functions accept a single scalar index argument.

The generated code uses column-major format to store and to access matrix data. However, many C applications use row-major indexing. To integrate the generated code with the example legacy code, which stores the matrices `matrixInput` and `matrixParam` using row-major format, the custom `get` functions use the column-major index input to calculate an equivalent row-major index. The generated code algorithm, which interprets matrix data using column-major format by default, performs the correct matrix math because the `get` functions effectively convert the legacy matrices to column-major format. The `set` function for the output, `matrixOutput`, also calculates a row-major index so the code writes the algorithm output to `matrixOutput` using row-major format. Alternatively, to integrate the column-major generated code with your row-major legacy code, you can manually convert the legacy code to column-major format by transposing your matrix data and algorithms.

View the example legacy header file `getsetHdrMatrix.h`. The file contains the extern prototypes for the `get` and `set` functions defined in `getsetSrc.c`.

Open the example model `rtwdemo_getset_matrix`. The model creates the data objects `matrixInput`, `matrixParam`, and `matrixOutput` in the base workspace. The objects correspond to the signals and parameter in the model.

```
load_system('rtwdemo_getset_matrix')
set_param('rtwdemo_getset_matrix','SimulationCommand','Update')
open_system('rtwdemo_getset_matrix')
```

Copyright 2015 The Mathworks, Inc.

In the base workspace, double-click the object `matrixInput` to view its properties. The object uses the custom storage class `GetSet`. The property `HeaderFile` is specified as `getsetHdrMatrix.h`. This legacy header file contains the `get` and `set` function prototypes.

In the model Configuration Parameters dialog box, on the **Code Generation > Custom Code** pane, the example legacy source file `getsetSrc.c` is identified for inclusion during the build process. This legacy source file contains the `get` and `set` function definitions and the definition of the global structure variable `ex_getset_data`.

Generate code with the example model.

```

rtwbuild('rtwdemo_getset_matrix');

Starting build procedure for model: rtwdemo_getset_matrix
Successful completion of build procedure for model: rtwdemo_getset_matrix

```

In the code generation report, view the file `rtwdemo_getset_matrix.c`. The model step function uses the legacy `get` and `set` functions to execute the algorithm.

```

rtwdemodbtype(fullfile('rtwdemo_getset_matrix_ert_rtw',...
 'rtwdemo_getset_matrix.c'),'/* Model step function */','}',1,1)

```

```

/* Model step function */
void rtwdemo_getset_matrix_step(void)
{
 int32_T i;
 int32_T i_0;
 int32_T i_1;

```

```

int32_T matrixOutput_tmp;

/* Product: '<Root>/Product' incorporates:
 * Constant: '<Root>/Constant'
 * Inport: '<Root>/In1'
 */
for (i_0 = 0; i_0 < 3; i_0++) {
 for (i = 0; i < 3; i++) {
 matrixOutput_tmp = i + 3 * i_0;
 set_matrixOutput(matrixOutput_tmp, 0.0);
 for (i_1 = 0; i_1 < 5; i_1++) {
 set_matrixOutput(matrixOutput_tmp, get_matrixParam(3 * i_1 + i) *
 get_matrixInput(5 * i_0 + i_1) + get_matrixOutput(3 *
 i_0 + i));
 }
 }
}

```

## Specify Header File or Function Naming Scheme for All Data Items

By default, you specify a header file name, `get` function name, and `set` function name for each data item, such as a signal or parameter, that uses the custom storage class `GetSet`.

To configure a single header file, `get` function naming scheme, or `set` function naming scheme to use for every data item, you can use the Custom Storage Class Designer to create your own copy of `GetSet`. You can specify the header file or function names in a single location.

Follow these steps to create your own custom storage class by creating your own data class package, creating a copy of `GetSet`, and applying the new custom storage class to data items in your model.

- 1 Create your own data class package, `myPackage`, by copying the example package folder `+SimulinkDemos` and renaming the copied folder as `+myPackage`. Modify the `Parameter` and `Signal` class definitions so that they use the custom storage class definitions from `myPackage`. For an example, see “Create Data Class Package” on page 26-26.
- 2 Set your current folder to the folder that contains the package folder. Alternatively, add the folder containing the package folder to your MATLAB path.
- 3 Open the Custom Storage Class Designer.

```
cscdesigner('myPackage')
```

- 4 Select the custom storage class `GetSet`. Click **Copy** to create a copy called `GetSet_1`.
- 5 Select the new custom storage class `GetSet_1`. In the **General** tab, set **Name** to `myGetSet`.
- 6 Set the drop-down list **Header file** to `Specify`. In the new text box, set **Header file** to `myFcnHdr.h`. Click **Apply**.
- 7 On the **Access Function Attributes** tab, set the drop-down lists **Get function** and **Set function** to `Specify`.
- 8 In the new boxes, set **Get function** to `myGetFcn_$N` and **Set function** to `mySetFcn_$N`. Click **OK**. Click **Yes** in response to the message about saving changes.

When you generate code, the token `$N` expands into the name of the data item that uses this custom storage class.

- 9 Apply the custom storage class `myGetSet` from your package to a data item. For example, create a `myPackage.Parameter` object in the base workspace.

```
myParam = myPackage.Parameter(15.23);
myParam.CoderInfo.StorageClass = 'Custom';
myParam.CoderInfo.CustomStorageClass = 'myGetSet';
```

- 10 Use the object to set a parameter value in your model. When you generate code, the code algorithm accesses the parameter through the functions that you specified. The code uses an `#include` directive to include the header file that you specified.

## Access Scalar and Array Data Through Macro Instead of Function Call

If you implement the `get` mechanism for scalar or array data as a macro instead of a function, you can generate code that omits parentheses when reading that data.

- For scalar data, your macro must yield the scalar value.
- For array data, your macro must yield the starting memory address.

Create your own `AccessFunction` storage class by using the Custom Storage Class Designer, as described in “Specify Header File or Function Naming Scheme for All Data Items” on page 26-59. In the Designer, on the **Access Function Attributes** tab, select **Get data through macro (omit parentheses)**.

## GetSet Custom Storage Class Restrictions

- GetSet does not support complex signals.
- Multiple data in the same model cannot use the same GetFunction or SetFunction.
- Some blocks do not directly support GetSet.
- Custom S-functions do not directly support GetSet.

To use GetSet with an unsupported block or a custom S-function:

- 1 Insert a Signal Conversion block at the output of the block or function.
- 2 In the Signal Conversion block dialog box, select **Exclude this block from 'Block reduction' optimization**.
- 3 Assign the custom storage class GetSet to the output of the Signal Conversion block.

## Integrate External Application Code with Code Generated from PID Controller

This example shows how to generate C code from a control algorithm model and integrate that code with existing, external application code. In the complete application, which consists of three modules, the algorithm module must exchange data with other modules through global variables. In the example, you configure the generated code to interact with existing external variables, resemble the external code in appearance and organization, and conform to specific coding requirements.

### Inspect External Code

Set your current folder to a writable location.

Copy the script `prepare_ext_code` to your current folder and run the script. The script copies external code files into several folders.

```
try
copyfile(fullfile(matlabroot, 'examples', 'ecoder', 'main', 'prepare_ext_code.m'), ...
 'prepare_ext_code.m', 'f');
catch
end
run('prepare_ext_code.m');
```

In your current folder, open `ext_code_main.c`. This application code represents an embedded system with a trivial scheduling algorithm (a while loop) and three modules whose algorithms run in every execution cycle: `ex_ext_inputs_proc`, `ex_ext_ctrl_alg`, and `ex_ext_outputs_proc`.

```
type('ext_code_main.c')
```

In the `shared` folder, inspect `ex_ext_projTypes.h`. The file defines two custom data types (typedef) that the data in the modules use.

```
type(fullfile('shared', 'ex_ext_projTypes.h'))
```

In the `io_drivers` folder, inspect `ex_sensor_accessors.c`. This file defines functions, `get_fromSensor_flow` and `get_fromSensor_temp`, that return raw data recorded by a flow sensor and a temperature sensor. For this example, the functions return trivial sinusoidal stimuli for the control algorithm.

```
type(fullfile('io_drivers', 'ex_sensor_accessors.c'))
```

In the `ex_ext_inputs_proc` folder, inspect `ex_ext_inputs_proc.c`. The `ex_ext_inputs_proc` module reads the sensor data (by calling the accessor functions), filters the data, and stores it in two global variables, `PROC_INPUT_FLOW` and `PROC_INPUT_TEMP`. These global variables are defined in the file `ex_ext_proc_inputs.c` and declared in `ex_ext_proc_inputs.h`.

```
type(fullfile('ex_ext_inputs_proc', 'ex_ext_inputs_proc.c'))
```

The filter algorithm in this module and the algorithms in the other two modules require state data, which must persist between execution cycles of the application. Each module stores relevant state data as global variables. For example, in the `ex_ext_inputs_proc` module, `ex_ext_inputs_proc.c` defines these variables:

- `flowFilterIn_state_data`
- `tempFilterIn_state_data`
- `flowFilterIn_tmp_data`
- `tempFilterIn_tmp_data`

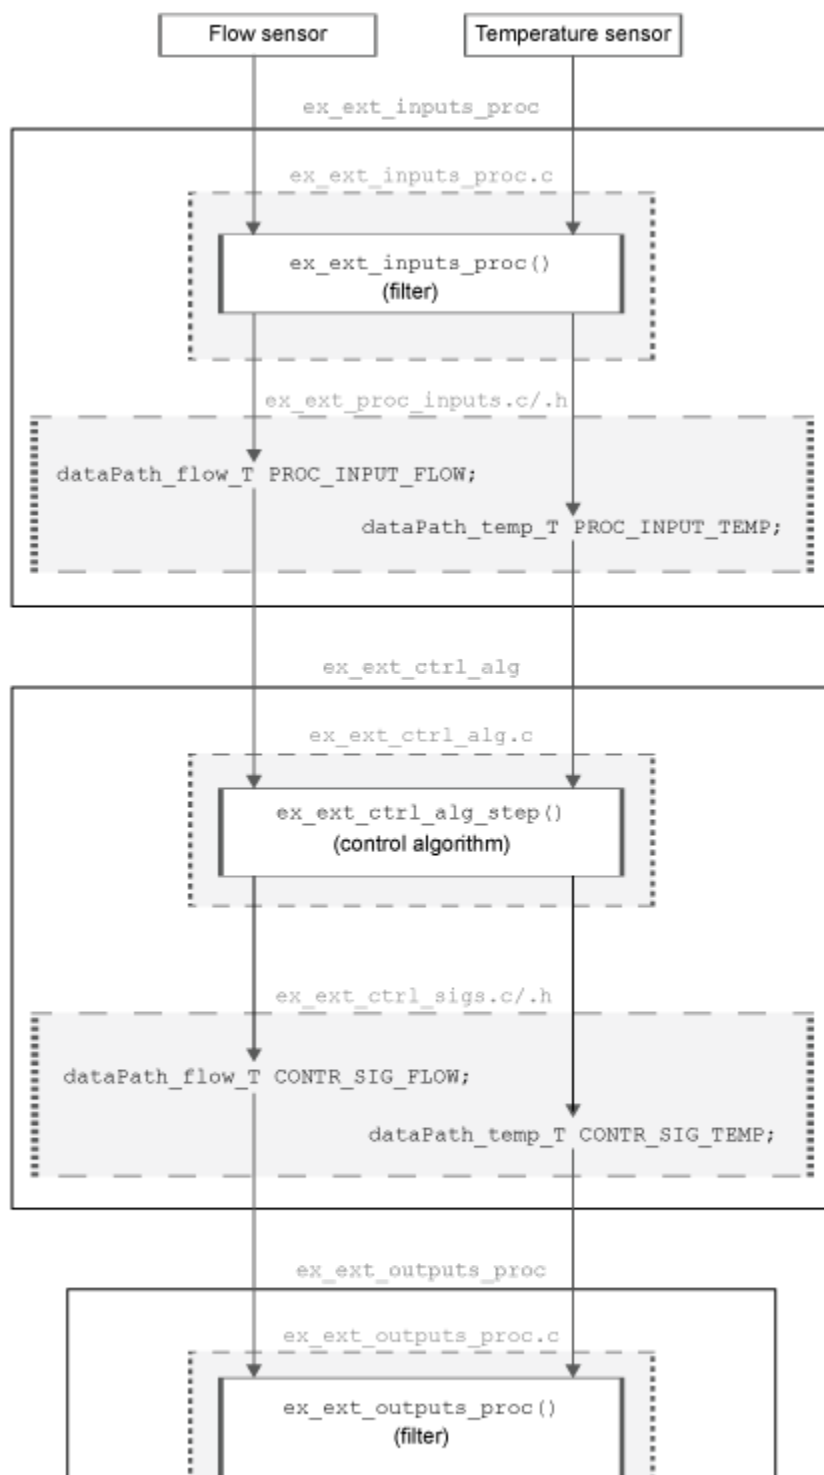

The empty `ex_ext_ctrl_alg` folder is a placeholder for the generated code. The `ex_ext_ctrl_alg` module must perform PID control on the filtered flow and temperature measurements. Later, you examine the requirements for this code, which are based on the code in the other modules.

