TRANS_EST2 =
0.2286  0.7714
0.0032  0.9968
```

```
EMIS_EST2 =
0.1436  0.2348  0.1837  0.1963  0.2350  0.0066
0.4355  0.1089  0.1144  0.1082  0.1109  0.1220
```

`hmmtrain` uses an iterative algorithm that alters the matrices `TRANS_GUESS` and `EMIS_GUESS` so that at each step the adjusted matrices are more likely to generate the observed sequence, `seq`. The algorithm halts when the matrices in two successive iterations are within a small tolerance of each other.

If the algorithm fails to reach this tolerance within a maximum number of iterations, whose default value is 100, the algorithm halts. In this case, `hmmtrain` returns the last values of `TRANS_EST` and `EMIS_EST` and issues a warning that the tolerance was not reached.

If the algorithm fails to reach the desired tolerance, increase the default value of the maximum number of iterations with the command:

```
hmmtrain(seq, TRANS_GUESS, EMIS_GUESS, 'maxiterations', maxiter)
```

where `maxiter` is the maximum number of steps the algorithm executes.

Change the default value of the tolerance with the command:

```
hmmtrain(seq, TRANS_GUESS, EMIS_GUESS, 'tolerance', tol)
```

where `tol` is the desired value of the tolerance. Increasing the value of `tol` makes the algorithm halt sooner, but the results are less accurate.

Two factors reduce the reliability of the output matrices of `hmmtrain`:

- The algorithm converges to a local maximum that does not represent the true transition and emission matrices. If you suspect this, use different initial guesses for the matrices `TRANS_EST` and `EMIS_EST`.
- The sequence `seq` may be too short to properly train the matrices. If you suspect this, use a longer sequence for `seq`.

Estimating Posterior State Probabilities

The posterior state probabilities of an emission sequence `seq` are the conditional probabilities that the model is in a particular state when it generates a symbol in `seq`, given that `seq` is emitted. You compute the posterior state probabilities with `hmmdecode`:

```
PSTATES = hmmdecode(seq, TRANS, EMIS)
```

The output `PSTATES` is an M -by- L matrix, where M is the number of states and L is the length of `seq`. `PSTATES(i, j)` is the conditional probability that the model is in state i when it generates the j th symbol of `seq`, given that `seq` is emitted.

`hmmdecode` begins with the model in state 1 at step 0, prior to the first emission. `PSTATES(i, 1)` is the probability that the model is in state i at the following step 1. To change the initial state, see “Changing the Initial State Distribution” on page 26-10.

To return the logarithm of the probability of the sequence `seq`, use the second output argument of `hmmdecode`:

```
[PSTATES, logpseq] = hmmdecode(seq, TRANS, EMIS)
```

The probability of a sequence tends to 0 as the length of the sequence increases, and the probability of a sufficiently long sequence becomes less than the smallest positive number your computer can represent. `hmmdecode` returns the logarithm of the probability to avoid this problem.

Changing the Initial State Distribution

By default, Statistics and Machine Learning Toolbox hidden Markov model functions begin in state 1. In other words, the distribution of initial states has all of its probability mass concentrated at state 1. To assign a different distribution of probabilities, $p = [p_1, p_2, \dots, p_M]$, to the M initial states, do the following:

- 1 Create an $M+1$ -by- $M+1$ augmented transition matrix, \hat{T} of the following form:

$$\hat{T} = \begin{bmatrix} 0 & p \\ 0 & T \end{bmatrix}$$

where T is the true transition matrix. The first column of \hat{T} contains $M+1$ zeros. p must sum to 1.

- 2 Create an $M+1$ -by- N augmented emission matrix, \hat{E} , that has the following form:

$$\hat{E} = \begin{bmatrix} 0 \\ E \end{bmatrix}$$

If the transition and emission matrices are `TRANS` and `EMIS`, respectively, you create the augmented matrices with the following commands:

```
TRANS_HAT = [0 p; zeros(size(TRANS,1),1) TRANS];
```

```
EMIS_HAT = [zeros(1,size(EMIS,2)); EMIS];
```

Design of Experiments

Passive data collection leads to a number of problems in statistical modeling. Observed changes in a response variable may be correlated with, but not caused by, observed changes in individual factors (process variables). Simultaneous changes in multiple factors may produce interactions that are difficult to separate into individual effects. Observations may be dependent, while a model of the data considers them to be independent.

Designed experiments address these problems. In a designed experiment, the data-producing process is actively manipulated to improve the quality of information and to eliminate redundant data. A common goal of all experimental designs is to collect data as parsimoniously as possible while providing sufficient information to accurately estimate model parameters.

For example, a simple model of a response y in an experiment with two controlled factors x_1 and x_2 might look like this:

$$y = \beta_0 + \beta_1x_1 + \beta_2x_2 + \beta_3x_1x_2 + \varepsilon$$

Here ε includes both experimental error and the effects of any uncontrolled factors in the experiment. The terms β_1x_1 and β_2x_2 are main effects and the term $\beta_3x_1x_2$ is a two-way interaction effect. A designed experiment would systematically manipulate x_1 and x_2 while measuring y , with the objective of accurately estimating β_0 , β_1 , β_2 , and β_3 .

Full Factorial Designs

In this section...

“Multilevel Designs” on page 27-3

“Two-Level Designs” on page 27-3

Multilevel Designs

To systematically vary experimental factors, assign each factor a discrete set of levels. Full factorial designs measure response variables using every treatment (combination of the factor levels). A full factorial design for n factors with N_1, \dots, N_n levels requires $N_1 \times \dots \times N_n$ experimental runs—one for each treatment. While advantageous for separating individual effects, full factorial designs can make large demands on data collection.

As an example, suppose a machine shop has three machines and four operators. If the same operator always uses the same machine, it is impossible to determine if a machine or an operator is the cause of variation in production. By allowing every operator to use every machine, effects are separated. A full factorial list of treatments is generated by the Statistics and Machine Learning Toolbox function `fullfact`:

```
dFF = fullfact([3,4])
```

```
dFF =
     1     1
     2     1
     3     1
     1     2
     2     2
     3     2
     1     3
     2     3
     3     3
     1     4
     2     4
     3     4
```

Each of the $3 \times 4 = 12$ rows of `dFF` represent one machine/operator combination.

Two-Level Designs

Many experiments can be conducted with two-level factors, using two-level designs. For example, suppose the machine shop in the previous example always keeps the same

operator on the same machine, but wants to measure production effects that depend on the composition of the day and night shifts. The Statistics and Machine Learning Toolbox function `ff2n` generates a full factorial list of treatments:

```
dFF2 = ff2n(4)
```

```
dFF2 =  
 0      0      0      0  
 0      0      0      1  
 0      0      1      0  
 0      0      1      1  
 0      1      0      0  
 0      1      0      1  
 0      1      1      0  
 0      1      1      1  
 1      0      0      0  
 1      0      0      1  
 1      0      1      0  
 1      0      1      1  
 1      1      0      0  
 1      1      0      1  
 1      1      1      0  
 1      1      1      1
```

Each of the $2^4 = 16$ rows of `dFF2` represent one schedule of operators for the day (0) and night (1) shifts.

Fractional Factorial Designs

In this section...

“Introduction to Fractional Factorial Designs” on page 27-5

“Plackett-Burman Designs” on page 27-5

“General Fractional Designs” on page 27-6

Introduction to Fractional Factorial Designs

Two-level designs are sufficient for evaluating many production processes. Factor levels of ± 1 can indicate categorical factors, normalized factor extremes, or simply “up” and “down” from current factor settings. Experimenters evaluating process *changes* are interested primarily in the factor directions that lead to process improvement.

For experiments with many factors, two-level full factorial designs can lead to large amounts of data. For example, a two-level full factorial design with 10 factors requires $2^{10} = 1024$ runs. Often, however, individual factors or their interactions have no distinguishable effects on a response. This is especially true of higher order interactions. As a result, a well-designed experiment can use fewer runs for estimating model parameters.

Fractional factorial designs use a fraction of the runs required by full factorial designs. A subset of experimental treatments is selected based on an evaluation (or assumption) of which factors and interactions have the most significant effects. Once this selection is made, the experimental design must separate these effects. In particular, significant effects should not be confounded, that is, the measurement of one should not depend on the measurement of another.

Plackett-Burman Designs

Plackett-Burman designs are used when only main effects are considered significant. Two-level Plackett-Burman designs require a number of experimental runs that are a multiple of 4 rather than a power of 2. The MATLAB function `hadamard` generates these designs:

```
dPB = hadamard(8)
```

```
dPB =
```

```

1    1    1    1    1    1    1    1
1   -1    1   -1    1   -1    1   -1
```

| | | | | | | | |
|---|----|----|----|----|----|----|----|
| 1 | 1 | -1 | -1 | 1 | 1 | -1 | -1 |
| 1 | -1 | -1 | 1 | 1 | -1 | -1 | 1 |
| 1 | 1 | 1 | 1 | -1 | -1 | -1 | -1 |
| 1 | -1 | 1 | -1 | -1 | 1 | -1 | 1 |
| 1 | 1 | -1 | -1 | -1 | -1 | 1 | 1 |
| 1 | -1 | -1 | 1 | -1 | 1 | 1 | -1 |

Binary factor levels are indicated by ± 1 . The design is for eight runs (the rows of **dpB**) manipulating seven two-level factors (the last seven columns of **dpB**). The number of runs is a fraction $8/2^7 = 0.0625$ of the runs required by a full factorial design. Economy is achieved at the expense of confounding main effects with any two-way interactions.

General Fractional Designs

At the cost of a larger fractional design, you can specify which interactions you wish to consider significant. A design of resolution R is one in which no n -factor interaction is confounded with any other effect containing less than $R - n$ factors. Thus, a resolution III design does not confound main effects with one another but may confound them with two-way interactions (as in “Plackett-Burman Designs” on page 27-5), while a resolution IV design does not confound either main effects or two-way interactions but may confound two-way interactions with each other.

Specify general fractional factorial designs using a full factorial design for a selected subset of basic factors and generators for the remaining factors. Generators are products of the basic factors, giving the levels for the remaining factors. Use the Statistics and Machine Learning Toolbox function `fracfact` to generate these designs:

```
dfF = fracfact('a b c d bcd acd')
dfF =
-1    -1    -1    -1    -1    -1
-1    -1    -1     1     1     1
-1    -1     1    -1     1     1
-1    -1     1     1    -1    -1
-1     1    -1    -1     1    -1
-1     1    -1     1    -1     1
-1     1     1    -1    -1     1
-1     1     1     1     1    -1
 1    -1    -1    -1    -1     1
 1    -1    -1     1     1    -1
 1    -1     1    -1     1     1
 1    -1     1     1    -1     1
 1     1    -1    -1     1     1
 1     1    -1     1    -1    -1
```

```

1    1    1    -1   -1   -1
1    1    1    1    1    1
    
```

This is a six-factor design in which four two-level basic factors (a, b, c, and d in the first four columns of `dfF`) are measured in every combination of levels, while the two remaining factors (in the last three columns of `dfF`) are measured only at levels defined by the generators `bcd` and `acd`, respectively. Levels in the generated columns are products of corresponding levels in the columns that make up the generator.

The challenge of creating a fractional factorial design is to choose basic factors and generators so that the design achieves a specified resolution in a specified number of runs. Use the Statistics and Machine Learning Toolbox function `fracfactgen` to find appropriate generators:

```

generators = fracfactgen('a b c d e f',4,4)
generators =
    'a'
    'b'
    'c'
    'd'
    'bcd'
    'acd'
    
```

These are generators for a six-factor design with factors a through f, using $2^4 = 16$ runs to achieve resolution IV. The `fracfactgen` function uses an efficient search algorithm to find generators that meet the requirements.

An optional output from `fracfact` displays the confounding pattern of the design:

```

[dfF,confounding] = fracfact(generators);
confounding
confounding =
    'Term'      'Generator'      'Confounding'
    'X1'       'a'              'X1'
    'X2'       'b'              'X2'
    'X3'       'c'              'X3'
    'X4'       'd'              'X4'
    'X5'       'bcd'            'X5'
    'X6'       'acd'            'X6'
    'X1*X2'    'ab'            'X1*X2 + X5*X6'
    'X1*X3'    'ac'            'X1*X3 + X4*X6'
    'X1*X4'    'ad'            'X1*X4 + X3*X6'
    'X1*X5'    'abcd'          'X1*X5 + X2*X6'
    'X1*X6'    'cd'            'X1*X6 + X2*X5 + X3*X4'
    
```

| | | |
|---------|--------|-------------------------|
| 'X2*X3' | 'bc' | 'X2*X3 + X4*X5' |
| 'X2*X4' | 'bd' | 'X2*X4 + X3*X5' |
| 'X2*X5' | 'cd' | 'X1*X6 + X2*X5 + X3*X4' |
| 'X2*X6' | 'abcd' | 'X1*X5 + X2*X6' |
| 'X3*X4' | 'cd' | 'X1*X6 + X2*X5 + X3*X4' |
| 'X3*X5' | 'bd' | 'X2*X4 + X3*X5' |
| 'X3*X6' | 'ad' | 'X1*X4 + X3*X6' |
| 'X4*X5' | 'bc' | 'X2*X3 + X4*X5' |
| 'X4*X6' | 'ac' | 'X1*X3 + X4*X6' |
| 'X5*X6' | 'ab' | 'X1*X2 + X5*X6' |

The confounding pattern shows that main effects are effectively separated by the design, but two-way interactions are confounded with various other two-way interactions.

Response Surface Designs

| In this section... |
|---|
| “Introduction to Response Surface Designs” on page 27-9 |
| “Central Composite Designs” on page 27-9 |
| “Box-Behnken Designs” on page 27-13 |

Introduction to Response Surface Designs

Quadratic response surfaces are simple models that provide a maximum or minimum without making additional assumptions about the form of the response. Quadratic models can be calibrated using full factorial designs with three or more levels for each factor, but these designs generally require more runs than necessary to accurately estimate model parameters. This section discusses designs for calibrating quadratic models that are much more efficient, using three or five levels for each factor, but not using all combinations of levels.

Central Composite Designs

Central composite designs (CCDs), also known as Box-Wilson designs, are appropriate for calibrating full quadratic models. There are three types of CCDs—circumscribed, inscribed, and faced—pictured below:

Each design consists of a factorial design (the corners of a cube) together with center and star points that allow for estimation of second-order effects. For a full quadratic model with n factors, CCDs have enough design points to estimate the $(n+2)(n+1)/2$ coefficients in a full quadratic model with n factors.

The type of CCD used (the position of the factorial and star points) is determined by the number of factors and by the desired properties of the design. The following table summarizes some important properties. A design is rotatable if the prediction variance depends only on the distance of the design point from the center of the design.

| Design | Rotatable | Factor Levels | Uses Points Outside ± 1 | Accuracy of Estimates |
|---------------------|-----------|---------------|-----------------------------|--|
| Circumscribed (CCC) | Yes | 5 | Yes | Good over entire design space |
| Inscribed (CCI) | Yes | 5 | No | Good over central subset of design space |

| Design | Rotatable | Factor Levels | Uses Points Outside ± 1 | Accuracy of Estimates |
|-------------|-----------|---------------|-----------------------------|---|
| Faced (CCF) | No | 3 | No | Fair over entire design space; poor for pure quadratic coefficients |

Generate CCDs with the Statistics and Machine Learning Toolbox function `ccdesign`:

```
dCC = ccdesign(3,'type','circumscribed')
dCC =
-1.0000    -1.0000    -1.0000
-1.0000    -1.0000     1.0000
-1.0000     1.0000    -1.0000
-1.0000     1.0000     1.0000
 1.0000    -1.0000    -1.0000
 1.0000    -1.0000     1.0000
 1.0000     1.0000    -1.0000
 1.0000     1.0000     1.0000
-1.6818         0         0
 1.6818         0         0
 0    -1.6818         0
 0     1.6818         0
 0         0    -1.6818
 0         0     1.6818
 0         0         0
 0         0         0
 0         0         0
 0         0         0
 0         0         0
 0         0         0
 0         0         0
 0         0         0
 0         0         0
 0         0         0
 0         0         0
 0         0         0
```

The repeated center point runs allow for a more uniform estimate of the prediction variance over the entire design space.

Box-Behnken Designs

Like the designs described in “Central Composite Designs” on page 27-9, Box-Behnken designs are used to calibrate full quadratic models. Box-Behnken designs are rotatable

and, for a small number of factors (four or less), require fewer runs than CCDs. By avoiding the corners of the design space, they allow experimenters to work around extreme factor combinations. Like an inscribed CCD, however, extremes are then poorly estimated.

The geometry of a Box-Behnken design is pictured in the following figure.

Design points are at the midpoints of edges of the design space and at the center, and do not contain an embedded factorial design.

Generate Box-Behnken designs with the Statistics and Machine Learning Toolbox function `bbdesign`:

```
dBB = bbdesign(3)
```

```
dBB =
    -1    -1     0
    -1     1     0
     1    -1     0
     1     1     0
    -1     0    -1
```

| | | |
|----|----|----|
| -1 | 0 | 1 |
| 1 | 0 | -1 |
| 1 | 0 | 1 |
| 0 | -1 | -1 |
| 0 | -1 | 1 |
| 0 | 1 | -1 |
| 0 | 1 | 1 |
| 0 | 0 | 0 |
| 0 | 0 | 0 |
| 0 | 0 | 0 |

Again, the repeated center point runs allow for a more uniform estimate of the prediction variance over the entire design space.

D-Optimal Designs

Introduction to D-Optimal Designs

Traditional experimental designs (“Full Factorial Designs” on page 27-3, “Fractional Factorial Designs” on page 27-5, and “Response Surface Designs” on page 27-9) are appropriate for calibrating linear models in experimental settings where factors are relatively unconstrained in the region of interest. In some cases, however, models are necessarily nonlinear. In other cases, certain treatments (combinations of factor levels) may be expensive or infeasible to measure. D-optimal designs are model-specific designs that address these limitations of traditional designs.

A D-optimal design is generated by an iterative search algorithm and seeks to minimize the covariance of the parameter estimates for a specified model. This is equivalent to maximizing the determinant $D = |X^T X|$, where X is the design matrix of model terms (the columns) evaluated at specific treatments in the design space (the rows). Unlike traditional designs, D-optimal designs do not require orthogonal design matrices, and as a result, parameter estimates may be correlated. Parameter estimates may also be locally, but not globally, D-optimal.

There are several Statistics and Machine Learning Toolbox functions for generating D-optimal designs:

| Function | Description |
|----------|--|
| candexch | Uses a row-exchange algorithm to generate a D-optimal design with a specified number of runs for a specified model and a specified candidate set. This is the second component of the algorithm used by rowexch. |

| Function | Description |
|-----------------------|---|
| <code>candgen</code> | Generates a candidate set for a specified model. This is the first component of the algorithm used by <code>rowexch</code> . |
| <code>cordexch</code> | Uses a coordinate-exchange algorithm to generate a D-optimal design with a specified number of runs for a specified model. |
| <code>daugment</code> | Uses a coordinate-exchange algorithm to augment an existing D-optimal design with additional runs to estimate additional model terms. |
| <code>dcovary</code> | Uses a coordinate-exchange algorithm to generate a D-optimal design with fixed covariate factors. |
| <code>rowexch</code> | Uses a row-exchange algorithm to generate a D-optimal design with a specified number of runs for a specified model. The algorithm calls <code>candgen</code> and then <code>candexch</code> . (Call <code>candexch</code> separately to specify a candidate set.) |

The following sections explain how to use these functions to generate D-optimal designs.

Note The Statistics and Machine Learning Toolbox function `rsmdemo` generates simulated data for experimental settings specified by either the user or by a D-optimal design generated by `cordexch`. It uses the `rstool` interface to visualize response surface models fit to the data, and it uses the `nlintool` interface to visualize a nonlinear model fit to the data.

Generate D-Optimal Designs

Two Statistics and Machine Learning Toolbox algorithms generate D-optimal designs:

- The `cordexch` function uses a coordinate-exchange algorithm
- The `rowexch` function uses a row-exchange algorithm

Both `cordexch` and `rowexch` use iterative search algorithms. They operate by incrementally changing an initial design matrix X to increase $D = |X^T X|$ at each step. In both algorithms, there is randomness built into the selection of the initial design and into the choice of the incremental changes. As a result, both algorithms may return locally, but not globally, D-optimal designs. Run each algorithm multiple times and select the best result for your final design. Both functions have a 'tries' parameter that automates this repetition and comparison.

At each step, the row-exchange algorithm exchanges an entire row of X with a row from a design matrix C evaluated at a candidate set of feasible treatments. The `rowexch` function automatically generates a C appropriate for a specified model, operating in two steps by calling the `candgen` and `candexch` functions in sequence. Provide your own C by calling `candexch` directly. In either case, if C is large, its static presence in memory can affect computation.

The coordinate-exchange algorithm, by contrast, does not use a candidate set. (Or rather, the candidate set is the entire design space.) At each step, the coordinate-exchange algorithm exchanges a single element of X with a new element evaluated at a neighboring point in design space. The absence of a candidate set reduces demands on memory, but the smaller scale of the search means that the coordinate-exchange algorithm is more likely to become trapped in a local minimum than the row-exchange algorithm.

For example, suppose you want a design to estimate the parameters in the following three-factor, seven-term interaction model:

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3 + \beta_{12} x_1 x_2 + \beta_{13} x_1 x_3 + \beta_{23} x_2 x_3 + \varepsilon$$

Use `cordexch` to generate a D-optimal design with seven runs:

```
nfactors = 3;
nruns = 7;
[dCE,X] = cordexch(nfactors,nruns,'interaction','tries',10)
dCE =
    -1     1     1
    -1    -1    -1
     1     1     1
    -1     1    -1
     1    -1     1
     1    -1    -1
    -1    -1     1
X =
     1    -1     1     1    -1    -1     1
     1    -1    -1    -1     1     1     1
     1     1     1     1     1     1     1
     1    -1     1    -1    -1     1    -1
     1     1    -1     1    -1     1    -1
     1     1    -1    -1    -1    -1     1
     1    -1    -1     1     1    -1    -1
```

Columns of the design matrix X are the model terms evaluated at each row of the design dCE . The terms appear in order from left to right:

- 1 Constant term
- 2 Linear terms (1, 2, 3)
- 3 Interaction terms (12, 13, 23)

Use `X` in a linear regression model fit to response data measured at the design points in `dCE`.

Use `rowexch` in a similar fashion to generate an equivalent design:

```
[dRE,X] = rowexch(nfactors,nruns,'interaction','tries',10)
```

```
dRE =
```

```
-1 -1 1
 1 -1 1
 1 -1 -1
 1 1 1
-1 -1 -1
-1 1 -1
-1 1 1
```

```
X =
```

```
1 -1 -1 1 1 -1 -1
1 1 -1 1 -1 1 -1
1 1 -1 -1 -1 -1 1
1 1 1 1 1 1 1
1 -1 -1 -1 1 1 1
1 -1 1 -1 -1 1 -1
1 -1 1 1 -1 -1 1
```

Augment D-Optimal Designs

In practice, you may want to add runs to a completed experiment to learn more about a process and estimate additional model coefficients. The `daugment` function uses a coordinate-exchange algorithm to augment an existing D-optimal design.

For example, the following eight-run design is adequate for estimating main effects in a four-factor model:

```
dCEmain = cordexch(4,8)
```

```
dCEmain =
```

```
1 -1 -1 1
-1 -1 1 1
-1 1 -1 1
1 1 1 -1
```

| | | | |
|----|----|----|----|
| 1 | 1 | 1 | 1 |
| -1 | 1 | -1 | -1 |
| 1 | -1 | -1 | -1 |
| -1 | -1 | 1 | -1 |

To estimate the six interaction terms in the model, augment the design with eight additional runs:

```
dCEinteraction = daugment(dCEmain,8,'interaction')
dCEinteraction =
    1    -1    -1     1
   -1    -1     1     1
   -1     1    -1     1
    1     1     1    -1
    1     1     1     1
   -1     1    -1    -1
    1    -1    -1    -1
   -1    -1     1    -1
   -1     1     1     1
   -1    -1    -1    -1
    1    -1     1    -1
    1     1    -1     1
   -1     1     1    -1
    1     1    -1    -1
    1    -1     1     1
    1     1     1    -1
```

The augmented design is full factorial, with the original eight runs in the first eight rows.

The 'start' parameter of the `candexch` function provides the same functionality as `daugment`, but uses a row exchange algorithm rather than a coordinate-exchange algorithm.

Specify Fixed Covariate Factors

In many experimental settings, certain factors and their covariates are constrained to a fixed set of levels or combinations of levels. These cannot be varied when searching for an optimal design. The `dcovary` function allows you to specify fixed covariate factors in the coordinate exchange algorithm.

For example, suppose you want a design to estimate the parameters in a three-factor linear additive model, with eight runs that necessarily occur at different times. If the

process experiences temporal linear drift, you may want to include the run time as a variable in the model. Produce the design as follows:

```
time = linspace(-1,1,8)';
[dCV,X] = dcovary(3,time,'linear')
dCV =
-1.0000    1.0000    1.0000   -1.0000
 1.0000   -1.0000   -1.0000   -0.7143
-1.0000   -1.0000   -1.0000   -0.4286
 1.0000   -1.0000    1.0000   -0.1429
 1.0000    1.0000   -1.0000    0.1429
-1.0000    1.0000   -1.0000    0.4286
 1.0000    1.0000    1.0000    0.7143
-1.0000   -1.0000    1.0000    1.0000
X =
 1.0000   -1.0000    1.0000    1.0000   -1.0000
 1.0000    1.0000   -1.0000   -1.0000   -0.7143
 1.0000   -1.0000   -1.0000   -1.0000   -0.4286
 1.0000    1.0000   -1.0000    1.0000   -0.1429
 1.0000    1.0000    1.0000   -1.0000    0.1429
 1.0000   -1.0000    1.0000   -1.0000    0.4286
 1.0000    1.0000    1.0000    1.0000    0.7143
 1.0000   -1.0000   -1.0000    1.0000    1.0000
```

The column vector `time` is a fixed factor, normalized to values between ± 1 . The number of rows in the fixed factor specifies the number of runs in the design. The resulting design `dCV` gives factor settings for the three controlled model factors at each time.

Specify Categorical Factors

Categorical factors take values in a discrete set of levels. Both `cordexch` and `rowexch` have a `'categorical'` parameter that allows you to specify the indices of categorical factors and a `'levels'` parameter that allows you to specify a number of levels for each factor.

For example, the following eight-run design is for a linear additive model with five factors in which the final factor is categorical with three levels:

```
dCEcat = cordexch(5,8,'linear','categorical',5,'levels',3)
dCEcat =
-1    -1     1     1     2
-1    -1    -1    -1     3
 1     1     1     1     3
```

```
1    1    -1   -1    2
1    -1   -1    1    3
-1   1    -1    1    1
-1   1    1    -1   3
1    -1    1    -1   1
```

Specify Candidate Sets

The row-exchange algorithm exchanges rows of an initial design matrix X with rows from a design matrix C evaluated at a candidate set of feasible treatments. The `rowexch` function automatically generates a C appropriate for a specified model, operating in two steps by calling the `candgen` and `candexch` functions in sequence. Provide your own C by calling `candexch` directly.

For example, the following uses `rowexch` to generate a five-run design for a two-factor pure quadratic model using a candidate set that is produced internally:

```
dRE1 = rowexch(2,5,'purequadratic','tries',10)
dRE1 =
-1    1
 0    0
 1   -1
 1    0
 1    1
```

The same thing can be done using `candgen` and `candexch` in sequence:

```
[dC,C] = candgen(2,'purequadratic') % Candidate set, C
dC =
-1   -1
 0   -1
 1   -1
-1    0
 0    0
 1    0
-1    1
 0    1
 1    1
C =
 1   -1   -1    1    1
 1    0   -1    0    1
 1    1   -1    1    1
 1   -1    0    1    0
```

```

1      0      0      0      0
1      1      0      1      0
1     -1      1      1      1
1      0      1      0      1
1      1      1      1      1
treatments = candexch(C,5,'tries',10) % D-opt subset
treatments =
2
1
7
3
4
dRE2 = dC(treatments,:) % Display design
dRE2 =
0     -1
-1    -1
-1     1
1     -1
-1     0

```

You can replace `C` in this example with a design matrix evaluated at your own candidate set. For example, suppose your experiment is constrained so that the two factors cannot have extreme settings simultaneously. The following produces a restricted candidate set:

```

constraint = sum(abs(dC),2) < 2; % Feasible treatments
my_dC = dC(constraint,:)
my_dC =
0     -1
-1     0
0     0
1     0
0     1

```

Use the `x2fx` function to convert the candidate set to a design matrix:

```

my_C = x2fx(my_dC, 'purequadratic')
my_C =
1      0     -1      0      1
1     -1      0      1      0
1      0      0      0      0
1      1      0      1      0
1      0      1      0      1

```

Find the required design in the same manner:

```
my_treatments = candexch(my_C,5,'tries',10) % D-opt subset
my_treatments =
    2
    4
    5
    1
    3
my_dRE = my_dC(my_treatments,:) % Display design
my_dRE =
    -1    0
     1    0
     0    1
     0   -1
     0    0
```

Improve an Engine Cooling Fan Using Design for Six Sigma Techniques

This example shows how to improve the performance of an engine cooling fan through a Design for Six Sigma approach using Define, Measure, Analyze, Improve, and Control (DMAIC). The initial fan does not circulate enough air through the radiator to keep the engine cool during difficult conditions. First the example shows how to design an experiment to investigate the effect of three performance factors: fan distance from the radiator, blade-tip clearance, and blade pitch angle. It then shows how to estimate optimum values for each factor, resulting in a design that produces airflows beyond the goal of 875 ft³ per minute using test data. Finally it shows how to use simulations to verify that the new design produces airflow according to the specifications in more than 99.999% of the fans manufactured. This example uses MATLAB, Statistics and Machine Learning Toolbox, and Optimization Toolbox.

Define the Problem

This example addresses an engine cooling fan design that is unable to pull enough air through the radiator to keep the engine cool during difficult conditions, such as stop-and-go traffic or hot weather). Suppose you estimate that you need airflow of at least 875 ft³/min to keep the engine cool during difficult conditions. You need to evaluate the current design and develop an alternative design that can achieve the target airflow.

Assess Cooling Fan Performance

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load OriginalFan
```

The data consists of 10,000 measurements (historical production data) of the existing cooling fan performance.

Plot the data to analyze the current fan's performance.

```
plot(originalfan)
xlabel('Observation')
```

```
ylabel('Max Airflow (ft^3/min)')
title('Historical Production Data')
```

The data is centered around 842 ft³/min and most values fall within the range of about 8 ft³/min. The plot does not tell much about the underlying distribution of data, however. Plot the histogram and fit a normal distribution to the data.

```
figure()
histfit(originalfan) % Plot histogram with normal distribution fit
format shortg
xlabel('Airflow (ft^3/min)')
ylabel('Frequency (counts)')
title('Airflow Histogram')
```

```
pd = fitdist(originalfan,'normal') % Fit normal distribution to data
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 841.652 [841.616, 841.689]
sigma = 1.8768 [1.85114, 1.90318]
```

`fitdist` fits a normal distribution to data and estimates the parameters from data. The estimate for the mean airflow speed is 841.652 ft³/min, and the 95% confidence interval for the mean airflow speed is (841.616, 841.689). This estimate makes it clear that the

current fan is not close to the required 875 ft³/min. There is need to improve the fan design to achieve the target airflow.

Determine Factors That Affect Fan Performance

Evaluate the factors that affect cooling fan performance using design of experiments (DOE). The response is the cooling fan airflow rate (ft³/min). Suppose that the factors that you can modify and control are:

- Distance from radiator
- Pitch angle
- Blade tip clearance

In general, fluid systems have nonlinear behavior. Therefore, use a response surface design to estimate any nonlinear interactions among the factors. Generate the experimental runs for a Box-Behnken design on page 27-13 in coded (normalized) variables [-1, 0, +1].

```
CodedValue = bbdesign(3)
```

```
CodedValue =
```

```
-1    -1    0
-1     1    0
 1    -1    0
 1     1    0
-1     0   -1
-1     0    1
 1     0   -1
 1     0    1
 0    -1   -1
 0    -1    1
 0     1   -1
 0     1    1
 0     0    0
 0     0    0
 0     0    0
```

The first column is for the distance from radiator, the second column is for the pitch angle, and the third column is for the blade tip clearance. Suppose you want to test the effects of the variables at the following minimum and maximum values.

Distance from radiator: 1 to 1.5 inches

Pitch angle: 15 to 35 degrees
 Blade tip clearance: 1 to 2 inches

Randomize the order of the runs, convert the coded design values to real-world units, and perform the experiment in the order specified.

```
runorder = randperm(15);      % Random permutation of the runs
bounds = [1 1.5;15 35;1 2]; % Min and max values for each factor

RealValue = zeros(size(CodedValue));
for i = 1:size(CodedValue,2) % Convert coded values to real-world units
    zmax = max(CodedValue(:,i));
    zmin = min(CodedValue(:,i));
    RealValue(:,i) = interp1([zmin zmax],bounds(i,:),CodedValue(:,i));
end
```

Suppose the at the end of the experiments, you collect the following response values in the variable TestResult.

```
TestResult = [837 864 829 856 880 879 872 874 834 833 860 859 874 876 875]';
```

Display the design values and the response.

```
disp({'Run Number', 'Distance', 'Pitch', 'Clearance', 'Airflow'})
disp(sortrows([runorder' RealValue TestResult]))
```

| 'Run Number' | 'Distance' | 'Pitch' | 'Clearance' | 'Airflow' |
|--------------|------------|---------|-------------|-----------|
| 1 | 1.5 | 35 | 1.5 | 856 |
| 2 | 1.25 | 25 | 1.5 | 876 |
| 3 | 1.5 | 25 | 1 | 872 |
| 4 | 1.25 | 25 | 1.5 | 875 |
| 5 | 1 | 35 | 1.5 | 864 |
| 6 | 1.25 | 25 | 1.5 | 874 |
| 7 | 1.25 | 15 | 2 | 833 |
| 8 | 1.5 | 15 | 1.5 | 829 |
| 9 | 1.25 | 15 | 1 | 834 |
| 10 | 1 | 15 | 1.5 | 837 |
| 11 | 1.5 | 25 | 2 | 874 |
| 12 | 1 | 25 | 1 | 880 |
| 13 | 1.25 | 35 | 1 | 860 |
| 14 | 1 | 25 | 2 | 879 |
| 15 | 1.25 | 35 | 2 | 859 |

Save the design values and the response in a table.

```
Expmt = table(runorder', CodedValue(:,1), CodedValue(:,2), CodedValue(:,3), ...
    TestResult, 'VariableNames', {'RunNumber', 'D', 'P', 'C', 'Airflow'});
```

D stands for Distance, P stands for Pitch, and C stands for Clearance. Based on the experimental test results, the airflow rate is sensitive to the changing factors values. Also, four experimental runs meet or exceed the target airflow rate of 875 ft³/min (runs 2, 4, 12, and 14). However, it is not clear which, if any, of these runs is the optimal one. In addition, it is not obvious how robust the design is to variation in the factors. Create a model based on the current experimental data and use the model to estimate the optimal factor settings.

Improve the Cooling Fan Performance

The Box-Behnken design enables you to test for nonlinear (quadratic) effects. The form of the quadratic model is:

$$AF = \beta_0 + \beta_1 * Distance + \beta_2 * Pitch + \beta_3 * Clearance + \beta_4 * Distance * Pitch + \beta_5 * Distance * Clearance + \beta_6 * Pitch * Clearance + \beta_7 * Distance^2 + \beta_8 * Pitch^2 + \beta_9 * Clearance^2,$$

where AF is the airflow rate and B_i is the coefficient for the term i . Estimate the coefficients of this model using the `fitlm` function from Statistics and Machine Learning Toolbox.

```
mdl = fitlm(Expmt, 'Airflow~D*P*C-D:P:C+D^2+P^2+C^2');
```

Display the magnitudes of the coefficients (for normalized values) in a bar chart.

```
figure()
h = bar(mdl.Coefficients.Estimate(2:10));
set(h, 'facecolor', [0.8 0.8 0.9])
legend('Coefficient')
set(gcf, 'units', 'normalized', 'position', [0.05 0.4 0.35 0.4])
set(gca, 'xticklabel', mdl.CoefficientNames(2:10))
ylabel('Airflow (ft^3/min)')
xlabel('Normalized Coefficient')
title('Quadratic Model Coefficients')
```

The bar chart shows that *Pitch* and *Pitch*² are dominant factors. You can look at the relationship between multiple input variables and one output variable by generating a response surface plot. Use `plotSlice` to generate response surface plots for the model `mdl` interactively.

```
plotSlice(mdl)
```

The plot shows the nonlinear relationship of airflow with pitch. Move the blue dashed lines around and see the effect the different factors have on airflow. Although you can use `plotSlice` to determine the optimum factor settings, you can also use Optimization Toolbox to automate the task.

Find the optimal factor settings using the constrained optimization function `fmincon`.

Write the objective function.

```
f = @(x) -x2fx(x, 'quadratic')*mdl.Coefficients.Estimate;
```

The objective function is a quadratic response surface fit to the data. Minimizing the negative airflow using `fmincon` is the same as maximizing the original objective function. The constraints are the upper and lower limits tested (in coded values). Set the initial starting point to be the center of the design of the experimental test matrix.

```
lb = [-1 -1 -1]; % Lower bound
ub = [1 1 1];   % Upper bound
```

```
x0 = [0 0 0]; % Starting point
[optfactors,fval] = fmincon(f,x0,[],[],[],[],[],lb,ub,[]); % Invoke the solver
```

Local minimum found that satisfies the constraints.

Optimization completed because the objective function is non-decreasing in feasible directions, to within the default value of the function tolerance, and constraints are satisfied to within the default value of the constraint tolerance.

Convert the results to a maximization problem and real-world units.

```
maxval = -fval;
maxloc = (optfactors + 1)';
bounds = [1 1.5;15 35;1 2];
maxloc=bounds(:,1)+maxloc .* ((bounds(:,2) - bounds(:,1))/2);
disp('Optimal Values:')
disp({'Distance', 'Pitch', 'Clearance', 'Airflow'})
disp([maxloc' maxval])
```

```
Optimal Values:
    'Distance'    'Pitch'    'Clearance'    'Airflow'
           1         27.275           1         882.26
```

The optimization result suggests placing the new fan one inch from the radiator, with a one-inch clearance between the tips of the fan blades and the shroud.

Because pitch angle has such a significant effect on airflow, perform additional analysis to verify that a 27.3 degree pitch angle is optimal.

```
load AirflowData
tbl = table(pitch,airflow);
mdl2 = fitlm(tbl,'airflow~pitch^2');
mdl2.Rsquared.Ordinary
```

```
ans =
```

```
0.99632
```

The results show that a quadratic model explains the effect of pitch on the airflow well.

Plot the pitch angle against airflow and impose the fitted model.

```
figure()
plot(pitch,airflow,'.r')
```

```
hold on
ylim([840 885])
line(pitch,mdl2.Fitted,'color','b')
title('Fitted Model and Data')
xlabel('Pitch angle (degrees)')
ylabel('Airflow (ft3/min)')
legend('Test data','Quadratic model','Location','se')
hold off
```

Find the pitch value that corresponds to the maximum airflow.

```
pitch(find(airflow==max(airflow)))
```

ans =

27

The additional analysis confirms that a 27.3 degree pitch angle is optimal.

The improved cooling fan design meets the airflow requirements. You also have a model that approximates the fan performance well based on the factors you can modify in the design. Ensure that the fan performance is robust to variability in manufacturing and installation by performing a sensitivity analysis.

Sensitivity Analysis

Suppose that, based on historical experience, the manufacturing uncertainty is as follows.

| Factor | Real Values | Coded Values |
|------------------------|-----------------------|-------------------------|
| Distance from radiator | 1.00 +/- 0.05 inch | 1.00 +/- 0.20 inch |
| Blade pitch angle | 27.3 +/- 0.25 degrees | 0.227 +/- 0.028 degrees |
| Blade tip clearance | 1.00 +/- 0.125 inch | -1.00 +/- 0.25 inch |

Verify that these variations in factors will enable to maintain a robust design around the target airflow. The philosophy of Six Sigma targets a defect rate of no more than 3.4 per 1,000,000 fans. That is, the fans must hit the 875 ft³/min target 99.999% of the time.

You can verify the design using Monte Carlo simulation. Generate 10,000 random numbers for three factors with the specified tolerance. First, set the state of the random number generators so results are consistent across different runs.

```
rng('default')
```

Perform the Monte Carlo simulation. Include a noise variable that is proportional to the noise in the fitted model, mdl (that is, the RMS error of the model). Because the model coefficients are in coded variables, you must generate `dist`, `pitch`, and `clearance` using the coded definition.

```
dist = random('normal',optfactors(1),0.20,[10000 1]);
pitch = random('normal',optfactors(2),0.028,[10000 1]);
clearance = random('normal',optfactors(3),0.25,[10000 1]);
noise = random('normal',0,mdl2.RMSE,[10000 1]);
```

Calculate airflow for 10,000 random factor combinations using the model.

```
simfactor = [dist pitch clearance];  
X = x2fx(simfactor, 'quadratic');
```

Add noise to the model (the variation in the data that the model did not account for).

```
simflow = X*mdl.Coefficients.Estimate+noise;
```

Evaluate the variation in the model's predicted airflow using a histogram. To estimate the mean and standard deviation, fit a normal distribution to data.

```
pd = fitdist(simflow, 'normal');  
histfit(simflow)  
hold on  
text(pd.mu+2,300,['Mean: ' num2str(round(pd.mu))])  
text(pd.mu+2,280,['Standard deviation: ' num2str(round(pd.sigma))])  
hold off  
xlabel('Airflow (ft^3/min)')  
ylabel('Frequency')  
title('Monte Carlo Simulation Results')
```

The results look promising. The average airflow is 882 ft³/min and appears to be better than 875 ft³/min for most of the data.

Determine the probability that the airflow is at 875 ft³/min or below.

```
format long
pfail = cdf(pd,875)
pass = (1-pfail)*100

pfail =

1.509289008603141e-07
```

```
pass =  
99.999984907109919
```

The design appears to achieve at least 875 ft³/min of airflow 99.999% of the time.

Use the simulation results to estimate the process capability.

```
S = capability(simflow,[875.0 890])  
pass = (1-S.Pl)*100
```

```
S =  
  
mu: 8.822982645666709e+02  
sigma: 1.424806876923940  
P: 0.999999816749816  
Pl: 1.509289008603141e-07  
Pu: 3.232128339675335e-08  
Cp: 1.754623760237126  
Cpl: 1.707427788957002  
Cpu: 1.801819731517250  
Cpk: 1.707427788957002
```

```
pass =  
99.9999849071099
```

The Cp value is 1.75. A process is considered high quality when Cp is greater than or equal to 1.6. The Cpk is similar to the Cp value, which indicates that the process is centered. Now implement this design. Monitor it to verify the design process and to ensure that the cooling fan delivers high-quality performance.

Control Manufacturing of the Improved Cooling Fan

You can monitor and evaluate the manufacturing and installation process of the new fan using control charts. Evaluate the first 30 days of production of the new cooling fan. Initially, five cooling fans per day were produced. First, load the sample data from the new process.

```
load spcdata
```

Plot the X-bar and S charts.

```
figure()
controlchart(spcflow, 'chart', {'xbar', 's'}) % Reshape the data into daily sets
xlabel('Day')
```

According to the results, the manufacturing process is in statistical control, as indicated by the absence of violations of control limits or nonrandom patterns in the data over time. You can also run a capability analysis on the data to evaluate the process.

```
[row,col] = size(spcflow);
S2 = capability(reshape(spcflow,row*col,1),[875.0 890])
pass = (1-S.Pl)*100
```

S2 =

```
mu: 8.821061141685465e+02
sigma: 1.423887508874697
P: 0.999999684316149
Pl: 3.008932155898586e-07
Pu: 1.479063578225176e-08
Cp: 1.755756676295137
Cpl: 1.663547652525458
Cpu: 1.847965700064817
Cpk: 1.663547652525458
```

pass =

99.9999699106784

The Cp value of 1.755 is very similar to the estimated value of 1.73. The Cpk value of 1.66 is smaller than the Cp value. However, only a Cpk value less than 1.33, which indicates that the process shifted significantly toward one of the process limits, is a concern. The process is well within the limits and it achieves the target airflow (875 ft³/min) more than 99.999% of the time.

Statistical Process Control

- “Control Charts” on page 28-2
- “Capability Studies” on page 28-6

Control Charts

A control chart displays measurements of process samples over time. The measurements are plotted together with user-defined *specification limits* and process-defined *control limits*. The process can then be compared with its specifications—to see if it is *in control* or *out of control*.

The chart is just a monitoring tool. Control activity might occur if the chart indicates an undesirable, systematic change in the process. The control chart is used to discover the variation, so that the process can be adjusted to reduce it.

Control charts are created with the `controlchart` function. Any of the following chart types may be specified:

- Xbar or mean
- Standard deviation
- Range
- Exponentially weighted moving average
- Individual observation
- Moving range of individual observations
- Moving average of individual observations
- Proportion defective
- Number of defectives
- Defects per unit
- Count of defects

Control rules are specified with the `controlrules` function. The following example illustrates how to use Western Electric rules to mark out of control measurements on an Xbar chart.

First load the sample data.

```
load parts;
```

Construct the Xbar control chart using the Western Electric 2 rule (2 of 3 points at least 2 standard errors above the center line) to mark the out of control measurements.

```
st = controlchart(runout, 'rules', 'we2');
```

For a better understanding of the Western Electric 2 rule, calculate and plot the 2 standard errors line on the chart.

```
x = st.mean;
cl = st.mu;
se = st.sigma./sqrt(st.n);
hold on
plot(cl+2*se, 'm')
```

Identify the measurements that violate the control rule.

```
R = controlrules('we2',x,cl,se);
I = find(R)
```

I =

```
21
23
24
25
26
```

Capability Studies

Before going into production, many manufacturers run a *capability study* to determine if their process will run within specifications enough of the time. *Capability indices* produced by such a study are used to estimate expected percentages of defective parts.

Capability studies are conducted with the *capability function*. The following capability indices are produced:

- μ — Sample mean
- σ — Sample standard deviation
- P — Estimated probability of being within the lower (L) and upper (U) specification limits
- Pl — Estimated probability of being below L
- Pu — Estimated probability of being above U
- $C_p = (U-L)/(6*\sigma)$
- $C_{pl} = (\mu-L)/(3.*\sigma)$
- $C_{pu} = (U-\mu)/(3.*\sigma)$
- $C_{pk} = \min(C_{pl}, C_{pu})$

As an example, simulate a sample from a process with a mean of 3 and a standard deviation of 0.005:

```
rng default; % For reproducibility
data = normrnd(3,0.005,100,1);
```

Compute capability indices if the process has an upper specification limit of 3.01 and a lower specification limit of 2.99:

```
S = capability(data,[2.99 3.01])
```

```
S = struct with fields:
```

```
mu: 3.0006
sigma: 0.0058
P: 0.9129
Pl: 0.0339
Pu: 0.0532
Cp: 0.5735
Cpl: 0.6088
Cpu: 0.5382
```

Cpk: 0.5382

Visualize the specification and process widths:

```
capaplot(data, [2.99 3.01]);  
grid on
```

Tall Arrays

- “Logistic Regression with Tall Arrays” on page 29-31
- “Bayesian Optimization with Tall Arrays” on page 29-41

Tall Array Support, Usage Notes, and Limitations

Descriptive Statistics and Visualization

| Function | Notes or Limitations |
|--------------|--|
| geomean | |
| harmmean | |
| kurtosis | |
| range | |
| skewness | |
| zscore | |
| confusionmat | |
| corr | Only the 'Pearson' type is supported. |
| tabulate | |
| crosstab | The fourth output, <code>labels</code> , is returned as a cell array containing M unevaluated tall cell arrays, where M is the number of input grouping variables. Each unevaluated tall cell array, <code>labels{j}</code> , contains the labels for one grouping variable. |

| Function | Notes or Limitations |
|----------|---|
| grpstats | <ul style="list-style-type: none">• If the input data is a tall array, then all grouping variables must also be tall and have the same number of rows as the data.• The <code>whichstats</code> option cannot be specified as a function handle. In addition to the current built-in options, <code>whichstats</code> can also be:<ul style="list-style-type: none">• 'Count' — Number of non-NaNs.• 'NNZ' — Number of nonzeros and non-NaNs.• 'Kurtosis' — Compute kurtosis.• 'Skewness' — Compute skewness.• 'all-stats' — Compute all summary statistics.• Group order is not guaranteed to be the same as the in-memory <code>grpstats</code> computation.• Summary statistics for <i>nonnumeric</i> variables return NaNs.• <code>grpstats</code> always operates on the first dimension.• If the input is a tall table, then the output is also a tall table. However, rather than including row names, the output tall table contains an extra variable <code>GroupLabel</code> that contains the same information. |

| Function | Notes or Limitations |
|----------------|--|
| binScatterPlot | This function is specifically designed for visualizing large data sets. Instead of plotting millions of data points, which is not very feasible, binScatterPlot summarizes the data points into bins. This “scatter plot of bins” reveals high-level trends in the data. |
| ksdensity | <ul style="list-style-type: none">• Some options that require extra passes or sorting of the input data are not supported:<ul style="list-style-type: none">• 'BoundaryCorrection'• 'Censoring'• 'Support' (support is always unbounded).• Uses standard deviation (instead of median absolute deviation) to compute the bandwidth. |

Probability Distributions

| Function | Notes or Limitations |
|--------------------------------|---|
| <p><code>datasample</code></p> | <ul style="list-style-type: none"> • <code>datasample</code> is useful as a precursor to plotting and fitting a random subset of a large data set. Sampling a large data set preserves trends in the data without requiring the use of all the data points. If the sample is small enough to fit in memory, then you can apply plotting and fitting functions that do not directly support tall arrays. • <code>datasample</code> supports sampling only along the first dimension of the data. • For tall arrays, <code>datasample</code> does not support sampling with replacement. You must specify <code>'Replace', false</code>, for example, <code>datasample(data,k,'Replace',false)</code>. • The value of <code>'Weights'</code> must be a numeric tall array of the same height as <code>data</code>. • For the syntax <code>[Y,idx] = datasample(___)</code>, the output <code>idx</code> is a tall logical vector of the same height as <code>data</code>. The vector indicates whether each data point is included in the sample. • If you specify a random number stream, then the underlying generator must support multiple streams and substreams. If you do not specify a random number stream, then <code>datasample</code> uses the stream controlled by <code>tallrng</code>. |

Cluster Analysis

| Function | Notes or Limitations |
|----------|--|
| kmeans | <p>Only random sample initialization is supported. Supported syntaxes:</p> <ul style="list-style-type: none"> • <code>idx = kmeans(X,k)</code> performs classic k-means clustering. • <code>[idx,C] = kmeans(X,k)</code> also returns the k cluster centroid locations. • <code>[idx,C,sumd] = kmeans(X,k)</code> additionally returns the k within-cluster sums of point-to-centroid distances. • <code>[___] = kmeans(___,Name,Value)</code> specifies additional name-value pair options using any of the other syntaxes. Valid options are: <ul style="list-style-type: none"> • <code>'Start'</code> — Method used to choose the initial cluster centroid positions. Value can be: <ul style="list-style-type: none"> • <code>'plus'</code> (default) — Select k observations from X using a variant of the <code>kmeans++</code> algorithm adapted for tall data. • <code>'sample'</code> — Select k observations from X at random. • Numeric matrix — A k-by-p matrix to explicitly specify starting locations. • <code>'Options'</code> — An options structure created using the <code>statset</code> function. For tall arrays, <code>kmeans</code> uses the fields listed here and ignores all other fields in the options structure: |

| Function | Notes or Limitations |
|----------|--|
| | <ul style="list-style-type: none"> • 'Display' — Level of display. Choices are 'iter' (default), 'off', and 'final'. • 'MaxIter' — Maximum number of iterations. Default is 100. • 'TolFun' — Convergency tolerance for the within-cluster sums of point-to-centroid distances. Default is 1e-4. This option field only works with tall arrays. |

Regression

| Function | Notes or Limitations |
|--|---|
| <p>The <code>loss</code> and <code>predict</code> methods of these regression classes support tall arrays:</p> <ul style="list-style-type: none"> • <code>CompactRegressionSVM</code> • <code>CompactRegressionGP</code> • <code>CompactRegressionTree</code> • <code>CompactRegressionEnsemble</code> • <code>RegressionLinear</code> • <code>RegressionKernel</code> | <ul style="list-style-type: none"> • You can use models trained on either in-memory or tall data with these methods. • The <code>loss</code> method of <code>CompactRegressionTree</code> only supports one output argument. |
| <p>The <code>resume</code> method of <code>RegressionKernel</code> supports tall arrays.</p> | <ul style="list-style-type: none"> • You can use models trained on either in-memory or tall data. • The default value for the 'IterationLimit' name-value pair argument is relaxed to 20 when you work with tall arrays. • <code>resume</code> uses a block-wise strategy. For details, see the "Algorithms" on page 32-7003 section of <code>fitrkernel</code>. |

| Function | Notes or Limitations |
|-------------|---|
| cvpartition | <ul style="list-style-type: none">• When you use cvpartition with tall arrays, the first input argument must be a grouping variable, tGroup. If you specify a tall scalar as the first input argument, cvpartition gives an error.• cvpartition supports only Holdout cross-validation for tall arrays; for example, c = cvpartition(tGroup, 'HoldOut', p) . By default, cvpartition randomly partitions observations into a training set and a test set with stratification, using the class information in tGroup. The parameter p is a scalar such that $0 < p < 1$.• To create nonstratified Holdout partitions, specify the value of the 'Stratify' name-value pair argument as false; for example, c = cvpartition(tGroup, 'Holdout', p, 'Stratify', false). |

| Function | Notes or Limitations |
|------------|--|
| fitrkernel | <ul style="list-style-type: none">• The default values for these name-value pair arguments are different when you work with tall arrays.<ul style="list-style-type: none">• 'Verbose' — Default value is 1.• 'BetaTolerance' — Default value is relaxed to 1e-3.• 'GradientTolerance' — Default value is relaxed to 1e-5.• 'IterationLimit' — Default value is relaxed to 20.• If 'KernelScale' is 'auto', then fitrkernel uses the random stream controlled by tallrng for subsampling. For reproducibility, you must set a random number seed for both the global stream and the random stream controlled by tallrng.• If 'Lambda' is 'auto', then fitrkernel might take an extra pass through the data to calculate the number of observations in X.• fitrkernel uses a block-wise strategy. For details, see “Algorithms” on page 32-7003. |

| Function | Notes or Limitations |
|----------|--|
| fitlm | <ul style="list-style-type: none"> • If any input argument to <code>fitlm</code> is a tall array, then all of the other inputs must be tall arrays as well. This includes nonempty variables supplied with the 'Weights' and 'Exclude' name-value pairs. • The 'RobustOpts' name-value pair is not supported with tall arrays. • For tall data, <code>fitlm</code> returns a <code>CompactLinearModel</code> object that contains most of the same properties as a <code>LinearModel</code> object. The main difference is that the compact object is sensitive to memory requirements. The compact object does not include properties that include the data, or that include an array of the same size as the data. The compact object does not contain these <code>LinearModel</code> properties: <ul style="list-style-type: none"> • Diagnostics • Fitted • ObservationInfo • ObservationNames • Residuals • Steps • Variables <p>You can compute the residuals directly from the compact object returned by <code>LM = fitlm(X,Y)</code> using</p> <pre>RES = Y - predict(LM,X); S = LM.RMSE; histogram(RES,linspace(-3*S,3*S,51))</pre> |

| Function | Notes or Limitations |
|----------|---|
| | <ul style="list-style-type: none"><li data-bbox="798 296 1313 390">• If the <code>CompactLinearModel</code> object is missing lower order terms that include categorical factors:<ul style="list-style-type: none"><li data-bbox="836 418 1323 512">• The <code>plotEffects</code> and <code>plotInteraction</code> methods are not supported.<li data-bbox="836 522 1228 616">• The <code>anova</code> method with the <code>'components'</code> option is not supported. |

| Function | Notes or Limitations |
|----------|--|
| fitglm | <ul style="list-style-type: none">• If any input argument to <code>fitglm</code> is a tall array, then all of the other inputs must be tall arrays as well. This includes nonempty variables supplied with the 'Weights', 'Exclude', 'Offset', and 'BinomialSize' name-value pairs.• The default number of iterations is 5. You can change the number of iterations using the 'Options' name-value pair to pass in an options structure. Create an options structure using <code>statset</code> to specify a different value for <code>MaxIter</code>.• For tall data, <code>fitglm</code> returns a <code>CompactGeneralizedLinearModel</code> object that contains most of the same properties as a <code>GeneralizedLinearModel</code> object. The main difference is that the compact object is sensitive to memory requirements. The compact object does not include properties that include the data, or that include an array of the same size as the data. The compact object does not contain these <code>GeneralizedLinearModel</code> properties:<ul style="list-style-type: none">• Diagnostics• Fitted• Offset• ObservationInfo• ObservationNames• Residuals• Steps• Variables |

| Function | Notes or Limitations |
|----------|---|
| | <p>You can compute the residuals directly from the compact object returned by <code>GLM = fitglm(X,Y)</code> using</p> <pre>RES = Y - predict(GLM,X); S = sqrt(GLM.SSE/GLM.DFE); histogram(RES,linspace(-3*S,3*S,51))</pre> |

| Function | Notes or Limitations |
|----------|---|
| lasso | <ul style="list-style-type: none"> • With tall arrays, <code>lasso</code> uses an algorithm based on ADMM (Alternating Direction Method of Multipliers). • No elastic net support. The 'Alpha' parameter is always 1. • No cross-validation ('CV' parameter) support, which includes the related parameter 'MCReps'. • The output <code>FitInfo</code> does not contain the additional fields 'SE', 'LambdaMinMSE', 'Lambda1SE', 'IndexMinMSE', and 'Index1SE'. • The 'Options' parameter is not supported because it does not contain options that apply to the ADMM algorithm. You can tune the ADMM algorithm using name-value pair arguments. • Supported name-value pair arguments are: <ul style="list-style-type: none"> • 'Lambda' • 'LambdaRatio' • 'NumLambda' • 'Standardize' • 'PredictorNames' • 'RelTol' • 'Weights' • Additional name-value pair arguments to control the ADMM algorithm are: <ul style="list-style-type: none"> • 'Rho' — Augmented Lagrangian parameter, ρ. The default value is automatic selection. |

| Function | Notes or Limitations |
|----------|--|
| | <ul style="list-style-type: none"><li data-bbox="836 296 1322 392">• 'AbsTol' — Absolute tolerance used to determine convergence. The default value is $1e-4$.<li data-bbox="836 401 1322 461">• 'MaxIter' — Maximum number of iterations. The default value is $1e4$.<li data-bbox="836 470 1322 565">• 'B0' — Initial values for the coefficients x. Logistic Regression with Tall Arrays

This example shows how to use logistic regression and other techniques to perform data analysis on tall arrays. Tall arrays represent data that is too large to fit into computer memory.

Get Data into MATLAB®

Create a datastore that references the folder location with the data. The data can be contained in a single file, a collection of files, or an entire folder. Treat 'NA' values as missing data so that `datastore` replaces them with NaN values. Select a subset of the variables to work with, and include the name of the airline (`UniqueCarrier`) as a categorical variable. Create a tall table on top of the datastore.

```
ds = datastore('airlinesmall.csv');
ds.TreatAsMissing = 'NA';
ds.SelectedVariableNames = {'DayOfWeek', 'UniqueCarrier', ...
    'ArrDelay', 'DepDelay', 'Distance'};
ds.SelectedFormats{2} = '%C';
tt = tall(ds);
tt.DayOfWeek = categorical(tt.DayOfWeek, 1:7, ...
    {'Sun', 'Mon', 'Tues', 'Wed', 'Thu', 'Fri', 'Sat'}, 'Ordinal', true)
```

Starting parallel pool (parpool) using the 'local' profile ...
connected to 12 workers.

tt =

Mx5 tall table

Late Flights

Determine the flights that are late by 20 minutes or more by defining a logical variable that is true for a late flight. Add this variable to the tall table of data, noting that it is not yet evaluated. A preview of this variable includes the first few rows.

```
tt.LateFlight = tt.ArrDelay>=20
```

```
tt =
```

```
Mx6 tall table

```

```
Evaluation completed in 12 sec
```

```
m =
```

0.1580

Late Flights by Carrier

Examine whether certain types of flights tend to be late. First, check to see if certain carriers are more likely to have late flights.

```
tt.LateFlight = double(tt.LateFlight);
late_by_carrier = gather(grpstats(tt, 'UniqueCarrier', 'mean', 'DataVar', 'LateFlight'))
```

Evaluating tall expression using the Parallel Pool 'local':

- Pass 1 of 1: Completed in 5 sec

Evaluation completed in 17 sec

late_by_carrier =

| 'AA' | AA | 14930 | 0.16236 |
| 'HA' | HA | 273 | 0.047619 |

Carriers B6 and EV have higher proportions of late flights. Carriers AQ, ML (1), and HA have relatively few flights, but lower proportions of them are late.

Late Flights by Day of Week

Next, check to see if different days of the week tend to have later flights.

```
late_by_day = gather(grpstats(tt, 'DayOfWeek', 'mean', 'DataVar', 'LateFlight'))
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 3 sec
Evaluation completed in 12 sec
```

```
late_by_day =
```

```
7x4 table
```

| GroupLabel | DayOfWeek | GroupCount | mean_LateFlight |
|------------|-----------|------------|-----------------|
| 'Wed' | Wed | 18240 | 0.18399 |
| 'Tues' | Tues | 18163 | 0.15526 |
| 'Fri' | Fri | 15839 | 0.12899 |
| 'Sat' | Sat | 16958 | 0.15603 |
| 'Mon' | Mon | 18077 | 0.14234 |
| 'Sun' | Sun | 18019 | 0.15117 |
| 'Thu' | Thu | 18227 | 0.18418 |

Wednesdays and Thursdays have the highest proportion of late flights, while Fridays have the lowest proportion.

Late Flights by Distance

Check to see if longer or shorter flights tend to be late. First, look at the density of the flight distance for flights that are late, and compare that with flights that are on time.

```
ksdensity(tt.Distance(tt.LateFlight==1))  
hold on  
ksdensity(tt.Distance(tt.LateFlight==0))  
hold off  
legend('Late', 'On time')
```

Evaluating tall expression using the Parallel Pool 'local':

- Pass 1 of 2: Completed in 3 sec

- Pass 2 of 2: Completed in 2 sec

Evaluation completed in 7 sec

Evaluating tall expression using the Parallel Pool 'local':

- Pass 1 of 2: Completed in 2 sec

- Pass 2 of 2: Completed in 2 sec

Evaluation completed in 6 sec

Flight distance does not make a dramatic difference in whether a flight is early or late. However, the density appears to be slightly higher for on-time flights at distances of about 400 miles. The density is also higher for late flights at distances of about 2000 miles. Calculate some simple descriptive statistics for the late and on-time flights.

```
late_by_distance = gather(grpstats(tt, 'LateFlight', {'mean' 'std'}, 'DataVar', 'Distance'))
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 2 sec
Evaluation completed in 6 sec
```

```
late_by_distance =
```

```
2x5 table
```

| GroupLabel | LateFlight | GroupCount | mean_Distance | std_Distance |
|------------|------------|------------|---------------|--------------|
| '0' | 0 | 1.04e+05 | 693.14 | 544.75 |
| '1' | 1 | 19519 | 750.24 | 574.12 |

Late flights are about 60 miles longer on average, although this value makes up only a small portion of the standard deviation of the distance values.

Logistic Regression Model

Build a model for the probability of a late flight, using both continuous variables (such as Distance) and categorical variables (such as DayOfWeek) to predict the probabilities. This model can help to determine if the previous results observed for each predictor individually also hold true when you consider them together.

```
glm = fitglm(tt, 'LateFlight~Distance+DayOfWeek', 'Distribution', 'binomial')
```

```
Iteration [1]: 0% completed
Iteration [1]: 100% completed
Iteration [2]: 0% completed
Iteration [2]: 100% completed
Iteration [3]: 0% completed
Iteration [3]: 100% completed
Iteration [4]: 0% completed
Iteration [4]: 100% completed
Iteration [5]: 0% completed
Iteration [5]: 100% completed
```

```
glm =
```

```
Compact generalized linear regression model:
logit(LateFlight) ~ 1 + DayOfWeek + Distance
Distribution = Binomial
```

```
Estimated Coefficients:
```

| | Estimate | SE | tStat | pValue |
|----------------|------------|------------|---------|------------|
| (Intercept) | -1.855 | 0.023052 | -80.469 | 0 |
| DayOfWeek_Mon | -0.072603 | 0.029798 | -2.4365 | 0.01483 |
| DayOfWeek_Tues | 0.026909 | 0.029239 | 0.92029 | 0.35742 |
| DayOfWeek_Wed | 0.2359 | 0.028276 | 8.343 | 7.2452e-17 |
| DayOfWeek_Thu | 0.23569 | 0.028282 | 8.3338 | 7.8286e-17 |
| DayOfWeek_Fri | -0.19285 | 0.031583 | -6.106 | 1.0213e-09 |
| DayOfWeek_Sat | 0.033542 | 0.029702 | 1.1293 | 0.25879 |
| Distance | 0.00018373 | 1.3507e-05 | 13.602 | 3.8741e-42 |

```
123319 observations, 123311 error degrees of freedom
```

```
Dispersion: 1
```

```
Chi^2-statistic vs. constant model: 504, p-value = 8.74e-105
```

The model confirms that the previously observed conclusions hold true here as well:

- The Wednesday and Thursday coefficients are positive, indicating a higher probability of a late flight on those days. The Friday coefficient is negative, indicating a lower probability.
- The Distance coefficient is positive, indicating that longer flights have a higher probability of being late.

All of these coefficients have very small p-values. This is common with data sets that have many observations, since one can reliably estimate small effects with large amounts of data. In fact, the uncertainty in the model is larger than the uncertainty in the estimates for the parameters in the model.

Prediction with Model

Predict the probability of a late flight for each day of the week, and for distances ranging from 0 to 3000 miles. Create a table to hold the predictor values by indexing the first 100 rows in the original table `tt`.

```
x = gather(tt(1:100,{'Distance' 'DayOfWeek'}));
x.Distance = linspace(0,3000)';
x.DayOfWeek(:) = 'Sun';
plot(x.Distance,predict(glm,x));

days = {'Sun' 'Mon' 'Tues' 'Wed' 'Thu' 'Fri' 'Sat'};
hold on
for j=2:length(days)
    x.DayOfWeek(:) = days{j};
    plot(x.Distance,predict(glm,x));
end
legend(days)
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 0 sec
Evaluation completed in 1 sec
```

According to this model, a Wednesday or Thursday flight of 500 miles has the same probability of being late, about 18%, as a Friday flight of about 3000 miles.

Since these probabilities are all much less than 50%, the model is unlikely to predict that any given flight will be late using this information. Investigate the model more by focusing on the flights for which the model predicts a probability of 20% or more of being late, and compare that to the actual results.

```
C = gather(crosstab(tt.LateFlight, predict(glm, tt) > .20))
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 3 sec
Evaluation completed in 3 sec
```

C =

| | |
|-------|------|
| 99613 | 4391 |
| 18394 | 1125 |

Among the flights predicted to have a 20% or higher probability of being late, about 20% were late $1125 / (1125 + 4391)$. Among the remainder, less than 16% were late $18394 / (18394 + 99613)$.

Bayesian Optimization with Tall Arrays

This example shows how to use Bayesian optimization to select optimal parameters for training a kernel classifier by using the `bayesopt` function. The sample data set `airlinesmall.csv` is a large data set that contains a tabular file of airline flight data. This example creates a tall table containing the data and uses it to run the optimization procedure.

Get Data into MATLAB®

Create a datastore that references the folder location with the data. The data can be contained in a single file, a collection of files, or an entire folder. For folders that contain a collection of files, you can specify the entire folder location, or use the wildcard character, `'*.csv'`, to include multiple files with the same file extension in the datastore. Select a subset of the variables to work with, and treat `'NA'` values as missing data so that datastore replaces them with NaN values. Create a tall table that contains the data in the datastore.

```
ds = datastore('airlinesmall.csv');
ds.SelectedVariableNames = {'Month', 'DayofMonth', 'DayOfWeek', ...
                           'DepTime', 'ArrDelay', 'Distance', 'DepDelay'};
ds.TreatAsMissing = 'NA';
tt = tall(ds) % Tall table
```

Starting parallel pool (parpool) using the 'local' profile ...
connected to 6 workers.

tt =

M×7 tall table

| Month | DayofMonth | DayOfWeek | DepTime | ArrDelay | Distance | DepDelay |

```

```

10      21      3      642      8      308
10      26      1     1021      8      296
10      23      5     2055     21     480
10      23      5     1332     13     296
10      22      4      629      4     373
10      28      3     1446     59     308
10       8      4      928      3     447
10      10      6      859     11     954
:        :        :        :        :        :
:        :        :        :        :        :

```

Standardize the predictor data after removing NaN values.

```
X = (X - nanmean(X))./nanstd(X);
```

Partition Data Set

Split the data set into training and test sets. Specify a 1/3 holdout sample for the test set.

```
rng(0) % For reproducibility
Partition = cvpartition(Y,'Holdout',1/3);
trainingInds = training(Partition); % Indices for the training set
testInds = test(Partition); % Indices for the test set
```

Perform Bayesian Optimization

Define the variables `sigma` and `lambda` to find the optimal values for the 'KernelScale' and 'Lambda' name-value pair arguments. Use `optimizableVariable` and specify a wide range for the variables because optimal values are unknown. Apply logarithmic transformation to the variables to search for the optimal values on a log scale.

```
N = gather(numel(Y)); % Evaluate the length of the tall array in memory
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 8 sec
Evaluation completed in 10 sec
```

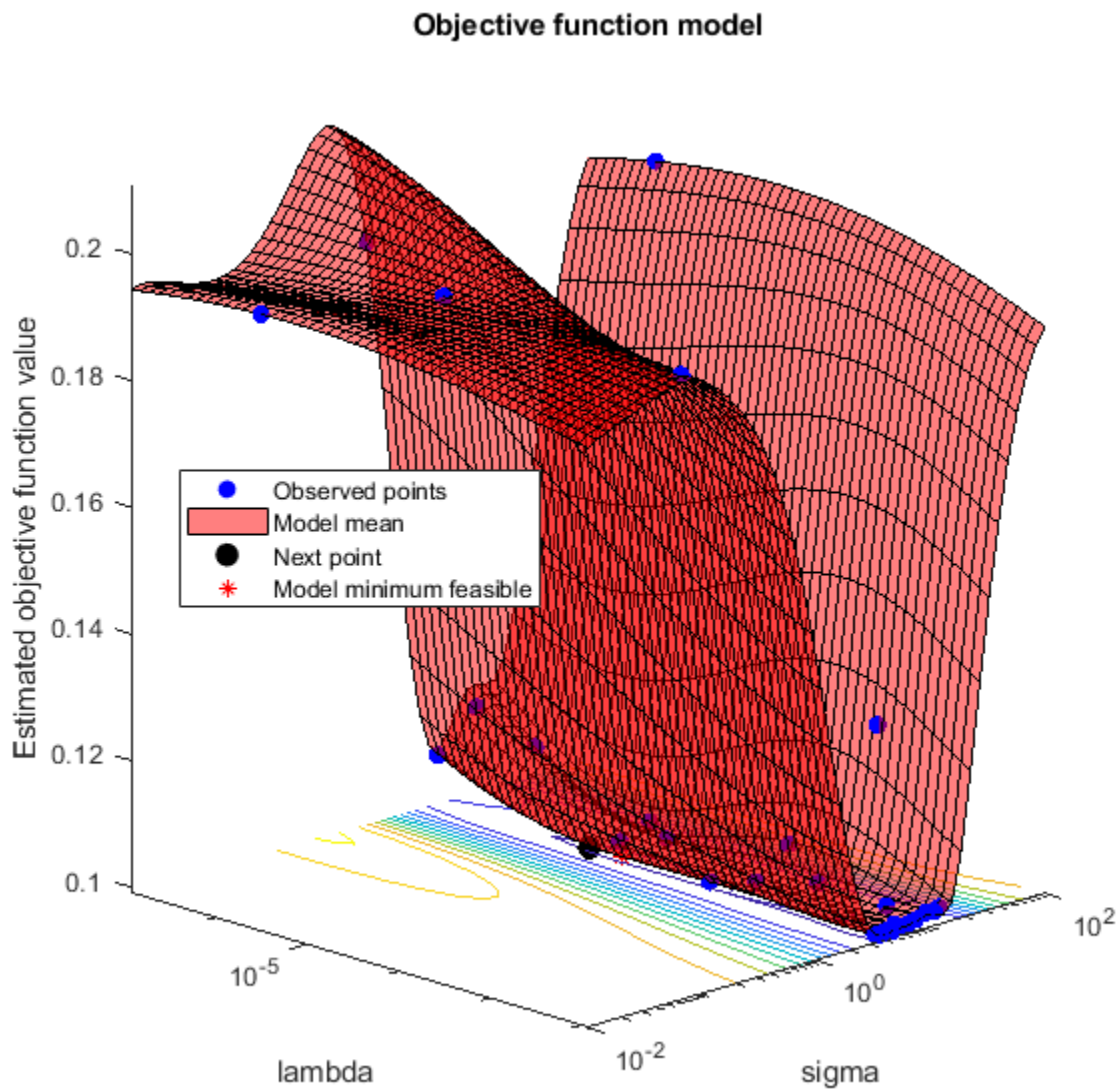

```
sigma = optimizableVariable('sigma',[1e-2,1e2],'Transform','log');
lambda = optimizableVariable('lambda',[(1e-3)/N,(1e2)/N],'Transform','log');
```

Create the objective function for Bayesian optimization. The objective function takes the input `z = [sigma,lambda]` and computes the classification loss value `z` for the binary Gaussian kernel classification model trained using the `fitckernel` function. Set 'Verbose',0 within `fitckernel` to suppress the iterative display of diagnostic information.

```
minfn = @(z)gather(loss(fitckernel(X(trainingInds,:),Y(trainingInds), ...
    'KernelScale',z.sigma,'Lambda',z.lambda,'Verbose',0), ...
    X(testInds,:),Y(testInds)));
```

Optimize the parameters `[sigma,lambda]` of the kernel classification model with respect to the classification loss by using `bayesopt`. By default, `bayesopt` displays iterative information about the optimization at the command line. For reproducibility, set the `AcquisitionFunctionName` option to 'expected-improvement-plus'. The default acquisition function depends on run time and, therefore, can give varying results.

```
results = bayesopt(minfn,[sigma,lambda],'AcquisitionFunctionName','expected-improvement-plus');
```

```

Return the best feasible point in the Bayesian model results by using the `bestPoint` function. Use the default criterion `min-visited-upper-confidence-interval`, which determines the best feasible point as the visited point that minimizes an upper confidence interval on the objective function value.

```
zbest = bestPoint(results)
```

```
zbest=1x2 table
    sigma    lambda
```

```
3.7395      8.8939e-09
```

The table `zbest` contains the optimal estimated values for the `'KernelScale'` and `'Lambda'` name-value pair arguments. You can specify these values when training a new optimized kernel classifier by using `Mdl = fitckernel(X(trainingInds,:),Y(trainingInds),'KernelScale',zbest.sigma,'Lambda',zbest.lambda)`.

For tall arrays, the optimization procedure can take a long time. If the data set is too large to run the optimization procedure, you can try to optimize the parameters by using only partial data. Use the `datasample` function and specify `'Replace','false'` to sample data without replacement.

Quick Start Parallel Computing for Statistics and Machine Learning Toolbox

Note To use parallel computing as described in this chapter, you must have a Parallel Computing Toolbox license.

In this section...

“What Is Parallel Statistics Functionality?” on page 30-2

“How To Compute in Parallel” on page 30-4

What Is Parallel Statistics Functionality?

You can use any of the Statistics and Machine Learning Toolbox functions with Parallel Computing Toolbox constructs such as `parfor` and `spmd`. However, some functions, such as those with interactive displays, can lose functionality in parallel. In particular, displays and interactive usage are not effective on workers (see “Vocabulary for Parallel Computation” on page 30-8).

Additionally, the following functions are enhanced to use parallel computing internally. These functions use `parfor` internally to parallelize calculations.

- `bootci`
- `bootstrp`
- `candexch`
- `cordexch`
- `crossval`
- `daugment`
- `dcovary`
- `jackknife`
- `kmeans`
- `lasso`
- `lassoglm`

- `nnmf`
- `plsregress`
- `rowexch`
- `sequentialfs`
- `TreeBagger`
- `TreeBagger.growTrees`

The following functions for fitting multiclass models for support vector machines and other classifiers are also enhanced to use parallel computing internally.

- `fitcecoc`
- Methods of the class `ClassificationECOC`:
 - `resubEdge`
 - `resubLoss`
 - `resubMargin`
 - `resubPredict`
 - `crossval`
- Methods of the class `CompactClassificationECOC`
 - `edge`
 - `loss`
 - `margin`
 - `predict`
- Methods of the class `ClassificationPartitionedECOC`
 - `kfoldEdge`
 - `kfoldLoss`
 - `kfoldMargin`
 - `kfoldPredict`

This chapter gives the simplest way to use these enhanced functions in parallel. For more advanced topics, including the issues of reproducibility and nested `parfor` loops, see the other sections in this chapter.

For information on parallel statistical computing at the command line, enter

```
help parallelstats
```

How To Compute in Parallel

To have a function compute in parallel:

1. “Set Up a Parallel Environment” on page 30-4
2. “Set the UseParallel Option to true” on page 30-4
3. “Call the Function Using the Options Structure” on page 30-4

Set Up a Parallel Environment

To run a statistical computation in parallel, first set up a parallel environment.

Note Setting up a parallel environment can take several seconds.

For a multicore machine, enter the following at the MATLAB command line:

```
parpool(n)
```

n is the number of workers you want to use.

Set the UseParallel Option to true

Create an options structure with the `statset` function. To run in parallel, set the `UseParallel` option to true:

```
paroptions = statset('UseParallel',true);
```

Call the Function Using the Options Structure

Call your function with syntax that uses the options structure. For example:

```
% Run crossval in parallel
cvMse = crossval('mse',x,y,'predfun',regf,'Options',paroptions);

% Run bootstrp in parallel
sts = bootstrp(100,@(x)[mean(x) std(x)],y,'Options',paroptions);

% Run TreeBagger in parallel
b = TreeBagger(50,meas,spec,'OOBPred','on','Options',paroptions);
```

For more complete examples of parallel statistical functions, see “Use Parallel Processing for Regression TreeBagger Workflow” on page 30-6, “Implement Jackknife Using Parallel Computing” on page 30-19, “Implement Cross-Validation Using Parallel Computing” on page 30-21, and “Implement Bootstrap Using Parallel Computing” on page 30-24.

After you have finished computing in parallel, close the parallel environment:

```
delete mypool
```

Tip To save time, keep the pool open if you expect to compute in parallel again soon.

Use Parallel Processing for Regression TreeBagger Workflow

This example shows you how to:

- Use an ensemble of bagged regression trees to estimate feature importance.
- Improve computation speed by using parallel computing.

The sample data is a database of 1985 car imports with 205 observations, 25 predictors, and 1 response, which is insurance risk rating, or "symboling." The first 15 variables are numeric and the last 10 are categorical. The symboling index takes integer values from -3 to 3.

Load the sample data and separate it into predictor and response arrays.

```
load imports-85;  
Y = X(:,1);  
X = X(:,2:end);
```

Set up the parallel environment to use two cores.

```
mypool = parpool(2)
```

```
Starting parallel pool (parpool) using the 'local' profile ...  
connected to 2 workers.
```

```
mypool =
```

```
Pool with properties:
```

```
    Connected: true  
    NumWorkers: 2  
    Cluster: local  
    AttachedFiles: {}  
    AutoAddClientPath: true  
    IdleTimeout: 30 minutes (30 minutes remaining)  
    SpmdEnabled: true
```

Set the options to use parallel processing.

```
paroptions = statset('UseParallel',true);
```

Estimate feature importance using leaf size 1 and 5000 trees in parallel. Time the function for comparison purposes.

```
tic
b = TreeBagger(5000,X,Y,'Method','r','OOBVarImp','on', ...
    'cat',16:25,'MinLeafSize',1,'Options',paroptions);
toc
```

Elapsed time is 70.545251 seconds.

Perform the same computation in serial for timing comparison.

```
tic
b = TreeBagger(5000,X,Y,'Method','r','OOBVarImp','on', ...
    'cat',16:25,'MinLeafSize',1);
toc
```

Elapsed time is 140.747353 seconds.

The results show that computing in parallel takes a fraction of the time it takes to compute serially. Note that the elapsed time can vary depending on your operating system.

Concepts of Parallel Computing in Statistics and Machine Learning Toolbox

| In this section... |
|--|
| “Subtleties in Parallel Computing” on page 30-8 |
| “Vocabulary for Parallel Computation” on page 30-8 |

Subtleties in Parallel Computing

There are two main subtleties in parallel computations:

- Nested parallel evaluations (see “No Nested `parfor` Loops” on page 30-12). Only the outermost `parfor` loop runs in parallel, the others run serially.
- Reproducible results when using random numbers (see “Reproducibility in Parallel Statistical Computations” on page 30-14). How can you get exactly the same results when repeatedly running a parallel computation that uses random numbers?

Vocabulary for Parallel Computation

- `worker` — An independent MATLAB session that runs code distributed by the client.
- `client` — The MATLAB session with which you interact, and that distributes jobs to workers.
- `parfor` — A Parallel Computing Toolbox function that distributes independent code segments to workers (see “Working with `parfor`” on page 30-11).
- `random stream` — A pseudorandom number generator, and the sequence of values it generates. MATLAB implements random streams with the `RandStream` class.
- `reproducible computation` — A computation that can be exactly replicated, even in the presence of random numbers (see “Reproducibility in Parallel Statistical Computations” on page 30-14).

When to Run Statistical Functions in Parallel

In this section...

“Why Run in Parallel?” on page 30-9

“Factors Affecting Speed” on page 30-9

“Factors Affecting Results” on page 30-10

Why Run in Parallel?

The main reason to run statistical computations in parallel is to gain speed, meaning to reduce the execution time of your program or functions. “Factors Affecting Speed” on page 30-9 discusses the main items affecting the speed of programs or functions. “Factors Affecting Results” on page 30-10 discusses details that can cause a parallel run to give different results than a serial run.

Note Some Statistics and Machine Learning Toolbox functions have built-in parallel computing capabilities. See Quick Start Parallel Computing for Statistics and Machine Learning Toolbox on page 30-2. You can also use any Statistics and Machine Learning Toolbox functions with Parallel Computing Toolbox functions such as `parfor` loops. To decide when to call functions in parallel, consider the factors affecting speed and results.

Factors Affecting Speed

Some factors that can affect the speed of execution of parallel processing are:

- Parallel environment setup. It takes time to run `parpool` to begin computing in parallel. If your computation is fast, the setup time can exceed any time saved by computing in parallel.
- Parallel overhead. There is overhead in communication and coordination when running in parallel. If function evaluations are fast, this overhead could be an appreciable part of the total computation time. Thus, solving a problem in parallel can be slower than solving the problem serially. For an example, see Improving Optimization Performance with Parallel Computing in MATLAB Digest, March 2009.
- No nested `parfor` loops. This is described in “Working with `parfor`” on page 30-11. `parfor` does not work in parallel when called from within another `parfor` loop. If you have programmed your custom functions to take advantage of parallel processing, the

limitation of no nested `parfor` loops can cause a parallel function to run slower than expected.

- When executing serially, `parfor` loops run slightly slower than `for` loops.
- Passing parameters. Parameters are automatically passed to worker sessions during the execution of parallel computations. If there are many parameters, or they take a large amount of memory, passing parameters can slow the execution of your computation.
- Contention for resources: network and computing. If the pool of workers has low bandwidth or high latency, parallel computation can be slow.

Factors Affecting Results

Some factors can affect results when using parallel processing. You might need to adjust your code to run in parallel, for example, you need independent loops and the workers must be able to access the variables. Some important factors are:

- Persistent or global variables. If any functions use persistent or global variables, these variables can take different values on different worker processors. The body of a `parfor` loop cannot contain global or persistent variable declarations.
- Accessing external files. The order of computations is not guaranteed during parallel processing, so external files can be accessed in unpredictable order, leading to unpredictable results. Furthermore, if multiple processors try to read an external file simultaneously, the file can become locked, leading to a read error, and halting function execution.
- Noncomputational functions, such as `input`, `plot`, and `keyboard`, can behave badly when used in your custom functions. Do not use these functions in a `parfor` loop, because they can cause a worker to become nonresponsive, since it is waiting for input.
- `parfor` does not allow `break` or `return` statements.
- The random numbers you use can affect the results of your computations. See “Reproducibility in Parallel Statistical Computations” on page 30-14.

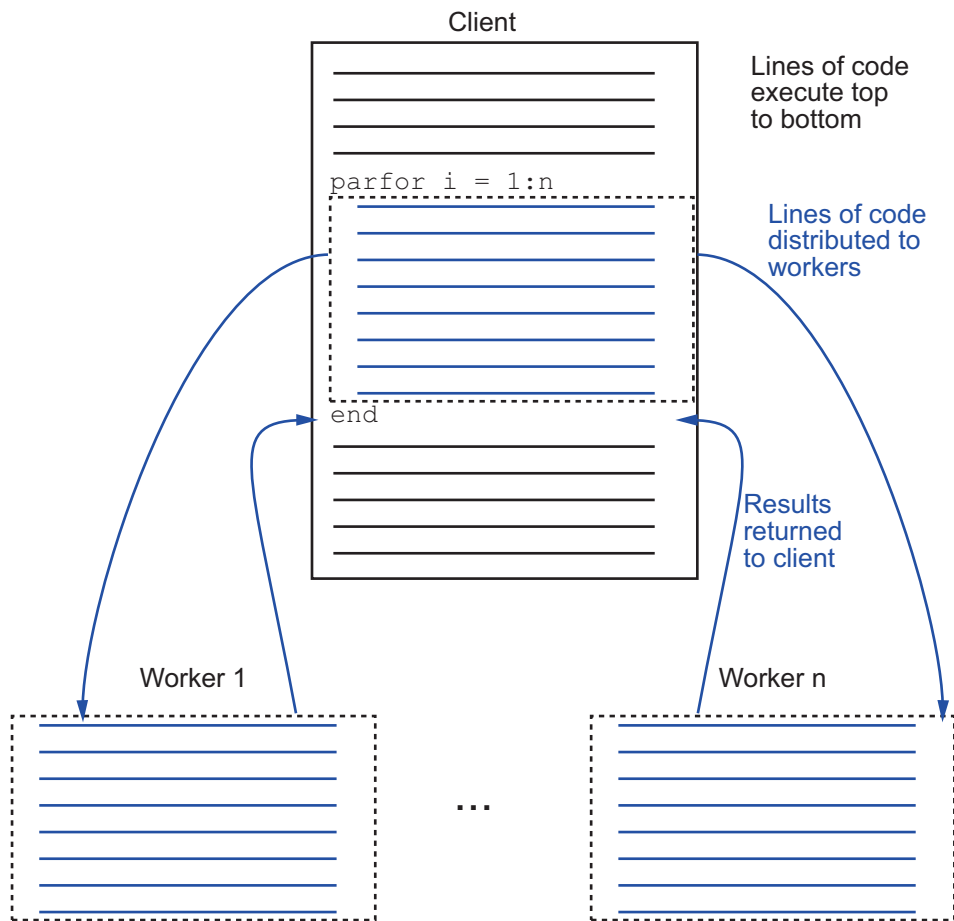

For advice on converting `for` loops to use `parfor`, see “Parallel for-Loops (`parfor`)” (Parallel Computing Toolbox).

Working with parfor

| In this section... |
|--|
| “How Statistical Functions Use parfor” on page 30-11 |
| “Characteristics of parfor” on page 30-12 |

How Statistical Functions Use parfor

parfor is a Parallel Computing Toolbox function similar to a `for` loop. Parallel statistical functions call `parfor` internally. `parfor` distributes computations to worker processors.

Characteristics of parfor

You might need to adjust your code to run in parallel, for example, you need independent loops and the workers must be able to access the variables. For advice on using `parfor`, see "Parallel for-Loops (`parfor`)" (Parallel Computing Toolbox).

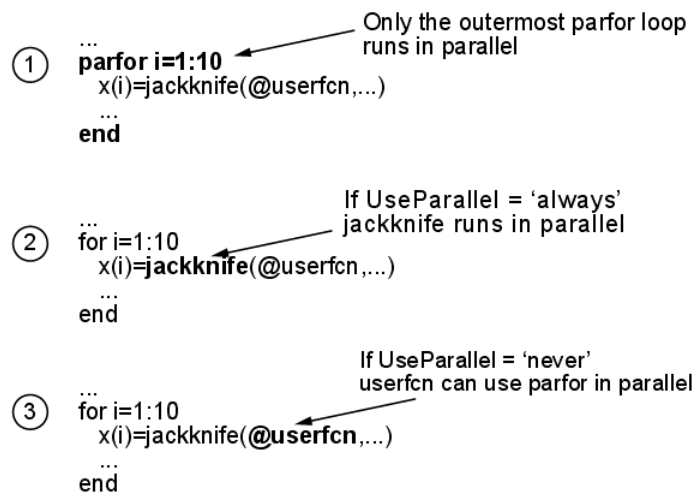

No Nested parfor Loops

`parfor` does not work in parallel when called from within another `parfor` loop, or from an `spmd` block. Parallelization occurs only at the outermost level.

Suppose, for example, you want to apply `jackknife` to your function `userfcn`, which calls `parfor`, and you want to call `jackknife` in a loop. The following figure shows three cases:

- 1 The outermost loop is `parfor`. Only that loop runs in parallel.
- 2 The outermost `parfor` loop is in `jackknife`. Only `jackknife` runs in parallel.
- 3 The outermost `parfor` loop is in `userfcn`. `userfcn` uses `parfor` in parallel.

Bold indicates the function that runs in parallel

When parfor Runs in Parallel

For help converting nested loops to use `parfor`, see “Convert for-Loops Into parfor-Loops” (Parallel Computing Toolbox).

See also Quick Start Parallel Computing for Statistics and Machine Learning Toolbox on page 30-2.

Reproducibility in Parallel Statistical Computations

In this section...

“Issues and Considerations in Reproducing Parallel Computations” on page 30-14

“Running Reproducible Parallel Computations” on page 30-14

“Parallel Statistical Computation Using Random Numbers” on page 30-15

Issues and Considerations in Reproducing Parallel Computations

A reproducible computation is one that gives the same results every time it runs. Reproducibility is important for:

- Debugging — To correct an anomalous result, you need to reproduce the result.
- Confidence — When you can reproduce results, you can investigate and understand them.
- Modifying existing code — When you change existing code, you want to ensure that you do not break anything.

Generally, you do not need to ensure reproducibility for your computation. Often, when you want reproducibility, the simplest technique is to run in serial instead of in parallel. In serial computation you can simply call the `rng` function as follows:

```
s = rng % Obtain the current state of the random stream
% run the statistical function
rng(s) % Reset the stream to the previous state
% run the statistical function again, obtain identical results
```

This section addresses the case when your function uses random numbers, and you want reproducible results in parallel. This section also addresses the case when you want the same results in parallel as in serial.

Running Reproducible Parallel Computations

To run a Statistics and Machine Learning Toolbox function reproducibly:

- 1 Set the `UseSubstreams` option to `true`.

- 2 Set the `Streams` option to a type that supports substreams: `'mlfg6331_64'` or `'mrg32k3a'`. For information on these streams, see “Choosing a Random Number Generator” (MATLAB).
- 3 To compute in parallel, set the `UseParallel` option to `true`.
- 4 Call the function with the options structure.
- 5 To reproduce the computation, reset the stream, then call the function again.

To understand why this technique gives reproducibility, see “How Substreams Enable Reproducible Parallel Computations” on page 30-16.

For example, to use the `'mlfg6331_64'` stream for reproducible computation:

- 1 Create an appropriate options structure:

```
s = RandStream('mlfg6331_64');
options = statset('UseParallel',true, ...
    'Streams',s,'UseSubstreams',true);
```

- 2 Run your parallel computation. For instructions, see Quick Start Parallel Computing for Statistics and Machine Learning Toolbox on page 30-2.
- 3 Reset the random stream:

```
reset(s);
```
- 4 Rerun your parallel computation. You obtain identical results.

For an example of a parallel computation run this reproducible way, see “Reproducible Parallel Bootstrap” on page 30-26.

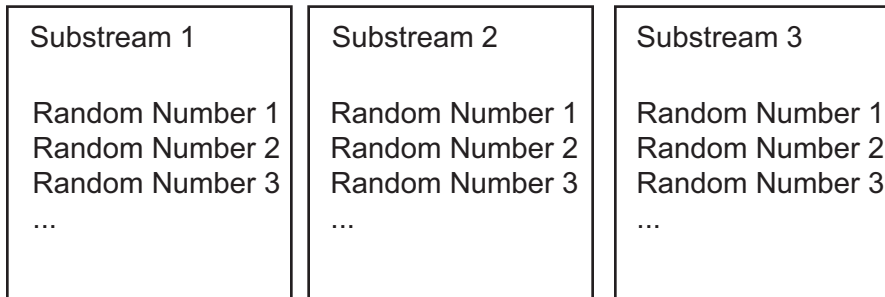

Parallel Statistical Computation Using Random Numbers

What Are Substreams?

A substream is a portion of a random stream that `RandStream` can access quickly. There is a number M such that for any positive integer k , `RandStream` can go to the kM th pseudorandom number in the stream. From that point, `RandStream` can generate the subsequent entries in the stream. Currently, `RandStream` has $M = 2^{72}$, about $5e21$, or more.

The entries in different substreams have good statistical properties, similar to the properties of entries in a single stream: independence, and lack of k -way correlation at various lags. The substreams are so long that you can view the substreams as being independent streams, as in the following picture.

Two `RandStream` stream types support substreams: `'mlfg6331_64'` and `'mrg32k3a'`.

How Substreams Enable Reproducible Parallel Computations

When MATLAB performs computations in parallel with `parfor`, each worker receives loop iterations in an unpredictable order. Therefore, you cannot predict which worker gets which iteration, so cannot determine the random numbers associated with each iteration.

Substreams allow MATLAB to tie each iteration to a particular sequence of random numbers. `parfor` gives each iteration an index. The iteration uses the index as the substream number. Since the random numbers are associated with the iterations, not with the workers, the entire computation is reproducible.

To obtain reproducible results, simply reset the stream, and all the substreams generate identical random numbers when called again. This method succeeds when all the workers use the same stream, and the stream supports substreams. This concludes the discussion of how the procedure in “Running Reproducible Parallel Computations” on page 30-14 gives reproducible parallel results.

Random Numbers on the Client or Workers

A few functions generate random numbers on the client before distributing them to parallel workers. The workers do not use random numbers, so operate purely deterministically. For these functions, you can run a parallel computation reproducibly using any random stream type.

The functions that operate this way include:

- `crossval`
- `plsregress`
- `sequentialfs`

To obtain identical results, reset the random stream on the client, or the random stream you pass to the client. For example:

```
s = rng % Obtain the current state of the random stream
% run the statistical function
rng(s) % Reset the stream to the previous state
% run the statistical function again, obtain identical results
```

While this method enables you to run reproducibly in parallel, the results can differ from a serial computation. The reason for the difference is `parfor` loops run in reverse order from `for` loops. Therefore, a serial computation can generate random numbers in a different order than a parallel computation. For unequivocal reproducibility, use the technique in “Running Reproducible Parallel Computations” on page 30-14.

Distributing Streams Explicitly

For testing or comparison using particular random number algorithms, you must set the random number generators. How do you set these generators in parallel, or initialize streams on each worker in a particular way? Or you might want to run a computation using a different sequence of random numbers than any other you have run. How can you ensure the sequence you use is statistically independent?

Parallel Statistics and Machine Learning Toolbox functions allow you to set random streams on each worker explicitly. For information on *creating* multiple streams, enter `help RandStream/create` at the command line. To create four independent streams using the 'mrg32k3a' generator:

```
s = RandStream.create('mrg32k3a', 'NumStreams', 4, ...
    'CellOutput', true);
```

Pass these streams to a statistical function using the `Streams` option. For example:

```
parpool(4) % if you have at least 4 cores
s = RandStream.create('mrg32k3a', 'NumStreams', 4, ...
    'CellOutput', true); % create 4 independent streams
paroptions = statset('UseParallel', true, ...
    'Streams', s); % set the 4 different streams
```

```
x = [randn(700,1); 4 + 2*randn(300,1)];  
latt = -4:0.01:12;  
myfun = @(X) ksdensity(X,latt);  
pdfestimate = myfun(x);  
B = bootstrp(200,myfun,x,'Options',paroptions);
```

This method of distributing streams gives each worker a different stream for the computation. However, it does not allow for a reproducible computation, because the workers perform the 200 bootstraps in an unpredictable order. If you want to perform a reproducible computation, use substreams as described in “Running Reproducible Parallel Computations” on page 30-14.

If you set the `UseSubstreams` option to `true`, then set the `Streams` option to a single random stream of the type that supports substreams (`'mlfg6331_64'` or `'mrg32k3a'`). This setting gives reproducible computations.

Implement Jackknife Using Parallel Computing

This example is from the `jackknife` function reference page, but runs in parallel.

```
mypool=parpool()
Starting parpool using the 'local' profile ... connected to 2 workers.
```

```
mypool =
```

```
Pool with properties:
```

```
AttachedFiles: {0x1 cell}
NumWorkers: 2
IdleTimeout: 30
Cluster: [1x1 parallel.cluster.Local]
RequestQueue: [1x1 parallel.RequestQueue]
SpmEnabled: 1
```

```
opts = statset('UseParallel',true);
sigma = 5;
rng('default')
y = normrnd(0,sigma,100,1);
m = jackknife(@var, y,1,'Options',opts);
n = length(y);
bias = -sigma^2 / n % known bias formula
jbias = (n - 1)*(mean(m)-var(y,1)) % jackknife bias estimate
```

```
bias =
```

```
-0.2500
```

```
jbias =
```

```
-0.3378
```

This simple example is not a good candidate for parallel computation:

```
% How long to compute in serial?
tic;m = jackknife(@var,y,1);toc
Elapsed time is 0.022771 seconds.

% How long to compute in parallel?
tic;m = jackknife(@var,y,1,'Options',opts);toc
Elapsed time is 0.299066 seconds.
```

jackknife does not use random numbers, so gives the same results every time, whether run in parallel or serial.

Implement Cross-Validation Using Parallel Computing

In this section...

“Simple Parallel Cross Validation” on page 30-21

“Reproducible Parallel Cross Validation” on page 30-22

Simple Parallel Cross Validation

This example is the same as the first in the `crossval` function reference page, but runs in parallel.

```
mypool = parpool()
Starting parpool using the 'local' profile ... connected to 2 workers.
```

```
mypool =
```

```
Pool with properties:
```

```
AttachedFiles: {0x1 cell}
NumWorkers: 2
IdleTimeout: 30
Cluster: [1x1 parallel.cluster.Local]
RequestQueue: [1x1 parallel.RequestQueue]
SpmEnabled: lopts = statset('UseParallel',true);
```

```
load('fisheriris');
y = meas(:,1);
X = [ones(size(y,1),1),meas(:,2:4)];
regf=@(XTRAIN,ytrain,XTEST)(XTEST*regress(ytrain,XTRAIN));

cvMse = crossval('mse',X,y,'Predfun',regf,'Options',opts)

cvMse =

    0.1028
```

This simple example is not a good candidate for parallel computation:

```
% How long to compute in serial?
tic;cvMse = crossval('mse',X,y,'Predfun',regf);toc
Elapsed time is 0.073438 seconds.
```

```
% How long to compute in parallel?
tic;cvMse = crossval('mse',X,y,'Predfun',regf,...
    'Options',opts);toc
Elapsed time is 0.289585 seconds.
```

Reproducible Parallel Cross Validation

To run `crossval` in parallel in a reproducible fashion, set the options and reset the random stream appropriately (see “Running Reproducible Parallel Computations” on page 30-14).

```
mypool = parpool()
```

```
Starting parpool using the 'local' profile ... connected to 2 workers.
```

```
mypool =
```

```
Pool with properties:
```

```
AttachedFiles: {0x1 cell}
NumWorkers: 2
IdleTimeout: 30
Cluster: [1x1 parallel.cluster.Local]
RequestQueue: [1x1 parallel.RequestQueue]
SpmEnabled: 1
```

```
s = RandStream('mlfg6331_64');
opts = statset('UseParallel',true,...
    'Streams',s,'UseSubstreams',true);

load('fisheriris');
y = meas(:,1);
X = [ones(size(y,1),1),meas(:,2:4)];
regf=@(XTRAIN,ytrain,XTEST)(XTEST*regress(ytrain,XTRAIN));

cvMse = crossval('mse',X,y,'Predfun',regf,'Options',opts)

cvMse =

    0.1020
```

```
Reset the stream:
```

```
reset(s)
cvMse = crossval('mse',X,y,'Predfun',regf,'Options',opts)

cvMse =
    0.1020
```

Implement Bootstrap Using Parallel Computing

In this section...

“Bootstrap in Serial and Parallel” on page 30-24

“Reproducible Parallel Bootstrap” on page 30-26

Bootstrap in Serial and Parallel

Here is an example timing a bootstrap in parallel versus in serial. The example generates data from a mixture of two Gaussians, constructs a nonparametric estimate of the resulting data, and uses a bootstrap to get a sense of the sampling variability.

- 1 Generate the data:

```
% Generate a random sample of size 1000,  
% from a mixture of two Gaussian distributions  
x = [randn(700,1); 4 + 2*randn(300,1)];
```

- 2 Construct a nonparametric estimate of the density from the data:

```
latt = -4:0.01:12;  
myfun = @(X) ksdensity(X,latt);  
pdfestimate = myfun(x);
```

- 3 Bootstrap the estimate to get a sense of its sampling variability. Run the bootstrap in serial for timing comparison.

```
tic;B = bootstrp(200,myfun,x);toc
```

Elapsed time is 10.878654 seconds.

- 4 Run the bootstrap in parallel for timing comparison:

```
mypool = parpool()  
Starting parpool using the 'local' profile ... connected to 2 workers.
```

```
mypool =
```

```
Pool with properties:
```

```
AttachedFiles: {0x1 cell}  
NumWorkers: 2  
IdleTimeout: 30  
Cluster: [1x1 parallel.cluster.Local]
```

```
RequestQueue: [1x1 parallel.RequestQueue]
SpmEnabled: 1

opt = statset('UseParallel',true);
tic;B = bootstrp(200,myfun,x,'Options',opt);toc

Elapsed time is 6.304077 seconds.
```

Computing in parallel is nearly twice as fast as computing in serial for this example.

Overlay the `ksdensity` density estimate with the 200 bootstrapped estimates obtained in the parallel bootstrap. You can get a sense of how to assess the accuracy of the density estimate from this plot.

```
hold on
for i=1:size(B,1),
    plot(latt,B(i,:), 'c:')
end
plot(latt,pdfestimate);
xlabel('x');ylabel('Density estimate')
```

Reproducible Parallel Bootstrap

To run the example in parallel in a reproducible fashion, set the options appropriately (see “Running Reproducible Parallel Computations” on page 30-14). First set up the problem and parallel environment as in “Bootstrap in Serial and Parallel” on page 30-24. Then set the options to use substreams along with a stream that supports substreams.

```
s = RandStream('mlfg6331_64'); % has substreams
opts = statset('UseParallel',true,...
    'Streams',s,'UseSubstreams',true);
B2 = bootstrap(200,myfun,x,'Options',opts);
```

To rerun the bootstrap and get the same result:

```
reset(s) % set the stream to initial state
B3 = bootstrp(200,myfun,x,'Options',opts);
isequal(B2,B3) % check if same results

ans =
     1
```

Code Generation Workflows at Command Line

| |
|---|
| In this section... |
| “General Code Generation Support and Limitations” on page 31-2 |
| “Code Generation Workflow” on page 31-3 |
| “Code Generation Workflow for Prediction” on page 31-5 |
| “Code Generation Workflow for Nearest Neighbor Searcher” on page 31-7 |

Certain Statistics and Machine Learning Toolbox functions have been enabled to generate C code using MATLAB Coder. However, such functions have limitations that can require workflow adjustments. To determine which Statistics and Machine Learning Toolbox functions support code generation and whether there are limitations, see “Code Generation Support, Usage Notes, and Limitations” on page 31-40.

Note To generate code that uses Statistics and Machine Learning Toolbox functions, you must install MATLAB Coder software.

General Code Generation Support and Limitations

The `codegen` function, which is included in MATLAB Coder, generates C code for a function given these conditions:

- Call the function within a MATLAB function that you define, for example, `foo.m`, and then generate code from `foo.m`. That is, MATLAB Coder cannot generate code for functions at the top level. All functions within `foo.m` must support code generation. For a list of all functions that support code generation, see “Functions and Objects Supported for C/C++ Code Generation — Category List” (MATLAB Coder).
- The input arguments of `foo.m` cannot be classification or regression model objects. That is, the `-args` option of `codegen` does not accept these objects. For supported classification and regression models, work around this limitation by saving the model at the command line using `saveCompactModel`. Then load the model within `foo.m` using `loadCompactModel`.
- The MATLAB Coder limitations also apply to Statistics and Machine Learning Toolbox for code generation. In particular, code generation does not support categorical arrays, sparse matrices, and tables. For details, see “MATLAB Language Features Supported for C/C++ Code Generation” (MATLAB Coder).

- Code generation in Statistics and Machine Learning Toolbox does not support strings.

Code Generation Workflow

To generate code for Statistics and Machine Learning Toolbox functions at the command line or using the MATLAB Coder app, follow these steps:

- 1 Define a MATLAB function, as you would normally, using functions from Statistics and Machine Learning Toolbox that support code generation. Ensure that you type the `%#codegen` compiler directive somewhere in the function. Add the `%#codegen` directive (or pragma) to your function after the function signature to indicate that you intend to generate code for the MATLAB® algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation.

For example, to generate code that estimates the interquartile range of a data set, define this function.

```
function r = iqrCodeGen(x) %#codegen
%IQRCODEGEN Estimate interquartile range
% iqrCodeGen returns the interquartile range of the data x,
% a single- or double-precision vector.
r = iqr(x);
end
```

You can allow for optional input arguments by specifying `varargin` as an input argument. For an example, see “Specify Variable-Sized Arguments for Code Generation” on page 31-48.

- 2 To generate C code, you must have access to a C compiler, and the compiler must be configured properly. For more details, see “Setting Up Your C Compiler” (MATLAB Coder). For example, to set up the compiler for MEX-code generation, enter

```
mex -setup
```

- 3 Determine the environment in which you plan to deploy the generated code. Generated code can run:

- Inside the MATLAB environment as a C-MEX file
- Outside the MATLAB environment as a standalone executable
- Outside the MATLAB environment as a shared utility linked to another standalone executable

Generating a MEX file allows you to analyze its input and output arguments using MATLAB tools before deploying the function outside the MATLAB environment. In a MEX function, you can include code for verification, but not for code generation by declaring those commands as extrinsic using `coder.extrinsic`. Extrinsic commands can include functions that do not have code generation support. All extrinsic commands in the MEX function run in MATLAB, but `codegen` does not generate code for them.

If you plan to deploy the code outside the MATLAB environment, then you must generate a standalone executable. One way to specify your compiler choice is by using the `-config` option of `codegen`. For example, to generate a static C executable, specify `-config:exe` when you call `codegen`. For more details on setting code generation options, see the `-config` option of `codegen` and “Configure Build Settings” (MATLAB Coder).

- 4 Generate code for the function. When you generate code, you must define the size, class, and complexity of all inputs to the function. Create a commensurate variable in the Workspace.
 - To generate code at the command line, use `codegen`. Declare all input argument dimensions and data types when you call `codegen` using the `-args` option.
 - To specify the data type and exact dimensions, pass such a variable with the desired dimensions. For example, to specify that the MEX file generated from `iqrCodeGen.m` must accept a double-precision numeric column vector with 100 elements, enter:

```
testX = randn(100,1);  
codegen iqrCodeGen.m -args {testX} -report
```

The `-report` flag generates a code generation report.

- To specify that at least one of the dimensions can have any length, then create a variable by using `coder.typeof`. Specify the data type, maximal dimensions, and which dimension can vary, respectively. Such a specification is convenient for an input data set that, at compile time, has an unknown number of observations. For example, to specify that the MEX file generated from `iqrCodeGen.m` can accept a double-precision numeric column vector of any length, enter:

```
testX = coder.typeof(0,[Inf,1],[1,0]);  
codegen iqrCodeGen.m -args {testX} -report
```

For an example, see “Specify Variable-Sized Arguments for Code Generation” on page 31-48.

- To specify character array, such as supported name-value pair arguments, declare the character array as a constant using `coder.Constant`. For example, suppose that 'Name' is a valid name-value pair argument for `iqrCodeGen.m`, and the corresponding value, `value`, is numeric. Enter:

```
codegen iqrCodeGen.m -args {testX,coder.Constant('Name'),value} -report
```

- To generate code using the MATLAB Coder app, see “Generate MEX Functions by Using the MATLAB Coder App” (MATLAB Coder).

Irrespective of how you generate code, MATLAB creates a folder in your current working folder containing, among other things, the generated code. In the example, suppose that you generate the code on a 64-bit windows machine and `pwd` is your current working folder. Then, the generated MEX-file is `iqrCodeGen_mex.mexw64` in `pwd/codegen/mex/iqrCodeGen`.

- 5 If code generation failed, then review the report. A report link populates at the command line, but you can also find the report in the `html` folder at the same level as the MEX file. In the report, MATLAB Coder identifies:
 - Readiness issues, that is, MATLAB Coder flags unsupported features or functions.
 - Build issues, that is, coding patterns that are not supported for code generation.

After viewing the report, modify your MATLAB code until you get a successful build.

Code Generation Workflow for Prediction

Certain classification and regression model classes have a `predict` function that supports code generation. Because prediction requires a trained classification or regression model object, you must adjust your workflow slightly to accommodate code generation. The `-args` option of `codegen` does not accept these objects. For supported classification and regression models, work around this limitation by using `saveCompactModel` and `loadCompactModel` as described below. The following steps describe a brief workflow for label prediction using a classification model. For more detailed example code, see “Specify Variable-Sized Arguments for Code Generation” on page 31-48.

To generate code for label prediction using a classification model at the command line, follow these steps (for regression model prediction, the workflow is similar):

1. Train a classification model object equipped with a code-generation enabled `predict` function. Ensure that you specify only those name-value pairs arguments that are enabled for code-generation. For example, to train a support vector machine (SVM) using the predictor data in `X` and class labels in `Y`, enter:

```
load fisheriris
inds = ~strcmp(species,'setosa');
X = meas(inds,3:4);
Y = species(inds);
Mdl = fitcsvm(X,Y);
```

This step can include data preprocessing, feature selection, and optimizing the model using, for example, cross-validation.

2. Save the classification model to disk using `saveCompactModel`. For example, enter `saveCompactModel(Mdl,'SVMModel');`

MATLAB™ makes the full classification model `Mdl` compact, and then saves it to the MATLAB binary file `SVMModel.mat` as a structure array in the current working folder.

3. Define a MATLAB function that returns predicted labels for input predictor data. Within the function, load the trained classification model, and then pass the loaded model to `predict`. For example, define this function, which predicts labels using the SVM model `Mdl`.

```
type predictLabelsSVM.m % Display contents of predictLabelsSVM.m file

function label = predictLabelsSVM(x) %#codegen
%PREDICTLABELSSVM Label new observations using trained SVM model Mdl
% predictLabelsSVM predicts the vector of labels label using
% the saved SVM model Mdl and the predictor data x.
Mdl = loadCompactModel('SVMModel');
label = predict(Mdl,x);
end
```

Ensure that you type the `%#codegen` compiler directive somewhere in the function.

4. Set up the compiler for MEX-code generation and generate code for the function. For more details, see steps 2-5 of “Code Generation Workflow” on page 31-3.

```
mex -setup
```

```
MEX configured to use 'Microsoft Visual C++ 2015 (C)' for C language compilation.
Warning: The MATLAB C and Fortran API has changed to support MATLAB
```

variables with more than $2^{32}-1$ elements. You will be required to update your code to utilize the new API. You can find more information about this at: https://www.mathworks.com/help/matlab/matlab_external/upgrading-mex-files-to-use-

To choose a different C compiler, execute one from the following:
 For MinGW64 Compiler (C): `mex -setup:B:\matlab\bin\win64\mexopts\mingw64.xml C`
 For Intel C++ Composer XE 2013 with Microsoft Visual Studio 2013 (C): `mex -setup:B:\matlab\bin\win64\mexopts\icc2013.xml C`
 For Microsoft Visual C++ 2013 (C): `mex -setup:B:\matlab\bin\win64\mexopts\msvc2013.xml C`
 For Microsoft Visual C++ 2015 (C): `mex -setup:B:\matlab\bin\win64\mexopts\msvc2015.xml C`
 For Microsoft Visual C++ 2012 (C): `mex -setup:B:\matlab\bin\win64\mexopts\msvc2012.xml C`

To choose a different language, execute one from the following:
`mex -setup C++`
`mex -setup FORTRAN`

```
codegen predictLabelsSVM.m -args {X} -report
```

Code generation successful: To view the report, open('codegen\mex\predictLabelsSVM\html')

5. Verify whether `predictLabelsSVM` and the MEX-file returns the expected labels by passing some predictor data. Then, compare the predicted labels. For example,

```
labels1 = resubPredict(Mdl);
labels2 = predictLabelsSVM(X);
labels3 = predictLabelsSVM_mex(X);
verifyMEX = isequal(labels1,labels2,labels3)
```

```
verifyMEX = logical
           1
```

`isequal` returns logical 1 (true) if all the inputs are equal. The comparison confirms that the `predictLabelsSVM` function and MEX-file return the expected labels.

Code Generation Workflow for Nearest Neighbor Searcher

Nearest neighbor searcher objects, `ExhaustiveSearcher` and `KDTreeSearcher`, can be an input argument of a function you define for code generation. The `-args` option of `codegen` accept a compile-time constant searcher object.

This example shows how to generate code for finding the nearest neighbor using an exhaustive searcher object at the command line. This example shows two different

methods depending on the way you use the object: load the object by using `loadCompactModel` in a function you define, or pass a compile-time constant object to the generated code.

Train Exhaustive Nearest Neighbor Searcher

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng('default');           % For reproducibility
n = size(meas,1);         % Sample size
qIdx = randsample(n,5);   % Indices of query data
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);
```

Prepare an exhaustive nearest neighbor searcher using the training data. Specify the 'Distance' and 'P' name-value pair arguments to use the Minkowski distance with an exponent of 1 for finding the nearest neighbor.

```
Mdl = ExhaustiveSearcher(X,'Distance','minkowski','P',1);
```

Find the index of the training data (X) that is the nearest neighbor of each point in the query data (Y).

```
Idx = knnsearch(Mdl,Y);
```

Set Up C Compiler

To generate C code, you must have access to a C compiler, and the compiler must be configured properly. You can use `mex -setup` to change the default compiler. For more details, see “Set Up Your C Compiler” (MATLAB Coder).

```
mex -setup
```

```
MEX configured to use 'Microsoft Visual C++ 2015 (C)' for C language compilation.
Warning: The MATLAB C and Fortran API has changed to support MATLAB
variables with more than 2^32-1 elements. You will be required
to update your code to utilize the new API.
You can find more information about this at:
https://www.mathworks.com/help/matlab/matlab\_external/upgrading-mex-files-to-use-
```

To choose a different C compiler, execute one from the following:

```

For MinGW64 Compiler (C): mex -setup:B:\matlab\bin\win64\mexopts\mingw64.xml C
For Intel C++ Composer XE 2013 with Microsoft Visual Studio 2013 (C): mex -setup:B:\matlab\bin\win64\mexopts\icc2013.xml C
For Microsoft Visual C++ 2013 (C): mex -setup:B:\matlab\bin\win64\mexopts\msvc2013.xml C
For Microsoft Visual C++ 2015 (C): mex -setup:B:\matlab\bin\win64\mexopts\msvc2015.xml C
For Microsoft Visual C++ 2012 (C): mex -setup:B:\matlab\bin\win64\mexopts\msvc2012.xml C

```

To choose a different language, execute one from the following:

```

mex -setup C++
mex -setup FORTRAN

```

Generate Code Using `saveCompactModel` and `loadCompactModel`

Generate code that loads an exhaustive searcher, takes query data as an input argument, and then finds the nearest neighbor.

Save the exhaustive searcher to a file using `saveCompactModel`.

```
saveCompactModel(Mdl, 'searcherModel')
```

`saveCompactModel` saves the model to the MATLAB binary file `searcherModel.mat` as a structure array in the current folder.

Define a function `myknnsearch1` that takes query data as an input argument. Within the function, load the searcher object by using `loadCompactModel`, and then pass the loaded model to `knnsearch`.

```
type myknnsearch1.m % Display contents of myknnsearch1.m file
```

```

function idx = myknnsearch1(x) %#codegen
Mdl = loadCompactModel('searcherModel');
idx = knnsearch(Mdl,x);
end

```

Be sure to type the `%#codegen` compiler directive somewhere in the function.

Generate code for `myknnsearch1` by using `codegen`. Specify the data type and dimension of the input argument by using `coder.typeof`. For more details, see “Specify Variable-Sized Arguments for Code Generation” on page 31-48.

```
codegen myknnsearch1.m -args {coder.typeof(Y,[Inf,4],[1,0])} -report
```

Warning: C Compiler produced warnings. See the build log for further details.

Code generation successful (with warnings): To view the report, open('codegen\mex\myknnsearch1.m')

Verify that `myknnsearch1` and the MEX file return the expected indices by passing the query data (`Y`).

```
myIdx1 = myknnsearch1(Y);
myIdx1_mex = myknnsearch1_mex(Y);
verifyMEX1 = isequal(Idx,myIdx1,myIdx1_mex)

verifyMEX1 = logical
    1
```

`isequal` returns logical 1 (true) if all the inputs are equal. This comparison confirms that `myknnsearch1` and the MEX file return the expected results.

Generate Code with Constant Folded Model Object

Define a function `myknnsearch2` that takes both an exhaustive searcher model and query data as input arguments instead of loading the model in the function.

```
type myknnsearch2.m % Display contents of myknnsearch2.m file

function idx = myknnsearch2(Mdl,x) %#codegen
idx = knnsearch(Mdl,x);
end
```

To generate code that takes the model object as well as the query data, designate the model object as a compile-time constant by using `coder.Constant` and include the constant folded model object in the `-args` value of `codegen`.

```
codegen myknnsearch2.m -args {coder.Constant(Mdl),coder.typeof(Y,[Inf,4],[1,0])} -report
```

Warning: C Compiler produced warnings. See the build log for further details.

Code generation successful (with warnings): To view the report, open('codegen\mex\myknnsearch2.m')

Verify that `myknnsearch2` and the MEX file return the expected results.

```
myIdx2 = myknnsearch2(Mdl,Y);
myIdx2_mex = myknnsearch2_mex(Mdl,Y);
verifyMEX2 = isequal(Idx,myIdx2,myIdx2_mex)

verifyMEX2 = logical
    1
```

Generate Code with Name-Value Pair Arguments

Define a function that takes a model object, query data, and name-value pair arguments.

```
type myknnsearch3.m % Display contents of myknnsearch3.m file

function idx = myknnsearch3(Mdl,x,varargin) %#codegen
idx = knnsearch(Mdl,x,varargin{:});
end
```

To generate code that allows a user-defined exponent for the Minkowski distance, include `{coder.Constant('P'),0}` in the `-args` value of `codegen`.

```
codegen myknnsearch3.m -args {coder.Constant(Mdl),coder.typeof(Y,[Inf,4],[1,0]),coder.Constant('P'),0}
```

Warning: C Compiler produced warnings. See the build log for further details.

Code generation successful (with warnings): To view the report, open('codegen\mex\myknnsearch3.m')

Verify that `myknnsearch3` and the MEX file return the expected results.

```
newIdx = knnsearch(Mdl,Y,'P',2);
myIdx3 = myknnsearch3(Mdl,Y,'P',2);
myIdx3_mex = myknnsearch3_mex(Mdl,Y,'P',2);
verifyMEX3 = isequal(newIdx,myIdx3,myIdx3_mex)

verifyMEX3 = logical
    1
```

Code Generation Workflow Using MATLAB Coder App

This example shows how to generate code for Statistics and Machine Learning Toolbox™ functions involving model objects by using the MATLAB® Coder™ app.

Certain classification and regression model objects have a `predict` function that supports code generation. Prediction requires a trained classification or regression model object, but the `-args` option of `codegen` does not accept these objects. Therefore, you must adjust your workflow slightly to accommodate code generation by using the `saveCompactModel` and `loadCompactModel` functions. Save a trained model by using the `saveCompactModel` function, and load the model by using the `loadCompactModel` function in the *entry-point* function. The entry-point function, also known as the *top-level* or *primary* function, is a function you define for code generation.

In this example, you train a classification ensemble model using *k*-nearest-neighbor weak learners. After training and saving the classification model, define the entry-point function and write a script to test the function. Then, use the MATLAB Coder app to generate code.

Train Classification Model

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Train a classification ensemble model with *k*-nearest-neighbor weak learners by using the random subspace method. For details of classifications that use a random subspace ensemble, see “Random Subspace Classification” on page 18-134.

```
learner = templateKNN('NumNeighbors',2);  
Mdl = fitensemble(X,Y,'Method','Subspace','NPredToSample',5, ...  
    'Learners',learner,'NumLearningCycles',13);
```

Save Model Using `saveCompactModel`

Save the trained ensemble model to a file named `knnEnsemble.mat` in your current folder.

```
saveCompactModel(Mdl,'knnEnsemble')
```

Define Entry-Point Function

In a new file in your current folder, define an entry-point function named `myknnEnsemblePredict` that does the following:

- Accept input data (`X`), the file name of the saved model (`fileName`), and valid name-value pair arguments of the `predict` function (`varargin`).
- Load a trained ensemble model by using `loadCompactModel`.
- Predict labels and corresponding scores from the loaded model.

type `myknnEnsemblePredict.m` % Display the contents of `myknnEnsemblePredict.m` file.

```
function [label,score] = myknnEnsemblePredict(X,fileName,varargin) %#codegen
CompactMdl = loadCompactModel(fileName);
[label,score] = predict(CompactMdl,X,varargin{:});
end
```

Note: If you click the **Open Live Script** button (located in the upper-right section of this page) and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file (`myknnEnsemblePredict.m`) and the test file (`test_myknnEnsemblePredict.m`, described later on).

Set Up C Compiler

To generate C code, you must have access to a C compiler, and the compiler must be configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Set Up Your C Compiler” (MATLAB Coder).

```
mex -setup
```

```
MEX configured to use 'Microsoft Visual C++ 2015 (C)' for C language compilation.
Warning: The MATLAB C and Fortran API has changed to support MATLAB
variables with more than 2^32-1 elements. You will be required
to update your code to utilize the new API.
You can find more information about this at:
https://www.mathworks.com/help/matlab/matlab_external/upgrading-mex-files-to-use-
```

To choose a different C compiler, execute one from the following:

```
For MinGW64 Compiler (C): mex -setup:B:\matlab\bin\win64\mexopts\mingw64.xml C
For Intel C++ Composer XE 2013 with Microsoft Visual Studio 2013 (C): mex -setup:B:\m
For Microsoft Visual C++ 2013 (C): mex -setup:B:\matlab\bin\win64\mexopts\msvc2013.xml
For Microsoft Visual C++ 2015 (C): mex -setup:B:\matlab\bin\win64\mexopts\msvc2015.xml
```

For Microsoft Visual C++ 2012 (C): `mex -setup:B:\matlab\bin\win64\mexopts\msvc2012.xml`

To choose a different language, execute one from the following:

```
mex -setup C++
mex -setup FORTRAN
```

Create Test File

Write a test script that calls the `myknnEnsemblePredict` function. In the test script, specify the input arguments and name-value pair arguments that you use in the generated code. You use this test script to define input types automatically when generating code using the MATLAB Coder app.

In this example, create the `test_myknnEnsemblePredict.m` file in your current folder, as shown.

```
type test_myknnEnsemblePredict.m % Display the contents of test_myknnEnsemblePredict.m
%% Load Sample data
load ionosphere

%% Test myknnEnsemblePredict
[label,score] = myknnEnsemblePredict(X,'knnEnsemble','Learners',1:13);
```

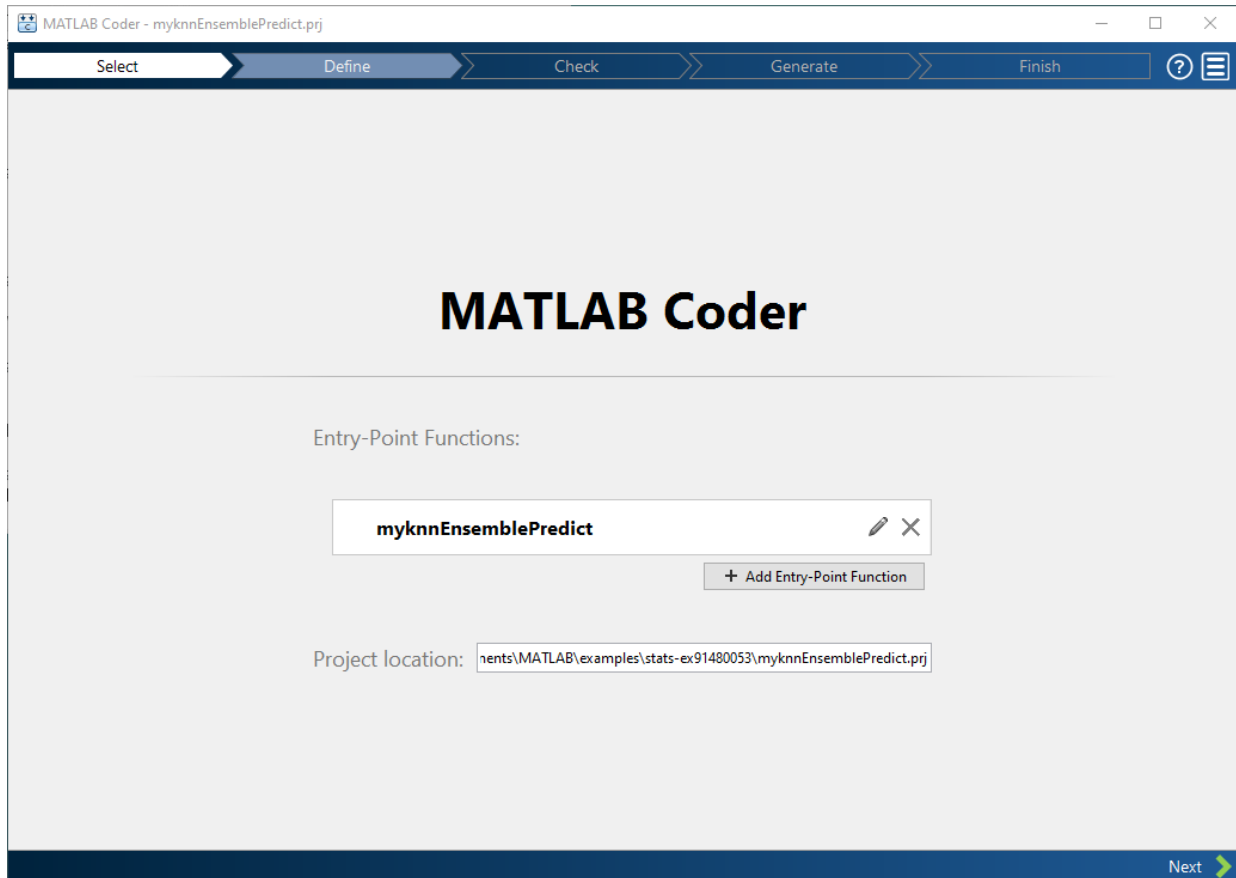

For details, see “Automatically Define Input Types by Using the App” (MATLAB Coder).

Generate Code Using MATLAB Coder App

The MATLAB Coder app generates C or C++ code from MATLAB® code. The workflow-based user interface steps you through the code generation process. The following steps describe a brief workflow of the MATLAB Code App. For more details, see MATLAB Coder and “C Code Generation Using the MATLAB Coder App” (MATLAB Coder).

1. Open the MATLAB Code App and Select the Entry-Point Function File.

On the **Apps** tab, in the **Apps** section, click the **Show more** arrow to open the apps gallery. Under **Code Generation**, click **MATLAB Coder**. The app opens the **Select Source Files** page. Enter or select the name of the entry-point function, `myknnEnsemblePredict`.

Click **Next** to go to the **Define Input Types** page.

2. Define Input Types

Because C uses static typing, MATLAB Coder must determine the properties of all variables in the MATLAB files at compile time. Therefore, you need to specify the properties of the entry-point function inputs.

Enter or select the test script `test_myknnEnsemblePredict` and click **Autodefine Input Types**.

The MATLAB Coder app recognizes input types of the myknnEnsemblePredict function based on the test script.

Modify the input types:

- X — The app infers that input X is double(351 x 34). The number of predictors must be fixed to be the same as the number of predictors in the trained model. However, you can have a different number of observations for prediction. If the number of observations is unknown, change double(351 x 34) to double(:351 x 34) or double(:inf x 34). The setting double(:351 x 34) allows the number of observations up to 351, and the setting double(:inf x 34) allows an unbounded

number of observations. In this example, specify `double(:inf x 34)` by clicking 351 and selecting `:inf`.

- `fileName` — Click **char**, select **Define Constant**, and type the file name with single quotes, `'knnEnsemble'`.
- `varargin{1}` — Names in name-value pair arguments must be compile-time constants. Click **char**, select **Define Constant**, and type `'Learners'`.
- `varargin{2}` — To allow user-defined indices up to 13 weak learners in the generated code, change `double(1 x 13)` to `double(1 x :13)`.

Define Input Types

To convert MATLAB to C, you must define the type of each input for every entry point function. [Learn more](#)

To **automatically define input types**, call `myknnEnsemblePredict` or enter a script that calls `myknnEnsemblePredict` in the MATLAB prompt below:

```
>> test_myknnEnsemblePredict
```

Autodefine Input Types

myknnEnsemblePredict.m Number of outputs: 2

| | |
|-------------|------------------|
| X | double(inf x 34) |
| fileName | 'knnEnsemble' |
| varargin | cell(1 x 2) + |
| varargin(1) | 'Learners' |
| varargin(2) | double(1 x :13) |

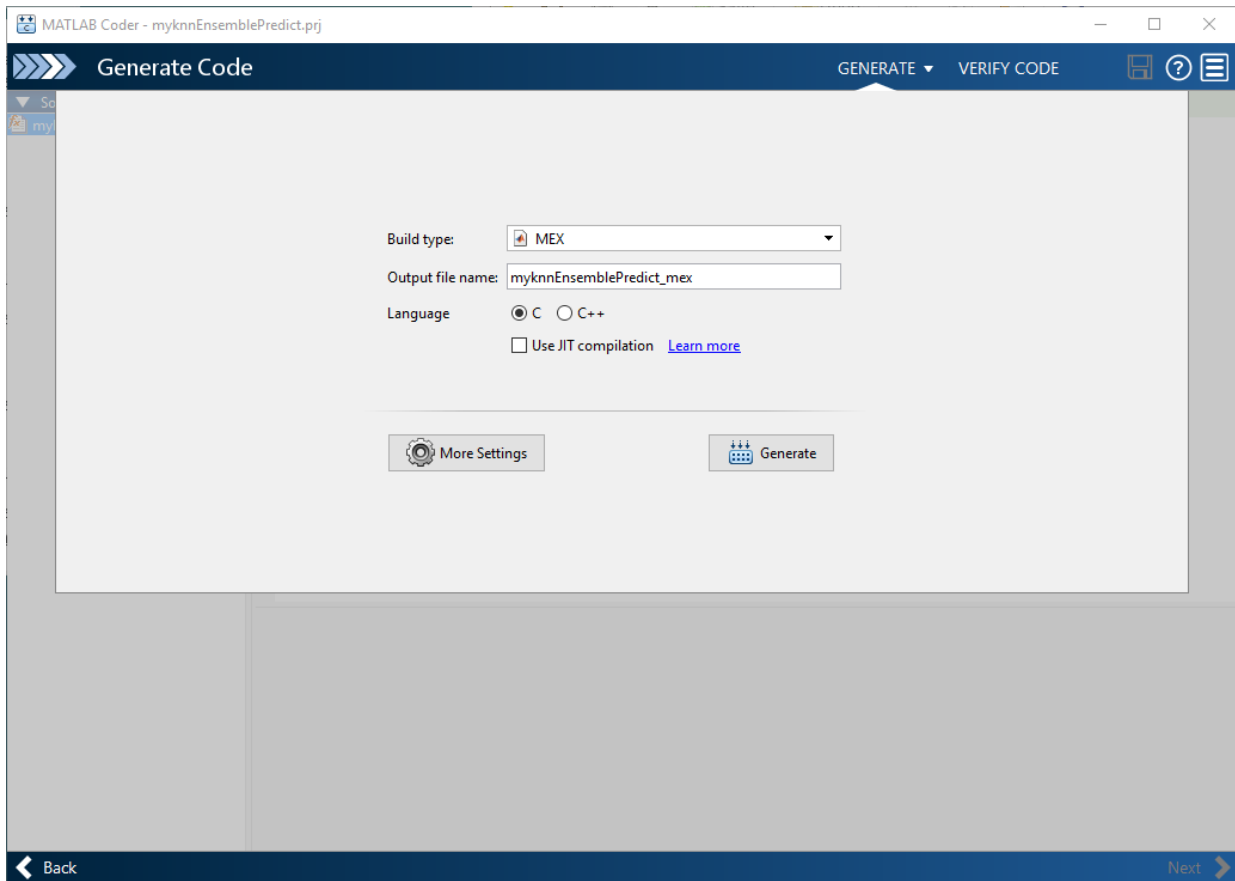

Add global

Back Next

Click **Next** to go to the **Check for Run-Time Issues** page. This optional step generates a MEX file, runs the MEX function, and reports issues. Click **Next** to go to the **Generate Code** page.

3. Generate C Code

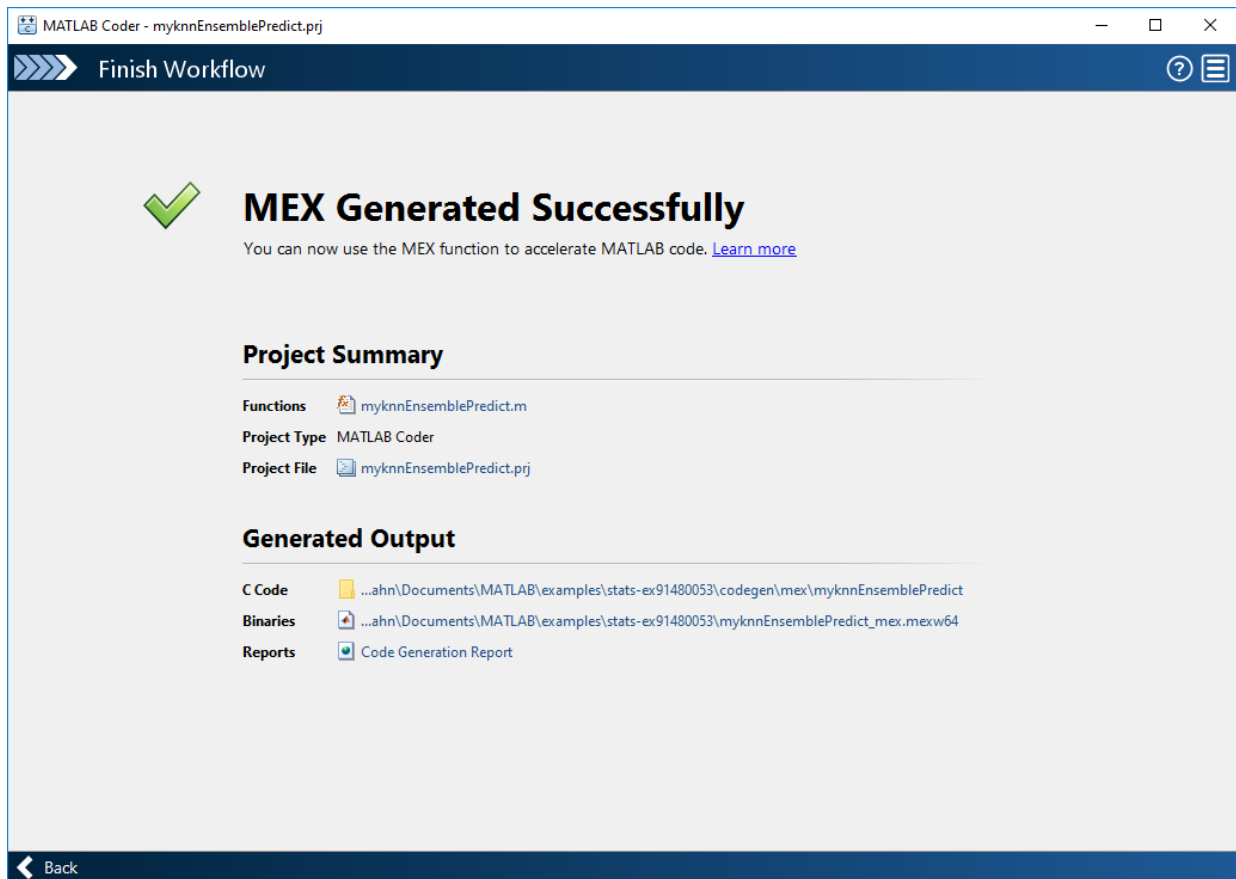

Set **Build type** to MEX and click **Generate**. The app generates a MEX function, `myknnEnsemblePredict_mex`, which you can use to analyze its input and output arguments in MATLAB before deploying the function outside the MATLAB environment. For details on setting a build type, see “Configure Build Settings” (MATLAB Coder).

Click **Next** to go to the **Finish Workflow** page.

4. Review the Finish Workflow Page

The **Finish Workflow** page indicates that code generation succeeded. This page also provides a project summary and links to generated output.

Generate Code Using Script

You can convert a MATLAB Coder project to the equivalent script of MATLAB commands after you define input types. Then you run the script to generate code. For details, see “Convert MATLAB Coder Project to MATLAB Script” (MATLAB Coder).

On the MATLAB Coder app toolbar, click the **Open action menu** button.

Select **Convert to script**, and then click **Save**. The app creates the file `myknnEnsemblePredict_script.m`, which reproduces the project in a configuration object and runs the codegen function.

Display the contents of the file `myknnEnsemblePredict_script.m`.

type `myknnEnsemblePredict_script.m`

```
% MYKNNENSEMBLEPREDICT_SCRIPT Generate MEX-function myknnEnsemblePredict_mex
% from myknnEnsemblePredict.
%
% Script generated from project 'myknnEnsemblePredict.prj' on 17-Nov-2017.
%
% See also CODER, CODER.CONFIG, CODER.TYPEOF, CODEGEN.

%% Create configuration object of class 'coder.MexCodeConfig'.
cfg = coder.config('mex');
cfg.GenerateReport = true;
cfg.ReportPotentialDifferences = false;

%% Define argument types for entry-point 'myknnEnsemblePredict'.
ARGS = cell(1,1);
ARGS{1} = cell(4,1);
ARGS{1}{1} = coder.typeof(0,[Inf 34],[1 0]);
ARGS{1}{2} = coder.Constant('knnEnsemble');
ARGS{1}{3} = coder.Constant('Learners');
ARGS{1}{4} = coder.typeof(0,[1 13],[0 1]);

%% Invoke MATLAB Coder.
codegen -config cfg myknnEnsemblePredict -args ARGS{1} -nargout 2
```

Run the script.

`myknnEnsemblePredict_script`

Warning: C Compiler produced warnings. See the build log for further details.

Code generation successful (with warnings): To view the report, open('codegen\mex\myknn')

Verify Generated Code

Verify that `myknnEnsemblePredict` and the MEX function return the expected results.

```
[label1,score1] = predict(Mdl,X,'Learners',1:10);  
[label2,score2] = myknnEnsemblePredict(X,'knnEnsemble','Learners',1:10);  
[label3,score3] = myknnEnsemblePredict_mex(X,'knnEnsemble','Learners',1:10);  
verifyMEX_label = isequal(label1,label2,label3)  
  
verifyMEX_label = logical  
1  
  
verifyMEX_score = isequal(score1,score2,score3)  
  
verifyMEX_score = logical  
1
```

`isequal` returns logical 1 (true) if all the inputs are equal.

The `score3` output from the MEX function might include round-off differences compared with the output from the `predict` function. In this case, you can compare `score1` and `score3`, allowing a small tolerance.

```
find(abs(score1-score3) > 1e-12)  
  
ans =  
  
0x1 empty double column vector
```

The comparisons confirm that `myknnEnsemblePredict` and the MEX function return the expected results.

C Code Generation and Classification Learner App

Classification Learner is well suited for choosing and training classification models interactively, but it does not automatically generate C code from a function that labels data based on a trained model. This example shows how to generate C code from a function that predicts labels using an exported classification model. The example builds a model that predicts the credit rating of a business given various financial ratios, according to these steps:

- 1 Use the credit rating data set in the file `CreditRating_Historical.dat`, which is included with Statistics and Machine Learning Toolbox.
- 2 Reduce the data dimensionality using PCA.
- 3 Train a set of models that support C code generation for label prediction.
- 4 Export the model with the minimum 5-fold, cross-validated classification accuracy.
- 5 Generate code from a function that transforms the new predictor data and then predicts corresponding labels using the exported model.

Load the historical credit rating data set in the file `CreditRating_Historical.dat`, which is on the MATLAB path, into a table.

```
creditrating = readtable('CreditRating_Historical.dat');
```

On the **Apps** tab, click **Classification Learner**.

In Classification Learner, on the **Classification Learner** tab, in the **File** section, click **New Session** and select **From Workspace**.

In the New Session dialog box, select the table `creditrating`. All variables, except the one identified as the response, are double-precision numeric vectors. Click **Start Session** to compare classification models based on the 5-fold, cross-validated classification accuracy.

Classification Learner loads the data and plots a scatter plot of the variables `WC_TA` versus `ID`. Because identification numbers are not helpful to display in a plot, choose `RE_TA` for **X** under **Predictors**.

The scatter plot suggests that the two variables can separate the classes AAA, BBB, BB, and CCC fairly well. However, the observations corresponding to the remaining classes are mixed into these classes.

Identification numbers are not helpful for prediction. Therefore, in the **Features** section, click **Feature Selection** and then clear the **ID** check box. You can also remove unnecessary predictors from the beginning by using the check boxes in the New Session dialog box. This example shows how to remove unused predictors for code generation when you have included all predictors.

In the **Features** section, click **PCA**, and then select **Enable PCA**. This action applies PCA to the predictor data, and then transforms the data before training the models. Classification Learner uses only components that collectively explain 95% of the variability.

Select the following classification models and options, which support code generation for label prediction, and then perform cross-validation (for more details, see “Code Generation Support, Usage Notes, and Limitations” on page 31-40). To select each model, in the **Model Type** section, click the **Show more** arrow, and then click the model. After selecting a model and specifying any options, close any open menus, and then click **Train** in the **Training** section.

| Models and Options to Select | Description |
|---|---|
| Under Decision Trees , select All Trees | Classification trees of various complexities |
| Under Support Vector Machines , select All SVMs | SVMs of various complexities and using various kernels. Complex SVMs require time to fit. |
| Under Ensemble Classifiers , select Boosted Trees . In the Model Type section, click Advanced . Reduce Maximum number of splits to 5 and increase Number of learners to 100 . | Boosted ensemble of classification trees |
| Under Ensemble Classifiers , select Bagged Trees . In the Model Type section, click Advanced . Increase Maximum number of splits to 50 and increase Number of learners to 100 . | Random forest of classification trees |

After cross-validating each model type, the Data Browser displays each model and its 5-fold, cross-validated classification accuracy, and highlights the model with the best accuracy.

▼ Current Model

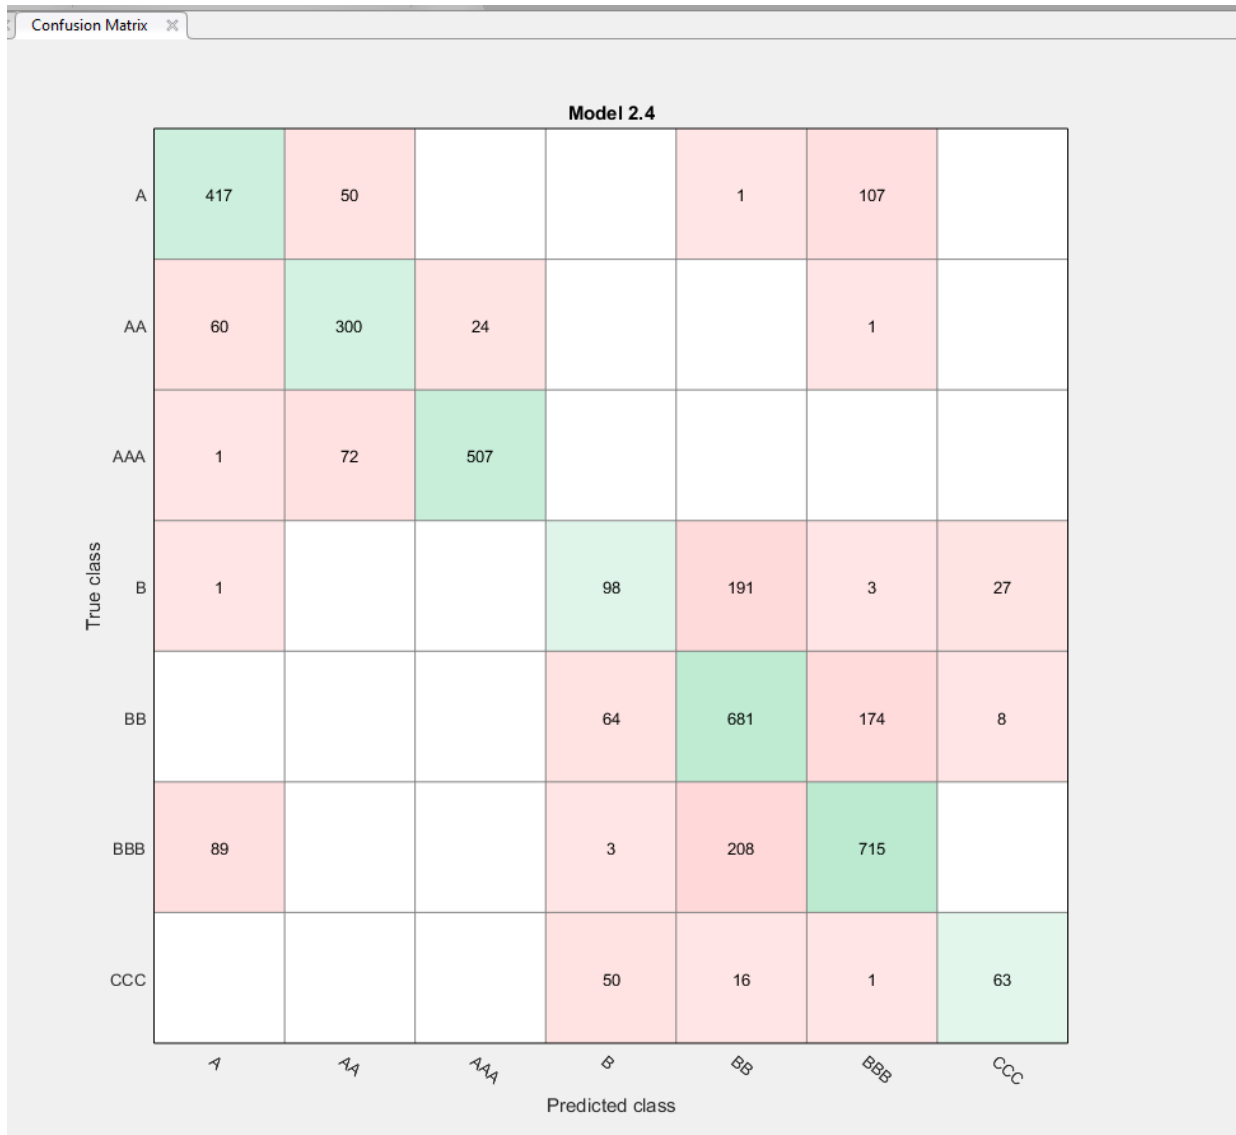

Model 4: Trained

Results

| | |
|------------------|---------------|
| Accuracy | 70.6% |
| Prediction speed | ~4900 obs/sec |
| Training time | 15.212 sec |

Select the model that yields the maximum 5-fold, cross-validated classification accuracy, which is the error-correcting output codes (ECOC) model of Fine Gaussian SVM learners. With PCA enabled, Classification Learner uses two predictors out of six.

In the **Plots** section, click **Confusion Matrix**.

The model does well distinguishing between A, B, and C classes. However, the model does not do as well distinguishing between particular levels within those groups, the lower B levels in particular.

In the **Export** section, click **Export Model**, and then select **Export Compact Model**. Click **OK** in the dialog box.

The structure `trainedModel` appears in the MATLAB Workspace. The field `ClassificationSVM` of `trainedModel` contains the compact model.

At the command line, save the compact model to a file called `ClassificationLearnerModel.mat` in your current folder.

```
saveCompactModel(trainedModel.ClassificationSVM, 'ClassificationLearnerModel');
```

To preprocess new data in the same way you preprocessed the training data, you need the following three model parameters:

- `removeVars` — Column vector of at most p elements identifying indices of variables to remove from the data, where p is the number of predictor variables in the raw data
- `pcaCenters` — Row vector of exactly q PCA centers
- `pcaCoefficients` — q -by- r matrix of PCA coefficients, where r is at most q

Specify the indices of predictor variables that you removed while selecting data using **Feature Selection** in Classification Learner. Extract the PCA statistics from `trainedModel`.

```
removeVars = 1;  
pcaCenters = trainedModel.PCACenters;  
pcaCoefficients = trainedModel.PCACoefficients;
```

Save the model parameters to a file named `ModelParameters.mat` in your current folder.

```
save('ModelParameters.mat', 'removeVars', 'pcaCenters', 'pcaCoefficients');
```

In your current folder, define a function named `mypredictCL.m` that:

- Accepts a numeric matrix (X) of raw observations containing the same predictor variables as the ones passed into Classification Learner
- Loads the classification model in `ClassificationLearnerModel.mat` and the model parameters in `ModelParameters.mat`
- Removes the predictor variables corresponding to the indices in `removeVars`
- Transforms the remaining predictor data using the PCA centers (`pcaCenters`) and coefficients (`pcaCoefficients`) estimated by Classification Learner

- Returns predicted labels using the model

```
function label = mypredictCL(X) %#codegen
%MPREDICTCL Classify credit rating using model exported from
%Classification Learner
% MYPREDICTCL loads trained classification model (SVM) and model
% parameters (removeVars, pcaCenters, and pcaCoefficients), removes the
% columns of the raw matrix of predictor data in X corresponding to the
% indices in removeVars, transforms the resulting matrix using the PCA
% centers in pcaCenters and PCA coefficients in pcaCoefficients, and then
% uses the transformed data to classify credit ratings. X is a numeric
% matrix with n rows and 7 columns. label is an n-by-1 cell array of
% predicted labels.

% Load trained classification model and model parameters
SVM = loadCompactModel('ClassificationLearnerModel');
data = coder.load('ModelParameters');
removeVars = data.removeVars;
pcaCenters = data.pcaCenters;
pcaCoefficients = data.pcaCoefficients;
SVM = loadCompactModel('ClassificationLearnerModel');

% Remove unused predictor variables
keepvars = 1:size(X,2);
idx = ~ismember(keepvars,removeVars);
keepvars = keepvars(idx);
XwoID = X(:,keepvars);

% Transform predictors via PCA
Xpca = bsxfun(@minus,XwoID,pcaCenters)*pcaCoefficients;

% Generate label from SVM
label = predict(SVM,Xpca);
end
```

Create a double-precision matrix called `x` for code generation using `coder.typeof`. Specify that the number of rows of `x` is arbitrary, but that `x` must have `p` columns.

```
p = size(creditrating,2) - 1;
x = coder.typeof(0,[Inf,p],[1 0]);
```

Generate a MEX function from `mypredictCL.m`. Use the `-args` option to specify `x` as an argument.

```
codegen -config:mex mypredictCL.m -args x
```

codegen generates the MEX file `mypredictCL_mex.mexw64` in your current folder. The file extension depends on your platform.

Verify that the MEX function returns the expected labels.

Remove the response variable from the original data set, and then randomly draw 15 observations.

```
rng('default'); % For reproducibility
m = 15;
testsampleT = datasample(creditrating(:,1:(end - 1)),m);
```

Predict corresponding labels by using `predictFcn` in the classification model trained by Classification Learner.

```
testLabels = trainedModel.predictFcn(testsampleT);
```

Convert the resulting table to a matrix.

```
testsample = table2array(testsampleT);
```

The columns of `testsample` correspond to the columns of the predictor data loaded by Classification Learner.

Pass the test data to `mypredictCL`. The function `mypredictCL` predicts corresponding labels by using `predict` and the classification model trained by Classification Learner.

```
testLabelsPredict = mypredictCL(testsample);
```

Predict corresponding labels by using the generated MEX function `mypredictCL_mex`.

```
testLabelsMEX = mypredictCL_mex(testsample);
```

Compare the sets of predictions.

```
sum(strcmp(testLabels,testLabelsPredict)) == m
sum(strcmp(testLabels,testLabelsMEX)) == m
```

```
ans =
```

```
    logical
```

```
    1
```

```
ans =
```

logical

1

predictFcn, mypredictCL, and the MEX function return the same values.

Predict Class Labels Using MATLAB Function Block

This example shows how to add a MATLAB Function block to a Simulink® for label prediction. The MATLAB Function block accepts streaming data, and predicts the label and classification score using a trained, support vector machine (SVM) classification model. For details on using the MATLAB Function block, see “Create Model That Uses MATLAB Function Block” (Simulink).

The `ionosphere` data set, which is included in the Statistics and Machine Learning Toolbox™, contains radar-return qualities (Y) and predictor data (X). Radar returns are either of good quality ('g') or of bad quality ('b').

Load the `ionosphere` data set. Determine the sample size.

```
load ionosphere
n = numel(Y)
```

```
n =
    351
```

The MATLAB Function block cannot return cell arrays. So, convert the response variable to a logical vector whose elements are 1 if the radar returns are good, and 0 otherwise.

```
Y = strcmp(Y, 'g');
```

Suppose that the radar returns are detected in sequence, and you have the first 300 observations, but you have not received the last 51 yet. Partition the data into present and future samples.

```
prsntX = X(1:300, :);
prsntY = Y(1:300);
ftrX = X(301:end, :);
ftrY = Y(301:end);
```

Train an SVM model using all, presently available data. Specify predictor data standardization.

```
Mdl = fitcsvm(prsntX, prsntY, 'Standardize', true);
```

Mdl is a `ClassificationSVM` model. At the command line, you can use Mdl to make predictions for new observations. However, you cannot use Mdl as an input argument in a function meant for code generation.

Prepare Mdl to be loaded within the function using `saveCompactModel`.

```
saveCompactModel(Mdl, 'SVMIonosphere');
```

`saveCompactModel` compacts Mdl, and then saves it in the MAT-file `SVMIonosphere.mat`.

Define a function named `svmIonospherePredict.m` that predicts whether a radar return is of good quality. The function should:

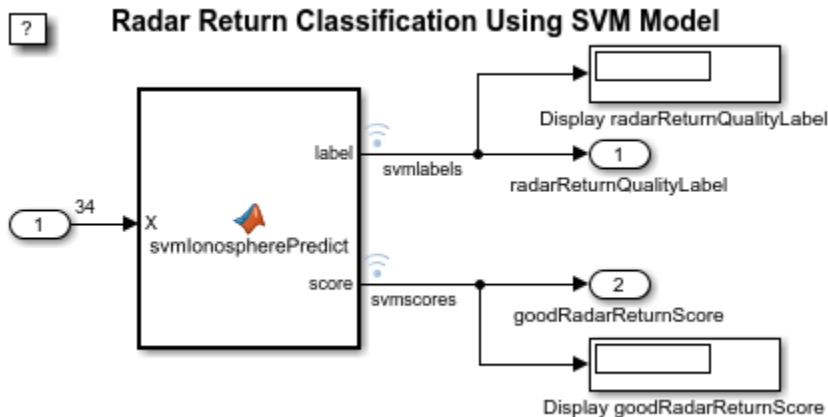

- Include the code generation directive `codegen` somewhere in the function.
- Accept radar-return predictor data. The data must be commensurate with X except for the number of rows.
- Load `SVMIonosphere.mat` using `loadCompactModel`.
- Return predicted labels and classification scores for predicting the quality of the radar return as good (that is, the positive-class score).

```
function [label,score] = svmIonospherePredict(X) %codegen
%svmIonospherePredict Predict radar-return quality using SVM model
% svmIonospherePredict predicts labels and estimates classification
% scores of the radar returns in the numeric matrix of predictor data X
% using the compact SVM model in the file SVMIonosphere.mat. Rows of X
% correspond to observations and columns to predictor variables. label
% is the predicted label and score is the confidence measure for
% classifying the radar-return quality as good.
%
% Copyright 2016 The MathWorks Inc.
Mdl = loadCompactModel('SVMIonosphere');
[label,bothscores] = predict(Mdl,X);
score = bothscores(:,2);
end
```

`svmIonospherePredict.m` is located in your `mlr/help/toolbox/stats/examples` folder, where `mlr` is the value of `matlabroot`.

Load the Simulink® model `slexSVMIonospherePredictExample.slx`.

```
SimMdlName = 'slexSVMIonospherePredictExample';
open_system(SimMdlName);
```

The figure displays the Simulink® model. When the input node detects a radar return, it directs that observation into the MATLAB Function block that dispatches to `svmIonospherePredict.m`. After predicting the label and score, the model returns these values to the workspace and displays the values within the model one at a time. When you load `slexSVMIonospherePredictExample.slx`, MATLAB® also loads the data set that it requires called `radarReturnInput`. However, this example shows how to construct the required data set.

The model expects to receive input data as a structure array called `radarReturnInput` containing these fields:

- `time` - The points in time at which the observations enter the model. In the example, the duration includes the integers from 0 though 50. The orientation must correspond to the observations in the predictor data. So, for this example, `time` must be a column vector.
- `signals` - A 1-by-1 structure array describing the input data, and containing the fields `values` and `dimensions`. `values` is a matrix of predictor data. `dimensions` is the number of predictor variables.

Create an appropriate structure array for future radar returns.

```

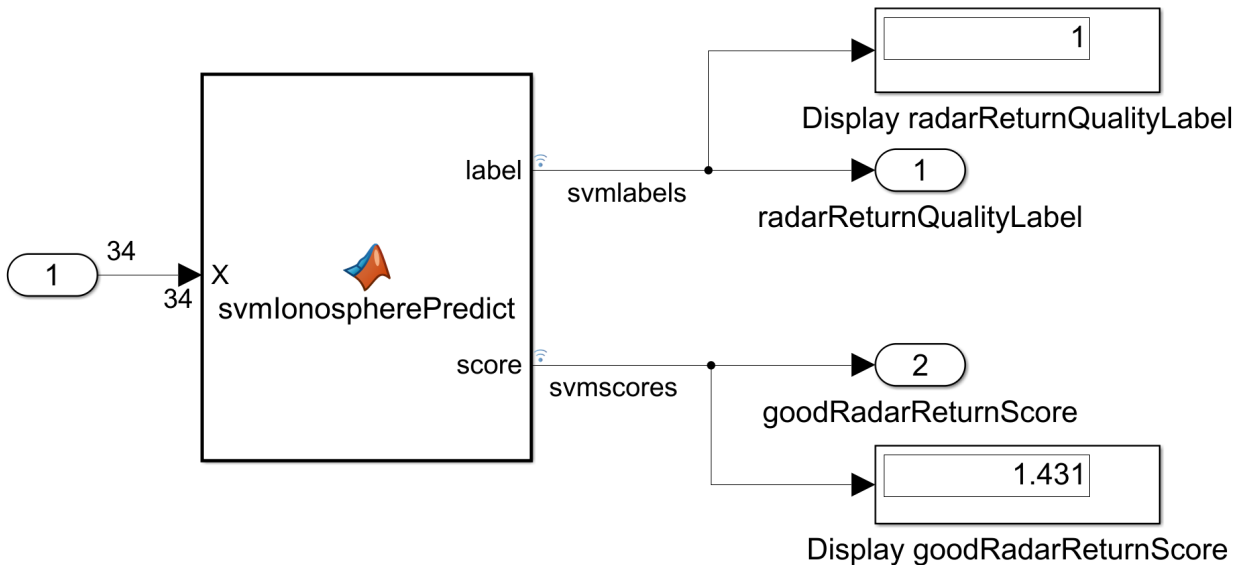

radarReturnInput.time = (0:50)';
radarReturnInput.signals(1).values = ftrX;
radarReturnInput.signals(1).dimensions = size(ftrX,2);
    
```

You can change the name from `radarReturnInput`, and then specify the new name in the model. However, Simulink® expects the structure array to contain the described field names.

Simulate the model using the data held out of training, that is, the data in `radarReturnInput`.

```
sim(SimMdlName);
```

Radar Return Classification Using SVM Model

The figure shows the model after it processes all observations in `radarReturnInput` one at a time. The predicted label of `X(351, :)` is 1 and its positive-class score is 1.431. The variables `tout`, `yout`, and `svmlogsout` appear in the workspace. `yout` and `svmlogsout` are SimulinkData.Dataset objects containing the predicted labels and scores. For more details, see “Data Format for Logged Simulation Data” (Simulink).

Extract the simulation data from the simulation log.

```
labelsSL = svmlogout.getElement(1).Values.Data;  
scoresSL = svmlogout.getElement(2).Values.Data;
```

`labelsSL` is a 51-by-1 numeric vector of predicted labels. `labelsSL(j) = 1` means that the SVM model predicts that radar return `j` in the future sample is of good quality, and `0` means otherwise. `scoresSL` is a 51-by-1 numeric vector of positive-class scores, that is, signed distances from the decision boundary. Positive scores correspond to predicted labels of 1, and negative scores correspond to predicted labels of 0.

Predict labels and positive-class scores at the command line using `predict`.

```
[labelCMD,scoresCMD] = predict(Mdl,ftrX);  
scoresCMD = scoresCMD(:,2);
```

`labelCMD` and `scoresCMD` are commensurate with `labelsSL` and `scoresSL`.

Compare the future-sample, positive-class scores returned by `slexSVMIonospherePredictExample` to those returned by calling `predict` at the command line.

```
err = sum((scoresCMD - scoresSL).^2);  
err < eps
```

```
ans =  
  
    logical  
  
    1
```

The sum of squared deviations between the sets of scores is negligible.

If you also have a Simulink® Coder™ license, then you can generate C code from `slexSVMIonospherePredictExample.slx` in Simulink® or from the command line using `rtwbuild`. For more details, see “Generate C Code for a Model” (Simulink Coder).

Code Generation Support, Usage Notes, and Limitations

To generate C code from built-in Statistics and Machine Learning Toolbox functions, you must install MATLAB Coder software.

- All functions in this table generate reference C code.
- You cannot call any function at the top level. Instead, call the function within a function that you define, and then generate code from the defined function.
- The MATLAB Coder limitations also apply to Statistics and Machine Learning Toolbox for code generation. In particular, code generation does not support categorical arrays, sparse matrices, and tables. For details, see “MATLAB Language Features Supported for C/C++ Code Generation” (MATLAB Coder).
- Code generation in Statistics and Machine Learning Toolbox does not support strings.

This table lists the built-in Statistics and Machine Learning Toolbox functions that support code generation.

An asterisk (*) indicates that the reference page has usage notes and limitations for C/C++ code generation.

Specify Variable-Sized Arguments for Code Generation

This example shows how to generate code from a prediction function that has variable-sized input arguments. Specifically, the example creates a function that predicts labels based on a trained classification tree. At compile time, the number of observations to label and the number of subtrees are unknown.

Load Fisher's iris data set. Convert the labels to a character matrix.

```
load fisheriris
species = char(species);
```

Train a classification tree using the entire data set.

```
Mdl = fitctree(meas,species);
```

Mdl is a `ClassificationTree` model.

Save the trained classification tree to a file called `ClassTreeIris.mat` in your current folder.

```
MdlName = 'ClassTreeIris';
saveCompactModel(Mdl,MdlName);
```

In your current folder, define a function called `mypredictTree.m` that:

- Accepts measurements with columns corresponding to `meas` and accepts valid name-value pair arguments
- Loads a trained classification tree
- Predicts labels and corresponding scores, node numbers, and class numbers from the loaded classification tree

```
function [label,score,node,cnum] = mypredictTree(x,savedmdl,varargin) %#codegen
%MYPREDICTTREE Predict iris species using classification tree
% MYPREDICTTREE predicts iris species for the n observations in the
% n-by-4 matrix x using the classification tree stored in the MAT-file
% whose name is in savedmdl, and then returns the predictions in the
% array label. Each row of x contains the lengths and widths of the petal
% and sepal of an iris (see the fisheriris data set). For other output
% argument descriptions, see the predict reference page.
CompactMdl = loadCompactModel(savedmdl);
[label,score,node,cnum] = predict(CompactMdl,x,varargin{:});
```

```
end
```

Define code generation variables for the predictor data and subtrees from which to predict labels using `coder.typeof`. Specify that the predictor data variable is double-precision with the same number of columns as the predictor data used in training the model, but that the number of observations (rows) is arbitrary. Specify that the number of subtrees from which to predict labels is a double-precision row vector with an arbitrary number of columns.

```
p = numel(Mdl.PredictorNames);
x = coder.typeof(0,[Inf,p],[1,0]);
subtrees = coder.typeof(0,[1,Inf],[0,1]);
```

Generate a MEX function from `mypredictTree.m`. Because C uses static typing, `codegen` must determine the properties of all variables in MATLAB® files at compile time. To designate arguments as compile-time constants, use `coder.Constant`.

```
codegen mypredictTree.m -config:mex -args {x,coder.Constant(MdlName),coder.Constant('S
```

`codegen` generates the MEX file `mypredictTree_mex.mexw64` in your current folder. The file extension depends on your platform. Although `predict` accepts single-precision values, double-precision values, and 'all' for 'SubTrees', you can specify only double-precision values when you use the MEX function for prediction.

Predict labels for a random selection of 15 values from the training data using the generated MEX function and the subtree at pruning level 1. Compare the labels from the MEX function with those predicted by `predict`.

```
rng(1); % For reproducibility
Xnew = datasample(meas,15);
labelsMEX = mypredictTree_mex(Xnew,MdlName,'Subtrees',1)
labelsPREDICT = predict(Mdl,Xnew,'Subtrees',1)
```

```
labelsMEX =
```

```
15x1 cell array
```

```
 {'versicolor'}
 {'virginica' }
 {'setosa'    }
 {'setosa'    }
```

```
{'setosa'   }  
{'setosa'   }  
{'setosa'   }  
{'versicolor'}  
{'versicolor'}  
{'versicolor'}  
{'versicolor'}  
{'virginica' }  
{'setosa'   }  
{'virginica' }  
{'setosa'   }
```

labelsPREDICT =

15x10 char array

```
'versicolor'  
'virginica '  
'setosa    '  
'setosa    '  
'setosa    '  
'setosa    '  
'setosa    '  
'setosa    '  
'versicolor'  
'versicolor'  
'versicolor'  
'versicolor'  
'virginica '  
'setosa    '  
'virginica '  
'setosa    '
```

The predicted labels are the same as the MEX function labels except for the data type. When the 'Subtrees' value is an arbitrary double at compile time and the response is a character array, `codegen` must cast the predicted labels as a cell array of character vectors.

System Objects for Classification and Code Generation

This example shows how to generate C code from a MATLAB® System object™ that classifies images of digits using a trained classification model. This example also shows how to use the System object for classification in Simulink®. A benefit of using System objects over a MATLAB function is System objects are more appropriate for processing large amounts of streaming data. For more details, see “What Are System Objects?” (MATLAB).

This example is based on “C Code Generation for Image Classifier”, which is an alternative workflow to “Digit Classification Using HOG Features” (Computer Vision System Toolbox).

Load Data

Load the `digitimages`.

```
load digitimages.mat
```

`images` is a 28-by-28-by-3000 array of `uint16` integers. Each page is a raster image of a digit. Each element is a pixel intensity. Corresponding labels are in the 3000-by-1 numeric vector `Y`. For more details, enter `Description` at the command line.

Store the number of observations and number of predictor variables. Create a data partition that specifies to hold out 20% of the data. Extract training and test set indices from the data partition.

```
rng(1); % For reproducibility
n = size(images,3);
p = numel(images(:,:,1));
cvp = cvpartition(n,'Holdout',0.20);
idxTrn = training(cvp);
idxTest = test(cvp);
```

Rescale Data

Rescale the pixel intensities so that they range in the interval [0,1] within each image. Specifically, suppose p_{ij} is pixel intensity j within image i . For image i , rescale all of its pixel intensities using this formula:

$$\hat{p}_{ij} = \frac{p_{ij} - \min_j(p_{ij})}{\max_j(p_{ij}) - \min_j(p_{ij})}$$

```
X = double(images);

for i = 1:n
    minX = min(min(X(:,:,i)));
    maxX = max(max(X(:,:,i)));
    X(:,:,i) = (X(:,:,i) - minX)/(maxX - minX);
end
```

Reshape Data

For code generation, the predictor data for training must be in a table of numeric variables or a numeric matrix.

Reshape the data to a matrix such that predictor variables correspond to columns and images to rows. Because reshape takes elements column-wise, transpose its result.

```
X = reshape(X,[p,n])';
```

Train and Optimize Classification Models

Cross-validate an ECOC model of SVM binary learners and a random forest based on the training observations. Use 5-fold cross-validation.

For the ECOC model, specify predictor standardization and optimize classification error over the ECOC coding design and the SVM box constraint. Explore all combinations of these values:

- For the ECOC coding design, use one-versus-one and one-versus-all.
- For the SVM box constraint, use three logarithmically-spaced values from 0.1 to 100 each. For all models, store the 5-fold cross-validated misclassification rates.

```
coding = {'onevsone' 'onevsall'};
boxconstraint = logspace(-1,2,3);
cvLossECOC = nan(numel(coding),numel(boxconstraint)); % For preallocation

for i = 1:numel(coding)
    for j = 1:numel(boxconstraint)
        t = templateSVM('BoxConstraint',boxconstraint(j),'Standardize',true);
        CVMdl = fitcecoc(X(idxTrn,:),Y(idxTrn),'Learners',t,'KFold',5,...
            'Coding',coding{i});
        cvLossECOC(i,j) = kfoldLoss(CVMdl);
        fprintf('cvLossECOC = %f for model using %s coding and box constraint=%f\n',...
            cvLossECOC(i,j),coding{i},boxconstraint(j))
```

```

end
end

cvLossECOC = 0.058333 for model using onevsone coding and box constraint=0.100000
cvLossECOC = 0.057083 for model using onevsone coding and box constraint=3.162278
cvLossECOC = 0.050000 for model using onevsone coding and box constraint=100.000000
cvLossECOC = 0.120417 for model using onevsall coding and box constraint=0.100000
cvLossECOC = 0.121667 for model using onevsall coding and box constraint=3.162278
cvLossECOC = 0.127917 for model using onevsall coding and box constraint=100.000000

```

For the random forest, vary the maximum number of splits using the values in the sequence $\{3^2, 3^3, \dots, 3^m\}$. m is such that 3^m is no greater than $n - 1$.

```

n = size(X,1);
m = floor(log(n - 1)/log(3));
maxNumSplits = 3.^(2:m);
cvLossRF = nan(numel(maxNumSplits));
for i = 1:numel(maxNumSplits)
    t = templateTree('MaxNumSplits',maxNumSplits(i));
    CVMdl = fitcensemble(X(idxTrn,:),Y(idxTrn),'Method','bag','Learners',t,...
        'KFold',5);
    cvLossRF(i) = kfoldLoss(CVMdl);
    fprintf('cvLossRF = %f for model using %d as the maximum number of splits\n',...
        cvLossRF(i),maxNumSplits(i))
end

```

```

cvLossRF = 0.323750 for model using 9 as the maximum number of splits
cvLossRF = 0.198333 for model using 27 as the maximum number of splits
cvLossRF = 0.075417 for model using 81 as the maximum number of splits
cvLossRF = 0.017083 for model using 243 as the maximum number of splits
cvLossRF = 0.012083 for model using 729 as the maximum number of splits
cvLossRF = 0.012083 for model using 2187 as the maximum number of splits

```

For each algorithm, determine the hyperparameter indices that yield the minimal misclassification rates.

```

minCVLossECOC = min(cvLossECOC(:))
linIdx = find(cvLossECOC == minCVLossECOC,1);
[bestI,bestJ] = ind2sub(size(cvLossECOC),linIdx);
bestCoding = coding{bestI}
bestBoxConstraint = boxconstraint(bestJ)

minCVLossRF = min(cvLossRF(:))
linIdx = find(cvLossRF == minCVLossRF,1);

```

```
[bestI,bestJ] = ind2sub(size(cvLossRF),linIdx);
bestMNS = maxNumSplits(bestI)
```

```
minCVLossECOC =
```

```
    0.0500
```

```
bestCoding =
```

```
    'onevsone'
```

```
bestBoxConstraint =
```

```
    100
```

```
minCVLossRF =
```

```
    0.0121
```

```
bestMNS =
```

```
    729
```

The random forest achieves a smaller cross-validated misclassification rate.

Train an ECOC model and a random forest using the training data. Supply the optimal hyperparameter combinations.

```
t = templateSVM('BoxConstraint',bestBoxConstraint,'Standardize',true);
MdlECOC = fitcecoc(X(idxTrn,:),Y(idxTrn),'Learners',t,'Coding',bestCoding);
t = templateTree('MaxNumSplits',bestMNS);
MdlRF = fitcensemble(X(idxTrn,:),Y(idxTrn),'Method','bag','Learners',t);
```

Create a variable for the test sample images, and use the trained models to predict test sample labels.

```
testImages = X(idxTest,:);
testLabelsECOC = predict(MdlECOC,testImages);
testLabelsRF = predict(MdlRF,testImages);
```

Save Classification Model to Disk

MdlECOC and MdlRF are predictive classification models, but you must prepare them for code generation. Save MdlECOC and MdlRF to your present working directory using `saveCompactModel`.

```
saveCompactModel(MdlECOC, 'DigitImagesECOC');  
saveCompactModel(MdlRF, 'DigitImagesRF');
```

Create System Object for Prediction

Create two System objects that, one for the ECOC model and the other for the random forest, that:

- Load the previously saved trained model using `loadCompactModel`
- Makes sequential predictions by the `step` method
- Enforces no size changes to the input data
- Enforces double-precision, scalar output

```
classdef ECOCClassifier < matlab.System  
    % ECOCCLASSIFIER Predict image labels from trained ECOC model  
    %  
    % ECOCCLASSIFIER loads the trained ECOC model from  
    % |'DigitImagesECOC.mat'|, and predicts labels for new observations  
    % based on the trained model. The ECOC model in  
    % |'DigitImagesECOC.mat'| was cross-validated using the training data  
    % in the sample data |digitimages.mat|.   
  
    properties(Access = private)  
        CompactMdl % The compacted, trained ECOC model  
    end  
  
    methods(Access = protected)  
  
        function setupImpl(obj)  
            % Load ECOC model from file  
            obj.CompactMdl = loadCompactModel('DigitImagesECOC');  
        end  
  
        function y = stepImpl(obj,u)  
            y = predict(obj.CompactMdl,u);  
        end  
    end  
end
```

```

function flag = isInputSizeLockedImpl(obj,index)
    % Return true if input size is not allowed to change while
    % system is running
    flag = true;
end

function dataout = getOutputDataTypeImpl(~)
    dataout = 'double';
end

function sizeout = getOutputSizeImpl(~)
    sizeout = [1 1];
end
end
end

classdef RFClassifier < matlab.System
    % RFCLASSIFIER Predict image labels from trained random forest
    %
    % RFCLASSIFIER loads the trained random forest from
    % |'DigitImagesRF.mat'|, and predicts labels for new observations based
    % on the trained model. The random forest in |'DigitImagesRF.mat'|
    % was cross-validated using the training data in the sample data
    % |digitimages.mat|.

    properties(Access = private)
        CompactMdl % The compacted, trained random forest
    end

    methods(Access = protected)

        function setupImpl(obj)
            % Load random forest from file
            obj.CompactMdl = loadCompactModel('DigitImagesRF');
        end

        function y = stepImpl(obj,u)
            y = predict(obj.CompactMdl,u);
        end

        function flag = isInputSizeLockedImpl(obj,index)
            % Return true if input size is not allowed to change while

```

```
        % system is running
        flag = true;
    end

    function dataout = getOutputDataTypeImpl(~)
        dataout = 'double';
    end

    function sizeout = getOutputSizeImpl(~)
        sizeout = [1 1];
    end
end
end
```

For System object basic requirements, see “Define Basic System Objects” (MATLAB).

Define Prediction Functions for Code Generation

Define two MATLAB functions called `predictDigitECOC50.m` and `predictDigitRF50.m`. The functions should:

- Include the code generation directive `%#codegen`.
- Accept image data commensurate with `X`.
- Predict labels using the `ECOCClassifier` and `RFClassifier` System objects, respectively.
- Return predicted labels.

```
function label = predictDigitECOC50(X) %#codegen
%PREDICTDIGITECOC50 Classify digit in image using ECOC Model System object
% PREDICTDIGITECOC50 classifies the 28-by-28 images in the rows of X
% using the compact ECOC model in the System object ECOCClassifier, and
% then returns class labels in label.
classifier = ECOCClassifier;
label = step(classifier,X);
end
```

```
function label = predictDigitRF50(X) %#codegen
%PREDICTDIGITRF50 Classify digit in image using RF Model System object
% PREDICTDIGITRF50 classifies the 28-by-28 images in the rows of X
```

```

% using the compact random forest in the System object RFClassifier, and
% then returns class labels in label.
classifier = RFClassifier;
label = step(classifier,X);
end

```

Compile MATLAB Function to MEX File

Compile the prediction function that achieves better test-sample accuracy to a MEX file using `codegen`. Specify the test set images using the `-args` argument.

```

if(minCVLossECOC <= minCVLossRF)
    codegen predictDigitECOC50 -args testImages
else
    codegen predictDigitRFS0 -args testImages
end

```

Verify that the generated MEX file produces the same predictions as the MATLAB function.

```

if(minCVLossECOC <= minCVLossRF)
    mexLabels = predictDigitECOC50_mex(testImages);
    verifyMEX = sum(mexLabels == testLabelsECOC) == numel(testLabelsECOC)
else
    mexLabels = predictDigitRFS0_mex(testImages);
    verifyMEX = sum(mexLabels == testLabelsRF) == numel(testLabelsRF)
end

```

```

verifyMEX =

    logical

     1

```

`verifyMEX` is 1, which indicates that the predictions made by the generated MEX file and the corresponding MATLAB function are the same.

Predict Labels Using System Objects in Simulink

Create a video file that displays the test-set images frame by frame.

```

v = VideoWriter('testImages.avi','Uncompressed AVI');
v.FrameRate = 1;

```

```

open(v);
dim = sqrt(p)*[1 1];
for j = 1:size(testImages,1)
    writeVideo(v,reshape(testImages(j,:),dim));
end
close(v);

```

Define a function called `scalePixelIntensities.m` that converts RGB images to grayscale, and then scales the resulting pixel intensities so that their values are in the interval `[0,1]`.

```

function x = scalePixelIntensities(imdat)
%SCALEPIXELINTENSITIES Scales image pixel intensities
% SCALEPIXELINTENSITIES scales the pixel intensities of the image such
% that the result x is a row vector of values in the interval [0,1].

imdat = rgb2gray(imdat);

minimdat = min(min(imdat));
maximdat = max(max(imdat));
x = (imdat - minimdat)/(maximdat - minimdat);

end

```

Load the Simulink® model `slexClassifyAndDisplayDigitImages.slx`.

```

SimMdlName = 'slexClassifyAndDisplayDigitImages';
open_system(SimMdlName);

```

The figure displays the Simulink® model. At the beginning of simulation, the From Multimedia File block loads the video file of the test-set images. For each image in the video:

- 1 The From Multimedia File block converts and outputs the image to a 28-by-28 matrix of pixel intensities.
- 2 The Process Data block scales the pixel intensities using `scalePixelIntensities.m`, and outputs a 1-by-784 vector of scaled intensities.
- 3 The Classification Subsystem block predicts labels given the processed image data. The block chooses the System object that minimizes classification error. In this case, the block chooses the random forest. The block outputs a double-precision scalar label.
- 4 The Data Type Conversion block converts the label to an `int32` scalar.
- 5 The Insert Text block embeds the predicted label on the current frame.
- 6 The To Video Display block displays the annotated frame.

Simulate the model.

```
sim(SimMdlName)
```

The model displays all 600 test-set images and its prediction quickly; the last image remains in the video display. You can generate predictions and display them with corresponding images one by one by pressing the **Step Forward** button instead.

If you also have a Simulink® Coder™ license, then you can generate C code from `slexClassifyAndDisplayDigitImages.slx` in Simulink® or from the command line using `rtwbuild`. For more details, see “Generate C Code for a Model” (Simulink Coder).

Predict Class Labels Using Stateflow

This example shows how to use a Stateflow® chart for label prediction. The example trains a discriminant analysis model for the Fisher iris data set by using `fitcdiscr`, and defines a function for code generation that loads the trained model and predicts labels for new data. The Stateflow chart in this example accepts streaming data and predicts labels using the function you define.

Fisher's iris data set, which is included in Statistics and Machine Learning Toolbox™, contains species (`species`) and measurements (`meas`) on sepal length, sepal width, petal length, and petal width for 150 iris specimens. The data set contains 50 specimens from each of three species: *setosa*, *versicolor*, and *virginica*.

Load the Fisher iris data set.

```
load fisheriris
```

Convert `species` to an index vector where 1, 2, and 3 correspond to *setosa*, *versicolor*, and *virginica*, respectively.

```
species = grp2idx(species);
```

Partition the data into a training set and a test set.

```
rng('default') % For reproducibility
idx1 = randperm(150,75)';
idx2 = setdiff((1:150)',idx1);
X = meas(idx1,:);
Y = species(idx1,:);
trainX = meas(idx2,:);
trainY = species(idx2,:);
```

Use `trainX` and `trainY` to train a model, and use `X` and `Y` to test the trained model.

Train a quadratic discriminant analysis model.

```
Mdl = fitcdiscr(trainX,trainY,'DiscrimType','quadratic');
```

`Mdl` is a `ClassificationDiscriminant` model. At the command line, you can use `Mdl` to make predictions for new observations. However, you cannot use `Mdl` as an input argument in a function for code generation. Prepare `Mdl` to be loaded within the function by using `saveCompactModel`.

```
saveCompactModel(Mdl,'DiscrIris');
```

`saveCompactModel` compacts `Mdl` and saves it in the MAT-file `DiscrIris.mat`.

To display the predicted species in the display box of the Stateflow® model, define an enumeration class by using a `classdef` block in the MATLAB file `IrisSpecies.m`.

```
classdef IrisSpecies < Simulink.IntEnumType
    enumeration
        Setosa(1)
        Versicolor(2)
        Virginica(3)
    end
end
```

For details about enumerated data, see “Define Enumerated Data Types” (Stateflow).

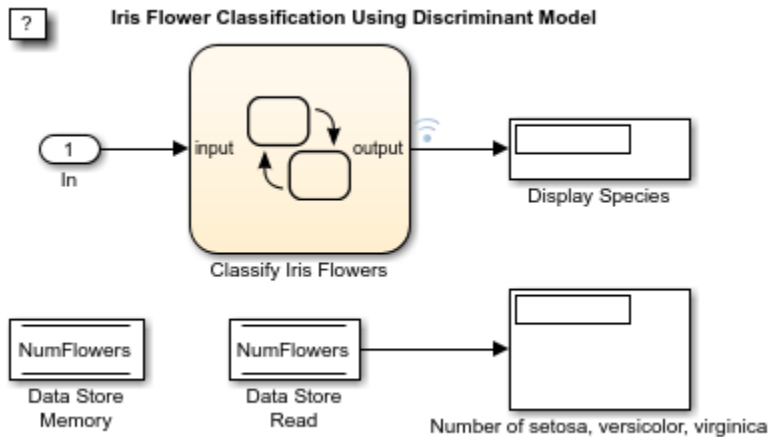

Define a function named `mypredict.m` that predicts the iris species from new measurement data by using the trained model. The function should:

- Include the code generation directive `%#codegen` somewhere in the function.
- Accept iris measurement data. The data must be consistent with `X` except for the number of rows.
- Load `DiscrIris.mat` using `loadCompactModel`.
- Return predicted iris species.

```
function label = mypredict(X) %#codegen
%MYPREDICT Predict species of iris flowers using discriminant model
% mypredict predicts species of iris flowers using the compact
% discriminant model in the file DiscrIris.mat. Rows of X correspond to
% observations and columns correspond to predictor variables. label is
% the predicted species.
mdl = loadCompactModel('DiscrIris');
labelTemp = predict(mdl,X);
label = IrisSpecies(labelTemp);
end
```

Open the Simulink® model `sf_countflowers.slx`.

```
sfName = 'sf_countflowers';
open_system(sfName);
```

The figures display the Simulink® model and the flow graph contained in the Stateflow® chart. When the input node detects measurement data, it directs the data into the chart. The chart then predicts a species of iris flower and counts the number of flowers for each species. The chart returns the predicted species to the workspace and displays the species within the model, one at a time. The data store memory block NumFlowers stores the number of flowers for each species.

The chart expects to receive input data as a structure array called `fisheririsInput` containing these fields:

- `time` - The points in time at which the observations enter the model. In the example, the duration includes the integers from 0 through 74. The orientation of `time` must correspond to the observations in the predictor data. So, for this example, `time` must be a column vector.
- `signals` - A 1-by-1 structure array describing the input data and containing the fields `values` and `dimensions`. The `values` field is a matrix of predictor data. The `dimensions` field is the number of predictor variables.

Create an appropriate structure array for iris flower measurements.

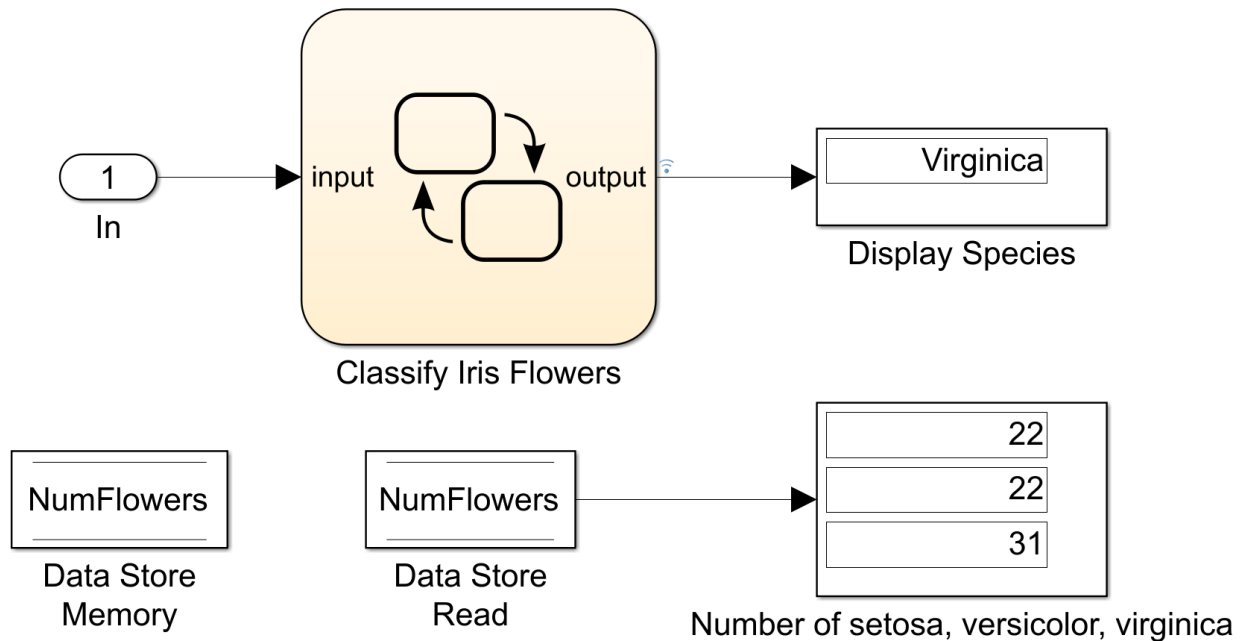

```
fisheririsInput.time = [0:74]';
fisheririsInput.signals.dimensions = 4;
fisheririsInput.signals.values = X;
```

You can change the name from `fisheririsInput`, and then specify the new name in the model. However, Stateflow® expects the structure array to contain the described field names. For more details, see “Loading Data Structures to Root-Level Inputs” (Simulink).

Simulate the model.

```
sim(sfName)
```

Iris Flower Classification Using Discriminant Model

The figure shows the model after it processes all observations in `fisheririsInput`, one at a time. The predicted species of `X(75, :)` is `virginica`. The number of setosa, versicolor, and virginica in `X` is 22, 22, and 31, respectively.

The variable `logout` appears in the workspace. `logout` is a `SimulinkData.Dataset` object containing the predicted species. Extract the predicted species data from the simulation log.

```
labelSF = logout.getElement(1).Values.Data;
```

Predict species at the command line using `predict`.

```
labelCMD = predict(Mdl,X);
```

Compare the predicted species returned by `sf_countflowers` to those returned by calling `predict` at the command line.

```
isequal(labelCMD,labelSF)
```

```
ans =
```

```
    logical
```

```
     1
```

`isequal` returns logical 1 (true) if all the inputs are equal. This comparison confirms that `sf_countflowers` returns the expected results.

If you also have a Simulink® Coder™ license, then you can generate C code from `sf_countflowers.slx` in Simulink® or from the command line using `rtwbuild`. For more details, see “Generate C Code for a Model” (Simulink Coder).

Human Activity Recognition Simulink Model for Smartphone Deployment

This example shows how to prepare a Simulink® model that classifies human activity based on smartphone sensor signals for code generation and smartphone deployment. The example provides two Simulink models that are ready for deployment to an Android device and an iOS device. After you install the required support package for a target device, train the classification model and deploy the Simulink model to the device.

Prerequisites

Simulink support packages are required for the Simulink models in this example.

- Download and Install Simulink Support Package for Android Devices (required for Android deployment)
- Download and Install Simulink Support Package for Apple iOS Devices (required for iOS deployment)

Load Sample Data Set

Load the `humanactivity` data set.

```
load humanactivity
```

The `humanactivity` data set contains 24,075 observations of five different physical human activities: Sitting, Standing, Walking, Running, and Dancing. Each observation has 60 features extracted from acceleration data measured by smartphone accelerometer sensors. The data set contains the following variables:

- `actid` — Response vector containing the activity IDs in integers: 1, 2, 3, 4, and 5 representing Sitting, Standing, Walking, Running, and Dancing, respectively
- `actnames` — Activity names corresponding to the integer activity IDs
- `feat` — Feature matrix of 60 features for 24,075 observations
- `featlabels` — Labels of the 60 features

The Sensor HAR (human activity recognition) App [1] was used to create the `humanactivity` data set. When measuring the raw acceleration data with this app, a person placed a smartphone in a pocket so that the smartphone was upside down and the screen faced toward the person. The software then calibrated the measured raw data accordingly and extracted the 60 features from the calibrated data. For details about the

calibration and feature extraction, see [2] and [3], respectively. The Simulink models described later also use the raw acceleration data and include blocks for calibration and feature extraction.

Prepare Data

This example uses 90% of the observations to train a model that classifies the five types of human activities and 10% of the observations to validate the trained model. Use `cvpartition` to specify a 10% holdout for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(actid,'Holdout',0.10);
trainingInds = training(Partition); % Indices for the training set
XTrain = feat(trainingInds,:);
YTrain = actid(trainingInds);
testInds = test(Partition); % Indices for the test set
XTest = feat(testInds,:);
YTest = actid(testInds);
```

Convert the feature matrix `XTrain` and the response vector `YTrain` into a table to load the training data set in the Classification Learner app.

```
tTrain = array2table([XTrain YTrain]);
```

Specify the variable name for each column of the table.

```
tTrain.Properties.VariableNames = [featlabels' 'Activities'];
```

Train Boosted Tree Ensemble Using Classification Learner App

Train a classification model by using the Classification Learner app. To open the Classification Learner app, enter `classificationLearner` at the command line. Alternatively, click the **Apps** tab, and click the arrow at the right of the **Apps** section to open the gallery. Then, under **Machine Learning**, click **Classification Learner**.

On the **Classification Learner** tab, in the **File** section, click **New Session** and select **From Workspace**.

In the New Session dialog box, click the arrow for **Workspace Variable**, and then select the table `tTrain`. Classification Learner detects the predictors and the response from the table.

Add All Remove All

[How to prepare data](#)

Response variable is numeric. Distinct values will be interpreted as class labels.

Validation

Cross-Validation
Protects against overfitting by partitioning the data set into folds and estimating accuracy on each fold.

Cross-validation folds: 5 folds

Holdout Validation
Recommended for large data sets.

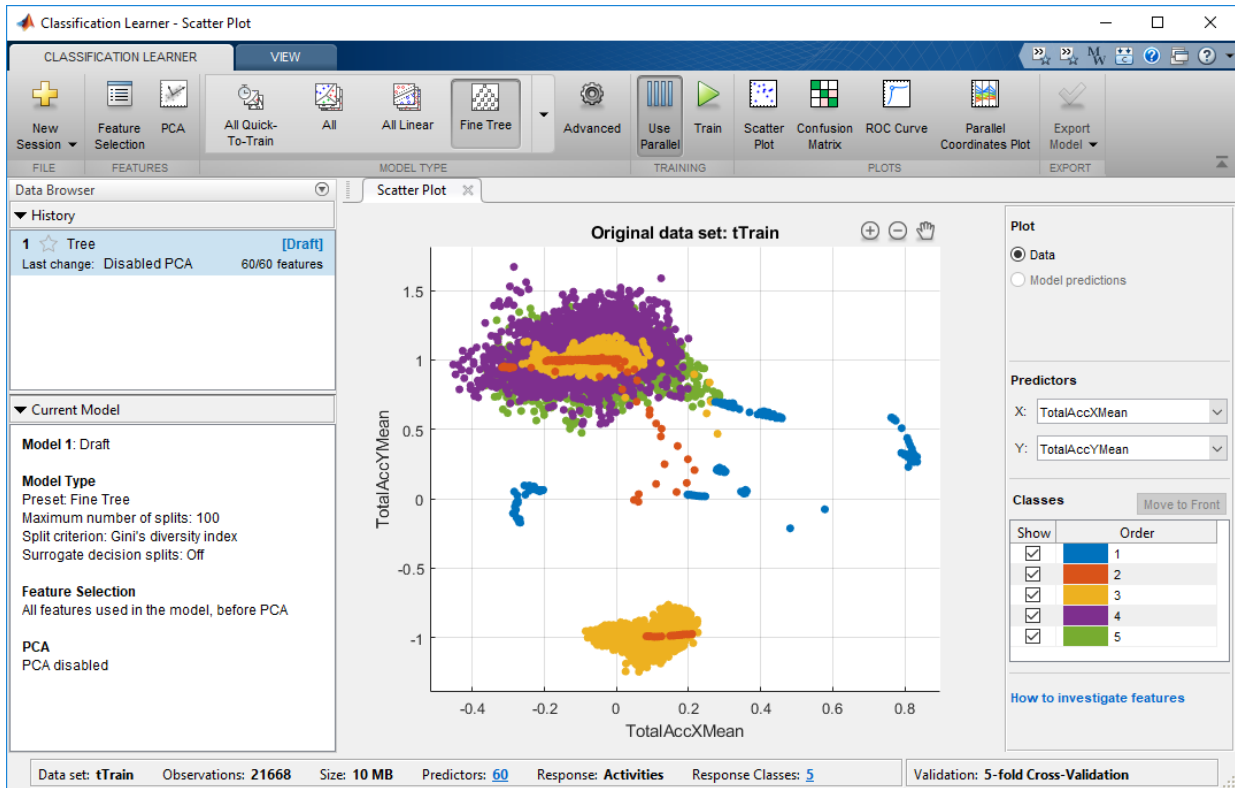

Percent held out: 25%

No Validation
No protection against overfitting.

[Read about validation](#)

Start Session
Cancel

The default option is 5-fold cross-validation, which protects against overfitting. Click **Start Session**. Classification Learner loads the data set and plots a scatter plot of the first two features.

On the **Classification Learner** tab, click the arrow at the right of the **Model Type** section to open the gallery. Then, under **Ensemble Classifiers**, click **Boosted Trees**.

The Current Model pane of the Data Browser displays the default settings of the boosted tree ensemble model.

On the **Classification Learner** tab, in the **Training** section, click **Train**. When the training is complete, the History pane of the Data Browser displays the 5-fold, cross-validated classification accuracy.

On the **Classification Learner** tab, in the **Export** section, click **Export Model**, and then select **Export Compact Model**. Click **OK** in the dialog box. The structure `trainedModel` appears in the MATLAB Workspace. The field `ClassificationEnsemble` of `trainedModel` contains the compact model. Extract the trained model from the structure.

```
classificationEnsemble = trainedModel.ClassificationEnsemble;
```

Train Boosted Tree Ensemble at Command Line

Alternatively, you can train the same classification model at the command line.

```
template = templateTree('MaxNumSplits',20);
classificationEnsemble = fitcensemble(XTrain,YTrain, ...
    'Method','AdaBoostM2', ...
    'NumLearningCycles',30, ...
    'Learners',template, ...
    'LearnRate',0.1, ...
    'ClassNames',[1; 2; 3; 4; 5]);
```

Perform 5-fold cross-validation for `classificationEnsemble` and compute the validation accuracy.

```
partitionedModel = crossval(classificationEnsemble,'KFold',5);
validationAccuracy = 1-kfoldLoss(partitionedModel)

validationAccuracy = 0.9831
```

Evaluate Performance on Test Data

Evaluate performance on the test data set.

```
testAccuracy = 1-loss(classificationEnsemble,XTest,YTest)

testAccuracy = 0.9763
```

The trained model correctly classifies 97.63% of the human activities on the test data set. This result confirms that the trained model does not overfit to the training data set.

Save Trained Model

For code generation including a classification model object, use `saveCompactModel` and `loadCompactModel`.

Save the trained model by using `saveCompactModel`.

```
saveCompactModel(classificationEnsemble,'EnsembleModel.mat');
```

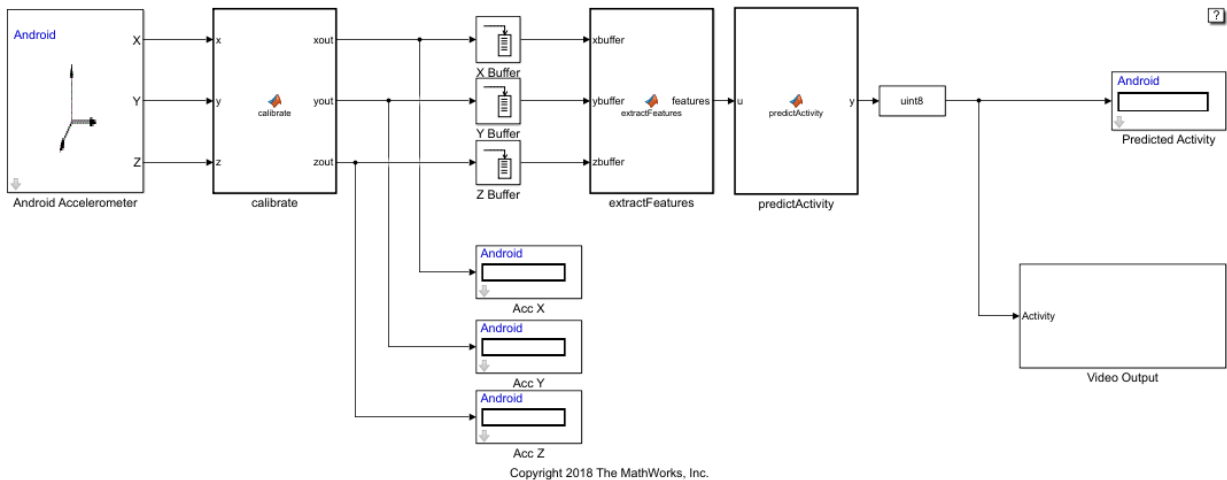

The function block **predictActivity** in the Simulink models loads the trained model by using `loadCompactModel` and uses the trained model to classify new data.

Deploy Simulink Model to Device

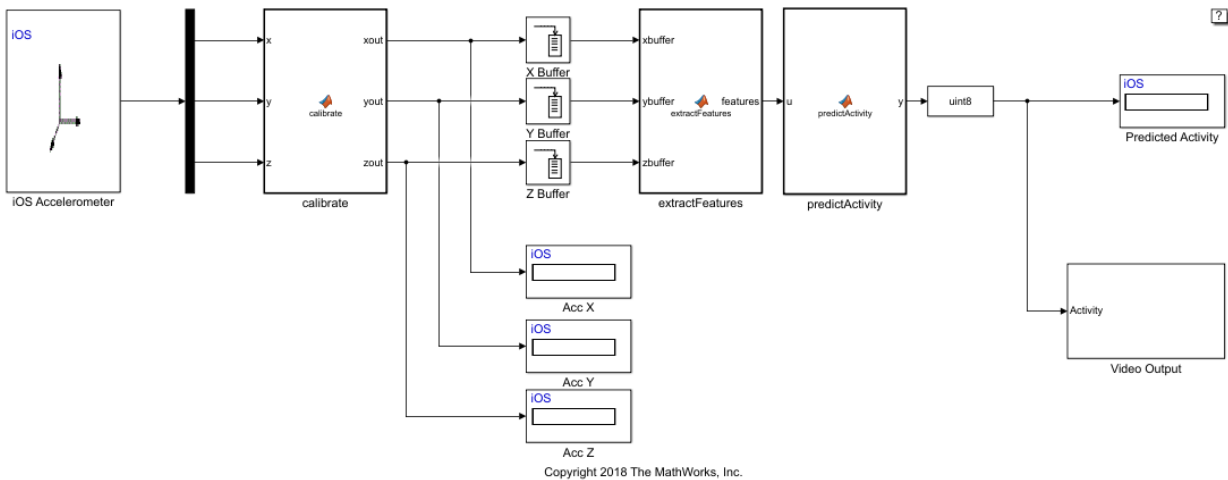

Now that you have prepared a classification model, you can open the Simulink model, depending on which type of smartphone you have, and deploy the model to your device.

Note that the Simulink model requires the `EnsembleModel.mat` file and the calibration matrix file `slexHARAndroidCalibrationMatrix.mat` or `slexHARi0SCalibrationMatrix.mat`. If you click the **Open Live Script** button and open this example in MATLAB®, then MATLAB® opens the example folder that includes these calibration matrix files.

Type `slexHARAndroidExample` to open the Simulink model for Android deployment.

Type `slexHARi0SExample` to open the Simulink model for iOS deployment.

The two Simulink models classify human activity based on acceleration data measured by a smartphone sensor. The models include the following blocks:

- The **Accelerometer** block receives raw acceleration data from accelerometer sensors on the device.
- The **calibrate** block is a MATLAB Function block that calibrates the raw acceleration data. This block uses the calibration matrix in the `slexHARAndroidCalibrationMatrix.mat` file or the `slexHARiOSCalibrationMatrix.mat` file. If you click the **Open Live Script** button and open this example in MATLAB®, then MATLAB® opens the example folder that includes these files.
- The display blocks **Acc X**, **Acc Y**, and **Acc Z** are connected to the **calibrate** block and display calibrated data points for each axis on the device.
- Each of the **Buffer** blocks, **X Buffer**, **Y Buffer**, and **Z Buffer**, buffers 32 samples of an accelerometer axis with 12 samples of overlap between buffered frames. After collecting 20 samples, each **Buffer** block joins the 20 samples with 12 samples from the previous frame and passes the total 32 samples to the **extractFeatures** block. Each **Buffer** block receives an input sample every 0.1 second and outputs a buffered frame including 32 samples every 2 seconds.
- The **extractFeatures** block is a MATLAB Function block that extracts 60 features from a buffered frame of 32 accelerometer samples. This function block uses DSP System Toolbox™ and Signal Processing Toolbox™.

- The **predictActivity** block is a MATLAB Function block that loads the trained model from the `EnsembleModel.mat` file by using `loadCompactModel` and classifies the user activity using the extracted features. The output is an integer between 1 and 5, corresponding to Sitting, Standing, Walking, Running, and Dancing, respectively.
- The **Predicted Activity** block displays the classified user activity values on the device.
- The **Video Output** subsystem uses a multiport switch block to choose the corresponding user activity image data to display on the device. The **Convert to RGB** block decomposes the selected image into separate RGB vectors and passes the image to the **Activity Display** block.

To deploy the Simulink model to your device, follow the steps in Run Model on Android Devices or Run Model on iOS Devices. After the configuration process is complete, click **Deploy to Hardware** to create an app with the same name as the model. Run the app, place the device in the same way as described earlier for collecting the training data, and try the five activities. The app displays the classified activity accordingly.

To ensure the accuracy of the app, you need to place your device in the same way as described for collecting the training data. If you want to place your device in a different location or orientation, then collect the data in your own way and use your data to train the classification model.

The accuracy of the app can be different from the accuracy of the test data set (`testaccuracy`), depending on the device. To improve the app, you can consider using additional sensors and updating the calibration matrix. Also, you can add another output block for audio feedback to the output subsystem using Audio System Toolbox™. Use a ThingSpeak™ write block to publish classified activities and acceleration data from your device to the Internet of Things. For details, see <https://thingspeak.com/>.

Functions — Alphabetical List

addedvarplot

Added variable plot

Syntax

```
addedvarplot(X,y,num,inmodel)  
addedvarplot(X,y,num,inmodel,stats)
```

Description

`addedvarplot(X,y,num,inmodel)` displays an added variable plot using the predictive terms in X , the response values in y , the added term in column `num` of X , and the model with current terms specified by `inmodel`. X is an n -by- p matrix of n observations of p predictive terms. y is vector of n response values. `num` is a scalar index specifying the column of X with the term to be added. `inmodel` is a logical vector of p elements specifying the columns of X in the current model. By default, all elements of `inmodel` are `false`.

Note `addedvarplot` automatically includes a constant term in all models. Do not enter a column of 1s directly into X .

`addedvarplot(X,y,num,inmodel,stats)` uses the `stats` output from the `stepwisefit` function to improve the efficiency of repeated calls to `addedvarplot`. Otherwise, this syntax is equivalent to the previous syntax.

Added variable plots are used to determine the unique effect of adding a new term to a multilinear model. The plot shows the relationship between the part of the response unexplained by terms already in the model and the part of the new term unexplained by terms already in the model. The “unexplained” parts are measured by the residuals of the respective regressions. A scatter of the residuals from the two regressions forms the added variable plot.

In addition to the scatter of residuals, the plot produced by `addedvarplot` shows 95% confidence intervals on predictions from the fitted line. The fitted line has intercept zero

because, under typical linear model assumptions, both of the plotted variables have mean zero. The slope of the fitted line is the coefficient that the new term would have if it were added to the model with terms `inmodel`.

Added variable plots are sometimes known as partial regression leverage plots.

Examples

Load the data in `hald.mat`, which contains observations of the heat of reaction of various cement mixtures:

```
load hald
whos
```

| Name | Size | Bytes | Class | Attributes |
|-------------|-------|-------|--------|------------|
| Description | 22x58 | 2552 | char | |
| hald | 13x5 | 520 | double | |
| heat | 13x1 | 104 | double | |
| ingredients | 13x4 | 416 | double | |

Create an added variable plot to investigate the addition of the third column of `ingredients` to a model consisting of the first two columns:

```
inmodel = [true true false false];
addedvarplot(ingredients,heat,3,inmodel)
```

The wide scatter and the low slope of the fitted line are evidence against the statistical significance of adding the third column to the model.

See Also

`stepwise` | `stepwisefit`

Introduced before R2006a

addK

Class: clustering.evaluation.ClusterCriterion

Package: clustering.evaluation

Evaluate additional numbers of clusters

Syntax

```
eva_out = addK(eva, klist)
```

Description

`eva_out = addK(eva, klist)` returns a clustering evaluation object `eva_out` that contains the evaluation data stored in the input object `eva`, plus additional evaluation data for the proposed number of clusters specified in `klist`.

Input Arguments

eva — Clustering evaluation data

clustering evaluation object

Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using `evalclusters`.

klist — Additional numbers of clusters to evaluate

vector of positive integer values

Additional numbers of clusters to evaluate, specified as a vector of positive integer values. If any values in `klist` overlap with clustering solutions already evaluated in the input object `eva`, then `addK` ignores the overlapping values.

Output Arguments

eva_out — Updated clustering evaluation data

clustering evaluation object

Updated clustering evaluation data, returned as a clustering evaluation object. `eva_out` contains data on the proposed clustering solutions included in the input clustering evaluation object `eva`, plus data on the additional proposed numbers of clusters specified in `klist`.

For all clustering evaluation object classes, `addK` updates the `InspectedK` and `CriterionValues` properties to include the proposed clustering solutions specified in `klist` and their corresponding criterion values. `addK` might also update the `OptimalK` and `OptimalY` properties to reflect the new optimal number of clusters and optimal clustering solution.

For certain cluster evaluation objects classes, `addK` might also update the following additional property values:

- For gap evaluation objects — `LogW`, `ExpectedLogW`, `StdLogW`, and `SE`
- For silhouette evaluation objects — `ClusterSilhouettes`

Examples

Evaluate Additional Numbers of Clusters

Create a clustering evaluation object using `evalclusters`, then use `addK` to evaluate additional numbers of clusters.

Load the sample data.

```
load fisheriris
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Cluster the flower measurement data using `kmeans`, and use the Calinski-Harabasz criterion to evaluate proposed solutions of one through five clusters.

```
eva = evalclusters(meas, 'kmeans', 'calinski', 'klist', 1:5)
```

```
eva =  
  CalinskiHarabaszEvaluation with properties:  
  
    NumObservations: 150  
      InspectedK: [1 2 3 4 5]  
  CriterionValues: [NaN 513.9245 561.6278 530.4871 456.1279]  
      OptimalK: 3
```

The clustering evaluation object `eva` contains data on each proposed clustering solution. The returned value of `OptimalK` indicates that the optimal solution is three clusters.

Evaluate proposed solutions of 6 through 10 clusters using the same criteria. Add these evaluations to the original clustering evaluation object `eva`.

```
eva = addK(eva,6:10)
```

```
eva =  
  CalinskiHarabaszEvaluation with properties:  
  
    NumObservations: 150  
      InspectedK: [1 2 3 4 5 6 7 8 9 10]  
  CriterionValues: [1x10 double]  
      OptimalK: 3
```

The updated values for `InspectedK` and `CriterionValues` show that `eva` now evaluates proposed solutions of 1 through 10 clusters. The `OptimalK` value still equals 3, indicating that three clusters remain the optimal solution.

addlevels

Add levels to nominal or ordinal arrays

Note The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

Syntax

`B = addlevels(A,newlevels)`

Description

`B = addlevels(A,newlevels)` adds new levels specified by `newlevels` to the nominal or ordinal array `A`. `addlevels` adds the new levels at the end of the list of possible levels in `A`, but does not modify the value of any element. `B` does not contain elements at the new levels.

Examples

Add Levels To A Nominal Array

Add levels for additional species to Fisher's iris data.

Create a nominal array of the existing species in Fisher's iris data.

```
load fisheriris
species = nominal(species);
getlevels(species)

ans = 1x3 nominal array
      setosa      versicolor      virginica
```

Add two additional species.

```
species = addlevels(species,{'spuria','ruthenica'});
getlevels(species)

ans = 1x5 nominal array
      setosa      versicolor      virginica      spuria      ruthenica
```

Even though there are new levels, there are no elements in `species` that are in these new levels.

```
sum(species=='spuria')
ans = 0

sum(species=='ruthenica')
ans = 0
```

- “Add and Drop Category Levels” on page 2-24

Input Arguments

A — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created with `nominal` or `ordinal`.

newlevels — Levels to add

string array | cell array of character vectors | 2-D character matrix

Levels to add to the input `nominal` or `ordinal` array, specified as a string array, a cell array of character vectors, or a 2-D character matrix.

Data Types: `char` | `string` | `cell`

Output Arguments

B — Nominal or ordinal array

`nominal array` | `ordinal array`

Nominal or ordinal array, returned as a nominal or ordinal array object.

See Also

`droplevels` | `mergelevels` | `nominal` | `ordinal` | `reorderlevels`

Topics

“Add and Drop Category Levels” on page 2-24

Introduced in R2007a

addlistener

Class: grandstream

Add listener for event

Syntax

```
el = addlistener(hsource, 'eventname', callback)
el = addlistener(hsource, property, 'eventname', callback)
```

Description

`el = addlistener(hsource, 'eventname', callback)` creates a listener for the event named `eventname`, the source of which is handle object `hsource`. If `hsource` is an array of source handles, the listener responds to the named event on any handle in the array. `callback` is a function handle that is invoked when the event is triggered.

`el = addlistener(hsource, property, 'eventname', callback)` adds a listener for a property event. `eventname` must be `'PreGet'`, `'PostGet'`, `'PreSet'`, or `'PostSet'`. `property` must be either a property name or cell array of property names, or a `meta.property` or array of `meta.property`. The properties must belong to the class of `hsource`. If `hsource` is scalar, `property` can include dynamic properties.

For all forms, `addlistener` returns an `event.listener`. To remove a listener, delete the object returned by `addlistener`. For example, `delete(el)` calls the handle class `delete` method to remove the listener and delete it from the workspace.

See Also

`delete` | `dynamicprops` | `event.listener` | `events` | `meta.property` | `notify` | `grandstream` | `reset`

anova

Class: GeneralizedLinearMixedModel

Analysis of variance for generalized linear mixed-effects model

Syntax

```
stats = anova(glme)
stats = anova(glme, Name, Value)
```

Description

`stats = anova(glme)` returns a table, `stats`, that contains the results of F -tests to determine if all coefficients representing each fixed-effects term in the generalized linear mixed-effects model `glme` are equal to 0.

`stats = anova(glme, Name, Value)` returns a table, `stats`, using additional options specified by one or more `Name, Value` pair arguments. For example, you can specify the method used to compute the approximate denominator degrees of freedom for the F -tests.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

DFMethod — Method for computing approximate denominator degrees of freedom

'residual' (default) | 'none'

Method for computing approximate denominator degrees of freedom to use in the F -test, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

| Value | Description |
|------------|--|
| 'residual' | The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects. |
| 'none' | All degrees of freedom are set to infinity. |

The denominator degrees of freedom for the F -statistic correspond to the column DF2 in the output structure stats.

Example: 'DFMethod', 'none'

Output Arguments

stats — Results of F -tests for fixed-effects terms

table

Results of F -tests for fixed-effects terms, returned as a table with one row for each fixed-effects term in glme and the following columns.

| Column Name | Description |
|-------------|---|
| Term | Name of the fixed-effects term |
| FStat | F -statistic for the term |
| DF1 | Numerator degrees of freedom for the F -statistic |
| DF2 | Denominator degrees of freedom for the F -statistic |
| pValue | p -value for the term |

Each fixed-effects term is a continuous variable, a grouping variable, or an interaction between two or more continuous or grouping variables. For each fixed-effects term, `anova` performs an F -test (marginal test) to determine if all coefficients representing the fixed-effects term are equal to 0.

To perform tests for the type III hypothesis, when fitting the generalized linear mixed-effects model `fitglm`, you must use the 'effects' contrasts for the 'DummyVarCoding' name-value pair argument.

Examples

F-Tests for Fixed Effects

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept

grouped by factory, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is `log`. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defect}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log \mu_{ij} = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- `defectsij` is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- `newprocessij`, `time_devij`, and `temp_devij` are the measurements for each variable that correspond to factory i during batch j . For example, `newprocessij` indicates whether the batch produced by factory i during batch j used the new process.
- `supplier_Cij` and `supplier_Bij` are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)
  Distribution', 'Poisson', 'Link', 'log', 'FitMethod', 'Laplace', 'DummyVarCoding', 'effects')
```

```
glme =
```

Generalized linear mixed-effects model fit by ML

Model information:

| | |
|-----------------------------|---------|
| Number of observations | 100 |
| Fixed effects coefficients | 6 |
| Random effects coefficients | 20 |
| Covariance parameters | 1 |
| Distribution | Poisson |
| Link | Log |
| FitMethod | Laplace |

Formula:

defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1 | factory)

Model fit statistics:

| | | | |
|--------|--------|---------------|----------|
| AIC | BIC | LogLikelihood | Deviance |
| 416.35 | 434.58 | -201.17 | 402.35 |

Fixed effects coefficients (95% CIs):

| Name | Estimate | SE | tStat | DF | pValue |
|---------------|-----------|----------|----------|----|------------|
| '(Intercept)' | 1.4689 | 0.15988 | 9.1875 | 94 | 9.8194e-15 |
| 'newprocess' | -0.36766 | 0.17755 | -2.0708 | 94 | 0.041122 |
| 'time_dev' | -0.094521 | 0.82849 | -0.11409 | 94 | 0.90941 |
| 'temp_dev' | -0.28317 | 0.9617 | -0.29444 | 94 | 0.76907 |
| 'supplier_C' | -0.071868 | 0.078024 | -0.9211 | 94 | 0.35936 |
| 'supplier_B' | 0.071072 | 0.07739 | 0.91836 | 94 | 0.36078 |

| Lower | Upper |
|-----------|-----------|
| 1.1515 | 1.7864 |
| -0.72019 | -0.015134 |
| -1.7395 | 1.5505 |
| -2.1926 | 1.6263 |
| -0.22679 | 0.083051 |
| -0.082588 | 0.22473 |

Random effects covariance parameters:

Group: factory (20 Levels)

| Name1 | Name2 | Type | Estimate |
|---------------|---------------|-------|----------|
| '(Intercept)' | '(Intercept)' | 'std' | 0.31381 |

Group: Error

| Name | Estimate |
|--------------------|----------|
| 'sqrt(Dispersion)' | 1 |

Perform an F -test to determine if all fixed-effects coefficients are equal to 0.

```
stats = anova(glme)
```

```
stats =
```

```
ANOVA MARGINAL TESTS: DFMETHOD = 'RESIDUAL'
```

| Term | FStat | DF1 | DF2 | pValue |
|---------------|----------|-----|-----|------------|
| '(Intercept)' | 84.41 | 1 | 94 | 9.8194e-15 |
| 'newprocess' | 4.2881 | 1 | 94 | 0.041122 |
| 'time_dev' | 0.013016 | 1 | 94 | 0.90941 |
| 'temp_dev' | 0.086696 | 1 | 94 | 0.76907 |
| 'supplier' | 0.59212 | 2 | 94 | 0.5552 |

The P -values for the intercept, newprocess, time_dev, and temp_dev are the same as in the coefficient table of the glme display. The small P -values for the intercept and newprocess indicate that these are significant predictors at the 5% significance level. The large P -values for time_dev and temp_dev indicate that these are not significant predictors at this level.

The P -value of 0.5552 for supplier measures the combined significance for both coefficients representing the categorical variable supplier. This includes the dummy variables supplier_C and supplier_B as shown in the coefficient table of the glme display. The large P -value indicates that supplier is not a significant predictor at the 5% significance level.

Tips

- For each fixed-effects term, anova performs an F -test (marginal test) to determine if all coefficients representing the fixed-effects term are equal to 0.

When fitting a generalized linear mixed-effects (GLME) model using fitglme and one of the maximum likelihood fit methods ('Laplace' or 'ApproximateLaplace'):

- If you specify the 'CovarianceMethod' name-value pair argument as 'conditional', then the F -tests are conditional on the estimated covariance parameters.

- If you specify the 'CovarianceMethod' name-value pair as 'JointHessian', then the F -tests account for the uncertainty in estimation of covariance parameters.

When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods ('MPL' or 'REML'), `anova` uses the fitted linear mixed effects model from the final pseudo likelihood iteration for inference on fixed effects.

addTerms

Class: GeneralizedLinearModel

Add terms to generalized linear model

Syntax

```
mdl1 = addTerms(mdl, terms)
```

Description

`mdl1 = addTerms(mdl, terms)` returns a generalized linear model the same as `mdl` but with additional terms.

Input Arguments

mdl

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

terms

Terms to add to the `mdl` regression model. Specify as either a:

- Text representing one or more terms to add. For details, see “Wilkinson Notation” on page 32-21.
- Row or rows in the terms matrix (see `modelspec` in `fitglm`). For example, if there are three variables A, B, and C:

```
[0 0 0] represents a constant term or intercept  
[0 1 0] represents B; equivalently, A^0 * B^1 * C^0  
[1 0 1] represents A*C  
[2 0 0] represents A^2  
[0 1 2] represents B*(C^2)
```

Output Arguments

mdl1

Generalized linear model, the same as `mdl` but with additional terms given in `terms`. You can set `mdl1` equal to `mdl` to overwrite `mdl`.

Examples

Add a term to a generalized linear regression model

Create a model using just one predictor, then add a second.

Generate artificial data for the model, Poisson random numbers with two underlying predictors `X(1)` and `X(2)`.

```
rng default % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data. Use just the first predictor in the model.

```
mdl = fitglm(X,y,...
    'y ~ x1','distr','poisson')
```

```
mdl =
Generalized linear regression model:
log(y) ~ 1 + x1
Distribution = Poisson
```

Estimated Coefficients:

| | Estimate | SE | tStat | pValue |
|-------------|----------|-----------|--------|--------|
| | _____ | _____ | _____ | _____ |
| (Intercept) | 2.7784 | 0.014043 | 197.85 | 0 |
| x1 | 1.1732 | 0.0033653 | 348.6 | 0 |

```
100 observations, 98 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 1.25e+05, p-value = 0
```

Add the second predictor to the model.

```
mdl1 = addTerms(mdl, 'x2')
```

```
mdl1 =
Generalized linear regression model:
  log(y) ~ 1 + x1 + x2
  Distribution = Poisson
```

Estimated Coefficients:

| | Estimate | SE | tStat | pValue |
|-------------|----------|-----------|--------|--------|
| (Intercept) | 1.0405 | 0.022122 | 47.034 | 0 |
| x1 | 0.9968 | 0.003362 | 296.49 | 0 |
| x2 | 1.987 | 0.0063433 | 313.24 | 0 |

```
100 observations, 97 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 2.95e+05, p-value = 0
```

Definitions

Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

| Wilkinson Notation | Factors in Standard Notation |
|---|------------------------------|
| 1 | Constant (intercept) term |
| A^k , where k is a positive integer | A, A^2, \dots, A^k |
| $A + B$ | A, B |
| $A*B$ | $A, B, A*B$ |

| Wilkinson Notation | Factors in Standard Notation |
|--------------------|------------------------------|
| A:B | A*B only |
| -B | Do not include B |
| A*B + C | A, B, C, A*B |
| A + B + C + A:B | A, B, C, A*B |
| A*B*C - A:B:C | A, B, C, A*B, A*C, B*C |
| A*(B + C) | A, B, C, A*B, A*C |

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

For details, see Wilkinson and Rogers [1].

Alternatives

step adds or removes terms from a model using a greedy one-step algorithm.

addTerms

Class: LinearModel

Add terms to linear regression model

Syntax

```
mdl1 = addTerms(mdl, terms)
```

Description

`mdl1 = addTerms(mdl, terms)` returns a linear model `mdl1` that is the same as the input model `mdl`, but with additional terms as specified by `terms`.

Input Arguments

mdl — Full, fitted linear regression model

LinearModel object

Full, fitted linear regression model, specified as a `LinearModel` object constructed using `fitlm` or `stepwiselm`.

terms — Terms to add to regression model

formula | matrix

Terms to add to the regression model `mdl`, specified as one of the following:

- Formula representing one or more terms to add. For details, see Wilkinson Notation on page 32-25.
- Row or rows in the terms matrix (see the `modelspec` argument description in the fitting function `fitlm`). For example, if there are three variables A, B, and C:

```
[0 0 0] represents a constant term or intercept  
[0 1 0] represents B; equivalently, A^0 * B^1 * C^0  
[1 0 1] represents A*C
```

```
[2 0 0] represents A^2  
[0 1 2] represents B*(C^2)
```

Output Arguments

mdl1 — Regression model with additional terms

`LinearModel` object

Regression model with additional terms, returned as a `LinearModel` object. `mdl1` is the same as `mdl` but includes the additional terms specified in `terms`. To overwrite `mdl`, set `mdl1` equal to `mdl`.

Examples

Add Terms to Linear Regression Model

Create a model of the `carsmall` data without any interactions, then add an interaction term.

Load the `carsmall` data and make a model of the MPG as a function of weight and model year.

```
load carsmall  
tbl = table(MPG,Weight);  
tbl.Year = categorical(Model_Year);  
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Add an interaction term to `mdl`.

```
terms = 'Year*Weight';  
mdl1 = addTerms(mdl,terms)  
  
mdl1 =  
Linear regression model:  
MPG ~ 1 + Weight*Year + Weight^2
```

Estimated Coefficients:

| Estimate | SE | tStat | pValue |
|----------|----|-------|--------|
|----------|----|-------|--------|

| | | | | |
|----------------|-------------|------------|----------|------------|
| (Intercept) | 48.045 | 6.779 | 7.0874 | 3.3967e-10 |
| Weight | -0.012624 | 0.0041455 | -3.0454 | 0.0030751 |
| Year_76 | 2.7768 | 3.0538 | 0.90931 | 0.3657 |
| Year_82 | 16.416 | 4.9802 | 3.2962 | 0.0014196 |
| Weight:Year_76 | -0.00020693 | 0.00092403 | -0.22394 | 0.82333 |
| Weight:Year_82 | -0.0032574 | 0.0018919 | -1.7217 | 0.088673 |
| Weight^2 | 1.0121e-06 | 6.12e-07 | 1.6538 | 0.10177 |

Number of observations: 94, Error degrees of freedom: 87
 Root Mean Squared Error: 2.76
 R-squared: 0.89, Adjusted R-Squared 0.882
 F-statistic vs. constant model: 117, p-value = 1.88e-39

Definitions

Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

| Wilkinson Notation | Factors in Standard Notation |
|---|------------------------------|
| 1 | Constant (intercept) term |
| A^k , where k is a positive integer | A, A^2, \dots, A^k |
| $A + B$ | A, B |
| $A*B$ | $A, B, A*B$ |
| $A:B$ | $A*B$ only |
| $-B$ | Do not include B |
| $A*B + C$ | $A, B, C, A*B$ |
| $A + B + C + A:B$ | $A, B, C, A*B$ |
| $A*B*C - A:B:C$ | $A, B, C, A*B, A*C, B*C$ |
| $A*(B + C)$ | $A, B, C, A*B, A*C$ |

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1 .

For details, see Wilkinson and Rogers [1].

Alternatives

Use `stepwiselm` to select a model from a starting model, continuing until no single step is beneficial.

Use `removeTerms` to remove particular terms.

Use `step` to optimally improve the model by adding or removing terms.

adtest

Anderson-Darling test

Syntax

```
h = adtest(x)
h = adtest(x,Name,Value)
[h,p] = adtest( ___ )
[h,p,adstat,cv] = adtest( ___ )
```

Description

`h = adtest(x)` returns a test decision for the null hypothesis that the data in vector `x` is from a population with a normal distribution, using the Anderson-Darling test on page 32-33. The alternative hypothesis is that `x` is not from a population with a normal distribution. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, or 0 otherwise.

`h = adtest(x,Name,Value)` returns a test decision for the Anderson-Darling test with additional options specified by one or more name-value pair arguments. For example, you can specify a null distribution other than normal, or select an alternative method for calculating the *p*-value.

`[h,p] = adtest(___)` also returns the *p*-value, `p`, of the Anderson-Darling test, using any of the input arguments from the previous syntaxes.

`[h,p,adstat,cv] = adtest(___)` also returns the test statistic, `adstat`, and the critical value, `cv`, for the Anderson-Darling test.

Examples

Anderson-Darling Test for a Normal Distribution

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades
x = grades(:,1);
```

Test the null hypothesis that the exam grades come from a normal distribution. You do not need to specify values for the population parameters.

```
[h,p,adstat,cv] = adtest(x)
```

```
h = logical
    0
```

```
p = 0.1854
```

```
adstat = 0.5194
```

```
cv = 0.7470
```

The returned value of `h = 0` indicates that `adtest` fails to reject the null hypothesis at the default 5% significance level.

Anderson-Darling Test for Extreme Value Distribution

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades
x = grades(:,1);
```

Test the null hypothesis that the exam grades come from an extreme value distribution. You do not need to specify values for the population parameters.

```
[h,p] = adtest(x, 'Distribution', 'ev')
```

```
h = logical
    0
```

```
p = 0.0714
```

The returned value of $h = 0$ indicates that `adtest` fails to reject the null hypothesis at the default 5% significance level.

Anderson-Darling Test Using Specified Probability Distribution

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades
x = grades(:,1);
```

Create a normal probability distribution object with mean $\mu = 75$ and standard deviation $\sigma = 10$.

```
dist = makedist('normal','mu',75,'sigma',10)
```

```
dist =
    NormalDistribution

    Normal distribution
         mu = 75
        sigma = 10
```

Test the null hypothesis that x comes from the hypothesized normal distribution.

```
[h,p] = adtest(x,'Distribution',dist)
```

```
h = logical
    0
```

```
p = 0.4687
```

The returned value of $h = 0$ indicates that `adtest` fails to reject the null hypothesis at the default 5% significance level.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector. Missing observations in `x`, indicated by `NaN`, are ignored.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Alpha',0.01,'MCTol',0.01` conducts the hypothesis test at the 1% significance level, and determines the p-value, `p`, using a Monte Carlo simulation with a maximum Monte Carlo standard error for `p` of 0.01.

Distribution — Hypothesized distribution

'norm' (default) | 'exp' | 'ev' | 'logn' | 'weibull' | probability distribution object

Hypothesized distribution of data vector `x`, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

| | |
|-----------|----------------------------|
| 'norm' | Normal distribution |
| 'exp' | Exponential distribution |
| 'ev' | Extreme value distribution |
| 'logn' | Lognormal distribution |
| 'weibull' | Weibull distribution |

In this case, you do not need to specify population parameters. Instead, `adtest` estimates the distribution parameters from the sample data and tests `x` against a composite hypothesis that it comes from the selected distribution family with parameters unspecified.

Alternatively, you can specify any continuous probability distribution object for the null distribution. In this case, you must specify all the distribution parameters, and `adtest`

tests x against a simple hypothesis that it comes from the given distribution with its specified parameters.

Example: `'Distribution', 'exp'`

Alpha — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

MCTol — Maximum Monte Carlo standard error

positive scalar value

Maximum Monte Carlo standard error on page 32-34 for the p -value, p , specified as the comma-separated pair consisting of `'MCTol'` and a positive scalar value. If you use `MCTol`, `adtest` determines p using a Monte Carlo simulation, and the name-value pair argument `Asymptotic` must have the value `false`.

Example: `'MCTol', 0.01`

Data Types: `single` | `double`

Asymptotic — Method for calculating p -value

`false` (default) | `true`

Method for calculating the p -value of the Anderson-Darling test, specified as the comma-separated pair consisting of `'Asymptotic'` and either `true` or `false`. If you specify `'true'`, `adtest` estimates the p -value using the limiting distribution of the Anderson-Darling test statistic. If you specify `false`, `adtest` calculates the p -value based on an analytical formula. For sample sizes greater than 120, the limiting distribution estimate is likely to be more accurate than the small sample size approximation method.

- If you specify a distribution family with unknown parameters for the `Distribution` name-value pair, `Asymptotic` must be `false`.
- If you use `MCTol` to calculate the p -value using a Monte Carlo simulation, `Asymptotic` must be `false`.

Example: `'Asymptotic', true`

Data Types: `logical`

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If $h = 1$, this indicates the rejection of the null hypothesis at the `Alpha` significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the `Alpha` significance level.

p — *p*-value

scalar value in the range [0,1]

p-value of the Anderson-Darling test, returned as a scalar value in the range [0,1]. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. *p* is calculated using one of these methods:

- If the hypothesized distribution is a fully specified probability distribution object, `adtest` calculates *p* analytically. If `'Asymptotic'` is `true`, `adtest` uses the asymptotic distribution of the test statistic. If you specify a value for `'MCTol'`, `adtest` uses a Monte Carlo simulation.
- If the hypothesized distribution is specified as a distribution family with unknown parameters, `adtest` retrieves the critical value from a table and uses inverse interpolation to determine the *p*-value. If you specify a value for `'MCTol'`, `adtest` uses a Monte Carlo simulation.

adstat — Test statistic

scalar value

Test statistic for the Anderson-Darling test, returned as a scalar value.

- If the hypothesized distribution is a fully specified probability distribution object, `adtest` computes `adstat` using specified parameters.
- If the hypothesized distribution is specified as a distribution family with unknown parameters, `adtest` computes `adstat` using parameters estimated from the sample data.

cv — Critical value

scalar value

Critical value for the Anderson-Darling test at the significance level α , returned as a scalar value. `adtest` determines `cv` by interpolating into a table based on the specified α significance level.

Definitions

Anderson-Darling Test

The Anderson-Darling test is commonly used to test whether a data sample comes from a normal distribution. However, it can be used to test for another hypothesized distribution, even if you do not fully specify the distribution parameters. Instead, the test estimates any unknown parameters from the data sample.

The test statistic belongs to the family of quadratic empirical distribution function statistics, which measure the distance between the hypothesized distribution, $F(x)$ and the empirical cdf, $F_n(x)$ as

$$n \int_{-\infty}^{\infty} (F_n(x) - F(x))^2 w(x) dF(x),$$

over the ordered sample values $x_1 < x_2 < \dots < x_n$, where $w(x)$ is a weight function and n is the number of data points in the sample.

The weight function for the Anderson-Darling test is

$$w(x) = [F(x)(1 - F(x))]^{-1},$$

which places greater weight on the observations in the tails of the distribution, thus making the test more sensitive to outliers and better at detecting departure from normality in the tails of the distribution.

The Anderson-Darling test statistic is

$$A_n^2 = -n - \sum_{i=1}^n \frac{2i-1}{n} [\ln(F(X_i)) + \ln(1 - F(X_{n+1-i}))],$$

where $\{X_1 < \dots < X_n\}$ are the ordered sample data points and n is the number of data points in the sample.

In `adtest`, the decision to reject or not reject the null hypothesis is based on comparing the p -value for the hypothesis test with the specified significance level, not on comparing the test statistic with the critical value.

Monte Carlo Standard Error

The Monte Carlo standard error is the error due to simulating the p -value.

The Monte Carlo standard error is calculated as

$$SE = \sqrt{\frac{(\hat{p})(1 - \hat{p})}{\text{mc reps}}},$$

where \hat{p} is the estimated p -value of the hypothesis test, and `mc reps` is the number of Monte Carlo replications performed.

`adtest` chooses the number of Monte Carlo replications, `mc reps`, large enough to make the Monte Carlo standard error for \hat{p} less than the value specified for `MCTol`.

Introduced in R2013a

andrewsplot

Andrews plot

Syntax

```
andrewsplot(X)
andrewsplot(X, ..., 'Standardize', standopt)
andrewsplot(X, ..., 'Quantile', alpha)
andrewsplot(X, ..., 'Group', group)
andrewsplot(X, ..., 'PropName', PropVal, ...)
h = andrewsplot(X, ...)
```

Description

`andrewsplot(X)` creates an Andrews plot of the multivariate data in the matrix X . The rows of X correspond to observations, the columns to variables. Andrews plots represent each observation by a function $f(t)$ of a continuous dummy variable t over the interval $[0,1]$. $f(t)$ is defined for the i th observation in X as

$$f(t) = X(i,1) / \sqrt{2} + X(i,2) \sin(2\pi t) + X(i,3) \cos(2\pi t) + \dots$$

`andrewsplot` treats NaN values in X as missing values and ignores the corresponding rows.

`andrewsplot(X, ..., 'Standardize', standopt)` creates an Andrews plot where *standopt* is one of the following:

- 'on' — scales each column of X to have mean 0 and standard deviation 1 before making the plot.
- 'PCA' — creates an Andrews plot from the principal component scores of X , in order of decreasing eigenvalue. (See `pca`.)
- 'PCAStd' — creates an Andrews plot using the standardized principal component scores. (See `pca`.)

`andrewsplot(X, ..., 'Quantile', alpha)` plots only the median and the α and $(1 - \alpha)$ quantiles of $f(t)$ at each value of t . This is useful if X contains many observations.

`andrewsplot(X, ..., 'Group', group)` plots the data in different groups with different colors. Groups are defined by `group`, a numeric array containing a group index for each observation. `group` can also be a categorical array, character matrix, string array, or cell array of character vectors containing a group name for each observation.

`andrewsplot(X, ..., 'PropName', PropVal, ...)` sets optional lineseries object properties to the specified values for all lineseries objects created by `andrewsplot`. (See Line Properties.)

`h = andrewsplot(X, ...)` returns a column vector of handles to the lineseries objects created by `andrewsplot`, one handle per row of X . If you use the 'Quantile' input parameter, `h` contains one handle for each of the three lineseries objects created. If you use both the 'Quantile' and the 'Group' input parameters, `h` contains three handles for each group.

Examples

Create Andrews Plot to Visualize Grouped Data

This example shows how to create an Andrews plot to visualize grouped sample data.

Load the sample data.

```
load fisheriris
```

Create an Andrews plot, grouping the sample data by species.

```
andrewsplot(meas, 'group', species)
```

Create a second, simplified Andrews plot that only displays the median and quartiles of each group.

```
andrewsplot(meas, 'group', species, 'quantile', .25)
```

Introduced before R2006a

anova

Class: CompactLinearModel

Analysis of variance for linear model

Syntax

```
tbl = anova mdl
tbl = anova(mdl, anovatype)
tbl = anova(mdl, anovatype, sstype)
```

Description

`tbl = anova(mdl)` returns a table with summary ANOVA statistics.

`tbl = anova(mdl, anovatype)` returns ANOVA statistics of the chosen type.

`tbl = anova(mdl, anovatype, sstype)` computes ANOVA statistics using the chosen type of sum of squares.

Input Arguments

mdl — Linear model object

LinearModel object | CompactLinearModel object

Linear model object, specified as a full LinearModel object constructed using `fitlm` or `stepwiselm`, or a compacted CompactLinearModel object constructed using `compact`.

anovatype — ANOVA type

'component' (default) | 'summary'

ANOVA type, specified as one of the following:

- 'component' — `tbl` displays a 'components' ANOVA table, with sums of squares and *F* tests attributable to each term in the model except the constant term.

- 'summary' — `tbl` displays a summary ANOVA table with an F test for the model as a whole.
 - If there are both linear and higher-order terms, there is also an F test for the higher-order terms as a group.
 - If `mdl` is a full `LinearModel` object and the sample data contains replications (multiple observations sharing the same predictor values), there is also an F test for lack-of-fit computed by decomposing the residual sum of squares into a sum of squares for the replicated observations and the remaining sum of squares. If `mdl` is a compacted `CompactLinearModel` object, then the ANOVA table presents, but does not decompose, the residual sum of squares.

sstype — Sum of squares type

'h' (default) | 1 | 2 | 3

Sum of squares type, specified as one of the following:

| Value | Description |
|-------|---|
| 1 | Type I sum of squares. The reduction in residual sum of squares obtained by adding that term to a fit that already includes the terms listed before it. |
| 2 | Type II sum of squares. The reduction in residual sum of squares obtained by adding that term to a model consisting of all other terms that do not contain the term in question |
| 3 | Type III sum of squares. The reduction in residual sum of squares obtained by adding that term to a model containing all other terms, but with their effects constrained to obey the usual "sigma restrictions" that make models estimable. |
| 'h' | Hierarchical model. Similar to Type II, but uses both continuous and categorical factors to determine the hierarchy of terms. |

For Type III sum of squares:

- If `mdl` is a `CompactLinearModel` object and the model is non-hierarchical, `anova` errors.
- If `mdl` is a full `LinearModel` object and the model is non-hierarchical, then `anova` refits the model using effects coding whenever it needs to compute Type III sums of squares.
- If `mdl` is either a `CompactLinearModel` or a `LinearModel` object and the model is hierarchical, `anova` computes the results without refitting the model.

`sstype` only applies if `anovatype` is 'component'.

For more information about sum of squares types, see the `sstype` argument on the `anovan` function reference page.

Data Types: `char` | `string` | `single` | `double`

Output Arguments

tbl — ANOVA summary statistics table

table

ANOVA summary statistics table, returned as table

The contents of `tbl` depends on the ANOVA type specified in `anovatype`.

- If `anovatype` is 'component', then `tbl` contains:
 - Sum of squares
 - Degrees of freedom
 - Mean squares
 - F statistic
 - p -value
 - Formula used for model
- If `anovatype` is 'summary', then `tbl` contains:
 - Total Sum of Squares
 - Model Sum of Squares
 - Linear Sum of Squares (present if model has powers or interactions)

- Nonlinear Sum of Squares (present if model has powers or interactions)
- Residual Sum of Squares
 - Lack-of-fit Sum of Squares (present if model has replicates)
 - Pure error Sum of Squares (present if model has replicates)

Examples

Component ANOVA Table for Linear Model

Create a component ANOVA table from a model of the `hospital` data.

Load the `hospital` data and make a model of the blood pressure as a function of age and gender.

```
load hospital
tbl = table(hospital.Age, hospital.Sex, hospital.BloodPressure(:,2), ...
           'VariableNames', {'Age', 'Sex', 'BloodPressure'});
tbl.Sex = categorical(tbl.Sex);
mdl = fitlm(tbl, 'BloodPressure ~ Sex + Age^2');
```

Create an ANOVA table.

```
tbl = anova(mdl)
```

```
tbl =
```

```
4x5 table
```

| | SumSq | DF | MeanSq | F | pValue |
|-------|--------|-----|--------|---------|----------|
| | ----- | --- | ----- | ----- | ----- |
| Age | 18.705 | 1 | 18.705 | 0.40055 | 0.52831 |
| Sex | 222.09 | 1 | 222.09 | 4.7558 | 0.031643 |
| Age^2 | 30.934 | 1 | 30.934 | 0.66242 | 0.41772 |
| Error | 4483.1 | 96 | 46.699 | | |

Summary ANOVA Table for Linear Model

Create a summary ANOVA table from a model of the `carsmall` data.

Load the `carsmall` data and make a model of the MPG as a function of weight and model year.

```
load carsmall
cars = table(MPG,Weight);
cars.Year = ordinal(Model_Year);
mdl = fitlm(cars,'MPG ~ Year + Weight^2');
```

Create a summary ANOVA table.

```
tbl = anova(mdl,'summary')
```

```
tbl =
```

```
7x5 table
```

| | SumSq | DF | MeanSq | F | pValue |
|---------------|--------|-----|--------|--------|------------|
| | ----- | --- | ----- | ----- | ----- |
| Total | 6005.3 | 93 | 64.573 | | |
| Model | 5317 | 4 | 1329.3 | 171.88 | 5.5208e-41 |
| . Linear | 5240.3 | 3 | 1746.8 | 225.87 | 1.7302e-41 |
| . Nonlinear | 76.688 | 1 | 76.688 | 9.9164 | 0.0022303 |
| Residual | 688.27 | 89 | 7.7334 | | |
| . Lack of fit | 663.77 | 86 | 7.7183 | 0.9451 | 0.62874 |
| . Pure error | 24.5 | 3 | 8.1667 | | |

The summary ANOVA table shows tests for groups of terms. The nonlinear group consists of just the `Weight^2` term, so it has the same *P*-value as that term in the component ANOVA table. The *F* statistic comparing the residual sum of squares to a "pure error" estimate from replicated observations shows no evidence of lack of fit.

- "ANOVA" on page 11-21

Alternatives

More complete ANOVA statistics are available in the `anova1`, `anova2`, and `anovan` functions.

anova

Class: LinearMixedModel

Analysis of variance for linear mixed-effects model

Syntax

```
stats = anova(lme)
stats = anova(lme, Name, Value)
```

Description

`stats = anova(lme)` returns the dataset array `stats` that includes the results of the F -tests for each fixed-effects term in the linear mixed-effects model `lme`.

`stats = anova(lme, Name, Value)` also returns the dataset array `stats` with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a LinearMixedModel object constructed using `fitlme` or `fitlmematrix`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

DFMethod — Method for computing approximate degrees of freedom`'residual' (default) | 'satterthwaite' | 'none'`

Method for computing approximate degrees of freedom to use in the F -test, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

| | |
|------------------------------|---|
| <code>'residual'</code> | Default. The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects. |
| <code>'satterthwaite'</code> | Satterthwaite approximation. |
| <code>'none'</code> | All degrees of freedom are set to infinity. |

For example, you can specify the Satterthwaite approximation as follows.

Example: `'DFMethod', 'satterthwaite'`

Output Arguments

stats — Results of F -tests for fixed-effects terms`dataset array`

Results of F -tests for fixed-effects terms, returned as a dataset array with the following columns.

| | |
|--------|---|
| Term | Name of the fixed effects term |
| Fstat | F -statistic for the term |
| DF1 | Numerator degrees of freedom for the F -statistic |
| DF2 | Denominator degrees of freedom for the F -statistic |
| pValue | p -value of the test for the term |

There is one row for each fixed-effects term. Each term is a continuous variable, a grouping variable, or an interaction between two or more continuous or grouping variables. For each fixed-effects term, `anova` performs an F -test (marginal test) to determine if all coefficients representing the fixed-effects term are 0. To perform tests for

the type III hypothesis, you must use the 'effects' contrasts while fitting the linear mixed-effects model.

Examples

F-Tests for Fixed Effects

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'shift.mat'))
```

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

```
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift. Use the restricted maximum likelihood method and 'effects' contrasts.

'effects' contrasts indicate that the coefficients sum to 0, and fitlme creates two contrast-coded variables in the fixed-effects design matrix, \$X\$1 and \$X\$2, where

$$Shift_Evening = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

and

$$Shift_Morning = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases} .$$

The model corresponds to

$$\begin{aligned} \text{MorningShift : } QCDev_{im} &= \beta_0 + \beta_2 \text{Shift_Morning}_i + b_{0m} + \epsilon_{im}, & m = 1, 2, \dots, 5, \\ \text{EveningShift : } QCDev_{im} &= \beta_0 + \beta_1 \text{Shift_Evening}_i + b_{0m} + \epsilon_{im}, \\ \text{NightShift : } QCDev_{im} &= \beta_0 - \beta_1 \text{Shift_Evening}_i - \beta_2 \text{Shift_Morning}_i + b_{0m} + \epsilon_{im}, \end{aligned}$$

where $b \sim N(0, \sigma_b^2)$ and $\epsilon \sim N(0, \sigma^2)$.

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)', ...
'FitMethod', 'REML', 'DummyVarCoding', 'effects')
```

```
lme =
```

Linear mixed-effects model fit by REML

Model information:

| | |
|-----------------------------|----|
| Number of observations | 15 |
| Fixed effects coefficients | 3 |
| Random effects coefficients | 5 |
| Covariance parameters | 2 |

Formula:

```
QCDev ~ 1 + Shift + (1 | Operator)
```

Model fit statistics:

| | | | |
|--------|--------|---------------|----------|
| AIC | BIC | LogLikelihood | Deviance |
| 58.913 | 61.337 | -24.456 | 48.913 |

Fixed effects coefficients (95% CIs):

| Name | Estimate | SE | tStat | DF | pValue |
|-----------------|----------|---------|---------|----|-----------|
| '(Intercept)' | 3.6525 | 0.94109 | 3.8812 | 12 | 0.0021832 |
| 'Shift_Evening' | -0.53293 | 0.31206 | -1.7078 | 12 | 0.11339 |
| 'Shift_Morning' | -0.91973 | 0.31206 | -2.9473 | 12 | 0.012206 |

| Lower | Upper |
|---------|----------|
| 1.6021 | 5.703 |
| -1.2129 | 0.14699 |
| -1.5997 | -0.23981 |

Random effects covariance parameters (95% CIs):

Group: Operator (5 Levels)

| Name1 | Name2 | Type | Estimate | Lower | Upper |
|---------------|---------------|-------|----------|---------|--------|
| '(Intercept)' | '(Intercept)' | 'std' | 2.0457 | 0.98207 | 4.2612 |

| Name | Estimate | Lower | Upper |
|-----------|----------|---------|-------|
| 'Res Std' | 0.85462 | 0.52357 | 1.395 |

Perform an F -test to determine if all fixed-effects coefficients are 0.

```
anova(lme)
```

```
ans =
```

```
ANOVA MARGINAL TESTS: DFMETHOD = 'RESIDUAL'
```

| Term | FStat | DF1 | DF2 | pValue |
|---------------|--------|-----|-----|-----------|
| '(Intercept)' | 15.063 | 1 | 12 | 0.0021832 |
| 'Shift' | 11.091 | 2 | 12 | 0.0018721 |

The P -value for the constant term, 0.0021832, is the same as in the coefficient table in the `lme` display. The P -value of 0.0018721 for `Shift` measures the combined significance for both coefficients representing `Shift`.

ANOVA for Fixed-Effects in LME Model

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'fertilizer.mat'))
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently. Use the `'effects'` contrasts when fitting the data for the type III sum of squares.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)', ...
'DummyVarCoding', 'effects')
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

| | |
|-----------------------------|----|
| Number of observations | 60 |
| Fixed effects coefficients | 20 |
| Random effects coefficients | 18 |
| Covariance parameters | 3 |

```
Formula:
```

```
Yield ~ 1 + Tomato*Fertilizer + (1 | Soil) + (1 | Soil:Tomato)
```

```
Model fit statistics:
```

| | | | |
|--------|--------|---------------|----------|
| AIC | BIC | LogLikelihood | Deviance |
| 522.57 | 570.74 | -238.29 | 476.57 |

```
Fixed effects coefficients (95% CIs):
```

| Name | Estimate | SE | tStat | DF |

```

Perform an analysis of variance to test for the fixed-effects.

```
anova(lme)
```

```
ans =
```

```
ANOVA MARGINAL TESTS: DFMETHOD = 'RESIDUAL'
```

| Term | FStat | DF1 | DF2 | pValue |
|---------------------|--------|-----|-----|------------|
| '(Intercept)' | 1004.2 | 1 | 40 | 5.9086e-30 |
| 'Tomato' | 7.1663 | 4 | 40 | 0.00018935 |
| 'Fertilizer' | 58.833 | 3 | 40 | 1.0024e-14 |
| 'Tomato:Fertilizer' | 1.4182 | 12 | 40 | 0.19804 |

The P -value for the constant term, 5.9086e-30, is the same as in the coefficient table in the lme display. The P -values of 0.00018935, 1.0024e-14, and 0.19804 for **Tomato**, **Fertilizer**, and **Tomato:Fertilizer** represent the combined significance for all tomato coefficients, fertilizer coefficients, and coefficients representing the interaction between the tomato and fertilizer, respectively. The P -value of 0.19804 indicates that the interaction between tomato and fertilizer is not significant.

Satterthwaite Approximation for Degrees of Freedom

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'))
```

weight contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define Subject and Program as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit the model using the 'effects' contrasts.

```
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)',...
            'DummyVarCoding','effects')
```

```
lme =
```

Linear mixed-effects model fit by ML

Model information:

| | |
|-----------------------------|-----|
| Number of observations | 120 |
| Fixed effects coefficients | 9 |
| Random effects coefficients | 40 |
| Covariance parameters | 4 |

Formula:

```
y ~ 1 + InitialWeight + Program*Week + (1 + Week | Subject)
```

Model fit statistics:

| | | | |
|---------|--------|---------------|----------|
| AIC | BIC | LogLikelihood | Deviance |
| -22.981 | 13.257 | 24.49 | -48.981 |

Fixed effects coefficients (95% CIs):

| Name | Estimate | SE | tStat | DF |
|------------------|-----------|-----------|----------|-----|
| '(Intercept)' | 0.77122 | 0.24309 | 3.1725 | 111 |
| 'InitialWeight' | 0.0031879 | 0.0013814 | 2.3078 | 111 |
| 'Program_A' | -0.11017 | 0.080377 | -1.3707 | 111 |
| 'Program_B' | 0.25061 | 0.08045 | 3.1151 | 111 |
| 'Program_C' | -0.14344 | 0.080475 | -1.7824 | 111 |
| 'Week' | 0.19881 | 0.033727 | 5.8946 | 111 |
| 'Program_A:Week' | -0.025607 | 0.058417 | -0.43835 | 111 |
| 'Program_B:Week' | 0.013164 | 0.058417 | 0.22535 | 111 |
| 'Program_C:Week' | 0.0049357 | 0.058417 | 0.084492 | 111 |

| pValue | Lower | Upper |
|------------|------------|-----------|
| 0.0019549 | 0.28951 | 1.2529 |
| 0.022863 | 0.00045067 | 0.0059252 |
| 0.17323 | -0.26945 | 0.0491 |
| 0.0023402 | 0.091195 | 0.41003 |
| 0.077424 | -0.3029 | 0.016031 |
| 4.1099e-08 | 0.13198 | 0.26564 |
| 0.66198 | -0.14136 | 0.090149 |
| 0.82212 | -0.10259 | 0.12892 |
| 0.93282 | -0.11082 | 0.12069 |

Random effects covariance parameters (95% CIs):

Group: Subject (20 Levels)

| Name1 | Name2 | Type | Estimate | Lower |
|---------------|---------------|--------|----------|---------|
| '(Intercept)' | '(Intercept)' | 'std' | 0.18407 | 0.12281 |
| 'Week' | '(Intercept)' | 'corr' | 0.66841 | 0.21076 |
| 'Week' | 'Week' | 'std' | 0.15033 | 0.11004 |

| Upper |
|---------|
| 0.27587 |
| 0.88573 |
| 0.20537 |

Group: Error

| Name | Estimate | Lower | Upper |
|-----------|----------|----------|---------|
| 'Res Std' | 0.10261 | 0.087882 | 0.11981 |

The *P*-values 0.022863 and 4.1099e-08 indicate significant effects of the initial weights of the subjects and the time factor in the amount of weight lost. The weight loss of subjects who are in program B is significantly different relative to the weight loss of subjects that are in program A. The lower and upper limits of the covariance parameters for the random effects do not include zero, thus they are significant.

Perform an F-test that all fixed-effects coefficients are zero.

```
anova(lme)
```

```
ans =
```

```
ANOVA MARGINAL TESTS: DFMETHOD = 'RESIDUAL'
```

| Term | FStat | DF1 | DF2 | pValue |
|-----------------|----------|-----|-----|------------|
| '(Intercept)' | 10.065 | 1 | 111 | 0.0019549 |
| 'InitialWeight' | 5.326 | 1 | 111 | 0.022863 |
| 'Program' | 3.6798 | 3 | 111 | 0.014286 |
| 'Week' | 34.747 | 1 | 111 | 4.1099e-08 |
| 'Program:Week' | 0.066648 | 3 | 111 | 0.97748 |

The *P*-values for the constant term, initial weight, and week are the same as in the coefficient table in the previous `lme` output display. The *P*-value of 0.014286 for `Program` represents the combined significance for all program coefficients. Similarly, the *P*-value for the interaction between program and week (`Program:Week`) measures the combined significance for all coefficients representing this interaction.

Now, use the Satterthwaite method to compute the degrees of freedom.

```
anova(lme, 'DFMethod', 'satterthwaite')
```

```
ans =
```

```
ANOVA MARGINAL TESTS: DFMETHOD = 'SATTERTHWAITE'
```

| Term | FStat | DF1 | DF2 | pValue |
|-----------------|----------|-----|--------|------------|
| '(Intercept)' | 10.065 | 1 | 20.445 | 0.004695 |
| 'InitialWeight' | 5.326 | 1 | 20 | 0.031827 |
| 'Program' | 3.6798 | 3 | 19.14 | 0.030233 |
| 'Week' | 34.747 | 1 | 20 | 9.1346e-06 |
| 'Program:Week' | 0.066648 | 3 | 20 | 0.97697 |

The Satterthwaite method produces smaller denominator degrees of freedom and slightly larger *P*-values.

Tips

- For each fixed-effects term, `anova` performs an *F*-test (marginal test), that all coefficients representing the fixed-effects term are 0. To perform tests for type III

hypotheses, you must set the 'DummyVarCoding' name-value pair argument to 'effects' contrasts while fitting your linear mixed-effects model.

`LinearMixedModel` | `fitlme` | `fitlmematrix`

anova1

One-way analysis of variance

Syntax

```
p = anova1(y)
p = anova1(y,group)
p = anova1(y,group,displayopt)
[p,tbl] = anova1(____)
[p,tbl,stats] = anova1(____)
```

Description

`p = anova1(y)` returns the p -value for a balanced one-way ANOVA on page 9-3. It also displays the standard ANOVA table (`tbl`) and a box plot of the columns of `y`. `anova1` tests the hypothesis that the samples in `y` are drawn from populations with the same mean against the alternative hypothesis that the population means are not all the same.

`p = anova1(y,group)` returns the p -value for a balanced one-way ANOVA by group. It also displays the standard ANOVA table and a box-plot on page 32-72 of the observations of `y` by group.

`p = anova1(y,group,displayopt)` enables the ANOVA table and box plot displays when `displayopt` is 'on' (default) and suppresses the displays when `displayopt` is 'off'.

`[p,tbl] = anova1(____)` returns the ANOVA table (including column and row labels) in the cell array `tbl`. To copy a text version of the ANOVA table to the clipboard, select **Edit > Copy Text**.

`[p,tbl,stats] = anova1(____)` returns a structure, `stats`, which you can use to perform a multiple comparison test on page 9-26. A multiple comparison test enables you to determine which pairs of group means are significantly different. To perform this test, use `multcompare`, providing the `stats` structure as an input argument.

Examples

One-Way ANOVA

Create sample data matrix `y` with columns that are constants, plus random normal disturbances with mean 0 and standard deviation 1.

```
y = meshgrid(1:5);  
rng default; % For reproducibility  
y = y + normrnd(0,1,5,5)
```

`y =`

```
    1.5377    0.6923    1.6501    3.7950    5.6715  
    2.8339    1.5664    6.0349    3.8759    3.7925  
   -1.2588    2.3426    3.7254    5.4897    5.7172  
    1.8622    5.5784    2.9369    5.4090    6.6302  
    1.3188    4.7694    3.7147    5.4172    5.4889
```

Perform one-way ANOVA.

```
p = anova1(y)
```

`p =`

```
    0.0023
```

ANOVA Table

| Source | SS | df | MS | F | Prob>F |
|---------|---------|----|---------|------|--------|
| Columns | 53.7238 | 4 | 13.4309 | 6.05 | 0.0023 |
| Error | 44.408 | 20 | 2.2204 | | |
| Total | 98.1318 | 24 | | | |

The ANOVA table shows the between-groups variation (Columns) and within-groups variation (Error). *SS* is the sum of squares, and *df* is the degrees of freedom. The total degrees of freedom is total number of observations minus one, which is $25 - 1 = 24$. The between-groups degrees of freedom is number of groups minus one, which is $5 - 1 = 4$. The within-groups degrees of freedom is total degrees of freedom minus the between groups degrees of freedom, which is $24 - 4 = 20$.

MS is the mean squared error, which is SS/df for each source of variation. The *F*-statistic is the ratio of the mean squared errors ($13.4309/2.2204$). The *p*-value is the probability that the test statistic can take a value greater than the value of the computed test

statistic, i.e., $P(F > 6.05)$. The small p -value of 0.0023 indicates that differences between column means are significant.

Compare Beam Strength Using One-Way ANOVA

Input the sample data.

```
strength = [82 86 79 83 84 85 86 87 74 82 ...
            78 75 76 77 79 79 77 78 82 79];
alloy = {'st', 'st', 'st', 'st', 'st', 'st', 'st', 'st', ...
        'al1', 'al1', 'al1', 'al1', 'al1', 'al1', ...
        'al2', 'al2', 'al2', 'al2', 'al2', 'al2'};
```

The data are from a study of the strength of structural beams in Hogg (1987). The vector strength measures deflections of beams in thousandths of an inch under 3000 pounds of force. The vector alloy identifies each beam as steel ('st'), alloy 1 ('al1'), or alloy 2 ('al2'). Although alloy is sorted in this example, grouping variables do not need to be sorted.

Test the null hypothesis that the steel beams are equal in strength to the beams made of the two more expensive alloys. Turn the figure display off and return the ANOVA results in a cell array.

```
[p, tbl] = anova1(strength, alloy, 'off')
```

```
p = 1.5264e-04
```

```
tbl = 4x6 cell array
      Columns 1 through 5
```

| | | | | |
|-------------|--------------|---------|---------------|---------------|
| {'Source' } | {'SS' } | {'df' } | {'MS' } | {'F' } |
| {'Groups' } | {[184.8000]} | {[2]} | {[92.4000]} | {[15.4000]} |
| {'Error' } | {[102.0000]} | {[17]} | {[6.0000]} | {0x0 double } |
| {'Total' } | {[286.8000]} | {[19]} | {0x0 double } | {0x0 double } |

```
Column 6
```

| |
|----------------|
| {'Prob>F' } |
| {[1.5264e-04]} |
| {0x0 double } |
| {0x0 double } |

The total degrees of freedom is total number of observations minus one, which is $20 - 1 = 19$. The between-groups degrees of freedom is number of groups minus one, which is $3 - 1 = 2$. The within-groups degrees of freedom is total degrees of freedom minus the between groups degrees of freedom, which is $19 - 2 = 17$.

MS is the mean squared error, which is SS/df for each source of variation. The F -statistic is the ratio of the mean squared errors. The p -value is the probability that the test statistic can take a value greater than or equal to the value of the test statistic. The p -value of $1.5264e-04$ suggests rejection of the null hypothesis.

You can retrieve the values in the ANOVA table by indexing into the cell array. Save the F -statistic value and the p -value in the new variables `Fstat` and `pvalue`.

```
Fstat = tbl{2,5}
Fstat = 15.4000
pvalue = tbl{2,6}
pvalue = 1.5264e-04
```

Multiple Comparisons for One-Way ANOVA

Input the sample data.

```
strength = [82 86 79 83 84 85 86 87 74 82 ...
            78 75 76 77 79 79 77 78 82 79];
alloy = {'st', 'st', 'st', 'st', 'st', 'st', 'st', 'st', 'st', ...
        'al1', 'al1', 'al1', 'al1', 'al1', 'al1', ...
        'al2', 'al2', 'al2', 'al2', 'al2', 'al2'};
```

The data are from a study of the strength of structural beams in Hogg (1987). The vector `strength` measures deflections of beams in thousandths of an inch under 3000 pounds of force. The vector `alloy` identifies each beam as steel (`st`), alloy 1 (`al1`), or alloy 2 (`al2`). Although `alloy` is sorted in this example, grouping variables do not need to be sorted.

Perform one-way ANOVA using `anova1`. Return the structure `stats`, which contains the statistics `multcompare` needs for performing “Multiple Comparisons” on page 9-26.

```
[~,~,stats] = anova1(strength,alloy);
```

ANOVA Table

| Source | SS | df | MS | F | Prob>F |
|--------|-------|----|------|------|--------|
| Groups | 184.8 | 2 | 92.4 | 15.4 | 0.0002 |
| Error | 102 | 17 | 6 | | |
| Total | 286.8 | 19 | | | |

The small p -value of 0.0002 suggests that the strength of the beams is not the same.

Perform a multiple comparison of the mean strength of the beams.

```
[c,~,~,gnames] = multcompare(stats);
```

Display the comparison results with the corresponding group names.

```
[gnames(c(:,1)), gnames(c(:,2)), num2cell(c(:,3:6))]
```

```
ans =
```

```
3x6 cell array
```

```
Columns 1 through 5
```

```
{'st' }    {'al1'}    {[ 3.6064]}    {[ 7]}    {[10.3936]}
{'st' }    {'al2'}    {[ 1.6064]}    {[ 5]}    {[ 8.3936]}
{'al1'}    {'al2'}    {[ -5.6280]}    {[ -2]}    {[ 1.6280]}
```

Column 6

```
{[1.6831e-04]}  
{[ 0.0040]}  
{[ 0.3560]}
```

The first two columns show the pair of groups that are compared. The fourth column shows the difference between the estimated group means. The third and fifth columns show the lower and upper limits for the 95% confidence intervals of the true difference of means. The sixth column shows the p -value for a hypothesis that the true difference of means for the corresponding groups is equal to zero.

The first two rows show that both comparisons involving the first group (steel) have confidence intervals that do not include zero. Because the corresponding p -values (1.6831e-04 and 0.0040, respectively) are small, those differences are significant.

The third row shows that the differences in strength between the two alloys is not significant. A 95% confidence interval for the difference is [-5.6,1.6], so you cannot reject the hypothesis that the true difference is zero. The corresponding p -value of 0.3560 in the sixth column confirms this result.

In the figure, the blue bar represents the comparison interval for mean material strength for steel. The red bars represent the comparison intervals for the mean material strength for alloy 1 and alloy 2. Neither of the red bars overlap with the blue bar, which indicates that the mean material strength for steel is significantly different from that of alloy 1 and alloy 2. To confirm the significant difference by clicking the bars that represent alloy 1 and 2.

- “Perform One-Way ANOVA” on page 9-6

Input Arguments

y — sample data

vector | matrix

Sample data, specified as a vector or a matrix.

- If y is a vector, you must specify the **group** input argument. **group** must be a categorical variable, numeric vector, logical vector, character array, string array, or

cell array of character vectors, with one name for each element of y . The `anova1` function treats the y values corresponding to the same value of `group` as part of the same group. Use this design when groups have different numbers of elements (unbalanced ANOVA).

$$y = [y_1 \ y_2 \ y_3 \ y_4 \ y_5 \ \dots \ y_N]$$

$$g = \{ 'A', 'A', 'C', 'B', 'B', \dots, 'D' \}$$

- If y is a matrix and you do not specify `group`, `anova1` treats each column of y as a separate group. In this design, the function evaluates whether the population means of the columns are equal. Use this design when each group has the same number of elements (balanced ANOVA).

$$Y = \begin{matrix} & \begin{matrix} \text{group 1} \\ \downarrow \end{matrix} & \begin{matrix} \text{group 2} \\ \downarrow \end{matrix} & & \begin{matrix} \text{group k} \\ \downarrow \end{matrix} \\ \begin{bmatrix} y_{11} & y_{12} & \dots & y_{1k} \\ y_{21} & y_{22} & \dots & y_{2k} \\ \vdots & \vdots & & \\ y_{n1} & y_{n2} & \dots & y_{nk} \end{bmatrix} \end{matrix}$$

- If y is a matrix and you specify `group`, then `group` must be a character array, string array, or cell array of character vectors, with one name for each column of y . The `anova1` function treats the columns that have the same group name as part of the same group.

$$Y = \begin{bmatrix} Y_{11} & Y_{12} & Y_{13} & Y_{14} & \cdots & Y_{1k} \\ Y_{21} & Y_{22} & Y_{23} & Y_{24} & \cdots & Y_{2k} \\ \vdots & \vdots & \vdots & \vdots & & \\ \vdots & \vdots & \vdots & \vdots & & \\ Y_{n1} & Y_{n2} & Y_{n3} & Y_{n4} & \cdots & Y_{nk} \end{bmatrix}$$

 $\text{group} = \{\text{'Red'}, \text{'Black'}, \text{'Red'}, \text{'Yellow'}, \dots, \text{'Black'}\}$

If `group` contains empty or NaN-valued elements, `anova1` disregards the corresponding observations in `y`.

Data Types: `single` | `double`

group — Grouping variable

numeric vector | logical vector | character array | string array | cell array of character vectors

Grouping variable, specified as a numeric or logical vector, character array, string array, or cell array of character vectors, containing group names.

- If `y` is a vector, `group` must be a categorical variable, numeric vector, logical vector, character array, string array, or cell array of character vectors, with one name for each element of `y`. The `anova1` function treats the `y` values corresponding to the same value of `group` as part of the same group.

$$Y = [y_1 \ y_2 \ y_3 \ y_4 \ y_5 \ \cdots \ y_N]$$

 $g = \{\text{'A'}, \text{'A'}, \text{'C'}, \text{'B'}, \text{'B'}, \dots, \text{'D'}\}$

N is the total number of observations.

- If `y` is a matrix, then `group` must be a character array, string array, or cell array of character vectors, with one group name for each column of `y`. The `anova1` function treats the columns of `y` that have the same group name as part of the same group.

$$Y = \begin{bmatrix} Y_{11} & Y_{12} & Y_{13} & Y_{14} & \cdots & Y_{1k} \\ Y_{21} & Y_{22} & Y_{23} & Y_{24} & \cdots & Y_{2k} \\ \vdots & \vdots & \vdots & \vdots & & \\ \vdots & \vdots & \vdots & \vdots & & \\ Y_{n1} & Y_{n2} & Y_{n3} & Y_{n4} & \cdots & Y_{nk} \end{bmatrix}$$

`group = {'Red', 'Black', 'Red', 'Yellow', . . . , 'Black'}`

If you do not want to specify group names, enter an empty array (`[]`) or omit this argument.

If `group` contains empty or NaN-valued elements, the corresponding observations in `y` are disregarded.

For more information on grouping variables, see “Grouping Variables” on page 2-57.

For example, if `y` is a vector, with observations categorized into groups 1, 2, and 3, then you can specify the grouping variables as follows.

Example: `'group', [1,2,1,3,1,...,3,1]`

For example, if `y` is a matrix, with six columns categorized into groups red, white, and black, then you can specify the grouping variables as follows.

Example: `'group', {'white', 'red', 'white', 'black', 'red'}`

Data Types: `single | double | logical | char | string | cell`

displayopt – Indicator to display ANOVA table and box plot

`'on'` (default) | `'off'`

Indicator to display ANOVA table and box plot, specified as `'on'` or `'off'`. When `displayopt` is `'off'`, `anova1` returns the output arguments, only. It does not display the standard ANOVA table and box-plot of the columns of `y`.

Example: `p = anova(x,group,'off')`

Output Arguments

p — *p*-value for the *F*-test

scalar value

p-value for the *F*-test, returned as a scalar value. *p*-value is the probability that the *F*-statistic can take a value larger than the computed test-statistic value. `anova1` tests the null hypothesis that all group means are equal to each other against the alternative hypothesis that at least one group mean is different from the others. The function derives the *p*-value from the cdf of the *F*-distribution.

A *p*-value that is smaller than the significance level indicates that at least one of the sample means is significantly different from the others. Common significance levels are 0.05 or 0.01.

tbl — ANOVA table

cell array

ANOVA table, returned as a cell array. `tbl` has six columns.

| Column | Definition |
|--------|--|
| source | The source of the variability. |
| SS | The sum of squares due to each source. |
| df | The degrees of freedom associated with each source. Suppose <i>N</i> is the total number of observations and <i>k</i> is the number of groups. Then, <i>N</i> - <i>k</i> is the within-groups degrees of freedom (Error), <i>k</i> - 1 is the between-groups degrees of freedom (Columns), and <i>N</i> - 1 is the total degrees of freedom. $N - 1 = (N - k) + (k - 1)$ |
| MS | The mean squares for each source, which is the ratio <i>SS</i> / <i>df</i> . |
| F | <i>F</i> -statistic, which is the ratio of the mean squares. |

| Column | Definition |
|--------|--|
| Prob>F | The p -value, which is the probability that the F -statistic can take a value larger than the computed test-statistic value. <code>anova1</code> derives this probability from the cdf of F -distribution. |

The rows of the ANOVA table show the variability in the data that is divided by the source.

| Row | Definition |
|--------|---|
| Groups | Variability due to the differences among the group means (variability <i>between</i> groups) |
| Error | Variability due to the differences between the data in each group and the group mean (variability <i>within</i> groups) |
| Total | Total variability |

stats — Statistics for multiple comparison tests

structure

Statistics for multiple comparison tests on page 9-26, returned as a structure. `stats` has six fields.

| Field name | Definition |
|---------------------|---|
| <code>gnames</code> | Names of the groups |
| <code>n</code> | Number of observations in each group |
| <code>source</code> | Source of the <code>stats</code> output |
| <code>means</code> | Estimated values of the means |
| <code>df</code> | Error (within-groups) degrees of freedom ($N - k$, where N is the total number of observations and k is the number of groups) |
| <code>s</code> | Square root of the mean squared error |

Definitions

Box-Plot

`anova1` returns box plots of the observations in `y`, by group. Box plots provide a visual comparison of the group location parameters.

If `y` is a vector, then the plot shows one box for each value of `group`. If `y` is a matrix and you do not specify `group`, then the plot shows one box for each column of `y`. On each box, the central mark is the median and the edges of the box are the 25th and 75th percentiles (1st and 3rd quantiles). The whiskers extend to the most extreme data points that are not considered outliers. The outliers are plotted individually. The interval endpoints are the extremes of the notches. The extremes correspond to $q2 - 1.57(q3 - q1)/\sqrt{n}$ and $q2 + 1.57(q3 - q1)/\sqrt{n}$, where $q2$ is the median (50th percentile), $q1$ and $q3$ are the 25th and 75th percentiles, respectively, and n is the number of observations without any NaN values.

Two medians are significantly different at the 5% significance level if their intervals do not overlap. This test is different from the F -test that ANOVA performs, but large differences in the center lines of the boxes correspond to large F -statistic values and correspondingly small p -values. For more information about box plots, see `boxplot`.

Introduced before R2006a

anova2

Two-way analysis of variance

anova2 performs two-way analysis of variance (ANOVA) with balanced designs. To perform two-way ANOVA with unbalanced designs, see `anovan`.

Syntax

```
p = anova2(y, reps)
p = anova2(y, reps, displayopt)
[p, tbl] = anova2( ___ )
[p, tbl, stats] = anova2( ___ )
```

Description

`p = anova2(y, reps)` returns the p -values for a balanced two-way ANOVA for comparing the means of two or more columns and two or more rows of the observations in `y`.

`reps` is the number of replicates for each combination of factor groups, which must be constant, indicating a balanced design. For unbalanced designs, use `anovan`. The `anova2` function tests the main effects for column and row factors and their interaction effect. To test the interaction effect, `reps` must be greater than 1.

`anova2` also displays the standard ANOVA table.

`p = anova2(y, reps, displayopt)` enables the ANOVA table display when `displayopt` is 'on' (default) and suppresses the display when `displayopt` is 'off'.

`[p, tbl] = anova2(___)` returns the ANOVA table (including column and row labels) in cell array `tbl`. To copy a text version of the ANOVA table to the clipboard, select **Edit > Copy Text** menu.

`[p, tbl, stats] = anova2(___)` returns a `stats` structure, which you can use to perform a multiple comparison test on page 9-26. A multiple comparison test enables you

to determine which pairs of group means are significantly different. To perform this test, use `multcompare`, providing the `stats` structure as input.

Examples

Two-Way ANOVA

Load the sample data.

```
load popcorn
popcorn
```

```
popcorn =
```

```
    5.5000    4.5000    3.5000
    5.5000    4.5000    4.0000
    6.0000    4.0000    3.0000
    6.5000    5.0000    4.0000
    7.0000    5.5000    5.0000
    7.0000    5.0000    4.5000
```

The data is from a study of popcorn brands and popper types (Hogg 1987). The columns of the matrix `popcorn` are brands, Gourmet, National, and Generic, respectively. The rows are popper types, oil and air. In the study, researchers popped a batch of each brand three times with each popper, that is, the number of replications is 3. The first three rows correspond to the oil popper, and the last three rows correspond to the air popper. The response values are the yield in cups of popped popcorn.

Perform a two-way ANOVA. Save the ANOVA table in the cell array `tbl` for easy access to results.

```
[p,tbl] = anova2(popcorn,3);
```

| ANOVA Table | | | | | |
|-------------|--------|----|---------|------|--------|
| Source | SS | df | MS | F | Prob>F |
| Columns | 15.75 | 2 | 7.875 | 56.7 | 0 |
| Rows | 4.5 | 1 | 4.5 | 32.4 | 0.0001 |
| Interaction | 0.0833 | 2 | 0.04167 | 0.3 | 0.7462 |
| Error | 1.6667 | 12 | 0.13889 | | |
| Total | 22 | 17 | | | |

The column Prob>F shows the p -values for the three brands of popcorn (0.0000), the two popper types (0.0001), and the interaction between brand and popper type (0.7462). These values indicate that popcorn brand and popper type affect the yield of popcorn, but there is no evidence of an interaction effect of the two.

Display the cell array containing the ANOVA table.

```
tbl
```

```
tbl =
```

```
6x6 cell array
```

Columns 1 through 5

| | | | | |
|------------------|-------------|---------|--------------|--------------|
| {'Source' } | {'SS' } | {'df' } | {'MS' } | {'F' } |
| {'Columns' } | {[15.7500]} | {[2]} | {[7.8750]} | {[56.7000]} |
| {'Rows' } | {[4.5000]} | {[1]} | {[4.5000]} | {[32.4000]} |
| {'Interaction' } | {[0.0833]} | {[2]} | {[0.0417]} | {[0.3000]} |
| {'Error' } | {[1.6667]} | {[12]} | {[0.1389]} | {0x0 double} |
| {'Total' } | {[22]} | {[17]} | {0x0 double} | {0x0 double} |

Column 6

| |
|----------------|
| {'Prob>F' } |
| {[7.6790e-07]} |
| {[1.0037e-04]} |
| {[0.7462]} |
| {0x0 double } |
| {0x0 double } |

Store the *F*-statistic for the factors and factor interaction in separate variables.

```
Fbrands = tbl{2,5}
Fpoppertype = tbl{3,5}
Finteraction = tbl{4,5}
```

```
Fbrands =
```

```
56.7000
```

```
Fpoppertype =
```

```
32.4000
```

```
Finteraction =
```

```
0.3000
```

Multiple Comparisons for Two-Way ANOVA

Load the sample data.

```
load popcorn
popcorn
```

```
popcorn =
  5.5000  4.5000  3.5000
  5.5000  4.5000  4.0000
  6.0000  4.0000  3.0000
  6.5000  5.0000  4.0000
  7.0000  5.5000  5.0000
  7.0000  5.0000  4.5000
```

The data is from a study of popcorn brands and popper types (Hogg 1987). The columns of the matrix `popcorn` are brands (Gourmet, National, and Generic). The rows are popper types oil and air. In the study, researchers popped a batch of each brand three times with each popper. The values are the yield in cups of popped popcorn.

Perform a two-way ANOVA. Also compute the statistics that you need to perform a multiple comparison test on the main effects.

```
[~,~,stats] = anova2(popcorn,3,'off')
```

```
stats =
  struct with fields:
    source: 'anova2'
    sigmasq: 0.1389
    colmeans: [6.2500 4.7500 4]
    coln: 6
    rowmeans: [4.5000 5.5000]
    rown: 9
    inter: 1
    pval: 0.7462
    df: 12
```

The `stats` structure includes

- The mean squared error (`sigmasq`)
- The estimates of the mean yield for each popcorn brand (`colmeans`)
- The number of observations for each popcorn brand (`coln`)
- The estimate of the mean yield for each popper type (`rowmeans`)
- The number of observations for each popper type (`rown`)
- The number of interactions (`inter`)
- The p -value that shows the significance level of the interaction term (`pval`)
- The error degrees of freedom (`df`).

Perform a multiple comparison test to see if the popcorn yield differs between pairs of popcorn brands (columns).

```
c = multcompare(stats)
```

Note: Your model includes an interaction term. A test of main effects can be difficult to interpret when the model includes interactions.

```
c =
```

```
1.0000    2.0000    0.9260    1.5000    2.0740    0.0000
1.0000    3.0000    1.6760    2.2500    2.8240    0.0000
2.0000    3.0000    0.1760    0.7500    1.3240    0.0116
```

The first two columns of `c` show the groups that are compared. The fourth column shows the difference between the estimated group means. The third and fifth columns show the lower and upper limits for 95% confidence intervals for the true mean difference. The sixth column contains the p -value for a hypothesis test that the corresponding mean difference is equal to zero. All p -values (0, 0, and 0.0116) are very small, which indicates that the popcorn yield differs across all three brands.

The figure shows the multiple comparison of the means. By default, the group 1 mean is highlighted and the comparison interval is in blue. Because the comparison intervals for the other two groups do not intersect with the intervals for the group 1 mean, they are highlighted in red. This lack of intersection indicates that both means are different than group 1 mean. Select other group means to confirm that all group means are significantly different from each other.

Perform a multiple comparison test to see the popcorn yield differs between the two popper types (rows).

```
c = multcompare(stats, 'Estimate', 'row')
```

Note: Your model includes an interaction term. A test of main effects can be difficult to interpret when the model includes interactions.

```
c =
```

```
1.0000    2.0000   -1.3828   -1.0000   -0.6172    0.0001
```

The small p -value of 0.0001 indicates that the popcorn yield differs between the two popper types (air and oil). The figure shows the same results. The disjoint comparison intervals indicate that the group means are significantly different from each other.

- “Perform Two-Way ANOVA” on page 9-18

Input Arguments

y — Sample data

matrix

Sample data, specified as a matrix. The columns correspond to groups of one factor, and the rows correspond to the groups of the other factor and the replications. Replications are the measurements or observations for each combination of groups (levels) of the row and column factor. For example, in the following data the row factor A has three levels, column factor B has two levels, and there are two replications ($\text{reps} = 2$). The subscripts indicate row, column, and replication, respectively.

$$\begin{array}{cc}
 B = 1 & B = 2 \\
 \left[\begin{array}{cc}
 y_{111} & y_{121} \\
 y_{112} & y_{122} \\
 y_{211} & y_{221} \\
 y_{212} & y_{222} \\
 y_{311} & y_{321} \\
 y_{312} & y_{322}
 \end{array} \right] & \left. \begin{array}{l} \\ \\ \\ \\ \\ \\ \end{array} \right\} \begin{array}{l} A = 1 \\ \\ A = 2 \\ \\ A = 3 \end{array}
 \end{array}$$

Data Types: `single` | `double`

reps — Number of replications

1 (default) | an integer number

Number of replications for each combination of groups, specified as an integer number. For example, the following data has two replications ($\text{reps} = 2$) for each group combination of row factor A and column factor B .

$$\begin{array}{cc}
 B = 1 & B = 2 \\
 \left. \begin{array}{cc}
 y_{111} & y_{121} \\
 y_{112} & y_{122} \\
 y_{211} & y_{221} \\
 y_{212} & y_{222} \\
 y_{311} & y_{321} \\
 y_{312} & y_{322}
 \end{array} \right\} A = 1 \\
 \left. \begin{array}{cc}
 y_{211} & y_{221} \\
 y_{212} & y_{222}
 \end{array} \right\} A = 2 \\
 \left. \begin{array}{cc}
 y_{311} & y_{321} \\
 y_{312} & y_{322}
 \end{array} \right\} A = 3
 \end{array}$$

- When `reps` is 1 (default), `anova2` returns two p -values in vector `p`:
 - The p -value for the null hypothesis that all samples from factor B (i.e., all column samples in y) are drawn from the same population.
 - The p -value for the null hypothesis, that all samples from factor A (i.e., all row samples in y) are drawn from the same population.
- When `reps` is greater than 1, `anova2` also returns the p -value for the null hypothesis that factors A and B have no interaction (i.e., the effects due to factors A and B are *additive*).

Example: `p = anova(y, 3)` specifies that each combination of groups (levels) has three replications.

Data Types: `single` | `double`

displayopt — Indicator to display the ANOVA table

'on' (default) | 'off'

Indicator to display the ANOVA table as a figure, specified as 'on' or 'off'.

Output Arguments

p — p -value

scalar value

p -value for the F -test, returned as a scalar value. A small p -value indicates that the results are statistically significant. Common significance levels are 0.05 or 0.01. For example:

- A sufficiently small p -value for the null hypothesis for group means of row factor A suggests that at least one row-sample mean is significantly different from the other row-sample means; i.e., there is a main effect due to factor A
- A sufficiently small p -value for the null hypothesis for group (level) means of column factor B suggests that at least one column-sample mean is significantly different from the other column-sample means; i.e., there is a main effect due to factor B .
- A sufficiently small p -value for combinations of groups (levels) of factors A and B suggests that there is an interaction between factors A and B .

tbl – ANOVA table

cell array

ANOVA table, returned as a cell array. `tbl` has six columns.

| Column name | Definition |
|-------------|--|
| source | Source of the variability. |
| SS | Sum of squares due to each source. |
| df | Degrees of freedom associated with each source. |
| MS | Mean squares for each source, which is the ratio SS/df . |
| F | F -statistic, which is the ratio of the mean squares. |
| Prob>F | p -value, which is the probability that the F -statistic can take a value larger than the computed test-statistic value. <code>anova2</code> derives this probability from the cdf of the F -distribution. |

The rows of the ANOVA table show the variability in the data, divided by the source into three or four parts, depending on the value of `reps`.

| Row | Definition |
|---------|---|
| Columns | Variability due to the differences among the column means |

| Row | Definition |
|-------------|---|
| Rows | Variability due to the differences among the row means |
| Interaction | Variability due to the interaction between rows and columns (if <code>reps</code> is greater than its default value of 1) |
| Error | Remaining variability not explained by any systematic source |

Data Types: `cell`

stats — Statistics for multiple comparison test

structure

Statistics for multiple comparisons tests on page 9-26, returned as a structure. Use `multcompare` to perform multiple comparison tests, supplying `stats` as an input argument. `stats` has nine fields.

| Field | Definition |
|-----------------------|--|
| <code>source</code> | Source of the <code>stats</code> output |
| <code>sigmasq</code> | Mean squared error |
| <code>colmeans</code> | Estimated values of the column means |
| <code>coln</code> | Number of observations for each group in columns |
| <code>rowmeans</code> | Estimated values of the row means |
| <code>rown</code> | Number of observations for each group in rows |
| <code>inter</code> | Number of interactions |
| <code>pval</code> | p -value for the interaction term |
| <code>df</code> | Error degrees of freedom $(reps - 1) * r * c$ where <code>reps</code> is the number of replications and <code>c</code> and <code>r</code> are the number of groups in factors, respectively. |

Data Types: `struct`

Topics

“Perform Two-Way ANOVA” on page 9-18

“Two-Way ANOVA” on page 9-15

“Multiple Comparisons” on page 9-26

Introduced before R2006a

anovan

N-way analysis of variance

Syntax

```
p = anovan(y,group)
p = anovan(y,group,Name,Value)
[p,tbl] = anovan(____)
[p,tbl,stats] = anovan(____)
[p,tbl,stats,terms] = anovan(____)
```

Description

`p = anovan(y,group)` returns a vector of p -values, one per term, for multiway (n -way) analysis of variance (ANOVA) for testing the effects of multiple factors on the mean of the vector y .

`anovan` also displays a figure showing the standard ANOVA table.

`p = anovan(y,group,Name,Value)` returns a vector of p -values for multiway (n -way) ANOVA using additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify which predictor variable is continuous, if any, or the type of sum of squares to use.

`[p,tbl] = anovan(____)` returns the ANOVA table (including factor labels) in cell array `tbl` for any of the input arguments specified in the previous syntaxes. Copy a text version of the ANOVA table to the clipboard by using the `Copy Text` item on the **Edit** menu.

`[p,tbl,stats] = anovan(____)` returns a `stats` structure that you can use to perform a multiple comparison test on page 9-26, which enables you to determine which pairs of group means are significantly different. You can perform such a test using the `multcompare` function by providing the `stats` structure as input.

`[p,tbl,stats,terms] = anovan(____)` returns the main and interaction terms used in the ANOVA computations in `terms`.

Examples

Three-Way ANOVA

Load the sample data.

```
y = [52.7 57.5 45.9 44.5 53.0 57.0 45.9 44.0]';  
g1 = [1 2 1 2 1 2 1 2];  
g2 = {'hi'; 'hi'; 'lo'; 'lo'; 'hi'; 'hi'; 'lo'; 'lo'};  
g3 = {'may'; 'may'; 'may'; 'may'; 'june'; 'june'; 'june'; 'june'};
```

`y` is the response vector and `g1`, `g2`, and `g3` are the grouping variables (factors). Each factor has two levels, and every observation in `y` is identified by a combination of factor levels. For example, observation `y(1)` is associated with level 1 of factor `g1`, level 'hi' of factor `g2`, and level 'may' of factor `g3`. Similarly, observation `y(6)` is associated with level 2 of factor `g1`, level 'hi' of factor `g2`, and level 'june' of factor `g3`.

Test if the response is the same for all factor levels.

```
p = anovan(y, {g1,g2,g3})
```

Analysis of Variance

| Source | Sum Sq. | d. f. | Mean Sq. | F | Prob>F |
|--------|---------|-------|----------|-------|--------|
| X1 | 3.781 | 1 | 3.781 | 0.82 | 0.4174 |
| X2 | 199.001 | 1 | 199.001 | 42.95 | 0.0028 |
| X3 | 0.061 | 1 | 0.061 | 0.01 | 0.914 |
| Error | 18.535 | 4 | 4.634 | | |
| Total | 221.379 | 7 | | | |

Constrained (Type III) sums of squares.

$p = 3 \times 1$

0.4174
0.0028
0.9140

In the ANOVA table, X1, X2, and X3 correspond to the factors g1, g2, and g3, respectively. The p -value 0.4174 indicates that the mean responses for levels 1 and 2 of the factor g1 are not significantly different. Similarly, the p -value 0.914 indicates that the mean responses for levels 'may' and 'june', of the factor g3 are not significantly different. However, the p -value 0.0028 is small enough to conclude that the mean responses are

significantly different for the two levels, 'hi' and 'lo' of the factor g2. By default, anovan computes p -values just for the three main effects.

Test the two-factor interactions. This time specify the variable names.

```
p = anovan(y,{g1 g2 g3}, 'model', 'interaction', 'varnames', {'g1', 'g2', 'g3'})
```

| Analysis of Variance | | | | | |
|----------------------|---------|-------|----------|---------|--------|
| Source | Sum Sq. | d. f. | Mean Sq. | F | Prob>F |
| g1 | 3.781 | 1 | 3.781 | 336.11 | 0.0347 |
| g2 | 199.001 | 1 | 199.001 | 17689 | 0.0048 |
| g3 | 0.061 | 1 | 0.061 | 5.44 | 0.2578 |
| g1*g2 | 18.301 | 1 | 18.301 | 1626.78 | 0.0158 |
| g1*g3 | 0.211 | 1 | 0.211 | 18.78 | 0.1444 |
| g2*g3 | 0.011 | 1 | 0.011 | 1 | 0.5 |
| Error | 0.011 | 1 | 0.011 | | |
| Total | 221.379 | 7 | | | |

Constrained (Type III) sums of squares.

```
p = 6×1
```

```
0.0347
0.0048
0.2578
0.0158
0.1444
```

0.5000

The interaction terms are represented by $g1*g2$, $g1*g3$, and $g2*g3$ in the ANOVA table. The first three entries of p are the p -values for the main effects. The last three entries are the p -values for the two-way interactions. The p -value of 0.0158 indicates that the interaction between $g1$ and $g2$ is significant. The p -values of 0.1444 and 0.5 indicate that the corresponding interactions are not significant.

Two-Way ANOVA for Unbalanced Design

Load the sample data.

```
load carbig
```

The data has measurements on 406 cars. The variable `org` shows where the cars were made and `when` shows when in the year the cars were manufactured.

Study how the mileage depends on when and where the cars were made. Also include the two-way interactions in the model.

```
p = anovan(MPG, {org when}, 'model', 2, 'varnames', {'origin', 'mfg date'})
```

Analysis of Variance

| Source | Sum Sq. | d. f. | Mean Sq. | F | Prob>F |
|-----------------|---------|-------|----------|--------|--------|
| origin | 5727.2 | 2 | 2863.58 | 115.09 | 0 |
| mfg date | 4710.3 | 2 | 2355.15 | 94.65 | 0 |
| origin*mfg date | 120.5 | 4 | 30.12 | 1.21 | 0.3059 |
| Error | 9679.1 | 389 | 24.88 | | |
| Total | 24252.6 | 397 | | | |

Constrained (Type III) sums of squares.

$p = 3 \times 1$

0.0000
0.0000
0.3059

The 'model', 2 name-value pair argument represents the two-way interactions. The p -value for the interaction term, 0.3059, is not small, indicating little evidence that the effect of the time of manufacture (mfg date) depends on where the car was made (origin). The main effects of origin and manufacturing date, however, are significant, both p -values are 0.

Multiple Comparisons for Three-Way ANOVA

Load the sample data.

```
y = [52.7 57.5 45.9 44.5 53.0 57.0 45.9 44.0]';  
g1 = [1 2 1 2 1 2 1 2];  
g2 = {'hi'; 'hi'; 'lo'; 'lo'; 'hi'; 'hi'; 'lo'; 'lo'};  
g3 = {'may'; 'may'; 'may'; 'may'; 'june'; 'june'; 'june'; 'june'};
```

`y` is the response vector and `g1`, `g2`, and `g3` are the grouping variables (factors). Each factor has two levels, and every observation in `y` is identified by a combination of factor levels. For example, observation `y(1)` is associated with level 1 of factor `g1`, level 'hi' of factor `g2`, and level 'may' of factor `g3`. Similarly, observation `y(6)` is associated with level 2 of factor `g1`, level 'hi' of factor `g2`, and level 'june' of factor `g3`.

Test if the response is the same for all factor levels. Also compute the statistics required for multiple comparison tests.

```
[~,~,stats] = anovan(y,{g1 g2 g3}, 'model', 'interaction', ...  
    'varnames', {'g1', 'g2', 'g3'});
```

Analysis of Variance

| Source | Sum Sq. | d. f. | Mean Sq. | F | Prob>F |
|--------|---------|-------|----------|---------|--------|
| g1 | 3.781 | 1 | 3.781 | 336.11 | 0.0347 |
| g2 | 199.001 | 1 | 199.001 | 17689 | 0.0048 |
| g3 | 0.061 | 1 | 0.061 | 5.44 | 0.2578 |
| g1*g2 | 18.301 | 1 | 18.301 | 1626.78 | 0.0158 |
| g1*g3 | 0.211 | 1 | 0.211 | 18.78 | 0.1444 |
| g2*g3 | 0.011 | 1 | 0.011 | 1 | 0.5 |
| Error | 0.011 | 1 | 0.011 | | |
| Total | 221.379 | 7 | | | |

Constrained (Type III) sums of squares.

The p -value of 0.2578 indicates that the mean responses for levels 'may' and 'june' of factor g3 are not significantly different. The p -value of 0.0347 indicates that the mean responses for levels 1 and 2 of factor g1 are significantly different. Similarly, the p -value of 0.0048 indicates that the mean responses for levels 'hi' and 'lo' of factor g2 are significantly different.

Perform multiple comparison tests to find out which groups of the factors g1 and g2 are significantly different.

```
results = multcompare(stats, 'Dimension', [1 2])
```

results = 6×6

| | | | | | |
|--------|--------|---------|---------|---------|--------|
| 1.0000 | 2.0000 | -6.8604 | -4.4000 | -1.9396 | 0.0280 |
| 1.0000 | 3.0000 | 4.4896 | 6.9500 | 9.4104 | 0.0177 |
| 1.0000 | 4.0000 | 6.1396 | 8.6000 | 11.0604 | 0.0143 |
| 2.0000 | 3.0000 | 8.8896 | 11.3500 | 13.8104 | 0.0108 |
| 2.0000 | 4.0000 | 10.5396 | 13.0000 | 15.4604 | 0.0095 |
| 3.0000 | 4.0000 | -0.8104 | 1.6500 | 4.1104 | 0.0745 |

multcompare compares the combinations of groups (levels) of the two grouping variables, g1 and g2. In the results matrix, the number 1 corresponds to the combination of level 1 of g1 and level hi of g2, the number 2 corresponds to the combination of level 2 of g1 and level hi of g2. Similarly, the number 3 corresponds to

the combination of level 1 of `g1` and level `lo` of `g2`, and the number 4 corresponds to the combination of level 2 of `g1` and level `lo` of `g2`. The last column of the matrix contains the p -values.

For example, the first row of the matrix shows that the combination of level 1 of `g1` and level `hi` of `g2` has the same mean response values as the combination of level 2 of `g1` and level `hi` of `g2`. The p -value corresponding to this test is 0.0280, which indicates that the mean responses are significantly different. You can also see this result in the figure. The blue bar shows the comparison interval for the mean response for the combination of level 1 of `g1` and level `hi` of `g2`. The red bars are the comparison intervals for the mean response for other group combinations. None of the red bars overlap with the blue bar, which means the mean response for the combination of level 1 of `g1` and level `hi` of `g2` is significantly different from the mean response for other group combinations.

You can test the other groups by clicking on the corresponding comparison interval for the group. The bar you click on turns to blue. The bars for the groups that are significantly different are red. The bars for the groups that are not significantly different are gray. For example, if you click on the comparison interval for the combination of level 1 of `g1` and level `lo` of `g2`, the comparison interval for the combination of level 2 of `g1` and level `lo` of `g2` overlaps, and is therefore gray. Conversely, the other comparison intervals are red, indicating significant difference.

- “ANOVA with Random Effects” on page 9-48
- “Multiple Comparisons” on page 9-26

Input Arguments

y — Sample data

numeric vector

Sample data, specified as a numeric vector.

Data Types: `single` | `double`

group — Grouping variables

cell array

Grouping variables, i.e. the factors and factor levels of the observations in `y`, specified as a cell array. Each of the cells in `group` contains a list of factor levels identifying the

observations in y with respect to one of the factors. The list within each cell can be a categorical array, numeric vector, character matrix, string array, or single-column cell array of character vectors, and must have the same number of elements as y .

$$\begin{array}{rcccccccc} y & = & [& y_1, & y_2, & y_3, & y_4, & y_5, & \dots, & y_N &] \\ & & & \uparrow & \uparrow & \uparrow & \uparrow & \uparrow & & \uparrow & \\ g1 & = & \{ & 'A', & 'A', & 'C', & 'B', & 'B', & \dots, & 'D' & \} \\ g2 & = & [& 1 & 2 & 1 & 3 & 1 & \dots, & 2 &] \\ g3 & = & \{ & 'hi', & 'mid', & 'low', & 'mid', & 'hi', & \dots, & 'low' & \} \end{array}$$

By default, `anovan` treats all grouping variables as fixed effects.

For example, in a study you want to investigate the effects of gender, school, and the education method on the academic success of elementary school students, then you can specify the grouping variables as follows.

Example: `{'Gender','School','Method'}`

Data Types: `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'alpha',0.01,'model','interaction','sstype',2` specifies `anovan` to compute the 99% confidence bounds and p-values for the main effects and two-way interactions using type II sum of squares.

alpha — Confidence level

0.05 (default) | scalar value in the range 0 to 1

Confidence level for confidence bounds, specified as the comma-separated pair consisting of `'alpha'` and a scalar value in the range 0 to 1. For a value α , the confidence level is $100*(1-\alpha)\%$.

Example: `'alpha',0.01` corresponds to 99% confidence intervals

Data Types: `single` | `double`

continuous — Indicator for continuous predictors

vector of indices

Indicator for continuous predictors, representing which grouping variables should be treated as continuous predictors rather than as categorical predictors, specified as the comma-separated pair consisting of 'continuous' and a vector of indices.

For example, if there are three grouping variables and second one is continuous, then you can specify as follows.

Example: `continuous', [2]`

Data Types: `single` | `double`

display — Indicator to display ANOVA table

'on' (default) | 'off'

Indicator to display ANOVA table, specified as the comma-separated pair consisting of 'display' and 'on' or 'off'. When `displayopt` is 'off', `anovan` only returns the output arguments, and does not display the standard ANOVA table as a figure.

Example: `'display', 'off'`

model — Type of the model

'linear' (default) | 'interaction' | 'full' | integer value | terms matrix

Type of the model, specified as the comma-separated pair consisting of 'model' and one of the following:

- 'linear' — The default 'linear' model computes only the p -values for the null hypotheses on the N main effects.
- 'interaction' — The 'interaction' model computes the p -values for null

hypotheses on the N main effects and the $\binom{N}{2}$ two-factor interactions.

- 'full' — The 'full' model computes the p -values for null hypotheses on the N main effects and interactions at all levels.
- An integer — For an integer value of k , ($k \leq N$) for model type, `anovan` computes all interaction levels through the k th level. For example, the value 3 means main effects plus two- and three-factor interactions. The values $k = 1$ and $k = 2$ are equivalent to the 'linear' and 'interaction' specifications, respectively. The value $k = N$ is equivalent to the 'full' specification.

- **Terms matrix** — A matrix of term definitions having the same form as the input to the `x2fx` function. All entries must be 0 or 1 (no higher powers).

For more precise control over the main and interaction terms that `anovan` computes, you can specify a matrix containing one row for each main or interaction term to include in the ANOVA model. Each row defines one term using a vector of N zeros and ones. The table below illustrates the coding for a 3-factor ANOVA for factors A , B , and C .

| Matrix Row | ANOVA Term |
|------------|------------------------|
| [1 0 0] | Main term A |
| [0 1 0] | Main term B |
| [0 0 1] | Main term C |
| [1 1 0] | Interaction term AB |
| [1 0 1] | Interaction term AC |
| [0 1 1] | Interaction term BC |
| [1 1 1] | Interaction term ABC |

For example, if there are three factors A , B , and C , and `'model'`, `[0 1 0;0 0 1;0 1 1]`, then `anovan` tests for the main effects B and C , and the interaction effect BC , respectively.

A simple way to generate the terms matrix is to modify the `terms` output, which codes the terms in the current model using the format described above. If `anovan` returns `[0 1 0;0 0 1;0 1 1]` for `terms`, for example, and there is no significant interaction BC , then you can recompute ANOVA on just the main effects B and C by specifying `[0 1 0;0 0 1]` for `model`.

Example: `'model',[0 1 0;0 0 1;0 1 1]`

Example: `'model','interaction'`

Data Types: `char` | `string` | `single` | `double`

nested — Nesting relationships

matrix of 0's and 1's

Nesting relationships among the grouping variables, specified as the comma-separated pair consisting of `'nested'` and a matrix M of 0's and 1's, i.e. $M(i,j) = 1$ if variable i is nested in variable j .

For example, if there are two grouping variables District and School, where School is nested in District, then you can express this relationship as follows.

Example: 'nested', [0,0;1 0]

Data Types: single | double

random — Indicator for random variables

vector of indices

Indicator for random variables, representing which grouping variables are random, specified as the comma-separated pair consisting of 'random' and a vector of indices. By default, `anovan` treats all grouping variables as fixed.

`anovan` treats an interaction term as random if any of the variables in the interaction term is random.

Example: 'random', [3]

Data Types: single | double

sstype — Type of sum of squares

3 (default) | 1 | 2 | 'h'

Type of sum squares, specified as the comma-separated pair consisting of 'sstype' and the following:

- 1 — Type I sum of squares. The reduction in residual sum of squares obtained by adding that term to a fit that already includes the terms listed before it.
- 2 — Type II sum of squares. The reduction in residual sum of squares obtained by adding that term to a model consisting of all other terms that do not contain the term in question.
- 3 — Type III sum of squares. The reduction in residual sum of squares obtained by adding that term to a model containing all other terms, but with their effects constrained to obey the usual “sigma restrictions” that make models estimable.
- 'h' — Hierarchical model. Similar to type 2, but with continuous as well as categorical factors used to determine the hierarchy of terms.

The sum of squares for any term is determined by comparing two models. For a model containing main effects but no interactions, the value of `sstype` only influences computations on unbalanced data.

Suppose you are fitting a model with two factors and their interaction, and that the terms appear in the order A , B , AB . Let $R(\cdot)$ represent the residual sum of squares for a model,

so for example $R(A, B, AB)$ is the residual sum of squares fitting the whole model, $R(A)$ is the residual sum of squares fitting just the main effect of A , and $R(1)$ is the residual sum of squares fitting just the mean. The three types of sums of squares are as follows:

| Term | Type 1 Sum of Squares | Type 2 Sum of Squares | Type 3 Sum of Squares |
|------|-------------------------|-------------------------|--------------------------|
| A | $R(1) - R(A)$ | $R(B) - R(A, B)$ | $R(B, AB) - R(A, B, AB)$ |
| B | $R(A) - R(A, B)$ | $R(A) - R(A, B)$ | $R(A, AB) - R(A, B, AB)$ |
| AB | $R(A, B) - R(A, B, AB)$ | $R(A, B) - R(A, B, AB)$ | $R(A, B) - R(A, B, AB)$ |

The models for Type 3 sum of squares have sigma restrictions imposed. This means, for example, that in fitting $R(B, AB)$, the array of AB effects is constrained to sum to 0 over A for each value of B , and over B for each value of A .

Example: 'sstype', 'h'

Data Types: single | double | char | string

varnames — Names of grouping variables

X_1, X_2, \dots, X_N (default) | character matrix | string array | cell array of character vectors

Names of grouping variables, specified as the comma-separating pair consisting of 'varnames' and a character matrix, a string array, or a cell array of character vectors.

Example: 'varnames', {'Gender', 'City'}

Data Types: char | string | cell

Output Arguments

p — p-values

vector

p-values, returned as a vector.

Output vector p contains p -values for the null hypotheses on the N main effects and any interaction terms specified. Element $p(1)$ contains the p -value for the null hypotheses that samples at all levels of factor A are drawn from the same population; element $p(2)$ contains the p -value for the null hypotheses that samples at all levels of factor B are drawn from the same population; and so on.

For example, if there are three factors A , B , and C , and 'model', $[0 \ 1 \ 0; 0 \ 0 \ 1; 0 \ 1 \ 1]$, then the output vector \mathbf{p} contains the p -values for the null hypotheses on the main effects B and C and the interaction effect BC , respectively.

A sufficiently small p -value corresponding to a factor suggests that at least one group mean is significantly different from the other group means; that is, there is a main effect due to that factor. It is common to declare a result significant if the p -value is less than 0.05 or 0.01.

tbl – ANOVA table

cell array

ANOVA table, returned as a cell array. The ANOVA table has seven columns:

| Column name | Definition |
|-------------|--|
| source | Source of the variability. |
| SS | Sum of squares due to each source. |
| df | Degrees of freedom associated with each source. |
| MS | Mean squares for each source, which is the ratio SS/df . |
| Singular? | Indication of whether the term is singular. |
| F | F -statistic, which is the ratio of the mean squares. |
| Prob>F | The p -values, which is the probability that the F -statistic can take a value larger than a computed test-statistic value. <code>anovan</code> derives these probabilities from the cdf of F -distribution. |

The ANOVA table also contains the following columns if at least one of the grouping variables is specified as random using the name-value pair argument 'random':

| Column name | Definition |
|-------------|--|
| Type | Type of each source; 'fixed' for a fixed effect or 'random' for a random effect. |

| Column name | Definition |
|----------------|--|
| Expected MS | Text representation of the expected value for the mean square. $Q(\text{source})$ represents a quadratic function of <code>source</code> and $V(\text{source})$ represents the variance of <code>source</code> . |
| MS denom | Denominator of the F -statistic. |
| d.f. denom | Degrees of freedom for the denominator of the F -statistic. |
| Denom. defn. | Text representation of the denominator of the F -statistic. $MS(\text{source})$ represents the mean square of <code>source</code> . |
| Var. est. | Variance component estimate. |
| Var. lower bnd | Lower bound of the 95% confidence interval for the variance component estimate. |
| Var. upper bnd | Upper bound of the 95% confidence interval for the variance component estimate. |

stats — Statistics

structure

Statistics to use in a multiple comparison test on page 9-26 using the `multcompare` function, returned as a structure.

`anovan` evaluates the hypothesis that the different groups (levels) of a factor (or more generally, a term) have the same effect, against the alternative that they do not all have the same effect. Sometimes it is preferable to perform a test to determine which pairs of levels are significantly different, and which are not. Use the `multcompare` function to perform such tests by supplying the `stats` structure as input.

The `stats` structure contains the fields listed below, in addition to a number of other fields required for doing multiple comparisons using the `multcompare` function:

| Field | Description |
|---------------------|------------------------|
| <code>coeffs</code> | Estimated coefficients |

| Field | Description |
|-----------|--|
| coefnames | Name of term for each coefficient |
| vars | Matrix of grouping variable values for each term |
| resid | Residuals from the fitted model |

The `stats` structure also contains the following fields if at least one of the grouping variables is specified as random using the name-value pair argument `'random'`:

| Field | Description |
|---------|--|
| ems | Expected mean squares |
| denom | Denominator definition |
| rtnames | Names of random terms |
| varest | Variance component estimates (one per random term) |
| varci | Confidence intervals for variance components |

terms — Main and interaction terms

matrix

Main and interaction terms, returned as a matrix. The terms are encoded in the output matrix `terms` using the same format described above for input `model`. When you specify `model` itself in this format, the matrix returned in `terms` is identical.

Introduced before R2006a

anova

Class: RepeatedMeasuresModel

Analysis of variance for between-subject effects

Syntax

```
anovatbl = anova(rm)
anovatbl = anova(rm, 'WithinModel', WM)
```

Description

`anovatbl = anova(rm)` returns the analysis of variance results for the repeated measures model `rm`.

`anovatbl = anova(rm, 'WithinModel', WM)` returns the analysis of variance results it performs using the response or responses specified by the within-subject model `WM`.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

WM — Within-subject model

'separatemeans' (default) | 'orthogonalcontrasts' | character vector or string scalar defining a model specification | r -by- nc matrix specifying nc contrasts

Within-subject model, specified as one of the following:

- 'separatemeans' — The response is the average of the repeated measures (average across the within-subject model).

- `'orthogonalcontrasts'` — This is valid when the within-subject model has a single numeric factor T . Responses are the average, the slope of centered T , and, in general, all orthogonal contrasts for a polynomial up to $T^{(p-1)}$, where p is the number of rows in the within-subject model. `anova` multiplies Y , the response you use in the repeated measures model `rm` by the orthogonal contrasts, and uses the columns of the resulting product matrix as the responses.

`anova` computes the orthogonal contrasts for T using the Q factor of a QR factorization on page 32-111 of the Vandermonde matrix on page 32-111.

- A character vector or string scalar that defines a model specification in the within-subject factors. Responses are defined by the terms in that model. `anova` multiplies Y , the response matrix you use in the repeated measures model `rm` by the terms of the model, and uses the columns of the result as the responses.

For example, if there is a Time factor and `'Time'` is the model specification, then `anova` uses two terms, the constant and the uncentered Time term. The default is `'1'` to perform on the average response.

- An r -by- nc matrix, C , specifying nc contrasts among the r repeated measures. If Y represents the matrix of repeated measures you use in the repeated measures model `rm`, then the output `tbl` contains a separate analysis of variance for each column of $Y*C$.

The `anova` table contains a separate univariate analysis of variance results for each response.

Example: `'WithinModel', 'Time'`

Example: `'WithinModel', 'orthogonalcontrasts'`

Output Arguments

`anovatbl` — Results of analysis of variance

table

Results of analysis of variance for between-subject effects, returned as a table. This includes all terms on the between-subjects model and the following columns.

| Column Name | Definition |
|-------------|------------------------|
| Within | Within-subject factors |

| Column Name | Definition |
|-------------|--|
| Between | Between-subject factors |
| SumSq | Sum of squares |
| DF | Degrees of freedom |
| MeanSq | Mean squared error |
| F | F -statistic |
| pValue | p -value corresponding to the F -statistic |

Examples

Analysis of Variance for Average Response

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model where the measurements are the responses and the `species` is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform analysis of variance.

```
anova(rm)
```

```
ans =
```

3x7 table

| Within | Between | SumSq | DF | MeanSq | F | pValue |
|----------|----------|--------|-----|---------|--------|-------------|
| Constant | constant | 7201.7 | 1 | 7201.7 | 19650 | 2.0735e-158 |
| Constant | species | 309.61 | 2 | 154.8 | 422.39 | 1.1517e-61 |
| Constant | Error | 53.875 | 147 | 0.36649 | | |

There are 150 observations and 3 species. The degrees of freedom for species is $3 - 1 = 2$, and for error it is $150 - 3 = 147$. The small *P*-value of 1.1517e-61 indicates that the measurements differ significantly according to species.

Panel Data

Load the sample panel data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'panelData.mat'));
```

The dataset array, `panelData`, contains yearly observations on eight cities for 6 years. The first variable, `Growth`, measures economic growth (the response variable). The second and third variables are city and year indicators, respectively. The last variable, `Employ`, measures employment (the predictor variable). This is simulated data.

Store the data in a table array and define city as a nominal variable.

```
t = table(panelData.Growth, panelData.City, panelData.Year, ...
    'VariableNames', {'Growth', 'City', 'Year'});
```

Convert the data in a proper format to do repeated measures analysis.

```
t = unstack(t, 'Growth', 'Year', 'NewDataVariableNames', ...
    {'year1', 'year2', 'year3', 'year4', 'year5', 'year6'});
```

Add the mean employment level over the years as a predictor variable to the table `t`.

```
t(:,8) = table(grpstats(panelData.Employ, panelData.City));
t.Properties.VariableNames{'Var8'} = 'meanEmploy';
```

Define the within-subjects variable.

```
Year = [1 2 3 4 5 6]';
```

Fit a repeated measures model, where the growth figures over the 6 years are the responses and the mean employment is the predictor variable.

```
rm = fitrm(t, 'year1-year6 ~ meanEmploy', 'WithinDesign', Year);
```

Perform analysis of variance.

```
anovatbl = anova(rm, 'WithinModel', Year)
```

```
anovatbl =
```

```
3x7 table
```

| Within | Between | SumSq | DF | MeanSq | F | pValue |
|-----------|------------|------------|----|------------|----------|-----------|
| Contrast1 | constant | 588.17 | 1 | 588.17 | 0.038495 | 0.85093 |
| Contrast1 | meanEmploy | 3.7064e+05 | 1 | 3.7064e+05 | 24.258 | 0.0026428 |
| Contrast1 | Error | 91675 | 6 | 15279 | | |

Longitudinal Data

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'longitudinalData.mat'));
```

The matrix Y contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of Y corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M'];
```

Store the data in a proper table array format to do repeated measures analysis.

```
t = table(Gender, Y(:,1), Y(:,2), Y(:,3), Y(:,4), Y(:,5), ...
'VariableNames', {'Gender', 't0', 't2', 't4', 't6', 't8'});
```

Define the within-subjects variable.

```
Time = [0 2 4 6 8]';
```

Fit a repeated measures model, where blood levels are the responses and gender is the predictor variable.

```
rm = fitrm(t, 't0-t8 ~ Gender', 'WithinDesign', Time);
```

Perform analysis of variance.

```
anovatbl = anova(rm)
```

```
anovatbl =
```

```
3x7 table
```

| Within | Between | SumSq | DF | MeanSq | F | pValue |
|----------|----------|--------|----|--------|--------|------------|
| Constant | constant | 54702 | 1 | 54702 | 1079.2 | 1.1897e-14 |
| Constant | Gender | 2251.7 | 1 | 2251.7 | 44.425 | 1.0693e-05 |
| Constant | Error | 709.6 | 14 | 50.685 | | |

There are 2 genders and 16 observations, so the degrees of freedom for gender is $(2 - 1) = 1$ and for error it is $(16 - 2) * (2 - 1) = 14$. The small *p*-value of 1.0693e-05 indicates that there is a significant effect of gender on blood pressure.

Repeat analysis of variance using orthogonal contrasts.

```
anovatbl = anova(rm, 'WithinModel', 'orthogonalcontrasts')
```

```
anovatbl =
```

```
15x7 table
```

| Within | Between | SumSq | DF | MeanSq | F | pValue |

| Time^4 | Error | 82.977 | 14 | 5.9269 | | |

Definitions

Vandermonde Matrix

Vandermonde matrix is the matrix where columns are the powers of the vector a , that is, $V(i,j) = a(i)^{(n-j)}$, where n is the length of a .

QR Factorization

QR factorization of an m -by- n matrix A is the factorization that matrix into the product $A = Q*R$, where R is an m -by- n upper triangular matrix and Q is an m -by- m unitary matrix.

ansaribradley

Ansari-Bradley test

Syntax

```
h = ansaribradley(x,y)
h = ansaribradley(x,y,Name,Value)
[h,p] = ansaribradley( ___ )
[h,p,stats] = ansaribradley( ___ )
```

Description

`h = ansaribradley(x,y)` returns a test decision for the null hypothesis that the data in vectors `x` and `y` comes from the same distribution, using the Ansari-Bradley test on page 32-117. The alternative hypothesis is that the data in `x` and `y` comes from distributions with the same median and shape but different dispersions (e.g., variances). The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, or 0 otherwise.

`h = ansaribradley(x,y,Name,Value)` returns a test decision for the Ansari-Bradley test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level, conduct a one-sided test, or use a normal approximation to calculate the value of the test statistic.

`[h,p] = ansaribradley(___)` also returns the p -value, `p`, of the test, using any of the input arguments in the previous syntaxes.

`[h,p,stats] = ansaribradley(___)` also returns the structure `stats` containing information about the test statistic.

Examples

Ansari-Bradley Test for Equal Variances

Load the sample data. Create data vectors of miles per gallon (MPG) measurements for the model years 1982 and 1976.

```
load carsmall
x = MPG(Model_Year==82);
y = MPG(Model_Year==76);
```

Test the null hypothesis that the miles per gallon measured in cars from 1982 and 1976 have equal variances.

```
[h,p,stats] = ansaribradley(x,y)
```

```
h = 0
```

```
p = 0.8426
```

```
stats = struct with fields:
    W: 526.9000
    Wstar: 0.1986
```

The returned value of $h = 0$ indicates that `ansaribradley` does not reject the null hypothesis at the default 5% significance level.

Ansari-Bradley One-Sided Hypothesis Test

Load the sample data. Create data vectors of miles per gallon (MPG) measurements for the model years 1982 and 1976.

```
load carsmall
x = MPG(Model_Year==82);
y = MPG(Model_Year==76);
```

Test the null hypothesis that the miles per gallon measured in cars from 1982 and 1976 have equal variances, against the alternative hypothesis that the variance of cars from 1982 is greater than that of cars from 1976.

```
[h,p,stats] = ansaribradley(x,y,'Tail','right')
```

```
h = 0
```

```
p = 0.5787

stats = struct with fields:
    W: 526.9000
    Wstar: 0.1986
```

The returned value of `h = 0` indicates that `ansaribradley` does not reject the null hypothesis that the variance in miles per gallon is the same for the two model years, when the alternative is that the variance of cars from 1982 is greater than that of cars from 1976.

Input Arguments

x — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array.

- If `x` and `y` are specified as vectors, they do not need to be the same length.
- If `x` and `y` are specified as matrices, they must have the same number of columns. `ansaribradley` performs separate tests along each column and returns a vector of results.
- If `x` and `y` are specified as multidimensional arrays on page 32-117, `ansaribradley` works along the first nonsingleton dimension on page 32-118. `x` and `y` must have the same size along all remaining dimensions.

Data Types: `single` | `double`

y — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array.

- If `x` and `y` are specified as vectors, they do not need to be the same length.
- If `x` and `y` are specified as matrices, they must have the same number of columns. `ansaribradley` performs separate tests along each column and returns a vector of results.

- If x and y are specified as multidimensional arrays on page 32-117, `ansaribradley` works along the first nonsingleton dimension on page 32-118. x and y must have the same size along all remaining dimensions.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Tail', 'right', 'Alpha', 0.01` specifies a right-tailed hypothesis test at the 1% significance level.

Alpha — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

Dim — Dimension

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix along which to test the means, specified as the comma-separated pair consisting of `'Dim'` and a positive integer value. For example, specifying `'Dim', 1` tests the column means, while `'Dim', 2` tests the row means.

Example: `'Dim', 2`

Data Types: `single` | `double`

Tail — Type of alternative hypothesis

`'both'` (default) | `'left'` | `'right'`

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

| | |
|---------|--|
| 'both' | Test the alternative hypothesis that the dispersion parameters of x and y are not equal. |
| 'right' | Test the alternative hypothesis that the dispersion parameter of x is greater than that of y . |
| 'left' | Test the alternative hypothesis that the dispersion parameter of x is less than that of y . |

Example: 'Tail', 'right'

Method — Computation method

'exact' | 'approximate'

Computation method for the test statistic, specified as the comma-separated pair consisting of 'Method' and one of the following.

| | |
|---------------|---|
| 'exact' | Compute p using an exact calculation of the distribution of the test statistic W . This is the default if n , the total number of rows in x and y , is 25 or less. Note that n is computed before any NaN values (representing missing data) are removed. |
| 'approximate' | Compute p using a normal approximation for the statistic W^* . This is the default if n , the total number of rows in x and y , is greater than 25. |

Example: 'Method', 'exact'

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as 1 or 0.

- If $h = 1$, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p — *p*-value

scalar value in the range [0,1]

p -value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

stats — Test statistics

structure

Test statistics for the Ansari-Bradley test, returned as a structure containing:

- W — Value of the test statistic, which is the sum of the Ansari-Bradley ranks for the x sample.
- W_{star} — Approximate normal statistic W^* .

Definitions

Ansari-Bradley Test

The Ansari-Bradley test is a nonparametric alternative to the two-sample F -test of equal variances. It does not require the assumption that x and y come from normal distributions. The dispersion of a distribution is generally measured by its variance or standard deviation, but the Ansari-Bradley test can be used with samples from distributions that do not have finite variances.

This test requires that the samples have equal medians. Under that assumption, and if the distributions of the samples are continuous and identical, the test is independent of the distributions. If the samples do not have the same medians, the results can be misleading. In that case, Ansari and Bradley recommend subtracting the median, but then the distribution of the resulting test under the null hypothesis is no longer independent of the common distribution of x and y . If you want to perform the tests with medians subtracted, you should subtract the medians from x and y before calling `ansaribradley`.

Multidimensional Array

A multidimensional array has more than two dimensions. For example, if x is a 1-by-3-by-4 array, then x is a three-dimensional array.

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if `x` is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of `x`.

Introduced before R2006a

aoctool

Interactive analysis of covariance

Syntax

```
aoctool(x,y,group)
aoctool(x,y,group,alpha)
aoctool(x,y,group,alpha,xname,yname,gname)
aoctool(x,y,group,alpha,xname,yname,gname,displayopt)
aoctool(x,y,group,alpha,xname,yname,gname,displayopt,model)
h = aoctool(...)
[h,atab,ctab] = aoctool(...)
[h,atab,ctab,stats] = aoctool(...)
```

Description

`aoctool(x,y,group)` fits a separate line to the column vectors, `x` and `y`, for each group defined by the values in the array `group`. `group` may be a categorical variable, numeric vector, character array, string array, or cell array of character vectors. These types of models are known as one-way analysis of covariance (ANOCOVA) models. The output consists of three figures:

- An interactive graph of the data and prediction curves
- An ANOVA table
- A table of parameter estimates

You can use the figures to change models and to test different parts of the model. More information about interactive use of the `aoctool` function appears in “Analysis of Covariance Tool” on page 9-58.

`aoctool(x,y,group,alpha)` determines the confidence levels of the prediction intervals. The confidence level is $100(1-\alpha)\%$. The default value of `alpha` is 0.05.

`aoctool(x,y,group,alpha,xname,yname,gname)` specifies the name to use for the `x`, `y`, and `g` variables in the graph and tables. If you enter simple variable names for the

`x`, `y`, and `g` arguments, the `aocool` function uses those names. If you enter an expression for one of these arguments, you can specify a name to use in place of that expression by supplying these arguments. For example, if you enter `m(:,2)` as the `x` argument, you might choose to enter `'Col 2'` as the `xname` argument.

`aocool(x,y,group,alpha,xname,yname,gname,displayopt)` enables the graph and table displays when `displayopt` is `'on'` (default) and suppresses those displays when `displayopt` is `'off'`.

`aocool(x,y,group,alpha,xname,yname,gname,displayopt,model)` specifies the initial model to fit. The value of `model` can be any of the following:

- `'same mean'` — Fit a single mean, ignoring grouping
- `'separate means'` — Fit a separate mean to each group
- `'same line'` — Fit a single line, ignoring grouping
- `'parallel lines'` — Fit a separate line to each group, but constrain the lines to be parallel
- `'separate lines'` — Fit a separate line to each group, with no constraints

`h = aocool(...)` returns a vector of handles to the line objects in the plot.

`[h,atab,ctab] = aocool(...)` returns cell arrays containing the entries in ANOVA table (`atab`) and the table of coefficient estimates (`ctab`). (You can copy a text version of either table to the clipboard by using the `Copy Text` item on the **Edit** menu.)

`[h,atab,ctab,stats] = aocool(...)` returns a `stats` structure that you can use to perform a follow-up multiple comparison test. The ANOVA table output includes tests of the hypotheses that the slopes or intercepts are all the same, against a general alternative that they are not all the same. Sometimes it is preferable to perform a test to determine which pairs of values are significantly different, and which are not. You can use the `multcompare` function to perform such tests by supplying the `stats` structure as input. You can test either the slopes, the intercepts, or population marginal means (the heights of the curves at the mean `x` value).

Examples

This example illustrates how to fit different models non-interactively. After loading the smaller car data set and fitting a separate-slopes model, you can examine the coefficient estimates.

```

load carsmall
[h,a,c,s] = aoctool(Weight,MPG,Model_Year,0.05,...
                  ' ',' ',' ','off','separate lines');
c(:,1:2)
ans =
  'Term'      'Estimate'
  'Intercept' [45.97983716833132]
  ' 70'       [-8.58050531454973]
  ' 76'       [-3.89017396094922]
  ' 82'       [12.47067927549897]
  'Slope'     [-0.00780212907455]
  ' 70'       [ 0.00195840368824]
  ' 76'       [ 0.00113831038418]
  ' 82'       [-0.00309671407243]

```

Roughly speaking, the lines relating MPG to Weight have an intercept close to 45.98 and a slope close to -0.0078. Each group's coefficients are offset from these values somewhat. For instance, the intercept for the cars made in 1970 is $45.98 - 8.58 = 37.40$.

Next, try a fit using parallel lines. (The ANOVA table shows that the parallel-lines fit is significantly worse than the separate-lines fit.)

```

[h,a,c,s] = aoctool(Weight,MPG,Model_Year,0.05,...
                  ' ',' ',' ','off','parallel lines');
c(:,1:2)
ans =
  'Term'      'Estimate'
  'Intercept' [43.38984085130596]
  ' 70'       [-3.27948192983761]
  ' 76'       [-1.35036234809006]
  ' 82'       [ 4.62984427792768]
  'Slope'     [-0.00664751826198]

```

Again, there are different intercepts for each group, but this time the slopes are constrained to be the same.

Introduced before R2006a

append

Class: TreeBagger

Append new trees to ensemble

Syntax

```
B = append(B, other)
```

Description

`B = append(B, other)` appends the trees from the `other` ensemble to those in `B`. This method checks for consistency of the `X` and `Y` properties of the two ensembles, as well as consistency of their compact objects and out-of-bag indices, before appending the trees. The output ensemble `B` takes training parameters such as `FBoot`, `Prior`, `Cost`, and `other` from the `B` input. There is no attempt to check if these training parameters are consistent between the two objects.

See Also

`CompactTreeBagger.combine`

barttest

Bartlett's test

Syntax

```
ndim = barttest(x,alpha)
[ndim,prob,chisquare] = barttest(x,alpha)
```

Description

`ndim = barttest(x,alpha)` returns the number of dimensions necessary to explain the nonrandom variation in the data matrix `x` at the `alpha` significance level.

`[ndim,prob,chisquare] = barttest(x,alpha)` also returns the significance values for the hypothesis tests `prob`, and the χ^2 values associated with the tests `chisquare`.

Examples

Determine Dimensions Needed to Explain Nonrandom Data Variation

Generate a 20-by-6 matrix of random numbers from a multivariate normal distribution with mean `mu = [0 0]` and covariance `sigma = [1 0.99; 0.99 1]`.

```
rng default % for reproducibility
mu = [0 0];
sigma = [1 0.99; 0.99 1];
X = mvnrnd(mu,sigma,20); % columns 1 and 2
X(:,3:4) = mvnrnd(mu,sigma,20); % columns 3 and 4
X(:,5:6) = mvnrnd(mu,sigma,20); % columns 5 and 6
```

Determine the number of dimensions necessary to explain the nonrandom variation in data matrix `X`. Report the significance values for the hypothesis tests.

```
[ndim, prob] = barttest(X,0.05)
```

```
ndim = 3
prob = 5×1
    0.0000
    0.0000
    0.0000
    0.5148
    0.3370
```

The returned value of `ndim` indicates that three dimensions are necessary to explain the nonrandom variation in X .

Input Arguments

x — Input data

matrix of scalar values

Input data, specified as a matrix of scalar values.

Data Types: `single` | `double`

alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as a scalar value in the range (0,1).

Example: 0.1

Data Types: `single` | `double`

Output Arguments

ndim — Number of dimensions

positive integer value

Number of dimensions, returned as a positive integer value. The dimension is determined by a series of hypothesis tests. The test for `ndim = 1` tests the hypothesis that the variances of the data values along each principal component are equal, the test for `ndim`

= 2 tests the hypothesis that the variances along the second through last components are equal, and so on. The null hypothesis is that the number of dimensions is equal to the number of the largest unequal eigenvalues of the covariance matrix of `x`.

prob — Significance value

vector of scalar values in the range $(0, 1)$

Significance value for the hypothesis tests, returned as a vector of scalar values in the range $(0, 1)$. Each element in `prob` corresponds to an element of `chisquare`.

chisquare — Test statistics

vector of scalar values

Test statistics for each dimension's hypothesis test, returned as a vector of scalar values.

BayesianOptimization

Bayesian optimization results

Description

A `BayesianOptimization` object contains the results of a Bayesian optimization. It is the output of `bayesopt` or a fit function that accepts the `OptimizeHyperparameters` name-value pair such as `fitcdiscr`. In addition, a `BayesianOptimization` object contains data for each iteration of `bayesopt` that can be accessed by a plot function or an output function.

Creation

Create a `BayesianOptimization` object using the `bayesopt` function or a fit function with the `OptimizeHyperparameters` name-value pair.

Properties

Problem Definition Properties

ObjectiveFcn — ObjectiveFcn argument that bayesopt used
function handle

This property is read-only.

ObjectiveFcn argument that bayesopt used, returned as a function handle.

- If you called `bayesopt` directly, `ObjectiveFcn` is the `bayesopt` objective function argument.
- If you called a fit function with the `OptimizeHyperparameters` name-value pair, `ObjectiveFcn` is the logarithm of one plus the cross-validation loss.

Data Types: `function_handle`

VariableDescriptions — VariableDescriptions argument that bayesopt used

vector of `optimizableVariable` objects

This property is read-only.

VariableDescriptions argument that bayesopt used, returned as a vector of `optimizableVariable` objects.

- If you called `bayesopt` directly, `VariableDescriptions` is the bayesopt variable description argument.
- If you called a fit function with the `OptimizeHyperparameters` name-value pair, `VariableDescriptions` is the vector of hyperparameters.

Options — Options that bayesopt used

structure

This property is read-only.

Options that bayesopt used, returned as a structure.

- If you called `bayesopt` directly, `Options` is the options used in bayesopt, which are the name-value pairs See bayesopt “Input Arguments” on page 32-157.
- If you called a fit function with the `OptimizeHyperparameters` name-value pair, `Options` are the default bayesopt options, modified by the `HyperparameterOptimizationOptions` name-value pair.

Options is a read-only structure containing the following fields.

| Option Name | Meaning |
|---------------------------------------|--|
| <code>AcquisitionFunctionName</code> | Acquisition function name. See “Acquisition Function Types” on page 10-4. |
| <code>IsObjectiveDeterministic</code> | <code>true</code> means the objective function is deterministic, <code>false</code> otherwise. |
| <code>ExplorationRatio</code> | Used only when <code>AcquisitionFunctionName</code> is 'expected-improvement-plus' or 'expected-improvement-per-second-plus'. See “Plus” on page 10-6. |
| | |
| <code>MaxObjectiveEvaluations</code> | Objective function evaluation limit. |

| Option Name | Meaning |
|------------------------------------|---|
| MaxTime | Time limit. |
| XConstraintFcn | Deterministic constraints on variables. See “Deterministic Constraints – XConstraintFcn” on page 10-44. |
| ConditionalVariableFcn | Conditional variable constraints. See “Conditional Constraints – ConditionalVariableFcn” on page 10-45. |
| NumCoupledConstraints | Number of coupled constraints. See “Coupled Constraints” on page 10-47. |
| CoupledConstraintTolerances | Coupled constraint tolerances. See “Coupled Constraints” on page 10-47. |
| AreCoupledConstraintsDeterministic | Logical vector specifying whether each coupled constraint is deterministic. |
| Verbose | Command-line display level. |
| OutputFcn | Function called after each iteration. See “Bayesian Optimization Output Functions” on page 10-23. |
| SaveVariableName | Variable name for the @assignInBase output function. |
| SaveFileName | File name for the @saveToFile output function. |
| PlotFcn | Plot function called after each iteration. See “Bayesian Optimization Plot Functions” on page 10-14 |
| InitialX | Points where bayesopt evaluated the objective function. |
| InitialObjective | Objective function values at InitialX. |
| InitialConstraintViolations | Coupled constraint function values at InitialX. |
| InitialErrorValues | Error values at InitialX. |

| Option Name | Meaning |
|---------------------------------|--|
| InitialObjectiveEvaluationTimes | Objective function evaluation times at InitialX. |
| InitialIterationTimes | Time for each iteration, including objective function evaluation and other computations. |

Data Types: struct

Solution Properties

MinObjective — Minimum observed value of objective function

real scalar

This property is read-only.

Minimum observed value of objective function, returned as a real scalar. When there are coupled constraints or evaluation errors, this value is the minimum over all observed points that are feasible according to the final constraint and Error models.

Data Types: double

XAtMinObjective — Observed point with minimum objective function value

1-by-D table

This property is read-only.

Observed point with minimum objective function value, returned as a 1-by-D table, where D is the number of variables.

Data Types: table

MinEstimatedObjective — Minimum estimated value of objective function

real scalar

This property is read-only.

Minimum estimated value of objective function, returned as a real scalar. `MinEstimatedObjective` uses the final objective model.

`MinEstimatedObjective` is the same as the `CriterionValue` result of `bestPoint` with default criterion.

Data Types: double

XAtMinEstimatedObjective — Point with minimum estimated objective function value

1-by-D table

This property is read-only.

Point with minimum estimated objective function value, returned as a 1-by-D table, where D is the number of variables. XAtMinEstimatedObjective uses the final objective model.

Data Types: table

NumObjectiveEvaluations — Number of objective function evaluations

positive integer

This property is read-only.

Number of objective function evaluations, returned as a positive integer. This includes the initial evaluations to form a posterior model as well as evaluation during the optimization iterations.

Data Types: double

TotalElapsedTime — Total elapsed time of optimization in seconds

positive scalar

This property is read-only.

Total elapsed time of optimization in seconds, returned as a positive scalar.

Data Types: double

NextPoint — Next point to evaluate if optimization continues

1-by-D table

This property is read-only.

Next point to evaluate if optimization continues, returned as a 1-by-D table, where D is the number of variables.

Data Types: table

Trace Properties

XTrace — Points where the objective function was evaluated

T-by-D table

This property is read-only.

Points where the objective function was evaluated, returned as a T-by-D table, where T is the number of evaluation points and D is the number of variables.

Data Types: table

ObjectiveTrace — Objective function values

column vector of length T

This property is read-only.

Objective function values, returned as a column vector of length T, where T is the number of evaluation points. `ObjectiveTrace` contains the history of objective function evaluations.

Data Types: double

ObjectiveEvaluationTimeTrace — Objective function evaluation times

column vector of length T

This property is read-only.

Objective function evaluation times, returned as a column vector of length T, where T is the number of evaluation points. `ObjectiveEvaluationTimeTrace` includes the time in evaluating coupled constraints, because the objective function computes these constraints.

Data Types: double

IterationTimeTrace — Iteration times

column vector of length T

This property is read-only.

Iteration times, returned as a column vector of length T, where T is the number of evaluation points. `IterationTimeTrace` includes both objective function evaluation time and other overhead.

Data Types: double

ConstraintsTrace — Coupled constraint values

T-by-K array

This property is read-only.

Coupled constraint values, returned as a T-by-K array, where T is the number of evaluation points and K is the number of coupled constraints.

Data Types: double

ErrorTrace — Error indications

column vector of length T of -1 or 1 entries

This property is read-only.

Error indications, returned as a column vector of length T of -1 or 1 entries, where T is the number of evaluation points. Each 1 entry indicates that the objective function errored or returned NaN on the corresponding point in XTrace. Each -1 entry indicates that the objective function value was computed.

Data Types: double

FeasibilityTrace — Feasibility indications

logical column vector of length T

This property is read-only.

Feasibility indications, returned as a logical column vector of length T, where T is the number of evaluation points. Each 1 entry indicates that the final constraint model predicts feasibility at the corresponding point in XTrace.

Data Types: logical

FeasibilityProbabilityTrace — Probability that evaluation point is feasible

column vector of length T

This property is read-only.

Probability that evaluation point is feasible, returned as a column vector of length T, where T is the number of evaluation points. The probabilities come from the final constraint model, including the error constraint model, on the corresponding points in XTrace.

Data Types: double

IndexOfMinimumTrace — Which evaluation gave minimum feasible objective

column vector of integer indices of length T

This property is read-only.

Which evaluation gave minimum feasible objective, returned as a column vector of integer indices of length T, where T is the number of evaluation points. Feasibility is determined with respect to the constraint models that existed at each iteration, including the error constraint model.

Data Types: double

ObjectiveMinimumTrace — Minimum observed objective

column vector of length T

This property is read-only.

Minimum observed objective, returned as a column vector of integer indices of length T, where T is the number of evaluation points.

Data Types: double

EstimatedObjectiveMinimumTrace — Minimum estimated objective

column vector of length T

This property is read-only.

Minimum estimated objective, returned as a column vector of integer indices of length T, where T is the number of evaluation points. The estimated objective at each iteration is determined with respect to the objective model that existed at that iteration.

Data Types: double

UserDataTrace — Auxiliary data from the objective function

cell array of length T

This property is read-only.

Auxiliary data from the objective function, returned as a cell array of length T, where T is the number of evaluation points. Each entry in the cell array is the `UserData` returned in the third output of the objective function.

Data Types: cell

Object Functions

| | |
|--------------------------------|--|
| bestPoint | Best point in a Bayesian optimization according to a criterion |
| plot | Plot Bayesian optimization results |
| predictConstraints | Predict coupled constraint violations at a set of points |
| predictError | Predict error value at a set of points |
| predictObjective | Predict objective function at a set of points |
| predictObjectiveEvaluationTime | Predict objective function run times at a set of points |
| resume | Resume a Bayesian optimization |

Examples

Create a BayesianOptimization Object Using bayesopt

This example shows how to create a BayesianOptimization object by using bayesopt to minimize cross-validation loss.

Optimize hyperparameters of a KNN classifier for the ionosphere data, that is, find KNN hyperparameters that minimize the cross-validation loss. Have bayesopt minimize over the following hyperparameters:

- Nearest-neighborhood sizes from 1 to 30
- Distance functions 'chebychev', 'euclidean', and 'minkowski'.

For reproducibility, set the random seed, set the partition, and set the AcquisitionFunctionName option to 'expected-improvement-plus'. Set options give no iterative display.

```
load ionosphere
rng default
num = optimizableVariable('n',[1,30],'Type','integer');
dst = optimizableVariable('dst',{'chebychev','euclidean','minkowski'},'Type','categorical');
c = cvpartition(351,'Kfold',5);
fun = @(x)kfoldLoss(fitcknn(X,Y,'CVPartition',c,'NumNeighbors',x.n,...
    'Distance',char(x.dst),'NSMethod','exhaustive'));
```

```
results = bayesopt(fun,[num,dst],'Verbose',0,...  
    'AcquisitionFunctionName','expected-improvement-plus')
```

```
results =
```

```
BayesianOptimization with properties:
```

```
    ObjectiveFcn: [function_handle]
  VariableDescriptions: [1x2 optimizableVariable]
        Options: [1x1 struct]
    MinObjective: 0.1197
    XAtMinObjective: [1x2 table]
  MinEstimatedObjective: 0.1213

Create a BayesianOptimization Object Using a Fit Function

This example shows how to minimize the cross-validation loss in the `ionosphere` data using Bayesian optimization of an SVM classifier.

Load the data.

```
load ionosphere
```

Optimize the classification using the 'auto' parameters.

```
rng default % For reproducibility
Mdl = fitcsvm(X,Y,'OptimizeHyperparameters','auto')
```

Topics

“Bayesian Optimization Workflow” on page 10-30

Introduced in R2016b

bayesopt

Select optimal machine learning hyperparameters using Bayesian optimization

Syntax

```
results = bayesopt(fun,vars)
results = bayesopt(fun,vars,Name,Value)
```

Description

`results = bayesopt(fun,vars)` attempts to find values of `vars` that minimize `fun(vars)`.

`results = bayesopt(fun,vars,Name,Value)` modifies the optimization process according to the `Name,Value` arguments.

Examples

Create a BayesianOptimization Object Using bayesopt

This example shows how to create a `BayesianOptimization` object by using `bayesopt` to minimize cross-validation loss.

Optimize hyperparameters of a KNN classifier for the `ionosphere` data, that is, find KNN hyperparameters that minimize the cross-validation loss. Have `bayesopt` minimize over the following hyperparameters:

- Nearest-neighborhood sizes from 1 to 30
- Distance functions 'chebychev', 'euclidean', and 'minkowski'.

For reproducibility, set the random seed, set the partition, and set the `AcquisitionFunctionName` option to 'expected-improvement-plus'. Set options give no iterative display.

```
load ionosphere
rng default
num = optimizableVariable('n',[1,30],'Type','integer');
dst = optimizableVariable('dst',{'chebychev','euclidean','minkowski'},'Type','categorical');
c = cvpartition(351,'Kfold',5);
fun = @(x)kfoldLoss(fitcknn(X,Y,'CVPartition',c,'NumNeighbors',x.n,...
    'Distance',char(x.dst),'NSMethod','exhaustive'));
results = bayesopt(fun,[num,dst],'Verbose',0,...
    'AcquisitionFunctionName','expected-improvement-plus')
```

```
results =
```

```

Bayesian Optimization with Coupled Constraints

A coupled constraint is one that can be evaluated only by evaluating the objective function. In this case, the objective function is the cross-validated loss of an SVM model. The coupled constraint is that the number of support vectors is no more than 100. The model details are in “Optimize a Cross-Validated SVM Classifier Using bayesopt” on page 10-54.

Create the data for classification.

```
rng default
grnpop = mvnrnd([1,0],eye(2),10);
redpop = mvnrnd([0,1],eye(2),10);
redpts = zeros(100,2);
grnpts = redpts;
for i = 1:100
    grnpts(i,:) = mvnrnd(grnpop(randi(10),,:),eye(2)*0.02);
    redpts(i,:) = mvnrnd(redpop(randi(10),,:),eye(2)*0.02);
end
cdata = [grnpts;redpts];
grp = ones(200,1);
grp(101:200) = -1;
c = cvpartition(200,'KFold',10);
sigma = optimizableVariable('sigma',[1e-5,1e5],'Transform','log');
box = optimizableVariable('box',[1e-5,1e5],'Transform','log');
```

The objective function is the cross-validation loss of the SVM model for partition c. The coupled constraint is the number of support vectors minus 100.5. This ensures that 100

support vectors give a negative constraint value, but 101 support vectors give a positive value. The model has 200 data points, so the coupled constraint values range from -99.5 (there is always at least one support vector) to 99.5. Positive values mean the constraint is not satisfied.

```
function [objective,constraint] = mysvmfun(x,cdata,grp,c)
SVMModel = fitcsvm(cdata,grp,'KernelFunction','rbf',...
    'BoxConstraint',x.box,...
    'KernelScale',x.sigma);
cvModel = crossval(SVMModel,'CVPartition',c);
objective = kfoldLoss(cvModel);
constraint = sum(SVMModel.IsSupportVector)-100.5;
```

```
fun = @(x)mysvmfun(x,cdata,grp,c);
```

Set the NumCoupledConstraints to 1 so the optimizer knows that there is a coupled constraint. Set options to plot the constraint model.

```
results = bayesopt(fun,[sigma,box],'IsObjectiveDeterministic',true,...
    'NumCoupledConstraints',1,'PlotFcn',...
    {@plotMinObjective,@plotConstraintModels},...
    'AcquisitionFunctionName','expected-improvement-plus','Verbose',0);
```

Constraint 1 model

Most points lead to an infeasible number of support vectors.

Parallel Bayesian Optimization

Improve the speed of a Bayesian optimization by using parallel objective function evaluation.

Prepare variables and the objective function for Bayesian optimization.

The objective function is the cross-validation error rate for the ionosphere data, a binary classification problem. Use `fitcsvm` as the classifier, with `BoxConstraint` and `KernelScale` as the parameters to optimize.

```
load ionosphere
box = optimizableVariable('box',[1e-4,1e3],'Transform','log');
kern = optimizableVariable('kern',[1e-4,1e3],'Transform','log');
vars = [box,kern];
fun = @(vars)kfoldLoss(fitcsvm(X,Y,'BoxConstraint',vars.box,'KernelScale',vars.kern,..
    'Kfold',5));
```

Search for the parameters that give the lowest cross-validation error by using parallel Bayesian optimization.

```
results = bayesopt(fun,vars,'UseParallel',true);
```

```
Copying objective function to workers...
Done copying objective function to workers.
```

| 0.00083077 | 0.0090062 |

Observed objective function value = 0.10256
 Estimated objective function value = 0.11786
 Function evaluation time = 0.32152

Best estimated feasible point (according to models):
 box kern

```

_____
0.0011252    0.011984

```

```

Estimated objective function value = 0.11786
Estimated function evaluation time = 0.28326

```

Return the best feasible point in the Bayesian model results by using the `bestPoint` function. Use the default criterion `min-visited-upper-confidence-interval`, which determines the best feasible point as the visited point that minimizes an upper confidence interval on the objective function value.

```
zbest = bestPoint(results)
```

```

zbest=1x2 table
      box      kern
_____
0.0011252    0.011984

```

The table `zbest` contains the optimal estimated values for the `'BoxConstraint'` and `'KernelScale'` name-value pair arguments. Use these values to train a new optimized classifier.

```
Mdl = fitcsvm(X,Y,'BoxConstraint',zbest.box,'KernelScale',zbest.kern);
```

Observe that the optimal parameters are in `Mdl`.

```
Mdl.BoxConstraints(1)
```

```
ans = 0.0011
```

```
Mdl.KernelParameters.Scale
```

```
ans = 0.0120
```

- “Optimize a Cross-Validated SVM Classifier Using `bayesopt`” on page 10-54

Input Arguments

fun — Objective function

function handle | `parallel.pool.Constant` whose Value is a function handle

Objective function, specified as a function handle or, when the `UseParallel` name-value pair is `true`, a `parallel.pool.Constant` whose `Value` is a function handle. Typically, `fun` returns a measure of loss (such as a misclassification error) for a machine learning model that has tunable hyperparameters to control its training. `fun` has these signatures:

```
objective = fun(x)
% or
[objective,constraints] = fun(x)
% or
[objective,constraints,UserData] = fun(x)
```

`fun` accepts `x`, a 1-by-D table of variable values, and returns `objective`, a real scalar representing the objective function value `fun(x)`.

Optionally, `fun` also returns:

- `constraints`, a real vector of coupled constraint violations. For a definition, see “Coupled Constraints” on page 32-169. `constraint(j) > 0` means constraint `j` is violated. `constraint(j) < 0` means constraint `j` is satisfied.
- `UserData`, an entity of any type (such as a scalar, matrix, structure, or object). For an example of a custom plot function that uses `UserData`, see “Create a Custom Plot Function” on page 10-16.

For details about using `parallel.pool.Constant` with `bayesopt`, see “Placing the Objective Function on Workers” on page 10-10.

Example: `@objfun`

Data Types: `function_handle`

vars — Variable descriptions

vector of `optimizableVariable` objects defining the hyperparameters to be tuned

Variable descriptions, specified as a vector of `optimizableVariable` objects defining the hyperparameters to be tuned.

Example: `[X1,X2]`, where `X1` and `X2` are `optimizableVariable` objects

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

```
Example: results =
bayesopt(fun, vars, 'AcquisitionFunctionName', 'expected-improvement-
plus')
```

Algorithm Control

AcquisitionFunctionName — Function to choose next evaluation point

'expected-improvement-per-second-plus' (default) | 'expected-improvement' | 'expected-improvement-plus' | 'expected-improvement-per-second' | 'lower-confidence-bound' | 'probability-of-improvement'

Function to choose next evaluation point, specified as one of the listed choices. For algorithm descriptions, see “Acquisition Function Types” on page 10-4.

```
Example: 'AcquisitionFunctionName', 'expected-improvement-per-second'
```

Data Types: char

IsObjectiveDeterministic — Specify deterministic objective function

false (default) | true

Specify deterministic objective function, specified as `false` or `true`. If `fun` is stochastic (that is, `fun(x)` can return different values for the same `x`), then set `IsObjectiveDeterministic` to `false`. In this case, `bayesopt` estimates a noise level during optimization.

```
Example: 'IsObjectiveDeterministic', true
```

Data Types: logical

ExplorationRatio — Propensity to explore

0.5 (default) | positive real

Propensity to explore, specified as a positive real. Applies to the 'expected-improvement-plus' and 'expected-improvement-per-second-plus' acquisition functions. See “Plus” on page 10-6.

```
Example: 'ExplorationRatio', 0.2
```

Data Types: double

GActiveSetSize — Fit Gaussian Process model to GActiveSetSize or fewer points

300 (default) | positive integer

Fit Gaussian Process model to `GActiveSetSize` or fewer points, specified as a positive integer. When `bayesopt` has visited more than `GActiveSetSize` points, subsequent iterations that use a GP model fit the model to `GActiveSetSize` points. `bayesopt` chooses points uniformly at random without replacement among visited points. Using fewer points leads to faster GP model fitting, at the expense of possibly less accurate fitting.

Example: `'GActiveSetSize',80`

Data Types: `double`

UseParallel — Compute in parallel

false (default) | true

Compute in parallel, specified as `false` (do not compute in parallel) or `true` (compute in parallel). `bayesopt` performs parallel objective function evaluations concurrently on parallel workers. For algorithmic details, see “Parallel Bayesian Optimization” on page 10-9.

Example: `'UseParallel',true`

Data Types: `logical`

ParallelMethod — Imputation method for parallel worker objective function values

'clipped-model-prediction' (default) | 'model-prediction' | 'max-observed' | 'min-observed'

Imputation method for parallel worker objective function values, specified as `'clipped-model-prediction'`, `'model-prediction'`, `'max-observed'`, or `'min-observed'`. To generate a new point to evaluate, `bayesopt` fits a Gaussian process to all points, including the points being evaluated on workers. To fit the process, `bayesopt` imputes objective function values for the points that are currently on workers. `ParallelMethod` specifies the method used for imputation.

- `'clipped-model-prediction'` — Impute the maximum of these quantities:
 - Mean Gaussian process prediction at the point x
 - Minimum observed objective function among feasible points visited

- Minimum model prediction among all feasible points
- `'model-prediction'` — Impute the mean Gaussian process prediction at the point x .
- `'max-observed'` — Impute the maximum observed objective function value among feasible points.
- `'min-observed'` — Impute the minimum observed objective function value among feasible points.

Example: `'ParallelMethod', 'max-observed'`

Data Types: char

MinWorkerUtilization — Tolerance on number of active parallel workers

`floor(0.8*Nworkers)` (default) | positive integer

Tolerance on the number of active parallel workers, specified as a positive integer. After `bayesopt` assigns a point to evaluate, and before it computes a new point to assign, it checks whether fewer than `MinWorkerUtilization` workers are active. If so, `bayesopt` assigns random points within bounds to all available workers. Otherwise, `bayesopt` calculates the best point for one worker. `bayesopt` creates random points much faster than fitted points, so this behavior leads to higher utilization of workers, at the cost of possibly poorer points. For details, see “Parallel Bayesian Optimization” on page 10-9.

Example: `'MinWorkerUtilization', 3`

Data Types: double

Starting and Stopping

MaxObjectiveEvaluations — Objective function evaluation limit

`30` (default) | positive integer

Objective function evaluation limit, specified as a positive integer.

Example: `'MaxObjectiveEvaluations', 60`

Data Types: double

MaxTime — Time limit

`Inf` (default) | positive real

Time limit, specified as a positive real. The time limit is in seconds, as measured by `tic` and `toc`.

Run time can exceed `MaxTime` because `bayesopt` does not interrupt function evaluations.

Example: `'MaxTime',3600`

Data Types: `double`

NumSeedPoints — Number of initial evaluation points

4 (default) | positive integer

Number of initial evaluation points, specified as a positive integer. `bayesopt` chooses these points randomly within the variable bounds, according to the setting of the `Transform` setting for each variable (uniform for `'none'`, logarithmically spaced for `'log'`).

Example: `'NumSeedPoints',10`

Data Types: `double`

Constraints

XConstraintFcn — Deterministic constraints on variables

[] (default) | function handle

Deterministic constraints on variables, specified as a function handle.

For details, see “Deterministic Constraints — `XConstraintFcn`” on page 10-44.

Example: `'XConstraintFcn',@xconstraint`

Data Types: `function_handle`

ConditionalVariableFcn — Conditional variable constraints

[] (default) | function handle

Conditional variable constraints, specified as a function handle.

For details, see “Conditional Constraints — `ConditionalVariableFcn`” on page 10-45.

Example: `'ConditionalVariableFcn',@condfun`

Data Types: `function_handle`

NumCoupledConstraints — Number of coupled constraints

0 (default) | positive integer

Number of coupled constraints, specified as a positive integer. For details, see “Coupled Constraints” on page 10-47.

Note `NumCoupledConstraints` is required when you have coupled constraints.

Example: `'NumCoupledConstraints',3`

Data Types: `double`

AreCoupledConstraintsDeterministic — Indication of whether coupled constraints are deterministic

`true` for all coupled constraints (default) | logical vector

Indication of whether coupled constraints are deterministic, specified as a logical vector of length `NumCoupledConstraints`. For details, see “Coupled Constraints” on page 10-47.

Example: `'AreCoupledConstraintsDeterministic',[true,false,true]`

Data Types: `logical`

Reports, Plots, and Halting

Verbose — Command-line display level

`1` (default) | `0` | `2`

Command-line display level, specified as `0`, `1`, or `2`.

- `0` — No command-line display.
- `1` — At each iteration, display the iteration number, result report (see the next paragraph), objective function model, objective function evaluation time, best (lowest) observed objective function value, best (lowest) estimated objective function value, and the observed constraint values (if any). When optimizing in parallel, the display also includes a column showing the number of active workers, counted after assigning a job to the next worker.

The result report for each iteration is one of the following:

- **Accept** — The objective function returns a finite value, and all constraints are satisfied.
- **Best** — Constraints are satisfied, and the objective function returns the lowest value among feasible points.

- **Error** — The objective function returns a value that is not a finite real scalar.
- **Infeas** — At least one constraint is violated.
- **2** — Same as 1, adding diagnostic information such as time to select the next point, model fitting time, indication that "plus" acquisition functions declare overexploiting, and parallel workers are being assigned to random points due to low parallel utilization.

Example: 'Verbose',2

Data Types: double

OutputFcn — Function called after each iteration

{ } (default) | function handle | cell array of function handles

Function called after each iteration, specified as a function handle or cell array of function handles. An output function can halt the solver, and can perform arbitrary calculations, including creating variables or plotting. Specify several output functions using a cell array of function handles.

There are two built-in output functions:

- **@assignInBase** — Constructs a `BayesianOptimization` instance at each iteration and assigns it to a variable in the base workspace. Choose a variable name using the `SaveVariableName` name-value pair.
- **@saveToFile** — Constructs a `BayesianOptimization` instance at each iteration and saves it to a file in the current folder. Choose a file name using the `SaveFileName` name-value pair.

You can write your own output functions. For details, see “Bayesian Optimization Output Functions” on page 10-23.

Example: 'OutputFcn',{@saveToFile @myOutputFunction}

Data Types: cell | function_handle

SaveFileName — File name for the @saveToFile output function

'BayesoptResults.mat' (default) | character vector

File name for the `@saveToFile` output function, specified as a character vector. The file name can include a path, such as `'../optimizations/September2.mat'`.

Example: 'SaveFileName','September2.mat'

Data Types: char

SaveVariableName — Variable name for the @assignInBase output function

'BayesoptResults' (default) | character vector

Variable name for the @assignInBase output function, specified as a character vector.

Example: 'SaveVariableName', 'September2Results'

Data Types: char

PlotFcn — Plot function called after each iteration

{@plotObjectiveModel,@plotMinObjective} (default) | 'all' | function handle | cell array of function handles

Plot function called after each iteration, specified as 'all', a function handle, or a cell array of function handles. A plot function can halt the solver, and can perform arbitrary calculations, including creating variables, in addition to plotting.

Specify no plot function as [].

'all' calls all built-in plot functions. Specify several plot functions using a cell array of function handles.

The built-in plot functions appear in the following tables.

| Model Plots — Apply When $D \leq 2$ | Description |
|-------------------------------------|---|
| @plotAcquisitionFunction | Plot the acquisition function surface. |
| @plotConstraintModels | Plot each constraint model surface. Also plots a $P(\text{feasible})$ surface. Negative values indicate feasible points. Also plot the error model, if it exists, which ranges from -1 to 1. Negative values mean that the model probably does not error, positive values mean that it probably does error. The model is: Plotted error = $-2 * \text{Probability}(\text{error}) + 1$. |
| @plotObjectiveEvaluationTimeModel | Plot the objective function evaluation time model surface. |

| Model Plots — Apply When $D \leq 2$ | Description |
|-------------------------------------|--|
| @plotObjectiveModel | Plot the fun model surface, the estimated location of the minimum, and the location of the next proposed point to evaluate. For one-dimensional problems, plot envelopes one credible interval above and below the mean function, and envelopes one noise standard deviation above and below the mean. |

| Trace Plots — Apply to All D | Description |
|--------------------------------|--|
| @plotObjective | Plot each observed function value versus the number of function evaluations. |
| @plotObjectiveEvaluationTime | Plot each observed function evaluation run time versus the number of function evaluations. |
| @plotMinObjective | Plot the minimum observed and estimated function values versus the number of function evaluations. |
| @plotElapsedTime | Plot three curves: the total elapsed time of the optimization, the total function evaluation time, and the total modeling and point selection time, all versus the number of function evaluations. |

You can write your own plot functions. For details, see “Bayesian Optimization Plot Functions” on page 10-14.

Note When there are coupled constraints, iterative display and plot functions can give counterintuitive results such as:

- A *minimum objective* plot can increase.
- The optimization can declare a problem infeasible even when it showed an earlier feasible point.

The reason for this behavior is that the decision about whether a point is feasible can change as the optimization progresses. `bayesopt` determines feasibility with respect to its constraint model, and this model changes as `bayesopt` evaluates points. So a “minimum objective” plot can increase when the minimal point is later deemed infeasible, and the iterative display can show a feasible point that is later deemed infeasible.

Example: 'PlotFcn','all'

Data Types: char | cell | function_handle

Initialization

InitialX — Initial evaluation points

NumSeedPoints-by-D random initial points within bounds (default) | N-by-D table

Initial evaluation points, specified as an N-by-D table, where N is the number of evaluation points, and D is the number of variables.

Note If only InitialX is provided, it is interpreted as initial points to evaluate. The objective function is evaluated at InitialX.

If any other initialization parameters are also provided, InitialX is interpreted as prior function evaluation data. The objective function is not evaluated. Any missing values are set to NaN.

Data Types: table

InitialObjective — Objective values corresponding to InitialX

[] (default) | length-N vector

Objective values corresponding to InitialX, specified as a length-N vector, where N is the number of evaluation points.

Example: 'InitialObjective',[17;-3;-12.5]

Data Types: double

InitialConstraintViolations — Constraint violations of coupled constraints

[] (default) | N-by-K matrix

Constraint violations of coupled constraints, specified as an N-by-K matrix, where N is the number of evaluation points and K is the number of coupled constraints. For details, see “Coupled Constraints” on page 10-47.

Data Types: double

InitialErrorValues — Errors for InitialX

[] (default) | length-N vector with entries -1 or 1

Errors for `InitialX`, specified as a length-`N` vector with entries `-1` or `1`, where `N` is the number of evaluation points. Specify `-1` for no error, and `1` for an error.

Example: `'InitialErrorValues', [-1, -1, -1, -1, 1]`

Data Types: `double`

InitialUserData — Initial data corresponding to InitialX

`[]` (default) | length-`N` cell vector

Initial data corresponding to `InitialX`, specified as a length-`N` cell vector, where `N` is the number of evaluation points.

Example: `'InitialUserData', {2, 3, -1}`

Data Types: `cell`

InitialObjectiveEvaluationTimes — Evaluation times of objective function at InitialX

`[]` (default) | length-`N` vector

Evaluation times of objective function at `InitialX`, specified as a length-`N` vector, where `N` is the number of evaluation points. Time is measured in seconds.

Data Types: `double`

InitialIterationTimes — Times for the first N iterations

`{}` (default) | length-`N` vector

Times for the first `N` iterations, specified as a length-`N` vector, where `N` is the number of evaluation points. Time is measured in seconds.

Data Types: `double`

Output Arguments

results — Bayesian optimization results

`BayesianOptimization` object

Bayesian optimization results, returned as a `BayesianOptimization` object.

Definitions

Coupled Constraints

Coupled constraints are those constraints whose value comes from the objective function calculation. See “Coupled Constraints” on page 10-47.

bbdesign

Box-Behnken design

Syntax

```
dBB = bbdesign(n)
[dBB,blocks] = bbdesign(n)
[...] = bbdesign(n,param,val)
```

Description

`dBB = bbdesign(n)` generates a Box-Behnken design for `n` factors. `n` must be an integer 3 or larger. The output matrix `dBB` is m -by- n , where m is the number of runs in the design. Each row represents one run, with settings for all factors represented in the columns. Factor values are normalized so that the cube points take values between -1 and 1.

`[dBB,blocks] = bbdesign(n)` requests a blocked design. The output `blocks` is an m -by-1 vector of block numbers for each run. Blocks indicate runs that are to be measured under similar conditions to minimize the effect of inter-block differences on the parameter estimates.

`[...] = bbdesign(n,param,val)` specifies one or more optional parameter/value pairs for the design. The following table lists valid parameter/value pairs.

| Parameter | Description | Values |
|-------------|-------------------------------------|--|
| 'center' | Number of center points. | Integer. The default depends on <code>n</code> . |
| 'blocksize' | Maximum number of points per block. | Integer. The default is <code>Inf</code> . |

Examples

The following creates a 3-factor Box-Behnken design:

```

dBB = bbdesign(3)
dBB =
    -1    -1     0
    -1     1     0
     1    -1     0
     1     1     0
    -1     0    -1
    -1     0     1
     1     0    -1
     1     0     1
     0    -1    -1
     0    -1     1
     0     1    -1
     0     1     1
     0     0     0
     0     0     0
     0     0     0

```

The center point is run 3 times to allow for a more uniform estimate of the prediction variance over the entire design space.

Visualize the design as follows:

```

plot3(dBB(:,1),dBB(:,2),dBB(:,3),'ro',...
      'MarkerFaceColor','b')
X = [1 -1 -1 -1 1 -1 -1 -1 1 1 -1 -1; ...
     1 1 1 -1 1 1 1 -1 1 1 -1 -1];
Y = [-1 -1 1 -1 -1 -1 1 -1 1 -1 1 -1; ...
     1 -1 1 1 1 -1 1 1 1 -1 1 -1];
Z = [1 1 1 1 -1 -1 -1 -1 -1 -1 -1 -1; ...
     1 1 1 1 -1 -1 -1 -1 1 1 1 1];
line(X,Y,Z,'Color','b')
axis square equal

```

bestPoint

Best point in a Bayesian optimization according to a criterion

Syntax

```
x = bestPoint(results)
x = bestPoint(results,Name,Value)
[x,CriterionValue] = bestPoint( ___ )
[x,CriterionValue,iteration] = bestPoint( ___ )
```

Description

`x = bestPoint(results)` returns the best feasible point in the Bayesian model results according to the default criterion 'min-visited-upper-confidence-interval'.

`x = bestPoint(results,Name,Value)` modifies the best point using name-value pairs.

`[x,CriterionValue] = bestPoint(___)`, for any previous syntax, also returns the value of the criterion at x.

`[x,CriterionValue,iteration] = bestPoint(___)` also returns the iteration number at which the best point was returned. Applies when the Criterion name-value pair is 'min-observed', 'min-visited-mean', or the default 'min-visited-upper-confidence-interval'.

Examples

Best Point of an Optimized KNN Classifier

This example shows how to obtain the best point of an optimized classifier.

Optimize a KNN classifier for the `ionosphere` data, meaning find parameters that minimize the cross-validation loss. Minimize over nearest-neighborhood sizes from 1 to 30, and over the distance functions 'chebychev', 'euclidean', and 'minkowski'.

For reproducibility, set the random seed, and set the `AcquisitionFunctionName` option to 'expected-improvement-plus'.

```
load ionosphere
rng default
num = optimizableVariable('n',[1,30],'Type','integer');
dst = optimizableVariable('dst',{'chebychev','euclidean','minkowski'},'Type','categorical');
c = cvpartition(351,'Kfold',5);
fun = @(x)kfoldLoss(fitcknn(X,Y,'CVPartition',c,'NumNeighbors',x.n,...
    'Distance',char(x.dst),'NSMethod','exhaustive'));
results = bayesopt(fun,[num,dst],'Verbose',0,...
    'AcquisitionFunctionName','expected-improvement-plus');
```

Obtain the best point according to the default 'min-visited-upper-confidence-interval' criterion.

```
x = bestPoint(results)
```

```
x =
```

```
1x2 table
```

```

n      dst
--  -----

```

```
1 chebychev
```

The lowest estimated cross-validation loss occurs for ten nearest neighbors and 'chebychev' distance.

Careful examination of the objective function model plot shows a point with one nearest neighbor and 'chebychev' distance that has a lower objective function value. Find this point using a different criterion.

```
x = bestPoint(results, 'Criterion', 'min-observed')
```

```
x =
```

```
1x2 table
```

| n | dst |
|---|-----------|
| 1 | chebychev |

Also find the minimum observed objective function value, and the iteration number at which it was observed.

```
[x,CriterionValue,iteration] = bestPoint(results, 'Criterion', 'min-observed')
```

```
x =
```

```
1x2 table
```

| n | dst |
|---|-----------|
| 1 | chebychev |

```
CriterionValue =
```

```
0.1197
```

```
iteration =
```

Input Arguments

results — Bayesian optimization results

BayesianOptimization object

Bayesian optimization results, specified as a BayesianOptimization object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: `x = bestPoint(results, 'Criterion', 'min-observed')`

Criterion — Best point criterion

'min-visited-upper-confidence-interval' (default) | criterion name

Best point criterion, specified as a criterion name. The names are case-insensitive, do not require - characters, and require only enough characters to make the name uniquely distinguishable.

| Criterion Name | Meaning |
|---------------------------------|--|
| 'min-observed' | x is the feasible point with minimum observed objective. |
| 'min-mean' | x is the feasible point where the objective model mean is minimized. |
| 'min-upper-confidence-interval' | x is the feasible point minimizing an upper confidence interval of the objective model. See <code>alpha</code> . |
| 'min-visited-mean' | x is the feasible point where the objective model mean is minimized among the visited points. |

| Criterion Name | Meaning |
|---|---|
| 'min-visited-upper-confidence-interval' | x is the feasible point minimizing an upper confidence interval of the objective model among the visited points. See alpha. |

Example: 'Criterion', 'min-visited-mean'

Data Types: char

alpha — Probability that modeled objective mean exceeds CriterionValue

0.01 (default) | scalar between 0 and 1

Probability that the modeled objective mean exceeds CriterionValue, specified as a scalar between 0 and 1. alpha relates to the 'min-upper-confidence-interval' and 'min-visited-upper-confidence-interval' Criterion values. The definition for the upper confidence interval is the value Y where

$$P(\text{mean}_Q(\text{fun}(x)) > Y) = \text{alpha},$$

where fun is the objective function, and the mean is calculated with respect to the posterior distribution Q.

Example: 'alpha', 0.05

Data Types: double

Output Arguments

x — Best point

1-by-D table

Best point, returned as a 1-by-D table, where D is the number of variables. The meaning of “best” is with respect to Criterion.

CriterionValue — Value of criterion

real scalar

Value of criterion, returned as a real scalar. The value depends on the setting of the Criterion name-value pair, which has a default value of 'min-visited-upper-confidence-interval'.

| Criterion Name | Meaning |
|---|---|
| 'min-observed' | Minimum observed objective. |
| 'min-mean' | Minimum of model mean. |
| 'min-upper-confidence-interval' | Value Y satisfying the equation $P(\text{mean}_Q(\text{fun}(x)) > Y) = \text{alpha}$. |
| 'min-visited-mean' | Minimum of observed model mean. |
| 'min-visited-upper-confidence-interval' | Value Y satisfying the equation $P(\text{mean}_Q(\text{fun}(x)) > Y) = \text{alpha}$ among observed points. |

iteration — Iteration number at which best point was observed

positive integer

Iteration number at which best point was observed, returned as a positive integer. The best point is defined by CriterionValue.

Introduced in R2016b

betacdf

Beta cumulative distribution function

Syntax

```
p = betacdf(x,a,b)
p = betacdf(x,a,b,'upper')
```

Description

`p = betacdf(x,a,b)` returns the beta cdf at each of the values in `x` using the corresponding parameters in `a` and `b`. `x`, `a`, and `b` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `a` and `b` must all be positive, and the values in `x` must lie on the interval $[0,1]$.

`p = betacdf(x,a,b,'upper')` returns the complement of the beta cdf at each of the values in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The beta cdf for a given value `x` and given pair of parameters `a` and `b` is

$$p = F(x | a, b) = \frac{1}{B(a, b)} \int_0^x t^{a-1} (1-t)^{b-1} dt$$

where $B(\cdot)$ is the Beta function.

Examples

Compute Beta Distribution CDF

Compute the cdf for a beta distribution with parameters `a = 2` and `b = 2`.

```
x = 0.1:0.2:0.9;
a = 2;
b = 2;
p = betacdf(x,a,b)

p = 1×5
    0.0280    0.2160    0.5000    0.7840    0.9720
```

```
a = [1 2 3];
p = betacdf(0.5,a,a)

p = 1×3
    0.5000    0.5000    0.5000
```

Topics

“Beta Distribution” on page B-4

Introduced before R2006a

betafit

Beta parameter estimates

Syntax

```
phat = betafit(data)
[phat,pci] = betafit(data,alpha)
```

Description

`phat = betafit(data)` computes the maximum likelihood estimates of the beta distribution parameters a and b from the data in the vector `data` and returns a column vector containing the a and b estimates, where the beta cdf is given by

$$F(x | a, b) = \frac{1}{B(a, b)} \int_0^x t^{a-1} (1-t)^{b-1} dt$$

and $B(\cdot)$ is the Beta function. The elements of `data` must lie in the open interval $(0, 1)$, where the beta distribution is defined. However, it is sometimes also necessary to fit a beta distribution to data that include exact zeros or ones. For such data, the beta likelihood function is unbounded, and standard maximum likelihood estimation is not possible. In that case, `betafit` maximizes a modified likelihood that incorporates the zeros or ones by treating them as if they were values that have been left-censored at `sqrt(realmin)` or right-censored at `1-eps/2`, respectively.

`[phat,pci] = betafit(data,alpha)` returns confidence intervals on the a and b parameters in the 2-by-2 matrix `pci`. The first column of the matrix contains the lower and upper confidence bounds for parameter a , and the second column contains the confidence bounds for parameter b . The optional input argument `alpha` is a value in the range $[0, 1]$ specifying the width of the confidence intervals. By default, `alpha` is `0.05`, which corresponds to 95% confidence intervals. The confidence intervals are based on a normal approximation for the distribution of the logs of the parameter estimates.

Examples

This example generates 100 beta distributed observations. The true a and b parameters are 4 and 3, respectively. Compare these to the values returned in `p` by the beta fit. Note that the columns of `ci` both bracket the true parameters.

```
data = betarnd(4,3,100,1);  
[p,ci] = betafit(data,0.01)  
p =  
    5.5328    3.8097  
ci =  
    3.6538    2.6197  
    8.3781    5.5402
```

Topics

“Beta Distribution” on page B-4

Introduced before R2006a

betainv

Beta inverse cumulative distribution function

Syntax

`X = betainv(P,A,B)`

Description

`X = betainv(P,A,B)` computes the inverse of the beta cdf with parameters specified by `A` and `B` for the corresponding probabilities in `P`. `P`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that are all the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `A` and `B` must all be positive, and the values in `P` must lie on the interval $[0, 1]$.

The inverse beta cdf for a given probability p and a given pair of parameters a and b is

$$x = F^{-1}(p | a, b) = \{x : F(x | a, b) = p\}$$

where

$$p = F(x | a, b) = \frac{1}{B(a, b)} \int_0^x t^{a-1} (1-t)^{b-1} dt$$

and $B(\cdot)$ is the Beta function. Each element of output `X` is the value whose cumulative probability under the beta cdf defined by the corresponding parameters in `A` and `B` is specified by the corresponding value in `P`.

Examples

```
p = [0.01 0.5 0.99];
x = betainv(p,10,5)
```

```
x =  
    0.3726    0.6742    0.8981
```

According to this result, for a beta cdf with $a = 10$ and $b = 5$, a value less than or equal to 0.3726 occurs with probability 0.01. Similarly, values less than or equal to 0.6742 and 0.8981 occur with respective probabilities 0.5 and 0.99.

Algorithms

The `betainv` function uses Newton's method with modifications to constrain steps to the allowable range for x , i.e., $[0\ 1]$.

Introduced before R2006a

betalike

Beta negative log-likelihood

Syntax

```
nlogL = betalike(params,data)
[nlogL,AVAR] = betalike(params,data)
```

Description

`nlogL = betalike(params,data)` returns the negative of the beta log-likelihood function for the beta parameters a and b specified in vector `params` and the observations specified in the column vector `data`.

The elements of `data` must lie in the open interval $(0, 1)$, where the beta distribution is defined. However, it is sometimes also necessary to fit a beta distribution to data that include exact zeros or ones. For such data, the beta likelihood function is unbounded, and standard maximum likelihood estimation is not possible. In that case, `betalike` computes a modified likelihood that incorporates the zeros or ones by treating them as if they were values that have been left-censored at `sqrt(realmin)` or right-censored at $1 - \text{eps}/2$, respectively.

`[nlogL,AVAR] = betalike(params,data)` also returns `AVAR`, which is the asymptotic variance-covariance matrix of the parameter estimates if the values in `params` are the maximum likelihood estimates. `AVAR` is the inverse of Fisher's information matrix. The diagonal elements of `AVAR` are the asymptotic variances of their respective parameters.

`betalike` is a utility function for maximum likelihood estimation of the beta distribution. The likelihood assumes that all the elements in the data sample are mutually independent. Since `betalike` returns the negative beta log-likelihood function, minimizing `betalike` using `fminsearch` is the same as maximizing the likelihood.

Examples

This example continues the `betafit` example, which calculates estimates of the beta parameters for some randomly generated beta distributed data.

```
r = betarnd(4,3,100,1);  
[nlogl,AVAR] = betalike(betafit(r),r)  
nlogl =
```

```
-27.5996
```

```
AVAR =
```

```
0.2783    0.1316  
0.1316    0.0867
```

betapdf

Beta probability density function

Syntax

`Y = betapdf(X,A,B)`

Description

`Y = betapdf(X,A,B)` computes the beta pdf at each of the values in `X` using the corresponding parameters in `A` and `B`. `X`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions of the other inputs. The parameters in `A` and `B` must all be positive, and the values in `X` must lie on the interval $[0, 1]$.

The beta probability density function for a given value x and given pair of parameters a and b is

$$y = f(x | a, b) = \frac{1}{B(a, b)} x^{a-1} (1-x)^{b-1} I_{[0,1]}(x)$$

where $B(\cdot)$ is the Beta function. The uniform distribution on $(0, 1)$ is a degenerate case of the beta pdf where $a = 1$ and $b = 1$.

A *likelihood function* is the pdf viewed as a function of the parameters. Maximum likelihood estimators (MLEs) are the values of the parameters that maximize the likelihood function for a fixed value of x .

Examples

```
a = [0.5 1; 2 4]
a =
    0.5000    1.0000
    2.0000    4.0000
```

```
y = betapdf(0.5,a,a)
y =
    0.6366    1.0000
    1.5000    2.1875
```

betarnd

Beta random numbers

Syntax

```
R = betarnd(A,B)
R = betarnd(A,B,m,n,...)
R = betarnd(A,B,[m,n,...])
```

Description

`R = betarnd(A,B)` generates random numbers from the beta distribution with parameters specified by `A` and `B`. `A` and `B` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `A` or `B` is expanded to a constant array with the same dimensions as the other input.

`R = betarnd(A,B,m,n,...)` or `R = betarnd(A,B,[m,n,...])` generates an `m`-by-`n`-by-... array containing random numbers from the beta distribution with parameters `A` and `B`. `A` and `B` can each be scalars or arrays of the same size as `R`.

Examples

```
a = [1 1;2 2];
b = [1 2;1 2];

r = betarnd(a,b)
r =
    0.6987    0.6139
    0.9102    0.8067

r = betarnd(10,10,[1 5])
r =
    0.5974    0.4777    0.5538    0.5465    0.6327

r = betarnd(4,2,2,3)
```

```
r =  
    0.3943    0.6101    0.5768  
    0.5990    0.2760    0.5474
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

betastat

Beta mean and variance

Syntax

`[M,V] = betastat(A,B)`

Description

`[M,V] = betastat(A,B)`, with $A > 0$ and $B > 0$, returns the mean of and variance for the beta distribution with parameters specified by A and B . A and B can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of M and V . A scalar input for A or B is expanded to a constant array with the same dimensions as the other input.

The mean of the beta distribution with parameters a and b is $a / (a + b)$ and the variance is

$$\frac{ab}{(a+b+1)(a+b)^2}$$

Examples

If parameters a and b are equal, the mean is $1/2$.

```
a = 1:6;
[m,v] = betastat(a,a)
m =
    0.5000    0.5000    0.5000    0.5000    0.5000    0.5000
v =
    0.0833    0.0500    0.0357    0.0278    0.0227    0.0192
```

binocdf

Binomial cumulative distribution function

Syntax

```
y = binocdf(x,N,p)
y = binocdf(x,N,p, 'upper')
```

Description

`y = binocdf(x,N,p)` computes a binomial cdf at each of the values in `x` using the corresponding number of trials in `N` and probability of success for each trial in `p`. `x`, `N`, and `p` can be vectors, matrices, or multidimensional arrays that are all the same size. A scalar input is expanded to a constant array with the same dimensions of the other inputs. The values in `N` must all be positive integers, the values in `x` must lie on the interval $[0, N]$, and the values in `p` must lie on the interval $[0, 1]$.

`y = binocdf(x,N,p, 'upper')` returns the complement of the binomial cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The binomial cdf for a given value x and a given pair of parameters n and p is

$$y = F(x | n, p) = \sum_{i=0}^x \binom{n}{i} p^i (1-p)^{(n-i)} I_{(0,1,\dots,n)}(i).$$

The result, y , is the probability of observing up to x successes in n independent trials,

where the probability of success in any given trial is p . The indicator function $I_{(0,1,\dots,n)}(i)$ ensures that x only adopts values of $0, 1, \dots, n$.

Examples

Compute Binomial CDF

If a baseball team plays 162 games in a season and has a 50-50 chance of winning any game, then the probability of that team winning more than 100 games in a season is:

```
1 - binocdf(100,162,0.5)
```

```
ans = 0.0010
```

The result is 0.001 (i.e., 1-0.999). If a team wins 100 or more games in a season, this result suggests that it is likely that the team's true probability of winning any game is greater than 0.5.

Introduced before R2006a

binofit

Binomial parameter estimates

Syntax

```
phat = binofit(x,n)
[phat,pci] = binofit(x,n)
[phat,pci] = binofit(x,n,alpha)
```

Description

`phat = binofit(x,n)` returns a maximum likelihood estimate of the probability of success in a given binomial trial based on the number of successes, x , observed in n independent trials. If $x = (x(1), x(2), \dots, x(k))$ is a vector, `binofit` returns a vector of the same size as x whose i th entry is the parameter estimate for $x(i)$. All k estimates are independent of each other. If $n = (n(1), n(2), \dots, n(k))$ is a vector of the same size as x , the binomial fit, `binofit`, returns a vector whose i th entry is the parameter estimate based on the number of successes $x(i)$ in $n(i)$ independent trials. A scalar value for x or n is expanded to the same size as the other input.

`[phat,pci] = binofit(x,n)` returns the probability estimate, `phat`, and the 95% confidence intervals, `pci`. `binofit` uses the Clopper-Pearson method to calculate confidence intervals.

`[phat,pci] = binofit(x,n,alpha)` returns the $100(1 - \text{alpha})\%$ confidence intervals. For example, `alpha = 0.01` yields 99% confidence intervals.

Note `binofit` behaves differently than other Statistics and Machine Learning Toolbox functions that compute parameter estimates, in that it returns independent estimates for each entry of x . By comparison, `expfit` returns a single parameter estimate based on all the entries of x .

Unlike most other distribution fitting functions, the `binofit` function treats its input x vector as a collection of measurements from separate samples. If you want to treat x as a

single sample and compute a single parameter estimate for it, you can use `binofit(sum(x),sum(n))` when `n` is a vector, and `binofit(sum(X),N*length(X))` when `n` is a scalar.

Examples

This example generates a binomial sample of 100 elements, where the probability of success in a given trial is 0.6, and then estimates this probability from the outcomes in the sample.

```
r = binornd(100,0.6);
[phat,pci] = binofit(r,100)
phat =
    0.5800
pci =
    0.4771    0.6780
```

The 95% confidence interval, `pci`, contains the true value, 0.6.

binoinv

Binomial inverse cumulative distribution function

Syntax

```
X = binoinv(Y,N,P)
```

Description

`X = binoinv(Y,N,P)` returns the smallest integer X such that the binomial cdf evaluated at X is equal to or exceeds Y . You can think of Y as the probability of observing X successes in N independent trials where P is the probability of success in each trial. Each X is a positive integer less than or equal to N .

Y , N , and P can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in N must be positive integers, and the values in both P and Y must lie on the interval $[0\ 1]$.

Examples

If a baseball team has a 50-50 chance of winning any game, what is a reasonable range of games this team might win over a season of 162 games?

```
binoinv([0.05 0.95],162,0.5)
ans =
    71    91
```

This result means that in 90% of baseball seasons, a .500 team should win between 71 and 91 games.

Topics

“Binomial Distribution” on page B-9

Introduced before R2006a

binopdf

Binomial probability density function

Syntax

`Y = binopdf(X,N,P)`

Description

`Y = binopdf(X,N,P)` computes the binomial pdf at each of the values in `X` using the corresponding number of trials in `N` and probability of success for each trial in `P`. `Y`, `N`, and `P` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions of the other inputs.

The parameters in `N` must be positive integers, and the values in `P` must lie on the interval $[0, 1]$.

The binomial probability density function for a given value x and given pair of parameters n and p is

$$y = f(x | n, p) = \binom{n}{x} p^x q^{(n-x)} I_{(0,1,\dots,n)}(x)$$

where $q = 1 - p$. The result, y , is the probability of observing x successes in n independent trials, where the probability of success in any *given* trial is p . The indicator function $I_{(0,1,\dots,n)}(x)$ ensures that x only adopts values of 0, 1, ..., n .

Examples

A Quality Assurance inspector tests 200 circuit boards a day. If 2% of the boards have defects, what is the probability that the inspector will find no defective boards on any given day?

```
binopdf(0,200,0.02)
ans =
    0.0176
```

What is the most likely number of defective boards the inspector will find?

```
defects=0:200;
y = binopdf(defects,200,.02);
[x,i]=max(y);
defects(i)
ans =
    4
```

binornd

Binomial random numbers

Syntax

```
R = binornd(N,P)
R = binornd(N,P,m,n,...)
R = binornd(N,P,[m,n,...])
```

Description

`R = binornd(N,P)` generates random numbers from the binomial distribution with parameters specified by the number of trials, `N`, and probability of success for each trial, `P`. `N` and `P` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `N` or `P` is expanded to a constant array with the same dimensions as the other input.

`R = binornd(N,P,m,n,...)` or `R = binornd(N,P,[m,n,...])` generates an `m`-by-`n`-by-... array containing random numbers from the binomial distribution with parameters `N` and `P`. `N` and `P` can each be scalars or arrays of the same size as `R`.

Examples

```
n = 10:10:60;

r1 = binornd(n,1./n)
r1 =
     2     1     0     1     1     2

r2 = binornd(n,1./n,[1 6])
r2 =
     0     1     2     1     3     1

r3 = binornd(n,1./n,1,6)
r3 =
     0     1     1     1     0     3
```

Algorithms

The `binornd` function uses the direct method using the definition of the binomial distribution as a sum of Bernoulli random variables.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

binostat

Binomial mean and variance

Syntax

```
[M,V] = binostat(N,P)
```

Description

`[M,V] = binostat(N,P)` returns the mean of and variance for the binomial distribution with parameters specified by the number of trials, N , and probability of success for each trial, P . N and P can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of M and V . A scalar input for N or P is expanded to a constant array with the same dimensions as the other input.

The mean of the binomial distribution with parameters n and p is np . The variance is npq , where $q = 1 - p$.

Examples

```
n = logspace(1,5,5)
n =
    10    100   1000  10000 100000
```

```
[m,v] = binostat(n,1./n)
m =
    1    1    1    1    1
v =
    0.9000  0.9900  0.9990  0.9999  1.0000
```

```
[m,v] = binostat(n,1/2)
m =

binScatterPlot

Scatter plot of bins for tall arrays

Syntax

```
binScatterPlot(X,Y)
binScatterPlot(X,Y,nbins)
binScatterPlot(X,Y,Xedges,Yedges)
binScatterPlot(X,Y,Name,Value)
h = binScatterPlot( ___ )
```

Description

`binScatterPlot(X,Y)` creates a binned scatter plot of the data in `X` and `Y`. The `binScatterPlot` function uses an automatic binning algorithm that returns bins with a uniform area, chosen to cover the range of elements in `X` and `Y` and reveal the underlying shape of the distribution.

`binScatterPlot(X,Y,nbins)` specifies the number of bins to use in each dimension.

`binScatterPlot(X,Y,Xedges,Yedges)` specifies the edges of the bins in each dimension using the vectors `Xedges` and `Yedges`.

`binScatterPlot(X,Y,Name,Value)` specifies additional options with one or more name-value pair arguments using any of the previous syntaxes. For example, you can specify `'Color'` and a valid color option to change the color theme of the plot, or `'Gamma'` with a positive scalar to adjust the level of detail.

`h = binScatterPlot(___)` returns a `Histogram2` object. Use this object to inspect properties of the plot.

Examples

Binned Scatter Plot of Normally-Distributed Random Data

Create two tall vectors of random data. Create a binned scatter plot for the data.

```
X = tall(randn(1e5,1));
```

```
Starting parallel pool (parpool) using the 'local' profile ...  
connected to 12 workers.
```

```
Y = tall(randn(1e5,1));  
binScatterPlot(X,Y)
```

```
Evaluating tall expression using the Parallel Pool 'local':  
Evaluation completed in 1 sec
```

```
Evaluating tall expression using the Parallel Pool 'local':  
Evaluation completed in 0 sec
```

The resulting figure contains a slider to adjust the level of detail in the image.

Specify Number of Scatter Plot Bins

Specify a scalar value as the third input argument to use the same number of bins in each dimension, or a two-element vector to use a different number of bins in each dimension.

Plot a binned scatter plot of random data sorted into 100 bins in each dimension.

```
X = tall(randn(1e5,1));
```

```
Starting parallel pool (parpool) using the 'local' profile ...  
connected to 12 workers.
```

```
Y = tall(randn(1e5,1));  
binScatterPlot(X,Y,100)
```

```
Evaluating tall expression using the Parallel Pool 'local':  
Evaluation completed in 0 sec  
Evaluating tall expression using the Parallel Pool 'local':  
Evaluation completed in 0 sec
```

Use 20 bins in the x-dimension and continue to use 100 bins in the y-dimension.

```
binScatterPlot(X,Y,[20 100])
```

```
Evaluating tall expression using the Parallel Pool 'local':  
Evaluation completed in 0 sec  
Evaluating tall expression using the Parallel Pool 'local':  
Evaluation completed in 0 sec
```

Specify Bin Edges for Scatter Plot

Plot a binned scatter plot of random data with specific bin edges. Use bin edges of Inf and $-\text{Inf}$ to capture outliers.

Create a binned scatter plot with 100 bin edges between [-2 2] in each dimension. The data outside the specified bin edges is not included in the plot.

```
X = tall(randn(1e5,1));
```

```
Starting parallel pool (parpool) using the 'local' profile ...  
connected to 12 workers.
```

```
Y = tall(randn(1e5,1));  
Xedges = linspace(-2,2);  
Yedges = linspace(-2,2);  
binScatterPlot(X,Y,Xedges,Yedges)
```

```
Evaluating tall expression using the Parallel Pool 'local':  
Evaluation completed in 1 sec
```

Use coarse bins extending to infinity on the edges of the plot to capture outliers.

```
Xedges = [-Inf linspace(-2,2) Inf];  
Yedges = [-Inf linspace(-2,2) Inf];  
binScatterPlot(X,Y,Xedges,Yedges)
```

```
Evaluating tall expression using the Parallel Pool 'local':  
Evaluation completed in 0 sec
```

Adjust Plot Color Theme

Plot a binned scatter plot of random data, specifying 'Color' as 'c'.

```
X = tall(randn(1e5,1));
```

```
Starting parallel pool (parpool) using the 'local' profile ...  
connected to 12 workers.
```

```
Y = tall(randn(1e5,1));  
binScatterPlot(X,Y,'Color','c')
```

```
Evaluating tall expression using the Parallel Pool 'local':  
Evaluation completed in 4 sec  
Evaluating tall expression using the Parallel Pool 'local':  
Evaluation completed in 0 sec
```

Input Arguments

X, Y — Data to distribute among bins (as separate arguments)

tall vectors | tall matrices | tall multidimensional arrays

Data to distribute among bins, specified as separate arguments of tall vectors, matrices, or multidimensional arrays. *X* and *Y* must be the same size. If *X* and *Y* are not vectors, then `binScatterPlot` treats them as single column vectors, `X(:)` and `Y(:)`.

Corresponding elements in *X* and *Y* specify the *x* and *y* coordinates of 2-D data points, `[X(k), Y(k)]`. The underlying data types of *X* and *Y* can be different, but `binScatterPlot` concatenates these inputs into a single *N*-by-2 tall matrix of the dominant underlying data type.

`binScatterPlot` ignores all NaN values. Similarly, `binScatterPlot` ignores Inf and -Inf values, unless the bin edges explicitly specify Inf or -Inf as a bin edge.

Note If *X* or *Y* contain integers of type `int64` or `uint64` that are larger than `flintmax`, then it is recommended that you explicitly specify the bin edges. `binScatterPlot` automatically bins the input data using double precision, which lacks integer precision for numbers greater than `flintmax`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

nbins — Number of bins in each dimension

scalar | vector

Number of bins in each dimension, specified as a positive scalar integer or two-element vector of positive integers. If you do not specify `nbins`, then `binScatterPlot` automatically calculates how many bins to use based on the values in *X* and *Y*.

- If `nbins` is a scalar, then `binScatterPlot` uses that many bins in each dimension.
- If `nbins` is a vector, then `nbins(1)` specifies the number of bins in the *x*-dimension and `nbins(2)` specifies the number of bins in the *y*-dimension.

Example: `binScatterPlot(X,Y,20)` uses 20 bins in each dimension.

Example: `binScatterPlot(X,Y,[10 20])` uses 10 bins in the *x*-dimension and 20 bins in the *y*-dimension.

Xedges — Bin edges in x-dimension

vector

Bin edges in x-dimension, specified as a vector. `Xedges(1)` is the first edge of the first bin in the x-dimension, and `Xedges(end)` is the outer edge of the last bin.

The value $[X(k), Y(k)]$ is in the (i, j) th bin if $Xedges(i) \leq X(k) < Xedges(i+1)$ **and** $Yedges(j) \leq Y(k) < Yedges(j+1)$. The last bins in each dimension also include the last (outer) edge. For example, $[X(k), Y(k)]$ falls into the i th bin in the last row if $Xedges(end-1) \leq X(k) \leq Xedges(end)$ **and** $Yedges(i) \leq Y(k) < Yedges(i+1)$.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Yedges — Bin edges in y-dimension

vector

Bin edges in y-dimension, specified as a vector. `Yedges(1)` is the first edge of the first bin in the y-dimension, and `Yedges(end)` is the outer edge of the last bin.

The value $[X(k), Y(k)]$ is in the (i, j) th bin if $Xedges(i) \leq X(k) < Xedges(i+1)$ **and** $Yedges(j) \leq Y(k) < Yedges(j+1)$. The last bins in each dimension also include the last (outer) edge. For example, $[X(k), Y(k)]$ falls into the i th bin in the last row if $Xedges(end-1) \leq X(k) \leq Xedges(end)$ **and** $Yedges(i) \leq Y(k) < Yedges(i+1)$.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `binScatterPlot(X, Y, 'BinWidth', [5 10])`

BinMethod — Binning algorithm`'auto'` (default) | `'scott'` | `'integers'`

Binning algorithm, specified as the comma-separated pair consisting of `'BinMethod'` and one of these values.

| Value | Description |
|------------|---|
| 'auto' | The default 'auto' algorithm uses a maximum of 100 bins and chooses a bin width to cover the data range and reveal the shape of the underlying distribution. |
| 'scott' | Scott's rule is optimal if the data is close to being jointly normally distributed. This rule is appropriate for most other distributions, as well. It uses a bin size of $[3.5 * \text{std}(X) * \text{numel}(X)^{-1/4}, 3.5 * \text{std}(Y) * \text{numel}(Y)^{-1/4}]$. |
| 'integers' | The integer rule is useful with integer data, as it creates a bin for each integer. It uses a bin width of 1 and places bin edges halfway between integers. To avoid accidentally creating too many bins, you can use this rule to create a limit of 65536 bins (2^{16}). If the data range is greater than 65536, then the integer rule uses wider bins instead. |

Note The BinMethod property of the resulting Histogram2 object always has a value of 'manual'.

BinWidth — Width of bins in each dimension

scalar | vector

Width of bins in each dimension, specified as the comma-separated pair consisting of 'BinWidth' and a scalar or two-element vector of positive integers, [xWidth yWidth]. A scalar value indicates the same bin width for each dimension.

If you specify BinWidth, then binScatterPlot can use a maximum of 1024 bins (2^{10}) along each dimension. If instead the specified bin width requires more bins, then binScatterPlot uses a larger bin width corresponding to the maximum number of bins.

Example: `binScatterPlot(X,Y,'BinWidth',[5 10])` uses bins with size 5 in the x-dimension and size 10 in the y-dimension.

Color — Plot color theme

'b' (default) | 'y' | 'm' | 'c' | 'r' | 'g' | 'k'

Plot color theme, specified as the comma-separated pair consisting of 'Color' and one of these options.

| Option | Description |
|--------|-------------|
| 'b' | Blue |
| 'm' | Magenta |
| 'c' | Cyan |
| 'r' | Red |
| 'g' | Green |
| 'y' | Yellow |
| 'k' | Black |

Gamma — Gamma correction

1 (default) | positive scalar

Gamma correction, specified as the comma-separated pair consisting of 'Gamma' and a positive scalar. Use this option to adjust the brightness and color intensity to affect the amount of detail in the image.

- $\text{gamma} < 1$ — As gamma decreases, the shading of bins with smaller bin counts becomes progressively darker, including more detail in the image.
- $\text{gamma} > 1$ — As gamma increases, the shading of bins with smaller bin counts becomes progressively lighter, removing detail from the image.
- The default value of 1 does not apply any correction to the display.

XBinLimits — Bin limits in x-dimension

vector

Bin limits in x-dimension, specified as the comma-separated pair consisting of 'XBinLimits' and a two-element vector, [xbmin,xbmax]. The vector indicates the first and last bin edges in the x-dimension.

binScatterPlot only plots data that falls within the bin limits inclusively, `Data(Data(:,1)>=xbmin & Data(:,1)<=xbmax)`.

YBinLimits — Bin limits in y-dimension

vector

Bin limits in y-dimension, specified as the comma-separated pair consisting of 'YBinLimits' and a two-element vector, [ybmin, ybmax]. The vector indicates the first and last bin edges in the y-dimension.

binScatterPlot only plots data that falls within the bin limits inclusively, `Data(Data(:,2)>=ybmin & Data(:,2)<=ybmax)`.

Output Arguments**h — Binned scatter plot**

histogram2 object

Binned scatter plot, returned as a histogram2 object. For more information, see Histogram2.

See Also**Introduced in R2016b**

biplot

Biplot

Syntax

```
biplot(coefs)
h = biplot(coefs, 'Name', Value)
```

Description

`biplot(coefs)` creates a biplot of the coefficients in the matrix `coefs`. The biplot is 2-D if `coefs` has two columns or 3-D if it has three columns. `coefs` usually contains principal component coefficients created with `pca`, `pcacov`, or factor loadings estimated with `factoran`. The axes in the biplot represent the principal components or latent factors (columns of `coefs`), and the observed variables (rows of `coefs`) are represented as vectors.

A biplot allows you to visualize the magnitude and sign of each variable's contribution to the first two or three principal components, and how each observation is represented in terms of those components.

`biplot` imposes a sign convention, forcing the element with largest magnitude in each column of `coefs` to be positive. This flips some of the vectors in `coefs` to the opposite direction, but often makes the plot easier to read. Interpretation of the plot is unaffected, because changing the sign of a coefficient vector does not change its meaning.

`biplot` scales the scores so that they fit on the plot: It divides each score by the maximum absolute value of all scores, and multiplies by the maximum coefficient length of `coefs`. Then `biplot` changes the sign of score coordinates according to the sign convention for the `coefs`.

`h = biplot(coefs, 'Name', Value)` specifies one or more name/value input pairs and returns a column vector of handles to the graphics objects created by `biplot`. The `h` contains, in order, handles corresponding to variables (line handles, followed by marker handles, followed by text handles), to observations (if present, marker handles followed by text handles), and to the axis lines.

Input Arguments

Name-Value Pair Arguments

Scores

Plots both `coefs` and the scores in the matrix `scores` in the biplot. `scores` usually contains principal component scores created with `pca` or factor scores estimated with `factoran`. Each observation (row of scores) is represented as a point in the biplot.

VarLabels

Labels each vector (variable) with the text in the character array, string array or cell array `varLabels`.

ObsLabels

Uses the text in the character array, string array or cell array `obsLabels` as observation names when displaying data cursors.

Positive

- `true` — restricts the biplot to the positive quadrant (in 2-D) or octant (in 3-D).
- `false` — makes the biplot over the range $\pm \max(\text{coefs}(:))$ for all coordinates.

Default: `false`

PropertyName

Specifies optional property name/value pairs for all Primitive Line graphics objects created by `biplot`.

Examples

Biplot of Coefficients and Scores

Load the sample data.

```
load carsmall
```

Define the variable matrix and delete the rows with missing values.

```
x = [Acceleration Displacement Horsepower MPG Weight];  
x = x(all(~isnan(x),2),:);
```

Perform a principal component analysis of the data.

```
[coefs,score] = pca(zscore(x));
```

View the data and the original variables in the space of the first three principal components.

```
vbls = {'Accel','Disp','HP','MPG','Wgt'};  
biplot(coefs(:,1:3),'Scores',score(:,1:3),'Varlabels',vbls);
```

bootci

Bootstrap confidence interval

Syntax

```
ci = bootci(nboot,bootfun,...)
ci = bootci(nboot,{bootfun,...},'alpha',alpha)
ci = bootci(nboot,{bootfun,...},...,'type',type)
ci = bootci(nboot,
{bootfun,...},...,'type','student','nbootstd',nbootstd)
ci = bootci(nboot,
{bootfun,...},...,'type','student','stderr',stderr)
ci = bootci(nboot,{bootfun,...},...,'Weights',weights)
ci = bootci(nboot,{bootfun,...},...,'Options',options)
[ci,bootstat] = bootci(...)
```

Description

`ci = bootci(nboot,bootfun,...)` computes the 95% bootstrap confidence interval of the statistic computed by the function `bootfun`. `nboot` is a positive integer indicating the number of bootstrap samples used in the computation. `bootfun` is a function handle specified with `@`. The third and later input arguments to `bootci` are data (scalars, column vectors, or matrices) that are used to create inputs to `bootfun`. `bootci` creates each bootstrap sample by sampling with replacement from the rows of the non-scalar data arguments (these must have the same number of rows). Scalar data are passed to `bootfun` unchanged.

If `bootfun` returns a scalar, `ci` is a vector containing the lower and upper bounds of the confidence interval. If `bootfun` returns a vector of length m , `ci` is an array of size 2-by- m , where `ci(1,:)` are lower bounds and `ci(2,:)` are upper bounds. If `bootfun` returns an array of size m -by- n -by- p -by-..., `ci` is an array of size 2-by- m -by- n -by- p -by-..., where `ci(1,:,:,:,...)` is an array of lower bounds and `ci(2,:,:,:,...)` is an array of upper bounds.

`ci = bootci(nboot,{bootfun,...},'alpha',alpha)` computes the $100*(1-\text{alpha})$ bootstrap confidence interval of the statistic defined by the function `bootfun`.

`bootfun` and the data that `bootci` passes to it are contained in a single cell array. `alpha` is a scalar between 0 and 1. The default value of `alpha` is 0.05.

`ci = bootci(nboot,{bootfun,...},..., 'type', type)` computes the bootstrap confidence interval of the statistic defined by the function `bootfun`. `type` is the confidence interval type, chosen from among the following:

- 'norm' or 'normal' — Normal approximated interval with bootstrapped bias and standard error.
- 'per' or 'percentile' — Basic percentile method.
- 'cper' or 'corrected percentile' — Bias corrected percentile method.
- 'bca' — Bias corrected and accelerated percentile method. This is the default.
- 'stud' or 'student' — Studentized confidence interval.

`ci = bootci(nboot, {bootfun,...},..., 'type', 'student', 'nbootstd', nbootstd)` computes the studentized bootstrap confidence interval of the statistic defined by the function `bootfun`. The standard error of the bootstrap statistics is estimated using bootstrap, with `nbootstd` bootstrap data samples. `nbootstd` is a positive integer value. The default value of `nbootstd` is 100.

`ci = bootci(nboot, {bootfun,...},..., 'type', 'student', 'stderr', stderr)` computes the studentized bootstrap confidence interval of statistics defined by the function `bootfun`. The standard error of the bootstrap statistics is evaluated by the function `stderr`. `stderr` is a function handle. `stderr` takes the same arguments as `bootfun` and returns the standard error of the statistic computed by `bootfun`.

`ci = bootci(nboot,{bootfun,...},..., 'Weights', weights)` specifies observation weights. `weights` must be a vector of non-negative numbers with at least one positive element. The number of elements in `weights` must be equal to the number of rows in non-scalar input arguments to `bootfun`. To obtain one bootstrap replicate, `bootstrp` samples N out of N with replacement using these weights as multinomial sampling probabilities.

`ci = bootci(nboot,{bootfun,...},..., 'Options', options)` specifies options that govern the computation of bootstrap iterations. One option requests that `bootci` perform bootstrap iterations using multiple processors, if the Parallel Computing Toolbox is available. Two options specify the random number streams to be used in bootstrap resampling. This argument is a struct that you can create with a call to `statset`. You can

retrieve values of the individual fields with a call to `statget`. Applicable `statset` parameters are:

- `'UseParallel'` — If `true` and if a `parpool` of the Parallel Computing Toolbox is open, compute bootstrap iterations in parallel. If the Parallel Computing Toolbox is not installed, or a `parpool` is not open, computation occurs in serial mode. Default is `false`, or serial computation.
- `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. Default is `false`. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`.
- `Streams` — A `RandStream` object or cell array of such objects. If you do not specify `Streams`, `bootci` uses the default stream or streams. If you choose to specify `Streams`, use a single object except in the case
 - You have an open Parallel pool
 - `UseParallel` is `true`
 - `UseSubstreams` is `false`

In that case, use a cell array the same size as the Parallel pool.

`[ci,bootstat] = bootci(...)` also returns the bootstrapped statistic computed for each of the `nboot` bootstrap replicate samples. Each row of `bootstat` contains the results of applying `bootfun` to one bootstrap sample. If `bootfun` returns a matrix or array, then this output is converted to a row vector for storage in `bootstat`.

Examples

Compute the confidence interval for the capability index in statistical process control:

```
y = normrnd(1,1,30,1);           % Simulated process data
LSL = -3; USL = 3;              % Process specifications
capable = @(x)(USL-LSL)/(6* std(x)); % Process capability
ci = bootci(2000,capable,y)      % BCa confidence interval
ci =
    0.8122
    1.2657

sci = bootci(2000,{capable,y},'type','student') % Studentized ci
sci =
    0.7739
    1.2707
```

Introduced in R2006a

bootstrap

Bootstrap sampling

Syntax

```
bootstat = bootstrap(nboot,bootfun,d1,...)
[bootstat,bootsam] = bootstrap(...)
bootstat = bootstrap(...,'Name',Value)
```

Description

`bootstat = bootstrap(nboot,bootfun,d1,...)` draws `nboot` bootstrap data samples, computes statistics on each sample using `bootfun`, and returns the results in the matrix `bootstat`. `nboot` must be a positive integer. `bootfun` is a function handle specified with `@`. Each row of `bootstat` contains the results of applying `bootfun` to one bootstrap sample. If `bootfun` returns a matrix or array, then this output is converted to a row vector for storage in `bootstat`.

The third and later input arguments (`d1, ...`) are data (scalars, column vectors, or matrices) used to create inputs to `bootfun`. `bootstrap` creates each bootstrap sample by sampling with replacement from the rows of the non-scalar data arguments (these must have the same number of rows). `bootfun` accepts scalar data unchanged.

`[bootstat,bootsam] = bootstrap(...)` returns an `n`-by-`nboot` matrix of bootstrap indices, `bootsam`. Each column in `bootsam` contains indices of the values that were drawn from the original data sets to constitute the corresponding bootstrap sample. For example, if `d1, ...` each contain 16 values, and `nboot = 4`, then `bootsam` is a 16-by-4 matrix. The first column contains the indices of the 16 values drawn from `d1, ...`, for the first of the four bootstrap samples, the second column contains the indices for the second of the four bootstrap samples, and so on. (The bootstrap indices are the same for all input data sets.) To get the output samples `bootsam` without applying a function, set `bootfun` to empty (`[]`).

`bootstat = bootstrap(...,'Name',Value)` uses additional arguments specified by one or more `Name,Value` pair arguments. The name-value pairs must appear after the data arguments. The available name-value pairs:

- 'Weights' — Observation weights. The `weights` value must be a vector of nonnegative numbers with at least one positive element. The number of elements in `weights` must be equal to the number of rows in non-scalar input arguments to `bootstrap`. To obtain one bootstrap replicate, `bootstrap` samples N out of N with replacement using these weights as multinomial sampling probabilities.
- 'Options' — The value is a structure that contains options specifying whether to compute bootstrap iterations in parallel, and specifying how to use random numbers during the bootstrap sampling. Create the options structure with `statset`. Applicable `statset` parameters are:
 - 'UseParallel' — If `true` and if a `parpool` of the Parallel Computing Toolbox is open, compute bootstrap iterations in parallel. If the Parallel Computing Toolbox is not installed, or a `parpool` is not open, computation occurs in serial mode. Default is `false`, meaning serial computation.
 - `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. Default is `false`. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`.
 - `Streams` — A `RandStream` object or cell array of such objects. If you do not specify `Streams`, `bootstrap` uses the default stream or streams. If you choose to specify `Streams`, use a single object except in the case
 - You have an open Parallel pool
 - `UseParallel` is `true`
 - `UseSubstreams` is `false`

In that case, use a cell array the same size as the Parallel pool.

Examples

Bootstrapping a Correlation Coefficient Standard Error

This example shows how to compute a correlation coefficient standard error using bootstrap resampling of the sample data.

Load a data set containing the LSAT scores and law-school GPA for 15 students. These 15 data points are resampled to create 1000 different data sets, and the correlation between the two variables is computed for each data set.