In the `ex_ext_outputs_proc` folder, inspect `ex_ext_outputs_proc.c`. This module reads the PID output signals from global variables named `CONTR_SIG_FLOW` and `CONTR_SIG_TEMP`. The `ex_ext_ctrl_alg` module (the generated code) must define these variables. The `ex_ext_outputs_proc` module then filters these signals and passes the filtered values to functions that represent device drivers for actuators (for example, a valve and a heater filament).

```
type(fullfile('ex_ext_outputs_proc', 'ex_ext_outputs_proc.c'))
```

The actuator functions are defined in the `io_drivers` folder in the file `ex_actuator_accessors.c`.

The figure shows the intended flow of data through the system. The figure also shows the code files that define and declare the data (global variables) that cross the module boundaries.

## Inspect Simulink Model and Determine Requirements for Generated Code

Open the example model `ex_ext_ctrl_alg`.

```
open_system('ex_ext_ctrl_alg')
```

The blocks in the model implement the required PID control algorithm. The model uses default code generation settings for an ERT-based system target file (`ert.tlc`).

To complete the application by performing the function of the `ex_ext_ctrl_alg` module, the code generated from this model must:

- Use the custom data types `dataPath_flow_T` and `dataPath_temp_T` from the external file `ex_ext_projTypes.h`.
- Read filtered sensor data from the global variables `PROC_INPUT_FLOW` and `PROC_INPUT_TEMP`. The generated code must not define these variables because the module `ex_ext_inputs_proc` defines them, declaring them in `ex_ext_proc_inputs.h`.
- Write PID control signals to global variables named `CONTR_SIG_FLOW` and `CONTR_SIG_TEMP`. The generated code must define these variables and declare them in a file named `ex_ext_ctrl_sigs.h`. Then, the `ex_ext_outputs_proc` module can read the raw control signals from them.
- Conform to variable naming standards that govern the external application. For example, the generated code must store state data in global variables whose names end in `_data`. In addition, for this example, the names of local function variables must end in `_local`.
- Conform to standards that govern the organization of the code in each of the external files. For example, each file contains sections, delimited by comments, that aggregate similar code constructs such as type definitions, variable declarations, and function definitions.

So that you and others can interact with the control algorithm during execution, for this example, you also configure the generated code to define and declare `const` global variables named `PARAM_setpoint_flow` and `PARAM_setpoint_temp`, which represent the PID controller setpoints. The definitions must appear in a file named `ex_ext_ctrl_params.c` and the declarations must appear in a file named `ex_ext_ctrl_params.h`.

## Configure Model to Use Custom Data Types

Set your current folder to the shared folder.

Use the function `Simulink.importExternalCTypes` to generate `Simulink.AliasType` objects that represent the custom data types `dataPath_flow_T` and `dataPath_temp_T`.

```
cd('shared')
Simulink.importExternalCTypes('ex_ext_projTypes.h');
```

The objects appear in the base workspace.

In the `ex_ext_ctrl_alg` model, select **View > Model Data Editor**.

In the Model Data Editor, for the Inport block that represents `PROC_INPUT_FLOW`, set **Data Type** to `dataPath_flow_T`.

For the Inport block that represents `PROC_INPUT_TEMP`, set **Data Type** to `dataPath_temp_T`.

Select the **Signals** tab.

In the model, select the output signal of each Constant block. In the Model Data Editor, set **Data Type** to **Inherit: Inherit via back propagation**. With this setting, each Constant block inherits its output data type from the block immediately downstream, in this case, a Sum block.

Alternatively, to configure the data types, at the command prompt, use these commands.

```
set_param('ex_ext_ctrl_alg/In1', 'OutDataTypeStr', 'dataPath_flow_T')
set_param('ex_ext_ctrl_alg/In2', 'OutDataTypeStr', 'dataPath_temp_T')
set_param('ex_ext_ctrl_alg/Flow Setpt', 'OutDataTypeStr', ...
 'Inherit: Inherit via back propagation')
set_param('ex_ext_ctrl_alg/Temp Setpt', 'OutDataTypeStr', ...
 'Inherit: Inherit via back propagation')
```

Update the block diagram. The diagram shows that, due to data type inheritance and propagation, all of the signals in the model use a custom data type.

### Configure Interface Data

Configure the model to generate code that accesses and defines the correct global variables such as `PROC_INPUT_FLOW` and `CONTR_SIG_TEMP`.

In the Model Data Editor, select the **Inports/Outputs** tab and set the **Change view** drop-down list to **Code**.

Select the rows that correspond to the two Inport blocks.

For either row, set **Storage Class** to `ImportFromFile` and **Header File** to `ex_ext_proc_inputs.h`. With the storage class `ImportFromFile`, each Inport block appears in the generated code as a global variable. However, the generated code does not define the variable, instead including (`#include`) the variable declaration from `ex_ext_proc_inputs.h`.

For the rows that correspond to the Outport blocks, set:

- **Storage Class** to `ExportToFile`
- **Header file** to `ex_ext_ctrl_sigs.h`
- **Definition File** to `ex_ext_ctrl_sigs.c`

With `ExportToFile`, the generated code defines the global variable.

Alternatively, to configure the signals, at the command prompt, use these commands.

```
temp = Simulink.Signal;
temp.CoderInfo.StorageClass = 'Custom';
temp.CoderInfo.CustomStorageClass = 'ImportFromFile';
temp.CoderInfo.CustomAttributes.HeaderFile = 'ex_ext_proc_inputs.h';

portHandles = get_param('ex_ext_ctrl_alg/In1', 'portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle, 'SignalObject', copy(temp))

portHandles = get_param('ex_ext_ctrl_alg/In2', 'portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle, 'SignalObject', copy(temp))

temp.CoderInfo.CustomStorageClass = 'ExportToFile';
temp.CoderInfo.CustomAttributes.HeaderFile = 'ex_ext_ctrl_sigs.h';
temp.CoderInfo.CustomAttributes.DefinitionFile = 'ex_ext_ctrl_sigs.c';

set_param('ex_ext_ctrl_alg/Out1', 'SignalObject', copy(temp))
set_param('ex_ext_ctrl_alg/Out2', 'SignalObject', copy(temp))
```

To apply a storage class to a block parameter, such as the **Constant value** parameter of a Constant block, you must create a parameter object such as `Simulink.Parameter`. You can use the Model Data Editor to create parameter objects.

Select the **Parameters** tab and set **Change view** to `Design`.

In the model, select the Constant block labeled Flow Setpt.

In the Model Data Editor, set **Value** to `PARAM_setpoint_flow`.

Next to `PARAM_setpoint_flow`, click the action button (with three vertical dots) and select **Create**.

In the Create New Data dialog box, set **Value** to `Simulink.Parameter(3)`.

Set **Location** to `Model Workspace` and click **Create**.

In the `PARAM_setpoint_flow` property dialog box, set **Storage class** to `Const`.

Set **HeaderFile** to `ex_ext_ctrl_params.h` and **DefinitionFile** to `ex_ext_ctrl_params.c`.

For the other Constant block, use the Model Data Editor to create a `Simulink.Parameter` object named `PARAM_setpoint_temp` with value 2.

Alternatively, to configure the blocks, at the command prompt, use these commands.

```
PARAM_setpoint_flow = Simulink.Parameter(3);
PARAM_setpoint_flow.CoderInfo.StorageClass = 'Custom';
PARAM_setpoint_flow.CoderInfo.CustomStorageClass = 'Const';
PARAM_setpoint_flow.CoderInfo.CustomAttributes.HeaderFile = 'ex_ext_ctrl_params.h';
PARAM_setpoint_flow.CoderInfo.CustomAttributes.DefinitionFile = 'ex_ext_ctrl_params.c';
```

```
PARAM_setpoint_temp = copy(PARAM_setpoint_flow);
PARAM_setpoint_temp.Value = 2;
```

```
mdlwks = get_param('ex_ext_ctrl_alg', 'ModelWorkspace');
assignin(mdlwks, 'PARAM_setpoint_flow', copy(PARAM_setpoint_flow))
assignin(mdlwks, 'PARAM_setpoint_temp', copy(PARAM_setpoint_temp))
```

```
set_param('ex_ext_ctrl_alg/Flow Setpt', 'Value', 'PARAM_setpoint_flow')
set_param('ex_ext_ctrl_alg/Temp Setpt', 'Value', 'PARAM_setpoint_temp')
```

```
clear temp PARAM_setpoint_flow PARAM_setpoint_temp mdlwks portHandles outportHandle
```

### Configure Internal Data

In the external code, internal data that does not participate in the module interfaces, such as state data and local variables in functions, conform to naming schemes. In the model,

configure internal data that appears in the generated code to mimic these naming schemes.

In the model Configuration Parameters dialog box, inspect the **Code Generation > Symbols** pane. When you specify values for the naming schemes under **Identifier format control**:

- $\$R$  represents the name of the model, `ex_ext_ctrl_alg`.
- $\$N$  represents the name of each model element to which the scheme applies, such as a signal, block state, or standard data structure.
- $\$M$  represents name-mangling text that the code generator inserts, if necessary, to avoid name clashes. For most naming rules, this token is required.

Set **Global variables** to  $\$R\$N\_data\$M$ . This setting controls the names of global variables, such as those that represent state data. The naming scheme  $\$R\$N\_data\_\$M$  most closely approximates the scheme that the state variables in the external code use.

Set **Local temporary variables** and **Local block output variables** to  $\$N\_local\$M$ .

Alternatively, to set the configuration parameters, at the command prompt, use these commands.

```
set_param('ex_ext_ctrl_alg','CustomSymbolStrGlobalVar','RN_data$M')
set_param('ex_ext_ctrl_alg','CustomSymbolStrTmpVar','N_localM')
set_param('ex_ext_ctrl_alg','CustomSymbolStrBlkIO','N_localM')
```

Configure the state data in the model to appear in the generated code as separate global variables instead of fields of the standard DWork structure. In the model, select **Code > C/C++ Code > Configure Model in Code Perspective**.

Underneath the block diagram, under **Code Mappings > Data Defaults**, for the **Internal data** row, in the **Storage Class** column select `ExportedGlobal`.

Alternatively, to configure this default storage class, use these commands at the command prompt:

```
coder.mapping.create('ex_ext_ctrl_alg');
coder.mapping.defaults.set('ex_ext_ctrl_alg','InternalData',...
 'StorageClass','ExportedGlobal');
```

### Configure Organization of Code in Each Generated File

Set your current folder to the `ex_ext_ctrl_alg` folder.

```
cd(fullfile('.', 'ex_ext_ctrl_alg'))
```

At the command prompt, navigate to the folder that contains the built-in code generation template `ert_code_template.cgt`. By default, when you generate code with the system target file `ert.tlc`, this template governs the organization and, in part, the appearance of the code in each generated file.

```
currentFolder = pwd;
cd(fullfile(matlabroot, 'toolbox', 'rtw', 'targets', 'ecoder'))
```

Copy the `ert_code_template.cgt` file to your clipboard.

Return to the `ex_ext_ctrl_alg` folder. To avoid overwriting your clipboard, instead of using the command prompt to navigate to the folder, you can use the **Back** button in MATLAB.

```
cd(currentFolder)
clear currentFolder
```

Paste the file into the `ex_ext_ctrl_alg` folder. Rename the file as `ex_my_code_template.cgt`.

Open the file and replace all of the contents with this code.

```
type(fullfile(matlabroot, 'examples', 'ecoder', 'ex_my_code_template.cgt'))
```

This new template conforms more closely to the organization of the external files. For example, the template organizes similar code constructs into named sections (delimited by comments) and, at the top of the template, specifies only minimal information about each generated file.

In the model, select **Configuration Parameters > Code Generation > Templates**.

Under **Code templates** and **Data templates**, set the four configuration parameters to `ex_my_code_template.cgt`.

Alternatively, to copy the file and set the parameters, at the command prompt, use these commands.

```
copyfile(fullfile(matlabroot, 'examples', 'ecoder', 'ex_my_code_template.cgt'), ...
 'ex_my_code_template.cgt', 'f')
set_param('ex_ext_ctrl_alg', 'ERTSrcFileBannerTemplate', 'ex_my_code_template.cgt')
set_param('ex_ext_ctrl_alg', 'ERTHdrFileBannerTemplate', 'ex_my_code_template.cgt')
```

```
set_param('ex_ext_ctrl_alg', 'ERTDataSrcFileTemplate', 'ex_my_code_template.cgt')
set_param('ex_ext_ctrl_alg', 'ERTDataHdrFileTemplate', 'ex_my_code_template.cgt')
```

### Generate and Inspect Code

Because the external code already defines a main function, select **Configuration Parameters > Generate code only** and clear **Configuration Parameters > Generate an example main program**.

```
set_param('ex_ext_ctrl_alg', 'GenCodeOnly', 'on')
set_param('ex_ext_ctrl_alg', 'GenerateSampleERTMain', 'off')
```

Generate code from the model.

```
rtwbuild('ex_ext_ctrl_alg')
```

In the code generation report, inspect the generated files. The code meets the requirements. For example, `ex_ext_ctrl_sigs.c` defines the control output signals, `CONTR_SIG_FLOW` and `CONTR_SIG_TEMP`.

```
file = fullfile('ex_ext_ctrl_alg_ert_rtw', 'ex_ext_ctrl_sigs.c');
rtwdemodbtype(file, 'dataPath_flow_T CONTR_SIG_FLOW;', ...
 'dataPath_temp_T CONTR_SIG_TEMP;', 1, 1)
```

The setpoint parameters appear in `ex_ext_ctrl_params.c`.

```
file = fullfile('ex_ext_ctrl_alg_ert_rtw', 'ex_ext_ctrl_params.c');
rtwdemodbtype(file, 'const dataPath_flow_T PARAM_setpoint_flow = 3.0;', ...
 'const dataPath_temp_T PARAM_setpoint_temp = 2.0;', 1, 1)
```

The file `ex_ext_ctrl_alg.c` defines global variables to store state data. The variables follow the naming scheme that you specified.

```
file = fullfile('ex_ext_ctrl_alg_ert_rtw', 'ex_ext_ctrl_alg.c');
rtwdemodbtype(file, 'dataPath_temp_T ex_ext_Integrator_DSTATE_b_data', ...
 'dataPath_flow_T ex_ext_ctrl_Filter_DSTATE_data;', 1, 1)
```

In the same file, the model execution function, `ex_ext_ctrl_alg_step`, creates local function variables to store temporary calculations. The variables follow the naming scheme that you specified.

```
rtwdemodbtype(file, 'dataPath_flow_T Diff_local;', ...
 'dataPath_temp_T FilterCoefficient_localn;', 1, 1)
```

Some of the global and local variable names contain extra mangling characters that prevent name clashes. These extra characters correspond to the \$M token that you specified in the naming schemes.

The generated code files are in the generated folders `ex_ext_ctrl_alg_ert_rtw` and `s_lprj`. You must configure file management systems and build tools to use these folders and files.

## Configure Generated Code According to Interface Control Document Interactively

This example shows how to configure code generation settings for a model according to specifications in an interface control document (ICD). Store necessary Simulink variables and objects, such as `Simulink.Parameter` objects, in a data dictionary.

An ICD describes the data interface between two software components. To exchange and share data, the components declare and define global variables that store signal and parameter values. The ICD names the variables and lists characteristics such as data type, physical units, and parameter values. When you create models of the components in Simulink, you can configure the generated code to conform to the interface specification.

In this example, the ICD is a Microsoft® Excel® workbook.

### Explore Interface Control Document

Navigate to the folder `matlabroot/examples/ecoder` (open). Copy this file to a writable, working folder:

- `ex_ICD_PCG_inter.xls`

In Microsoft® Excel® or another compatible program, open the `ex_ICD_PCG_inter.xls` workbook and view the first worksheet, `Signals`. Each row of the worksheet describes a signal that crosses the interface boundary.

Inspect the cell values in the worksheet. The `Owner` column indicates the name of the component that allocates memory for each signal. The `DataType` column indicates the signal data type in memory. For example, the worksheet uses the expression `Bus:EngSensors` to indicate a structure type named `EngSensors`.

In the `Parameters` worksheet, the `Value` column indicates the value of each parameter. If the value of the parameter is nonscalar, the value is stored in its own separate worksheet, which has the same name as the parameter.

In the `Numeric Types` worksheet, each row represents a named numeric data type. In this ICD, the data use fixed-point data types (Fixed-Point Designer). The `IsAlias` column indicates whether the C code uses the name of the data type (for example, `s16En3`) or uses the name of the primitive integer data type that corresponds to the word length (such as `short`). The `DataScope` column indicates whether the generated code exports or imports the definition of the type.

In the **Structure Types** worksheet, each row represents either a structure type or a field of a structure type. For structure types, the value in the **Data Type** column is `struct`. Subsequent rows that do not use `struct` represent fields of the preceding structure type. This ICD defines a structure type, `EngSensors`, with four fields: `throttle`, `speed`, `ego`, and `map`.

In the **Enumerated Types** worksheet, similar to the **Structure Types** worksheet, each row represents either an enumerated type or an enumeration member. This ICD defines an enumerated type `sldemo_FuelModes`.

### Write External Code

Some data items in the ICD belong to `other_component`, which is a component that exists outside of MATLAB. Create the code files that define and declare this external data.

Create the header file `ex_inter_types.h` in your current folder. This file defines the structure type `EngSensors` and numeric data types such as `u8En7`.

```
#ifndef INTER_TYPES_H__
#define INTER_TYPES_H__

typedef short s16En3;

typedef short s16En7;

typedef unsigned char u8En7;

typedef short s16En15;

/* Structure type for instrument measurements. */
typedef struct {
 /* Throttle angle. */
 s16En3 throttle;

 /* Engine speed. */
 s16En3 speed;

 /* EGO sensors. */
 s16En7 ego;

 /* Manifold pressure. */
 u8En7 map;
} EngSensors;
```

```
#endif
```

Create the source file `ex_inter_sigs.c` in your current folder. This file defines the imported signal `sensors`.

```
#include "ex_inter_sigs.h"
```

```
EngSensors sensors; /* Instrument measurements. */
```

Create the header file `ex_inter_sigs.h` in your current folder.

```
#include "ex_inter_types.h"
```

```
extern EngSensors sensors; /* Instrument measurements. */
```

### **Explore Example Model**

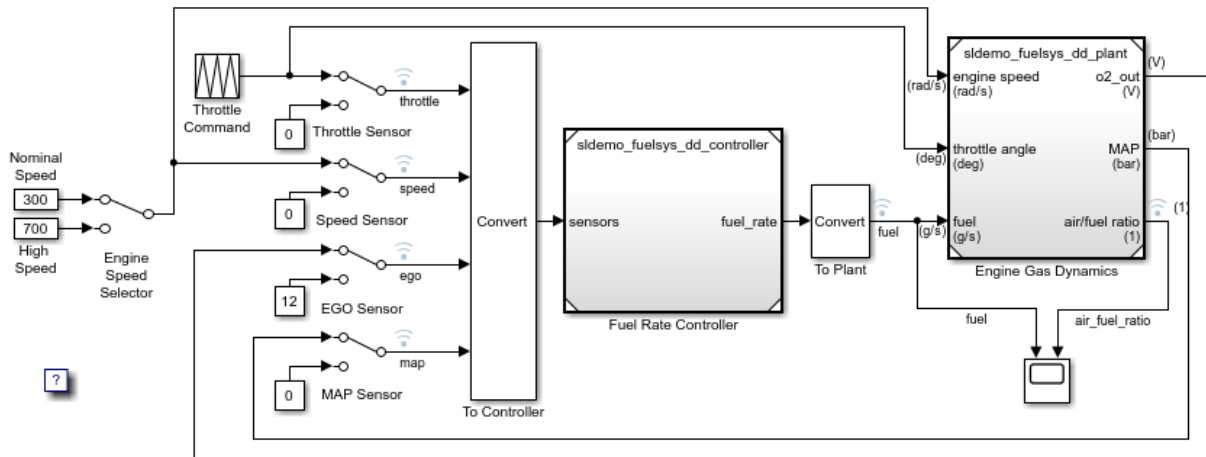

Run the script `prepare_sl-demo_fuelsys_dd_inter`. For this example, the script prepares a system model, `sl-demo_fuelsys_dd`.

```
run(fullfile(matlabroot, 'examples', 'ecoder', 'main', 'prepare_sl-demo_fuelsys_dd_inter'))
```

Open the system model `sl-demo_fuelsys_dd`.

```
sl-demo_fuelsys_dd
```

## Fault-Tolerant Fuel Control System

The sensor switches simulate any combination of sensor failures.  
The Engine Speed Selector switch simulates different engine speeds (rad/s).