```
load lawdata
rng default % For reproducibility
[bootstat,bootsam] = bootstrp(1000,@corr,lsat,gpa);
```

Display the first 5 bootstrapped correlation coefficients.

```
bootstat(1:5,:)
```

```
ans = 5×1
    0.9874
    0.4918
    0.5459
    0.8458
    0.8959
```

Display the indices of the data selected for the first 5 bootstrap samples.

```
bootsam(:,1:5)
```

```
ans = 15×5
    13     3    11     8    12
    14     7     1     7     4
     2    14     5    10     8
    14    12     1    11    11
    10    15     2    12    14
     2    10    13     5    15
     5     1    11    11     9
     9    13     5    10     3
    15    15    15     3     3
    15    11     1     2     4
    :
```

```
figure
histogram(bootstat)
```

The histogram shows the variation of the correlation coefficient across all the bootstrap samples. The sample minimum is positive, indicating that the relationship between LSAT score and GPA is not accidental.

Finally, compute a bootstrap standard of error for the estimated correlation coefficient.

```
se = std(bootstat)
```

```
se = 0.1285
```

Estimate the Density of Bootstrapped Statistic

This example shows how to estimate the kernel density of bootstrapped means.

Compute a sample of 100 bootstrapped means of random samples taken from the vector Y .

```
rng default; % For reproducibility
y = exprnd(5,100,1);
m = bootstrp(100,@mean,y);
```

Plot an estimate of the density of these bootstrapped means.

```
figure;
[fi,xi] = ksdensity(m);
plot(xi,fi);
```

Bootstrapping Multiple Statistics

This example shows how to compute and plot the means and standard deviations of bootstrapped 100 samples from a data vector.

Compute a sample of 100 bootstrapped means and standard deviations of random samples taken from the vector `y`.

```
rng('default') % For reproducibility
y = exprnd(5,100,1);
stats = bootstrp(100,@(x)[mean(x) std(x)],y);
```

Plot the bootstrap estimate pairs.

```
plot(stats(:,1),stats(:,2),'o')
```

Bootstrapping a Regression Model

This example shows how to estimate the standard errors for a coefficient vector in a linear regression by bootstrapping the residuals.

Load the sample data.

```
load hald
```

Perform a linear regression and compute the residuals.

```
x = [ones(size(heat)),ingredients];  
y = heat;  
b = regress(y,x);  
yfit = x*b;  
resid = y - yfit;
```

Estimate the standard errors by bootstrapping the residuals.

```
se = std(bootstrp(...  
        1000,@(bootr)regress(yfit+bootr,x),resid))
```

```
se = 1×5
```

```
    56.1752    0.5940    0.5815    0.5989    0.5691
```

Introduced before R2006a

boxplot

Box plot

Syntax

```
boxplot(x)
```

```
boxplot(x,g)
```

```
boxplot(ax, ___ )
```

```
boxplot( ___ ,Name,Value)
```

Description

`boxplot(x)` creates a box plot of the data in `x`. If `x` is a vector, `boxplot` plots one box. If `x` is a matrix, `boxplot` plots one box for each column of `x`.

On each box, the central mark indicates the median, and the bottom and top edges of the box indicate the 25th and 75th percentiles, respectively. The whiskers extend to the most extreme data points not considered outliers, and the outliers are plotted individually using the '+' symbol.

`boxplot(x,g)` creates a box plot using one or more grouping variables contained in `g`. `boxplot` produces a separate box for each set of `x` values that share the same `g` value or values.

`boxplot(ax, ___)` creates a box plot using the axes specified by the axes graphic object `ax`, using any of the previous syntaxes.

`boxplot(___ ,Name,Value)` creates a box plot with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the box style or order.

Examples

Create a Box Plot

Load the sample data.

```
load carsmall
```

Create a box plot of the miles per gallon (MPG) measurements. Add a title and label the axes.

```
boxplot(MPG)  
xlabel('All Vehicles')  
ylabel('Miles per Gallon (MPG)')  
title('Miles per Gallon for All Vehicles')
```

The boxplot shows that the median miles per gallon for all vehicles in the sample data is approximately 24. The minimum value is about 9, and the maximum value is about 44.

Create Box Plots for Grouped Data

Load the sample data.

```
load carsmall
```

Create a box plot of the miles per gallon (MPG) measurements from the sample data, grouped by the vehicles' country of origin (`Origin`). Add a title and label the axes.

```
boxplot(MPG,Origin)
title('Miles per Gallon by Vehicle Origin')
xlabel('Country of Origin')
ylabel('Miles per Gallon (MPG)')
```

Each box visually represents the MPG data for cars from the specified country. Italy's "box" appears as a single line because the sample data contains only one observation for this group.

Create Notched Box Plots

Generate two sets of sample data. The first sample, x_1 , contains random numbers generated from a normal distribution with $\mu = 5$ and $\sigma = 1$. The second sample, x_2 , contains random numbers generated from a normal distribution with $\mu = 6$ and $\sigma = 1$.

```
rng default % For reproducibility
x1 = normrnd(5,1,100,1);
x2 = normrnd(6,1,100,1);
```

Create notched box plots of x_1 and x_2 . Label each box with its corresponding μ value.

```
figure
boxplot([x1,x2], 'Notch', 'on', 'Labels', {'mu = 5', 'mu = 6'})
title('Compare Random Data from Different Distributions')
```

The boxplot shows that the difference between the medians of the two groups is approximately 1. Since the notches in the box plot do not overlap, you can conclude, with 95% confidence, that the true medians do differ.

The following figure shows the box plot for the same data with the maximum whisker length specified as 1.0 times the interquartile range. Data points beyond the whiskers are displayed using +.

```
figure
boxplot([x1,x2], 'Notch', 'on', 'Labels', {'mu = 5', 'mu = 6'}, 'Whisker', 1)
title('Compare Random Data from Different Distributions')
```

With the smaller whiskers, `boxplot` displays more data points as outliers.

Create Compact Box Plots

Create a 100-by-25 matrix of random numbers generated from a standard normal distribution to use as sample data.

```
rng default % For reproducibility
x = randn(100,25);
```

Create two box plots for the data in `x` on the same figure. Use the default formatting for the top plot, and compact formatting for the bottom plot.

```
figure

subplot(2,1,1)
boxplot(x)

subplot(2,1,2)
boxplot(x, 'PlotStyle', 'compact')
```

Each plot presents the same data, but the compact formatting may improve readability for plots with many boxes.

- “Box Plots” on page 4-6

Input Arguments

x — Input data

numeric vector | numeric matrix

Input data, specified as a numeric vector or numeric matrix. If **x** is a vector, `boxplot` plots one box. If **x** is a matrix, `boxplot` plots one box for each column of **x**.

On each box, the central mark indicates the median, and the bottom and top edges of the box indicate the 25th and 75th percentiles, respectively. The whiskers extend to the most extreme data points not considered outliers, and the outliers are plotted individually using the '+' symbol.

Data Types: `single` | `double`

g — Grouping variables

numeric vector | character array | string array | cell array | categorical array

Grouping variables, specified as a numeric vector, character array, string array, cell array, or categorical array. You can specify multiple grouping variables in `g` by using a cell array of these variable types or a matrix. If you specify multiple grouping variables, they must all be the same length.

If `x` is a vector, then the grouping variables must contain one row for each element of `x`. If `x` is a matrix, then the grouping variables must contain one row for each column of `x`. Groups that contain a missing value (NaN), an empty character vector, or an empty string in a grouping variable are omitted, and are not counted in the number of groups considered by other parameters.

By default, `boxplot` sorts character and string grouping variables in the order they initially appear in the data, categorical grouping variables by the order of their levels, and numeric grouping variables in numeric order. To control the order of groups, do one of the following:

- Use categorical variables in `g` and specify the order of their levels.
- Use the 'GroupOrder' name-value pair argument.
- Pre-sort your data.

Data Types: `single` | `double` | `char` | `string` | `cell` | `categorical`

ax — Axes on which to plot

axes graphic object

Axes on which to plot, specified as an axes graphic object. If you do not specify `ax`, then `boxplot` creates the plot using the current axis. For more information on creating an axes graphic object, see `axes` and `Axes`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Notch', 'on', 'Labels', {'mu = 5', 'mu = 6'}` creates a notched box plot and labels the two boxes $\mu = 5$ and $\mu = 6$, from left to right

Box Appearance

BoxStyle — Box style

`'outline'` | `'filled'`

Box style, specified as the comma-separated pair consisting of `'BoxStyle'` and one of the following.

| Name | Value |
|------------------------|---|
| <code>'outline'</code> | Plot boxes using an unfilled box with dashed whiskers. This is the default if <code>'PlotStyle'</code> is <code>'traditional'</code> . |
| <code>'filled'</code> | Plot boxes using a narrow filled box with lines for whiskers. This is the default if <code>'PlotStyle'</code> is <code>'compact'</code> . |

Example: `'BoxStyle', 'filled'`

Colors — Box colors

RGB triplet | character vector or string scalar of color names

Box colors, specified as the comma-separated pair consisting of `'Colors'` and an RGB triplet, character vector, or string scalar. An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color, respectively. Each intensity must be in the range $[0,1]$.

The following table lists the available color characters and their equivalent RGB triplet values.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| Yellow | 'y' | [1 1 0] |
| Magenta | 'm' | [1 0 1] |
| Cyan | 'c' | [0 1 1] |
| Red | 'r' | [1 0 0] |
| Green | 'g' | [0 1 0] |
| Blue | 'b' | [0 0 1] |
| White | 'w' | [1 1 1] |
| Black | 'k' | [0 0 0] |

You can specify multiple colors either as a character vector or string scalar of color names (for example, 'rgbm') or a three-column matrix of RGB values. The sequence is replicated or truncated as required, so for example, 'rb' gives boxes that alternate red and blue.

If you do not specify the name-value pair 'ColorGroup', then `boxplot` uses the same color scheme for all boxes. If you do specify 'ColorGroup', then the default is a modified `hsv` colormap.

Example: 'Colors', 'rgbm'

MedianStyle — Median style

'line' | 'target'

Median style, specified as the comma-separated pair consisting of 'MedianStyle' and one of the following.

| Name | Value |
|----------|--|
| 'line' | Draw a line to represent the median in each box. This is the default when 'PlotStyle' is 'traditional'. |
| 'target' | Draw a black dot inside a white circle to represent the median in each box. This is the default when 'PlotStyle' is 'compact'. |

Example: 'MedianStyle', 'target'

Notch — Marker for comparison intervals

'off' (default) | 'on' | 'marker'

Marker for comparison intervals, specified as the comma-separated pair consisting of 'Notch' and one of the following.

| Name | Value |
|----------|--|
| 'off' | Omit comparison intervals from box display. |
| 'on' | If 'PlotStyle' is 'traditional', draw comparison intervals using notches. If 'PlotStyle' is 'compact', draw comparison intervals using triangular markers. |
| 'marker' | Draw comparison intervals using triangular markers. |

Two medians are significantly different at the 5% significance level if their intervals do not overlap. `boxplot` represents interval endpoints using the extremes of the notches or the centers of the triangular markers. The notch extremes correspond to $q_2 - 1.57(q_3 - q_1)/\sqrt{n}$ and $q_2 + 1.57(q_3 - q_1)/\sqrt{n}$, where q_2 is the median (50th percentile), q_1 and q_3 are the 25th and 75th percentiles, respectively, and n is the number of observations without any NaN values. If the sample size is small, the notches might extend beyond the end of the box.

Example: 'Notch', 'on'

OutlierSize — Marker size for outliers

positive numeric value

Marker size for outliers, specified as the comma-separated pair consisting of 'OutlierSize' and a positive numeric value. The specified value represents the marker size in points.

If 'PlotStyle' is 'traditional', then the default value for `OutlierSize` is 6. If 'PlotStyle' is 'compact', then the default value for `OutlierSize` is 4.

Example: 'OutlierSize', 8

Data Types: single | double

PlotStyle — Plot style

'traditional' (default) | 'compact'

Plot style, specified as the comma-separated pair consisting of 'PlotStyle' and one of the following.

| Name | Value |
|---------------|--|
| 'traditional' | Plot boxes using a traditional box style. |
| 'compact' | Plot boxes using a smaller box style designed for plots with many groups. This style changes the defaults for some other parameters. |

Example: 'PlotStyle', 'compact'

Symbol — Symbol and color for outliers

line specification

Symbol and color for outliers, specified as the comma-separated pair consisting of 'Symbol' and a line specification. See the LineSpec parameter in plot for available line specifications.

If 'PlotStyle' is 'traditional', then the default value is 'r+', which plots each outlier using a red '+' symbol.

If 'PlotStyle' is 'compact', then the default value is 'o', which plots each outlier using an 'o' symbol in the same color as the corresponding box.

If you omit the symbol, then the outliers appear invisible. If you omit the color, then the outliers appear in the same color as the box.

Example: 'kx'

Widths — Box width

numeric scalar | numeric vector

Box width, specified as the comma-separated pair consisting of 'Widths' and a numeric scalar or numeric vector. If the number of boxes is not equal to the number of width values specified, then the list of values is replicated or truncated as necessary.

This name-value pair argument does not alter the spacing between boxes. Therefore, if you specify a large value for 'Widths', the boxes might overlap.

The default box width is equal to half of the minimum separation between boxes, which is 0.5 when the 'Positions' name-value pair argument takes its default value.

Example: 'Widths',0.3

Data Types: single | double

Group Appearance

ColorGroup — Grouping variable for box color change

[] (default) | numeric vector | character array | string array | cell array | categorical array

Grouping variable for box color change, specified as the comma-separated pair consisting of 'ColorGroup' and a grouping variable. The grouping variable is a numeric vector, character array, string array, cell array, or categorical array. The box color changes when the specified grouping variable changes. The default value [] indicates that the box color does not change based on the group.

Data Types: single | double | char | string | cell | categorical

FactorDirection — Order of factors on plot

'data' (default) | 'list' | 'auto'

Order of factors on plot, specified as the comma-separated pair consisting of 'FactorDirection' and one of the following.

| Name | Value |
|--------|---|
| 'data' | Factors appear with the first value next to the plot origin. |
| 'list' | Factors appear left-to-right if on the x-axis, or top-to-bottom if on the y-axis. |
| 'auto' | If the grouping variables are numeric, then boxplot uses 'data'. If the grouping variables are character arrays, string arrays, cell arrays, or categorical arrays, then boxplot uses 'list'. |

FullFactors — Plot all group factors

'off' (default) | 'on'

Plot all group factors, specified as the comma-separated pair consisting of 'FullFactors' and either 'off' or 'on'. If 'off', then boxplot plots one box for each unique row of grouping variables. If 'on', then boxplot plots one box for each

possible combination of grouping variable values, including combinations that do not appear in the data.

Example: 'FullFactors', 'on'

FactorGap — Distance between different grouping factors

[] | positive numeric value | vector of positive numeric values | 'auto'

Distance between different grouping factors, specified as the comma-separated pair consisting of 'FactorGap' and a positive numeric value, a vector of positive numeric values, or 'auto'. If you specify a vector, then the vector length must be less than or equal to the number of grouping variables.

'FactorGap' represents the distance of the gap between different factors of a grouping variable, expressed as a percentage of the width of the plot. For example, if you specify [3, 1], then the gap is three percent of the width of the plot between groups with different values of the first grouping variable, and one percent between groups with the same value of the first grouping variable but different values for the second.

If you specify 'auto', then `boxplot` selects a gap distance automatically. The value [] indicates no change in gap size between different factors.

If 'PlotStyle' is 'traditional', then the default value for FactorGap is []. If 'PlotStyle' is 'compact', then the default value is 'auto'.

Example: 'FactorGap', [3,1]

Data Types: single | double | char | string

FactorSeparator — Separation between grouping factors

[] | positive integer | vector of positive integers | 'auto'

Separation between grouping factors, specified as the comma-separated pair consisting of 'FactorSeparator' and a positive integer or a vector of positive integers, or 'auto'. If you specify a vector, then the length of the vector should be less than or equal to the number of grouping variables. The integer values must be in the range [1,G], where G is the number of grouping variables.

'FactorSeparator' specifies which factors should have their values separated by a grid line. For example, [1,2] adds a separator line when the first or second grouping variable changes value.

If 'PlotStyle' is 'traditional', then the default value for FactorSeparator is []. If 'PlotStyle' is 'compact', then the default value is 'auto'.

Example: 'FactorSeparator', [1,2]

Data Types: single | double | char | string

GroupOrder — Plotting order of groups

[] (default) | string array | cell array

Plotting order of groups, specified as the comma-separated pair consisting of 'GroupOrder' and a string array or cell array containing the names of the grouping variables. If you have multiple grouping variables, separate values with a comma. You can also use categorical arrays as grouping variables to control the order of the boxes. The default value [] does not reorder the boxes.

Data Types: string | cell

Data Limits and Maximum Distances

DataLim — Extreme data limits

[-Inf, Inf] (default) | two-element numeric vector

Extreme data limits, specified as the comma-separated pair consisting of 'DataLim' and a two-element numeric vector containing the lower and upper limits, respectively. The values specified for 'DataLim' are used by 'ExtremeMode' to determine which data points are extreme.

Data Types: single | double

ExtremeMode — Handling method for extreme data

'clip' (default) | 'compress'

Handling method for extreme data, specified as the comma-separated pair consisting of 'ExtremeMode' and one of the following.

| Name | Value |
|--------|---|
| 'clip' | If any data values fall outside the limits specified by 'DataLim', then boxplot displays these values at DataLim on the plot. |

| Name | Value |
|------------|---|
| 'compress' | If any data values fall outside the limits specified by 'DataLim', then <code>boxplot</code> displays these values evenly distributed in a region just outside <code>DataLim</code> , retaining the relative order of the points. |

If any data points lie outside the limit specified by 'DataLim', then the limit is marked with a dotted line. If any data points are compressed, then two gray lines mark the compression region. Values at `-Inf` or `Inf` can be clipped or compressed, but `NaN` values do not appear on the plot. Box notches are drawn to scale and may extend beyond the bounds if the median is inside the limit. Box notches are not drawn if the median is outside the limits.

Example: 'ExtremeMode', 'compress'

Jitter — Maximum outlier displacement distance

numeric value

Maximum outlier displacement distance, specified as the comma-separated pair consisting of 'Jitter' and a numeric value. `Jitter` is the maximum distance to displace outliers along the factor axis by a uniform random amount, in order to make duplicate points visible. If you specify 'Jitter' equal to 1, then the jitter regions just touch between the closest adjacent groups.

If 'PlotStyle' is 'traditional', then the default value for `Jitter` is 0. If 'PlotStyle' is 'compact', then the default value is 0.5.

Example: 'Jitter', 1

Data Types: single | double

Whisker — Maximum whisker length

1.5 (default) | positive numeric value

Maximum whisker length, specified as the comma-separated pair consisting of 'Whisker' and a positive numeric value.

`boxplot` draws points as outliers if they are greater than $q_3 + w \times (q_3 - q_1)$ or less than $q_1 - w \times (q_3 - q_1)$, where w is the maximum whisker length, and q_1 and q_3 are the 25th and 75th percentiles of the sample data, respectively.

The default value for 'Whisker' corresponds to approximately $\pm 2.7\sigma$ and 99.3 percent coverage if the data are normally distributed. The plotted whisker extends to the *adjacent value*, which is the most extreme data value that is not an outlier.

Specify 'Whisker' as 0 to give no whiskers and to make every point outside of q_1 and q_3 an outlier.

Example: 'Whisker', 0

Data Types: single | double

Plot Appearance

Labels — Box labels

character array | string array | cell array | numeric vector | numeric matrix

Box labels, specified as the comma-separated pair consisting of 'Labels' and a character array, string array, cell array, or numeric vector containing the box label names. Specify one label per x value or one label per group. To specify multiple label variables, use a numeric matrix or a cell array containing any of the accepted data types.

To remove labels from a plot, use the following command: `set(gca, 'XTickLabel', {''})`.

Data Types: char | string | cell | single | double

LabelOrientation — Label orientation

'inline' | 'horizontal'

Label orientation, specified as the comma-separated pair consisting of 'LabelOrientation' and one of the following.

| Name | Value |
|--------------|--|
| 'inline' | Rotate box labels to be vertical. This is the default when 'PlotStyle' is 'compact'. |
| 'horizontal' | Leave box labels horizontal. This is the default when 'PlotStyle' is 'traditional'. |

If the labels are on the y axis, then both settings leave the labels horizontal.

Example: 'LabelOrientation', 'inline'

LabelVerbosity — Labels to display on plot

'all' | 'minor' | 'majorminor'

Labels to display on plot, specified as the comma-separated pair consisting of LabelVerbosity and one of the following.

| Name | Value |
|--------------|---|
| 'all' | Display a label for every factor. This is the default when 'PlotStyle' is 'traditional'. |
| 'minor' | Display a label for a factor only when that factor has a different value from the previous group. |
| 'majorminor' | Display a label for a factor when that factor or any factor major to it has a different value from the previous group. This is the default when 'PlotStyle' is 'compact'. |

Example: 'LabelVerbosity', 'minor'

Orientation — Plot orientation

'vertical' (default) | 'horizontal'

Plot orientation, specified as the comma-separated pair consisting of Orientation and one of the following.

| Name | Value |
|--------------|-----------------------|
| 'vertical' | Plot x on the y-axis. |
| 'horizontal' | Plot x on the x-axis. |

Example: 'horizontal'

Positions — Box positions

numeric vector

Box positions, specified as the comma-separated pair consisting of 'Positions' and a numeric vector containing one entry for each group or x value. The default is $1:NumGroups$, where $NumGroups$ is the number of groups.

Data Types: single | double

Tips

- `boxplot` creates a visual representation of the data, but does not return numeric values. To calculate the relevant summary statistics for the sample data, use the following functions:
 - `min` — Find the minimum value in the sample data.
 - `max` — Find the maximum value in the sample data.
 - `median` — Find the median value in the sample data.
 - `quantile` — Find the quantile values in the sample data.
 - `grpstats` — Calculate summary statistics for the sample data, organized by group.
- You can see data values and group names using the data cursor (MATLAB) in the figure window. The cursor shows the original values of any points affected by the `datalim` parameter. You can label the group to which an outlier belongs using the `gname` function.
- To modify graphics properties of a box plot component, use `findobj` with the `Tag` property to find the component's handle. `Tag` values for box plot components depend on parameter settings, and are listed in the following table.

| Parameter Settings | Tag Values |
|-----------------------------------|--|
| All settings | <ul style="list-style-type: none"> • 'Box' • 'Outliers' |
| When 'PlotStyle' is 'traditional' | <ul style="list-style-type: none"> • 'Median' • 'Upper Whisker' • 'Lower Whisker' • 'Upper Adjacent Value' • 'Lower Adjacent Value' |
| When 'PlotStyle' is 'compact' | <ul style="list-style-type: none"> • 'Whisker' • 'MedianOuter' • 'MedianInner' |
| When 'Notch' is 'marker' | <ul style="list-style-type: none"> • 'NotchLo' • 'NotchHi' |

boundary

Piecewise distribution boundaries

Syntax

```
[p,q] = boundary(pd)  
[p,q] = boundary(pd,j)
```

Description

`[p,q] = boundary(pd)` returns the boundary points between segments in `pd`, the piecewise distribution. `p` is a vector of the cumulative probabilities at the boundaries, and `q` is a vector of the corresponding quantiles.

`[p,q] = boundary(pd,j)` returns boundary values of the `j`th boundary.

Examples

Boundaries in `paretotails` Object

Generate a sample data set and create a `paretotails` object by fitting a piecewise distribution with Pareto tails to the generated data. Find the boundary points between segments in a `paretotails` object by using the object function `boundary`.

Generate a sample data set containing 20% outliers.

```
rng('default'); % For reproducibility  
left_tail = -exprnd(1,100,1);  
right_tail = exprnd(5,100,1);  
center = randn(800,1);  
x = [left_tail;center;right_tail];
```

Create a `paretotails` object by fitting a piecewise distribution to `x`. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities so that a

fitted object consists of the empirical distribution for the middle 80% of the data set and generalized Pareto distributions (GPDs) for the lower and upper 10% of the data set.

```
pd = paretotails(x,0.1,0.9)
```

```
pd =  
Piecewise distribution with 3 segments  
  -Inf < x < -1.33251    (0 < p < 0.1): lower tail, GPD(-0.0063504,0.567017)  
 -1.33251 < x < 1.80149 (0.1 < p < 0.9): interpolated empirical cdf  
  1.80149 < x < Inf     (0.9 < p < 1): upper tail, GPD(0.24874,3.00974)
```

Return the boundary values between the piecewise segments by using the `boundary` function.

```
[p,q] = boundary(pd)
```

```
p = 2×1
```

```
 0.1000  
 0.9000
```

```
q = 2×1
```

```
-1.3325  
 1.8015
```

The values in `p` are the cumulative probabilities at the boundaries, and the values in `q` are the corresponding quantiles.

Plot the cdf of the `paretotails` object and mark the boundary points on the figure.

```
xi = sort(x);  
plot(xi,cdf(pd,xi))  
hold on  
plot(q,p,'ro')  
legend('Pareto Tails Object','Boundary Points','Location','best')  
hold off
```

Input Arguments

pd — Piecewise distribution with Pareto tails

paretotails object

Piecewise distribution with Pareto tails, specified as a `paretotails` object.

j — Boundary index

positive integer

Boundary index indicating which boundary to return, specified as a positive integer.

Data Types: `single` | `double`

Output Arguments

p — Cumulative probability at boundary

numeric vector of range $(0, 1)$ values

Cumulative probability at each boundary, returned as a numeric vector of range $(0, 1)$ values.

q — Quantile at boundary

numeric vector

Quantile at each boundary, returned as a numeric vector.

clustering.evaluation.CalinskiHarabaszEvaluation class

Package: clustering.evaluation

Superclasses:

Calinski-Harabasz criterion clustering evaluation object

Description

`clustering.evaluation.CalinskiHarabaszEvaluation` is an object consisting of sample data, clustering data, and Calinski-Harabasz criterion values used to evaluate the optimal number of clusters. Create a Calinski-Harabasz criterion clustering evaluation object using `evalclusters`.

Construction

`eva = evalclusters(x, clust, 'CalinskiHarabasz')` creates a Calinski-Harabasz criterion clustering evaluation object.

`eva = evalclusters(x, clust, 'CalinskiHarabasz', Name, Value)` creates a Calinski-Harabasz criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

Input Arguments

x — Input data

matrix

Input data, specified as an N -by- P matrix. N is the number of observations, and P is the number of variables.

Data Types: `single` | `double`

clust — Clustering algorithm

'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

| | |
|------------------|--|
| 'kmeans' | Cluster the data in <i>x</i> using the kmeans clustering algorithm, with 'EmptyAction' set to 'singleton' and 'Replicates' set to 5. |
| 'linkage' | Cluster the data in <i>x</i> using the clusterdata agglomerative clustering algorithm, with 'Linkage' set to 'ward'. |
| 'gmdistribution' | Cluster the data in <i>x</i> using the gmdistribution Gaussian mixture distribution algorithm, with 'SharedCov' set to true and 'Replicates' set to 5. |

If *criterion* is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can specify a clustering algorithm using a function handle (MATLAB). The function must be of the form `C = clustfun(DATA,K)`, where *DATA* is the data to be clustered, and *K* is the number of clusters. The output of `clustfun` must be one of the following:

- A vector of integers representing the cluster index for each observation in *DATA*. There must be *K* unique values in this vector.
- A numeric *n*-by-*K* matrix of score for *n* observations and *K* classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If *criterion* is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can also specify `clust` as a *n*-by-*K* matrix containing the proposed clustering solutions. *n* is the number of observations in the sample data, and *K* is the number of proposed clustering solutions. Column *j* contains the cluster indices for each of the *N* points in the *j*th clustering solution.

Data Types: single | double | char | string | function_handle

Specify optional comma-separated pairs of *Name*, *Value* arguments. *Name* is the argument name and *Value* is the corresponding value. *Name* must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: 'KList', [1:6] specifies to test 1, 2, 3, 4, 5, and 6 clusters to find the optimal number.

KList — List of number of clusters to evaluate

vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of 'KList' and a vector of positive integer values. You must specify KList when `clust` is a clustering algorithm name or a function handle. When `criterion` is 'gap', `clust` must be a character vector, a string scalar, or a function handle, and you must specify KList.

Example: 'KList', [1:6]

Data Types: single | double

Properties

ClusteringFunction

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name or function handle. If the clustering solutions are provided in the input, ClusteringFunction is empty.

CriterionName

Name of the criterion used for clustering evaluation, stored as a valid criterion name.

CriterionValues

Criterion values corresponding to each proposed number of clusters in InspectedK, stored as a vector of numerical values.

Distance

Distance metric used for clustering data, stored as a valid distance metric name.

InspectedK

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

Missing

Logical flag for excluded data, stored as a column vector of logical values. If `Missing` equals `true`, then the corresponding value in the data matrix `x` is not used in the clustering solution.

NumObservations

Number of observations in the data matrix `X`, minus the number of missing (NaN) values in `X`, stored as a positive integer value.

OptimalK

Optimal number of clusters, stored as a positive integer value.

OptimalY

Optimal clustering solution corresponding to `OptimalK`, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, `OptimalY` is empty.

X

Data used for clustering, stored as a matrix of numerical values.

Methods**Inherited Methods**

| | |
|----------------------|--|
| <code>addK</code> | Evaluate additional numbers of clusters |
| <code>plot</code> | Plot clustering evaluation object criterion values |
| <code>compact</code> | Compact clustering evaluation object |

Examples

Evaluate the Clustering Solution Using Calinski-Harabasz Criterion

Evaluate the optimal number of clusters using the Calinski-Harabasz clustering evaluation criterion.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Evaluate the optimal number of clusters using the Calinski-Harabasz criterion. Cluster the data using kmeans.

```
rng('default'); % For reproducibility
eva = evalclusters(meas,'kmeans','CalinskiHarabasz','KList',[1:6])

eva =
  CalinskiHarabaszEvaluation with properties:

    NumObservations: 150
      InspectedK: [1 2 3 4 5 6]
  CriterionValues: [NaN 513.9245 561.6278 530.4871 456.1279 469.5068]
      OptimalK: 3
```

The `OptimalK` value indicates that, based on the Calinski-Harabasz criterion, the optimal number of clusters is three.

Plot the Calinski-Harabasz criterion values for each number of clusters tested.

```
figure;
plot(eva);
```

The plot shows that the highest Calinski-Harabasz value occurs at three clusters, suggesting that the optimal number of clusters is three.

Create a grouped scatter plot to examine the relationship between petal length and width. Group the data by suggested clusters.

```
PetalLength = meas(:,3);  
PetalWidth = meas(:,4);  
ClusterGroup = eva.OptimalY;  
figure;  
gscatter(PetalLength,PetalWidth,ClusterGroup,'rbg','xod');
```

The plot shows cluster 3 in the lower-left corner, completely separated from the other two clusters. Cluster 3 contains flowers with the smallest petal widths and lengths. Cluster 1 is in the upper-right corner, and contains flowers with the largest petal widths and lengths. Cluster 2 is near the center of the plot, and contains flowers with measurements between these two extremes.

Definitions

Calinski-Harabasz Criterion

The Calinski-Harabasz criterion is sometimes called the variance ratio criterion (VRC). The Calinski-Harabasz index is defined as

$$VRC_k = \frac{SS_B}{SS_W} \times \frac{(N - k)}{(k - 1)},$$

, where SS_B is the overall between-cluster variance, SS_W is the overall within-cluster variance, k is the number of clusters, and N is the number of observations.

The overall between-cluster variance SS_B is defined as

$$SS_B = \sum_{i=1}^k n_i \|m_i - m\|^2,$$

where k is the number of clusters, m_i is the centroid of cluster i , m is the overall mean of the sample data, and $\|m_i - m\|$ is the L^2 norm (Euclidean distance) between the two vectors.

The overall within-cluster variance SS_W is defined as

$$SS_W = \sum_{i=1}^k \sum_{x \in c_i} \|x - m_i\|^2,$$

where k is the number of clusters, x is a data point, c_i is the i th cluster, m_i is the centroid of cluster i , and $\|x - m_i\|$ is the L^2 norm (Euclidean distance) between the two vectors.

Well-defined clusters have a large between-cluster variance (SS_B) and a small within-cluster variance (SS_W). The larger the VRC_k ratio, the better the data partition. To determine the optimal number of clusters, maximize VRC_k with respect to k . The optimal number of clusters is the solution with the highest Calinski-Harabasz index value.

The Calinski-Harabasz criterion is best suited for k -means clustering solutions with squared Euclidean distances.

candexch

D-optimal design from candidate set using row exchanges

Syntax

```
rlist = candexch(C,nrows)
rlist = candexch(C,nrows,Name,Value)
```

Description

`rlist = candexch(C,nrows)` uses a row-exchange algorithm to select a *D*-optimal design from the candidate set *C*.

`rlist = candexch(C,nrows,Name,Value)` generates a *D*-optimal design with additional options specified by one or more *Name, Value* pair arguments.

Input Arguments

C

N-by-*P* matrix containing the values of *P* model terms at each of *N* points.

Default:

nrows

The desired number of rows in the design.

Name-Value Pair Arguments

Specify optional comma-separated pairs of *Name, Value* arguments. *Name* is the argument name and *Value* is the corresponding value. *Name* must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as *Name1, Value1, . . . , NameN, ValueN*.

display

When 'on', displays iteration number. Disable the display by setting to 'off'.

Default: 'on', except when the UseParallel option is true

init

nrows-by-P matrix giving an initial design.

Default: A random subset of the rows of C

maxiter

Maximum number of iterations, a positive integer.

Default: 10

options

A structure that specifies whether to run in parallel, and specifies the random stream or streams. Create the `options` structure with `statset`. Option fields:

- `UseParallel` — Set to `true` to compute in parallel. Default is `false`.
- `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. Default is `false`. To compute reproducibly, set `Streams` to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'.
- `Streams` — A `RandStream` object or cell array of such objects. If you do not specify `Streams`, `candexch` uses the default stream or streams. If you choose to specify `Streams`, use a single object except in the case
 - You have an open Parallel pool
 - `UseParallel` is `true`
 - `UseSubstreams` is `false`

In that case, use a cell array the same size as the Parallel pool.

Default: []

start

An `nobs`-by-`p` matrix of factor settings, specifying a set of `nobs` fixed design points to include in the design. `candexch` finds `nrows` additional rows to add to the `start` design.

The parameter provides the same functionality as the `daugment` function, using a row-exchange algorithm rather than a coordinate-exchange algorithm.

Default: []

tries

Number of times to try to generate a design from a new starting point. The algorithm uses random points for each try, except possibly the first.

Default: 1

Output Arguments

rlist

Vector of length `n` rows listing the selected rows.

Examples

This example shows how to generate a D -optimal design when there is a restriction on the candidate set, so the `rowexch` function isn't appropriate.

```
F = (fullfact([5 5 5])-1)/4; % factor settings in unit cube
T = sum(F,2)<=1.51;        % find rows matching a restriction
F = F(T,:);               % take only those rows
C = [ones(size(F,1),1) F F.^2];
                           % compute model terms including
                           % a constant and all squared terms
R = candexch(C,12);       % find a D-optimal 12-point subset
X = F(R,:);               % get factor settings
```

Algorithms

`candexch` selects a starting design X at random, and uses a row-exchange algorithm to iteratively replace rows of X by rows of C in an attempt to improve the determinant of $X' * X$.

Alternatives

The `rowexch` function also generates D -optimal designs using a row-exchange algorithm, but it automatically generates a candidate set that is appropriate for a specified model. The `daugment` function augments a set of fixed design points using a coordinate-exchange algorithm; the 'start' parameter provides the same functionality using the row exchange algorithm.

Introduced before R2006a

candgen

Candidate set generation

Syntax

```
dC = candgen(nfactors, 'model')
[dC,C] = candgen(nfactors, 'model')
[... ] = candgen(nfactors, 'model', 'Name', value)
```

Description

`dC = candgen(nfactors, 'model')` generates a candidate set `dC` of treatments appropriate for estimating the parameters in the `model` with `nfactors` factors. `dC` has `nfactors` columns and one row for each candidate treatment. `model` is one of the following:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

Alternatively, `model` can be a matrix specifying polynomial terms of arbitrary order. In this case, `model` should have one column for each factor and one row for each term in the model. The entries in any row of `model` are powers for the factors in the columns. For example, if a model has factors X_1 , X_2 , and X_3 , then a row `[0 1 2]` in `model` specifies the term $(X_1.^0) .* (X_2.^1) .* (X_3.^2)$. A row of all zeros in `model` specifies a constant term, which can be omitted.

`[dC,C] = candgen(nfactors, 'model')` also returns the design matrix `C` evaluated at the treatments in `dC`. The order of the columns of `C` for a full quadratic model with n terms is:

- 1 The constant term
- 2 The linear terms in order 1, 2, ..., n

- 3 The interaction terms in order (1, 2), (1, 3), ..., (1, n), (2, 3), ..., ($n - 1$, n)
- 4 The squared terms in order 1, 2, ..., n

Other models use a subset of these terms, in the same order.

Pass C to `candexch` to generate a D -optimal design using a coordinate-exchange algorithm.

[...] = `candgen(nfactors, 'model', 'Name', value)` specifies one or more optional name/value pairs for the design. Valid parameters and their values are listed in the following table. Specify *Name* inside single quotes.

| Name | Value |
|-------------|--|
| bounds | Lower and upper bounds for each factor, specified as a 2-by- <code>nfactors</code> matrix. Alternatively, this value can be a cell array containing <code>nfactors</code> elements, each element specifying the vector of allowable values for the corresponding factor. |
| categorical | Indices of categorical predictors. |
| levels | Vector of number of levels for each factor. |

Note The `rowexch` function automatically generates a candidate set using `candgen`, and then creates a D -optimal design from that candidate set using `candexch`. Call `candexch` separately to specify your own candidate set to the row-exchange algorithm.

Examples

The following example uses `rowexch` to generate a five-run design for a two-factor pure quadratic model using a candidate set that is produced internally:

```
dRE1 = rowexch(2,5,'purequadratic','tries',10)
dRE1 =
    -1     1
     0     0
     1    -1
     1     0
     1     1
```

The same thing can be done using `candgen` and `candexch` in sequence:

```
[dC,C] = candgen(2,'purequadratic') % Candidate set, C
dC =
  -1  -1
   0  -1
   1  -1
  -1   0
   0   0
   1   0
  -1   1
   0   1
   1   1
C =
   1  -1  -1   1   1
   1   0  -1   0   1
   1   1  -1   1   1
   1  -1   0   1   0
   1   0   0   0   0
   1   1   0   1   0
   1  -1   1   1   1
   1   0   1   0   1
   1   1   1   1   1
treatments = candexch(C,5,'tries',10) % Find D-opt subset
treatments =
  2
  1
  7
  3
  4
dRE2 = dC(treatments,:) % Display design
dRE2 =
   0  -1
  -1  -1
  -1   1
   1  -1
  -1   0
```

canoncorr

Canonical correlation

Syntax

```
[A,B] = canoncorr(X,Y)
[A,B,r] = canoncorr(X,Y)
[A,B,r,U,V] = canoncorr(X,Y)
[A,B,r,U,V,stats] = canoncorr(X,Y)
```

Description

`[A,B] = canoncorr(X,Y)` computes the sample canonical coefficients for the n -by- d_1 and n -by- d_2 data matrices X and Y . X and Y must have the same number of observations (rows) but can have different numbers of variables (columns). A and B are d_1 -by- d and d_2 -by- d matrices, where $d = \min(\text{rank}(X), \text{rank}(Y))$. The j th columns of A and B contain the canonical coefficients, i.e., the linear combination of variables making up the j th canonical variable for X and Y , respectively. Columns of A and B are scaled to make the covariance matrices of the canonical variables the identity matrix (see U and V below). If X or Y is less than full rank, `canoncorr` gives a warning and returns zeros in the rows of A or B corresponding to dependent columns of X or Y .

`[A,B,r] = canoncorr(X,Y)` also returns a 1-by- d vector containing the sample canonical correlations. The j th element of r is the correlation between the j th columns of U and V (see below).

`[A,B,r,U,V] = canoncorr(X,Y)` also returns the canonical variables, scores. U and V are n -by- d matrices computed as

```
U = (X-repmat(mean(X),N,1))*A
V = (Y-repmat(mean(Y),N,1))*B
```

`[A,B,r,U,V,stats] = canoncorr(X,Y)` also returns a structure `stats` containing

information relating to the sequence of d null hypotheses $H_0^{(k)}$, that the $(k+1)$ st through d th correlations are all zero, for $k = 0:(d-1)$. `stats` contains seven fields, each a 1-by-

d vector with elements corresponding to the values of k, as described in the following table:

| Field | Description |
|--------|--|
| Wilks | Wilks' lambda (likelihood ratio) statistic |
| df1 | Degrees of freedom for the chi-squared statistic, and the numerator degrees of freedom for the F statistic |
| df2 | Denominator degrees of freedom for the F statistic |
| F | Rao's approximate F statistic for $H_0^{(k)}$ |
| pF | Right-tail significance level for F |
| chisq | Bartlett's approximate chi-squared statistic for $H_0^{(k)}$ with Lawley's modification |
| pChisq | Right-tail significance level for chisq |

stats has two other fields (dfe and p) which are equal to df1 and pChisq, respectively, and exist for historical reasons.

Examples

Compute Sample Canonical Correlation

Load the sample data.

```
load carbig;
X = [Displacement Horsepower Weight Acceleration MPG];
nans = sum(isnan(X),2) > 0;
```

Compute the sample canonical correlation.

```
[A,B,r,U,V] = canoncorr(X(~nans,1:3),X(~nans,4:5));
```

Plot the canonical variables scores.

```
plot(U(:,1),V(:,1),'.')
xlabel('0.0025*Disp+0.020*HP-0.000025*Wgt')
ylabel('-0.17*Accel-0.092*MPG')
```

Introduced before R2006a

capability

Process capability indices

Syntax

```
S = capability(data,specs)
```

Description

`S = capability(data,specs)` estimates capability indices for measurements in `data` given the specifications in `specs`. `data` can be either a vector or a matrix of measurements. If `data` is a matrix, indices are computed for the columns. `specs` can be either a two-element vector of the form `[L,U]` containing lower and upper specification limits, or (if `data` is a matrix) a two-row matrix with the same number of columns as `data`. If there is no lower bound, use `-Inf` as the first element of `specs`. If there is no upper bound, use `Inf` as the second element of `specs`.

The output `S` is a structure with the following fields:

- `mu` — Sample mean
- `sigma` — Sample standard deviation
- `P` — Estimated probability of being within limits
- `Pl` — Estimated probability of being below `L`
- `Pu` — Estimated probability of being above `U`
- `Cp` — $(U-L)/(6*\text{sigma})$
- `Cpl` — $(\text{mu}-L)/(3.*\text{sigma})$
- `Cpu` — $(U-\text{mu})/(3.*\text{sigma})$
- `Cpk` — $\min(\text{Cpl},\text{Cpu})$

Indices are computed under the assumption that data values are independent samples from a normal population with constant mean and variance.

Indices divide a “specification width” (between specification limits) by a “process width” (between control limits). Higher ratios indicate a process with fewer measurements outside of specification.

Examples

Compute Capability Indices

Simulate a sample from a process with a mean of 3 and a standard deviation of 0.005.

```
rng default; % for reproducibility
data = normrnd(3,0.005,100,1);
```

Compute capability indices if the process has an upper specification limit of 3.01 and a lower specification limit of 2.99.

```
S = capability(data,[2.99 3.01])
```

```
S = struct with fields:
    mu: 3.0006
    sigma: 0.0058
    P: 0.9129
    Pl: 0.0339
    Pu: 0.0532
    Cp: 0.5735
    Cpl: 0.6088
    Cpu: 0.5382
    Cpk: 0.5382
```

Visualize the specification and process widths.

```
capaplot(data,[2.99 3.01]);
grid on
```

capaplot | histfit

Introduced in R2006b

capaplot

Process capability plot

Syntax

```
p = capaplot(data,specs)
[p,h] = capaplot(data,specs)
```

Description

`p = capaplot(data,specs)` estimates the mean and variance for the observations in input vector `data`, and plots the pdf of the resulting T distribution. The observations in `data` are assumed to be normally distributed. The output, `p`, is the probability that a new observation from the estimated distribution will fall within the range specified by the two-element vector `specs`. The portion of the distribution between the lower and upper bounds specified in `specs` is shaded in the plot.

`[p,h] = capaplot(data,specs)` additionally returns handles to the plot elements in `h`.

`capaplot` treats NaN values in `data` as missing, and ignores them.

Examples

Create a Process Capability Plot

Randomly generate sample data from a normal process with a mean of 3 and a standard deviation of 0.005.

```
rng default; % For reproducibility
data = normrnd(3,0.005,100,1);
```

Compute capability indices if the process has an upper specification limit of 3.01 and a lower specification limit of 2.99.

```
S = capability(data,[2.99 3.01])
```

```
S = struct with fields:
```

```
  mu: 3.0006  
  sigma: 0.0058  
  P: 0.9129  
  PL: 0.0339  
  Pu: 0.0532  
  Cp: 0.5735  
  Cpl: 0.6088  
  Cpu: 0.5382  
  Cpk: 0.5382
```

Visualize the specification and process widths.

```
capaplot(data,[2.99 3.01]);  
grid on
```

Introduced before R2006a

caseread

Read case names from file

Syntax

```
names = caseread('filename')  
names = caseread
```

Description

`names = caseread('filename')` reads the contents of *filename* and returns a matrix of names. *filename* is the name of a file in the current folder, or the complete path name of any file elsewhere. `caseread` treats each line as a separate case.

`names = caseread` displays the **Select File to Open** dialog box for interactive selection of the input file.

Examples

Read the file `months.dat` created using the `casewrite` function.

```
type months.dat
```

```
January  
February  
March  
April  
May
```

```
names = caseread('months.dat')  
names =  
January  
February  
March  
April  
May
```

See Also

casewrite | gname | tblread | tdfread

Introduced before R2006a

casewrite

Write case names to file

Syntax

```
casewrite(strmat, 'filename')  
casewrite(strmat)
```

Description

`casewrite(strmat, 'filename')` writes the contents of matrix `strmat` to `filename`. Each row of `strmat` represents one case name. `filename` is the name of a file in the current folder, or the complete path name of any file elsewhere. `casewrite` writes each name to a separate line in `filename`.

`casewrite(strmat)` displays the **Select File to Write** dialog box for interactive specification of the output file.

Examples

```
strmat = char('January', 'February', ...  
             'March', 'April', 'May')
```

```
strmat =  
January  
February  
March  
April  
May
```

```
casewrite(strmat, 'months.dat')  
type months.dat
```

```
January  
February  
March
```

April
May

caseread | gname | tblwrite | tdfread

Introduced before R2006a

clustering.evaluation.DaviesBouldinEvaluation class

Package: clustering.evaluation

Superclasses:

Davies-Bouldin criterion clustering evaluation object

Description

`clustering.evaluation.DaviesBouldinEvaluation` is an object consisting of sample data, clustering data, and Davies-Bouldin criterion values used to evaluate the optimal number of clusters. Create a Davies-Bouldin criterion clustering evaluation object using `evalclusters`.

Construction

`eva = evalclusters(x, clust, 'DaviesBouldin')` creates a Davies-Bouldin criterion clustering evaluation object.

`eva = evalclusters(x, clust, 'DaviesBouldin', Name, Value)` creates a Davies-Bouldin criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

Input Arguments

x — Input data

matrix

Input data, specified as an N -by- P matrix. N is the number of observations, and P is the number of variables.

Data Types: `single` | `double`

clust — Clustering algorithm

'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

| | |
|------------------|--|
| 'kmeans' | Cluster the data in <i>x</i> using the kmeans clustering algorithm, with 'EmptyAction' set to 'singleton' and 'Replicates' set to 5. |
| 'linkage' | Cluster the data in <i>x</i> using the clusterdata agglomerative clustering algorithm, with 'Linkage' set to 'ward'. |
| 'gmdistribution' | Cluster the data in <i>x</i> using the gmdistribution Gaussian mixture distribution algorithm, with 'SharedCov' set to true and 'Replicates' set to 5. |

If criterion is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can specify a clustering algorithm using a function handle (MATLAB). The function must be of the form `C = clustfun(DATA,K)`, where *DATA* is the data to be clustered, and *K* is the number of clusters. The output of `clustfun` must be one of the following:

- A vector of integers representing the cluster index for each observation in *DATA*. There must be *K* unique values in this vector.
- A numeric *n*-by-*K* matrix of score for *n* observations and *K* classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If criterion is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can also specify `clust` as a *n*-by-*K* matrix containing the proposed clustering solutions. *n* is the number of observations in the sample data, and *K* is the number of proposed clustering solutions. Column *j* contains the cluster indices for each of the *N* points in the *j*th clustering solution.

Data Types: single | double | char | string | function_handle

Specify optional comma-separated pairs of *Name*, *Value* arguments. *Name* is the argument name and *Value* is the corresponding value. *Name* must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: 'KList', [1:5] specifies to test 1, 2, 3, 4, and 5 clusters to find the optimal number.

KList — List of number of clusters to evaluate

vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of 'KList' and a vector of positive integer values. You must specify KList when `clust` is a clustering algorithm name or a function handle. When `criterion` is 'gap', `clust` must be a character vector, a string scalar, or a function handle, and you must specify KList.

Example: 'KList', [1:6]

Data Types: single | double

Properties

ClusteringFunction

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name or function handle. If the clustering solutions are provided in the input, ClusteringFunction is empty.

CriterionName

Name of the criterion used for clustering evaluation, stored as a valid criterion name.

CriterionValues

Criterion values corresponding to each proposed number of clusters in InspectedK, stored as a vector of numerical values.

InspectedK

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

Missing

Logical flag for excluded data, stored as a column vector of logical values. If `Missing` equals `true`, then the corresponding value in the data matrix `x` is not used in the clustering solution.

NumObservations

Number of observations in the data matrix `X`, minus the number of missing (NaN) values in `X`, stored as a positive integer value.

OptimalK

Optimal number of clusters, stored as a positive integer value.

OptimalY

Optimal clustering solution corresponding to `OptimalK`, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, `OptimalY` is empty.

X

Data used for clustering, stored as a matrix of numerical values.

Methods**Inherited Methods**

| | |
|----------------------|--|
| <code>addK</code> | Evaluate additional numbers of clusters |
| <code>plot</code> | Plot clustering evaluation object criterion values |
| <code>compact</code> | Compact clustering evaluation object |

Examples

Evaluate the Clustering Solution Using Davies-Bouldin Criterion

Evaluate the optimal number of clusters using the Davies-Bouldin clustering evaluation criterion.

Generate sample data containing random numbers from three multivariate distributions with different parameter values.

```
rng('default'); % For reproducibility
mu1 = [2 2];
sigma1 = [0.9 -0.0255; -0.0255 0.9];

mu2 = [5 5];
sigma2 = [0.5 0 ; 0 0.3];

mu3 = [-2, -2];
sigma3 = [1 0 ; 0 0.9];

N = 200;

X = [mvnrnd(mu1,sigma1,N);...
     mvnrnd(mu2,sigma2,N);...
     mvnrnd(mu3,sigma3,N)];
```

Evaluate the optimal number of clusters using the Davies-Bouldin criterion. Cluster the data using `kmeans`.

```
E = evalclusters(X,'kmeans','DaviesBouldin','klist',[1:6])
```

```
E =
  DaviesBouldinEvaluation with properties:

    NumObservations: 600
      InspectedK: [1 2 3 4 5 6]
  CriterionValues: [NaN 0.4663 0.4454 0.8316 1.0444 0.9236]
      OptimalK: 3
```

The `OptimalK` value indicates that, based on the Davies-Bouldin criterion, the optimal number of clusters is three.

Plot the Davies-Bouldin criterion values for each number of clusters tested.

```
figure;
plot(E)
```

The plot shows that the lowest Davies-Bouldin value occurs at three clusters, suggesting that the optimal number of clusters is three.

Create a grouped scatter plot to visually examine the suggested clusters.

```
figure;  
gscatter(X(:,1),X(:,2),E.OptimalY,'rbg','xod')
```

The plot shows three distinct clusters within the data: Cluster 1 is in the lower-left corner, cluster 2 is in the upper-right corner, and cluster 3 is near the center of the plot.

Definitions

Davies-Bouldin Criterion

The Davies-Bouldin criterion is based on a ratio of within-cluster and between-cluster distances. The Davies-Bouldin index is defined as

$$DB = \frac{1}{k} \sum_{i=1}^k \max_{j \neq i} \{D_{i,j}\},$$

where $D_{i,j}$ is the within-to-between cluster distance ratio for the i th and j th clusters. In mathematical terms,

$$D_{i,j} = \frac{(\bar{d}_i + \bar{d}_j)}{d_{i,j}}.$$

\bar{d}_i is the average distance between each point in the i th cluster and the centroid of the i th cluster. \bar{d}_j is the average distance between each point in the j th cluster and the centroid of the j th cluster. $d_{i,j}$ is the Euclidean distance between the centroids of the i th and j th clusters.

The maximum value of $D_{i,j}$ represents the worst-case within-to-between cluster ratio for cluster i . The optimal clustering solution has the smallest Davies-Bouldin index value.

cat

Class: dataset

Concatenate dataset arrays

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
ds = cat(dim, ds1, ds2, ...)
```

Description

`ds = cat(dim, ds1, ds2, ...)` concatenates the dataset arrays `ds1`, `ds2`, ... along dimension `dim` by calling the `dataset/horzcat` or `dataset/vertcat` method. `dim` must be 1 or 2.

See Also

`horzcat` | `vertcat`

catsplit

Class: classregtree

Categorical splits used for branches in decision tree

Note classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

Syntax

```
v=catsplit(t)
v=catsplit(t,j)
```

Description

v=catsplit(t) returns an n-by-2 cell array v. Each row in v gives left and right values for a categorical split. For each branch node j based on a categorical predictor variable z, the left child is chosen if z is in v(j,1) and the right child is chosen if z is in v(j,2). The splits are in the same order as nodes of the tree. Nodes for these splits can be found by running cuttype and selecting 'categorical' cuts from top to bottom.

v=catsplit(t,j) takes an array j of rows and returns the splits for the specified rows.

See Also

classregtree

cdf

Cumulative distribution function for Gaussian mixture distribution

Syntax

```
y = cdf(gm,X)
```

Description

`y = cdf(gm,X)` returns the cumulative distribution function (cdf) of the Gaussian mixture distribution `gm`, evaluated at the values in `X`.

Examples

Compute cdf Values

Create a `gmdistribution` object and compute its cdf values.

Define the distribution parameters (means and covariances) of a two-component bivariate Gaussian mixture distribution.

```
mu = [1 2;-3 -5];  
sigma = [1 1]; % shared diagonal covariance matrix
```

Create a `gmdistribution` object by using the `gmdistribution` function. By default, the function creates an equal proportion mixture.

```
gm = gmdistribution(mu,sigma)
```

```
gm =
```

```
Gaussian mixture distribution with 2 components in 2 dimensions  
Component 1:  
Mixing proportion: 0.500000  
Mean:      1      2
```

```
Component 2:
Mixing proportion: 0.500000
Mean:      -3      -5
```

Compute the cdf values of gm.

```
X = [0 0;1 2;3 3;5 3];
cdf(gm,X)
```

```
ans = 4×1
```

```
    0.5011
    0.6250
    0.9111
    0.9207
```

Plot cdf

Create a gmdistribution object and plot its cdf.

Define the distribution parameters (means, covariances, and mixing proportions) of two bivariate Gaussian mixture components.

```
p = [0.4 0.6];           % Mixing proportions
mu = [1 2;-3 -5];      % Means
sigma = cat(3,[2 .5],[1 1]) % Covariances 1-by-2-by-2 array
```

```
sigma =
sigma(:,:,1) =

    2.0000    0.5000
```

```
sigma(:,:,2) =

    1    1
```

The `cat` function concatenates the covariances along the third array dimension. The defined covariance matrices are diagonal matrices. `sigma(1, :, i)` contains the diagonal elements of the covariance matrix of component `i`.

Create a `gmdistribution` object by using the `gmdistribution` function.

```
gm = gmdistribution(mu,sigma,p)
```

```
gm =
```

```
Gaussian mixture distribution with 2 components in 2 dimensions
```

```
Component 1:
```

```
Mixing proportion: 0.400000
```

```
Mean:      1      2
```

```
Component 2:
```

```
Mixing proportion: 0.600000
```

```
Mean:     -3     -5
```

Plot the cdf of the Gaussian mixture distribution by using `ezsurf`.

```
ezsurf(@(x,y)cdf(gm,[x y]),[-10 10],[-10 10])
```

Input Arguments

gm — Gaussian mixture distribution

gmdistribution object

Gaussian mixture distribution, also called Gaussian mixture model (GMM), specified as a *gmdistribution* object.

You can create a *gmdistribution* object using *gmdistribution* or *fitgmdist*. Use the *gmdistribution* function to create a *gmdistribution* object by specifying the

distribution parameters. Use the `fitgmdist` function to fit a `gmdistribution` model to data given a fixed number of components.

X — Values at which to evaluate cdf

n-by-*m* numeric matrix

Values at which to evaluate the cdf, specified as an *n*-by-*m* numeric matrix, where *n* is the number of observations and *m* is the number of variables in each observation.

Data Types: `single` | `double`

Output Arguments

y — cdf values

n-by-1 numeric vector

cdf values of the Gaussian mixture distribution `gm`, evaluated at `X`, returned as an *n*-by-1 numeric vector, where *n* is the number of observations in `X`.

ccdesign

Central composite design

Syntax

```
dCC = ccdesign(n)
[dCC,blocks] = ccdesign(n)
[...] = ccdesign(n,'Name',value)
```

Description

`dCC = ccdesign(n)` generates a central composite design for n factors. n must be an integer 2 or larger. The output matrix `dCC` is m -by- n , where m is the number of runs in the design. Each row represents one run, with settings for all factors represented in the columns. Factor values are normalized so that the cube points take values between -1 and 1.

`[dCC,blocks] = ccdesign(n)` requests a blocked design. The output `blocks` is an m -by-1 vector of block numbers for each run. Blocks indicate runs that are to be measured under similar conditions to minimize the effect of inter-block differences on the parameter estimates.

`[...] = ccdesign(n,'Name',value)` specifies one or more optional name/value pairs for the design. Valid parameters and their values are listed in the following table. Specify *Name* in single quotes.

| Parameter | Description | Values | Value Description |
|-----------|--------------------------|-----------|---|
| center | Number of center points. | Integer | Number of center points to include. |
| | | 'uniform' | Select number of center points to give uniform precision. |

| Parameter | Description | Values | Value Description |
|-----------|---|-----------------|---|
| | | 'orthogonal' | Select number of center points to give an orthogonal design. This is the default. |
| fraction | Fraction of full-factorial cube, expressed as an exponent of 1/2. | 0 | Whole design. Default when $n \leq 4$. |
| | | 1 | 1/2 fraction. Default when $4 < n \leq 7$ or $n > 11$. |
| | | 2 | 1/4 fraction. Default when $7 < n \leq 9$ |
| | | 3 | 1/8 fraction. Default when $n = 10$. |
| | | 4 | 1/16 fraction. Default when $n = 11$. |
| type | Type of CCD. | 'circumscribed' | Circumscribed (CCC). This is the default. |
| | | 'inscribed' | Inscribed (CCI). |
| | | 'faced' | Faced (CCF). |
| blocksize | Maximum number of points per block. | Integer | The default is Inf. |

Examples

Two-Factor Central Composite Design

Create a 2-factor central composite design.

```
dCC = ccdesign(2, 'type', 'circumscribed')
```

```
dCC = 16×2
```

```
-1.0000    -1.0000  
-1.0000     1.0000  
 1.0000    -1.0000  
 1.0000     1.0000  
-1.4142         0  
 1.4142         0  
         0    -1.4142  
         0     1.4142  
         0         0  
         0         0  
         ⋮
```

The center point is run 8 times to reduce the correlations among the coefficient estimates.

Visualize the design.

```
plot(dCC(:,1),dCC(:,2),'ro','MarkerFaceColor','b')  
X = [1 -1 -1 -1; 1 1 1 -1];  
Y = [-1 -1 1 -1; 1 -1 1 1];  
line(X,Y,'Color','b')  
axis square equal
```

`bbdesign`

Introduced before R2006a

cdf

Package: prob

Cumulative distribution function

Syntax

```
y = cdf('name', x, A)
y = cdf('name', x, A, B)
y = cdf('name', x, A, B, C)
y = cdf('name', x, A, B, C, D)
```

```
y = cdf(pd, x)
```

```
y = cdf(____, 'upper')
```

Description

`y = cdf('name', x, A)` returns the cumulative distribution function (cdf) for the one-parameter distribution family specified by 'name' and the distribution parameter A, evaluated at the values in `x`.

`y = cdf('name', x, A, B)` returns the cdf for the two-parameter distribution family specified by 'name' and the distribution parameters A and B, evaluated at the values in `x`.

`y = cdf('name', x, A, B, C)` returns the cdf for the three-parameter distribution family specified by 'name' and the distribution parameters A, B, and C, evaluated at the values in `x`.

`y = cdf('name', x, A, B, C, D)` returns the cdf for the four-parameter distribution family specified by 'name' and the distribution parameters A, B, C, and D, evaluated at the values in `x`.

`y = cdf(pd, x)` returns the cdf of the probability distribution object `pd`, evaluated at the values in `x`.

`y = cdf(____, 'upper')` returns the complement of the cdf using an algorithm that more accurately computes the extreme upper-tail probabilities. 'upper' can follow any of the input arguments in the previous syntaxes.

Examples

Compute Normal Distribution cdf

Create a standard normal distribution object with the mean, μ , equal to 0 and the standard deviation, σ , equal to 1.

```
mu = 0;  
sigma = 1;  
pd = makedist('Normal',mu,sigma);
```

Define the input vector `x` to contain the values at which to calculate the cdf.

```
x = [-2,-1,0,1,2];
```

Compute the cdf values for the standard normal distribution at the values in `x`.

```
y = cdf(pd,x)
```

```
y =
```

```
    0.0228    0.1587    0.5000    0.8413    0.9772
```

Each value in `y` corresponds to a value in the input vector `x`. For example, at the value `x` equal to 1, the corresponding cdf value `y` is equal to 0.8413.

Alternatively, you can compute the same cdf values without creating a probability distribution object. Use the `cdf` function, and specify a standard normal distribution using the same parameter values for μ and σ .

```
y2 = cdf('Normal',x,mu,sigma)
```

```
y2 =
```

```
0.0228    0.1587    0.5000    0.8413    0.9772
```

The cdf values are the same as those computed using the probability distribution object.

Compute Poisson Distribution cdf

Create a Poisson distribution object with the rate parameter, λ , equal to 2.

```
lambda = 2;  
pd = makedist('Poisson', lambda);
```

Define the input vector x to contain the values at which to calculate the cdf.

```
x = [0, 1, 2, 3, 4];
```

Compute the cdf values for the Poisson distribution at the values in x .

```
y = cdf(pd, x)
```

```
y =
```

```
0.1353    0.4060    0.6767    0.8571    0.9473
```

Each value in y corresponds to a value in the input vector x . For example, at the value x equal to 3, the corresponding cdf value y is equal to 0.8571.

Alternatively, you can compute the same cdf values without creating a probability distribution object. Use the `cdf` function, and specify a Poisson distribution using the same value for the rate parameter, λ .

```
y2 = cdf('Poisson', x, lambda)
```

```
y2 =
```

```
0.1353    0.4060    0.6767    0.8571    0.9473
```

The cdf values are the same as those computed using the probability distribution object.

Plot Standard Normal Distribution cdf

Create a standard normal distribution object.

```
pd = makedist('Normal')
```

```
pd =  
  NormalDistribution  
  
  Normal distribution  
    mu = 0  
    sigma = 1
```

Specify the x values and compute the cdf.

```
x = -3:.1:3;  
cdf_normal = cdf(pd,x);
```

Plot the cdf of the standard normal distribution.

```
plot(x,cdf_normal, 'LineWidth',2)
```

Plot Gamma Distribution cdf

Create three gamma distribution objects. The first uses the default parameter values. The second specifies $a = 1$ and $b = 2$. The third specifies $a = 2$ and $b = 1$.

```
pd_gamma = makedist('Gamma')
```

```
pd_gamma =  
GammaDistribution
```

```
Gamma distribution  
a = 1  
b = 1
```

```
pd_12 = makedist('Gamma','a',1,'b',2)
```

```
pd_12 =  
GammaDistribution  
  
Gamma distribution  
a = 1  
b = 2
```

```
pd_21 = makedist('Gamma','a',2,'b',1)
```

```
pd_21 =  
GammaDistribution  
  
Gamma distribution  
a = 2  
b = 1
```

Specify the x values and compute the cdf for each distribution.

```
x = 0:.1:5;  
cdf_gamma = cdf(pd_gamma,x);  
cdf_12 = cdf(pd_12,x);  
cdf_21 = cdf(pd_21,x);
```

Create a plot to visualize how the cdf of the gamma distribution changes when you specify different values for the shape parameters a and b.

```
figure;  
J = plot(x,cdf_gamma);  
hold on;  
K = plot(x,cdf_12,'r--');  
L = plot(x,cdf_21,'k-.');  
set(J,'LineWidth',2);  
set(K,'LineWidth',2);  
legend([J K L], 'a = 1, b = 1', 'a = 1, b = 2', 'a = 2, b = 1', 'Location', 'southeast');  
hold off;
```

Fit Pareto Tails to t Distribution and Compute the cdf

Fit Pareto tails to a t distribution at cumulative probabilities 0.1 and 0.9.

```
t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);
[p,q] = boundary(obj)
```

p =

```
0.1000
0.9000
```

```
q =
    -1.8487
     2.0766
```

Compute the cdf at the values in `q`.

```
cdf(obj,q)
```

```
ans =
    0.1000
    0.9000
```

Input Arguments

'name' — Probability distribution name

character vector or string scalar of probability distribution name

Probability distribution name, specified as one of the probability distribution names in this table.

| name | Distribution | Input Parameter A | Input Parameter B | Input Parameter C | Input Parameter D |
|--------------------|---|-----------------------------|---|-------------------|-------------------|
| 'Beta' | "Beta Distribution" on page B-4 | a : first shape parameter | b : second shape parameter | — | — |

Example: 'Normal'

x — Values at which to evaluate cdf

scalar value | array of scalar values

Values at which to evaluate the cdf, specified as a scalar value or an array of scalar values.

If one or more of the input arguments *x*, *A*, *B*, *C*, and *D* are arrays, then the array sizes must be the same. In this case, `cdf` expands each scalar input into a constant array of the same size as the array inputs.

Example: [0.1,0.25,0.5,0.75,0.9]

Data Types: single | double

A — First probability distribution parameter

scalar value | array of scalar values

First probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments *x*, *A*, *B*, *C*, and *D* are arrays, then the array sizes must be the same. In this case, `cdf` expands each scalar input into a constant array of the same size as the array inputs.

Data Types: single | double

B — Second probability distribution parameter

scalar value | array of scalar values

Second probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments *x*, *A*, *B*, *C*, and *D* are arrays, then the array sizes must be the same. In this case, `cdf` expands each scalar input into a constant array of the same size as the array inputs.

Data Types: `single` | `double`

C — Third probability distribution parameter

scalar value | array of scalar values

Third probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments x , A , B , C , and D are arrays, then the array sizes must be the same. In this case, `cdf` expands each scalar input into a constant array of the same size as the array inputs.

Data Types: `single` | `double`

D — Fourth probability distribution parameter

scalar value | array of scalar values

Fourth probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments x , A , B , C , and D are arrays, then the array sizes must be the same. In this case, `cdf` expands each scalar input into a constant array of the same size as the array inputs.

Data Types: `single` | `double`

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created with a function or app in this table.

| Function or App | Description |
|----------------------------|--|
| <code>makedist</code> | Create a probability distribution object using specified parameter values. |
| <code>fitdist</code> | Fit a probability distribution object to sample data. |
| Distribution Fitter | Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace. |

| Function or App | Description |
|-----------------|--|
| paretotails | Create a piecewise distribution object that has generalized Pareto distributions in the tails. |

Output Arguments

y — cdf values

scalar value | array of scalar values

cdf values, returned as a scalar value or an array of scalar values. **y** is the same size as **x** after any necessary scalar expansion. Each element in **y** is the cdf value of the distribution, specified by the corresponding elements in the distribution parameters (**A**, **B**, **C**, and **D**) or the probability distribution object (**pd**), evaluated at the corresponding element in **x**.

Alternative Functionality

- **cdf** is a generic function that accepts either a distribution by its name 'name' or a probability distribution object **pd**. It is faster to use a distribution-specific function, such as **normcdf** for the normal distribution and **binocdf** for the binomial distribution. For a list of distribution-specific functions, see “Supported Distributions” on page 5-17.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument 'name' must be a compile-time constant. For example, to use the normal distribution, include `coder.Constant('Normal')` in the `-args` value of `codegen`.
- Code generation does not support the probability distribution object (pd) input argument.

cdfplot

Empirical cumulative distribution function plot

Syntax

```
cdfplot(X)
h = cdfplot(X)
[h,stats] = cdfplot(X)
```

Description

`cdfplot(X)` displays a plot of the empirical cumulative distribution function (cdf) for the data in the vector `X`. The empirical cdf $F(x)$ is defined as the proportion of `X` values less than or equal to `x`.

This plot is useful for examining the distribution of a sample of data. You can overlay a theoretical cdf on the same plot to compare the empirical distribution of the sample to the theoretical distribution.

The `kstest`, `kstest2`, and `lillietest` functions compute test statistics that are derived from the empirical cdf. You may find the empirical cdf plot produced by `cdfplot` useful in helping you to understand the output from those functions.

`h = cdfplot(X)` returns a handle to the cdf curve.

`[h,stats] = cdfplot(X)` also returns a `stats` structure with the following fields.

| Field | Description |
|---------------------------|---------------------------------|
| <code>stats.min</code> | Minimum value |
| <code>stats.max</code> | Maximum value |
| <code>stats.mean</code> | Sample mean |
| <code>stats.median</code> | Sample median (50th percentile) |
| <code>stats.std</code> | Sample standard deviation |

Examples

Compare Empirical cdf with Sampling Distribution

This example shows how to plot the empirical cdf of sample data and compare it with a plot of the cdf for the sampling distribution. In practice, the sampling distribution would be unknown, and would be chosen to match the empirical cdf.

Generate random sample data from an extreme value distribution with a location parameter $\mu = 0$ and scale parameter $\sigma = 3$.

```
rng default; % For reproducibility
y = evrnd(0,3,100,1);
```

Plot the empirical cdf of the sample data on the same figure as the cdf of the sampling distribution.

```
cdfplot(y)
hold on
x = -20:0.1:10;
f = evcdf(x,0,3);
plot(x,f,'m')
legend('Empirical','Theoretical','Location','NW')
```

`ecdf`

Introduced before R2006a

cell2dataset

Convert cell array to dataset array

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
ds = cell2dataset(C)
ds = cell2dataset(C,Name,Value)
```

Description

`ds = cell2dataset(C)` converts a cell array to a dataset array.

`ds = cell2dataset(C,Name,Value)` performs the conversion using additional options specified by one or more `Name,Value` pair arguments.

Examples

Convert Cell Array to Dataset Array

Convert a cell array to a dataset array using the default options.

Create a cell array to convert.

```
C = {'Name', 'Gender', 'SystolicBP', 'DiastolicBP';
     'CLARK', 'M', 124, 93;
     'BROWN', 'F', 122, 80;
     'MARTIN', 'M', 130, 92}
```

```
C = 4x4 cell array
     {'Name' }      {'Gender'}      {'SystolicBP'}      {'DiastolicBP'}
```

```
{'CLARK' } {'M' } {[ 124]} {[ 93]}
{'BROWN' } {'F' } {[ 122]} {[ 80]}
{'MARTIN' } {'M' } {[ 130]} {[ 92]}
```

Convert the cell array to a dataset array.

```
ds = cell2dataset(C)
```

```
ds =
  Name          Gender  SystolicBP  DiastolicBP
  'CLARK'       'M'         124        93
  'BROWN'       'F'         122        80
  'MARTIN'      'M'         130        92
```

The first row of C become the variable names in the output dataset array, ds.

Create a Dataset Array with Multicolumn Variables

Convert a cell array to a dataset array containing multicolumn variables.

Create a cell array to convert.

```
C = {'Name', 'Gender', 'SystolicBP', 'DiastolicBP';
     'CLARK', 'M', 124, 93;
     'BROWN', 'F', 122, 80;
     'MARTIN', 'M', 130, 92}
```

```
C = 4x4 cell array
  {'Name' } {'Gender'} {'SystolicBP'} {'DiastolicBP'}
  {'CLARK' } {'M' } {[ 124]} {[ 93]}
  {'BROWN' } {'F' } {[ 122]} {[ 80]}
  {'MARTIN' } {'M' } {[ 130]} {[ 92]}
```

Convert the cell array to a dataset array, combining the systolic and diastolic blood pressure measurements into one variable named `BloodPressure`.

```
ds = cell2dataset(C, 'NumCols', [1,1,2]);
ds.Properties.VarNames{3} = 'BloodPressure';
ds
```

```
ds =
  Name           Gender  BloodPressure
  'CLARK'        'M'      124           93
  'BROWN'        'F'      122           80
  'MARTIN'       'M'      130           92
```

The output dataset array has three observations and three variables.

- “Create a Dataset Array from Workspace Variables” on page 2-69
- “Create a Dataset Array from a File” on page 2-75

Input Arguments

C — Input cell array

cell array

Input cell array to convert to a dataset array, specified as an M -by- N cell array. Each column of C becomes a variable in the output dataset array, ds . By default, `cell2dataset` assumes that the first row of C contains variable names.

Data Types: `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'ReadVarNames', false, 'ReadObsNames', true` specifies that the first row of the cell array does not contain variable names, but the first column contains observation names.

ReadVarNames — Indicator for whether or not to read variable names

`true` (default) | `false`

Indicator for whether or not to read variable names from the first row of the input cell array, specified as the comma-separated pair consisting of `'ReadVarNames'` and either `true` or `false`. The default value is `true`, unless variable names are specified using the

name-value pair argument `VarNames`. When `ReadVarNames` is `false`, `cell2dataset` creates default variable names if you do not provide any.

Example: `'ReadVarNames', false`

VarNames — Variable names for output dataset array

cell array of character vectors

Variable names for the output dataset array, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of character vectors. You must provide a variable name for each variable in `ds`. The names must be valid MATLAB identifiers, and must be unique.

Example: `'VarNames', {'myVar1', 'myVar2', 'myVar3'}`

ReadObsNames — Indicator for whether or not to read observation names

`false` (default) | `true`

Indicator for whether or not to read observation names from the input cell array, specified as the comma-separated pair consisting of `'ReadObsNames'` and either `true` or `false`. When `ReadObsNames` has the value `true`, `cell2dataset` creates observation names in `ds` using the first column of `C`, and sets `ds.Properties.DimNames` equal to `{C{1,1}, 'Variables'}`.

Example: `'ReadObsNames', true`

ObsNames — Observation names for output dataset array

cell array of character vectors

Observation names for the output dataset array, specified as the comma-separated pair consisting of `'ObsNames'` and a cell array of character vectors. The names do not need to be valid MATLAB identifiers, but they must be unique.

NumCols — Number of columns for each variable

vector of nonnegative integers

Number of columns for each variable in `ds`, specified as the comma-separated pair consisting of `'NumCols'` and a vector of nonnegative integers. When the number of columns for a variable is greater than one, `cell2dataset` combines multiple columns in `C` into a single variable in `ds`. The vector you assign to `NumCols` must sum to `size(C,2)`, or `size(C,1)` if `ReadObsNames` is equal to `true`.

For example, to convert a cell array with eight columns into a dataset array with five variables, specify a vector with five elements that sum to eight, such as 'NumCols', [1, 1, 3, 1, 2].

Output Arguments

ds — Output dataset array

dataset array

Output dataset array, returned by default with a variable for each column of C, an observation for each row of C (except for the first row), and variable names corresponding to the first row of C.

- If you set `ReadVarNames` equal to `false` (or specify `VarNames`), then there is an observation in `ds` for each row of C, and `cell2dataset` creates default variable names (or uses the names in `VarNames`).
- If you set `ReadObsNames` equal to `true`, then `cell2dataset` uses the first column of C as observation names.
- If you specify `NumCols`, then the number of variables in `ds` is equal to the length of the specified vector of column numbers.

“Create a Dataset Array from a File” on page 2-75

“Dataset Arrays” on page 2-139

Introduced in R2012b

cellstr

Class: dataset

Create cell array of character vectors from dataset array

Note The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

`B = cellstr(A)`
`B = cellstr(A, VARS)`

Description

`B = cellstr(A)` returns the contents of the dataset `A`, converted to a cell array of character vectors. The variables in the dataset must support the conversion and must have compatible sizes.

`B = cellstr(A, VARS)` returns the contents of the dataset variables specified by `VARS`. `VARS` is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector.

See Also

`dataset.double` | `dataset.replacedata`

chi2cdf

Chi-square cumulative distribution function

Syntax

```
p = chi2cdf(x,v)
p = chi2cdf(x,v,'upper')
```

Description

`p = chi2cdf(x,v)` computes the chi-square cdf at each of the values in `x` using the corresponding degrees of freedom in `v`. `x` and `v` can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The degrees of freedom parameters in `v` must be positive, and the values in `x` must lie on the interval `[0 Inf]`.

`p = chi2cdf(x,v,'upper')` returns the complement of the chi-square cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The χ^2 cdf for a given value x and degrees-of-freedom ν is

$$p = F(x | \nu) = \int_0^x \frac{t^{(\nu-2)/2} e^{-t/2}}{2^{\nu/2} \Gamma(\nu/2)} dt$$

where $\Gamma(\cdot)$ is the Gamma function.

The chi-square density function with ν degrees-of-freedom is the same as the gamma density function with parameters $\nu/2$ and 2.

Examples

Compute Chi-Square CDF

```
probability = chi2cdf(5,1:5)
```

```
probability = 1×5
```

```
    0.9747    0.9179    0.8282    0.7127    0.5841
```

```
probability = chi2cdf(1:5,1:5)
```

```
probability = 1×5
```

```
    0.6827    0.6321    0.6084    0.5940    0.5841
```

Topics

“Chi-Square Distribution” on page B-28

Introduced before R2006a

chi2gof

Chi-square goodness-of-fit test

Syntax

```
h = chi2gof(x)
h = chi2gof(x,Name,Value)
[h,p] = chi2gof(____)
[h,p,stats] = chi2gof(____)
```

Description

`h = chi2gof(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a normal distribution with a mean and variance estimated from `x`, using the chi-square goodness-of-fit test on page 32-345. The alternative hypothesis is that the data does not come from such a distribution. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = chi2gof(x,Name,Value)` returns a test decision for the chi-square goodness-of-fit test with additional options specified by one or more name-value pair arguments. For example, you can test for a distribution other than normal, or change the significance level of the test.

`[h,p] = chi2gof(____)` also returns the *p*-value `p` of the hypothesis test, using any of the input arguments from the previous syntaxes.

`[h,p,stats] = chi2gof(____)` also returns the structure `stats`, containing information about the test statistic.

Examples

Test for Normal Distribution

Create a standard normal probability distribution object. Generate a data vector x using random numbers from the distribution.

```
pd = makedist('Normal');  
rng default; % for reproducibility  
x = random(pd,100,1);
```

Test the null hypothesis that the data in x comes from a population with a normal distribution.

```
h = chi2gof(x)
```

```
h = 0
```

The returned value $h = 0$ indicates that `chi2gof` does not reject the null hypothesis at the default 5% significance level.

Test Hypothesis at Different Significance Level

Create a standard normal probability distribution object. Generate a data vector x using random numbers from the distribution.

```
pd = makedist('Normal');  
rng default; % for reproducibility  
x = random(pd,100,1);
```

Test the null hypothesis that the data in x comes from a population with a normal distribution at the 1% significance level.

```
[h,p] = chi2gof(x,'Alpha',0.01)
```

```
h = 0
```

```
p = 0.3775
```

The returned value $h = 0$ indicates that `chi2gof` does not reject the null hypothesis at the 1% significance level.

Test for Weibull Distribution Using Probability Distribution Object

Load the light bulb lifetime sample data.

```
load lightbulb
```

Create a vector from the first column of the data matrix, which contains the lifetime in hours of the light bulbs.

```
x = lightbulb(:,1);
```

Test the null hypothesis that the data in `x` comes from a population with a Weibull distribution. Use `fitdist` to create a probability distribution object with `A` and `B` parameters estimated from the data.

```
pd = fitdist(x,'Weibull');  
h = chi2gof(x,'CDF',pd)
```

```
h = 1
```

The returned value `h = 1` indicates that `chi2gof` rejects the null hypothesis at the default 5% significance level.

Test for Poisson Distribution

Create six bins, numbered 0 through 5, to use for data pooling.

```
bins = 0:5;
```

Create a vector containing the observed counts for each bin and compute the total number of observations.

```
obsCounts = [6 16 10 12 4 2];  
n = sum(obsCounts);
```

Fit a Poisson probability distribution object to the data and compute the expected count for each bin. Use the transpose operator `.'` to transform `bins` and `obsCounts` from row vectors to column vectors.

```
pd = fitdist(bins','Poisson','Frequency',obsCounts');  
expCounts = n * pdf(pd,bins);
```

Test the null hypothesis that the data in `obsCounts` comes from a Poisson distribution with a lambda parameter equal to `lambdaHat`.

```
[h,p,st] = chi2gof(bins, 'Ctrs',bins,...
                  'Frequency',obsCounts, ...
                  'Expected',expCounts,...
                  'NParams',1)

h = 0

p = 0.4654

st = struct with fields:
    chi2stat: 2.5550
    df: 3
    edges: [-0.5000 0.5000 1.5000 2.5000 3.5000 5.5000]
    O: [6 16 10 12 6]
    E: [7.0429 13.8041 13.5280 8.8383 6.0284]
```

The returned value `h = 0` indicates that `chi2gof` does not reject the null hypothesis at the default 5% significance level. The vector `E` contains the expected counts for each bin under the null hypothesis, and `O` contains the observed counts for each bin.

Test for Normal Distribution Using Function Handle

Use the probability distribution function `normcdf` as a function handle in the chi-square goodness-of-fit test (`chi2gof`).

Test the null hypothesis that the sample data in the input vector `x` comes from a normal distribution with parameters μ and σ equal to the mean (`mean`) and standard deviation (`std`) of the sample data, respectively.

```
rng('default') % For reproducibility
x = normrnd(50,5,100,1);
h = chi2gof(x, 'cdf',{@normcdf,mean(x),std(x)})

h = 0
```

The returned result `h = 0` indicates that `chi2gof` does not reject the null hypothesis at the default 5% significance level.

Input Arguments

x — Sample data

vector

Sample data for the hypothesis test, specified as a vector.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'NBins',8,'Alpha',0.01` pools the data into eight bins and conducts the hypothesis test at the 1% significance level.

NBins — Number of bins

10 (default) | positive integer value

Number of bins to use for the data pooling, specified as the comma-separated pair consisting of `'NBins'` and a positive integer value. If you specify a value for `NBins`, do not specify a value for `Ctrs` or `Edges`.

Example: `'NBins',8`

Data Types: `single` | `double`

Ctrs — Bin centers

vector

Bin centers, specified as the comma-separated pair consisting of `'Ctrs'` and a vector of center values for each bin. If you specify a value for `Ctrs`, do not specify a value for `NBins` or `Edges`.

Example: `'Ctrs',[1 2 3 4 5]`

Data Types: `single` | `double`

Edges — Bin edges

vector

Bin edges, specified as the comma-separated pair consisting of 'Edges' and a vector of edge values for each bin. If you specify a value for Edges, do not specify a value for NBins or Ctrs.

Example: 'Edges', [-2.5 -1.5 -0.5 0.5 1.5 2.5]

Data Types: single | double

CDF — cdf of hypothesized distribution

probability distribution object | function handle | cell array

The cdf of the hypothesized distribution, specified as the comma-separated pair consisting of 'CDF' and a probability distribution object, function handle, or cell array.

- If CDF is a probability distribution object, the degrees of freedom account for whether you estimate the parameters using `fitdist` or specify them using `makedist`.
- If CDF is a function handle, the distribution function must take `x` as its only argument.
- If CDF is a cell array, the first element must be a function handle, and the remaining elements must be parameter values, one per cell. The function must take `x` as its first argument, and the other parameters in the array as later arguments.

If you specify a value for CDF, do not specify a value for Expected.

Example: 'CDF', `pd_object`

Data Types: single | double

Expected — Expected counts

vector of nonnegative values

Expected counts for each bin, specified as the comma-separated pair of 'Expected' and a vector of nonnegative values. If Expected depends on estimated parameters, use `NParams` to ensure that `chi2gof` correctly calculates the degrees of freedom. If you specify a value for Expected, do not specify a value for CDF.

Example: 'Expected', [19.1446 18.3789 12.3224 8.2432 4.1378]

Data Types: single | double

NParams — Number of estimated parameters

positive integer value

Number of estimated parameters used to describe the null distribution, specified as the comma-separated pair consisting of 'NParams' and a positive integer value. This value

adjusts the degrees of freedom of the test based on the number of estimated parameters used to compute the cdf or expected counts.

The default value for `NParams` depends on how you specify the null distribution:

- If you specify CDF as a probability distribution object, `NParams` is equal to the number of estimated parameters used to create the object.
- If you specify CDF as a function name or handle, the default value of `NParams` is 0.
- If you specify CDF as a cell array, the default value of `NParams` is the number of parameters in the array.
- If you specify `Expected`, the default value of `NParams` is 0.

Example: `'NParams',1`

Data Types: `single` | `double`

EMin — Minimum expected count per bin

5 (default) | nonnegative integer value

Minimum expected count per bin, specified as the comma-separated pair consisting of `'EMin'` and a nonnegative integer value. If the bin at the extreme end of either tail has an expected value less than `EMin`, it is combined with a neighboring bin until the count in each extreme bin is at least 5. If any interior bins have a count less than 5, `chi2gof` displays a warning, but does not combine the interior bins. In that case, you should use fewer bins, or provide bin centers or edges, to increase the expected counts in all bins. Specify `EMin` as 0 to prevent the combining of bins.

Example: `'EMin',0`

Data Types: `single` | `double`

Frequency — Frequency

vector of nonnegative integer values

Frequency of data values, specified as the comma-separated pair consisting of `'Frequency'` and a vector of nonnegative integer values that is the same length as the vector `x`.

Example: `'Frequency',[20 16 13 10 8]`

Data Types: `single` | `double`

Alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

Example: 'Alpha',0.01

Data Types: single | double

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as 1 or 0.

- If $h = 1$, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p — *p*-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

stats — Test statistics

structure

Test statistics, returned as a structure containing the following:

- `chi2stat` — Value of the test statistic.
- `df` — Degrees of freedom of the test.
- `edges` — Vector of bin edges after pooling.
- `0` — Vector of observed counts for each bin.
- `E` — Vector of expected counts for each bin.

Definitions

Chi-Square Goodness-of-Fit Test

The chi-square goodness-of-fit test determines if a data sample comes from a specified probability distribution, with parameters estimated from the data.

The test groups the data into bins, calculating the observed and expected counts for those bins, and computing the chi-square test statistic

$$\chi^2 = \sum_{i=1}^N (O_i - E_i)^2 / E_i ,$$

where O_i are the observed counts and E_i are the expected counts based on the hypothesized distribution. The test statistic has an approximate chi-square distribution when the counts are sufficiently large.

Algorithms

chi2gof compares the value of the test statistic to a chi-square distribution with degrees of freedom equal to $nbins - 1 - nparams$, where $nbins$ is the number of bins used for the data pooling and $nparams$ is the number of estimated parameters used to determine the expected counts. If there are not enough degrees of freedom to conduct the test, chi2gof returns the p -value as NaN.

Topics

“Chi-Square Distribution” on page B-28

Introduced before R2006a

chi2inv

Chi-square inverse cumulative distribution function

Syntax

$X = \text{chi2inv}(P, V)$

Description

$X = \text{chi2inv}(P, V)$ computes the inverse of the chi-square cdf with degrees of freedom specified by V for the corresponding probabilities in P . P and V can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The degrees of freedom parameters in V must be positive, and the values in P must lie in the interval $[0 \ 1]$.

The inverse chi-square cdf for a given probability p and ν degrees of freedom is

$$x = F^{-1}(p | \nu) = \{x : F(x | \nu) = p\}$$

where

$$p = F(x | \nu) = \int_0^x \frac{t^{(\nu-2)/2} e^{-t/2}}{2^{\nu/2} \Gamma(\nu/2)} dt$$

and $\Gamma(\cdot)$ is the Gamma function. Each element of output X is the value whose cumulative probability under the chi-square cdf defined by the corresponding degrees of freedom parameter in V is specified by the corresponding value in P .

Examples

Find a value that exceeds 95% of the samples from a chi-square distribution with 10 degrees of freedom.

```
x = chi2inv(0.95,10)
x =
    18.3070
```

You would observe values greater than 18.3 only 5% of the time by chance.

Topics

“Chi-Square Distribution” on page B-28

Introduced before R2006a

chi2pdf

Chi-square probability density function

Syntax

```
Y = chi2pdf(X,V)
```

Description

`Y = chi2pdf(X,V)` computes the chi-square pdf at each of the values in `X` using the corresponding degrees of freedom in `V`. `X` and `V` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of the output `Y`. A scalar input is expanded to a constant array with the same dimensions as the other input. The degrees of freedom parameters in `V` must be positive, and the values in `X` must lie on the interval `[0 Inf]`.

The chi-square pdf for a given value x and ν degrees of freedom is

$$y = f(x | \nu) = \frac{x^{(\nu-2)/2} e^{-x/2}}{2^{\nu/2} \Gamma(\nu / 2)}$$

where $\Gamma(\cdot)$ is the Gamma function.

If x is standard normal, then x^2 is distributed chi-square with one degree of freedom. If x_1, x_2, \dots, x_n are n independent standard normal observations, then the sum of the squares of the x 's is distributed chi-square with n degrees of freedom (and is equivalent to the gamma density function with parameters $\nu/2$ and 2).

Examples

```
nu = 1:6;  
x = nu;  
y = chi2pdf(x,nu)
```

y =
0.2420 0.1839 0.1542 0.1353 0.1220 0.1120

The mean of the chi-square distribution is the value of the degrees of freedom parameter, nu. The above example shows that the probability density of the mean falls as nu increases.

Extended Capabilities

Topics

“Chi-Square Distribution” on page B-28

Introduced before R2006a

chi2rnd

Chi-square random numbers

Syntax

```
R = chi2rnd(V)
R = chi2rnd(V,m,n,...)
R = chi2rnd(V,[m,n,...])
```

Description

`R = chi2rnd(V)` generates random numbers from the chi-square distribution with degrees of freedom parameters specified by `V`. `V` can be a vector, a matrix, or a multidimensional array. `R` is the same size as `V`. The degrees of freedom parameters in `V` must be positive.

`R = chi2rnd(V,m,n,...)` or `R = chi2rnd(V,[m,n,...])` generates an `m`-by-`n`-by-... array containing random numbers from the chi-square distribution with degrees of freedom parameter `V`. `V` can be a scalar or an array of the same size as `R`.

Examples

Note that the first and third commands are the same, but are different from the second command.

```
r = chi2rnd(1:6)
r =
    0.0037    3.0377    7.8142    0.9021    3.2019    9.0729
```

```
r = chi2rnd(6,[1 6])
r =
    6.5249    2.6226   12.2497    3.0388    6.3133    5.0388
```

```
r = chi2rnd(1:6,1,6)
r =
    0.7638    6.0955    0.8273    3.2506    1.5469   10.9197
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

Topics

“Chi-Square Distribution” on page B-28

Introduced before R2006a

chi2stat

Chi-square mean and variance

Syntax

```
[M,V] = chi2stat(NU)
```

Description

`[M,V] = chi2stat(NU)` returns the mean of and variance for the chi-square distribution with degrees of freedom parameters specified by `NU`. `NU` can be a vector, a matrix, or a multidimensional array. The degrees of freedom parameters in `NU` must be positive.

The mean of the chi-square distribution is ν , the degrees of freedom parameter, and the variance is 2ν .

Examples

```
nu = 1:10;
nu = nu'*nu;
[m,v] = chi2stat(nu)
m =
 1  2  3  4  5  6  7  8  9 10
 2  4  6  8 10 12 14 16 18 20
 3  6  9 12 15 18 21 24 27 30
 4  8 12 16 20 24 28 32 36 40
 5 10 15 20 25 30 35 40 45 50
 6 12 18 24 30 36 42 48 54 60
 7 14 21 28 35 42 49 56 63 70
 8 16 24 32 40 48 56 64 72 80
 9 18 27 36 45 54 63 72 81 90
10 20 30 40 50 60 70 80 90 100

v =
 2  4  6  8 10 12 14 16 18 20
```

“Chi-Square Distribution” on page B-28

Introduced before R2006a

children

Class: `classregtree`

Child nodes

Note `classregtree` has been removed. Use `fitctree`, `fitrtree`, `ClassificationTree`, or `RegressionTree` instead.

Syntax

```
C = children(t)
C = children(t,nodes)
```

Description

`C = children(t)` returns an n -by-2 array `C` containing the numbers of the child nodes for each node in the tree `t`, where n is the number of nodes. Leaf nodes have child node 0.

`C = children(t,nodes)` takes a vector `nodes` of node numbers and returns the children for the specified nodes.

`classregtree` | `numnodes` | `parent`

cholcov

Cholesky-like covariance decomposition

Syntax

```
T = cholcov(SIGMA)
[T,num] = cholcov(SIGMA)
[T,num] = cholcov(SIGMA,θ)
```

Description

`T = cholcov(SIGMA)` computes T such that $SIGMA = T' * T$. $SIGMA$ must be square, symmetric, and positive semi-definite. If $SIGMA$ is positive definite, then T is the square, upper triangular Cholesky factor. If $SIGMA$ is not positive definite, T is computed from an eigenvalue decomposition of $SIGMA$. T is not necessarily triangular or square in this case. Any eigenvectors whose corresponding eigenvalue is close to zero (within a small tolerance) are omitted. If any remaining eigenvalues are negative, T is empty.

`[T,num] = cholcov(SIGMA)` returns the number `num` of negative eigenvalues of $SIGMA$, and T is empty if `num` is positive. If `num` is zero, $SIGMA$ is positive semi-definite. If $SIGMA$ is not square and symmetric, `num` is NaN and T is empty.

`[T,num] = cholcov(SIGMA,θ)` returns `num` equal to zero if $SIGMA$ is positive definite, and T is the Cholesky factor. If $SIGMA$ is not positive definite, `num` is a positive integer and T is empty. `[...] = cholcov(SIGMA,1)` is equivalent to `[...] = cholcov(SIGMA)`.

Examples

The following 4-by-4 covariance matrix is rank-deficient:

```
C1 = [2 1 1 2;1 2 1 2;1 1 2 2;2 2 2 3]
C1 =
     2     1     1     2
     1     2     1     2
     1     1     2     2
```

```
      2      2      2      3
rank(C1)
ans =
      3
```

Use `cholcov` to factor C1:

```
T = cholcov(C1)
T =
    -0.2113    0.7887   -0.5774         0
     0.7887   -0.2113   -0.5774         0
     1.1547    1.1547    1.1547    1.7321
```

```
C2 = T'*T
C2 =
    2.0000    1.0000    1.0000    2.0000
    1.0000    2.0000    1.0000    2.0000
    1.0000    1.0000    2.0000    2.0000
    2.0000    2.0000    2.0000    3.0000
```

Use T to generate random data with the specified covariance:

```
C3 = cov(randn(1e6,3)*T)
C3 =
    1.9973    0.9982    0.9995    1.9975
    0.9982    1.9962    0.9969    1.9956
    0.9995    0.9969    1.9980    1.9972
    1.9975    1.9956    1.9972    2.9951
```

`chol` | `cov`

Introduced in R2007a

classcount

Class: classregtree

Class counts

Note classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

Syntax

`P = classcount(t)`
`P = classcount(t,nodes)`

Description

`P = classcount(t)` returns an n -by- m array P of class counts for the nodes in the classification tree t , where n is the number of nodes and m is the number of classes. For any node number i , the class counts $P(i, :)$ are counts of observations (from the data used in fitting the tree) from each class satisfying the conditions for node i .

`P = classcount(t,nodes)` takes a vector `nodes` of node numbers and returns the class counts for the specified nodes.

ClassificationBaggedEnsemble class

Classification ensemble grown by resampling

Description

`ClassificationBaggedEnsemble` combines a set of trained weak learner models and data on which these learners were trained. It can predict ensemble response for new data by aggregating predictions from its weak learners.

Construction

Create a bagged classification ensemble object using `fitcensemble`.

Properties

`CategoricalPredictors`

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

`ClassNames`

List of the elements in `Y` with duplicates removed. `ClassNames` can be a numeric vector, categorical vector, logical vector, character array, or cell array of character vectors. `ClassNames` has the same data type as the data in the argument `Y`.

`CombineWeights`

Character vector describing how `ens` combines weak learner weights, either `'WeightedSum'` or `'WeightedAverage'`.

ExpandedPredictorNames

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

FitInfo

Numeric array of fit information. The `FitInfoDescription` property describes the content of this array.

FitInfoDescription

Character vector describing the meaning of the `FitInfo` array.

FResample

Numeric scalar between 0 and 1. `FResample` is the fraction of training data `fitcensemble` resampled at random for every weak learner when constructing the ensemble.

HyperparameterOptimizationResults

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- 'bayesopt' (default) — Object of class `BayesianOptimization`
- 'gridsearch' or 'randomsearch' — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

Method

Character vector describing the method that creates `ens`.

ModelParameters

Parameters used in training `ens`.

NumTrained

Number of trained weak learners in `ens`, a scalar.

PredictorNames

Cell array of names for the predictor variables, in the order in which they appear in `X`.

ReasonForTermination

Character vector describing the reason `fitcensemble` stopped adding weak learners to the ensemble.

Replace

Logical value indicating if the ensemble was trained with replacement (`true`) or without replacement (`false`).

ResponseName

Character vector with the name of the response variable `Y`.

ScoreTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. `'none'` means no transformation; equivalently, `'none'` means `@(x)x`. For a list of built-in transformation functions and the syntax of custom transformation functions, see `fitctree`.

Add or change a `ScoreTransform` function using dot notation:

```
ens.ScoreTransform = 'function'
```

or

```
ens.ScoreTransform = @function
```

Trained

Trained learners, a cell array of compact classification models.

TrainedWeights

Numeric vector of trained weights for the weak learners in `ens`. `TrainedWeights` has `T` elements, where `T` is the number of weak learners in `learners`.

UseObsForLearner

Logical matrix of size `N`-by-`NumTrained`, where `N` is the number of observations in the training data and `NumTrained` is the number of trained weak learners.

`UseObsForLearner(I, J)` is `true` if observation `I` was used for training learner `J`, and is `false` otherwise.

W

Scaled weights, a vector with length `n`, the number of rows in `X`. The sum of the elements of `W` is 1.

X

Matrix of predictor values that trained the ensemble. Each column of `X` represents one variable, and each row represents one observation.

Y

A categorical array, cell array of character vectors, character array, logical vector, or a numeric vector with the same number of rows as `X`. Each row of `Y` represents the classification of the corresponding row of `X`.

Methods

| | |
|---|--|
| <code>oobEdge</code> | Out-of-bag classification edge |
| <code>oobLoss</code> | Out-of-bag classification error |
| <code>oobMargin</code> | Out-of-bag classification margins |

| <code>margin</code> | Classification margins |
| <code>predict</code> | Predict labels using ensemble of classification models |
| <code>predictorImportance</code> | Estimates of predictor importance |
| <code>removeLearners</code> | Remove members of compact classification ensemble |

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Train Bagged Ensemble of Classification Trees

Load the ionosphere data set.

```
load ionosphere
```

Train a bagged ensemble of 100 classification trees using all measurements.

```
rng(1) % For reproducibility  
Mdl = fitensemble(X,Y,'Method','bag')
```

```
Mdl =
  classreg.learning.classif.ClassificationBaggedEnsemble
    ResponseName: 'Y'
    CategoricalPredictors: []
      ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
    NumObservations: 351
    NumTrained: 100
    Method: 'Bag'
    LearnerNames: {'Tree'}
    ReasonForTermination: 'Terminated normally after completing the requested number of iterations'
    FitInfo: []
    FitInfoDescription: 'None'
    FResample: 1
    Replace: 1
    UseObsForLearner: [351x100 logical]
```

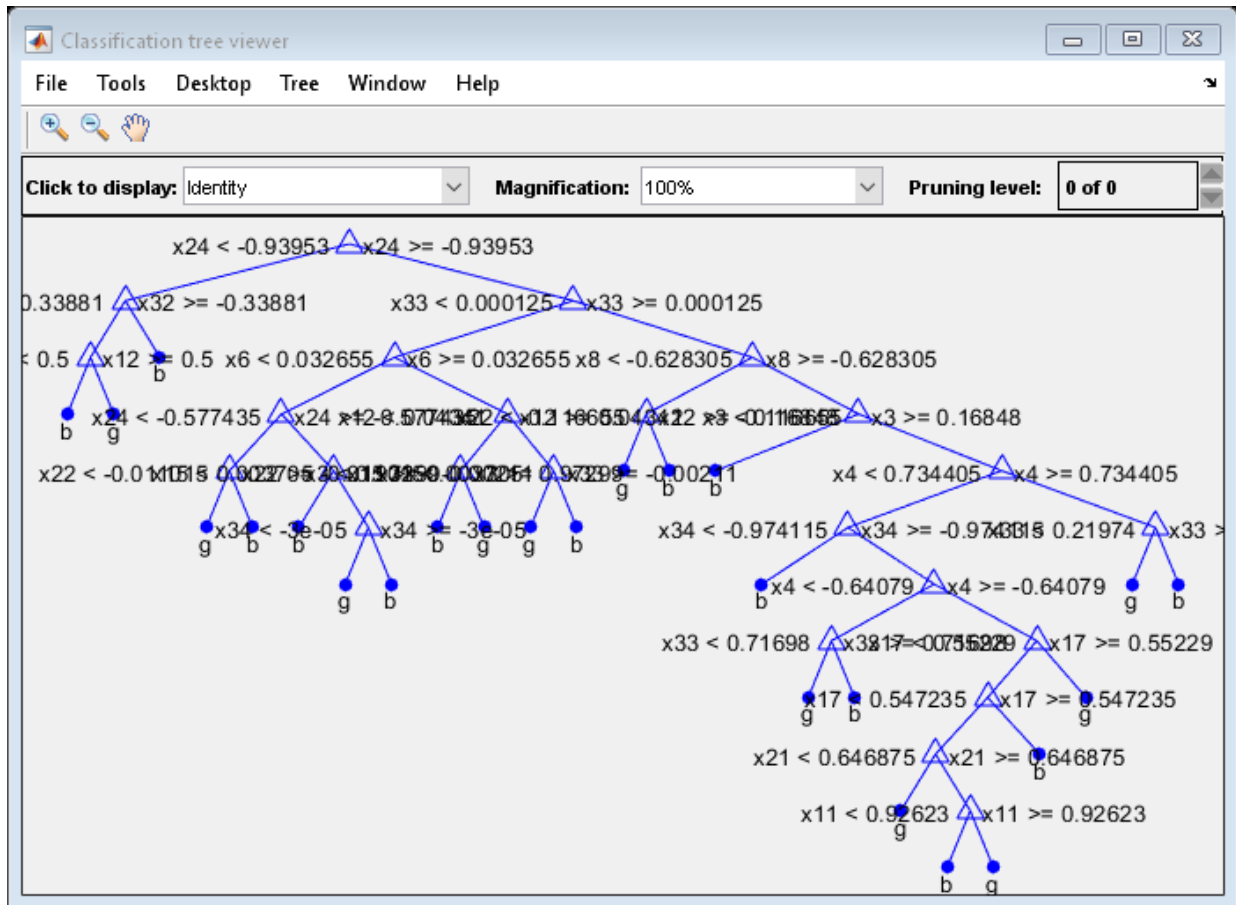

Properties, Methods

Mdl is a `ClassificationBaggedEnsemble` model object.

Mdl.Trained is the property that stores a 100-by-1 cell vector of the trained classification trees (`CompactClassificationTree` model objects) that compose the ensemble.

Plot a graph of the first trained classification tree.

```
view(Mdl.Trained{1}, 'Mode', 'graph')
```

By default, `fitcensemble` grows deep decision trees for bagged ensembles.

Estimate the in-sample misclassification rate.

`L = resubLoss(Mdl)`

`L = 0`

`L` is 0, which indicates that `Mdl` is perfect at classifying the training data.

Tip

For a bagged ensemble of classification trees, the `Trained` property of `ens` stores a cell vector of `ens.NumTrained CompactClassificationTree` model objects. For a textual or graphical display of tree `t` in the cell vector, enter

```
view(ens.Trained{t})
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `predict` function supports code generation.
- When you train an ensemble by using `fitcensemble`, code generation limitations for classification trees also apply to ensembles of classification trees. For more details, see “Code Generation” on page 32-0 of the `CompactClassificationTree` class.

For code generation examples, see “Code Generation Workflow for Prediction” on page 31-5 and “Specify Variable-Sized Arguments for Code Generation” on page 31-48. For more information, see topics in “Code Generation”.

ClassificationECOC class

Superclasses:

Multiclass model for support vector machines or other classifiers

Description

`ClassificationECOC` is an error-correcting output codes on page 32-382 (ECOC) classifier for multiclass learning by reduction to multiple binary classifiers such as support vector machines (SVMs). Train a `ClassificationECOC` classifier using `fitcecoc` and the training data.

Trained `ClassificationECOC` classifiers store the training data, parameter values, prior probabilities, and coding matrices. You can use these classifiers to:

- Estimate resubstitution predictions. For details, see `resubPredict`.
- Predict labels or posterior probabilities for new data. For details, see `predict`.

Construction

`Mdl = fitcecoc(Tbl, ResponseVarName)` returns a full, trained, multiclass error-correcting output codes (ECOC) model on page 32-1873 using the predictors in table `Tbl` and the class labels in `Tbl.ResponseVarName`. By default, `fitcecoc` uses $K(K - 1)/2$ binary support vector machine (SVM) models using the one-versus-one coding design on page 32-1869, where K is the number of unique class labels (levels). `Mdl` is a `ClassificationECOC` model.

`Mdl = fitcecoc(Tbl, formula)` returns an ECOC model using the predictor data and class labels in table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used for training.

`Mdl = fitcecoc(Tbl, Y)` returns an ECOC model using the predictors in table `Tbl` and the class labels in vector `Y`.

`Mdl = fitcecoc(X, Y)` returns a full trained ECOC model using the predictors `X` and the class labels `Y`.

`Mdl = fitcecoc(____, Name, Value)` returns an ECOC model with additional options specified by one or more `Name, Value` pair arguments, using any of the previous syntaxes. For example, specify different binary learners, a different coding design, or cross-validation. It is good practice to cross-validate using the `Kfold Name, Value` pair argument. The cross-validation results determine how well the ECOC classifier generalizes.

If you specify one of the following five options, then `Mdl` is a `ClassificationPartitionedECOC` model: `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'Kfold'`, or `'Leaveout'`. Otherwise, `Mdl` is a `ClassificationECOC` classifier.

Input Arguments

Tbl — Sample data

table

Sample data, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not accepted.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, specify a formula using `formula`.

If `Tbl` does not contain the response variable, specify a response variable using `Y`. The length of response variable and the number of `Tbl` rows must be equal.

Note For training linear classification models, `fitcecoc` does not support tables. That is, if `Learners` is `'linear'` or contains a linear classification model learner template (see `templateLinear`), you cannot supply `Tbl`, `ResponseVarName`, or `formula`. Supply a matrix of predictor data (`X`) and an array of responses (`Y`) instead.

Data Types: table

ResponseVarName — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

It is a good practice to specify the order of the classes by using the `ClassNames` name-value pair argument.

Data Types: `char`

formula — Explanatory model of response and subset of predictor variables

character vector

Explanatory model of the response and a subset of the predictor variables, specified as a character vector in the form of `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char`

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Class labels to which the ECOC model is trained, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors.

If `Y` is a character array, then each element must correspond to one row of the array.

The length of `Y` and the number of rows of `Tbl` or `X` must be equal.

It is good practice to specify the class order using the `ClassNames` name-value pair argument.

Data Types: `char` | `cell` | `categorical` | `logical` | `single` | `double`

X — Predictor data

matrix of numeric values

Predictor data to which the ECOC classifier is trained, specified as a matrix of numeric values.

- If `Learners` is `'linear'` or contains a linear classification model learner template (see `templateLinear`), the rows of `X` must correspond to predictor (feature) variables, and columns must correspond to observations (instances or examples). This orientation enhances memory-allocation management of high-dimensional data.
- Otherwise, each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one predictor.

The length of `Y` and the number of rows of `X` must be equal.

Data Types: `double` | `single`

Note The software treats NaN, empty character vector (''), and `<undefined>` elements as missing data. The software removes rows of `X` corresponding to missing values in `Y`. However, the treatment of missing values in `X` varies among binary learners. For details, see the training functions for your binary learners: `fitcdiscr`, `fitcknn`, `fitclinear`, `fitcnb`, `fitcsvm`, `fitctree`, or `fitcensemble`. Removing observations decreases the effective training or cross-validation sample size.

Properties

BinaryLearners — Trained binary learners

cell vector of model objects

Trained binary learners, specified as a cell vector of model objects. `BinaryLearners` has as many elements as classes in `Y`.

The software trained `BinaryLearner{j}` according to the binary problem specified by `CodingMatrix(:,j)`. For example, for multiclass learning using SVM learners, each element of `BinaryLearners` is a `CompactClassificationSVM` classifier.

Data Types: `cell`

BinaryLoss — Binary learner loss function

character vector representing the loss function name

Binary learner loss function, specified as a character vector representing the loss function name.

If you train using binary learners that use different loss functions, then the software sets `BinaryLoss` to 'hamming'. To potentially increase accuracy, set a different binary loss function than this default during prediction or loss computation using the `BinaryLoss` name-value pair argument of `predict` or `loss`.

Data Types: char

BinaryY — Binary learner class labels

numeric matrix

Binary learner class labels, specified as a numeric matrix. `BinaryY` is a `NumObservations-by-L` matrix, where L is the number of binary learners (`size(CodingMatrix,2)`).

Elements of `BinaryY` are -1, 0, or 1, and the value corresponds to a dichotomous class assignment. This table describes how learner j assigns observation k to a dichotomous class corresponding to the value of `BinaryY(k,j)`.

| Value | Dichotomous Class Assignment |
|-------|---|
| -1 | Negative class |
| 0 | Before training, learner j removes observations in class i from the data set. |
| 1 | Positive class |

Data Types: double

CategoricalPredictors — Indices of categorical predictors

vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: single | double

ClassNames — Unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` has the same data type as class labels (`Y`). `ClassNames` also determines the class order.

Data Types: categorical | char | logical | single | double | cell

CodingMatrix — Class-assignment codes

numeric matrix

Class-assignment codes for the binary learners, specified as a numeric matrix. `CodingMatrix` is a K -by- L matrix, where K is the number of classes and L is the number of binary learners.

Elements of `CodingMatrix` are -1 , 0 , or 1 , and the value corresponds to a dichotomous class assignment. This table describes the meaning of `CodingMatrix(i, j)`, that is, the class that learner j assigns to observations in class i .

| Value | Dichotomous Class Assignment |
|-------|---|
| -1 | Negative class |
| 0 | Before training, learner j removes observations in class i from the data set. |
| 1 | Positive class |

Data Types: double | single | int8 | int16 | int32 | int64

CodingName — Coding design name

character vector

Coding design name, specified as a character vector. For more details, see “Coding Design” on page 32-384.

Data Types: char

Cost — Misclassification costs

square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. `Cost` has K rows and columns, where K is the number of classes.

`Cost(i, j)` is the cost of classifying a point into class j if its true class is i . The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: `double`

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

HyperparameterOptimizationResults — Description of the cross-validation optimization of hyperparameters

BayesianOptimization object | table of hyperparameters and associated values

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- `'bayesopt'` (default) — Object of class `BayesianOptimization`
- `'gridsearch'` or `'randomsearch'` — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

Data Types: `table`

LearnerWeights — Binary learner weights

numeric row vector

Binary learner weights, specified as a numeric row vector. `LearnerWeights` has length equal to the number of binary learners (`size(CodingMatrix, 2)`).

`LearnerWeights(j)` is the sum of the observation weights that binary learner j used to train its classifier.

The software uses `LearnerWeights` to fit posterior probabilities by minimizing the Kullback-Leibler divergence.

Data Types: `double` | `single`

ModelParameters — Parameter values

object

Parameter values, e.g., the name-value pair argument values, used to train the ECOC classifier, specified as an object. `ModelParameters` does not contain estimated parameters.

Access properties of `ModelParameters` using dot notation. For example, list the templates containing parameters the binary learners using `Mdl.ModelParameters.BinaryLearner`.

NumObservations — Number of observations

positive numeric scalar

Number of observations in the training data, specified as a positive numeric scalar.

Data Types: `double`

PredictorNames — Predictor names

cell array of character vectors

Predictor names in order of their appearance in predictor data (X), specified as a cell array of character vectors. The length of `PredictorNames` is equal to the number of columns in X .

Data Types: `cell`

Prior — Prior class probabilities

numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. `Prior` has as many elements as classes in `ClassNames`, and the order of the elements corresponds to the elements of `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: double

ResponseName — Response variable name

character array

Response variable name, specified as a character array.

Data Types: char

ScoreTransform — Score transformation function to apply to predicted scores

character vector | function handle

Score transformation function to apply to predicted scores, specified as a character vector or function handle.

To change the score transformation function to, for example, *function*, use dot notation.

- For a built-in function, enter this code and replace *function* with a character vector in the table.

```
Mdl.ScoreTransform = 'function';
```

| Value | Description |
|----------------------|--|
| 'doublelogit' | $1/(1 + e^{-2x})$ |
| 'invlogit' | $\log(x / (1-x))$ |
| 'ismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0 |
| 'logit' | $1/(1 + e^{-x})$ |
| 'none' or 'identity' | x (no transformation) |
| 'sign' | -1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$ |
| 'symmetric' | $2x - 1$ |

| Value | Description |
|------------------|---|
| 'symmetricismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1 |
| 'symmetriclogit' | $2/(1 + e^{-x}) - 1$ |

- For a MATLAB function, or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Data Types: char | function_handle

W — Observation weights

numeric vector

Observation weights used to train the classifier, specified as a numeric vector. **W** has `NumObservations` elements.

The software normalizes the weights used for training so that `nansum(W)` is 1.

Data Types: single | double

X — Unstandardized predictor data used to train the classifier

numeric matrix

Unstandardized predictor data used to train the classifier, specified as a numeric matrix. **X** is a `NumObservations-by-p` matrix, where *p* is the number of predictors.

Each row of **X** corresponds to one observation, and each column corresponds to one variable.

Data Types: single | double

Y — Observed class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Observed class labels used to train the classifier, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. **Y** has

NumObservations elements, and is the same data type as the input argument Y of fitcecoc.

Each row of Y represents the observed classification of the corresponding row of Tbl or X.

Methods

| | |
|--------------|--|
| compact | Compact multiclass, error-correcting output codes model |
| crossval | Cross-validate multiclass, error-correcting output codes model |

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Train Multiclass Model Using SVM Learners

Train an error-correcting output codes (ECOC) multiclass model using support vector machine (SVM) binary learners.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Train an ECOC multiclass model using the default options.

```
Mdl = fitcecoc(X,Y)
```

```
Mdl =
  ClassificationECOC
      ResponseName: 'Y'
  CategoricalPredictors: []
          ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
   BinaryLearners: {3x1 cell}
        CodingName: 'onevsone'
```

Properties, Methods

Mdl is a `ClassificationECOC` model. By default, `fitcecoc` uses SVM binary learners, and uses a one-versus-one coding design. You can access Mdl properties using dot notation.

Display the coding design matrix.

```
Mdl.ClassNames
```

```
ans = 3x1 cell array
    {'setosa' }
    {'versicolor'}
    {'virginica' }
```

```
CodingMat = Mdl.CodingMatrix
```

```
CodingMat = 3x3
```

```
     1     1     0
    -1     0     1
     0    -1    -1
```

A one-versus-one coding design on three classes yields three binary learners. Columns of `CodingMat` correspond to learners, and rows correspond to classes. The class order corresponds to the order in `Mdl.ClassNames`. For example, `CodingMat(:,1)` is `[1; -1; 0]` and indicates that the software trains the first SVM binary learner using all observations classified as 'setosa' and 'versicolor'. Since 'setosa' corresponds to 1, it is the positive class, and since 'versicolor' corresponds to -1, it is the negative class.

You can access each binary learner using cell indexing and dot notation.

```
Mdl.BinaryLearners{1}           % The first binary learner
```

```
ans =
  classreg.learning.classif.CompactClassificationSVM
      ResponseName: 'Y'
  CategoricalPredictors: []
          ClassNames: [-1 1]
      ScoreTransform: 'none'
              Beta: [4x1 double]
              Bias: 1.4505
      KernelParameters: [1x1 struct]
```

```
Properties, Methods
```

Compute the in-sample classification error.

```
isLoss = resubLoss(Mdl)
```

```
isLoss = 0.0067
```

The classification error is small, but the classifier might have been overfit. You can cross-validate the classifier using `crossval`.

Inspect Binary Learner Properties of ECOC Classifiers

You can access properties of binary learners, such as estimated parameters, using dot notation.

Load Fisher's iris data set. Use the petal dimensions as predictors.

```
load fisheriris
X = meas(:,3:4);
Y = species;
```

Train an ECOC classifier using the SVM binary learners and the default coding design (one-versus-one). Standardize the predictors and save the support vectors.

```
t = templateSVM('Standardize',1,'SaveSupportVectors',true);
predictorNames = {'petalLength','petalWidth'};
responseName = 'irisSpecies';
classNames = {'setosa','versicolor','virginica'}; % Specify class order
Mdl = fitcecoc(X,Y,'Learners',t,'ResponseName',responseName,...
    'PredictorNames',predictorNames,'ClassNames',classNames)
```

`t` is a template object that contains options for SVM classification. All properties are empty (`[]`), except for `Method`, `SaveSupportVectors`, `StandardizeData`, and `Type`. `fitcecoc` uses the default values of the empty properties. `Mdl` is a `ClassificationECOC` classifier. You can access its properties using dot notation.

Display the class names and coding design matrix.

```
Mdl.ClassNames
Mdl.CodingMatrix
L = size(Mdl.CodingMatrix,2); % Number of SVMs
```

The columns correspond to SVM binary learners, and the rows to the distinct classes. The row order corresponds to the order of the `ClassNames` property of `Mdl`. For each column:

- A 1 indicates that `fitcecoc` trained the SVM using observations in the corresponding class as members of the positive group.
- A -1 indicates that `fitcecoc` trained the SVM using observations in the corresponding class as members of the negative group.
- A 0 indicates that the SVM did not use observations in the corresponding class.

For example, `fitcecoc` assigns all observations to 'setosa' or 'versicolor', but not 'virginica' in the first SVM.

You can access properties of the SVMs using cell subscripting and dot notation. Store the standardized support vectors of each SVM. Unstandardize the support vectors.

```
sv = cell(L,1); % Preallocate for support vector indices
for j = 1:L;
    SVM = Mdl.BinaryLearners{j};
    sv{j} = SVM.SupportVectors;
    sv{j} = bsxfun(@plus,bsxfun(@times,sv{j},SVM.Sigma),SVM.Mu);
end
```

`sv` is a cell array of matrices containing the unstandardized support vectors for the SVMs.

Plot the data, and identify the support vectors.

```
figure;
h = zeros(3 + L,1); % Preallocate for handles
h(1:3) = gscatter(X(:,1),X(:,2),Y);
hold on;
markers = {'ko','ro','bo'};
for j = 1:L;
    svs = sv{j};
    h(j + 3) = plot(svs(:,1),svs(:,2),markers{j},...
        'MarkerSize',10 + (j - 1)*3);
end
title 'Fisher's Iris -- ECOC Support Vectors';
xlabel(predictorNames{1});
ylabel(predictorNames{2});
legend(h,[classNames',{'Support vectors - SVM 1',...
    'Support vectors - SVM 2','Support vectors - SVM 3'}],...
    'Location','Best')
hold off
```

You can pass `Mdl` to:

- `predict` to classify new observations
- `resubLoss` to estimate the in-sample classification error
- `crossval` to perform 10-fold cross validation.

Cross-Validate ECOC Classifier

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
rng(1); % For reproducibility
```

Create an SVM template. It is good practice to standardize the predictors.

```
t = templateSVM('Standardize',1)

t =
Fit template for classification SVM.

          Alpha: [0x1 double]
    BoxConstraint: []
          CacheSize: []
    CachingMethod: ''
          ClipAlphas: []
DeltaGradientTolerance: []
          Epsilon: []
          GapTolerance: []
          KKTolerance: []
    IterationLimit: []
    KernelFunction: ''
          KernelScale: []
          KernelOffset: []
KernelPolynomialOrder: []
          NumPrint: []
              Nu: []
    OutlierFraction: []
    RemoveDuplicates: []
    ShrinkagePeriod: []
          Solver: ''
    StandardizeData: 1
    SaveSupportVectors: []
```

```
VerbosityLevel: []  
Version: 2  
Method: 'SVM'  
Type: 'classification'
```

`t` is an SVM template. All of its properties are empty, except for `StandardizeData`, `Method`, and `Type`. When the software trains the ECOC classifier, it sets the applicable properties to their default values.

Train the ECOC classifier. It is good practice to specify the class order.

```
Mdl = fitcecoc(X,Y,'Learners',t,...  
    'ClassNames',{'setosa','versicolor','virginica'});
```

`Mdl` is a `ClassificationECOC` classifier. You can access its properties using dot notation.

Cross-validate `Mdl` using 10-fold cross-validation.

```
CVMdl = crossval(Mdl);
```

`CVMdl` is a `ClassificationPartitionedECOC` cross-validated ECOC classifier.

Estimate the generalization error.

```
oosLoss = kfoldLoss(CVMdl)
```

```
oosLoss = 0.0400
```

The out-of-sample classification error is 4%, which indicates that the ECOC classifier generalizes fairly well.

Definitions

Error-Correcting Output Codes Model

An error-correcting output codes (ECOC) model reduces the problem of classification with three or more classes to a set of binary classifiers.

ECOC classification requires a coding design, which determines the classes that the binary learners train on, and a decoding scheme, which determines how the results (predictions) of the binary classifiers are aggregated.

Suppose that:

- There are three classes.
- The coding design is one-versus-one.
- The decoding scheme uses loss g .
- The learners are SVMs.

To build this classification model, ECOC follows these steps.

- 1 A one-versus-one coding design is

| | Learner 1 | Learner 2 | Learner 3 |
|---------|-----------|-----------|-----------|
| Class 1 | 1 | 1 | 0 |
| Class 2 | -1 | 0 | 1 |
| Class 3 | 0 | -1 | -1 |

Learner 1 trains on observations having Class 1 and Class 2, and treats Class 1 as the positive class and Class 2 as the negative class. The other learners are trained similarly. Let M be the coding design matrix with elements m_{kl} , and s_l be the predicted classification score for the positive class of learner l .

- 2 A new observation is assigned to the class (\hat{k}) that minimizes the aggregation of the losses for the L binary learners. That is,

$$\hat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{l=1}^L |m_{kl}| g(m_{kl}, s_l)}{\sum_{l=1}^L |m_{kl}|}.$$

ECOC models can improve classification accuracy, even compared to other multiclass models [2].

Coding Design

A coding design is a matrix where elements direct which classes are trained by each binary learner, that is, how the multiclass problem is reduced to a series of binary problems.

Each row of the coding design corresponds to a distinct class, and each column corresponds to a binary learner. In a ternary coding design (adopted by the software), for a particular column (or binary learner):

- Rows containing a 1 indicate to the binary learner to group all observations in the corresponding classes into a positive class.
- Rows containing a -1 indicate to the binary learner to group all observations in the corresponding classes into a negative class.
- Rows containing a 0 indicate to the binary learner to ignore all observations in the corresponding classes.

Coding matrices with large, minimal, pair-wise row distances based on the Hamming measure are desirable. For details on the pair-wise row distance, see “Random Coding Design Matrices” on page 32-1877 and [4].

This table describes popular coding designs. For the example, suppose K (the number of distinct classes) is 3.

| Coding Design | Description | Number of Learners | Minimal Pair-Wise Row Distance |
|----------------------|--|--------------------|--------------------------------|
| one-versus-all (OVA) | For each binary learner, one class is positive and the rest are negative. This design exhausts all combinations of positive class assignments. | K | 2 |

| Coding Design | Description | Number of Learners | Minimal Pair-Wise Row Distance |
|----------------------|--|-------------------------|--------------------------------|
| one-versus-one (OVO) | For each binary learner, one class is positive, another is negative, and the rest are ignored. This design exhausts all combinations of class pair assignments. | $K(K - 1)/2$ | 1 |
| binary complete | This design partitions the classes into all binary combinations, and does not ignore any classes. That is, all class assignments are -1 and 1 with at least one positive and negative class in the assignment for each binary learner. | $2^{K-1} - 1$ | 2^{K-2} |
| ternary complete | This design partitions the classes into all ternary combinations. That is, all class assignments are 0, -1, and 1 with at least one positive and negative class in the assignment for each binary learner. | $(3^K - 2^{K+1} + 1)/2$ | 3^{K-2} |

| Coding Design | Description | Number of Learners | Minimal Pair-Wise Row Distance |
|---------------|---|---|--------------------------------|
| ordinal | For the first binary learner, the first class is negative, and the rest positive. For the second binary learner, the first two classes are negative, and the rest positive, and so on. | $K - 1$ | 1 |
| dense random | For each binary learner, the software randomly assigns classes into positive or negative classes, with at least one of each type. For more details, see “Random Coding Design Matrices” on page 32-1877. | Random, but approximately $10 \log_2 K$ | Variable |
| sparse random | For each binary learner, the software randomly assigns classes as positive or negative with probability 0.25 for each, and ignores classes with probability 0.5. For more details, see “Random Coding Design Matrices” on page 32-1877. | Random, but approximately $15 \log_2 K$ | Variable |

This plot compares the number of binary learners for the coding designs with increasing K .

Algorithms

Random Coding Design Matrices

For a given number of classes, for example, K , the software generates random coding design matrices as follows.

- 1 The software generates one of the following:
 - a Dense random — The software assigns a 1 or -1 with equal probability to each element of the K -by- L_d coding design matrix, where $L_d \approx \lceil 10 \log_2 K \rceil$.

- b** Sparse random — The software assigns a 1 to each element of the K -by- L_s coding design matrix with probability 0.25, a -1 with probability 0.25, and a 0 with probability 0.5, where $L_s \approx \lceil 15 \log_2 K \rceil$.
- 2** If a column does not contain at least one 1 and at least one -1, then the software removes that column.
- 3** For distinct columns u and v , if $u = v$ or $u = -v$, then the software removes v from the coding design matrix.

The software randomly generates 10,000 matrices by default, and retains the matrix with the largest, minimal pairwise row distance based on the Hamming measure ([4]) given by

$$\Delta(k_1, k_2) = 0.5 \sum_{l=1}^L |m_{k_1, l} - m_{k_2, l}|,$$

where $m_{k,l}$ is an element of coding design matrix j .

Support Vector Storage

For linear, SVM binary learners, and for efficiency, `fitcecoc` empties the properties `Alpha`, `SupportVectorLabels`, and `SupportVectors`. `fitcecoc` lists `Beta`, rather than `Alpha`, in the model display.

To store `Alpha`, `SupportVectorLabels`, and `SupportVectors`, pass a linear, SVM template that specifies storing support vectors to `fitcecoc`. For example, enter:

```
t = templateSVM('SaveSupportVectors', 'on')
Mdl = fitcecoc(X, Y, 'Learners', t);
```

You can remove the support vectors and related values by passing the resulting `ClassificationECOC` model to `discardSupportVectors`.

Alternatives

You can use these alternative algorithms to train a multiclass model:

- Classification ensembles—see `fitcensemble` and `ClassificationEnsemble`
- Classification trees—see `fitctree` and `ClassificationTree`

- Discriminant analysis classifiers—see `fitcdiscr` and `ClassificationDiscriminant`
- k -nearest neighbor classifiers—see `fitcknn` and `ClassificationKNN`
- Naive Bayes classifiers—see `fitcnb` and `ClassificationNaiveBayes`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `predict` function supports code generation.
- When you train an ECOC model by using `fitcecoc`, the following restrictions apply.
 - You cannot fit posterior probabilities by using the `'FitPosterior'` name-value pair argument.
 - All binary learners must be either SVM classifiers or linear classification models. For the `'Learners'` name-value pair argument, you can specify:
 - `'svm'` or `'linear'`
 - An SVM template object or a cell vector of such objects (see `templateSVM`)
 - A linear classification model template object or a cell vector of such objects (see `templateLinear`)

- Code generation limitations for SVM classifiers and linear classification models also apply to ECOC classifiers, depending on the choice of binary learners. For more details, see “Code Generation” on page 32-0 of the `ClassificationSVM` class and “Code Generation” on page 32-0 of the `ClassificationLinear` class.

For code generation examples, see “Code Generation Workflow for Prediction” on page 31-5 and “Specify Variable-Sized Arguments for Code Generation” on page 31-48. For more information, see topics in “Code Generation”.

Introduced in R2014b

ClassificationDiscriminant class

Superclasses:

Discriminant analysis classification

Description

A `ClassificationDiscriminant` object encapsulates a discriminant analysis classifier, which is a Gaussian mixture model for data generation. A `ClassificationDiscriminant` object can predict responses for new data using the `predict` method. The object contains the data used for training, so can compute resubstitution predictions.

Construction

`Mdl = fitcdiscr(Tbl, ResponseVarName)` returns a fitted discriminant analysis model based on the input variables (also known as predictors, features, or attributes) contained in the table `Tbl` and output (response or labels) contained in `ResponseVarName`.

`Mdl = fitcdiscr(Tbl, formula)` returns a fitted discriminant analysis model based on the predictor data and class labels in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`.

`Mdl = fitcdiscr(Tbl, Y)` returns a fitted discriminant analysis model based on the input variables contained in the table `Tbl` and response `Y`.

`Mdl = fitcdiscr(X, Y)` returns a discriminant analysis classifier based on the input variables `X` and response `Y`.

`Mdl = fitcdiscr(____, Name, Value)` fits a classifier with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can specify the cost of misclassification, prior probabilities for each class, or observation weights.

Input Arguments

Tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

ResponseVarName — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

It is a good practice to specify the order of the classes by using the `ClassNames` name-value pair argument.

Data Types: `char`

formula — Explanatory model of response and subset of predictor variables

character vector

Explanatory model of the response and a subset of the predictor variables, specified as a character vector in the form of `'Y~X1+X2+X3'`. In this form, `Y` represents the response

variable, and X1, X2, and X3 represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char`

Y — Class labels

numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Each row of `Y` represents the classification of the corresponding row of `X`.

The software considers NaN, '' (empty character vector), and <undefined> values in `Y` to be missing values. Consequently, the software does not train using observations with a missing response.

Data Types: `single` | `double` | `logical` | `char` | `cell`

X — Predictor data

numeric matrix

Predictor values, specified as a numeric matrix. Each column of `X` represents one variable, and each row represents one observation.

`fitcdiscr` considers NaN values in `X` as missing values. `fitcdiscr` does not use observations with missing values for `X` in the fit.

Data Types: `single` | `double`

Properties

BetweenSigma

p-by-p matrix, the between-class covariance, where p is the number of predictors.

CategoricalPredictors

Categorical predictor indices, which is always empty (`[]`).

ClassNames

List of the elements in the training data Y with duplicates removed. `ClassNames` can be a categorical array, cell array of character vectors, character array, logical vector, or a numeric vector. `ClassNames` has the same data type as the data in the argument Y .

Coeffs

k -by- k structure of coefficient matrices, where k is the number of classes. `Coeffs(i, j)` contains coefficients of the linear or quadratic boundaries between classes i and j . Fields in `Coeffs(i, j)`:

- `DiscrimType`
- `Class1` — `ClassNames(i)`
- `Class2` — `ClassNames(j)`
- `Const` — A scalar
- `Linear` — A vector with p components, where p is the number of columns in X
- `Quadratic` — p -by- p matrix, exists for quadratic `DiscrimType`

The equation of the boundary between class i and class j is

$$\text{Const} + \text{Linear} * x + x' * \text{Quadratic} * x = 0,$$

where x is a column vector of length p .

If `fitcdiscr` had the `FillCoeffs` name-value pair set to 'off' when constructing the classifier, `Coeffs` is empty (`[]`).

Cost

Square matrix, where `Cost(i, j)` is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`. The number of rows and columns in `Cost` is the number of unique classes in the response.

Change a `Cost` matrix using dot notation: `obj.Cost = costMatrix`.

Delta

Value of the Delta threshold for a linear discriminant model, a nonnegative scalar. If a coefficient of `obj` has magnitude smaller than `Delta`, `obj` sets this coefficient to 0, and

so you can eliminate the corresponding predictor from the model. Set `Delta` to a higher value to eliminate more predictors.

`Delta` must be 0 for quadratic discriminant models.

Change `Delta` using dot notation: `obj.Delta = newDelta`.

DeltaPredictor

Row vector of length equal to the number of predictors in `obj`. If `DeltaPredictor(i) < Delta` then coefficient `i` of the model is 0.

If `obj` is a quadratic discriminant model, all elements of `DeltaPredictor` are 0.

DiscrimType

Character vector specifying the discriminant type. One of:

- 'linear'
- 'quadratic'
- 'diagLinear'
- 'diagQuadratic'
- 'pseudoLinear'
- 'pseudoQuadratic'

Change `DiscrimType` using dot notation: `obj.DiscrimType = newDiscrimType`.

You can change between linear types, or between quadratic types, but cannot change between linear and quadratic types.

Gamma

Value of the Gamma regularization parameter, a scalar from 0 to 1. Change Gamma using dot notation: `obj.Gamma = newGamma`.

- If you set 1 for linear discriminant, the discriminant sets its type to 'diagLinear'.
- If you set a value between `MinGamma` and 1 for linear discriminant, the discriminant sets its type to 'linear'.
- You cannot set values below the value of the `MinGamma` property.

- For quadratic discriminant, you can set either 0 (for `DiscrimType 'quadratic'`) or 1 (for `DiscrimType 'diagQuadratic'`).

HyperparameterOptimizationResults

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- `'bayesopt'` (default) — Object of class `BayesianOptimization`
- `'gridsearch'` or `'randomsearch'` — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

LogDetSigma

Logarithm of the determinant of the within-class covariance matrix. The type of `LogDetSigma` depends on the discriminant type:

- Scalar for linear discriminant analysis
- Vector of length `K` for quadratic discriminant analysis, where `K` is the number of classes

MinGamma

Nonnegative scalar, the minimal value of the `Gamma` parameter so that the correlation matrix is invertible. If the correlation matrix is not singular, `MinGamma` is 0.

ModelParameters

Parameters used in training `obj`.

Mu

Class means, specified as a `K`-by-`p` matrix of scalar values class means of size. `K` is the number of classes, and `p` is the number of predictors. Each row of `Mu` represents the mean of the multivariate normal distribution of the corresponding class. The class indices are in the `ClassNames` attribute.

NumObservations

Number of observations in the training data, a numeric scalar. `NumObservations` can be less than the number of rows of input data `X` when there are missing values in `X` or response `Y`.

PredictorNames

Cell array of names for the predictor variables, in the order in which they appear in the training data `X`.

Prior

Numeric vector of prior probabilities for each class. The order of the elements of `Prior` corresponds to the order of the classes in `ClassNames`.

Add or change a `Prior` vector using dot notation: `obj.Prior = priorVector`.

ResponseName

Character vector describing the response variable `Y`.

ScoreTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means $@(x)x$. For a list of built-in transformation functions and the syntax of custom transformation functions, see `fitcdiscr`.

Implement dot notation to add or change a `ScoreTransform` function using one of the following:

- `cobj.ScoreTransform = 'function'`
- `cobj.ScoreTransform = @function`

Sigma

Within-class covariance matrix or matrices. The dimensions depend on `DiscrimType`:

- 'linear' (default) — Matrix of size p -by- p , where p is the number of predictors
- 'quadratic' — Array of size p -by- p -by- K , where K is the number of classes

- 'diagLinear' — Row vector of length p
- 'diagQuadratic' — Array of size 1-by-p-by-K
- 'pseudoLinear' — Matrix of size p-by-p
- 'pseudoQuadratic' — Array of size p-by-p-by-K

W

Scaled weights, a vector with length n, the number of rows in X.

X

Matrix of predictor values. Each column of X represents one predictor (variable), and each row represents one observation.

Xcentered

X data with class means subtracted. If $Y(i)$ is of class j ,

$$Xcentered(i, :) = X(i, :) - \mu(j, :),$$

where μ is the class mean property.

Y

A categorical array, cell array of character vectors, character array, logical vector, or a numeric vector with the same number of rows as X. Each row of Y represents the classification of the corresponding row of X.

Methods

| resubEdge | Classification edge by resubstitution |
| resubLoss | Classification error by resubstitution |
| resubMargin | Classification margins by resubstitution |
| resubPredict | Predict resubstitution response of classifier |

Inherited Methods

| | |
|----------------|--|
| compareHoldout | Compare accuracies of two classification models using new data |
| edge | Classification edge |
| logP | Log unconditional probability density for discriminant analysis classifier |
| loss | Classification error |
| mahal | Mahalanobis distance to class means |
| margin | Classification margins |
| nLinearCoeffs | Number of nonzero linear coefficients |
| predict | Predict labels using discriminant analysis classification model |

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Train Discriminant Analysis Model

Load Fisher's iris data set.

```
load fisheriris
```

Train a discriminant analysis model using the entire data set.

```
Mdl = fitcdiscr(meas,species)
```

```
Mdl =
  ClassificationDiscriminant
      ResponseName: 'Y'
  CategoricalPredictors: []
          ClassNames: {'setosa' 'versicolor' 'virginica'}
      ScoreTransform: 'none'
    NumObservations: 150
          DiscrimType: 'linear'
```

```
Mu: [3x4 double]
Coeffs: [3x3 struct]
```

Properties, Methods

`Mdl` is a `ClassificationDiscriminant` model. To access its properties, use dot notation. For example, display the group means for each predictor.

```
Mdl.Mu
```

```
ans = 3x4
```

```
    5.0060    3.4280    1.4620    0.2460
    5.9360    2.7700    4.2600    1.3260
    6.5880    2.9740    5.5520    2.0260
```

To predict labels for new observations, pass `Mdl` and predictor data to `predict`.

Definitions

Discriminant Classification

The model for discriminant analysis is:

- Each class (Y) generates data (X) using a multivariate normal distribution. That is, the model assumes X has a Gaussian mixture distribution (`gmdistribution`).
 - For linear discriminant analysis, the model has the same covariance matrix for each class, only the means vary.
 - For quadratic discriminant analysis, both means and covariances of each class vary.

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \arg \min_{y=1,\dots,K} \sum_{k=1}^K \hat{P}(k|x) C(y|k),$$

where

- \hat{y} is the predicted classification.
- K is the number of classes.
- $\hat{P}(k | x)$ is the posterior probability on page 20-7 of class k for observation x .
- $C(y | k)$ is the cost on page 20-8 of classifying an observation as y when its true class is k .

For details, see “Prediction Using Discriminant Analysis Models” on page 20-7.

Regularization

Regularization is the process of finding a small set of predictors that yield an effective predictive model. For linear discriminant analysis, there are two parameters, γ and δ , that control regularization as follows. `cvshrink` helps you select appropriate values of the parameters.

Let Σ represent the covariance matrix of the data X , and let \hat{X} be the centered data (the data X minus the mean by class). Define

$$D = \text{diag}(\hat{X}^T * \hat{X}).$$

The regularized covariance matrix $\tilde{\Sigma}$ is

$$\tilde{\Sigma} = (1 - \gamma)\Sigma + \gamma D.$$

Whenever $\gamma \geq \text{MinGamma}$, $\tilde{\Sigma}$ is nonsingular.

Let μ_k be the mean vector for those elements of X in class k , and let μ_0 be the global mean vector (the mean of the rows of X). Let C be the correlation matrix of the data X , and let

\tilde{C} be the regularized correlation matrix:

$$\tilde{C} = (1 - \gamma)C + \gamma I,$$

where I is the identity matrix.

The linear term in the regularized discriminant analysis classifier for a data point x is

$$(x - \mu_0)^T \tilde{\Sigma}^{-1} (\mu_k - \mu_0) = \left[(x - \mu_0)^T D^{-1/2} \right] \left[\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right].$$

The parameter δ enters into this equation as a threshold on the final term in square

brackets. Each component of the vector $\left[\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right]$ is set to zero if it is smaller in magnitude than the threshold δ . Therefore, for class k , if component j is thresholded to zero, component j of x does not enter into the evaluation of the posterior probability.

The `DeltaPredictor` property is a vector related to this threshold. When $\delta \geq \text{DeltaPredictor}(i)$, all classes k have

$$\left| \tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right| \leq \delta.$$

Therefore, when $\delta \geq \text{DeltaPredictor}(i)$, the regularized classifier does not use predictor i .

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `predict` function supports code generation.
- When you train a discriminant analysis model by using `fitcdiscr` or create a compact discriminant analysis model by using `makecdiscr`, the following restrictions apply.

- The class labels input argument value (Y) cannot be a categorical array.
- The value of the 'ClassNames' name-value pair argument cannot be a categorical array.
- The value of the 'ScoreTransform' name-value pair argument cannot be an anonymous function.

For code generation examples, see “Code Generation Workflow for Prediction” on page 31-5 and “Specify Variable-Sized Arguments for Code Generation” on page 31-48. For more information, see topics in “Code Generation”.

Topics

“Discriminant Analysis Classification” on page 20-2

Introduced in R2011b

ClassificationEnsemble class

Superclasses:

Ensemble classifier

Description

`ClassificationEnsemble` combines a set of trained weak learner models and data on which these learners were trained. It can predict ensemble response for new data by aggregating predictions from its weak learners. It stores data used for training, can compute resubstitution predictions, and can resume training if desired.

Construction

Create a classification ensemble object using `fitcensemble`.

Properties

`CategoricalPredictors`

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

`ClassNames`

List of the elements in `Y` with duplicates removed. `ClassNames` can be a numeric vector, categorical vector, logical vector, character array, or cell array of character vectors. `ClassNames` has the same data type as the data in the argument `Y`.

`CombineWeights`

Character vector describing how `ens` combines weak learner weights, either `'WeightedSum'` or `'WeightedAverage'`.

Cost

Square matrix, where $\text{Cost}(i, j)$ is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`. The number of rows and columns in `Cost` is the number of unique classes in the response. This property is read-only.

ExpandedPredictorNames

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

FitInfo

Numeric array of fit information. The `FitInfoDescription` property describes the content of this array.

FitInfoDescription

Character vector describing the meaning of the `FitInfo` array.

HyperparameterOptimizationResults

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- `'bayesopt'` (default) — Object of class `BayesianOptimization`
- `'gridsearch'` or `'randomsearch'` — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

LearnerNames

Cell array of character vectors with names of weak learners in the ensemble. The name of each learner appears just once. For example, if you have an ensemble of 100 trees, `LearnerNames` is `{'Tree'}`.

Method

Character vector describing the method that creates `ens`.

ModelParameters

Parameters used in training `ens`.

NumObservations

Numeric scalar containing the number of observations in the training data.

NumTrained

Number of trained weak learners in `ens`, a scalar.

PredictorNames

Cell array of names for the predictor variables, in the order in which they appear in `X`.

Prior

Numeric vector of prior probabilities for each class. The order of the elements of `Prior` corresponds to the order of the classes in `ClassNames`. The number of elements of `Prior` is the number of unique classes in the response. This property is read-only.

ReasonForTermination

Character vector describing the reason `fitcensemble` stopped adding weak learners to the ensemble.

ResponseName

Character vector with the name of the response variable `Y`.

ScoreTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means $@(x)x$. For a list of built-in transformation functions and the syntax of custom transformation functions, see `fitctree`.

Add or change a `ScoreTransform` function using dot notation:

```
ens.ScoreTransform = 'function'
```

or

```
ens.ScoreTransform = @function
```

Trained

A cell vector of trained classification models.

- If Method is 'LogitBoost' or 'GentleBoost', then ClassificationEnsemble stores trained learner j in the CompactRegressionLearner property of the object stored in Trained{ j }. That is, to access trained learner j , use `ens.Trained{j}.CompactRegressionLearner`.
- Otherwise, cells of the cell vector contain the corresponding, compact classification models.

TrainedWeights

Numeric vector of trained weights for the weak learners in ens. TrainedWeights has T elements, where T is the number of weak learners in learners.

UsePredForLearner

Logical matrix of size P -by-NumTrained, where P is the number of predictors (columns) in the training data X . UsePredForLearner(i, j) is true when learner j uses predictor i , and is false otherwise. For each learner, the predictors have the same order as the columns in the training data X .

If the ensemble is not of type Subspace, all entries in UsePredForLearner are true.

W

Scaled weights, a vector with length n , the number of rows in X . The sum of the elements of W is 1.

X

Matrix of predictor values that trained the ensemble. Each column of X represents one variable, and each row represents one observation.

Y

Numeric vector, categorical vector, logical vector, character array, or cell array of character vectors. Each row of Y represents the classification of the corresponding row of X.

Methods

| | |
|--------------|---|
| compact | Compact classification ensemble |
| crossval | Cross validate ensemble |
| resubEdge | Classification edge by resubstitution |
| resubLoss | Classification error by resubstitution |
| resubMargin | Classification margins by resubstitution |
| resubPredict | Predict ensemble response by resubstitution |
| resume | Resume training ensemble |

Inherited Methods

| | |
|---------------------|--|
| compareHoldout | Compare accuracies of two classification models using new data |
| edge | Classification edge |
| loss | Classification error |
| margin | Classification margins |
| predict | Predict labels using ensemble of classification models |
| predictorImportance | Estimates of predictor importance |
| removeLearners | Remove members of compact classification ensemble |

Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects \(MATLAB\)](#).

Examples

Train Boosted Classification Ensemble

Load the ionosphere data set.

```
load ionosphere
```

Train a boosted ensemble of 100 classification trees using all measurements and the AdaBoostM1 method.

```
Mdl = fitcensemble(X,Y,'Method','AdaBoostM1')
```

```
Mdl =  
  classreg.learning.classif.ClassificationEnsemble  
      ResponseName: 'Y'  
  CategoricalPredictors: []  
      ClassNames: {'b' 'g'}  
      ScoreTransform: 'none'  
  NumObservations: 351  
      NumTrained: 100  
      Method: 'AdaBoostM1'  
      LearnerNames: {'Tree'}  
  ReasonForTermination: 'Terminated normally after completing the requested number o  
      FitInfo: [100x1 double]  
  FitInfoDescription: {2x1 cell}
```

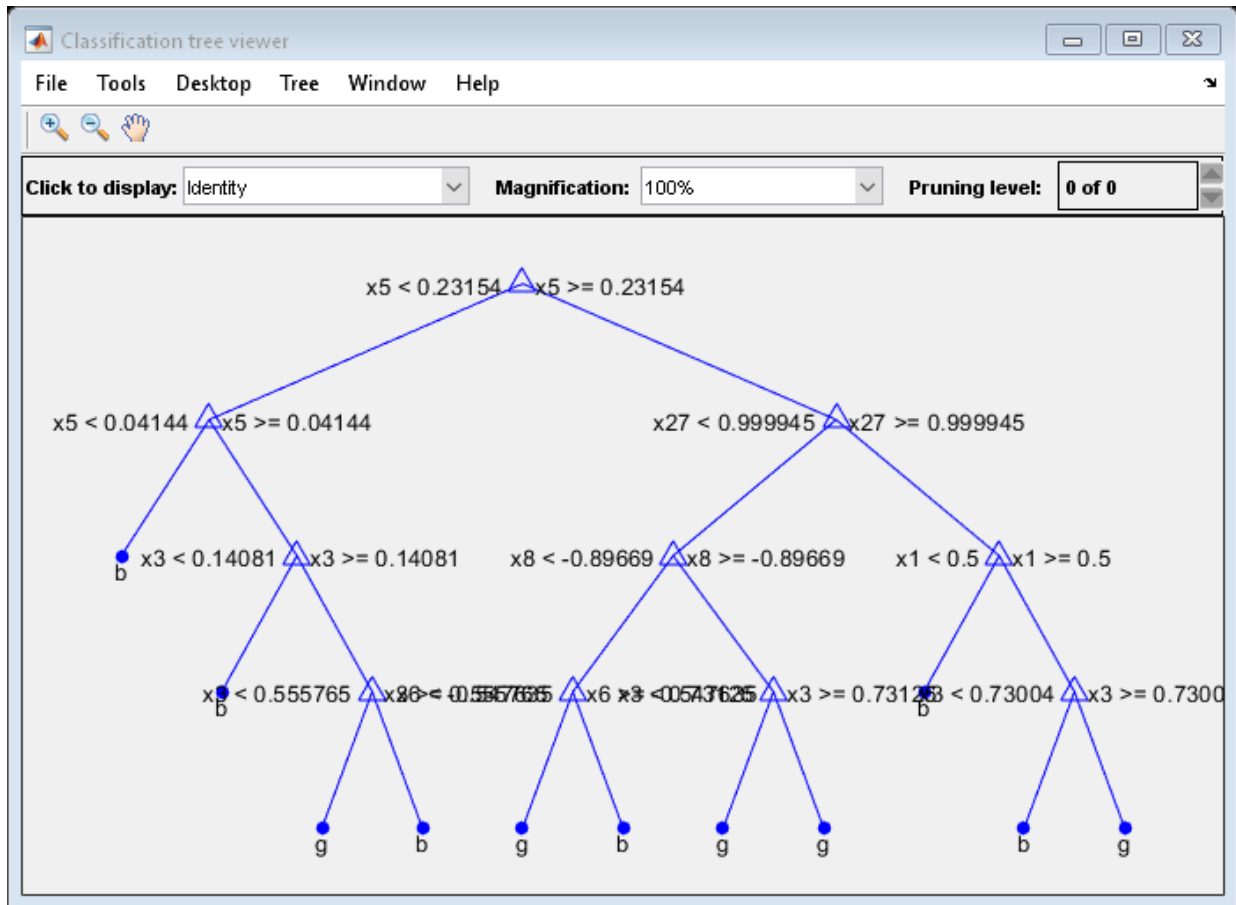

Properties, Methods

Mdl is a ClassificationEnsemble model object.

Mdl.Trained is the property that stores a 100-by-1 cell vector of the trained classification trees (CompactClassificationTree model objects) that compose the ensemble.

Plot a graph of the first trained classification tree.

```
view(Mdl.Trained{1},'Mode','graph')
```

By default, `fitcensemble` grows shallow trees for boosted ensembles of trees.

Predict the label of the mean of X .

```
predMeanX = predict(Mdl,mean(X))
```

```
predMeanX = 1x1 cell array
    {'g'}
```

Tip

For an ensemble of classification trees, the `Trained` property of `ens` stores an `ens.NumTrained-by-1` cell vector of compact classification models. For a textual or graphical display of tree `t` in the cell vector, enter:

- `view(ens.Trained{t}.CompactRegressionLearner)` for ensembles aggregated using LogitBoost or GentleBoost.
- `view(ens.Trained{t})` for all other aggregation methods.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `predict` function supports code generation.
- When you train an ensemble by using `fitcensemble`, code generation limitations for classification trees also apply to ensembles of classification trees. For more details, see “Code Generation” on page 32-0 of the `CompactClassificationTree` class.

For code generation examples, see “Code Generation Workflow for Prediction” on page 31-5 and “Specify Variable-Sized Arguments for Code Generation” on page 31-48. For more information, see topics in “Code Generation”.

Introduced in R2011a

ClassificationKNN class

k-nearest neighbor classification

Description

A nearest-neighbor classification object, where both distance metric (“nearest”) and number of neighbors can be altered. The object classifies new observations using the `predict` method. The object contains the data used for training, so can compute resubstitution predictions.

Construction

`mdl = fitcknn(Tbl, ResponseVarName)` returns a classification model based on the input variables (also known as predictors, features, or attributes) in the table `Tbl` and output (response) `Tbl.ResponseVarName`.

`mdl = fitcknn(Tbl, formula)` returns a classification model based on the predictor data and class labels in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used for training.

`mdl = fitcknn(Tbl, Y)` returns a classification model based on the input variables (also known as predictors, features, or attributes) in the table `Tbl` and output (response) `Y`.

`mdl = fitcknn(X, Y)` returns a classification model based on the input variables `X` and output (response) `Y`.

`mdl = fitcknn(____, Name, Value)` fits a model with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can specify the tie-breaking algorithm, distance metric, or observation weights.

Input Arguments

Tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

ResponseVarName — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

It is a good practice to specify the order of the classes by using the `ClassNames` name-value pair argument.

Data Types: `char`

formula — Explanatory model of response and subset of predictor variables

character vector

Explanatory model of the response and a subset of the predictor variables, specified as a character vector in the form of `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char`

Y — Class labels

numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Each row of `Y` represents the classification of the corresponding row of `X`.

The software considers `NaN`, `''` (empty character vector), and `<undefined>` values in `Y` to be missing values. Consequently, the software does not train using observations with a missing response.

Data Types: `single` | `double` | `logical` | `char` | `cell`

X — Predictor data

numeric matrix

Predictor data, specified as numeric matrix.

Each row corresponds to one observation (also known as an instance or example), and each column corresponds to one predictor variable (also known as a feature).

The length of `Y` and the number of rows of `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Data Types: `double` | `single`

Properties

BreakTies

Character vector specifying the method `predict` uses to break ties if multiple classes have the same smallest cost. By default, ties occur when multiple classes have the same number of nearest points among the `K` nearest neighbors.

- 'nearest' — Use the class with the nearest neighbor among tied groups.
- 'random' — Use a random tiebreaker among tied groups.
- 'smallest' — Use the smallest index among tied groups.

'BreakTies' applies when 'IncludeTies' is false.

Change BreakTies using dot notation: `mdl.BreakTies = newBreakTies`.

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

ClassNames

List of elements in the training data `Y` with duplicates removed. `ClassNames` can be a numeric vector, vector of categorical variables, logical vector, character array, or cell array of character vectors. `ClassNames` has the same data type as the data in the argument `Y`.

Change `ClassNames` using dot notation: `mdl.ClassNames = newClassNames`

Cost

Square matrix, where `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i` (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`. The number of rows and columns in `Cost` is the number of unique classes in the response.

Change a `Cost` matrix using dot notation: `obj.Cost = costMatrix`.

Distance

Character vector or function handle specifying the distance metric. The allowable character vectors depend on the `NSMethod` parameter, which you set in `fitcknn`, and which exists as a field in `ModelParameters`.

| NSMethod | Distance Metric Names |
|-----------------|---|
| exhaustive | Any distance metric of ExhaustiveSearcher |
| kdtree | 'cityblock', 'chebychev', 'euclidean', or 'minkowski' |

For definitions, see “Distance Metrics” on page 18-16.

The distance metrics of ExhaustiveSearcher:

| Value | Description |
|---------------|--|
| 'cityblock' | City block distance. |
| 'chebychev' | Chebychev distance (maximum coordinate difference). |
| 'correlation' | One minus the sample linear correlation between observations (treated as sequences of values). |
| 'cosine' | One minus the cosine of the included angle between observations (treated as vectors). |
| 'euclidean' | Euclidean distance. |
| 'hamming' | Hamming distance, percentage of coordinates that differ. |
| 'jaccard' | One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ. |
| 'mahalanobis' | Mahalanobis distance, computed using a positive definite covariance matrix C . The default value of C is the sample covariance matrix of X , as computed by <code>nancov(X)</code> . To specify a different value for C , set the <code>DistParameter</code> property of <code>mdl</code> using dot notation. |
| 'minkowski' | Minkowski distance. The default exponent is 2. To specify a different exponent, set the <code>DistParameter</code> property of <code>mdl</code> using dot notation. |
| 'seuclidean' | Standardized Euclidean distance. Each coordinate difference between X and a query point is scaled, meaning divided by a scale value S . The default value of S is the standard deviation computed from X , $S = \text{nanstd}(X)$. To specify another value for S , set the <code>DistParameter</code> property of <code>mdl</code> using dot notation. |
| 'spearman' | One minus the sample Spearman's rank correlation between observations (treated as sequences of values). |

| Value | Description |
|------------------|--|
| @ <i>distfun</i> | Distance function handle. <i>distfun</i> has the form <pre>function D2 = DISTFUN(ZI,ZJ) % calculation of distance ...</pre> where <ul style="list-style-type: none"> • ZI is a 1-by-N vector containing one row of X or Y. • ZJ is an M2-by-N matrix containing multiple rows of X or Y. • D2 is an M2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(J, :). |

Change Distance using dot notation: `mdl.Distance = newDistance`.

If NSMethod is `kdtree`, you can use dot notation to change Distance only among the types `'cityblock'`, `'chebychev'`, `'euclidean'`, or `'minkowski'`.

DistanceWeight

Character vector or function handle specifying the distance weighting function.

| DistanceWeight | Meaning |
|------------------|---|
| 'equal' | No weighting |
| 'inverse' | Weight is 1/distance |
| 'squaredinverse' | Weight is 1/distance ² |
| @ <i>fcn</i> | <i>fcn</i> is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, <code>'inversesquared'</code> is equivalent to <code>@(d)d.^(-2)</code> . |

Change DistanceWeight using dot notation: `mdl.DistanceWeight = newDistanceWeight`.

DistParameter

Additional parameter for the distance metric.

| Distance Metric | Parameter |
|-----------------|--|
| 'mahalanobis' | Positive definite covariance matrix C. |
| 'minkowski' | Minkowski distance exponent, a positive scalar. |
| 'seuclidean' | Vector of positive scale values with length equal to the number of columns of X. |

For values of the distance metric other than those in the table, `DistParameter` must be `[]`.

You can alter `DistParameter` using dot notation: `mdl.DistParameter = newDistParameter`. However, if `Distance` is `mahalanobis` or `seuclidean`, then you cannot alter `DistParameter`.

ExpandedPredictorNames

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

HyperparameterOptimizationResults

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- 'bayesopt' (default) — Object of class `BayesianOptimization`
- 'gridsearch' or 'randomsearch' — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

IncludeTies

Logical value indicating whether `predict` includes all the neighbors whose distance values are equal to the `K`th smallest distance. If `IncludeTies` is `true`, `predict` includes all these neighbors. Otherwise, `predict` uses exactly `K` neighbors (see 'BreakTies').

Change `IncludeTies` using dot notation: `mdl.IncludeTies = newIncludeTies`.

ModelParameters

Parameters used in training `mdl`.

Mu

Numeric vector of predictor means with length `numel(PredictorNames)`.

If you did not standardize `mdl` when you trained it using `fitcknn`, then `Mu` is empty (`[]`).

NumNeighbors

Positive integer specifying the number of nearest neighbors in `X` to find for classifying each point when predicting. Change `NumNeighbors` using dot notation:

```
mdl.NumNeighbors = newNumNeighbors.
```

NumObservations

Number of observations used in training `mdl`. This can be less than the number of rows in the training data, because data rows containing NaN values are not part of the fit.

PredictorNames

Cell array of names for the predictor variables, in the order in which they appear in the training data `X`. Change `PredictorNames` using dot notation: `mdl.PredictorNames = newPredictorNames.`

Prior

Numeric vector of prior probabilities for each class. The order of the elements of `Prior` corresponds to the order of the classes in `ClassNames`.

Add or change a `Prior` vector using dot notation: `obj.Prior = priorVector.`

ResponseName

Character vector describing the response variable `Y`. Change `ResponseName` using dot notation: `mdl.ResponseName = newResponseName.`

Sigma

Numeric vector of predictor standard deviations with length `numel(PredictorNames)`.

If you did not standardize `mdl` when you trained it using `fitcknn`, then `Sigma` is empty (`[]`).

W

Numeric vector of nonnegative weights with the same number of rows as `Y`. Each entry in `W` specifies the relative importance of the corresponding observation in `Y`.

X

Numeric matrix of unstandardized predictor values. Each column of `X` represents one predictor (variable), and each row represents one observation.

Y

A numeric vector, vector of categorical variables, logical vector, character array, or cell array of character vectors, with the same number of rows as `X`.

`Y` is of the same type as the passed-in `Y` data.

Methods

| | |
|-----------------------------|---|
| <code>compareHoldout</code> | Compare accuracies of two models using new data |
| <code>crossval</code> | Cross-validated k -nearest neighbor classifier |
| <code>edge</code> | Edge of k -nearest neighbor classifier |
| <code>loss</code> | Loss of k -nearest neighbor classifier |
| <code>margin</code> | Margin of k -nearest neighbor classifier |
| <code>predict</code> | Predict labels using k -nearest neighbor classification model |
| <code>resubEdge</code> | Edge of k -nearest neighbor classifier by resubstitution |
| <code>resubLoss</code> | Loss of k -nearest neighbor classifier by resubstitution |
| <code>resubMargin</code> | Margin of k -nearest neighbor classifier by resubstitution |
| <code>resubPredict</code> | Predict resubstitution response of k -nearest neighbor classifier |

Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects \(MATLAB\)](#).

Examples

Train a *k*-Nearest Neighbor Classifier

Construct a *k*-nearest neighbor classifier for Fisher's iris data, where *k*, the number of nearest neighbors in the predictors, is 5.

Load Fisher's iris data.

```
load fisheriris
X = meas;
Y = species;
```

X is a numeric matrix that contains four petal measurements for 150 irises. Y is a cell array of character vectors that contains the corresponding iris species.

Train a 5-nearest neighbors classifier. It is good practice to standardize noncategorical predictor data.

```
Mdl = fitcknn(X,Y,'NumNeighbors',5,'Standardize',1)
```

```
Mdl =
  ClassificationKNN
      ResponseName: 'Y'
  CategoricalPredictors: []
          ClassNames: {'setosa' 'versicolor' 'virginica'}
      ScoreTransform: 'none'
  NumObservations: 150
          Distance: 'euclidean'
      NumNeighbors: 5
```

Properties, Methods

Mdl is a trained `ClassificationKNN` classifier, and some of its properties display in the Command Window.

To access the properties of Mdl, use dot notation.

```
Mdl.ClassNames
ans = 3x1 cell array
    {'setosa' }
```

```
{'versicolor'}  
{'virginica' }
```

`Mdl.Prior`

```
ans = 1×3
```

```
0.3333    0.3333    0.3333
```

`Mdl.Prior` contains the class prior probabilities, which you can specify using the 'Prior' name-value pair argument in `fitcknn`. The order of the class prior probabilities corresponds to the order of the classes in `Mdl.ClassNames`. By default, the prior probabilities are the respective relative frequencies of the classes in the data.

You can also reset the prior probabilities after training. For example, set the prior probabilities to 0.5, 0.2, and 0.3 respectively.

```
Mdl.Prior = [0.5 0.2 0.3];
```

You can pass `Mdl` to, for example, `predict` to label new measurements, or `crossval` to cross-validate the classifier.

- “Predict Classification Using KNN Classifier” on page 18-38
- “Modify KNN Classifier” on page 18-38

Definitions

Prediction

`ClassificationKNN` predicts the classification of a point X_{new} using a procedure equivalent to this:

- 1 Find the `NumNeighbors` points in the training set X that are nearest to X_{new} .
- 2 Find the `NumNeighbors` response values Y to those nearest points.

- 3 Assign the classification label `Ynew` that has smallest expected misclassification cost among the values in `Y`.

For details, see “Posterior Probability” on page 32-4801 and “Expected Cost” on page 32-4802 in the `predict` documentation.

Tips

The `compact` function reduces the size of most classification models by removing the training data properties, and any other properties that are not required to predict the label of new observations. Because k NN classification models require all of the training data to predict labels, you cannot reduce the size of a `ClassificationKNN` model.

Alternatives

`knnsearch` finds the k -nearest neighbors of points. `rangearch` finds all the points within a fixed distance. You can use these functions for classification, as shown in “Classify Query Data” on page 18-24. If you want to perform classification, `ClassificationKNN` can be more convenient, in that you can construct a classifier in one step and classify in other steps. Also, `ClassificationKNN` has cross-validation options.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `predict` function supports code generation.
- When you train a k -nearest neighbor classification model by using `fitcknn`, the following restrictions apply.
 - The class labels input argument value (`Y`) cannot be a categorical array.

- Code generation does not support categorical predictors. You cannot supply training data in a table that contains at least one categorical predictor, and you cannot use the 'CategoricalPredictors' name-value pair argument. To dummy-code variables that you want treated as categorical, preprocess the categorical data by using `dummyvar` before fitting the model.
- The value of the 'ClassNames' name-value pair argument cannot be a categorical array.
- The value of the 'Distance' name-value pair argument cannot be a custom distance function.
- The value of the 'DistanceWeight' name-value pair argument can be a custom distance weight function, but it cannot be an anonymous function.
- The value of the 'ScoreTransform' name-value pair argument cannot be an anonymous function.

For code generation examples, see “Code Generation Workflow for Prediction” on page 31-5 and “Specify Variable-Sized Arguments for Code Generation” on page 31-48. For more information, see topics in “Code Generation”.

ClassificationLinear class

Linear model for binary classification of high-dimensional data

Description

`ClassificationLinear` is a trained linear model object for binary classification; the linear model is a support vector machine (SVM) or logistic regression model. `fitclinear` fits a `ClassificationLinear` model by minimizing the objective function using techniques that reduce computation time for high-dimensional data sets (e.g., stochastic gradient descent). The classification loss plus the regularization term compose the objective function.

Unlike other classification models, and for economical memory usage, `ClassificationLinear` model objects do not store the training data. However, they do store, for example, the estimated linear model coefficients, prior-class probabilities, and the regularization strength.

You can use trained `ClassificationLinear` models to predict labels or classification scores for new data. For details, see `predict`.

Construction

`Mdl = fitclinear(X,Y)` returns a trained linear classification model object that contains the results of fitting a binary support vector machine to the predictor data `X` and class labels `Y`.

`Mdl = fitclinear(____,Name,Value)` returns a trained linear classification model with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes. For example, you can specify to implement logistic regression, specify to cross-validate, or specify the type of regularization.

If you specify one of the following four options, then `Mdl` is a `ClassificationPartitionedLinear` model: `'CrossVal'`, `'CVPartition'`, `'Holdout'`, or `'KFold'`.

Note Unlike other classification model objects:

- For economical memory usage, `ClassificationLinear` model objects do not store the training data or training process details (for example, convergence history).
 - You cannot cross-validate by passing a trained `ClassificationLinear` model object to `crossval`. Instead, specify the appropriate cross-validation name-value pair argument when you train the model using `fitclinear`.
-

Input Arguments

X — Predictor data

full matrix | sparse matrix

Predictor data, specified as an n -by- p full or sparse matrix.

The length of Y and the number of observations in X must be equal.

Note If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn'`, `'columns'`, then you might experience a significant reduction in optimization-execution time.

Data Types: `single` | `double`

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Class labels to which the classification model is trained, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors.

- `ClassificationLinear` only supports binary classification. Either Y must contain exactly two distinct classes, or you must specify two classes for training using the `'ClassNames'` name-value pair argument. For multiclass learning, see `fitcecoc`.
- If Y is a character array, then each element must correspond to one row of the array.
- The length of Y and the number of observations in X must be equal.
- It is good practice to specify the class order using the `ClassNames` name-value pair argument.

Data Types: char | cell | categorical | logical | single | double

For more details, see `fitlinear`.

Properties

Linear Classification Properties

Lambda — Regularization term strength

nonnegative scalar | vector of nonnegative values

Regularization term strength, specified as a nonnegative scalar or vector of nonnegative values.

Data Types: double | single

Learner — Linear classification model type

'logistic' | 'svm'

Linear classification model type, specified as 'logistic' or 'svm'.

In this table, $f(x) = x\beta + b$.

- β is a vector of p coefficients.
- x is an observation from p predictor variables.
- b is the scalar bias.

| Value | Algorithm | Loss Function | FittedLoss Value |
|------------|------------------------|--|------------------|
| 'logistic' | Logistic regression | Deviance (logistic): $\ell[y, f(x)] = \log\{1 + \exp[-yf(x)]\}$ | 'logit' |
| 'svm' | Support vector machine | Hinge: $\ell[y, f(x)] = \max[0, 1 - yf(x)]$ | 'hinge' |

Beta — Linear coefficient estimates

numeric vector

Linear coefficient estimates, specified as a numeric vector with length equal to the number of predictors.

Data Types: double

Bias — Estimated bias term

numeric scalar

Estimated bias term or model intercept, specified as a numeric scalar.

Data Types: double

FittedLoss — Loss function used to fit linear model

'hinge' | 'logit'

Loss function used to fit the linear model, specified as 'hinge' or 'logit'.

| Value | Algorithm | Loss Function | Learner Value |
|---------|------------------------|--|---------------|
| 'hinge' | Support vector machine | Hinge: $\ell[y, f(x)] = \max[0, 1 - yf(x)]$ | 'svm' |
| 'logit' | Logistic regression | Deviance (logistic): $\ell[y, f(x)] = \log\{1 + \exp[-yf(x)]\}$ | 'logistic' |

Regularization — Complexity penalty type

'lasso (L1)' | 'ridge (L2)'

Complexity penalty type, specified as 'lasso (L1)' or 'ridge (L2)'.

The software composes the objective function for minimization from the sum of the average loss function (see `FittedLoss`) and a regularization value from this table.

| Value | Description |
|--------------|---|
| 'lasso (L1)' | Lasso (L_1) penalty: $\lambda \sum_{j=1}^p \beta_j $ |

| Value | Description |
|--------------|---|
| 'ridge (L2)' | Ridge (L_2) penalty: $\frac{\lambda}{2} \sum_{j=1}^p \beta_j^2$ |

λ specifies the regularization term strength (see Lambda).

The software excludes the bias term (β_0) from the regularization penalty.

Other Classification Properties

CategoricalPredictors — Indices of categorical predictors

[]

Indices of categorical predictors, whose value is always empty ([]) because a ClassificationLinear model does not support categorical predictors.

ClassNames — Unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. ClassNames has the same data type as class labels (Y). ClassNames also determines the class order.

Data Types: categorical | char | logical | single | double | cell

Cost — Misclassification costs

square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. Cost has K rows and columns, where K is the number of classes.

$\text{Cost}(i, j)$ is the cost of classifying a point into class j if its true class is i . The order of the rows and columns of Cost corresponds to the order of the classes in ClassNames.

Data Types: double

ModelParameters — Parameters used for training model

structure

Parameters used for training the `ClassificationLinear` model, specified as a structure.

Access fields of `ModelParameters` using dot notation. For example, access the relative tolerance on the linear coefficients and the bias term by using `Mdl.ModelParameters.BetaTolerance`.

Data Types: `struct`

PredictorNames — Predictor names

cell array of character vectors

Predictor names in order of their appearance in predictor data (X), specified as a cell array of character vectors. The length of `PredictorNames` is equal to the number of columns in X.

Data Types: `cell`

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

Expanded predictor names, specified as a cell array of character vectors.

Because a `ClassificationLinear` model does not support categorical predictors, `ExpandedPredictorNames` and `PredictorNames` are equal.

Data Types: `cell`

Prior — Prior class probabilities

numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. `Prior` has as many elements as classes in `ClassNames`, and the order of the elements corresponds to the elements of `ClassNames`.

Data Types: `double`

ScoreTransform — Score transformation function to apply to predicted scores

function name | function handle

Score transformation function to apply to predicted scores, specified as a function name or function handle.

For linear classification models and before transformation, the predicted classification score for the observation x (row vector) is $f(x) = x\beta + b$, where β and b correspond to `Mdl.Beta` and `Mdl.Bias`, respectively.

To change the score transformation function to, e.g., *function*, use dot notation.

- For a built-in function, enter this code and replace *function* with a character vector in the table.

```
Mdl.ScoreTransform = 'function';
```

| Value | Description |
|----------------------|---|
| 'doublelogit' | $1/(1 + e^{-2x})$ |
| 'invlogit' | $\log(x / (1-x))$ |
| 'ismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0 |
| 'logit' | $1/(1 + e^{-x})$ |
| 'none' or 'identity' | x (no transformation) |
| 'sign' | -1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$ |
| 'symmetric' | $2x - 1$ |
| 'symmetricismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1 |
| 'symmetriclogit' | $2/(1 + e^{-x}) - 1$ |

- For a MATLAB function, or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function must accept a matrix of the original scores for each class, and then return a matrix of the same size representing the transformed scores for each class.

Data Types: char | function_handle

ResponseName — Response variable name

character array

Response variable name, specified as a character array.

Data Types: char

Methods

| | |
|--------------|---|
| edge | Classification edge for linear classification models |
| loss | Classification loss for linear classification models |
| margin | Classification margins for linear classification models |
| predict | Predict labels for linear classification models |
| selectModels | Choose subset of regularized, binary linear classification models |

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Train Linear Classification Model

Train a binary, linear classification model using support vector machines, dual SGD, and ridge regularization.

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

Identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Train a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™

documentation. Train the model using the entire data set. Determine how well the optimization algorithm fit the model to the data by extracting a fit summary.

```
rng(1); % For reproducibility
[Mdl,FitInfo] = fitlinear(X,Ystats)
```

```
Mdl =
  ClassificationLinear
    ResponseName: 'Y'
    ClassNames: [0 1]
    ScoreTransform: 'none'
         Beta: [34023x1 double]
         Bias: -1.0059
         Lambda: 3.1674e-05
         Learner: 'svm'
```

Properties, Methods

```
FitInfo = struct with fields:
         Lambda: 3.1674e-05
         Objective: 5.3783e-04
         PassLimit: 10
         NumPasses: 10
         BatchLimit: []
         NumIterations: 238561
         GradientNorm: NaN
         GradientTolerance: 0
         RelativeChangeInBeta: 0.0562
         BetaTolerance: 1.0000e-04
         DeltaGradient: 1.4582
         DeltaGradientTolerance: 1
         TerminationCode: 0
         TerminationStatus: {'Iteration limit exceeded.'}
         Alpha: [31572x1 double]
         History: []
         FitTime: 0.2543
         Solver: {'dual'}
```

Mdl is a `ClassificationLinear` model. You can pass Mdl and the training or new data to `loss` to inspect the in-sample classification error. Or, you can pass Mdl and new predictor data to `predict` to predict class labels for new observations.

`FitInfo` is a structure array containing, among other things, the termination status (`TerminationStatus`) and how long the solver took to fit the model to the data (`FitTime`). It is good practice to use `FitInfo` to determine whether optimization-termination measurements are satisfactory. Because training time is small, you can try to retrain the model, but increase the number of passes through the data. This can improve measures like `DeltaGradient`.

Predict Class Labels Using Linear Classification Model

Load the NLP data set.

```
load nlpdata
n = size(X,1); % Number of observations
```

Identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Hold out 5% of the data.

```
rng(1); % For reproducibility
cvp = cvpartition(n,'Holdout',0.05)
```

```
cvp =
Hold-out cross validation partition
  NumObservations: 31572
   NumTestSets: 1
   TrainSize: 29994
   TestSize: 1578
```

`cvp` is a `CVPartition` object that defines the random partition of n data into training and test sets.

Train a binary, linear classification model using the training set that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation. For faster training time, orient the predictor data matrix so that the observations are in columns.

```
idxTrain = training(cvp); % Extract training set indices
X = X';
Mdl = fitlinear(X(:,idxTrain),Ystats(idxTrain),'ObservationsIn','columns');
```

Predict observations and classification error for the hold out sample.

```
idxTest = test(cvp); % Extract test set indices
labels = predict(Mdl,X(:,idxTest),'ObservationsIn','columns');
L = loss(Mdl,X(:,idxTest),Ystats(idxTest),'ObservationsIn','columns')

L = 7.1753e-04
```

Mdl misclassifies fewer than 1% of the out-of-sample observations.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `predict` function supports code generation.
- When you train a linear classification model by using `fitclinear`, the following restrictions apply.
 - The predictor data input argument value (X) must be a full, numeric matrix.
 - The class labels input argument value (Y) cannot be a categorical array.
 - The value of the 'ClassNames' name-value pair argument or property cannot be a categorical array.
 - You can specify only one regularization strength, either 'auto' or a nonnegative scalar for the 'Lambda' name-value pair argument.
 - The value of the 'ScoreTransform' name-value pair argument cannot be an anonymous function.

For code generation examples, see “Code Generation Workflow for Prediction” on page 31-5 and “Specify Variable-Sized Arguments for Code Generation” on page 31-48. For more information, see topics in “Code Generation”.

Introduced in R2016a

ClassificationNaiveBayes class

Superclasses:

Naive Bayes classification

Description

`ClassificationNaiveBayes` is a naive Bayes on page 32-451 classifier for multiclass learning. Use `fitcnb` and the training data to train a `ClassificationNaiveBayes` classifier.

Trained `ClassificationNaiveBayes` classifiers store the training data, parameter values, data distribution, and prior probabilities. You can use these classifiers to:

- Estimate resubstitution predictions. For details, see `resubPredict`.
- Predict labels or posterior probabilities for new data. For details, see `predict`.

Construction

`Mdl = fitcnb(Tbl,ResponseVarName)` returns a multiclass naive Bayes model (`Mdl`), trained by the predictors in table `Tbl` and class labels in `Tbl.ResponseVarName`.

`Mdl = fitcnb(Tbl,formula)` returns a multiclass naive Bayes model (`Mdl`), trained by the predictor data and class labels in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used for training.

`Mdl = fitcnb(Tbl,Y)` returns a multiclass naive Bayes model (`Mdl`), trained by the predictors in the table `Tbl` and class labels in the vector `Y`.

`Mdl = fitcnb(X,Y)` returns a multiclass naive Bayes model (`Mdl`), trained by predictors `X` and class labels `Y`.

`Mdl = fitcnb(____,Name,Value)` returns a naive Bayes classifier with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes. For example, you can specify a distribution to model the data, prior probabilities for the classes, or the kernel smoothing window bandwidth.

Predict labels for new data by passing the data and `Mdl` to `predict`.

If you set one of the following five options, then `Mdl` is a `ClassificationPartitionedModel` model: `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`. Otherwise, `Mdl` is a `ClassificationNaiveBayes` classifier.

Input Arguments

Tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: table

ResponseVarName — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

It is a good practice to specify the order of the classes by using the `ClassNames` name-value pair argument.

Data Types: `char`

formula — Explanatory model of response and subset of predictor variables

character vector

Explanatory model of the response and a subset of the predictor variables, specified as a character vector in the form of `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char`

Y — Class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Class labels to which the naive Bayes classifier is trained, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Each element of `Y` defines the class membership of the corresponding row of `X`. `Y` supports K class levels.

If `Y` is a character array, then each row must correspond to one class label.

The length of `Y` and the number of rows of `X` must be equivalent.

Data Types: `cell` | `char` | `double` | `logical`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of `Y` and the number of rows of `X` must be equivalent.

Data Types: double

Note: The software treats NaN, empty character vector (''), and <undefined> elements as missing values.

- If Y contains missing values, then the software removes them and the corresponding rows of X.
- If X contains any rows composed entirely of missing values, then the software removes those rows and the corresponding elements of Y.
- If X contains missing values and you set 'Distribution', 'mn', then the software removes those rows of X and the corresponding elements of Y.
- If a predictor is not represented in a class, that is, if all of its values are NaN within a class, then the software returns an error.

Removing rows of X and corresponding elements of Y decreases the effective training or cross-validation sample size.

Properties

CategoricalPredictors — Indices of categorical predictors

vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

Data Types: single | double

CategoricalLevels — Multivariate multinomial levels

cell vector of numeric vectors

Multivariate multinomial levels, specified as a cell vector of numeric vectors. `CategoricalLevels` has length equal to the number of predictors (`size(X,2)`).

The cells of `CategoricalLevels` correspond to predictors that you specified as 'mvmn' (i.e., having a multivariate multinomial distribution) during training. Cells that do not correspond to a multivariate multinomial distribution are empty ([]).

If predictor j is multivariate multinomial, then `CategoricalLevels{j}` is a list of all distinct values of predictor j in the sample (NaNs removed from `unique(X(:,j))`).

Data Types: `cell`

ClassNames — Distinct class names

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Distinct class names, specified as a categorical or character array, logical or numeric vector, or cell vector of character vectors.

`ClassNames` is the same data type as `Y`, and has as K elements or rows for character arrays.

Cost — Misclassification cost

square matrix

Misclassification cost, specified as a K -by- K square matrix.

The value of `Cost(i,j)` is the cost of classifying a point into class j if its true class is i . The order of the rows and columns of `Cost` correspond to the order of the classes in `ClassNames`.

The value of `Cost` does not influence training. You can reset `Cost` after training `Mdl` using dot notation, e.g., `Mdl.Cost = [0 0.5; 1 0];`.

Data Types: `double` | `single`

DistributionNames — Predictor distributions

'normal' (default) | 'kernel' | 'mn' | 'mvnm' | cell array of character vectors

Predictor distributions `fitcnb` uses to model the predictors, specified as a character vector or cell array of character vectors.

This table summarizes the available distributions.

| Value | Description |
|----------|------------------------------------|
| 'kernel' | Kernel smoothing density estimate. |

| Value | Description |
|----------|---|
| 'mn' | Multinomial bag-of-tokens model on page 32-451. Indicates that all predictors have this distribution. |
| 'mvmn' | Multivariate multinomial distribution. |
| 'normal' | Normal (Gaussian) distribution. |

If `Distribution` is a 1-by- P cell array of character vectors, then the software models feature j using the distribution in element j of the cell array.

Data Types: cell | char

DistributionParameters — Distribution parameter estimates

cell array

Distribution parameter estimates, specified as a cell array. `DistributionParameters` is a K -by- D cell array, where cell (k,d) contains the distribution parameter estimates for instances of predictor d in class k . The order of the rows corresponds to the order of the classes in the property `ClassNames`, and the order of the predictors corresponds to the order of the columns of X .

If class k has no observations for predictor j , then `DistributionParameters{k,j}` is empty (`[]`).

The elements of `DistributionParameters` depends on the distributions of the predictors. This table describes the values in `DistributionParameters{k,j}`.

| Distribution of Predictor j | Value |
|-------------------------------|--|
| kernel | A <code>KernelDistribution</code> model. Display properties using cell indexing and dot notation. For example, to display the estimated bandwidth of the kernel density for predictor 2 in the third class, use <code>Mdl.DistributionParameters{3,2}.BandWidth</code> . |
| mn | A scalar representing the probability that token j appears in class k . For details, see “Algorithms” on page 32-452. |

| Distribution of Predictor j | Value |
|-------------------------------|--|
| mvmn | A numeric vector containing the probabilities for each possible level of predictor j in class k . The software orders the probabilities by the sorted order of all unique levels of predictor j (stored in the property <code>CategoricalLevels</code>). For more details, see “Algorithms” on page 32-452. |
| normal | A 2-by-1 numeric vector. The first element is the sample mean and the second element is the sample standard deviation. |

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

HyperparameterOptimizationResults — Description of the cross-validation optimization of hyperparameters

BayesianOptimization object | table of hyperparameters and associated values

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- 'bayesopt' (default) — Object of class `BayesianOptimization`
- 'gridsearch' or 'randomsearch' — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

Data Types: table

Kernel — Kernel smoother types

'normal' (default) | 'box' | 'epanechnikov' | 'triangle' | cell array of character vectors

Kernel smoother types, specified as a character vector or cell array of character vectors. `Kernel` has length equal to the number of predictors (`size(X,2)`). `Kernel{j}` corresponds to predictor j , and contains a character vector describing the type of kernel smoother. This table describes the supported kernel smoother types. Let $I\{u\}$ denote the indicator function.

| Value | Kernel | Formula |
|----------------|------------------|--|
| 'box' | Box (uniform) | $f(x) = 0.5I\{ x \leq 1\}$ |
| 'epanechnikov' | Epanechnikov | $f(x) = 0.75(1 - x^2)I\{ x \leq 1\}$ |
| 'normal' | Gaussian | $f(x) = \frac{1}{\sqrt{2\pi}} \exp(-0.5x^2)$ |
| 'triangle' | Triangular | $f(x) = (1 - x)I\{ x \leq 1\}$ |

If a cell is empty ([]), then the software did not fit a kernel distribution to the corresponding predictor.

ModelParameters — Parameter values used to train object

Parameter values used to train the classifier (such as the name-value pair argument values), specified as an object. This table summarizes the properties of `ModelParameters`. The properties correspond to the name-value pair argument values set for training the classifier.

| Property | Purpose |
|--------------------------------|---|
| <code>DistributionNames</code> | Data distribution or distributions. This is the same value as the property <code>DistributionNames</code> . |
| <code>Kernel</code> | Kernel smoother type. This is the same as the property <code>Kernel</code> . |
| <code>Method</code> | Training method. For naive Bayes, the value is 'NaiveBayes'. |

| Property | Purpose |
|----------|---|
| Support | Kernel-smoothing density support. This is the same as the property Support. |
| Type | Learning type. For classification, the value is 'classification'. |
| Width | Kernel smoothing window width. This is the same as the property Width. |

Access fields of `ModelParameters` using dot notation. For example, access the kernel support using `Mdl.ModelParameters.Support`.

NumObservations — Number of training observations

numeric scalar

Number of training observations, specified as a numeric scalar.

If `X` or `Y` contain missing values, then `NumObservations` might be less than the length of `Y`.

Data Types: double

PredictorNames — Predictor names

character vector

Predictor names, specified as a cell vector of character vectors. The order of the elements in `PredictorNames` corresponds to the order in `X`.

Data Types: cell

Prior — Class prior probabilities

numeric vector

Class prior probabilities, specified as a numeric row vector. `Prior` is a 1-by-`K` vector, and the order of its elements correspond to the elements of `ClassNames`.

`fitcnb` normalizes the prior probabilities you set using the name-value pair parameter '`Prior`' so that $\text{sum}(\text{Prior}) = 1$.

The value of `Prior` does not change the best-fitting model. Therefore, you can reset `Prior` after training `Mdl` using dot notation, e.g., `Mdl.Prior = [0.2 0.8];`.

Data Types: double | single

ResponseName — Response name

character vector

Response name, specified as a character vector.

Data Types: char

ScoreTransform — Classification score transformation function

character vector | function handle

Classification score transformation function, specified as a character vector or function handle.

To change the score transformation function to e.g., *function*, use dot notation.

- For a built-in function, enter a character vector.

```
Mdl.ScoreTransform = 'function';
```

This table lists available, built-in functions.

| Value | Description |
|----------------------|---|
| 'doublelogit' | $1/(1 + e^{-2x})$ |
| 'invlogit' | $\log(x / (1-x))$ |
| 'ismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0 |
| 'logit' | $1/(1 + e^{-x})$ |
| 'none' or 'identity' | x (no transformation) |
| 'sign' | -1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$ |
| 'symmetric' | $2x - 1$ |
| 'symmetricismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1 |
| 'symmetriclogit' | $2/(1 + e^{-x}) - 1$ |

- For a MATLAB function, or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Data Types: char | function_handle

Support — Kernel smoother density support

cell vector

Kernel smoother density support, specified as a cell vector. Support has length equal to the number of predictors (`size(X,2)`). The cells represent the regions to apply the kernel density.

This table describes the supported options.

| Value | Description |
|---------------------------|---|
| 1-by-2 numeric row vector | For example, [L,U], where L and U are the finite lower and upper bounds, respectively, for the density support. |
| 'positive' | The density support is all positive real values. |
| 'unbounded' | The density support is all real values. |

If a cell is empty ([]), then the software did not fit a kernel distribution to the corresponding predictor.

W — Observation weights

numeric vector

Observation weights, specified as a numeric vector.

The length of *W* is NumObservations.

`fitcnb` normalizes the value you set for the name-value pair parameter 'Weights' so that the weights within a particular class sum to the prior probability for that class.

Data Types: double

Width — Kernel smoother window width

numeric matrix

Kernel smoother window width, specified as a numeric matrix. `Width` is a K -by- P matrix, where K is the number of classes in the data, and P is the number of predictors (`size(X, 2)`).

`Width(k, j)` is the kernel smoother window width for the kernel smoothing density of predictor j within class k . NaNs in column j indicate that the software did not fit predictor j using a kernel density.

X — Unstandardized predictor data

numeric matrix

Unstandardized predictor data, specified as a numeric matrix. `X` has `NumObservations` rows and P columns.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

The software excludes rows removed due to missing values from `X`.

Data Types: `double`

Y — Observed class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Observed class labels, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `Y` is the same data type as the input argument `Y` of `fitcnb`.

Each row of `Y` represents the observed classification of the corresponding row of `X`.

The software excludes elements removed due to missing values from `Y`.

Methods

| | |
|--------------|--|
| compact | Compact naive Bayes classifier |
| crossval | Cross-validated naive Bayes classifier |
| resubEdge | Classification edge for naive Bayes classifiers by resubstitution |
| resubLoss | Classification loss for naive Bayes classifiers by resubstitution |
| resubMargin | Classification margins for naive Bayes classifiers by resubstitution |
| resubPredict | Predict naive Bayes classifier resubstitution response |

Inherited Methods

| | |
|----------------|--|
| compareHoldout | Compare accuracies of two classification models using new data |
| edge | Classification edge for naive Bayes classifiers |
| logP | Log unconditional probability density for naive Bayes classifier |
| loss | Classification error for naive Bayes classifier |
| margin | Classification margins for naive Bayes classifiers |
| predict | Predict labels using naive Bayes classification model |

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Train a Naive Bayes Classifier

Construct a naive Bayes classifier for Fisher's iris data. Also, specify prior probabilities after training.

Load Fisher's iris data.

```
load fisheriris
X = meas;
Y = species;
```

X is a numeric matrix that contains four petal measurements for 150 irises. Y is a cell array of character vectors that contains the corresponding iris species.

Train a naive Bayes classifier.

```
Mdl = fitcnb(X,Y)

Mdl =
  ClassificationNaiveBayes
      ResponseName: 'Y'
  CategoricalPredictors: []
      ClassNames: {'setosa' 'versicolor' 'virginica'}
      ScoreTransform: 'none'
      NumObservations: 150
      DistributionNames: {'normal' 'normal' 'normal' 'normal'}
      DistributionParameters: {3x4 cell}
```

Properties, Methods

Mdl is a trained `ClassificationNaiveBayes` classifier, and some of its properties display in the Command Window. By default, the software treats each predictor as independent, and fits them using normal distributions.

To access the properties of Mdl, use dot notation.

Mdl.ClassNames

```
ans = 3x1 cell array
    {'setosa' }
    {'versicolor'}
    {'virginica' }
```

Mdl.Prior

```
ans = 1x3
    0.3333    0.3333    0.3333
```

`Mdl.Prior` contains the class prior probabilities, which are settable using the name-value pair argument `'Prior'` in `fitcnb`. The order of the class prior probabilities corresponds to the order of the classes in `Mdl.ClassNames`. By default, the prior probabilities are the respective relative frequencies of the classes in the data.

You can also reset the prior probabilities after training. For example, set the prior probabilities to 0.5, 0.2, and 0.3 respectively.

```
Mdl.Prior = [0.5 0.2 0.3];
```

You can pass `Mdl` to e.g., `predict` to label new measurements, or `crossval` to cross validate the classifier.

Definitions

Bag-of-Tokens Model

In the bag-of-tokens model, the value of predictor j is the nonnegative number of occurrences of token j in this observation. The number of categories (bins) in this multinomial model is the number of distinct tokens, that is, the number of predictors.

Naive Bayes

Naive Bayes is a classification algorithm that applies density estimation to the data.

The algorithm leverages Bayes theorem, and (naively) assumes that the predictors are conditionally independent, given the class. Though the assumption is usually violated in practice, naive Bayes classifiers tend to yield posterior distributions that are robust to biased class density estimates, particularly where the posterior is 0.5 (the decision boundary) [1].

Naive Bayes classifiers assign observations to the most probable class (in other words, the maximum a posteriori decision rule). Explicitly, the algorithm:

- 1 Estimates the densities of the predictors within each class.
- 2 Models posterior probabilities according to Bayes rule. That is, for all $k = 1, \dots, K$,

$$\hat{P}(Y = k | X_1, \dots, X_P) = \frac{\pi(Y = k) \prod_{j=1}^P P(X_j | Y = k)}{\sum_{k=1}^K \pi(Y = k) \prod_{j=1}^P P(X_j | Y = k)},$$

where:

- Y is the random variable corresponding to the class index of an observation.
 - X_1, \dots, X_P are the random predictors of an observation.
 - $\pi(Y = k)$ is the prior probability that a class index is k .
- 3** Classifies an observation by estimating the posterior probability for each class, and then assigns the observation to the class yielding the maximum posterior probability.

If the predictors compose a multinomial distribution, then the posterior probability

$\hat{P}(Y = k | X_1, \dots, X_P) \propto \pi(Y = k) P_{mn}(X_1, \dots, X_P | Y = k)$, where $P_{mn}(X_1, \dots, X_P | Y = k)$ is the probability mass function of a multinomial distribution.

Algorithms

- If you specify 'Distribution', 'mn' when training Mdl using `fitcnb`, then the software fits a multinomial distribution using the bag-of-tokens model on page 32-2034. The software stores the probability that token j appears in class k in the property `DistributionParameters{k,j}`. Using additive smoothing [2], the estimated probability is

$$P(\text{token } j | \text{class } k) = \frac{1 + c_{jk}}{P + c_k},$$

where:

•

$c_{j|k} = n_k \frac{\sum_{i: y_i \in \text{class } k} x_{ij} w_i}{\sum_{i \in \text{class } k} w_i}$; which is the weighted number of occurrences of token j in class k .

• n_k is the number of observations in class k .

•

w_i is the weight for observation i . The software normalizes weights within a class such that they sum to the prior probability for that class.

•

$c_k = \sum_{j=1}^P c_{j|k}$; which is the total weighted number of occurrences of all tokens in class k .

• If you specify 'Distribution', 'mvmn' when training Mdl using fitcnb, then:

- 1 For each predictor, the software collects a list of the unique levels, stores the sorted list in `CategoricalLevels`, and considers each level a bin. Each predictor/class combination is a separate, independent multinomial random variable.
- 2 For predictor j in class k , the software counts instances of each categorical level using the list stored in `CategoricalLevels{j}`.
- 3 The software stores the probability that predictor j , in class k , has level L in the property `DistributionParameters{k, j}`, for all levels in `CategoricalLevels{j}`. Using additive smoothing [2], the estimated probability is

$$P(\text{predictor } j = L \mid \text{class } k) = \frac{1 + m_{j|k}(L)}{m_j + m_k},$$

where:

-

$m_{j|k}(L) = n_k \frac{\sum_{i: y_i \in \text{class } k} I\{x_{ij} = L\} w_i}{\sum_{i: y_i \in \text{class } k} w_i}$; which is the weighted number of observations for which predictor j equals L in class k .

- n_k is the number of observations in class k .
-
- $I\{x_{ij} = L\} = 1$ if $x_{ij} = L$, 0 otherwise.
-
- w_i is the weight for observation i . The software normalizes weights within a class such that they sum to the prior probability for that class.
- m_j is the number of distinct levels in predictor j .
- m_k is the weighted number of observations in class k .

ClassificationPartitionedECOC class

Superclasses:

Cross-validated multiclass model for support vector machines or other classifiers

Description

ClassificationPartitionedECOC is a set of error-correcting output codes (ECOC) models trained on cross-validated folds. Estimate the quality of classification by cross-validation using one or more “kfold” functions: `kfoldPredict`, `kfoldLoss`, `kfoldMargin`, `kfoldEdge`, and `kfoldfun`.

Every “kfold” method uses models trained on in-fold observations to predict the response for out-of-fold observations. For example, suppose you cross-validate using five folds. In this case, the software randomly assigns each observation into five roughly equal-sized groups. The training fold contains four of the groups (i.e., roughly 4/5 of the data) and the test fold contains the other group (i.e., roughly 1/5 of the data). In this case, cross-validation proceeds as follows.

- 1 The software trains the first model (stored in `CVMDL.Trained{1}`) using the observations in the last four groups and reserves the observations in the first group for validation.
- 2 The software trains the second model (stored in `CVMDL.Trained{2}`) using the observations in the first group and last three groups, and reserves the observations in the second group for validation.
- 3 The software proceeds in a similar fashion for the third, fourth, and fifth models.

If you validate by calling `kfoldPredict`, it computes predictions for the observations in group 1 using the first model, group 2 for the second model, and so on. In short, the software estimates a response for every observation using the model trained without that observation.

Construction

`CVMDL = crossval(Mdl)` returns a cross-validated ECOC model from `Mdl`, an ECOC model. For details, see `crossval`.

Alternatively, `CVMdl = fitcecoc(X,Y,Name,Value)` returns a cross-validated ECOC model when `Name` is one of 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'. For syntax details, see `fitcecoc`.

Properties

Cross-Validation Properties

CrossValidatedModel — Cross-validated model name

character vector

Cross-validated model name, specified as a character vector.

For example, 'ECOC' specifies a cross-validated ECOC model.

Data Types: char

KFold — Number of cross-validated folds

positive integer

Number of cross-validated folds, specified as a positive integer.

Data Types: double

ModelParameters — Cross-validation parameter values

object

Cross-validation parameter values, e.g., the name-value pair argument values used to cross-validate the ECOC classifier, specified as an object. `ModelParameters` does not contain estimated parameters.

Access properties of `ModelParameters` using dot notation.

NumObservations — Number of observations

positive numeric scalar

Number of observations in the training data, specified as a positive numeric scalar.

Data Types: double

Partition — Data partition

cvpartition model

Data partition indicating how the software splits the data into cross-validation folds, specified as a `cvpartition` model.