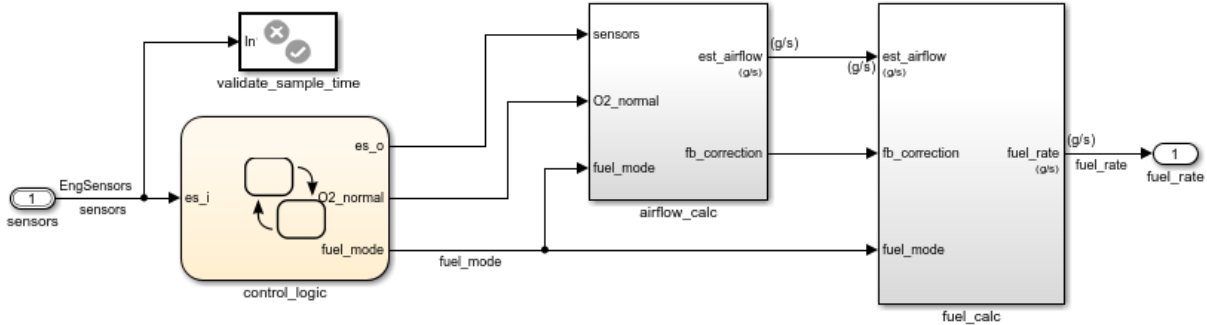

Copyright 1990-2017 The MathWorks, Inc.

This system model references a controller model. In this example, you generate code from the controller model.

Open the controller model `sldemo_fuelsys_dd_controller`.

`sldemo_fuelsys_dd_controller`

## Fuel Rate Controller

Copyright 1990-2017 The MathWorks, Inc.

Some of the signals in the controller model have names, for example, the input signal `sensors`. Some block parameters in the model refer to Simulink.Parameter objects in a data dictionary. For example, in the `airflow_calc` subsystem, the Pumping Constant block uses the parameter objects `PumpCon`, `SpeedVect`, and `PressVect`. These parameter objects set the values of the corresponding block parameters. You can apply code generation settings to the signals and parameter objects.

The controller model is linked to a data dictionary, `sldemo_fuelsys_dd_controller.sldd`. In the lower-left corner of the model, click the dictionary badge to open the dictionary in the Model Explorer. Then, in the Model Explorer **Model Hierarchy** pane, select the **Design Data** node.

The dictionary already stores:

- The parameter objects
- Simulink.NumericType objects such as `u8En7`
- A Simulink.Bus object, `EngSensors`
- The definition of an enumerated data type, `sldemo_FuelModes`

### Configure Model According to ICD

Navigate to the root level of the controller model and select **View > Model Data Editor**.

In the Model Data Editor, activate the **Change scope** button. The Model Data Editor now shows information about data items in the subsystems.

Click the **Show/refresh additional information** button. The Model Data Editor now shows information about data objects (the Simulink.Parameter objects in the data dictionary) that the model uses.

Select the **Inports/Outports** tab (which is selected by default).

In the model, select the Inport block labeled sensors. The Model Data Editor highlights the corresponding row.

In the ICD, select the **Signals** tab.

Use the Model Data Editor to configure the signal according to the information in the ICD:

- Set the value in the **Data Type** column to Bus: EngSensors. In this case, the value is already set.
- Set the **Change view** drop-down list to Code and, for sensors, set **Storage Class** to ImportFromFile. Use this storage class because the **Owner** column in the ICD implies that a different component, not sldemo\_fuelsys\_dd\_controller, provides the C-code definition of the sensors variable. With this storage class, the generated code does not define the variable.
- Set **Header File** to ex\_inter\_sigs.h. When you use a storage class that represents imported data, such as ImportFromFile, you cannot specify **Definition File** in the Model Data Editor. Instead, include the definition file (in this case, ex\_inter\_sigs.c) in the code generation and build process by using **Configuration Parameters > Code Generation > Custom Code > Additional build information > Source files**.

In the model, select the Outport block labeled fuel\_rate.

Use the Model Data Editor to configure fuel\_rate according to the ICD. To access design properties such as minimum value (**Min**) and physical unit (**Unit**), set **Change view** to Design. For code generation settings, because the ICD specifies sldemo\_fuelsys\_dd\_controller as the owner of the other signals, set **Storage Class** to ExportToFile.

Inspect the **Signals** tab.

Set **Change view** to Code and configure code generation settings for the signal `fuel_mode`.

You cannot use the Model Data Editor to configure design properties for `fuel_mode` (such as data type) because `fuel_mode` is an output of a Stateflow chart. In the model, navigate into the chart.

Select **View > Model Explorer > Model Explorer**.

In the Model Explorer **Contents** pane (the middle pane), select the `fuel_mode` data item.

In the Dialog pane (the right pane), configure `fuel_mode` according to the ICD. In this case, the signal data type is already set, so you can specify only the description.

Navigate to the root level of the model.

In the ICD and the Model Data Editor, select the **Parameters** tab. In the Model Data Editor, set **Change view** to Design.

In the Model Data Editor, use the **Filter contents** box to search for the first parameter, `PressEst`. The Model Data Editor shows two rows: One row that corresponds to the parameter object `PressEst` and one row that corresponds to the block parameter that uses `PressEst`.

Use the Model Data Editor to configure `PressEst` according to the ICD. The parameter value (the **Value** column) is already set. Because the ICD specifies `sldemo_fuelsys_dd_controller` as the owner of `PressEst`, set **Storage Class** to `ExportToFile`.

Use the Model Data Editor to configure the other parameters. Optionally, to apply a change to multiple parameters at once, select multiple rows in the data table.

In the lower-left corner of the model, click the dictionary badge to open the data dictionary in the Model Explorer.

In the **Model Hierarchy** pane, select the **Design Data** node.

In the **Contents** pane (the middle pane), select the `Simulink.NumericType` object `u8En7`. This object represents one of the primitive `typedef` statements in `ex_inter_types.h`.

In the ICD, select the **Numeric Types** tab.

Use the Model Explorer Dialog pane (the right pane) to configure the object according to the ICD.

Use the Model Explorer to configure the other `Simulink.NumericType` objects. You can use the **Contents** pane to perform batch operations.

In the **Contents** pane, click the `Simulink.Bus` object `EngSensors`. This object represents the structure type that `ex_inter_types.h` defines.

In the Dialog pane (the right pane), click **Launch Bus Editor**.

In the ICD, select the **Structure Types** tab.

Use the Bus Editor to configure the bus object and the signal elements in the bus (such as `throttle`) according to the ICD.

In the ICD, select the **Enumerated Types** tab.

In the Model Explorer **Contents** pane, click the enumerated type definition `sldemo_FuelModes`.

Use the Dialog pane to configure the type according to the ICD. Set **Storage Type** to `Native Integer` and **Data Scope** to `Exported`.

### **Generate and Inspect Code**

Configure the controller model to compile the generated code into an executable by clearing the model configuration parameter **Generate code only**.

Generate code from the controller model.

```
Starting build procedure for model: sldemo_fuelsys_dd_controller
Successful completion of build procedure for model: sldemo_fuelsys_dd_controller
```

The generated header file `sldemo_FuelModes.h` defines the enumeration `sldemo_FuelModes`.

```
typedef enum {
 LOW = 1, /* Default value */
 RICH,
 DISABLED
} sldemo_FuelModes;
```

The file `sldemo_fuelsys_dd_controller_types.h` includes (`#include`) the external header file `ex_inter_types.h`, which defines data types such as `u8En7` and the structure type `EngSensors`.

```
#include "ex_inter_types.h"
```

The file `sldemo_fuelsys_dd_controller_private.h` includes the header file `ex_inter_sigs.h`. This external header file contains the extern declaration of the signal sensors, which a different software component owns.

The data header file `global_data.h` declares the exported parameters and signals that the ICD specifies. To share this data, other components can include this header file.

```
/* Exported data declaration */

/* Declaration for custom storage class: ExportToFile */
extern u8En7 PressEst[855];
extern s16En15 PumpCon[551];
extern s16En15 RampRateKiZ[25];
extern s16En3 SpeedEst[1305];
extern s16En7 ThrotEst[551];
extern sldemo_FuelModes fuel_mode;
extern s16En7 fuel_rate;
```

The data definitions (memory allocation) appear in the source files that the ICD specifies: `params.c` and `signals.c`. For example, `params.c` defines and initializes the parameter `RampRateKiZ`.

```
s16En15 RampRateKiZ[25] = { 393, 786, 1180, 1573, 1966, 786, 1573, 2359, 3146,
 3932, 1180, 2359, 3539, 4719, 5898, 1573, 3146, 4719, 6291, 7864, 1966, 3932,
 5898, 7864, 9830 } ;
```

The algorithm is in the model `step` function in the file `sldemo_fuelsys_dd_controller.c`. The algorithm uses the global data that the ICD identifies. For example, the algorithm uses the value of the signal `fuel_mode` in a switch block to control the flow of execution.

```
/* SwitchCase: '<S10>/Switch Case' */
switch (fuel_mode) {
 case LOW:
```

```
/* Outputs for IfAction SubSystem: '<S10>/low_mode' incorporates:
 * ActionPort: '<S12>/Action Port'
 */
/* DiscreteFilter: '<S12>/Discrete Filter' incorporates:
 * DiscreteIntegrator: '<S1>/Discrete Integrator'
 */
DiscreteFilter_tmp = (int16_T)(int32_T)((int32_T)((int32_T)((int32_T)
 rtDWork.DiscreteIntegrator_DSTATE << 14) - (int32_T)(-12137 * (int32_T)
 rtDWork.DiscreteFilter_states_g) >> 14);
```

## Configure Generated Code According to Interface Control Document

Import specifications from an interface control document (ICD), configure code generation settings for a model according to the specifications, and store the settings in data dictionaries.

An ICD describes the data interface between two software components. To exchange and share data, the components declare and define global variables that store signal and parameter values. The ICD names the variables and lists characteristics such as data type, physical units, and parameter values. When you create models of the components in Simulink, you can configure the generated code to conform to the interface specification.

In this example, the ICD is a Microsoft® Excel® workbook.

### Explore Interface Control Document

Navigate to the folder `matlabroot/examples/ecoder` (open). Copy this file to a writable, working folder:

- `ex_ICD_PCG.xls`

Navigate to the folder `matlabroot/examples/ecoder/main` (open). Copy this file to the same writable, working folder:

- `ex_importICD_PCG.m`

In Microsoft® Excel® or another compatible program, open the `ex_ICD_PCG.xls` workbook and view the first worksheet, `Signals`. Each row of the worksheet describes a signal that crosses the interface boundary.

Inspect the cell values in the worksheet. The `Owner` column indicates the name of the component that allocates memory for each signal. The `DataType` column indicates the signal data type in memory. For example, the worksheet uses the expression `Bus : EngSensors` to represent a structure type named `EngSensors`.

In the `Parameters` worksheet, the `Value` column indicates the value of each parameter. If the value of the parameter is nonscalar, the value is stored in its own separate worksheet, which has the same name as the parameter.

In the `Numeric Types` worksheet, each row represents a named numeric data type. In this ICD, the data use fixed-point data types (Fixed-Point Designer). The `IsAlias` column

indicates whether the C code uses the name of the data type (for example, `u8En7`) or uses the name of the primitive integer data type that corresponds to the word length. The `DataScope` column indicates whether the generated code exports or imports the definition of the type.

In the `Structure Types` worksheet, each row represents either a structure type or a field of a structure type. For structure types, the value in the `DataType` column is `struct`. Subsequent rows that do not use `struct` represent fields of the preceding structure type. This ICD defines a structure type, `EngSensors`, with four fields: `throttle`, `speed`, `ego`, and `map`.

In the `Enumerated Types` worksheet, similar to the `Structure Types` worksheet, each row represents either an enumerated type or an enumeration member. This ICD defines an enumerated type `sldemo_FuelModes`.

### Write External Code

Some data items in the ICD belong to `other` component, which is a component that exists outside of MATLAB. Create the code files that define and declare this external data.

Create the source file `ex_inter_sigs.c` in your current folder. This file defines the imported signal sensors.

```
#include "ex_inter_sigs.h"

EngSensors sensors; /* Instrument measurements. */
```

Create the header file `ex_inter_sigs.h` in your current folder.

```
#include "ex_inter_types.h"

extern EngSensors sensors; /* Instrument measurements. */
```

Create the header file `ex_inter_types.h` in your current folder. This file defines the structure type `EngSensors` and numeric data types such as `u8En7`.

```
#ifndef INTER_TYPES_H__
#define INTER_TYPES_H__

typedef short s16En3;
```

```
typedef short s16En7;

typedef unsigned char u8En7;

typedef short s16En15;

/* Structure type for instrument measurements. */
typedef struct {
 /* Throttle angle. */
 s16En3 throttle;

 /* Engine speed. */
 s16En3 speed;

 /* EGO sensors. */
 s16En7 ego;

 /* Manifold pressure. */
 u8En7 map;
} EngSensors;

#endif
```

### **Explore Example Model**

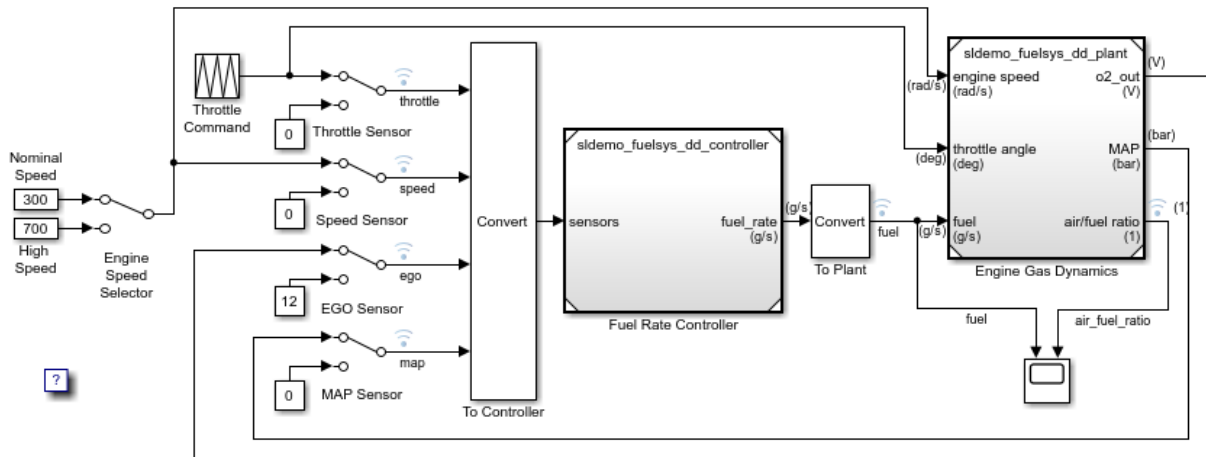

Run the script `prepare_slldemo_fuelsys_dd`. The script prepares a system model, `slldemo_fuelsys_dd`, for this example.

```
run(fullfile(matlabroot, 'examples', 'ecoder', 'main', 'prepare_slldemo_fuelsys_dd'))
```

Open the system model, `slldemo_fuelsys_dd`.

```
slldemo_fuelsys_dd
```

## Fault-Tolerant Fuel Control System

The sensor switches simulate any combination of sensor failures.  
The Engine Speed Selector switch simulates different engine speeds (rad/s).

Copyright 1990-2017 The MathWorks, Inc.

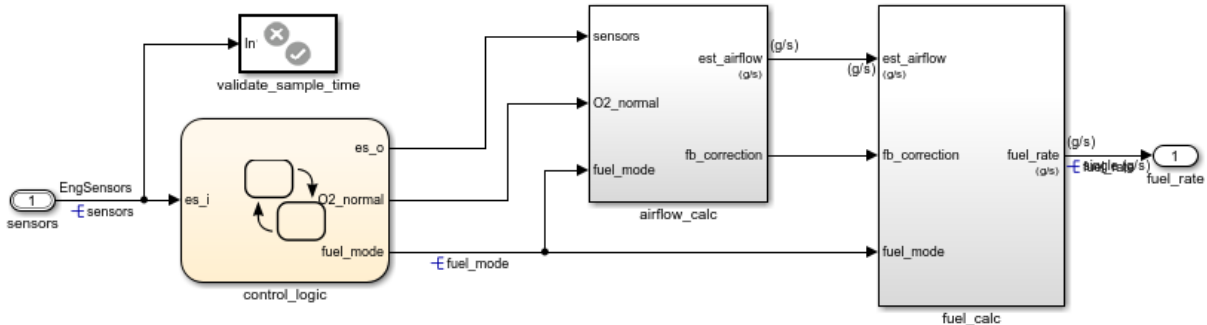

This system model references a controller model. In this example, you generate code from the controller model.

Open the controller model, `sldemo_fuelsys_dd_controller`.

`sldemo_fuelsys_dd_controller`

## Fuel Rate Controller

Copyright 1990-2017 The MathWorks, Inc.

Data items in the controller model refer to `Simulink.Signal` and `Simulink.Parameter` objects in the base workspace. For example, the input signal `sensors` refers to a `Simulink.Signal` object that has the same name. These objects store settings such as data types, block parameter values, and physical units. The names of these data items and objects match the names of the signals and parameters in the ICD.

### Import ICD Specifications into Simulink

To configure code generation settings for the data items, import the settings from the ICD.

Open the example script `ex_importICD_PCG`. The script imports the data from each worksheet of the ICD into variables in the base workspace. It then configures the properties of the `Simulink.Signal` and `Simulink.Parameter` objects in the base workspace by using the imported data.

```
edit('ex_importICD_PCG')
```

If the base workspace already contains a data object that corresponds to a target data item in the ICD, the script configures the properties of the existing object. If the object does not exist, the script creates the object.

Run the `ex_importICD_PCG` script.

```
run('ex_importICD_PCG')
```

The script configures the data objects in the base workspace for code generation according to the specifications in the ICD. The `Simulink.Bus` object `EngSensors` represents the structure type from the ICD. The `Simulink.NumericType` objects, such as `u8En7`, represent the fixed-point data types.

```
ans =
```

```
'Cannot redefine enumerated type sldemo_FuelModes because open models and existing
```

### Generate and Inspect Code

Configure the controller model to compile the generated code into an executable by clearing the model configuration parameter **Generate code only**.

Generate code from the controller model.

```
Starting build procedure for model: sldemo_fuelsys_dd_controller
Successful completion of build procedure for model: sldemo_fuelsys_dd_controller
```

The generated header file `sldemo_FuelModes.h` defines the enumeration `sldemo_FuelModes`.

```
typedef enum {
 LOW = 1, /* Default value */
 RICH,
 DISABLED
} sldemo_FuelModes;
```

The file `sldemo_fuelsys_dd_controller_types.h` includes (`#include`) the external header file `ex_inter_types.h`, which defines data types such as `u8En7` and the structure type `EngSensors`.

```
#include "ex_inter_types.h"
```

The file `sldemo_fuelsys_dd_controller_private.h` includes the header file `ex_inter_sigs.h`. This external header file contains the `extern` declaration of the signal sensors, which a different software component owns.

The data header file `global_data.h` declares the exported parameters and signals that the ICD specifies. To share this data, other components can include this header file.

```
/* Exported data declaration */

/* Declaration for custom storage class: ExportToFile */
extern u8En7 PressEst[855]; /* Lookup table to estimate pressure on sensor 1 */
extern s16En15 PumpCon[551]; /* Lookup table to determine pumping constant based on engine speed */
extern s16En15 RampRateKiZ[25]; /* Lookup table to determine throttle rate. */
extern s16En3 SpeedEst[1305]; /* Lookup table to estimate engine speed on sensor 1 */
extern s16En7 ThrotEst[551]; /* Lookup table to estimate throttle angle on sensor 1 */
extern sldemo_FuelModes fuel_mode; /* Fueling mode of engine. Enrich air/fuel mixture based on engine speed */
extern int16_T fuel_rate; /* Fuel rate setpoint. */
```

The data definitions (memory allocation) appear in the source files that the ICD specifies, `params.c` and `signals.c`. For example, `params.c` defines and initializes the parameter `RampRateKiZ`.

```
s16En15 RampRateKiZ[25] = { 393, 786, 1180, 1573, 1966, 786, 1573, 2359, 3146,
 3932, 1180, 2359, 3539, 4719, 5898, 1573, 3146, 4719, 6291, 7864, 1966, 3932,
 5898, 7864, 9830 } ; /* Lookup table to determine throttle rate. */
```

The algorithm is in the model `step` function in the file `sldemo_fuelsys_dd_controller.c`. The algorithm uses the global data that the ICD identifies. For example, the algorithm uses the value of the signal `fuel_mode` in a switch block to control the flow of execution.

```
/* SwitchCase: '<S10>/Switch Case' incorporates:
 * Constant: '<S11>/shutoff'
 */
switch (fuel_mode) {
case LOW:
/* Outputs for IfAction SubSystem: '<S10>/low_mode' incorporates:
 * ActionPort: '<S12>/Action Port'
 */
/* DiscreteFilter: '<S12>/Discrete Filter' incorporates:
 * DiscreteIntegrator: '<S1>/Discrete Integrator'
 */
DiscreteFilter_tmp = (int16_T)(int32_T)((int32_T)((int32_T)((int32_T)
rtDWork.DiscreteIntegrator_DSTATE << 14) - (int32_T)(-12137 * (int32_T)
rtDWork.DiscreteFilter_states_g) >> 14);
```

### Change Ownership of Data in ICD

When you make changes to the ICD, you can reuse the `ex_importICD_PCG` script to reconfigure the model. Change the ownership of the signal sensors, the structure type, and the fixed-point data types from `other_component` to `sldemo_fuelsys_dd_controller`.

In the ICD, on the `signals` worksheet, for the signal sensors, set these cell values:

- Owner to `sldemo_fuelsys_dd_controller`
- HeaderFile to `global_data.h`
- DefinitionFile to `signals.c`

On the `Numeric Types` worksheet, for all of the fixed-point data types, set:

- DataScope to `Exported`
- HeaderFile to `exported_types.h`.

On the `Structure Types` worksheet, for the structure type `EngSensors`, set:

- DataScope to `Exported`
- HeaderFile to `exported_types.h`.

Rerun the `ex_importICD_PCG` script.

```
ans =
```

```
'Cannot redefine enumerated type sldemo_FuelModes because open models and existing
```

Generate code from the model.

```
Starting build procedure for model: sldemo_fuelsys_dd_controller
Successful completion of build procedure for model: sldemo_fuelsys_dd_controller
```

The generated file `exported_types.h` defines the structure type `EngSensors` and the fixed-point data types.

```
typedef int16_T s16En3;
typedef int16_T s16En7;
typedef uint8_T u8En7;
```

```

/* Structure type for instrument measurements. */
typedef struct {
 s16En3 throttle;
 s16En3 speed;
 s16En7 ego;
 u8En7 map;
} EngSensors;

typedef int16_T s16En15;

```

The file `signals.c` now includes the definition of the signal sensors.

```

/* Exported data definition */

/* Definition for custom storage class: ExportToFile */
sldemo_FuelModes fuel_mode; /* Fueling mode of engine. Enrich air/fuel mixture. */
int16_T fuel_rate; /* Fuel rate setpoint. */
EngSensors sensors; /* Instrument measurements. */

```

## Migrate Base Workspace Data to Data Dictionary

Objects and variables that you create in the base workspace (for example, `Simulink.Parameter` objects) are not saved with the model. When you end your MATLAB session, the objects and variables do not persist. To permanently store the objects and variables, link one or more models to one or more data dictionaries.