Trained — Compact classifiers trained on cross-validation folds

cell array of `CompactClassificationECOC` models

Compact classifiers trained on cross-validation folds, specified cell as a array of `CompactClassificationECOC` models. `Trained` has k cells, where k is the number of folds.

Data Types: `cell`

W — Observation weights

numeric vector

Observation weights used to cross-validate the model, specified as a numeric vector. `W` has `NumObservations` elements.

The software normalizes the weights used for training so that `nansum(W)` is 1.

Data Types: `single` | `double`

X — Unstandardized predictor data used to cross-validate the classifier

numeric matrix

Unstandardized predictor data used to cross-validate the classifier, specified as a numeric matrix. `X` is a `NumObservations-by-p` matrix, where p is the number of predictors.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

Data Types: `single` | `double`

Y — Observed class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Observed class labels used to cross-validate the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `Y` has `NumObservations` elements, and is the same data type as the input argument `Y` that you passed to `fitcecoc` to cross-validate the model.

Each row of `Y` represents the observed classification of the corresponding row of `X`.

Data Types: char | cell | categorical | logical | single | double

ECOC Properties

BinaryLoss — Binary learner loss function

character vector representing the loss function name

Binary learner loss function, specified as a character vector representing the loss function name.

If you train using binary learners that use different loss functions, then the software sets `BinaryLoss` to 'hamming'. To potentially increase accuracy, set a different binary loss function than this default during prediction or loss computation using the `BinaryLoss` name-value pair argument of `predict` or `loss`.

Data Types: char

BinaryY — Binary learner class labels

numeric matrix | []

Binary learner class labels, specified as a numeric matrix or [].

- If the coding matrix is the same across folds, then `BinaryY` is a `NumObservations-by-L` matrix, where L is the number of binary learners (`size(CodingMatrix,2)`).

Elements of `BinaryY` are -1, 0, or 1, and the value corresponds to a dichotomous class assignment. This table describes how learner j assigns observation k to a dichotomous class corresponding to the value of `BinaryY(k,j)`.

| Value | Dichotomous Class Assignment |
|-------|---|
| -1 | Negative class |
| 0 | Before training, learner j removes observations in class i from the data set. |
| 1 | Positive class |

- If the coding matrix varies across folds, then `BinaryY` is empty ([]).

Data Types: double

CodingMatrix — Codes specifying class assignments

numeric matrix | []

Codes specifying class assignments for the binary learners, specified as a numeric matrix or [].

- If the coding matrix is the same across folds, then `CodingMatrix` is a K -by- L matrix, where K is the number of classes and L is the number of binary learners.

Elements of `CodingMatrix` are -1, 0, or 1, and the value corresponds to a dichotomous class assignment. This table describes how learner j assigns observations in class k to a dichotomous class corresponding to the value of `CodingMatrix(k, j)`.

| Value | Dichotomous Class Assignment |
|-------|---|
| -1 | Negative class |
| 0 | Before training, learner j removes observations in class i from the data set. |
| 1 | Positive class |

- If the coding matrix varies across folds, then `CodingMatrix` is empty ([]). Obtain the coding matrix for each fold using the `Trained` property. For example, `CVMdl.Trained{1}.CodingMatrix` is the coding matrix in the first fold of the cross-validated ECOC model `CVMdl`.

Data Types: char | double | single | int8 | int16 | int32 | int64

Other Classification Properties

CategoricalPredictors — Indices of categorical predictors

vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

Data Types: single | double

ClassNames — Unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` has the same data type as class labels (`Y`). `ClassNames` also determines the class order.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Cost — Misclassification costs

square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. `Cost` has K rows and columns, where K is the number of classes.

$\text{Cost}(i, j)$ is the cost of classifying a point into class j if its true class is i . The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: `double`

PredictorNames — Predictor names

cell array of character vectors

Predictor names in order of their appearance in predictor data (X), specified as a cell array of character vectors. The length of `PredictorNames` is equal to the number of columns in X .

Data Types: `cell`

Prior — Prior class probabilities

numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. `Prior` has as many elements as classes in `ClassNames`, and the order of the elements corresponds to the elements of `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: `double`

ResponseName — Response variable name

character array

Response variable name, specified as a character array.

Data Types: char

ScoreTransform — Score transformation function to apply to predicted scores

function name | function handle

Score transformation function to apply to predicted scores, specified as a function name or function handle.

For linear classification models and before transformation, the predicted classification score for the observation x (row vector) is $f(x) = x\beta + b$, where β and b correspond to `Mdl.Beta` and `Mdl.Bias`, respectively.

To change the score transformation function to, e.g., *function*, use dot notation.

- For a built-in function, enter this code and replace *function* with a character vector in the table.

```
Mdl.ScoreTransform = 'function';
```

| Value | Description |
|----------------------|--|
| 'doublelogit' | $1/(1 + e^{-2x})$ |
| 'invlogit' | $\log(x / (1-x))$ |
| 'ismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0 |
| 'logit' | $1/(1 + e^{-x})$ |
| 'none' or 'identity' | x (no transformation) |
| 'sign' | -1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$ |
| 'symmetric' | $2x - 1$ |

| Value | Description |
|------------------|---|
| 'symmetricismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1 |
| 'symmetriclogit' | $2/(1 + e^{-x}) - 1$ |

- For a MATLAB function, or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function must accept a matrix of the original scores for each class, and then return a matrix of the same size representing the transformed scores for each class.

Data Types: char | function_handle

Methods

kfoldEdge Classification edge for observations not used for training
kfoldfun Cross validate function
kfoldLoss Classification loss for observations not used for training
kfoldMargin Classification margins for observations not used for training
kfoldPredict Predict responses for observations not used for training

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Cross-Validate ECOC Classifier

Load Fisher's iris data set.

```
load fisheriris
X = meas;
```

```
Y = species;
rng(1); % For reproducibility
```

Create an SVM template. It is good practice to standardize the predictors.

```
t = templateSVM('Standardize',1)
```

```
t =
Fit template for classification SVM.

          Alpha: [0x1 double]
    BoxConstraint: []
          CacheSize: []
    CachingMethod: ''
          ClipAlphas: []
DeltaGradientTolerance: []
          Epsilon: []
          GapTolerance: []
          KKTolerance: []
    IterationLimit: []
    KernelFunction: ''
          KernelScale: []
          KernelOffset: []
KernelPolynomialOrder: []
          NumPrint: []
          Nu: []
    OutlierFraction: []
    RemoveDuplicates: []
    ShrinkagePeriod: []
          Solver: ''
    StandardizeData: 1
    SaveSupportVectors: []
    VerbosityLevel: []
          Version: 2
          Method: 'SVM'
          Type: 'classification'
```

`t` is an SVM template. All of its properties are empty, except for `StandardizeData`, `Method`, and `Type`. When the software trains the ECOC classifier, it sets the applicable properties to their default values.

Train the ECOC classifier. It is good practice to specify the class order.

```
Mdl = fitcecoc(X,Y,'Learners',t,...  
    'ClassNames',{ 'setosa', 'versicolor', 'virginica' });
```

Mdl is a `ClassificationECOC` classifier. You can access its properties using dot notation.

Cross-validate Mdl using 10-fold cross-validation.

```
CVMdl = crossval(Mdl);
```

CVMdl is a `ClassificationPartitionedECOC` cross-validated ECOC classifier.

Estimate the generalization error.

```
oosLoss = kfoldLoss(CVMdl)
```

```
oosLoss = 0.0400
```

The out-of-sample classification error is 4%, which indicates that the ECOC classifier generalizes fairly well.

Train ECOC Classifiers Using Ensembles and Parallel Computing

Train a one-versus-all ECOC classifier using a GentleBoost ensemble of decision trees with surrogate splits. Estimate the classification error using 10-fold cross-validation.

Load and inspect the `arrhythmia` data set.

```
load arrhythmia  
[n,p] = size(X)  
isLabels = unique(Y);  
nLabels = numel(isLabels)  
tabulate(categorical(Y))
```

```
n =
```

```
452
```

```
p =
```

```
279
```

```
nLabels =  
13  
  
Value    Count    Percent  
1        245      54.20%  
2         44      9.73%  
3         15      3.32%  
4         15      3.32%  
5         13      2.88%  
6         25      5.53%  
7          3      0.66%  
8          2      0.44%  
9          9      1.99%  
10        50     11.06%  
14         4      0.88%  
15         5      1.11%  
16        22      4.87%
```

There are 279 predictors, and a relatively small sample size of 452. There are 16 distinct labels, but only 13 are represented in the response (Y), and each label describes various degrees of arrhythmia. 54.20% of the observations are in class 1.

Create an ensemble template. You must specify at least three arguments: a method, a number of learners, and the type of learner. For this example, specify 'GentleBoost' for the method, 100 for the number of learners, and a decision tree template that uses surrogate splits since there are missing observations.

```
tTree = templateTree('surrogate','on');  
tEnsemble = templateEnsemble('GentleBoost',100,tTree);
```

tEnsemble is a template object. Most of its properties are empty, but the software fills them with their default values during training.

Train a one-versus-all ECOC classifier using the ensembles of decision trees as binary learners. If you have a Parallel Computing Toolbox license, then you can speed up the computation by specifying to use parallel computing. This sends each binary learner to a worker in the pool (the number of workers depends on your system configuration). Also, specify that the prior probabilities are $1/K$, where $K = 13$, which is the number of distinct classes.

```
pool = parpool; % Invoke workers
options = statset('UseParallel',true);
Mdl = fitcecoc(X,Y,'Coding','onevsall','Learners',tEnsemble,...
    'Prior','uniform','Options',options);
```

Starting parallel pool (parpool) using the 'local' profile ... connected to 2 workers.

Mdl is a `ClassificationECOC` model.

Cross-validate the ECOC classifier using 10-fold cross-validation.

```
CVMdl = crossval(Mdl,'Options',options);
```

Warning: One or more folds do not contain points from all the groups.

CVMdl is a `ClassificationPartitionedECOC` model. The warning indicates that some classes are not represented while the software trains at least one fold. Therefore, those folds cannot predict labels for the missing classes. You can inspect the results of a fold using cell indexing and dot notation, e.g., access the results of the first fold by entering `CVMdl.Trained{1}`. Your results might vary.

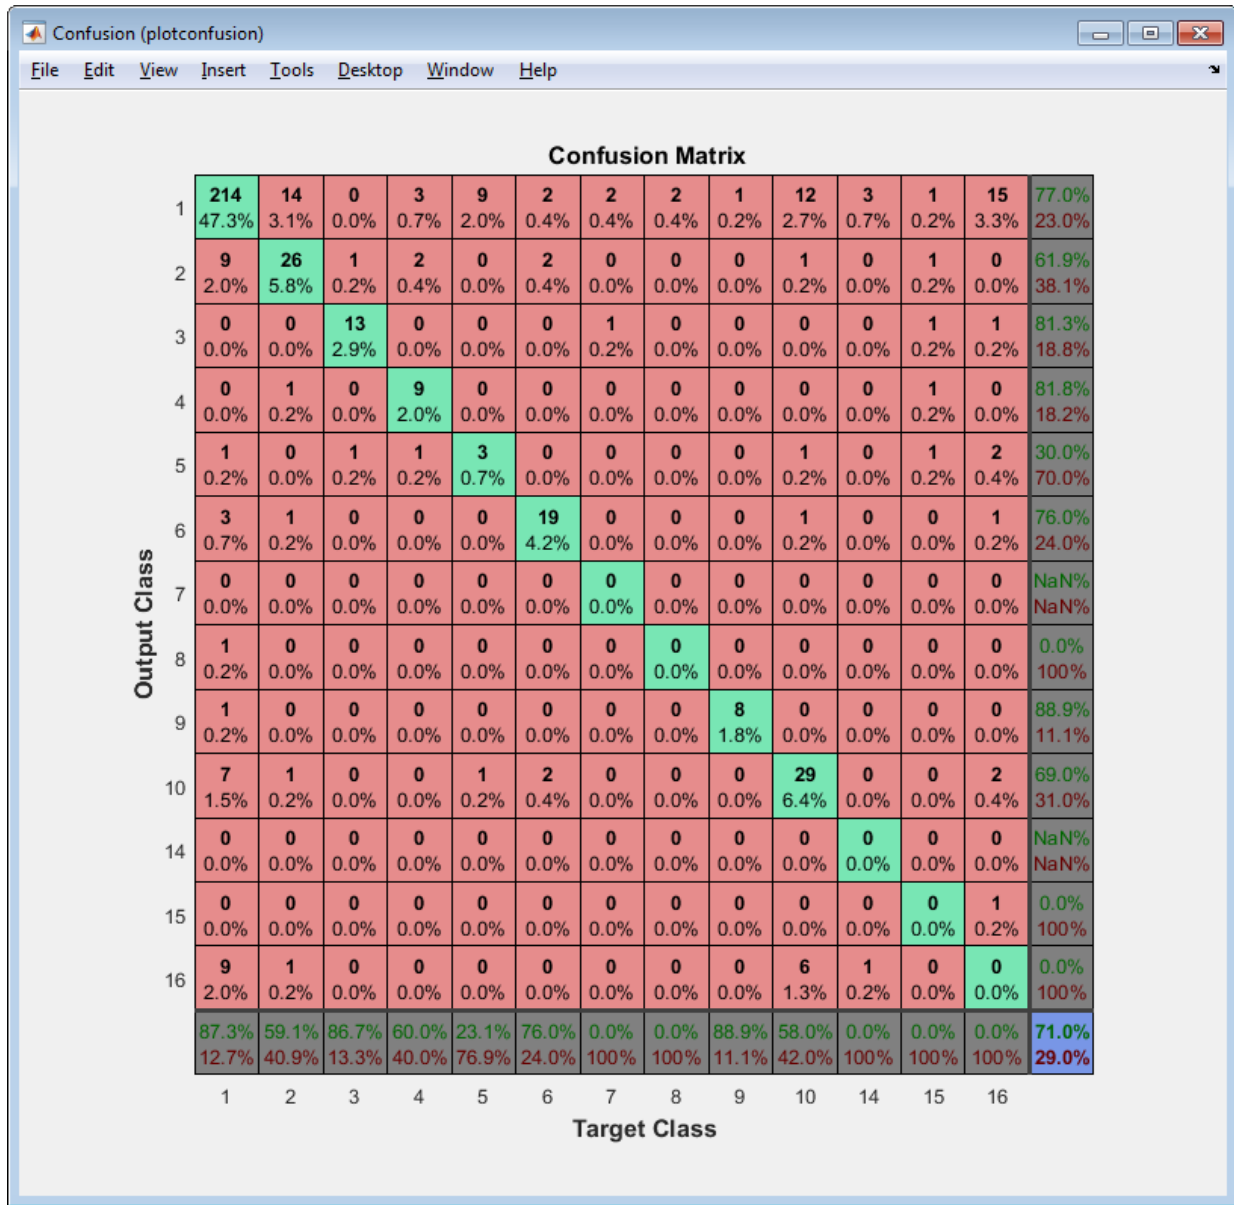

Use the cross-validated ECOC classifier to predict out-of-fold labels. You can compute the confusion matrix using `confusionmat`. However, if you have a Neural Network Toolbox license, you can plot the confusion matrix using `plotconfusion`. The input arguments of `plotconfusion` are not vectors of the true and predicted labels like `confusionmat`, but indicator matrices of the true and predicted labels. Both start as K -by- n matrices of 0s. If observation j has label index k (or has predicted label k), then element (k,j) of the true label indicator matrix (or predicted label indicator matrix) is 1. You can convert label indices returned by `predict`, `resubPredict`, or `kfoldPredict` to label indicator matrices using linear indexing. For details on linear indexing, see `sub2ind` and `ind2sub`.

```
oofLabel = kfoldPredict(CVMdl,'Options',options);
ConfMat = confusionmat(Y,oofLabel);
```

```
% Convert the integer label vector to a class-identifier matrix.
[~,grp00F] = ismember(oofLabel,isLabels);
oofLabelMat = zeros(nLabels,n);
idxLinear = sub2ind([nLabels n],grp00F,(1:n)');
oofLabelMat(idxLinear) = 1; % Flags the row corresponding to the class
[~,grpY] = ismember(Y,isLabels);
YMat = zeros(nLabels,n);
idxLinearY = sub2ind([nLabels n],grpY,(1:n)');
YMat(idxLinearY) = 1;
```

```
figure;  
plotconfusion(YMat,oofLabelMat);  
h = gca;  
h.XTickLabel = [num2cell(isLabels); {' '}];  
h.YTickLabel = [num2cell(isLabels); {' '}];
```

Algorithms

32-468 For linear, SVM binary learners, and for efficiency, `fitcecoc` empties the properties

Alpha, SupportVectorLabels, and SupportVectors. fitcecoc lists Beta, rather than Alpha, in the model display.

To store Alpha, SupportVectorLabels, and SupportVectors, pass a linear, SVM template that specifies storing support vectors to fitcecoc. For example, enter:

```
t = templateSVM('SaveSupportVectors','on')
Mdl = fitcecoc(X,Y,'Learners',t);
```

You can remove the support vectors and related values by passing the resulting ClassificationECOC model to discardSupportVectors.

ClassificationPartitionedEnsemble class

Cross-validated classification ensemble

Description

`ClassificationPartitionedEnsemble` is a set of classification ensembles trained on cross-validated folds. Estimate the quality of classification by cross validation using one or more “kfold” methods: `kfoldPredict`, `kfoldLoss`, `kfoldMargin`, `kfoldEdge`, and `kfoldfun`.

Every “kfold” method uses models trained on in-fold observations to predict response for out-of-fold observations. For example, suppose you cross validate using five folds. In this case, every training fold contains roughly 4/5 of the data and every test fold contains roughly 1/5 of the data. The first model stored in `Trained{1}` was trained on `X` and `Y` with the first 1/5 excluded, the second model stored in `Trained{2}` was trained on `X` and `Y` with the second 1/5 excluded, and so on. When you call `kfoldPredict`, it computes predictions for the first 1/5 of the data using the first model, for the second 1/5 of data using the second model, and so on. In short, response for every observation is computed by `kfoldPredict` using the model trained without this observation.

Construction

`cvens = crossval(ens)` creates a cross-validated ensemble from `ens`, a classification ensemble. For syntax details, see the `crossval` method reference page.

`cvens = fitcensemble(X,Y,Name,Value)` creates a cross-validated ensemble when `Name` is one of 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'. For syntax details, see the `fitcensemble` function reference page.

Properties

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the

predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

ClassNames

List of the elements in `Y` with duplicates removed. `ClassNames` can be a numeric vector, vector of categorical variables, logical vector, character array, or cell array of character vectors. `ClassNames` has the same data type as the data in the argument `Y`.

Combiner

Cell array of combiners across all folds.

Cost

Square matrix, where `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i` (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`. The number of rows and columns in `Cost` is the number of unique classes in the response. This property is read-only.

CrossValidatedModel

Name of the cross-validated model, a character vector.

Kfold

Number of folds used in a cross-validated ensemble, a positive integer.

ModelParameters

Object holding parameters of `cvens`.

NumObservations

Number of data points used in training the ensemble, a positive integer.

NTrainedPerFold

Number of data points used in training each fold of the ensemble, a positive integer.

Partition

Partition of class `cvpartition` used in creating the cross-validated ensemble.

PredictorNames

Cell array of names for the predictor variables, in the order in which they appear in *X*.

Prior

Numeric vector of prior probabilities for each class. The order of the elements of *Prior* corresponds to the order of the classes in *ClassNames*. The number of elements of *Prior* is the number of unique classes in the response. This property is read-only.

ResponseName

Name of the response variable *Y*, a character vector.

ScoreTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means $@(x)x$. For a list of built-in transformation functions and the syntax of custom transformation functions, see *fitctree*.

Add or change a *ScoreTransform* function using dot notation:

```
ens.ScoreTransform = 'function'
```

or

```
ens.ScoreTransform = @function
```

Trainable

Cell array of ensembles trained on cross-validation folds. Every ensemble is full, meaning it contains its training data and weights.

Trained

Cell array of compact ensembles trained on cross-validation folds.

W

Scaled weights, a vector with length *n*, the number of rows in *X*.

X

A matrix of predictor values. Each column of X represents one variable, and each row represents one observation.

Y

A numeric column vector with the same number of rows as X. Each entry in Y is the response to the data in the corresponding row of X.

Methods

| | |
|-----------|--|
| kfoldEdge | Classification edge for observations not used for training |
| kfoldLoss | Classification loss for observations not used for training |
| resume | Resume training learners on cross-validation folds |

Inherited Methods

| | |
|--------------|---|
| kfoldEdge | Classification edge for observations not used for training |
| kfoldfun | Cross validate function |
| kfoldLoss | Classification loss for observations not used for training |
| kfoldMargin | Classification margins for observations not used for training |
| kfoldPredict | Predict response for observations not used for training |

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Evaluate K-Fold Cross-Validation Error for Classification Ensemble

Evaluate the k-fold cross-validation error for a classification ensemble that models the Fisher iris data.

Load the sample data set.

```
load fisheriris
```

Train an ensemble of 100 boosted classification trees using AdaBoostM2.

```
t = templateTree('MaxNumSplits',1); % Weak learner template tree object  
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Create a cross-validated ensemble from ens and find the k-fold cross-validation error.

```
rng(10,'twister') % For reproducibility  
cvens = crossval(ens);  
L = kfoldLoss(cvens)
```

```
L = 0.0467
```

ClassificationPartitionedLinear class

Cross-validated linear model for binary classification of high-dimensional data

Description

`ClassificationPartitionedLinear` is a set of linear classification models trained on cross-validated folds. To obtain a cross-validated, linear classification model, use `fitcllinear` and specify one of the cross-validation options. You can estimate the quality of classification, or how well the linear classification model generalizes, using one or more of these “kfold” methods: `kfoldPredict`, `kfoldLoss`, `kfoldMargin`, and `kfoldEdge`.

Every “kfold” method uses models trained on in-fold observations to predict the response for out-of-fold observations. For example, suppose that you cross-validate using five folds. In this case, the software randomly assigns each observation into five roughly equally sized groups. The training fold contains four of the groups (that is, roughly 4/5 of the data) and the test fold contains the other group (that is, roughly 1/5 of the data). In this case, cross-validation proceeds as follows:

- 1 The software trains the first model (stored in `CVMDL.Trained{1}`) using the observations in the last four groups and reserves the observations in the first group for validation.
- 2 The software trains the second model, which is stored in `CVMDL.Trained{2}`, using the observations in the first group and last three groups. The software reserves the observations in the second group for validation.
- 3 The software proceeds in a similar fashion for the third through fifth models.

If you validate by calling `kfoldPredict`, it computes predictions for the observations in group 1 using the first model, group 2 for the second model, and so on. In short, the software estimates a response for every observation using the model trained without that observation.

Note Unlike other cross-validated, classification models, `ClassificationPartitionedLinear` model objects do not store the predictor data set.

Construction

`CVMdl = fitclinear(X,Y,Name,Value)` creates a cross-validated, linear classification model when `Name` is either `'CrossVal'`, `'CVPartition'`, `'Holdout'`, or `'KFold'`. For more details, see `fitclinear`.

Properties

Cross-Validation Properties

CrossValidatedModel — Cross-validated model name

character array

Cross-validated model name, specified as a character array.

For example, `'Linear'` specifies a cross-validated linear model for binary classification or regression.

Data Types: `char`

KFold — Number of cross-validated folds

positive integer

Number of cross-validated folds, specified as a positive integer.

Data Types: `double`

ModelParameters — Cross-validation parameter values

object

Cross-validation parameter values, e.g., the name-value pair argument values used to cross-validate the linear model, specified as an object. `ModelParameters` does not contain estimated parameters.

Access properties of `ModelParameters` using dot notation.

NumObservations — Number of observations

positive numeric scalar

Number of observations in the training data, specified as a positive numeric scalar.

Data Types: `double`

Partition — Data partition

cvpartition model

Data partition indicating how the software splits the data into cross-validation folds, specified as a cvpartition model.

Trained — Linear classification models trained on cross-validation folds

cell array of ClassificationLinear model objects

Linear classification models trained on cross-validation folds, specified as a cell array of ClassificationLinear models. Trained has k cells, where k is the number of folds.

Data Types: cell

W — Observation weights

numeric vector

Observation weights used to cross-validate the model, specified as a numeric vector. W has NumObservations elements.

The software normalizes W so that the weights for observations within a particular class sum up to the prior probability of that class.

Data Types: single | double

Y — Observed class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Observed class labels used to cross-validate the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Y has NumObservations elements, and is the same data type as the input argument Y that you passed to fitclinear to cross-validate the model.

Each row of Y represents the observed classification of the corresponding observation in the predictor data.

Data Types: char | cell | categorical | logical | single | double

Other Classification Properties**CategoricalPredictors — Indices of categorical predictors**

vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

ClassNames — Unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` has the same data type as class labels (`Y`). `ClassNames` also determines the class order.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Cost — Misclassification costs

square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. `Cost` has K rows and columns, where K is the number of classes.

`Cost(i, j)` is the cost of classifying a point into class j if its true class is i . The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`.

Data Types: `double`

PredictorNames — Predictor names

cell array of character vectors

Predictor names in their order of appearance in predictor data used to train `CVMdl`, specified as a cell array of character vectors. `PredictorNames` has length equal to the number of predictor variables in the predictor data.

Data Types: `cell`

Prior — Prior class probabilities

numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. `Prior` has as many elements as classes in `ClassNames`, and the order of the elements corresponds to the elements of `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: `double`

ResponseName — Response variable name

character array

Response variable name, specified as a character array.

Data Types: `char`

ScoreTransform — Score transformation function to apply to predicted scores

function name | function handle

Score transformation function to apply to predicted scores, specified as a function name or function handle.

For linear classification models and before transformation, the predicted classification score for the observation x (row vector) is $f(x) = x\beta + b$, where β and b correspond to `Mdl.Beta` and `Mdl.Bias`, respectively.

To change the score transformation function to, e.g., *function*, use dot notation.

- For a built-in function, enter this code and replace *function* with a character vector in the table.

```
Mdl.ScoreTransform = 'function';
```

| Value | Description |
|---------------|--|
| 'doublelogit' | $1/(1 + e^{-2x})$ |
| 'invlogit' | $\log(x / (1-x))$ |
| 'ismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0 |
| 'logit' | $1/(1 + e^{-x})$ |

| Value | Description |
|----------------------|---|
| 'none' or 'identity' | x (no transformation) |
| 'sign' | -1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$ |
| 'symmetric' | $2x - 1$ |
| 'symmetricismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1 |
| 'symmetriclogit' | $2/(1 + e^{-x}) - 1$ |

- For a MATLAB function, or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function must accept a matrix of the original scores for each class, and then return a matrix of the same size representing the transformed scores for each class.

Data Types: char | function_handle

Methods

kfoldEdge Classification edge for observations not used for training
kfoldLoss Classification loss for observations not used in training
kfoldMargin Classification margins for observations not used in training
kfoldPredict Predict labels for observations not used for training

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Create Cross-Validated Binary Linear Classification Model

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

Identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Cross-validate a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```
rng(1); % For reproducibility
CVMdl = fitlinear(X,Ystats,'CrossVal','on')
```

```
CVMdl =
  classreg.learning.partition.ClassificationPartitionedLinear
    CrossValidatedModel: 'Linear'
      ResponseName: 'Y'
    NumObservations: 31572
           KFold: 10
      Partition: [1x1 cvpartition]
    ClassNames: [0 1]
    ScoreTransform: 'none'
```

Properties, Methods

CVMdl is a `ClassificationPartitionedLinear` cross-validated model. Because `fitlinear` implements 10-fold cross-validation by default, `CVMdl.Trained` contains ten `ClassificationLinear` models that contain the results of training linear classification models for each of the folds.

Estimate labels for out-of-fold observations and estimate the generalization error by passing CVMdl to `kfoldPredict` and `kfoldLoss`, respectively.

```
oofLabels = kfoldPredict(CVMdl);
ge = kfoldLoss(CVMdl)
```

```
ge = 7.6017e-04
```

The estimated generalization error is less than 0.1% misclassified observations.

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, implement 5-fold cross-validation.

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-6} through $10^{-0.5}$.

```
Lambda = logspace(-6, -0.5, 11);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Estimate the coefficients using SpARSA. Lower the tolerance on the gradient of the objective function to 1e-8.

```
X = X';  
rng(10); % For reproducibility  
CVMdl = fitlinear(X, Ystats, 'ObservationsIn', 'columns', 'KFold', 5, ...  
    'Learner', 'logistic', 'Solver', 'sparsa', 'Regularization', 'lasso', ...  
    'Lambda', Lambda, 'GradientTolerance', 1e-8)  
  
CVMdl =  
    classreg.learning.partition.ClassificationPartitionedLinear  
    CrossValidatedModel: 'Linear'
```

```

    ResponseName: 'Y'
    NumObservations: 31572
    KFold: 5
    Partition: [1×1 cvpartition]
    ClassNames: [0 1]
    ScoreTransform: 'none'

```

Properties, Methods

```
numCLModels = numel(CVMdl.Trained)
```

```
numCLModels = 5
```

CVMdl is a `ClassificationPartitionedLinear` model. Because `fitlinear` implements 5-fold cross-validation, CVMdl contains 5 `ClassificationLinear` models that the software trains on each fold.

Display the first trained linear classification model.

```
Mdl1 = CVMdl.Trained{1}
```

```
Mdl1 =
```

```
ClassificationLinear
```

```
    ResponseName: 'Y'
```

```
    ClassNames: [0 1]
```

```
    ScoreTransform: 'logit'
```

```
        Beta: [34023×11 double]
```

```
        Bias: [-13.2904 -13.2904 -13.2904 -13.2904 -9.9357 -7.0782 -5.4335 -4.54
```

```
        Lambda: [1.0000e-06 3.5481e-06 1.2589e-05 4.4668e-05 1.5849e-04 5.6234e-04
```

```
        Learner: 'logistic'
```

Properties, Methods

Mdl1 is a `ClassificationLinear` model object. `fitlinear` constructed Mdl1 by training on the first four folds. Because `Lambda` is a sequence of regularization strengths, you can think of Mdl1 as 11 models, one for each regularization strength in `Lambda`.

Estimate the cross-validated classification error.

```
ce = kfoldLoss(CVMdl);
```

Because there are 11 regularization strengths, `ce` is a 1-by-11 vector of classification error rates.

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitclinear(X,Ystats,'ObservationsIn','columns',...  
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...  
    'Lambda',Lambda,'GradientTolerance',1e-8);  
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated, classification error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;  
[h,hL1,hL2] = plotyy(log10(Lambda),log10(ce),...  
    log10(Lambda),log10(numNZCoeff));  
hL1.Marker = 'o';  
hL2.Marker = 'o';  
ylabel(h(1),'log_{10} classification error')  
ylabel(h(2),'log_{10} nonzero-coefficient frequency')  
xlabel('log_{10} Lambda')  
title('Test-Sample Statistics')  
hold off
```

Choose the index of the regularization strength that balances predictor variable sparsity and low classification error. In this case, a value between 10^{-4} to 10^{-1} should suffice.

```
idxFinal = 7;
```

Select the model from Mdl with the chosen regularization strength.

```
MdlFinal = selectModels(Mdl,idxFinal);
```

MdlFinal is a ClassificationLinear model containing one regularization strength. To estimate labels for new observations, pass MdlFinal and the new data to predict.

Introduced in R2016a

ClassificationPartitionedLinearECOC class

Cross-validated linear error-correcting output codes model for multiclass classification of high-dimensional data

Description

`ClassificationPartitionedLinearECOC` is a set of error-correcting output codes (ECOC) models composed of linear classification models, trained on cross-validated folds. Estimate the quality of classification by cross-validation using one or more “kfold” functions: `kfoldPredict`, `kfoldLoss`, `kfoldMargin`, and `kfoldEdge`.

Every “kfold” method uses models trained on in-fold observations to predict the response for out-of-fold observations. For example, suppose that you cross-validate using five folds. In this case, the software randomly assigns each observation into five roughly equal-sized groups. The training fold contains four of the groups (that is, roughly 4/5 of the data) and the test fold contains the other group (that is, roughly 1/5 of the data). In this case, cross-validation proceeds as follows.

- 1 The software trains the first model (stored in `CVMDL.Trained{1}`) using the observations in the last four groups and reserves the observations in the first group for validation.
- 2 The software trains the second model (stored in `CVMDL.Trained{2}`) using the observations in the first group and last three groups. The software reserves the observations in the second group for validation.
- 3 The software proceeds in a similar fashion for the third, fourth, and fifth models.

If you validate by calling `kfoldPredict`, it computes predictions for the observations in group 1 using the first model, group 2 for the second model, and so on. In short, the software estimates a response for every observation using the model trained without that observation.

Note Unlike other cross-validated ECOC models, `ClassificationPartitionedLinearECOC` model objects do not store the predictor data set.

Construction

`CVMdl = fitcecoc(X,Y,'Learners',t,Name,Value)` returns a cross-validated, linear ECOC model when:

- `t` is 'Linear' or a template object returned by `templateLinear`.
- `Name` is one of 'CrossVal', 'CVPartition', 'Holdout', or 'Kfold'.

For more details, see `fitcecoc`.

Properties

Cross-Validation Properties

CrossValidatedModel — Cross-validated model name

character vector

Cross-validated model name, specified as a character vector.

For example, 'ECOC' specifies a cross-validated ECOC model.

Data Types: `char`

KFold — Number of cross-validated folds

positive integer

Number of cross-validated folds, specified as a positive integer.

Data Types: `double`

ModelParameters — Cross-validation parameter values

object

Cross-validation parameter values, e.g., the name-value pair argument values used to cross-validate the ECOC classifier, specified as an object. `ModelParameters` does not contain estimated parameters.

Access properties of `ModelParameters` using dot notation.

NumObservations — Number of observations

positive numeric scalar

Number of observations in the training data, specified as a positive numeric scalar.

Data Types: double

Partition — Data partition

cvpartition model

Data partition indicating how the software splits the data into cross-validation folds, specified as a cvpartition model.

Trained — Compact classifiers trained on cross-validation folds

cell array of CompactClassificationECOC models

Compact classifiers trained on cross-validation folds, specified as a cell array of CompactClassificationECOC models. Trained has k cells, where k is the number of folds.

Data Types: cell

W — Observation weights

numeric vector

Observation weights used to cross-validate the model, specified as a numeric vector. W has NumObservations elements.

The software normalizes the weights used for training so that $\text{nansum}(W)$ is 1.

Data Types: single | double

Y — Observed class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Observed class labels used to cross-validate the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Y has NumObservations elements, and is the same data type as the input argument Y that you passed to fitcecoc to cross-validate the model.

Each row of Y represents the observed classification of the observation in the predictor data.

Data Types: char | cell | categorical | logical | single | double

ECOC Properties**BinaryLoss — Binary learner loss function**

character vector representing the loss function name

Binary learner loss function, specified as a character vector representing the loss function name.

If you train using binary learners that use different loss functions, then the software sets `BinaryLoss` to 'hamming'. To potentially increase accuracy, set a different binary loss function than this default during prediction or loss computation using the `BinaryLoss` name-value pair argument of `predict` or `loss`.

Data Types: char

BinaryY — Binary learner class labels

numeric matrix | []

Binary learner class labels, specified as a numeric matrix or [].

- If the coding matrix is the same across folds, then `BinaryY` is a `NumObservations-by-L` matrix, where L is the number of binary learners (`size(CodingMatrix,2)`).

Elements of `BinaryY` are -1, 0, or 1, and the value corresponds to a dichotomous class assignment. This table describes how learner j assigns observation k to a dichotomous class corresponding to the value of `BinaryY(k,j)`.

| Value | Dichotomous Class Assignment |
|-------|---|
| -1 | Negative class |
| 0 | Before training, learner j removes observations in class i from the data set. |
| 1 | Positive class |

- If the coding matrix varies across folds, then `BinaryY` is empty ([]).

Data Types: double

CodingMatrix — Codes specifying class assignments

numeric matrix | []

Codes specifying class assignments for the binary learners, specified as a numeric matrix or [].

- If the coding matrix is the same across folds, then `CodingMatrix` is a K -by- L matrix. K is the number of classes and L is the number of binary learners.

Elements of `CodingMatrix` are -1, 0, or 1, and the value corresponds to a dichotomous class assignment. This table describes how learner j assigns observations in class k to a dichotomous class corresponding to the value of `CodingMatrix(k, j)`.

| Value | Dichotomous Class Assignment |
|-------|---|
| -1 | Negative class |
| 0 | Before training, learner j removes observations in class i from the data set. |
| 1 | Positive class |

- If the coding matrix varies across folds, then `CodingMatrix` is empty (`[]`). Obtain the coding matrix for each fold using the `Trained` property. For example, `CVMDL.Trained{1}.CodingMatrix` is the coding matrix in the first fold of the cross-validated ECOC model `CVMDL`.

Data Types: `char` | `double` | `single` | `int8` | `int16` | `int32` | `int64`

Other Classification Properties

CategoricalPredictors — Indices of categorical predictors

vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

ClassNames — Unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` has the same data type as class labels (`Y`). `ClassNames` also determines the class order.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Cost — Misclassification costs

square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. `Cost` has K rows and columns, where K is the number of classes.

`Cost(i, j)` is the cost of classifying a point into class j if its true class is i . The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: `double`

PredictorNames — Predictor names

cell array of character vectors

Predictor names in their order of appearance in predictor data used to train `CVMdl`, specified as a cell array of character vectors. `PredictorNames` has length equal to the number of predictor variables in the predictor data.

Data Types: `cell`

Prior — Prior class probabilities

numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. `Prior` has as many elements as classes in `ClassNames`, and the order of the elements corresponds to the elements of `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: `double`

ResponseName — Response variable name

character array

Response variable name, specified as a character array.

Data Types: char

ScoreTransform — Score transformation function to apply to predicted scores

function name | function handle

Score transformation function to apply to predicted scores, specified as a function name or function handle.

For linear classification models and before transformation, the predicted classification score for the observation x (row vector) is $f(x) = x\beta + b$, where β and b correspond to `Mdl.Beta` and `Mdl.Bias`, respectively.

To change the score transformation function to, e.g., *function*, use dot notation.

- For a built-in function, enter this code and replace *function* with a character vector in the table.

```
Mdl.ScoreTransform = 'function';
```

| Value | Description |
|----------------------|---|
| 'doublelogit' | $1/(1 + e^{-2x})$ |
| 'invlogit' | $\log(x / (1-x))$ |
| 'ismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0 |
| 'logit' | $1/(1 + e^{-x})$ |
| 'none' or 'identity' | x (no transformation) |
| 'sign' | -1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$ |
| 'symmetric' | $2x - 1$ |
| 'symmetricismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1 |
| 'symmetriclogit' | $2/(1 + e^{-x}) - 1$ |

- For a MATLAB function, or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function must accept a matrix of the original scores for each class, and then return a matrix of the same size representing the transformed scores for each class.

Data Types: char | function_handle

Methods

| | |
|--------------|--|
| kfoldEdge | Classification edge for observations not used for training |
| kfoldLoss | Classification loss for observations not used in training |
| kfoldMargin | Classification margins for observations not used in training |
| kfoldPredict | Predict labels for observations not used for training |

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Create Cross-Validated Multiclass Linear Classification Model

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels.

Cross-validate a multiclass, linear classification model that can identify which MATLAB® toolbox a documentation web page is from based on counts of words on the page.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners','linear','CrossVal','on')

CVMdl =
    classreg.learning.partition.ClassificationPartitionedLinearECOC
```

```
CrossValidatedModel: 'Linear'  
  ResponseName: 'Y'  
  NumObservations: 31572  
    KFold: 10  
    Partition: [1x1 cvpartition]  
    ClassNames: [1x13 categorical]  
  ScoreTransform: 'none'
```

Properties, Methods

`CVMdl` is a `ClassificationPartitionedLinearECOC` cross-validated model. Because `fitcecoc` implements 10-fold cross-validation by default, `CVMdl.Trained` contains a 10-by-1 cell vector of ten `CompactClassificationECOC` models that contain the results of training ECOC models composed of binary, linear classification models for each of the folds.

Estimate labels for out-of-fold observations and estimate the generalization error by passing `CVMdl` to `kfoldPredict` and `kfoldLoss`, respectively.

```
oofLabels = kfoldPredict(CVMdl);  
ge = kfoldLoss(CVMdl)
```

```
ge = 0.0958
```

The estimated generalization error is about 10% misclassified observations.

To improve generalization error, try specifying another solver, such as `LBFGS`. To change default options when training ECOC models composed of linear classification models, create a linear classification model template using `templateLinear`, and then pass the template to `fitcecoc`.

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for an ECOC model composed of linear classification models that use logistic regression learners, implement 5-fold cross-validation.

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels.

For simplicity, use the label 'others' for all observations in Y that are not 'simulink', 'dsp', or 'comm'.

```
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-7} through 10^{-2} .

```
Lambda = logspace(-7,-2,11);
```

Create a linear classification model template that specifies to use logistic regression learners, use lasso penalties with strengths in Lambda, train using SpaRSA, and lower the tolerance on the gradient of the objective function to $1e-8$.

```
t = templateLinear('Learner','logistic','Solver','sparsa',...  
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns.

```
X = X';  
rng(10); % For reproducibility  
CVMdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','KFold',5);
```

CVMdl is a ClassificationPartitionedLinearECOC model.

Dissect CVMdl, and each model within it.

```
numECOCModels = numel(CVMdl.Trained)
```

```
numECOCModels = 5
```

```
ECOCmdl1 = CVMdl.Trained{1}
```

```
ECOCmdl1 =  
    classreg.learning.classif.CompactClassificationECOC  
    ResponseName: 'Y'  
    ClassNames: [comm    dsp    simulink  others]  
    ScoreTransform: 'none'  
    BinaryLearners: {6x1 cell}
```

```
CodingMatrix: [4×6 double]
```

```
Properties, Methods
```

```
numCLModels = numel(ECOCmdl.BinaryLearners)
```

```
numCLModels = 6
```

```
CLMdl1 = ECOCmdl.BinaryLearners{1}
```

```
CLMdl1 =
```

```
ClassificationLinear
```

```
  ResponseName: 'Y'
```

```
  ClassNames: [-1 1]
```

```
  ScoreTransform: 'logit'
```

```
    Beta: [34023×11 double]
```

```
    Bias: [-0.3125 -0.3596 -0.3596 -0.3596 -0.3596 -0.3596 -0.1593 -0.0737 -
```

```
    Lambda: [1.0000e-07 3.1623e-07 1.0000e-06 3.1623e-06 1.0000e-05 3.1623e-05
```

```
    Learner: 'logistic'
```

```
Properties, Methods
```

Because `fitcecoc` implements 5-fold cross-validation, `CVMdl` contains a 5-by-1 cell array of `CompactClassificationECOC` models that the software trains on each fold. The `BinaryLearners` property of each `CompactClassificationECOC` model contains the `ClassificationLinear` models. The number of `ClassificationLinear` models within each compact ECOC model depends on the number of distinct labels and coding design. Because `Lambda` is a sequence of regularization strengths, you can think of `CLMdl1` as 11 models, one for each regularization strength in `Lambda`.

Determine how well the models generalize by plotting the averages of the 5-fold classification error for each regularization strength. Identify the regularization strength that minimizes the generalization error over the grid.

```
ce = kfoldLoss(CVMdl);
```

```
figure;
```

```
plot(log10(Lambda), log10(ce))
```

```
[~, minCEIdx] = min(ce);
```

```
minLambda = Lambda(minCEIdx);
```

```
hold on
```

```
plot(log10(minLambda), log10(ce(minCEIdx)), 'ro');
```

```

ylabel('log_{10} 5-fold classification error')
xlabel('log_{10} Lambda')
legend('MSE', 'Min classification error')
hold off

```

Train an ECOC model composed of linear classification model using the entire data set, and specify the minimal regularization strength.

```

t = templateLinear('Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',minLambda,'GradientTolerance',1e-8);
MdlFinal = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns');

```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Introduced in R2016a

ClassificationPartitionedModel class

Cross-validated classification model

Description

`ClassificationPartitionedModel` is a set of classification models trained on cross-validated folds. Estimate the quality of classification by cross validation using one or more “kfold” methods: `kfoldPredict`, `kfoldLoss`, `kfoldMargin`, `kfoldEdge`, and `kfoldfun`.

Every “kfold” method uses models trained on in-fold observations to predict the response for out-of-fold observations. For example, suppose you cross validate using five folds. In this case, the software randomly assigns each observation into five roughly equally sized groups. The training fold contains four of the groups (i.e., roughly 4/5 of the data) and the test fold contains the other group (i.e., roughly 1/5 of the data). In this case, cross validation proceeds as follows:

- The software trains the first model (stored in `CVMDL.Trained{1}`) using the observations in the last four groups and reserves the observations in the first group for validation.
- The software trains the second model (stored in `CVMDL.Trained{2}`) using the observations in the first group and last three groups, and reserves the observations in the second group for validation.
- The software proceeds in a similar fashion for the third to fifth models.

If you validate by calling `kfoldPredict`, it computes predictions for the observations in group 1 using the first model, group 2 for the second model, and so on. In short, the software estimates a response for every observation using the model trained without that observation.

Construction

`CVMDL = crossval(Mdl)` creates a cross-validated classification model from a classification model (`Mdl`).

Alternatively:

- `CVDiscrMdl = fitcdiscr(X,Y,Name,Value)`
- `CVKNNMdl = fitcknn(X,Y,Name,Value)`
- `CVNBMDL = fitcnb(X,Y,Name,Value)`
- `CVSVMMDL = fitcsvm(X,Y,Name,Value)`
- `CVTreeMdl = fitctree(X,Y,Name,Value)`

create a cross-validated model when name is either 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'. For syntax details, see `fitcdiscr`, `fitcknn`, `fitcnb`, `fitcsvm`, and `fitctree`.

Input Arguments

Mdl

A classification model. Mdl can be any of the following:

- A classification tree trained using `fitctree`
- A discriminant analysis classifier trained using `fitcdiscr`
- A naive Bayes classifier trained using `fitcnb`
- A nearest-neighbor classifier trained using `fitcknn`
- A support vector machine classifier trained using `fitcsvm`

Properties

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

If Mdl is a trained discriminant analysis classifier, then `CategoricalPredictors` is always empty (`[]`).

ClassNames

Unique class labels used in training the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors.

Cost

Square matrix, where $Cost(i, j)$ is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`. The number of rows and columns in `Cost` is the number of unique classes in the response.

If `CVModel` is a cross-validated `ClassificationDiscriminant`, `ClassificationKNN`, or `ClassificationNaiveBayes` model, then you can change its cost matrix to e.g., `CostMatrix`, using dot notation.

```
CVModel.Cost = CostMatrix;
```

CrossValidatedModel

Name of the cross-validated model, which is a character vector.

KFold

Number of folds used in cross-validated model, which is a positive integer.

ModelParameters

Object holding parameters of `CVModel`.

Partition

The partition of class `CVPartition` used in creating the cross-validated model.

PredictorNames

Predictor variable names, specified as a cell array of character vectors. The order of the elements of `PredictorNames` corresponds to the order in which the predictor names appear in the training data.

Prior

Numeric vector of prior probabilities for each class. The order of the elements of `Prior` corresponds to the order of the classes in `ClassNames`.

If `CVModel` is a cross-validated `ClassificationDiscriminant` or `ClassificationNaiveBayes` model, then you can change its vector of priors to e.g., `priorVector`, using dot notation.

```
CVModel.Prior = priorVector;
```

ResponseName

Response variable name, specified as a character vector.

ScoreTransform

Score transformation, specified as a character vector or function handle. `ScoreTransform` represents a built-in transformation function or a function handle for transforming predicted classification scores.

To change the score transformation function to *function*, for example, use dot notation.

- For a built-in function, enter a character vector.

```
Mdl.ScoreTransform = 'function';
```

This table describes the available built-in functions.

| Value | Description |
|----------------------|--|
| 'doublelogit' | $1/(1 + e^{-2x})$ |
| 'invlogit' | $\log(x / (1-x))$ |
| 'ismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0 |
| 'logit' | $1/(1 + e^{-x})$ |
| 'none' or 'identity' | x (no transformation) |
| 'sign' | -1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$ |

| Value | Description |
|------------------|---|
| 'symmetric' | $2x - 1$ |
| 'symmetricismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1 |
| 'symmetriclogit' | $2/(1 + e^{-x}) - 1$ |

- For a MATLAB function or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Trained

The trained learners, which is a cell array of compact classification models.

W

The scaled weights, which is a vector with length n , the number of rows in X .

X

Numeric matrix of predictor values. Each column of X represents one variable, and each row represents one observation.

Y

Categorical or character array, logical or numeric vector, or cell array of character vectors specifying the class labels for each observation. Y has the same number of rows as X , and each entry of Y is the response to the data in the corresponding row of X .

Methods

| | |
|---------------------------|---|
| <code>kfoldEdge</code> | Classification edge for observations not used for training |
| <code>kfoldfun</code> | Cross validate function |
| <code>kfoldLoss</code> | Classification loss for observations not used for training |
| <code>kfoldMargin</code> | Classification margins for observations not used for training |
| <code>kfoldPredict</code> | Predict response for observations not used for training |

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Evaluate the Classification Error of a Classification Tree Classifier

Evaluate the k -fold cross-validation error for a classification tree model.

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification tree using default options.

```
Mdl = fitctree(meas,species);
```

Cross validate the classification tree model.

```
CVMDL = crossval(Mdl);
```

Estimate the 10-fold cross-validation loss.

```
L = kfoldLoss(CVMDL)
```

```
L = 0.0533
```

Estimate Posterior Probabilities for Test Samples

Estimate positive class posterior probabilities for the test set of an SVM algorithm.

Load the `ionosphere` data set.

```
load ionosphere
```

Train an SVM classifier. Specify a 20% holdout sample. It is good practice to standardize the predictors and specify the class order.

```
rng(1) % For reproducibility
CVSVMModel = fitcsvm(X,Y,'Holdout',0.2,'Standardize',true,...
    'ClassNames',{'b','g'});
```

`CVSVMModel` is a trained `ClassificationPartitionedModel` cross-validated classifier.

Estimate the optimal score function for mapping observation scores to posterior probabilities of an observation being classified as 'g'.

```
ScoreCVSVMModel = fitSVMPosterior(CVSVMModel);
```

`ScoreSVMModel` is a trained `ClassificationPartitionedModel` cross-validated classifier containing the optimal score transformation function estimated from the training data.

Estimate the out-of-sample positive class posterior probabilities. Display the results for the first 10 out-of-sample observations.

```
[~,OOSPostProbs] = kfoldPredict(ScoreCVSVMModel);
indx = ~isnan(OOSPostProbs(:,2));
hoObs = find(indx); % Holdout observation numbers
OOSPostProbs = [hoObs, OOSPostProbs(indx,2)];
table(OOSPostProbs(1:10,1),OOSPostProbs(1:10,2),...
    'VariableNames',{'ObservationIndex','PosteriorProbability'})
```

```
ans =
```

```
10x2 table
```

```
ObservationIndex    PosteriorProbability

Topics

“Cross Validating a Discriminant Analysis Classifier” on page 20-23

ClassificationSVM

Support vector machine (SVM) for one-class and binary classification

Description

`ClassificationSVM` is a support vector machine (SVM) classifier on page 32-528 for one-class and two-class learning. Trained `ClassificationSVM` classifiers store training data, parameter values, prior probabilities, support vectors, and algorithmic implementation information. Use these classifiers to perform tasks such as fitting a score-to-posterior-probability transformation function (see `fitPosterior`) and predicting labels for new data (see `predict`).

Creation

Create a `ClassificationSVM` object by using `fitcsvm`.

Properties

SVM Properties

Alpha — Trained classifier coefficients

numeric vector

This property is read-only.

Trained classifier coefficients, specified as an s -by-1 numeric vector. s is the number of support vectors in the trained classifier, `sum(Mdl.IsSupportVector)`.

`Alpha` contains the trained classifier coefficients from the dual problem, that is, the estimated Lagrange multipliers. If you remove duplicates by using the `RemoveDuplicates` name-value pair argument of `fitcsvm`, then for a given set of duplicate observations that are support vectors, `Alpha` contains one coefficient corresponding to the entire set. That is, MATLAB attributes a nonzero coefficient to one

observation from the set of duplicates and a coefficient of 0 to all other duplicate observations in the set.

Data Types: `single` | `double`

Beta — Linear predictor coefficients

numeric vector

This property is read-only.

Linear predictor coefficients, specified as a numeric vector. The length of `Beta` is equal to the number of predictors used to train the model.

MATLAB expands categorical variables in the predictor data using full dummy encoding. That is, MATLAB creates one dummy variable for each level of each categorical variable. `Beta` stores one value for each predictor variable, including the dummy variables. For example, if there are three predictors, one of which is a categorical variable with three levels, then `Beta` is a numeric vector containing five values.

If `KernelParameters.Function` is `'linear'`, then the classification score for the observation x is

$$f(x) = (x / s)' \beta + b.$$

`Mdl` stores β , b , and s in the properties `Beta`, `Bias`, and `KernelParameters.Scale`, respectively.

To estimate classification scores manually, you must first apply any transformations to the predictor data that were applied during training. Specifically, if you specify `'Standardize', true` when using `fitcsvm`, then you must standardize the predictor data manually by using the mean `Mdl.Mu` and standard deviation `Mdl.Sigma`, and then divide the result by the kernel scale in `Mdl.KernelParameters.Scale`.

All SVM functions, such as `resubPredict` and `predict`, apply any required transformation before estimation.

If `KernelParameters.Function` is not `'linear'`, then `Beta` is empty (`[]`).

Data Types: `single` | `double`

Bias — Bias term

scalar

This property is read-only.

Bias term, specified as a scalar.

Data Types: `single` | `double`

BoxConstraints — Box constraints

numeric vector

This property is read-only.

Box constraints, specified as a numeric vector of n -by-1 box constraints on page 32-526. n is the number of observations in the training data (see the `NumObservations` property).

If you remove duplicates by using the `RemoveDuplicates` name-value pair argument of `fitcsvm`, then for a given set of duplicate observations, MATLAB sums the box constraints and then attributes the sum to one observation. MATLAB attributes the box constraints of θ to all other observations in the set.

Data Types: `single` | `double`

CacheInfo — Caching information

structure array

This property is read-only.

Caching information, specified as a structure array. The caching information contains the fields described in this table.

| Field | Description |
|-----------|---|
| Size | The cache size (in MB) that the software reserves to train the SVM classifier. For details, see 'CacheSize'. |
| Algorithm | The caching algorithm that the software uses during optimization. Currently, the only available caching algorithm is <code>Queue</code> . You cannot set the caching algorithm. |

Display the fields of `CacheInfo` by using dot notation. For example, `Mdl.CacheInfo.Size` displays the value of the cache size.

Data Types: `struct`

IsSupportVector — Support vector indicator

logical vector

This property is read-only.

Support vector indicator, specified as an n -by-1 logical vector that flags whether a corresponding observation in the predictor data matrix is a “Support Vector” on page 32-528. n is the number of observations in the training data (see NumObservations).

If you remove duplicates by using the RemoveDuplicates name-value pair argument of fitcsvm, then for a given set of duplicate observations that are support vectors, IsSupportVector flags only one observation as a support vector.

Data Types: logical

KernelParameters — Kernel parameters

structure array

This property is read-only.

Kernel parameters, specified as a structure array. The kernel parameters property contains the fields listed in this table.

| Field | Description |
|----------|--|
| Function | Kernel function used to compute the elements of the Gram matrix on page 32-2079. For details, see 'KernelFunction'. |
| Scale | Kernel scale parameter used to scale all elements of the predictor data on which the model is trained. For details, see 'KernelScale'. |

To display the values of KernelParameters, use dot notation. For example, Mdl.KernelParameters.Scale displays the kernel scale parameter value.

The software accepts KernelParameters as inputs and does not modify them.

Data Types: struct

Nu — One-class learning parameter

positive scalar

This property is read-only.

One-class learning on page 32-527 parameter ν , specified as a positive scalar.

Data Types: `single` | `double`

OutlierFraction — Proportion of outliers

numeric scalar

This property is read-only.

Proportion of outliers in the training data, specified as a numeric scalar.

Data Types: `double`

Solver — Optimization routine

'ISDA' | 'L1QP' | 'SMO'

This property is read-only.

Optimization routine used to train the SVM classifier, specified as 'ISDA', 'L1QP', or 'SMO'. For more details, see 'Solver'.

Data Types: `char`

SupportVectorLabels — Support vector class labels

s-by-1 numeric vector

This property is read-only.

Support vector class labels, specified as an *s*-by-1 numeric vector. *s* is the number of support vectors in the trained classifier, `sum(Mdl.IsSupportVector)`.

A value of +1 in `SupportVectorLabels` indicates that the corresponding support vector is in the positive class (`ClassNames{2}`). A value of -1 indicates that the corresponding support vector is in the negative class (`ClassNames{1}`).

If you remove duplicates by using the `RemoveDuplicates` name-value pair argument of `fitsvm`, then for a given set of duplicate observations that are support vectors, `SupportVectorLabels` contains one unique support vector label.

Data Types: `single` | `double`

SupportVectors — Support vectors

s-by-*p* numeric matrix

This property is read-only.

Support vectors in the trained classifier, specified as an s -by- p numeric matrix. s is the number of support vectors in the trained classifier, `sum(Mdl.IsSupportVector)`, and p is the number of predictor variables in the predictor data.

`SupportVectors` contains rows of the predictor data X that MATLAB considers to be support vectors. If you specify `'Standardize', true` when training the SVM classifier using `fitcsvm`, then `SupportVectors` contains the standardized rows of X .

If you remove duplicates by using the `RemoveDuplicates` name-value pair argument of `fitcsvm`, then for a given set of duplicate observations that are support vectors, `SupportVectors` contains one unique support vector.

Data Types: `single` | `double`

Other Classification Properties

CategoricalPredictors — Categorical predictor indices

vector of positive integers | []

This property is read-only.

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

Data Types: `single` | `double`

ClassNames — Unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Unique class labels used in training the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors.

Data Types: `single` | `double` | `logical` | `char` | `cell` | `categorical`

Cost — Misclassification cost

numeric square matrix

This property is read-only.

Misclassification cost, specified as a numeric square matrix, where $\text{Cost}(i, j)$ is the cost of classifying a point into class j if its true class is i .

During training, the software updates the prior probabilities by incorporating the penalties described in the cost matrix.

- For two-class learning, Cost always has this form: $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$. The rows correspond to the true class and the columns correspond to the predicted class. The order of the rows and columns of Cost corresponds to the order of the classes in ClassNames .
- For one-class learning, $\text{Cost} = 0$.

For more details, see Algorithms on page 32-531.

Data Types: `double`

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

This property is read-only.

Expanded predictor names, specified as a cell array of character vectors.

If the model uses dummy variable encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

Data Types: `char` | `cell`

Gradient — Training data gradient values

numeric vector

This property is read-only.

Training data gradient values, specified as a numeric vector. The length of `Gradient` is equal to the number of observations (see `NumObservations`).

Data Types: `single` | `double`

ModelParameters — Parameters used to train model

structure array

This property is read-only.

Parameters used to train the `ClassificationSVM` model, specified as a structure array. `ModelParameters` contains parameter values such as the name-value pair argument values used to train the SVM classifier. `ModelParameters` does not contain estimated parameters.

Access the fields of `ModelParameters` by using dot notation. For example, access the initial values for estimating Alpha by using `Mdl.ModelParameters.Alpha`.

Data Types: `struct`

Mu — Predictor means

numeric vector | []

This property is read-only.

Predictor means, specified as a numeric vector. If you specify `'Standardize', 1` or `'Standardize', true` when you train an SVM classifier using `fitcsvm`, then the length of `Mu` is equal to the number of predictors.

MATLAB expands categorical variables in the predictor data using full dummy encoding. That is, MATLAB creates one dummy variable for each level of each categorical variable. `Mu` stores one value for each predictor variable, including the dummy variables. However, MATLAB does not standardize the columns that contain categorical variables.

If you set `'Standardize', false` when you train the SVM classifier using `fitcsvm`, then `Mu` is an empty vector ([]).

Data Types: `single` | `double`

NumObservations — Number of observations

numeric scalar

This property is read-only.

Number of observations in the training data stored in `X` and `Y`, specified as a numeric scalar.

Data Types: `single` | `double`

PredictorNames — Predictor variable names

cell array of character vectors

This property is read-only.

Predictor variable names, specified as a cell array of character vectors. The order of the elements of `PredictorNames` corresponds to the order in which the predictor names appear in the training data.

Data Types: `char` | `cell`

Prior — Prior probabilities

numeric vector

This property is read-only.

Prior probabilities for each class, specified as a numeric vector. The order of the elements of `Prior` corresponds to the elements of `Mdl.ClassNames`.

For two-class learning, if you specify a cost matrix, then the software updates the prior probabilities by incorporating the penalties described in the cost matrix.

For more details, see Algorithms on page 32-531.

Data Types: `single` | `double`

ResponseName — Response variable name

character vector

This property is read-only.

Response variable name, specified as a character vector.

Data Types: `char`

ScoreTransform — Score transformation

character vector | function handle

Score transformation, specified as a character vector or function handle.

`ScoreTransform` represents a built-in transformation function or a function handle for transforming predicted classification scores.

To change the score transformation function to *function*, for example, use dot notation.

- For a built-in function, enter a character vector.

```
Mdl.ScoreTransform = 'function';
```

This table describes the available built-in functions.

| Value | Description |
|----------------------|---|
| 'doublelogit' | $1/(1 + e^{-2x})$ |
| 'invlogit' | $\log(x / (1-x))$ |
| 'ismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0 |
| 'logit' | $1/(1 + e^{-x})$ |
| 'none' or 'identity' | x (no transformation) |
| 'sign' | -1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$ |
| 'symmetric' | $2x - 1$ |
| 'symmetricismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1 |
| 'symmetriclogit' | $2/(1 + e^{-x}) - 1$ |

- For a MATLAB function or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Data Types: char | function_handle

Sigma — Predictor standard deviations

[] (default) | numeric vector

This property is read-only.

Predictor standard deviations, specified as a numeric vector.

If you specify 'Standardize', true when you train the SVM classifier using `fitcsvm`, then the length of Sigma is equal to the number of predictor variables.

MATLAB expands categorical variables in the predictor data using full dummy encoding. That is, MATLAB creates one dummy variable for each level of each categorical variable.

`Sigma` stores one value for each predictor variable, including the dummy variables. However, MATLAB does not standardize the columns that contain categorical variables.

If you set `'Standardize', false` when you train the SVM classifier using `fitcsvm`, then `Sigma` is an empty vector (`[]`).

Data Types: `single` | `double`

W — Observation weights

`ones(n, 1)` (default) | numeric vector

This property is read-only.

Observation weights used to train the SVM classifier, specified as an n -by-1 numeric vector. n is the number of observations (see `NumObservations`).

`fitcsvm` normalizes the observation weights specified in the `'Weights'` name-value pair argument so that the elements of `W` within a particular class sum up to the prior probability of that class.

Data Types: `single` | `double`

X — Unstandardized predictors

numeric matrix | table

This property is read-only.

Unstandardized predictors used to train the SVM classifier, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

MATLAB excludes observations containing at least one missing value, and removes corresponding elements from `Y`.

Data Types: `single` | `double`

Y — Class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Class labels used to train the SVM classifier, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Y is the same data type as the input argument Y of `fitcsvm`.

Each row of Y represents the observed classification of the corresponding row of X .

MATLAB excludes elements containing missing values, and removes corresponding observations from X .

Data Types: `single` | `double` | `logical` | `char` | `cell` | `categorical`

Convergence Control Properties

ConvergenceInfo — Convergence information

structure array

This property is read-only.

Convergence information, specified as a structure array.

| Field | Description |
|----------------------|---|
| Converged | Logical flag indicating whether the algorithm converged (1 indicates convergence). |
| ReasonForConvergence | Character vector indicating the criterion the software uses to detect convergence. |
| Gap | Scalar feasibility gap between the dual and primal objective functions. |
| GapTolerance | Scalar feasibility gap tolerance. Set this tolerance, for example to $1e-2$, by using the name-value pair argument <code>'GapTolerance', 1e-2</code> of <code>fitcsvm</code> . |
| DeltaGradient | Scalar-attained gradient difference between upper and lower violators |

| Field | Description |
|------------------------|--|
| DeltaGradientTolerance | Scalar tolerance for the gradient difference between upper and lower violators. Set this tolerance, for example to $1e-2$, by using the name-value pair argument 'DeltaGradientTolerance', $1e-2$ of <code>fitcsvm</code> . |
| LargestKKTViolation | Maximal scalar Karush-Kuhn-Tucker (KKT) violation value. |
| KKTTolerance | Scalar tolerance for the largest KKT violation. Set this tolerance, for example to $1e-3$, by using the name-value pair argument 'KKTTolerance', $1e-3$ of <code>fitcsvm</code> . |
| History | Structure array containing convergence information at set optimization iterations. The fields are: <ul style="list-style-type: none"> • NumIterations: numeric vector of iteration indices for which the software records convergence information • Gap: numeric vector of Gap values at the iterations • DeltaGradient: numeric vector of DeltaGradient values at the iterations • LargestKKTViolation: numeric vector of LargestKKTViolation values at the iterations • NumSupportVectors: numeric vector indicating the number of support vectors at the iterations • Objective: numeric vector of Objective values at the iterations |
| Objective | Scalar value of the dual objective function. |

Data Types: struct

NumIterations — Number of iterations

positive integer

This property is read-only.

Number of iterations required by the optimization routine to attain convergence, specified as a positive integer.

To set the limit on the number of iterations to 1000, for example, specify 'IterationLimit', 1000 when you train the SVM classifier using `fitcsvm`.

Data Types: double

ShrinkagePeriod — Number of iterations between reductions of active set

nonnegative integer

This property is read-only.

Number of iterations between reductions of the active set, specified as a nonnegative integer.

To set the shrinkage period to 1000, for example, specify 'ShrinkagePeriod', 1000 when you train the SVM classifier using `fitcsvm`.

Data Types: single | double

Hyperparameter Optimization Properties**HyperparameterOptimizationResults — Description of cross-validation optimization of hyperparameters**

object (default) | table

This property is read-only.

Description of the cross-validation optimization of hyperparameters, specified as a `BayesianOptimization` object or a table of hyperparameters and associated values. This property is nonempty when the 'OptimizeHyperparameters' name-value pair argument of `fitcsvm` is nonempty at creation. The value of `HyperparameterOptimizationResults` depends on the setting of the `Optimizer` field in the `HyperparameterOptimizationOptions` structure of `fitcsvm` at creation, as described in this table.

| Setting of Optimizer Field | Value |
|--------------------------------|---|
| 'bayesopt' (default) | Object of class BayesianOptimization |
| 'gridsearch' or 'randomsearch' | Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst) |

Data Types: struct | table

Object Functions

| | |
|-----------------------|---|
| compact | Reduce size of support vector machine (SVM) classifier |
| compareHoldout | Compare accuracies of two classification models using new data |
| crossval | Cross-validate support vector machine (SVM) classifier |
| discardSupportVectors | Discard support vectors for linear support vector machine (SVM) classifier |
| edge | Find classification edge for support vector machine (SVM) classifier |
| fitPosterior | Fit posterior probabilities for support vector machine (SVM) classifier |
| loss | Find classification error for support vector machine (SVM) classifier |
| margin | Find classification margins for support vector machine (SVM) classifier |
| predict | Predict labels using support vector machine (SVM) classifier |
| resubEdge | Find classification edge for support vector machine (SVM) classifier by resubstitution |
| resubLoss | Find classification loss for support vector machine (SVM) classifier by resubstitution |
| resubMargin | Find classification margins for support vector machine (SVM) classifier by resubstitution |
| resubPredict | Predict resubstitution responses for support vector machine (SVM) classifier |
| resume | Resume training support vector machine (SVM) classifier |

Examples

Train SVM Classifier

Load Fisher's iris data set. Remove the sepal lengths and widths and all observed setosa irises.

```
load fisheriris
inds = ~strcmp(species,'setosa');
X = meas(inds,3:4);
y = species(inds);
```

Train an SVM classifier using the processed data set.

```
SVModel = fitcsvm(X,y)
```

```
SVModel =
  ClassificationSVM
      ResponseName: 'Y'
  CategoricalPredictors: []
      ClassNames: {'versicolor' 'virginica'}
      ScoreTransform: 'none'
  NumObservations: 100
          Alpha: [24x1 double]
          Bias: -14.4149
  KernelParameters: [1x1 struct]
      BoxConstraints: [100x1 double]
      ConvergenceInfo: [1x1 struct]
  IsSupportVector: [100x1 logical]
      Solver: 'SMO'
```

Properties, Methods

`SVModel` is a trained `ClassificationSVM` classifier. Display the properties of `SVModel`. For example, to determine the class order, use dot notation.

```
classOrder = SVModel.ClassNames
```

```
classOrder = 2x1 cell array
    {'versicolor'}
    {'virginica' }
```

The first class ('versicolor') is the negative class, and the second ('virginica') is the positive class. You can change the class order during training by using the 'ClassNames' name-value pair argument.

Plot a scatter diagram of the data and circle the support vectors.

```
sv = SVMModel.SupportVectors;  
figure  
gscatter(X(:,1),X(:,2),y)  
hold on  
plot(sv(:,1),sv(:,2),'ko','MarkerSize',10)  
legend('versicolor','virginica','Support Vector')  
hold off
```

The support vectors are observations that occur on or beyond their estimated class boundaries.

You can adjust the boundaries (and, therefore, the number of support vectors) by setting a box constraint during training using the `'BoxConstraint'` name-value pair argument.

Train and Cross-Validate SVM Classifier

Load the ionosphere data set.

```
load ionosphere
```

Train and cross-validate an SVM classifier. Standardize the predictor data and specify the order of the classes.

```
rng(1); % For reproducibility
CVSVMModel = fitcsvm(X,Y,'Standardize',true,...
    'ClassNames',{'b','g'},'CrossVal','on')

CVSVMModel =
    classreg.learning.partition.ClassificationPartitionedModel
    CrossValidatedModel: 'SVM'
    PredictorNames: {1x34 cell}
    ResponseName: 'Y'
    NumObservations: 351
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
```

Properties, Methods

`CVSVMModel` is a `ClassificationPartitionedModel` cross-validated SVM classifier. By default, the software implements 10-fold cross-validation.

Alternatively, you can cross-validate a trained `ClassificationSVM` classifier by passing it to `crossval`.

Inspect one of the trained folds using dot notation.

```
CVSVMModel.Trained{1}

ans =
  classreg.learning.classif.CompactClassificationSVM
      ResponseName: 'Y'
  CategoricalPredictors: []
      ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
      Alpha: [78x1 double]
      Bias: -0.2209
  KernelParameters: [1x1 struct]
      Mu: [1x34 double]
      Sigma: [1x34 double]
  SupportVectors: [78x34 double]
  SupportVectorLabels: [78x1 double]
```

Properties, Methods

Each fold is a `CompactClassificationSVM` classifier trained on 90% of the data.

Estimate the generalization error.

```
genError = kfoldLoss(CVSVMModel)
```

```
genError = 0.1168
```

On average, the generalization error is approximately 12%.

- Using Support Vector Machines on page 18-190

Definitions

Box Constraint

A box constraint is a parameter that controls the maximum penalty imposed on margin-violating observations, which helps to prevent overfitting (regularization).

If you increase the box constraint, then the SVM classifier assigns fewer support vectors. However, increasing the box constraint can lead to longer training times.

Gram Matrix

The Gram matrix of a set of n vectors $\{x_1, \dots, x_n; x_j \in R^p\}$ is an n -by- n matrix with element (j, k) defined as $G(x_j, x_k) = \langle \phi(x_j), \phi(x_k) \rangle$, an inner product of the transformed predictors using the kernel function ϕ .

For nonlinear SVM, the algorithm forms a Gram matrix using the rows of the predictor data X . The dual formalization replaces the inner product of the observations in X with corresponding elements of the resulting Gram matrix (called the “kernel trick”). Consequently, nonlinear SVM operates in the transformed predictor space to find a separating hyperplane.

Karush-Kuhn-Tucker Complementarity Conditions

KKT complementarity conditions are optimization constraints required for optimal nonlinear programming solutions.

In SVM, the KKT complementarity conditions are

$$\begin{cases} \alpha_j [y_j f(x_j) - 1 + \xi_j] = 0 \\ \xi_j (C - \alpha_j) = 0 \end{cases}$$

for all $j = 1, \dots, n$, where $f(x_j) = \phi(x_j)' \beta + b$, ϕ is a kernel function (see Gram matrix on page 32-2079), and ξ_j is a slack variable. If the classes are perfectly separable, then $\xi_j = 0$ for all $j = 1, \dots, n$.

One-Class Learning

One-class learning, or unsupervised SVM, aims to separate data from the origin in the high-dimensional predictor space (not the original predictor space), and is an algorithm used for outlier detection.

The algorithm resembles that of SVM for binary classification on page 32-2080. The objective is to minimize the dual expression

$$0.5 \sum_{jk} \alpha_j \alpha_k G(x_j, x_k)$$

with respect to $\alpha_1, \dots, \alpha_n$, subject to

$$\sum \alpha_j = n\nu$$

and $0 \leq \alpha_j \leq 1$ for all $j = 1, \dots, n$. The value of $G(x_j, x_k)$ is in element (j, k) of the Gram matrix on page 32-2079.

A small value of ν leads to fewer support vectors and, therefore, a smooth, crude decision boundary. A large value of ν leads to more support vectors and, therefore, a curvy, flexible decision boundary. The optimal value of ν should be large enough to capture the data complexity and small enough to avoid overtraining. Also, $0 < \nu \leq 1$.

For more details, see [5].

Support Vector

Support vectors are observations corresponding to strictly positive estimates of $\alpha_1, \dots, \alpha_n$.

SVM classifiers that yield fewer support vectors for a given training set are preferred.

Support Vector Machines for Binary Classification

The SVM binary classification algorithm searches for an optimal hyperplane that separates the data into two classes. For separable classes, the optimal hyperplane maximizes a margin (space that does not contain any observations) surrounding itself, which creates boundaries for the positive and negative classes. For inseparable classes, the objective is the same, but the algorithm imposes a penalty on the length of the margin for every observation that is on the wrong side of its class boundary.

The linear SVM score function is

$$f(x) = x'\beta + b,$$

where:

- x is an observation (corresponding to a row of X).

- The vector β contains the coefficients that define an orthogonal vector to the hyperplane (corresponding to `Mdl.Beta`). For separable data, the optimal margin length is $2 / \|\beta\|$.
- b is the bias term (corresponding to `Mdl.Bias`).

The root of $f(x)$ for particular coefficients defines a hyperplane. For a particular hyperplane, $f(z)$ is the distance from point z to the hyperplane.

The algorithm searches for the maximum margin length, while keeping observations in the positive ($y = 1$) and negative ($y = -1$) classes separate.

- For separable classes, the objective is to minimize $\|\beta\|$ with respect to the β and b subject to $y_j f(x_j) \geq 1$, for all $j = 1, \dots, n$. This is the primal formalization for separable classes.
- For inseparable classes, the algorithm uses slack variables (ξ_j) to penalize the objective function for observations that cross the margin boundary for their class. $\xi_j = 0$ for observations that do not cross the margin boundary for their class, otherwise $\xi_j \geq 0$.

The objective is to minimize $0.5 \|\beta\|^2 + C \sum \xi_j$ with respect to the β , b , and ξ_j subject to $y_j f(x_j) \geq 1 - \xi_j$ and $\xi_j \geq 0$ for all $j = 1, \dots, n$, and for a positive scalar box constraint on page 32-2078 C. This is the primal formalization for inseparable classes.

The algorithm uses the Lagrange multipliers method to optimize the objective, which introduces n coefficients $\alpha_1, \dots, \alpha_n$ (corresponding to `Mdl.Alpha`). The dual formalizations for linear SVM are as follows:

- For separable classes, minimize

$$0.5 \sum_{j=1}^n \sum_{k=1}^n \alpha_j \alpha_k y_j y_k x_j' x_k - \sum_{j=1}^n \alpha_j$$

with respect to $\alpha_1, \dots, \alpha_n$, subject to $\sum \alpha_j y_j = 0$, $\alpha_j \geq 0$ for all $j = 1, \dots, n$, and Karush-Kuhn-Tucker (KKT) complementarity conditions on page 32-2079.

- For inseparable classes, the objective is the same as for separable classes, except for the additional condition $0 \leq \alpha_j \leq C$ for all $j = 1, \dots, n$.

The resulting score function is

$$\hat{f}(x) = \sum_{j=1}^n \hat{\alpha}_j y_j x' x_j + \hat{b}.$$

\hat{b} is the estimate of the bias and $\hat{\alpha}_j$ is the j th estimate of the vector $\hat{\alpha}$, $j = 1, \dots, n$. Written this way, the score function is free of the estimate of β as a result of the primal formalization.

The SVM algorithm classifies a new observation z using $\text{sign}(\hat{f}(z))$.

In some cases, a nonlinear boundary separates the classes. Nonlinear SVM works in a transformed predictor space to find an optimal, separating hyperplane.

The dual formalization for nonlinear SVM is

$$0.5 \sum_{j=1}^n \sum_{k=1}^n \alpha_j \alpha_k y_j y_k G(x_j, x_k) - \sum_{j=1}^n \alpha_j$$

with respect to $\alpha_1, \dots, \alpha_n$, subject to $\sum \alpha_j y_j = 0$, $0 \leq \alpha_j \leq C$ for all $j = 1, \dots, n$, and the KKT complementarity conditions. $G(x_k, x_j)$ are elements of the Gram matrix on page 32-2079. The resulting score function is

$$\hat{f}(x) = \sum_{j=1}^n \hat{\alpha}_j y_j G(x, x_j) + \hat{b}.$$

For more details, see Understanding Support Vector Machines on page 18-184, [1], and [3].

Algorithms

- For the mathematical formulation of the SVM binary classification algorithm, see “Support Vector Machines for Binary Classification” on page 32-2080 and “Understanding Support Vector Machines” on page 18-184.
- NaN, <undefined>, and empty character vector (' ') values indicate missing values. `fitcsvm` removes entire rows of data corresponding to a missing response. When computing total weights (see the next bullets), `fitcsvm` ignores any weight corresponding to an observation with at least one missing predictor. This action can lead to unbalanced prior probabilities in balanced-class problems. Consequently, observation box constraints might not equal `BoxConstraint`.
- `fitcsvm` removes observations that have zero weight or prior probability.
- For two-class learning, if you specify the cost matrix `C` (see `Cost`), then the software updates the class prior probabilities p (see `Prior`) to p_c by incorporating the penalties described in `C`.

Specifically, `fitcsvm` completes these steps:

- 1 Compute $p_c^* = p' C$.
- 2 Normalize p_c^* so that the updated prior probabilities sum to 1.

$$p_c = \frac{1}{\sum_{j=1}^K p_{c,j}^*} p_c^*$$

K is the number of classes.

- 3 Reset the cost matrix to the default

$$C = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$

- 4 Remove observations from the training data corresponding to classes with zero prior probability.
- For two-class learning, `fitcsvm` normalizes all observation weights (see `Weights`) to sum to 1. The function then renormalizes the normalized weights to sum up to the

updated prior probability of the class to which the observation belongs. That is, the total weight for observation j in class k is

$$w_j^* = \frac{w_j}{\sum_{\forall j \in \text{Class } k} w_j} p_{c,k}.$$

w_j is the normalized weight for observation j ; $p_{c,k}$ is the updated prior probability of class k (see previous bullet).

- For two-class learning, `fitcsvm` assigns a box constraint to each observation in the training data. The formula for the box constraint of observation j is

$$C_j = nC_0w_j^*.$$

n is the training sample size, C_0 is the initial box constraint (see the

'BoxConstraint' name-value pair argument), and w_j^* is the total weight of observation j (see previous bullet).

- If you set 'Standardize', true and the 'Cost', 'Prior', or 'Weights' name-value pair argument, then `fitcsvm` standardizes the predictors using their corresponding weighted means and weighted standard deviations. That is, `fitcsvm` standardizes predictor j (x_j) using

$$x_j^* = \frac{x_j - \mu_j^*}{\sigma_j^*}.$$

$$\mu_j^* = \frac{1}{\sum_k w_k^*} \sum_k w_k^* x_{jk}.$$

x_{jk} is observation k (row) of predictor j (column).

$$(\sigma_j^*)^2 = \frac{v_1}{v_1^2 - v_2} \sum_k w_k^* (x_{jk} - \mu_j^*)^2.$$

$$v_1 = \sum_j w_j^*.$$

$$v_2 = \sum (w_j^*)^2.$$

- Assume that p is the proportion of outliers that you expect in the training data, and that you set 'OutlierFraction', p .
 - For one-class learning, the software trains the bias term such that $100p\%$ of the observations in the training data have negative scores.
 - The software implements robust learning for two-class learning. In other words, the software attempts to remove $100p\%$ of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.
- If your predictor data contains categorical variables, then the software generally uses full dummy encoding for these variables. The software creates one dummy variable for each level of each categorical variable.
 - The PredictorNames property stores one element for each of the original predictor variable names. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then PredictorNames is a 1-by-3 cell array of character vectors containing the original names of the predictor variables.
 - The ExpandedPredictorNames property stores one element for each of the predictor variables, including the dummy variables. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then ExpandedPredictorNames is a 1-by-5 cell array of character vectors containing the names of the predictor variables and the new dummy variables.
 - Similarly, the Beta property stores one beta coefficient for each predictor, including the dummy variables.
 - The SupportVectors property stores the predictor values for the support vectors, including the dummy variables. For example, assume that there are m support vectors and three predictors, one of which is a categorical variable with three levels. Then SupportVectors is an n -by-5 matrix.
 - The X property stores the training data as originally input and does not include the dummy variables. When the input is a table, X contains only the columns used as predictors.

- For predictors specified in a table, if any of the variables contain ordered (ordinal) categories, the software uses ordinal encoding for these variables.
 - For a variable with k ordered levels, the software creates $k - 1$ dummy variables. The j th dummy variable is -1 for levels up to j , and $+1$ for levels $j + 1$ through k .
 - The names of the dummy variables stored in the `ExpandedPredictorNames` property indicate the first level with the value $+1$. The software stores $k - 1$ additional predictor names for the dummy variables, including the names of levels $2, 3, \dots, k$.
- All solvers implement $L1$ soft-margin minimization.
- For one-class learning, the software estimates the Lagrange multipliers, $\alpha_1, \dots, \alpha_n$, such that

$$\sum_{j=1}^n \alpha_j = nv.$$

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.
- When you train an SVM model by using `fitcsvm`, the following restrictions apply.
 - The class labels input argument value (Y) cannot be a categorical array.
 - Code generation does not support categorical predictors. You cannot supply training data in a table that contains at least one categorical predictor, and you cannot use the 'CategoricalPredictors' name-value pair argument. To dummy-code variables that you want treated as categorical, preprocess the categorical data by using `dummyvar` before fitting the model.
 - The value of the 'ClassNames' name-value pair argument cannot be a categorical array.
 - The value of the 'ScoreTransform' name-value pair argument cannot be an anonymous function. For generating code that predicts posterior probabilities given new observations, pass a trained SVM model to `fitPosterior` or `fitSVMPosterior`. The `ScoreTransform` property of the returned model contains an anonymous function that represents the score-to-posterior-probability function and is configured for code generation.

For code generation examples, see “Code Generation Workflow for Prediction” on page 31-5 and “Specify Variable-Sized Arguments for Code Generation” on page 31-48. For more information, see topics in “Code Generation”.

ClassificationTree class

Superclasses:

Binary decision tree for classification

Description

A `ClassificationTree` object represents a decision tree with binary splits for classification. An object of this class can predict responses for new data using the `predict` method. The object contains the data used for training, so it can also compute resubstitution predictions.

Construction

`tree = fitctree(TBL, ResponseVarName)` returns a fitted binary classification decision tree based on the input variables (also known as predictors, features, or attributes) contained in the table `TBL` and output (response or labels) contained in `ResponseVarName`. The returned binary tree splits branching nodes based on the values of a column of `TBL`.

`tree = fitctree(TBL, formula)` returns a fitted binary classification decision tree based on the input variables contained in the table `TBL`. `formula` is a formula that identifies the response and predictor variables in `TBL` used to fit `tree`. The returned binary tree splits branching nodes based on the values of a column of `TBL`.

`tree = fitctree(TBL, Y)` returns a fitted binary classification decision tree based on the input variables contained in the table `TBL` and output in vector `Y`. The returned binary tree splits branching nodes based on the values of a column of `TBL`.

`tree = fitctree(X, Y)` returns a fitted binary classification decision tree based on the input variables contained in matrix `X` and output `Y`. The returned binary tree splits branching nodes based on the values of a column of `X`.

`tree = fitctree(____, Name, Value)` fits a tree with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example,

you can specify the algorithm used to find the best split on a categorical predictor or grow a cross-validated tree.

Input Arguments

Tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix. Each row of `X` corresponds to one observation, and each column corresponds to one predictor variable.

`fitctree` considers NaN values in `X` as missing values. `fitctree` does not use observations with all missing values for `X` in the fit. `fitctree` uses observations with some missing values for `X` to find splits on variables for which these observations have valid values.

Data Types: `single` | `double`

ResponseVarName — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

It is a good practice to specify the order of the classes by using the `ClassNames` name-value pair argument.

Data Types: `char`

formula — Response and predictor variables to use in model training

character vector

Response and predictor variables to use in model training, specified as a character vector in the form of `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then any variables in `Tbl` that do not appear in `formula` are not used to train the model.

Data Types: `char`

Y — Class labels

numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Class labels, specified as a numeric vector, categorical vector, logical vector, character array, or cell array of character vectors. Each row of `Y` represents the classification of the corresponding row of `X`.

When fitting the tree, `fitctree` considers `NaN`, `' '` (empty character vector), and `<undefined>` values in `Y` to be missing values. `fitctree` does not use observations with missing values for `Y` in the fit.

For numeric `Y`, consider fitting a regression tree using `fitrtree` instead.

Data Types: `single` | `double` | `char` | `logical` | `cell`

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

AlgorithmForCategorical — Algorithm for best categorical predictor split

'Exact' | 'PullLeft' | 'PCA' | 'OVAbyClass'

Algorithm to find the best split on a categorical predictor with C categories for data and $K \geq 3$ classes, specified as the comma-separated pair consisting of 'AlgorithmForCategorical' and one of the following values.

| Value | Description |
|--------------|---|
| 'Exact' | Consider all $2^{C-1} - 1$ combinations. |
| 'PullLeft' | Start with all C categories on the right branch. Consider moving each category to the left branch as it achieves the minimum impurity for the K classes among the remaining categories. From this sequence, choose the split that has the lowest impurity. |
| 'PCA' | Compute a score for each category using the inner product between the first principal component of a weighted covariance matrix (of the centered class probability matrix) and the vector of class probabilities for that category. Sort the scores in ascending order, and consider all $C - 1$ splits. |
| 'OVAbyClass' | Start with all C categories on the right branch. For each class, order the categories based on their probability for that class. For the first class, consider moving each category to the left branch in order, recording the impurity criterion at each move. Repeat for the remaining classes. From this sequence, choose the split that has the minimum impurity. |

fitctree automatically selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For $K = 2$ classes,

`fitctree` always performs the exact search. To specify a particular algorithm, use the `'AlgorithmForCategorical'` name-value pair argument.

Example: `'AlgorithmForCategorical', 'PCA'`

CategoricalPredictors — Categorical predictors list

numeric or logical vector | cell array of character vectors | character matrix | `'all'`

Categorical predictors list, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the following:

- A numeric vector with indices from 1 through `p`, where `p` is the number of columns of `X`.
- A logical vector of length `p`, where a `true` entry means that the corresponding column of `X` is a categorical variable.
- A cell array of character vectors, where each element in the array is the name of a predictor variable. The names must match entries in `PredictorNames` values.
- A character matrix, where each row of the matrix is a name of a predictor variable. The names must match entries in `PredictorNames` values. Pad the names with extra blanks so each row of the character matrix has the same length.
- `'all'`, meaning all predictors are categorical.

By default, if the predictor data is in a matrix (`X`), the software assumes that none of the predictors are categorical. If the predictor data is in a table (`Tbl`), the software assumes that a variable is categorical if it contains, logical values, values of the unordered data type `categorical`, or a cell array of character vectors.

Example: `'CategoricalPredictors', 'all'`

Data Types: `single` | `double` | `char` | `logical` | `cell`

ClassNames — Names of classes to use for training

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of `'ClassNames'` and a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` must have the same data type as `Y`.

If `ClassNames` is a character array, then each element must correspond to one *row* of the array.

Use `ClassNames` to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a', 'b', 'c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames', {'a', 'c'}`.

The default value for `ClassNames` is the set of all distinct class names in `Y`.

Example: `'ClassNames', {'b', 'g'}`

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Cost — Cost of misclassification

`square matrix` | `structure`

Cost of misclassification of a point, specified as the comma-separated pair consisting of `'Cost'` and one of the following:

- Square matrix, where `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i` (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of `Cost`, also specify the `ClassNames` name-value pair argument.
- Structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same data type as `Y`, and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i, j)=1` if `i~=j`, and `Cost(i, j)=0` if `i=j`.

Data Types: `single` | `double` | `struct`

CrossVal — Flag to grow cross-validated decision tree

`'off'` (default) | `'on'`

Flag to grow a cross-validated decision tree, specified as the comma-separated pair consisting of `'CrossVal'` and `'on'` or `'off'`.

If `'on'`, `fitctree` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the `'KFold'`, `'Holdout'`, `'Leaveout'`, or

'CVPartition' name-value pair arguments. You can only use one of these four arguments at a time when creating a cross-validated tree.

Alternatively, cross validate `tree` later using the `crossval` method.

Example: 'CrossVal', 'on'

CVPartition — Partition for cross-validated tree

`cvpartition` object

Partition to use in a cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object created using `cvpartition`.

If you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.

Holdout — Fraction of data for holdout validation

0 (default) | scalar value in the range [0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

If you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout', 0.1

Data Types: `single` | `double`

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify, e.g., 'KFold', k , then the software:

- 1 Randomly partitions the data into k sets
- 2 For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets
- 3 Stores the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',8`

Data Types: `single` | `double`

Leaveout — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. Specify `'on'` to use leave-one-out cross-validation.

If you use `'Leaveout'`, you cannot use any of the `'CVPartition'`, `'Holdout'`, or `'KFold'` name-value pair arguments.

Example: `'Leaveout','on'`

MaxNumCategories — Maximum category levels

`10` (default) | nonnegative scalar value

Maximum category levels, specified as the comma-separated pair consisting of `'MaxNumCategories'` and a nonnegative scalar value. `fitctree` splits a categorical predictor using the exact search algorithm if the predictor has at most `MaxNumCategories` levels in the split node. Otherwise, `fitctree` finds the best categorical split using one of the inexact algorithms.

Passing a small value can lead to loss of accuracy and passing a large value can increase computation time and memory overload.

Example: `'MaxNumCategories',8`

MaxNumSplits — Maximal number of decision splits

`size(X,1) - 1` (default) | positive integer

Maximal number of decision splits (or branch nodes), specified as the comma-separated pair consisting of `'MaxNumSplits'` and a positive integer. `ClassificationTree` splits `MaxNumSplits` or fewer branch nodes. For more details on splitting behavior, see Algorithms on page 32-2126.

Example: `'MaxNumSplits',5`

Data Types: `single` | `double`

MergeLeaves — Leaf merge flag`'on' (default) | 'off'`

Leaf merge flag, specified as the comma-separated pair consisting of 'MergeLeaves' and 'on' or 'off'.

If MergeLeaves is 'on', then ClassificationTree:

- Merges leaves that originate from the same parent node, and that yields a sum of risk values greater or equal to the risk associated with the parent node
- Estimates the optimal sequence of pruned subtrees, but does not prune the classification tree

Otherwise, ClassificationTree does not merge leaves.

Example: 'MergeLeaves', 'off'

MinLeafSize — Minimum number of leaf node observations`1 (default) | positive integer value`

Minimum number of leaf node observations, specified as the comma-separated pair consisting of 'MinLeafSize' and a positive integer value. Each leaf has at least MinLeafSize observations per tree leaf. If you supply both MinParentSize and MinLeafSize, fitctree uses the setting that gives larger leaves: $\text{MinParentSize} = \max(\text{MinParentSize}, 2 * \text{MinLeafSize})$.

Example: 'MinLeafSize', 3

Data Types: single | double

MinParentSize — Minimum number of branch node observations`10 (default) | positive integer value`

Minimum number of branch node observations, specified as the comma-separated pair consisting of 'MinParentSize' and a positive integer value. Each branch node in the tree has at least MinParentSize observations. If you supply both MinParentSize and MinLeafSize, fitctree uses the setting that gives larger leaves: $\text{MinParentSize} = \max(\text{MinParentSize}, 2 * \text{MinLeafSize})$.

Example: 'MinParentSize', 8

Data Types: single | double

NumVariablesToSample — Number of predictors to select at random for each split

'all' | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of 'NumVariablesToSample' and a positive integer value. You can also specify 'all' to use all available predictors.

Example: 'NumVariablesToSample',3

Data Types: single | double

PredictorNames — Predictor variable names

cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.
 - The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.
 - By default, PredictorNames is {'x1', 'x2', ...}.
- If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, ClassificationTree uses only the predictor variables in PredictorNames and the response variable in training.
 - PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.
 - By default, PredictorNames contains the names of all predictor variables.
 - It is a good practice to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength', 'SepalWidth', 'PetalLength', 'PetalWidth'}

Data Types: cell

Prior — Prior probabilities

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following.

- A character vector:
 - 'empirical' determines class probabilities from class frequencies in Y. If you pass observation weights, `fitctree` uses the weights to compute the class probabilities.
 - 'uniform' sets all class probabilities equal.
- A vector (one scalar value for each class). To specify the class order for the corresponding elements of `Prior`, also specify the `ClassNames` name-value pair argument.
- A structure `S` with two fields:
 - `S.ClassNames` containing the class names as a variable of the same type as `Y`
 - `S.ClassProbs` containing a vector of corresponding probabilities

If you set values for both `weights` and `prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: 'Prior', 'uniform'

Prune — Flag to estimate optimal sequence of pruned subtrees

'on' (default) | 'off'

Flag to estimate the optimal sequence of pruned subtrees, specified as the comma-separated pair consisting of 'Prune' and 'on' or 'off'.

If `Prune` is 'on', then `ClassificationTree` grows the classification tree without pruning it, but estimates the optimal sequence of pruned subtrees. Otherwise, `ClassificationTree` grows the classification tree without estimating the optimal sequence of pruned subtrees.

To prune a trained `ClassificationTree` model, pass it to `prune`.

Example: 'Prune', 'off'

PruneCriterion — Pruning criterion

'error' (default) | 'impurity'

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and 'error' or 'impurity'.

Example: 'PruneCriterion', 'impurity'

ResponseName — Response variable name

'Y' (default) | character vector

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector representing the name of the response variable.

This name-value pair is not valid when using the ResponseVarName or formula input arguments.

Example: 'ResponseName', 'IrisType'

ScoreTransform — Score transform function

'none' | character vector | function handle

Score transform function, specified as the comma-separated pair consisting of 'ScoreTransform' and a function handle for transforming scores. Your function must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Alternatively, you can specify one of the following character vectors representing a built-in transformation function.

| Value | Description |
|----------------------|--|
| 'doublelogit' | $1/(1 + e^{-2x})$ |
| 'invlogit' | $\log(x / (1-x))$ |
| 'ismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0 |
| 'logit' | $1/(1 + e^{-x})$ |
| 'none' or 'identity' | x (no transformation) |
| 'sign' | -1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$ |
| 'symmetric' | $2x - 1$ |

| Value | Description |
|------------------|---|
| 'symmetricismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1 |
| 'symmetriclogit' | $2/(1 + e^{-x}) - 1$ |

Example: 'ScoreTransform', 'logit'

SplitCriterion — Split criterion

'gdi' (default) | 'twoing' | 'deviance'

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'gdi' (Gini's diversity index), 'twoing' for the twoing rule, or 'deviance' for maximum deviance reduction (also known as cross entropy).

Example: 'SplitCriterion', 'deviance'

Surrogate — Surrogate decision splits flag

'off' (default) | 'on' | 'all' | positive integer value

Surrogate decision splits on page 32-2126 flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer value.

- When set to 'on', `fitctree` finds at most 10 surrogate splits at each branch node.
- When set to 'all', `fitctree` finds all surrogate splits at each branch node. The 'all' setting can use considerable time and memory.
- When set to a positive integer value, `fitctree` finds at most the specified number of surrogate splits at each branch node.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also lets you compute measures of predictive association between predictors. For more details, see “Node Splitting Rules” on page 32-2126.

Example: 'Surrogate', 'on'

Data Types: single | double | char

Weights — Observation weights

ones(size(x,1),1) (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The software weights the observations in each row of X or Tbl

with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows in `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector. For example, if weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors when training the model.

`fitctree` normalizes the weights in each class to add up to the value of the prior probability of the class.

Data Types: `single` | `double`

Properties

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

CategoricalSplits

An n -by-2 cell array, where n is the number of categorical splits in `tree`. Each row in `CategoricalSplits` gives left and right values for a categorical split. For each branch node with categorical split j based on a categorical predictor variable z , the left child is chosen if z is in `CategoricalSplits(j,1)` and the right child is chosen if z is in `CategoricalSplits(j,2)`. The splits are in the same order as nodes of the tree. Find the nodes for these splits by selecting `'categorical'` cuts from top to bottom in the `CutType` property.

Children

An n -by-2 array containing the numbers of the child nodes for each node in `tree`, where n is the number of nodes. Leaf nodes have child node `0`.

ClassCount

An n -by- k array of class counts for the nodes in `tree`, where n is the number of nodes and k is the number of classes. For any node number i , the class counts `ClassCount(i,:)`

are counts of observations (from the data used in fitting the tree) from each class satisfying the conditions for node *i*.

ClassNames

List of the elements in *Y* with duplicates removed. **ClassNames** can be a categorical array, cell array of character vectors, character array, logical vector, or a numeric vector. **ClassNames** has the same data type as the data in the argument *Y*.

ClassProbability

An *n*-by-*k* array of class probabilities for the nodes in *tree*, where *n* is the number of nodes and *k* is the number of classes. For any node number *i*, the class probabilities **ClassProbability**(*i*, :) are the estimated probabilities for each class for a point satisfying the conditions for node *i*.

Cost

Square matrix, where **Cost**(*i*, *j*) is the cost of classifying a point into class *j* if its true class is *i* (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of **Cost** corresponds to the order of the classes in **ClassNames**. The number of rows and columns in **Cost** is the number of unique classes in the response. This property is read-only.

CutCategories

An *n*-by-2 cell array of the categories used at branches in *tree*, where *n* is the number of nodes. For each branch node *i* based on a categorical predictor variable *X*, the left child is chosen if *X* is among the categories listed in **CutCategories**{*i*, 1}, and the right child is chosen if *X* is among those listed in **CutCategories**{*i*, 2}. Both columns of **CutCategories** are empty for branch nodes based on continuous predictors and for leaf nodes.

CutPoint contains the cut points for 'continuous' cuts, and **CutCategories** contains the set of categories.

CutPoint

An *n*-element vector of the values used as cut points in *tree*, where *n* is the number of nodes. For each branch node *i* based on a continuous predictor variable *X*, the left child is chosen if $X < \text{CutPoint}(i)$ and the right child is chosen if $X \geq \text{CutPoint}(i)$. **CutPoint** is NaN for branch nodes based on categorical predictors and for leaf nodes.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

CutType

An n -element cell array indicating the type of cut at each node in `tree`, where n is the number of nodes. For each node i , `CutType{i}` is:

- 'continuous' — If the cut is defined in the form $X < v$ for a variable X and cut point v .
- 'categorical' — If the cut is defined by whether a variable X takes a value in a set of categories.
- '' — If i is a leaf node.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

CutPredictor

An n -element cell array of the names of the variables used for branching in each node in `tree`, where n is the number of nodes. These variables are sometimes known as *cut variables*. For leaf nodes, `CutPredictor` contains an empty character vector.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

ExpandedPredictorNames

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

HyperparameterOptimizationResults

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- 'bayesopt' (default) — Object of class `BayesianOptimization`
- 'gridsearch' or 'randomsearch' — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

IsBranchNode

An n -element logical vector that is `true` for each branch node and `false` for each leaf node of `tree`.

ModelParameters

Parameters used in training `tree`. To display all parameter values, enter `tree.ModelParameters`. To access a particular parameter, use dot notation.

NumObservations

Number of observations in the training data, a numeric scalar. `NumObservations` can be less than the number of rows of input data `X` when there are missing values in `X` or response `Y`.

NodeClass

An n -element cell array with the names of the most probable classes in each node of `tree`, where n is the number of nodes in the tree. Every element of this array is a character vector equal to one of the class names in `ClassNames`.

NodeError

An n -element vector of the errors of the nodes in `tree`, where n is the number of nodes. `NodeError(i)` is the misclassification probability for node i .

NodeProbability

An n -element vector of the probabilities of the nodes in `tree`, where n is the number of nodes. The probability of a node is computed as the proportion of observations from the original data that satisfy the conditions for the node. This proportion is adjusted for any prior probabilities assigned to each class.

NodeRisk

An n -element vector of the risk of the nodes in the tree, where n is the number of nodes. The risk for each node is the measure of impurity (Gini index or deviance) for this node

weighted by the node probability. If the tree is grown by twoing, the risk for each node is zero.

NodeSize

An n -element vector of the sizes of the nodes in `tree`, where n is the number of nodes. The size of a node is defined as the number of observations from the data used to create the tree that satisfy the conditions for the node.

NumNodes

The number of nodes in `tree`.

Parent

An n -element vector containing the number of the parent node for each node in `tree`, where n is the number of nodes. The parent of the root node is 0.

PredictorNames

Cell array of character vectors containing the predictor names, in the order which they appear in `X`.

Prior

Numeric vector of prior probabilities for each class. The order of the elements of `Prior` corresponds to the order of the classes in `ClassNames`. The number of elements of `Prior` is the number of unique classes in the response. This property is read-only.

PruneAlpha

Numeric vector with one element per pruning level. If the pruning level ranges from 0 to M , then `PruneAlpha` has $M + 1$ elements sorted in ascending order. `PruneAlpha(1)` is for pruning level 0 (no pruning), `PruneAlpha(2)` is for pruning level 1, and so on.

PruneList

An n -element numeric vector with the pruning levels in each node of `tree`, where n is the number of nodes. The pruning levels range from 0 (no pruning) to M , where M is the distance between the deepest leaf and the root node.

ResponseName

A character vector that specifies the name of the response variable (Y).

RowsUsed

An n -element logical vector indicating which rows of the original predictor data (X) were used in fitting. If the software uses all rows of X, then RowsUsed is an empty array ([]).

ScoreTransform

Function handle for transforming predicted classification scores, or character vector representing a built-in transformation function.

none means no transformation, or $@(x)x$.

To change the score transformation function to, e.g., *function*, use dot notation.

- For available functions (see `fitctree`), enter

```
Mdl.ScoreTransform = 'function';
```

- You can set a function handle for an available function, or a function you define yourself by entering

```
tree.ScoreTransform = @function;
```

SurrogateCutCategories

An n -element cell array of the categories used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutCategories{k}` is a cell array. The length of `SurrogateCutCategories{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutCategories{k}` is either an empty character vector for a continuous surrogate predictor, or is a two-element cell array with categories for a categorical surrogate predictor. The first element of this two-element cell array lists categories assigned to the left child by this surrogate split, and the second element of this two-element cell array lists categories assigned to the right child by this surrogate split. The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutCategories` contains an empty cell.

SurrogateCutFlip

An n -element cell array of the numeric cut assignments used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutFlip{k}` is a numeric vector. The length of `SurrogateCutFlip{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutFlip{k}` is either zero for a categorical surrogate predictor, or a numeric cut assignment for a continuous surrogate predictor. The numeric cut assignment can be either -1 or $+1$. For every surrogate split with a numeric cut C based on a continuous predictor variable Z , the left child is chosen if $Z < C$ and the cut assignment for this surrogate split is $+1$, or if $Z \geq C$ and the cut assignment for this surrogate split is -1 . Similarly, the right child is chosen if $Z \geq C$ and the cut assignment for this surrogate split is $+1$, or if $Z < C$ and the cut assignment for this surrogate split is -1 . The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutFlip` contains an empty array.

SurrogateCutPoint

An n -element cell array of the numeric values used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutPoint{k}` is a numeric vector. The length of `SurrogateCutPoint{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutPoint{k}` is either NaN for a categorical surrogate predictor, or a numeric cut for a continuous surrogate predictor. For every surrogate split with a numeric cut C based on a continuous predictor variable Z , the left child is chosen if $Z < C$ and `SurrogateCutFlip` for this surrogate split is $+1$, or if $Z \geq C$ and `SurrogateCutFlip` for this surrogate split is -1 . Similarly, the right child is chosen if $Z \geq C$ and `SurrogateCutFlip` for this surrogate split is $+1$, or if $Z < C$ and `SurrogateCutFlip` for this surrogate split is -1 . The order of the surrogate split variables at each node is matched to the order of variables returned by `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutPoint` contains an empty cell.

SurrogateCutType

An n -element cell array indicating types of surrogate splits at each node in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutType{k}` is a cell array with the types of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The order of the surrogate split variables at each node is matched to the order of variables in

SurrogateCutPredictor. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, **SurrogateCutType** contains an empty cell. A surrogate split type can be either 'continuous' if the cut is defined in the form $Z < V$ for a variable Z and cut point V or 'categorical' if the cut is defined by whether Z takes a value in a set of categories.

SurrogateCutPredictor

An n -element cell array of the names of the variables used for surrogate splits in each node in **tree**, where n is the number of nodes in **tree**. Every element of **SurrogateCutPredictor** is a cell array with the names of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, **SurrogateCutPredictor** contains an empty cell.

SurrogatePredictorAssociation

An n -element cell array of the predictive measures of association for surrogate splits in **tree**, where n is the number of nodes in **tree**. For each node k , **SurrogatePredictorAssociation{k}** is a numeric vector. The length of **SurrogatePredictorAssociation{k}** is equal to the number of surrogate predictors found at this node. Every element of **SurrogatePredictorAssociation{k}** gives the predictive measure of association between the optimal split and this surrogate split. The order of the surrogate split variables at each node is the order of variables in **SurrogateCutPredictor**. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, **SurrogatePredictorAssociation** contains an empty cell.

W

The scaled weights, a vector with length n , the number of rows in **X**.

X

A matrix of predictor values. Each column of **X** represents one variable, and each row represents one observation.

Y

A categorical array, cell array of character vectors, character array, logical vector, or a numeric vector. Each row of **Y** represents the classification of the corresponding row of **X**.

Methods

Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects \(MATLAB\)](#).

Examples

Grow a Classification Tree

Grow a classification tree using the `ionosphere` data set.

```
load ionosphere
tc = fitctree(X,Y)

tc =
  ClassificationTree
      ResponseName: 'Y'
  CategoricalPredictors: []
          ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
      NumObservations: 351
```

Properties, Methods

Control Tree Depth

You can control the depth of the trees using the `MaxNumSplits`, `MinLeafSize`, or `MinParentSize` name-value pair parameters. `fitctree` grows deep decision trees by default. You can grow shallower trees to reduce model complexity or computation time.

Load the `ionosphere` data set.

```
load ionosphere
```

The default values of the tree depth controllers for growing classification trees are:

- `n - 1` for `MaxNumSplits`. `n` is the training sample size.
- `1` for `MinLeafSize`.
- `10` for `MinParentSize`.

These default values tend to grow deep trees for large training sample sizes.

Train a classification tree using the default values for tree depth control. Cross validate the model using 10-fold cross validation.

```
rng(1); % For reproducibility
MdlDefault = fitctree(X,Y,'CrossVal','on');
```

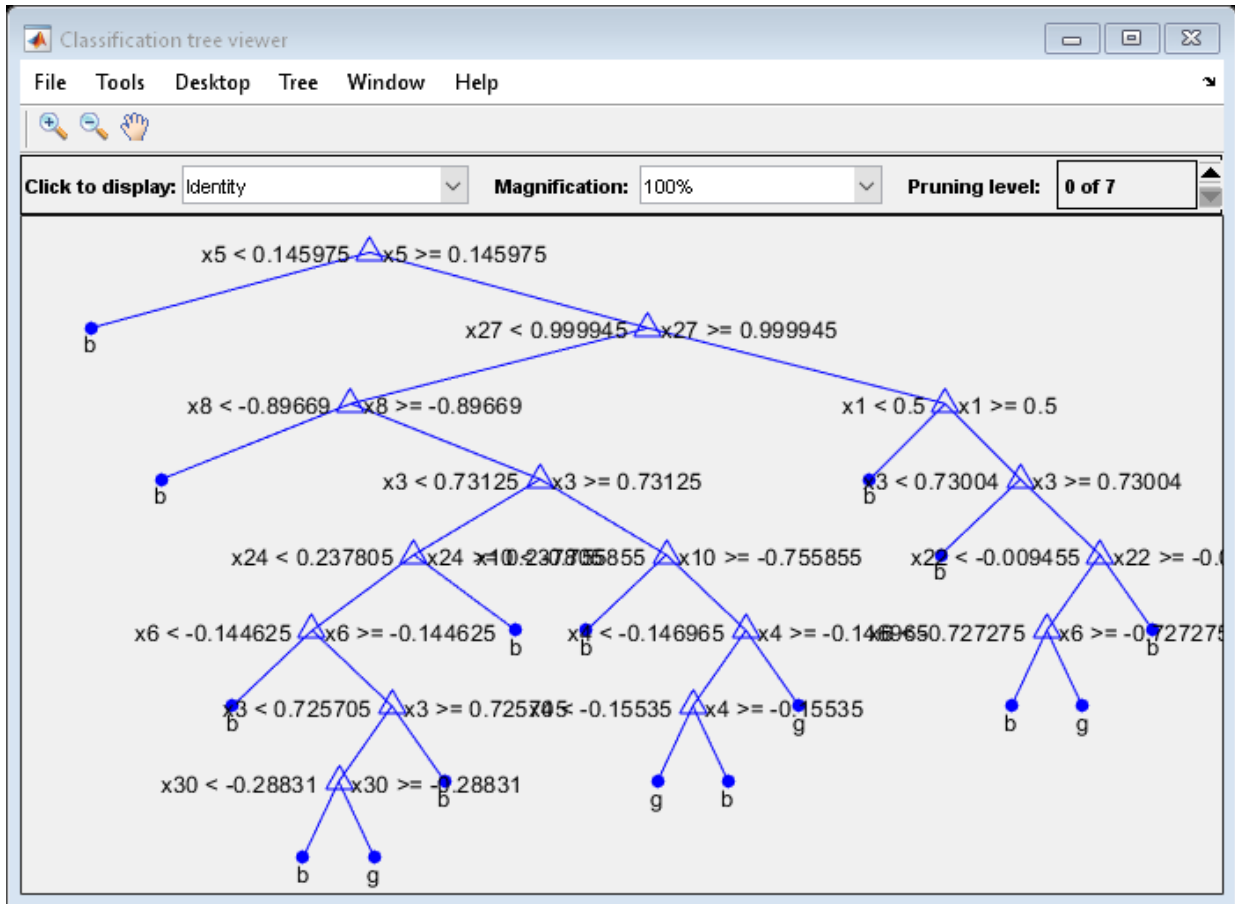

Draw a histogram of the number of imposed splits on the trees. Also, view one of the trees.

```
numBranches = @(x)sum(x.IsBranch);
mdlDefaultNumSplits = cellfun(numBranches, MdlDefault.Trained);

figure;
histogram(mdlDefaultNumSplits)
```

```
view(MdlDefault.Trained{1}, 'Mode', 'graph')
```

The average number of splits is around 15.

Suppose that you want a classification tree that is not as complex (deep) as the ones trained using the default number of splits. Train another classification tree, but set the maximum number of splits at 7, which is about half the mean number of splits from the default classification tree. Cross validate the model using 10-fold cross validation.

```
Mdl7 = fitctree(X,Y,'MaxNumSplits',7,'CrossVal','on');
view(Mdl7.Trained{1},'Mode','graph')
```

Compare the cross validation classification errors of the models.

```
classErrorDefault = kfoldLoss(MdlDefault)
```

```
classErrorDefault = 0.1140
```

```
classError7 = kfoldLoss(Mdl7)
```

```
classError7 = 0.1254
```

Mdl7 is much less complex and performs only slightly worse than MdlDefault.

Definitions

Impurity and Node Error

ClassificationTree splits nodes based on either impurity or node error.

Impurity means one of several things, depending on your choice of the SplitCriterion name-value pair argument:

- Gini's Diversity Index (gdi) — The Gini index of a node is

$$1 - \sum_i p^2(i),$$

where the sum is over the classes i at the node, and $p(i)$ is the observed fraction of classes with class i that reach the node. A node with just one class (a pure node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance (' deviance ') — With $p(i)$ defined the same as for the Gini index, the deviance of a node is

$$-\sum_i p(i) \log_2 p(i).$$

A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule (' twoing ') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let $L(i)$ denote the fraction of members of class i in the left child node after a split, and $R(i)$ denote the fraction of members of class i in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R) \left(\sum_i |L(i) - R(i)| \right)^2,$$

where $P(L)$ and $P(R)$ are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and hence similar to the parent node, and so the split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If j is the class with the largest number of training samples at a node, the node error is

$$1 - p(j).$$

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `predict` function supports code generation.
- When you train a classification tree using `fitctree`, the following restrictions apply.
 - The class labels input argument value (Y) cannot be a categorical array.
 - Code generation does not support categorical predictors. You cannot supply training data in a table that contains at least one categorical predictor, and you cannot use the 'CategoricalPredictors' name-value pair argument. To dummy-code variables that you want treated as categorical, preprocess the categorical data by using `dummyvar` before fitting the model.
 - The value of the 'ClassNames' name-value pair argument cannot be a categorical array.
 - The value of the 'ScoreTransform' name-value pair argument cannot be an anonymous function.
 - You cannot use surrogate splits, that is, the value of the 'Surrogate' name-value pair argument must be 'off'.

For code generation examples, see “Code Generation Workflow for Prediction” on page 31-5 and “Specify Variable-Sized Arguments for Code Generation” on page 31-48. For more information, see topics in “Code Generation”.

Introduced in R2011a

classify

Discriminant analysis

Syntax

```
class = classify(sample,training,group)
class = classify(sample,training,group,'type')
class = classify(sample,training,group,'type',prior)
[class,err] = classify(...)
[class,err,POSTERIOR] = classify(...)
[class,err,POSTERIOR,logp] = classify(...)
[class,err,POSTERIOR,logp,coeff] = classify(...)
```

Description

`class = classify(sample,training,group)` classifies each row of the data in `sample` into one of the groups in `training`. `sample` and `training` must be matrices with the same number of columns. `group` is a grouping variable for `training`. Its unique values define groups; each element defines the group to which the corresponding row of `training` belongs. `group` can be a categorical variable, a numeric vector, a character array, a string array, or a cell array of character vectors. `training` and `group` must have the same number of rows. `classify` treats NaNs, empty character vectors, and empty strings in `group` as missing data values, and ignores the corresponding rows of `training`. The output `class` indicates the group to which each row of `sample` has been assigned, and is of the same type as `group`.

`class = classify(sample,training,group,'type')` allows you to specify the type of discriminant function. Specify `type` inside single quotes. `type` is one of:

- `linear` — Fits a multivariate normal density to each group, with a pooled estimate of covariance. This is the default.
- `diaglinear` — Similar to `linear`, but with a diagonal covariance matrix estimate (naive Bayes classifiers).
- `quadratic` — Fits multivariate normal densities with covariance estimates stratified by group.

- `diagquadratic` — Similar to `quadratic`, but with a diagonal covariance matrix estimate (naive Bayes classifiers).
- `mahalanobis` — Uses Mahalanobis distances with stratified covariance estimates.

`class = classify(sample, training, group, 'type', prior)` allows you to specify prior probabilities for the groups. `prior` is one of:

- A numeric vector the same length as the number of unique values in `group` (or the number of levels defined for `group`, if `group` is categorical). If `group` is numeric or categorical, the order of `prior` must correspond to the ordered values in `group`. Otherwise, the order of `prior` must correspond to the order of the first occurrence of the values in `group`.
- A 1-by-1 structure with fields:
 - `prob` — A numeric vector.
 - `group` — Of the same type as `group`, containing unique values indicating the groups to which the elements of `prob` correspond.

As a structure, `prior` can contain groups that do not appear in `group`. This can be useful if `training` is a subset a larger training set. `classify` ignores any groups that appear in the structure but not in the `group` array.

- The character vector or string scalar `'empirical'`, indicating that group prior probabilities should be estimated from the group relative frequencies in `training`.

`prior` defaults to a numeric vector of equal probabilities, i.e., a uniform distribution. `prior` is not used for discrimination by Mahalanobis distance, except for error rate calculation.

`[class, err] = classify(...)` also returns an estimate `err` of the misclassification error rate based on the `training` data. `classify` returns the apparent error rate, i.e., the percentage of observations in `training` that are misclassified, weighted by the prior probabilities for the groups.

`[class, err, POSTERIOR] = classify(...)` also returns a matrix `POSTERIOR` of estimates of the posterior probabilities that the j th training group was the source of the i th sample observation, i.e., $Pr(\text{group } j | \text{obs } i)$. `POSTERIOR` is not computed for Mahalanobis discrimination.

`[class, err, POSTERIOR, logp] = classify(...)` also returns a vector `logp` containing estimates of the logarithms of the unconditional predictive probability density

of the sample observations, $p(\text{obs } i) = \sum p(\text{obs } i | \text{group } j) \text{Pr}(\text{group } j)$ over all groups. `logp` is not computed for Mahalanobis discrimination.

`[class,err,POSTERIOR,logp,coeff] = classify(...)` also returns a structure array `coeff` containing coefficients of the boundary curves between pairs of groups. Each element `coeff(I,J)` contains information for comparing group I to group J in the following fields:

- `type` — Type of discriminant function, from the `type` input.
- `name1` — Name of the first group.
- `name2` — Name of the second group.
- `const` — Constant term of the boundary equation (K)
- `linear` — Linear coefficients of the boundary equation (L)
- `quadratic` — Quadratic coefficient matrix of the boundary equation (Q)

For the `linear` and `diaglinear` types, the `quadratic` field is absent, and a row `x` from the sample array is classified into group I rather than group J if $\theta < K+x*L$. For the other types, `x` is classified into group I if $\theta < K+x*L+x*Q*x'$.

Examples

Classify Using Discriminant Analysis

For training data, use Fisher's sepal measurements for iris versicolor and virginica:

```
load fisheriris
SL = meas(51:end,1);
SW = meas(51:end,2);
group = species(51:end);
h1 = gscatter(SL,SW,group,'rb','v^',[],'off');
set(h1,'LineWidth',2)
legend('Fisher versicolor','Fisher virginica',...
       'Location','NW')
```

Classify a grid of measurements on the same scale:

```
[X,Y] = meshgrid(linspace(4.5,8),linspace(2,4));
X = X(:); Y = Y(:);
[C,err,P,logp,coeff] = classify([X Y],[SL SW],...
                               group,'Quadratic');
```

Visualize the classification:

```
hold on;
gscatter(X,Y,C,'rb','.',1,'off');
K = coeff(1,2).const;
L = coeff(1,2).linear;
Q = coeff(1,2).quadratic;
```

```
% Function to compute  $K + L*v + v'*Q*v$  for multiple vectors
%  $v=[x;y]$ . Accepts  $x$  and  $y$  as scalars or column vectors.
f = @(x,y) K + [x y]*L + sum(([x y]*Q) .* [x y], 2);

h2 = ezplot(f,[4.5 8 2 4]);
set(h2,'Color','m','LineWidth',2)
axis([4.5 8 2 4])
xlabel('Sepal Length')
ylabel('Sepal Width')
title('{\bf Classification with Fisher Training Data}')
```

Alternative Functionality

The `fitcdiscr` function also performs discriminant analysis. You can train a classifier by using the `fitcdiscr` function and predict labels of new data by using the `predict` function. The `fitcdiscr` supports cross-validation and hyperparameter optimization and does not require you to fit the classifier every time you make a new prediction or you change prior probabilities.

Introduced before R2006a

classname

Class: classregtree

Class names for classification decision tree

Note classregtree has been removed. Use `fitctree`, `fitrtree`, `ClassificationTree`, or `RegressionTree` instead.

Syntax

CNAMES = classname(T)
CNAMES = classname(T,J)

Description

CNAMES = classname(T) returns a cell array of character vectors with class names for this classification decision tree.

CNAMES = classname(T,J) takes an array J of class numbers and returns the class names for the specified numbers.

See Also

classregtree

classprob

Class: classregtree

Class probabilities

Note classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

Syntax

`P = classprob(t)`
`P = classprob(t,nodes)`

Description

`P = classprob(t)` returns an n -by- m array `P` of class probabilities for the nodes in the classification tree `t`, where n is the number of nodes and m is the number of classes. For any node number `i`, the class probabilities `P(i, :)` are the estimated probabilities for each class for a point satisfying the conditions for node `i`.

`P = classprob(t,nodes)` takes a vector `nodes` of node numbers and returns the class probabilities for the specified nodes.

classregtree

Class: classregtree

Construct classification and regression trees

Note classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

Syntax

```
t = classregtree(X,y)
t = classregtree(X,y, 'Name', value)
```

Description

`t = classregtree(X,y)` creates a decision tree `t` for predicting the response `y` as a function of the predictors in the columns of `X`. `X` is an n -by- m matrix of predictor values. If `y` is a vector of n response values, `classregtree` performs regression. If `y` is a categorical variable, character array, or cell array of character vectors, `classregtree` performs classification. Either way, `t` is a binary tree where each branching node is split based on the values of a column of `X`. NaN values in `X` or `y` are taken to be missing values. Observations with all missing values for `X` or missing values for `y` are not used in the fit. Observations with some missing values for `X` are used to find splits on variables for which these observations have valid values.

`t = classregtree(X,y, 'Name', value)` specifies one or more optional parameter name/value pairs. Specify *Name* in single quotes. The following options are available:

For all trees:

- `categorical` — Vector of indices of the columns of `X` that are to be treated as unordered categorical variables
- `method` — Either 'classification' (default if `y` is text or a categorical variable) or 'regression' (default if `y` is numeric).

- **names** — A cell array of names for the predictor variables, in the order in which they appear in the X from which the tree was created.
- **prune** — 'on' (default) to compute the full tree and the optimal sequence of pruned subtrees, or 'off' for the full tree without pruning.
- **minparent** — A number k such that impure nodes must have k or more observations to be split (default is 10).
- **minleaf** — A minimal number of observations per tree leaf (default is 1). If you supply both 'minparent' and 'minleaf', `classregtree` uses the setting which results in larger leaves: $\text{minparent} = \max(\text{minparent}, 2 * \text{minleaf})$
- **mergeleaves** — 'on' (default) to merge leaves that originate from the same parent node and give the sum of risk values greater or equal to the risk associated with the parent node. If 'off', `classregtree` does not merge leaves.
- **nvartosample** — Number of predictor variables randomly selected for each split. By default all variables are considered for each decision split.
- **stream** — Random number stream. Default is the MATLAB default random number stream.
- **surrogate** — 'on' to find surrogate splits at each branch node. Default is 'off'. If you set this parameter to 'on', `classregtree` can run significantly slower and consume significantly more memory.
- **weights** — Vector of observation weights. By default the weight of every observation is 1. The length of this vector must be equal to the number of rows in X.

For regression trees only:

- **getoler** — Defines tolerance on quadratic error per node for regression trees. Splitting nodes stops when quadratic error per node drops below $\text{getoler} * \text{qed}$, where qed is the quadratic error for the entire data computed before the decision tree is grown: $\text{qed} = \text{norm}(y - \text{ybar})$ with ybar estimated as the average of the input array Y. Default value is 1e-6.

For classification trees only:

- **cost** — Square matrix C, where $C(i, j)$ is the cost of classifying a point into class j if its true class is i (default has $C(i, j) = 1$ if $i \neq j$, and $C(i, j) = 0$ if $i = j$). Alternatively, this value can be a structure S having two fields: S.group containing the group names as a categorical variable, character array, or cell array of character vectors; and S.cost containing the cost matrix C.

- `splitcriterion` — Criterion for choosing a split. One of `'gdi'` (default) or Gini's diversity index, `'twoing'` for the twoing rule, or `'deviance'` for maximum deviance reduction.
- `priorprob` — Prior probabilities for each class, specified as `'empirical'` or `'equal'`, or as a vector (one value for each distinct group name) or as a structure `S` with two fields:
 - `S.group` containing the group names as a categorical variable, character array, or cell array of character vectors.
 - `S.prob` containing a vector of corresponding probabilities.

If the input value is `'empirical'` (default), class probabilities are determined from class frequencies in `Y`. If the input value is `'equal'`, all class probabilities are set equal. If both observation weights and class prior probabilities are supplied, the weights are renormalized to add up to the value of the prior probability in the respective class.

Introduced in R2007a

cluster

Construct agglomerative clusters from linkages

Syntax

```
T = cluster(Z, 'cutoff', c)
T = cluster(Z, 'cutoff', c, 'depth', d)
T = cluster(Z, 'cutoff', c, 'criterion', criterion)
T = cluster(Z, 'maxclust', n)
```

Description

`T = cluster(Z, 'cutoff', c)` constructs clusters from the agglomerative hierarchical cluster tree, `Z`, as generated by the `linkage` function. `Z` is a matrix of size $(m - 1)$ -by-3, where m is the number of observations in the original data. `c` is a threshold for cutting `Z` into clusters. Clusters are formed when a node and all of its subnodes have inconsistent value less than `c`. All leaves at or below the node are grouped into a cluster. `t` is a vector of size m containing the cluster assignments of each observation.

If `c` is a vector, `T` is a matrix of cluster assignments with one column per cutoff value.

`T = cluster(Z, 'cutoff', c, 'depth', d)` evaluates inconsistent values by looking to a depth `d` below each node. The default depth is 2.

`T = cluster(Z, 'cutoff', c, 'criterion', criterion)` uses the specified criterion for forming clusters, where `criterion` is 'inconsistent' (default) or 'distance'. The 'distance' criterion uses the distance between the two subnodes merged at a node to measure node height. All leaves at or below a node with height less than `c` are grouped into a cluster.

`T = cluster(Z, 'maxclust', n)` constructs a maximum of `n` clusters using the 'distance' criterion. `cluster` finds the smallest height at which a horizontal cut through the tree leaves `n` or fewer clusters.

If `n` is a vector, `T` is a matrix of cluster assignments with one column per maximum value.

Examples

Compare Cluster Assignments to Classes

Compare cluster assignments of flowers to their species classification.

Load the sample data.

```
load fisheriris
```

Compute three clusters of the Fisher iris data using the 'average' method and the 'chebychev' metric.

```
Z = linkage(meas, 'average', 'chebychev');  
c = cluster(Z, 'maxclust', 3);
```

Create a dendrogram plot of Z. To see the three clusters, use 'ColorThreshold' with a cutoff halfway between the third-from-last and second-from-last linkages.

```
cutoff = median([Z(end-2,3) Z(end-1,3)]);  
dendrogram(Z, 'ColorThreshold', cutoff)
```

Display the last two rows of `Z` to see how the three clusters are combined into one. `linkage` combines the 293rd (blue) cluster with the 297th (red) cluster to form the 298th cluster with a linkage of 1.7583. `linkage` then combines the 296th (green) cluster with the 298th cluster.

```
lastTwo = Z(end-1:end,:)
```

```
lastTwo =
```

```
293.0000 297.0000 1.7583
296.0000 298.0000 3.4445
```

See how the cluster assignments correspond to the three species. For example, one of the clusters contains 50 flowers of the second species and 40 flowers of the third species.

```
crosstab(c,species)
```

```
ans =
```

```
    0    0   10  
    0   50   40  
   50    0    0
```

Cluster Data and Plot Result

Randomly generate sample data with 20,000 observations.

```
rng('default') % For reproducibility  
X = rand(20000,3);
```

Create a hierarchical cluster tree using Ward's linkage. In this case, 'savememory' is set to 'on' by default. In general, choose the best value for 'savememory' based on the dimensions of X and the available memory.

```
Z = linkage(X,'ward');
```

Cluster data into four groups and plot the result.

```
c = cluster(Z,'Maxclust',4);  
scatter3(X(:,1),X(:,2),X(:,3),10,c)
```

Introduced before R2006a

cluster

Construct clusters from Gaussian mixture distribution

Syntax

```
idx = cluster(gm,X)
[idx,nlogL] = cluster(gm,X)
[idx,nlogL,P] = cluster(gm,X)
[idx,nlogL,P,logpdf] = cluster(gm,X)
[idx,nlogL,P,logpdf,d2] = cluster(gm,X)
```

Description

`idx = cluster(gm,X)` partitions the data in X into k clusters determined by the k Gaussian mixture components in gm . The value in `idx(i)` is the cluster index of observation i and indicates the component with the largest posterior probability given the observation i .

`[idx,nlogL] = cluster(gm,X)` also returns the negative loglikelihood of the Gaussian mixture model gm given the data X .

`[idx,nlogL,P] = cluster(gm,X)` also returns the posterior probabilities of each Gaussian mixture component in gm given each observation in X .

`[idx,nlogL,P,logpdf] = cluster(gm,X)` also returns a logarithm of the estimated probability density function (pdf) evaluated at each observation in X .

`[idx,nlogL,P,logpdf,d2] = cluster(gm,X)` also returns the squared Mahalanobis distance of each observation in X to each Gaussian mixture component in gm .

Examples

Cluster Data

Generate random variates that follow a mixture of two bivariate Gaussian distributions by using the `mvnrnd` function. Fit a Gaussian mixture model (GMM) to the generated data by using the `fitgmdist` function. Then, use the `cluster` function to partition the data into two clusters determined by the fitted GMM components.

Define the distribution parameters (means and covariances) of two bivariate Gaussian mixture components.

```
mu1 = [2 2];           % Mean of the 1st component
sigma1 = [2 0; 0 1];  % Covariance of the 1st component
mu2 = [-2 -1];       % Mean of the 2nd component
sigma2 = [1 0; 0 1]; % Covariance of the 2nd component
```

Generate an equal number of random variates from each component, and combine the two sets of random variates.

```
rng('default') % For reproducibility
r1 = mvnrnd(mu1,sigma1,1000);
r2 = mvnrnd(mu2,sigma2,1000);
X = [r1; r2];
```

The combined data set `X` contains random variates following a mixture of two bivariate Gaussian distribution.

Fit a two-component GMM to `X`.

```
gm = fitgmdist(X,2);
```

Plot `X` by using `scatter`. Visualize the fitted model `gm` by using `pdf` and `ezcontour`.

```
figure
scatter(X(:,1),X(:,2),10,'.') % Scatter plot with points of size 10
hold on
ezcontour(@(x,y)pdf(gm,[x y]),[-6 8],[-4 6])
```

Partition the data into clusters by passing the fitted GMM and the data to `cluster`.

```
idx = cluster(gm,X);
```

Use `gscatter` to create a scatter plot grouped by `idx`.

```
figure;  
gscatter(X(:,1),X(:,2),idx);  
legend('Cluster 1','Cluster 2','Location','best');
```

Input Arguments

gm — Gaussian mixture distribution

`gmdistribution` object

Gaussian mixture distribution, also called Gaussian mixture model (GMM), specified as a `gmdistribution` object.

You can create a `gmdistribution` object using `gmdistribution` or `fitgmdist`. Use the `gmdistribution` function to create a `gmdistribution` object by specifying the

distribution parameters. Use the `fitgmdist` function to fit a `gmdistribution` model to data given a fixed number of components.

X — Data

n-by-*m* numeric matrix

Data, specified as an *n*-by-*m* numeric matrix, where *n* is the number of observations and *m* is the number of variables in each observation.

To provide meaningful clustering results, *X* must come from the same population as the data used to create `gm`.

If a row of *X* contains NaNs, then `cluster` excludes the row from the computation. The corresponding value in `idx`, `P`, `logpdf`, and `d2` is NaN.

Data Types: `single` | `double`

Output Arguments

idx — Cluster index

n-by-1 positive integer vector

Cluster index, returned as an *n*-by-1 positive integer vector, where *n* is the number of observations in *X*.

`idx(i)` is the cluster index of observation *i* and indicates the Gaussian mixture component with the largest posterior probability given the observation *i*.

nlogL — Negative loglikelihood

numeric value

Negative loglikelihood value of the Gaussian mixture model `gm` given the data *X*, returned as a numeric value.

P — Posterior probability

n-by-*k* numeric vector

Posterior probability of each Gaussian mixture component in `gm` given each observation in *X*, returned as an *n*-by-*k* numeric vector, where *n* is the number of observations in *X* and *k* is the number of mixture components in `gm`.

$P(i, j)$ is the posterior probability of the j th Gaussian mixture component given observation i , `Probability(component j | observation i)`.

logpdf — Logarithm of estimated pdf

n-by-1 numeric vector

Logarithm of the estimated pdf, evaluated at each observation in X , returned as an *n*-by-1 numeric vector, where *n* is the number of observations in X .

`logpdf(i)` is the logarithm of the estimated pdf at observation i . The `cluster` function computes the estimated pdf by using the likelihood of each component given each observation and the component probabilities.

$$\text{logpdf}(i) = \log \sum_{j=1}^k L(C_j | O_i) P(C_j),$$

where $L(C_j | O_i)$ is the likelihood of component j given observation i , and $P(C_j)$ is the probability of component j . The `cluster` function computes the likelihood term by using the multivariate normal pdf of the j th Gaussian mixture component evaluated at observation i . The component probabilities are the mixing proportions of mixture components, the `ComponentProportion` property of `gm`.

d2 — Squared Mahalanobis distance

n-by-*k* numeric matrix

Squared Mahalanobis distance of each observation in X to each Gaussian mixture component in `gm`, returned as an *n*-by-*k* numeric matrix, where *n* is the number of observations in X and *k* is the number of mixture components in `gm`.

`d2(i, j)` is the squared distance of observation i to the j th Gaussian mixture component.

clustering.evaluation.ClusterCriterion class

Package: clustering.evaluation

Clustering evaluation object

Description

Create a clustering evaluation object using `evalclusters`.

Properties

ClusteringFunction

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name or function handle. If the clustering solutions are provided in the input, `ClusteringFunction` is empty.

CriterionName

Name of the criterion used for clustering evaluation, stored as a valid criterion name.

CriterionValues

Criterion values corresponding to each proposed number of clusters in `InspectedK`, stored as a vector of numerical values.

InspectedK

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

Missing

Logical flag for excluded data, stored as a column vector of logical values. If `Missing` equals `true`, then the corresponding value in the data matrix `x` is not used in the clustering solution.

NumObservations

Number of observations in the data matrix X , minus the number of missing (NaN) values in X , stored as a positive integer value.

OptimalK

Optimal number of clusters, stored as a positive integer value.

OptimalY

Optimal clustering solution corresponding to `OptimalK`, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, `OptimalY` is empty.

X

Data used for clustering, stored as a matrix of numerical values.

Methods

| | |
|----------------------|--|
| <code>addK</code> | Evaluate additional numbers of clusters |
| <code>plot</code> | Plot clustering evaluation object criterion values |
| <code>compact</code> | Compact clustering evaluation object |

Topics

Class Attributes (MATLAB)
Property Attributes (MATLAB)

clusterdata

Agglomerative clusters from data

Syntax

```
T = clusterdata(X,cutoff)
T = clusterdata(X,Name,Value)
```

Description

`T = clusterdata(X,cutoff)` returns the cluster indices (T) for each observation (row) of the data (X) while adhering to a threshold for cutting the hierarchical tree (cutoff).

`T = clusterdata(X,Name,Value)` clusters with additional options specified by one or more Name,Value pair arguments.

Input Arguments

X

Matrix with two or more rows. The rows represent observations, the columns represent categories or dimensions.

cutoff

When $0 < \text{cutoff} < 2$, `clusterdata` forms clusters when inconsistent values are greater than `cutoff` (see `inconsistent`). When `cutoff` is an integer ≥ 2 , `clusterdata` interprets `cutoff` as the maximum number of clusters to keep in the hierarchical tree generated by `linkage`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Criterion

Either 'inconsistent' or 'distance'.

Cutoff

Cutoff for inconsistent or distance metric, a positive scalar. When $0 < \text{Cutoff} < 2$, `clusterdata` forms clusters when inconsistent values are greater than `Cutoff` (see `inconsistent`). When `Cutoff` is an integer ≥ 2 , `clusterdata` interprets `Cutoff` as the maximum number of clusters to keep in the hierarchical tree generated by `linkage`.

Depth

Depth for computing inconsistent values, a positive integer.

Distance

Any of the distance metric names allowed by `pdist`:

| Value | Description |
|--------------------|---|
| 'euclidean' | Euclidean distance (default). |
| 'squaredeuclidean' | Squared Euclidean distance. (This option is provided for efficiency only. It does not satisfy the triangle inequality.) |
| 'seuclidean' | Standardized Euclidean distance. Each coordinate difference between observations is scaled by dividing by the corresponding element of the standard deviation, $S = \text{nanstd}(X)$. |
| 'mahalanobis' | Mahalanobis distance using the sample covariance of X , $C = \text{nancov}(X)$. |
| 'cityblock' | City block distance. |
| 'minkowski' | Minkowski distance. The default exponent is 2. To use a different exponent P , specify P after 'minkowski', where P is a positive scalar value: 'minkowski', P |
| 'chebychev' | Chebychev distance (maximum coordinate difference). |

| Value | Description |
|------------------|---|
| 'cosine' | One minus the cosine of the included angle between points (treated as vectors). |
| 'correlation' | One minus the sample correlation between points (treated as sequences of values). |
| 'hamming' | Hamming distance, which is the percentage of coordinates that differ. |
| 'jaccard' | One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ. |
| 'spearman' | One minus the sample Spearman's rank correlation between observations (treated as sequences of values). |
| @ <i>distfun</i> | <p>Custom distance function handle. A distance function has the form</p> <pre>function D2 = DISTFUN(ZI,ZJ) % calculation of distance ...</pre> <p>where</p> <ul style="list-style-type: none"> • ZI is a 1-by-n vector containing a single observation. • ZJ is an m2-by-n matrix containing multiple observations. <code>distfun</code> must accept a matrix ZJ with an arbitrary number of observations. • D2 is an m2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(k, :). <p>If your data is not sparse, generally it is faster to use a built-in distance than to use a function handle.</p> |

For more information on these distance metrics, see “Distance Metrics” on page 32-4572.

Linkage

Any of the linkage methods allowed by the `linkage` function:

- 'average'
- 'centroid'

- 'complete'
- 'median'
- 'single'
- 'ward'
- 'weighted'

For details, see the definitions in the `linkage` function reference page.

Maxclust

Maximum number of clusters to form, a positive integer.

Savememory

Either 'on' or 'off'. When applicable, the 'on' setting causes `clusterdata` to construct clusters without computing the distance matrix. `Savememory` is applicable when:

- Linkage is 'centroid', 'median', or 'ward'
- Distance is 'euclidean' (default)

When `Savememory` is 'on', linkage run time is proportional to the number of dimensions (number of columns of `X`). When `Savememory` is 'off', linkage memory requirement is proportional to N^2 , where N is the number of observations. So choosing the best (least-time) setting for `Savememory` depends on the problem dimensions, number of observations, and available memory. The default `Savememory` setting is a rough approximation of an optimal setting.

Default: 'on' when `X` has 20 columns or fewer, or the computer does not have enough memory to store the distance matrix; otherwise 'off'

Output Arguments

T

`T` is a vector of size `m` containing a cluster number for each observation.

- When $0 < \text{cutoff} < 2$, `T = clusterdata(X, cutoff)` is equivalent to:

```
Y = pdist(X,'euclid');
Z = linkage(Y,'single');
T = cluster(Z,'Cutoff',cutoff);
```

- When cutoff is an integer ≥ 2 , `T = clusterdata(X,cutoff)` is equivalent to:

```
Y = pdist(X,'euclid');
Z = linkage(Y,'single');
T = cluster(Z,'Maxclust',cutoff);
```

Examples

Create Hierarchical Cluster Tree From Sample Data

This example shows how to create a hierarchical cluster tree from sample data, and visualize the clusters using a 3-dimensional scatter plot.

Generate sample data matrices containing random numbers from the standard uniform distribution.

```
rng('default'); % For reproducibility
X = [gallery('uniformdata',[10 3],12);...
     gallery('uniformdata',[10 3],13)+1.2;...
     gallery('uniformdata',[10 3],14)+2.5];
```

Compute the distances between items and create a hierarchical cluster tree from the sample data. List all of the items in cluster 2.

```
T = clusterdata(X,'Maxclust',3);
find(T==2)
```

```
ans = 10×1
```

```
11
12
13
14
15
16
17
18
19
```

20

Plot the data with each cluster shown in a different color.

```
scatter3(X(:,1),X(:,2),X(:,3),100,T,'filled')
```

Create Hierarchical Cluster Tree Using Ward's Linkage

This example shows how to create a hierarchical cluster tree using Ward's linkage, and visualize the clusters using a 3-dimensional scatter plot.

Create a 20,000-by-3 matrix of sample data generated from the standard uniform distribution.

```
rng('default'); % For reproducibility  
X = rand(20000,3);
```

Create a hierarchical cluster tree from the sample data using Ward's linkage. Set 'savememory' to 'on' to construct clusters without computing the distance matrix.

```
c = clusterdata(X,'Linkage','ward','Savememory','on','Maxclust',4);
```

Plot the data with each cluster shown in a different color.

```
scatter3(X(:,1),X(:,2),X(:,3),10,c)
```

Tips

- The centroid and median methods can produce a cluster tree that is not monotonic. This occurs when the distance from the union of two clusters, r and s , to a third cluster is less than the distance between r and s . In this case, in a dendrogram drawn with the default orientation, the path from a leaf to the root node takes some downward steps. To avoid this, use another method. The following image shows a nonmonotonic cluster tree.

In this case, cluster 1 and cluster 3 are joined into a new cluster, while the distance between this new cluster and cluster 2 is less than the distance between cluster 1 and cluster 3. This leads to a nonmonotonic tree.

- You can provide the output `T` to other functions including `dendrogram` to display the tree, `cluster` to assign points to clusters, `inconsistent` to compute inconsistent measures, and `cophenet` to compute the cophenetic correlation coefficient.

Introduced before R2006a

cmdscale

Classical multidimensional scaling

Syntax

```
Y = cmdscale(D)
[Y,e] = cmdscale(D)
[Y,e] = cmdscale(D,p)
```

Description

`Y = cmdscale(D)` takes an n -by- n distance matrix D , and returns an n -by- p configuration matrix Y . Rows of Y are the coordinates of n points in p -dimensional space for some $p < n$. When D is a Euclidean distance matrix, the distances between those points are given by D . p is the dimension of the smallest space in which the n points whose inter-point distances are given by D can be embedded.

`[Y,e] = cmdscale(D)` also returns the eigenvalues of $Y*Y'$. When D is Euclidean, the first p elements of e are positive, the rest zero. If the first k elements of e are much larger than the remaining $(n-k)$, then you can use the first k columns of Y as k -dimensional points whose inter-point distances approximate D . This can provide a useful dimension reduction for visualization, e.g., for $k = 2$.

D need not be a Euclidean distance matrix. If it is non-Euclidean or a more general dissimilarity matrix, then some elements of e are negative, and `cmdscale` chooses p as the number of positive eigenvalues. In this case, the reduction to p or fewer dimensions provides a reasonable approximation to D only if the negative elements of e are small in magnitude.

`[Y,e] = cmdscale(D,p)` also accepts a positive integer p between 1 and n . p specifies the dimensionality of the desired embedding Y . If a p dimensional embedding is possible, then Y will be of size n -by- p and e will be of size p -by-1. If only a q dimensional embedding with $q < p$ is possible, then Y will be of size n -by- q and e will be of size p -by-1. Specifying p may reduce the computational burden when n is very large.

You can specify D as either a full dissimilarity matrix, or in upper triangle vector form such as is output by `pdist`. A full dissimilarity matrix must be real and symmetric, and

have zeros along the diagonal and positive elements everywhere else. A dissimilarity matrix in upper triangle form must have real, positive entries. You can also specify `D` as a full similarity matrix, with ones along the diagonal and all other elements less than one. `cmdscale` transforms a similarity matrix to a dissimilarity matrix in such a way that distances between the points returned in `Y` equal or approximate $\sqrt{1-D}$. To use a different transformation, you must transform the similarities prior to calling `cmdscale`.

Examples

Construct a Map Using Multidimensional Scaling

This example shows how to construct a map of 10 US cities based on the distances between those cities, using `cmdscale`.

First, create the distance matrix and pass it to `cmdscale`. In this example, `D` is a full distance matrix: it is square and symmetric, has positive entries off the diagonal, and has zeros on the diagonal.

```
cities = ...
{'Atl', 'Chi', 'Den', 'Hou', 'LA', 'Mia', 'NYC', 'SF', 'Sea', 'WDC'};
D = [
    0  587 1212  701 1936  604  748 2139 2182  543;
    587  0  920  940 1745 1188  713 1858 1737  597;
    1212 920  0  879  831 1726 1631  949 1021 1494;
    701  940  879  0 1374  968 1420 1645 1891 1220;
    1936 1745  831 1374  0 2339 2451  347  959 2300;
    604 1188 1726  968 2339  0 1092 2594 2734  923;
    748  713 1631 1420 2451 1092  0 2571 2408  205;
    2139 1858  949 1645  347 2594 2571  0  678 2442;
    2182 1737 1021 1891  959 2734 2408  678  0 2329;
    543  597 1494 1220 2300  923  205 2442 2329  0];
[Y,eigvals] = cmdscale(D);
```

Next, look at the eigenvalues returned by `cmdscale`. Some of these are negative, indicating that the original distances are not Euclidean. This is because of the curvature of the earth.

```
format short g
[eigvals eigvals/max(abs(eigvals))]
```

```
ans =
```

```

9.5821e+06      1
1.6868e+06      0.17604
 8157.3         0.0008513
 1432.9         0.00014954
 508.67         5.3085e-05
 25.143         2.624e-06
4.6705e-10      4.8741e-17
 -897.7         -9.3685e-05
-5467.6         -0.0005706
-35479          -0.0037026

```

However, in this case, the two largest positive eigenvalues are much larger in magnitude than the remaining eigenvalues. So, despite the negative eigenvalues, the first two coordinates of Y are sufficient for a reasonable reproduction of D .

```

Dtriu = D(find(tril(ones(10), -1)))';
maxrelerr = max(abs(Dtriu-pdist(Y(:,1:2))))./max(Dtriu)

```

```

maxrelerr =
    0.0075371

```

Here is a plot of the reconstructed city locations as a map. The orientation of the reconstruction is arbitrary.

```

plot(Y(:,1),Y(:,2),'.')
text(Y(:,1)+25,Y(:,2),cities)
xlabel('Miles')
ylabel('Miles')

```

Evaluate Reconstructions Using Different Distance Metrics

Determine how the quality of reconstruction varies when you reduce points to distances using different metrics.

Generate ten points in 4-D space that are close to 3-D space. Take a linear transformation of the points so that their transformed values are close to a 3-D subspace that does not align with the coordinate axes.

```
rng default % Set the seed for reproducibility
A = [normrnd(0,1,10,3) normrnd(0,0.1,10,1)];
```

```
B = randn(4,4);  
X = A*B;
```

Reduce the points in X to distances by using the Euclidean metric. Find a configuration Y with the inter-point distances.

```
D = pdist(X, 'euclidean');  
Y = cmdscale(D);
```

Compare the quality of the reconstructions when using 2, 3, or 4 dimensions. The small `maxerr3` value indicates that the first 3 dimensions provide a good reconstruction.

```
maxerr2 = max(abs(pdist(X)-pdist(Y(:,1:2))))
```

```
maxerr2 = 0.1631
```

```
maxerr3 = max(abs(pdist(X)-pdist(Y(:,1:3))))
```

```
maxerr3 = 0.0187
```

```
maxerr4 = max(abs(pdist(X)-pdist(Y)))
```

```
maxerr4 = 7.9936e-15
```

Reduce the points in X to distances by using the 'cityblock' metric. Find a configuration Y with the inter-point distances.

```
D = pdist(X, 'cityblock');  
[Y,e] = cmdscale(D);
```

Evaluate the quality of the reconstruction. `e` contains at least one negative element of large magnitude, which might account for the poor quality of the reconstruction.

```
maxerr = max(abs(pdist(X)-pdist(Y)))
```

```
maxerr = 9.0488
```

```
min(e)
```

```
ans = -5.6586
```

Introduced before R2006a

coefCI

Class: CompactGeneralizedLinearModel

Confidence intervals of coefficient estimates of generalized linear model

Syntax

```
ci = coefCI mdl  
ci = coefCI(mdl,alpha)
```

Description

`ci = coefCI(mdl)` returns confidence intervals for the coefficients in `mdl`.

`ci = coefCI(mdl,alpha)` returns confidence intervals with confidence level $1 - \alpha$.

Input Arguments

mdl

Generalized linear model, specified as a full `GeneralizedLinearModel` object constructed using `fitglm` or `stepwiseglm`, or a compacted `CompactGeneralizedLinearModel` object constructed using `compact`.

alpha

Scalar from 0 to 1, the probability that the confidence interval does not contain the true value.

Default: 0.05

Output Arguments

ci

k-by-2 matrix of confidence intervals. The jth row of **ci** is the confidence interval of coefficient j of **mdl**. The name of coefficient j of **mdl** is in **mdl.CoefficientNames**.

Examples

Confidence Interval for Coefficients of a Generalized Linear Model

Find confidence intervals for the coefficients of a fitted generalized nonlinear model.

Generate artificial data for the model using Poisson random numbers with two underlying predictors **X(1)** and **X(2)**.

```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,...
    'y ~ x1 + x2','distr','poisson')
```

```
mdl =
Generalized linear regression model:
log(y) ~ 1 + x1 + x2
Distribution = Poisson
```

Estimated Coefficients:

| | Estimate | SE | tStat | pValue |
|-------------|----------|-----------|--------|--------|
| (Intercept) | 1.0405 | 0.022122 | 47.034 | 0 |
| x1 | 0.9968 | 0.003362 | 296.49 | 0 |
| x2 | 1.987 | 0.0063433 | 313.24 | 0 |

```

Definitions

Confidence Interval

Assume that model assumptions hold (data comes from a generalized linear model represented by the formula *mdl*. Formula and the specified link function, and with observations that are independent conditional on the predictor values). Then row *j* of the confidence interval matrix *ci* gives a confidence interval [*ci(j,1)*, *ci(j,2)*] computed such that, with repeated experimentation, a proportion $1 - \alpha$ of the intervals will contain the true value of the coefficient.

coefCI

Class: GeneralizedLinearMixedModel

Confidence intervals for coefficients of generalized linear mixed-effects model

Syntax

```
feCI = coefCI(glme)
feCI = coefCI(glme, Name, Value)
[feCI, reCI] = coefCI( ___ )
```

Description

`feCI = coefCI(glme)` returns the 95% confidence intervals for the fixed-effects coefficients in the generalized linear mixed-effects model `glme`.

`feCI = coefCI(glme, Name, Value)` returns the confidence intervals using additional options specified by one or more `Name, Value` pair arguments. For example, you can specify a different confidence level or the method used to compute the approximate degrees of freedom.

`[feCI, reCI] = coefCI(___)` also returns the confidence intervals for the random-effects coefficients using any of the previous syntaxes.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Alpha — Confidence level

0.05 (default) | scalar value in the range [0,1]

Confidence level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range [0,1]. For a value α , the confidence level is $100 \times (1 - \alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha',0.01

Data Types: single | double

DFMethod — Method for computing approximate degrees of freedom

'residual' (default) | 'none'

Method for computing approximate degrees of freedom, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

| Value | Description |
|------------|---|
| 'residual' | The degrees of freedom value is assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects. |
| 'none' | The degrees of freedom is set to infinity. |

Example: 'DFMethod','none'

Output Arguments

feCI — Fixed-effects confidence intervals

p -by-2 matrix

Fixed-effects confidence intervals, returned as a p -by-2 matrix. `feCI` contains the confidence limits that correspond to the p -by-1 fixed-effects vector returned by the `fixedEffects` method. The first column of `feCI` contains the lower confidence limits and the second column contains the upper confidence limits.

When fitting a GLME model using `fitglme` and one of the maximum likelihood fit methods ('Laplace' or 'ApproximateLaplace'):

- If you specify the 'CovarianceMethod' name-value pair argument as 'conditional', then the confidence intervals are conditional on the estimated covariance parameters.
- If you specify the 'CovarianceMethod' name-value pair argument as 'JointHessian', then the confidence intervals account for the uncertainty in the estimated covariance parameters.

When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods ('MPL' or 'REMP'), `coefci` uses the fitted linear mixed effects model from the final pseudo likelihood iteration to compute confidence intervals on the fixed effects.

reCI — Random-effects confidence intervals

q-by-2 matrix

Random-effects confidence intervals, returned as a q -by-2 matrix. `reCI` contains the confidence limits corresponding to the q -by-1 random-effects vector `B` returned by the `randomEffects` method. The first column of `reCI` contains the lower confidence limits, and the second column contains the upper confidence limits.

When fitting a GLME model using `fitglme` and one of the maximum likelihood fit methods ('Laplace' or 'ApproximateLaplace'), `coefCI` computes the confidence intervals using the conditional mean squared error of prediction (CMSEP) approach conditional on the estimated covariance parameters and the observed response. Alternatively, you can interpret the confidence intervals from `coefCI` as approximate Bayesian credible intervals conditional on the estimated covariance parameters and the observed response.

When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods ('MPL' or 'REMP'), `coefci` uses the fitted linear mixed effects model from the final pseudo likelihood iteration to compute confidence intervals on the random effects.

Examples

95% Confidence Intervals for Fixed Effects

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|fact
```

Use `fixedEffects` to display the estimates and names of the fixed-effects coefficients in `glme`.

```
[beta, betanames] = fixedEffects(glme)
```

```
beta =
```

```
    1.4689
   -0.3677
   -0.0945
   -0.2832
   -0.0719
    0.0711
```

```
betanames =
```

6x1 table

```
      Name
-----
'(Intercept) '
'newprocess '
'time_dev '
'temp_dev '
'supplier_C '
'supplier_B '
```

Each row of `beta` contains the estimated value for the coefficient named in the corresponding row of `betanames`. For example, the value `-0.0945` in row 3 of `beta` is the estimated coefficient for the predictor variable `time_dev`.

Compute the 95% confidence intervals for the fixed-effects coefficients.

```
feCI = coefCI(glme)
```

```
feCI =
```

```
  1.1515    1.7864
 -0.7202   -0.0151
 -1.7395    1.5505
 -2.1926    1.6263
 -0.2268    0.0831
 -0.0826    0.2247
```

Column 1 of `feCI` contains the lower bound of the 95% confidence interval. Column 2 contains the upper bound. Row 1 corresponds to the intercept term. Rows 2, 3, and 4 correspond to `newprocess`, `time_dev`, and `temp_dev`, respectively. Rows 5 and 6 correspond to the indicator variables `supplier_C` and `supplier_B`, respectively. For example, the 95% confidence interval for the coefficient for `time_dev` is `[-1.7395, 1.5505]`. Some of the confidence intervals include 0, which indicates that those predictors are not significant at the 5% significance level. To obtain specific *P*-values for each fixed-effects term, use `fixedEffects`. To test significance for entire terms, use `anova`.

99% Confidence Intervals for Random Effects

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)
```

Use `randomEffects` to compute and display the estimates of the empirical Bayes predictors (EBPs) for the random effects associated with `factory`.

```
[B, Bnames] = randomEffects(glme)
```

B =

```

-0.1351
-0.1627
-0.3208
0.0584

```

Bnames =

20x3 table

| Group | Level | Name |
|-----------|-------|---------------|
| 'factory' | '1' | '(Intercept)' |
| 'factory' | '2' | '(Intercept)' |
| 'factory' | '3' | '(Intercept)' |
| 'factory' | '4' | '(Intercept)' |
| 'factory' | '5' | '(Intercept)' |
| 'factory' | '6' | '(Intercept)' |
| 'factory' | '7' | '(Intercept)' |
| 'factory' | '8' | '(Intercept)' |
| 'factory' | '9' | '(Intercept)' |
| 'factory' | '10' | '(Intercept)' |
| 'factory' | '11' | '(Intercept)' |
| 'factory' | '12' | '(Intercept)' |
| 'factory' | '13' | '(Intercept)' |
| 'factory' | '14' | '(Intercept)' |
| 'factory' | '15' | '(Intercept)' |
| 'factory' | '16' | '(Intercept)' |
| 'factory' | '17' | '(Intercept)' |
| 'factory' | '18' | '(Intercept)' |
| 'factory' | '19' | '(Intercept)' |
| 'factory' | '20' | '(Intercept)' |

Each row of **B** contains the estimated EBPs for the random-effects coefficient named in the corresponding row of **Bnames**. For example, the value -0.2633 in row 3 of **B** is the estimated coefficient of '(Intercept)'' for level '3' of factory.

Compute the 99% confidence intervals of the EBPs for the random effects.

```

[feCI, reCI] = coefCI(glme, 'Alpha', 0.01);
reCI

```

reCI =

| | |
|---------|--------|
| -0.2125 | 0.7951 |
| -0.3510 | 0.6595 |
| -0.8219 | 0.2954 |
| -0.9953 | 0.1440 |
| 0.0730 | 1.0176 |
| -0.6362 | 0.4224 |
| -0.1796 | 0.7877 |
| -0.7044 | 0.3738 |
| -0.6795 | 0.3880 |
| -0.6142 | 0.4509 |
| -0.5487 | 0.5777 |
| -0.3677 | 0.7219 |
| -0.2908 | 0.7883 |
| -0.3322 | 0.7551 |
| -0.2572 | 0.8126 |
| -0.8451 | 0.3416 |
| -0.7214 | 0.4513 |
| -0.7482 | 0.4228 |
| -0.9333 | 0.2916 |
| -0.5064 | 0.6232 |

Column 1 of `reCI` contains the lower bound of the 99% confidence interval. Column 2 contains the upper bound. Each row corresponds to a level of `factory`, in the order shown in `Bnames`. For example, row 3 corresponds to the coefficient of `'(Intercept)'` for level `'3'` of `factory`, which has a 99% confidence interval of `[-0.8219, 0.2954]`. For additional statistics related to each random-effects term, use `randomEffects`.

coefCI

Class: CompactLinearModel

Confidence intervals of coefficient estimates of linear model

Syntax

```
ci = coefCI mdl  
ci = coefCI(mdl, alpha)
```

Description

`ci = coefCI(mdl)` returns confidence intervals for the coefficients in `mdl`.

`ci = coefCI(mdl, alpha)` returns confidence intervals using the confidence level $1 - \alpha$.

Input Arguments

mdl — Linear model object

LinearModel object | CompactLinearModel object

Linear model object, specified as a full LinearModel object constructed using `fitlm` or `stepwiselm`, or a compacted CompactLinearModel object constructed using `compact`.

alpha — Confidence interval

0.05 (default) | numeric value in the range [0,1]

Confidence interval, specified as a numeric value in the range [0,1]. `alpha` is the probability that the confidence interval does not contain the true value.

Output Arguments

ci — Confidence intervals

numeric matrix

Confidence intervals, returned as a k -by-2 numeric matrix. The j th row of `ci` is the confidence interval of coefficient j of `mdl`. The name of coefficient j is stored in the `mdl` property `CoefficientNames`.

Examples

Fit Linear Model Using Default Confidence Intervals

Fit a linear regression model for auto mileage based on the `carbig` data. Then obtain the default 95% confidence intervals for the resulting model coefficients.

Load the data and create a table.

```
load carbig
Origin = nominal(Origin);
tbl = table(Horsepower,Weight,MPG,Origin);
```

Fit a linear regression model. Use horsepower, weight, and origin as predictor variables, and miles per gallon as the response variable.

```
modelspec = 'MPG ~ 1 + Horsepower + Weight + Origin';
mdl = fitlm(tbl,modelspec);
```

View the names of the coefficients.

```
mdl.CoefficientNames
```

```
ans = 1x9 cell array
    Columns 1 through 4
```

```
    {'(Intercept)'}    {'Horsepower'}    {'Weight'}    {'Origin_France'}
```

```
    Columns 5 through 7
```

```
    {'Origin_Germany'}    {'Origin_Italy'}    {'Origin_Japan'}
```

Columns 8 through 9

```
{'Origin_Sweden'} {'Origin_USA'}
```

Find confidence intervals for the coefficients of the model.

```
ci = coefCI mdl
```

```
ci = 9x2
```

```
43.3611    59.9390

-18.5820   -1.5036
-17.3114   -0.9642
```

Fit Linear Model with Custom Confidence Intervals

Fit a linear regression model for auto mileage based on the `carbig` data. Then obtain confidence intervals for the resulting model coefficients at the 99% level.

Load the data and create a table.

```
load carbig
Origin = nominal(Origin);
tbl = table(Horsepower,Weight,MPG,Origin);
```

Fit a linear regression model using horsepower, weight, and origin as the predictor variables, and miles per gallon as the response variable.

```
modelspec = 'MPG ~ 1 + Horsepower + Weight + Origin';
mdl = fitlm(tbl,modelspec);
```

Find 99% confidence intervals for the coefficients.

```
ci = coefCI(mdl,.01)
```

```
ci = 9x2
```

```
40.7365    62.5635
-0.0816   -0.0246
-0.0062   -0.0034

-19.8995    1.6238
```

The confidence intervals are wider than the default 5% confidence intervals.

Definitions

Confidence Interval

Assume that model assumptions hold (data comes from a generalized linear model represented by the formula `mdl.Formula`, and with observations that are independent conditional on the predictor values). Then row `j` of the confidence interval matrix `ci` gives a confidence interval `[ci(j,1), ci(j,2)]` computed such that, with repeated experimentation, a proportion `1 - alpha` of the intervals will contain the true value of the coefficient.

Alternatives

You can create the intervals from the model coefficients in `mdl.Coefficients.Estimate` and an appropriate multiplier of the standard errors `sqrt(diag(mdl.CoefficientCovariance))`. The multiplier is `tinvc(1-alpha/2, dof)`, where `level` is the confidence level, and `dof` is the degrees of freedom (number of data points minus the number of coefficients).

coefCI

Class: LinearMixedModel

Confidence intervals for coefficients of linear mixed-effects model

Syntax

```
feCI = coefCI(lme)
feCI = coefCI(lme, Name, Value)
[feCI, reCI] = coefCI( ___ )
```

Description

`feCI = coefCI(lme)` returns the 95% confidence intervals for the fixed-effects coefficients in the linear mixed-effects model `lme`.

`feCI = coefCI(lme, Name, Value)` returns the 95% confidence intervals for the fixed-effects coefficients in the linear mixed-effects model `lme` with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the confidence level or method to compute the degrees of freedom.

`[feCI, reCI] = coefCI(___)` also returns the 95% confidence intervals for the random-effects coefficients in the linear mixed-effects model `lme`.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a `LinearMixedModel` object constructed using `fitlme` or `fitlmematrix`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Alpha — Confidence level

0.05 (default) | scalar value in the range 0 to 1

Confidence level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range 0 to 1. For a value α , the confidence level is $100*(1-\alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha',0.01

Data Types: single | double

DFMethod — Method for computing approximate degrees of freedom

'residual' (default) | 'satterthwaite' | 'none'

Method for computing approximate degrees of freedom for confidence interval computation, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

| | |
|-----------------|---|
| 'residual' | Default. The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects. |
| 'satterthwaite' | Satterthwaite approximation. |
| 'none' | All degrees of freedom are set to infinity. |

For example, you can specify the Satterthwaite approximation as follows.

Example: 'DFMethod','satterthwaite'

Output Arguments

feCI — Fixed-effects confidence intervals

p-by-2 matrix

Fixed-effects confidence intervals, returned as a *p*-by-2 matrix. **feCI** contains the confidence limits that correspond to the *p* fixed-effects estimates in the vector **beta** returned by the `fixedEffects` method. The first column of **feCI** has the lower confidence limits and the second column has the upper confidence limits.

reCI — Random-effects confidence intervals

q-by-2 matrix

Random-effects confidence intervals, returned as a *q*-by-2 matrix. **reCI** contains the confidence limits corresponding to the *q* random-effects estimates in the vector **B** returned by the `randomEffects` method. The first column of **reCI** has the lower confidence limits and the second column has the upper confidence limits.

Examples

95% Confidence Intervals for Fixed-Effects Coefficients

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'))
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight, Program, Subject, Week, y);  
tbl.Subject = nominal(tbl.Subject);  
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl, 'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Compute the fixed-effects coefficient estimates.

```
fe = fixedEffects(lme)
```

```
fe =
```

```
0.6610
0.0032
0.3608
-0.0333
0.1132
0.1732
0.0388
0.0305
0.0331
```

The first estimate, 0.6610, corresponds to the constant term. The second row, 0.0032, and the third row, 0.3608, are estimates for the coefficient of initial weight and week, respectively. Rows four to six correspond to the indicator variables for programs B-D, and the last three rows correspond to the interaction of programs B-D and week.

Compute the 95% confidence intervals for the fixed-effects coefficients.

```
fecI = coefCI(lme)
```

```
fecI =
```

```
0.1480    1.1741
0.0005    0.0059
0.1004    0.6211
-0.2932   0.2267
-0.1471   0.3734
0.0395    0.3069
-0.1503   0.2278
-0.1585   0.2196
-0.1559   0.2221
```

Some confidence intervals include 0. To obtain specific P -values for each fixed-effects term, use the `fixedEffects` method. To test for entire terms use the `anova` method.

Confidence Intervals with Specified Options

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and a potentially correlated random effect for intercept and acceleration grouped by model year. First, store the data in a table.

```
tbl = table(Acceleration,Horsepower,Model_Year,MPG);
```

Fit the model.

```
lme = fitlme(tbl, 'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');
```

Compute the fixed-effects coefficient estimates.

```
fe = fixedEffects(lme)
```

```
fe = 3×1
```

```
50.1325  
-0.5833  
-0.1695
```

Compute the 99% confidence intervals for fixed-effects coefficients using the residuals method to determine the degrees of freedom. This is the default method.

```
feCI = coefCI(lme, 'Alpha', 0.01)
```

```
feCI = 3×2
```

```
44.2690    55.9961  
-0.9300    -0.2365  
-0.1883    -0.1507
```

Compute the 99% confidence intervals for fixed-effects coefficients using the Satterthwaite approximation to compute the degrees of freedom.

```
feCI = coefCI(lme, 'Alpha', 0.01, 'DFMethod', 'satterthwaite')
feCI = 3×2
    44.0949    56.1701
   -0.9640   -0.2025
   -0.1884   -0.1507
```

The Satterthwaite approximation produces similar confidence intervals than the residual method.

Compute Confidence Intervals for Random Effects

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'shift.mat'))
```

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

```
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if there is significant difference in the performance according to the time of the shift.

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)');
```

Compute the estimate of the BLUPs for random effects.

```
randomEffects(lme)
```

```
ans = 5×1
    0.5775
```

```
1.1757
-2.1715
2.3655
-1.9472
```

Compute the 95% confidence intervals for random effects.

```
[~,reCI] = coefCI(lme)
```

```
reCI = 5×2
```

```
-1.3916    2.5467
-0.7934    3.1449
-4.1407   -0.2024
 0.3964    4.3347
-3.9164    0.0219
```

Compute the 99% confidence intervals for random effects using the residuals method to determine the degrees of freedom. This is the default method.

```
[~,reCI] = coefCI(lme, 'Alpha', 0.01)
```

```
reCI = 5×2
```

```
-2.1831    3.3382
-1.5849    3.9364
-4.9322    0.5891
-0.3951    5.1261
-4.7079    0.8134
```

Compute the 99% confidence intervals for random effects using the Satterthwaite approximation to determine the degrees of freedom.

```
[~,reCI] = coefCI(lme, 'Alpha', 0.01, 'DFMethod', 'satterthwaite')
```

```
reCI = 5×2
```

```
-2.6840    3.8390
-2.0858    4.4372
-5.4330    1.0900
-0.8960    5.6270
-5.2087    1.3142
```

The Satterthwaite approximation might produce smaller DF values than the residual method. That is why these confidence intervals are larger than the previous ones computed using the residual method.

coefCI

Class: NonLinearModel

Confidence intervals of coefficient estimates of nonlinear regression model

Syntax

```
ci = coefCI mdl
ci = coefCI(mdl,alpha)
```

Description

`ci = coefCI(mdl)` returns confidence intervals for the coefficients in `mdl`.

`ci = coefCI(mdl,alpha)` returns confidence intervals with confidence level $1 - \alpha$.

Input Arguments

mdl

Nonlinear regression model, constructed by `fitnlm`.

alpha

Scalar from 0 to 1, the probability that the confidence interval does not contain the true value.

Default: 0.05

Output Arguments

ci

k-by-2 matrix of confidence intervals. The jth row of **ci** is the confidence interval of coefficient j of **mdl**. The name of coefficient j of **mdl** is in **mdl.CoeffNames**.

Examples

Default Confidence Intervals

Create a nonlinear model for auto mileage based on the **carbig** data. Then obtain confidence intervals for the resulting model coefficients.

Load the data and create a nonlinear model.

```
load carbig
ds = dataset(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1) + ...
    b(3)*x(:,2) + b(4)*x(:,1).*x(:,2);
beta0 = [1 1 1 1];
mdl = fitnlm(ds,modelfun,beta0)
```

mdl =

Nonlinear regression model:

MPG ~ b1 + b2*Horsepower + b3*Weight + b4*Horsepower*Weight

Estimated Coefficients:

| | Estimate | SE | tStat | pValue |
|----|------------|------------|---------|------------|
| b1 | 63.558 | 2.3429 | 27.127 | 1.2343e-91 |
| b2 | -0.25084 | 0.027279 | -9.1952 | 2.3226e-18 |
| b3 | -0.010772 | 0.00077381 | -13.921 | 5.1372e-36 |
| b4 | 5.3554e-05 | 6.6491e-06 | 8.0542 | 9.9336e-15 |

Number of observations: 392, Error degrees of freedom: 388

```
Root Mean Squared Error: 3.93
R-Squared: 0.748, Adjusted R-Squared 0.746
F-statistic vs. constant model: 385, p-value = 7.26e-116
```

All the coefficients have extremely small p -values. This means a confidence interval around the coefficients will not contain the point θ , unless the confidence level is very high.

Find 95% confidence intervals for the coefficients of the model.

```
ci = coefCI mdl
```

```
ci =
    58.9515    68.1644
   -0.3045   -0.1972
   -0.0123   -0.0093
    0.0000    0.0001
```

The confidence interval for `b4` seems to contain θ . Examine it in more detail.

```
ci(4,:)
ans =
    1.0e-04 *
    0.4048    0.6663
```

As expected, the confidence interval does not contain the point θ .

- “Nonlinear Regression Workflow” on page 13-15

Definitions

Confidence Interval

Assume that model assumptions hold (the data comes from a model represented by the formula `mdl`. Formula, with independent normally distributed errors). Then row `j` of the

confidence interval matrix `ci` gives a confidence interval `[ci(j,1),ci(j,2)]` that contains coefficient `j` with probability `1 - alpha`.

Alternatives

You can create the intervals from the model coefficients in `mdl.Coefficients.Estimate` and an appropriate multiplier of the standard errors `sqrt(diag(mdl.CoefficientCovariance))`. The multiplier is `tinv(1-alpha/2,dof)`, where `level` is the confidence level, and `dof` is the degrees of freedom (number of data points minus the number of coefficients).

“Nonlinear Regression” on page 13-2

coefTest

Class: CompactGeneralizedLinearModel

Linear hypothesis test on generalized linear regression model coefficients

Syntax

```
p = coefTest mdl
p = coefTest mdl,H
p = coefTest mdl,H,C
[p,F] = coefTest mdl,...
[p,F,r] = coefTest mdl,...
```

Description

`p = coefTest(mdl)` computes the p -value for an F test that all coefficient estimates in `mdl` are zero, except for the intercept term.

`p = coefTest(mdl,H)` performs an F test that $H*B = 0$, where B represents the coefficient vector.

`p = coefTest(mdl,H,C)` performs an F test that $H*B = C$.

`[p,F] = coefTest(mdl,...)` returns the F test statistic.

`[p,F,r] = coefTest(mdl,...)` returns the numerator degrees of freedom for the test.

Input Arguments

mdl

Generalized linear model, specified as a full `GeneralizedLinearModel` object constructed using `fitglm` or `stepwiseglm`, or a compacted `CompactGeneralizedLinearModel` object constructed using `compact`.

H

Numeric matrix having one column for each coefficient in the model. When H is an input, the output p is the p -value for an F test that $H*B = 0$, where B represents the coefficient vector.

C

Numeric vector with the same number of rows as H. When C is an input, the output p is the p -value for an F test that $H*B = C$, where B represents the coefficient vector.

Output Arguments

p

p -value of the F test (see “Definitions” on page 32-642).

F

Value of the test statistic for the F test (see “Definitions” on page 32-642).

r

Numerator degrees of freedom for the F test (see “Definitions” on page 32-642). The F statistic has r degrees of freedom in the numerator and $mdl.DFE$ degrees of freedom in the denominator.

Examples

Test Generalized Linear Model Coefficients

Test a generalized linear model to see if its coefficients differ from zero.

Create a generalized linear regression model of Poisson data.

```
X = 2 + randn(100,1);  
mu = exp(1 + X/2);  
y = poissrnd(mu);  
mdl = fitglm(X,y,'y ~ x1','distr','poisson');
```

Test whether the fitted model has coefficients that differ significantly from zero.

```
p = coefTest mdl
```

```
p = 3.1394e-36
```

There is no doubt that the coefficient of `x1` is nonzero.

- “Generalized Linear Model Workflow” on page 12-40

Definitions

Test Statistics

The p -value, F statistic, and numerator degrees of freedom are valid under these assumptions:

- The data comes from a model represented by the formula `mdl.Formula`.
- The observations are independent conditional on the predictor values.

Suppose these assumptions hold. Let β represent the (unknown) coefficient vector of the linear regression. Suppose H is a full-rank matrix of size r -by- s , where s is the number of terms in β . Let v be a vector the same size as β . The following is a test statistic for the hypothesis that $H\beta = v$:

$$F = (H\hat{\beta} - v)'(HCH')^{-1}(H\hat{\beta} - v).$$

Here $\hat{\beta}$ is the estimate of the coefficient vector β in `mdl.Coeffs`, and C is the estimated covariance of the coefficient estimates in `mdl.CoeffCov`. When the hypothesis is true, the test statistic F has an “F Distribution” on page B-42 with r and u degrees of freedom.

Alternatives

The values of commonly used test statistics are available in the `mdl.Coefficients` table.

coefTest

Class: GeneralizedLinearMixedModel

Hypothesis test on fixed and random effects of generalized linear mixed-effects model

Syntax

```
pVal = coefTest(glme)
pVal = coefTest(glme,H)
pVal = coefTest(glme,H,C)
pVal = coefTest(glme,H,C,Name,Value)
[pVal,F,DF1,DF2] = coefTest( ___ )
```

Description

`pVal = coefTest(glme)` returns the p -value of an F -test of the null hypothesis that all fixed-effects coefficients of the generalized linear mixed-effects model `glme`, except for the intercept, are equal to 0.

`pVal = coefTest(glme,H)` returns the p -value of an F -test using a specified contrast matrix, H . The null hypothesis is $H_0: H\beta = 0$, where β is the fixed-effects vector.

`pVal = coefTest(glme,H,C)` returns the p -value for an F -test using the hypothesized value, C . The null hypothesis is $H_0: H\beta = C$, where β is the fixed-effects vector.

`pVal = coefTest(glme,H,C,Name,Value)` returns the p -value for an F -test on the fixed- and/or random-effects coefficients of the generalized linear mixed-effects model `glme`, with additional options specified by one or more name-value pair arguments. For example, you can specify the method to compute the approximate denominator degrees of freedom for the F -test.

`[pVal,F,DF1,DF2] = coefTest(___)` also returns the F -statistic, F , and the numerator and denominator degrees of freedom for F , respectively $DF1$ and $DF2$, using any of the previous syntaxes.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

H — Fixed-effects contrasts

m -by- p matrix

Fixed-effects contrasts, specified as an m -by- p matrix, where p is the number of fixed-effects coefficients in glme. Each row of H represents one contrast. The columns of H (left to right) correspond to the rows of the p -by-1 fixed-effects vector beta (top to bottom) whose estimate is returned by the fixedEffects method.

Data Types: single | double

C — Hypothesized value

m -by-1 vector

Hypothesized value for testing the null hypothesis $H\beta = C$, specified as an m -by-1 vector. Here, β is the vector of fixed-effects whose estimate is returned by fixedEffects.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

DFMethod — Method for computing approximate degrees of freedom

'residual' (default) | 'none'

Method for computing approximate degrees of freedom, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

| Value | Description |
|------------|---|
| 'residual' | The degrees of freedom value is assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects. |
| 'none' | The degrees of freedom is set to infinity. |

Example: 'DFMethod', 'none'

REContrast — Random-effects contrasts

m-by-q matrix

Random-effects contrasts, specified as the comma-separated pair consisting of 'REContrast' and an *m-by-q* matrix, where q is the number of random effects parameters in `glme`. The columns of the matrix (left to right) correspond to the rows of the q -by-1 random-effects vector B (top to bottom), whose estimate is returned by the `randomEffects` method.

Data Types: `single` | `double`

Output Arguments

pVal — p -value

scalar value

p -value for the F -test on the fixed- and/or random-effects coefficients of the generalized linear mixed-effects model `glme`, returned as a scalar value.

When fitting a GLME model using `fitglme` and one of the maximum likelihood fit methods ('Laplace' or 'ApproximateLaplace'), `coefTest` uses an approximation of the conditional mean squared error of prediction (CMSEP) of the estimated linear combination of fixed- and random-effects to compute p -values. This accounts for the uncertainty in the fixed-effects estimates, but not for the uncertainty in the covariance parameter estimates. For tests on fixed effects only, if you specify the 'CovarianceMethod' name-value pair argument in `fitglme` as 'JointHessian', then `coefTest` accounts for the uncertainty in the estimation of covariance parameters.

When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods ('MPL' or 'REMP'), `coefTest` bases the inference on the fitted linear mixed effects model from the final pseudo likelihood iteration.

F — F-statistic

scalar value

F -statistic, returned as a scalar value.

DF1 — Numerator degrees of freedom for F

scalar value

Numerator degrees of freedom for the F -statistic F , returned as a scalar value.

- If you test the null hypothesis $H_0: H\beta = 0$ or $H_0: H\beta = C$, then DF1 is equal to the number of linearly independent rows in H .
- If you test the null hypothesis $H_0: H\beta + KB = C$, then DF1 is equal to the number of linearly independent rows in $[H, K]$.

DF2 — Denominator degrees of freedom for F

scalar value

Denominator degrees of freedom for the F -statistic F , returned as a scalar value. The value of DF2 depends on the option specified by the 'DFMethod' name-value pair argument.

Examples

Test the Significance of Coefficients

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- `defectsij` is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- `newprocessij`, `time_devij`, and `temp_devij` are the measurements for each variable that correspond to factory i during batch j . For example, `newprocessij` indicates whether the batch produced by factory i during batch j used the new process.

- `supplier_Cij` and `supplier_Bij` are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)')
```

Test if there is any significant difference between supplier C and supplier B.

```
H = [0,0,0,0,1,-1];
```

```
[pVal,F,DF1,DF2] = coefTest(glme,H)
```

```
pVal =
```

```
0.2793
```

```
F =
```

```
1.1842
```

```
DF1 =
```

```
1
```

```
DF2 =
```

```
94
```

The large P -value indicates that there is no significant difference between supplier C and supplier B at the 5% significance level. Here, `coefTest` also returns the F -statistic, the numerator degrees of freedom, and the approximate denominator degrees of freedom.

Test if there is any significant difference between supplier A and supplier B.

If you specify the 'DummyVarCoding' name-value pair argument as 'effects' when fitting the model using `fitglme`, then

$$\beta_A + \beta_B + \beta_C = 0,$$

where β_A , β_B , and β_C correspond to suppliers A, B, and C, respectively. β_A is the effect of A minus the average effect of A, B, and C. To determine the contrast matrix corresponding to a test between supplier A and supplier B,

$$\beta_B - \beta_A = \beta_B - (-\beta_B - \beta_C) = 2\beta_B + \beta_C.$$

From the output of `disp(glme)`, column 5 of the contrast matrix corresponds to β_C , and column 6 corresponds to β_B . Therefore, the contrast matrix for this test is specified as $H = [0, 0, 0, 0, 1, 2]$.

```
H = [0,0,0,0,1,2];
```

```
[pVal,F,DF1,DF2] = coefTest(glme,H)
```

```
pVal =
```

```
0.6177
```

```
F =
```

```
0.2508
```

```
DF1 =
```

```
1
```

```
DF2 =
```

```
94
```

The large P -value indicates that there is no significant difference between supplier A and supplier B at the 5% significance level.

coefTest

Class: CompactLinearModel

Linear hypothesis test on linear regression model coefficients

Syntax

```
p = coefTest mdl
p = coefTest mdl, H
p = coefTest mdl, H, C
[p, F] = coefTest mdl, ___
[p, F, r] = coefTest mdl, ___
```

Description

`p = coefTest(mdl)` computes the p -value for an F test that all coefficient estimates in `mdl` are zero, except for the intercept term.

`p = coefTest(mdl, H)` performs an F test that $H \times B = 0$, where B represents the coefficient vector.

`p = coefTest(mdl, H, C)` performs an F test that $H \times B = C$.

`[p, F] = coefTest(mdl, ___)` returns the F test statistic, F , using any of the previous syntaxes.

`[p, F, r] = coefTest(mdl, ___)` returns the numerator degrees of freedom, r , for the test.

Input Arguments

mdl — Linear model object

LinearModel object | CompactLinearModel object

Linear model object, specified as a full `LinearModel` object constructed using `fitlm` or `stepwiselm`, or a compacted `CompactLinearModel` object constructed using `compact`.

H — Hypothesized model coefficients

numeric matrix

Hypothesized model coefficients, specified as a numeric matrix with one column for each coefficient in the model. If H is an input, then the output p is the p -value for an F test that $H \times B = 0$, where B represents the coefficient vector.

C — Hypothesized value

numeric vector

Hypothesized value for testing the null hypothesis, specified as a numeric vector with the same number of rows as H . When C is an input, the output p is the p -value for an F test that $H \times B = C$, where B represents the coefficient vector.

Output Arguments

p — p -value for F test

numeric value in the range [0,1]

p -value of the F test, returned as a numeric value in the range [0,1].

F — Test statistic for F test

numeric value

Value of the test statistic for the F test, returned as a numeric value.

r — Numerator degrees of freedom for F test

positive integer

Numerator degrees of freedom for the F test, returned as a positive integer. The F statistic has r degrees of freedom in the numerator and `mdl.DFE` degrees of freedom in the denominator.

Examples

Test Significance of Linear Regression Model

Fit a linear regression model of mileage as a function of the weight, weight squared, and model year from the `carsmall` data set. Test the coefficients to see if all should be zero.

Load the data and make a table, where the model year is an ordinal variable.

```
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight + Weight^2');
```

Test the model for significant differences from a constant model.

```
p = coefTest(mdl)
```

```
p =
    5.5208e-41
```

The returned *P*-value indicates that the fitted model contains more than the intercept term.

Test Significance of Linear Model Coefficient

Test the `Weight^2` coefficient in a linear model of mileage as a function of the weight, weight squared, and model year.

Load the data and make a table, where the model year is an ordinal variable.

```
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight + Weight^2');
```

Test the significance of the `Weight^2` coefficient. To do so, find the coefficient corresponding to `Weight^2`.

```
mdl.CoefficientNames
```

```
ans = 1x5 cell array
      {'(Intercept)'}      {'Weight'}      {'Year_76'}      {'Year_82'}      {'Weight^2'}
```

Weight^2 is the fifth (final) coefficient.

Test the significance of the Weight^2 coefficient.

```
p = coefTest mdl, [0 0 0 0 1]
```

```
p = 0.0022
```

Definitions

Test Statistics

The p -value, F statistic, and numerator degrees of freedom are valid under these assumptions:

- The data comes from a model represented by the formula `mdl.Formula`.
- The observations are independent conditional on the predictor values.

Suppose these assumptions hold. Let β represent the (unknown) coefficient vector of the linear regression. Suppose H is a full-rank matrix of size r -by- s , where s is the number of terms in β . Let v be a vector the same size as β . The following is a test statistic for the hypothesis that $H\beta = v$:

$$F = (H\hat{\beta} - v)' (HCH')^{-1} (H\hat{\beta} - v).$$

Here $\hat{\beta}$ is the estimate of the coefficient vector β in `mdl.Coeffs`, and C is the estimated covariance of the coefficient estimates in `mdl.CoeffCov`. When the hypothesis is true, the test statistic F has an “F Distribution” on page B-42 with r and u degrees of freedom.

Alternatives

The values of commonly used test statistics are available in the `mdl.Coefficients` table.

anova provides a test for each model term.

coefTest

Class: LinearMixedModel

Hypothesis test on fixed and random effects of linear mixed-effects model

Syntax

```
pVal = coefTest(lme)
pVal = coefTest(lme,H)
pVal = coefTest(lme,H,C)
pVal = coefTest(lme,H,C,Name,Value)
[pVal,F,DF1,DF2] = coefTest( ___ )
```

Description

`pVal = coefTest(lme)` returns the p -value for an F -test that all fixed-effects coefficients except for the intercept are 0.

`pVal = coefTest(lme,H)` returns the p -value for an F -test on fixed-effects coefficients of linear mixed-effects model `lme`, using the contrast matrix `H`. It tests the null hypothesis that $H_0: H\beta = 0$, where β is the fixed-effects vector.

`pVal = coefTest(lme,H,C)` returns the p -value for an F -test on fixed-effects coefficients of the linear mixed-effects model `lme`, using the contrast matrix `H`. It tests the null hypothesis that $H_0: H\beta = C$, where β is the fixed-effects vector.

`pVal = coefTest(lme,H,C,Name,Value)` returns the p -value for an F -test on the fixed- and/or random-effects coefficients of the linear mixed-effects model `lme`, with additional options specified by one or more name-value pair arguments. For example, 'REContrast',`K` tells `coefTest` to test the null hypothesis that $H_0: H\beta + KB = C$, where β is the fixed-effects vector and B is the random-effects vector.

`[pVal,F,DF1,DF2] = coefTest(___)` also returns the F -statistic F , and the numerator and denominator degrees of freedom for F , respectively $DF1$ and $DF2$.

Input Arguments

lme — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, specified as a `LinearMixedModel` object constructed using `fitlme` or `fitlmematrix`.

H — Fixed-effects contrasts

m -by- p matrix

Fixed-effects contrasts, specified as an m -by- p matrix, where p is the number of fixed-effects coefficients in `lme`. Each row of `H` represents one contrast. The columns of `H` (left to right) correspond to the rows of the p -by-1 fixed-effects vector `beta` (top to bottom), returned by the `fixedEffects` method.

Data Types: `single` | `double`

C — Hypothesized value

m -by-1 vector

Hypothesized value for testing the null hypothesis $H \cdot \text{beta} = C$, specified as an m -by-1 matrix. Here, `beta` is the vector of fixed-effects estimates returned by the `fixedEffects` method.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

DFMethod — Method for computing approximate denominator degrees of freedom

'residual' (default) | 'satterthwaite' | 'none'

Method for computing the approximate denominator degrees of freedom for the F -test, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

| | |
|-----------------|---|
| 'residual' | Default. The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects. |
| 'satterthwaite' | Satterthwaite approximation. |
| 'none' | All degrees of freedom are set to infinity. |

For example, you can specify the Satterthwaite approximation as follows.

Example: 'DFMethod', 'satterthwaite'

REContrast — Random-effects contrasts

m-by-*q* matrix

Random-effects contrasts, specified as the comma-separated pair consisting of 'REContrast' and an *m*-by-*q* matrix *K*, where *q* is the number of random effects parameters in `lme`. The columns of *K* (left to right) correspond to the rows of the random-effects best linear unbiased predictor vector *B* (top to bottom), returned by the `randomEffects` method.

Data Types: `single` | `double`

Output Arguments

pVal — *p*-value

scalar value

p-value for the *F*-test on the fixed and/or random-effects coefficients of the linear mixed-effects model `lme`, returned as a scalar value.

F — *F*-statistic

scalar value

F-statistic, returned as a scalar value.

DF1 — Numerator degrees of freedom for F

scalar value

Numerator degrees of freedom for *F*, returned as a scalar value.

- If you test the null hypothesis $H_0: H\beta = 0$, or $H_0: H\beta = C$, then DF1 is equal to the number of linearly independent rows in H .
- If you test the null hypothesis $H_0: H\beta + KB = C$, then DF1 is equal to the number of linearly independent rows in $[H, K]$.

DF2 — Denominator degrees of freedom for F

scalar value

Denominator degrees of freedom for F, returned as a scalar value. The value of DF2 depends on the option you select for DFMethod.

Examples

Test Fixed-Effects Coefficients for Categorical Data

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'shift.mat'))
```

The data shows the absolute deviations from the target quality characteristic measured from the products that five operators manufacture during three different shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

```
shift.Shift = nominal(shift.Shift);  
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if there is significant difference in the performance according to the time of the shift.

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)')
```

```
lme =
```

Linear mixed-effects model fit by ML

Model information:

|-----------------------------|----|
| Number of observations | 15 |
| Fixed effects coefficients | 3 |
| Random effects coefficients | 5 |
| Covariance parameters | 2 |

Formula:

QCDev ~ 1 + Shift + (1 | Operator)

Model fit statistics:

| | | | |
|--------|--------|---------------|----------|
| AIC | BIC | LogLikelihood | Deviance |
| 59.012 | 62.552 | -24.506 | 49.012 |

Fixed effects coefficients (95% CIs):

| Name | Estimate | SE | tStat | DF | pValue |
|-----------------|----------|---------|----------|----|-----------|
| '(Intercept)' | 3.1196 | 0.88681 | 3.5178 | 12 | 0.0042407 |
| 'Shift_Morning' | -0.3868 | 0.48344 | -0.80009 | 12 | 0.43921 |
| 'Shift_Night' | 1.9856 | 0.48344 | 4.1072 | 12 | 0.0014535 |

| | |
|---------|---------|
| Lower | Upper |
| 1.1874 | 5.0518 |
| -1.4401 | 0.66653 |
| 0.93227 | 3.0389 |

Random effects covariance parameters (95% CIs):

Group: Operator (5 Levels)

| Name1 | Name2 | Type | Estimate | Lower |
|---------------|---------------|-------|----------|---------|
| '(Intercept)' | '(Intercept)' | 'std' | 1.8297 | 0.94915 |

| |
|--------|
| Upper |
| 3.5272 |

Group: Error

| Name | Estimate | Lower | Upper |
|-----------|----------|---------|--------|
| 'Res Std' | 0.76439 | 0.49315 | 1.1848 |

Test if all fixed-effects coefficients except for the intercept are 0.

pVal = coefTest(lme)

```
pVal =  
7.5956e-04
```

The small *P*-value indicates that not all fixed-effects coefficients are 0.

Test the significance of the `Shift` term using a contrast matrix.

```
H = [0 1 0; 0 0 1];  
pVal = coefTest(lme,H)
```

```
pVal =  
7.5956e-04
```

Test the significance of the `Shift` term using the `anova` method.

```
anova(lme)
```

```
ans =
```

```
ANOVA MARGINAL TESTS: DFMETHOD = 'RESIDUAL'
```

| Term | FStat | DF1 | DF2 | pValue |
|---------------|--------|-----|-----|------------|
| '(Intercept)' | 12.375 | 1 | 12 | 0.0042407 |
| 'Shift' | 13.864 | 2 | 12 | 0.00075956 |

The *P*-value for `Shift`, 0.00075956, is the same as the *P*-value of the previous hypothesis test.

Test if there is any difference between the evening and morning shifts.

```
pVal = coefTest(lme,[0 1 -1])
```

```
pVal =  
3.6147e-04
```

This small P -value indicates that the performance of the operators are not the same in the morning and the evening shifts.

Hypothesis Tests for Fixed-Effects Coefficients

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'))
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight, Program, Subject, Week, y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl, 'y ~ InitialWeight + Program*Week + (Week|Subject)')
```

```
lme =
```

Linear mixed-effects model fit by ML

Model information:

| | |
|-----------------------------|-----|
| Number of observations | 120 |
| Fixed effects coefficients | 9 |
| Random effects coefficients | 40 |
| Covariance parameters | 4 |

Formula:

```
y ~ 1 + InitialWeight + Program*Week + (1 + Week | Subject)
```

Model fit statistics:

| | | | |

| 0.74944 | -0.15849 | 0.21957 |
| 0.72915 | -0.15592 | 0.22214 |

Random effects covariance parameters (95% CIs):

Group: Subject (20 Levels)

| Name1 | Name2 | Type | Estimate | Lower |
|---------------|---------------|--------|----------|---------|
| '(Intercept)' | '(Intercept)' | 'std' | 0.18407 | 0.12281 |
| 'Week' | '(Intercept)' | 'corr' | 0.66841 | 0.21077 |
| 'Week' | 'Week' | 'std' | 0.15033 | 0.11004 |

Upper
0.27587
0.88573
0.20537

Group: Error

| Name | Estimate | Lower | Upper |
|-----------|----------|----------|---------|
| 'Res Std' | 0.10261 | 0.087882 | 0.11981 |

Test for the significance of the interaction between Program and Week.

```
H = [0 0 0 0 0 0 1 0 0;
      0 0 0 0 0 0 0 1 0;
      0 0 0 0 0 0 0 0 1];
pVal = coefTest(lme,H)
```

```
pVal =
    0.9775
```

The high P -value indicates that the interaction between Program and Week is not statistically significant.

Now, test whether all coefficients involving Program are 0.

```
H = [0 0 1 0 0 0 0 0 0;
      0 0 0 1 0 0 0 0 0;
      0 0 0 0 1 0 0 0 0;
      0 0 0 0 0 0 1 0 0;
      0 0 0 0 0 0 0 1 0;
      0 0 0 0 0 0 0 0 1];
C = [0;0;0;0;0;0];
pVal = coefTest(lme,H,C)
```

```
pVal =
    0.0274
```

The P -value of 0.0274 indicates that not all coefficients involving Program are zero.

Hypothesis Tests for Fixed- and Random-Effects Coefficients

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into an array. The new dataset array, `flu2`, must have the response variable, `FluRate`, the nominal variable, `Region`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10, 'NewDataVarName', 'FluRate', ...  
            'IndVarName', 'Region');  
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with fixed effects for the region and a random intercept that varies by `Date`.

```
lme = fitlme(flu2, 'FluRate ~ 1 + Region + (1|Date)')
```

```
lme =
```

```
Linear mixed-effects model fit by ML

[LinearMixedModel](#) | [anova](#) | [coefCI](#)

coefTest

Class: NonLinearModel

Linear hypothesis test on nonlinear regression model coefficients

Syntax

```
p = coefTest mdl
p = coefTest mdl,H
p = coefTest mdl,H,C
[p,F] = coefTest mdl,...
[p,F,r] = coefTest mdl,...
```

Description

`p = coefTest(mdl)` computes the p -value for an F test that all coefficient estimates in `mdl` are zero.

`p = coefTest(mdl,H)` performs an F test that $H*B = 0$, where B represents the coefficient vector.

`p = coefTest(mdl,H,C)` performs an F test that $H*B = C$.

`[p,F] = coefTest(mdl,...)` returns the F test statistic.

`[p,F,r] = coefTest(mdl,...)` returns the numerator degrees of freedom for the test.

Input Arguments

mdl

Nonlinear regression model, constructed by `fitnlm`.

H

Numeric matrix having one column for each coefficient in the model. When **H** is an input, the output **p** is the p -value for an F test that $H*B = 0$, where **B** represents the coefficient vector.

C

Numeric vector with the same number of rows as **H**. When **C** is an input, the output **p** is the p -value for an F test that $H*B = C$, where **B** represents the coefficient vector.

Output Arguments

p

p -value of the F test (see “Definitions” on page 32-672).

F

Value of the test statistic for the F test (see “Definitions” on page 32-672).

r

Numerator degrees of freedom for the F test (see “Definitions” on page 32-672). The F statistic has **r** degrees of freedom in the numerator and `mdl.DFE` degrees of freedom in the denominator.

Examples

Test Nonlinear Regression Model Coefficients

Make a nonlinear model of mileage as a function of the weight from the `carsmall` data set. Test the coefficients to see if all should be zero.

Create an exponential model of car mileage as a function of weight from the `carsmall` data. Scale the weight by a factor of 1000 so all the variables are roughly equal in size.

```
load carsmall  
X = Weight;
```

```
y = MPG;
modelfun = 'y ~ b1 + b2*exp(-b3*x/1000)';
beta0 = [1 1 1];
mdl = fitnlm(X,y,modelfun,beta0);
```

Test the model for significant differences from a constant model.

```
p = coefTest(mdl)
```

```
p = 1.3708e-36
```

There is no doubt that the model contains nonzero terms.

Definitions

Test Statistics

The p -value, F statistic, and numerator degrees of freedom are valid under these assumptions:

- The data comes from a normal distribution.
- The entries are independent.

Suppose these assumptions hold. Let β represent the unknown coefficient vector of the linear regression. Suppose H is a full-rank matrix of size r -by- s , where s is the number of terms in β . Let v be a vector the same size as β . The following is a test statistic for the hypothesis that $H\beta = v$:

$$F = (H\hat{\beta} - v)' (HCH')^{-1} (H\hat{\beta} - v).$$

Here $\hat{\beta}$ is the estimate of the coefficient vector β in `mdl.Coeffs`, and C is the estimated covariance of the coefficient estimates in `mdl.CoeffCov`. When the hypothesis is true, the test statistic F has an “F Distribution” on page B-42 with r and u degrees of freedom.

Alternatives

The values of commonly used test statistics are available in the *mdl.Coefficients* table.

coefstest

Class: RepeatedMeasuresModel

Linear hypothesis test on coefficients of repeated measures model

Syntax

```
tbl = coefstest(rm,A,C,D)
```

Description

`tbl = coefstest(rm,A,C,D)` returns a table `tbl` containing the multivariate analysis of variance (manova) for the repeated measures model `rm`.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

A — Specification representing between-subjects model

a-by-*p* matrix

Specification representing the between-subjects model, specified as an *a*-by-*p* numeric matrix, with rank $a \leq p$.

Data Types: `single` | `double`

C — Specification representing within-subjects hypothesis

r-by-*c* matrix

Specification representing the within-subjects (within time) hypotheses, specified as an *r*-by-*c* numeric matrix, with rank $c \leq r \leq n - p$.

Data Types: single | double

D — Hypothesized value

0 (default) | scalar value | a -by- c matrix

Hypothesized value, specified as a scalar value or an a -by- c matrix.

Data Types: single | double

Output Arguments

tbl — Results of multivariate analysis of variance

table

Results of multivariate analysis of variance for the repeated measures model `rm`, returned as a table containing the following columns.

| | |
|-----------|---|
| Statistic | Type of test statistic used |
| Value | Value of the corresponding test statistic |
| F | F -statistic value |
| RSquare | Measure of variance explained |
| df1 | Numerator degrees of freedom for the F -statistic |
| df2 | Denominator degrees of freedom for the F -statistic |
| pValue | p -value associated with the test statistic value |

Examples

Test Coefficients for First and Last Repeated Measures

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Test that the coefficients of all terms in the between-subjects model are the same for the first and last repeated measurement variable.

```
coefstest(rm, eye(8), [1 0 0 0 0 0 0 -1]')
```

```
ans =
```

```
4x7 table
```

| Statistic | Value | F | RSquare | df1 | df2 | pValue |
|-----------|---------|--------|---------|-----|-----|---------|
| Pillai | 0.3355 | 1.3884 | 0.3355 | 8 | 22 | 0.25567 |
| Wilks | 0.6645 | 1.3884 | 0.3355 | 8 | 22 | 0.25567 |
| Hotelling | 0.50488 | 1.3884 | 0.3355 | 8 | 22 | 0.25567 |
| Roy | 0.50488 | 1.3884 | 0.3355 | 8 | 22 | 0.25567 |

The *P*-value of 0.25567 indicates that there is not enough statistical evidence to conclude that the coefficients of all terms in the between-subjects model for the first and last repeated measures variable are different.

Tips

- This test is defined as $A*B*C = D$, where *B* is the matrix of coefficients in the repeated measures model. *A* and *C* are numeric matrices of the proper size for this multiplication. *D* is a scalar or numeric matrix of the proper size. The default is $D = 0$.

combine

Class: CompactTreeBagger

Combine two ensembles

Syntax

```
B1 = combine(B1,B2)
```

Description

`B1 = combine(B1,B2)` appends decision trees from ensemble B2 to those stored in B1 and returns ensemble B1. This method requires that the class and variable names be identical in both ensembles.

See Also

`TreeBagger.append`

combnk

Enumeration of combinations

Syntax

```
C = combnk(v, k)
```

Description

`C = combnk(v, k)` returns all combinations of the n elements in `v` taken k at a time.

`C = combnk(v, k)` produces a matrix `C` with k columns and $n!/k!(n - k)!$ rows, where each row contains k of the elements in the vector `v`.

It is not practical to use this function if `v` has more than about 15 elements.

Examples

Combinations of characters.

```
C = combnk('tendrill',4);  
last5 = C(31:35,:)  
last5 =  
tedr  
tenl  
teni  
tenr  
tend
```

Combinations of elements from a numeric vector.

```
c = combnk(1:4,2)  
c =  
 3  4  
 2  4  
 2  3
```

compact

Class: ClassificationDiscriminant

Compact discriminant analysis classifier

Syntax

```
cobj = compact(obj)
```

Description

`cobj = compact(obj)` creates a compact version of `obj`.

Input Arguments

obj

Discriminant analysis classifier created using `fitcdiscr`.

Output Arguments

cobj

Compact classifier. `cobj` has class `CompactClassificationDiscriminant`. You can predict classifications using `cobj` exactly as you can using `obj`. However, since `cobj` does not contain training data, you cannot perform some actions, such as cross validation.