Data dictionaries also enable you to track changes made to the objects and variables, which helps you to:

- Reconcile the data stored in MATLAB with the data stored in the ICD.
  - Export data from MATLAB to the ICD.
- 1 In the top model, `sldemo_fuel_sys_dd`, select **File > Model Properties > Link to Data Dictionary**.
  - 2 In the Model Properties dialog box, select **Data Dictionary**. Click **New**.
  - 3 In the Create a new Data Dictionary dialog box, set **File name** to `sysDict` and click **Save**.
  - 4 In the Model Properties dialog box, click **OK**.
  - 5 Click **OK** in response to the message about migrating referenced variables.

- 6 Click **Yes** in response to the message about removing the imported items from the base workspace.
- 7 Click **OK** in response to the message about enumerated type migration.

The variables and objects that the models use all exist in the new data dictionary `sysDict.sldd`, which is in your current folder. All three models in the model reference hierarchy are linked to this dictionary.

### Create Reference Dictionary

To establish clear ownership of the data that you store in a dictionary, create reference dictionaries.

- 1 Open the controller model, `sldemo_fuelsys_dd_controller`. Select **File > Model Properties > Link to Data Dictionary**. Click **New**.
- 2 Set the name of the new dictionary to `ctrlDict.sldd` and click **Save**. In the Model Properties dialog box, click **OK**.
- 3 In response to the message about changing the dictionary or moving the data, click **Move Data**. Click **Yes** in response to the message about migrating data.

The variables and objects that the controller model uses now exist in the referenced dictionary `ctrlDict.sldd`. Because `sysDict.sldd` references `ctrlDict.sldd`, you can view all of the data by opening `sysDict.sldd` in the Model Explorer.

Now that the model data acquire code generation settings from objects and variables that are stored in data dictionaries, you can modify the `ex_importICD_PCG` script so it accesses the dictionaries instead of the base workspace. For more information about the programmatic interface for data dictionaries, see “Store Data in Dictionary Programmatically” (Simulink).

### Store Enumerated Type Definition in Data Dictionary

You can import the definition of the enumerated type `sldemo_FuelModes` into the controller dictionary. See “Enumerations in Data Dictionary” (Simulink).

### Store Signal and State Design Attributes Inside or Outside of Model File

In this example, you use `Simulink.Signal` objects to specify design attributes such as data types, minimum and maximum values, and physical units. The signal objects store these specifications outside of the model file.

Alternatively, you can store these specifications in the model file by using block and port parameters, which you can access through the Model Data Editor, the Property Inspector, and other dialog boxes.

To decide where to store the specifications, see “Store Design Attributes of Signals and States” (Simulink).

## Generate Local Variables with Localizable Custom Storage Class

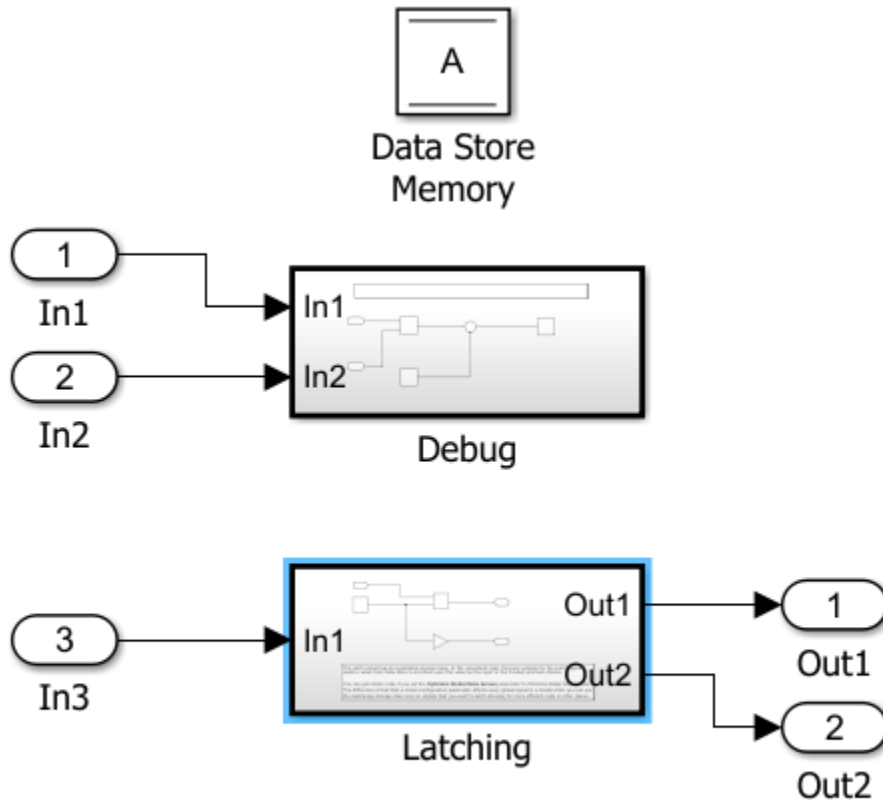

For signals, if possible, generate variables that are local to functions rather than in global storage. Generating local variables prevents the code generator from implementing optimizations that remove these variables from the generated code. Local variables improve observability, readability, and are helpful in debugging the generated code.

Minimizing the use of global variables by using local variables interacts with stack usage control. For example, stack size can determine the number of local and global variables that the code generator can allocate in the generated code. For more information, see “Customize Stack Space Allocation” (Simulink Coder).

### Example Model

The model `rtwdemo_localizable_csc` contains two signals that have a `Localizable` custom storage class. In the `Latching` subsystem, the signal with the label `Latch` has a `Localizable` custom storage class. In the `Debug` subsystem, the signal with the label `Debug` has a `Localizable` custom storage class.

Copyright 2017 The MathWorks, Inc.

## Generate Code with Localizable Storage Class

- 1 Open the model.

```
model='rtwdemo_localizable_csc';
open_system(model);
```

- 2 To observe the specification, for each signal, open the Signal Properties dialog box and select the **Code Generation** tab. The **Signal object class** parameter is set to

Simulink.Signal. The **Storage class** parameter is set to Localizable (Custom).

- 3 Build the model. The Debug\_b function contains this code:

```
static void Debug_b(const real_T rtu_In1[6], const real_T rtu_In2[6], real_T
 rtd_A[6])
{
 real_T Debug;
 int32_T i;
 for (i = 0; i < 6; i++) {
 Debug = rtu_In1[i] * rtu_In2[i];
 rtd_A[i] += Debug;
 }
}
```

The Latching function contains this code:

```
static void Latching(const real_T rtu_In1[36], real_T rty_Out1[6], real_T
 rty_Out2[6], real_T rtd_A[6])
{
 real_T Latch[6];
 int32_T i;
 int32_T i_0;
 for (i = 0; i < 6; i++) {
 rty_Out2[i] = -rtd_A[i];
 Latch[i] = rtd_A[i];
 }

 for (i = 0; i < 6; i++) {
 rty_Out1[i] = 0.0;
 for (i_0 = 0; i_0 < 6; i_0++) {
 rty_Out1[i] += rtu_In1[6 * i_0 + i] * Latch[i_0];
 }
 }
}
```

Both functions contain variables for holding intermediate values. The Debug\_b function contains the variable Debug. The Latching function contains the variable Latch.

## Generate Code Without Localizable Storage Class

- 1 Change the signal storage class from Localizable to ExportToFile. For each signal, open the **Signal Properties** dialog box. On the **Code Generation** tab, for the **Storage class** parameter, select ExportToFile. The rtwdemo\_localizable\_csc.c file contains these two global variable declarations:

```
real_T Debug[6];
real_T Latch[6];
```

The Debug\_b function contains this code:

```

static void Debug_b(const real_T rtu_In1[6], const real_T rtu_In2[6], real_T
 rtd_A[6])
{
 int32_T i;
 for (i = 0; i < 6; i++) {
 Debug[i] = rtu_In1[i] * rtu_In2[i];
 rtd_A[i] += Debug[i];
 }
}

```

The Latching function contains this code:

```

static void Latching(const real_T rtu_In1[36], real_T rty_Out1[6], real_T
 rty_Out2[6], real_T rtd_A[6])
{
 int32_T i;
 int32_T i_0;
 for (i = 0; i < 6; i++) {
 Latch[i] = rtd_A[i];
 rty_Out2[i] = -Latch[i];
 }

 for (i = 0; i < 6; i++) {
 rty_Out1[i] = 0.0;
 for (i_0 = 0; i_0 < 6; i_0++) {
 rty_Out1[i] += rtu_In1[6 * i_0 + i] * Latch[i_0];
 }
 }
}

```

The code readability and observability is the same as with the Localizable storage class specification except the labeled signals are global variables.

- 2 Remove the Debug and Latch labels. Build the model. The Debug\_b function contains this code:

```

static void Debug(const real_T rtu_In1[6], const real_T rtu_In2[6], real_T
 rtd_A[6])
{
 int32_T i;
 for (i = 0; i < 6; i++) {
 rtd_A[i] += rtu_In1[i] * rtu_In2[i];
 }
}

```

The Latching function contains this code:

```

static void Latching(const real_T rtu_In1[36], real_T rty_Out1[6], real_T
 rty_Out2[6], real_T rtd_A[6])
{
 int32_T i;
 int32_T i_0;
 for (i = 0; i < 6; i++) {
 rty_Out2[i] = -rtd_A[i];
 rty_Out1[i] = 0.0;
 for (i_0 = 0; i_0 < 6; i_0++) {
 rty_Out1[i] += rtu_In1[6 * i_0 + i] * rtd_A[i_0];
 }
 }
}

```

Without the `Localizable` or `ExportToFile` custom storage classes, the code generator removes the `Debug` and `Latch` variables. Without these variables, the readability and observability of the generated code decreases.

### Additional Information

- For the code generator to localize signals with the `Localizable` Custom storage class specification, in the Configuration Parameters dialog box, you must select the Enable Local Block Outputs parameter. This parameter is on by default.
- You can specify the same `Localizable` storage class on two signals that are in different reusable subsystems. Therefore, you can create a library block from a reusable subsystem with a `Localizable` custom storage class specification.
- The code generator does not create a local variable for a signal that must stay global. A few cases in which the code generator can not localize a signal are:
  - Input and output signals of a Nonreusable subsystem even when the **Function interface** parameter is set to `Allow arguments`.
  - Signal is holding a state because its receiver and drive blocks execute at different rates.
  - `Localizable` specification is on a signal that crosses the boundary of a conditionally executed subsystem.

# Data Object Wizard in Embedded Coder

---

## Create Data Objects for Code Generation with Data Object Wizard

To specify code generation options for signal lines, block parameters, and states in a model, you can use data objects that you store in a workspace or data dictionary. For basic information about data objects, see “Data Objects” (Simulink).