Examples

Compare the size of the discriminant analysis classifier for Fisher's iris data to the compact version of the classifier:

```
load fisheriris
fullobj = fitcdiscr(meas,species);
cobj = compact(fullobj);
b = whos('fullobj'); % b.bytes = size of fullobj
c = whos('cobj'); % c.bytes = size of cobj
[b.bytes c.bytes] % shows cobj uses 60% of the memory

ans =
    18578    11498
```

ClassificationDiscriminant | fitcdiscr

Topics

“Discriminant Analysis Classification” on page 20-2

compact

Class: ClassificationECOC

Compact multiclass, error-correcting output codes model

Syntax

```
CMdl = compact(Mdl)
```

Description

`CMdl = compact(Mdl)` returns a compact, multiclass, error-correcting output codes (ECOC) model (`CMdl`), which is the compact version of the trained ECOC model `Mdl`.

`CMdl` does not contain the training data, whereas `Mdl` contains the training data in its properties `Mdl.X` and `Mdl.Y`.

Input Arguments

Mdl — Multiclass ECOC model

ClassificationECOC model

Multiclass ECOC model, specified as a `ClassificationECOC` model returned by `fitcecoc`.

Output Arguments

CMdl — Compact ECOC model

CompactClassificationECOC model

Compact ECOC model, returned as a `CompactClassificationECOC` model.

Predict class labels using `CMdl` exactly as you would using `Mdl`. However, since `CMdl` does not contain training data, you cannot implement cross validation.

Examples

Reduce the Size of Full ECOC Models

Full ECOC models (i.e., `ClassificationECOC` models) hold the training data. For efficiency, you might not want to predict new labels using a large classifier.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
```

Train an ECOC model using SVM binary classifiers. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

`t` is an SVM template object. The software uses default values for empty options in `t` during training. `Mdl` is a `ClassificationECOC` model.

Reduce the size of the trained ECOC model.

```
CMdl = compact(Mdl)
```

```
CMdl =
  classreg.learning.classif.CompactClassificationECOC
      ResponseName: 'Y'
  CategoricalPredictors: []
      ClassNames: [setosa    versicolor    virginica]
      ScoreTransform: 'none'
  BinaryLearners: {3x1 cell}
      CodingMatrix: [3x3 double]
```

Properties, Methods

`CMdl` is a `CompactClassificationECOC` model. It does not store the training data nor some of the properties that `Mdl` stores.

Display how much memory each classifier uses.

```
whos('Mdl','CMdl')
```

| Name | Size | Bytes | Class |
|------|------|-------|---|
| CMdl | 1x1 | 12956 | classreg.learning.classif.CompactClassificationECOC |
| Mdl | 1x1 | 25784 | ClassificationECOC |

The full ECOC model (Mdl) is approximately double the size of the compact ECOC model (CMdl).

You can remove Mdl from the MATLAB® Workspace, and pass CMdl and new predictor values to `predict` to efficiently label new observations.

See Also

[ClassificationECOC](#) | [CompactClassificationECOC](#) | [fitcecoc](#) | [predict](#)

compact

Class: ClassificationEnsemble

Compact classification ensemble

Syntax

```
cens = compact(ens)
```

Description

`cens = compact(ens)` creates a compact version of `ens`. You can predict classifications using `cens` exactly as you can using `ens`. However, since `cens` does not contain training data, you cannot perform some actions, such as cross validation.

Input Arguments

ens

A classification ensemble created with `fitcensemble`.

Output Arguments

cens

A compact classification ensemble. `cens` has class `CompactClassificationEnsemble`.

Examples

View Size of Compact Classification Ensemble

Compare the size of a classification ensemble for the Fisher iris data to the compact version of the ensemble.

Load the Fisher iris data set.

```
load fisheriris
```

Train an ensemble of 100 boosted classification trees using AdaBoostM2.

```
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Create a compact version of ens and compare ensemble sizes.

```
cens = compact(ens);
b = whos('ens'); % b.bytes = size of ens
c = whos('cens'); % c.bytes = size of cens
[b.bytes c.bytes] % Shows cens uses less memory
```

```
ans = 1x2
```

```
392654    352622
```

The compact version of the ensemble uses less memory than the full ensemble. Note that the ensemble sizes can vary slightly, depending on your operating system.

compact

Class: ClassificationNaiveBayes

Compact naive Bayes classifier

Syntax

```
CMdl = compact(Mdl)
```

Description

`CMdl = compact(Mdl)` returns a compact naive Bayes classifier (`CMdl`), which is the compact version of the trained naive Bayes classifier `Mdl`.

`CMdl` stores less than `Mdl`, e.g., `CMdl` does not store the training data.

Input Arguments

Mdl — Fully trained naive Bayes classifier

ClassificationNaiveBayes model

A fully trained naive Bayes classifier, specified as a `ClassificationNaiveBayes` model trained by `fitcnb`.

Output Arguments

CMdl — Compact naive Bayes classifier

CompactClassificationNaiveBayes model

Compact naive Bayes classifier, returned as a `CompactClassificationNaiveBayes` model.

Predict class labels using `CMdl` exactly as you would using `Mdl`. However, since `CMdl` does not contain training data, you cannot perform certain tasks, such as cross validation.

Examples

Reduce the Size of Naive Bayes Classifiers

Full naive Bayes classifiers (i.e., `ClassificationNaiveBayes` models) hold the training data. For efficiency, you might not want to predict new labels using a large classifier. This example shows how to reduce the size of a full naive Bayes classifier.

Load the ionosphere data set.

```
load ionosphere
X = X(:,3:end); % Remove two predictors for stability
```

Train a naive Bayes classifier. Assume that each predictor is conditionally, normally distributed given its label. It is good practice to specify the order of the labels.

```
Mdl = fitcnb(X,Y,'ClassNames',{'b','g'})
```

```
Mdl =
  ClassificationNaiveBayes
      ResponseName: 'Y'
   CategoricalPredictors: []
           ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
      NumObservations: 351
   DistributionNames: {1x32 cell}
   DistributionParameters: {2x32 cell}
```

Properties, Methods

`Mdl` is a `ClassificationNaiveBayes` model.

Reduce the size of the naive Bayes classifier.

```
CMdl = compact(Mdl)
```

```
CMdl =
  classreg.learning.classif.CompactClassificationNaiveBayes
      ResponseName: 'Y'
   CategoricalPredictors: []
           ClassNames: {'b' 'g'}
```

```
ScoreTransform: 'none'  
DistributionNames: {1x32 cell}  
DistributionParameters: {2x32 cell}
```

Properties, Methods

`CMdl` is a `CompactClassificationNaiveBayes` model.

Display how much memory each classifier uses.

```
whos('Mdl', 'CMdl')
```

| Name | Size | Bytes | Class |
|-------------------|------|--------|--|
| <code>CMdl</code> | 1x1 | 15244 | <code>classreg.learning.classif.CompactClassificationNaiveBayes</code> |
| <code>Mdl</code> | 1x1 | 111374 | <code>ClassificationNaiveBayes</code> |

The full naive Bayes classifier (`Mdl`) is much larger than the compact naive Bayes classifier (`CMdl`).

You can remove `Mdl` from the MATLAB® Workspace, and pass `CMdl` and new predictor values to `predict` to efficiently label new observations.

See Also

`ClassificationNaiveBayes` | `CompactClassificationNaiveBayes` | `fitcnb` | `predict`

compact

Reduce size of support vector machine (SVM) classifier

Syntax

```
CompactSVMModel = compact(SVMModel)
```

Description

`CompactSVMModel = compact(SVMModel)` returns a compact support vector machine (SVM) classifier (`CompactSVMModel`), the compact version of the trained SVM classifier `SVMModel`. `CompactSVMModel` is a `CompactClassificationSVM` object.

`CompactSVMModel` does not contain the training data, whereas `SVMModel` contains the training data in its `X` and `Y` properties. Therefore, although you can predict class labels using `CompactSVMModel`, you cannot perform tasks such as cross-validation with the compact SVM classifier.

Examples

Reduce Size of SVM Classifiers

Reduce the size of a full SVM classifier by removing the training data. Full SVM classifiers (that is, `ClassificationSVM` classifiers) hold the training data. To improve efficiency, use a smaller classifier.

Load the `ionosphere` data set.

```
load ionosphere
```

Train an SVM classifier. Standardize the predictor data and specify the order of the classes.

```
SVMModel = fitcsvm(X,Y,'Standardize',true,...  
    'ClassNames',{'b','g'})
```

```
SVMMModel =  
  ClassificationSVM  
    ResponseName: 'Y'  
    CategoricalPredictors: []  
      ClassNames: {'b' 'g'}  
      ScoreTransform: 'none'  
    NumObservations: 351  
      Alpha: [90x1 double]  
      Bias: -0.1343  
    KernelParameters: [1x1 struct]  
      Mu: [1x34 double]  
      Sigma: [1x34 double]  
    BoxConstraints: [351x1 double]  
    ConvergenceInfo: [1x1 struct]  
    IsSupportVector: [351x1 logical]  
    Solver: 'SMO'
```

Properties, Methods

SVMMModel is a **ClassificationSVM** classifier.

Reduce the size of the SVM classifier.

```
CompactSVMMModel = compact(SVMMModel)
```

```
CompactSVMMModel =  
  classreg.learning.classif.CompactClassificationSVM  
    ResponseName: 'Y'  
    CategoricalPredictors: []  
      ClassNames: {'b' 'g'}  
      ScoreTransform: 'none'  
    Alpha: [90x1 double]  
    Bias: -0.1343  
    KernelParameters: [1x1 struct]  
      Mu: [1x34 double]  
      Sigma: [1x34 double]  
    SupportVectors: [90x34 double]  
    SupportVectorLabels: [90x1 double]
```

Properties, Methods

`CompactSVMModel` is a `CompactClassificationSVM` classifier.

Display the amount of memory each classifier uses.

```
whos('SVMModel', 'CompactSVMModel')
```

| Name | Size | Bytes | Class |
|------------------------------|------|--------|--|
| <code>CompactSVMModel</code> | 1x1 | 30512 | <code>classreg.learning.classif.CompactClassi</code> |
| <code>SVMModel</code> | 1x1 | 140834 | <code>ClassificationSVM</code> |

The full SVM classifier (`SVMModel`) is more than four times larger than the compact SVM classifier (`CompactSVMModel`).

To label new observations efficiently, you can remove `SVMModel` from the MATLAB® Workspace, and then pass `CompactSVMModel` and new predictor values to `predict`.

To further reduce the size of your compact SVM classifier, use the `discardSupportVectors` function to discard support vectors.

Input Arguments

SVMModel — Full, trained SVM classifier

`ClassificationSVM` classifier

Full, trained SVM classifier, specified as a `ClassificationSVM` model trained with `fitsvm`.

See Also

`ClassificationSVM` | `CompactClassificationSVM` | `discardSupportVectors` | `fitsvm`

Introduced in R2014a

compact

Class: ClassificationTree

Compact tree

Syntax

```
ctree = compact(tree)
```

Description

`ctree = compact(tree)` creates a compact version of `tree`.

Input Arguments

tree

A classification tree created using `fitctree`.

Output Arguments

ctree

A compact decision tree. `ctree` has class `CompactClassificationTree`. You can predict classifications using `ctree` exactly as you can using `tree`. However, since `ctree` does not contain training data, you cannot perform some actions, such as cross validation.

Examples

Create a Compact Classification Tree

Compare the size of the classification tree for Fisher's iris data to the compact version of the tree.

```
load fisheriris
fulltree = fitctree(meas,species);
ctree = compact(fulltree);
b = whos('fulltree'); % b.bytes = size of fulltree
c = whos('ctree'); % c.bytes = size of ctree
[b.bytes c.bytes] % shows ctree uses half the memory
```

```
ans = 1x2
```

```
11260    4572
```

[ClassificationTree](#) | [CompactClassificationTree](#) | [fitctree](#) | [predict](#)

compact

Class: LinearModel

Compact linear regression model

Syntax

```
compactMdl = compact(mdl)
```

Description

`compactMdl = compact(mdl)` returns a compact linear regression model, `compactMdl`, which is the compact version of the full, fitted linear regression model `mdl`.

Input Arguments

mdl — Full, fitted linear regression model

LinearModel object

Full, fitted linear regression model, specified as a `LinearModel` object constructed using `fitlm` or `stepwiselm`.

Output Arguments

compactMdl — Compact linear regression model

CompactLinearModel object

Compact linear regression model, returned as a `CompactLinearModel` object.

Predict response values using `compactMdl` exactly as you would using `mdl`. However, since `compactMdl` does not contain training data, you cannot perform certain tasks, such as cross-validation.

Examples

Compact a Linear Regression Model

This example shows how to reduce the size of a full, fitted linear regression model by discarding the sample data and some information related to the fitting process.

Load the data into the workspace.

```
load(fullfile(matlabroot, 'examples', 'stats', 'largedata4reg.mat'))
```

The simulated sample data contains 15,000 observations and 45 predictor variables.

Fit a simple linear regression model to the data.

```
mdl = fitlm(X,Y)
```

```
mdl =
```

```
Linear regression model:
```

```
    y ~ [Linear formula with 46 terms in 45 predictors]
```

```
Estimated Coefficients:
```

| | Estimate | SE | tStat | pValue |

Introduced in R2016a

compact

Class: GeneralizedLinearModel

Compact generalized linear regression model

Syntax

```
compactMdl = compact(mdl)
```

Description

`compactMdl = compact(mdl)` returns a compact generalized linear regression model, `compactMdl`, which is the compact version of the full, fitted regression model `mdl`. The compact model uses less memory than the full model because it does not include a copy of the data or anything comparable in size to the data. However, the compact model also does not support properties (such as `Residuals`) or methods (such as `addTerms`) that require the data.

Input Arguments

mdl — Full, fitted generalized linear regression model

GeneralizedLinearModel object

Full, fitted generalized linear regression model, specified as a GeneralizedLinearModel object constructed using `fitglm` or `stepwiseglm`.

Output Arguments

compactMdl — Compact generalized linear regression model

CompactGeneralizedLinearModel object

Compact generalized linear regression model, returned as a CompactGeneralizedLinearModel object.

Predict response values using `compactMdl` exactly as you would using `mdl`. However, since `compactMdl` does not contain training data, you cannot perform certain tasks, such as cross-validation.

Examples

Compact a Generalized Linear Regression Model

Reduce the size of a full, fitted generalized linear regression model by discarding the sample data and some information related to the fitting process.

Load the data into the workspace. The simulated sample data contains 15,000 observations and 45 predictor variables.

```
load(fullfile(matlabroot, 'examples', 'stats', 'largedata4reg.mat'))
```

Fit a generalized linear regression model to the data using the first 15 predictor variables.

```
mdl = fitglm(X(:,1:15),Y)
```

```
mdl =
```

```
Generalized linear regression model:
```

```
  y ~ [Linear formula with 16 terms in 15 predictors]
```

```
  Distribution = Normal
```

```
Estimated Coefficients:
```

| | Estimate | SE | tStat | pValue |

`CompactGeneralizedLinearModel` | `GeneralizedLinearModel` | `fitglm` | `stepwiseglm`

Introduced in R2016b

compact

Class: RegressionEnsemble

Create compact regression ensemble

Syntax

```
cens = compact(ens)
```

Description

`cens = compact(ens)` creates a compact version of `ens`. You can predict regressions using `cens` exactly as you can using `ens`. However, since `cens` does not contain training data, you cannot perform some actions, such as cross validation.

Input Arguments

ens

A regression ensemble created with `fitensemble`.

Output Arguments

cens

A compact regression ensemble. `cens` is of class `CompactRegressionEnsemble`.

Examples

View Size of Compact Regression Ensemble

Compare the size of a regression ensemble for the `carsmall` data to the size of the compact version of the ensemble.

Load the `carsmall` data set and select acceleration, number of cylinders, displacement, horsepower, and vehicle weight as predictors.

```
load carsmall
X = [Acceleration Cylinders Displacement Horsepower Weight];
```

Train an ensemble of regression trees.

```
ens = fitensemble(X,MPG);
```

Create a compact version of `ens` and compare ensemble sizes.

```
cens = compact(ens);
b = whos('ens');
c = whos('cens');
[b.bytes c.bytes] % b.bytes = size of ens and c.bytes = size of cens
```

```
ans = 1×2
```

```
415490    389558
```

The compact ensemble uses less memory.

See Also

[CompactRegressionEnsemble](#) | [RegressionEnsemble](#)

compact

Class: RegressionGP

Create compact Gaussian process regression model

Syntax

```
cgprMdl = compact(gprMdl)
```

Description

`cgprMdl = compact(gprMdl)` returns a compact version of the trained Gaussian process regression (GPR) model, `gprMdl`.

Input Arguments

gprMdl — Gaussian process regression model

RegressionGP object

Gaussian process regression model, specified as a RegressionGP object.

Output Arguments

cgprMdl — Compact Gaussian process regression model

CompactRegressionGP object

Compact Gaussian process regression model, returned as a CompactRegressionGP object.

Examples

Compute Predictions and Regression Loss for Test Data

Generate example training data.

```
rng(1) % For reproducibility
n = 100000;
X = linspace(0,1,n)';
X = [X,X.^2];
y = 1 + X*[1;2] + sin(20*X*[1;-2]) + 0.2*randn(n,1);
```

Train a GPR model using the subset of regressors ('sr') approximation method and predict using the subset of data ('sd') method. Use 50 points in the active set and sparse greedy matrix approximation ('sgma') method for active set selection. Because the scales of the first and second predictors are different, it is good practice to standardize the data.

```
gprMdl = fitrgp(X,y,'KernelFunction','squaredExponential','FitMethod',...
'sr','PredictMethod','sd','Basis','none','ActiveSetSize',50,...
'ActiveSetMethod','sgma','Standardize',1,'KernelParameters',[1;1]);
```

`fitrgp` accepts any combination of fitting, prediction, and active set selection methods. In some cases it might not be possible to compute the standard deviations of the predicted responses, hence the prediction intervals. See “Tips” on page 32-710. And, in some cases, using the exact method might be expensive because of the size of the training data.

Create a compact GPR object.

```
cgprMdl = compact(gprMdl);
```

Generate the test data.

```
n = 4000;
Xnew = linspace(0,1,n)';
Xnew = [Xnew,Xnew.^2];
ynew = 1 + Xnew*[1;2] + sin(20*Xnew*[1;-2]) + 0.2*randn(n,1);
```

Use the compact object to predict the response in test data and the prediction intervals.

```
[ypred,~,yci] = predict(cgprMdl,Xnew);
```

Plot the true response, predicted response, and prediction intervals.

```
figure;
plot(ynew,'r');
```

```
hold on;  
plot(ypred, 'b')  
plot(yci(:,1), 'k--');  
plot(yci(:,2), 'k--');  
legend('Data', 'Pred', 'Lower 95%', 'Upper 95%', 'Location', 'Best');  
xlabel('x');  
ylabel('y');  
hold off
```

Compute the mean squared error loss on the test data using the trained GPR model.

```
L = loss(cgprMdl, Xnew, ynew)
```

```
L = 0.0497
```

Tips

- The compact object does not contain the training data that `fitrgp` uses in training the GPR model, `gprMdl`.
- You can use the compact object to make predictions (see `predict`) or compute the regression error (see `loss`).
- Computation of standard deviations, `ysd`, and prediction intervals, `yint`, is not supported when `PredictMethod` is `'bcd'`.
- If `gprMdl` is a `CompactRegressionGP` object, you cannot compute standard deviations, `ysd`, or prediction intervals, `yint`, for `PredictMethod` equal to `'sr'` or `'fic'`. To compute `ysd` and `yint` for `PredictMethod` equal to `'sr'` or `'fic'`, use the full regression (`RegressionGP`) object.

`CompactRegressionGP` | `fitrgp` | `loss` | `predict`

Introduced in R2015b

compact

Class: RegressionSVM

Compact support vector machine regression model

Syntax

```
compactMdl = compact mdl
```

Description

`compactMdl = compact(mdl)` returns a compact support vector machine (SVM) regression model, `compactMdl`, which is the compact version of the full, trained SVM regression model `mdl`.

`compactMdl` does not contain the training data, whereas `mdl` contains the training data in its properties `mdl.X` and `mdl.Y`.

Input Arguments

mdl — Full, trained SVM regression model

RegressionSVM model

Full, trained SVM regression model, specified as a RegressionSVM model returned by `fitrsvm`.

Output Arguments

compactMdl — Compact SVM regression model

CompactRegressionSVM model

Compact SVM regression model, returned as a CompactRegressionSVM model.

Predict response values using `compactMdl` exactly as you would using `mdl`. However, since `compactMdl` does not contain training data, you cannot perform certain tasks, such as cross validation.

Examples

Compact an SVM Regression Model

This example shows how to reduce the size of a full, trained SVM regression model by discarding the training data and some information related to the training process.

This example uses the `abalone` data from the UCI Machine Learning Repository. Download the data and save it in your current directory with the name `'abalone.data'`. Read the data into a `table`.

```
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);  
rng default % for reproducibility
```

The sample data contains 4177 observations. All of the predictor variables are continuous except for `sex`, which is a categorical variable with possible values 'M' (for males), 'F' (for females), and 'I' (for infants). The goal is to predict the number of rings on the abalone, and thereby determine its age, using physical measurements.

Train an SVM regression model using a Gaussian kernel function and an automatic kernel scale. Standardize the data.

```
mdl = fitrsvm(tbl,'Var9','KernelFunction','gaussian','KernelScale','auto','Standardize'  
mdl =
```

```
RegressionSVM  
    PredictorNames: {1x8 cell}  
    ResponseName: 'Var9'  
    CategoricalPredictors: 1  
    ResponseTransform: 'none'  
    Alpha: [3635x1 double]  
    Bias: 10.8144  
    KernelParameters: [1x1 struct]  
        Mu: [1x10 double]  
        Sigma: [1x10 double]  
    NumObservations: 4177
```

```

    BoxConstraints: [4177x1 double]
    ConvergenceInfo: [1x1 struct]
    IsSupportVector: [4177x1 logical]
    Solver: 'SMO'

```

Properties, Methods

Compact the model.

```
compactMdl = compact mdl
```

```
compactMdl =
```

```

classreg.learning.regr.CompactRegressionSVM
    PredictorNames: {1x8 cell}
    ResponseName: 'Var9'
    CategoricalPredictors: 1
    ResponseTransform: 'none'
    Alpha: [3635x1 double]
    Bias: 10.8144
    KernelParameters: [1x1 struct]
    Mu: [1x10 double]
    Sigma: [1x10 double]
    SupportVectors: [3635x10 double]

```

Properties, Methods

The compacted model discards the training data and some information related to the training process.

Compare the size of the full model `mdl` and the compact model `compactMdl`.

```
vars = whos('compactMdl','mdl');
[vars(1).bytes,vars(2).bytes]
```

```
ans =
```

```
323793    775968
```

The compacted model consumes about half the memory of the full model.

Reduce Memory Consumption of SVM Regression Model

This example shows how to reduce the memory consumption of a full, trained SVM regression model by compacting the model and discarding the support vectors.

Load the `carsmall` sample data.

```
load carsmall
rng default % for reproducibility
```

Train a linear SVM regression model using `Weight` as the predictor variable and `MPG` as the response variable. Standardize the data.

```
mdl = fitrsvm(Weight,MPG,'Standardize',true);
```

Note that `MPG` contains several `NaN` values. When training a model, `fitrsvm` will remove rows that contain `NaN` values from both the predictor and response data. As a result, the trained model uses only 94 of the 100 total observations contained in the sample data.

Compact the regression model to discard the training data and some information related to the training process.

```
compactMdl = compact(mdl);
```

`compactMdl` is a `CompactRegressionSVM` model that has the same parameters, support vectors, and related estimates as `mdl`, but no longer stores the training data.

Discard the support vectors and related estimates for the compacted model.

```
mdlOut = discardSupportVectors(compactMdl);
```

`mdlOut` is a `CompactRegressionSVM` model that has the same parameters as `mdl` and `compactMdl`, but no longer stores the support vectors and related estimates.

Compare the sizes of the three SVM regression models, `compactMdl`, `mdl`, and `mdlOut`.

```
vars = whos('compactMdl','mdl','mdlOut');
[vars(1).bytes,vars(2).bytes,vars(3).bytes]
```

```
ans =
```

```
3601      13727      2305
```

The compacted model `compactMdl` consumes 3601 bytes of memory, while the full model `mdl` consumes 13727 bytes of memory. The model `mdlOut`, which also discards the support vectors, consumes 2305 bytes of memory.

`CompactRegressionSVM` | `RegressionSVM` | `fitrsvm`

Introduced in R2015b

compact

Class: RegressionTree

Compact regression tree

Syntax

```
ctree = compact(tree)
```

Description

`ctree = compact(tree)` creates a compact version of `tree`.

Input Arguments

tree

A regression tree created using `fitrtree`.

Output Arguments

ctree

A compact regression tree. `ctree` has class `CompactRegressionTree`. You can predict regressions using `ctree` exactly as you can using `tree`. However, since `ctree` does not contain training data, you cannot perform some actions, such as cross validation.

Examples

Reduce Memory Consumption of Regression Tree Model

Compare the size of a full regression tree model to the compacted model.

Load the `carsmall` data set. Consider `Acceleration`, `Displacement`, `Horsepower`, and `Weight` as predictor variables.

```
load carsmall
X = [Acceleration Cylinders Displacement Horsepower Weight];
```

Grow a regression tree using the entire data set.

```
Mdl = fitrtree(X,MPG)

Mdl =
  RegressionTree
      ResponseName: 'Y'
  CategoricalPredictors: []
      ResponseTransform: 'none'
      NumObservations: 94
```

Properties, Methods

`Mdl` is a `RegressionTree` model. It is a full model, that is, it stores information such as the predictor and response data `fitrtree` used in training. For a properties list of full regression tree models, see `RegressionTree`.

Create a compact version of the full regression tree. That is, one that contains enough information to make predictions only.

```
CMdl = compact(Mdl)

CMdl =
  classreg.learning.regr.CompactRegressionTree
      ResponseName: 'Y'
  CategoricalPredictors: []
      ResponseTransform: 'none'
```

Properties, Methods

`CMdl` is a `CompactRegressionTree` model. For a properties list of compact regression tree models, see `CompactRegressionTree`.

Inspect the amounts of memory that the full and compact regression trees consume.

```
mdlInfo = whos('Mdl');  
cMdlInfo = whos('CMdl');  
[mdlInfo.bytes cMdlInfo.bytes]
```

```
ans = 1×2
```

```
11778    6276
```

```
cMdlInfo.bytes/mdlInfo.bytes
```

```
ans = 0.5329
```

In this case, the compact regression tree model consumes about 25% less memory than the full model consumes.

      MinLeafSize:      1  
      InBagFraction:    1  
      SampleWithReplacement: 1  
      ComputeOOBPrediction: 0  
      ComputeOOBPredictorImportance: 0  
      Proximity:        []  
      ClassNames:      'b'      'g'
```

Properties, Methods

Mdl is a `TreeBagger` model object that contains the training data, among other things.

Create a compact version of Mdl.

```
CMdl = compact(Mdl)
```

```
CMdl =  
  CompactTreeBagger  
Ensemble with 100 bagged decision trees:  
      Method:          classification  
      NumPredictors:    34  
      ClassNames:      'b' 'g'
```

Properties, Methods

CMdl is a `CompactTreeBagger` model object. CMdl is almost the same as Mdl. One exception is that it does not store the training data.

Compare the amounts of space consumed by Mdl and CMdl.

```
mdlInfo = whos('Mdl');
cMdlInfo = whos('CMdl');
[mdlInfo.bytes cMdlInfo.bytes]

ans = 1x2

    1031399    890204
```

Mdl consumes more space than CMdl.

CMdl.Trees stores the trained classification trees (CompactClassificationTree model objects) that compose Mdl.

Display a graph of the first tree in the compact model.

```
view(CMdl.Trees{1}, 'Mode', 'graph');
```

By default, `TreeBagger` grows deep trees.

Predict the label of the mean of X using the compact ensemble.

```
predMeanX = predict(CMdl,mean(X))
```

```
predMeanX = 1x1 cell array
    {'g'}
```

CompactClassificationDiscriminant class

Compact discriminant analysis class

Description

A `CompactClassificationDiscriminant` object is a compact version of a discriminant analysis classifier. The compact version does not include the data for training the classifier. Therefore, you cannot perform some tasks with a compact classifier, such as cross validation. Use a compact classifier for making predictions (classifications) of new data.

Construction

`cobj = compact(obj)` constructs a compact classifier from a full classifier.

`cobj = makecdiscr(Mu, Sigma)` constructs a compact discriminant analysis classifier from the class means `Mu` and covariance matrix `Sigma`. For syntax details, see `makecdiscr`.

Input Arguments

obj

Discriminant analysis classifier, created using `fitcdiscr`.

Properties

BetweenSigma

p-by-p matrix, the between-class covariance, where p is the number of predictors.

CategoricalPredictors

Categorical predictor indices, which is always empty (`[]`).

ClassNames

List of the elements in the training data Y with duplicates removed. `ClassNames` can be a categorical array, cell array of character vectors, character array, logical vector, or a numeric vector. `ClassNames` has the same data type as the data in the argument Y .

Coeffs

k -by- k structure of coefficient matrices, where k is the number of classes. `Coeffs(i, j)` contains coefficients of the linear or quadratic boundaries between classes i and j . Fields in `Coeffs(i, j)`:

- `DiscrimType`
- `Class1` — `ClassNames(i)`
- `Class2` — `ClassNames(j)`
- `Const` — A scalar
- `Linear` — A vector with p components, where p is the number of columns in X
- `Quadratic` — p -by- p matrix, exists for quadratic `DiscrimType`

The equation of the boundary between class i and class j is

$$\text{Const} + \text{Linear} * x + x' * \text{Quadratic} * x = 0,$$

where x is a column vector of length p .

If `fitcdiscr` had the `FillCoeffs` name-value pair set to 'off' when constructing the classifier, `Coeffs` is empty (`[]`).

Cost

Square matrix, where `Cost(i, j)` is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`. The number of rows and columns in `Cost` is the number of unique classes in the response.

Change a `Cost` matrix using dot notation: `obj.Cost = costMatrix`.

Delta

Value of the Delta threshold for a linear discriminant model, a nonnegative scalar. If a coefficient of `obj` has magnitude smaller than `Delta`, `obj` sets this coefficient to 0, and

so you can eliminate the corresponding predictor from the model. Set `Delta` to a higher value to eliminate more predictors.

`Delta` must be 0 for quadratic discriminant models.

Change `Delta` using dot notation: `obj.Delta = newDelta`.

DeltaPredictor

Row vector of length equal to the number of predictors in `obj`. If `DeltaPredictor(i) < Delta` then coefficient `i` of the model is 0.

If `obj` is a quadratic discriminant model, all elements of `DeltaPredictor` are 0.

DiscrimType

Character vector specifying the discriminant type. One of:

- 'linear'
- 'quadratic'
- 'diagLinear'
- 'diagQuadratic'
- 'pseudoLinear'
- 'pseudoQuadratic'

Change `DiscrimType` using dot notation: `obj.DiscrimType = newDiscrimType`.

You can change between linear types, or between quadratic types, but cannot change between linear and quadratic types.

Gamma

Value of the `Gamma` regularization parameter, a scalar from 0 to 1. Change `Gamma` using dot notation: `obj.Gamma = newGamma`.

- If you set 1 for linear discriminant, the discriminant sets its type to 'diagLinear'.
- If you set a value between `MinGamma` and 1 for linear discriminant, the discriminant sets its type to 'linear'.
- You cannot set values below the value of the `MinGamma` property.

- For quadratic discriminant, you can set either 0 (for `DiscrimType 'quadratic'`) or 1 (for `DiscrimType 'diagQuadratic'`).

LogDetSigma

Logarithm of the determinant of the within-class covariance matrix. The type of `LogDetSigma` depends on the discriminant type:

- Scalar for linear discriminant analysis
- Vector of length `K` for quadratic discriminant analysis, where `K` is the number of classes

MinGamma

Nonnegative scalar, the minimal value of the `Gamma` parameter so that the correlation matrix is invertible. If the correlation matrix is not singular, `MinGamma` is 0.

Mu

Class means, specified as a `K`-by-`p` matrix of scalar values class means of size. `K` is the number of classes, and `p` is the number of predictors. Each row of `Mu` represents the mean of the multivariate normal distribution of the corresponding class. The class indices are in the `ClassNames` attribute.

PredictorNames

Cell array of names for the predictor variables, in the order in which they appear in the training data `X`.

Prior

Numeric vector of prior probabilities for each class. The order of the elements of `Prior` corresponds to the order of the classes in `ClassNames`.

Add or change a `Prior` vector using dot notation: `obj.Prior = priorVector`.

ResponseName

Character vector describing the response variable `Y`.

ScoreTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means

@(x)x. For a list of built-in transformation functions and the syntax of custom transformation functions, see `fitcdiscr`.

Implement dot notation to add or change a `ScoreTransform` function using one of the following:

- `cobj.ScoreTransform = 'function'`
- `cobj.ScoreTransform = @function`

Sigma

Within-class covariance matrix or matrices. The dimensions depend on `DiscrimType`:

- `'linear'` (default) — Matrix of size `p-by-p`, where `p` is the number of predictors
- `'quadratic'` — Array of size `p-by-p-by-K`, where `K` is the number of classes
- `'diagLinear'` — Row vector of length `p`
- `'diagQuadratic'` — Array of size `1-by-p-by-K`
- `'pseudoLinear'` — Matrix of size `p-by-p`
- `'pseudoQuadratic'` — Array of size `p-by-p-by-K`

Methods

| | |
|-----------------------------|--|
| <code>compareHoldout</code> | Compare accuracies of two classification models using new data |
| <code>edge</code> | Classification edge |
| <code>logP</code> | Log unconditional probability density for discriminant analysis classifier |
| <code>loss</code> | Classification error |
| <code>mahal</code> | Mahalanobis distance to class means |
| <code>margin</code> | Classification margins |
| <code>nLinearCoeffs</code> | Number of nonzero linear coefficients |
| <code>predict</code> | Predict labels using discriminant analysis classification model |

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Construct a Compact Discriminant Analysis Classifier

Load the sample data.

```
load fisheriris
```

Construct a discriminant analysis classifier for the sample data.

```
fullobj = fitcdiscr(meas,species);
```

Construct a compact discriminant analysis classifier, and compare its size to that of the full classifier.

```
cobj = compact(fullobj);
b = whos('fullobj'); % b.bytes = size of fullobj
c = whos('cobj'); % c.bytes = size of cobj
[b.bytes c.bytes] % shows cobj uses 60% of the memory
```

```
ans = 1x2
```

```
18279    11642
```

The compact classifier is smaller than the full classifier.

Construct Classifier Using Means and Covariances

Construct a compact discriminant analysis classifier from the means and covariances of the Fisher iris data.

```
load fisheriris
mu(1,:) = mean(meas(1:50,:));
```

```
mu(2,:) = mean(meas(51:100,:));
mu(3,:) = mean(meas(101:150,:));

mm1 = repmat(mu(1,:),50,1);
mm2 = repmat(mu(2,:),50,1);
mm3 = repmat(mu(3,:),50,1);
cc = meas;
cc(1:50,:) = cc(1:50,:) - mm1;
cc(51:100,:) = cc(51:100,:) - mm2;
cc(101:150,:) = cc(101:150,:) - mm3;
sigstar = cc' * cc / 147;
cpct = makecdiscr(mu,sigstar,...
    'ClassNames',{'setosa','versicolor','virginica'});
```

Definitions

Discriminant Classification

The model for discriminant analysis is:

- Each class (Y) generates data (X) using a multivariate normal distribution. That is, the model assumes X has a Gaussian mixture distribution (`gmdistribution`).
 - For linear discriminant analysis, the model has the same covariance matrix for each class, only the means vary.
 - For quadratic discriminant analysis, both means and covariances of each class vary.

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \arg \min_{y=1,\dots,K} \sum_{k=1}^K \hat{P}(k|x) C(y|k),$$

where

- \hat{y} is the predicted classification.
- K is the number of classes.
- $\hat{P}(k|x)$ is the posterior probability on page 20-7 of class k for observation x .

- $C(y | k)$ is the cost on page 20-8 of classifying an observation as y when its true class is k .

For details, see “Prediction Using Discriminant Analysis Models” on page 20-7.

Regularization

Regularization is the process of finding a small set of predictors that yield an effective predictive model. For linear discriminant analysis, there are two parameters, γ and δ , that control regularization as follows. `cvshrink` helps you select appropriate values of the parameters.

Let Σ represent the covariance matrix of the data X , and let \hat{X} be the centered data (the data X minus the mean by class). Define

$$D = \text{diag}(\hat{X}^T * \hat{X}).$$

The regularized covariance matrix $\tilde{\Sigma}$ is

$$\tilde{\Sigma} = (1 - \gamma)\Sigma + \gamma D.$$

Whenever $\gamma \geq \text{MinGamma}$, $\tilde{\Sigma}$ is nonsingular.

Let μ_k be the mean vector for those elements of X in class k , and let μ_0 be the global mean vector (the mean of the rows of X). Let C be the correlation matrix of the data X , and let

\tilde{C} be the regularized correlation matrix:

$$\tilde{C} = (1 - \gamma)C + \gamma I,$$

where I is the identity matrix.

The linear term in the regularized discriminant analysis classifier for a data point x is

$$(x - \mu_0)^T \tilde{\Sigma}^{-1} (\mu_k - \mu_0) = \left[(x - \mu_0)^T D^{-1/2} \right] \left[\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right].$$

The parameter δ enters into this equation as a threshold on the final term in square

brackets. Each component of the vector $[\tilde{C}^{-1}D^{-1/2}(\mu_k - \mu_0)]$ is set to zero if it is smaller in magnitude than the threshold δ . Therefore, for class k , if component j is thresholded to zero, component j of x does not enter into the evaluation of the posterior probability.

The `DeltaPredictor` property is a vector related to this threshold. When $\delta \geq \text{DeltaPredictor}(i)$, all classes k have

$$|\tilde{C}^{-1}D^{-1/2}(\mu_k - \mu_0)| \leq \delta.$$

Therefore, when $\delta \geq \text{DeltaPredictor}(i)$, the regularized classifier does not use predictor i .

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `predict` function supports code generation.
- When you train a discriminant analysis model by using `fitcdiscr` or create a compact discriminant analysis model by using `makecdiscr`, the following restrictions apply.
 - The class labels input argument value (Y) cannot be a categorical array.
 - The value of the 'ClassNames' name-value pair argument cannot be a categorical array.
 - The value of the 'ScoreTransform' name-value pair argument cannot be an anonymous function.

For code generation examples, see “Code Generation Workflow for Prediction” on page 31-5 and “Specify Variable-Sized Arguments for Code Generation” on page 31-48. For more information, see topics in “Code Generation”.

Introduced in R2011b

CompactClassificationECOC class

Compact multiclass model for support vector machines or other classifiers

Description

CompactClassificationECOC is a compact, multiclass, error-correcting output codes (ECOC) model.

The compact classifier does not include the data used for training the ECOC multiclass model. Therefore, you cannot perform tasks, such as cross-validation, using the compact classifier.

Use a compact ECOC multiclass model for labeling new data (in other words, predicting the labels of new data).

Construction

`CompactMdl = compact(Mdl)` returns a compact, multiclass ECOC model (CompactModel) from a full, trained, multiclass, ECOC model (Mdl).

`CompactMdl = fitcecoc(X,Y,'Learners',t)` returns a compact ECOC model composed of linear classification models (ClassificationLinear model objects). `t` must be the character vector 'linear' or a linear-classification-model template object returned by `templateLinear`. For more details, see `fitcecoc`.

Input Arguments

Mdl — Full, trained, multiclass, ECOC model
ClassificationECOC classifier

Full, trained, multiclass, ECOC model, specified as a ClassificationECOC classifier trained by `fitcecoc`.

X — Predictor data
full matrix | sparse matrix

Predictor data, specified as an n -by- p full or sparse matrix.

The length of Y and the number of observations in X must be equal.

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Class labels to which the classification linear model is trained, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors.

If Y is a character array, each element must correspond to one row of the array. The length of Y and the number of observations in X must be equal.

Data Types: char | cell | categorical | logical | single | double

Properties

BinaryLearners — Trained binary learners

cell vector of model objects

Trained binary learners, specified as a cell vector of model objects. `BinaryLearners` has as many elements as classes in Y .

The software trained `BinaryLearner{j}` according to the binary problem specified by `CodingMatrix(:,j)`. For example, for multiclass learning using SVM learners, each element of `BinaryLearners` is a `CompactClassificationSVM` classifier.

Data Types: cell

BinaryLoss — Binary learner loss function

character vector representing the loss function name

Binary learner loss function, specified as a character vector representing the loss function name.

If you train using binary learners that use different loss functions, then the software sets `BinaryLoss` to 'hamming'. To potentially increase accuracy, set a different binary loss function than this default during prediction or loss computation using the `BinaryLoss` name-value pair argument of `predict` or `loss`.

Data Types: char

CategoricalPredictors — Indices of categorical predictors

vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`**ClassNames — Unique class labels**

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` has the same data type as class labels (`Y`). `ClassNames` also determines the class order.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`**CodingMatrix — Class-assignment codes**

numeric matrix

Class-assignment codes for the binary learners, specified as a numeric matrix. `CodingMatrix` is a K -by- L matrix, where K is the number of classes and L is the number of binary learners.

Elements of `CodingMatrix` are `-1`, `0`, or `1`, and the value corresponds to a dichotomous class assignment. This table describes the meaning of `CodingMatrix(i, j)`, that is, the class that learner j assigns to observations in class i .

| Value | Dichotomous Class Assignment |
|-------|---|
| -1 | Negative class |
| 0 | Before training, learner j removes observations in class i from the data set. |
| 1 | Positive class |

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64`**Cost — Misclassification costs**

square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. `Cost` has K rows and columns, where K is the number of classes.

`Cost(i, j)` is the cost of classifying a point into class j if its true class is i . The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: `double`

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

LearnerWeights — Binary learner weights

numeric row vector

Binary learner weights, specified as a numeric row vector. `LearnerWeights` has length equal to the number of binary learners (`size(CodingMatrix, 2)`).

`LearnerWeights(j)` is the sum of the observation weights that binary learner j used to train its classifier.

The software uses `LearnerWeights` to fit posterior probabilities by minimizing the Kullback-Leibler divergence.

Data Types: `double` | `single`

PredictorNames — Predictor names

cell array of character vectors

Predictor names in order of their appearance in predictor data (X), specified as a cell array of character vectors. The length of `PredictorNames` is equal to the number of columns in X .

Data Types: `cell`

Prior — Prior class probabilities

numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. `Prior` has as many elements as classes in `ClassNames`, and the order of the elements corresponds to the elements of `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: double

ResponseName — Response variable name

character array

Response variable name, specified as a character array.

Data Types: char

ScoreTransform — Score transformation function to apply to predicted scores

character vector | function handle

Score transformation function to apply to predicted scores, specified as a character vector or function handle.

To change the score transformation function to, for example, *function*, use dot notation.

- For a built-in function, enter this code and replace *function* with a character vector in the table.

```
Mdl.ScoreTransform = 'function';
```

| Value | Description |
|---------------|--|
| 'doublelogit' | $1/(1 + e^{-2x})$ |
| 'invlogit' | $\log(x / (1-x))$ |
| 'ismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0 |
| 'logit' | $1/(1 + e^{-x})$ |

| Value | Description |
|----------------------|---|
| 'none' or 'identity' | x (no transformation) |
| 'sign' | -1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$ |
| 'symmetric' | $2x - 1$ |
| 'symmetricismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1 |
| 'symmetriclogit' | $2/(1 + e^{-x}) - 1$ |

- For a MATLAB function, or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Data Types: char | function_handle

Methods

| | |
|-----------------------|--|
| compareHoldout | Compare accuracies of two classification models using new data |
| discardSupportVectors | Discard support vectors of linear support vector machine binary learners |
| edge | Classification edge for multiclass, error-correcting output codes model |
| loss | Classification loss for multiclass, error-correcting output codes model |
| margin | Classification margins for multiclass, error-correcting output codes model |
| predict | Predict labels using multiclass, error-correcting output codes model |
| selectModels | Choose subset of regularized linear classification models |

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Reduce the Size of Full ECOC Models

Full ECOC models (i.e., `ClassificationECOC` classifiers) hold the training data. For efficiency, you might not want to predict new labels using a large classifier.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Train an ECOC model using default SVMs as binary learners.

```
Mdl = fitcecoc(X,Y)

Mdl =
  ClassificationECOC
      ResponseName: 'Y'
  CategoricalPredictors: []
          ClassNames: {'setosa' 'versicolor' 'virginica'}
      ScoreTransform: 'none'
      BinaryLearners: {3x1 cell}
          CodingName: 'onevsone'
```

Properties, Methods

`Mdl` is a `ClassificationECOC` model.

Reduce the size of the ECOC model.

```
CMdl = compact(Mdl)

CMdl =
  classreg.learning.classif.CompactClassificationECOC
```

```

        ResponseName: 'Y'
    CategoricalPredictors: []
        ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
    BinaryLearners: {3x1 cell}
    CodingMatrix: [3x3 double]

```

Properties, Methods

`CMdl` is a `CompactClassificationECOC` model.

Display how much memory each classifier consumes.

```
whos('Mdl', 'CMdl')
```

| Name | Size | Bytes | Class |
|------|------|-------|---|
| CMdl | 1x1 | 12764 | classreg.learning.classif.CompactClassificationECOC |
| Mdl | 1x1 | 25337 | ClassificationECOC |

The full ECOC model (`Mdl`) is almost twice the size of the compact ECOC model (`CMdl`).

You can remove `Mdl` from the MATLAB® Workspace, and pass `CMdl` and new predictor values to `predict` to efficiently label new observations.

Train and Cross-Validate ECOC Classifiers

Train an ECOC classifier using different binary learners and the one-versus-all coding design. Then, cross validate the classifier.

Load Fisher's iris data set.

```

load fisheriris
X = meas;
Y = species;
classNames = unique(species(~strcmp(species, ''))) % Remove empty classes

classNames = 3x1 cell array
    {'setosa' }
    {'versicolor'}

```

```
{'virginica' }
```

```
K = numel(classNames) % Number of classes
```

```
K = 3
```

```
rng(1); % For reproducibility
```

`classNames` are the unique classes in the data set, and `K` is the number of classes. You can use `classNames` to specify the order of the classes during training.

For a one-versus-all coding design, there are `K = 3` binary learners. Specify templates for the binary learners such that:

- Binary learner 1 and 2 are naive Bayes classifiers. By default, each predictor is conditionally, normally distributed given its label.
- Binary learner 3 is an SVM classifier. Specify to use the Gaussian kernel.

```
tNB = templateNaiveBayes();  
tSVM = templateSVM('KernelFunction','gaussian');  
tLearners = {tNB tNB tSVM};
```

`tNB` and `tSVM` are template objects for naive Bayes and SVM learning, respectively. They indicate what options to use during training. Most of their properties are empty, except for those specified using name-value pair arguments. The software fills in the empty properties with their default values during training.

Train and cross-validate an ECOC classifier using the binary learner templates and the one-versus-all coding design. Specify the order of the classes. By default, naive Bayes classifiers use posterior probabilities as scores, whereas SVM classifiers use distance from the decision boundary. Therefore, to aggregate the binary learners, you must specify fitting posterior probabilities.

```
CVMDL = fitcecoc(X,Y,'ClassNames',classNames,'CrossVal','on',...  
    'Learners',tLearners,'FitPosterior',1);
```

`CVMDL` is not a `ClassificationECOC` model, but a `ClassificationPartitionedECOC` cross-validated model. By default, the software implements 10-fold cross-validation. The scores across the binary learners are in the same form (that is, they are posterior probabilities), so the software can aggregate the results of the binary classifications properly.

Inspect one of the trained folds using dot notation.

```
CVMdl.Trained{1}
```

```
ans =
  classreg.learning.classif.CompactClassificationECOC
      ResponseName: 'Y'
  CategoricalPredictors: []
          ClassNames: {'setosa' 'versicolor' 'virginica'}
      ScoreTransform: 'none'
  BinaryLearners: {3x1 cell}
      CodingMatrix: [3x3 double]
```

Properties, Methods

Each fold is a `CompactClassificationECOC` model trained on 90% of the data.

You can access the results of the binary learners using dot notation and cell indexing. Display the trained SVM classifier (the third binary learner) in the first fold.

```
CVMdl.Trained{1}.BinaryLearners{3}
```

```
ans =
  classreg.learning.classif.CompactClassificationSVM
      ResponseName: 'Y'
  CategoricalPredictors: []
          ClassNames: [-1 1]
      ScoreTransform: '@(S) sigmoid(S, -4.016609e+00, -3.242911e-01) '
          Alpha: [33x1 double]
          Bias: -0.1346
  KernelParameters: [1x1 struct]
      SupportVectors: [33x4 double]
  SupportVectorLabels: [33x1 double]
```

Properties, Methods

Estimate the generalization error.

```
genError = kfoldLoss(CVMdl)
```

```
genError = 0.0333
```

On average, the generalization error is approximately 3%.

Algorithms

Random Coding Design Matrices

For a given number of classes, for example, K , the software generates random coding design matrices as follows.

- 1 The software generates one of the following:
 - a Dense random — The software assigns a 1 or -1 with equal probability to each element of the K -by- L_d coding design matrix, where $L_d \approx \lceil 10 \log_2 K \rceil$.
 - b Sparse random — The software assigns a 1 to each element of the K -by- L_s coding design matrix with probability 0.25, a -1 with probability 0.25, and a 0 with probability 0.5, where $L_s \approx \lceil 15 \log_2 K \rceil$.
- 2 If a column does not contain at least one 1 and at least one -1, then the software removes that column.
- 3 For distinct columns u and v , if $u = v$ or $u = -v$, then the software removes v from the coding design matrix.

The software randomly generates 10,000 matrices by default, and retains the matrix with the largest, minimal pairwise row distance based on the Hamming measure ([4]) given by

$$\Delta(k_1, k_2) = 0.5 \sum_{l=1}^L |m_{k_1 l}| |m_{k_2 l}| |m_{k_1 l} - m_{k_2 l}|,$$

where $m_{k,l}$ is an element of coding design matrix j .

Support Vector Storage

For linear, SVM binary learners, and for efficiency, `fitcecoc` empties the properties `Alpha`, `SupportVectorLabels`, and `SupportVectors`. `fitcecoc` lists `Beta`, rather than `Alpha`, in the model display.

To store `Alpha`, `SupportVectorLabels`, and `SupportVectors`, pass a linear, SVM template that specifies storing support vectors to `fitcecoc`. For example, enter:

```
t = templateSVM('SaveSupportVectors','on')
Mdl = fitcecoc(X,Y,'Learners',t);
```

You can remove the support vectors and related values by passing the resulting ClassificationECOC model to `discardSupportVectors`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `predict` function supports code generation.
- When you train an ECOC model by using `fitcecoc`, the following restrictions apply.
 - You cannot fit posterior probabilities by using the `'FitPosterior'` name-value pair argument.
 - All binary learners must be either SVM classifiers or linear classification models. For the `'Learners'` name-value pair argument, you can specify:
 - `'svm'` or `'linear'`
 - An SVM template object or a cell vector of such objects (see `templateSVM`)
 - A linear classification model template object or a cell vector of such objects (see `templateLinear`)

- Code generation limitations for SVM classifiers and linear classification models also apply to ECOC classifiers, depending on the choice of binary learners. For more details, see “Code Generation” on page 32-0 of the `ClassificationSVM` class and “Code Generation” on page 32-0 of the `ClassificationLinear` class.

For code generation examples, see “Code Generation Workflow for Prediction” on page 31-5 and “Specify Variable-Sized Arguments for Code Generation” on page 31-48. For more information, see topics in “Code Generation”.

`ClassificationECOC` | `compact` | `fitcecoc`

Introduced in R2014b

CompactClassificationEnsemble class

Compact classification ensemble class

Description

Compact version of a classification ensemble (of class `ClassificationEnsemble`). The compact version does not include the data for training the classification ensemble. Therefore, you cannot perform some tasks with a compact classification ensemble, such as cross validation. Use a compact classification ensemble for making predictions (classifications) of new data.

Construction

`ens = compact(fullEns)` constructs a compact decision ensemble from a full decision ensemble.

Input Arguments

fullEns

A classification ensemble created by `fitensemble`.

Properties

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

ClassNames

List of the elements in Y with duplicates removed. `ClassNames` can be a numeric vector, vector of categorical variables, logical vector, character array, or cell array of character vectors. `ClassNames` has the same data type as the data in the argument Y .

CombineWeights

Character vector describing how `ens` combines weak learner weights, either 'WeightedSum' or 'WeightedAverage'.

Cost

Square matrix, where $\text{Cost}(i, j)$ is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`. The number of rows and columns in `Cost` is the number of unique classes in the response. This property is read-only.

ExpandedPredictorNames

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

NumTrained

Number of trained weak learners in `ens`, a scalar.

PredictorNames

A cell array of names for the predictor variables, in the order in which they appear in X .

Prior

Numeric vector of prior probabilities for each class. The order of the elements of `Prior` corresponds to the order of the classes in `ClassNames`. The number of elements of `Prior` is the number of unique classes in the response. This property is read-only.

ResponseName

Character vector with the name of the response variable Y .

ScoreTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means $@(x)x$. For a list of built-in transformation functions and the syntax of custom transformation functions, see `fitctree`.

Add or change a ScoreTransform function using dot notation:

```
ens.ScoreTransform = 'function'
```

or

```
ens.ScoreTransform = @function
```

Trained

A cell vector of trained classification models.

- If Method is 'LogitBoost' or 'GentleBoost', then CompactClassificationEnsemble stores trained learner j in the CompactRegressionLearner property of the object stored in Trained{ j }. That is, to access trained learner j , use `ens.Trained{j}.CompactRegressionLearner`.
- Otherwise, cells of the cell vector contain the corresponding, compact classification models.

TrainedWeights

Numeric vector of trained weights for the weak learners in `ens`. TrainedWeights has T elements, where T is the number of weak learners in `learners`.

UsePredForLearner

Logical matrix of size P -by-`NumTrained`, where P is the number of predictors (columns) in the training data X . `UsePredForLearner(i, j)` is true when learner j uses predictor i , and is false otherwise. For each learner, the predictors have the same order as the columns in the training data X .

If the ensemble is not of type `Subspace`, all entries in `UsePredForLearner` are true.

Methods

| | |
|----------------------------------|--|
| <code>compareHoldout</code> | Compare accuracies of two classification models using new data |
| <code>edge</code> | Classification edge |
| <code>loss</code> | Classification error |
| <code>margin</code> | Classification margins |
| <code>predict</code> | Predict labels using ensemble of classification models |
| <code>predictorImportance</code> | Estimates of predictor importance |
| <code>removeLearners</code> | Remove members of compact classification ensemble |

Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects \(MATLAB\)](#).

Examples

Reduce Size of Classification Ensemble

Create a compact classification ensemble for efficiently making predictions on new data.

Load the `ionosphere` data set.

```
load ionosphere
```

Train a boosted ensemble of 100 classification trees using all measurements and the `AdaBoostM1` method.

```
Mdl = fitensemble(X,Y,'Method','AdaBoostM1')

Mdl =
  classreg.learning.classif.ClassificationEnsemble
      ResponseName: 'Y'
  CategoricalPredictors: []
          ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
      NumObservations: 351
```

```

        NumTrained: 100
        Method: 'AdaBoostM1'
        LearnerNames: {'Tree'}
ReasonForTermination: 'Terminated normally after completing the requested number of
        FitInfo: [100x1 double]
FitInfoDescription: {2x1 cell}

```

Properties, Methods

`Mdl` is a `ClassificationEnsemble` model object that contains the training data, among other things.

Create a compact version of `Mdl`.

```
CMDl = compact(Mdl)
```

```

CMDl =
  classreg.learning.classif.CompactClassificationEnsemble
      ResponseName: 'Y'
  CategoricalPredictors: []
      ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
      NumTrained: 100

```

Properties, Methods

`CMdl` is a `CompactClassificationEnsemble` model object. `CMdl` is almost the same as `Mdl`. One exception is that `CMdl` does not store the training data.

Compare the amounts of space consumed by `Mdl` and `CMdl`.

```

mdlInfo = whos('Mdl');
cMdlInfo = whos('CMdl');
[mdlInfo.bytes cMdlInfo.bytes]

```

```
ans = 1x2
```

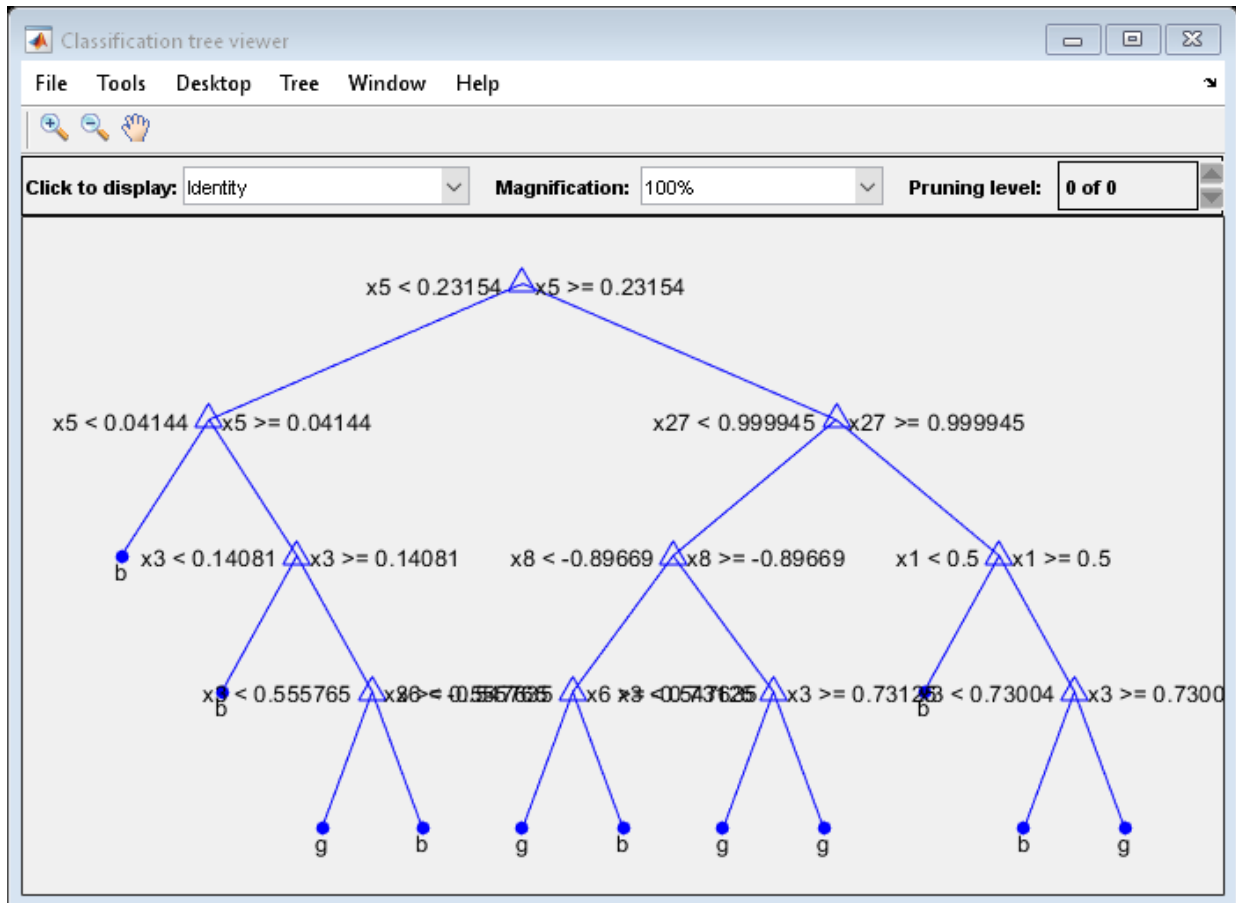

```
      818912      573200
```

`Mdl` consumes more space than `CMdl`.

`CMdl.Trained` stores the trained classification trees (`CompactClassificationTree` model objects) that compose `Mdl`.

Display a graph of the first tree in the compact ensemble.

```
view(CMdl.Trained{1}, 'Mode', 'graph');
```

By default, `fitensemble` grows shallow trees for boosted ensembles of trees.

Predict the label of the mean of `X` using the compact ensemble.

```
predMeanX = predict(CMdl,mean(X))
```

```
predMeanX = 1x1 cell array
    {'g'}
```

Tip

For an ensemble of classification trees, the `Trained` property of `ens` stores an `ens.NumTrained-by-1` cell vector of compact classification models. For a textual or graphical display of tree `t` in the cell vector, enter:

- `view(ens.Trained{t}.CompactRegressionLearner)` for ensembles aggregated using LogitBoost or GentleBoost.
- `view(ens.Trained{t})` for all other aggregation methods.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `predict` function supports code generation.
- When you train an ensemble by using `fitcensemble`, code generation limitations for classification trees also apply to ensembles of classification trees. For more details, see “Code Generation” on page 32-0 of the `CompactClassificationTree` class.

For code generation examples, see “Code Generation Workflow for Prediction” on page 31-5 and “Specify Variable-Sized Arguments for Code Generation” on page 31-48. For more information, see topics in “Code Generation”.

Introduced in R2011a

CompactClassificationNaiveBayes class

Compact naive Bayes classifier

Description

CompactClassificationNaiveBayes is a compact naive Bayes on page 32-765 classifier.

The compact classifier does not include the data used for training the naive Bayes classifier. Therefore, you cannot perform tasks, such as cross validation, using the compact classifier.

Use a compact naive Bayes classifier to label new data (i.e., predicting the labels of new data) more efficiently.

Construction

`CMdl = compact(Mdl)` returns a compact naive Bayes classifier (CMdl) from a full, trained naive Bayes classifier (Mdl).

Input Arguments

Mdl — Fully trained naive Bayes classifier

ClassificationNaiveBayes model

A fully trained naive Bayes classifier, specified as a ClassificationNaiveBayes model trained by `fitcnb`.

Properties

CategoricalPredictors — Indices of categorical predictors

vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

CategoricalLevels — Multivariate multinomial levels

cell vector of numeric vectors

Multivariate multinomial levels, specified as a cell vector of numeric vectors. `CategoricalLevels` has length equal to the number of predictors (`size(X,2)`).

The cells of `CategoricalLevels` correspond to predictors that you specified as 'mvmn' (i.e., having a multivariate multinomial distribution) during training. Cells that do not correspond to a multivariate multinomial distribution are empty (`[]`).

If predictor j is multivariate multinomial, then `CategoricalLevels{j}` is a list of all distinct values of predictor j in the sample (NaNs removed from `unique(X(:,j))`).

Data Types: `cell`

ClassNames — Distinct class names

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Distinct class names, specified as a categorical or character array, logical or numeric vector, or cell vector of character vectors.

`ClassNames` is the same data type as `Y`, and has as K elements or rows for character arrays.

Cost — Misclassification cost

square matrix

Misclassification cost, specified as a K -by- K square matrix.

The value of `Cost(i,j)` is the cost of classifying a point into class j if its true class is i . The order of the rows and columns of `Cost` correspond to the order of the classes in `ClassNames`.

The value of `Cost` does not influence training. You can reset `Cost` after training `Mdl` using dot notation, e.g., `Mdl.Cost = [0 0.5; 1 0];`.

Data Types: double | single

DistributionNames — Predictor distributions

'normal' (default) | 'kernel' | 'mn' | 'mvnm' | cell array of character vectors

Predictor distributions `fitcnb` uses to model the predictors, specified as a character vector or cell array of character vectors.

This table summarizes the available distributions.

| Value | Description |
|----------|---|
| 'kernel' | Kernel smoothing density estimate. |
| 'mn' | Multinomial bag-of-tokens model on page 32-451. Indicates that all predictors have this distribution. |
| 'mvnm' | Multivariate multinomial distribution. |
| 'normal' | Normal (Gaussian) distribution. |

If `Distribution` is a 1-by- P cell array of character vectors, then the software models feature j using the distribution in element j of the cell array.

Data Types: cell | char

DistributionParameters — Distribution parameter estimates

cell array

Distribution parameter estimates, specified as a cell array. `DistributionParameters` is a K -by- D cell array, where cell (k,d) contains the distribution parameter estimates for instances of predictor d in class k . The order of the rows corresponds to the order of the classes in the property `ClassNames`, and the order of the predictors corresponds to the order of the columns of X .

If class k has no observations for predictor j , then `Distribution{ k , j }` is empty (`[]`).

The elements of `DistributionParameters` depends on the distributions of the predictors. This table describes the values in `DistributionParameters{ k , j }`.

| Distribution of Predictor j | Value |
|-------------------------------|--|
| kernel | A <code>KernelDistribution</code> model. Display properties using cell indexing and dot notation. For example, to display the estimated bandwidth of the kernel density for predictor 2 in the third class, use <code>Mdl.DistributionParameters{3,2}.Bandwidth</code> . |
| mn | A scalar representing the probability that token j appears in class k . For details, see “Algorithms” on page 32-452. |
| mvmn | A numeric vector containing the probabilities for each possible level of predictor j in class k . The software orders the probabilities by the sorted order of all unique levels of predictor j (stored in the property <code>CategoricalLevels</code>). For more details, see “Algorithms” on page 32-452. |
| normal | A 2-by-1 numeric vector. The first element is the sample mean and the second element is the sample standard deviation. |

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

Kernel — Kernel smoother types

'normal' (default) | 'box' | 'epanechnikov' | 'triangle' | cell array of character vectors

Kernel smoother types, specified as a character vector or cell array of character vectors. `Kernel` has length equal to the number of predictors (`size(X,2)`). `Kernel{j}` corresponds to predictor j , and contains a character vector describing the type of kernel

smoother. This table describes the supported kernel smoother types. Let $I\{u\}$ denote the indicator function.

| Value | Kernel | Formula |
|----------------|------------------|--|
| 'box' | Box (uniform) | $f(x) = 0.5I\{ x \leq 1\}$ |
| 'epanechnikov' | Epanechnikov | $f(x) = 0.75(1 - x^2)I\{ x \leq 1\}$ |
| 'normal' | Gaussian | $f(x) = \frac{1}{\sqrt{2\pi}} \exp(-0.5x^2)$ |
| 'triangle' | Triangular | $f(x) = (1 - x)I\{ x \leq 1\}$ |

If a cell is empty ([]), then the software did not fit a kernel distribution to the corresponding predictor.

PredictorNames — Predictor names

character vector

Predictor names, specified as a cell vector of character vectors. The order of the elements in PredictorNames corresponds to the order in X.

Data Types: cell

Prior — Class prior probabilities

numeric vector

Class prior probabilities, specified as a numeric row vector. Prior is a 1-by-K vector, and the order of its elements correspond to the elements of ClassNames.

fitcnb normalizes the prior probabilities you set using the name-value pair parameter 'Prior' so that $\text{sum}(\text{Prior}) = 1$.

The value of Prior does not change the best-fitting model. Therefore, you can reset Prior after training Mdl using dot notation, e.g., `Mdl.Prior = [0.2 0.8];`.

Data Types: double | single

ResponseName — Response name

character vector

Response name, specified as a character vector.

Data Types: char

ScoreTransform — Classification score transformation function

character vector | function handle

Classification score transformation function, specified as a character vector or function handle.

To change the score transformation function to e.g., *function*, use dot notation.

- For a built-in function, enter a character vector.

```
Mdl.ScoreTransform = 'function';
```

This table lists available, built-in functions.

| Value | Description |
|----------------------|---|
| 'doublelogit' | $1/(1 + e^{-2x})$ |
| 'invlogit' | $\log(x / (1-x))$ |
| 'ismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0 |
| 'logit' | $1/(1 + e^{-x})$ |
| 'none' or 'identity' | x (no transformation) |
| 'sign' | -1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$ |
| 'symmetric' | $2x - 1$ |
| 'symmetricismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1 |
| 'symmetriclogit' | $2/(1 + e^{-x}) - 1$ |

- For a MATLAB function, or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Data Types: char | function_handle

Support — Kernel smoother density support

cell vector

Kernel smoother density support, specified as a cell vector. **Support** has length equal to the number of predictors (`size(X,2)`). The cells represent the regions to apply the kernel density.

This table describes the supported options.

| Value | Description |
|---------------------------|---|
| 1-by-2 numeric row vector | For example, [L,U], where L and U are the finite lower and upper bounds, respectively, for the density support. |
| 'positive' | The density support is all positive real values. |
| 'unbounded' | The density support is all real values. |

If a cell is empty ([]), then the software did not fit a kernel distribution to the corresponding predictor.

Width — Kernel smoother window width

numeric matrix

Kernel smoother window width, specified as a numeric matrix. **Width** is a K -by- P matrix, where K is the number of classes in the data, and P is the number of predictors (`size(X,2)`).

$Width(k,j)$ is the kernel smoother window width for the kernel smoothing density of predictor j within class k . NaNs in column j indicate that the software did not fit predictor j using a kernel density.

Methods

| | |
|-----------------------------|--|
| <code>compareHoldout</code> | Compare accuracies of two classification models using new data |
| <code>edge</code> | Classification edge for naive Bayes classifiers |
| <code>logP</code> | Log unconditional probability density for naive Bayes classifier |
| <code>loss</code> | Classification error for naive Bayes classifier |
| <code>margin</code> | Classification margins for naive Bayes classifiers |
| <code>predict</code> | Predict labels using naive Bayes classification model |

Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects \(MATLAB\)](#).

Examples

Reduce the Size of Naive Bayes Classifiers

Full naive Bayes classifiers (i.e., `ClassificationNaiveBayes` models) hold the training data. For efficiency, you might not want to predict new labels using a large classifier. This example shows how to reduce the size of a full naive Bayes classifier.

Load the `ionosphere` data set.

```
load ionosphere
X = X(:,3:end); % Remove two predictors for stability
```

Train a naive Bayes classifier. Assume that each predictor is conditionally, normally distributed given its label. It is good practice to specify the order of the labels.

```
Mdl = fitcnb(X,Y,'ClassNames',{'b','g'})

Mdl =
  ClassificationNaiveBayes
      ResponseName: 'Y'
  CategoricalPredictors: []
      ClassNames: {'b' 'g'}
```

```

    ScoreTransform: 'none'
    NumObservations: 351
    DistributionNames: {1x32 cell}
    DistributionParameters: {2x32 cell}

```

Properties, Methods

`Mdl` is a `ClassificationNaiveBayes` model.

Reduce the size of the naive Bayes classifier.

```
CMdl = compact(Mdl)
```

```

CMdl =
  classreg.learning.classif.CompactClassificationNaiveBayes
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
    DistributionNames: {1x32 cell}
    DistributionParameters: {2x32 cell}

```

Properties, Methods

`CMdl` is a `CompactClassificationNaiveBayes` model.

Display how much memory each classifier uses.

```
whos('Mdl', 'CMdl')
```

| Name | Size | Bytes | Class |
|------|------|--------|---|
| CMdl | 1x1 | 15244 | classreg.learning.classif.CompactClassificationNaiveBayes |
| Mdl | 1x1 | 111374 | ClassificationNaiveBayes |

The full naive Bayes classifier (`Mdl`) is much larger than the compact naive Bayes classifier (`CMdl`).

You can remove `Mdl` from the MATLAB® Workspace, and pass `CMdl` and new predictor values to `predict` to efficiently label new observations.

Train and Cross Validate Naive Bayes Classifiers

Load the ionosphere data set.

```
load ionosphere
X = X(:,3:end); % Remove two predictors for stability
```

Train and cross validate a naive Bayes classifier. Assume that each predictor is conditionally, normally distributed given its label. It is good practice to specify the order of the classes.

```
rng(1); % For reproducibility
CVMdl = fitcnb(X,Y,'ClassNames',{ 'b', 'g'}, 'CrossVal', 'on')

CVMdl =
    classreg.learning.partition.ClassificationPartitionedModel
    CrossValidatedModel: 'NaiveBayes'
    PredictorNames: {1x32 cell}
    ResponseName: 'Y'
    NumObservations: 351
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
```

Properties, Methods

CVMdl is not a `ClassificationNaiveBayes` model, but a `ClassificationPartitionedModel` cross-validated, naive Bayes model. By default, the software implements 10-fold cross validation.

Alternatively, you can cross validate a trained `ClassificationNaiveBayes` model by passing it to `crossval`.

Inspect one of the trained folds using dot notation.

```
CVMdl.Trained{1}

ans =
    classreg.learning.classif.CompactClassificationNaiveBayes
    ResponseName: 'Y'
```

```
CategoricalPredictors: []  
    ClassNames: {'b' 'g'}  
    ScoreTransform: 'none'  
    DistributionNames: {1x32 cell}  
    DistributionParameters: {2x32 cell}
```

Properties, Methods

Each fold is a `CompactClassificationNaiveBayes` model trained on 90% of the data.

Estimate the generalization error.

```
genError = kfoldLoss(CVMdl)
```

```
genError = 0.1795
```

On average, the generalization error is approximately 17%.

One way to attempt reducing an unsatisfactory generalization error is to specify different conditional distributions for the predictors, or tune the parameters of the conditional distributions.

Definitions

Bag-of-Tokens Model

In the bag-of-tokens model, the value of predictor j is the nonnegative number of occurrences of token j in this observation. The number of categories (bins) in this multinomial model is the number of distinct tokens, that is, the number of predictors.

Naive Bayes

Naive Bayes is a classification algorithm that applies density estimation to the data.

The algorithm leverages Bayes theorem, and (naively) assumes that the predictors are conditionally independent, given the class. Though the assumption is usually violated in practice, naive Bayes classifiers tend to yield posterior distributions that are robust to

biased class density estimates, particularly where the posterior is 0.5 (the decision boundary) [1].

Naive Bayes classifiers assign observations to the most probable class (in other words, the maximum a posteriori decision rule). Explicitly, the algorithm:

- 1 Estimates the densities of the predictors within each class.
- 2 Models posterior probabilities according to Bayes rule. That is, for all $k = 1, \dots, K$,

$$\hat{P}(Y = k | X_1, \dots, X_P) = \frac{\pi(Y = k) \prod_{j=1}^P P(X_j | Y = k)}{\sum_{k=1}^K \pi(Y = k) \prod_{j=1}^P P(X_j | Y = k)},$$

where:

- Y is the random variable corresponding to the class index of an observation.
 - X_1, \dots, X_P are the random predictors of an observation.
 - $\pi(Y = k)$ is the prior probability that a class index is k .
- 3 Classifies an observation by estimating the posterior probability for each class, and then assigns the observation to the class yielding the maximum posterior probability.

If the predictors compose a multinomial distribution, then the posterior probability

$\hat{P}(Y = k | X_1, \dots, X_P) \propto \pi(Y = k) P_{mn}(X_1, \dots, X_P | Y = k)$, where $P_{mn}(X_1, \dots, X_P | Y = k)$ is the probability mass function of a multinomial distribution.

Algorithms

- If you specify 'Distribution', 'mn' when training Mdl using fitcnb, then the software fits a multinomial distribution using the bag-of-tokens model on page 32-2034. The software stores the probability that token j appears in class k in the property DistributionParameters{ k, j }. Using additive smoothing [2], the estimated probability is

$$P(\text{token } j \mid \text{class } k) = \frac{1 + c_{j|k}}{P + c_k},$$

where:

-

$$c_{j|k} = n_k \frac{\sum_{i: y_i \in \text{class } k} x_{ij} w_i}{\sum_{i \in \text{class } k} w_i};$$

which is the weighted number of occurrences of token j in class k .

- n_k is the number of observations in class k .

-

w_i is the weight for observation i . The software normalizes weights within a class such that they sum to the prior probability for that class.

-

$$c_k = \sum_{j=1}^P c_{j|k};$$

which is the total weighted number of occurrences of all tokens in class k .

- If you specify 'Distribution', 'mvmn' when training Mdl using fitcnb, then:

- 1 For each predictor, the software collects a list of the unique levels, stores the sorted list in `CategoricalLevels`, and considers each level a bin. Each predictor/class combination is a separate, independent multinomial random variable.
- 2 For predictor j in class k , the software counts instances of each categorical level using the list stored in `CategoricalLevels{j}`.
- 3 The software stores the probability that predictor j , in class k , has level L in the property `DistributionParameters{k, j}`, for all levels in `CategoricalLevels{j}`. Using additive smoothing [2], the estimated probability is

$$P(\text{predictor } j = L \mid \text{class } k) = \frac{1 + m_{j|k}(L)}{m_j + m_k},$$

where:

-

$m_{j|k}(L) = n_k \frac{\sum_{i: y_i \in \text{class } k} I\{x_{ij} = L\} w_i}{\sum_{i: y_i \in \text{class } k} w_i}$; which is the weighted number of observations for which predictor j equals L in class k .

- n_k is the number of observations in class k .
-
- $I\{x_{ij} = L\} = 1$ if $x_{ij} = L$, 0 otherwise.
-
- w_i is the weight for observation i . The software normalizes weights within a class such that they sum to the prior probability for that class.
- m_j is the number of distinct levels in predictor j .
- m_k is the weighted number of observations in class k .

CompactClassificationSVM

Compact support vector machine (SVM) for one-class and binary classification

Description

`CompactClassificationSVM` is a compact version of the support vector machine (SVM) classifier. The compact classifier does not include the data used for training the SVM classifier. Therefore, you cannot perform some tasks, such as cross-validation, using the compact classifier. Use a compact SVM classifier for tasks such as predicting the labels of new data.

Creation

Create a `CompactClassificationSVM` model from a full, trained `ClassificationSVM` classifier by using `compact`.

Properties

SVM Properties

Alpha — Trained classifier coefficients

numeric vector

This property is read-only.

Trained classifier coefficients, specified as an s -by-1 numeric vector. s is the number of support vectors in the trained classifier, `sum(Mdl.IsSupportVector)`.

`Alpha` contains the trained classifier coefficients from the dual problem, that is, the estimated Lagrange multipliers. If you remove duplicates by using the `RemoveDuplicates` name-value pair argument of `fitcsvm`, then for a given set of duplicate observations that are support vectors, `Alpha` contains one coefficient corresponding to the entire set. That is, MATLAB attributes a nonzero coefficient to one

observation from the set of duplicates and a coefficient of 0 to all other duplicate observations in the set.

Data Types: `single` | `double`

Beta — Linear predictor coefficients

numeric vector

This property is read-only.

Linear predictor coefficients, specified as a numeric vector. The length of `Beta` is equal to the number of predictors used to train the model.

MATLAB expands categorical variables in the predictor data using full dummy encoding. That is, MATLAB creates one dummy variable for each level of each categorical variable. `Beta` stores one value for each predictor variable, including the dummy variables. For example, if there are three predictors, one of which is a categorical variable with three levels, then `Beta` is a numeric vector containing five values.

If `KernelParameters.Function` is `'linear'`, then the classification score for the observation x is

$$f(x) = (x / s)' \beta + b.$$

`Mdl` stores β , b , and s in the properties `Beta`, `Bias`, and `KernelParameters.Scale`, respectively.

To estimate classification scores manually, you must first apply any transformations to the predictor data that were applied during training. Specifically, if you specify `'Standardize', true` when using `fitcsvm`, then you must standardize the predictor data manually by using the mean `Mdl.Mu` and standard deviation `Mdl.Sigma`, and then divide the result by the kernel scale in `Mdl.KernelParameters.Scale`.

All SVM functions, such as `resubPredict` and `predict`, apply any required transformation before estimation.

If `KernelParameters.Function` is not `'linear'`, then `Beta` is empty (`[]`).

Data Types: `single` | `double`

Bias — Bias term

scalar

This property is read-only.

Bias term, specified as a scalar.

Data Types: `single` | `double`

KernelParameters – Kernel parameters

structure array

This property is read-only.

Kernel parameters, specified as a structure array. The kernel parameters property contains the fields listed in this table.

| Field | Description |
|----------|--|
| Function | Kernel function used to compute the elements of the Gram matrix on page 32-2079. For details, see 'KernelFunction'. |
| Scale | Kernel scale parameter used to scale all elements of the predictor data on which the model is trained. For details, see 'KernelScale'. |

To display the values of `KernelParameters`, use dot notation. For example, `Mdl.KernelParameters.Scale` displays the kernel scale parameter value.

The software accepts `KernelParameters` as inputs and does not modify them.

Data Types: `struct`

SupportVectorLabels – Support vector class labels

s-by-1 numeric vector

This property is read-only.

Support vector class labels, specified as an *s*-by-1 numeric vector. *s* is the number of support vectors in the trained classifier, `sum(Mdl.IsSupportVector)`.

A value of +1 in `SupportVectorLabels` indicates that the corresponding support vector is in the positive class (`ClassNames{2}`). A value of -1 indicates that the corresponding support vector is in the negative class (`ClassNames{1}`).

If you remove duplicates by using the `RemoveDuplicates` name-value pair argument of `fitsvm`, then for a given set of duplicate observations that are support vectors, `SupportVectorLabels` contains one unique support vector label.

Data Types: `single` | `double`

SupportVectors — Support vectors

s-by-*p* numeric matrix

This property is read-only.

Support vectors in the trained classifier, specified as an *s*-by-*p* numeric matrix. *s* is the number of support vectors in the trained classifier, `sum(Mdl.IsSupportVector)`, and *p* is the number of predictor variables in the predictor data.

`SupportVectors` contains rows of the predictor data *X* that MATLAB considers to be support vectors. If you specify `'Standardize'`, `true` when training the SVM classifier using `fitcsvm`, then `SupportVectors` contains the standardized rows of *X*.

If you remove duplicates by using the `RemoveDuplicates` name-value pair argument of `fitcsvm`, then for a given set of duplicate observations that are support vectors, `SupportVectors` contains one unique support vector.

Data Types: `single` | `double`

Other Classification Properties

CategoricalPredictors — Categorical predictor indices

vector of positive integers | `[]`

This property is read-only.

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

ClassNames — Unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Unique class labels used in training the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors.

Data Types: `single` | `double` | `logical` | `char` | `cell` | `categorical`

Cost — Misclassification cost

numeric square matrix

This property is read-only.

Misclassification cost, specified as a numeric square matrix, where $\text{Cost}(i, j)$ is the cost of classifying a point into class j if its true class is i .

During training, the software updates the prior probabilities by incorporating the penalties described in the cost matrix.

- For two-class learning, Cost always has this form: $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$. The rows correspond to the true class and the columns correspond to the predicted class. The order of the rows and columns of Cost corresponds to the order of the classes in `ClassNames`.
- For one-class learning, $\text{Cost} = 0$.

For more details, see Algorithms on page 32-531.

Data Types: `double`

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

This property is read-only.

Expanded predictor names, specified as a cell array of character vectors.

If the model uses dummy variable encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

Data Types: `char` | `cell`

Mu — Predictor means

numeric vector | []

This property is read-only.

Predictor means, specified as a numeric vector. If you specify `'Standardize', 1` or `'Standardize', true` when you train an SVM classifier using `fitcsvm`, then the length of `Mu` is equal to the number of predictors.

MATLAB expands categorical variables in the predictor data using full dummy encoding. That is, MATLAB creates one dummy variable for each level of each categorical variable. `Mu` stores one value for each predictor variable, including the dummy variables. However, MATLAB does not standardize the columns that contain categorical variables.

If you set `'Standardize'`, `false` when you train the SVM classifier using `fitcsvm`, then `Mu` is an empty vector (`[]`).

Data Types: `single` | `double`

PredictorNames — Predictor variable names

cell array of character vectors

This property is read-only.

Predictor variable names, specified as a cell array of character vectors. The order of the elements of `PredictorNames` corresponds to the order in which the predictor names appear in the training data.

Data Types: `char` | `cell`

Prior — Prior probabilities

numeric vector

This property is read-only.

Prior probabilities for each class, specified as a numeric vector. The order of the elements of `Prior` corresponds to the elements of `Mdl.ClassNames`.

For two-class learning, if you specify a cost matrix, then the software updates the prior probabilities by incorporating the penalties described in the cost matrix.

For more details, see Algorithms on page 32-531.

Data Types: `single` | `double`

ScoreTransform — Score transformation

character vector | function handle

Score transformation, specified as a character vector or function handle. `ScoreTransform` represents a built-in transformation function or a function handle for transforming predicted classification scores.

To change the score transformation function to *function*, for example, use dot notation.

- For a built-in function, enter a character vector.

```
Mdl.ScoreTransform = 'function';
```

This table describes the available built-in functions.

| Value | Description |
|----------------------|---|
| 'doublelogit' | $1/(1 + e^{-2x})$ |
| 'invlogit' | $\log(x / (1-x))$ |
| 'ismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0 |
| 'logit' | $1/(1 + e^{-x})$ |
| 'none' or 'identity' | x (no transformation) |
| 'sign' | -1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$ |
| 'symmetric' | $2x - 1$ |
| 'symmetricismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1 |
| 'symmetriclogit' | $2/(1 + e^{-x}) - 1$ |

- For a MATLAB function or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Data Types: char | function_handle

Sigma — Predictor standard deviations

[] (default) | numeric vector

This property is read-only.

Predictor standard deviations, specified as a numeric vector.

If you specify `'Standardize'`, `true` when you train the SVM classifier using `fitcsvm`, then the length of `Sigma` is equal to the number of predictor variables.

MATLAB expands categorical variables in the predictor data using full dummy encoding. That is, MATLAB creates one dummy variable for each level of each categorical variable. `Sigma` stores one value for each predictor variable, including the dummy variables. However, MATLAB does not standardize the columns that contain categorical variables.

If you set `'Standardize'`, `false` when you train the SVM classifier using `fitcsvm`, then `Sigma` is an empty vector (`[]`).

Data Types: `single` | `double`

Object Functions

| | |
|------------------------------------|---|
| <code>compareHoldout</code> | Compare accuracies of two classification models using new data |
| <code>discardSupportVectors</code> | Discard support vectors for linear support vector machine (SVM) classifier |
| <code>edge</code> | Find classification edge for support vector machine (SVM) classifier |
| <code>fitPosterior</code> | Fit posterior probabilities for compact support vector machine (SVM) classifier |
| <code>loss</code> | Find classification error for support vector machine (SVM) classifier |
| <code>margin</code> | Find classification margins for support vector machine (SVM) classifier |
| <code>predict</code> | Predict labels using support vector machine (SVM) classifier |

Examples

Reduce Size of SVM Classifiers

Reduce the size of a full SVM classifier by removing the training data. Full SVM classifiers (that is, `ClassificationSVM` classifiers) hold the training data. To improve efficiency, use a smaller classifier.

Load the `ionosphere` data set.

```
load ionosphere
```

Train an SVM classifier. Standardize the predictor data and specify the order of the classes.

```
SVMMModel = fitcsvm(X,Y,'Standardize',true,...
    'ClassNames',{'b','g'})
```

```
SVMMModel =
  ClassificationSVM
    ResponseName: 'Y'
  CategoricalPredictors: []
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
  NumObservations: 351
    Alpha: [90x1 double]
    Bias: -0.1343
  KernelParameters: [1x1 struct]
    Mu: [1x34 double]
    Sigma: [1x34 double]
  BoxConstraints: [351x1 double]
  ConvergenceInfo: [1x1 struct]
  IsSupportVector: [351x1 logical]
  Solver: 'SMO'
```

Properties, Methods

SVMMModel is a ClassificationSVM classifier.

Reduce the size of the SVM classifier.

```
CompactSVMMModel = compact(SVMMModel)
```

```
CompactSVMMModel =
  classreg.learning.classif.CompactClassificationSVM
    ResponseName: 'Y'
  CategoricalPredictors: []
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
    Alpha: [90x1 double]
    Bias: -0.1343
  KernelParameters: [1x1 struct]
    Mu: [1x34 double]
    Sigma: [1x34 double]
  SupportVectors: [90x34 double]
```

```
SupportVectorLabels: [90x1 double]
```

Properties, Methods

`CompactSVMModel` is a `CompactClassificationSVM` classifier.

Display the amount of memory each classifier uses.

```
whos('SVMModel','CompactSVMModel')
```

| Name | Size | Bytes | Class |
|------------------------------|------|--------|---|
| <code>CompactSVMModel</code> | 1x1 | 30512 | <code>classreg.learning.classif.CompactClassif</code> |
| <code>SVMModel</code> | 1x1 | 140834 | <code>ClassificationSVM</code> |

The full SVM classifier (`SVMModel`) is more than four times larger than the compact SVM classifier (`CompactSVMModel`).

To label new observations efficiently, you can remove `SVMModel` from the MATLAB® Workspace, and then pass `CompactSVMModel` and new predictor values to `predict`.

To further reduce the size of your compact SVM classifier, use the `discardSupportVectors` function to discard support vectors.

Train and Cross-Validate SVM Classifier

Load the ionosphere data set.

```
load ionosphere
```

Train and cross-validate an SVM classifier. Standardize the predictor data and specify the order of the classes.

```
rng(1); % For reproducibility
CVSVMModel = fitcsvm(X,Y,'Standardize',true,...
    'ClassNames',{'b','g'},'CrossVal','on')

CVSVMModel =
    classreg.learning.partition.ClassificationPartitionedModel
    CrossValidatedModel: 'SVM'
```

```

    PredictorNames: {1x34 cell}
    ResponseName: 'Y'
    NumObservations: 351
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'

```

Properties, Methods

`CVSVMModel` is a `ClassificationPartitionedModel` cross-validated SVM classifier. By default, the software implements 10-fold cross-validation.

Alternatively, you can cross-validate a trained `ClassificationSVM` classifier by passing it to `crossval`.

Inspect one of the trained folds using dot notation.

```
CVSVMModel.Trained{1}
```

```

ans =
    classreg.learning.classif.CompactClassificationSVM
        ResponseName: 'Y'
    CategoricalPredictors: []
        ClassNames: {'b' 'g'}
        ScoreTransform: 'none'
            Alpha: [78x1 double]
            Bias: -0.2209
    KernelParameters: [1x1 struct]
        Mu: [1x34 double]
        Sigma: [1x34 double]
    SupportVectors: [78x34 double]
    SupportVectorLabels: [78x1 double]

```

Properties, Methods

Each fold is a `CompactClassificationSVM` classifier trained on 90% of the data.

Estimate the generalization error.

```
genError = kfoldLoss(CVSVMModel)
```

```
genError = 0.1168
```

On average, the generalization error is approximately 12%.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.
- When you train an SVM model by using `fitcsvm`, the following restrictions apply.
 - The class labels input argument value (Y) cannot be a categorical array.
 - Code generation does not support categorical predictors. You cannot supply training data in a table that contains at least one categorical predictor, and you

cannot use the 'CategoricalPredictors' name-value pair argument. To dummy-code variables that you want treated as categorical, preprocess the categorical data by using `dummyvar` before fitting the model.

- The value of the 'ClassNames' name-value pair argument cannot be a categorical array.
- The value of the 'ScoreTransform' name-value pair argument cannot be an anonymous function. For generating code that predicts posterior probabilities given new observations, pass a trained SVM model to `fitPosterior` or `fitSVMPosterior`. The `ScoreTransform` property of the returned model contains an anonymous function that represents the score-to-posterior-probability function and is configured for code generation.

For code generation examples, see “Code Generation Workflow for Prediction” on page 31-5 and “Specify Variable-Sized Arguments for Code Generation” on page 31-48. For more information, see topics in “Code Generation”.

Introduced in R2014a

CompactClassificationTree class

Compact classification tree

Description

Compact version of a classification tree (of class `ClassificationTree`). The compact version does not include the data for training the classification tree. Therefore, you cannot perform some tasks with a compact classification tree, such as cross validation. Use a compact classification tree for making predictions (classifications) of new data.

Construction

`ctree = compact(tree)` constructs a compact decision tree from a full decision tree.

Input Arguments

tree

A decision tree constructed using `fitctree`.

Properties

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

CategoricalSplits

An n -by-2 cell array, where n is the number of categorical splits in `tree`. Each row in `CategoricalSplits` gives left and right values for a categorical split. For each branch

node with categorical split j based on a categorical predictor variable z , the left child is chosen if z is in `CategoricalSplits(j,1)` and the right child is chosen if z is in `CategoricalSplits(j,2)`. The splits are in the same order as nodes of the tree. Find the nodes for these splits by selecting 'categorical' cuts from top to bottom in the `CutType` property.

Children

An n -by-2 array containing the numbers of the child nodes for each node in `tree`, where n is the number of nodes. Leaf nodes have child node 0.

ClassCount

An n -by- k array of class counts for the nodes in `tree`, where n is the number of nodes and k is the number of classes. For any node number i , the class counts `ClassCount(i,:)` are counts of observations (from the data used in fitting the tree) from each class satisfying the conditions for node i .

ClassNames

List of the elements in Y with duplicates removed. `ClassNames` can be a numeric vector, vector of categorical variables, logical vector, character array, or cell array of character vectors. `ClassNames` has the same data type as the data in the argument Y .

If the value of a property has at least one dimension of length k , then `ClassNames` indicates the order of the elements along that dimension (e.g., `Cost` and `Prior`).

ClassProbability

An n -by- k array of class probabilities for the nodes in `tree`, where n is the number of nodes and k is the number of classes. For any node number i , the class probabilities `ClassProbability(i,:)` are the estimated probabilities for each class for a point satisfying the conditions for node i .

Cost

Square matrix, where `Cost(i,j)` is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`. The number of rows and columns in `Cost` is the number of unique classes in the response. This property is read-only.

CutCategories

An n -by-2 cell array of the categories used at branches in `tree`, where n is the number of nodes. For each branch node i based on a categorical predictor variable x , the left child is chosen if x is among the categories listed in `CutCategories{i,1}`, and the right child is chosen if x is among those listed in `CutCategories{i,2}`. Both columns of `CutCategories` are empty for branch nodes based on continuous predictors and for leaf nodes.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

CutPoint

An n -element vector of the values used as cut points in `tree`, where n is the number of nodes. For each branch node i based on a continuous predictor variable x , the left child is chosen if $x < \text{CutPoint}(i)$ and the right child is chosen if $x \geq \text{CutPoint}(i)$. `CutPoint` is NaN for branch nodes based on categorical predictors and for leaf nodes.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

CutType

An n -element cell array indicating the type of cut at each node in `tree`, where n is the number of nodes. For each node i , `CutType{i}` is:

- 'continuous' — If the cut is defined in the form $x < v$ for a variable x and cut point v .
- 'categorical' — If the cut is defined by whether a variable x takes a value in a set of categories.
- '' — If i is a leaf node.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

CutPredictor

An n -element cell array of the names of the variables used for branching in each node in `tree`, where n is the number of nodes. These variables are sometimes known as *cut variables*. For leaf nodes, `CutPredictor` contains an empty character vector.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

ExpandedPredictorNames

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

IsBranchNode

An n -element logical vector that is `true` for each branch node and `false` for each leaf node of `tree`.

NodeClass

An n -element cell array with the names of the most probable classes in each node of `tree`, where n is the number of nodes in the tree. Every element of this array is a character vector equal to one of the class names in `ClassNames`.

NodeError

An n -element vector of the errors of the nodes in `tree`, where n is the number of nodes. `NodeError(i)` is the misclassification probability for node i .

NodeProbability

An n -element vector of the probabilities of the nodes in `tree`, where n is the number of nodes. The probability of a node is computed as the proportion of observations from the original data that satisfy the conditions for the node. This proportion is adjusted for any prior probabilities assigned to each class.

NodeRisk

An n -element vector of the risk of the nodes in the tree, where n is the number of nodes. The risk for each node is the measure of impurity (Gini index or deviance) for this node weighted by the node probability. If the tree is grown by twoing, the risk for each node is zero.

NodeSize

An n -element vector of the sizes of the nodes in `tree`, where n is the number of nodes. The size of a node is defined as the number of observations from the data used to create the tree that satisfy the conditions for the node.

NumNodes

The number of nodes in `tree`.

Parent

An n -element vector containing the number of the parent node for each node in `tree`, where n is the number of nodes. The parent of the root node is 0.

PredictorNames

A cell array of names for the predictor variables, in the order in which they appear in X .

Prior

Numeric vector of prior probabilities for each class. The order of the elements of `Prior` corresponds to the order of the classes in `ClassNames`. The number of elements of `Prior` is the number of unique classes in the response. This property is read-only.

PruneAlpha

Numeric vector with one element per pruning level. If the pruning level ranges from 0 to M , then `PruneAlpha` has $M + 1$ elements sorted in ascending order. `PruneAlpha(1)` is for pruning level 0 (no pruning), `PruneAlpha(2)` is for pruning level 1, and so on.

PruneList

An n -element numeric vector with the pruning levels in each node of `tree`, where n is the number of nodes. The pruning levels range from 0 (no pruning) to M , where M is the distance between the deepest leaf and the root node.

ResponseName

Character vector describing the response variable Y .

ScoreTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means $@(x)x$. For a list of built-in transformation functions and the syntax of custom transformation functions, see `fitctree`.

Add or change a `ScoreTransform` function using dot notation:

```
ctree.ScoreTransform = 'function'
or
ctree.ScoreTransform = @function
```

SurrogateCutCategories

An n -element cell array of the categories used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutCategories{k}` is a cell array. The length of `SurrogateCutCategories{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutCategories{k}` is either an empty character vector for a continuous surrogate predictor, or is a two-element cell array with categories for a categorical surrogate predictor. The first element of this two-element cell array lists categories assigned to the left child by this surrogate split and the second element of this two-element cell array lists categories assigned to the right child by this surrogate split. The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutVar`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutCategories` contains an empty cell.

SurrogateCutFlip

An n -element cell array of the numeric cut assignments used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrSurrogateCutFlip{k}` is a numeric vector. The length of `SurrogateCutFlip{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutFlip{k}` is either zero for a categorical surrogate predictor, or a numeric cut assignment for a continuous surrogate predictor. The numeric cut assignment can be either -1 or $+1$. For every surrogate split with a numeric cut C based on a continuous predictor variable Z , the left child is chosen if $Z < C$ and the cut assignment for this surrogate split is $+1$, or if $Z \geq C$ and the cut assignment for this surrogate split is -1 . Similarly, the right child is chosen if $Z \geq C$ and the cut assignment for this surrogate split is $+1$, or if $Z < C$ and the cut assignment for this surrogate split is -1 . The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split

variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutFlip` contains an empty array.

SurrogateCutPoint

An n -element cell array of the numeric values used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutPoint{k}` is a numeric vector. The length of `SurrogateCutPoint{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutPoint{k}` is either NaN for a categorical surrogate predictor, or a numeric cut for a continuous surrogate predictor. For every surrogate split with a numeric cut C based on a continuous predictor variable Z , the left child is chosen if $Z < C$ and `SurrogateCutFlip` for this surrogate split is $+1$, or if $Z \geq C$ and `SurrogateCutFlip` for this surrogate split is -1 . Similarly, the right child is chosen if $Z \geq C$ and `SurrogateCutFlip` for this surrogate split is $+1$, or if $Z < C$ and `SurrogateCutFlip` for this surrogate split is -1 . The order of the surrogate split variables at each node is matched to the order of variables returned by `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutPoint` contains an empty cell.

SurrogateCutType

An n -element cell array indicating types of surrogate splits at each node in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutType{k}` is a cell array with the types of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutType` contains an empty cell. A surrogate split type can be either 'continuous' if the cut is defined in the form $Z < V$ for a variable Z and cut point V or 'categorical' if the cut is defined by whether Z takes a value in a set of categories.

SurrogateCutPredictor

An n -element cell array of the names of the variables used for surrogate splits in each node in `tree`, where n is the number of nodes in `tree`. Every element of `SurrogateCutPredictor` is a cell array with the names of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutPredictor` contains an empty cell.

SurrogatePredictorAssociation

An n -element cell array of the predictive measures of association for surrogate splits in tree, where n is the number of nodes in tree. For each node k , SurrogatePredictorAssociation{k} is a numeric vector. The length of SurrogatePredictorAssociation{k} is equal to the number of surrogate predictors found at this node. Every element of SurrogatePredictorAssociation{k} gives the predictive measure of association between the optimal split and this surrogate split. The order of the surrogate split variables at each node is the order of variables in SurrogateCutPredictor. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrogatePredictorAssociation contains an empty cell.

Methods

| | |
|----------------------|--|
| compareHoldout | Compare accuracies of two classification models using new data |
| edge | Classification edge |
| loss | Classification error |
| margin | Classification margins |
| surrogateAssociation | Mean predictive measure of association for surrogate splits in decision tree |

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Construct a Compact Classification Tree

Construct a compact classification tree for the Fisher iris data.

```
load fisheriris
tree = fitctree(meas,species);
ctree = compact(tree);
```

Compare the size of the resulting tree to that of the original tree.

```
t = whos('tree'); % t.bytes = size of tree in bytes
c = whos('ctree'); % c.bytes = size of ctree in bytes
[c.bytes t.bytes]

ans = 1x2
```

```
         4572         11260
```

The compact tree is smaller than the original tree.

Definitions

Impurity and Node Error

ClassificationTree splits nodes based on either impurity or node error.

Impurity means one of several things, depending on your choice of the SplitCriterion name-value pair argument:

- Gini's Diversity Index (gdi) — The Gini index of a node is

$$1 - \sum_i p^2(i),$$

where the sum is over the classes i at the node, and $p(i)$ is the observed fraction of classes with class i that reach the node. A node with just one class (a pure node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance ('deviance') — With $p(i)$ defined the same as for the Gini index, the deviance of a node is

$$-\sum_i p(i) \log_2 p(i).$$

A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule ('twoing') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let $L(i)$ denote the fraction of members of class i in the left child node after a split, and $R(i)$ denote the fraction of members of class i in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R) \left(\sum_i |L(i) - R(i)| \right)^2,$$

where $P(L)$ and $P(R)$ are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and hence similar to the parent node, and so the split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If j is the class with the largest number of training samples at a node, the node error is

$$1 - p(j).$$

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `predict` function supports code generation.
- When you train a classification tree using `fitctree`, the following restrictions apply.
 - The class labels input argument value (Y) cannot be a categorical array.
 - Code generation does not support categorical predictors. You cannot supply training data in a table that contains at least one categorical predictor, and you cannot use the 'CategoricalPredictors' name-value pair argument. To dummy-code variables that you want treated as categorical, preprocess the categorical data by using `dummyvar` before fitting the model.

- The value of the 'ClassNames' name-value pair argument cannot be a categorical array.
- The value of the 'ScoreTransform' name-value pair argument cannot be an anonymous function.
- You cannot use surrogate splits, that is, the value of the 'Surrogate' name-value pair argument must be 'off'.

For code generation examples, see “Code Generation Workflow for Prediction” on page 31-5 and “Specify Variable-Sized Arguments for Code Generation” on page 31-48. For more information, see topics in “Code Generation”.

Introduced in R2011a

CompactLinearModel class

Compact linear regression model class

Description

`CompactLinearModel` is a compact linear regression model object. It consumes less memory than a full, fitted linear regression model (`LinearModel` model) because it does not store the data used to fit the model. Because the compact model does not store the input data, you cannot use it to perform certain tasks. However, you can use a compact linear regression model to predict responses using new input data.

Construction

`compactMdl = compact(mdl)` returns a compact linear regression model `compactMdl` from the full, fitted linear regression model `mdl`. For more information, see `compact`.

Input Arguments

mdl — Full, fitted linear regression model

`LinearModel` object

Full, fitted linear regression model, specified as a `LinearModel` object.

Properties

CoefficientCovariance — Covariance matrix of coefficient estimates

numeric matrix

Covariance matrix of coefficient estimates, stored as a p -by- p matrix of numeric values. p is the number of coefficients in the fitted model.

CoefficientNames — Coefficient names

cell array of character vectors

Coefficient names, stored as a cell array of character vectors containing a label for each coefficient.

Coefficients — Coefficient values

table

Coefficient values, stored as a table. `Coefficients` has one row for each coefficient and the following columns:

- `Estimate` — Estimated coefficient value
- `SE` — Standard error of the estimate
- `tStat` — t statistic for a test that the coefficient is zero
- `pValue` — p -value for the t statistic

To obtain any of these columns as a vector, index into the property using dot notation. For example, in `mdl` the estimated coefficient vector is

```
beta = mdl.Coefficients.Estimate
```

Use `coefTest` to perform other tests on the coefficients.

DFE — Degrees of freedom for error

positive integer value

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients, stored as a positive integer value.

Formula — Model information

`LinearFormula` object | `NonLinearFormula` object

Model information, stored as a `LinearFormula` object or `NonLinearFormula` object. If you fit a linear or generalized linear regression model, then `Formula` is a `LinearFormula` object. If you fit a nonlinear regression model, then `Formula` is a `NonLinearFormula` object.

LogLikelihood — Log likelihood

numeric value

Log likelihood of the model distribution at the response values, stored as a numeric value. The mean is fitted from the model, and other parameters are estimated as part of the model fit.

ModelCriterion — Criterion for model comparison

structure

Criterion for model comparison, stored as a structure with the following fields:

- **AIC** — Akaike information criterion. $AIC = -2 \cdot \log L + 2 \cdot m$, where $\log L$ is the loglikelihood and m is the number of estimated parameters.
- **AICc** — Akaike information criterion corrected for the sample size. $AICc = AIC + (2 \cdot m \cdot (m + 1)) / (n - m - 1)$, where n is the number of observations.
- **BIC** — Bayesian information criterion. $BIC = -2 \cdot \log L + m \cdot \log(n)$.
- **CAIC** — Consistent Akaike information criterion. $CAIC = -2 \cdot \log L + m \cdot (\log(n) + 1)$.

Information criteria are model selection tools that you can use to compare multiple models fit to the same data. These criteria are likelihood-based measures of model fit that include a penalty for complexity (specifically, the number of parameters). Different information criteria are distinguished by the form of the penalty.

When you compare multiple models, the model with the lowest information criterion value is the best-fitting model. The best-fitting model can vary depending on the criterion used for model comparison.

To obtain any of the criterion values as a scalar, index into the property by using dot notation. For example, in the model `mdl`, the AIC value `aic` is:

```
aic = mdl.ModelCriterion.AIC
```

MSE — Mean squared error

numeric value

Mean squared error (residuals), stored as a numeric value. Mean square error is calculated as $MSE = SSE / DFE$, where MSE is the mean square error, SSE is the sum of squared errors, and DFE is the degrees of freedom.

NumCoefficients — Number of model coefficients

positive integer

Number of model coefficients, stored as a positive integer. `NumCoefficients` includes coefficients that are set to zero when the model terms are rank deficient.

NumEstimatedCoefficients — Number of estimated coefficients

positive integer

Number of estimated coefficients in the model, stored as a positive integer. `NumEstimatedCoefficients` does not include coefficients that are set to zero when the model terms are rank deficient. `NumEstimatedCoefficients` is the degrees of freedom for regression.

NumObservations — Number of observations

positive integer

Number of observations the fitting function used in fitting, stored as a positive integer. This is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the `Excluded` name-value pair) or rows with missing values.

NumPredictors — Number of predictor variables

positive integer

Number of predictor variables used to fit the model, stored as a positive integer.

NumVariables — Number of variables

positive integer

Number of variables in the input data, stored as a positive integer. `NumVariables` is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

PredictorNames — Names of predictors used to fit the model

cell array of character vectors

Names of predictors used to fit the model, stored as a cell array of character vectors.

ResponseName — Response variable name

character vector

Response variable name, stored as a character vector.

RMSE — Root mean squared error

numeric value

Root mean squared error (residuals), stored as a numeric value. The root mean squared error (RMSE) is equal to $RMSE = \sqrt{MSE}$, where MSE is the mean squared error.

Robust — Robust fit information

structure

Robust fit information, stored as a structure with the following fields:

| Field | Description |
|---------|--|
| WgtFun | Robust weighting function, such as 'bisquare' (see <code>robustfit</code>) |
| Tune | Value specified for tuning parameter (can be []) |
| Weights | Vector of weights used in final iteration of robust fit. This field is empty for compacted <code>CompactLinearModel</code> models. |

This structure is empty unless `fitlm` constructed the model using robust regression.

Rsquared — R-squared value for the model

structure

R-squared value for the model, stored as a structure.

For a linear or nonlinear model, `Rsquared` is a structure with two fields:

- `Ordinary` — Ordinary (unadjusted) R-squared
- `Adjusted` — R-squared adjusted for the number of coefficients

For a generalized linear model, `Rsquared` is a structure with five fields:

- `Ordinary` — Ordinary (unadjusted) R-squared
- `Adjusted` — R-squared adjusted for the number of coefficients
- `LLR` — Log-likelihood ratio
- `Deviance` — Deviance
- `AdjGeneralized` — Adjusted generalized R-squared

The R-squared value is the proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:

$$Rsquared = SSR/SST = 1 - SSE/SST.$$

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in `mdl` is

```
r2 = mdl.Rsquared.Adjusted
```

SSE — Sum of squared errors

numeric value

Sum of squared errors (residuals), stored as a numeric value.

The Pythagorean theorem implies

$$SST = SSE + SSR.$$

SSR — Regression sum of squares

numeric value

Regression sum of squares, stored as a numeric value. The regression sum of squares is equal to the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies

$$SST = SSE + SSR.$$

SST — Total sum of squares

numeric value

Total sum of squares, stored as a numeric value. The total sum of squares is equal to the sum of squared deviations of response vector y from $\text{mean}(y)$.

The Pythagorean theorem implies

$$SST = SSE + SSR.$$

VariableInfo — Information about input variables

table

Information about input variables contained in `Variables`, stored as a table with one row for each model term and the following columns.

| Field | Description |
|-------|--|
| Class | Character vector giving variable class, such as 'double' |

| Field | Description |
|---------------|--|
| Range | Cell array giving variable range: <ul style="list-style-type: none"> • Continuous variable — Two-element vector [<i>min</i>, <i>max</i>], the minimum and maximum values • Categorical variable — Cell array of distinct variable values |
| InModel | Logical vector, where <code>true</code> indicates the variable is in the model |
| IsCategorical | Logical vector, where <code>true</code> indicates a categorical variable |

VariableNames — Names of variables used in fit

cell array of character vectors

Names of variables used in fit, stored as a cell array of character vectors.

- If the fit is based on a table or dataset, this property provides the names of the variables in that table or dataset.
- If the fit is based on a predictor matrix and response vector, `VariableNames` is the values in the `VarNames` name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

Methods

| | |
|------------------------------|---|
| <code>anova</code> | Analysis of variance for linear model |
| <code>coefCI</code> | Confidence intervals of coefficient estimates of linear model |
| <code>coefTest</code> | Linear hypothesis test on linear regression model coefficients |
| <code>disp</code> | Display linear regression model |
| <code>feval</code> | Evaluate linear regression model prediction |
| <code>plotEffects</code> | Plot main effects of each predictor in linear regression model |
| <code>plotInteraction</code> | Plot interaction effects of two predictors in linear regression model |
| <code>plotSlice</code> | Plot of slices through fitted linear regression surface |
| <code>predict</code> | Predict response of linear regression model |
| <code>random</code> | Simulate responses for linear regression model |

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Compact a Linear Regression Model

This example shows how to reduce the size of a full, fitted linear regression model by discarding the sample data and some information related to the fitting process.

Load the data into the workspace.

```
load(fullfile(matlabroot, 'examples', 'stats', 'largedata4reg.mat'))
```

The simulated sample data contains 15,000 observations and 45 predictor variables.

Fit a simple linear regression model to the data.

```
mdl = fitlm(X,Y)
```

```
mdl =
```

```
Linear regression model:
```

```
    y ~ [Linear formula with 46 terms in 45 predictors]
```

```
Estimated Coefficients:
```

Number of observations: 15000, Error degrees of freedom: 14954
 Root Mean Squared Error: 0.00151
 R-squared: 1, Adjusted R-Squared 1
 F-statistic vs. constant model: 2.82e+08, p-value = 0

The compact model discards the original sample data and some information related to the fitting process.

Compare the size of the full model `mdl` and the compact model `compactMdl`.

```
vars = whos('compactMdl','mdl');
[vars(1).bytes,vars(2).bytes]
```

```
ans = 1x2
```

```
83329    11410264
```

The compacted model consumes less memory than the full model.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `predict` and `random` functions support code generation.
- When you fit a model by using `fitlm` or `stepwiselm`, you cannot supply training data in a table that contains at least one categorical predictor, and you cannot use the `'CategoricalVars'` name-value pair argument. Code generation does not support categorical predictors. To dummy-code variables that you want treated as categorical, preprocess the categorical data by using `dummyvar` before fitting the model.

For code generation examples, see “Code Generation Workflow for Prediction” on page 31-5 and “Specify Variable-Sized Arguments for Code Generation” on page 31-48. For more information, see topics in “Code Generation”.

Introduced in R2016a

CompactGeneralizedLinearModel class

Compact generalized linear regression model class

Description

`CompactGeneralizedLinearModel` is a compact generalized linear regression model object. It consumes less memory than a full generalized linear regression model (`GeneralizedLinearModel`) because it does not store the data used to fit the model. The compact model does not store the input data, so you cannot use it to perform certain tasks. However, you can use a compact generalized linear regression model to predict responses using new input data.

Fitting operations (`fitlm`, `fitglm`, ...) automatically use compact objects when you work with tall arrays. Fitting operations with in-memory tables and arrays produce full objects. You can use the `compact` method to make them smaller.

Construction

`compactMdl = compact(mdl)` returns a compact generalized linear regression model `compactMdl` from the full generalized linear regression model `mdl`. For more information, see `compact`.

Input Arguments

mdl — Full generalized linear regression model

`GeneralizedLinearModel` object

Full generalized linear regression model, specified as a `GeneralizedLinearModel` object.

Properties

CoefficientCovariance — Covariance matrix of coefficient estimates

numeric matrix

Covariance matrix of coefficient estimates, stored as a p -by- p matrix of numeric values. p is the number of coefficients in the fitted model.

CoefficientNames — Coefficient names

cell array of character vectors

Coefficient names, stored as a cell array of character vectors containing a label for each coefficient.

Coefficients — Coefficient values

table

Coefficient values, stored as a table. `Coefficients` has one row for each coefficient and the following columns:

- `Estimate` — Estimated coefficient value
- `SE` — Standard error of the estimate
- `tStat` — t statistic for a test that the coefficient is zero
- `pValue` — p -value for the t statistic

To obtain any of these columns as a vector, index into the property using dot notation. For example, in `mdl` the estimated coefficient vector is

```
beta = mdl.Coefficients.Estimate
```

Use `coefTest` to perform other tests on the coefficients.

Deviance — Deviance of fit

numeric value

Deviance of fit, stored as a numeric value. Deviance is useful for comparing two models when one is a special case of the other. The difference between the deviance of the two models has a chi-square distribution with degrees of freedom equal to the difference in the number of estimated parameters between the two models. For more information on deviance, see “Deviance” on page 32-2780.

DFE — Degrees of freedom for error

positive integer value

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients, stored as a positive integer value.

Dispersion — Scale factor of the variance of the response

structure

Scale factor of the variance of the response, stored as a structure. `Dispersion` multiplies the variance function for the distribution.

For example, the variance function for the binomial distribution is $p(1-p)/n$, where p is the probability parameter and n is the sample size parameter. If `Dispersion` is near 1, the variance of the data appears to agree with the theoretical variance of the binomial distribution. If `Dispersion` is larger than 1, the data are “overdispersed” relative to the binomial distribution.

DispersionEstimated — Flag to indicate use of dispersion scale factor

logical value

Flag to indicate use of dispersion scale factor, stored as a logical value. Use `DispersionEstimated` to indicate whether `fitglm` used the `Dispersion` scale factor to compute standard errors for the coefficients in `Coefficients.SE`. If `DispersionEstimated` is false, then `fitglm` used the theoretical value of the variance.

- `DispersionEstimated` can be false only for 'binomial' or 'poisson' distributions.
- To set `DispersionEstimated`, set the `DispersionFlag` name-value pair in `fitglm`.

Distribution — Generalized distribution information

structure

Generalized distribution information, stored as a structure with the following fields relating to the generalized distribution.

| Field | Description |
|-------|---|
| Name | Name of the distribution. Options are: 'normal', 'binomial', 'poisson', 'gamma', or 'inverse gaussian'. |

| Field | Description |
|------------------|---|
| DevianceFunction | Function that computes the components of the deviance as a function of the fitted parameter values and the response values. |
| VarianceFunction | Function that computes the theoretical variance for the distribution as a function of the fitted parameter values. When <code>DispersionEstimated</code> is true, <code>Dispersion</code> multiplies the variance function in the computation of the coefficient standard errors. |

Formula — Model information

LinearFormula object | NonLinearFormula object

Model information, stored as a `LinearFormula` object or `NonLinearFormula` object. If you fit a linear or generalized linear regression model, then `Formula` is a `LinearFormula` object. If you fit a nonlinear regression model, then `Formula` is a `NonLinearFormula` object.

Link — Link function

structure

Link function, stored as a structure with the following fields.

| Field | Description |
|------------------|--|
| Name | Name of the link function, or '' if you specified the link as a function handle rather than a character vector |
| LinkFunction | The function that defines f , a function handle |
| DevianceFunction | Derivative of f , a function handle |
| VarianceFunction | Inverse of f , a function handle |

The link is a function f that links the distribution parameter μ to the fitted linear combination Xb of the predictors:

$$f(\mu) = Xb.$$

LogLikelihood — Log likelihood

numeric value

Log likelihood of the model distribution at the response values, stored as a numeric value. The mean is fitted from the model, and other parameters are estimated as part of the model fit.

ModelCriterion — Criterion for model comparison

structure

Criterion for model comparison, stored as a structure with the following fields:

- **AIC** — Akaike information criterion. $AIC = -2 \cdot \log L + 2 \cdot m$, where $\log L$ is the loglikelihood and m is the number of estimated parameters.
- **AICc** — Akaike information criterion corrected for the sample size. $AICc = AIC + (2 \cdot m \cdot (m + 1)) / (n - m - 1)$, where n is the number of observations.
- **BIC** — Bayesian information criterion. $BIC = -2 \cdot \log L + m \cdot \log(n)$.
- **CAIC** — Consistent Akaike information criterion. $CAIC = -2 \cdot \log L + m \cdot (\log(n) + 1)$.

Information criteria are model selection tools that you can use to compare multiple models fit to the same data. These criteria are likelihood-based measures of model fit that include a penalty for complexity (specifically, the number of parameters). Different information criteria are distinguished by the form of the penalty.

When you compare multiple models, the model with the lowest information criterion value is the best-fitting model. The best-fitting model can vary depending on the criterion used for model comparison.

To obtain any of the criterion values as a scalar, index into the property by using dot notation. For example, in the model `mdl`, the AIC value `aic` is:

```
aic = mdl.ModelCriterion.AIC
```

NumCoefficients — Number of model coefficients

positive integer

Number of model coefficients, stored as a positive integer. `NumCoefficients` includes coefficients that are set to zero when the model terms are rank deficient.

NumEstimatedCoefficients — Number of estimated coefficients

positive integer

Number of estimated coefficients in the model, stored as a positive integer. `NumEstimatedCoefficients` does not include coefficients that are set to zero when the model terms are rank deficient. `NumEstimatedCoefficients` is the degrees of freedom for regression.

NumObservations — Number of observations

positive integer

Number of observations the fitting function used in fitting, stored as a positive integer. This is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the `Excluded` name-value pair) or rows with missing values.

NumPredictors — Number of predictor variables

positive integer

Number of predictor variables used to fit the model, stored as a positive integer.

NumVariables — Number of variables

positive integer

Number of variables in the input data, stored as a positive integer. `NumVariables` is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

PredictorNames — Names of predictors used to fit the model

cell array of character vectors

Names of predictors used to fit the model, stored as a cell array of character vectors.

ResponseName — Response variable name

character vector

Response variable name, stored as a character vector.

Rquared — R-squared value for the model

structure

R-squared value for the model, stored as a structure.

For a linear or nonlinear model, `Rquared` is a structure with two fields:

- `Ordinary` — Ordinary (unadjusted) R-squared
- `Adjusted` — R-squared adjusted for the number of coefficients

For a generalized linear model, `Rquared` is a structure with five fields:

- **Ordinary** — Ordinary (unadjusted) R-squared
- **Adjusted** — R-squared adjusted for the number of coefficients
- **LLR** — Log-likelihood ratio
- **Deviance** — Deviance
- **AdjGeneralized** — Adjusted generalized R-squared

The R-squared value is the proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:

$$Rsquared = SSR/SST = 1 - SSE/SST.$$

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in `mdl` is

```
r2 = mdl.Rsquared.Adjusted
```

SSE — Sum of squared errors

numeric value

Sum of squared errors (residuals), stored as a numeric value.

The Pythagorean theorem implies

$$SST = SSE + SSR.$$

SSR — Regression sum of squares

numeric value

Regression sum of squares, stored as a numeric value. The regression sum of squares is equal to the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies

$$SST = SSE + SSR.$$

SST — Total sum of squares

numeric value

Total sum of squares, stored as a numeric value. The total sum of squares is equal to the sum of squared deviations of response vector y from $\text{mean}(y)$.

The Pythagorean theorem implies

$SST = SSE + SSR$.

VariableInfo — Information about input variables

table

Information about input variables contained in `Variables`, stored as a table with one row for each model term and the following columns.

| Field | Description |
|----------------------------|--|
| <code>Class</code> | Character vector giving variable class, such as 'double' |
| <code>Range</code> | Cell array giving variable range: <ul style="list-style-type: none">• Continuous variable — Two-element vector $[min, max]$, the minimum and maximum values• Categorical variable — Cell array of distinct variable values |
| <code>InModel</code> | Logical vector, where <code>true</code> indicates the variable is in the model |
| <code>IsCategorical</code> | Logical vector, where <code>true</code> indicates a categorical variable |

VariableNames — Names of variables used in fit

cell array of character vectors

Names of variables used in fit, stored as a cell array of character vectors.

- If the fit is based on a table or dataset, this property provides the names of the variables in that table or dataset.
- If the fit is based on a predictor matrix and response vector, `VariableNames` is the values in the `VarNames` name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

Methods

| | |
|---------------------------|--|
| <code>coefCI</code> | Confidence intervals of coefficient estimates of generalized linear model |
| <code>coefTest</code> | Linear hypothesis test on generalized linear regression model coefficients |
| <code>devianceTest</code> | Analysis of deviance |
| <code>disp</code> | Display generalized linear regression model |
| <code>feval</code> | Evaluate generalized linear regression model prediction |
| <code>plotSlice</code> | Plot of slices through fitted generalized linear regression surface |
| <code>predict</code> | Predict response of generalized linear regression model |
| <code>random</code> | Simulate responses for generalized linear regression model |

Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects \(MATLAB\)](#).

Examples

Compact a Generalized Linear Regression Model

Reduce the size of a full, fitted generalized linear regression model by discarding the sample data and some information related to the fitting process.

Load the data into the workspace. The simulated sample data contains 15,000 observations and 45 predictor variables.

```
load(fullfile(matlabroot, 'examples', 'stats', 'largedata4reg.mat'))
```

Fit a generalized linear regression model to the data using the first 15 predictor variables.

```
mdl = fitglm(X(:,1:15),Y)
```

```
mdl =
```

```
Generalized linear regression model:
```

```
    y ~ [Linear formula with 16 terms in 15 predictors]
```

Distribution = Normal

Estimated Coefficients:

- “Generalized Linear Model Workflow” on page 12-40

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `predict` and `random` functions support code generation.
- When you fit a model by using `fitglm` or `stepwiseglm`, the following restrictions apply.
 - Code generation does not support categorical predictors. You cannot supply training data in a table that contains at least one categorical predictor, and you cannot use the 'CategoricalVars' name-value pair argument. To dummy-code variables that you want treated as categorical, preprocess the categorical data by using `dummyvar` before fitting the model..

- The `Link`, `Derivative`, and `Inverse` fields of the 'Link' name-value pair argument cannot be anonymous functions. That is, you cannot generate code using a generalized linear model that was created using anonymous functions for links. Instead, define functions for link components.

For code generation examples, see “Code Generation Workflow for Prediction” on page 31-5 and “Specify Variable-Sized Arguments for Code Generation” on page 31-48. For more information, see topics in “Code Generation”.

Introduced in R2016b

CompactRegressionEnsemble class

Compact regression ensemble class

Description

Compact version of a regression ensemble (of class `RegressionEnsemble`). The compact version does not include the data for training the regression ensemble. Therefore, you cannot perform some tasks with a compact regression ensemble, such as cross validation. Use a compact regression ensemble for making predictions (regressions) of new data.

Construction

`ens = compact(fullEns)` constructs a compact decision ensemble from a full decision ensemble.

Input Arguments

fullEns

A regression ensemble created by `fitensemble`.

Properties

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

CombineWeights

A character vector describing how the ensemble combines learner predictions.

ExpandedPredictorNames

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

NumTrained

Number of trained learners in the ensemble, a positive scalar.

PredictorNames

A cell array of names for the predictor variables, in the order in which they appear in X .

ResponseName

A character vector with the name of the response variable Y .

ResponseTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means $@(x)x$.

Add or change a `ResponseTransform` function using dot notation:

```
ens.ResponseTransform = @function
```

Trained

The trained learners, a cell array of compact regression models.

TrainedWeights

A numeric vector of weights the ensemble assigns to its learners. The ensemble computes predicted response by aggregating weighted predictions from its learners.

Methods

| | |
|---------------------|---|
| loss | Regression error |
| predict | Predict responses using ensemble of regression models |
| predictorImportance | Estimates of predictor importance |
| removeLearners | Remove members of compact regression ensemble |

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Reduce Size of Regression Ensemble

Create a compact regression ensemble for efficiently making predictions on new data.

Load the `carsmall` data set. Consider a model that explains a car's fuel economy (MPG) using its weight (`Weight`) and number of cylinders (`Cylinders`).

```
load carsmall
X = [Weight Cylinders];
Y = MPG;
```

Train a boosted ensemble of 100 regression trees using the `LSBoost`. Specify that `Cylinders` is a categorical variable.

```
Mdl = fitensemble(X,Y,'PredictorNames',{'W','C'},...
    'CategoricalPredictors',2)
```

```
Mdl =
classreg.learning.regr.RegistrationEnsemble
    PredictorNames: {'W' 'C'}
    ResponseName: 'Y'
    CategoricalPredictors: 2
    ResponseTransform: 'none'
    NumObservations: 94
```

```
        NumTrained: 100
          Method: 'LSBoost'
        LearnerNames: {'Tree'}
ReasonForTermination: 'Terminated normally after completing the requested number o
          FitInfo: [100x1 double]
FitInfoDescription: {2x1 cell}
  Regularization: []
```

Properties, Methods

Mdl is a RegressionEnsemble model object that contains the training data, among other things.

Create a compact version of Mdl.

```
CMDl = compact(Mdl)
```

```
CMDl =
  classreg.learning.regr.CompactRegressionEnsemble
    PredictorNames: {'W' 'C'}
    ResponseName: 'Y'
  CategoricalPredictors: 2
    ResponseTransform: 'none'
    NumTrained: 100
```

Properties, Methods

CMdl is a CompactRegressionEnsemble model object. CMdl is almost the same as Mdl. One exception is that CMdl does not store the training data.

Compare the amounts of space consumed by Mdl and CMdl.

```
mdlInfo = whos('Mdl');
cMdlInfo = whos('CMdl');
[mdlInfo.bytes cMdlInfo.bytes]
```

```
ans = 1x2
```

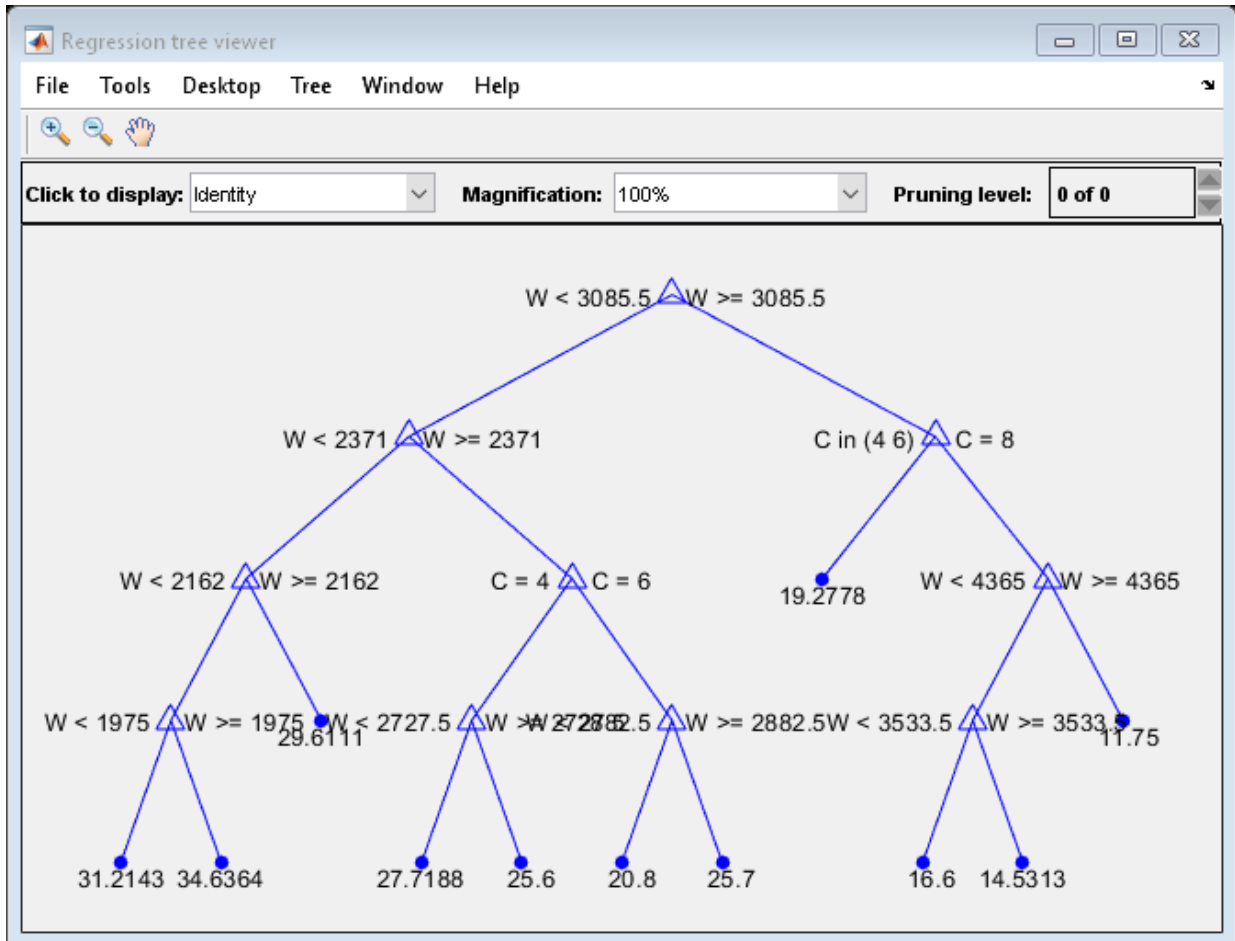

```
    450606    429282
```

Mdl consumes more space than CMdl.

CMdl.Trained stores the trained regression trees (CompactRegressionTree model objects) that compose MdL.

Display a graph of the first tree in the compact ensemble.

```
view(CMdl.Trained{1}, 'Mode', 'graph');
```

By default, fitensemble grows shallow trees for boosted ensembles of trees.

Predict the fuel economy of a typical car using the compact ensemble.

```
typicalX = [mean(X(:,1)) mode(X(:,2))];  
predMeanX = predict(CMdl,typicalX)
```

```
predMeanX = 26.1787
```

Tip

For a compact ensemble of regression trees, the `Trained` property of `ens` stores a cell vector of `ens.NumTrained CompactRegressionTree` model objects. For a textual or graphical display of tree `t` in the cell vector, enter

```
view(ens.Trained{t})
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `predict` function supports code generation.
- When you train an ensemble by using `fitensemble`, code generation limitations for regression trees also apply to ensembles of regression trees. For more details, see “Code Generation” on page 32-0 of the `CompactRegressionTree` class.

For code generation examples, see “Code Generation Workflow for Prediction” on page 31-5 and “Specify Variable-Sized Arguments for Code Generation” on page 31-48. For more information, see topics in “Code Generation”.

Introduced in R2011a

CompactRegressionGP class

Compact Gaussian process regression model class

Description

`CompactRegressionGP` is a compact Gaussian process regression (GPR) model. The compact model consumes less memory than a full model, because it does not include the data used for training the GPR model.

Because the compact model does not include the training data, you cannot perform some tasks, such as cross-validation, using the compact model. However, you can use the compact model for making predictions or calculate regression loss for new data (use `predict` and `loss`).

Construction

`compactMdl = compact(gprMdl)` returns a compact GPR model, `compactMdl`, from a full, trained GPR model, `gprMdl`. For more information, see `compact`.

Input Arguments

gprMdl — Full, trained Gaussian process regression model

RegressionGP model

Full, trained Gaussian process regression model, specified as a `RegressionGP` model, returned by `fitrgp`.

Properties

Fitting

FitMethod — Method used to estimate the parameters

'none' | 'exact' | 'sd' | 'sr' | 'fic'

Method used to estimate the basis function coefficients, β ; noise standard deviation, σ ; and kernel parameters, θ , of the GPR model, stored as a character vector. It can be one of the following.

| Fit Method | Description |
|------------|---|
| 'none' | No estimation. <code>fitrgp</code> uses the initial parameter values as the parameter values. |
| 'exact' | Exact Gaussian process regression. |
| 'sd' | Subset of data points approximation. |
| 'sr' | Subset of regressors approximation. |
| 'fic' | Fully independent conditional approximation. |

BasisFunction — Explicit basis function

'none' | 'constant' | 'linear' | 'pureQuadratic' | function handle

Explicit basis function used in the GPR model, stored as a character vector or a function handle. It can be one of the following. If n is the number of observations, the basis function adds the term $\mathbf{H}^*\boldsymbol{\beta}$ to the model, where \mathbf{H} is the basis matrix and $\boldsymbol{\beta}$ is a p -by-1 vector of basis coefficients.

| Explicit Basis | Basis Matrix |
|----------------|---|
| 'none' | Empty matrix. |
| 'constant' | $\mathbf{H} = \mathbf{1}$ (n -by-1 vector of 1s, where n is the number of observations) |
| 'linear' | $\mathbf{H} = [\mathbf{1}, \mathbf{X}]$ |

| Explicit Basis | Basis Matrix |
|-----------------|--|
| 'pureQuadratic' | $\mathbf{H} = [\mathbf{1}, \mathbf{X}, \mathbf{X}_2],$ <p>where</p> $\mathbf{X}_2 = \begin{bmatrix} x_{11}^2 & x_{12}^2 & \cdots & x_{1d}^2 \\ x_{21}^2 & x_{22}^2 & \cdots & x_{2d}^2 \\ \vdots & \vdots & \vdots & \vdots \\ x_{n1}^2 & x_{n2}^2 & \cdots & x_{nd}^2 \end{bmatrix}.$ |
| Function handle | <p>Function handle, <code>hfcn</code>, that <code>fitrgp</code> calls as:</p> $\mathbf{H} = \text{hfcn}(\mathbf{X}),$ <p>where \mathbf{X} is an n-by-d matrix of predictors and \mathbf{H} is an n-by-p matrix of basis functions.</p> |

Data Types: char | function_handle

CategoricalPredictors — Indices of categorical predictors

vector of positive integers

Categorical predictor indices, specified as a vector of positive integers.

`CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: single | double

Beta — Estimated coefficients

vector

Estimated coefficients for the explicit basis functions, stored as a vector. You can define the explicit basis function by using the `BasisFunction` name-value pair argument in `fitrgp`.

Data Types: double

Sigma — Estimated noise standard deviation

scalar value

Estimated noise standard deviation of the GPR model, stored as a scalar value.

Data Types: double

ModelParameters — Parameters used for training

GPParams object

Parameters used for training the GPR model, stored as a GPParams object.

Kernel Function**KernelFunction — Form of the covariance function**

'squaredExponential' | 'matern32' | 'matern52' | 'ardsquaredexponential' | 'ardmatern32' | 'ardmatern52' | function handle

Form of the covariance function used in the GPR model, stored as a character vector containing the name of the built-in covariance function or a function handle. It can be one of the following.

| Function | Description |
|-------------------------|---|
| 'squaredexponential' | Squared exponential kernel. |
| 'matern32' | Matern kernel with parameter 3/2. |
| 'matern52' | Matern kernel with parameter 5/2. |
| 'ardsquaredexponential' | Squared exponential kernel with a separate length scale per predictor. |
| 'ardmatern32' | Matern kernel with parameter 3/2 and a separate length scale per predictor. |
| 'ardmatern52' | Matern kernel with parameter 5/2 and a separate length scale per predictor. |

| Function | Description |
|-----------------|---|
| Function handle | A function handle that <code>fitrgp</code> can call like this: $K_{mn} = \text{kfcn}(X_m, X_n, \text{theta})$ where X_m is an m -by- d matrix, X_n is an n -by- d matrix and K_{mn} is an m -by- n matrix of kernel products such that $K_{mn}(i,j)$ is the kernel product between $X_m(i,:)$ and $X_n(j,:)$. <code>theta</code> is the r -by-1 unconstrained parameter vector for <code>kfcn</code> . |

Data Types: `char` | `function_handle`

KernelInformation — Information about the parameters of the kernel function structure

Information about the parameters of the kernel function used in the GPR model, stored as a structure with the following fields.

| Field Name | Description |
|----------------------|---|
| Name | Name of the kernel function |
| KernelParameters | Vector of the estimated kernel parameters |
| KernelParameterNames | Names associated with the elements of <code>KernelParameters</code> . |

Data Types: `struct`

Prediction

PredictMethod — Method used to make predictions

`'exact'` | `'bcd'` | `'sd'` | `'sr'` | `'fic'`

Method that `predict` uses to make predictions from the GPR model, stored as a character vector. It can be one of the following.

| PredictMethod | Description |
|----------------------|-----------------------------------|
| <code>'exact'</code> | Exact Gaussian process regression |
| <code>'bcd'</code> | Block Coordinate Descent |

| PredictMethod | Description |
|---------------|---|
| 'sd' | Subset of Data points approximation |
| 'sr' | Subset of Regressors approximation |
| 'fic' | Fully Independent Conditional approximation |

Alpha — Weights

numeric vector

Weights used to make predictions from the trained GPR model, stored as a numeric vector. `predict` computes the predictions for a new predictor matrix X_{new} by using the product

$$\mathbf{K}(\mathbf{X}_{new}, \mathbf{A}) * \alpha .$$

$\mathbf{K}(\mathbf{X}_{new}, \mathbf{A})$ is the matrix of kernel products between \mathbf{X}_{new} and active set vector \mathbf{A} and α is a vector of weights.

Data Types: double

ResponseTransform — Transformation applied to predicted response

character vector

Transformation applied to the predicted response, stored as a character vector describing how the response values the model predicts are transformed. In `RegressionGP`, `ResponseTransform` is 'none' and `RegressionGP` does not use `ResponseTransform` when making predictions.

Data Types: char | function_handle

Active Set Selection

ActiveSetVectors — Subset of training data

matrix

Subset of training data used to make predictions from the GPR model, stored as a matrix. `predict` computes the predictions for a new predictor matrix X_{new} by using the product

$$\mathbf{K}(\mathbf{X}_{new}, \mathbf{A}) * \alpha .$$

$\mathbf{K}(\mathbf{X}_{new}, \mathbf{A})$ is the matrix of kernel products between \mathbf{X}_{new} and active set vector \mathbf{A} and α is a vector of weights.

`ActiveSetVectors` is equal to the training data X for exact GPR fitting and a subset of the training data X for sparse GPR methods. When there are categorical predictors in the model, `ActiveSetVectors` contains dummy variables for the corresponding predictors.

Data Types: double

ActiveSetMethod — Method used to select the active set

'sgma' | 'entropy' | 'likelihood' | 'random'

Method used to select the active set for sparse methods ('sd', 'sr', or 'fic'), stored as a character vector. It can be one of the following.

| ActiveSetMethod | Description |
|------------------------|---|
| 'sgma' | Sparse greedy matrix approximation |
| 'entropy' | Differential entropy-based selection |
| 'likelihood' | Subset of regressors log likelihood-based selection |
| 'random' | Random selection |

The selected active set is used in parameter estimation or prediction, depending on the choice of `FitMethod` and `PredictMethod` in `fitrgp`.

ActiveSetSize — Size of the active set

integer value

Size of the active set for sparse methods ('sd', 'sr', or 'fic'), stored as an integer value.

Data Types: double

Methods

loss Regression error for Gaussian process regression model
 predict Predict response of Gaussian process regression model

Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects \(MATLAB\)](#).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `predict` function supports code generation.
- When you train a Gaussian process regression model by using `fitrgp`, the following restrictions apply.
 - Code generation does not support categorical predictors. You cannot supply training data in a table that contains at least one categorical predictor, and you cannot use the `'CategoricalPredictors'` name-value pair argument. To dummy-code variables that you want treated as categorical, preprocess the categorical data by using `dummyvar` before fitting the model.
 - The value of the `'ResponseTransform'` name-value pair argument cannot be an anonymous function.

For code generation examples, see “Code Generation Workflow for Prediction” on page 31-5 and “Specify Variable-Sized Arguments for Code Generation” on page 31-48. For more information, see topics in “Code Generation”.

Introduced in R2015b

CompactRegressionSVM class

Compact support vector machine regression model

Description

CompactRegressionSVM is a compact support vector machine (SVM) regression model. It consumes less memory than a full, trained support vector machine model (RegressionSVM model) because it does not store the data used to train the model.

Because the compact model does not store the training data, you cannot use it to perform certain tasks, such as cross validation. However, you can use a compact SVM regression model to predict responses using new input data.

Construction

`compactMdl = compact mdl` returns a compact SVM regression model `compactMdl` from a full, trained SVM regression model, `mdl`. For more information, see `compact`.

Input Arguments

mdl — Full, trained SVM regression model

RegressionSVM model

Full, trained SVM regression model, specified as a RegressionSVM model returned by `fitrsvm`.

Properties

Alpha — Dual problem coefficients

vector of numeric values

Dual problem coefficients, specified as a vector of numeric values. Alpha contains m elements, where m is the number of support vectors in the trained SVM regression model.

The dual problem introduces two Lagrange multipliers for each support vector. The values of `Alpha` are the differences between the two estimated Lagrange multipliers for the support vectors. For more details, see “Understanding Support Vector Machine Regression” on page 25-2.

If you specified to remove duplicates using `RemoveDuplicates`, then, for a particular set of duplicate observations that are support vectors, `Alpha` contains one coefficient corresponding to the entire set. That is, MATLAB attributes a nonzero coefficient to one observation from the set of duplicates and a coefficient of 0 to all other duplicate observations in the set.

Data Types: `single` | `double`

Beta — Primal linear problem coefficients

vector of numeric values | ' [] '

Primal linear problem coefficients, stored as a numeric vector of length p , where p is the number of predictors in the SVM regression model.

The values in `Beta` are the linear coefficients for the primal optimization problem.

If the model is obtained using a kernel function other than ' `linear` ', this property is empty (' [] ').

The `predict` method computes predicted response values for the model as $YFIT = (X/S) \times Beta + Bias$, where S is the value of the kernel scale stored in the `KernelParameters.Scale` property.

Data Types: `double`

Bias — Bias term

scalar value

Bias term in the SVM regression model, stored as a scalar value.

Data Types: `double`

CategoricalPredictors — Indices of categorical predictors

vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

Data Types: `single` | `double`

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

KernelParameters — Kernel function parameters

structure

Kernel function parameters, stored as a structure with the following fields.

| Field | Description |
|----------|---|
| Function | Kernel function name (a character vector). |
| Scale | Numeric scale factor used to divide predictor values. |

You can specify values for `KernelParameters.Function` and `KernelParameters.Scale` by using the `KernelFunction` and `KernelScale` name-value pair arguments in `fitrsvm`, respectively.

Data Types: `struct`

Mu — Predictor means

vector of numeric values | `' []'`

Predictor means, stored as a vector of numeric values.

If the training data is standardized, then `Mu` is a numeric vector of length p , where p is the number of predictors used to train the model. In this case, the `predict` method centers predictor matrix X by subtracting the corresponding element of `Mu` from each column.

If the training data is not standardized, then `Mu` is empty (`' []'`).

Data Types: `single` | `double`

PredictorNames — Predictor names

cell array of character vectors

Predictor names, stored as a cell array of character vectors containing the name of each predictor in the order in which they appear in `X`. `PredictorNames` has a length equal to the number of columns in `X`.

Data Types: `cell`

ResponseName — Response variable name

character vector

Response variable name, stored as a character vector.

Data Types: `char`

ResponseTransform — Response transformation function

'none' | function handle

Response transformation function, stored as 'none' or a function handle. `ResponseTransform` describes how the software transforms raw response values.

For a MATLAB function, or a function that you define, enter its function handle. For example, you can enter `Mdl.ResponseTransform = @function`, where *function* accepts a numeric vector of the original responses and returns a numeric vector of the same size containing the transformed responses.

Data Types: `char` | `function_handle`

Sigma — Predictor standard deviations

vector of numeric values | '[]'

Predictor standard deviations, stored as a vector of numeric values.

If the training data is standardized, then `Sigma` is a numeric vector of length p , where p is the number of predictors used to train the model. In this case, the `predict` method scales the predictor matrix `X` by dividing each column by the corresponding element of `Sigma`, after centering each element using `Mu`.

If the training data is not standardized, then `Sigma` is empty ('[]').

Data Types: `single` | `double`

SupportVectors — Support vectors

matrix of numeric values

Support vectors, stored as an m -by- p matrix of numeric values. m is the number of support vectors (`sum(Mdl.IsSupportVector)`), and p is the number of predictors in `X`.

If you specified to remove duplicates using `RemoveDuplicates`, then for a given set of duplicate observations that are support vectors, `SupportVectors` contains one unique support vector.

Data Types: `single` | `double`

Methods

| | |
|------------------------------------|---|
| <code>discardSupportVectors</code> | Discard support vectors |
| <code>loss</code> | Regression error for support vector machine regression model |
| <code>predict</code> | Predict responses using support vector machine regression model |

Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects \(MATLAB\)](#).

Examples

Compact an SVM Regression Model

This example shows how to reduce the size of a full, trained SVM regression model by discarding the training data and some information related to the training process.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current directory with the name `'abalone.data'`. Read the data into a `table`.

```
tbl = readtable('abalone.data', 'Filetype', 'text', 'ReadVariableNames', false);  
rng default % for reproducibility
```

The sample data contains 4177 observations. All of the predictor variables are continuous except for `sex`, which is a categorical variable with possible values `'M'` (for males), `'F'` (for females), and `'I'` (for infants). The goal is to predict the number of rings on the abalone, and thereby determine its age, using physical measurements.

Train an SVM regression model using a Gaussian kernel function and an automatic kernel scale. Standardize the data.

```
mdl = fitrsvm(tbl, 'Var9', 'KernelFunction', 'gaussian', 'KernelScale', 'auto', 'Standardize
```

```
mdl =
```

```
RegressionSVM
    PredictorNames: {1x8 cell}
    ResponseName: 'Var9'
    CategoricalPredictors: 1
    ResponseTransform: 'none'
        Alpha: [3635x1 double]
        Bias: 10.8144
    KernelParameters: [1x1 struct]
        Mu: [1x10 double]
        Sigma: [1x10 double]
    NumObservations: 4177
    BoxConstraints: [4177x1 double]
    ConvergenceInfo: [1x1 struct]
    IsSupportVector: [4177x1 logical]
    Solver: 'SMO'
```

Properties, Methods

Compact the model.

```
compactMdl = compact(mdl)
```

```
compactMdl =
```

```
classreg.learning.regr.CompactRegressionSVM
    PredictorNames: {1x8 cell}
    ResponseName: 'Var9'
    CategoricalPredictors: 1
    ResponseTransform: 'none'
        Alpha: [3635x1 double]
        Bias: 10.8144
    KernelParameters: [1x1 struct]
        Mu: [1x10 double]
        Sigma: [1x10 double]
    SupportVectors: [3635x10 double]
```

Properties, Methods

The compacted model discards the training data and some information related to the training process.

Compare the size of the full model `mdl` and the compact model `compactMdl`.

```
vars = whos('compactMdl','mdl');
[vars(1).bytes,vars(2).bytes]
```

ans =

```
323793    775968
```

The compacted model consumes about half the memory of the full model.

Introduced in R2015b

CompactRegressionTree class

Compact regression tree

Description

Compact version of a regression tree (of class `RegressionTree`). The compact version does not include the data for training the regression tree. Therefore, you cannot perform some tasks with a compact regression tree, such as cross validation. Use a compact regression tree for making predictions (regressions) of new data.

Construction

`ctree = compact(tree)` constructs a compact decision tree from a full decision tree.

Input Arguments

tree — Full, trained regression tree

`RegressionTree` object

Full, trained regression tree, specified as a `RegressionTree` object constructed by `fitrtree`.

Properties

`CategoricalPredictors`

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

CategoricalSplits

An n -by-2 cell array, where n is the number of categorical splits in `tree`. Each row in `CategoricalSplits` gives left and right values for a categorical split. For each branch node with categorical split j based on a categorical predictor variable z , the left child is chosen if z is in `CategoricalSplits(j,1)` and the right child is chosen if z is in `CategoricalSplits(j,2)`. The splits are in the same order as nodes of the tree. Nodes for these splits can be found by running `cuttype` and selecting 'categorical' cuts from top to bottom.

Children

An n -by-2 array containing the numbers of the child nodes for each node in `tree`, where n is the number of nodes. Leaf nodes have child node 0.

CutCategories

An n -by-2 cell array of the categories used at branches in `tree`, where n is the number of nodes. For each branch node i based on a categorical predictor variable x , the left child is chosen if x is among the categories listed in `CutCategories{i,1}`, and the right child is chosen if x is among those listed in `CutCategories{i,2}`. Both columns of `CutCategories` are empty for branch nodes based on continuous predictors and for leaf nodes.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

CutPoint

An n -element vector of the values used as cut points in `tree`, where n is the number of nodes. For each branch node i based on a continuous predictor variable x , the left child is chosen if `CutPoint < v(i)` and the right child is chosen if `x >= CutPoint(i)`. `CutPoint` is NaN for branch nodes based on categorical predictors and for leaf nodes.

CutType

An n -element cell array indicating the type of cut at each node in `tree`, where n is the number of nodes. For each node i , `CutType{i}` is:

- 'continuous' — If the cut is defined in the form $x < v$ for a variable x and cut point v .

- `'categorical'` — If the cut is defined by whether a variable x takes a value in a set of categories.
- `''` — If i is a leaf node.

`CutPoint` contains the cut points for `'continuous'` cuts, and `CutCategories` contains the set of categories.

CutPredictor

An n -element cell array of the names of the variables used for branching in each node in `tree`, where n is the number of nodes. These variables are sometimes known as *cut variables*. For leaf nodes, `CutPredictor` contains an empty character vector.

`CutPoint` contains the cut points for `'continuous'` cuts, and `CutCategories` contains the set of categories.

ExpandedPredictorNames

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

IsBranchNode

An n -element logical vector `ib` that is `true` for each branch node and `false` for each leaf node of `tree`.

NodeError

An n -element vector `e` of the errors of the nodes in `tree`, where n is the number of nodes. `e(i)` is the misclassification probability for node i .

NodeMean

An n -element numeric array with mean values in each node of `tree`, where n is the number of nodes in the tree. Every element in `NodeMean` is the average of the true Y values over all observations in the node.

NodeProbability

An n -element vector `p` of the probabilities of the nodes in `tree`, where n is the number of nodes. The probability of a node is computed as the proportion of observations from the

original data that satisfy the conditions for the node. This proportion is adjusted for any prior probabilities assigned to each class.

NodeRisk

An n -element vector of the risk of the nodes in the tree, where n is the number of nodes. The risk for each node is the node error weighted by the node probability.

NodeSize

An n -element vector `sizes` of the sizes of the nodes in `tree`, where n is the number of nodes. The size of a node is defined as the number of observations from the data used to create the tree that satisfy the conditions for the node.

NumNodes

The number of nodes n in `tree`.

Parent

An n -element vector `p` containing the number of the parent node for each node in `tree`, where n is the number of nodes. The parent of the root node is 0.

PredictorNames

A cell array of names for the predictor variables, in the order in which they appear in `X`.

PruneAlpha

Numeric vector with one element per pruning level. If the pruning level ranges from 0 to M , then `PruneAlpha` has $M + 1$ elements sorted in ascending order. `PruneAlpha(1)` is for pruning level 0 (no pruning), `PruneAlpha(2)` is for pruning level 1, and so on.

PruneList

An n -element numeric vector with the pruning levels in each node of `tree`, where n is the number of nodes. The pruning levels range from 0 (no pruning) to M , where M is the distance between the deepest leaf and the root node.

ResponseName

Name of the response variable `Y`, a character vector.

ResponseTransform

Function handle for transforming the raw response values (mean squared error). The function handle must accept a matrix of response values and return a matrix of the same size. The default 'none' means $@(x)x$, or no transformation.

Add or change a ResponseTransform function using dot notation:

```
ctree.ResponseTransform = @function
```

SurrogateCutCategories

An n -element cell array of the categories used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutCategories{k}` is a cell array. The length of `SurrogateCutCategories{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutCategories{k}` is either an empty character vector for a continuous surrogate predictor, or is a two-element cell array with categories for a categorical surrogate predictor. The first element of this two-element cell array lists categories assigned to the left child by this surrogate split, and the second element of this two-element cell array lists categories assigned to the right child by this surrogate split. The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutCategories` contains an empty cell.

SurrogateCutFlip

An n -element cell array of the numeric cut assignments used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutFlip{k}` is a numeric vector. The length of `SurrogateCutFlip{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutFlip{k}` is either zero for a categorical surrogate predictor, or a numeric cut assignment for a continuous surrogate predictor. The numeric cut assignment can be either -1 or $+1$. For every surrogate split with a numeric cut C based on a continuous predictor variable Z , the left child is chosen if $Z < C$ and the cut assignment for this surrogate split is $+1$, or if $Z \geq C$ and the cut assignment for this surrogate split is -1 . Similarly, the right child is chosen if $Z \geq C$ and the cut assignment for this surrogate split is $+1$, or if $Z < C$ and the cut assignment for this surrogate split is -1 . The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutFlip` contains an empty array.

SurrogateCutPoint

An n -element cell array of the numeric values used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutPoint{k}` is a numeric vector. The length of `SurrogateCutPoint{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutPoint{k}` is either NaN for a categorical surrogate predictor, or a numeric cut for a continuous surrogate predictor. For every surrogate split with a numeric cut C based on a continuous predictor variable Z , the left child is chosen if $Z < C$ and `SurrogateCutFlip` for this surrogate split is +1, or if $Z \geq C$ and `SurrogateCutFlip` for this surrogate split is -1. Similarly, the right child is chosen if $Z \geq C$ and `SurrogateCutFlip` for this surrogate split is +1, or if $Z < C$ and `SurrogateCutFlip` for this surrogate split is -1. The order of the surrogate split variables at each node is matched to the order of variables returned by `SurrogateCutVar`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutPoint` contains an empty cell.

SurrogateCutType

An n -element cell array indicating types of surrogate splits at each node in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutType{k}` is a cell array with the types of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutType` contains an empty cell. A surrogate split type can be either 'continuous' if the cut is defined in the form $Z < V$ for a variable Z and cut point V or 'categorical' if the cut is defined by whether Z takes a value in a set of categories.

SurrogateCutPredictor

An n -element cell array of the names of the variables used for surrogate splits in each node in `tree`, where n is the number of nodes in `tree`. Every element of `SurrogateCutPredictor` is a cell array with the names of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutPredictor` contains an empty cell.

SurrogatePredictorAssociation

An n -element cell array of the predictive measures of association for surrogate splits in tree, where n is the number of nodes in tree. For each node k , SurrogatePredictorAssociation{ k } is a numeric vector. The length of SurrogatePredictorAssociation{ k } is equal to the number of surrogate predictors found at this node. Every element of SurrogatePredictorAssociation{ k } gives the predictive measure of association between the optimal split and this surrogate split. The order of the surrogate split variables at each node is the order of variables in SurrogateCutPredictor. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrogatePredictorAssociation contains an empty cell.

Methods

| | |
|----------------------|--|
| loss | Regression error |
| surrogateAssociation | Mean predictive measure of association for surrogate splits in decision tree |
| predict | Predict responses using regression tree |
| predictorImportance | Estimates of predictor importance |
| view | View tree |

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Construct and Compact a Regression Tree

Load the sample data.

```
load carsmall
```

Construct a regression tree for the sample data.

```
tree = fitrtree([Weight, Cylinders],MPG,...  
    'MinParentSize',20,...  
    'PredictorNames',{'W','C'});
```

Make a compact version of the tree.

```
ctree = compact(tree);
```

Compare the size of the compact tree to that of the full tree.

```
t = whos('tree'); % t.bytes = size of tree in bytes  
c = whos('ctree'); % c.bytes = size of ctree in bytes  
[c.bytes t.bytes]
```

```
ans = 1×2
```

```
3708      6954
```

The compact tree is smaller than the full tree.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `predict` function supports code generation.
- When you train a regression tree model by using `fitrtree`, the following restrictions apply.
 - Code generation does not support categorical predictors. You cannot supply training data in a table that contains at least one categorical predictor, and you cannot use the `'CategoricalPredictors'` name-value pair argument. To dummy-code variables that you want treated as categorical, preprocess the categorical data by using `dummyvar` before fitting the model..
 - The value of the `'ResponseTransform'` name-value pair argument cannot be an anonymous function.

- You cannot use surrogate splits, that is, the value of the 'Surrogate' name-value pair argument must be 'off'.

CompactTreeBagger class

Compact ensemble of decision trees grown by bootstrap aggregation

Description

`CompactTreeBagger` class is a lightweight class that contains the trees grown using `TreeBagger`. `CompactTreeBagger` does not preserve any information about how `TreeBagger` grew the decision trees. It does not contain the input data used for growing trees, nor does it contain training parameters such as minimal leaf size or number of variables sampled for each decision split at random. You can only use `CompactTreeBagger` for predicting the response of the trained ensemble given new data `X`, and other related functions.

`CompactTreeBagger` lets you save the trained ensemble to disk, or use it in any other way, while discarding training data and various parameters of the training configuration irrelevant for predicting response of the fully grown ensemble. This reduces storage and memory requirements, especially for ensembles trained on large data sets.

Construction

`CompactTreeBagger` Create `CompactTreeBagger` object

`CMdl = compact(Mdl)` creates a compact version of `Mdl`, a `TreeBagger` model object. You can predict regressions using `CMdl` exactly as you can using `Mdl`. However, since `CMdl` does not contain training data, you cannot perform some actions, such as make out-of-bag predictions using `oobPredict`.

Methods

| | |
|-----------------------------|---|
| <code>combine</code> | Combine two ensembles |
| <code>error</code> | Error (misclassification probability or MSE) |
| <code>margin</code> | Classification margin |
| <code>mdsprox</code> | Multidimensional scaling of proximity matrix |
| <code>meanMargin</code> | Mean classification margin |
| <code>outlierMeasure</code> | Outlier measure for data |
| <code>predict</code> | Predict responses using ensemble of bagged decision trees |
| <code>proximity</code> | Proximity matrix for data |
| <code>setDefaultYfit</code> | Set default value for <code>predict</code> |

Properties

ClassNames

The `ClassNames` property is a cell array containing the class names for the response variable `Y` supplied to `TreeBagger`. This property is empty for regression trees.

DefaultYfit

The `DefaultYfit` property controls what predicted value `CompactTreeBagger` returns when no prediction is possible, for example when the `predict` method needs to predict for an observation which has only false values in the matrix supplied through `'useifort'` argument.

For classification, you can set this property to either `' '` or `'MostPopular'`. If you choose `'MostPopular'` (default), the property value becomes the name of the most probable class in the training data.

For regression, you can set this property to any numeric scalar. The default is the mean of the response for the training data.

DeltaCriterionDecisionSplit

The `DeltaCriterionDecisionSplit` property is a numeric array of size 1-by-*Nvars* of changes in the split criterion summed over splits on each variable, averaged across the entire ensemble of grown trees.

Method

The `Method` property is 'classification' for classification ensembles and 'regression' for regression ensembles.

NumPredictorSplit

The `NumPredictorSplit` property is a numeric array of size 1-by-*Nvars*, where every element gives a number of splits on this predictor summed over all trees.

NumTrees

The `NumTrees` property is a scalar equal to the number of decision trees in the ensemble.

PredictorNames

The `PredictorNames` property is a cell array containing the names of the predictor variables (features). These names are taken from the optional 'names' parameter that supplied to `TreeBagger`. The default names are 'x1', 'x2', etc.

SurrogateAssociation

The `SurrogateAssociation` property is a matrix of size *Nvars*-by-*Nvars* with predictive measures of variable association, averaged across the entire ensemble of grown trees. If you grew the ensemble setting 'surrogate' to 'on', this matrix for each tree is filled with predictive measures of association averaged over the surrogate splits. If you grew the ensemble setting 'surrogate' to 'off' (default), `SurrogateAssociation` is diagonal.

Trees

The `Trees` property is a cell array of size `NumTrees`-by-1 containing the trees in the ensemble.

Examples

Reduce Size of Bag of Trees

Create a compact bag of trees for efficiently making predictions on new data.

Load the ionosphere data set.

```
load ionosphere
```

Train a bag of 100 classification trees using all measurements and the AdaBoostM1 method.

```
Mdl = TreeBagger(100,X,Y,'Method','classification')
```

```
Mdl =
```

```
    TreeBagger
Ensemble with 100 bagged decision trees:
      Training X:      [351x34]
      Training Y:      [351x1]
      Method:          classification
      NumPredictors:   34
      NumPredictorsToSample: 6
      MinLeafSize:     1
      InBagFraction:   1
      SampleWithReplacement: 1
      ComputeOOBPrediction: 0
      ComputeOOBPredictorImportance: 0
      Proximity:       []
      ClassNames:      'b'          'g'
```

```
    Properties, Methods
```

Mdl is a TreeBagger model object that contains the training data, among other things.

Create a compact version of Mdl.

```
CMdl = compact(Mdl)
```

```
CMdl =
```

```
    CompactTreeBagger
Ensemble with 100 bagged decision trees:
```

```
Method:      classification
NumPredictors: 34
ClassNames: 'b' 'g'
```

Properties, Methods

`CMdl` is a `CompactTreeBagger` model object. `CMdl` is almost the same as `Mdl`. One exception is that it does not store the training data.

Compare the amounts of space consumed by `Mdl` and `CMdl`.

```
mdlInfo = whos('Mdl');
cMdlInfo = whos('CMdl');
[mdlInfo.bytes cMdlInfo.bytes]

ans = 1×2

    1031399    890204
```

`Mdl` consumes more space than `CMdl`.

`CMdl.Trees` stores the trained classification trees (`CompactClassificationTree` model objects) that compose `Mdl`.

Display a graph of the first tree in the compact model.

```
view(CMdl.Trees{1}, 'Mode', 'graph');
```

By default, TreeBagger grows deep trees.

Predict the label of the mean of X using the compact ensemble.

```
predMeanX = predict(CMdl,mean(X))
```

```
predMeanX = 1x1 cell array
    {'g'}
```

Copy Semantics

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes \(MATLAB\)](#) in the MATLAB Object-Oriented Programming documentation.

Tip

The `Trees` property of `CMdl` stores a cell vector of `CMdl.NumTrees` `CompactClassificationTree` or `CompactRegressionTree` model objects. For a textual or graphical display of tree `t` in the cell vector, enter

```
view(CMdl.Trees{t})
```

CompactTreeBagger

Class: CompactTreeBagger

Create CompactTreeBagger object

Description

When you use the `TreeBagger` constructor to grow trees, it creates a `CompactTreeBagger` object. You can obtain the compact object from the full `TreeBagger` object using the `TreeBagger/compact` method. You do not create an instance of `CompactTreeBagger` directly.

Introduced in R2009a

compare

Class: GeneralizedLinearMixedModel

Compare generalized linear mixed-effects models

Syntax

```
results = compare(glme, altglme)
results = compare(glme, altglme, Name, Value)
```

Description

`results = compare(glme, altglme)` returns the results of a likelihood ratio test on page 32-863 that compares the generalized linear mixed-effects models `glme` and `altglme`. To conduct a valid likelihood ratio test, both models must use the same response vector in the fit, and `glme` must be nested in `altglme`. Always input the smaller model first, and the larger model second.

`compare` tests the following null and alternate hypotheses:

- H_0 : Observed response vector is generated by `glme`.
- H_1 : Observed response vector is generated by model `altglme`.

`results = compare(glme, altglme, Name, Value)` returns the results of a likelihood ratio test using additional options specified by one or more `Name, Value` pair arguments. For example, you can check if the first input model, `glme`, is nested in the second input model, `altglme`.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

You can create a `GeneralizedLinearMixedModel` object by fitting a generalized linear mixed-effects model to your sample data using `fitglm`. To conduct a valid likelihood ratio test on two models that have response distributions other than normal, you must fit both models using the 'ApproximateLaplace' or 'Laplace' fit method. Models with response distributions other than normal that are fitted using 'MPL' or 'REML' cannot be compared using a likelihood ratio test.

altglm — Alternative generalized linear mixed-effects model

`GeneralizedLinearMixedModel` object

Alternative generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. `altglm` must fit to the same response vector as `glm`, but with different model specifications. `glm` must be nested in `altglm`, such that you can obtain `glm` from `altglm` by setting some of the model parameters of `altglm` to fixed values such as 0.

You can create a `GeneralizedLinearMixedModel` object by fitting a generalized linear mixed-effects model to your sample data using `fitglm`. To conduct a valid likelihood ratio test on two models that have response distributions other than normal, you must fit both models using the 'ApproximateLaplace' or 'Laplace' fit method. Models with response distributions other than normal that are fitted using 'MPL' or 'REML' cannot be compared using a likelihood ratio test.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

CheckNesting — Indicator to check nesting between two models

`true` (default) | `false`

Indicator to check nesting on page 32-863 between two models, specified as the comma-separated pair consisting of 'CheckNesting' and either `true` or `false`. If 'CheckNesting' is `true`, then `compare` checks if the smaller model `glm` is nested in the larger model `altglm`. If the nesting requirements are not satisfied, then `compare` returns an error. If 'CheckNesting' is `false`, then `compare` does not perform this check.

Example: 'CheckNesting', `true`

Output Arguments

results — Results of likelihood ratio test

table

Results of the likelihood ratio test, returned as a table with two rows. The first row is for `glme`, and the second row is for `altglme`. The columns of `results` contain the following.

| Column Name | Description |
|-------------|--|
| Model | Name of the model |
| DF | Degrees of freedom |
| AIC | Akaike information criterion for the model |
| BIC | Bayesian information criterion for the model |
| LogLik | Maximized log likelihood for the model |
| LRStat | Likelihood ratio test statistic for comparing <code>altglme</code> and <code>glme</code> |
| deltaDF | DF for <code>altglme</code> minus DF for <code>glme</code> |
| pValue | p -value for the likelihood ratio test |

Examples

Compare Mixed-Effects Models

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a fixed-effects-only model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Specify the response distribution as Poisson, the link function as log, and the fit method as Laplace. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

```
FEglme = fitglm(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier', 'Dist
```

Fit a second model that uses the same fixed-effects predictors, response distribution, link function, and fit method. This time, include a random-effects intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).

- `newprocessij`, `time.devij`, and `temp.devij` are the measurements for each variable that correspond to factory *i* during batch *j*. For example, `newprocessij` indicates whether the batch produced by factory *i* during batch *j* used the new process.
- `supplier.Cij` and `supplier.Bij` are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory *i* during batch *j*.
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory *i* that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|facto
```

Compare the two models using a theoretical likelihood ratio test. Specify 'CheckNesting' as true, so compare returns a warning if the nesting requirements are not satisfied.

```
results = compare(FEglme, glme, 'CheckNesting', true)
```

```
results =
```

THEORETICAL LIKELIHOOD RATIO TEST

| Model | DF | AIC | BIC | LogLik | LRStat | deltaDF |
|--------|----|--------|--------|---------|--------|---------|
| FEglme | 6 | 431.02 | 446.65 | -209.51 | | |
| glme | 7 | 416.35 | 434.58 | -201.17 | 16.672 | 1 |

```
pValue
```

```
4.4435e-05
```

Since `compare` did not return an error, the nesting requirements are satisfied. The small *P*-value indicates that `compare` rejects the null hypothesis that the observed response vector is generated by the model `FEglme`, and instead accepts the alternate model `glme`.

The smaller AIC and BIC values for `glme` also support the conclusion that `glme` provides a better fitting model for the response.

Definitions

Likelihood Ratio Test

A *likelihood ratio test* compares the specifications of two nested models by assessing the significance of restrictions to an extended model with unrestricted parameters. Under the null hypothesis H_0 , the likelihood ratio test statistic has an approximate chi-squared reference distribution with degrees of freedom `deltaDF`.

When comparing two models, `compare` computes the p -value for the likelihood ratio test by comparing the observed likelihood ratio test statistic with this chi-squared reference distribution. A small p -value leads to a rejection of H_0 in favor of H_1 , and acceptance of the alternate model `altglme`. On the other hand, a large p -value indicates that we cannot reject H_0 , and reflects insufficient evidence to accept the model `altglme`.

The p -values obtained using the likelihood ratio test can be conservative when testing for the presence or absence of random-effects terms, and anti-conservative when testing for the presence or absence of fixed-effects terms. Instead, use the `fixedEffects` or `coefTest` methods to test for fixed effects.

To conduct a valid likelihood ratio test on GLME models, both models must be fitted using a Laplace or approximate Laplace fit method. Models fitted using a maximum pseudo likelihood (MPL) or restricted maximum pseudo likelihood (REMP) method cannot be compared using a likelihood ratio test. When comparing models fitted using MPL, the maximized log likelihood of the pseudodata from the final pseudo likelihood iteration is used in the likelihood ratio test. If you compare models with non-normal distributions fitted using MPL, then `compare` gives a warning that the likelihood ratio test is using maximized log likelihood of pseudodata from the final pseudo likelihood iteration. To use the true maximized log likelihood in the likelihood ratio test, fit both `glme` and `altglme` using approximate Laplace or Laplace prior to model comparison.

Nesting Requirements

To conduct a valid likelihood ratio test, `glme` must be nested in `altglme`. The `'CheckNesting'`, `true` name-value pair argument checks the following requirements, and returns an error if any are not satisfied:

- You must fit both models (`glme` and `altglme`) using the `'ApproximateLaplace'` or `'Laplace'` fit method. You cannot compare GLME models fitted using `'MPL'` or `'REML'` using a likelihood ratio test.
- You must fit both models using the same response vector, response distribution, and link function.
- The smaller model (`glme`) must be nested within the larger model (`altglme`), such that you can obtain `glme` from `altglme` by setting some of the model parameters of `altglme` to fixed values such as 0.
- The maximized log likelihood of the larger model (`altglme`) must be greater than or equal to the maximized log likelihood of the smaller model (`glme`).
- The weight vectors used to fit `glme` and `altglme` must be identical.
- The random-effects design matrix of the larger model (`altglme`) must contain the random-effects design matrix of the smaller model (`glme`).
- The fixed-effects design matrix of the larger model (`altglme`) must contain the fixed-effects design matrix of the smaller model (`glme`).

Akaike and Bayesian Information Criteria

The *Akaike information criterion* (AIC) is $AIC = -2\log L_M + 2(param)$.

$\log L_M$ depends on the method used to fit the model.

- If you use `'Laplace'` or `'ApproximateLaplace'`, then $\log L_M$ is the maximized log likelihood.
- If you use `'MPL'`, then $\log L_M$ is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.
- If you use `'REML'`, then $\log L_M$ is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

$param$ is the total number of parameters estimated in the model. For most GLME models, $param$ is equal to $nc + p + 1$, where nc is the total number of parameters in the random-effects covariance, excluding the residual variance, and p is the number of fixed-effects coefficients. However, if the dispersion parameter is fixed at 1.0 for binomial or Poisson distributions, then $param$ is equal to $(nc + p)$.

The *Bayesian information criterion* (BIC) is $BIC = -2*\log L_M + \ln(n_{eff})(param)$.

$\log L_M$ depends on the method used to fit the model.

- If you use 'Laplace' or 'ApproximateLaplace', then $\log L_M$ is the maximized log likelihood.
- If you use 'MPL', then $\log L_M$ is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.
- If you use 'REML', then $\log L_M$ is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

n_{eff} is the effective number of observations.

- If you use 'MPL', 'Laplace', or 'ApproximateLaplace', then $n_{eff} = n$, where n is the number of observations.
- If you use 'REML', then $n_{eff} = n - p$.

$param$ is the total number of parameters estimated in the model. For most GLME models, $param$ is equal to $nc + p + 1$, where nc is the total number of parameters in the random-effects covariance, excluding the residual variance, and p is the number of fixed-effects coefficients. However, if the dispersion parameter is fixed at 1.0 for binomial or Poisson distributions, then $param$ is equal to $(nc + p)$.

A lower value of deviance indicates a better fit. As the value of deviance decreases, both AIC and BIC tend to decrease. Both AIC and BIC also include penalty terms based on the number of parameters estimated, p . So, when the number of parameters increase, the values of AIC and BIC tend to increase as well. When comparing different models, the model with the lowest AIC or BIC value is considered as the best fitting model.

For models fitted using 'MPL' and 'REML', AIC and BIC are based on the log likelihood (or restricted log likelihood) of pseudo data from the final pseudo likelihood iteration. Therefore, a direct comparison of AIC and BIC values between models fitted using 'MPL' and 'REML' is not appropriate.

compare

Class: LinearMixedModel

Compare linear mixed-effects models

Syntax

```
results = compare(lme, altlme)
results = compare( ____, Name, Value)

[results, siminfo] = compare(lme, altlme, 'NSim', nsim)
[results, siminfo] = compare( ____, Name, Value)
```

Description

`results = compare(lme, altlme)` returns the results of a likelihood ratio test on page 32-878 that compares the linear mixed-effects models `lme` and `altlme`. Both models must use the same response vector in the fit and `lme` must be nested in `altlme` for a valid theoretical likelihood ratio test. Always input the smaller model first, and the larger model second.

`compare` tests the following null and alternate hypotheses:

H_0 : Observed response vector is generated by `lme`.

H_1 : Observed response vector is generated by model `altlme`.

It is recommended that you fit `lme` and `altlme` using the maximum likelihood (ML) method prior to model comparison. If you use the restricted maximum likelihood (REML) method, then both models must have the same fixed-effects design matrix.

To test for fixed effects, use `compare` with the simulated likelihood ratio test on page 32-879 when `lme` and `altlme` are fit using ML or use the `fixedEffects`, `anova`, or `coefTest` methods.

`results = compare(____, Name, Value)` also returns the results of a likelihood ratio test that compares linear mixed-effects models `lme` and `altlme` with additional options specified by one or more `Name, Value` pair arguments.

For example, you can check if the first input model is nested in the second input model.

`[results, siminfo] = compare(lme, altlme, 'NSim', nsim)` returns the results of a simulated likelihood ratio test that compares linear mixed-effects models `lme` and `altlme`.

You can fit `lme` and `altlme` using ML or REML. Also, `lme` does not have to be nested in `altlme`. If you use the restricted maximum likelihood (REML) method to fit the models, then both models must have the same fixed-effects design matrix.

`[results, siminfo] = compare(____, Name, Value)` also returns the results of a simulated likelihood ratio test that compares linear mixed-effects models `lme` and `altlme` with additional options specified by one or more `Name, Value` pair arguments.

For example, you can change the options for performing the simulated likelihood ratio test, or change the confidence level of the confidence interval for the *p*-value.

Input Arguments

lme — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, specified as a `LinearMixedModel` object constructed using `fitlme` or `fitlmematrix`.

altlme — Alternative linear mixed-effects model

`LinearMixedModel` object

Alternative linear mixed-effects model fit to the same response vector but with different model specifications, specified as a `LinearMixedModel` object. `lme` must be nested in `altlme`, that is, `lme` should be obtained from `altlme` by setting some parameters to fixed values, such as 0. You can create a linear mixed-effects object using `fitlme` or `fitlmematrix`.

nsim — Number of replications for simulations

positive integer number

Number of replications for simulations in the simulated likelihood ratio test, specified as a positive integer number. You must specify `nsim` to do a simulated likelihood ratio test.

Example: `'NSim',1000`

Data Types: `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Alpha — Confidence level

0.05 (default) | scalar value in the range 0 to 1

Confidence level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range 0 to 1. For a value α , the confidence level is $100*(1-\alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha',0.01`

Data Types: `single` | `double`

Options — Options for performing simulated likelihood ratio test

structure

Options for performing the simulated likelihood ratio test, specified as the comma-separated pair consisting of `'Options'`, and a structure created by `statset('LinearMixedModel')`.

`compare` uses the following fields.

- | | |
|----------------------------|---|
| <code>'UseParallel'</code> | <ul style="list-style-type: none">• <code>False</code> for serial computation. Default.• <code>True</code> for parallel computation. |
|----------------------------|---|

'UseSubstreams'

- False for not using a separate substream of the random number generator for each iteration. Default.
- True for using a separate substream of the random number generator for each iteration. You can only use this option with random stream types that support substreams.

'Streams'

- If 'UseSubstreams' is True, then 'Streams' must be a single random number stream, or a scalar cell array containing a single stream.
- If 'UseSubstreams' is False and
 - 'UseParallel' is False, then 'Streams' must be a single random number stream, or a scalar cell array containing a single stream.
 - 'UseParallel' is True, then 'Streams' must be equal to the number of processors used. If a parallel pool is open, then the 'Streams' is the same length as the size of the parallel pool. If 'UseParallel' is True, a parallel pool might open up for you. But since 'Streams' must be equal to the number of processors used, it is best to open a pool explicitly using the `parpool` command, before calling `compare` with the `'UseParallel','True'` option.

For information on parallel statistical computing at the command line, enter

`help parallelstats`

Data Types: struct

CheckNesting — Indicator to check nesting between two models`false (default) | true`

Indicator to check nesting on page 32-880 between two models, specified as the comma-separated pair consisting of 'CheckNesting' and one of the following.

| | |
|--------------------|---|
| <code>false</code> | Default. No checks. |
| <code>true</code> | <code>compare</code> checks if the smaller model <code>lme</code> is nested in the bigger model <code>altlme</code> . |

`lme` must be nested in the alternate model `altlme` for a valid theoretical likelihood ratio test on page 32-878. `compare` returns an error message if the nesting requirements are not satisfied.

Although valid for both tests, the nesting requirements are weaker for the simulated likelihood ratio test on page 32-879.

Example: `'CheckNesting', true`

Data Types: `single | double`

Output Arguments

results — Results of likelihood ratio test or simulated likelihood ratio test`dataset array`

Results of the likelihood ratio test or simulated likelihood ratio test, returned as a dataset array with two rows. The first row is for `lme`, and the second row is for `altlme`. The columns of `results` depend on whether the test is a likelihood ratio or a simulated likelihood ratio test.

- If you use the likelihood ratio test on page 32-878, then `results` contains the following columns.

| | |
|--------------------|---|
| <code>Model</code> | Name of the model |
| <code>DF</code> | Degrees of freedom, that is, the number of free parameters in the model |
| <code>AIC</code> | Akaike information criterion for the model |

| | |
|---------|---|
| BIC | Bayesian information criterion for the model |
| LogLik | Maximized log likelihood for the model |
| LRStat | Likelihood ratio test statistic for comparing <code>altlme</code> versus <code>lme</code> |
| deltaDF | DF for <code>altlme</code> minus DF for <code>lme</code> |
| pValue | <i>p</i> -value for the likelihood ratio test |

- If you use the simulated likelihood ratio test on page 32-879, then `results` contains the following columns.

| | |
|--------|---|
| Model | Name of the model |
| DF | Degrees of freedom, that is, the number of free parameters in the model |
| LogLik | Maximized log likelihood for the model |
| LRStat | Likelihood ratio test statistic for comparing <code>altlme</code> versus <code>lme</code> |
| pValue | <i>p</i> -value for the likelihood ratio test |
| Lower | Lower limit of the confidence interval for <code>pValue</code> |
| Upper | Upper limit of the confidence interval for <code>pValue</code> |

siminfo — Simulation output structure

Simulation output, returned as a structure with the following fields.

| | |
|--------------------------|--|
| <code>nsim</code> | Value set for <code>nsim</code> . |
| <code>alpha</code> | Value set for 'Alpha'. |
| <code>pValueSim</code> | Simulation-based <i>p</i> -value. |
| <code>pValueSimCI</code> | Confidence interval for <code>pValueSim</code> . The first element of the vector is the lower limit and the second element of the vector contains the upper limit. |

| | |
|---------|---|
| deltaDF | The number of free parameters in <code>altlme</code> minus the number of free parameters in <code>lme</code> . DF for <code>altlme</code> minus DF for <code>lme</code> . |
| TH0 | A vector of simulated likelihood ratio test statistics under the null hypothesis that the model <code>lme</code> generated the observed response vector <code>y</code> . |

Examples

Test for Random Effects

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into an array. The new dataset array, `flu2`, must have the response variable, `FluRate`, the nominal variable, `Region`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...  
            'IndVarName','Region');  
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model, with a varying intercept and varying slope for each region, grouped by `Date`.

```
altlme = fitlme(flu2,'FluRate ~ 1 + Region + (1 + Region|Date)');
```

Fit a linear mixed-effects model with fixed effects for the region and a random intercept that varies by `Date`.

```
lme = fitlme(flu2,'FluRate ~ 1 + Region + (1|Date)');
```

Compare the two models. Also check if `lme2` is nested in `lme`.

```
compare(lme, altlme, 'CheckNesting', true)
```

```
ans =
```

THEORETICAL LIKELIHOOD RATIO TEST

| Model | DF | AIC | BIC | LogLik | LRStat | deltaDF | pValue |
|---------------------|----|---------|---------|---------|--------|---------|--------|
| <code>lme</code> | 11 | 318.71 | 364.35 | -148.36 | | | |
| <code>altlme</code> | 55 | -305.51 | -77.346 | 207.76 | 712.22 | 44 | 0 |

The small p -value of 0 indicates that model `altlme` is significantly better than the simpler model `lme`.

Test for Fixed and Random Effects

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'fertilizer.mat'));
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently.

```
lmeBig = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Refit the model after removing the interaction term `Tomato:Fertilizer` and the random-effects term (`1 | Soil`).

```
lmeSmall = fitlme(ds, 'Yield ~ Fertilizer + Tomato + (1|Soil:Tomato)');
```

Compare the two models using the simulated likelihood ratio test with 1000 replications. You must use this test to test for both fixed- and random-effect terms. Note that both models are fit using the default fitting method, ML. That's why, there is no restriction on the fixed-effects design matrices. If you use restricted maximum likelihood (REML) method, both models must have identical fixed-effects design matrices.

```
[table, siminfo] = compare(lmeSmall, lmeBig, 'nsim', 1000)
```

```
table =
```

```
SIMULATED LIKELIHOOD RATIO TEST: NSIM = 1000, ALPHA = 0.05
```

| Model | DF | AIC | BIC | LogLik | LRStat | pValue |
|----------|----|--------|--------|---------|--------|---------|
| lmeSmall | 10 | 511.06 | 532 | -245.53 | | |
| lmeBig | 23 | 522.57 | 570.74 | -238.29 | 14.491 | 0.57343 |

```
Lower      Upper
```

```
0.54211    0.60431
```

```
siminfo =
```

```
struct with fields:
```

```
    nsim: 1000
    alpha: 0.0500
    pvalueSim: 0.5734
    pvalueSimCI: [0.5421 0.6043]
    deltaDF: 13
    TH0: [1000x1 double]
```

The high P -value suggests that the larger model, `lme` is not significantly better than the smaller model, `lme2`. The smaller values of “Akaike and Bayesian Information Criteria” on page 32-880 for `lme2` also support this.

Models with Correlated and Uncorrelated Random Effects

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and the cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year.

First, prepare the design matrices.

```
X = [ones(406,1) Acceleration Horsepower];
Z = [ones(406,1) Acceleration];
Model_Year = nominal(Model_Year);
G = Model_Year;
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'});
```

Refit the model with uncorrelated random effects for intercept and acceleration. First prepare the random effects design and the random effects grouping variables.

```
Z = {ones(406,1),Acceleration};
G = {Model_Year,Model_Year};

lme2 = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept'}},{'Acceleration'}},'RandomEffectGroups',...
{'Model_Year','Model_Year'});
```

Compare `lme` and `lme2` using the simulated likelihood ratio test.

```
compare(lme2,lme,'CheckNesting',true,'NSim',1000)
```

```
ans =
```

```
SIMULATED LIKELIHOOD RATIO TEST: NSIM = 1000, ALPHA = 0.05
```

| Model | DF | AIC | BIC | LogLik | LRStat | pValue | Lower |
|-------|----|--------|--------|---------|--------|----------|----------|
| lme2 | 6 | 2194.5 | 2218.3 | -1091.3 | | | |
| lme | 7 | 2193.5 | 2221.3 | -1089.7 | 3.0323 | 0.094905 | 0.077462 |

```
Upper
```

```
0.11477
```

The high p -value indicates that `lme2` is not a significantly better fit than `lme`.

Simulated Likelihood Ratio Test Using Parallel Computing

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'fertilizer.mat'));
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;  
ds.Tomato = nominal(ds.Tomato);  
ds.Soil = nominal(ds.Soil);  
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Refit the model after removing the interaction term `Tomato:Fertilizer` and the random-effects term `(1|Soil)`.

```
lme2 = fitlme(ds, 'Yield ~ Fertilizer + Tomato + (1|Soil:Tomato)');
```

Create the options structure for `LinearMixedModel`.

```
opt = statset('LinearMixedModel')
```

```
opt =
```

```
struct with fields:
```

```

    Display: 'off'
  MaxFunEvals: []
    MaxIter: 10000
    TolBnd: []

```

Change the options for parallel testing.

```
opt.UseParallel = true;
```

Start a parallel environment.

```
mypool = parpool();
```

```
Starting parallel pool (parpool) using the 'local' profile ...
connected to 12 workers.
```

Compare `lme2` and `lme` using the simulated likelihood ratio test with 1000 replications and parallel computing.

```
compare(lme2, lme, 'nsim', 1000, 'Options', opt)
```

```
ans =
```

```
SIMULATED LIKELIHOOD RATIO TEST: NSIM = 1000, ALPHA = 0.05
```

| Model | DF | AIC | BIC | LogLik | LRStat | pValue | Lower |
|-------------------|----|--------|--------|---------|--------|---------|---------|
| <code>lme2</code> | 10 | 511.06 | 532 | -245.53 | | | |
| <code>lme</code> | 23 | 522.57 | 570.74 | -238.29 | 14.491 | 0.54446 | 0.51301 |

```
Upper
```

```
0.57564
```

The high p -value suggests that the larger model, `lme` is not significantly better than the smaller model, `lme2`. The smaller values of AIC and BIC for `lme2` also support this.

Definitions

Likelihood Ratio Test

Under the null hypothesis H_0 , the observed likelihood ratio test statistic has an approximate chi-squared reference distribution with degrees of freedom `deltaDF`. When comparing two models, `compare` computes the p -value for the likelihood ratio test by comparing the observed likelihood ratio test statistic with this chi-squared reference distribution.

The p -values obtained using the likelihood ratio test can be conservative when testing for the presence or absence of random-effects terms and anticonservative when testing for the presence or absence of fixed-effects terms. Hence, use the `fixedEffects`, `anova`, or `coefTest` method or the simulated likelihood ratio test while testing for fixed effects.

Simulated Likelihood Ratio Test

To perform the simulated likelihood ratio test, `compare` first generates the reference distribution of the likelihood ratio test statistic under the null hypothesis. Then, it assesses the statistical significance of the alternate model by comparing the observed likelihood ratio test statistic to this reference distribution.

`compare` produces the simulated reference distribution of the likelihood ratio test statistic under the null hypothesis as follows:

- Generate random data `ysim` from the fitted model `lme`.
- Fit the model specified in `lme` and alternate model `altlme` to the simulated data `ysim`.
- Calculate the likelihood ratio test statistic using results from step 2 and store the value.
- Repeat step 1 to 3 `nsim` times.

Then, `compare` computes the p -value for the simulated likelihood ratio test by comparing the observed likelihood ratio test statistic with the simulated reference distribution. The p -value estimate is the ratio of the number of times the simulated likelihood ratio test statistic is equal to or exceeds the observed value plus one, to the number of replications plus one.

Suppose the observed likelihood ratio statistic is T , and the simulated reference distribution is stored in vector T_{H_0} . Then,

$$p\text{-value} = \frac{\left[\sum_{j=1}^{nsim} I(T_{H_0}(j) \geq T) \right] + 1}{nsim + 1}.$$

To account for the uncertainty in the simulated reference distribution, `compare` computes a $100 \cdot (1 - \alpha)\%$ confidence interval for the true p -value.

You can use the simulated likelihood ratio test to compare arbitrary linear mixed-effects models. That is, when you are using the simulated likelihood ratio test, `lme` does not have to be nested within `altlme`, and you can fit `lme` and `altlme` using either maximum likelihood (ML) or restricted maximum likelihood (REML) methods. If you use the restricted maximum likelihood (REML) method to fit the models, then both models must have the same fixed-effects design matrix.

Nesting Requirements

The 'CheckNesting', 'True' name-value pair argument checks the following requirements.

For a simulated likelihood ratio test:

- You must use the same method to fit both models (`lme` and `altlme`). `compare` cannot compare a model fit using ML to a model fit using REML.
- You must fit both models to the same response vector.
- If you use REML to fit `lme` and `altlme`, then both models must have the same fixed-effects design matrix.
- The maximized log likelihood or restricted log likelihood of the bigger model (`altlme`) must be greater than or equal to that of the smaller model (`lme`).

For a theoretical test, 'CheckNesting', 'True' checks all the requirements listed for a simulated likelihood ratio test and the following:

- Weight vectors you use to fit `lme` and `altlme` must be identical.
- If you use ML to fit `lme` and `altlme`, the fixed-effects design matrix of the bigger model (`altlme`) must contain that of the smaller model (`lme`).
- The random-effects design matrix of the bigger model (`altlme`) must contain that of the smaller model (`lme`).

Akaike and Bayesian Information Criteria

Akaike information criterion (AIC) is $AIC = -2 \cdot \log L_M + 2 \cdot (nc + p + 1)$, where $\log L_M$ is the maximized log likelihood (or maximized restricted log likelihood) of the model, and $nc + p + 1$ is the number of parameters estimated in the model. p is the number of fixed-effects coefficients, and nc is the total number of parameters in the random-effects covariance excluding the residual variance.

Bayesian information criterion (BIC) is $BIC = -2 \cdot \log L_M + \ln(n_{eff}) \cdot (nc + p + 1)$, where $\log L_M$ is the maximized log likelihood (or maximized restricted log likelihood) of the model, n_{eff} is the effective number of observations, and $(nc + p + 1)$ is the number of parameters estimated in the model.

- If the fitting method is maximum likelihood (ML), then $n_{eff} = n$, where n is the number of observations.

- If the fitting method is restricted maximum likelihood (REML), then $n_{eff} = n - p$.

A lower value of deviance indicates a better fit. As the value of deviance decreases, both AIC and BIC tend to decrease. Both AIC and BIC also include penalty terms based on the number of parameters estimated, p . So, when the number of parameters increase, the values of AIC and BIC tend to increase as well. When comparing different models, the model with the lowest AIC or BIC value is considered as the best fitting model.

Deviance

`LinearMixedModel` computes the deviance of model M as minus two times the loglikelihood of that model. Let L_M denote the maximum value of the likelihood function for model M . Then, the deviance of model M is

$$-2 * \log L_M.$$

A lower value of deviance indicates a better fit. Suppose M_1 and M_2 are two different models, where M_1 is nested in M_2 . Then, the fit of the models can be assessed by comparing the deviances Dev_1 and Dev_2 of these models. The difference of the deviances is

$$Dev = Dev_1 - Dev_2 = 2(\log LM_2 - \log LM_1).$$

Usually, the asymptotic distribution of this difference has a chi-square distribution with degrees of freedom v equal to the number of parameters that are estimated in one model but fixed (typically at 0) in the other. That is, it is equal to the difference in the number of parameters estimated in M_1 and M_2 . You can get the p -value for this test using `1 - chi2cdf(Dev, V)`, where $Dev = Dev_2 - Dev_1$.

However, in mixed-effects models, when some variance components fall on the boundary of the parameter space, the asymptotic distribution of this difference is more complicated. For example, consider the hypotheses

$$H_0: D = \begin{pmatrix} D_{11} & 0 \\ 0 & 0 \end{pmatrix}, \text{ } D \text{ is a } q\text{-by-}q \text{ symmetric positive semidefinite matrix.}$$

$$H_1: D \text{ is a } (q+1)\text{-by-}(q+1) \text{ symmetric positive semidefinite matrix.}$$

That is, H_1 states that the last row and column of D are different from zero. Here, the bigger model M_2 has $q + 1$ parameters and the smaller model M_1 has q parameters. And Dev has a 50:50 mixture of χ^2_q and $\chi^2_{(q+1)}$ distributions (Stram and Lee, 1994).

compareHoldout

Class: ClassificationKNN

Compare accuracies of two models using new data

`compareHoldout` statistically assesses the accuracies of two classification models. The function first compares their predicted labels against the true labels, and then it detects whether the difference between the misclassification rates is statistically significant.

You can assess whether the accuracies of the classification models are different, or whether one classification model performs better than another. `compareHoldout` can conduct several McNemar test on page 32-1031 variations, including the asymptotic test, the exact-conditional test, and the mid- p -value test. For cost-sensitive assessment on page 32-1029, available tests include a chi-square test (requires an Optimization Toolbox license) and a likelihood ratio test.

Syntax

```
h = compareHoldout(C1,C2,T1,T2,ResponseVarName)
```

```
h = compareHoldout(C1,C2,T1,T2,Y)
```

```
h = compareHoldout(C1,C2,X1,X2,Y)
```

```
h = compareHoldout(C1,C2,X1,X2,Y,Name,Value)
```

```
[h,p,e1,e2] = compareHoldout( ___ )
```

Description

`h = compareHoldout(C1,C2,T1,T2,ResponseVarName)` returns the test decision from testing the null hypothesis that the trained classification models C1 and C2 have equal accuracy for predicting the true class labels `ResponseVarName`. The alternative hypothesis is that the labels have unequal accuracy.

The first classification model C1 uses predictor data T1 and C2 uses T2. The software conducts the mid- p -value McNemar test to compare the accuracies.

$h = 1$ indicates to reject the null hypothesis at the 5% significance level. $h = 0$ indicates to not reject the null hypothesis at 5% level.

Examples of tests you can conduct include:

- Compare the accuracies of a simple classification model and a model that is more complex by passing the same set of predictor data (i.e., $T1 = T2$).
- Compare the accuracies of two perhaps different models using two perhaps different sets of predictors.
- Perform various types of feature selection. For example, you can compare the accuracy of a model trained using a set of predictors to the accuracy of one trained on a subset or different set of those predictors. You can arbitrarily choose the set of predictors, or use a feature selection technique like PCA or sequential feature selection (see `pca` and `sequentialfs`).

`h = compareHoldout(C1,C2,T1,T2,Y)` returns the test decision from testing the null hypothesis that the trained classification models `C1` and `C2` have equal accuracy for predicting the true class labels `Y`. The alternative hypothesis is that the labels have unequal accuracy.

The first classification model `C1` uses predictor data `T1` and `C2` uses `T2`. The software conducts the mid- p -value McNemar test to compare the accuracies.

`h = compareHoldout(C1,C2,X1,X2,Y)` returns the test decision from testing the null hypothesis that the trained classification models `C1` and `C2` have equal accuracy for predicting the true class labels `Y`. The alternative hypothesis is that the labels have unequal accuracy.

The first classification model `C1` uses predictor data `X1` and `C2` uses `X2`. The software conducts the mid- p -value McNemar test to compare the accuracies.

`h = compareHoldout(C1,C2,X1,X2,Y,Name,Value)` returns the result of the hypothesis test with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the type of alternative hypothesis, and the type of test, or you can supply a cost matrix.

`[h,p,e1,e2] = compareHoldout(___)` returns the p -value for the hypothesis test (p) and the respective classification losses on page 32-906 of each set of predicted class labels ($e1$ and $e2$) using any of the input arguments in the previous syntaxes.

Input Arguments

C1 — Trained *k*NN classification model

ClassificationKNN model object

Trained *k*NN classification model, specified as a ClassificationKNN model object. That is, C1 is a trained classification model returned by fitcknn.

C2 — Trained classification model

trained classification model object | trained, compact classification model object

Trained classification model, specified as any trained or compact classification model object described in this table.

| Trained Model Type | Model Object | Returned By |
|--|-----------------------------------|--------------|
| Classification tree | ClassificationTree | fitctree |
| Discriminant analysis | ClassificationDiscriminant | fitcdiscr |
| Ensemble of bagged classification models | ClassificationBaggedEnsemble | fitcensemble |

| Compact SVM | CompactClassificationSVM | compact |

| Trained Model Type | Model Object | Returned By |
|-----------------------------|---------------------------|-------------|
| Compact classification tree | CompactClassificationTree | compact |

T1 — Test-set predictor table for first classification model

table

Test-set predictor table for the first classification model, C1, specified as a table. Each row of T1 corresponds to one observation, and each column corresponds to one predictor variable. Optionally, T1 can contain an additional column for the response variable. T1 must contain all the predictors used to train C1. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

T1 and T2 must have the same number of rows, and must have the same response values. If T1 and T2 contain the response variable used to train C1 and C2, then, you do not need to specify ResponseVarName or Y.

Data Types: table

T2 — Test-set predictor table for second classification model

table

Test-set predictor data for the second classification model, C2, specified as a table. Each row of T2 corresponds to one observation, and each column corresponds to one predictor variable. Optionally, T2 can contain an additional column for the response variable. T2 must contain all the predictors used to train C2. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

T1 and T2 must have the same number of rows and the same response values. If T1 and T2 contain the response variable used to train C1 and C2, then, you do not need to specify ResponseVarName or Y.

Data Types: table

ResponseVarName — Response variable name

name of a variable in T1 and T2

Response variable name, specified as the name of a variable in T1 and T2. If T1 and T2 contain the response variable used to train C1 and C2, then you do not need to specify ResponseVarName.

If you specify ResponseVarName, then you must do so as a character vector. For example, if the response variable is stored as T1.Response, then specify it as

'Response'. Otherwise, the software treats all columns of T1 and T2, including Response, as predictors.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

X1 — Test-set predictor data for first classification model

numeric matrix

Test-set predictor data for the first classification model, C1, specified as a numeric matrix.

Each row of X1 corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a predictor or feature). The variables used to train C1 must compose X1.

The number of rows in X1 and X2 must equal the length of Y.

Data Types: `double` | `single`

X2 — Test-set predictor data for second classification model

numeric matrix

Test-set predictor data for the second classification model, C2, specified as a numeric matrix.

Each row of X2 corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a predictor or feature). The variables used to train C2 must compose X2.

The number of rows in X2 and X1 must equal the length of Y.

Data Types: `double` | `single`

Y — True class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors | character vector

True class labels, specified as a categorical or character array, a logical or numeric vector, a cell array of character vectors, or a character vector.

If you specify any array except a character vector, then `compareHoldout` treats all variables or columns in X1 and X2 as predictor variables.

If you specify a character vector, then `X1` and `X2` must be tables, their response variables must have the same name and values, and `Y` must be the common name. For example, if `X1.Labels` and `X2.Labels` are the response variables, then `Y` must be `'Labels'` and `X1.Labels` and `X2.Labels` must be equivalent.

If `Y` is a character array, then each element must correspond to one row of the array.

The number of rows in `X1` and `X2` must equal the length of `Y`.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'Alternative', 'greater', 'Test', 'asymptotic', 'Cost', [0 2; 1 0]` specifies to test whether the first set of first predicted class labels is more accurate than the second set, to conduct the asymptotic McNemar test, and to penalize misclassifying observations with the true label `ClassNames{1}` twice as much as for misclassifying observations with the true label `ClassNames{2}`.

Alpha — Hypothesis test significance level

`0.05` (default) | scalar value in the interval (0,1)

Hypothesis test significance level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the interval (0,1).

Example: `'Alpha', 0.1`

Data Types: `single` | `double`

Alternative — Alternative hypothesis to assess

`'unequal'` (default) | `'greater'` | `'less'`

Alternative hypothesis to assess, specified as the comma-separated pair consisting of `'Alternative'` and one of these values listed in the table.

| Value | Alternative hypothesis |
|---------------------|--|
| 'unequal' (default) | For predicting Y, the set of predictions resulting from C1 applied to X1 and C2 applied to X2 have unequal accuracies. |
| 'greater' | For predicting Y, the set of predictions resulting from C1 applied to X1 is more accurate than C2 applied to X2. |
| 'less' | For predicting Y, the set of predictions resulting from C1 applied to X1 is less accurate than C2 applied to X2. |

Example: 'Alternative', 'greater'

Data Types: char

ClassNames — Class names

categorical vector | cell array of character vectors | character array | logical vector | numeric vector

Class names, specified as the comma-separated pair consisting of 'ClassNames' and a categorical or character array, logical or numeric vector, or cell array of character vectors. You must set ClassNames using the data type of Y.

If ClassNames is a character array, then each element must correspond to one *row* of the array.

Use ClassNames to:

- Specify the order of any input argument dimension that corresponds to class order. For example, use ClassNames to specify the order of the dimensions of Cost.
- Select a subset of classes for testing. For example, suppose that the set of all distinct class names in Y is {'a', 'b', 'c'}. To train and test models using observations from classes 'a' and 'c' only, specify 'ClassNames', {'a', 'c'}.

The default is the set of all distinct class names in Y.

Example: 'ClassNames', {'b', 'g'}

Data Types: categorical | char | logical | single | double | cell

Cost — Misclassification cost

square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure array. If you specify:

- If you specify the square matrix `Cost`, then `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of `Cost`, additionally specify the `ClassNames` name-value pair argument.
- If you specify the structure `S`, then `S` must have two fields:
 - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`. You can use this field to specify the order of the classes.
 - `S.ClassificationCosts`, which contains the cost matrix, with rows and columns ordered as in `S.ClassNames`

If you specify `Cost`, then `compareHoldout` cannot conduct one-sided, exact, or mid- p tests. You must also specify `'Alternative'`, `'unequal'`, `'Test'`, `'asymptotic'`. For cost-sensitive testing options, see the `CostTest` name-value pair argument.

It is a best practice to supply the same cost matrix used to train the classification models.

The default is $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$.