You can use the Data Object Wizard to create data objects for:

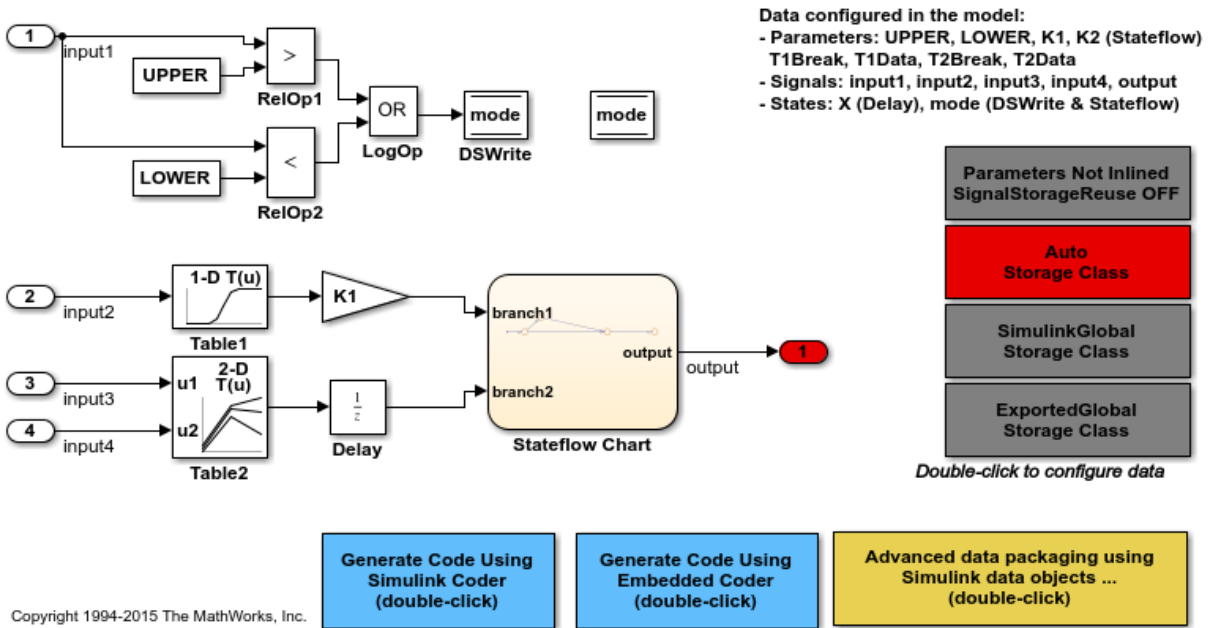

- New or existing models that do not use data objects.
- Existing models to which you have added signal lines or blocks.

This example shows how to use the Data Object Wizard to create and configure data objects for code generation from the built-in package `Simulink`.

### Create Data Objects

Open the example model `rtwdemo_basicsc`.

```
open_system('rtwdemo_basicsc')
```

Copyright 1994-2015 The MathWorks, Inc.

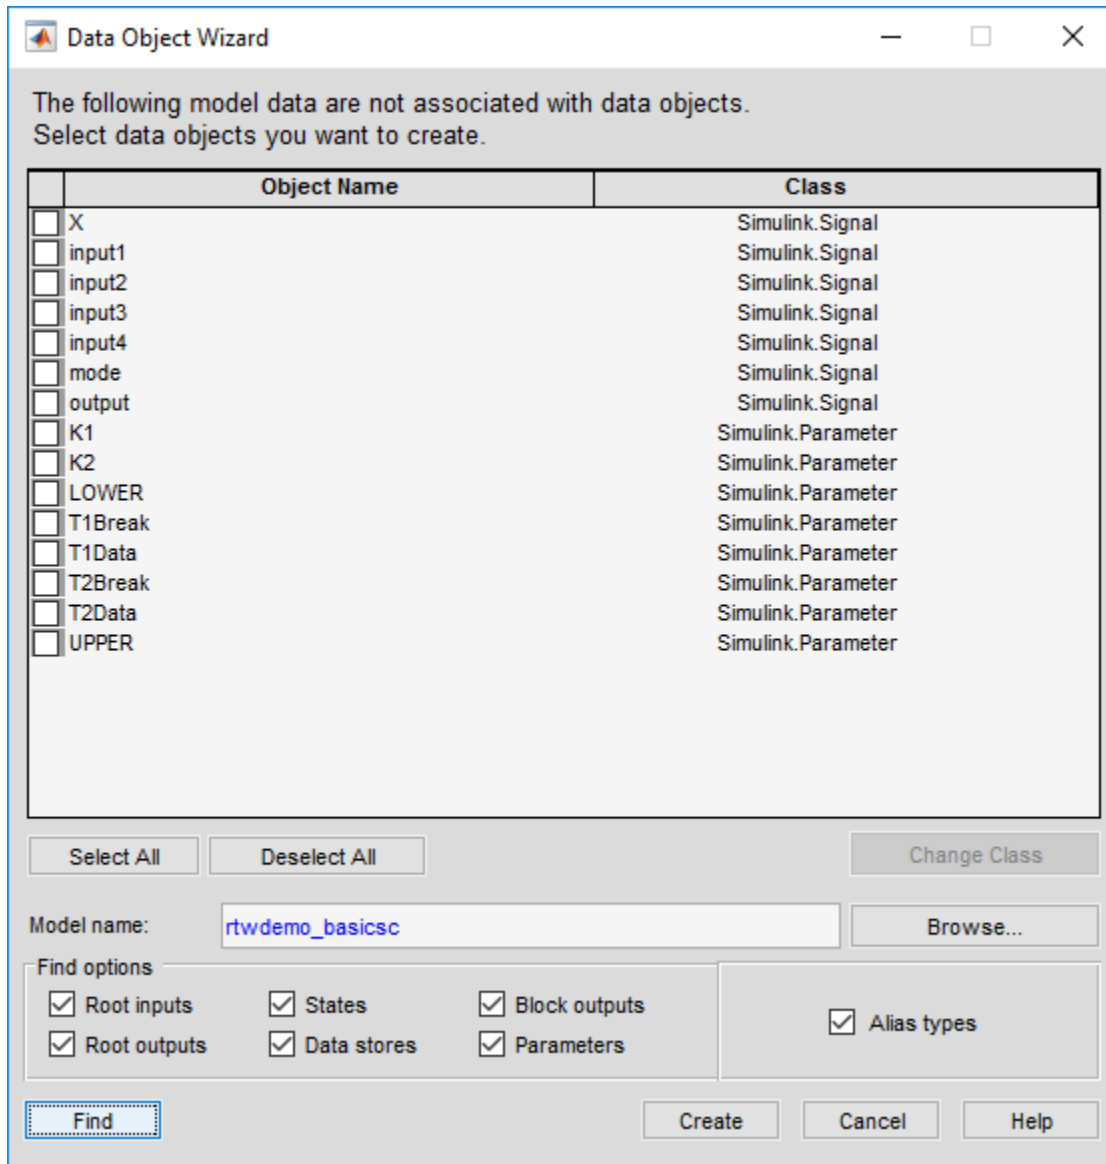

The model creates numeric variables in the base workspace. Blocks in the model use these variables to set parameter values (such as the **Gain** parameter of a Gain block). Some of the signals and block states in the model have explicit names, such as input1.

In the model, select **Code > Data Objects > Data Object Wizard**.

In the Data Object Wizard, click **Find**. The wizard proposes the creation of Simulink.Parameter objects to replace the variables and the creation of Simulink.Signal objects to represent the signals and states.

The wizard finds only signals, parameters, data stores, and states whose storage class is set to Auto. For example, if you use the Signal Properties dialog box to specify a storage class other than Auto for a signal line, the wizard does not propose a data object.

Click **Select All**.

Click **Create**. The data objects appear in the base workspace.

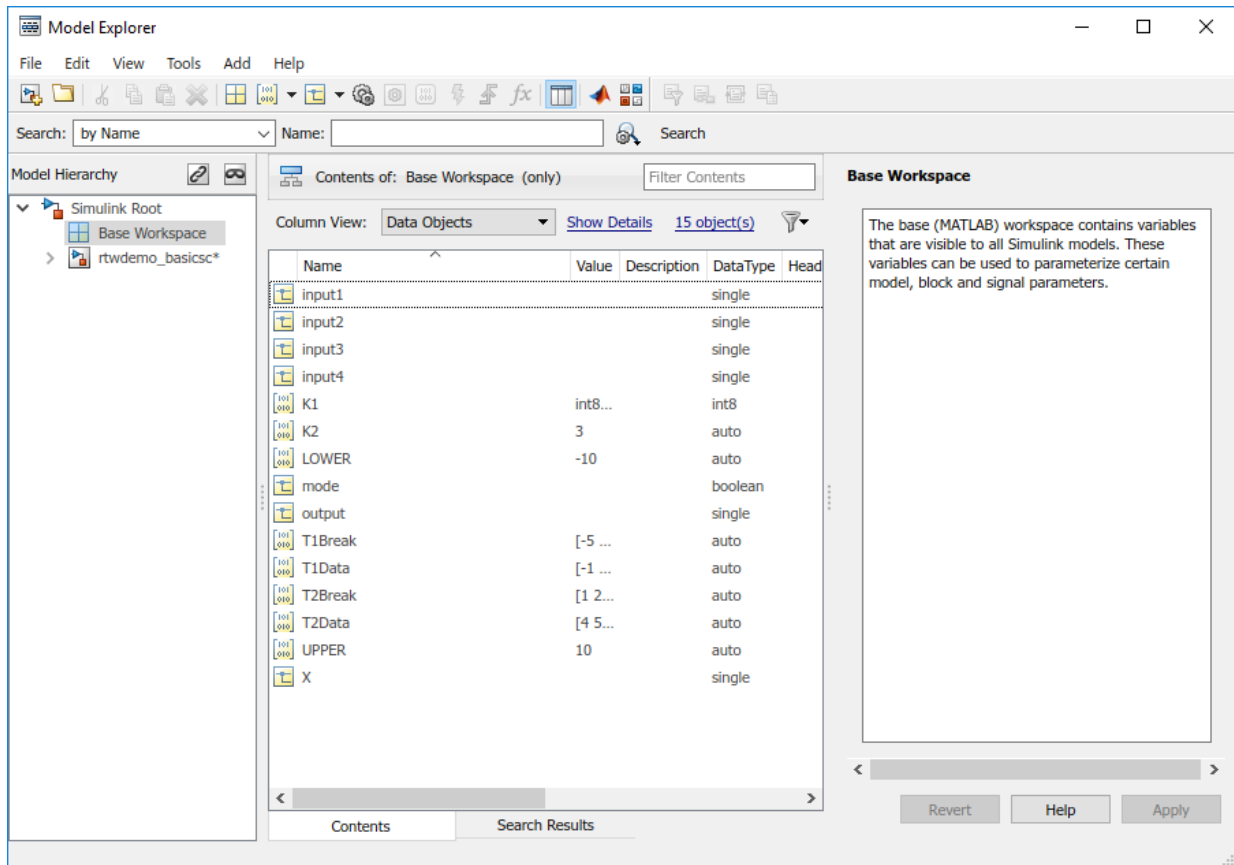

For detailed information about the options that you can choose in the Data Object Wizard, see “Create Data Objects for a Model Using Data Object Wizard” (Simulink).

### **Set Storage Class for Data Objects**

Storage classes determine how the generated code uses variables to represent signals, parameters, and states. For data objects from the built-in package Simulink, the default storage class is Auto. To specify storage classes for the new data objects, you can use the Model Explorer.

Open the Model Explorer.

In the **Model Hierarchy** pane, select **Base Workspace**.

In the **Contents** pane, from the drop-down list **Column View**, select **Storage Class**.

Select all of the new data objects. For example, select the object `input1`, hold **Shift**, and select the object `X`.

Set the property `StorageClass` for all of the data objects to `ExportToFile`. To change the storage class for all of the selected objects, in the **StorageClass** column, click any of the objects. In the drop-down list, select `ExportToFile`. The change that you make propagates to all of the selected objects.

Specify the `HeaderFile` property for all of the objects as `myExportedHdrFile.h`.

In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`. With this setting, the code generator honors custom storage classes such as `ExportToFile`.

### Generate and Inspect Code

Generate code from the model.

```
Starting build procedure for model: rtwdemo_basicsc
Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generation report, view the generated file `myExportedHdrFile.h`. The file contains `extern` declarations for the global variables that correspond to the data objects.

```
/* Exported data declaration */

/* Declaration for custom storage class: ExportToFile */
extern int8_T K1;
extern real_T K2;
extern real32_T LOWER;
extern real32_T T1Break[11];
extern real32_T T1Data[11];
extern real32_T T2Break[3];
extern real32_T T2Data[9];
extern real32_T UPPER;
extern real32_T X;
extern real32_T input1;
extern real32_T input2;
extern real32_T input3;
extern real32_T input4;
extern boolean_T mode;
extern real32_T output;
```

View the file `rtwdemo_basicsc.c`. The file contains the definitions for the global variables. The code assigns numeric values for the variables that correspond to parameter objects.

```
/* Exported data definition */

/* Definition for custom storage class: ExportToFile */
int8_T K1 = 2;
real_T K2 = 3.0;
```

```
real32_T LOWER = -10.0F;
real32_T T1Break[11] = { -5.0F, -4.0F, -3.0F, -2.0F, -1.0F, 0.0F, 1.0F, 2.0F,
 3.0F, 4.0F, 5.0F } ;

real32_T T1Data[11] = { -1.0F, -0.99F, -0.98F, -0.96F, -0.76F, 0.0F, 0.76F,
 0.96F, 0.98F, 0.99F, 1.0F } ;

real32_T T2Break[3] = { 1.0F, 2.0F, 3.0F } ;

real32_T T2Data[9] = { 4.0F, 16.0F, 10.0F, 5.0F, 19.0F, 18.0F, 6.0F, 20.0F,
 23.0F } ;

real32_T UPPER = 10.0F;
real32_T X;
real32_T input1;
real32_T input2;
real32_T input3;
real32_T input4;
boolean_T mode;
real32_T output;
```

## Configure Code Generation for Model Entry-Point Functions

### What Is an Entry-Point Function?

An entry point is a location in code where a transfer of program control (execution) occurs. The main function (`main()`) is the entry point to a C/C++ program and is called when the application starts executing. Calls to other functions, for example from the `main` function, provide entry points to function code. Program control is transferred to the called function. The function code executes, and when finished, returns control to the `main` or other calling function.

When producing code for a model, the code generator defines a set of entry-point functions that you can call to execute the generated code. You can call the generated functions from external code or from a version of the generated main function that you modify.

The Code Interface Report section of the code generation report lists the entry-point functions that the code generator produces for a model. For more information, see “Analyze the Generated Code Interface” on page 38-19.

### Categories and Types of Generated Entry-Point Functions

The entry-point functions that the code generator produces for a model and the calling interface for the functions depends on whether the model is:

- Rate-based or is an export-function model
- Configured for reusable, multi-instance code generation

Depending on the style and configuration of a model, the code generator produces one or more of these entry-point functions.

| Function Category        | Function                      | Description                                                                                                                                                                                       |
|--------------------------|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Initialize/<br>Terminate | <code>model_initialize</code> | Initialization code for a model. At the start of the application code, call the function <i>once</i> . Do not use this function to reset the real-time model data structure ( <code>rtM</code> ). |

| Function Category | Function                                                  | Description                                                                                                                                                                                                                                                                                                             |
|-------------------|-----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   | <i>model_terminate</i>                                    | Code for turning off a system. For ERT-based models, you can suppress generation of this function by clearing the model configuration parameter "Terminate function required" (Simulink Coder) (set by default).                                                                                                        |
| Execution         | <i>model_step</i>                                         | For blocks in a rate-based model, output and update code. If you clear the model configuration parameter "Single output/update function" (Simulink Coder) (selected by default), instead of producing a <i>model_step</i> function, the code generator produces functions <i>model_output</i> and <i>model_update</i> . |
|                   | <i>model_function-name</i>                                | For an exported-function model, the exported function for a subsystem.                                                                                                                                                                                                                                                  |
|                   | <i>function-name</i>                                      | For an exported-function model, the exported function for a Simulink Function block.                                                                                                                                                                                                                                    |
|                   | <i>model_reset</i>                                        | If the model includes a Reset Function block, reset code generated. To reset conditions or state, call the function from the application code.                                                                                                                                                                          |
|                   | <i>ref-model</i>                                          | For a reference model, output and update code.                                                                                                                                                                                                                                                                          |
|                   | <i>isr_numinterrupt-number_vecinterrupt-vector-offset</i> | For an Async Interrupt block, interrupt service routine (ISR) code.                                                                                                                                                                                                                                                     |
| Shared utility    | <i>function-name</i>                                      | For shared utility functions, output code.                                                                                                                                                                                                                                                                              |

## Configure Whether Entry-Point Functions Are Reusable

By default, for top models, the code generator produces code that is not reusable or reentrant. Entry-point functions have a void-void interface. Code communicates with other code by directly accessing global data structures that reside in shared memory.

If your application requires reusable, multi-instance entry-point function code, you can configure the code generator to call each function (instance) with unique data. In this case, the code is reentrant.

You configure whether entry-point functions are reusable with the model configuration parameter “Code interface packaging” (Simulink Coder) and related parameters. The parameter settings that you choose depend on factors such as configuration selections for the system target file, programming language, and argument interface.

### **Default Configurations for Single-Instance C Entry-Point Functions**

By default, for GRT- and ERT-based system target files, the code generator produces single-instance C entry-point functions. The generated code:

- Creates an execution function with no arguments (`void`).
- Allocates memory statically (at compile time) for model data structures.

The default model configuration parameter settings for configuring single-instance entry-point function code are:

- “Language” (Simulink Coder) set to `C`.
- “Code interface packaging” (Simulink Coder) set to `Nonreusable function`.

### **Generate Reusable, Multi-Instance C Entry-Point Functions**

You can configure the code generator to produce reusable entry-point functions in C for either a GRT- or ERT-based system target file. However, the function interfaces that the code generator produces by default varies. Assuming that model configuration parameter “Language” (Simulink Coder) is set to `C` and “Code interface packaging” (Simulink Coder) is set to `Reusable function`, the code generator produces this entry-point function code for each system target file scenario.

| System Target File | Interface                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GRT-based          | <ul style="list-style-type: none"> <li>• Reusable, multi-instance C entry-point functions that are reentrant.</li> <li>• Packs values of model root-level Inport blocks and Output blocks into the real-time model data structure. Passes that structure to the execution function as an argument by reference.</li> <li>• Allocates memory dynamically at runtime for the data of a model instance. Allocates the memory by calling a function, such as <code>malloc</code>.</li> </ul> |
| ERT-based          | <ul style="list-style-type: none"> <li>• Reusable, multi-instance C entry-point functions that are reentrant.</li> <li>• Passes the value of each model root-level Inport block and Output block to the execution function as a separate argument.</li> <li>• Allocates memory statically for model data structures.</li> </ul>                                                                                                                                                          |

If you are using an ERT-based system target file and want to generate reusable, multi-instance C entry-point functions that are reentrant, set “Language” (Simulink Coder) to C and set “Code interface packaging” (Simulink Coder) to Reusable function. Also consider:

- Using dynamic memory allocation to initialize model data structures. Select “Use dynamic memory allocation for model initialization” (Simulink Coder).
- Packing values of model root-level Inport blocks into a structure, packing values of root-level Output blocks into a second structure, and passing the structures to the execution function as arguments by reference. Set “Pass root-level I/O as” (Simulink Coder) to Structure reference.
- Packing values of model root-level Inport blocks and Output blocks into the real-time model data structure and passing that structure to the execution function as an argument by reference. Set “Pass root-level I/O as” (Simulink Coder) to Part of model data structure.

### Generate Reusable, Multi-Instance C++ Entry-Point Functions

The C++ class interface encapsulates model data as class properties and entry-point functions as class methods. That interface is available for use with ERT-based system

target files. To use the interface, set “Language” (Simulink Coder) to C++ and set “Code interface packaging” (Simulink Coder) to C++ `class` . You can:

- Preview and customize the C++ class interface by clicking “Configure C++ Class Interface” (Simulink Coder). Customization means that you can generate code for integration with external code and, if necessary, make sure that the code complies with coding standards.
- Configure the visibility of class inheritance by specifying whether to generate the block parameter structure as a public, private, or protected data member. Set “Parameter visibility” (Simulink Coder) to `public` , `private`, or `protected`.
- Generate C++ interface code for model block parameters that meet code performance or tunability requirements. The code can be noninlined or inlined access methods. Set “Parameter access” (Simulink Coder) to `Method` or `Inlined method`.
- Generate C++ interface code for model root-level Inport and Outport blockset that meets code performance, data tunability, or data packaging requirements. The code can be one of these types of access methods.

| For Access Method Type     | Set “External I/O access” (Simulink Coder) To |
|----------------------------|-----------------------------------------------|
| Noninlined                 | Method                                        |
| Inlined                    | Inlined method                                |
| Noninlined structure-based | Structure-based method                        |
| Inlined structured-based   | Inlined structure-based method                |

## Configure Generated Entry-Point Function Declarations

Depending on application requirements, such as integration or compliance with code standards, you might need to configure how the code generator produces declarations for entry-point functions. Embedded Coder provides multiple configuration options.

- Apply a default function naming rule to a category of functions across a model. For example, a default naming rule can produce a `model_step` function for each rate in the multi-rate model. In the Code Mapping Editor, map a function category to a function customization template that is defined to use the function naming rule (see Code Mapping Editor). If necessary, you can override the default naming of function by using function prototype control (see “Customize Generated C Function Interfaces” on page 29-2 or “Customize Generated C++ Class Interfaces” on page 29-36).

- Configure a specific entry-point function interface, including function and argument naming, use of C type qualifiers (for example, `const`), and argument order. See “Generate Reusable, Multi-Instance C Entry-Point Functions” on page 28-4 and “Generate Reusable, Multi-Instance C++ Entry-Point Functions” on page 28-5.

## Configure Placement of Entry-Point Functions in Memory

If your application requires that you configure the placement of entry-point functions in memory, for example, to optimize the generated code for specific hardware, you can apply a default memory section to a category of functions across a model. In the Code Mapping Editor, map a function category to a function customization template that is defined to use a specific memory section. See Code Mapping Editor.

## How to Interface with Generated Entry-Point Functions

- 1 After generating code for a model, open and review the Code Interface Report. The report lists the generated entry-point functions and, if applicable, variables representing external input and output ports.
- 2 Add `#include` statements to your external code that include the generated header files that declare the model entry-point functions.
- 3 Add an `#include` statement that includes the generated file `rtwtypes.h`. This file provides necessary type definitions, `#define` statements, and enumerations.
- 4 Initialize target-specific data structures and hardware, such as ADCs or DACs.
- 5 If applicable, initialize data for each instance of a reusable model.
- 6 If applicable, write input data to generated variables that represent model Inport blocks.
- 7 Call the generated entry-point functions or, if appropriate, set up use of the `rt_OneStep` function.