Example: `'Cost', [0 1 2 ; 1 0 2; 2 2 0]`

Data Types: `double` | `single` | `struct`

CostTest — Cost-sensitive test type

`'likelihood'` (default) | `'chisquare'`

Cost-sensitive test type, specified as the comma-separated pair consisting of `'CostTest'` and `'chisquare'` or `'likelihood'`. Unless you specify a cost matrix using the `Cost` name-value pair argument, `compareHoldout` ignores `CostTest`.

This table summarizes the available options for cost-sensitive testing.

| Value | Asymptotic test type | Requirements |
|---------------------------|-----------------------|---|
| <code>'chisquare'</code> | Chi-square test | Optimization Toolbox license to implement <code>quadprog</code> |
| <code>'likelihood'</code> | Likelihood ratio test | None |

For more details, see “Cost-Sensitive Testing” on page 32-6369.

Example: `'CostTest', 'chisquare'`

Data Types: char

Test — Test to conduct

'asymptotic' | 'exact' | 'midp'

Test to conduct, specified as the comma-separated pair consisting of 'Test' and 'asymptotic', 'exact', and 'midp'. This table summarizes the available options for cost-insensitive testing.

| Value | Description |
|------------------|--------------------------------|
| 'asymptotic' | Asymptotic McNemar test |
| 'exact' | Exact-conditional McNemar test |
| 'midp' (default) | Mid- p -value McNemar test |

For more details, see “McNemar Tests” on page 32-6372.

For cost-sensitive testing, Test must be 'asymptotic'. When you specify the Cost name-value pair argument, and choose a cost-sensitive test using the CostTest name-value pair argument, 'asymptotic' is the default.

Example: 'Test', 'asymptotic'

Data Types: char

Note NaNs, <undefined> values, and empty character vectors ('') indicate missing values. compareHoldout:

- Removes missing values in Y and the corresponding rows of X1 and X2
 - Predicts classes whether X1 and X2 have missing observations.
-

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

h = 1 indicates the rejection of the null hypothesis at the Alpha significance level.

$h = 0$ indicates failure to reject the null hypothesis at the α significance level.

p — p-value

scalar in the interval [0,1]

p-value of the test, returned as a scalar in the interval [0,1]. p is the probability that a random test statistic is at least as extreme as the observed test statistic, given that the null hypothesis is true.

`compareHoldout` estimates p using the distribution of the test statistic, which varies with the type of test. For details on test statistics derived from the available variants of the McNemar test, see “McNemar Tests” on page 32-6372. For details on test statistics derived from cost-sensitive tests, see “Cost-Sensitive Testing” on page 32-6369.

e1 — Classification loss

scalar

Classification loss on page 32-1035, returned as a scalar. **e1** summarizes the accuracy of the first set of class labels predicting the true class labels (Y).

`compareHoldout` applies the first test-set predictor data (X1) to the first classification model (C1) to estimate the first set of class labels. Then, the function compares the estimated labels to Y to obtain the classification loss.

For cost-insensitive testing, **e1** is the misclassification rate. That is, **e1** is the proportion of misclassified observations, which is a scalar in the interval [0,1].

For cost-sensitive testing, **e1** is the misclassification cost. That is, **e1** is the weighted average of the misclassification costs, in which the weights are the respective estimated proportions of misclassified observations.

e2 — Classification loss

scalar

Classification loss on page 32-1035, returned as a scalar. **e2** summarizes the accuracy of the second set of class labels predicting the true class labels (Y). `compareHoldout` applies the second test-set predictor data (X2) to the second classification model (C2) to estimate the second set of class labels. Then the function compares the estimated labels to Y to obtain the classification loss.

For cost-insensitive testing, **e2** is the misclassification rate. That is, **e2** is the proportion of misclassified observations, which is a scalar in the interval [0,1].

For cost-sensitive testing, `e2` is the misclassification cost. That is, `e2` is the weighted average of the misclassification costs, in which the weights are the respective estimated proportions of misclassified observations.

Examples

Compare Accuracies of Two Different Classification Models

Train two classification models using different algorithms. Conduct a statistical test comparing the misclassification rates of the two models on a held-out set.

Load the `ionosphere` data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

`CVP` is a cross-validation partition object that specifies the training and test sets.

Train an SVM model and an ensemble of 100 bagged classification trees. For the SVM model, specify to use the radial basis function kernel and a heuristic procedure to determine the kernel scale.

```
C1 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true,...
    'KernelFunction','RBF','KernelScale','auto');
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','Bag');
```

`C1` is a trained `ClassificationSVM` model. `C2` is a trained `ClassificationBaggedEnsemble` model.

Test whether the two models have equal predictive accuracies. Use the same test-set predictor data for each model.

```
h = compareHoldout(C1,C2,X(idxTest,:),X(idxTest,:),Y(idxTest))
```

```
h = logical
    0
```

$h = 0$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Assess Whether One Classification Model Classifies Better Than Another

Train two classification models using the same algorithm, but adjust a hyperparameter to make the algorithm more complex. Conduct a statistical test to assess whether the simpler model has better accuracy in held-out data than the more complex model.

Load the `ionosphere` data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Train two SVM models: one that uses a linear kernel (the default for binary classification) and one that uses the radial basis function kernel. Use the default kernel scale of 1.

```
C1 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true);
C2 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true,...
    'KernelFunction','RBF');
```

C1 and C2 are trained `ClassificationSVM` models.

Test the null hypothesis that the simpler model (C1) is at most as accurate as the more complex model (C2). Because the test-set size is large, conduct the asymptotic McNemar test, and compare the results with the mid- p -value test (the cost-insensitive testing default). Request to return p -values and misclassification rates.

```
Asymp = zeros(4,1); % Preallocation
MidP = zeros(4,1);
```

```
[Asymp(1),Asymp(2),Asymp(3),Asymp(4)] = compareHoldout(C1,C2,...
  X(idxTest,:),X(idxTest,:),Y(idxTest),'Alternative','greater',...
  'Test','asymptotic');
[MidP(1),MidP(2),MidP(3),MidP(4)] = compareHoldout(C1,C2,...
  X(idxTest,:),X(idxTest,:),Y(idxTest),'Alternative','greater');
table(Asymp,MidP,'RowNames',{'h' 'p' 'e1' 'e2'})
```

```
ans =
```

```
4x2 table
```

| | Asymp | MidP |
|----|------------|------------|
| h | 1 | 1 |
| p | 7.2801e-09 | 2.7649e-10 |
| e1 | 0.13714 | 0.13714 |
| e2 | 0.33143 | 0.33143 |

The p -value is close to zero for both tests, which indicates strong evidence to reject the null hypothesis that the simpler model is less accurate than the more complex model. No matter what test you specify, `compareHoldout` returns the same type of misclassification measure for both models.

Conduct Cost-Sensitive Comparison of Two Classification Models

For data sets with imbalanced class representations, or for data sets with imbalanced false-positive and false-negative costs, you can statistically compare the predictive performances of two classification models by including a cost matrix in the analysis.

Load the `arrhythmia` data set. Determine the class representations in the data.

```
load arrhythmia;
Y = categorical(Y);
tabulate(Y);
```

| Value | Count | Percent |
|-------|-------|---------|
| 1 | 245 | 54.20% |
| 2 | 44 | 9.73% |
| 3 | 15 | 3.32% |

| | | |
|----|----|--------|
| 4 | 15 | 3.32% |
| 5 | 13 | 2.88% |
| 6 | 25 | 5.53% |
| 7 | 3 | 0.66% |
| 8 | 2 | 0.44% |
| 9 | 9 | 1.99% |
| 10 | 50 | 11.06% |
| 14 | 4 | 0.88% |
| 15 | 5 | 1.11% |
| 16 | 22 | 4.87% |

There are 16 classes, however some are not represented in the data set. Most observations are classified as not having arrhythmia (class 1). To summarize, the data set is highly discrete with imbalanced classes.

Combine all observations with arrhythmia (classes 2 through 15) into one class. Remove those observations with unknown arrhythmia status from the data set.

```
Y = Y(Y ~= '16');  
Y(Y ~= '1') = '2';  
X = X(Y ~= '16',:);
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility  
CVP = cvpartition(Y, 'holdout', 0.5);  
idxTrain = training(CVP); % Training-set indices  
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Create a cost matrix such that misclassifying a patient with arrhythmia into the no arrhythmia class is five times worse than misclassifying a patient without arrhythmia into the arrhythmia class. Classifying correctly incurs no cost. The rows indicate the true class and the columns indicate the predicted class. When conducting a cost-sensitive analysis, it is a good practice to specify the order of the classes.

```
cost = [0 1; 5 0];  
ClassNames = categorical([2 1]);
```

Train two boosting ensembles of 50 classification trees, one that uses AdaBoostM1 and the other that uses LogitBoost. Because there are missing values, specify to use surrogate splits. Train the models using the cost matrix.

```
t = templateTree('Surrogate','on');
numTrees = 50;
C1 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','AdaBoostM1',...
    'NumLearningCycles',numTrees,'Learners',t,'Cost',cost);
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','LogitBoost',...
    'NumLearningCycles',numTrees,'Learners',t,'Cost',cost);
```

C1 and C2 are trained ClassificationEnsemble models.

Test whether the AdaBoostM1 ensemble (C1) and the LogitBoost ensemble (C2) have equal predictive accuracy. Supply the cost matrix. Conduct the asymptotic, likelihood ratio, cost-sensitive test (the default when you pass in a cost matrix). Request to return p -values and misclassification costs.

```
[h,p,e1,e2] = compareHoldout(C1,C2,X(idxTest,:),X(idxTest,:),Y(idxTest),...
    'Cost',cost)
```

```
h = logical
    0
```

```
p = 0.7954
```

```
e1 = 1.6558
```

```
e2 = 1.6186
```

$h = 0$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Select Features Using Statistical Accuracy Comparison

Reduce classification model complexity by selecting a subset of predictor variables (features) from a larger set. Then, statistically compare the out-of-sample accuracy between the two models.

Load the ionosphere data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP);      % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Train an ensemble of 100 boosted classification trees using AdaBoostM1 and the entire set of predictors. Inspect the importance measure for each predictor.

```
t = templateTree('MaxNumSplits',1); % Weak-learner template tree object
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','AdaBoostM1',...
    'Learners',t);
predImp = predictorImportance(C2);
```

```
figure;
bar(predImp);
h = gca;
h.XTick = 1:2:h.XLim(2)
```

```
h =
  Axes with properties:
      XLim: [-0.2000 35.2000]
      YLim: [0 0.0090]
      XScale: 'linear'
      YScale: 'linear'
  GridLineStyle: '-'
  Position: [0.1300 0.1100 0.7750 0.8150]
      Units: 'normalized'
```

Show all properties

```
title('Predictor Importances');
xlabel('Predictor');
ylabel('Importance measure');
```

Identify the top five predictors in terms of their importance.

```
[~,idxSort] = sort(predImp, 'descend');
idx5 = idxSort(1:5);
```

Train another ensemble of 100 boosted classification trees using AdaBoostM1 and the five predictors with the best importance.

```
C1 = fitcensemble(X(idxTrain,idx5),Y(idxTrain), 'Method', 'AdaBoostM1', ...
    'Learners', t);
```

Test whether the two models have equal predictive accuracies. Specify the reduced test-set predictor data for C1 and the full test-set predictor data for C2.

```
[h,p,e1,e2] = compareHoldout(C1,C2,X(idxTest,idx5),X(idxTest,:),Y(idxTest))
```

```
h = logical
    0
```

```
p = 0.7744
```

```
e1 = 0.0914
```

```
e2 = 0.0857
```

$h = 0$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies. This result favors the simpler ensemble, C1.

Definitions

Cost-Sensitive Testing

Conduct cost-sensitive testing when the cost of misclassification is imbalanced. When conducting a cost-sensitive analysis, you can account for the cost imbalance in training the classification models, and then in statistically comparing them.

If the cost of misclassification is imbalanced, then the misclassification rate tends to be a poorly performing classification loss on page 32-6375. Use misclassification cost instead to compare classification models.

Misclassification costs are often unbalanced in applications. For example, consider classifying subjects based on a set of predictors into two categories: healthy and sick. Misclassifying a sick subject as healthy poses a danger to the subject's life. However, misclassifying a healthy subject as sick can cause some inconvenience, but does not pose any danger. In this situation, you assign misclassification costs such that misclassifying a sick subject as healthy is more costly than misclassifying a healthy subject as sick.

The definitions that follow summarize the cost-sensitive tests. In the definitions:

- n_{ijk} and $\hat{\pi}_{ijk}$ are the number and estimated proportion of test-sample observations with true class k that the first classification model assigns label i . The second classification model assigns label j . The unknown, true value of $\hat{\pi}_{ijk}$ is π_{ijk} . The test-set sample size

$$\text{is } \sum_{i,j,k} n_{ijk} = n_{test}. \quad \sum_{i,j,k} \pi_{ijk} = \sum_{i,j,k} \pi_{ijk} = 1. .$$

- c_{ij} is the relative cost of assigning label j to an observation with true class i . $c_{ii} = 0$, $c_{ij} \geq 0$, and, for at least one (i, j) pair, $c_{ij} > 0$.
- All subscripts take on integer values from 1 through K , which is the number of classes.
- The expected difference in the misclassification costs of the two classification models is

$$\delta = \sum_{i=1}^K \sum_{j=1}^K \sum_{k=1}^K (c_{ki} - c_{kj}) \pi_{ijk}.$$

- The hypothesis test is

$$H_0 : \delta = 0$$

$$H_1 : \delta \neq 0$$

The available cost-sensitive tests are appropriate for two-tailed testing.

Available, asymptotic tests that address imbalanced costs are a chi-square test and a likelihood ratio test.

- Chi-square test — The chi-square test statistic is based on the Pearson and Neyman chi-square test statistics, but with a Laplace correction factor to account for any $n_{ijk} = 0$. The test statistic is

$$t_{\chi^2}^* = \sum_{i \neq j} \sum_k \frac{(n_{ijk} + 1 - (n_{test} + K^3) \hat{\pi}_{ijk}^{(1)})^2}{n_{ijk} + 1}.$$

If $1 - F_{\chi^2}(t_{\chi^2}^*; 1) < \alpha$, then reject H_0 .

- $\hat{\pi}_{ijk}^{(1)}$ are estimated by minimizing $t_{\chi^2}^*$ under the constraint that $\delta = 0$.
- $F_{\chi^2}(x; 1)$ is the χ^2 C.D.F. with one degree of freedom evaluated at x .
- Likelihood ratio test — The likelihood ratio test is based on N_{ijk} , which are binomial random variables having sample size n_{test} and success probability π_{ijk} . They represent the random number of observations with true class k that the first classification model

assigns label i . The second classification model assigns label j . Jointly, their distribution is multinomial.

The test statistic is

$$t_{LRT}^* = 2 \log \left[\frac{P \left(\bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \pi_{ijk} = \pi_{ijk}^{(2)} \right)}{P \left(\bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \pi_{ijk} = \pi_{ijk}^{(3)} \right)} \right].$$

If $1 - F_{\chi^2}(t_{LRT}^*; 1) < \alpha$, then reject H_0 .

•

$\hat{\pi}_{ijk}^{(2)} = \frac{n_{ijk}}{n_{test}}$ is the unrestricted MLE of π_{ijk} .

•

$\hat{\pi}_{ijk}^{(3)} = \frac{n_{ijk}}{n_{test} + \lambda(c_{ki} - c_{kj})}$ is the MLE under the null hypothesis that $\delta = 0$. λ is the solution to

$$\sum_{i,j,k} \frac{n_{ijk}(c_{ki} - c_{kj})}{n_{test} + \lambda(c_{ki} - c_{kj})} = 0.$$

•

$F_{\chi^2}(x; 1)$ is the χ^2 C.D.F. with one degree of freedom evaluated at x .

McNemar Tests

McNemar Tests are hypothesis tests that compare two population proportions while addressing the issues resulting from two dependent, matched-pair samples.

One way to compare the predictive accuracies of two classification models is:

- 1 Partition the data into training and test sets.
- 2 Train both classification models using the training set.
- 3 Predict class labels using the test set.

- 4 Summarize the results in a two-by-two table resembling this figure.

| | | Model 2 | | |
|---------|-----------|-----------------|-----------------|----------------|
| | | Correct | Incorrect | |
| Model 1 | Correct | n_{11} | n_{12} | $n_{1\bullet}$ |
| | Incorrect | n_{21} | n_{22} | $n_{2\bullet}$ |
| | | $n_{\bullet 1}$ | $n_{\bullet 2}$ | n_{test} |

n_{ij} are the number of concordant pairs, that is, the number of observations that both models classify the same way (correctly or incorrectly). n_{ij} , $i \neq j$, are the number of discordant pairs, that is, the number of observations that models classify differently (correctly or incorrectly).

The misclassification rates for Models 1 and 2 are

$$\hat{\pi}_{2\bullet} = n_{2\bullet} / n$$

and $\hat{\pi}_{\bullet 2} = n_{\bullet 2} / n$, respectively. A two-sided test for comparing the accuracy of the two models is

$$\begin{aligned} H_0 &: \pi_{\bullet 2} = \pi_{2\bullet} \\ H_1 &: \pi_{\bullet 2} \neq \pi_{2\bullet} \end{aligned}$$

The null hypothesis suggests that the population exhibits marginal homogeneity, which reduces the null hypothesis to $H_0 : \pi_{12} = \pi_{21}$. Also, under the null hypothesis, $N_{12} \sim \text{Binomial}(n_{12} + n_{21}, 0.5)$ [1].

These facts are the basis for these, available McNemar test variants: the asymptotic, exact-conditional and mid-p-value McNemar tests. The definitions that follow summarize the available variants.

- Asymptotic — The asymptotic McNemar test statistics and rejection regions (for significance-level α) are:

- For one-sided tests, the test statistic

$$t_{a1}^* = \frac{n_{12} - n_{21}}{\sqrt{n_{12} + n_{21}}}.$$

If $1 - \Phi(|t_1^*|) < \alpha$, where Φ is the standard Gaussian C.D.F., then reject H_0 .

- For two-sided tests, the test statistic

$$t_{a2}^* = \frac{(n_{12} - n_{21})^2}{n_{12} + n_{21}}.$$

If $1 - F_{\chi^2}(t_2^*; m) < \alpha$, where $F_{\chi^2}(x; m)$ is the χ_m^2 C.D.F. evaluated at x , then reject H_0 .

This variant requires large-sample theory, specifically, the Gaussian approximation to the binomial distribution. Therefore:

- The total number of discordant pairs, $n_d = n_{12} + n_{21}$ must be greater than 10 ([1], Ch. 10.1.4).
- In general, asymptotic tests do not guarantee nominal coverage. The observed probability of falsely rejecting the null hypothesis can exceed α . Simulation studies in [18] suggest this, but the asymptotic McNemar test performs well in terms of statistical power.
- Exact Conditional — The exact-conditional McNemar test statistics and rejection regions (for significance-level α) are ([36], [38]):

- For one-sided tests, the test statistic

$$t_1^* = n_{12}$$

If $F_{\text{Bin}}(t_1^*; n_d, 0.5) < \alpha$, where $F_{\text{Bin}}(x; n, p)$ is the binomial C.D.F. with sample size n and success probability p evaluated at x , then reject H_0 .

- For two-sided tests, the test statistic

$$t_2^* = \min(n_{12}, n_{21})$$

If $F_{\text{Bin}}(t_2^*; n_d, 0.5) < \alpha / 2$, then reject H_0 .

The exact conditional test always attains nominal coverage. Simulation studies in [18] suggest that the test is conservative, and then show that the test lacks statistical power compared to other variants. For small or highly discrete test samples, consider using the mid- p -value test ([1], Ch. 3.6.3). For details, see Test and “McNemar Tests” on page 32-6372.

- Mid- p -value test — The mid- p -value McNemar test statistics and rejection regions (for significance-level α) are ([32]):
 - For one-sided tests, the test statistic

$$t_1^* = n_{12}$$

If $F_{\text{Bin}}(t_1^* - 1; n_{12} + n_{21}, 0.5) + 0.5f_{\text{Bin}}(t_1^*; n_{12} + n_{21}, 0.5) < \alpha$, where $F_{\text{Bin}}(x; n, p)$ and $f_{\text{Bin}}(x; n, p)$ are the binomial C.D.F. and P.D.F, respectively, with sample size n and success probability p evaluated at x , then reject H_0 .

- For two-sided tests, the test statistic

$$t_2^* = \min(n_{12}, n_{21})$$

If $F_{\text{Bin}}(t_2^* - 1; n_{12} + n_{21} - 1, 0.5) + 0.5f_{\text{Bin}}(t_2^*; n_{12} + n_{21}, 0.5) < \alpha / 2$, then reject H_0 .

The mid- p -value test addresses the over-conservative behavior of the exact conditional test. The simulation studies in [18] demonstrate that this test attains nominal coverage, and has good statistical power.

Classification Loss

Classification losses indicate the accuracy of a classification model or set of predicted labels. Two classification losses are misclassification rate and cost.

`compareHoldout` returns the classification losses (see `e1` and `e2`) under the alternative hypothesis (i.e., the unrestricted classification losses). n_{ijk} is the number of test-sample observations with true class k that the first classification model assigns label i and the second classification model assigns label j , and the corresponding estimated proportion is

$\hat{\pi}_{ijk} = \frac{n_{ijk}}{n_{test}}$. The test-set sample size is $\sum_{i,j,k} n_{ijk} = n_{test}$. The indices are taken from 1 through K , the number of classes.

- Misclassification rate, or classification error, is a scalar in the interval $[0,1]$ representing the proportion of misclassified observations. That is, the misclassification rate for the first classification model is

$$e_1 = \sum_{j=1}^K \sum_{k=1}^K \sum_{i \neq k} \hat{\pi}_{ijk}.$$

For the misclassification rate of the second classification model (e_2), switch the indices i and j in the formula.

Classification accuracy decreases as the misclassification rate increases to 1.

- Misclassification cost is a nonnegative scalar and is a measure of classification quality relative to the values the specified cost matrix elements. Its interpretation depends on the specified costs of misclassification. Misclassification cost is the weighted average of the costs of misclassification (specified in a cost matrix, C) in which the weights are the respective, estimated proportions of misclassified observations. The misclassification cost for the first classification model is

$$e_1 = \sum_{j=1}^K \sum_{k=1}^K \sum_{i \neq k} \hat{\pi}_{ijk} C_{ki},$$

where C_{kj} is the cost of classifying an observation into class j if its true class is k . For the misclassification cost of the second classification model (e_2), switch the indices i and j in the formula.

In general, for a fixed cost matrix, classification accuracy decreases as misclassification cost increases.

Tips

- One way to perform cost-insensitive feature selection is:
 - 1 Train the first classification model (C1) using the full predictor set.
 - 2 Train the second classification model (C2) using the reduced predictor set.
 - 3 Specify X1 as the full, test-set predictor data and X2 as the reduced test-set predictor data.
 - 4 Enter `compareHoldout(C1,C2,X1,X2,'Alternative','less')`. If `compareHoldout` returns 1, then there is enough evidence to suggest that the classification model that uses fewer predictors performs better than the model that uses the full predictor set.

Alternatively, you can assess whether there is a significant difference between the accuracies of the two models. To perform this assessment, remove the 'Alternative', 'greater' specification in step 4. `compareHoldout` conducts a two-sided test, and `h = 0` indicates that there is not enough evidence to suggest a difference in the accuracy of the two models.

- Cost-sensitive tests perform numerical optimization, which requires additional computational resources. The likelihood ratio test conducts numerical optimization indirectly by finding the root of a Lagrange multiplier in an interval. For some data sets, if the root lies close to the boundaries of the interval, then the method can fail. Therefore, if you have an Optimization Toolbox license, consider conducting the cost-sensitive chi-square test instead. For more details, see `CostTest` and “Cost-Sensitive Testing” on page 32-1029.

Alternatives

To directly compare the accuracy of two sets of class labels in predicting a set of true class labels, use `testcholdout`.

"Hypothesis Tests"

Introduced in R2015a

compareHoldout

Class: CompactClassificationDiscriminant

Compare accuracies of two classification models using new data

`compareHoldout` statistically assesses the accuracies of two classification models. The function first compares their predicted labels against the true labels, and then it detects whether the difference between the misclassification rates is statistically significant.

You can assess whether the accuracies of the classification models are different, or whether one classification model performs better than another. `compareHoldout` can conduct several McNemar test on page 32-1031 variations, including the asymptotic test, the exact-conditional test, and the mid- p -value test. For cost-sensitive assessment on page 32-1029, available tests include a chi-square test (requires an Optimization Toolbox license) and a likelihood ratio test.

Syntax

```
h = compareHoldout(C1,C2,X1,X2,Y)
h = compareHoldout(C1,C2,X1,X2,Y,Name,Value)
[h,p,e1,e2] = compareHoldout( ___ )
```

Description

`h = compareHoldout(C1,C2,X1,X2,Y)` returns the test decision from testing the null hypothesis that the trained classification models C1 and C2 have equal accuracy for predicting the true class labels Y. The alternative hypothesis is that the labels have unequal accuracy.

The first classification model C1 uses predictor data X1 and C2 uses X2. The software conducts the mid- p -value McNemar test to compare the accuracies.

`h = 1` indicates to reject the null hypothesis at the 5% significance level. `h = 0` indicates to not reject the null hypothesis at 5% level.

Examples of tests you can conduct include:

- Compare the accuracies of a simple classification model and a model that is more complex by passing the same set of predictor data (i.e., $X1 = X2$).
- Compare the accuracies of two perhaps different models using two perhaps different sets of predictors.
- Perform various types of feature selection. For example, you can compare the accuracy of a model trained using a set of predictors and one trained on a subset or different set of those predictors. You can arbitrarily choose the set of predictors, or use a feature selection technique like PCA or sequential feature selection (see `pca` and `sequentialfs`).

`h = compareHoldout(C1, C2, X1, X2, Y, Name, Value)` returns the result of the hypothesis test with additional options specified by one or more `Name, Value` pair arguments. For example, you can specify the type of alternative hypothesis, and the type of test, or you can supply a cost matrix.

`[h, p, e1, e2] = compareHoldout(___)` returns the p -value for the hypothesis test (p) and the respective classification losses on page 32-930 of each set of predicted class labels ($e1$ and $e2$) using any of the input arguments in the previous syntaxes.

Input Arguments

C1 — Trained discriminant analysis classification model

`ClassificationDiscriminant` model object |
`CompactClassificationDiscriminant` model object

Trained discriminant analysis classification model, specified as a `ClassificationDiscriminant` or `CompactClassificationDiscriminant` model object. That is, `C1` is a trained classification model returned by `fitcdiscr` or `compact`.

C2 — Trained classification model

trained classification model object | trained, compact classification model object

Trained classification model, specified as any trained or compact classification model object described in this table.

| Trained Model Type | Model Object | Returned By |
|-----------------------|---|------------------------|
| Classification tree | <code>ClassificationTree</code> | <code>fitctree</code> |
| Discriminant analysis | <code>ClassificationDiscriminant</code> | <code>fitcdiscr</code> |

| Trained Model Type | Model Object | Returned By |
|--|-----------------------------------|--------------|
| Ensemble of bagged classification models | ClassificationBaggedEnsemble | fitcensemble |
| Ensemble of classification models | ClassificationEnsemble | fitcensemble |
| Multiclass, error-correcting output codes (ECOC) | ClassificationECOC | fitcecoc |
| kNN | ClassificationKNN | fitcknn |
| Naive Bayes | ClassificationNaiveBayes | fitcnb |
| Support vector machine (SVM) | ClassificationSVM | fitcsvm |
| Compact discriminant analysis | CompactClassificationDiscriminant | compact |
| Compact ECOC | CompactClassificationECOC | compact |
| Compact ensemble of classification models | CompactClassificationEnsemble | compact |
| Compact naive Bayes | CompactClassificationNaiveBayes | compact |
| Compact SVM | CompactClassificationSVM | compact |
| Compact classification tree | CompactClassificationTree | compact |

X1 — Test-set predictor data for first classification model

numeric matrix

Test-set predictor data for the first classification model, C1, specified as a numeric matrix.

Each row of X1 corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a predictor or feature). The variables used to train C1 must compose X1.

The number of rows in X1 and X2 must equal the length of Y.

Data Types: double | single

X2 — Test-set predictor data for second classification model

numeric matrix

Test-set predictor data for the second classification model, `C2`, specified as a numeric matrix.

Each row of `X2` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a predictor or feature). The variables used to train `C2` must compose `X2`.

The number of rows in `X2` and `X1` must equal the length of `Y`.

Data Types: `double` | `single`

Y — True class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors | character vector

True class labels, specified as a categorical or character array, a logical or numeric vector, a cell array of character vectors, or a character vector.

If you specify any array except a character vector, then `compareHoldout` treats all variables or columns in `X1` and `X2` as predictor variables.

If you specify a character vector, then `X1` and `X2` must be tables, their response variables must have the same name and values, and `Y` must be the common name. For example, if `X1.Labels` and `X2.Labels` are the response variables, then `Y` must be `'Labels'` and `X1.Labels` and `X2.Labels` must be equivalent.

If `Y` is a character array, then each element must correspond to one row of the array.

The number of rows in `X1` and `X2` must equal the length of `Y`.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Alternative', 'greater', 'Test', 'asymptotic', 'Cost', [0 2; 1 0]` specifies to test whether the first set of first predicted class labels is more accurate than the second set, to conduct the asymptotic McNemar test, and to penalize misclassifying

observations with the true label `ClassNames{1}` twice as much as for misclassifying observations with the true label `ClassNames{2}`.

Alpha — Hypothesis test significance level

0.05 (default) | scalar value in the interval (0,1)

Hypothesis test significance level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the interval (0,1).

Example: 'Alpha',0.1

Data Types: single | double

Alternative — Alternative hypothesis to assess

'unequal' (default) | 'greater' | 'less'

Alternative hypothesis to assess, specified as the comma-separated pair consisting of 'Alternative' and one of these values listed in the table.

| Value | Alternative hypothesis |
|---------------------|--|
| 'unequal' (default) | For predicting Y, the set of predictions resulting from C1 applied to X1 and C2 applied to X2 have unequal accuracies. |
| 'greater' | For predicting Y, the set of predictions resulting from C1 applied to X1 is more accurate than C2 applied to X2. |
| 'less' | For predicting Y, the set of predictions resulting from C1 applied to X1 is less accurate than C2 applied to X2. |

Example: 'Alternative', 'greater'

Data Types: char

ClassNames — Class names

categorical vector | cell array of character vectors | character array | logical vector | numeric vector

Class names, specified as the comma-separated pair consisting of 'ClassNames' and a categorical or character array, logical or numeric vector, or cell array of character vectors. You must set `ClassNames` using the data type of Y.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `ClassNames` to:

- Specify the order of any input argument dimension that corresponds to class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost`.
- Select a subset of classes for testing. For example, suppose that the set of all distinct class names in `Y` is `{'a', 'b', 'c'}`. To train and test models using observations from classes `'a'` and `'c'` only, specify `'ClassNames', {'a', 'c'}`.

The default is the set of all distinct class names in `Y`.

Example: `'ClassNames', {'b', 'g'}`

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Cost — Misclassification cost

`square matrix` | `structure array`

Misclassification cost, specified as the comma-separated pair consisting of `'Cost'` and a square matrix or structure array. If you specify:

- If you specify the square matrix `Cost`, then `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of `Cost`, additionally specify the `ClassNames` name-value pair argument.
- If you specify the structure `S`, then `S` must have two fields:
 - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`. You can use this field to specify the order of the classes.
 - `S.ClassificationCosts`, which contains the cost matrix, with rows and columns ordered as in `S.ClassNames`

If you specify `Cost`, then `compareHoldout` cannot conduct one-sided, exact, or mid- p tests. You must also specify `'Alternative', 'unequal', 'Test', 'asymptotic'`. For cost-sensitive testing options, see the `CostTest` name-value pair argument.

It is a best practice to supply the same cost matrix used to train the classification models.

The default is $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$.

Example: `'Cost', [0 1 2 ; 1 0 2; 2 2 0]`

Data Types: `double` | `single` | `struct`

CostTest – Cost-sensitive test type`'likelihood' (default) | 'chisquare'`

Cost-sensitive test type, specified as the comma-separated pair consisting of 'CostTest' and 'chisquare' or 'likelihood'. Unless you specify a cost matrix using the Cost name-value pair argument, compareHoldout ignores CostTest.

This table summarizes the available options for cost-sensitive testing.

| Value | Asymptotic test type | Requirements |
|--------------|-----------------------|--|
| 'chisquare' | Chi-square test | Optimization Toolbox license to implement quadprog |
| 'likelihood' | Likelihood ratio test | None |

For more details, see “Cost-Sensitive Testing” on page 32-6369.

Example: 'CostTest', 'chisquare'

Data Types: char

Test – Test to conduct`'asymptotic' | 'exact' | 'midp'`

Test to conduct, specified as the comma-separated pair consisting of 'Test' and 'asymptotic', 'exact', and 'midp'. This table summarizes the available options for cost-insensitive testing.

| Value | Description |
|------------------|-----------------------------------|
| 'asymptotic' | Asymptotic McNemar test |
| 'exact' | Exact-conditional McNemar test |
| 'midp' (default) | Mid- <i>p</i> -value McNemar test |

For more details, see “McNemar Tests” on page 32-6372.

For cost-sensitive testing, Test must be 'asymptotic'. When you specify the Cost name-value pair argument, and choose a cost-sensitive test using the CostTest name-value pair argument, 'asymptotic' is the default.

Example: 'Test', 'asymptotic'

Data Types: char

Note NaNs, <undefined> values, and empty character vectors (' ') indicate missing values. `compareHoldout`:

- Removes missing values in Y and the corresponding rows of $X1$ and $X2$
 - Predicts classes whether $X1$ and $X2$ have missing observations.
-

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

$h = 1$ indicates the rejection of the null hypothesis at the Alpha significance level.

$h = 0$ indicates failure to reject the null hypothesis at the Alpha significance level.

p — *p*-value

scalar in the interval [0,1]

p-value of the test, returned as a scalar in the interval [0,1]. *p* is the probability that a random test statistic is at least as extreme as the observed test statistic, given that the null hypothesis is true.

`compareHoldout` estimates *p* using the distribution of the test statistic, which varies with the type of test. For details on test statistics derived from the available variants of the McNemar test, see “McNemar Tests” on page 32-6372. For details on test statistics derived from cost-sensitive tests, see “Cost-Sensitive Testing” on page 32-6369.

e1 — Classification loss

scalar

Classification loss on page 32-1035, returned as a scalar. *e1* summarizes the accuracy of the first set of class labels predicting the true class labels (Y).

`compareHoldout` applies the first test-set predictor data ($X1$) to the first classification model ($C1$) to estimate the first set of class labels. Then, the function compares the estimated labels to Y to obtain the classification loss.

For cost-insensitive testing, `e1` is the misclassification rate. That is, `e1` is the proportion of misclassified observations, which is a scalar in the interval $[0,1]$.

For cost-sensitive testing, `e1` is the misclassification cost. That is, `e1` is the weighted average of the misclassification costs, in which the weights are the respective estimated proportions of misclassified observations.

e2 – Classification loss

scalar

Classification loss on page 32-1035, returned as a scalar. `e2` summarizes the accuracy of the second set of class labels predicting the true class labels (`Y`). `compareHoldout` applies the second test-set predictor data (`X2`) to the second classification model (`C2`) to estimate the second set of class labels. Then the function compares the estimated labels to `Y` to obtain the classification loss.

For cost-insensitive testing, `e2` is the misclassification rate. That is, `e2` is the proportion of misclassified observations, which is a scalar in the interval $[0,1]$.

For cost-sensitive testing, `e2` is the misclassification cost. That is, `e2` is the weighted average of the misclassification costs, in which the weights are the respective estimated proportions of misclassified observations.

Examples

Compare Accuracies of Two Different Classification Models

Train two classification models using different algorithms. Conduct a statistical test comparing the misclassification rates of the two models on a held-out set.

Load the `ionosphere` data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Train an SVM model and an ensemble of 100 bagged classification trees. For the SVM model, specify to use the radial basis function kernel and a heuristic procedure to determine the kernel scale.

```
C1 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true,...
            'KernelFunction','RBF','KernelScale','auto');
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','Bag');
```

C1 is a trained `ClassificationSVM` model. C2 is a trained `ClassificationBaggedEnsemble` model.

Test whether the two models have equal predictive accuracies. Use the same test-set predictor data for each model.

```
h = compareHoldout(C1,C2,X(idxTest,:),X(idxTest,:),Y(idxTest))
```

```
h = logical
    0
```

`h = 0` indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Assess Whether One Classification Model Classifies Better Than Another

Train two classification models using the same algorithm, but adjust a hyperparameter to make the algorithm more complex. Conduct a statistical test to assess whether the simpler model has better accuracy in held-out data than the more complex model.

Load the `ionosphere` data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Train two SVM models: one that uses a linear kernel (the default for binary classification) and one that uses the radial basis function kernel. Use the default kernel scale of 1.

```
C1 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true);
C2 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true,...
    'KernelFunction','RBF');
```

C1 and C2 are trained ClassificationSVM models.

Test the null hypothesis that the simpler model (C1) is at most as accurate as the more complex model (C2). Because the test-set size is large, conduct the asymptotic McNemar test, and compare the results with the mid- p -value test (the cost-insensitive testing default). Request to return p -values and misclassification rates.

```
Asymp = zeros(4,1); % Preallocation
MidP = zeros(4,1);

[Asymp(1),Asymp(2),Asymp(3),Asymp(4)] = compareHoldout(C1,C2,...
    X(idxTest,:),X(idxTest,:),Y(idxTest),'Alternative','greater',...
    'Test','asymptotic');
[MidP(1),MidP(2),MidP(3),MidP(4)] = compareHoldout(C1,C2,...
    X(idxTest,:),X(idxTest,:),Y(idxTest),'Alternative','greater');
table(Asymp,MidP,'RowNames',{'h' 'p' 'e1' 'e2'})
```

ans =

4x2 table

| | Asymp | MidP |
|----|------------|------------|
| h | 1 | 1 |
| p | 7.2801e-09 | 2.7649e-10 |
| e1 | 0.13714 | 0.13714 |
| e2 | 0.33143 | 0.33143 |

The p -value is close to zero for both tests, which indicates strong evidence to reject the null hypothesis that the simpler model is less accurate than the more complex model. No

matter what test you specify, `compareHoldout` returns the same type of misclassification measure for both models.

Conduct Cost-Sensitive Comparison of Two Classification Models

For data sets with imbalanced class representations, or for data sets with imbalanced false-positive and false-negative costs, you can statistically compare the predictive performances of two classification models by including a cost matrix in the analysis.

Load the `arrhythmia` data set. Determine the class representations in the data.

```
load arrhythmia;  
Y = categorical(Y);  
tabulate(Y);
```

| Value | Count | Percent |
|-------|-------|---------|
| 1 | 245 | 54.20% |
| 2 | 44 | 9.73% |
| 3 | 15 | 3.32% |
| 4 | 15 | 3.32% |
| 5 | 13 | 2.88% |
| 6 | 25 | 5.53% |
| 7 | 3 | 0.66% |
| 8 | 2 | 0.44% |
| 9 | 9 | 1.99% |
| 10 | 50 | 11.06% |
| 14 | 4 | 0.88% |
| 15 | 5 | 1.11% |
| 16 | 22 | 4.87% |

There are 16 classes, however some are not represented in the data set. Most observations are classified as not having arrhythmia (class 1). To summarize, the data set is highly discrete with imbalanced classes.

Combine all observations with arrhythmia (classes 2 through 15) into one class. Remove those observations with unknown arrhythmia status from the data set.

```
Y = Y(Y ~= '16');  
Y(Y ~= '1') = '2';  
X = X(Y ~= '16', :);
```

Create a partition that evenly splits the data into training and testing sets.

```

rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices

```

CVP is a cross-validation partition object that specifies the training and test sets.

Create a cost matrix such that misclassifying a patient with arrhythmia into the no arrhythmia class is five times worse than misclassifying a patient without arrhythmia into the arrhythmia class. Classifying correctly incurs no cost. The rows indicate the true class and the columns indicate the predicted class. When conducting a cost-sensitive analysis, it is a good practice to specify the order of the classes.

```

cost = [0 1;5 0];
ClassNames = categorical([2 1]);

```

Train two boosting ensembles of 50 classification trees, one that uses AdaBoostM1 and the other that uses LogitBoost. Because there are missing values, specify to use surrogate splits. Train the models using the cost matrix.

```

t = templateTree('Surrogate','on');
numTrees = 50;
C1 = fitensemble(X(idxTrain,:),Y(idxTrain),'Method','AdaBoostM1',...
    'NumLearningCycles',numTrees,'Learners',t,'Cost',cost);
C2 = fitensemble(X(idxTrain,:),Y(idxTrain),'Method','LogitBoost',...
    'NumLearningCycles',numTrees,'Learners',t,'Cost',cost);

```

C1 and C2 are trained ClassificationEnsemble models.

Test whether the AdaBoostM1 ensemble (C1) and the LogitBoost ensemble (C2) have equal predictive accuracy. Supply the cost matrix. Conduct the asymptotic, likelihood ratio, cost-sensitive test (the default when you pass in a cost matrix). Request to return p -values and misclassification costs.

```

[h,p,e1,e2] = compareHoldout(C1,C2,X(idxTest,:),X(idxTest,:),Y(idxTest),...
    'Cost',cost)

```

```

h = logical
    0

```

```

p = 0.7954

```

```

e1 = 1.6558

```

```
e2 = 1.6186
```

`h = 0` indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Select Features Using Statistical Accuracy Comparison

Reduce classification model complexity by selecting a subset of predictor variables (features) from a larger set. Then, statistically compare the out-of-sample accuracy between the two models.

Load the ionosphere data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Train an ensemble of 100 boosted classification trees using AdaBoostM1 and the entire set of predictors. Inspect the importance measure for each predictor.

```
t = templateTree('MaxNumSplits',1); % Weak-learner template tree object
C2 = fitensemble(X(idxTrain,:),Y(idxTrain),'Method','AdaBoostM1',...
    'Learners',t);
predImp = predictorImportance(C2);
```

```
figure;
bar(predImp);
h = gca;
h.XTick = 1:2:h.XLim(2)
```

```
h =
    Axes with properties:
```

```
    XLim: [-0.2000 35.2000]
    YLim: [0 0.0090]
```

```
XScale: 'linear'  
YScale: 'linear'  
GridLineStyle: '-'  
Position: [0.1300 0.1100 0.7750 0.8150]  
Units: 'normalized'
```

Show all properties

```
title('Predictor Importances');  
xlabel('Predictor');  
ylabel('Importance measure');
```

Identify the top five predictors in terms of their importance.

```
[~,idxSort] = sort(predImp, 'descend');  
idx5 = idxSort(1:5);
```

Train another ensemble of 100 boosted classification trees using AdaBoostM1 and the five predictors with the best importance.

```
C1 = fitcensemble(X(idxTrain,idx5),Y(idxTrain), 'Method', 'AdaBoostM1', ...  
    'Learners', t);
```

Test whether the two models have equal predictive accuracies. Specify the reduced test-set predictor data for C1 and the full test-set predictor data for C2.

```
[h,p,e1,e2] = compareHoldout(C1,C2,X(idxTest,idx5),X(idxTest,:),Y(idxTest))
```

```
h = logical  
    0
```

```
p = 0.7744
```

```
e1 = 0.0914
```

```
e2 = 0.0857
```

$h = 0$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies. This result favors the simpler ensemble, C1.

Definitions

Cost-Sensitive Testing

Conduct cost-sensitive testing when the cost of misclassification is imbalanced. When conducting a cost-sensitive analysis, you can account for the cost imbalance in training the classification models, and then in statistically comparing them.

If the cost of misclassification is imbalanced, then the misclassification rate tends to be a poorly performing classification loss on page 32-6375. Use misclassification cost instead to compare classification models.

Misclassification costs are often unbalanced in applications. For example, consider classifying subjects based on a set of predictors into two categories: healthy and sick.

Misclassifying a sick subject as healthy poses a danger to the subject's life. However, misclassifying a healthy subject as sick can cause some inconvenience, but does not pose any danger. In this situation, you assign misclassification costs such that misclassifying a sick subject as healthy is more costly than misclassifying a healthy subject as sick.

The definitions that follow summarize the cost-sensitive tests. In the definitions:

- n_{ijk} and $\hat{\pi}_{ijk}$ are the number and estimated proportion of test-sample observations with true class k that the first classification model assigns label i . The second classification model assigns label j . The unknown, true value of $\hat{\pi}_{ijk}$ is π_{ijk} . The test-set sample size

$$\text{is } \sum_{i,j,k} n_{ijk} = n_{test} \cdot \sum_{i,j,k} \pi_{ijk} = \sum_{i,j,k} \pi_{ijk} = 1. .$$

- c_{ij} is the relative cost of assigning label j to an observation with true class i . $c_{ii} = 0$, $c_{ij} \geq 0$, and, for at least one (i,j) pair, $c_{ij} > 0$.
- All subscripts take on integer values from 1 through K , which is the number of classes.
- The expected difference in the misclassification costs of the two classification models is

$$\delta = \sum_{i=1}^K \sum_{j=1}^K \sum_{k=1}^K (c_{ki} - c_{kj}) \pi_{ijk}.$$

- The hypothesis test is

$$H_0 : \delta = 0$$

$$H_1 : \delta \neq 0$$

The available cost-sensitive tests are appropriate for two-tailed testing.

Available, asymptotic tests that address imbalanced costs are a chi-square test and a likelihood ratio test.

- Chi-square test — The chi-square test statistic is based on the Pearson and Neyman chi-square test statistics, but with a Laplace correction factor to account for any $n_{ijk} = 0$. The test statistic is

$$t_{\chi^2}^* = \sum_{i \neq j} \sum_k \frac{(n_{ijk} + 1 - (n_{test} + K^3) \hat{\pi}_{ijk}^{(1)})^2}{n_{ijk} + 1}.$$

If $1 - F_{\chi^2}(t_{\chi^2}^*; 1) < \alpha$, then reject H_0 .

-
- $\hat{\pi}_{ijk}^{(1)}$ are estimated by minimizing $t_{\chi^2}^*$ under the constraint that $\delta = 0$.
- $F_{\chi^2}(x; 1)$ is the χ^2 C.D.F. with one degree of freedom evaluated at x .
- Likelihood ratio test — The likelihood ratio test is based on N_{ijk} , which are binomial random variables having sample size n_{test} and success probability π_{ijk} . They represent the random number of observations with true class k that the first classification model assigns label i . The second classification model assigns label j . Jointly, their distribution is multinomial.

The test statistic is

$$t_{LRT}^* = 2 \log \left[\frac{P \left(\bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \pi_{ijk} = \pi_{ijk}^{(2)} \right)}{P \left(\bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \pi_{ijk} = \pi_{ijk}^{(3)} \right)} \right].$$

If $1 - F_{\chi^2}(t_{LRT}^*; 1) < \alpha$, then reject H_0 .

-
- $\hat{\pi}_{ijk}^{(2)} = \frac{n_{ijk}}{n_{test}}$ is the unrestricted MLE of π_{ijk} .
-

$\hat{\pi}_{ijk}^{(3)} = \frac{n_{ijk}}{n_{test} + \lambda(c_{ki} - c_{kj})}$ is the MLE under the null hypothesis that $\delta = 0$. λ is the solution to

$$\sum_{i,j,k} \frac{n_{ijk}(c_{ki} - c_{kj})}{n_{test} + \lambda(c_{ki} - c_{kj})} = 0.$$

- $F_{\chi^2}(x;1)$ is the χ^2 C.D.F. with one degree of freedom evaluated at x .

McNemar Tests

McNemar Tests are hypothesis tests that compare two population proportions while addressing the issues resulting from two dependent, matched-pair samples.

One way to compare the predictive accuracies of two classification models is:

- 1 Partition the data into training and test sets.
- 2 Train both classification models using the training set.
- 3 Predict class labels using the test set.
- 4 Summarize the results in a two-by-two table resembling this figure.

| | | Model 2 | | |
|---------|-----------|-----------------|-----------------|----------------|
| | | Correct | Incorrect | |
| Model 1 | Correct | n_{11} | n_{12} | $n_{1\bullet}$ |
| | Incorrect | n_{21} | n_{22} | $n_{2\bullet}$ |
| | | $n_{\bullet 1}$ | $n_{\bullet 2}$ | n_{test} |

n_{ii} are the number of concordant pairs, that is, the number of observations that both models classify the same way (correctly or incorrectly). n_{ij} , $i \neq j$, are the number of discordant pairs, that is, the number of observations that models classify differently (correctly or incorrectly).

The misclassification rates for Models 1 and 2 are

$$\hat{\pi}_{2\bullet} = n_{2\bullet} / n$$

and $\hat{\pi}_{\bullet 2} = n_{\bullet 2} / n$, respectively. A two-sided test for comparing the accuracy of the two models is

$$\begin{aligned} H_0 &: \pi_{\bullet 2} = \pi_{2\bullet} \\ H_1 &: \pi_{\bullet 2} \neq \pi_{2\bullet} \end{aligned}$$

The null hypothesis suggests that the population exhibits marginal homogeneity, which reduces the null hypothesis to $H_0 : \pi_{12} = \pi_{21}$. Also, under the null hypothesis, $N_{12} \sim \text{Binomial}(n_{12} + n_{21}, 0.5)$ [1].

These facts are the basis for these, available McNemar test variants: the asymptotic, exact-conditional and mid-p-value McNemar tests. The definitions that follow summarize the available variants.

- Asymptotic — The asymptotic McNemar test statistics and rejection regions (for significance-level α) are:
 - For one-sided tests, the test statistic

$$t_{a1}^* = \frac{n_{12} - n_{21}}{\sqrt{n_{12} + n_{21}}}.$$

If $1 - \Phi\left(\left|t_1^*\right|\right) < \alpha$, where Φ is the standard Gaussian C.D.F., then reject H_0 .

- For two-sided tests, the test statistic

$$t_{a2}^* = \frac{(n_{12} - n_{21})^2}{n_{12} + n_{21}}.$$

If $1 - F_{\chi^2}\left(t_2^*; m\right) < \alpha$, where $F_{\chi^2}(x; m)$ is the χ_m^2 C.D.F. evaluated at x , then reject H_0 .

This variant requires large-sample theory, specifically, the Gaussian approximation to the binomial distribution. Therefore:

- The total number of discordant pairs, $n_d = n_{12} + n_{21}$ must be greater than 10 ([1], Ch. 10.1.4).
- In general, asymptotic tests do not guarantee nominal coverage. The observed probability of falsely rejecting the null hypothesis can exceed α . Simulation studies in [18] suggest this, but the asymptotic McNemar test performs well in terms of statistical power.
- Exact Conditional — The exact-conditional McNemar test statistics and rejection regions (for significance-level α) are ([36], [38]):
 - For one-sided tests, the test statistic

$$t_1^* = n_{12}$$

If $F_{\text{Bin}}(t_1^*; n_d, 0.5) < \alpha$, where $F_{\text{Bin}}(x; n, p)$ is the binomial C.D.F. with sample size n and success probability p evaluated at x , then reject H_0 .

- For two-sided tests, the test statistic

$$t_2^* = \min(n_{12}, n_{21})$$

If $F_{\text{Bin}}(t_2^*; n_d, 0.5) < \alpha / 2$, then reject H_0 .

The exact conditional test always attains nominal coverage. Simulation studies in [18] suggest that the test is conservative, and then show that the test lacks statistical power compared to other variants. For small or highly discrete test samples, consider using the mid- p -value test ([1], Ch. 3.6.3). For details, see Test and “McNemar Tests” on page 32-6372.

- Mid- p -value test — The mid- p -value McNemar test statistics and rejection regions (for significance-level α) are ([32]):
 - For one-sided tests, the test statistic

$$t_1^* = n_{12}$$

If $F_{\text{Bin}}(t_1^* - 1; n_{12} + n_{21}, 0.5) + 0.5f_{\text{Bin}}(t_1^*; n_{12} + n_{21}, 0.5) < \alpha$, where $F_{\text{Bin}}(x; n, p)$ and $f_{\text{Bin}}(x; n, p)$ are the binomial C.D.F. and P.D.F, respectively, with sample size n and success probability p evaluated at x , then reject H_0 .

- For two-sided tests, the test statistic

$$t_2^* = \min(n_{12}, n_{21})$$

If $F_{\text{Bin}}(t_2^* - 1; n_{12} + n_{21} - 1, 0.5) + 0.5f_{\text{Bin}}(t_2^*; n_{12} + n_{21}, 0.5) < \alpha / 2$, then reject H_0 .

The mid- p -value test addresses the over-conservative behavior of the exact conditional test. The simulation studies in [18] demonstrate that this test attains nominal coverage, and has good statistical power.

Classification Loss

Classification losses indicate the accuracy of a classification model or set of predicted labels. Two classification losses are misclassification rate and cost.

`compareHoldout` returns the classification losses (see `e1` and `e2`) under the alternative hypothesis (i.e., the unrestricted classification losses). n_{ijk} is the number of test-sample observations with true class k that the first classification model assigns label i and the second classification model assigns label j , and the corresponding estimated proportion is

$\hat{\pi}_{ijk} = \frac{n_{ijk}}{n_{test}}$. The test-set sample size is $\sum_{i,j,k} n_{ijk} = n_{test}$. The indices are taken from 1 through K , the number of classes.

- Misclassification rate, or classification error, is a scalar in the interval $[0, 1]$ representing the proportion of misclassified observations. That is, the misclassification rate for the first classification model is

$$e_1 = \sum_{j=1}^K \sum_{k=1}^K \sum_{i \neq k} \hat{\pi}_{ijk}$$

For the misclassification rate of the second classification model (e_2), switch the indices i and j in the formula.

Classification accuracy decreases as the misclassification rate increases to 1.

- Misclassification cost is a nonnegative scalar and is a measure of classification quality relative to the values the specified cost matrix elements. Its interpretation depends on the specified costs of misclassification. Misclassification cost is the weighted average of the costs of misclassification (specified in a cost matrix, C) in which the weights are the respective, estimated proportions of misclassified observations. The misclassification cost for the first classification model is

$$e_1 = \sum_{j=1}^K \sum_{k=1}^K \sum_{i \neq k} \hat{\pi}_{ijk} c_{ki},$$

where c_{kj} is the cost of classifying an observation into class j if its true class is k . For the misclassification cost of the second classification model (e_2), switch the indices i and j in the formula.

In general, for a fixed cost matrix, classification accuracy decreases as misclassification cost increases.

Tips

- One way to perform cost-insensitive feature selection is:
 - 1 Train the first classification model (C1) using the full predictor set.
 - 2 Train the second classification model (C2) using the reduced predictor set.
 - 3 Specify X1 as the full, test-set predictor data and X2 as the reduced test-set predictor data.
 - 4 Enter `compareHoldout(C1,C2,X1,X2,'Alternative','less')`. If `compareHoldout` returns 1, then there is enough evidence to suggest that the classification model that uses fewer predictors performs better than the model that uses the full predictor set.

Alternatively, you can assess whether there is a significant difference between the accuracies of the two models. To perform this assessment, remove the 'Alternative', 'greater' specification in step 4. `compareHoldout` conducts a two-sided test, and $h = 0$ indicates that there is not enough evidence to suggest a difference in the accuracy of the two models.

- Cost-sensitive tests perform numerical optimization, which requires additional computational resources. The likelihood ratio test conducts numerical optimization

indirectly by finding the root of a Lagrange multiplier in an interval. For some data sets, if the root lies close to the boundaries of the interval, then the method can fail. Therefore, if you have an Optimization Toolbox license, consider conducting the cost-sensitive chi-square test instead. For more details, see `CostTest` and “Cost-Sensitive Testing” on page 32-1029.

Alternatives

To directly compare the accuracy of two sets of class labels in predicting a set of true class labels, use `testcholdout`.

Introduced in R2015a

compareHoldout

Class: CompactClassificationECOC

Compare accuracies of two classification models using new data

`compareHoldout` statistically assesses the accuracies of two classification models. The function first compares their predicted labels against the true labels, and then it detects whether the difference between the misclassification rates is statistically significant.

You can assess whether the accuracies of the classification models are different, or whether one classification model performs better than another. `compareHoldout` can conduct several McNemar test on page 32-1031 variations, including the asymptotic test, the exact-conditional test, and the mid- p -value test. For cost-sensitive assessment on page 32-1029, available tests include a chi-square test (requires an Optimization Toolbox license) and a likelihood ratio test.

Syntax

```
h = compareHoldout(C1,C2,T1,T2,ResponseVarName)
```

```
h = compareHoldout(C1,C2,T1,T2,Y)
```

```
h = compareHoldout( ___,Name,Value)
```

```
h = compareHoldout(C1,C2,X1,X2,Y)
```

```
h = compareHoldout(C1,C2,X1,X2,Y,Name,Value)
```

```
[h,p,e1,e2] = compareHoldout( ___)
```

Description

`h = compareHoldout(C1,C2,T1,T2,ResponseVarName)` returns the test decision from testing the null hypothesis that the trained classification models `C1` and `C2` have equal accuracy for predicting the true class labels `ResponseVarName`. The alternative hypothesis is that the labels have unequal accuracy.

The first classification model `C1` uses predictor data `T1` and `C2` uses `T2`. The software conducts the mid- p -value McNemar test to compare the accuracies.

$h = 1$ indicates to reject the null hypothesis at the 5% significance level. $h = 0$ indicates to not reject the null hypothesis at 5% level.

Examples of tests you can conduct include:

- Compare the accuracies of a simple classification model and a model that is more complex by passing the same set of predictor data (i.e., $X1 = X2$).
- Compare the accuracies of two perhaps different models using two perhaps different sets of predictors.
- Perform various types of feature selection. For example, you can compare the accuracy of a model trained using a set of predictors to the accuracy of one trained on a subset or different set of those predictors. You can arbitrarily choose the set of predictors, or use a feature selection technique like PCA or sequential feature selection (see `pca` and `sequentialfs`).

`h = compareHoldout(C1,C2,T1,T2,Y)` returns the test decision from testing the null hypothesis that the trained classification models C1 and C2 have equal accuracy for predicting the true class labels Y. The alternative hypothesis is that the labels have unequal accuracy.

`h = compareHoldout(____,Name,Value)` returns the result of the hypothesis test with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes. For example, you can specify the type of alternative hypothesis, and the type of test, or you can supply a cost matrix.

`h = compareHoldout(C1,C2,X1,X2,Y)` returns the test decision from testing the null hypothesis that the trained classification models C1 and C2 have equal accuracy for predicting the true class labels Y. The alternative hypothesis is that the labels have unequal accuracy.

The first classification model C1 uses predictor data X1 and C2 uses X2. The software conducts the mid- p -value McNemar test to compare the accuracies.

$h = 1$ indicates to reject the null hypothesis at the 5% significance level. $h = 0$ indicates to not reject the null hypothesis at 5% level.

`h = compareHoldout(C1,C2,X1,X2,Y,Name,Value)` returns the result of the hypothesis test with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the type of alternative hypothesis, and the type of test, or you can supply a cost matrix.

`[h,p,e1,e2] = compareHoldout(___)` returns the p -value for the hypothesis test (p) and the respective classification losses on page 32-957 of each set of predicted class labels ($e1$ and $e2$) using any of the input arguments in the previous syntaxes.

Limitations

- `compareHoldout` does not compare ECOC models composed of linear classification models (that is, `ClassificationLinear` model objects). To compare ECOC models composed of linear classification models, use `testcholdout` instead.

Input Arguments

C1 — Trained, full or compact, multiclass error-correcting output codes model

`ClassificationECOC` model object | `CompactClassificationECOC` model object

Trained, full or compact, multiclass, error-correcting output codes (ECOC) model, specified as a `ClassificationECOC` or `CompactClassificationECOC` model object. That is, C1 is a trained classification model returned by `fitcecoc` or `compact`.

C1.BinaryLearners cannot contain `ClassificationLinear` model objects.

C2 — Trained classification model

trained classification model object | trained, compact classification model object

Trained classification model, specified as any trained or compact classification model object described in this table.

| Trained Model Type | Model Object | Returned By |
|--|---|---------------------------|
| Classification tree | <code>ClassificationTree</code> | <code>fitctree</code> |
| Discriminant analysis | <code>ClassificationDiscriminant</code> | <code>fitcdiscr</code> |
| Ensemble of bagged classification models | <code>ClassificationBaggedEnsemble</code> | <code>fitcensemble</code> |
| Ensemble of classification models | <code>ClassificationEnsemble</code> | <code>fitcensemble</code> |

| Trained Model Type | Model Object | Returned By |
|--|-----------------------------------|-------------|
| Multiclass, error-correcting output codes (ECOC) | ClassificationECOC | fitcecoc |
| kNN | ClassificationKNN | fitcknn |
| Naive Bayes | ClassificationNaiveBayes | fitcnb |
| Support vector machine (SVM) | ClassificationSVM | fitcsvm |
| Compact discriminant analysis | CompactClassificationDiscriminant | compact |
| Compact ECOC | CompactClassificationECOC | compact |
| Compact ensemble of classification models | CompactClassificationEnsemble | compact |
| Compact naive Bayes | CompactClassificationNaiveBayes | compact |
| Compact SVM | CompactClassificationSVM | compact |
| Compact classification tree | CompactClassificationTree | compact |

T1 — Test-set predictor table for first classification model

table

Test-set predictor table for the first classification model, C1, specified as a table. Each row of T1 corresponds to one observation, and each column corresponds to one predictor variable. Optionally, T1 can contain an additional column for the response variable. T1 must contain all of the predictors used to train C1. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

T1 and T2 must have the same number of rows, and must have the same response values. If T1 and T2 contain the response variable used to train C1 and C2, then, you do not need to specify ResponseVarName or Y.

Data Types: table

T2 — Test-set predictor table for second classification model

table

Test-set predictor data for the second classification model, C2, specified as a table. Each row of T2 corresponds to one observation, and each column corresponds to one predictor

variable. Optionally, T2 can contain an additional column for the response variable. T2 must contain all of the predictors used to train C2. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

T1 and T2 must have the same number of rows and the same response values. If T1 and T2 contain the response variable used to train C1 and C2, then, you do not need to specify ResponseVarName or Y.

Data Types: `table`

ResponseVarName — Response variable name

name of a variable in T1 and T2

Response variable name, specified as the name of a variable in T1 and T2. If T1 and T2 contain the response variable used to train C1 and C2, then you do not need to specify ResponseVarName.

If you specify ResponseVarName, then you must do so as a character vector. For example, if the response variable is stored as T1.Response, then specify it as 'Response'. Otherwise, the software treats all columns of T1 and T2, including Response, as predictors.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

X1 — Test-set predictor data for first classification model

numeric matrix

Test-set predictor data for the first classification model, C1, specified as a numeric matrix.

Each row of X1 corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a predictor or feature). The variables used to train C1 must compose X1.

The number of rows in X1 and X2 must equal the length of Y.

Data Types: `double` | `single`

X2 — Test-set predictor data for second classification model

numeric matrix

Test-set predictor data for the second classification model, C2, specified as a numeric matrix.

Each row of `X2` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a predictor or feature). The variables used to train `C2` must compose `X2`.

The number of rows in `X2` and `X1` must equal the length of `Y`.

Data Types: `double` | `single`

Y — True class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors | character vector

True class labels, specified as a categorical or character array, a logical or numeric vector, a cell array of character vectors, or a character vector.

If you specify any array except a character vector, then `compareHoldout` treats all variables or columns in `X1` and `X2` as predictor variables.

If you specify a character vector, then `X1` and `X2` must be tables, their response variables must have the same name and values, and `Y` must be the common name. For example, if `X1.Labels` and `X2.Labels` are the response variables, then `Y` must be `'Labels'` and `X1.Labels` and `X2.Labels` must be equivalent.

If `Y` is a character array, then each element must correspond to one row of the array.

The number of rows in `X1` and `X2` must equal the length of `Y`.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Alternative', 'greater', 'Test', 'asymptotic', 'Cost', [0 2; 1 0]` specifies to test whether the first set of first predicted class labels is more accurate than the second set, to conduct the asymptotic McNemar test, and to penalize misclassifying observations with the true label `ClassNames{1}` twice as much as for misclassifying observations with the true label `ClassNames{2}`.

Alpha — Hypothesis test significance level

0.05 (default) | scalar value in the interval (0,1)

Hypothesis test significance level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the interval (0,1).

Example: 'Alpha',0.1

Data Types: single | double

Alternative — Alternative hypothesis to assess

'unequal' (default) | 'greater' | 'less'

Alternative hypothesis to assess, specified as the comma-separated pair consisting of 'Alternative' and one of these values listed in the table.

| Value | Alternative hypothesis |
|---------------------|--|
| 'unequal' (default) | For predicting Y, the set of predictions resulting from C1 applied to X1 and C2 applied to X2 have unequal accuracies. |
| 'greater' | For predicting Y, the set of predictions resulting from C1 applied to X1 is more accurate than C2 applied to X2. |
| 'less' | For predicting Y, the set of predictions resulting from C1 applied to X1 is less accurate than C2 applied to X2. |

Example: 'Alternative', 'greater'

Data Types: char

ClassNames — Class names

categorical vector | cell array of character vectors | character array | logical vector | numeric vector

Class names, specified as the comma-separated pair consisting of 'ClassNames' and a categorical or character array, logical or numeric vector, or cell array of character vectors. You must set ClassNames using the data type of Y.

If ClassNames is a character array, then each element must correspond to one *row* of the array.

Use ClassNames to:

- Specify the order of any input argument dimension that corresponds to class order. For example, use ClassNames to specify the order of the dimensions of Cost.

- Select a subset of classes for testing. For example, suppose that the set of all distinct class names in Y is $\{ 'a', 'b', 'c' \}$. To train and test models using observations from classes 'a' and 'c' only, specify 'ClassNames', $\{ 'a', 'c' \}$.

The default is the set of all distinct class names in Y .

Example: 'ClassNames', $\{ 'b', 'g' \}$

Data Types: categorical | char | logical | single | double | cell

Cost — Misclassification cost

square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure array. If you specify:

- If you specify the square matrix $Cost$, then $Cost(i, j)$ is the cost of classifying a point into class j if its true class is i . That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of $Cost$, additionally specify the `ClassNames` name-value pair argument.
- If you specify the structure S , then S must have two fields:
 - `S.ClassNames`, which contains the class names as a variable of the same data type as Y . You can use this field to specify the order of the classes.
 - `S.ClassificationCosts`, which contains the cost matrix, with rows and columns ordered as in `S.ClassNames`

If you specify $Cost$, then `compareHoldout` cannot conduct one-sided, exact, or mid- p tests. You must also specify 'Alternative', 'unequal', 'Test', 'asymptotic'. For cost-sensitive testing options, see the `CostTest` name-value pair argument.

It is a best practice to supply the same cost matrix used to train the classification models.

The default is $Cost(i, j) = 1$ if $i \neq j$, and $Cost(i, j) = 0$ if $i = j$.

Example: 'Cost', $[0 \ 1 \ 2 \ ; \ 1 \ 0 \ 2; \ 2 \ 2 \ 0]$

Data Types: double | single | struct

CostTest — Cost-sensitive test type

'likelihood' (default) | 'chisquare'

Cost-sensitive test type, specified as the comma-separated pair consisting of 'CostTest' and 'chisquare' or 'likelihood'. Unless you specify a cost matrix using the Cost name-value pair argument, compareHoldout ignores CostTest.

This table summarizes the available options for cost-sensitive testing.

| Value | Asymptotic test type | Requirements |
|--------------|-----------------------|--|
| 'chisquare' | Chi-square test | Optimization Toolbox license to implement quadprog |
| 'likelihood' | Likelihood ratio test | None |

For more details, see “Cost-Sensitive Testing” on page 32-6369.

Example: 'CostTest', 'chisquare'

Data Types: char

Test — Test to conduct

'asymptotic' | 'exact' | 'midp'

Test to conduct, specified as the comma-separated pair consisting of 'Test' and 'asymptotic', 'exact', and 'midp'. This table summarizes the available options for cost-insensitive testing.

| Value | Description |
|------------------|-----------------------------------|
| 'asymptotic' | Asymptotic McNemar test |
| 'exact' | Exact-conditional McNemar test |
| 'midp' (default) | Mid- <i>p</i> -value McNemar test |

For more details, see “McNemar Tests” on page 32-6372.

For cost-sensitive testing, Test must be 'asymptotic'. When you specify the Cost name-value pair argument, and choose a cost-sensitive test using the CostTest name-value pair argument, 'asymptotic' is the default.

Example: 'Test', 'asymptotic'

Data Types: char

Note NaNs, <undefined> values, and empty character vectors ('') indicate missing values. compareHoldout:

- Removes missing values in Y and the corresponding rows of X1 and X2
 - Predicts classes whether X1 and X2 have missing observations.
-

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

$h = 1$ indicates the rejection of the null hypothesis at the Alpha significance level.

$h = 0$ indicates failure to reject the null hypothesis at the Alpha significance level.

p — *p*-value

scalar in the interval [0,1]

p-value of the test, returned as a scalar in the interval [0,1]. *p* is the probability that a random test statistic is at least as extreme as the observed test statistic, given that the null hypothesis is true.

`compareHoldout` estimates *p* using the distribution of the test statistic, which varies with the type of test. For details on test statistics derived from the available variants of the McNemar test, see “McNemar Tests” on page 32-6372. For details on test statistics derived from cost-sensitive tests, see “Cost-Sensitive Testing” on page 32-6369.

e1 — Classification loss

scalar

Classification loss on page 32-1035, returned as a scalar. **e1** summarizes the accuracy of the first set of class labels predicting the true class labels (Y).

`compareHoldout` applies the first test-set predictor data (X1) to the first classification model (C1) to estimate the first set of class labels. Then, the function compares the estimated labels to Y to obtain the classification loss.

For cost-insensitive testing, **e1** is the misclassification rate. That is, **e1** is the proportion of misclassified observations, which is a scalar in the interval [0,1].

For cost-sensitive testing, `e1` is the misclassification cost. That is, `e1` is the weighted average of the misclassification costs, in which the weights are the respective estimated proportions of misclassified observations.

e2 — Classification loss

scalar

Classification loss on page 32-1035, returned as a scalar. `e2` summarizes the accuracy of the second set of class labels predicting the true class labels (`Y`). `compareHoldout` applies the second test-set predictor data (`X2`) to the second classification model (`C2`) to estimate the second set of class labels. Then the function compares the estimated labels to `Y` to obtain the classification loss.

For cost-insensitive testing, `e2` is the misclassification rate. That is, `e2` is the proportion of misclassified observations, which is a scalar in the interval `[0,1]`.

For cost-sensitive testing, `e2` is the misclassification cost. That is, `e2` is the weighted average of the misclassification costs, in which the weights are the respective estimated proportions of misclassified observations.

Examples

Compare Accuracies of Two Different Classification Models

Train two classification models using different algorithms. Conduct a statistical test comparing the misclassification rates of the two models on a held-out set.

Load the ionosphere data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y, 'holdout', 0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

`CVP` is a cross-validation partition object that specifies the training and test sets.

Train an SVM model and an ensemble of 100 bagged classification trees. For the SVM model, specify to use the radial basis function kernel and a heuristic procedure to determine the kernel scale.

```
C1 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true,...
    'KernelFunction','RBF','KernelScale','auto');
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','Bag');
```

C1 is a trained `ClassificationSVM` model. C2 is a trained `ClassificationBaggedEnsemble` model.

Test whether the two models have equal predictive accuracies. Use the same test-set predictor data for each model.

```
h = compareHoldout(C1,C2,X(idxTest,:),X(idxTest,:),Y(idxTest))

h = logical
    0
```

$h = 0$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Assess Whether One Classification Model Classifies Better Than Another

Train two classification models using the same algorithm, but adjust a hyperparameter to make the algorithm more complex. Conduct a statistical test to assess whether the simpler model has better accuracy in held-out data than the more complex model.

Load the `ionosphere` data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Train two SVM models: one that uses a linear kernel (the default for binary classification) and one that uses the radial basis function kernel. Use the default kernel scale of 1.

```
C1 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true);
C2 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true,...
    'KernelFunction','RBF');
```

C1 and C2 are trained ClassificationSVM models.

Test the null hypothesis that the simpler model (C1) is at most as accurate as the more complex model (C2). Because the test-set size is large, conduct the asymptotic McNemar test, and compare the results with the mid- p -value test (the cost-insensitive testing default). Request to return p -values and misclassification rates.

```
Asymp = zeros(4,1); % Preallocation
MidP = zeros(4,1);

[Asymp(1),Asymp(2),Asymp(3),Asymp(4)] = compareHoldout(C1,C2,...
    X(idxTest,:),X(idxTest,:),Y(idxTest),'Alternative','greater',...
    'Test','asymptotic');
[MidP(1),MidP(2),MidP(3),MidP(4)] = compareHoldout(C1,C2,...
    X(idxTest,:),X(idxTest,:),Y(idxTest),'Alternative','greater');
table(Asymp,MidP,'RowNames',{'h' 'p' 'e1' 'e2'})
```

ans =

4x2 table

| | Asymp | MidP |
|----|------------|------------|
| h | 1 | 1 |
| p | 7.2801e-09 | 2.7649e-10 |
| e1 | 0.13714 | 0.13714 |
| e2 | 0.33143 | 0.33143 |

The p -value is close to zero for both tests, which indicates strong evidence to reject the null hypothesis that the simpler model is less accurate than the more complex model. No matter what test you specify, `compareHoldout` returns the same type of misclassification measure for both models.

Conduct Cost-Sensitive Comparison of Two Classification Models

For data sets with imbalanced class representations, or for data sets with imbalanced false-positive and false-negative costs, you can statistically compare the predictive performances of two classification models by including a cost matrix in the analysis.

Load the `arrhythmia` data set. Determine the class representations in the data.

```
load arrhythmia;
Y = categorical(Y);
tabulate(Y);
```

| Value | Count | Percent |
|-------|-------|---------|
| 1 | 245 | 54.20% |
| 2 | 44 | 9.73% |
| 3 | 15 | 3.32% |
| 4 | 15 | 3.32% |
| 5 | 13 | 2.88% |
| 6 | 25 | 5.53% |
| 7 | 3 | 0.66% |
| 8 | 2 | 0.44% |
| 9 | 9 | 1.99% |
| 10 | 50 | 11.06% |
| 14 | 4 | 0.88% |
| 15 | 5 | 1.11% |
| 16 | 22 | 4.87% |

There are 16 classes, however some are not represented in the data set. Most observations are classified as not having arrhythmia (class 1). To summarize, the data set is highly discrete with imbalanced classes.

Combine all observations with arrhythmia (classes 2 through 15) into one class. Remove those observations with unknown arrhythmia status from the data set.

```
Y = Y(Y ~= '16');
Y(Y ~= '1') = '2';
X = X(Y ~= '16',:);
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Create a cost matrix such that misclassifying a patient with arrhythmia into the no arrhythmia class is five times worse than misclassifying a patient without arrhythmia into the arrhythmia class. Classifying correctly incurs no cost. The rows indicate the true class and the columns indicate the predicted class. When conducting a cost-sensitive analysis, it is a good practice to specify the order of the classes.

```
cost = [0 1;5 0];  
ClassNames = categorical([2 1]);
```

Train two boosting ensembles of 50 classification trees, one that uses AdaBoostM1 and the other that uses LogitBoost. Because there are missing values, specify to use surrogate splits. Train the models using the cost matrix.

```
t = templateTree('Surrogate','on');  
numTrees = 50;  
C1 = fitensemble(X(idxTrain,:),Y(idxTrain),'Method','AdaBoostM1',...  
    'NumLearningCycles',numTrees,'Learners',t,'Cost',cost);  
C2 = fitensemble(X(idxTrain,:),Y(idxTrain),'Method','LogitBoost',...  
    'NumLearningCycles',numTrees,'Learners',t,'Cost',cost);
```

C1 and C2 are trained ClassificationEnsemble models.

Test whether the AdaBoostM1 ensemble (C1) and the LogitBoost ensemble (C2) have equal predictive accuracy. Supply the cost matrix. Conduct the asymptotic, likelihood ratio, cost-sensitive test (the default when you pass in a cost matrix). Request to return p -values and misclassification costs.

```
[h,p,e1,e2] = compareHoldout(C1,C2,X(idxTest,:),X(idxTest,:),Y(idxTest),...  
    'Cost',cost)
```

```
h = logical  
    0
```

```
p = 0.7954
```

```
e1 = 1.6558
```

```
e2 = 1.6186
```

$h = 0$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Select Features Using Statistical Accuracy Comparison

Reduce classification model complexity by selecting a subset of predictor variables (features) from a larger set. Then, statistically compare the out-of-sample accuracy between the two models.

Load the ionosphere data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP);      % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Train an ensemble of 100 boosted classification trees using AdaBoostM1 and the entire set of predictors. Inspect the importance measure for each predictor.

```
t = templateTree('MaxNumSplits',1); % Weak-learner template tree object
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','AdaBoostM1',...
    'Learners',t);
predImp = predictorImportance(C2);
```

```
figure;
bar(predImp);
h = gca;
h.XTick = 1:2:h.XLim(2)
```

```
h =
```

```
  Axes with properties:
```

```
      XLim: [-0.2000 35.2000]
      YLim: [0 0.0090]
      XScale: 'linear'
      YScale: 'linear'
  GridLineStyle: '-'
  Position: [0.1300 0.1100 0.7750 0.8150]
      Units: 'normalized'
```

Show all properties

```
title('Predictor Importances');
xlabel('Predictor');
ylabel('Importance measure');
```

Identify the top five predictors in terms of their importance.

```
[~,idxSort] = sort(predImp, 'descend');
idx5 = idxSort(1:5);
```

Train another ensemble of 100 boosted classification trees using AdaBoostM1 and the five predictors with the best importance.

```
C1 = fitcensemble(X(idxTrain,idx5),Y(idxTrain),'Method','AdaBoostM1',...
    'Learners',t);
```

Test whether the two models have equal predictive accuracies. Specify the reduced test-set predictor data for C1 and the full test-set predictor data for C2.

```
[h,p,e1,e2] = compareHoldout(C1,C2,X(idxTest,idx5),X(idxTest,:),Y(idxTest))
```

```
h = logical
    0
```

```
p = 0.7744
```

```
e1 = 0.0914
```

```
e2 = 0.0857
```

$h = 0$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies. This result favors the simpler ensemble, C1.

Definitions

Cost-Sensitive Testing

Conduct cost-sensitive testing when the cost of misclassification is imbalanced. When conducting a cost-sensitive analysis, you can account for the cost imbalance in training the classification models, and then in statistically comparing them.

If the cost of misclassification is imbalanced, then the misclassification rate tends to be a poorly performing classification loss on page 32-6375. Use misclassification cost instead to compare classification models.

Misclassification costs are often unbalanced in applications. For example, consider classifying subjects based on a set of predictors into two categories: healthy and sick. Misclassifying a sick subject as healthy poses a danger to the subject's life. However, misclassifying a healthy subject as sick can cause some inconvenience, but does not pose any danger. In this situation, you assign misclassification costs such that misclassifying a sick subject as healthy is more costly than misclassifying a healthy subject as sick.

The definitions that follow summarize the cost-sensitive tests. In the definitions:

- n_{ijk} and $\hat{\pi}_{ijk}$ are the number and estimated proportion of test-sample observations with true class k that the first classification model assigns label i . The second classification model assigns label j . The unknown, true value of $\hat{\pi}_{ijk}$ is π_{ijk} . The test-set sample size

$$\sum_{i,j,k} n_{ijk} = n_{test} \cdot \sum_{i,j,k} \pi_{ijk} = \sum_{i,j,k} \pi_{ijk} = 1.$$

- c_{ij} is the relative cost of assigning label j to an observation with true class i . $c_{ii} = 0$, $c_{ij} \geq 0$, and, for at least one (i,j) pair, $c_{ij} > 0$.
- All subscripts take on integer values from 1 through K , which is the number of classes.
- The expected difference in the misclassification costs of the two classification models is

$$\delta = \sum_{i=1}^K \sum_{j=1}^K \sum_{k=1}^K (c_{ki} - c_{kj}) \pi_{ijk}.$$

- The hypothesis test is

$$H_0 : \delta = 0$$

$$H_1 : \delta \neq 0$$

The available cost-sensitive tests are appropriate for two-tailed testing.

Available, asymptotic tests that address imbalanced costs are a chi-square test and a likelihood ratio test.

- Chi-square test — The chi-square test statistic is based on the Pearson and Neyman chi-square test statistics, but with a Laplace correction factor to account for any $n_{ijk} = 0$. The test statistic is

$$t_{\chi^2}^* = \sum_{i \neq j} \sum_k \frac{(n_{ijk} + 1 - (n_{test} + K^3) \hat{\pi}_{ijk}^{(1)})^2}{n_{ijk} + 1}.$$

If $1 - F_{\chi^2}(t_{\chi^2}^*; 1) < \alpha$, then reject H_0 .

- $\hat{\pi}_{ijk}^{(1)}$ are estimated by minimizing $t_{\chi^2}^*$ under the constraint that $\delta = 0$.
- $F_{\chi^2}(x;1)$ is the χ^2 C.D.F. with one degree of freedom evaluated at x .
- Likelihood ratio test — The likelihood ratio test is based on N_{ijk} , which are binomial random variables having sample size n_{test} and success probability π_{ijk} . They represent the random number of observations with true class k that the first classification model assigns label i . The second classification model assigns label j . Jointly, their distribution is multinomial.

The test statistic is

$$t_{LRT}^* = 2 \log \left[\frac{P \left(\bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \pi_{ijk} = \pi_{ijk}^{(2)} \right)}{P \left(\bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \pi_{ijk} = \pi_{ijk}^{(3)} \right)} \right].$$

If $1 - F_{\chi^2}(t_{LRT}^*; 1) < \alpha$, then reject H_0 .

- $\hat{\pi}_{ijk}^{(2)} = \frac{n_{ijk}}{n_{test}}$ is the unrestricted MLE of π_{ijk} .
- $\hat{\pi}_{ijk}^{(3)} = \frac{n_{ijk}}{n_{test} + \lambda(c_{ki} - c_{kj})}$ is the MLE under the null hypothesis that $\delta = 0$. λ is the solution to

$$\sum_{i,j,k} \frac{n_{ijk}(c_{ki} - c_{kj})}{n_{test} + \lambda(c_{ki} - c_{kj})} = 0.$$
- $F_{\chi^2}(x;1)$ is the χ^2 C.D.F. with one degree of freedom evaluated at x .

McNemar Tests

McNemar Tests are hypothesis tests that compare two population proportions while addressing the issues resulting from two dependent, matched-pair samples.

One way to compare the predictive accuracies of two classification models is:

- 1 Partition the data into training and test sets.
- 2 Train both classification models using the training set.
- 3 Predict class labels using the test set.
- 4 Summarize the results in a two-by-two table resembling this figure.

| | | Model 2 | | |
|---------|-----------|-----------------|-----------------|----------------|
| | | Correct | Incorrect | |
| Model 1 | Correct | n_{11} | n_{12} | $n_{1\bullet}$ |
| | Incorrect | n_{21} | n_{22} | $n_{2\bullet}$ |
| | | $n_{\bullet 1}$ | $n_{\bullet 2}$ | n_{test} |

n_{ii} are the number of concordant pairs, that is, the number of observations that both models classify the same way (correctly or incorrectly). n_{ij} , $i \neq j$, are the number of discordant pairs, that is, the number of observations that models classify differently (correctly or incorrectly).

The misclassification rates for Models 1 and 2 are

$$\hat{\pi}_{2\bullet} = n_{2\bullet} / n$$

and $\hat{\pi}_{\bullet 2} = n_{\bullet 2} / n$, respectively. A two-sided test for comparing the accuracy of the two models is

$$\begin{aligned} H_0 &: \pi_{\bullet 2} = \pi_{2\bullet} \\ H_1 &: \pi_{\bullet 2} \neq \pi_{2\bullet} \end{aligned}$$

The null hypothesis suggests that the population exhibits marginal homogeneity, which reduces the null hypothesis to $H_0 : \pi_{12} = \pi_{21}$. Also, under the null hypothesis, $N_{12} \sim \text{Binomial}(n_{12} + n_{21}, 0.5)$ [1].

These facts are the basis for these, available McNemar test variants: the asymptotic, exact-conditional and mid-p-value McNemar tests. The definitions that follow summarize the available variants.

- Asymptotic — The asymptotic McNemar test statistics and rejection regions (for significance-level α) are:

- For one-sided tests, the test statistic

$$t_{a1}^* = \frac{n_{12} - n_{21}}{\sqrt{n_{12} + n_{21}}}.$$

If $1 - \Phi\left(\left|t_1^*\right|\right) < \alpha$, where Φ is the standard Gaussian C.D.F., then reject H_0 .

- For two-sided tests, the test statistic

$$t_{a2}^* = \frac{(n_{12} - n_{21})^2}{n_{12} + n_{21}}.$$

If $1 - F_{\chi^2}\left(t_2^*; m\right) < \alpha$, where $F_{\chi^2}(x; m)$ is the χ_m^2 C.D.F. evaluated at x , then reject H_0 .

This variant requires large-sample theory, specifically, the Gaussian approximation to the binomial distribution. Therefore:

- The total number of discordant pairs, $n_d = n_{12} + n_{21}$ must be greater than 10 ([1], Ch. 10.1.4).
- In general, asymptotic tests do not guarantee nominal coverage. The observed probability of falsely rejecting the null hypothesis can exceed α . Simulation studies in [18] suggest this, but the asymptotic McNemar test performs well in terms of statistical power.
- Exact Conditional — The exact-conditional McNemar test statistics and rejection regions (for significance-level α) are ([36], [38]):

- For one-sided tests, the test statistic

$$t_1^* = n_{12}$$

If $F_{\text{Bin}}(t_1^*; n_d, 0.5) < \alpha$, where $F_{\text{Bin}}(x; n, p)$ is the binomial C.D.F. with sample size n and success probability p evaluated at x , then reject H_0 .

- For two-sided tests, the test statistic

$$t_2^* = \min(n_{12}, n_{21})$$

If $F_{\text{Bin}}(t_2^*; n_d, 0.5) < \alpha / 2$, then reject H_0 .

The exact conditional test always attains nominal coverage. Simulation studies in [18] suggest that the test is conservative, and then show that the test lacks statistical power compared to other variants. For small or highly discrete test samples, consider using the mid- p -value test ([1], Ch. 3.6.3). For details, see `Test` and “McNemar Tests” on page 32-6372.

- Mid- p -value test — The mid- p -value McNemar test statistics and rejection regions (for significance-level α) are ([32]):

- For one-sided tests, the test statistic

$$t_1^* = n_{12}$$

If $F_{\text{Bin}}(t_1^* - 1; n_{12} + n_{21}, 0.5) + 0.5f_{\text{Bin}}(t_1^*; n_{12} + n_{21}, 0.5) < \alpha$, where $F_{\text{Bin}}(x; n, p)$ and $f_{\text{Bin}}(x; n, p)$ are the binomial C.D.F. and P.D.F, respectively, with sample size n and success probability p evaluated at x , then reject H_0 .

- For two-sided tests, the test statistic

$$t_2^* = \min(n_{12}, n_{21})$$

If $F_{\text{Bin}}(t_2^* - 1; n_{12} + n_{21} - 1, 0.5) + 0.5f_{\text{Bin}}(t_2^*; n_{12} + n_{21}, 0.5) < \alpha / 2$, then reject H_0 .

The mid- p -value test addresses the over-conservative behavior of the exact conditional test. The simulation studies in [18] demonstrate that this test attains nominal coverage, and has good statistical power.

Classification Loss

Classification losses indicate the accuracy of a classification model or set of predicted labels. Two classification losses are misclassification rate and cost.

`compareHoldout` returns the classification losses (see `e1` and `e2`) under the alternative hypothesis (i.e., the unrestricted classification losses). n_{ijk} is the number of test-sample observations with true class k that the first classification model assigns label i and the second classification model assigns label j , and the corresponding estimated proportion is

$\hat{\pi}_{ijk} = \frac{n_{ijk}}{n_{test}}$. The test-set sample size is $\sum_{i,j,k} n_{ijk} = n_{test}$. The indices are taken from 1 through K , the number of classes.

- Misclassification rate, or classification error, is a scalar in the interval $[0,1]$ representing the proportion of misclassified observations. That is, the misclassification rate for the first classification model is

$$e_1 = \sum_{j=1}^K \sum_{k=1}^K \sum_{i \neq k} \hat{\pi}_{ijk}.$$

For the misclassification rate of the second classification model (e_2), switch the indices i and j in the formula.

Classification accuracy decreases as the misclassification rate increases to 1.

- Misclassification cost is a nonnegative scalar and is a measure of classification quality relative to the values the specified cost matrix elements. Its interpretation depends on the specified costs of misclassification. Misclassification cost is the weighted average of the costs of misclassification (specified in a cost matrix, C) in which the weights are the respective, estimated proportions of misclassified observations. The misclassification cost for the first classification model is

$$e_1 = \sum_{j=1}^K \sum_{k=1}^K \sum_{i \neq k} \hat{\pi}_{ijk} c_{ki},$$

where c_{kj} is the cost of classifying an observation into class j if its true class is k . For the misclassification cost of the second classification model (e_2), switch the indices i and j in the formula.

In general, for a fixed cost matrix, classification accuracy decreases as misclassification cost increases.

Tips

- One way to perform cost-insensitive feature selection is:
 - 1 Train the first classification model (C1) using the full predictor set.
 - 2 Train the second classification model (C2) using the reduced predictor set.
 - 3 Specify X1 as the full, test-set predictor data and X2 as the reduced test-set predictor data.
 - 4 Enter `compareHoldout(C1,C2,X1,X2,'Alternative','less')`. If `compareHoldout` returns 1, then there is enough evidence to suggest that the classification model that uses fewer predictors performs better than the model that uses the full predictor set.

Alternatively, you can assess whether there is a significant difference between the accuracies of the two models. To perform this assessment, remove the 'Alternative', 'greater' specification in step 4. `compareHoldout` conducts a two-sided test, and `h = 0` indicates that there is not enough evidence to suggest a difference in the accuracy of the two models.

- Cost-sensitive tests perform numerical optimization, which requires additional computational resources. The likelihood ratio test conducts numerical optimization indirectly by finding the root of a Lagrange multiplier in an interval. For some data sets, if the root lies close to the boundaries of the interval, then the method can fail. Therefore, if you have an Optimization Toolbox license, consider conducting the cost-sensitive chi-square test instead. For more details, see `CostTest` and “Cost-Sensitive Testing” on page 32-1029.

Alternatives

To directly compare the accuracy of two sets of class labels in predicting a set of true class labels, use `testcholdout`.

compareHoldout

Class: CompactClassificationEnsemble

Compare accuracies of two classification models using new data

`compareHoldout` statistically assesses the accuracies of two classification models. The function first compares their predicted labels against the true labels, and then it detects whether the difference between the misclassification rates is statistically significant.

You can assess whether the accuracies of the classification models are different, or whether one classification model performs better than another. `compareHoldout` can conduct several McNemar test on page 32-1031 variations, including the asymptotic test, the exact-conditional test, and the mid- p -value test. For cost-sensitive assessment on page 32-1029, available tests include a chi-square test (requires an Optimization Toolbox license) and a likelihood ratio test.

Syntax

```
h = compareHoldout(C1,C2,T1,T2,ResponseVarName)
```

```
h = compareHoldout(C1,C2,T1,T2,Y)
```

```
h = compareHoldout( ___,Name,Value)
```

```
h = compareHoldout(C1,C2,X1,X2,Y)
```

```
h = compareHoldout( ___,Name,Value)
```

```
[h,p,e1,e2] = compareHoldout( ___)
```

Description

`h = compareHoldout(C1,C2,T1,T2,ResponseVarName)` returns the test decision from testing the null hypothesis that the trained classification models C1 and C2 have equal accuracy for predicting the true class labels in `ResponseVarName`. The alternative hypothesis is that the labels have unequal accuracy.

The first classification model C1 uses predictor data in table T1 and C2 uses T2. The software conducts the mid- p -value McNemar test to compare the accuracies.

$h = 1$ indicates to reject the null hypothesis at the 5% significance level. $h = 0$ indicates to not reject the null hypothesis at 5% level.

Examples of tests you can conduct include:

- Compare the accuracies of a simple classification model and a model that is more complex by passing the same set of predictor data (i.e., $T1 = T2$).
- Compare the accuracies of two perhaps different models using two perhaps different sets of predictors.
- Perform various types of feature selection. For example, compare the accuracies of a model trained using a set of predictors and one trained on a subset or different set of those predictors. You can arbitrarily choose the set of predictors, or use a feature selection technique like PCA or sequential feature selection (see `pca` and `sequentialfs`).

`h = compareHoldout(C1,C2,T1,T2,Y)` returns the test decision from testing the null hypothesis that the trained classification models `C1` and `C2` have equal accuracy for predicting the true class labels `Y`. The alternative hypothesis is that the labels have unequal accuracy.

`h = compareHoldout(____, Name, Value)` returns the result of the hypothesis test with additional options specified by one or more `Name, Value` pair arguments, using any of the previous syntaxes. For example, specify the type of alternative hypothesis, specify the type of test, or supply a cost matrix.

`h = compareHoldout(C1,C2,X1,X2,Y)` returns the test decision from testing the null hypothesis that the trained classification models `C1` and `C2` have equal accuracy for predicting the true class labels `Y`. The alternative hypothesis is that the labels have unequal accuracy.

The first classification model `C1` uses predictor data `X1` and `C2` uses `X2`. The software conducts the mid- p -value McNemar test to compare the accuracies.

`h = compareHoldout(____, Name, Value)` returns the result of the hypothesis test with additional options specified by one or more `Name, Value` pair arguments. For example, specify the type of alternative hypothesis, specify the type of test, or supply a cost matrix.

`[h,p,e1,e2] = compareHoldout(____)` returns the p -value for the hypothesis test (p) and the respective classification losses on page 32-983 of each set of predicted class labels ($e1$ and $e2$).

Input Arguments

C1 — Trained ensemble of classification models

ClassificationBaggedEnsemble model object | ClassificationEnsemble model object | CompactClassificationEnsemble model object

Trained ensemble of classification models, specified as a ClassificationBaggedEnsemble, ClassificationEnsemble, or CompactClassificationEnsemble model object. That is, C1 is a trained classification model returned by fitensemble or compact.

C2 — Trained classification model

trained classification model object | trained, compact classification model object

Trained classification model, specified as any trained or compact classification model object described in this table.

| Trained Model Type | Model Object | Returned By |
|--|-----------------------------------|-------------|
| Classification tree | ClassificationTree | fitctree |
| Discriminant analysis | ClassificationDiscriminant | fitcdiscr |
| Ensemble of bagged classification models | ClassificationBaggedEnsemble | fitensemble |
| Ensemble of classification models | ClassificationEnsemble | fitensemble |
| Multiclass, error-correcting output codes (ECOC) | ClassificationECOC | fitcecoc |
| kNN | ClassificationKNN | fitcknn |
| Naive Bayes | ClassificationNaiveBayes | fitcnb |
| Support vector machine (SVM) | ClassificationSVM | fitcsvm |
| Compact discriminant analysis | CompactClassificationDiscriminant | compact |
| Compact ECOC | CompactClassificationECOC | compact |
| Compact ensemble of classification models | CompactClassificationEnsemble | compact |

| Trained Model Type | Model Object | Returned By |
|-----------------------------|---------------------------------|-------------|
| Compact naive Bayes | CompactClassificationNaiveBayes | compact |
| Compact SVM | CompactClassificationSVM | compact |
| Compact classification tree | CompactClassificationTree | compact |

T1 — Test-set predictor table for first classification model

table

Test-set predictor table for the first classification model, C1, specified as a table. Each row of T1 corresponds to one observation, and each column corresponds to one predictor variable. Optionally, T1 can contain an additional column for the response variable. T1 must contain all of the predictors used to train C1. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

T1 and T2 must have the same number of rows, and must have the same response values. If T1 and T2 contain the response variable used to train C1 and C2, then, you do not need to specify ResponseVarName or Y.

Data Types: table

T2 — Test-set predictor table for second classification model

table

Test-set predictor data for the second classification model, C2, specified as a table. Each row of T2 corresponds to one observation, and each column corresponds to one predictor variable. Optionally, T2 can contain an additional column for the response variable. T2 must contain all of the predictors used to train C2. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

T1 and T2 must have the same number of rows and the same response values. If T1 and T2 contain the response variable used to train C1 and C2, then, you do not need to specify ResponseVarName or Y.

Data Types: table

X1 — Test-set predictor data for first classification model

numeric matrix

Test-set predictor data for the first classification model, C1, specified as a numeric matrix.

Each row of X1 corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a predictor or feature). The variables used to train C1 must compose X1.

The number of rows in X1 and X2 must equal the length of Y.

Data Types: `double` | `single`

X2 — Test-set predictor data for second classification model

numeric matrix

Test-set predictor data for the second classification model, C2, specified as a numeric matrix.

Each row of X2 corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a predictor or feature). The variables used to train C2 must compose X2.

The number of rows in X2 and X1 must equal the length of Y.

Data Types: `double` | `single`

ResponseVarName — Response variable name

name of a variable in T1 and T2

Response variable name, specified as the name of a variable in T1 and T2. If T1 and T2 contain the response variable used to train C1 and C2, then you do not need to specify ResponseVarName.

If you specify ResponseVarName, then you must do so as a character vector. For example, if the response variable is stored as T1.Response, then specify it as 'Response'. Otherwise, the software treats all columns of T1 and T2, including Response, as predictors.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char`

Y — True class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors | character vector

True class labels, specified as a categorical or character array, a logical or numeric vector, a cell array of character vectors, or a character vector.

If you specify any array except a character vector, then `compareHoldout` treats all variables or columns in `X1` and `X2` as predictor variables.

If you specify a character vector, then `X1` and `X2` must be tables, their response variables must have the same name and values, and `Y` must be the common name. For example, if `X1.Labels` and `X2.Labels` are the response variables, then `Y` must be `'Labels'` and `X1.Labels` and `X2.Labels` must be equivalent.

If `Y` is a character array, then each element must correspond to one row of the array.

The number of rows in `X1` and `X2` must equal the length of `Y`.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Alternative','greater','Test','asymptotic','Cost',[0 2;1 0]` specifies to test whether the first set of first predicted class labels is more accurate than the second set, to conduct the asymptotic McNemar test, and to penalize misclassifying observations with the true label `ClassNames{1}` two times the penalty of misclassifying observations with the true label `ClassNames{2}`.

Alpha — Hypothesis test significance level

`0.05` (default) | scalar value in the interval (0,1)

Hypothesis test significance level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the interval (0,1).

Example: `'Alpha',0.1`

Data Types: `single` | `double`

Alternative — Alternative hypothesis to assess

`'unequal'` (default) | `'greater'` | `'less'`

Alternative hypothesis to assess, specified as the comma-separated pair consisting of 'Alternative' and one of these values listed in the table.

| Value | Alternative hypothesis |
|---------------------|--|
| 'unequal' (default) | For predicting Y, the set of predictions resulting from C1 applied to X1 and C2 applied to X2 have unequal accuracies. |
| 'greater' | For predicting Y, the set of predictions resulting from C1 applied to X1 is more accurate than C2 applied to X2. |
| 'less' | For predicting Y, the set of predictions resulting from C1 applied to X1 is less accurate than C2 applied to X2. |

Example: 'Alternative', 'greater'

Data Types: char

ClassNames — Class names

categorical vector | cell array of character vectors | character array | logical vector | numeric vector

Class names, specified as the comma-separated pair consisting of 'ClassNames' and a categorical or character array, logical or numeric vector, or cell array of character vectors. You must set ClassNames using the data type of Y.

If ClassNames is a character array, then each element must correspond to one *row* of the array.

Use ClassNames to:

- Specify the order of any input argument dimension that corresponds to class order. For example, use ClassNames to specify the order of the dimensions of Cost.
- Select a subset of classes for testing. For example, suppose that the set of all distinct class names in Y is {'a', 'b', 'c'}. To train and test models using observations from classes 'a' and 'c' only, specify 'ClassNames', {'a', 'c'}.

The default is the set of all distinct class names in Y.

Example: 'ClassNames', {'b', 'g'}

Data Types: categorical | char | logical | single | double | cell

Cost — Misclassification cost

square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure array. If you specify:

- If you specify the square matrix `Cost`, then `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of `Cost`, additionally specify the `ClassNames` name-value pair argument.
- If you specify the structure `S`, then `S` must have two fields:
 - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`. You can use this field to specify the order of the classes.
 - `S.ClassificationCosts`, which contains the cost matrix, with rows and columns ordered as in `S.ClassNames`

If you specify `Cost`, then `compareHoldout` cannot conduct one-sided, exact, or mid- p tests. You must also specify 'Alternative', 'unequal', 'Test', 'asymptotic'. For cost-sensitive testing options, see the `CostTest` name-value pair argument.

It is a best practice to supply the same cost matrix used to train the classification models.

The default is $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$.

Example: 'Cost', [0 1 2 ; 1 0 2; 2 2 0]

Data Types: double | single | struct

CostTest — Cost-sensitive test type

'likelihood' (default) | 'chisquare'

Cost-sensitive test type, specified as the comma-separated pair consisting of 'CostTest' and 'chisquare' or 'likelihood'. Unless you specify a cost matrix using the `Cost` name-value pair argument, `compareHoldout` ignores `CostTest`.

This table summarizes the available options for cost-sensitive testing.

| Value | Asymptotic test type | Requirements |
|--------------|-----------------------|---|
| 'chisquare' | Chi-square test | Optimization Toolbox license to implement <code>quadprog</code> |
| 'likelihood' | Likelihood ratio test | None |

For more details, see “Cost-Sensitive Testing” on page 32-6369.

Example: 'CostTest', 'chisquare'

Data Types: char

Test — Test to conduct

'asymptotic' | 'exact' | 'midp'

Test to conduct, specified as the comma-separated pair consisting of 'Test' and 'asymptotic', 'exact', and 'midp'. This table summarizes the available options for cost-insensitive testing.

| Value | Description |
|------------------|-----------------------------------|
| 'asymptotic' | Asymptotic McNemar test |
| 'exact' | Exact-conditional McNemar test |
| 'midp' (default) | Mid- <i>p</i> -value McNemar test |

For more details, see “McNemar Tests” on page 32-6372.

For cost-sensitive testing, `Test` must be 'asymptotic'. When you specify the `Cost` name-value pair argument, and choose a cost-sensitive test using the `CostTest` name-value pair argument, 'asymptotic' is the default.

Example: 'Test', 'asymptotic'

Data Types: char

Note NaNs, <undefined> values, and empty character vectors (' ') indicate missing values. `compareHoldout`:

- Removes missing values in Y and the corresponding rows of X1 and X2
 - Predicts classes whether X1 and X2 have missing observations.
-

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

$h = 1$ indicates the rejection of the null hypothesis at the Alpha significance level.

$h = 0$ indicates failure to reject the null hypothesis at the Alpha significance level.

p – p-value

scalar in the interval [0,1]

p-value of the test, returned as a scalar in the interval [0,1]. p is the probability that a random test statistic is at least as extreme as the observed test statistic, given that the null hypothesis is true.

compareHoldout estimates p using the distribution of the test statistic, which varies with the type of test. For details on test statistics derived from the available variants of the McNemar test, see “McNemar Tests” on page 32-6372. For details on test statistics derived from cost-sensitive tests, see “Cost-Sensitive Testing” on page 32-6369.

e1 – Classification loss

scalar

Classification loss on page 32-1035, returned as a scalar. e1 summarizes the accuracy of the first set of class labels predicting the true class labels (Y).

compareHoldout applies the first test-set predictor data (X1) to the first classification model (C1) to estimate the first set of class labels. Then, the function compares the estimated labels to Y to obtain the classification loss.

For cost-insensitive testing, e1 is the misclassification rate. That is, e1 is the proportion of misclassified observations, which is a scalar in the interval [0,1].

For cost-sensitive testing, e1 is the misclassification cost. That is, e1 is the weighted average of the misclassification costs, in which the weights are the respective estimated proportions of misclassified observations.

e2 – Classification loss

scalar

Classification loss on page 32-1035, returned as a scalar. e2 summarizes the accuracy of the second set of class labels predicting the true class labels (Y). compareHoldout applies the second test-set predictor data (X2) to the second classification model (C2) to estimate the second set of class labels. Then the function compares the estimated labels to Y to obtain the classification loss.

For cost-insensitive testing, `e2` is the misclassification rate. That is, `e2` is the proportion of misclassified observations, which is a scalar in the interval $[0,1]$.

For cost-sensitive testing, `e2` is the misclassification cost. That is, `e2` is the weighted average of the misclassification costs, in which the weights are the respective estimated proportions of misclassified observations.

Examples

Compare Accuracies of Two Different Classification Models

Train two classification models using different algorithms. Conduct a statistical test comparing the misclassification rates of the two models on a held-out set.

Load the `ionosphere` data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

`CVP` is a cross-validation partition object that specifies the training and test sets.

Train an SVM model and an ensemble of 100 bagged classification trees. For the SVM model, specify to use the radial basis function kernel and a heuristic procedure to determine the kernel scale.

```
C1 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true,...
    'KernelFunction','RBF','KernelScale','auto');
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','Bag');
```

`C1` is a trained `ClassificationSVM` model. `C2` is a trained `ClassificationBaggedEnsemble` model.

Test whether the two models have equal predictive accuracies. Use the same test-set predictor data for each model.

```
h = compareHoldout(C1,C2,X(idxTest,:),X(idxTest,:),Y(idxTest))
h = logical
    0
```

$h = 0$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Assess Whether One Classification Model Classifies Better Than Another

Train two classification models using the same algorithm, but adjust a hyperparameter to make the algorithm more complex. Conduct a statistical test to assess whether the simpler model has better accuracy in held-out data than the more complex model.

Load the `ionosphere` data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Train two SVM models: one that uses a linear kernel (the default for binary classification) and one that uses the radial basis function kernel. Use the default kernel scale of 1.

```
C1 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true);
C2 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true,...
    'KernelFunction','RBF');
```

C1 and C2 are trained `ClassificationSVM` models.

Test the null hypothesis that the simpler model (C1) is at most as accurate as the more complex model (C2). Because the test-set size is large, conduct the asymptotic McNemar test, and compare the results with the mid- p -value test (the cost-insensitive testing default). Request to return p -values and misclassification rates.

```

Asymp = zeros(4,1); % Preallocation
MidP = zeros(4,1);

[Asymp(1),Asymp(2),Asymp(3),Asymp(4)] = compareHoldout(C1,C2,...
    X(idxTest,:),X(idxTest,:),Y(idxTest),'Alternative','greater',...
    'Test','asymptotic');
[MidP(1),MidP(2),MidP(3),MidP(4)] = compareHoldout(C1,C2,...
    X(idxTest,:),X(idxTest,:),Y(idxTest),'Alternative','greater');
table(Asymp,MidP,'RowNames',{'h' 'p' 'e1' 'e2'})

```

```
ans =
```

```
4x2 table
```

| | Asymp | MidP |
|----|------------|------------|
| h | 1 | 1 |
| p | 7.2801e-09 | 2.7649e-10 |
| e1 | 0.13714 | 0.13714 |
| e2 | 0.33143 | 0.33143 |

The p -value is close to zero for both tests, which indicates strong evidence to reject the null hypothesis that the simpler model is less accurate than the more complex model. No matter what test you specify, `compareHoldout` returns the same type of misclassification measure for both models.

Conduct Cost-Sensitive Comparison of Two Classification Models

For data sets with imbalanced class representations, or for data sets with imbalanced false-positive and false-negative costs, you can statistically compare the predictive performances of two classification models by including a cost matrix in the analysis.

Load the `arrhythmia` data set. Determine the class representations in the data.

```

load arrhythmia;
Y = categorical(Y);
tabulate(Y);

```

| Value | Count | Percent |
|-------|-------|---------|
| 1 | 245 | 54.20% |

| | | |
|----|----|--------|
| 2 | 44 | 9.73% |
| 3 | 15 | 3.32% |
| 4 | 15 | 3.32% |
| 5 | 13 | 2.88% |
| 6 | 25 | 5.53% |
| 7 | 3 | 0.66% |
| 8 | 2 | 0.44% |
| 9 | 9 | 1.99% |
| 10 | 50 | 11.06% |
| 14 | 4 | 0.88% |
| 15 | 5 | 1.11% |
| 16 | 22 | 4.87% |

There are 16 classes, however some are not represented in the data set. Most observations are classified as not having arrhythmia (class 1). To summarize, the data set is highly discrete with imbalanced classes.

Combine all observations with arrhythmia (classes 2 through 15) into one class. Remove those observations with unknown arrhythmia status from the data set.

```
Y = Y(Y ~= '16');
Y(Y ~= '1') = '2';
X = X(Y ~= '16',:);
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Create a cost matrix such that misclassifying a patient with arrhythmia into the no arrhythmia class is five times worse than misclassifying a patient without arrhythmia into the arrhythmia class. Classifying correctly incurs no cost. The rows indicate the true class and the columns indicate the predicted class. When conducting a cost-sensitive analysis, it is a good practice to specify the order of the classes.

```
cost = [0 1;5 0];
ClassNames = categorical([2 1]);
```

Train two boosting ensembles of 50 classification trees, one that uses AdaBoostM1 and the other that uses LogitBoost. Because there are missing values, specify to use surrogate splits. Train the models using the cost matrix.

```
t = templateTree('Surrogate','on');
numTrees = 50;
C1 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','AdaBoostM1',...
    'NumLearningCycles',numTrees,'Learners',t,'Cost',cost);
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','LogitBoost',...
    'NumLearningCycles',numTrees,'Learners',t,'Cost',cost);
```

C1 and C2 are trained ClassificationEnsemble models.

Test whether the AdaBoostM1 ensemble (C1) and the LogitBoost ensemble (C2) have equal predictive accuracy. Supply the cost matrix. Conduct the asymptotic, likelihood ratio, cost-sensitive test (the default when you pass in a cost matrix). Request to return p -values and misclassification costs.

```
[h,p,e1,e2] = compareHoldout(C1,C2,X(idxTest,:),X(idxTest,:),Y(idxTest),...
    'Cost',cost)
```

```
h = logical
    0
```

```
p = 0.7954
```

```
e1 = 1.6558
```

```
e2 = 1.6186
```

$h = 0$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Select Features Using Statistical Accuracy Comparison

Reduce classification model complexity by selecting a subset of predictor variables (features) from a larger set. Then, statistically compare the out-of-sample accuracy between the two models.

Load the ionosphere data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```

rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP);      % Test-set indices

```

CVP is a cross-validation partition object that specifies the training and test sets.

Train an ensemble of 100 boosted classification trees using AdaBoostM1 and the entire set of predictors. Inspect the importance measure for each predictor.

```

t = templateTree('MaxNumSplits',1); % Weak-learner template tree object
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','AdaBoostM1',...
    'Learners',t);
predImp = predictorImportance(C2);

```

```

figure;
bar(predImp);
h = gca;
h.XTick = 1:2:h.XLim(2)

```

```
h =
```

```
  Axes with properties:
```

```

        XLim: [-0.2000 35.2000]
        YLim: [0 0.0090]
        XScale: 'linear'
        YScale: 'linear'
  GridLineStyle: '-'
  Position: [0.1300 0.1100 0.7750 0.8150]
        Units: 'normalized'

```

```
Show all properties
```

```

title('Predictor Importances');
xlabel('Predictor');
ylabel('Importance measure');

```

Identify the top five predictors in terms of their importance.

```
[~,idxSort] = sort(predImp, 'descend');
idx5 = idxSort(1:5);
```

Train another ensemble of 100 boosted classification trees using AdaBoostM1 and the five predictors with the best importance.

```
C1 = fitcensemble(X(idxTrain,idx5),Y(idxTrain), 'Method', 'AdaBoostM1', ...
    'Learners', t);
```

Test whether the two models have equal predictive accuracies. Specify the reduced test-set predictor data for C1 and the full test-set predictor data for C2.

```
[h,p,e1,e2] = compareHoldout(C1,C2,X(idxTest,idx5),X(idxTest,:),Y(idxTest))
```

$h = \text{logical}$
 \emptyset

$p = 0.7744$

$e1 = 0.0914$

$e2 = 0.0857$

$h = \emptyset$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies. This result favors the simpler ensemble, C1.

Definitions

Cost-Sensitive Testing

Conduct cost-sensitive testing when the cost of misclassification is imbalanced. When conducting a cost-sensitive analysis, you can account for the cost imbalance in training the classification models, and then in statistically comparing them.

If the cost of misclassification is imbalanced, then the misclassification rate tends to be a poorly performing classification loss on page 32-6375. Use misclassification cost instead to compare classification models.

Misclassification costs are often unbalanced in applications. For example, consider classifying subjects based on a set of predictors into two categories: healthy and sick. Misclassifying a sick subject as healthy poses a danger to the subject's life. However, misclassifying a healthy subject as sick can cause some inconvenience, but does not pose any danger. In this situation, you assign misclassification costs such that misclassifying a sick subject as healthy is more costly than misclassifying a healthy subject as sick.

The definitions that follow summarize the cost-sensitive tests. In the definitions:

- n_{ijk} and $\hat{\pi}_{ijk}$ are the number and estimated proportion of test-sample observations with true class k that the first classification model assigns label i . The second classification model assigns label j . The unknown, true value of $\hat{\pi}_{ijk}$ is π_{ijk} . The test-set sample size

$$\text{is } \sum_{i,j,k} n_{ijk} = n_{\text{test}}. \quad \sum_{i,j,k} \pi_{ijk} = \sum_{i,j,k} \pi_{ijk} = 1. .$$

- c_{ij} is the relative cost of assigning label j to an observation with true class i . $c_{ii} = 0$, $c_{ij} \geq 0$, and, for at least one (i, j) pair, $c_{ij} > 0$.
- All subscripts take on integer values from 1 through K , which is the number of classes.
- The expected difference in the misclassification costs of the two classification models is

$$\delta = \sum_{i=1}^K \sum_{j=1}^K \sum_{k=1}^K (c_{ki} - c_{kj}) \pi_{ijk}.$$

- The hypothesis test is

$$H_0 : \delta = 0$$

$$H_1 : \delta \neq 0$$

The available cost-sensitive tests are appropriate for two-tailed testing.

Available, asymptotic tests that address imbalanced costs are a chi-square test and a likelihood ratio test.

- Chi-square test — The chi-square test statistic is based on the Pearson and Neyman chi-square test statistics, but with a Laplace correction factor to account for any $n_{ijk} = 0$. The test statistic is

$$t_{\chi^2}^* = \sum_{i \neq j} \sum_k \frac{(n_{ijk} + 1 - (n_{test} + K^3) \hat{\pi}_{ijk}^{(1)})^2}{n_{ijk} + 1}.$$

If $1 - F_{\chi^2}(t_{\chi^2}^*; 1) < \alpha$, then reject H_0 .

- $\hat{\pi}_{ijk}^{(1)}$ are estimated by minimizing $t_{\chi^2}^*$ under the constraint that $\delta = 0$.
- $F_{\chi^2}(x; 1)$ is the χ^2 C.D.F. with one degree of freedom evaluated at x .
- Likelihood ratio test — The likelihood ratio test is based on N_{ijk} , which are binomial random variables having sample size n_{test} and success probability π_{ijk} . They represent the random number of observations with true class k that the first classification model

assigns label i . The second classification model assigns label j . Jointly, their distribution is multinomial.

The test statistic is

$$t_{LRT}^* = 2 \log \left[\frac{P \left(\bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \pi_{ijk} = \pi_{ijk}^{(2)} \right)}{P \left(\bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \pi_{ijk} = \pi_{ijk}^{(3)} \right)} \right].$$

If $1 - F_{\chi^2}(t_{LRT}^*; 1) < \alpha$, then reject H_0 .

•

• $\hat{\pi}_{ijk}^{(2)} = \frac{n_{ijk}}{n_{test}}$ is the unrestricted MLE of π_{ijk} .

•

• $\hat{\pi}_{ijk}^{(3)} = \frac{n_{ijk}}{n_{test} + \lambda(c_{ki} - c_{kj})}$ is the MLE under the null hypothesis that $\delta = 0$. λ is the solution to

$$\sum_{i,j,k} \frac{n_{ijk}(c_{ki} - c_{kj})}{n_{test} + \lambda(c_{ki} - c_{kj})} = 0.$$

•

• $F_{\chi^2}(x; 1)$ is the χ^2 C.D.F. with one degree of freedom evaluated at x .

McNemar Tests

McNemar Tests are hypothesis tests that compare two population proportions while addressing the issues resulting from two dependent, matched-pair samples.

One way to compare the predictive accuracies of two classification models is:

- 1 Partition the data into training and test sets.
- 2 Train both classification models using the training set.
- 3 Predict class labels using the test set.

- 4 Summarize the results in a two-by-two table resembling this figure.

| | | Model 2 | | |
|---------|-----------|-----------------|-----------------|----------------|
| | | Correct | Incorrect | |
| Model 1 | Correct | n_{11} | n_{12} | $n_{1\bullet}$ |
| | Incorrect | n_{21} | n_{22} | $n_{2\bullet}$ |
| | | $n_{\bullet 1}$ | $n_{\bullet 2}$ | n_{test} |

n_{ij} are the number of concordant pairs, that is, the number of observations that both models classify the same way (correctly or incorrectly). n_{ij} , $i \neq j$, are the number of discordant pairs, that is, the number of observations that models classify differently (correctly or incorrectly).

The misclassification rates for Models 1 and 2 are

$$\hat{\pi}_{2\bullet} = n_{2\bullet} / n$$

and $\hat{\pi}_{\bullet 2} = n_{\bullet 2} / n$, respectively. A two-sided test for comparing the accuracy of the two models is

$$\begin{aligned} H_0 &: \pi_{\bullet 2} = \pi_{2\bullet} \\ H_1 &: \pi_{\bullet 2} \neq \pi_{2\bullet} \end{aligned}$$

The null hypothesis suggests that the population exhibits marginal homogeneity, which reduces the null hypothesis to $H_0 : \pi_{12} = \pi_{21}$. Also, under the null hypothesis, $N_{12} \sim \text{Binomial}(n_{12} + n_{21}, 0.5)$ [1].

These facts are the basis for these, available McNemar test variants: the asymptotic, exact-conditional and mid-p-value McNemar tests. The definitions that follow summarize the available variants.

- Asymptotic — The asymptotic McNemar test statistics and rejection regions (for significance-level α) are:

- For one-sided tests, the test statistic

$$t_{a1}^* = \frac{n_{12} - n_{21}}{\sqrt{n_{12} + n_{21}}}.$$

If $1 - \Phi(|t_1^*|) < \alpha$, where Φ is the standard Gaussian C.D.F., then reject H_0 .

- For two-sided tests, the test statistic

$$t_{a2}^* = \frac{(n_{12} - n_{21})^2}{n_{12} + n_{21}}.$$

If $1 - F_{\chi^2}(t_2^*; m) < \alpha$, where $F_{\chi^2}(x; m)$ is the χ_m^2 C.D.F. evaluated at x , then reject H_0 .

This variant requires large-sample theory, specifically, the Gaussian approximation to the binomial distribution. Therefore:

- The total number of discordant pairs, $n_d = n_{12} + n_{21}$ must be greater than 10 ([1], Ch. 10.1.4).
- In general, asymptotic tests do not guarantee nominal coverage. The observed probability of falsely rejecting the null hypothesis can exceed α . Simulation studies in [18] suggest this, but the asymptotic McNemar test performs well in terms of statistical power.
- Exact Conditional — The exact-conditional McNemar test statistics and rejection regions (for significance-level α) are ([36], [38]):

- For one-sided tests, the test statistic

$$t_1^* = n_{12}$$

If $F_{\text{Bin}}(t_1^*; n_d, 0.5) < \alpha$, where $F_{\text{Bin}}(x; n, p)$ is the binomial C.D.F. with sample size n and success probability p evaluated at x , then reject H_0 .

- For two-sided tests, the test statistic

$$t_2^* = \min(n_{12}, n_{21})$$

If $F_{\text{Bin}}(t_2^*; n_d, 0.5) < \alpha / 2$, then reject H_0 .

The exact conditional test always attains nominal coverage. Simulation studies in [18] suggest that the test is conservative, and then show that the test lacks statistical power compared to other variants. For small or highly discrete test samples, consider using the mid- p -value test ([1], Ch. 3.6.3). For details, see `Test` and “McNemar Tests” on page 32-6372.

- Mid- p -value test — The mid- p -value McNemar test statistics and rejection regions (for significance-level α) are ([32]):
 - For one-sided tests, the test statistic

$$t_1^* = n_{12}$$

If $F_{\text{Bin}}(t_1^* - 1; n_{12} + n_{21}, 0.5) + 0.5f_{\text{Bin}}(t_1^*; n_{12} + n_{21}, 0.5) < \alpha$, where $F_{\text{Bin}}(x; n, p)$ and $f_{\text{Bin}}(x; n, p)$ are the binomial C.D.F. and P.D.F, respectively, with sample size n and success probability p evaluated at x , then reject H_0 .

- For two-sided tests, the test statistic

$$t_2^* = \min(n_{12}, n_{21})$$

If $F_{\text{Bin}}(t_2^* - 1; n_{12} + n_{21} - 1, 0.5) + 0.5f_{\text{Bin}}(t_2^*; n_{12} + n_{21}, 0.5) < \alpha / 2$, then reject H_0 .

The mid- p -value test addresses the over-conservative behavior of the exact conditional test. The simulation studies in [18] demonstrate that this test attains nominal coverage, and has good statistical power.

Classification Loss

Classification losses indicate the accuracy of a classification model or set of predicted labels. Two classification losses are misclassification rate and cost.

`compareHoldout` returns the classification losses (see `e1` and `e2`) under the alternative hypothesis (i.e., the unrestricted classification losses). n_{ijk} is the number of test-sample observations with true class k that the first classification model assigns label i and the second classification model assigns label j , and the corresponding estimated proportion is

$\hat{\pi}_{ijk} = \frac{n_{ijk}}{n_{test}}$. The test-set sample size is $\sum_{i,j,k} n_{ijk} = n_{test}$. The indices are taken from 1 through K , the number of classes.

- Misclassification rate, or classification error, is a scalar in the interval $[0,1]$ representing the proportion of misclassified observations. That is, the misclassification rate for the first classification model is

$$e_1 = \sum_{j=1}^K \sum_{k=1}^K \sum_{i \neq k} \hat{\pi}_{ijk}.$$

For the misclassification rate of the second classification model (e_2), switch the indices i and j in the formula.

Classification accuracy decreases as the misclassification rate increases to 1.

- Misclassification cost is a nonnegative scalar and is a measure of classification quality relative to the values the specified cost matrix elements. Its interpretation depends on the specified costs of misclassification. Misclassification cost is the weighted average of the costs of misclassification (specified in a cost matrix, C) in which the weights are the respective, estimated proportions of misclassified observations. The misclassification cost for the first classification model is

$$e_1 = \sum_{j=1}^K \sum_{k=1}^K \sum_{i \neq k} \hat{\pi}_{ijk} C_{ki},$$

where C_{kj} is the cost of classifying an observation into class j if its true class is k . For the misclassification cost of the second classification model (e_2), switch the indices i and j in the formula.

In general, for a fixed cost matrix, classification accuracy decreases as misclassification cost increases.

Tips

- One way to perform cost-insensitive feature selection is:
 - 1 Train the first classification model (C1) using the full predictor set.
 - 2 Train the second classification model (C2) using the reduced predictor set.
 - 3 Specify X1 as the full, test-set predictor data and X2 as the reduced test-set predictor data.
 - 4 Enter `compareHoldout(C1,C2,X1,X2,'Alternative','less')`. If `compareHoldout` returns 1, then there is enough evidence to suggest that the classification model that uses fewer predictors performs better than the model that uses the full predictor set.

Alternatively, you can assess whether there is a significant difference between the accuracies of the two models. To perform this assessment, remove the 'Alternative', 'greater' specification in step 4. `compareHoldout` conducts a two-sided test, and `h = 0` indicates that there is not enough evidence to suggest a difference in the accuracy of the two models.

- Cost-sensitive tests perform numerical optimization, which requires additional computational resources. The likelihood ratio test conducts numerical optimization indirectly by finding the root of a Lagrange multiplier in an interval. For some data sets, if the root lies close to the boundaries of the interval, then the method can fail. Therefore, if you have an Optimization Toolbox license, consider conducting the cost-sensitive chi-square test instead. For more details, see `CostTest` and “Cost-Sensitive Testing” on page 32-1029.

Alternatives

To directly compare the accuracy of two sets of class labels in predicting a set of true class labels, use `testcholdout`.

Introduced in R2015a

compareHoldout

Class: CompactClassificationNaiveBayes

Compare accuracies of two classification models using new data

`compareHoldout` statistically assesses the accuracies of two classification models. The function first compares their predicted labels against the true labels, and then it detects whether the difference between the misclassification rates is statistically significant.

You can assess whether the accuracies of the classification models are different, or whether one classification model performs better than another. `compareHoldout` can conduct several McNemar test on page 32-1031 variations, including the asymptotic test, the exact-conditional test, and the mid- p -value test. For cost-sensitive assessment on page 32-1029, available tests include a chi-square test (requires an Optimization Toolbox license) and a likelihood ratio test.

Syntax

```
h = compareHoldout(C1,C2,T1,T2,ResponseVarName)
```

```
h = compareHoldout(C1,C2,T1,T2,Y)
```

```
h = compareHoldout(C1,C2,X1,X2,Y,Name,Value)
```

```
h = compareHoldout(C1,C2,X1,X2,Y)
```

```
h = compareHoldout(C1,C2,X1,X2,Y,Name,Value)
```

```
[h,p,e1,e2] = compareHoldout(____)
```

Description

`h = compareHoldout(C1,C2,T1,T2,ResponseVarName)` returns the test decision from testing the null hypothesis that the trained classification models C1 and C2 have equal accuracy for predicting the true class labels stored as `ResponseVarName`. The alternative hypothesis is that the labels have unequal accuracy.

The first classification model C1 uses predictor data in table T1 and C2 uses T2. The software conducts the mid- p -value McNemar test to compare the accuracies.

$h = 1$ indicates to reject the null hypothesis at the 5% significance level. $h = 0$ indicates to not reject the null hypothesis at 5% level.

Examples of tests you can conduct include:

- Compare the accuracies of a simple classification model and a model that is more complex by passing the same set of predictor data (i.e., $T1 = T2$).
- Compare the accuracies of two perhaps different models using two perhaps different sets of predictors.
- Perform various types of feature selection. For example, you can compare the accuracy of a model trained using a set of predictors to the accuracy of one trained on a subset or different set of those predictors. You can arbitrarily choose the set of predictors, or use a feature selection technique like PCA or sequential feature selection (see `pca` and `sequentialfs`).

`h = compareHoldout(C1,C2,T1,T2,Y)` returns the test decision from testing the null hypothesis that the trained classification models `C1` and `C2` have equal accuracy for predicting the true class labels `Y`. The alternative hypothesis is that the labels have unequal accuracy.

`h = compareHoldout(C1,C2,X1,X2,Y,Name,Value)` returns the result of the hypothesis test with additional options specified by one or more `Name, Value` pair arguments. For example, you can specify the type of alternative hypothesis, and the type of test, or you can supply a cost matrix.

`h = compareHoldout(C1,C2,X1,X2,Y)` returns the test decision from testing the null hypothesis that the trained classification models `C1` and `C2` have equal accuracy for predicting the true class labels `Y`. The alternative hypothesis is that the labels have unequal accuracy.

The first classification model `C1` uses predictor data `X1` and `C2` uses `X2`. The software conducts the mid- p -value McNemar test to compare the accuracies.

`h = compareHoldout(C1,C2,X1,X2,Y,Name,Value)` returns the result of the hypothesis test with additional options specified by one or more `Name, Value` pair arguments. For example, you can specify the type of alternative hypothesis, and the type of test, or you can supply a cost matrix.

`[h,p,e1,e2] = compareHoldout(____)` returns the p -value for the hypothesis test (p) and the respective classification losses on page 32-1009 of each set of predicted class labels ($e1$ and $e2$) using any of the input arguments in the previous syntaxes.

Input Arguments

C1 — Trained naive Bayes classification model

`ClassificationNaiveBayes` model object | `CompactClassificationNaiveBayes` model object

Trained naive Bayes classification model, specified as a `ClassificationNaiveBayes` or `CompactClassificationNaiveBayes` model object. That is, C1 is a trained classification model returned by `fitcnb` or `compact`.

C2 — Trained classification model

trained classification model object | trained, compact classification model object

Trained classification model, specified as any trained or compact classification model object described in this table.

| Trained Model Type | Model Object | Returned By |
|--|--|---------------------------|
| Classification tree | <code>ClassificationTree</code> | <code>fitctree</code> |
| Discriminant analysis | <code>ClassificationDiscriminant</code> | <code>fitcdiscr</code> |
| Ensemble of bagged classification models | <code>ClassificationBaggedEnsemble</code> | <code>fitcensemble</code> |
| Ensemble of classification models | <code>ClassificationEnsemble</code> | <code>fitcensemble</code> |
| Multiclass, error-correcting output codes (ECOC) | <code>ClassificationECOC</code> | <code>fitcecoc</code> |
| kNN | <code>ClassificationKNN</code> | <code>fitcknn</code> |
| Naive Bayes | <code>ClassificationNaiveBayes</code> | <code>fitcnb</code> |
| Support vector machine (SVM) | <code>ClassificationSVM</code> | <code>fitsvm</code> |
| Compact discriminant analysis | <code>CompactClassificationDiscriminant</code> | <code>compact</code> |
| Compact ECOC | <code>CompactClassificationECOC</code> | <code>compact</code> |
| Compact ensemble of classification models | <code>CompactClassificationEnsemble</code> | <code>compact</code> |

| Trained Model Type | Model Object | Returned By |
|-----------------------------|---------------------------------|-------------|
| Compact naive Bayes | CompactClassificationNaiveBayes | compact |
| Compact SVM | CompactClassificationSVM | compact |
| Compact classification tree | CompactClassificationTree | compact |

T1 — Test-set predictor table for first classification model

table

Test-set predictor table for the first classification model, C1, specified as a table. Each row of T1 corresponds to one observation, and each column corresponds to one predictor variable. Optionally, T1 can contain an additional column for the response variable. T1 must contain all of the predictors used to train C1. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

T1 and T2 must have the same number of rows, and must have the same response values. If T1 and T2 contain the response variable used to train C1 and C2, then, you do not need to specify Y.

Data Types: table

T2 — Test-set predictor table for second classification model

table

Test-set predictor data for the second classification model, C2, specified as a table. Each row of T2 corresponds to one observation, and each column corresponds to one predictor variable. Optionally, T2 can contain an additional column for the response variable. T2 must contain all of the predictors used to train C2. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

T1 and T2 must have the same number of rows and the same response values. If T1 and T2 contain the response variable used to train C1 and C2, then, you do not need to specify Y.

Data Types: table

X1 — Test-set predictor data for first classification model

numeric matrix

Test-set predictor data for the first classification model, C1, specified as a numeric matrix.

Each row of X1 corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a predictor or feature). The variables used to train C1 must compose X1.

The number of rows in X1 and X2 must equal the length of Y.

Data Types: `double` | `single`

X2 — Test-set predictor data for second classification model

numeric matrix

Test-set predictor data for the second classification model, C2, specified as a numeric matrix.

Each row of X2 corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a predictor or feature). The variables used to train C2 must compose X2.

The number of rows in X2 and X1 must equal the length of Y.

Data Types: `double` | `single`

ResponseVarName — Response variable name

name of a variable in T1 and T2

Response variable name, specified as the name of a variable in T1 and T2. If T1 and T2 contain the response variable used to train C1 and C2, then you do not need to specify ResponseVarName.

If you specify ResponseVarName, then you must do so as a character vector. For example, if the response variable is stored as `T1.Response`, then specify it as `'Response'`. Otherwise, the software treats all columns of T1 and T2, including Response, as predictors.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Y — True class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors | character vector

True class labels, specified as a categorical or character array, a logical or numeric vector, a cell array of character vectors, or a character vector.

If you specify any array except a character vector, then `compareHoldout` treats all variables or columns in `X1` and `X2` as predictor variables.

If you specify a character vector, then `X1` and `X2` must be tables, their response variables must have the same name and values, and `Y` must be the common name. For example, if `X1.Labels` and `X2.Labels` are the response variables, then `Y` must be `'Labels'` and `X1.Labels` and `X2.Labels` must be equivalent.

If `Y` is a character array, then each element must correspond to one row of the array.

The number of rows in `X1` and `X2` must equal the length of `Y`.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Alternative','greater','Test','asymptotic','Cost',[0 2;1 0]` specifies to test whether the first set of first predicted class labels is more accurate than the second set, to conduct the asymptotic McNemar test, and to penalize misclassifying observations with the true label `ClassNames{1}` twice as much as for misclassifying observations with the true label `ClassNames{2}`.

Alpha — Hypothesis test significance level

`0.05` (default) | scalar value in the interval (0,1)

Hypothesis test significance level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the interval (0,1).

Example: `'Alpha',0.1`

Data Types: `single` | `double`

Alternative — Alternative hypothesis to assess

`'unequal'` (default) | `'greater'` | `'less'`

Alternative hypothesis to assess, specified as the comma-separated pair consisting of `'Alternative'` and one of these values listed in the table.

| Value | Alternative hypothesis |
|---------------------|--|
| 'unequal' (default) | For predicting Y, the set of predictions resulting from C1 applied to X1 and C2 applied to X2 have unequal accuracies. |
| 'greater' | For predicting Y, the set of predictions resulting from C1 applied to X1 is more accurate than C2 applied to X2. |
| 'less' | For predicting Y, the set of predictions resulting from C1 applied to X1 is less accurate than C2 applied to X2. |

Example: 'Alternative', 'greater'

Data Types: char

ClassNames — Class names

categorical vector | cell array of character vectors | character array | logical vector | numeric vector

Class names, specified as the comma-separated pair consisting of 'ClassNames' and a categorical or character array, logical or numeric vector, or cell array of character vectors. You must set ClassNames using the data type of Y.

If ClassNames is a character array, then each element must correspond to one *row* of the array.

Use ClassNames to:

- Specify the order of any input argument dimension that corresponds to class order. For example, use ClassNames to specify the order of the dimensions of Cost.
- Select a subset of classes for testing. For example, suppose that the set of all distinct class names in Y is {'a', 'b', 'c'}. To train and test models using observations from classes 'a' and 'c' only, specify 'ClassNames', {'a', 'c'}.

The default is the set of all distinct class names in Y.

Example: 'ClassNames', {'b', 'g'}

Data Types: categorical | char | logical | single | double | cell

Cost — Misclassification cost

square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure array. If you specify:

- If you specify the square matrix `Cost`, then `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of `Cost`, additionally specify the `ClassNames` name-value pair argument.
- If you specify the structure `S`, then `S` must have two fields:
 - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`. You can use this field to specify the order of the classes.
 - `S.ClassificationCosts`, which contains the cost matrix, with rows and columns ordered as in `S.ClassNames`

If you specify `Cost`, then `compareHoldout` cannot conduct one-sided, exact, or mid- p tests. You must also specify `'Alternative'`, `'unequal'`, `'Test'`, `'asymptotic'`. For cost-sensitive testing options, see the `CostTest` name-value pair argument.

It is a best practice to supply the same cost matrix used to train the classification models.

The default is $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$.

Example: `'Cost', [0 1 2 ; 1 0 2; 2 2 0]`

Data Types: `double` | `single` | `struct`

CostTest — Cost-sensitive test type

`'likelihood'` (default) | `'chisquare'`

Cost-sensitive test type, specified as the comma-separated pair consisting of `'CostTest'` and `'chisquare'` or `'likelihood'`. Unless you specify a cost matrix using the `Cost` name-value pair argument, `compareHoldout` ignores `CostTest`.

This table summarizes the available options for cost-sensitive testing.

| Value | Asymptotic test type | Requirements |
|---------------------------|-----------------------|---|
| <code>'chisquare'</code> | Chi-square test | Optimization Toolbox license to implement <code>quadprog</code> |
| <code>'likelihood'</code> | Likelihood ratio test | None |

For more details, see “Cost-Sensitive Testing” on page 32-6369.

Example: `'CostTest', 'chisquare'`

Data Types: char

Test — Test to conduct

'asymptotic' | 'exact' | 'midp'

Test to conduct, specified as the comma-separated pair consisting of 'Test' and 'asymptotic', 'exact', and 'midp'. This table summarizes the available options for cost-insensitive testing.

| Value | Description |
|------------------|-----------------------------------|
| 'asymptotic' | Asymptotic McNemar test |
| 'exact' | Exact-conditional McNemar test |
| 'midp' (default) | Mid- <i>p</i> -value McNemar test |

For more details, see “McNemar Tests” on page 32-6372.

For cost-sensitive testing, Test must be 'asymptotic'. When you specify the Cost name-value pair argument, and choose a cost-sensitive test using the CostTest name-value pair argument, 'asymptotic' is the default.

Example: 'Test', 'asymptotic'

Data Types: char

Note NaNs, <undefined> values, and empty character vectors ('') indicate missing values. compareHoldout:

- Removes missing values in Y and the corresponding rows of X1 and X2
 - Predicts classes whether X1 and X2 have missing observations.
-

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

h = 1 indicates the rejection of the null hypothesis at the Alpha significance level.

$h = 0$ indicates failure to reject the null hypothesis at the Alpha significance level.

p – p-value

scalar in the interval [0,1]

p-value of the test, returned as a scalar in the interval [0,1]. p is the probability that a random test statistic is at least as extreme as the observed test statistic, given that the null hypothesis is true.

compareHoldout estimates p using the distribution of the test statistic, which varies with the type of test. For details on test statistics derived from the available variants of the McNemar test, see “McNemar Tests” on page 32-6372. For details on test statistics derived from cost-sensitive tests, see “Cost-Sensitive Testing” on page 32-6369.

e1 – Classification loss

scalar

Classification loss on page 32-1035, returned as a scalar. e1 summarizes the accuracy of the first set of class labels predicting the true class labels (Y).

compareHoldout applies the first test-set predictor data (X1) to the first classification model (C1) to estimate the first set of class labels. Then, the function compares the estimated labels to Y to obtain the classification loss.

For cost-insensitive testing, e1 is the misclassification rate. That is, e1 is the proportion of misclassified observations, which is a scalar in the interval [0,1].

For cost-sensitive testing, e1 is the misclassification cost. That is, e1 is the weighted average of the misclassification costs, in which the weights are the respective estimated proportions of misclassified observations.

e2 – Classification loss

scalar

Classification loss on page 32-1035, returned as a scalar. e2 summarizes the accuracy of the second set of class labels predicting the true class labels (Y). compareHoldout applies the second test-set predictor data (X2) to the second classification model (C2) to estimate the second set of class labels. Then the function compares the estimated labels to Y to obtain the classification loss.

For cost-insensitive testing, e2 is the misclassification rate. That is, e2 is the proportion of misclassified observations, which is a scalar in the interval [0,1].

For cost-sensitive testing, `e2` is the misclassification cost. That is, `e2` is the weighted average of the misclassification costs, in which the weights are the respective estimated proportions of misclassified observations.

Examples

Compare Accuracies of Two Different Classification Models

Train two classification models using different algorithms. Conduct a statistical test comparing the misclassification rates of the two models on a held-out set.

Load the `ionosphere` data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

`CVP` is a cross-validation partition object that specifies the training and test sets.

Train an SVM model and an ensemble of 100 bagged classification trees. For the SVM model, specify to use the radial basis function kernel and a heuristic procedure to determine the kernel scale.

```
C1 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true,...
    'KernelFunction','RBF','KernelScale','auto');
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','Bag');
```

`C1` is a trained `ClassificationSVM` model. `C2` is a trained `ClassificationBaggedEnsemble` model.

Test whether the two models have equal predictive accuracies. Use the same test-set predictor data for each model.

```
h = compareHoldout(C1,C2,X(idxTest,:),X(idxTest,:),Y(idxTest))
```

```
h = logical
    0
```

$h = 0$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Assess Whether One Classification Model Classifies Better Than Another

Train two classification models using the same algorithm, but adjust a hyperparameter to make the algorithm more complex. Conduct a statistical test to assess whether the simpler model has better accuracy in held-out data than the more complex model.

Load the `ionosphere` data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Train two SVM models: one that uses a linear kernel (the default for binary classification) and one that uses the radial basis function kernel. Use the default kernel scale of 1.

```
C1 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true);
C2 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true,...
    'KernelFunction','RBF');
```

C1 and C2 are trained `ClassificationSVM` models.

Test the null hypothesis that the simpler model (C1) is at most as accurate as the more complex model (C2). Because the test-set size is large, conduct the asymptotic McNemar test, and compare the results with the mid- p -value test (the cost-insensitive testing default). Request to return p -values and misclassification rates.

```
Asymp = zeros(4,1); % Preallocation
MidP = zeros(4,1);
```

```
[Asymp(1),Asymp(2),Asymp(3),Asymp(4)] = compareHoldout(C1,C2,...
  X(idxTest,:),X(idxTest,:),Y(idxTest),'Alternative','greater',...
  'Test','asymptotic');
[MidP(1),MidP(2),MidP(3),MidP(4)] = compareHoldout(C1,C2,...
  X(idxTest,:),X(idxTest,:),Y(idxTest),'Alternative','greater');
table(Asymp,MidP,'RowNames',{'h' 'p' 'e1' 'e2'})
```

```
ans =
```

```
4x2 table
```

| | Asymp | MidP |
|----|------------|------------|
| h | 1 | 1 |
| p | 7.2801e-09 | 2.7649e-10 |
| e1 | 0.13714 | 0.13714 |
| e2 | 0.33143 | 0.33143 |

The p -value is close to zero for both tests, which indicates strong evidence to reject the null hypothesis that the simpler model is less accurate than the more complex model. No matter what test you specify, `compareHoldout` returns the same type of misclassification measure for both models.

Conduct Cost-Sensitive Comparison of Two Classification Models

For data sets with imbalanced class representations, or for data sets with imbalanced false-positive and false-negative costs, you can statistically compare the predictive performances of two classification models by including a cost matrix in the analysis.

Load the `arrhythmia` data set. Determine the class representations in the data.

```
load arrhythmia;
Y = categorical(Y);
tabulate(Y);
```

| Value | Count | Percent |
|-------|-------|---------|
| 1 | 245 | 54.20% |
| 2 | 44 | 9.73% |
| 3 | 15 | 3.32% |

| | | |
|----|----|--------|
| 4 | 15 | 3.32% |
| 5 | 13 | 2.88% |
| 6 | 25 | 5.53% |
| 7 | 3 | 0.66% |
| 8 | 2 | 0.44% |
| 9 | 9 | 1.99% |
| 10 | 50 | 11.06% |
| 14 | 4 | 0.88% |
| 15 | 5 | 1.11% |
| 16 | 22 | 4.87% |

There are 16 classes, however some are not represented in the data set. Most observations are classified as not having arrhythmia (class 1). To summarize, the data set is highly discrete with imbalanced classes.

Combine all observations with arrhythmia (classes 2 through 15) into one class. Remove those observations with unknown arrhythmia status from the data set.

```
Y = Y(Y ~= '16');
Y(Y ~= '1') = '2';
X = X(Y ~= '16',:);
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y, 'holdout', 0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Create a cost matrix such that misclassifying a patient with arrhythmia into the no arrhythmia class is five times worse than misclassifying a patient without arrhythmia into the arrhythmia class. Classifying correctly incurs no cost. The rows indicate the true class and the columns indicate the predicted class. When conducting a cost-sensitive analysis, it is a good practice to specify the order of the classes.

```
cost = [0 1; 5 0];
ClassNames = categorical([2 1]);
```

Train two boosting ensembles of 50 classification trees, one that uses AdaBoostM1 and the other that uses LogitBoost. Because there are missing values, specify to use surrogate splits. Train the models using the cost matrix.

```
t = templateTree('Surrogate','on');
numTrees = 50;
C1 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','AdaBoostM1',...
    'NumLearningCycles',numTrees,'Learners',t,'Cost',cost);
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','LogitBoost',...
    'NumLearningCycles',numTrees,'Learners',t,'Cost',cost);
```

C1 and C2 are trained ClassificationEnsemble models.

Test whether the AdaBoostM1 ensemble (C1) and the LogitBoost ensemble (C2) have equal predictive accuracy. Supply the cost matrix. Conduct the asymptotic, likelihood ratio, cost-sensitive test (the default when you pass in a cost matrix). Request to return p -values and misclassification costs.

```
[h,p,e1,e2] = compareHoldout(C1,C2,X(idxTest,:),X(idxTest,:),Y(idxTest),...
    'Cost',cost)
```

```
h = logical
    0
```

```
p = 0.7954
```

```
e1 = 1.6558
```

```
e2 = 1.6186
```

$h = 0$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Select Features Using Statistical Accuracy Comparison

Reduce classification model complexity by selecting a subset of predictor variables (features) from a larger set. Then, statistically compare the out-of-sample accuracy between the two models.

Load the ionosphere data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```

rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP);      % Test-set indices

```

CVP is a cross-validation partition object that specifies the training and test sets.

Train an ensemble of 100 boosted classification trees using AdaBoostM1 and the entire set of predictors. Inspect the importance measure for each predictor.

```

t = templateTree('MaxNumSplits',1); % Weak-learner template tree object
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','AdaBoostM1',...
    'Learners',t);
predImp = predictorImportance(C2);

```

```

figure;
bar(predImp);
h = gca;
h.XTick = 1:2:h.XLim(2)

```

```
h =
```

```
  Axes with properties:
```

```

        XLim: [-0.2000 35.2000]
        YLim: [0 0.0090]
        XScale: 'linear'
        YScale: 'linear'
  GridLineStyle: '-'
  Position: [0.1300 0.1100 0.7750 0.8150]
        Units: 'normalized'

```

```
Show all properties
```

```

title('Predictor Importances');
xlabel('Predictor');
ylabel('Importance measure');

```

Identify the top five predictors in terms of their importance.

```
[~,idxSort] = sort(predImp, 'descend');
idx5 = idxSort(1:5);
```

Train another ensemble of 100 boosted classification trees using AdaBoostM1 and the five predictors with the best importance.

```
C1 = fitensemble(X(idxTrain,idx5),Y(idxTrain), 'Method', 'AdaBoostM1', ...
    'Learners', t);
```

Test whether the two models have equal predictive accuracies. Specify the reduced test-set predictor data for C1 and the full test-set predictor data for C2.

```
[h,p,e1,e2] = compareHoldout(C1,C2,X(idxTest,idx5),X(idxTest,:),Y(idxTest))
```

$h = \text{logical}$
 θ

$p = 0.7744$

$e1 = 0.0914$

$e2 = 0.0857$

$h = \theta$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies. This result favors the simpler ensemble, C1.

Definitions

Cost-Sensitive Testing

Conduct cost-sensitive testing when the cost of misclassification is imbalanced. When conducting a cost-sensitive analysis, you can account for the cost imbalance in training the classification models, and then in statistically comparing them.

If the cost of misclassification is imbalanced, then the misclassification rate tends to be a poorly performing classification loss on page 32-6375. Use misclassification cost instead to compare classification models.

Misclassification costs are often unbalanced in applications. For example, consider classifying subjects based on a set of predictors into two categories: healthy and sick. Misclassifying a sick subject as healthy poses a danger to the subject's life. However, misclassifying a healthy subject as sick can cause some inconvenience, but does not pose any danger. In this situation, you assign misclassification costs such that misclassifying a sick subject as healthy is more costly than misclassifying a healthy subject as sick.

The definitions that follow summarize the cost-sensitive tests. In the definitions:

- n_{ijk} and $\hat{\pi}_{ijk}$ are the number and estimated proportion of test-sample observations with true class k that the first classification model assigns label i . The second classification model assigns label j . The unknown, true value of $\hat{\pi}_{ijk}$ is π_{ijk} . The test-set sample size

$$\text{is } \sum_{i,j,k} n_{ijk} = n_{\text{test}} \cdot \sum_{i,j,k} \pi_{ijk} = \sum_{i,j,k} \pi_{ijk} = 1. .$$

- c_{ij} is the relative cost of assigning label j to an observation with true class i . $c_{ii} = 0$, $c_{ij} \geq 0$, and, for at least one (i, j) pair, $c_{ij} > 0$.
- All subscripts take on integer values from 1 through K , which is the number of classes.
- The expected difference in the misclassification costs of the two classification models is

$$\delta = \sum_{i=1}^K \sum_{j=1}^K \sum_{k=1}^K (c_{ki} - c_{kj}) \pi_{ijk}.$$

- The hypothesis test is

$$H_0 : \delta = 0$$

$$H_1 : \delta \neq 0$$

The available cost-sensitive tests are appropriate for two-tailed testing.

Available, asymptotic tests that address imbalanced costs are a chi-square test and a likelihood ratio test.

- Chi-square test — The chi-square test statistic is based on the Pearson and Neyman chi-square test statistics, but with a Laplace correction factor to account for any $n_{ijk} = 0$. The test statistic is

$$t_{\chi^2}^* = \sum_{i \neq j} \sum_k \frac{(n_{ijk} + 1 - (n_{test} + K^3) \hat{\pi}_{ijk}^{(1)})^2}{n_{ijk} + 1}.$$

If $1 - F_{\chi^2}(t_{\chi^2}^*; 1) < \alpha$, then reject H_0 .

- $\hat{\pi}_{ijk}^{(1)}$ are estimated by minimizing $t_{\chi^2}^*$ under the constraint that $\delta = 0$.
- $F_{\chi^2}(x; 1)$ is the χ^2 C.D.F. with one degree of freedom evaluated at x .
- Likelihood ratio test — The likelihood ratio test is based on N_{ijk} , which are binomial random variables having sample size n_{test} and success probability π_{ijk} . They represent the random number of observations with true class k that the first classification model

assigns label i . The second classification model assigns label j . Jointly, their distribution is multinomial.

The test statistic is

$$t_{LRT}^* = 2 \log \left[\frac{P \left(\bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \pi_{ijk} = \pi_{ijk}^{(2)} \right)}{P \left(\bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \pi_{ijk} = \pi_{ijk}^{(3)} \right)} \right].$$

If $1 - F_{\chi^2}(t_{LRT}^*; 1) < \alpha$, then reject H_0 .

•

$\hat{\pi}_{ijk}^{(2)} = \frac{n_{ijk}}{n_{test}}$ is the unrestricted MLE of π_{ijk} .

•

$\hat{\pi}_{ijk}^{(3)} = \frac{n_{ijk}}{n_{test} + \lambda(c_{ki} - c_{kj})}$ is the MLE under the null hypothesis that $\delta = 0$. λ is the solution to

$$\sum_{i,j,k} \frac{n_{ijk}(c_{ki} - c_{kj})}{n_{test} + \lambda(c_{ki} - c_{kj})} = 0.$$

•

$F_{\chi^2}(x; 1)$ is the χ^2 C.D.F. with one degree of freedom evaluated at x .

McNemar Tests

McNemar Tests are hypothesis tests that compare two population proportions while addressing the issues resulting from two dependent, matched-pair samples.

One way to compare the predictive accuracies of two classification models is:

- 1 Partition the data into training and test sets.
- 2 Train both classification models using the training set.
- 3 Predict class labels using the test set.

- 4 Summarize the results in a two-by-two table resembling this figure.

| | | Model 2 | | |
|---------|-----------|-----------------|-----------------|----------------|
| | | Correct | Incorrect | |
| Model 1 | Correct | n_{11} | n_{12} | $n_{1\bullet}$ |
| | Incorrect | n_{21} | n_{22} | $n_{2\bullet}$ |
| | | $n_{\bullet 1}$ | $n_{\bullet 2}$ | n_{test} |

n_{ij} are the number of concordant pairs, that is, the number of observations that both models classify the same way (correctly or incorrectly). n_{ij} , $i \neq j$, are the number of discordant pairs, that is, the number of observations that models classify differently (correctly or incorrectly).

The misclassification rates for Models 1 and 2 are

$$\hat{\pi}_{2\bullet} = n_{2\bullet} / n$$

and $\hat{\pi}_{\bullet 2} = n_{\bullet 2} / n$, respectively. A two-sided test for comparing the accuracy of the two models is

$$\begin{aligned} H_0 &: \pi_{\bullet 2} = \pi_{2\bullet} \\ H_1 &: \pi_{\bullet 2} \neq \pi_{2\bullet} \end{aligned}$$

The null hypothesis suggests that the population exhibits marginal homogeneity, which reduces the null hypothesis to $H_0 : \pi_{12} = \pi_{21}$. Also, under the null hypothesis, $N_{12} \sim \text{Binomial}(n_{12} + n_{21}, 0.5)$ [1].

These facts are the basis for these, available McNemar test variants: the asymptotic, exact-conditional and mid-p-value McNemar tests. The definitions that follow summarize the available variants.

- Asymptotic — The asymptotic McNemar test statistics and rejection regions (for significance-level α) are:

- For one-sided tests, the test statistic

$$t_{a1}^* = \frac{n_{12} - n_{21}}{\sqrt{n_{12} + n_{21}}}.$$

If $1 - \Phi(|t_1^*|) < \alpha$, where Φ is the standard Gaussian C.D.F., then reject H_0 .

- For two-sided tests, the test statistic

$$t_{a2}^* = \frac{(n_{12} - n_{21})^2}{n_{12} + n_{21}}.$$

If $1 - F_{\chi^2}(t_2^*; m) < \alpha$, where $F_{\chi^2}(x; m)$ is the χ_m^2 C.D.F. evaluated at x , then reject H_0 .

This variant requires large-sample theory, specifically, the Gaussian approximation to the binomial distribution. Therefore:

- The total number of discordant pairs, $n_d = n_{12} + n_{21}$ must be greater than 10 ([1], Ch. 10.1.4).
- In general, asymptotic tests do not guarantee nominal coverage. The observed probability of falsely rejecting the null hypothesis can exceed α . Simulation studies in [18] suggest this, but the asymptotic McNemar test performs well in terms of statistical power.
- Exact Conditional — The exact-conditional McNemar test statistics and rejection regions (for significance-level α) are ([36], [38]):

- For one-sided tests, the test statistic

$$t_1^* = n_{12}$$

If $F_{\text{Bin}}(t_1^*; n_d, 0.5) < \alpha$, where $F_{\text{Bin}}(x; n, p)$ is the binomial C.D.F. with sample size n and success probability p evaluated at x , then reject H_0 .

- For two-sided tests, the test statistic

$$t_2^* = \min(n_{12}, n_{21})$$

If $F_{\text{Bin}}(t_2^*; n_d, 0.5) < \alpha / 2$, then reject H_0 .

The exact conditional test always attains nominal coverage. Simulation studies in [18] suggest that the test is conservative, and then show that the test lacks statistical power compared to other variants. For small or highly discrete test samples, consider using the mid- p -value test ([1], Ch. 3.6.3). For details, see `Test` and “McNemar Tests” on page 32-6372.

- Mid- p -value test — The mid- p -value McNemar test statistics and rejection regions (for significance-level α) are ([32]):
 - For one-sided tests, the test statistic

$$t_1^* = n_{12}$$

If $F_{\text{Bin}}(t_1^* - 1; n_{12} + n_{21}, 0.5) + 0.5f_{\text{Bin}}(t_1^*; n_{12} + n_{21}, 0.5) < \alpha$, where $F_{\text{Bin}}(x; n, p)$ and $f_{\text{Bin}}(x; n, p)$ are the binomial C.D.F. and P.D.F, respectively, with sample size n and success probability p evaluated at x , then reject H_0 .

- For two-sided tests, the test statistic

$$t_2^* = \min(n_{12}, n_{21})$$

If $F_{\text{Bin}}(t_2^* - 1; n_{12} + n_{21} - 1, 0.5) + 0.5f_{\text{Bin}}(t_2^*; n_{12} + n_{21}, 0.5) < \alpha / 2$, then reject H_0 .

The mid- p -value test addresses the over-conservative behavior of the exact conditional test. The simulation studies in [18] demonstrate that this test attains nominal coverage, and has good statistical power.

Classification Loss

Classification losses indicate the accuracy of a classification model or set of predicted labels. Two classification losses are misclassification rate and cost.

`compareHoldout` returns the classification losses (see `e1` and `e2`) under the alternative hypothesis (i.e., the unrestricted classification losses). n_{ijk} is the number of test-sample observations with true class k that the first classification model assigns label i and the second classification model assigns label j , and the corresponding estimated proportion is

$\hat{\pi}_{ijk} = \frac{n_{ijk}}{n_{test}}$. The test-set sample size is $\sum_{i,j,k} n_{ijk} = n_{test}$. The indices are taken from 1 through K , the number of classes.

- Misclassification rate, or classification error, is a scalar in the interval $[0,1]$ representing the proportion of misclassified observations. That is, the misclassification rate for the first classification model is

$$e_1 = \sum_{j=1}^K \sum_{k=1}^K \sum_{i \neq k} \hat{\pi}_{ijk}.$$

For the misclassification rate of the second classification model (e_2), switch the indices i and j in the formula.

Classification accuracy decreases as the misclassification rate increases to 1.

- Misclassification cost is a nonnegative scalar and is a measure of classification quality relative to the values the specified cost matrix elements. Its interpretation depends on the specified costs of misclassification. Misclassification cost is the weighted average of the costs of misclassification (specified in a cost matrix, C) in which the weights are the respective, estimated proportions of misclassified observations. The misclassification cost for the first classification model is

$$e_1 = \sum_{j=1}^K \sum_{k=1}^K \sum_{i \neq k} \hat{\pi}_{ijk} C_{ki},$$

where C_{kj} is the cost of classifying an observation into class j if its true class is k . For the misclassification cost of the second classification model (e_2), switch the indices i and j in the formula.

In general, for a fixed cost matrix, classification accuracy decreases as misclassification cost increases.

Tips

- One way to perform cost-insensitive feature selection is:
 - 1 Train the first classification model (C1) using the full predictor set.
 - 2 Train the second classification model (C2) using the reduced predictor set.
 - 3 Specify X1 as the full, test-set predictor data and X2 as the reduced test-set predictor data.
 - 4 Enter `compareHoldout(C1,C2,X1,X2,'Alternative','less')`. If `compareHoldout` returns 1, then there is enough evidence to suggest that the classification model that uses fewer predictors performs better than the model that uses the full predictor set.

Alternatively, you can assess whether there is a significant difference between the accuracies of the two models. To perform this assessment, remove the 'Alternative', 'greater' specification in step 4. `compareHoldout` conducts a two-sided test, and `h = 0` indicates that there is not enough evidence to suggest a difference in the accuracy of the two models.

- Cost-sensitive tests perform numerical optimization, which requires additional computational resources. The likelihood ratio test conducts numerical optimization indirectly by finding the root of a Lagrange multiplier in an interval. For some data sets, if the root lies close to the boundaries of the interval, then the method can fail. Therefore, if you have an Optimization Toolbox license, consider conducting the cost-sensitive chi-square test instead. For more details, see `CostTest` and “Cost-Sensitive Testing” on page 32-1029.

Alternatives

To directly compare the accuracy of two sets of class labels in predicting a set of true class labels, use `testcholdout`.

compareHoldout

Compare accuracies of two classification models using new data

`compareHoldout` statistically assesses the accuracies of two classification models. The function first compares their predicted labels against the true labels, and then it detects whether the difference between the misclassification rates is statistically significant.

You can assess whether the accuracies of the classification models are different, or whether one classification model performs better than another. `compareHoldout` can conduct several McNemar test on page 32-1031 variations, including the asymptotic test, the exact-conditional test, and the mid- p -value test. For cost-sensitive assessment on page 32-1029, available tests include a chi-square test (requires an Optimization Toolbox license) and a likelihood ratio test.

Syntax

```
h = compareHoldout(C1,C2,T1,T2,ResponseVarName)
```

```
h = compareHoldout(C1,C2,T1,T2,Y)
```

```
h = compareHoldout( ___,Name,Value)
```

```
h = compareHoldout(C1,C2,X1,X2,Y)
```

```
h = compareHoldout( ___,Name,Value)
```

```
[h,p,e1,e2] = compareHoldout( ___)
```

Description

`h = compareHoldout(C1,C2,T1,T2,ResponseVarName)` returns the test decision from testing the null hypothesis that the trained classification models C1 and C2 have equal accuracy for predicting the true class labels `TBL.ResponseVarName`. The alternative hypothesis is that the labels have unequal accuracy.

The first classification model C1 uses the predictor data in table T1 and C2 uses T2.

The software conducts the mid- p -value McNemar test to compare the accuracies. $h = 1$ indicates to reject the null hypothesis at the 5% significance level. $h = 0$ indicates to not reject the null hypothesis at 5% level.

Examples of tests you can conduct include:

- Compare the accuracies of a simple classification model and a model that is more complex by passing the same set of predictor data (i.e., $T1 = T2$).
- Compare the accuracies of two perhaps different models using two perhaps different sets of predictors.
- Perform various types of feature selection. For example, you can compare the accuracy of a model trained using a set of predictors to the accuracy of one trained on a subset or different set of those predictors. You can arbitrarily choose the set of predictors, or use a feature selection technique like PCA or sequential feature selection (see `pca` and `sequentialfs`).

`h = compareHoldout(C1,C2,T1,T2,Y)` returns the result of the hypothesis test for predicting the true class labels Y .

`h = compareHoldout(____,Name,Value)` returns the result of the hypothesis test with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can specify the type of alternative hypothesis, and the type of test, or you can supply a cost matrix.

`h = compareHoldout(C1,C2,X1,X2,Y)` returns the test decision from testing the null hypothesis that the trained classification models $C1$ and $C2$ have equal accuracy for predicting the true class labels Y . The alternative hypothesis is that the labels have unequal accuracy.

The first classification model $C1$ uses the predictor data in matrix $X1$ and $C2$ uses $X2$.

`h = compareHoldout(____,Name,Value)` returns the result of the hypothesis test with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can specify the type of alternative hypothesis, and the type of test, or you can supply a cost matrix.

`[h,p,e1,e2] = compareHoldout(____)` returns the p -value for the hypothesis test (p) and the respective classification losses on page 32-1035 of each set of predicted class labels ($e1$ and $e2$), using any of the input arguments in the previous syntaxes.

Examples

Compare Accuracies of Two Different Classification Models

Train two classification models using different algorithms. Conduct a statistical test comparing the misclassification rates of the two models on a held-out set.

Load the `ionosphere` data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Train an SVM model and an ensemble of 100 bagged classification trees. For the SVM model, specify to use the radial basis function kernel and a heuristic procedure to determine the kernel scale.

```
C1 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true,...
    'KernelFunction','RBF','KernelScale','auto');
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','Bag');
```

C1 is a trained `ClassificationSVM` model. C2 is a trained `ClassificationBaggedEnsemble` model.

Test whether the two models have equal predictive accuracies. Use the same test-set predictor data for each model.

```
h = compareHoldout(C1,C2,X(idxTest,:),X(idxTest,:),Y(idxTest))
```

```
h = logical
    0
```

`h = 0` indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Assess Whether One Classification Model Classifies Better Than Another

Train two classification models using the same algorithm, but adjust a hyperparameter to make the algorithm more complex. Conduct a statistical test to assess whether the simpler model has better accuracy in held-out data than the more complex model.

Load the ionosphere data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Train two SVM models: one that uses a linear kernel (the default for binary classification) and one that uses the radial basis function kernel. Use the default kernel scale of 1.

```
C1 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true);
C2 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true,...
    'KernelFunction','RBF');
```

C1 and C2 are trained ClassificationSVM models.

Test the null hypothesis that the simpler model (C1) is at most as accurate as the more complex model (C2). Because the test-set size is large, conduct the asymptotic McNemar test, and compare the results with the mid- p -value test (the cost-insensitive testing default). Request to return p -values and misclassification rates.

```
Asymp = zeros(4,1); % Preallocation
MidP = zeros(4,1);

[Asymp(1),Asymp(2),Asymp(3),Asymp(4)] = compareHoldout(C1,C2,...
    X(idxTest,:),X(idxTest,:),Y(idxTest),'Alternative','greater',...
    'Test','asymptotic');
[MidP(1),MidP(2),MidP(3),MidP(4)] = compareHoldout(C1,C2,...
    X(idxTest,:),X(idxTest,:),Y(idxTest),'Alternative','greater');
table(Asymp,MidP,'RowNames',{'h' 'p' 'e1' 'e2'})
```

```
ans =
```

```
4x2 table
```

| | Asymp | MidP |
|----|------------|------------|
| h | 1 | 1 |
| p | 7.2801e-09 | 2.7649e-10 |
| e1 | 0.13714 | 0.13714 |
| e2 | 0.33143 | 0.33143 |

The p -value is close to zero for both tests, which indicates strong evidence to reject the null hypothesis that the simpler model is less accurate than the more complex model. No matter what test you specify, `compareHoldout` returns the same type of misclassification measure for both models.

Conduct Cost-Sensitive Comparison of Two Classification Models

For data sets with imbalanced class representations, or for data sets with imbalanced false-positive and false-negative costs, you can statistically compare the predictive performances of two classification models by including a cost matrix in the analysis.

Load the `arrhythmia` data set. Determine the class representations in the data.

```
load arrhythmia;  
Y = categorical(Y);  
tabulate(Y);
```

| Value | Count | Percent |
|-------|-------|---------|
| 1 | 245 | 54.20% |
| 2 | 44 | 9.73% |
| 3 | 15 | 3.32% |
| 4 | 15 | 3.32% |
| 5 | 13 | 2.88% |
| 6 | 25 | 5.53% |
| 7 | 3 | 0.66% |
| 8 | 2 | 0.44% |
| 9 | 9 | 1.99% |
| 10 | 50 | 11.06% |

| | | |
|----|----|-------|
| 14 | 4 | 0.88% |
| 15 | 5 | 1.11% |
| 16 | 22 | 4.87% |

There are 16 classes, however some are not represented in the data set. Most observations are classified as not having arrhythmia (class 1). To summarize, the data set is highly discrete with imbalanced classes.

Combine all observations with arrhythmia (classes 2 through 15) into one class. Remove those observations with unknown arrhythmia status from the data set.

```
Y = Y(Y ~= '16');
Y(Y ~= '1') = '2';
X = X(Y ~= '16',:);
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Create a cost matrix such that misclassifying a patient with arrhythmia into the no arrhythmia class is five times worse than misclassifying a patient without arrhythmia into the arrhythmia class. Classifying correctly incurs no cost. The rows indicate the true class and the columns indicate the predicted class. When conducting a cost-sensitive analysis, it is a good practice to specify the order of the classes.

```
cost = [0 1;5 0];
ClassNames = categorical([2 1]);
```

Train two boosting ensembles of 50 classification trees, one that uses AdaBoostM1 and the other that uses LogitBoost. Because there are missing values, specify to use surrogate splits. Train the models using the cost matrix.

```
t = templateTree('Surrogate','on');
numTrees = 50;
C1 = fitensemble(X(idxTrain,:),Y(idxTrain),'Method','AdaBoostM1',...
'NumLearningCycles',numTrees,'Learners',t,'Cost',cost);
C2 = fitensemble(X(idxTrain,:),Y(idxTrain),'Method','LogitBoost',...
'NumLearningCycles',numTrees,'Learners',t,'Cost',cost);
```

C1 and C2 are trained ClassificationEnsemble models.

Test whether the AdaBoostM1 ensemble (C1) and the LogitBoost ensemble (C2) have equal predictive accuracy. Supply the cost matrix. Conduct the asymptotic, likelihood ratio, cost-sensitive test (the default when you pass in a cost matrix). Request to return p -values and misclassification costs.

```
[h,p,e1,e2] = compareHoldout(C1,C2,X(idxTest,:),X(idxTest,:),Y(idxTest),...  
    'Cost',cost)
```

```
h = logical  
    0
```

```
p = 0.7954
```

```
e1 = 1.6558
```

```
e2 = 1.6186
```

`h = 0` indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Select Features Using Statistical Accuracy Comparison

Reduce classification model complexity by selecting a subset of predictor variables (features) from a larger set. Then, statistically compare the out-of-sample accuracy between the two models.

Load the `ionosphere` data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility  
CVP = cvpartition(Y,'holdout',0.5);  
idxTrain = training(CVP); % Training-set indices  
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Train an ensemble of 100 boosted classification trees using `AdaBoostM1` and the entire set of predictors. Inspect the importance measure for each predictor.

```
t = templateTree('MaxNumSplits',1); % Weak-learner template tree object
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','AdaBoostM1',...
    'Learners',t);
predImp = predictorImportance(C2);

figure;
bar(predImp);
h = gca;
h.XTick = 1:2:h.XLim(2)

h =
  Axes with properties:
      XLim: [-0.2000 35.2000]
      YLim: [0 0.0090]
      XScale: 'linear'
      YScale: 'linear'
  GridLineStyle: '-'
  Position: [0.1300 0.1100 0.7750 0.8150]
  Units: 'normalized'

  Show all properties

title('Predictor Importances');
xlabel('Predictor');
ylabel('Importance measure');
```

Identify the top five predictors in terms of their importance.

```
[~,idxSort] = sort(predImp, 'descend');
idx5 = idxSort(1:5);
```

Train another ensemble of 100 boosted classification trees using AdaBoostM1 and the five predictors with the best importance.

```
C1 = fitcensemble(X(idxTrain,idx5),Y(idxTrain), 'Method', 'AdaBoostM1', ...
    'Learners', t);
```

Test whether the two models have equal predictive accuracies. Specify the reduced test-set predictor data for C1 and the full test-set predictor data for C2.

```
[h,p,e1,e2] = compareHoldout(C1,C2,X(idxTest,idx5),X(idxTest,:),Y(idxTest))
```

```
h = logical
    0
```

```
p = 0.7744
```

```
e1 = 0.0914
```

```
e2 = 0.0857
```

$h = 0$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies. This result favors the simpler ensemble, C1.

Input Arguments

C1 — Trained support vector machine classification model

`ClassificationSVM` model object | `CompactClassificationSVM` model object

Trained support vector machine (SVM) classification model, specified as a `ClassificationSVM` or `CompactClassificationSVM` model object. That is, C1 is a trained classification model returned by `fitcsvm` or `compact`.

C2 — Trained classification model

trained classification model object | trained, compact classification model object

Trained classification model, specified as any trained or compact classification model object described in this table.

| Trained Model Type | Model Object | Returned By |
|--|---|---------------------------|
| Classification tree | <code>ClassificationTree</code> | <code>fitctree</code> |
| Discriminant analysis | <code>ClassificationDiscriminant</code> | <code>fitcdiscr</code> |
| Ensemble of bagged classification models | <code>ClassificationBaggedEnsemble</code> | <code>fitcensemble</code> |
| Ensemble of classification models | <code>ClassificationEnsemble</code> | <code>fitcensemble</code> |
| Multiclass, error-correcting output codes (ECOC) | <code>ClassificationECOC</code> | <code>fitcecoc</code> |

| Trained Model Type | Model Object | Returned By |
|---|-----------------------------------|-------------|
| kNN | ClassificationKNN | fitcknn |
| Naive Bayes | ClassificationNaiveBayes | fitcnb |
| Support vector machine (SVM) | ClassificationSVM | fitcsvm |
| Compact discriminant analysis | CompactClassificationDiscriminant | compact |
| Compact ECOC | CompactClassificationECOC | compact |
| Compact ensemble of classification models | CompactClassificationEnsemble | compact |
| Compact naive Bayes | CompactClassificationNaiveBayes | compact |
| Compact SVM | CompactClassificationSVM | compact |
| Compact classification tree | CompactClassificationTree | compact |

T1 — Test-set predictor table for first classification model

table

Test-set predictor table for the first classification model, C1, specified as a table. Each row of T1 corresponds to one observation, and each column corresponds to one predictor variable. Optionally, T1 can contain an additional column for the response variable. T1 must contain all of the predictors used to train C1. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

T1 and T2 must have the same number of rows, and must have the same response values. If T1 and T2 contain the response variable used to train C1 and C2, then, you do not need to specify Y.

Data Types: table

T2 — Test-set predictor table for second classification model

table

Test-set predictor data for the second classification model, C2, specified as a table. Each row of T2 corresponds to one observation, and each column corresponds to one predictor variable. Optionally, T2 can contain an additional column for the response variable. T2 must contain all of the predictors used to train C2. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

T1 and T2 must have the same number of rows and the same response values. If T1 and T2 contain the response variable used to train C1 and C2, then, you do not need to specify Y.

Data Types: `table`

X1 — Test-set predictor data for first classification model

numeric matrix

Test-set predictor data for the first classification model, C1, specified as a numeric matrix.

Each row of X1 corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a predictor or feature). The variables used to train C1 must compose X1.

The number of rows in X1 and X2 must equal the length of Y.

Data Types: `double` | `single`

X2 — Test-set predictor data for second classification model

numeric matrix

Test-set predictor data for the second classification model, C2, specified as a numeric matrix.

Each row of X2 corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a predictor or feature). The variables used to train C2 must compose X2.

The number of rows in X2 and X1 must equal the length of Y.

Data Types: `double` | `single`

ResponseVarName — Response variable name

name of a variable in T1 and T2

Response variable name, specified as the name of a variable in T1 and T2. If T1 and T2 contain the response variable used to train C1 and C2, then you do not need to specify ResponseVarName.

If you specify ResponseVarName, then you must do so as a character vector. For example, if the response variable is stored as `T1.Response`, then specify it as `'Response'`. Otherwise, the software treats all columns of T1 and T2, including Response, as predictors.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Y — True class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors | character vector

True class labels, specified as a categorical or character array, a logical or numeric vector, a cell array of character vectors, or a character vector.

If you specify any array except a character vector, then `compareHoldout` treats all variables or columns in `X1` and `X2` as predictor variables.

If you specify a character vector, then `X1` and `X2` must be tables, their response variables must have the same name and values, and `Y` must be the common name. For example, if `X1.Labels` and `X2.Labels` are the response variables, then `Y` must be `'Labels'` and `X1.Labels` and `X2.Labels` must be equivalent.

If `Y` is a character array, then each element must correspond to one row of the array.

The number of rows in `X1` and `X2` must equal the length of `Y`.

Data Types: categorical | char | logical | single | double | cell

Note NaNs, `<undefined>` values, and empty character vectors (`' '`) indicate missing values. `compareHoldout`:

- Removes missing values in `Y` and the corresponding rows of `X1` and `X2`
 - Predicts classes whether `X1` and `X2` have missing observations.
-

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Alternative', 'greater', 'Test', 'asymptotic', 'Cost', [0 2; 1 0]` specifies to test whether the first set of first predicted class labels is more accurate than

the second set, to conduct the asymptotic McNemar test, and to penalize misclassifying observations with the true label `ClassNames{1}` twice as much as for misclassifying observations with the true label `ClassNames{2}`.

Alpha — Hypothesis test significance level

0.05 (default) | scalar value in the interval (0,1)

Hypothesis test significance level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the interval (0,1).

Example: 'Alpha',0.1

Data Types: single | double

Alternative — Alternative hypothesis to assess

'unequal' (default) | 'greater' | 'less'

Alternative hypothesis to assess, specified as the comma-separated pair consisting of 'Alternative' and one of these values listed in the table.

| Value | Alternative hypothesis |
|---------------------|--|
| 'unequal' (default) | For predicting Y, the set of predictions resulting from C1 applied to X1 and C2 applied to X2 have unequal accuracies. |
| 'greater' | For predicting Y, the set of predictions resulting from C1 applied to X1 is more accurate than C2 applied to X2. |
| 'less' | For predicting Y, the set of predictions resulting from C1 applied to X1 is less accurate than C2 applied to X2. |

Example: 'Alternative','greater'

Data Types: char

ClassNames — Class names

categorical vector | cell array of character vectors | character array | logical vector | numeric vector

Class names, specified as the comma-separated pair consisting of 'ClassNames' and a categorical or character array, logical or numeric vector, or cell array of character vectors. You must set `ClassNames` using the data type of Y.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `ClassNames` to:

- Specify the order of any input argument dimension that corresponds to class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost`.
- Select a subset of classes for testing. For example, suppose that the set of all distinct class names in `Y` is `{'a', 'b', 'c'}`. To train and test models using observations from classes 'a' and 'c' only, specify `'ClassNames', {'a', 'c'}`.

The default is the set of all distinct class names in `Y`.

Example: `'ClassNames', {'b', 'g'}`

Data Types: `categorical | char | logical | single | double | cell`

Cost — Misclassification cost

`square matrix | structure array`

Misclassification cost, specified as the comma-separated pair consisting of `'Cost'` and a square matrix or structure array. If you specify:

- If you specify the square matrix `Cost`, then `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of `Cost`, additionally specify the `ClassNames` name-value pair argument.
- If you specify the structure `S`, then `S` must have two fields:
 - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`. You can use this field to specify the order of the classes.
 - `S.ClassificationCosts`, which contains the cost matrix, with rows and columns ordered as in `S.ClassNames`

If you specify `Cost`, then `compareHoldout` cannot conduct one-sided, exact, or mid- p tests. You must also specify `'Alternative', 'unequal', 'Test', 'asymptotic'`. For cost-sensitive testing options, see the `CostTest` name-value pair argument.

It is a best practice to supply the same cost matrix used to train the classification models.

The default is $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$.

Example: `'Cost', [0 1 2 ; 1 0 2; 2 2 0]`

Data Types: `double | single | struct`

CostTest — Cost-sensitive test type

'likelihood' (default) | 'chisquare'

Cost-sensitive test type, specified as the comma-separated pair consisting of 'CostTest' and 'chisquare' or 'likelihood'. Unless you specify a cost matrix using the Cost name-value pair argument, compareHoldout ignores CostTest.

This table summarizes the available options for cost-sensitive testing.

| Value | Asymptotic test type | Requirements |
|--------------|-----------------------|--|
| 'chisquare' | Chi-square test | Optimization Toolbox license to implement quadprog |
| 'likelihood' | Likelihood ratio test | None |

For more details, see “Cost-Sensitive Testing” on page 32-6369.

Example: 'CostTest', 'chisquare'

Data Types: char

Test — Test to conduct

'asymptotic' | 'exact' | 'midp'

Test to conduct, specified as the comma-separated pair consisting of 'Test' and 'asymptotic', 'exact', and 'midp'. This table summarizes the available options for cost-insensitive testing.

| Value | Description |
|------------------|-----------------------------------|
| 'asymptotic' | Asymptotic McNemar test |
| 'exact' | Exact-conditional McNemar test |
| 'midp' (default) | Mid- <i>p</i> -value McNemar test |

For more details, see “McNemar Tests” on page 32-6372.

For cost-sensitive testing, Test must be 'asymptotic'. When you specify the Cost name-value pair argument, and choose a cost-sensitive test using the CostTest name-value pair argument, 'asymptotic' is the default.

Example: 'Test', 'asymptotic'

Data Types: char

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

$h = 1$ indicates the rejection of the null hypothesis at the `Alpha` significance level.

$h = 0$ indicates failure to reject the null hypothesis at the `Alpha` significance level.

p — *p*-value

scalar in the interval [0,1]

p-value of the test, returned as a scalar in the interval [0,1]. *p* is the probability that a random test statistic is at least as extreme as the observed test statistic, given that the null hypothesis is true.

`compareHoldout` estimates *p* using the distribution of the test statistic, which varies with the type of test. For details on test statistics derived from the available variants of the McNemar test, see “McNemar Tests” on page 32-6372. For details on test statistics derived from cost-sensitive tests, see “Cost-Sensitive Testing” on page 32-6369.

e1 — Classification loss

scalar

Classification loss on page 32-1035, returned as a scalar. `e1` summarizes the accuracy of the first set of class labels predicting the true class labels (*Y*).

`compareHoldout` applies the first test-set predictor data (*X1*) to the first classification model (*C1*) to estimate the first set of class labels. Then, the function compares the estimated labels to *Y* to obtain the classification loss.

For cost-insensitive testing, `e1` is the misclassification rate. That is, `e1` is the proportion of misclassified observations, which is a scalar in the interval [0,1].

For cost-sensitive testing, `e1` is the misclassification cost. That is, `e1` is the weighted average of the misclassification costs, in which the weights are the respective estimated proportions of misclassified observations.

e2 — Classification loss

scalar

Classification loss on page 32-1035, returned as a scalar. `e2` summarizes the accuracy of the second set of class labels predicting the true class labels (Y). `compareHoldout` applies the second test-set predictor data ($X2$) to the second classification model ($C2$) to estimate the second set of class labels. Then the function compares the estimated labels to Y to obtain the classification loss.

For cost-insensitive testing, `e2` is the misclassification rate. That is, `e2` is the proportion of misclassified observations, which is a scalar in the interval $[0,1]$.

For cost-sensitive testing, `e2` is the misclassification cost. That is, `e2` is the weighted average of the misclassification costs, in which the weights are the respective estimated proportions of misclassified observations.

Definitions

Cost-Sensitive Testing

Conduct cost-sensitive testing when the cost of misclassification is imbalanced. When conducting a cost-sensitive analysis, you can account for the cost imbalance in training the classification models, and then in statistically comparing them.

If the cost of misclassification is imbalanced, then the misclassification rate tends to be a poorly performing classification loss on page 32-6375. Use misclassification cost instead to compare classification models.

Misclassification costs are often unbalanced in applications. For example, consider classifying subjects based on a set of predictors into two categories: healthy and sick. Misclassifying a sick subject as healthy poses a danger to the subject's life. However, misclassifying a healthy subject as sick can cause some inconvenience, but does not pose any danger. In this situation, you assign misclassification costs such that misclassifying a sick subject as healthy is more costly than misclassifying a healthy subject as sick.

The definitions that follow summarize the cost-sensitive tests. In the definitions:

- n_{ijk} and $\hat{\pi}_{ijk}$ are the number and estimated proportion of test-sample observations with true class k that the first classification model assigns label i . The second classification

model assigns label j . The unknown, true value of $\hat{\pi}_{ijk}$ is π_{ijk} . The test-set sample size

$$\text{is } \sum_{i,j,k} n_{ijk} = n_{test} \cdot \sum_{i,j,k} \pi_{ijk} = \sum_{i,j,k} \pi_{ijk} = 1. .$$

- c_{ij} is the relative cost of assigning label j to an observation with true class i . $c_{ii} = 0$, $c_{ij} \geq 0$, and, for at least one (i,j) pair, $c_{ij} > 0$.
- All subscripts take on integer values from 1 through K , which is the number of classes.
- The expected difference in the misclassification costs of the two classification models is

$$\delta = \sum_{i=1}^K \sum_{j=1}^K \sum_{k=1}^K (c_{ki} - c_{kj}) \pi_{ijk}.$$

- The hypothesis test is

$$H_0 : \delta = 0$$

$$H_1 : \delta \neq 0$$

The available cost-sensitive tests are appropriate for two-tailed testing.

Available, asymptotic tests that address imbalanced costs are a chi-square test and a likelihood ratio test.

- Chi-square test — The chi-square test statistic is based on the Pearson and Neyman chi-square test statistics, but with a Laplace correction factor to account for any $n_{ijk} = 0$. The test statistic is

$$t_{\chi^2}^* = \sum_{i \neq j} \sum_k \frac{(n_{ijk} + 1 - (n_{test} + K^3) \hat{\pi}_{ijk}^{(1)})^2}{n_{ijk} + 1}.$$

If $1 - F_{\chi^2}(t_{\chi^2}^*; 1) < \alpha$, then reject H_0 .

- $\hat{\pi}_{ijk}^{(1)}$ are estimated by minimizing $t_{\chi^2}^*$ under the constraint that $\delta = 0$.
- $F_{\chi^2}(x; 1)$ is the χ^2 C.D.F. with one degree of freedom evaluated at x .

- Likelihood ratio test — The likelihood ratio test is based on N_{ijk} , which are binomial random variables having sample size n_{test} and success probability π_{ijk} . They represent the random number of observations with true class k that the first classification model assigns label i . The second classification model assigns label j . Jointly, their distribution is multinomial.

The test statistic is

$$t_{LRT}^* = 2 \log \left[\frac{P \left(\bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \pi_{ijk} = \pi_{ijk}^{(2)} \right)}{P \left(\bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \pi_{ijk} = \pi_{ijk}^{(3)} \right)} \right].$$

If $1 - F_{\chi^2}(t_{LRT}^*; 1) < \alpha$, then reject H_0 .

•

• $\hat{\pi}_{ijk}^{(2)} = \frac{n_{ijk}}{n_{test}}$ is the unrestricted MLE of π_{ijk} .

•

• $\hat{\pi}_{ijk}^{(3)} = \frac{n_{ijk}}{n_{test} + \lambda(c_{ki} - c_{kj})}$ is the MLE under the null hypothesis that $\delta = 0$. λ is the solution to

$$\sum_{i,j,k} \frac{n_{ijk}(c_{ki} - c_{kj})}{n_{test} + \lambda(c_{ki} - c_{kj})} = 0.$$

•

• $F_{\chi^2}(x; 1)$ is the χ^2 C.D.F. with one degree of freedom evaluated at x .

McNemar Tests

McNemar Tests are hypothesis tests that compare two population proportions while addressing the issues resulting from two dependent, matched-pair samples.

One way to compare the predictive accuracies of two classification models is:

- 1 Partition the data into training and test sets.

- 2 Train both classification models using the training set.
- 3 Predict class labels using the test set.
- 4 Summarize the results in a two-by-two table resembling this figure.

| | | Model 2 | | |
|---------|-----------|-----------------|-----------------|----------------|
| | | Correct | Incorrect | |
| Model 1 | Correct | n_{11} | n_{12} | $n_{1\bullet}$ |
| | Incorrect | n_{21} | n_{22} | $n_{2\bullet}$ |
| | | $n_{\bullet 1}$ | $n_{\bullet 2}$ | n_{test} |

n_{ii} are the number of concordant pairs, that is, the number of observations that both models classify the same way (correctly or incorrectly). n_{ij} , $i \neq j$, are the number of discordant pairs, that is, the number of observations that models classify differently (correctly or incorrectly).

The misclassification rates for Models 1 and 2 are

$$\hat{\pi}_{2\bullet} = n_{2\bullet} / n$$

and $\hat{\pi}_{\bullet 2} = n_{\bullet 2} / n$, respectively. A two-sided test for comparing the accuracy of the two models is

$$H_0 : \pi_{\bullet 2} = \pi_{2\bullet}$$

$$H_1 : \pi_{\bullet 2} \neq \pi_{2\bullet}$$

The null hypothesis suggests that the population exhibits marginal homogeneity, which reduces the null hypothesis to $H_0 : \pi_{12} = \pi_{21}$. Also, under the null hypothesis, $N_{12} \sim \text{Binomial}(n_{12} + n_{21}, 0.5)$ [1].

These facts are the basis for these, available McNemar test variants: the asymptotic, exact-conditional and mid-p-value McNemar tests. The definitions that follow summarize the available variants.

- Asymptotic — The asymptotic McNemar test statistics and rejection regions (for significance-level α) are:

- For one-sided tests, the test statistic

$$t_{a1}^* = \frac{n_{12} - n_{21}}{\sqrt{n_{12} + n_{21}}}.$$

If $1 - \Phi\left(\left|t_1^*\right|\right) < \alpha$, where Φ is the standard Gaussian C.D.F., then reject H_0 .

- For two-sided tests, the test statistic

$$t_{a2}^* = \frac{(n_{12} - n_{21})^2}{n_{12} + n_{21}}.$$

If $1 - F_{\chi^2}\left(t_2^*; m\right) < \alpha$, where $F_{\chi^2}(x; m)$ is the χ_m^2 C.D.F. evaluated at x , then reject H_0 .

This variant requires large-sample theory, specifically, the Gaussian approximation to the binomial distribution. Therefore:

- The total number of discordant pairs, $n_d = n_{12} + n_{21}$ must be greater than 10 ([1], Ch. 10.1.4).
- In general, asymptotic tests do not guarantee nominal coverage. The observed probability of falsely rejecting the null hypothesis can exceed α . Simulation studies in [18] suggest this, but the asymptotic McNemar test performs well in terms of statistical power.
- Exact Conditional — The exact-conditional McNemar test statistics and rejection regions (for significance-level α) are ([36], [38]):

- For one-sided tests, the test statistic

$$t_1^* = n_{12}$$

If $F_{\text{Bin}}(t_1^*; n_d, 0.5) < \alpha$, where $F_{\text{Bin}}(x; n, p)$ is the binomial C.D.F. with sample size n and success probability p evaluated at x , then reject H_0 .

- For two-sided tests, the test statistic

$$t_2^* = \min(n_{12}, n_{21})$$

If $F_{\text{Bin}}(t_2^*; n_d, 0.5) < \alpha / 2$, then reject H_0 .

The exact conditional test always attains nominal coverage. Simulation studies in [18] suggest that the test is conservative, and then show that the test lacks statistical power compared to other variants. For small or highly discrete test samples, consider using the mid- p -value test ([1], Ch. 3.6.3). For details, see `Test` and “McNemar Tests” on page 32-6372.

- Mid- p -value test — The mid- p -value McNemar test statistics and rejection regions (for significance-level α) are ([32]):

- For one-sided tests, the test statistic

$$t_1^* = n_{12}$$

If $F_{\text{Bin}}(t_1^* - 1; n_{12} + n_{21}, 0.5) + 0.5f_{\text{Bin}}(t_1^*; n_{12} + n_{21}, 0.5) < \alpha$, where $F_{\text{Bin}}(x; n, p)$ and $f_{\text{Bin}}(x; n, p)$ are the binomial C.D.F. and P.D.F, respectively, with sample size n and success probability p evaluated at x , then reject H_0 .

- For two-sided tests, the test statistic

$$t_2^* = \min(n_{12}, n_{21})$$

If $F_{\text{Bin}}(t_2^* - 1; n_{12} + n_{21} - 1, 0.5) + 0.5f_{\text{Bin}}(t_2^*; n_{12} + n_{21}, 0.5) < \alpha / 2$, then reject H_0 .

The mid- p -value test addresses the over-conservative behavior of the exact conditional test. The simulation studies in [18] demonstrate that this test attains nominal coverage, and has good statistical power.

Classification Loss

Classification losses indicate the accuracy of a classification model or set of predicted labels. Two classification losses are misclassification rate and cost.

`compareHoldout` returns the classification losses (see `e1` and `e2`) under the alternative hypothesis (i.e., the unrestricted classification losses). n_{ijk} is the number of test-sample observations with true class k that the first classification model assigns label i and the second classification model assigns label j , and the corresponding estimated proportion is

$\hat{\pi}_{ijk} = \frac{n_{ijk}}{n_{test}}$. The test-set sample size is $\sum_{i,j,k} n_{ijk} = n_{test}$. The indices are taken from 1 through K , the number of classes.

- Misclassification rate, or classification error, is a scalar in the interval $[0,1]$ representing the proportion of misclassified observations. That is, the misclassification rate for the first classification model is

$$e_1 = \sum_{j=1}^K \sum_{k=1}^K \sum_{i \neq k} \hat{\pi}_{ijk}.$$

For the misclassification rate of the second classification model (e_2), switch the indices i and j in the formula.

Classification accuracy decreases as the misclassification rate increases to 1.

- Misclassification cost is a nonnegative scalar and is a measure of classification quality relative to the values the specified cost matrix elements. Its interpretation depends on the specified costs of misclassification. Misclassification cost is the weighted average of the costs of misclassification (specified in a cost matrix, C) in which the weights are the respective, estimated proportions of misclassified observations. The misclassification cost for the first classification model is

$$e_1 = \sum_{j=1}^K \sum_{k=1}^K \sum_{i \neq k} \hat{\pi}_{ijk} c_{ki},$$

where c_{kj} is the cost of classifying an observation into class j if its true class is k . For the misclassification cost of the second classification model (e_2), switch the indices i and j in the formula.

In general, for a fixed cost matrix, classification accuracy decreases as misclassification cost increases.

Alternative Functionality

To directly compare the accuracy of two sets of class labels in predicting a set of true class labels, use `testcholdout`.

compareHoldout

Class: CompactClassificationTree

Compare accuracies of two classification models using new data

`compareHoldout` statistically assesses the accuracies of two classification models. The function first compares their predicted labels against the true labels, and then it detects whether the difference between the misclassification rates is statistically significant.

You can assess whether the accuracies of the classification models are different, or whether one classification model performs better than another. `compareHoldout` can conduct several McNemar test on page 32-1031 variations, including the asymptotic test, the exact-conditional test, and the mid-*p*-value test. For cost-sensitive assessment on page 32-1029, available tests include a chi-square test (requires an Optimization Toolbox license) and a likelihood ratio test.

Syntax

```
h = compareHoldout(C1,C2,T1,T2,ResponseVarName)
```

```
h = compareHoldout(C1,C2,T1,T2,Y)
```

```
h = compareHoldout( ____,Name,Value)
```

```
h = compareHoldout(C1,C2,X1,X2,Y)
```

```
h = compareHoldout(C1,C2,X1,X2,Y,Name,Value)
```

```
[h,p,e1,e2] = compareHoldout( ____,Name,Value)
```

```
[h,p,e1,e2] = compareHoldout( ____,Name,Value)
```

Description

`h = compareHoldout(C1,C2,T1,T2,ResponseVarName)` returns the test decision from testing the null hypothesis that the trained classification models `C1` and `C2` have equal accuracy for predicting the true class labels `ResponseVarName`. The alternative hypothesis is that the labels have unequal accuracy.

$h = 1$ indicates to reject the null hypothesis at the 5% significance level. $h = 0$ indicates to not reject the null hypothesis at 5% level.

The first classification model C1 uses predictor data in table T1 and C2 uses T2. The software conducts the mid- p -value McNemar test to compare the accuracies.

Examples of tests you can conduct include:

- Compare the accuracies of a simple classification model and a model that is more complex by passing the same set of predictor data (i.e., $X1 = X2$).
- Compare the accuracies of two perhaps different models using two perhaps different sets of predictors.
- Perform various types of feature selection. For example, you can compare the accuracy of a model trained using a set of predictors to the accuracy of one trained on a subset or different set of those predictors. You can arbitrarily choose the set of predictors, or use a feature selection technique like PCA or sequential feature selection (see `pca` and `sequentialfs`).

`h = compareHoldout(C1,C2,T1,T2,Y)` returns the test decision from testing the null hypothesis that the trained classification models C1 and C2 have equal accuracy for predicting the true class labels Y. The alternative hypothesis is that the labels have unequal accuracy.

The first classification model C1 uses predictor data om table T1 and C2 uses T2. The software conducts the mid- p -value McNemar test to compare the accuracies.

`h = compareHoldout(____,Name,Value)` returns the result of the hypothesis test with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the type of alternative hypothesis, and the type of test, or you can supply a cost matrix.

`h = compareHoldout(C1,C2,X1,X2,Y)` returns the test decision from testing the null hypothesis that the trained classification models C1 and C2 have equal accuracy for predicting the true class labels Y. The alternative hypothesis is that the labels have unequal accuracy.

The first classification model C1 uses predictor data X1 and C2 uses X2. The software conducts the mid- p -value McNemar test to compare the accuracies.

`h = compareHoldout(C1,C2,X1,X2,Y,Name,Value)` returns the result of the hypothesis test with additional options specified by one or more `Name,Value` pair

arguments. For example, you can specify the type of alternative hypothesis, and the type of test, or you can supply a cost matrix.

`[h,p,e1,e2] = compareHoldout(___)` returns the p -value for the hypothesis test (p) and the respective classification losses on page 32-1061 of each set of predicted class labels ($e1$ and $e2$) using any of the input arguments in the previous syntaxes.

`[h,p,e1,e2] = compareHoldout(___)` returns the p -value for the hypothesis test (p) and the respective classification losses on page 32-1061 of each set of predicted class labels ($e1$ and $e2$) using any of the input arguments in the previous syntaxes.

Input Arguments

C1 — Trained classification tree

`ClassificationTree` model object | `CompactClassificationTree` model object

Trained classification tree, specified as a `ClassificationTree` or `CompactClassificationTree` model object. That is, C1 is a trained classification model returned by `fitctree` or `compact`.

C2 — Trained classification model

trained classification model object | trained, compact classification model object

Trained classification model, specified as any trained or compact classification model object described in this table.

| Trained Model Type | Model Object | Returned By |
|--|---|---------------------------|
| Classification tree | <code>ClassificationTree</code> | <code>fitctree</code> |
| Discriminant analysis | <code>ClassificationDiscriminant</code> | <code>fitcdiscr</code> |
| Ensemble of bagged classification models | <code>ClassificationBaggedEnsemble</code> | <code>fitcensemble</code> |
| Ensemble of classification models | <code>ClassificationEnsemble</code> | <code>fitcensemble</code> |
| Multiclass, error-correcting output codes (ECOC) | <code>ClassificationECOC</code> | <code>fitcecoc</code> |
| k NN | <code>ClassificationKNN</code> | <code>fitcknn</code> |

| Trained Model Type | Model Object | Returned By |
|---|-----------------------------------|-------------|
| Naive Bayes | ClassificationNaiveBayes | fitcnb |
| Support vector machine (SVM) | ClassificationSVM | fitcsvm |
| Compact discriminant analysis | CompactClassificationDiscriminant | compact |
| Compact ECOC | CompactClassificationECOC | compact |
| Compact ensemble of classification models | CompactClassificationEnsemble | compact |
| Compact naive Bayes | CompactClassificationNaiveBayes | compact |
| Compact SVM | CompactClassificationSVM | compact |
| Compact classification tree | CompactClassificationTree | compact |

T1 — Test-set predictor table for first classification model

table

Test-set predictor table for the first classification model, C1, specified as a table. Each row of T1 corresponds to one observation, and each column corresponds to one predictor variable. Optionally, T1 can contain an additional column for the response variable. T1 must contain all the predictors used to train C1. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

T1 and T2 must have the same number of rows, and must have the same response values. If T1 and T2 contain the response variable used to train C1 and C2, then, you do not need to specify Y.

Data Types: table

T2 — Test-set predictor table for second classification model

table

Test-set predictor data for the second classification model, C2, specified as a table. Each row of T2 corresponds to one observation, and each column corresponds to one predictor variable. Optionally, T2 can contain an additional column for the response variable. T2 must contain all the predictors used to train C2. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

T1 and T2 must have the same number of rows and the same response values. If T1 and T2 contain the response variable used to train C1 and C2, then, you do not need to specify Y.

Data Types: `table`

X1 — Test-set predictor data for first classification model

numeric matrix

Test-set predictor data for the first classification model, C1, specified as a numeric matrix.

Each row of X1 corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a predictor or feature). The variables used to train C1 must compose X1.

The number of rows in X1 and X2 must equal the length of Y.

Data Types: `double` | `single`

X2 — Test-set predictor data for second classification model

numeric matrix

Test-set predictor data for the second classification model, C2, specified as a numeric matrix.

Each row of X2 corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a predictor or feature). The variables used to train C2 must compose X2.

The number of rows in X2 and X1 must equal the length of Y.

Data Types: `double` | `single`

ResponseVarName — Response variable name

name of a variable in T1 and T2

Response variable name, specified as the name of a variable in T1 and T2. If T1 and T2 contain the response variable used to train C1 and C2, then you do not need to specify ResponseVarName.

If you specify ResponseVarName, then you must do so as a character vector. For example, if the response variable is stored as `T1.Response`, then specify it as `'Response'`. Otherwise, the software treats all columns of T1 and T2, including Response, as predictors.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Y — True class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors | character vector

True class labels, specified as a categorical or character array, a logical or numeric vector, a cell array of character vectors, or a character vector.

If you specify any array except a character vector, then `compareHoldout` treats all variables or columns in `X1` and `X2` as predictor variables.

If you specify a character vector, then `X1` and `X2` must be tables, their response variables must have the same name and values, and `Y` must be the common name. For example, if `X1.Labels` and `X2.Labels` are the response variables, then `Y` must be `'Labels'` and `X1.Labels` and `X2.Labels` must be equivalent.

If `Y` is a character array, then each element must correspond to one row of the array.

The number of rows in `X1` and `X2` must equal the length of `Y`.

Data Types: categorical | char | logical | single | double | cell

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Alternative', 'greater', 'Test', 'asymptotic', 'Cost', [0 2; 1 0]` specifies to test whether the first set of first predicted class labels is more accurate than the second set, to conduct the asymptotic McNemar test, and to penalize misclassifying observations with the true label `ClassNames{1}` twice as much as for misclassifying observations with the true label `ClassNames{2}`.

Alpha — Hypothesis test significance level

0.05 (default) | scalar value in the interval (0,1)

Hypothesis test significance level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the interval (0,1).

Example: 'Alpha',0.1

Data Types: single | double

Alternative — Alternative hypothesis to assess

'unequal' (default) | 'greater' | 'less'

Alternative hypothesis to assess, specified as the comma-separated pair consisting of 'Alternative' and one of these values listed in the table.

| Value | Alternative hypothesis |
|---------------------|--|
| 'unequal' (default) | For predicting Y, the set of predictions resulting from C1 applied to X1 and C2 applied to X2 have unequal accuracies. |
| 'greater' | For predicting Y, the set of predictions resulting from C1 applied to X1 is more accurate than C2 applied to X2. |
| 'less' | For predicting Y, the set of predictions resulting from C1 applied to X1 is less accurate than C2 applied to X2. |

Example: 'Alternative', 'greater'

Data Types: char

ClassNames — Class names

categorical vector | cell array of character vectors | character array | logical vector | numeric vector

Class names, specified as the comma-separated pair consisting of 'ClassNames' and a categorical or character array, logical or numeric vector, or cell array of character vectors. You must set ClassNames using the data type of Y.

If ClassNames is a character array, then each element must correspond to one *row* of the array.

Use ClassNames to:

- Specify the order of any input argument dimension that corresponds to class order. For example, use ClassNames to specify the order of the dimensions of Cost.
- Select a subset of classes for testing. For example, suppose that the set of all distinct class names in Y is {'a', 'b', 'c'}. To train and test models using observations from classes 'a' and 'c' only, specify 'ClassNames', {'a', 'c'}.

The default is the set of all distinct class names in Y.

Example: 'ClassNames', {'b', 'g'}

Data Types: categorical | char | logical | single | double | cell

Cost — Misclassification cost

square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure array. If you specify:

- If you specify the square matrix `Cost`, then `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of `Cost`, additionally specify the `ClassNames` name-value pair argument.
- If you specify the structure `S`, then `S` must have two fields:
 - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`. You can use this field to specify the order of the classes.
 - `S.ClassificationCosts`, which contains the cost matrix, with rows and columns ordered as in `S.ClassNames`

If you specify `Cost`, then `compareHoldout` cannot conduct one-sided, exact, or mid- p tests. You must also specify 'Alternative', 'unequal', 'Test', 'asymptotic'. For cost-sensitive testing options, see the `CostTest` name-value pair argument.

It is a best practice to supply the same cost matrix used to train the classification models.

The default is $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$.

Example: 'Cost', [0 1 2 ; 1 0 2; 2 2 0]

Data Types: double | single | struct

CostTest — Cost-sensitive test type

'likelihood' (default) | 'chisquare'

Cost-sensitive test type, specified as the comma-separated pair consisting of 'CostTest' and 'chisquare' or 'likelihood'. Unless you specify a cost matrix using the `Cost` name-value pair argument, `compareHoldout` ignores `CostTest`.

This table summarizes the available options for cost-sensitive testing.

| Value | Asymptotic test type | Requirements |
|--------------|-----------------------|--|
| 'chisquare' | Chi-square test | Optimization Toolbox license to implement quadprog |
| 'likelihood' | Likelihood ratio test | None |

For more details, see “Cost-Sensitive Testing” on page 32-6369.

Example: 'CostTest', 'chisquare'

Data Types: char

Test — Test to conduct

'asymptotic' | 'exact' | 'midp'

Test to conduct, specified as the comma-separated pair consisting of 'Test' and 'asymptotic', 'exact', and 'midp'. This table summarizes the available options for cost-insensitive testing.

| Value | Description |
|------------------|-----------------------------------|
| 'asymptotic' | Asymptotic McNemar test |
| 'exact' | Exact-conditional McNemar test |
| 'midp' (default) | Mid- <i>p</i> -value McNemar test |

For more details, see “McNemar Tests” on page 32-6372.

For cost-sensitive testing, Test must be 'asymptotic'. When you specify the Cost name-value pair argument, and choose a cost-sensitive test using the CostTest name-value pair argument, 'asymptotic' is the default.

Example: 'Test', 'asymptotic'

Data Types: char

Note NaNs, <undefined> values, and empty character vectors (' ') indicate missing values. compareHoldout:

- Removes missing values in Y and the corresponding rows of X1 and X2
 - Predicts classes whether X1 and X2 have missing observations.
-

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

$h = 1$ indicates the rejection of the null hypothesis at the Alpha significance level.

$h = 0$ indicates failure to reject the null hypothesis at the Alpha significance level.

p — p -value

scalar in the interval [0,1]

p -value of the test, returned as a scalar in the interval [0,1]. p is the probability that a random test statistic is at least as extreme as the observed test statistic, given that the null hypothesis is true.

`compareHoldout` estimates p using the distribution of the test statistic, which varies with the type of test. For details on test statistics derived from the available variants of the McNemar test, see “McNemar Tests” on page 32-6372. For details on test statistics derived from cost-sensitive tests, see “Cost-Sensitive Testing” on page 32-6369.

e1 — Classification loss

scalar

Classification loss on page 32-1035, returned as a scalar. **e1** summarizes the accuracy of the first set of class labels predicting the true class labels (Y).

`compareHoldout` applies the first test-set predictor data ($X1$) to the first classification model ($C1$) to estimate the first set of class labels. Then, the function compares the estimated labels to Y to obtain the classification loss.

For cost-insensitive testing, **e1** is the misclassification rate. That is, **e1** is the proportion of misclassified observations, which is a scalar in the interval [0,1].

For cost-sensitive testing, **e1** is the misclassification cost. That is, **e1** is the weighted average of the misclassification costs, in which the weights are the respective estimated proportions of misclassified observations.

e2 — Classification loss

scalar

Classification loss on page 32-1035, returned as a scalar. `e2` summarizes the accuracy of the second set of class labels predicting the true class labels (`Y`). `compareHoldout` applies the second test-set predictor data (`X2`) to the second classification model (`C2`) to estimate the second set of class labels. Then the function compares the estimated labels to `Y` to obtain the classification loss.

For cost-insensitive testing, `e2` is the misclassification rate. That is, `e2` is the proportion of misclassified observations, which is a scalar in the interval $[0,1]$.

For cost-sensitive testing, `e2` is the misclassification cost. That is, `e2` is the weighted average of the misclassification costs, in which the weights are the respective estimated proportions of misclassified observations.

Examples

Compare Accuracies of Two Different Classification Models

Train two classification models using different algorithms. Conduct a statistical test comparing the misclassification rates of the two models on a held-out set.

Load the `ionosphere` data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

`CVP` is a cross-validation partition object that specifies the training and test sets.

Train an SVM model and an ensemble of 100 bagged classification trees. For the SVM model, specify to use the radial basis function kernel and a heuristic procedure to determine the kernel scale.

```
C1 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true,...
    'KernelFunction','RBF','KernelScale','auto');
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','Bag');
```

C1 is a trained `ClassificationSVM` model. C2 is a trained `ClassificationBaggedEnsemble` model.

Test whether the two models have equal predictive accuracies. Use the same test-set predictor data for each model.

```
h = compareHoldout(C1,C2,X(idxTest,:),X(idxTest,:),Y(idxTest))
```

```
h = logical
    0
```

`h = 0` indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Assess Whether One Classification Model Classifies Better Than Another

Train two classification models using the same algorithm, but adjust a hyperparameter to make the algorithm more complex. Conduct a statistical test to assess whether the simpler model has better accuracy in held-out data than the more complex model.

Load the ionosphere data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Train two SVM models: one that uses a linear kernel (the default for binary classification) and one that uses the radial basis function kernel. Use the default kernel scale of 1.

```
C1 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true);
C2 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true,...
    'KernelFunction','RBF');
```

C1 and C2 are trained `ClassificationSVM` models.

Test the null hypothesis that the simpler model (C1) is at most as accurate as the more complex model (C2). Because the test-set size is large, conduct the asymptotic McNemar test, and compare the results with the mid- p -value test (the cost-insensitive testing default). Request to return p -values and misclassification rates.

```
Asymp = zeros(4,1); % Preallocation
MidP = zeros(4,1);

[Asymp(1),Asymp(2),Asymp(3),Asymp(4)] = compareHoldout(C1,C2,...
    X(idxTest,:),X(idxTest,:),Y(idxTest),'Alternative','greater',...
    'Test','asymptotic');
[MidP(1),MidP(2),MidP(3),MidP(4)] = compareHoldout(C1,C2,...
    X(idxTest,:),X(idxTest,:),Y(idxTest),'Alternative','greater');
table(Asymp,MidP,'RowNames',{'h' 'p' 'e1' 'e2'})
```

ans =

4x2 table

| | Asymp | MidP |
|----|------------|------------|
| h | 1 | 1 |
| p | 7.2801e-09 | 2.7649e-10 |
| e1 | 0.13714 | 0.13714 |
| e2 | 0.33143 | 0.33143 |

The p -value is close to zero for both tests, which indicates strong evidence to reject the null hypothesis that the simpler model is less accurate than the more complex model. No matter what test you specify, `compareHoldout` returns the same type of misclassification measure for both models.

Conduct Cost-Sensitive Comparison of Two Classification Models

For data sets with imbalanced class representations, or for data sets with imbalanced false-positive and false-negative costs, you can statistically compare the predictive performances of two classification models by including a cost matrix in the analysis.

Load the `arrhythmia` data set. Determine the class representations in the data.

```
load arrhythmia;
Y = categorical(Y);
tabulate(Y);
```

| Value | Count | Percent |
|-------|-------|---------|
| 1 | 245 | 54.20% |
| 2 | 44 | 9.73% |
| 3 | 15 | 3.32% |
| 4 | 15 | 3.32% |
| 5 | 13 | 2.88% |
| 6 | 25 | 5.53% |
| 7 | 3 | 0.66% |
| 8 | 2 | 0.44% |
| 9 | 9 | 1.99% |
| 10 | 50 | 11.06% |
| 14 | 4 | 0.88% |
| 15 | 5 | 1.11% |
| 16 | 22 | 4.87% |

There are 16 classes, however some are not represented in the data set. Most observations are classified as not having arrhythmia (class 1). To summarize, the data set is highly discrete with imbalanced classes.

Combine all observations with arrhythmia (classes 2 through 15) into one class. Remove those observations with unknown arrhythmia status from the data set.

```
Y = Y(Y ~= '16');
Y(Y ~= '1') = '2';
X = X(Y ~= '16',:);
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Create a cost matrix such that misclassifying a patient with arrhythmia into the no arrhythmia class is five times worse than misclassifying a patient without arrhythmia into the arrhythmia class. Classifying correctly incurs no cost. The rows indicate the true class and the columns indicate the predicted class. When conducting a cost-sensitive analysis, it is a good practice to specify the order of the classes.

```
cost = [0 1;5 0];  
ClassNames = categorical([2 1]);
```

Train two boosting ensembles of 50 classification trees, one that uses AdaBoostM1 and the other that uses LogitBoost. Because there are missing values, specify to use surrogate splits. Train the models using the cost matrix.

```
t = templateTree('Surrogate', 'on');  
numTrees = 50;  
C1 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','AdaBoostM1',...  
    'NumLearningCycles',numTrees,'Learners',t,'Cost',cost);  
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','LogitBoost',...  
    'NumLearningCycles',numTrees,'Learners',t,'Cost',cost);
```

C1 and C2 are trained ClassificationEnsemble models.

Test whether the AdaBoostM1 ensemble (C1) and the LogitBoost ensemble (C2) have equal predictive accuracy. Supply the cost matrix. Conduct the asymptotic, likelihood ratio, cost-sensitive test (the default when you pass in a cost matrix). Request to return p -values and misclassification costs.

```
[h,p,e1,e2] = compareHoldout(C1,C2,X(idxTest,:),X(idxTest,:),Y(idxTest),...  
    'Cost',cost)
```

```
h = logical  
    0
```

```
p = 0.7954
```

```
e1 = 1.6558
```

```
e2 = 1.6186
```

$h = 0$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Select Features Using Statistical Accuracy Comparison

Reduce classification model complexity by selecting a subset of predictor variables (features) from a larger set. Then, statistically compare the out-of-sample accuracy between the two models.

Load the ionosphere data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP);      % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Train an ensemble of 100 boosted classification trees using AdaBoostM1 and the entire set of predictors. Inspect the importance measure for each predictor.

```
t = templateTree('MaxNumSplits',1); % Weak-learner template tree object
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','AdaBoostM1',...
    'Learners',t);
predImp = predictorImportance(C2);
```

```
figure;
bar(predImp);
h = gca;
h.XTick = 1:2:h.XLim(2)
```

```
h =
  Axes with properties:
      XLim: [-0.2000 35.2000]
      YLim: [0 0.0090]
      XScale: 'linear'
      YScale: 'linear'
  GridLineStyle: '-'
  Position: [0.1300 0.1100 0.7750 0.8150]
  Units: 'normalized'
```

Show all properties

```
title('Predictor Importances');
xlabel('Predictor');
ylabel('Importance measure');
```

Identify the top five predictors in terms of their importance.

```
[~,idxSort] = sort(predImp, 'descend');
idx5 = idxSort(1:5);
```

Train another ensemble of 100 boosted classification trees using AdaBoostM1 and the five predictors with the best importance.

```
C1 = fitcensemble(X(idxTrain,idx5),Y(idxTrain), 'Method', 'AdaBoostM1', ...
    'Learners', t);
```

Test whether the two models have equal predictive accuracies. Specify the reduced test-set predictor data for C1 and the full test-set predictor data for C2.

```
[h,p,e1,e2] = compareHoldout(C1,C2,X(idxTest,idx5),X(idxTest,:),Y(idxTest))
```

$h = \text{logical}$
 θ

$p = 0.7744$

$e1 = 0.0914$

$e2 = 0.0857$

$h = \theta$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies. This result favors the simpler ensemble, C1.

Definitions

Cost-Sensitive Testing

Conduct cost-sensitive testing when the cost of misclassification is imbalanced. When conducting a cost-sensitive analysis, you can account for the cost imbalance in training the classification models, and then in statistically comparing them.

If the cost of misclassification is imbalanced, then the misclassification rate tends to be a poorly performing classification loss on page 32-6375. Use misclassification cost instead to compare classification models.

Misclassification costs are often unbalanced in applications. For example, consider classifying subjects based on a set of predictors into two categories: healthy and sick. Misclassifying a sick subject as healthy poses a danger to the subject's life. However, misclassifying a healthy subject as sick can cause some inconvenience, but does not pose any danger. In this situation, you assign misclassification costs such that misclassifying a sick subject as healthy is more costly than misclassifying a healthy subject as sick.

The definitions that follow summarize the cost-sensitive tests. In the definitions:

- n_{ijk} and $\hat{\pi}_{ijk}$ are the number and estimated proportion of test-sample observations with true class k that the first classification model assigns label i . The second classification model assigns label j . The unknown, true value of $\hat{\pi}_{ijk}$ is π_{ijk} . The test-set sample size

$$\text{is } \sum_{i,j,k} n_{ijk} = n_{\text{test}}. \quad \sum_{i,j,k} \pi_{ijk} = \sum_{i,j,k} \pi_{ijk} = 1. .$$

- c_{ij} is the relative cost of assigning label j to an observation with true class i . $c_{ii} = 0$, $c_{ij} \geq 0$, and, for at least one (i, j) pair, $c_{ij} > 0$.
- All subscripts take on integer values from 1 through K , which is the number of classes.
- The expected difference in the misclassification costs of the two classification models is

$$\delta = \sum_{i=1}^K \sum_{j=1}^K \sum_{k=1}^K (c_{ki} - c_{kj}) \pi_{ijk}.$$

- The hypothesis test is

$$H_0 : \delta = 0$$

$$H_1 : \delta \neq 0$$

The available cost-sensitive tests are appropriate for two-tailed testing.

Available, asymptotic tests that address imbalanced costs are a chi-square test and a likelihood ratio test.

- Chi-square test — The chi-square test statistic is based on the Pearson and Neyman chi-square test statistics, but with a Laplace correction factor to account for any $n_{ijk} = 0$. The test statistic is

$$t_{\chi^2}^* = \sum_{i \neq j} \sum_k \frac{(n_{ijk} + 1 - (n_{test} + K^3) \hat{\pi}_{ijk}^{(1)})^2}{n_{ijk} + 1}.$$

If $1 - F_{\chi^2}(t_{\chi^2}^*; 1) < \alpha$, then reject H_0 .

- $\hat{\pi}_{ijk}^{(1)}$ are estimated by minimizing $t_{\chi^2}^*$ under the constraint that $\delta = 0$.
- $F_{\chi^2}(x; 1)$ is the χ^2 C.D.F. with one degree of freedom evaluated at x .
- Likelihood ratio test — The likelihood ratio test is based on N_{ijk} , which are binomial random variables having sample size n_{test} and success probability π_{ijk} . They represent the random number of observations with true class k that the first classification model

assigns label i . The second classification model assigns label j . Jointly, their distribution is multinomial.

The test statistic is

$$t_{LRT}^* = 2 \log \left[\frac{P \left(\bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \pi_{ijk} = \pi_{ijk}^{(2)} \right)}{P \left(\bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \pi_{ijk} = \pi_{ijk}^{(3)} \right)} \right].$$

If $1 - F_{\chi^2}(t_{LRT}^*; 1) < \alpha$, then reject H_0 .

•

• $\hat{\pi}_{ijk}^{(2)} = \frac{n_{ijk}}{n_{test}}$ is the unrestricted MLE of π_{ijk} .

•

• $\hat{\pi}_{ijk}^{(3)} = \frac{n_{ijk}}{n_{test} + \lambda(c_{ki} - c_{kj})}$ is the MLE under the null hypothesis that $\delta = 0$. λ is the solution to

$$\sum_{i,j,k} \frac{n_{ijk}(c_{ki} - c_{kj})}{n_{test} + \lambda(c_{ki} - c_{kj})} = 0.$$

•

• $F_{\chi^2}(x; 1)$ is the χ^2 C.D.F. with one degree of freedom evaluated at x .

McNemar Tests

McNemar Tests are hypothesis tests that compare two population proportions while addressing the issues resulting from two dependent, matched-pair samples.

One way to compare the predictive accuracies of two classification models is:

- 1 Partition the data into training and test sets.
- 2 Train both classification models using the training set.
- 3 Predict class labels using the test set.

- 4 Summarize the results in a two-by-two table resembling this figure.

| | | Model 2 | | |
|---------|-----------|-----------------|-----------------|----------------|
| | | Correct | Incorrect | |
| Model 1 | Correct | n_{11} | n_{12} | $n_{1\bullet}$ |
| | Incorrect | n_{21} | n_{22} | $n_{2\bullet}$ |
| | | $n_{\bullet 1}$ | $n_{\bullet 2}$ | n_{test} |

n_{ij} are the number of concordant pairs, that is, the number of observations that both models classify the same way (correctly or incorrectly). $n_{ij}, i \neq j$, are the number of discordant pairs, that is, the number of observations that models classify differently (correctly or incorrectly).

The misclassification rates for Models 1 and 2 are

$$\hat{\pi}_{2\bullet} = n_{2\bullet} / n$$

and $\hat{\pi}_{\bullet 2} = n_{\bullet 2} / n$, respectively. A two-sided test for comparing the accuracy of the two models is

$$\begin{aligned} H_0 &: \pi_{\bullet 2} = \pi_{2\bullet} \\ H_1 &: \pi_{\bullet 2} \neq \pi_{2\bullet} \end{aligned}$$

The null hypothesis suggests that the population exhibits marginal homogeneity, which reduces the null hypothesis to $H_0 : \pi_{12} = \pi_{21}$. Also, under the null hypothesis, $N_{12} \sim \text{Binomial}(n_{12} + n_{21}, 0.5)$ [1].

These facts are the basis for these, available McNemar test variants: the asymptotic, exact-conditional and mid-p-value McNemar tests. The definitions that follow summarize the available variants.

- Asymptotic — The asymptotic McNemar test statistics and rejection regions (for significance-level α) are:

- For one-sided tests, the test statistic

$$t_{a1}^* = \frac{n_{12} - n_{21}}{\sqrt{n_{12} + n_{21}}}.$$

If $1 - \Phi(|t_1^*|) < \alpha$, where Φ is the standard Gaussian C.D.F., then reject H_0 .

- For two-sided tests, the test statistic

$$t_{a2}^* = \frac{(n_{12} - n_{21})^2}{n_{12} + n_{21}}.$$

If $1 - F_{\chi^2}(t_2^*; m) < \alpha$, where $F_{\chi^2}(x; m)$ is the χ_m^2 C.D.F. evaluated at x , then reject H_0 .

This variant requires large-sample theory, specifically, the Gaussian approximation to the binomial distribution. Therefore:

- The total number of discordant pairs, $n_d = n_{12} + n_{21}$ must be greater than 10 ([1], Ch. 10.1.4).
- In general, asymptotic tests do not guarantee nominal coverage. The observed probability of falsely rejecting the null hypothesis can exceed α . Simulation studies in [18] suggest this, but the asymptotic McNemar test performs well in terms of statistical power.
- Exact Conditional — The exact-conditional McNemar test statistics and rejection regions (for significance-level α) are ([36], [38]):

- For one-sided tests, the test statistic

$$t_1^* = n_{12}$$

If $F_{\text{Bin}}(t_1^*; n_d, 0.5) < \alpha$, where $F_{\text{Bin}}(x; n, p)$ is the binomial C.D.F. with sample size n and success probability p evaluated at x , then reject H_0 .

- For two-sided tests, the test statistic

$$t_2^* = \min(n_{12}, n_{21})$$

If $F_{\text{Bin}}(t_2^*; n_d, 0.5) < \alpha / 2$, then reject H_0 .

The exact conditional test always attains nominal coverage. Simulation studies in [18] suggest that the test is conservative, and then show that the test lacks statistical power compared to other variants. For small or highly discrete test samples, consider using the mid- p -value test ([1], Ch. 3.6.3). For details, see `Test` and “McNemar Tests” on page 32-6372.

- Mid- p -value test — The mid- p -value McNemar test statistics and rejection regions (for significance-level α) are ([32]):
 - For one-sided tests, the test statistic

$$t_1^* = n_{12}$$

If $F_{\text{Bin}}(t_1^* - 1; n_{12} + n_{21}, 0.5) + 0.5f_{\text{Bin}}(t_1^*; n_{12} + n_{21}, 0.5) < \alpha$, where $F_{\text{Bin}}(x; n, p)$ and $f_{\text{Bin}}(x; n, p)$ are the binomial C.D.F. and P.D.F, respectively, with sample size n and success probability p evaluated at x , then reject H_0 .

- For two-sided tests, the test statistic

$$t_2^* = \min(n_{12}, n_{21})$$

If $F_{\text{Bin}}(t_2^* - 1; n_{12} + n_{21} - 1, 0.5) + 0.5f_{\text{Bin}}(t_2^*; n_{12} + n_{21}, 0.5) < \alpha / 2$, then reject H_0 .

The mid- p -value test addresses the over-conservative behavior of the exact conditional test. The simulation studies in [18] demonstrate that this test attains nominal coverage, and has good statistical power.

Classification Loss

Classification losses indicate the accuracy of a classification model or set of predicted labels. Two classification losses are misclassification rate and cost.

`compareHoldout` returns the classification losses (see `e1` and `e2`) under the alternative hypothesis (i.e., the unrestricted classification losses). n_{ijk} is the number of test-sample observations with true class k that the first classification model assigns label i and the second classification model assigns label j , and the corresponding estimated proportion is

$\hat{\pi}_{ijk} = \frac{n_{ijk}}{n_{test}}$. The test-set sample size is $\sum_{i,j,k} n_{ijk} = n_{test}$. The indices are taken from 1 through K , the number of classes.

- Misclassification rate, or classification error, is a scalar in the interval $[0,1]$ representing the proportion of misclassified observations. That is, the misclassification rate for the first classification model is

$$e_1 = \sum_{j=1}^K \sum_{k=1}^K \sum_{i \neq k} \hat{\pi}_{ijk}.$$

For the misclassification rate of the second classification model (e_2), switch the indices i and j in the formula.

Classification accuracy decreases as the misclassification rate increases to 1.

- Misclassification cost is a nonnegative scalar and is a measure of classification quality relative to the values the specified cost matrix elements. Its interpretation depends on the specified costs of misclassification. Misclassification cost is the weighted average of the costs of misclassification (specified in a cost matrix, C) in which the weights are the respective, estimated proportions of misclassified observations. The misclassification cost for the first classification model is

$$e_1 = \sum_{j=1}^K \sum_{k=1}^K \sum_{i \neq k} \hat{\pi}_{ijk} C_{ki},$$

where C_{kj} is the cost of classifying an observation into class j if its true class is k . For the misclassification cost of the second classification model (e_2), switch the indices i and j in the formula.

In general, for a fixed cost matrix, classification accuracy decreases as misclassification cost increases.

Tips

- One way to perform cost-insensitive feature selection is:
 - 1 Train the first classification model (C1) using the full predictor set.
 - 2 Train the second classification model (C2) using the reduced predictor set.
 - 3 Specify X1 as the full, test-set predictor data and X2 as the reduced test-set predictor data.
 - 4 Enter `compareHoldout(C1,C2,X1,X2,'Alternative','less')`. If `compareHoldout` returns 1, then there is enough evidence to suggest that the classification model that uses fewer predictors performs better than the model that uses the full predictor set.

Alternatively, you can assess whether there is a significant difference between the accuracies of the two models. To perform this assessment, remove the 'Alternative','greater' specification in step 4. `compareHoldout` conducts a two-sided test, and `h = 0` indicates that there is not enough evidence to suggest a difference in the accuracy of the two models.

- Cost-sensitive tests perform numerical optimization, which requires additional computational resources. The likelihood ratio test conducts numerical optimization indirectly by finding the root of a Lagrange multiplier in an interval. For some data sets, if the root lies close to the boundaries of the interval, then the method can fail. Therefore, if you have an Optimization Toolbox license, consider conducting the cost-sensitive chi-square test instead. For more details, see `CostTest` and “Cost-Sensitive Testing” on page 32-1029.

Alternatives

To directly compare the accuracy of two sets of class labels in predicting a set of true class labels, use `testcholdout`.

Introduced in R2015a

confusionmat

Confusion matrix

Syntax

```
C = confusionmat(group,grouphat)
C = confusionmat(group,grouphat,'Order',grouporder)
[C,order] = confusionmat( ___ )
```

Description

`C = confusionmat(group,grouphat)` returns the confusion matrix `C` determined by the known and predicted groups in `group` and `grouphat`, respectively.

`C = confusionmat(group,grouphat,'Order',grouporder)` uses `grouporder` to order the rows and columns of `C`.

`[C,order] = confusionmat(___)` also returns the order of the rows and columns of `C` in the variable `order` using any of the input arguments in previous syntaxes.

Examples

Display Confusion Matrix

Display the confusion matrix for data with two misclassifications and one missing classification.

Create vectors for the known groups and the predicted groups.

```
g1 = [3 2 2 3 1 1]';    % Known groups
g2 = [4 2 3 NaN 1 1]';  % Predicted groups
```

Return the confusion matrix.

```
C = confusionmat(g1,g2)
```

```
C = 4x4
     2     0     0     0
     0     1     1     0
     0     0     0     1
     0     0     0     0
```

The indices of the rows and columns of the confusion matrix `C` are identical and arranged by default in the sorted order of `[g1;g2]`, that is, `(1,2,3,4)`.

The confusion matrix shows that the two data points known to be in group 1 are classified correctly. For group 2, one of the data points is misclassified into group 3. Also, one of the data points known to be in group 3 is misclassified into group 4. `confusionmat` treats the NaN value in the grouping variable `g2` as a missing value and does not include it in the rows and columns of `C`.

Specify Group Order of Confusion Matrix

Display the confusion matrix for data with two misclassifications and one missing classification, and specify the group order.

Create vectors for the known groups and the predicted groups.

```
g1 = [3 2 2 3 1 1]'; % Known groups
g2 = [4 2 3 NaN 1 1]'; % Predicted groups
```

Specify the group order and return the confusion matrix.

```
C = confusionmat(g1,g2,'Order',[4 3 2 1])
```

```
C = 4x4
     0     0     0     0
     1     0     0     0
     0     1     1     0
     0     0     0     2
```

The indices of the rows and columns of the confusion matrix `C` are identical and arranged in the order specified by the group order, that is, `(4,3,2,1)`.

The second row of the confusion matrix `C` shows that one of the data points known to be in group 3 is misclassified into group 4. The third row of `C` shows that one of the data points belonging to group 2 is misclassified into group 3, and the fourth row shows that the two data points known to be in group 1 are classified correctly. `confusionmat` treats the NaN value in the grouping variable `g2` as a missing value and does not include it in the rows and columns of `C`.

Display Confusion Matrix for Classification

Perform classification on a sample of the `fisheriris` data set and display the confusion matrix for the resulting classification.

Load Fisher's iris data set.

```
load fisheriris
```

Randomize the measurements and groups in the data.

```
rng(0, 'twister'); % For reproducibility
numObs = length(species);
p = randperm(numObs);
meas = meas(p,:);
species = species(p);
```

Train a discriminant analysis classifier by using measurements in the first half of the data.

```
half = floor(numObs/2);
training = meas(1:half,:);
trainingSpecies = species(1:half);
Mdl = fitcdiscr(training, trainingSpecies);
```

Predict labels for the measurements in the second half of the data by using the trained classifier.

```
sample = meas(half+1:end,:);
grouphat = predict(Mdl, sample);
```

Specify the group order and display the confusion matrix for the resulting classification.

```
group = species(half+1:end);
[C, order] = confusionmat(group, grouphat, 'Order', {'setosa', 'versicolor', 'virginica'})
```

```

C = 3x3

    29     0     0
     0    22     2
     0     0    22

order = 3x1 cell array
    {'setosa'   }
    {'versicolor'}
    {'virginica' }

```

The confusion matrix shows that the measurements belonging to setosa and virginica are classified correctly, while two of the measurements belonging to versicolor are misclassified as virginica. The output `order` contains the order of the rows and columns of the confusion matrix in the sequence specified by the group order `{'setosa', 'versicolor', 'virginica'}`.

Display Confusion Matrix for Classification Using Tall Arrays

Perform classification on a tall array of the `fisheriris` data set and display the confusion matrix for the known and predicted tall labels.

Load Fisher's iris data set.

```
load fisheriris
```

Convert the in-memory arrays, `meas` and `species`, to tall arrays.

```
tx = tall(meas);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
connected to 12 workers.
```

```
ty = tall(species);
```

Find the number of observations in the tall array.

```
numObs = gather(length(ty)); % gather collects tall array into memory
```

```
Evaluating tall expression using the Parallel Pool 'local':
Evaluation completed in 0 sec
```

Set the random number stream for reproducibility, and randomly select training samples.

```
s = RandStream('mlfg6331_64'); % For reproducibility
numTrain = floor(numObs/2);
[txTrain,trIdx] = datasample(s,tx,numTrain,'Replace',false);
tyTrain = ty(trIdx);
```

Fit a decision tree classifier model on the training samples.

```
mdl = fitctree(txTrain,tyTrain);
```

```
Evaluating tall expression using the Parallel Pool 'local':
Evaluation completed in 2 sec
Evaluating tall expression using the Parallel Pool 'local':
Evaluation completed in 1 sec
Evaluating tall expression using the Parallel Pool 'local':
Evaluation completed in 1 sec
Evaluating tall expression using the Parallel Pool 'local':
Evaluation completed in 1 sec
Evaluating tall expression using the Parallel Pool 'local':
Evaluation completed in 1 sec
Evaluating tall expression using the Parallel Pool 'local':
Evaluation completed in 0 sec
```

Predict labels for the test samples by using the trained model.

```
txTest = tx(~trIdx,:);
label = predict(mdl,txTest);
```

Display the confusion matrix for the resulting classification.

```
tyTest = ty(~trIdx);
[C,order] = confusionmat(tyTest,label)
```

```
C =
```

```
3x3 tall double matrix
```

```
    20     0     0
     0    27     2
     0     1    25
```

```
order =
```

```
3x1 tall cell array
```

```
{'setosa'    }
{'versicolor'}
{'virginica' }
```

The confusion matrix shows that two measurements in the versicolor class are misclassified as virginica, and one measurement in the virginica class is misclassified as versicolor. All the measurements belonging to setosa are classified correctly.

Input Arguments

group — Known groups

numeric vector | logical vector | character array | string array | cell array of character vectors | categorical vector

Known groups for categorizing observations, specified as a numeric vector, logical vector, character array, string array, cell array of character vectors, or categorical vector.

`group` is a grouping variable of the same type as `grouphat`. The `group` argument must have the same number of observations as `grouphat`, as described in “Grouping Variables” on page 2-57. The `confusionmat` function treats character arrays and string arrays as cell arrays of character vectors. Additionally, `confusionmat` treats NaN, empty, and 'undefined' values in `group` as missing values and does not count them as distinct groups or categories.

Example: {'Male', 'Female', 'Female', 'Male', 'Female'}

Data Types: single | double | logical | char | string | cell | categorical

grouphat — Predicted groups

numeric vector | logical vector | character array | string array | cell array of character vectors | categorical vector

Predicted groups for categorizing observations, specified as a numeric vector, logical vector, character array, string array, cell array of character vectors, or categorical vector.

`grouphat` is a grouping variable of the same type as `group`. The `grouphat` argument must have the same number of observations as `group`, as described in “Grouping Variables” on page 2-57. The `confusionmat` function treats character arrays and string arrays as cell arrays of character vectors. Additionally, `confusionmat` treats NaN, empty, and 'undefined' values in `grouphat` as missing values and does not count them as distinct groups or categories.

Example: [1 0 0 1 0]

Data Types: single | double | logical | char | string | cell | categorical

grouporder — Group order

numeric vector | logical vector | character array | string array | cell array of character vectors | categorical vector

Group order, specified as a numeric vector, logical vector, character array, string array, cell array of character vectors, or categorical vector.

`grouporder` is a grouping variable containing all the distinct elements in `group` and `grouphat`. Specify `grouporder` to define the order of the rows and columns of `C`. If `grouporder` contains elements that are not in `group` or `grouphat`, the corresponding entries in `C` are 0.

By default, `grp2idx` computes the group order using `grp2idx(s)`, where `s = [group;grouphat]`. The group order depends on the data type of `s`.

- For numeric and logical vectors, the order is the sorted order of `s`.
- For categorical vectors, the order is the order returned by `categories(s)`.
- For other data types, the order is the order of first appearance in `s`.

Example: 'order',{'setosa','versicolor','virginica'}

Data Types: single | double | logical | char | string | cell | categorical

Output Arguments

C — Confusion matrix

matrix

Confusion matrix, returned as a square matrix with size equal to the total number of distinct elements in the `group` and `grouphat` arguments. `C(i,j)` is the count of observations known to be in group `i` but predicted to be in group `j`.

The rows and columns of `C` have identical ordering of the same group indices, computed by `grp2idx` using `grp2idx([group;grouphat])` or specified by `grouporder`.

The `confusionmat` function treats NaN, empty, and 'undefined' values in the grouping variables as missing values and does not include them in the rows and columns of `C`.

order — Order of rows and columns

numeric vector | logical vector | categorical vector | cell array of character vectors

Order of rows and columns in `C`, returned as a numeric vector, logical vector, categorical vector, or cell array of character vectors. If `group` and `groupcat` are character arrays, string arrays, or cell arrays of character vectors, then the variable `order` is a cell array of character vectors. Otherwise, `order` is of the same type as `group` and `groupcat`.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

controlchart

Shewhart control charts

Syntax

```
controlchart(X)
controlchart(x,group)
controlchart(X,group)
[stats,plotdata] = controlchart(x,[group])
controlchart(x,group,'name',value)
```

Description

`controlchart(X)` produces an xbar chart of the measurements in matrix *X*. Each row of *X* is considered to be a subgroup of measurements containing replicate observations taken at the same time. The rows should be in time order. If *X* is a time series object, the time samples should contain replicate observations.

The chart plots the means of the subgroups in time order, a center line (CL) at the average of the means, and upper and lower control limits (UCL, LCL) at three standard errors from the center line. The standard error is the estimated process standard deviation divided by the square root of the subgroup size. Process standard deviation is estimated from the average of the subgroup standard deviations. Out of control measurements are marked as violations and drawn with a red circle. Data cursor mode is enabled, so clicking any data point displays information about that point.

`controlchart(x,group)` accepts a grouping variable `group` for a vector of measurements *x*. `group` is a categorical variable, numeric vector, character vector, string array, or cell array of character vectors the same length as *x*. Consecutive measurements *x*(*n*) sharing the same value of `group`(*n*) for $1 \leq n \leq \text{length}(x)$ are defined to be a subgroup. Subgroups can have different numbers of observations.

`controlchart(X,group)` accepts a grouping variable `group` for a matrix of measurements in *X*. In this case, `group` is only used to label the time axis; it does not change the default grouping by rows.

`[stats,plotdata] = controlchart(x,[group])` returns a structure `stats` of subgroup statistics and parameter estimates, and a structure `plotdata` of plotted values. `plotdata` contains one record for each chart.

The fields in `stats` and `plotdata` depend on the chart type.

The fields in `stats` are selected from the following:

- `mean` — Subgroup means
- `std` — Subgroup standard deviations
- `range` — Subgroup ranges
- `n` — Subgroup size, or total inspection size or area
- `i` — Individual data values
- `ma` — Moving averages
- `mr` — Moving ranges
- `count` — Count of defects or defective items
- `mu` — Estimated process mean
- `sigma` — Estimated process standard deviation
- `p` — Estimated proportion defective
- `m` — Estimated mean defects per unit

The fields in `plotdata` are the following:

- `pts` — Plotted point values
- `cl` — Center line
- `lcl` — Lower control limit
- `ucl` — Upper control limit
- `se` — Standard error of plotted point
- `n` — Subgroup size
- `ooc` — Logical that is true for points that are out of control

`controlchart(x,group,'name',value)` specifies one or more of the following optional parameter name/value pairs, with *name* in single quotes:

- `charttype` — The name of a chart type chosen from among the following:

- 'xbar' — Xbar or mean
- 's' — Standard deviation
- 'r' — Range
- 'ewma' — Exponentially weighted moving average
- 'i' — Individual observation
- 'mr' — Moving range of individual observations
- 'ma' — Moving average of individual observations
- 'p' — Proportion defective
- 'np' — Number of defectives
- 'u' — Defects per unit
- 'c' — Count of defects

Alternatively, a parameter can be a string array or cell array listing multiple compatible chart types. There are four sets of compatible types:

- 'xbar', 's', 'r', and 'ewma'
 - 'i', 'mr', and 'ma'
 - 'p' and 'np'
 - 'u' and 'c'
- **display** — Either 'on' (default) to display the control chart, or 'off' to omit the display
 - **label** — A character vector, string array, or cell array of character vectors, one per subgroup. This label is displayed as part of the data cursor for a point on the plot.
 - **lambda** — A parameter between 0 and 1 controlling how much the current prediction is influenced by past observations in an EWMA plot. Higher values of 'lambda' give less weight to past observations and more weight to the current observation. The default is 0.4.
 - **limits** — A three-element vector specifying the values of the lower control limit, center line, and upper control limits. Default is to estimate the center line and to compute control limits based on the estimated value of sigma. Not permitted if there are multiple chart types.
 - **mean** — Value for the process mean, or an empty value (default) to estimate the mean from X. This is the μ parameter for \bar{p} and \bar{np} charts, the mean defects per unit for \bar{u} and \bar{c} charts, and the normal μ parameter for other charts.

- `nsigma` — The number of sigma multiples from the center line to a control limit. Default is 3.
- `parent` — The handle of the axes to receive the control chart plot. Default is to create axes in a new figure. Not permitted if there are multiple chart types.
- `rules` — The name of a control rule, or a string array or cell array containing multiple control rule names. These rules, together with the control limits, determine if a point is marked as out of control. The default is to apply no control rules, and to use only the control limits to decide if a point is out of control. See `controlrules` for more information. Control rules are applied to charts that measure the process level (`xbar`, `i`, `c`, `u`, `p`, and `np`) rather than the variability (`r`, `s`), and they are not applied to charts based on moving statistics (`ma`, `mr`, `ewma`).
- `sigma` — Either a value for sigma, or a method of estimating sigma chosen from among `'std'` (the default) to use the average within-subgroup standard deviation, `'range'` to use the average subgroup range, and `'variance'` to use the square root of the pooled variance. When creating `i`, `mr`, or `ma` charts for data not in subgroups, the estimate is always based on a moving range.
- `specs` — A vector specifying specification limits. Typically this is a two-element vector of lower and upper specification limits. Since specification limits typically apply to individual measurements, this parameter is primarily suitable for `i` charts. These limits are not plotted on `r`, `s`, or `mr` charts.
- `unit` — The total number of inspected items for `p` and `np` charts, and the size of the inspected unit for `u` and `c` charts. In both cases `X` must be the count of the number of defects or defectives found. Default is 1 for `u` and `c` charts. This argument is required (no default) for `p` and `np` charts.
- `width` — The width of the window used for computing the moving ranges and averages in `mr` and `ma` charts, and for computing the sigma estimate in `i`, `mr`, and `ma` charts. Default is 5.

Examples

XBar and R Charts

Load the sample data.

```
load parts
```

Create `xbar` and `r` control charts for the data.

```
st = controlchart(runout, 'charttype', {'xbar' 'r'});
```

Display the process mean and standard deviation.

```
fprintf('Parameter estimates: mu = %g, sigma = %g\n',st.mu,st.sigma);
```

```
Parameter estimates: mu = -0.0863889, sigma = 0.130215
```

controlrules

Topics

"Grouping Variables" on page 2-57

Introduced in R2006b

controlrules

Western Electric and Nelson control rules

Syntax

```
R = controlrules('rules',x,cl,se)
[R,RULES] = controlrules('rules',x,cl,se)
```

Description

`R = controlrules('rules',x,cl,se)` determines which points in the vector `x` violate the control rules in `rules`. `cl` is a vector of center-line values. `se` is a vector of standard errors. (Typically, control limits on a control chart are at the values `cl - 3*se` and `cl + 3*se`.) `rules` is the name of a control rule, or a string array or cell array containing multiple control rule names. If `x` has n values and `rules` contains m rules, then `R` is an n -by- m logical array, with `R(i, j)` assigned the value 1 if point `i` violates rule `j`, 0 if it does not.

The following are accepted values for `rules` (specified inside single quotes):

- `we1` — 1 point above `cl + 3*se`
- `we2` — 2 of 3 above `cl + 2*se`
- `we3` — 4 of 5 above `cl + se`
- `we4` — 8 of 8 above `cl`
- `we5` — 1 below `cl - 3*se`
- `we6` — 2 of 3 below `cl - 2*se`
- `we7` — 4 of 5 below `cl - se`
- `we8` — 8 of 8 below `cl`
- `we9` — 15 of 15 between `cl - se` and `cl + se`
- `we10` — 8 of 8 below `cl - se` or above `cl + se`
- `n1` — 1 point below `cl - 3*se` or above `cl + 3*se`

- n2 — 9 of 9 on the same side of cl
- n3 — 6 of 6 increasing or decreasing
- n4 — 14 alternating up/down
- n5 — 2 of 3 below $cl - 2*se$ or above $cl + 2*se$, same side
- n6 — 4 of 5 below $cl - se$ or above $cl + se$, same side
- n7 — 15 of 15 between $cl - se$ and $cl + se$
- n8 — 8 of 8 below $cl - se$ or above $cl + se$, either side
- we — All Western Electric rules
- n — All Nelson rules

For multi-point rules, a rule violation at point i indicates that the set of points ending at point i triggered the rule. Point i is considered to have violated the rule only if it is one of the points violating the rule's condition.

Any points with NaN as their x , cl , or se values are not considered to have violated rules, and are not counted in the rules for other points.

Control rules can be specified in the `controlchart` function as values for the 'rules' parameter.

`[R,RULES] = controlrules('rules',x,cl,se)` returns a cell array of text RULES listing the rules applied.

Examples

Use Western Electric Control Rule

Load the sample data.

```
load parts;
```

Create an Xbar chart using the we2 rule to mark out of control measurements.

```
st = controlchart(runout,'rules','we2');
x = st.mean;
cl = st.mu;
se = st.sigma./sqrt(st.n);
```

```
hold on
plot(cl+2*se, 'm')
```

You can see the out of control points marked with a red circle.

Use `controlrules` to identify the measurements that violate the control rule.

```
R = controlrules('we2',x,cl,se);
I = find(R)
```

```
I = 6×1
```

```

Introduced in R2006b

cophenet

Cophenetic correlation coefficient

Syntax

```
c = cophenet(Z,Y)
[c,d] = cophenet(Z,Y)
```

Description

`c = cophenet(Z,Y)` computes the cophenetic correlation coefficient for the hierarchical cluster tree represented by `Z`. `Z` is the output of the `linkage` function. `Y` contains the distances or dissimilarities used to construct `Z`, as output by the `pdist` function. `Z` is a matrix of size $(m-1)$ -by-3, with distance information in the third column. `Y` is a vector of size $m*(m-1)/2$.

`[c,d] = cophenet(Z,Y)` returns the cophenetic distances `d` in the same lower triangular distance vector format as `Y`.

The cophenetic correlation for a cluster tree is defined as the linear correlation coefficient between the cophenetic distances obtained from the tree, and the original distances (or dissimilarities) used to construct the tree. Thus, it is a measure of how faithfully the tree represents the dissimilarities among observations.

The cophenetic distance between two observations is represented in a dendrogram by the height of the link at which those two observations are first joined. That height is the distance between the two subclusters that are merged by that link.

The output value, `c`, is the cophenetic correlation coefficient. The magnitude of this value should be very close to 1 for a high-quality solution. This measure can be used to compare alternative cluster solutions obtained using different algorithms.

The cophenetic correlation between `Z(:,3)` and `Y` is defined as

$$c = \frac{\sum_{i<j} (Y_{ij} - y)(Z_{ij} - z)}{\sqrt{\sum_{i<j} (Y_{ij} - y)^2 \sum_{i<j} (Z_{ij} - z)^2}}$$

where:

- Y_{ij} is the distance between objects i and j in Y .
- Z_{ij} is the cophenetic distance between objects i and j , from $Z(:,3)$.
- y and z are the average of Y and $Z(:,3)$, respectively.

Examples

```
X = [rand(10,3); rand(10,3)+1; rand(10,3)+2];
Y = pdist(X);
Z = linkage(Y,'average');

% Compute Spearman's rank correlation between the
% dissimilarities and the cophenetic distances
[c,D] = cophenet(Z,Y);
r = corr(Y',D','type','spearman')
r =
    0.8279
```

Introduced before R2006a

copulacdf

Copula cumulative distribution function

Syntax

```
y = copulacdf('Gaussian',u,rho)
```

```
y = copulacdf('t',u,rho,nu)
```

```
y = copulacdf(family,u,alpha)
```

Description

`y = copulacdf('Gaussian',u,rho)` returns the cumulative probability of the Gaussian copula, with linear correlation parameters `rho` evaluated at the points in `u`.

`y = copulacdf('t',u,rho,nu)` returns the cumulative probability of the *t* copula, with linear correlation parameters, `rho`, and degrees of freedom parameter `nu` evaluated at the points in `u`.

`y = copulacdf(family,u,alpha)` returns the cumulative probability of the bivariate Archimedean copula of the type specified by `family`, with scalar parameter `alpha` evaluated at the points in `u`.

Examples

Compute the Clayton Copula cdf

Define two 10-by-10 matrices containing the values at which to compute the cdf.

```
u = linspace(0,1,10);  
[u1,u2] = meshgrid(u,u);
```

Compute the cdf of a Clayton copula that has an alpha parameter equal to 1, at the values in `u`.

```
y = copulacdf('Clayton',[u1(:),u2(:)],1);
```

Plot the cdf as a surface, and label the axes.

```
surf(u1,u2,reshape(y,10,10))  
xlabel('u1')  
ylabel('u2')
```

- "Generate Correlated Data Using Rank Correlation" on page 5-141

Input Arguments

u — Values at which to evaluate cdf

matrix of scalar values in the range [0,1]

Values at which to evaluate the cdf, specified as a matrix of scalar values in the range [0,1]. If *u* is an *n*-by-*p* matrix, then its values represent *n* points in the *p*-dimensional unit hypercube. If *u* is an *n*-by-2 matrix, then its values represent *n* points in the unit square.

If you specify a bivariate Archimedean copula type ('Clayton', 'Frank', or 'Gumbel'), then *u* must be an *n*-by-2 matrix.

Data Types: single | double

rho — Linear correlation parameters

scalar values | matrix of scalar values

Linear correlation parameters for the copula, specified as a scalar value or matrix of scalar values.

- If *u* is an *n*-by-*p* matrix, then *rho* is a *p*-by-*p* correlation matrix.
- If *u* is an *n*-by-2 matrix, then *rho* can be a scalar correlation coefficient.

Data Types: single | double

nu — Degrees of freedom

positive integer value

Degrees of freedom for the *t* copula, specified as a positive integer value.

Data Types: single | double

family — Bivariate Archimedean copula family

'Clayton' | 'Frank' | 'Gumbel'

Bivariate Archimedean copula family, specified as one of the following.

| | |
|-----------|----------------|
| 'Clayton' | Clayton copula |
| 'Frank' | Frank copula |
| 'Gumbel' | Gumbel copula |

alpha — Bivariate Archimedean copula parameter

scalar value

Bivariate Archimedean copula parameter, specified as a scalar value. Permitted values for alpha depend on the specified copula family.

| Copula Family | Permitted Alpha Values |
|---------------|------------------------|
| 'Clayton' | $[0, \infty)$ |
| 'Frank' | $(-\infty, \infty)$ |
| 'Gumbel' | $[1, \infty)$ |

Data Types: single | double

Output Arguments**y — Cumulative distribution function**

vector of scalar values

Cumulative distribution function of the copula, evaluated at the points in `u`, returned as a vector of scalar values.

Topics

“Generate Correlated Data Using Rank Correlation” on page 5-141

“Copulas: Generate Correlated Samples” on page 5-161

Introduced in R2006a

copulafit

Fit copula to data

Syntax

```
rhohat = copulafit('Gaussian',u)

[rhohat,nuhat] = copulafit('t',u)
[rhohat,nuhat,nuci] = copulafit('t',u)

paramhat = copulafit(family,u)
[paramhat,paramci] = copulafit(family,u)

___ = copulafit( ___,Name,Value)
```

Description

`rhohat = copulafit('Gaussian',u)` returns an estimate, `rhohat`, of the matrix of linear correlation parameters for a Gaussian copula, given the data in `u`.

`[rhohat,nuhat] = copulafit('t',u)` returns an estimate, `rhohat`, of the matrix of linear correlation parameters for a t copula, and an estimate of the degrees of freedom parameter, `nuhat`, given the data in `u`.

`[rhohat,nuhat,nuci] = copulafit('t',u)` also returns an approximate 95% confidence interval, `nuci`, for the degrees of freedom estimated in `nuhat`.

`paramhat = copulafit(family,u)` returns an estimate, `paramhat`, of the copula parameter for a bivariate Archimedean copula of the type specified by `family`, given the data in `u`.

`[paramhat,paramci] = copulafit(family,u)` also returns an approximate 95% confidence interval, `paramci`, for the copula parameter estimated in `paramhat`.

`___ = copulafit(___,Name,Value)` returns any of the previous syntaxes, with additional options specified by one or more `Name, Value` pair arguments. For example,

you can specify the confidence interval to compute, or specify control parameters for the iterative parameter estimation algorithm using a options structure.

Examples

Fit a t Copula to Data

Load and plot simulated stock return data.

```
load stockreturns
x = stocks(:,1);
y = stocks(:,2);

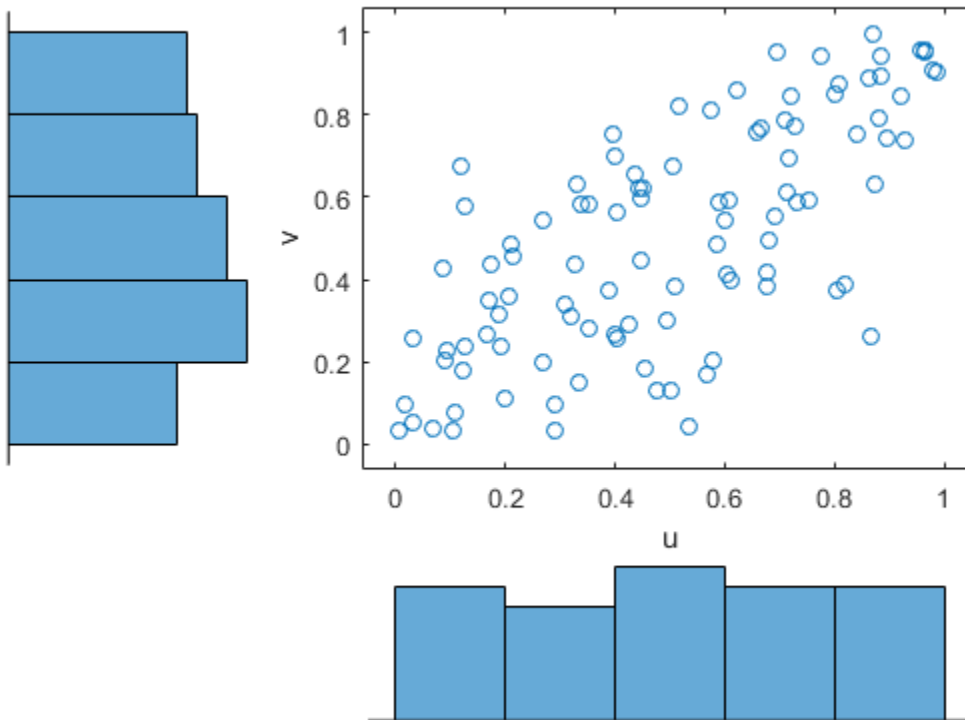

figure;
scatterhist(x,y)
```

Transform the data to the copula scale (unit square) using a kernel estimator of the cumulative distribution function.

```
u = ksdensity(x,x,'function','cdf');
v = ksdensity(y,y,'function','cdf');
```

```
figure;
scatterhist(u,v)
xlabel('u')
ylabel('v')
```

Fit a t copula to the data.

```
rng default % For reproducibility
[Rho,nu] = copulafit('t',[u v],'Method','ApproximateML')
```

Rho =

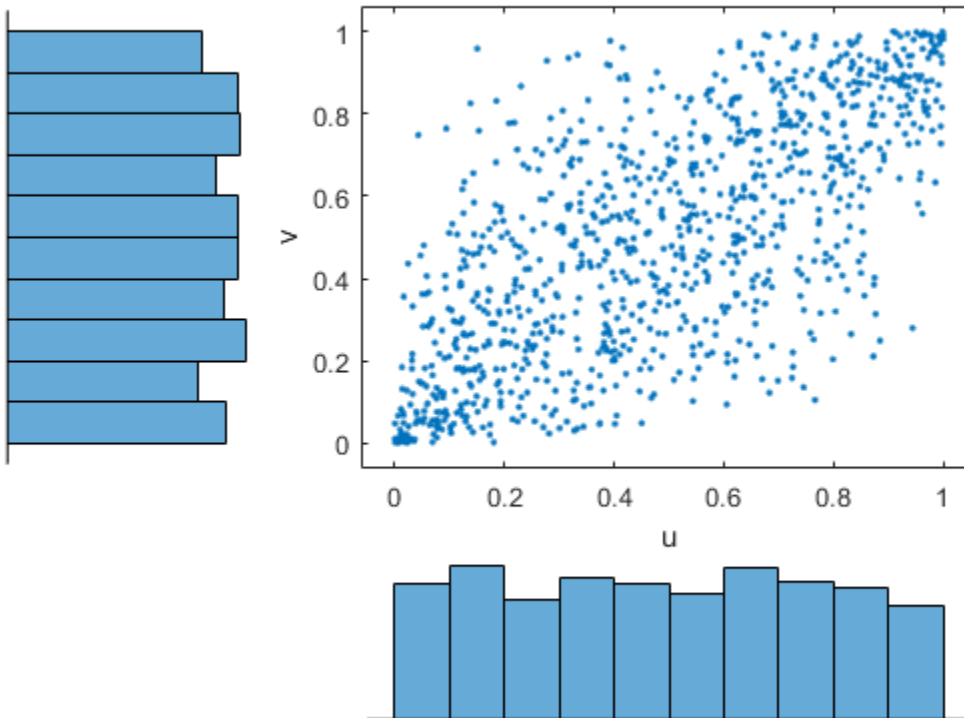

```
1.0000    0.7220
0.7220    1.0000
```

nu =

2.6133e+06

Generate a random sample from the t copula.

```
r = copularnd('t',Rho,nu,1000);  
u1 = r(:,1);  
v1 = r(:,2);  
  
figure;  
scatterhist(u1,v1)  
xlabel('u')  
ylabel('v')  
set(get(gca,'children'),'marker','.')
```

Transform the random sample back to the original scale of the data.

```
x1 = ksdensity(x,u1,'function','icdf');  
y1 = ksdensity(y,v1,'function','icdf');  
  
figure;  
scatterhist(x1,y1)  
set(get(gca,'children'),'marker','.')
```

- “Generate Correlated Data Using Rank Correlation” on page 5-141

Input Arguments

u — Copula values

matrix of scalar values in the range (0,1)

Copula values, specified as a matrix of scalar values in the range (0,1). If **u** is an n -by- p matrix, then its values represent n points in the p -dimensional unit hypercube. If **u** is an n -by-2 matrix, then its values represent n points in the unit square.

If you specify a bivariate Archimedean copula type ('Clayton', 'Frank', or 'Gumbel'), then **u** must be an n -by-2 matrix.

Data Types: `single` | `double`

family — Bivariate Archimedean copula family

'Clayton' | 'Frank' | 'Gumbel'

Bivariate Archimedean copula family, specified as one of the following.

| | |
|-----------|----------------|
| 'Clayton' | Clayton copula |
| 'Frank' | Frank copula |
| 'Gumbel' | Gumbel copula |

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: 'Alpha',0.01,'Method','ApproximateML' computes 99% confidence intervals for the estimated copula parameter and uses an approximation method to fit the copula.

Alpha — Significance level for confidence intervals

0.05 (default) | scalar value in the range (0,1)

Significance level for confidence intervals, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1). `copulafit` returns approximate $100 \times (1-\text{Alpha})\%$ confidence intervals.

Example: 'Alpha',0.01

Data Types: single | double

Method — Method for fitting t copula

'ML' (default) | 'ApproximateML'

Method for fitting t copula, specified as the comma-separated pair consisting of 'Method' and either 'ML' or 'ApproximateML'.

If you specify 'ApproximateML', then `copulafit` fits a t copula for large samples by maximizing an objective function that approximates the profile log likelihood for the degrees of freedom parameter [1]. This method can be significantly faster than maximum likelihood ('ML'), but the estimates and confidence limits may not be accurate for small to moderate sample sizes.

Example: 'Method', 'ApproximateML'

Options — Control parameter specifications

structure

Control parameter specifications, specified as the comma-separated pair consisting of 'Options' and an options structure created by `statset`. To see the fields and default values used by `copulafit`, type `statset('copulafit')` at the command prompt.

This name-value pair is not applicable when you specify the copula type as 'Gaussian'.

Data Types: struct

Output Arguments

rhohat — Estimated correlation parameters for the fitted Gaussian copula

matrix of scalar values

Estimated correlation parameters for the fitted Gaussian copula, given the data in `u`, returned as a matrix of scalar values.

nuhat — Estimated degrees of freedom parameter for the fitted t copula

scalar value

Estimated degrees of freedom parameter for the fitted t copula, returned as a scalar value.

nuci — Approximate confidence interval for the degrees of freedom parameter

1-by-2 matrix of scalar values

Approximate confidence interval for the degrees of freedom parameter, returned as a 1-by-2 matrix of scalar values. The first column contains the lower boundary, and the second column contains the upper boundary. By default, `copulafit` returns the approximate 95% confidence interval. You can specify a different confidence interval using the 'Alpha' name-value pair.

paramhat — Estimated copula parameter for the fitted Archimedean copula

scalar value

Estimated copula parameter for the fitted Archimedean copula, returned as a scalar value.

paramci — Approximate confidence interval for the copula parameter

1-by-2 matrix of scalar values

Approximate confidence interval for the copula parameter, returned as a 1-by-2 matrix of scalar values. The first column contains the lower boundary, and the second column contains the upper boundary. By default, `copulafit` returns the approximate 95% confidence interval. You can specify a different confidence interval using the 'Alpha' name-value pair.

Algorithms

By default, `copulafit` uses maximum likelihood to fit a copula to `u`. When `u` contains data transformed to the unit hypercube by parametric estimates of their marginal cumulative distribution functions, this is known as the *Inference Functions for Margins (IFM)* method. When `u` contains data transformed by the empirical cdf (see `ecdf`), this is known as *Canonical Maximum Likelihood (CML)*.

Introduced in R2007b

copulaparam

Copula parameters as function of rank correlation

Syntax

```
rho = copulaparam('Gaussian', r)
```

```
rho = copulaparam('t', r, nu)
```

```
alpha = copulaparam(family, r)
```

```
___ = copulaparam( ___, Name, Value)
```

Description

`rho = copulaparam('Gaussian', r)` returns the linear correlation parameters, `rho`, that correspond to a Gaussian copula with Kendall's rank correlation, `r`.

`rho = copulaparam('t', r, nu)` returns the linear correlation parameters, `rho`, that correspond to a *t* copula with Kendall's rank correlation, `r`, and degrees of freedom, `nu`.

`alpha = copulaparam(family, r)` returns the copula parameter, `alpha`, that corresponds to a bivariate Archimedean copula of the type specified by `family`, with Kendall's rank correlation, `r`.

`___ = copulaparam(___, Name, Value)` returns the correlation parameter using any of the previous syntaxes, with additional options specified by one or more `Name, Value` pair arguments. For example, you can specify whether the input rank correlation value is Spearman's *rho* or Kendall's *tau*.

Examples

Generate Correlated Data Using the Inverse cdf

Generate correlated random data from a beta distribution using a bivariate Gaussian copula with Kendall's *tau* rank correlation equal to -0.5.

Compute the linear correlation parameter from the rank correlation value.

```
rng default % For reproducibility
tau = -0.5;
rho = copulaparam('Gaussian',tau)

rho = -0.7071
```

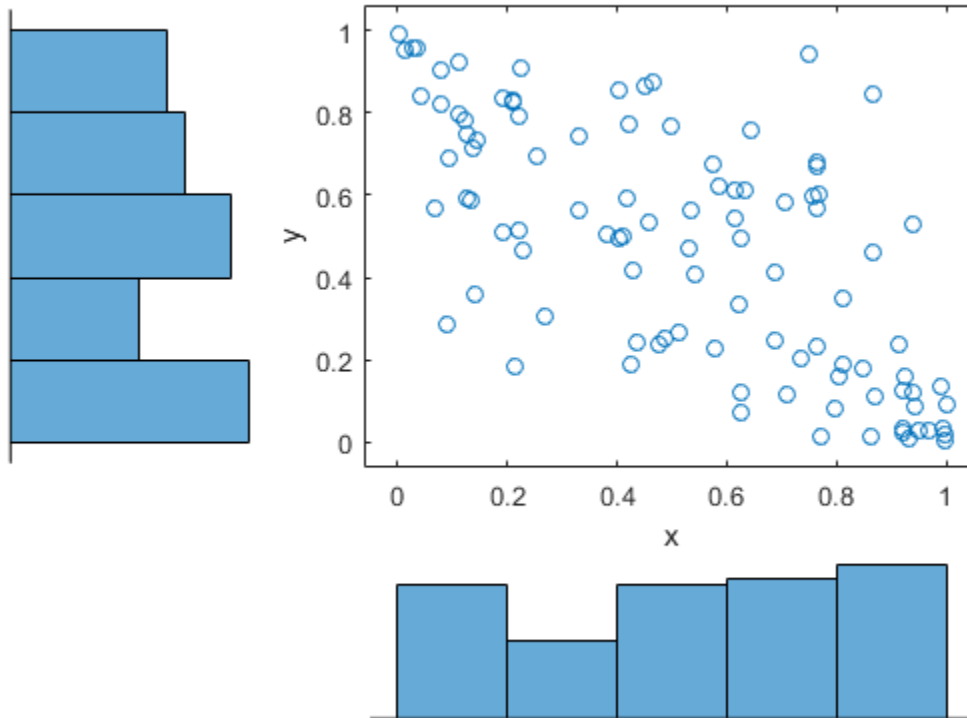

Use a Gaussian copula to generate a two-column matrix of dependent random values.

```
u = copularnd('gaussian',rho,100);
```

Each column contains 100 random values between 0 and 1, inclusive, sampled from a continuous uniform distribution.

Create a `scatterhist` plot to visualize the random numbers generated using the copula.

```
figure
scatterhist(u(:,1),u(:,2))
```

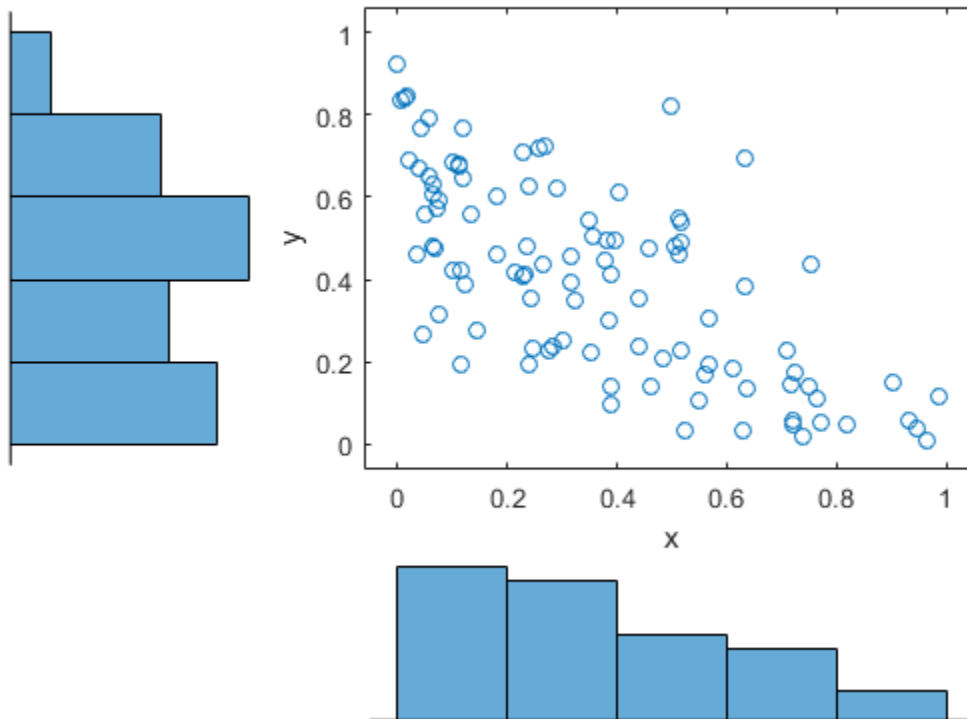

The histograms show that the data in each column of the copula has a marginal uniform distribution. The scatterplot shows that the data in the two columns is negatively correlated.

Use the inverse cdf function `betainv` to transform each column of the uniform marginal distributions into random numbers from a beta distribution. In the first column, the first shape parameter A is equal to 1, and a second shape parameter B is equal to 2. In the second column, the first shape parameter A is equal to 1.5, and a second shape parameter B is equal to 2.

```
b = [betainv(u(:,1),1,2), betainv(u(:,2),1.5,2)];
```

Create a scatterhist plot to visualize the correlated beta distribution data.

```
figure
scatterhist(b(:,1),b(:,2))
```

The histograms show the marginal beta distributions for each variable. The scatterplot shows the negative correlation.

Verify that the sample has a rank correlation approximately equal to the initial value for Kendall's τ .

```
tau_sample = corr(b, 'type', 'kendall')
```

```
tau_sample = 2x2
```

```
1.0000    -0.5135
```

-0.5135 1.0000

The sample rank correlation of -0.5135 is approximately equal to the -0.5 initial value for *tau*.

- “Generate Correlated Data Using Rank Correlation” on page 5-141

Input Arguments

r — Copula rank correlation

scalar value | matrix of scalar values

Copula rank correlation, returned as a scalar value or matrix of scalar values.

- If *r* is a scalar correlation coefficient, then *rho* is a scalar correlation coefficient corresponding to a bivariate copula.
- If *r* is a *p*-by-*p* correlation matrix, then *rho* is a *p*-by-*p* correlation matrix.

If the copula is specified as one of the bivariate Archimedean copula types ('Clayton', 'Frank', or 'Gumbel'), then *r* is a scalar value.

nu — Degrees of freedom

positive integer value

Degrees of freedom for the *t* copula, specified as a positive integer value.

Data Types: single | double

family — Bivariate Archimedean copula family

'Clayton' | 'Frank' | 'Gumbel'

Bivariate Archimedean copula family, specified as one of the following.

| | |
|-----------|----------------|
| 'Clayton' | Clayton copula |
| 'Frank' | Frank copula |
| 'Gumbel' | Gumbel copula |

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: 'type', 'Spearman' computes Spearman's rank correlation.

type — Type of rank correlation

'Kendall' (default) | 'Spearman'

Type of rank correlation, specified as the comma-separated pair consisting of 'type' and one of the following.

- 'Kendall' — Indicates that the input value for r is a Kendall's τ correlation value
- 'Spearman' — Indicates that the input value for r is a Spearman's ρ rank correlation value

copulaparam uses an approximation to Spearman's rank correlation for copula families that do not have an existing analytic formula. The approximation is based on a smooth fit to values computed at discrete values of the copula parameters. For a t copula, the approximation is accurate for degrees of freedom larger than 0.05.

Example: 'type', 'Spearman'

Output Arguments

rho — Linear correlation parameter

scalar value | matrix of scalar values

Linear correlation parameter, returned as a scalar value or matrix of scalar values.

- If r is a scalar correlation coefficient, then ρ is a scalar correlation coefficient corresponding to a bivariate copula.
- If r is a p -by- p correlation matrix, then ρ is a p -by- p correlation matrix.

alpha — Bivariate Archimedian copula parameter

scalar value

Bivariate Archimedean copula parameter, returned as a scalar value. Permitted values for alpha depend on the specified copula family.

| Copula Family | Permitted Alpha Values |
|---------------|------------------------|
| 'Clayton' | $[0, \infty)$ |
| 'Frank' | $(-\infty, \infty)$ |
| 'Gumbel' | $[1, \infty)$ |

Data Types: single | double

Topics

“Generate Correlated Data Using Rank Correlation” on page 5-141

“Copulas: Generate Correlated Samples” on page 5-161

Introduced in R2006a

copulapdf

Copula probability density function

Syntax

```
y = copulapdf('Gaussian',u,rho)
```

```
y = copulapdf('t',u,rho,nu)
```

```
y = copulapdf(family,u,alpha)
```

Description

`y = copulapdf('Gaussian',u,rho)` returns the probability density of the Gaussian copula with linear correlation parameters, `rho`, evaluated at the points in `u`.

`y = copulapdf('t',u,rho,nu)` returns the probability density of the t copula with linear correlation parameters, `rho`, and degrees of freedom parameter, `nu`, evaluated at the points in `u`.

`y = copulapdf(family,u,alpha)` returns the probability density of the bivariate Archimedean copula of the type specified by `family`, with scalar parameter, `alpha`, evaluated at the points in `u`.

Examples

Compute the Clayton Copula pdf

Define two 10-by-10 matrices containing the values at which to compute the pdf.

```
u = linspace(0,1,10);  
[u1,u2] = meshgrid(u,u);
```

Compute the pdf of a Clayton copula that has an alpha parameter equal to 1, at the values in `u`.

```
y = copulapdf('Clayton',[u1(:),u2(:)],1);
```

Plot the pdf as a surface, and label the axes.

```
surf(u1,u2,reshape(y,10,10))  
xlabel('u1')  
ylabel('u2')
```

- “Generate Correlated Data Using Rank Correlation” on page 5-141

Input Arguments

u — Values at which to evaluate pdf

matrix of scalar values in the range [0,1]

Values at which to evaluate the pdf, specified as a matrix of scalar values in the range [0,1]. If *u* is an *n*-by-*p* matrix, then its values represent *n* points in the *p*-dimensional unit hypercube. If *u* is an *n*-by-2 matrix, then its values represent *n* points in the unit square.

If you specify a bivariate Archimedean copula type ('Clayton', 'Frank', or 'Gumbel'), then *u* must be an *n*-by-2 matrix.

Data Types: single | double

rho — Linear correlation parameters

scalar values | matrix of scalar values

Linear correlation parameters for the copula, specified as a scalar value or matrix of scalar values.

- If *u* is an *n*-by-*p* matrix, then *rho* is a *p*-by-*p* correlation matrix.
- If *u* is an *n*-by-2 matrix, then *rho* can be a scalar correlation coefficient.

Data Types: single | double

nu — Degrees of freedom

positive integer value

Degrees of freedom for the *t* copula, specified as a positive integer value.

Data Types: single | double

family — Bivariate Archimedean copula family

'Clayton' | 'Frank' | 'Gumbel'

Bivariate Archimedean copula family, specified as one of the following.

| | |
|-----------|----------------|
| 'Clayton' | Clayton copula |
| 'Frank' | Frank copula |
| 'Gumbel' | Gumbel copula |

alpha — Bivariate Archimedean copula parameter

scalar value

Bivariate Archimedean copula parameter, specified as a scalar value. Permitted values for alpha depend on the specified copula family.

| Copula Family | Permitted Alpha Values |
|---------------|------------------------|
| 'Clayton' | $[0, \infty)$ |
| 'Frank' | $(-\infty, \infty)$ |
| 'Gumbel' | $[1, \infty)$ |

Data Types: single | double

Output Arguments

y — Probability density function

vector of scalar values

Probability density function, evaluated at the values in `u`, returned as a vector of scalar values.

copulastat

Copula rank correlation

Syntax

```
r = copulastat('Gaussian', rho)
```

```
r = copulastat('t', rho, nu)
```

```
r = copulastat(family, alpha)
```

```
r = copulstat( ____, Name, Value)
```

Description

`r = copulastat('Gaussian', rho)` returns the Kendall's rank correlation, r , that corresponds to a Gaussian copula with linear correlation parameters ρ .

`r = copulastat('t', rho, nu)` returns the Kendall's rank correlation, r , that corresponds to a t copula with linear correlation parameters, ρ , and degrees of freedom parameter, ν .

`r = copulastat(family, alpha)` returns the Kendall's rank correlation, r , that corresponds to a bivariate Archimedean copula that has the type specified by `family` and scalar parameter `alpha`.

`r = copulstat(____, Name, Value)` returns the copula rank correlation with additional options specified by one or more `Name, Value` pair arguments, using any of the previous syntaxes. For example, you can return Spearman's ρ rank correlation.

Examples

Compute the Gaussian Copula Rank Correlation

Compute the rank correlation for a Gaussian copula with the specified linear correlation parameter `rho`.

```
rho = -.7071;  
tau = copulastat('gaussian',rho)
```

```
tau = -0.5000
```

Use the copula to generate dependent random values from a beta distribution that has parameters `a` and `b` equal to 2.

```
rng default % For reproducibility  
u = copularnd('gaussian',rho,100);  
b = betainv(u,2,2);
```

Verify that the sample has a rank correlation approximately equal to `tau`.

```
tau_sample = corr(b,'type','k')
```

```
tau_sample = 2×2
```

```
    1.0000    -0.5135  
   -0.5135    1.0000
```

- “Generate Correlated Data Using Rank Correlation” on page 5-141

Input Arguments

`rho` — Linear correlation parameters

scalar values | matrix of scalar values

Linear correlation parameters for the copula, specified as a scalar value or matrix of scalar values.

- If `rho` is a scalar correlation coefficient, then `r` is a scalar correlation coefficient corresponding to a bivariate copula.
- If `rho` is a p -by- p correlation matrix, then `r` is a p -by- p correlation matrix.

Data Types: `single` | `double`

nu — Degrees of freedom

positive integer value

Degrees of freedom for the t copula, specified as a positive integer value.

Data Types: single | double

family — Bivariate Archimedean copula family

'Clayton' | 'Frank' | 'Gumbel'

Bivariate Archimedean copula family, specified as one of the following.

| | |
|-----------|----------------|
| 'Clayton' | Clayton copula |
| 'Frank' | Frank copula |
| 'Gumbel' | Gumbel copula |

alpha — Bivariate Archimedean copula parameter

scalar value

Bivariate Archimedean copula parameter, specified as a scalar value. Permitted values for alpha depend on the specified copula family.

| Copula Family | Permitted Alpha Values |
|---------------|------------------------|
| 'Clayton' | $[0, \infty)$ |
| 'Frank' | $(-\infty, \infty)$ |
| 'Gumbel' | $[1, \infty)$ |

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'type', 'Spearman' computes Spearman's rank correlation.

type — Type of rank correlation

'Kendall' (default) | 'Spearman'

Type of rank correlation, specified as the comma-separated pair consisting of 'type' and one of the following.

- 'Kendall' — Compute Kendall's *tau*.
- 'Spearman' — Compute Spearman's *rho* (rank correlation).

`copulastat` uses an approximation to Spearman's rank correlation for copula families that do not have an existing analytic formula. The approximation is based on a smooth fit to values computed at discrete values of the copula parameters. For a *t* copula, the approximation is accurate for degrees of freedom larger than 0.05.

Example: 'type', 'Spearman'

Output Arguments

r — Copula rank correlation

scalar value | matrix of scalar values

Copula rank correlation, returned as a scalar value or matrix of scalar values.

- If *rho* is a scalar correlation coefficient, then *r* is a scalar correlation coefficient corresponding to a bivariate copula.
- If *rho* is a *p*-by-*p* correlation matrix, then *r* is a *p*-by-*p* correlation matrix.

Topics

"Generate Correlated Data Using Rank Correlation" on page 5-141

"Copulas: Generate Correlated Samples" on page 5-161

Introduced in R2006a

copularnd

Copula random numbers

Syntax

```
u = copularnd('Gaussian',rho,n)
```

```
u = copularnd('t',rho,nu,n)
```

```
u = copularnd(family,alpha,n)
```

Description

`u = copularnd('Gaussian',rho,n)` returns n random vectors generated from a Gaussian copula with linear correlation parameters ρ .

`u = copularnd('t',rho,nu,n)` returns n random vectors generated from a t copula with linear correlation parameters ρ and degrees of freedom ν .

`u = copularnd(family,alpha,n)` returns n random vectors generated from a bivariate Archimedean copula that has the type specified by `family` and the scalar parameter α .

Examples

Generate Correlated Data Using the Inverse cdf

Generate correlated random data from a beta distribution using a bivariate Gaussian copula with Kendall's τ rank correlation equal to -0.5.

Compute the linear correlation parameter from the rank correlation value.

```
rng default % For reproducibility
tau = -0.5;
rho = copulaparam('Gaussian',tau)
```

```
rho = -0.7071
```

Use a Gaussian copula to generate a two-column matrix of dependent random values.

```
u = copularnd('gaussian',rho,100);
```

Each column contains 100 random values between 0 and 1, inclusive, sampled from a continuous uniform distribution.

Create a scatterhist plot to visualize the random numbers generated using the copula.

```
figure  
scatterhist(u(:,1),u(:,2))
```

The histograms show that the data in each column of the copula has a marginal uniform distribution. The scatterplot shows that the data in the two columns is negatively correlated.

Use the inverse cdf function `betainv` to transform each column of the uniform marginal distributions into random numbers from a beta distribution. In the first column, the first shape parameter A is equal to 1, and a second shape parameter B is equal to 2. In the second column, the first shape parameter A is equal to 1.5, and a second shape parameter B is equal to 2.

```
b = [betainv(u(:,1),1,2), betainv(u(:,2),1.5,2)];
```

Create a `scatterhist` plot to visualize the correlated beta distribution data.

```
figure  
scatterhist(b(:,1),b(:,2))
```

The histograms show the marginal beta distributions for each variable. The scatterplot shows the negative correlation.

Verify that the sample has a rank correlation approximately equal to the initial value for Kendall's *tau*.

```
tau_sample = corr(b, 'type', 'kendall')
```

```
tau_sample = 2x2
```

```
    1.0000    -0.5135  
   -0.5135     1.0000
```

The sample rank correlation of -0.5135 is approximately equal to the -0.5 initial value for τ .

- “Generate Correlated Data Using Rank Correlation” on page 5-141

Input Arguments

rho — Linear correlation parameters

scalar values | matrix of scalar values

Linear correlation parameters for the copula, specified as a scalar value or matrix of scalar values.

- If ρ is a p -by- p correlation matrix, then the output argument u is an n -by- p matrix.
- If ρ is a scalar correlation coefficient, then the output argument u is an n -by-2 matrix.

Data Types: single | double

n — Number of random vectors to return

positive scalar value

Number of random vectors to return, specified as a positive scalar value.

- If you specify the copula type as 'Gaussian' or 't', and ρ is a p -by- p correlation matrix, then u is an n -by- p matrix.
- If you specify the copula type as 'Gaussian' or 't', and ρ is a scalar correlation coefficient, then u is an n -by-2 matrix.
- If you specify the copula type as 'Clayton', 'Frank', or 'Gumbel', then u is an n -by-2 matrix.

Data Types: single | double

nu — Degrees of freedom

positive integer value

Degrees of freedom for the t copula, specified as a positive integer value.

Data Types: single | double

family — Bivariate Archimedean copula family

'Clayton' | 'Frank' | 'Gumbel'

Bivariate Archimedean copula family, specified as one of the following.

| | |
|-----------|----------------|
| 'Clayton' | Clayton copula |
| 'Frank' | Frank copula |
| 'Gumbel' | Gumbel copula |

alpha — Bivariate Archimedean copula parameter

scalar value

Bivariate Archimedean copula parameter, specified as a scalar value. Permitted values for alpha depend on the specified copula family.

| Copula Family | Permitted Alpha Values |
|---------------|------------------------|
| 'Clayton' | $[0, \infty)$ |
| 'Frank' | $(-\infty, \infty)$ |
| 'Gumbel' | $[1, \infty)$ |

Data Types: single | double

Output Arguments**u — Copula random numbers**

matrix of scalar values

Copula random numbers, returned as a matrix of scalar values. Each column of u is a sample from a `Uniform(0, 1)` marginal distribution.

- If you specify the copula type as 'Gaussian' or 't', and rho is a p -by- p correlation matrix, then u is an n -by- p matrix.
- If you specify the copula type as 'Gaussian' or 't', and rho is a scalar correlation coefficient, then u is an n -by-2 matrix.
- If you specify the copula type as 'Clayton', 'Frank', or 'Gumbel', then u is an n -by-2 matrix.

Topics

“Generate Correlated Data Using Rank Correlation” on page 5-141

“Copulas: Generate Correlated Samples” on page 5-161

Introduced in R2006a

cordexch

Coordinate exchange

Syntax

```
dCE = cordexch(nfactors, nruns)
[dCE, X] = cordexch(nfactors, nruns)
[dCE, X] = cordexch(nfactors, nruns, 'model')
[dCE, X] = cordexch(..., 'name', value)
```

Description

`dCE = cordexch(nfactors, nruns)` uses a coordinate-exchange algorithm to generate a D -optimal design `dCE` with `nruns` runs (the rows of `dCE`) for a linear additive model with `nfactors` factors (the columns of `dCE`). The model includes a constant term.

`[dCE, X] = cordexch(nfactors, nruns)` also returns the associated design matrix `X`, whose columns are the model terms evaluated at each treatment (row) of `dCE`.

`[dCE, X] = cordexch(nfactors, nruns, 'model')` uses the linear regression model specified in `model`. `model` is one of the following:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

The order of the columns of `X` for a full quadratic model with n terms is:

- 1 The constant term
- 2 The linear terms in order 1, 2, ..., n
- 3 The interaction terms in order (1, 2), (1, 3), ..., (1, n), (2, 3), ..., ($n - 1$, n)
- 4 The squared terms in order 1, 2, ..., n

Other models use a subset of these terms, in the same order.

Alternatively, *model* can be a matrix specifying polynomial terms of arbitrary order. In this case, *model* should have one column for each factor and one row for each term in the model. The entries in any row of *model* are powers for the factors in the columns. For example, if a model has factors X1, X2, and X3, then a row [0 1 2] in *model* specifies the term $(X1.^0) \cdot (X2.^1) \cdot (X3.^2)$. A row of all zeros in *model* specifies a constant term, which can be omitted.

[dCE,X] = cordexch(..., 'name', value) specifies one or more optional name/value pairs for the design. Valid parameters and their values are listed in the following table. Specify *name* inside single quotes.

| name | Value |
|-------------|---|
| bounds | Lower and upper bounds for each factor, specified as a 2-by-nfactors matrix. Alternatively, this value can be a cell array containing nfactors elements, each element specifying the vector of allowable values for the corresponding factor. |
| categorical | Indices of categorical predictors. |
| display | Either 'on' or 'off' to control display of the iteration counter. The default is 'on'. |
| excludefun | Handle to a function that excludes undesirable runs. If the function is <i>f</i> , it must support the syntax $b = f(S)$, where <i>S</i> is a matrix of treatments with nfactors columns and <i>b</i> is a vector of Boolean values with the same number of rows as <i>S</i> . <i>b</i> (<i>i</i>) is true if the method should exclude <i>i</i> th row <i>S</i> . |
| init | Initial design as a nruns-by-nfactors matrix. The default is a randomly selected set of points. |
| levels | Vector of number of levels for each factor. Not used when bounds is specified as a cell array. |
| maxiter | Maximum number of iterations. The default is 10. |
| tries | Number of times to try to generate a design from a new starting point. The algorithm uses random points for each try, except possibly the first. The default is 1. |

| name | Value |
|---------|---|
| options | <p>A structure that specifies whether to run in parallel, and specifies the random stream or streams. Create the <code>options</code> structure with <code>statset</code>. Option fields:</p> <ul style="list-style-type: none"> • <code>UseParallel</code> — Set to <code>true</code> to compute in parallel. Default is <code>false</code>. • <code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code>. • <code>Streams</code> — A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code>, <code>cordexch</code> uses the default stream or streams. If you choose to specify <code>Streams</code>, use a single object except in the case <ul style="list-style-type: none"> • You have an open <code>Parallel</code> pool • <code>UseParallel</code> is <code>true</code> • <code>UseSubstreams</code> is <code>false</code> <p>In that case, use a cell array the same size as the <code>Parallel</code> pool.</p> |

Examples

Suppose you want a design to estimate the parameters in the following three-factor, seven-term interaction model:

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3 + \beta_{12} x_1 x_2 + \beta_{13} x_1 x_3 + \beta_{23} x_2 x_3 + \varepsilon$$

Use `cordexch` to generate a *D*-optimal design with seven runs:

```
nfactors = 3;
nruns = 7;
[dCE,X] = cordexch(nfactors,nruns,'interaction','tries',10)
dCE =
    -1     1     1
    -1    -1    -1
     1     1     1
```

$$X = \begin{bmatrix} -1 & 1 & -1 & & & & \\ 1 & -1 & 1 & & & & \\ 1 & -1 & -1 & & & & \\ -1 & -1 & 1 & & & & \\ 1 & -1 & 1 & 1 & -1 & -1 & 1 \\ 1 & -1 & -1 & -1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & -1 & 1 & -1 & -1 & 1 & -1 \\ 1 & 1 & -1 & 1 & -1 & 1 & -1 \\ 1 & 1 & -1 & -1 & -1 & -1 & 1 \\ 1 & -1 & -1 & 1 & 1 & -1 & -1 \end{bmatrix}$$

Columns of the design matrix X are the model terms evaluated at each row of the design dCE. The terms appear in order from left to right: constant term, linear terms (1, 2, 3), interaction terms (12, 13, 23). Use X to fit the model, as described in “Linear Regression” on page 11-11, to response data measured at the design points in dCE.

Algorithms

Both `cordexch` and `rowexch` use iterative search algorithms. They operate by incrementally changing an initial design matrix X to increase $D = |X^T X|$ at each step. In both algorithms, there is randomness built into the selection of the initial design and into the choice of the incremental changes. As a result, both algorithms may return locally, but not globally, D -optimal designs. Run each algorithm multiple times and select the best result for your final design. Both functions have a 'tries' parameter that automates this repetition and comparison.

Unlike the row-exchange algorithm used by `rowexch`, `cordexch` does not use a candidate set. (Or rather, the candidate set is the entire design space.) At each step, the coordinate-exchange algorithm exchanges a single element of X with a new element evaluated at a neighboring point in design space. The absence of a candidate set reduces demands on memory, but the smaller scale of the search means that the coordinate-exchange algorithm is more likely to become trapped in a local minimum.

`daugment` | `dcovary` | `rowexch`

Introduced before R2006a

corr

Linear or rank correlation

Syntax

```
rho = corr(X)
rho = corr(X,Y)
[rho,pval] = corr(X,Y)
[rho,pval] = corr( ____,Name,Value)
```

Description

`rho = corr(X)` returns a matrix of the pairwise linear correlation coefficient between each pair of columns in the input matrix `X`.

`rho = corr(X,Y)` returns a matrix of the pairwise correlation coefficient between each pair of columns in the input matrices `X` and `Y`.

`[rho,pval] = corr(X,Y)` also returns `pval`, a matrix of *p*-values for testing the hypothesis of no correlation against the alternative hypothesis of a nonzero correlation.

`[rho,pval] = corr(____,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntaxes. For example, `'Type','Kendall'` specifies computing Kendall's tau correlation coefficient.

Examples

Find Correlation Between Two Matrices

Find the correlation between two matrices and compare it to the correlation between two column vectors.

Generate sample data.

```
rng('default')
X = randn(30,4);
Y = randn(30,4);
```

Introduce correlation between column two of the matrix X and column four of the matrix Y .

```
Y(:,4) = Y(:,4)+X(:,2);
```

Calculate the correlation between columns of X and Y .

```
[rho,pval] = corr(X,Y)
```

```
rho = 4×4
```

```
-0.1686    -0.0363     0.2278     0.3245
 0.3022     0.0332    -0.0866     0.7653
-0.3632    -0.0987    -0.0200    -0.3693
-0.1365    -0.1804     0.0853     0.0279
```

```
pval = 4×4
```

```
0.3731    0.8489     0.2260     0.0802
0.1045    0.8619     0.6491     0.0000
0.0485    0.6039     0.9166     0.0446
0.4721    0.3400     0.6539     0.8837
```

As expected, the correlation coefficient between column two of X and column four of Y , $\text{rho}(2,4)$, is the highest, and it represents a high positive correlation between the two columns. The corresponding p -value, $\text{pval}(2,4)$, is zero to the four digits shown. Because the p -value is less than the significance level of 0.05 , it indicates rejection of the hypothesis that no correlation exists between the two columns.

Calculate the correlation between X and Y using `corrcoef`.

```
[r,p] = corrcoef(X,Y)
```

```
r = 2×2
```

```
1.0000    -0.0329
-0.0329     1.0000
```

```
p = 2x2
    1.0000    0.7213
    0.7213    1.0000
```

The MATLAB® function `corrcoef`, unlike the `corr` function, converts the input matrices X and Y into column vectors, $X(:)$ and $Y(:)$, before computing the correlation between them. Therefore, the introduction of correlation between column two of matrix X and column four of matrix Y no longer exists, because those two columns are in different sections of the converted column vectors.

The value of the off-diagonal elements of r , which represents the correlation coefficient between X and Y , is low. This value indicates little to no correlation between X and Y . Likewise, the value of the off-diagonal elements of p , which represents the p -value, is much higher than the significance level of 0.05 . This value indicates that not enough evidence exists to reject the hypothesis of no correlation between X and Y .

Test Alternative Hypotheses for Correlation

Test alternative hypotheses for positive, negative, and nonzero correlation between the columns of two matrices. Compare values of the correlation coefficient and p -value in each case.

Generate sample data.

```
rng('default')
X = randn(50,4);
Y = randn(50,4);
```

Introduce positive correlation between column one of the matrix X and column four of the matrix Y .

```
Y(:,4) = Y(:,4)+0.7*X(:,1);
```

Introduce negative correlation between column two of X and column two of Y .

```
Y(:,2) = Y(:,2)-2*X(:,2);
```

Test the alternative hypothesis that the correlation is greater than zero.

```
[rho,pval] = corr(X,Y,'Tail','right')
```

```
rho = 4×4
```

```
    0.0627    -0.1438    -0.0035     0.7060  
   -0.1197   -0.8600   -0.0440     0.1984  
   -0.1119     0.2210   -0.3433     0.1070  
   -0.3526   -0.2224     0.1023     0.0374
```

```
pval = 4×4
```

```
    0.3327     0.8405     0.5097     0.0000  
    0.7962     1.0000     0.6192     0.0836  
    0.7803     0.0615     0.9927     0.2298  
    0.9940     0.9397     0.2398     0.3982
```

As expected, the correlation coefficient between column one of X and column four of Y , $\text{rho}(1,4)$, has the highest positive value, representing a high positive correlation between the two columns. The corresponding p -value, $\text{pval}(1,4)$, is zero to the four digits shown, which is lower than the significance level of 0.05 . These results indicate rejection of the null hypothesis that no correlation exists between the two columns and lead to the conclusion that the correlation is greater than zero.

Test the alternative hypothesis that the correlation is less than zero.

```
[rho,pval] = corr(X,Y,'Tail','left')
```

```
rho = 4×4
```

```
    0.0627    -0.1438    -0.0035     0.7060  
   -0.1197   -0.8600   -0.0440     0.1984  
   -0.1119     0.2210   -0.3433     0.1070  
   -0.3526   -0.2224     0.1023     0.0374
```

```
pval = 4×4
```

```
    0.6673     0.1595     0.4903     1.0000  
    0.2038     0.0000     0.3808     0.9164  
    0.2197     0.9385     0.0073     0.7702  
    0.0060     0.0603     0.7602     0.6018
```

As expected, the correlation coefficient between column two of X and column two of Y , $\text{rho}(2,2)$, has the smallest negative value (-0.86), representing a high negative correlation between the two columns. The corresponding p -value, $\text{pval}(2,2)$, is zero to the four digits shown, which is lower than the significance level of 0.05 . Again, these results indicate rejection of the null hypothesis and lead to the conclusion that the correlation is less than zero.

Test the alternative hypothesis that the correlation is not zero.

```
[rho,pval] = corr(X,Y)
```

```
rho = 4x4
```

```
    0.0627    -0.1438    -0.0035     0.7060
   -0.1197   -0.8600   -0.0440     0.1984
   -0.1119     0.2210   -0.3433     0.1070
   -0.3526   -0.2224     0.1023     0.0374
```

```
pval = 4x4
```

```
    0.6654     0.3190     0.9807     0.0000
    0.4075     0.0000     0.7615     0.1673
    0.4393     0.1231     0.0147     0.4595
    0.0120     0.1206     0.4797     0.7964
```

The p -values, $\text{pval}(1,4)$ and $\text{pval}(2,2)$, are both zero to the four digits shown. Because the p -values are lower than the significance level of 0.05 , the correlation coefficients $\text{rho}(1,4)$ and $\text{rho}(2,2)$ are significantly different from zero. Therefore, the null hypothesis is rejected; the correlation is not zero.

Input Arguments

X — Input matrix

matrix

Input matrix, specified as an n -by- k matrix. The rows of X correspond to observations, and the columns correspond to variables.

Example: $X = \text{randn}(10,5)$

Data Types: `single` | `double`

Y — Input matrix

matrix

Input matrix, specified as an n -by- k_2 matrix when X is specified as an n -by- k_1 matrix. The rows of Y correspond to observations, and the columns correspond to variables.

Example: `Y = randn(20,7)`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `corr(X,Y, 'Type', 'Kendall', 'Rows', 'complete')` returns Kendall's tau correlation coefficient using only the rows that contain no missing values.

Type — Type of correlation

'Pearson' (default) | 'Kendall' | 'Spearman'

Type of correlation, specified as the comma-separated pair consisting of 'Type' and one of these values.

| Value | Description |
|------------|--|
| 'Pearson' | "Pearson's Linear Correlation Coefficient" on page 32-1132 |
| 'Kendall' | "Kendall's Tau Coefficient" on page 32-1133 |
| 'Spearman' | "Spearman's Rho" on page 32-1134 |

`corr` computes the p -values for Pearson's correlation using a Student's t distribution for a transformation of the correlation. This correlation is exact when X and Y come from a normal distribution. `corr` computes the p -values for Kendall's tau and Spearman's rho using either the exact permutation distributions (for small sample sizes) or large-sample approximations.

Example: `'Type', 'Spearman'`

Rows — Rows to use in computation`'all' (default) | 'complete' | 'pairwise'`

Rows to use in computation, specified as the comma-separated pair consisting of 'Rows' and one of these values.

| Value | Description |
|------------|---|
| 'all' | Use all rows of the input regardless of missing values (NaNs). |
| 'complete' | Use only rows of the input with no missing values. |
| 'pairwise' | Compute $\rho(i, j)$ using rows with no missing values in column i or j . |

The 'complete' value, unlike the 'pairwise' value, always produces a positive definite or positive semidefinite ρ . Also, the 'complete' value generally uses fewer observations to estimate ρ when rows of the input (X or Y) contain missing values.

Example: 'Rows', 'pairwise'

Tail — Alternative hypothesis`'both' (default) | 'right' | 'left'`

Alternative hypothesis, specified as the comma-separated pair consisting of 'Tail' and one of the values in the table. 'Tail' specifies the alternative hypothesis against which to compute p -values for testing the hypothesis of no correlation.

| Value | Description |
|---------|---|
| 'both' | Test the alternative hypothesis that the correlation is not θ . |
| 'right' | Test the alternative hypothesis that the correlation is greater than θ . |
| 'left' | Test the alternative hypothesis that the correlation is less than θ . |

corr computes the p -values for the two-tailed test by doubling the more significant of the two one-tailed p -values.

Example: 'Tail', 'left'

Output Arguments

rho — Pairwise linear correlation coefficient

matrix

Pairwise linear correlation coefficient, returned as a matrix.

- If you input only a matrix X , rho is a symmetric k -by- k matrix, where k is the number of columns in X . The entry $\text{rho}(a, b)$ is the pairwise linear correlation coefficient between column a and column b in X .
- If you input matrices X and Y , rho is a k_1 -by- k_2 matrix, where k_1 and k_2 are the number of columns in X and Y , respectively. The entry $\text{rho}(a, b)$ is the pairwise linear correlation coefficient between column a in X and column b in Y .

pval — p -values

matrix

p -values, returned as a matrix. Each element of pval is the p -value for the corresponding element of rho .

If $\text{pval}(a, b)$ is small (less than 0.05), then the correlation $\text{rho}(a, b)$ is significantly different from zero.

Definitions

Pearson's Linear Correlation Coefficient

Pearson's linear correlation coefficient is the most commonly used linear correlation coefficient. For column X_a in matrix X and column Y_b in matrix Y , having means

$\bar{X}_a = \sum_{i=1}^n (X_{a,i}) / n$, and $\bar{Y}_b = \sum_{j=1}^n (X_{b,j}) / n$, Pearson's linear correlation coefficient $\text{rho}(a, b)$ is defined as:

$$\rho(a,b) = \frac{\sum_{i=1}^n (X_{a,i} - \bar{X}_a)(Y_{b,i} - \bar{Y}_b)}{\left\{ \sum_{i=1}^n (X_{a,i} - \bar{X}_a)^2 \sum_{j=1}^n (Y_{b,j} - \bar{Y}_b)^2 \right\}^{1/2}},$$

where n is the length of each column.

Values of the correlation coefficient can range from -1 to $+1$. A value of -1 indicates perfect negative correlation, while a value of $+1$ indicates perfect positive correlation. A value of 0 indicates no correlation between the columns.

Kendall's Tau Coefficient

Kendall's tau is based on counting the number of (i,j) pairs, for $i < j$, that are concordant—

that is, for which $X_{a,i} - X_{a,j}$ and $Y_{b,i} - Y_{b,j}$ have the same sign. The equation for Kendall's tau includes an adjustment for ties in the normalizing constant and is often referred to as tau-b.

For column X_a in matrix X and column Y_b in matrix Y , Kendall's tau coefficient is defined as:

$$\tau = \frac{2K}{n(n-1)},$$

where $K = \sum_{i=1}^{n-1} \sum_{j=i+1}^n \xi^*(X_{a,i}, X_{a,j}, Y_{b,i}, Y_{b,j})$, and

$$\xi^*(X_{a,i}, X_{a,j}, Y_{b,i}, Y_{b,j}) = \begin{cases} 1 & \text{if } (X_{a,i} - X_{a,j})(Y_{b,i} - Y_{b,j}) > 0 \\ 0 & \text{if } (X_{a,i} - X_{a,j})(Y_{b,i} - Y_{b,j}) = 0 \\ -1 & \text{if } (X_{a,i} - X_{a,j})(Y_{b,i} - Y_{b,j}) < 0 \end{cases}$$

Values of the correlation coefficient can range from -1 to $+1$. A value of -1 indicates that one column ranking is the reverse of the other, while a value of $+1$ indicates that the two rankings are the same. A value of 0 indicates no relationship between the columns.

Spearman's Rho

Spearman's rho is equivalent to “Pearson's Linear Correlation Coefficient” on page 32-1132 applied to the rankings of the columns X_a and Y_b .

If all the ranks in each column are distinct, the equation simplifies to:

$$rho(a,b) = 1 - \frac{6 \sum d^2}{n(n^2 - 1)},$$

where d is the difference between the ranks of the two columns, and n is the length of each column.

Tips

The difference between `corr(X,Y)` and the MATLAB function `corrcoef(X,Y)` is that `corrcoef(X,Y)` returns a matrix of correlation coefficients for two column vectors X and Y . If X and Y are not column vectors, `corrcoef(X,Y)` converts them to column vectors.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with the limitation:

Only the 'Pearson' type is supported.

For more information, see “Tall Arrays” (MATLAB).

See Also

`corrcoef` | `corrcoef` | `partialcorr` | `tiedrank`

Introduced before R2006a

corrcoef

Convert covariance matrix to correlation matrix

Syntax

```
R = corrcoef(C)
[R,sigma] = corrcoef(C)
```

Description

`R = corrcoef(C)` computes the correlation matrix `R` corresponding to the covariance matrix `C`. `C` must be square, symmetric, and positive semi-definite.

`[R,sigma] = corrcoef(C)` also computes the vector of standard deviations `sigma`.

Examples

Use `cov` and `corrcoef` to compute covariances and correlations, respectively, for sample data on weight and blood pressure (systolic, diastolic) in `hospital.mat`:

```
load hospital
X = [hospital.Weight hospital.BloodPressure];
C = cov(X)
C =
    706.0404    27.7879    41.0202
    27.7879    45.0622    23.8194
    41.0202    23.8194    48.0590
R = corrcoef(X)
R =
    1.0000    0.1558    0.2227
    0.1558    1.0000    0.5118
    0.2227    0.5118    1.0000
```

Compare `R` with the correlation matrix computed from `C` by `corrcoef`:

```
corrcoef(C)
ans =
```

| | | |
|--------|--------|--------|
| 1.0000 | 0.1558 | 0.2227 |
| 0.1558 | 1.0000 | 0.5118 |
| 0.2227 | 0.5118 | 1.0000 |

Introduced in R2007b

covarianceParameters

Class: GeneralizedLinearMixedModel

Extract covariance parameters of generalized linear mixed-effects model

Syntax

```
psi = covarianceParameters(glme)
[psi,dispersion] = covarianceParameters(glme)
[psi,dispersion,stats] = covarianceParameters(glme)
[ ___ ] = covarianceParameters(glme,Name,Value)
```

Description

`psi = covarianceParameters(glme)` returns the estimated prior covariance parameters of random-effects predictors in the generalized linear mixed-effects model `glme`.

`[psi,dispersion] = covarianceParameters(glme)` also returns an estimate of the dispersion parameter.

`[psi,dispersion,stats] = covarianceParameters(glme)` also returns a cell array `stats` containing the covariance parameter estimates and related statistics.

`[___] = covarianceParameters(glme,Name,Value)` returns any of the above output arguments using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the confidence level for the confidence limits of covariance parameters.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Alpha — Confidence level

0.05 (default) | scalar value in the range [0,1]

Confidence level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range [0,1]. For a value α , the confidence level is $100 \times (1 - \alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha',0.01

Data Types: single | double

Output Arguments

psi — Estimated prior covariance parameters

cell array

Estimated prior covariance parameters for the random-effects predictors, returned as a cell array of length R , where R is the number of grouping variables used in the model. `psi{r}` contains the covariance matrix of random effects associated with grouping variable g_r , where $r = 1, 2, \dots, R$. The order of grouping variables in `psi` is the same as the order entered when fitting the model. For more information on grouping variables, see “Grouping Variables” on page 2-57.

dispersion — Dispersion parameter

scalar value

Dispersion parameter, returned as a scalar value.

stats — Covariance parameter estimates and related statistics

cell array

Covariance parameter estimates and related statistics, returned as a cell array of length $(R + 1)$, where R is the number of grouping variables used in the model. The first R cells of `stats` each contain a dataset array with the following columns.

| Column Name | Description |
|-------------|--|
| Group | Grouping variable name |
| Name1 | Name of the first predictor variable |
| Name2 | Name of the second predictor variable |
| Type | If Name1 and Name2 are the same, then Type is <code>std</code> (standard deviation). If Name1 and Name2 are different, then Type is <code>corr</code> (correlation). |
| Estimate | If Name1 and Name2 are the same, then Estimate is the standard deviation of the random effect associated with predictor Name1 or Name2. If Name1 and Name2 are different, then Estimate is the correlation between the random effects associated with predictors Name1 and Name2. |
| Lower | Lower limit of the confidence interval for the covariance parameter |
| Upper | Upper limit of the confidence interval for the covariance parameter |

Cell $R + 1$ contains related statistics for the dispersion parameter.

It is recommended that the presence or absence of covariance parameters in `glme` be tested using the `compare` method, which uses a likelihood ratio test.

When fitting a GLME model using `fitglme` and one of the maximum likelihood fit methods ('Laplace' or 'ApproximateLaplace'), `covarianceParameters` derives the confidence intervals in `stats` based on a Laplace approximation to the log likelihood of the generalized linear mixed-effects model.

When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods ('MPL' or 'REML'), `covarianceParameters` derives the confidence intervals in `stats` based on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Examples

Obtain Estimated Covariance Parameters

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the

coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)
```

Compute and display the estimate of the prior covariance parameter for the random-effects predictor.

```
[psi,dispersion,stats] = covarianceParameters(glme);
psi{1}
```

```
ans =
```

```
0.0985
```

`psi{1}` is an estimate of the prior covariance matrix of the first grouping variable. In this example, there is only one grouping variable (`factory`), so `psi{1}` is an estimate of σ_b^2 .

Display the dispersion parameter.

```
dispersion
```

```
dispersion =
```

```
1
```

Display the estimated standard deviation of the random effect associated with the predictor. The first cell of `stats` contains statistics for `factory`, while the second cell contains statistics for the dispersion parameter.

```
stats{1}
```

```
ans =
```

```
COVARIANCE TYPE: ISOTROPIC
```

| Group | Name1 | Name2 | Type | Estimate |
|---------|---------------|---------------|-------|----------|
| factory | '(Intercept)' | '(Intercept)' | 'std' | 0.31381 |
| Lower | Upper | | | |
| 0.19253 | 0.51148 | | | |

The estimated standard deviation of the random effect associated with the predictor is 0.31381. The 95% confidence interval is [0.19253, 0.51148]. Because the confidence interval does not contain 0, the random intercept is significant at the 5% significance level.

`GeneralizedLinearMixedModel` | `compare` | `fitglm` | `fixedEffects` | `randomEffects`

covarianceParameters

Class: LinearMixedModel

Extract covariance parameters of linear mixed-effects model

Syntax

```
psi = covarianceParameters(lme)
[psi,mse] = covarianceParameters(lme)
[psi,mse,stats] = covarianceParameters(lme)
[psi,mse,stats] = covarianceParameters(lme,Name,Value)
```

Description

`psi = covarianceParameters(lme)` returns the estimated covariance parameters that parameterize the prior covariance of random effects.

`[psi,mse] = covarianceParameters(lme)` also returns an estimate of the residual variance.

`[psi,mse,stats] = covarianceParameters(lme)` also returns a cell array, `stats`, containing the covariance parameters and related statistics.

`[psi,mse,stats] = covarianceParameters(lme,Name,Value)` returns the covariance parameters and related statistics in `stats` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the confidence level for the confidence limits of covariance parameters.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a `LinearMixedModel` object constructed using `fitlme` or `fitlmematrix`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Alpha — Confidence level

0.05 (default) | scalar value in the range 0 to 1

Confidence level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range 0 to 1. For a value α , the confidence level is $100*(1-\alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha',0.01

Data Types: single | double

Output Arguments

psi — Estimate of covariance parameters

cell array

Estimate of covariance parameters that parameterize the prior covariance of the random effects, returned as a cell array of length R , such that `psi{r}` contains the covariance matrix of random effects associated with grouping variable g_r , $r = 1, 2, \dots, R$. The order of grouping variables is the same order you enter when you fit the model.

mse — Residual variance estimate

scalar value

Residual variance estimate, returned as a scalar value.

stats — Covariance parameter estimates and related statistics

cell array

Covariance parameter estimates and related statistics, returned as a cell array of length $(R + 1)$ containing dataset arrays with the following columns.

| | |
|----------|--|
| Group | Grouping variable name |
| Name1 | Name of the first predictor variable |
| Name2 | Name of the second predictor variable |
| Type | std (standard deviation), if Name1 and Name2 are the same corr (correlation), if Name1 and Name2 are different |
| Estimate | Standard deviation of the random effect associated with predictor Name1 or Name2, if Name1 and Name2 are the same Correlation between the random effects associated with predictors Name1 and Name2, if Name1 and Name2 are different |
| Lower | Lower limit of a 95% confidence interval for the covariance parameter |
| Upper | Upper limit of a 95% confidence interval for the covariance parameter |

`stats{r}` is a dataset array containing statistics on covariance parameters for the r th grouping variable, $r = 1, 2, \dots, R$. `stats{R+1}` contains statistics on the residual standard deviation. The dataset array for the residual error has the fields Group, Name, Estimate, Lower, and Upper.

Examples

Two Random-Effects Terms for Intercept

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'fertilizer.mat'));
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five

plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` is the fixed-effects variable, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently. This model corresponds to

$$y_{ijk} = \beta_0 + \sum_{j=2}^5 \beta_{2j} I[T]_{ij} + b_{0jk}(S * T)_{jk} + \epsilon_{ijk},$$

where $i = 1, 2, \dots, 60$ corresponds to the observations, $j = 2, \dots, 5$ corresponds to the tomato types, and $k = 1, 2, 3$ corresponds to the blocks (soil). S_k represents the k th soil type, and $(S * T)_{jk}$ represents the j th tomato type nested in the k th soil type. $I[T]_{ij}$ is the dummy variable representing the level j of the tomato type.

The random effects and observation error have the following prior distributions:

$b_{0k} \sim N(0, \sigma_S^2)$, $b_{0jk} \sim N(0, \sigma_{S*T}^2)$, and $\epsilon_{ijk} \sim N(0, \sigma^2)$.

```
lme = fitlme(ds, 'Yield ~ Fertilizer + (1|Soil) + (1|Soil:Tomato)');
```

Compute the covariance parameter estimates (estimates of σ_S^2 and σ_{S*T}^2) of the random-effects terms.

```
psi = covarianceParameters(lme)
```

```
psi =
```

```
2x1 cell array
```

```
{[2.4628e-17]}
```

```
{[ 352.8481]}
```

Compute the residual variance (σ^2).

151.9007
```

Potentially Correlated Random-Effects Terms

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'));
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a dataset array. Define `Subject` and `Program` as categorical variables.

```
ds = dataset(InitialWeight, Program, Subject, Week, y);  
ds.Subject = nominal(ds.Subject);  
ds.Program = nominal(ds.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

For 'reference' dummy variable coding, `fitlme` uses Program A as reference and creates the necessary dummy variables $I[\cdot]$. This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 \text{Week}_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i \\ + \beta_5 I[PD]_i + b_{0m} + b_{1m} \text{Week}_{im} + \epsilon_{im}$$

where i corresponds to the observation number, $i = 1, 2, \dots, 120$, and m corresponds to the subject number, $m = 1, 2, \dots, 20$. β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$,

and b_{0m} and b_{1m} are random effects. IW stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For example, $I[PB]_i$ is the dummy variable representing Program B.

The random effects and observation error have the following prior distributions:

$$\begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N\left(0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix}\right)$$

and

$$\epsilon_{im} \sim N(0, \sigma^2).$$

```
lme = fitlme(ds, 'y ~ InitialWeight + Program + (Week|Subject)');
```

Compute the estimates of covariance parameters for the random effects.

```
[psi,mse,stats] = covarianceParameters(lme)
```

```
psi =
```

```
1x1 cell array
```

```
{2x2 double}
```

```
mse =
```

```
0.0105
```

```
stats =
```

```
2x1 cell array
```

```
{3x7 classreg.regr.lmeutils.titledataset}
```

```
{1x5 classreg.regr.lmeutils.titledataset}
```

`mse` is the estimated residual variance. It is the estimate for σ^2 .

To see the covariance parameters estimates for the random-effects terms (σ_0^2 , σ_1^2 , and $\sigma_{0,1}$), index into `psi`.

```
psi{1}
```

```
ans =
```

```
    0.0572    0.0490  
    0.0490    0.0624
```

The estimate of the variance of the random effects term for the intercept, σ_0^2 , is 0.0572.

The estimate of the variance of the random effects term for week, σ_1^2 , is 0.0624. The estimate for the covariance of the random effects terms for the intercept and week, $\sigma_{0,1}$, is 0.0490.

`stats` is a 2-by-1 cell array. The first cell of `stats` contains the confidence intervals for the standard deviation of the random effects and the correlation between the random effects for intercept and week. To display them, index into `stats`.

```
stats{1}
```

```
ans =
```

```
COVARIANCE TYPE: FULLCHOLESKY
```

| Group | Name1 | Name2 | Type | Estimate |
|---------|---------------|---------------|--------|----------|
| Subject | '(Intercept)' | '(Intercept)' | 'std' | 0.23927 |
| Subject | 'Week' | '(Intercept)' | 'corr' | 0.81971 |
| Subject | 'Week' | 'Week' | 'std' | 0.2497 |

| Lower | Upper |
|---------|---------|
| 0.14365 | 0.39854 |
| 0.38662 | 0.95658 |
| 0.18303 | 0.34067 |

The display shows the name of the grouping parameter (`Group`), the random-effects variables (`Name1`, `Name2`), the type of the covariance parameters (`Type`), the estimate

(Estimate) for each parameter, and the 95% confidence intervals for the parameters (Lower, Upper). The estimates in this table are related to the estimates in `psi` as follows.

The standard deviation of the random-effects term for intercept is $0.23927 = \sqrt{0.0527}$. Likewise, the standard deviation of the random effects term for week is $0.2497 = \sqrt{0.0624}$. Finally, the correlation between the random-effects terms of intercept and week is $0.81971 = 0.0490 / (0.23927 * 0.2497)$.

Note that this display also shows which covariance pattern you use when fitting the model. In this case, the covariance pattern is `FullCholesky`. To change the covariance pattern for the random-effects terms, you must use the `'CovariancePattern'` name-value pair argument when fitting the model.

The second cell of `stats` includes similar statistics for the residual standard deviation. Display the contents of the second cell.

```
stats{2}
```

```
ans =
```

| Group | Name | Estimate | Lower | Upper |
|-------|-----------|----------|----------|---------|
| Error | 'Res Std' | 0.10261 | 0.087882 | 0.11981 |

The estimate for residual standard deviation is the square root of `mse`, $0.10261 = \sqrt{0.0105}$.

Two Grouping Variables

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and weight, a potentially correlated random effect for intercept and acceleration grouped by model year, and an independent random effect for weight, grouped by the origin of the car. This model corresponds to

$$\text{MPG}_{imk} = \beta_0 + \beta_1 \text{Acc}_i + \beta_2 \text{Weight}_i + b_{10m} + b_{11m} \text{Acc}_i + b_{21k} \text{Weight}_i + \epsilon_{imk}$$

where $m = 1, 2, \dots, 13$ represents the levels for the variable `Model_Year`, and $k = 1, 2, \dots, 8$ represents the levels for the variable `Origin`. MPG_{imk} is the miles per gallon for the i th observation, $|m|$ th model year, and $|k|$ th origin that correspond to the i th observation. The random-effects terms and the observation error have the following prior distributions:

$$b_{1m} = \begin{pmatrix} b_{10m} \\ b_{11m} \end{pmatrix} \sim N \left(0, \begin{pmatrix} \sigma_{10}^2 & \sigma_{10,11} \\ \sigma_{10,11} & \sigma_{11}^2 \end{pmatrix} \right),$$

$$b_{2k} \sim N(0, \sigma_2^2),$$

$$\epsilon_{imk} \sim N(0, \sigma^2).$$

Here, the random-effects term b_{1m} represents the first random effect at level m of the first grouping variable. The random-effects term b_{10m} corresponds to the first random effects term (1), for the intercept (0), at the m th level (m) of the first grouping variable. Likewise b_{11m} is the level m for the first predictor (1) in the first random-effects term (1).

Similarly, b_{2k} stands for the second random effects-term at level k of the second grouping variable.

σ_{10}^2 is the variance of the random-effects term for the intercept, σ_{11}^2 is the variance of the random effects term for the predictor acceleration, and $\sigma_{10,11}$ is the covariance of the random-effects terms for the intercept and the predictor acceleration. σ_2^2 is the variance of the second random-effects term, and σ^2 is the residual variance.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Weight];
Z = {[ones(406,1) Acceleration],[Weight]};
Model_Year = nominal(Model_Year);
Origin = nominal(Origin);
G = {Model_Year,Origin};
```

Fit the model using the design matrices.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Weight'},'RandomEffectPredictors',...
{{'Intercept','Acceleration'},{'Weight'}},'RandomEffectGroups',{'Model_Year','Origin'});
```

Compute the estimates of covariance parameters for the random effects.

```
[psi,mse,stats] = covarianceParameters(lme)
```

```
psi =
```

```
2x1 cell array

    {2x2 double }
    {[6.7012e-08]}
```

```
mse =
```

```
9.0943
```

```
stats =
```

```
3x1 cell array

    {3x7 classreg.regr.lmeutils.titleddataset}
    {1x7 classreg.regr.lmeutils.titleddataset}
    {1x5 classreg.regr.lmeutils.titleddataset}
```

The residual variance `mse` is 9.0755. `psi` is a 2-by-1 cell array, and `stats` is a 3-by-1 cell array. To see the contents, you must index into these cell arrays.

First, index into the first cell of `psi`.

```
psi{1}
```

```
ans =
```

```
7.5087    -0.7811
-0.7811     0.1054
```

The first cell of `psi` contains the covariance parameters for the correlated random effects for intercept σ_{10}^2 as 8.5160, and for acceleration σ_{11}^2 as 0.1087. The estimate for the covariance of the random-effects terms for the intercept and acceleration $\sigma_{10,11}$ is -0.8387.

Now, index into the second cell of `psi`.

```
psi{2}
```

```
ans =
```

```
6.7012e-08
```

The second cell of `psi` contains the estimate for the variance of the random-effects term for weight σ_2^2 .

Index into the first cell of `stats`.

```
stats{1}
```

```
ans =
```

```
COVARIANCE TYPE: FULLCHOLESKY
```

| Group | Name1 | Name2 | Type |
|------------|----------------|----------------|--------|
| Model_Year | 'Intercept' | 'Intercept' | 'std' |
| Model_Year | 'Acceleration' | 'Intercept' | 'corr' |
| Model_Year | 'Acceleration' | 'Acceleration' | 'std' |

| Estimate | Lower | Upper |
|----------|----------|----------|
| 2.7402 | 0.98498 | 7.6232 |
| -0.87787 | -0.98567 | -0.26087 |
| 0.3247 | 0.18498 | 0.56994 |

This table shows the standard deviation estimates for the random-effects terms for intercept and acceleration. Note that the standard deviations estimates are the square roots of the diagonal elements in the first cell of `psi`. Specifically, $2.9182 = \text{sqrt}(8.5160)$ and $0.32968 = \text{sqrt}(0.1087)$. The correlation is a function of the covariance of intercept and acceleration, and the standard deviations of intercept and acceleration. The covariance of intercept and acceleration is the off-diagonal value in the first cell of `psi`, -0.8387 . So, the correlation is $-0.8387 / (0.32968 * 2.92182) = -0.87$.

The grouping variable for intercept and acceleration is `Model_Year`.

Index into the second cell of `stats`.

```
stats{2}
```

```
ans =
```

```
COVARIANCE TYPE: FULLCHOLESKY
```

| Group | Name1 | Name2 | Type | Estimate |
|------------|------------|----------|-------|------------|
| Origin | 'Weight' | 'Weight' | 'std' | 0.00025887 |
| Lower | Upper | | | |
| 9.1176e-05 | 0.00073497 | | | |

The second cell of `stats` has the standard deviation estimate and the 95% confidence limits for the standard deviation of the random-effects term for `Weight`. The grouping variable is `Origin`.

Index into the third cell of `stats`.

```
stats{3}
```

```
ans =
```

| Group | Name | Estimate | Lower | Upper |
|-------|-----------|----------|--------|--------|
| Error | 'Res Std' | 3.0157 | 2.8052 | 3.2419 |

The third cell of `stats` contains the estimate for residual standard deviation and the 95% confidence limits. The estimate for residual standard deviation is the square root of `mse`, $\sqrt{9.0755} = 3.0126$.

Construct 99% confidence intervals for the covariance parameters.

```
[~,~,stats] = covarianceParameters(lme, 'Alpha', 0.01);  
stats{1}
```

```
ans =
```

COVARIANCE TYPE: FULLCHOLESKY

coxphfit

Cox proportional hazards regression

Syntax

```
b = coxphfit(X,T)
b = coxphfit(X,T,Name,Value)
[b,logl,H,stats] = coxphfit( ___ )
```

Description

`b = coxphfit(X,T)` returns a p -by-1 vector, `b`, of coefficient estimates for a Cox proportional hazards regression on page 32-1167 of the observed responses `T` on the predictors `X`, where `T` is either an n -by-1 vector or an n -by-2 matrix, and `X` is an n -by- p matrix.

The model does not include a constant term, and `X` cannot contain a column of 1s.

`b = coxphfit(X,T,Name,Value)` returns a vector of coefficient estimates, with additional options specified by one or more `Name, Value` pair arguments.

`[b,logl,H,stats] = coxphfit(___)` also returns the loglikelihood, `logl`, a structure, `stats`, that contains additional statistics, and a two-column matrix, `H`, that contains the `T` values in the first column and the estimated baseline cumulative hazard, in the second column. You can use any of the input arguments in the previous syntaxes.

Examples

Use Cox Proportional Hazards Regression to Model Lifetime of Light Bulbs

Load the sample data.

```
load(fullfile(matlabroot,'examples','stats','lightbulb.mat'));
```

The first column of the light bulb data has the lifetime (in hours) of two different types of bulbs. The second column has the binary variable indicating whether the bulb is fluorescent or incandescent. 0 indicates that the bulb is incandescent, and 1 indicates that it is fluorescent. The third column contains the censorship information, where 0 indicates the bulb was observed until failure, and 1 indicates the bulb was censored.

Fit a Cox proportional hazards model for the lifetime of the light bulbs, also accounting for censoring. The predictor variable is the type of bulb.

```
b = coxphfit(lightbulb(:,2),lightbulb(:,1), ...  
'Censoring',lightbulb(:,3))  
  
b = 4.7262
```

The estimate of the hazard ratio is $e^b = 112.8646$. This means that the hazard for the incandescent bulbs is 112.86 times the hazard for the fluorescent bulbs.

Change Algorithm Parameters for Cox Proportional Hazards Model

Load the sample data.

```
load(fullfile(matlabroot,'examples','stats','lightbulb.mat'));
```

The first column of the data has the lifetime (in hours) of two types of bulbs. The second column has the binary variable indicating whether the bulb is fluorescent or incandescent. 1 indicates that the bulb is fluorescent and 0 indicates that it is incandescent. The third column contains the censorship information, where 0 indicates the bulb is observed until failure, and 1 indicates the item (bulb) is censored.

Fit a Cox proportional hazards model, also accounting for censoring. The predictor variable is the type of bulb.

```
b = coxphfit(lightbulb(:,2),lightbulb(:,1),...  
'Censoring',lightbulb(:,3))  
  
b = 4.7262
```

Display the default control parameters for the algorithm `coxphfit` uses to estimate the coefficients.

```
statset('coxphfit')
```

```
ans = struct with fields:
    Display: 'off'
    MaxFunEvals: 200
    MaxIter: 100
    TolBnd: 1.0000e-06
    TolFun: 1.0000e-08
    TolTypeFun: []
    TolX: 1.0000e-08
    TolTypeX: []
    GradObj: []
    Jacobian: []
    DerivStep: []
    FunValCheck: []
    Robust: []
    RobustWgtFun: []
    WgtFun: []
    Tune: []
    UseParallel: []
    UseSubstreams: []
    Streams: {}
    OutputFcn: []
```

Save the options under a different name and change how the results will be displayed and the maximum number of iterations, `Display` and `MaxIter`.

```
coxphopt = statset('coxphfit');
coxphopt.Display = 'final';
coxphopt.MaxIter = 50;
```

Run `coxphfit` with the new algorithm parameters.

```
b = coxphfit(lightbulb(:,2),lightbulb(:,1),...
'Censoring',lightbulb(:,3),'Options',coxphopt)
```

Successful convergence: Norm of gradient less than `OPTIONS.TolFun`

```
b = 4.7262
```

`coxphfit` displays a report on the final iteration. Changing the maximum number of iterations did not affect the coefficient estimate.

Fit and Compare Cox and Weibull Survivor Functions

Generate Weibull data depending on predictor X.

```
rng('default') % for reproducibility
X = 4*rand(100,1);
A = 50*exp(-0.5*X);
B = 2;
y = wblrnd(A,B);
```

The response values are generated from a Weibull distribution with a shape parameter depending on the predictor variable X and a scale parameter of 2.

Fit a Cox proportional hazards model.

```
[b,logL,H,stats] = coxphfit(X,y);
[b logL]
```

```
ans =
```

```
0.9409 -331.1479
```

The coefficient estimate is 0.9409 and the log likelihood value is -331.1479.

Request the model statistics.

```
stats
```

```
stats =
```

```
struct with fields:
```

```
    covb: 0.0158
    beta: 0.9409
     se: 0.1256
     z: 7.4889
     p: 6.9462e-14
   csres: [100x1 double]
   devres: [100x1 double]
  martres: [100x1 double]
   schres: [100x1 double]
  sschres: [100x1 double]
```

```
scores: [100x1 double]
sscores: [100x1 double]
```

The covariance matrix of the coefficient estimates, `covb`, contains only one value, which is equal to the variance of the coefficient estimate in this example. The coefficient estimate, `beta`, is the same as `b` and is equal to 0.9409. The standard error of the coefficient estimate, `se`, is 0.1256, which is the square root of the variance 0.0158. The z -statistic, `z`, is $\text{beta}/\text{se} = 0.9409/0.1256 = 7.4880$. The p -value, `p`, indicates that the effect of `X` is significant.

Plot the Cox estimate of the baseline survivor function together with the known Weibull function.

```
stairs(H(:,1),exp(-H(:,2)), 'LineWidth',2)
xx = linspace(0,100);
line(xx,1-wblcdf(xx,50*exp(-0.5*mean(X)),B), 'color', 'r', 'LineWidth',2)
xlim([0,50])
legend('Estimated Survivor Function', 'Weibull Survivor Function')
```

The fitted model gives a close estimate to the survivor function of the actual distribution.

- “Hazard and Survivor Functions for Different Groups” on page 14-18
- “Survivor Functions for Two Groups” on page 14-25
- “Cox Proportional Hazards Model for Censored Data” on page 14-37
- “Cox Proportional Hazards Model with Time-Dependent Covariates” on page 14-42

Input Arguments

X — Observations on predictor variables

matrix

Observations on predictor variables, specified as an n -by- p matrix of p predictors for each of n observations.

The model does not include a constant term, thus X cannot contain a column of 1s.

If X , T , or the value of 'Frequency' or 'Strata' contain NaN values, then `coxphfit` removes rows with NaN values from all data when fitting a Cox model.

Data Types: double

T — Time-to-event data

vector | two-column matrix

Time-to-event data, specified as an n -by-1 vector or a two-column matrix.

- When T is an n -by-1 vector, it represents the event time of right-censored time-to-event data.
- When T is an n -by-2 matrix, each row represents the risk interval (start,stop] in the counting process format for time-dependent covariates. The first column is the start time and the second column is the stop time. For an example, see “Cox Proportional Hazards Model with Time-Dependent Covariates” on page 14-42.

If X , T , or the value of 'Frequency' or 'Strata' contain NaN values, then `coxphfit` removes rows with NaN values from all data when fitting a Cox model.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: 'Baseline', 0, 'Censoring', censoreddata, 'Frequency', freq specifies that `coxphfit` calculates the baseline hazard rate relative to 0, considering the censoring information in the vector `censoreddata`, and the frequency of observations on T and X given in the vector `freq`.

B0 — Coefficient initial values

0.01/std(X) (default) | numeric vector

Coefficient initial values, specified as the comma-separated value consisting of 'B0' and a numeric vector.

Data Types: double

Baseline — X values at which to compute the baseline hazard

mean(X) (default) | scalar value

X values at which to compute the baseline hazard, specified as the comma-separated pair consisting of 'Baseline' and a scalar value.

The default is mean(X), so the hazard rate at X is $h(t) \cdot \exp((X - \text{mean}(X)) \cdot b)$. Enter 0 to compute the baseline relative to 0, so the hazard rate at X is $h(t) \cdot \exp(X \cdot b)$. Changing the baseline does not affect the coefficient estimates, but the hazard ratio changes.

Example: 'Baseline',0

Data Types: double

Censoring — Indicator for censoring

array of 0s (default) | array of 0s and 1s

Indicator for censoring, specified as the comma-separated pair consisting of 'Censoring' and a Boolean array of the same size as T. Use 1 for observations that are right censored and 0 for observations that are fully observed. The default is all observations are fully observed. For an example, see “Cox Proportional Hazards Model for Censored Data” on page 14-37.

Example: 'Censoring',cens

Data Types: logical

Frequency — Frequency or weights of observations

array of 1s (default) | vector of nonnegative scalar values

Frequency or weights of observations, specified as the comma-separated pair consisting of 'Frequency' and an array that is the same size as T containing nonnegative scalar values. The array can contain integer values corresponding to frequencies of observations or nonnegative values corresponding to observation weights.

If X, T, or the value of 'Frequency' or 'Strata' contain NaN values, then `coxphfit` removes rows with NaN values from all data when fitting a Cox model.

The default is 1 per row of X and T.

Example: 'Frequency',w

Data Types: double

Strata — Stratification variables

[] (default) | matrix of real values

Stratification variables, specified as the comma-separated pair consisting of a matrix of real values. The matrix must have the same number of rows as T, with each row corresponding to an observation.

If X, T, or the value of 'Frequency' or 'Strata' contain NaN values, then `coxphfit` removes rows with NaN values from all data when fitting a Cox model.

The default, [], is no stratification variable.

Example: 'Strata',Gender

Data Types: single | double

Ties — Method to handle tied failure times

'breslow' (default) | 'efron'

Method to handle tied failure times, specified as the comma-separated pair consisting of 'Ties' and either 'breslow' or 'efron'.

Example: 'Ties', 'efron'

Options — Algorithm control parameters

structure

Algorithm control parameters for the iterative algorithm used to estimate b, specified as the comma-separated pair consisting of 'Options' and a structure. A call to `statset` creates this argument. For parameter names and default values, type `statset('coxphfit')`. You can set the options under a new name and use that in the name-value pair argument.

Example: 'Options',`statset('coxphfit')`

Output Arguments

b — Coefficient estimates

vector

Coefficient estimates for a Cox proportional hazards regression on page 32-1167, returned as a p -by-1 vector.

logl — Loglikelihood

scalar

Loglikelihood of the fitted model, returned as a scalar.

You can use log likelihood values to compare different models and assess the significance of effects of terms in the model.

H — Estimated baseline cumulative hazard

two-column matrix | $(2+k)$ column matrix

Estimated baseline cumulative hazard rate evaluated at T values, returned as one of the following.

- If the model is unstratified, then H is a two-column matrix. The first column of the matrix contains T values, and the second column contains cumulative hazard rate estimates.
- If the model is stratified, then H is a $(2+k)$ column matrix, where the last k columns correspond to the stratification variables using the `Strata` name-value pair argument.

stats — Coefficient statistics

structure

Coefficient statistics, returned as a structure that contains the following fields.

| | |
|---------|--|
| beta | Coefficient estimates (same as b) |
| se | Standard errors of coefficient estimates, b |
| z | z -statistics for b (that is, b divided by standard error) |
| p | p -values for b |
| covb | Estimated covariance matrix for b |
| csres | Cox-Snell residuals |
| devres | Deviance residuals |
| martres | Martingale residuals |
| schres | Schoenfeld residuals |

| | |
|---------|-----------------------------|
| sschres | Scaled Schoenfeld residuals |
| scores | Score residuals |
| sscores | Scaled score residuals |

coxphfit returns the Cox-Snell, martingale, and deviance residuals as a column vector with one row per observation. It returns the Schoenfeld, scaled Schoenfeld, score, and scaled score residuals as matrices of the same size as X. Schoenfeld and scaled Schoenfeld residuals of censored data are NaNs.

Definitions

Cox Proportional Hazards Regression

Cox proportional hazards regression is a semiparametric method for adjusting survival rate estimates to remove the effect of confounding variables and to quantify the effect of predictor variables. The method represents the effects of explanatory and confounding variables as a multiplier of a common baseline hazard function, $h_0(t)$.

For a baseline relative to 0, this model corresponds to

$$h(X_i, t) = h_0(t) \exp \left[\sum_{j=1}^p x_{ij} \cdot b_j \right],$$

where $X_i = (x_{i1}, x_{i2}, \dots, x_{ip})$ is the predictor variable for the i th subject, $h(X_i, t)$ is the hazard rate at time t for X_i , and $h_0(t)$ is the baseline hazard rate function. The baseline hazard function is the nonparametric part of the Cox proportional hazards regression function, whereas the impact of the predictor variables is a loglinear regression. The assumption is that the baseline hazard function depends on time, t , but the predictor variables do not depend on time. See “Cox Proportional Hazards Model” on page 14-30 for details, including the extensions for stratification and time-dependent variables, tied events, and observation weights.

Introduced before R2006a

createns

Create nearest neighbor searcher object

Syntax

```
NS = createns(X)  
NS = createns(X,Name,Value)
```

Description

`NS = createns(X)` creates either an `ExhaustiveSearcher` or `KDTreeSearcher` model object using the n -by- K numeric matrix of the training data X .

`NS = createns(X,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify `NSMethod` to determine which type of object to create.

Examples

Train Default Exhaustive Nearest Neighbor Searcher

Load Fisher's iris data set.

```
load fisheriris  
X = meas;  
[n,k] = size(X)
```

```
n = 150
```

```
k = 4
```

X has 150 observations and 4 predictors.

Prepare an exhaustive nearest neighbor searcher using the entire data set as training data.

```
Mdl1 = ExhaustiveSearcher(X)

Mdl1 =
    ExhaustiveSearcher with properties:

        Distance: 'euclidean'
    DistParameter: []
           X: [150x4 double]
```

Mdl1 is an `ExhaustiveSearcher` model object, and its properties appear in the Command Window. The object contains information about the trained algorithm, such as the distance metric. You can alter property values using dot notation.

Alternatively, you can prepare an exhaustive nearest neighbor searcher by using `createns` and specifying `'exhaustive'` as the search method.

```
Mdl2 = createns(X, 'NSMethod', 'exhaustive')

Mdl2 =
    ExhaustiveSearcher with properties:

        Distance: 'euclidean'
    DistParameter: []
           X: [150x4 double]
```

Mdl2 is also an `ExhaustiveSearcher` model object, and it is equivalent to Mdl1.

To search X for the nearest neighbors to a batch of query data, pass the `ExhaustiveSearcher` model object and the query data to `knnsearch` or `rangesearch`.

Grow Default Kd-Tree

Grow a four-dimensional Kd-tree that uses the Euclidean distance.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
[n,k] = size(X)
```

```
n = 150
```

```
k = 4
```

X has 150 observations and 4 predictors.

Grow a four-dimensional Kd-tree using the entire data set as training data.

```
Mdl1 = KDTreeSearcher(X)
```

```
Mdl1 =  
  KDTreeSearcher with properties:  
  
    BucketSize: 50  
    Distance: 'euclidean'  
  DistParameter: []  
           X: [150x4 double]
```

Mdl1 is a KDTreeSearcher model object, and its properties appear in the Command Window. The object contains information about the grown four-dimensional Kd-tree, such as the distance metric. You can alter property values using dot notation.

Alternatively, you can grow a Kd-tree by using createns.

```
Mdl2 = createns(X)
```

```
Mdl2 =  
  KDTreeSearcher with properties:  
  
    BucketSize: 50  
    Distance: 'euclidean'  
  DistParameter: []  
           X: [150x4 double]
```

Mdl2 is also a KDTreeSearcher model object, and it is equivalent to Mdl1. Because X has four columns and the default distance metric is Euclidean, createns creates a KDTreeSearcher model by default.

To find the nearest neighbors in X to a batch of query data, pass the KDTreeSearcher model object and the query data to knnsearch or rangesearch.

Grow Kd-Tree Using Minkowski Distance Metric

Grow a Kd-tree that uses the Minkowski distance with an exponent of five.

Load Fisher's iris data set. Create a variable for the petal dimensions.

```
load fisheriris
X = meas(:,3:4);
```

Grow a Kd-tree. Specify the Minkowski distance with an exponent of five.

```
Mdl = createns(X, 'Distance', 'minkowski', 'P', 5)
```

```
Mdl =
  KDTreeSearcher with properties:
    BucketSize: 50
    Distance: 'minkowski'
    DistParameter: 5
    X: [150x2 double]
```

Because X has two columns and the distance metric is Minkowski, `createns` creates a `KDTreeSearcher` model object by default.

Search for Nearest Neighbors of Query Data Using Mahalanobis Distance

Create an exhaustive searcher object by using the `createns` function. Pass the object and query data to the `knnsearch` function to find *k*-nearest neighbors.

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng('default'); % For reproducibility
n = size(meas,1); % Sample size
qIdx = randsample(n,5); % Indices of query data
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);
```

Prepare an exhaustive nearest neighbor searcher using the training data. Specify the Mahalanobis distance for finding nearest neighbors.

```
Mdl = createns(X, 'Distance', 'mahalanobis')
```

```
Mdl =
ExhaustiveSearcher with properties:

    Distance: 'mahalanobis'
  DistParameter: [4x4 double]
           X: [145x4 double]
```

Because the distance metric is Mahalanobis, `createns` creates an `ExhaustiveSearcher` model object by default.

The software uses the covariance matrix of the predictors (columns) in the training data for computing the Mahalanobis distance. To display this value, use `Mdl.DistParameter`.

```
Mdl.DistParameter
```

```
ans = 4x4

    0.6547    -0.0368    1.2320    0.5026
   -0.0368    0.1914   -0.3227   -0.1193
    1.2320   -0.3227    3.0671    1.2842
    0.5026   -0.1193    1.2842    0.5800
```

Find the indices of the training data (`Mdl.X`) that are the two nearest neighbors of each point in the query data (`Y`).

```
IdxNN = knnsearch(Mdl, Y, 'K', 2)
```

```
IdxNN = 5x2

     5     6
    98    95
   104   128
   135    65
   102   115
```

Each row of `IdxNN` corresponds to a query data observation. The column order corresponds to the order of the nearest neighbors with respect to ascending distance. For example, based on the Mahalanobis metric, the second nearest neighbor of `Y(3, :)` is `X(128, :)`.

Input Arguments

X — Training data

numeric matrix

Training data, specified as a numeric matrix. X has n rows, each corresponding to an observation (that is, an instance or example), and K columns, each corresponding to a predictor (that is, a feature).

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `NS = createns(X, 'Distance', 'mahalanobis')` creates an `ExhaustiveSearcher` model object that uses the Mahalanobis distance metric when searching for nearest neighbors.

For Exhaustive and Kd-Tree Nearest Neighbor Searchers

NSMethod — Nearest neighbor search method

'kdtree' | 'exhaustive'

Nearest neighbor search method used to define the type of object created, specified as the comma-separated pair consisting of 'NSMethod' and 'kdtree' or 'exhaustive'.

- 'kdtree' — `createns` creates a `KDTreeSearcher` model object using the Kd-tree algorithm.
- 'exhaustive' — `createns` creates an `ExhaustiveSearcher` model object using the exhaustive search algorithm.

The default value is 'kdtree' when these three conditions are true:

- The number of columns of X (K) is less than or equal to 10 (that is, $K \leq 10$).
- X is not sparse.
- Distance is 'euclidean', 'cityblock', 'chebychev', or 'minkowski'.

Otherwise, the default value is 'exhaustive'.

Example: 'NSMethod', 'exhaustive'

Distance – Distance metric

'euclidean' (default) | character vector or string scalar of distance metric name | custom distance function

Distance metric used when you call `knnsearch` or `rangesearch` to find nearest neighbors for future query points, specified as the comma-separated pair consisting of 'Distance' and a character vector or string scalar of distance metric name or function handle.

For both types of nearest neighbor searchers, createns supports these distance metrics.

| Value | Description |
|-------------|---|
| 'chebychev' | Chebychev distance (maximum coordinate difference). |
| 'cityblock' | City block distance. |
| 'euclidean' | Euclidean distance. |
| 'minkowski' | Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument. |

If createns uses the exhaustive search algorithm ('NSMethod' is 'exhaustive'), then createns also supports these distance metrics.

| Value | Description |
|---------------|---|
| 'correlation' | One minus the sample linear correlation between observations (treated as sequences of values) |
| 'cosine' | One minus the cosine of the included angle between observations (treated as row vectors) |
| 'hamming' | Hamming distance, which is the percentage of coordinates that differ |
| 'jaccard' | One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ |

| Value | Description |
|---------------|--|
| 'mahalanobis' | Mahalanobis distance |
| 'seuclidean' | Standardized Euclidean distance |
| 'spearman' | One minus the sample Spearman's rank correlation between observations (treated as sequences of values) |

If `createns` uses the exhaustive search algorithm ('NSMethod' is 'exhaustive'), then you can also specify a function handle for a custom distance metric by using @ (for example, @distfun). A custom distance function must:

- Have the form `function D2 = distfun(ZI,ZJ)`.
- Take as arguments:
 - A 1-by- K vector ZI containing a single row from X or from the query points Y , where K is the number of columns in X .
 - An m -by- K matrix ZJ containing multiple rows of X or Y , where m is a positive integer.
- Return an m -by-1 vector of distances $D2$, where $D2(j)$ is the distance between the observations ZI and $ZJ(j, :)$.

For more details, see “Distance Metrics” on page 18-16.

Example: 'Distance', 'minkowski'

P — Exponent for Minkowski distance metric

2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of 'P' and a positive scalar. This argument is valid only if 'Distance' is 'minkowski'.

Example: 'P',3

Data Types: single | double

For Exhaustive Nearest Neighbor Searchers

Cov — Covariance matrix for Mahalanobis distance metric

nancov(X) (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of 'Cov' and a K -by- K positive definite matrix, where K is the number of columns in X . This argument is valid only if 'Distance' is 'mahalanobis'.

Example: 'Cov', eye(3)

Data Types: single | double

Scale — Scale parameter value for standardized Euclidean distance metric

nanstd(X) (default) | nonnegative numeric vector

Scale parameter value for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of 'Scale' and a nonnegative numeric vector of length K , where K is the number of columns in X . The software scales each difference between the training and query data using the corresponding element of Scale. This argument is valid only if 'Distance' is 'seuclidean'.

Example: 'Scale', quantile(X , 0.75) - quantile(X , 0.25)

Data Types: single | double

For Nearest Neighbor Searchers Using Kd-Tree

BucketSize — Maximum number of data points in each leaf node

50 (default) | positive integer

Maximum number of data points in each leaf node of the Kd-tree, specified as the comma-separated pair consisting of 'BucketSize' and a positive integer.

This argument is valid only when you create a KDTreeSearcher model object.

Example: 'BucketSize', 10

Data Types: single | double

Output Arguments

NS — Nearest neighbor searcher

ExhaustiveSearcher model object | KDTreeSearcher model object

Nearest neighbor searcher, returned as an ExhaustiveSearcher model object or a KDTreeSearcher model object.

Once you create a nearest neighbor searcher model object, you can find the neighboring points in the training data to the query data by performing a nearest neighbor search using `knnsearch` or a radius search using `rangesearch`.

`ExhaustiveSearcher` | `KDTreeSearcher` | `knnsearch` | `rangesearch`

Topics

“k-Nearest Neighbor Search and Radius Search” on page 18-19

Introduced in R2010a

crosstab

Cross-tabulation

Syntax

```
tbl = crosstab(x1,x2)
tbl = crosstab(x1,...,xn)
[tbl,chi2,p] = crosstab(____)
[tbl,chi2,p,labels] = crosstab(____)
```

Description

`tbl = crosstab(x1,x2)` returns a cross-tabulation, `tbl`, of two vectors of the same length, `x1` and `x2`.

`tbl = crosstab(x1,...,xn)` returns a multi-dimensional cross-tabulation, `tbl`, of data for multiple input vectors, `x1`, `x2`, ..., `xn`.

`[tbl,chi2,p] = crosstab(____)` also returns the chi-square statistic, `chi2`, and its *p*-value, `p`, for a test that `tbl` is independent in each dimension. You can use any of the previous syntaxes.

`[tbl,chi2,p,labels] = crosstab(____)` also returns a cell array, `labels`, which contains one column of labels for each input argument, `x1 ... xn`.

Examples

Cross-Tabulate Two Data Vectors

Create two sample data vectors, containing three and four distinct values, respectively.

```
x = [1 1 2 3 1];
y = [1 2 5 3 1];
```

Cross-tabulate `x` and `y`.

```
table = crosstab(x,y)
```

```
table = 3×4
```

```
     2     1     0     0
     0     0     0     1
     0     0     1     0
```

The rows in `table` correspond to the three distinct values in `x`, and the columns correspond to the four distinct values in `y`.

Cross-Tabulate Independent Data Vectors

Generate two independent vectors, `x1` and `x2`, each containing 50 discrete uniform random numbers in the range 1:3.

```
rng default; % for reproducibility
x1 = unidrnd(3,50,1);
x2 = unidrnd(3,50,1);
```

Cross-tabulate `x1` and `x2`.

```
[table,chi2,p] = crosstab(x1,x2)
```

```
table = 3×3
```

```
     1     6     7
     5     5     2
    11     7     6
```

```
chi2 = 7.5449
```

```
p = 0.1097
```

The returned `p` value of `0.1097` indicates that, at the 5% significance level, `crosstab` fails to reject the null hypothesis that `table` is independent in each dimension.

Cross-Tabulate Grouped Data

Load the sample data, which contains measurements of large model cars during the years 1970-1982.

```
load carbig
```

Cross-tabulate the data of four-cylinder cars (`cyl4`) based on model year (`when`) and country of origin (`org`).

```
[table,chi2,p,labels] = crosstab(cyl4,when,org);
```

Use `labels` to determine the index location in `table` for the number of four-cylinder cars made in the USA during the late period of the data.

```
labels
```

```
labels = 3x3 cell array
    {'Other'  }    {'Early'}    {'USA'  }
    {'Four'   }    {'Mid'  }    {'Europe'}
    {'0x0 double}  {'Late' }    {'Japan' }
```

The first column of `labels` corresponds to the data in `cyl4`, and indicates that row 2 of `table` contains data on cars with four cylinders. The second column of `labels` corresponds to the data in `when`, and indicates that column 3 of `table` contains data on cars made during the late period. The third column of `labels` corresponds to the data in `org`, and indicates that location 1 of the third dimension of `table` contains data on cars made in the USA.

Therefore, `table(2,3,1)` contains the number of four-cylinder cars made in the USA during the late period.

```
table(2,3,1)
```

```
ans = 38
```

The data contains 38 four-cylinder cars made in the USA during the late period.

Generate Contingency Table Using `crosstab`

Load the hospital data.

load `hospital`

The `hospital` dataset array contains data on 100 hospital patients, including last name, gender, age, weight, smoking status, and systolic and diastolic blood pressure measurements.

To determine whether smoking status is independent of gender, use `crosstab` to create a 2-by-2 contingency table of smokers and nonsmokers, grouped by gender.

```
[tbl,chi2,p,labels] = crosstab(hospital.Sex, hospital.Smoker)
```

```
tbl =
```

```
    40    13
    26    21
```

```
chi2 =
```

```
    4.5083
```

```
p =
```

```
    0.0337
```

```
labels =
```

```
    2x2 cell array
```

```
    {'Female'}    {'0'}
```

```
    {'Male' }    {'1'}
```

The rows of the resulting contingency table `tbl` correspond to the patient's gender, with row 1 containing data for females and row 2 containing data for males. The columns correspond to the patient's smoking status, with column 1 containing data for nonsmokers and column 2 containing data for smokers. The returned result `chi2 = 4.5083` is the value of the chi-squared test statistic for a Pearson's chi-squared test of

independence. The returned value $p = 0.0337$ is an approximate P -value based on the chi-squared distribution.

Input Arguments

x1 — Input vector

vector of grouping variables

Input vector, specified as a vector of grouping variables. All input vectors, including x_1 , x_2 , ..., x_n , must be the same length.

Data Types: `single` | `double` | `char` | `string` | `logical`

x2 — Input vector

vector of grouping variables

Input vector, specified as a vector of grouping variables. All input vectors, including x_1 , x_2 , ..., x_n , must be the same length.

Data Types: `single` | `double` | `char` | `string` | `logical`

x1, ..., xn — Input vectors

vectors of grouping variables

Input vectors, specified as vectors of grouping variables. If you use this syntax to specify more than two input vectors, then `crosstab` generates a multi-dimensional cross-tabulation table. All input vectors, including x_1 , x_2 , ..., x_n , must be the same length.

Data Types: `single` | `double` | `char` | `string` | `logical`

Output Arguments

tbl — Cross-tabulation table

matrix of integer values

Cross-tabulation table, returned as a matrix of integer values.

If you specify two input vectors, x_1 and x_2 , then `tbl` is an m -by- n matrix, where m is the number of distinct values in x_1 and n is the number of distinct values in x_2 .

If you specify three or more input vectors, then `tbl(i, j, ..., n)` is a count of indices where `grp2idx(x1)` is `i`, `grp2idx(x2)` is `j`, `grp2idx(x3)` is `k`, and so on.

chi2 — Chi-square statistic

positive scalar value

Chi-square statistic, returned as a positive scalar value. The null hypothesis is that the proportion in any entry of `tbl` is the product of the proportions in each dimension.

p — p-Value

scalar value in the range `[0, 1]`

p-value for the chi-square test statistic, returned as a scalar value in the range `[0, 1]`. `crosstab` tests that `tbl` is independent in each dimension.

labels — Data labels

cell array

Data labels, returned as a cell array. The entries in the first column are labels for the rows of `tbl`, the entries in the second column are labels for the columns, and so on, for a multi-dimensional `tbl`.

Algorithms

`crosstab` uses `grp2idx` to assign a positive integer to each distinct value. `tbl(i, j)` is a count of indices where `grp2idx(x1)` is `i` and `grp2idx(x2)` is `j`. The numerical order of `grp2idx(x1)` and `grp2idx(x2)` order rows and columns of `tbl`, respectively.

In this case, the returned value of `tbl(i, j, ..., n)` is a count of indices where `grp2idx(x1)` is `i`, `grp2idx(x2)` is `j`, `grp2idx(x3)` is `k`, and so on.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with the limitation:

The fourth output, `labels`, is returned as a cell array containing `M` unevaluated tall cell arrays, where `M` is the number of input grouping variables. Each unevaluated tall cell array, `labels{j}`, contains the labels for one grouping variable.

For more information, see “Tall Arrays” (MATLAB).

“Grouping Variables” on page 2-57

Introduced before R2006a

crossval

Loss estimate using cross validation

Syntax

```
vals = crossval(fun,X)
vals = crossval(fun,X,Y,...)
mse = crossval('mse',X,y,'Predfun',predfun)
mcr = crossval('mcr',X,y,'Predfun',predfun)
val = crossval(criterion,X1,X2,...,y,'Predfun',predfun)
vals = crossval(...,'name',value)
```

Description

`vals = crossval(fun,X)` performs 10-fold cross validation for the function `fun`, applied to the data in `X`.

`fun` is a function handle to a function with two inputs, the training subset of `X`, `XTRAIN`, and the test subset of `X`, `XTEST`, as follows:

```
testval = fun(XTRAIN,XTEST)
```

Each time it is called, `fun` should use `XTRAIN` to fit a model, then return some criterion `testval` computed on `XTEST` using that fitted model.

`X` can be a column vector or a matrix. Rows of `X` correspond to observations; columns correspond to variables or features. Each row of `vals` contains the result of applying `fun` to one test set. If `testval` is a non-scalar value, `crossval` converts it to a row vector using linear indexing and stored in one row of `vals`.

`vals = crossval(fun,X,Y,...)` is used when data are stored in separate variables `X`, `Y`, All variables (column vectors, matrices, or arrays) must have the same number of rows. `fun` is called with the training subsets of `X`, `Y`, ... , followed by the test subsets of `X`, `Y`, ... , as follows:

```
testvals = fun(XTRAIN,YTRAIN,...,XTEST,YTEST,...)
```

`mse = crossval('mse', X, y, 'Predfun', predfun)` returns `mse`, a scalar containing a 10-fold cross validation estimate of mean-squared error for the function `predfun`. `X` can be a column vector, matrix, or array of predictors. `y` is a column vector of response values. `X` and `y` must have the same number of rows.

`predfun` is a function handle called with the training subset of `X`, the training subset of `y`, and the test subset of `X` as follows:

```
yfit = predfun(XTRAIN, ytrain, XTEST)
```

Each time it is called, `predfun` should use `XTRAIN` and `ytrain` to fit a regression model and then return fitted values in a column vector `yfit`. Each row of `yfit` contains the predicted values for the corresponding row of `XTEST`. `crossval` computes the squared errors between `yfit` and the corresponding response test set, and returns the overall mean across all test sets.

`mcr = crossval('mcr', X, y, 'Predfun', predfun)` returns `mcr`, a scalar containing a 10-fold cross validation estimate of misclassification rate (the proportion of misclassified samples) for the function `predfun`. The matrix `X` contains predictor values and the vector `y` contains class labels. `predfun` should use `XTRAIN` and `YTRAIN` to fit a classification model and return `yfit` as the predicted class labels for `XTEST`. `crossval` computes the number of misclassifications between `yfit` and the corresponding response test set, and returns the overall misclassification rate across all test sets.

`val = crossval(criterion, X1, X2, ..., y, 'Predfun', predfun)`, where *criterion* is 'mse' or 'mcr', returns a cross validation estimate of mean-squared error (for a regression model) or misclassification rate (for a classification model) with predictor values in `X1`, `X2`, ... and, respectively, response values or class labels in `y`. `X1`, `X2`, ... and `y` must have the same number of rows. `predfun` is a function handle called with the training subsets of `X1`, `X2`, ..., the training subset of `y`, and the test subsets of `X1`, `X2`, ..., as follows:

```
yfit=predfun(X1TRAIN, X2TRAIN, ..., ytrain, X1TEST, X2TEST, ...)
```

`yfit` should be a column vector containing the fitted values.

`vals = crossval(..., 'name', value)` specifies one or more optional parameter name/value pairs from the following table. Specify *name* inside single quotes.

| Name | Value |
|-----------|---|
| holdout | A scalar specifying the ratio or the number of observations p for holdout cross validation. When $0 < p < 1$, approximately $p*n$ observations for the test set are randomly selected. When p is an integer, p observations for the test set are randomly selected. |
| kfold | A positive integer that is greater than 1 specifying the number of folds k for k -fold cross validation. |
| leaveout | Specifies leave-one-out cross validation. The value must be 1. |
| mcreps | A positive integer specifying the number of Monte-Carlo repetitions for validation. If the first input of <code>crossval</code> is 'mse' or 'mcr', <code>crossval</code> returns the mean of mean-squared error or misclassification rate across all of the Monte-Carlo repetitions. Otherwise, <code>crossval</code> concatenates the values <code>vals</code> from all of the Monte-Carlo repetitions along the first dimension. |
| partition | An object <code>c</code> of the <code>cvpartition</code> on page 32-1269 class, specifying the cross validation type and partition. |
| stratify | A column vector <code>group</code> specifying groups for stratification. Both training and test sets have roughly the same class proportions as in <code>group</code> . NaNs, empty character vectors, and empty strings in <code>group</code> are treated as missing data values, and the corresponding rows of the data are ignored. |
| options | <p>A structure that specifies whether to run in parallel, and specifies the random stream or streams. Create the <code>options</code> structure with <code>statset</code>. Option fields:</p> <ul style="list-style-type: none"> • <code>UseParallel</code> — Set to <code>true</code> to compute in parallel. Default is <code>false</code>. • <code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'. • <code>Streams</code> — A <code>RandStream</code> object or cell array consisting of one such object. If you do not specify <code>Streams</code>, <code>crossval</code> uses the default stream. |

Only one of `kfold`, `holdout`, `leaveout`, or `partition` can be specified, and `partition` cannot be specified with `stratify`. If both `partition` and `mcreps` are specified, the first Monte-Carlo repetition uses the partition information in the `cvpartition` object, and the `repartition` method is called to generate new partitions for each of the remaining repetitions. If no cross validation type is specified, the default is 10-fold cross validation.

Note When using cross validation with classification algorithms, stratification is preferred. Otherwise, some test sets may not include observations from all classes.

Examples

Example 1

Compute mean-squared error for regression using 10-fold cross validation:

```
load('fisheriris');
y = meas(:,1);
X = [ones(size(y,1),1),meas(:,2:4)];

regf=@(XTRAIN,ytrain,XTEST)(XTEST*regress(ytrain,XTRAIN));

cvMse = crossval('mse',X,y,'predfun',regf)
cvMse =
    0.1015
```

Example 2

Compute misclassification rate using stratified 10-fold cross validation:

```
load('fisheriris');
y = species;
X = meas;
cp = cvpartition(y,'k',10); % Stratified cross-validation

classf = @(XTRAIN, ytrain,XTEST)(classify(XTEST,XTRAIN,...
ytrain));

cvMCR = crossval('mcr',X,y,'predfun',classf,'partition',cp)
```

```
cvMCR =  
    0.0200
```

Example 3

Compute the confusion matrix using stratified 10-fold cross validation:

```
load('fisheriris');  
y = species;  
X = meas;  
order = unique(y); % Order of the group labels  
cp = cvpartition(y,'k',10); % Stratified cross-validation  
  
f = @(xtr,ytr,xte,yte)confusionmat(yte,...  
    classify(xte,xtr,ytr),'order',order);  
  
cfMat = crossval(f,X,y,'partition',cp);  
cfMat = reshape(sum(cfMat),3,3)  
cfMat =  
    50     0     0  
     0    48     2  
     0     1    49
```

cfMat is the summation of 10 confusion matrices from 10 test sets.

cvpartition

Topics

“Grouping Variables” on page 2-57

Introduced in R2008a

crossval

Class: ClassificationDiscriminant

Cross-validated discriminant analysis classifier

Syntax

```
cvmodel = crossval(obj)
cvmodel = crossval(obj,Name,Value)
```

Description

`cvmodel = crossval(obj)` creates a partitioned model from `obj`, a fitted discriminant analysis classifier. By default, `crossval` uses 10-fold cross validation on the training data to create `cvmodel`.

`cvmodel = crossval(obj,Name,Value)` creates a partitioned model with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

obj

Discriminant analysis classifier, produced using `fitcdiscr`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

CVPartition

Object of class `cvpartition`, created by the `cvpartition` function. `crossval` splits the data into subsets with `cvpartition`.

Use only one of these options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Default: []

Holdout

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. Use only one of these options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

KFold

Number of folds to use in a cross-validated classifier, a positive integer value greater than 1.

Use only one of these options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Default: 10

Leaveout

Set to 'on' for leave-one-out cross validation.

Use only one of these options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Examples

Create a classification model for the Fisher iris data, and then create a cross-validation model. Evaluate the quality the model using `kfoldLoss`.

```
load fisheriris
obj = fitcdiscr(meas,species);
cvmodel = crossval(obj);
L = kfoldLoss(cvmodel)
```

L =
0.0200

Tips

- Assess the predictive performance of obj on cross-validated data using the “kfold” methods and properties of cvmodel, such as kfoldLoss.

Alternatives

You can create a cross-validation classifier directly from the data, instead of creating a discriminant analysis classifier followed by a cross-validation classifier. To do so, include one of these options in fitcdiscr: 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

crossval

Class: ClassificationECOC

Cross-validate multiclass, error-correcting output codes model

Syntax

```
CVMDL = crossval(MDL)
CVMDL = crossval(MDL, Name, Value)
```

Description

`CVMDL = crossval(MDL)` returns a cross-validated (partitioned), multiclass, error-correcting output codes (ECOC) model (`CVMDL`) from a trained ECOC model (`MDL`).

By default, `crossval` uses 10-fold cross validation on the training data to create `CVMDL`.

`CVMDL = crossval(MDL, Name, Value)` returns a partitioned ECOC model with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the number of folds or a holdout sample proportion.

Input Arguments

MDL — Multiclass ECOC model

ClassificationECOC model

Multiclass ECOC model, specified as a `ClassificationECOC` model returned by `fitcecoc`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

CVPartition — Cross-validation partition

[] (default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object as created by cvpartition. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: 'CVPartition', 'Holdout', 'Kfold', or 'Leaveout'.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500, 'Kfold', 5)`. Then, you can specify the cross-validated model by using 'CVPartition', `cvp`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p , then the software completes these steps:

- 1 Randomly select and reserve $p*100\%$ of the data as validation data, and train the model using the rest of the data.
- 2 Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, Kfold, or Leaveout.

Example: 'Holdout', 0.1

Data Types: double | single

Kfold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'Kfold' and a positive integer value greater than 1. If you specify 'Kfold', k , then the software completes these steps.

- 1 Randomly partition the data into k sets.
- 2 For each set, reserve the set as validation data, and train the model using the other $k - 1$ sets.
- 3 Store the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

Leaveout — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout', 'on'`, then, for each of the n observations (where n is the value in the `NumObservations` property of the model), the software completes these steps:

- 1 Reserve the observation as validation data, and train the model using the other $n - 1$ observations.
- 2 Store the n compact, trained models in the cells of an n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout', 'on'`

Data Types: `char`

Options — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.

- Specify 'Options', `statset('UseParallel',1)`.

Output Arguments

CVMdl — Cross-validated ECOC model

ClassificationPartitionedECOC model

Cross-validated ECOC model, returned as a ClassificationPartitionedECOC model.

Examples

Cross-Validate ECOC Classifier

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
rng(1); % For reproducibility
```

Create an SVM template. It is good practice to standardize the predictors.

```
t = templateSVM('Standardize',1)
```

```
t =
Fit template for classification SVM.
```

```
          Alpha: [0x1 double]
BoxConstraint: []
  CacheSize: []
CachingMethod: ''
   ClipAlphas: []
DeltaGradientTolerance: []
      Epsilon: []
   GapTolerance: []
  KKTolerance: []
IterationLimit: []
KernelFunction: ''
   KernelScale: []
  KernelOffset: []
```

```
KernelPolynomialOrder: []
  NumPrint: []
  Nu: []
  OutlierFraction: []
  RemoveDuplicates: []
  ShrinkagePeriod: []
  Solver: ''
  StandardizeData: 1
  SaveSupportVectors: []
  VerbosityLevel: []
  Version: 2
  Method: 'SVM'
  Type: 'classification'
```

`t` is an SVM template. All of its properties are empty, except for `StandardizeData`, `Method`, and `Type`. When the software trains the ECOC classifier, it sets the applicable properties to their default values.

Train the ECOC classifier. It is good practice to specify the class order.

```
Mdl = fitcecoc(X,Y,'Learners',t,...
  'ClassNames',{'setosa','versicolor','virginica'});
```

`Mdl` is a `ClassificationECOC` classifier. You can access its properties using dot notation.

Cross-validate `Mdl` using 10-fold cross-validation.

```
CVMdl = crossval(Mdl);
```

`CVMdl` is a `ClassificationPartitionedECOC` cross-validated ECOC classifier.

Estimate the generalization error.

```
oosLoss = kfoldLoss(CVMdl)
```

```
oosLoss = 0.0400
```

The out-of-sample classification error is 4%, which indicates that the ECOC classifier generalizes fairly well.

Cross Validate an ECOC Classifier Using Parallel Computing

Consider the `arrhythmia` data set. There are 16 classes in the study, 13 of which are represented in the data. The first class indicates that the subject did not have arrhythmia, and the last class indicates that the subject's arrhythmia state was not recorded. Suppose that the other classes are ordinal levels indicating the severity of arrhythmia.

Train an ECOC classifier with a custom coding design specified by the description of the classes.

Load the `arrhythmia` data set.

```
load arrhythmia
Y = categorical(Y);
K = unique(Y); % Number of distinct classes
```

Construct a coding matrix that describes the nature of the classes.

```
OrdMat = designecoc(11,'ordinal');
nOM = size(OrdMat);
class1VS0rd = [1; -ones(11,1); 0];
class1VSClass16 = [1; zeros(11,1); -1];
OrdVSClass16 = [0; ones(11,1); -1];
Coding = [class1VS0rd class1VSClass16 OrdVSClass16,...
          [zeros(1,nOM(2)); OrdMat; zeros(1,nOM(2))]];
```

Train an ECOC classifier using the custom coding design (`Coding`) and parallel computing. Specify to use an ensemble of 50 classification trees boosted using `GentleBoost`.

```
t = templateEnsemble('GentleBoost',50,'Tree');
options = statset('UseParallel',1);
Mdl = fitcecoc(X,Y,'Coding',Coding,'Learners',t,'Options',options);
```

`Mdl` is a `ClassificationECOC` model. You can access its properties using dot notation.

Cross validate `Mdl` using 8-fold cross validation and parallel computing.

```
rng(1); % For reproducibility
CVMdl = crossval(Mdl,'Options',options,'KFold',8);
```

Warning: One or more folds do not contain points from all the groups.

Since some of the classes have low relative frequency, some of the folds do not train using observations from those classes. `CVMdl` is a `ClassificationPartitionedECOC` cross-validated ECOC model.

Estimate the generalization error using parallel computing.

```
oosLoss = kfoldLoss(CVMdl, 'Options', options)
```

```
oosLoss =
```

```
    0.3208
```

The out-of-sample classification error is 32%, which indicates that this model does not generalize well. To improve the model, try training using a different boosting method, such as `RobustBoost`, or a different algorithm altogether, such as `SVM`.

- “Quick Start Parallel Computing for Statistics and Machine Learning Toolbox” on page 30-2

Tips

Assess the predictive performance of `Mdl` on cross-validated data using the `kfold` functions and properties of `CVMdl`, such as `kfoldLoss`.

Alternatives

Instead of training an ECOC model and then cross validating it, you can create a cross-validated ECOC model directly using `fitcecoc` and by specifying any of these name-value pair arguments: `CrossVal`, `CVPartition`, `Holdout`, `Leaveout`, or `KFold`.

crossval

Class: ClassificationEnsemble

Cross validate ensemble

Syntax

```
cvens = crossval(ens)
cvens = crossval(ens,Name,Value)
```

Description

`cvens = crossval(ens)` creates a cross-validated ensemble from `ens`, a classification ensemble. Default is 10-fold cross validation.

`cvens = crossval(ens,Name,Value)` creates a cross-validated ensemble with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

`ens`

A classification ensemble created with `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`cvpartition`

A partition of class `cvpartition`. Sets the partition for cross validation.

Use no more than one of the name-value pairs `cvpartition`, `holdout`, `kfold`, or `leaveout`.

holdout

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated tree: `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

kfold

Number of folds for cross validation, a numeric positive scalar greater than 1.

Use no more than one of the name-value pairs `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

leaveout

If `'on'`, use leave-one-out cross validation.

Use no more than one of the name-value pairs `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

nprint

Printout frequency, a positive integer scalar. Use this parameter to observe the training of cross-validation folds.

Default: `'off'`, meaning no printout

Output Arguments

cvens

A cross-validated classification ensemble of class `ClassificationPartitionedEnsemble`.

Examples

Cross-Validate Classification Ensemble

Create a cross-validated classification model for the Fisher iris data, and assess its quality using the `kfoldLoss` method.

Load the Fisher iris data set.

```
load fisheriris
```

Train an ensemble of 100 boosted classification trees using `AdaBoostM2`.

```
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Create a cross-validated ensemble from `ens` and find the classification error averaged over all folds.

```
rng(10,'twister') % For reproducibility
cvens = crossval(ens);
L = kfoldLoss(cvens)
```

```
L = 0.0467
```

Alternatives

You can create a cross-validation ensemble directly from the data, instead of creating an ensemble followed by a cross-validation ensemble. To do so, include one of these five options in `fitcensemble`: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

See Also

`ClassificationPartitionedEnsemble` | `cvpartition`

crossval

Class: ClassificationKNN

Cross-validated *k*-nearest neighbor classifier

Syntax

```
cvmodel = crossval mdl
cvmodel = crossval mdl, Name, Value
```

Description

`cvmodel = crossval(mdl)` creates a partitioned model from `mdl`, a fitted KNN classification model. By default, `crossval` uses 10-fold cross validation on the training data to create `cvmodel`.

`cvmodel = crossval(mdl, Name, Value)` creates a partitioned model with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

mdl — Classifier model

classifier model object

k-nearest neighbor classifier model, returned as a classifier model object.

Note that using the 'CrossVal', 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a model of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `mdl` is of class `ClassificationKNN`, and you can use the `predict` method to make predictions.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

CVPartition

Object of class `cvpartition`, created by the `cvpartition` function. `crossval` splits the data into subsets with `cvpartition`.

Use only one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Holdout

Holdout validation tests the specified fraction of the data, and uses the remaining data for training. Specify a numeric scalar from 0 to 1. Use only one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

KFold

Number of folds to use in a cross-validated tree, a positive integer greater than 1.

Use only one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Default: 10

Leaveout

Set to 'on' for leave-one-out cross validation.

Use only one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Output Arguments

cvmodel

Partitioned model of class `ClassificationPartitionedModel`.

Examples

Cross-Validated K-Nearest Neighbor Model

Construct a cross-validated k -nearest neighbor model, and assess classification performance using the model.

Load the data.

```
load fisheriris
X = meas;
Y = species;
```

Construct a classifier for nearest neighbors.

```
mdl = fitcknn(X,Y);
```

Construct a cross-validated classifier.

```
cvmdl = crossval(mdl)
```

```
cvmdl =
classreg.learning.partition.ClassificationPartitionedModel
  CrossValidatedModel: 'KNN'
    PredictorNames: {'x1' 'x2' 'x3' 'x4'}
      ResponseName: 'Y'
  NumObservations: 150
        KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
```

Properties, Methods

Find the cross-validated loss of the classifier.

```
cvmdlloss = kfoldLoss(cvmdl)
```

```
cvmdlloss = 0.0467
```

The cross-validated loss is less than 5%. You can expect `mdl` to have a similar error rate.

- “Examine Quality of KNN Classifier” on page 18-37
- “Modify KNN Classifier” on page 18-38

Tips

- Assess the predictive performance of `mdl` on cross-validated data using the “kfold” methods and properties of `cvmodel`, such as `kfoldLoss`.

Alternatives

You can create a cross-validated model directly from the data, instead of creating a model followed by a cross-validated model. To do so, include one of these options in `fitcknn`: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

crossval

Class: ClassificationNaiveBayes

Cross-validated naive Bayes classifier

Syntax

```
CVmdl = crossval(Mdl)
CVmdl = crossval(Mdl,Name,Value)
```

Description

`CVmdl = crossval(Mdl)` returns a partitioned naive Bayes classifier (`CVSMdl`) from a trained naive Bayes classifier (`Mdl`).

By default, `crossval` uses 10-fold cross validation on the training data to create `CVmdl`.

`CVmdl = crossval(Mdl,Name,Value)` returns a partitioned naive Bayes classifier with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify a holdout sample proportion.

Input Arguments

Mdl — Fully trained naive Bayes classifier

ClassificationNaiveBayes model

A fully trained naive Bayes classifier, specified as a `ClassificationNaiveBayes` model trained by `fitcnb`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

CVPartition — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: 'CVPartition', 'Holdout', 'Kfold', or 'Leaveout'.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500, 'Kfold', 5)`. Then, you can specify the cross-validated model by using 'CVPartition', `cvp`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p , then the software completes these steps:

- 1 Randomly select and reserve $p*100\%$ of the data as validation data, and train the model using the rest of the data.
- 2 Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, Kfold, or Leaveout.

Example: 'Holdout', 0.1

Data Types: `double` | `single`

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'Kfold' and a positive integer value greater than 1. If you specify 'Kfold', k , then the software completes these steps.

- 1 Randomly partition the data into k sets.
- 2 For each set, reserve the set as validation data, and train the model using the other $k - 1$ sets.
- 3 Store the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

Leaveout — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout', 'on'`, then, for each of the n observations (where n is the value in the `NumObservations` property of the model), the software completes these steps:

- 1 Reserve the observation as validation data, and train the model using the other $n - 1$ observations.
- 2 Store the n compact, trained models in the cells of an n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout', 'on'`

Data Types: `char`

Output Arguments

CVMDL — Cross-validated naive Bayes classifier

`ClassificationPartitionedModel` model

Cross-validated naive Bayes classifier, returned as a `ClassificationPartitionedModel` model.

Examples

Cross Validate a Naive Bayes Classifier Using crossval

Load the ionosphere data set.

```
load ionosphere
X = X(:,3:end); % Remove first two predictors for stability
rng(1);        % For reproducibility
```

Train a naive Bayes classifier. It is good practice to define the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X,Y, 'ClassNames', {'b', 'g'});
```

Mdl is a trained `ClassificationNaiveBayes` classifier. 'b' is the negative class and 'g' is the positive class.

Cross validate the classifier using 10-fold cross validation.

```
CVMDL = crossval(Mdl)
```

```
CVMDL =
classreg.learning.partition.ClassificationPartitionedModel
  CrossValidatedModel: 'NaiveBayes'
  PredictorNames: {1x32 cell}
  ResponseName: 'Y'
  NumObservations: 351
  KFold: 10
  Partition: [1x1 cvpartition]
  ClassNames: {'b' 'g'}
  ScoreTransform: 'none'
```

Properties, Methods

```
FirstModel = CVMDL.Trained{1}
```

```
FirstModel =
classreg.learning.classif.CompactClassificationNaiveBayes
  ResponseName: 'Y'
  CategoricalPredictors: []
```

```

        ClassNames: {'b' 'g'}
        ScoreTransform: 'none'
        DistributionNames: {1x32 cell}
        DistributionParameters: {2x32 cell}

```

Properties, Methods

`CVMDL` is a `ClassificationPartitionedModel` cross-validated classifier. The software:

- 1 Randomly partitions the data into 10, equally sized sets.
- 2 Trains a naive Bayes classifier on nine of the sets.
- 3 Repeats steps 1 and 2 $k = 10$ times. It excludes one partition each time, and trains on the other nine partitions.
- 4 Combines generalization statistics for each fold.

`FirstModel` is the first of the 10 trained classifiers. It is a `CompactClassificationNaiveBayes` model.

You can estimate the generalization error by passing `CVMDL` to `kfoldLoss`.

Specify a Holdout-Sample Proportion for Naive Bayes Cross Validation

By default, `crossval` uses 10-fold cross validation to cross validate a naive Bayes classifier. You have several other options, such as specifying a different number of folds or holdout-sample proportion. This example shows how to specify a holdout-sample proportion.

Load the `ionosphere` data set.

```

load ionosphere
X = X(:,3:end); % Remove first two predictors for stability
rng(1);        % For reproducibility

```

Train a naive Bayes classifier. Assume that each predictor is conditionally, normally distributed given its label. It is good practice to define the class order.

```

Mdl = fitcnb(X,Y,'ClassNames',{'b','g'});

```

Mdl is a trained `ClassificationNaiveBayes` classifier. 'b' is the negative class and 'g' is the positive class.

Cross validate the classifier by specifying a 30% holdout sample.

```
CVMdl = crossval(Mdl, 'Holdout', 0.30)
```

```
CVMdl =  
classreg.learning.partition.ClassificationPartitionedModel  
  CrossValidatedModel: 'NaiveBayes'  
  PredictorNames: {1x32 cell}  
  ResponseName: 'Y'  
  NumObservations: 351  
  KFold: 1  
  Partition: [1x1 cvpartition]  
  ClassNames: {'b' 'g'}  
  ScoreTransform: 'none'
```

Properties, Methods

```
TrainedModel = CVMdl.Trained{1}
```

```
TrainedModel =  
classreg.learning.classif.CompactClassificationNaiveBayes  
  ResponseName: 'Y'  
  CategoricalPredictors: []  
  ClassNames: {'b' 'g'}  
  ScoreTransform: 'none'  
  DistributionNames: {1x32 cell}  
  DistributionParameters: {2x32 cell}
```

Properties, Methods

CVMdl is a `ClassificationPartitionedModel`. TrainedModel is a `CompactClassificationNaiveBayes` classifier trained using 70% of the data.

Estimate the generalization error.

```
kfoldLoss(CVMdl)
```

```
ans = 0.2571
```

The out-of-sample misclassification error is approximately 2.6%.

Tips

Assess the predictive performance of `Mdl` on cross-validated data using the “`kfold`” function and properties of `CVMdl`, such as `kfoldLoss`.

Alternatives

Instead of creating a naive Bayes classifier followed by a cross-validation classifier, create a cross-validated classifier directly using `fitcnb` and by specifying any of these name-value pair arguments: `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'Leaveout'`, or `'KFold'`.

crossval

Cross-validate support vector machine (SVM) classifier

Syntax

```
CVSVMMModel = crossval(SVMMModel)
CVSVMMModel = crossval(SVMMModel,Name,Value)
```

Description

`CVSVMMModel = crossval(SVMMModel)` returns a cross-validated (partitioned) support vector machine (SVM) classifier (`CVSVMMModel`) from a trained SVM classifier (`SVMMModel`). By default, `crossval` uses 10-fold cross-validation on the training data to create `CVSVMMModel`, a `ClassificationPartitionedModel` classifier.

`CVSVMMModel = crossval(SVMMModel,Name,Value)` returns a partitioned SVM classifier with additional options specified by one or more name-value pair arguments. For example, you can specify the number of folds or holdout sample proportion.

Examples

Cross-Validate SVM Classifier

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Standardize the predictor data and specify the order of the classes.

```
SVMMModel = fitcsvm(X,Y,'Standardize',true,'ClassNames',{'b','g'});
```

`SVMMModel` is a trained `ClassificationSVM` classifier. 'b' is the negative class and 'g' is the positive class.

Cross-validate the classifier using 10-fold cross-validation.

```
CVSVMModel = crossval(SVMModel)
```

```
CVSVMModel =
  classreg.learning.partition.ClassificationPartitionedModel
    CrossValidatedModel: 'SVM'
      PredictorNames: {1x34 cell}
      ResponseName: 'Y'
      NumObservations: 351
      KFold: 10
      Partition: [1x1 cvpartition]
      ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
```

Properties, Methods

```
FirstModel = CVSVMModel.Trained{1}
```

```
FirstModel =
  classreg.learning.classif.CompactClassificationSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
      ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
      Alpha: [78x1 double]
      Bias: -0.2209
      KernelParameters: [1x1 struct]
        Mu: [1x34 double]
        Sigma: [1x34 double]
      SupportVectors: [78x34 double]
      SupportVectorLabels: [78x1 double]
```

Properties, Methods

CVSVMModel is a `ClassificationPartitionedModel` cross-validated classifier. During cross-validation, the software completes these steps:

- 1 Randomly partition the data into 10 sets of equal size.
- 2 Train an SVM classifier on nine of the sets.

- 3 Repeat steps 1 and 2 $k = 10$ times. The software leaves out one partition each time and trains on the other nine partitions.
- 4 Combine generalization statistics for each fold.

`FirstModel` is the first of the 10 trained classifiers. It is a `CompactClassificationSVM` classifier.

You can estimate the generalization error by passing `CVSVMModel` to `kfoldLoss`.

Specify Holdout Sample Proportion for SVM Cross-Validation

Specify a holdout sample proportion for cross-validation. By default, `crossval` uses 10-fold cross-validation to cross-validate an SVM classifier. However, you have several other options for cross-validation. For example, you can specify a different number of folds or holdout sample proportion.

Load the `ionosphere` data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class.

```
SVModel = fitcsvm(X,Y,'Standardize',true,'ClassNames',{'b','g'});
```

`SVModel` is a trained `ClassificationSVM` classifier.

Cross-validate the classifier by specifying a 15% holdout sample.

```
CVSVMModel = crossval(SVModel,'Holdout',0.15)
```

```
CVSVMModel =
  classreg.learning.partition.ClassificationPartitionedModel
  CrossValidatedModel: 'SVM'
  PredictorNames: {1x34 cell}
  ResponseName: 'Y'
  NumObservations: 351
  KFold: 1
  Partition: [1x1 cvpartition]
  ClassNames: {'b' 'g'}
  ScoreTransform: 'none'
```

Properties, Methods

CVSVMModel is a ClassificationPartitionedModel.

Display properties of the classifier trained using 85% of the data.

```
TrainedModel = CVSVMModel.Trained{1}
```

```
TrainedModel =  
  classreg.learning.classif.CompactClassificationSVM  
    ResponseName: 'Y'  
  CategoricalPredictors: []  
    ClassNames: {'b' 'g'}  
    ScoreTransform: 'none'  
      Alpha: [74x1 double]  
      Bias: -0.2952  
    KernelParameters: [1x1 struct]  
      Mu: [1x34 double]  
      Sigma: [1x34 double]  
    SupportVectors: [74x34 double]  
    SupportVectorLabels: [74x1 double]
```

Properties, Methods

TrainedModel is a CompactClassificationSVM classifier trained using 85% of the data.

Estimate the generalization error.

```
kfoldLoss(CVSVMModel)
```

```
ans = 0.0769
```

The out-of-sample misclassification error is approximately 8%.

Input Arguments

SVMModel — Full, trained SVM classifier

ClassificationSVM classifier

Full, trained SVM classifier, specified as a ClassificationSVM model trained with `fitcsvm`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `crossval(SVMModel, 'KFold', 5)` specifies using five folds in a cross-validated model.

CVPartition — Cross-validation partition

[] (default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500, 'KFold', 5)`. Then, you can specify the cross-validated model by using 'CVPartition', `cvp`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p , then the software completes these steps:

- 1 Randomly select and reserve $p*100\%$ of the data as validation data, and train the model using the rest of the data.

- 2 Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

KFold — Number of folds

`10` (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1. If you specify `'KFold',k`, then the software completes these steps.

- 1 Randomly partition the data into k sets.
- 2 For each set, reserve the set as validation data, and train the model using the other $k - 1$ sets.
- 3 Store the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

Leaveout — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout','on'`, then, for each of the n observations (where n is the value in the `NumObservations` property of the model), the software completes these steps:

- 1 Reserve the observation as validation data, and train the model using the other $n - 1$ observations.
- 2 Store the n compact, trained models in the cells of an n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout', 'on'`

Data Types: `char`

Tips

Assess the predictive performance of `SVMModel` on cross-validated data by using the “kfold” methods and properties of `CVSVMModel`, such as `kfoldLoss`.

Alternative Functionality

Instead of training an SVM classifier and then cross-validating it, you can create a cross-validated classifier directly by using `fitcsvm` and specifying any of these name-value pair arguments: `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'Leaveout'`, or `'KFold'`.

`CompactClassificationSVM` | `cvpartition` | `fitcsvm`

Introduced in R2014a

crossval

Class: ClassificationTree

Cross-validated decision tree

Syntax

```
cvmodel = crossval(model)
cvmodel = crossval(model,Name,Value)
```

Description

`cvmodel = crossval(model)` creates a partitioned model from `model`, a fitted classification tree. By default, `crossval` uses 10-fold cross validation on the training data to create `cvmodel`.

`cvmodel = crossval(model,Name,Value)` creates a partitioned model with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

model

A classification model, produced using `fitctree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

CVPartition

Object of class `cvpartition`, created by the `cvpartition` function. `crossval` splits the data into subsets with `cvpartition`.

Use only one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Holdout

Holdout validation tests the specified fraction of the data, and uses the remaining data for training. Specify a numeric scalar from 0 to 1. Use only one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

KFold

Number of folds to use in a cross-validated tree, a positive integer greater than 1.

Use only one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Default: 10

Leaveout

Set to 'on' for leave-one-out cross validation.

Use only one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Output Arguments

cvmodel

Partitioned model of class `ClassificationPartitionedModel`.

Examples

Create a Cross-Validation Model

Create a classification model for the ionosphere data, then create a cross-validation model. Evaluate the quality the model using `kfoldLoss`.

```
load ionosphere
tree = fitctree(X,Y);
cvmodel = crossval(tree);
L = kfoldLoss(cvmodel)

L = 0.1111
```

Tips

- Assess the predictive performance of `model` on cross-validated data using the “kfold” methods and properties of `cvmodel`, such as `kfoldLoss`.

Alternatives

You can create a cross-validation tree directly from the data, instead of creating a decision tree followed by a cross-validation tree. To do so, include one of these five options in `fitctree`: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

See Also

`crossval` | `fitctree`

crossval

Class: RegressionEnsemble

Cross validate ensemble

Syntax

```
cvens = crossval(ens)
cvens = crossval(ens,Name,Value)
```

Description

`cvens = crossval(ens)` creates a cross-validated ensemble from `ens`, a regression ensemble. Default is 10-fold cross validation.

`cvens = crossval(ens,Name,Value)` creates a cross-validated ensemble with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

`ens`

A regression ensemble created with `fitrensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`cvpartition`

A partition of class `cvpartition`. Sets the partition for cross validation.

Use no more than one of the name-value pairs `cvpartition`, `holdout`, `kfold`, and `leaveout`.

holdout

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated tree: `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

kfold

Number of folds for cross validation, a positive integer value greater than 1.

Use no more than one of the name-value pairs `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

leaveout

If `'on'`, use leave-one-out cross-validation.

Use no more than one of the name-value pairs `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

nprint

Printout frequency, a positive integer scalar. Use this parameter to observe the training of cross-validation folds.

Default: `'off'`, meaning no printout

Output Arguments

cvens

A cross-validated classification ensemble of class `RegressionPartitionedEnsemble`.

Examples

Create Cross-Validated Regression Model

Create a cross-validated regression model for the `carsmall` data, and evaluate its quality using the `kfoldLoss` method.

Load the `carsmall` data set and select acceleration, displacement, horsepower, and vehicle weight as predictors.

```
load carsmall;  
X = [Acceleration Displacement Horsepower Weight];
```

Train a regression ensemble.

```
rens = fitensemble(X,MPG);
```

Create a cross-validated ensemble from `rens` and find the cross-validation loss.

```
rng(10,'twister') % For reproducibility  
cvens = crossval(rens);  
L = kfoldLoss(cvens)
```

```
L = 31.8744
```

Alternatives

You can create a cross-validation ensemble directly from the data, instead of creating an ensemble followed by a cross-validation ensemble. To do so, include one of these five options in `fitensemble`: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

See Also

`RegressionPartitionedEnsemble` | `cvpartition` | `kfoldLoss`

crossval

Class: RegressionGP

Cross-validate Gaussian process regression model

Syntax

```
cvMdl = crossval(gprMdl)
cvmdl = crossval(gprMdl, Name, Value)
```

Description

`cvMdl = crossval(gprMdl)` returns the partitioned model, `cvMdl`, built from the Gaussian process regression (GPR) model, `gprMdl`, using 10-fold cross validation.

`cvmdl` is a `RegressionPartitionedModel` object, and `gprMdl` is a `RegressionGP` (full) object.

`cvmdl = crossval(gprMdl, Name, Value)` returns the partitioned model, `cvmdl`, with additional options specified by one or more `Name, Value` pair arguments. For example, you can specify the number of folds or the fraction of the data to use for testing.

Input Arguments

gprMdl — Gaussian process regression model

RegressionGP object

Gaussian process regression model, specified as a `RegressionGP` (full) object. You cannot call `crossval` on a compact regression object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

CVPartition — Random partition for a *k*-fold cross validation

`cvpartition` object

Random partition for a *k*-fold cross validation, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` object.

Example: 'CVPartition', `cvp` uses the random partition defined by `cvp`.

If you specify `CVPartition`, then you cannot specify `Holdout`, `KFold`, or `LeaveOut`.

Holdout — Fraction of data to use for testing

scalar value in the range from 0 to 1

Fraction of the data to use for testing in holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range from 0 to 1. If you specify 'Holdout', *p*, then `crossval`:

1. Randomly reserves $p*100\%$ of the data as validation data, and trains the model using the rest of the data
2. Stores the compact, trained model in `cvgprMdl.Trained`.

Example: 'Holdout', 0.3 uses 30% of the data for testing and 70% of the data for training.

If you specify `Holdout`, then you cannot specify `CVPartition`, `KFold`, or `Leaveout`.

Data Types: `single` | `double`

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in cross-validated GPR model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. `Kfold` must be greater than 1. If you specify 'Kfold', *k* then `crossval`:

1. Randomly partitions the data into *k* sets.
2. For each set, reserves the set as test data, and trains the model using the other *k* - 1 sets.
3. Stores the *k* compact, trained models in the cells of a *k*-by-1 cell array in `cvgprMdl.Trained`.

Example: 'KFold', 5 uses 5 folds in cross-validation. That is, for each fold, it uses that fold as test data, and trains the model on the remaining 4 folds.

If you specify `KFold`, then you cannot specify `CVPartition`, `Holdout`, or `Leaveout`.

Data Types: `single` | `double`

Leaveout — Indicator for leave-one-out cross-validation

'off' (default) | 'on'

Indicator for leave-one-out cross-validation, specified as the comma-separated pair consisting of 'LeaveOut' and either 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the n observations, `crossval`:

1. Reserves the observation as test data, and trains the model using the other $n - 1$ observations.
2. Stores the n compact, trained models in the cells of a n -by-1 cell array in `cvgprMdl.Trained`.

Example: 'Leaveout', 'on'

If you specify `Leaveout`, then you cannot specify `CVPartition`, `Holdout`, or `KFold`.

Output Arguments

cvgprMdl — Partitioned Gaussian process regression model

`RegressionPartitionedModel` object

Partitioned Gaussian process regression model, returned as a `RegressionPartitionedModel` object.

Examples

Partition Data for Cross-Validation

Download the housing data [1], from the UCI Machine Learning Repository [4].

The dataset has 506 observations. The first 13 columns contain the predictor values and the last column contains the response values. The goal is to predict the median value of owner-occupied homes in suburban Boston as a function of 13 predictors.

Load the data and define the response vector and the predictor matrix.

```
load('housing.data');  
X = housing(:,1:13);  
y = housing(:,end);
```

Fit a GPR model using the squared exponential kernel function with separate length scale for each predictor. Standardize the predictor variables.

```
gprMdl = fitrgp(X,y,'KernelFunction','ardsquaredexponential','Standardize',1);
```

Create a cross-validation partition for data using predictor 4 as a grouping variable.

```
rng('default') % For reproducibility  
cvp = cvpartition(X(:,4),'kfold',10);
```

Create a 10-fold cross-validated model using the partitioned data in `cvp`.

```
cvgprMdl = crossval(gprMdl,'CVPartition',cvp);
```

Compute the regression loss for in-fold observations using models trained on out-of-fold observations.

```
L = kfoldLoss(cvgprMdl)
```

```
L =
```

```
9.5299
```

Predict the response for in-fold observations, i.e. observations not used for training.

```
ypred = kfoldPredict(cvgprMdl);
```

For every fold, `kfoldPredict` predicts responses for observations in that fold using the models trained on out-of-fold observations.

Plot the actual responses and prediction data.

```
plot(y,'r.');
```

```
hold on;  
plot(ypred,'b--.');
```

```
axis([0 510 -15 65]);  
legend('True response','GPR prediction','Location','Best');  
hold off;
```

Train GPR Model Using 4-Fold Cross Validation

Download the abalone data [2], [3], from the UCI Machine Learning Repository [4] and save it in your current directory with the name 'abalone.data'.

Read the data into a table.

```
tbl = readtable('abalone.data', 'Filetype', 'text', 'ReadVariableNames', false);
```

The dataset has 4177 observations. The goal is to predict the age of abalone from 8 physical measurements.

Fit a GPR model using the subset of regressors (sr) method for parameter estimation and fully independent conditional (fic) method for prediction. Standardize the predictors and use a squared exponential kernel function with a separate length scale for each predictor.

```
gprMdl = fitrgp(tbl, tbl(:, end), 'KernelFunction', 'ardsquaredexponential', ...
    'FitMethod', 'sr', 'PredictMethod', 'fic', 'Standardize', 1);
```

Cross-validate the model using 4-fold cross validation. This partitions the data into 4 sets. For each set, `fitrgp` uses that set (25% of the data) as the test data, and trains the model on the remaining 3 sets (75% of the data).

```
rng('default') % For reproducibility
cvgprMdl = crossval(gprMdl, 'KFold', 4);
```

Compute the loss over individual folds.

```
L = kfoldLoss(cvgprMdl, 'mode', 'individual')
```

```
L =
```

```
4.3669
4.6896
4.0565
4.3162
```

Compute the average cross-validated loss on over all folds. The default is the mean squared error.

```
L2 = kfoldLoss(cvgprMdl)
```

```
L2 =
```

```
4.3573
```

This is equal to the mean loss over individual folds.

```
mse = mean(L)
```

```
mse =
```

```
4.3573
```

- “Train GPR Model Using Cross-Validation” on page 32-2291

Tips

- You can only use one of the name-value pair arguments at a time.
- You cannot compute the prediction intervals for a cross-validated model.

Alternatives

Alternatively, you can train a cross-validated model using the related name-value pair arguments in `fitrgp`.

If you supply a custom 'ActiveSet' in the call to `fitrgp`, then you cannot cross validate the GPR model.

Topics

"Train GPR Model Using Cross-Validation" on page 32-2291

Introduced in R2015b

crossval

Class: RegressionSVM

Cross-validated support vector machine regression model

Syntax

```
CVMdl = crossval mdl
CVMdl = crossval mdl, Name, Value
```

Description

`CVMdl = crossval(mdl)` returns a cross-validated (partitioned) support vector machine regression model, `CVMdl`, from a trained SVM regression model, `mdl`.

`CVMdl = crossval(mdl, Name, Value)` returns a cross-validated model with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

mdl — Full, trained SVM regression model

RegressionSVM model

Full, trained SVM regression model, specified as a RegressionSVM model returned by `fitcsvm`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

CVPartition — Cross-validation partition

[] (default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object as created by cvpartition. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500, 'KFold', 5)`. Then, you can specify the cross-validated model by using 'CVPartition', `cvp`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p , then the software completes these steps:

- 1 Randomly select and reserve $p*100\%$ of the data as validation data, and train the model using the rest of the data.
- 2 Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Holdout', 0.1

Data Types: double | single

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold', k , then the software completes these steps.

- 1 Randomly partition the data into k sets.

- 2 For each set, reserve the set as validation data, and train the model using the other $k - 1$ sets.
- 3 Store the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

Leaveout — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout', 'on'`, then, for each of the n observations (where n is the value in the `NumObservations` property of the model), the software completes these steps:

- 1 Reserve the observation as validation data, and train the model using the other $n - 1$ observations.
- 2 Store the n compact, trained models in the cells of an n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout', 'on'`

Data Types: `char`

Output Arguments

CVMdl — Cross-validated SVM regression model

`RegressionPartitionedSVM` model

Cross-validated SVM regression model, returned as a `RegressionPartitionedSVM` model.

Examples

Train Cross-Validated SVM Regression Model Using crossval

This example shows how to train a cross-validated SVM regression model using `crossval`.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current folder with the name `'abalone.data'`. Read the data into a `table`.

```
tbl = readtable('abalone.data', 'Filetype', 'text', 'ReadVariableNames', false);
rng default % for reproducibility
```

The sample data contains 4177 observations. All the predictor variables are continuous except for sex, which is a categorical variable with possible values 'M' (for males), 'F' (for females), and 'I' (for infants). The goal is to predict the number of rings on the abalone and determine its age using physical measurements.

Train an SVM regression model, using a Gaussian kernel function with a kernel scale equal to 2.2. Standardize the data.

```
mdl = fitrsvm(tbl, 'Var9', 'KernelFunction', 'gaussian', 'KernelScale', 2.2, 'Standardize', true);
```

`mdl` is a trained `RegressionSVM` regression model.

Cross validate the model using 10-fold cross validation.

```
CVmdl = crossval(mdl)
```

```
CVmdl =
```

```
classreg.learning.partition.RegistrationPartitionedSVM
  CrossValidatedModel: 'SVM'
  PredictorNames: {1x8 cell}
  CategoricalPredictors: 1
  ResponseName: 'Var9'
  NumObservations: 4177
  KFold: 10
  Partition: [1x1 cvpartition]
  ResponseTransform: 'none'
```

Properties, Methods

CVMDL is a `RegressionPartitionedSVM` cross-validated regression model. The software:

1. Randomly partitions the data into 10 equally sized sets.
2. Trains an SVM regression model on nine of the 10 sets.
3. Repeats steps 1 and 2 $k = 10$ times. It leaves out one of the partitions each time, and trains on the other nine partitions.
4. Combines generalization statistics for each fold.

Calculate the resubstitution loss for the cross-validated model.

```
loss = kfoldLoss(CVMDL)
```

```
loss =
```

```
4.5712
```

Specify Cross-Validation Holdout Proportion for SVM Regression

This example shows how to specify a holdout proportion for training a cross-validated SVM regression model.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current folder with the name `'abalone.data'`. Read the data into a `table`.

```
tbl = readtable('abalone.data', 'Filetype', 'text', 'ReadVariableNames', false);  
rng default % for reproducibility
```

The sample data contains 4177 observations. All the predictor variables are continuous except for `sex`, which is a categorical variable with possible values 'M' (for males), 'F' (for females), and 'I' (for infants). The goal is to predict the number of rings on the abalone and determine its age using physical measurements.

Train an SVM regression model, using a Gaussian kernel function with an automatic kernel scale. Standardize the data.

```
mdl = fitrsvm(tbl, 'Var9', 'KernelFunction', 'gaussian', 'KernelScale', 'auto', 'Standardize
```

mdl is a trained RegressionSVM regression model.

Cross validate the regression model by specifying a 10% holdout sample.

```
CVMdl = crossval(mdl, 'Holdout', 0.1)
```

```
CVMdl =
```

```
classreg.learning.partition.RegistrationPartitionedSVM
  CrossValidatedModel: 'SVM'
  PredictorNames: {1x8 cell}
  CategoricalPredictors: 1
  ResponseName: 'Var9'
  NumObservations: 4177
  KFold: 1
  Partition: [1x1 cvpartition]
  ResponseTransform: 'none'
```

Properties, Methods

CVMdl is a RegressionPartitionedSVM model object.

Calculate the resubstitution loss for the cross-validated model.

```
loss = kfoldLoss(CVMdl)
```

```
loss =
```

```
5.2499
```

Alternatives

Instead of training an SVM regression model and then cross-validating it, you can create a cross-validated model directly by using `fitrsvm` and specifying any of these name-value pair arguments: 'CrossVal', 'CVPartition', 'Holdout', 'Leaveout', or 'KFold'.

`CompactRegressionSVM` | `RegressionPartitionedSVM` | `RegressionSVM` | `fitrsvm` | `kfoldLoss` | `kfoldPredict`

Introduced in R2015b

crossval

Class: RegressionTree

Cross-validated decision tree

Syntax

```
cvmodel = crossval(model)
cvmodel = crossval(model,Name,Value)
```

Description

`cvmodel = crossval(model)` creates a partitioned model from `model`, a fitted regression tree. By default, `crossval` uses 10-fold cross validation on the training data to create `cvmodel`.

`cvmodel = crossval(model,Name,Value)` creates a partitioned model with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

model

A regression model, produced using `fitrtree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

CVPartition

Object of class `cvpartition`, created by the `cvpartition` function. `crossval` splits the data into subsets with `cvpartition`.

Use only one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Default: []

Holdout

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated tree: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

KFold

Number of folds to use in a cross-validated tree, a positive integer value greater than 1.

Use only one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Default: 10

Leaveout

Set to 'on' for leave-one-out cross-validation.

Output Arguments

cvmodel

A partitioned model of class `RegressionPartitionedModel`.

Examples

Cross-Validate Regression Tree

Load the `carsmall` data set. Consider `Acceleration`, `Displacement`, `Horsepower`, and `Weight` as predictor variables.

```
load carsmall
X = [Acceleration Displacement Horsepower Weight];
```

Grow a regression tree using the entire data set.

```
Mdl = fitrtree(X,MPG);
```

`Mdl` is a `RegressionTree` model.

Cross-validate the regression tree using 10-fold cross-validation.

```
CVMDL = crossval(Mdl);
```

`CVMDL` is a `RegressionPartitionedModel` cross-validated model. `crossval` stores the ten trained, compact regression trees in the `Trained` property of `CVMDL`.

Display the compact regression tree that `crossval` trained using all observations except those in the first fold.

```
CVMDL.Trained{1}
```

```
ans =
  classreg.learning.regr.CompactRegressionTree
      PredictorNames: {'x1' 'x2' 'x3' 'x4'}
      ResponseName: 'Y'
      CategoricalPredictors: []
      ResponseTransform: 'none'
```

Properties, Methods

Estimate the generalization error of `Mdl` by computing the 10-fold cross-validated mean-squared error.

```
L = kfoldLoss(CVMDL)
```

```
L = 23.8065
```

Tips

- Assess the predictive performance of `model` on cross-validated data using the “kfold” methods and properties of `cvmodel`, such as `kfoldLoss`.

Alternatives

You can create a cross-validation tree directly from the data, instead of creating a decision tree followed by a cross-validation tree. To do so, include one of these five options in `fitrtree`: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

See Also

`crossval` | `fitrtree`

cutcategories

Class: classregtree

Cut categories

Note classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

Syntax

```
C = cutcategories(t)
C = cutcategories(t,nodes)
```

Description

`C = cutcategories(t)` returns an n -by-2 cell array `C` of the categories used at branches in the decision tree `t`, where n is the number of nodes. For each branch node i based on a categorical predictor variable x , the left child is chosen if x is among the categories listed in `C{i,1}`, and the right child is chosen if x is among those listed in `C{i,2}`. Both columns of `C` are empty for branch nodes based on continuous predictors and for leaf nodes.

`C = cutcategories(t,nodes)` takes a vector `nodes` of node numbers and returns the categories for the specified nodes.

See Also

`classregtree` | `cutpoint` | `cuttype` | `cutvar`

cutpoint

Class: classregtree

Decision tree cut point values

Note classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

Syntax

```
v = cutpoint(t)
v = cutpoint(t,nodes)
```

Description

`v = cutpoint(t)` returns an n -element vector v of the values used as cut points in the decision tree t , where n is the number of nodes. For each branch node i based on a continuous predictor variable x , the left child is chosen if $x < v(i)$ and the right child is chosen if $x \geq v(i)$. v is NaN for branch nodes based on categorical predictors and for leaf nodes.

`v = cutpoint(t,nodes)` takes a vector `nodes` of node numbers and returns the cut points for the specified nodes.

References

[1] Breiman, L., J. Friedman, R. Olshen, and C. Stone. *Classification and Regression Trees*. Boca Raton, FL: CRC Press, 1984.

See Also

classregtree | cutcategories | cuttype | cutvar

cuttype

Class: classregtree

Cut types

Note classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

Syntax

```
c = cuttype(t)
c = cuttype(t,nodes)
```

Description

`c = cuttype(t)` returns an n -element cell array `c` indicating the type of cut at each node in the tree `t`, where n is the number of nodes. For each node i , `c{i}` is:

- `'continuous'` — If the cut is defined in the form $x < v$ for a variable x and cut point v .
- `'categorical'` — If the cut is defined by whether a variable x takes a value in a set of categories.
- `''` — If i is a leaf node.

`cutvar` returns the cut points for `'continuous'` cuts, and `cutcategories` returns the set of categories.

`c = cuttype(t,nodes)` takes a vector `nodes` of node numbers and returns the cut types for the specified nodes.

References

- [1] Breiman, L., J. Friedman, R. Olshen, and C. Stone. *Classification and Regression Trees*. Boca Raton, FL: CRC Press, 1984.

See Also

`classregtree` | `cutcategories` | `cutvar` | `numnodes`

cutvar

Class: classregtree

Cut variable names

Note classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

Syntax

```
v = cutvar(t)
v = cutvar(t,nodes)
[v,num] = cutvar(...)
```

Description

`v = cutvar(t)` returns an n -element cell array `v` of the names of the variables used for branching in each node of the tree `t`, where n is the number of nodes. These variables are sometimes known as *cut variables*. For leaf nodes, `v` contains an empty character vector.

`v = cutvar(t,nodes)` takes a vector `nodes` of node numbers and returns the cut variables for the specified nodes.

`[v,num] = cutvar(...)` also returns a vector `num` containing the number of each variable.

References

See Also

children | classregtree | numnodes

cvloss

Class: ClassificationTree

Classification error by cross validation

Syntax

```
E = cvloss(tree)
[E,SE] = cvloss(tree)
[E,SE,Nleaf] = cvloss(tree)
[E,SE,Nleaf,BestLevel] = cvloss(tree)
[ ___ ] = cvloss(tree,Name,Value)
```

Description

`E = cvloss(tree)` returns the cross-validated classification error (loss) for `tree`, a classification tree. The `cvloss` method uses stratified partitioning to create cross-validated sets. That is, for each fold, each partition of the data has roughly the same class proportions as in the data used to train `tree`.

`[E,SE] = cvloss(tree)` returns the standard error of `E`.

`[E,SE,Nleaf] = cvloss(tree)` returns the number of leaves of `tree`.

`[E,SE,Nleaf,BestLevel] = cvloss(tree)` returns the optimal pruning level for `tree`.

`[___] = cvloss(tree,Name,Value)` cross validates with additional options specified by one or more `Name, Value` pair arguments, using any of the previous syntaxes. You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Input Arguments

tree — Trained classification tree

ClassificationTree model object

Trained classification tree, specified as a ClassificationTree model object produced by fitctree.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Subtrees — Pruning level

0 (default) | vector of nonnegative integers | 'all'

Pruning level, specified as the comma-separated pair consisting of 'Subtrees' and a vector of nonnegative integers in ascending order or 'all'.

If you specify a vector, then all elements must be at least 0 and at most `max(tree.PruneList)`. 0 indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify 'all', then cvloss operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

cvloss prunes tree to each level indicated in Subtrees, and then estimates the corresponding output arguments. The size of Subtrees determines the size of some output arguments.

To invoke Subtrees, the properties PruneList and PruneAlpha of tree must be nonempty. In other words, grow tree by setting 'Prune', 'on', or by pruning tree using prune.

Example: 'Subtrees', 'all'

TreeSize — Tree size

'se' (default) | 'min'

Tree size, specified as the comma-separated pair consisting of 'TreeSize' and one of the following character vectors:

- 'se' — `cvloss` uses the smallest tree whose cost is within one standard error of the minimum cost.
- 'min' — `cvloss` uses the minimal cost tree.

Example: 'TreeSize', 'min'

KFold — Number of cross-validation samples

10 (default) | positive integer value greater than 1

Number of cross-validation samples, specified as the comma-separated pair consisting of `KFold` and a positive integer value greater than 1.

Example: 'KFold', 8

Output Arguments

E — Cross-validation classification error

numeric vector | scalar value

Cross-validation classification error (loss), returned as a vector or scalar depending on the setting of the `Subtrees` name-value pair.

SE — Standard error

numeric vector | scalar value

Standard error of `E`, returned as a vector or scalar depending on the setting of the `Subtrees` name-value pair.

Nleaf — Number of leaf nodes

numeric vector | scalar value

Number of leaf nodes in `tree`, returned as a vector or scalar depending on the setting of the `Subtrees` name-value pair. Leaf nodes are terminal nodes, which give classifications, not splits.

BestLevel — Best pruning level

scalar value

Best pruning level, returned as a scalar value. By default, a scalar representing the largest pruning level that achieves a value of E within SE of the minimum error. If you set `TreeSize` to 'min', `BestLevel` is the smallest value in `Subtrees`.

Examples

Compute the Cross-Validation Error

Compute the cross-validation error for a default classification tree.

Load the ionosphere data set.

```
load ionosphere
```

Grow a classification tree using the entire data set.

```
Mdl = fitctree(X,Y);
```

Compute the cross-validation error.

```
rng(1); % For reproducibility  
E = cvloss(Mdl)
```

```
E = 0.1111
```

E is the 10-fold misclassification error.

Find the Best Pruning Level Using Cross Validation

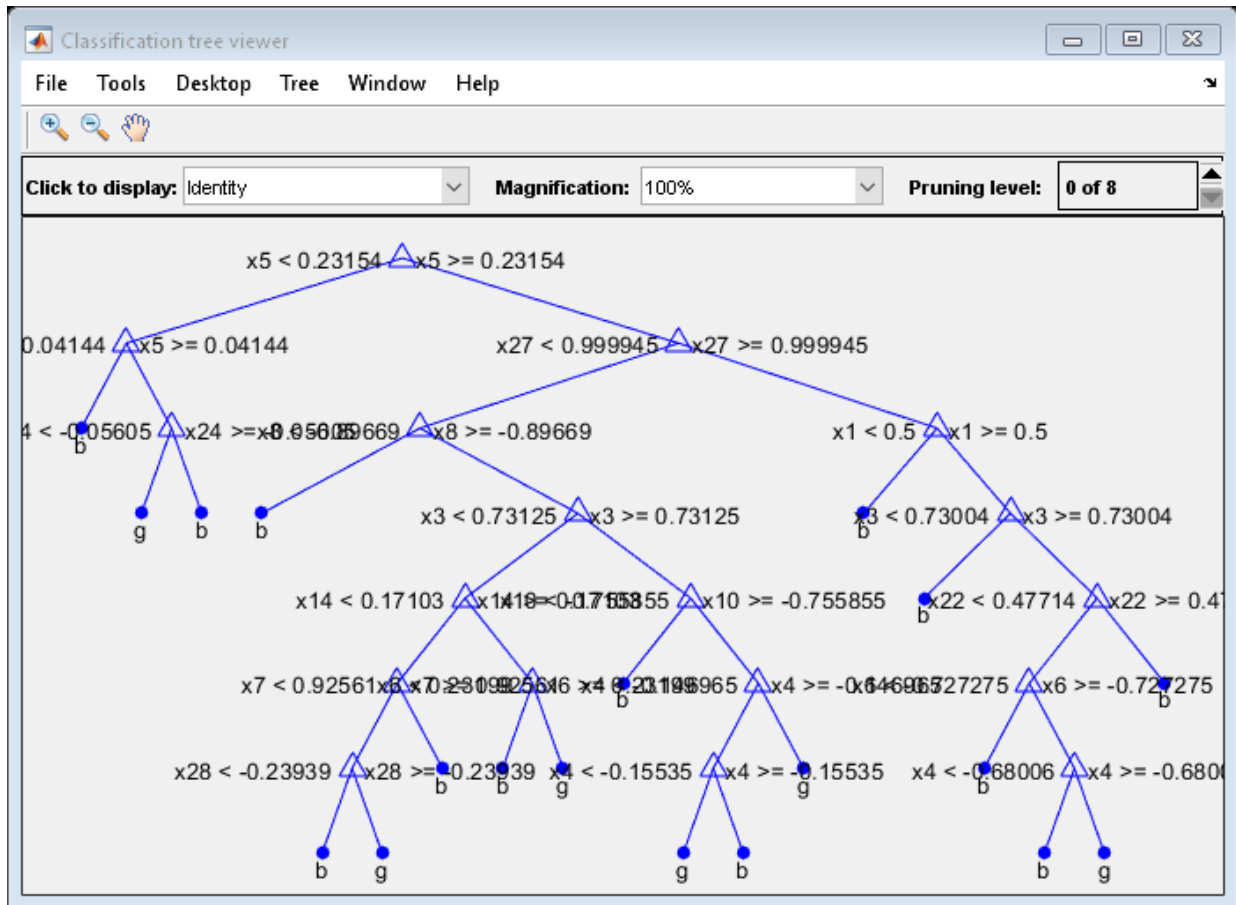

Apply k -fold cross validation to find the best level to prune a classification tree for all of its subtrees.

Load the ionosphere data set.

```
load ionosphere
```

Grow a classification tree using the entire data set. View the resulting tree.

```
Mdl = fitctree(X,Y);  
view(Mdl, 'Mode', 'graph')
```

Compute the 5-fold cross-validation error for each subtree except for the highest pruning level. Specify to return the best pruning level over all subtrees.

```
rng(1); % For reproducibility
m = max(Mdl.PruneList) - 1

m = 7

[E,~,~,bestLevel] = cvloss(Mdl,'SubTrees',0:m,'KFold',5)

E = 8x1
```

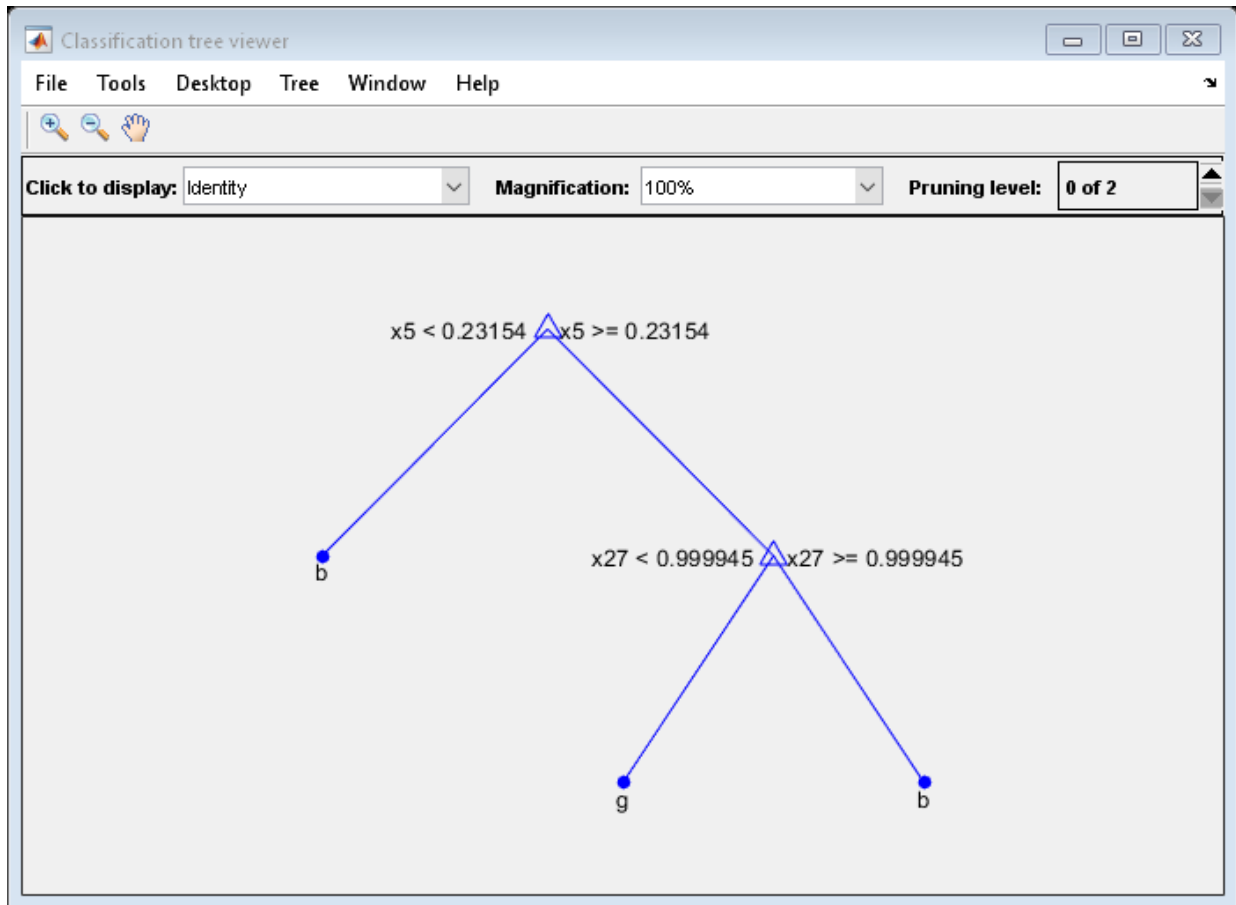

```
0.1368  
0.1339  
0.1311  
0.1339  
0.1339  
0.1254  
0.0997  
0.1738
```

```
bestLevel = 6
```

Of the 7 pruning levels, the best pruning level is 6.

Prune the tree to the best level. View the resulting tree.

```
MdlPrune = prune(Mdl, 'Level', bestLevel);  
view(MdlPrune, 'Mode', 'graph')
```

Alternatives

You can construct a cross-validated tree model with `crossval`, and call `kfoldLoss` instead of `cvloss`. If you are going to examine the cross-validated tree more than once, then the alternative can save time.

However, unlike `cvloss`, `kfoldLoss` does not return `SE`, `Nleaf`, or `BestLevel`. `kfoldLoss` also does not allow you to examine any error other than the classification error.

See Also

`crossval` | `fitctree` | `kfoldLoss` | `loss`

cvloss

Class: RegressionTree

Regression error by cross validation

Syntax

```
E = cvloss(tree)
[E,SE] = cvloss(tree)
[E,SE,Nleaf] = cvloss(tree)
[E,SE,Nleaf,BestLevel] = cvloss(tree)
[E,...] = cvloss(tree,Name,Value)
```

Description

`E = cvloss(tree)` returns the cross-validated regression error (loss) for `tree`, a regression tree.

`[E,SE] = cvloss(tree)` returns the standard error of `E`.

`[E,SE,Nleaf] = cvloss(tree)` returns the number of leaves (terminal nodes) in `tree`.

`[E,SE,Nleaf,BestLevel] = cvloss(tree)` returns the optimal pruning level for `tree`.

`[E,...] = cvloss(tree,Name,Value)` cross validates with additional options specified by one or more `Name, Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Input Arguments

tree — Trained regression tree

RegressionTree object

Trained regression tree, specified as a `RegressionTree` object constructed using `fitrtree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Subtrees — Pruning level

0 (default) | vector of nonnegative integers | 'all'

Pruning level, specified as the comma-separated pair consisting of 'Subtrees' and a vector of nonnegative integers in ascending order or 'all'.

If you specify a vector, then all elements must be at least 0 and at most `max(tree.PruneList)`. 0 indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify 'all', then `cvloss` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`cvloss` prunes `tree` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `tree` must be nonempty. In other words, grow `tree` by setting 'Prune', 'on', or by pruning `tree` using `prune`.

Example: 'Subtrees', 'all'

TreeSize — Tree size

'se' (default) | 'min'

Tree size, specified as the comma-separated pair consisting of 'TreeSize' and one of the following:

- 'se' — `cvloss` uses the smallest tree whose cost is within one standard error of the minimum cost.

- 'min' — `cvloss` uses the minimal cost tree.

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1.

Example: 'KFold',8

Output Arguments

E — Mean squared error

scalar value | numeric vector

Cross-validation mean squared error (loss), returned as a vector or scalar depending on the setting of the `Subtrees` name-value pair.

SE — Standard error

scalar value | numeric vector

Standard error of E, returned as vector or scalar depending on the setting of the `Subtrees` name-value pair.

Nleaf — Number of leaf nodes

vector of integer values

Number of leaf nodes in `tree`, returned as a vector or scalar depending on the setting of the `Subtrees` name-value pair. Leaf nodes are terminal nodes, which give responses, not splits.

BestLevel — Best pruning level

scalar value

Best pruning level as defined in the `TreeSize` name-value pair, returned as a scalar whose value depends on `TreeSize`:

- If `TreeSize` is 'se', then `BestLevel` is the largest pruning level that achieves a value of E within SE of the minimum error.
- If `TreeSize` is 'min', then `BestLevel` is the smallest value in `Subtrees`.

Examples

Compute the Cross-Validation Error

Compute the cross-validation error for a default regression tree.

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];

Grow a regression tree using the entire data set.

Mdl = fitrtree(X,MPG);
```

Compute the cross-validation error.

```
rng(1); % For reproducibility
E = cvloss(Mdl)

E = 25.7383
```

`E` is the 10-fold weighted, average MSE (weighted by number of test observations in the folds).

Find the Best Pruning Level Using Cross Validation

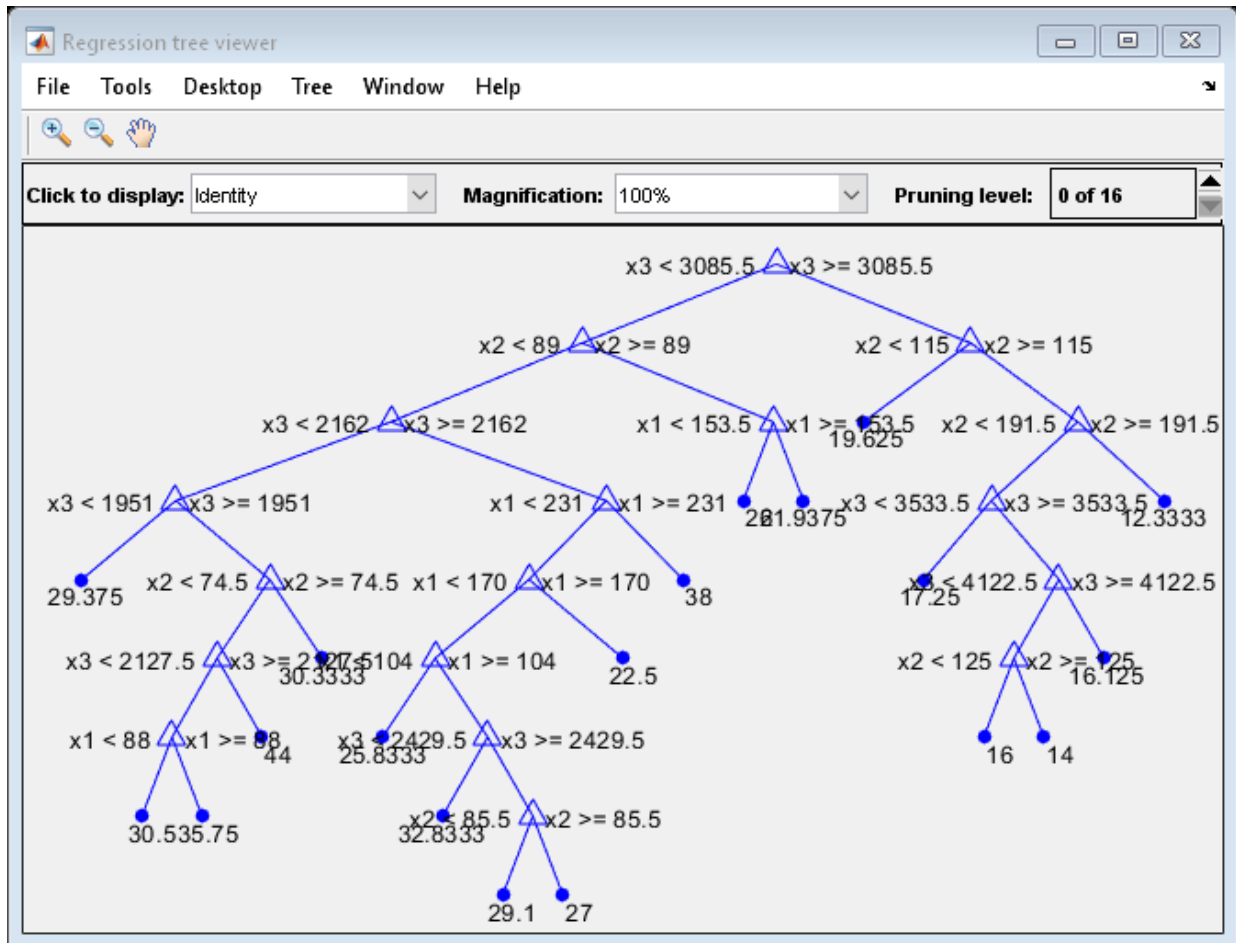

Apply k -fold cross validation to find the best level to prune a regression tree for all of its subtrees.

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];

Grow a regression tree using the entire data set. View the resulting tree.

Mdl = fitrtree(X,MPG);
view(Mdl, 'Mode', 'graph')
```

Compute the 5-fold cross-validation error for each subtree except for the first two lowest and highest pruning level. Specify to return the best pruning level over all subtrees.

```
rng(1); % For reproducibility
m = max(Mdl.PruneList) - 1

m = 15

[~,~,~,bestLevel] = cvloss(Mdl, 'SubTrees', 2:m, 'KFold', 5)

bestLevel = 14
```

Of the 15 pruning levels, the best pruning level is 14.

Prune the tree to the best level. View the resulting tree.

```
MdlPrune = prune(Mdl, 'Level', bestLevel);  
view(MdlPrune, 'Mode', 'graph')
```

Alternatives

You can construct a cross-validated tree model with `crossval`, and call `kfoldLoss` instead of `cvloss`. If you are going to examine the cross-validated tree more than once, then the alternative can save time.

However, unlike `cvloss`, `kfoldLoss` does not return `SE`, `Nleaf`, or `BestLevel`.

cvpartition class

Data partitions for cross validation

Description

An object of the `cvpartition` class defines a random partition on a set of data of a specified size. Use this partition to define test and training sets for validating a statistical model using cross validation.

Construction

`cvpartition` Create cross-validation partition for data

Methods

| | |
|--------------------------|---|
| <code>disp</code> | Display <code>cvpartition</code> object |
| <code>display</code> | Display <code>cvpartition</code> object |
| <code>repartition</code> | Repartition data for cross-validation |
| <code>test</code> | Test indices for cross-validation |
| <code>training</code> | Training indices for cross-validation |

Properties

| | |
|-----------------|---|
| NumObservations | Number of observations (including observations with missing group values) |
| NumTestSets | Number of test sets |
| TestSize | Size of each test set |
| TrainSize | Size of each training set |
| Type | Type of partition |

Copy Semantics

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes \(MATLAB\)](#) in the MATLAB Object-Oriented Programming documentation.

Examples

Use a 10-fold stratified cross validation to compute the misclassification error for `classify` on iris data.

```
load('fisheriris');
CV0 = cvpartition(species,'k',10);
err = zeros(CV0.NumTestSets,1);
for i = 1:CV0.NumTestSets
    trIdx = CV0.training(i);
    teIdx = CV0.test(i);
    ytest = classify(meas(teIdx,:),meas(trIdx,:),...
        species(trIdx,:));
    err(i) = sum(~strcmp(ytest,species(teIdx)));
end
cvErr = sum(err)/sum(CV0.TestSize);
```

cvpartition

Class: cvpartition

Create cross-validation partition for data

Syntax

```
c = cvpartition(n,'KFold',k)
c = cvpartition(n,'HoldOut',p)

c = cvpartition(group,'KFold',k)
c = cvpartition(group,'KFold',k,'Stratify',stratifyOption)
c = cvpartition(group,'HoldOut',p)
c = cvpartition(group,'HoldOut',p,'Stratify',stratifyOption)

c = cvpartition(n,'LeaveOut')

c = cvpartition(n,'resubstitution')
```

Description

`c = cvpartition(n,'KFold',k)` constructs an object `c` of the `cvpartition` class on page 32-1269 defining a random nonstratified partition for `k`-fold cross-validation on `n` observations. The partition divides the observations into `k` disjoint subsamples (or folds), chosen randomly but with roughly equal size. The default value of `k` is 10.

`c = cvpartition(n,'HoldOut',p)` creates a random nonstratified partition for holdout validation on `n` observations. This partition divides the observations into a training set and a test (or holdout) set. The parameter `p` must be a scalar. When $0 < p < 1$, `cvpartition` randomly selects approximately $p*n$ observations for the test set. When `p` is an integer, `cvpartition` randomly selects `p` observations for the test set. The default value of `p` is 1/10.

`c = cvpartition(group,'KFold',k)` creates a random partition for a stratified `k`-fold cross-validation. `group` is a numeric vector, categorical array, character array, string

array, or cell array of character vectors indicating the class of each observation. Each subsample has roughly equal size and roughly the same class proportions as in `group`.

When you supply `group` as the first input argument to `cvpartition`, the function creates cross-validation partitions that do not include rows of observations corresponding to missing values in `group`.

`c = cvpartition(group, 'Kfold', k, 'Stratify', stratifyOption)` returns an object `c` defining a random partition for `k`-fold cross-validation. When you supply `group` as the first input argument to `cvpartition`, then the function implements stratification by default. If you also specify `'Stratify', false`, then the function creates nonstratified random partitions.

You can specify `'Stratify', true` only if the first input argument to `cvpartition` is `group`.

`c = cvpartition(group, 'HoldOut', p)` randomly partitions observations into a training set and a holdout (or test) set with stratification, using the class information in `group`. Both the training and test sets have roughly the same class proportions as in `group`.

`c = cvpartition(group, 'HoldOut', p, 'Stratify', stratifyOption)` returns an object `c` defining a random partition into a training set and a holdout (or test) set. When you supply `group` as the first input argument to `cvpartition`, then the function implements stratification by default. If you also specify `'Stratify', false`, then the function creates nonstratified random partitions.

`c = cvpartition(n, 'LeaveOut')` creates a random partition for leave-one-out cross-validation on `n` observations. Leave-one-out is a special case of `'Kfold'` in which the number of folds equals the number of observations.

`c = cvpartition(n, 'resubstitution')` creates an object `c` that does not partition the data. Both the training set and the test set contain all of the original `n` observations.

Examples

Find Misclassification Rate for K-Fold Cross-Validation

Use stratified 10-fold cross-validation to compute misclassification rate.

Load Fisher's iris data set.

```
load fisheriris;  
y = species;  
X = meas;
```

Create a random partition for a stratified 10-fold cross-validation.

```
c = cvpartition(y, 'KFold', 10);
```

Create a function that computes the number of misclassified test samples.

```
fun = @(xTrain,yTrain,xTest,yTest)(sum(~strcmp(yTest,...  
    classify(xTest,xTrain,yTrain))));
```

Return the estimated misclassification rate using cross-validation.

```
rate = sum(crossval(fun,X,y,'partition',c))...  
    /sum(c.TestSize)  
  
rate = 0.0200
```

Create Nonstratified Partition

Find the proportion of each class in a 5-fold nonstratified partition of the fisheriris data.

Load Fisher's iris data set.

```
load fisheriris;
```

Find the number of instances of each class in the data.

```
[C,~,idx] = unique(species);  
C % Unique classes
```

```
C = 3x1 cell array  
    {'setosa'   }  
    {'versicolor'}  
    {'virginica' }
```

```
n = accumarray(idx(:,1),1) % Number of instances for each class in species
```

```
n = 3×1
    50
    50
    50
```

The three classes occur in equal proportion.

Create a random, nonstratified 5-fold partition.

```
cv = cvpartition(species, 'KFold', 5, 'Stratify', false)
```

```
cv =
K-fold cross validation partition
  NumObservations: 150
   NumTestSets: 5
  TrainSize: 120 120 120 120 120
  TestSize: 30 30 30 30 30
```

Show that the three classes do not occur in equal proportion for each fold of the data set.

```
for i = 1:cv.NumTestSets
    disp(['Fold ', num2str(i)])
    testClasses = species(cv.test(i));
    [C,~,idx] = unique(testClasses);
    C % Unique classes
    nCount = accumarray(idx(:,1),1) % Number of instances for each class in a fold
end
```

```
Fold 1
```

```
C = 3×1 cell array
    {'setosa'   }
    {'versicolor'}
    {'virginica' }
```

```
nCount = 3×1
```

```
    8
   13
    9
```

```
Fold 2
```

```
C = 3x1 cell array
    {'setosa' }
    {'versicolor'}
    {'virginica' }
```

```
nCount = 3x1
```

```
    10
    11
     9
```

Fold 3

```
C = 3x1 cell array
    {'setosa' }
    {'versicolor'}
    {'virginica' }
```

```
nCount = 3x1
```

```
    10
     8
    12
```

Fold 4

```
C = 3x1 cell array
    {'setosa' }
    {'versicolor'}
    {'virginica' }
```

```
nCount = 3x1
```

```
    12
     8
    10
```

Fold 5

```
C = 3x1 cell array
    {'setosa' }
```

```

    {'versicolor'}
    {'virginica' }

nCount = 3×1

    10
    10
    10

```

Because `cv` is a random nonstratified partition of the `fisheriris` data, the class proportions in each of the five folds are not guaranteed to be equal to the class proportions in `species`. That is, the classes do not occur equally in each fold, as they do in `species`. Cross-validation produces randomness in the results, so your number of instances for each class in a fold can vary from those shown.

Create Nonstratified Holdout Set for Tall Array

Compare the number of instances for each class in a nonstratified holdout set with a stratified holdout set of a tall array.

Create a numeric vector of two classes, where class 1 and class 2 occur in the ratio 1:10.

```

group = [ones(20,1);2*ones(200,1)]
group = 220×1

```

```

    1
    1
    1
    1
    1
    1
    1
    1
    1
    1
    1
    :

```

Create a tall array from `group`.

```
tgroup = tall(group)
```

```
Starting parallel pool (parpool) using the 'local' profile ...  
connected to 12 workers.
```

```
tgroup =
```

```
220x1 tall double column vector
```

```
1  
1  
1  
1  
1  
1  
1  
1  
1  
1  
:  
:
```

Holdout is the only `cvpartition` option that is supported for tall arrays. Create a random, nonstratified holdout partition.

```
CV0 = cvpartition(tgroup, 'Holdout', 1/4, 'Stratify', false)
```

```
CV0 =
```

```
Hold-out cross validation partition
```

```
NumObservations: [1x1 tall]
```

```
NumTestSets: 1
```

```
TrainSize: [1x1 tall]
```

```
TestSize: [1x1 tall]
```

Return the result of `CV0.test` to memory by using the `gather` function.

```
testIdx0 = gather(CV0.test);
```

```
Evaluating tall expression using the Parallel Pool 'local':
```

```
Evaluation completed in 1 sec
```

Find the number of times each class occurs in the holdout set.

```
accumarray(group(testIdx0), 1) % Number of instances for each class in the holdout set
```

```
ans = 2x1
```

```
3
```

52

`cvpartition` produces randomness in the results, so your number of instances for each class can vary from those shown.

Because `CV0` is a nonstratified partition, class 1 and class 2 in the holdout set are not guaranteed to occur in the same ratio that they do in `tgroup`. However, because of the inherent randomness in `cvpartition`, you can sometimes obtain a holdout set for which the classes occur in the same ratio that they do in `tgroup` even though you specify `'Stratify', false`. A similar result can be illustrated for the training set.

Return the result of `CV0.training` to memory.

```
trainIdx0 = gather(CV0.training);
```

```
Evaluating tall expression using the Parallel Pool 'local':
Evaluation completed in 0 sec
```

Find the number of times each class occurs in the training set.

```
accumarray(group(trainIdx0),1) % Number of instances for each class in the training set
```

```
ans = 2x1
```

```
    17
   148
```

The classes in the nonstratified training set are not guaranteed to occur in the same ratio that they do in `tgroup`.

Create a random, stratified holdout partition.

```
CV1 = cvpartition(tgroup, 'Holdout', 1/4)
```

```
CV1 =
Hold-out cross validation partition
  NumObservations: [1x1 tall]
  NumTestSets: 1
  TrainSize: [1x1 tall]
  TestSize: [1x1 tall]
```

Return the result of `CV1.test` to memory.

```
testIdx1 = gather(CV1.test);
```

```
Evaluating tall expression using the Parallel Pool 'local':  
Evaluation completed in 0 sec
```

Find the number of times each class occurs in the holdout set.

```
accumarray(group(testIdx1),1) % Number of instances for each class in the holdout set
```

```
ans = 2×1
```

```
    5  
   50
```

In the case of the stratified holdout partition, the class ratio in the holdout set and the class ratio in `tgroup` are the same (1:10).

Algorithms

- If you supply `group` as the first input argument to `cvpartition`, the function creates cross-validation partitions that do not include rows of observations corresponding to missing values in `group`.
- When you supply `group` as the first input argument to `cvpartition`, then the function implements stratification by default. You can specify `'Stratify', false` to create nonstratified random partitions.
- You can specify `'Stratify', true` only if the first input argument to `cvpartition` is `group`.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

- When you use `cvpartition` with tall arrays, the first input argument must be a grouping variable, `tGroup`. If you specify a tall scalar as the first input argument, `cvpartition` gives an error.
- `cvpartition` supports only `Holdout` cross-validation for tall arrays; for example, `c = cvpartition(tGroup, 'HoldOut', p)`. By default, `cvpartition` randomly partitions observations into a training set and a test set with stratification, using the class information in `tGroup`. The parameter `p` is a scalar such that $0 < p < 1$.
- To create nonstratified `Holdout` partitions, specify the value of the `'Stratify'` name-value pair argument as `false`; for example, `c = cvpartition(tGroup, 'Holdout', p, 'Stratify', false)`.

For more information, see “Tall Arrays” (MATLAB).

Topics

“Grouping Variables” on page 2-57

Introduced in R2008a

cvshrink

Class: ClassificationDiscriminant

Cross-validate regularization of linear discriminant

Syntax

```
err = cvshrink(obj)
[err,gamma] = cvshrink(obj)
[err,gamma,delta] = cvshrink(obj)
[err,gamma,delta,numpred] = cvshrink(obj)
[err,...] = cvshrink(obj,Name,Value)
```

Description

`err = cvshrink(obj)` returns a vector of cross-validated classification error values for differing values of the regularization parameter Gamma.

`[err,gamma] = cvshrink(obj)` also returns the vector of Gamma values.

`[err,gamma,delta] = cvshrink(obj)` also returns the vector of Delta values.

`[err,gamma,delta,numpred] = cvshrink(obj)` returns the vector of number of nonzero predictors for each setting of the parameters Gamma and Delta.

`[err,...] = cvshrink(obj,Name,Value)` cross validates with additional options specified by one or more Name, Value pair arguments.

Input Arguments

obj

Discriminant analysis classifier, produced using `fitcdiscr`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

delta

- **Scalar delta** — `cvshrink` uses this value of `delta` with every value of `gamma` for regularization.
- **Row vector delta** — For each `i` and `j`, `cvshrink` uses `delta(j)` with `gamma(i)` for regularization.
- **Matrix delta** — The number of rows of `delta` must equal the number of elements in `gamma`. For each `i` and `j`, `cvshrink` uses `delta(i, j)` with `gamma(i)` for regularization.

Default: 0

gamma

Vector of Gamma values for cross-validation.

Default: 0:0.1:1

NumDelta

Number of Delta intervals for cross-validation. For every value of Gamma, `cvshrink` cross-validates the discriminant using `NumDelta + 1` values of Delta, uniformly spaced from zero to the maximal Delta at which all predictors are eliminated for this value of Gamma. If you set `delta`, `cvshrink` ignores `NumDelta`.

Default: 0

NumGamma

Number of Gamma intervals for cross-validation. `cvshrink` cross-validates the discriminant using `NumGamma + 1` values of Gamma, uniformly spaced from `MinGamma` to 1. If you set `gamma`, `cvshrink` ignores `NumGamma`.

Default: 10

verbose

Verbosity level, an integer from 0 to 2. Higher values give more progress messages.

Default: 0

Output Arguments

err

Numeric vector or matrix of errors. `err` is the misclassification error rate, meaning the average fraction of misclassified data over all folds.

- If `delta` is a scalar (default), `err(i)` is the misclassification error rate for `obj` regularized with `gamma(i)`.
- If `delta` is a vector, `err(i, j)` is the misclassification error rate for `obj` regularized with `gamma(i)` and `delta(j)`.
- If `delta` is a matrix, `err(i, j)` is the misclassification error rate for `obj` regularized with `gamma(i)` and `delta(i, j)`.

gamma

Vector of Gamma values used for regularization. See “Gamma and Delta” on page 32-1287.

delta

Vector or matrix of Delta values used for regularization. See “Gamma and Delta” on page 32-1287.

- If you give a scalar for the `delta` name-value pair, the output `delta` is a row vector the same size as `gamma`, with entries equal to the input scalar.
- If you give a row vector for the `delta` name-value pair, the output `delta` is a matrix with the same number of columns as the row vector, and with the number of rows equal to the number of elements of `gamma`. The output `delta(i, j)` is equal to the input `delta(j)`.
- If you give a matrix for the `delta` name-value pair, the output `delta` is the same as the input matrix. The number of rows of `delta` must equal the number of elements in `gamma`.

numpred

Numeric vector or matrix containing the number of predictors in the model at various regularizations. `numpred` has the same size as `err`.

- If `delta` is a scalar (default), `numpred(i)` is the number of predictors for `obj` regularized with `gamma(i)` and `delta`.
- If `delta` is a vector, `numpred(i,j)` is the number of predictors for `obj` regularized with `gamma(i)` and `delta(j)`.
- If `delta` is a matrix, `numpred(i,j)` is the number of predictors for `obj` regularized with `gamma(i)` and `delta(i,j)`.

Examples

Regularize Data with Many Predictors

Regularize a discriminant analysis classifier, and view the tradeoff between the number of predictors in the model and the classification accuracy.

Create a linear discriminant analysis classifier for the `ovariancancer` data. Set the `SaveMemory` and `FillCoeffs` options to keep the resulting model reasonably small.

```
load ovariancancer
obj = fitcdiscr(obs,grp,...
    'SaveMemory','on','FillCoeffs','off');
```

Use 10 levels of `Gamma` and 10 levels of `Delta` to search for good parameters. This search is time-consuming. Set `Verbose` to 1 to view the progress.

```
rng('default') % for reproducibility
[err,gamma,delta,numpred] = cvshrink(obj,...
    'NumGamma',9,'NumDelta',9,'Verbose',1);
```

```
Done building cross-validated model.
Processing Gamma step 1 out of 10.
Processing Gamma step 2 out of 10.
Processing Gamma step 3 out of 10.
Processing Gamma step 4 out of 10.
Processing Gamma step 5 out of 10.
Processing Gamma step 6 out of 10.
```

```
Processing Gamma step 7 out of 10.  
Processing Gamma step 8 out of 10.  
Processing Gamma step 9 out of 10.  
Processing Gamma step 10 out of 10.
```

Plot the classification error rate against the number of predictors.

```
plot(err,numpred,'k.')  
xlabel('Error rate');  
ylabel('Number of predictors');
```

- “Regularize a Discriminant Analysis Classifier” on page 20-28

Definitions

Gamma and Delta

Regularization is the process of finding a small set of predictors that yield an effective predictive model. For linear discriminant analysis, there are two parameters, γ and δ , that control regularization as follows. `cvshrink` helps you select appropriate values of the parameters.

Let Σ represent the covariance matrix of the data X , and let \hat{X} be the centered data (the data X minus the mean by class). Define

$$D = \text{diag}(\hat{X}^T * \hat{X}).$$

The regularized covariance matrix $\tilde{\Sigma}$ is

$$\tilde{\Sigma} = (1 - \gamma)\Sigma + \gamma D.$$

Whenever $\gamma \geq \text{MinGamma}$, $\tilde{\Sigma}$ is nonsingular.

Let μ_k be the mean vector for those elements of X in class k , and let μ_0 be the global mean vector (the mean of the rows of X). Let C be the correlation matrix of the data X , and let

\tilde{C} be the regularized correlation matrix:

$$\tilde{C} = (1 - \gamma)C + \gamma I,$$

where I is the identity matrix.

The linear term in the regularized discriminant analysis classifier for a data point x is

$$(x - \mu_0)^T \tilde{\Sigma}^{-1} (\mu_k - \mu_0) = \left[(x - \mu_0)^T D^{-1/2} \right] \left[\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right].$$

The parameter δ enters into this equation as a threshold on the final term in square

brackets. Each component of the vector $\left[\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right]$ is set to zero if it is smaller

in magnitude than the threshold δ . Therefore, for class k , if component j is thresholded to zero, component j of x does not enter into the evaluation of the posterior probability.

The `DeltaPredictor` property is a vector related to this threshold. When $\delta \geq \text{DeltaPredictor}(i)$, all classes k have

$$|\tilde{C}^{-1}D^{-1/2}(\mu_k - \mu_0)| \leq \delta.$$

Therefore, when $\delta \geq \text{DeltaPredictor}(i)$, the regularized classifier does not use predictor i .

Tips

- Examine the `err` and `numpred` outputs to see the tradeoff between cross-validated error and number of predictors. When you find a satisfactory point, set the corresponding `gamma` and `delta` properties in the model using dot notation. For example, if (i, j) is the location of the satisfactory point, set

```
obj.Gamma = gamma(i);  
obj.Delta = delta(i,j);
```

Topics

“Regularize a Discriminant Analysis Classifier” on page 20-28

“Discriminant Analysis Classification” on page 20-2

cvshrink

Class: RegressionEnsemble

Cross validate shrinking (pruning) ensemble

Syntax

```
vals = cvshrink(ens)
[vals,nlearn] = cvshrink(ens)
[vals,nlearn] = cvshrink(ens,Name,Value)
```

Description

`vals = cvshrink(ens)` returns an L-by-T matrix with cross-validated values of the mean squared error. L is the number of `lambda` values in the `ens.Regularization` structure. T is the number of `threshold` values on weak learner weights. If `ens` does not have a `Regularization` property filled in by the `regularize` method, pass a `lambda` name-value pair.

`[vals,nlearn] = cvshrink(ens)` returns an L-by-T matrix of the mean number of learners in the cross-validated ensemble.

`[vals,nlearn] = cvshrink(ens,Name,Value)` cross validates with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

A regression ensemble, created with `fitrensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

cvpartition

A partition created with `cvpartition` to use in a cross-validated tree. You can only use one of these four options at a time: `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

holdout

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated tree: `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

kfold

Number of folds to use in a cross-validated tree, a positive integer. If you do not supply a cross-validation method, `cvshrink` uses 10-fold cross validation. You can only use one of these four options at a time: `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

Default: 10

lambda

Vector of nonnegative regularization parameter values for lasso. If empty, `cvshrink` does not perform cross validation.

Default: []

leaveout

Use leave-one-out cross validation by setting to `'on'`. You can only use one of these four options at a time: `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

threshold

Numeric vector with lower cutoffs on weights for weak learners. `cvshrink` discards learners with weights below `threshold` in its cross-validation calculation.

Default: 0

Output Arguments

vals

L-by-T matrix with cross-validated values of the mean squared error. L is the number of values of the regularization parameter '`lambda`', and T is the number of '`threshold`' values on weak learner weights.

nlearn

L-by-T matrix with cross-validated values of the mean number of learners in the cross-validated ensemble. L is the number of values of the regularization parameter '`lambda`', and T is the number of '`threshold`' values on weak learner weights.

Examples

Cross-Validate Regression Ensemble

Create a regression ensemble for predicting mileage from the `carsmall` data. Cross-validate the ensemble.

Load the `carsmall` data set and select displacement, horsepower, and vehicle weight as predictors.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Train an ensemble of bagged regression trees.

```
ens = fitensemble(X,MPG,'Method','Bag','Learners','Tree');
```

Specify values for `lambda` and `threshold`. Use these values to cross-validate the ensemble.

```
rng(10, 'twister') % For reproducibility
[vals, nlearn] = cvshrink(ens, 'lambda', [.01 .1 1], 'threshold', [0 .01 .1])

vals = 3×3

    17.7488    17.6537   123.2749
    17.7374    17.6304   123.4240
    17.6531    17.5540   101.2271

nlearn = 3×3

    13.1000    11.6000     3.4000
    13.2000    11.6000     3.4000
    13.1000    11.6000     3.7000
```

Clearly, setting a threshold of 0.1 leads to unacceptable errors, while a threshold of 0.01 gives similar errors to a threshold of 0 . The mean number of learners with a threshold of 0.01 is 11.6 , whereas the mean number is about 13.1 when the threshold is 0 .

datasample

Randomly sample from data, with or without replacement

Syntax

```
y = datasample(data,k)
y = datasample(data,k,dim)
y = datasample( ___,Name,Value)
y = datasample(s, ___)
[y,idx] = datasample( ___)
```

Description

`y = datasample(data,k)` returns k observations sampled uniformly at random, with replacement, from the data in `data`.

`y = datasample(data,k,dim)` returns a sample taken along dimension `dim` of `data`.

`y = datasample(___,Name,Value)` returns a sample for any of the input arguments in the previous syntaxes, with additional options specified by one or more name-value pair arguments. For example, `'Replace',false` specifies sampling without replacement.

`y = datasample(s, ___)` uses the random number stream `s` to generate random numbers. The option `s` can precede any of the input arguments in the previous syntaxes.

`[y,idx] = datasample(___)` also returns an index vector indicating which values `datasample` sampled from `data` using any of the input arguments in the previous syntaxes.

Examples

Sample Unique Values from Vector

Create the random number stream for reproducibility.

```
s = RandStream('mlfg6331_64');  
Draw five unique values from the integers 1 to 10.  
y = datasample(s,1:10,5,'Replace',false)  
y = 1×5  
     9     8     3     6     2
```

Generate Random Characters for Specified Probabilities

Create the random number stream for reproducibility.

```
s = RandStream('mlfg6331_64');  
Generate 48 random characters from the sequence ACGT per specified probabilities.  
seq = datasample(s,'ACGT',48,'Weights',[0.15 0.35 0.35 0.15])  
seq =  
'GGCGGCGCAAGGCGCCGGACCTGGCTGCACGCCGTTCCCTGCTACTCG'
```

Select Random Subset of Matrix Columns

Set the random seed for reproducibility of the results.

```
rng(10,'twister')  
Generate a matrix with 10 rows and 1000 columns.  
X = randn(10,1000);  
Create the random number stream for reproducibility within datasample.  
s = RandStream('mlfg6331_64');  
Randomly select five unique columns from X.  
Y = datasample(s,X,5,2,'Replace',false)
```

$Y = 10 \times 5$

```

```

Create a Bootstrap Replicate Data Set

Resample observations from a dataset array to create a bootstrap replicate data set. See “Bootstrap Resampling” on page 3-16 for more information about bootstrapping.

Load the sample data set.

```
load hospital
```

Create a data set that has the same size as the `hospital` data set and contains random samples chosen with replacement from the `hospital` data set.

```
y = datasample(hospital,size(hospital,1));
```

Sample in Parallel from Two Data Vectors

Select samples from data based on indices of a sample chosen from another vector.

Generate two random vectors.

```
x1 = randn(100,1);
x2 = randn(100,1);
```

Select a sample of 10 elements from vector `x1`, and return the indices of the sample in vector `idx`.

```
[y1,idx] = datasample(x1,10);
```

Select a sample of 10 elements from vector `x2` using the indices in vector `idx`.

```
y2 = x2(idx);
```

Input Arguments

data — Input data

vector | matrix | multidimensional array | table | dataset array

Input data from which to sample, specified as a vector, matrix, multidimensional array, table, or dataset array. By default, `datasample` samples from the first nonsingleton dimension of `data`. For example, if `data` is a matrix, then `datasample` samples from the rows. Change this behavior with the `dim` input argument.

Data Types: `single` | `double` | `logical` | `char` | `string` | `table`

k — Number of samples

positive integer

Number of samples, specified as a positive integer.

Example: `datasample(data,100)` returns 100 observations sampled uniformly and at random from the data in `data`.

Data Types: `single` | `double`

dim — Dimension to sample

1 (default) | positive integer

Dimension to sample, specified as a positive integer. For example, if `data` is a matrix and `dim` is 2, `y` contains a selection of columns in `data`. If `data` is a table or dataset array and `dim` is 2, `y` contains a selection of variables in `data`. Use `dim` to ensure sampling along a specific dimension regardless of whether `data` is a vector, matrix, or N -dimensional array.

Data Types: `single` | `double`

s — Random number stream

global stream (default) | `RandStream`

Random number stream, specified as the global stream or `RandStream`. For example, `s = RandStream('mlfg6331_64')` creates a random number stream that uses the

multiplicative lagged Fibonacci generator algorithm. For details, see “Creating and Controlling a Random Number Stream” (MATLAB).

The `rng` function provides a simple way to control the global stream. For example, `rng(seed)` seeds the random number generator using the nonnegative integer seed. For details, see “Managing the Global Stream” (MATLAB).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Replace', false, 'Weights', ones(datasize,1)` samples without replacement and with probability proportional to the elements of `Weights`, where `datasize` is the size of the dimension being sampled.

Replace — Indicator for sampling with replacement

true (default) | false

Indicator for sampling with replacement, specified as the comma-separated pair consisting of 'Replace' and either true or false.

Sample with replacement if 'Replace' is true, or without replacement if 'Replace' is false. If 'Replace' is false, then `k` must not be larger than the size of the dimension being sampled. For example, if `data = [1 3 Inf; 2 4 5]` and `y = datasample(data,k,'Replace',false)`, then `k` cannot be larger than 2.

Data Types: logical

Weights — Sampling weights

ones(datasize,1) (default) | vector of nonnegative numeric values

Sampling weights, specified as the comma-separated pair consisting of 'Weights' and a vector of nonnegative numeric values. The vector is of size `datasize`, where `datasize` is the size of the dimension being sampled. The vector must have at least one positive value and cannot contain NaN values. The `datasample` function samples with probability proportional to the elements of 'Weights'.

Example: `'Weights',[0.1 0.5 0.35 0.46]`

Data Types: single | double

Output Arguments

y — Sample

vector | matrix | multidimensional array | table | dataset array

Sample, returned as a vector, matrix, multidimensional array, table, or dataset array.

- If `data` is a vector, then `y` is a vector containing `k` elements selected from `data`.
- If `data` is a matrix and `dim = 1`, then `y` is a matrix containing `k` rows selected from `data`. Or, if `dim = 2`, then `y` is a matrix containing `k` columns selected from `data`.
- If `data` is an N -dimensional array and `dim = 1`, then `y` is an N -dimensional array of samples taken along the first nonsingleton dimension of `data`. Or, if you specify a value for the `dim` name-value pair argument, `datasample` samples along the dimension `dim`.
- If `data` is a table and `dim = 1`, then `y` is a table containing `k` rows selected from `data`. Or, if `dim = 2`, then `y` is a table containing `k` variables selected from `data`.
- If `data` is a dataset array and `dim = 1`, then `y` is a dataset array containing `k` rows selected from `data`. Or, if `dim = 2`, then `y` is a dataset array containing `k` variables selected from `data`.

If the input `data` contains missing observations that are represented as NaN values, `datasample` samples from the entire input, including the NaN values. For example, `y = datasample([NaN 6 14],2)` can return `y = NaN 14`.

When the sample is taken with replacement (default), `y` can contain repeated observations from `data`. Set the `Replace` name-value pair argument to `false` to sample without replacement.

idx — Indices

vector

Indices, returned as a vector indicating which elements `datasample` chooses from `data` to create `y`. For example:

- If `data` is a vector, then `y = data(idx)`.
- If `data` is a matrix and `dim = 1`, then `y = data(idx,:)`.
- If `data` is a matrix and `dim = 2`, then `y = data(:,idx)`.

Tips

- To sample random integers with replacement from a range, use `randi`.
- To sample random integers without replacement, use `randperm` or `datasample`.
- To randomly sample from data, with or without replacement, use `datasample`.

Algorithms

`datasample` uses `randperm`, `rand`, or `randi` to generate random values. Therefore, `datasample` changes the state of the MATLAB global random number generator. Control the random number generator using `rng`.

For selecting weighted samples without replacement, `datasample` uses the algorithm of Wong and Easton [1].

Alternative Functionality

You can use `randi` or `randperm` to generate indices for random sampling with or without replacement, respectively. However, `datasample` can be more convenient to use because it samples directly from your data. `datasample` also allows weighted sampling.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

- `datasample` is useful as a precursor to plotting and fitting a random subset of a large data set. Sampling a large data set preserves trends in the data without requiring the use of all the data points. If the sample is small enough to fit in memory, then you can apply plotting and fitting functions that do not directly support tall arrays.
- `datasample` supports sampling only along the first dimension of the data.
- For tall arrays, `datasample` does not support sampling with replacement. You must specify `'Replace', false`, for example, `datasample(data,k,'Replace',false)`.
- The value of `'Weights'` must be a numeric tall array of the same height as `data`.
- For the syntax `[Y,idx] = datasample(____)`, the output `idx` is a tall logical vector of the same height as `data`. The vector indicates whether each data point is included in the sample.
- If you specify a random number stream, then the underlying generator must support multiple streams and substreams. If you do not specify a random number stream, then `datasample` uses the stream controlled by `tallrng`.

For more information, see “Tall Arrays” (MATLAB).

Introduced in R2011b

dataset class

Arrays for statistical data

Note The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Description

Dataset arrays are used to collect heterogeneous data and metadata including variable and observation names into a single container variable. Dataset arrays are suitable for storing column-oriented or tabular data that are often stored as columns in a text file or in a spreadsheet, and can accommodate variables of different types, sizes, units, etc.

Dataset arrays can contain different kinds of variables, including numeric, logical, character, categorical, and cell. However, a dataset array is a different class than the variables that it contains. For example, even a dataset array that contains only variables that are double arrays cannot be operated on as if it were itself a double array. However, using dot subscripting, you can operate on variable in a dataset array as if it were a workspace variable.

You can subscript dataset arrays using parentheses much like ordinary numeric arrays, but in addition to numeric and logical indices, you can use variable and observation names as indices.

Construction

Use the `dataset` constructor to create a dataset array from variables in the MATLAB workspace. You can also create a dataset array by reading data from a text or spreadsheet file. You can access each variable in a dataset array much like fields in a structure, using dot subscripting. See the following section for a list of operations available for dataset arrays.

dataset

Construct dataset array

Methods

| | |
|--------------------|---|
| cat | Concatenate dataset arrays |
| cellstr | Create cell array of character vectors from dataset array |
| dataset2cell | Convert dataset array to cell array |
| dataset2struct | Convert dataset array to structure |
| datasetfun | Apply function to dataset array variables |
| disp | Display dataset array |
| display | Display dataset array |
| double | Convert dataset variables to double array |
| end | Last index in indexing expression for dataset array |
| export | Write dataset array to file |
| get | Access dataset array properties |
| horzcat | Horizontal concatenation for dataset arrays |
| intersect | Set intersection for dataset array observations |
| isempty | True for empty dataset array |
| ismember | Dataset array elements that are members of set |
| ismissing | Find dataset array elements with missing values |
| join | Merge observations |
| length | Length of dataset array |
| ndims | Number of dimensions of dataset array |
| numel | Number of elements in dataset array |
| replacedata | Replace dataset variables |
| replaceWithMissing | Insert missing data indicators into a dataset array |
| set | Set and display properties |
| setdiff | Set difference for dataset array observations |
| setxor | Set exclusive or for dataset array observations |
| single | Convert dataset variables to single array |
| size | Size of dataset array |
| sortrows | Sort rows of dataset array |
| stack | Stack data from multiple variables into single variable |
| subsasgn | Subscripted assignment to dataset array |
| subsref | Subscripted reference for dataset array |
| summary | Print summary of dataset array |
| union | Set union for dataset array observations |

Properties

A dataset array `D` has properties that store metadata (information about your data). Access or assign to a property using `P = D.Properties.PropName` or `D.Properties.PropName = P`, where `PropName` is one of the following:

| | |
|----------------|---|
| Description | Character vector describing data set |
| DimNames | Two-element cell array of character vectors giving names of dimensions of data set |
| ObsNames | Cell array of nonempty, distinct character vectors giving names of observations in data set |
| Units | Units of variables in data set |
| UserData | Variable containing additional information associated with data set |
| VarDescription | Cell array of character vectors giving descriptions of variables in data set |
| VarNames | Cell array giving names of variables in data set |

Copy Semantics

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes \(MATLAB\)](#) in the MATLAB Object-Oriented Programming documentation.

Examples

Load a dataset array from a `.mat` file and create some simple subsets:

```
load hospital
h1 = hospital(1:10,:)
h2 = hospital(:,{'LastName' 'Age' 'Sex' 'Smoker'})

% Access and modify metadata
hospital.Properties.Description
hospital.Properties.VarNames{4} = 'Wgt'

% Create a new dataset variable from an existing one
hospital.AtRisk = hospital.Smoker | (hospital.Age > 40)
```

```
% Use individual variables to explore the data
boxplot(hospital.Age,hospital.Sex)
h3 = hospital(hospital.Age<30,...
    {'LastName' 'Age' 'Sex' 'Smoker'})

% Sort the observations based on two variables
h4 = sortrows(hospital,{'Sex','Age'})
```

Topics

“Dataset Arrays” on page 2-139

dataset

Class: dataset

Construct dataset array

Note The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
A = dataset(varspec, 'ParamName', Value)
A = dataset('File', filename, 'ParamName', Value)
A = dataset('XLSFile', filename, 'ParamName', Value)
A = dataset('XPTFile', xptfilename, 'ParamName', Value)
```

Description

`A = dataset(varspec, 'ParamName', Value)` creates dataset array `A` using the workspace variable input method `varspec` and one or more optional name/value pairs (see Parameter Name/Value Pairs).

The input method `varspec` can be one or more of the following:

- `VAR` — a workspace variable. `dataset` uses the workspace name for the variable name in `A`. To include multiple variables, specify `VAR_1, VAR_2, ..., VAR_N`. Variables can be arrays of any size, but all variables must have the same number of rows. `VAR` can also be an expression. In this case, `dataset` creates a default name automatically.
- `{VAR, name}` — a workspace variable, `VAR` and a variable name, `name`. `dataset` uses `name` as the variable name. To include multiple variables and names, specify `{VAR_1, name_1}, {VAR_2, name_2}, ..., {VAR_N, name_N}`.
- `{VAR, name_1, ..., name_m}` — an `m`-columned workspace variable, `VAR`. `dataset` uses the names `name_1, ..., name_m` as variable names. You must include a name for every column in `VAR`. Each column becomes a separate variable in `A`.

You can combine these input methods to include as many variables and names as needed. Names must be valid, unique MATLAB identifiers. For example input combinations, see Examples. For optional name/value pairs see Inputs.

To convert numeric arrays, cell arrays, structure arrays, or tables to dataset arrays, you can also use (respectively):

- `mat2dataset`
- `cell2dataset`
- `struct2dataset`
- `table2dataset`

Note Dataset arrays may contain built-in types or array objects as variables. Array objects must implement each of the following:

- Standard MATLAB parenthesis indexing of the form `var(i, ...)`, where `i` is a numeric or logical vector corresponding to rows of the variable
 - A `size` method with a `dim` argument
 - A `vertcat` method
-

`A = dataset('File', filename, 'ParamName', Value)` creates dataset array `A` from column-oriented data in the text file specified by `filename`. Variables in `A` are of type `double` if data in the corresponding column of the file, following the column header, are entirely numeric; otherwise the variables in `A` are cell arrays of character vectors. `dataset` converts empty fields to either `NaN` (for a numeric variable) or the empty character vector (for a character-valued variable). `dataset` ignores insignificant white space in the file. You cannot specify both a file and workspace variables as input. See Name/Value Pairs for more information.

`A = dataset('XLSFile', filename, 'ParamName', Value)` creates dataset array `A` from column-oriented data in the Excel spreadsheet specified by `filename`. Variables in `A` are of type `double` if data in the corresponding column of the spreadsheet, following the column header, are entirely numeric; otherwise the variables in `A` are cell arrays of character vectors. See Name/Value Pairs for more information.

`A = dataset('XPTFile', xptfilename, 'ParamName', Value)` creates a dataset array from a SAS® XPORT format file. Variable names from the XPORT format file are

preserved. Numeric data types in the XPORT format file are preserved but all other data types are converted to cell arrays of character vectors. The XPORT format allows for 28 missing data types. `dataset` represents these in the file by an upper case letter, ' . ' or ' _ '. `dataset` converts all missing data to NaN values in A. See Name/Value Pairs for more information.

Parameter Name/Value Pairs

Specify one or more of the following name/value pairs when constructing a dataset:

VarNames

A cell array `{name_1, ..., name_m}` naming the `m` variables in A with the specified variable names. Names must be valid, unique MATLAB identifiers. The number of names must equal the number of variables in A. You cannot use the `VarNames` parameter if you provide names for individual variables using `{VAR, name}` pairs. To specify `VarNames` when using a file as input, set `ReadVarNames` to `false`.

ObsNames

A cell array `{name_1, ..., name_n}` naming the `n` observations in A with the specified observation names. The names need not be valid MATLAB identifiers, but must be unique. The number of names must equal the number of observations (rows) in A. To specify `ObsNames` when using a file as input, set `ReadObsNames` to `false`.

Name/value pairs available when using text files as inputs:

Delimiter

A character vector indicating the character separating columns in the file. Values are

- `'\t'` (tab, the default when no `format` is specified)
- `' '` (space, the default when a `format` is specified)
- `','` (comma)
- `';'` (semicolon)
- `'|'` (bar)

Format

A format character vector, as accepted by `textscan`. `dataset` reads the file using `textscan`, and creates variables in A according to the conversion specifiers in the format

character vector. You may also provide any name/value pairs accepted by `textscan`. Using the `Format` parameter is much faster for large files. If `ReadObsNames` is `true`, then `format` should include a format specifier for the first column of the file.

HeaderLines

Numeric value indicating the number of lines to skip at the beginning of a file.

Default: 0

TreatAsEmpty

Specifies characters to treat as the empty character vector in a numeric column. Values may be a character array or a cell array of character vectors. The parameter applies only to numeric columns in the file; `dataset` does not accept numeric literals such as `'-99'`.

Name/value pairs available when using text files or Excel spreadsheets as inputs:

ReadVarNames

A logical value indicating whether (`true`) or not (`false`) to read variable names from the first row of the file. The default is `true`. If `ReadVarNames` is `true`, variable names in the column headers of the file or range (if using an Excel spreadsheet) cannot be empty.

ReadObsNames

A logical value indicating whether (`true`) or not (`false`) to read observation names from the first column of the file or range (if using an Excel spreadsheet). The default is `false`. If `ReadObsNames` and `ReadVarNames` are both `true`, `dataset` saves the header of the first column in the file or range as the name of the first dimension in `A.Properties.DimNames`.

When reading from an XPT format file, the `ReadObsNames` parameter name/value pair determines whether or not to try to use the first variable in the file as observation names. Specify as a logical value (default `false`). If the contents of the first variable are not valid observation names then `dataset` reads the variable into a variable of the dataset array and does not set the observation names.

Name/value pairs available when using Excel spreadsheets as input:

Sheet

A positive scalar value of type `double` indicating the sheet number, or a quoted sheet name.

Range

A character vector of the form `'C1:C2'` where `C1` and `C2` are the names of cells at opposing corners of a rectangular region to be read, as for `xls read`. By default, the rectangular region extends to the right-most column containing data. If the spreadsheet contains empty columns between columns of data, or if the spreadsheet contains figures or other non-tabular information, specify a range that contains only data.

Examples

Create a dataset array from workspace variables, including observation names:

```
load cereal
cereal = dataset(Calories,Protein,Fat,Sodium,Fiber,Carbo,...
    Sugars,'ObsNames',Name)
cereal.Properties.VarDescription = Variables(4:10,2);
```

Create a dataset array from a single, multi-columned workspace variable, designating variable names for each column:

```
load cities
categories = cellstr(categories);
cities = dataset({ratings,categories{:}},...
    'ObsNames',cellstr(names))
```

Load data from a text or spreadsheet file

```
patients = dataset('File','hospital.dat',...
    'Delimiter',',','ReadObsNames',true)
patients2 = dataset('XLSFile','hospital.xls',...
    'ReadObsNames',true)
```

- 1 Load patient data from the CSV file `hospital.dat` and store the information in a `dataset` array with observation names given by the first column in the data (patient identification):

```
patients = dataset('file','hospital.dat', ...
                  'format','%S%S%S%f%f%f%f%f%f%f', ...
                  'Delimiter',' ',' ','ReadObsNames',true);
```

You can also load the data without specifying a format. `dataset` will automatically create `dataset` variables that are either double arrays or cell arrays of character vectors, depending on the contents of the file:

```
patients = dataset('file','hospital.dat',...
                  'delimiter',' ','...',...
                  'ReadObsNames',true);
```

- 2 Make the {0,1}-valued variable `smoke` nominal, and change the labels to 'No' and 'Yes':

```
patients.smoke = nominal(patients.smoke,{'No','Yes'});
```

- 3 Add new levels to `smoke` as placeholders for more detailed histories of smokers:

```
patients.smoke = addlevels(patients.smoke,...
                          {'0-5 Years','5-10 Years','LongTerm'});
```

- 4 Assuming the nonsmokers have never smoked, relabel the 'No' level:

```
patients.smoke = setlabels(patients.smoke,'Never','No');
```

- 5 Drop the undifferentiated 'Yes' level from `smoke`:

```
patients.smoke = droplevels(patients.smoke,'Yes');
```

Warning: `OLDLEVELS` contains categorical levels that were present in `A`, caused some array elements to have undefined levels.

Note that smokers now have an undefined level.

- 6 Set each smoker to one of the new levels, by observation name:

```
patients.smoke('YPL-320') = '5-10 Years';
```

Introduced in R2007a

dataset2cell

Class: dataset

Convert dataset array to cell array

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

`C = dataset2cell(D)`

Description

`C = dataset2cell(D)` converts the dataset array `D` to a cell array `C`. Each variable of `D` becomes a column in `C`. If `D` is an `M`-by-`N` array, then `C` is `(M+1)`-by-`N`, with the variable names of `D` in the first row. If `D` contains observation names, then `C` is `(M+1)`-by-`(N+1)`, with the observation names in the first column.

“Dataset Arrays” on page 2-139

dataset2struct

Class: dataset

Convert dataset array to structure

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
S = dataset2struct(D)
S = dataset2struct(D, 'AsScalar', true)
```

Description

`S = dataset2struct(D)` converts a dataset array to a structure array. Each variable of `D` becomes a field in `S`. If `D` is an M -by- N dataset array, then `S` is M -by-1 and has N fields. If `D` contains observation names, then `S` contains those names in the additional field `ObsNames`.

`S = dataset2struct(D, 'AsScalar', true)` converts a dataset array to a scalar structure. Each variable of `D` becomes a field in `S`. If `D` is an M -by- N dataset array, then `S` has N fields, each of which as M rows. If `D` contains observation names, then `S` contains those names in the additional field `ObsNames`.

Input Arguments

D

M -by- N dataset array.

Output Arguments

S

M -by-1 structure array, with N fields. If the input dataset array contains observation names, then S has an additional field `ObsNames`.

If you specify `'AsScalar', true`, then S is a scalar structure, with N fields, each with M rows.

Examples

Convert Dataset Array to Structure Array

Load sample dataset array.

```
load('hospital')
```

Create a dataset array, D , that has only a subset of the observations and variables.

```
D = hospital(1:8,{'LastName', 'Sex', 'Age'});  
size(D)
```

```
ans = 1×2
```

```
      8      3
```

The dataset array D has 8 observations and 3 variables.

Convert D to a structure array.

```
S = dataset2struct(D)
```

```
S = 8x1 struct array with fields:
```

```
  ObsNames  
  LastName  
  Sex  
  Age
```

The structure is 8x1, corresponding to the 8 observations in the dataset array. S also has the field `ObsNames`, since D had observation names.

Display the field data for the first element of S.

S(1)

```
ans = struct with fields:
  ObsNames: 'YPL-320'
  LastName: 'SMITH'
  Sex: Male
  Age: 38
```

This information corresponds to the first observation (row) of the dataset array.

Convert Dataset Array to Scalar Structure

Load sample dataset array.

```
load('hospital')
```

Create a dataset array, D, that has only a subset of the observations and variables.

```
D = hospital(1:8,{'LastName','Sex','Age'});
size(D)
```

```
ans = 1x2
      8      3
```

The dataset array D has 8 observations and 3 variables.

Convert D to a scalar structure array.

```
S = dataset2struct(D, 'AsScalar', true)
```

```
S = struct with fields:
  ObsNames: {8x1 cell}
  LastName: {8x1 cell}
  Sex: [8x1 nominal]
```

```
Age: [8x1 double]
```

The data in the fields of the scalar structure is 8x1, corresponding to the 8 observations in the dataset array. `S` also has the field `ObsNames`, since `D` had observation names.

Display the data for the field `LastName`.

```
S.LastName
```

```
ans = 8x1 cell array
    {'SMITH' }
    {'JOHNSON' }
    {'WILLIAMS' }
    {'JONES' }
    {'BROWN' }
    {'DAVIS' }
    {'MILLER' }
    {'WILSON' }
```

The structure field `LastName` contains all of the data that was in the original dataset array variable, `LastName`.

dataset2table

Convert dataset array to table

Syntax

```
t = dataset2table(ds)
```

Description

`t = dataset2table(ds)` converts a dataset array to a table.

Examples

Convert Dataset Array to Table

Load the sample data, which contains nutritional information for 77 cereals.

```
load cereal;
```

Create a dataset array containing the calorie, protein, fat, and name data for the first five cereals. Label the variables.

```
Calories = Calories(1:5);  
Protein = Protein(1:5);  
Fat = Fat(1:5);  
Name = Name(1:5);
```

```
cereal = dataset(Calories,Protein,Fat,'ObsNames',Name)  
cereal.Properties.VarDescription = Variables(4:6,2);
```

```
cereal =
```

| | Calories | Protein | Fat |
|-----------|----------|---------|-----|
| 100% Bran | 70 | 4 | 1 |

| | | | |
|---------------------------|-----|---|---|
| 100% Natural Bran | 120 | 3 | 5 |
| All-Bran | 70 | 4 | 1 |
| All-Bran with Extra Fiber | 50 | 4 | 0 |
| Almond Delight | 110 | 2 | 2 |

Convert the dataset array to a table.

```
t = dataset2table(cereal)
```

```
t =
```

```
5x3 table
```

| | Calories | Protein | Fat |
|---------------------------|----------|---------|-------|
| | _____ | _____ | _____ |
| 100% Bran | 70 | 4 | 1 |
| 100% Natural Bran | 120 | 3 | 5 |
| All-Bran | 70 | 4 | 1 |
| All-Bran with Extra Fiber | 50 | 4 | 0 |
| Almond Delight | 110 | 2 | 2 |

Input Arguments

ds — Input dataset array

dataset array

Input dataset array to convert to a table, specified as a dataset array. Each variable in **ds** becomes a variable in the output table **t**.

Output Arguments

t — Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see “Tables” (MATLAB).

“Tables” (MATLAB)

Introduced in R2013b

datasetfun

Class: dataset

Apply function to dataset array variables

Note The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
b = datasetfun(fun,A)
[b,c,...] = datasetfun(fun,A)
[b,...] = datasetfun(fun,A,...,'UniformOutput',false)
[b,...] = datasetfun(fun,A,...,'DatasetOutput',true)
[b,...] = datasetfun(fun,A,...,'DataVars',vars)
[b,...] = datasetfun(fun,A,...,'ObsNames',obsnames)
[b,...] = datasetfun(fun,A,...,'ErrorHandler',efun)
```

Description

`b = datasetfun(fun,A)` applies the function specified by `fun` to each variable of the dataset array `A`, and returns the results in the vector `b`. The *i*th element of `b` is equal to `fun` applied to the *i*th dataset variable of `A`. `fun` is a function handle to a function that takes one input argument and returns a scalar value. `fun` must return values of the same class each time it is called, and `datasetfun` concatenates them into the vector `b`. The outputs from `fun` must be one of the following types: numeric, logical, character, structure, or cell.

To apply functions that return results that are nonscalar or of different sizes and types, use the `'UniformOutput'` or `'DatasetOutput'` parameters described below.

Do not rely on the order in which `datasetfun` computes the elements of `b`, which is unspecified.

If `fun` is bound to more than one built-in function or file, (that is, if it represents a set of overloaded functions), `datasetfun` follows MATLAB dispatching rules in calling the function. (See “Function Precedence Order” (MATLAB).)

`[b,c,...] = datasetfun(fun,A)`, where `fun` is a function handle to a function that returns multiple outputs, returns vectors `b`, `c`, ..., each corresponding to one of the output arguments of `fun`. `datasetfun` calls `fun` each time with as many outputs as there are in the call to `datasetfun`. `fun` may return output arguments having different classes, but the class of each output must be the same each time `fun` is called.

`[b,...] = datasetfun(fun,A,...,'UniformOutput',false)` allows you to specify a function `fun` that returns values of different sizes or types. `datasetfun` returns a cell array (or multiple cell arrays), where the *i*th cell contains the value of `fun` applied to the *i*th dataset variable of `A`. Setting `'UniformOutput'` to `true` is equivalent to the default behavior.

`[b,...] = datasetfun(fun,A,...,'DatasetOutput',true)` specifies that the output(s) of `fun` are returned as variables in a dataset array (or multiple dataset arrays). `fun` must return values with the same number of rows each time it is called, but it may return values of any type. The variables in the output dataset array(s) have the same names as the variables in the input. Setting `'DatasetOutput'` to `false` (the default) specifies that the type of the output(s) from `datasetfun` is determined by `'UniformOutput'`.

`[b,...] = datasetfun(fun,A,...,'DataVars',vars)` allows you to apply `fun` only to the dataset variables in `A` specified by `vars`. `vars` is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector.

`[b,...] = datasetfun(fun,A,...,'ObsNames',obsnames)` specifies observation names for the dataset output when `'DatasetOutput'` is `true`.

`[b,...] = datasetfun(fun,A,...,'ErrorHandler',efun)`, where `efun` is a function handle, specifies the MATLAB function to call if the call to `fun` fails. The error-handling function is called with the following input arguments:

- A structure with the fields `identifier`, `message`, and `index`, respectively containing the identifier of the error that occurred, the text of the error message, and the linear index into the input array(s) at which the error occurred
- The set of input arguments at which the call to the function failed

The error-handling function should either re-throw an error, or return the same number of outputs as `fun`. These outputs are then returned as the outputs of `datasetfun`. If `'UniformOutput'` is true, the outputs of the error handler must also be scalars of the same type as the outputs of `fun`. For example, the following code could be saved in a file as the error-handling function:

```
function [A,B] = errorFunc(S,varargin)

warning(S.identifier,S.message);
A = NaN;
B = NaN;
```

If an error-handling function is not specified, the error from the call to `fun` is rethrown.

Examples

Work With Datasets Using Function Handles

Use function handles to compute the mean and plot a histogram of selected variables in a dataset array.

Load the sample data.

```
load hospital
```

Use `datasetfun` to compute the means of the `Weight` and `BloodPressure` variables, and store the results in a dataset array.

```
stats = datasetfun(@mean,hospital,...
    'DataVars',{'Weight','BloodPressure'},...
    'UniformOutput',false)

stats = 1x2 cell array
    {[154]}    {1x2 double}
```

The variable `BloodPressure` contains two columns: One for the systolic measurement, and one for the diastolic measurement.

Display the mean of the blood pressure variable.

```
stats{2}
```

```
ans = 1×2  
  
122.7800  82.9600
```

Plot a histogram of the blood pressure variable.

```
datasetfun(@hist,hospital,...  
           'DataVars','BloodPressure',...  
           'UniformOutput',false);  
title({'\bf Blood Pressure'})  
legend('Systolic','Diastolic','Location','N')
```

grpstats

daugment

D-optimal augmentation

Syntax

```
dCE2 = daugment(dCE,mruns)
[dCE2,X] = daugment(dCE,mruns)
[dCE2,X] = daugment(dCE,mruns,model)
[dCE2,X] = daugment(...,param1,val1,param2,val2,...)
```

Description

`dCE2 = daugment(dCE,mruns)` uses a coordinate-exchange algorithm to *D*-optimally add `mruns` runs to an existing experimental design `dCE` for a linear additive model.

`[dCE2,X] = daugment(dCE,mruns)` also returns the design matrix `X` associated with the augmented design.

`[dCE2,X] = daugment(dCE,mruns,model)` uses the linear regression model specified in `model`. `model` is one of the following:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

The order of the columns of `X` for a full quadratic model with n terms is:

- 1 The constant term
- 2 The linear terms in order 1, 2, ..., n
- 3 The interaction terms in order (1, 2), (1, 3), ..., (1, n), (2, 3), ..., ($n - 1$, n)
- 4 The squared terms in order 1, 2, ..., n

Other models use a subset of these terms, in the same order.

Alternatively, *model* can be a matrix specifying polynomial terms of arbitrary order. In this case, *model* should have one column for each factor and one row for each term in the model. The entries in any row of *model* are powers for the factors in the columns. For example, if a model has factors X1, X2, and X3, then a row [0 1 2] in *model* specifies the term $(X1.^0) \cdot (X2.^1) \cdot (X3.^2)$. A row of all zeros in *model* specifies a constant term, which can be omitted.

[dCE2,X] = daugment(...,param1, val1,param2, val2,...) specifies additional parameter/value pairs for the design. Valid parameters and their values are listed in the following table.

| Parameter | Value |
|----------------|---|
| 'bounds' | Lower and upper bounds for each factor, specified as a 2-by-nfactors matrix, where nfactors is the number of factors. Alternatively, this value can be a cell array containing nfactors elements, each element specifying the vector of allowable values for the corresponding factor. |
| 'categorical' | Indices of categorical predictors. |
| 'display' | Either 'on' or 'off' to control display of the iteration counter. The default is 'on'. |
| 'excludedefun' | Handle to a function that excludes undesirable runs. If the function is <i>f</i> , it must support the syntax $b = f(S)$, where <i>S</i> is a matrix of treatments with nfactors columns, where nfactors is the number of factors, and <i>b</i> is a vector of Boolean values with the same number of rows as <i>S</i> . <i>b</i> (<i>i</i>) is true if the <i>i</i> th row <i>S</i> should be excluded. |
| 'init' | Initial design as an mruns-by-nfactors matrix, where nfactors is the number of factors. The default is a randomly selected set of points. |
| 'levels' | Vector of number of levels for each factor. |
| 'maxiter' | Maximum number of iterations. The default is 10. |

| Parameter | Value |
|-----------|--|
| 'options' | <p>The value is a structure that contains options specifying whether to compute multiple tries in parallel, and specifying how to use random numbers when generating the starting points for the tries. Create the options structure with <code>statset</code>. Applicable <code>statset</code> parameters are:</p> <ul style="list-style-type: none"> • 'UseParallel' — If <code>true</code> and if a <code>parpool</code> of the Parallel Computing Toolbox is open, compute in parallel. If the Parallel Computing Toolbox is not installed, or a <code>parpool</code> is not open, computation occurs in serial mode. Default is <code>false</code>, meaning serial computation. • <code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code>. • <code>Streams</code> — A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code>, <code>daugment</code> uses the default stream or streams. If you choose to specify <code>Streams</code>, use a single object except in the case <ul style="list-style-type: none"> • You have an open Parallel pool • <code>UseParallel</code> is <code>true</code> • <code>UseSubstreams</code> is <code>false</code> <p>In that case, use a cell array the same size as the Parallel pool.</p> |
| 'tries' | <p>Number of times to try to generate a design from a new starting point. The algorithm uses random points for each try, except possibly the first. The default is 1.</p> |

Note The `daugment` function augments an existing design using a coordinate-exchange algorithm; the `'start'` parameter of the `candexch` function provides the same functionality using a row-exchange algorithm.

Examples

The following eight-run design is adequate for estimating main effects in a four-factor model:

```
dCEmain = cordexch(4,8)
dCEmain =
    1    -1    -1    1
   -1    -1     1    1
   -1     1    -1    1
    1     1     1   -1
    1     1     1    1
   -1     1    -1   -1
    1    -1    -1   -1
   -1    -1     1   -1
```

To estimate the six interaction terms in the model, augment the design with eight additional runs:

```
dCEinteraction = daugment(dCEmain,8,'interaction')
dCEinteraction =
    1    -1    -1     1
   -1    -1     1     1
   -1     1    -1     1
    1     1     1    -1
    1     1     1     1
   -1     1    -1    -1
    1    -1    -1    -1
   -1    -1     1    -1
   -1     1     1     1
   -1    -1    -1    -1
    1    -1     1    -1
    1     1    -1     1
   -1     1     1    -1
    1     1    -1    -1
    1    -1     1     1
    1     1     1    -1
```

The augmented design is full factorial, with the original eight runs in the first eight rows.

candexch | cordexch | dcovary

Introduced before R2006a

dcovary

D-optimal design with fixed covariates

Syntax

```
dCV = dcovary(nfactors, fixed)
[dCV, X] = dcovary(nfactors, fixed)
[dCV, X] = dcovary(nfactors, fixed, model)
[dCV, X] = daugment(..., param1, val1, param2, val2, ...)
```

Description

`dCV = dcovary(nfactors, fixed)` uses a coordinate-exchange algorithm to generate a *D*-optimal design for a linear additive model with `nfactors` factors, subject to the constraint that the model include the fixed covariate factors in `fixed`. The number of runs in the design is the number of rows in `fixed`. The design `dCV` augments `fixed` with initial columns for treatments of the model terms.

`[dCV, X] = dcovary(nfactors, fixed)` also returns the design matrix `X` associated with the design.

`[dCV, X] = dcovary(nfactors, fixed, model)` uses the linear regression model specified in `model`. `model` is one of the following:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

The order of the columns of `X` for a full quadratic model with n terms is:

- 1 The constant term
- 2 The linear terms in order 1, 2, ..., n
- 3 The interaction terms in order (1, 2), (1, 3), ..., (1, n), (2, 3), ..., ($n - 1$, n)

4 The squared terms in order 1, 2, ..., n

Other models use a subset of these terms, in the same order.

Alternatively, *model* can be a matrix specifying polynomial terms of arbitrary order. In this case, *model* should have one column for each factor and one row for each term in the model. The entries in any row of *model* are powers for the factors in the columns. For example, if a model has factors X_1 , X_2 , and X_3 , then a row `[0 1 2]` in *model* specifies the term $(X_1.^0) \cdot (X_2.^1) \cdot (X_3.^2)$. A row of all zeros in *model* specifies a constant term, which can be omitted.

`[dCV,X] = daugment(...,param1,val1,param2,val2,...)` specifies additional parameter/value pairs for the design. Valid parameters and their values are listed in the following table.

| Parameter | Value |
|---------------|---|
| 'bounds' | Lower and upper bounds for each factor, specified as a 2-by- <code>nfactors</code> matrix. Alternatively, this value can be a cell array containing <code>nfactors</code> elements, each element specifying the vector of allowable values for the corresponding factor. |
| 'categorical' | Indices of categorical predictors. |
| 'display' | Either 'on' or 'off' to control display of the iteration counter. The default is 'on'. |
| 'excldefun' | Handle to a function that excludes undesirable runs. If the function is f , it must support the syntax $b = f(S)$, where S is a matrix of treatments with <code>nfactors</code> columns and b is a vector of Boolean values with the same number of rows as S . $b(i)$ is true if the i th row S should be excluded. |
| 'init' | Initial design as an <code>mruns</code> -by- <code>nfactors</code> matrix. The default is a randomly selected set of points. |
| 'levels' | Vector of number of levels for each factor. |
| 'maxiter' | Maximum number of iterations. The default is 10. |

| Parameter | Value |
|-----------|---|
| 'options' | <p>The value is a structure that contains options specifying whether to compute multiple tries in parallel, and specifying how to use random numbers when generating the starting points for the tries. Create the options structure with <code>statset</code>. Applicable <code>statset</code> parameters are:</p> <ul style="list-style-type: none"> • 'UseParallel' — If <code>true</code> and if a <code>parpool</code> of the Parallel Computing Toolbox is open, compute in parallel. If the Parallel Computing Toolbox is not installed, or a <code>parpool</code> is not open, computation occurs in serial mode. Default is <code>false</code>, meaning serial computation. • <code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code>. • <code>Streams</code> — A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code>, <code>dcovary</code> uses the default stream or streams. If you choose to specify <code>Streams</code>, use a single object except in the case <ul style="list-style-type: none"> • You have an open Parallel pool • <code>UseParallel</code> is <code>true</code> • <code>UseSubstreams</code> is <code>false</code> <p>In that case, use a cell array the same size as the Parallel pool.</p> |
| 'tries' | <p>Number of times to try to generate a design from a new starting point. The algorithm uses random points for each try, except possibly the first. The default is 1.</p> |

Examples

Example 1

Suppose you want a design to estimate the parameters in a three-factor linear additive model, with eight runs that necessarily occur at different times. If the process

experiences temporal linear drift, you may want to include the run time as a variable in the model. Produce the design as follows:

```
time = linspace(-1,1,8)';
[dCV1,X] = dcovary(3,time,'linear')
dCV1 =
-1.0000    1.0000    1.0000   -1.0000
 1.0000   -1.0000   -1.0000   -0.7143
-1.0000   -1.0000   -1.0000   -0.4286
 1.0000   -1.0000    1.0000   -0.1429
 1.0000    1.0000   -1.0000    0.1429
-1.0000    1.0000   -1.0000    0.4286
 1.0000    1.0000    1.0000    0.7143
-1.0000   -1.0000    1.0000    1.0000
X =
 1.0000   -1.0000    1.0000    1.0000   -1.0000
 1.0000    1.0000   -1.0000   -1.0000   -0.7143
 1.0000   -1.0000   -1.0000   -1.0000   -0.4286
 1.0000    1.0000   -1.0000    1.0000   -0.1429
 1.0000    1.0000    1.0000   -1.0000    0.1429
 1.0000   -1.0000    1.0000   -1.0000    0.4286
 1.0000    1.0000    1.0000    1.0000    0.7143
 1.0000   -1.0000   -1.0000    1.0000    1.0000
```

The column vector `time` is a fixed factor, normalized to values between ± 1 . The number of rows in the fixed factor specifies the number of runs in the design. The resulting design dCV gives factor settings for the three controlled model factors at each time.

Example 2

The following example uses the `dummyvar` function to block an eight-run experiment into 4 blocks of size 2 for estimating a linear additive model with two factors:

```
fixed = dummyvar([1 1 2 2 3 3 4 4]);
dCV2 = dcovary(2,fixed(:,1:3),'linear')
dCV2 =
 1    1    1    0    0
-1   -1    1    0    0
-1    1    0    1    0
 1   -1    0    1    0
 1    1    0    0    1
-1   -1    0    0    1
-1    1    0    0    0
 1   -1    0    0    0
```

The first two columns of dCV2 contain the settings for the two factors; the last three columns are dummy variable codings for the four blocks.

delete

Class: grandstream

Delete handle object

Syntax

`delete(h)`

Description

`delete(h)` deletes the handle object `h`, where `h` is a scalar handle. The `delete` method deletes a handle object but does not clear the handle from the workspace. A deleted handle is no longer valid.

Dendrogram plot

Syntax

```
dendrogram(tree)
dendrogram(tree,Name,Value)
```

```
dendrogram(tree,P)
dendrogram(tree,P,Name,Value)
```

```
H = dendrogram( ___ )
[H,T,outperm] = dendrogram( ___ )
```

Description

`dendrogram(tree)` generates a dendrogram plot of the hierarchical binary cluster tree. A dendrogram consists of many *U*-shaped lines that connect data points in a hierarchical tree. The height of each *U* represents the distance between the two data points being connected.

- If there are 30 or fewer data points in the original data set, then each leaf in the dendrogram corresponds to one data point.
- If there are more than 30 data points, then `dendrogram` collapses lower branches so that there are 30 leaf nodes. As a result, some leaves in the plot correspond to more than one data point.

`dendrogram(tree,Name,Value)` uses additional options specified by one or more name-value pair arguments.

`dendrogram(tree,P)` generates a dendrogram plot with no more than *P* leaf nodes. If there are more than *P* data points in the original data set, then `dendrogram` collapses the lower branches of the tree. As a result, some leaves in the plot correspond to more than one data point.

`dendrogram(tree,P,Name,Value)` uses additional options specified by one or more name-value pair arguments.

`H = dendrogram(___)` generates a dendrogram plot and returns a vector of line handles. You can use any of the input arguments from the previous syntaxes.

`[H,T,outperm] = dendrogram(___)` also returns a vector containing the leaf node number for each object in the original data set, `T`, and a vector giving the order of the node labels of the leaves as shown in the dendrogram, `outperm`.

- It is useful to return `T` when the number of leaf nodes, `P`, is less than the total number of data points, so that some leaf nodes in the display correspond to multiple data points.
- The order of the node labels given in `outperm` is from left to right for a horizontal dendrogram, and from bottom to top for a vertical dendrogram.

Examples

Plot Dendrogram

Generate sample data.

```
rng('default') % For reproducibility
X = rand(10,3);
```

Create a hierarchical binary cluster tree using `linkage`. Then, plot the dendrogram using the default options.

```
tree = linkage(X,'average');

figure()
dendrogram(tree)
```

Specify Dendrogram Leaf Node Order

Generate sample data.

```
rng('default') % For reproducibility  
X = rand(10,3);
```

Create a hierarchical binary cluster tree using linkage.

```
tree = linkage(X, 'average');
```

```
D = pdist(X);  
leafOrder = optimalleaforder(tree,D)  
  
leafOrder = 1×10  
      3      7      6      1      4      9      5      8      10      2
```

Plot the dendrogram using an optimal leaf order.

```
figure()  
dendrogram(tree, 'Reorder', leafOrder)
```

The order of the leaf nodes in the dendrogram plot corresponds - from left to right - to the permutation in `leafOrder`.

Specify Number of Nodes in Dendrogram Plot

Generate sample data.

```
rng('default') % For reproducibility
X = rand(100,2);
```

There are 100 data points in the original data set, X.

Create a hierarchical binary cluster tree using `linkage`. Then, plot the dendrogram for the complete tree (100 leaf nodes) by setting the input argument P equal to 0.

```
tree = linkage(X,'average');
dendrogram(tree,0)
```

Now, plot the dendrogram with only 25 leaf nodes. Return the mapping of the original data points to the leaf nodes shown in the plot.

```
figure
[~,T] = dendrogram(tree,25);
```

List the original data points that are in leaf node 7 of the dendrogram plot.

```
find(T==7)
```

```
ans = 7×1
```

```
7
33
60
```

70
74
76
86

Change Dendrogram Orientation and Line Width

Generate sample data.

```
rng('default') % For reproducibility  
X = rand(10,3);
```

Create a hierarchical binary cluster tree using `linkage`. Then, plot the dendrogram with a vertical orientation, using the default color threshold. Return handles to the lines so you can change the dendrogram line widths.

```
tree = linkage(X,'average');  
H = dendrogram(tree,'Orientation','left','ColorThreshold','default');  
set(H,'LineWidth',2)
```

Input Arguments

tree — Hierarchical binary cluster tree

matrix returned by `linkage`

Hierarchical binary cluster tree, specified as an $(M - 1)$ -by-3 matrix that you generate using `linkage`, where M is the number of data points in the original data set.

P — Maximum number of leaf nodes

30 (default) | positive integer value

Maximum number of leaf nodes to include in the dendrogram plot, specified as a positive integer value.

- If there are P or fewer data points in the original data set, then each leaf in the dendrogram corresponds to one data point.
- If there are more than P data points, then `dendrogram` collapses lower branches so that there are P leaf nodes. As a result, some leaves in the plot correspond to more than one data point.

If you do not specify P , then `dendrogram` uses 30 as the maximum number of leaf nodes. To display the complete tree, set P equal to 0.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Orientation', 'left', 'Reorder', myOrder` specifies a vertical dendrogram with leaves in the order specified by `myOrder`.

Reorder — Order of leaf nodes

vector

Order of leaf nodes in the dendrogram plot, specified as the comma-separated pair consisting of `'Reorder'` and a vector giving the order of nodes in the complete tree. The order vector must be a permutation of the vector $1:M$, where M is the number of data points in the original data set. Specify the order from left to right for horizontal dendrograms, and from bottom to top for vertical dendrograms.

If M is greater than the number of leaf nodes in the dendrogram plot, P (by default, P is 30), then you can only specify a permutation vector that does not separate the groups of leaves that correspond to collapsed nodes.

Data Types: `single` | `double`

CheckCrossing — Indicator for whether to check for crossing branches

`true` (default) | `false`

Indicator for whether to check for crossing branches in the dendrogram plot, specified as the comma-separated pair consisting of `'CheckCrossing'` and either `true` or `false`. This option is only useful when you specify a value for `Reorder`.

When `CheckCrossing` has the value `true`, `dendrogram` issues a warning if the order of the leaf nodes causes crossing branches in the plot. If the dendrogram plot does not show a complete tree (because the number of data points in the original data set is greater than `P`), `dendrogram` only issues a warning when the order of the leaf nodes causes branch to cross in the dendrogram as shown in the plot. That is, there is no warning if the order causes crossing branches in the complete tree but not in the dendrogram as shown in the plot.

Data Types: `logical`

ColorThreshold — Threshold for unique colors

`'default'` | scalar value in the range $(0, \max(\text{tree}(:, 3)))$

Threshold for unique colors in the dendrogram plot, specified as the comma-separated pair consisting of `'ColorThreshold'` and either `'default'` or a scalar value in the range $(0, \max(\text{tree}(:, 3)))$. If `ColorThreshold` has the value T , then `dendrogram` assigns a unique color to each group of nodes in the dendrogram whose linkage is less than T .

- If `ColorThreshold` has the value `'default'`, then the threshold, T , is 70% of the maximum linkage, $0.7 * \max(\text{tree}(:, 3))$.
- If you do not specify a value for `ColorThreshold`, or if you specify a threshold outside the range $(0, \max(\text{tree}(:, 3)))$, then `dendrogram` uses only one color for the dendrogram plot.

Orientation — Orientation of dendrogram

`'top'` (default) | `'bottom'` | `'left'` | `'right'`

Orientation of the dendrogram in the figure window, specified as the comma-separated pair consisting of `'Orientation'` and one of these values:

| | |
|-----------------------|---------------|
| <code>'top'</code> | Top to bottom |
| <code>'bottom'</code> | Bottom to top |
| <code>'left'</code> | Left to right |
| <code>'right'</code> | Right to left |

Labels — Label for each data point

character array | string array | cell array of character vectors

Label for each data point in the original data set, specified as the comma-separated pair consisting of `'Labels'` and a character array, string array or cell array of character

vectors. `dendrogram` labels any leaves in the dendrogram plot containing a single data point with that data point's label.

Output Arguments

H — Handles to lines

vector

Handles to lines in the dendrogram plot, returned as a vector.

T — Leaf node numbers

column vector

Leaf node numbers for each data point in the original data set, returned as a column vector of length M , where M is the number of data points in the original data set.

When there are fewer than P data points in the original data (P is 30, by default), all data points are displayed in the dendrogram, with each node containing a single data point. In this case, T is the identity map, $T = (1:M)'$.

T is useful when P is less than the total number of data points. That is, when some leaf nodes in the dendrogram display correspond to multiple data points. For example, to find out which data points are contained in leaf node k of the dendrogram plot, use `find(T==k)`.

outperm — Permutation of node labels

vector

Permutation of the node labels of the leaves of the dendrogram as shown in the plot, returned as a row vector. `outperm` gives the order from left to right for a horizontal dendrogram, and from bottom to top for a vertical dendrogram. If there are P leaves in the dendrogram plot, `outperm` is a permutation of the vector $1:P$.

Introduced before R2006a

Description property

Class: dataset

Character vector describing data set

Note The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Description

`Description` is a character vector describing the data set. The default is an empty character vector.

designecoc

Coding matrix for reducing error-correcting output code to binary

Syntax

```
M = designecoc(K,name)
M = designecoc(K,name,Name,Value)
```

Description

`M = designecoc(K,name)` returns the coding matrix `M` that reduces the error-correcting output code (ECOC) design specified by `name` and `K` classes to a binary problem. `M` has `K` rows and `L` columns, with each row corresponding to a class and each column corresponding to a binary learner. `name` and `K` determine the value of `L`.

You can view or customize `M`, and then specify it as the coding matrix for training an ECOC multiclass classifier using `fitcecoc`.

`M = designecoc(K,name,Name,Value)` returns the coding matrix with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the number of trials when generating a dense or sparse, random coding matrix.

Examples

Train ECOC Classifiers Using a Custom Coding Design

Consider the `arrhythmia` data set. There are 16 classes in the study, 13 of which are represented in the data. The first class indicates that the subject did not have arrhythmia, and the last class indicates that the subject's arrhythmia state was not recorded. Suppose that the other classes are ordinal levels indicating the severity of arrhythmia. Train an ECOC classifier using a custom coding design specified by the description of the classes.

Load the arrhythmia data set.

```
load arrhythmia
K = 13; % Number of distinct classes
```

Construct a coding matrix that describes the nature of the classes.

```
OrdMat = designcoc(11,'ordinal');
nOM = size(OrdMat);
class1VS0rd = [1; -ones(11,1); 0];
class1VSClass16 = [1; zeros(11,1); -1];
OrdVSClass16 = [0; ones(11,1); -1];
Coding = [class1VS0rd class1VSClass16 OrdVSClass16,...
          [zeros(1,nOM(2)); OrdMat; zeros(1,nOM(2))]]
```

```
Coding = 13×13
```

```
    1    1    0    0    0    0    0    0    0    0    0    0    0 ...
   -1    0    1   -1   -1   -1   -1   -1   -1   -1   -1   -1   -1
   -1    0    1    1   -1   -1   -1   -1   -1   -1   -1   -1   -1
   -1    0    1    1    1   -1   -1   -1   -1   -1   -1   -1   -1
   -1    0    1    1    1    1   -1   -1   -1   -1   -1   -1   -1
   -1    0    1    1    1    1    1   -1   -1   -1   -1   -1   -1
   -1    0    1    1    1    1    1    1   -1   -1   -1   -1   -1
   -1    0    1    1    1    1    1    1    1   -1   -1   -1   -1
   -1    0    1    1    1    1    1    1    1    1   -1   -1   -1
   :
```

Train an ECOC classifier using the custom coding design `Coding` and specify that the binary learners are decision trees.

```
Mdl = fitcecoc(X,Y,'Coding',Coding,'Learner','Tree');
```

Estimate the in-sample classification error.

```
genErr = resubLoss(Mdl)
```

```
genErr = 0.1460
```

Choose Among Several Random Coding Designs

If you request a random coding matrix by specifying `sparserandom` or `denserandom`, then, by default, `designecoc` generates 10,000 random matrices. Then, it chooses the matrix with the largest, minimal, pair-wise row distances based on the Hamming measure. You can specify to generate more matrices to increase the chance of obtaining a better one, or you can generate several coding matrices, and then see which performs best.

Load the `arrhythmia` data set. Reserve the observations classified into class 16 (i.e., those that do not have an arrhythmia classification) as new data.

```
load arrhythmia
oosIdx = Y == 16;
isIdx = ~oosIdx;
Y = categorical(Y(isIdx));
tabulate(Y)
```

| Value | Count | Percent |
|-------|-------|---------|
| 1 | 245 | 56.98% |
| 2 | 44 | 10.23% |
| 3 | 15 | 3.49% |
| 4 | 15 | 3.49% |
| 5 | 13 | 3.02% |
| 6 | 25 | 5.81% |
| 7 | 3 | 0.70% |
| 8 | 2 | 0.47% |
| 9 | 9 | 2.09% |
| 10 | 50 | 11.63% |
| 14 | 4 | 0.93% |
| 15 | 5 | 1.16% |

```
K = numel(unique(Y));
```

Generate four random coding design matrices such that the first two are dense and the second two are sparse. Specify to find the best out of 20,000 variates.

```
rng(1); % For reproducibility

Coding = cell(4,1); % Preallocate for coding matrices
CodingTypes = {'denserandom', 'denserandom', 'sparserandom', 'sparserandom'};
for j = 1:4;
    Coding{j} = designecoc(K, CodingTypes{j}, 'NumTrials', 2e4);
end
```

Coding is a 4-by-1 cell array, where each cell is a coding design matrix. The matrices have K rows, but the number of columns (i.e., binary learners) might vary.

Train and cross validate ECOC classifiers using the 15-fold cross validation. Specify that each ECOC classifier be trained using a classification tree, and the random coding matrix stored in Coding.

```
Mdl = cell(4,1); % Preallocate for the ECOC classifiers
for j = 1:4;
    Mdl{j} = fitcecoc(X(isIdx,:),Y,'Learners','tree',...
        'Coding',Coding{j},'KFold',15);
end
```

```
Warning: One or more folds do not contain points from all the groups.
```

```
Warning: One or more folds do not contain points from all the groups.
```

```
Warning: One or more folds do not contain points from all the groups.
```

```
Warning: One or more folds do not contain points from all the groups.
```

Mdl is a 4-by-1 cell array of ClassificationPartitionedECOC models. Several classes have low relative frequency in the data, and so there is a chance that, during cross validation, some in-sample folds will not train using observations from those classes.

Estimate the 15-fold classification error for each classifier.

```
genErr = nan(4,1);
for j = 1:4;
    genErr(j) = kfoldLoss(Mdl{j});
end
```

```
genErr
```

```
genErr = 4×1
```

```
    0.2349
    0.2140
    0.2116
    0.2279
```

Though the generalization error is still high, the best performing model, based solely on the out-of-sample classification error, is the model that used the coding design Coding{3}.

You can try to improve the generalization error by tuning some parameters of the binary learners. For example, you can specify to use the twoing rule or deviance for the split criterion, rather than the default Gini's diversity index. You might also specify to use surrogate splits since there are missing values in the data.

Input Arguments

K — Number of classes

positive integer

Number of classes, specified as a positive integer.

K specifies the number of rows of the coding matrix M.

Data Types: single | double

name — Coding design name

'binarycomplete' | 'denserandom' | 'onevsall' | 'onevsone' |
'sparserandom' | ...

Coding design name, specified as 'binarycomplete', 'denserandom', 'onevsall', 'onevsone', or 'sparserandom'. This table summarizes the available coding schemes.

| Value | Number of Binary Learners | Description |
|---------------------------|---------------------------|--|
| 'allpairs' and 'onevsone' | $K(K - 1)/2$ | For each binary learner, one class is positive, another is negative, and the software ignores the rest. This design exhausts all combinations of class pair assignments. |

| Value | Number of Binary Learners | Description |
|------------------|---|--|
| 'binarycomplete' | $2^{(K-1)} - 1$ | This design partitions the classes into all binary combinations, and does not ignore any classes. For each binary learner, all class assignments are -1 and 1 with at least one positive and negative class in the assignment. |
| 'denserandom' | Random, but approximately $10 \log_2 K$ | For each binary learner, the software randomly assigns classes into positive or negative classes, with at least one of each type. For more details, see "Random Coding Design Matrices" on page 32-1877. |
| 'onevsall' | K | For each binary learner, one class is positive and the rest are negative. This design exhausts all combinations of positive class assignments. |
| 'ordinal' | $K - 1$ | For the first binary learner, the first class is negative, and the rest positive. For the second binary learner, the first two classes are negative, the rest positive, and so on. |

| Value | Number of Binary Learners | Description |
|-------------------|---|---|
| 'sparsestrandom' | Random, but approximately $15 \log_2 K$ | For each binary learner, the software randomly assigns classes as positive or negative with probability 0.25 for each, and ignores classes with probability 0.5. For more details, see “Random Coding Design Matrices” on page 32-1877. |
| 'ternarycomplete' | $(3^K - 2^{(K+1)} + 1) / 2$ | This design partitions the classes into all ternary combinations. All class assignments are 0, -1, and 1 with at least one positive and one negative class in the assignment. |

Data Types: char

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'NumTrials', 1000` specifies to generate 1000 random matrices.

NumTrials — Number of random coding matrices to generate
10000 (default) | positive integer

Number of random coding matrices to generate, specified as the comma-separated pair consisting of 'NumTrials' and a positive integer.

The software:

- Generates `NumTrials` matrices, and selects the one with the maximal, pair-wise row distance.

- Ignores `NumTrials` for all values of `name` except `'denserandom'` and `'sparserandom'`.

Example: `'NumTrials', 1000`

Data Types: `single` | `double`

Output Arguments

M — Coding matrix

numeric matrix

Coding matrix that reduces an ECOC scheme to binary, returned as a numeric matrix. `M` has `K` rows and `L` columns, where `L` is the number of binary learners. Each row corresponds to a class and each column corresponds to a binary learner.

The elements of `M` are `-1`, `0`, or `1`, and the value corresponds to a dichotomous class assignment. This table describes the meaning of `M(i, j)`, that is, the class that learner `j` assigns to observations in class `i`.

| Value | Dichotomous Class Assignment |
|-------|---|
| -1 | Negative class |
| 0 | Before training, learner <code>j</code> removes observations in class <code>i</code> from the data set. |
| 1 | Positive class |

The binary learners for designs `denserandom`, `binarycomplete`, and `onevsall` do not assign `0` to observations in any class.

Tips

- The number of binary learners grows with the number of classes. For a problem with many classes, the `binarycomplete` and `ternarycomplete` coding designs are not efficient. However:
 - If $K \leq 4$, then use `ternarycomplete` coding design rather than `sparserandom`.
 - If $K \leq 5$, then use `binarycomplete` coding design rather than `denserandom`.

You can display the coding design matrix of a trained ECOC classifier by entering `Mdl.CodingMatrix` into the Command Window.

- You should form a coding matrix using intimate knowledge of the application, and taking into account computational constraints. If you have sufficient computational power and time, then try several coding matrices and choose the one with the best performance (e.g., check the confusion matrices for each model using `confusionmat`).
- Leave-one-out cross-validation (`Leaveout`) is inefficient for data sets with many observations. Instead, use k -fold cross-validation (`KFold`).

Algorithms

Custom Coding Design Matrices

Custom coding matrices must have a certain form. The software validates custom coding matrices by ensuring:

- Every element is -1, 0, or 1.
- Every column contains at least one -1 and one 1.
- For all distinct column vectors u and v , $u \neq v$ and $u \neq -v$.
- All row vectors are unique.
- The matrix can separate any two classes. That is, you can travel from any row to any other row following these rules:
 - You can move vertically from 1 to -1 or -1 to 1.
 - You can move horizontally from a nonzero element to another nonzero element.
 - You can use a column of the matrix for a vertical move only once.

If it is not possible to move from row i to row j using these rules, then classes i and j cannot be separated by the design. For example, in the coding design

$$\begin{bmatrix} 1 & 0 \\ -1 & 0 \\ 0 & 1 \\ 0 & -1 \end{bmatrix}$$

classes 1 and 2 cannot be separated from classes 3 and 4 (that is, you cannot move horizontally from the -1 in row 2 to column 2 since there is a 0 in that position). Therefore, the software rejects this coding design.

Random Coding Design Matrices

For a given number of classes, for example, K , the software generates random coding design matrices as follows.

- 1 The software generates one of the following:
 - a Dense random — The software assigns a 1 or -1 with equal probability to each element of the K -by- L_d coding design matrix, where $L_d \approx \lceil 10 \log_2 K \rceil$.
 - b Sparse random — The software assigns a 1 to each element of the K -by- L_s coding design matrix with probability 0.25, a -1 with probability 0.25, and a 0 with probability 0.5, where $L_s \approx \lceil 15 \log_2 K \rceil$.
- 2 If a column does not contain at least one 1 and at least one -1, then the software removes that column.
- 3 For distinct columns u and v , if $u = v$ or $u = -v$, then the software removes v from the coding design matrix.

The software randomly generates 10,000 matrices by default, and retains the matrix with the largest, minimal pairwise row distance based on the Hamming measure ([4]) given by

$$\Delta(k_1, k_2) = 0.5 \sum_{l=1}^L |m_{k_1 l} - m_{k_2 l}|,$$

where $m_{k,l}$ is an element of coding design matrix j .

Introduced in R2014b

devianceTest

Class: CompactGeneralizedLinearModel

Analysis of deviance

Syntax

```
tbl = devianceTest mdl)
```

Description

`tbl = devianceTest(mdl)` returns an analysis of deviance table for the `mdl` generalized linear model. `tbl` gives the result of a test of whether the fitted model fits significantly better than a constant model.

Input Arguments

`mdl`

Generalized linear model, specified as a full `GeneralizedLinearModel` object constructed using `fitglm` or `stepwiseglm`, or a compacted `CompactGeneralizedLinearModel` object constructed using `compact`.

Output Arguments

`tbl`

Table containing two rows and four columns.

- The first row relates to a constant model.
- The second row relates to the full model in `mdl`.
- The columns are:

| | |
|----------|--|
| Deviance | Deviance is twice the difference between the log likelihoods of the corresponding model (mdl or constant) and the saturated model. The test statistic for the deviance test is twice the difference between the log likelihoods of the tested model mdl and the constant model. For more information, see Deviance on page 32-1362. |
| DFE | Error degrees of freedom. It is the number of observations minus the number of parameters in the corresponding model. |
| chi2Stat | <p>F statistic or Chi-squared statistic, depending on whether the dispersion is estimated (F statistic) or not (Chi-squared statistic)</p> <ul style="list-style-type: none"> • Chi-squared statistic is the difference between the deviance of the constant model and the deviance of the full model. • F statistic is the difference between the deviance of the constant model and the deviance of the full model, divided by the estimated dispersion. |
| pValue | p -value associated with the test. It is the Chi-squared statistic with (number of coefficients in the model minus one) degrees of freedom, or F statistic with (number of coefficients in the model minus one) numerator degrees of freedom, and DFE denominator degrees of freedom. |

Examples

Deviance Test

Perform a deviance test on a generalized linear model.

Construct a generalized linear model.

```
rng('default') % for reproducibility
X = randn(100,5);
mu = exp(X(:, [1 4 5]) * [.4; .2; .3]);
y = poissrnd(mu);
mdl = fitglm(X,y, 'linear', 'Distribution', 'poisson');
```

Test whether the model differs from a constant in a statistically significant way.

```
tbl = devianceTest(mdl)
```

```
tbl =
```

```
2x4 table
```

| | Deviance | DFE | chi2Stat | pValue |
|-------------------------------------|----------|-----|----------|------------|
| log(y) ~ 1 | 128.58 | 99 | | |
| log(y) ~ 1 + x1 + x2 + x3 + x4 + x5 | 83.726 | 94 | 44.858 | 1.5502e-08 |

The *p*-value is very small, indicating that the model significantly differs from a constant.

Definitions

Deviance

Deviance of a model M_1 is twice the difference between the loglikelihood of that model and the saturated model, M_S . The saturated model is the model with the maximum number of parameters that can be estimated. For example, if there are n observations y_i , $i = 1, 2, \dots, n$, with potentially different values for $X_i^T\beta$, then you can define a saturated

model with n parameters. Let $L(b,y)$ denote the maximum value of the likelihood function for a model. Then the deviance of model M_1 is

$$-2(\log L(b_1, y) - \log L(b_S, y)),$$

where b_1 are the estimated parameters for model M_1 and b_S are the estimated parameters for the saturated model. The deviance has a chi-square distribution with $n - p$ degrees of freedom, where n is the number of parameters in the saturated model and p is the number of parameters in model M_1 .

If M_1 and M_2 are two different generalized linear models, then the fit of the models can be assessed by comparing the deviances D_1 and D_2 of these models. The difference of the deviances is

$$\begin{aligned} D = D_2 - D_1 &= -2(\log L(b_2, y) - \log L(b_S, y)) + 2(\log L(b_1, y) - \log L(b_S, y)) \\ &= -2(\log L(b_2, y) - \log L(b_1, y)). \end{aligned}$$

Asymptotically, this difference has a chi-square distribution with degrees of freedom v equal to the number of parameters that are estimated in one model but fixed (typically at 0) in the other. That is, it is equal to the difference in the number of parameters estimated in M_1 and M_2 . You can get the p -value for this test using $1 - \text{chi2cdf}(D, V)$, where $D = D_2 - D_1$.

designMatrix

Class: GeneralizedLinearMixedModel

Fixed- and random-effects design matrices

Syntax

```
D = designMatrix(glme)
D = designMatrix(glme, 'Fixed')

D = designMatrix(glme, 'Random')
Dsub = designMatrix(glme, 'Random', gnumbers)
[Dsub, gnames] = designMatrix(glme, 'Random', gnumbers)
```

Description

`D = designMatrix(glme)` or `D = designMatrix(glme, 'Fixed')` returns the fixed-effects design matrix for the generalized linear mixed-effects model `glme`.

`D = designMatrix(glme, 'Random')` returns the random-effects design matrix for the generalized linear mixed-effects model `glme`.

`Dsub = designMatrix(glme, 'Random', gnumbers)` returns a subset of the random-effects design matrix for the generalized linear mixed-effects model `glme` that corresponds to the grouping variables indicated by `gnumbers`.

`[Dsub, gnames] = designMatrix(glme, 'Random', gnumbers)` also returns the grouping variable names that correspond to `gnumbers`.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

gnumbers — Grouping variable numbers

array of integer values

Grouping variable numbers, specified as an array of integer values containing elements in the range $[1,R]$, where R is the length of the cell array that contains the grouping variables for the generalized linear mixed-effects model `glme`.

For example, you can specify the grouping variables g_1 , g_3 , and g_r as `[1,3,r]`.

Data Types: `single` | `double`

Output Arguments

D — Design matrix

matrix

Design matrix of a generalized linear mixed-effects model `glme` returned as one of the following:

- Fixed-effects design matrix — n -by- p matrix consisting of the fixed-effects design matrix of `glme`, where n is the number of observations and p is the number of fixed-effects terms.
- Random-effects design matrix — n -by- k matrix, consisting of the random-effects design matrix of `glme`. Here, k is equal to `length(B)`, where `B` is the random-effects coefficients vector of generalized linear mixed-effects model `glme`. The random-effects design matrix is returned as a sparse matrix. For more information, see “Sparse Matrices” (MATLAB).

If `glme` has R grouping variables g_1, g_2, \dots, g_R , with levels m_1, m_2, \dots, m_R , respectively, and if q_1, q_2, \dots, q_R are the lengths of the random-effects vectors that are associated with g_1, g_2, \dots, g_R , respectively, then `B` is a column vector of length $q_1*m_1 + q_2*m_2 + \dots + q_R*m_R$.

`B` is made by concatenating the empirical Bayes predictors of random effects vectors corresponding to each level of each grouping variable as `[g1level1; g1level2; ...; g1levelm1; g2level1; g2level2; ...; g2levelm2; ...; gRlevel1; gRlevel2; ...; gRlevelmR]'`.

Data Types: `single` | `double`

Dsub — Submatrix of random-effects design matrix

matrix

Submatrix of random-effects design matrix that corresponds to the grouping variables specified by `gnumbers`, returned as an n -by- k matrix, where k is length of the column vector `Bsub`.

`Bsub` contains the concatenated empirical Bayes predictors of random-effects vectors, corresponding to each level of the grouping variables, specified by `gnumbers`.

If, for example, `gnumbers` is `[1, 3, r]`, this corresponds to the grouping variables g_1 , g_3 , and g_r . Then, `Bsub` contains the empirical Bayes predictors of random-effects vectors corresponding to each level of the grouping variables g_1 , g_3 , and g_r , such as

```
[g1level1; g1level2; ...; g1levelm1; g3level1; g3level2; ...; g3levelm3;  
grlevel1; grlevel2; ...; grlevelmr]'.
```

Thus, `Dsub*Bsub` represents the contribution of all random effects corresponding to grouping variables g_1 , g_3 , and g_r to the response of `glme`.

If `gnumbers` is empty, then `Dsub` is the full random-effects design matrix.

Data Types: `single` | `double`

gnames — Names of grouping variables

k -by-1 cell array

Names of grouping variables corresponding to the integers in `gnumbers` if the design type is 'Random', returned as a k -by-1 cell array. If the design type is 'Fixed', then `gnames` is an empty matrix `[]`.

Data Types: `cell`

Examples

Obtain Fixed- and Random-Effects Design Matrices

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij}).$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|fact
```

Extract the fixed-effects design matrix and display rows 1 through 10.

```
Dfe = designMatrix(glme, 'Fixed');
disp(Dfe(1:10, :))
```

```

designMatrix

Class: LinearMixedModel

Fixed- and random-effects design matrices

Syntax

```
D = designMatrix(lme)
D = designMatrix(lme, 'Fixed')

D = designMatrix(lme, 'Random')
Dsub = designMatrix(lme, 'Random', gnumbers)
[Dsub, gnames] = designMatrix(lme, 'Random', gnumbers)
```

Description

`D = designMatrix(lme)` or `D = designMatrix(lme, 'Fixed')` returns the fixed-effects design matrix for the linear mixed-effects model `lme`.

`D = designMatrix(lme, 'Random')` returns the random-effects design matrix for the linear mixed-effects model `lme`.

`Dsub = designMatrix(lme, 'Random', gnumbers)` returns a subset of the random-effects design matrix for the linear mixed-effects model `lme` corresponding to the grouping variables indicated by the integers in `gnumbers`.

`[Dsub, gnames] = designMatrix(lme, 'Random', gnumbers)` also returns the grouping variable names corresponding to the integers in `gnumbers`.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a `LinearMixedModel` object constructed using `fitlme` or `fitlmematrix`.

gnumbers — Grouping variable numbers

integer array

Grouping variable numbers, specified as an integer array, where R is the length of the cell array that contains the grouping variables for the linear mixed-effects model `lme`.

For example, you can specify the grouping variables g_1 , g_3 , and g_r as follows.

Example: `[1,3,r]`

Data Types: `double` | `single`

Output Arguments

D — Design matrix

matrix

Design matrix of a linear mixed-effects model `lme` returned as one of the following:

- Fixed-effects design matrix — n -by- p matrix consisting of the fixed-effects design of `lme`, where n is the number of observations and p is the number of fixed-effects terms.
- Random-effects design matrix — n -by- k matrix, consisting of the random-effects design matrix of `lme`. Here, k is equal to `length(B)`, where `B` is the random-effects coefficients vector of linear mixed-effects model `lme`.

If `lme` has R grouping variables g_1, g_2, \dots, g_R , with levels m_1, m_2, \dots, m_R , respectively, and if q_1, q_2, \dots, q_R are the lengths of the random-effects vectors that are associated with g_1, g_2, \dots, g_R , respectively, then `B` is a column vector of length $q_1*m_1 + q_2*m_2 + \dots + q_R*m_R$.

`B` is made by concatenating the best linear unbiased predictors of random-effects vectors corresponding to each level of each grouping variable as `[g1level1; g1level2; ...; g1levelm1; g2level1; g2level2; ...; g2levelm2; ...; gRlevel1; gRlevel2; ...; gRlevelmR]'`.

Data Types: `single` | `double`

Dsub — Submatrix of random-effects design matrix

matrix

Submatrix of random-effects design matrix corresponding to the grouping variables indicated by the integers in `gnumbers`, returned as an n -by- k matrix, where k is length of the column vector `Bsub`.

`Bsub` contains the concatenated best linear unbiased predictors (BLUPs) of random-effects vectors, corresponding to each level of the grouping variables, specified by `gnumbers`.

If, for example, `gnumbers` is `[1,3,r]`, this corresponds to the grouping variables g_1 , g_3 , and g_r . Then, `Bsub` contains the concatenated BLUPs of random-effects vectors corresponding to each level of the grouping variables g_1 , g_3 , and g_r , such as

```
[g1level1; g1level2; ...; g1levelm1; g3level1; g3level2; ...; g3levelm3;
grlevel1; grlevel2; ...; grlevelmr]'.
```

Thus, `Dsub*Bsub` represents the contribution of all random effects corresponding to grouping variables g_1 , g_3 , and g_r to the response of `lme`.

If `gnumbers` is empty, then `Dsub` is the full random-effects design matrix.

Data Types: `single` | `double`

gnames — Names of grouping variables

k -by-1 cell array

Names of grouping variables corresponding to the integers in `gnumbers` if the design type is 'Random', returned as a k -by-1 cell array. If the design type is 'Fixed', then `gnames` is an empty matrix `[]`.

Data Types: `cell`

Examples

Display Fixed- and Random-Effects Design Matrices

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'shift.mat'));
```

The data shows the deviations from the target quality characteristic measured from the products that 5 operators manufacture during three different shifts, morning, evening,

and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

```
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift.

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)');
```

Display the fixed-effects design matrix.

```
designMatrix(lme)
```

```
ans = 15×3
```

```
    1    1    0
    1    0    0
    1    0    1
    1    1    0
    1    0    0
    1    0    1
    1    1    0
    1    0    0
    1    0    1
    1    1    0
    :
```

The column of 1s represents the constant term in the model. `fitlme` takes the evening shift as the reference group and creates two dummy variables to represent the morning and night shifts, respectively.

Display the random-effects design matrix.

```
designMatrix(lme, 'random')
```

```
ans =
    (1,1)    1
    (2,1)    1
```

```
(3,1)      1
(4,2)      1
(5,2)      1
(6,2)      1
(7,3)      1
(8,3)      1
(9,3)      1
(10,4)     1
(11,4)     1
(12,4)     1
(13,5)     1
(14,5)     1
(15,5)     1
```

The first number, i , in the $(i,|j|)$ indices corresponds to the observation number, and $|j|$ corresponds to the level of the grouping variable, `Operator`, i.e., the operator number.

Show the full display of the random-effects design matrix.

```
full(designMatrix(lme, 'random'))
```

```
ans = 15x5
```

```
 1     0     0     0     0
 1     0     0     0     0
 1     0     0     0     0
 0     1     0     0     0
 0     1     0     0     0
 0     1     0     0     0
 0     0     1     0     0
 0     0     1     0     0
 0     0     1     0     0
 0     0     0     1     0
  :
```

Each column corresponds to a level of the grouping variable, `Operator`.

Random-Effects Design Matrix of Multiple Grouping Variables

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'fertilizer.mat'));
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;  
ds.Tomato = nominal(ds.Tomato);  
ds.Soil = nominal(ds.Soil);  
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Store and examine the full random-effects design matrix.

```
D = full(designMatrix(lme, 'random'));
```

The first three columns of matrix `D` contain the indicator variables `fitlme` creates for the three levels (Loamy, Silty, Sandy, respectively) of the first grouping variable, `Soil`. The next 15 columns contain the indicator variables created for the second grouping variable, `Tomato` nested under `Soil`. These are basically the elementwise products of the dummy variables representing the levels of `Soil` (Loamy, Silty, and Sandy, respectively) and the levels of `Tomato` (Cherry, Grape, Heirloom, Plum, Vine, respectively).

Subset of the Random-Effects Design Matrix

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'fertilizer.mat'));
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five

plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Compute the random-effects design matrix for the second grouping variable, and display the first 12 rows.

```
[Dsub,gname] = designMatrix(lme, 'random', 2);
full(Dsub(1:12,:))
```

```
ans = 12×15
```

```

0     0     0     0     0     0     0     0     1     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0
0     0     0     0     0     1     0     0     0     0     0     0     0     0
0     0     0     0     0     1     0     0     0     0     0     0     0     0
0     0     0     0     0     1     0     0     0     0     0     0     0     0
0     0     0     0     0     1     0     0     0     0     0     0     0     0
0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     1     0     0     0     0     0     0
:
```

`Dsub` contains the dummy variables created for the second grouping variable, that is, tomato nested under soil. These are the elementwise products of the dummy variables representing the levels of `Soil` (Loamy, Silty, Sandy, respectively) and the levels of `Tomato` (Cherry, Grape, Heirloom, Plum, Vine, respectively).

Display the name of the grouping variable.

`gname`

```
gname = 1x1 cell array  
      {'Soil:Tomato'}
```

dfittool

Open Distribution Fitter app

Note The `distributionFitter` function was introduced in R2017a as a replacement for the `dfittool` function. Both functions continue to work to start the Distribution Fitter app.

This page contains programmatic syntax information for the Distribution Fitter app. For general usage information, see **Distribution Fitter**.

Syntax

```
dfittool
dfittool(y)
dfittool(y,cens)
dfittool(y,cens,freq)
dfittool(y,cens,freq,dsname)
```

Description

`dfittool` opens the Distribution Fitter app, or brings focus to the app if it is already open.

`dfittool(y)` opens the Distribution Fitter app populated with the data specified by the vector `y`.

`dfittool(y,cens)` uses the vector `cens` to specify whether each observation in `y` is censored.

`dfittool(y,cens,freq)` uses the vector `freq` to specify the frequency of each element of `y`.

`dfittool(y,cens,freq,dsname)` creates a data set with the name `dsname`, using the data vector, `y`, censoring indicator, `cens`, and frequency vector, `freq`.

Examples

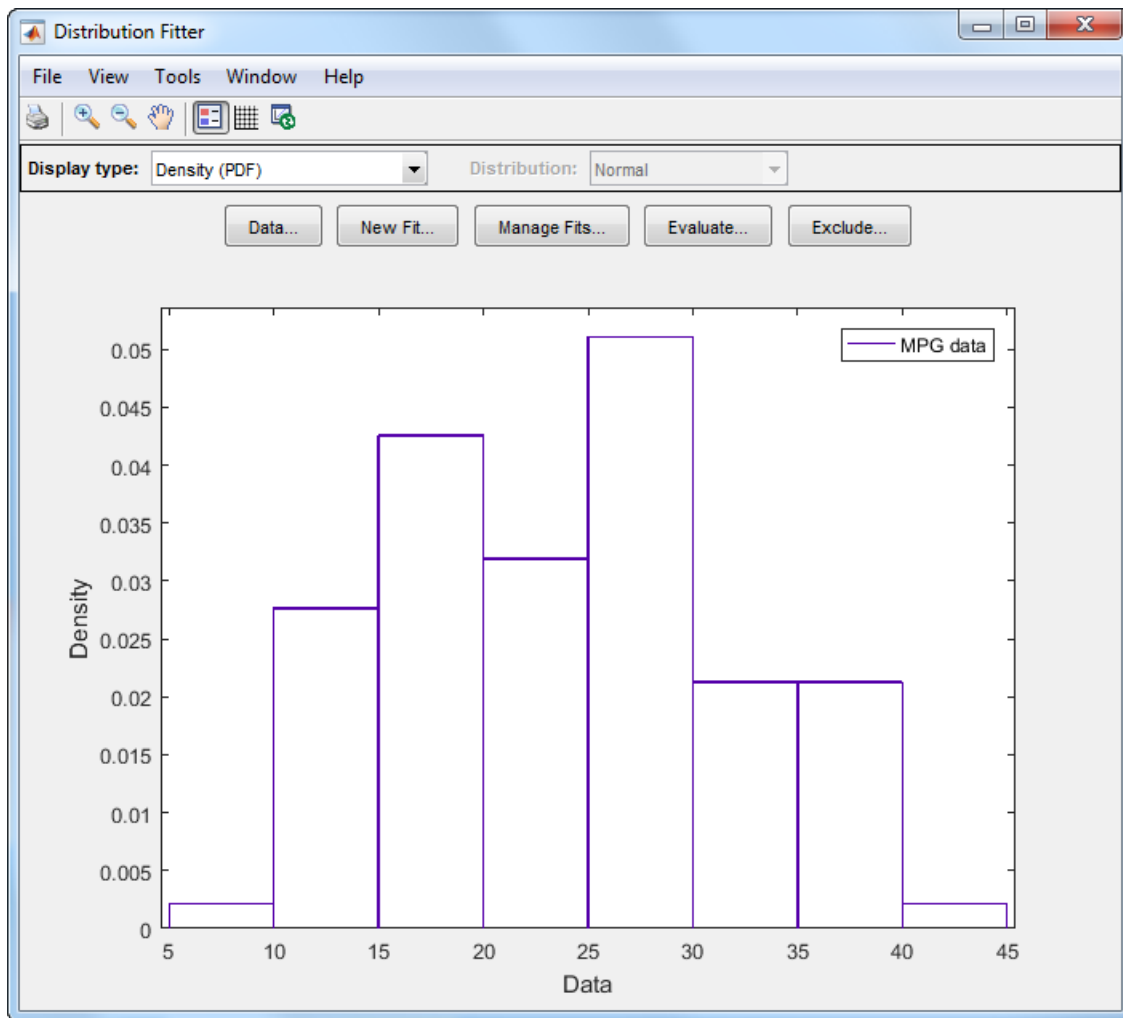

Open Distribution Fitter App with Existing Data

Load the `carsmall` sample data.

```
load carsmall
```

Open the Distribution Fitter app using the MPG miles per gallon data.

```
dfittool(MPG)
```

The Distribution Fitter app opens, populated with the MPG data, and displays the density (PDF) plot. You can use the app to display different plots and fit distributions to this data.

Open Distribution Fitter App with Censoring Data

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'lightbulb.mat'))
```

The first column of the data contains the lifetime (in hours) of two types of light bulbs. The second column contains information about the type of light bulb. 1 indicates fluorescent bulbs, and 0 indicates the incandescent bulb. The third column contains censoring information. 1 indicates censored data, and 0 indicates the exact failure time. This is simulated data.

Open the Distribution Fitter app using the first column of `lightbulb` as the input data, and the third column as the censoring data. Name the data `lifetime`.

```
dfittool(lightbulb(:,1),lightbulb(:,3),[], 'lifetime')
```

To open the Data dialog box, click **Data**. In the **Manage data sets** pane, click to highlight the `lifetime` data set row. Finally, to open the View Data Set dialog, click **View**. The lifetime data appears in the second column and the corresponding censoring indicator appears in the third column.

- “Fit a Distribution Using the Distribution Fitter App” on page 5-96

Input Arguments

y — Input data

array of scalar values | variable representing an array of scalar values

Input data, specified as an array of scalar values or a variable representing an array of such values.

Data Types: single | double

cens — Censoring indicator

zeros(n) (default) | vector of 0 and 1 values

Censoring indicator, specified as a vector of 0 and 1 values. The length of cens must be equal to the length of y. If $y(j)$ is censored, then $(cens(j) == 1)$. If $y(j)$ is not

censored, then `(cens(j)==0)`. If `cens` is omitted or empty, then no `y` values are censored.

If you have frequency data (`freq`) but not censoring data (`cens`), then you must specify empty brackets (`[]`) for `cens`.

Data Types: `single` | `double`

freq — Frequency data

`ones(n)` (default) | vector of scalar values

Frequency data, specified as a vector of scalar values. The length of `freq` must be equal to the length of `y`. If `freq` is omitted or empty, then all `y` values have a frequency of 1.

If you have frequency data (`freq`) but not censoring data (`cens`), then you must specify empty brackets (`[]`) for `cens`.

Data Types: `single` | `double`

dsname — Data set name

character vector | string scalar

Data set name, specified as a character vector enclosed in single quotes or a string scalar enclosed in double quotes.

If you want to specify a data set name, but do not have censoring data (`cens`) or frequency data (`freq`), then you must specify empty brackets (`[]`) for both `freq` and `cens`.

Example: `'MyData'`

Data Types: `char` | `string`

Dimensions property

Class: grandset

Number of dimensions

Description

Number of dimensions in the point set. The `Dimensions` property of a point set contains a positive integer that indicates the number of dimensions for which the points have values. For example, a point set with `Dimensions=5` produces points that each have five values.

Set this property by specifying the number of dimensions when constructing a new point set. After construction, you cannot change the value. The default number of dimensions is 2.

DimNames property

Class: dataset

Two-element cell array of character vectors giving names of dimensions of data set

Note The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Description

A two-element cell array of character vectors giving the names of the two dimensions of the data set. The default is `{'Observations' 'Variables'}`.

discardSupportVectors

Class: CompactClassificationECOC

Discard support vectors of linear support vector machine binary learners

Syntax

```
Mdl = discardSupportVectors(MdlSV)
```

Description

`Mdl = discardSupportVectors(MdlSV)` returns a trained, multiclass, error-correcting output codes (ECOC) model (`Mdl`) containing at least one linear, support vector machine (SVM) binary learner. `Mdl` is similar to the trained ECOC model `MdlSV`, except:

- The `Alpha`, `SupportVectors`, and `SupportVectorLabels` properties of all linear SVM binary learners are empty (`[]`).
- If you display any linear SVM binary learners stored in the cell array of trained models `Mdl.BinaryLearners`, the software lists the `Beta` property instead of `Alpha`.

Input Arguments

MdlSV — Full or compact, trained, multiclass ECOC model

ClassificationECOC model | CompactClassificationECOC model

Full or compact, trained, multiclass ECOC model containing at least one linear, SVM binary learner, specified as a `ClassificationECOC` or `CompactClassificationECOC` model.

Output Arguments

Mdl — Full or compact, trained, multiclass ECOC model

ClassificationECOC model | CompactClassificationECOC model

Full or compact, trained, multiclass ECOC model, returned as a `ClassificationECOC` or `CompactClassificationECOC` model. `Mdl` is the same type as `MdlSV`.

The properties `Alpha`, `SupportVectorLabels`, and `SupportVectors` of all linear, SVM binary learners in the cell array `Mdl.BinaryLearners` are empty. The software lists the property `Beta` when you display any linear, SVM binary learner, and does not list `Alpha`.

Examples

Retain and Discard Support Vectors of SVM Binary Learners

By default, `fitcecoc` empties the `Alpha`, `SupportVectorLabels`, and `SupportVectors` properties of the linear, SVM binary learners stored in the `BinaryLearners` property of the trained ECOC model. You can retain the support vectors and related values, and then discard them from the model.

Load Fisher's iris data set.

```
load fisheriris
rng(1); % For reproducibility
```

Train an ECOC model using the entire data set. Specify retaining the support vectors by passing in the appropriate SVM template.

```
t = templateSVM('SaveSupportVectors',true);
MdlSV = fitcecoc(meas,species,'Learners',t);
```

`Mdl` is a trained `ClassificationECOC` model. By default, `fitcecoc` uses linear, SVM binary learners. It implements a one-versus-one coding design, which requires three binary learners for three-class learning.

Access the estimated α values using dot notation.

```
alpha = cell(3,1);
alpha{1} = MdlSV.BinaryLearners{1}.Alpha;
alpha{2} = MdlSV.BinaryLearners{2}.Alpha;
alpha{3} = MdlSV.BinaryLearners{3}.Alpha;
alpha
```

```
alpha =
```

```
3x1 cell array

{ 3x1 double}
{ 3x1 double}
{23x1 double}
```

`alpha` is a 3-by-1 cell array that stores the estimated values of α .

Discard the support vectors and related values from the ECOC model.

```
Mdl = discardSupportVectors(MdlSV);
```

`Mdl` is similar to `MdlSV`, except that the `Alpha`, `SupportVectorLabels`, and `SupportVectors` of all linear SVM binary learners are empty (`[]`).

```
areAllEmpty = @(x)isempty([x.Alpha x.SupportVectors x.SupportVectorLabels]);
cellfun(areAllEmpty,Mdl.BinaryLearners)
```

```
ans =
```

```
3x1 logical array

1
1
1
```

Compare the sizes of the two ECOC models.

```
vars = whos('MdlSV','Mdl');
100*(1 - vars(1).bytes/vars(2).bytes)
```

```
ans =
```

```
5.1575
```

`Mdl` is about 5% smaller than `MdlSV`.

Reduce your memory footprint by compacting `Mdl`, and then clearing `MdlSV` and `Mdl` from the workspace.

```
CMdl = compact(Mdl);  
clear MdlSV Mdl;
```

Predict the label for a random row of the training data using the more efficient SVM model.

```
idx = randsample(size(meas,1),1)  
predictedLabel = predict(CMdl,meas(idx,:))  
trueLabel = species(idx)
```

```
idx =
```

```
    63
```

```
predictedLabel =
```

```
    1x1 cell array
```

```
    {'versicolor'}
```

```
trueLabel =
```

```
    1x1 cell array
```

```
    {'versicolor'}
```

Tip

For linear, SVM binary learners, and for efficiency, `fitcecoc` empties the properties `Alpha`, `SupportVectorLabels`, and `SupportVectors`. `fitcecoc` lists `Beta`, rather than `Alpha`, in the model display.

To store `Alpha`, `SupportVectorLabels`, and `SupportVectors`, pass a linear, SVM template that specifies storing support vectors to `fitcecoc`. For example, enter:

```
t = templateSVM('SaveSupportVectors','on')  
Mdl = fitcecoc(X,Y,'Learners',t);
```

You can remove the support vectors and related values by passing the resulting `ClassificationECOC` model to `discardSupportVectors`.

Algorithms

For each linear, SVM binary learner in an ECOC model, `predict` and `resubPredict` estimate SVM scores $[f(x)]$ using

$$f(x) = x'\beta + b.$$

β is the `Beta` property and b is the `Bias` property of the binary learners. You can access these properties for each linear, SVM binary learner in the cell array `Mdl.BinaryLearners`. For more details on the SVM score calculation, see “Support Vector Machines for Binary Classification” on page 32-2080.

Introduced in R2015a

discardSupportVectors

Discard support vectors for linear support vector machine (SVM) classifier

Syntax

```
Mdl = discardSupportVectors(MdlSV)
```

Description

`Mdl = discardSupportVectors(MdlSV)` returns the trained, linear support vector machine (SVM) model `Mdl`. Both `Mdl` and the trained, linear SVM model `MdlSV` are the same type of object. That is, they both are either `ClassificationSVM` objects or `CompactClassificationSVM` objects. However, `Mdl` and `MdlSV` differ in the following ways:

- The `Alpha`, `SupportVectors`, and `SupportVectorLabels` properties are empty (`[]`) in `Mdl`.
- If you display `Mdl`, the software lists the `Beta` property instead of `Alpha`.

Examples

Discard Support Vectors

Create a linear SVM model that is more memory-efficient by discarding support vectors and other related parameters.

Load the ionosphere data set.

```
load ionosphere
```

Train a linear SVM model using the entire data set.

```
MdlSV = fitcsvm(X,Y)
```

```
MdlSV =
  ClassificationSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
      ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
    NumObservations: 351
      Alpha: [103x1 double]
      Bias: -3.8828
    KernelParameters: [1x1 struct]
      BoxConstraints: [351x1 double]
    ConvergenceInfo: [1x1 struct]
    IsSupportVector: [351x1 logical]
    Solver: 'SMO'
```

Properties, Methods

Display the number of support vectors in `MdlSV`.

```
numSV = size(MdlSV.SupportVectors,1)
```

```
numSV = 103
```

Display the number of predictor variables in `X`.

```
p = size(X,2)
```

```
p = 34
```

By default, `fitcsvm` trains a linear SVM model for two-class learning. The software lists `Alpha` in the display. The model includes 103 support vectors and 34 predictors. If you discard the support vectors, the resulting model consumes less memory.

Discard the support vectors and other related parameters.

```
Mdl = discardSupportVectors(MdlSV)
```

```
Mdl =
  ClassificationSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
      ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
```

```

    NumObservations: 351
           Beta: [34x1 double]
           Bias: -3.8828
KernelParameters: [1x1 struct]
           BoxConstraints: [351x1 double]
           ConvergenceInfo: [1x1 struct]
           IsSupportVector: [351x1 logical]
           Solver: 'SMO'

```

Properties, Methods

Display the coefficients in `Mdl`.

```
Mdl.Alpha
```

```
ans =
```

```
[]
```

Display the support vectors in `Mdl`.

```
Mdl.SupportVectors
```

```
ans =
```

```
[]
```

Display the support vector class labels in `Mdl`.

```
Mdl.SupportVectorLabels
```

```
ans =
```

```
[]
```

The software lists `Beta` in the display instead of `Alpha`. The `Alpha`, `SupportVectors`, and `SupportVectorLabels` properties are empty.

Compare the sizes of the models.

```
vars = whos('MdlSV', 'Mdl');
100*(1 - vars(1).bytes/vars(2).bytes)
```

```
ans = 20.5951
```

Mdl is about 20% smaller than MdLSV.

Remove MdLSV from the workspace.

```
clear MdLSV
```

Reduce Memory Consumption of SVM Models

Compact an SVM model by discarding the stored support vectors and other related estimates. Predict the label for a row of the training data by using the compacted model.

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM model using the default options.

```
MdLSV = fitcsvm(X,Y);
```

MdLSV is a ClassificationSVM model containing nonempty values for its Alpha, SupportVectors, and SupportVectorLabels properties.

Reduce the size of the SVM model by discarding the training data, support vectors, and related estimates.

```
CMdLSV = compact(MdLSV); % Discard training data
CMdl = discardSupportVectors(CMdLSV); % Discard support vectors
```

CMdl is a CompactClassificationSVM model.

Compare the sizes of the SVM models MdLSV and CMdl.

```
vars = whos('MdLSV','CMdl');
100*(1 - vars(1).bytes/vars(2).bytes)
```

```
ans = 97.1896
```

The compacted model CMdl consumes much less memory than the full model.

Predict the label for a random row of the training data by using CMdl. The predict function accepts compacted SVM models, and, for linear SVM models, does not require

the Alpha, SupportVectors, and SupportVectorLabels properties to predict labels for new observations.

```
idx = randsample(size(X,1),1)
idx = 147
predictedLabel = predict(CMdl,X(idx,:))
predictedLabel = 1x1 cell array
    {'b'}

trueLabel = Y(idx)
trueLabel = 1x1 cell array
    {'b'}
```

Input Arguments

MdlSV — Trained, linear SVM model

ClassificationSVM model | CompactClassificationSVM model

Trained, linear SVM model, specified as a ClassificationSVM or CompactClassificationSVM model.

If the field MdlSV.KernelParameters.Function is not 'linear' (that is, MdlSV is not a linear SVM model), the software returns an error.

Tips

- For a trained, linear SVM model, the SupportVectors property is an n_{sv} -by- p matrix. n_{sv} is the number of support vectors (at most the training sample size) and p is the number of predictors, or features. The Alpha and SupportVectorLabels properties are vectors with n_{sv} elements. These properties can be large for complex data sets containing many observations or examples. The Beta property is a vector with p elements.
- If the trained SVM model has many support vectors, use discardSupportVectors to reduce the amount of space consumed by the trained, linear SVM model. You can

display the size of the support vector matrix by entering `size(MdlSV.SupportVectors)`.

Algorithms

`predict` and `resubPredict` estimate SVM scores $f(x)$, and subsequently label and estimate posterior probabilities using

$$f(x) = x'\beta + b.$$

β is `Mdl.Beta` and b is `Mdl.Bias`, that is, the `Beta` and `Bias` properties of `Mdl`, respectively. For more details, see “Support Vector Machines for Binary Classification” on page 32-2080.

See Also

`ClassificationECOC` | `ClassificationSVM` | `CompactClassificationSVM` | `discardSupportVectors` | `fitsvm` | `templateSVM`

Introduced in R2015a

discardSupportVectors

Class: CompactRegressionSVM

Discard support vectors

Syntax

```
mdlOut = discardSupportVectors(mdl)
```

Description

`mdlOut = discardSupportVectors(mdl)` returns the trained, linear support vector machine (SVM) regression model `mdlOut`, which is similar to the trained, linear SVM regression model `mdl`, except:

- The `Alpha` and `SupportVectors` properties are empty (`[]`).
- If you display `mdlOut`, the software lists the `Beta` property instead of the `Alpha` property.

Input Arguments

mdl — Trained, linear SVM regression model

RegressionSVM model | CompactRegressionSVM model

Trained, linear SVM regression model, specified as a `RegressionSVM` or `CompactRegressionSVM` model.

If you train the model using a kernel function that is not linear (i.e., if the field `mdl.KernelFunction` is something other than `'linear'`), the software returns an error. You can only discard support vectors for linear models.

Output Arguments

mdlOut — Trained, linear SVM regression model

RegressionSVM model | CompactRegressionSVM model

Trained, linear SVM regression model, returned as a RegressionSVM or CompactRegressionSVM model. mdlOut is the same type as mdl.

After discarding the support vectors, the properties Alpha and SupportVector are empty ([]). The software lists the property Beta in its display, and does not list the property Alpha. The predict and resubPredict methods compute predicted responses using the coefficients stored in the Beta property.

Examples

Discard Support Vectors for SVM Regression Model

This model shows how to reduce the disk space used by a trained, linear SVM regression model by discarding the support vectors and other related parameters.

Load the carsmall data set. Specify Horsepower and Weight as the predictor variables (X), and MPG as the response variable (Y).

```
load carsmall
X = [Horsepower,Weight];
Y = MPG;
```

Train a linear SVM regression model, standardizing the data. Display the number of support vectors.

```
mdl = fitrsvm(X,Y,'Standardize',true)
numSV = size(mdl.SupportVectors,1)
```

```
mdl =
```

```
RegressionSVM
    PredictorNames: {'x1' 'x2'}
      ResponseName: 'Y'
  CategoricalPredictors: []
      ResponseTransform: 'none'
```

```

        Alpha: [77x1 double]
        Bias: 22.9131
KernelParameters: [1x1 struct]
        Mu: [109.3441 2.9625e+03]
        Sigma: [45.3545 805.9668]
NumObservations: 93
  BoxConstraints: [93x1 double]
ConvergenceInfo: [1x1 struct]
IsSupportVector: [93x1 logical]
  Solver: 'SMO'

```

Properties, Methods

```
numSV =
```

```
77
```

By default, `fitrsvm` trains a linear SVM regression model. The software lists `Alpha` in the display. The model has 77 support vectors.

Note that the predictor and response variables contain several `NaN` values. When training a model, `fitrsvm` will remove rows that contain `NaN` values from both the predictor and response data. As a result, the trained model uses only 93 of the 100 total observations contained in the sample data.

Discard the support vectors and other related parameters.

```
mdlOut = discardSupportVectors(mdl)
mdlOut.Alpha
mdlOut.SupportVectors
```

```
mdlOut =
```

```

RegressionSVM
  PredictorNames: {'x1' 'x2'}
  ResponseName: 'Y'
CategoricalPredictors: []
  ResponseTransform: 'none'
        Beta: [2x1 double]
        Bias: 22.9131
KernelParameters: [1x1 struct]
        Mu: [109.3441 2.9625e+03]

```

```
          Sigma: [45.3545 805.9668]
NumObservations: 93
  BoxConstraints: [93x1 double]
ConvergenceInfo: [1x1 struct]
IsSupportVector: [93x1 logical]
          Solver: 'SMO'
```

Properties, Methods

```
ans =
```

```
 []
```

```
ans =
```

```
 []
```

The software lists **Beta** in the display instead of **Alpha**. The **Alpha** and **SupportVectors** properties are empty.

Compare the sizes of the models.

```
vars = whos('mdl','mdlOut');
[vars(1).bytes,vars(2).bytes]
```

```
ans =
```

```
    15004    13156
```

`mdlOut` consumes less memory than `mdl` because it does not store the support vectors.

Reduce Memory Consumption of SVM Regression Model

This example shows how to reduce the memory consumption of a full, trained SVM regression model by compacting the model and discarding the support vectors.

Load the `carsmall` sample data.

```
load carsmall
rng default % for reproducibility
```

Train a linear SVM regression model using `Weight` as the predictor variable and `MPG` as the response variable. Standardize the data.

```
mdl = fitrsvm(Weight,MPG,'Standardize',true);
```

Note that `MPG` contains several `NaN` values. When training a model, `fitrsvm` will remove rows that contain `NaN` values from both the predictor and response data. As a result, the trained model uses only 94 of the 100 total observations contained in the sample data.

Compact the regression model to discard the training data and some information related to the training process.

```
compactMdl = compact(mdl);
```

`compactMdl` is a `CompactRegressionSVM` model that has the same parameters, support vectors, and related estimates as `mdl`, but no longer stores the training data.

Discard the support vectors and related estimates for the compacted model.

```
mdlOut = discardSupportVectors(compactMdl);
```

`mdlOut` is a `CompactRegressionSVM` model that has the same parameters as `mdl` and `compactMdl`, but no longer stores the support vectors and related estimates.

Compare the sizes of the three SVM regression models, `compactMdl`, `mdl`, and `mdlOut`.

```
vars = whos('compactMdl','mdl','mdlOut');
[vars(1).bytes,vars(2).bytes,vars(3).bytes]
```

```
ans =
```

```
          3601          13727          2305
```

The compacted model `compactMdl` consumes 3601 bytes of memory, while the full model `mdl` consumes 13727 bytes of memory. The model `mdlOut`, which also discards the support vectors, consumes 2305 bytes of memory.

Tips

For a trained, linear SVM regression model, the `SupportVectors` property is an n_{sv} -by- p matrix. n_{sv} is the number of support vectors (at most the training sample size) and p is the number of predictor variables. If any of the predictors are categorical, then p includes the

number of dummy variables necessary to account for all of the categorical predictor levels. The `Alpha` property is a vector with n_{sv} elements.

The `SupportVectors` and `Alpha` properties can be large for complex data sets that contain many observations or examples. However, the `Beta` property is a vector with p elements, which may be considerably smaller. You can use a trained SVM regression model to predict response values even if you discard the support vectors because the `predict` and `resubPredict` methods use `Beta` to compute the predicted responses.

If the trained, linear SVM regression model has many support vectors, use `discardSupportVectors` to reduce the amount of disk space that the trained, linear SVM regression model consumes. You can display the size of the support vector matrix by entering `size mdlIn.SupportVectors`.

Algorithms

The `predict` and `resubPredict` estimate response values using the formula

$$f(x) = \left(\frac{X}{S} \right) \beta + \beta_0,$$

where:

- β is the Beta value, stored as `mdl.Beta`.
- β_0 is the bias value, stored as `mdl.Bias`.
- X is the training data.
- S is the kernel scale value, stored as `mdl.KernelParameters.Scale`.

In this way, the software can use the value of `mdl.Beta` to make predictions even after discarding the support vectors.

Syntax

disp(ds)

Description

disp(ds) prints the dataset array ds, including variable names and observation names (if present), without printing the dataset name. In all other ways it's the same as leaving the semicolon off an expression.

For numeric or categorical variables that are 2-D and have three or fewer columns, disp prints the actual data using either short g, long g, or bank format, depending on the current command line setting. Otherwise, disp prints the size and type of each dataset element.

For character variables that are 2-D and 10 or fewer characters wide, disp prints quoted text. Otherwise, disp prints the size and type of each dataset element.

For cell variables that are 2-D and have three or fewer columns, disp prints the contents of each cell (or its size and type if too large). Otherwise, disp prints the size of each dataset element.

For time series variables, disp prints columns for both the time and the data. If the variable is 2-D and has three or fewer columns, disp prints the actual data. Otherwise, disp prints the size and type of each dataset element.

For other types of variables, disp prints the size and type of each dataset element.

disp

Class: CompactGeneralizedLinearModel

Display generalized linear regression model

Syntax

```
disp mdl
```

Description

`disp(mdl)` displays the `mdl` linear model.

Input Arguments

mdl

Generalized linear model, specified as a full `GeneralizedLinearModel` object constructed using `fitglm` or `stepwiseglm`, or a compacted `CompactGeneralizedLinearModel` object constructed using `compact`.

Examples

Display a Generalized Linear Regression Model

Create and display a generalized linear regression model.

Create a generalized linear regression model of Poisson data.

```
X = 2 + randn(100,1);  
mu = exp(1 + X/2);  
y = poissrnd(mu);
```

```
mdl = fitglm(X,y,...  
            'y ~ x1','distr','poisson');
```

Display the model.

```
disp(mdl)
```

Generalized linear regression model:

```
log(y) ~ 1 + x1  
Distribution = Poisson
```

Estimated Coefficients:

| | Estimate | SE | tStat | pValue |
|-------------|----------|----------|--------|------------|
| (Intercept) | 0.99516 | 0.080089 | 12.426 | 1.8947e-35 |
| x1 | 0.50906 | 0.025557 | 19.919 | 2.7949e-88 |

100 observations, 98 error degrees of freedom

Dispersion: 1

Chi²-statistic vs. constant model: 374, p-value = 2.53e-83

Alternatives

Enter *mdl* at the command line to obtain a display, where *mdl* is the name of your model.

disp

Class: GeneralizedLinearMixedModel

Display generalized linear mixed-effects model

Syntax

```
disp(glme)
```

Description

`disp(glme)` displays fitted generalized linear mixed-effects model `glme`.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

Examples

Display a Generalized Linear Mixed-Effects Model

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new

manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- `defectsij` is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).

- `newprocessij`, `time_devij`, and `temp_devij` are the measurements for each variable that correspond to factory *i* during batch *j*. For example, `newprocessij` indicates whether the batch produced by factory *i* during batch *j* used the new process.
- `supplier_Cij` and `supplier_Bij` are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory *i* during batch *j*.
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory *i* that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)')
```

Display the model.

```
disp(glme)
```

Random effects covariance parameters:

Group: factory (20 Levels)

| Name1 | Name2 | Type | Estimate |
|---------------|---------------|-------|----------|
| '(Intercept)' | '(Intercept)' | 'std' | 0.31381 |

Group: Error

| Name | Estimate |
|--------------------|----------|
| 'sqrt(Dispersion)' | 1 |

The `Model information` table displays the total number of observations in the sample data (100), the number of fixed- and random-effects coefficients (6 and 20, respectively), and the number of covariance parameters (1). It also indicates that the response variable has a Poisson distribution, the link function is Log, and the fit method is Laplace.

`Formula` indicates the model specification using Wilkinson's notation.

The `Model fit statistics` table displays statistics used to assess the goodness of fit of the model. This includes the Akaike information criterion (AIC), Bayesian information criterion (BIC) values, log likelihood (LogLikelihood), and deviance (Deviance) values.

The `Fixed effects coefficients` table indicates that `fitglm` returned 95% confidence intervals. It contains one row for each fixed-effects predictor, and each column contains statistics corresponding to that predictor. Column 1 (Name) contains the name of each fixed-effects coefficient, column 2 (Estimate) contains its estimated value, and column 3 (SE) contains the standard error of the coefficient. Column 4 (tStat) contains the *t*-statistic for a hypothesis test that the coefficient is equal to 0. Column 5 (DF) and column 6 (pValue) contain the degrees of freedom and *P*-value that correspond to the *t*-statistic, respectively. The last two columns (Lower and Upper) display the lower and upper limits, respectively, of the 95% confidence interval for each fixed-effects coefficient.

`Random effects covariance parameters` displays a table for each grouping variable (here, only `factory`), including its total number of levels (20), and the type and

estimate of the covariance parameter. Here, `std` indicates that `fitglm` returns the standard deviation of the random effect associated with the factory predictor, which has an estimated value of 0.31381. It also displays a table containing the error parameter type (here, the square root of the dispersion parameter), and its estimated value of 1.

The standard display generated by `fitglm` does not provide confidence intervals for the random-effects parameters. To compute and display these values, use `covarianceParameters`.

Definitions

Akaike and Bayesian Information Criteria

The *Akaike information criterion* (AIC) is $AIC = -2\log L_M + 2(param)$.

$\log L_M$ depends on the method used to fit the model.

- If you use 'Laplace' or 'ApproximateLaplace', then $\log L_M$ is the maximized log likelihood.
- If you use 'MPL', then $\log L_M$ is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.
- If you use 'REML', then $\log L_M$ is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

$param$ is the total number of parameters estimated in the model. For most GLME models, $param$ is equal to $nc + p + 1$, where nc is the total number of parameters in the random-effects covariance, excluding the residual variance, and p is the number of fixed-effects coefficients. However, if the dispersion parameter is fixed at 1.0 for binomial or Poisson distributions, then $param$ is equal to $(nc + p)$.

The *Bayesian information criterion* (BIC) is $BIC = -2*\log L_M + \ln(n_{eff})(param)$.

$\log L_M$ depends on the method used to fit the model.

- If you use 'Laplace' or 'ApproximateLaplace', then $\log L_M$ is the maximized log likelihood.
- If you use 'MPL', then $\log L_M$ is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.

- If you use 'REML', then $\log L_M$ is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

n_{eff} is the effective number of observations.

- If you use 'MPL', 'Laplace', or 'ApproximateLaplace', then $n_{eff} = n$, where n is the number of observations.
- If you use 'REML', then $n_{eff} = n - p$.

$param$ is the total number of parameters estimated in the model. For most GLME models, $param$ is equal to $nc + p + 1$, where nc is the total number of parameters in the random-effects covariance, excluding the residual variance, and p is the number of fixed-effects coefficients. However, if the dispersion parameter is fixed at 1.0 for binomial or Poisson distributions, then $param$ is equal to $(nc + p)$.

A lower value of deviance indicates a better fit. As the value of deviance decreases, both AIC and BIC tend to decrease. Both AIC and BIC also include penalty terms based on the number of parameters estimated, p . So, when the number of parameters increase, the values of AIC and BIC tend to increase as well. When comparing different models, the model with the lowest AIC or BIC value is considered as the best fitting model.

For models fitted using 'MPL' and 'REML', AIC and BIC are based on the log likelihood (or restricted log likelihood) of pseudo data from the final pseudo likelihood iteration. Therefore, a direct comparison of AIC and BIC values between models fitted using 'MPL' and 'REML' is not appropriate.

Class: LinearMixedModel

Display linear mixed-effects model

Syntax

```
display(lme)
```

Description

`display(lme)` displays the fitted linear mixed-effects model `lme`.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a LinearMixedModel object constructed using `fitlme` or `fitlmematrix`.

Examples

Randomized Block Design

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'shift.mat'));
```

The dataset array shows the absolute deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts, morning, evening, and night. This is a randomized block design, where the operators are the

blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

```
shift.Shift = nominal(shift.Shift);  
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift.

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)');
```

Display the model.

```
disp(lme)
```

|-----------|----------|---------|--------|
| 'Res Std' | 0.76439 | 0.49315 | 1.1848 |

This display includes the model performance statistics, “Akaike and Bayesian Information Criteria” on page 32-1421, “Akaike and Bayesian Information Criteria” on page 32-1421, loglikelihood, and “Deviance” on page 32-1422.

The fixed-effects coefficients table includes the names and estimates of the coefficients in the first two columns. The third column SE shows the standard errors of the coefficients. The column *tStat* includes the *t*-statistic values that correspond to each coefficient. DF is the residual degrees of freedom, and the *pValue* is the *p*-value that corresponds to the corresponding *t*-statistic value. The columns Lower and Upper display the lower and upper limits of a 95% confidence interval for each fixed-effects coefficient.

The first table for the random effects shows the types and the estimates of the random effects covariance parameters, with the lower and upper limits of a 95% confidence interval for each parameter. The display also shows the name of the grouping variable, operator, and the total number of levels, 5.

The second table for the random effects shows the estimate of the observation error, with the lower and upper limits of a 95% confidence interval.

Definitions

Akaike and Bayesian Information Criteria

Akaike information criterion (AIC) is $AIC = -2*\log L_M + 2*(nc + p + 1)$, where $\log L_M$ is the maximized log likelihood (or maximized restricted log likelihood) of the model, and $nc + p$

+ 1 is the number of parameters estimated in the model. p is the number of fixed-effects coefficients, and nc is the total number of parameters in the random-effects covariance excluding the residual variance.

Bayesian information criterion (BIC) is $BIC = -2*\log L_M + \ln(n_{eff})*(nc + p + 1)$, where $\log L_M$ is the maximized log likelihood (or maximized restricted log likelihood) of the model, n_{eff} is the effective number of observations, and $(nc + p + 1)$ is the number of parameters estimated in the model.

- If the fitting method is maximum likelihood (ML), then $n_{eff} = n$, where n is the number of observations.
- If the fitting method is restricted maximum likelihood (REML), then $n_{eff} = n - p$.

A lower value of deviance indicates a better fit. As the value of deviance decreases, both AIC and BIC tend to decrease. Both AIC and BIC also include penalty terms based on the number of parameters estimated, p . So, when the number of parameters increase, the values of AIC and BIC tend to increase as well. When comparing different models, the model with the lowest AIC or BIC value is considered as the best fitting model.

Deviance

`LinearMixedModel` computes the deviance of model M as minus two times the loglikelihood of that model. Let L_M denote the maximum value of the likelihood function for model M . Then, the deviance of model M is

$$-2 * \log L_M.$$

A lower value of deviance indicates a better fit. Suppose M_1 and M_2 are two different models, where M_1 is nested in M_2 . Then, the fit of the models can be assessed by comparing the deviances Dev_1 and Dev_2 of these models. The difference of the deviances is

$$Dev = Dev_1 - Dev_2 = 2(\log LM_2 - \log LM_1).$$

Usually, the asymptotic distribution of this difference has a chi-square distribution with degrees of freedom v equal to the number of parameters that are estimated in one model but fixed (typically at 0) in the other. That is, it is equal to the difference in the number of parameters estimated in M_1 and M_2 . You can get the p -value for this test using `1 - chi2cdf(Dev, V)`, where $Dev = Dev_2 - Dev_1$.

However, in mixed-effects models, when some variance components fall on the boundary of the parameter space, the asymptotic distribution of this difference is more complicated. For example, consider the hypotheses

$H_0: D = \begin{pmatrix} D_{11} & 0 \\ 0 & 0 \end{pmatrix}$, D is a q -by- q symmetric positive semidefinite matrix.

$H_1: D$ is a $(q+1)$ -by- $(q+1)$ symmetric positive semidefinite matrix.

That is, H_1 states that the last row and column of D are different from zero. Here, the bigger model M_2 has $q + 1$ parameters and the smaller model M_1 has q parameters. And Dev has a 50:50 mixture of χ^2_q and $\chi^2_{(q+1)}$ distributions (Stram and Lee, 1994).

Class: dataset

Display dataset array

Note The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

`display(ds)`

Description

`display(ds)` prints the dataset array `ds`, including variable names and observation names (if present). `dataset` calls `display` when you do not use a semicolon to terminate a statement

For numeric or categorical variables that are 2-D and have three or fewer columns, `display` prints the actual data. Otherwise, `display` prints the size and type of each dataset element.

For character variables that are 2-D and 10 or fewer characters wide, `display` prints quoted text. Otherwise, `display` prints the size and type of each dataset element.

For cell variables that are 2-D and have three or fewer columns, `display` prints the contents of each cell (or its size and type if too large). Otherwise, `display` prints the size of each dataset element.

For time series variables, `display` prints columns for both the time and the data. If the variable is 2-D and has three or fewer columns, `display` prints the actual data. Otherwise, `display` prints the size and type of each dataset element.

For other types of variables, `display` prints the size and type of each dataset element.

distributionFitter(y)  
distributionFitter(y,cens)  
distributionFitter(y,cens,freq)  
distributionFitter(y,cens,freq,dsname)
```

Description

`distributionFitter` opens the Distribution Fitter app, or brings focus to the app if it is already open.

`distributionFitter(y)` opens the Distribution Fitter app populated with the data specified by the vector `y`.

`distributionFitter(y,cens)` uses the vector `cens` to specify whether each observation in `y` is censored.

`distributionFitter(y,cens,freq)` uses the vector `freq` to specify the frequency of each element of `y`.

`distributionFitter(y,cens,freq,dsname)` creates a data set with the name `dsname`, using the data vector, `y`, censoring indicator, `cens`, and frequency vector, `freq`.

Examples

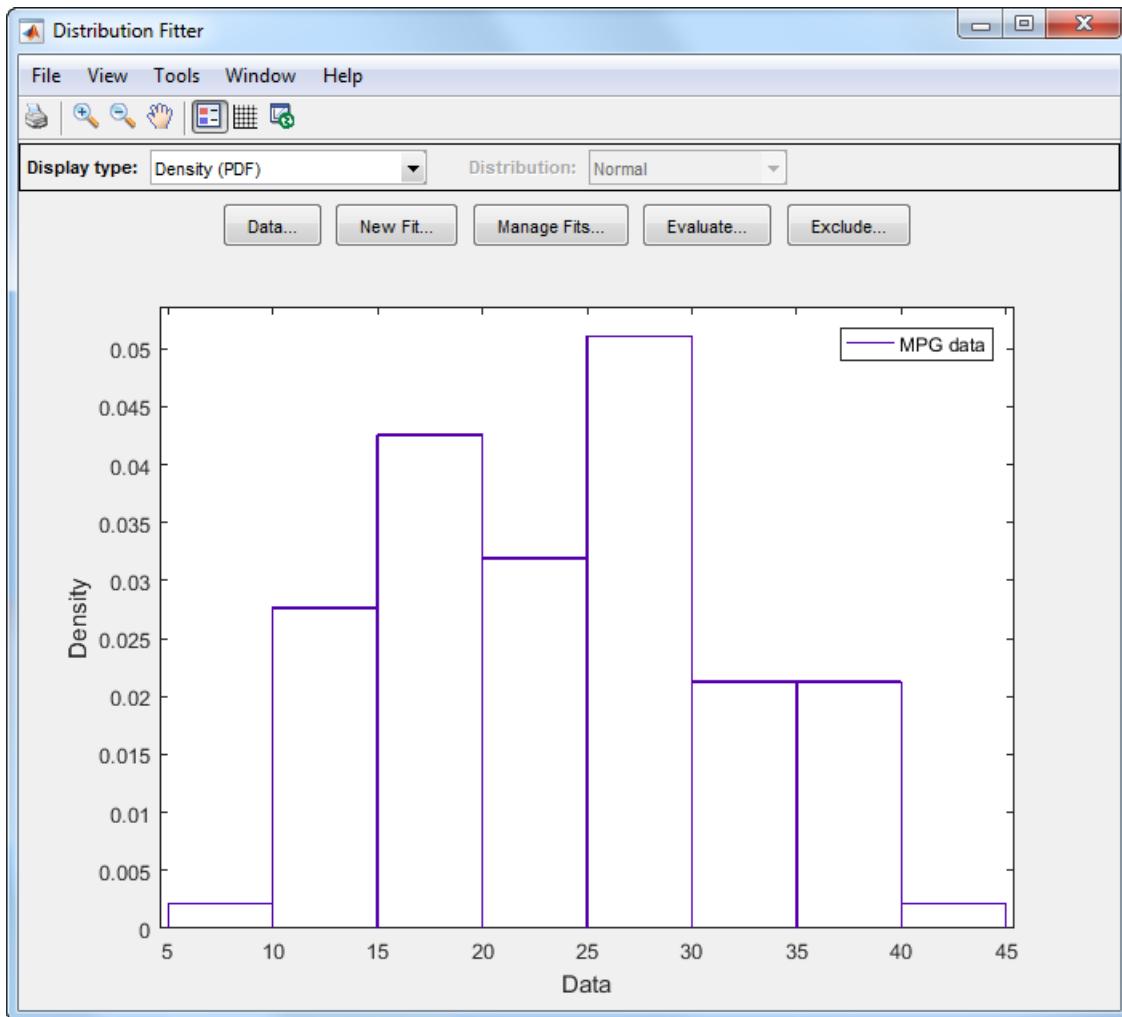

Open Distribution Fitter App with Existing Data

Load the carsmall sample data.

```
load carsmall
```

Open the Distribution Fitter app using the MPG miles per gallon data.

```
distributionFitter(MPG)
```

The Distribution Fitter app opens, populated with the MPG data, and displays the density (PDF) plot. You can use the app to display different plots and fit distributions to this data.

Open Distribution Fitter App with Censoring Data

Load the sample data.

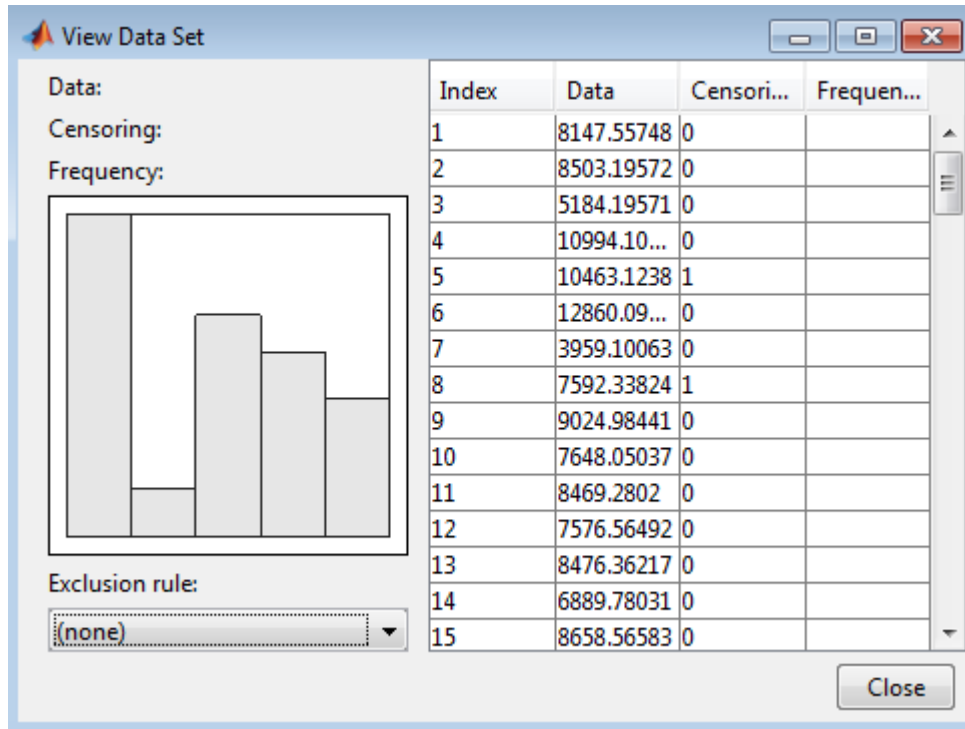

```
load(fullfile(matlabroot, 'examples', 'stats', 'lightbulb.mat'))
```

The first column of the data contains the lifetime (in hours) of two types of light bulbs. The second column contains information about the type of light bulb. 1 indicates fluorescent bulbs, and 0 indicates the incandescent bulb. The third column contains censoring information. 1 indicates censored data, and 0 indicates the exact failure time. This is simulated data.

Open the Distribution Fitter app using the first column of `lightbulb` as the input data, and the third column as the censoring data. Name the data `lifetime`.

```
distributionFitter(lightbulb(:,1),lightbulb(:,3),[], 'lifetime')
```

To open the Data dialog box, click **Data**. In the **Manage data sets** pane, click to highlight the `lifetime` data set row. Finally, to open the View Data Set dialog, click **View**. The lifetime data appears in the second column and the corresponding censoring indicator appears in the third column.

- “Fit a Distribution Using the Distribution Fitter App” on page 5-96

Input Arguments

y – Input data

array of scalar values | variable representing an array of scalar values

Input data, specified as an array of scalar values or a variable representing an array of such values.

Data Types: single | double

cens – Censoring indicator

zeros(n) (default) | vector of 0 and 1 values

Censoring indicator, specified as a vector of 0 and 1 values. The length of cens must be equal to the length of y. If $y(j)$ is censored, then $(cens(j) == 1)$. If $y(j)$ is not

censored, then `(cens(j)==0)`. If `cens` is omitted or empty, then no `y` values are censored.

If you have frequency data (`freq`) but not censoring data (`cens`), then you must specify empty brackets (`[]`) for `cens`.

Data Types: `single` | `double`

freq — Frequency data

`ones(n)` (default) | vector of scalar values

Frequency data, specified as a vector of scalar values. The length of `freq` must be equal to the length of `y`. If `freq` is omitted or empty, then all `y` values have a frequency of 1.

If you have frequency data (`freq`) but not censoring data (`cens`), then you must specify empty brackets (`[]`) for `cens`.

Data Types: `single` | `double`

dsname — Data set name

character vector | string scalar

Data set name, specified as a character vector enclosed in single quotes or a string scalar enclosed in double quotes.

If you want to specify a data set name, but do not have censoring data (`cens`) or frequency data (`freq`), then you must specify empty brackets (`[]`) for both `freq` and `cens`.

Example: `'MyData'`

Data Types: `char` | `string`

Probability Distribution Function

Interactive density and distribution plots

Description

The Probability Distribution Function user interface creates an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution. Explore the effects of changing parameter values on the shape of the plot, either by specifying parameter values or using interactive sliders.

Required Products

- MATLAB
- Statistics and Machine Learning Toolbox

Open the Probability Distribution Function App

- At the command prompt, enter `disttool`.

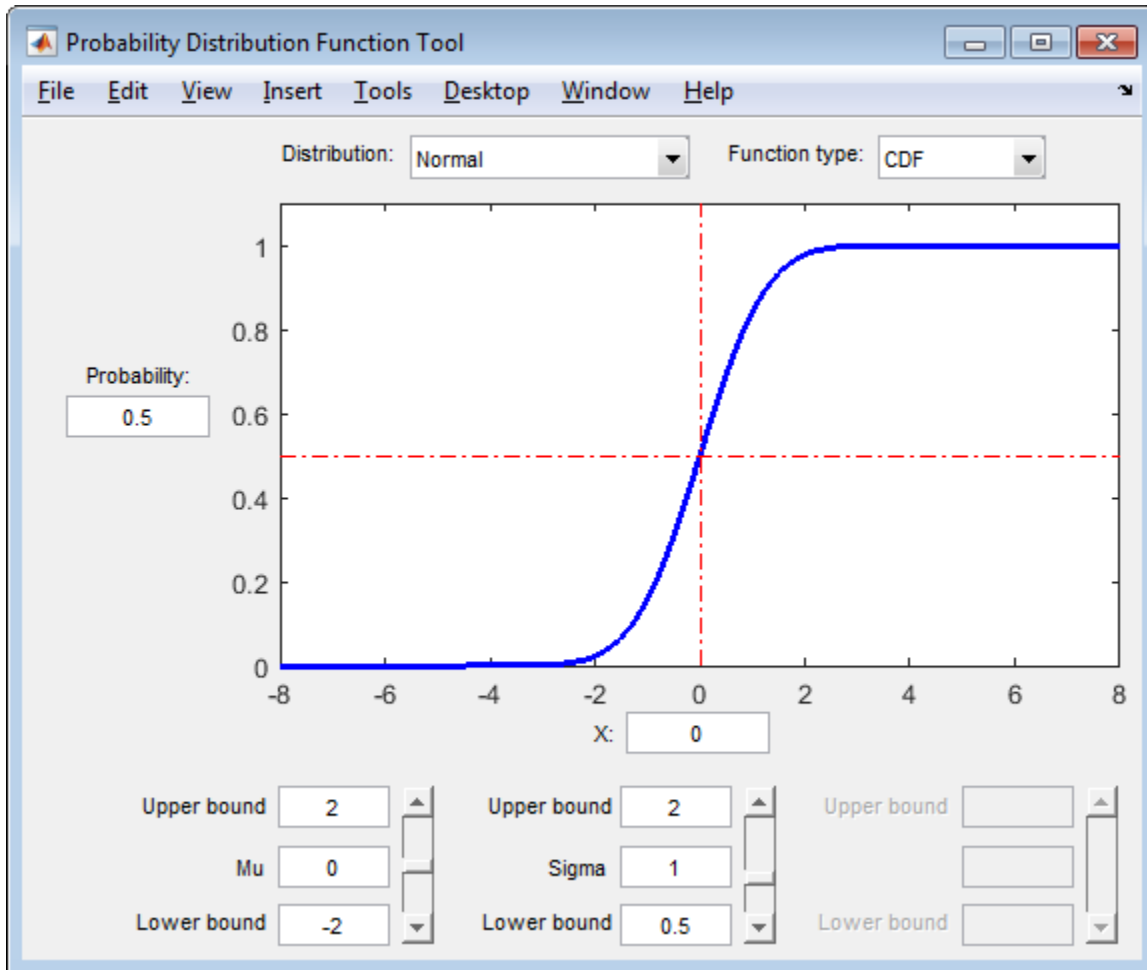

Examples

Explore the Probability Distribution Function User Interface

This example shows how to use the Probability Distribution Function user interface to explore the shape of cdf and pdf plots for different probability distributions and parameter values.

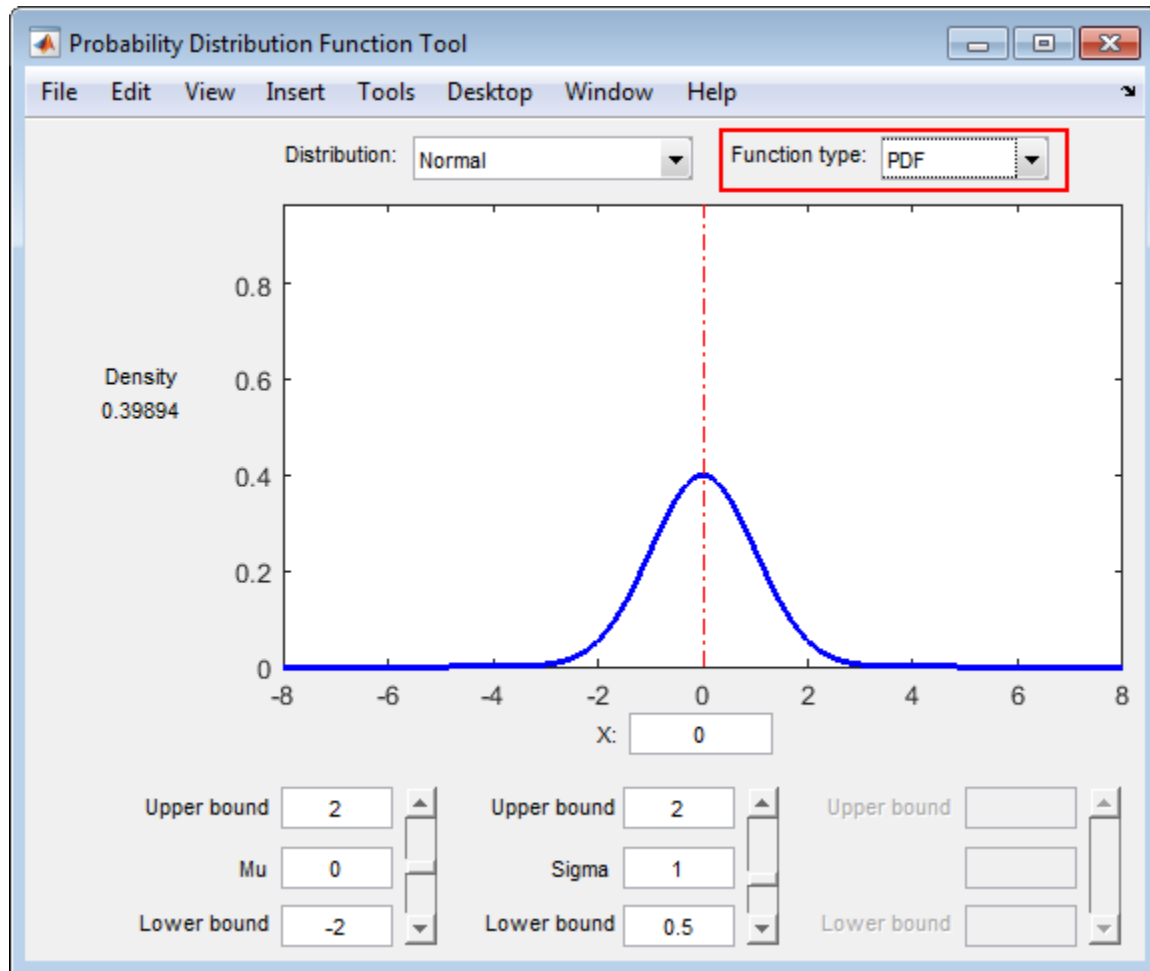

Open the Probability Distribution Function user interface.

```
disttool
```

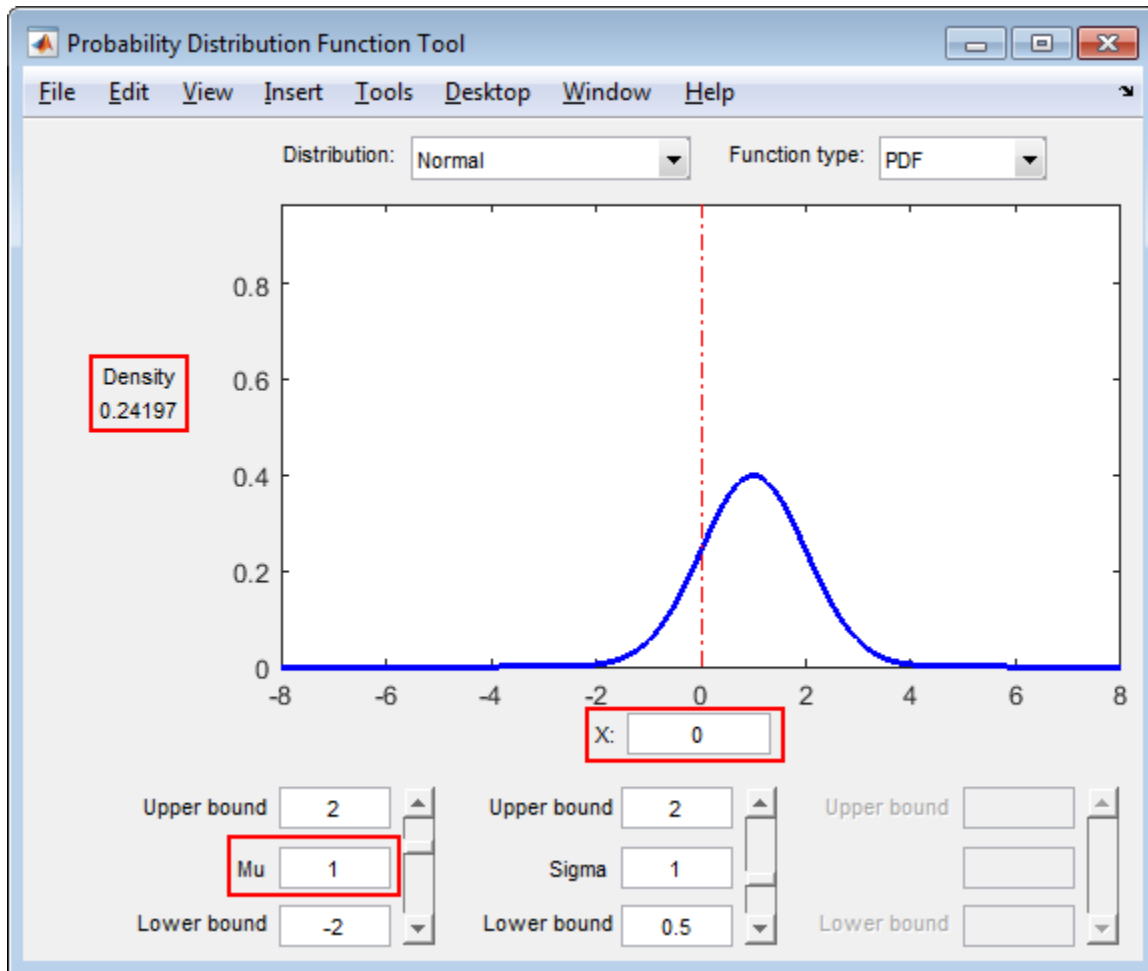

The interface opens with a plot of the cdf of the Normal distribution. The initial parameter settings are $\mu = 0$ and $\sigma = 1$.

Select PDF from the **Function type** drop-down menu to plot the pdf of the Normal distribution using the same parameter values.

Change the value of the location parameter μ to 1.

As the parameter values change, the shape of the plot also changes. Also, the value of X remains the same, but the density value changes because of the new parameter value.

Use the **Distribution** drop-down menu to change the distribution type from Normal to **Weibull**.

The shape of the plot changes, along with the names and values of the parameters.

Parameters

Distribution — Probability distribution

Normal (default) | Exponential | Poisson | Weibull | ...

Specify the probability distribution to explore by selecting a distribution name from the drop-down list. The drop-down list includes approximately 25 probability distribution options, including Normal, Exponential, Poisson, Weibull, and more.

Function type — Probability distribution function type

CDF (default) | PDF

Specify the probability distribution function type as CDF (cumulative distribution function) or PDF (probability density function) by selecting the function name from the drop-down list.

Probability — Cumulative distribution function value

numeric value in the range [0,1]

Specify the cumulative distribution function (cdf) value of interest as a numeric value in the range [0,1]. The corresponding random variable value appears in the **X** field below the plot. Alternatively, you can specify a value for **X**, and the **Probability** value will update automatically.

This option only appears if **Function type** is CDF. If **Function type** is PDF, then the probability density at the specified **X** value displays to the left of the plot.

X — Random variable

numeric value

Specify the random variable of interest as a numeric value. If the **Function type** is CDF, then the corresponding cumulative distribution function (cdf) value appears in the **Probability** field to the left of the plot. Alternatively, you can specify a value for **Probability**, and the **X** value will update automatically. If the **Function type** is PDF, then the corresponding probability density value appears to the left of the plot.

Parameters — Parameter boundaries and values

numeric value

Specify the parameter boundaries and values as numeric values. Each column contains a field for the upper bound, value, and lower bound of one parameter. The name and number of available parameters changes based on the distribution specified in the **Distribution** drop-down list. For example, if you select the Normal distribution, then `disttool` enables two columns: One column for the **Mu** parameter and one column for the **Sigma** parameter. If you select the **Exponential** distribution, then `disttool` enables one column for the **Mu** parameter.

Tips

To change the value of **X** (on the y-axis), or **Probability** or **Density** (on the x-axis):

- Type the values of interest into the **Probability** or **X** fields;
- Click on the point of interest on the plot; or
- Click and drag the reference lines across the plot.

Functions

`distributionFitter` | `fitdist` | `makedist`

Introduced before R2006a

double

Class: dataset

Convert dataset variables to double array

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
b = double(A)
b = double(a,vars)
```

Description

`b = double(A)` returns the contents of the dataset `A`, converted to one double array. The classes of the variables in the dataset must support the conversion.

`b = double(a,vars)` returns the contents of the dataset variables specified by `vars`. `vars` is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector.

See Also

`dataset` | `replacedata` | `single`

droplevels

Drop levels from a nominal or ordinal array

Note The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

Syntax

```
B = droplevels(A)
B = droplevels(A,oldlevels)
```

Description

`B = droplevels(A)` drops unused levels from the nominal or ordinal array `A`. The array `B` has the same size, type, and values as `A`, but has a list of potential levels that includes only those present in some element of `A`.

`B = droplevels(A,oldlevels)` removes the specified levels `oldlevels` from `A`.

`droplevels` removes levels, but does not remove elements. Elements of `B` that correspond to elements of `A` having levels in `oldlevels` all have an undefined level.

Examples

Drop Levels From an Ordinal Array

Bin patient ages into ordinal levels corresponding to 10-year intervals.

```
load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90)', '%d'), {'s'});
A = ordinal(hospital.Age, labels, [], edges);
getlabels(A)
```

```
ans = 1x10 cell array
  Columns 1 through 7
    {'0s'}    {'10s'}    {'20s'}    {'30s'}    {'40s'}    {'50s'}    {'60s'}

  Columns 8 through 10
    {'70s'}    {'80s'}    {'90s'}
```

Drop any levels that have no patients in them.

```
A = droplevels(A);
getlabels(A)

ans = 1x4 cell array
    {'20s'}    {'30s'}    {'40s'}    {'50s'}
```

- “Add and Drop Category Levels” on page 2-24

Input Arguments

A — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created with `nominal` or `ordinal`.

oldlevels — Levels to remove

string array | cell array of character vectors | 2-D character matrix

Levels to remove from the `nominal` or `ordinal` array, specified as a string array, a cell array of character vectors, or a 2-D character matrix.

Data Types: `char` | `string` | `cell`

Output Arguments

B — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, returned as a nominal or ordinal array object.

`addlevels` | `mergelevels` | `nominal` | `ordinal` | `reorderlevels`

Topics

“Add and Drop Category Levels” on page 2-24

Introduced in R2007a

dummyvar

Create dummy variables

Syntax

`D = dummyvar(group)`

Description

`D = dummyvar(group)` returns a matrix `D` containing zeros and ones, whose columns are dummy variables for the grouping variable `group`. Columns of `group` represent categorical predictor variables, with values indicating categorical levels. Rows of `group` represent observations across variables.

`group` can be a numeric vector or categorical column vector representing levels within a single variable, a cell array containing one or more grouping variables, or a numeric matrix or cell array of categorical column vectors representing levels within multiple variables. If `group` is a numeric vector or matrix, values in any column must be positive integers in the range from 1 to the number of levels for the corresponding variable. In this case, `dummyvars` treats each column as a separate numeric grouping variable. With multiple grouping variables, the sets of dummy variable columns are in the same order as the grouping variables in `group`.

The order of the dummy variable columns in `D` matches the order of the groups defined by `group`. When `group` is a categorical vector, the groups and their order match the output of the `categories(group)` function. When `group` is a numeric vector, `dummyvar` assumes that the groups and their order are `1:max(group)`. In this respect, `dummyvars` treats a numeric grouping variable differently than `grp2idx`.

If `group` is n -by- p , `D` is n -by- S , where S is the sum of the number of levels in each of the columns of `group`. The number of levels in any column of `group` is the maximum positive integer in the column or the number of categorical levels. Levels are considered distinct if they appear in different columns of `group`, even if they have the same value. Columns of `D` are, from left to right, dummy variables created from the first column of `group`, followed by dummy variables created from the second column of `group`, etc.

`dummyvar` treats NaN values or undefined categorical levels in `group` as missing data and returns NaN values in `D`.

Dummy variables are used in regression analysis and ANOVA to indicate values of categorical predictors.

Note If a column of 1s is introduced in the matrix `D`, the resulting matrix `X = [ones(size(D,1),1) D]` will be rank deficient. The matrix `D` itself will be rank deficient if `group` has multiple columns. This is because dummy variables produced from any column of `group` always sum to a column of 1s. Regression and ANOVA calculations often address this issue by eliminating one dummy variable (implicitly setting the coefficients for dropped columns to zero) from each group of dummy variables produced by a column of `group`.

Examples

Suppose you are studying the effects of two machines and three operators on a process. Use `group` to organize predictor data on machine-operator combinations:

```
machine = [1 1 1 1 2 2 2 2]';  
operator = [1 2 3 1 2 3 1 2]';  
group = [machine operator]  
group =  
     1     1  
     1     2  
     1     3  
     1     1  
     2     2  
     2     3  
     2     1  
     2     2
```

Use `dummyvar` to create dummy variables for a regression or ANOVA calculation:

```
D = dummyvar(group)  
D =  
     1     0     1     0     0  
     1     0     0     1     0  
     1     0     0     0     1  
     1     0     1     0     0  
     0     1     0     1     0
```

| | | | | |
|---|---|---|---|---|
| 0 | 1 | 0 | 0 | 1 |
| 0 | 1 | 1 | 0 | 0 |
| 0 | 1 | 0 | 1 | 0 |

The first two columns of D represent observations of machine 1 and machine 2, respectively; the remaining columns represent observations of the three operators.

dwtest

Durbin-Watson test

Syntax

```
p = dwtest(r,x)
p = dwtest(r,x,Name,Value)
[p,d] = dwtest(____)
```

Description

`p = dwtest(r,x)` returns the p -value for the Durbin-Watson test on page 32-1455 of the null hypothesis that the residuals from a linear regression are uncorrelated. The alternative hypothesis is that there is autocorrelation among the residuals.

`p = dwtest(r,x,Name,Value)` returns the p -value for the Durbin-Watson test with additional options specified by one or more name-value pair arguments. For example, you can conduct a one-sided test or calculate the p -value using a normal approximation.

`[p,d] = dwtest(____)` also returns the Durbin-Watson test statistic, d , using any of the input arguments from the previous syntaxes.

Examples

Test Residuals For Correlation

Load the sample census data.

```
load census
```

Create a design matrix using the census date (`cdate`) as the predictor. Add a column of 1 values to include a constant term.

```
n = length(cdate);
x = [ones(n,1),cdate];
```

Fit a linear regression to the data.

```
[b,bint,r] = regress(pop,x);
```

Test the null hypothesis that there is no autocorrelation among the residuals, r .

```
[p,d] = dwtest(r,x)
```

```
p = 3.6190e-15
```

```
d = 0.1308
```

The returned value $p = 3.6190e-15$ indicates rejection of the null hypothesis at the 5% significance level.

One-Sided Hypothesis Test

Load the sample census data.

```
load census
```

Create a design matrix using the census date (`cdate`) as the predictor. Add a column of 1 values to include a constant term.

```
n = length(cdate);  
x = [ones(n,1),cdate];
```

Fit a linear regression to the data.

```
[b,bint,r] = regress(pop,x);
```

Test the null hypothesis that there is no autocorrelation among regression residuals, against the alternative hypothesis that the autocorrelation is greater than zero.

```
[p,d] = dwtest(r,x,'Tail','right')
```

```
p = 1.8095e-15
```

```
d = 0.1308
```

The returned value $p = 1.8095e-15$ indicates rejection of the null hypothesis at the 5% significance level, in favor of the alternative hypothesis that the autocorrelation among residuals is greater than zero.

Input Arguments

x — Design matrix

matrix

Design matrix for a linear regression, specified as a matrix. Include a column of 1 values in the design matrix so the model contains a constant term.

Data Types: `single` | `double`

r — Regression residuals

vector

Regression residuals, specified as a vector. Obtain `r` by performing a linear regression using a function such as `regress`, or by using the backslash operator.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Tail','right','Method','approximate'` specifies a right-tailed hypothesis test and calculates the p -value using a normal approximation.

Method — Computation method for p -value

`'exact'` | `'approximate'`

Computation method for the p -value, specified as the comma-separated pair consisting of `'Method'` and one of the following.

- | | |
|----------------------------|---|
| <code>'exact'</code> | Calculate an exact p -value using the Pan algorithm. This is the default if the sample size is less than 400. |
| <code>'approximate'</code> | Calculate the p -value using a normal approximation. This is the default if the sample size is 400 or larger. |

Example: `'Method','exact'`

Tail — Type of alternative hypothesis

'both' (default) | 'right' | 'left'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

| | |
|---------|--|
| 'both' | Test the alternate hypothesis that autocorrelation among the residuals is not zero. |
| 'right' | Test the alternative hypothesis that autocorrelation among the residuals is greater than zero. |
| 'left' | Test the alternative hypothesis that autocorrelation among the residuals is less than zero. |

Example: 'Tail', 'right'

Output Arguments

p — p-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

d — Test statistic

nonnegative scalar value

Test statistic of the hypothesis test, returned as a nonnegative scalar value.

Definitions

Durbin-Watson Test

The Durbin-Watson test is used to test the null hypothesis that linear regression residuals are uncorrelated, against the alternative that autocorrelation exists.

The test statistic for the Durbin-Watson test is

$$d = \frac{\sum_{t=2}^T (e_t - e_{t-1})^2}{\sum_{t=1}^T e_t^2},$$

where T is the number of observations, and e_t is the residual at time t .

The p -value of the Durbin-Watson test is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. A significantly small p -value casts doubt on the validity of the null hypothesis and indicates correlation among residuals. The p -value can be calculated exactly using the Pan algorithm. Alternatively, the p -value can be estimated using a normal approximation.

regress

Introduced in R2006a

dwtest

Class: LinearModel

Durbin-Watson test of linear model

Syntax

```
P = dwtest mdl
[P,DW] = dwtest mdl
[P,DW] = dwtest mdl,method
[P,DW] = dwtest mdl,method,tail
```

Description

`P = dwtest(mdl)` returns the p -value of the Durbin-Watson test on the `mdl` linear model.

`[P,DW] = dwtest(mdl)` also returns the Durbin-Watson statistic, `DW`.

`[P,DW] = dwtest(mdl,method)` specifies the method `dwtest` uses to compute the p -value.

`[P,DW] = dwtest(mdl,method,tail)` specifies the alternative hypothesis.

Input Arguments

mdl — Full, fitted linear regression model

LinearModel object

Full, fitted linear regression model, specified as a `LinearModel` object constructed using `fitlm` or `stepwiselm`.

method — Algorithm for computing p -value

'exact' | 'approximate'

Algorithm for computing the p -value, specified as one of the following:

- 'exact' — Calculates an exact p -value using Pan's algorithm.
- 'approximate' — Calculates the p -value using a normal approximation.

The default is 'exact' when the sample size is less than 400, 'approximate' otherwise.

tail — Alternative hypothesis to test

'both' (default) | 'right' | 'left'

Alternative hypothesis to test, specified as one of the following:

| Tail | Alternative Hypothesis |
|---------|---|
| 'both' | Serial correlation is not 0. |
| 'right' | Serial correlation is greater than 0 (right-tailed test). |
| 'left' | Serial correlation is less than 0 (left-tailed test). |

`dwtest` tests whether `mdl` has no serial correlation against the specified alternative hypotheses.

Output Arguments

P — p -value of the test

numeric value

p -value of the test, returned as a numeric value. `dwtest` tests if the residuals are uncorrelated, against the alternative that there is autocorrelation among them. Small values of P indicate that the residuals are correlated.

DW — Durbin-Watson statistic

numeric value

Durbin-Watson statistic, returned as a numeric value.

Examples

Test Residuals for Autocorrelation

Examine whether the residuals from a fitted model of census data over time have autocorrelated residuals.

Load the census data and create a linear model.

```
load census
mdl = fitlm(cdate,pop);
```

Find the P -value of the Durbin-Watson autocorrelation test.

```
P = dwtest(mdl)
```

```
P =
```

```
3.6190e-15
```

There is significant autocorrelation in the residuals.

Definitions

Durbin-Watson Statistic

Let r be the vector of residuals (in `mdl.residuals.response`). The Durbin-Watson statistic is

$$DW = \frac{\sum_{i=1}^{n-1} (r_{i+1} - r_i)^2}{\sum_{i=1}^n r_i^2}.$$

Algorithms

Approximate calculation of the p -value uses a normal approximation [1]. Exact calculation uses Pan's algorithm [2].

ecdf

Empirical cumulative distribution function

Syntax

```
[f,x] = ecdf(y)
[f,x] = ecdf(y,Name,Value)
[f,x,flo,fup] = ecdf( ___ )

ecdf( ___ )
ecdf(ax, ___ )
```

Description

`[f,x] = ecdf(y)` returns the empirical cumulative distribution function (cdf), `f`, evaluated at the points in `x`, using the data in the vector `y`.

In survival and reliability analysis, this empirical cdf is called the Kaplan-Meier estimate. And the data might correspond to survival or failure times.

`[f,x] = ecdf(y,Name,Value)` returns the empirical function values, `f`, evaluated at the points in `x`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the type of function to evaluate or which data is censored.

`[f,x,flo,fup] = ecdf(___)` also returns the 95% lower and upper confidence bounds for the evaluated function values. You can use any of the input arguments in the previous syntaxes.

`ecdf` computes the confidence bounds using Greenwood's formula on page 32-1472. They are not simultaneous confidence bounds.

`ecdf(___)` plots the evaluated function.

`ecdf(ax, ___)` plots the evaluated function using axes with the handle, `ax`, instead of the current axes returned by `gca`.

Examples

Compute Empirical Cumulative Distribution Function

Compute the Kaplan-Meier estimate of the cumulative distribution function (cdf) for simulated survival data.

Generate survival data from a Weibull distribution with parameters 3 and 1.

```
rng default; % for reproducibility
failuretime = random('wbl',3,1,15,1);
```

Compute the Kaplan-Meier estimate of the cdf for survival data.

```
[f,x] = ecdf(failuretime);
[f,x]
```

```
ans = 16×2
```

```
      0      0.0895
0.0667      0.0895
0.1333      0.1072
0.2000      0.1303
0.2667      0.1313
0.3333      0.2718
0.4000      0.2968
0.4667      0.6147
0.5333      0.6684
0.6000      1.3749
      :
```

Plot the estimated cdf.

```
figure()
plot(x,f)
```

Empirical Hazard Function of Right-Censored Data

Compute and plot the hazard function of simulated right-censored survival data.

Generate failure times from a Birnbaum-Saunders distribution.

```
rng default % for reproducibility
failuretime = random('birnbaumsaunders',0.3,1,100,1);
```

Assuming that the end of the study is at time 0.9, generate a logical array that indicates simulated failure times that are larger than 0.9 as censored data, and store this information in a vector.

```
T = 0.9;  
cens = (failuretime>T);
```

Plot the empirical hazard function for the data.

```
ecdf(failuretime,'function','cumulative hazard',...  
'censoring',cens,'bounds','on');
```

Compare Empirical Cumulative Distribution Function (CDF) with Known CDF

Generate right-censored survival data and compare the empirical cumulative distribution function (cdf) with the known cdf.

Generate failure times from an exponential distribution with mean failure time of 15.

```
rng default % for reproducibility
y = exprnd(15,75,1);
```

Generate drop-out times from an exponential distribution with mean failure time of 30.

```
d = exprnd(30,75,1);
```

Generate the observed failure times. They are the minimum of the generated failure times and the drop-out times.

```
t = min(y,d);
```

Create a logical array that indicates generated failure times that are larger than the drop-out times. The data for which this is true are censored.

```
censored = (y>d);
```

Compute the empirical cdf and confidence bounds.

```
[f,x,flc,fup] = ecdf(t,'censoring',censored);
```

Plot the cdf and confidence bounds.

```
figure()
ecdf(t,'censoring',censored,'bounds','on');
hold on
```

Superimpose a plot of the known population cdf.

```
xx = 0:.1:max(t);
yy = 1-exp(-xx/15);
plot(xx,yy,'g-','LineWidth',2)
axis([0 50 0 1])
legend('Empirical','LCB','UCB','Population',...
       'Location','SE')
hold off
```

Empirical Survivor Function with 99% Confidence Bounds

Generate survival data and plot the empirical survivor function with 99% confidence bounds.

Generate lifetime data from a Weibull distribution with parameters 100 and 2.

```
rng default % for reproducibility
R = wblrnd(100,2,100,1);
```

Plot the survivor function for the data with 99% confidence bounds.

```
ecdf(R, 'function', 'survivor', 'alpha', 0.01, 'bounds', 'on')
hold on
```

Fit the Weibull survivor function.

```
x = 1:1:250;
wblsurv = 1-cdf('weibull',x,100,2);
plot(x,wblsurv,'g-','LineWidth',2)
legend('Empirical','LCB','UCB','Population',...
'Location','NE')
```

The survivor function based on the actual distribution is within the confidence bounds.

- “Survivor Functions for Two Groups” on page 14-25

Input Arguments

y – Input data

column vector

Input data, specified as a column vector. For example, in survival or reliability analysis, data might be survival or failure times for each item or individual.

Data Types: `single` | `double`

ax — Axes handle

handle

Axes handle for the figure `ecdf` plots to, specified as a handle.

For instance, if `h` is a handle for a figure, then `ecdf` can plot to that figure as follows.

Example: `ecdf(h,x)`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'censoring',c,'function','cumulative hazard','alpha',0.025,'bounds','on'` specifies that `ecdf` returns the cumulative hazard function and plots the 97.5% confidence bounds, accounting for the censored data specified by vector `c`.

censoring — Indicator of censored data

array of 0s (default) | vector of 0s and 1s

Indicator of censored data, specified as the comma-separated pair including `'censoring'` and a Boolean array of the same size as `x`. Enter 1 for observations that are right-censored and 0 for observations that are fully observed. Default is all observations are fully observed.

For instance, if vector `cdata` stores the censored data information, you can enter the censoring information as follows.

Example: `'censoring',cdata`

Data Types: `logical`

frequency — Frequency of observations

array of 1s (default) | vector of nonnegative scalars

Frequency of observations, specified as the comma-separated pair consisting of `'frequency'` and a vector containing nonnegative integer counts. This vector is the

same size as the vector `x`. The `j`th element of this vector gives the number of times the `j`th element of `x` was observed. Default is one observation per element of `x`.
